(*p*-Methoxyphenyl)bis(*o*-pyridyl)phosphane (5): A solution of *n*BuLi (10 mL, 2.5 M in hexane, 25 mmol) in sodium-dried diethyl ether (40 mL) was cooled to −100°C by means of an ethanol/liquid nitrogen bath. A solution of *o*-bromopyridine (2.5 mL, 25 mmol) in diethyl ether (30 mL) was then rapidly added and the mixture was stirred for 1.5 h at −100°C. A solution of *p*-anisyldichlorophosphane (2.61 g, 12.5 mmol) in diethyl ether (30 mL) was then added dropwise and stirring was continued at −100°C for 1 h. After slowly warming to room temperature, the light-brown mixture was extracted with H_2SO_4 (2 N, 30 mL) and the aqueous layer was separated and made alkaline with NaOH. The crude product was extracted from the aqueous phase with diethyl ether. The solvent was evaporated from the combined extracts and the oily crude product was washed with methanol. The product (3.06 g, 10.4 mmol, 83.2%) was dried in vacuo. Single crystals were grown by vapor diffusion of hexane into a methanol/dichloromethane solution of the pyridylphosphane. M.p. 100−101°C. − ^{1}H NMR (200 MHz, $CDCl_3$): δ = 3.8 (s, 3 H, H^{12}), 7.0 (d, $^3J_{H-H}$ = 8.5 Hz, 2 H, H^9), 7.3 (m, 4 H, H^6 and H^8), 7.5 (t, $^3J_{H-H}$ = 7.3 Hz, 2 H, H^4), 7.7 (t, $^3J_{H-H}$ = 7.7 Hz, $^4J_{H-P}$ = 1.7 Hz, 2 H, H^5), 8.6 (m, 2 H, H^3). − $^{13}C\{^1H\}$ NMR (50 MHz, $CDCl_3$): δ = 55.5 (s, 1 C, C^{12}), 115.2 (d, $^2J_{C-P}$ = 8.7 Hz, 2 C, C^8), 123.1 (s, 2 C, C^4), 127.0 (d, $^1J_{C-P}$ = 7.3 Hz, 1 C, C^7), 128.7 (d, $^2J_{C-P}$ = 18.9 Hz, 2 C, C^6), 136.4 (d, $^3J_{C-P}$ = 2.9 Hz, 2 C, C^5), 137.7 (d, $^3J_{C-P}$ = 23.2 Hz, 2 C, C^9), 150.8 (d, $^3J_{C-P}$ = 11.6 Hz, 2 C, C^3), 162.0 (s, 1 C, C^{10}), 164.8 (d, $^1J_{C-P}$ = 4.4 Hz, 2 C, C^1). − $^{31}P\{^1H\}$ NMR (162 MHz, $CDCl_3$): δ = −2.3 (s). − MS: Exact mass: 294.0886.

(*p*-Thiomethoxyphenyl)bis(*o*-pyridyl)phosphane (6): A solution of *n*BuLi (4 mL, 2.5 M in hexane, 10 mmol) in sodium-dried diethyl ether (20 mL) was cooled to −100°C by means of an ethanol/liquid nitrogen bath. A solution of *o*-bromopyridine (1.0 mL, 10 mmol) in diethyl ether (20 mL) was then rapidly added and the mixture was stirred for 75 min at −100°C. A solution of *p*-thioanisyldichlorophosphane (1.13 g, 5 mmol) in diethyl ether (20 mL) was then added dropwise and stirring was continued at −100°C for 1 h. After slowly warming to room temperature, the light-yellow mixture was extracted with H_2SO_4 (2 N, 30 mL) and the aqueous layer was separated and made alkaline with NaOH. The white solid

product was obtained by extraction of the aqueous phase with diethyl ether. The product (0.60 g, 1.93 mmol, 38.7%) was dried in vacuo. Single crystals were grown by vapor diffusion of hexane into a methanol/dichloromethane solution of the pyridylphosphane. M.p. 122−123°C. − ^{1}H NMR (200 MHz, $CDCl_3$): δ = 2.5 (s, 3 H, H^{12}), 7.2 (m, 6 H, H^6, H^8, and H^9), 7.4 (t, $^3J_{H-H}$ = 7.7 Hz, 2 H, H^4), 7.6 (t, $^3J_{H-H}$ = 7.7 Hz, $^4J_{H-P}$ = 1.9 Hz, 2 H, H^5), 8.7 (d, $^3J_{H-H}$ = 4.7 Hz, 2 H, H^3). − $^{13}C\{^1H\}$ NMR (50 MHz, $CDCl_3$): δ = 14.8 (s, 1 C, C^{12}), 123.3 (s, 2 C, C^4), 126.5 (d, $^2J_{C-P}$ = 8.7 Hz, 2 C, C^8), 128.9 (d, $^2J_{C-P}$ = 20.3 Hz, 2 C, C^6), 132.3 (d, $^1J_{C-P}$ = 10.2 Hz, 1 C, C^7), 136.2 (s, 2 C, C^5), 136.6 (d, $^3J_{C-P}$ = 2.9 Hz, 2 C, C^9), 142.0 (s, 1 C, C^{10}), 150.9 (d, $^3J_{C-P}$ = 11.6 Hz, 2 C, C^3), 164.1 (d, $^1J_{C-P}$ = 4.4 Hz, 2 C, C^1). − $^{31}P\{^1H\}$ NMR (162 MHz, $CDCl_3$): δ = −1.6 (s). − MS: Exact mass: 310.0727.

X-ray Crystallography: X-ray diffraction data were collected with an Enraf−Nonius Kappa-CCD (compounds **1** and **3−6**) or a Nicolet R3m (compound **2**) diffractometer using Mo-K_α radiation (λ = 0.71073 Å). For **2**, cell parameters were obtained from 25 automatically centered reflections. Data collection (ω scan mode), data reduction, and cell refinement were carried out with the P3/P4 diffractometer program V4.27.[27] For the other compounds, the data were collected using ϕ or combined ϕ−ω scans with the Collect[28] data collection program. Denzo and Scalepack[29] programs were used for cell refinements and data reduction. All structures were solved by direct methods using either SHELXS-97[30] or SIR-97[31] programs with the WinGX[32] graphical user interface, or by using the SHELXTL v5.1[33] program package. Structure refinements were carried out with SHELXL-97.[34] All non-hydrogen atoms were refined anisotropically. For compounds **1−5**, the hydrogens were constrained to ride on their parent atom [U_{iso} = 1.2(C_{eq}) for aromatic hydrogens and U_{iso} = 1.5(C_{eq}) for methyl H atoms]. For compound **6**, all hydrogens were located from the difference Fourier map and refined isotropically with constant U_{iso} = 0.05 for aromatic hydrogens and U_{iso} = 0.08 for methyl hydrogens. Crystallographic data are summarized in Table 3 and selected bond lengths and angles are given in Tables 4 and 5.

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC-114003 to CCDC-114008. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, U.K. [Fax: (internat.) +44 (0)1223/ 336033; E-mail: deposit@ccdc.cam.ac.uk].

Charge-Transfer Complexes of Metal Dithiolenes XXVI[+] Azobipyridinium Dications and Radical Monocations as Acceptors

Carsten Handrosch,[a] Robert Dinnebier,[b] Gennadij Bondarenko,[c] Eberhard Bothe,[d] Frank Heinemann,[a] and Horst Kisch*[a]

Keywords: Metal dithiolenes / Charge-transfer complexes / Azo compounds / Electrical conductivity / High-resolution X-ray powder diffractometry

Combination of the planar redox-active ions $[ML_2]^{2-}$ (L = mnt^{2-} = maleonitrile-1,2- dithiolate; M = Ni (**1**), Pd (**2**), Pt (**3**); $dmit^{2-}$ = 2-thioxo-1,3-dithiol-4,5-dithiolate: M = Ni (**4**), Pd (**5**) and *trans*-4,4′-azobis(1-methyl-pyridinium), ($\mathbf{a}^{2+}$) affords 1:1 ion pairs exhibiting partial and complete electron transfer as evidenced by UV-Vis and EPR spectra. Replacement of planar $\mathbf{a}^{2+}$ by a non-planar dipyridinium ketone $\mathbf{b}^{2+}$ leads to the complexes **1b** and **4b**. **1a**, **2a**, and **3a** are predominantly composed of dications and dianions while **4a**, **5a**, and **4b** are rare examples of ion pairs consisting of two radical ions. Single crystal X-ray structural analyses was performed on **4a**, $\mathbf{a}(PF_6)_2$, and $\mathbf{a}(MeSO_4)_2$ while the structure of **1a** was resolved by powder X-ray diffractometry. The latter consists of mixed stacks of planar dianions and dications forming a slipped arrangement with the centers of the two ions displaced relative to each other by 250 pm. The short interplanar distances of 340 pm are in agreement with the presence of a weak charge-transfer interaction as indicated by the corresponding absorption band at about 1400 nm. A mean reorganization energy of 0.85 ±0.04 eV is calculated from the Hush equation for complexes **1a, 2a**, and **3a**. No ion pair charge-transfer band is observable for **4a**, **5a**, and **4b**. Surprisingly, in the solid state structure of **4a** the $[Ni(dmit)_2]^-$ monoanions do not form segregated columns as found in the many ion pairs with redox inert counterions, but prefer a mixed stack arrangement as observed also for **1a.** The specific electrical conductivity of pressed powder pellets of complexes exhibiting a charge-transfer band is in the range of 2×10^{-7} to 1×10^{-5} $\Omega^{-1}cm^{-1}$, increasing with increasing driving force of electron transfer in accordance with previous results. Different to that, the conductivity of the other complexes does not depend on driving force and is much higher (2×10^{-4} to 4×10^{-4} $\Omega^{-1}cm^{-1}$).

Introduction

The control of physical properties of a solid by variation of molecular parameters is a central topic in materials science.[2] In recent work we have found that ion-pair charge-transfer (IPCT) complexes consisting of redoxactive components provide ideal conditions to study the influence of weak supramolecular CT interactions on the electrical conductivity. It was found that for class I complexes of the type $\{A^{2+}[ML_2]^{2-}\}$ wherein the acceptor A^{2+} is a planar dicationic 4,4′- or 2,2′-bipyridinium derivative and the $[ML_2]^{2-}$ donor is a planar dithiolene metalate, L = 2-thioxo-1,3-dithiol-4,5-dithiolate ($dmit^{2-}$) and maleonitrile-1,2-dithiolate (mnt^{2-}), M = Ni, Pd, Pt, the electrical conductivity (σ) of pressed powder pellets increases linearly on a logarithmic scale from 10^{-11} to 10^{-3} $\Omega^{-1}cm^{-1}$ when the driving force of electron transfer from the donor to the acceptor (ΔG_{12}) is varied from 0.7 to −0.1 eV.[3][4] As ΔG_{12} is easily obtained from the solution redox potentials of the two components, the conductivity of the solid IPCT salts can be quantitatively predicted from these molecular parameters. Although the CT interaction is very weak as indicated by the small fraction of an electron transferred from the donor to the acceptor, which is 0.01 to 1%,[5] σ varies over eight orders of magnitude. No similar correlation existed when the d^8 central metal was replaced by a d^7 ion like Co(II).[6] In addition to this strong electronic influence on the electrical properties we have shown that steric alterations like *cis*-*trans* isomerization of the acceptor component may have also a significant effect. While in the case of $[Ni(mnt)_2]^{2-}$ the σ value does not change when the counterion *trans*-DPE-Me^{2+} (Figure 1) is replaced by the *cis*-isomer, it increases by one order of magnitude for the $[Ni(dmit)_2]^{2-}$ complex.[7] This finding suggested that a controlled change of conductivity through photoisomerization may become feasible. In order to investigate whether the observed effect is a unique property of DPE-Me^{2+} or of more general importance, in the present work the acceptor was modified by replacing the bridging ethene fragment by an azo group, well-known to undergo photoisomerization. In the following we report on the synthesis, solid state structure and electrical conductivity of ion pair complexes containing the *trans*-isomer of the new acceptor DPD-Me^{2+} (Figure 1).

Out of the four structures investigated by X-ray analysis three of them were resolved by the conventional single crystal method and one by the more unconventional powder diffractometry.

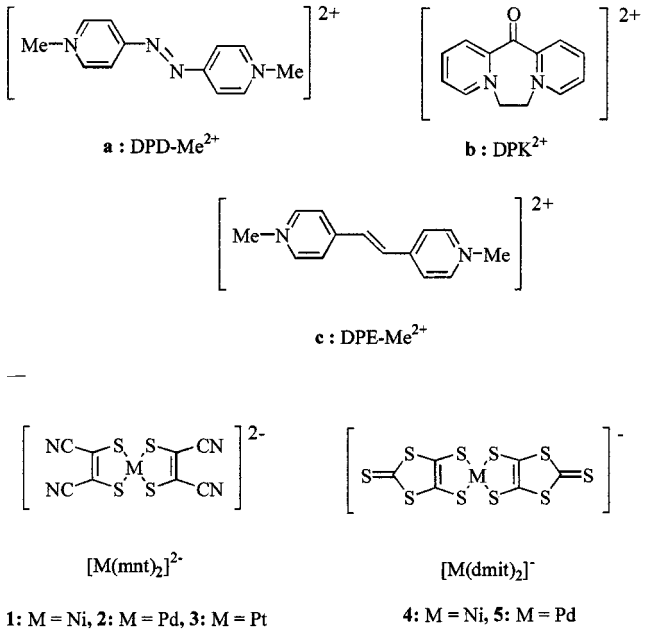

Figure 1. Isolated complexes

Results

DPD-Me(X)$_2$ [X = MeSO$_4$, PF$_6$]

The azoviologen salt **a**(MeSO$_4$)$_2$ was synthesized as described recently[8] and converted into **a**(PF$_6$)$_2$ by metathesis with NH_4PF_6. Single crystals of both salts were obtainable and their structures were solved by X-ray analysis. The observed bond lengths and angles for both compounds are equal within experimental error and therefore only the structure of **a**(PF$_6$)$_2$ × 2 (Me$_2$CO) is shortly discussed (Figure 2, Table 1) but the crystal data of **a**(MeSO$_4$)$_2$ are included in the Experimental Section. The N=N and C−N bond lengths of 123.6 and 143.5 pm agree well with the values of 123 and 141 pm reported for azobenzene[9] and with 127.3 and 143.3 pm calculated for a 4-[4-(dimethylamino)phenyl]azopyridinium salt.[10] Various attempts to isomerize $\mathbf{a}^{2+}$ failed. In all cases no change was observable in the UV-Vis spectrum upon irradiation at various wavelengths.

The cyclic voltammogram of **a**(PF$_6$)$_2$ in acetonitrile exhibits two reversible redox waves at −0.207 V and −0.536 V (vs. Ferrocene), which are assigned to the DPD-Me^{2+}/DPD-Me$^{\bullet+}$ and DPD-Me$^{\bullet+}$/DPD-Me^0 redox steps, respectively (Figure 3a). While the well-known radical cation of methylviologen [11a−d] is blue, DPD-Me$^{\bullet+}$ is deep red. It was generated in a spectroelectrochemical experiment by reduction of the dication at −0.3 V (vs. ref.). This electrolysis led to a constant absorbance at 452 nm ($\varepsilon_{452} = 4.4 \times 10^4$ M^{-1} cm^{-1}). In addition to this sharp band, a broad absorption developed in the range from 500 to 600 nm as depicted in Figure 3b.

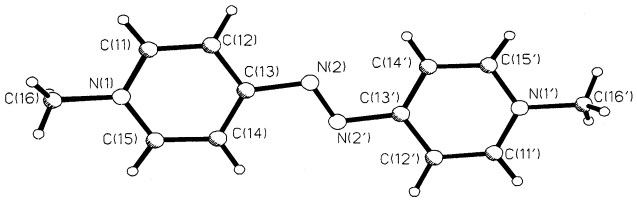

Figure 2. Molecular structure of **a**(PF$_6$)$_2$ × 2 (Me$_2$CO)

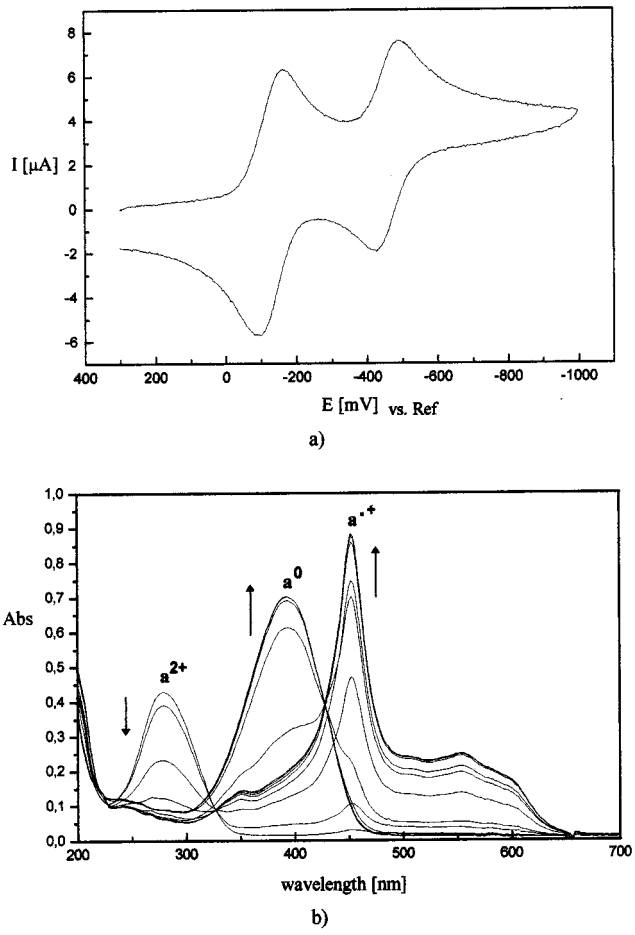

Figure 3. a) Cyclic voltammogram of **a**(PF$_6$)$_2$ in MeCN; v = 0.2 Vs^{-1}; MeCN; E vs. Ag/0.01 M $AgNO_3$; b) Spectroelectrochemistry of **a**(PF$_6$)2 in MeCN

These data agree very well with the one reported for the ethyl derivative DPD-Et$^{\bullet+}$ which was also generated electrochemically.[11c] But different to DPD-Me$^{\bullet+}$, no structural information is available for this ethyl or any other derivative. Further reduction at −0.7 V (vs. ref.) led to the yellow-colored neutral diimine with a single absorption band at 392 nm ($\varepsilon_{392} = 3.5 \times 10^4$ M^{-1} cm^{-1}). Isosbestic points are observed at 325 and 425 nm (Figure 3b).

Chemical reduction of DPD-Me^{2+} to the radical cation can be performed with $S_2O_3^{2-}$, NEt_3, Zn/HOAc, $[Zn(mnt)_2]^{2-}$, Na_2mnt or simply photochemically by dissolving **a**$(PF_6)_2$ in MeOH under diffuse daylight. The resulting red solutions were stable for several days when kept under dinitrogen at −25°C.

In agreement with the slightly twisted structure[12b] DPK^{2+} (Figure 1) is a slightly worse acceptor than DPD-Me^{2+} as indicated by the first reduction potential of −0.06 V (MeCN, vs. SCE)[3] (congruent with −0.45 V vs. ferrocene). Although the radical cation was generated electrochemically[12a] and characterized by resonance raman spectroscopy,[12b] no electronic absorption spectrum was reported. While DPK^{2+} starts absorbing only at about 400 nm, the deep red acetone solution of DPK$^{\bullet+}$, generated under dinitrogen through reduction with aqueous sodium thiosulfate, exhibits a broad maximum already at 507 nm ($\Delta\tilde{\nu}_{1/2} = 1435$ cm^{-1}).

Powder X-Ray Diffractometry of 1a

The complexes **1a** to **5a** were all precipitated by adding slowly a acetone solution of the dication to the dissolved dianion, as described recently.[3][6] All complexes gave satisfactory elemental analyses except **4a**, for which non-stoichiometric compositions of (DPD-Me)$_x$[Ni(dmit)$_2$], $x = 0.7$ to 0.9 were found (vide infra).

Since no single crystals of **1a** could be obtained, the structure was solved by powder X-ray structural analysis.[13] The resulting bond lengths suggest that the nickel component is present as dianion (Table 2). This is indicated by the observed mean Ni−S length of 219.1(4) pm, which is close to the Ni−S bond length of 217.4(2) pm in $\{MV^{2+}[Ni(mnt)_2]^{2-}\}$[14] and comparable $[Ni(mnt)_2]^{2-}$ complexes.[15] The corresponding value in $[Ni(mnt)_2]^-$ compounds is 214.3(2) pm.[16][17] Different to that, the observed N−N length of 131.2(2) pm strongly deviates both from the values of 123.6(5) and 135.5(8) pm observed for the dication (Table 1) and radical cation (Table 4), respectively, while the C−N bond length of 142.8(2) pm is not significantly different from 143.5(4) pm as found for the dication. On the other hand, the difference between the C−N and N=N length is 19.9 and 11.6 pm in DPD-Me^{2+} and **1a**, respectively, while it is negligible in DPD-Me$^{\bullet+}$. It is therefore proposed that the structure of **1a** consists of DPD-Me^{2+} and $[Ni(mnt)_2]^{2-}$ ions. These are arranged as mixed stacks (Figure 4), as also found in other class I IPCT complexes like $\{(MV)^{2+}[Ni(mnt)_2]^{2-}\}$,[14] $\{(DPE\text{-}R)^{2+}[Ni(mnt)_2]^{2-}\}$, [R = $(CH_2)_4CN$],[7] and $\{(MV)^{2+}[Pd(mnt)_2]^{2-}\}$.[18a] As observed in these structures, the two components of **1a** are slipped along the longest molecule axis by about 250 pm. Short interplanar distances are slightly below or above the corresponding sum of the van der Waals radii (Table 3).[18b,19] The average value of 340 pm is characteristic for dithiolene metalate IPCT complexes.[7][18][20]

Table 2. Selected bond lengths [pm] and angles [°] of **1a** with estimated standard deviations in parentheses

Single Crystal X-Ray Analysis of 4a

Suitable, dark-green single crystals of **4a** × DMF were obtained by crystallization from DMF/acetone under nitrogen atmosphere. The Ni−S bond lengths of 215−216 pm indicate the presence of the monoanion $[Ni(dmit)_2]^-$[21] since a value of 221 pm is expected for the dianion (Figure 5a, Table 4).[22] This is corroborated by the characteristic electronic absorption spectra (vide infra). The structure of the cationic component in **4a** significantly differs from that of the DPD-Me^{2+} dication as indicated by the comparison of the central CNNC fragments. In the dication the C13−N2 and N2−N2′ bond lengths are 143.5(4) and 123.6(5) pm, respectively, while in **4a** the values of the corresponding C13−N2, C7−N1 and N1−N2 bonds are 134.7(8), 137.7(8) and 135.5(8) pm. Thus, while for DPD-Me^{2+} the C−N bond is about 20 pm longer than the N=N bond, no significant difference is observed for the cation present in **4a**. Accordingly, complex **4a** is composed of two radical ions, a combination hitherto unknown for dithiolene metalate−viologen ion pairs. Contrary to the structure of **1a**, the two components are slipped only marginally relative to each other. In the resulting structure one of the azo nitrogen atoms (N1) is located 362 pm perpendicular above the central nickel ion. Although the distance is much longer than 318 pm, the sum of the corresponding van der Waals radii,[18b,19] it may suggest a weak coordinative interaction and would rationalize the much smaller slipping as compared to **1a**.

Compared to the interplanar distances within **1a**, those in **4a** are remarkably longer (Table 5) and the mean value of 365 pm is in the range of interplanar anion distances as reported for $[Ni(dmit)_2]^-$ complexes with more simple countercations.[21] All values are about 20 pm longer than the sum of the corresponding van der Waals radii. If at all,

this points to only very weak π interactions between the two components. The presence of weak hydrogen bonding between the ion pairs is suggested by the distance of 280 pm between the methyl group hydrogen atom of DPD-Me$^{\bullet+}$ and the nickel ion; the corresponding sum of the van der Waals radii is 283 pm.

As already mentioned in the discussion of the interplanar distances, the packing structure of **4a** significantly differs from the one generally observed for $[Ni(dmit)_2]^-$ monoanions. In the latter the anions form isolated stacks

which are separated by the cations.[21] In contrast to that, the structure of **4a** consists of mixed anion-cation stacks as typically observed for class I IPCT complexes like MV[Ni(mnt)$_2$],[4][14] although these contain a dication and dianion. These mixed stacks are orientated along the [010] direction as depicted in Figure 6.

Within a stack each DPD-Me[Ni(dmit)$_2$] pair is slipped relative to the other by nearly half of the ion pair length resulting in a steplike arrangement (Figure 5b). Viewed perpendicular to the planar components, parallel stacks appear which are separated by the DMF molecules preventing short interstack contacts between the thioxo sulfur atoms of neighboring dithiolenes, a type of interaction which is generally observable in the many complexes where $[Ni(dmit)_2]^-$ possesses a non-redoxactive counterion.[21] On the other hand when viewed along the components planes there is no separation by solvent molecules and strong interstack interactions between the non-thioxo sulfur atoms become feasible. All corresponding distances of 331 to 362 pm are shorter than the sum of the van der Waals radii (370 pm[19]) and are characteristic for such type of S···S interactions.[21] Furthermore the distance of 331 pm is shorter than ever reported for a 3-dimensional network of $[Ni(dmit)_2]^-$ anions. The overall arrangement in the solid can be viewed as consisting of wavy sheets of distorted nickel dithiolene hexagons, hold together by strong interstack S···S interactions. The latter is typical for $[M(dmit)_2]^-$ (M = Ni, Pd, Pt) as reported for many complexes with more simple counter

cations.[21] The ″holes″ in the $[Ni(dmit)_2]$ sheets are occupied by two DPD-$Me^{\bullet+}$ molecules. But in spite of the close packing of the radical cations, there is no evidence for a dimerization as known e.g. for $MV^{\bullet+}$ [11a,11b,23].

General Properties

Since the single-crystal structural analysis of **4a** × DMF revealed the presence of singly charged ions, electron transfer (ET) from $[Ni(dmit)_2]^{2-}$ to DPD-Me^{2+} must have occurred during the synthesis. This is thermodynamically feasible in all cases as indicated by the moderate to strong driving force of the reaction calculated from the redox potentials which were corrected for the actually involved concentrations (Table 6). Only the palladium complex **2a** and the DPK^{2+} ion pair **1b** have rather small ΔG_{12}(corr.) values of −0.08 eV and −0.07 eV, respectively. Accordingly, the UV-Vis-NIR solution absorption spectra of all DPD-Me^{2+} ion pairs except **2a** and **1b** indicate the presence of radical ions. For the mnt complexes **1a** and **3a** the diagnostic absorption of the $[Ni(mnt)_2]^-$ monoanion[24] appears at 862 nm and the DPD-$Me^{\bullet+}$ radical cation is observable at 452, 550(sh) and 600(sh) nm (Figure 7a). Based on a monoanion extinction coefficient of 8000 and 11700 M^{-1} cm^{-1} for M = Ni and Pt at 862 and 855 nm,[24] respectively, one calculates that the concentration of $[M(mnt)_2]^-$ is only 25 (**1a**) and 6% (**3a**), of the theoretical value. This suggests that the major species present is the dianion as also corroborated by the EPR spectra (vide infra). An almost complete ET can be deduced from the high absorbance of the $[Ni(dmit)_2]^-$ monoanion at 1145 nm (ε = 16250 M^{-1} cm^{-1})[25] and 1414 nm (ε = 18050 M^{-1} cm^{-1})[26] in the case of the dmit-complexes **4a**, **4b** and **5a,** respectively (Figure 7b). Small amounts of remaining dianion could form the ion pair $\{(DPD\text{-}Me^{\bullet+})_2[Ni(dmit)_2]^{2-}\}$ which would account for the non-stoichiometric composition of **4a** (vide supra). Absorptions of the radical cation are evident only in the spectrum of **5a** while they probably are superimposed by monoanion bands in the case of **4a** and **4b**.

The fact that no radical ion absorptions are observable in the spectra of **1b** and **2a** can be rationalized by the unfavorable driving force of ET (Table 6).

The diffuse reflectance spectra of **1a** and **3a** both exhibit very broad absorption bands reaching from around 700 nm to the NIR region at 2200 respectively 2400 nm (Figure 8a).

This is at much lower energy as compared to hitherto observed IPCT bands of mnt complexes which did not extend beyond λ_{max} = 1000 nm while the absorption maxima of **1a** and **3a** are around 1400 nm. As expected, the onset of this low-energy band correlates with the driving force of ET from the dianion to the dication and is therefore assigned to an IPCT transition. According to the Hush equation ($E_{IPCT} = \chi + \Delta G_{12}$) the reorganization energy χ is about the same for the DPD-Me^{2+} complexes **1a**, **2a**, and **3a** resulting in an average value of 0.85 ± 0.04 eV as calculated from the data summarized in Table 6 while 0.89 is obtained for the DPK compound **1b**. This indicates, that the different structure of the acceptor component in **1a** and **1b** does not lead to a significant change of the reorganisation energy.

The diffuse reflectance spectra of **4a**, **4b** and **5a** do not contain evidence for the presence of an IPCT band, in accordance with the absence of short interionic distances typical for π,π interactions (vide supra). The maxima at 1190 and 1490 nm can be assigned to the monoanions $[Ni(dmit)_2]^-$ and $[Pd(dmit)_2]^-$.[26] Although the low-energy tailing of **4a** and **5a** may suggest an IPCT character, its independence on the donor component excludes this possibility. More likely is the assignment to an interanion charge-transfer transition along the 3-D network of the dithiolene metalate as proposed for comparable systems.[27]

The presence of different amounts of radical ions in the mnt and dmit complexes, respectively, is suggested from the UV-Vis-NIR solution spectra. This is corroborated by ESR spectroscopy of the complexes **1a** and **4a**. The powder ESR spectra of **1a** at 77 K exhibits the three signals of the $[Ni(mnt)_2]^-$ monoanion (g_1 = 2.152, g_2 = 2.043, g_3 = 1.997) and an intense signal of the DPD-$Me^{\bullet+}$ radical cation (g = 2.006) (Figure 9a), which overlaps with the less intensive g_3 signal of the monoanion. The observed g values of the dithiolene metalate anion are in excellent agreement with the literature (g_1 = 2.160, g_2 = 2.042, g_3 = 1.998).[28] Due to the separated rhombic spectra of the monoanion and the signal of the DPD-$Me^{\bullet+}$ radical cation, it can be concluded that there are no magnetic interactions between them. For in that case only a single signal of the monoanion

would have been observed, as in $(NBu_4)[Ni(mnt)_2]$. This lack of interaction between the radicals is confirmed by the comparison of the spectra at room temp. and at 77 K. At both temperatures there are sharp signals of the two components, which are more intensive at the lower temperature (77 K). This is contrary to a mutual antiferromagnetic interaction between the components, in which case less intensive signals would be observed at 77 K than at room temp. From these results it is concluded that both components are magnetically diluted in the diamagnetic complex $\{DPD\text{-}Me^{2+}[Ni(mnt)_2]^{2-}\}$, which is in accordance with the electronic solution spectra showing only a small amount of the anion.

Contrary to that, the dmit complex **4a** exhibits an intensive broad signal at about $g = 2.046$ at room temperature (Figure 9b). At 77 K this apparently isotropic signal disappears, while peaks at $g_1 = 2.003$, $g_2 = 2.047$, $g_3 = 2.118$ emerge (Figure 9c). The small shoulder at the g_2 signal of the monoanion might be caused by the radical cation. These results suggest that the broad signal may be caused

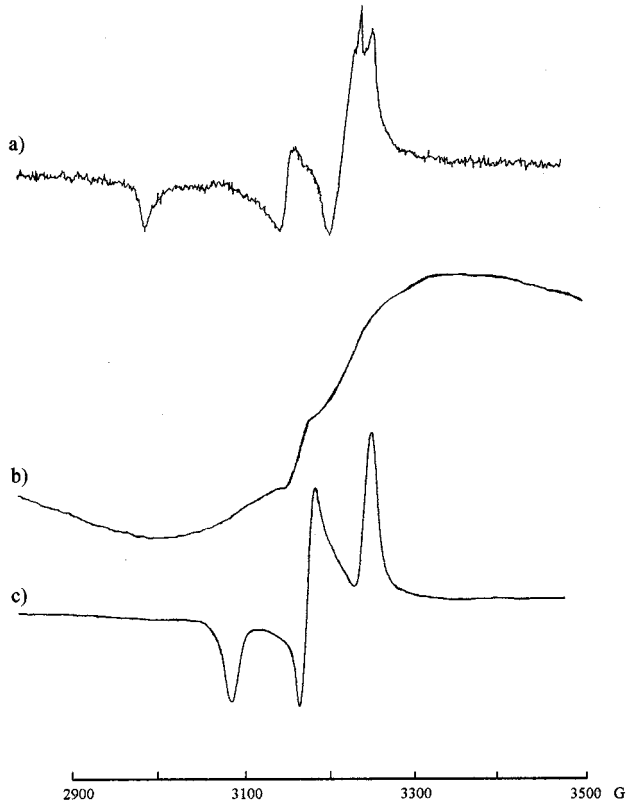

Figure 9. Powder ESR spectra; a) **1a** at 77 K, b) **4a** at room temp., c) **4a** at 77 K

by antiferromagnetic interactions between paramagnetic centers in partially oxidized (DPD-Me)[Ni(dmit)$_2$] containing also magnetically diluted monoanions. A similar broad signal was also reported for the partially oxidized (DEPZ)$_{0.35}$[Ni(dmit)$_2$], (DEPZ = diethylpyrazinium), but contrary to our results this broad signal persisted even at 77 K.[29] This antiferromagnetic interaction between the radicals in **4a** can be detected due to their much higher concentration than in **1a**. This is again in accordance with the high amounts of monoanions observed in the solution UV-spectra of the dmit complexes.

Electrical Conductivity

As expected from our previous findings that σ increases with a more negative driving force of ET when both components are planar and an IPCT band is present (class I complexes),[3] the conductivity increases from 2×10^{-7} over 4×10^{-6} to 1×10^{-5} Ω^{-1}cm^{-1} as ΔG_{12}(corr.) varies from −0.08 (**2a**) over −0.31 (**1a**) to −0.33 (**3a**) eV. The DPK^{2+} complex **1b** [ΔG_{12}(corr.) = −0.07 eV] does not follow this correlation which suggests that another factor must be responsible for this unexpected low conductivity of 1×10^{-9} Ω^{-1} cm^{-1}. Corresponding activation energies of 0.24 and 0.44 eV were measured for **1a** and **1b**, respectively, in the temperature range of 25 to 95°C. This remarkable difference is in sharp contrast to the only slightly different ΔG_{12}* (corr.) values of both complexes (**1a**: 0.11 eV; **1b**: 0.19 eV). It may be rationalized by recalling that the measured activation energy is composed of two components. The energy which is necessary for generation of conducting electrons and the energy barrier for electron transport through the crystal lattice. Since the former should be not too different as suggested by the solution ΔG_{12}*(corr.) values, it seems likely that the latter value is much higher for **1b**. The different acceptor geometries should lead to different crystal structures imposing unfavorable steric constraints for charge transport in the case of **1b**. A significant contribution of the radical species seems to be negligible since the conductivity of **3a** is about half an order of magnitude higher as compared to **1a** although the corresponding radical contents are 6 (**3a**) and 25% (**1a**, vide supra).

Contrary to the mnt complexes, the conductivity of the dmit compounds (4×10^{-4}, 3×10^{-4}, 2×10^{-4} Ω^{-1} cm^{-1} for **4a**, **4b** and **5a**, respectively) does not change significantly upon variation of the metal and acceptor. This suggests a different conduction mechanism which does not depend on electronic interaction between the two components but rather on the strong interstack S···S interactions between the monoanions (Figure 6), a well-known effect for [Ni(dmit)$_2$]$^-$ systems.[21]

Experimental Section

General Methods: Unless noted otherwise, all reactions and operations were carried out under nitrogen using standard Schlenk techniques. Solvents were dried and distilled before use. Spectra were recorded with the following instruments: NMR: Jeol FT-JNM-GX 270, EX 270 and Lambda LA 400. − ^{1}H NMR: The protio-solvent signal was used as an internal reference. Chemical shifts are quoted on the δ scale relative to tetramethylsilane. − ESR spectra were measured on a Radiopan 2543 spectrometer working in X band. − Elemental analyses: Carlo−Erba EA 1106 and 1108. − UV/Vis: Shimadzu UV-3101 PC. − Electrochemical investigations were performed with a three electrode cell with a Ag/0.01 M $AgNO_3$ reference, Pt counter and 2-mm diameter glassy carbon (CV) or Pt-gauze (spectroelectrochemistry) working electrode. Sample solutions were 4×10^{-4} M and TBA(PF$_6$) (10^{-1} M) was the supporting electrolyte. Potentials were referred to *Fc*/*Fc*$^+$ which was added to the solution as internal standard at the end of the measurement prior to the last scan. − For diffuse reflectance measurements the substances were spread on a corundum carrier (Ceram Tec) which also served as reflectance standard. The spectrometer was equipped with an intergrating shere unit. The onset of the absorption band of lowest energy was determined according to the method by Karvaly and Hevesi, originally developed for inorganic semiconductors,[30] which is independent on the sample concentration. Within the linear decrease of absorption on the low-energy side of the band, 5−6 points are selected and the term $[F(R_\infty)h\nu]^2$, with $F(R_\infty) = (1 - R_\infty)^2/2\ R_\infty$ (Kubelka−Munk function) is calculated for each of them. A plot of the first term vs. $h\nu$ affords a straight line which intersects the abscissa at the value E_{IPCT}. − Conductivity: Specific resistivities were measured for compacted pellets at ambient conditions by the conventional two-probe method as described previously.[3] Average values are given as obtained from 3−4 powder pellets; the mean deviation in these measurements was ± 18%. Activation energies E_a were measured in the range of 25−95°C at 5−6 temperatures in a thermostated oil

bath.[3] Arrhenius plots of log σ vs. $1/T$ exhibited excellent linearity with regression coefficients of 0.99 or better.

Powder X-ray Diffraction: For the powder X-ray diffraction experiments, several samples were sealed in glass capillaries (Hilgenberg glass no.50) of 0.5 mm diameter. High resolution powder diffraction data were collected at room temperature at the SUNY X3B1 beamline at the National Synchrotron Light Source, Brookhaven National Laboratory (Figure 10).

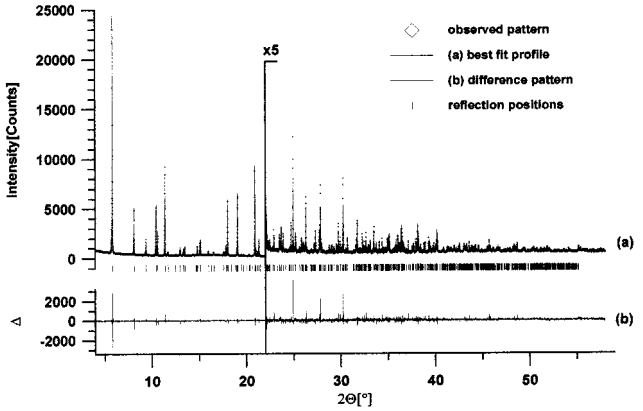

Figure 10. Rietveld plot of monoclinic **1a**. The asymmetric unit contains 23 atoms (17 non-hydrogen atoms). The spikes in the difference curve are the same as in the leBail type of fit and can be attributed to some anisotropical peak broadening which has not been refined.

X-rays of wavelength 1.14946(2) Å were selected by a double Si(111) monochromator. Wavelength and zero-point shift were determined from 8 well-defined reflections of the NIST1976 flat plate alumina standard. The diffracted beam was analyzed with a Ge(111) crystal and detected with a Na(Tl)I scintillation counter with a pulse-height discriminator in the counting chain. The incoming beam was monitored by an ion chamber for normalization for the decay of the primary beam. In this parallel beam configuration, the resolution is determined by the analyzer crystal instead of by slits. Data were taken for 3.3 s at each 2Θ from 2° to 56.805° 2Θ, for 4.3 s at each 2Θ from 40° to 48.3540° 2Θ and for 6.3 s at each 2Θ from 40° to 58.055° 2Θ in steps of 0.005° 2Θ during 2.5 GeV operation (max. 350 mA current). The three data sets were added up and normalized against 10^6 monitor counts.

Although Θ scans did not show serious crystallite size effects, the sample was spinned around the Θ axis during measurement for better statistics. Low angle diffraction peaks from (DPD-Me)[Ni(mnt)$_2$] showed strong asymmetry due to axial divergence and had a FWHM of 0.011° 2Θ, not significantly broader than the resolution of the spectrometer.

The diffraction pattern could be indexed based on a triclinic lattice using the program ITO.[31] The number of formula units per unit cell (Z) was found by geometrical considerations. Since Z was equal to 1 and the DPD-Me^{2+} cation as well as the [Ni(mnt)$_2$]$^{2-}$ ion contain a center of inversion, P-1 was chosen as the most likely space group, which was later confirmed by Rietveld refinement. A Le-Bail fit[32] using the program GSAS[33] worked well to extract 728 reflections up to 57.7° 2Θ. The peak profile function was modeled using a multiterm Simpson′s rule integration of the pseudo-Voigt function.[34] The strong asymmetry in the low-angle region was modeled by a lately implemented function[35] which accounts for the asymmetry due to axial divergence, leading to an strongly improved fit and therefore better profile R factors. Mainly because of the well-resolved peaks over the entire powder pattern, a minor non-constant shift of the peak positions was detected, which could be attributed to a small shift of wavelength. This effect could be satisfactory described by refining an additional sin Θ-depending term in addition to the zero point. A manual fit background using the program GUFI[36] was used in combination with a refinable 4-term cosine-series. The final profile agreement factors obtained were R-p = 5.35% and R-wp = 7.02%.

For the determination of the structure, two different procedures were used. In a direct method approach, the previously extracted intensities were used as input for the program SIRPOW92.[13c] It was possible to detect almost the entire [Ni(mnt)$_2$]$^{2-}$ anion and some fragment of the DPD-Me^{2+} cation. Alternatively, refinable starting parameters for the position and the orientation of the two independent molecules could also be derived from the single-crystal structure determination of the similar compound (MV)-[Ni(mnt)$_2$].[14] For the consecutive Rietveld refinements[37] in GSAS, all background, lattice and profile parameters obtained by the Lebail type of fit were fixed.

Since the shape of the two distinct molecules is known in very narrow limits, this additional information was used to stabilize the refinement by setting up rigid bodies derived from similar structures. Since both, the [Ni(mnt)$_2$]$^{2-}$ anion and DPD-Me^{2+} cation were located on a center of inversion, this reduced the number of refinable parameters for both molecules from 24 positional to 3 rotational parameters each. In order to allow the molecules to relax, the length, the width and in case of the [Ni(mnt)$_2$]$^{2-}$ anion also some out of plane bending of the outer atoms were refined as additional parameters. The refinement converged to a R-Bragg value around 15%.

Due to the high quality of the powder data, all (non-hydrogen) positional parameters remained very close to their rigid-body positions after turning them loose in a final cycle of refinement. Both molecules can be regarded as flat within the error limits. It was also possible to refine individual temperature factors. The final R values were R-p = 6.18%, R-wp = 8.47% and R-F = 7.53%, referring to the Rietveld criteria of fit for profile, weighted profile, and structure factor, respectively, defined in ref.[13a] Esd′s are a factor of six larger than Rietveld statistical estimates, as discussed in ref.[13a]

Single-Crystal X-ray Structure Analyses: Intensity data for the structural analyses of **a**(MeSO$_4$)$_2$, **a**(PF$_6$)2 × 2 (Me$_2$CO) and **4a** × DMF were collected on an automatic four-circle diffractometer (Siemens P4) at 200 K using Mo-K_α radiation (graphite monochromator). Data were corrected for Lorentz and polarization effects. In case of **4a** × DMF a semi-empirical absorption correction has been carried out. For **a**(MeSO$_4$)$_2$ and **a**(PF$_6$)2 × 2-(Me$_2$CO) absorption effects have been neglected. The structures were solved by direct methods and refined using full-matrix least-squares methods on F^2 (SHELXTL 5.03).[38] All non-hydrogen atoms with anisotropic displacement parameters. Hydrogen atom positions were taken from a difference fourier synthesis (exept for the H atoms of the DMF molecules in **4a** × DMF, which were geometrically positioned) and either refined isotropically [**a**(MeSO$_4$)$_2$, **a**(PF$_6$)2 × 2(Me$_2$CO)] or refined with a fixed isotropic displacement parameter (**4a** × DMF).

Orange platelets of **a**(MeSO$_4$)$_2$ were obtained when a saturated solution in methanol was layered with the same volume of acetone and allowed to cool from 20 to −20°C.

Long, orange-colored platelets of **a**(PF$_6$)2 × 2 (Me$_2$CO) were obtained when a saturated solution in acetone was layered with the same volume of 2-propanol and allowed to cool from 20 to −20°C.

[a] As defined in ref.[13a]

Dark-green platelets of **4a** × DMF were obtained when a saturated solution in $DMF_{abs}/MeOH_{abs}$ (v/v = 1:3) was allowed to cool slowly from 80 to −20°C.

Syntheses: 4,4′-Azopyridine,[39] DPD-Me$(MeSO_4)_2$ **a**$(MeSO_4)_2$,[8] DPK$(PF_6)_2$ **b**$(PF_6)_2$,[40] $(NBu_4)_2$[Ni$(mnt)_2$],[20] $(NBu_4)_2$[Pd$(mnt)_2$], $(NBu_4)_2$[Pt$(mnt)_2$],[25] $(NBu_4)_2$[Ni$(dmit)_2$] and $(NBu_4)_2$[Pd$(dmit)_2$][41] were prepared according to literature methods. – 4,4′-Azopyridine has been chromatographed prior to use on silica gel (eluent: acetone/petroleum ether/ethyl acetate, 1:3:1) under air. Until noted otherwise all syntheses were carried out under inert gas atmosphere in absolute solvents.

a$(PF_6)_2$: This synthesis was carried out under air. 1.5 g (8.16 × 10^{-3} mol) of 4,4′-azopyridine were dissolved in 36 mL of dimethylsulfate. An orange-colored precipitate was formed after 2 min and stirring at ambient temperature was continued for half an hour. The separated precipitate was dissolved in 500 mL of methanol/ethanol/acetone (v/v = 2 : 2 : 1) and 2.85 g (17.5 × 10^{-3} mol) of NH_4PF_6 in 30 mL of water/methanol (v/v = 1 : 1) were added to the dark-orange solution. After storing in the refrigerator for 2 h, the small orange-colored needles were filtered off through a filter funnel, washed twice with 10 mL of ethanol and dried in vacuo. Yield: 3.6 g (88%) of **a**(PF_6), orange-colored needles. – UV/Vis (acetone): λ_{max} = 280 nm, 450. – ^{1}H NMR (270 MHz, [D$_6$]acetone): δ = 4.80 [d, 6 H, NCH_3], 8.67 [d, 4 H, *3,3′*-, *5,5′*-aromatic H], 9.45 [d, 4 H, *2,2′*-, *4,4′*-aromatic H]. – $C_{12}H_{14}N_4P_2F_{12}$ (504.0): calcd. C 28.57, H 2.80, N 11.11; found C 28.61, H 2.77, N 11.01.

1a: A solution of 201.6 mg (0.40 × 10^{-3} mol) of **a**$(PF_6)_2$ in 40 mL of acetone was added dropwise to 330.0 mg (0.40 × 10^{-3} mol) of $(NBu_4)_2$[Ni$(mnt)_2$] in 50 mL of acetone. Rapidly a dark-brown precipitate was formed which was collected by filtration after standing in the refrigerator for 2 h. The microcrystalline solid was carefully washed both with 10 mL of methanol and acetone and dried in vacuo.Yield: 215 mg (97%) of **1a**, dark-brown microcrystalline powder. UV/Vis (solid): λ_{max} = 398 nm, 474, 1300. – UV/Vis (DMF): λ_{max} = 382 nm, 456, 550, 600, 872. – $C_{20}H_{14}N_8NiS_4$ (553.31): calcd. C 43.41, H 2.55, N 20.25, S 23.18; found C 43.27, H 2.46, N 20.16, S 23.00.

1b: To a solution of 741 mg (0.90 × 10^{-3} mol) of $(NBu_4)_2$[Ni$(mnt)_2$] in 30 mL of acetone, a solution of 453 mg (0.90 × 10^{-3} mol) of **b**$(PF_6)_2$ in 150 mL of acetone was added dropwise. Immediately a dark-brown solid started to precipitate and stirring was carried on for 45 min and the mixture was kept in the refrigerator for 3.5 h. The precipitate was filtered off through a filter funnel, washed three times with 5-mL portions of acetone and dried in vacuo. Yield: 450 mg (91%) of **1b**, dark-brown powder. UV/Vis (solid): λ_{max} = 410 nm, 489, 641(sh), 1224. – UV/Vis (DMF): λ_{max} = 385 nm, 481, 816. – $C_{21}H_{12}N_6NiOS_4$ (550.70): calcd. C 45.76, H 2.18, N 15.25, S 23.24; found C 45.84, H 1.99, N 15.24, S 23.83.

2a: A solution of 355 mg (0.70 × 10^{-3} mol) of **a**$(PF_6)_2$ in 50 mL of acetone was added dropwise within 30 min to 610 mg (0.70 × 10^{-3} mol) of $(NBu_4)_2$[Pd$(mnt)_2$] in 90 mL of acetone. Rapidly an olive-brown, microcrystalline precipitate was formed. Stirring was continued for half an hour, after which the precipitate was collected by filtration, washed twice with 10 mL of acetone and dried in vacuo. Yield: 410 mg (98%) of **2a**, olive-brown microcrystalline powder. UV/Vis (solid): λ_{max} = 350 nm, 449, 469, 639, 1124. – UV/Vis (DMF): λ_{max} = 452 nm, 550, 600, 1100. – $C_{20}H_{14}N_8PdS_4$ (600.04): calcd. C 39.97, H 2.33, N 18.65, S 21.32; found C 39.79, H 2.36, N 18.51, S 21.31.

3a: A solution of 86 mg (0.17 × 10^{-3} mol) of **a**$(PF_6)_2$ in 17 mL of acetone was added within 20 min dropwise to a solution of 166 mg (0.17 × 10^{-3} mol) of $(NBu_4)_2$[Pt$(mnt)_2$] in 26 mL of acetone. Rapidly an violet-brown, microcrystalline precipitate was formed. Stir-

ring was continued for 30 min, after which the precipitate was filtered off. After washing with 5 mL of acetone, the complex was recrystallized from 5 mL of DMF. After two weeks in the refrigerator the black, microcrystalline product was filtered off, washed twice with 2 mL of acetone and dried in vacuo. Yield: 85 mg (73%) of **3a**, dark-brown microcrystalline powder. UV/Vis (solid): λ_{max} = 486 nm, 1357. – UV/Vis (DMSO): λ_{max} = 460 nm, 550(sh), 600(sh), 870. – $C_{20}H_{14}N_8PtS_4$ (689.70): calcd. C 34.83, H 2.05, N 16.25, S 18.59; found C 34.71, H 1.85, N 16.10, S 18.50.

(DPD-Me)$_x$[Ni(dmit)$_2$]; x = 0.7–1.0 (4a): To a cooled (−35°C) solution of 280 mg (0.30×10^{-3} mol) of $(NBu_4)_2[Ni(dmit)_2]$ in 80 mL of acetone was added dropwise within 20 min a cooled (−30°C) solution of 150 mg (0.30×10^{-3} mol) of **a**$(PF_6)_2$ in 50 mL of acetone. During the addition the temperature of the mixture was kept between −35 and −30°C. The brown product started to precipitate immediately. The mixture was then cooled down to −40°C and the precipitate was filtered off as fast as possible (25 min). During the filtration the mixture was allowed to warm up to 0°C. After washing once with 5 mL of acetone and twice with 5 mL of methanol at room temp. the product was dried in vacuo.Yield: 185 mg (93%) of **4a**, dark-brown microcrystalline powder. UV/Vis (solid): λ_{max} = 440 nm, 1243. – UV/Vis (DMF): λ_{max} = 399 nm, 584, 626, 1145. – $C_{18}H_{14}N_4NiS_{10}$ (664.70): calcd.(x = 1.0) C 32.50, H 2.11, N 8.42, S 48.14; found C 32.56, H 2.29, N 8.30, S 47.56.; these values could not be reproduced, two new syntheses gave the following results: $C_{16.8}H_{12.6}N_{3.6}NiS_{10}$ (643.30): calcd.(x = 0.9) C 31.34, H 1.96, N 7.83; found C 31.10, H 1.43, N 8.03; and $C_{15.6}H_{11.2}N_{3.2}NiS_{10}$ (621.90): calcd.(x = 0.8) C 30.10, H 1.80, N 7.20; found C 29.92, H 1.72, N 6.92, respectively.

4b: To a solution of 720 mg (0.77×10^{-3} mol) of $(NBu_4)_2[Ni(dmit)_2]$ in 62 mL of acetone, a solution of 286 mg (0.77×10^{-3} mol) of **b**$(Br)_2$ in 11 mL of acetone/water (v/v = 2:1) was added dropwise. Immediately a grey solid started to precipitate and stirring was carried on for 30 min and the mixture was kept in the refrigerator overnight. The precipitate was filtered off through a filter funnel, washed three times with 5-mL portions of acetone and once with 5 mL of water and dried in vacuo. Yield: 485 mg (95%) **4b**, dark-grey powder. UV/Vis (solid): λ_{max} = 410 nm, 570 (sh), 600 (sh), 1300. – UV/Vis (DMF): λ_{max} = 400 nm, 450 (sh), 630 (sh), 800 (sh), 900 (sh), 1140. – $C_{19}H_{12}N_2NiOS_{10}$ (662.70): calcd. C 34.40, H 1.81, N 4.23, S 48.29; found C 34.77, H 1.86, N 4.25, S 47.54.

5a: A solution of 150 mg (0.30×10^{-3} mol) of **a**$(PF_6)_2$ in 20 mL of acetone was added dropwise within 20 min to a solution of 296 mg (0.30×10^{-3} mol) of $(NBu_4)_2[Pd(dmit)_2]$ in 63 mL of acetone/methanol (v/v = 20 : 1). Rapidly, brown microcrystals started to precipitate. Stirring was carried on for 30 min. After standing in the refrigerator overnight, the product was filtered off, washed twice with 5 mL of acetone and dried in vacuo. Yield: 65 mg (30%) of **5a**, dark-grey microcrystalline powder. UV/Vis (solid): λ_{max} = 434 nm, 1529. – UV/Vis (DMF/THF = 1:4): λ_{max} = 320 nm, 456, 559, 610, 1414. – $C_{18}H_{14}N_4PdS_{10}$ (712.40): calcd. C 30.32, H 1.97, N 7.86, S 44.92; found C 30.60, H 2.10, N 7.78, S 43.34.

Acknowledgments

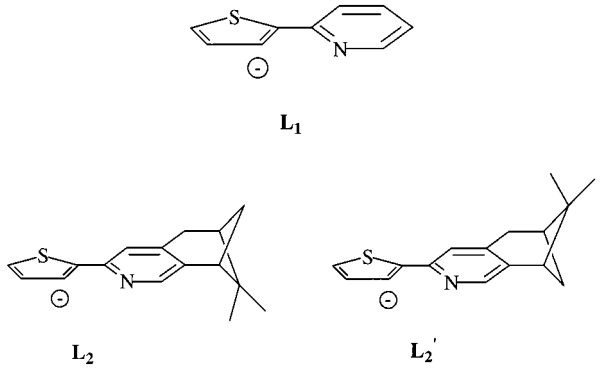
Predetermined Chirality in Mono- and Dinuclear Cyclometalated Rhodium(III) Complexes

Liana Ghizdavu,[a] Brunhilde Kolp,[a] Alex von Zelewsky,*[a] and Helen Stoeckli-Evans[b]

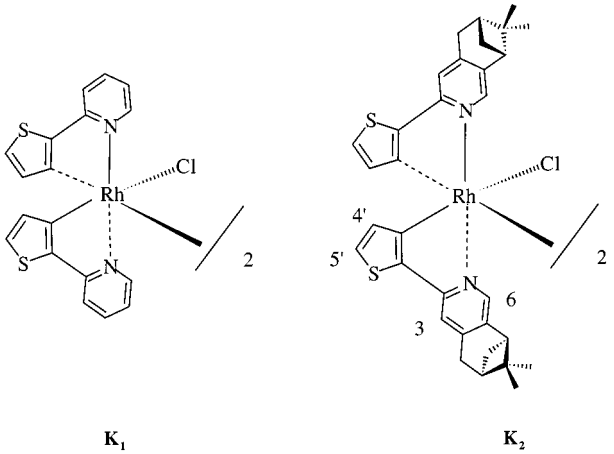
Keywords: Chirality / Dinuclear complexes / Rhodium

Dinuclear and polynuclear metal complexes with octahedral centers coordinated to di- or polydentate ligands are often obtained as complicated mixtures of various stereoisomers. Stereospecific synthesis of such species is therefore of high current interest. Chiral derivatives of pyridine can be used for this purpose. Dinuclear μ-chloro-bridged Rh^{III} complexes with two didentate, cyclometalated thienylpyridine-type ligands at each metal center are formed stereoselectively when pinene groups are fused to the pyridine rings. The two octahedral Rh^{III} centers have homochiral configurations, ΔΔ and ΛΛ. The heterochiral diastereomer ΔΛ is not observed. With (8*R*,10*R*)-2-(2′-thienyl)-4,5-pinenopyridine [Hth4,5-(*R*,*R*)ppy] the ΔΔ to ΛΛ ratio is 9:1 when the separation eluent contains NaCl. Modeling the ΛΛ and the ΔΔ isomers of the dinuclear species shows crowding of the pinene groups in both cases; however, the strain can be released by relatively small distortions only in the case of the ΛΛ isomer. NO_3^- cleaves the dichloro bridge, yielding the mononuclear species Δ[$Rh(L_2)_2(NO_3)$] (**2**) in a completely stereoselective manner when NaCl is replaced by KNO_3 in the eluent mixture. The molecular structure has been determined by X-ray structure analysis for both the ΔΔ and the mononuclear complex Δ[$Rh(L_2)_2(NO_3)$] (**2**) in order to confirm the configuration at the metal center. ^{1}H-NMR, ^{13}C-NMR and CD spectra were measured and the latter shows that the CD activity is solely due to the chirality at the metal center.



Introduction

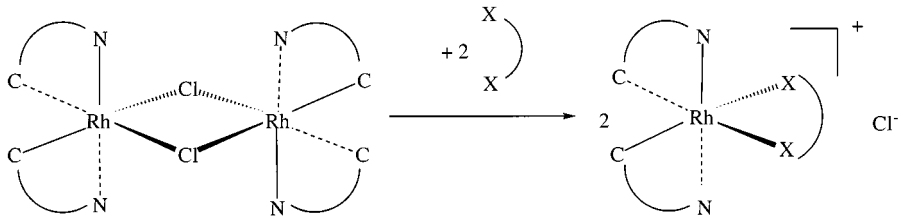
The selective generation of chiral metal centers in a predetermined configuration has been reported already in 1920 by Smirnoff,[1] who worked with A. Werner. In contrast to organic chemistry, where *stereoselective synthesis* was developed to a high degree of sophistication, progress in this field was rather slow in coordination chemistry. A recent, fairly comprehensive review[2] on the subject reveals a strongly increased interest in metal-centred chirality in recent years.



In earlier contributions, we reported the formation of dinuclear cyclometalated Rh^{III} complexes with thienylpyridine[3] or phenylpyridine.[4] 2-(2-Thienyl)pyridine (**L$_1$**, Scheme 1) gives, through a spontaneous cyclometalation, the dinuclear complex di-μ-chlorobis{bis[2-(thien-2′-yl)pyridinato-*N*,*C*$^{3'}$]rhodium} (**K$_1$**, Scheme 2).

It was shown that the formation of this complex is completely regioselective, i.e. only *C*,*C*-*cis*,*N*,*N*-*trans* isomers are obtained. The chirality at the metal centers follows an almost statistical distribution, yielding a ratio of ΔΔ/ΛΛ/ΔΛ of 1:1:2.[5][6] The two enantiomers ΔΔ and ΛΛ occur, of course, in an exact 1:1 ratio.

The introduction of a new family of chiral, enantiomerically pure pyridine-type ligands[7] prompted us to investigate the ability of these versatile molecules to form the dinuclear complexes in a stereoselective manner and to obtain derived mononuclear species with predetermined chirality at the metal center. For this purpose we used (8*R*,10*R*)-



Scheme 1. 2-(2-Thienyl)pyridine [thpy] (**L$_1$**), (8*R*,10*R*)-2-(2′-thienyl)-4,5-pinenopyridine [th4,5(*R*,*R*)ppy] (**L$_2$**) and (8*S*,10*S*)-2-(2′-thienyl)-4,5-pinenopyridine [th4,5(*S*,*S*)ppy] (**L$_2$′**)

Scheme 3

2-(2′-thienyl)-4,5-pinenopyridine (**L_2**, in Scheme 1) for the preparation of dinuclear complexes. This ligand forms SP-4 Pt^{II} complexes, which significantly deviate from planarity.[8] The enantiomeric purity of **L_2** is due to its synthesis from a chiral-pool precursor, (−)-myrtenal, which is commercially available in high enantiomeric purity. A first question was the stereochemical outcome of the formation of **K_2** (Scheme 2). If we assume the same regioselectivity as in the case of **K_1** (this assumption is a posteriori justified by our investigations), the three isomers ΔΔ, ΛΛ, ΔΛ are now all diastereomers.

In order to obtain more information about the stereochemistry of such complexes, cleaving reactions (Scheme 3) can be carried out with chiral and nonchiral diimines, diamines and other chelating ligands.[3] Further investigations of such reactions and their products are in progress. Cleavage of the dinuclear species with NO_3^- occurred unintentionally upon separation on TLC plates, and also with acetonitrile in an attempt to obtain crystals of an artificial racemate (vide infra).

Results and Discussion

The replacement of the achiral 2-(2-thienyl)pyridine **L_1** by the enantiomerically pure (8*R*,10*R*)-2-(2′-thienyl)-4,5-pinenopyridine **L_2** renders the ΔΔ/ΛΛ isomers of the dinuclear species diastereomers. Separation with ordinary chromatographic methods becomes therefore possible. TLC (preparative thin layer chromatography, with a mixture of solvents and NaCl) gave the ΔΔ.ΛΛ isomers in a ratio of ca. 9:1, indicating that no cleavage occurred. When replacing NaCl with KNO_3, (see Experimental Section) three products in a mass ratio of 61:28:11 are obtained. The major product can clearly be identified as the ΔΔ isomer.

Single-crystal structure determination of this shows a D_2-symmetric species, where the sterical constraints of ligand/ligand interactions are relatively small. Figure 1 is a representation of the experimentally determined structure (see Table 1 for detailed structural information). The two minor products isolated (28% and 11%) were found to be the Δ[Rh(L$_2$)$_2$(NO$_3$)] (**2**) and the Λ[Rh(L$_2$)$_2$(NO$_3$)] (**3**) complexes, respectively. Both species were examined by X-ray diffraction, and the structures are shown in Figures 3 and 4. These two monomeric, isomerically pure compounds behave in some respects almost as enantiomers, in others, however, their diastereomeric nature is quite evident. Since the CD activity is mainly determined by the configuration around the metal center, the respective spectra are almost mirror images (Figure 7). The NMR spectra are also very similar, small differences in shift values are, however, noticeable. The two compounds behave quite differently with respect to crystallization, which shows the importance of intermolecular interactions in the crystal packing.

The isomer ΔΔ, where the structure could be determined experimentally, shows a relatively low crowding in the region where the pineno moieties of the ligands of the two Rh centers make their closest approach. The observed angle of 170° for N−Rh−N at one center is the same as in the mononuclear complex Δ[Rh(L$_2$)$_2$(NO$_3$)] (**2**), which will be discussed in more detail later. This indicates that the deviation of the N−Rh−N angle from 180° is a purely "local" phenomenon, due to the bite angle of ca. 81° of the cyclometalated ligand. Because of the relatively low quality of the structural analysis of the ΔΔ dimer (see Experimental Section) an attempt was made to prepare an artificial ΔΔ.ΛΛ racemate, using the enantiomeric ligands L_2 and L_2', respectively. The dimers ΔΔ[Rh(L$_2$)$_2$(μ-Cl)]$_2$ (**1**) and ΛΛ[Rh(L$_2'$)$_2$(μ-Cl)]$_2$ (**5**) behave as true enantiomers and are identical in every respect, except for their CD spectra, which are mirror images. Mixing the two enantiomers in order to form the artificial racemate, however, yielded a product that was no longer soluble in pure CH_2Cl_2. CH_3CN had to be added and crystallization was carried out in a CH_3CN/CH_2Cl_2 solvent mixture. The resulting crystalline material turned out to be {Δ[Rh(L$_2$)$_2$Cl(CH$_3$CN)] Λ[Rh(L$_2'$)$_2$Cl(CH$_3$CN)]} (**6**) (Figure 5), indeed a racemate, but of one of the cleaved dimers, containing the monomeric enantiomers. Thus, the dimers are obviously not sufficiently inert towards the solvent (CH_3CN).

In order to gain more insight into the effects that influence the formation or (non-)formation of the three dinuclear diastereomers, the non-existing configurations were graphically constructed on computer (with the MSI Cerius[2] program) by "manual" manipulation of the X-ray structure of the ΔΔ isomer (Figure 2a). The "models" of the ΔΛ and the ΛΛ diasteromers were obtained using the same coordinates as for the ΔΔ isomer except for the μ-dicloro bridge (vide infra), but changing the absolute configuration at the metal centers to ΔΛ and ΛΛ, respectively. This was done by simply breaking the Rh−C bonds and inverting the ligand′s orientation on both sides of the ΛΛ diasteromer and only for one metal center for ΔΛ diasteromer.

In the ΔΛ and the ΛΛ "models" severe crowding of the pineno groups occurs. Figure 2b represents a structure in which the twist angle of the two N−Rh−N directions,

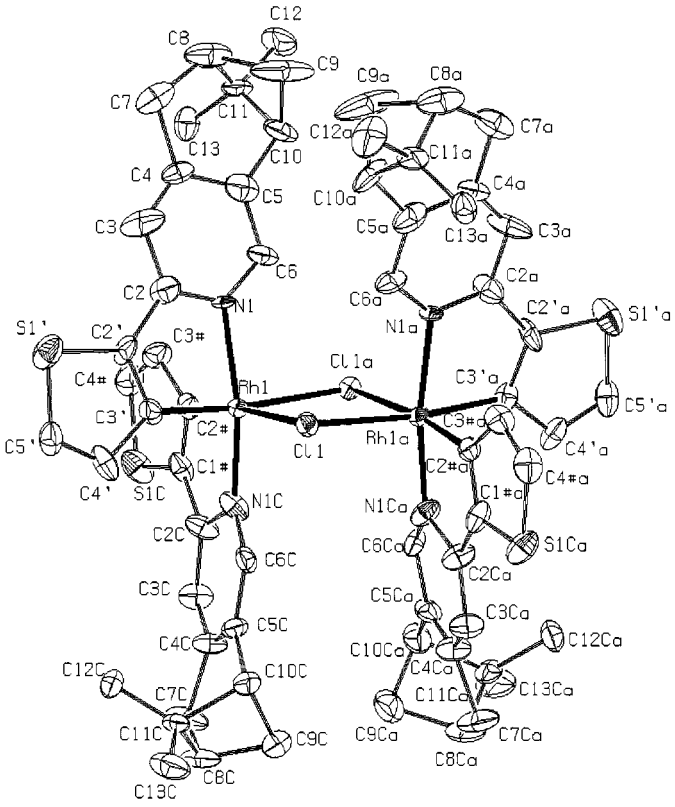

Figure 1a. Numbered ORTEP[18] plot with thermal ellipsoids drawn at 30% probability level of **1**

bution of ΔΔ/Δ/Λ of 61:28:11, mirrors the relative reactivities of the possible diastereomers of the dinuclear species. Only the ΔΔ isomer could be isolated, demonstrating the much higher reactivities towards the cleavage reaction of the ΛΛ and of the ΔΛ isomers that are most probably formed as intermediates.

A model of the "*meso*" isomer ΔΛ, which is still chiral due to the pineno groups, is shown in Figure 2c. Here the internal coordinates were taken from the ΔΔ isomer and the configuration at one Rh center was inverted. This reduces the symmetry of the dinuclear complex from D_2 to C_2. Figure 2c shows that the aromatic groups of the ligands on the two different Rh centers are now nearly perpendicular. The concomitant steric strain cannot be avoided through "distortions" of the complex. Experimentally no evidence indicated that the ΔΛ isomer is formed in this synthesis. From these observations it is concluded that only the ΔΔ isomer of the dimer shows a sufficiently low reactivity to be isolable. Another dimer must be formed as intermediate, which, however, reacts rapidly under the experimental conditions to yield the monomeric species Λ[Rh(L$_2$)$_2$(NO$_3$)] (**3**). Most probably this intermediate is the ΛΛ dimer, already observed in small proportions after separation of the raw product.

The third product obtained after separation on the TLC plates (61:*28*:11) was identified by X-ray diffraction methods as a mononuclear species Δ[Rh(L$_2$)$_2$(NO$_3$)] (**2**) (Figures 3a and 3b). Evidently, the enantiomerically pure mononuclear complex is obtained through cleavage of the dichloro

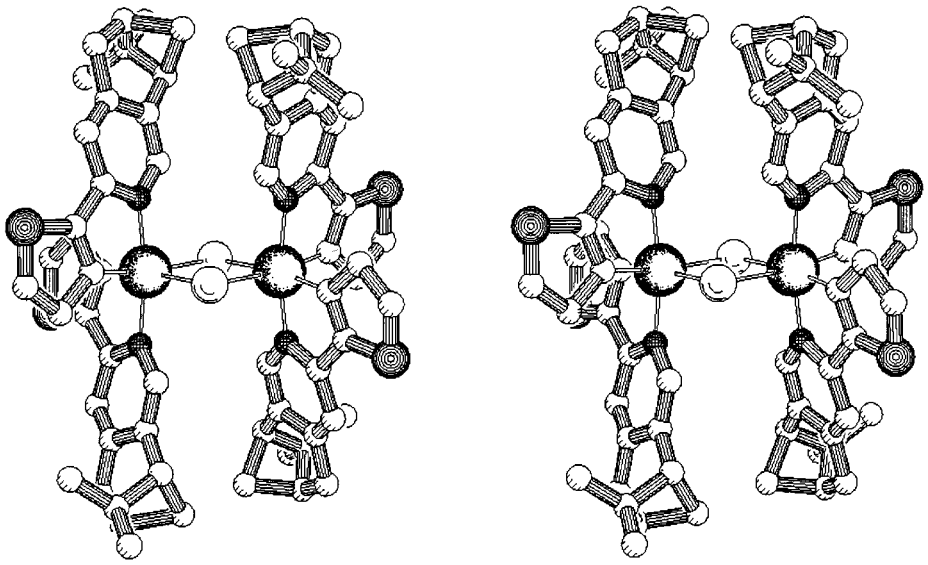

Figure 1b. Stereoview of the molecular structure of ΔΔ[Rh(L$_2$)$_2$(μ-Cl)]$_2$ (**1**); the hydrogen atoms have been omitted for clarity

which is 0° in the ΔΔ isomer, has been changed to 15° in the ΛΛ isomer. This distortion along one of the C_2 axes of the dinuclear species relieves the steric strains due to interligand repulsion considerably. It is therefore predicted that the ΛΛ isomer shows a "distortion" of this type, where the D_2 symmetry is conserved and the parallel orientation of the aromatic parts is maintained, but where the pineno groups are in less crowded positions. The product distribridge by NO_3^- used in the eluent during chromatography. As we will show in a forthcoming publication about a number of mononuclear complexes obtained through cleavage of the dinuclear species, it is a general phenomenon that the former can be obtained in enantiomerically pure form with predetermined chirality. Thus, the complex Δ[Rh(L$_2$)$_2$(NO$_3$)] (**2**) is the first example of a mononuclear species obtained from a diastereoselectively prepared dinuclear

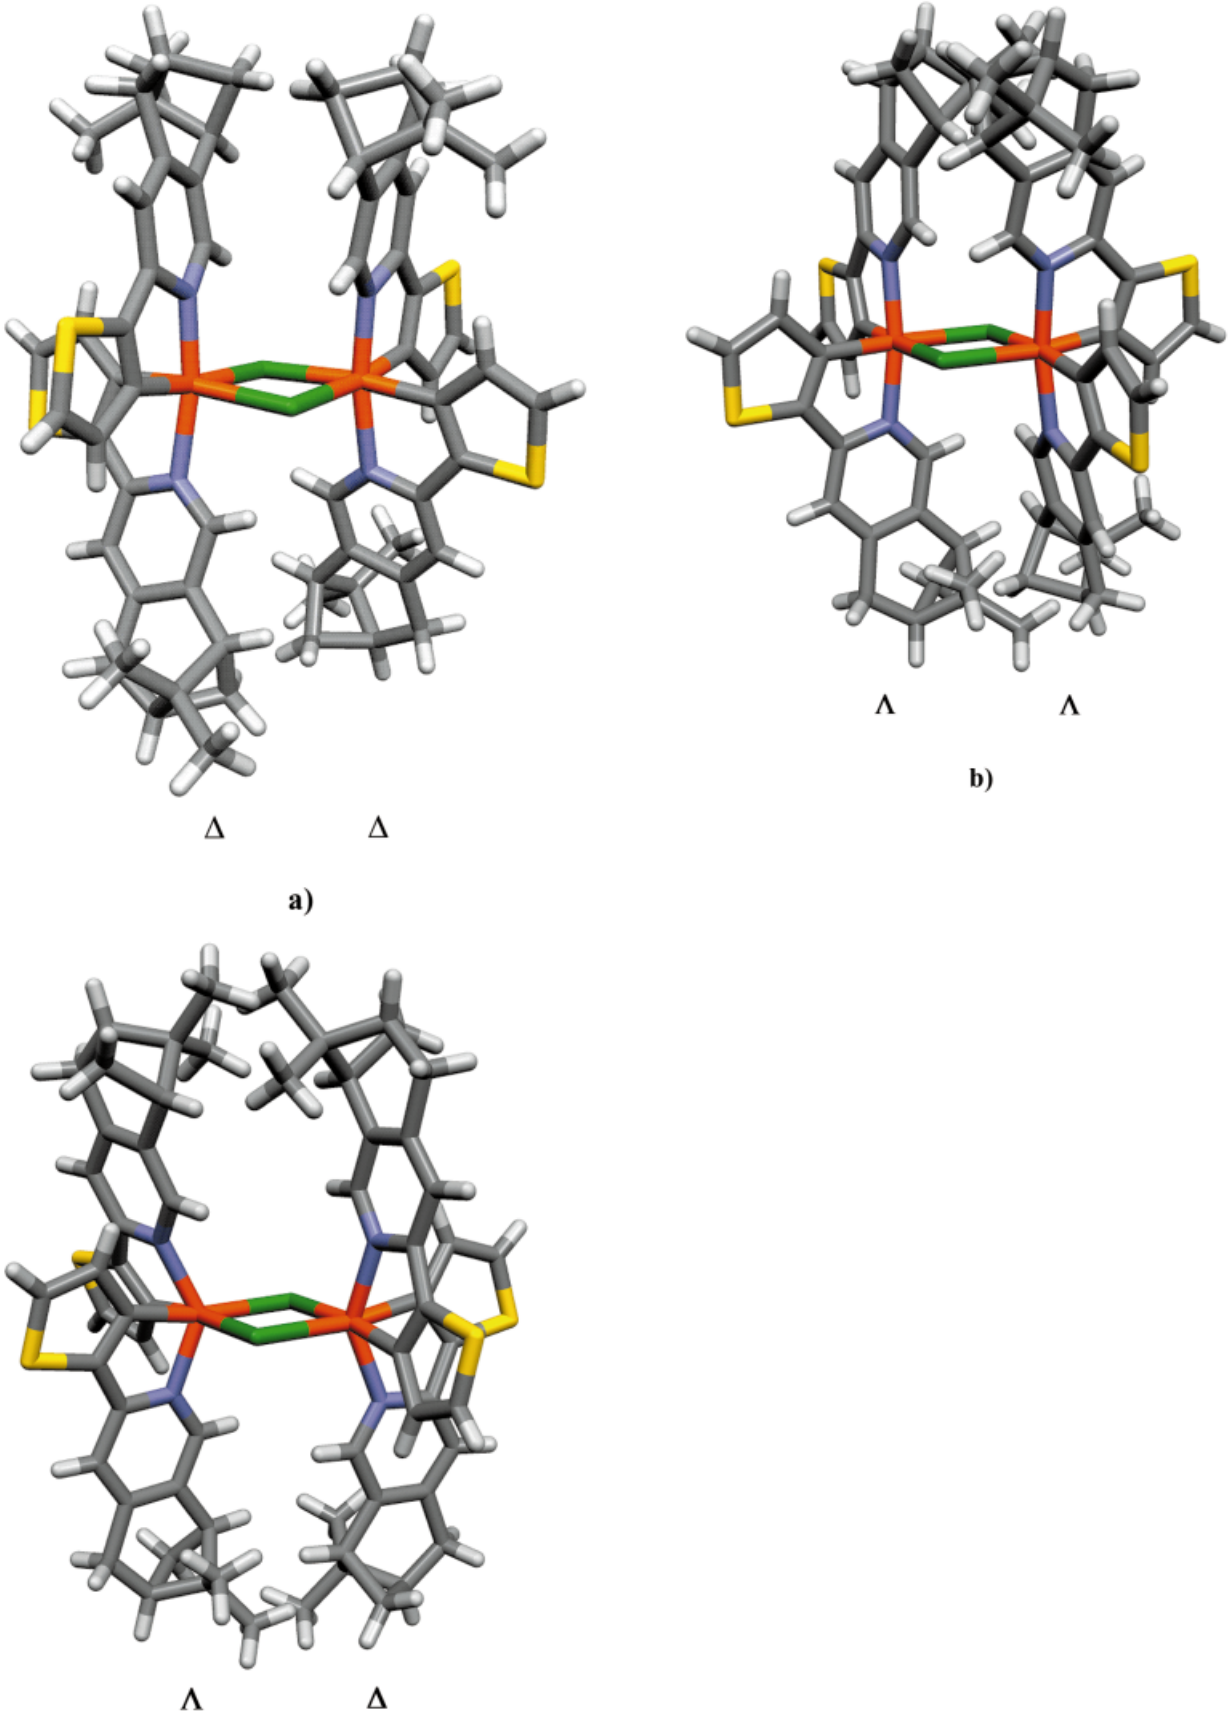

Figure 2. Cylinder plot of the molecular structure of ΔΔ[Rh(L_2)$_2$(μ-Cl)]$_2$ (**1**) (a), models of the ΛΛ structures (b) and ΔΛ (c) using the same internal coordinates as those measured in the ΔΔ isomer

compound that shows a *completely* predetermined chirality at the metal center.

NMR Spectroscopy

Figure 6 illustrates the aromatic region of the ^{1}H-NMR spectra for the $\Delta\Delta[Rh(L_2)_2(\mu\text{-}Cl)]_2$ (**1**), $\Delta[Rh(L_2)_2(NO_3)]$

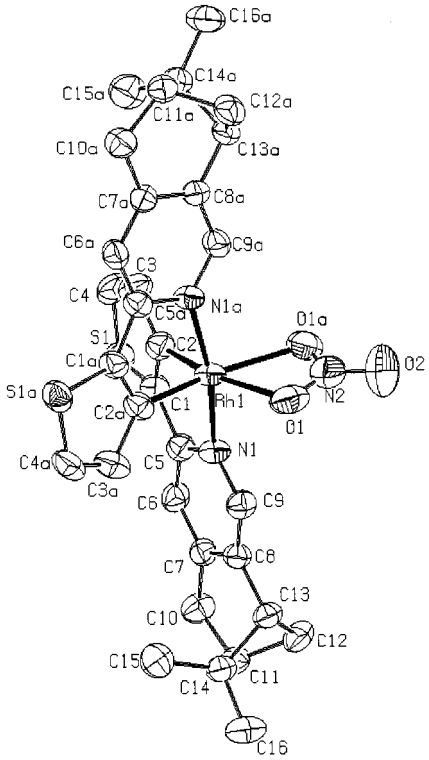

Figure 3a. Numbered ORTEP[18] plot with thermal ellipsoids represented at 50% probability level of **2**

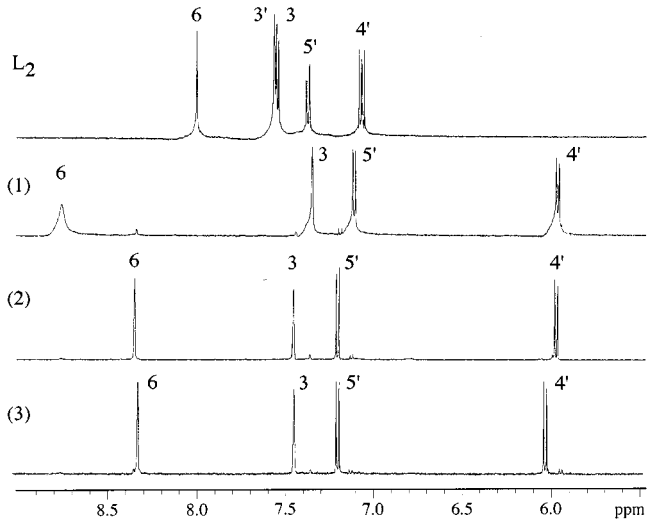

Figure 6. ^{1}H-NMR aromatic region spectra of $\Delta\Delta[Rh(L_2)_2(\mu\text{-}Cl)]_2$ (**1**), $\Delta[Rh(L_2)_2(NO_3)]$ (**2**), $\Lambda[Rh(L_2)_2(NO_3)]$ (**3**), (8*R*,10*R*)-2-(2′-thienyl)-4,5-pinenopyridine ($\mathbf{L_2}$)

(**2**), $\Lambda[Rh(L_2)_2(NO_3)]$ (**3**) complexes and the free ligand $\mathbf{L_2}$: (8*R*,10*R*)-2-(2′-thienyl)-4,5-pinenopyridine. Upon complexation with Rh^{III}, the signal corresponding to the proton 3′-H in the free (8*R*,10*R*)-2-(2′-thienyl)-4,5-pinenopyridine disappears. In agreement with the data from X-ray structure determination, the ^{1}H- and ^{13}C-NMR spectra indicate that the dinuclear complex $\Delta\Delta[Rh(L_2)_2(\mu\text{-}Cl)]_2$ (**1**) has D_2 symmetry and therefore all four ligands are equivalent. The ^{13}C-NMR spectrum of the $\Delta\Delta$ isomer shows 16 resonances; the signal at lowest field attributed to C-3′ is split due to the ^{13}C-^{103}Rh coupling (J_{Rh-C} = 36 Hz). The aromatic region of the ^{1}H-NMR spectra of the complexes is simple: Only four signals are observed due to the high symmetry. Relative to the free-ligand spectrum (see Figure 6) the proton chemical shifts of 4′-H, 5′-H and 3-H in all complexes appear upfield due to the positive ring current of the neighboring ligand coordinated at the same metal center. While the 5′-H and 3-H signals are only slightly shifted upfield, an important shift of ca. 1 ppm occurs for the signal of the 4′-H proton, which is pointing inside the pyridine ring of the neighboring ligand. There are three possible effects on the shift of the proton 6-H: (i) a deshielding by coordination to rhodium, (ii) a close proximity to the bridging Cl ligand, (iii) a negative ring current of the ligand situated at the other metal center. The corresponding signals of the two mononuclear complexes show a small downfield shift, and those of the $\Delta\Delta$ complex a much larger one. It seems therefore that in the mononuclear complexes Δ and Λ the shift of 6-H is mainly determined by the coordination to the rhodium center, whereas in the $\Delta\Delta$ isomer an additional influence in the same direction is observed, which is due to (iii). The limited solubility of the $\Delta[Rh(L_2)_2(NO_3)]$ (**2**) and $\Lambda[Rh(L_2)_2(NO_3)]$ (**3**) complexes in CD_3CN renders ^{13}C-NMR measurements impossible.

Electronic Spectra

The UV/Vis spectra of the dinuclear and mononuclear complexes show essentially two absorption bands at 282 and at 375 nm. These bands are likely to be due to charge transfer transitions.[5,9,10] Figure 7 shows the CD spectra of the Δ and Λ diastereomers of the mononuclear species. The near mirror symmetry of these spectra shows that the whole CD activity in this spectral range is mainly determined by the chiral configuration of the metal center.

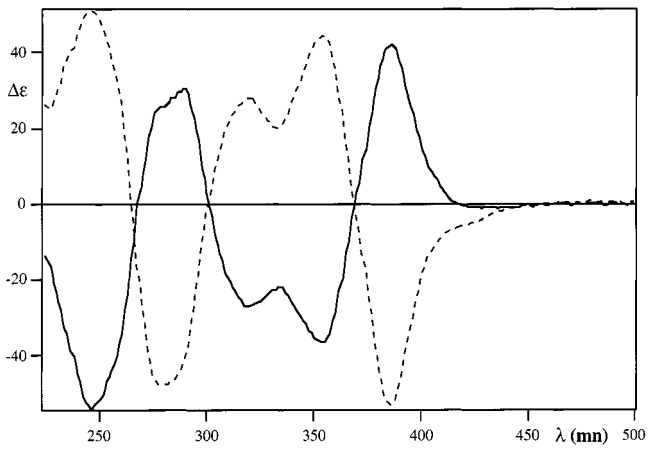

Figure 7. CD spectra of −−− $\Delta[Rh(L_2)_2(NO_3)]$ (**2**) and ---- $\Lambda[Rh(L_2)_2(NO_3)]$ (**3**) (c = 1.45 10^{-5} M in CH_3CN)

Conclusions and Outlook

The synthesis of the rhodium complexes with chiral thienylpyridine ligands yields two homochiral dimers (ΔΔ and ΛΛ), which are diastereomers, in a ratio of 9:1. The heterochiral dinuclear complex (ΔΛ) does not occur in measurable amounts. Through interactions between chiral ligands located at two adjacent metal centers, the absolute configurations of the latter are determined with a high selectivity. Cleavage of the dichloro bridge with NO_3^- or CH_3CN yields mononuclear species with predetermined chirality, since the configuration is retained during the cleavage reaction. As preliminary results indicate, stereochemically especially interesting reactions of this type occur with chiral diimines and diamines. The use of easily accessible chiral ligands thus gives the possibility of preparing stereoselectively Rh^{III} chelate complexes of various compositions. Such complexes may have interesting applications in the fields of bioinorganics[11] and photochemistry,[12][13] as well as in catalysis.

Experimental Section

General: All chemicals and reagent-grade products were obtained from Fluka, Aldrich or Merck and used, unless noted, without further purification. (+)-α-Pinene (> 97%; $[\alpha]_D^{20} = +45$), and (1*R*)-(−)-myrtenal (> 97%, $[\alpha]_D^{20} = -14.6$) were obtained from Fluka. The ligand $\mathbf{L_2}$ [(8*R*,10*R*)-2-(2′-thienyl)-4,5-pinenopyridine] and (2-thienylacetyl)pyridinium bromide were prepared according to literature procedures.[8] The enantiomer of $\mathbf{L_2}$ [(8*S*,10*S*)-2-(2′-thienyl)-4,5-pinenopyridine (abbreviated $\mathbf{L_2}'$)] was obtained analogously, starting from (+)-α-pinene, which was transformed into (+)-(*S*)-myrtenal by known procedures.[14] The product of crystallization of the artificial racemate {ΔΔ[Rh(L_2)$_2$Cl]$_2$ **(1)** ΛΛ[Rh(L_2')$_2$Cl]$_2$ **(5)**} was, in fact, {Δ[Rh(L_2)$_2$Cl(CH_3CN)] Λ[Rh(L_2')$_2$Cl(CH_3CN)]} (**6**) (see Results and Discussion), and was only characterized by X-ray structure analysis (see Figure 5).

Measurements: UV/Vis spectra were recorded with a Perkin-Elmer Lambda 5 and Perkin-Elmer Lambda 40 spectrometers; λ_{max} in nm, ε in <emphasis type="scaps">m^{-1} cm^{-1}. − NMR spectra were measured with a Varian Gemini-300 spectrometer operating at 300 MHz (for ^{1}H) and 75.46 MHz (for ^{13}C); δ in ppm with solvent as internal standard relative to $SiMe_4$, *J* in Hz. CD spectra: Jobin-Yvon and JASCO J-715 specropolarimeters; λ_{max} (Δε) in nm. − IR-spectral data were obtained with Perkin−Elmer 683 and Perkin−Elmer 16 PC FT-IR spectrometers; samples (1%) were compressed KBr pellets. − MS: VG-Instruments 7070E mass spectrometer equipped with an FAB inlet system. The elemental analyses were performed by CIBA Specialty Chemicals, Marly, Switzerland.

X-ray Structure Determination of ΔΔ[Rh(L_2)$_2$(μ-Cl)]$_2$ (1), Δ[Rh(L_2)$_2$(NO_3)] (2), Λ[Rh(L_2)$_2$(NO_3)] (3) and {Δ[Rh(L_2)$_2$Cl(CH_3CN)] Λ[Rh(L_2')$_2$Cl(CH_3 CN)]} (6). − Data Collection: Suitable orange block-like crystals of compounds **1** and **2**, and red block-like crystals of compound **3** were grown by slow diffusion of diethyl ether into CH_2Cl_2 solutions of the respective compounds. Suitable crystals of **6** were grown from a solution of CH_2Cl_2/CH_3CN as yellow plates. − Intensity data for compounds **1**, **2** and **6** were collected at 223 K with a Stoe Image Plate Diffraction System using graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å) and equipped with a φ circle. The image plate distance was 70 mm, φ scans of 0−200°, step Δφ = 1°, 2θ range 3.27−52.1°, resolution limits $d_{min} - d_{max}$ = 12.45−0.81 Å. − Intensity data for compound **3** was collected at room temperature with a Stoe AED2 4-circle diffractometer using graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å) with ω.2θ scans in the 2θ range 5−51°. Further crystallographic data are summarized in Tables 1 and 2.

Structure Solution and Refinement: The structure of compounds **1**, **2**, **3** and **6** were solved by direct methods with the program SHELXS-97.[15] The refinements and all further calculations were carried out with the program SHELXL-97.[16] For all four compounds the H atoms were included in calculated positions and treated as riding atoms with SHELXL-97[16] default parameters. The non-H atoms in all four compounds were refined anisotropically, using weighted full-matrix least squares on F^2. No corrections for extinction or absorption were applied. For all four compounds the coordinates correspond to the absolute structure of the molecules in the crystals. This is confirmed by reference to the absolute structure of the ligand used and the absolute structure factor parameters,[17] 0.13(9) for **1**, −0.16(7) for **2** and 0.03(5) for **3**. Compound **1** possesses crystallographic twofold symmetry and is associated with one whole molecule of diethyl ether, which is disordered over two sites related by a 2-fold axis (occupancy 0.5). Atoms C(9) and C(10) of one of the pinene ligands undergo considerable thermal motion. An attempt to split these atoms was unsuccessful leading to poor bond lengths and bond angles. Complex **2** crystallized with one molecule of dichloromethane per molecule of **2**. For compound **6** there are two independent molecules and two complete molecules of CH_3CN, one of which is disordered over two sites with occupancies of 0.5 each. The molecular structures and crystallographic numbering schemes are illustrated in the PLATON[18] drawings, Figures 1a, 3a, 4 and 5. − The CIF files, including complete tables of bond lengths, bond angles and torsion angles, have been deposited with the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ (UK). Deposition numbers are CCDC-114591 (**1**), -114592 (**2**), -114593 (**3**), -114594 (**6**).

Synthesis and Characterization

[Rh(L_2)$_2$(μ-Cl)]$_2$: With a modified literature procedure,[3] a mixture of $RhCl_3 \cdot 3H_2O$ (264 mg, 1 mmol) and th4,5ppy (766 mg, 3 mmol) was suspended in 20 mL of 2-methoxyethanol and dispersed during 10 min in an ultrasonic bath. The resulting solution, refluxed for 4 h, was concentrated and after addition of Et_2O, the brownish-orange precipitate was filtered off. Because the reaction was not complete, the unchanged ligand was recovered. The purification and separation of different diastereoisomers was done by preparative thin layer plate silica gel chromatography with CH_3CN/BuOH/H_2O/KNO_3 (4:1:1:0.1) as eluent. ΔΔ[Rh(L_2)$_2$(μ-Cl)]$_2$/Δ[Rh(L_2)$_2$(NO_3)]/Λ[Rh(L_2)$_2$(NO_3)] = 61.27:28.17:10.56. If KNO_3 is replaced by NaCl, a ratio ΔΔ[Rh(L_2)$_2$(μ-Cl)]$_2$/ΛΛ[Rh(L_2)$_2$(μ-Cl)]$_2$ of 9:1 is observed.

ΔΔ[Rh(L_2)$_2$(μ-Cl)]$_2$ (1): Yield (separation): 87 mg (27%). − ^{1}H NMR (CD_3CN, 300 MHz): δ = 8.76 (s, 4 H, 6-H), 7.37 (s, 4 H, 3-H), 7.13 (d, 4 H, ^3J = 4.8 Hz, 5′-H), 5.98 (d, 4 H, ^3J = 4.73 Hz, 4′-H), 3.14 (d, 8 H, ^3J = 2.48 Hz, 7-H), 2.97 (d×d, 4 H, ^4J = 5.5 Hz, ^3J = 5.5 Hz, 10-H), 2.78 (d×d×d, 4 H, ^2J = 9.7 Hz, ^3J = 5.8 Hz, ^3J = 5.9 Hz, 9-H^{exo}), 2.35 (t×d×d, 4 H, ^4J = 5.6 Hz, ^3J = 5.7 Hz, ^3J = 2.8 Hz, 8-H), 1.44 (s, 12 H, 13-H), 1.31 (d, 4 H, ^2J = 9.7 Hz, 9-H^{endo}), 0.78 (s, 12 H, 12-H). − ^{13}C NMR (CD_3CN, 75 MHz): δ = 165.59, 165.12 (quat), 160.3 (quat), 148.7 (tert), 147.4 (tert), 140.4 (quat), 135.5 (quat), 131.4 (tert), 127 (quat), 126.7 (tert), 45.4 (tert), 40.9 (tert), 40.1 (quat), 33.6 (sec), 32.3 (sec),

(8*S*,10*S*)-2-(2′-Thienyl)-4,5-pinenopyridine (L_2') (4): A method analogous to that already described for $\mathbf{L}_2$[8] was applied. A mixture of (2-thienylacetyl)pyridinium bromide (1.65 g, 6 mmol) in 10 mL of formamide, ammonium acetate (0.897 g, 11.6 mmol) (added under vigorous stirring) and (0.87 g, 6 mmol) of (+)-myrtenal was refluxed at 60°C for 16 h. The reaction was quenched by addition of water (10 mL) and the brownish solution was extracted with hexane (8 × 50 mL). After the mixture was dried with $MgSO_4$, the solvent was removed and an orange oil that solidified at 4°C was obtained. Yield: 75% (1.11 g). − ^{1}H NMR ($CDCl_3$, 300 MHz): δ = 8.07 (s, 1 H, 6-H), 7.50 (d×d, 1 H, ^3J = 3.7 Hz, ^4J = 1.2 Hz, 3′-H), 7.44 (s, 1 H, 3-H), 7.31 (d×d, 1 H, ^3J = 5.0 Hz, ^4J = 1.2 Hz, 5′-H), 7.07 (d×d, 1 H, ^3J = 5.0 Hz, ^3J = 3.7 Hz, 4′-H), 2.97 (d, 2 H, ^3J = 2.7 Hz, 7-H), 2.80 (d×d, 1 H, ^4J = 5.6 Hz, ^3J = 5.6 Hz, 10-H), 2.68 (d×d×d, 1 H, ^2J = 9.6 Hz, ^3J = 5.6 Hz, ^3J = 5.6 Hz, 9-H^{exo}), 2.28 (t×d×d, 1 H, ^4J = 5.6 Hz, ^3J = 5.6 Hz, ^3J = 2.7 Hz, 8-H), 1.38 (s, 3 H, 13-H), 1.20 (d, 2 H, ^2J = 9.6 Hz, 9-H^{endo}), 0.63 (s, 3 H, 12-H). − ^{13}C NMR ($CDCl_3$, 75 MHz): δ = 150.8 (quat), 145.7 (quat), 145.5 (quat), 145.2 (tert), 141.2 (quat), 127.8 (tert), 126.6 (tert), 123.5 (tert), 118.3 (tert), 44.4 (tert), 40.0 (tert), 39.3 (quat), 32.8 (sec), 31.9 (sec), 26.0 (prim), 21.4 (prim). − MS (EI); *m/z* (%): 255 (20) [M$^+$], 240 (10) [M$^+$ − CH_3], 212 (100) [M$^+$ − C_3H_7]. − UV/Vis (CH_2Cl_2): λ (ε) = 307 (15545), 292 (sh), 229 (6281). − IR (KBr): $\tilde{\nu}$ = 2920 (s), 1596 (w), 1536 (w), 1474 (m), 1384 (m), 1262 (w), 1220 (w), 1128 (w), 1054 (w), 942 (w), 828 (w), 692 (s) cm^{-1}. − $C_{16}H_{17}NS$ (255.38): calcd. C 75.25, H 6.71, N 5.48, S 12.55; found C 74.98, H 6.72, N 5.63, S 12.63.

ΛΛ[Rh(L_2')$_2$(μ-Cl)]$_2$ (5): This compound was synthesized as described for [Rh(L_2)$_2$m-Cl)]$_2$. Preparative thin layer plate silica gel chromatography with CH_3CN/BuOH/H_2O/KCl/NaCl (4:1:1:0.05:0.05) as eluent was used for the purification and separation of the different diastereoisomers. A ratio of ΛΛ[Rh(L_2')$_2$(μ-Cl)]$_2$/ΔΔ[Rh(L_2')$_2$(μ-Cl)]$_2$ = 9:1 was obtained. All data are identical with those of ΔΔ[Rh(L_2)$_2$(μ-Cl)]$_2$ except for the mirror-image CD spectra.

{Δ[Rh(L_2)$_2$Cl(CH_3CN)] Λ[Rh(L_2')$_2$Cl(CH_3CN)]} (6): This compound was obtained by "crystallization" of ΔΔ[Rh(L_2)$_2$(μ-Cl)]$_2$ and ΛΛ[Rh(L_2')$_2$(μ-Cl)]$_2$ from a CH_2Cl_2/CH_3CN mixture.

Acknowledgments

The authors wish to thank Raf Bruyndonckx for graphical representation of the ΛΛ and ΔΔ diastereomers and the Swiss National Science Foundation for financial support.

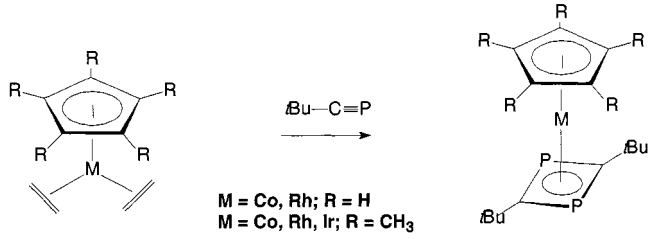
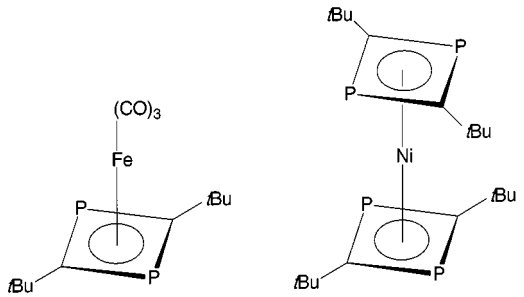
A Density Functional Study of the Dimerization of Phosphaalkynes in the Presence of Transition Metal Fragments



Steven Creve,[a] Minh Tho Nguyen,*[a] and Luc G. Vanquickenborne[a]

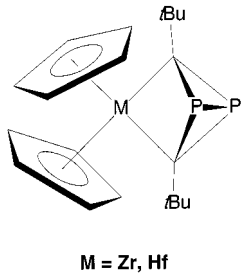
Keywords: Phosphaalkynes / Dimerization mechanism / Diphosphacyclobutenes / Density functional theory / Ab initio calculations

The dimerization of phosphaalkynes (R–C≡P, R = H, Me, *t*Bu) without and with the presence of transition metal fragments, including CpCo (Cp = cyclopentadienyl) and COT–Ti (COT = cyclooctatetraene), has been probed using density functional theory calculations (B3LYP with different basis sets). MP2 and CCSD(T) calculations were also performed for the $[H_2C_2P_2]$ systems. In an attempt to address the exciting controversy and uncertainty about phosphaalkyne dimerization, a number of dimer formation mechanisms proposed in the literature have been examined. Some new and plausible intermediates have also been identified.



1. Introduction

In 1986, two independent groups[1][2] first reported the cyclodimerization of a phosphaalkyne (R−C≡P) in the coordination sphere of cobalt, rhodium, and iridium centers, yielding a 1,3-diphosphacyclobutadiene ring (referred to hereafter as 1,3-DPCB), as shown in Scheme 1.



Scheme 1. Formation of 1,3-DPCB in metal complexes

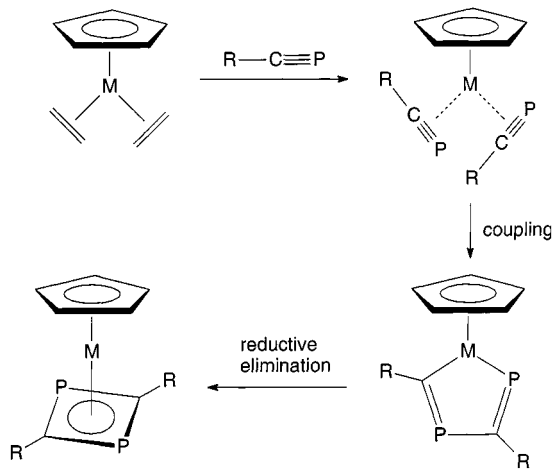
Soon afterwards, other similar complexes containing iron were discovered,[3][4] as well as a sandwich complex of nickel containing two 1,3-DPCB rings[5] (Scheme 2).

Scheme 2. Observation of 1,3-DPCB in Fe and Ni complexes

With Zr or Hf as metallic center, however, a 1,3-diphosphabicyclo[1.1.0]butanediyl ligand was shown to be formed[6][7] (Scheme 3).

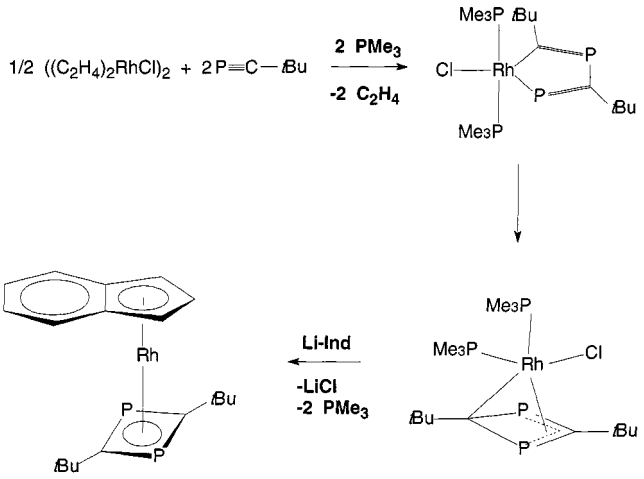
Scheme 3. Observation of bicyclic dimers in Zr, Hf complexes

Interestingly, it has been proven extremely difficult, if not impossible, to displace the η^4-ligated $P_2C_2tBu_2$ rings from any of these cornplexes, which is in clear contrast to the behavior of analogous cyclobutadiene rings.



As far as the formation of the 1,3-DPCB complexes is concerned (Scheme 4), it has been assumed that first a bis(π-phosphaalkyne) complex is formed, followed by a coupling process to give a 1-metalla-2,4-diphosphacyclopentadienyl complex. The latter can than undergo a reductive elimination yielding the product 1,3-DPCB complex. This mechanism was postulated by analogy to the reaction sequence taking place when cyclobutadiene complexes are formed out of alkynes.[8][9]

Further evidence for this reaction mechanism was provided by Binger et al. who found the existence of a 1,4-diphospha-2-rhodacyclopentadiene species as intermediate in the formation of the 1,3-DPCB complex[10] (Scheme 5). These authors were able to characterize the 1,4-diphospha-2-rhodacyclopentadiene species by X-ray diffraction studies.



However, no clear-cut evidence has been found yet proving or disproving that the mechanisms of formation of other complexes (such as shown in Schemes 1 and 2) also proceed via 1-metalla-2,4-diphosphacyclopentadienyl inter-

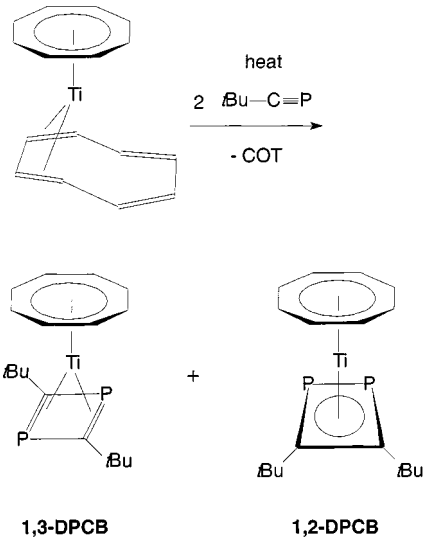
Scheme 4. Proposed formation mechanism of 1,3-DPCB involving metallacyclobutadiene intermediate



Scheme 5. Proposed formation mechanism of 1,3-DPCB in Rh complexes

mediates. Another interesting point is that, when using Co or Rh as metallic center, a 1,2-diphosphacyclobutadiene complex has never been detected (referred to hereafter as 1,2-DPCB). In fact, the first example of a 1,2-DPCB complex has only recently been characterized by making use of titanium[11][12] (Scheme 6).

In the case of Ti, both the 1,3-DPCB and 1,2-DPCB complexes have been found. While the latter has a large delocalization of electrons within the ring, the former shows two short and two long P−C bonds. Again, this is in contrast to the 1,3-DPCB complexes of Co and Rh, where the carbon-phosphorus ring is also largely delocalized. Without the presence of metal compounds, a cyclotetramerization of phosphaalkynes has been found upon heating, which leads to a tetraphosphacubane.[13] Formation of the latter has been postulated to involve a 1,3-DPCB intermediate.

