Received November 26, 2001
Accepted February 9, 2002

Two ways are shown to transform cardioactive cardenolides into cardenamides [17 $\beta$-(5-oxo-2,5-dihydropyrrol-3-yl)-5 $\beta, 14 \beta$-androstane derivatives], and their derivatives by replacement of their ring oxygen by N-R. Cardioactivity is strongly decreased by this transformation. The comparatively easily accessible 21-oxocardenamides [17 $\beta$-(2-maleimidyl)steroids] are strongly thiol reactive and show remarkable anticancer activity.
Keywords: $\mathrm{Na}^{+} / \mathrm{K}^{+}$-ATPase inhibition; Cardenolides; Cardenamides; Steroids; Lactams; 21-Oxocardenamides; Anticancer activity.

Cardenolides play a central role in the treatment of cardiac failure until today. Their main drawback is their narrow therapeutic range making an optimal treatment very difficult. This stimulates a search for better drugs for replacing of cardenolides - but so far without a breakthrough ${ }^{1}$. Therefore, we have tried to replace the ring oxygen of the cardenolide lactone ring by $N-R$ to get analogous lactams (cardenamides, 17 $\beta$-(5-oxo-2,5-dihydro-pyrrol-3-yl)-5 -androstane derivatives) and their derivatives and to see their influence on the cardioactivity as measured by the inhibition of guinea pig and/or human cardiac ATPase.

[^0]
## First M ethod

The cardenolide digitoxigenin 1 (Scheme 1) reacts at room temperature with ammonia or methylamine in methanol to the hemiacetal amide 5 (yield 53\%) or 6 with lactone ring opening, shift of the C20-C22 double

1, $R=H$
2, $R=A c$

3, $\mathrm{R}=\mathrm{H}$
4, $R=A c$

12, $\mathrm{R}=\mathrm{CH}_{3}$

14
bond under formation of an aldehyde group at C21 and hemiacetal formation with the $14-\mathrm{OH}$ group (isomerization), which subsequently condenses to the 14,21-epoxylactam $\mathbf{7}$ or $\mathbf{8}$ (refs ${ }^{2,3}$ ). With aniline, the lactone ring is not attacked even at $100^{\circ} \mathrm{C}$.

From compounds 5-8 the cardenamides $\mathbf{9}$ or $\mathbf{1 0}$ can be formed by treatment with $\mathrm{SbCl}_{3} / \mathrm{SiO}_{2}$ at $120{ }^{\circ} \mathrm{C}$ (54\%) or ethanol/ $\mathrm{H}_{2} \mathrm{SO}_{4}(0.2 \%)$ under reflux ${ }^{4}$ (33\%). Unfortunately, these procedures are also associated with the loss of $14 \beta-\mathrm{OH}$ and formation of the $\Delta^{14}$-double bond which is unfavourable for cardioactivity (cf. Table I: $\mathbf{1}$ vs 3; $\mathbf{2}$ vs 4).

Table I
Inhibition of the $\mathrm{Na}^{+}, \mathrm{K}^{+}$-ATPase of guinea pig heart (GPH) or human heart (HH) by lactones and lactams (n.d. means not determined)

| Compound | GPH |  | $\mathrm{HH}^{\mathrm{H}}$ |
| :---: | :---: | :---: | :---: |

| 4 | 100 | 13 | n.d. |
| 9 | 50 | 7 | n.d. |
| 10 | 100 | $\sim 35$ | n.d. |
| 15 | $1.03 \pm 0.19$ | 50 | 0.19 |
| 17 | 100 | 35 | n.d. |
| 18 | 100 | $\sim 30 \pm 1$ | 65.8 |
| 20 | 100 | 28 | n.d. |
| 22 | $\sim 75 \pm 5$ | 50 | n.d. |
| 23a | 100 | $28 \pm 4$ | n.d. |
| 23 | $\sim 56 \pm 4$ | 50 | n.d. |
| 24 | 100 | $30 \pm 1$ | n.d. |
| 25 | 100 | 15 | n.d. |
| 26 | 76 | 50 | 65.8 |
| 27 | $\sim 100$ | 50 | 66 |
| 28 | 27 | 50 | n.d. |
| 30 | n.d. | n.d. | 45 |

These transformations are restricted to the lactam derivatives: The oxygen analogue isodigitoxigenin 13 is not transformed into the $\Delta^{14}$-butenolide 14 under these conditions. $14 \beta-\mathrm{OH}$ is not a prerequisite for the formation of the $\Delta^{14}$-cardenamides. Their formation (11, 12) works as well starting with $\Delta^{14}$-cardenolides $(\mathbf{3}, \mathbf{4})$ under the same conditions.

## Second M ethod

Avoidance of isomerization and conservation of $14 \beta-\mathrm{OH}$ can be achieved by reaction of the (21R)-21-bromocardenolide 16 (Scheme 2) (from 15 by bromination with N -bromosuccinimide ${ }^{5}$ ) with ammonia or methylamine leading to the (21R)-21-hydroxycardenamide 17 (51\%) or the (21R)-21-

hydroxy-N-methylcardenamide 18 (60\%) containing the C20-C22 double bond and $14 \beta-\mathrm{OH}$ but an additional OH group at C21 (ref. ${ }^{6}$ ).
Treatment of $\mathbf{1 7}$ or $\mathbf{1 8}$ with $\mathrm{NaBH}_{4}$ does not remove the 21-OH group. Treatment of 18 with $\mathrm{SOCl}_{2}$ does not lead to the formation of the respective 21-CI derivative $\mathbf{2 1}$ (Scheme 3) but of the (21S)-14,21-epoxylactam 23. To remove $21-\mathrm{OH}$ from 18 it is reacted with tosyl chloride to the (21R)-tosylate 22 (48\%) followed by reduction with zinc/acetic acid to give the $14 \beta$-hydroxy-N-methylcardenamide ${ }^{6} 24$ (43\%) and its 20(22)-dihydro derivative (25; 17\%).

