Combination Tones in Non-Linear Systems

By FRANK MASSA

RCA Mfg. Co.
Camden, N. J.

THE purpose of this paper is to throw some light on an objectionable condition that occurs in a non-linear audio frequency system when two or more tones are being simultaneously reproduced: namely, the generation of combination tones consisting of sums and differences of small multiples of the original frequencies. Although it is generally known that such combination tones are generated, it may be surprising to learn that the magnitude of some of these tones may greatly exceed that of the simple harmonics. This being the case, it follows, of course, that more careful quantitative consideration will have to be given to combination tones if a high fidelity system is to simultaneously reproduce more than a single frequency.

Generation of Combination Tones

Assume that an amplifier has a non-linear characteristic between input and output such that some second, third, fourth, and fifth harmonics appear in the output when a single frequency is being reproduced. For such a system, if two frequencies, f_1 and f_2, are simultaneously applied to the input, it can be shown that a number of frequencies may appear in the output as indicated in Fig. 1. The increasing complexity of the combination frequencies with higher orders of non-linearity can be easily noted. For example, if only second and third harmonics were generated in the amplifier, with a single impressed frequency, the last two rows of combination tones would be absent when the two frequencies are applied. A quantitative expression for the magnitudes of the various combination frequencies shown in Fig. 1 is derived at the end of this article.

The generation of combination tones must be familiar to everyone. So-called "beat notes" which are observed when two frequencies are heard simultaneously are simply the differences of the two frequencies which are generated by the non-linear mechanism of the ear. The surprising fact, perhaps, is that the magnitudes of the simple combination tones may be much greater than those of the simple harmonics. Experimental confirmation of this statement was obtained by a simple test conducted on a conventional amplifier using the arrangement shown in Fig. 2.

First, the harmonic content present in the amplifier output was determined with a single frequency impressed on the input, and the results are shown by the curves in Fig. 3. These curves show the components as well as the total harmonic present at various output levels of the amplifier. Two frequencies of equal magnitude were next impressed on the input and the gain adjusted to an output of 23 volts (r.m.s.) at which setting the total harmonic present for single frequency reproduction is shown as less than 2%. The measured sum and difference frequencies for this condition shows a value of 7½%. This percentage is in reference to an assigned value of 100% for the magnitude of either fundamental in the output. The second harmonic of either fundamental when they are both present simultaneously is shown as about 3%. It must be remembered that these values are relative to either fundamental, which means that they should be multiplied by about 0.7 if the total r.m.s. output is assumed 100%.

At an output of 31 volts, where the second harmonic was 4% and the total harmonic 7½% (single frequency reproduction), the measured first order sum and difference tones were 14 and 15% respectively and the second order tones are shown at 10%

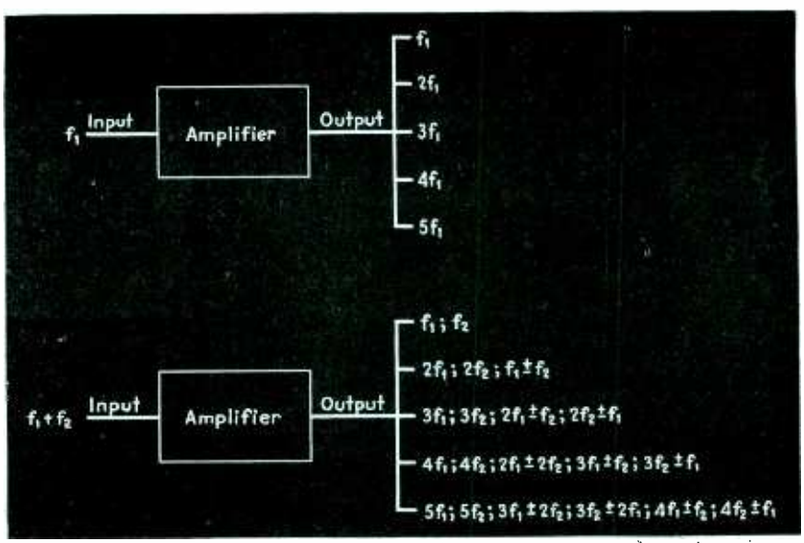

Fig. 1—Output frequencies of non-linear circuit with single and double sine wave input voltages

magnitude. Thus it is quite evident that combination tones of greater magnitude than simple harmonics may be generated in non-linear systems, even when as little as 2% total harmonic is generated by a single sine wave signal.

A few summarizing conclusions are listed below.

(a) Combination Tones More Disturbing Than Simple Harmonics

It has been shown that when two frequencies are simultaneously applied to a non-linear system, a series of combination frequencies are generated, of which the small order sum

Industry . . .

By E. L. DEETER

Research Engineer,
Orchard Paper Company, St. Louis, Mo.

microammeter and calibrated light valve are also located. Window traps for holding the samples to be tested are conveniently placed on the main body, as is also the filter slide. On the panel, covered openings are provided for the liquid color slides. These slides are of unusual construction in that they may be either hung on a nail or placed flat while containing fluids. The cohesion due to the small distance between the glass slides holds the liquid intact unless the container is completely inverted. The slides are cut from magnesium alloy and have glass covered slides that are easily replaced.

A description of the operations entailed in making a routine color test or match should be of help in explaining the functions of the light valve and shadow vane in the lamp house.

With all switches in the "off" position the main power switch is snapped on and the machine given several minutes to condition. The balancing circuit knob is now turned into the "on" position and the meter needle centered on mid-scale. A reflector is placed in the back window trap. One of the color filters is placed in the slide and the standard color is placed in the front window trap. The light source is next snapped on and with the calibrated light valve set at zero mid-scale the shadow vane in the lamp house is adjusted to bring the meter needle back to zero. The standard is now replaced with the sample to be matched against it. If the meter needle deviates from zero it indicates a mis-match, plus or minus. Again the meter needle is brought to zero by an adjustment of the calibrated light valve or iris diaphragm. When this condition obtains the reading on the light valve scale is indicative of the percentage difference in the tonal range of the sample and standard as far as that particular band of the spectrum is concerned. The other necessary filters are now placed consecutively and the above operations repeated. Red, blue and green Wratten filters are used.

Color Matching in the Paper

ALTHOUGH there are numerous color matching instruments on the market, including comparators, colorimeters and true spectrophotometers, many industries often require apparatus of special construction and design to handle efficiently their own specific products. In the paper manufacturing of specialties for instance, it becomes imperative to be able to match printing inks on repeat orders.

The instrument described by this article was constructed to fulfill such demands, that is, to designate color matches with high precision of colors or dyed papers by reflection or transmission methods.

A sensitive bridge circuit employing two RCA phototubes of the vacuum type was used and is shown in Fig. 1. A voltage divider across the charging voltage of the phototubes balances the system. By adjusting the voltage divider, the meter needle may be made to rest at mid-scale zero with no light on the tubes. When balanced electrically such a circuit exhibits characteristics illustrated in Fig. 2. Because the tubes are in series and must pass the same current, a larger quantity of light imposed on one tube as compared to the other produces a very definite shift of the intersecting curves, decreasing or increasing the mean total bias on the amplifier, a 38 pentode tube operating at 4 volts on the heater to increase stability.

The phototubes, type 919 and 917 are especially sensitive in a balanced circuit of this nature. These phototubes have top-cap connections, the anode being brought out to the cap on the one tube, the cathode on the other tube. As indicated in the wiring circuit, the grid cap of the amplifier tube connects only to the top-caps of the two phototubes. Short top-cap connections to the three tubes, result in an extremely high resistance leakage path. Leakage may be further decreased by coating the three tubes with a non-hygroscopic wax. The windows of the phototubes should be free from wax.

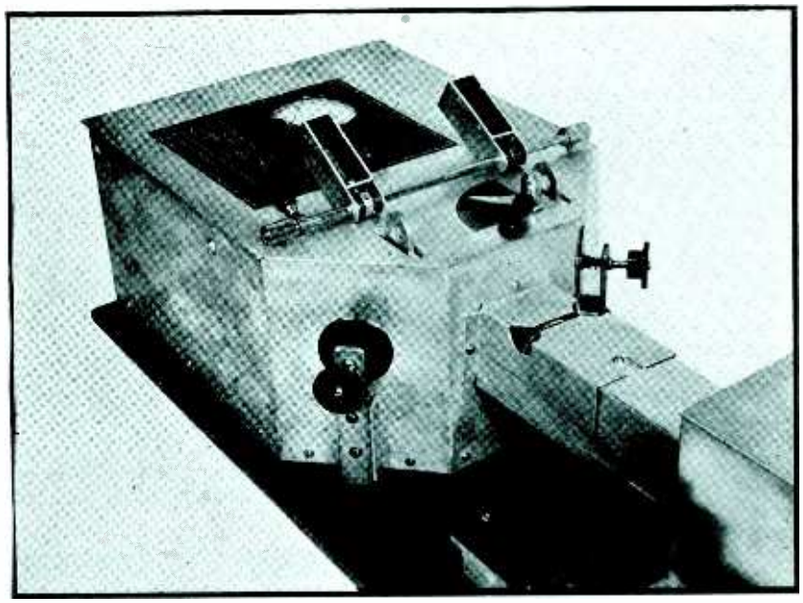

Fig. 5—Close-up view of housing containing electrical portion of the system, with liquid slides, light covers, and openings for sample and standard colors

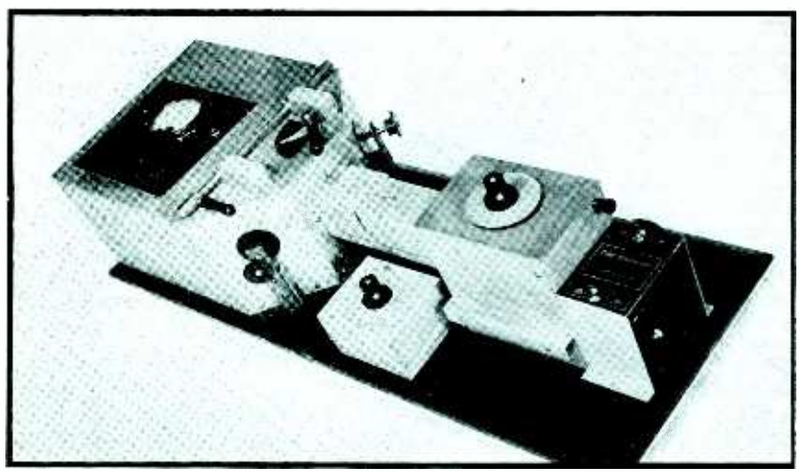

Fig. 4—General view of entire color matching device

A bias voltage divider on the pentode compensates for differences in phototube sensitivity by allowing shift of the grid-plate characteristics of the amplifier tube. Access to this adjustment is obtained at the end of the instrument by means of a screw driver. This adjustment requires attention only periodically.

The lamp house is located some distance from the main body to insure stability by reducing thermal variances in circuits. It contains the light source, a Mazda lamp of the concentrated filament type, operated at about 2800° K. The double condensing lens and light balancing shadow vane are also contained in this compartment.

Operating controls are placed on the main body panel where the 4 inch

equal to E, so that the voltmeter will show no deflection.

If a voltage (V_i) from an external source is now made to appear across R_i, a voltage change (V_o) will appear across R_o, and will be registered by the voltmeter. It will also appear, in series —opposition with V_i, on the amplifier input terminals, very nearly balancing out the effect of V_i on the input grid. It can be shown that, in equation form, $V_o = V_i\left(1-\frac{1}{1+G}\right)$, where G is as previously defined. If this gain is made quite large, voltage change across R_o (indicated by the meter) will be but negligently different from that impressed across R_i. Thus, the system becomes a voltmeter with an input resistance solely determined by R_i, and the large available current gain in the amplifier permits the use of a sturdy indicating meter while also obtaining high sensitivity for large values of R_i. The accuracy of such an instrument is determined primarily by the tolerances of R_i and the indicating meter—since appreciable variations in amplifier gain, if it is normally large, have only a second-order effect.

By using a wide range of input resistances (R_i), the instrument becomes an ammeter with corresponding wide ranges. By using high resistance dividers in place of R_i, it becomes a multirange voltmeter with low current drain. Connecting a standard potential, in series with an unknown resistance, across R_i converts the instrument into a direct-reading ohmmeter (with properly calibrated scale) capable of very high resistance measurements with low applied voltage.

The meter here described provides these three functions of current, voltage and resistance measurement in 22 different ranges, available by means of a selector switch, a sensitivity button and three pairs of binding posts. Reference to the schematic diagram of Fig. 1 will show that it is identical in principle to the system just described, except for the addition of various controls. The range selector switch is omitted from this drawing for simplification, and the three types of input circuits used are indicated. R_1 corresponds to R_i of Fig. 2, R_9 to R_o, and the combination of R_{10} and M_1 to $V.M.$ S_4 is a sensitivity button which changes the range of M_1 from 0.5 to 0.1 volt full-scale. B_7 corresponds to E, and R_7 is the adjustment for setting the equilibrium feed-back voltage across R_9 equal to the potential of E_7, (actually varying the "lock-in" potential on the grid of the tube 1). R_3 is the megohm scale zero adjustment which, according to a simple specified procedure, furnishes a standard potential of 0.5 volt for resistance measurements.

The d-c amplifier is battery coupled and operates conventionally, except that it is designed for low battery voltage and current drain—providing compactness and long battery life. The minimum voltage gain from input grid to R_9 is approximately 1000. According to the feed-back equation previously cited, this gives an inherent discrepancy of 0.1% between input and indicated voltages, and thus a rather large percentage change in gain does not affect the practical accuracy of the instrument.

If a potential of 0.5005 volt is made to appear across R_1, a voltage change of 0.5000 will occur across R_9, changing the bias on tube 1 by this amount, and be registered as full scale on the meter M_1. The grid-filament voltage on tube 1 thus changes by only 0.0005 volt. This small operating range of grid voltage on tube 1 reduces the error due to changing grid current in R_1 to a negligible minimum. Actually, only *change* of grid current with changing voltage across R_1 will produce error in current measurement,—this change being reduced by the small grid voltage range. However, by operating all tube filaments between 1.5 and 1.25 volts, the "static" value of grid current (largely ionic) is reduced to less than 10^{-10} amperes, and the value of the input resistor R_1 may thus be switched from low values to 5.0 megohms (highest used) without appreciable change in balance or zero setting. Moreover, the value of the dynamic input resistance ($-dE_g/dI_g$) around the operating point is thus raised to the order of 10,000 megohms—

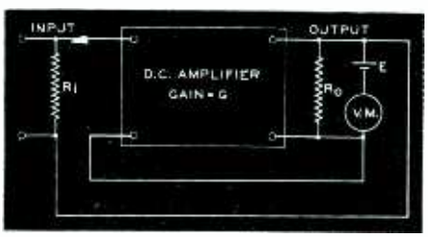

Fig. 2—Basic circuit of the meter

a negligible shunting effect on the highest input resistor used.

The negative feed-back circuit provides unusual stability of balance or zero setting. For instance, a small change in the mutual characteristic of tube 1, which ordinarily would throw the indicating meter off scale, will result in a similar small change in the equilibrium feed-back voltage, with a corresponding small change in meter reading. Shifts in the characteristic of the first tube, due to changes in element spacing, emission or supply voltages, are the most likely sources of such drift in zero setting. These are minimized by cushion mounting and small dissipation in tube 1, and very light drain on the supply batteries. After a short warm-up period, and with normal handling and vibration conditions, the actual zero drift is less than 2 scale divisions per hour and 0.2 scale division per minute.

The grid circuit of tube 1 contains a filter (R_4C_1) which greatly attenuates a-c components from the circuit under test (without appreciably decreasing the normal speed of the indicating meter), and protects tube 1 from very large overloads of d-c voltage. Interaction between the meter amplifier and any device under test is also thus prevented. C_2 and R_5 prevent the amplifier from oscillating at very high frequencies, where the over-all phase angle reverses to give positive feed-back. The general problem of stability in feed-back amplifiers is beyond the scope of this paper; however, an excellent analysis of this subject has been made by H. Nyquist —*Bell System Technical Journal*, Vol. XI, p. 126.

The plate current of tube 3, for no input to the instrument, is adjusted to balance the potential of B_7 by the drop in R_9. However, driving this tube to cut-off or saturation (by over voltage on the input or other means) cannot cause a damaging overload voltage to appear across the meter M_1 so long as the sensitivity button S_4 is not held down—thus practically eliminating the possibility of meter burnout. Combined with the protective elements in the input grid circuit, this makes the instrument practically foolproof.

Tremendous overloads can at most burn out one of the resistors in the input bank and will in no way damage the output meter. On the most sensitive ranges, 10 μa or less full scale, the instrument may be connected across a 110 volt power line, a-c or d-c, without damage of any sort.

A polarity reversal switch, S_3, is provided so that unbalance in either direction in the input circuit can always be indicated as a positive deflection on M_1. This is particularly useful in current or voltage measurements, in that the "high" terminal of the instrument may always be connected to the measuring point most remote from ground, irrespective of its polarity. S_2 is a switch by which the voltage of the filament battery may be conveniently checked on M_1.

The tolerances on the various input resistors and the meter are such that an overall accuracy of $\pm 2\%$ of full-scale reading is obtained for ambient temperatures between 50 deg. and 100 deg. F, and normal values of relative humidity. Very special precautions have been taken, in the

A Feedback D-C Meter

A portable, electronic, multi-purpose, d-c instrument having a resistance of 50 megohms per volt at greatest sensitivity, full-scale current sensitivity of 0.02 μa, capable of measuring resistances of the order of 200,000 megohms

By J. M. BRUMBAUGH and A. W. VANCE

RCA Manufacturing Co., Inc., Camden, N. J.

ORIGINALLY developed in the Electronic Research Laboratory for weak-current measurements on Iconoscopes, electron multipliers and associated devices, the meter to be described fulfills a long-standing need for a sensitive and accurate d-c measuring instrument which would also be portable, rugged, stable in adjustment, and not easily burned out or thrown off calibration when measuring small fractions of a micro-ampere. In satisfying these requirements, this meter, on its most most sensitive current range, gives 1 ma deflection for 0.00022 μa (0.02 μa full-scale). Provision is also made for multi-range voltage measurements at unusually low current drain, and for direct resistance measurements from .1 to 1000 megohms with less than 0.5 volts applied potential. (Measurements up to 200,000 megohms may be made by use of a 90 volt external battery.)

For certain types of d-c measurements, the use of the absolute null method, with a very sensitive indicating device, is desirable. For precision bridge measurements, or similar balance-indicator requirements, no essential improvements have been made over the suspension galvanometer having high current sensitivity and low internal resistance, with manual or automatic balancing. In many cases, however, where very weak currents are to be measured, as in electron tube investigations, a potential drop of a fraction of a volt in the measuring device is not objectionable, particularly if the value of this drop is indicated directly on the device. Thus it would seem that unusual current sensitivities might be attained by passing the current through a relatively high resistance, providing that a stable, high gain amplifier is available to drive an indicating instrument from extremely small input power.

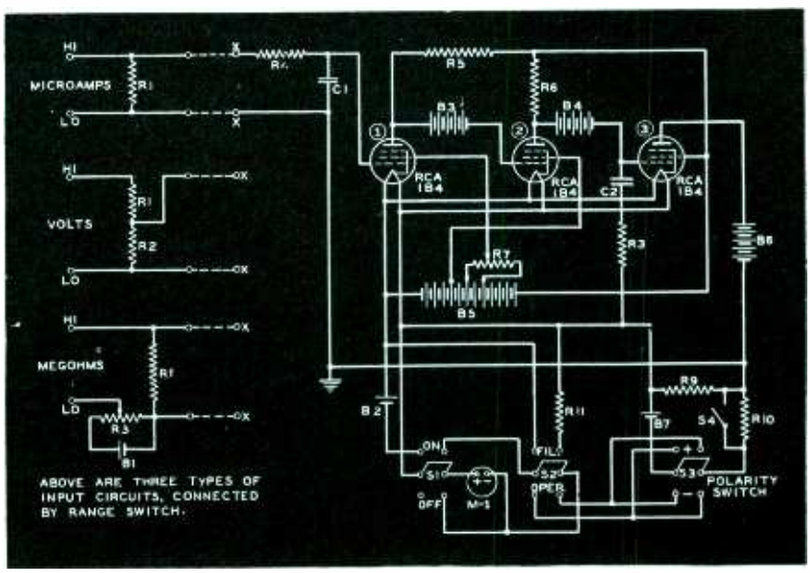

Fig. 1—Fundamental diagram of the RCA Ultra-sensitive D-C Meter

Special requirements for investigations in the RCA Electronics Research Department have resulted in the development of a d-c amplifier which is ideally applicable to this problem. In this design the effects of supply voltage and tube characteristic variations on calibration accuracy have been reduced to small second-order effects, and the tendency toward drifting has likewise been reduced to negligible proportions. This is accomplished by the use of a negative feed-back circuit, wherein the ability of an amplifier to give large amplification is utilized, not to produce large voltage gain but to provide substantially unity voltage gain of great constancy and accuracy, and give large power gain for driving a sturdy indicating meter.

The use of this principle has resulted in a rugged, self-contained and portable instrument having a maximum current sensitivity which is roughly equal to that of the most delicate suspension-reflection galvanometers—or about .00022 μa with 5.0 μw delivered to the indicating meter for 0.002 μw input to the instrument (0.1 volt across 5.0 megohms).

Ultra-sensitive D-C Meter

As now made the ultra-sensitive d-c meter consists essentially of a group of input circuits (selectable through a range switch), a d-c negative feed-back amplifier, and an indicating meter. The principle of operation may be most easily understood by referring to Fig. 2, which shows a d-c amplifier with its output connected in series with its input. In the actual instrument three stages are used to provide adequate gain and the proper phase relation for negative feed-back. When such an amplifier is connected in this manner, it will "lock-in" at what may be called its equilibrium condition—which represents a certain voltage on each plate and grid (with respect to cathode) and a certain feed-back voltage developed across R_o and returned to the input (i.e., the input tube receives its bias from the plate current of the output tube). If no potential is applied to R_i, the system will tend to maintain these voltage values with a constancy proportional to the gain G (amplifier voltage gain, without feed-back connection). Any tendency toward oscillation at very high frequency (where the phase angle reverses) is prevented by proper filtering. It may be assumed further that the amplifier is internally adjusted so that the equilibrium feed-back voltage is just

Fig. 2—Complete circuit diagram of pre-amplifier with values of reactance units

Pre-Amplifier

by C. F. SHEAFFER
KTUL, Tulsa, Okla.

$$f_1, f_2, = \frac{\sqrt{L^2(K-1)+KLCR_sR_0} \pm \sqrt{L^2(K-1)LCR_s(KR_0+4R_s)}}{2\pi LCR_s} \quad \ldots\ldots\ldots (4)$$

Equation (4) gives the proper value of the mid-frequencies on either side of the anti-resonant frequency of the tuned circuit being considered. The ratio of the two answers is therefore equal to the frequency spacing constant p, which will be explained later.

There remains now only to discover the value of the factor K, and determine whether or not it remains constant when other conditions of the equation are varied. This has been done empirically by summing up the impedances for the best fit. It was found that $K = 1.7$ was the most satisfactory value, and that while K varied somewhat with conditions, this value rendered the equation sufficiently accurate for design purposes. Lower values of K will also give a flat characteristic, but it has been found that the lower the value of K used, the more markedly does the total impedance at any given frequency depend on the associated circuits. Higher values of K require correspondingly higher values of R_s with a given frequency spacing.

The anti-resonant circuit is an energy storing device. The energy absorbed from the supply source must be dissipated in the resistance R_s after the supply is interrupted. This gives rise to an effect which is quite similar to the building up and dying out of sound energy in an acoustically live room. An equation which gives the time it takes oscillations set up in an anti-resonant circuit to die down to 1/1000 their original amplitude is

$$T = \frac{6.9R_s}{\pi F\sqrt{\frac{L}{C}}}$$

This equation is synonymous with reverberation time, and shows that the above mentioned effect will be small in comparison to normal reverberation provided the ratio $R_s/\sqrt{L/C}$ is not greater than 4.

Design Procedure

The following conditions were selected as suitable for the described instrument:

Surge impedance of each anti-resonant circuit = 5000 ohms = $\sqrt{L/C}$
Frequency range = 60 to 10000 cycles
Number of circuits to cover the range = 12
Individual coil Q = 10
Overall amplifier gain for flat characteristic = 30 db (approx.)

Each succeeding tuned circuit will be tuned to a frequency which is a given percentage of the one preceding it, so that if p is the multiplying factor and the initial frequency is 60 cycles the tuned circuit frequencies will be 60, 60p, $60p^2$, $60p^3$, . . . $60p^{(n-1)}$. p is therefore equal to the (n-1)th root of 10000/60, or approximately 1.6. The 12 frequencies are therefore 60, 96, 154, 245, 394, 630, 1000, 2560, 4100, 6550, 10300.

The resistance shunt value may be computed from equation (3), and will be 10,300 ohms, or approximately 10000 ohms. The inductance and capacity values are given in Fig. 2. The coils may be hand wound on paper spools and calibrated by varying the number of laminations in the core, but the building of high-Q iron core coils is quite an art, and a lot of worry and work will be saved if this job is turned over to one of the transformer companies.