In our previous work,[14] different equilibrium and transition structures on the $[C_2H_2P_2]$ potential energy surface have been calculated. It turned out that 1,2-DPCB tends to be more stable than the 1,3-DPCB by about 30−40 kJ/mol.

Scheme 6. Formation of both 1,3- and 1,2-DPCB when Ti complexes were used

Moreover, the activation energy for 1,2-DPCB formation in a head-to-head approach is also smaller.

All facts considered, a number of intriguing questions remain unanswered:

- Why is, in the case of Co and Rh, only the 1,3-DPCB complex found, and not the 1,2-DPCB, although the latter is more stable in free form, as found in previous work?[14]
- Concerning the free DPCB species, what is the influence of bulkier substituents on the carbon atoms, i.e. how large are steric effects in these systems? As a matter of fact, the available experiments have usually been carried out with phosphaalkynes R−C≡P where R = *t*Bu or other sterically hindered substituents.
- With Ti as metallic center, both 1,2-DPCB and 1,3-DPCB complexes are found. Remarkably, however, the 1,3-DPCB complex shows two different P−C bond lengths, in contrast to the Co and Rh cases, where a more delocalized DPCB ring is obtained.
- Finally, is the mechanism via metallacyclobutadiene intermediates indeed a valid reaction scheme?

In an attempt to obtain more insight into this interesting area of low-coordinated phosphorus chemistry, a computational study has been carried out on free DPCB species on the one hand ($R_2C_2P_2$, with R = H, CH_3, and *t*Bu), and some representative metal complexes on the other hand [Cp−Co−($R_2C_2P_2$), with R = H, CH_3, and Cp = cyclopentadienyl; COT−Ti-($H_2C_2P_2$) with COT = cyclooctatetraene].

2. Computational Details

The species considered include the important $[R_2C_2P_2]$ isomers with R = H, CH_3, and *t*Bu, [Cp−Co−($R_2C_2P_2$)] isomers (R = H, CH_3; Cp = cyclopentadienyl), and a number of COT−Ti-$[H_2C_2P_2]$ isomers (COT = eyclooctatetra-

ene). For the sake of comparison, we also calculated some isomers of Cp−Co−[H_4C_4].

All geometries have been optimized using the B3LYP density functional[15][16] with the 6−31G(d,p) basis set. For the metal elements, a (14s,9p,5d)/[8s,5p,3d] basis set was used,[17] augmented by two p functions,[18] one d function,[19] and one f function. For the free species ($R_2C_2P_2$) with R = H and CH_3, harmonic vibrational analyses have been performed as well at the B3LYP/6−31G(d,p) level. MP2 geometry optimizations using the 6−31G(d,p) basis set have been performed for the [$H_2C_2P_2$] compounds, including vibrational analysis. To obtain improved relative energies, coupled cluster CCSD(T)/6−311+G (2df,p) single-point calculations using the MP2-optimized geometries as well as B3LYP/6−311+G(2df,p) single-point calculations have also been carried out for the [$H_2C_2P_2$] isomers.

While the Gaussian 98 electronic structure program[20] was used for calculating the uncomplexed species, the Mulliken software[21] was used for calculations on complexed species. Both the geometry optimizations in Gaussian 98 and in the Mulliken software were performed with a convergence criterion of $4.5 \cdot 10^{-4}$ Hartree/Bohr for the gradients.

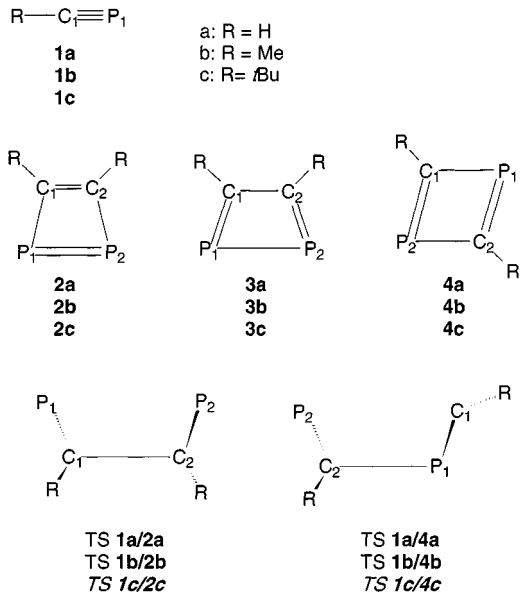


Figure 1. Schematic representations of noncomplexed species considered, along with the labeling conventions; labels in *italics* refer to species mentioned in the text, but not actually computed in this work

3. Results and Discussion

3.1 Uncomplexed Dimerization Products

Figure 1 shows schematic representations of the uncomplexed species considered in this work, along with the labeling conventions used throughout. Tables 1 and 2 contain the optimized geometrical parameters and relative energies, respectively. The minima considered include the free phosphaalkynes **1a−c**, the two valence isomers of 1,2-DPCB **2a−c** and **3a−c**, and 1,3-DPCB **4a−c**. While **1a/2a** and **1b/2b** are transition states for the so-called "head-to-head" cycloaddition of two RCP molecules leading to 1,2-DPCB, **1a/4a** and **1b/4b** describe the "head-to-tail" reaction yielding 1,3-DPCB. In the following paragraphs, mentioned geometrical parameters refer to the B3LYP-optimized values, unless otherwise noted.

Table 1. B3LYP/6−31G(d,p)-optimized bond lengths [Å] and angles [°] for the differently substituted uncomplexed diphosphacyclobutadienes under consideration; values in parentheses refer to MP2/6−31G(d,p)-optimized parameters (see Figure 1 for definition of structures and atom labels)

3.1.1 Dimerization of the Parent H−C≡P

Concerning the dimerization products of HCP, it is seen from Table 2 that these products are all bound with respect to the free phosphaalkynes. This fact is reproduced at all levels of theory, including B3LYP, MP2, and CCSD(T), with one exception, being **4a** at the MP2 level.

Both valence isomers **2a** and **3a** of the head-to-head dimers exist. While **2a** clearly shows a C=C bond (1.330 Å) and a P=P bond (2.071 Å), the reverse is seen for **3a**, having single C−C and P−P bonds (1.463 and 2.488 Å, respectively) and double C=P bonds (1.698 Å). Both **2a** and **3a** possess a trapezoid structure. Of the two valence isomers, **2a** with C=C and P=P π bonds is the most stable, lying 11 kJ/mol below **3a** at the B3LYP level and 12 kJ/mol at the C0SD(T) level.

The head-to-tail dimer **4a** has a parallelogram structure, with clearly distinguishable alternating single C−P and double C=P bonds (1.925 and 1.679 Å, respectively). The C−P−C angles turn out to be somewhat smaller than 90° (81.10); consequently, the P−C−P angles are larger than 90° (98.9°). **4a** turns out to be the least stable of the isomers considered here. Although it is bound by more than 20 kJ/mol with respect to the free phosphaalkyne at the B3LYP

and CCSD(T) levels, MP2 predicts it to be less stable than the separated monomers.

For the dimerization reaction, two transition states have been located. While TS **1a/2a** connects the free HCP molecules to the 1,2-DPCB having C=C and P=P π bonds, TS **1a/4a** represents the transition structure for head-to-tail dimerization. At the B3LYP level, the head-to-head process has an energy barrier of 98 kJ/mol, and the head-to-tail reaction passes over a 165 kJ/mol energy barrier. While MP2 is in good agreement with B3LYP and CCSD(T) concerning the former process, the MP2 head-to-tail energy barrier is considerably overestimated with respect to the B3LYP or CCSD(T) values. Most likely, this is due to the fact that MP2 is not able to treat nondynamical correlation energy, whereas the DFT and CCSD(T) can do so to some extent (vide infra). Qualitatively, however, all levels of theory confirm that the head-to-head product **2a** is both kinetically and thermodynamically favored over its head-to-tail counterpart.

In agreement with results of previous work,[14] the two HCP monomers approach each other in nearly perpendicular planes to form the 1,2- and 1,3-DPCB (TS **1a/2a** and **1a/4a**). In TS **1a/2a**, formation of the CP bond has clearly progressed further than the PP bond (C_1C_2 = 1.908 Å, in contrast to P_1P_2 = 4.068 Å). The same behavior is seen in TS **1a/4a**, where one forming CP bond is markedly shorther than the other (C_2P_1 = 1.960 Å versus C_1P_2 = 3.051 Å). Both transition structures thus imply a highly asynchronous formation of the two new chemical bonds. This suggests a radical mechanism for this symmetry-forbidden [2+2] cycloaddition.

In general, no severe geometrical differences between the MP2- and B3LYP-optimized structures are found. Concerning relative energies, however, a close examination of Table 2 shows that, while B3LYP yields results in excellent agreement with the CCSD(T) values, MP2 is often in considerable error with the CCSD(T) level.

It has to be noted, finally, that a proper description of the dimerization process of R−C≡P species requires a treatment using a multi-configurational wavefunction (MCSCF).

However, such a treatment is beyond the scope of the present work. Note also that density functional methods are generally believed to incorporate at least some part of the nondynamical correlation. Therefore, in view of the good agreement between our B3LYP and CCSD(T) calculations, we think that the present calculations provide a sufficiently accurate basis for drawing the conclusions described above.

3.1.2 Dimerization of Me−C≡P and *t*Bu−C≡P

In an attempt to tackle the question posed in the introduction concerning the influence of bulkier substituents on C, B3LYP calculations have been carried out for the heavier phosphaalkynes MeCP and *t*BuCP. Due to limitations in computational resources, harmonic frequency calculations have not been carried out for the latter, and TS **1c/2c** and **1c/4c** have not been calculated.

Substitution of H in the parent phosphaalkyne by CH_3 yields the following relative energy ordering for the dimers: **2b** < **3b** <**4b**, in analogy with the parent species. However, the stability with respect to the free phosphaalkynes is considerably changed upon Me substitution. The 1,3-DPCB **4b** lies now even higher in energy than the monomers. The reason for this alteration of relative stabilities has probably to be found in the stabilization of the monomers by larger alkyl substituents. The energy difference between **2b** and **4b** amounts to 48 kJ/mol, and has thus been decreased with respect to the unsubstituted case (53 kJ/mol). This fact possibly points to a slight destabilization of the 1,2-DPCB **2b** due to steric interactions between the two methyl groups. Another indication for steric repulsion between the methyl groups is found in the RC_1C_2 angle of **2b** which is 2.6° larger than the corresponding value for **2a**. The transition structures for head-to-head and head-to-tail cycloaddition reactions are found at 130 kJ/mol and 204 kJ/mol, respectively, relative to the monomers. As a consequence, the energy barriers have been increased with respect to the HCP case (due to stabilization of the MeCP monomers), whereas the relative ordering of the two TSs has remained nearly constant. Proceeding in the opposite direction, both DPCBs become less stable with regard to cycloreversion.

Replacing the hydrogen atom by the sterically demanding *t*Bu groups has considerable consequences on the relative stabilities. Only the 1,2-DPCB **2c** and 1,3-DPCB **4c** are stabilized with respect to the free monomers. The corresponding stabilization energies, however, amount to only 6 and 3 kJ/mol, respectively. It thus seems that replacing Me by *t*Bu further stabilizes the monomers. The energy gap between the two valence isomers **2c** and **3c** has further increased to 16 kJ/mol, whereas it was 6 kJ/mol for **2a-3a** and 10 kJ/mol for **2b-3b**. Most remarkable is the fact that the energy difference between the head-to-head adduct **2c** and

the head-to-tail dimer **4c** has decreased to only 3 kJ/mol, in favor of the former. This points to a considerable destabilization of **2c** by steric hindrance of the *t*Bu groups. Again, this observation is in agreement with an RC_1C_2 angle of 137.3° in **2c**, as compared with that of 129.7° for **2a**.

3.2 Metal Complexes of the R−C≡P Dimers

Overviewing the results gathered from calculations on the free R−C≡P dimers, it turns out that in all cases considered, the 1,2-DPCB dimer is the more stable. Therefore, it is most intriguing why, in the presence of transition metal fragments of Co, Rh, Ir, Fe, and Ni (see Schemes 1 and 2), only the 1,3-DPCB complexes are found. Interestingly, when Ti is used, both dimers are found (see Scheme 6). We have therefore carried out calculations on the model compounds shown in Figure 2. Two transition metal fragments have been considered: the 14e⁻ CpCo fragment (Cp cyclopentadiene) and the 12e⁻ COT−Ti fragment (COT = cyclooctatetraene). The calculations include full B3LYP geometry optimizations and energy calculations. The basis sets used are specified in a previous section. Optimized geometrical parameters and relative energies of the complexes considered are shown in Tables 3 and 4, respectively.

3.2.1 Cobalt Complexes of H−C≡P Dimers

While the uncomplexed 1,2-DPCB and 1,3-DPCB clearly show alternating single and double bonds, their complexed counterparts CpCo-**2a** and CpCo-**4a** have bond lengths between single and double [r(CC) ≈ 1.41 Å, r(CP) ≈ 1.81 Å, and r(PP) ≈ 2.23 Å). Complexation of the dimers thus yields a shortening of the single bonds and a lengthening of the double bonds. This is a geometrical indication that the DPCB rings become less antiaromatic if complexed to

a CpCo fragment. Another indication of this behavior is the fact that complexation of **4a**, which has a parallelogram structure, leads to CpCo-**4a** where the diphosphacyclobutadiene unit exhibits a rhombic structure with four equal CP bond lengths.

Concerning the relative stabilities of both CpCo-**2a** and CpCo-**4a**, it seems that complexation has not much altered the situation with respect to the free dimers. While in free form, 1,2-DPCB lies 53 kJ/mol below 1,3-DPCB (B3LYP), in complexed form this energy gap is slightly decreased to 46 kJ/mol. Experimentally observed complexes of CpCo, however, are formed of *t*BuCP instead of HCP. In the previous seetion, it was calculated that the **2a − 4a** energy gap decreases from 53 kJ/mol to 3 kJ/mol for **2c − 4c**. By transferring this energy effect to the CpCo-**2a** − CpCo-**4a** energy difference, one can estimate the energy gap between CpCo-**2c** and CpCo-**4c** to be −5 kJ/mol, in favor of the latter. Even if such a crude approximation would be correct, the energy difference is too small and as such it could not explain why exclusively CpCo-**4a** complexes are found experimentally, and not the CpCo-**2a** complexes. Therefore, it seems necessary to take a closer look at the way the DPCB complexes are formed.

It has been proposed in the literature,[6][22] that the formation of diphosphacyclobutadiene complexes proceeds by the reaction sequence shown in Scheme 4, in analogy with that of cyclobutadiene complexes resulting from bis(π-acetylene) complexes.[8][9] Therefore, a number of additional structures have also been calculated. These include the bis(π-phosphaalkyne) complexes CpCo-**6a** and CpCo-**7a**, and four possible cobalt species CpCo-**8a**−CpCo-**11a**. For the sake of comparison, the all-carbon analogues, shown in Figure 3, have been computed as well. For the latter molecules, Table 4 shows that the bis(π-acetylene) complex **B** lies higher in energy than the CpCoCb complex **A** by 237 kJ/mol. The cobalt complex **C** is found at an intermediate position of 173 kJ/mol. Hence, the **B** → **C** → **A** reaction seems possible for these species, and it has indeed been found experimentally.[8][9] A different situation appears when the acetylene molecules are replaced by H−C≡P species. Two bis(π-phosphaacetylene) complexes are possible, CpCo-**6a** and CpCo-**7a**. While in the former complex, the two HCP molecules are side-on coordinated in a head-to-head fashion, the latter complex has them oriented in a head-to-tail manner. The complexes are found at 247 and 245 kJ/mol above CpCo-**2a**, respectively, which is very similar to the situation of **A** and **B**. However, the cobalt complexes CpCo-**8a**, CpCo-**9a**, CpCo-**10a**, and CpCo-**11a** are found at a much higher relative energy than the bis(π-phosphaacetylene) complexes. Note that CpCo-**11a** has been calculated only for the sake of completeness, since it seems not possible that CpCo-**11a** can be formed starting from CpCo-**6a** or CpCo-**7a**. The relative energies of these cobalt complexes range from 308 to 349 kJ/mol, with respect to CpCo-**2a**. Hence, it is unlikely that these species intervene as intermediates, such as shown in Scheme 4. In this respect, it is noteworthy that direct fragmentation of a complexed cyclobutadiene ligand into two acetylene ligands, without prior formation of a cobaltacyclopentadiene intermediate, has been observed.[23] This result suggests that the reverse − direct formation of cyclobutadiene out of two acetylene ligands − is also possible. Since the cobalt intermediates appear to be too high in relative energy in the case of diphosphacyclobutadiene complexes, it is tempting to say that a direct reaction of CpCo-**6a** or CpCo-**7a** to CpCo-**2a** or CpCo-**4a** might be possible.

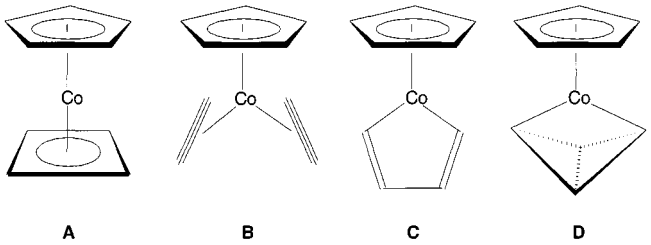

Figure 3. Schematic representations of the all-carbon complexes considered, along with the labeling conventions

Since Zr and Hf complexes containing a 1,3-diphosphabicyclo[1.1.0]butanediyl ligand have been found experimentally[6][7] (Scheme 3), the cobalt analog CpCo-**5a** has also been calculated. It is found at 256 kJ/mol relative to CpCo-**2a**. Note that CpCo-**5a** was optimized within C_s symmetry (MC_1C_2 mirror plane). Releasing all symmetry constraints yielded CpCo-**12a**, shown in Figure 4, which still possesses C_s symmetry, but now with an MP_1P_2 mirror plane. This structure, which has so far not been reported in the literature, possesses a tilted 1,3-diphosphabicyclo[1.1.0]-butanediyl ligand, so that a bond between Co and P_1 is formed. Selected geometrical parameters of this molecule are given in Table 5. While the C_1P_1 bond length amounts to 1.951 Å, indicating a single bond, the C_1P_2 distance of 1.811 Å suggests a partial double bond character between the C_1 and P_2 atoms. The folding angle $C_1P_1P_2C_2$ of 100.4° shows that the 1,3-diphosphabicyclo[1.1.0]butanediyl unit has opened up by about 8° with respect to CpCo-**5a**. The most striking feature of this molecule, however, is its energy. CpCo-**12a** is found at 181 kJ/mol relative to CpCo-**2a** and thus well below the bis(π-phosphaalkyne) complexes CpCo-**6a** and CpCo-**7a** (Table 4). Most likely, flattening of the 1,3-diphosphabicyclo[1.1.0]butanediyl unit in CpCo-**12a** *uniquely* leads to the 1,3-DPCB complex CpCo-**4a**. Therefore, CpCo-**12a** should be regarded as an important candidate for an intermediate in the formation of CpCo-**4a**.

3.2.2 Cobalt Complexes of CH_3−C≡P Dimers

In order to check the influence of larger R substituents on phosphaalkynes, the methyl analogues CpCo-**2b**−CpCo-**11b** have also been calculated (see Figure 2). It is seen from Table 4 that substituting H by CH_3 has a rather moderate effect on the relative energies. The energy gap between the 1,2-DPCB complex CpCo-**2b** and the 1,3-DPCB complex CpCo-**4b** has slightly increased with respect to the hydrogen analogues. The cobalt complexes CpCo-**8b**−CpCo-**11b** are now found at an even higher relative energy than was the

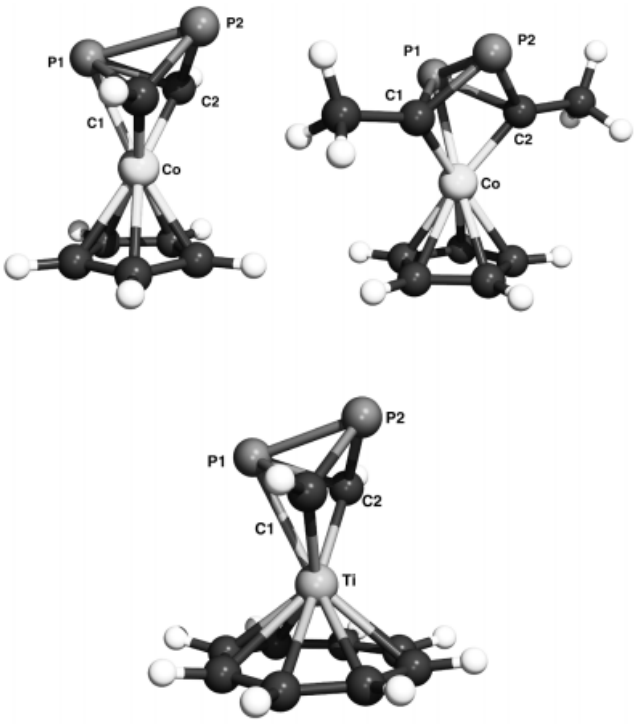

Figure 4. B3LYP-optimized structures of CpCo-**12a**, CpCo-**12b** and COT−Ti-**12a**

Table 5. B3LYP/6-31G(d,p)-optimized bond lengths [Å] and angles [°] of the CpCo-**12a**, CpCo-**12b** and COT−Ti-**12a** structures

	CpCo-**12a**	CpCo-**12b**	COT-Ti-**12a**
MP_1	2.299	2.299	2.625
MP_2	2.891	2.877	3.123
MC_1	1.907	1.908	2.104

$C_1P_1P_2C_2$	100.4	101.1	98.2

case for their hydrogen analogues. Hence, in the case of methyl substitution, it is also likely that the proposed reaction mechanism of Scheme 4 is not valid. The complex containing a tilted 1,3-diphosphabicyclo[1.1.0]butanediyl ligand CpCo-**12b** has also been located and is found at a relative energy of 190 kJ/mol. Hence, similar to the case for R = H, it possibly represents an important intermediate in the formation of DPCB complexes. As CpCo-**4b** represents the best approximation to the structure of the experimentally known CpCo-**4c**, some geometrical parameters of the latter have also been included in Table 3. While the calculated metal−phosphorus distances are somewhat longer than the experimental value (by about 0.02 Å), the metal−carbon bond is slightly underestimated by 0.01 Å. The other parameters are in good agreement with experimental values, and the geometry obtained using B3LYP optimization thus seems very reliable.

Since the Cp_2Zr complex of the 2,4-di-*tert*-butyl-1,3-diphosphabicyclo[1.1.0]butanediyl ligand is known[6] (see Scheme 3), it is also worth comparing the experimental geometry with calculated values for CpCo-**5b**. Table 3 shows that B3LYP yields good values for the C_1P_1 and P_1P_2 distances. The folding angle $C_1P_1P_2C_2$, however, is considerably overestimated with respect to the experimental one (93.4° versus 70°). Note, though, that the latter effect could be due to steric interactions of the two Cp ligands with the *t*Bu groups.

3.2.3 Titanium Complexes of H−C≡P Dimers

The situation changes quite drastically when COT−Ti is used as the complexing metal fragment (COT = cyclooctatetraene). Only complexes of the HCP molecule have been investigated in conjunction with this metal fragment, since our available computational resources did not allow larger systems to be calculated.

The energy difference between the 1,2-DPCB complex COT−Ti-**2a** and the 1,3-DPCB complex COT−Ti-**4a** amounts to 54 kJ/mol, in favor of the former. Both bis(π-phosphaalkyne) complexes COT−Ti-**6a** and COT−Ti-**7a** are found at about 270 kJ/mol above COT−Ti-**2a**.

So far, the situation is quite analogous to the case of cobalt complexes. However, more serious differences appear when turning our attention to the metalla complexes. The complexes COT−Ti-**8a** and COT−Ti-**10a** are now lying well below the bis(π-phosphaalkyne) complexes in relative energy. As such, for COT−Ti complexes, these findings support the reaction mechanism shown in Scheme 4. Another important difference − as compared with the cobalt complexes − concerns the COT−Ti-**5a** species, which contains a 1,3-diphosphabicyclo[1.1.0]butanediyl ligand. While in the case of Co, it was found at relative energies of 250−270 kJ/mol, it is now located at 174 kJ/mol. Hence, COT−Ti-**5a** is likely to be accessible from the bis(π-phosphaalkyne) complexes, and thus it possibly represents an important intermediate. In analogy to the CpCo-**12a** complex, containing a tilted 1,3-diphosphabicyclo[1.1.0]butanediyl ligand, COT−Ti-**12a** has also been located. While its geometry is shown in Figure 4, the corresponding optimized parameters are given in Table 5. Apart, of course, from the MC and MP distances, all values are very similar to the ones derived for CpCo-**12a** and CpCo-**12b**. The relative energy of the species COT−Ti-**12a** is calculated to be 163 kJ/mol with respect to COT−Ti-**2a**. Hence it is only 11 kJ/mol more stable than its analog containing a nontilted 1,3-diphosphabicyclo[1.1.0]butanediyl ligand. The species COT−Ti-**5a** and -**12a** as well as the metalla complexes COT−Ti-**8a**−COT−Ti-**10a** should be considered accessible from the bis(π-phosphaalkyne) complexes. This implies that all of them possibly represent important intermediates in the formation of DPCB complexes. Note that, in the case of Ti complexes, the complex COT−Ti-**11a** could not be located, in contrast to CpCo-**11a** and CpCo-**11b**.

As far as geometry is concerned, both COT−Ti-**2c** and COT−Ti-**4c** have been characterized experimentally by X-

ray diffraction.[11] Their geometrical parameters are also shown in Table 3. For these species, B3LYP seems to overestimate slightly the metal−phosphorus bond lengths by about 0.02 Å, while the reverse trend is noted for the metal −carbon distances (an underestimation of about 0.05 Å). The most striking discrepancy between experimental and optimized geometries is the fact that, for the 1,3-DPCB complex, B3LYP yields a rhombic C_2P_2 ligand, having four equal C−P distances, while the experimentally resolved structure shows alternating single and double C−P bonds. At this point, however, it is not elear whether such an inconsistency originates from either a shortcoming of the B3LYP method or an effect of crystal packing or even an electronic effect of the *t*Bu groups.

4. Conclusions

In an attempt to tackle some points of controversy and uncertainty concerning the formation and relative stabilities of DPCB complexes, calculations have been carried out on a number of important isomers of $[R_2C_2P_2]$ with R = H, CH_3, and *t*Bu, [Cp−Co−$(R_2C_2P_2)$] isomers (R = H, CH_3; Cp = cyclopentadienyl), and isomers of COT−Ti-$[H_2C_2P_2]$. Several of these points have been addressed, which lead to new insights into the chemistry of DPCB complexes.

• Concerning the uncomplexed species, the calculations confirm the previous results that the valence isomer of 1,2-DPCB having π bonds between the two C atoms and between the two P atoms tends to be the most stable diphosphacyclobutadiene. The other isomer is found 6 kJ/mol higher in energy for R = H, 10 kJ/mol for R = Me and 16 kJ/mol for R = *t*Bu. The 1,3-DPCB is considerably less stable than 1,2-DPCB for both R = H and Me (53 and 48 kJ/mol, respectively). Only for R = *t*Bu, the 1,2 and 1,3 dimers are found rather close in energy. The fact that the head-to-head dimer turns out to be the most stable, even when large substituents are used, emphasizes its intrinsic stability.

Calculation of the energy barriers for the cycloaddition of two R−C≡P molecules, confirms that the head-to-head reaction is not only thermodynamically favored, but also kinetically.

For the parent species (R = H), MP2, and CCSD(T) calculations show that B3LYP yields good results as compared to CCSD(T), whereas the MP2 method is often in considerable deviation with the CCSD(T) level.

• Calculations on the diphosphacyclobutadiene complexes of CpCo show that the relative stability of the head-to-head product versus the head-to-tail product remains almost unchanged as compared to the uncomplexed dimers. In order to check the reaction mechanism proposed in the literature, a number of additional complexes have been calculated, including cobalta species. Due to their high energy content, it is suggested that the 1-cobaltadiphosphacyclopentadiene complexes are unlikely to act as intermediates in the formation of diphosphacyclobutadiene ligands out of bis(π-phosphaalkyne) complexes. This observation is in sharp contrast to the available experimental observations for the all-carbon CpCoCb complexes. However, a rather remarkable and so far unknown species has been located theoretically, containing a tilted 1,3-diphosphabicyclo-[1.1.0]butanediyl ligand. In view of its relative energy, the latter complex is more likely to be an intermediate in the formation of diphosphacyclobutadiene complexes than the cobalta species.

An extension has also been made from R = H to R = Me. Theoretical findings show, however, that substituting H by Me does not affect the conclusions drawn above.

• While the COT−Ti complexes behave rather analogously to the CpCo complexes, one major difference is detected. The metalla ring intermediates, that turn out to be too high in relative energy in the case of CpCo complexes, seem now to be valuable candidates to intervene in the formation of COT−Ti DPCB complexes. As such, in the case of Ti complexes, several routes leading from the bis(π-phosphaalkyne) to the diphosphacyclobutadiene complexes seem to be possible. This fact may explain the experimental detection of complexes of both the 1,2- and 1,3-dimers.

A characterization of the complexes considered in this work by harmonic frequency analysis, as well as the location of transition structures connecting the various complexed species, seem thus necessary for a full understanding of the formation of diphosphacyclobutadiene complexes. At this very moment, these calculations are unfortunately quite beyond our computational limits. Nevertheless, we believe that the presented results add several new insights into this interesting problem in low-coordinated phosphorus chemistry.

Keywords: Aluminum / Lead / O ligands / Alkoxy carboxylates / Structure elucidation

A novel heterometallic aggregate $Pb_2Al_5(\mu_3\text{-}O)(\mu_4\text{-}O)(\mu\text{-}O\textit{i}Pr)_9(O\textit{i}Pr)_3(\mu\text{-}OAc)_3$ obtained from the interaction of $Pb(OAc)_2$ and $Al(O\text{–}\textit{i}Pr)_3$ is the first structurally characterized example based on lead and aluminum. This compound has been isolated in high yield and examined by ^{1}H-, ^{13}C-, and ^{27}Al NMR, and in the solid state by X-ray crystallography.

Introduction

The use of heterometallic alkoxides[1–3] as precursors for mixed metal oxides has increased significantly in recent times, with efforts directed towards understanding the relationship, with regard to both structure and properties, between the precursor and the final material.[4] Structural data, even for heterobimetallic alkoxides,[1] is still scarce. Lead and aluminum are important components of many such materials.[5]

The difficulty in preparing lead(II) alkoxides[6] has been overcome by using commonly accessible salts such as nitrate,[7] acetate,[8] halides, hydroxides, or β-diketonates.[9][10] In general metal acetates are the most common precursors associated with metal alkoxides. Structural features of the products[11] obtained by treating metal acetates with metal alkoxides show that the acetate ligand is bridging, or bridge-chelating, indicating the role of the carboxylate group in maintaining the stoichiometry during the various stages of the transformation that leads to mixed metal oxides.

This work reports on the synthesis and characterization of a heterobimetallic aggregate, $Pb_2Al_5(\mu_3\text{-}O)(\mu_4\text{-}O)(\mu\text{-}O\textit{i}Pr)_9(O\textit{i}Pr)_3(\mu\text{-}OAc)_3$, based on lead and aluminum. This compound represents a unique example in which aluminum is present in three different coordination environments. The pentacoordination around the lead center observed in this system is rare in molecular compounds, and has been reported to be found in high-T_c superconductors.[12]

Results and Discussion

Reactions between metal alkoxides and metal acetates have generally been reported to give oxo products by the elimination of an ester.[11] Simple addition products[8] have also been reported in room-temperature reactions. However, under refluxing conditions the formation of oxo species is spontaneous. The product $Pb_2Al_5(O)_2(O\textit{i}Pr)_{12}(OAc)_3$ was obtained in a high and reproducible yield, which excludes formation by accidental hydrolysis.

In the IR spectrum of the compound the difference of 150 cm^{-1} in the $\nu(CO_2)$ absorption frequency of the asymmetric (1610 cm^{-1}) and symmetric (1460 cm^{-1}) bands is indicative of the acetate group acting as bidentate ligand. The absorptions observed at 1090 cm^{-1} and 1020 cm^{-1} account for the presence of terminal and bridging isopropoxy groups, respectively.

At ambient temperature ^{1}H- and ^{13}C-NMR spectra of the compound are not structurally informative. However, the ^{27}Al-NMR spectrum shows a broad peak (δ = 32–58) centered at δ = 42.24, which is at a position characterisitic of both octahedral and tetrahedral symmetries around the aluminum centers.[13]

The X-ray crystallography and molecular structure of the compound is given in Figure 1 and the core is shown in Figure 2.

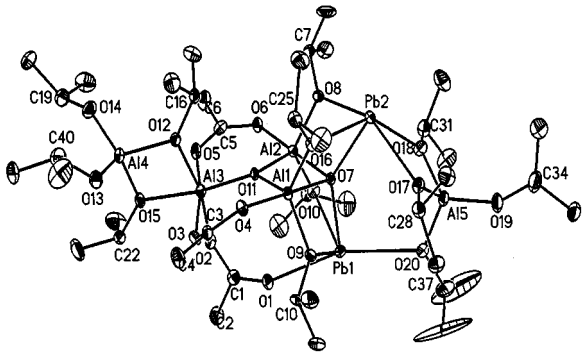

Figure 1. Molecular structure of $Pb_2Al_5(\mu_3\text{-}O)(\mu_4\text{-}O)(\mu\text{-}O\textit{i}Pr)_9(O\textit{i}Pr)_3(\mu\text{-}OAc)_3$; thermal ellipsoids are represented with 25% probability; hydrogen atoms have been omitted for clarity

Selected bond dimensions are summarized in Table 1. The compound has a Pb_2Al_5 unit linked by acetato, isopropoxo, and oxo groups, making a complex and interesting structure. There are two tetrahedral aluminum atoms [Al(5), Al(4)] which differ environmentally, two trigonal bipyramidal aluminum centers [Al(2) and Al(1)], and one which is octrahedrally surrounded [Al(3)]. This constitutes the first example of a system containing the same metal atom in three different coordination environments. Both the lead atoms are pentacoordinate, having different geometries

O(19)−Al(5)−O(17)	117.6(3)	O(18)−Al(5)−O(17)	92.1(2)

The coordination around Al(5) is completed by one terminal and three doubly bridging O*i*Pr groups. The angles subtended by O(20) are normal tetrahedral angles, while the acute angle [O(18)−Al(5)−O(17), 92.1°] due to the four-membered ring [−Pb(2)−O(17)−Al(5)−O(18)−] leads to a widening of the other two angles (average 117.8°). The second tetrahedral aluminum atom, Al(4), has two terminal and two μ-O*i*Pr groups. Four of the tetrahedral angles are almost normal. The larger deviations in case of the angles O(15)−Al(4)−O(12) [83.2(2)°] and O(14)−Al(4)−O(15) [119.1(3)°] are caused by two isopropoxy groups bridging to the octahedral Al(3). The former is quite comparable to the corresponding angle (83.1°) in $[Al(OiPr)_3]_4$.[14]

Al(2) and Al(1) are pentacoordinate with similar environments. The coordination around Al(1) is completed by two μ-O*i*Pr groups bridging with Pb(1) and Pb(2), and two oxo groups μ_3-O(11) and μ_4-O(7) and one bidentate acetate group bridging to Al(3). Al(1) and Al(2) almost lie in the plane constituted by O(11), O(10), O(8) and O(9), O(11), O(16), respectively. Bond angles at the pentacoordinated Al atoms to the axial oxygen atoms are close to linear, e.g. O(6)−Al(2)−O(7) = 178.9°. Octahedral Al(3), along with the coordination by oxo functionality O(1), is linked by three bridging OAc groups, two aluminum atoms [Al(1) and Al(2)] and one lead atom [Pb(1)], and two μ-O*i*Pr groups with Al(4), allowing the metal center to reach its most common coordination number six. Due to the complexity of the structure the angles for the octahedron range from 74.9(2)−100.1(2)°.

Among the Al−O*i*Pr bond lengths the terminal Al−O distances (average 1.701 Å) of the tetrahedral Al(4) and Al(5) are the shortest. In the bridging distances the pattern is Al−O (tetrahedral) (average 1.767 Å) < Al−O (trigonal-bipyramidal (average 1.797 Å) < Al−O (octahedral) (average. 1.951 Å). These are well within the range already reported in the literature.[14−16] The aluminum−oxygen bond lengths due to the bridging acetate groups are almost equal, whereas that of the bridging Pb(1) is somewhat shorter (see Table 1) The coordination around Pb(1) is completed by three μ-O*i*Pr groups bridging Al(1), Al(2), and Al(5), and a bidentate acetate group bridging Al(3) and μ_4-O(7). Pb(2) is surrounded by four bridging oxygen atoms of isopropoxy groups, two with Al(5) and one each with Al(1) and Al(2) and μ_4-O(7). Thus Pb_2O_9 essentially constitutes a bitetragonal-pyramidal geometry. The tetragonal angles for Pb(1) range from 73.2(2)° [O(9)−Pb(1)−O(1)] to 113.5(2)° [O(10)−Pb(1)−O(20)], while for Pb(2) the range is 61.9(2)° [O(17)−Pb(2)−O(18)] to 94.2(2)° [O(18)−Pb(2)−O(8)]. This difference is obviously a consequence of the different degree of constraint imposed by the coordinating groups. For Pb(1) the lead−oxygen distances cover the unusually wide range from 2.250(4) to 2.686(5) Å. However, for Pb(2) the range [2.234(4)−2. 491(4) Å] is comparable to reported[8] values.

The coordination geometry of the μ_3-O(11) group is almost planar (Σangles = 357.6°) while that around μ_4-O(7) is distorted tetrahedrally with angles ranging from 94.0(2)−138.6(2)°. This distortion is not as severe as ob-

served in the case of $Pb_2Ti_2(\mu_4\text{-}O)(\mu_3\text{-}OiPr)_2(\mu\text{-}OiPr)_4(OiPr)_4$[17] where the angles around μ_4-O range from 95.0(5) to 163.0(7)°.

For the two acetato moieties, bridging aluminum atoms, the C−O distances (average 1.259 Å) are almost similar. However, some asymmetry [C(1)−O(1) 1.228(9) Å, C(1)−O(2) 1.295(9) Å] is introduced for the third one attached to lead and aluminum atoms.

Conclusions

The first structurally characterized heterometallic aggregate based on lead and aluminum is found to have a high degree of asymmetry. It is the first reported occurence of the presence of the three identical metal centers (aluminum) in three different coordination environments. The asymmetry is also reflected by the fact that the pair of tetrahedral aluminum atoms and the tetragonal-pyramidal lead centers also differ in their coordinating groups.

Experimental Section

General: The reaction was performed under dry argon using standard Schlenck and glove-box techniques. Toluene and $CDCl_3$ were dried by standard procedures and stored over molecular sieves. Aluminum isopropoxide (Aldrich) was distilled prior to use. Anhydrous lead acetate was obtained by refluxing $Pb(OAc)_2 \cdot 3\,H_2O$ (BDH) with acetic anhydride (Qualigens). − IR: JASCO FT IR-5300; Nujol mulls between NaCl plates. − ^1H,^{13}C, and ^{27}Al NMR: JEOL-FX 90Q spectrometer ($CDCl_3$); $SiMe_4$ internal reference for ^1H- and ^{13}C-NMR spectra, $[Al(H_2O)_6]^{3+}$ external reference for ^{27}Al spectrum. Lead was estimated as lead chromate and aluminum as aluminum oxinate. O*i*Pr analysis was done by the method described by Bradley et al.[18]

Crystallography: The structure determination was performed by using a Siemens P4 diffractometer equipped with a CCD area detector and low-temperature device LTL. Mo-K_α radiation with λ = 0.71013 Å was used and the sample cooled to 193 K. Data reduction was performed with the program SAINT and absorption by SADABS. Computer calculations were carried out by using the SHELXS-97 (Sheldrick, **1990**) program package and the structure was solved by the heavy-atom method. The refinement was performed by SHELXL-97 (Sheldrick, **1997**) program with anisotropic thermal parameters for the non-hydrogen atoms. Hydrogen atoms were placed in calculated positions and refined as a riding model. The carbon atoms of one isopropyl group shows large anisotropic motion.

Crystallographic Data: $C_{42}H_{92}Al_5O_{20}Pb_2$; molecular mass 1466.44; a = 13.1182(3), b = 23.6499(4), c = 20.16104(3) Å; β = 96.885(1)°, V = 6348.1(2) Å^3, monoclinic system, space group $P2_1/n$, Z = 4, d = 1.534·10^{-9} g/cm^{-3}, μ = 5.427 mm^{-1}, 2θ = 2−49.42°, index range $-15 < h < 15$, $-22 < k < 27$, $-24 < l < 24$, max./min. transmission: 0.483/0.283, measured/unique/observed reflections: 29924/9671/7677 (R_{int} = 4.46%), no. of variables: 622, $R1$ = 0.0411, $wR2$ (all data) = 0.0970, weight (x/y) = 0.0442/12.2106, Goodness-of-fit = 1.090, $\Delta\rho$ = 1.411e/Å. The weighting scheme is $w^{-1} = \sigma^2F_o^2 + (xP)^2 + yP$ with $P = (F_o^2 + 2F_o^2)/3$. It should be noted that atoms C(38) and C(39) have large thermal parameters indicating rotational disorder. Calculations with split positions did not improve the result significantly. Additional data (except structure factor tables) have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-104505. Copies may be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@cam.ac.uk].

$Pb_2Al_5(O)_2(OiPr)_{12}(OAc)_3$: A suspension of lead acetate (2.41 g, 7.41 mmol) in toluene (ca. 25 mL) was added dropwise to a solution of aluminum isopropoxide (3.02 g, 14.8 mmol) in toluene (ca. 30 mL) with stirring at room temp. (25°C). The reaction mixture was heated slowly by raising the bath temperature to 100°C. At this stage all the acetate had dissolved and the stirring was continued for 1 h while maintaining the bath temp. A very small quantity of solid suspension was filtered off and the solution concentrated to 20 mL and kept at −15°C to afford a white crystalline product (4.51 g, yield 83%). − $C_{42}H_{93}Al_5O_{20}Pb_2$ (1467.49): calcd. Pb 28.25, Al 9.19, O*i*Pr 48.29; found Pb 28.50, Al 8.91, O*i*Pr 48.19. − ^1H NMR (25°C): δ = 1.24, [d, CH_3 (O*i*Pr)], 4.42 (sept., CH), 2.00 [s, CH_3 (OAc)]. − ^{13}C NMR: δ = 174.72, 177.37, 179.50 [CO (OAc)], 64.11, 64.31 (CH), 27.31 and 27.69 [CH_3 (O*i*Pr and OAc)]. − Single crystals were grown from toluene at −15°C.

Directed Syntheses of New Quaternary Niobium Oxysulfides: Crystal Structures and Properties of $K_4Nb_2S_{10}O$ and $Rb_4Nb_2S_{10}O$ Compared to $K_4Nb_2S_{11}$

Oliver Krause,[a] Peter Dürichen,[a] Christian Näther,[a] and Wolfgang Bensch*[a]

Keywords: Solid-state chemistry / Structure elucidation / Reactive flux syntheses / Oxysulfides / Niobium chalcogenides

The new compounds $K_4Nb_2S_{10}O$ and $Rb_4Nb_2S_{10}O$ have been synthesized by the reaction of potassium or rubidium alkaline polychalcogenides with NbO_2, Nb_2O_5, or mixtures of Nb and NbO. Their structures consist of discrete $[Nb_2Q_{11}]^{4-}$ anions (Q = O, S) built up of two face-sharing pentagonal bipyramids, which are connected via the alkali metal cations.

Introduction

Difficulties are encountered in syntheses of oxysulfides and oxyselenides of the Group 5 transition metals owing to the high oxophilicity of these metals. If there is a competition between the hard O^{2-} anion and the more polarizable chalcogenide anions Q^{2-} (Q = S, Se, Te), Group 5 metals (M = V, Nb, Ta) prefer to bond to oxygen. Previously reported compounds containing both oxygen and another chalcogen bound to the metal atom were obtained serendipitously because oxygen-contaminated starting materials were used in the attempted synthesis of other compounds. Traces of such oxygen-containing compounds are sufficient to partially substitute heavier chalcogenide anions, hence oxysulfides or oxometallates are obtained as side products. However, such compounds are of special interest because they combine the physical properties of pure transition metal chalcogenides with those of the pure oxides. Therefore, the directed synthesis of oxysulfides and oxyselenides is a challenge for the preparative solid-state chemist.

In the field of classical solvent-based chemistry, several compounds containing thiooxometallate units have been synthesized. It is assumed that an important step in the addition of oxygen is the hydrolysis of sulfidic species. Examples of such compounds reported previously are $R_2[Nb(O)(S_2)_2SH]$ and $R_4\{[Nb(S)_3]_2O\}$ (with R = Ph_4P^+, Et_4N^+),[1a] $R_2\{[(S_2)_2MoO]_2S\}$ and $R_2\{[(S_2)_2MoO]_2S]S\}_2$ (with R = Et_4N^+).[1b] The vanadium compound $(NH_4)_6(V_4S_{20}O_4) \cdot 5\ bpy \cdot 7\ H_2O$[2] is also known. It must also be noted that numerous ternary alkali oxysulfides of the composition $[MO_{4-x}S_x]^{2-}$ (M = Mo, W, Re) have been precipitated from aqueous solutions.[3a–3f]

In contrast to the numerous solvent-mediated reactions, examples of alkali or alkaline earth transition metal oxysulfides and -selenides prepared by solid-state reactions are rare. Examples are $Ba_6(NbS_4)(NbS_3O)_3$,[4] $Na_{1.9}Cu_2Se_2 \cdot Cu_2O$,[5] $Ba_6Ti_5S_{15}O$,[6] $Na_{1.9}Cu_2Se_2 \cdot Cu_2O$,[5] $A_4(UO_2)(S_2)$ (A = Na, Cs),[7] and $Na_4(UO_2)Cu_2S_4$.[8] $Ba_6(NbS_4)(NbS_3O)_3$ was obtained as a by-product during a classical high-temperature synthesis at 1273 K, the oxygen source being identified as $BaSO_4$.[4] The other compounds were prepared using the reactive flux method.

In the course of our investigations of A–M(V)–Q systems (A = alkali metal; M = V, Nb, Ta; Q = S, Se, Te), we have prepared several new compounds containing M_2Q_{11} units as basic building blocks.[9,10a] In this unit, the Nb atoms are sevenfold coordinated by chalcogen atoms and the polyhedron may be described as a distorted pentagonal bipyramid.

This unit can be connected in many different modes. In $K_4Nb_2S_{11}$[9,10a] and $Rb_4Ta_2S_{11}$,[9,10b] isolated monomeric species are found, whereas in $K_4Nb_2S_{14}$[10c] this unit is expanded by an additional polychalcogenide ligand. In $A_6Nb_4S_{22}$ (A = Rb, Cs),[10d] two of these units are directly connected, while in $K_6Nb_4S_{25}$ they are joined via one additional S_3 fragment.[10e] For the selenides, predominantly polymeric structures are found. $K_{12}Nb_6Se_{35}$ and $Rb_{12}Nb_6Se_{35}$[10f] are built up from infinite $_\infty{}^1[Nb_6Se_{35}]^{12-}$ anionic chains, in which the Nb_2Q_{11} units are linked either directly or through one Se atom. It must be pointed out that all geometrical changes on going from monomeric to dimeric or polymeric species can be rationalized on the basis of a simple topological description.[9] In the course of our efforts to synthesize further polymeric compounds, we have obtained two new compounds, which surprisingly contain oxygen in one of the terminal positions of the bipyramid. In $K_4Nb_2Se_{11}O$,[10g] infinite anionic chains are found, in which the M_2Q_{11} units are connected through one Se atom. In contrast, crystals of $Cs_4Nb_2Se_{11}O$[10g] contain both discrete monomeric anions and polymeric anions, where the latter are built up of Nb_2Q_{11} units connected either directly or through one additional Se_2 unit.

A careful analysis of the experimental conditions showed that the source of oxygen was a contamination of the niobium metal with niobium oxides. However, the accidental synthesis of the new niobium oxyselenides prompted us to

try to prepare oxysulfides and -selenides in a directed way. For the first investigations we selected the simplest compounds containing discrete monomeric Nb_2Q_{11} units. Here, we report on the directed syntheses of the two new oxysulfides $K_4Nb_2S_{10}O$ and $Rb_4Nb_2S_{10}O$. The structural and optical properties of these two new compounds are compared with those of the previously reported oxygen-free potassium compound.[10a]

Results and Discussion

Crystal Structures

$K_4Nb_2S_{10}O$ and $Rb_4Nb_2S_{10}O$ are isotypic with the potassium polysulfide $K_4Nb_2S_{11}$[10a] and crystallize in the noncentrosymmetric space group $Pca2_1$. Their structures consist of well-separated $[Nb_2S_{10}O]^{4-}$ anions connected through the alkali metal ions. In the complex anion $[Nb_2S_{10}O]^{4-}$, one of the two Nb atoms is bound to a terminal monosulfide S^{2-}, while the other is coordinated by the terminal O^{2-} ligand (Figure 1, A and B). The environment about the Nb atoms is completed by one η^2-S_2^{2-} unit, one μ^2-S^{2-} unit that bridges the two Nb atoms, and one additional S_2^{2-} anion, which is bound in an η^2 fashion to one Nb while one S atom of this unit serves as a second bridging atom to the opposite Nb. Hence, the coordination mode of the anion may be described as $[Nb_2(\mu\text{-}S)(\mu\text{-}\eta^2,\eta^1\text{-}S_2)_2(\eta^2S_2)_2(S)(O)]^{4-}$ (Figure 1, A and B). The resulting coordination polyhedron can be described as being composed of two distorted pentagonal bipyramids sharing common faces. The Nb−Nb bond length of 3.538 Å in the rubidium compound and 3.522 Å in the potassium compound are significantly longer than that in metallic Nb (2.858 Å), too long for an Nb−Nb bond (Table 1). Hence, the formal oxidation state of Nb can be assigned as +5.

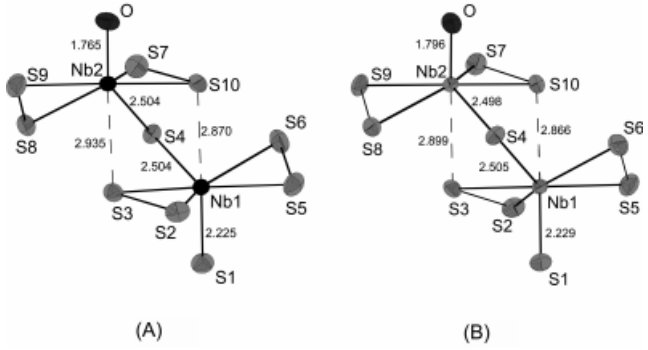

Figure 1. Structure of the $[Nb_2S_{10}O]^{4-}$ anion in (A) $Rb_4Nb_2S_{10}O$ and (B) $K_4Nb_2S_{10}O$ showing atom labelling (bond lengths are given in Å; displacement ellipsoids are drawn at a 50% probability level)

All interatomic distances in the anions of the two compounds are comparable (Table 1). The interatomic Nb−S distances may be divided into three groups. One short [Rb compound: Nb(1)−S(1): 2.225(3) Å; K compound: 2.229(3) Å], five more typical distances [Rb: Nb(1): 2.440(2) to 2.504(2) Å, Nb(2): 2.484(2) to 2.504(2) Å; K: Nb(1): 2.435(3) to 2.505(3) Å, Nb(2): 2.463(3) to 2.498(3) Å], and one longer separation [Rb: Nb(1)−S(10): 2.870(2), Nb(2)−S(3): 2.935(2) Å; K: 2.866(3), 2.899(3) Å] (Table 1). As was demonstrated in a previous communication, the long Nb−S separation must be treated as a weak interaction, while the short Nb−S bond lengths are close to an Nb−S double-bond length.[9] The S−S distances in the S_2^{2-} units range from 2.071(4) to 2.077(4) Å and are thus typical for S−S single bonds (Table 1). The Nb atoms are shifted from the plane of the pentagonal bipyramid towards the terminal chalcogen atoms by about 0.474 Å [Nb(1)] and 0.470 Å [Nb(2)] in the rubidium compound, and by 0.475 Å [Nb(1)] and 0.473 Å [Nb(2)] in the potassium compound (Table 1).

Table 1. Selected bond lengths [Å], deviation of the Nb atoms from the pentagonal plane [Å], and angles between the pentagonal planes [°] for $Rb_4Nb_2S_{10}O$, $K_4Nb_2S_{10}O$, and $K_4Nb_2S_{11}$

S(8)−S(9)	2.076(4)	2.073(4)	2.078(4)
Deviation of Nb from the pentagonal plane	Nb(1) 0.474 Nb(2) 0.470	Nb(1) 0.475 Nb(2) 0.473	Nb(1) 0.479 Nb(2) 0.474
Angle between pentagonal planes	128.4°	128.3°	129.4°

The Nb−O bond length of 1.765(7) Å [1.796(7) Å in $K_4Nb_2S_{10}O$] can be regarded as corresponding to an Nb=O double bond, and is comparable to those reported for $R_4\{[Nb(O)(Se_2)_2]_2Se_4\}$ (Nb−O: 1.671 Å) and $R_4\{[Nb(Se)_3]_2O\}$ ($R = Ph_4P^+$, Et_4N^+)[1a] (Nb−O: 1.682 Å), where Nb is sevenfold coordinated. In the binary oxides NbO and NbO_2, with Nb in a quadratic-planar environment, the Nb−O bond lengths are about 2.105 Å and 2.046 Å, respectively. The average Nb−O distance in a tetrahedral environment, as found in Nb_2O_5, is 1.725 Å.[11a] We note that Nb−O distances are scattered over a wide range, even those in NbO_6 octahedra (e.g. 1.751 to 2.554 Å in $Nb_{12}O_{29}$;[11b] 1.635 to 2.331 Å in $NaNbO_3$;[11c] 1.867 to 2.107 Å in $Rb_4Nb_{11}O_{30}$[11d]) and an NbO_7 pentagonal bipyramid (1.896 to 2.435 Å and 1.761 to 2.161 Å in $LaNb_5O_{14}$[11e]).

The packing of anions and cations in the rubidium compound is depicted in Figure 2, A and B. A projection onto the $a-b$ plane reveals an almost hexagonal arrangement of

the anions, with channels running parallel to the *c* axis, whereas a view parallel to [0 1 0] shows the separation of the anions by the alkali metal cations. The shortest intermolecular nonbonding S−S distances are 3.239 Å in $Rb_4Nb_2S_{10}O$ and 3.252 Å in $K_4Nb_2S_{10}O$, both of which are significantly shorter than the sum of the van der Waals radii of sulfur. The alkali metal cations are coordinated by S and O atoms in irregular polyhedra and have coordination numbers between 8 and 10. The A···S and A···O distances lie in the expected ranges for K^+ and Rb^+ cations and S^{2-} and O^{2-} anions[10d,12a,12b] (Table 2).

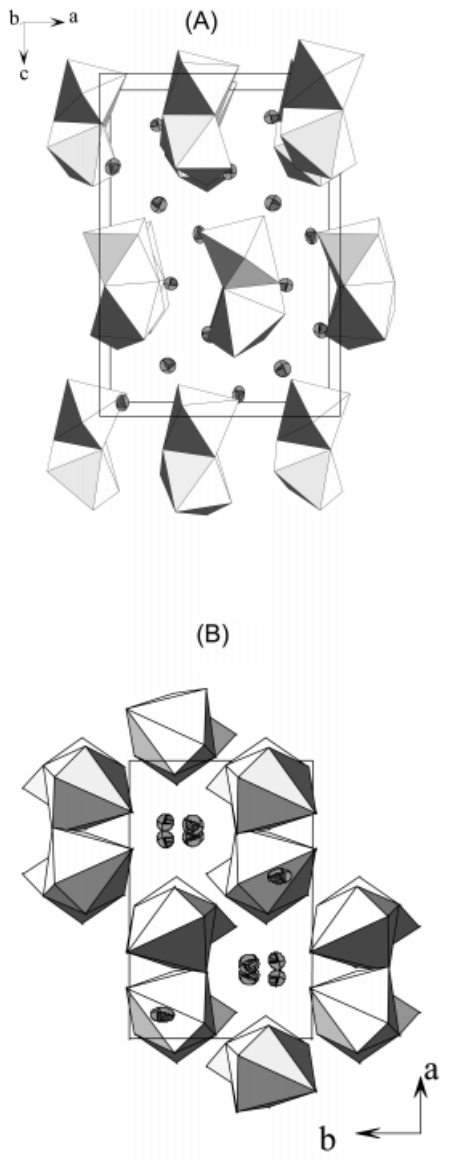

Figure 2. Crystal structure of $A_4Nb_2S_{10}O$ (A = K, Rb) showing (A) a view parallel to [0 1 0], and (B) a view parallel to [0 0 1]

Comparison of the interatomic distances in the $[Nb_2S_{10}O]^{4-}$ anion of $K_4Nb_2S_{10}O$ with those in the $[Nb_2S_{11}]^{4-}$ anion of $K_4Nb_2S_{11}$ shows that the introduction of the oxygen atom only slightly influences the distinct Nb−S distances (Table 1) The most marked deviation is observed for the Nb(2)−S(3) distance, positioned *trans* to Nb(2)−O, which is 0.040 Å longer than in $K_4Nb_2S_{11}$. The angle between the two pentagonal planes amounts to 128.3° in $K_4Nb_2S_{10}O$ and 129.4° in $K_4Nb_2S_{11}$ (Table 1).

Table 2. Coordination numbers (CN), shortest (min.), longest (max.), and average (< >) A···S distances, as well as A···O distances [Å] for the alkali metal cations (A) in $K_4Nb_2S_{10}O$, $Rb_4Nb_2S_{10}O$, and $K_4Nb_2S_{11}$ (cut-off$_K$ = 3.81 Å; cut-off$_{Rb}$ = 4.01 Å)

Synthetic Aspects

As pointed out in the Experimental Section, direct syntheses of the title compounds can be carried out using several Nb oxides such as NbO, NbO_2, or Nb_2O_5, as well as mixtures of elemental Nb with these oxides. However, if only small amounts of niobium oxides are present, e.g. only slightly contaminated Nb metal is used for the syntheses, mixtures of oxysulfides and the pure sulfides are obtained. This is exemplified by the synthesis of the two new compounds, $K_4Nb_2S_{10.7}O_{0.3}$ and $Rb_4Nb_2S_{10.7}O_{0.3}$, which were isolated in the course of our investigations. Because these compounds are isotypic with the title compounds, having only very small differences in their cell parameters, their identification by means of X-ray powder diffraction is not possible. Significant differences are only observed upon refinement of single-crystal data, and only with an oxygen content of several%. For an effective control of the syntheses of pure chalcogenides, oxysulfides, or oxyselenides, this is not an adequate method. Therefore, a much more sensitive method is needed for the fast and non-destructive characterization of these compounds. For this purpose, extremely sensitive spectroscopic methods are ideal. If small amounts of oxysulfides or oxyselenides are present, this can clearly be detected by the appearance of Nb−O absorption peaks in the IR spectra. The vibration of the Nb−O bond in $Rb_4Nb_2S_{10}O$ gives rise to a strong absorption near 850 cm^{-1} (see Figure 3, B and C), whereas for the pure sulfide this band is absent (Figure 3, A). Therefore, IR spectroscopy is a suitable tool for monitoring the synthesis of compounds of this class.

It should be noted that in the title compounds only one of the two terminal positions is occupied by oxygen. Therefore, several attempts were made to substitute both axial S atoms by O atoms. A large number of experiments were carried out using different combinations of Nb with Nb oxides (NbO, NbO_2, and Nb_2O_5) as well as only Nb oxides

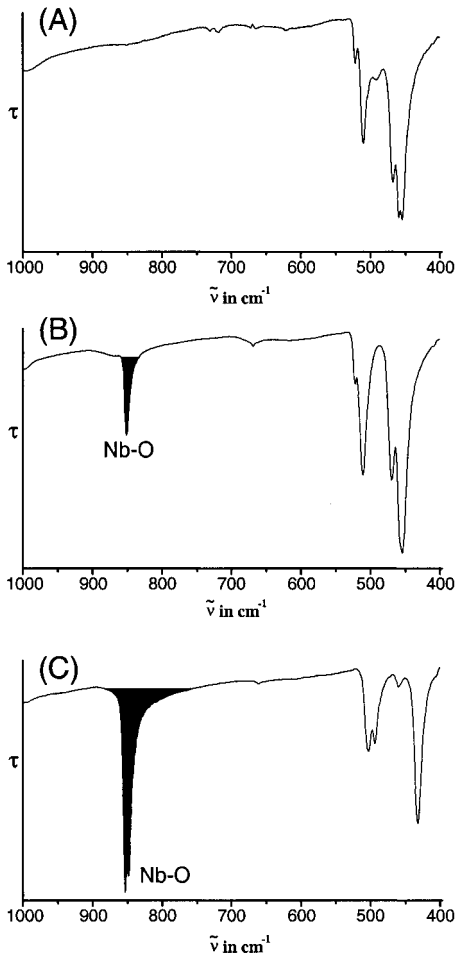

Figure 3. MIR spectra of (A) $K_4Nb_2S_{11}$, (B) $K_4Nb_2S_{10.7}O_{0.3}$, and (C) $K_4Nb_2S_{10}O$ (τ in arbitrary units)

as starting materials. However, the products of all these reactions consisted only of $Rb_4Nb_2S_{10}O$ or $K_4Nb_2S_{10}O$, alkali metal oxoniobates, and A_3NbS_4[13] (A = K, Rb) as the minor phases. In the case of the pure oxides, this is an interesting reaction from several points of view. First of all, most of the oxygen atoms of the niobium oxide must be replaced by sulfur atoms, which would be expected to be difficult considering the highly oxophilic character of Nb. Secondly, it is not obvious why only one oxygen remains unchanged, while in the products of the solution-mediated reactions both terminal positions are invariably occupied by oxygen. Concerning the reaction mechanism in the case of pure Nb_2O_5, a redox reaction between low-valent Nb and the S_x^{2-} polyanions in the melt can be excluded. Instead, it involves replacement of most of the oxygen by sulfur, where the large excess of sulfur does not allow the retention of oxygen at both the axial positions. However, even at lower concentrations, only one of the two possible positions is occupied by O. A further decrease of the sulfur content is not possible because no flux is generated. The reasons for this surprising reaction remain unclear, hence further investigations are needed.

UV/Vis Measurements

For a comparison of the optical properties, UV/Vis reflectance spectra of $K_4Nb_2S_{10}O$ and the pure sulfide were measured (Figure 4). Both compounds show a sharp absorption, from which an optical-band gap of 1.99 eV can be estimated for $K_4Nb_2S_{10}O$, while in the case of $K_4Nb_2S_{11}$ this band gap is shifted to higher energy by about 0.1 eV. The colour of the new material, as well as the value for the band gap, are consistent with its semiconducting nature.

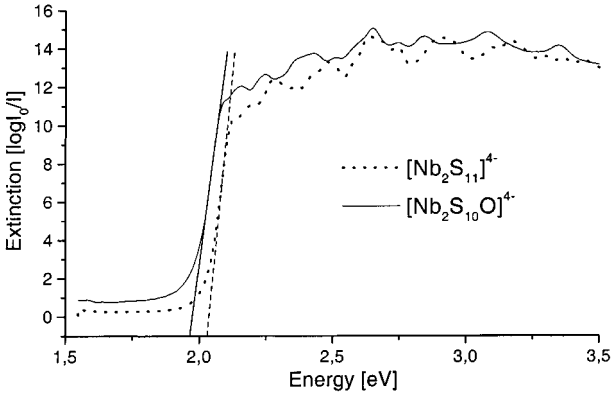

Figure 4. UV/Vis spectra of $K_4Nb_2S_{10}O$ and $K_4Nb_2S_{11}$

Conclusion

In the present paper we have shown that oxysulfides of niobium can be synthesized in a directed way by employing niobium oxides as starting materials. This synthetic approach can also be applied to selenide chemistry and we have shown that the polymeric oxyselenides first obtained accidentally can also be prepared using NbO, NbO_2, or Nb_2O_5. It can be assumed that the directed introduction of oxygen is generally applicable. However, in contrast to what is known from solution chemistry, in the reaction in the alkali metal polychalcogenide melts only one of the two terminal positions is selectively occupied by oxygen. Such reactions are not only of considerable interest from a synthetic point of view, but also to dramatically increase the number of new compounds in several ternary and multinary transition metal polychalcogenide systems. Moreover, the directed introduction offers the possibility of influencing or even modelling the physical properties of the compounds at a molecular level.

Experimental Section

Syntheses: The requisite alkali metal sulfides were first prepared by reactions of stoichiometric amounts of the elements in liquid ammonia. $K_4Nb_2S_{10}O$ and $Rb_4Nb_2S_{10}O$ were then synthesized by reactions of K_2S_3 and Rb_2S_3 with S and NbO in molar ratios of 2:4:1. As mentioned above, the preparation could also be carried out using several mixtures of Nb/NbO and NbO_2 or Nb_2O_5. The starting reagents were thoroughly mixed in a nitrogen-filled glovebox and then transferred to a Pyrex ampoule. The ampoule was evacuated to $6 \cdot 10^{-5}$ mbar and flame-sealed. The sample was heated

to 623 K and maintained at this temperature for 5 d. It was then cooled to 473 K at a rate of 3 K/h and to room temperature at a rate of 30 K/h. The excess polysulfide flux was removed by washing with dry DMF and diethyl ether and the residue was dried in vacuo. After optimization of the reaction parameters, yields of 50% based on niobium were achieved. The homogeneity of the product was checked by means of X-ray powder diffraction and MIR spectroscopy.

General Remarks: Single-crystal X-ray investigations were performed with a STOE AED II diffractometer (Mo-K_α radiation, graphite monochromator). The intensities were reduced to F_o. Lorentz, polarization, and empirical absorption corrections using ψ-scan data were applied. Both structures were solved by direct methods using SHELXS-86. Full-matrix least-squares refinements were performed against F^2 using SHELXL-93. All atoms were refined using anisotropic displacement parameters. Additional material relating to the structure determination can be ordered from the Fachinformationszentrum Karlsruhe, Gesellschaft für wissenschaftlich-technische Information mbH, D-76344 Eggenstein-Leopoldshafen, Germany, on quoting the numbers. CSD-410820 and -410821, the names of the authors, and the full journal citation. − MIR spectra were recorded with a Genesis FT-IR spectrometer (ATI Mattson) in the range 400−4000 cm^{-1} with a resolution of 2 cm^{-1}. Samples of the compounds were prepared as KBr pellets. − UV/Vis diffuse-reflectance measurements were made with a Leica Orthoplan microscope equipped with a Leica MPV-SP, an ICS quartz UV optic, and a xenon lamp as light source. The resolution was 1 nm and $BaSO_4$ was used as a standard for 100% reflectance. Absorption data were calculated from the reflectance data using the Kubelka−Munk function. The approximate band gap was determined from the intersection point on the energy axis of the line extrapolated from the linear part of the absorption edge in an $[F(R)]^2$ plot. − Powder diffraction measurements were made using a STADI P transmission powder diffractometer from STOE & CIE.

X-ray Crystallographic Study. − $K_4Nb_2S_{10}O$: Mol. mass 678.82, red crystal, size: 0.3 × 0.2 × 0.2 mm, a = 12.714(3) Å, b = 7.532(2) Å, c = 17.828(3) Å, V = 1707.2(7) $Å^3$ (room temp.), $\rho_{calc.}$ = 2.641 g cm^{-3}, orthorhombic, $Pca2_1$ (No. 29), Z = 4, μ = 3.517 mm^{-1}, 2824 reflections measured in the range 3° < 2θ < 53°, 2307 independent reflections used for refinement, R_{int} = 0.0466, 154 parameters, $w = 1/[\sigma^2(F_o^2) + (0.0417 \times P)^2 + (1.06 \times P)]$, R for 1765 $F_o > 4\sigma(F_o)$ = 0.0350, $wR2$ for all 2307 data = 0.0829, GooF = 1.028, residual electron density 1.23/−0.80 $eÅ^{-3}$. Pyrazolato Metal Complexes – Synthesis, Characterization, and X-ray Crystal Structures of Heterotrimetallic Re–M_2 Derivatives (M = Cu, Ag, Au)

G.Attilio Ardizzoia,*[a][+] Girolamo La Monica,[a][+] Angelo Maspero,[a] Norberto Masciocchi,[b][+] and Massimo Moret*[b]

Keywords: Pyrazolato ligands / Rhenium / Group-11 metals / Heterometallic complexes

By treating $[(CO)_3Re(Hpz)_2(pz)]$ (Hpz = pyrazole) with $[Cu(CH_3CN)_4]BF_4$, $AgNO_3$, or [Au(tht)Cl] (tht = tetrahydrothiophene) in acetonitrile in the presence of Et_3N, the corresponding trinuclear complexes $\{(CO)_3Re(pz)_3[M(CH_3CN)]_2\}$ (**1a–c**) have been obtained. Treatment of complexes **1a–c** with cyclohexyl isocyanide (*c*-$C_6H_{11}NC$) afforded the derivatives $\{(CO)_3Re(pz)_3[M(c\text{-}C_6H_{11}NC)]_2\}$ (**2a–c**). Complexes **2a–c** have been characterized in solution by ^{1}H-NMR spectroscopy and in the solid state by single-crystal X-ray diffraction analysis.

Introduction

The synthesis of di- and polynuclear complexes bearing ligands that hold the metal centers in close proximity is an important objective in metal coordination chemistry. Interest in such systems arises mainly because of their potential role in multi-metal-centered catalysis, both in biological and industrial reactions.[1] The major effort in this field is to find convenient binucleating ligands capable of producing the desired activities. Deprotonated pyrazoles (pyrazolate anions) represent a significant class of binucleating ligands because of their ability to coordinate in an *exo*-bidentate fashion.[2][3]

We have recently described the synthesis and structural properties of the mononuclear bis(pyrazole)pyrazolate complex of rhenium(I), $[(CO)_3Re(Hpz)_2(pz)]$ (Hpz = pyrazole).[4] This species belongs to a limited class of complexes that, from a coordination point of view, are comparable to protonated tris(pyrazolyl)borate molecules.[5] The other reported members of this class, $[(\eta^5\text{-}C_5Me_5)Ir(Hpz)(pz)_2]$,[6] $[(\eta^6\text{-}p\text{-cymene})Ru(Hpz)(pz)_2]$,[7] and $[(\eta^6\text{-mesitylene})Ru(Hpz)(pz)_2]$,[8] when deprotonated to give the anionic species $[(\eta^5\text{-}C_5Me_5)Ir(pz)_3]^-$, $[(\eta^6\text{-}p\text{-cymene})Ru(pz)_3]^-$, and $[(\eta^6\text{-mesitylene})Ru(pz)_3]^-$, have been shown to behave, in some respects, akin to the tris(pyrazolyl)borate anion, acting as organometallic ligands toward a variety of metal ions.[8][9]

We report herein on the reactivity of $[(CO)_3Re(Hpz)_2(pz)]$ towards Group-11 metal ions and show that, in the presence of an appropriate deprotonating agent, this complex gives rise to the formally dianionic species $[(CO)_3Re(pz)_3]^{2-}$, which is capable of coordinating two different metal centers through the lone pairs of its three monodentate pyrazolate groups. This leads to trimetallic species of general formula $[(CO)_3Re(pz)_3(ML)_2]$ [M = Cu^I, Ag^I, Au^I; L = CH_3CN, *c*-$C_6H_{11}NC$].

Results and Discussion

Reactions of $[(CO)_3Re(Hpz)_2(pz)]$ with $[Cu(CH_3CN)_4]BF_4$, $AgNO_3$, and [Au(tht)Cl] (tht = tetrahydrothiophene) in acetonitrile in the presence of Et_3N led to the formation of trimetallic species formulated as $\{(CO)_3Re(pz)_3[M(CH_3CN)]_2\}$ [M = Cu (**1a**), Ag (**1b**), Au (**1c**)] (Equation 1).

$$[(CO)_3Re(Hpz)_2(pz)] + 2\ ML_nX \xrightarrow[-Et_3NHX,\ -\ n\ L]{Et_3N\ /\ CH_3CN} [(CO)_3Re(pz)_3\{M(CH_3CN)\}_2] \qquad [1]$$

*(ML_nX = [Cu(CH$_3$CN)$_4$]BF$_4$, AgNO$_3$ or [Au(tht)Cl], for **1a-c**, respectively)*

The very low thermal stability of complexes **1a–c**, leading to loss of coordinated CH_3CN ligands and the formation of decomposition by-products, hampered any further characterization of these species. However, when reaction according to Equation 1 was carried out in the presence of stoichiometric amounts of *c*-$C_6H_{11}NC$, the readily characterizable species $\{(CO)_3Re(pz)_3[M(c\text{-}C_6H_{11}NC)]_2\}$ [M = Cu (**2a**), Ag (**2b**), Au (**2c**)] were obtained.

The IR spectra of all three species feature three strong ν(CO) bands in the 2000–1800 cm^{-1} region, typical for a *fac* stereochemistry at the rhenium center[10] and reminiscent of the spectrum of the starting rhenium complex $[Re(CO)_3(Hpz)_2(pz)]$. The positions of these absorptions are only marginally affected by the nature of the Group-11 metal (see Table 1). Moreover, no absorption attributable to the N–H stretching was detected, confirming the presence, in species **2**, of the $[(CO)_3Re(pz)_3]^{2-}$ core.

The pattern of the IR bands in the ν(NC) region merits further comment. While the copper (**2a**) and the silver (**2b**) derivatives show two absorptions (2210, 2164 and 2225, 2192 cm^{-1}, respectively), suggesting similar structures for

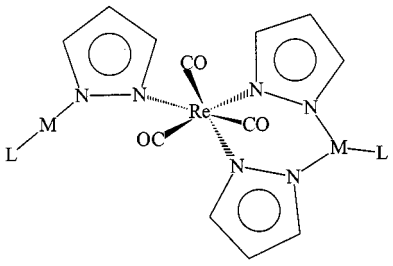
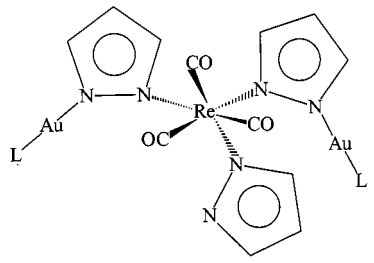
Table 1. Characteristic IR frequencies [cm^{-1}] for complexes **2a**−**c** (Nujol mulls)



Complex	ν(CO)	ν(NC)
2a	2002, 1885, 1868	2210, 2164
2b	1999, 1882, 1860	2225, 2192
2c	2002, 1884, 1860	2253

both complexes, marked differences are observed for the gold derivative **2c**. Indeed, this species shows only one ν(NC) stretching at 2253 cm^{-1}, suggesting a structure distinct from that of the copper and silver derivatives.

As far as complexes **2a** and **2b** are concerned, taking into account that three pyrazolato groups (elemental analyses) and three CO molecules (IR) complete the coordination sphere about the rhenium center, the presence of two cyclohexyl isocyanide ligands bound to two copper (or silver) centers in different coordinative environments can be inferred. Given the ability of silver and copper to sustain digonal and trigonal geometries, it can be presumed that both such stereochemistries are present in the heterometallic species **2a** and **2b**. Under this assumption, the ν(NC) absorption at lower energy (2164 cm^{-1} for **2a**; 2192 cm^{-1} for **2b**) can be attributed to the cyclohexyl isocyanide group coordinated to the (more electron-rich) trigonal Cu^{I} and Ag^{I} centers.



The different situation found in complex **2c** can be rationalized by taking into account the strong tendency of gold(I) to maintain a linear digonal coordination geometry; indeed, the presence in **2c** of two Au^{I} centers bonded to one pyrazolate nitrogen atom and one cyclohexyl isocyanide ligand each is consistent with the observation of a single ν(NC) absorption.

The proposed stuctures of **2a**−**c** (Scheme 1) have been unequivocally confirmed by single-crystal X-ray diffraction studies.

Scheme 1. Schematic drawing of the connectivity patterns for complexes **2a**−**2b** (a) and **2c** (b)

Crystal Structures of 2a, 2b, and 2c

Crystals of compounds **2a**−**2c** are built up from neutral heterotrimetallic molecules held together by van der Waals interactions (see below for a more detailed description of the intermolecular interactions in **2c**). Figures 1−3 show ORTEP views of the molecular conformations of each compound, as observed in the solid state. Salient geometrical parameters are summarized in Table 2.

All three complexes contain an octahedral Re^{I} center bearing three carbonyl groups in a *fac* arrangement and three pyrazolato ligands able to connect to a second metal ion in an *exo*-bidentate mode. In **2a** and **2b**, two pyrazolate ligands are linked to the same Group-11 metal center M(1) [Cu(1) and Ag(1) for **2a** and **2b**, respectively] resulting in an Re−[N−N]$_2$−M(I) six-membered ring in the typical boat conformation. The difference in the ionic radii of the Cu^{I} and Ag^{I} species is mainly reflected in the M−N(2) and M−N(4) distances, which are about 0.25 Å longer in the Ag derivative. This leads to a remarkable narrowing of the

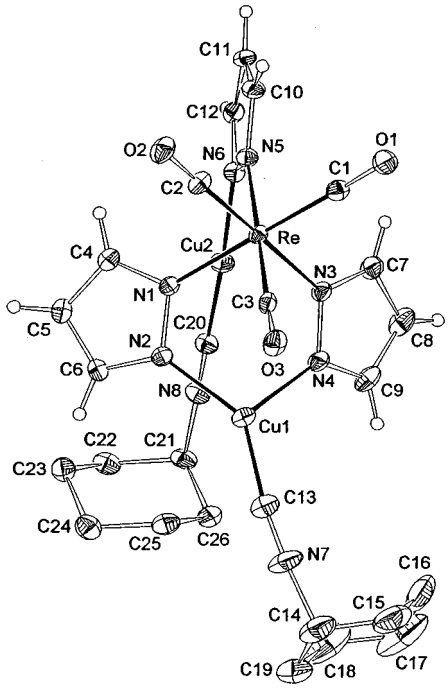

Figure 1. ORTEP drawing of complex **2a**, with partial labelling scheme; thermal ellipsoids are drawn at a 30% probability level; hydrogen atoms were given arbitrary radii

N(2)−M−N(4) angle in **2b** (see Table 2). The Cu^{I} [or Ag^{I}] center is further coordinated by a cyclohexyl isocyanide ligand, and therefore attains a planar-trigonal coordination environment [deviations from the coordination plane

amount to 0.084(4) and 0.016(4) Å for Cu(1) and Ag(1), respectively].

The remaining pyrazolate ligand is connected to the second Cu (**2a**) [or Ag (**2b**)] atom, the digonal coordination sphere of which is completed by another cyclohexyl isocyanide ligand. In this way, both molecules **2a** and **2b** contain one linearly coordinated and one trigonal-planar Group-11 metal ion, as was presumed on the basis of spectroscopic data. Nevertheless, the conformations of the Cu and Ag derivatives differ markedly in the solid state. Indeed, in **2a**, the Cu(1)−Re−N(5)−N(6) torsion angle is −0.2(5)° and

O(3)−C(3)−Re	177.0(6)	178.3(7)	173.3(10)

thus Cu(2) is nearly symmetrically buried within the pz(1−2) and pz(3−4) ligands, with an idealized mirror plane passing through Cu(1), Cu(2), Re, N(5), and N(6). On the contrary, the Ag(2)−CNC_6H_{11} moiety in **2b** is almost orthogonal to the Re−Ag(1) hinge [Ag(1)−Re−N(5)−N(6) 94.3(5)°]. Moreover, in terms of their "apparent" ionic radii, the Cu and Ag centers are about 0.1 Å larger in the trigonal than in the digonal environment.

In spite of the fact that all three complexes have the same general formula, the gold derivative **2c** has a completely different arrangement of the pyrazolate ligands. Owing to the lower tendency of gold for tricoordination, we observe a solid-state conformation with two digonally coordinated gold atoms, each bearing an isocyanide ligand and one nitrogen atom of a pyrazolato ligand. Thus, the third pyrazolato ligand is terminally bonded only to the rhenium atom in a monodentate fashion, leaving the second nitrogen lone pair unused.

While molecules **2a** and **2b** do not show significantly short intermolecular contacts in the crystals (which we have frequently observed for a number of Cu and Ag diazolato systems[11]), the packing of molecules **2c** reveals some additional features that merit further comment. Indeed, the crystal structure of **2c** reveals intermolecular interactions involving the gold atoms: Au(2)···Au(2)′ interactions of ca. 3.27 Å [relating molecules (x, y, z) and ($1-x$, $-y$, $-z$)] generate "dimeric" supramolecular entities; if the much looser Au(1)···Au(1)″ interactions [ca. 3.60 Å, relating (x, y, z) and ($-x$, $-y$, $-z$) molecules] are taken into account, an infinite 1-D concatenation of dimers can be envisaged, with pseudo-hexagonally packed chains of molecules running parallel to the a axis.

Solution Behaviour of 2a, 2b, and 2c

The structural analogies between complexes **2a** and **2b** found in the solid state were also seen in solution. The ^{1}H-NMR spectrum of **2b** recorded in CD_2Cl_2 at 303 K shows, beside the signals attributable to the cyclohexyl rings of the *c*-$C_6H_{11}NC$ ligands, a triplet centered at $\delta = 6.22$ ($J = 1.83$ Hz) attributable to C(4)−H of the pyrazolato rings, and two doublets ($\delta = 7.51$ and $\delta = 7.43$) attributable to C(3)−H and C(5)−H (Figure 4a). The observation of only one set of signals for each pyrazolato proton indicates that dynamic processes are operative that render all the pyrazolato groups present in the heterometallic species indistinguishable.

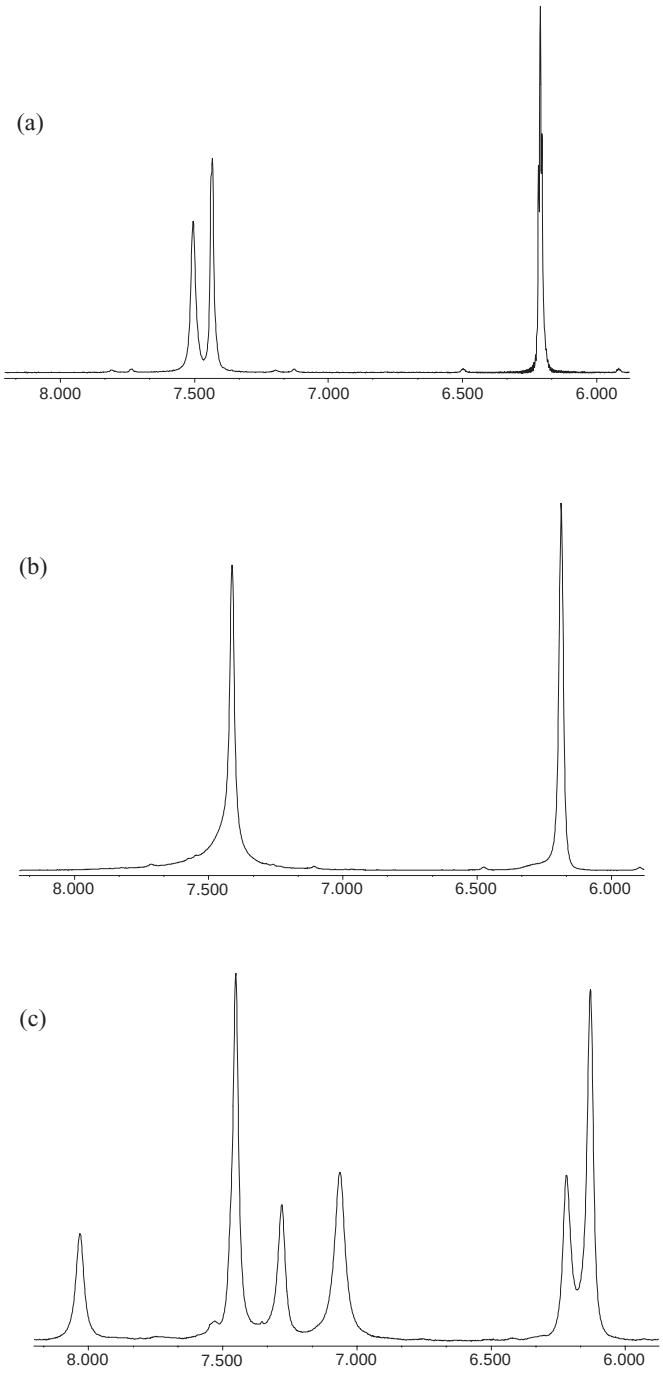
On lowering the temperature to 173 K, the ^{1}H-NMR spectrum of **2b** exhibits six signals at $\delta = 6.14$, 6.22, 7.07, 7.28, 7.45, and 8.03 in a 2:1:2:1:2:1 ratio, clearly attributable to C(4)−H (the two upfield signals) and C(3,5)−H of distinct pyrazolato groups (in a 2:1 ratio) (Figure 4c). Thus, although a partial broadening of the signals is still evident at this temperature, the observed pattern is consistent with the solid-state structure, indicating the almost complete freezing of the aforementioned dynamic process. At intermediate temperatures, the situation is less clear: The signals attributable to the protons in the 3- and 5-positions of the pyrazolate ligands collapse into a single resonance centered at $\delta = 7.41$ (Figure 4b). These features are seen over the 203−243 K range (with an increasing broadening of the signals); above 243 K, splitting into the two resonances observed at room temperature occurs.

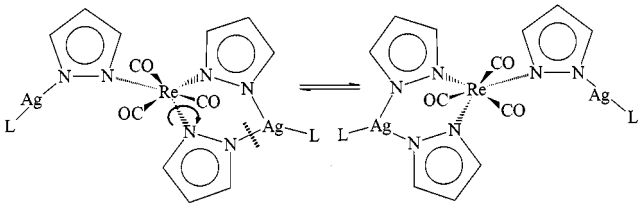
An interpretation of the fluxional behaviour based on a concerted mutual exchange between the trigonal and digonal silver centers (as depicted in Scheme 2) can explain the limiting spectra at low and high exchange rates,[12] but is not able to account for the equivalence of the six protons in the 3- and 5-positions of the pyrazolate rings detected at intermediate exchange rates.

The spectroscopic observations may be rationalized by assuming that the exchange between the trigonal and digonal silver centers shown in Scheme 2 passes through transient intermediate species (species B_i in Scheme 3, $i = 1-3$) containing two singly bridged and one monodentate pyrazolato, as found in the solid state for the gold(I) derivative **2c**.

In fact, two exchange processes may be operative: one relating to the equilibrium between the doubly bridged and singly bridged species, $A_i - B_i$ (Scheme 3), and the second, responsible for rendering the 3- and 5-positions of the pyrazolate rings indistinguishable, involving N(1)/N(2) scrambling ($B_i - B'_i$), which is frequently found in complexes containing anionic monodentate pyrazolate ligands.[13] Hence, the ^{1}H-NMR pattern can be attributed to the relative rates of these two processes. Schematically, we can write the equilibrium as shown in Equation 2.

In the intermediate temperature range, the lifetime of the species B_i is sufficiently long to permit "hopping" of the metal atom between the two nitrogen atoms of the monodentate pyrazolate ring, making the 3- and 5-protons indis-





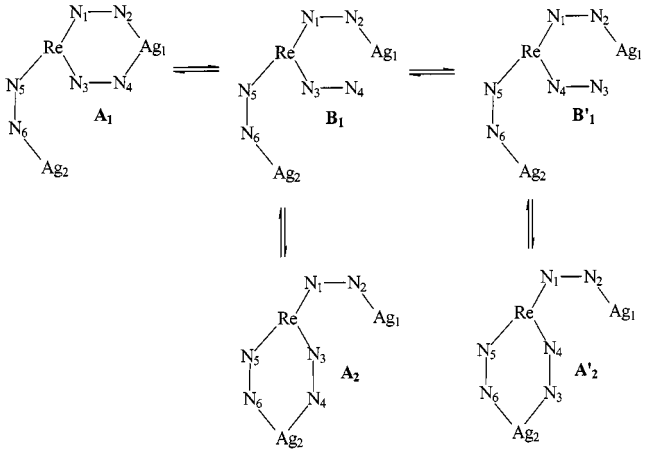


Figure 4. ^{1}H-NMR spectra (CD_2Cl_2 solution) in the pyrazolate-H region for compound **2b**: (a) at room temp., (b) at 213 K, and (c) at 173 K

Scheme 2. Concerted mutual exchange between the trigonal and digonal silver centers in complex **2b**

Scheme 3. Proposed mechanism for the dynamic process involving complex **2b**; similar equilibria are seen for all A_j species (see text)

$$A_i \rightleftharpoons \{B_i, B'_i\} \rightleftharpoons A_j \qquad [2]$$

tinguishable. At higher temperatures, the rapid opening/closure of the Ag−[N−N]$_2$−Ag metallocycle hampers this scrambling and hence the equilibration of the 3- and 5-positions. In terms of kinetic parameters (Arrhenius law), this corresponds qualitatively to rather different temperature dependences for the two processes, i.e. $\Delta E^{\neq}_{\text{open-close}} > \Delta E^{\neq}_{\text{scramble}}$ and $\ln A_{\text{open-close}} > \ln A_{\text{scramble}}$.

The room-temperature ^{1}H-NMR spectrum of the copper derivative **2a** closely matches that of species **2b** [two doublets centered at δ = 7.50 and 7.45, respectively; J = 1.92 Hz; a pseudo triplet at δ = 6.23]. On lowering the temperature to 173 K, all signals are broadened, but the overall spectral features do not change significantly. Indeed, the ^{1}H-NMR spectra of complex **2a** over the entire 303−173 K range are similar to those of **2b** in the "high" temperature range (above 243 K). This fact, assuming that the same fluxional processes active in **2b** also occur in **2a**, seems to indicate lower rigidity of the copper derivative compared to its silver counterpart.

As far as complex **2c** is concerned, the room-temperature ^{1}H-NMR spectrum shows, in the region of the pyrazole sig-

nals, three doublets (6 H, in a 1:1:1 ratio) centered at δ = 7.77 (J = 1.92 Hz), δ = 7.53 (J = 1.75 Hz), and δ = 7.43 (J = 1.75 Hz), respectively, along with two triplets (3 H, in a 1:2 ratio) centered at δ = 6.25 and δ = 6.21, respectively. On lowering the temperature, the second doublet and the downfield triplet broaden and disappear, and finally, at −40°C, only three signals remain. Further lowering of the temperature leads to a drastic change in the spectrum with the appearance of new, partially overlapped signals. Presently, we are unable to give a complete explanation of this behaviour. This effect might be a manifestation of exchange processes similar to those observed for **2b**, but the non-equivalence of the Re−[N−N]$_2$−Au fragments further increases the complexity of the spectrum.

Conclusions

We have demonstrated herein that the organometallic complex [(CO)$_3$Re(Hpz)$_2$(pz)], once deprotonated, can act as a multidentate ligand towards a variety of metal atoms. The analogy with the tris(pyrazolyl)borate anion is, however, partially obscured by the fact that "tripod-like" coordination of Group-11 metal atoms was not observed, probably because of the specific electronic/steric requirements of the present systems, which favour low coordination numbers. Preliminary studies of Re−Mn derivatives have revealed that triply bridged [(CO)$_3$Re(μ-pz)$_3$MnL$_n$] systems can indeed be prepared, but these will be reported in a forthcoming paper.

Additionally, variable-temperature NMR analyses have clearly revealed the nonrigidity of the isolated species and have indicated that fluxionality can be attributed to simultaneous scrambling of monodentate pyrazolato ligands and ring-opening/closure equilibria, leading to a rather complex "argentotropic" behaviour.[12]

Experimental Section

General: Solvents were dried and purified by standard methods. Pyrazole (Aldrich Chemical Co.) was used as supplied. − Infrared spectra were recorded with a Bio Rad FT-IR 7 instrument. − ^{1}H-NMR spectra were acquired with a Bruker AC-300 FT spectrometer operating at 300.13 MHz. − Elemental analyses were performed at the Microanalytical Laboratory of this university (C, H, N). − All reactions were carried out under dry nitrogen using standard Schlenk techniques.

{(CO)$_3$Re(μ-pz)$_3$[Cu(CyNC)]$_2$} (2a): [(CO)$_3$Re(Hpz)$_2$(pz)][4] (150 mg, 0.317 mmol) was dissolved in acetonitrile (10 mL) and solid [Cu(CH$_3$CN)$_4$](BF$_4$)[14] (210 mg, 0.668 mmol) was added under stirring. Triethylamine (0.5 mL) was then added and the yellow solution was stirred for a further 15 min. A solution of cyclohexyl isocyanide (90 μL) in degassed CH_2Cl_2 (ca. 2 mL) was then added, leading to a colorless solution. After stirring for 30 min, the solvent was completely evaporated, the residue was treated with ethanol, and the white solid was collected by filtration, washed with ethanol, and dried in vacuo (155 mg, 60% yield). − $C_{26}H_{31}Cu_2N_8O_3Re$ (816.87): calcd. C 38.23, H 3.83, N 13.73; found C 38.06, H 3.78, N 13.38. − Crystals suitable for X-ray structure analysis were obtained by slow diffusion of *n*-hexane into dichloromethane solutions of the complex.

{(CO)$_3$Re(μ-pz)$_3$[Ag(CyNC)]$_2$} (2b): To a solution of [(CO)$_3$Re(Hpz)$_2$(pz)] (100 mg, 0.21 mmol) in acetonitrile (4 mL), was added a solution of $AgNO_3$ (94 mg, 0.55 mmol) in water (ca. 2 mL). Triethylamine (0.5 mL) was then added dropwise to the colorless solution, resulting in the sudden deposition of a white solid. The suspension was stirred for a further 15 min, and then the solid was collected by filtration, washed with water, and dried in vacuo (compound **1b**). **1b** was suspended in CH_2Cl_2 (ca. 2 mL) and cyclohexyl isocyanide (60 μL) was added to the white suspension, giving a colorless solution. The solvent was then evaporated in vacuo and the residue was treated with Et_2O, filtered, and dried in vacuo (108 mg, 57% yield). − $C_{26}H_{31}Ag_2N_8O_3Re$ (905.53): calcd. C 34.51, H 3.46, N 12.39; found C 34.83, H 3.54, N 12.35. − Crystals suitable for X-ray structure analysis were obtained by slow diffusion of *n*-hexane into dichloromethane solutions of the complex.

{(CO)$_3$Re(μ-pz)$_3$[Au(CyNC)]$_2$} (2c): To a stirred solution of [(CO)$_3$Re(Hpz)$_2$(pz)] (200 mg, 0.422 mmol) in acetonitrile (ca. 6 mL) at 0°C under nitrogen, was added [Au(tht)Cl][15] (tht: tetrahydrothiophene) (269 mg, 0.883 mmol). Tributylamine (0.5 mL) was then added dropwise. After a few minutes, a white solid separated from the colorless solution. The suspension was kept at 0°C and stirred for a further 3 h. The white solid was then collected by filtration and dried in vacuo (compound **1c**). Cyclohexyl isocyanide (60 μL) was added to a suspension of **1c** in CH_2Cl_2 (ca. 3 mL), giving a colorless solution. This solution was then concentrated to dryness and the residue was treated with ethanol. The white solid obtained was filtered off, washed with ethanol, and dried in vacuo (261 mg, 57% yield). − $C_{26}H_{31}Au_2N_8O_3Re$ (1083.72): calcd. C 28.78, H 2.88, N 10.33; found C 28.81, H 2.80, N 10.26. − Crystals suitable for X-ray structure analysis were obtained by slow diffusion of *n*-hexane into dichloromethane solutions of the complex, with protection from light.

Crystallography:[16] Crystals of **2a−c** were studied by conventional single-crystal X-ray methods; an overview of the methodology used can be found in ref.[11b] Owing to disorder involving the cyclohexyl moieties in **2b** and **2c**, special procedures were adopted during the structure refinement. For **2b**, the cyclohexyl rings were each described by two models having 62/38% and 52/48% occupancy factors, respectively. In **2c**, only one cyclohexyl ring was found to be disordered (with a 54/46% ratio) but required, in order to achieve least-squares stability, a common (isotropic) atomic displacement parameter. Hydrogen atoms of the disordered groups were omitted from the structure factor calculations. A list of crystal data, refinement parameters, and final agreement factors is presented in Table 3.

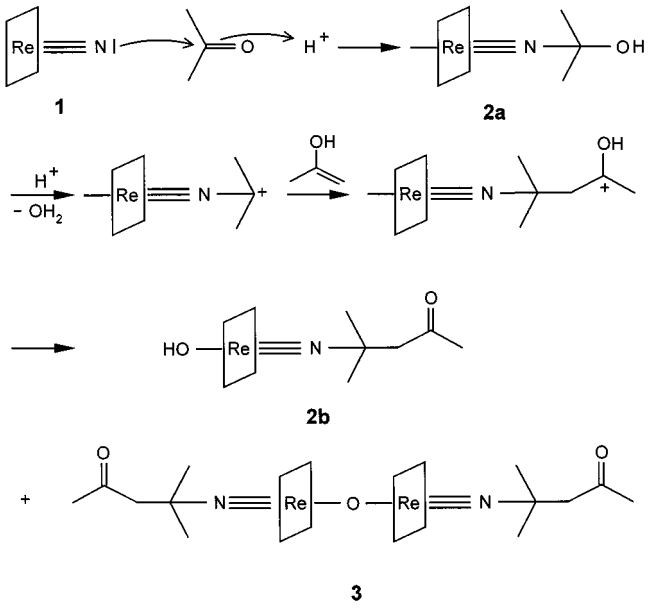
Synthesis and Investigations on Nitrido(phthalocyaninato)rhenium Complexes

Karsten Frick,[a] Ulrich Ziener,[a] and Michael Hanack*[a]

Keywords: Phthalocyanines / Rhenium / Nitrido(octa-*n*-alkylphthalocyaninato)rhenium compounds / Nucleophilic additions

The reactions of nitrido(tetra-*tert*-butylphthalocyaninato)-rhenium (**1**) with boron tribromide leading to (tBu$_4$Pc)-ReNBBr$_3$ (**4**) and with acetone to give the imido complex (tBu$_4$Pc)Re[NC(CH$_3$)$_2$CH$_2$C(O)CH$_3$]OH (**2b**) and its μ-oxo dimer **3** are reported. Starting from the corresponding 4,5-di-*n*-alkylphthalonitriles and ammonium perrhenate four soluble nitrido(octa-*n*-alkylphthalocyaninato)rhenium complexes **5**–**8** were synthesized. Nitrido(octa-*n*-pentylphthalocyaninato)rhenium (**6**) was treated with boron tribromide to afford [(C$_5$H$_{11}$)$_8$Pc]ReNBBr$_3$ (**9**).

To investigate the chemical and optoelectronic properties of hitherto unknown nitrido-bridged phthalocyaninato transition-metal/main-group complexes (PcMNPcM′: M = Re, Mo, W; M′ = Si, Ge, Sn) a suitable synthetic procedure was needed. The heavier transition-metal ions in high oxidation states, which are suitable to form the M−N triple bond, are used to prepare the nitrido complexes. N^{3-} (nitride) containing a triple bond is known as one of the strongest π-donor ligands.[1] Some (nitrido)metal complexes of porphyrins, e.g. (TPP)MnN,[2] (OEP)ReN[3] and others[4] have been prepared, some nitrido complexes with phthalocyanines are also known, namely PcMnN,[5] PcTcN,[6] PcReN[7] and the dinuclear complexes (PcFe)$_2$N[8] and (PcRu)$_2$N.[9] These nitrido(phthalocyaninato) complexes are practically all insoluble in organic solvents. Recently, we published the first soluble (phthalocyaninato)rhenium compound, (tBu$_4$Pc)ReN (**1**),[10] which exists in four structural isomers.



Here we report on the reaction of (tBu$_4$Pc)ReN (**1**) with boron tribromide leading to (tBu$_4$Pc)ReNBBr$_3$ (**4**) and the reaction of **1** with acetone to afford (tBu$_4$Pc)Re-[NC(CH$_3$)$_2$CH$_2$C(O)CH$_3$]OH (**2b**) and {(tBu$_4$Pc)Re-[NC(CH$_3$)$_2$CH$_2$C(O)CH$_3$]}$_2$O (**3**), which are the first μ-nitrido(phthalocyaninato) complexes between rhenium and boron or carbon, respectively. In addition we describe the synthesis of the octasubstituted (phthalocyaninato)rhenium complexes [(C$_4$H$_9$)$_8$Pc]ReN (**5**), [(C$_5$H$_{11}$)$_8$Pc]ReN (**6**), [(C$_6$H$_{13}$)$_8$Pc]ReN (**7**) and [(C$_7$H$_{15}$)$_8$Pc]ReN (**8**) and the reaction of **6** with BBr$_3$.

The reaction of a mixed-ligand nitridorhenium(V) complex, [ReN(Cl)(Me$_2$PhP)$_2$R$_2$tcb] [R$_2$tcb = *N*-(*N*,*N*-dialkylthiocarbamoyl)benzamidinate] with HCl and HBr in acetone to form a nitrene-like compound, Re[NC(CH$_3$)$_2$-CH$_2$C(O)CH$_3$]X$_3$(Me$_2$PhP)$_2$ (X = Cl, Br) was recently described.[11] On addition of few drops of concentrated HCl to a suspension of tBu$_4$PcReN (**1**) in acetone a colour change from blue to blue-green occurs with dissolution of the solid. A UV/Vis spectrum of this solution exhibits broader bands with a red shift of the Q band of 30 nm relative to that of the starting material. The change in colour may be due to protonation of either the isoindoline nitrogen atoms of **1**[12] or the nitrido N atom. In the mechanism given in ref.[11], firstly the formation of diacetone alcohol due to the addition of HCl and secondly the attack of the nitrido nitrogen atom at the C−OH group are described. A direct way seemed more appropriate to us, namely a nucleophilic attack of the nitrido N atom to the carbonyl C atom of acetone to form **2a**, which reacts with a second molecule of acetone to form **2b** as shown in Scheme 1. This suggestion avoids the formation of diacetone alcohol in the first step which is very much dependent upon the acid concentration and temperature. After a reaction time of several days, the condensation product **2b** of diacetone alcohol and **1** was isolated (Scheme 1). For charge compensation, the *trans* position at the rhenium atom is occupied by OH^-. While purifying the crude product by column chromatography on aluminium oxide a small amount of the μ-oxo dimer {(tBu$_4$Pc)Re[NC-(CH$_3$)$_2$CH$_2$C(O)CH$_3$]}$_2$O (**3**) is eluted (see below).

A comparison of the IR spectra of (tBu$_4$Pc)Re-[NC(CH$_3$)$_2$CH$_2$C(O)CH$_3$]OH (**2b**) with that of (tBu$_4$Pc)ReN (**1**) reveals the disappearance of $\tilde{\nu}_{Re\equiv N}$ = 978 cm^{-1} in **2b**, while additional bands at $\tilde{\nu}$ = 1123, 1148 and 3651 cm^{-1} appear. One of the two bands at $\tilde{\nu}$ = 1123 cm^{-1} and $\tilde{\nu}$ = 1148 cm^{-1} is assigned to the stretching vibration $\tilde{\nu}_{Re\equiv N}$.[1] There is no possible assignment for the origin of the other band. The C=O vibration of **2b** can be attributed to the band at $\tilde{\nu}_{C=O}$ = 1718 cm^{-1}. **A** weak but sharp band at $\tilde{\nu}$ = 3651 cm^{-1} is caused by the OH group. The ^{1}H-NMR spectrum of **2b** shows, besides the expected signals for the *tert*-butyl protons (δ = 1.74−1.95) and the protons in the aromatic region (δ = 8.13 and 9.35), three groups of signals at δ = 0.14, −0.80 and −2.08 in the ratio 3:2:6. They are assigned to CH$_3$ in the neighbourhood of the carbonyl group, the CH$_2$ group and the equivalent CH$_3$ groups, respectively. The splitting of these groups is either caused by aggregation effects or is due to the four isomers

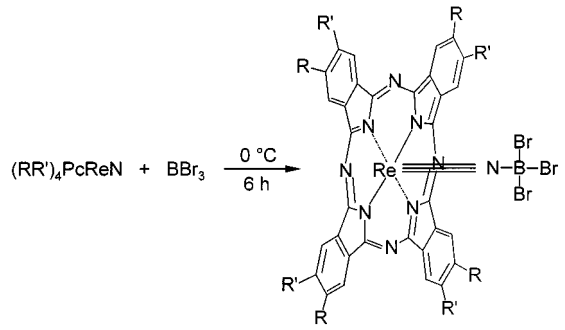
Scheme 1. Possible mechanism leading to **2b** and **3**

present in tetrasubstituted phthalocyanines.[13] The structure of **2b** is also proved by its ^{13}C-NMR spectrum. In addition to the signals already observed for **1**,[10] five signals for **2b** at δ = 202.07, 65.51, 47.40, 29.17 and 21.65 corresponding to the six C atoms of the axial ligand are observed.



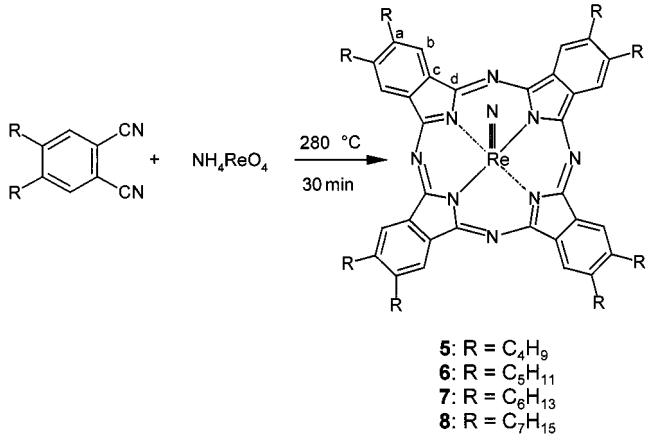
Besides some changes in intensity, the IR spectrum of **3** shows two new bands at $\tilde{\nu}$ = 727 and 802 cm^{-1}, which cannot be assigned and consequently no O−H vibration $\tilde{\nu}$ = 3651 cm^{-1} was observed. Dimeric phthalocyanines with a coplanar arrangement of the macrocycles and an ideal D_{4h} symmetry show a blue shift of the Q band,[14] which is also observed in **3** by 37 nm relative to **1**. From this shift the exciton coupling can be estimated to be about 1600 cm^{-1}, which is in accordance with the value for dimeric phthalocyanines.[14]

The ^{1}H-NMR spectrum of **3** exhibits in all regions sharp signals in the expected ratio of intensity. In the aromatic region several signals between δ = 9.46 and 8.20 are found besides signals due to the *tert*-butyl protons between δ = 2.63 and 2.05, which are attributed to the higher number of isomers. The low-field shift of the *tert*-butyl protons by about 0.5 ppm and the high-field shift of the protons of the axial imido ligand at δ = −0.63, −1.68 and −3.01 of about 0.7 to 1.0 in **3** are caused by the additional ring current of the second macrocycle.