24

21

23 (23a: O instead of $\mathrm{N}-\mathrm{CH}_{3}$ )

25

26, R = H
27, $\mathrm{R}=\mathrm{CH}_{3}$

Otherwise, oxidation ${ }^{7}$ of the allylic $21-\mathrm{OH}$ of $\mathbf{1 7}$ or $\mathbf{1 8}$ with active $\mathrm{MnO}_{2}$ or $\mathrm{CrO}_{3} \cdot 2 \mathrm{Py}$ leads to the 21-oxo derivative 26 (72\%) or 27 (70\%). In an analogous way 30 ( $31 \%$ from 28) is prepared from pentaacetylgitoxin 28 in order to elucidate the role of the sugar chain ${ }^{8}$ (Scheme 4). The 21,21-dibromogitoxigenin diacetate ${ }^{9} 19$ (Scheme 2) reacts with methylamine to the ring-opened 21,23-bis-(N-methylamide) ${ }^{10} 20$.

29

30

Scheme 4
Properties of the Compounds
The following properties of the compounds are in agreement with the given structures. The chromatographic mobility increases in the following order: diamide $\mathbf{2 0}<21$-OH-lactams $\mathbf{1 7}<\mathbf{1 8}<\mathrm{N}$-M e-lactam $\mathbf{2 4}<$ maleimide $\mathbf{2 6}$ <lactone $\mathbf{1 5}$ <maleimide $\mathbf{2 7}$ <21-tosylate $\mathbf{2 2}<14,21-0-\mathrm{N}$-Me-lactam $\mathbf{2 3}<$ 14,21-0-lactone 23a. This means that lactams and maleimides are more poIar than analogous lactones. Thiol reactivity: 26, 27, $\mathbf{3 0}$ are maleimide derivatives and as such add, SH groups to the C20-C22 double bond as shown by treatment with $\mathrm{H}_{2} \mathrm{~S} /$ pyridine at $0{ }^{\circ} \mathrm{C}$ : $\mathbf{2 6}$ and (somewhat faster) $\mathbf{2 7}$ form a more polar, sulfur-containing product (TLC). Colour reactions: Like the cardenolide ring, the cardenamide ring, too, reacts with 1,3-dinitrobenzene/ NaOH (Raymond reaction ${ }^{11}$ ) with the formation of a coloured
(violett and red, respectively) Meisenheimer complex, making a specific detection in TLC easy $\mathbf{9}, \mathbf{1 0}, \mathbf{1 1}, \mathbf{1 2}, \mathbf{2 4}$, as far as there are two hydrogens bound at C21. Cardenamides with an NH group are detected by the chlorine-benzidine reaction ${ }^{12}$. Lactone transformation into lactams shifts the wavelengths of the UV maxima by about 10 nm to shorter wavelengths, which is compensated or overcompensated by 21 -substituents. Wavelengths of the UV maxima increase in the following order: Iactams 9, $\mathbf{2 4}<$ 21-OH-lactams 17, 18 <lactones 1, 2, 15, 23a <diamide $20<21$-tosylate $22<$ maleimide 27. The molar absorption coefficients are nearly equal for all the compounds. In the IR spectra ( $v$ values given in $\mathrm{cm}^{-1}$ ) the transition from lactone to lactam ( $\mathbf{1 5} \rightarrow \mathbf{2 4}$ ) shifts the O-H-frequency to lower values, the $\mathrm{C}=0$-frequency is not strongly affected except for the lowering in the case of the maleimides 26 and 27. An amide band is found between 1670 and 1700 which is missing in case of the maleimides 26 and 27. The $C=C$ frequency between 1 600-1 635 is strongly shifted to 1690 by 14,21-epoxide formation in case of $\mathbf{2 3}$. In MS spectra most compounds (9, 20, 23, 24, 26) show the molecular ion, others split off $\mathrm{H}_{2} \mathrm{O}$ or $\mathrm{AcOH}(\mathbf{1 7}, \mathbf{1 8}$ or 27). The Iactam ring is especially stable as is seen in MS of 9: here the molecular peak is the basic peak. In ${ }^{1} \mathrm{H}$ NMR spectra only lactam ring protons are shifted compared with lactones. Comparing 15 and 24 the values for $\mathrm{C} 21-\mathrm{H}_{2}$ are lowered for about 1 ppm . In the presence of a C14-C15 double bond the same holds true ( $\mathbf{3}$ vs 9; 4 vs 11; 4 vs 12). These shifts are more or less compensated by substituents at C21 (17, 18, 20, 23).

