Dedicated to Professor Otto Exner on the occasion of his 65th birthday.

#### Abstract

The $\mathrm{p} K_{\mathrm{a}}$ of eighteen heterocyclic carboxylic acids derived from thiophene, furan, pyrrole, benzothiophene, benzofuran, indole, pyridine and quinoline have been determined by spectrophotometry and potentiometry. The values thus obtained are discussed using additive models of the Free-Wilson type. Some theoretical calculations within the AM1 approximation have been carried out in order to understand why annelation effects are dependent on the position, $\alpha$ or $\beta$, of the carboxylic group. In the case of pyridine and quinoline carboxylic acids, the problem of tautomerism between neutral and zwitterionic forms has been considered.

The use of different parameters to describe the effects of substituents on a molecule has arisen increasing interest in recent years, especially in QSAR methodology ${ }^{1}$. Nevertheless, there are no systematic studies concerning these parameters when the substituent is an heterocyclic group. We have previously reported ${ }^{2,3}$ the hypothesis that structural characteristics in a Free-Wilson type model could be used to describe heterocyclic substituents and now we want to report the use of this approach to study the $\mathrm{p} K_{\mathrm{a}}$ of a set of eighteen simple heterocyclic acids containing only one heteroatom.

In order to avoid the dispersion of values of the literature ${ }^{4}$ we decided to determine the $\mathrm{p} K_{\mathrm{a}}$ 's of all the above reported acids.

## EXPERIMENTAL

Heterocyclic compounds I-XVIII. These compounds were either commercially available or prepared according to standard procedures. Only 3 -pyrrolecarboxylic acid $V I$ was obtained using a new synthetic method ${ }^{5}$.

$\mathrm{p} K_{\mathrm{a}}$ determinations. The $\mathrm{p} K_{\mathrm{a}}$ of the heterocyclic acids at $20^{\circ} \mathrm{C}$ in water have been calculated by means of the relationship

$$
\mathrm{p} K_{\mathrm{a}}=\mathrm{pH}-\log \frac{D-D_{\mathrm{A}}-}{D_{\mathrm{AH}}-D}
$$

Collect. Czech. Chem. Commun. (Vol. 55) (1990)
using the spectrometric technique previously described ${ }^{6,7} . D_{\text {AH }}, D_{\text {A- }}$ and $D$ are the optical densities of the acid, its conjugated base and the equilibrium mixture for a given pH , all of them measured at a chosen wavelength. Measurements have been carried out with a Pye Unicam spectrophotometer equipped with thermostated cells and a Tacussel pH -meter ( $1 / 100$ ) coupled with a $12 / \mathrm{HS}$ electrode standardized with Titrisol buffers.

Acid concentration was comprised between $10^{-4}$ and $10^{-5} \mathrm{~mol} 1^{-1}$. The ionic strength was maintained constant by means of potassium chloride $\left(0 \cdot 1 \mathrm{~mol} \mathrm{l}^{-1}\right)$ and the titrations were carried out under nitrogen atmosphere with decarbonated sodium hydroxide.

The curve $D=f(\mathrm{pH})$ present an inflexion point I (see Fig. 1a) in which $D_{\mathrm{I}}=1 / 2\left(D_{\mathrm{AH}}+D_{\mathrm{A}}\right.$ ) (Eq. (l)) allowing the calculation of the $\mathrm{p} K_{\mathrm{a}}$. However, the precision in the determination of this point is considerably increased using the intersection point of the $D-D_{\mathrm{A}^{-}}=f(\mathrm{pH})$ (Eq. (2)) and $D_{\mathrm{AH}}-D=f(\mathrm{pH})$ (Eq. (3)) curves (Fig. 1b). The solution of the system of equations (2) and (3) led to a $\mathrm{p} K_{\mathrm{a}}$ value identical, but more precise, than that obtained from Eq. (1).

When the solubility in water is sufficient (about $10^{-2} \mathrm{~mol} .1^{-1}$ ), $\mathrm{p} K_{\mathrm{a}}$ 's have been determined by potentiometry using decinormal sodium hydroxide with the classical procedure described by' Albert and Serjeant ${ }^{8}$. The values thus obtained differ from the spectrophotometrically ones by less than $0.05 \mathrm{p} K_{\mathrm{a}}$ units. In both methods the temperature was keep constant at $20.0 \pm 0 \cdot 1^{\circ} \mathrm{C}$. The experimental results are gathered in Table I.