The unsubstituted PcReN does not react with acetone/HCl even after several days. This is due to the poor solubility of PcReN.

(Nitrido)metal complexes are suitable precursors to complexes with nitrogen bridges between the transition-metal rhenium (M) and main-group elements such as, for example, boron (M′) (M≡N−M′). We investigated the possibility of a reaction of **1** and $(C_5H_{11})_8$PcReN (**6**) with BBr_3. Nitrogen-bridged rhenium−boron complexes like $Br_4ReNBBr_3$,[15a] $Re(NBCl_3)Cl_2[P(CH_3)_2C_6H_5]_3$[15b] and $(PEt_2C_6H_5)_3X_2ReNBY_3$ (X = Cl, Br; Y = F, Cl, Br)[15c] are known.

The reaction of (tBu$_4$Pc)ReN (**1**) with the Lewis acid BBr_3 in dichloromethane at 0°C for 6 h leads to a bonding of the boron atom to the axial nitrogen atom of **1** (Scheme 2). After removing the solvent and the excess of BBr_3 under vacuum, (tBu$_4$Pc)ReNBBr$_3$ (**4**) was obtained, which is sensitive to moisture.



1: R = H, R' = *t*Bu
6: R = R' = C_5H_{11}
4: R = H, R' = *t*Bu (D_{4h}-isomer)
9: R = R' = C_5H_{11}

Scheme 2. Synthesis and Structure of (tBu$_4$Pc)ReNBBr$_3$ (**4**) and [$(C_5H_{11})_8$Pc]ReNBBr$_3$ (**9**)

In the FD MS and ionspray MS the M$^+$ peak of **4** was absent. However, (tBu$_4$Pc)ReNBBr$_2$, (tBu$_4$Pc)ReNBBr and BBr_3 were detected at m/z = 1107.5, 1029.6 and 250.8, respectively. The peak for **1** is also found in these spectra due to adventitious moisture present, which decomposes **4** to HBr, $B(OH)_3$ and **1**. The IR spectrum of **4** shows new vibrations compared to **1**. The Re−N triple bond vibration at $\tilde{\nu}_{Re\equiv N}$ = 978 cm^{-1} is shifted to 1196 cm^{-1}. This band matches with the vibrations reported for a nitrido bridge between the rhenium and the boron atom, which is assigned at $\tilde{\nu}$ = 1170 and 1180 cm^{-1}.[15b] This absorption at lower wavelength of $\tilde{\nu}_{Re\equiv N}$ is caused by the coupling with the B−N vibration of the presumably linear axis Re≡N−B.[15b] The extent of this coupling is lower than in complexes like Re≡N−C ($\tilde{\nu}_{Re\equiv N}$ = 1123 or 1148 cm^{-1} for **2b**) due to the higher frequency of $\tilde{\nu}_{N-C}$ relative to $\tilde{\nu}_{N-B}$. The latter appears at $\tilde{\nu}_{N-B}$ = 645 cm^{-1} and the BBr_3 stretching vibration at $\tilde{\nu}_{B-Br}$ = 671 cm^{-1}. In general, the N−B vibrations are located between 650 and 780 cm^{-1}.[16] The absorption at longer wavelength is due to the coupling with $\tilde{\nu}_{Re\equiv N}$. In the UV/Vis spectrum of **4** the Q band is red-shifted from λ = 697 to 725 nm due to the electron-withdrawing effect of the BBr_3 group. The band is broadened and shows a shoulder at λ = 755 nm. Furthermore, the ^{11}B-NMR spectrum of **4** gave unambiguous evidence for a boron−nitrogen bond. Relative to that of BBr_3 (δ = 38.15), the ^{11}B signal of (tBu$_4$Pc)ReNBBr$_3$ (**4**) is shifted to δ = −12.90 showing the influence of the aromatic Pc ring.

To improve the stability of nitrido-bridged (phthalocyaninato)rhenium complexes and keep the good solubility we replaced the large *tert*-butyl groups by alkyl chains. Therefore the (octaalkylphthalocyaninato)rhenium complexes, [$(C_4H_9)_8$Pc]ReN (**5**), [$(C_5H_{11})_8$Pc]ReN (**6**), [$(C_6H_{13})_8$Pc]ReN

(**7**) and [$(C_7H_{15})_8$Pc]ReN (**8**) were synthesized by treating the respective 4,5-di-*n*-alkylphthalodinitriles with ammonium perrhenate.[10] The phthalocyanines were purified by Soxhlet extraction with methanol followed by column chromatography with dichloromethane. The yields are lower than that of unsubstituted PcReN[17] but similar to the yield of (tBu$_4$Pc)ReN (**1**)[10] (Scheme 3).

Scheme 3. Synthesis and Structure of **5**−**8**

The IR spectra of **5**−**8** resemble other octa-*n*-alkyl-substituted (phthalocyanine)metal complexes[18] except in the region between 950 and 1000 cm^{-1}. A band of low intensity is observed in all IR spectra of **5**−**8**, which is assigned to the Re−N triple-bond stretching vibration.[1] These bands are in agreement with those found for PcReN[6] and (tBu$_4$Pc)ReN (**1**).[10] The UV/Vis spectra of the **5**−**8** show the Q band at λ = 705 nm (π-π* transition) for **5** and vibronic transitions at λ = 673 and 633 nm (in toluene) [**6** (CH_2Cl_2): λ = 708, 676, 638; **7** (toluene): λ = 704, 671, 634; **8** (CH_2Cl_2): λ = 708, 676, 638]. The slight blue shift of the Q band in **5**,**7** relative to **6**,**8** is caused by the change of solvent. Compounds **5**−**8** show a red shift of the Q band of about 30 nm relative to that of other octasubstituted phthalocyanines.[18] This difference may be caused by the high oxidation state of rhenium (+V). Similarly for (tBu$_4$Pc)ReN (**1**), the Q band is red-shifted by about 25 nm to λ = 697 nm.[10][20] We have no indication for exciton interaction of dimers or even larger aggregates,[21] so monomeric units of **5**−**8** were assumed in solution. The B band of **5**−**8** shows two maxima for **5** at λ = 369 and 351 nm [**6** (CH_2Cl_2): 361, 347 nm; **7** (toluene): 369, 350 nm; **8** (CH_2Cl_2): 361, 347 nm]. The FD MS spectra of **5**−**8** exhibit the expected peaks at 1161.5 (**5**; M^+), 1274.0 (**6**; M^+), 1385.7 (**7**; M^+) and 1498.3 (**8**; M^+) showing all the calculated isotope distribution. A singlet at low field in the ^{1}H-NMR spectrum of **5**−**8** is due to their high symmetry: For **5** this signal appears at δ = 9.21, at δ = 8.75 for **6**, at δ = 8.81 for **7** and at δ = 9.13 for **8** and is assigned to the eight aromatic protons. For **1**[10] three multiplets are found in the aromatic region due to the four isomers of tetrasubstituted phthalocyanines (C_{4h}, C_{2v}, D_{2h}, C_s) at δ = 8.39, 9.46, and 9.56 in the ratio of 1:1:1. The alkyl chains in **5**−**8** show the usual and expected signals at higher field. The methyl groups appear as triplets with coupling constants J = 7.04 Hz for **5**, 7.08 Hz for **6**, 6.88 Hz for **7** and 6.71 Hz for **8** (Figure 1). In the ^{13}C-NMR spectra of **5**−**8** four signals in the aromatic region for the carbon atoms C-a [144.28 (**8**)−144.08 (**6**)], C-b [122.84 (**5**)−122.66 (**6**)], C-c [135.12 (**8**)−134.98 (**6**)] and C-d [148.30 (**8**)−148.04 (**6**)] are observed. This pattern matches well with other octasubstituted phthalocyanines.[18] However, (tBu$_4$Pc)ReN (**1**) shows ten signals at lower field, which are all split or show at least a shoulder due to its structural isomers.[10] In the higher field between δ = 34.13 and 14.19 the expected number of signals for alkyl carbon atoms for compounds **5**−**8** are found (Figure 1).

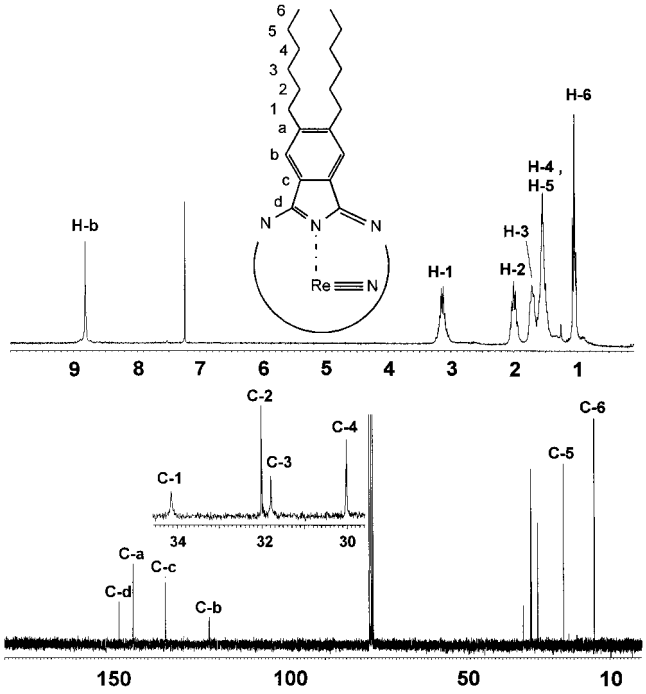


Figure 1. ^{1}H-and ^{13}C-NMR of ($C_6H_{13})_8$PcReN (**7**)

The solubility of **5**−**8** is good in common organic solvents (e.g. $CHCl_3$, toluene, THF, pyridine), but less than that of (tBu$_4$Pc)ReN (**1**). The solubility increases from [$(C_4H_9)_8$Pc]ReN (**5**) to [$(C_7H_{15})_8$Pc]ReN (**8**). However, they are quite insoluble in hexane, methanol and diethyl ether.

[$(C_5H_{11})_8$Pc]ReN (**6**) was treated with BBr_3 under the same conditions as for **4** to investigate the stability of the formed complex [$(C_5H_{11})_8$Pc]ReNBBr$_3$ (**9**) (Scheme 2). Compound **9** is less sensitive to moisture than **4** and hence it was possible to obtain the M^+ peak in the FAB MS at 1531.5 (M^+ + matrix) proving the higher stability of **9**. Peaks at 1450.4, 1372.4, 1286.5 and 1273.6 for [$(C_5H_{11})_8$Pc]ReNBBr$_2$, [$(C_5H_{11})_8$Pc]ReNBBr, [$(C_5H_{11})_8$Pc]-ReNB and [$(C_5H_{11})_8$Pc]ReN (**6**) have been also observed. The Re−N triple-bond stretching vibration in the IR spectrum of **9** is found in the expected region similar to that of **4** at $\tilde{\nu}_{Re\equiv N}$ = 1194 cm^{-1}. Furthermore, the vibrations of $\tilde{\nu}_{B-Br}$ = 677 cm^{-1}, $\tilde{\nu}_{N-B}$ = 650 cm^{-1} and the usual vibrations for octasubstituted phthalocyanines give definite evidence for the suggested structure of **9**. The Q band in

the UV/Vis spectrum of **9** is broadened and red-shifted to $\lambda = 738$ nm. The extent of this shift (30 nm) is the same as for (tBu$_4$Pc)ReNBBr$_3$ (**4**). The vibronic transitions at $\lambda = 676$ and 638 nm in **6** are also red-shifted to $\lambda = 701.5$ and 667.5 nm, respectively, due to the electron-withdrawing effect of the BBr_3 group, which is in accordance with **4**. In the same way the B band exhibits its maximum at $\lambda = 380$ nm. The ^{11}B-NMR spectrum of **9** shows a signal at $\delta = -12.75$, similar to the one observed for **4** ($\delta = -12.90$).

Experimental Section

4,5-Di-*n*-alkylphthalodinitriles were synthesized according to ref.[18] NH_4ReO_4 was prepared from Re metal,[21] which was a gift from Degussa AG. The solvents were purified by known procedures. − FT IR: Bruker IFS 48. − UV/Vis: Shimadzu UV−365. − MS: Varian Mat 711 (EI, FD). − ^{1}H, ^{13}C, ^{11}B NMR: Bruker AC 250 (^{1}H: 250.133 MHz; ^{13}C: 62.902; ^{11}B: 80.251). − Elemental analyses: Carlo Erba Elemental Analyser 1104, 1106.

(tBu$_4$Pc)Re[NC(CH$_3$)$_2$CH$_2$C(O)CH$_3$]OH (2b) and {tBu$_4$PcRe-[NC(CH$_3$)$_2$CH$_2$C(O)CH$_3$]}$_2$O (3): (tBu$_4$Pc)ReN (**1**)[10] (97 mg, 0.1 mmol) was suspended in 10 mL of acetone and treated with 5 drops of conc. HCl leading to dissolution and change of colour from blue to blue-green. After stirring at room temperature for 4 d in the dark, the solvent was removed and the residue chromatographed on Al_2O_3 with toluene as eluent to eliminate unchanged **1**. Two blue-green compounds were eluted with CH_2Cl_2 the first being the dimer **3** and the second the monomer **2b**. 59 mg (54%) of **2b** and 5 mg (2%) of **3**, both blue-green microcrystalline solids, were obtained.

2b: IR (KBr): $\tilde{\nu} = 3651$ cm^{-1}, 3076, 2959, 2903, 2866, 1718, 1614, 1485, 1337, 1281, 1258, 1155, 1148, 1123, 1113, 1090, 1049, 935, 833, 768, 756. − UV/Vis (CH_2Cl_2): λ (lg ε) = 246 nm (4.70), 270 (4.54), 286 (4.47), 356 (4.79), 557 (3.06), 579 (3.58), 601 (3.83), 626 (4.40), 695 (5.08). − MS (FD); *m/z* (%): 1053.4 (100) [M$^+$]. − ^{1}H NMR ($CDCl_3$): $\delta = -2.13$ to -2.08 [m, 6 H, C(CH_3)$_2$], 0.80 (m, 2 H, CH_2), 0.11−0.14 [m, 3 H, C(O)CH_3], 1.74−1.94 (m, 36 H, *t*Bu), 8.13−9.31 (m, 8 H, aromatic H). − ^{13}C NMR ($CDCl_3$): $\delta = 21.65$ [m, C(*C*H$_3$)$_2$], 29.17 [m, C(O)*C*H$_3$], 31.90−32.18 [m, C(*C*H$_3$)], 36.04−36.14 [m, *C*(CH$_3$)$_3$], 47.70 (m, *C*H$_2$), 65.51 [m, *C*(CH$_3$)$_2$], 119.30−119.40 (m, *C*H$_2$), 122.90 (m, C-b), 127.95 (m, C-a), 135.14−135.30 (m, C-c,), 137.78−138.00 (s, C-c′), 147.05−147.75 (m, C-d, C-d′), 153.61−153.78 (m, C-a′), 202.07 (C-O). − $C_{54}H_{60}N_9O_2Re$ (1053.3): calcd. C 61.58, H 5.74, N 11.97; found C 61.43, H 5.54, N 11.65.

3: IR (KBr): $\tilde{\nu} = 3071$ cm^{-1}, 2961, 2924, 2866, 1709, 1616, 1485, 1259, 1144, 1122, 1090, 802, 727. − UV/Vis (CH_2Cl_2): λ (lg ε) = 257 nm (4.65), 289 (4.48), 340 (4.48), 353 (4.52), 554 (3.50), 575 (3.57), 603 (3.91), 634 (4.14), 659 (4.85). − MS (FD); *m/z* (%): 2088.6 (100) [M$^+$]. − ^{1}H NMR ($CDCl_3$): $\delta = -3.03$ to -2.95 [m, 12 H, 2 × C(CH_3)$_2$], −1.73 to −1.64 (m, 4 H, 2 × CH_2), −0.66−0.63 [m, 6 H, 2 × C(O)CH_3], 1.99−2.21 (m, 72 H, *t*Bu), 8.20−9.37 (m, 24 H, aromatic H). − ^{13}C NMR (H/C COSY; $CDCl_3$): $\delta = 22.26$ [m, C(*C*H$_3$)$_2$], 29.65 [m, C(O)*C*H$_3$], 33.65 [m, C(*C*H$_3$)], 49.39 (m, *C*H$_2$), 119.89 (m, C-b′), 124.36 (m, C-b), 128.23. − $C_{108}H_{118}N_{18}O_3Re_2$ (2088.7): calcd. C 62.11, H 5.69, N 12.07; found C 64.86, H 6.88, N 9.17.

(tBu$_4$Pc)ReNBBr$_3$ (4) and [(C$_5$H$_{11}$)$_8$Pc]ReNBBr$_3$ (9): 0.053 mmol of the nitrido(phthalocyaninato)rhenium complexes (**1**,**6**)[10] was dissolved in 10 mL of CH_2Cl_2. Then 0.1 mL (1 mmol) BBr_3 was added dropwise at 0°C showing a change of colour from blue to green. The temperature was maintained for 6 h. Removal of the solvent and excess BBr_3 under vacuum gave 62.9 mg (100%) **4**, and 80.7 mg (100%) **9**, dark-green microcrystalline solids.

4: IR (KBr): $\tilde{\nu} = 3221$ cm^{-1}, 2961, 2905, 1612, 1481, 1408, 1366, 1331, 1283, 1257, 1196, 1155, 1092, 1051, 935, 833, 810, 766, 754, 671, 645. − UV/Vis (CH_2Cl_2): $\lambda = 382$ nm, 725, 775. − MS (FD); *m/z* (%): 1107.5 (5) [M$^+$ − Br], 937.7 (100) [M$^+$ − BBr_3], 921.8 (35) [M$^+$ − $NBBr_3$]. − MS (ionspray); *m/z* (%): 1029.6 (100) [M$^+$ − 2 × Br], 938.4 (80) [M$^+$ − BBr_3], 378.2 (10) [$ReNBBr_2$], 294.6 (57) [$ReNBBr_3$], 250.8 (69) [BBr_3] − ^{11}B NMR ($CDCl_3$/BF3·Et2O): $\delta = -12.90$ (s, 1B).

9: IR (KBr): $\tilde{\nu} = 3215$ cm^{-1}, 2955, 1616, 1456, 1337, 1259, 1194, 1109, 1036, 883, 804, 754, 735, 677, 650. − UV/Vis (CH_2Cl_2): $\lambda = 380$ nm, 668, 702, 738. − MS (FAB); *m/z* (%): 1531.5 (3) [M$^+$ + matrix], 1450.4 (4) [M$^+$ − Br + matrix], 1372.4 (7) [M$^+$ − 2 × Br + matrix], 1286.5 (18) [M$^+$ − 3 × Br + matrix], 1273.6 (100) [M$^+$ − BBr_3]. − ^{11}B NMR ($CDCl_3$/BF3·Et2O): $\delta = -12.75$ (s, 1 B).

Nitrido(octa-*n*-alkylphthalocyaninato)rhenium(V) [(R$_8$Pc)ReN] 5−8: 0.21 mmol of the appropriate 4,5-di-*n*-alkylphthalodinitriles was heated with 0.048 mmol NH_4ReO_4 to 280°C for 30 min. After cooling, the dark green reaction mixture was first chromatographed on Al_2O_3 (neutral, 10% H_2O) with dichloromethane as eluent (2 ×) to remove most of the impurities. Then the excess of dinitrile was extracted with methanol for 12 h by using a Soxhlet apparatus. 55 mg (5%) of **5,** 65 mg (5%) of **6**, 55 mg (4%) of **7** and 60 mg (4%) of **8** were obtained as dark green powders.

5: IR (KBr): $\tilde{\nu} = 2957$ cm^{-1}, 2930, 1620, 1497, 1456, 1403, 1335, 1113, 1082, 1030, 964, 905, 754, 733. − UV/Vis (toluene): $\lambda = 351$ nm, 369, 633, 673, 705. − MS (FD); *m/z* (%): 1161.5 (100) [M$^+$]. − ^{1}H NMR ($CDCl_3$): $\delta = 1.18$ (t, $J = 7.04$ Hz, 24 H, CH_3), 1.63−1.81 (m, 16 H, CH$_3$CH_2), 1.87−2.09 (m, 16 H, CH$_3$CH$_2$CH_2), 3.04−3.27 (m, 16 H, ArCH_2), 8.91 (s, 8 H, aromatic H). − ^{13}C NMR ($CDCl_3$): $\delta = 14.25$ (s, *C*H$_3$), 23.35 (s, CH$_3$*C*H$_2$), 33.81 (s, CH$_3$CH$_2$*C*H$_2$), 33.91 (s, Ar*C*H$_2$), 122.84 (s, C-b), 135.11 (s, C-c), 144.22 (s, C-a), 148.27 (s, C-d). − $C_{64}H_{72}N_9Re$ (1161.6): calcd. C 66.18, H 6.94, N 10.85; found C 66.39, H 6.53, N 10.45.

6: IR (KBr): $\tilde{\nu} = 2954$ cm^{-1}, 2927, 2868, 1618, 1498, 1456, 1406, 1337, 1110, 1079, 1018, 965, 891, 754, 732. − UV/Vis (CH_2Cl_2): $\lambda = 347$ nm, 361, 638, 676, 708. − MS (FD); *m/z* (%): 1274.0 (100) [M$^+$]. − ^{1}H NMR ($CDCl_3$): $\delta = 1.11$ (t, $J = 7.08$ Hz, 24 H, CH_3), 1.51−1.78 (m, 32 H, CH$_3$CH_2CH_2), 1.90−2.10 (m, 16 H, ArCH$_2$CH_2), 2.98−3.22 (m, 16 H, ArCH_2), 8.75 (s, 8 H, aromatic H). − ^{13}C NMR ($CDCl_3$): $\delta = 14.29$ (s, *C*H$_3$), 22.83 (s, CH$_3$*C*H$_2$), 31.46 (s, CH$_3$CH$_2$*C*H$_2$), 32.52 (s, ArCH$_2$*C*H$_2$), 34.07 (s, Ar*C*H$_2$), 122.66 (s, C-b), 134.98 (s, C-c), 144.08 (s, C-a), 148.04 (s, C-d). − $C_{72}H_{96}N_9Re$ (1273.8): calcd. Roles of π-Alkyne, Hydride–Alkynyl, and Vinylidene Metal Species in the Conversion of Alkynes into Vinylidene: New Theoretical Insights

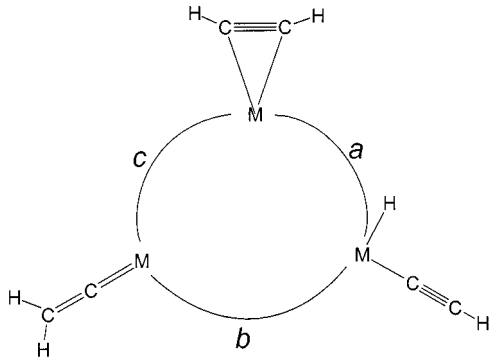
Enrique Peréz-Carreño,[a][+] Paola Paoli,[b] Andrea Ienco,[a] and Carlo Mealli*[a]

Keywords: Ab initio calculations / EHMO / Vinylidene complexes / Cobalt / Rhodium

The transformation of acetylene into vinylidene, as promoted by the metal fragment $[(pp_3)Co]^+$ [$pp_3 = P(CH_2CH_2PPh_2)_3$], is unimolecular and features the hydride–acetylide species as an intermediate. The paper describes a detailed ab initio study of the reaction, in particular with regard to the step involving 1,3-H shift. The best computational results are obtained by mimicking the pp_3 ligand with actual ethylenic chains rather than with single PH_3 molecules. The keypoints along the two-step reaction path (π-acetylene, hydride–acetylide, and vinylidene complexes, as well as intermediate transition states) have been optimized for Co^I and Rh^I derivatives at the MP2 level. For the fragment $[(pp_3)Co]^+$, the barrier associated with transformation of the hydride–acetylide intermediate to vinylidene (20.6 kcal/mol) is easier to surmount compared to that for reversion to the reactants (28.6 kcal/mol). The situation is reversed for the analogous Rh^I system, with the initial π-acetylene adduct being slightly more stable. Although higher in energy, the hydride–acetylide species is the experimentally detected product of the reaction of acetylene with the fragment $[(pp_3)Rh]^+$. The salient chemical aspects of the 1,3-H shift are discussed in terms of perturbation theory arguments. Parallel EHMO calculations, which have provided a relatively good consistency with the ab initio results, allow the proposal of an orbital rationale for the mode of migration of the hydride ligand along the substantially linear $Co–C_\alpha–C_\beta$ grouping.



Introduction

The conversion of unsubstituted or monosubstituted acetylene into vinylidene has been widely investigated both experimentally[1] and theoretically.[2] The strongly endothermic reaction $HC{\equiv}CH \rightarrow :C{=}CH_2$ (ca. 45 kcal/mol) becomes more feasible in the presence of numerous ancillary metal fragments. Following the first EHMO studies,[3] the problem of the metal-promoted interconversion has also been tackled by several groups using higher-level ab initio theory.[4] Briefly, we wish to summarize what is known about the reaction **I**, which may follow alternative pathways.

I

The least-motion 1,2-shift seems to be best promoted by d^6 metal fragments, which initially form π-adducts with the alkyne. For example, the early EHMO analysis was consistent with the latter mechanism in the case of $[CpMn(CO)_2]$.[3] More recent ab initio calculations were supportive of the same pathway for the fragment $Cl_2(PH_3)_2Ru$.[4a] There are cases, however, for which the formation of a metal hydride−acetylide species has been documented[5−7] and the question remains open as to whether the latter is the actual intermediate en route to the vinylidene complex (steps *a* and *b* in **II**, correspond to C−H oxidative addition followed by 1,3-H shift) or is merely formed as a side-product. If the latter were to be the case, the formation of vinylidene would also imply the reverse of step *a* (reductive elimination) followed by the 1,2-H shift itself (step *c*).

II

This point is still the subject of a passionate debate involving both experimentalists and theoreticians. The situation may vary considerably depending on the nature of the metal fragment. For example, in a recent theoretical study[4c] the possibility that 1−2 tautomerization or hydride−

acetylide formation might be involved in acetylene polymerization promoted by electron-deficient metal fragments [e.g. X_4W (X = F, Cl)] was ruled out. On the other hand, Werner et al.[5] reported that the hydride−acetylide is formed in the presence of the d^8 planar fragment $[Cl(PR_3)_2Rh]^+$. However, an ad hoc theoretical study[4b] showed that the straightforward 1,3-H shift cannot be pursued. More probably, the vinylidene species forms through a bimolecular mechanism where the hydrogen atom coordinated to one metal is transferred to the C_β acetylide atom of a second, properly oriented, complex molecule. The coordinated hydrogen atom in the latter follows the parallel path in the opposite direction. Although novel and interesting, the bimolecular mechanism cannot be invoked in all cases involving the hydride−acetylide species. We refer in particular to the chemistry supported by the ancillary d^8 metal fragment $[(pp_3)Co]^+$ [pp_3 = $P(CH_2CH_2PPh_2)_3$][6] or by the d^6 metal fragment $[Cp^*(dippe)_2Ru]^+$ dippe = $iPr_2PCH_2CH_2PiPr_2$].[7] Kinetic and spectroscopic studies of these species provide evidence that the reaction leading to vinylidene is first-order unimolecular. Most probably, the bulkiness of the phenyl substituents in pp_3 makes docking of two molecules difficult. Finally, the hydride−acetylide complexes $[(pp_3)CoH(C{\equiv}CR)]^+$ (the derivative with R = $SiMe_3$ could be structurally characterized since it is inert to further transformation[6]) generally undergo transformation into the most stable vinylidene complex, even in the solid state, i.e. simply upon warming the crystals. Mainly because of spatial constraints within the lattice, the unimolecular reaction implies minimal geometrical rearrangement. Thus, especially in the presence of a bulky acetylene substituent such as phenyl, it is unthinkable that the hydride−acetylide can undergo reversion to the π-adduct, and hence that the reaction proceeds through a 1,2-H shift. In any event, by disregarding the spatial constraints of the solid state, it is interesting to evaluate the barrier for the reverse C−H reductive elimination of the hydride−acetylide and, where possible, that for the conversion of the π-adduct into the final vinylidene complex.

In order to focus more intently on this point, and since the system reported by Bianchini et al.[6] {that involving the d^8 metal fragment $[(pp_3)Co]^+$} has never been theoretically investigated in detail, we have performed specific ab initio calculations (the MP2 level was selected to be consistent with the approach adopted in ref.[4b]). The same set of calculations has been carried out for the isoelectronic fragment $[(pp_3)Rh]^+$, which is reported to yield only the hydride−acetylide species.[8] The sufficiently satisfactory numerical results are reported herein. We also outline some important chemical implications using the qualitative language of Perturbation Theory. In fact, a pictorial MO analysis (EHMO method using the CACAO package[9]) allows the evolution of the MOs between structural key-points on the reaction coordinate, already indicated by the ab initio results, to be monitored. The two approaches are not inconsistent, so that ultimately the quantitative and qualitative theoretical inferences allow a good understanding of the system based on common chemical intuition.

Computational Details

EHMO Calculations

In MO calculations of the extended Hückel type,[10] a weighted-modified Wolfsberg−Helmholz formula[11] was used. Literature STO parameters were used for Co,[12] while standard values were used for the main group elements. The 3D drawings, correlation and interaction diagrams were generated using the program CACAO.[9]

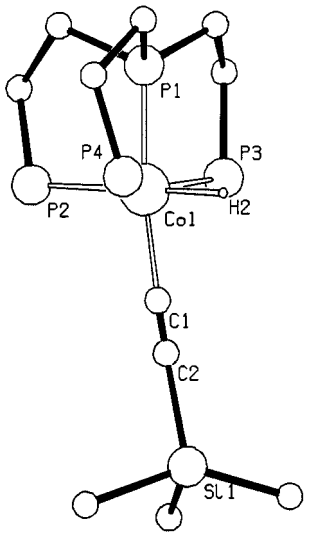
Ab Initio Calculations

The ab initio calculations were performed with the Gaussian-94[13] program at the MP2 level (electron correlation by second-order Møller−Plesset perturbation) using the ECP (effective core potential) approximation for some atoms. Specifically, the 17-electron ECP of Hay and Wadt[14] was adopted by using the [3s3p2d]/(5s5p5d) and [3s3p2d]/(5s5p4d) basis functions for cobalt and rhodium, respectively. Moreover, in order to further reduce the computational burden, 10- and 2-electron ECPs were adopted for phosphorus and carbon atoms, respectively, by using the [2s2p]/(4s4p) basis set.[15] For the H atoms, the D95 set was adopted.[16] Single-point energy calculations on the optimized structures were carried out using the same effective core potential for the metal and the 6-31G* basis set[17] for the other atoms. Unless otherwise specified, we discuss energies at these highest basis sets. Finally, to test the reliability of the ECP approximation, the computations were repeated using the ECP only for the transition metal, while a 6−31G basis set was used for the remaining atoms. The differences are not substantial, as can be seen on inspection of the data in Table 1.

In all cases, the geometries of the stationary points were fully optimized at the MP2 level using the analytical gradient under the C_s symmetry constraint. The transition state structures were relaxed after introducing small perturbations to ensure that they were indeed associated with the corresponding reactants and products. In the complexes with independent PH_3 ligands, the true minima or the transition state points on the potential energy surface were detected by calculating the second energy derivative matrix. Only for one of the optimized structures containing the actual model of the ligand pp_3 (refer later to **3a** in Figure 1) were the frequencies calculated. Although one imaginary frequency was found (not unexpectedly in view of the imposed C_s symmetry, see the later discussion), the optimized structures were still considered acceptable from a chemical viewpoint.

Results and Discussion

Ab Initio Calculations: Modelling Strategies and Energetic Trends



The tripodal ligand pp_3 was first mimicked with four independent PH_3 molecules, as is a common practise in MO calculations. As a result, various isomers of the general for-

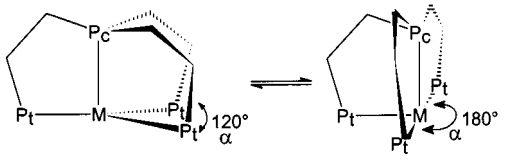
[a] Average values of the two complex cations $[(pp_3)Co-C{=}CHPh]^+$ reported in ref.[6] – [b] For metal atoms, the effective core potential (ECP) of Hay and Wadt was chosen. – [c] Values for the complex $[(PH_3)_4Co-CO]^+$ reported in ref.[18]

mula $[(PH_3)_4Co(C_2H_2)]^+$ could be optimized, although the geometries were not fully consistent with the structural data available for $[(pp_3)Co(C_2HR)]^+$.[6] Data are available for the hydride–acetylide species with R = $SiMe_3$ (**III**), which is sufficiently stable for X-ray analysis. Conversely, the vinylidene isomer is most easily obtained for R = phenyl (**IV**). In this case, the transformation starting from the corresponding hydride–acetylide complex proceeds even in the solid state, simply upon warming the crystals.



III

The most obvious difference between **III** and **IV** is the shape of the L_4M ancillary fragment. While the skeleton of $(pp_3)Co$ is approximately trigonal-pyramidal in **III**, a butterfly shape (*pseudo*-C_{2v} symmetry) is observed in the hydride–acetylide complex **IV**. Because of the constraints due to the ethylenic chains, the interconversion can only occur through the pathway **V**. Thus, all of the P_c-M-P_t angles remain close to 90°, while one of the P_t-M-P_t angles

IV

opens out towards 180°. The latter angle, α, can be considered as a governing parameter in this type of reactivity as promoted by $(pp_3)M$ fragments (vide infra).

V

As mentioned above, the inadequacy of $(PH_3)_4Co$ as an ancillary fragment is evident as some parameters diverge significantly from the experimental values. In particular, one of the angles P_c-Co-P_t, which are all close to 90° in the actual fragment $(pp_3)Co$, is found to be as large as

145.5° at the transition state along the pathway **a** (see **II**). Another aspect is that the free PH_3 ligands are clearly subject to steric hindrance. Thus, in the optimized pseudo-octahedral hydride−acetylide complex, the two *trans*-axial phosphane ligands are not perfectly linear but are bent away from the equatorial ligands in order to avoid short contacts (angle of 157.7°). The same feature has been observed in the structure of $[(PH_3)_4CoCO]$[18] (the structural parameters of the latter are reported in Table 1), which would, however, be unattainable with the ligand pp_3. In fact, no vinylidene complex with four independent phosphane ligands has ever been reported. Indirectly, this may suggest that the variations of the stereochemistry about the metal atom impose a subtle orbital control on the acetylene−vinylidene transformation. Thus, we then focused on the results of MP2 calculations where the ligand pp_3 was mimicked with the model $P(CH_2CH_2PH_2)_3$ (terminal hydrogen atoms in place of the phenyl substituents). The need for the actual tripodal ligands in ab initio calculations has recently been stressed by other authors.[19]

To reduce the computational burden and to exploit at least one symmetry element, the skeletal atoms of one $P_cCH_2CH_2P_t$ arm as well as the cobalt atom were forced to be planar, thus ignoring the propensity of the aliphatic chains to be chiral. Indeed, use of this C_s approximation for the models **1a**, **2a**, and **3a** (see Figure 1) did not dramatically affect the results.[20] Moreover, comparison with the experimental cobalt structures **III** and **IV** was sufficiently satisfactory (see Table 1).

In the vinylidene model **3a**, the $C{=}CH_2$ group is not perfectly *trans* to the central P_1 atom (the calculated $C_\alpha{-}Co{-}P_1$ angle is 154.8° cf. the value of 164.5° found in the experimental structure). The P_4Co unit in the hydride−acetylide model **2a** even diverges significantly from the pseudo-C_{2v} symmetry found for the $(PH_3)_4Co$ model. In particular, the angle α defined in **V** is rather small (158.8°), in spite of the presence of the H ligand in its bisector. The corresponding angle in **3a**, $P_3{-}Co{-}P_4$, does not vary significantly (155.3°), although the experimental value is smaller (140.0°).

The transition states **4a** and **5a** were determined using the appropriate Gaussian-94 algorithm (STQN[21]), which exploits structural knowledge of both the reactant and the product, namely the pairs **1a**−**2a** and **2a**−**3a**, respectively. Furthermore, since our present computational capabilities are limited, no attempt was made to confirm that the detected transition states (**4a** and **5a**) were indeed the correct ones through calculation of the frequencies. Nevertheless, the latter species do not only exhibit a satisfactorily correct geometry for the P_4Co chromophore, but also appear chemically realistic. In particular, **4a** corresponds to the expected *agostic*-type adduct, which precedes the oxidative addition, while **5a** sheds new light on the mechanism leading to the formation of the vinylidene product. In fact, this structure differs somewhat from that calculated by Morokuma′s group[4a] for the process supported by the fragment $[Cl_2(PH_3)_2Ru]$, for which the formation of a hydride−acetylide species was ruled out. In the latter, the transferring

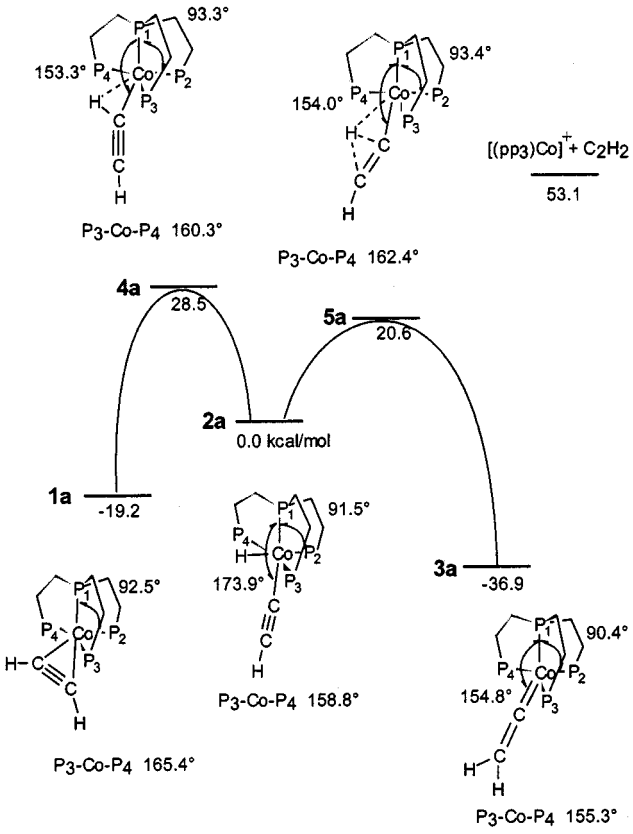


Figure 1. Optimized structures and relative energetics (MP2 level) along the pathway of interconversion between acetylene and vinylidene as promoted by the fragment $[P(CH_2CH_2PH_2)_3Co]^+$

hydrogen is strongly linked to the C_α atom (1.13 Å) and is far removed from C_β. Conversely, in **5a** a quasi-symmetrical bridging mode of hydrogen over the C−C linkage is observed. This is similar to the transition state detected[4b] for the unimolecular conversion of $[Cl(PH_3)_2RhH(C{\equiv}CH)]$ into $[Cl(PH_3)_2Rh(C{=}CH_2)]$, a process which is, however, disfavored with respect to the bimolecular one.

Before commenting on the energetics involved and on their evaluation in relation to the mechanism of the cobalt-induced reactions, we also present the parallel results (Figure 2) calculated using the fragment $[(pp_3)Rh]^+$. The latter is experimentally known to prevent the ultimate formation of the vinylidene complex[8b] starting from the hydride−acetylide isomer. Indeed, this species is the only stable product of the reaction of acetylene at the metal.

The structural keypoints are essentially similar to those in Figure 1. Perhaps the most obvious difference concerns the vinylidene structure **3b**, where the angle $P_1{-}Rh{-}C$ is smaller than that in **3a** (143.7° vs. 154.8°). This would seem to reveal a tendency of the $C{=}CH_2$ group to become better aligned with the bisector of the angle $P_1{-}M{-}P_2$, thus approaching more closely the behavior of the free phosphane model. In the latter C_{2v} structure, the $P_1{-}Co{-}C$ angle is as small as 130.2°.

Comparison of the data in Figures 1−2 and Table 1 reveals that the vinylidene species is most stabilized in the cobalt complex ($\Delta E = -36.9$ kcal/mol for **3a**) and that the

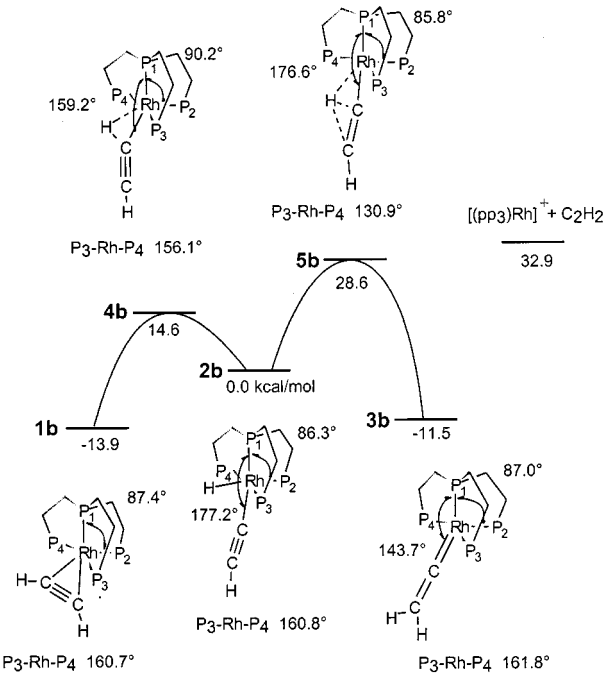

Figure 2. Optimized structures and relative energetics (MP2 level) along the pathway of interconversion between acetylene and vinylidene as promoted by the fragment $[P(CH_2CH_2PH_2)_3Rh]^+$

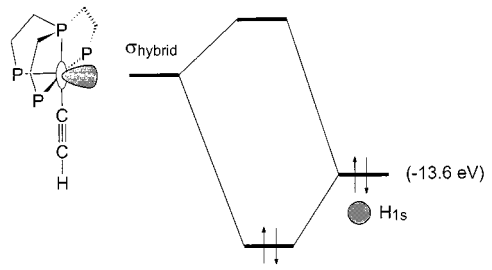
barrier associated with its formation is not large (20.6 kcal/mol for **5a**). In comparison, the rhodium vinylidene **3b** is much less stabilized (only −11.5 kcal/mol) and its associated barrier is larger (28.6 kcal/mol for **5b**). Furthermore, it is remarkable for rhodium that the barrier to reversion to the starting π-adduct is only 14.6 kcal/mol, practically half the magnitude of that calculated for cobalt. Concerning the transition states **4** in the direction of formation of the hydride−acetylide, the C−H oxidative addition of acetylene has a critically large value for cobalt (over 40 kcal/mol). Nevertheless, this does not seem unreasonable considering that the experimental reaction requires heating.[6] It must also be mentioned that, while the transition states of type **5**, i.e. between hydride−acetylide and vinylidene complexes (path *b* in **II**) have easily been detected, location of the transition states of type **4**, i.e. those involving an *agostic* interaction (path *a* in **II**), has proved much more time-consuming. The latter could only be determined through a trial and error approach based on small geometric modifications of the π-acetylene complexes **1**. Finally, like other authors before us,[4] we have not been able to detect a transition state between π-acetylene **1** and vinylidene **3** (path *c* in **II**). Only the most recent calculations[4c] on the system based on the fragment F_4W have led to the location of the corresponding transition state, following a systematic search after removing any possible symmetry.

In summary, the C−H oxidative addition process yielding complex **2** from **1** has been shown to be much more facilitated by rhodium than by cobalt, as is also the case for the reverse reductive elimination process. Moreover, the calculations have confirmed what was experimentally known, i.e. that the transformation **2** → **3** is quite straightforward with cobalt (it occurs in the solid state), but is impossible with rhodium. Besides having a larger associated barrier, the rhodium vinylidene complex does not seem to possess the necessary stability to be a terminal product. Another interesting numerical result, which confirms the better propensity of the cobalt fragment to function as an activator of acetylene, is contained in Figures 1 and 2. The energy of the separated fragments is distinctly higher for cobalt than for rhodium (53.1 vs. 32.9 kcal/mol), thus confirming the greater propensity of cobalt to promote this chemistry.



Considerations from the Viewpoint of Qualitative MO Theory

In this section, we mainly try to develop interpretational arguments concerning the second part of the pathway, leading from hydride−acetylide to vinylidene. The Hoffmann group, besides addressing the overall process of alkyne activation,[3] has also dedicated much attention to step of the C−H activation relative to the parallel dichotomy between η^2-ethylene and vinyl−hydride complexes.[22]

An intriguing aspect of the H migration ensuing from the hydride−acetylene adduct is the nature of the migrating hydrogen itself, i.e. whether it has proton or hydride character. Bianchini et al.[6] have reported that the vinylidene complex $[(pp_3)Co(C{=}CRH)]^+$ may be obtained not only through tautomerization of the alkyne HC≡CR by the 16-electron fragment $[(pp_3)Co]^+$, but also through straightforward protonation of the 18-electron acetylide complex $[(pp_3)Co(C{\equiv}CR)]$. More recently, de los Ríos et al.[7] reported that the isomerization of the hydride−acetylide species $[Cp^*RuH(C{\equiv}CR)(dippe)]^+$ to vinylidene is inhibited by strong acids such as HBF_4. While these facts are indicative of the strongly nucleophilic character of the acetylide C_β atom in the 18-electron complexes, it is difficult to envisage a proton migrating all the way from the metal atom.

In pseudo-octahedral Co^{III} complexes of type **III**, the orbital of the H ligand is energetically well below the σ hybrid of the fragment ML_5, **VI**. The latter, mainly z^2 in character, is destabilized by an antibonding interaction with the *trans*-axial phosphane, which promotes hybridization with the higher *s* and *pz* orbitals. In agreement with chemical intuition, the hydride is a donor.

In principle, a cooperating base could extract the H ligand as a proton and transfer it elsewhere. This is also the essence of the bimolecular mechanism proposed by Morokuma et al.,[4a] where the metal of the second molecule itself acts as the extracting base. In the present case, however, the process, which also occurs in the solid state, is not assisted by any external agent, nor is it feasible for two highly hindered complex molecules to get sufficiently close to one another. In the crystal, it is also hard to imagine a structural rearrangement that could bring the nucleophilic C_β atom sufficiently near the metal to extract the proton. Moreover,

VI

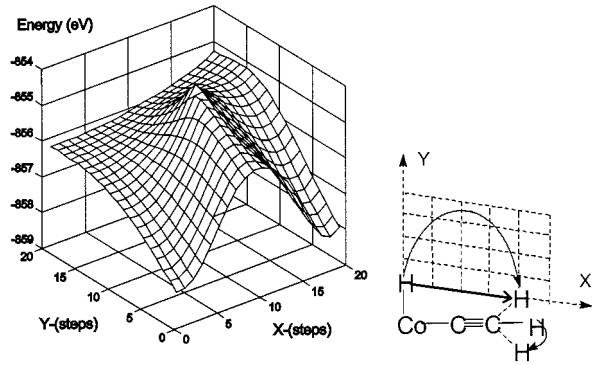


Figure 3. Potential energy surface (PES) calculated (EHMO method) on the small two-dimensional grid; the origin of the latter corresponds to the complex $[(PH_3)_4CoH(C{\equiv}CH)]^+$, with the *y* coordinate corresponding to the progressive separation of the H atom from the linear grouping $Co-C_\alpha-C_\beta$; the non-orthogonal *x* axis, which accounts for the non-equivalence of the $Co-H$ and $C_\beta-H$ bond lengths, describes the H shifting along the same grouping; irrespective of the *y* value, the $C_\alpha-C_\beta-H$ angle begins to bend as soon as the vectors $Co-C_\alpha-C_\beta$ and $C_\beta-H$ become orthogonal

if H^+ could separate from M^-, there would remain a hole in the overall MO picture (i.e. the empty H_{1s} orbital would lie below the occupied metal d block, including the high-lying metal σ lone pair). Thus, at least in the early stages of $M-H$ dissociation, the bonding electron pair is more reasonably assigned to the H atom. In any event, even though a net separation of charges may not be realistic, the extreme viewpoints of migration of a proton or a hydride are helpful in delineating the actual situation.

Although the ab initio calculations indicate that at the transition state the migrating H atom is close-bridging between the C_α and C_β atoms, a migration out of the domains of the latter atoms cannot, in principle, be excluded. However, since this would correspond to the heterolysis of two charged species, unassisted by any solvent, no satisfactory response can be expected based on ab initio theory. Indeed, as the calculations are based on a gaseous system, the attractive electrostatic interactions would overwhelm any opposing repulsive effect. An indirect confirmation of the possible coexistence of hydride and the species $[(pp_3)Co(C{\equiv}CR)]^{2+}$ might perhaps be provided by a straightforward optimization of the latter. Experimentally, the stability of the 16-electron pentacoordinated complex is confirmed by several crystal structures involving d^6 metals, mainly of the second and third transition rows,[23] and further support is provided by theoretical studies, including ab initio calculations with a proper orbital rationale.[24] In contrast, we are not aware of any stable Co^{III} species having a 16-electron count. Moreover, all our attempts to reach convergence for the model $[(pp_3)Co(C{\equiv}CR)]^{2+}$ (at the MP2 level) were unsuccessful because of large oscillations about the energy minimum. Thus, not even an indirect proof of the M^+-H^- heterolysis could be obtained.

While the existence of the *ion pair* cannot readily be demonstrated at the ab initio level, the extended Hückel method neglects the electrostatic term. Thus, in order to compare the MO behavior at any limiting geometrical situation, Figure 3 shows the EHMO 3D potential energy surface (PES). The latter is constructed on the two-dimensional grid appearing at the lower right-hand side of the figure, where the axes correspond to the increasing $M-H$ separation (positive *y*) and to the shifting of the H atom along the $M-C_\alpha-C_\beta-R$ direction (positive *x*). The origin corresponds to the hydride−acetylide Co^{III} complex itself.

In the early stages, the $[(pp_3)Co(C{\equiv}CR)]^{2+}$ fragment is kept in a fixed geometry and, in particular, the critical angle α, P_3-Co-P_4 (see **V**), is fixed at 150°. On approaching the final vinylidene product, narrowing of the terminal $C_\alpha-C_\beta-R$ angle is allowed. Interestingly, on the side of the surface facing the observer, there is a barrier which reproduces, at least geometrically, the transition state **5a** obtained by MP2 calculations (at EHMO level the barrier is large, ca. 50 kcal/mol). On the other hand, on descending the *y* axis (on the left side), the energetic cost of the $Co-H$ cleavage remains comparable so that, in principle, the hydride could migrate isolated behind the highest peak of the PES until it falls towards the C_β atom.

Some sound chemical inferences may be gained from the Walsh diagrams shown in Figure 4, which refer to alternative pathways indicated by the arrows in the small grid of Figure 3.

In the diagram on the far left, complete $M-H$ *heterolysis* is followed by coupling of the hydride with the C_β atom. The HOMO−LUMO gap, fairly large and constant over the central region, becomes small (ca. 0.5 eV) at some later point, so that even a change of the ground state can be hypothesized (singlet → triplet). Conversely, for the *close-contact* H migration, the gap is never smaller than 2 eV and none of the latter complications can be expected.

As the H atom moves parallel to the $Co-C_\alpha-C_\beta$ direction, the effects on some important MOs may be generalized, even if their extent depends on the initial $M-H$ separation. Figure 5 focuses on the behavior of only four levels. Starting from the left, these are the pair of occupied/empty σ and σ^*_{M-H} MOs of the hydride−acetylide species (see **VI**), and the pair of occupied/empty MOs corresponding to the in-plane π and π* levels of the acetylide.

As the H_{1s} orbital moves away from the direction of the metal σ hybrid, their overlap diminishes so that the σ^*_{M-H} level (LUMO) is stabilized. For an already long $M-H$ distance, this effect cannot be large as the LUMO energy would quickly reach the constant minimum, essentially the energy of the metal σ hybrid itself. In the left-hand diagram

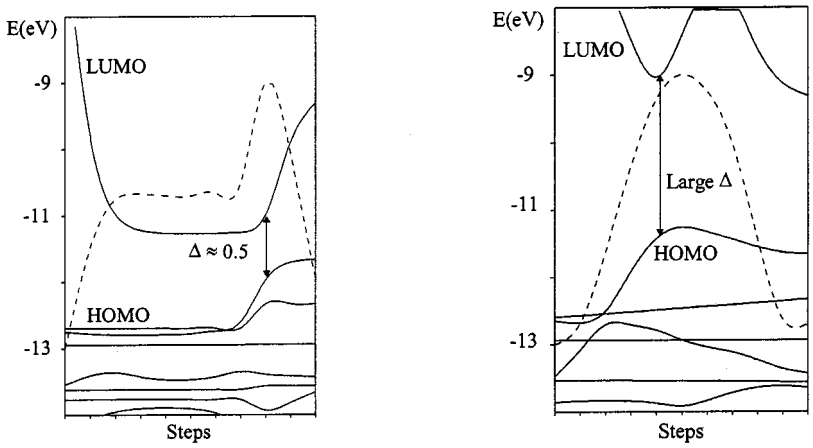

Figure 4. Walsh diagrams (EHMO calculations) relating to the two pathways indicated by the curved and straight arrows in the small grid of Figure 3, respectively; the far left-hand diagram corresponds to a H atom that migrates while physically separated from the rest of the molecule; the far right-hand diagram goes through the bridging H mode, corresponding to the ab initio transition state **5a** as depicted in Figure 1; the dashed lines refer to the total energy, for which each increment on the *y* axis corresponds to 0.6 eV

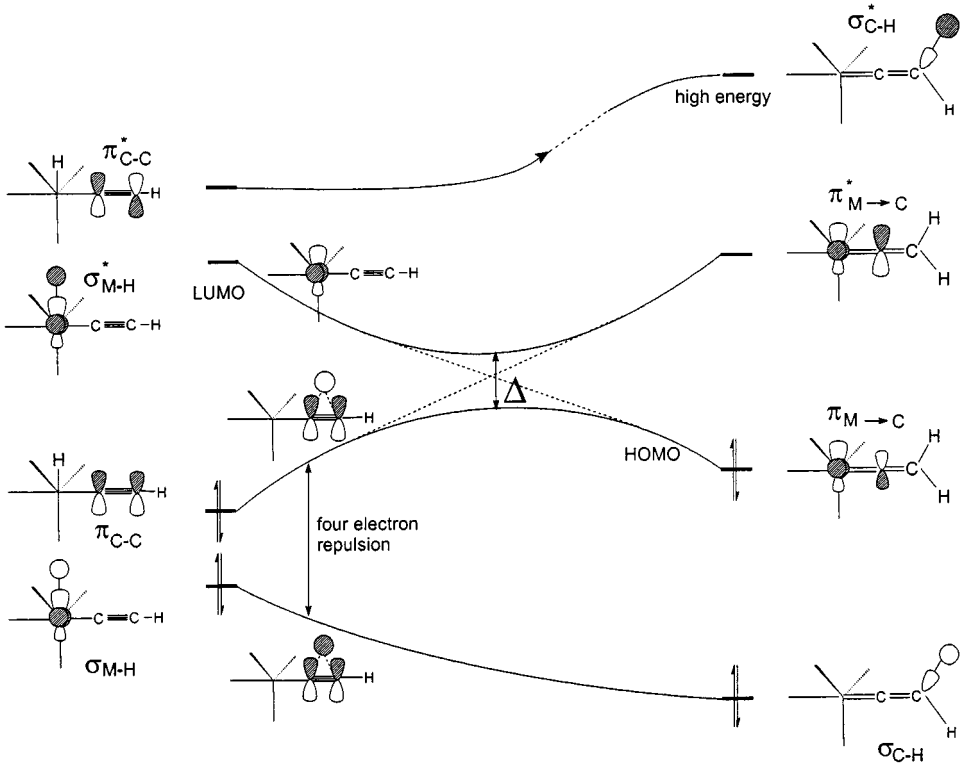

Figure 5. Schematic evolution of selected *in-plane* frontier MOs upon shifting of the H atom (initially the hydride ligand bound to the metal) along the linear grouping $Co-C_\alpha-C_\beta$; a four-electron repulsion between the hydride and one π-acetylene electron pair causes the destabilization of the HOMO, and hence is the origin of the barrier; the effect is subsequently counterbalanced by an interplay of orbital mixings, which brings metal character to the HOMO x^2-y^2 and involvement in some sort of back-donation

of Figure 4, the LUMO takes on C−H σ* character in the final steps and rises again until all of the character is transferred into high-lying MOs. Conversely, when the hydrogen atom is closer to the C−C linkage (right-hand diagram in Figure 4), the LUMO destabilizes soon after the initial stabilization. At the same time, a low-lying occupied level increases in energy and becomes the new HOMO.

Essentially, the origin of the *avoided* HOMO−LUMO crossing, highlighted in Figure 5, can be described as follows. On moving away from the metal, H_{1s} begins to interact with the π_{C-C} bonding MO, giving rise to diverging *in-phase* and *out-of-phase* combinations (the latter being the HOMO, as shown in Figure 5). At least initially, due to the shortness of the C≡C triple bond, π^*_{C-C} is too high to mix into the HOMO so as to alter the depicted repulsion between H_{1s} and π_{C-C}-based orbitals. Subsequently, the intermixing between all of the levels of Figure 5 (isosymmetric) becomes more significant. Thus, the descending LUMO (σ^*_{M-H}) and the rising HOMO evidently undergo an *avoided crossing*, which involves π^*_{C-C} as well. By virtue of

the latter, the pπ contribution from C_β disappears from both levels, which acquire a sort of π and π* character relative to $M-C_\alpha$ (see below). As mentioned above, the $C_\beta-H$ σ* character is only temporarily observed in the LUMO and is quickly transferred to higher levels.

Ultimately, the HOMO is largely centered on the metal and it can be assumed that its formal reduction has occurred, involving the electrons formerly on the hydride ligand. More precisely, the x^2-y^2 component, although not strictly a dπ orbital, can make some back-donation into the $C_\alpha p_\pi$ orbital through its most hybridized lobe, so that the M=C=C bonding formulation is reasonable. Moreover, it can be shown that the nature and extent of the back-donation are subtly governed by the geometrical flexibility of the pp_3 ligand (vide infra).

Recall that the vinylidene complex containing four independent PH_3 ligands was optimized with C_{2v} symmetry, as was the fragment $[(PH_3)_4Co]^+$. The latter of the type d^8-L_4M and with butterfly shape is characterized by an equatorial, occupied d_ϕ hybrid,[25] which is most suitable for back-donation. Significantly, in this complex, the grouping $C=CH_2$ is perfectly aligned with the bisector of the two angles P_1-Co-P_2 and P_3-Co-P_4. The same picture does not quite apply to the fragment $[(pp_3)Co]^+$, which is at most C_s and is somewhat reminiscent of threefold symmetry (Figure 1). Under these circumstances, the coordinated $C=CH_2$ grouping remains close to one apical position of the trigonal bipyramid (*trans* to P_1), with the angle P_1-Co-C_α deviating from linearity by only 15° (experiment[6]) or 25.2° (MP2 structure **3a** in Figure 1). As already discussed, the angle P_1-Co-P_2 is almost fixed at 90°, while the angle P_3-Co-P_4 (α in **V**) is free to open from 120° (up to 140° in the experimental structure and even more so in the optimized structure **3a**, i.e. 155.3°).

The angle P_3-Co-P_4 plays a major role in governing the dπ back-donation capabilities of d^8-L_4M fragments. Figure 6 shows the evolution of the frontier MOs of the trigonal-pyramidal fragment $[(PH_3)_4Co]^+$ (left side) on widening one equatorial P−Co−P angle over the range 120−180°. At the right-hand side, the fragment has a butterfly shape with the typical FMOs ($t_{2g} + d_\phi + \sigma_{hybrid}$).[25]

At the trigonal-pyramidal stage, the metal orbitals consist of two *e* sets (*xz*/*yz* orbitals, unperturbed, and *xy*/x^2-y^2 orbitals partially destabilized by the equatorial ligands) and of a higher a_1 level (σ_{hybrid}, largely z^2 in character and destabilized by the axial ligand). On widening of the angle, 1*e* and a_1 remain unaffected, but the 2*e* components diverge. In fact, the two equatorial ligands slip off two consecutive lobes of *xy* and progressively point more towards the nodes of the orbital, while an opposite trend is seen for x^2-y^2. Ultimately, *xy* becomes equivalent to *xz* and *yz* ("octahedral" t_{2g} set), while x^2-y^2 is so destabilized that its crossing with the higher z^2 (a_1) is attempted but *avoided* because of the equal symmetry (*a′* in C_s). The resultants of a z^2/x^2-y^2 mixing, usually difficult to visualize, are well illustrated by the CACAO pictures[9] in Figure 6. Thus, the former a_1 level reorientates the main σ lobe up to 45° in the plane *xz* and maintains the original σ character, albeit with

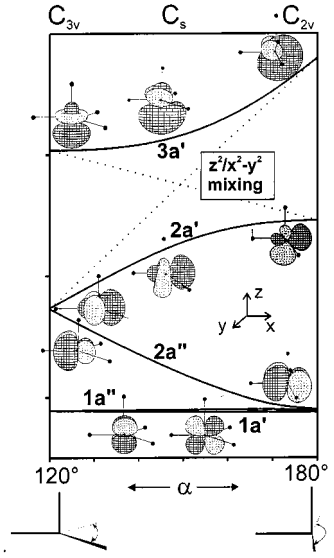

Figure 6. Evolution of the metal d orbitals during the interconversion of an L_4M metal fragment from trigonal-pyramidal to butterfly geometry, the unique governing factor being the opening of one equatorial L−M−L angle; avoided crossing between x^2-y^2 and z^2 slowly develops d_ϕ character at the former orbital, which is occupied in the d^8 configuration

reduced d orbital contribution. At the same time, the mixing transforms the most extended lobes of the somewhat hybridized z^2 and x^2-y^2 orbitals into a new orbital with progressively greater dπ character. At α = 180°, the well known d_ϕ hybrid typical of the L_4M fragments with butterfly shape is observed.[25] The ethylenic chains in the fragment $[(pp_3)Co]^+$ are resistant to full P−Co−P opening, so that an intermediate geometry can be stabilized as soon as the d_ϕ character is sufficient to allow back-donation into the vinylidene unit. This is most likely the key factor in interpreting the influence of the geometry of the ancillary ligand on the stability of the vinylidene complex.

Concluding Remarks

The experimental data and the present ab initio results indicate that, at least for the system $(pp_3)Co^I$, the hydride−acetylide species is the key basic intermediate en route to vinylidene. The essential qualitative arguments are shown schematically in Figure 7. The acetylene molecule adds to the d^8 metal through donation of its π bonding electron pairs into the acceptor σ hybrid orbital typical of the trigonal-pyramidal fragments. The metal bears a lone pair based on the occupied x^2-y^2 orbital, which is relatively high in energy. On opening of one P−M−P angle (α, see **V**), the metal develops the necessary d_ϕ character to trigger C−H oxidative addition (see Figure 6) and the pseudo-octahedral hydride−acetylide complex is formed.

Formally, the hydrogen ligand abstracts the lone pair from the metal so that a total of 12 valence electrons is consistently assigned to the whole grouping $H^- + CCH^-$. As soon as the hydride falls away from the position of maximum overlap with the σ metal hybrid, its electrons are re-

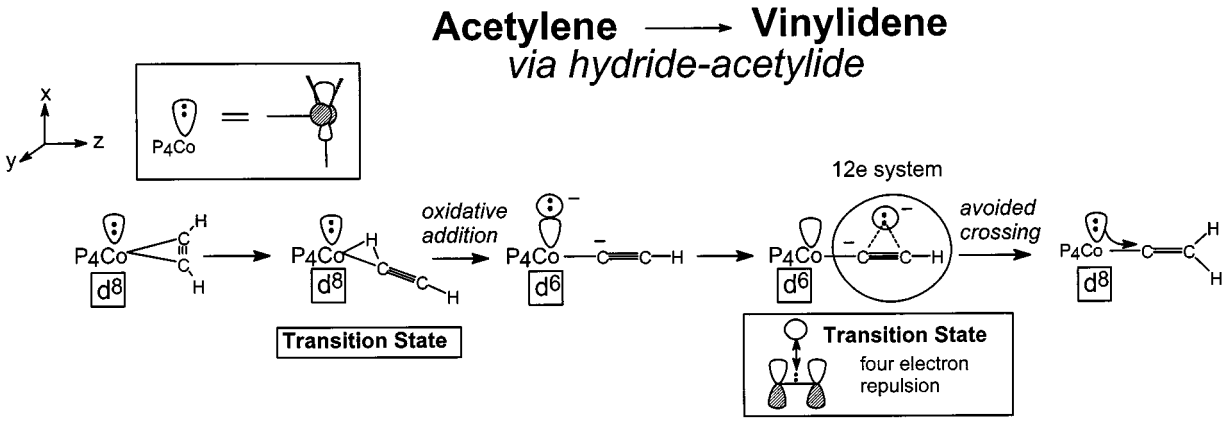

Figure 7. Structural highlights for the 1,3-shifts promoted by d^8 metal fragments; along this pathway, oxidative addition and reductive elimination of the metal involve a suitably modified orbital (originally x^2-y^2)

pelled by the electron cloud of the coplanar C−C π bond, as indicated in Figure 5. The four-electron repulsion is maximized at some point where the hydrogen bonds the two carbon atoms (transition state). The barrier is directly related to the destabilization of the HOMO, and the trend is inverted by an *avoided crossing mechanism.* By virtue of the latter, the hydride electron pair is returned to a metal orbital. This is essentially x^2-y^2, which characterizes the descending LUMO and ultimately concentrates into the HOMO. The final step on the pathway corresponds to the simple protonation of the C_β atom of the 18-electron acetylide complex, which occurs easily.[6]

At the transition state, the C_α−H and C_β−H distances are critically long, and are likely to limit the effects of the aforementioned four-electron repulsion. The calculated MP2 values are 1.32 and 1.48 Å, respectively. At longer C−H bridging distances, the energetics of the system would go steeply uphill toward the highest peak of the EHMO PES shown in Figure 3. Alternatively, the system might go around the peak by first elongating the M−H distance. In this case, the barrier would be essentially the energy of the M−H bond, which is too high. In fact, this is estimated to be no lower than 50 kcal/mol and significantly larger for second- and third-row transition metals.[26] Most probably because of the latter reason, the rhodium system stabilizes the hydrido−acetylide species and the barrier to vinylidene formation is distinctly higher than in the case of cobalt.

Even though the EHMO method neglects the important electrostatic component when charges are separated, it reveals an orbital drawback to the heterolysis. Namely, a small HOMO−LUMO gap along the pathway (left-hand diagram of Figure 4) would imply a necessity for a change in the ground state. If complete M−H heterolysis appears improbable, the hydrogen must start its migration as a hydride. When the C_β atom bears too great a negative charge, as is the case when it is bound to an electropositive silyl substituent, the migration may be inhibited and the hydride−acetylide species is stabilized.[6]

The general reactivity studied here has already received much theoretical attention. Despite this, no generalization of the results can yet be made. In the present study, we have not only performed ab initio calculations on a system which follows possibly unique pathways, but we have also offered some interpretations by exploiting the concepts of perturbation theory as well as by applying chemical intuition. From a quantitative point of view, it has become apparent that sufficiently good results are only obtainable with the most realistic model (use of the pp_3 ligand). At the same time, monitoring of the MO behavior along the reaction pathways has helped to resolve some major chemical ambiguities.

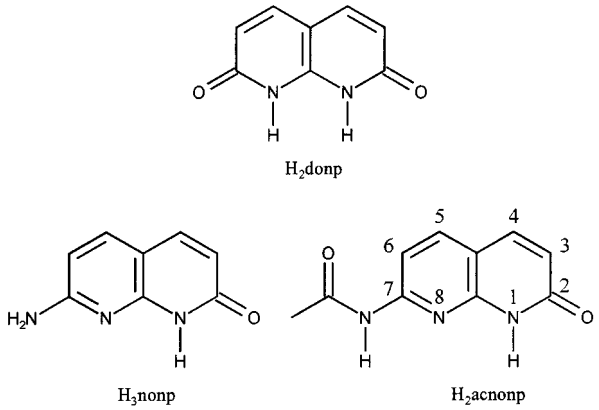
Di- and Tripalladium(II) and -platinum(II) Complexes Containing 7-Amino-1,8-naphthyridin-2-one as a Bridging Ligand − Oxidation of a $[Pt_3]^{6+}$ Core to $[Pt_3]^{8+}$

Bernhard Oskui[a] and William S. Sheldrick*[a]

Keywords: Platinum / Palladium / Platinum blues / Naphthyridine complexes / Trinuclear complexes

All three dinuclear complexes $[Pd_2(donp)_2(bpy)_2]$ (**1**) (H_2donp = 1,8-naphthyridin-2,7-dione), $[Pd_2(H_2nonp)_2(bpy)_2](ClO_4)_2$ (**2**), and $[Pt_2(H_2nonp)_2(bpy)_2](PF_6)_2$ (**3**) (H_3nonp = 7-amino-1,8-naphthyridin-2-one) exhibit the μ-1κN^1:2κN^8 bridging mode for their *head/tail* orientated naphthyridine ligands. Whereas **1** and **3** may be prepared by direct reaction of the dinucleating ligand with $[MCl_2(bpy)]$, formation of competing tripalladium(II) complexes must be avoided for **2** by employment of the precursor $H_2acnonp$ (7-acetamido-1,8-naphthyridin-2-one), which affords $[H_2nonp]^-$ on cleavage of its original acetyl group. A mixture of the *head/tail* (**4a**) and *head/head* (**4b**) isomers of $[Pd_3(Hnonp)_2(bpy)_3](ClO_4)_2$ is obtained when H_3nonp is treated with $[PdCl_2(bpy)]$ and LiOH at room temperature for 2 d, followed by precipitation with $LiClO_4$. Contrastingly exclusive formation of **4a** is observed upon refluxing this reaction mixture for 3 d in aqueous solution. The $[Hnonp]^{2-}$ ligands exhibit a μ$_3$-1κN^1:2κN^8:3κN^7 bridging mode that leads to short Pd···Pd interactions of 2.781(2) and 2.775(2) Å. Similar metal–metal distances of 2.771(3) and 2.816(3) Å are observed in *head/head*-$[Pt_3(acnonp)(Hnonp)(bpy)_3]Cl_2$ (**5**). An in situ 2e$^-$-oxidation (Ag^+/Ag) of the $[Pt_3]^{6+}$ core in triplatinum(II) species such as **5** formed by the reaction of $[PtCl_2(bpy)]$ with $H_2acnonp$ allows the isolation of diamagnetic dark-brown *head/head*-$[Pt_3(Hnonp)_2(NO_3)(bpy)_3](ClO_4)_2(NO_3)$ (**6**) with an average oxidation state of Pt (2.67+). The Pt–Pt distances of 2.723(2) and 2.670(2) Å are markedly shorter than in **5**.



Although the oligomeric class of molecules known as the platinum blues all formally contain Pt^{III}, the average oxidation state of their Group 10 metal atoms is usually much lower than +3.0.[1] Following the first report of the prototype platinum-acetamide blues in 1908,[2] some 70 years were to pass before Lippard et al.[3] were finally successful in structurally characterising *cis*-$[\{Pt_2(\mu\text{-}C_5H_4NO)_2(NH_3)_4\}_2](NO_3)_5$ (C_5H_4NO = α-pyridonate) as an adequate model analog. This paramagnetic tetranuclear complex (S = 1/2), with its average oxidation state of +2.25, exhibits a Pt−Pt distance of 2.775(1) Å in its outer α-pyridonate bridged dimeric sub-units, that are linked through an inner Pt−Pt interaction of length 2.877(1) Å. Similar alternating short supported [2.880(2), 2.778(1) Å] and longer unsupported [2.900(1), 2.934(1) Å] Pt−Pt bonds were subsequently established for the diamagnetic centrosymmetric octanuclear platinum−acetamide complex $[\{Pt_2(NHCOCH_3)_2(NH_3)_4\}_4](NO_3)_{10} \cdot 4\,H_2O$, in which the average oxidation state is once again +2.25.[4] Significantly shorter metal-metal distances of 2.702(6), 2.710(5), and 2.706(6) Å in the linear Pt_4 chain of $[\{Pt_2(C_4H_3NO)_2(NH_3)_4\}_2](NO_3)_6 \cdot 2\,H_2O$[5] ($C_4H_3NO$ = α-pyrrolidonate) are consistent with this so-called "α-pyrrolidone tan" being in the higher average oxidation state of Pt (2.5+). The spectroscopic, redox, and chemical properties of μ-*N,O*-pyrimidinate bridged (1-MeU = 1-methyluracilate, 1-MeT = 1-methylthyminate) blue and green oligomeric platinum complexes closely mirror those of the α-pyridone blues and an average oxidation state of Pt (2.75+) has been established for $[\{Pt_2Cl_2(1\text{-}MeT)_2(NH_3)_2\}_2Cl]PtCl_6 \cdot 6\,H_2O$.[6] However, this complex contains two individual diplatinum units [Pt−Pt distance, 2.699(1) Å], that are connected by a single chloride bridge, and is not, therefore, strictly comparable with the typical Pt_4 linear clusters discussed above.

Mixed intensely golden-tan trinuclear Pt_2Pd complexes of the type *cis*-$[L_2'Pt(\mu\text{-}L)_2Pd(\mu\text{-}L)_2PtL_2']X_2$ (L′ = en/2, NH_3; L = 1-MeU, 1-MeT; X = NO_3^-, ClO_4^-) have been characterised by Lippert and co-workers[7][8] and can be oxidised by conc. HNO_3 to deep purple-blue trications with an average oxidation state M (2.33+) and Pt−Pd distances in the range 2.634(1)−2.646(1) Å. This posed the question as to whether similar linear homonuclear Pt_3 complexes can also be prepared in the presence of suitable di- or trinucleating ligands and led to our recent characterisation[9] of the 1,8-naphthyridin-2,7-dionato (H_2donp, Scheme 1) compounds *cis*-$[M_3(donp)_2(bpy)_3]^{2+}$ (M = Pd, Pt), which exhibit relatively short supported $M^{II}\cdots M^{II}$ distances in the range 2.801−2.807 Å. The blue-green triplatinum(II) complex displays one-electron transfer waves at $E_{1/2}$ = 0.65 V to blue-violet *cis*-$[Pt_3(donp)_2(bpy)_3]^{3+}$ and $E_{1/2}$ = 1.30 V (in CH_3CN, vs. Ag/AgCl) to violet *cis*-$[Pt_3(donp)_2(bpy)_3]^{4+}$. As we were unsuccessful in isolating either the Pt (2.33+) or the Pt (2.67+) complex, we have now extended our studies to 7-amino-1,8-naphthyridin-2-one (H_3nonp) and 7-acetamido-1,8-naphthyridin-2-one ($H_2acnonp$, Scheme 1), in the expectation that the change in the sites of protonation from

Results

The reaction of H_2donp with [MCl_2(bpy)] (M = Pd, Pt) and LiOH at 1:1:2 molar ratio in refluxing aqueous solution generates the trinuclear complexes *cis*-[M_3(donp)$_2$(bpy)$_3$]$^{2+}$ rather than the stoichiometrically expected μ-N^1,N^8-bridged dimers *cis*-[M_2(donp)$_2$(bpy)$_2$].[9] Lowering the reaction temperature to 20 °C does, indeed, lead to precipitation of a sparingly soluble dinuclear Pd neutral complex, albeit in low yield. We could now show that *cis*-[Pd_2(donp)$_2$(bpy)$_2$] (**1**) can, in fact, be isolated as an orange precipitate in satisfactory yield (63%) by changing the solvent/base combination to CH_3OH/CH_3ONa and performing the reaction at room temperature. The formation of tripalladium(II) complexes of the type [Pd_3(Hnonp)$_2$(bpy)$_3$]$^{2+}$ (**4a**, **4b**) can likewise be avoided by treating [$PdCl_2$(bpy)] with H_2acnonp at an equimolar ratio in refluxing water in the absence of base. Addition of $LiClO_4$ leads to precipitation of *cis*-[Pd_2(H_2nonp)$_2$(bpy)$_2$](ClO_4)$_2$ (**2**), in which the naphthyridine monoanions H_2nonp$^-$, formed by cleavage of the acetyl group in the original ligand, adopt the bridging μ-N^1,N^8 coordination mode. The analogous diplatinum(II) complex *cis*-[Pt_2(H_2nonp)$_2$(bpy)$_2$](PF_6)$_2$ (**3**) can be isolated by adding an excess of NH_4PF_6 to an aqueous reaction solution of [$PtCl_2$(bpy)] and H_3nonp kept at pH 2 to suppress the metalation of the 7-amino function, which leads to formation of the preferred trinuclear dications.

Figures 1 and 2 depict the structures of the neutral dipalladium(II) complex **1** and the dication of the $Pt^{(II,II)}$ complex **3**. All three dinuclear species **1**–**3** display the μ-1κN^1:2κN^8 coordination mode with *head/tail* positioning of their bridging naphthyridine ligands. This binding pattern was also established for [Ru_2(monp)$_4$][10] (Hmonp = 7-methyl-1,8-naphthyridin-2-one) and [Ru_2(mphonp)$_4$(H_2O)][11] (Hmphonp = 5-methyl-7-phenyl-1,8-naphthyridin-2-one) and should be electronically favourable for [M_2]$^{4+}$ cores with occupied antibonding orbitals (e.g. [Ru_2]$^{4+}$, [Rh_2]$^{4+}$, [Pd_2]$^{4+}$), as it will enhance the interaction between the δ* orbitals of the dimetal unit and the π* molecular orbitals of the bridging aromatic anions[11]. In contrast, the dinucleating monp$^-$ ligands in [Mo_2(monp)$_4$] exhibit the alternative μ$_2$-1κN^1:2κO^2 coordination mode[10].

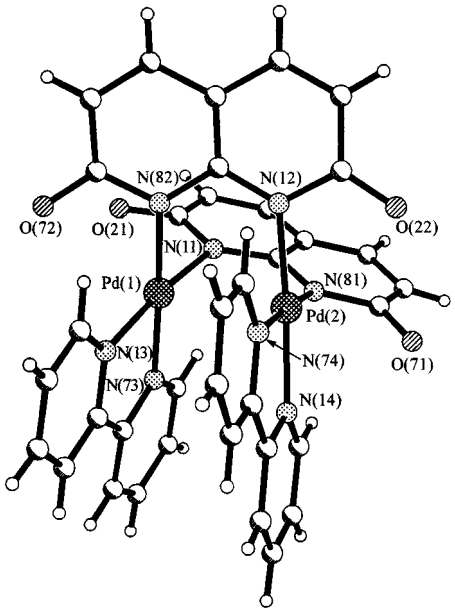

Figure 1. Molecular structure of [Pd_2(donp)$_2$(bpy)$_2$] (**1**)

The M···M distances of respectively 2.779(1) (M = Pd) and 2.789(1) Å (M = Pt) in the H_2nonp$^-$ complexes **2** and **3** are marginally shorter than that of 2.797(1) Å in the $Pd^{(II,II)}$ compound **1** (Table 1). This latter value lies in the range 2.794–2.804 Å established[9] for the analogous dinuclear complexes [M_2(onp)$_2$(bpy)$_2$]$^{2+}$ (Honp = 1,8-naphthyridin-2-one) and [M_2(monp)$_2$(bpy)$_2$]$^{2+}$ (M = Pd, Pt), which themselves are markedly shorter than the metal–metal distances of 2.841–2.974 Å previously reported for similar 1-methylthyminato- and 1-methyluracilato-bridged complexes.[12–17] The Pt···Pt separation of 2.899(2) Å in the di-

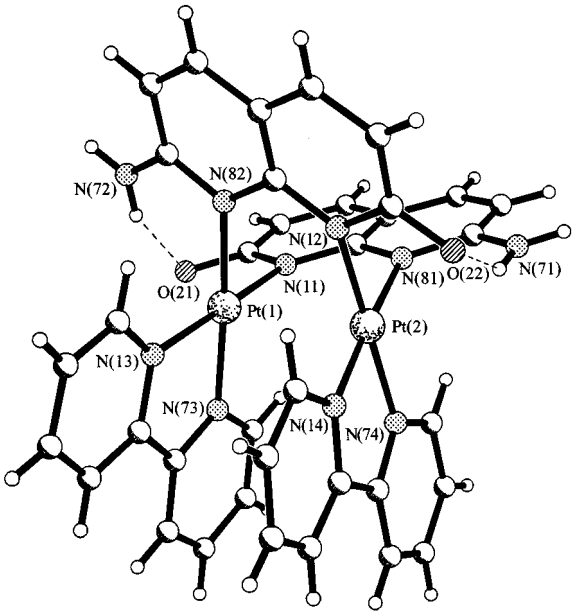

Figure 2. Structure of dication $[Pt_2(H_2nonp)_2(bpy)_2]^{2+}$ of **3**

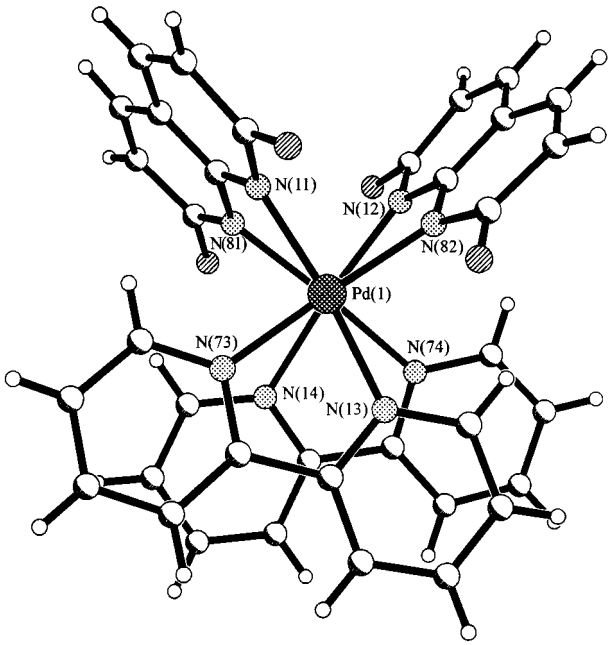

Figure 3. Projection of the structure of (**1**) along the Pd(1)···Pd(2) axis to demonstrate the pronounced relative twisting of the $donp^{2-}$ and bpy ligands

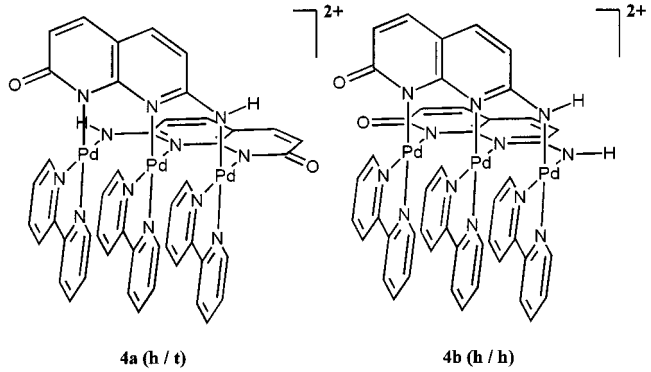
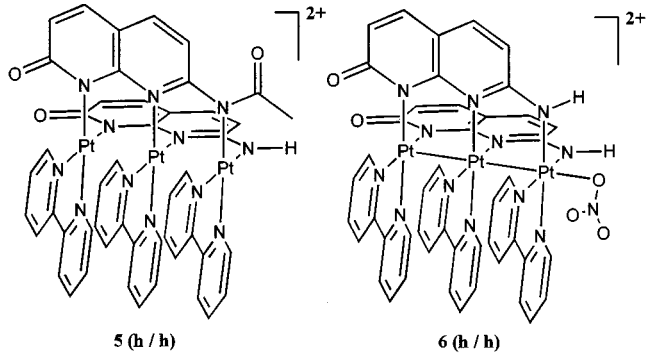
nuclear (bpy)Pt^{II} cation of $[Pt_2(C_4H_6NO)_2(bpy)_2](ClO_4)_2$ (C_4H_6NO = α-pyrrolidonate) also lies within this typical longer range.[18] μ-1κN^1:2κN^8 metal coordination in **1**−**3** leads to a significant widening of the $N^1\cdots N^8$ bite distance (respectively 2.34, 2.35, 2.40 Å) in comparison to the separation of these donor atoms in free naphthyridine ligands [e.g. 2.293(6) Å in Hmonp[19]]. Interestingly, the $N^1-M^1\cdots M^2$ angles in the H_2nonp^- complexes **2** [81.6(2)°] and **3** [81.5(4), 82.3(4)°] are considerably narrower than those observed for $N^8-M^2\cdots M^1$ [85.8(2)° in **2**, 85.8(4) and 86.3(5)° in **3**]. The analogous angles for the symmetrically 2,7-disubstituted $donp^{2-}$ ligands of **1** all lie within the range 81.3(2)−83.0(2) and are, therefore, similar to those for $N^1-M^1\cdots M^2$ in **2** and **3**. As the Pd^{II} and Pt^{II} atoms in **1**−**3** are not significantly displaced from the least-squares planes of their respective coordination spheres, the narrow $N^1\cdots N^8$ separations of the bridging naphthyridine ligands cause the square-planar MN_4 units to tilt away from one another at dihedral angles of 19.4(3) (**1**), 17.9(2) (**2**), and 18.0(4)° (**3**). Close intramolecular contacts between adjacent O^2 and O^7 atoms of the *cis*-positioned $donp^{2-}$ ligands in **1** lead to pronounced rotation of the naphthyridine (npy) and 2,2′-bipyridyl moieties relative to one another about the Pd(1)···Pd(2) axis. This state of affairs is illustrated in Figure 3 and manifests itself in the large average N(npy)−Pd(1)−Pd(2)−N(npy)′ and N(bpy)−Pd(1)−Pd(2)−N(bpy)′ torsion angles of 19.4(3) and 22.6(3)° in this compound. In contrast to **1**, the *head*/*tail* arrangement of the bridging H_2nonp^- ligands in **2** and **3** is stabilised by the formation of intramolecular O2···H−N^7 hydrogen bonds (Figure 2), with the consequence that the degree of twisting for the naphthyridine and 2,2′-bipyridyl ligands is significantly less pronounced in these complexes (Table 1).



Trinuclear Pd^{II} and Pt^{II} Complexes

Treatment of H_2donp[9] and H_3nonp with $[MCl_2(bpy)]$ (M = Pd, Pt) in aqueous solution in the presence of base leads to preferred formation of trinuclear complexes even at an equimolar ratio of the starting materials. A *head*/*head* positioning of the μ_3-1κN^1:2κN^8:3κO^7 coordinated $donp^{2-}$ ligands in $[M_3(donp)_2(bpy)_3]^{2+}$ (M = Pd, Pt) would afford the less favourable polar complexes, with formal charge balance at M^1 and M^2. Such isomers would also exhibit unfavourable short intramolecular contacts between adjacent O^2 atoms. As a result of these electronic and steric factors, favoured formation of the charge balanced *head*/*tail* isomers is observed upon refluxing aqueous solutions of this naphthyridine derivative with $[MCl_2(bpy)]$ and LiOH for 1−3 d at a 2:3:4 molar ratio.[9] In contrast to H_2donp with its protonated aromatic nitrogen atoms N^1 and N^8, the likewise dibasic H_3nonp is protonated at N^1 and the endocyclic amino nitrogen N^7, with the consequence that for a μ_3-1κN^1:2κN^8:3κN^7 bridging mode both the *head*/*head* and *head*/*tail* isomers of $[M_3(Hnonp)_2(bpy)_3]^{2+}$ will exhibit formal charge balance at M^1 and M^3 of a linear $[M_3]^{6+}$ core. Inspection of the structures of these isomers (Scheme 3) indicates, however, that, whereas the *head*/*tail* isomers could be stabilised by intramolecular $N^7-H\cdots O^2$ bonding between adjacent substituents, close contacts between neighbouring O^2 atoms of the *cis* sited $Hnonp^{2-}$ ligands in the *head*/*head* isomer would lead to pronounced relative twisting of the naphthyridine and 2,2′-bipyridyl ligands about the M···M axes, as in $[Pd_2(donp)_2(bpy)_2]$ **1**.



The reaction of H_3nonp with $[PdCl_2(bpy)]$ and LiOH in refluxing water does, indeed, lead to exclusive formation of the preferred isomers, *head*/*tail* $[Pd_3(Hnonp)_2(bpy)_3]^{2+}$ after 3 d. This dication, whose X-ray structure is depicted in Fig-

Scheme 3. *head*/*tail* and *head*/*head* isomers (**4a**, **4b**) of $[Pd_3(Hnonp\text{-}\mu_3\text{-}1\kappa N^1{:}2\kappa N^8{:}3\kappa N^7)_2(bpy)_3](ClO_4)_2$

Scheme 4. *head*/*head*-$[Pt_3(acnonp)(Hnonp)(bpy)_3]^{2+}$ (**5**) and *head*/*head*-$[Pt_3(Hnonp\text{-}\mu_3\text{-}1\kappa N^1{:}2\kappa N^8{:}3\kappa N^7)_2(NO_3)(bpy)_3](ClO_4)_2(NO_3)$ (**6**)

ure 4, can be precipitated as its dark-orange perchlorate (**4a**) by addition of $LiClO_4$ to the reaction solution. The closely similar Pd(1)···Pd(2) and Pd(2)···Pd(3) distances of 2.781(2) and 2.775(2) Å in **4a**, which are associated with a Pd(1)···Pd(2)···Pd(3) angle of 170.9(1)° are significantly shorter than those in the analogous $donp^{2-}$ complex $[Pd_3(donp)_2(bpy)_3](PF_6)_2$ (2.801(1), 2.804(1) Å). As observed in the dinuclear complexes **1**−**3**, tilting of the metal coordination planes dihedral angles $Pd(1)N_4$−$Pd(2)N_4$ 19.2(5)°, $Pd(2)N_4$−$Pd(3)N_4$ 19.6(4)°] is accompanied by marked twisting of the $Hnonp^{2-}$ and bpy ligand positions relative to the Pd(1)···Pd(2) and Pd(2)···Pd(3) vectors in **4a** (Table 1). Due to the fact that the Pd···Pd separations are markedly longer than the bridging N1···N8 and N8···N7 bite distances, wide C^9−N^1−Pd [128.0(7), 128.3(7)°) and C^7−N^7−Pd (129.3(8), 128.9(8)°] angles are required in this trinuclear complex.

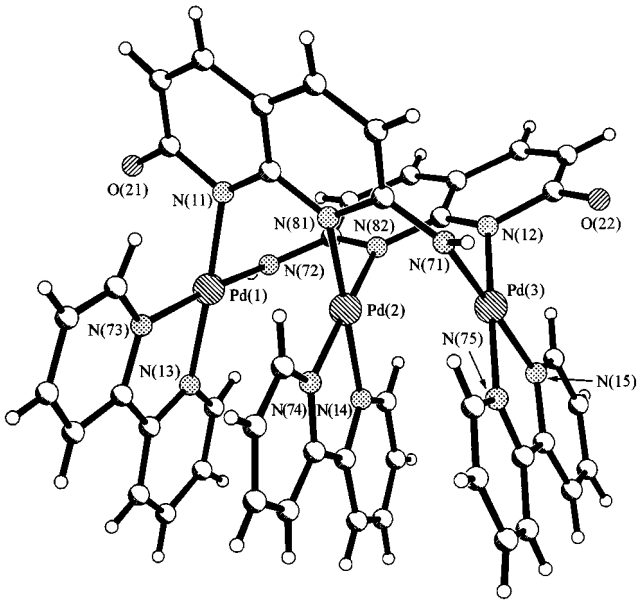

Figure 4. X-ray structure of the dication of *head*/*tail*-$[Pd_3(Hnonp)_2(bpy)_3](ClO_4)_2$ (**4a**)

A mixture of the *head*/*head* and *head*/*tail* isomers of $[Pd_3(Hnonp)_2(bpy)_3]^{2+}$ is obtained when H_3nonp is treated with $[PdCl_2(bpy)]$ and LiOH at room temperature for 2 d. The major product of this reaction **4b** (*head*/*head*) can be isolated in 32% yield by extracting the more soluble *head*/*tail* isomer **4a** with pyridine. **4b** was characterised by elemental analysis, mass spectrometry, and ^{1}H NMR spectroscopy. As both the C_2 symmetric *head*/*tail* and C_s symmetric *head*/*head* isomers exhibit 5 naphthyridine and 12 2,2′-bipyridyl magnetically inequivalent protons, it is not possible to distinguish **4a** and **4b** on the basis of their ^{1}H-NMR patterns. However, characteristic differences are apparent in Figure 5 for the bpy chemical shifts and the $Hnonp^{2-}$ amino H^7 resonance, which moves upfield from δ = 6.49 in **4a** to 6.28 in **4b**.

In contrast to the tripalladium(II) complex, an aqueous reaction solution of $Hnonp^{2-}$ and $[PtCl_2(bpy)]$ still contains a mixture of the *head*/*head* and *head*/*tail* isomers of $[Pt_3(Hnonp)_2(bpy)_3]^{2+}$, even after refluxing for periods longer than 3 d. It proved impossible to separate these products by solvent extraction or liquid chromatography, even though ^{1}H-NMR spectra indicated a predominance

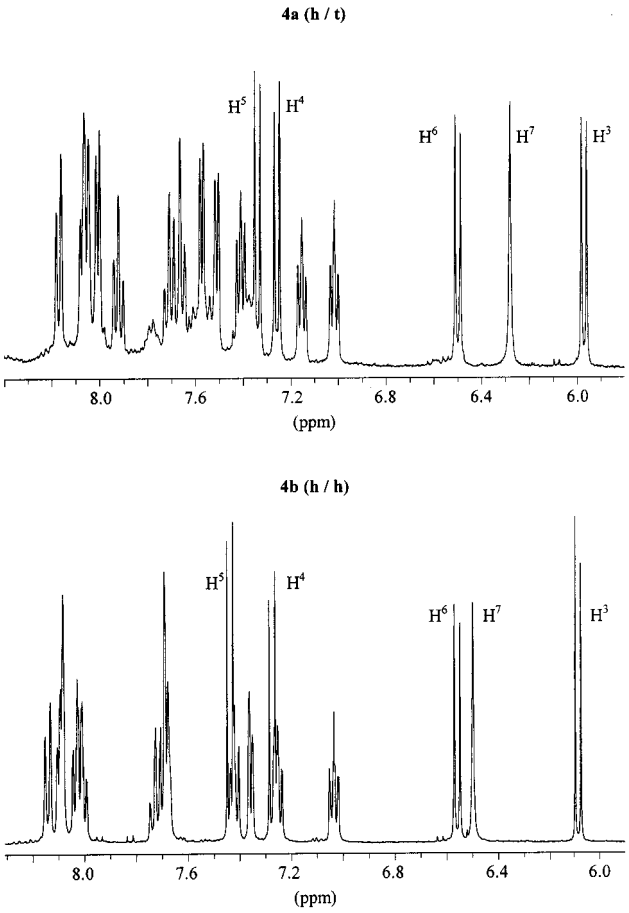

Figure 5. Proton NMR spectra ([D_6]DMSO) of the *head/tail* and *head/head* isomers (**4a**, **4b**) of $[Pd_3(Hnonp)_2(bpy)_3](ClO_4)_2$

(ca. 4:1) of the energetically more favourable *head/tail* isomer. The formation of trimers was confirmed by the presence of molecular ions $[M - PF_6]^+$ (*m/z* 1517) and $[M - 2\,PF_6]^+$ (*m/z* 1371) in the FAB mass spectrum of the product mixture. This lack of success in separating the isomers of $[Pt_3(Hnonp)_2(bpy)_3]^{2+}$ prompted us to study the reaction of H_2acnonp with $[PtCl_2(bpy)]$ in alkaline solution. As discussed previously, the facile cleavage of the 7-acetyl function of this naphthyridine derivative (presumably after initial coordination) enables the preparation of $[Pd_2(H_2nonp)_2(bpy)_2](ClO_4)_2$ **2**. After refluxing an aqueous 2:3:4 molar mixture of H_2acnonp, $[PtCl_2(bpy)]$ and LiOH for 1 d, addition of excess NH_4PF_6 leads to precipition of a dark-green solid, whose FAB mass spectrum contains (among others) the following molecular ions (*m/z*, %): 1559 (23) $[Pt_3(acnonp)(Hnonp)(bpy)_3(PF_6)]^+$, 1518 (4) $[Pt_3(Hnonp)_2(bpy)_3(PF_6)]^+$, 1414 (14) $[Pt_3(acnonp)(Hnonp)(bpy)_3]^+$, 1375 (5) $[Pt_3(Hnonp)_2(bpy)_3]^+$. Although satisfactory separation of the products contained in this mixture could not be achieved, a few green-blue crystals of *head/head*-$[Pt_3(Hacnonp)(Hnonp)(bpy)_3]Cl_2 \cdot x\,H_2O$ (**5**) could, on one occasion, be isolated by slow evaporation of a reaction solution. The X-ray structure of this triplatinum(II) complex, which exhibits Pt(1)···Pt(2) and Pt(2)···Pt(3) separations of 2.771(3) and 2.816(3) Å, is depicted in Figure 6. Tilt angles of 19.3(8) and 22.0(9)° are observed for the terminal PtN_4 coordination planes relative to the central PtN_4 unit and are associated with a Pt(1)···Pt(2)···Pt(3) angle of 168.0(1)°.

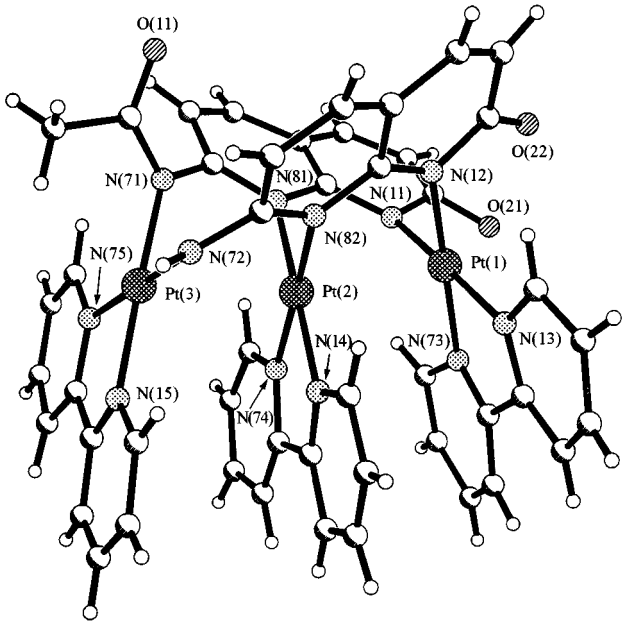

Figure 6. X-ray structure of the dication of *head/head*-$[Pt_3(acnonp)(Hnonp)(bpy)_3]Cl_2 \cdot x\,H_2O$ (**5**)

A Linear $[Pt_3]^{8+}$ Core

We have previously reported the CV characterisation of reversible one-electron oxidation steps for the $[Pt_3]^{6+}$ core in $[Pt_3(donp)_2(bpy)_3]^{2+}$ to $[Pt_3]^{7+}$ and $[Pt_3]^{8+}$, at respectively $E_{1/2}$ 0.65 and 1.30 V (vs. Ag/AgCl). Oxidation is accompanied by a shift in the main absorption maximum in the visible range to lower wavelengths and the appearance of a second maximum for the tri- and tetracations: $[Pt_3]^{6+}$ blue-green, λ_{max} = 710 nm, 555 nm, $[Pt_3]^{8+}$ violet, λ_{max} = 695 nm, 540 nm. Attempts to prepare $[Pt_3]^{7+}$ or $[Pt_3]^{8+}$ species were carried out with oxidants such as HNO_3 (conc.), $Na_2S_2O_8$, and $NOBF_4$. The first member of this list, HNO_3, was, for instance, used by Matsumoto to prepare violet $[\{Pt_2(GI)_2(bpy)_2\}_2](NO_3)_5 \cdot 2\,H_2O$ (GI = glutarimidate)[20]. However, only the addition of $NOBF_4$ to an acetonitrile solution of $[Pt_3(donp)_2(bpy)_3]^{2+}$ did, in fact, lead to a characteristic colour change from blue-green to violet, but did not allow the isolation of a solid oxidation product. As we had previously been unsuccessful in separating the *head/head* and *head/tail* isomers of $[Pt_3(Hnonp)_2(bpy)_3]^{2+}$, oxidation experiments were carried out directly on the aqueous reaction solutions obtained by treatment of $Hnonp^{2-}$ or $acnonp^{2-}$ with $[PtCl_2(bpy)]$. $[Pt_3]^{7+}$, or $[Pt_3]^{8+}$ species could, once again, not be isolated with the above oxidants.

The Ag^+/Ag couple has also occasionally been employed for the oxidation of platinum(II) complexes. For instance, both Kuyper[21] and Cotton[22] have demonstrated that Ag^I

can extract two electrons from dinuclear Pt^{II} complexes to afford $Pt(^{III, III})$ species with a Pt−Pt single bond. Although the mechanism of this redox process has not been fully elucidated, Lippert et al.[23][24] have isolated heteronuclear Pt_4Ag and Pt_2Ag complexes, which can be regarded as precursors. This approach finally led to the isolation of dark-brown *head/head*-$[Pt_3(Hnonp)_2(NO_3)(bpy)_3](ClO_4)_2(NO_3)$ (**6**) in low (23%) but reproducible yields by refluxing 2:3:4 aqueous solutions of H_2acnonp, $[PtCl_2(bpy)]$, and LiOH for 24 h in the presence of an excess of $AgNO_3$. After filtration of a black precipitate and addition of $LiClO_4$, crystals of **6** · 2 H_2O can be grown by gas diffusion of acetone into a nitromethane solution of the resulting dark-brown solid. The δ values of the aromatic protons of **6** (Figure 7) are shifted on average by 0.3 ppm to lower field (^{1}H NMR spectrum, [D_6]DMSO) in comparision to those recorded for the mixture of *head/head* and *head/tail* isomers of the triplatinum(II) complex $[Pt_3(Hnonp)_2(bpy)_3]^{2+}$. Cleavage of the original acetyl functions of the bridging naphthyridine ligands is confirmed by the absence of CH_3C(O) methyl resonances in this spectrum and by the X-ray structure presented in Figure 8, which also establishes the presence of the novel $[Pt_3]^{8+}$ core with its average oxidation state of Pt (2.67+). The diamagnetic trinuclear cation exhibits Pt(1)−Pt(2) and Pt(2)−Pt(3) distances of 2.723(2) and 2.670(2) Å, that are similar to those of 2.702(6)−2.710(5) in the respectively tetranuclear Pt (2.5+) and Pt (2.75+) complexes $[\{Pt_2(C_4H_3NO)_2(NH_3)_4\}_2](NO_3)_6 \cdot 3\,H_2O$ and $[\{Pt_2Cl_2(1\text{-MeT})_2(NH_3)_2\}_2Cl]PtCl_6 \cdot 6\,H_2O$.[6] One of the nitrate counterions in **6** is axially coordinated to Pt(3) at a distance of 2.42(3) Å, that is longer than that of the analogous interaction in the dinuclear complex $[Pt_2(\mu\text{-}C_5H_4NO)_2(NO_3)(H_2O)(NH_3)_4](NO_3)_3$ [2.193(7) Å].[25] This axial ligand is disordered in **6** at two different sites with site occupation factors of 0.52 and 0.48. In contrast to **4a** and **5**, the terminal metal atoms in **6**, Pt(1) and Pt(3), are displaced by respectively 0.064(8) and 0.071(8) Å towards the central atom Pt(2) and the chelating 2,2′-bipyridyl ligands adopt an effectively eclipsed orientation (Figure 9). The metrical data for **6** and the fact that the trinuclear cation is diamagnetic are in accordance with the presence of a $[Pt_3]^{8+}$ core, for which the Pt(1) and Pt(3) atoms can be assigned a formal oxidation state of 3+, with the central metal atom Pt(2) remaining at 2+. Interestingly the trimetal core retains the 48E electron count of tripalladium(II) or triplatinum(II) complexes such as **4a** or **5**, by means of its additional axial coordination of an NO_3^- anion.

6 represents, to our knowledge, the first example of a homonuclear triplatinum complex with an average oxidation state above 2+. Its isolation confirms the suitability of 2(7)-substituted naphthyridines as trinucleating ligands capable of supporting two metal−metal bonds. Previous examples are limited to the 46E $[Ru_3]^{2+}$ complex $[Ru_3(\mu\text{-mponp})_2(CO)_6]$ (hpmonp = 5-methyl-7-phenyl-1,8-naphthyridin-2-one)[26] with its Ru−Ru distances of 2.701(2) and 2.702(3) Å and the paramagnetic 47E complexes $[Rh_xIr_y(\mu\text{-dmonp})_2(CO)_2(cod)_2]^{2+}$ ($x = 0, 2$; $y = 3 - x$; Hdmonp = 5,7-dimethyl-1,8-naphthyridin-2-one), for which the Rh_2Ir cluster could be characterised by X-ray anaysis (Rh−Ir bond lengths, 2.768(2), 2.773(2) Å].[27]

Experimental Section

FAB MS: Fisons VG Autospec with 3-nitrobenzyl alcohol as matrix. − ^{1}H NMR: Bruker DRX 400; chemical shifts are reported as δ values relative to the signal of the deuterated solvent. − ^{195}Pt NMR: Bruker DRX 400, using a saturated K_2PtCl_4 solution as external standard with δ = −1628. − UV/Vis: Perkin−Elmer Lambda 15, λ_{max} is in nm, ε $dm^3 \cdot mol^{-1} \cdot cm^{-1}$. − Elementary analyses: Beller, Mikroanalytisches Labor, Göttingen. The naphthyridine derivatives H_3nonp[28] and H_2acnonp[29] were synthesized according to literature procedures; the starting compounds $[MCl_2(bpy)]$ (M = Pd, Pt) were prepared[30] from K_2MCl_4.