## Biological Activity

## $\mathrm{Na}^{+} / \mathrm{K}^{+}$-ATPase Inhibition and Guinea Pig Auricle Test

As a measure of cardioactivity the inhibition of $\mathrm{Na}^{+} / \mathrm{K}^{+}-$ATPase ( $\mathrm{Na}^{+} / \mathrm{K}^{+}-$ transporting adenosine triphosphatase, E.C.3.6.1.37) of guinea pig heart (GPH) and/or human heart ${ }^{13,14}(\mathrm{HH})$ were determined. The obtained values (Table I) are limited in number and, therefore, allow only preliminary conclusions as to more general structure-activity relationships. The change from lactone to lactam decreases the activity of the very active $\mathbf{1 5}$ by more than two orders of 10 ( $\mathbf{1 5}$ vs 24), also in the human heart ( $\mathbf{1 5}$ vs 26, 27, 30), but moderate for the least active $\mathbf{2 8}$ ( $\mathbf{2 8}$ vs $\mathbf{3 0}$ ). The activity of the little active $\mathbf{3}$ is nearly unchanged ( $\mathbf{3}$ vs $\mathbf{9}, \mathbf{1 0}$ ), but increased for the low active 23a ( $\mathbf{2 3 a}$ vs 23, the most active Iactam shown here). The change of NH by N -methyl has no influence ( $\mathbf{9}$ vs 10; $\mathbf{1 7}$ vs 18) or decreases the activity
slightly ( $\mathbf{2 6}$ vs 27). The hydrogenation of the C20-C22 double bond in the lactam ring decreases the activity ( $\mathbf{2 4} \mathrm{vs} \mathbf{2 5}$ ) as does the opening of the lactame ring ( $\mathbf{2 7}$ vs 20). Contrary to the experience in the cardenolide field, substitution at C21 has no influence ( $\mathbf{2 4}$ vs $\mathbf{1 8}$ ) or increases the activity ( $23 a$ vs 23; 24 vs 22; 24 vs 27). The sensitivity of human heart $\mathrm{Na}^{+} / \mathrm{K}^{+}-$ATPase is somewhat higher than that of guinea pig heart (27). Also in the isolated guinea pig auricle ${ }^{15}, \mathbf{1 8}$ shows a very weak activity ${ }^{16}$ (Table II).

## Anticancer Activity

The anticancer activity of maleimide derivatives 26, 27, 30 was tested in three cancer cell lines: Ehrlich mouse ascites tumor cells (EMAC), mouse melanosarcoma cells (B16) and human mammary carcinoma cells ${ }^{8}$ (MCA). The results are shown in Table III. For EMAC cells $\mathbf{3 0}$ is the most active in-

Table II

| 30 | 1.5 | 50 | 1.5 | n.d. | 89 | $45^{\text {a }}$ |

[^1]hibitor, demonstrating the favourable effect of the acetylated sugar chain, contrary to its effect in $\mathrm{Na}^{+} / \mathrm{K}^{+}-$ATPase inhibition. Comparison of $\mathbf{2 6}$ and 27 reveals the favourable effect of N -methyl in comparison with NH. Compound $\mathbf{2 7}$ is less active against B16 but more and equally active against EMAC and MCA. The anticancer active concentrations are far below
 anticancer activity is caused by the thiol reactivity of the compounds. The $\mathrm{Na}^{+} / \mathrm{K}^{+}$-ATPase inhibition by $\mathbf{3 0}$ is in GPH twice as strong as in EMAC.

## Discussion

Shortly after the synthesis of the cardenamides ${ }^{4,6} \mathbf{9 - 1 2 , 2 4}$ shown here, two other syntheses ${ }^{17,18}$ were published independently. These methods have the same or a higher number of steps and give about the same yield of cardenamides showing a strongly decreased cardiac activity ${ }^{18}$.

The reaction mechanisms of the first and second method (this paper) have the first step in common: the aminolysis of the lactone ring leading to the 23 -amide ${ }^{2,3}$, but they differ strongly in the reaction rate with amines, depending on the substiution at C 21 . The reaction times are:

$$
\text { for } 21-\mathrm{H}_{2}:>21 \text { days, for } 21-\mathrm{Br}, \mathrm{H}: \leq 2 \mathrm{~h} \text {, for } 21-\mathrm{Br}_{2} \text { : } \leq 1 \min (!)
$$

as measured by consumption of the starting material, thus demonstrating a steep increase in the reactivity caused by the -I-effect of $21-\mathrm{Br}$, which increases the positive partial charge at C23.

Further influences are the cardenolide structure,

$$
\Delta^{14} \text {-cardenolide }>14 \beta \text {-OH-cardenolide, }
$$

the basicity of the amine

$$
\mathrm{CH}_{3}-\mathrm{NH}_{2}\left(\mathrm{pK}_{\mathrm{b}} 3.35\right)>\mathrm{NH}_{3}\left(\mathrm{pK}_{\mathrm{b}} 5.0\right) \gg \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{2}\left(\mathrm{pK}_{\mathrm{b}} 9.30\right)
$$

and the solvent used

$$
\text { Pyridine }-\mathrm{H}_{2} \mathrm{O}>\mathrm{MeOH}>\text { Pyridine } \approx \mathrm{DMF} \approx \text { DM SO }
$$

showing clearly that protic solvents are favourable.
Both methods, however, differ markedly in the following steps:
In the first method, the primarily formed 23-amide undergoes isomerization to 5, 6. Only here the lactam (cardanamide) formation ${ }^{2,3}$ (7, 8)
seems possible. Dehydration of these compounds under acid or Lewis acid catalysis leads to the cardenamides ${ }^{4}$ 9-12.
The easy hydrolysis of cardanolides may be the cause that the oxygen analogue $\mathbf{1 3}$ does not form the respective lactone $\mathbf{1 4}$ under these conditions.