AM1 calculations. AM1 calculations ${ }^{9}$ were performed on a Vax 11/780 computer (Zaragoza). All molecules were fully optimized unless the planarity which was imposed.

## RESULTS AND DISCUSSION

## Five-Membered Heterocyclic Acids

These acids, $I-X I I$, can be described in a Free-Wilson way ( 0,1 matrix) using three descriptors:

1) number of cycles: one ( $X_{1}^{1}$ ) or two (benzoderivatives) $\left(X_{2}^{1}\right)$
2) position of the COOH group: $\alpha\left(X_{3}^{1}\right)$ or $\beta\left(X_{4}^{1}\right)$

Fig. 1
Determination of $\mathrm{p} K_{\mathrm{a}}$ by spectrophotometric titration: $a$ inflexion point method, $b$ intersection method
3) nature of the heteroatom: $\mathrm{S}\left(X_{5}^{1}\right), \mathrm{O}\left(X_{6}^{1}\right)$ or $\mathrm{NH}\left(X_{7}^{1}\right)$ leading to the following model:

$$
\mathrm{p} K_{\mathrm{a}}=a_{0}^{1}+a_{1}^{1}\left(X_{1}^{1}\right)+a_{2}^{1}\left(X_{2}^{1}\right)+a_{3}^{1}\left(X_{3}^{1}\right)+\ldots+a_{7}^{1}\left(X_{7}^{1}\right) . \quad(\text { Model } 1)
$$

The corresponding Free-Wilson matrix is then constructed in the usual way ${ }^{10}$, each heterocyclic substituent being unambiguously codified by a row vector. Using the averaged $\mathrm{p} K_{\mathrm{a}}$ values of Table I and following the usual procedure ${ }^{2,3}$ the coefficients of the model can be calculated:

$$
\begin{align*}
\mathrm{p} K_{\mathrm{a}} & =3.66+0.055\left(X_{1}^{1}\right)-0.055\left(X_{2}^{1}\right)-0.505\left(X_{3}^{1}\right)+0.505\left(X_{4}^{1}\right)- \\
& -0.23\left(X_{5}^{1}\right)-0.43\left(X_{6}^{1}\right)+0.66\left(X_{7}^{1}\right) ; \quad r^{2}=0.94, r_{\mathrm{A}}^{2}=0.91 . \tag{4}
\end{align*}
$$

Although this empirical model seems quite satisfactory, the very weak effect of annelation ( $a_{2}^{1}-a_{1}^{1}=0 \cdot 11$ ) results from averaging two opposite effects: (i) when the carboxylic group is in $\alpha$-position, the annelation effects amounts to $-0.43 \mathrm{p} K_{\mathrm{a}}$

Table I
Experimental $\mathrm{p} K_{\mathrm{a}}$ values (water, $20^{\circ} \mathrm{C}$ )

| Carboxylic acid | Spectrophotometry | Potentiometry |
| :--- | :---: | :---: |
| 2-Thiophene $I$ |  |  |
| 2-Furan $I I$ | $3 \cdot 48$ | $3 \cdot 50$ |
| 2-Pyrrole $I I I$ | $3 \cdot 17$ | $3 \cdot 15$ |
| 3-Thiopherie $I V$ | $4 \cdot 38$ | $4 \cdot 34$ |
| 3-Furan $V$ | - | $4 \cdot 08$ |
| 3-Pyrrole $V I$ | $4 \cdot 03$ | $3 \cdot 97$ |
| 2-Benzothiophene $V I I$ | - | $5 \cdot 01$ |
| 2-Benzofuran $V$ III | $3 \cdot 10$ | insoluble |
| 2-Indole $I X^{a}$ | $2 \cdot 79$ | $\sim 2 \cdot 9$ |
| 3-Benzothiophene $X$ | $3 \cdot 84$ | $3 \cdot 79$ |
| 3-Benzofuran $X I$ | $4 \cdot 24$ | insoluble |
| 3-Indole $X I I^{b}$ | $4 \cdot 18$ | insoluble |
| 2-Pyridine $X I I I$ | $5 \cdot 29$ | insoluble |
| 3-Pyridine $X I V$ | - | $5 \cdot 42$ |
| 4-Pyridine $X V$ | - | $4 \cdot 80$ |
| 2-Quinoline $X V I$ | - | $4 \cdot 87$ |
| 3-Quinoline $X V I I^{c}$ | - | $4 \cdot 96$ |
| 4-Quinoline $X V I I I^{d}$ | - | $4 \cdot 68$ |
|  | $4 \cdot 78$ | $4 \cdot 74$ |