The schematic diagram shows the arrangement of the tuned circuits and their associated switches which are SPDT with an off position in the center. They are connected so as to allow the application or removal of the resistance shunt, or shorting, as desired. The amplifier design is sufficiently indicated in the diagram and will not be discussed. The anti-resonant bank was placed in the output circuit so that the level would be high enough to override any hum picked up by the coils.

Application

A great many variations in the amplitude-frequency characteristic are possible. With the shunts removed sharp narrow peaks may be obtained at any of the tuned circuit frequencies. These are especially helpful in mimicking various telephone transmitter and loud speaker characteristics. A few acoustic effects similar to speaking into a cellar could be imitated by removing the resistance shunt from various low frequency coils.

The frequency discrimination for low, high, or band pass operation is very nearly as good as that afforded by the usual filter type equipment.

All coils may be shorted out and the series resistance opened up for flat characteristic operation. It may therefore be used as a regular pre-amplifier. The pre-amplifier set-up is especially satisfactory as it does away with insertion loss difficulties and affords a suitable means of introduction for low level mixer equipment.

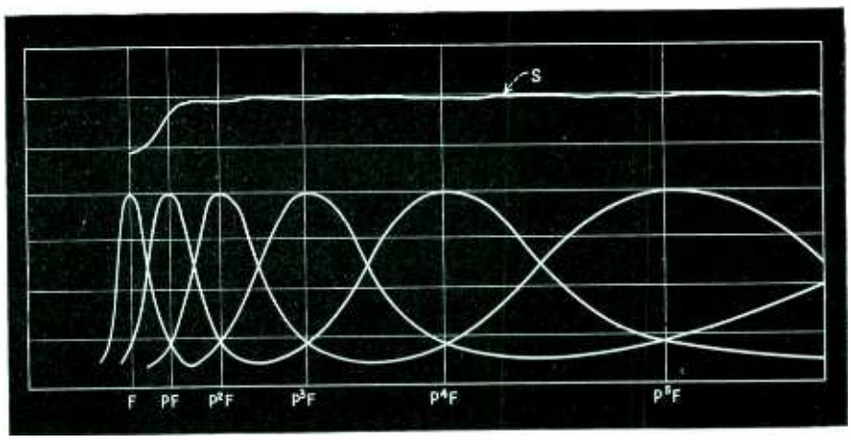

Fig. 1—Impedance Characteristics of several loaded anti-resonant circuits and their series sum

A Sound Illusion

SOUND effects requiring various frequency response characteristics are most satisfactorily created electrically so that they may be controlled by the engineer. This has usually been accomplished by means of a low and high pass filter combination arranged so that a frequency band of any desired width might be transmitted. Many of the effects obtainable from such a system may be more accurately simulated by transmitting two or more bands, however, and a more flexible means of controlling the amplitude-frequency characteristic is therefore desirable. It was also deemed likely that new uses could be discovered with an instrument offering greater flexibility. The device described in this paper has been designed to give a wide variety of amplitude-frequency characteristics and has proven, in many respects, to be superior to the filter method.

The instrument consists of a preamplifier into which is incorporated a series bank of anti-resonant circuits whose anti-resonant frequencies are systemmatically scattered throughout the audio spectrum. The unit is designed in such a manner that with all coil-condenser combinations in the circuit, the complete audio band is transmitted without frequency distortion. By shorting out various coil-condenser units, therefore, the transmitted band may be narrowed or cut into at any desired spot in the spectrum.

Theoretical Basis

In considering the principles involved in the design of the anti-resonant circuits, let us initially examine two circuits in series whose anti-resonant frequencies are, let us say, 1000 and 2000 cycles respectively. At the mid-frequency, which is approximately 1450 cycles, circuit 1 will have an impedance of $R - jX$ ohms and circuit 2 will have an impedance of $R' + jX'$ ohms. The total impedance at the mid-frequency will therefore be $R + R' + j(X' - X)$ ohms. If the same value of L/C is used in designing both circuits, X will equal X' and the impedance at the mid-frequency will be a pure resistance equal to $R + R'$. Now if some means of adjusting $R + R'$ with respect to the impedance at 1000 or 2000 cycles is devised, we could proceed to select values so that the total impedance at the mid-frequency was equal to that at either of the anti-resonant frequencies. The impedance of the combination would then remain approximately flat from 1000 to 2000 cycles. To these circuits we might now add others designed to have the same L/C ratio with anti-resonant frequencies at 125, 250, 500, 4000, and 8000 cycles; and with all these in series the impedance could then be made flat throughout the included band. It will be noticed that each frequency is a constant percentage of the one below it. This simplifies design procedure and is in keeping with the acoustical law which states that we perceive percentage frequency changes.

Mathematical Analysis

The magnitude of the resistive components of any two adjacent tuned circuits at their mid-frequency may be adjusted by shunting each with a suitably sized resistor. It is therefore necessary to set up an equation which will yield the size of the resistance shunt in terms of the other circuit constants.

The impedance of any coil-condenser combination at its anti-resonant frequency with a resistance shunt is

$$Z_{ars} = \frac{\left(\frac{L}{CR_0}\right)(R_s)}{\frac{L}{CR_0} + R_s} = \frac{L\,R_s}{L + R_s R_0 C} \quad . (1)$$

An approximate equation for the impedance at any frequency neglecting R_o (very nearly correct provided the coil Q is reasonably high and the frequency is removed from anti-resonance) may be rationalized to obtain the resistive component:

$$R_1 = \frac{R_s L^2}{R_s^2 C^2 \left(\omega L - \frac{1}{\omega C}\right)^2 + L^2} \quad \ldots\ldots (2)$$

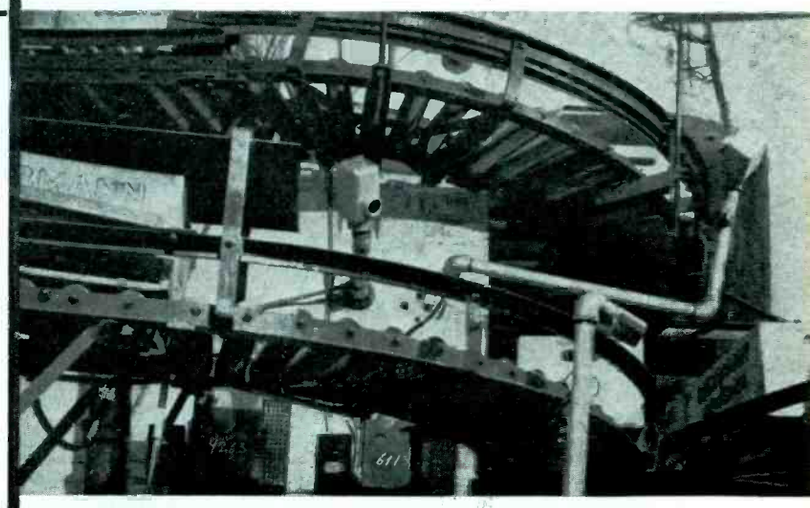
If the proper relations exist between the total impedance at the anti-resonant frequencies and the total impedance at the mid-frequencies, then the impedance characteristic will be approximately flat. It is assumed, therefore, that a similar relation exists between the impedance of an individual anti-resonant circuit at its mid- and anti-resonant frequencies. We proceed to set the right-hand side of eq. (1) equal to $K \times$ the right hand side of eq. (2), where K is a multiplying factor set to make the equation true.

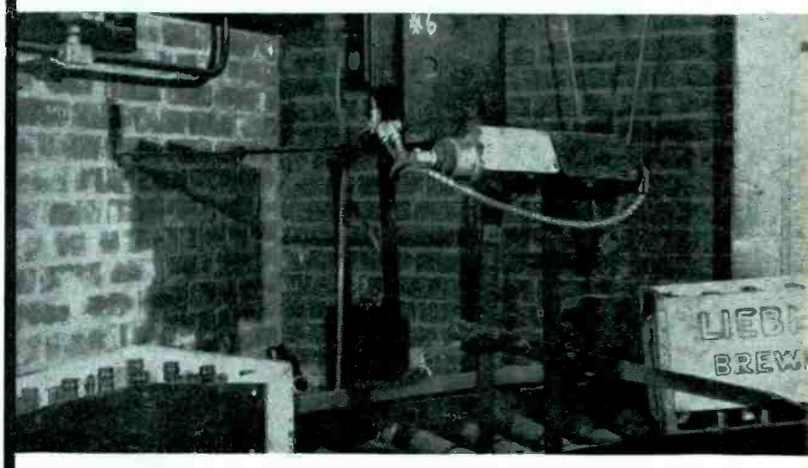
The equation is quadratic in R_s and ω, and may be solved to obtain the equations below:

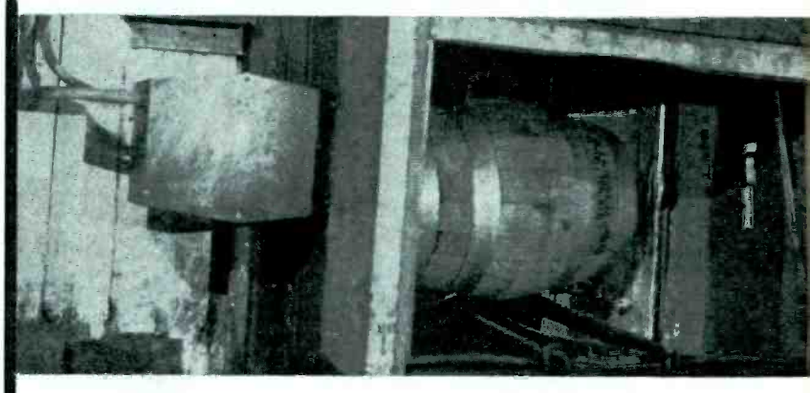
$$R_s = \frac{L}{C} \times \frac{KR_0 + \sqrt{K^2 R_0^2 + 4(K-1)\left(\omega L - \frac{1}{\omega c}\right)^2}}{2\left(\omega L - \frac{1}{\omega c}\right)^2} \quad \ldots (3)$$

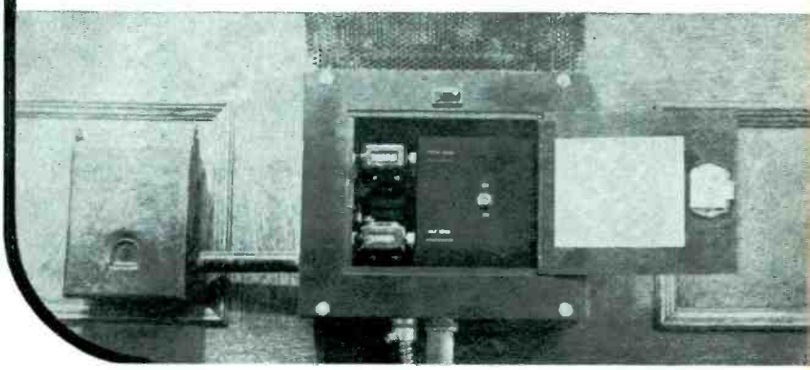
Phototubes count beer cases and kegs in New York breweries under conditions destructive to mechanical counters

Electronics Helps Make Beer









(Reading from top to bottom)

Outdoor case counter. Empty beer cases received at platform on floor below, travel upward on enclosed conveyor into storage room. Light source and phototube relay are mounted on the conveyor enclosure, and connected to a separate housing on the receiving platform below, where control switch, fuses, and magnetic counter are located

Two conveyors, two photo tube counters. Photorelay housings on wall behind conveyors. Counters are the non-reset type, completely enclosed, and directly actuated by the relay tube plate current. The cases separate at their outer edges as they round the curves; this enables an oblique light beam to count them. Normally they move fairly slowly, but occasionally they come down the long conveyor at such speed that it is impossible to follow them by eye. Mechanical counters at this point were pounded to pieces. The light beam system seems to stand up quite well

Case counter using two light beams. Here, the cases sometimes back up a few inches. As long as a case does not move back more than the distance between the light beams, any number of multiple interruptions result in only one count

Waterproof double-beam unit counting two sizes of kegs going down a runway. Large kegs interrupt both beams; small kegs only the lower one. The respective counts are registered on a unit shown by photograph below

Counters in an office some fifty feet away. The control switch, fuse panel, poliot light, and counters are located here. This system was designed and installed by the Luxtrol Company, New York City

One of the reasons industrial electronics moves forward so slowly is the fact that there are not enough engineers who know electronic engineering to put the profession on an organized basis. In the present stage of the business most of the "consulting" consists of tinkering by mechanical, electrical and radio engineers. Five thousand competent engineers who know their stuff, and a realization by manufacturing concerns that the information they want must be paid for, would be a good start in a real electronics industry.

How much is electronic equipment worth?

This brings up the problem of compensation. Engineers in large manufacturing concerns who make electron tubes, amplifiers, photo cells, etc., are being pestered constantly by engineers in various plants who have problems which they think can be solved by some mysterious hocus pocus called electronics. First thought is to call on these companies to solve their problems. "Please send blueprints and specifications."

The large companies cannot offend these boys because they buy lots of non-electronic material from the big companies every day. All the men in the control division can do is to try to help the fellow out and do it diplomatically. But they are not fond of the job and feel they are being imposed upon. They send me hundreds of such problems every year and once in a while one turns into a job. Sometimes the same problem comes in from more than one company indicating that the originator of the problem has called on the engineering and development divisions of several of the largest organizations of that kind in the world with the expectation that these large companies should turn their whole staff loose on this one job. I have never gotten enough business out of the inquiries received from the big companies to pay for handling them although I have spent months in time working up proposals for machines. The big companies feel that they should do the engineering but that I should tell them how. Like every one else I have my weak moments and do tell them. Fully 20% of these problems that I get have an electronic solution and half of the 20% would be profitable to the user.

Unless a fellow has the backing of some financial angel he will miss a good many meals before he gets much business as a consultant in industrial electronics. In order to get business you must be prepared to deliver a complete apparatus to do the trick. This puts the engineer in the manufacturing business. Even then you are sunk unless you get an order or a contract setting forth exactly what the machine is to do and then get a 25% cash advance. Sometimes you can sell engineering services. Recently I did a job on an engineering basis which saved the company $11,000, over the cost of what they would have had to pay me if I built the machines on contract for them.

Having got a job, how much should we charge?

The ordinary manufacturer of a gadget, built for resale, figures that the final retail price must be from three to five times the actual production cost, based on direct labor and material. Often, costly engineering and experimental work are required to develop a machine to do a special job. It should not be exorbitant to charge ten times the cost of the actual labor and material that goes into the machine, but it is difficult to sell the purchaser on this idea. In one instance, I delivered a machine that saved the manufacturer $100.00 every 24-hour day it operated and it replaced much needed help that was made available for another department. The price of the machine was $3,000.00 and upon receipt of the order I was requested to deliver it at the earliest possible moment. The machine was designed from the ground up and the actual cost was $600.00 in labor and material and delivered in six days. When it was delivered and put into operation everyone in the concern was highly pleased with its operation but when the day for payment came, the manager of the company said, "Surely you don't expect us to pay $3000.00 for a machine that took you only a week to build at a cost not exceeding $500.00." I promptly told him that I was taking that machine away that afternoon, that the deal was off, and that the machine was sold on what it did, not on what it cost me to build. (They had already spent several thousand dollar in trying to develop their own machine of this kind.) The superintendent was a listener-in and he came over and gave me a nudge, "Don't pay any attention to this fellow. We want another machine."

Should we give free advice?

I have built much automatic gauging equipment, mostly for measuring the diameters and lengths of straight rolls for roller bearings. The operation is simple in the extreme. You simply have your gauging part break a grid circuit to a vacuum tube which in turn causes the plate circuit to operate a relay and devise some mechanism for getting the piece out from under the micrometer and into the correct box. You, of course, have to compensate for temperature if your machine is to measure within a few millionths of an inch, synchronize the operations and feed the machine, make it variable in speed, design the spindles so they won't wear or get dirty and solve a number of other minor mechanical problems. Furthermore, it must operate a week or more without attention.

I had built a number of these machines and had them in operation when I saw an ad in one of the trade magazines reading something like this—

"The Punky Sink Company manufactures its parts by the very latest known methods of inspection. There is no question but what we have every known method of measurement and we are constantly applying it to our product. Nevertheless our doors are wide open to anyone who can show us better methods and we welcome with open arms anyone who can show us how to improve our product by gauging and inspection methods."

As the Punky Sink people are one of the biggest in the business and turn out millions of precision parts that should be measured automatically within tolerances of .0002, I thought here was a chance for some real business. So I wrote them and in about a week received a reply signed by an engineer. Although the plant was 600 miles from Cleveland I caught the first train and went forth.

I waited in the reception room about two hours (the engineer knew I was coming) and got a call to come back after lunch. Then another two hour wait and I got in the office. I did not see the engineer, however, but his assistant who proceeded to spend about an hour telling me how good they were and that I should consider it a privilege to make a spe-

A Consultant Talks About ELECTRONICS

By REX D. McDILL

ONE does not need to be a consultant in electronics very long before he discovers several things. In the first place, it is not one of the big-money businesses. Secondly, there is no other profession where the experimentally minded engineer can get more real enjoyment. Finally, one soon learns to classify prospects and clients in the following groups:

First, the fellow that wants you to come into his plant and design and build the apparatus to handle a particular job. Second, concerns that prefer to buy a machine or apparatus to do a particular thing. Third, the ones that employ you as a consultant and expect to pay you for it. Fourth, the engineers in various plants that expect you to tell them how to do it for the fun of doing it. This class is composed mostly of so-called research men who want to make a hit with the boss and from them the most inquiries are received. Fifth, the miscellaneous unprofitable inquiries, such as the letter cited below:

Gentlemen:

We have been informed that you manufacture a low-priced photocell that could be employed advantageously in a merchandise dispenser. The kind of cells we are mainly interested in are divided into two separate classes, namely, one that will detect one person from another by the slight difference in color, etc. After the dispensation of merchandise has been completed, there should be no repeat delivery to the same person for a considerable period, but another person who has not received any merchandise over a certain period can receive a full portion of it right after delivery has been completed to another person, without delay.

The second type of cell is one so arranged requiring the lapse of 10 or 15 seconds before another delivery can be made.

Trusting to hear from you by return mail, etc.

In the last five years I have received many letters of this type, most of them from small concerns. Such letters prove that there are still a lot of people who think that they can nail a photocell on a barn door and have the light from the lantern open it up at milking time. But when a large manufacturer writes in and states that it would be worth a couple of hundred dollars to devise a fully automatic means for keeping flies out of beverage bottles, you are getting into the money class and business is picking up.

What Is Electronics?

Industrial electronics is really not a part of electrical engineering and much less a part of radio engineering. It is principally mechanical engineering and the electronic part is simply used where mechanical methods are not available. It is for that reason that radio engineers are not particularly fitted for industrial electronic work unless they can visualize a mechanical machine operated by electronic controls.

Many problems can be solved with standard equipment, that is, equipment already being manufactured. Inquiries on such problems should be referred to companies manufacturing the standard units. My experience shows that it is not practical to build in the laboratory everything that is used in an installation. Where standard units can be bought, these are purchased direct from the maker.

There are a number of large organizations and a few moderate sized ones that could well afford to hire an industrial electronics engineer as a consultant to work directly with their engineering and manufacturing departments. Even though he does not turn out for them any piece of work that is highly profitable, he can usually steer them clear of costly but impractical developments in the electronics field.

Industrial electronics is 97 per cent mechanics and 3 per cent electronics. The 3 per cent is as essential as a hundred miles of track in the center of a transcontinental railroad. A thorough knowledge of the operation of telephone type relays and switches is probably as important to the industrial electronics engineer as a knowledge of what makes a vacuum tube act as a valve.

Crosstalk

►**EVERYBODY CARES** . . . In the conviction that better relations between capital and labor, between employer and employee, between management and stockholder are necessary before any lasting good times may be had in this country, *Electronics* presents in its October issue a plan by which such better relations may be attained.

We believe that American business is everyman's business; that employees, stockholders, consumers have an interest in and a right to know about industry's problems, where its money comes from, where it goes. We believe that everyone cares when plants are idle because of misunderstanding, mismanagement, or because of the selfish aims of a few.

We believe that the game now being played by capital and labor is destructive of everything that is right and just and that if it is not terminated, soon, it will ultimately destroy the democratic principle in this country; that in this game the middle man—the consumer—must inevitably play a more active part than merely supplying the ante. Capital and labor must get together as they have in other democratic countries long ago. Management can aid in attaining this happy liaison if it will tell the truth about itself, if it makes certain that the public learns the facts of business life. Some of these facts pertaining to the industries based upon the electron tube are told in the coming October issue.

►**CRYPTIC** . . . One of *Electronics'* good friends who signs his post card from Denmark as "guess who" has the following to say on the state of television abroad: "television in London not as good as RCA. Poorer background transmission. Poorer low frequency transmission. Sets range from $95 to $225. None smaller than 9 inch which is the trend. Trend now from 12 to 9 inch which is surprising. Economics is the reason. Tubes are shorter and tend to magnetic focus and deflection.

Television looks like the toy wife of radio rather than its master. 9000 sets in use; real British figure."

►**MS** . . . Stevens Institute of Technology, Hoboken, N. J., is offering for the first time an evening schedule of graduate courses leading to the degree Master of Science. Dr. Llewellyn of the Bell Laboratories will give a course in Vacuum Tube Electronics. Sessions begin the week of September 26. Prerequisite to enrollment is a degree in engineering or applied science. Thus, the Master's degree may now be taken by night; no longer are men required to take daytime courses.

Incidentally, RCA Institutes starts a course in television this fall; New York YMCA school has a course in electronics taught by Ralph H. Batcher.

►**RECORDINGS** . . . A marked development of the science of recording sounds on tape, on disc, on steel, on celluloid, on acetate coated rolls of paper has occurred in recent years. In this issue of *Electronics* appears an article on recording on steel tape. On September 1, station WQXR in New York City broadcast Act I of "Carmen," taken from a 7-mm cellulose tape on which the program was recorded by sapphire stylus. In a suburb of New York City, Count von Medala, one of the early workers in the recording art, demonstrates a simple method of recording and of immediate play back by cutting sound tracks on 16-mm film, 30 tracks being engraved on a single film width. In Washington, and elsewhere probably, entire court proceedings are being "taken down" on various recording media, individual bits of testimony being rushed to the transcribing people who divide it up and put it into typewritten matter as fast as the words are emitted in the courtroom.

In the court the advantages are that several transcribers can work on the record simultaneously and the fact that the actual voices of those giving testimony are mechanically recorded; there is no chance of a stenographer's error; and the testimony may be played back at any time.

►**DATES** . . . The important Fall dates are those of the Rochester Fall Meeting. This year they come on November 14, 15 and 16. The October issue of *Electronics* will contain the technical program—but judging from past performances, there is no need to wait until the program is published to make up one's mind about being in Rochester on these dates.

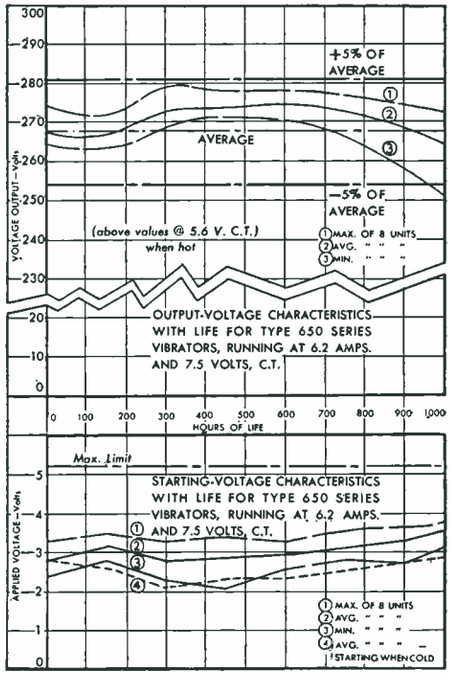
►**SORRY** . . . Every editor knows that he gets best response to an article when it contains an error. Therefore we are gratified to say that Mr. Carter's article on the Volume Indicator-Attenuator in July, has stirred up quite a bit of correspondence. Mr. Hollis Baird of 1XAL, however, states that the caption to Fig. 3 is practically all wrong; that the circuit won't measure harmonic output from transmitters. We believe Mr. Baird is correct. Mr. Carter made no such claims; we wrote the caption. Where we got the idea it would measure distortion we don't know, but forget it. Mr. Carter has discovered a more serious error, and as a result many letters have gone to him directly. It seems that resistor R-10 in the circuit of Fig. 2 should be returned to the junction of R-11 and R-12 and not to the bottom of R-12 as shown.

P. R. MALLORY & CO. Inc.

Only MALLORY Vibrators offer *all* these advantages

1 ***Low initial starting voltage*** maintained over useful life of vibrator, without sacrifice of operating performance.

2 ***Exceedingly long life*** with practically no decrease in output. Impartial life tests at foremost set manufacturers prove this to be true. That's why Mallory Vibrators are being chosen as original equipment in so many sets.



3 ***Substantially constant reed amplitude*** over wide range of battery voltages. Eliminates all possibility of reed breakage.