In the second method isomerization is possible in principle, but is overcome by the much faster SN 2 reaction of the C23-amide group with the bromo substituent at C21 with Walden inversion forming only the 21R epimers of the 21-hydroxycardenamides ${ }^{6,8}(\mathbf{1 7}, \mathbf{1 8})$ (only one spot found in TLC). The 21R configuration is deduced from the easy formation of the (21S)-14,21-epoxylactam 23 in analogy to the behaviour of the (21R/S)-21bromocardenolides: Only the (21R)-21-bromo derivative 16 forms quite easy the (21S)-14,21-epoxide 23a. The 17 $\beta$-configuration (excluding epimerization at C17 under amine treatment) of the cardenamide ring is concluded from ${ }^{1} \mathrm{H}$ NMR $(17 \alpha-\mathrm{H})$ and again the easy formation of 23. In $17 \alpha$-cardenolides the 14,21-epoxide formation is impossible for steric reasons.
The reaction of the 21,21-dibromocardenolide ${ }^{9} 19$ (Scheme 2) with methylamine leads to the respective 23-N-methylamide which forms the $21-\mathrm{COBr}$ derivative by loss of HBr . This does not react with the $23-\mathrm{N}-$ methylamide group by ring closure with formation of 27 (as can be deduced from different TLC mobility), but with the stronger nucleophile methylamine under formation of the 21,23 -diamide ${ }^{10} \mathbf{2 0}$. The amide bands I and II in the IR spectrum of $\mathbf{1 3}$ are incompatible with the structure of a 21,21-bis(methylamino)cardenolide (cf. Experimental).

## Removal of $21-\mathrm{OH}$

In 21-hydroxycardenolides, 21-OH is easily removed by treatment ${ }^{19}$ with $\mathrm{NaBH}_{4}$. This fails with 21-hydroxycardenamides because of their less easy hydrolysis which might be a prerequisite for the removal. Therefore, the reduction of the 21-tosylate was used which is accompagnied in part by hydrogenation of the C20-C22 double bond, leading to the 20(22)-dihydro derivative of 24 (25).

## Cardioactivity

The reason for the drop in activity of cardenamides compared to cardenolides (Table I) is not clear at present but it demonstrates the importance of the ring oxygen in the lactone ring for the activity. Because NH and

N -methyl derivatives do not differ essentially in their activity (Table I) additional hydrogen bond formation by NH is not responsible.

X-Ray structures of $\mathbf{1 5}$ (ref. ${ }^{20}$ ) and $\mathbf{2 6}$ (ref. ${ }^{21}$ ) do not show serious differences with respect to bond lengths and angles. A possible reason might be the change in the D-ring shape (in 15: $13 \alpha, 14 \beta$-half chair, in 26: between $13 \alpha, 14 \beta$-half chair and $14 \beta$-envelope), as long as it also exists in solution. $17 \alpha$-Configuration as a possible reason for loss of activity is likewise excluded as shown above ( $17 \alpha$-cardenolides are known as inactive). It is remarkable that, contrary to the cardenolide series, the presence or absence of $14 \beta-\mathrm{OH}$ has no influence on the activity. Therefore, an electronic effect in the cardeneamide ring could be taken into consideration. Changes in the wavelengths of the UV-absorption maximum reflect electronic changes in this chromophore. In this connection it is interesting to see the parallelism between the wavelength of UV-absorption maxima and biological activity: Iactams ( $\approx 205 \mathrm{~nm}$ ), low activity; Iactones ( $\approx 217 \mathrm{~nm}$ ), active; bufadienolides ( $\approx 300 \mathrm{~nm}$ ), more active.

## Anticancer Activity

The thiol reactivity of the maleimide derivatives 26, 27, $\mathbf{3 0}$ is similar to the well-known maleimide derivative showdomycin ${ }^{22}$. In this compound, the maleimide ring is linked to a ribofuranosyl residue in a "C-glycosidic" manner. This compound is well known as a broad-spectrum antibiotic and shows furthermore other biologic activities including antitumor activity ${ }^{22}$. Compounds 26, 27, 30 also show this activity which seems to be attractive for an in-depth investigation. In comparison to showdomycin, $\mathbf{3 0}$ is much less polar which causes a strongly different distribution in the body. The question of additional activities needs further research.