$[Pd_2(donp)_2(bpy)_2]$ (1): H_2donp (16.2 mg, 0.1 mmol) were stirred with 0.2 mL of 1 M NaOMe in 15 mL of MeOH for 30 min. $[PdCl_2(bpy)]$ (33.2 mg, 0.1 mmol) was added to the yellow solution and the suspension stirred for 17 h at room temperature. The resulting light orange precipitate was filtered off, washed with MeOH, and dried in vacuo to afford **1**. Yield 28.9 mg (63%). − $C_{36}H_{24}N_8O_4Pd_2 \cdot 4\,H_2O$ (917.5): calcd. C 47.1, H 3.5, N 12.2;

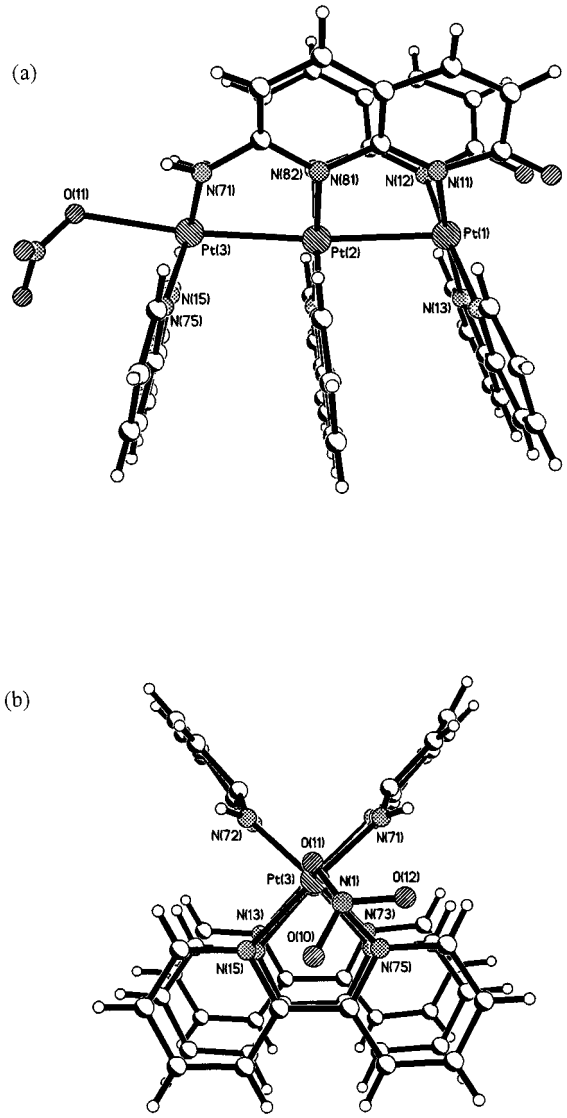

Figure 9. Projections of the trication of *head/head*-$[Pt_3(Hnonp)_2(NO_3)(bpy)_3](ClO_4)_2(NO_3)$ **6**: (a) parallel to the plane of the central 2,2′-bipyridyl plane and (b) along the Pt_3 axis

found C 47.7, H 3.7, N 12.2. − FAB MS; *m/z* (%): 845 (36) $[M]^+$, 685 (12) $[M - donp]^+$, 534 (29) $[M - 2\,bpy]^+$, 422 (100) $[M - donp - bpy - Pd]^+$. − UV/Vis (DMSO): λ_{max} (ε): 258 (2642), 308 (2637), 330 (2567), 344 (2561), 360 sh (1480), 440 sh (133). Crystals of **1** · 3.5 $C_7H_7NO_3$ for X-ray analysis were obtained by gas diffusion of acetone into a 3-nitrobenzyl alcohol solution of **1**.

$[Pd_2(H_2nonp)_2(bpy)_2](ClO_4)_2$ (2): $[PdCl_2(bpy)]$ (33.2 mg, 0.1 mmol) and H_2acnonp (20.3 mg, 0.1 mmol) were stirred in 20 mL of refluxing water for 2 d. After cooling, an excess of $LiClO_4$ was added to the solution and following centrifugation the resulting yellow precipitate dried in vacuo to afford **2**. Yield 45.4 mg (87%). − $C_{36}H_{28}Cl_2N_{10}O_{10}Pd_2 \cdot 2\,H_2O$ (1080.5): calcd. C 40.0, H 3.0, N 13.0; found C 40.0, H 3.0, N 13.1. − FAB MS; *m/z* (%): 945(31) $[M - ClO_4]^+$, 846 (27) $[M - 2\,ClO_4]^+$, 688 (19) $[M - 2\,ClO_4 - bpy]^+$, 534 (38) $[M - 2\,ClO_4 - 2\,bpy]^+$, 422 (100) $[M - 2\,ClO_4]^{2+}$, 260 (52) $[Pd(bpy)]^+$. − ^{1}H NMR ([D$_6$]DMSO): δ = 6.50 (d, 2 H, 3-H), 6.62 (d, 2 H, 6-H), 7.08 (m, 4 H, bpy), 7.53 (dd, 2 H, bpy), 7.61 (d, 2 H, bpy), 7.81 (d, 2 H, 4-H), 7.93 (d, 2 H, 5-H), 8.07 (dd, 2 H, bpy), 8.16 (dd, 2 H, bpy), 8.21 (d, 2 H, bpy), 8.26 (d, 2 H, bpy), 8.94 (s, 4 H, NH_2). − UV/Vis (DMSO): λ_{max} (ε): 262 (3501), 308 (5006), 325 sh (5000), 343 (7156), 368 sh (3012), 420 sh (216).

$[Pt_2(H_2nonp)_2(bpy)_2](PF_6)_2$ (3): $[PtCl_2(bpy)]$ (42.2 mg, 0.1 mmol) and H_3nonp (16.2 mg, 0.1 mmol) were mixed in 15 mL of water, whose pH was subsequently adjusted to 2 by addition of 0.1 M HNO_3. After heating for 40 h at 105 °C the deep-red solution was filtered and an excess of NH_4PF_6 added to the filtrate. The resulting violet precipitate was filtered off and dried in vacuo to afford **3**. Yield 45.9 mg (70%). − $C_{36}H_{28}F_{12}N_{10}O_2P_2Pt_2$ (1312.8): calcd. C 32.9, H 2.1, N 10.7; found C 32.3, H 1.9, N 10.8. − FAB MS; *m/z* (%): 1167 (30) $[M - PF_6]^+$, 1022 (60) $[M - 2\,PF_6]^+$, 861 (6) $[M - 2\,PF_6 - H_2nonp]^+$, 704 (11) $[M - 2\,PF_6 - H_2nonp - bpy]^+$, 511 (100) $[M - 2\,PF_6 - H_2nonp - bpy - Pt]^+$. − ^{1}H NMR ([D$_6$]DMSO): δ = 6.49 (d, 2 H, 3-H), 6.60 (d, 2 H, 6-H), 7.14 (dd, 2 H, bpy), 7.49 (d, 2 H, bpy), 7.53 (dd, 2 H, bpy), 7.79 (d, 2 H, 4-H), 7.91 (d, 2 H, 5-H), 8.01 (d, 2 H, bpy), 8.12 (dd, 2 H, bpy), 8.22 (d, 4 H, bpy), 8.27 (d, 2 H, bpy), 8.76 (s, 4 H, NH_2). − ^{195}Pt NMR ([D$_6$]DMSO): δ = −2285. − UV/Vis (DMSO): λ_{max} (ε): 259 (3442), 311 (3258), 349 (3960), 370 sh (2262), 460 sh (155), 550 (166). Crystals of **3** · 3 C_3H_7NO for X-ray analysis were grown by gas diffusion of *tert*-butyl methyl ether into a dimethylformamide (dmf) solution.

***headltail*-$[Pd_3(Hnonp)_2(bpy)_3](ClO_4)_2$ (4a):** A mixture of H_3nonp (32.2 mg, 0.2 mmol), $[PdCl_2(bpy)]$ (100.1 mg, 0.3 mmol) and $LiOH \cdot H_2O$ (16.8 mg, 0.4 mmol) was stirred at reflux in 40 mL of H_2O for 3 d. Following cooling, addition of an excess of $LiClO_4$ led to precipitation of dark-orange **4a**, which was dried in vacuo after centrifugation. Yield 79.6 mg (61%). − $C_{46}H_{34}Cl_2N_{12}O_{10}Pd_3 \cdot 4\,H_2O$ (1377.1): calcd. C 40.1, H 3.1, N 12.2; found C 40.3, H 3.7, N 12.3. − FAB MS; *m/z* (%): 1205 (43) $[M - ClO_4]^+$, 1106 (49) $[M - 2\,ClO_4]^+$, 951 (17) $[M - 2\,ClO_4 - bpy]^+$, 792 (31) $[M - 2\,ClO_4 - 2bpy]^+$, 638 (74) $[M - 2\,ClO_4 - 3\,bpy]^+$, 552 (100) $[M - 2\,ClO_4]^{2+}$. − ^{1}H NMR ([D$_6$]DMSO): δ = 6.08 (d, 2 H, 3-H), 6.49 (s, 2 H, NH), 6.55 (d, 2 H, 6-H), 7.03 (dd, 2 H, bpy), 7.25 (dd, 2 H, bpy), 7.27 (d, 2 H, 4-H), 7.35 (d, 2 H, bpy), 7.41 (dd, 2 H, bpy), 7.43 (d, 2 H, 5-H), 7.72 (m, 6 H, bpy), 8.00 (dd, 2 H, bpy), 8.02 (dd, 2 H, bpy), 8.09 (m, 4 H, bpy), 8.13 (d, 2 H, bpy). − UV/Vis (DMSO): λ_{max} (ε): 263 (7242), 307 (9065), 325 sh (7102), 352 (6250), 440 sh (1208), 530 sh (277). Crystals of **4a** · 7 H_2O for X-ray diffraction were obtained by slowly evaporating an acetone/water solution of the product.

***head/head*-$[Pd_3(Hnonp)_2(bpy)_3](ClO_4)_2$ (4b):** $[PdCl_2(bpy)]$ (100.1 mg, 0.3 mmol) was added to a suspension of H_3nonp (32.2 mg, 0.2 mmol) and $LiOH \cdot H_2O$ (16.8 mg, 0.4 mmol) in 40 mL of H_2O and the reaction mixture then stirred for 2 d at room temperature. After addition of an excess of $LiClO_4$, the resulting orange precipitate was washed with acetone and **4a** extracted with pyridine to leave **4b**, which was dried in vacuo. Yield 41.8 mg (32%). − $C_{46}H_{34}Cl_2N_{12}O_{10}Pd_3$ (1305.0): calcd. Oxygen Transfer from Chromyl Chloride to Alkynes and Allene − IR-Spectroscopic Identification of η^1-Ketene and Cyclopropanone Complexes of $O{=}CrCl_2$

Tobias Wistuba,[a] and Christian Limberg*[a]

Keywords: Photolysis / Alkynes / Matrix isolation / DFT / Oxygenations

Photolytically-induced reactions of chromyl chloride with acetylene and but-2-yne (dimethylacetylene) in low-temperature argon matrices yield *end-on* ketene and dimethylketene complexes of $O{=}CrCl_2$, respectively. The product formation probably results from an electrophilic attack of a Cr=O linkage on the C≡C triple bonds, leading to radical-like transition states or intermediates, which subsequently rearrange through 1,2-H or 1,2-methyl shifts. Consequently, allene is attacked at its central carbon and the allyl radical thus generated undergoes subsequent ring-closure to give a cyclopropanone complex of $O{=}CrCl_2$.

Introduction

The oxidation of olefins by chromyl chloride, which was established in the 19th century,[1] is still employed for the functionalization of C=C double bonds yielding epoxides, chlorohydrins, and dichlorides.[2] Although the associated mechanism has been the subject of extensive studies,[3] until recently the detailed course of these reactions remained speculative, and there was no evidence to support the intermediacy of the species that had been proposed to account for the experimental findings. Cook and Mayer wrote: "The nature and the chemistry of such intermediate chromium species is perhaps the most difficult aspect of these reactions to unravel",[4a] and indeed, this matter has received significant attention in the past.[2a,5] Substantial progress has, however, been made, especially within the last two years: Ziegler et al. have postulated, on the basis of exemplary DFT calculations in the case of ethylene,[6] that interactions with the $Cr(=O)_2$, Cr(=O)Cl, or $CrCl_2$ moieties represent the initial steps responsible for the formation of the three observed products (vide supra) when this olefin is oxidized. At the same time, we have been able to show that it is possible to photolytically induce olefin oxidations by chromyl chloride at 10 K in argon matrices. In this way, it has been possible to matrix-isolate complexes of ketones, aldehydes, and epoxides with the hitherto unknown oxo-metal halide $O{=}CrCl_2$, which represent the primary products of oxo-transfer reactions combined, in some cases, with 1,2-H migrations (cf. Scheme 1).[7] In fact $O{=}CrCl_2{\cdots}$epoxide complexes have been proposed as intermediates accounting for epoxide formation by others,[2a,6b] but the mechanism of the reactions occurring under photolytic matrix conditions is probably different from that which is operative under thermal conditions. The former most likely involves photoexcited chromyl chloride in its triplet state,[7b] which is not accessible under thermal conditions. Once in the excited state, chromyl chloride is capable of oxygenating olefins either via an epoxide-like or a radical-like transition state. The latter rearranges through a 1,2-H shift to generate a carbonyl complex, while the former yields epoxide complexes that have been postulated as being formed after a spin-crossover via glycolates in the thermal process (Scheme 1).[6b] Consequently, in spite of different initial transition states and intermediate geometries, the minima corresponding to the matrix-isolated species are common to the potential energy surfaces of both processes, making their identification, characterization, and investigation an important issue.

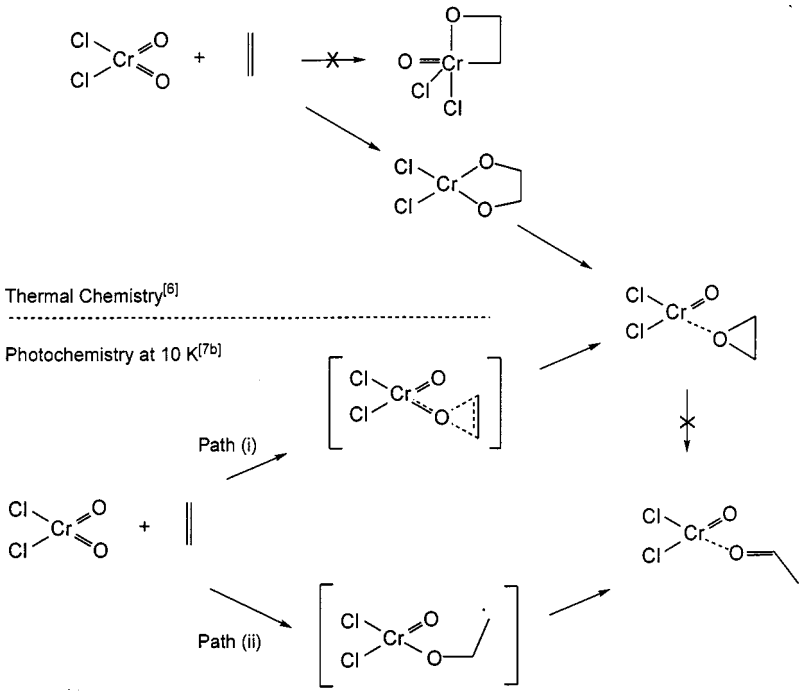
Results and Discussion



We have expanded our investigations concerning the photoreactions of chromyl chloride with unsaturated systems under matrix conditions from alkenes to alkynes and allene.

(a) CrO_2Cl_2/HCCH

Literature concerning the products of alkynes in oxidations with chromyl chloride under preparative conditions is scarce, but where reported diketones or α-C oxidation products have been obtained.[8] If the principles found for the matrix oxidations of olefins by chromyl chloride[7] also hold for alkynes, interesting products may be expected: an analogous route to path (i) in Scheme 1 would lead to an oxirene complex, while that corresponding to path (ii) would generate a η^1-ketene complex, as shown in Scheme 2 in the case of acetylene. Both are attractive targets:

(i) There have been many attempts to synthesize and characterize oxirenes. Such species have frequently been proposed as intermediates during the Wolff rearrangement or during oxidation reactions involving alkynes, and have

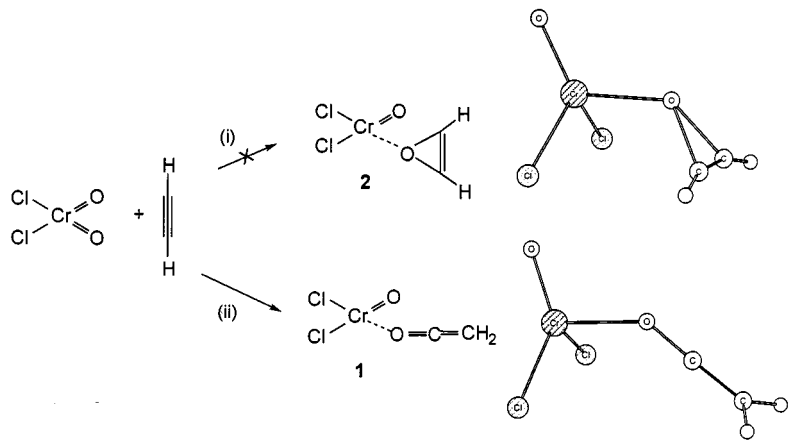


Scheme 1. Mechanistic possibilities for the photolytic olefin oxidation with CrO_2Cl_2 under matrix conditions[7b] vs. calculated intermediates[6]

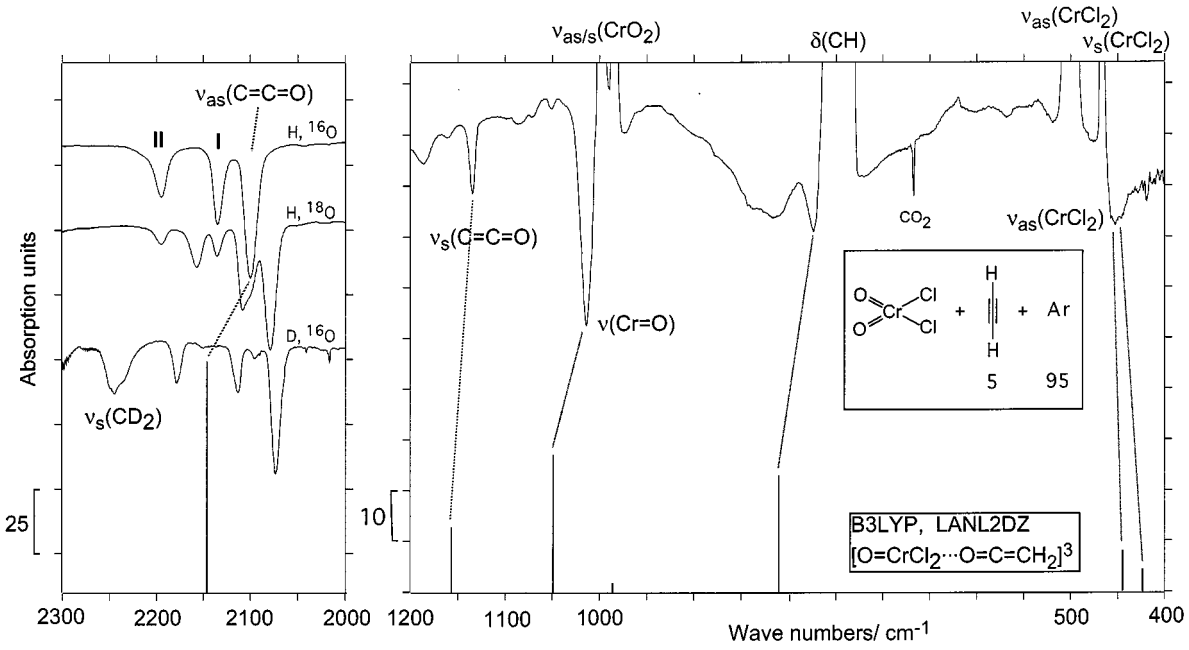
been the subject of numerous theoretical investigations.[9] To date, only one successful oxirene synthesis (photodecomposition of α-diazo ketones in Ar matrices[10]) has been reported, but as a stabilization can be expected from its coordination to a transition metal (cf. the case of cyclobutadiene[11]), the complex **2** shown in Scheme 2 seemed to be a reasonable product.

(ii) Although various complexes of ketenes have been analysed structurally,[12–15] none of these shows an *end-on* coordination mode.

DFT calculations (B3LYP/LANL2DZ) proved that for both complexes of the type $O{=}CrCl_2{\cdots}O{=}C{=}CH_2$, **1**, and $O{=}CrCl_2{\cdots}O(CH)_2$, **2**, minima can be found on the potential energy surface (triplet state structures of C_1 symmetry were optimized as shown in Scheme 2) but that, not surprisingly, **1** is more stable than **2** by 258.6 kJ/mol.

Our investigation of the reaction of chromyl chloride with alkynes in low-temperature matrices started with the simplest alkyne, i.e. acetylene, under conditions[7] that had already enabled the characterization of intermediates such as those depicted in Scheme 1. Since molecules do not undergo diffusion in the solid low-temperature matrices, the reservoir of collisional reactant pairs formed upon deposition is depleted as the photolytically-induced chemical reaction proceeds. The line-widths of the new bands observed were found to be independent of the chromyl chloride concentration and the relatively broad appearance of some of them is probably due to conformational isomers.

Scheme 2. Possible routes for a photolytically-induced reaction of chromyl chloride with acetylene at 7 K; optimized structures of **1** and **2** (B3LYP/LANL2DZ)



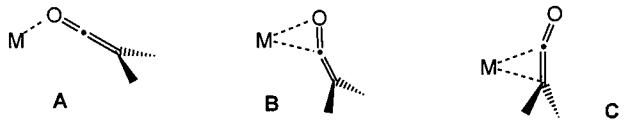


Figure 1. Upper trace: Difference between the IR spectrum (1800−350 cm^{-1}) of CrO_2Cl_2 isolated in an argon matrix doped with 5 mol-% acetylene at 7 K and the spectrum recorded of the same matrix after photolysis at 411 nm for 20 min. Lower trace: Line diagrams for the IR spectrum calculated for **1**; the upper trace of the offset shows the 2000−2200 cm^{-1} region of the spectrum, the middle trace the effects of the ^{18}O enrichment on this region, and the lower trace the effects of complete deuteriation

Identification of 1: Co-condensation of a mixture of acetylene in argon (5%) with chromyl chloride at 7 K yielded an IR spectrum of the unperturbed starting materials, which was subtracted from a spectrum recorded after subsequent photolysis (15 min at 411 nm). The result is shown in Figure 1 (the negative bands are attributable to consumed starting material). The band at 1014 cm^{-1} can be assigned to $\nu(Cr{=}O)$ of an $O{=}CrCl_2$ fragment, by analogy with the CrO_2Cl_2/ethylene case (1009 cm^{-1}).[7a] The band due to $\nu_{as}(CrCl_2)$, which had previously been observed at 452 cm^{-1}, can be discerned as a broad feature at 424 cm^{-1}, while the corresponding $\nu_s(CrCl_2)$ band, expected to appear around 380 cm^{-1}, is probably broadened into the base line (not shown in Figure 1).

In addition, a new intense band can be seen at 2095 cm^{-1}, which is accompanied by two less intense bands at 2132 and 2195 cm^{-1}. These are discussed separately below. The findings point to ketene as the oxidation product, since free ketene shows a $\nu_{as}(C{=}C{=}O)$ band at 2142 cm^{-1},[16] which can be expected to be red-shifted upon coordination to $O{=}CrCl_2$. The observed shift of 47 cm^{-1} is of the same order as that found for acetaldehyde[7a] (60 cm^{-1}). Since the absorption cross-section of $\nu_{as}(CCO)$ found for free ketene exceeds that of any other IR absorption by at least one order of magnitude (and can even be expected to be enhanced on complexation), all other IR absorptions due to the ketene ligand should have very low intensities in Figure 1. Indeed, apart from the absorptions mentioned so far, only two other definite bands − namely a weak but sharp band at 1135 cm^{-1} and a broad, low-intensity band at 773 cm^{-1} − can be detected. These show the same growth behaviour as the 2095 cm^{-1} band. All these observations thus provide further support for the formation of an $O{=}CrCl_2{\cdots}O{=}C{=}CH_2$ complex.

In principle, there are three possible coordination modes for ketene at a metal centre, which are depicted in Scheme 3: *end-on* **A**, *side-on* (O=C) **B**, and *side-on* (C=C) **C**. A few compounds are known where type **B** or **C** structures have been established by X-ray crystal structure analysis. Not surprisingly, ketene complexes of early, very oxophilic transition metals all display mode **B**,[12][13] while type **C** has mainly been observed by X-ray diffraction analysis of some structurally closely related complexes of Mn.[14] However, only recently, the first bond isomerism of a ketene metal complex has been demonstrated.[15] In order to permit assignment of the coordination mode of the ketene ligand in $O{=}CrCl_2{\cdots}O{=}C{=}CH_2$ as **A**, **B**, or **C**, DFT calculations (B3LYP, LANL2DZ), which have previously been shown to provide reliable information concerning the IR spectra and the corresponding isotopic shifts of such species,[7] were performed for individual complexes. Bearing in mind the results presented in Scheme 1, the theoretical investigation was started with a frequency calculation for complex **1** based on the structure shown in Scheme 2, which is, of course, only one of several possible conformations for type **A** coordination. The result has been included in Figure 1 in the form of a line diagram. As can be seen, the band pattern and the intensity ratios of the experimental spectrum are nicely reproduced. Additional support for the assignment of the experimental spectrum to **1** with an *end-on*-coordinated ketene ligand was provided by experiments employing ^{18}O-enriched CrO_2Cl_2: apart from $\nu(Cr{=}O)$, which is shifted by 43 cm^{-1} as $\nu(Cr{=}O)$ of $O{=}CrCl_2{\cdots}O{=}CHCH_3$,[7a] and $\nu_{as}(CCO)$ (21 cm^{-1}), the band at 1135 cm^{-1} also shows a

significant shift (22 cm^{-1}) and hence it can confidently be assigned to ν_s(CCO). Moreover, the ^{18}O shifts observed are in excellent agreement with those predicted by the calculation (cf. Table 1). Additional experiments employing C_2D_2 were performed, and the resulting shifts are also compared with the calculated values in Table 1. Naturally, these shifts are larger than those obtained upon ^{18}O enrichment, and hence the deviations between the experimental and calculated values are correspondingly higher. However, such deviations can arise from very small differences between the theoretical and actual structures.[17] Deuteriation additionally allows the observation of $\nu_{as}(CD_2)$ at 2260 cm^{-1}, which was the only other observable band besides ν_{as}(CCO) when free deuteriated ketene was generated by NO_2 oxidation of [D_2]acetylene in an Ar matrix.[18] Further calculations ruled out the two possible η^2-coordination modes **B** and **C** (vide infra). Taken together, the aforementioned results strongly support the assignment of all new bands below 2100 cm^{-1} to compound **1**, a metal complex with a ketene ligand in the *end-on* coordination mode **A**. The underlying reasons for the preference of $O{=}CrCl_2{\cdots}O{=}C{=}CH_2$ to adopt coordination mode **A** can be traced to the oxophilic nature of the *hard* d^2 Cr centre, which is electron-

Scheme 3. Possible coordination modes for ketenes at metal centres

poor and therefore not suitable for efficient back-bonding.

The Additional Bands: The above assignments leave only the two bands at 2132 cm^{-1} (**I**) and 2194 cm^{-1} (**II**) unaccounted for. The left-hand part of Figure 1 shows their positions and intensities, as well as their behaviour on isotopic enrichment in comparison to ν_{as}(CCO) of **1**. While the upper trace corresponds to the right-hand part of Figure 1, the middle trace is the result of an $^{18}O_2CrCl_2$ reaction (note that the satellites beside the shifted bands are due to the ^{16}O isotopomers, which formed simultaneously due to incomplete ^{18}O enrichment). D_2C_2 gave rise to the lower trace. The wavenumbers of **I** and **II** are rather high, and their ^{18}O shifts indicate that the corresponding vibrations should involve a significant motion of the oxygen. On the other hand, there must also be a contribution from the C−H vibrations, as indicated by the D shifts observed for these bands, although these are smaller than the shift found for ν_{as}(CCO) of **1**. The fact that the bands still appear in the same region after isotopic enrichment proves that they are *not* the result of a Fermi resonance or an overtone. Their characteristics are therefore also indicative of ν_{as}(CCO) vibrations, but as they show markedly different isotopic shifts and positions in comparison to ν_{as}(CCO) of **1**, they have to be assigned to ν_{as}(CCO) vibrations of two independent species that are related to, but are nevertheless significantly different from **1**. Interestingly, it proved possible to decrease the intensity of the ν_{as}(CCO) band of **1** in favour of the bands **I** and **II** by irradiation with light of the wavelengths 313 and 545 nm.

By optimizing the structures of over a dozen different complexes and calculating their IR spectra (plus isotopic shifts), the following facts could be established:

(i) Neither different matrix sites nor different conformations are responsible for these bands, as these could not explain the significantly different positions and isotopic shifts of **I** and **II**.

(ii) The change of spin state from triplet to singlet has a large effect on the IR properties of the $O{=}CrCl_2$ fragment, but the effects on the $O{=}C{=}CH_2$ unit are negligible.

(iii) A coordination mode of type **B** would not be expected to cause a shift of $\nu_{as}(C{=}C{=}O)$ to higher wavenumbers compared to that in **1**. Moreover, a structure with a corresponding starting geometry changed its mode to **A** during the optimization.

(iv) A mode of type **C** would, in fact, cause a shift of $\nu_{as}(C{=}C{=}O)$ to higher wavenumbers, but a corresponding complex would additionally show a band half as intense as $\nu_{as}(C{=}C{=}O)$ at ca. 890 cm^{-1}. No band can be seen in this region of the experimental spectrum (Figure 1).

(v) Oxirene or formyl carbene complexes do not show bands of significant intensity in the region 2000−2200 cm^{-1}, nor does oxiranylidene, which has recently been identified in low-temperature matrices.[19]

Consequently, a reaction of **1** with an excess of acetylene was then considered as a possible explanation for bands **I**

Table 1. Frequencies obtained experimentally on photolysis of $Cr^{16}O_2Cl_2$ and $Cr^{18}O_2Cl_2$ isolated in HCCH (or DCCD)/Ar matrices (5%), as well as calculated frequencies for **1** (B3LYP/LANL2DZ) in cm^{-1} (intensities given in parentheses); the assignments are based on the spectrum of free ketene,[16] as well as on the results of the calculation

and **II**, even though the concentrations and conditions chosen do not usually permit reactions with significantly more than one equivalent of a substrate. However, acetylene is a very special case in that it forms aggregates even at very low pressures in the gas phase.[20a] A real matrix *isolation* of acetylene can therefore only be achieved by diluting it with argon to such a low concentration that would preclude study of its reaction with chromyl chloride as the number of collisional pairs formed upon co-condensation would become too low. The concentration amounted to 5% in the experiment described above, and consequently oligomers of acetylene were also isolated in the matrices, as indicated by their characteristic bands.[20] As a result, the structures of the matrices could not, of course, be treated statistically: the ratio of chromyl chloride molecules with just *one* acetylene molecule as a nearest neighbour to those with more than one such neighbour was significantly decreased compared to the situation under standard conditions. Thus, the bands **I** and **II** may well result from species incorporating more than one equivalent of acetylene, and indeed, a decrease of the acetylene concentration down to the lowest possible level of 2% (where the signal-to-noise ratio is still acceptable in the difference spectrum following irradiation) led to a significant decrease in the intensities of these bands in relation to the intensity of ν_{as}(CCO) attributable to **1**. Bearing in mind the effects observed upon photolysis at 313 and 545 nm, respectively, the corresponding species must be accessible by direct reaction of **1** with acetylene. A reaction of the ketene moiety can be excluded as no product can be envisaged that would still exhibit a band at a higher wavenumber than 2100 cm^{-1} (with a significant ^{18}O shift). The most likely reaction at the metal centre is a complex formation (i.e. a weak or even strong binding of acetylene). Unfortunately, DFT calculations are not adequate for describing the simultaneous complexation of acetylene and ketene at an $O{=}CrCl_2$ fragment (at least not with the B3LYP functional),[21] hence it was not possible to unequivocally assign the bands **I** and **II** to alkyne complexes of **1**.

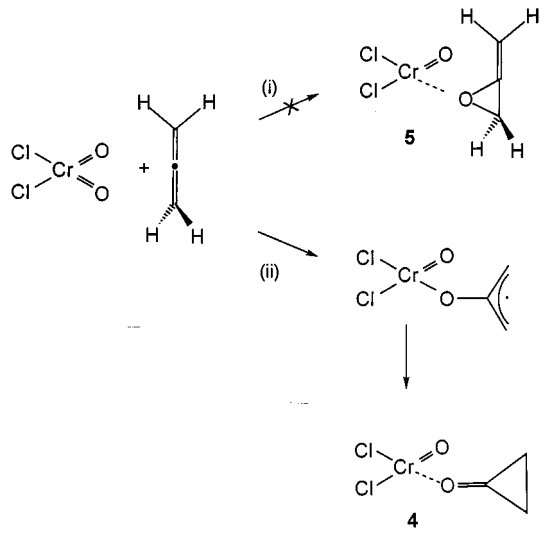
(b) CrO_2Cl_2/CH_3CCCH_3

Next, but-2-yne was employed as a reactant in order to find out whether the corresponding dimethylketene derivative $O{=}CrCl_2{\cdots}O{=}C{=}C(CH_3)_2$, **3**, is formed, or whether the methyl groups prevent rearrangement by 1,2-migration (no methyl shift has ever been observed for any analogous olefin reactions[7b]). Provided that the above arguments in the case of acetylene are correct, formation of **3** should also be accompanied by the generation of two additional species. The concentrations of the latter, however, should be much lower: in contrast to acetylene, but-2-yne does not show a pronounced tendency to aggregate, so that a reaction of chromyl chloride molecules with *two* equivalents of alkyne should, on statistical grounds, only be possible for the small fraction of molecules that have two alkyne neighbours in the solid matrix (ca. 10% for a 5:95 ratio of butyne/Ar vs. 34% with just *one* neighbour[22]).

Following the reaction of but-2-yne with chromyl chloride, the bands for the $O{=}CrCl_2$ fragment could be found as before. In addition, a band at 2072 cm^{-1} was observed, suggesting that a dimethylketene complex **3** had indeed been formed. This was further corroborated by repeating the experiment with $^{18}O_2CrCl_2$ (leading to shifts comparable to those found previously for **1**), as well as by calculations (B3LYP/LANL2DZ) concerning the structure and frequencies of such a complex, the latter being in good agreement with the experimental frequencies (cf. Table 2). As anticipated (vide supra), two additional bands could be observed at higher wavenumbers beside the ν_{as}(C=C=O) band of **3**, albeit with only minor intensities.

The fact that **3** was formed by a 1,2-methyl migration suggests that such a shift should, in principle, also be possible in the case of olefins. However, in the latter case, a low degree of methylation leaves open too many alternative 1,2-H migration routes, while permethylation makes path (i) in Scheme 1 more favourable. The transition state associated with the analogous path (i) in Scheme 2 is of course very high in energy (**2** itself was calculated to form in an *endothermic* reaction, while formation of **1** is exothermic by −246 kJ/mol). The transition state energy will be lowered only slightly if H is substituted by Me. Consequently, there is only one low-energy path open for alkynes, which probably involves attack of a Cr=O bond at the triple bond in a fashion analogous to path (ii) in Scheme 1. After passing through the corresponding radical-like transition state, a methyl shift yields **3**. The postulation of such a transition state prompted a further experiment that might support its existence: thus, allene was employed as the unsaturated component.

(c) $CrO_2Cl_2/CH_2{=}C{=}CH_2$



If radical-like transition states, produced by attack of the Cr=O function at the unsaturated bonds, do indeed govern product formation in the reactions of alkenes and alkynes, allene can be expected to be attacked at the central carbon, as this would lead to a resonance stabilized allyl radical as shown in Scheme 4. A downhill route involving a 1,2-H or 1,2-Me shift would then not be accessible, but the reaction could proceed through a subsequent ring-closure to yield a cyclopropanone complex (NO_2 oxidation of allene in low-temperature matrices leads to cyclopropanone).[24]

A terminal attack at the allene followed by a 1,2-H shift would yield acrolein, or, alternatively, an epoxidation of one olefinic bond may be envisaged [compare path (i) in Scheme 4].

Following co-condensation of a 5% allene/argon mixture with chromyl chloride, the usual photolysis at 411 nm led to the bands of $O{=}CrCl_2$, which were seen at 1012 and 447 cm^{-1}. Additionally, an intense matrix-split band was observed at 1800 cm^{-1}, which must be attributable to a ν(C=O) vibration in view of the marked ^{18}O-shift and the negligible D-shift observed when experiments were performed with $^{18}O_2CrCl_2$ and $D_2C{=}C{=}CD_2$, respectively. All

Scheme 4. Proposed mechanism of the photolytically-induced reaction of chromyl chloride with allene at 7 K

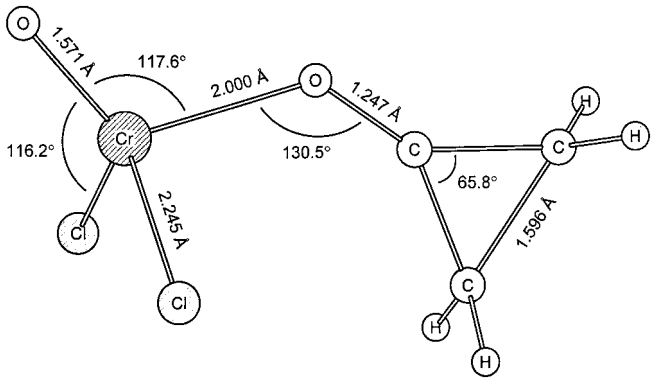

Figure 2. The optimized structure calculated for $OCrCl_2$···cyclopropanone, **4**, by means of DFT using LANL2DZ basis sets (B3LYP); selected bond lengths and angles are given in Å and°

bands and their isotopic shifts are shown in Table 3, along with the theoretical frequencies and the calculated isotopic shifts for an optimized structure of the cyclopropanone···$Cr(O)Cl_2$ complex **4** (Figure 2). As can be seen, the agreement is very good, hence it can safely be concluded that **4** was indeed formed. This supports the hypothesis of a radical-like transition state in carbonylations with chromyl chloride under matrix conditions. The simultaneous formation of the allene oxide complex **5** in Scheme 4 can be ruled out on the basis of further calculations concerning its frequencies.[26] This finding is not surprising as the barrier leading to **5** is probably much higher than that associated with the conversion of the allyl radical to **4**. Moreover, **5** itself is less stable than **4** by 59 kJ/mol.

Conclusions

We have shown herein that the reactions of chromyl chloride with acetylene and but-2-yne (dimethylacetylene) under matrix conditions yield η^1-ketene and -dimethylketene complexes of $O{=}CrCl_2$, respectively. The oxidation of allene leads exclusively to a cyclopropanone complex, probably through an initial radical-like attack of a Cr=O functionality at the central carbon, with subsequent ring-closure. The formation of all products is consistent with the general reactivity pattern observed previously for chromyl chloride in reactions with olefins,[7] and supports the idea that radical-like transition states are involved in the corresponding carbonylation reactions.

In the past, H-atom transfers by metal-oxo species have been rationalized in terms of intuitions based on analogy with organic radical chemistry, i.e. unpaired electron density was thought to be transferred to the oxygen of the metal compounds, which then determined its propensity to take part in radical reactions. In the meantime, it has been established that chromyl chloride – a d^0 system having no unpaired spin density – can in fact abstract hydrogen atoms from saturated organic systems. This has led to progress in current thinking, from considerations of radicals and spin density to a new approach based on the thermochemistry of the H-atom transfer step and, therefore, on the bond strengths.[27]

These fundamental discoveries made for the *C–H activation* by chromyl chloride naturally raise questions concerning the initial steps of its reactions with *unsaturated systems*. It could be envisaged that in these oxidations chromyl chloride might also follow one reaction route (among others) where it behaves akin to a fleeting main group oxygen radical, giving rise to a radical intermediate or transition state, which finally undergoes rearrangement to produce the isolated carbonyl products. This is exactly what we seem to have found for the matrix reactions of chromyl chloride under photolytic conditions as outlined in the above. However, under thermal conditions (−80°C), an analogous reactivity can only be postulated provided that a necessary condition holds, i.e. that the thermochemistry is favourable or at least only slightly unfavourable,[27] in other words that the CrO–C bond formed in the course of the Cr=O attack at the carbon of an unsaturated bond must be sufficiently strong to drive the reaction in the direction of carbonylation. Addition of an organic radical to a Cr=O function is indeed likely to be very exothermic,[4b] and the CrO–C bond energy released can therefore easily overcompensate the loss of π-bonding energy if a similar addition is considered for an unsaturated bond. This has certainly been the case in our experiments, which have, however, started from chromyl chloride in an excited state.[7b] Therefore, it is not yet certain as to whether CrO–C bond formation is sufficiently exothermic to make a corresponding attack energetically favourable under thermal conditions as well. This subtle problem will only be resolved following an experimental determination of the Cr(V)O–C bond energy

Experimental Section

Computational Methods: Density functional calculations were carried out using the Gaussian-94/DFT[28] series of programs. The structures of **1–3** were optimized with the LANL2DZ basis set using in each case the B3LYP formulation of density functional theory, i.e. Becke's three-parameter exchange functional and the Lee–Yang–Parr correlation functional. Harmonic vibrational frequencies and infrared intensities were predicted at these levels by numerical second derivatives using analytically calculated first derivatives. No scaling was applied and no negative frequencies were obtained.

Experimental: Liquid helium cooling gave temperatures of ca. 7 K inside a shroud maintained at a pressure below 10^{-7} Torr. Mixtures were prepared in a vacuum line using standard manometric techniques and were then deposited on the cold support. A CsI window was used for all the IR experiments; the slow spray-on deposition was favoured for CrO_2Cl_2 with the sample maintained at −65°C.

The photolysis source was a 200 W medium-pressure arc. The radiation was filtered with a Balzers interference filter (band-pass ca. 15 nm). IR spectra were recorded in transmission mode over the ranges 4000–300 and 1000–200 cm^{-1}, with a resolution of 1 cm^{-1}, on a Bruker IFS 88 spectrophotometer.

CrO_2Cl_2 (99.99% pure), but-2-yne, and acetylene (99% pure) were supplied by Aldrich and further purified by fractional condensation in high vacuum prior to use. Argon (99.999% pure, Messer Grieshheim), [D_2]acetylene (99% pure, Campro Scientific), and [D_4]allene (98% pure, Campro Scientific) were used as received.

^{18}O-enrichment of CrO_2Cl_2 can be achieved according to a published procedure. Allene was synthesized according to ref.[7b]

Synthesis and Single-Crystal X-ray Diffraction Studies on New Methylindium(III) Alkoxides

Michael Veith,*[a] Sven Hill,[a] and Volker Huch[a]

Keywords: Indium / O ligands / N ligands / C ligands

New heteroleptic indium compounds have been synthesized starting from indium(III) halides and hexamethyldisilazyllithium to form $MeXInN(SiMe_3)_2$ [X = Cl (**1**), Br (**2**)], and then subsequent alcoholysis to afford the molecules $[ClMeIn(OtBu)]_2$ (**3**), $[BrMeIn(OtBu)]_2$ (**4**), $\{ClMeIn[O(C_6H_4)OMe]\}_2$ (**5**), $\{[(SiMe_3)_2N]MeIn(OtBu)\}_2$ (**6**) and $[MeIn(OtBu)_2]_2$ (**7**). The molecular structures of molecules **3**–**7** have been obtained by single crystal X-ray diffraction studies. The structures of the compounds **3**–**7** are almost identical: **3**–**5** crystallize in the monoclinic crystal system with two dimeric molecules per unit cell in the space group $P2_1/c$, **6** crystallizes in the monoclinic space group $C2/c$ with four molecules per unit cell, and compound **7** crystallizes in the triclinic crystal system with one dimeric molecule per unit cell in the space group $P\bar{1}$. The central centrosymmetric In_2O_2 ring, common to all the compounds, is achieved by two bridging oxygen atoms. Due to the additional coordination by an oxygen atom of the methoxy group, the coordination number of the metal center rises from 4 to "4+1" if the O*t*Bu ligand (compounds **3**, **4**, **6**, and **7**) is exchanged for a methoxyphenol ligand (compound **5**). In addition to the In_2O_2 ring the compound **5** possesses two annealed five-membered InO_2C_2 rings. The common indium methyl group of all compounds, which is transfered by an original route from the silicon to the indium atom, is used to compare structural and spectroscopic properties of the molecules, as there is a correlation between the In–C bond length and the chemical shift of the methyl group which depends on the ligand system used.

Introduction

The interest in organometallic precursors for use in the area of surface coating has been growing over the last few years. In particular the use of metal alkoxides in metal-organic chemical vapor deposition (MOCVD) or in the sol-gel process has become increasingly popular. In the field of indium alkoxides, however, few studies have been made when contrasted with the lower homologous aluminum and gallium. Indium compounds and ceramics possess a wide variety of interesting properties, which are important in modern technologies. Pure indium oxides, for example, are used as heat insulators,[1] and mixed indium-tin oxides for transparent and conductive ceramics.[2][3] Furthermore, indium compounds find applications in the solar[4–6] and the semiconductor industries.[7] Only a few indium compounds, however, are known to be used in CVD. Indium alkoxides used as an In/O source might be interesting precursors for MOCVD.[8] Apart from some indium compounds of the type $R_2In(OR)$,[9–11] some indium aryloxides,[12–14] some $In(OR)_3$[15] compounds and some heterometallic alkoxides of the type $In[M(OiPr)_4]_3$ with M = Al, Ga,[16] only two dialkylindium alkoxides $[(tBu_2InOEt)_2$[17] and $(tBu_2InOMe)_2$[18]] have been fully characterized by single-crystal X-ray analysis to date.

The authors report here on the synthesis and X-ray crystal-structure analysis (see Table 2) of some new (alkoxo)indium compounds as well as the first monoalkylindium dialkoxide. The principle idea of the reactions described was to introduce selected ligands into indium-centered molecules, and to analyze the structural changes brought about by these ligands. These changes should be monitored in the solid state by X-ray diffraction techniques.

Syntheses of the Indium-Centered Molecules 1–7

Tris(hexamethyldisilazyl)indium, $In[N(SiMe_3)_2]_3$, has been described previously together with $Ga[N(SiMe_3)_2]_3$ and $Al[N(SiMe_3)_2]_3$.[19][20] It is easily obtained by the reaction of $InCl_3$ with three equivalents of $LiN(SiMe_3)_2$.[19] This silylamide was synthesized by Bürger et al. in 1971 and structurally characterized by Power et al. in 1993.[19][20] In the present work the interest is in the reactions of $InCl_3$ with $LiN(SiMe_3)_2$ in molar ratios which differ from 1:3. A molar ratio of 1:2 was first tried. The nonpolar solvent toluene was used to exclude the donation of a basic solvent to the metal center (Equation 1). The reaction solution of $LiN(SiMe_3)_2$ and $InCl_3$ was refluxed for 24 h as the reaction rate was too slow at room temp. The surprising result of this synthesis was a monochloro substitution and migration of a methyl group from an $[N(SiMe_3)_2]$ group to the metal atom to form compound **1**. The first evidence of the methyl group transfer was given by the spectroscopic analysis of the product; the ^{1}H-NMR spectrum of the resulting product $ClMeIn[N(SiMe_3)_2]$ (**1**) shows two signals with an integration ratio of 1:6, in contrast to the singlet expected for the disubstituted product $ClIn[N(SiMe_3)_2]_2$. The ^{13}C-NMR spectrum also shows two NMR signals, indicating the migration of a methyl group. Similar methyl-group transfers are known for gallium compounds.[21][22] The C/H/N, In,

and Cl analyses performed also give values which correspond exactly with those calculated for **1**. So far, it has not been possible to select a suitable crystal for single-crystal X-ray analysis.

$$2\ LiN(SiMe_3)_2 + InCl_3 \rightarrow \underset{\mathbf{1}}{MeClIn[N(SiMe_3)_2]} + LiCl\ \downarrow\ + \text{side products} \quad (1)$$

If the reaction is carried out in an equimolar ratio the result is similar except that the yield of **1** is less. The change to a polar solvent, such as diethyl ether or THF, also leads to the same results.

In order to insert the first alkoxo ligand into the molecule, **1** was subjected to an alcoholysis reaction (Equation 2). The reaction solution was again refluxed for 24 h to speed up the reaction rate. The alcohol was added in excess to secure a complete reaction.

$$MeClIn[N(SiMe_3)_2] + 2\ HO\mathit{t}Bu \rightarrow \underset{\mathbf{3}}{ClMeIn(O\mathit{t}Bu)} + HN(SiMe_3)_2 + HO\mathit{t}Bu \quad (2)$$

After removing the volatiles under reduced pressure and dissolving the residue in hexane, **3** was crystallized from hexane at low temperatures (−30°C) and purified by sublimation (10^{-2} Torr/120°C; yield: 64%). The ^{1}H-NMR spectrum of **3** shows two signals in an integration ratio of 3:1, corresponding to the ratio of the methyl protons of the *tert*-butyl group and the methyl group. The ^{13}C-NMR spectrum shows three signals as expected, corresponding to the metal-bonded methyl group and two signals for the *tert*-butyl group. In the hope of increasing the yield, the more reactive $InBr_3$ was used as a starting compound instead of $InCl_3$. Compound **2** BrMeIn[N(SiMe$_3$)$_2$] was synthesized according to the same procedure reported for compound **1** (Equation 3).

$$2\ LiN(SiMe_3)_2 + InBr_3 \rightarrow \underset{\mathbf{2}}{MeBrIn[N(SiMe_3)_2]} + LiBr\ \downarrow\ + \text{side products} \quad (3)$$

The ^{1}H- and ^{13}C-NMR spectra of **2** are similar to that of **1**. The following alcoholysis of **2** was carried out under the same conditions as described for **3** (Equation 4). The yield of the reaction (70%) was not much higher than for the reaction with $InCl_3$, for which reason $InCl_3$ was used again in subsequent syntheses. The ^{1}H- and ^{13}C-NMR spectra of **4** are very similar to that of **3**.

$$MeBrIn[N(SiMe_3)_2] + 2\ HO\mathit{t}Bu \rightarrow \underset{\mathbf{4}}{BrMeIn(O\mathit{t}Bu)} + HN(SiMe_3)_2 + HO\mathit{t}Bu \quad (4)$$

With the introduction of the MeO(C$_6$H$_4$)O ligand to the indium atom instead of the O*t*Bu ligand, a further possibility of coordination was offered to the metal center. In this way attempts were made to prevent the molecule from dimerising. The synthesis of **5** is almost analogous to the synthesis of **3** and **4** (Equation 5), with the exception that crystallization of **5** did not occur from hexane at low temperatures, but directly from the mother liquor (yield: 60%). The ^{1}H-NMR spectrum of **5** shows a signal for the metal-bonded methyl group and one signal for the methoxy group. In the ^{13}C-NMR spectrum only two signals are found, corresponding to the metal-bonded methyl group and the OMe group.

$$MeClIn[N(SiMe_3)_2] + 2\ HO(C_6H_4)OMe \rightarrow \underset{\mathbf{5}}{ClMeIn[O(C_6H_4)OMe]} + HN(SiMe_3)_2 + HO(C_6H_4)OMe \quad (5)$$

For the synthesis of MeIn(O*t*Bu)[N(SiMe$_3$)$_2$] (**6**) an analogous procedure to that for **3**, **4**, and **5** was chosen to introduce the [N(SiMe$_3$)$_2$] ligand into the system. The reaction of **3** with Li[N(SiMe$_3$)$_2$] in a molar ratio of 1:1 was performed under refluxing toluene. During this reaction no methyl-group transfer of trimethylsilyl to indium was observed and **6** was formed together with lithium chloride (Equation 6).

$$ClMeIn(O\mathit{t}Bu) + LiN(SiMe_3)_2 \rightarrow \underset{\mathbf{6}}{[(SiMe_3)_2N]MeIn(O\mathit{t}Bu)} + LiCl \quad (6)$$

Compound **6** could be isolated by crystallization from hexane at low temperatures (yield: 60%). The ^{1}H-NMR spectrum of **6** shows three signals in a ratio of 1:3:6 corresponding to the signals of the metal-bonded methyl group, the *tert*-butyl group and the [N(SiMe$_3$)$_2$] group. Within the ^{13}C-NMR spectrum, four signals are visible in accordance with the singlets of the methyl group, the [N(SiMe$_3$)$_2$] group and the two signals of the *tert*-butyl group.

In order to replace the amino function by an alcohol group, **6** was subject of an alcoholysis. The synthesis was carried out in refluxing toluene with a double equivalent of *tert*-butyl alcohol (Equation 7). After removing the volatiles in vacuo and dissolving the residue in hexane, MeIn(O*t*Bu)$_2$ (**7**) was separated from the solvent by crystallization at low temperatures (−30°C).

$$[(SiMe_3)_2N]MeIn(O\mathit{t}Bu) + 2\ HO\mathit{t}Bu \rightarrow \underset{\mathbf{7}}{MeIn(O\mathit{t}Bu)_2} + HN[SiMe_3]_2 + HO\mathit{t}Bu \quad (7)$$

An adequate yield of **7** (60%) was only possible if the reaction took place in a very dilute solution. In a concentrated solution, a mixture of **3**, **6**, and **7** was obtained. After purification of **7** by sublimation (10^{-2} Torr/120°C), the ^{1}H-NMR spectrum shows two signals (ratio 1:6) corresponding to the metal-bonded methyl group and the two *tert*-butyl groups. As expected in the ^{13}C-NMR spectra three signals are visible.

Metal alkoxides are often synthesized by the reaction of alkylmetal compounds with alcohol.[23] Therefore, **7** was treated with *tert*-butyl alcohol in toluene and refluxed for several hours to replace the methyl group by the *tert*-butyl group. Surprisingly, even after refluxing the solvent for

24 h, no reaction took place (Equation 8). In conclusion, the metal−carbon bond in **7** seems to be remarkably stable.

$$MeIn(OtBu)_2 + 2\ HOtBu \not\rightarrow In(OtBu)_3 + CH_4 \uparrow + HOtBu \quad (8)$$

Crystal Structures of Compounds 3, 4, 5, 6, and 7

The molecular structures of the compounds **3**, **4**, **5**, **6**, and **7** have been determined by single-crystal X-ray analysis. The crystal structures of the molecules are shown in Figures 1−5. Selected bond lengths and angles are given in Table 1.

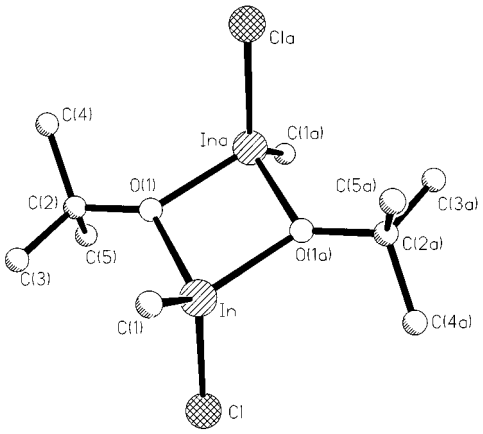

Figure 1. Molecular structure of $[ClMeIn(OtBu)]_2$ (**3**); hydrogen atoms are omitted for clarity

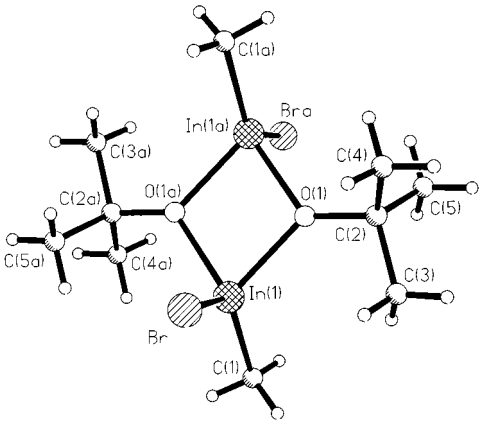

Figure 2. Molecular structure of $[BrMeIn(OtBu)]_2$ (**4**)

Crystal Structures of 3 and 4

The compounds $[ClMeIn(OtBu)]_2$ (**3**) and $[BrMeIn(OtBu)]_2$ (**4**) are similar, except for the different halogen atoms. Both compounds crystallize in a monoclinic crystal system with two molecules per unit cell, in the space group $P2_1/c$, and are isostructural. The compounds form centrosymmetric dimers (crystal symmetry: C_i). The dimerisation is achieved by two bridging oxygen atoms. The In_2O_2 ring is planar by symmetry requirements. The indium atoms in both compounds are present in a strongly distorted tetrahedral environment. The oxygen atoms in both the structures possess an almost trigonal planar coordination sphere (358.3° for **3**; 358.7° for **4**) and thus are sp^2-hybridized. The bond lengths within the In_2O_2 ring of both the molecules are rather similar [211.5(7) pm in **3** and 212.1(7) pm in **4**]. The In−C lengths in both compounds are also within the same range [211.8(6) pm for **3** and 210(1) pm for **4**], but

about 10 pm shorter than in other comparable compounds.[17] The In–X bond lengths (X = halogen atom) are normal by comparison with standard compounds.[24] As a consequence of the short In–C length, compared to the In–X length, the carbon atoms experience a stronger repulsion to the bridging oxygen atoms. This leads to different C–In–In and X–In–In angles. The C–In–In angle in compound **3**, for example, is found to be 129.8(2)°; 22.2° larger than the X–In–In angle [107.6(5)°]. In compound **4** the effect is similar: The C–In–In angle [127.6(4)°] is 20.4° larger than the X–In–In angle [107.2(5)°]. The difference in the C–In–In angles of compounds **3** and **4** can be explained by the different halogen atoms; thus, the X–In–C angle in **4** [124.5(4)°] is larger than the corresponding angle in **3** [122.4(2)°] because of the larger bromine atom. The bonding angles within the In_2O_2 rings of the two compounds are almost identical (see Table 1). The larger In–O–In angles are due to the hard-shell oxygen atoms, whereas the soft-shell indium atoms allow more acute angles.

Crystal Structure of 5

The compound $\{ClMeIn[O(C_6H_4)OMe]\}_2$ (**5**) crystallizes in the monoclinic crystal system with two molecules per unit cell in the space group $P2_1/c$. The dimerisation of "monomers" to form the centrosymmetric dimer **5** can be understood in terms of the tendency of indium(III) to achieve higher coordination numbers, while a polycycle is formed due to the presence of further basic ligands (methoxy group) (see Figure 3). Besides an In_2O_2 ring, the dimeric molecule contains two five-membered InO_2C_2 rings and two six-membered phenyl rings, all fused together. The central In_2O_2 ring with respect to the bridging oxygen atoms is the same as that described for **3** and **4**. The In_2O_2 ring is planar because of centrosymmetry, whereas the phenyl ring is planar due to electronic considerations. On the other hand the atoms within the InO_2C_2 ring are not equiplanar and have a dihedral angle which differs by about 5° from planarity. In contrast to the compounds described above, the indium atoms in **5** possess a "4+1" coordination sphere with a strongly distorted tetrahedral environment: $In(ClCO_2)$ plus additional coordination by an oxygen atom of the $O(C_6H_4)OMe$ group. The O–In–O angles within the In_2O_2 ring are more acute, and the In–O–In angles even larger, when compared to **3** and **4**. The In–O bond lengths are also longer compared to **3** and **4**; the mean value of the bonds [220.4(4) pm] being 9 pm longer when compared to those of **3** and **4**. The bond between In(1) and O(2) within the InO_2C_2 ring [240.6(5) pm] may be classified as coordinative due to its length. From a general point of view, the In–O lengths are comparable to values of the oxopentaindium alkoxide cluster reported by Bradley et al.[25] Alcock et al. described an indium compound, $[Me_2In(OC_6H_4CHO)]_2$, which is similar to **5**.[14] The dimeric molecule consists of a central In_2O_2 ring, two six-membered InO_2C_3 rings, and two phenyl rings all fused together. The O–In–O angles inside the In_2O_2 ring are larger [74.8(1)°] and the In–O–In angles more acute [105.2(1)°] compared to those of **5**. The mean value of the In–O bond lengths in $[Me_2In(OC_6H_4CHO)]_2$ [228.6(3) pm] is about 8 pm longer compared to

that of **5**. The In−C bond lengths hardly differ between $[Me_2In(OC_6H_4CHO)]_2$ [212.1(2) pm] and **5**. The bond lengths between In−C and In−Cl hardly differ between compounds **5** and **3**. This is very surprising, because the coordination numbers of the indium atoms are not equal in the two compounds. All oxygen atoms in **5** possess a more or less distorted trigonal environment and are sp^2-hybridized. The distortion of O(2) (356.4°) is higher as compared to that of O(1) (359.35°).

Crystal Structure of 6

As with **3**, **4**, and **5** compound $\{MeIn(OtBu)[N(SiMe_3)_2]\}_2$ (**6**) crystallizes in the monoclinic crystal system with four molecules per unit cell in the space group *C*2/*c*. The crystal-structure analysis shows again a centrosymmetric dimer (crystal symmetry: C_i) with a planar In_2O_2 ring, which originates by a base attack of the more electronegative oxygen atoms (as compared to the nitrogen atoms) on the indium atom. In contrast to **3**, **4**, and **5**, no halogen atom is bonded to the metal atom but a nitrogen atom, belonging to a $[N(SiMe_3)_2]$ ligand, is present. The In−O−In angle [105.40(1)°] within the In_2O_2 ring is slightly smaller than in **5**, but larger than in **3** or **4**. The In−O lengths within the In_2O_2 ring [214.50 (7) pm] are longer than for **3** and **4**, which could be explained by the less electronegative $N(SiMe_3)_2$ ligand when compared to the halogen atom. The indium atoms possess a highly distorted tetrahedral coordination sphere. The oxygen atoms are almost trigonal planar coordinated (359.04°) and thus are sp^2-hybridized. The In−C and In−N bond lengths are within the range of values described in the literature.[26] The C−In−In and N−In−In angle in compound **6** are almost the same as the corresponding angles in **3** and **4**, due to the almost equal bond lengths between In−C and In−N.

Crystal Structure of 7

Compound $[MeIn(OtBu)_2]_2$ (**7**) crystallizes in a triclinic crystal system with one dimeric molecule per unit cell in the space group *P*−1. As for the compounds **3**−**6**, **7** also exists as a centrosymmetric dimer (crystal symmetry: C_i). At the metal atom, three alkoxo ligands are present besides the methyl group (Figure 5). The bond angles within the In_2O_2 ring [In−O−In 103.6(2)°, O−In−O 76.4(2)°] are comparable with both the corresponding angles in **3** and **4** and those of the ethoxy compound, $[tBu_2In(OEt)]_2$, described by Hursthouse et al.[17] The indium atoms have a distorted tetrahedral coordination sphere. The oxygen atoms O(1) and O(1a) possess a slightly distorted trigonal-planar environment, whereas O(2) and O(2a) are in the apices of an angle. The In−O bond lengths within the In_2O_2 ring [212.8(8) pm] are comparable to the bond lengths in compounds **3**−**6** and $[tBu_2In(OEt)]_2$. The In−O bond lengths to the terminal oxygen atoms are 12 pm shorter than the bond lengths within the In_2O_2 ring, due to the different coordination numbers of the oxygen atoms.

Conclusion

All compounds reported here have a metal-bound methyl group in common. This group can be used as a sensor to compare the different compounds with different ligand spheres. One way to use this sensor is to compare the dependence on the ligands of the In−C bond length in the molecules. It was expected that there would be a correlation between the electronegativity of the ligands and the In−C bond length. Generally speaking, the more electronegative chlorine atom in compound **3** should cause an electron withdrawal from the indium atom and therefore lead to a smaller In−C bond length than in the case of compound **4** where there is a less electronegative bromine atom. Inspection of the In−C bond lengths confirms this assumption, except for compounds **3** and **4** (Table 1). The In−C bond in **3** [211.8(6) pm] is surprisingly slightly longer than in **4** [210(12) pm], but if the halogen atom is substituted by a nitrogen atom, as in **6**, which is less electronegative, the In−C bond [216(5) pm] is elongated. In compound **7**, where the halogen atom is substituted by a more electronegative oxygen atom, the bond length [213.6 (7) pm] is reduced compared to **6** and is in the region of that found for **3** and **4**. In compound **5**, the situation is more complicated; because of the change of the coordination number from 4 to "4+1", the In−C bond should be quite long but with 212.9(7) pm the bond length has a mean value which seems to be the result of the three electronegative oxygen ligands. In any case the electronegativity is not the only parameter which has to be considered in the change of the In−C bond length; the size and the steric requirement of the ligand must also be taken into account. On this theme, the most sterically demanding ligand, the $[N(SiMe_3)_2]$ group in **6**, gives the longest In−C bond length. The O*t*Bu group in **7**, which is sterically less demanding than the $[N(SiMe_3)_2]$ group, leads to a slightly shorter In−C bond length. The $MeO(C_6H_4)O$ group in **5** is sterically not as demanding as the $[N(SiMe_3)_2]$ and the O*t*Bu group, but the ligand does offer an additional intramolecular coordination site such that the coordination number of the metal atom and the

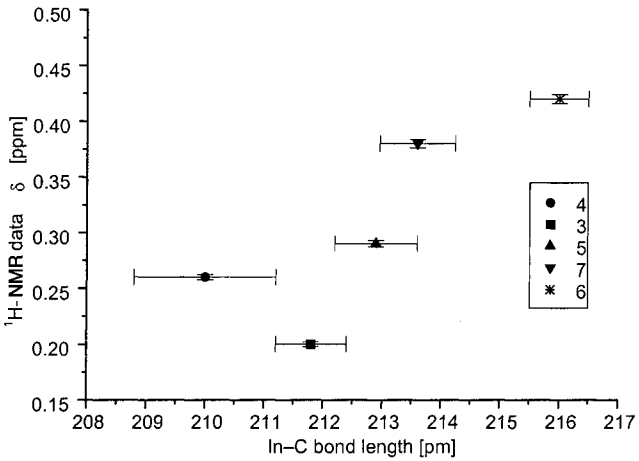

Figure 6. Chemical shift of the molecules **3**−**7** vs. In−C bond lengths

In−C bond lengths are increased, however not as much as expected because of the electronegativity of the ligands. In our experiment, we find a correlation between the ^{1}H-NMR data and the In−C bond lengths. The compound with the longest In−C bond, compound **6**, has the highest chemical shift (δ = 0.42) followed by compound **7** and compound **5**. The ^{1}H-NMR shifts for **3** and **4**, however, are reversed (Figure 6).

Experimental Section

General: All manipulations were performed under purified and dried nitrogen using a modified Stock apparatus. Solvents were distilled from Na/K alloy prior to use. $InCl_3$ and $InBr_3$ were prepared according to known procedures.[27] *tert*-Butyl alcohol was dried by distillation from sodium. − ^{1}H and ^{13}C NMR: Bruker AC 200 spectrometer, quoted to [D$_6$]benzene by using the solvent signal as internal reference. − Elemental analyses: LECO CHN 900 analyser. − Metal and halogen analyses: Standard methods. − The crystal structures of compounds **3**−**7** were obtained from X-ray diffraction of single crystals. The most important parameters for the crystals and the structure determination have been summarized in Table 2. Diffraction data were collected with a Stoe AED 2 diffractometer. The structures were solved by direct methods (SHELXS-86)[28] and refined by full-matrix least-squares procedures on all F^2 values (SHELXS-97).[29] All nonhydrogen atoms were refined anisotropically. Crystallographic data for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication CCDC-121777−121781 (**3**−**7**). Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 IEZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Synthesis of {ClMeIn[N(SiMe$_3$)$_2$]}$_2$ (1): A solution of $LiN(SiMe_3)_2$ (3.0 g,17.92 mmol) in toluene (40 mL) was added dropwise to a stirred suspension of $InCl_3$ (1.98 g, 8.96 mmol) in toluene (30 mL). A weak exothermic reaction took place. The reaction solution was refluxed for 24 h, and after removing the volatiles under reduced pressure, the product purified by sublimation (10^{-2} Torr/100°C). Yield: 1.89 g, 65.0% (based on $InCl_3$). − ^{1}H NMR: δ = 0.30 (s, 3 H, $InCH_3$), 0.28 {s, 18 H, N[Si(CH_3)$_3$]}. − ^{13}C NMR: δ = 5.03 {s, 6 C, N[Si(CH_3)$_3$]$_2$}, 6.60 (s, 1 C, In*C*H$_3$). − $C_7H_{21}ClInNSi$ (325.67): calcd. C 30.57, H 7.64, Cl 7.52, In 24.37, N 5.94; found C 30.28, H 7.47, Cl 7.26, In 23.96, N 5.65.

Synthesis of {BrMeIn[N(SiMe$_3$)$_2$]}$_2$ (2): Compound **2** was synthesized in an analogous manner to **1**. Yield: 1.47 g, 70.0% (based on $InBr_3$). − ^{1}H NMR: δ = 0.30 (s, 3 H, $InCH_3$), 0.28 {s, 18 H, N[Si(CH_3)$_3$]}. − ^{13}C NMR: δ = 5.03 {s, 6 C, N[Si(CH_3)$_3$]$_2$}, 6.60 (s, 1 C, $InCH_3$).

Synthesis of [ClMeIn(O*t*Bu)]$_2$ (3): An excess of *tert*-butyl alcohol (0.88 mL, 9.2 mmol) was added to a stirred solution of ClMeIn[N(SiMe$_3$)]$_2$ (**1**) (1.50 g, 4.6 mmol) in toluene (25 mL). The reaction solution was refluxed for 24 h, and, after removing the volatiles under reduced pressure, the residue dissolved in a small amount of hexane. The product crystallized at low temperatures (−30°C) within 12 h and was further purified by sublimation (10^{-2} Torr/120°C). Yield 0.7 g, 64% (based on $InCl_3$). − ^{1}H NMR: δ = 0.20 (s, 3 H, $InCH_3$), 1.13 [s, 9 H, C(CH_3)$_3$]. − ^{13}C NMR: δ = 6.8 (s, $InCH_3$), 33.45 [s, C(*C*H$_3$)$_3$], 75.00 [s, *C*(CH$_3$)$_3$]. − $C_5H_{12}ClInO$ (238.41): calcd. C 25.16, H 5.03, Cl 14.87, In 48.16; found C 24.39, H 5.02, Cl 14.75, In 48.96.

Synthesis of [BrMeIn(O*t*Bu)]$_2$ (4): Compound **4** was synthesized in an analogous manner to **3**. Yield: 1.02 g, 70% (based on $InBr_3$). − ^{1}H NMR: δ = 0.26 (s, 3 H, $InCH_3$), 1.13 [s, 9 H, C(CH_3)$_3$]. − ^{13}C NMR: δ = 6.93 (s, $InCH_3$), 33.55 [s, C(*C*H$_3$)$_3$], 75.42 [s, *C*(CH$_3$)$_3$]. − $C_5H_{12}BrInO$ (282.87): calcd. C 21.22, H 4.24, Br 28.26, In 40.60; found C 20.88, H 4.23, Br 29.87, In 41.50.

Synthesis of {ClMeIn[O(C$_6$H$_4$)OMe]}$_2$ (5): An excess of 2-methoxyphenol (3.0 mL, 27.0 mmol) was added to a stirred solution of ClMeIn[N(SiMe$_3$)$_2$] (**1**) (4.40 g, 13.5 mmol) in toluene (80 mL). The reaction solution was refluxed for 24 h and the product crystallized from the mother liquor while cooling. Yield 2.30 g, 60% (based on $InCl_3$). − ^{1}H NMR: δ = 0.29 (s, 3 H, $InCH_3$), 3.13 (s,3 H, OCH_3). − ^{13}C NMR: δ = 6.8 (s, $InCH_3$), 55.88 (s, OCH_3). − $C_8H_{10}ClInO_2$ (288.43): calcd. C 33.30, H 3.46, Cl 12.30, In 39.80; found C 33.20, H 3.87, Cl 12.40, In 39.70.

Synthesis of {Me[N(SiMe$_3$)$_2$]In(O*t*Bu)}$_2$ (6): A solution of LiN(SiMe$_3$)$_2$ (2.53 g, 15.2 mmol) in toluene (50 mL)was added dropwise to a stirred solution of ClMeIn(O*t*Bu) (**3**) (3.3 g, 15.2 mmol) in toluene (150 mL). The reaction solution was refluxed for 24 h and, after removing the volatiles under reduced pressure, the residue dissolved in a small amount of hexane. The product crystallized at low temperatures (−30°C) within 12 h and was further purified by sublimation (10^{-2} Torr/115°C). Yield 3.30 g, 60% (based on $InCl_3$). − ^{1}H NMR: δ = 0.34 [s, 18 H, Si(CH_3)$_3$], 0.42 (s, 3 H, $InCH_3$), 1.27 [s, 9 H, C(CH_3)$_3$]. − ^{13}C NMR: δ = 5.78 (s, $SiMe_3$), 6.8 (s, $InCH_3$), 33.95 [s, C(*C*H$_3$)$_3$], 73.93 [s, *C*(CH$_3$)$_3$]. − $C_{11}H_{60}InNOSi_2$ (363.36): calcd. C 36.34, H 8.25, In 31.61, N 3.85; found C 36.29, H 8.66, In 32.00, N 3.67.

Synthesis of [MeIn(O*t*Bu)$_2$]$_2$ (7): An excess of *tert*-butyl alcohol (1.74 mL, 18.2 mmol) was added to a stirred solution of Me[N(SiMe$_3$)$_2$]In(O*t*Bu) (**6**) (3.3 g, 9.10 mmol) in toluene (150 mL). The reaction solution was refluxed for 24 h, and, after removing the volatiles under reduced pressure, the residue dissolved in a small amount of hexane. The product crystallized at low temperatures (−30°C) within 2 d and was purified by sublimation (10^{-2} Torr/120°C). Yield 1.50 g, 60% (based on $InCl_3$). − ^{1}H NMR: δ = 0.38 (s, 3 H, $InCH_3$), 1.39 [s, 18 H, C(CH_3)$_3$]. − ^{13}C NMR: δ = 6.92 (s, $InCH_3$), 34.71 [s, C(*C*H$_3$)$_3$], 69.91 [s, *C*(CH$_3$)$_3$]. − $C_9H_{21}InO_2$ (276.08): calcd. C 39.15, H 7.6, In 41.61; found C 39.30, H 7.82, In 41.3.

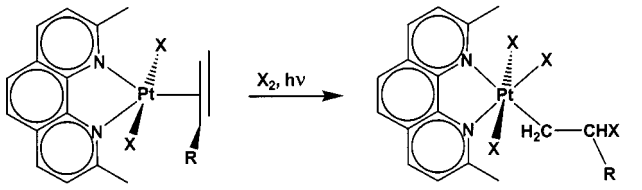
Halogenation of Alkenes in Five-Coordinate Platinum(II) Complexes – A Route to Stable (β-Haloalkyl)platinum(IV) Species

Francesco Paolo Fanizzi,*[a] Luciana Maresca,[a] Concetta Pacifico,[a] Giovanni Natile,*[a] Maurizio Lanfranchi,[b] and Antonio Tiripicchio[b]

Keywords: Haloalkyl complexes / Five-coordinate platinum complexes / Alkene complexes / Olefin halogenation / Oxidative addition / Platinum

Five-coordinate complexes $[PtX_2(olefin)(2,9\text{-}Me_2\text{-}phen)]$ (**1**; 2,9-Me_2-phen = 2,9-dimethyl-1,10-phenanthroline; olefin = ethene denoted by **a**, propene by **b**, 1-butene by **c**; X = Cl denoted by **x**, Br by **y**) undergo photoactivated reactions with Cl_2 and Br_2 to give the (β-haloalkyl)platinum(IV) complexes $[Pt(CH_2CHRX)(2,9\text{-}Me_2\text{-}phen)X_3]$ (**2**). Bromination of the chloro species **1ax** leads to the formation of the Pt^{IV} species **2axy** containing the bromide, the bromoalkyl, and the phenanthroline ligands in the equatorial plane and two chloride ions in axial positions. The iodo complexes **1**(**a**–**c**)**z** are not oxidized by iodine even under UV irradiation but react readily with Cl_2 or Br_2 to give **2**(**a**–**c**)**x** and **2**(**a**–**c**)**y**. The structure of **2ay**, the first structurally characterized (β-haloalkyl)platinum complex, has been determined by X-ray diffraction methods. The stereochemistry of the (β-haloalkyl)platinum(IV) complexes is in accord with a simultaneous addition of two halogen atoms to the coordinated olefin and to the metal center.



Introduction

Although free olefins are very easily halogenated, only few reports have dealt with the halogenation of olefins coordinated to a metal center.[1] In the particular case of (olefin)platinum(II) complexes, reaction with X_2 generally leads to oxidation of the metal center and release of the π-olefin ligand to form Pt^{IV} species. In some cases the reaction also involves the π-coordinated olefin, giving rise to the formation of an organic fragment which is retained by the metal center.[2] For instance the chelate *o*-styryldimethylarsane complex $\{PtBr_2[o\text{-}(AsMe_2)C_6H_4CH{=}CH_2]\}$ reacts with bromine to give a Pt^{IV} product containing a metal−carbon σ bond, $\{PtBr_3[o\text{-}(AsMe_2)C_6H_4CHBrCH_2]\}_2$.[3] Similarly, the Zeise salt $K[PtCl_3(C_2H_4)]$ reacts with chlorine gas in water to give $[Pt(CH_2CH_2Cl)Cl_5]^{2-}$ together with some $[Pt(CH_2CH_2OH)Cl_5]^{2-}$.[4] The latter products have been extensively investigated as model compounds for the functionalization of alkanes mediated by platinum salts.[5] To the best of the authors knowledge $[Pt(CH_2CH_2Cl)Cl_5]^{2-}$ is the only example of a (β-haloalkyl)platinum complex so far reported.

The reason for which β-haloalkyl complexes are extremely rare in transition metal chemistry is to be found in the propensity of these species to undergo β-elimination reactions.[6] An alternative route to the synthesis of haloalkyl compounds is the oxidative addition of terminal dihaloalkanes $[X(CH_2)_nX]$ to transition metal complexes to yield $\{ML_m[(CH_2)_nX]\}$ compounds, which can be used as building blocks for the synthesis of homo- and heterometallic polymethylene-bridged dendritic macromolecules.[7] Again the isolation of the ω-haloalkyl complexes $\{ML_m[(CH_2)_nX]\}$ is easily accomplished when $n = 1$ or $n > 2$, whereas for $n = 2$ the β-haloalkyl species is much more difficult to prepare. As an example the oxidative addition of 1,2-diiodoethane to the $[PtMe_2(phen)]$ complex results in the formation of $[PtMe_2(phen)X_2]$ and the evolution of ethylene gas together with dimethylene-bridged dimeric or polymeric species.[8] Having investigated the reactivity of olefins in 4-coordinate platinum(II) complexes[9] attention was directed to the reactivity of olefins in five-coordinate substrates and, in particular, their reaction with halogens. These species were considered to be appealing substrates[10] because of: i) their thermodynamic stability, ii) their coordination geometry (the saturated coordination sphere should prevent direct attack of the halide on the metal center), and iii) the increased electronic charge on the olefinic carbon atoms (due to the efficient π-back donation from filled platinum d orbitals) which could render the alkene prone to the attack by electrophiles. Here the halogenation of the five-coordinate trigonal bipyramidal Pt compounds $[PtX_2(olefin)(2,9\text{-}Me_2phen)]$ (**1**) (2,9-Me_2-phen = 2,9-dimethyl-1,10-phenanthroline; olefin = ethene denoted by **a**, propene by **b**, 1-butene by **c**; X = Cl denoted by **x**, Br by **y**) to give the (β-haloalkyl)platinum(IV) complexes $[Pt(CH_2CHRX)(2,9\text{-}Me_2\text{-}phen)X_3]$ (**2**) (Scheme 1) is reported, together with the X-ray structure of **2ay** [the first for a (β-haloalkyl)platinum complex].

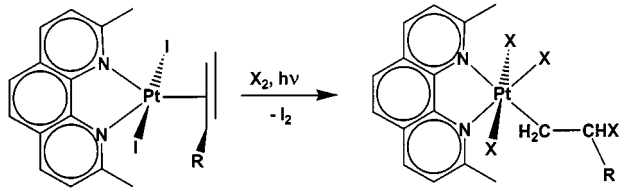
Results and Discussion

The Five-Coordinate Precursor

Five-coordinate trigonal bipiramydal Pt^{II} complexes [Pt(N−N)(olefin)XY] (X=halide, Y= halide or hydrocarbyl group; N−N = bidentate nitrogen ligand) represent a well-characterized class of platinum compounds.[10] The presence on the trigonal plane of a π-acceptor olefin ligand which draws electron charge from the metal center, so favouring the coordination of both ends of the bidentate nitrogen donor, plays a crucial role in stabilizing the five-coordinate geometry in these species.[11][12]



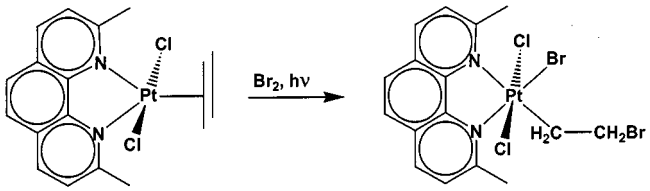
When N−N = 2,9-Me_2-1,10-phenanthroline the five-coordinate complexes are particularly stable if compared to analogous species with other bidentate nitrogen ligands.[10] Such a stabilization stems from the release, in the five-coordinate species, of the steric interaction between the *ortho*-methyl substituents of the phenanthroline and the *cis*-halogen ligands built up in square planar [$Pt^{II}X_2$(2,9-Me_2-phen)][13] and octahedral [$Pt^{IV}X_4$(2,9-Me_2-phen)][14] complexes.

Due to the steric strain the [PtX_2(2,9-Me_2-phen)] complexes easily dissociate one end of the phenanthroline chelate to form a T-shaped, coordinatively unsaturated, platinum species which is highly susceptible to addition reactions.[13][15] The addition product, [$Pt^{II}X_2$(2,9-Me_2-phen)(L)], can be either a square-planar species [L = CO, PPh_3, Me_2SO, Me_2S, PhNO, Py, $NH_2(CH_2)_2CH_3$], with the phenanthroline ligand monocoordinate to the platinum center (and exchanging in solution the donor nitrogen atoms at the coordination site) or, in the case of L = alkene[11] and alkyne,[16] a five-coordinate trigonal-bipyramidal (tbp) species with the halogen ions in the axial positions and the phenanthroline ligand acting as chelate and lying, together with the L ligand, in the trigonal plane.

Octahedral [PtX_4(2,9-Me_2-phen)] complexes also react with excess C_2H_4 to give reductive elimination of halogen (which, in turn, reacts with excess C_2H_4 to give 1,2-dihaloethane) and formation of the five-coordinate Pt^{II} species [$PtX_2(C_2H_4)$(2,9-Me_2-phen)].[14]

The Halogenation Reaction

In $CHCl_3$ solution and in the presence of light the five-coordinate complexes [PtX_2(olefin)(2,9-Me_2-phen)] (**1**) (olefin = ethene denoted by **a**, propene by **b**; 1-butene by **c**; X = Cl denoted by **x**, Br by **y**) react with Cl_2 and Br_2 to give the β-haloalkyl complexes [$Pt^{IV}(CH_2CHRX)$(2,9-Me_2-phen)X_3] (**2**) (see Scheme 1). The reaction requires photoactivation which is not required in the case of oxidative addition of X_2 to either the square-planar species [Pt(2,9-Me_2-phen)X_2][14] or to the free olefins. The iodo complexes **1(a−c)z** are not oxidized by iodine even under UV irradiation, while they react readily with Cl_2 or Br_2 to give **2(a−c)x** and **2(a−c)y**, respectively (see Scheme 2).



R = H, 1az; Me, 1bz; Et, 1cz

X = Cl, R = H, 2ax; Me, 2bx; Et, 2cx
X = Br, R = H, 2ay; Me, 2by; Et, 2cy

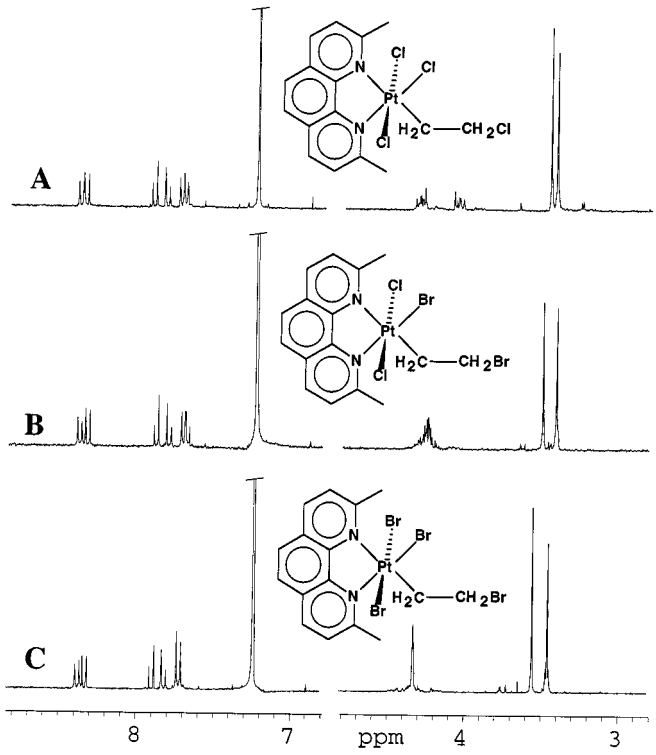
Scheme 2

The bromination of the chloro species **1ax** leads to the formation of a Pt^{IV} species **2axy** containing, besides the phenanthroline and the two chloride ligands, one bromide and a bromoalkyl ligand (see Scheme 3). Comparison of the ^{1}H-NMR spectra of the mixed halide complex with those of the chloro and bromo complexes **2ax** and **2ay** (Figure 1) led to the conclusion that the bromide, the bromoalkyl, and the phenanthroline ligands occupy equatorial positions while the two chloride ions occupy axial sites. The presence of a single sharp IR absorption (330 cm^{-1}) typical of two chloride ions mutually *trans* in an octahedral environment is in accord with this conclusion.[17]

1ax 2axy

Scheme 3

The use of $PhICl_2$, instead of chlorine gas, in the halogenation of **1ax**, did not eliminate the need for photoactivation, indicating that the reactive species is the Cl_2 released from the iodobenzene complex. Moreover, as observed for other photochlorination reactions,[18] the rate of halogenation of **1ax** by Cl_2 or $PhICl_2$ is strongly reduced if the reaction is carried out in benzene instead of chloroform. On the other hand the reaction of **1ax** with *N*-chlorosuccinimide (as substituted for the halogen) in the absence or presence of a radical initiator (benzoyl peroxide) did not give a significant amount of **2ax**.



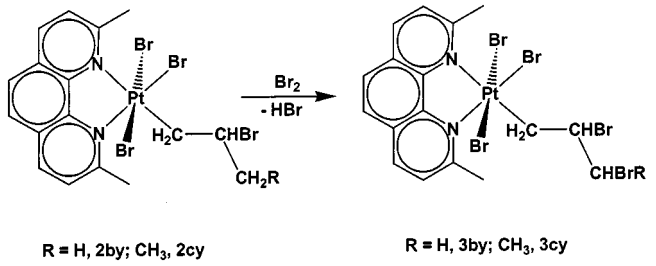


Figure 1. Comparison of the ^{1}H-NMR spectra for **2ax** (**A**), **2axy** (**B**), and **2ay** (**C**) complexes

The haloethyl complexes **2a**(**x**, **y**) are stable for days in chloroform solution and, if kept in the dark, can also withstand an excess of halogen. For prolonged reaction time with excess bromine the complexes **2**(**b**, **c**)**y** undergo substitution at the γ-carbon atom with formation of the β,γ-dihaloalkyl species [Pt($CH_2CHBrCH_2Br$)(2,9-Me_2-phen)Br_3] (**3by**) and [Pt($CH_2CHBrCHBrMe$)(2,9-Me_2-phen)Br_3] (**3cy**), respectively (see Scheme 4). This γ-halogenation reaction is much faster for **2cy** than for **2by** and does not take place, under similar conditions, for the chloro species **2**(**b**, **c**)**x**. Analogous effects of substituents (activation by alkyl radicals and deactivation by halogens, with Cl stronger deactivator than Br) are observed in the halogenation of alkanes.[19] It should be noted that in the case of **3cy** the presence of two chiral centres at the β- and γ-carbon atoms leads to the formation of two diastereoisomers. Interestingly ^{1}H-NMR experiments show a kinetic preference for one of the two diastereoisomers (ratio of major, **M** to minor, **m**, isomer of 80:20) (Figure 2).

Scheme 4

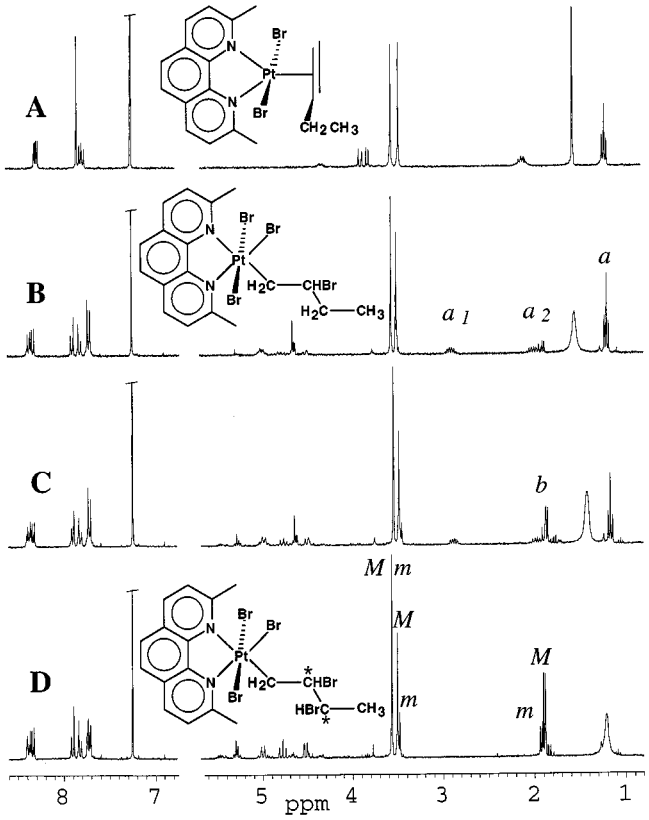

Figure 2. ^{1}H-NMR spectra recorded during the reaction of **1cy** (**A**) with Br_2; the initially formed **2cy** species (**B**), characterized by the terminal CH_3 (a) and the two diastereotopic CH_2 protons (a1 and a2) reacts further (spectra **C** and **D**) to give two new species in which the terminal CH_3 is a doublet (only one proton in γ position) and correspond to different isomers (major and minor) of **3cy**; spectra were taken: (**B**) 8 min after Br_2 addition under neon light irradiation, (**C**) and (**D**) after 20 and 60 min incubation in the dark, respectively

Stereochemistry of the β-Haloalkyl Complexes

^{1}H-NMR spectra of the new Pt^{IV} complexes are reported in Table 1. The protons of one half of the coordinated phenanthroline ligand do not show measurable coupling with ^{195}Pt as a consequence of the weakening of the Pt−N bond *trans* to the haloalkyl ligand.

In the case of the ethene (**a**) precursor the α- and β-CH_2 protons give rise to an AA′XX′ spin system of various complexity. Both the $C_α$-H_2 and $C_β$-H_2 protons show ^{195}Pt coupling, however only in the case of **2ax** could both α-H_2 and β-H_2 values be given, in all other cases only the values for $C_α$-H_2 were measured.

In the case of 1-propene and 1-butene complexes halogenation occurs specifically at the alkyl-substituted carbon atom in accord with the preference expected for an electrophilic attack. In the β-halopropyl complexes **2bx** and **2by** the $C_α$-H_2 protons exhibit two different ^3J(H−H) couplings (ca. 10 and 2 Hz, respectively) indicating that one is *anti* and the other *gauche* to $C_β$-H. (Figure 3). A connectivity (^{1}H NOESY experiments) between the β-Me group and only one of the $C_α$-H protons suggests that the Me group is *gauche* and the halide ion *anti* to the platinum center. The

[a] Values of J_{H-H} (in parentheses) and J_{Pt-H} [in brackets] are given when assignable. Integral values are given in braces.

Me substituent of the phenanthroline ligand *cis* to the β-haloalkyl group (easily distinguishable from that *trans* to the β-haloalkyl group because of its coupling with ^{195}Pt) has a cross peak [NOESY spectrum of **2b**(**x**, **y**)] with the C_α-H weakly coupled with the C_β-H (2 Hz) indicating that this C_α-H is *anti* to the β-Me group. The resulting preferred conformation of the β-haloalkyl group is that shown in the formula of Figure 3. The different couplings of the two C_α-H protons with the platinum center [$^2J(Pt-H) \approx 100$ and 70 Hz, respectively], and the relatively small value of the $^3J(Pt-C_\beta-H)$ coupling (18 Hz), are also in accord with this conformation of the β-haloalkyl group.

In the β-halo-*n*-buthyl complexes **2c**(**x**, **y**) the α-CH_2 signals are quite similar to those found for **2b**(**x**, **y**). Moreover two multiplets (ca. 0.9 ppm apart from each other) are observed for the diastereotopic γ-CH_2 protons, and a triplet for the terminal CH_3.

X-ray Structure of 2ay

The X-ray structure of [Pt(CH_2CH_2Br)(2,9-Me_2-phen)Br_3] (**2ay**) is shown in Figure 4 together with the atomic labeling scheme; relevant bond lengths and angles are reported in Table 2. The octahedral complex adopts a *mer* configuration with the two N(1) and N(2) atoms from the 2,9-Me_2-phen chelating ligand and the σ-bonded C(15) atom of the β-bromoethyl group lying in the same plane.

The three Pt−Br bonds have nearly equal length, whereas the Pt−N(2) bond [2.217(10) Å] is much longer than the Pt−N(1) bond [2.110(10) Å] reflecting the much greater *trans* influence of the haloalkyl group with respect to the bromide ion. The Pt and Br(4) atoms are, as expected, in *anti* positions [Pt−C(15)−C(16)−Br(4) torsion angle of −170.8(6)°]. Due to the lengthening of the Pt−N(2) bond the clash between the methyl substituent C(14) of the phen

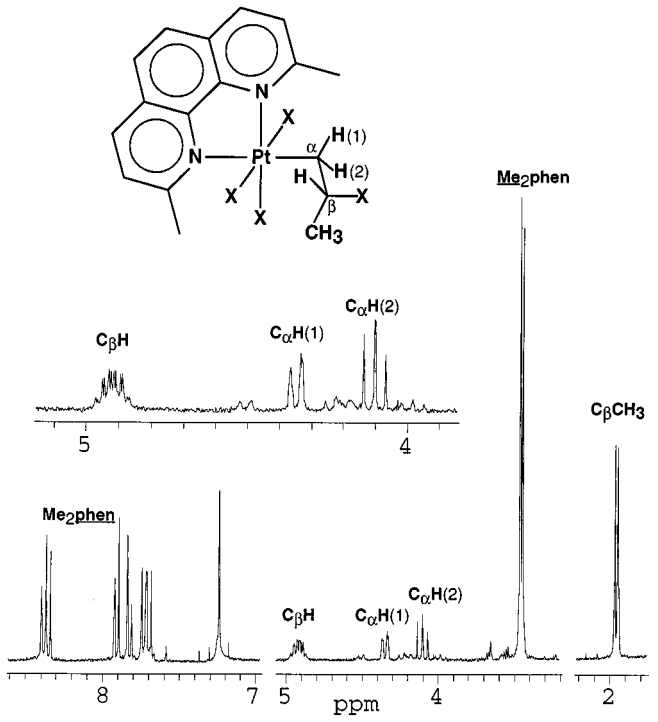

Figure 3. ^{1}H-NMR spectrum of **2bx** showing that J_{HH} and J_{PtH} for the α and β protons of the haloalkyl group are in accord with a preferred conformer having the Me and halide substituents on the β-carbon atom, respectively, *gauche* and *anti* to the Pt atom

the same type of distortion already observed for (2,9-dimethylphenanthroline)platinum(II)[13] and -platinum(IV)[14] complexes: a) tilting of the plane of the chelating moiety (N−C−C−N) with respect to the equatorial coordination plane [dihedral angle between N(1)−C(5)−C(9)−N(2) and Br(2)−Pt−C(15) planes of 32.9(5)°]; b) narrowing of the angle between the *cis* ligands coplanar with Me_2-phen [Br(2)−Pt−C(15) = 83.8(4)°]; c) bowlike distortion of the phen ligand [dihedral angle between the outer rings of the phen ligand of 15.0(5)°]. It is to be noted that the presence of the two axial ligands reduces the tilting of the phen ligand with respect to the equatorial coordination plane which is smaller than that found in [$PtBr_2$(2,9-Me_2-phen)][13] [angles between the N−C−C−N and Br−Pt−Br planes of 41.9(4)°]. A decrease in the tilting angle of the phenanthroline on going from square planar Pt^{II} to octahedral Pt^{IV} species has already been observed in the case of [PtI_2(2,9-Me_2-4,7-Ph_2phen)] and [PtI_4(2,9-Me_2-4,7-Ph_2-phen)] complexes.[14]

Insight Into the Halogenation Mechanism

The experimental results of the present investigation strongly suggest that the radical species $X^\bullet$ is responsible for the attack on the coordinated olefin. In accord with this hypothesis are: i) The scarce reactivity of our substrates with iodine (halogenation of olefins by a radical mechanism requires a much higher activation energy in the case of iodine with respect to chlorine and bromine).[20] ii) The use of $PhICl_2$ (instead of Cl_2) which could act as an ion source (Cl^+) does not eliminate the need for photoactivation. iii)

The reduced reactivity of chlorine in benzene due to the formation of chlorine atom−benzene π complexes.[18]

It is noteworthy that the bromination of **1ax** leads to the formation of the mixed-halide Pt^{IV} species **2axy**, which contains the phenanthroline, the bromide, and the bromoalkyl ligand in equatorial positions and the two chloride ions in axial positions. This stereochemistry gives an indication of a nearly simultaneous addition of the halogen atoms to the olefin and to the metal center, preventing a possible scrambling of ligands in the five-coordinate intermediate formed after the addition of one halogen atom to the π-olefin. Also the observation that *N*-chlorosuccinimide (as substitute of the halogen) under radical conditions (presence of benzoyl peroxide) does not react with the five-coordinate olefin complexes to yield the β-haloalkyl species, can be taken as evidence that the photoactivation of the halogen must take place while the halogen molecule is already close to the platinum center and to the olefin ligand.

In spite of the several investigations concerned with the oxidative addition of halogens to square-planar platinum complexes,[21] only in a few cases were (olefin)platinum complexes involved, and the reaction very rarely gave products which retained the organic fragment bound to the platinum center. Oxidative addition of halogen or alkyl halide to three-coordinate Pt^0 species [Pt(2,9-Me_2-phen)(olefin)] results in an electrophilic attack to the metal center and formation of the five-coordinate trigonal-bipyramidal Pt^{II} complexes [Pt(olefin)(2,9-Me_2-phen)XY] (X = halide Y = hydrocarbyl or halide).[22] Only in one case was evidence found of a further oxidation reaction involving the five-coordinate species, but no attempt was made to characterize the products.[22] Successful halogenation of the coordinate olefin has been reported, so far, for the bromination of [$PtBr_2${*o*-(Me_2As)C_6H_4CH=CH_2}][3] and the chlorination of Zeise′s salt in water.[4] In the former case the reaction with bromine led to a Pt^{IV} dimer, {$PtBr_3$[*o*-(Me_2As)C_6H_4CHBrCH_2]}$_2$, in which the olefin of the chelate dimethyl(*o*-styryl)arsane ligand was converted into a β-haloalkyl group σ-bonded to the metal center. A synchronous *cis* addition of a polarized bromine molecule with the negative end attacking the platinum center and the positive end attacking the double bond was suggested.

In the reaction of Zeise′s salt with chlorine, $[Pt(CH_2CH_2Cl)Cl_5]^{2+}$, together with some $[[Pt(CH_2CH_2OH)Cl_5]^{2+}$, was formed and the reaction mechanism was assumed to imply external attack of halogen to ethene subsequent to oxidation of platinum(II) to platinum(IV) as observed for olefin complexes of palladium.[23] The oxidation of Zeise′s salt in water with $[PtCl_6]^{2-}$ produces only $[Pt(CH_2CH_2OH)Cl_5]^{2+}$, and in the latter case the reverse sequence of reactions, that is nucleophilic attack of the solvent on the coordinated ethylene ligand followed by oxidation of the (β-hydroxyalkyl)platinum(II) species just formed was suggested.[24] A cross oxidation involving simultaneously the metal center and the olefin ligand can be envisaged in this case, where the coordinatively saturated trigonal-bipyramidal platinum(II) species does not allow an attack on the metal center as first step.

Conclusions

The five-coordinate complexes [PtX_2(olefin)(2,9-Me_2-phen)] react in the presence of light with Cl_2 and Br_2 to give the β-haloalkyl complexes [Pt^{IV}(CH_2CHRX)(2,9-Me_2-phen)X_3]. The reaction requires photoactivation which is not required in the oxidative addition of X_2 to either the square-planar species [Pt(2,9-Me_2-phen)X_2] or to the free olefins. Experimental data suggest that the radical species $X^{\cdot}$ is responsible for attack on the coordinated olefin ligand in the five-coordinate platinum(II) species, by a cross oxidation which involves also the metal center. Such a reaction is completely different from other reported halogenation reactions of square-planar Pt^{II} complexes for which the oxidation to Pt^{IV} precedes the attack on the coordinated olefin ligand. Further work is in progress to elucidate the mechanism of the halogenation reaction in coordinatively saturated five-coordinate (olefin)platinum(II) complexes.

Experimental Section

General: Commercial reagent-grade chemicals, ethylene, propene, 1-butene, chlorine (Matheson); bromine, iodine, *N*-chlorosuccinimide (NCS), and benzoyl peroxide (Aldrich) were used without further purification. $PhICl_2$ was prepared according to a literature method.[25] Starting complexes [PtX_2(2,9-Me_2-phen)] (**1**) (2,9-Me_2-phen = 2,9-dimethyl-1,10-phenanthroline; X = Cl, **x**; Br, **y**; I, **z**) were prepared as already described.[11] − ^{1}H NMR: Bruker AM 300 instrument. COSY and NOESY spectra were recorded by using the automated Bruker microprograms, a mixing time of 1 s was used in the NOESY experiments. − IR: KBr pellets with Perkin−Elmer 283 and FT 1600 spectrophotometers. − Microanalyses: Dipartimento Farmaco-chimico Microanalytical Service (Bari University) with a Carlo Erba 1106 Elemental Analyzer.

Synthesis of the Five-Coordinate Complexes: [PtX_2(olefin)(2,9-Me_2-phen)] (olefin = ethylene, **a**; propene, **b**; 1-butene, **c**; X = Cl, **x**; Br, **y**; I, **z**) were prepared from the corresponding square-planar species **1**(**x**−**z**) by direct uptake of the olefin.[11]

Synthesis of the (β-Haloalkyl)platinum(IV) Complexes: [Pt(CH_2CHRX)(2,9-Me_2-phen)X_3] (**2**); X= Cl (**x**) or Br (**y**); R= H (**a**), Me (**b**) or Et (**c**). The five-coordinate olefin complex [PtX_2(olefin)(2,9-Me_2-phen)] (0.2 mmol) was dissolved in chloroform (10 mL) and treated with excess halide (chlorine gas was bubbled for 5 min through the solution while bromine was added as pure liquid (0.4 mL). The solution was left under neon light (two OSRAM L36 W/10 Daylight tubes) for 5 min (**1cy**) or 10 min (all other complexes), then the (β-chloroalkyl)- (yellow) or (β-bromoalkyl)platinum(IV) complexes (orange) were precipitated by addition of *n*-pentane to the filtered solution. The solid was collected, washed with *n*-pentane and dried in air. The oxidation of the chloro complex **1ax** with bromine gave the mixed Pt^{IV} halide complex [Pt(CH_2CH_2Br)(2,9-Me_2-phen)Cl_2Br] (**2axy**). Yields of the isolated products were always above 80%. − $C_{16}H_{16}Cl_4N_2Pt$ (**2ax**; 573.2): calcd. H 2.6, N 3.6; found C 27.6, H 2.5, N 3.4. − The reaction of the iodo complexes **1az** with excess I_2 (1:10 molar ratio) was performed in an NMR tube (ca. $5\cdot10^{-3}$ M in $CDCl_3$) and monitored by ^1H NMR. No oxidation of the starting complex was detected after several h even after prolonged UV irradiation. The analogous reactions of **1az** with excess Cl_2 (bubbled for 5 min trough the solution) or Br_2, monitored by ^1H NMR, showed, after exposure to a neon light for 10 min, the formation of **2ax** or **2ay,** respectively. − The oxidation of **1ax** with excess $PhICl_2$ was also performed in an NMR tube exposed to neon light (ca. $2\cdot10^{-3}$ M in $CDCl_3$; 1:5 complex/oxidant molar ratio) and monitored by ^1H NMR. When the solvent was $CDCl_3$, complete conversion of **1ax** into **2ax** was observed within 2 h of light exposure. In contrast, when the solvent was C_6D_6 only 5% conversion was observed after 2 h of light exposure. − Reactions of **1ax** with *N*-chlorosuccinimide (1:10, complex/oxidant molar ratio), in the absence and presence of a radical promoter (1:1, oxidant/benzoyl peroxide molar ratio) were also performed (complex concentration ca. $5\cdot10^{-3}$ M in $CDCl_3$) in an NMR tube exposed to neon light. In both cases no conversion of **1ax** into **2ax** was observed after 24 h (^1H NMR).