4 ***Low mechanical noise.***

5 ***Lower vibration level.***

6 ***Permanent alignment of component parts*** and *reduction of unwanted vibrations.*

7 ***Long life*** obtained through use of highest-grade tungsten contacts — producing a minimum of contact erosion and absolute freedom from "chatter" and "bounce".

Long production experience in building present designs — long inspection experience in testing them — assure uniform high quality. Write for *production-built* samples.

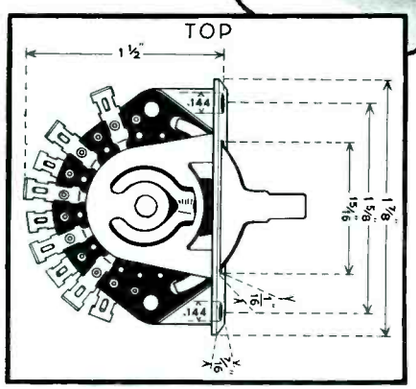
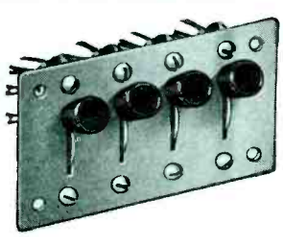
CENTRALAB Low Capacity LEVER ACTION SWITCH



A space-saving lever action switch that can be furnished singly or assembled to an attractive mounting plate with any required number of switches in a group. Each switch will take up to 12 contacts that can be used in countless shorting or non-shorting switching sequences. Contacts are of the long lived double wipe type.

Centralab Lever Action Switches are furnished with either two or three positions. Index action can be positive in all positions, or spring return to center from either side.



for:

- **BROADCASTING** In control panels for commercial and amateur transmitters.
- **RADIO RECEIVING** Band changing, I.F. selectivity, sensitivity, tone, and similar controls.
- **PUBLIC ADDRESS** Centralized sound, inter-communicator, call systems.
- **TEST INSTRUMENTS** Signal generators, analyzers, tube testers, multi-meters.
- **INDUSTRIAL USE** Electronic apparatus, signalling devices, business machines.

. . . and any other application where multiple contact, low capacity switches are required to operate at low voltages and currents.

ENGINEERS: *Send for specification sheet number 628 for further electrical and mechanical details.*

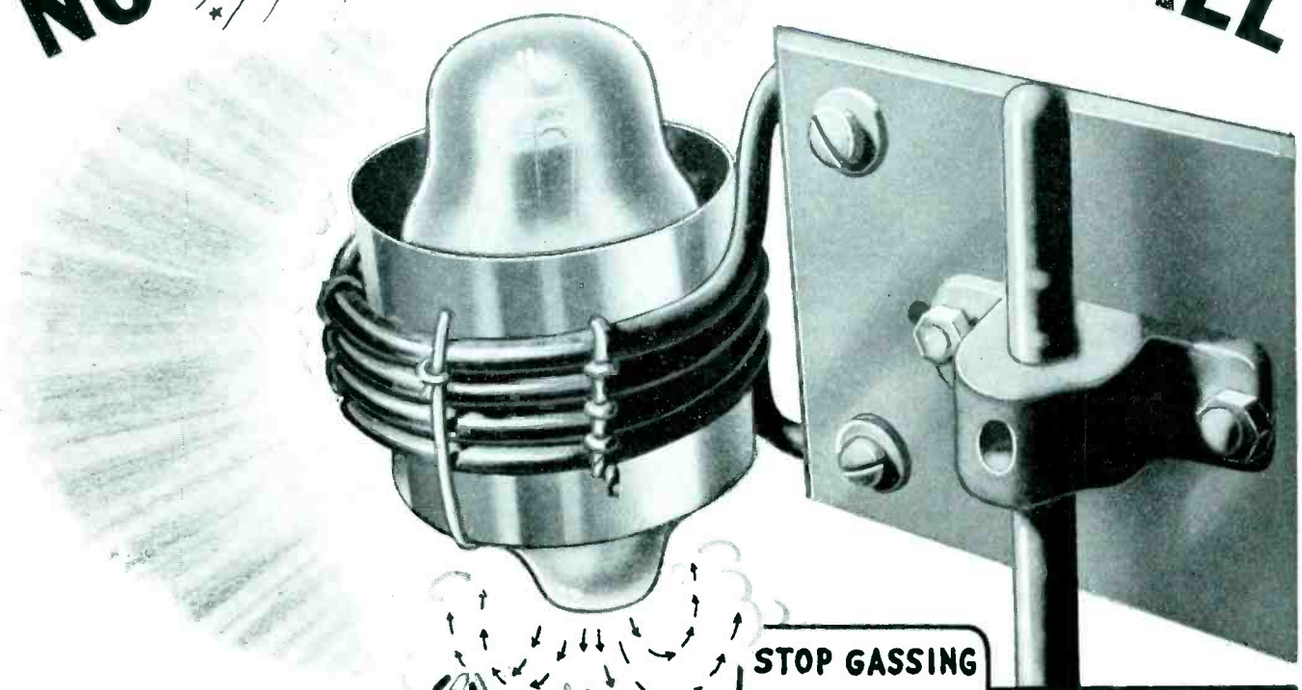
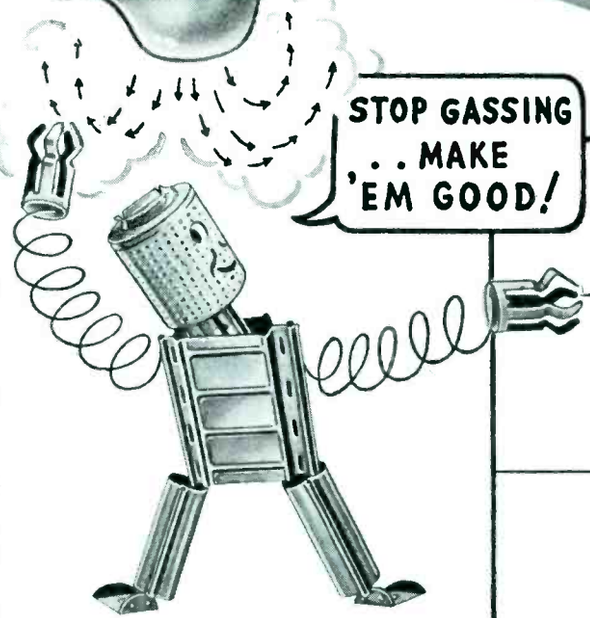
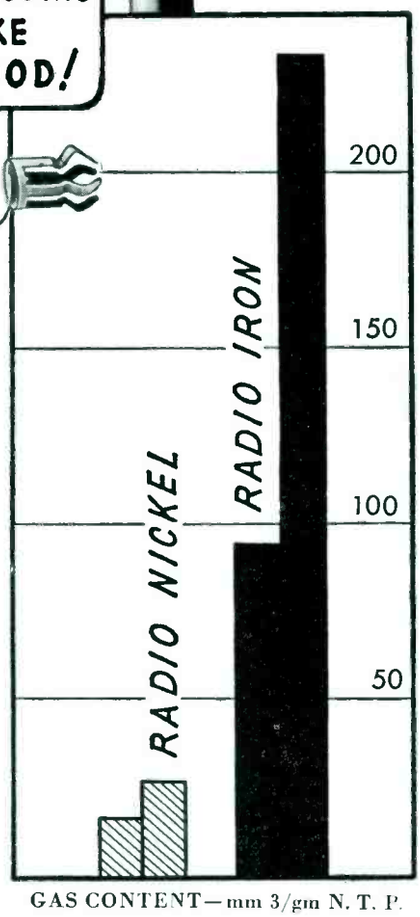
NO TRICKLE FROM NICKEL







GAS CONTENT—mm 3/gm N. T. P.

Two unusual properties in Nickel combine to eliminate "after gassing" from radio tubes

JUST a slow trickle of gas from metal parts after a tube is sealed... and that's one more tube in the waste can. Or still worse, a tube that soon fails in service. But from parts made of Nickel there's no "after gas", for two reasons:

First, Nickel has a low affinity for gas. As you'll see by the chart shown at right, its gas content is *less than one-tenth* that of iron. Second, to do a better job of removing gas during bombardment, much higher temperatures can be employed for Nickel than for iron or steel.

So with less gas to begin with, and higher permissible exhausting temperatures, Nickel gives up its gas more quickly, easily and completely. As a result, gas does not bleed into tubes after sealing — which means fewer rejections, more dependable service, longer lived tubes and better reputation for the tube maker.

Just as Nickel's low gas content and strength at high temperature combine to help the tube maker, so can other properties of Nickel and Nickel alloys combine to help you. Write for technical information, and for your copy of "Nickel in the Radio Industry". Address "Electrical Research", c/o

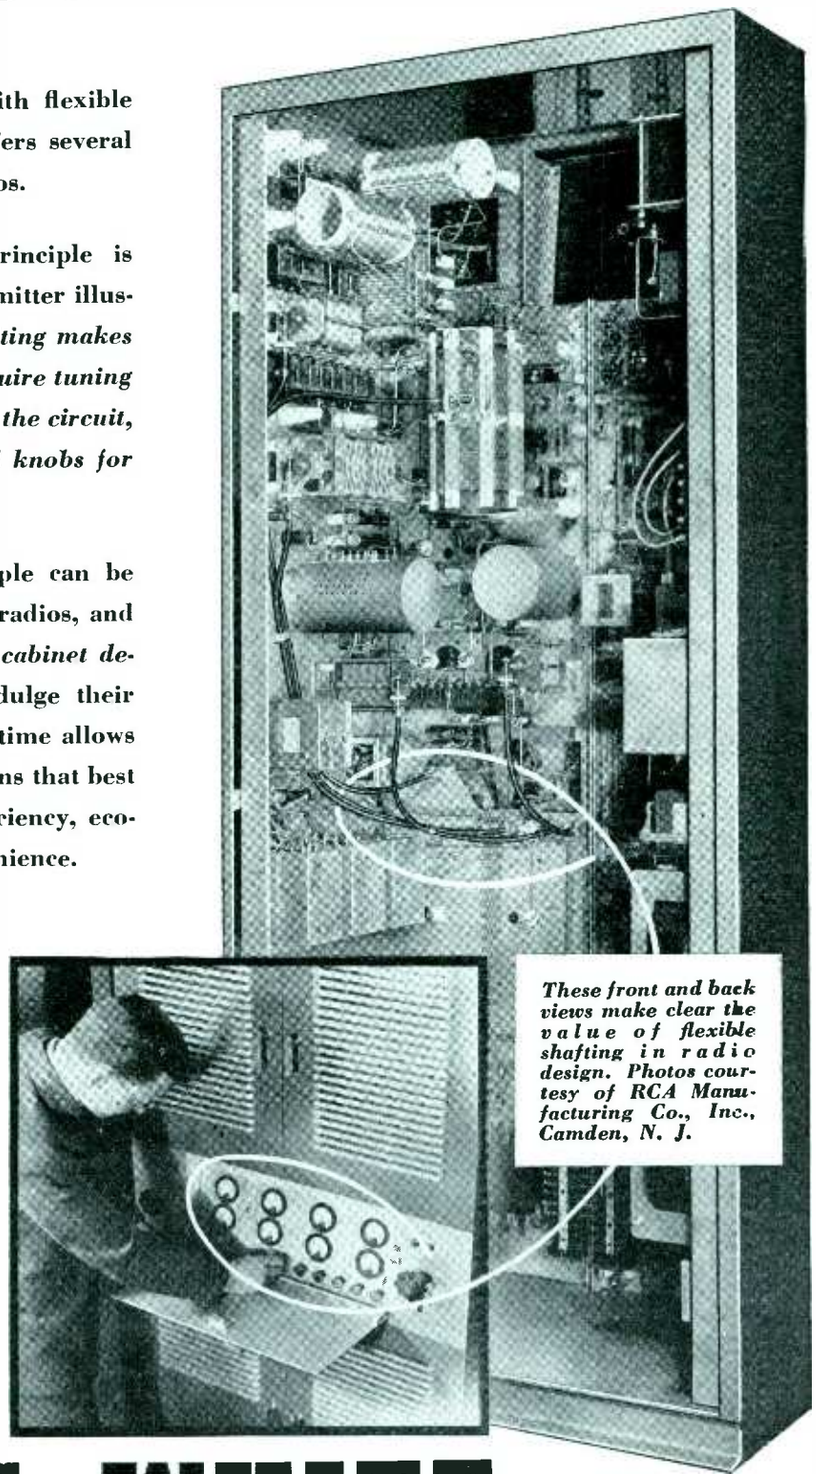
FLEXIBLE SHAFTS can be used to advantage in HOME RADIOS

Remote control of tuning elements with flexible shafts is a principle of design that offers several worth while advantages for home radios.

An effective application of the principle is furnished by the RCA Broadcast Transmitter illustrated. See how *the use of flexible shafting makes it possible to place all elements that require tuning in the optimum position with respect to the circuit, and at the same time, to locate control knobs for maximum operating convenience.*

It is quite obvious that this principle can be applied with equal advantage to home radios, and that its use *removes all restrictions to cabinet design.* It permits radio stylists to indulge their ingenuity to the limit and at the same time allows tuning elements to be located in positions that best satisfy the requirements of circuit efficiency, economical assembly and servicing convenience.



These front and back views make clear the value of flexible shafting in radio design. Photos courtesy of RCA Manufacturing Co., Inc., Camden, N. J.

DEPARTMENTS

ENDED R-F PENTODES

lowed that shielding of the leads in the zone between the mount proper and the glass seal could be minimized. That this was true proved fortunate because numerous welding operations take place in this rather limited space during the assembly of tube parts, and shielding would, therefore, be awkward and expensive.

Shielding between leads in the glass of the stem has been accomplished by inserting a conical-shaped piece of metal in the opening in the glass "button" provided for exhaust purposes. This cone conforms closely to the shape of the exhaust opening for maximum shielding effectiveness and is held in place and grounded by welding it to the shell lead. The cone is of sufficient length to extend

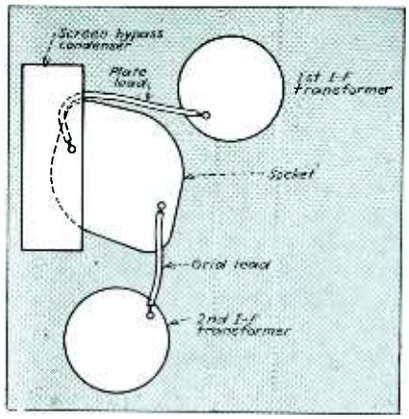

Fig. 2—Long grid and plate leads in conventional superheterodyne circuit

partially into the exhaust tube proper. To shield the base pins one from the other, a cylindrical piece of metal is used and shaped to conform to the inner dimensions of the locating base plug. This shield is grounded by a lead that extends into the shell pin of the base, the connection being soldered at the time the tube is based. Shield and lead are in one piece and are rather easily stamped and formed. Fig. 1 is a pictorial representation of both shields as positioned relative to other parts of the tube. It should be noted that the two parts overlap for complete shielding; the stem cone extends into the shielding range of the base insert.

The effectiveness of this shielding is maximum between two leads when they are diametrically opposite in the base-pin circle. The capacitance measured between two such leads is less than 0.0002 $\mu\mu$f. The shield in the base locating lug is equally effective in shielding the socket terminals of the conventional wafer socket. Since this capacitance between socket terminals is also at a minimum for opposite pins, the conventional basing arrangement was revised for the pentodes to place the control grid and plate leads opposite one another.

The single-ended construction of these new tubes lends itself well to radio-receiver designs and offers distinct advantages over the usual top-cap construction. The fact that the

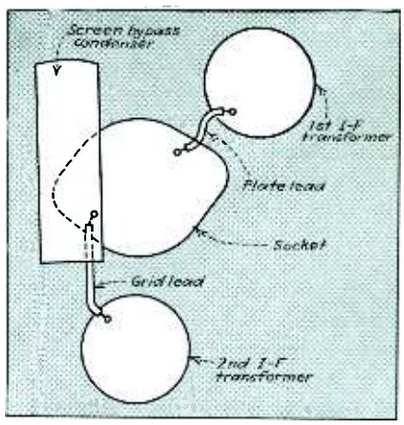

Fig. 3—Grid and plate leads shortened by rotating tube socket through 90° angle

flexible lead connecting the control grid to its associated circuit is no longer required, results in elimination of loose or broken grid connectors and leads, simplification of tube renewal, cleaner appearance of chassis, more stable amplifiers, greater uniformity of gain in amplifiers, and lowered cost.

It is well known that capacitive coupling between the input circuits of two successive amplifier tubes operating in cascade causes regeneration, and when sufficient coupling is present produces actual oscillations. In conventional radio receivers having a radio-frequency amplifier ahead of the converter stage, the capacitance coupling between the grid leads of the amplifier and converter tubes often causes regeneration which becomes quite a serious problem when the gain of the amplifier is high. It is frequently necessary to place a shield between the two grid leads in order to obtain more stable amplifier operation. In designs which do not use a shield, the physical relation of the two grid leads affects the amount of regeneration present and any change in the relative position of the two leads will change the gain of the amplifier.

These developmental pentodes afford a simple solution to this problem. Since the grid lead of each type is brought out to a pin in the base of the tube, the lead connecting the grid to the input circuit may be made of

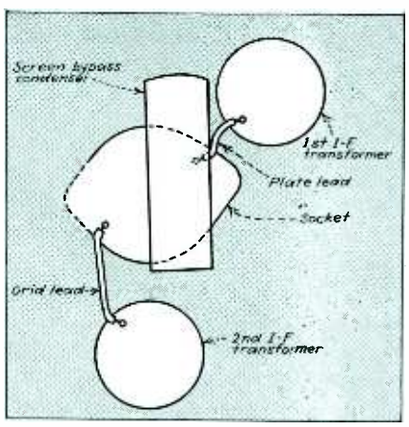

Fig. 4—Leads to by-pass may be reduced in length by properly positioning condenser

stiff wire and thus fixed in position. In addition, the proximity of the metal chassis to the lead affords additional shielding of the lead. The reduction in this feedback capacitance makes possible the use of a tube design having greater amplification. Moreover, because the coupling capacitance is not variable, variations in gain are minimized.

The improvement due to the new design is illustrated by the results of the following test. One of the single-ended pentodes was put in the radio-frequency stage of a popular commercial automobile receiver. The amplifier, using a conventional tube, had a gain of 30. The gain with the new single-ended tube was 45,

TABLE OF TENTATIVE AVERAGE CHARACTERISTICS, SINGLE-ENDED TYPES

	Develop. Type Similar to 6K7	Develop. Type Similar to 6J7	Develop. Type Similar to 6F5	Develop. Type Similar to 6Q7

* With shell connected to cathode.

with good stability. However, when a tube, like the new one except that the grid was connected to a top cap in the conventional manner, was placed in the amplifier, oscillation occurred when the amplifier and converter grid leads were as much as one inch apart. Moving them one and one-half inches apart stopped the oscillation but a shield between the two leads was required in order to stabilize the amplifier.

In another test, the developmental single-ended pentodes were substituted for conventional top-cap types in a small four-tube, tuned-radio-frequency receiver of popular design. An improvement in the uniformity of sensitivity throughout the tuning range was realized, due to the reduction of regeneration. The reduction in regeneration was affected by the improved shielding of the grid leads due to their proximity to the metal chassis. A substantial improvement in sensitivity at the low-frequency end of the range, where regeneration was negligible, was also realized because of the increased transconductance of the new tubes.

When the grid-plate transconductance of any tube is increased, whether it be a radio-frequency amplifier, audio-frequency amplifier, or power output tube, some special precautions are in order if full advantage of the increased transconductance is to be realized.

When these new tubes are used in intermediate-frequency amplifiers of present receiver designs, it may be necessary to modify the interstage transformers to obtain optimum operation. The L/C ratio of the modified transformers should be lower (in order to have lower impedance) and, thus, maintain the same degree of regeneration in the receiver without a change in the selectivity. This change may not be necessary in receivers having only a small amount of regeneration initially, but will be quite essential in receivers having high-impedance transformers and operating with considerable regeneration present.

Bringing the grid lead of the interstage transformer down to the bottom of the unit may change the capacitance coupling of the two circuits, and thus affect the gain and selectivity of the stage. In such cases it will be necessary to change the inductive coupling of the transformer slightly to correct for this condition.

In the design of amplifiers using conventional tubes, it is necessary to give consideration to the mechanical layout of the component parts in order to reduce feedback effects. Since both the grid and plate leads of the single-ended tube terminate beneath the chassis, the use of the single-ended type may require that further attention be given to the arrangement of the component parts for best results. Figs. 2 and 3 illustrate this point. In Fig. 2 the socket and intermediate-frequency transformers are mounted in such a way as to necessitate rather long grid and plate leads as indicated. Fig. 3 shows the revised mounting where the socket and input transformer have been rotated through 90°. It is readily seen that this arrangement leads to very short grid and plate leads. Measurements of the effective grid-plate capacitance were made for the two conditions illustrated and showed a reduction from a value of 0.006 $\mu\mu$f to a value of 0.0046 $\mu\mu$f. This reduction improved the stability of the amplifier.

It has been found that additional shielding which also reduces the effective grid-plate capacitance, may be obtained by placing the screen by-pass condenser close to and across the tube socket. Fig. 3 illustrates this positioning of the by-pass condenser, and may be compared to Fig. 4. Measurements of the effective grid-plate capacitance for the two positions of screen by-pass condensers were made and reduction from 0.0046 $\mu\mu$f to 0.0038 $\mu\mu$f was found. The stability of the amplifier was further increased by this change.

The effect of the kind of socket on the input circuit was investigated and results indicate that wafer-type sockets in general are entirely satisfactory for tubes of the single-ended design. The dielectric losses are the important considerations. Moulded types of sockets, in general, exhibit wider variations in the loading characteristic but socket manufacturers are improving their designs to provide for their use with tubes of the single-ended type.

Measurements have been made of the loading produced in the input circuit by tubes and socket components. These results, together with the calculated reduction in gain are shown for a frequency of 450 kc. and a wafer-type socket.

Component	Conductance in micromhos	Shunt Resistance in megohms	Reduction in gain*
Socket	**0.06**	**16.5**	**1.2%**
Base	**0.09**	**11.0**	**1.7%**
Unbased Tubes	**0.07**	**14.0**	**1.4%**
All components	**0.22**	**4.5**	**4.3%**

* Value calculated for input circuit impedance of 0.2 megohm.

From the above table, it is readily seen that for typical i-f circuits the loss in gain due to all components is less than 5% and the loss due to the base and socket is less than 3%. These losses, when compared to those of conventional top-cap metal tubes, are more than offset by the improved gain provided by the high transconductance of the single-ended design.

Industrial Tube Terminology

Names and definitions of tube types employed in industrial electronics, arranged according to type of space employed, cathode, and control structure, compiled by the General Electric Company as guide to terms in industrial field

Generic Term	Output Energy	Character of Space	Control Means	Type Cathode	Names	Definition
Electronic Tubes (or tanks)	Electrical	High-Vacuum	None	Thermionic	Kenotron	A kenotron is a high-vacuum thermionic tube in which no means is provided for controlling the unidirectional current flow.
				Photoelectric	Phototube	A phototube is a vacuum tube in which electron emission is produced directly by radiation falling upon an electrode. A high-vacuum phototube is one which is evacuated to such a degree that its electrical characteristics are essentially unaffected by gaseous ionization.
			Electrostatic	Thermionic	Pliotron	A pliotron is a high-vacuum thermionic tube in which one or more electrodes are employed to control the unidirectional current flow.
			Electro-magnetic	Thermionic	Magnetron	A magnetron is a high-vacuum thermionic tube in which a magnetic field is employed to control the unidirectional current flow.
		Gas-Filled	None	Thermionic	Phanotron	A phanotron is a hot-cathode, gas-discharge tube in which no means is provided for controlling the unidirectional current flow.
				Cold	Glow Tube	A glow tube is a cold-cathode, gas-discharge tube in which no means is provided for controlling the unidirectional current flow.
				Pool	Pool Tube (or Tank)	A pool tube (or tank) is a gas-discharge tube (or tank) with a pool-type cathode (liquid or solid) in which no means is provided for controlling the unidirectional current flow.
				Photoelectric	Phototube	See phototube definition under " High-Vacuum Tubes ". A gas phototube is one into which a quantity of gas has been introduced, usually for the purpose of increasing its sensitivity.
			Electrostatic Electrode	Thermionic	Thyratron	A thyratron is a hot-cathode, gas-discharge tube in which one or more electrodes are employed to control electrostatically the starting of the unidirectional current flow.
				Cold	Grid-Glow Tube	A grid-glow tube is a cold-cathode, gas-discharge tube in which one or more electrodes are employed to control electrostatically the starting of the unidirectional current flow.
				Pool	Grid-Pool Tube (or tank)	A grid-pool tube (or tank) is a gas-discharge tube (or tank) with a pool-type cathode (liquid or solid) in which one or more electrodes are provided for controlling electrostatically the starting of the unidirectional current flow.
	Light		Ignition Electrode	Pool	Ignitron	An ignitron is a gas-discharge tube (or tank) with a pool-type cathode (liquid or solid) in which an ignition electrode is employed to control the starting of the unidirectional current flow in each operative cycle.
	Ultra-Violet					
	X-Ray					
	Cathode-Ray		Electro-magnetic			

EDITOR'S NOTE: The names and definitions stated above have not been standardized by NEMA or ASA, but have been offered to these bodies for approval. The list represents a consolidation of the terms employed by the General Electric Company and the Westinghouse Electric and Manufacturing Company, with which companies they are now standard. Magnetic Recording

A survey of the distinguishing characteristics of recording on magnetic material, such as steel tape or wire, with a description of a modern machine of this type with suggestions for its application

By S. J. BEGUN

Acoustic Consultants Incorporated, New York, N. Y.