[^0]units (pairs $I$ and $V I I, I I$ and $V I I I, I I I$ and $I X$ ) and (ii) when it is in $\beta$-position, the effect amounts to $+0.21 \mathrm{p} K_{\mathrm{a}}$ units (pairs $I V$ and $X, V$ and $X I, V I$ and $X I I$ ).

Therefore, we tried another Free-Wilson model which uses two descriptors:

1) number of cycles/ COOH position: one cycle, $\alpha\left(X_{1}^{2}\right)$, one cycle, $\beta\left(X_{2}^{2}\right)$, two cycles, $\alpha\left(X_{3}^{2}\right)$ or two cycles, $\beta\left(X_{4}^{2}\right)$
2) nature of the heteroatom: $\mathrm{S}\left(X_{5}^{2}\right), \mathrm{O}\left(X_{6}^{2}\right)$ or $\mathrm{NH}\left(X_{7}^{2}\right)$ the model being:

$$
\begin{equation*}
\mathrm{p} K_{\mathrm{a}}=a_{0}^{2}+a_{1}^{2}\left(X_{1}^{2}\right)+a_{2}^{2}\left(X_{2}^{2}\right)+a_{3}^{2}\left(X_{3}^{2}\right)+\ldots+a_{7}^{2}\left(X_{7}^{2}\right) . \tag{Model2}
\end{equation*}
$$

The same procedure leads to Eq. (5):

$$
\begin{align*}
& \mathrm{p} K_{\mathrm{a}}=3.96-0.29\left(X_{1}^{2}\right)+0.40\left(X_{2}^{2}\right)-0.72\left(X_{3}^{2}\right)+0.61\left(X_{4}^{2}\right)- \\
& -0.23\left(X_{5}^{2}\right)-0.43\left(X_{6}^{2}\right)+0.66\left(X_{7}^{2}\right) ; \quad r^{2}=0.992, r_{\mathrm{A}}^{2}=0.986 \tag{5}
\end{align*}
$$

This model, not only is better in a statistical sense, but it describes correctly the dependence of the annelation on the position of the carboxylic group: $a_{3}^{2}-a_{1}^{2}=$ $=-0.43, a_{4}^{2}-a_{2}^{2}=+0.21$. The heteroatom effect is identical in both models and independent of annelation and on the COOH position (Scheme 1). The acidity decreases from furan $(-0.43)$ to thiophene $(-0.23)$, and pyrrole $(+0.66)$, following the electron release ability of the heteroatom which stabilizes the undissociated acid.

In an attempt to understand why the annelation effect increases the acidity of the carboxylic group when located in the $\alpha$-position $(-0.43)$ but decreases it when in the $\beta$-position ( +0.21 ) we have carried out some calculations (AM1 method ${ }^{9}$ ). As we have shown previously ${ }^{11}$, there is a linear relationship between $\mathrm{p} K_{\mathrm{a}}$ values and the charge of the acidic hydrogen. Table II shows the heats of formation and the charges of the COOH hydrogen for the two most stable conformations of furan, benzofuran, benzene and naphthalene carboxylic acids.

z

E

$$
\bullet=O, C H
$$

z

E

Scheme 1

Considering the averaged values of $q_{\mathrm{H}}$ for both conformations (since they are quite similar in energy), we have found a correlation of the form $\Delta \mathrm{p} K_{\mathrm{a}}=-0 \cdot 17-$ $-234.4 \Delta q_{\mathrm{H}} ; r^{2}=0.94$, i.e. when annelation increases the charge on the hydrogen (2-benzofuran, $+0.00105 ; \alpha$-naphthalene, $+0.0016 ; \beta$-naphthalene, +0.00015 ) the $\mathrm{p} K_{\mathrm{a}}$ decreases ( $-0.37,-0.50$ and -0.04 , respectively), whereas when annelation decreases the charge on the hydrogen (3-benzofuran, -0.0016 ), the $\mathrm{p} K_{\mathrm{a}}$ increases $(+0 \cdot 18)$.