## EXPERIMENTAL

Thin layer chromatography (TLC) was done on TLC plates (Kieselgel 60 F254 Merck). Mobile phases: a, chloroform-acetone (95:5); b, chloroform-acetone (90:10); c, chloro-form-acetone (70:30); d, chloroform-ethanol (97.5:2.5); e, chloroform-ethanol (95:5); f , chloroform-ethanol ( $80: 20$ ). In brackets $(\mathrm{n} \times$ ): number of developments if $\mathrm{n}>1$. Detection: $\mathrm{H}_{3} \mathrm{PO}_{4} / \mathrm{UV} 266 \mathrm{~nm}$ (ref. ${ }^{23}$ ), 1,3-dinitrobenzene (m-DNB)/ NaOH (ref. ${ }^{11}$ ), fluorescein/ $\mathrm{H}_{2} \mathrm{O}_{2}$ (ref. ${ }^{24}$ ) (results given in brackets in this range without specification of the reagent). With specification of the reagent: $\mathrm{SbCl}_{3}$ (ref. ${ }^{25}$ ), trichloroacetic acid-chloroamine T (TCE) ${ }^{26}$, fluorescein-bromine (detection of isolated double bonds, ref. ${ }^{27}$ ), UV fluorescence at 366 nm (UV), chlorine-benzidine (detection of NH, ref. ${ }^{12}$ ). The relative mobility ( $\mathrm{R}_{\mathrm{x}=100}$ ) related to a standard substance is given. Colours: blue (bl), brown (br), dark (d), yellow (y), green (gr), red (r), mauve (m), violet (v), orange (or), negative (neg.), positive (pos.), bright (bt). Pre-
parative layer chromatography (PLC) was done at analytical TLC plates ( 0.25 mm thickness) with loading up to 50 mg . Higher amounts (up to 200 mg ) were separated at plates of 2 mm thickness (Merck). Detection: UV 254 and/or 366 nm or spraying $\mathrm{H}_{2} \mathrm{O}$ or $\mathrm{I}_{2}$ - vapour contact. Elution: acetone. Corrected melting points (m.p.) were determined with the Boetius melting point microscope apparatus (VEB Analytik, Dresden). Solvent for crystallization is given in parentheses. To detect decomposition the melt was investigated by TLC. Ultraviolet spectra $\left[\lambda_{\max }\right.$ in $\left.n m(\log \varepsilon)\right]$ were recorded with the spectral-photometer DK-2A (Beckman Instruments Inc., Fullerton, U.S.A.) in ethanol. Infrared spectra ( KBr , wavenumbers in $\mathrm{cm}^{-1}$ ) were recorded on Specord 75 IR (VEB Carl Zeiss, Jena, Germany) or Spectromom 2000 (MOM, Budapest, Hungary). Intensities: strong (st), very strong (vst), weak (w), medium (m), shoulder (sh), sharp (s), broad (br).

Electron impact mass spectra (MS, m/e is given) were recorded with a mass spectrometer MS 902 S (AEI, Manchester, G.B.). The composition of the important ions is secured by high resolution: resolution 10 000, 10\% valley. Difference between found and calculated values maximal $\pm 3$ millimasses. Electron energy: 70 eV . Source temperature is given at each compound. ${ }^{1} \mathrm{H}$ NMR spectra were measured on an NMR spectrometer KRH 100 (Central Scientific Instruments Construction, Academy of Sciences, Berlin, Germany) and BS 497 (TESLA, Brno, Czechoslovakia) at 100 MHz in the continuous wave mode in $\mathrm{CDCl}_{3}$. Chemical shifts in ppm ( $\delta$-scale) were referred to internal TMS. Coupling constants (J) were given in Hz . Aqueous solutions used: $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}(5 \%), \mathrm{KHCO}_{3}(10 \%)$. Solutions in organic solvents were dried with anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$. Pyridine was removed by washing with concentrated $\mathrm{CuSO}_{4}$ solution. Solvents were removed using a rotatory evaporator at 13 mm Hg and low bath temperatures.

## 17ß-(5-Oxo-2,5-dihydropyrrol-3-yl)-5 $\beta$-androst-14-en-3 3 -ol (9)

First method: A solution of $\mathbf{1}(250 \mathrm{mg}, 0.92 \mathrm{mmol})$ in methanol ( MeOH ) ( 12 ml ) was saturated with gaseous $\mathrm{NH}_{3}$ at $0^{\circ} \mathrm{C}$. The mixture was heated in a steel autoclave at $110{ }^{\circ} \mathrm{C}$ for 17 h . The evaporation residue is crude ${ }^{2,3} 5$ ( 271 mg ). To its solution in ethanol ( 27 ml ), $\mathrm{H}_{2} \mathrm{SO}_{4}(2 \%, 2.7 \mathrm{ml})$ was added and the mixture was heated to reflux for 2 h . The major part of ethanol was distilled off at $25^{\circ} \mathrm{C}$, to the residue chloroform was added and washed until neutral. PLC (b, $3 \times$ ) yields 9 ( $77 \mathrm{mg}, 33 \%, 0.22 \mathrm{mmol}$ ).