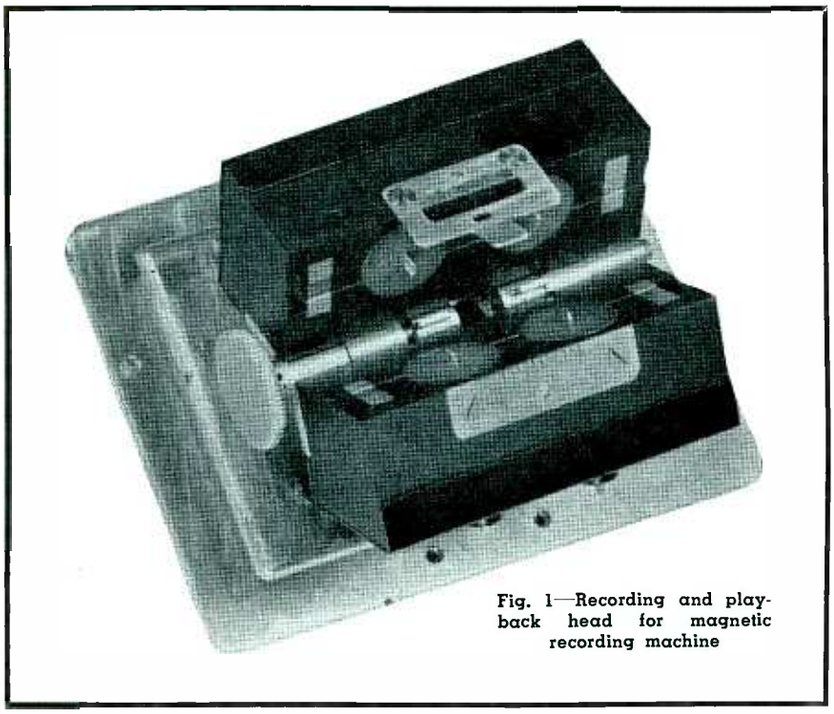

Fig. 1—Recording and playback head for magnetic recording machine

MAGNETIC sound recording and reproducing has by now been developed to the same high degree of perfection as the long available mechanical and optical systems. It is, therefore, logical to ask the question what can this method of sound recording add to the art. An answer to this question naturally can only be positive if this third method has something desirable which the two other known methods of sound recording and reproducing do not possess.

The principal of magnetic recording is, so far, very little known in this country. It is the idea of this article to analyze the specific values of this third method of sound recording and make a comparison with the generally familiar methods.

Magnetic sound recording is done on steel tape and wire. The signal is impressed upon the sound carrier either by perpendicular or longitudinal magnetization. Perpendicular magnetization leaves in the sound carrier magnetic forces rectangular to the motion of the sound carrier, while longitudinal magnetization leaves magnetic forces in the direction of the motion of the sound carrier.

Whether perpendicular or longitudinal magnetization is used, or whether steel tape or steel wire is employed as a sound carrier, magnetic recording involves three operations.

1. The sound carrier is magnetically prepared for recording by magnetic saturation.
2. The signal is impressed upon the sound carrier by superposition of the action of the signal current on a polarizing current.
3. The signal is reproduced by exciting a pickup with the magnetic forces of the record.

Usually an identical magnetic head is used for saturating, recording, and reproducing. As shown in Fig. 1, such a magnetic head consists of two sets of coils and pole pieces touching or closely placed on the opposite sides of the sound carrier. If perpendicular magnetization is employed, the pole pieces are aligned; for longitudinal magnetization, the pole pieces are slightly offset.

Magnetic recording has these distinguishing characteristics:

1. The record impressed upon the sound carrier may be obliterated by a simple electro-magnetic process.
2. Frequent rerecordings are possible since the impression of a signal affects only the magnetic structure of the sound carrier.
3. Extensive tests have established that the same record on a magnetic sound carrier may be reproduced an infinite number of times. In these tests a magnetic sound record on a magnetic tape was reproduced for more than 300,000 times, with the results shown in Fig. 2. It is seen that the signal level decreased 3 db during the first 20,000 reproductions, and that the total signal loss approached an asymptotic value of 4.5 db.
4. The recording and reproducing operations are not affected by vibrations and mechanical shocks. This is due to the fact that the adjustment

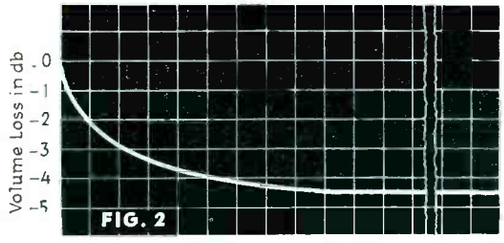

Fig. 2—Effect of continued playings on volume

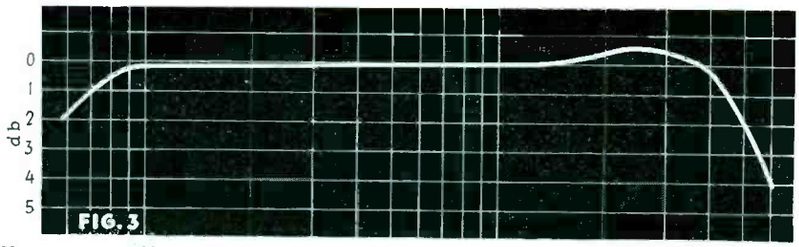

Fig. 3—Overall frequency response of the BBC recording machine

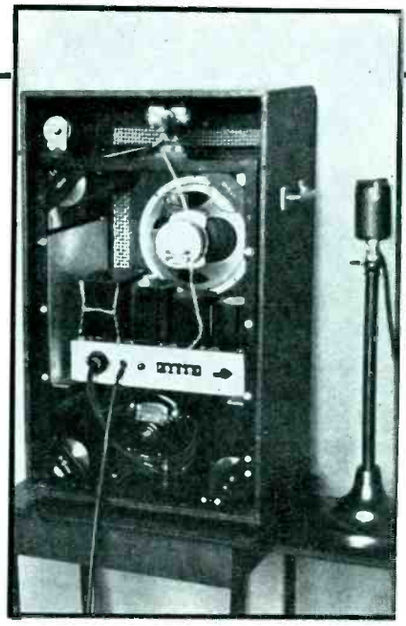
of the pole pieces is not very critical. The alignment between sound carrier and pole pieces can be taken care of even if the mechanical system driving the sound carrier is exposed to most severe mechanical vibration. No other system of reproducing is known which can stand such severe vibrations.

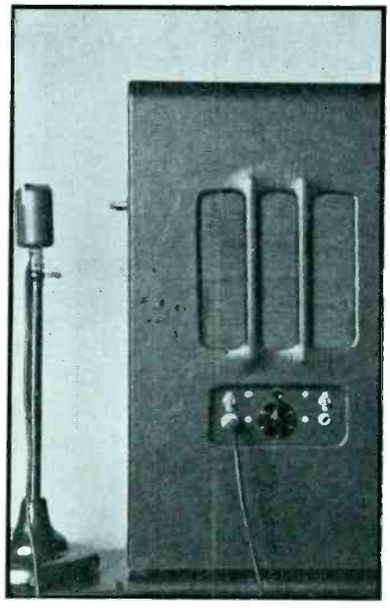
5. Specially developed pole pieces eliminate all problems of wear and tear during prolonged recording and reproducing operations. This was established in extensive tests carried out with a short endless tape loop; the ends were joined by brazing. The loop was played over one million times without any observable change in the pole pieces or brazed joint and without affecting the mechanical and magnetic characteristics of the tape.

Magnetic recording combines these unique advantages with a high quality of reproduction meeting all practical requirements. This is borne out in a recent article[1] describing a magnetic broadcasting machine of the British Broadcasting Corporation which has an overall response curve shown in Fig. 3. This overall response is considerably improved by the specially developed pole pieces.

The signal can be recorded at least 40 db above noise level and in this respect magnetic recording matches the best other methods.

In addition, a magnetic recording machine enables flutter-free recording and reproduction of even piano music. Such a machine developed for objective study of music, voice, and languages is shown. Four guide rollers are mounted in the corners of a frame structure. An endless magnetic tape is helically wound around these four





Figs. 4 and 5—Views of Dr. Begun's recording machine

Fig. 6—German dictating machine using magnetic material

Interior of Dr. Begun's recording machine

guide rollers. The first and the last loop on the guide rollers are joined together over two cross-over rollers.

A resiliently mounted motor drives through a belt one of the guide rollers. The sound carrier is frictionally engaged with the four guide rollers so that the three idle rollers have the effect of fly wheels and any irregularity of speed of the motor driven roller will be compensated by the three idle rollers. Guide bars mounted in front of the rollers maintain the proper spacing of the individual tape loops.

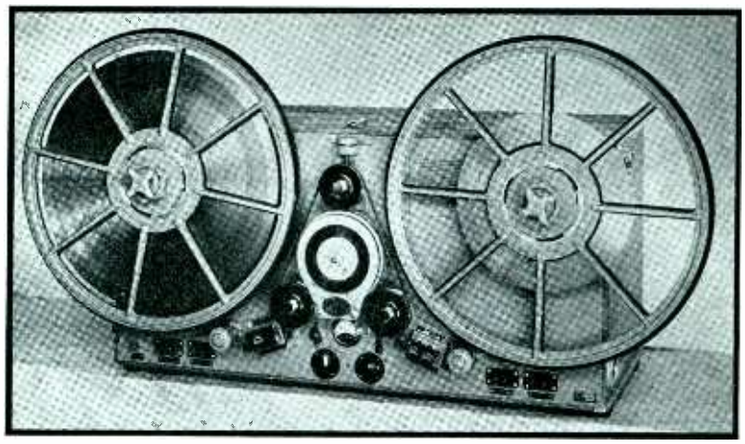
The cabinet enclosing the magnetic recorder also houses the amplifier and speaker. The endless tape may be made sufficiently long to give a recording time of from fifteen seconds to several minutes. Recording and reproducing is controlled by a simple push-button operation. After pressing the button, the machine will record until the sound carrier has completed one cycle. Then the record will be automatically reproduced as many times as desired, giving the student an opportunity to study his recording. The user does not require experience or technical skill for making recordings.

acoustic liveliness for which film and broadcasting studios now require expensive and cumbersome reverberation chambers. Its flexibility permits control of the reverberation effects in accordance with special needs and the production of echo effects.

Such machines may also be used in combination with display advertising to describe the products shown either in a moving or a continuously changing exhibit. The flexibility of magnetic recording permits the quick substitution of a new message and an infinite number of playbacks of the recorded message. The machine may be combined and synchronized with a picture-changing mechanism. Such a machine is also useful for sending out warning signals such as weather reports, S.O.S. signals, burglar alarms. An endless magnetic recording machine may be combined with a short wave transmitter tuned for the police radio wave length so as to announce the location and tell that a burglary has taken place or that a fire has broken out.

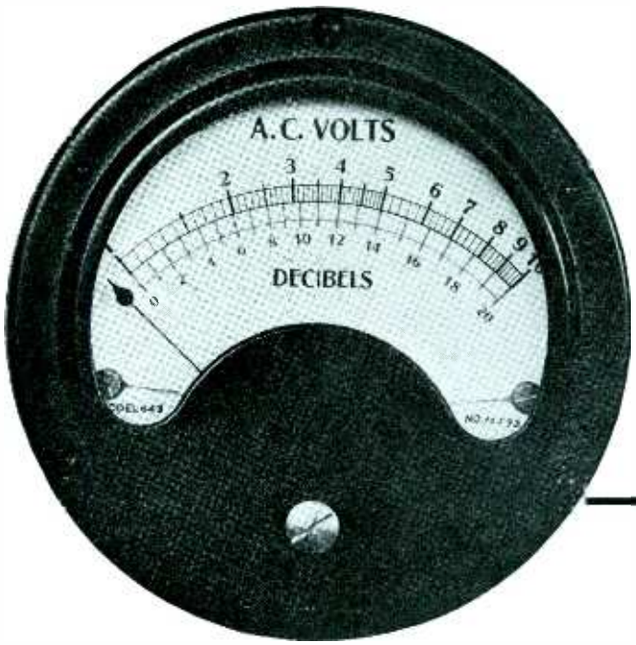
Magnetic recording is also ideal for use as a dictating machine and other business applications. A photo is shown of the driving mechanism of a magnetic wire dictating machine which is displacing in Germany the wax cylinder dictating machines. An exchangeable magnetic wire spool arranged for quick mounting on the top of the machine is not shown.

European broadcasting unit using steel tape



A machine of this type lends itself for a variety of applications by using a number of displaced magnetic heads and suitable attenuating and mixing networks. For example, such a machine can be used as a flexible synthetic reverberation apparatus that will solve the problem of adding

The foregoing applications show that all problems connected with the manufacture of practical magnetic recording machines have been solved, and that nothing can prevent its finding wide industrial and educational applications.



ELECTRONIC VOLTMETER Using Feedback

By STUART BALLANTINE

Ballantine Laboratories, Inc., Boonton, N. J.

THE VACUUM tube a-c voltmeter has become one of the most useful instruments in the electrical and communication laboratory. Its high input impedance and the wide frequency range which may be covered by proper design give it a considerable advantage over the older types of indicating instruments. Its sensitivity is limited however to a few tenths of a volt, which is insufficient for many measurements in communication and other branches of "weak current" engineering. Another disadvantage is the non-linearity of the scale for small voltages, which restricts the useful scale length and in multi-range instruments necessitates the use of several scales. For most purposes the ideal scale is a logarithmic one reading from 1 to 10. With such a scale the percentage of error of reading is uniform over the entire scale, and a uniform decibel scale can be provided for those applications where it is desirable to express results in decibels. The various voltage ranges can be made multiples of 10, which permits the use of a single scale for all ranges, and eliminates the optical confusion of the conventional multi-range instrument.

The instrument to be described here was developed several years ago to overcome these disadvantages. It is about one hundred times as sensitive as the conventional electronic voltmeter, permitting readings down to 0.001 volt. Its upper limit is 100 volts, which is equal to that of most multi-range vacuum-tube instruments. This high sensitivity permits it to be used to read voltages which heretofore have required amplification prior to measurement. For example, a very satisfactory sound-meter can be obtained merely by connecting a calibrated microphone to its terminals, no intermediate amplification being necessary. The frequency range extends from 10 cycles to 100,000 cycles, which completely covers the audio range, the frequencies used in supersonic signalling and the range of a large number of carrier communication systems. By connecting the instrument across suitable resistors a very sensitive ammeter is obtained and currents can be measured which are thousands of times smaller than can be measured with ordinary sensitive vacuum thermo-couples or rectifier instruments.

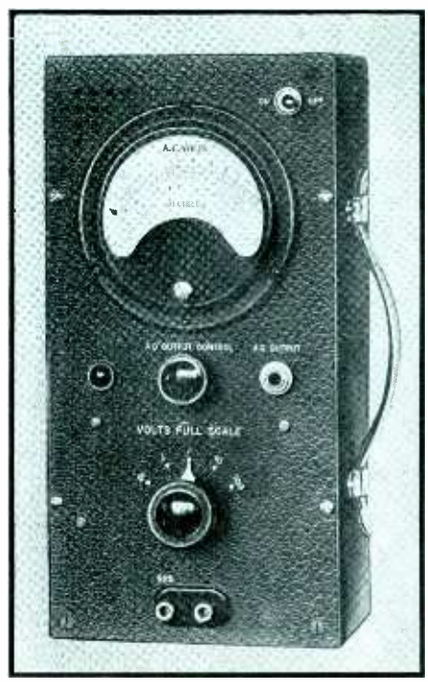


Fig. 1—Above. External view of the electronic voltmeter

Fig. 6—Upper Left. Scale showing logarithmic calibration of voltmeter, and auxiliary decibel scale

Principles of Operation

The instrument is entirely self-contained, is a-c operated, and readings are independent (within 1%) of line voltage from 110 to 120 volts. The scale is calibrated in root-mean-square values of a sinusoidal wave. Readings are accurate to within 2% over most of the range. An external view of the voltmeter is shown in Fig. 1.

The instrument comprises essentially a multistage amplifier, diode rectifier and a special d-c meter in which the deflection is proportional to the logarithm of the current. In addition a feedback circuit is provided whereby some of the rectified current is brought back to the input circuit of the amplifier. The writer has

shown[1] that by feeding back energy of reversed phase to the input of such a system, the rectifier characteristic can be straightened out and distortion considerably reduced. This principle of negative feedback, as was pointed out in the above reference, is also applicable to all sorts of electrical transmission systems such as telephone repeaters, power amplifiers, radio transmitters and receivers, where a number of advantages are obtained which have been well summarized by H. S. Black[2] and others. In the Model 300 voltmeter the application of feedback has the effect of straightening out the rectifier characteristic so that it resembles that of an ideal rectifier. As a result the output current can be made rigidly proportional to the a-c voltage applied to the input terminals of the amplifier. This method of securing a linear relation between rectified output and input voltage is superior (for voltmeter purposes) to the more usual method which relies upon the application of high voltages and/or the use of high series resistance. By making the resistance of the associated circuit small the automatic bias is reduced and the rectified current becomes more nearly proportional to the average value of an alternating current wave, whereas in the latter method it is proportional to the peak value. This is an advantage in that the effect of harmonics is reduced (depending of course upon their order and phase) and the readings become more nearly an indication of the true r.m.s. value of the fundamental, which is usually what we want to know.

Operating Principle

The principle of operation may be illustrated schematically by Fig. 4 which shows the application to a two-stage amplifier. The negative feedback path includes the insulating condenser C, the rectifier R, d-c meter M, and resistors R_2 and R_1. The rectified current on one half of the cycle (plus that through R_2) flows through R_1 and introduces a negative voltage in the input circuit which opposes the applied voltage. On the other half of the cycle the rectifier current is zero (or small) and the current through R_1 is that through branch circuit R_2M. As a result of this feedback the overall amplification is reduced and the output current tends to become independent of the amplification and to depend mainly on the value of R_1. The stability is therefore very much improved because the effect of any factor tending to change the amplification—such as variation in line-voltage, tubes, circuit constants, etc., —is reduced in proportion to the reduction in amplification. In addition the relation between d-c rectifier current and input voltage is made accurately linear in spite of the curvature of the particular rectifier employed.

The linearisation of the rectifier characteristic by the feedback may be very simply exhibited graphically. Let E_1 represent the voltage between grid and cathode of the first tube, E_0 the input voltage, I_2 the current through the rectifier and R_1 the coupling resistance. Let,

$$I_2 = f(E_1) \qquad (1)$$

represent the E-I characteristic of the amplifier and rectifier. Now,

$$E_1 = E_0 - R_1 I_2 \qquad (2)$$

hence

$$I_2 = (E_0 - E_1)/R_1. \qquad (3)$$

We are interested in the relation between E_0 and I_2 which can be found by solving (1) and (3) graphically. Plot (1) and (3) as shown in Fig. 3. The relation between I_2 and E_0 is then obtained from the intersections of the curves for various values of E_0. This relation is plotted in Fig. 3 which indicates the linearisation obtained under the assumed conditions—a square-law rectifier characteristic and feedback sufficient to reduce the gain about 10 to 1. It will be noticed that the action is analogous to that obtained by placing a large resistance in series with the rectifier, a well known expedient for securing linearisation. The equations are the same and the graphical construction is the familiar one for series resistance. This is consistent with the fact that constant current feedback raises the effective output resistance of the output tube. (In the foregoing we have purposely neglected the current through R_2).

The linearisation effect of feedback is also shown by the oscillograms in Fig. 2. These show the relation between the rectifier current and the input voltage. The lower oscillogram was taken with feedback, while the upper one was taken without feedback and shows considerable curvature, which would produce a non-linear relationship between d-c output and input voltages, especially if the circuit constants were adjusted to indicate average rather than peak values.

The overall sensitivity of the arrangement as a volt-meter depends mainly on one resistance (R_1) which can be constructed to have a high stability as regards both temperature variations and ageing. The applica-

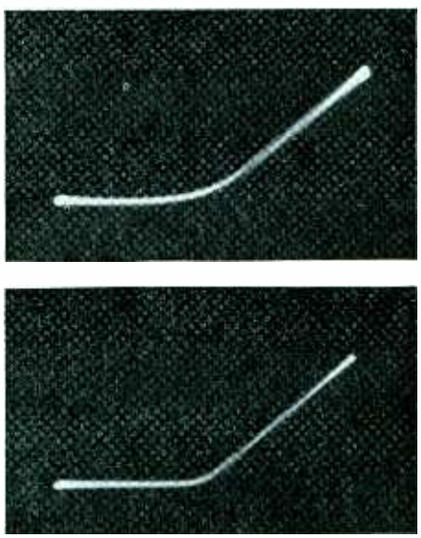

Fig. 2 — Effect of feedback in straightening rectifier characteristic. Upper curve, without; lower curve, with feedback

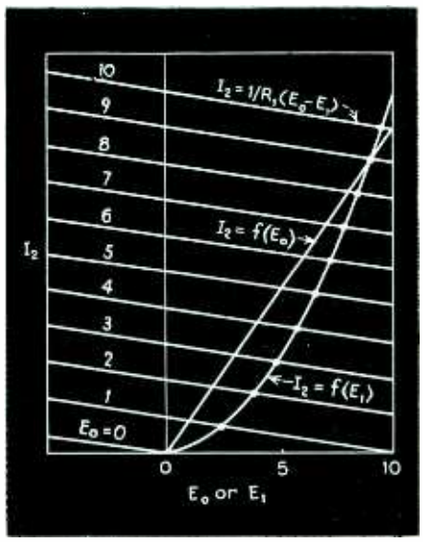

Fig. 3—Graphical construction showing linearisation of rectifier characteristic by negative feedback

[1] U. S. Patent 1,723,719 filed January 9, 1923.
[2] *Bell System Technical Journal*, Jan. 1934.

tion of preliminary amplification to electronic voltmeters has heretofore been unsuccessful because of instability, and inconvenient because of the resultant necessity of providing means for standardization at frequent intervals. Since the calibration of the voltmeter depends only on R_1 it can be adjusted once and for all with confidence in its future stability in spite of tube replacements and other variations.

Range switching is accomplished in the input circuit as shown in Fig. 4. In view of the wide frequency range covered ordinary high impedance resistance attenuators are useless and a combination resistance-capacity network is employed. (Not shown in detail in Fig. 4). The input impedance is that of a 500,000 ohm resistance shunted by a 25 $\mu\mu$f capacitance. One side of the input circuit is grounded. The accuracy which has been obtained in the attenuator and the "flatness" in the whole system are illustrated by the frequency characteristics of the several ranges shown in Fig. 5. In this diagram the ordinates represent meter readings for a constant input voltage of variable frequency.

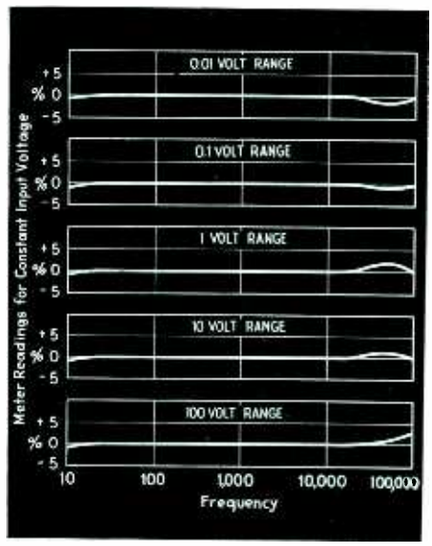

Fig. 5—Overall frequency characteristic of electronic voltmeter for the various ranges

Logarithmic Scale

One of the most important and novel features of the instrument is the logarithmic scale. As pointed out above, this extends from 1 to 10 and permits range switching in decade steps. Also a uniform percentage accuracy of reading is afforded over the entire scale. A photograph of the scale is shown in Fig. 6. A substantially uniform scale of decibels is also provided, printed in red and positioned below the voltage scale. This will be found useful in many applications.

Use as an Amplifier

In order to increase the usefulness of the instrument in the laboratory provision is made so that it can be used as an amplifier. An output jack is provided and by plugging in this jack the rectifier and meter are cut out of the circuit and a 20,000 ohm potentiometer is substituted. The gain of the amplifier is adjustable in steps of 10 (20 db) by means of the range switch and for finer adjustment the potentiometer knob (located just below the meter) may be used. The output impedance at full gain adjustment on the output potentiometer is a resistance of 20,000 ohms. The maximum voltage gain (output/input voltage) is 3100, or 70 db. The overall frequency characteristic as an amplifier is flat within 1 db to 100,000 cycles. The harmonic distortion on output voltages up to 30 volts is low. At this output voltage level the residual a-c hum is negligibly small, amounting to 0.05 volt or 0.2% (— 56 db).