The annelation effects we have been discussing $(-0.43$ and +0.21$)$ are averaged values for thiophene, furan and pyrrole. A more detailed examination shows that these effects are larger for pyrrole-indole pairs $(-0.54$ and +0.28$)$ as if the pyrrole ring could transmit better the annelation effect.

[^1]
## Six-Membered Heterocyclic Acids

To discuss the $\mathrm{p} K_{\mathrm{a}}$ of compounds $X I I I-X V I I I$ it is necessary to take into account the existence of a tautomer equilibrium between neutral and zwitterionic forms ${ }^{12,13}$. Consider, for instance, the case of nicotinic acid XIV which is the best known ${ }^{12}$ (Scheme 2).

A

$$
\begin{aligned}
& K_{\text {exp }}^{\mathrm{a}}=K_{3}+K_{L} ; \mathrm{P} K_{\mathrm{a}}^{a}=2.07 \\
& K_{\text {exp }}^{\mathrm{b}}=K_{1}+K_{2} ; \mathrm{P} K_{\mathrm{a}}^{\mathrm{b}}=4.80
\end{aligned}
$$

Scheme 2

The microscopic constants we have calculated (different from those reported elsewhere ${ }^{12}$ ) are in agreement with the experimental values for model compounds XIX and $X X$ (in our hands, the $\mathrm{p} K_{\mathrm{a}}$ of compound $X X$ is $1 \cdot 87$ ), with the apparent values of nicotinic acid (proton gained, 2.07 (ref. ${ }^{12}$ ) and proton lost, $4.80-$ Table I) and with the tautomeric constant $K_{\mathrm{T}}$ determined by UV, which corresponds to $91 \%$ of zwitterion. Since the other acids, $X I I I$ and $X V$, also exist at $>90 \%$ in this form ${ }^{12,13}$ and presumably the same occurs in quinoline derivatives, $X V I-X V I I I$, it is possible to study an additive Free-Wilson model (Model 3) for the proton loss of zwitterions (microscopic equilibrium constant $K_{2}$ ) using Table I values:

$$
\mathrm{p} K_{\mathrm{a}}=a_{0}^{3}+a_{1}^{3}\left(X_{1}^{3}\right)+a_{2}^{3}\left(X_{2}^{3}\right)+\ldots+a_{5}^{3}\left(X_{5}^{3}\right) . \quad(\text { Model } 3)
$$

Model 3, in which the number of cycles [one ( $X_{1}^{3}$ ) or two $\left(X_{2}^{3}\right)$ ] and the position of the COOH group $\left[\alpha\left(X_{3}^{3}\right), \beta\left(X_{4}^{3}\right)\right.$ or $\left.\gamma\left(X_{5}^{3}\right)\right]$ are taken into account was treated in the usual way (Free-Wilson matrix, multiregression), leading to Eq. (6):

$$
\begin{gather*}
\mathrm{p} K_{\mathrm{a}}=4 \cdot 715+0 \cdot 115\left(X_{1}^{3}\right)-0 \cdot 115\left(X_{2}^{3}\right)+0 \cdot 27\left(X_{3}^{3}\right)-0 \cdot 17\left(X_{4}^{3}\right)-0 \cdot 10\left(X_{5}^{3}\right) \\
r^{2}=0.887, r_{\mathrm{A}}^{2}=0.718 \tag{6}
\end{gather*}
$$

The quality of fitness is less good in part due to the fact that we are dealing with apparent $\mathrm{p}_{\mathrm{a}}$ 's, but also, probably, because the annelation effect is not independent of the position of the COOH group.