Synthesis of the (β,γ-Dibromoalkyl)platinum(IV) Complexes [Pt($CH_2CHBrCH_2Br$)(2,9-Me_2-phen)Br_3] (3by) and [Pt($CH_2CHBrCHBrMe$)(2,9-Me_2-phen)Br_3] (3cy): Besides the β-haloalkyl complexes described above the reaction of the five-coordinate complexes **1by** and **1cy** with excess Br_2 can also afford products of further halogenation. The reactants were placed in an NMR tube (complex concentration ca. $5\cdot10^{-3}$ M, Br_2 concentration ca. 10^{-1} M, in $CDCl_3$), exposed for 10 min to neon light irradiation, and than post-incubated in the dark (1 h in the case of **1by**; 12 h in the case of **1cy**). Quantitative formation of new species was detected by ^1H NMR. The new species could be isolated as orange solids by addition of pentane to the filtered solution and were identified, on the basis of their ^1H-NMR spectra and microanalytical data, as the β,γ-dihaloalkyl complexes [Pt($CH_2CHBrCH_2Br$)(2,9-Me_2-phen)Br_3] (**3by**) and [Pt($CH_2CHBrCHMeBr$)(2,9-Me_2-phen)Br_3] (**3cy**), respectively. The latter compound is found in two diastereoisomeric forms (major and minor, 80:20 molar ratio), due to the presence of two chiral centers. Yields of the isolated products **3by** and **3cy** were above 70%. − $C_{17}H_{17}Br_5N_2Pt$ (**3by**; 843.9): calcd. C 24.2, H 2.0, N 3.3; found C 24.0, H 1.9, N 3.1. − $C_{18}H_{19}Br_5N_2Pt$ (**3cy**; 858.0): calcd. C 25.2, H 2.2, N 3.3; found C 25.1, H 2.2, N 3.2.

X-ray Data Collection, Structure Determination, and Refinement of Complex 2ay: Crystals of **2ay** were obtained from CH_2Cl_2/Et_2O solution. The crystallographic data are summarized in Table 3. Accurate unit-cell parameters were determined by least-squares refinement of the setting angles of 30 randomly distributed and carefully centered reflections with θ in the range 24−44°. The data collection was performed at 293 K with a Siemens AED diffractometer by using the θ/2θ scan mode. One standard reflection was monitored every 100 measurements, no significant decay was noticed over the time of data collection. The structure was solved by direct methods (SIR92[26]) and refined by full-matrix least squares based on F_o^2 using the SHELXL-97 program,[27] first with isotropic then with anisotropic thermal parameters for all the non-hydrogen atoms. All the hydrogen atoms were placed at their geometrically calculated positions and refined "riding" on their parent carbon atoms. The weighting scheme used was $w = 1/[\sigma^2(F_o^2) + (0.1028P)^2 + 11.5518P]$ where $P = (F_o^2 + 2F_c^2)/3$. All calculations were carried out with the ENCORE 91 of the "Centro di Studio per la Strutturistica Diffrattometrica" del CNR, Parma. Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic data Centre, registration number CCDC-111824. Copies of the data may be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Table 3. Crystal data and structure refinement for **2ay**

Formula	$C_{16}H_{16}Br_4N_2Pt$
Molecular weight	751.04
Temperature [K]	273(2)
Wavelength	1.54184 Å

Synthesis, Chemistry, and Characterization of Perfluoroaromatic Selenium Derivatives

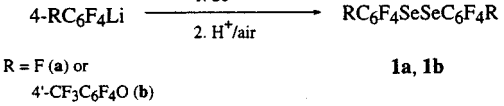
Thomas M. Klapötke,*[a] Burkhard Krumm,[a] and Kurt Polborn[a][+]

Dedicated to Professor W.-P. Fehlhammer on the occasion of his 60th birthday

Keywords: Selenium / Fluorine / Multinuclear NMR / Raman spectroscopy / X-ray crystallography

The reaction of perfluoroaryllithium RC_6F_4Li, where R = F or 4-$CF_3C_6F_4O$, respectively, with selenium gives the known diselanes $(RC_6F_4Se)_2$ (**1a**, **1b)**. Redox reactions of **1** with hydrogen peroxide result in the formation of the seleninic acids RC_6F_4SeOOH which crystallize as hydrates (**2a**, **2b**); with mercury give the bis(arylseleno)mercuries $(RC_6F_4Se)_2Hg$ (**3a**, **3b**); with sulfuryl chloride or bromine give the selenenyl chlorides (**4a**, **4b**) or selenenyl bromides (**5a**, **5b**). Selenenyl chlorides (**4a**, **4b**) react with a variety of trimethylsilyl reagents Me_3SiX (X = Br, CN, NMe_2, NEt_2) to form **5a**, **5b**; selenocyanates RC_6F_4SeCN (**6a**, **6b**); selenenyl amides $RC_6F_4SeNMe_2$ (**7a**, **7b**) and $RC_6F_4SeNEt_2$ (**8a**, **8b**). A new synthetic route to diorgano selanes is developed by reaction of **4a**, **4b** with perfluoroaryllithium to give the symmetric $(RC_6F_4)_2Se$ (**9a**, **9b**). All derivatives are thoroughly characterized and in addition the molecular structures of **2a**, **6a**, and **9a** are established by X-ray crystallography.

Introduction



Selenium compounds with perfluorinated substituents have been known for three decades.[1][2] A considerable part consists of selenium species bound to perfluoroalkyl groups, which is reviewed by Haas.[3] However, the chemistry of perfluoroaromatic selenium species is rather limited to a few compounds. The diselanes $C_6F_5SeSeC_6F_5$ and (4-$CF_3C_6F_4)_2Se_2$, as well as the selane $C_6F_5SeC_6F_5$, have been reported to be synthesized by either rather low yield methods and/or requiring high temperatures,[4] or by reaction of the appropriate Grignard R_FMgBr (R_F = C_6F_5 or 4-$CF_3C_6F_4$) where in addition considerable amounts of the unwanted selane $(R_F)_2Se$ are formed.[5] Very recently, a high-yield synthesis of a new diselane [4-(4′-$CF_3C_6F_4O)C_6F_4]_2Se_2$ was reported by reaction of in situ generated 4-(4′-$CF_3C_6F_4O)C_6F_4Li$ with selenium.[6] This method is extended in this report to the synthesis of the known $C_6F_5SeSeC_6F_5$. Our findings show, that in the reaction of C_6F_5MgBr, which is easily formed by reacting C_6F_5Br and magnesium, with selenium no formation of the diselane is observed. This fact is likely to be attributed to the significantly increased reactivity of C_6F_5Li than C_6F_5MgBr towards selenium.

Pentafluorobenzeneselenenyl chloride, C_6F_5SeCl, is reported to be synthesized by chlorination of C_6F_5SeH as well as pentafluorobenzeneseleninic acid, C_6F_5SeOOH, by hydrolysis of $C_6F_5SeCl_3$.[5] The preparation of the bis(arylseleno)mercury $(C_6F_5Se)_2Hg$ is reported to proceed at elevated temperatures.[2] For those materials simplified routes were found and employed.

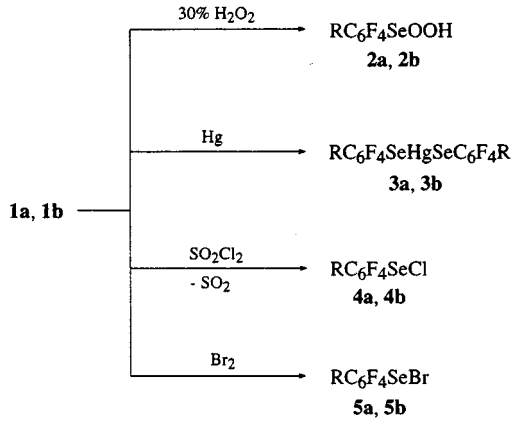
For some of the mentioned derivatives NMR data have been published.[7–10] The to date only crystal structure of a pentafluorophenylselenium derivative is established for the diselane $C_6F_5SeSeC_6F_5$.[11]

Results and Discussion

Suitable stable starting materials for the chemistry done in this work are the diselanes $C_6F_5SeSeC_6F_5$ (**1a**) and [4-(4′-$CF_3C_6F_4O)C_6F_4]_2Se_2$ (**1b**). As already indicated, they are accessible via the respective aryllithium reagents, generated in situ by lithiation of C_6F_5H, respectively 4-(4′-$CF_3C_6F_4O)C_6F_4H$,[12] with *n*-butyllithium (Scheme 1).

Scheme 1

The diselanes **1a**, **1b** undergo oxidation reactions with hydrogen peroxide, sulfuryl chloride, and bromine to give the seleninic acids **2a**, **2b**, the selenenyl chlorides **4a**, **4b**, and bromides **5a**, **5b**. Reduction with elemental mercury results in the formation of the bis(arylseleno)mercuries **3a**, **3b**. All reactions occur readily at ambient temperature. Sulfuryl chloride and bromine have to be employed in large excess, otherwise the back reaction occurs (Scheme 2).



The selenenyl chlorides **4a**, **4b** are useful precursors for further chemistry at the selenium center.

The trimethylsilyl nucleophiles Me_3SiX (X = Br, CN, NMe_2, NEt_2) react readily at 25°C under loss of trimethyl-

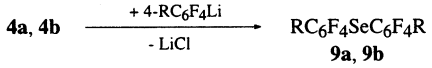
Scheme 2



silylchloride to give **5a**, **5b**, the selenocyanates **6a**, **6b**, and the selenenylamides **7a**, **7b** and **8a**, **8b** (Scheme 3).

Scheme 3

Compounds **5**, **7**, and **8** are extremely moisture and light sensitive materials and tend to decompose at 25°C under re-formation of **1**, which can be suppressed by storage in the dark at 0°C. The reaction of **4** with Me_3SiBr displays an alternative route to synthesize **5**.

The reaction of **4a**, **4b** with 4-RC_6F_4Li is a new straightforward synthesis of diorganoselanes, here shown for the symmetric $(C_6F_5)_2Se$ (**9a**) and the new [4-(4′-$CF_3C_6F_4O)C_6F_4]_2Se$ (**9b**) (Scheme 4).

Scheme 4

Spectra

Table 1 illustrates the influence of the substituent attached to selenium for RC_6F_4Se derivatives on the ^{77}Se- and ^{19}F-NMR shift. For ^{19}F NMR are listed the resonances of the *ortho*-fluorine atoms (in 2- and 5-position to Se). In general, the resonances of the aromatic fluorine atoms appear in the ^{19}F-NMR spectrum as parts of AA′BB′, respectively AA′BB′X for C_6F_5Se, patterns. While the *ortho*- and *meta*-fluorine resonances were referred to multiplets, the resonances of the *para*-fluorine atoms in C_6F_5Se derivatives **1a**−**9a** can be solved first order (triplets of triplets, see Experimental Section). Changing from R = F to 4-$CF_3C_6F_4O$ results in a small but significant low field shift of 0.1−0.5 ppm for the *ortho*-fluorine resonances in the ^{19}F-NMR spectrum. This effect is much more pronounced for the ^{77}Se resonances (0−11 ppm). The ^{77}Se resonances are split into triplets due to coupling to the *ortho*-fluorine atoms (pentets for **9a/b**); the value for the $^3J_{SeF}$ coupling constant is in the range 13−28 Hz. A high field shift of the ^{77}Se resonance occurs for the here investigated derivatives in the following order: −SeCl (**4a/b**), $-SeNMe_2$ (**7a/b**), $-SeNEt_2$ (**8a/b**), −SeBr (**5a/b**), −SeSe− (**1a/b**), −SeCN (**6a/b**), −Se− (**9a/b**). A similar tendency is observed and discussed in detail for CF_3Se derivatives.[13] The derivatives −SeOOH (**2a/b**) and −SeHgSe− (**3a/b**) represent the most extreme ^{77}Se-NMR shifts in this work, but are measured in different solvents than the above.

[a] $CDCl_3$. − [b] CD_3CN. − [c] C_6D_6.

Table 2 summarizes the ^{13}C-NMR data of C_6F_5Se derivatives **1a-9a** (from recording of ^{13}C-NMR data of the $CF_3C_6F_4OC_6F_4Se$ derivatives **1b**−**9b** was refrained due to the increased complexity of the resonances, requiring significantly higher number of accumulations). All resonances are split into multiplets due to couplings to the entire fluorine atoms present in the ring. Remarkable are the shift differences of the resonances of the C-1 carbon atoms, depending on the nature of the substituent bonded to selenium (range of δ = 95−123). The resonances of C-2/3/4 appear mainly at the same position (C-2 δ = ca. 137, C-3 δ = ca. 147 and C-4 δ = ca. 143). The values of the $^nJ_{CF}$ coupling constants are in the range of ca. 2−260 Hz (n = 1−4) (omitted in the Experimental Section). Further NMR characterization include $^{14}N/^{15}N$ NMR data of **6a**, **7a** and **8a**, as well as ^{199}Hg-NMR shifts for **3a/3b** (see Experimental Section).

Additionally to IR spectra the Raman spectra were recorded. In the Raman spectra are some important selenium containing vibrations visible which are difficult to observe in IR. Figure 1 depicts the Raman spectrum of the selenocyanate **6a** as a representative example. The CN stretching frequency is very intense at 2167 cm^{-1} (of medium to weak

intensity in IR). The frequencies of νSeSe 282 (**1a**)/284 (**1b**) cm^{-1}, νSeCl 398 (**4a**)/375 (**4b**) cm^{-1}, νSeBr 289 (**5a**)/292 (**5b**) cm^{-1}, and νSeN 552 (**7a**) are assigned and appear as the strongest absorptions in Raman and very weak or not observable in IR. The SeN vibration for **8a** is tentatively assigned at 515 cm^{-1}. Definite assignment of the νSeC vibration is not possible.

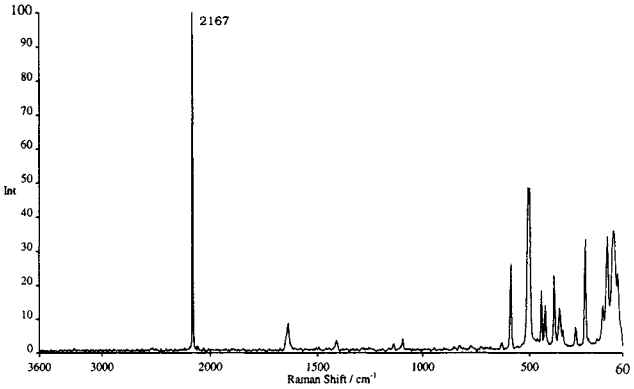

Figure 1. Raman spectrum of **6a**

Crystal Structures

As already indicated, the only crystal structure available of a selenium species having attached a C_6F_5 group, is established for the diselane $C_6F_5SeSeC_6F_5$.[11] The seleninic acid **2a** is recrystallized from water and forms crystals of a monohydrate. A view of the unit cell is shown in Figure 2. Strong hydrogen bonding is present on H(1)···O(3) = 1.76 Å and weak on O(2)···H(3Z) = 2.09 Å. The SeC distance Se(1)−C(1) = 1.962 Å is slightly lengthened compared to regular SeC bonds (see below), probably due to the strong electron-withdrawing effect of the SeOOH moiety. Interestingly, the molecular structure of the nonfluorinated analogue, C_6H_5SeOOH, is anhydrous, though crystallized from water.[14] Here, as well as in *p*-ClC_6H_4SeOOH,[15] strong intermolecular hydrogen bonds between two discrete SeOOH moieties are present.

The structure of the selenocyanate **6a**, shown in Figure 3, consists of two independent molecules. The phenyl rings

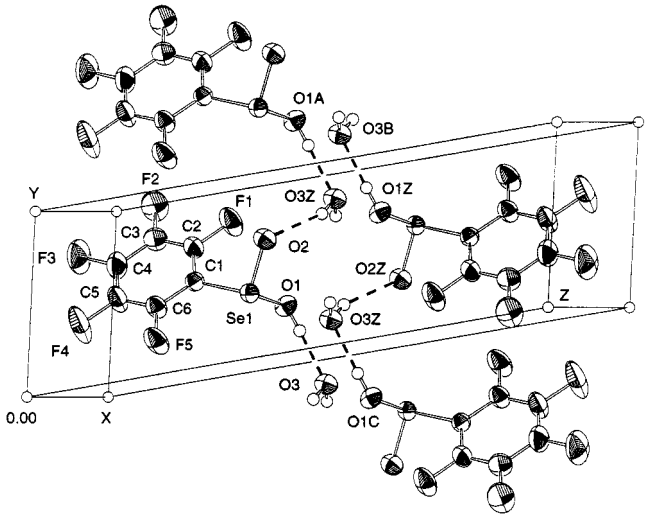

Figure 2. ORTEP plot of **2a** (unit cell); selected bond lengths [Å], angles [°]: Se(1)−O(1) 1.741(3), Se(1)−O(2) 1.638(3), Se(1)−C(1) 1.962(4), O(1)−H(1) 0.82, H(1)···O(3) 1.76, O(2)···H(3Z) 2.09; O(2)−Se(1)−O(1) 102.0(2), O(1)−Se(1)−C(1) 94.2(2), C(6)−C(1)−Se(1) 119.5(3), C(2)−C(1)−Se(1) 122.8(3), C(6)−C(1)−C(2) 117.6(4), F(1)−C(2)−C(1) 120.5(4), F(5)−C(6)−C(1) 119.7(4)

of both molecules are tilt by 35.0° to each other. The out of plane angle between the SeCN moiety and the phenyl ring is 71.5°, respectively 69.9°. There are two short intermolecular contacts involving the Se and N atom in each chain of identical molecules of N(1)···Se(1B) = 2.964 Å and N(1A)···Se(1C′) = 2.957 Å. Between the two independent molecules exist no direct Se···N contacts. The Se(1)−C(7) distance of 1.850 Å, respectively Se(1A)−C(7A) of 1.850 Å, is significantly shorter than a regular SeC bond, than expected, due to the greater contribution of *s* character by the cyano C atom, creating partial double-bond character. The Se(1)−C(1) bond length of 1.920 Å, respectively, Se(1A)−C(1A) of 1.906 Å, represents a typical SeC single bond. The CN bond length for N(1)−C(7) = 1.120 Å, respectively N(1A)−C(7A) = 1.111 Å, is consistent with cyano triple bonds. The only other existing crystal structures of aromatic selenocyanates are of 1,4-diselenocyanatobenzene, *p*-$C_6H_4(SeCN)_2$,[16] and of 3-selenocyanatopyridine, *m*-$C_5H_4N(SeCN)$.[17] Both structures show similar features and intermolecular SeN contacts of 3.06/3.32 Å[16] and 2.84/3.39 Å.[17]

The crystal structure of the selane **9a** is shown in Figure 4. Compound **9a** crystallizes in the noncentrosymmetric space group $P2_1$, allowing the determination of the absolute configuration of the structure. Flack′s parameter refined to −0.006(9) which suggests the correctness of the absolute configuration. The SeC distances Se(1)−C(1) = 1.920 Å, Se(1)−C(7) = 1.903 Å are similar to those found for $C_6F_5SeSeC_6F_5$ 1.899/1.921 Å.[11] The dihedral angle C(2)−C(1)−Se(1)−C(7) is 60.9°; the angle between the planes of both rings is 82.8°. The CSeC angle of 96.61(14)°, is as expected smaller than found for $(C_6F_5)_2S$ [CSC 100.6(5)°][18] and 4-$CF_3C_6F_4OC_6F_5$ [COC 116.2(2)°][12] but larger than found for $(C_6F_5)_2Te$ [CTeC 93.3(5)°].[19]

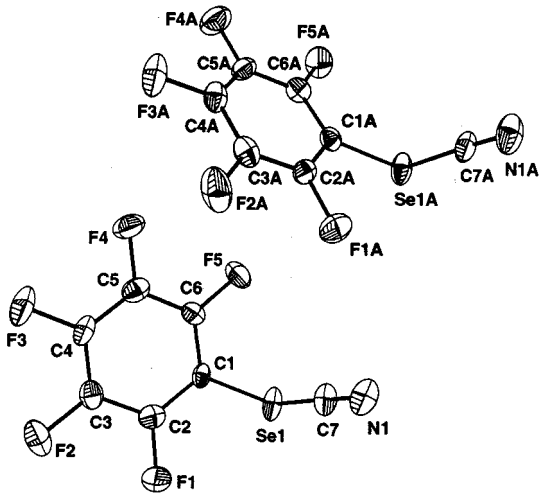

Figure 3. ORTEP plot of **6a**; selected bond lengths [Å], angles [°]: Se(1)−C(7) 1.850(10), Se(1)−C(1) 1.920(7), N(1)−C(7) 1.120(11), Se(1A)−C(7A) 1.856(11), Se(1A)−C(1A) 1.906(8), N(1A)−C(7A) 1.111(12); C(7)−Se(1)−C(1) 95.3(4), N(1)−C(7)−Se(1) 177.4(9), C(7A)−Se(1A)−C(1A) 94.7(4), N(1A)−C(7A)−Se(1A) 175.4(9)

Conclusion

Perfluoroaromatic diselanes, obtained in high yields from perfluoroaromatic lithium reagents, were used to prepare selenenyl chlorides and related derivatives. Further exploration of their synthetic potential is underway.

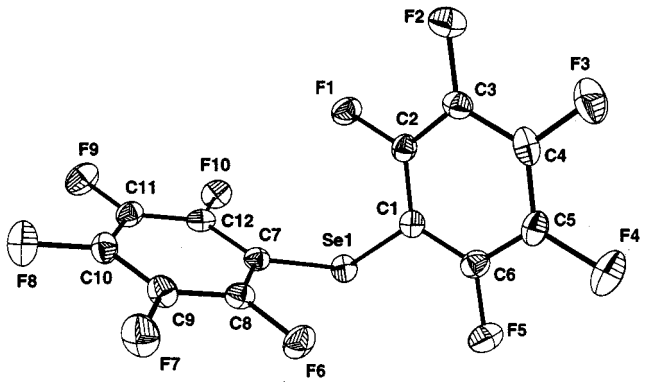

Figure 4. ORTEP plot of **9a**; selected bond lengths [Å], angles [°]: Se(1)−C(1) 1.920(4), Se(1)−C(7) 1.903(4); C(7)−Se(1)−C(1) 96.61(14), C(6)−C(1)−C(2) 117.4(4), C(6)−C(1)−Se(1) 121.0(3), C(2)−C(1)−Se(1) 121.6(3), C(2)−C(1)−Se(1)−C(7) 60.91

Experimental Section

General: The solvents were dried with common methods. Commercially available chemicals were used as received. − NMR: JEOL GSX270 and EX400; chemical shifts are reported with respect to $(CH_3)_4Si$ (^1H, ^{13}C), CH_3NO_2 (^{14}N, ^{15}N), $CFCl_3$ (^{19}F), $(CH_3)_2Se$ (^{77}Se) and $(CH_3)_2Hg$ (^{199}Hg). − IR: Nicolet 520 FT-IR (as KBr pellets or neat liquids). − Raman: Perkin−Elmer Spectrum 2000R NIR FT (Nd: YAG laser, 1064 nm). − MS: Finnigan MAT 90. Multi-isotope containing fragments refer to the isotope with the highest abundance (for example ^{80}Se). − Elemental analyses: C,H,N: in-house; F: Mikroanalytisches Labor Beller, Göttingen. − All reactions are carried out under dry nitrogen atmosphere.

X-ray Crystallography: An Enraf Nonius CAD 4 diffractometer was employed for data collection using Mo-K_α radiation. The structures were solved by direct methods (SHELXS86) and were refined by means of the full-matrix least squares procedures using SHELXL93 (Table 3). All nonhydrogen atoms were refined anisotropically. For the hydrogen atoms in **2a** a riding model was employed. Further details of the crystal-structure investigations may be obtained from the Fachinformationszentrum Karlsruhe, D-76344 Eggenstein-Leopoldshafen, Germany, on quoting the depository numbers CSD-410719, -410718 and -410720 for **2a**, **6a**, and **9a**, respectively.

CAUTION! *Experiments involving perfluoroaromatic lithium reagents should be handled with care, conducted at low temperatures and under strict exclusion of moisture!*

Bis(pentafluorophenyl)diselane (1a): Into a solution of 30 mmol of pentafluorobenzene in 150 mL of anhydrous ether, 30 mmol of *n*BuLi (2.5 M in hexane) is added dropwise at −70°C during a period of 30 min. After 1 h stirring at −70°C, 35.5 mmol of selenium is added in one portion. The resulting mixture is allowed to warm up to ambient temperature within 4 h. 20 mL of 10% HCl and 20 mL of H_2O are added for hydrolysis. After filtration from excess selenium and several extractions with ether/water the combined etheral extracts are dried with anhydrous $MgSO_4$. The etheral solution is stirred for 24 h in the presence of air. After removal of the solvent the residue is sublimed at 40°C/0.01 Torr and yielded orange needles of **1** (81%), m.p. 52−54°C (ref.[5] 49−50°C). − ^{19}F NMR ($CDCl_3$): δ = −125.6 (2-F, m, 2 F), −149.0 (4-F, tt, 1 F, $^3J_{F-F}$ = 20.8 Hz, $^4J_{F-F}$ = 3.5 Hz), −159.7 (3-F, m, 2 F). − IR (KBr): $\tilde{\nu}$ = 1641 m, 1633 m, 1587 w, 1513 s, 1489 s, 1393 m, 1376 m, 1349 w, 1282 m, 1249 w, 1146 m, 1105 m, 1086 s, 1081 s, 1029 w, 1014 m, 974 s, 819 s, 722 w, 626 w, 379 w, 310 w cm^{-1}. − Raman (100 mW): $\tilde{\nu}$ = 1634 (34), 1494 (8), 1395 (32), 1284 (10), 821 (30), 626 (9), 588 (43), 498 (54), 444 (31), 390 (34), 362 (18), 282 (100) [νSeSe], 242 (30), 225 (21), 164 (35), 100 (18) cm^{-1}. − EI MS (70 eV): *m/z* (%) = 494 (28) [M$^+$], 414 (1) [M$^+$ − Se], 334 (13) [M$^+$ − 2 Se], 327 (2) [$C_6F_5Se_2^+$], 247 (100) [$C_6F_5Se^+$], 197 (24) [$C_5F_3Se^+$], 167 (79) [$C_6F_5^+$], 155 (24) [$C_5F_5^+$], 117 (21) [$C_5F_3^+$], 93 (9) [$C_3F_3^+$]. − ^{19}F NMR data in CCl_4 given in ref.[2]; elemental analysis given in ref.[4]

Bis(4-(4′-trifluoromethyl-tetrafluorophenoxy)tetrafluorophenyl)-diselane (1b): 1b is prepared analogously and fully characterized according to ref.[6] − Raman (100 mW): $\tilde{\nu}$ = 1661 (47), 1632 (61), 1489 (6), 1432 (7), 1394 (64), 1344 (6), 1279 (7), 1226 (5), 1142 (5), 878 (5), 825 (22), 801 (9), 719 (18), 656 (6), 642 (8), 539 (16), 498 (82), 443 (30), 389 (42), 361 (13), 284 (100) [νSeSe], 246 (27), 162 (22), 151 (24), 116 (14) cm^{-1}.

Pentafluorobenzeneseleninic Acid Monohydrate (2a), 4-(4′-Trifluoromethyltetrafluorophenoxy)tetrafluorobenzeneseleninic Acid Monohydrate (2b): Into a solution of 1.0 mmol **1a** in 5 mL of CH_2Cl_2 is added 3 mL of H_2O_2 (30% in water). Immediate decolorization occurred and the mixture is stirred for 1 h. After removal of all volatiles in vacuum, the residue is recrystallized from water.

2a is obtained as colorless crystals (80%), m.p. 132−133°C (ref.[5] 123−123.5°C). − ^{1}H NMR (CD_3CN): δ = 3.65 (s). − ^{19}F NMR (CD_3CN): δ = −142.4 (2-F, m, 2 F), −150.6 (4-F, tt, 1 F, $^3J_{F-F}$ = 19.9 Hz, $^4J_{F-F}$ = 5.2 Hz), −161.9 (3-F, m, 2 F). − IR (KBr): $\tilde{\nu}$ = 3480/3258/2900/2408 vbr [νOH], 1672 m, 1640 m, 1588 w, 1521 s, 1486 s, 1470 m, 1385 m, 1379 m, 1349 w, 1294 m, 1276 w, 1110 m, 1099 s, 1040 w, 1016 m, 974 s, 931 m, 862 s, 841 m, 804 w, 756 w, 722 w, 684 m, 622 m, 586 w, 550 w, 495 w, 391 m, 353 m, 318 m, 300 m cm^{-1}. − Raman (100 mW): $\tilde{\nu}$ = 3250 (6), 1640 (22), 1140 (9), 1102 (14), 859 (99), 807 (17), 685 (62), 586 (69), 497 (83), 443 (46), 392 (100), 357 (39), 301 (22), 279 (21), 242 (30), 202 (71), 185 (48), 166 (27), 118 (32) cm^{-1}. − EI MS (70 eV): *m/z* (%) = 264 (19) [$C_6F_5SeOH^+$], 247 (44) [$C_6F_5Se^+$], 197 (9) [$C_5F_3Se^+$], 184 (36) [$C_6F_5OH^+$], 168 (100) [$C_6F_5H^+$], 155 (15) [$C_5F_5^+$], 117 (13) [$C_5F_3^+$], 93 (7) [$C_3F_3^+$]. Elemental analysis given in ref.[5]

2b (colorless powder, 72%, m.p. 152−155°C (dec.) is prepared from **1b** in a similar fashion and recrystallized from acetonitrile/water. − ^{1}H NMR (CD_3CN): δ = 3.52 (s). − ^{19}F NMR (CD_3CN): δ = −57.4 (4′-CF_3, t, 3 F, $^4J_{F-F}$ = 21.7 Hz), −142.1 (2-F, m, 2 F), −142.5 (3′-F, m, 2 F), −155.7 (2′-F, m, 2F), −156.6 (3-F, m, 2 F). − IR (KBr): $\tilde{\nu}$ = 3480 / 2870 / 2413 vbr [νOH], 1661 m, 1635 m, 1512 s, 1489 s, 1430 m, 1390 m, 1350 s, 1278 w, 1234 s, 1192 m, 1153 s, 1125 m, 1029 m, 1003 s, 979 s, 921 w, 878 m, 857 m, 837 m, 795 w, 718 m, 695 m, 643 w, 496 w, 420 w, 373 m, 320 m, 297 w cm^{-1}. − Raman (100 mW): $\tilde{\nu}$ = 1663 (20), 1637 (17), 1490 (7), 1429 (7), 1392 (9), 1352 (8), 1134 (7), 916 (7), 861 (9), 816 (27), 789 (12), 721 (20), 705 (18), 540 (17), 496 (62), 443 (28), 413 (20), 388 (37), 308 (14), 286 (17), 215 (16), 145 (26), 85 (100) cm^{-1}. − EI MS (70 eV): *m/z* (%) = 478 (2) [$CF_3C_6F_4OC_6F_4SeOH^+$], 461 (23) [$CF_3C_6F_4OC_6F_4Se^+$], 382 (100) [$CF_3C_6F_4OC_6F_4H^+$], 363 (39) [382 − F$^+$], 313 (19) [382 − CF_3^+], 244 (6) [$OC_6F_4Se^+$], 217 (7) [$CF_3C_6F_4^+$], 149 (16) [$C_6F_4H^+$], 117 (5) [$C_5F_3^+$]. − $C_{13}H_3F_{11}O_4Se$ (511.12): calcd. C 30.55, H 0.59, F 40.89; found C 30.49, H 0.38, F 40.6.

Bis(pentafluorophenylseleno)- and Bis[4-(4′-trifluoromethyltetrafluorophenoxy)tetrafluorophenylseleno]mercury (3a) and (3b): Into a solution of 1.0 mmol of **1a** in 10 mL of benzene is added 2.2 mmol of mercury. After stirring for 24 h the mixture is filtered from excess mercury. After removal of the solvent, the residue is recrystallized from chloroform to give pale yellow-green crystals **3a**, m.p. 173−175°C (ref.[2] 171−173°C) (86%). − ^{19}F NMR (C_6D_6): δ = −126.2 (2-F, m, 2 F), −156.1 (4-F, t, 1 F, $^3J_{F-F}$ = 21.7 Hz), −161.4 (3-F, m, 2 F). ^{19}F-NMR data in ether given in ref.[2] − ^{199}Hg NMR (C_6D_6): δ = −1562 (s). − IR (KBr): $\tilde{\nu}$ = 1638 m, 1633 m, 1586 w, 1518 s, 1483 s, 1394 m, 1369 m, 1343 w, 1293 w, 1141 m, 1101 m, 1094 m, 1086 m, 1014 m, 972 s, 821 s, 722 w, 622 w, 370 w, 312 w cm^{-1}. − Raman (100 mW): $\tilde{\nu}$ = 1636 (25), 1395 (31), 1289 (10), 824 (42), 625 (11), 588 (45), 499 (47), 445 (27), 396 (33), 373 (16), 364 (19), 284 (8), 243 (42), 228 (19), 202 (100), 177 (47), 151 (31), 100 (24) cm^{-1}. − EI MS (70 eV): *m/z* (%) = 696 (15) [M$^+$], 616 (1) [M$^+$ − Se], 494 (30) [M$^+$ − Hg], 414 (1) [M$^+$ − HgSe], 334 (2) [M$^+$ − Hg − 2 Se], 327 (2) [$C_6F_5Se_2^+$], 247 (100) [$C_6F_5Se^+$], 202 (12) [Hg$^+$], 197 (14) [$C_5F_3Se^+$], 167 (37) [$C_6F_5^+$], 155 (15) [$C_5F_5^+$], 117 (9) [$C_5F_3^+$], 93 (4) [$C_3F_3^+$]. − $C_{12}F_{10}HgSe_2$ (692.63): calcd. C 20.81, F 27.43; found C 20.92, F 27.6.

3b (pale yellow powder, m.p. 175−177 °C (dec.) (71%) is prepared from **1b** in a similar fashion and recrystallized from dichloromethane. − ^{19}F NMR (C_6D_6): δ = −56.4 (4′-CF_3, t, 3 F, $^4J_{F-F}$ = 21.7 Hz), −125.7 (2-F, m, 2 F), −140.8 (3′-F, m, 2 F), −155.9 (2′-F/3-F, m, 4 F). − ^{199}Hg NMR (C_6D_6): δ = −1573 (s). − IR (KBr): $\tilde{\nu}$ = 1658 m, 1630 w, 1513 s, 1483 s, 1430 m, 1394 w, 1352 s, 1273 w, 1232 s, 1193 m, 1160 m, 1127 m, 1026 m, 997 s, 972 m, 879 m, 824 w, 797 w, 719 m, 641 w, 378 w cm^{-1}. − Raman (100 mW): $\tilde{\nu}$ = 1660 (4), 1630 (5), 1394 (5), 826 (4), 725 (3), 540 (4), 503 (15), 440 (6), 394 (15), 280 (6), 245 (13), 226 (9), 198 (47), 148 (24), 83 (100) cm^{-1}. − EI MS (70 eV): *m/z* (%) = 1124 (6) [M$^+$], 1105 (1) [M$^+$ − F], 1044 (2) [M$^+$ − Se], 964 (4) [M$^+$ − 2 Se], 922 (24) [M$^+$ − Hg], 903 (2) [M$^+$ − Hg − F], 842 (4) [M$^+$ − HgSe], 762 (18) [M$^+$ − Hg − 2 Se], 461 (100) [$CF_3C_6F_4OC_6F_4Se^+$], 442 (5) [461 − F$^+$], 381 (74) [$CF_3C_6F_4OC_6F_4H^+$], 362 (29) [381 − F$^+$], 312 (17) [381 − CF_3^+], 244 (14) [$OC_6F_4Se^+$], 228 (6) [$C_6F_4Se^+$], 217 (11) [$CF_3C_6F_4^+$], 202 (42) [Hg$^+$], 148 (13) [$C_6F_4^+$], 117 (11) [$C_5F_3^+$], 69

(7) [CF_3^+]. − $C_{26}F_{22}HgO_2Se_2$ (1120.77): calcd. C 27.86, F 37.30; found C 27.75, F 37.3.

Pentafluorobenzeneselenenyl Chloride (4a), 4-(4′-Trifluoromethyltetrafluorophenoxy)tetrafluorobenzeneselenenyl Chloride (4b): Into a solution of 8.5 mmol of **1a** in 50 mL of CH_2Cl_2 is added 35 mL of sulfuryl chloride and heated 1 h to reflux. Then the solvent and excess sulfuryl chloride is slowly distilled off (under SO_2 evolution and darkening of the solution). The liquid residue is distilled in vacuum, the receiving flask is cooled with ice. Dark red **4a** is obtained in 70% yield, b.p. 25−26°C/0.01 Torr (ref.[5] 80°C/10 Torr). − ^{19}F NMR ($CDCl_3$): δ = −122.5 (2-F, m, 2 F), −145.5 (4-F, tt, 1 F, $^3J_{F-F}$ = 20.8 Hz, $^4J_{F-F}$ = 5.2 Hz), −159.1 (3-F, m, 2 F). − IR (liquid film/KBr): $\tilde{\nu}$ = 1633 m, 1514 s, 1492 s, 1396 m, 1377 w, 1350 w, 1288 m, 1259 w, 1152 w, 1108 m, 1091 s, 1013 w, 980 s, 824 m, 724 w, 627 w, 393 w cm^{-1}. − Raman (100 mW): $\tilde{\nu}$ = 1635 (31), 1494 (4), 1398 (26), 1290 (7), 1152 (4), 826 (20), 588 (37), 499 (51), 444 (22), 398 (100) [νSeCl], 381 (65), 283 (9), 245 (17), 225 (12), 156 (14), 133 (19) cm^{-1}. − EI MS (70 eV): *m/z* (%) = 282 (1) [M^+], 263 (1) [M^+ − F], 247 (100) [$C_6F_5Se^+$], 197 (11) [$C_5F_3Se^+$], 167 (18) [$C_6F_5^+$], 155 (6) [$C_5F_5^+$], 117 (5) [$C_5F_3^+$], 93 (3) [$C_3F_3^+$]. Elemental analysis given in ref.[5]

4b: (red-brown crystals, m.p. 50−52°C) is prepared from **1b** in a similar fashion and purified by sublimation at 40−50°C/0.01 Torr (91%). − ^{19}F NMR ($CDCl_3$): δ = −56.4 (4′-CF_3, t, 3 F, $^4J_{F-F}$ = 21.7 Hz), −122.3 (2-F, m, 2 F), −139.6 (3′-F, m, 2 F), −154.0 (2′-F, m, 2 F), −154.6 (3-F, m, 2 F). − IR (KBr): $\tilde{\nu}$ = 1659 m, 1630 m, 1605 w, 1513 s, 1490 s, 1431 m, 1394 m, 1344 s, 1262 w, 1229 s, 1193 m, 1156 m, 1122 m, 1029 m, 1002 s, 980 s, 877 m, 822 w, 798 w, 717 m, 643 w, 498 w cm^{-1}. − Raman (100 mW): $\tilde{\nu}$ = 1662 (8), 1630 (14), 1483 (2), 1429 (3), 1395 (17), 1348 (3), 1268 (2), 1232 (2), 1145 (3), 1117 (2), 827 (8), 719 (8), 658 (2), 647 (2), 633 (2), 568 (5), 538 (12), 500 (27), 452 (9), 441 (15), 412 (6), 390 (46), 375 (100) [νSeCl], 305 (5), 281 (8), 246 (10), 232 (5), 169 (12), 144 (14), 128 (19) cm^{-1}. − EI MS (70 eV): *m/z* (%) = 496 (9) [M^+], 477 (1) [M^+ − F], 461 (31) [M^+ − Cl], 381 (100) [M^+ − SeCl], 362 (41) [381 − F^+], 312 (23) [381 − CF_3^+], 244 (5) [$OC_6F_4Se^+$], 228 (2) [$C_6F_4Se^+$], 217 (6) [$CF_3C_6F_4^+$], 148 (16) [$C_6F_4^+$], 117 (7) [$C_5F_3^+$], 69 (13) [CF_3^+]. − $C_{13}ClF_{11}OSe$ (495.54): calcd. C 31.51, F 42.18; found C 31.39, F 41.9.

Pentafluorobenzeneselenenyl Bromide (5a), 4-(4′-Trifluoromethyltetrafluorophenoxy)tetrafluorobenzeneselenenyl Bromide (5b): A solution of 25 mmol of bromine in 3 mL of CH_2Cl_2 is added to a solution of 3 mmol of **1a** in 10 mL of CH_2Cl_2 at 25°C. The mixture is stirred for 2 h (^{19}F NMR shows reaction completed after 1 h) and all volatile materials are removed in vacuum at 25°C. The remaining residue is distilled under light exclusion (nevertheless under decomposition) to give **5a** as a black-red liquid, b.p. ca. 38°C/0.01 Torr (59%). The solid yellow residue consisted of the diselane **1a**, which can be recovered and rebrominated to form **5a**.

Alternative procedure: Into a solution of 1.0 mmol of **4a** in 10 mL of CH_2Cl_2 is added 2.0 mmol of Me_3SiBr at 25°C. The mixture is stirred for 10 h and after removal of all volatile materials in vacuum, the residue is distilled under light exclusion to give **5a** (60%). The yellow residue consisted of the diselane **1a**, which can be recovered and recycled to form **4a**.

5a: ^{19}F NMR ($CDCl_3$): δ = −122.3 (2-F, m, 2 F), −146.2 (4-F, tt, 1 F, $^3J_{F-F}$ = 19.9 Hz, $^4J_{F-F}$ = 5.2 Hz), −159.3 (3-F, m, 2 F). − IR (liquid film/KBr): $\tilde{\nu}$ = 1633 m, 1513 s, 1491 s, 1395 m, 1377 w, 1349 w, 1287 m, 1255 w, 1150 w, 1107 m, 1090 s, 1033 w, 1012 m, 980 s, 823 m, 723 w, 626 w cm^{-1}. − Raman (100 mW): $\tilde{\nu}$ = 1633 (25), 1397 (25), 1289 (13), 825 (19), 588 (26), 498 (32), 444 (17), 383 (16), 289 (100) [νSeBr], 243 (17), 223 (15), 153 (14), 119 (14) cm^{-1}. − EI MS (70 eV): *m/z* (%) = 326 (7) [M^+], 247 (100) [$C_6F_5Se^+$], 197 (15) [$C_5F_3Se^+$], 167 (8) [$C_6F_5^+$], 155 (18) [$C_5F_5^+$], 117 (11) [$C_5F_3^+$], 93 (5) [$C_3F_3^+$]. − C_6BrF_5Se (325.92): calcd. C 22.11, F 29.15; found C 22.03, F 29.1.

5b: (chocolate-brown solid, m.p. 64−66°C) is prepared from **1b** (and alternatively **4b**) in a similar fashion and purified by vacuum sublimation (51%). Compound **5b** as well partly decomposes under bromine evolution and formation of **1b** (residue). − ^{19}F NMR ($CDCl_3$): δ = −56.4 (4′-CF_3, t, 3 F, $^4J_{F-F}$ = 21.7 Hz), −122.1 (2-F, m, 2 F), −139.6 (3′-F, m, 2 F), −154.1 (2′-F, m, 2 F), −154.6 (3-F, m, 2 F). − IR (KBr): $\tilde{\nu}$ = 1659 m, 1629 m, 1608 w, 1513 s, 1490 s, 1431 m, 1394 m, 1344 s, 1278 w, 1263 w, 1229 s, 1193 m, 1156 m, 1122 m, 1029 m, 1001 s, 979 s, 877 m, 824 w, 797 w, 717 m, 644 w, 498 w cm^{-1}. − Raman (100 mW): $\tilde{\nu}$ = 1660 (16), 1630 (20), 1429 (5), 1393 (22), 1344 (6), 828 (11), 724 (11), 539 (9), 501 (39), 440 (12), 392 (31), 358 (6), 292 (100) [νSeBr], 279 (17), 245 (15), 160 (12), 141 (16), 127 (12) cm^{-1}. − EI MS (70 eV): *m/z* (%) = 540 (3) [M^+], 461 (14) [M^+ − Br], 381 (100) [M^+ − SeBr], 362 (44) [381 − F^+], 313 (21) [381 − CF_3^+], 217 (4) [$CF_3C_6F_4^+$], 148 (17) [$C_6F_4^+$], 117 (5) [$C_5F_3^+$]. − $C_{13}BrF_{11}OSe$ (539.99): calcd. C 28.91, F 38.70; found C 29.16, F 38.8.

Pentafluorophenylselenocyanate (6a), 4-(4′-Trifluoromethyltetrafluorophenoxy)tetrafluorophenylselenocyanate (6b): Into a solution of 1.5 mmol of **4a** in 5 mL of CH_2Cl_2 is added 2.0 mmol of Me_3SiCN at 25°C. Immediate decolorization occurred and the mixture is stirred for 30 min. After removal of all volatiles in vacuum, the residue is sublimed at 35°C/0.01 Torr. **6a** is obtained as colorless crystals, m.p. 41−42°C (83%). − ^{19}F NMR ($CDCl_3$): δ = −124.4 (2-F, m, 2 F), −146.2 (4-F, tt, 1 F, $^3J_{F-F}$ = 20.8 Hz, $^4J_{F-F}$ = 5.2 Hz), −157.8 (3-F, m, 2 F). − ^{14}N NMR ($CDCl_3$): δ = −91 (br, $\Delta\nu_{1/2}$ = 800 Hz). − ^{15}N NMR ($CDCl_3$): δ = −91.1 (s). − IR (KBr): $\tilde{\nu}$ = 2167 m [νCN], 1646 m, 1638 m, 1589 w, 1519 s, 1493 s, 1409 m, 1379 m, 1352 w, 1293 w, 1255 w, 1147 w, 1108 m, 1096 s, 1083 m, 1015 m, 1006 w, 975 s, 825 s, 722 m, 628 m, 507 m, 426 w, 353 w, 344 w, 312 w cm^{-1}. − Raman (100 mW): $\tilde{\nu}$ = 2167 (100) [νCN], 1639 (9), 1412 (4), 1099 (4), 629 (3), 588 (26), 507 (48), 500 (48), 445 (18), 428 (14), 386 (23), 362 (13), 346 (4), 285 (8), 241 (33), 157 (14), 136 (34), 107 (36) cm^{-1}. − EI MS (70 eV): *m/z* (%) = 273 (100) [M^+], 254 (1) [M^+ − F], 247 (53) [$C_6F_5Se^+$], 197 (26) [$C_5F_3Se^+$], 193 (73) [M^+ − Se], 167 (21) [$C_6F_5^+$], 155 (24) [$C_5F_5^+$], 117 (56) [$C_5F_3^+$], 93 (18) [$C_3F_3^+$], 80 (38) [Se^+]. − C_7F_5NSe (272.04): calcd. Synthesis, Mesomorphism, and Spectroscopic Characterization of Bis[4-(*n*-alkoxy)-5-(*p*-*n*-tetradecylphenylazo)]-Substituted (*N*,*N*′-Salicylidenediaminato)nickel(II) Complexes

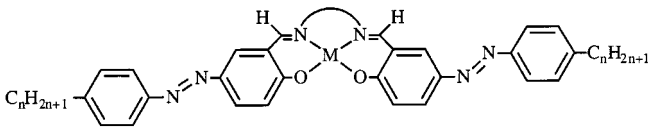
Iolinda Aiello,[a] Mauro Ghedini,*[b] Massimo La Deda,[a] Daniela Pucci,[a] and Oriano Francescangeli[c]



Keywords: Metallomesogens / Nickel / Salicylidenediamines / Azo compounds / (*E*)/(*Z*) photoisomerization / Isomerizations

The bis[4-(*n*-$C_mH_{2m+1}O$)-5-(*p*-$C_{14}H_{29}C_6H_4N{=}N$)]-substituted *N*,*N*′-salicylidenediamines $H_2[L_N(m,14)]$ (*N* = 1: 1,2-diaminoethane; *N* = 2: 1,3-diaminopropane; *N* = 3: 1,3-diamino-2,2-dimethylpropane; *m* = 6 or 18) have been synthesized. Both the *N* = 2 and 3 series of compounds display a smectic C (SmC) mesophase, with clearing points well below 100 °C. By treating the $H_2[L_N(m,14)]$ ligands with an Ni^{II} salt, liquid crystalline mononuclear complexes with "unconventional" (lateral-tailed) molecular shape form. These $Ni[L_N(m,14)]$ complexes, showing nematic and smectic disordered phases, are stable over a quite large temperature range and have been characterized by different spectroscopic techniques. The newly synthesized mesogens exhibit lower transition temperatures and higher thermal stability than homologous complexes $Ni[L_N(14)]$ with a "conventional" rod-like molecular geometry.

Introduction

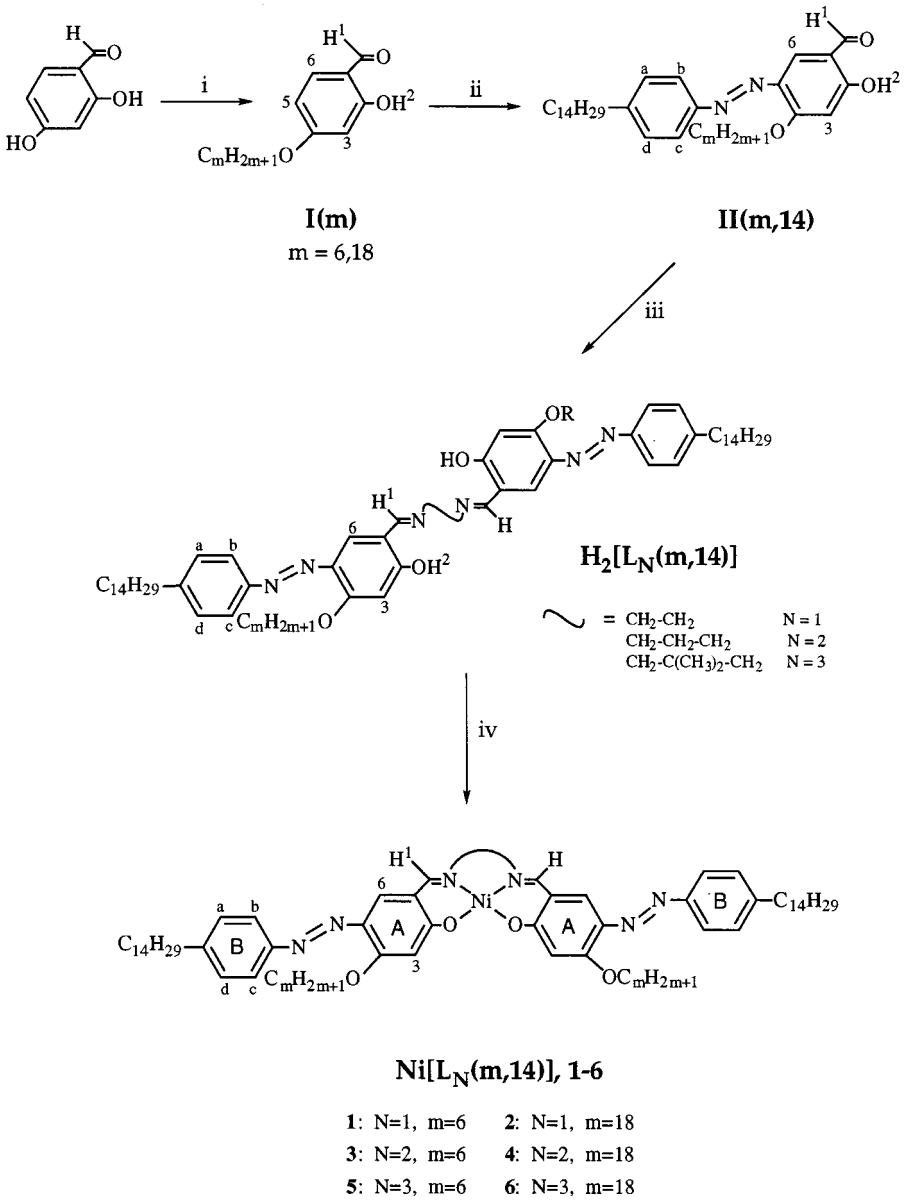
The photoisomerization of liquid crystals containing an azobenzene core has been envisaged as useful tool in designing optical switching materials based on light-induced isothermal phase transitions.[1,4] In an endeavour to improve or explore possible new applications of mesomorphic species, metal atoms have been incorporated into mesogenic molecular structures and a further class of materials (*metallomesogens*), for which some physical properties (e.g. optical, electrical, or magnetic) depend on the nature of the metal centre, is now available.[5] In principle, new materials can be obtained from compounds whose molecular structures combine different features; thus, in particular, photoisomerizable metal-based liquid crystals could be relevant for applications in electrooptic devices.

We are currently concerned with the design and synthesis of metallomesogens[6,7] and with reference to the abovementioned uses have recently reported[8] rod-like thermotropic complexes of Ni^{II}, Cu^{II}, or VO^{2+} with a series of bis[5-(*p*-*n*-alkylphenylazo)]-substituted *N*,*N*′-salicylidenediamines (see Scheme 1). The results of such a comparative investigation indicate that: i) the mesomorphism appears for N⌒N = 1,2-diaminoethane or 1,3-diaminopropane only; ii) the lowest clearing temperatures are shown by the Ni^{II} species and iii) the better mesomorphic properties (namely larger mesomorphic range) are obtained for the ligands bearing the *n*-$C_{14}H_{29}$ alkyl chains. However, all these mesogens display poor thermal stability, and strong decomposition is observed when, at about 300 °C, the mesophase to isotropic liquid transition occurs. This drawback severely limits any practical applications; therefore, in order to preserve chemical stability, the melting transition temperatures of these materials must decrease − i.e. a different molecular structure has to be considered.

M[L_N(n)]

M = Cu, Ni, VO ; n = 6,14

⌒ = CH_2-CH_2 ; CH_2-CH_2-CH_2 ; CH_2-$C(CH_3)_2$-CH_2



Scheme 1. General formula of the $M[L_N(n)]$ complexes (ref.[8])

The relationship between chemical structure and mesogenic properties is an extensively investigated area in the field of liquid crystal chemistry and, although the greater part of the available data concerns organic species,[9] some rules could also be of use for the metallomesogens. In particular, it has been proven that lateral addition of long alkyl chains to a rod-like molecular structure gives rise to a class of "nonconventional" liquid crystals, whose mesophase-isotropic transition temperatures are significantly lower than those of the corresponding rod-like compounds.[10] Thus, speculating on this trend, low-temperature phase transitions could be predicted for metallomesogens with similar structural features.

The target of the research work we are presently involved in is to obtain thermally stable photoactive metal-contain-

Scheme 2. Synthetic route to Ni[L_N(*m*,14)] complexes **1**–**6**; reagents and conditions: i) KOH, *n*-$C_mH_{2m+1}Br$, ethanol; ii) 4-(*n*-tetradecyl)-aniline, HCl, $NaNO_2$, NaOH, water; iii) *N* = 1,2-diaminoethane or 1,3-diaminopropane or 1,3-diamino-2,2-dimethylpropane, ethanol; iv) $Ni(CH_3COO)_2 \cdot 4\,H_2O$, ethanol

ing liquid crystals. As an extension of the previous study,[8] this paper reports on the synthesis, mesomorphic behaviour, and spectroscopic properties of the complexes that the Ni^{II} ion forms with a series of salicylidenediamino ligands obtained by the symmetric addition of two aliphatic tails to the bis[5-(*p*-*n*-tetradecylphenylazo)]-substituted *N*,*N*′-salicylidenediamine skeleton (see Scheme 2).

Results and Discussion

Synthesis

The H_2[L_N(*m*,14)] ligands were synthesized in satisfactory yields as outlined in Scheme 2. The starting material, 2,4-dihydroxybenzaldehyde, was treated first with the appropriate alkyl bromide *n*-$C_mH_{2m+1}Br$ [intermediates **I(6)** for *m* = 6 and **I(18)** for *m* = 18], and then coupled with the diazonium chloride obtained from the 4-*n*-tetradecylaniline. Finally, the new formed intermediates **II(6,14)** and **II(18,14)** were condensed with the selected diamines (namely 1,2-diaminoethane, *N* = 1; 1,3-diaminopropane, *N* = 2; and 1,3-diamino-2,2-dimethylpropane, *N* = 3). The H_2[L_N(*m*,14)] compounds are orange solids which, by treatment with nickel(II) acetate tetrahydrate, give the corresponding Ni[L_N(*m*,14)] complexes **1**–**6** (Scheme 2) as brown to red solids.

The ligands and complexes were characterized by IR and ^{1}H-NMR spectroscopies and their purity confirmed by elemental analysis (see Experimental Section). These data as a whole account for the general formula shown in

Scheme 2. Moreover, both the IR and ^{1}H-NMR spectra, except for the signal attributable to the *n*-$C_mH_{2m+1}O$ chain, compare well with those of the previously described $H_2[L_N(n)]$ and $Ni[L_N(n)]$ compounds (see Scheme 1).[8] Thus, for complexes **1**–**6**, an $[L_N(m,14)]$ bonding mode, like that which the $[L_N(n)]$ groups exhibit in $Ni[L_N(n)]$ and expected for ligands containing the salicylidenediaminato core, is proposed (see Scheme 2).

Mesomorphism

The thermal behaviour of all the newly synthesized compounds belonging to the three homologous series $N = 1-3$, was investigated by combining polarized optical microscopy (POM), miscibility tests with reference compounds, differential scanning calorimetry (DSC) and variable-temperature low-angle X-ray diffraction (XRD) measurements.

The transition temperatures and associated enthalpies for both the ligands $H_2[L_N(m,14)]$ and their related Ni^{II} complexes are reported in Tables 1 and 2, respectively.

Table 1. Transition temperatures, phase assignments[a] and enthalpy changes for the $H_2[L_N(m,14)]$ ligands

Ligand	Transition	T [°C]	ΔH [kJmol^{-1}]
$H_2[L_1(6,14)]$	Cr−I	94.5	69.1
$H_2[L_1(18,14)]$	Cr−Cr′	85.6	28.4
	Cr′−I	106.4	72.7

Ligands

None of the $H_2[L_1(m,14)]$ ligands displays mesomorphic behaviour, melting directly to an isotropic liquid at about 100°C; a crystal-to-crystal transition at 86°C (DSC, XRD) appears only for the $m = 18$ homologues.

Increasing the bridge size promotes liquid crystalline behaviour ($N = 2$ and 3 series). The smectic C (SmC) mesophase is the only one observed in these compounds, irrespective of the bridging diamine or the length of the lateral *n*-$C_mH_{2m+1}O-$ group. In particular, an enantiotropic ($m = 6$) or monotropic ($m = 18$) SmC phase, featuring the typical schlieren texture, is exhibited by the $H_2[L_2(m,14)]$ couple, showing clearing temperatures ranging from 66°C ($m = 18$) to 83°C ($m = 6$). Worthy of note is an exothermic peak detected at 65°C (DSC) for the $H_2[L_2(6,14)]$ sample just after the formation of the SmC phase, indicating a transition to a thermodynamically more stable form before reaching the isotropic liquid. In contrast, in the $H_2[L_2(18,14)]$ compound, a crystal-to-crystal transition is observed at 52°C (DSC, XRD). For both the $H_2[L_2(m,14)]$ species, an SmC mesophase first appears on cooling from the isotropic liquid but, on further cooling, crystallization does not occur and the samples solidify into a glassy state retaining the structure of the SmC phase.

Finally, both the $N = 3$ compounds give an SmC phase showing a sanded texture. On cooling down from the isotropic liquid, the SmC phase is not restored for $H_2[L_3(6,14)]$ and the sample becomes an amorphous solid (POM, DSC, XRD).

At room temperature, the compound with the longest lateral chain, $H_2[L_3(18,14)]$, is a viscous material, slightly birefringent when sheared, whose XRD patterns reveals a semicrystalline structure with a hexagonal smectic-like structure. As the temperature is increased, the material becomes more fluid and an SmC phase is observed at 48°C, before reaching the clearing point at 52°C. Upon cooling, the SmC phase reappears at 41°C and the SmC texture remains until solidification (without crystallization) occurs.

As expected, the results obtained for the $N = 2$ and 3 series demonstrate that longer lateral tails or bulkier bridges gradually decrease the transition temperatures, whereas the thermal stability of the mesophase progressively reduces. Moreover, since liquid crystalline properties were not observed for any of the $[L_N(14)]$ series,[8] the $H_2[L_N(m,14)]$ thermal behaviour is a further example of the role the lateral *n*-$C_mH_{2m+1}O-$ chains could play in mesomorphism.[9]

Complexes

All the $Ni[L_N(m,14)]$ complexes (except for **1**) are liquid crystals which exhibit higher clearing points and larger mesomorphic ranges than those of the corresponding ligands.

Of the $N = 1$ species, **1** ($m = 6$) melts directly to the isotropic liquid at 214°C but the lengthening of the lateral aliphatic chain to $m = 18$ (complex **2**), induces mesomorphism. Indeed **2** shows an enantiotropic SmC phase, stable in

the range 65−101°C. Upon cooling, this mesophase reappears at 88°C and is supercooled to room temperature.

The mesomorphic behaviour of the Ni[L_2(*m*,14)] series proves to be quite sensitive to changes in the lateral alkoxy tail length and confirms the general trend that longer chains promote more ordered phases. Thus, compound **3** (*m* = 6) displays a nematic (N) phase showing a homeotropic texture over its entire temperature range, whereas the upper homologues **4** (*m* = 18) exhibits an SmC (blurred "schlieren" texture) followed by an SmA phase. This latter mesophase becomes more and more fluid and displays homeotropic zones as the temperature is increased. However, both complexes exhibit mesogenic behaviour over a temperature range of about 100°C; the corresponding clearing peaks, only detected by POM observations, were not observed in the DSC scans. When cooled from the isotropic liquid to room temperature, both compounds **3** and **4** transformed into an amorphous solid (XRD).

Finally, of the *N* = 3 derivatives, the Ni[L_3(*m*,14)] complexes **5** and **6** exhibit an SmA phase, identified from the appearance, via batônnetes, of the focal conic fan texture at 128°C (**5**) and 118°C (**6**). On cooling from the isotropic liquid, in compound **5** the SmA phase develops at 280°C and remains stable until, at 103°C, crystallization takes place (POM, XRD). In contrast, for compound **6** no crystallization or glass transition was observed until −20°C.

However, for these three series of Ni[L_N(*m*,14)] complexes it is possible to conclude that the clearing points decrease by about 50°C (for *N* = 2) or 100°C (for *N* = 1,3) as the lateral chain changes from $C_6H_{13}O$ to $C_{18}H_{37}O$, while they rise only slightly as the number of the carbon atoms of the bridging diamine increases (from 2, *N* = 1, to 3, *N* = 2, 3). A similar trend is not observed for the melting transitions and, consequently, for the stability range of the different mesophases.

Azobenzene (*E*)/(Z) Photoisomerization Measurements

Experiments concerning the (*E*)/(*Z*) photoisomerization were performed at room temperature in dichloromethane solutions on Ni[L_2(18,14)] and, for the sake of comparison, on its rod-like homologues Ni[L_2(14)] and on both of the uncomplexed ligands H_2[L_2(18,14)] and H_2[L_2(14)].

The absorption spectra of azobenzenes in their thermally stable (*E*) configuration exhibit absorption maxima at about 350 and 450 nm, and it was observed that irradiation at about 360 nm induces (*E*)/(*Z*)-N=N isomerization.[11] Absorptions at similar wavelengths were also recognized in the spectra of the azo compounds considered; nevertheless under the experimental conditions used, no spectral changes attributable to (*Z*) isomers were detected after irradiation.

Based on the spectral features, Rau[11] classified the substituted azobenzenes into three different classes depending on the electronic effects the different substituents exert: namely, the azobenzene type, the aminobenzene type, and the pseudo stilbenes, the latter class containing the azobenzenes substituted with electron-donating and -accepting groups. Each of these classes behave differently as far as the (*Z*)/(*E*) isomerization is concerned and, in particular, the donor-acceptor azobenzenes isomerize on a millisecond time scale at room temperature.[11] The lack of spectral evidence for the (*E*)/(*Z*) isomerization of Ni[L_2(18,14)], Ni[L_2(14)], H_2[L_2(18,14)], or H_2[L_2(14)] could therefore be ascribed to a very fast (*Z*)/(*E*) thermal isomerization process which takes place in the time required to move the sample from the irradiating lamp to the spectrometer (see Experimental Section). These results suggest that in the compounds examined each molecular half (see Scheme 2) behaves as a pseudo stilbene. Moreover, since the *n*-$C_{14}H_{19}$ chain is a common feature of these species, an investigation comparing the ligands with the corresponding Ni^{II} complexes and the rod-like molecules with the lateral alkoxy-substituted ones indicates that neither complexation to an Ni^{II} ion nor the addition of a lateral alkoxy chain to the aromatic ring A (Scheme 2) changes the photophysical properties of these N=N-containing molecules significantly.

Conclusions

The present investigation was planned in order to explore a convenient synthetic route to prepare thermally stable photoisomerizable metallomesogens. All the members of the Ni[L_N(*m*,14)] series display thermotropic mesomorphism except for the complex Ni[L_1(6,14)]. In no case was decomposition observed, the mesophases are stable over a rather large temperature range, and the clearing temperatures decrease as the lateral chains increase in length.

These results prove that the addition of two lateral *n*-alkoxy tails to bis[5-(*p*-*n*-alkylphenylazo)]-substituted *N*,*N*′-salicylidenediaminato species produces the correct molecular geometry for nematic and smectic metal-containing liquid crystalline compounds with good thermal stability. Indeed, a comparison of the newly synthesized mesogens with the corresponding rod-like complexes[8] (Scheme 1) shows that the lateral chains i) lower both the melting and clearing temperatures by some 100°C (*N* = 2) or 200°C (*N* = 1), ii) promote mesomorphism in the *N* = 3 derivatives, and iii) cause more disordered mesophases (N and S_A) to appear in the *N* = 1 and 2 series. Thus, as far as the thermal behaviour is concerned, the addition of lateral groups to metallomesogens with a rod-like structure induces effects similar to those observed for organic liquid crystals.[10]

Practical applications which require metal-based mesogenic optical switching materials can now be considered. Moreover, it has been recently reported that some complexes containing the (salicylidenediaminato)nickel(II) core display second-order nonlinear optical properties,[12] and this makes coordination compounds such as those reported herein even more attractive materials.

Experimental Section

General: IR: Perkin−Elmer F.T.2000; as KBr pellets. − ^{1}H NMR: Bruker WH-300 spectrometer; in $CDCl_3$ solutions, with TMS as internal standard. − Elemental analyses: Perkin−Elmer 2400 analyzer. − Phase transitions and optical textures: Zeiss Axioscope polarizing microscope equipped with a Linkam C0 600 heating stage. − Transition temperatures and enthalpies: Perkin−Elmer DSC-7 differential scanning calorimeter (DSC) operating at a scanning rate of 10.0 °C/min; the apparatus was calibrated with indium (156.6 °C, 3.3 kJ mol). − X-ray diffraction: INEL CPS-120 powder diffractometer using a monochromatized Cu-K_α radiation (λ = 1.54 Å). − Room-temperature absorption spectra of aerated dichloromethane solutions: Perkin−Elmer Lambda 5 spectrometer. − Irradiation experiments: At selected wavelengths by using the 150-W xenon lamp of a Spex Fluorolog II Spectrofluorimeter. − All the commercially available chemicals were used without further purification. The reference compounds $H_2[L_2(14)]$ and $Ni[L_2(14)]$ were prepared as previously reported.[8]

4-(*n*-Hexyloxy)-2-hydroxybenzaldehyde [I(6)]: KOH (0.81 g, 14.5 mmol) and subsequently an ethanolic solution (10 mL) of 1-bromohexane (3.5 mL, 21.7 mmol) was added to a solution of 2,4-dihydroxybenzaldehyde (2.0 g, 14.5 mmol) in ethanol (30 mL). The resulting mixture was heated at reflux for 24 h, allowed to cool to room temp. and 15 mL of H_2O was added. The brownish solid formed was filtered and washed with diethyl ether. The organic layer was dried with Na_2SO_4 and the solvent removed under reduced pressure to afford a yellow oil, which was purified by column chromatography on silica gel (diethyl ether/petroleum ether, 1:1 v:v). Yield 1.82 g (55%). − IR (KBr): $\tilde{\nu}$ = 1677 cm^{-1} (CHO). − ^{1}H NMR ($CDCl_3$): δ = 11.49 (s, 1 H, H^2), 9.70 (s, 1 H, H^1), 7.42 (d, 1 H, H^6), 6.53 (dd, 1 H, H^5), 6.41 (d, 1 H, H^3), 4.03 (t, 2 H, OCH_2).

2-Hydroxy-4-(*n*-octadecyloxy)benzaldehyde [I(18)]: Compound **I(18)** was prepared according to the procedure decribed for **I(6)**. The white solid afforded was purified by recrystallization from ethanol. Yield 2.86 g (50)%. M.p. 60 °C. − IR (KBr): $\tilde{\nu}$ = 1676 cm^{-1} (CHO). − ^{1}H NMR ($CDCl_3$): δ = 11.50 (s, 1 H, H^2), 9.70 (s, 1 H, H^1), 7.41 (d, 1 H, H^6), 6.52 (dd, 1 H, H^5), 6.41 (d, 1 H, H^3), 4.00 (t, 2 H, OCH_2). − $C_{25}H_{42}O_3$ (390.6): calcd. C 76.87, H 10.84; found C 76.67, H 10.84.

4-(*n*-Hexyloxy)-2-hydroxy-5-{[*p*-(*n*-tetradecyl)phenyl]azo}benzaldehyde [II(6,14)]: 4-(*n*-Tetradecylyl)aniline (1.3 g, 45.0 mmol) was dissolved in water (15 mL) and HCl (1.12 mL, 13.49 mmol). The solution was cooled to 0 °C and an aqueous solution (8 mL) of $NaNO_2$ (0.3 g, 48.6 mmol) was added dropwise. **I(6)** (1 g, 45.0 mmol), dissolved in NaOH (5.17 mL, 2 N) and ethanol (3 mL), was added to the solution of the diazonium salt. The reaction mixture was stirred for 1 h at 0 °C and then allowed to warm slowly to room temp. The brown solid formed was filtered, washed several times with H_2O and dissolved in dichloromethane. The organic layer was dried with anhydrous Na_2SO_4, the solvent removed and the crude product purified by column chromatography on silica gel (diethyl ether/petroleum ether, 1:4 v:v). Further purification by recrystallization from methanol afforded the pure product as a yellow solid. Yield 0.70 g (30%). M.p. 81 °C. − IR (KBr): $\tilde{\nu}$ = 1653 cm^{-1} (CHO). − ^{1}H NMR ($CDCl_3$): δ = 14.62 (s, 1 H, H^2), 9.81 (s, 1 H, H^1), 7.93 (s, 1 H, H^6), 7.81 (d, 2 H, $H^{b,c}$), 7.30 (d, 2 H, $H^{a,d}$), 6.58 (s, 1 H, H^3), 4.21 (t, 2 H, OCH_2), 2.67 (t, 2 H, CH_2). − $C_{33}H_{50}N_2O_3$ (522.77): calcd. C 75.82, H 9.64, N 5.36; found C 75.78, H 9.60, N 5.15.

2-Hydroxy-4-(*n*-octadecyloxy)-5-{[4-(*n*-tetradecyl)phenyl]azo}benzaldehyde [II(18,14)]: Compound **II(18,14)** was prepared according to the procedure decribed for **II(6,14)**. Yellow. Yield 0.70 g (40%). M.p. 79 °C. − IR (KBr): $\tilde{\nu}$ = 1653 cm^{-1} (CHO). − ^{1}H NMR ($CDCl_3$): δ = 11.63 (s, 1 H, H^2), 9.82 (s, 1 H, H^1), 7.95 (s, 1 H, H^6), 7.82 (d, 2 H, $H^{b,c}$), 7.31 (d, 2 H, $H^{a,d}$), 6.59 (s, 1 H, H^3), 4.22 (t, 2 H, OCH_2), 2.68 (t, 2 H, CH_2). − $C_{45}H_{74}N_2O_3$ (691.09): calcd. C 78.21, H 10.19, N 4.05; found C 78.31, H 10.15, N 4.34.

***N,N'*-Bis[4-(*n*-hexyloxy)-2-hydroxy-5-{[*p*-(*n*-tetradecyl)phenyl]azo}-benzylidene]ethylenediamine {$H_2[L_1(6,14)]$}:** A mixture of **II(6,14)** (0.25 g, 0.47 mmol) and 1,2-diaminoethane (0.016 mL, 0.23 mmol) in ethanol (15 mL) was refluxed for 4 h. The precipitate was then filtered off and purified by recrystallization from chloroform/ethanol to yield 0.21 g (82%) of a red solid. − ^{1}H NMR ($CDCl_3$): δ = 14.07 (br. s, 2 H, H^2), 8.31 (s, 2 H, H^1), 7.78 (d, 4 H, $H^{b,c}$), 7.69 (s, 2 H, H^6), 7.28 (d, 4 H, $H^{a,d}$), 6.54 (s, 2 H, H^3), 4.16 (t, 4 H, OCH_2), 3.90 (s, 4 H, NCH_2), 2.67 (t, 4 H, CH_2). − $C_{68}H_{102}N_6O_4$ (1069.61): calcd. C 76.36, H 9.80, N 7.86; found C 76.39, H 9.83, N, 7.24.

$H_2[L_1(18,14)]$: Prepared according to the procedure described for $H_2[L_1(6,14)]$ with the appropriate diamine. Yellow orange. Yield 0.230 g (75%). − ^{1}H NMR ($CDCl_3$): δ = 14.10 (br. s, 2 H, H^2), 8.31 (s, 2 H, H^1), 7.77 (d, 4 H, $H^{b,c}$), 7.68 (s, 2 H, H^6), 7.27 (d, 4 H, $H^{a,d}$), 6.53 (s, 2 H, H^3), 4.17 (t, 4 H, OCH_2), 3.69 (s, 4 H, NCH_2), 2.66 (t, 4 H, CH_2). − $C_{92}H_{152}N_6O_4$ (1404.26): calcd. C 78.58, H 10.89, N 5.98; found C 78.88, H 11.24, N 5.80.

$H_2[L_2(6,14)]$: Prepared as described for $H_2[L_1(6,14)]$ with the appropriate diamine. Orange, yield 0.21 g (81%). − ^{1}H NMR ($CDCl_3$): δ = 14.30 (br. s, 2 H, H^2), 8.28 (s, 2 H, H^1), 7.77 (d, 4 H, $H^{b,c}$), 7.68 (s, 2 H, H^6), 7.27 (d, 4 H, $H^{a,d}$), 6.52 (s, 2 H, H^3), 4.17 (t, 4 H, OCH_2), 3.69 (t, 4 H, NCH_2), 2.66 (t, 4 H, CH_2), 2.12 (m, 2 H, NCH_2CH_2). − $C_{69}H_{104}N_6O_4$ (1081.62): calcd. C 76.62, H 9.69, N 7.77; found C 76.70, H 9.70, N 7.75.

$H_2[L_2(18,14)]$: Prepared according to the procedure decribed for $H_2[L_1(6,14)]$ with the appropriate diamine. Yellow orange, yield 0.28 g (90%). − ^{1}H NMR ($CDCl_3$): δ = 14.26 (br. s, 2 H, H^2), 8.29 (s, 2 H, H^1), 7.78 (d, 4 H, $H^{b,c}$), 7.69 (s, 2 H, H^6), 7.27 (d, 4 H, $H^{a,d}$), 6.53 (s, 2 H, H^3), 4.17 (t, 4 H, OCH_2), 3.69 (t, 4 H, NCH_2), 2.66 (t, 4 H, CH_2), 2.13 (m, 2 H, NCH_2CH_2). − $C_{93}H_{154}N_6O_4$ (1420.28): calcd. C 78.65, H 10.93, N 5.92; found C 78.60, H 10.70, N 5.99.

$H_2[L_3(6,14)]$: Prepared according to the procedure decribed for $H_2[L_1(6,14)]$ with the appropriate diamine. Dark red, yield 0.21 g (70%). − ^{1}H NMR ($CDCl_3$): δ = 14.48 (br. s, 2 H, H^2), 8.25 (s, 2 H, H^1), 7.78 (d, 4 H, $H^{b,c}$), 7.70 (s, 2 H, H^6), 7.27 (d, 4 H, $H^{a,d}$), 6.53 (s, 2 H, H^3), 4.18 (t, 4 H, CH_2), 3.46 (s, 4 H, NCH_2), 2.66 (t, 4 H, OCH_2), 1.32 [s, 6 H, $C(CH_3)_2$]. − $C_{71}H_{108}N_6O_4$ (1109.68): calcd. C 76.85, H 9.81, N 7.50; found C 76.81, H 9.79, N 7.55.

$H_2[L_3(18,14)]$: Prepared according to the procedure decribed for $H_2[L_1(6,14)]$ with the appropriate diamine. Dark orange, yield 0.23 g (73%). − ^{1}H NMR ($CDCl_3$): δ = 14.51 (br. s, 2 H, H^2), 8.25 (s, 2 H, H^1), 7.77 (d, 4 H, $H^{b,c}$), 7.70 (s, 2 H, H^6), 7.27 (d, 4 H, $H^{a,d}$), 6.53 (s, 2 H, H^3), 4.17 (t, 4 H, OCH_2), 3.46 (s, 4 H, NCH_2), 2.66 (t, 4 H, CH_2), 1.25 [s, 6 H, $C(CH_3)_2$]. − $C_{95}H_{158}N_6O_4$ (1448.34): calcd. C 78.78, H 5.80, N 11.00; found C 78.72, H 5.90, N 11.50.

$Ni[L_1(6,14)]$ (1): A mixture of nickel(II) acetate tetrahydrate (0.02 g, 0.09 mmol) and an equimolar amount of $H_2[L_1(6,14)]$ (0.1 g) in ethanol (15 mL) was refluxed for 4 h. The dark red solid formed was filtered off and the pure product was obtained by recrystallization from chloroform/ethanol. Yield 0.09 g (86%). − ^{1}H NMR ($CDCl_3$): δ = 7.70 (d, 4 H, $H^{b,c}$), 7.55 (s, 2 H, H^6), 7.32 (br. s, 2 H, H^1), 7.19 (d, 4 H, $H^{a,d}$), 6.60 (s, 2 H, H^3), 4.09 (t, 4 H, OCH_2), 3.33 (s, 4 H, NCH_2), 2.61 (t, 4 H, CH_2). − $C_{68}H_{102}N_6NiO_4$

(1126.29): calcd. C 72.52, H 9.13, N 7.46; found C 72.62, H 9.12, N 7.46.

Ni[L_1(18,14)] (2): Prepared according to the procedure decribed for Ni[L_1(6,14)] with the appropriate ligand. Brick red, yield 0.073 g (70%). − ^{1}H NMR ($CDCl_3$): δ = 7.72 (d, 4 H, $H^{b,c}$), 7.57 (s, 2 H, H^6), 7.39 (d, 2 H, H^1), 7.22 (d, 4 H, $H^{a,d}$), 6.62 (s, 2 H, H^3), 4.09 (t, 4 H, OCH_2), 3.37 (s, 4 H, NCH_2), 2.63 (t, 4 H, CH_2). − $C_{92}H_{150}N_6NiO_4$ (1462.93): calcd. Metal Tetrahydridoborates and Tetrahydroborato Metallates, 24[+] Solvates of Sodium Bis(borane)dimethylamide

Heinrich Nöth*[a] and Steffen Thomas[a]

Keywords: Sodium bis(borane)dimethylamide solvates / X-ray structure / Reduction

The reaction of sodium metal with dimethylamine–borane in THF yields $Na[(H_3B)_2NMe_2]$ (**1**) which can be isolated as $\{Na[(H_3B)_2NMe_2]\}_5$·THF or as $Na[(H_3B)_2NMe_2]$·15-crown-5 (**2**) and $Na[(H_3B)_2NMe_2]$·benzo-15-crown-5 (**3**) after addition of the appropriate crown ether to the THF solution of **1**. Reaction of **1** with $ZrCl_4$ yields $Me_2HN–BH_2–NMe_2–BH_3$ (**4**), the structure of which has been determined. In THF solution, **1** reduces aldehydes, ketones, acyl chlorides, and esters to the corresponding alcohols. It also reacts slowly with nitriles and allylbenzene. Compound $(\mathbf{1})_5$·THF crystallizes in an extended three-dimensional lattice, in which the Na atoms are coordinated by 6–9 hydridic H atoms, while **3** is a molecular compound in the solid state. Only one hydrogen atom of each BH_3 group coordinates to the sodium center. On the other hand, **4** forms dimeric associates in the solid state through N–H···H–B interactions.

Introduction

As reducing agents, lithium dialkylamidotrihydridoborates, $Li(H_3BNR_2)$, have many advantages over MBH_4 compounds (M = Li, Na) and, in some respects, over $LiAlH_4$ as well.[2] The structures of the solvates of these amidotrihydridoborates $M(R_2NBH_3)$·*n*L depend on the type and number of ligands L;[3] all of them are characterized by metal−nitrogen bonds as well as M···H−B interactions. A metal−nitrogen interaction is not possible in alkali metal salts of the anion $H_3B-NMe_2-BH_3^-$ because the nitrogen atom is tetracoordinated. However, the hydridic atoms of this anion with an alkali metal cation is of interest, particularly in comparison to solvates of alkali metal tetrahydridoborates.[1]

Synthesis

Compound $Na[H_3B-NMe_2-BH_3]$ (**1**) was first obtained by addition of NaH to $Me_2NB_2H_5$[4] according to Equation 1. It was isolated as a hemidioxanate. **1** is also formed when $NaBH_4$ is allowed to react with $Me_2NB_2H_5$ in diglyme, as described by Equation 2.[5] A possible synthesis from $NaNMe_2$ and BH_3·THF is difficult to perform because pure $NaNMe_2$ is not readily accessible. We now report an efficient synthesis starting from the readily available $Me_2NH·BH_3$ and elemental sodium in the presence of THF. This process is described by Equation 3.

$$\mu\text{-}Me_2NB_2H_5 + NaH \rightarrow Na[H_3B-NMe_2-BH_3]\ (\mathbf{1}) \quad (1)$$

$$\mu\text{-}Me_2NB_2H_5 + 2\ NaBH_4 \rightarrow Na[H_3B-NMe_2-BH_3] + NaB_2H_7 \quad (2)$$

$$4\ Me_2NH·BH_3 + 2\ Na \rightarrow 2\ Na[H_3B-NMe_2-BH_3] + H_2 + 2\ Me_2NH \quad (3)$$

Compound **1** slowly decomposes in THF solution with formation of $NaBH_4$ and dimeric dimethylaminoborane (Equation 4). In addition, small amounts of $(Me_2N)_2BH$ [$\delta^{11}B = 29.7$, $^1J(^{11}BH) = 132$ Hz][6] can be detected in the ^{11}B-NMR spectrum of the solution. Experimental evidence has shown that the faster the rate of formation of **1**, the lower the amount of by-products. A higher reaction rate can be achieved by providing an excess of sodium metal, if possible in a highly dispersed form. The shortest reaction times were achieved by using sodium metal dispersed on an Al_2O_3 support, which allowed the conversion of 0.1 mol of $Me_2NH·BH_3$ into **1** within 30 min.

$$2\ \mathbf{1} \rightarrow 2\ NaBH_4 + [Me_2NBH_2]_2 \quad (4)$$

Following the dissolution of solid **1**·*n*THF in toluene, single crystals were obtained, which were shown to be $\{Na[H_3B-NMe_2-BH_3]\}_5$·THF by X-ray structure analysis. Addition of 15-crown-5 or benzo-15-crown-5 to the THF solution of **1** yielded the 1:1 solvates of the crown ethers $[Na(15\text{-crown-5})][H_3B-NMe_2-BH_3]$ (**2**) and $[Na(\text{benzo-15-crown})][H_3B-NMe_2-BH_3]$ (**3**). Single crystals could only be obtained in the case of **3**.[7]

IR and NMR Spectra

While the IR spectra of covalently bonded BH_4 groups, particularly of mononuclear tetrahydroborates, usually provide conclusive evidence with regard to the bonding mode of the BH_4 ligand,[8] this is not the case if highly polar tetrahydridoborates are present, as would be expected for **1**.[9] Nevertheless, the IR spectra of 3 different compounds derived from **1**, depicted in Figure 1, show quite drastic differences in the B−H stretching region. Consequently, the

structures of **1** in THF solution, in solid $(\mathbf{1})_5$·THF, and in **3** must be significantly different. We attribute the strong band of **1** seen at 2291 cm^{-1} to $\nu_{as}BH_3$, and the band of medium intensity at 2251 cm^{-1} to ν_sBH_3.

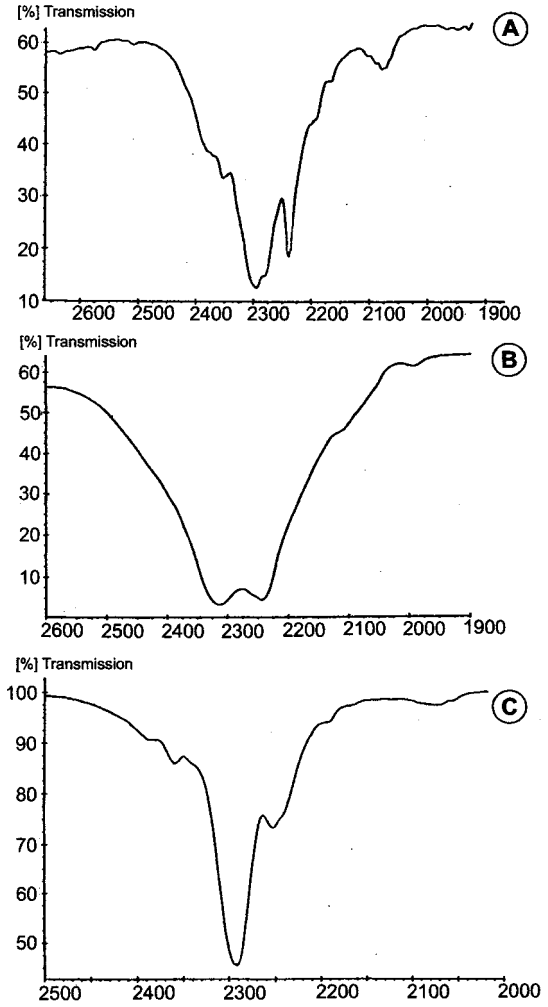

Figure 1. IR spectra in the B−H stretching band region of (A) solid $(\mathbf{1})_5$·THF, (B) **1** in THF solution, and (C) **3** in nujol

On the other hand, the IR spectrum of $(\mathbf{1})_5$·THF in nujol shows two strong bands at 2312 and 2244 cm^{-1}, along with shoulders, which cannot be unequivocally assigned. These observations suggest that the anion in **1** must have a different structure to that seen in THF solution. Compound **3** gives a better resolved IR spectrum. The three intense bands at 2294, 2281 and 2239 cm^{-1}, correspond to BH_3 groups in which a single hydrogen bond is present (ν_{MHB} = 2239 cm^{-1}), with the strongest bands being attributable to $\nu_{as}BH_3$. The presence of BH_3 groups in **1**−**3** is clearly demonstrated by 1:3:3:1 quadruplets in the ^{11}B-NMR spectrum with $^1J(^{11}B^1H)$ values ranging from 90 to 92 Hz, typical for tetracoordinated B atoms.

Reactions

Compound **1** may be a useful reducing agent having properties akin to those of $NaBH_4$. Some "standard" reductions were therefore tested, employing an acyl chloride, an aldehyde, two ketones, an ester and amide, as well as a nitrile, a carboxylic acid, and allylbenzene. Alcohols were obtained as reduction products of benzoyl chloride, benzaldehyde, acetophenone, and cyclohexanone. All other functional groups were reduced only slowly. Moreover, not all of the available hydride was utilized in the reactions (Table 1). The reaction of $ZrCl_4$ with **1** in a 1:4 molar reaction yielded small quantities of $Me_2NH{-}BH_2{-}NMe_2{-}BH_3$ (**4**). This compound is well known.[10] Its crystal structure has now been determined (vide infra).

X-ray Structures

The crown ether complex **3** was shown to be a molecular compound (or contact ion pair) in the solid state by X-ray crystallography. The compound crystallizes from THF solution in the monoclinic system, space group *Cc*, $Z = 8$.

Figure 2 shows that the anion $H_3B{-}NMe_2{-}BH_3^-$ coordinates to the sodium center through one hydridic H atom per BH_3 group. Thus, the coordination number at the sodium center is seven, resulting from two hydrogen and five oxygen atoms. The latter are arranged almost in a plane, and the Na atom resides above this plane with Na−O lengths ranging from 2.426(3) to 2.513(3) Å. Two different Na−B lengths [2.944(5) and 3.110(6) Å] indicate that the anion is not symmetrically coordinated to the metal center. On the other hand, the B−N−B bond angle is close to the ideal tetrahedral angle.

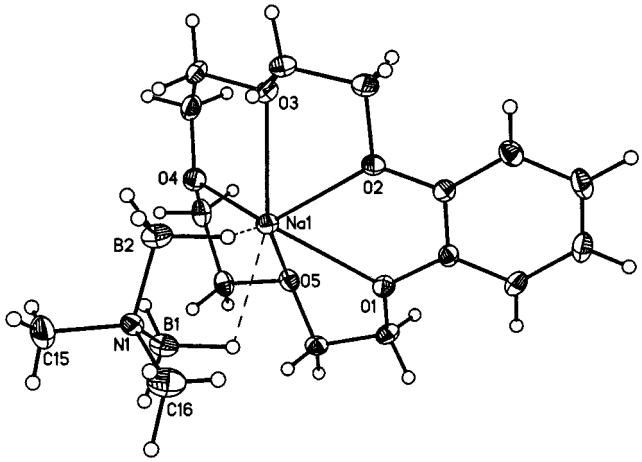

Figure 2. Molecular structure of **3** in the crystal; thermal ellipsoids represent a 25% probability; estimated standard deviations are shown in parentheses; selected atom distances [Å] and bond angles [°]: Na1−O1 2.469(3), Na1−O2 2.465(3), Na1−O3 2.449(3), Na1−O4 2.426(3), Na1−O5 2.513(3), Na1···B1 2.944(5), Na1···B2 3.110(6), N1−B1 1.580(6), N1−B2 1.580(6); O2−Na1−O1 63.9(1), O3−Na1−O2 65.9(1), O4−Na1−O3 68.0(1), O4−Na1−O5 67.64(9), O1−Na1−O5 65.29(1), B1−Na1−B2 51(1), C15−N1−C16 108.3(3), B1−N1−B2 110.9(3), B1−N1−C15 109.9(3), B2−N1−C15 109.2(3)

In contrast to **3**, the structure of compound $(\mathbf{1})_5$·THF is much more complex in the solid state. There are five different "molecules" of **1** in the asymmetric unit. This is rep-

resented in Figure 3, while Figure 4 shows a plot of the three-dimensional array.

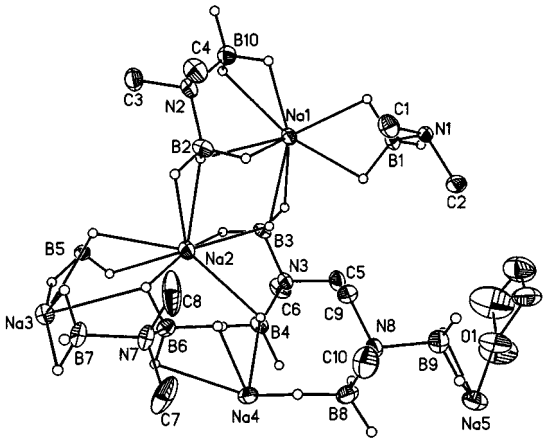

Figure 3. Atoms in the asymmetric unit of $(\mathbf{1})_5$·THF in an ORTEP representation with thermal ellipsoids at a 25% probability level; selected atom distances [Å] and bond angles [°]: Na1···B1 2.828(4), Na1···B2 2.899(3), Na1···B3 2.850(5), Na1···B10 2.888(5), Na2···B6 2.943(5), Na4···B6 2.970(5), Na5···B9 2.795(6), Na5−O1 2.310(4), N1−B1 1.588(5), N2−B2 1.581(6), N2−B10 1.588(5); B1−Na1−B3 107.6(2), B1−Na1−B2 124.5(2), B1−Na1−B10 118.5(2), B2−Na1−B10 53.4(2), B3−Na2−B2 88.7(2), B3−Na2−B6 135.9(1), B3−Na2−B5 119.5(2), B3−Na2−B4 51.4(1), B7−Na3−B7′ 86.9(1), B7−Na3−B5 135.6(1), B7−Na3−B4′ 120.2(1), B7−Na3−B6 51.7(1), B1′−Na4−B4 86.9(1), B1′−Na4−B6 122.5(1), Ba′−Na4−B8 86.2(1), B1′−Na4−B5′ 53.2, O1−Na5−B9 109.0(2), O1−Na5−B10′ 109.0(2), O1−Na5−B5′ 103.4(2), B9−Na5−B10′ 129.4(2), B3−N3−B4 110.7(3), B2−N2−B10 110.2(3), C3−N2−C4 108.9(3)

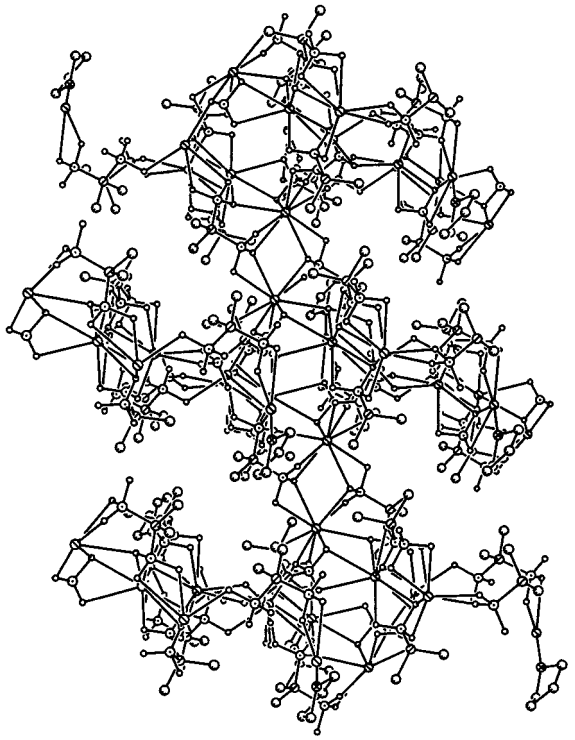

Figure 4. Plot of the three-dimensional array of the unit $(\mathbf{1})_5$·THF; view down the *b* axis

All hydrogen atoms of the BH_3 groups are involved in Na···H−B interactions; one shows contacts with two different Na atoms (as a $\mu^2{}_1$ bridge), while the other two H atoms coordinate either through a $\mu^1{}_1$ interaction to two different Na atoms or through a $\mu^1{}_2$ interaction to one Na center (see the "coordination polyhedra" in Figure 5). If we consider only the corresponding boron atoms ($NaOB_3$ polyhedron), then a slightly distorted tetrahedral array is observed with O−Na5−B bond angles ranging from 103.4(2)° to 109.0(2)°. Atom Na1 is surrounded by five boron atoms at distances of 2.828(4) to 2.899(5) Å, as well as by nine H atoms. Nine H atoms are associated with atom Na3, while Na4, like Na2, is coordinated by eight hydridic hydrogen atoms. In contrast, but in line with expectation, the B−N−B bond angles of all five different $H_3B{-}NMe_2{-}BH_3^-$ anions are close to the ideal tetrahedral bond angle, varying only from 108.9(3) to 110.2(3)°. Moreover, the B−N bond lengths are equal within the standard deviation, the average value being 1.58 Å, which is typical for a B−N single bond involving sp^3-type atoms (in cubic BN 1.56 Å[11]). Figure 4 depicts the three-dimensional array of atoms in the solid state of compound (**1**)5·THF. One must assume that this lattice is broken up into smaller units upon dissolution in solvents such as THF.

Figure 6 shows the molecular structure of two molecules of the amine−borane **4**. This species represents the BN analogue of 2,2,4,4-tetramethylbutane. The two terminal B−N bonds [1.600(2), 1.599(2) Å] have equal lengths, while the central B−N bond is slightly but significantly shorter [1.583(2) Å]. Interestingly, the B−N−B and the N−B−N bond angles are slightly wider than might be expected for tetracoordinated N and B atoms [113.4(1), 113.9(1)°].

N−C bond lengths in **4** lie in the expected range (1.477−1.487 Å) for single bonds.[12] The most interesting aspect of the structure of **4** in the solid state is its association. Crystallographically, there is a center of inversion between each pair of molecules, resulting in close contacts between the NH proton with two hydridic hydrogen atoms of the BH_3 group (H1−H3c 2.27 Å, H1a−H3b 2.38 Å; angle N1a−H1a−H3c 151°, N1a−H1a−H3b 135°) . This implies that the observed packing is a result of a dipolar interaction between hydrogen atoms of opposite polarization. Such interactions have previously been observed in the case of $H_3N{-}BH_3$,[13] and other amine−boranes[14] and have also been invoked as being responsible for determining the conformations of BH_3 adducts of triazacyclohexanes and heteroatom-azacyclohexanes $[S_{2-n}(NMe)_{n+1}(CH_2)_3]$.[15]

Discussion

Sodium bis(borane)dimethylamide is readily obtained in excellent yield by allowing elemental sodium to react with dimethylamine−borane in the presence of THF. Under similar conditions, elemental Li reacts with $Me_2NH{\cdot}BH_3$ with formation of $Li(Me_2NBH_3)$ but not of $Li(H_3B{-}NMe_2{-}BH_3)$.[16] It seems likely that $Na(Me_2NBH_3)$, which should be formed initially, is a very

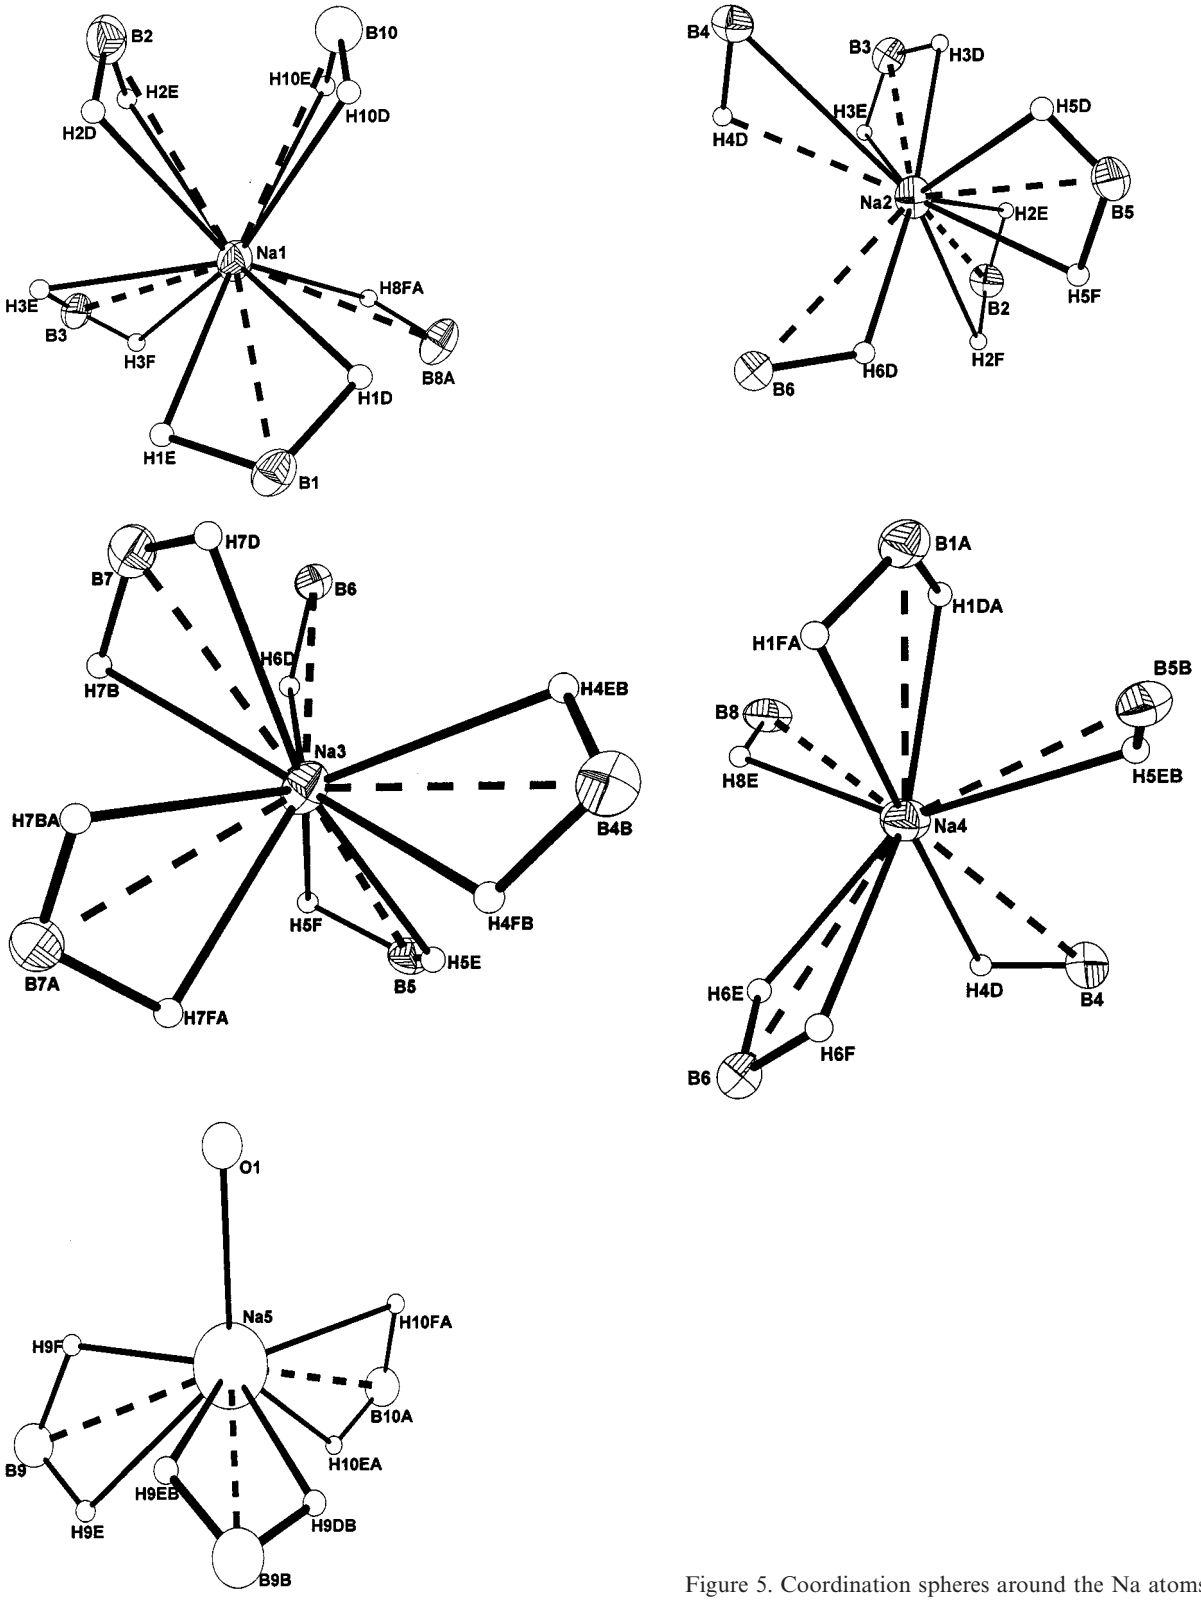

Figure 5. Coordination spheres around the Na atoms in $(\mathbf{1})_5$·THF

strong base and thus displaces Me_2NH from the amine–borane according to Equation 5.

$$Na(Me_2NBH_3) + Me_2NH{\cdot}BH_3 \rightarrow Na(H_3B{-}NMe_2{\cdots}BH_3) + Me_2NH \quad (5)$$

Compound **1** is soluble in THF (up to 1.57 M at 25°C) and may be present in solution as an ion pair $(THF)_nNa(H_3B{-}NMe_2{-}BH_3)$, possibly with a structure similar to that adopted by the crown-ether solvate **3**. On the other hand, differences are seen in the IR spectra of a

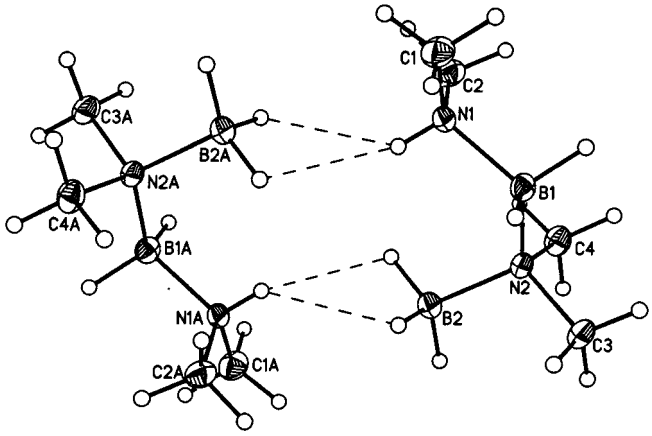

Figure 6. ORTEP plot of two molecules of **4**; thermal ellipsoids are depicted at a 25% probability level; selected bond lengths [Å] and bond angles [°]: B1−N1 1.599(2), B1−N2 1.589(2), B2−N2 1.600(2), N2−C3 1.488(2), N2−C4 1.481(2), N1−C2 1.477(2), N1−C1 1.483(2); N1−B1−N2 113.9(1), B2−N2−B1 113.4(1), C3−N2−B1 105.0(1), C3−N2−B2 108.3(1), C2−N1−B1 116.5(1)

THF solution of **1** and of the well-defined compound **3**. Nevertheless, these spectra are not too dissimilar when compared to that of $(\mathbf{1})_5$·THF.

The good solubility of **1** in THF is in remarkable contrast to the limited solubility of $NaBH_4$ in this solvent. Therefore, **1** in THF solution may represent a promising reducing agent, as has been shown for typical organic functional groups. Compared to $NaBH_4$, compound **1** is a stronger reducing agent in that it also reduces benzoic acid, benzamide, ethyl benzoate, and benzonitrile. It also acts as a mild hydroboration agent, for example attacking styrene. The structures of (**1**)5·THF and **3** have no precedent in the field of alkali metal hydridoborates. Thus, **3** is the first example where "single" M···H−B bridges are present, while (**1**)5·THF forms a three-dimensional array comprising 7−9 coordinated sodium atoms (taking into account only O and H atoms), involving all hydridic hydrogen atoms of the anion $H_3B-NMe_2-BH_3$. The bridging mode of the BH_3 units resembles that of BH_4 groups in dimeric $LiBH_4$·TMEDA[17] and in dimeric $NaBH_4$·PMDETA,[1] e.g. two hydrogen atoms bridge to two different Na centers, while one hydrogen atom connects to two metal centers.