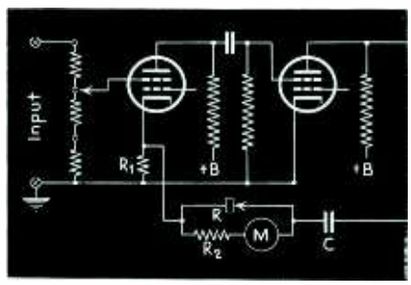

Fig. 4—Schematic diagram showing the application of negative feedback to two stage amplifier-rectifier system

In addition to its use as a wide-range voltmeter, the instrument can be used as an ammeter to measure a wide range of currents by connecting it across suitable resistances. Up to 100,000 cycles, resistance as high as 10,000 ohms may be connected in shunt with negligible error due to the shunting effect of the input capacity of the meter (25 $\mu\mu$f). This would make a current of 10^{-7} ampere (one-tenth microampere) measurable. To see what this unusual sensitivity means we may compare this performance with that of a conventional vacuum thermocouple. A standard 1000-ohm couple and meter combination requires a current of about 1 ma. for full-scale deflection. Possibly a current of one-fifth of this value, or 200 microamperes would be readable with accuracy. With the same 1000-ohm resistance shunt the electronic voltmeter would be capable of reading down to 1 microampere, an increase in sensitivity of 200 to 1.

Other Uses

A number of other uses for this instrument will readily suggest themselves to the engineer, among which the following may be mentioned:

(1) Frequency characteristic and gain measurements on amplifiers. The wide voltage range of the voltmeter makes it possible to read both input and output voltages. Voltage gains up to 100,000 (100 db) are measurable in this way.

(2) Transmission losses on telephone circuits, filters and other apparatus (including carrier systems up to 100 kc) by applying a known voltage at the sending end and using the voltmeter to read the level at the receiving end.

(3) Acoustic measurements; noise measurements and measurements of frequency characteristic of loudspeakers, public address systems and radio receivers, using a calibrated microphone connected to the input terminals.

(4) Vibration studies and geophysical measurements using a contact microphone connected to the input terminals. For these applications the uniform response at very low frequencies is of particular advantage.

(5) Bridge measurements, especially at low audio, high audio and supersonic frequencies where balance is difficult to detect aurally with telephones.

(6) Measurements in supersonic engineering.

(7) Servicing of public address and sound systems, photo-cells, amplifiers, loud speakers, etc.

(8) Maintenance of circuits and apparatus in radio broadcasting stations.

TUBES AT WORK

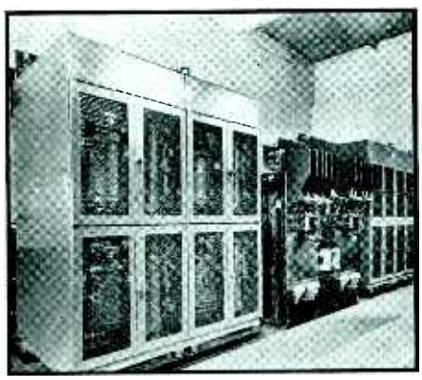
Mercury Rectifier Runs B. & O. Electric Train

TO MAKE ROOM for a street extension near the Howard Street Tunnel of the Baltimore & Ohio electrified line, in Baltimore, it was recently necessary to move a substation comprising two synchronous converters of a total capacity of 3000 kw., which supply power at 670 volts for the feeders within the Howard Street Tunnel. One available site, on



Rectifier installation replaces converter equipment

property owned by the railroad, was located but a few feet from the original location, but directly over the tunnel. It was feared that the vibration from the rotating converter units would weaken the tunnel walls if the substation were set up in this location. Consequently it was decided to retire the converters from active service and to replace them with mercury arc rectifiers.

The rectifier installation operates completely without vibration, and its foundation requirements are much less rigid than those of the rotating equipment. However, it is necessary that absolute freedom from interruption of service be attained. Consequently, two four-section rectifiers were used, each with sufficient overload capacity to carry the full load of two trains with a total of six electric locomotives. Each rectifier is rated at 3000 kw., with a 150 per cent overload capacity for two hours, or 300 per cent for five minutes.

The mercury rectifiers have shown an appreciable saving in power over the former converter equipment. Savings result primarily from the fact that the no-load losses of the rectifier are approximately 35 kw. less than for the equivalent rotating converter capacity. In this particular railroad installation there are frequent periods when no upgrade trains are in the tunnel, and consequently the equipment is not loaded. However, a heavy overload may occur almost immediately when a train enters the tunnel section. The spare capacity of the rectifiers is available almost instantaneously, through the use of remote-controlled ignition switches. The rectifier system has been in use for two and a half months without failure or a single instance of "backfire." The same personnel that operated the converter equipment has been trained to take over the new duties associated with the rectifier installation.

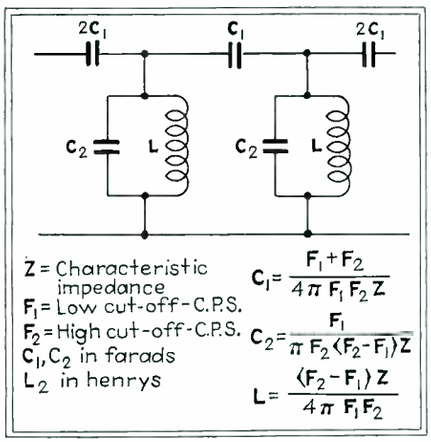
A Cathode-Ray Null Indicator

By E. B. MCNULTY

GOOD SENSITIVITY together with ease of operation is desirable in every type of instrument but especially so in inductance and capacitance bridges which are necessarily cumbersome on account of the dual balance. In such circuits a visual indicator is of great advantage, because it will indicate the direction of the balance as well as the balance itself. The most common types of visual indicators in use today are the meter and rectifier, the neon light, and the electric eye. The meter and rectifier are not recommended, because at the beginning of the balance there is great danger of harm to the meter, although it is suitable in all other respects. The neon light is of very little advantage over the phones, for it does not aid in finding the vicinity of the null point. The

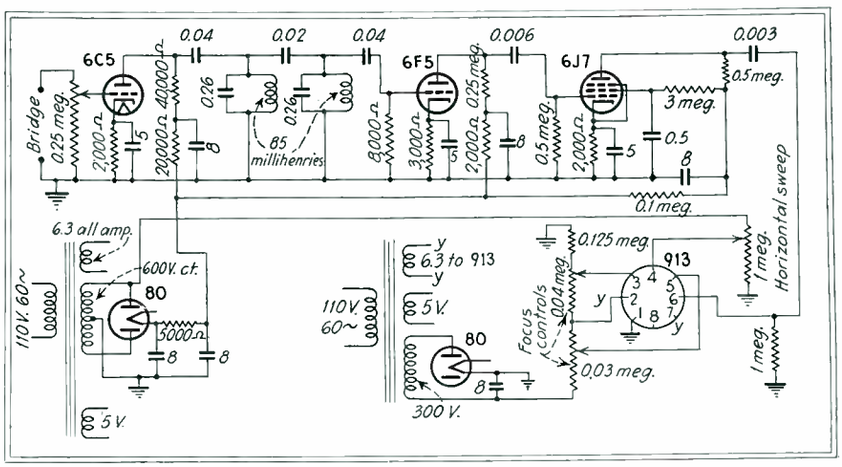


Design data for filter in null indicator

magic eye is good provided one uses a protective resistance in the grid circuit in order to prevent harm to the tube at the beginning of the balance. Greater ease and nicety of operation may be secured by the substitution of the 913 cathode ray tube in place of the magic eye. This change is quite inexpensive and well worth the slight additional cost.

It is quite simple to apply the cathode ray tube to the purpose at hand. A 60-cycle sweep circuit should be connected to the horizontal plates and the signal from the bridge should be coupled to the vertical plates. The null point is had when the vertical length of the pattern is smallest. The 60-cycle potential is applied to the horizontal plates as a precautionary measure against possible harm to the tube.

The 913 has a sensitivity of about 5 volts per millimeter, if operated at 300 volts anode potential. For most bridges



Complete circuit diagram of a bridge null indicator employing a cathode-ray tube

a sensitivity of 0.1 of a millivolt is more than sufficient, and hence the total voltage gain for one millimeter deflection required is approximately 50,000. Under given circuit constants a 6J7 will give a gain of 350, a 6F5 a gain of 50, and a 6C5 a gain of 10. This set of tubes will afford us more than sufficient gain for the purpose.

It is a well recognized fact that the addition of an amplifier will increase the harmonic content. Since the oscilloscope, as used here, will not distinguish between the fundamental and harmonics, it is necessary to add a filter. The filter should be of the band-pass type and should be designed to pass all frequencies from approximately 950 to 1050 cps. without an appreciable diminution in gain. This will permit the use of an oscillator of but 5% stability. The type of band-pass filter together with its formulae are given in the accompanying figure.

It was found that the most suitable position for the filter was immediately after the plate of the 6C5. The necessary condensers and inductances to suit the characteristic impedance of the line at this point are commercially obtainable, and the loss in gain due to the filter is less than in any other position. In the calculations 933 cycles was used for frequency cut-off on the low side and 1067 cycles on the high side. These limits were used in order that the parts necessary for the filter could be obtained commercially. At first sight it may seem strange that the pentode follows the triodes, but since the filter

MANUFACTURERS OF PURE NICKEL SEAMLESS CATHODE SLEEVES, AND
ALSO PURE NICKEL LOCKSEAM CATHODE SLEEVES UNDER U. S. PATENTS

SUPERIOR TUBING

should be placed towards the beginning of the amplifier in order to allow greater gain to be used without any special precaution against oscillations and stray pick-up, this order was selected and it works out quite well.

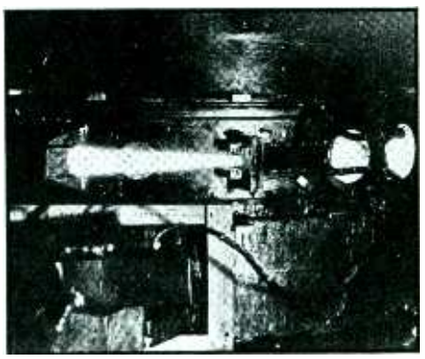
The filter must be adjusted closely in order that good results may be obtained. This can be done by the aid of a beat-frequency oscillator or a good inductance and capacitance bridge. The former is the better method. The coils and condensers should be lined up in much the same way as I.F. transformers.

There are only a few constructional precautions. The entire filter should be shielded and it is well to shield each inductance from the other. One system is to mount the band-pass arrangement in a transformer case and to insert a metal plate between the chokes. The leads from the 6F5 to the 6J7 should, of course, be shielded. Arrangement should be made to couple the amplifier to the bridge with the least possible capacity effect. This can be done by connecting the ground terminal of the bridge to the ground of the amplifier, and by connecting the remaining terminal of the bridge to the grid of the first tube in the amplifier through the gain control. The capacity across the bridge will be only that of the tube which is very small, about 4.5 mmf. A good external ground should be connected to the ground terminal of the bridge. The whole assembly can be housed in a metal shield about 10 x 8 x 8 inches. One transformer may be used instead of the two given in the diagram.

The band-pass filter can be made to pass any other band of frequencies by the application of the formulae given in the diagram.

To put the null indicator into operation it is only necessary to adjust the focus controls of the oscilloscope until

CYCLOTRON BEAM



The beam shown in this photo is caused by the impact of high speed particles on the air as they emerge from the exit window of the cyclotron at the University of California. The beam, nearly a foot long, is produced by particles whose energy is about 6,000,000 electron volts. Ordinarily the beam is used to bombard materials placed just within the exit window

vacuum tube relay, actuates one pen of a two-pen chronograph. The other pen of the chronograph is controlled by a time standard, such as a 1000-cycle clock, calibrated to whatever degree of accuracy is necessary. The tape from the chronograph is then examined to give the period of the oscillating ring, from which the high frequency current in the exciter ring can be computed directly, or obtained from a calibration chart. The impedance of the instrument is extremely low, much lower than that available from other high frequency ammeters.

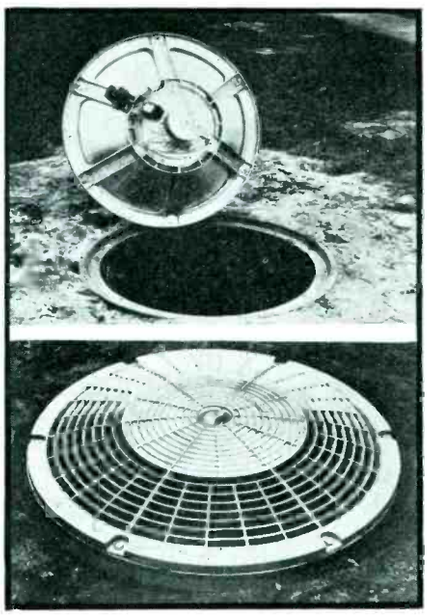
Eddy-Current Oven Roasts Coffee

ACCORDING to information received from Samuel Wein, the Uniroast Co., of New York, have demonstrated a new method of roasting coffee, by the use of a high frequency current generated by a thyratron inverter circuit. Ordinarily the coffee bean is subjected to heat from the outside layers, where the large exposed area permits many of the essential oils to be lost before the bean is roasted through. The eddy-current system on the other hand affects all portions of the bean simultaneously, and as a result the roasting process is completed in a shorter time. The machine for roasting the coffee handles two pounds at a time, supplied from a hopper having a 50-lb. capacity.

SUB-SURFACE LOUD-SPEAKER



At the recent gymnastic festival at Breslau, commands to the participants were carried through loudspeakers mounted in the surface of the ground and covered by a protective metal grill

A Simple-Constructed Attenuation Network

By Francis King, WJTN

In most attenuator problems, the "T" type of pad fills the bill. In such a pad three separate resistors are connected in such a manner as to give the proper matching load to both impedances, between which it is connected, and the desired amount of loss for the particular purpose at hand. This is shown in Fig. 1.

By making a simple change in the legs of the network, which is merely one of arrangement, we take one of the legs of the "T" pad and move it to the opposite end of the parallel leg. This arrangement, called a "Z" pad from its schematic appearance, is shown in Fig. 2.

Since in the "Z" pad all resistances are in effect in series, it is obvious that

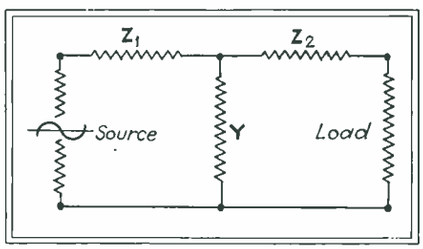


Fig. 1—Conventional "T" attenuator

a single resistor unit may be used. Figure 3 is a sketch showing the proper terminals for both input and output connections, and the sections are marked so that comparison may be made with other types of pads. For pads having both input and output impedances the same, a single 1500-ohm resistor will cover all attenuations between 4 and 48 db and from 50 to 600 ohms in and out.

For example, consider an attenuation network to be inserted in a 500 ohm line

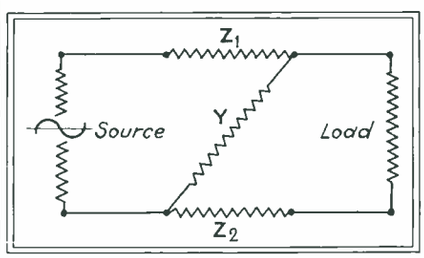

Fig. 2—"Z" pad equivalent to that in Fig. 1

with a loss of 18 decibels. From any of the several charts available we find that a "T" pad has sections Z_1, Y and Z_2 of 388, 128 and 388 ohms each respectively. Thus with an ohmmeter we measure the first section from A to B in Fig. 3 and set the first clip at the point of 388 ohms. From this point B we measure to point C for the Y or parallel section and adjust this clip to 128 ohms. Again, from this point, we measure to D for 388 ohms and set the last clip. The total resistance necessary is, then, 804 ohms.

Assuming another case, in which we wished to match 3000 ohms to 500 ohms and wished to attenuate the signal 15

Western Electric

RADIO TELEPHONE BROADCASTING EQUIPMENT

decibels, from available charts or formulae we find that $Z_1 = 2745$ ohms, $Y = 449.9$ ohms and $Z_2 = 83$ ohms. For a "Z" pad we would measure the first section on the resistor between terminals A and B and set at the value 2745 ohms. Next section Y between terminals B and C is made 450 ohms. Finally section Z_2 between terminals C and D is given the value of 83 ohms, completing the network. In this case, as well as in the case of the 500 ohm pad, the input will be terminals A and C and the output will be terminals B and D. The total series resistance is 3278 ohms. A resistor having a total of 3500 ohms would be satisfactory for the purpose.

way of binding post bushing, special impregnation of the selector switch and other mounting elements in the input circuits, to prevent leakage errors across the grid circuit due to very high humidities.

Applications

Some of the more common applications to which this instrument is particularly suited are as follows: Measurement of ion and weak electron currents in various thermionic tube circuits; secondary emission currents; leakage currents between tube elements and between circuit elements; potentials and currents in AVC and AFC circuits; general insulation tests, particularly where the use of low voltage is desirable; weak electron-beam currents in cathode ray and special tubes for television purposes; minute currents in phototubes as used in densitometers, control circuits, etc.; electrolysis and corrosion currents and potentials; and galvanic currents and potentials in biological research.

An Electronic Consultant

(*Continued from page* 12)

cial trip to learn how well their engineering department functioned. At the end of the discourse I suggested that I might possibly be of use at some future time if they had something they couldn't do or felt like it was too simple for them to fool with. I walked down the four flights of stairs and I caught a train home.

There is a sequel, however. Later on, business had dwindled in the gauging line so I sent out a circular letter to names got out of a trade register. One of the letters went to Punky Sink and I got another call from them. After the 600-mile train ride, this time I got in to see the engineer in about 20 minutes and found a new face. A pleasant sort of a chap and with him were two confederates. All of the gentlemen were armed with high speed centrifugal information pumps. It seemed like they had just designed a trick assembly and were manufacturing it but unfortunately they admitted that their gauging method was not so hot. Would I please tell them how to gauge this assembly? No, I would not tell them how to gauge the assembly but would sell them an automatic gauge that I would guarantee to do the job at the rate of one hundred a minute. The gauge was discussed at length when one of the bright boys spoke up and said they don't want me to build an automatic gauge for their use. They could do it themselves. What they wanted to know was how to do it. I said sure I would tell them how and when could I start in? He said right now. I asked about an order to cover the engineering fee and when I gave him a very nominal figure for the job he nearly fainted.

He said, "you see we can't pay you to do that; we have engineers for that purpose."

One of my most happy experiences, however, has been with a large New England concern making an enormous quantity of little gadgets. It took me two years to sell them since they were (as they called themselves) "hard headed Yankees." They never pumped me but gave me every help for the month I was in their factory. The chief engineer was a farmer-type of fellow who liked to tell stories but a gentleman from the word go and the smartest mechanical engineer I have ever met. This outfit is sorting over a million gadgets a day on my machine and are happy over the whole set-up. Incidentally they are saving money. I might venture to say that ten times the cost of the machines would not buy them if they could not be replaced.

My experience with Punky Sink has been repeated several times with others, but I always keep coming back hoping that the next call will lead to a job and sometimes it does.

Decide Whether to Take Credit or Cash

For example the High Class Mfg. Co. made a small part that went into a radio set. I had built testing machines for this part and sold a number of them. They did not cost much to build but saved the manufacturers of small parts a lot of money, and I sold them at a good profit. Nearly everybody that bought one was pleased with the machine but some objected to paying for it, after they saw it, because it was so simple. Even though they could pay for it out of 60 days' savings, they felt my price was unreasonable.

One of these companies had an engineer who had written monographs on how they tested these small parts and stated that his concern had an automatic machine based on his principles. After reading his printed stories I surmised that they might be having difficulty with his circuit and dropped them a note. Eventually I sold them two units. The engineer got the credit and I got the business.

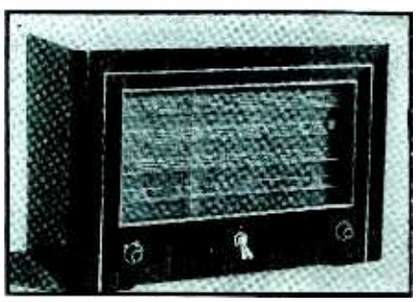
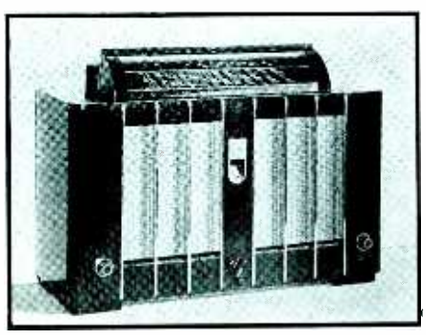
TWO NEW STATION SELECTORS



This tuning indicator consists of glass imprinted with calls and locations, on four separate bands. Side lighting illuminates only the markings for the band then in use



The latest sets released in Germany reveal unusual tuning arrangements. Above is the "retractable" type featured by Telefunken. The station indicator folds down into the cabinet when not in use

Announcing!

the greatest SINGLE IMPROVEMENT in the history of instantaneous recording equipment

PRESTO 6-D RECORDING TURNTABLE EQUIPPED WITH AUTOMATIC EQUALIZER

THE NEW PRESTO AUTOMATIC RECORDING EQUALIZER*

It does a job no human skill can duplicate. It compensates smoothly and accurately for the progressive attenuation of high frequencies on 33-1/3 rpm recordings and as it varies the equalization it keeps the output of the recording amplifier at a constant level. It makes the quality of your 15-minute recordings the same from beginning to end . . . no hollow, tubby quality near the center of the record due to loss of highs . . . no shrill rasping reproduction at the outside due to over-equalization. And it's completely automatic in operation . . . requires no attention from the operator during recording.

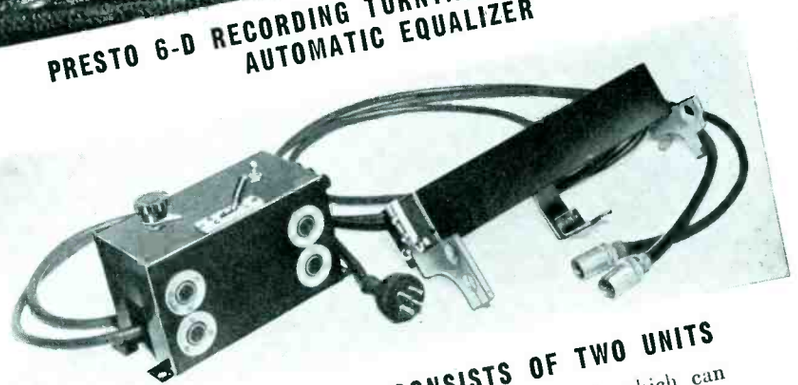
This new device can be installed on your Presto recorder in less than ten minutes. Simply loosen two screws and clamp the slider unit onto the over head feed mechanism.

Plug the cables into the control box, connect to the 500 ohm input of your recording amplifier and your equipment is ready to make the finest instantaneous recordings you ever heard.

Price of Presto automatic recording equalizer complete $156.00 net to broadcasting stations. (F.O.B. New York)

*Patents pending.

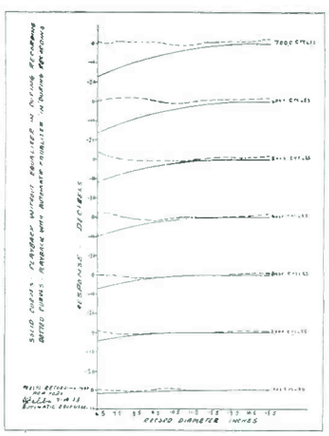
Place Your Order Today and be Certain of Prompt Delivery.



THE NEW EQUALIZER CONSISTS OF TWO UNITS

1. A control box containing the tuned circuit which can be adjusted to peak at either 6000 or 8000 cycles, receptacles for the cables from two slider units, a cable connecting to the amplifier input and a changeover switch to connect the unit to either of two turntables.

2. A slider type, variable resistance network which engages with the cutting head mounting and moves across the surface of the disc with the cutting head. One resistor adjusts the slope of the amplifier curve to compensate for the changing groove radius. The second, a T pad, controls the amplifier gain in steps of ¼ db. to compensate for the insertion loss of the equalizer.



Solid curves show the losses of high frequencies for various groove radii. Dotted lines show the correction made by the Presto Automatic Frequency Equalizer. Note that throughout the portion of the record used in making 15 minute transcriptions, the frequency response is uniform within 2 db. up to 7,000 cycles. Without equalization the loss at a groove radius of 3½" is 15 db. at 7,000 cycles and over 8 db. at 4,000 cycles. The Presto 1-B high fidelity cutting head was used in making the records for measurement.