Second method: Crude 5 ( $100 \mathrm{mg}, 0.27 \mathrm{mmol}$ ) was dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( 10 ml ), mixed with silica gel ( 5 g ) and $\mathrm{SbCl}_{3}(100 \mathrm{mg}, 0.44 \mathrm{mmol})$ and heated at $120^{\circ} \mathrm{C}$ for 20 min . Elution with acetone with $4 \%$ of pyridine, washing and PLC yields 9 ( $56 \mathrm{mg}, 54 \%$ ). TLC (b, $3 \times$ ): $\mathrm{R}_{1}$ : 58 ( $\mathrm{SbCl}_{3}$ : bl, m-DNB: r). UV: $\leq 205$. IR: 3400 (sh), 3250 (st, N-H), 1715 (vst), 1640 (vst, amide I), 1600 (m, $\Delta^{20(22)}$ ), 1445 (st), 1375 (w), 1270 (st, amide III), 1 065, $1040,760,700 . \mathrm{MS}\left(170{ }^{\circ} \mathrm{C}\right): 355 \mathrm{BP}(\mathrm{M}), 340$ vst $\left(\mathrm{M}-\mathrm{CH}_{3}\right), 337$ vst ( $\mathrm{M}-\mathrm{H}_{2} \mathrm{O}$ ), 322 vst $\left(\mathrm{M}-\mathrm{H}_{2} \mathrm{O}-\mathrm{CH}_{3}\right), 283$ st $\left(\mathrm{M}-\mathrm{H}_{2} \mathrm{O}-\mathrm{C}_{4} \mathrm{H}_{6}\right.$ : ring A), $203 \mathrm{w}, 110\left(\mathrm{C}_{6} \mathrm{H}_{8} \mathrm{NO}\right.$ : butenamide ring + $\left.17-\mathrm{CH}+16-\mathrm{CH}_{2}+\mathrm{H}\right) .{ }^{1} \mathrm{H}$ NMR: $5.91(\mathrm{~s}, 1 \mathrm{H}, 22-\mathrm{H}) ; 5.20\left(\mathrm{~m}, 2 \mathrm{H}, 15-\mathrm{H}_{2}\right) ; 4.12(\mathrm{~s}, 1 \mathrm{H}$, $3 \alpha-\mathrm{H}) ; 3.95\left(\mathrm{~s}, 2 \mathrm{H}, 21-\mathrm{H}_{2}\right) ; 2.88(\mathrm{~m}, 1 \mathrm{H}, 17 \alpha-\mathrm{H}) ; 2.65(\mathrm{~s}, \mathrm{NH}) ; 1.02\left(\mathrm{~s}, 3 \mathrm{H}, 19-\mathrm{H}_{3}\right) ; 0.79(\mathrm{~s}$, $3 \mathrm{H}, 18-\mathrm{H}_{3}$ ).
$17 \beta$-(5-Oxo-2,5-dihydropyrrol-3-yl)-5 $\beta$-androst-14-en-3 3 -yl Acetate (11)
Compound 4 ( $827 \mathrm{mg}, 2.08 \mathrm{mmol}$ ) was dissolved in MeOH ( 200 ml ) and saturated with gaseous $\mathrm{NH}_{3}$ at $0{ }^{\circ} \mathrm{C}$. Evaporation at room temperature after 5 days gave 992 mg residue. To its
solution in chloroform ( 50 ml ), $\mathrm{SbCl}_{3}(992 \mathrm{mg}, 4.35 \mathrm{mmol})$ and $\mathrm{SiO}_{2}(50 \mathrm{~g})$ were added and the mixture was evaporated. Heating the residue at $120^{\circ} \mathrm{C}$ for 20 min , elution with acetone with $4 \%$ of pyridine, evaporation, solution in chloroform, washing successively with dilute $\mathrm{HCl}, \mathrm{KHCO}_{3}$ and water, evaporation. Column chromatography (silica gel 0.03-0.2 mm, Merck) with chloroform-acetone gave 11 ( $693 \mathrm{mg}, 81 \%$ ). TLC (c, $3 \times$ ): $\mathrm{R}_{\mathrm{F}} 0.42 ; \mathrm{R}_{1} 89$ (m-DNB: r). MS (170 $\left.{ }^{\circ} \mathrm{C}\right)$ : $411(\mathrm{M})$, $393\left(\mathrm{M}-\mathrm{H}_{2} \mathrm{O}\right), 110\left(\mathrm{C}_{6} \mathrm{H}_{8} \mathrm{ON}\right.$ : butenamide ring $+17-\mathrm{CH}+$ $16-\mathrm{CH}_{2}+\mathrm{H}$ ). The byproduct was $9(59 \mathrm{mg}, 8 \%)$ with properties as above.

17 $\beta$-(1-M ethyl-5-oxo-2,5-dihydropyrrol-3-yl)-5
Compound 15 ( $500 \mathrm{mg}, 1.26 \mathrm{mmol}$ ) was dissolved in pyridine ( 15 ml ), methylamine ( $33 \%$ in water, $3.5 \mathrm{ml}, 37.1 \mathrm{mmol}$ ) was added and after 2 days at room temperature the mixture was evaporated. To a solution of the residue ( 1.07 g ) in pyridine ( 10 ml ), acetic anhydride $(10 \mathrm{ml})$ and, after $16 \mathrm{~h}, \mathrm{MeOH}(6 \mathrm{ml})$ were added. One hour later the mixture was evaporated. The residue ( 1.123 g ) was dissolved in chloroform ( 20 ml ), silica gel ( 11 g ) and $\mathrm{SbCl}_{3}$ $(1.13 \mathrm{~g}, 4.96 \mathrm{mmol})$ were added and the solvent was removed. Treatment as above (second method) and column chromatography (silica gel $0.03-0.2 \mathrm{~mm}$, Merck) with chloroformacetone yields 12 ( $215 \mathrm{mg}, 41 \%$ ). TLC (c, $3 \times$ ): $\mathrm{R}_{\mathrm{F}} 0.71, \mathrm{R}_{1} 120\left(\mathrm{SbCl}_{3}: \mathrm{bl}, \mathrm{m}-\mathrm{DNB}: \mathrm{r}, \mathrm{NH}\right.$ : neg.). ## 14-Hydroxy-17 $\beta$-(N-methylmaleinimidoyl)-5 $\beta, 14 \beta$-androstane-3 $\beta, 16 \beta$-diyl Diacetate (27)