Conclusion

Compound **1** is a nice example where changes in the coordination mode of the $H_3B-NMe_2-BH_3^-$ anion, as brought about by different ligands, can be studied. It is evident from the examples presented here that an expected three-dimensional structure of **1** (which is not yet known) breaks up into smaller units upon solvation. $(\mathbf{1})_5$·THF still retains the three-dimensional association, which most likely breaks down into ion pairs in THF solution or upon addition of a crown ether. This is in agreement with previous structural studies on $Li(R_2NBH_3)$ ether solvates[3] and on $LiBH_4$ ether solvates.[9][18] Although $NaBH_4$ has been known for more than 40 years, its structural chemistry remains largely unexplored. Compound **1** would seem to represent another reducing agent that may compete with lithium amidohydridoborates as a convenient and easy to handle reagent.

Experimental Section

General: All experiments were performed under anhydrous conditions in flame-dried glassware using Schlenk techniques and N_2 as a protecting gas. − NMR spectra were recorded with a Bruker AC 200 or a JEOL GSX 270 instrument (^1H, ^{13}C: reference C_6D_6 or $SiMe_4$; ^{11}B: ext. BF3·OEt2; ^7Li ext. aq. LiCl). − IR: Nicolet 520 FT-IR spectrometer.

Preparation of a Solution of Sodium Bis(borane)dimethylamide (1) in THF: Sodium pieces (2.00 g, 87 mmol) were suspended in stirred THF (150 mL). Then, a concentrated solution of $Me_2NH{\cdot}BH_3$ (5.1 g, 87 mmol) in THF was added and the mixture was refluxed for 6 d. A turbid solution was formed and a gas was evolved, leaving sodium pellets. The solution showed the following ^{11}B-NMR signals: δ = −42.4 (very weak, $NaBH_4$), −12.5 [q, $^1J(^{11}B^1H)$ = 91 Hz, **1**], 6.3 [very weak t, $(Me_2NBH_2)_2$], 29.7 [d, $^1J(^{11}B^1H)$ = 128 Hz, $(Me_2N)_2BH$]. 1.0 g (43 mmol) of Na was recovered. All volatile materials were then removed from the solution in vacuo (down to 10^{-3} Torr). Yield: 3.8 g of **1** (ca. 92%) as a fine white powder. − Solubility: 1.57 M in THF at 25°C. − IR (cm^{-1}, BH region): $\tilde{\nu}$ = 2384 w, 2359 w, 2291 vs, 2251 m. − $C_2H_{12}B_2NNa$ (94.73): calcd. B 22.82, N 14.79, Na 22.99; found B 22.1, N 13.9, Na 20.5.

Pentakis[sodium bis(borane)dimethylamide]·Tetrahydrofuran [$(\mathbf{1})_5$·THF]: Prepared as described for **1**. All volatiles were removed at 10 Torr. The solid residue was then suspended in toluene (20 mL) and the suspension was heated to reflux. Insoluble material was then removed from the hot solution by filtration through a G3 glass frit. Pentane (10 mL) was added to the filtrate, which subsequently became turbid. After cooling to −20°C, crystals of m.p. 7°C were deposited. The supernatant solution was separated by means of a syringe. Further crystals separated from this solution. Although these were largely intergrown, single crystals could easily be separated. − ^{11}B NMR (THF): δ = −10.1 [q, $^1J(^{11}B^1H)$ = 91 Hz]. − ^1H NMR (C_6D_6): δ = 2.33 (s, 30 H), 3.56 (m, 8 H, THF). − IR (cm^{-1}, Nujol): $\tilde{\nu}$ = 2312 vs, 2244 vs, 1627 w, 1579 w, 1469 vs, 1445 m, 1427 w, 1398 w, 1384 w, 1370 w, 1214 vs, 1177 vs, 1159 vs, 1032 s, 1031 vs, 935 m, 914 m, 819 m. − $C_{14}H_{68}B_{10}N_5Na_5O$ (545.77): calcd. C 30.81, H 12.56, N 12.83; found C 30.62, H 12.52, N 12.65.

Sodium Bis(borane)dimethylamide·15-Crown-5 (2): (**1**)5·THF (1.1 g, 2.02 mmol) was dissolved in THF (10 mL) and 15-crown-5 (2 mL, 10 mmol) was added to the stirred solution by means of a syringe. The solution showed ^{11}B-NMR signals at δ = −9.4 [q, $^1J(^{11}B^1H)$ = 91 Hz, **1**] and −12.4 (s) in a 21:1 ratio. Crystals separated from the solution within 2 d at −14°C. They were extensively intergrown and no single crystal could be separated. Yield: 2.3 g of **2** (73%); m.p. 175°C. − ^{11}B NMR: δ = −7.6 [q, $^1J(^{11}B^1H)$ = 92 Hz] in DMF; δ = −9.2 [q, $^1J(^{11}B^1H)$ = 91 Hz] in glyme, besides very weak signals at δ = 21.0 and 11.9; δ = −9.3 [q, $^1J(^{11}B^1H)$ = 91 Hz] in toluene, δ = −9.4 [q, $^1J(^{11}B^1H)$ = 93 Hz] in diethyl ether; δ = −9.3 [q, $^1J(^{11}B^1H)$ = 90 Hz] in benzene. − IR (cm^{-1}, BH region): $\tilde{\nu}$ = 2340 s, 2293 vs, 2237 s, 2163 m. − $C_{12}H_{32}B_2NNaO_5$ (315.00): calcd. C 45.76, H 10.24, B 6.86, N 4.45; found C 47.30, H 10.45, B 6.50, N 3.93.

Sodium Bis(borane)dimethylamide·Benzo-15-crown-5 (3): The crown ether (1.34 g, 5 mmol) was dissolved in THF (20 mL) with stirring.

To this solution was added a solution of **1** in THF (3.36 mL, 1.49 M). After concentrating the solution in vacuo to a volume of ca. 10 mL, crystals separated within 2 months at −14°C, which were eventually isolated. Yield: 1.49 g of **2** (82%); m.p. 129°C (dec.). − ^{11}B NMR (DMSO): δ = −7.9 [q, $^{1}J(^{11}B^{1}H)$ = 90 Hz]. − IR (cm^{-1}, BH region): $\tilde{\nu}$ = 2295 vs, 2281 vs, 2239 vs, 2168 sh, 2194 sh. − $C_{18}H_{32}B_2NNaO_5$ (363.04): calcd. C 52.93, H 8.88, B 5.96, N 3.86; found C 53.12, H 8.91, B 5.74, N 3.44.

Reductions: To a 1.57 M solution of **1** in THF (32 mL, 50 mmol) was added the appropriate organic compound (usually 50 mmol). The mixture was refluxed for 2 h (5 min in the case of benzoyl chloride). After cooling to ambient temperature, 15 mL of a 6 M HCl solution was added, followed by NaOH until the solution was basic. The mixture was extracted with diethyl ether (3 × 15 mL), the combined extracts were dried with $MgSO_4$, and the reaction product was finally isolated by distillation. All compounds were characterized by their ^{1}H- and ^{13}C-NMR spectra.

Benzyl Alcohol from Benzoyl Chloride: From C_6H_5COCl (7.05 g, 50 mmol) was obtained $C_6H_5CH_2OH$. Yield: 4.49 g (83%); b.p. 93°C/10 Torr.

Table 1. Hydrogen consumptions for some reductions using **1** in THF solution

Substrate	Hydride equiv.	H_2 evolved	Hydride consumed
Ethyl benzoate	42	345 cm^3, 15.6 mmol	26.5 mmol
Benzamide	42	525 cm^3, 23.7 mmol	18.3 mmol
Benzonitrile	42	550 cm^3, 24.8 mmol	17.2 mmol
Benzoic acid	63	790 cm^3, 35.7 mmol	27.3 mmol
Allylbenzene	21	345 cm^3, 15.6 mmol	5.4 mmol

[a] $w^{-1} = \sigma^2F_o^2 + (xP)^2 + yP$; $P = (F_o^2 + 2F_c^2)/3$.

Benzyl Alcohol from Benzaldehyde: From C_6H_5CHO (5.30 g, 50 mmol) was obtained $C_6H_5CH_2OH$. Yield: 4.32 g (80%); b.p. 90−93°C/10 Torr.

1-Phenylethanol from Acetophenone: From $C_6H_5COCH_3$ (6.00 g, 50 mmol) was obtained $C_6H_5CH_2CH_2OH$. Yield: 4.58 g (75%); b.p. 95−97°C/10 Torr.

Cyclohexanol from Cyclohexanone: From $C_6H_{10}O$ (4.90 g, 50 mmol) was obtained $C_6H_{11}OH$. Yield: 3.81 g (76%); b.p. 58−62°C/10 Torr.

Hydride Consumption by Various Organic Compounds: A solution of **1** in THF (4.5 mL, 1.57 M) was placed in a two-necked flask. Then, the organic compound (20 mmol) was slowly added and the mixture was refluxed for 3 d. The hydrogen gas released after addition of 15 mL of a 6 M HCl solution was collected, the volume of which allowed the hydride consumption to be determined. The results of these experiments are collected in Table 1.

Dimethylamine−Dimethylaminoborane−Borane (4): $ZrCl_4$ (1.16 g, 5.00 mmol) was suspended in THF (80 mL). To the stirred brownish suspension was added a solution of **1** in THF (13.6 mL, 1.47 M, 20 mmol). A clear solution resulted, which was stored at −78°C. Crystals of **4** separated over a period of 2 weeks. The yield of **4** was not determined, but was rather low. − ^{11}B NMR (THF): δ = −13.2 [q, $^{1}J(^{11}B^{1}H)$ = 198 Hz], 2.0 [t, $^{1}J(^{11}B^{1}H)$ = 96 Hz]. − ^{1}H NMR (C_6D_6): δ = 5.0 (br., NH, 1 H) 2.3 (NMe, 6 H), 1.8 (Me_2NH, 6 H), 2.0 (q, ^{1}J = 108 Hz), 1.95 (q, ^{1}J = 96 Hz). − ^{13}C NMR (C_6D_6): δ = 52.4 (NMe_2), 42.7 ($HNMe_2$). − IR (cm^{-1}, νBH region): $\tilde{\nu}$ = 2447 s, 2390 vs, 2353 vs, 2345 vs, 2315 vs, 2293 vs, 2283 s, 2253 s, 2165 m, 2109 m, 2084 m, 2061 m. − $C_4H_{18}B_2N_2$ (115.82): calcd. C 52.93, H 8.88, B 5.96, N 3.82; found C 53.12, H 8.91, B 5.74, N 3.44.

X-ray Structure Determinations: Crystals were transferred into cooled perfluoroether oil, a single crystal was selected and placed

on top of a glass fibre, which was mounted on the goniometer head of the diffractometer. Most measurements were performed with a Siemens P4 diffractometer equipped with a graphite monochromator, an Mo-K_α tube, an LT2 low-temperature device, and an area detector. For one compound, a Siemens P3m diffractometer was employed. − Reflection data sets were collected either in the hemisphere mode (SMART program) with $\Delta\varphi = 0.3°$ per frame, or in the $\omega/2\Theta$ mode. Lorentz and polarization corrections were applied in the data reduction, but not an absorption correction. The structures were solved by direct methods (SHELXT programs). Non-hydrogen atoms were refined anisotropically, while all H atoms bound to boron atoms were refined isotropically in their found positions. Hydrogen atoms attached to carbon atoms were placed in calculated positions and included in the refinement as a riding model. The THF molecule in compound $(\mathbf{1})_5$·THF was found to be disordered; atoms were placed in split positions and SOFs were refined for two different sites. A summary of the relevant crystallographic data and information relating to the data collection, structure solution, and refinement is given in Table 2. − Additional data (except F_o/F_c tables) have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-125203−125205 Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, U.K. [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Intermediates and Products of the Hexachlorodisilane Cleavage of Group 14 Element Phosphanes and Amines − Molecular Structure of Di-*tert*-butyl(trichlorosilyl)phosphane in the Gas Phase Determined by Electron Diffraction and *ab Initio* Calculations

Wolf-W. du Mont,*[a] Lars Müller,[a] Reiner Martens,[a] Paul M. Papathomas,[b] Bruce A. Smart,[b] Heather E. Robertson,[b] and David W. H. Rankin*[b]

Keywords: Phosphanes / Disilanes / Disilanylamines / Germanes / Stannanes / Stannanes

Reactions of dialkyl(trimethylsilyl)phosphanes RR′PSiMe$_3$ (**1**: R, R′ = *t*Bu; **3**: R, R′ = *i*Pr; **5**: R = *i*Pr, R′ = *t*Bu) with Si_2Cl_6 provide stable trichlorosilylphosphanes RR′PSiCl$_3$ (**2**, **4**, **6**); the reactions of silyl- and stannylamines of *i*Pr$_2$NMMe$_3$ (M = Si: **11**; M = Sn: **12**) with Si_2Cl_6, however, provide the stable pentachlorodisilanylamine *i*Pr$_2$NSi$_2$Cl$_5$ (**13**). Heating of **1** with the technical mixture Me$_2$(Cl)SiSiCl$_2$Me/(MeCl$_2$Si)$_2$ yields the stable silylphosphane *t*Bu$_2$PSiMe$_2$Cl (**8**) and the disilanylphosphane *t*Bu$_2$PSi(Me)(Cl)Si(Me)Cl$_2$ (**9**). Methylation of **9** with MeLi gave *t*Bu$_2$PSi$_2$Me$_5$ **10**, which was isolated in a pure state. Reactions of *t*Bu(*i*Pr)PSiMe$_3$ (**5**) and of organometal phosphanes *t*Bu(*i*Pr)PMR$_3$ (**14**: M = Ge, R = Me; **17a–c**: M = Sn; R = Me, Et, *n*Bu) with Si_2Cl_6 were monitored by ^{31}P, ^{29}Si, and ^{119}Sn NMR. – In the first step of these reactions, new *t*Bu(*i*Pr)PSi$_2$Cl$_5$ (**7**) is formed. **7** is accompanied by increasing amounts of *t*Bu(*i*Pr)PSiCl$_3$ (**6**) and Me$_3$GeSiCl$_3$ (**15**)/(Me$_3$Ge)$_2$Si(SiCl$_3$)$_2$ (**16**) or traces of compounds R$_3$SnSiCl$_3$ (**19a–c**) that decompose providing (R$_3$Sn)$_2$Si(SiCl$_3$)$_2$ (**18a–c**) and *n*Bu$_3$SnSi(SiCl$_3$)$_3$ (**20c**). Subsequently, compounds **19a–c** decompose providing increasing amounts of **18a–c**. Stannylphosphane **17b** is also cleaved by SiCl$_4$ leading to **6** with liberation of Et$_3$SnCl, whereas **17b** *is formed* from the reaction of **5** with Et$_3$SnCl under liberation of Me$_3$SiCl. The suggestion of an extra stabilisation of P–Si bonds of trichlorosilylphosphanes was subjected to direct evidence through the structure determination of the trichlorosilylphosphane *t*Bu$_2$PSiCl$_3$ (**2**) in the gas phase by electron diffraction. This crowded molecule has a "normal" P–Si bond length of 225.0(12) pm; its C_1 symmetric conformation with both *t*Bu groups and the SiCl$_3$ group twisted about 17° from the perfectly staggered positions, and with each of the three groups tilted about 6° away from each other, allows to reduce steric strain.

Introduction

Trihalosilyl compounds are of importance as trifunctional precursors for the synthesis of highly functionalised silicon compounds. The cleavage of trimethylgermyl and -stannyl phosphanes with hexachlorodisilane was reported to furnish trichlorosilylphosphanes as well as trichlorosilyltrimethylgermane and trichlorosilyltrimethylstannane.[1] This novel reductive trichlorosilylation of Me$_3$Ge and Me$_3$Sn groups attached to phosphorus was thought to be due to nucleophilic attack of Me$_3$Ge and Me$_3$Sn groups by latent trichlorosilyl anions. Such anions are generated from one SiCl$_3$ group of Si_2Cl_6 when the other silicon atom is attacked by a phosphorus nucleophile leading to an adduct.[2] Because in situ-generated trichlorosilyl anions are also the key precursors in reactions of trichlorosilane/triethylamine mixtures with various organic halides leading to products of reductive *C*-trichlorosilylations,[3,4] we recently used the "Benkeser" type of reaction of chlorotrimethylstannane with the trichlorosilane/triethylamine reagent as an alternative route to trichlorosilyltrimethylstannane.[5] In the course of the extension of this type of reductive trichlorosilylation for the preparation of trihalosilyl derivatives of main group elements, we were surprised by the nature of the products from the trichlorosilane/triethylamine reagent with chlorotrimethylgermane[6] and dichlorodimethylgermane.[6,7] Contradictory data concerning liquid Me$_3$Ge−SiCl$_3$ and solid (Me$_3$Ge)$_2$Si(SiCl$_3$)$_2$[1,6] led us to study the "Benkeser" type of reaction of organotin and organogermanium halides with the trichlorosilane/triethylamine reagent in detail by heteronuclear NMR.[6,7]

$$Me_3GeCl + HSiCl_3 + NEt_3 \longrightarrow Me_3GeSiCl_3 + (Me_3Ge)_2Si(SiCl_3)_2 + HNEt_3Cl + SiCl_4\ (ref.^{[7]}) \quad (1)$$

$$4\ Me_3GeSiCl_3 \longrightarrow (Me_3Ge)_2Si(SiCl_3)_2 + SiCl_4 + 2\ Me_3GeCl \quad (2)$$

The observation of unexpected products of the constitution (Me$_3$M)$_2$Si(SiCl$_3$)$_2$ (M = Ge, Sn) from these reactions led us to reinvestigate also, by heteronuclear NMR-spectroscopy, the course of the hexachlorodisilane cleavage of P−Ge and P−Sn bonds which yields trichlorosilylphos-

phanes accompanied by new trichlorosilyl compounds containing Si−Ge and Si−Sn bonds.[1] These reactions are expected to be related to the known cleavage of trimethylsilylphosphanes tBu$_2$PSiMe$_3$ (**1**) and tBuP(SiMe$_3$)$_2$ with hexachlorodisilane, which allowed the isolation of the related trichlorosilylphosphanes tBu$_2$PSiCl$_3$ (**2**) and tBuP(SiMe$_3$)(SiCl$_3$) in high yields.[8] As "model" phosphanes we chose silyl-, germyl-, and stannylphosphane derivatives containing the tBu(iPr)P group, which are moderately bulky and fairly accessible from the corresponding chlorophosphane on the HSiCl$_3$/NEt$_3$ pathway[5] followed by methylation and transmetalation reactions.[9]

Reactions of Hexachlorodisilane with Silyl-, Germyl-, and Stannylphosphanes Followed by NMR Spectroscopy

1. Reactions of Chlorodisilanes with Silylphosphanes

The reaction of Si$_2$Cl$_6$ with tBu$_2$PSiMe$_3$ (**1**) was reported to provide trichlorosilylphosphane tBu$_2$PSiCl$_3$ (**2**) in high yield under mild conditions.[8] Similarly, iPr$_2$PSiMe$_3$ (**3**) was easily cleaved to give iPr$_2$PSiCl$_3$ (**4**) in fair yield. After distillation of **2** and **4**, the residues contained orange oils that are expected to contain yet undefined polysilanes, possibly with a certain degree of SiPR$_2$ functions. Addition of Si$_2$Cl$_6$ to tBu(iPr)PSiMe$_3$ (**5**) at 0°C provided a red-brown solution, which turned brown on warming to room temperature. ^{31}P-NMR spectra showed that 5 min after mixing the compounds about 75% **5** was accompanied by about 8% of tBu(iPr)PSiCl$_3$ (**6**), 8% of tBu(iPr)PSi$_2$Cl$_5$ (**7**), and about 3−4% each of two other new phosphorus compounds. After 80 min compound **7** appeared as the main product. After 13 h, **5** was completely consumed and **6** became the main product (about 55%), accompanied by **7** (about 40%) and two other phosphanes. After 10 d at room temp. more than 90% of **6** and less than 10% of other phosphanes were present in solution.

$$\underset{\mathbf{1,3}}{R_2PSiMe_3} + Si_2Cl_6 \longrightarrow \underset{\mathbf{2,4}}{R_2PSiCl_3} + Me_3SiCl + \textit{other products} \quad (3)$$

1, 2: R = tBu[1]
3, 4: R = iPr

$$\underset{\mathbf{5}}{(t\text{Bu})(i\text{Pr})PSiMe_3} + Si_2Cl_6 \longrightarrow \underset{\mathbf{6}}{(t\text{Bu})(i\text{Pr})PSiCl_3} + \underset{\mathbf{7}}{(t\text{Bu})(i\text{Pr})PSi_2Cl_5} + SiCl_4 + Me_3SiCl + \textit{other products} \quad (4)$$

$$\mathbf{1} + Me_2(Cl)SiSiCl_2Me + (MeCl_2Si)_2 \longrightarrow \underset{\mathbf{8}}{t\text{Bu}_2PSiMe_2Cl} + \underset{\mathbf{9}}{t\text{Bu}_2PSi(Me)(Cl)Si(Me)Cl_2} \quad (5)$$

The reaction of tBu$_2$PSiMe$_3$ (**1**) with an excess of the industrial disilane fraction Me$_2$(Cl)SiSiCl$_2$Me/(MeCl$_2$Si)$_2$ required heating for several hours. Distillation provided satisfactory yields of the silylphosphane tBu$_2$PSiMe$_2$Cl (**8**)[10] as first fraction and the new disilanylphosphane tBu$_2$PSi(Me)(Cl)Si(Me)Cl$_2$ **9** as second fraction. Both compounds are thermally stable at room temperature, but very sensitive to oxygen and moisture. The constitution of **9** was confirmed by ^{1}H-, ^{13}C-, ^{29}Si-, and ^{31}P-NMR spectra. Disilanylphosphane **9** (about 50% yield) is obviously the product of a transsilylation of **1** with (MeCl$_2$Si)$_2$. The formation of **8** from **1** (24%) with Me$_2$(Cl)SiSiCl$_2$Me is more surprising. The formation of **8** by transsilylation of **1** with Me$_2$SiCl$_2$ is known to proceed significantly more slowly than the reaction of **1** with MeSiCl$_3$.[10] Adding **9** to an excess of methyllithium led to permethylation giving tBu$_2$PSi$_2$Me$_5$ (**10**), which was then isolated in a pure state.

2. Reactions of Si$_2$Cl$_6$ with iPr$_2$NMMe$_3$ (11: M = Si; 12: M = Sn)

Heating the mixture of Si$_2$Cl$_6$ and iPr$_2$NSiMe$_3$ (**11**) for 6 h at 60°C led to complete consumption of **11**. Distillation provided iPr$_2$NSi$_2$Cl$_5$ (**13**) in fair yield. The stannylamine **12** is more reactive: after mixing **12** and Si$_2$Cl$_6$ at 0°C and warming to room temperature, the formation of crude **13** and Me$_3$SnCl was quantitative.

$$\underset{\mathbf{11}: M = Si;\ \mathbf{12}: M = Sn}{i\text{Pr}_2NMMe_3} + Si_2Cl_6 \longrightarrow \underset{\mathbf{13}}{i\text{Pr}_2NSi_2Cl_5} + Me_3MCl \quad (6)$$

$$\underset{\mathbf{14}}{(t\text{Bu})(i\text{Pr})PGeMe_3} + Si_2Cl_6 \longrightarrow \mathbf{6} + \underset{\mathbf{15}}{\mathbf{7}} + Me_3GeSiCl_3 + \underset{\mathbf{16}}{(Me_3Ge)_2Si(SiCl_3)_2} + SiCl_4 + Me_3GeCl \quad (7)$$

3. Reaction of Si$_2$Cl$_6$ with tBu(iPr)PGeMe$_3$ (14)

Five minutes after mixing the starting materials, about 30% of **14** was consumed in favour of five new phosphorus compounds, among them **6** and **7**. After 3 h, 50% of **14** had been consumed, **6** was the main product and small amounts of **7** (among other P-containing compounds) were also present. A ^{29}Si-NMR spectrum confirmed the presence of Me$_3$GeSiCl$_3$ (**15**) (a rather broad signal, ^{29}Si = +17.7)[7] and (Me$_3$Ge)$_2$Si(SiCl$_3$)$_2$ (**16**) (two signals, at δ ^{29}Si = +16.8 and −84.9, the upfield one being less intense)[7] as well as SiCl$_4$. One peak of the ^{29}Si doublet, doublet pattern of **6** (from Si,P and Si,H couplings) shows "enhanced intensity", possibly due to accidental overlap with the singlet signal of another new germylsilane [δ ^{29}Si = +10.1; probably Me$_3$GeSi(SiCl$_3$)$_3$[9]]. This signal is quite intense in the earliest stage of the reaction. After several days, when **14** had been completely consumed and the crude yield of **6** was close to 90%, the ^{29}Si-NMR pattern of **6** exhibited the expected four lines of equal intensity. Evidence for the formation of Me$_3$GeCl was provided by ^{13}C-NMR spectra of the reaction mixture.

4. Reaction of Si$_2$Cl$_6$ with Stannylphosphanes tBu(iPr)PSnR$_3$ (17a−c: R = Me, Et, nBu)

***t*Bu(*i*Pr)PSnMe$_3$ (17a):** Twenty minutes after mixing the starting materials **17a** had been completely consumed. Silylphosphane **6** and the branched bis(stannyl)silane **18a** were the main products; small amounts of disilanylphosphane **7** (less than 10% of **6**, by ^{31}P-NMR), stannylsilane **19a** (about 25% of **18a**), and a further stannylsilane [δ ^{29}Si = +11.3

and −88; probably $Me_3SnSi(SiCl_3)_3$[9]] were also present. After 15 h, the crude yields (by NMR) of **6** and of **18a** were both more than 90%.

***t*Bu(*i*Pr)PSnEt$_3$ (17b):** After 5 min, **17b** had been consumed and large amounts of the disilanylphosphane **7** were present. Tin-NMR spectra showed the presence of large amounts of $Et_3SnSiCl_3$ (**19b**) accompanied by **18b**[7] and Et_3SnCl. From such a sample, mass spectrometric evidence for **19b** ($M^+ - Et$) was provided. Within one hour, however, trichlorosilylphosphane **6** and the branched bis(stannyl)silane **18b** became the main products at the expense of **7** and **19b**. Besides **18b**, the presence of a further branched silylstannane was indicated by ^{29}Si-NMR ($\delta\ ^{29}Si = +11.7$ and −88).

In an additional experiment, **17b** was mixed with $SiCl_4$ at room temperature. NMR spectra revealed that **17b** was consumed and that trichlorosilylphosphane **6** and Et_3SnCl were formed, accompanied by some *t*Bu(*i*Pr)PH.

$$\underset{\textbf{17a–c}}{(t\text{Bu})(i\text{Pr})\text{PSnR}_3} + \text{Si}_2\text{Cl}_6 \longrightarrow \textbf{6} + \textbf{7} + \underset{\textbf{19a–c}}{\text{R}_3\text{SnSiCl}_3} + \underset{\textbf{18a–c}}{(\text{R}_3\text{Sn})_2\text{Si}(\text{SiCl}_3)_2} \quad (8)$$

a: R = Me
b: R = Et
c: R = *n*Bu

$$+ \underset{\textbf{20a–c}}{\text{R}_3\text{SnSi}(\text{SiCl}_3)_3} + \text{SiCl}_4 + \text{R}_3\text{SnCl}$$

$$\underset{\textbf{17b}}{(t\text{Bu})(i\text{Pr})\text{PSnEt}_3} + \text{SiCl}_4 \longrightarrow \underset{\textbf{6}}{(t\text{Bu})(i\text{Pr})\text{PSiCl}_3} + \text{Et}_3\text{SnCl} \quad (9)$$

***t*Bu(*i*Pr)PSn(*n*Bu)$_3$ (17c):** as in the cases described above, consumption of the stannylphosphane **17c** was very fast. After 2 h, **7** and **19c**[7] were the main products and after 12 d, **6** and $n\text{Bu}_3\text{SnSi}(\text{SiCl}_3)_3$ (**20c**) were the predominant species. After an even longer reaction time (2 months), stannylsilane **19c** was completely decomposed and in addition to **20c**, the branched bis(stannyl)silane **18c** could also be detected by ^{29}Si- and ^{119}Sn-NMR.[7]

Discussion of the Reactions

1. Cleavage of Sn−N and Sn−P Bonds with Si_2Cl_6

Si_2Cl_6 cleaves stannylamines and stannylphosphanes quantitatively within a few minutes under mild conditions by transmetalation-like SnR_3/Si_2Cl_5 exchange reactions providing large amounts of the corresponding pentachlorodisilanylamines and -phosphanes and the trialkylchlorostannanes (Equation 6, Equation 10a). From such reactions, diisopropyl(pentachlorodisilanyl)amine **13** can be isolated in pure state; pentachlorodisilanylphosphane **7**, however, serves as a source of $SiCl_2$ or $SiCl_3^-$ moieties towards the trialkylchlorostannanes, leading by $Cl^-/SiCl_3^-$ exchange to trichlorosilylstannanes $R_3SnSiCl_3$ **19** (Equation 10b).

$$\textbf{17} + \text{Si}_2\text{Cl}_6 \xrightarrow{(10a)} \textbf{7} + \text{R}_3\text{SnCl} \xrightarrow{(10b)} \textbf{6} + \textbf{19} \quad (10)$$

$$4\ \textbf{19} \longrightarrow \textbf{18} + 2\ \text{R}_3\text{SnCl} + \text{SiCl}_4 \quad (11)$$

$$4\ \textbf{19} \longrightarrow \textbf{20} + 3\ \text{R}_3\text{SnCl} \quad (12)$$

$$\textbf{19} + 3\ \textbf{7} \longrightarrow \textbf{20} + 3\ \textbf{6} \quad (13)$$

These compounds can be detected by NMR in solution, but they are not persistent under the reaction conditions (presence of phosphorus nucleophiles). Their decomposition furnishes new branched stannylsilanes $(R_3Sn)_2Si(SiCl_3)_2$ **18** and $R_3SnSi(SiCl_3)_3$ **20** (Equations 11, 12). The previous assignments of NMR data of compounds **15** and **19a** made in ref.[1] have to be withdrawn (see the following section, Table 1). The isolated solids were not **15** and **19a**,[1] but **16** and **18a**.[7] The formation of compounds **20** from **19** (which is favoured by bulkier alkyl groups at tin) can be explained as being reaction steps analogous to those that occur in the course of the base-catalysed disproportionation of Si_2Cl_6, i.e. $Cl^-/SiCl_3^-$ exchange or $SiCl_2$ insertion at the most branched Si atom of an oligochlorosilane.[11–13] Disilanylphosphane **7** can also be a source of $SiCl_3^-$ or $SiCl_2$ (Equation 13). The predominant formation of bis(stannyl)silanes **18a**, **b** and the related germanium compound **16**[7] deserves further investigation; the formation of a second Si−Sn or Si−Ge bond leading from **15/19** to intermediates $(R_3M)_2SiCl_2$ (M = Ge, Sn) as precursors for **16/18** is apparently affected by bulkier alkyl groups at Ge or Sn.

2. Cleavage of Trimethylgermylphosphane 14 by Si_2Cl_6

This reaction proceeds much more slowly than the reaction of stannylphosphanes **17**. Disilanylphosphane **7** is already being consumed by its reaction with Me_3GeCl before its formation by the cleavage of **14** can be quantitative. Formation of trichlorosilylphosphane **6** is slower than in the stannylphosphane reactions, but finally it is also close to quantitative. Contribution of a *direct* $GeMe_3/SiCl_3$ exchange (that was previously proposed[1]) to the formation of $Me_3GeSiCl_3$ (**15**) and **6** cannot be ruled out. Even at an early phase of the reaction, approximately equal amounts of **15** and the branched bis(germyl)silane **16** are present in solution. Experiments with pure **15** show that the presence of Me_3GeCl (its decomposition product !) inhibits the base-catalysed decomposition.[7] The formation of deeply coloured precipitates on addition of Si_2Cl_6 to the phosphanes at 0°C deserves further attention. Phosphanes are known to catalyse the disproportionation,[14] they can coordinate with Si_2Cl_6,[2] and they can activate disilanes for radical reactions with $n\text{Bu}_3\text{SnH}$.[15]

3. Cleavage of Trimethylsilylphosphanes by Si_2Cl_6 and by the Disilane Fraction

Silylphosphane **5** reacts more slowly than the stannylphosphanes but faster than the germylphosphane **14** with Si_2Cl_6 (silylphosphane **5** requires more than 2 h, germylphosphane **14** about a day, and stannylphosphanes **17a-c** less than 20 min to be consumed completely). In the course of the decomposition of disilanylphosphane **7** in the presence of Me_3SiCl, the compound $Me_3SiSiCl_3$ was not detected by ^{29}Si NMR. This compound is known to disproportionate in the presence of N- or P-nucleophiles.[16] Silylphosphane **1** reacts with $(MeCl_2Si)_2$ by transsilylation yielding $t\text{Bu}_2\text{PSi(Me)(Cl)Si(Me)Cl}_2$ (**9**), a stable disilanylphosphane. $Me_2(Cl)SiSiCl_2Me$, however, suffered from Si−Si bond cleavage by **1** by attaching the chlorodimethylsilyl group to phosphorus, i.e. "the more electrophilic sily-

lene" MeSiCl (that allows better base-stabilisation) was lost when tBu$_2$PSiMe$_2$Cl (**8**) was formed. Whether **8** is in fact the *kinetic* product, i.e. whether the higher chlorinated silylphosphanes (like R$_2$PSiCl$_2$Me, R$_2$PSiCl$_3$) profit from extra stabilisation of their P−Si bonds compared with di- and trialkylsilylphosphanes, deserves further investigation.

Characterisation of New Germyl- and Stannylsilanes by NMR Spectroscopy

Assignments were supported by measurements on pure samples of **15** and **18a** from independent syntheses using the trichlorosilane/triethylamine route.[7]

In the series of compounds Me$_3$E−SiCl$_3$ (E = C, Si, Ge) the ^{29}Si resonances of the trichlorosilyl groups appear in the range 18 ± 1 ppm (Table 1). The ^{29}Si nuclei of the SiCl$_3$ groups of the branched compounds (Me$_3$E)$_2$Si(SiCl$_3$)$_2$ exhibit rather similar resonances. Our previous assignments of **15** and **19a**, however, were wrong[1]. Contributions from the electric field gradient (from the p-electron imbalance at Si) to σ_{para} will overcome inductive effects on δ^{29}Si (electronegativity range C >> Ge > Si, Sn). In the case of compounds Me$_3$ESiCl$_3$, however, the ^{13}C resonances of the methyl groups adjacent to C (δ = +24.4), Ge (δ = −2.8), and Sn (δ = −8.1) follow the inductive trend. Again, the related resonances of the branched compounds **16** and **18a** appear not far from those of **15** and **19a**.

The central silicon atoms of the branched bis(germyl)- and bis(stannyl)silanes (R$_3$E)$_2$Si(SiCl$_3$)$_2$ appear at rather low frequency, the tin compounds **18a−c** even lower frequency than the germanium derivative **16**. The ^{29}Si shift of the central atom of stannylsilane **20c** appears at significantly higher frequqency than that of the bis(stannyl)silane **18a**. The ^{119}Sn resonances of compounds **18a-c**, **19a-c**, and **20c** appear in a narrow range from δ = −45 to −70.[7]

Characterisation of New Disilanylphosphanes by NMR

Characteristic coupling patterns allowed safe assignments of the ^{31}P-NMR and ^{29}Si-NMR spectra of transient and persistent disilanylphosphanes (Table 2). Compared with organic subsituents or hydrogen, chlorine atoms at silicon lead to increased couplings ^1J and ^2J (^{31}P, ^{29}Si).[10,18] ^{29}Si-NMR shifts allow distinction between disilanylphosphanes (CN 4 at both Si) and phosphane-hexachlorodisilane adducts (one Si with CN 5 [low frequency], one Si with CN 4).[2]

Experimental and Calculated Structure of 2

Ab initio Calculations

Preliminary calculations on tBu$_2$PSiCl$_3$ were carried out at the 3-21G*/SCF level, assuming C_s symmetry. Vibrational-frequency calculations revealed the presence of a single imaginary frequency (74i cm^{-1}), indicating that the C_s structure represents a transition state connecting two equivalent C_1 minima. This structure can be regarded as

[a] All distances (r_a) in pm, all angles in°. See Figure 1 for atom numbering.

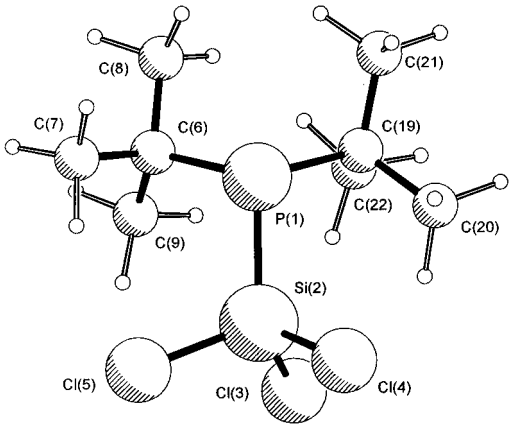

Figure 1. The molecular structure of tBu$_2$PSiCl$_3$ as determined by gas-phase electron diffraction

being derived from a fully staggered structure with *tert*-butyl and $SiCl_3$ groups twisted in the same sense by around 15−20°, increasing the minimum distance between H atoms on neighbouring *tert*-butyl groups from 195.4 pm (C_s) to 211.1 pm (C_1) and reducing the molecular energy by 16.8 kJ mol^{-1} at the 3-21G*/SCF level of theory. All subsequent calculations were carried out in C_1 symmetry. Selected geometric parameters are shown in Table 3 and the atom numbering is shown in Figure 1.

The computational facilities available to us restricted geometry optimisations to the 3-21G*/SCF, 6-31G*/SCF, and 6-31G*/MP2 levels, which should give an acceptably accurate geometry, since tBu$_2$PSiCl$_3$ is not expected to contain any significant multiple-bond character and there are few electronegative atoms.

With the 6-31G* basis set, raising the level of theory from SCF to MP2 produced little change (Table 3). Bond lengths were generally within ca. 1 pm; for example, the Si(2)−Cl(3) bond length is predicted to be 206.6 and 206.5 pm at the SCF and MP2 levels, respectively, and similarly the P(1)−C(19) bond length to be 192.0 and 191.0 pm at the same levels. Only the P−Si bond length changed appreciably, shortening from 227.0 pm to 224.9 pm. Bond angles generally varied by little more then 1°, although angles around the central phosphorus atom differed by up to 2°. At the SCF level the Si−P−C(6), Si−P−C(19), and C(6)−P−C(19) bond angles were predicted to be 106.3°, 105.4°, and 111.8° and to 104.9°, 103.9°, and 111.0° at the higher level.

Although the overall symmetry of tBu$_2$PSiCl$_3$ is predicted to be C_1, the $SiCl_3$ and two *tert*-butyl groups were all found to exhibit approximate local C_3 symmetry. At the 6-31G*/MP2 level, the calculated Si−Cl bond lengths lie in the range 205.4 to 206.5 pm, with internal Cl−Si−Cl angles ranging from 105.3° to 106.5°. Similarly, for the *tert*-butyl groups the C−C bond lengths are calculated to range from 153.0 to 153.7 pm, with internal P−C−C angles from 106.9° to 109.9°.

Molecular Model

The large number of geometric parameters needed to define the structure of tBu$_2$PSiCl$_3$ in C_1 symmetry made it necessary to introduce a number of assumptions into the GED refinement. At first the tBu and $SiCl_3$ groups had no symmetry and 9 parameters were used to define the C-(methyl) and Cl positions in each groups. The number of parameters was reduced only when (a) they were shown to be defined effectively entirely by restraints and (b) they were uncorrelated with the refining parameters. This procedure allows deviations from local symmetry to be fully explored rather than applying local symmetry without testing the validity of the assumptions. In this case the refined structures of *tert*-butyl and $SiCl_3$ groups showed insignificant variation from C_3 local symmetry. Therefore all further refinements were carried out assuming this symmetry. Moreover, within the levels of experimental uncertainty all six C−C bond lengths were also found to be indistinguishable and therefore were constrained to be equal. Since hydrogen

[a] See text for atom numbering and parameter definitions. − [b] *ab initio* values quoted are mean values.

atom positions are poorly defined by the experimental data, all CH_3 groups were assumed to be identical and to have local C_{3v} symmetry.

In total 24 independent geometrical parameters were used to describe the structure of tBu$_2$PSiCl$_3$ in C_1 symmetry (Table 4). The bond length parameters are C−H, p_1, C−C, p_2, the mean and difference of P(1)−C(6) and P(1)−C(19), p_3 and p_4, Si−Cl, p_5, and P−Si, p_6. The bond angles are C−C−H, p_7, the average of the P−C−C bond angles, p_8, the difference between the averages of the P−C−C bond angles found in each of the *tert*-butyl groups, p_9, and the average P−Si−Cl angle, p_{10}.

The remaining parameters are best described with a coordinate system in which the P−Si bond defines the z axis, with P(1) at the origin and Si(2) in the positive z direction. The Cl atoms are arranged initially so that the z axis is an axis of local 3-fold symmetry, with Cl(3) lying in the xz plane in the positive x direction. By assuming a right-handed set of coordinate axes the y axis is also defined.

The $SiCl_3$ torsion angle is a rotation about the z axis, p_{11}, anticlockwise when viewed down the axis from Si to P. The $SiCl_3$ axial and equatorial tilts are anticlockwise rotations at Si(2) about the y axis, p_{12}, and the x axis, p_{13}, respectively. All subsequent torsion and tilt angle directions are anticlockwise when viewed down the rotation axis.

The *tert*-butyl groups were generated by initially placing a methyl group carbon at the origin [i.e. same position as P(1)] so that its three H atoms were arranged with local C_{3v} symmetry about the z axis and one H in the xz plane in the positive x direction. The methyl torsion, p_{14}, and tilt, p_{15}, are rotations about the z axis and x axis, respectively. The methyl group is then translated along the positive z axis by the average C−C bond length and the central carbon of the *tert*-butyl group is placed at the origin. The correct P−C−C bond angle is generated by rotating the methyl group about the y axis. The two remaining methyl groups are defined by replicating the first methyl group and then rotating about the z axis by 120° and −120°, respectively. The *tert*-butyl torsion angle is a rotation of the group about the z axis, while the axial and equatorial tilts are rotations about the y axis and x axis, respectively. Positive axial tilts move *tert*-butyl or $SiCl_3$ groups towards the phosphorus lone pair and equatorial tilts move these groups around the 3-fold belt. Parameters introduced here are the mean and difference of the butyl torsion angles, p_{16} and p_{17}, mean and difference of the butyl axial tilts, p_{18} and p_{19}, and the mean and difference of the butyl equatorial tilts, p_{20} and p_{21}. The *tert*-butyl groups are then translated along the positive z axis by their respective P−C bond lengths.

The three groups that were initially placed along the z axis are moved into their final positions by rotating both *tert*-butyl groups about the y axis by their respective "dip" angles to allow a nonplanar PC_2Si fragment, and then about the x axis by an equal amount in opposite directions to give the correct angles about phosphorus. This introduces three final parameters: the mean and difference of the butyl dip angles, p_{22} and p_{23}, and the *tert*-butyl rotation angle, p_{24}.

Electron Diffraction Refinement

The radial distribution curve for tBu$_2$PSiCl$_3$ (Figure 2) consists of five distinct peaks at distances of ca. 110, 155, 205, 280, and 340 pm together with shoulders and weaker peaks above 400 pm. The peaks at 110 and 155 pm correspond to C−H and C−C scattering, respectively, and the intense peak at 205 pm to scattering from Si−Cl bonds, broadened by contributions associated with the P−Si and P−C bonds. The peak at 280 pm consists mainly of scattering from P···C non-bonded pairs, while the intense broad peak at 340 pm is attributed to scattering from a number of nonbonded atom pairs, with major contributions from Cl···Cl and P···Cl pairs.

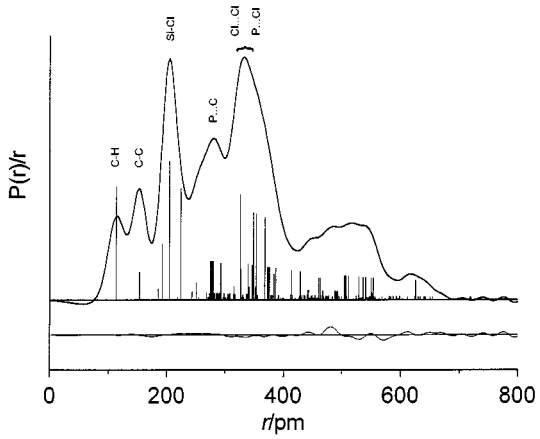

Figure 2. Experimental and difference (experimental − theoretical) radial distribution curves, $P(r)/r$, for tBu$_2$PSiCl$_3$. Before Fourier inversion the data were multiplied by $s\cdot\exp(-0.00002s^2)/(Z_{Si} - f_{Si})(Z_{Cl} - f_{Cl})$.

The starting parameters for the r_a structure refinement were taken from the theoretical geometry optimised at the 6-31G*/MP2 level. The program ASYM40[19] was used to convert the theoretical (6-31G*/SCF) Cartesian force field to one described by symmetry coordinates and this was scaled to obtain root-mean-square amplitudes of vibration (u). Scaling factors were chosen to be 0.90, 0.85, and 0.80 for bond stretches, angle bends and torsions, respectively. The presence of a large number of low-frequency vibrational modes led to overestimated predictions of the perpendicular amplitudes of vibration (k). Since these values were considered to be unreliable, corrections for shrinkage effects were not included.

Since the molecular structure contained a large number of similar interatomic distances, the SARACEN method[20] was employed in the GED refinements. Twelve geometrical and twelve vibrational amplitude restraints were used (Table 5). Values for geometrical restraints were taken to be those predicted at the 6-31G*/MP2 level, while amplitude restraints were based upon the force-field calculations at the 6-31G*/SCF level. Uncertainties were 0.5 pm for bond length differences, 1° for bond angles and 0.5° for bond angle differences. Torsion angles were assigned uncertainties of 2°, and 1° for differences. Uncertainties of 10% were assigned to vibrational amplitude restraints. The methyl tilt

Table 5. Flexible restraints

Number	Description	Parameter definition	Calculated value (Uncertainty)	Refined value
Geometrical restraints:				
1	P−C bond length difference	p_4	−0.2(5)	−0.14
2	Mean C−C−H angle	p_7	109.5(10)	109.2
3	P−C−C angle difference	p_9	−0.07(50)	0.05
4	Methyl torsion angle	p_{11}	4.0(20)	6.2
5	$SiCl_3$ torsion angle	p_{13}	194.0(20)	194.1
6	Butyl torsion angle difference	p_{17}	288.0(10)	288.3
7	C(6)−P−C(19) angle	p_{25}	111.0(10)	110.6
8	[Si−P−C(6)] − [Si−P−C(19)]	$p_{26} - p_{27}$	1.03(50)	0.6
9	P−C(6)−C(7) angle	p_{31}	105.7(10)	104.9
10	[P−C(6)−C(8)] − [P−C(6)−C(9)]	$p_{32} - p_{33}$	−7.7(10)	−7.3
11	[P−C(19)−C(20)] − [P−C(19)−C(21)]	$p_{34} - p_{35}$	1.1(5)	1.0
12	P−C(19)−C(22) angle	p_{36}	116.9(10)	115.7
Vibrational Restraints:				
13	P(1)−Si(2)	u_1	5.9(6)	5.5
14	P(1)···C(6)	u_2	5.8(6)	5.6
15	P(1)···Cl(3)	u_7	10.1(10)	8.9
16	Si(2)···C(6)	u_{16}	9.2(10)	9.3
17	Si(2)···C(7)	u_{18}	12.5(10)	12.4
18	Si(2)···C(8)	u_{19}	9.5(10)	10.7
19	Si(2)···C(9)	u_{20}	15.3(10)	15.4
20	Cl(3)···C(6)	u_{25}	18.9(20)	19.8
21	Cl(3)···C(7)	u_{27}	20.5(20)	22.7
22	Cl(3)···C(8)	u_{28}	20.0(20)	21.5
23	Cl(3)···C(9)	u_{29}	27.8(30)	24.8
24	Cl(4)···C(8)	u_{36}	12.3(10)	12.6

parameter, p_{12}, which helped define the position of the hydrogen atoms, was fixed, since little information is contained in the experimental data because of the poor scattering ability of hydrogen.

The use of flexible restraints allowed the refinement of 41 independent parameters, comprising 23 geometrical parameters and 18 amplitudes of vibration.

In the final refinement the R factors R_G and R_D were 0.091 and 0.077 respectively. Experimental and calculated radial distribution curves are shown in Figure 2, while Figure 3 displays the experimental and calculated molecular scattering intensity curves. Final refined parameters are listed in Table 4, selected interatomic distances and the corresponding amplitudes of vibration in Table 6 and the least-squares correlation matrix in Table 7.

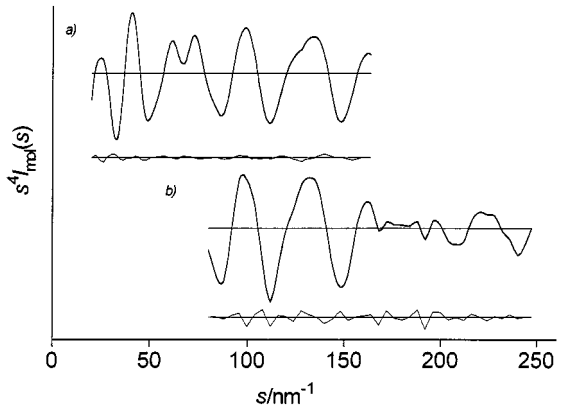

Figure 3. Experimental and final weighted difference (experimental − theoretical) molecular scattering intensities for tBu$_2$PSiCl$_3$. Camera distances were *(a)* 259 mm and *(b)* 95 mm

Discussion

The SARACEN method[20] has allowed the refinement of all significant structural parameters for tBu$_2$PSiCl$_3$. The highest possible molecular symmetry is C_s, but the perfectly staggered arrangement of all *tert*-butyl and $SiCl_3$ groups leads to parallel 1:3 interactions between two methyl groups or between a methyl group and a chlorine atom. The steric interactions of Y(MX$_3$)$_3$ groups are typically minimised by twisting the three groups by 15−20°, and this is what happens in this case, reducing the symmetry to C_1.

Overall, good agreement between theory and experiment was found; theoretical bond-length, bond-angle, and dihedral-angle predictions were in general found to be within one or two standard deviations of the experimental value. The introduction of electron correlation at the MP2 level is seen to be important in obtaining an accurate prediction of the P−Si distance; the 6-31G*/MP2 value at 224.9 pm is essentially identical to the experimental value of 225.0(12) pm, whilst the 6-31G*/SCF uncorrelated computation overestimates the distance at 227.0 pm. The P−Si bond length is also effectively identical to those found by GED in other compounds such as silylphosphane[21] [224.9(3) pm], silylmethylphosphane[21] [224.8(3) pm] and silyldimethylphosphane[21] [224.5(3) pm]. In H_2P-SiF_3, P−Si has been found[22] to be 220.7(3) pm, consistent with the fact that fluorine substituents at silicon result in a significant shortening of the P−Si bond length relative to that of H-substituted compounds. Substitution of the less electronegative chlorine for the silyl hydrogens does not seem to have a significant effect.[2]

Table 6. Selected interatomic distances (r_a) and root-mean-square amplitudes of vibration for tBu$_2$PSiCl$_3$ from the GED study[a]

Number	Atom pair	r_a/pm	u/pm

48	Cl(5)···C(22)	553.3(29)	17.4(tied to u_{27})
49	C(7)···C(8)	251.3(7)	4.5(9)

[a] See Figure 1 for atom numbering; all other distances were included in the refinement, but are not listed here.

All P−Si−Cl angle predictions were within one standard deviation of the experimentally determined values, and angles about the central phosphorus within two standard deviations. The angles about the central phosphorus [C−P−C 110.6(3)° and Si−P−C 103.6(3)°] are considerably larger than for the corresponding angles in silyldimethylphosphane[20] [C−P−C 100.8(12)° and Si−P−C 99.0(5)°], but can be attributed to the strong electron withdrawing character of the $SiCl_3$ group and to steric interactions between the *tert*-butyl groups. Axial tilts are all close to 6°, implying that $SiCl_3$ and *tert*-butyl groups are all tilted away from each other and towards the phosphorus lone pair. The equatorial tilts of the *tert*-butyl groups are smaller (ca. 2°) and towards one another. This implies that the residual steric interactions between two *tert*-butyl groups (after widening of the angle) are less than those between *tert*-butyl and $SiCl_3$ groups

Experimental Section

General: ^{1}H-, ^{13}C-, ^{29}Si-, and ^{31}P-NMR spectra: Bruker AC-200 spectrometer (200 MHz for ^{1}H, 50.3 MHz for ^{13}C, 81 MHz for ^{31}P, 39.8 MHz for ^{29}Si); solvent [D$_6$]benzene; shifts are given relative to TMS (^{1}H, ^{13}C, ^{29}Si) and 85% H_3PO_4 (^{31}P). − MS: Finnigan Mat 8430. − Elemental analyses: Carlo Erba analytical gas chromatograph. − All experiments were carried out under deoxygenated dry nitrogen as inert gas; solvents were dried according to standard procedures.

Ab initio Calculations: All calculations were performed on Dec Alpha 1000 4/200 and 8400 3/500 computers using the GAUSSIAN94 program.[23] Geometry optimisations were performed using the standard 3-21G*[24−26] and 6-31G*[27−29] basis sets at the SCF level and at the correlated MP2 level with the 6-31G* basis. Vibrational frequencies were calculated from analytic second derivatives at the 3-21G*/SCF and 6-31G*/SCF levels to determine the nature of stationary points and to provide estimates of amplitudes of vibration (u) for use in the GED refinements.

Electron Diffraction Measurements: Electron scattering intensities were recorded on Kodak Electron Image plates with the Edinburgh gas-diffraction apparatus operating at ca. 44.5 kV (electron wavelength ca. 5.7 pm).[30] Nozzle-to-plate distances for the metal inlet nozzle were 94.7 and 259.2 mm yielding data in the range s 20−360 nm^{-1}; four and three plates were exposed at the short and long distances, respectively. The sample and nozzle temperatures were maintained at ca. 423 and 448 K respectively during the exposure periods.

The scattering pattern of benzene was also recorded for the purpose of calibration; this was analysed in exactly the same way as for tBu$_2$PSiCl$_3$ so as to minimise systematic errors in the wavelengths and camera distances. Nozzle-to-plate distances, weighting functions used to set up the off diagonal weight matrix, correlation parameters, final scale factors and electron wavelengths for the measurements are collected in Table 8.

The electron scattering patterns were converted into digital form with a computer-controlled Joyce Loebl MDM6 microdensitometer and a scanning program described elsewhere.[31] The programs used for data reduction[31] and least squares refinement[32] have been

Table 8. Nozzle-to-plate distances [mm], weighting functions [nm^{-1}], correlation parameters and electron wavelengths [pm] used in the electron diffraction study

Nozzle-to-plate distance[a]	Δs	s_{min}	sw_1	sw_2	s_{max}	Correlation Parameter	Scale Factor[b]	Electron Wavelength

described previously; the complex scattering factors were those listed by Ross et al.[33]

Reaction of Diisopropyl(trimethylsilyl)phosphane 3 with Si_2Cl_6: Hexachlorodisilane (3.15 g, 11.7 mmol) was added dropwise to ice-cooled **1** (2.2 g, 11.6 mmol). A strongly exothermic reaction occurred. After 2 h stirring at room temperature, trimethylchlorosilane was distilled off from the red liquid; subsequent distillation at 2.5 mbar provided 2.3 g (78%) **4** as a colourless liquid, b.p. 65 °C.[34]

Reaction of *tert*-Butyl(isopropyl)(trimethylsilyl)phosphane 5[9] with Si_2Cl_6 Followed by Heteronuclear NMR: Hexachlorodisilane (0.43 g, 1.6 mmol) is added dropwise to ice-cooled **5** (0.33 g, 1.6 mmol). After warming up to room temperature, the brown liquid was transferred into an NMR tube. For results see Table 9.

NMR data of disilanylphosphane **7**: δ^{31}P 8.3 [s, $^1J(^{31}P, ^{29}Si) \pm 126.0$ Hz; $^2J(^{31}P, ^{29}Si) \pm 22.2$ Hz]; δ^{29}Si 13.2 [d, d, $^1J(^{31}P, ^{29}Si) \pm 125.5$ Hz; $^3J(^{29}Si, ^1H) \pm 8.7$ Hz], −0.4 [d, $^2J(^{31}P, ^{29}Si) \pm 24.0$ Hz].

Reaction of Di-*tert*-butyl(trimethylsilyl)phosphane (1) with the Disilane Fraction: A mixture of 6.21 g (28.43 mmol) of silylphosphane **1** and 12.52 g of a freshly distilled *WACKER AG.* technical disilane fraction sample [$Me_2(Cl)SiSiCl_2Me/(MeCl_2Si)_2$ ratio about 1:1; corresponding to about 28 mmol of each of the two disilanes] was heated to 100 °C. After 16 h, a ^{31}P-NMR spectrum confirms complete consumption of silylphosphane **1**. Distillation at 1 mbar allowed separation of two fractions: b.p. 55−60 °C, 1.6 g (24%) *t*Bu$_2$PSiMe$_2$Cl (**8**),[10] and b.p. 110−114 °C, 4.4 g (48%) *t*Bu$_2$PSi(Me(Cl)Si(Me)Cl$_2$ (**9**).

8: ^{1}H NMR: $\delta = 1.28$ (d, $J = \pm 11.4$ Hz, 18 H), 0.6 (d, $J = \pm 3.5$ Hz); ^{31}P NMR: $\delta = 0.8$ (s, ^1J (^{31}P, ^{29}Si = ± 67.5 Hz).[10]

NMR data of **9**: ^{1}H NMR: $\delta = 1.26$ [d, $^3J(^{31}P, ^1H) \pm 12$ Hz, PCCH_3, 18 H], 0.87 [d, $^3J(^{31}P, ^1H) \pm 3.7$ H, PSiCH_3,, 3 H], 0.78 (s, SiSiCH_3, 3 H). – ^{13}C NMR: $\delta = 34.2$ [d, $^1J(^{31}P, ^{13}C) \pm 26.5$ Hz, P*C*], 33.1 [d, $^2J(^{31}P, ^{13}C) \pm 12.4$ Hz, C-*C*H$_3$], 7.1 (s, SiSi-*C*), 4.9 [d, $^2J(^{31}P, ^{13}C) \pm 8.3$ Hz, PSi-*C*]. – ^{29}Si NMR: $\delta = 12.1$ [d, $^1J(^{31}P, ^{29}Si) \pm 100.2$ Hz, P-*Si*], 26.8 [d, $^2J(^{31}P, ^{29}Si) \pm 21.9$ Hz, PSi-*Si*]. – ^{31}P NMR: $\delta = 8.6$ [s, ^1J (^{31}P, ^{29}Si) ± 100.8 Hz, ^2J (^{31}P, ^{29}Si) ± 22.0 Hz].

Synthesis of Di-*tert*-butyl(pentamethyldisilanyl)phosphane (10): Methyllithium dissolved in ether (28.5 mL of a 1.6 M solution, 45.6 mmol) was added slowly to a solution of 4.52 g (13.8 mmol) **19** in ether at −20 °C. Stirring was continued for 2 h at room tempature, and subsequently the mixture was heated under reflux for 30 min. After separation of the solution from lithium chloride, dis-

(*) Broad.

Reaction of *tert*-Butyl(isopropyl)(trimethylgermyl)phosphane 14 with Si_2Cl_6 Followed by Heteronuclear NMR: Hexachlorodisilane (0.35 g, 1.3 mmol) was added dropwise to ice-cooled **14** (0.33 g, 1.3 mmol). A violet precipitate could be observed. After warming up to room temperature, the brown liquid was transferred into an NMR tube. For NMR results see Tables 10 and 11.

Reaction of *tert*-butyl(isopropyl)(trimethylstannyl)phosphane 17a with Si_2Cl_6 followed by heteronuclear NMR: Hexachlorodisilane (0.4 g, 1.5 mmol) was added dropwise to ice-cooled **17a** (0.41 g, 1.4 mmol). A red precipitate could be observed. After warming up to room temperature, the yellow liquid was transferred into an NMR tube. For NMR results see Tables 12, 13, and 14.

Reaction of *tert*-Butyl(isopropyl)(triethylstannyl)phosphane (17b) with Si_2Cl_6 Followed by Heteronuclear NMR: Hexachlorodisilane (0.24 g, 0.89 mmol) was added dropwise to ice-cooled **17b** (0.29 g, 0.86 mmol). The liquid turned red, then yellow and, at room temperature, green. The green liquid was transferred into an NMR tube. For NMR results see Table 15.

^{29}Si-NMR after 5 h: [$SiCl_4$: relative intensity = 100%] δ^{29}Si = 21.0/−108.1 (50%/9%) [$(Et_3Sn)_2Si(SiCl_3)_2$ (**19b**)], 11.8 (d,d) (4 lines, 20% each) [*t*Bu(*i*Pr)$PSiCl_3$ (**6**)], 12.1 (35%)[20b]; in a separate experiment, a spectrum with about 12 h acquisition time allowed the resolution of two signals for **20b**: δ^{29}Si = 11.7 ($SiCl_3$), −88.0 [$Si(SiCl_3)_3$]. For NMR results see Table 16.

Reaction of *tert*-Butyl(isopropyl)(tri-*n*-butylstannyl)phosphane (17c) with Si_2Cl_6 Followed by Heteronuclear NMR: Hexachlorodisilane (0.27 g, 1.0 mmol) was added dropwise to ice-cooled **17c** (0.4 g, 0.95 mmol). After warming up to room temperature, the greenish-yellow solution was transferred into an NMR tube (see the following tables).

Adding excess of the disilane (0.4 g, 1.5 mmol) at −20 °C to **17c** (0.27 g, 1.0 mmol) led qualitatively to the same products, but in a quite different distribution (faster consumption of **7** and of **18c**;

Synthesis, Crystal Structure, Spectroscopy, and Theoretical Investigations of Tetrahedrally Distorted Copper(II) Chelates with $[CuN_2S_2]$ Coordination Sphere

Stephan Knoblauch,[a] Roland Benedix,[b] Martin Ecke,[a] Thomas Gelbrich,[c] Joachim Sieler,[a] Fernando Somoza,[a] and Horst Hennig*[a]

Keywords: Copper chelates / EPR spectroscopy / Electronic structure / Schiff base ligands / Structure elucidation

A series of tetrahedrally distorted copper(II) complexes with thiolate and imine coordination were synthesized. Schiff bases derived from 4-benzoyl-3-methyl-1-phenyl-2-pyrazoline-5-thione and various diamines were used as tetradentate ligands to obtain tetrahedrally distorted metal chelates with $[CuN_2S_2]$ complex units. Crystal structures of the complexes **1**, **2**, **5** and **6** and of ligand H_2**5** have been determined by means of single-crystal X-ray structure analysis. The structure data show a strong influence of the diamine building blocks on the tetrahedral distortion of the copper(II) complexes. Results of Extended Hückel LCAO calculations correlate strongly with structural, electrochemical, UV/Vis- and EPR-spectroscopic features obtained experimentally. The calculations confirm for the whole complex series a strong delocalization of the frontier orbitals. The highest fully occupied molecular orbital shows a weak contribution, resulting from thiolate donor atoms, whereas the antibonding singly occupied molecular orbitals (SOMOs) are distributed between the copper(II) centre (ca. 35–40%) and the N_2S_2 donor set. The SOMO energy significantly lowers with increasing tetrahedral distortion of the coordination sphere. The influence of the tetrahedral distortion of copper(II) complexes on redox potentials, UV/Vis and EPR spectra is discussed.

Introduction

Numerous examples of copper coordination in the active sites of proteins are known.[1][2] These highly specialized molecules fulfil special requirements to manage electron and dioxygen transfer.[3][4] Particularly the Cu^I/Cu^{II} redox couple is a matter of importance.[5] Since the elucidation of crystal structures of plastocyanin (e.g. *Populus nigra*[6]) and azurin (e.g. *Pseudomonas aeruginosa*[7]), much attention is focused on modelling these *Type I* copper active sites,[8][9] also with respect to their unusual spectroscopic and electronic properties.[10][11] Moreover, the Cu_A electron transfer site in *cytochrome c oxidase* contains copper thiolate bonds.[12] With respect to the biomimetic modelling of these active sites, the chemistry of copper complexes with simultaneous imine and thiolate coordination has expanded during the last two decades.

The uncommon electron transfer properties of copper(II) ions in a low-symmetry environment of imino and thiolato donor sets led us to photochemical studies of various copper(II) chelates of $[CuN_2S_2]$ constitution.[13] It could be shown, that $[CuN_2S_2]$ chelates with Schiff base ligands derived from appropriate pyrazoline-5-thiones lead to unusual photo-induced electron transfer reactions, when irradiated in the presence of (porphyrin)metal(III) compounds and cycloolefins like α-pinene.[14–16] However, the role of the $[CuN_2S_2]$ complexes in these coupled electron transfer processes could not be sufficiently explained.

The $[CuN_2S_2]$ complexes **1**–**4**, **7**, and **9** and the corresponding ligands (H_2**1**–H_2**4**, H_2**7**, and H_2**9**) were synthesized for the first time whereas **5**, **6**, and **8** are already known from the literature.[17][18] The complex series **1**–**9** belong to the relatively few examples of stable copper(II) complexes with thiolate coordination[19] and are characterized by UV/Vis-spectroscopic similarity to Blue copper proteins.[20–23] The Schiff base ligands (see Figure 1) were obtained by condensation of 4-benzoyl-3-methyl-1-phenyl-2-pyrazoline-5-thione with selected diamines as proposed by Toftlund.[17] The choice of the bridging diamines was planned with the aim to control the geometry around the copper centre. Parallel with the structural changes of the Schiff base ligands a change in the spectral features of the corresponding Cu^{II} complexes occurs.[24][25] However, the UV/Vis spectra of that kind of copper(II) Schiff base complexes featuring large π-systems are not very well understood. EHT-LCAO calculations were carried out, therefore, as an approach to better understand the spectroscopic as well as electronic properties of these compounds. The calculations are based on crystal-structure data obtained for complexes **1**, **2**, **5**, and **6**. Crystal-structure data of the 2,2′-biphenylene-bridged compound **8** were taken from the literature.[17]

The goal of this study is to find the geometrical parameters introduced by the different ligand backbones which govern the deformations of the usually preferred planar coordination sphere for copper(II) ions in $[CuN_2S_2]$ chelates. An attempt is made to correlate EHMO data with UV/Vis-

and EPR-spectroscopic results as well as previously reported electrochemical parameters.[13]

Results and Discussion

Structures of the Schiff Base Ligand H_2**5** and of the Copper(II) Complexes 1, 2, 5, and 6

The crystal structure of the ligand H_2**5** has been determined to estimate the influence of the metal ion on the structural changes which occur upon deprotonation and coordination (see Figure 2 and Table 1).

Because no viable solution resulted perceiving $Z = 8$ and *C*2/*c*, space group *Cc* was applied yielding two independent molecules in the asymmetric unit. Figure 3 displays these molecules superimposed along the ethylenediamine fragments N(1)−C(35)−C(36)−N(2) and N(7)−C(71)−C(72)−N(8), respectively. This proves that the two molecules within the asymmetric unit are conformationally independent. Both molecules crystallize in the thioketone tautomeric form and show no symmetry. Considering the C(35)−C(36) [or C(71)−C(72)] axis, H_2**5** shows an antiperiplanar conformation which is changed to a gauche arrangement upon deprotonation and coordination of copper(II) ions. In addition, the ligand H_2**5** is characterized by two weak hydrogen bonds between the pyrazolinethione S atoms and the N atoms of the bridging ethylenediamine unit (Figure 2 and Table 2).

In agreement with available crystal-structure data of **8**,[17] none of the investigated complexes show two-fold symmetry. In general, neither **1**, **2**, **5**, nor **6** can be ordered to any symmetry element (C_1). The intermolecular distances between single molecules of **1**, **2**, **5**, and **6** in the corresponding crystal lattices refer to discrete monomeric species without any interactions. Crystal data of **1**, **2**, **5**, and **6** are listed in Table 1. Selected bond lengths and angles are given in Table 3 and perspective views are displayed in Figures 4, 5, and 6.

The copper(II) centre in all considered complexes is surrounded by a more or less flattened tetrahedron of two imine nitrogen atoms and two thiolate sulfur atoms. Figure 7 visualizes the most important geometrical parameters of the coordination spheres in **1**, **2**, **5**, **6**, and **8**. The deviation from the planar arrangement can be assessed in a first approach by means of the interplanar angles between the two planes defined by the atoms N(1)−Cu−S(1) and N(2)−Cu−S(2)

(θ), or by the sum (Σ) of each of the four angles N(1)−Cu−S(1), S(1)−Cu−S(2), S(2)−Cu−N(2), and N(2)−Cu−N(1) (Σ = 360° for an ideal planar arrangement and Σ = 437.6° for an ideal tetrahedral arrangement of all donor atoms in CuN_2S_2 units).

In complex **1**, the copper(II) ion is bound to the imine and thiolate donors in an essentially planar arrangement (see Figure 4). The copper ion in the crystal lattice of **1** deviates by 0.0413 Å from the calculated least-squares plane of the four donor atoms $N_{(1)}-N_{(2)}-S_{(1)}-S_{(2)}$. As expected,

θ increases in the order **1**, **2**, **5**, **6**, and **8** due to increasing steric demands of the different diamine backbones (Table 3). Depending on the amine bridge used, five- [**1**−**5**, Cu−N(1)−C(35)−C(36)−N(2)], six- [**6**−**7**, Cu−N(1)−C(35)−C(36)−C(37)−N(2)], or seven-membered chelate rings (**8**−**9**) form.

Even though complexes **1** and **5** both feature five-membered chelate rings, complex **1** with a bridging naphthyl unit shows distinct differences in θ values from the dihedral angle determined for complex **5**. This can be attributed to the different ligand flexibilities resulting from hindered rotation around the bond C(35)−C(36) in **1** or to larger conjugative effects of the aromatic bridging units forcing the system **1** into a planar donor arrangement to attain a more efficient π overlap.

In agreement with complexes containing comparably combined *N*,*S*-coordinating ligands,[26] a larger bite angle for the two N donors (N_1−Cu−N_2 in Figure 7) increases the tendency to form a pseudotetrahedral coordination sphere. This angle is influenced by both the steric demands of the corresponding backbone **R** connecting the N donors and the conformational flexibility of **R**. Consequently, a stronger distortion was observed for **6** [N(1)−Cu−N(2): 91.6°, θ = 42.5°] and **8** than for **1**, **2** and **5** due to the larger N(1)−Cu−N(2) bite angle.

A comparable Schiff base Cu^{II} complex synthesized by Gullotti consisting of 3-formyl-1-phenyl-2(1*H*)-pyridinethione and a propylene bridge shows a weaker effect on the coordination geometry (N−Cu−N′: 89.2°; N−Cu−N′/S−Cu-S′: 19.6°).[27] On the other hand, Bereman observed a particularly strong tetrahedral distortion of 53° for [*N*,*N*′-trimethylenebis(methyl 2-amino-1-cyclopentenedithiocarboxylato)]copper(II) (N−Cu−N′: 93.1°; N−Cu−N′/S−Cu−S′: 53°).[28] Steric influence of the different ligand frameworks and bonding behaviour of the coordinating sulfur donors may be responsible for the observed differences.

The geometry of the pyrazole units of the chelates **1**, **2**, **5**, and **6** shows no significant changes due to the influence of different backbones **R** (see Table 3). The pyrazole rings including the sulfur donors are almost planar in all cases and none of the atoms in the units S(1)−N(3)−N(4)−C(2)−C(3)−C(5) and S(2)−N(5)−N(6)−C(19)−C(20)−C(22), deviate more than 0.0618 Å [S(1) in **1**] from the least-squares planes defined by these atoms.

The sulfur−sulfur distances (3.13, 3.17, 3.08 Å) and S(1)−Cu−S(2) angles (88.3, 90.2, 87.3°) for **1**, **5**, **6**, respectively are also nearly uneffected by the different diamine bridges. This finding shows that, if in a first approximation the S_2Cu fragment remains almost unchanged, the geometrical changes forcing the system from planar to pseudotetrahedral donor arrangements are mainly a result of the different positions of the imine donors relative to the copper ion, and the different modes of coordination are obtained through simultaneous torsions along the bisector of the S_1−Cu−S_2 angle (Figure 7).

EHMO Calculations Related with UV/Vis, EPR, and Electrochemical Data

The UV/Vis spectra of H_2**1**−H_2**9** were used to estimate the spectral changes occurring upon deprotonation and coordination of the copper(II) ion. All ligands feature three intense bands in the region between 270 and 450 nm (Table 4). The two bands in the ultraviolet part of the spectrum are, in accordance to their intensities, attributable to π-π* transitions within the aromatic system and the azomethine or the thiolate chromophore, respectively. These absorptions appear at lower energies for the Schiff bases with aromatic coupling between the two imine groups via phenyl or biphenyl units (H_2**1**−H_2**4**, H_2**8**−H_2**9**), since the larger system of conjugated double bonds gives rise to a smaller energy gap between the highest occupied (HOMO) and the lowest unoccupied molecular orbitals (LUMO). The third absorption peaks in the visible region are less intense for H_2**1**−H_2**9**, but they can also be attributed to π-π* transitions since their intensities are too high for forbidden n-π* transitions. These bands disappear upon coordination of the metal ion.

To elucidate the electronic structure of copper complexes **1**−**9** in relation to their spectroscopic features, Extended Hückel MO calculations were performed. According to L. Hennig,[17] the UV/Vis spectra of the analogous complexes with hydrogen atoms instead of phenyl groups bound to the imine functions are nearly identically with those of **1**−**9**. This shows that electronic transitions are not significantly influenced by the phenyl groups on C(1) and C(18). In order to simplify molecules **1**−**9**, the smaller hydrogen-substituted systems were used as model fragments for the EHMO calculations, and the two hydrogen atoms were calculated in ideal positions.

Figure 8 displays the frontier orbital region of the fragment derived from the ethylene-bridged [CuN_2S_2] complex **5** belonging to the point group C_1. In agreement with previous MO calculations on copper dithiolates,[29][30] the highest singly occupied MO (SOMO) correlates with an antibonding orbital. It is formed by σ-type lone-pair orbitals of the ligand and a copper d orbital described as an admixture of d_{xy}, d_{xz}, and $d_{x^2-y^2}$ functions. The orbital mixing correlates with the absence of any symmetry element. The intricate stereochemistry of **1**−**9** prevents σ/π separation of the interacting orbitals.

As expected, the orbital structure of the lower lying MOs differs remarkably when compared with copper complexes of the [CuN_2S_2] type with saturated ligands (aliphatic thiol-

ates).[31] In this case, the MOs arranged below the SOMO are typical sulfur lone-pair orbitals, whereas **1**−**9** are distinguished by largely delocalized MOs. The doubly occupied orbitals 6*a* and 5*a* are delocalized over the phenylpyrazole building block of the ligand with a ca. 20% contribution of the sulfur donor atoms. The following four orbitals at lower energies are mainly delocalized within the imine and pyrazole fragment with a more (4*a*, 1*a*) or less (3*a*, 2*a*) strong contribution of the thiolate sulfur. The three lowest unoccupied MOs calculated are mainly localized at the imine and pyrazole fragment.

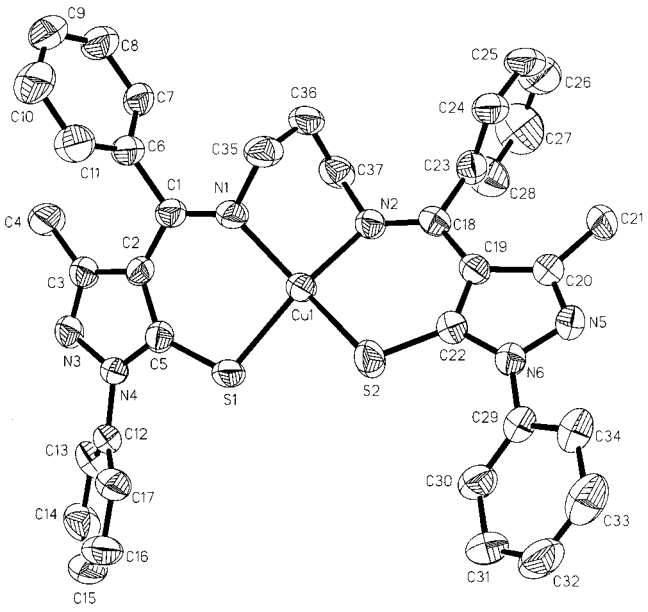

Figure 6. Molecular structure of complex **6** ($\theta = 42.5°$); hydrogen atoms and solvent molecules are omitted for clarity (ORTEP drawing with 50% probability ellipsoids)

The orbital characteristics obtained for the ethylene-bridged ligand system **5** agree with those of **1**, **6** and **8** distinguished by different *N*,*N*′-diamine backbones. Interestingly, the nearly planar complex **1** shows primarily an MO-localized at the imine functions arranged between the S-containing orbitals.

Single vacancy on the copper-containing SOMO and the existence of lower lying sulfur lone-pair orbitals should lead to the appearance of LMCT absorption in the low-energy region of the electronic spectra of the $[CuN_2S_2]$ complexes **1**−**9** (Table 5). Usually, the UV/Vis spectra of these complexes are dominated by three LMCT bands of σ and π symmetry in the range 350−500 nm.[25] In the electronic spectra of the complexes with the pyrazole-based thiolate ligands **1**−**9** two absorption bands in the regions 484−660 nm and 410−530 nm were assigned to transitions from sulfur-containing MOs to the SOMO.[19] A third absorption at shorter wavelength should be superimposed by the long-wavelength side of the intraligand (IL) π-π* absorption bands. Due to the strong delocalization calculated for the S-containing donor orbitals of the electronic transitions, the lowest energy absorption of the complexes **1**−**9** should possess π-π* character.

Increasing tetrahedral distortion of $[CuN_2S_2]$ complexes leads to red-shifted absorption in the UV/Vis spectra.[10][32] EHMO calculations confirm these experimental findings. With an increasing dihedral angle θ between the planes N_1CuS_1 and N_2CuS_2, the energy of the SOMO (its antibonding nature is the largest in the planar arrangement) is

successively decreased with increasing θ, whereas the energies of the doubly occupied S-containing MOs and the lowest unoccupied MOs remain nearly constant. In order to make the energetical changes in the frontier orbital region more obvious and to simplify the MO analysis by excluding the backbones between the two imine nitrogen atoms a purposely idealized C_{2v} model system **A** with planar NC_3S groups has been considered (Figure 9). Fixed averaged bond lengths and angles obtained from the structural data of complexes **1**, **5**, and **6** have been used as idealized geometrical parameters of the NS ligands. The hydrogen atoms were calculated in ideal positions.

The results of EHT calculations clearly show the overlap between d functions and ligand orbitals of appropriate symmetry to be most effective for $\theta = 0$. One ligand of the model fragment was fixed and the other ligand was stepwise rotated around the bisector of the N_1-Cu-S_1 angle simulating an increasing θ. This method has limitations in fitting to the actual structures that are in contrast to the actual molecules, the S_1-Cu-S_2 bite angles are successively increased in the model fragment with increasing θ. Regardless of this limitation, the more the ligand field is distorted (pointgroup changes from C_{2v} for $\theta = 0$ to C_2 for $\theta > 0$), the more the SOMO is stabilized (Figure 10). The SOMO ($2b_2$ for $\theta = 0$ or $3b$ for $\theta > 0$) is an antibonding orbital constructed with σ-type lone-pair orbitals from the four donor atoms and the copper d_{xy} AO. A considerable admixture of Cu p functions to $3b$ is observed for the nonplanar C_2 systems.

The highest fully occupied MO ($1a_2$ for $\theta = 0$, $2a$ for $\theta > 0$) is vice versa destabilized with increasing θ, but no orbital crossing occurs between SOMO $3b$ and the fully occupied orbital $2a$ for $0 \leq \theta \leq 90°$. The unoccupied π* MOs $3a$ and $4b$ and the π MO $2b$ are nearly unaffected by the

geometrical changes, and the levels 1*b* and 1*a* display only minor shifts. Generally it is hard to detect any further trends for these levels and for the interpretation of the electronic spectra of complexes **1**−**9**, because of the orbital mixing of all close-lying orbitals of the same symmetry type (*a* or *b*).

The results of the EHMO calculations are also in good agreement with the EPR data for complexes **1**−**9**. All complexes considered display typical Cu^{II} EPR signals with the four copper lines showing additional hyperfine splitting due to the coordination of two nitrogen donors (Table 6). The a_0^{Cu} values for **1**−**4** are as expected for planar Cu^{II} chromophores ($79-80\times10^{-4}$ cm^{-1}), while **5** shows a decreased a_0^{Cu} value due to a noticeable tetrahedral distortion. With a stronger deviation from the planar donor arrangement, the a_0^{Cu} values decline considerably, with the lowest value being obtained for **9**.

Because of the relatively low g values, the copper d orbital contribution to the SOMO of **1**−**9** was estimated from the EPR data.[33] The results obtained are comparable with data from MO calculations yielding a copper contribution to the SOMO of approximately 30−40%. The overall copper contribution on this orbital splits between the p and d functions and remains unaffected by the tetrahedral twist, but the more distorted systems show weaker contributions of the d functions to the SOMO. This finding points to an increased covalency in the tetrahedrally more distorted complexes.

The stepwise decrease of the energy of the SOMO with an increasing dihedral angle θ also influences the redox potentials of compounds **1**−**9**. A detailed description of this electrochemical behaviour of **1**−**9** is given elsewhere,[13] but the trend is that the higher the degree of distortion, the easier the compound can be reduced (Table 6). However, the positive shift of the reduction potentials with increasing tetrahedral distortion within the complex series can only be found after separating the aromatic bridged complexes **1**−**4**, **8**, and **9** from the aliphatic bridged compounds **5**−**7**. This result shows the limits of EHMO calculations in predicting the electrochemical behavior of the considered complexes. The oxidation potentials of **1**−**9** seem to be independent of the coordination geometry. In correlation to the calculated orbitals, the nature of the orbital where the electron is removed from is obviously similar for all considered complexes.

Conclusions

The tetrahedral distortion of the donor sphere in the considered complexes can be influenced by the choice of diamines used for the preparation of the Schiff base ligands. The stereochemistry observed for the different complexes is mainly a result of the interaction between the steric requirements introduced by the ligands and the increasing stabilizing bonding interactions (SOMO) which occur when the ligand field is distorted from planarity. The MO studies of these complexes are complicated by the orbital mixing correlating with the absence of any symmetry elements. The presented results confirm that the unpaired electron is localized in an antibonding orbital formed by σ-type lone pairs of the ligand and a mixed copper p and d contribution. The energy of the SOMO drops and the Cu p contribution increases with larger tetrahedral distortion of the [CuN_2S_2] group. These effects are reflected in bathochromically shifted CT absorptions in the UV/Vis spectra and positively shifted reduction potentials. The increased covalence nature in the tetrahedrally distorted complexes is manifested in declining coupling constants a_0^{Cu} in the EPR spectra of the studied complexes.

Experimental Section

General: Analytical-grade chemicals were used as received from Fluka (several diamines), Laborchemie Apolda [$Cu(CH_3COO)_2$-H_2O] and Merck (solvents for spectroscopy). Elemental analysis were carried out with a Heraeus CHN-O-RAPID analysator. NMR spectra were recorded with a 400-MHz spectrometer (Unity 400, Varian) at room temperature in $CDCl_3$. Electronic spectra were measured with a CARY 3 UV/Vis spectrometer (Varian). An ESP 300E (Bruker) spectrometer (X-band 9.8 GHz) was used to record the ESR spectra at 293 K and at 130 K. − The Schiff base ligands H_2**5**, H_2**6**, and H_2**8** were synthesized according to a literature procedure.[18] This method was extended to prepare the new ligands H_2**1**−H_2**4**, H_2**7**, and H_2**9**.

Schiff Base $H_2$1: M.p. 267°C. − ^{1}H NMR ($CDCl_3$): δ = 7.21−7.83 (m, aromatic H), 1.58 (s, −CH_3), 16.10 (s, >N−H···). − ^{13}C NMR ($CDCl_3$): δ = 15.62 (s, −CH_3), 151.65 (s, >C=N−N), 113.46 (s, >C=), 168.95 (s, >C=S), 166.29 (s, >C=N), 125.50−139.25 (m, aromatic C). − $C_{44}H_{34}N_6S_2$ (710.9): calcd. C 74.34, H 4.82, N 11.82, S 9.02; found C 73.4, H 4.9, N 11.3, S 9.1.

Cu Complex 7: M.p. 262°C. − $C_{39}H_{36}CuN_6S_2$ (716.4): calcd. C 65.39, H 5.06, Cu 8.87, N 11.73, S 8.95; found C 64.2, H 5.1, Cu 9.6, N 12.1, S 8.2.

Cu Complex 8: M.p. > 306°C (decomp.). − $C_{46}H_{34}CuN_6S_2$ (798.5): calcd. C 69.19, H 4.29, Cu 7.97, N 10.52, S 8.03; found C 68.7, H 4.4, Cu 7.7, N 10.4, S 7.7.

Cu Complex 9: M.p. 346°C (decomp.). − $C_{54}H_{38}CuN_6S_2$ (898.6): calcd. C 72.18, H 4.26, Cu 7.07, N 9.35, S 7.14; found C 71.6, H 4.3, Cu 8.0, N 9.3, S 7.9.

X-ray Crystal-Structure Determination: Detailed structure data for H_2**5**, **1**, **2**, **5**, and **6** can be obtained from the Cambridge Crystallographic Data Centre. The deposition numbers are CCDC-101708 (H_2**5**), -101711 (**1**), -101712 (**2**), -101710 (**5**), and -101713 (**6**). Suitable crystals were obtained by diffusion of *n*-decane or *n*-hexane into saturated solutions of **1**, **2** and **6** in $CHCl_3$. Crystals of **5** precipitated during slow concentration of a saturated ethanolic solution at −20°C, single crystals of H_2**5** precipitated from an EtOH/$CHCl_3$ mixture. Crystallographic data for H_2**5**, **1**, **2**, **5**, and **6** are listed in Table 1. Selected bond lengths and angles are given in Tables 2 and 3. Figures 2−6 display thermal-ellipsoid drawings of 50% probability. Crystals were mounted on a glass pin. Data were collected at room temperature with a Siemens CCD diffractometer (SMART) operating in the ω-scan mode (**1**, **5**, **6**) or a Stoe four-circle diffractometer (STADI 4) operating in the ω/2θ-scan mode (**2**). Data for H_2**5** were collected with a Nonius CCD diffractometer. All diffractometers were equipped with a monochromator utilizing Mo-K_α radiation (λ = 0.7107 Å). Empirical absorption correction (SADABS[34]) was applied for **1**, **5**, and **6.** A ψ-scan correction was used for **2.** All observed reflections of H_2**5**, **1**, **5**, and **6** were used for refinement of unit-cell parameters. 80 reflections with 20° < Θ < 25° were selected for complex **2**. All structures were solved using direct methods (SHELXS[35]). Parameters were refined by full-matrix least-squares techniques (SHELXL[36]). Partly, the hydrogen atoms were calculated in ideal positions and their isotropic thermal parameters were fixed. For **5**, the water hydrogen atoms could not be localized in the structure.

Calculational Methods: The Extended Hückel LCAO Calculations[37] were carried out using methods as proposed by Mealli.[38] Considering the calculation of transition metal complexes, the weighted H_{ij} formula (modified Wolfberg-Helmholtz relation) for the off-diagonal elements (H_{ij}) was used, to take into consideration the counterintuitive orbital mixing.[39] Single Slater-type orbitals were used for the main-group elements as well as for the s and p functions of the metal ion, whereas d wave functions were taken as contracted linear combinations of two Slater-type functions as proposed by Richardson.[40] The crystallographic data (atomic coordinates) of the complexes **1**, **2**, **5**, **6**, and **8** (Cambridge Crystallographic Data Centre) were taken for the calculations to fit the molecular geometry. In all cases the phenyl rings on C(1) and C(18) were replaced by hydrogen atoms calculated in ideal positions. Atomic coordinates for dimethyl *N*,*N*′-ethylenebis(L-cysteinato)-*S*,*S*′]copper(II) were included for comparison (Cambridge Crystallographic Data Centre).

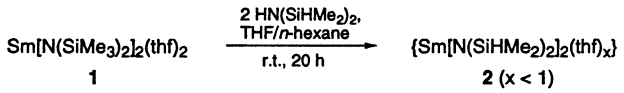
The First Oligomeric Samarium(II) Silylamide: Coordinative Saturation through Agostic Sm···SiH Interactions

Iris Nagl,[a] Wolfgang Scherer,[a] Maxim Tafipolsky,[a] and Reiner Anwander*[a]

Keywords: Agostic interactions / Samarium / Silylamide / Transsilylamination / Trinuclear complex



$Sm[N(SiMe_3)_2]_2(thf)_2$ reacts with 1,1,3,3-tetramethyldisilazane by a transsilylamination reaction to form the hexane-soluble $Sm[N(SiHMe_2)_2]_2(thf)_x$ in high yield. An X-ray diffraction study reveals a novel trinuclear complex of composition $Sm\{[\mu\text{-}N(SiHMe_2)_2]_2Sm[N(SiHMe_2)_2](thf)\}_2$ featuring a bent array of metal centers. Multiple metal···SiH β-agostic interactions sterically and electronically saturate the samarium(II) centers implying a new coordination mode of the bridging amide ligands.

Introduction

Sterically encumbered amide ligands are known to stabilize the lower oxidation states of transition metals efficiently.[1][2] However, complexes of strong reductants such as $Sm^{(II)}$ ($E_0 = -1.55$ V) display an intrinsic instability in the presence of β-H atoms and functional groups.[3] Donor ligand coordination and ate complex formation usually add to complex stability by counteracting oligonuclear aggregation and subsequent disproportionation reactions.[2][4] Recently, we introduced the bis(dimethylsilyl)amide ligand, $N(SiHMe_2)_2$, into organolanthanide chemistry which imparts (i) increased complex stability relative to the similarly sized $NiPr_2$ ligand, and (ii) enhanced steric flexibility relative to the commonly employed $N(SiMe_3)_2$ ligand.[5] In addition, the Si−H moiety proved to be an excellent spectroscopic probe prone to unique agostic, "Ln···SiH", interactions.[6] This paper describes how the Si−H functionality can also provide a stabilizing environment in samarium(II) chemistry.

Results and Discussion

When $SmI_2(thf)_2$[7] was allowed to react with 1.95 equivalents of $Li[N(SiHMe_2)_2]$, in THF at ambient temperature, the color of the suspension turned from dark green to black. Evaporation of the solvent gave a residue whose IR spectrum showed the presence of samarium-bonded $N(SiHMe_2)_2$ ligands. However, tractable $Sm^{(II)}$ species soluble in *n*-hexane or toluene could not be isolated.

Scheme 1. Synthesis of complex **2**

In order to exclude any ate complex formation or alkali metal salt contamination, we performed a transsilylamination reaction, using $Sm[N(SiMe_3)_2]_2(thf)_2$[4a] (**1**) and $HN(SiHMe_2)_2$ as reagents (Scheme 1). A similar transsilylamination reaction was recently used to form $Na[N(SiHMe_2)_2]$ by exploiting the difference in the pK_a values of the parent silylamines [pK_a(THF): 25.8 $HN(SiMe_3)_2$), 22.6 $HN(SiHMe_2)_2$].[8] Following this procedure, the compound $Sm[N(SiHMe_2)_2]_2(thf)_x$ (**2**) was obtained in almost quantitative yield. IR spectroscopy confirmed the coordination of the bis(dimethylsilyl)amide ligand by the appearance of a very strong SiH stretching vibration at 2040 cm^{-1} (free silylamine: 2118 cm^{-1}). Additionally, a broad lower energy shoulder at approximately 1936 cm^{-1}, indicative of agostic interactions, was observed. The ^1H NMR spectrum of **2**, measured in [D_8]tetrahydrofuran, showed two resonances at $\delta = -2.47$ and -12.18 in a ratio of 6:1, respectively, as would be expected for an intact $N(SiHMe_2)_2$ ligand. Recrystallization of compound **2** from *n*-hexane/THF (4:1) solutions at −35°C yielded black, rhombic single crystals (**2a**). Both the crude reaction product **2** and the crystals **2a** gave similar ^1H NMR spectra in [D_6]benzene displaying at least five resonances. Although a variable-temperature ^1H NMR spectroscopic study showed the coalescence of some signals at −60°C, which is in agreement with the presence of differently coordinated amide ligands, the resonances ranging from $\delta = 14$ to -40 proved of little diagnostic value.

An X-ray crystallographic study of **2a** revealed an unprecedented, trinuclear molecular structure of composition $Sm\{[\mu\text{-}N(SiHMe_2)_2]_2Sm[N(SiHMe_2)_2](thf)\}_2$. As shown in Figure 1, three samarium(II) atoms are arranged in a bent fashion ("Sm···Sm···Sm" 130°). In contrast, the structurally related heteroleptic complexes $Yb\{[\mu\text{-}DAC]Yb[N(SiMe_3)_2]\}_2$ (DAC = deprotonated 4,13-diaza-18-crown-6)[3c] and $Mn\{[\mu\text{-}NHC_6H_3iPr_2\text{-}2,6]_2Mn[N(SiMe_3)_2]\}_2$[9] show almost linear arrays of metal centers ["M···M···M" 176.9(1)° and 170.3(1)°, respectively]. The central Sm(1) is formally four-coordinate − the nitrogen atoms of the bridging amide ligands producing a distorted tetrahedral SmN_4 core coordination ["N−Sm(1)−N"

84.00(7)−143.83(7)°]. The formal four-coordination of the terminal samarium atoms, which are approximately related by a C_2 axis through Sm(1), is completed by terminal amide and THF donor ligands.

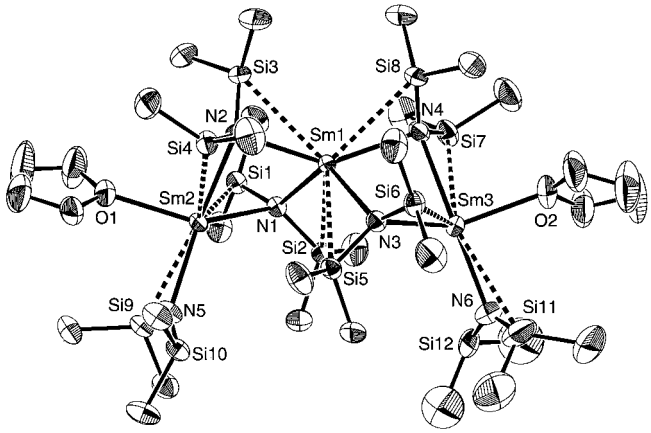

Figure 1. Molecular structure of **2a** (PLATON, 50% probability level). Hydrogen atoms and one part of the disordered Si(12)Me_2 group are omitted for clarity. Selected interatomic distances (Å) and angles (°): Sm(1)−Sm(2) 3.6920(2), Sm(1)−Sm(3) 3.6999(3), Sm···Si 3.2317(9)-3.342(1); N−Sm(2)−N 81.09(7)-146.27(7), N−Sm(2)−O(1) 88.35(8)-136.76(7), N−Sm(3)−N 82.48(7)−152.8(1), N−Sm(3)−O(2) 89.5(1)-134.61(9), Sm(1)−N(1)−Si(1) 132.7(1), Sm(1)−N(1)−Si(2) 96.04(9), Sm(1)−N(2)−Si(3) 94.7(1), Sm(1)−N(2)−Si(4) 128.0(1), Sm(1)−N(3)−Si(5) 96.10(9), Sm(1)−N(3)−Si(6) 130.5(1), Sm(1)−N(4)−Si(7) 127.7(1), Sm(1)−N(4)−Si(8) 95.0(1), Sm(2)−N(1)−Si(1) 92.1(1), Sm(2)−N(1)−Si(2) 122.4(1), Sm(2)−N(2)−Si(3) 127.9(1), Sm(2)−N(2)−Si(4) 93.7(1), Sm(2)−N(5)−Si(9) 100.5(1), Sm(2)−N(5)−Si(10) 130.8(1), Sm(3)−N(3)−Si(5) 122.3(1), Sm(3)−N(3)−Si(6) 92.9(1), Sm(3)−N(4)−Si(7) 94.5(1), Sm(3)−N(4)−Si(8) 127.6(1), Sm(3)−N(6)−Si(11) 106.8(2).

The coordination mode of the bridging amide ligands is asymmetric since the N atoms are located closer to the central Sm(1) atom [av. Sm(1)−N 2.633 Å]. The remaining Sm−N bond lengths associated with the bridging amide ligands range from 2.664(2) to 2.723(2) Å and are the longest Sm−N σ-bonds observed so far. In comparison, the bridging Sm−N bond lengths in $MSm[N(SiMe_3)_2]_3$ average 2.560(6) Å (M = Na) and 2.529(3) Å (M = K), respectively,[2] while the Sm−N bond lengths in $Sm[HB(3,5\text{-}Me_2pz)_3]_2$ (pz = pyrazolyl) are 2.617(4) Å.[10] The two terminal amide ligands are *cis*-orientated and have Sm−N lengths [av. 2.470 Å] comparable with those of the formally four-coordinate complex **1** [av. 2.433 Å]. The Sm−O distances average 2.552 Å and are in the expected range {**1**, av. 2.596 Å; $Sm[N(SiMe_3)(C_6H_3iPr_2\text{-}2,6)]_2(thf)_2$, av. 2.550 Å}.[4]

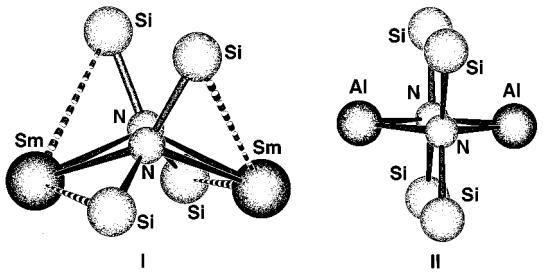

Figure 2. Bridging modes of the $N(SiHMe_2)_2$ ligand

A closer examination of the bridging silylamide ligands reveals a novel coordination mode featuring "SiNSi moieties" tilted towards the metal centers (**I** in Figure 2). This asymmetric ligand coordination is confirmed by the Sm−N−Si angles, which vary between 92.1(1) and 132.7(1)°. Apparently, coordinatively unsaturated and electron-deficient Sm^{II} centers favor the formation of close Sm···SiH β-agostic interactions involving all of the $SiHMe_2$ groups. The resulting Sm−Si (av. 3.273 Å) and Sm−H contacts (av. 2.75 Å) are remarkably short. In contrast, the shortest Sm−Si distance in **1** showing Sm···$SiCH_3$ contacts is 3.467 Å.[4a] The two terminal amide ligands in complex **2a** also show close Sm···SiH contacts. Taking the Sm···SiH β-agostic interactions into account a coordination number of 8 and 7 can be assigned to the central and terminal Sm atoms, respectively. The complex $\{Me_2Al[(\mu\text{-}N(SiHMe_2)_2]\}_2$ displays an unperturbated geometry (**II** in Figure 2) due to minimum attractive Al···SiH interactions [Al−N−Si 111.5(1)°].[11]

Conclusions

We have reported the first homotrinuclear samarium(II) amide featuring an unusual oligomeric structure. Considering the solid-state structures of mononuclear, solvated $Sm[N(SiMe_3)_2]_2(thf)_2$ (**1**) and dinuclear, unsolvated $\{Yb[N(SiMe_3)_2]_2\}_2$,[12] on one hand this novel structural motif might be attributable to the decreased steric bulk of $N(SiHMe_2)_2$,[5] which favors aggregation. On the other hand β-agostic Sm···SiH interactions seem to be markedly stronger than Sm(Yb)···$SiCH_3$ γ-agostic interactions as evidenced by the displacement of donor (THF) molecules. The toleration of SiH functionalities might have implications for the use of $Sm^{(II)}$ reagents in organic synthesis. We are currently investigating the feasibility of ligand exchange reactions of $Sm[N(SiHMe_2)_2]_2(thf)_x$ (**2**) with bulky protic subtrates.

Experimental Section

General: All manipulations were performed in a argon-filled glovebox (MBraun MB150B-G-II). Solvent pretreatment and physical characterizations were conducted as described previously.[5] $SmI_2(thf)_2$,[7] $Li[N(SiHMe_2)_2]$[8] and **1**[4a] were synthesized according to known procedures.

Sm^{II} Silylamide 2 (2a): A solution of 1,1,3,3-tetramethyldisilazane (0.587 g, 4.40 mmol) in THF (5 mL) was added to a solution of **1** (1.231 g, 2.00 mmol) in THF (15 mL) and stirred at ambient temperature for 20 h, whereupon the color of the solution turned from purple to black. Evaporation of the THF afforded a black powder **2** (yield > 95%) which completely dissolved in *n*-hexane and gave crystals of **2a** after recrystallization from *n*-hexane/THF. − IR (Nujol): $\tilde{\nu}$ = 2040 s, 1936 m sh, 1243 vs, 1039 vs, 954 vs, 893 vs, 836 vs, 785 s, 762 s, 680 m, 626 m, 599 w cm^{-1}. − ^1H NMR (270.16 MHz, $[D_8]$THF): δ = −2.47 (s, 6 H), −12.18 (s, 1 H). − ^{13}C (67.93 MHz, $[D_8]$THF): δ = 14.7. − MS (CI); *m/z* (%): 547 {2, $Sm[N(SiHMe_2)_2]$}, 532 [3, $\{Sm[N(SiHMe_2)_2]_3 - Me\}^+$], 415 {21, $Sm[N(SiHMe_2)_2]_2$}. − $C_{32}H_{100}N_6O_2Si_{12}Sm_3{\cdot}C_6H_{14}$ (1475.47): calcd. C 30.93, H 7.79, N 5.70; found (**2**) C 29.5, H 7.4, N 5.6; found (**2a**) C 29.7, H 7.6, N 5.6.

X-ray Crystal Structure Analysis of 2a: $C_{32}H_{100}N_6O_2Si_{12}Sm_3$, M = 1389.35; monoclinic, space group $P2_1/c$, a = 11.4620(7), b = 28.873(2), c = 22.064(1) Å, β = 96.605(6), V = 7253.4(8) Å^3, T = 173(1) K, Z = 4, $F(000)$ = 2816, D_c = 1.272 g cm^{-3}, μ = 2.62 mm^{-1}. 122106 (17029 unique) Bragg reflections with $\sin\Theta/\lambda_{max}$ = 0.66 Å^{-1} were collected on an image plate system from STOE IPDS[13] with a rotating anode generator (Nonius FR591; Mo-K_α, λ = 0.71073 Å). 12806 independent reflections. Full-matrix least-squares refinement of 537 parameters against 11255 observed reflections reflections ($\sin\Theta/\lambda_{max}$ = 0.6 Å^{-1}) converged to $R1$ = 0.023, $wR2$ = 0.061, residual electron density: +0.95/-0.46 eÅ^{-3}.[14] The terminal Si(12)Me_2 moiety was described by a disordering model with two split Si positions. One of the resulting $SiMe_2$ groups (occupation factor 0.43) displays an additional Sm···SiH β-agostic interaction. The positions of the agostic hydrogen atoms in the nondisordered $SiHMe_2$ groups were refined. Furthermore, disordered *n*-hexane molecules were located in a potential solvent accessible area of 243 Å^3. However, the BYPASS method[15] was applied to account for the disordered solvent contribution to the structure factor in the final refinements. Structure graphics were performed with the programs PLATON[16] and SCHAKAL.[17] Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-118713. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

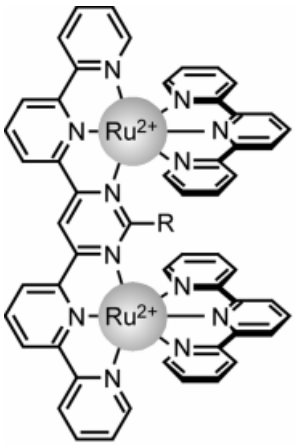
Absorption and Emission Properties of Di- and Trinuclear Ruthenium(II) Rack-Type Complexes

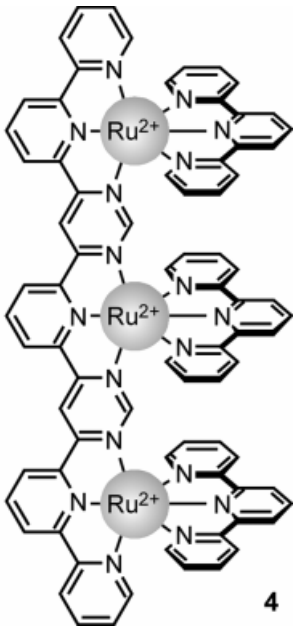


Paola Ceroni,[a] Alberto Credi,[a] Vincenzo Balzani,*[a] Sebastiano Campagna,*[b] Garry S. Hanan,[c] Claudia R. Arana,[c] and Jean-Marie Lehn*[c]

Keywords: Ruthenium complexes / Luminescence / Bridging ligands / Terpyridine ligands / Polynuclear metal complexes

The absorption spectra and the luminescence properties of three dinuclear Ru^{II} complexes and one trinuclear Ru^{II} complex have been investigated. All the complexes have rack-type structures. The dinuclear complexes **1**, **2**, and **3** incorporate a bis-tridentate bridging ligand made up of a pyrimidine and four pyridine moieties, as well as two 2,2′:6′,2"-terpyridyl (tpy) ligands. The trinuclear complex **4** incorporates a tris-tridentate bridging ligand made up of two pyrimidine and five pyridine moieties, as well as three tpy ligands. The absorption spectra of the complexes show a large number of ligand-centered (LC) and metal-to-ligand charge-transfer (MLCT) bands. All the complexes exhibit emission from a triplet MLCT state, with maxima in the spectral range 840–950 nm (lifetimes between 40 and 80 ns) at 298 K in fluid solution, and in the spectral range 760–810 nm (lifetimes between 2 and 3 μs) at 77 K in rigid matrices. A fine tuning of the absorption and luminescence properties of complexes **1**–**3** can be achieved by changing the substituents on the pyrimidine ring of the bridging ligand. Efficient energy transfer within the rack structure **4** occurs from the (upper-lying) central metal-based chromophore to the (lower-lying) peripheral ones.