THE ELECTRON ART

Each month the world's technical literature is scanned to see what physicists and engineers are doing with tubes, for presentation in tabloid form to Electronics' readers

New Metal for Grids

By R. K. KENNEDY
Kemet Laboratories Co., New York

THE IDEAL METAL for receiving tube grids must possess great stiffness, a great tensile strength, and a high surface work function, and it must retain these properties even at temperatures up to 700 or 800 deg. C. Its surface conditions must be such, chemically, as to remain practically unaffected even after receiving a condensate of metals or oxides when the getter is flashed or from the distillation of oxide-coated cathode surface materials. This is necessary to assure a minimum of grid emission.

In addition to these characteristics, it is necessary that the wire, when formed on a mandrel, should produce grids of uniform dimensions. Experimental work, carried out recently in the laboratory and confirmed by production tests in radio tube factories, has shown that such wire must come within a narrow range of tensile strength. In the case of one nickel-molybdenum-iron alloy, Hastelloy A (Moly Alloy), this range lies between the limits of 130,000 and 140,000 lb. per sq. in., and for a relatively new alloy of similar composition but containing more molybdenum, known as Hastelloy B (Moly Alloy Type HB) it is between 150,000 and 160,000 lb. per sq. in. Although the tensile strength is a dependable index of performance in the grid-making operation, the elastic limit or yield point is probably the governing factor.

While it is true that the present-day choice of materials represents the optimum balance of the qualities most required in a particular tube design, the physical properties of the more recently introduced alloy promise to alleviate the situation considerably. Up to now, materials for No. 1 or control grids—those usually operating under the most exacting conditions—have included molybdenum, Hastelloy alloy A (Moly Alloy) and chromium-nickel alloys. This is the order of their stiffness, but the inverse order of their resistance to the effect of contamination and the resultant increase in emissivity caused by deposited oxides.

Under less stringent operating conditions, such as exist at grids further from the cathode or at their support rods, other materials have been found satisfactory. Several of the heavy metals are very stiff even at elevated temperatures, but unfortunately in many cases, when used for control grids, they may emit electrons, thereby altering the tube characteristics and causing undesirable distortion.

The presence of molybdenum in Hastelloy A (Moly Alloy) imparts to this alloy a high degree of stiffness which is retained even at considerably elevated temperatures. However, the new alloy, Hastelloy B (Moly Alloy Type HB), which contains a larger amount of molybdenum, possesses even greater stiffness. While an exact evaluation of the property of stiffness is not given by the usual physical tests, the short-time tensile properties at elevated temperatures present a ready indication of what may be expected.

The short-time ultimate tensile strength of the new alloy is unusually high at the usual operating temperatures of 500 to 800 deg. C. The alloy is fairly ductile and can be drawn into wire down to a diameter of about 0.003 in. It is readily formed over a mandrel. In addition, like the other nickel-molybdenum-iron alloy, its emissivity is not strongly affected by condensates of getter or cathode materials. Recently, however, to reduce grid emission still further, grid wire of these alloys has been gold plated and copper plated, and results of several tests conducted with this wire indicate that it has considerable merit.

SUPER ELECTRON MICROSCOPE

This electron microscope, constructed in the Siemens and Halske plant in Germany, at present has a useful magnification of 2000 diameters, but can be extended by employing higher accelerating voltages to about 30,000 diameters, which is 6 times as great as that possible with the best optical methods. Voltages up to 100,000 volts are used in the present work

Abstract of Italian Papers on Electrical Science

A NEW INSTITUTION, known as the Centro Volti di Electrologia has been founded in Italy with the high consent of the Duce and the National Committee of Research. Its principal object will be the improvement of electrical knowledge by means of new cultural exchanges between Italian and foreign scientists. The society publishes the *Bulletin of the Centro Volti di Electrologia*, the purpose of which is the dissemination of Italian research in the field of electrical studies throughout the world.

The first issue of the *Bulletin* contains an outline of the organization of the society, an illustrated article on its center of activity, the stately Dendramin-Calergi Palace in Venice. Two technical articles, from other Italian publications, are given and almost 200 papers are abstracted from Italian sources. These abstracts are printed on individual cards 3 in. by 4 in. in English as well as Italian.

Annual subscription rate is 30 L. The *Bulletin* may be obtained from the Centro Volpi di Electrologia, Dendramin-Calergi Palace, Venice, Italy.

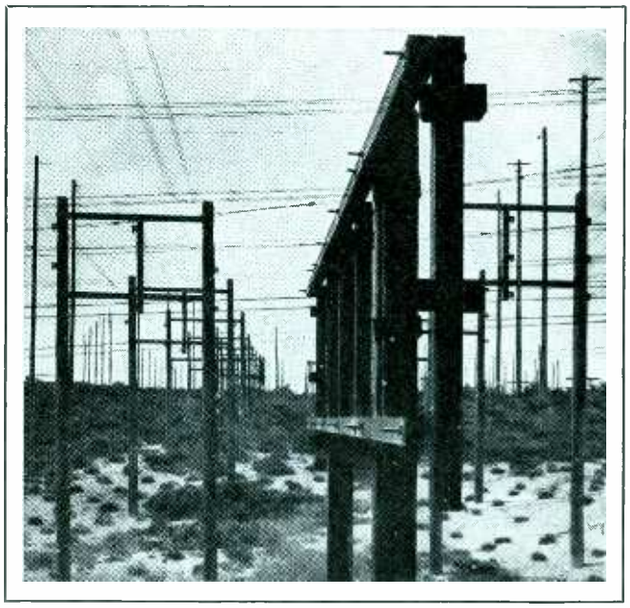
Tubes as Voltage Recorders

THE USE OF gas tube voltage recorders as applied to telephone practice is described by L. K. Swart in the July issue of the *Bell Laboratories Record*. In telephone practice it is sometimes necessary to determine the magnitude and time of occurrence of voltages which are induced in telephone circuits from neighboring power lines. The desirable characteristics of not consuming power except when recording voltage fluctuations and being ready for operation continuously have been met in a voltage recorder controlled by cold cathode tubes which become conducting when the applied voltage exceeds a critical value. Records of disturbances with any desired range of voltages can be handled readily by using several tubes in a suitable circuit arrangement.

The cold cathode tubes employed have

Station Power

Shown above is a busy scene in the main office of RCA Communications, located in the heart of downtown New York, 66 Broad Street. This is one of the many services of the Radio Corporation of America.



At the Riverhead, Long Island, receiving station of RCA Communications are scores of antennas. This is the point of reception of European features that are heard on hundreds of American radio stations.

THE POWER of a broadcasting station is not measured in kilowatts alone, but in ability to hold an audience. The world-wide communications services of RCA may seem to have little connection with the power of broadcasting stations. But when power is considered in terms of audience rather than kilowatts the connection is clear. All radio broadcasting stemmed from communications. RCA research in this field has constantly led to improvements in transmitting radio programs . . . more power to stations.

In the home no radio program is better than the radio receiver. RCA research has been responsible for a large part of the steady improvement in home receivers. This research is of a practical nature that not only improves instruments but makes them available at low prices. All of which means . . . more power to stations.

RCA presents the "Magic Key" every Sunday, 2 to 3 P. M., E. D. S. T., on the NBC Blue Network

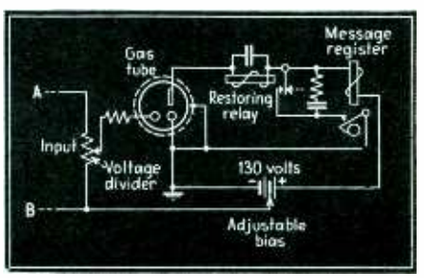
RCA Communications, Inc. RCA Institutes, Inc. Radiomarine Corporation of America

two activated cathodes and a non-activated anode. They contain a mixture of gases at low pressure of which the most important constituent is either neon or argon. The circuit to be tested is connected to the two cathodes which act as the control electrode.

When the voltage across the two cathodes exceeds the breakdown or critical value, the gas in the tubes becomes ionized. The ionization within the tubes reduces the impedance of the circuit of which the anode forms an essential part and allows sufficient current to pass to actuate the recording relay equipment.

One method of extinguishing the tubes after the disturbing voltage is recorded makes use of a restoring relay which removes the actuating voltage from the message register as soon as the discharge has been recorded.

The simplified wiring diagram of Fig. 1 shows a single stage recorder



with one suitable method for restoring the tubes to normal use. By means of the voltage divider across the input circuit, the voltage at which the gas tube breaks down, in terms of the disturbing input voltage, may be varied at will.

Several types of voltage recorders have been constructed on these principles. The simplest are those in which a Veeder counter is actuated by means of a ratchet wheel whenever the message register is operated. Other recorders have been constructed to give on paper tape a permanent record of the magnitude of the voltage as well as the time of occurrence of the disturbance.

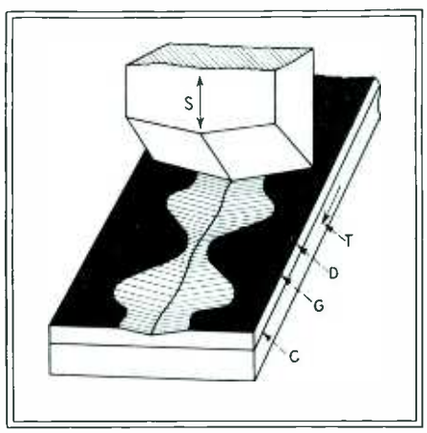
METAL TUBES IN GERMANY

The use of horizontal element structures in a new series of metal tubes by Telefunken gives a compact assembly. Metal tubes are new in Germany and not yet popularized. Only one manufacturer's line features them in the present Berlin Radio Show

Philips-Miller Recording System

A SYSTEM OF mechanical recording which is used with optical reproduction is described by R. Vermeulen in the June issue of the *Journal of the Society of Motion Picture Engineers* under the title "The Philips-Miller Method of Recording Sound". The method of recording is mechanical in operation and is suitable for "playback" immediately after being produced, since it does not require processing.

The sound track is engraved upon a strip of film composed of a celluloid base which is coated with a layer of transparent gelatin about 50 microns thick, upon which is superimposed a very thin opaque coating, about 3 to 5 microns thick. A cutter in the shape of an obtuse angle wedge is displaced perpendicularly to the plane of the film strip in synchronism with the sound vibrations to be recorded. The cutter removes a shaving from the gelatin layer passing below it and in so doing leaves



Cutting head of the Philips-Miller recording system, showing removal of opaque coating from transparent base

a transparent trace against an opaque background. Because of the shape of the cutter, the transparent trace produces a linear magnification of the cutter motion. When only the center of the cutter is effective, a narrow trace is recorded, but when the cutter is depressed several microns, the slit widens considerably.

Because the recording is mechanical in operation and does not require subsequent processing, the film strip can be handled throughout in ordinary daylight. Through the use of an optical reproducing system, a long playing time is obtained, the wear on the sound channel is small, while the absence of mechanical reaction upon the sound film drive enables a low power drive unit to be employed.

The article discusses suitable angles which have been determined for the cutting head, the frequency characteristics of the recorder or cutter, shows the construction of the driving system, and discusses the advantages of this recording system over the customary photographic methods of recording.

A New Type of Vacuum Steel

A NEW TYPE of lead-in structure for vacuum-, gas-, or oil-tight chambers is described by W. E. Dahls, in the July issue of *Electrical Engineering*. In this seal, porcelain bushings are sealed to metal by means of a glass which serves as a bonding agency. The advantage of using porcelain rather than glass as a seal to metal is that the porcelain will maintain its shape to much higher temperatures than glass, and therefore only a minimum amount of skill and labor would be required to make the joint.

The prerequisites for making an ideal seal between glass, metal and porcelain are: (1) both the metal and porcelain must be wet by the glass; (2) the metal, glass and porcelain must all have the same coefficients of expansion up to the temperature where the glass is sufficiently viscose to relieve stresses quickly; (3) all component parts must be vacuum tight. In practice the proper requirements need only be such that the metal, glass and porcelain should have coefficients of expansion sufficiently alike that upon cooling after the seal is made, the stresses developed due to the differences in thermal contraction are not great enough to cause a fracture of the glass or porcelain, or to leave the completed seal mechanically weak.

In this article the requirements for suitable glass porcelain metal seals are discussed as well as the wetting of the materials by the glass, and the thermal expansion of the three substances.

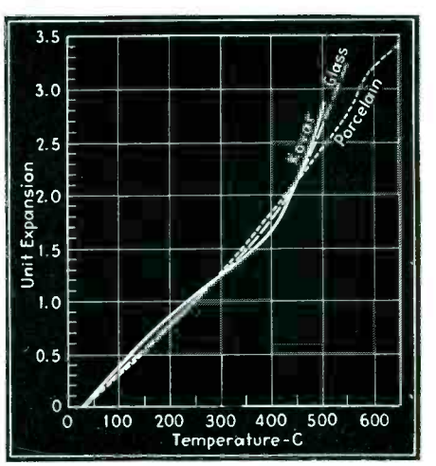


Fig. 1—Expansion characteristics of metal glass and porcelain suitable for making vacuum tight seals

Fig. 1 shows the expansion characteristics of the three materials used in one type of seal. This seal is made at a high temperature (usually between 900 and 1100 deg. C.) and consequently, the Kovar metal and glass have expanded considerably more than the porcelain. After the seal is made and cooling is started, the metal tends to contract faster than the porcelain and consequently stresses are set up in the seal. In order that these stresses may be relieved at the lower temperature, the glass must permit the metal to move with respect to the porcelain by an

amount equal to the difference in contraction between the metal and porcelain in cooling from the temperature at which the seal is made to the lower temperature.

An analysis given by the author shows that it is impossible to obtain complete release of stress in a metal-glass-porcelain seal for a heat treatment of any reasonable time. By so adjusting the seal design that stress release will continue to as low a temperature as practically feasible, a satisfactory, strong seal can be made.

Shape of the Magnetron Characteristic

AN ATTEMPT to determine the shape of the cut-off curve in magnetrons from theoretical consideration is given in an article by E. G. Linder, "Effects of High Energy Electron Random Motion Upon the Shape of the Magnetron Cut-Off Curve" published in the May issue of the *Journal of Applied Physics*.

In this article, the differential equations of motion for electrons in the magnetron are derived and experimental verification of the theory is given.

In a perfectly symmetrical, cylindrical magnetron, neglecting space charge effects and the initial velocity of the electron, and assuming that the electrons move only under the action of the electric and magnetic fields, the cut-off curve would have the general shape shown in Fig. 1 A. The anode cur-

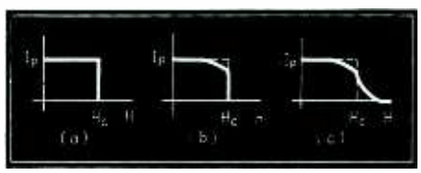

Fig. 1 — Magnetron characteristics for various emission conditions

rent I_b remains constant until the magnetic field reaches the critical value H_b when I_b drops abruptly to zero. If the space charge is considered, the anode currents no longer remain constant as the magnetic field approaches its critical value. The increasing curvature of the electron trajectories and the longer transit time cause an increase in space charge and a consequent decrease in anode current before the cut-off point is reached. However, when the magnetic field reaches its critical value H_c, the anode current drops abruptly to zero as shown in Fig. 1 B. If initial velocities are also considered the curve takes the form shown in Fig. 1 C where the first part of the curve is identical with that of Fig. 1 B. For field intensities greater than H_c an abrupt drop in anode current no longer occurs. At the critical point, only those electrons having zero initial velocity fail to reach the anode, but those having a higher initial velocity require greater fields for their cut-off. This yields a curve of the form shown, which is the form always observed experimentally if the emission current is sufficiently large to cause appreciable space charge.

THE INDUSTRY IN REVIEW

Fabricated Plate Capacitors . . . . . *By Gordon V. Peck**

OF WIDESPREAD interest to those engaged in radio chassis and circuit design, is the recent announcement of the type FP capacitor incorporating the newly developed anode material known as "fabricated plate". Since this new anode material represents a fundamental capacitor development, a brief review of the capacity characterstic and industrial history should be of interest.

The capacity of a dry electrolytic unit is determined by the surface area of the anode exposed to the electrolyte and the thickness of the anode film. Capacitance is developed in the insulating oxide film which lies between the anode plate and the electrolyte, which is the cathode electrode. The so-called cathode foil is used for the sole purpose of establishing a low resistance contact to the electrolyte and its surface area has no bearing on the anode capacity.

In paper dielectric capacitors, the capacitance is developed between the two metallic electrodes and not between one electrode and the electrolyte as in electrolytic units. No capacity gain, through added surface area, is possible unless the electrodes are actually increased in physical size.

Early types of dry electrolytic capacitors were made with plain aluminum anode foil and were commercially identified by Type SP representing "smooth plate".

Approximately four years ago etched plate Type EP dry electrolytic capacitors were made available and their use has increased through the intervening years. The Type EP capacitor provided the first commercial realization of capacity gain through increased anode area and made possible a substantial decrease in physical size over the original smooth plate type.

In the case of etched plate capacitors, the increased anode surface area was accomplished through a special acid etching process. Anode plate, prepared in this manner, produced ratios, as compared to smooth plate of an average of 4 to 1. The capacity ratio of etched plate units varies somewhat with forming voltage.

Now, however, aluminum foil and the subsequent roughening methods are being supplanted by the latest anode development known as fabricated plate produced by spraying molten aluminum directly onto a chloride-free fabric carrier and commercially identified as "FP" plate. The process is accomplished through specially designed automatic machinery that turns out this FP plate at high speed.

Some years ago the first experiments involving the spraying of aluminum for anode development were carried on in the Magnavox plant at Fort Wayne, Indiana. While the original work done in this regard was confined largely to spraying aluminum onto aluminum foil for use as wet electrolytic anodes, considerable experience and technique were accumulated which helped make fabricated plate possible. Later, the Mallory Research Division started the commercial development of the fabric carrier type of sprayed plate now in current use by both companies.

Of outstanding interest is the high ratio obtainable and the consequent reduction in capacitor size made possible through the fabricated plate development. The high ratio is obtained by utilizing the entire thickness of the plate and the great surface area afforded by the many threadlike fibres of the fabric which are coated with a continuous layer of aluminum. FP plate is porous, and light may be seen throughout its entire area. Naturally, this porosity permits excellent electrolyte contact during impregnation with consequent low series resistance characteristics.

Unlike etched plate anode foil, which varies considerably in ratio with forming voltage, fabricated plate, due to its welded particle structure, is practically unaffected. This largely accounts for the remarkably uniform capacity characteristic of FP plate and permanency of this characteristic throughout the life of the capacitor.

The ratio of 10 to 1, temporarily adopted as standard for all FP plate, does not represent the maximum ratio attainable. Fabricated plate capacitors with a ratio of 20 to 1 have been made in the laboratory. While ratios of 30 to 1 and higher have been obtained experimentally, the practical ratio limit has not been determined at this writing.

Aluminum for the spraying operation is purchased in wire form, which is readily obtainable in the high purity desired for anode material. This assures uniform production of capacitors having excellent shelf and operating life characteristics. The use of a single standard gauge of wire for all spraying purposes completely rectifies an inventory problem formerly encountered in the necessity of stocking large quantities of numerous gauges and widths of foil for anode purposes.

Electrical connection to the anode in foil type capacitors was made by cutting and folding a portion of the foil to form a tab to which the terminal or lead wire was riveted. The tabbing of fabricated plate is accomplished by inserting a special aluminum tab at pre-determined intervals along the fabric carrier, the tabs being welded permanently into position by the molten aluminum from the spray guns. This new tab is the culmination of extensive development work and provides advantages with regard to capacitor construction details and operating efficiency generally impossible with the fragile foil tabs used on the original anodes.

In developing the most practical capacitor design for housing the fabricated plate cartridge, the metal cased Type FP capacitor first announced to the trade in March 1938 was evolved. This unique, completely standardized capacitor permits, for the first time in this industry, low cost mass production of a compact trouble-free unit having an exceptional range of application.

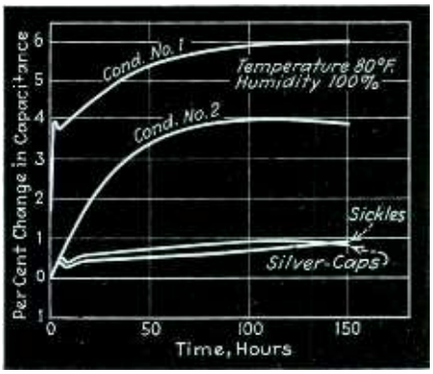
New Products

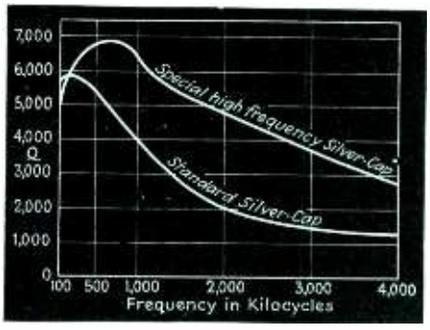
Tube Tester

AN INEXPENSIVE, accurate tube tester, the new "dynoptimum", has been put on the market by Radio City Products Company, 88 Park place, New York. This instrument tests all of the latest type tubes as well as old types, including the new OZ4 and other cold cathode rectifiers. It tests all metal, MG spray shield and glass tubes, all ballast types.

Hot interelement shorts and leakage between all individual elements, hot cathode leakage, sectional defects of full wave rectifiers, duo diodes and all multi-purpose tubes are tested. The meter is a three inch D'Arsonval, 2% accuracy, with a direct reading "Good-Bad" multi-colored scale and calibrated reference scale. Directly on the meter is an accurate line voltage indicator, smoothly controlled for line voltage variation.

STABILIZED CAPACITORS





A most significant development of recent origin is that of tuning components which are remarkably stable with changes in humidity and temperature. The curves above show a direct comparison of the capacity stability between two standard moulded mica condensers and a two Silver Cap (Sickles) units at 80 deg. F and 100 percent humidity. The lower curve gives readings of Q over a wide band of frequencies

Remote Control Tube

RAYTHEON type RK-62 is a gas-filled triode which may be used as an extremely sensitive detector of high frequency signals.

For controlling model airplanes, the tube appears to be unequalled. It is operated in the standard self-quenching super regenerative circuit in which the usual phones are replaced by a sensitive relay and a low capacity bypass condenser. One model plane may have three or four of these receivers tuned to different frequencies. Transmitters on the ground are used to actuate the relays and each performs some function necessary to operate the plane realistically.

Other Raytheon tubes recently announced are the RX884 and RX885. These are gas filled triodes designed for sweep circuit oscillators or grid controlled rectifiers. The former has a 6.3 volt filament; the latter operates from 2.5 volts.

Photoelectric Control

FOR USE in all general applications is Model No. 50 of the United Cinephone Corp., 43-37 33rd St., Long Island City, N. Y. The relay is complete with light source of a 32 CP automobile type bulb. It operates control at distance of 25 ft. 110 volt 60 cycles AC. The internal telephone type relay carries a load of 2 amps. 110 volt 60 cycles A.C. non-inductive. Impulses required are $\frac{1}{20}$ of sec. between operations. The unit contains one 6J5 amplifier tube and one 1105 photocell. The lens is a 2" focal length Bausch & Lomb.

Cased Bypass Condensers

NEW P. R. Mallory Cased Bypass Condensers, Type CB, are now available in two working voltages, 400 and 600, a wide variety of capacities, and in single and multiple section types. For convenience Mallory has combined the usual 200-volt listing with the 400-volt ratings but has retained the small size of the 200-volt type. This eliminates unnecessary items. In making this change the insulation of former 200-volt units was increased to equal the required insulation for 400-volt rating.

Glass Insulated Magnet Wire

A NEW Deltabeston magnet wire, insulated with fiber glass, has been announced by the General Electric Co., Bridgeport, as an addition to the present line of Deltabeston asbestos-insulated magnet wire. Deltabeston glass-insulated magnet wire, like Deltabeston asbestos-insulated magnet wire, is available in round, square, and rectangular shapes.

Condenser Tester

AN A-C BRIDGE for measuring leakage of electrolytic condensers has been developed by Clough-Brengle, Chicago. This Model 130 unit has a capacity from 1 $\mu\mu$f to 100 μf, resistance from 10 ohms to 500 megohms, power factor of condensers from 0 to 50%, and transformer turns ratios from .01 to 100.

Police Radio Transmitter

DESIGNATED as MI-7814, the new transmitter is wholly self contained and requires no external power supply. Class "A" high level modulator provides 100% modulation. It includes a convenient sized hand-type mike with a switch to control the transmitter built into the microphone. Two pilot lights on the instrument panel indicate the transmitter's operation. It is crystal controlled. Battery drain is 18 amps. for 8 watts output on the uhf band. R.C.A. Mfg. Co., Camden, N. J.

RCA also announces 25-watt PM speaker (MI-6260) for indoor and outdoor applications where a small, lightweight unit of good performance is required. Frequency range 140 to 8000 cycles.