Compound 18 ( $500 \mathrm{mg}, 0.99 \mathrm{mmol}$ ) was oxidised with $\mathrm{MnO}_{2}$ for $4 \mathrm{~h}(5 \mathrm{~g}, 57.5 \mathrm{mmol})$ as above. PLC (d, $3 \times$ ) yields 27 ( $351 \mathrm{mg}, 70 \%$ ). M.p. 172-177 ${ }^{\circ} \mathrm{C}$ (chloroform-ethanol 9 : 1). TLC (e, $2 \times$ ): R ${ }_{18}$ 145, R ${ }_{15} 107$ (or, neg., NH: neg.). IR: 3450 (sh), 1730 (vst), 1700 (vst), 1620 w, 1445 , 1375 (st), 1245 (vst), 1 080, 1015 (st), 880, 685; N-H: 3150 (st, br), 3045 (m). MS ( $175{ }^{\circ} \mathrm{C}$ ): 501 st ( M ), 441 vst ( $\mathrm{M}-\mathrm{AcOH}$ ), 381 ( $\mathrm{M}-2 \mathrm{AcOH}$ ), 363 ( $\mathrm{M}-2 \mathrm{AcOH}-$ $\left.\mathrm{H}_{2} \mathrm{O}\right)$, $348\left(\mathrm{M}-2 \mathrm{AcOH}-\mathrm{H}_{2} \mathrm{O}-\mathrm{CH}_{3}\right), 314 \mathrm{st}\left(\mathrm{M}-\mathrm{AcOH}-\mathrm{H}_{2} \mathrm{O}-\mathrm{N}\right.$-methylmaleimide ring), $263(203+\mathrm{AcOH}), 205\left(\mathrm{C}_{11} \mathrm{H}_{11} \mathrm{NO}_{3}: \Delta^{16}\right.$-ring $\mathrm{D}+14-\mathrm{OH}+\mathrm{N}$-methylmaleimide ring + $\left.13 \beta-\mathrm{CH}_{3}\right) 203 \mathrm{BP}\left(\mathrm{C}_{15} \mathrm{H}_{23}\right)$.

## Reaction of $\mathbf{2 6} / \mathbf{2 7}$ with $\mathrm{H}_{2} \mathrm{~S}$

Compound 26 ( $10 \mathrm{mg}, 0.02 \mathrm{mmol}$ ) was dissolved in pyridine ( 2 ml ) and saturated with $\mathrm{H}_{2} \mathrm{~S}$ at $0^{\circ} \mathrm{C}$. TLC ( $\mathrm{d}, 2 \times$ ) shows that after 24 h 26 was transformed mainly ( $90 \%$ ) to a more polar product which contains $\mathrm{S}^{2+}: \mathrm{R}_{26} 77\left(\mathrm{H}_{3} \mathrm{PO}_{4}: y\right.$, iodine-azide-starch reagent ${ }^{28}$ for $\mathrm{S}^{2+}$ : pos.).

Compound 27 reacts analogously but somewhat faster: after $15 \mathrm{~h} 100 \%$ transformation. $R_{27} 14$ (y, $\mathrm{S}^{2+}$ : pos.).
$3 \beta$-[3,4-Di-O-acetyl-2,6-dideoxy- $\beta$-d-ribo-hexopyranosyl-(1 $\rightarrow 4$ )-3-0-acetyl-2,6-dideoxy-$\beta$-d-ribo-hexopyranosyl-(1 $\rightarrow 4$ )-3-0-acetyl-2,6-dideoxy- $\beta$-d-ribo-hexopyranosyl)oxy]-14-hydroxy-17 -(N-methylmaleimidoyl)-5 $\beta, 14 \beta$-androstane-16 -yl Acetate (30)

Penta-O-acetylgitoxin 28 ( $2 \mathrm{~g}, 2.02 \mathrm{mmol}$ ) in $\mathrm{CCl}_{4}$ ( 200 ml ) was brominated with N -bromosuccinimide ( $1.44 \mathrm{~g}, 8.09 \mathrm{mmol}$ ) according to the standard procedure (see preparation of 17). The reaction mixture was filtered and the filtrate was washed successively with $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}, \mathrm{KHCO}_{3}$, water and dried. Methylamine ( $2 \mathrm{ml}, 33 \%$ in ethanol, 21.2 mmol ) was added to the solution of the bromination product. After 20 h at room temperature the mixture was washed successively with $0.1 \mathrm{~m} \mathrm{HCl}, \mathrm{KHCO}_{3}$ and water, dried and evaporated in vacuo. The oily residue obtained was chromatographed on silica gel ( 100 g ). Elution with chloroform-ethanol (98:2) gave the 21-hydroxy-N-methyllactam 29 ( $627 \mathrm{mg}, 30.4 \%$ ) which was dried over $\mathrm{P}_{2} \mathrm{O}_{5}$ in vacuo, dissolved in chloroform ( 20 ml ) and shaken with active $\mathrm{MnO}_{2}$ $(6.8 \mathrm{~g}, 78.2 \mathrm{mmol})$ for 2 h . The reaction product was purified on silica gel ( 30 g ). Elution with chloroform provided $30(527 \mathrm{mg}, 84.2 \%$ from 29) which crystallized from ether-methanol-pentane as needles, m.p. $156-159{ }^{\circ} \mathrm{C} . \mathrm{MS}: 631\left(\mathrm{C}_{34} \mathrm{H}_{49} \mathrm{NO}_{10}: \mathrm{M}^{+}-3^{\prime \prime}, 3^{\prime \prime \prime}, 4^{\prime \prime \prime}\right.$-tri-Oacetyl(digitoxosyl) $)_{2}$ ), $613\left(631-\mathrm{H}_{2} \mathrm{O}\right), 571\left(631-\mathrm{CH}_{3} \mathrm{COOH}\right), 553\left(613-\mathrm{CH}_{3} \mathrm{COOH}\right), 511$ (631-2 CH 3 COOH ), 493 ( $613-2 \mathrm{CH}_{3} \mathrm{COOH}$ ), 459 (aglycon: $\mathrm{M}^{+}-3^{\prime}, 3^{\prime \prime}, 3^{\prime \prime \prime}, 4^{\prime \prime \prime}$-tetra-O-acetyl(digitoxosyl) $)_{3}$, 442 ( $459-\mathrm{OH}$ ), 399 ( $459-\mathrm{CH}_{3} \mathrm{COOH}$ ), $387\left(\mathrm{C}_{18} \mathrm{H}_{27} \mathrm{O}_{9}: 3^{\prime \prime}, 3^{\prime \prime \prime}, 4^{\prime \prime \prime}\right.$-tri-O-acetyl(digitoxosyl) $)_{2}$, 382 ( $442-\mathrm{CH}_{3} \mathrm{COOH}$ ), 327 (387- CH COOH ), $231\left(\mathrm{C}_{10} \mathrm{H}_{15} \mathrm{O}_{6}\right.$ : $3^{\prime \prime \prime}, 4^{\prime \prime \prime}$-di-O-acetyldigitoxosyloxy), $215\left(\mathrm{C}_{10} \mathrm{H}_{15} \mathrm{O}_{5}\right.$ : 3"', $4^{\prime \prime \prime}$-di-O-acetyldigitoxosyl), 155 (215$\mathrm{CH}_{3} \mathrm{COOH}$ ), 95 ( $215-2 \mathrm{CH}_{3} \mathrm{COOH}$ ). MS (high resolution): 459.2618 (calculated for $\mathrm{C}_{26} \mathrm{H}_{37} \mathrm{NO}_{6}: 459.2621$ ), 399.2397 (calculated for $\mathrm{C}_{24} \mathrm{H}_{33} \mathrm{NO}_{4}: 399.2409$ ).