Introduction



The assembly of molecular components into large, well-defined, and functional arrays (supramolecular species) is currently a major research theme.[1][2] Ruthenium(II) and osmium(II) complexes with polypyridine-type and related ligands are particularly useful units in the design of photo- and redox-active multi-component systems.[3] Some of us have recently reported the synthesis of rack-type polynuclear Ru^{II} complexes based on bis-tridentate and tris-tridentate bridging ligands made up of pyrimidine and pyridine coordinating moieties, as well as 2,2′:6′,2″-terpyridyl (tpy) ligands.[4][5] Such systems, as well as the related ladder-[6a] and grid-type[6b−6d] multi-metallic assemblies, exhibit structures of potentially great interest for the development of photonic and electronic devices.[1−3,7] We report herein the results of an investigation on the absorption spectra and luminescence properties of three dinuclear Ru^{II} complexes **1**−**3** and a trinuclear Ru^{II} complex **4** with rack-type structures. The synthesis and NMR characterization of the trinuclear complex are also described.

Results and Discussion

The dinucleating bis-tridentate ligands of complexes **1**−**3** differ only in the nature of the substituents attached at the pyrimidine unit. X-ray crystal structure analyses[4] of **1**−**3** have shown that the metal-to-metal distance and the center-to-center distance of the central pyridine units of the tpy ligands increase with increasing size of the substituent. Non-negligible differences have also been found in the pinching angle of the bis-tridentate ligand and in the convergence angle of the two ancillary tpy ligands. The sub-

stituents can, of course, also be expected to influence the electronic properties of the ligands.

NMR Characterization of Complex 4

The proton chemical shifts measured for the three terpyridine (tpy) ligands and the tris-tridentate ligand present in **4** are collected in Tables 1 and 2, respectively. Also included in Table 1 are the chemical shift differences (in ppm) between the tpy units of complex **4** and $[Ru(tpy)_2]^{2+}$ **5** ($\Delta\delta$ **5**),[8] and in Table 2, the chemical shift differences (in ppm) between **4** and **1** ($\Delta\delta$ **1**). The importance of comparing the ^1H chemical shifts to those of a related complex rather than to those of the free ligand should be clear. Shielding effects exist between the terminal pyridines in the free ligand because of nitrogen lone pair induced helication.[9] On forming the trimetallic complex, these shielding effects are no longer present, making most of the protons in the free ligand strongly deshielded in the metal complex. The assignments were made by the following methods: comparing proton coupling constants, decoupling experiments, comparing spectra, and verifying heterocycle connectivity using NOE.[10]

Table 1. Proton chemical shifts (in ppm) of terpyridine ligands in **4** and chemical shift differences between **4** and $[Ru(tpy)_2]^{2+}$ **5**[a] in CD_3CN; T denotes peripheral tpy hydrogens and T* denotes central tpy hydrogens

	T6	T5	T4	T3	T3′	T4′

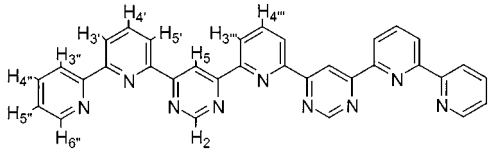
4 (H_{T*})	6.80 [b]	6.80 [b]	7.74	8.29	8.65 [b]	8.64 [b]
$\Delta\delta$ **5**	−0.53	−0.50	−0.17	−0.19	−0.09	+0.24

[a] Data for **5** taken from ref.[8] – [b] Central position of multiplet.

In the trimetallic complex **4**, the tpy protons are in a peripheral-to-central ratio of 2:1. The central tpy protons (H_{T*}) are more shielded than the peripheral tpy protons (H_T), as would be expected as the central tpy site is flanked by two peripheral tpy′s, whereas the peripheral tpy′s have only the central one in their vicinity.



Comparison of the chemical shifts of central pyridine in the ligand with those of the central pyridines in $[Ru(tpy)_2]^{2+}$ (**5**) allows determination of the $\Delta\delta$ **5** values for $H_{3'''}$ and $H_{4'''}$. The values are indicative of greater deshielding for $H_{3'''}$ than for $H_{4'''}$. This may be due to the preferred orientation of the terminal pyridine on the central terpyridine towards one side of the central pyridine of **L**, resulting in greater deshielding at $H_{3'''}$ and H_5 (Figure 1). The large deshielding value for H_5 in **4** as compared to **1** ($\Delta\delta$ **1**) may be explained in terms of the distorted positioning of the terminal pyridine of the central and peripheral terpyridines in **4** (Figure 1). The individual terpyridines sites in **1** are disymmetric in the solid state, as shown by the X-ray structure.[4] The terpyridines in **4** may behave similarly. This is also supported by NOE interactions, which are found between H_{T5} and H_{T5*} as well as H_{T6} and H_{T5*}. The motion represented in Figure 1, which is expected to be fast on the NMR timescale, leads to an averaged symmetry.

Absorption Spectra

The absorption spectra of compounds **1**, **2**, and **4** (acetonitrile solution, 298 K) are shown in Figures 2 and 3. The wavelengths of the absorption maxima and the values of the molar absorption coefficients for complexes **1**−**4** and the model compound $[Ru(tpy)_2]^{2+}$ (**5**) in the visible region are listed in Table 3.

The UV region of the absorption spectrum of each of the complexes is dominated by a variety of intense bands that can be assigned to ligand-centered (LC) transitions of the tpy ligands and of the multi-tridentate bridging ligands. In the visible region, several weaker bands are present, attributable to metal−to−ligand charge-transfer (MLCT) transitions.[3] At first glance, one could distinguish three types

of ligand units (tpy, bpy, and pyrimidine) in the metal coordination spheres, but it should be noted that the latter two units are conjugated so that it is probably more correct to treat the multi-tridentate bridging ligands as single large molecules.[2]

Complexes 1−3: Electrochemical measurements[4] show that these complexes undergo two (metal-centered) oxidation processes at about +1.4 and +1.5 V vs. SCE, and several (ligand-centered) reduction processes. The separation between the two oxidation waves of the formally equivalent Ru^{II} ions shows that the metal−metal interaction through the bis-tridentate ligands is not negligible, as is typical for this kind of bridging ligand.[3d] The first two reduction processes, which occur around −0.5 and −1.1 V, can be assigned to successive reductions of the bridging ligand. As expected,[3a] reduction of the tpy ligands occurs at more negative potentials (around −1.5 V).

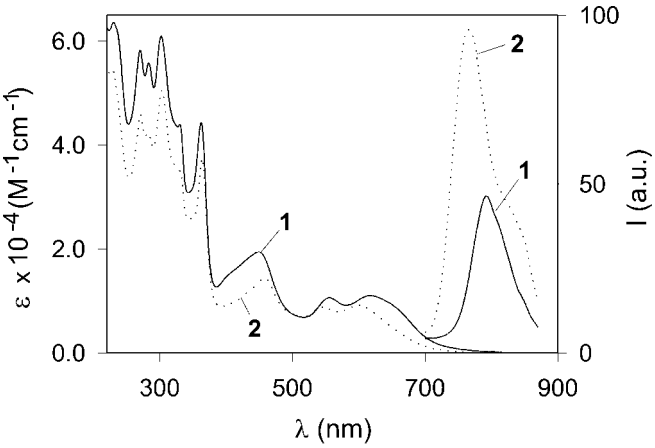

Figure 2. Absorption spectra in acetonitrile solution at 298 K (left scale) and emission spectra in a rigid butyronitrile matrix at 77 K (λ_{ex} = 480 nm; right scale) of compounds **1** and **2**

The three MLCT absorption bands observed for compounds **1**−**3** in the visible region (Figure 2 and Table 3) can be straightforwardly assigned in the light of the electrochemical results. The two low energy bands, with maxima around 600 and 550 nm, are due to CT transitions to the first and second LUMO′s of the bridging ligand, respectively, while the higher energy band, with a maximum at around 450 nm, is due to a transition to the first LUMO of the tpy ligands. The difference between the potentials of the first and second reduction waves is much larger than the energy separation between the two lowest energy absorption bands because the second wave is associated with reduction of an already reduced ligand. This interpretation is consistent with the results obtained for a closely related dinuclear Ru^{II} rack containing an anthryl subunit.[11]

As can be seen from Figure 2, the presence of the methyl substituent on the pyrimidine ring in **2** displaces the

Ru→bridging ligand bands to higher energy and the Ru→tpy band to lower energy compared to the situation in **1**. This is due to the electron-donating nature of the methyl group, which has two effects: (i) it increases the electron density on the bridging ligand and therefore raises the energy of its LUMO′s; (ii) by increasing the σ-donor power of the pyrimidine nitrogens, it increases the electron density on the metal and therefore decreases the energy of the MLCT band involving the tpy ligands, which are unaffected by the pyrimidine substituent. The phenyl substituent present in **3** has a similar, albeit smaller, effect.

Complex 4: In the trinuclear compound **4**, the two lateral subunits are equivalent, but different from the central one. As expected, because of the larger number of subunits, the molar absorbance is enhanced compared to that of the dinuclear compounds over the entire UV/vis domain (Figures 2 and 3, Table 3). The lowest-lying MLCT band is displaced to lower energy compared to that of the dinuclear species, due to the more extended electronic delocalization on the bridging ligand (BL), which leads to a stabilization of its LUMO. Such a low-lying MLCT band (as well as the MLCT band involving the second LUMO of the bridging ligand) should receive contributions from two different Ru→BL transitions because, as mentioned above, the peripheral Ru^{II} metal ions are different from an electronic viewpoint compared to the central Ru^{II} metal ion, since the latter is coordinated by two pyrimidine rings. The central metal ion should be more difficult to oxidize than the peripheral ones, because pyrimidines are better electron acceptors than pyridines.[12] Indeed, this was confirmed by electrochemical studies. In fact, **4** exhibits a two-electron oxidation at +1.47 V vs. SCE in acetonitrile solution, associated with the peripheral non-interacting metal centers, followed by a one-electron oxidation process at +1.88 V, attributable to oxidation of the central metal subunit.[5] Although the lowest-lying MLCT band for **4** is large and exhibits a pronounced shoulder in its red tail, the expected two bands are not resolved, probably owing to their broadness and slight energy difference (Figure 3). Interestingly, two bands are evident in the absorption spectrum of the complex in the region corresponding to the Ru→tpy CT transitions (compare the 400−500 nm region in the absorption spectra shown in Figures 2 and 3). On the basis of the above considerations and the redox properties of **4**, these absorption bands can be assigned, in order of increasing energy, to Ru(peripheral)→tpy CT transition(s) and Ru(central)→tpy CT transition(s), respectively.

Luminescence Properties

The emission spectra of compounds **1**, **2**, and **4** (rigid butyronitrile matrix at 77 K) are shown in Figures 2 and 3. The wavelengths of the emission maxima and the excited-state lifetimes of all the complexes are collected in Table 3.

On the basis of the emission energies, spectra, and lifetimes,[3] the relatively weak emission exhibited by all the complexes can be assigned to the lowest ^{3}MLCT level,

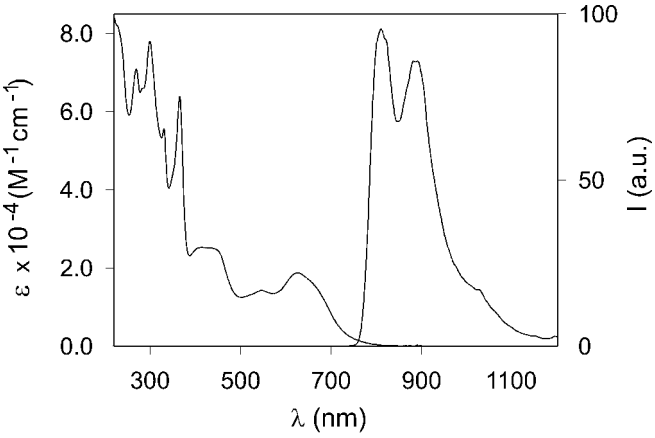

Figure 3. Absorption spectrum in acetonitrile solution at 298 K (left scale) and emission spectrum in a rigid butyronitrile matrix at 77 K (λ_{ex} = 488 nm; right scale) of compound **4**

which is associated with the bridging ligand. As already discussed for the absorption spectra, the nature of the substituent on the pyrimidine ring of the bridging ligand is responsible for fine-tuning the emission energy in **1**−**3**, with **2** exhibiting the highest energy emission (Table 3). The emission energy of **4** is lower than those of **1**−**3**, as expected considering the electronic and redox properties of the bridging ligand in **4**,[5] and according to the interpretation of the absorption data.

Compared with $[Ru(tpy)_2]^{2+}$,[3] the luminescence lifetimes of compounds **1**−**3** are longer at room temperature and shorter at 77 K (Table 3). This can be explained by recalling that the radiationless decay of the luminescent excited state in Ru^{II} polypyridine compounds occurs via an upper-lying metal-centered triplet (^{3}MC) level at high temperature and by vibronic coupling directly to the ground state at low temperature.[3] Since in compounds **1**−**3** the luminescent level is lower in energy than in $[Ru(tpy)_2]^{2+}$,[3] the activation energy for radiationless decay via the upper-lying MC level should be larger (with the reasonable assumption that in these complexes the ^{3}MC excited state has approximately the same energy), and the coupling with the ground state should be stronger. The shorter lifetime at room temperature and the longer lifetime at 77 K for **2** compared with **1** (Table 3) is in line with such an interpretation.

As mentioned above, the two metal-based chromophores of **1**−**3** are identical, whereas in **4** the central metal-based chromophore is different from the peripheral ones. Considering the different acceptor abilities of pyridine and pyrimidine rings and the oxidation behaviour of the complex (see above), the lowest ^{3}MLCT state of each peripheral subunit should be lower in energy than the corresponding level involving the central subunit. Because **4** contains two *different* metal-based chromophores, potentially luminescent from their respective lowest-lying ^{3}MLCT level,[3] two emissions could in principle occur. The insensitivity of the emission spectrum of **4** to the excitation wavelength (both at 77 K and at room temperature), the matching between the absorption and excitation spectra, and the pres-

ence of a single exponential luminescence decay with the same lifetime under all the experimental conditions, indicate that only the lowest-lying MLCT level of the assembly, associated with the peripheral chromophores, undergoes deactivation through radiative decay, whereas the upper-lying MLCT level, associated with the central subunit, transfers its electronic energy to the nearby chromophore. Thus, efficient energy transfer from the central chromophore to the peripheral ones occurs within the trinuclear rack.

Finally, the luminescence lifetimes of **1**−**3** at 77 K roughly obey the energy gap law,[13] but **4** exhibits a longer lifetime than expected in comparison with the dinuclear systems (**1**−**3**). This is probably due to the greater delocalization of the acceptor ligand of the MLCT luminescent level in **4**, which decreases the vibronic coupling between excited and ground states, thereby reducing the Franck−Condon factors for non-radiative decay.[14]

Conclusion

The absorption spectra and the luminescence properties of one trinuclear and three dinuclear ruthenium(II) rack-type complexes have been studied. The absorption spectra of the complexes show a multitude of LC and MLCT bands. All the complexes exhibit luminescence from the lowest-lying ^{3}MLCT level, both at 298 K in fluid solution and at 77 K in rigid matrices. The absorption and emission properties of the dinuclear compounds **1**−**3** are fine-tuned by the substituents on the pyrimidine ring incorporated in the bridging ligand framework. Excited-state decays are governed by direct vibronic coupling with the ground state at 77 K and by thermally-activated population of a close-lying ^{3}MC level at room temperature. In **4**, efficient electronic energy transfer occurs from the upper-lying central chromophore to the lower-lying peripheral ones. This result is of interest with regard to the possible development of larger (disymmetric) racks exhibiting vectorial energy and/or electron transfer within their structures

Experimental Section

The syntheses, characterization, and structures of compounds **1**−**3** have been described in detail elsewhere;[4] synthetic procedures for the preparation of **4** have also been outlined previously.[5] NMR instrumentation and methods used were as reported previously.[4]

Absorption and Luminescence Measurements: Absorption spectra were recorded with a Perkin−Elmer λ6 spectrophotometer in acetonitrile solution at room temperature. Luminescence experiments were performed in dilute (ca. 10^{-5} M) acetonitrile solution at room temperature and in rigid butyronitrile matrices at 77 K. Corrected luminescence spectra in the 700−850 nm range were obtained with a Perkin−Elmer LS-50 spectrofluorimeter. Corrected luminescence spectra in the 800−1200 nm range were obtained with an in-house constructed near-infrared spectrofluorimeter consisting of an Ar ion laser as excitation source (λ_{ex} = 488 nm), a monochromator (Edinburgh) with a grating of 1200 L/mm, and a liquid nitrogen cooled germanium detector and preamplifier (Northcoast, model EO-817 L). The sample (air-equilibrated CH_3CN solution) was placed in a 10 mm × 10 mm cuvette, and a beam chopper (Stanford Research, model SR540) was placed between the excitation source and the sample; luminescence was monitored at right angles to the excitation. A muon filter (Northcoast, model 829B) was used as an electronic signal filter, after the signal had been sent to a lock−in amplifier (Stanford Research, model SR510). Luminescence lifetimes were measured with an Edinburgh single-photon counting apparatus (D_2 lamp, λ_{ex} = 310 nm). Estimated errors are as follows: molar absorption coefficients, 10%; absorption maxima, ±2 nm; emission maxima in the visible range, ±2 nm; emission maxima in the near-infrared range, ±4 nm; emission quantum yields, 20%; excited-state lifetimes, 10%.

Preparation of Complex 4: To $Ru(tpy)Cl_3$ (0.0324 g, 0.0735 mmol) and free tris-tridentate ligand (0.0102 g, 0.0188 mmol) was added propan-2-ol/water (20 mL, 1:1) and *N*-ethylmorpholine (0.5 mL). The mixture was heated under reflux for 40 h, then cooled to room temperature and filtered. Excess aqueous NH_4PF_6 was added to the solution and the precipitate was collected. The solid was purified by successive recrystallizations from acetonitrile/toluene to afford **4** (0.0264 g, 58%) as a green solid. − M.p. > 300°C. − ^{1}H NMR (CD_3CN, 400 MHz); the subscript T indicates protons of the peripheral terpyridine ligands and T* indicates protons of the central terpyridine ligand: δ = 9.29 (s, 1 H, H_5), 9.20 (d, *J* = 8.4 Hz, 2 H, $H_{3''''}$), 9.12 (d, *J* = 8.4 Hz, 2 H, $H_{5'}$), 8.82 (d, *J* = 8.2 Hz, 2 H, $H_{3'}$), 8.65 (d, *J* = 8.4 Hz, 6 H, $H_{T3',\ T3'*}$), 8.64 (m, 2 H, $H_{4'''',T4'*}$), 8.51 (m, 4 H, $H_{4',T4'}$), 8.46 (d, *J* = 7.2 Hz, 2 H, $H_{3''}$), 8.34 (d, *J* = 8.2 Hz, 4 H, H_{T3}), 8.29 (d, *J* = 8.0 Hz, 2 H, H_{T3*}), 7.92 (td, *J* = 7.8, 1.5 Hz, 2 H, $H_{4''}$), 7.80 (td, *J* = 8.0, 1.5 Hz, 4 H, H_{T4}), 7.74 (td, *J* = 8.2, 1.9 Hz, 2 H, H_{T4*}), 7.27 (d, *J* = 5.0 Hz, 2 H, $H_{6''}$), 7.14 (ddd, *J* = 7.5, 5.7, 1.2 Hz, 2 H, $H_{5''}$), 7.01 (d, *J* = 5.5 Hz, 4 H, H_{T6}), 6.94 (ddd, *J* = 7.4, 5.7, 1.5 Hz, 4 H, H_{T5}), 6.80 (m, 4 H, $H_{T6*,T5*}$), 6.15 (d, *J* = 0.8 Hz, 1 H, H_2). − ^{13}C{^{1}H} NMR (CD_3COCD_3, 100 MHz): δ = 166.89, 165.32, 161.39, 158.43, 157.96, 157.07, 156.89, 155.57, 155.07, 154.67, 154.51, 153.92, 153.81, 153.16, 140.31, 140.16, 139.68, 139.65, 138.64, 137.13, 136.97, 129.59, 128.95, 128.86, 128.67, 127.93, 126.83, 125.67, 125.19, 124.98, 124.50, 118.50 (one overlapped resonance). − FAB: *m*/*z* (%): 2272 (40) $[M - PF_6]^+$, 2126 (100) $[M - 2\ PF_6]^+$, 1981 (62) $[M - 3\ PF_6]^+$, 1063 (36) $[M - 2\ PF_6]^{2+}$, 991 (78) $[M - 3\ PF_6]^{2+}$, 918 (33) $[M - 4\ PF_6]^{2+}$. − $C_{78}H_{54}F_{36}N_{18}P_6Ru_3{\cdot}4CH_3CN$: calcd. Dynamic Combinatorial Chemistry: Substrate H-Bonding Directed Assembly of Receptors Based on Bipyridine-Metal Complexes

Ivan Huc,[a] Michael J. Krische,[a] Daniel P. Funeriu,[a] and Jean-Marie Lehn*[a]

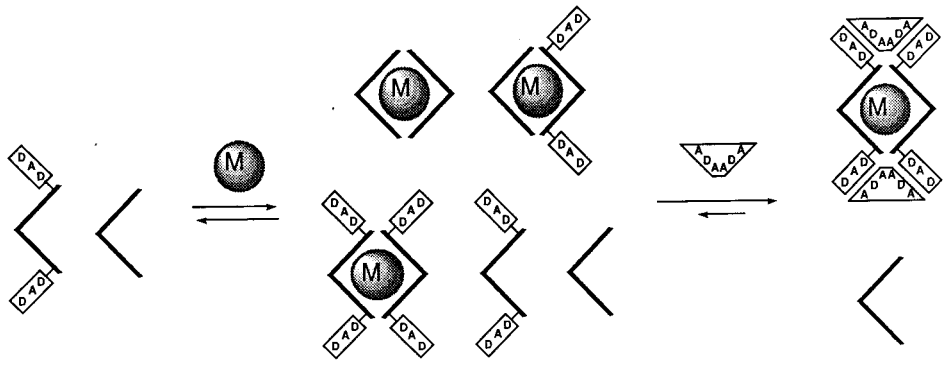
Keywords: Combinatorial chemistry / Molecular recognition / Functionalized bipyridine metal complexes / Janus molecules / Hydrogen bonding

The functionalized ligands **1** and **2** bearing hydrogen-bonding recognition groups have been synthesized. Their assembly by metal ions such as Cu^{I} and Pd^{II} having different coordination geometries generates different receptor architectures for the binding of suitable substrates. Addition of the complementary bis(imide) Janus molecules (**4**–**7**) to [**1a**, **2a**, CuTf] or to [**1b**, **2b**, $Pd(BF_4)_2$] mixtures leads to a moderate selective increase of the fraction of the $[(\mathbf{1a})_2Cu]^+$ or $[(\mathbf{1b})_2Pd]^{2+}$ complex depending on the Janus substrate used. Largest enhancements are observed for those Janus substrates that may be expected to display highest geometrical complementarity with the two complexes. These results represent a process directed by target binding based on dynamic combinatorial chemistry.

Introduction

The reversible connection of molecular building blocks generates potentially a set of molecular or supramolecular entities containing in principle all possible combinations of the constituents whose proportions are controlled by thermodynamic equilibria. This process may be considered as defining a dynamic combinatorial chemistry (DCC) that gives access to virtual combinatorial libraries (VCLs). In the presence of a species that binds one of the (real or virtual) members of such a library, a selective increase of the amount of this specific constituent may be expected, amounting to a target-directed enhancement of a member of the library. This is the case in the selective self-assembly of a pentameric circular helicate induced by the strong binding of a chloride ion, which led us to the DCC/VCL concept.[1] The latter was formulated in detail and extended to the recognition-induced assembly of an enzyme inhibitor.[2a] A major aspect of DCC is the search for suitable reversible processes.

Dynamic combinations of building blocks have made use of covalent linkages, such as the reversible formation of imines,[2] esters,[3] disulfides,[4] or the photoisomerization of alkenes[5] for the generation of equilibrating combinatorial libraries of receptor or substrate molecules. They may also be based on non-covalent linkages such as metal coordination,[1][6] hydrophobic effects,[7] or hydrogen bonding.[8] In the present work, we have taken advantage of the reversible assembly of ligands bearing recognition groups on a transition metal center for generating dynamic mixtures of artificial receptors.



The coordination of organic ligands to metal ions has proved an efficient approach to create cavities of defined shape and size and to preorganize recognition groups in space to generate binding cavities.[9] The combination of different ligands or the formation of coordination isomers has led to the construction of libraries of self-assembled receptors, in systems where each receptor was studied as a separate entity.[10] The use of *reversible* coordination to metal centers for assembling receptors has also been reported. It was shown that an appropriate guest can act as a template for the preferential formation of the receptor.[11]

In the present study, we take advantage of this phenomenon to identify, in a dynamic mixture of coordination receptors bearing hydrogen-bonding units, those presenting best complementarity to a particular substrate molecule of Janus type,[12] i.e. a molecule having two recognition faces. As depicted in Scheme 1, the mixture is based on the *reversible* coordination of pairs of ligands to a transition metal ion. Using two different ligands, a mixture of three different complexes can be generated. Each complex is defined by a recognition capability, which results from the combination of the recognition elements of its ligands. Thus, a complex made of two ligands possessing hydrogen-bonding functions with a Donor-Acceptor-Donor (DAD) pattern, potentially has an enhanced affinity for Janus molecules having twice the complementary ADA hydrogen-bonding pattern. Indeed, this complex may form six hydrogen bonds with the two faces of a Janus molecule, whilst the free ligand or a complex bearing only one such ligand can only form three hydrogen bonds with one face. Thus, a better recognition may be achieved by a combination of the recognition elements of two ligands than from one ligand only.

The main consequence of the involvment of two ligands from the same complex in the recognition event is the selective stabilization of the complex since the Janus molecule bridges the ligands through noncovalent interactions. The equilibria should thus be shifted towards the formation of the complex displaying the best complementarity to the Janus molecule. The free energy associated with this equilibrium shift corresponds to the differential binding energy of

Scheme 1. Dynamic mixture of ligands and complexes formed upon coordination of two different ligands to a transition metal; stabilization of a receptor complex (molding) with a complementary Janus substrate molecule; one ligand bears two recognition groups with DAD hydrogen-bonding pattern; the Janus-type substrate presents two complementary ADA patterns

the Janus molecule to one complex with respect to the other components of the mixture.

Another consequence of the equilibrium shift is the release of the other ligand from the complexes. Using an appropriate stoichiometry of ligands, metal ion, and Janus substrate molecule, this may ultimately lead to a situation where only one ligand participates to the coordination, the other remaining free in solution (Scheme 1). A good receptor is thus identified simply from the fact that it becomes more abundant in the presence of its complementary substrate.

Ligand Components

As metal coordination components, 2,2′-bipyridine units bearing diacylaminopyridine DAD hydrogen-bonding motifs in position 4 and 4′ were used (Figure 1). Molecules such as **1** possess one bidendate metal-binding center and can hydrogen-bond to two imide functions via a complementary DAD/ADA array of three hydrogen bonds.[13] Ligands **2** also have 4,4′-carboxamide groups, but lack the diacylaminopyridine moiety. This should confer on them electronic properties and affinities for transition metals

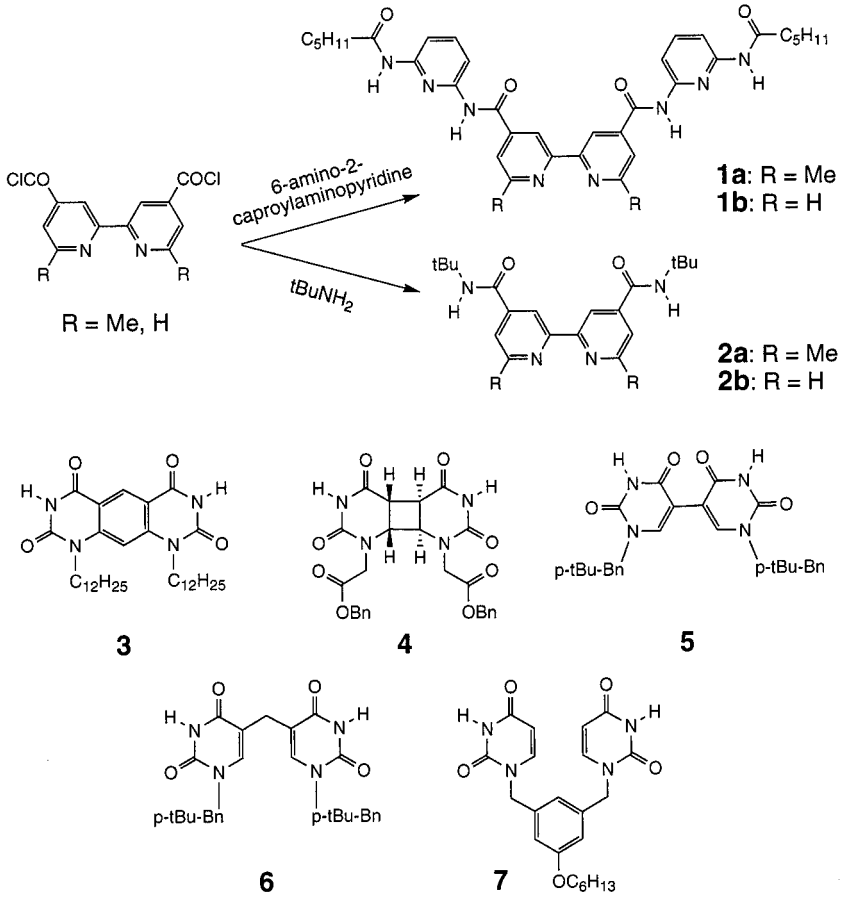

Figure 1. Functionalized ligands and substrate Janus molecules

similar to that of **1**, while keeping low hydrogen-bonding capacity to imide functions. Ligands **1** and **2** were prepared from the coupling of a 2,2′-bipyridine-4,4′-dicarbonyl chloride and either tBuNH$_2$ or 6-amino-2-caproylaminopyridine.

Janus molecules **3**−**7** all possess two hydrogen-bonding ADA imide functions as prime recognition elements. They thus all belong to the same interactional space and only differ by their geometrical properties. In **3** and **4**, the imide groups are rigidly held in parallel planes. In **5**, **6**, and **7** the imides are separated by an increasing number of single bonds, a feature that goes along with reduced preorganization and larger conformational freedom.

Copper(I) Complexes

Formation

Cu^I ions coordinate two bipyridine ligands in a distorted tetrahedral geometry, thus holding them in an approximately perpendicular arrangement ($\Phi \approx 90°$ in Figure 2). The 2,2′-bipyridine ligands **1a** and **2a** having methyl groups in the 6,6′ positions were preferred to **1b** and **2b** because their complexes with Cu^I are less labile, and less sensitive to oxidation by air. In pure chloroform at room temperature, the ligands exchange slowly on the NMR time scale. The signals observed in the ^{1}H-NMR spectrum of a solution of **1a**, **2a** (1 mM each) and CuTf (0.5 mM) can be assigned to a mixture of the five possible species by comparison with the individual spectra of **1a**, **2a**, (**1a**)$_2$CuTf, and (**2a**)$_2$CuTf. A series of six singlets is seen at $\delta = 2-2.8$, that correspond to the signals of the methyl substituents *ortho* to the bipyridine nitrogen atom (Figure 3A): one singlet for each free ligand, one singlet for each homocomplex, and two singlets of equal intensity for the mixed complex (**1a**)(**2a**)CuTf. Integration of these signals allows to measure the proportion of each species in the mixture. Due to a slightly higher intrinsic affinity of **2a** for Cu^I, (**2a**)$_2$CuTf is more abundant than (**1a**)$_2$CuTf, and **2a** and **1a**, respectively, represent 27% and 73% of the free ligands.

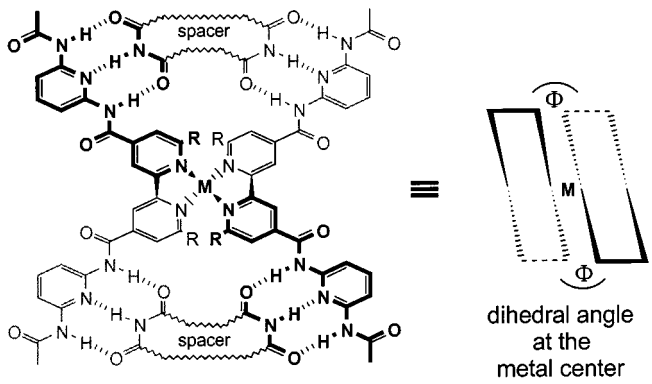

Figure 2. Schematic representation of the bridging of two ligands of a transition metal complex through hydrogen bonding to Janus molecules; the coordination sphere of the metal center determines the relative orientation of the aminopyridine moieties (Φ); the degree of complementarity of the Janus molecules is set by their spacer

Binding of Substrate Molecules

When a substrate **3**, **4**, **5**, or **7** (1 mM) is added to the mixture of complexes and ligands, the ratios [**1a**]/[**2a**] and [(**1a**)$_2$CuTf]/[(**2a**)$_2$CuTf] remained unchanged (Figure 3B). The signals assigned to **1a**, (**1a**)$_2$CuTf, and (**1a**)(**2a**)CuTf shifted upon the formation of hydrogen-bonded complexes, while those corresponding to **2a** and (**2a**)$_2$CuTf did not shift. This indicates that hydrogen bonding occurs between the imide and the diacylaminopyridine groups without specificity. None of these Janus molecules is capable of bridging two ligands on a same complex. On the other hand, hydrogen bonding of the Janus molecules to **2a** and (**2a**)$_2$CuTf is negligible. These results also indicate that hydrogen bonding to **1a** does not enhance its affinity for copper through any electronic effect.

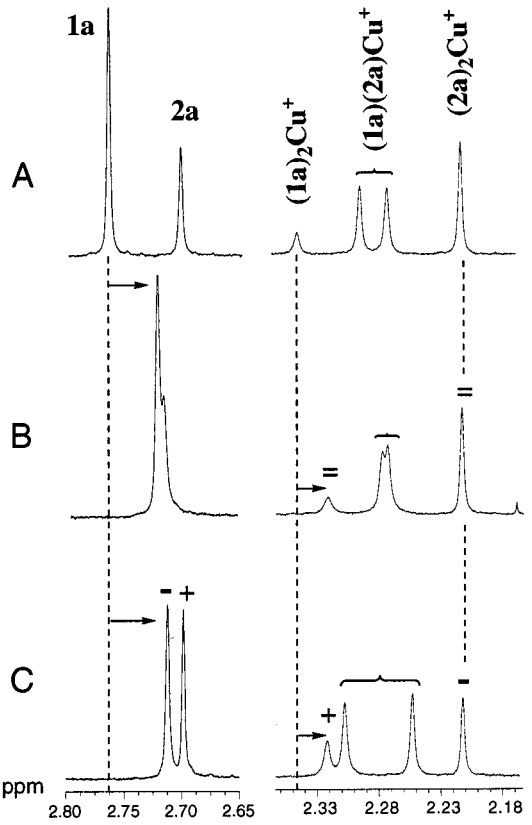

Figure 3. Part of the 500-MHz ^{1}H-NMR spectrum of a $CDCl_3$ solution of **1a**, **2a** (1 mM each) and CuTf (0.5 mM) at 298 K; the region at $\delta = 2.36-2.65$ is omitted for clarity; arrows indicate some of the shifts observed upon the addition of bis(imide) Janus substrate; A: no substrate added; B: **5** added (1 mM); C: **6** added (1 mM)

When the bis(imide) **6** (1 mM) was added to the mixture, similar shifts were observed, but the proportions between the different species were also modified (Figure 3C). The amount of (**1a**)$_2$CuTf was multiplied by a factor 2.3, and the proportions of **1a** in the free ligand decreased from 73 to 52%. Concomitantly the amount of (**2a**)$_2$CuTf decreased whilst the proportion of **2a** in the free ligands increased from 27 to 48%. The free energy difference between the two entities formed may be estimated to be about 4 kJ/mol.

The diacylaminopyridine groups of two different ligands in a Cu^{I} complex are more or less perpendicular. The capability of a Janus molecule to stabilize $(\mathbf{1a})_2$CuTf upon forming simultaneously hydrogen bonds with both ligands of the complex is thus linked to its ability of positioning its imide groups perpendicularly to each other. The results indicate that only **6** is able to do so at sufficiently low entropic and enthalpic costs. Thus, these experiments allowed to identify one Janus molecule to which $(\mathbf{1a})_2$CuTf binds selectively. However, the affinity for **6** remained small, and we searched for larger effects by changing the geometry of the complex. This was achieved by using Pd^{II} instead of Cu^{I}.

Palladium(II) Complexes

Formation

Pd^{II} can coordinate two 2,2′-bipyridines such as **1b** and **2b** which have no substituents in the 6 and 6′ positions in a square-planar arrangement ($\Phi \approx 0°$ in Figure 2). As a consequence, within a complex with **1b**, the aminopyridine moieties are held in the same plane. To form hydrogen bonds to both ligands of this complex, a Janus molecule should thus have coplanar imides diverging at an angle of ca. 120°, such as in **3** and **4**.

The bis(bipyridine)$-Pd(BF_4)_2$ complexes are not readily soluble in pure chloroform. In the following experiments this was circumvented by adding small amounts of DMSO (5%) to the mixtures, resulting in a satisfactory solubility whilst keeping competing hydrogen-bonding to the solvent low. In this solvent however, the ligand exchange is fast on the NMR time scale. For a mixture of **1b**, **2b**, and $Pd(BF_4)_2$, each ligand appears as one set of signals in the ^{1}H-NMR spectrum. The chemical shift of each signal is an average of its value for the free ligand and for the ligand complexed to Pd^{II}. From the chemical shift, one can access the proportion of free and complexed ligand, as illustrated by the titration experiment shown in Figure 4.

Increasing amounts of $Pd(BF_4)_2$ were added to a solution of **1b** and **2b** (1 mM each). Coordination to Pd^{II} causes a downfield shift of the bipyridines 3-H/3′-H, and amide NH signals. It is interesting to note that the 3-H/3′-H signal of **2b** shifts more at the beginning of the titration before reaching its limit value, whilst the 3-H/3′-H signal of **1b** follows a sigmoidal curve. As with Cu^{I}, this arises from a slightly larger affinity of ligand **2b** for Pd^{II}. During the titration, **1b** is involved in the complexes only in a second step, when the amount of free **2b** becomes smaller. When $[Pd(BF_4)_2]$ = 0.5 mM, 65% of **2b** and 35% of **1b** are coordinated to Pd^{II}.

Substrate Binding

The effect of the presence of the Janus molecules on the ^{1}H-NMR signals was first evaluated on **1b**, $(\mathbf{1b})_2Pd(BF_4)_2$, **2b**, $(\mathbf{2b})_2Pd(BF_4)_2$ individually. For **1b** and $(\mathbf{1b})_2Pd(BF_4)_2$ the introduction of imide units resulted in shifts similar to those observed for **1a** and $(\mathbf{1a})_2$CuTf: downfield shift of the amide NH signals, and upfield shift of the bipyridine 3-H/3′-H signals. Since shifts occur both upon hydrogen bonding of **1b** to imides and upon its coordination to metal centers, these signals cannot be used as reliable probes for either phenomenon. However, the presence of the Janus molecules had no effect on the spectra of **2b** and $(\mathbf{2b})_2Pd(BF_4)_2$, as was also the case for **2a** and $(\mathbf{2a})_2$CuTf. Thus, a shift of the signals of **2b**, and in particular of the signals of 3-H/3′-H, can be assigned directly to its coordination to Pd^{II}.

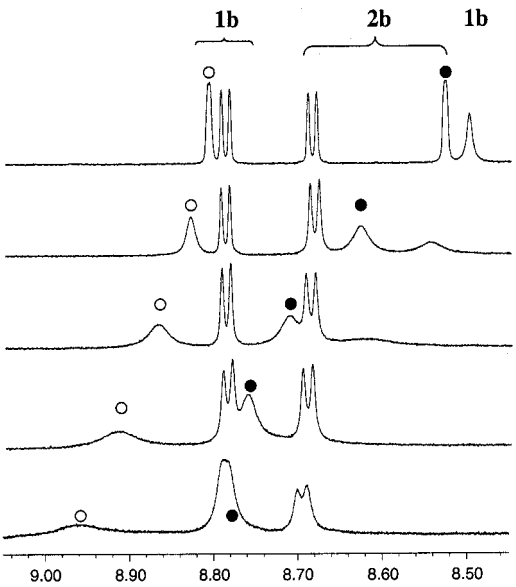

Figure 4. Part of the 500-MHz ^{1}H-NMR spectrum of a 95:5 $CDCl_3$/[D_6]DMSO solution of **1b**, **2b** (1 mM each) and $Pd(BF_4)_2$ (0, 0.25, 0.5, 0.75 and 1 mM from top to bottom) at 298 K; the circles mark the signals assigned to the bipyridine 3-H and 3′-H of **1b** (o) and **2b** (•); these signals shift upon the formation of bipyridine−palladium complexes; the doublets at δ = 8.79 and 8.69 were assigned to **1b** and **2b**, respectively (bipyridine 5-H and 5′-H); the singlet at δ = 8.50 (top spectrum) was assigned to **1b** (pentyl−CON*H*−)

In a last series of experiments, we measured the effect of the addition of Janus molecules (1 mM) on a dynamic mixture of **1b**, **2b** (1 mM each) and $Pd(BF_4)_2$ (0.5 mM). The results are summarized in the Table 1. They show that Janus molecules cause a release of **2b** from the Pd^{II} complexes, and therefore an increase of the coordination of **1b** to Pd^{II}. This is best explained by a selective stabilization of $(\mathbf{1b})_2Pd(BF_4)_2$ upon formation of hydrogen-bonded bridges between these Janus molecules and the ligands. This occurs despite the presence of DMSO in the solvent. The effect can be enhanced upon cooling the mixture down to 273 K (Figure 5): association becomes stronger, and the proportion of **2b** involved in coordination to Pd^{II} drops below 5% in the case of **3**.

Nevertheless, the selectivity for **3** remains low, and despite their structural differences, all the Janus molecules have some effectiveness to shift the equilibrium towards a better coordination of **1b** to Pd^{II}. One possible explanation is a flexibility in the positioning of the ligands about the metal center. The angle Φ (Figure 2) may deviate substan-

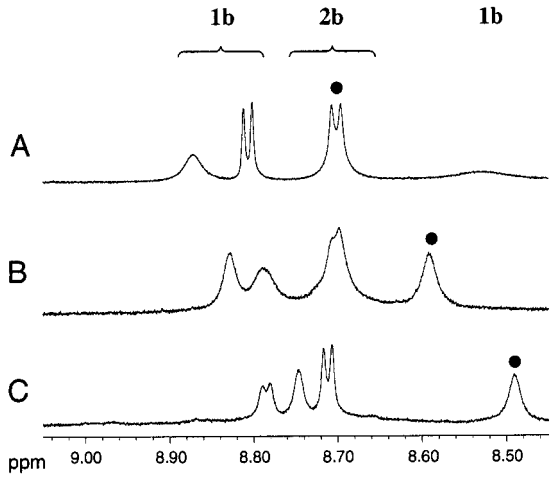

Figure 5. Part of the 500-MHz ^{1}H-NMR spectrum of a 95:5 $CDCl_3$/[D_6]DMSO solution of **1b**, **2b** (1 mM each), and $Pd(BF_4)_2$ (0.5 mM) at 298 K; A: no wedge added; B: **3** added (1 mM); C: same as B at 213 K; the circle marks the bipyridine 3-H and 3′-H of **2b**; in A, this signal overlaps with the bipyridine 5-H and 5′-H of **2b**

tially from zero, thus allowing $(\mathbf{1b})_2Pd(BF_4)_2$ to accommodate imides at various distances and orientations.

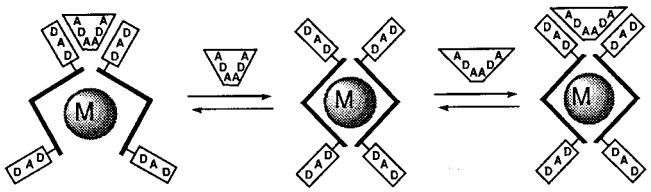

Table 1. Proportions (± 5%) of **1b** and **2b** involved in the coordination with Pd^{II} in a mixture of **1b**, **2b** (1 mM each), $Pd(BF_4)_2$ (0.5 mM), and various Janus molecules (1 mM)[a]

	Janus molecule

[a] At 298 K. The proportion of the different complexes was calculated from the chemical shift of the bipyridine 3-H/3′-H signal in **2b**. – [b] At 273 K.

Cooperativity

The metal complexes involving two ligands **1** have two binding sites for Janus molecules (Scheme 2). The experiments above were performed using two equivalents of Janus molecule (1 mM) with respect to the metal. We looked for the conceivable presence of some degree of cooperativity between these two binding sites by examining the effect of *a single equivalent* (0.5 mM) of Janus molecule on the same dynamic mixtures as above ([**1**] = [**2**] = 1 mM, [metal] = 0.5 mM). In the case of a strong negative cooperativity between the binding sites, one equivalent of Janus molecule should be as effective as two for the stabilization of complexes $(\mathbf{1})_2$(metal) (Scheme 2). In the case of a strong positive cooperativity, one equivalent of Janus molecule should have a stabilizing effect of exactly half the effect of two equivalents. In none of our systems, however, we observed a clear cooperativity, and the results were always between these ideal cases.

Scheme 2. Negative (left) and positive (right) cooperativity; the binding of a Janus molecule to the complex may favor or disfavor the binding of a second Janus molecule

Conclusion

The present results demonstrate a selective enhancement of a constituent of a dynamic combinatorial set of metal complexes acting as receptors for the binding of a complementary substrate species. They are based on the simultaneous operation of reversible metal ion coordination for the exploration of the combinatorial space and of substrate binding through hydrogen bonding, for the amplification of a given constituent of the dynamic library.

A variety of other reversible molecular or supramolecular processes may be envisaged for gaining access to dynamic combinatorial libraries, real or virtual, adapted to the molecular recognition of specific partners.

Experimental Section

General: ^{1}H- and ^{13}C-NMR spectra were recorded with a Bruker WM-200 (200 MHz) or a Bruker 500 (500 MHz) spectrometer at 298 K. Chemical shifts are reported as δ values relative to the residual solvent peak. – Yields are calculated on isolated compounds and are unoptimized. The following compounds were prepared according to literature procedures: 2,2′-bipyridine-4,4′-dicarbonyl chloride,[14] 6,6′-dimethyl-2,2′-bipyridine-4,4′-dicarbonyl chloride,[15] 2-amino-6-caproylaminopyridine,[16] Janus molecule **3**,[12] uracil photodimer **4**,[17] 5,5′-diuracil and methylene 5,5′-diuracil.[18]

General Procedure for the Preparation of Ligands 1 and 2: 2,2′-Bipyridine-4,4′-dicarbonyl chloride (0.5 mmol) was dissolved in anhydrous toluene (5 mL), and either freshly distilled tBuNH$_2$ (5 equiv.) or 2-amino-6-caproylaminopyridine (2.1 equiv.) was added. The suspension was stirred at room temperature for 24 h under an anhydrous atmosphere. The solvent was then evaporated and the solid residue triturated in saturated aqueous $NaHCO_3$. The suspension was filtered and the solid was washed thoroughly with saturated aqueous $NaHCO_3$ and water, and finally dried under vacuum. Recrystallization from EtOAc/EtOH afforded analytically pure **1a**, **1b**, **2a**, and **2b**.

Self-Assembly, Structure, and Physical Properties of Tetranuclear Zn_{II} and Co_{II} Complexes of [2 × 2] Grid-Type

Javier Rojo,[a] Francisco J. Romero-Salguero,[a] Jean-Marie Lehn,*[a] Gerhard Baum,[b] and Dieter Fenske[b]

Keywords: Grid complexes / Self-assembly / Co / Zn / Coordination chemistry / Bis(tridentate) ligands

The tretrametallic [2 × 2] grid-type complexes **1–4** are formed by self-assembly of the bis(tridentate) ligands **5** and **6** with Zn^{II} and Co^{II} cations. They have been characterized by spectroscopic studies in solution as well as by crystal structure determination. The substituents in the central pyrimidine ring play an important role in terms of geometry and physical properties of the complexes. They induce an orthogonal orientation of the ligand in the complexes which is critical for the formation of ordered monolayers and extended self-organized arrays of grids. The physical properties of the complexes such as metal–metal interaction and π-π* stacking between the ligands may be modulated by changing these substituents.

Introduction

The self-assembly of suitable polydentate ligands with metal ions allows the preparation of well-defined inorganic supramolecular architectures in solution. In recent years, much effort has focused on the generation of inorganic arrays of various types in view of their promising physicochemical properties and their potential application in nanotechnology.[1−10]

The design of the ligand is the crucial for controlling the structure and properties of the final assemblies. Recently, our laboratory has reported the synthesis of bidentate ligands based on terpyridine subunits[11] and their self-assembly with metal ions of octahedral coordination to generate complexes of grid-type geometry.[12] The physicochemical properties of the [2 × 2] cobalt(II) grids formed indicate an electronic communication between the metallic centers suggesting that these inorganic assemblies could have applications in molecular information storage.[13] Moreover, the self-organization of such building blocks could lead to highly ordered monolayers[14] (e.g. "grids of grids") presenting magnetic domains or into which it might be possible to write information in the form of different metal redox states using for instance scanning probe microscopy techniques.

For generating such extended arrays, it is necessary that the basic grid components present regular, undistorted structures where the ligands are arranged in orthogonal fashion. Based on previous results, this arrangement depends in particular on the substituent present at the C^2 position of the pyrimidine ring.[15]

In the present work, we describe the formation as well as the structural and physico-chemical properties of the [2 × 2] grid-type complexes **1−4** obtained by the self-assembly of zinc(II) and cobalt(II) ions with the ligands **5** and **6** bearing a phenyl and a *p*-(dimethylamino)phenyl substituent, respectively, on the central pyrimidine (Scheme 1). The interaction between the phenyl ring and the pyridine units of the perpendicular ligands in the complexes induces an orthogonal arrangement suitable for applications in self-organizing systems.

Results and Discussion

Synthesis of Ligands 5 and 6 and of the Corresponding Grid Complexes 1−4

The synthesis of the bis(tridentate) ligand **5** has been reported previously.[11] Ligand **6** was obtained as described in Scheme 2. The reaction of equivalent amounts of ligands **5** or **6** and of the metal salts $Co(BF_4)_2$, $Co(DMSO)_4Tf_2$, or $ZnTf_2$ in acetonitrile leads to clear solutions from which the metal complexes **1−4** were isolated by precipitation with ethyl ether and centrifugation (**1** and **2**) or by simply removing the solvent under reduced pressure (**3** and **4**) (Scheme 1). These compounds were purified by recrystallization from acetonitrile/ethyl ether and characterized by physical and spectroscopic techniques as described below. The assembly rates of ligands **5** and **6** with Co^{II} and Zn^{II} ions to give complexes **1** and **2**, are appreciably slower than when the ligand does not present a phenyl substituent in the 2-position of the pyrimidine ring.[12] In the latter case, the self-assembly takes a few hours in contrast to the one night to two days for ligands **5** and **6**. This may be attributed to the steric hindrance introduced by the central phenyl substituent which must insert between two other ligands in the final grid complex (see below). All new compounds had spectral and analytical properties in agreement with their structure.

^{1}H-NMR Spectra

The metal complexation leads to remarkable changes in the proton-NMR spectra with large modifications in the chemical shifts of the protons of the ligand. The metal binding induces a conformational change in the ligand. The most stable conformation of the ligand is that which adopts a *transoid* conformation around all C−C bonds linking the heterocyclic units;[11,16,17] in this form the nitrogen lone pairs of the heterocycle deshield the ligand protons adjacent to the interannular bonds (5-H, 5′-H, 3′-H, and 3′′-H). In the metal complex, the ligand presents a *cisoid* conformation to allow the formation of chelating coordination bonds with the metal centers and this deshielding effect disappears. The formation of the coordinative nitrogen−metal bonds as well as the positioning of the ligands in the complex also contribute to the chemical shift changes.

The proton-NMR spectra of ligand **5** and its Zn complex **1** as well as of ligand **6** and its Zn complex **3** are represented in Figures 1 and 2, respectively. The corresponding chemical shifts are listed in Table 1. The spectra of the cobalt(II) complexes **2** and **4** present special features due to the magnetic anisotropy effects of the ions; they will be described elsewhere.[18]

Scheme 2. Synthesis of the ligand **6**, i) *n*BuLi, THF, 4,6-dichloropyrimidine; ii) $Pd(Ph_3P)_4$, toluene

The major changes observed in the NMR spectra on complexation reside in the shielding of the phenyl protons. In the free ligand, these protons appear as a multiplet at low field corresponding to the *ortho* protons centered at δ = 8.78 and another multiplet centered at δ = 7.59 for the *meta* and *para* protons in the case of ligand **5** and an AA′BB′ system at δ = 8.79 and 6.87 for ligand **6**. The *ortho* protons are deshielded due to the presence of the two nitrogen lone pairs of the pyrimidine ring. When the zinc complexes **1** and **3** are formed, the multiplets are split into five and three well defined signals, respectively. The *ortho*, *ortho′* and *meta*, *meta′* protons of the phenyl ring, which are equivalent in ligands **5** and **6**, become nonequivalent in the complexes **1** and **3**. Moreover, all the aromatic protons are markedly shielded giving signals between δ = 7.0 and 4.96. These two observations suggest that in solution the complexes **1** and **3** adopt a very compact structure where the phenyl rings of the two ligands on one face of the grid structure insert between the two ligands on the other face. As a result, the phenyl protons are subject to strong shielding effects due to the heteocyclic units, thus inducing large shifts; furthermore, rotation around the phenyl−pyrimidine C−C bond is blocked, leading to nonequivalence of the *o*, *o′* and *m*, *m′* protons. This has been confirmed by a ROESY NMR experiment where a NOE interaction between 3′′′-H and 3′-H and 4′-H as well as between 3′′′-H^i and 5-H and 5′-H is observed for complex **1**.

In the Zn complex **3**, the signal of the methyl substituents on the amino group appears as a broad resonance centered

at δ = 3.07 in the proton-NMR spectrum. Due to the complex structure the rotation around the N−C bond is hindered. A variable-temperature experiment was performed (Figure 3). When the sample was heated to 333 K the broad band sharpened to a fine singlet for the two chemically equivalent methyl groups. When the temperature was lowered to 243 K, the signal at δ = 3.07 split into two singlets at δ = 3.25 and 2.88. A NOESY experiment allowed the assignment of the low-field peak as the signal of internal methyl group and the other one of the external methyl group. With a coalescence temperature T_c of 290 K a free energy of activation $\Delta G_c^{\geq}$ for the rotation around the N−C bond may be calculated as $\Delta G_c^{\geq} = 4.57T_c\cdot(9.97 + \log T_c/\delta\nu)$ where δν is the chemical shift difference between the two signals,[19] giving a value of 13.6 kcal/mol.

In this variable-temperature experiment the other signals in the spectrum did not change except those corresponding to the phenyl ring which may be affected by small changes in the complex structure with temperature. The data also show that at the highest temperature reached, rotation of

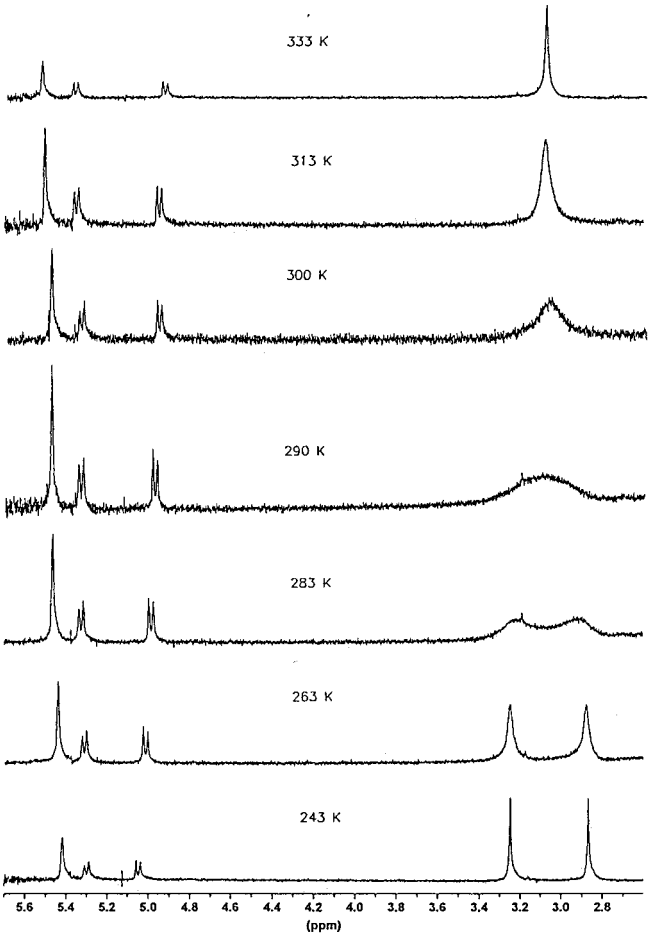

Figure 3. Proton-NMR spectra at different temperatures for the Zn_4 complex **3** at 300 MHz in CD_3CN (heteroaromatic protons not shown)

the phenyl group with respect to the pyrimidine ring is still slow on the NMR time scale, indicating that no significant dissociation of the complex is taking place. One may note that the phenyl ring rotation is thus a probe for investigating the kinetics of ligand exchange in such grid complexes.[18]

Crystal Structures of the Complexes 1, 2, and 4

The structures of the Zn^{II} and Co^{II} complexes **1**, **2**, and **4** of ligands **5** and **6** were investigated by X-ray crystallography. Those of **1** and **2** are represented in Figures 4 and 5. In all three structures the complexes present a [2 × 2] grid-type architecture in which the four metal ions form a square and lie close to an average common plane.

In the complex $\{[\mathbf{5}_4Zn_4](CF_3SO_3)_8\}$ (**1**) the Zn^{II} ions display a distorted octahedral coordination (Figure 4). The Zn−Zn distances lie in the range of 6.584−6.767 Å. The Zn−N bond lengths are between 2.053 and 2.184 Å for the pyridine nitrogen atoms and between 2.231 and 2.373 Å for the pyrimidine nitrogen atoms. The distances between the heteroaromatic rings of one ligand and the phenyl ring of the orthogonal one (3.25−3.50 Å) indicate van der Waals contact and π−π stacking interaction.

The complex $\{[\mathbf{5}_4Co_4](BF_4)_8\}$ (**2**) crystallizes with two molecules per unit cell. The metal ions also display a distorted octahedral coordination with Co,Co distances between 6.453−6.570 Å (Figure 5). The Co−N bond lengths lie between 2.041−2.175 Å for pyridine nitrogens and are slighly longer (2.213−2.309 Å) for the pyrimidine nitrogens. Again the short distances between phenyl and pyridine rings indicate π, π stacking.

In the case of $\{[\mathbf{6}_4Co_4](CF_3SO_3)_8\}$ (**4**), the overall quality of the crystal structure data is at this stage too low for a detailed description. However, the analysis indicates without doubt the [2 × 2] grid-type arrangement. Crystals of better quality are required for improving the structural data.

The central substituent in position 2 of the pyrimidine ring plays an important role in the geometrical features of the final complexes. It has been shown that in the case of rack-type metal ion coordination arrays, a methyl substituent was the best suited for the formation of complexes presenting the least distorted ligand geometry.[15] In the case of a cobalt(II) [2 × 2] grid complex of the type studied here, the presence of a methyl substituent on the central pyrimidine ring was found to cause a divergent, outward bending of the planes of the ligands, a CH_3 group being apparently somewhat too large.[12] On the contrary, when there is no substituent in that position, the situation is opposite and an inward, convergent bending is observed in the corresponding $(Zn^{II})_4$ complex.[20] An intermediate situation is found in the present case of a phenyl substituent which has a thickness intermediate between the steric requirements of CH_3 and H. Insertion of the phenyl group between two ligands in complexes **1** and **2** induces an almost parallel arrangement of the average planes of the ligands, thus leading to an overall geometry of the [2 × 2] grid complexes close to a regular square (Figures 4 and 5).

UV/Vis Absorption and Emission Spectra

The absorption maxima (λ_{max}) and extinction coefficients (ε) for ligands **5** and **6** in chloroform and for complexes **1**, **2**, **3**, and **4** in acetonitrile are listed in Table 2. The UV region of the absorption spectra shows strong absorption bands at 280−290 and 350−375 which correspond to ligand-centered (LC) π-π* transition bands. In the ligands, these bands appear at higher energies.

In the case of complexes **2**, **3**, and **4**, absorption bands are observed in the visible region. The zinc complex **3** presents a remarkable deep red color, corresponding to an intense absorption band at 516 nm which could be due to a donor-acceptor charge transfer transition between the electron-rich (dimethylamino)phenyl group and the pyridine rings held in stacking position by the structure of the complex. The broad bands centered between 400−475 and 532 nm in the Co complexes **2** and **4**, respectively, could correspond to Co^{II}−bipyridine MLCT and the very broad

[a] Metal-to-ligand charge-transfer transitions. – [b] Ligand-centered transitions, probably of donor-acceptor type for **3**.

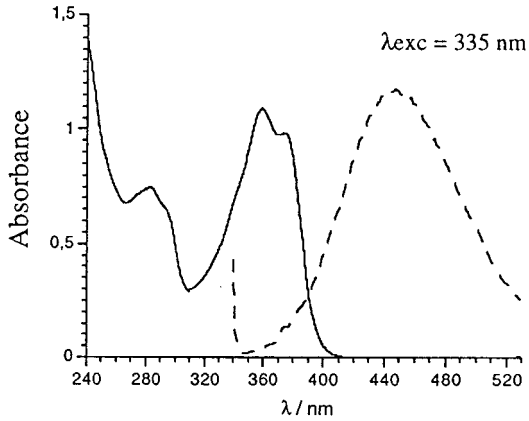

Figure 6. Electronic absorption and emission (broken line) spectra of the Zn_4 grid complex **1** in acetonitrile

shoulder at lower energy to Co^{II}–pyrimidine MLCT transitions.

The strong fluorescence of the zinc complex **1** is noteworthy. Whereas ligand **5** in chloroform exhibits only a weak emission at about 410 nm when irradiated at 272 nm, complex **1** in acetonitrile presents an intense emission at 450 nm under excitation at 335 nm at room temperature (Figure 6).[21] Since the Zn^{II} ions are of d^{10} electronic configuration and possess no low-lying metal-centered excited states, the fluorescence of **1** may be ascribed to emission from the lowest ligand-centered excited singlet level, its high intensity being due to the rigidity of the complex, which decreases the radiationless decay relative to that for the free ligand **5**. The absence of emission for the cobalt complex **2** is due to the presence of the low-lying nonemissive Co^{II}-centered MLCT excited state which inhibits luminescence,

as has been previously observed for other cobalt complexes.[22] Ligand **6** and its metal complexes **3** and **4** show no emission. Radiationless decay of the ligand-centered levels may take place in **3** and **4** through the low-energy charge transfer and MLCT excited states.

Electrochemical Properties

Preliminary studies indicated that the present grid-type species, in particular the Co^{II} complexes **2** and **4** present remarkable electrochemical properties, in line with those reported earlier for the related $(Co^{II})_4$ grid bearing no phenyl group on the pyrimidine rings.[12] Thus, for instance, eight successive reductions are observed for **2** at about −0.10, −0.24, −0.45, −0.77, −1.00, −1.22, −1.38, and −1.54 V (in DMF). Similar values are also found for **4**. Detailed investigations are in progress and will be reported together with data on related complexes.

Conclusion

The formation of the four tetrametallic complexes **1**−**4** from the ligands **5** and **6** and Co^{II} and Zn^{II} metal ions with octahedral coordination confirms the generality of the self-assembly of such grid-type architectures. The stacking interactions introduced by the phenyl ring provide high stability to the complexes as well as structural features suitable for their use as components in extended self-organized arrays. The introduction of an electron-donating group on the phenyl ring provides means for modulating the electronic properties of the ligand and therefore the properties of the final complexes. The control which may thus be progressively achieved over both the structural and electronic features of these tetrametallic grid complexes makes them particularly attractive as components in the construction of inorganic architectures for multicellular ion-dot supramolecular devices.

Experimental Section

Materials: Precipitates were isolated by high-speed spinning in a Hettich Universal centrifuge (ca. 3000 rpm, 5 min). − Unless otherwise noted, ^{1}H-NMR spectra were measured in CD_3CN calibrated to the residual solvent peak at 200 MHz with a Bruker AC 200 spectrometer. − Melting points were obtained with a digital Thomas Hoover (Electrotherma) apparatus. − Infrared absorption spectra were recorded on a Perkin−Elmer 1600 series FTIR spectrometer in KBr, an electronic absortion espectra on a Cary 219 spectrometer in CH_3CN with λ_{max} in nm and ε ($\times 10^4$) in M^{-1} cm^{-1}. − Fast atom bombardment (FAB) mass spectrometry was performed on a ZAB-HF VG spectrometer with *m*-nitrobenzyl alcohol as the matrix and electrospray (ES) mass spectra were obtained with a triple quadrupole mass spectrometer Quattro II (Micromass) mass spectrometry. Spectroscopic studies were performed in spectroscopic-grade solvents. − All solvents were reagent-grade and used without further purification.

Complex $(5_4Zn_4)(CF_3SO_3)_8$ (1): To a suspension of 4,6-bis(2′′,2′-bipyrid-6′-yl)-2-phenylpyrimidine[11] (20 mg, 0.043 mmol) in acetonitrile (6 mL) was added zinc triflate (16 mg, 0.043 mmol) and the mixture was stirred at room temperature for 18 h. Diethyl ether was added to the reaction and the precipitate was isolated by centrifugation and purified by recrystallization from acetonitrile/diethyl ether to afford **1** as a white solid (22 mg, 63%). − M.p. > 300 °C. − ^{1}H NMR (400 MHz): δ = 9.57 (s, 1 H, 5-H), 9.17 (d, 2 H, *J* = 6.3 Hz, 5′-H), 8.63 (m, 4 H, 4′-H, 3′-H), 8.25 (d, 2 H, *J* = 8.2 Hz, 3′′-H), 7.92 (t, 2 H, *J* = 7.7 Hz, 4′′-H), 7.10 (dd, 2 H, *J* = 6.5, 5.2 Hz, 5′′-H), 7.00 (t, 1 H, *J* = 7.4 Hz, 3′′′-H^i), 6.87 (t, 1 H, *J* = 7.6 Hz, 4′′′-H), 6.82 (d, 2 H, *J* = 5.2 Hz, 6′′-H), 6.27 (t, 1 H, *J* = 7.6 Hz, 3′′′-H), 5.80 (d, 1 H, *J* = 7.2 Hz, 2′′′-H^i), 7.38 (d, 1 H, *J* = 7.6 Hz, 2′′′-H). − FAB MS; *m*/*z* (%): 3123 (2) [*M* − 149 (− Tf)], 3014 (7) [*M* − 298 (− 2 Tf)], 2863 (8) [*M* − 447 (− 3 Tf)], 2714 (5) [*M* − 596 (−4 Tf)], 2566 (3) [*M* − 745 (−5 Tf)]. − $C_{128}H_{80}F_{24}N_{24}O_{24}S_8Zn_4$ (3312.17): calcd. C 46.42, H 2.43, N 10.15; found C 46.46, H 2.15, N 10.04. − IR (KBr): $\tilde{\nu}$ = 3089, 1600, 1465, 1256, 1162, 1029, 776, 637. − UV/Vis: λ (ε_{max}) = 282 (4.9), 294 (4.2), 358 (7.2), 375 (6.5).

Complex $(5_4Co_4)(BF_4)_8$ (2): To a suspension of 4,6-bis(2′′,2′-bipyrid-6′-yl)-2-phenylpyrimidine[11] (20 mg, 0.043 mmol) in acetonitrile (6 mL) was added cobalt tetrafluoroborate (15 mg, 0.043 mmol) and the mixture was stirred at reflux for 2 d. Diethyl ether was added to the reaction and the precipitate was isolated by centrifugation and purified by recrystallization from acetonitrile/diethyl ether to afford **2** as a slightly brown solid (23 mg, 77%). − M.p. > 300 °C. − FAB MS; *m*/*z* (%): 2701 (20) [*M* − 87 (− BF_4)], 2614 (81) [*M* − 174 (− 2 BF_4)], 2528 (95) [*M* − 261 (− 3 BF_4)], 2441 (48) [*M* − 348 (− 4 BF_4)], 2354 (16) [*M* − 435 (− 5 BF_4)], 1307 (37) [{*M* − 174 (− 2 BF_4)}/2], 1264 (100) [{*M* − 261 (− BF_4)}/2], 1220 (83) [{*M* − 348 (− 4 BF_4)}/2]. − $C_{120}H_{80}B_8Co_4F_{32}N_{24}$ (2788.31): calcd. C 51.69, H 2.89, N 12.06; found C 51.47, H 2.90, N 11.87. − IR (KBr): $\tilde{\nu}$ = 3072, 1600, 1463, 1228, 773, 656. − UV/Vis: λ (ε_{max}) = 279 (1.8), 291 (0.7), 361 (0.9), 371 (0.8), 430 (0.1).

4,6-Dichloro-2-[4′-(dimethylamino)phenyl]pyrimidine (7): To *p*-bromo(dimethylamino)benzene (5 g, 24.988 mmol) in ethyl ether (80 mL) at room temperature under argon was added one equiv. of 1.6 M *n*BuLi in hexane (15.6 mL, 24.988 mmol). The mixture was stirred for 5 min and then cooled at −70 °C. Then, one equiv. of 4,6-dichloropyrimidine (3.7 g, 24.988 mmol) was added. After 1 h 15 min, the temperature of the mixture was allowed to rise to 0 °C, a solution of acetic acid, water, and THF (1.6:0.25:5 mL) was added dropwise, and the mixture was immediately treated with a solution of DDQ (5.9 g, 26 mmol) in THF (25 mL). The solution was stirred at room temperature for 15 min, cooled to 0 °C and a cold 3 M aqueous solution of NaOH (10 mL, 30 mmol) was added followed by water (10 mL) 15 min later. The organic phase was removed and the aqueous layer was extracted with chloroform (5 × 100 mL). The combined organic layers were dried (Na_2SO_4) and the solvent was removed under low pressure. The residue was purified by chromatography on silica gel using hexane/ethyl acetate (6:1) as eluent giving 1.33 g (20% yield) of **7** as yellow needles. − M.p. 174−175 °C. − ^{1}H NMR: δ = 8.29 (d, 2 H, *J* = 8.9 Hz, Ar), 7.06 (s, 1 H, 4-H), 6.71 (d, 2 H, *J* = 8.9 Hz, Ar), 3.07 [s, 6 H, $(CH_3)_2N$]. − ^{13}C NMR: δ = 166.1, 161.5, 153.1, 130.5, 122.2, 116.2, 111.3, 40.1. − EI MS; *m*/*z* (%): 269 (64) [M^+ + 1], 268 (14) [M^+], 267 (100) [M^+ − 1]. − $C_{12}H_{11}Cl_2N_3$ (268.14): calcd. C 53.93, H 4.15, N 15.73; found C 53.65, H 4.05, N 15.71. − IR (KBr): $\tilde{\nu}$ = 3109, 2899, 1609, 1536, 1385, 1190, 1093, 819, 778.

4,6-Bis(2′′,2′-bipyrid-6′-yl)-2-[4′′-(dimethylamino)phenyl]pyrimidine (6): To 4,6-dichloro-2-[4′-(dimethylamino)phenyl]pyrimidine (**7**) (250 mg, 0.9323 mmol), 1.5 equiv. of 6-tributylstannyl-2,2′-

bipyridine[11] (622 mg, 1.3984 mmol) and 10% of tetrakis(triphenylphosphane)palladium (0) (108 mg, 0.0932 mmol) was added toluene (15 mL) and the mixture was refluxed overnight under argon. Then, the solvent was removed under low pressure and the residue was washed with MeOH (10 mL). Without further purification, again 1.5 equiv. of 6-tributylstannyl-2,2′-bipyridine (622 mg, 1.3984 mmol), 10% of tetrakis(triphenylphosphane)palladium(0) (108 mg, 0.0932 mmol), and toluene (15 mL) were added to the solid. The mixture was heated at reflux for 24 h under argon. The solvent was removed and the slurry residue was treated with MeOH (10 mL). The solid was filtered and washed with more MeOH (10 mL) to give 230 mg (53%) of **6** as a yellow solid. − M.p. 302−304 °C (calcination). − ^{1}H NMR: δ = 9.54 (s, 1 H, 5-H), 8.85 (d, 2 H, *J* = 7.9 Hz, 3′′-H), 8.79 (m, 4 H, 6′′-H, Ar), 8.66 (d, 2 H, *J* = 8.9 Hz, 3′-H or 5′-H), 8.59 (d, 2 H, *J* = 7.8 Hz, 3′-H or 5′-H), 8.07 (t, 2 H, *J* = 7.8 Hz, 4′-H), 7.91 (dt, 2 H, *J* = 7.8, 1.8 Hz, 4′′-H), 7.38 (dd, 2 H, *J* = 6.7, 4.9 Hz, 5′′-H) 6.87 (d, 2 H, *J* = 9 Hz, Ar), 3.11 (s, 6 H, 2× CH_3). − ^{13}C NMR: δ = 172.7, 163.9, 158.1, 155.5, 149.2, 137.9, 136.7, 129.7, 129.5, 123.9, 122.7, 122.2, 121.7, 121.3, 121.0, 111.7, 110.1, 40.3. − MS (FAB); *m*/*z*: 508 [M^+ + 1]. − HRMS: $C_{32}H_{26}N_7$: calcd. 508.2250, found: 508.2235. − UV/Vis: λ(ε_{max}) = 284 (10.0), 312 (7.9), 348 (8.4); 402 (0.7). − The reaction was tried in a single step using double amount of reagents but only poor yields were obtained.

Complex $(6_4Zn_4)(CF_3SO_3)_8$ (3): To a suspension of 4,6-bis(2′′,2′-bipyrid-6′-yl)-2-[4′′-(dimethylamino)phenyl]pyrimidine (**6**) (20 mg, 0.039 mmol) in acetonitrile (8 mL) was added zinc triflate (14 mg, 0.039 mmol) and the mixture was refluxed for 48 h under argon. The solvent was removed under low pressure and the solid recrystallized from acetonitrile/diethyl ether to afford **3** as a deep red solid (27 mg, 79%). − M.p. > 300 °C. − ^{1}H NMR (300 MHz): δ = 9.67 (s, 1 H, 5-H), 9.29 (d, 2 H, *J* = 7.4 Hz, 5′-H), 8.61 (d, 2 H, *J* = 7.5 Hz, 3′-H), 8.54 (t, 2 H, *J* = 8.1 Hz, 4′-H), 8.27 (d, 2 H, *J* = 8.2 Hz, 3′′-H), 7.90 (dt, 2 H, *J* = 7.8, 1.6 Hz, 4′′-H), 7.09 (dd, 2 H, *J* = 7.6, 6.1, 5′′-H), 6.86 (d, 2 H, *J* = 5.2 Hz, 6′′-H), 5.49 (S_b, 2 H, 2′′-H^i, 3′′′-H^i), 5.34 (d, 1 H, *J* = 9.0 Hz, 2′′′-H), 4.96 (d, 1 H, *J* = 8.0 Hz, 3′′′-H), 3.07 (S_b, 6 H, 2 × CH_3). − ES MS; *m*/*z*: 1593.7 [M − 298 (− 2 Tf)], 1012.6 [M − 447 (− 3 Tf)], 720 [M − 596 (− 4 Tf)]. − $C_{136}H_{100}F_{24}N_{28}0_{24}S_8Zn_4$ (3484.45): calcd. C 46.88, H 2.89, N 11.26; found C 47.12, H 3.06, N 11.00. − UV/Vis: λ(ε_{max}) = 261 (1.3), 282 (0.9), 295 (0.8), 357 (1.3), 371 (1.3), 516 (5.5).

Complex $(6_4Co_4)(CF_3SO_3)_8$ (4): To a suspension of 4,6-bis(2′′,2′-bipyrid-6′-yl)-2-[4′′-(dimethylamino)phenyl]pyrimidine (**6**) (10 mg, 0.0197 mmol) in acetonitrile (5 mL) was added cobalt triflate tetrakis(DMSO) (16 mg, 0.0197 mmol) and the mixture was refluxed for 48 h under argon. The solvent was removed under low pressure and the solid recrystallized from acetonitrile/diethyl ether to afford **4** as a dark solid (10 mg, 60%). − M.p. > 300 °C. − FAB MS; *m*/*z* (%): 3309.7 (4) [M − 149 (− Tf)], 3159.4 (9) [M − 298 (− 2 Tf)], 3010.5 (7) [M − 447 (− 3 Tf)], 2861.6 (3) [M − 596 (− 4 Tf)], 2713.5 (1) [M − 745(− 5 Tf)]. − $C_{136}H_{100}Co_4F_{24}N_{28}O_{24}S_8$ (3458.66): calcd. C 47.23, H 2.91, N 11.34; found C 47.49, H 2.62, N 11.31. − UV/Vis: λ(ε_{max}) = 267 (19.8), 292 (13.2), 365 (18.5), 532 (1.1).

Crystal Structure Determinations: The measurements were carried out with a STOE-IPDS diffractometer with graphit-monochromatized Mo-K_α radiation. Table 3 summarizes the crystal data, data collection, and refinement parameters. All calculations were performed with the SHELX-97 package.[24] All structures were solved by direct methods and were refined by full-matrix least squares based on F^2. All hydrogen atoms, disordered anions and solvent molecules with an occupation factor less than 1.0 were refined isotropically. All of the C−H hydrogen atoms in all structures were placed in calculated positions with U(H) = 1.5U_{eq}(C) for methyl groups and U(H) = 1.2U_{eq}(C) for all other. Molecular graphics performed with SCHAKAL96.[25] Single crystals of the complexes were obtained by slow vapor diffusion of diethyl ether into aceto-

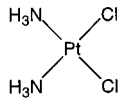
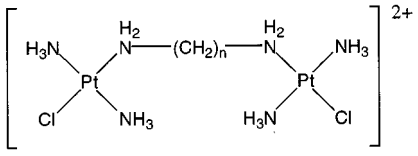
A Tetranuclear Platinum Compound Designed to Overcome Cisplatin Resistance

Bart A. J. Jansen,[a] Judith van der Zwan,[a] Jan Reedijk,*[a] Hans den Dulk,[b] and Jaap Brouwer[b]



Keywords: Antitumor drugs / Platinum / DNA / Dendrimers / L1210 Mouse leukemia

The synthesis and characterisation of the first generation of a poly(propyleneimine) dendrimer DAB(PA)$_4$, substituted with four *trans*-diamminechloroplatinum moieties is reported. The compound DAB(PA-tPt-Cl)$_4$ was designed to overcome two problems often associated with cisplatin resistance in cancer cells: (i) deactivation of the platinum species by intracellular thiolates and (ii) improved repair of crosslinks with DNA. The four-armed molecule can be expected to form crosslinks with DNA that are very different from the adducts formed by cisplatin. Also, the tetranuclear compound has four leaving groups, while cisplatin has only two. Therefore, DAB(PA-tPt-Cl)$_4$ would be less susceptible towards inactivation by reaction with intracellular thiolates. A reaction with an excess of the model nucleobase guanosine 5′-monophosphate (GMP) confirmed that the tetranuclear compound is capable of binding a maximum of four nucleobases. Therefore, the inactivation of one or two arms would still leave the molecule with enough reactivity to form crosslinks with DNA. Cytotoxicity tests were performed on two mouse leukemia L1210 cell lines, both sensitive and resistant towards cisplatin, and in seven human tumor cell lines. In all cell lines, the tetranuclear compound showed a low cytotoxicity. It is suggested that the low activity is related to the structure of the compound. Probably the high charge (+6) at physiological pH and its branched structure hamper the molecule in crossing the cell membranes.



Introduction

Since the discovery of cisplatin as antitumor drug, much effort has been undertaken to find new platinum compounds applicable as a drug against cancer.[1−3] One of the main objectives in platinum antitumor chemistry is to find compounds with activity against cancer cells having intrinsic or acquired resistance against cisplatin.[3] It is now generally accepted that the antitumor activity of cisplatin stems from the complex events that occur after its binding to DNA.[1−3] Known mechanisms for cisplatin resistance include improved recognition of DNA adducts by DNA repair mechanisms, decreased drug accumulation in the cell (due to decreased influx) and increased intracellular levels of the heavy-metal scavengers glutathione (GSH) and metallothionein (MT).[4−6]

Many derivatives with structures similar to cisplatin were found to be cross resistant with cisplatin. One approach to overcome cisplatin resistance is the preparation of drugs that bind to DNA in a structurally different way compared to cisplatin.[1] In this respect, the dinuclear 1,1/t,t platinum complexes,[7][8] with the general formula [{*trans*-PtCl(NH$_3$)$_2$}μ-{NH$_2$(CH$_2$)$_n$NH$_2$}](NO$_3$)$_2$ (n = 4, 6), are very interesting (Scheme 1). These compounds consist of two monofunctional [PtCl(NH$_3$)$_2$] moieties connected by a flexible diamine linker. This type of compounds was found to be active against cisplatin resistant cancers in vivo.[8] The striking difference in DNA binding behavior of such compounds is illustrated by the hairpin structure of an interstrand adduct of 1,1/t,t (n = 4) with a dsDNA octamer.[9] Binding of cisplatin to DNA is mainly restricted to intrastrand crosslinks between adjacent purine bases, with only 5−10% interstrand crosslinks.[10][11] In contrast, the number of interstrand crosslinks is reported to be much larger (50%) for dinuclear platinum compounds.[12]

Cisplatin

1,1/t,t (n=4, 6)

Scheme 1. Cisplatin and a dinuclear compound of the 1,1/t,t type

Recently, the diaminoalkyl linker was replaced by the naturally occurring polyamines spermine and spermidine.[13] The protonated, noncoordinating secondary amines in these molecules may have an additional interaction with

DNA by hydrogen bonding and electrostatic interaction. At the moment, the most promising variation appears to be the bifunctional trinuclear compound BBR 3464 [μ-*trans*-$Pt(NH_3)_2\{transPtCl(NH_3)_2[NH_2(CH_2)_6NH_2]\}_2](NO_3)_4$.[14][15] This cationic compound can be seen as a linear molecule with two ends capable of DNA binding, and a central platinum moiety that is restricted to noncovalent interactions. BBR 3464, with a total charge of +4, has now entered clinical trials.[14]

It has been suggested that the increased number of interstrand crosslinks is the reason for the high activity of dinuclear compounds against cisplatin-resistant cell lines.[12] From this point of view, it is interesting to investigate variatons on the dinuclear 1,1/t,t compounds with a number of DNA-binding moieties higher than two. One way to obtain more DNA-binding moieties is to increase the number of platinated "arms". A dinuclear molecule may be considered as having two arms. Statistically, additional arms should increase the number of interstrand adducts formed compared to dinuclear compounds. An additional advantage of this type of compound could be that after deactivation of one, or even two, of its arms by GSH or MT, the molecule still retains enough active arms left to form a bifunctional adduct with DNA.

In this paper, the synthesis and characterisation is reported of a novel tetranuclear platinum compound $DAB(PA\text{-}tPt\text{-}Cl)_4$ based on the first generation of the commercially available butanediamine poly(propyleneimine) dendrimer $DAB(PA)_4$ (Scheme 2). This first generation dendrimer provides four amine end-groups that can be functionalized by platinum. The structure was characterized by ^{195}Pt NMR, elemental analysis, and a pH titration followed by ^1H NMR spectroscopy. The reactivity of the platinated arms towards DNA was checked by a test reaction with guanosine monophosphate (GMP), monitored by ^1H NMR. The in vitro cytotoxicity was tested on L1210 mouse leukemia cell lines, including cell lines resistant towards cisplatin. As a reference, cisplatin was tested as well.

Scheme 2. The first generation poly(propyleneimine) dendrimer $DAB(PA)_4$, and the tetranuclear platinum complex $DAB(PA\text{-}tPt\text{-}Cl)_4$

Results and Discussion

Synthesis and Characterisation

For the preparation of the dendritic platinum complex $DAB(PA\text{-}tPt\text{-}Cl)_4$, a variation on the common synthesis of dinuclear compounds was applied.[16] The polyamine was reacted with an excess of the monoactivated solvent species *trans*-$[PtCl(NH_3)_2(dmf)]NO_3$. The chloride salt of the tetranuclear complex was obtained by quenching the reaction with an excess of LiCl. The excess of LiCl is later removed by extraction with ethanol or methanol. *trans*-$[PtCl_2(NH_3)_2]$ is easily separated from the product, while it has a low solubility in water, in contrast to $(PA\text{-}tPt\text{-}Cl)_4$.

^{195}Pt shows a single signal at $\delta = -2425$, which is identical to that of the $[PtClN_3]$ coordination sphere found for the dinuclear 1,1/t,t compounds.[17] The two tertiary amine atoms present in $DAB(PA)_4$ are potential coordination sites for platinum, although they are poorer donors than the four primary amines. In order to confirm the coordination site, pH titrations of the complex and the free ligand were followed by ^1H NMR spectroscopy (Figure 1). The spectrum shows shifted peaks and a different pH dependence compared to the free ligand.

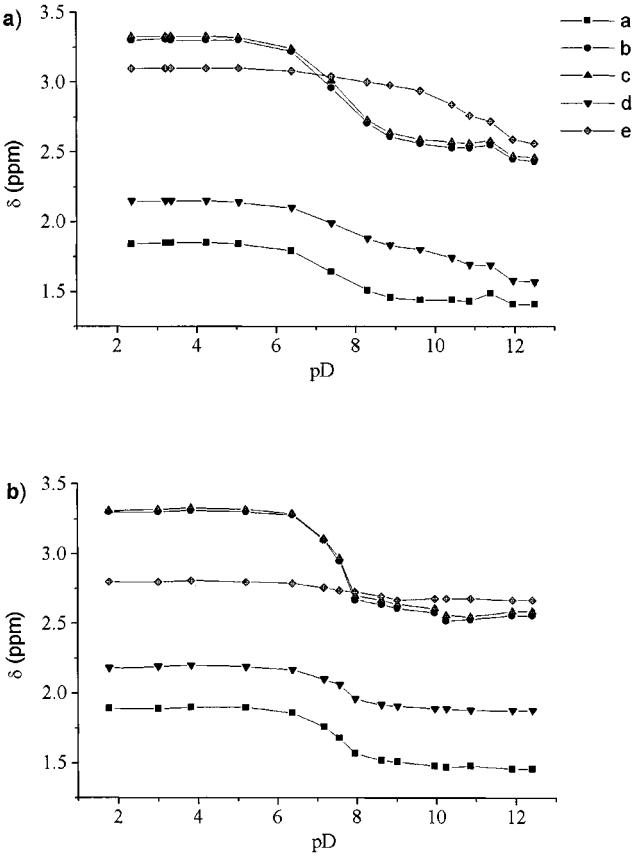

Figure 1. Titration curves of the proton signals of a) the ligand $DAB(PA)_4$ and b) the platinum complex $DAB(PA\text{-}tPt\text{-}Cl)_4$

The titration curve of $DAB(PA)_4$ is in general agreement with the data recently determined for this compound using natural abundant ^{15}N spectroscopy.[18] Upon lowering the

pH, first the primary and then the tertiary nitrogens are protonated. The protons shifted most upfield show only small pH dependence and are identified as protons **a** and **d** (Scheme 2). Protons **b** and **c** show overlapping signals at all pH values, and are identified by their total integral value of 12 protons. The remaining peak is assigned to **e**. The assignment was confirmed by a [^{1}H,^{1}H] COSY NMR experiment. Metalation should protect the amines from protonation. In the titration of the complex, pH dependence of the shift of proton **e** is only marginal compared to its behavior in the free ligand. In contrast protons **b** and **c** show a strong pH dependence in both titrations. This allows the conclusion that platinum is coordinated at the primary amines. At physiological pH, the tertiary amines are hydronated, thus giving the molecule a total charge of +6. This high positive charge is likely to give strong coulomb interactions with a polyanion like DNA.

Reaction with GMP, a Model Nucleobase

The coordination of DAB(PA-tPt-Cl)$_4$ with the model nucleobase guanine-5′-monophosphate (GMP) was studied by ^{1}H NMR spectroscopy. The reaction was performed in D_2O at 313 K, with a molar ratio of 5:1 ([GMP]:[DAB(PA-tPt-Cl)$_4$]). Results are summarized in Table 1. Signals of a platinated product appeared immediately after mixing the two compounds. After four days the reaction was judged to be complete. The single signal in ^{195}Pt NMR at $\delta = -2560$ proves that all platinum has reacted. Also, the ratios of platinated and free GMP were found constant. This ratio was determined from the integral values of the GMP H8 signals at $\delta = 8.05$ (H8, free) and $\delta = 8.72$ (H8*, platinated). The ratio of the integral values of H1′ at $\delta = 5.87$ and of H1′* at $\delta = 5.96$ was constant as well.

Table 1. NMR Data for the complexation of DAB(PA-tPt-Cl)$_4$ with GMP

	δH8	δH1′	$J_{1'-2'}$ (Hz)	δ^{195}Pt
GMP	8.05	5.87	5.7 (d)	–
DAB(PA-tPt-GMP)$_4$	8.72	5.96	3.6 (d)	−2560
DAB(PA-tPt-Cl)$_4$	–	–	–	−2425

The values of H8* and H1′* are indicative of platination at N7. Also, the decrease in the coupling constant $J_{1'-2'}$ agrees with that observed before in the reaction of dinuclear 1,1/t,t compounds with GMP.[17] The ^{195}Pt value of the GMP adduct lies near the values for dinuclear compounds as well. Apparently all four arms of the tetranuclear compound are available for binding to DNA. The binding of each separate arm is comparable to that of the ends of dinuclear 1,1/t,t compounds. However, the actual number of "arms" binding to DNA may be smaller in cells due to partial inactivation by binding to other cellular targets like GSH. This illustrates a feature of tetrafunctional compounds that might be advantageous compared to bifunctional compounds like cisplatin or the 1,1/t,t compounds. The tetrafunctional compound is still able to form crosslinks with DNA even after two of its functional groups are deactivated.

Biological Activity

Cisplatin and the tetranuclear compound DAB(PA-tPt-Cl)$_4$ were tested on L1210/0 mouse leukemia cells, and on the cisplatin resistant L1210/2 cell line. These cell lines are described in literature.[19][20] The drug concentrations at 50% growth inhibition (IC_{50}) are presented in Table 2. As expected, cisplatin was found to be cytotoxic against the L1210/0 cells, and less cytotoxic in the resistant lines. The found IC_{50} values are comparable to literature.[19][20] The resistance factor (rf, IC_{50} for the resistant cell line divided by the IC_{50} for the sensitive cells) was found to be 3.1. In contrast, the tetranuclear compound appeared to be equally toxic in L1210/0 and L1210/2 (rf = 0.8). However, the cytotoxicity of DAB(PA-tPt-Cl)$_4$ was low compared to cisplatin in both cell lines.

Table 2. IC_{50} values obtained in cisplatin-sensitive L1010/0 mouse leukemia cells (A) and the resistant L1210/2 cell line (B). Resistance factors (*rf*) for cisplatin and DAB(PA)$_4$ were calculated (*rf* = B/A)

	IC_{50} (μM) L1210/0 (A)	Resistance factor L1210/2 (B)	*rf* = B/A
DAB(PA-tPt-Cl)$_4$	12.4	9.3	0.8
cisplatin	1.5	4.6	3.1

DAB(PA-tPt-Cl)$_4$ was also tested in 7 human tumor cell lines. IC_{50} values are shown in Table 3. The tetranuclear compound showed a low cytotoxicity in all cell lines, which is in accordance with the results in L1210 mouse leukemia. In some cell lines, the IC_{50} value could not be determined because it was out of the used concentration range. In the other cases, the IC_{50} value of DAB(PA-tPt-Cl)$_4$ was found 13−20 times higher than that of cisplatin.

Conclusion

The results in this paper show that it is possible to functionalize the four amino endgroups of the first generation of a poly(propyleneimine) dendrimer DAB(PA)$_4$ selectively with *trans*-diamminechloroplatinum moieties in high yield. The tetranuclear platinum compound DAB(PA-tPt-Cl)$_4$ is able to bind four molecules of GMP at their N7 positions. The arms of the tetranuclear compound are capable of binding GMP in a way similar to the ends of dinuclear 1,1/t,t compounds. The compound shows low cytotoxicity towards L1210/0 and L1210/2 mouse leukemia cell lines and seven human tumor cell lines. The low cytotoxicity may as well be caused by transport problems across the cell membranes the compound has to pass to reach DNA. The high charge (+6 at neutral or acidic pH) in combination with the branched structure may cause these problems. The high charge makes diffusion through the apolar membrane un-

Table 3. IC_{50} values determined in seven human tumor cell lines using the microculture sulforhodamine B (SRB) test

likely. However, the efficient uptake of the trinuclear compound BBR 3464 (with a charge of +4) in L1210 cells[15] shows that a high charge does not necessarily hamper the influx of a compound. In literature it has been suggested that charged linear dinuclear compounds may enter the cell through the same gates and channels as the structurally related polyamines spermine and spermidine.[1] Such gates may be unable to accommodate transport of a compound with a branched structure such as DAB(PA-tPt-Cl)$_4$.

In order to establish a structure-activity relationship, we are currently preparing a family of di- and polynuclear platinum compounds. It would be interesting to study their cellular uptake and cytotoxicity, related to their charge and structure. This should improve our insight into the mechanism of action of this new class of platinum compounds.

The authors are indebted to the EU for a grant as Host Institute in the EU programme Human Capital and Mobility. Also support and sponsorship by COST Action D8/00097/97 (biocoordination chemistry) is kindly acknowledged. The authors wish to thank Johnson & Matthey (Reading, UK) for their generous loan of K_2PtCl_4. This work has been performed under auspices of the joint BIOMAC Research Graduate School of Leiden University and Delft University of Technology.

Experimental Section

General Remarks: The complex *trans*-[$PtCl_2(NH_3)_2$] was prepared according to literature procedures[20] from K_2PtCl_4. K_2PtCl_4 was obtained from Johnson & Matthey (Reading, UK). Other chemicals were obtained from Aldrich and were used without further purification.

Titrations were carried out in D_2O. The pH was adjusted by adding trace amounts of 1 M DCl and NaOD to the NMR solutions. pH Measurements were carried out with a Radiometer PHM 80 pH meter, using a Hamilton combination glass electrode. The pH was corrected for the deuterium isotope effect by adding 0.4 units to the display readout. − NMR spectra were taken on a Bruker DPX 300 spectrometer with a 5-mm multi-nucleus probe. Temperature was kept constant by a variable temperature unit. ^{1}H NMR spectra were determined with respect to external TMS. ^{195}Pt spectra were calibrated by using K_2PtCl_4 as an external reference at δ = −1614.

Syntheses

[DAB(PA-*trans*-Pt(NH_3)$_2$Cl]Cl_4 (DAB(PA-tPt-Cl)$_4$): This synthesis was based on literature procedures for the preparation of dinuclear 1,1/t,t compounds.[16] *trans*-$PtCl_2(NH_3)_2$ (0.70 g, 2.3 mmol) was activated by treatment with $AgNO_3$ (0.30 g, 2.3 mmol) in 13 mL of DMF. After stirring overnight in the dark, AgCl was removed by filtration. A solution of the ligand DAB(PA)$_4$ (0.16 g, 0.5 mmol) in 1 mL of DMF was added dropwise and the reaction mixture was stirred at 40°C in the dark. After 16 hours the reaction was quenched with a tenfold excess of LiCl. DMF was removed in vacuo, and the remaining yellow gel was treated with small portions of warm EtOH to remove LiCl. Unreacted *trans*-$PtCl_2(NH_3)_2$ was removed by adding a minimum amount of cold water, after which the remaining yellow solid was filtered off. Lyophilization of the solution yields an off-white solid (564 mg, 0.37 mmol, yield 90%). In some batches, small amounts of a brown sticky material developed after standing at room temperature for several weeks. This problem could be circumvented by storage at −20°C. More pure product has been obtained by repeated washing of the crude material with MeOH and warm EtOH. Mixing of the remaining solid with water, followed by filtration of the solution and lyophilization results in a white powder (0.13 g, 0.09 mmol, yield 17%). Analysis: ^{1}H NMR (D_2O, pD = 12) δ (ppm) = 2.67 (t (J = 7.2 Hz), 8 H, e), 2.60−2.45 (m, 12 H, b+c), 1.88 (m, 8 H, d), 1.46 (s, 4 H, a); ^{195}Pt NMR (D_2O): δ (ppm) = −2425; calculated for $C_{16}H_{64}N_{14}Cl_8Pt_4$ (1516.72): C 12.67, H 4.25, N 12.93; found C 12.92, H 4.29, N 12.04. Although the nitrogen analysis is slightly lower (7%) than calculated, only one signal was observed in ^{195}Pt NMR. Therefore it is concluded that the impurity is unlikely to be a platinum compound interfering in the cytotoxicity tests.

Cytotoxic Studies

Cytoxicity assays in L1210 cell lines were based on literature procedures.[19][20] The cell lines L1210/0 and L1210/2 were cultured in McCoy's 5a medium supplemented with 10% fetal calf serum(Gibco, Paisley, Scotland), penicillin (100 units/ml: Duchefa, Netherlands) and streptomycin (100μg/ml: Duchefa, Netherlands). During growth, the cells grew partly in suspension and partly weakly adherent to the flasks. The cytotoxicity of cisplatin and DAB(PA-tPt-Cl)$_4$ were determined by measuring the inhibition of cell growth (cell growth assay, CGA). For the CGA, cells (5×10^4/mL) were pre-cultured in 24 multi-well plates for 24 h at 37°C in an incubator with 5% CO_2 and subsequently treated with at least three different concentrations of cisplatin (0−16 μM) or DAB(PA-tPt-Cl)$_4$ (0−66 μM) for 3 days. Cell numbers were determined with a counting chamber. Each platinum concentration was tested in at least two independent experiments.

In vitro cytotoxicity assays in human tumor cell lines were performed at the Dr. Daniel den Hoed Kliniek (Rotterdam Cancer Institute), Department of Medical Oncology (Rotterdam, the Netherlands). The seven well-characterized cell lines used were MCF7 and EVSA-T (breast cancer), WIDR (colon cancer), IGROV (ovarian cancer), M19 (melanoma), A498 (renal cancer) and H226 (nonsmall cell lung cancer). ID_{50} values were determined using the microculture sulforhodamine B test (SRB).[22]

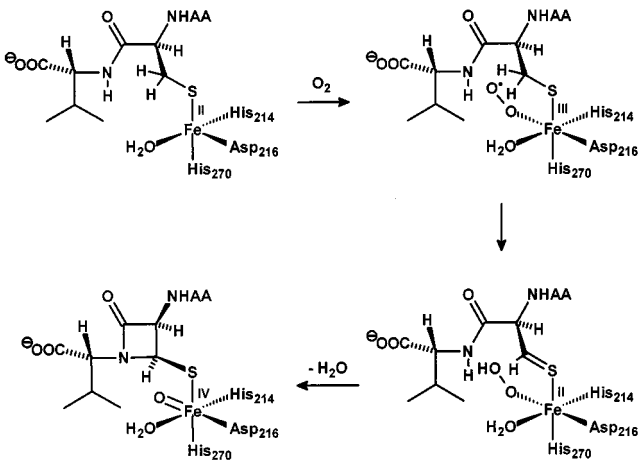
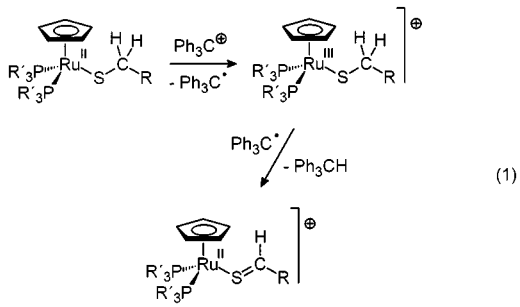
Enantioselective Organic Syntheses Using Chiral Transition Metal Complexes, 8[+] Chiral Rhenium Complexes of Functionalized Thioaldehydes



Nicolai Burzlaff[a] and Wolfdieter A. Schenk*[a]

Dedicated to Professor Helmut Werner on the occasion of his 65th birthday

Keywords: Captopril / Cysteine / Rhenium / S ligands / Thioaldehydes



Chiral racemic rhenium thioaldehyde complexes [CpRe(NO)(PPh$_3$)(η^2-S=CHR)]PF$_6$ (**2a–g**) bearing functionalized aliphatic groups R [R = CH$_2$Ph (**a**), COOEt (**b**), CH$_2$COOMe (**c**), CH$_2$C(O)NHCH$_2$Ph (**d**), (*R*)-CH(NC$_8$H$_4$O$_2$)COOMe (**e**), (*S*,*S*)-CH(Me)C(O)NC$_4$H$_7$COOMe (**f**), C$_4$H$_3$O (**g**)] have been obtained by hydride abstraction from the corresponding thiolate complexes [CpRe(NO)(PPh$_3$)(SCH$_2$R)] (**1a–g**). With the exception of **2b**, only single stereoisomers with *like* configurations at rhenium and the thioaldehyde carbon atom were obtained. In some cases, the corresponding sulfinate complexes [CpRe(NO)(PPh$_3$)(SO$_2$CH$_2$R)] (**3d–f**) were formed as by-products. The analogous toluenesulfinate complex [CpRe(NO)(PPh$_3$){SO$_2$(4-C$_6$H$_4$CH$_3$)}] (**3a**) has been prepared from [CpRe(NO)(PPh$_3$)(THF)]BF$_4$ (**8**), and the structure of **3e** has been determined by X-ray crystallography. The use of phosphorus ligands other than PPh$_3$ was briefly explored with the synthesis of [CpRe(NO)(PR′$_3$)(η^2-S=CHR)]PF$_6$ (**5a–d**) [R′ = OPh, R = Ph (**a**), 4-C$_6$H$_4$Cl (**b**), R′ = *i*Pr, R = Ph (**c**), H (**d**)]. Nucleophilic addition of NaSMe to [CpRe(NO)(PPh$_3$){η^2-S=CH(4-C$_6$H$_4$OMe)}]PF$_6$ (**5e**) gave the dithioacetal complex [CpRe(NO)(PPh$_3$){SCH(SMe)(4-C$_6$H$_4$OMe)}] (**9**) in high yield and with low diastereoselectivity. Diels–Alder additions of **5a**, **e** with 2,3-dimethylbutadiene and 2,3-dimethoxybutadiene gave complexes of cyclic thioethers (**10a–c**). From the relative rates of reaction (**5a** >> **5e**) and the low diastereoselectivity, it was concluded that the cycloadditions as well as the nucleophilic addition proceed via the linkage isomers [CpRe(NO)(PR′$_3$)(η^1-S=CHR)]PF$_6$.

The central step of penicillin biosynthesis leading to the formation of the β-lactam ring is initiated by a hydrogen atom abstraction from the α position of an iron(III)-coordinated cysteine moiety. The thioaldehyde intermediate thus formed undergoes nucleophilic attack by the deprotonated amide group of the cysteine[2] (Scheme 1).

Scheme 1. Hydride abstraction and ring closure steps of penicillin biosynthesis[2]

We have in the past reported a similar and very efficient synthesis of ruthenium thioaldehyde complexes from the corresponding thiolates and triphenylcarbenium salts.[3] Mechanistically, this reaction proceeds through a one-electron oxidation of Ru^{II} to Ru^{III}, followed by hydrogen atom abstraction (Equation 1).[4]

For ruthenium, this synthesis appears to be limited to complexes of aromatic thioaldehydes. However, the same reaction carried out on rhenium thiolates of the type [CpRe(NO)(PPh$_3$)(SCH$_2$R)] also gave the corresponding thioaldehyde complexes with R = H, CH$_3$.[5] We report herein on an extension of this methodology to complexes of aliphatic thioaldehydes, particularly those bearing functional groups on the side chain.

Complexes of aliphatic thioaldehydes have hitherto attracted only limited attention. Cobalt and rhodium thioacetaldehyde complexes have been synthesized either by nucleophilic substitution of α-(bromoethyl) complexes or by

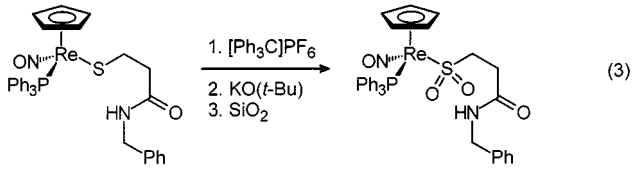
hydrogenation of a thioketene complex.[6][7] A phenylthioacetaldehyde complex of ruthenium has been obtained by H_2S addition to the corresponding vinylidene complex.[8] Thioaldehyde complexes of titanium and zirconium are generally accessible by intramolecular methane elimination from $[L_nM(CH_3)(SCH_2R)]$ complexes[9][10] or simply by α-deprotonation of thiolate ligands.[11] Complexes of η^4-coordinated unsaturated thioaldehydes have been obtained by metal-induced ring-opening of thietes.[12] However, in none of these cases have any substrates bearing functional groups on the side chain been involved.

Results

Synthesis of Thioaldehyde Complexes

Treatment of the thiolate complexes **1a**−**c**[1] with triphenylcarbenium hexafluorophosphate at −70°C as described previously[5] gave the expected thioaldehyde complexes **2a**−**c** in fair to good yields (Equation 2).