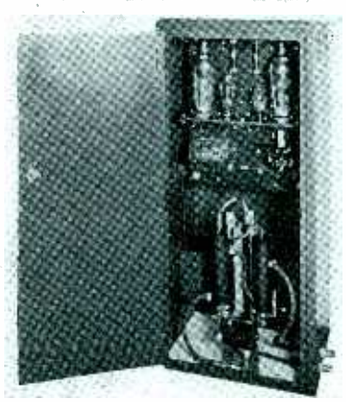
Capacitors

HERMETICALLY sealed in round aluminum containers, the Type TLA Cornell-Dubilier (South Plainfield, N. J.) capacitors are impregnated and filled with fire-proof Dykanol, the same high dielectric impregnant as used in the TJ-U transmitting capacitors. The capacitors are suitable for use in high power amplifiers and medium powered transmitters.

Physical size and shape of the containers of these capacitors simulate electrolytic capacitors, allowing for simple and neat assembly into power unit. The staple characteristics of Dykanol permits the operation of these capacitors at 10% above rating without injury to unit. Details in new catalog No. 161.

Ignitron Welding Timer

TYPE SP-11 of Westinghouse is inexpensive, and will mount two sizes of ignitron tubes. On low duty cycle, the WL-652 tube will carry 1500 amps. at 220, 440 or 550 volts, while the WL-651 will carry 2800 amps at 440 and 550 volts or 4300 amps. at 220 volts. The current rating is decreased at duty cycles above about 3.5%. Other qualities are: high accuracy of control; adjustable to pass current for any exact



number of cycles from 1 to 15; for longer periods, it is adjustable from 1 to 30 cycles; welding machine current starts and stops at current zero eliminating line current transients.

THE Westinghouse 37 line of panel instruments covers industrial and radio applications and includes rectox types, thermocouple types, a-c and d-c meters.

Insulated Test Clips

A NEW AND improved product made from neoprene, I. E. Du Pont de Nemours, (Wilmington, Del.) chloroprene rubber has been introduced by the manufacturers, Muelier Electric Co. This material exhibits the properties of rubber strength, resilience, elasticity and abrasion resistance and will maintain these properties virtually unchanged after extended exposure to oils, chemicals, heat, ozone and aging.

Modulation Indicator

TO WARN of over-modulation the Modulite is a gas-filled glass tube 12 in. long and 16 mm in diameter. The inside of the glass is coated with fluorescent material which glows when excited by positive ions or by u-v when it is connected to the r-f stage of a transmitter. Overmodulation is evidenced by a red glow in the tube. It is useful for amateur and other transmitters which are required by rules of the FCC not to overmodulate. Acoustic Consultants, Inc., Rockefeller Center, New York.

Portable Pee Wee Transmitter

COMPLETE TRANSMITTER and power supply on a single small chassis and operating from a 6 volt storage battery, this unit is primarily intended for rural service where a-c is not available or as a portable mobile or emergency transmitter. The current drain is 9 amps. fully loaded with key down and 1.4 amps. at standby. It contains metal rather than glass tubes. General Transformer Corp., 1295 W. Van Buren St., Chicago, Ill.

Television Capacitors

TWO NEW TYPES of Pyranol capacitors, one designed for use in television transmitting sets and the other for radio transmitting sets, have been announced by the radio transmitter division of the General Electric Company, Schenectady.

The television capacitor, for use in kinescope deflecting circuits, is approximately 2 inches in diameter and 9 inches long, excluding leads. It is equipped with a heavy-duty ceramic insulator at the high-voltage terminal, and a molded Textolite cup-washer with a flexible lead at the low-voltage terminal. Both terminals are insulated from the case, one at rated voltage and the other at 400 volts d-c.

The new capacitors for radio transmitters, also in cylindrical cases, are available in ratings up to 2000 volts d-c. Approximately 2 inches in diameter, they range in length from 3 to 6½ inches. They are hermetically sealed and equipped with ceramic insulators and an adjustable clamp-type mounting bracket. See Bulletin GEA-3018.

Phototube Relay

A NEW G-M Laboratories, Inc., Chicago, phototube relay is suitable for experimental or research work for educational problems or lecture demonstrations. Known as Type 1224A the unit comes with a wiring diagram in the base and is furnished as a kit for student assembly or completely assembled and ready for use.

Tube Shields

GOAT RADIO Tube Parts, Inc., Brooklyn, has announced a new line of tube shields to fit the new 1.4 volt, low drain, 50 ma. series of battery tubes. Also a new series of tube shields for the Bantam Tubes now offered by several radio tube manufacturers. Samples and literature are available.

Resistors

A SERIES of wire-wound resistors in 5, 10 and 20 watts size are announced by Continental Carbon, Inc., Cleveland, Ohio. A low temperature coefficient wire wound on porcelain tubes with copper leads makes up the essential elements of these units.

Electrolytic Condenser

A COMPACT DRY condenser in a 1 in. diameter can, with simple ring mounting is announced by Aerovox Corp., Brooklyn, in single, double, and triple sections.

A more thorough means of testing condensers is provided in the new Aerovox condenser and resistance bridge. This instrument measures capacity from 100 $\mu\mu$f to 100 μf, and power factor from 0 to 50%. It measures resistance values from 10 ohms to 1 megohm in 5 ranges and insulation resistance between 350 megohms to infinity at 500 volts and down to 10 megohms at lower voltage.

Stable Condensers

SILVERED mica condensers have been announced by Aerovox. These fall into the category of the newer units which are remarkably free from capacity drift due to temperature or humidity changes.

Bushing

A COMBINATION bushing and strain relief for cord sets has been developed by General Electric Co., Bridgeport, Conn. It is of particular interest to radio manufacturers because of the necessity of protecting sets against damage from insecure cords. It is unnecessary to tie knots as a measure of strain relief.

75 Watt Rheostat

A 75 WATT power rheostat-potentiometer is now made available by the Ohmite Manufacturing Company of Chicago.

The new Model "G" incorporates the outstanding features of the other Ohmite models. It has the protection of vitreous enamel which covers and separates the individual turns of wire, binding the entire assembly rigidly to the porcelain core—dissipates heat rapidly, and is mechanically strong.

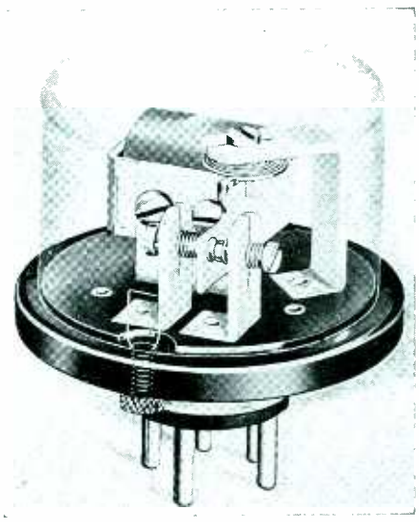
The entire shaft and bushing assembly is insulated from the electrical circuit by a ceramic driving hub. The rheostat can be mounted directly upon metal panels without further insulation.

Microdyne Pickup

A NEW COMPENSATED Microdyne can be purchased at the same price of ordinary pickups according to Audak Company, 500 Fifth Ave., New York City. By means of a new inductor and a newly developed low-pass filter, coupled within the pickup, the response is flat from 500 to 8,000 cycles and has a gradually rising characteristic from 500 cycles down, reaching about 12 db at 50 cycles.

Sensitive Relay

TYPE 3-A relay is compact, sturdy and is an instrument of rapid, positive action at low power input according to Sigma Instruments, Inc., 388 Trapelo Rd., Belmont, Mass. It handles non-inductive loads up to 150 watts at 110 volts a.c., and requires only 12 milli



watts for its operation and can be installed directly in a variety of vacuum tube circuits. It is obtainable in various field resistances. Size is 2⅜x2¼ in. This instrument has essentially the same characteristics as the type 2-A but incorporates structural modifications.

Fasteners

SEMS — a pre-assembled Shakeproof Lock Washer and standard machine screw—is the latest addition to Shakeproof's line of metal fastening products. This new assembly unit saves time and money by reducing labor costs, speeding up production and eliminating such waste as lost lock washers. Each screw is equipped with the correct size of lock washer for its particular type of head. As the lock washer cannot drop off, no screw can be applied without having a lock washer under the head. Tests in both large and small production plants indicate not only immediate cost savings, but faster and better production. Literature describing SEMS in detail available from Shakeproof Lock Washer Co., 2501 North Keeler Avenue, Chicago, Illinois.

Program Controller

WHEREVER VARIABLE temperature control is required over any period of time a program control offered by Wheelco Instruments Co., 1933 S. Halsted St., Chicago, Ill. is available. This consists of a program unit and a controller mounted integrally. To the temperature control setting pointer of the Wheelco Capacitrol is attached an idler arm which rides on the edge of the contoured disk of the program unit. The temperature of a furnace may be controlled at any point set by the pointer. The disk can be cut to any time cycle desired with any variation of temperature control.

Electronic Welding Contactor

FOR WELDING mild steel products and other readily-welded metals, a new "Weld-o-trol" electronic power switch for controling the primary of welding transformers and suitable for use with existing timing devices, is announced by Westinghouse E. & M. Co., East Pittsburgh. With either sealed-off or continuously pumped ignitron tubes, the Weld-o-trol offers an instantaneous power switch for producing uniform welds, and is free of moving parts, arcing contacts and noise. Available ratings, are roughly equivalent to 300 and 600 ampere conventional welding contactors.

Sound Distribution System

FOR SCHOOLS having 20 rooms or less, Model TES, Operadio Mfg. Co., St. Charles, Ill. Master control, unit amplifiers, ten loud speakers, ten speaker cabinets, microphone and stand are included in the unit. Each room can be talked to singly or all rooms simultaneously, and a radio set and high impedance phonograph unit can be used.

Frequency Meter

SUPERCEDING Type 101 micrometer frequency meter the Lampkin Laboratories, Bradenton, Fla., have developed Type 103 which is especially suitable for transmitter checking in compliance with FCC requirements.

Flux

A NON-CORROSIVE soldering flux for brass, tin, bronze and copper, designed primarily to meet the needs of fast soldering on a mass-production basis, is now being marketed by The Ohio Carbon Company, 12508 Berea Road, Cleveland, Ohio. It is stated to penetrate the joints thoroughly and quickly, and was originally evolved in the Company's laboratories for use on a specially difficult soldering problem in their own manufacturing processes where all commercial liquid soldering fluxes had been unsuccessful.

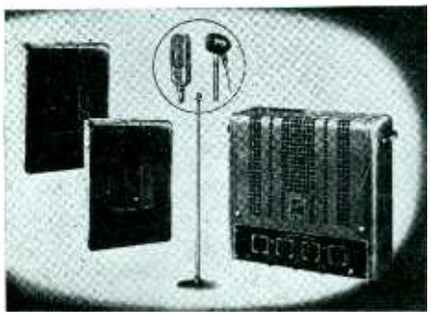
Transmitters. Lists complete line for amateurs, commercial, and experimental communication service. Transmitter Equipment Mfg. Co., 130 Cedar St., New York City.

Capacity and Resistance Bridge. Manual gives practical instructions for miscellaneous application, also the theory and functioning. Price 50c. Aerovox Corp., 70 Washington St., Brooklyn, N. Y.

New Products

Sound Systems

MODEL FR60 is a 60 watt public address system of Webster-Company, Chicago, which incorporates a high speed expander, multi-stage degeneration, remote control and dual tone compensation.



The amplifier is equipped with 4 input mixing circuits and has variable output connections. Besides the amplifier, this system is furnished with two P. M. speakers and either velocity or dynamic type microphone.

MODEL S-40 will handle any number of rooms up to 40 and is an enlarged and improved edition of the S-20. It is compact, centralized, completely self-contained and includes separate communication system which allows engaging in a two-way conversation simultaneously with the regular program. Programs can be picked up in any room and fed to any one or all other rooms. A 6-tube superheterodyne with push button tuner is included.

12 in. Speaker

FIVE MODELS of 12 in. permanent magnet speakers have been introduced by Jensen Radio Mfg. Co., Chicago. These speakers vary in sensitivity, power and capacity and response. They list from $9.85 to $34.75.

Sound System

A DUAL CHANNEL remote control amplifier and sound system has been designed by Transformer Corp. of America (Clarion). Full control of the two channels from any distance within hearing range of the system is obtained and no audio signal voltage is carried by the controlled circuit.

Oscillator Doubler

THE "OD-10" crystal unit is intended to be used with other foundation units such as the "BD-40" and "PA-300". Combined, these three units constitute a 300-watt all-band transmitter of modern design. The "OD-10" can be used as a beginner's transmitter with outputs as high as 25 watts on two bands with a single crystal. The entire unit is self-supporting and fastens directly to a panel with four mounting screws. Hammarlund Mfg. Co., 424 W. 33rd St., New York.

Inter-Communication and Paging System

NEW REMLER Co., Ltd., San Francisco, Cal., 24-station apparatus permits two way conversation between master and any individual station or any group of outlying stations. It also permits paging of up to 24 stations simultaneously.

Phonograph, radio and microphone inputs are provided, making the system particularly desirable for schools and other institutional installations.

Noise-suppressing Antenna System

A NOISE-SUPPRESSING all-wave antenna system at a popular price is announced by Technical Appliance Corp., 17 East 16 St., New York City. This antenna system efficiently handles both standard broadcast and short-wave signals. It comprises one long aerial, transformer unit, twisted-pair downlead, set coupler, and necessary accessories. Everything comes assembled, wired and soldered, and can be strung up in an hour or less, without tools or special skill. Model 600 lists at $5.00.

Sound Film Recorder

A NEW PROFESSIONAL 16 mm sound film recorder is introduced by Electrical Research Products, Inc., and announced by Western Electric Co., 195 Broadway, New York City. It has two immediate applications: Direct recordings may be made independently, and by electrically interlocking the machine with a 35 mm recorder both sizes of negative may be made simultaneously. It can also be used to re-record from existing 35 mm.

Three Channel Electronic Mixer

QUITE DIFFERENT from the ordinary type of electronic mixer in which two or more plate circuits are connected over a common load resistor and coupled to an amplifier, a new Jefferson Electric Co., Bellwood, Ill., circuit overcomes the shunting effect on the load resistance of the tube actuated by the d-c plate resistance of the tubes not actuated. This shunting effect of the idle tubes decreases the load resistance network which performs in such manner as to keep the load resistance, acting on each individual tube, never lower than required for a minimum of distortion.

Individual volume controls are in the output circuits rather than in the grid circuits, where high resistance potentiometers would have to be used, not considering the fact that in changing sources the potentiometers would have to be changed to conform to their respective source impedances. The mixer is hum-free by thorough filtering of plate and "C" supplies.

Cupaloy Castings

ENLISTED AS an ally of the ignitron tube in making possible continuous welds for use in construction of high-vacuum thermionic tubes for radio sets is the new product to come out of the Westinghouse laboratory. By a process of juggling atoms, Cupaloy comes close to being pure copper with steel strength. For welding tips, it has shown a service life several times greater than pure copper and from 50 to 200% longer than that of other low resistance alloys.

Voltmeter

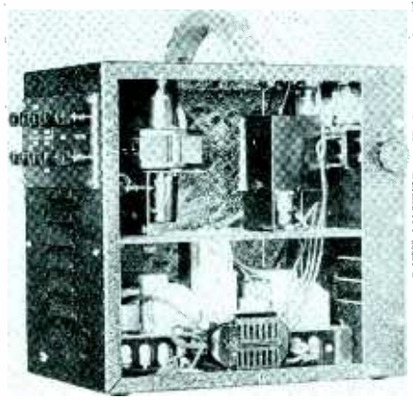
A NEW INSTRUMENT Model 4900-S measures d-c volts by means of a potentiometer. A built-in power supply, furnishes the balancing voltage. The instrument takes no current from the source being measured up to 250 volts d-c. Five ranges of resistance cover from .05 ohms to 10 megohms. Hickok Electrical Instrument Co., Cleveland, O.

An impressive assembly of servicing equipment has been called the Show Lab by Hickok. It is designed to be a useful set of tools as well as to aid the dealer and serviceman to merchandise the service they are to offer.

Electrostatic Voltmeter

FOR MEASUREMENTS of a-c or d-c voltage on grounded systems. Available from General Electric Co., the instrument is available in ratings of 3, 5, 10, 15 and 20 kv and is designed for fast response and ability to hold its calibration.

G.E. also announces temperature-compensated instruments for reducing temperature errors over a wide range of condition. Ratings are 150 and 150/300 volts.



Another new G.E. product is a portable photoelectric contact-making galvanometer for factory or laboratory, for permanent or temporary installations, for use with bridges or other apparatus requiring an external galvanometer. One application is in the field of temperature measurement and control. Sensitivity of 2.2 microvolts per division is obtainable.

Field Intensity Meter

PORTABLE, LIGHT, fully self-contained and ruggedly constructed is this new product of Federal Telegraph Co., Newark, N. J. Single control tuning and a minimum of controls simplify operation. A single switch changes the built-in coils at will. No plug-in coils nor thermocouples are used.

Plate Transformer

A NEW PLATE transformer was announced by Jefferson Electric Co., designed for operation from either 115 volt 60 cycle primary, or from 6 volt d-c for operation in conjunction with a vibrator unit. This transformer, No. 465-301, delivers 300 volts d-c at 100 ma from either 115 volt 60 cycle or 6 volt d-c primary supply. The 6 volt primary is tapped to supply heater voltage for a rectifier unit when the 110 volt primary is used. This transformer is assembled in sturdy black enameled housings of upright type with secondary leads out of bottom.

Pickup

AN INDUCTOR type of unit with 1½ ounce needle pressure and wide in frequency response is available from Bruno Laboratories, New York. In this unit the needle is the armature and it may be changed easily. The output is high, equalling that of a modern microphone. To avoid resonance and to silence the pickup, the inertia of the arm has been increased by making it out of non-resonant alloy. It is acoustically compensated by electrical rather than mechanical means. This new Bruno unit is known as the Symphonic.

Speed Nuts

THE SPEED NUT System of Tinnerman Stove & Range Co., Fulton Road, Cleveland, O., is an aid in assembly problems because of its spring tension fastening. It eliminates conventional nuts and lock washers, affords a firmer and better fastening means, and reduces assembly time and costs. 250 specific shapes and sizes are available for specific applications. Bulletins are available.

Electrolytic Capacitors

DESIGNED for motor-starting and other a-c applications, the Cornell-Dubilier, South Plainfield, N. J., Type ETN dry electrolytic capacitors are hermetically sealed in small aluminum cans and are externally insulated with an impregnated fibre sleeve or container. Low power-factor and freedom from internal corrosion are their important qualities.

These capacitors have been designed for operation involving a maximum of 20 starts per hour, each start of 3 seconds duration. They are especially suited for use with fractional horsepower motors.

Pilot Light Assembly

A 1 IN. PILOT light assembly is being manufactured by Dial Light Co. of Amer., 136 Liberty St., New York. This Model 100 uses Mazda S6 lamp removable from front of assembly. It can be furnished with smooth or faceted jewels and comes in 5 colors. Catalog is available.

pH Meter

A NEW LINE of instruments for automatic pH recording and control with the glass electrode is announced by Coleman Electric Co., 310 Madison St., Maywood, Ill. A hermetically sealed amplifier is an integral part of the device. It will measure pH to approximately 0.02.

Lifter

A PRACTICAL and durable device to prevent accident to fingers or hands of operators. May be used to lift feed and position metal blanks in stamping machines and die press operations. Industrial Products Co., 756 W. Somerset St., Philadephia.

Microphone

A "ROUND-THE-NECK" microphone for those who must move around and cannot be bothered with holding a microphone in a proper position. This is a crystal microphone and the output is considerably greater than that obtainable from a lapel mike or a hand mike. Sundt Engineering Co., 4238 Lincoln Ave., Chicago.

U. S. PATENTS

Electron Tube Applications

Engine indicator. An indicator for observing pressure variations by means of a cathode ray oscillograph. No. 2,113,376. Nathan Janco, Houston, Tex. See also No. 2,085,203 on a means for examining a series of cycles of events wherein pressure varies in repetitious manner. C. H. Schlesman, Socony Vacuum Oil Co.; No. 2,067,256, W. P. Brush, San Francisco, on an ignition testing system comprising electron tubes; and No. 2,117,141 on a vehicle electric power supply system using rectifiers. Carl Breer and G. C. Goode, Chrysler Corp.

Measuring equipment. Several patents to the Bailey Meter Co. on methods of measuring rate of flow, etc. No. 2,080,789, No. 2,109,222, and No. 2,112,682 to John D. Ryder; and No. 2,112,683 to R. E. Woolley.

Flaw detector. Patents on detecting flaws in metallic bodies. No. 2,109,455 to W. C. Barnes and H. W. Keevil, Highland Park, Ill., and No. 2,113,783 and 2,113,785 to the Sperry Products, Inc.

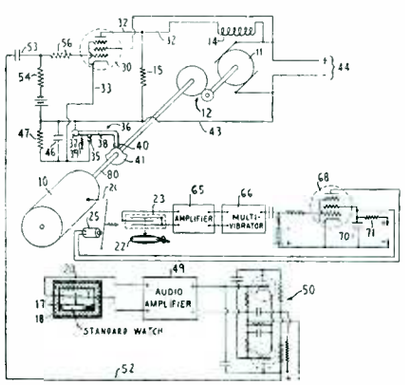
Ion concentration. Method for continuous measurement of hydrogen ion concentration of solutions. E. D. Doyle and G. A. Perley, Leeds & Northrup Co. No. 2,108,294. See also No. 2,058,761 to A. O. Beckman and H. E. Fracker, National Technical Laboratories, Pasadena, on an apparatus for testing acidity.

Welding equipment. Patents relating to the control of welding voltages or time. No. 2,045,801 and No. 2,045,803 to Walther Richter, A. O. Smith Corp.; No. 2,071,773 to Watson Sidney, RCA; and No. 2,085,696 to D. V. Edwards, Montclair, N. J.; also No. 2,054,343 to David Sciaky, Paris, France, and No. 2,111,014, E. H. Vedder, Westinghouse.

Transient measurement. The method for the determination of electrical properties of matter for geophysical prospecting. No. 2,113,749. L. Statham, Standard Oil Development Co.

Light meter. A device for indicating the intensity of ultraviolet rays comprising a piece of fluorescent glass transparent to visible and long ultraviolet radiations and opaque to radiations below 3200 Angstrom units, light sensitive surfaces, etc. L. F. Bird, the Hanovaia Chemical & Mfg. Co. No. 2,114,163.

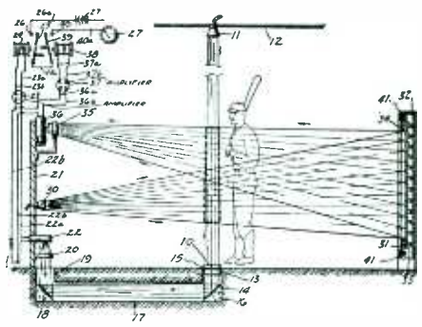
Watch testing. Method of recording the rate of a watch by picking up the sound of watch ticks, amplifying them, comparing them on a chronograph with the ticks from a standard watch. R. H.



Caldwell and V. T. Braman, the Bulova Watch Co. No. 2,113,825.

Measuring equipment. Two patents to the Leeds & Northrup Co., Philadelphia. No. 2,113,164 and No. 2,113,436.

Strike indicator. A photoelectric method of determining in a baseball

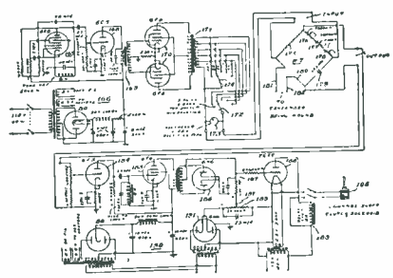


game whether a pitched ball is a strike or not. John Oram, Dallas, Tex. No. 2,113,899.

Prospecting. Method of determining the character of subterranean formation adjacent to a bore hole. R. W. Lohman, the Elliott Core Drilling Co. No. 2,114,056.

Impedance measurement. Method of testing phase differences due to the impedance property in human individuals. Samuel Bagno, New York, N. Y. No. 2,111,135.

Control system. System for continuously measuring the capacity of a con-



denser during its winding operation. R. W. Knight, RCA. No. 2,111,786.

Printing. Apparatus for making halftone printing plates or engravings, comprising means to scan a picture, translating the picture shadings into electrical pulsations, an oscillator having a resonant circuit actuated by electrical pulsations to produce a varying frequency, amplifying the variation in frequency, and applying it to an engraving machine. A. Brimberg, Brooklyn, N. Y. No. 2,112,010.

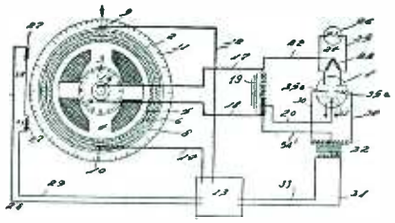
Aircraft indicator. A cathode ray type of pitch and bank indicator. S. H. Anderson, Fort Monmouth, N. J. No. 2,114,283.

Frequency meter. An electron tube device. F. V. Hunt, General Radio Co. No. 2,119,389.

Potential measurement. Determining the value of potentials by automatic opposition by energizing by illumination a phototube to produce a voltage and current without auxiliary electromotive force, connecting the unknown potential in opposition to the photo-

tube and actuating by the current resulting from this connection an electromagnetically movable coil. Peter Wulff, Munich. No. 2,119,374.