## 14-Hydroxy-17 $\beta$-(1,2-N -methylcarbamoylvinyl)-5 $\beta, 14 \beta$-androstane-3 $3 \beta, 16 \beta$-diyl Diacetate (20)

Compound 15 ( $250 \mathrm{mg}, 0.53 \mathrm{mmol}$ ) was brominated with NBS ( $281 \mathrm{mg}, 1.58 \mathrm{mmol}$ ) by the standard procedure. The crude reaction product (containing besides the 21-bromo derivative 16 the 21,21-dibromo derivative 19) was dissolved in chloroform ( 27 ml ), methylamine ( $33 \%$ in $\mathrm{H}_{2} \mathrm{O}, 0.23 \mathrm{ml}, 2.44 \mathrm{mmol}$ ) was added and the mixture was shaken for 10 min . PLC (f) and elution of the zone $R_{F} 0.21$ yields 20 ( $25 \mathrm{mg}, 23 \%$ from 15). Clusters of fine needles
 UV: 218 (4.087). IR: 3400 (st, br), 3300 (sh, N-H), 1735 (vst), 1635 (vst, amide I), 1535 (st, amide II), 1455 (w, N-Me), 1 380, 1370 (m, C-N), 1 255-1 230 (vst, br), 1155 (w), 1025 (m, C-N). MS ( $160{ }^{\circ} \mathrm{C}$ ): $532 \mathrm{w}(\mathrm{M}), 501$ st $\left(\mathrm{M}-\mathrm{CH}_{3} \mathrm{NH}_{2}\right), 472(\mathrm{M}-\mathrm{AcOH}), 441$ vst ( $\mathrm{M}-$ $\left.\mathrm{AcOH}-\mathrm{CH}_{3} \mathrm{NH}_{2}\right), 400\left(\mathrm{M}-2 \mathrm{CONHCH}_{3}-\mathrm{CH}_{3}-\mathrm{H}\right), 381$ st $\left(\mathrm{M}-2 \mathrm{AcOH}-\mathrm{CH}_{3}-\mathrm{NH}_{2}\right), 263$ $(203+\mathrm{AcOH}), 203 \mathrm{BP}\left(\mathrm{C}_{15} \mathrm{H}_{23}\right){ }^{1} \mathrm{H}$ NMR: $6.22(\mathrm{~s}, 1 \mathrm{H}, 22-\mathrm{H}) ; 5.37$ (tr, $\left.1 \mathrm{H}, 16 \alpha-\mathrm{H}\right) ; 5.11$ (s, $1 \mathrm{H}, 3 \alpha-\mathrm{H}) ; 3.02(\mathrm{~d}, 1 \mathrm{H}, 17 \alpha-\mathrm{H}) ; 2.80$ and $2.85\left(2 \mathrm{~d}, 2 \times 3 \mathrm{H}, 2 \times \mathrm{N}^{2}-\mathrm{CH}_{3},+\mathrm{D}_{2} \mathrm{O}\right.$ : one s); 2.52 (q, $1 \mathrm{H}, 15 \alpha-\mathrm{H}$ ); 2.12 (s, $3 \mathrm{H}, 3 \beta-\mathrm{OAc}$ ); 1.88 (s, $3 \mathrm{H}, 16 \beta-\mathrm{OAc}$ ); 1.06 (s, $3 \mathrm{H}, 18-\mathrm{H}_{3}$ ); 0.98 (s, $3 \mathrm{H}, 19-\mathrm{H}_{3}$ ). For $\mathrm{C}_{29} \mathrm{H}_{44} \mathrm{NO}_{7}$ (532.7) calculated: $65.39 \% \mathrm{C}, 8.29 \% \mathrm{H}, 5.21 \% \mathrm{~N}$; found: $65.37 \% \mathrm{C}, 8.31 \% \mathrm{H}, 5.23 \% \mathrm{~N}$.

We gratefully acknowledge the skillful assistance of Mrs H. Timm.