Unbalance determination. Method of determining the unbalance of a rotatable body consisting in generating two a-c voltages of the same frequency, one voltage being derived from the unbalanced forces in the body, impressing this voltage on the grid of a tube



and impressing the second voltage on the plate and a smaller amount of the second voltage on a grid but with 180 deg. phase difference. The d-c current in the plate circuit is measured. This is a function of the first a-c voltage and its phase relation to the second a-c voltage to determine the angle and amount of unbalance in the rotatable body. Jens Sivertsen. Tinius Olsen Testing Machine Co. No. 2,118,770.

British Patents

Flaw detector. Liquid in a container is inspected for the detection of solid matter, etc., in the liquid by passing light through the liquid to a phototube, and so arranging the amplifying circuit that impulses are produced by abrupt change in the phototube current due to the presenence of solid particles in the liquid. G. P. Stout. No. 469,949.

Reflectance measurement. Apparatus for comparing the color of light diffusely reflected from surfaces, comprising means for directing light or different colors normally on to the surface of a sample, phototube to be affected substantially only by light reflected diffusely from the surface, and a measuring device operatively associated with the phototube. General Electric Co. No. 469,999; also No. 470,454.

Photometer. In a photometer the phototube is smaller than the scale plate over which the pointer of the measuring instrument moves, and is disposed within the area of the plate. Weston. No. 470,134.

Counting system. Pulse counting, frequency dividing, or measuring apparatus comprising a condenser which on the operation of a switching device is

FIG. 3.

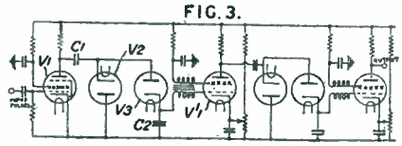

FIG. 1.

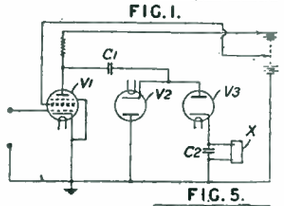

FIG. 5.

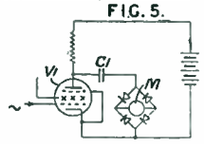


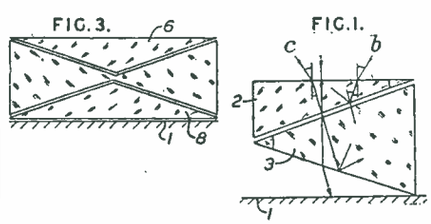
charged through one unidirectional conducting device and discharged through a similar one. E. L. C. White. No. 471,731.

Pyrometer. In the measurement of high temperatures, the difference between the energy radiated by a highly heated body on two different wavelengths is utilized as a measure of the temperature. Also, a system for automatic temperature control. British Thomson-Houston Co. No. 472,146. See also No. 472,147 on a photoelectric photometer, Truecolour Film, Ltd.

Fuse control. A projectile is provided with a source of light adapted to throw out a beam of light on a target. For example, an aircraft and a light-sensitive cell adapted to receive the light reflected by the target and to cause thereby the ignition of a primer to explode the projectile. L. M. Ericsson. No. 472,322.

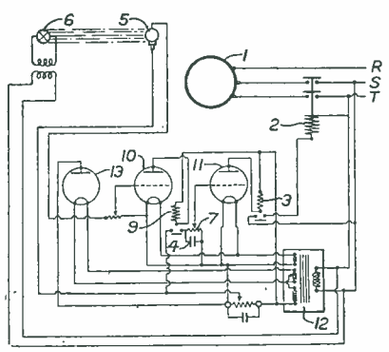
Direction finding. Two patents to F. Johnske. No. 472,419 and 472,420, on direction-finding systems.

Exposure meter. For limiting the light falling on the cell of a photoelectric exposure meter to rays having an angle of incidence not exceeding a predetermined limit, at least two transparent bodies having a definite refractive index are arranged in the light path, and are separated by a medium of lower refractive index. No. 472,448. Zeiss Ikon.



Engraving. A method of producing plates of the kind in which the printing surfaces are reticulated; the design to be copied is arranged upon a surface which is explored by one or more phototubes, the currents so generated being applied to one or more electromagnetically operated gravers caused to explore a second surface, moved at a speed bearing a suitable relationship to the speed of the first surface, and to remove appropriate parts of a protective coating upon a printing plate arranged upon the second surface. F. Alice. No. 470,435.

Escalator control. Automatic control of moving stairways by photoelectric means. No. 472,963.



Metal-working apparatus. In a heat-treating process and apparatus for cutting, welding, or surface treating metals a portion of the work is heated to the required temperature and the work and source of heat moved relatively to present successive portions for heating, the movement being controlled by radiation from the heated surface by electronic means. Linde Air Products Co. No. 470,546.

Conveyor system. A switching device for guiding a carrier in a pneumatic conveyor system is operated by changes in plate current of a grid-controlled tube, the grid biassing potential of which is controlled by the moving carrier. Lamson Pneumatic Tube Co., Ltd. No. 470,560.

Sorting system. Method for examining and sorting documents, such as ballot papers or competition coupons, according to the arrangement of symbols such as numerals or letters in selected positions in columns on the document or a page or sheet thereof. Each sheet is examined by comparing it with a standard sheet, on which the markings have been made in predetermined arrangement, and the comparison is effected by simultaneously scanning the sheet under examination and the standard sheet. L. J. Blumenthal. No. 470,638.

Infra-red ray detectors. A pair of thermo-electric current generators of minute mass, onto one of which rays from a distant radiator are focused by means of a parabolic mirror while the other is completely shielded from such rays. R. Wood, L. Mosley, and H. Dunkley. No. 470,846.

Exposure meter. A polarizing filter of the kind which may be angularly adjusted to remove disturbing reflections from the field of view is mounted in or in front of the view opening of a photoelectric exposure meter. Zeiss Ikon. No. 471,016.

Ignition system. A tripping voltage applied to the grid of a tube causes the discharge of a condenser through the primary of a transformer, the condenser being arranged across a supply of unidirectional current, and the secondary winding connected to a distributor feeding the engine spark plugs. For applying the tripping voltage, an engine-driven perforated disc may control a photoelectric tube in circuit with the grid of the tube. British Thomson-Houston Co. No. 472,688.

Copying. In a system for producing monochromatic pictures corresponding to the colors of a polychromatic picture, color separated pictures or corresponding negatives are scanned by photoelectric means. No. 472,870. B. Bubnoff.

Vehicle control. Infra-red rays transmitted by a vehicle control signal at a crossroad. No. 473,044.

NEW BOOKS

Radio-Frequency Electrical Measurements

By HUGH A. BROWN. *Second edition. McGraw-Hill Book Co., New York. Price, $4.00. 384 pages.*

AS A GUIDE for radio engineering laboratory instruction, Prof. Brown's book is intended to be useful to the practicing engineer, the student of communications, and the radio amateur. Individual chapters deal with measurements of circuit constants; measurement of frequency; antenna measurements; electro-magnetic-wave measurements; measurement of electron tube coefficients and amplifier performance; electromotive force, current, and power; measurement of wave form; and modulation, receiver, and piezo-electric crystal measurements. There are frequent references to the technical literature, and the material chosen for treatment is well selected.

The manner in which the subject matter is treated is, however, another story. Prof. Brown never regains the clear, lucid style of the first eight pages, and frequently leaves the reader with the impression that, for a second edition, the volume is pretty heavy with technical ambiguities and loose statements. A first class job of technical editing would have improved the second edition considerably.—B.D.

Motion Picture Sound Engineering

Research Council of the Academy of Motion Picture Arts and Sciences. *D. Van Nostrand Co., New York,* 1938. (550 *pages,* 380 *illus. Price* $6.00).

A SERIES of lectures given to classes enrolled in sound engineering courses offered by the Research Council of the Academy of Motion Picture Arts and Sciences has provided the basic material from which the chapters of this book were prepared. The first of two parts into which the book is divided deals with equipment and the applications of electrical and acoustic principles to motion picture engineering. In the second part, the foundation is laid for an understanding of the physical principles applied. Thirty-nine chapters deal with the wide range of subjects likely to confront the technician engaged in motion picture recording, processing, or projection. Five chapters deal specifically with electron tubes and their circuits, and many more are of direct interest to the communication engineer.

Some question might be raised as to the meaning of gamma of a light valve, printing machine, or photoelectric cell, used without explanation in the section on film processing, especially since the term, as used, is not commonly employed in photographic or electrical work. Equations for decibels are converted from a power basis to one of current and voltage without stating the requirements of constancy of terminating impedances; indiscriminate use is made of s_m and G_m for transconductance, and the statement on page 347 that "the mutual conductance value is about the same for all tubes of the same size, so that tubes of high μ also have high plate impedance" might well be questioned. Such ambiguities and inconsistencies as have come to the reviewer's attention are not regarded as being serious for the purpose for which the book is intended, and are exceedingly difficult to avoid where manuscripts are prepared by several authors. Indeed, with many persons co-operating in the preparation of this book, it is no minor accomplishment to get all the manuscripts to the printer!

Material is taken, when necessary, from various acknowledged sources. Aside from the credit lines, no bibliographical references are given which might lead the reader to more detailed treatments of the various subjects.

No single book could possibly treat exhaustively those branches of physics and engineering with which sound motion picture technicians may be expected to be familiar. But "Motion Picture Sound Engineering" does a remarkably good job of treating (in less than 600 pages) the essentials of sound recording and reproducing, film processing, transmission circuits, electron tubes and their circuits, and the fundamentals of electric circuit theory. To the technician it should quickly become an important reference work on sound motion picture.—B. D.

Photoelectric Cell Applications

By R. C. WALKER and T. M. C. LANCE. *Third edition. Pitman Publishing Co., New York. 1938. Price $6.00. 336 pages. 200 illustrations.*

THE TITLE GIVES a good description of the contents of the book although such devices as iconoscopes and electron multipliers which are rather advanced elaborations of the photoelectric cell are also treated. The first chapter discusses the characteristics of alkali metal phototubes, and this is followed by a chapter on the fundamentals of applying photoelectric devices. The remaining chap-

ters are devoted to applying photoelectric units to counting, timing, and mechanical handling of goods; alarms, indicators, and safety devices; advertising; sound reproduction; telephotography; television; scientific instruments; and miscellaneous applications.

The text is descriptive in character, and only a few equations of the simplest algebraic variety are used. No attempt is made to treat the more involved aspects of the photoelectric effect or to go into circuit analysis. For those who desire this type of information, the authors have provided a bibliography at the end of each chapter. But for those who desire an introduction to the use and application of photoelectric devices, this volume should fill a persistent demand. The text does very well in fulfilling the authors' intention of "simplicity of treatment, with the hope that our descriptions may prove helpful to the practical man and suggest to him means of attacking some of his problems with a new weapon".—B.D.

Introduction to Radio Engineering

(Einführung in die Funktechnik. Verstärkung, Enfang, Sendung)

BY FRIEDRICH BENZ. *Julius Springer, Vienna. 1937. 411 pages, 443 figures. Price 15 R.M., Bound 16.80 R.M.*

THIS BOOK covers a very wide range of well-chosen material of fundamental importance in radio engineering. The material is modern and is concisely treated without undue elaboration of any particular subject. Enough mathematics, including some use of differential equations and series expansions, is used to cover the theoretical developments satisfactorily. Complex numbers are explained and used in the calculation of a-c problems. Numerical problems and their solutions are given at numerous places in the text. It is not possible to give in any detail the subject matter which is covered other than to state broadly that the book gives the fundamentals of almost all subjects of interest to the radio engineer. The references are almost entirely to German articles; likewise, the specific descriptions of apparatus such as receivers are of German devices.

The book suffers by reason of the inclusion of a number of fairly serious errors, some accidental and some of fact. In the explanation of the internal plate resistance of a vacuum tube (page 108), reference is made to a figure (Fig. 107) in which the abscissas are grid voltage where they should be plate voltage. In another place (bottom page 112), the statement is made that the alternating voltage on the plate of a triode is in phase opposition to the grid voltage regardless of the character of the plate load impedance which would only be true in case the internal plate resistance of the tube is negligible. In Fig. 12, page 113, in the expression for the voltage between the grid and plate, the component U_{gw} should have a minus sign and also in Fig. 113, page 115, the various voltages given for U_g should be minus. On page 124 the misleading statement is made with respect to shot-effect that "The frequencies of these alternating currents lie in the audible region." On page 237 with respect to screen-grid tubes "with careful shielding", the effective grid-anode capacity is given as a few tenths of a centimeter whereas it should read hundredths or thousandths. On page 237, the nomenclature with respect to plate and grid neutralization is reversed, at least from American practice. On page 323, just above equation (8), the equation $R_w = 2\,R_a$ should read $R_w = 4\,R_a$. By reason of this error, equation (8) should have the numerator "4" instead of "2", and also equation (10), page 327, should have "2" for a numerator. This error occurs also in the text at the bottom of page 326. In Fig. 363, page 329, representing the circuit diagram of the grid-dynatron, the grid and plate voltages should be interchanged.

The average radio engineer, however, will find much of value both for reading and reference. This book should be valuable to one desiring to combine improvement of his technical German vocabulary with worthwhile reading.—J.M.M.

PUBLIC LOUDSPEAKERS

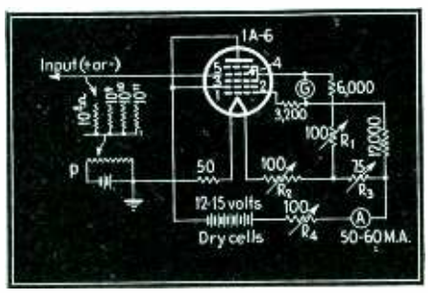
In Germany, thousands of loudspeakers are being installed permanently in the public square of every town and large village, so the populace can hear political speeches and news of world events from headquarters at Berlin and Munich. Above is a loudspeaker installation "camouflaged" as a clock tower

Electron Art

(*Continued from page 59*)

A Simple D-C Amplifier

FOR MANY YEARS the problem of stable amplification at zero frequency and preferably with readily available equipment has engaged the attention of electronic technicians. The d-c amplifier using a standard tube is described by



Tatel, Moncton and Luhr, in the July issue of the *Review of Scientific Instruments*.

The authors point out that most standard radio tubes are not suitable for measurements of very low currents because the cathode is oxide coated and therefore the emission is unstable, or because the grids are improperly arranged. For good insulation, the lead from the control grid should emerge separately from the top of the glass tube and this requirement automatically restricts the choice to such tubes as the 1A6, or the 1C6. The 1A6 tube was chosen because it operates with a filament current of only 50 to 60 milliamperes.

Fig. 1 shows the diagram of the complete single tube amplifier. With the exception of the high resistance grid leaks and the galvanometer, all of the parts may be purchased at any radio supply house for a modest sum. The diagram is essentially that described by DuBridge and Brown in the *Review of Scientific Instruments* for April 1933. The variable resistors, R_1, R_2, R_3 and R_4 are for the purpose of balancing and adjusting the filament current, whereas the circuit itself is balanced by changing R_2 and R_3 until a condition is found for which a small change of R_4 causes the galvanometer to reverse its deflection. The resistor R_1 is used as a fine adjustment of this balance.

With a Leeds & Northrup galvanometer having a sensitivity of 2.2×10^7 mm per volt, and an internal resistance of 470 ohms, a scale deflection of 10,000 mm per volt applied to the input grid has been obtained. With a grid leak of 10^{11} ohms, this represents a current sensitivity of 10^{-15} ampere per mm of deflection of the galvanometer. The authors do not mention that they found it necessary to treat the tube or the high resistances in any other than the usual procedure.

Influence of Magnetic Field on Plate Resistance

ONE OF THE research items in the August issue of the *Electro-Technical Journal*, monthly publication of the Institute of Electrical Engineers of Japan, deals with the effect of magnetic field on the i. r. of a thermionic tube.

By measuring the static plate characteristics of the tube with and without a magnetic field applied, it is shown, as might be expected, that the magnetic field produces considerable effect on the internal resistance. The measured characteristics are shown in Fig. 1. Curve A shows the characteristics when the magnetic field is not applied. B shows the application of the magnetic field perpendicular to the surface of the plate of the vacuum tube, and C shows the condition in which the magnetic field is applied parallel to the plane of the

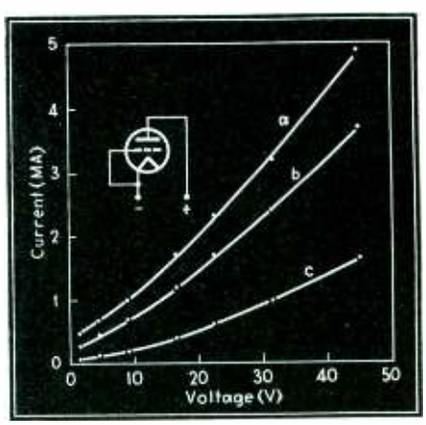


plate as shown in Fig. 2. It is found that the internal resistance varies from 10,000 to 25,000 ohms due entirely to the influence of this magnetic field.

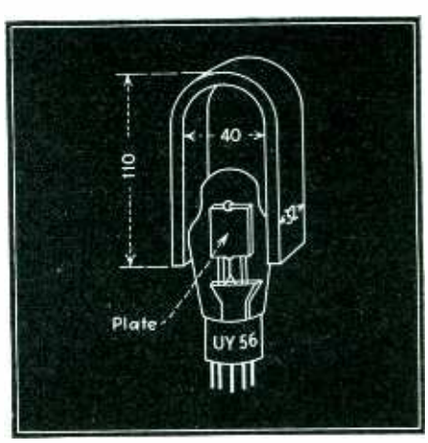

Presumably the magnitude of the effect will depend upon the structure of the electrodes. Qualitatively, however, the effect has been observed in two different types of tubes, and there is no reason to suppose that other types would not also show the same effect.

POSITIONS WANTED

CATHODE RAY TUBE ENGINEER: Three years design, development and production cathode ray and associated tubes. Background, ten years radio tube, photocell and rectifier production and development. Associate IRE, 35, married. Past patent disclosures, important patent application pending. Competent take charge television tube program for some concern entering this field. PW-157, Electronics, 330 West 42nd St., New York City.

YOUNG MAN, now employed, desires permanent connection anywhere. Best of references. Experience, four years broadcast engineer and three years development and manufacture inter-communication equipment. PW-158, Electronics, 520 North Michigan Ave., Chicago, Illinois.

POSITIONS WANTED

RADIO ENGINEER 35, 13 years experience, superhetrodyne development, research, marine receiver, and test equipment radiotelegraphers license. PW-160, Electronics, 330 West 42nd Street, New York City.

BROADCAST ENGINEER, first class radiotelephone license, familiar with broadcast procedure and equipment. Ambitious: desirous of furthering experience. Age 20, single, available immediately any location. PW-161, Electronics, 330 West 42nd Street, New York City.

REPRESENTATIVE WANTED

WANTED district Representative by old, established manufacturer of electronic equipment selling direct to industrial accounts. RW-159, Electronics, 330 West 42nd Street, New York City.

NEW Handbook and Catalogue for Designers

CONTAINING REVISED NEMA STANDARDS

Many improvements have been made in the last year in laminated phenolic plastic products in which field DILECTO is a leader. Special grades have been perfected which offer much higher electrical and mechanical properties than were thought possible a few years ago. This new DILECTO catalog gives specific technical data on these new grades. It also gives the new NEMA standards on laminated plastics. You can bring all your data up to date by getting a copy of this new DILECTO catalog.

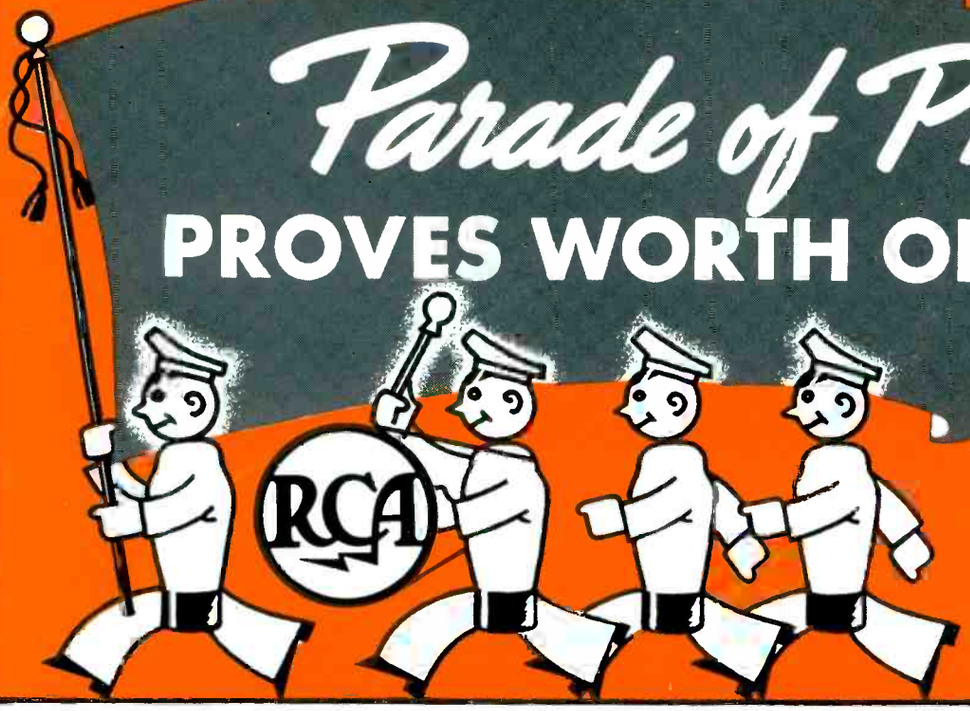
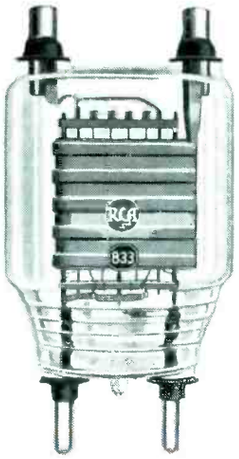
Parade of Progress

PROVES WORTH OF RCA POLICY!



"To provide you with the finest in transmitting tubes, at the lowest possible cost," is a creed with RCA. And these recent RCA accomplishments are the result!

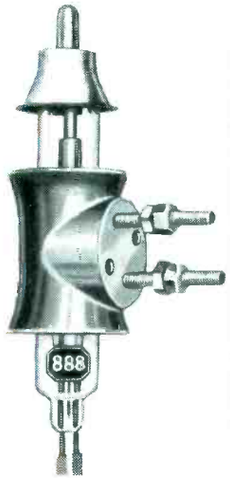
BROADCAST ECONOMY



The RCA 833 combines high efficiency with economy. Two of these tubes, each rated at 500 watts by F. C. C. may be used as final r-f stage in 1 kw. transmitters.

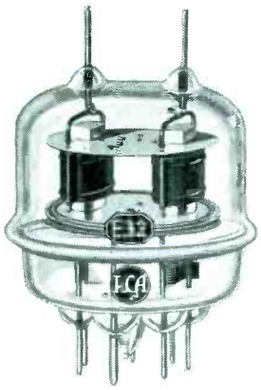
Another RCA achievement in money-saving design is the air-cooled power tube available in two types —891-R and 892-R. These tubes provide the design advantages of water-cooled tube construction, eliminate the expense water cooling incurs.

HIGH POWER U.H.F. TRANSMISSION



In the field of water-cooled tubes RCA offers the 887 and 888 which make possible the opening with adequate power of the enormous territory between 3 and 1¼ meters. These tubes are rated at 1200 watts max. input for wave lengths down to 1¼ meters. Power input and output capability for 1¼ meters is many times that of any other tube available.

LINE OF SIGHT TRANSMISSION

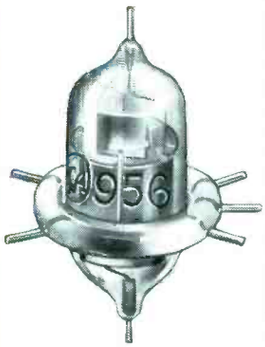


The RCA 832 gives exceptional performance at frequencies from 100 to 300 MC. Is designed primarily for use as a push-pull U.H.F. power amplifier with maximum ratings at wave lengths as short as two meters. With reduced ratings it may be operated at wave lengths down to one meter. Excellent for use in transmitters intended for line of sight communication.

TELEVISION AMPLIFIERS

With interest in television mounting steadily, RCA engineers designed the 1852 and 1853 primarily for use in the picture channel amplifier circuit of television receivers. While these are not transmitting tubes they are an important RCA contribution to the industry and as such, belong in this parade of progress.

ULTRA-HIGH FREQUENCY APPLICATION



RCA's sensational acorn family, used chiefly by amateurs, is an outstanding advance in ultra-high frequency communication. Illustrated here is the RCA 956, a super-control r-f pentode which controls gain in r-f and permits a reduction in cross modulation. Other members of the acorn family are the RCA 954 and 955.

RCA presents the Magic Key, Sundays, 2 to 3 P. M., E. D. S. T., on the NBC Blue Network.