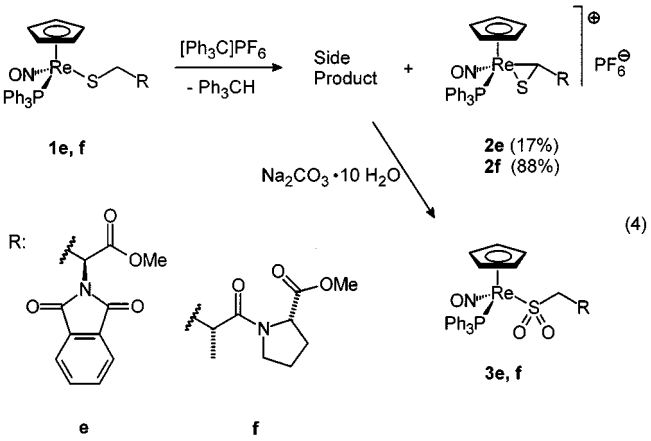
(2)

1a - c

R: CH_2Ph (**a**), C(O)OEt (**b**), $CH_2C(O)OMe$ (**c**)

2a (81%)
2b (76%)
2c (58%)

The method has its limitations, however. Similar reactions with R = $CH{=}CH_2$, CH_2NHAc, or $CH_2C(O)NHCH_2Ph$ gave inseparable mixtures of products, among which the expected thioaldehyde complexes could only be identified spectroscopically. In one such case, base hydrolysis of the reaction mixture led to the formation of the corresponding sulfinate complex **3d** along with some starting material **1d** (Equation 3).



(3)

1d **3d** (25%)

Similarly, the thiolate complexes derived from the methyl esters of (*R*)-*N*-phthaloylcysteine (**1e**) and *N*-[(*S*)-3-mercapto-2-methylpropionyl]-(*S*)-proline (Captopril) (**1f**) gave the corresponding thioaldehyde complexes in poor (**2e**) and good yields (**2f**). The formation of side products became more pronounced at low temperature; their hydrolysis again gave the sulfinate complexes **3e**, **f** (Equation 4), which could be isolated by chromatography.

The new thioaldehyde complexes were obtained as brownish-yellow microcrystalline materials, which were found to be soluble only in polar organic solvents such as dichloromethane or acetone. A dominant feature of their

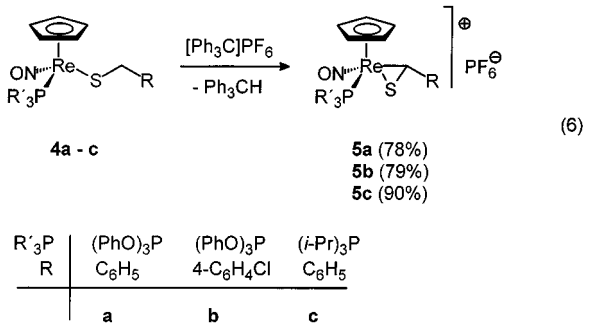
e **f**

infrared spectra, besides the absorptions of the ester and amide groups, is an intense NO stretching absorption around 1750 cm^{-1}. In the ^1H- and ^{13}C-NMR spectra, the thioformyl group gives resonances near $\delta(^1H) = 6$ and $\delta(^{13}C) = 45$, which confirms the $\eta^2(C,S)$-coordination of the thioaldehyde ligand.[5] For this coordination mode, the existence of diastereoisomers with *syn* and *anti* arrangements of the Cp ligand and the substituent at the thioformyl group can be expected. For **2b**, two isomers in an 80:20 ratio were indeed found, whereas **2a** and **2c** were obtained as single diastereoisomers. Low-temperature NMR spectra did not reveal any dynamic phenomena down to −60°C. The complexes **1e**, **f**, which contain enantiomerically pure thiolate ligands, were employed in this synthesis as diastereomeric mixtures with opposing configurations at rhenium. As a consequence, **2e**, **f** were obtained as 1:1 mixtures of diastereoisomers. The same reaction carried out on diastereomerically pure (R_{Re},R_C)-**1e**[1] gave **2e** as a single isomer, indicating that the hydride abstraction proceeds with retention of configuration at rhenium.

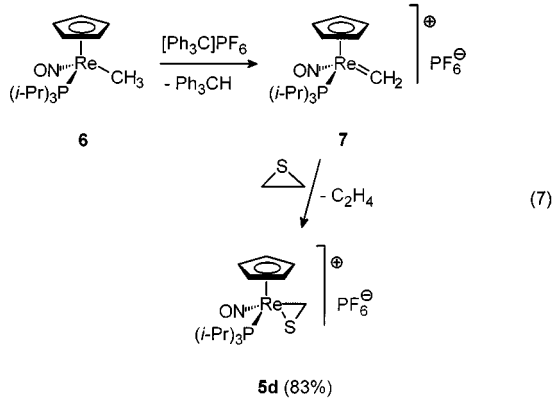
Treatment of the (2-furyl)methylthiolate complex **1g** with triphenylcarbenium hexafluorophosphate gave only an intractable, dark-purple mixture. As noted previously, the dehydrogenation of thiolate complexes may in some cases be brought about using ferrocenium hexafluorophosphate as a one-electron oxidant.[4] Using this method we obtained the expected (2-furyl)methanethial complex **2g** in acceptable yield as a single diastereoisomer (Equation 5).



(5)

1g **2g** (41%)

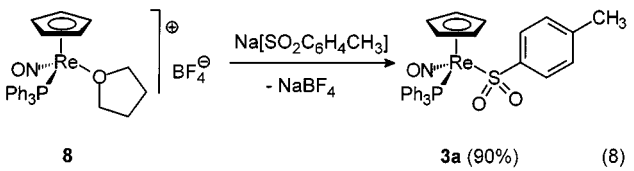
Again, **2g** was obtained as a yellow crystalline compound and its spectroscopic properties were very similar to those of the analogous thiobenzaldehyde complex.[5]



The use of other rhenium complexes with different steric and electronic properties was investigated briefly. The triphenylphosphite complexes **4a**, **b** and the triisopropylphosphane complex **4c**[13] reacted cleanly with triphenylcarbenium hexafluorophosphate, giving good yields of the corre-

sponding thiobenzaldehyde complexes **5a**−**c**, again as single diastereoisomers (Equation 6).

(6)



Finally, the thioformaldehyde complex **5d** was obtained from the methyl complex **6** by a reaction sequence closely analogous to the synthesis of $[CpRe(NO)(PPh_3)(S{=}CH_2)]PF_6$ originally reported by Gladysz[14] (Equation 7).

(7)

The thioaldehyde complexes **5a**−**d** are spectroscopically very similar to their triphenylphosphane analogues. The variation of the electron density at rhenium is apparent from the shift of ν(NO) to higher frequencies for L = $P(OPh)_3$ and, for L = $P(iPr)_3$ in particular, from the 5 ppm upfield shift of the ^{13}C resonance of the thiocarbonyl carbon atom.

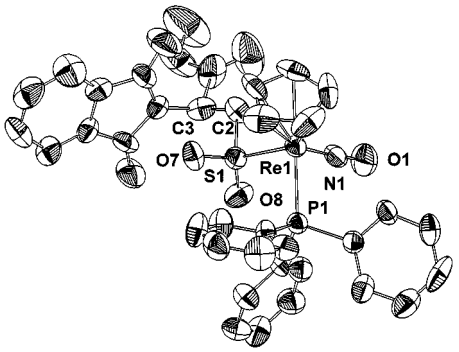
Since rhenium sulfinate complexes $[CpRe(NO)(PPh_3)(SO_2R)]$ have not been described previously, we decided to prepare an authentic example by a ligand substitution reaction (Equation 8).

(8)

Complexes **3a**, **d**−**f** were obtained as light-yellow materials and were found to be readily soluble in dichloromethane and chloroform. Their infrared spectra show an intense ν(NO) absorption around 1700 cm^{-1} and two medium-intensity bands at 1150−1180 and 1038−1055 cm^{-1} due to $\nu_{asym}(SO_2)$ and $\nu_{sym}(SO_2)$. A further characteristic feature of sulfinate complexes is a low field ^{13}C-NMR signal[15] due to the α-carbon atom, which is found at δ = 157 for **3a** and at δ = 70 for **3d**.

Crystal and Molecular Structure of 3e

The identity of the sulfinate complexes was finally confirmed by an X-ray structure determination of the cysteine derivative **3e**. The compound crystallized as an acetone solvate in the centrosymmetric space group $P\bar{1}$, which indicates that racemization of the cysteine-derived ligand must have occurred en route to **3e**. Indeed, the sample of **1e** used in this reaction had been obtained under sufficiently alkaline conditions (NaOEt/HOEt) to effect racemization at the α carbon atom.[1] Figure 1 shows a view of the molecule in its (*S*,*S*) configuration.



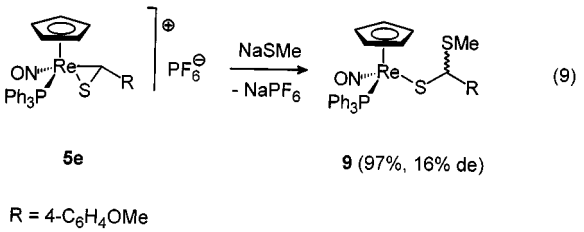


Figure 1. Molecular structure $[CpRe(NO)(PPh_3)\{SO_2CH_2CH(NC_8H_4O_2)COOMe\}]$ (**3e**). Selected distances [pm] and angles [°] (standard deviations in parentheses): Re(1)−S(1) 235.8(4), Re(1)−P(1) 236.8(4), Re(1)−N(1) 174(2), N(1)−O(1) 121(2), S(1)−C(2) 178(2), S(1)−O(7) 146.3(11), S(1)−O(8) 145.3(11),; S(1)−Re(1)−P(1) 92.82(14), S(1)−Re(1)−N(1) 94.2(4), P(1)−Re(1)−N(1) 90.9(4), Re(1)−S(1)−C(2) 103.4(5), Re(1)−S(1)−O(7) 111.2(4), Re(1)−S(1)−O(8) 117.8(5), O(7)−S(1)−O(8) 114.4(7); P(1)−Re(1)−S(1)−C(2) 161.5(12).

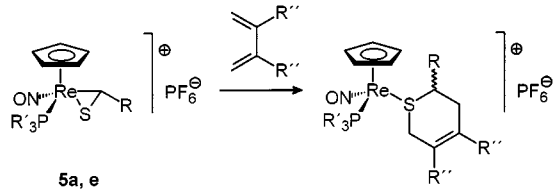
It is interesting to compare the molecular dimensions of **3e** with those of the starting thiolate complex **1e**.[1] All relevant bond lengths except those involving the sulfur atom are the same within one standard deviation. The S−Re and S−C bonds in **3e** are 4 pm shorter due to the contraction of the valence orbitals at the sulfur atom resulting from the increase of the formal oxidation state and the attachment of two highly electronegative oxygen atoms, respectively. The most conspicuous difference between the structures of **1e** and **3e** concerns the bond angles at rhenium. In **1e**, the angle S−Re−N is widened to 102.35(11)°.[1] A similar distortion has been found in other thiolate complexes, e.g. $[CpRe(NO)(PPh_3)\{SCH(Ph)(2\text{-}C_6H_4Me)\}]$ [101.3(2)°][16] and $[CpRe(NO)\{P(iPr)_3\}(SCH_3)]$ [102.2(4)°].[13] In **3e**, however, the N−Re−S angle [94.2(4)°] is close to the value of a regular octahedron, despite the fact that a sulfinate ligand is sterically more demanding than a thiolate group.

Reactions of Thioaldehyde Complexes

Typical reactions of transition metal thioaldehyde complexes include nucleophilic additions and [2+4]-cycload-

ditions.[17–19] We have found previously that thiolates add rapidly to cationic η^1-thioaldehyde complexes of ruthenium.[4] In a similar experiment, **5e**[5] was treated with sodium methylthiolate in acetone. An almost quantitative yield of the dithioacetal complex **9** was isolated as a mixture of two diastereoisomers (Equation 9).

(9)



5e

9 (97%, 16% de)

R = 4-C_6H_4OMe

Complex **9** was obtained as a yellow oil and was found to be soluble in most common organic solvents. The spectroscopic properties of **9** are very similar to those of other thiolate complexes of the type [CpRe(NO)(PPh_3)(SR)].[1] Particularly characteristic is an intense ν(NO) absorption at ca. 1650 cm^{-1} and, in the ^{13}C-NMR spectrum, two low field signals due to the α carbon at sulfur in the two diastereoisomers, 1 ppm apart and split into doublets through coupling with phosphorus.

The complexes were next subjected to Diels–Alder-type additions with 2,3-dimethylbutadiene and 2,3-dimethoxybutadiene (Equation 10).

5a, e

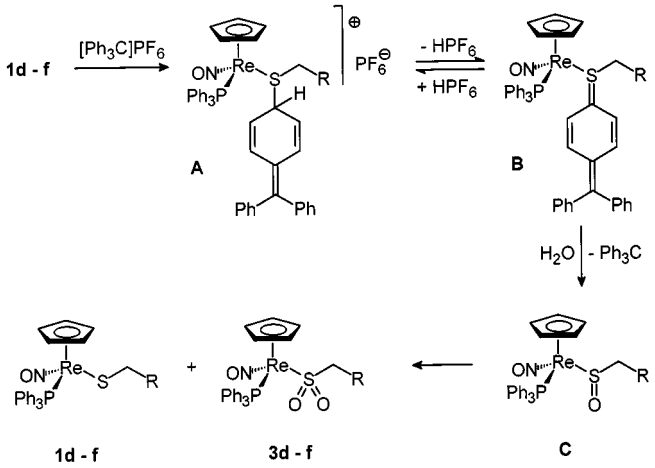
R′′	CH_3	OCH_3	CH_3
	5a	**5a**	**5e**
	10a	**10b**	**10c**

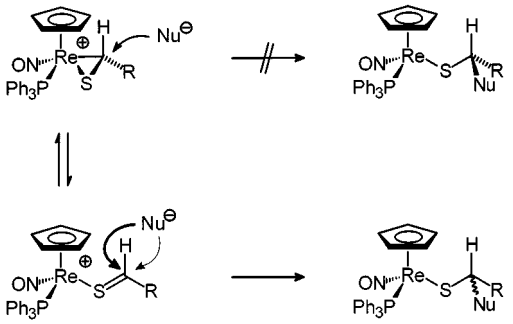
(10)

The triphenylphosphane complex **5e** reacted sluggishly; even after 5 d at room temperature the isolated yield of the adduct **10c** was only 12%. In contrast, the triphenylphosphite complex **5a** gave good yields of the cycloaddition products **10a**, **b** in less than 1 h. Again, the diastereoselectivity was disappointingly low. **10a–c** were obtained as yellow crystalline solids. In the ^{1}H-NMR spectra, some of the signals of the minor diastereoisomers of **10a**, **b** are broadened due to slightly hindered inversion at sulfur.[20][21] In this regard, **10a**, **b** are quite similar to the analogous cycloadducts of the ruthenium thioaldehyde complexes reported previously.[4]



Discussion

There is a striking similarity between the synthesis of thioaldehyde complexes through β-hydride abstraction discovered in this laboratory (Equation 1)[3][4] and the formation of the thioaldehyde intermediate in penicillin biosynthesis (Scheme 1).[2] Both involve the coordination of a thiolate group to a d^6 transition metal complex followed by a one-electron oxidation to give the corresponding d^5 system, and H atom abstraction from the carbon atom in the position β to the metal. In view of this, it seemed a worthwhile undertaking to extend our investigations to thioaldehyde complexes derived from cysteine and other functionalized thiolates. Reactivity studies would then perhaps provide a deeper insight into the inner workings of isopenicillin N synthase (IPNS).



The coordination of prochiral alkenes and heteroalkenes to the chiral Lewis acid $[CpRe(NO)(PPh_3)]^+$ is, in general, accompanied by a high degree of diastereoselectivity.[22] For purely steric reasons, an *anti* arrangement of the Cp ring at rhenium and the substituent R is preferred. This is apparently also true for thiobenzaldehydes[5] and the aliphatic thioaldehydes forming the basis of this study. In the case of the thioacetaldehyde complex [CpRe(NO)(PPh_3)(S=$CHCH_3$)]PF_6, we have been able to detect the minor (*RS*,*SR*)-diastereoisomer by low-temperature NMR.[5] The equilibration of the diastereoisomers proceeds via the corresponding η^1-(*S*) isomers, which can often be observed separately,[23][24] e.g. in the case of the similar ruthenium complexes [CpRu(PMe_3)$_2$(S=CHR)]PF_6.[4] This is in contrast to the thioformaldehyde complexes [CpRe(NO)(PPh_3)(S=CH_2)]PF_6[14] and **5d**, as well as the ester derivative **2b**, which are static at room temperature. The energy of the π* level of the C=S double bond, which is raised by +I substituents and lowered by −M substituents, obviously determines the activation energy for the $\eta^2 \rightarrow \eta^1 \rightarrow \eta^2$ rearrangement.

Although in general the hydride abstraction with triphenylcarbenium salts gave good results, it was not always devoid of side reactions. Thus, starting from the thiolate complexes **1d–f**, the ^{31}P-NMR spectra of the crude reaction mixtures invariably featured a prominent signal at δ = 11, which is typical of thioether complexes [CpRe(NO)(PPh_3)(SRR′)]PF_6.[5] Attempted isolation of these byproducts led to further decomposition, which, after workup under basic conditions, ultimately resulted in the formation of the sulfinate complexes **3d–f** (Equation 3, 4). A likely explanation for this course of events is summarized in Scheme 2.

Electrophilic attack by the trityl cation gives an unstable thioether complex **A**. Under basic conditions, provided for example by chromatography on silica, **A** is deprotonated to give a resonance-stabilized metallated sulfur ylide **B**, which, in turn, is hydrolyzed to a sulfenate complex **C**. Transition metal sulfenate complexes remain a rare and little-understood class of compounds.[25] While there are some examples of quite stable complexes,[25–27] others seem to have a pronounced tendency to undergo a redistribution of their oxygen atoms.[28] Such a disproportionation would ulti-

Scheme 2. Formation of sulfinate side products **3d**−**f**

Scheme 3. Stereochemical course of nucleophilic attack at the carbon atom

mately produce the observed sulfinate complexes **3d**−**f** along with the starting compounds **1d**−**f**.

A comparison of spectroscopic and structural data of the sulfinate complex **3e** and the corresponding thiolate **1e**[1] reveals further insights into the bonding in low-valent transition metal thiolate complexes. The importance of antibonding interactions between the p-type lone pairs at sulfur and the occupied d orbitals at the metal has been stressed repeatedly.[29][30] In sulfinate complexes such as **3e** the sulfur electrons are no longer available for such π interactions. As a consequence, the electron density at rhenium is lowered compared to that in **1e**, which is most obvious from a 50 cm^{-1} hypsochromic shift of ν(NO). Furthermore, the N−Re−S angle, which in **1e** is widened to more than 102° to minimize antibonding,[13] is now lowered again to 94°. Thus, in hindsight the structure of **3e** offers additional proof of our contention that bond angles in low-valent transition metal thiolate complexes are influenced by π-antibonding interactions to a similar extent as bond lengths and dihedral angles.[29]

The disappointingly low diastereoselectivity of the nucleophilic addition (Equation 9) deserves some comment. If this reaction were analogous to the addition of nucleophiles to coordinated alkenes,[31][32] i.e. backside attack by Nu^- accompanied by cleavage of the metal−carbon bond, then the diastereoselectivity should somehow reflect the high diastereoisomer ratio of the starting thioaldehyde complexes. If, on the other hand, the η^2-thioaldehyde complexes described here are in rapid equilibrium with their η^1-isomers − such equilibria have been observed in many other cases, including the closely related ruthenium complexes $[CpRu(PR'_3)_2(S{=}CHR)]$[4] − then a much lower asymmetric induction would be expected (Scheme 3).

In the Diels−Alder addition (Equation 10), the less stable but more reactive η^1-isomers also play a decisive role. We have seen previously that with decreasing electron donation from the supporting phosphane ligands, the isomer ratio shifts in favor of the η^1 form.[4] As a consequence, the triphenylphosphite complex **5a** reacts with dienes much more rapidly than the triphenylphosphane complex **5e** does. The diastereoselectivity, on the other hand, is again too low to be synthetically useful.

Conclusions

We have demonstrated herein that the synthesis of thioaldehyde complexes through β-hydride abstraction can be extended to aliphatic thioaldehydes, and that it tolerates ester and amide functionalities. In particular, the successful synthesis of the cysteine-derived thioaldehyde complex **2e** offers additional proof of the mechanism of penicillin biosynthesis proposed by Baldwin.[2] Nucleophilic additions and cycloadditions at the C=S function proceed via the more reactive η^1 linkage isomers. In order to achieve high diastereoselectivities in these reactions, it will be necessary to employ less electron-donating and sterically more demanding phosphorus ligands.

Experimental Section

All experiments were carried out in Schlenk tubes under an atmosphere of nitrogen using suitably purified solvents. − IR: Perkin−Elmer 283, Bruker IFS 25. − ^{1}H NMR: Bruker AMX 400, δ values relative to TMS. − ^{13}C NMR: Bruker AMX 400, δ values relative to TMS; assignments were routinely checked by DEPT; in some cases the ^{13}C-NMR signals of quaternary carbon atoms were too weak to be detected. − ^{31}P NMR: Bruker AMX 400, δ values relative to 85% H_3PO_4. The ^{1}H- and ^{13}C-NMR signals of phenyl groups are unremarkable and have therefore been omitted from the lists of spectral data. − Elemental analyses: Analytical Laboratory of the Institut für Anorganische Chemie. The following starting materials were obtained as described in the literature: [CpRe(NO)(PPh$_3$)(SR)] (**1a**−**g**),[1] [CpRe(NO)(PR′$_3$)(SR)] (**4a**−**c**),[13] [CpRe(NO)(PPh$_3$){η^2-S=CH(4-C_6H_4OMe)}]PF_6 (**5e**),[5] [CpRe(NO){P(*i*Pr)$_3$}(CH_3)] (**6**),[13] [CpRe(NO)(PPh$_3$)(OC_4H_8)]BF_4 (**8**),[33] sodium methylthiolate.[34] All other reagents were used as purchased.

[CpRe(NO)(PPh$_3$)(η^2-S=CHCH$_2$Ph)]PF_6 (2a): At −70°C, a solution of $[Ph_3C]PF_6$ (66 mg, 0.17 mmol) in dichloromethane (5 mL) was added to a solution of **1a** (102 mg, 0.15 mmol) in the same solvent (10 mL). The mixture was allowed to warm to 20°C and then concentrated in vacuo to a volume of 2 mL. Addition of diethyl ether led to precipitation of the product, which was filtered off, washed with diethyl ether, and dried in vacuo. Yield 100 mg (81%); m.p. 108°C. − ^{1}H NMR (400 MHz, [D$_6$]acetone, 20°C):

δ = 3.03 [dd, ^2J(H,H) = 13.8 Hz, ^3J(H,H) = 9.6 Hz, 1 H, CH_2], 3.93 [dd, ^2J(H,H) = 13.8 Hz, ^3J(H,H) = 3.0 Hz, 1 H, CH_2], 6.00 [ddd, ^3J(H,H) = 9.6 Hz, ^3J(H,H) = 3.6 Hz, ^3J(P,H) = 2.0 Hz, 1 H, SCH], 6.33 (s, 5 H, C_5H_5). − ^{13}C NMR (100 MHz, [D$_6$]acetone, 20°C): δ = 48.5 (s, SCH_2), 54.0 (s, SCH), 101.4 (s, C_5H_5). − ^{31}P NMR (162 MHz, [D$_6$]acetone, 20°C): δ = 6.9 (s). − IR (CH_2Cl_2): $\tilde{\nu}$ = 1744 cm^{-1} (NO). − $C_{31}H_{28}F_6NOP_2ReS$ (824.8): calcd. X-ray Structure Determination of [CpRe(NO)(PPh$_3$){SO$_2$CH$_2$CH(NC$_8$H$_4$O$_2$)COOMe}] · [D$_6$]acetone (3e · [D$_6$]acetone): $C_{35}H_{30}N_2O_7PReS \cdot C_3D_6O$: molecular mass 904.0, crystal size 0.3 × 0.15 × 0.05 mm, obtained from a saturated [D$_6$]acetone solution; triclinic crystal system, space group $P\bar{1}$ (No. 2), a = 8.4564(4), b = 13.229(2), c = 18.647(3) Å, α = 102.036(14)°, β = 93.63(2)°, γ = 102.69(2)°; V = 1977.1(10) Å^3, Z = 2, d_{calcd} = 1.519 g cm^{-3}; μ(Mo-K_α) = 1.82 cm^{-1}. Data were collected at 293 K in the range 2° < θ < 23° from one-half of the reflection sphere (Enraf−Nonius CAD4 diffractometer, graphite monochromator, Mo-K_α radiation, λ = 0.70930 Å). Of the 5926 measured reflections, 5485 were symmetry-independent and 3044 were classified as observed [$I_O > 2\sigma(I_O)$]. An empirical absorption correction based on the counts of 4 reflections was applied. The structure was solved by the Patterson method by using the program package SHELXS-86[35] with hydrogen atoms included in their calculated positions. Refinement using the program package SHELXL-93[36] gave R_1 = 0.066, wR_2 = 0.121. The 5 highest maxima of a final difference Fourier map were below 0.895 e·Å^{-3}. Further details of the structure determination may be obtained from the Fachinformationszentrum Karlsruhe, D-76344 Eggenstein-Leopoldshafen, on quoting the depository number CSD-408460.

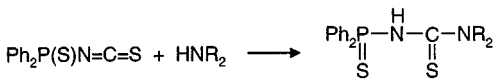
Keywords: Metallacycles / Solid-state structures / Heterocycles / Oxidations



Direct oxidation of $PhC(O)NHPPh_2$, $H_2NC(S)NHPPh_2$, $(C_5H_4N)C(S)NHPPh_2$ with O_2, S_8, or Se gives $[PhC(O)NHP(O)Ph_2]$ (**1**), $[H_2NC(S)NHP(S)Ph_2]$ (**2**), $[H_2NC(O)NHP(S)Ph_2]$ (**3**), $[PhC(O)NHP(S)Ph_2]$ (**4**), $[(C_5H_4N)C(S)NHP(S)Ph_2]$ (**5**), and $[H_2NC(S)NHP(Se)Ph_2]$ (**6**). Deprotonation of **1**, **2**, **4**–**6** with potassium *tert*-butoxide gives $K[PhC(O)NP(O)Ph_2]$ (**7**), $K[H_2NC(S)NP(S)Ph_2]$ (**8**), $K[PhC(O)NP(S)Ph_2]$ (**9**), $K[(C_5H_4N)C(S)NP(S)Ph_2]$ (**10**), and $K[H_2NC(S)NP(Se)Ph_2]$ (**11**). Reaction of **4** with KOBu and $[Cu(Ph_3P)_2][NO_3]$ gives $[Cu(Ph_3P)(PhC(O)NP(S)Ph_2)]$ (**12**) which is the first crystallographically characterised example of a non-ionic six-membered "true" heterocycle (i.e. a ring in which every heterocatom is different). **9** and **10** were treated with $[PdCl_2(COD)]$ to give $[Pd\{PhC(O)NP(S)Ph_2\}_2]$ (**13**) and $[Pd\{(C_5H_4N)C(O)NP(S)Ph_2\}_2]$ (**14**), respectively The anion of **8** coordinates to zinc forming $[Zn\{H_2NC(S)NP(S)Ph_2\}_2]$ (**15**). Treatment of **2** or **8** with $[PtCl_2(COD)]$ gives $[Pt\{H_2NC(S)NP(S)Ph_2\}\{H_2NC(S)NHP(S)Ph_2\}]^+Cl^-$ (**16**) and $[Pt\{H_2NC(S)NP(S)Ph_2\}_2]$ (**17**), respectively. The X-ray structures of **12**, **15–17** are reported.

Introduction

We have reported extensively[1] on the coordination chemistry of imidophosphinates in part as a consequence of their relationship to *acac*. Furthermore, monochalcogenides and molecules of the type $[Ph_2PNHP(E)Ph_2]$ (E = O, S, or Se)[2−11] have been developed and shown to chelate to range of late transition metals through both phosphorus and chalcogen donor atoms. The chemistry of phosphane derivatives of urea and thiourea were first studied during the 1960s. Three known methods of preparing such derivatives are shown below (Equation 1 and 2).[12−20]

(1)

(2)

Schmutzler et al. reported that the reaction of thiourea and chlorodiphenylphosphane at −20 °C did not give the expected *N*,*N*′-bis(diphenylphosphanyl)thiourea, $Ph_2PHNC(S)NHPPh_2$, but only gave $Ph_2P-P(S)Ph_2$.[21] Later, Bhattacharyya et al. carried out the reaction at room temperature and obtained *N*,*N*′-bis(diphenylphosphanyl)-thiourea in up to 46 % yield.[22] We have recently described[23] the formation of some phosphanylurea and related systems Here, we report on the oxidation of the phosphanylurea and phosphanyl-thiourea derivatives. Demonstrative examples of coordination complexes are also described, including the first example of a non-ionic six-membered "true" heterocycle.

Results and Discussion

The ligands were synthesised by direct oxidation of the phosphanylureas or phosphanylthioureas with the appropriate oxidising reagents generalised in Equation 1. $PhC(O)NHPPh_2$ oxidises readily with oxygen by dissolving it in tetrahydrofuran and stirring overnight exposed to air. However, $H_2NC(S)NHPPh_2$ is more stable and does not oxidise in air, when treated with aqueous hydrogen peroxide as well as the oxidation of P^{III} to P=O, most of the C=S is converted into C=O in the course of the reaction, the by-product, $H_2NC(O)NHP(O)Ph_2$,was identified by ^{31}P-NMR, infrared, and mass spectroscopy.

Oxidation of the phosphanylurea/thiourea derivatives by elemental sulfur is readily achieved in tetrahydrofuran at room temperature. $H_2NC(O/S)NHPPh_2$ react with S_8 to form (Equation 3) $[H_2NC(S)NHP(S)Ph_2]$ (**2**) and $[H_2NC(O)NHP(S)Ph_2]$ (**3**), respectively. Treatment of $RC(O)NHPPh_2$ (R = Ph and Py, 3-C_5H_4N, Py = pyridyl) with S_8 gave $[PhC(O)NHP(S)Ph_2]$ (**4**) and $[PyC(O)NHP(S)Ph_2]$ (**5**), respectively.

$[H_2NC(S)NHP(Se)Ph_2]$ (**6**) was prepared by allowing $H_2NC(S)NHPPh_2$ to react with grey selenium in tetrahydrofuran with warming for one hour. The solution was then filtered and its solvent removed to give a white powder.

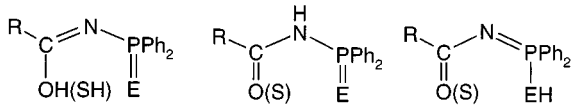

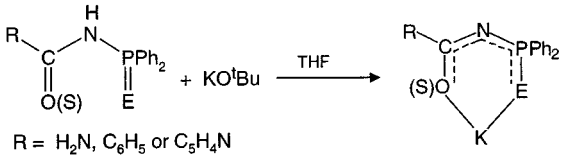

Figure 1. Tautomeric forms of RC(E)NHP(E′)Ph_2 (E = O or S; E′ = O, S, or Se)

After trituration with diethyl ether the product was obtained in 67 % yield.

All of the compounds are air stable colourless solids except **6** which turns red when exposed to air over a week; it can be stored under nitrogen almost indefinitely. The ^{31}P-NMR showed the shifts of P^{III} to P^{V} shown in Table 1. All the P=O, S, and Se derivatives display singlets in their phosphorus NMR spectra.

Compounds **1**−**6** can exist in three tautomeric forms (**A** − **C**, Figure 1). Their infrared spectra (Table 2) suggest form (**B**) is predominant in the solid state. The spectra of the compounds show peaks at around 3200 cm^{-1} indicating ν(NH) character. The vibrations at around 1665 cm^{-1} and 1100 cm^{-1} are indicative of ν(C=O) and ν(C=S) double bonds. The bands at around 1470 cm^{-1} are characteristic of ν(C−N) single bond [lower than ca. 1650 cm^{-1} for ν(C=N)]. All these compounds also have bands around 850 cm^{-1} reflecting the single bond character of ν(PN) compared to the double bond vibration at higher frequency around 1300 cm^{-1}. Furthermore vibrations at around 630 cm^{-1} and 1180 cm^{-1} for ν(P=S) and ν(P=O) support structure (**B**) in solid state.

Compounds **1**, **2**, **4**−**6** were easily deprotonated upon treatment with KO*t*Bu in THF at room temperature to give K[PhC(O)NP(O)Ph_2] (**7**), K[H_2NC(S)NP(S)Ph_2] (**8**), K[PhC(O)NP(S)Ph_2] (**9**), K[PyC(O)NP(S)Ph_2] (**10**), and K[H_2NC(S)NP(Se)Ph_2] (**11**) (Equation 4). The solutions were filtered through celite and the solvent removed to give the products analytically pure. All the compounds are colourless in appearance.

(4)

It can be seen by ^{31}P NMR that the displacement of an amino proton by an electropositive element (potassium) in general shields the nucleus under scrutiny and it is observed at lower frequency (Table 1). Upon deprotonation the ν(C=O) vibration shifts around 130 cm^{-1} to lower frequency, whilst the ν(C=S) cannot be easily identified. Concurrently the bond order of the P−N bond has increased and the & uψ;(CN) is observed at higher frequency in the deprotonated compounds.

The X-ray structure of **4** shows[24] the compound is in the keto form with the proton bonded to the nitrogen and not to the terminal chalcogen atoms. The geometry of this compound can be compared with [*i*Pr_2P(S)NHP(S)*i*Pr_2]

which also exists in a *syn* conformation.[27] The molecular structure of K[PhC(O)NP(S)Ph_2] **9** shows the ligand is coordinated to potassium via oxygen and sulfur donor atoms in a six-membered chelate ring arrangement in which the ring can be viewed as a true heterocycle containing six different atoms from Groups 1, 14, 15, and 16 of the periodic table. There are few previous crystallographic determinations to make comparisons. The most appropriate is K[N{P(S)Ph_2}$_2$].[28]

Reaction of K[PhC(O)NP(S)Ph_2] **9** with Cu(PPh_3)$_2$(NO_3) gives Cu(PhC(O)NP(S)Ph_2)(PPh_3) **12** which is the first example of a non-ionic six-membered true heterocycle. In **12** the X-ray structure (Table 3, Figure 2) reveals that copper is trigonal [Cu lies 0.03 Å out of the Cu−O−S−P(2) mean plane) and that the Cu−S−P−N−C−O ring is non-planar in what can best be described as a pseudo boat conformation. The P(1)−S−Cu−O mean plane [max. deviation 0.16 Å for Cu] is inclined by 142° to the O−C(37)−N−P(1) mean plane [max. deviation 0.01 Å for C(37)].

Table 3. Selected bond lengths [Å] and angles [°] in [Cu(PPh_3)-(PhC(O)NP(S)Ph_2)] **12**

Cu−O 2.013(2)	P(1)−N 1.621(3)
Cu−P(2) 2.1897(10)	N−C(37) 1.326(4)
Cu−S 2.223(1)	C(37)−O 1.270(3)
S−P(1) 2.011(1)	
O−Cu−P(2) 112.4(1)	N−P(1)−S 119.0(1)
O−Cu−S 106.2(1)	C(37)−N−P(1) 121.1(2)
P(2)−Cu−S 141.3(4)	O−C(37)−N 126.4(3)
P(1)−S−Cu 92.3(1)	C(37)−O−Cu 125.7(2)

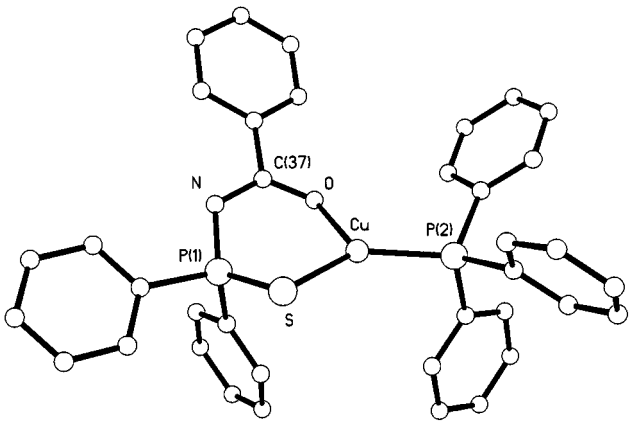

Figure 2. Molecular structure of [Cu(PPh_3)(PhC(O)NP(S)Ph_2)] **12** in the crystal

Two equivalents of the ligand salt K[PhC(O)NP(S)Ph_2] (**9**) was treated with [$PdCl_2$(COD)] in dichloromethane to give an orange solution immediately (Equation 5). The product [Pd{PhC(O)NP(S)Ph_2}$_2$] (**13**) was triturated with petroleum ether and a yield of 57 % was collected. [Pd{PyC(O)NP(S)Ph_2}$_2$] (**14**) was prepared in the same way with K[PyC(O)NP(S)Ph_2] (**10**) and [$PdCl_2$(COD)] and was isolated as red powder (93 %). The compounds **13** and **14** show the correct parent ion mass numbers [779 and 780 *m/z*] and isotope distributions in their FAB mass spectra and have satisfactory elemental analysis. The $^{31}P\{^1H\}$ NMR spectra display a singlet for both compounds at δ = 30 for **13** and 31 for **14** whilst their infrared spectra show similar features with the vibrational patterns simplified compared to the ligand salts and free ligands. The P=S vibrational frequencies have shifted around 50 cm^{-1} lower compared to the free ligands. In compound **13** the ν(CO) band is reduced significantly by 166 cm^{-1} which is in the range of a C−O single bond. The ν(CO) band for **14** appears to be a lot more complicated and are assigned at 1609, 1585, 1551, and 1508 cm^{-1}. The ν(PN) band in the palladium complexes have shifted [926 and 804 cm^{-1} for **13**; 920 and 818 cm^{-1} for **14**] to a higher frequency indicating an increase in the P−N bond order. The ligands seem to have coordinated to a palladium atom through their PS and CO donor groups to form metal complexes as six-membered chelate compounds. There are two possible isomers, *cis* or *trans*, that these compounds can form.

$$[PdCl_2(COD)] + 2K[RC(O)NP(S)Ph_2] \longrightarrow$$

R = C_6H_5 or C_5H_4N

$$[Pd\{RC(O)NP(S)Ph_2\}_2] + 2KCl \quad (5)$$

Ojima et al.[14][15] proposed that some diphenylphosphanylthioylthioureato metal(II) complexes have a chelate structure consisting of five different atoms − C, N, P, 2 S, and M^{II}. One of those complexes, where M = Ni, was later confirmed by Iwamoto et al.[29] with a molecular structure from X-ray crystallography studies however there has been little further work done in this area.

The zinc complex [Zn{H_2NC(S)NP(S)Ph_2}$_2$] (**15**) was obtained by the addition of $ZnCl_2$ to a tetrahydrofuran solution of K[H_2NC(S)NP(S)Ph_2] (Equation 6) in 75 % yield.

$$ZnCl_2 + 2K[H_2NC(S)NP(S)Ph_2] \longrightarrow$$

$$[Zn\{H_2NC(S)NP(S)Ph_2\}_2] + 2KCl \quad (6)$$

The X-ray structure of **15** (Table 4, Figure 3) reveals the expected tetrahedral coordination at zinc with the ZnS_2PCN ring adopting an approximately boat conformation Zn(1)−S(1)−S(2)−C(1) [max. deviation 0.08 Å for S(2)] is inclined by 137° to P(1)−N(1)−C(1)−S(1) [max. deviation 0.29 Å for N(1)].

Table 4. Selected bond lengths [Å] and angles [°] in [Zn{H_2NC-(S)NP(S)Ph_2}$_2$] **15**

Zn(1)−S(1) 2.351(2)	Zn(1)−S(2) 2.338(2)

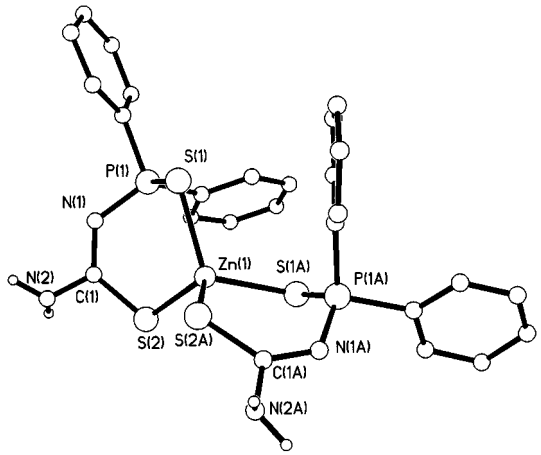

Figure 3. Molecular structure of $[Zn\{H_2NC(S)NP(S)Ph_2\}_2]$ **15** in the crystal

Reaction of equimolar amounts of $[H_2NC(S)NHP(S)Ph_2]$ (**2**) and $[PtCl_2(COD)]$ in dichloromethane was expected to give a six-membered chelate complex $PtCl_2\{H_2NC(S)NHP(S)Ph_2\}$. However, two singlets with unresolved ^2J platinum satellites were observed in the ^{31}P-NMR spectrum. Mass spectrometry reveals that two ligands have coordinated to the metal centre. The two NMR signals may be assigned to a neutral and a deprotonated ligand in $Pt\{H_2NC(S)NHP(S)Ph_2\}\{H_2NC(S)NP(S)Ph_2\}]Cl$ (**16**) (vide infra). The reaction was repeated using 2 molar equivalents of $K[H_2NC(S)NP(S)Ph_2]$, in dichloromethane to give the yellow crystalline $[Pt\{H_2NC(S)NP(S)Ph_2\}_2]$ (**17**) (Equation. 7).

$$[PtCl_2(COD)] + 2K[H_2NC(S)NP(S)Ph_2] \longrightarrow [Pt\{H_2NC(S)NP(S)Ph_2\}_2] + 2KCl \quad (7)$$

Compound **17** displays a singlet [δ = 33] with characteristic ^2J platinum coupling [^2J(P−Pt) = 114 Hz]. Compound **16** and **17** both displayed the correct mass values with the appropriate isotope distributions for $[Pt\{H_2NC(S)NP(S)Ph_2\}_2]$ obtained from FAB mass spectroscopy. Confirmation of the stoichiometry in the complexes was obtained from satisfactory elemental analysis data.

The infrared spectrum of compound **16** shows a close similarity to[23] $[Pt\{H_2NC(S)NHPPh_2\}_2]^{2+} \cdot 2\,Cl^-$ but with additional peaks at 598 and 576 cm^{-1} due to the two different phosphorus-sulfur vibrations Two broad ν(PN) vibrations are observed at 922 and 883 cm^{-1}. Close inspection of the peaks due to the NH_2 groups reveals two overlapping peaks resulting in very broad bands. Compound **17** displays an infrared spectrum which is very similar to that of **15**; with the ν(PS) vibration in **17** seen at 577 cm^{-1} and the ν(PN) vibration as a broad band at 883 cm^{-1}.

The X-ray structure of **16** (Table 5, Figure 4) shows that the two chelates are bound to a platinum atom by four sulfur donor atoms forming two six-membered rings in the *trans* configuration. Interestingly only one ligand is deprotonated which is supported by the notable differences in the P−N bond lengths for the two rings [P(1)−N(1) 1.56(3) P(21)−N(21) 1.65(2) Å] with deprotonation giving the shorter P−N length which is comparable to those in **15**. Furthermore the presence of the N−H proton in chelate **A** is supported by the close proximity of the chloride counter ion which H-bonds to the NH and NH_2 groups [N(22)···Cl(1) 3.38 Å, N−H···Cl 154°; N(21)···Cl(1) 3.10 Å, N−H···Cl 125°] to give a six-membered H−N−C−N−H−Cl ring. The chloride ion also H-bonds to the adjacent cation [N(2′)···Cl(1) 3.40 Å, N−H···Cl 160°] thus linking the cations and anions into chains. The square planar complex contains two six-membered rings though there are significant differences in ring conformation which may be due to one chelate ring being deprotonated. In chelate **A** (neutral ligand) the two Pt−S bond lengths are 2.317(7) and 2.322(8) Å with no significant differences between the sulfur donors bound by carbon and phosphorus atoms; the P=S bond length [1.97(1) Å] is similar to those in $[PhC(O)NHP(S)Ph_2]$ [1.94(6) Å] and $[\{(PhO)_2P(S)NC(S)N(nPr)_2\}_2Ni]$[30] which haa a P−S bond with substantial delocalisation and a bond length of 1.978(1) Å. The P−N and N−C bonds distances are appropriate for a limited degree of delocalisation and compare well with those in $[Pt\{H_2NC(S)NHPPh_2\}_2]^{2+} \cdot 2\,Cl^-$ [1.676(1) and 1.38(2) Å]. The most dramatic change observed is the lengthening of the C=S bond by about 0.1 Å compared to that in $[Pt\{H_2NC(S)NHPPh_2\}_2]^{2+} \cdot 2\,Cl^-$ to an observed single bond value [1.75(3) Å] similar to that in $[\{Ph_2(S)PNC(S)NH(CH_3)\}_2Ni]$ [1.760(9) Å].[29] There are significant differences in bond lengths in chelate **B** (deprotonated anionic ligand). The two Pt−S and P=S bond lengths are similar to those in chelate **A**. The P−N appears to be partially double [1.56(3) Å] and the C−N and C=S are similar to those in the neutral ligand The ring conformations are different; **A** is a "twist chair" conformation whilst **B** contains a relatively planar fragment −S(2)−P(1)−N(1)−C(1)−S(1) [max deviation 0.25 Å for N(1)] which is inclined by 63° to the Pt(1)−S(1)−S(2) plane.

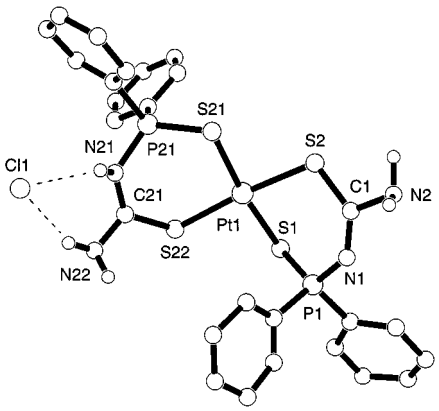

Figure 4. Molecular structure of *trans*-$[Pt\{H_2NC(S)NP(S)Ph_2\}\{H_2NC(S)NHP(S)Ph_2\}]^+Cl^-$ **16** in the crystal

N(21)−P(21)−S(21)	113.4(9)	N(1)−P(1)−S(1)	118(1)
S(22)−C(21)−N(22)	112(2)	S(2)−C(1)−N(2)	110(2)

The X-ray structure of **17** (Table 6, Figure 5) reveals that the two deprotonated ligands are bound to the square planar platinum atom in a *cis* configuration. The PtS_4 coordination sphere resembles that in bis(dithiobiureto)palladium(II)[31] and imidodiphosphinatoplatinum(II).[32] The bond lengths within the rings of **17** are similar to those of ring **B** in **16** and the ring conformations mostly closely resembles that of the deprotonated ring **B** in **16**. In **17** both rings consist of fairly planar S−P−N−C−S backbones [max. deviations for the two rings being 0.25 Å for C(1) and 0.31 Å for C(21)] which are inclined to the coordination plane by 60° in each case.

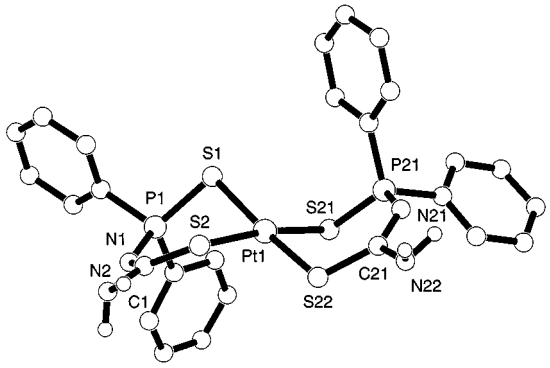

Figure 5. Molecular structure of *cis*-[Pt{$H_2NC(S)NP(S)Ph_2$}$_2$]·(Et_2O) **17** in the crystal

When we attempted to react [$H_2NC(S)NHP(Se)Ph_2$] **6** with [$PtCl_2$(COD)], red selenium deposited out of solution. The reaction was monitored by ^{31}P NMR which revealed a signal at 70 ppm with platinum-satellites which identified the product as [Pt{$H_2NC(S)NHPPh_2$}$_2$]$^{2+}$ · 2 Cl^-.

This work has demonstrated the ease of formation of hybrid organic/inorganic ligands which have elements of *acac* and imidophosphinate ligand systems. The usefulness of these ligands in metal specific coordination and catalysis awaits investigation.

Experimental Section

General: Diethyl ether, petroleum ether (60−80 °C) and tetrahydrofuran were purified by reflux over sodium and distillation under nitrogen. Dichloromethane was heated to reflux over powdered calcium hydride and distilled under nitrogen. − Infrared spectra were recorded from KBr discs on a Perkin−Elmer system spectrometer. − ^{31}P NMR spectra on a Jeol FX90Q operating at 36.21MHz; ^1H-, ^{13}C-, and ^{31}P-NMR spectra on a Bruker AC250 operating at 250, 62.9, and 101.3MHz respectively. − Fast atom bombardment mass spectra were measured by the Swansea mass spectrometry service.

[PhC(O)NHP(O)Ph_2] (1): A solution of $PhC(O)NHPPh_2$ (760 mg, 2.49 mmol) in THF (50 mL) was stirred overnight in air. The solution was filtered and the filtrate was reduced to dryness to give a white powder. It was recrystallised from CH_2Cl_2/Et_2O to give a yield of 795 mg (99 %). M.p. 197−199 °C. − ^{31}P NMR ($CDCl_3$): δ = 24. − IR (KBr disc, cm^{-1}): 3159 m, 3066 s, 2842 mw, 1669 vs, 1591 m, 1500 s, 1456 vs, 1439 vs, 1267 s, 1199 vs, 1128 vs, 1108 s, 1072 m, 1027 m, 998 w, 875 m, 838 s, 807 w, 754 s, 728 vs, 711 vs, 692 vs, 525 vs, 476 w, 296 w. − FAB (*m/z*): 344 $[M + Na]^+$ and 322 $[M + H]^+$. − $C_{19}H_{16}NO_2P$ (321.32): found C 70.66, H 4.72, N 3.87; (calcd. C 71.02, H 5.02, N 4.36 %).

[$H_2NC(S)NHP(S)Ph_2$] (2): To a suspension of $H_2NC(S)NH_2$ (8.5 g, 112 mmol) in THF (300 mL) was added Et_3N (15.5 mL, 111 mmol) and DMAP (100 mg, 10 mmol). A THF (200 mL) solution of Ph_2PCl (15 mL, 83 mmol) was then added dropwise over 3 h. The solution was filtered into another flask containing S (2.7 g, 83 mmol) and the residue washed with THF (100 mL). After 30 min of stirring the solution was evaporated to dryness and extracted with CH_2Cl_2 (200 mL). The extract was concentrated and triturated with Et_2O to give a microcrystalline product 9.4 g (39 %). Mp: 144−145 °C. − ^{31}P NMR ($CDCl_3$): δ = 52. − IR (KBr disc, cm^{-1}): 3381 w, 3294 s, 3141 m−sh, 3074 s, 2943 w, 2877 w, 1619 vs, 1586 w, 1484 vs, 1425 vs, 1309 w, 1278 m, 1111 s, 1102 s, 1054 s, 1029 m, 997 m, 835 s, 810 s, 749 s, 719 vs, 690 s, 642 s, 632 s, 614 m, 572 m, 521 vs, 495 s, 482 s, 464 m, 418 w, 404 m, 347 w, 301 m. − FAB (*m/z*): 315 $[M + Na]^+$ and 293 $[M]^+$. − $C_{13}H_{13}N_2PS_2$ (292.35): found C 53.18, H 4.46, N 9.91; (calcd. C 53.41, H 4.48, N 9.58 %).

[$H_2NC(O)NHP(S)Ph_2$] 3: To a solution of $H_2NC(O)NHPPh_2$ (3.5 g, 14.3 mmol) in THF (100 mL) was added S (451 mg, 14.1 mmol). The reaction was stirred for 4 h. The solution was filtered and the solvent removed to give a yield of 2.5 g (62 %). Mp: 162−166 °C. − ^{31}P NMR ($CDCl_3$): δ = 53. − IR

(KBr disc, cm^{-1}): 3492 m, 3333 m, 3187 m, 3056 w, 2956 vw, 1704 vs, 1682 vs, 1650 vs, 1615 vs, 1461 vs, 1436 vs, 1343 m, 1246 w, 1178 w, 1106 vs, 998 w, 912 m, 872 w, 747 s, 716 vs, 692 vs, 656 m, 634 m, 613 m, 590 m, 513 m, 496 s, 460 w. − FAB (*m*/*z*): 299 $[M + Na]^+$ and 277 $[M]^+$. $C_{13}H_{13}N_2OPS$ (276.29): found C 55.88, H 4.74, N 10.14; (calcd. [Pt{$H_2NC(S)NHP(S)Ph_2$}{$H_2NC(S)NP(S)Ph_2$}]$^+$Cl$^-$ 16: To a solution of [$H_2NC(S)NHP(S)Ph_2$] (78 mg, 267 μmol) in CH_2Cl_2 (20 mL) was added [$PtCl_2$(COD)] (100 mg, 267 μmol) giving yellow precipitates immediately. After overnight stirring the residue was filtered to give a yield of 96 mg (85 %). Decomp. temp: >160 °C. − ^{31}P NMR (CH_3OH/C_6D_6 insert): δ = 29.25, 29.54 [^2J(P−Pt) broad unresolved]. − IR (KBr disc, cm^{-1}): 3261 m, 3055 m, 2697 vw, 1603 s, 1500 s, 1437 vs, 1390 m, 1312 s, 1184 w, 1163 vw, 1106 vs, 998 w, 922 vw, 883 w, 748 m, 708 s, 688 s, 618 w, 598 m, 576 s, 551 m, 495 m, 365 vw. − FAB (*m*/*z*): 777 [M − H]$^+$. − $C_{26}H_{26}ClN_4P_2PtS_4$ (815.24): found C 38.66, H 3.10, N 7.05; (calcd. C 38.41, H 2.97, N 6.88 %).

[Pt{$H_2NC(S)NP(S)Ph_2$}$_2$] 17: To a suspension of K[$H_2NC(S)NP(S)Ph_2$] (61 mg, 184 μmol) in CH_2Cl_2 (10 mL) was added [$PtCl_2$(COD)] (32 mg, 85 μmol) gave a yellow solution. After 1 h stirring the solution was filtered through celite and the filtrate kept in a refrigerator overnight; a yellow crystalline product was collected (35 mg, 53 %). Mp: 144−148 °C. − ^{31}P NMR (CH_2Cl_2/C_6D_6 insert): δ = 33 [^2J(P−Pt) 114 Hz]. − IR (KBr disc, cm^{-1}): 3460 w, 3328 w, 3157 vw, 3053 vw, 1588 vs, 1484 vs, 1436 vs, 1308 s, 1161 m, 1112 s, 1105 s, 1027 vw, 999 w, 883 s, 748 m, 720 s, 707 vs, 691 s, 577 vs, 558 s, 502 m, 356 vw. − FAB (*m*/*z*): 778 [M + H]$^+$ and 777 [M]$^+$. − $C_{26}H_{24}N_4P_2PtS_4$ (777.77): found C 39.75, H 2.81, N 6.81; (calcd. C 40.15, H 3.11, N 7.20 %).

Crystallography: Details of the data collections and refinements are summarised in Table 7 Experimental details for **1** and **9** have been previously reported.[24] Data were collected at room temperature using a KUMA KM-4 and Mo radiation for **12** or with a SMART system for **15** and using Cu radiation with ω scans with a Rigaku AFC7S diffractometer for **16** and **17**. Intensities were corrected for Lorentz-polarisation and for absorption. The structures were solved by the heavy atom method or by direct methods. The positions of the hydrogen atoms were idealised. Refinements were by full-matrix least squares based on *F* using teXsan[25] (**16**, **17**) or using F^2 and SHELXTL[26] (**12**, **15**). Crystallographic Data for the structural analyses has been deposited with the Cambridge Crystallographic data centre, CCDC Nos: 115899, 115900, 115901, and 115902 Copies of this information may be obtained free of charge from The Director CCDC, 12 Union Road, Cambridge, CB2 1EZ UK. Formation of the [(*s-trans*-η⁴-Butadiene)TaCp*Cp]⁺ Cation and Its Reaction with Organic Carbonyl Derivatives

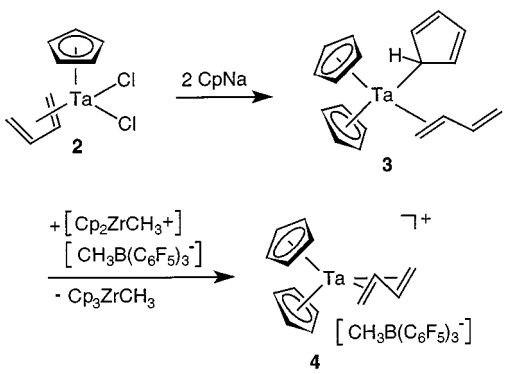
Hans Christian Strauch,[a] Gerhard Erker,*[a] Roland Fröhlich,[a][+] and Maija Nissinen[a][+]

Keywords: Group-5 bent metallocene cation complexes / (Butadiene)tantalocene cation / (*s-trans*-η⁴-Butadiene)metal complex / Ethene polymerization / Metallocenes / Homogeneous catalysis



(Butadiene)TaCp*Cl_2 (**6**) was treated with CpNa to yield (η²-butadiene)TaCp*CpCl (**7**). Subsequent reaction with $[Cp_2ZrCH_3^+][CH_3B(C_6F_5)_3^-]$ resulted in transfer of the chloride ligand from tantalum to zirconium with formation of the [(*s-trans*-η⁴-butadiene)TaCp*Cp]⁺ cation [**8**, with $CH_3B(C_6F_5)_3^-$ anion]. Complex **8** was characterized spectroscopically and by an X-ray crystal structure analysis. The group-5 [(*s-trans*-η⁴-C_4H_6)TaCp*Cp]⁺ bent metallocene cation complex **8** reacts with ketones (acetone, adamantanone) to yield the corresponding seven-membered 2-tantalatetrahydrooxepine cation complexes (**9**, **10**). 1-Cyanoadamantane reacts with **8** to yield the 2-tantala-3,6-dihydro-2*H*-azepine cation system **11**. Activation of **8** with methylalumoxane gives an active ethene polymerization catalyst.

Introduction

(Butadiene)zirconocene (**1**) was the first organometallic example exhibiting a stable *s-trans*-η⁴-conjugated diene coordination to a single transition metal center.[1] Since then a variety of additional examples have been found and described,[2] but mononuclear (*s-trans*-η⁴-butadiene)metal complexes are still not too frequently encountered. The (butadiene)zirconocene system has turned out to be a very useful reagent in organic and organometallic synthesis, serving as a mildly nucleophilic C_4-building block,[3] and it has successfully been applied as a suitable catalyst precursor in homogeneous metallocene Ziegler catalysis.[4] Therefore, we considered it desirable to expand the scope of such (butadiene) bent metallocene chemistry and search for additional examples of (η⁴-butadiene)metallocenes that are structurally and chemically related to the parent system **1** and its congeners.

We have recently synthesized the group-5 metal analogue of (butadiene)hafnocene. Our synthesis started from the readily available complex (η-cyclopentadienyl)(*s-cis*-η⁴-butadiene)$TaCl_2$ (**2**)[5] that was treated with two molar equivalents of CpNa to yield $(\eta^5\text{-Cp})_2(\eta^1\text{-Cp})(\eta^2\text{-butadiene})$tantalum (**3**). Subsequent treatment with $[Cp_2ZrCH_3^+][CH_3B(C_6F_5)_3^-]$[6] led to a clean transfer of a Cp-anion ligand to give the neutral Cp_3ZrCH_3[7] and the [(*s-trans*-η⁴-butadiene)$TaCp_2$]⁺ cation complex **4** (isolated with $CH_3B(C_6F_5)_3^-$ anion).[8] Spectroscopically and structurally complex **4** behaves as an isoelectronic analogue of the neutral (*s-trans*-η⁴-butadiene)hafnocene. The system **4** appears to be the first simple cationic group-5 equivalent of the well-established group-4 (η⁴-conjugated diene)metallocene complexes.[9] First scouting experiments have revealed that **4** also adds a variety of unsaturated reagents, similarly as **1**, to yield heterometallacyclic ring systems,[10] although the reactivity of the cationic group-5 metal complex system **4** seemed to be lower than that of the group-4 analogue **1**.

We have now developed a synthetic pathway to a second example of a group-5 (*s-trans*-η⁴-butadiene)metallocene cation system. The system contains a pentamethylcyclopentadienyl ligand that allows for a different synthetic entry and results in increased activities of the group-5 bent metallocene systems. Moreover, the presence of two differently substituted cyclopentadienide moieties at tantalum introduces an additional stereochemical marker into the system that has been useful in controlling the dynamic features of a variety of derived organometallic ring systems. The preparation of [(*s-trans*-η⁴-butadiene)TaCp*Cp]⁺ (**8**), its structural and spectroscopic characterization and the preliminary results of a few representative addition reactions are described in this article.

Results and Discussion

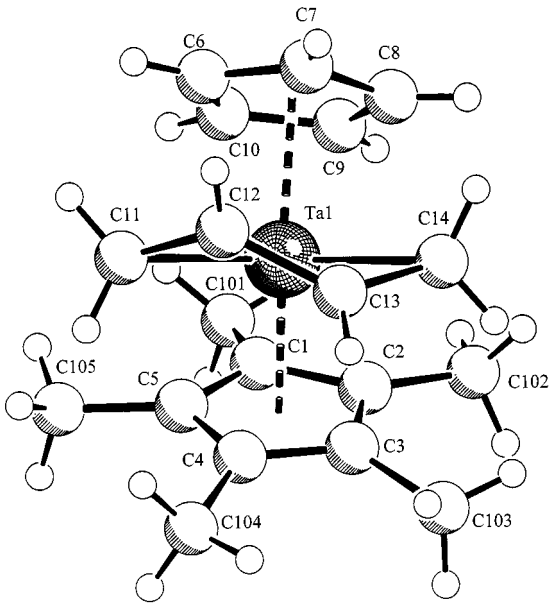
Our synthesis of the new group-5 (butadiene) bent metallocene cation system **8** starts from Cp^*TaCl_4 (**5**) which is readily available by treatment of $TaCl_5$ with (trimethylsilyl)-pentamethylcyclopentadiene, as described by W. A. Herrmann et al.[11] This was then treated with ca. one molar equivalent of the oligomeric (butadiene)magnesium reagent,[12] according to the procedure developed by H. Yasuda et al.,[13] to yield (*s-cis*-η^4-butadiene)$TaCp^*Cl_2$ (**6**). We have then treated **6** with ca. one molar equivalent of sodium cyclopentadienide in tetrahydrofuran at 0 °C. This resulted in the formation of the (η^2-butadiene)TaCp*CpCl complex **7**, isolated in 45% yield as a pale brown solid.

The η^2-coordination of the butadiene ligand to the tantalum center in **7** was deduced from its NMR spectra.[14] The ^{13}C-NMR spectrum shows two pairs of butadiene resonances at δ = 111.2 and 157.4 (noncoordinated $H_2C^4{=}C^3H$ moiety) and δ = 42.4 and 60.4 (η^2-coordinated $H_2C^1{=}C^2H$ unit). The η^2-butadiene ligand features ^{1}H-NMR resonances at δ = 0.88, 1.37 (1-H, 1-H′), 0.71 (2-H) of the coordinated vinyl group and δ = 6.33 (3-H), 4.27, and 4.00 (4-H,H′) of the free butadiene vinyl moiety.

Scheme 2

Complex **7** was then treated with $[Cp_2ZrCH_3^+]$-$[CH_3B(C_6F_5)_3^-]$[6] at room temperature in toluene solution. The tantalum-containing product precipitated as an oil, and it was shown by NMR spectroscopy that the supernatant toluene phase contained the neutral zirconium product $Cp_2Zr(CH_3)Cl$.[15] The oil was recovered and solidified by treatment with pentane and shown to consist of [CpCp* Ta(butadiene)$^+$][$CH_3B(C_6F_5)_3^-$] (**8**, isolated in > 80% yield). Thus, treatment of Cp*Cp(η^2-butadiene)TaCl (**7**) with the $Cp_2ZrCH_3^+$ cation has selectively resulted in transfer of the chloride ligand from tantalum to zirconium. The resulting tantalum complex contains an *s-trans*-η^4-butadiene ligand. This is evident from the NMR spectra which are to be compared with the characteristic NMR features of the *s-trans*-η^4-C_4H_6 ligand system in (*s-trans*-η^4-butadiene)zirconocene[1][9] [^{1}H NMR: δ = 1.2 (1-,4-H_{anti}), 3.2 (1-,4-H_{syn}), 2.9 (2-,3-H)] or in [(*s-trans*-η^4-C_4H_6)$TaCp_2$]$^+$ cation (**4**)[8] [^{1}H NMR: δ = 1.45 (1-,4-H_{anti}), 3.15 (1-,4-H_{syn}), 2.95 (2-,3-H) in [D_5]bromobenzene; ^{13}C NMR: δ = 57.8 (C-1, -4), 90.1 (C-2, -3) in [D_2]dichloromethane]. Due to the lower symmetry (**4**: C_2; **8**: C_1) the [(*s-trans*-η^4-butadiene)TaCp*Cp]$^+$ cation exhibits four ^{13}C-NMR signals of the η^4-coordinated *s-trans*-C_4H_6 ligand at δ = 59.8 (C-1), 64.3 (C-4), 91.2 (C-2), and 93.6 (C-3). As expected, all six butadiene hydrogen atoms are different due to the unsymmetric structure of **8** in solution. The corresponding ^{1}H-NMR signals appear in the very characteristical range as expected for the (*s-trans*-η^4-butadiene)Ta$^+$ moiety at δ = 0.88 (1-H_{anti}), 2.91 (1-H_{syn}), 1.61 (4-H_{anti}), 2.53 (4-H_{syn}), 3.04 (2-H), 1.61 (3-H).

Pentane vapor was allowed to diffuse into a solution containing 30 mg of **8** in 2 mL of dichloromethane to give single crystals suited for the X-ray crystal structure analysis (see Figure 1). This analysis confirmed the formation of the [(*s-trans*-η^4-butadiene)TaCp*Cp]$^+$ cation complex. The Ta−C(butadiene) distances are between 2.35 and 2.28 Å. Unfortunately, the structure suffers from considerable disorder problems (for details see the Experimental Section) so that structural details will not be discussed (Cp-ring and the butadiene ligand were refined with restraints).



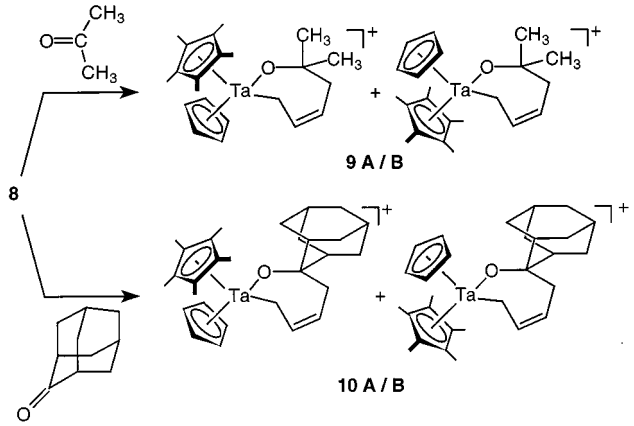


Figure 1. Molecular geometry of **8** in the crystal (cation only)

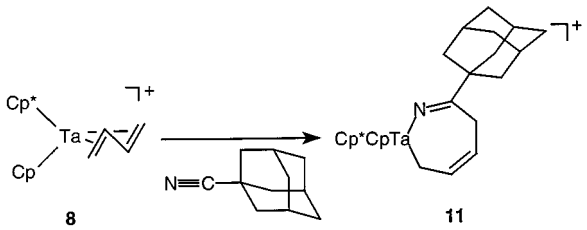
Both (butadiene)zirconocene and (butadiene)tantalocene cation react with a variety of organic carbonyl compounds and derivatives to yield the corresponding seven-membered 2-metalla-tetrahydrooxepine systems.[8−10] In order to characterize the chemical behavior of **8** we have consequently treated the [(*s-trans*-η^4-butadiene)TaCp*Cp]$^+$ cation complex with a few selected ketones and with a nitrile.

Complex **8** reacts with excess acetone at 50 °C (3 h) resulting in the incorporation of one equivalent of the carbonyl compound. The tantalatetrahydrooxepine cation **9** was isolated in ca. 70% yield. The NMR spectra show that two isomers were formed in a 1:1 ratio. These exhibit the same atom connectivity. They constitute two conformational isomers (isotopomers).[16] It is well-known that such metallatetrahydrooxepines contain nonplanar seven-

membered ring frameworks.[10] To a first approximation these contain two nearly planar subunits (in **9** the planes are defined by the atoms C3,Ta,O,C7,C6 and C3−C6) with an angle between these two planes of ca. 40−50°. Thus, in the case of **9** the two diastereoisomers are characterized by having the $C^4{=}C^5$ double bond oriented *syn* or *anti* to the Cp* ligand. Often such isotopomers rapidly equilibrate on the NMR time scale,[8][10] but in the case of **9** the thermally induced ring-inversion process seems to be kinetically hindered, potentially by an unfavorable transannular Cp*/CH_3 1,3-interaction in the transition state, so that the isomers **9A** and **9B** are distinguished by their separate NMR signals at 150/600 MHz at ambient temperature.



We observe a ^{1}H NMR Cp singlet for **9A** at δ = 5.78, for **9B** at δ = 6.04. Complex **9A** exhibits two methyl singlets at δ = 1.40 and 1.22; the corresponding 7-CH_3 signals of **9B** are at δ = 1.49 and 1.09, and each of the complexes exhibits distinctly different AB-type multiplets of their C^6H_2 and C^3H_2 groups (for details see the Experimental Section).

Scheme 3

Even the bulky ketone 2-adamantanone reacts analogously with the [(*s-trans*-η⁴-butadiene)TaCp*Cp]⁺ cation (**8**). The seven-membered metallacyclic cation complex **10** [with $CH_3B(C_6F_5)_3^-$ anion] was isolated from the reaction mixture in close to 60% yield. Again, a mixture of two isotopomers was observed by NMR spectroscopy at ambient temperature in a 70:30 ratio. The major isomer **10A** exhibits a ^{1}H-NMR Cp singlet at δ = 5.77, whereas the minor **10B** shows the corresponding Cp signal at δ = 6.01 (for additional spectroscopic data see the Experimental Section).

1-Cyanoadamantane reacts cleanly with **8** to yield the 3,6-dihydro-2-tantala-2*H*-azepine cation **11** (> 70% isolated). In this case only a single set of NMR resonances was observed (^{1}H-NMR Cp signal at δ = 5.67, 6-H/H′ multiplet at δ = 3.32 and 1.77, 3-H/H′ multiplet at δ = 1.55 and 0.85). From these data it is not clear whether only a single isotopomer of **11** is present or if the two possible diastereomers **11A/B** are rapidly interconverting by thermally induced ring inversion which is rapid on the NMR time scale under the conditions of the measurement.[8]

Scheme 4

Both the complexes [(*s-trans*-η⁴-butadiene)TaCp$_2$]⁺ cation (**4**) and [(*s-trans*-η⁴-butadiene)TaCp*Cp]⁺ (**8**) may serve as organometallic precursors for the generation of active homogeneous metallocene Ziegler catalyst systems. In a few scouting experiments we have treated **4** or **8** with a large excess of methylalumoxane in toluene. Subsequent introduction of ethene led to the formation of polyethylene (for details see Table 1 and the Experimental Section).

Table 1. Ethene polymerization with the homogeneous **4**/MAO and **8**/MAO Ziegler catalysts[a]

[a] Reactions in 220 mL of toluene, Büchi glass autoclave at 2 bar ethene pressure. − [b] kg [PE]/mol(cat)·bar·h.

Our study has shown that [Cp*CpTa(*s-trans*-η⁴-butadiene)]⁺ cation as a second example of a stable (*s-trans*-η⁴-conjugated diene)tantalocene cation complex is readily available. The *s-trans*-η⁴-diene coordination mode appears to be even more favored at the group-5 than at the group-4 bent metallocene − the corresponding isoelectronic hafnocene complexes feature a thermodynamically favored *s-cis*-η⁴-diene coordination[17] [the (*s-trans*-η⁴-diene)HfCp$_2$ isomers can be generated photochemically at low temperature].[9] The (butadiene)tantalocene cation examples known so far seem to react cleanly with a variety of unsaturated organic substrates by selective carbon−carbon coupling. These new readily available reagents are potentially useful as stoichiometric C_4-delivering building blocks in organic synthesis and as catalyst precursors.

Experimental Section

Reactions were carried out under argon using Schlenk-type glassware or in a glovebox. Solvents (including deuterated solvents used for the spectroscopic characterization) were dried and distilled under argon prior to use {dichloromethane, bromobenzene: P_4O_{10} (Sicapent); ether, pentane: $LiAlH_4$; THF: potassium/benzophenone; toluene: sodium/benzophenone; CD_2Cl_2, $CDCl_3$: P_4O_{10}

(Sicapent); [D_6]benzene, [D_8]THF: sodium/potassium alloy; [D_5]bromobenzene: CaH_2; [D_8]toluene: potassium}. For more general information including a list of spectrometers and instrumentation used for physical characterization see ref.[8] The complexes Cp^*TaCl_4 (**5**),[11] (butadiene)$TaCp^*Cl_2$ (**6**),[13] and the reagents "butadiene-magnesium"[12] and $[Cp_2ZrCH_3^+][CH_3B(C_6F_5)_3^-]$[6] were prepared according to literature procedures. For a compilation of 1D- and 2D-NMR experiments used for spectroscopic characterization see ref.[18]

Preparation of (η^2-Butadiene)(η^5-cyclopentadienyl)(η^5-pentamethylcyclopentadienyl)tantalum Chloride (7): A solution of sodium cyclopentadienide (479 mg, 5.44 mmol) in 10 mL of tetrahydrofuran was added at 0 °C to a solution of 2.00 g (4.53 mmol) of (butadiene)$TaCp^*Cl_2$ (**6**) in 50 mL of THF. The reaction mixture was stirred for 15 h at room temperature. The solvent was removed in vacuo. The residue was taken up in 30 mL of toluene and filtered. The filtrate was concentrated to dryness in vacuo and the remaining solid stirred with 30 mL of pentane. The product was collected by filtration, washed twice with pentane (2 × 20 mL), and dried to yield 962 mg (45%) of **7** as a pale brownish solid, m.p. 150 °C (decomp.). − ^{1}H NMR ([D_8]THF, 599.8 MHz, 298 K): δ = 6.33 (ddd, $^3J_{HH}$ = 16.9 Hz, $^3J_{HH}$ = 10.1 Hz, $^3J_{HH}$ = 5.7 Hz, 1 H, 3-H), 5.08 (s, 5 H, Cp-H), 4.27 (ptd, $^3J_{HH}$ = 16.9 Hz, $^2J_{HH}$ = 1.2 Hz, 1 H, 4-H′), 4.00 (ddd, $^3J_{HH}$ = 10.1 Hz, $^2J_{HH}$ = 1.2 Hz, $^4J_{HH}$ = 1.5 Hz, 1 H, 4-H), 1.74 [s, 15 H, $C_5(CH_3)_5$], 1.37 (dd, $^3J_{HH}$ = 12.6 Hz, $^2J_{HH}$ = 6.7 Hz, 1 H, 1-H′), 0.88 (dd, $^3J_{HH}$ = 9.7 Hz, $^2J_{HH}$ = 6.7 Hz, 1 H, 1-H), 0.71 (m, 1 H, 2-H). − 1D-TOCSY NMR ([D_8]THF, 599.8 MHz, 298 K): Isomer **A**: irradiation at δ = 1.37 (1-H′), response at δ = 6.33 (3-H), 4.27 (4-H′), 4.00 (4-H), 0.88 (1-H), 0.70 (2-H). − GCOSY NMR ([D_8]THF, 599.8 MHz, 298 K): δ = 6.33/4.27, 4.00, 0.73 (3-H/4-H′, 4-H, 2-H), 4.27/6.33, 4.00 (4-H′/3-H, 4-H), 4.00/6.33, 4.27 (4-H/3-H, 4-H′),1.37/0.88, 0.73 (1-H′/1-H, 2-H), 0.88/1.37, 0.73 (1-H/1-H′, 2-H), 0.73/6.33, 1.37, 0.88 (2-H/3-H, 1-H′). − ^{13}C NMR ([D_8]THF, 150.8 MHz, 298 K): δ = 157.4 (C-3), 119.6 [$C_5(CH_3)_5$], 114.9 (C-Cp), 111.2 (C-4), 60.4 (C-2), 42.4 (C-1), 20.6 [$C_5(CH_3)_5$]. − GHSQC ([D_8]THF, 150.8 MHz/599.8 MHz, 298 K): δ = 157.4/6.33 (C-3/3-H), 114.9/5.08 (C-Cp/Cp-H), 111.2/4.27 (C-4/4-H′), 111.2/4.00 (C-4/4-H), 60.4/0.70 (C-2/2-H), 42.4/1.37 (C-1/1-H′), 42.4/0.88 (C-1/1-H), 20.6/1.74 [$C_5(CH_3)_5$]. − IR (KBr): $\tilde{\nu}$ = 3108 (vw), 3085 (vw), 2906 (m), 2857 (m), 1593 (w), 1485 (vw), 1434 (m), 1377 (s), 1260 (w), 1100 (s), 1081 (s), 1028 (s), 1011 (s), 831 (vs), 808 (s), 715 (vs), 663 (w) cm^{-1}. − $C_{19}H_{26}ClTa$ (470.8): calcd. Preparation of (*s-trans*-η^4-Butadiene)(η^5-cyclopentadienyl)(η^5-pentamethylcyclopentadienyl)tantalum Methyltris(pentafluorophenyl)-borate (8): The reagent $[Cp_2ZrCH_3^+][CH_3B(C_6F_5)_3^-]$ was generated in situ by treatment of 1.50 g (2.93 mmol) of $B(C_6F_5)_3$ with 753 mg (3.00 mmol) of $Cp_2Zr(CH_3)_2$ in 20 mL of toluene. The resulting orange-colored solution was added with stirring at ambient temperature to a solution of 1.55 g (3.30 mmol) of **7** in 20 mL of toluene. The reaction mixture was stirred for 10 min. Then the oily product was allowed to separate from the solution. The supernatant liquid was removed. The remaining oil was washed with toluene (3 × 15 mL) and dried in vacuo. The dark grey solid was suspended in 20 mL of pentane and then collected by filtration, washed with pentane (2 × 20 mL) and then dried in vacuo to yield 2.29 g (81%) of **8**, m.p. 191 °C (decomp.). − ^{1}H NMR ([D_2]dichloromethane, 599.8 MHz, 298 K): δ = 5.13 (s, 5 H, Cp-H), 3.75−3.68 (m, 1 H, 2-H), 3.46 (dd, $^2J_{HH}$ = 5.4 Hz, $^3J_{HH}$ = 7.7 Hz, 1 H, 1-H′), 3.09−3.07 (m, 1 H, 4-H′), 2.20−2.17 (m, 2 H, 3-H, 4-H), 1.88 [s, 15 H, $C_5(CH_3)_5$], 1.42 (ddd, $^2J_{HH}$ = 5.4 Hz, $^3J_{HH}$ = 16.2 Hz, $^4J_{HH}$ = 1.2 Hz, 1 H, 1-H), 0.48 [br. s, 3 H, *Me*-$B(C_6F_5)_3$]. − ^{1}H NMR ([D_5]bromobenzene, 599.8 MHz, 298 K): δ = 4.44 (s, 5 H, Cp-H), 3.07−3.01 (m, 1 H, 2-H), 2.91 (m, 1 H, 1-H′), 2.53 (m, 1 H, 4-H′), 1.61 (m, 2 H, 3-H, 4-H), 1.32 [s, 15 H, $C_5(CH_3)_5$], 0.88 (dd, $^2J_{HH}$ = 4.0 Hz, $^3J_{HH}$ = 16.0 Hz, 1 H, 1-H), 1.12 [br. s, 3 H, *Me*-$B(C_6F_5)_3$]. − 1D-TOCSY NMR ([D_2]dichloromethane, 599.8 MHz, 298 K): irradiation at δ = 3.71 (2-H): response at δ = 3.46 (1-H′), 3.08 (4-H′), 2.18 (3-H, 4-H), 1.42 (1-H). − GCOSY NMR ([D_2]dichloromethane, 599.8 MHz, 298 K): δ = 3.71/3.46, 2.18, 1.42 (2-H/1-H′, 3-H, 1-H), 3.46/3.71, 1.42 (1-H′/2-H, 1-H), 3.08/2.18 (4-H′/3-H, 4-H), 2.18/3.71, 3.08 (3-H, 4-H/2-H, 4-H′), 1.42/3.71, 3.46 (1-H/2-H, 1-H′). − ^{13}C NMR ([D_2]dichloromethane, 150.8 MHz, 298 K): δ = 148.7 [d, $^1J_{CF}$ = 232 Hz, *o*-$B(C_6F_5)_3$], 137.8 [d, $^1J_{CF}$ = 234 Hz, *p*-$B(C_6F_5)_3$], 136.8 [d, $^1J_{CF}$ = 235 Hz, *m*-$B(C_6F_5)_3$], 129.1 [br. m, *ipso*-$B(C_6F_5)_3$], 109.5 [$C_5(CH_3)_5$], 98.6 (C-Cp), 93.6 (C-3), 91.2 (C-2), 64.3 (C-4), 59.8 (C-1), 12.2 [$C_5(CH_3)_5$], 10.4 [br. s, *Me*-$B(C_6F_5)_3$]. − ^{13}C NMR ([D_5]bromobenzene, 150.8 MHz, 298 K): δ = 148.7 [d, $^1J_{CF}$ = 230 Hz, *o*-$B(C_6F_5)_3$], 137.6 [d, $^1J_{CF}$ = 232 Hz, *p*-$B(C_6F_5)_3$], 136.5 [d, $^1J_{CF}$ = 234 Hz, *m*-$B(C_6F_5)_3$], 108.3 [$C_5(CH_3)_5$], 97.4 (C-Cp), 92.9 (C-3), 90.6 (C-2), 63.8 (C-4), 59.2 (C-1), 11.2 [$C_5(CH_3)_5$], 11.0 [br. s, *Me*-$B(C_6F_5)_3$] (*ipso*-C of C_6F_5 not found). − GHSQC ([D_2]dichloromethane, 150.8/599.8 MHz, 298 K): δ = 98.6/5.13 (C-Cp/Cp-H), 93.6/2.18 (C-3/3-H), 91.2/3.71 (C-2/2-H), 64.3/3.08 (C-4/4-H′), 64.3/2.18 (C-4/4-H), 59.2/3.46 (C-1/1-H′), 59.2/1.42 (C-1/1-H), 12.2/1.88 ($C_5(CH_3)_5$/$C_5(CH_3)_5$), 11.0/0.48 (*Me*-$B(C_6F_5)_3$). − ^{11}B NMR ([D_2]dichloromethane, 64.2 MHz): δ = 15.0. − ^{19}F NMR ([D_2]dichloromethane, 282.4 MHz, 298 K): δ = −130 [m, 6 F, *o*-$CH_3B(C_6F_5)_3$], −163 [m, 3 F, *p*-$CH_3B(C_6F_5)_3$], −166 [m, 6 F, *m*-$CH_3B(C_6F_5)_3$]. − IR (KBr): $\tilde{\nu}$ = 3132 (vw), 2963 (w), 2921 (w), 1642 (m), 1512 (vs), 1456 (vs), 1383 (w), 1265 (m), 1087 (vs), 979−934 (br. m), 842 (m), 804 (w) cm^{-1}. − $C_{38}H_{29}BF_{15}Ta$ (962.4): calcd. X-ray Crystal Structure Analysis of 8: Formula $C_{19}H_{26}Ta \cdot B(C_6F_5)_3CH_3 \cdot CH_2Cl_2$, M = 1047.30, red crystal, 0.40 × 0.30 × 0.15 mm, a = 9.369(1), b = 12.479(1), c = 17.647(1) Å, α = 102.13(1), β = 102.11(1), γ = 102.59(1)°, V = 1896.7(3) Å^3, $\rho_{calcd.}$ = 1.834 g cm^{-3}, F(000) = 1024 e, μ = 31.43 cm^{-1}, absorption correction by SORTAV (0.366 ≤ T ≤ 0.650), Z = 2, triclinic, space group $P\bar{1}$ (No. 2), λ = 0.71073 Å, T = 198 K, φ and ω scans, 16502 reflections collected (±h, ±k, ±l), [(sinθ)/λ] = 0.67 Å^{-1}, 9284 independent and 8161 observed reflections [$I \geq 2\,\sigma(I)$], 470 refined parameters, R = 0.056, wR^2 = 0.145, max. residual electron density 2.07 (−1.75) e Å^{-3}, hydrogen atoms calculated and refined as riding atoms. The butadiene unit is severely disordered, carbon atoms C11−C14 are refined isotropically and with restraints [DFIX 1.38(1) for C11−C12 and C13−C14, DFIX 1.47(1) for C12−C13, SADI (0.1) for C11−C13 and C12−C14]. This disorder affects also the neighboring Cp ring, especially the closest carbon atoms C6, C7, and C8 show large displacement parameters. Therefore the Cp ring is refined isotropically as rigid group. All other non-hydrogen atoms including the solvent molecule CH_2Cl_2 are refined anisotropically. The data set was collected with a Nonius Kappa CCD diffractometer, equipped with a rotating anode generator FR591. Programs used: data collection COLLECT, data reduction DENZO-SMN, absorption correction SORTAV, structure solution SHELXS-97, structure refinement SHELXL-97, graphics SCHAKAL-92. Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-115170. Copies of the data can be obtained free of charge on application to CCDC, 12 Union

Preparation of 2-(η⁵-Cyclopentadienyl)-7,7-dimethyl-2-(η⁵-pentamethylcyclopentadienyl)-2,3,6,7-tetrahydro-2-tantalaoxepine Methyltris(pentafluorophenyl)borate (9): Acetone (36.2 mg, 620 μmol) was added to a solution of 300 mg (310 μmol) of **8** in 5 mL of bromobenzene at ambient temperature. The mixture was stirred for 3 h at 50 °C. The product was then precipitated at room temperature by the addition of 10 mL of pentane. The solvent was decanted off. The residue was dissolved in 5 mL of dichloromethane and the product again precipitated by adding 10 mL of pentane. The solvents were removed and the product dried in vacuo, then suspended in 10 mL of pentane and collected by filtration. Yield of **9**: 230 mg (72%), m.p. 74°C (decomp.). − ^{1}H NMR ([D$_2$]dichloromethane, 599.8 MHz, 298 K): The ^{1}H-NMR spectrum shows the presence of two isomers, **9A** and **9B** in a 50:50 ratio. Preparation of 7-(1-Adamantyl)-2-(η⁵-cyclopentadienyl)-3,6-dihydro-2-(η⁵-pentamethylcyclopentadienyl)-2-tantala-2*H*-azepine Methyltris(pentafluorophenyl)borate (11): 1-Cyanoadamantane (55.3 mg, 340 μmol) was added to a solution of 300 mg (310 μmol) of **8** in 10 mL of bromobenzene. The mixture was kept for 2 h at 50 °C. Pentane (15 mL) was added to precipitate the product. The supernatant liquid was decanted. The residue was dissolved in 5 mL of

dichloromethane and the product again precipitated by adding 10 mL of pentane. The solvent was decanted off and the product dried in vacuo, suspended in 10 mL of pentane and then collected by filtration to yield 252 mg (72%) of **11**, m.p. 205 °C (decomp.). – ^{1}H NMR ([D$_2$]dichloromethane, 599.8 MHz, 298 K): δ = 6.34 (m, 1 H, 4-H), 5.67 (s, 5 H, Cp-H), 4.82 (m, 1 H, 5-H), 3.32 (dd, $^2J_{HH}$ = 12.7 Hz, $^3J_{HH}$ = 8.4 Hz, 1 H, 6-H′), 2.01 [s, 15 H, C$_5$(CH_3)$_5$], 2.10–2.07, 1.86–1.79, 1.75–1.65 (m, 15 H, adamantyl), 1.77 (ddd, $^2J_{HH}$ = 12.7 Hz, $^3J_{HH}$ = 7.1 Hz, $^4J_{HH}$ = 2.0 Hz, 1 H, 6-H), 1.55 (dd, $^2J_{HH}$ = 10.4 Hz, $^3J_{HH}$ = 7.9 Hz, 1 H, 3-H′), 0.85 (ddd, $^2J_{HH}$ = 10.4 Hz, $^3J_{HH}$ = 7.8 Hz, $^4J_{HH}$ = 1.8 Hz, 1 H, 3-H), 0.47 [br. s, 3 H, *Me*-B(C$_6$F$_5$)$_3$]. – 1D-TOCSY NMR ([D$_2$]dichloromethane, 599.8 MHz, 298 K): irradiation at δ = 4.82 (5-H): response at δ = 6.35 (4-H), 3.32 (6-H′), 1.77 (6-H), 1.55 (3-H′), 0.85 (3-H). – GCOSY NMR ([D$_2$]dichloromethane, 599.8 MHz, 298 K): δ = 6.35/4.82, 1.55, 0.85 (4-H/5-H, 3-H′, 3-H), 4.82/6.35, 3.32, 1.77 (5-H/4-H, 6-H′, 6-H), 3.32/4.82, 1.77 (6-H′/5-H, 6-H), 1.77/4.82, 3.32 (6-H/5-H, 6-H′), 1.55/6.35, 0.85 (3-H′/4-H, 3-H), 0.85/6.35, 1.55 (3-H/4-H, 3-H′). – ^{13}C NMR ([D$_2$]dichloromethane, 150.8 MHz, 298 K): δ = 190.1 (C-7), 148.6 [d, $^1J_{CF}$ = 231 Hz, *p*-B(C$_6$F$_5$)$_3$], 139.6 (C-4), 137.8 [d, $^1J_{CF}$ = 233 Hz, *p*-B(C$_6$F$_5$)$_3$], 136.4 [d, $^1J_{CF}$ = 232 Hz, *m*-B(C$_6$F$_5$)$_3$], 118.1 [C_5(CH$_3$)$_5$], 112.5 (C-5), 107.5 (C-Cp), 35.2 (C-3), 27.6 (C-6), 43.3, 38.7, 36.5, 28.2 (C-adamantyl), 11.9 [C$_5$(*C*H$_3$)$_5$], 10.4 [br. s, *Me*-B(C$_6$F$_5$)$_3$]. – GHSQC ([D$_2$]dichloromethane, 150.8/599.8 MHz, 298 K): δ = 139.6/6.35 (C-4/4-H), 112.5/4.82 (C-5/5-H), 107.5/5.67 (C-Cp/Cp-H), 35.2/1.55 (C-3/3-H′), 35.2/0.85 (C-3/3-H), 27.6/3.32 (C-6/6-H′), 27.6/1.77 (C-6/6-H), 11.9/2.01 [C$_5$(*C*H$_3$)$_5$/C$_5$(CH_3)$_5$], 10.4/0.48 [*Me*-B(C$_6$F$_5$)$_3$]. – ^{11}B NMR ([D$_2$]dichloromethane, 64.2 MHz): δ = –15.0. – ^{19}F NMR ([D$_2$]dichloromethane, 282.4 MHz): δ = -130 [m, 6 F, *o*-CH$_3$B(C$_6$F$_5$)$_3$], –163 [m, 3 F, *p*-CH$_3$B(C$_6$F$_5$)$_3$], –166 [m, 6 F, *m*-CH$_3$B(C$_6$F$_5$)$_3$]. – IR (KBr): $\tilde{\nu}$ = 3120 (vw), 2959 (w), 2915 (m), 2852 (w), 1665 (w), 1640 (w), 1510 (s), 1457 (vs), 1381 (w), 1264 (m), 1085 (vs), 1016–951 (br. m), 838 (m), 803 (m) cm^{-1}. – C$_{49}$H$_{44}$BNF$_{15}$Ta (1123.6): calcd. Ethene Polymerization Reactions: The ethene polymerization reactions were carried out in a Büchi glass autoclave. The reaction vessel was charged with 200 mL of toluene and 20 mL (0.033 mol) of a 10.5% solution of methylalumoxane in toluene. The mixture was brought to the preset reaction temperature and saturated with ethene at 2 bar for 1 h with stirring (700 min^{-1}). Then the polymerization reaction was started by the injection of 2 mL of a toluene solution of the catalyst precursors **4** or **8** (see Table 1). The polymerization was stopped after 30 min by quenching with CH$_3$OH/2 N aqueous HCl (1:1) and the polyethylene isolated (m.p. by DSC). For further details see Table 1.

Acknowledgments

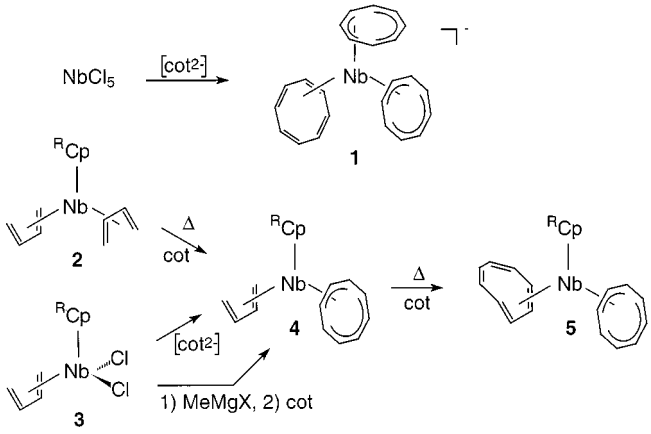
Group 5 Metal Complexes with Cyclooctatetraene: Formation and Characterization of (Butadiene)(cyclooctatetraene)(cyclopentadienyl)tantalum Systems

Hans Christian Strauch,[a] Klaus Bergander,[a][+] Gerald Kehr,[a][+] Roland Fröhlich,[a][++] and Gerhard Erker*[a]

Keywords: Diene complexes / η^3-Cyclooctatetraene metal complex / $B(C_6F_5)_3$ addition / Tantalum / Bicyclo[5.1.0]octadienyl metal complex



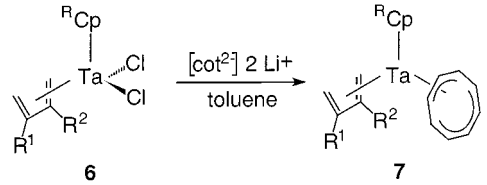
The [(η^4-diene)(η^5-^{R}Cp)$TaCl_2$] complexes **6a-e** (diene = butadiene, isoprene or 2,3-dimethylbutadiene; ^{R}Cp = pentamethylcyclopentadienyl, methylcyclopentadienyl or cyclopentadienyl) react with cyclooctatetraene dianion (employed as [(cot)Li_2]) to yield the (η^4-diene)(η^3-cyclooctatetraene)(η^5-^{R}Cp)tantalum complexes **7**. The η^3-cot coordination was confirmed by an X-ray crystal structure analysis of the compound [(*supine*-*s*-*cis*-η^4-C_4H_6)(η^3-cot)(η^5-Cp*)Ta] **7a**. In solution, the cot ligand of all the complexes **7** is fluxional. Two isomers [*supine* and *prone* orientation of the (diene)CpTa subunit] were found for the (η^4-butadiene)(η^3-cot)CpTa system (**7e**/**7e**′ = 95:5). Complex **7e** cleanly adds the organometallic Lewis acid $B(C_6F_5)_3$ to yield the betaine system [(η^4-C_4H_6){$C_8H_8B(C_6F_5)_3$}Cp*Ta] **8**, which contains a substituted bicyclo[5.1.0]octadienyl ligand.

Introduction

Cyclooctatetraene binds to the electropositive d-block metals of the left side of the periodic table (and to the f-elements) in a variety of coordination modes.[1] η^8-Coordination, η^4-conjugated diene-like and also η^2-bonding of the cot ligand can be found[2−4] and, most interestingly, η^3-coordination is not uncommon.[5] In these cases a π^5-section of the C_8H_8 ligand remains uncoordinated, which formally leads to an unsymmetrical, potentially dipolar electronic distribution at the M(η^3-C_8H_8) subunit. Such complexes were first reported by Schrock et al. The [(η^4-cot)(η^3-cot)$_2$Nb]$^-$ anion (**1**) is a typical example.[5] Recent examples include the [(*supine*-η^4-*s*-*cis*-butadiene)CpNb(η^3-cot)] system (**4**)[6] and its Cp*Nb analogue.[7] We have now prepared a series of related tantalum complexes. This work supplements the Nb-series, reported recently, but also has revealed a variety of subtle, but important, differences and variations.

Results and Discussion

Most examples of Cp- and Cp*Nb(η^4-butadiene)(η^3-cyclooctatetraene) complexes known so far have been prepared either by butadiene ligand displacement starting from [Cp(η^4-butadiene)$_2$Nb] **2** or by trapping of the bent metallocene analogue Cp*(η^4-butadiene)Nb, generated in situ, with cyclooctatetraene.[5−7] For this study we have exclusively used the [^{R}Cp(η^4-diene)$TaCl_2$] complexes **6** as precursors[8] and treated them with the cyclooctatetraene dianion[9] to form the corresponding [^{R}Cp(η^4-diene)(η^3-cyclooctatetraene)Ta] complexes **7** [^{R}Cp = η^5-C_5H_5, η^5-$C_5H_4(CH_3)$ or η^5-$C_5(CH_3)_5$; diene = butadiene, isoprene or 2,3-dimethylbutadiene].



Scheme 1. Previous syntheses of (cot)Nb complexes

A typical example is the reaction of [(η^4-butadiene)(η^5-pentamethylcyclopentadienyl)$TaCl_2$] **(6a)** with the cyclooctatetraene dianion (employed as the corresponding dilithium salt). The reaction is carried out in toluene solution and takes about 15 h at 50°C to go to completion. Workup gives the product **7a** as a very dark-colored solid in approximately 50% yield. Dark red single crystals suitable for an X-ray crystal structure analysis were obtained from a toluene/pentane solution.

Complex **7a** has a central tantalum atom that is surrounded by a trigonal array of three π ligands. The pentamethylcyclopentadienyl ligand is η^5-coordinated [average Ta−C(Cp*) distance = 2.439(6) Å]. The η^4-*s*-*cis*-butadiene

Scheme 2. Preparation of the (η^4-diene)(η^3-cot)^{R}CpTa complexes **7**

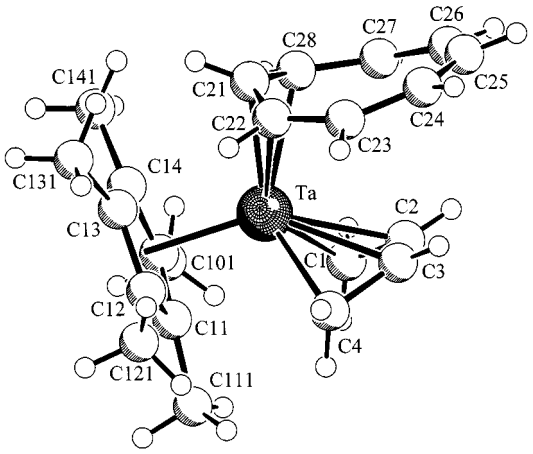

Figure 1. Molecular structure of **7a** with unsystematical atom numbering scheme

ligand opens toward the Cp* ligand (i.e. *supine*[8] oriented) and the Ta−C_4H_6 subunit exhibits some metallacyclopentene structural properties. It can probably best be described as approaching a metallacyclic σ^2,π-type structure as is often observed for early transition metal conjugated diene complexes.[10−12] This description is supported by the observed long-short-long bond alternation of the carbon framework of the butadiene ligand in complex **7a** (see Table 1). Also, the bonds between tantalum and the terminal diene ligand carbon atoms are markedly shorter [Ta−C1 = 2.252(6), Ta−C4 = 2.240(6) Å] than the bonds to the internal butadiene carbon centers [Ta−C2 = 2.433(5), Ta−C3 = 2.424(5) Å]. Similar conjugated diene C−C lengths were observed for both the [Cp*(η^4-butadiene)(η^3-cot)Nb] complex **4a**[7] and the related [(MeCp)(η^4-cot)(η^3-cot)Nb] complex **5a**.[6] These three systems, however, differ markedly in their relative M−C(diene) lengths (see Table 1). From these data a trend becomes apparent and it is possible to assign to the new tantalum complex **7a** the most pronounced σ-complex character of the M(diene) subunit in this series of compounds.

The cot ligand in **7a** is only η^3-coordinated. The central Ta−C21 bond length is 2.239(5) Å. It is the shortest metal to carbon bond of this group. The adjacent (η^3-cot)Ta linkages are slightly longer at 2.426(5) Å (Ta−C28) and 2.455(5) Å (Ta−C22). The next pair of distances (Ta···C27: 3.228(5) Å and Ta···C23: 3.333(5) Å) lie outside the range of a significant bonding interaction. The η^3-cot ligand in **7a** is coordinated in a *prone* orientation[8] and the ligand is slightly folded away from tantalum (see Table 1). There is no significant bond alternation visible in the η^3-C_8H_8 framework, so it appears that the cot ligand in **7a** has substantially retained its aromatic character with regard to its structural properties. It is structurally apart from the examples of "semiaromatic" cot character, that have recently been reported in the literature.[8b,13]

[a] **7a**: [Cp*(*supine-s-cis*-η^4-C_4H_6)(*prone*-η^3-cot)Ta], this work; **4a**: [Cp*(*supine-s-cis*-η^4-C_4H_6)(*prone*-η^3-cot)Nb], from ref.[7]; **5a**: [(MeCp)(*supine*-η^4-cot)(*prone*-η^3-cot)Nb], from ref.[6] bond lengths in Å, angles in deg. − [b] Angles of fold along the indicated vectors. − [c] Values not given.

In solution, complex **7a** shows a singlet for the methyl groups of the Cp* ligand in the ^{1}H NMR spectrum at δ = 1.46 ([D_8]toluene, ^{13}C NMR: δ = 109.7 and 10.6). There is only a single resonance for the cot ligand in the ^{1}H NMR spectrum which remains sharp even down to 143 K (δ = 5.18 in $CDCl_2F/CDClF_2$).[14] The resonance in the ^{13}C NMR spectrum for the cot ligand of **7a** is observed at δ = 102.5 ([D_8]toluene), which is between the corresponding resonances of free cyclooctatetraene (δ = 131) and Li_2(cot) (δ = 90). We assume that a rapid interchange is responsible for this symmetrized appearance of the cot ligand in the ^{1}H/^{13}C NMR spectra.[15] We regard it unlikely that **7a** exhibits a fundamentally different structure in solution and in the solid state. An η^8-cot bonding situation would mean that **7a** would have more than 18 valence electrons as the other ligands have retained their coordination character as η^5-Cp* and (σ^2,π)η^4-C_4H_6 (see below). We therefore regard it very likely that a rapid equilibration on the NMR times-

Table 2. A comparison of selected ^{1}H NMR and ^{13}C NMR spectroscopic data of the complexes **7**[a] and **4a**[b]

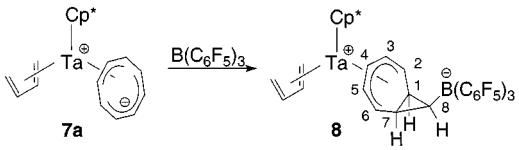
[a] Complexes **7** in [D$_8$]toluene at 298 K, this work. − [b] **4a** in [D$_6$]benzene at 303 K, from ref.[7]

cale of the (η^3-cot)Ta subunit causes the simple spectroscopic features that were observed.

In solution a single set of signals in the NMR spectrum is observed, i.e. only a single stereoisomer is present in solution. This is likely to contain the η^4-butadiene ligand in the *supine* orientation, with its "open" side pointing toward the Cp* ligand as was observed in the X-ray crystal structure of **7a**. The complex shows the typical signals in the ^{1}H NMR spectrum of a σ^2,π-structured η^4-butadiene ligand at the metal center[10−12] [δ = −0.92 (1-/4-H$_{anti}$), 3.05 (1-/4-H$_{syn}$), 4.45 (2-/3-H)]. The corresponding signals in the ^{13}C NMR spectrum of the butadiene ligand of **7a** are observed at δ = 47.4 (C1/4) and δ = 127.5 (C2/3).



The complexes **7b** and **7c** show very similar NMR spectra (see Table 2). In each case a single isomer of the [Cp*(η^4-diene)(cot)Ta] system is observed. This is also the case for the [(MeCp)(butadiene)(cot)Ta] complex **7d**, but a different situation is encountered with the [Cp(η^4-butadiene)(cot)Ta] system. In this case, a mixture of two stereoisomers **7e** and **7e′** in a ratio of 95:5 is observed in solution by NMR spectroscopy. Each shows the typical single resonance for the cot ligand in the ^{1}H and ^{13}C NMR spectra (δ = 100.7, major isomer **7e**; δ = 100.4, minor isomer **7e′**). Both complexes also exhibit sets of resonances in their ^{1}H- and ^{13}C NMR spectra which are typical for σ^2,π-type *s-cis*-η^4-butadiene ligands at the group 5 metal center,[8][12] but the two are quite different from each other. We therefore assume that this is the first case in this series of complexes where we observe both a *supine* and a *prone* [Cp(butadiene)(cot)Ta] isomer. In view of the spectroscopic similarity with the other members of the series of complexes **7** (and **4a**, see Table 2) we assign to the major isomer (**7e**) the "conventional" *supine*-type structure, and to the minor isomer (**7e′**) the *prone* orientation of the C_4H_6 and Cp ligands at the tantalum center.

Scheme 3. The (*supine* and *prone*-η^4-diene)(η^3-cot)CpTa isomers **76e** and **7e′**

We have recently shown that (butadiene)zirconocene and related group 4 metal complexes add the organometallic Lewis acid B(C$_6$F$_5$)$_3$[16] to a terminal carbon atom of the butadiene ligand to form a (π-allyl)metalloceneborate betaine complex that is of interest as an active, single-component Ziegler-type catalyst.[17] Complex **7a** was, therefore, also treated with B(C$_6$F$_5$)$_3$ but reacted differently. A single compound (**8**) that still contained the intact η^4-butadiene ligand was formed. This is evident from the typical features of the ^{1}H and ^{13}C NMR spectra of the C_4H_6 moiety [δ = 0.18, 2.86 (1-/4-H), 5.48 (2-H); δ = 54.2 (C1) and 118.6 (C2)]. The B(C$_6$F$_5$)$_3$ reagent was found to add to the cot ligand. In contrast to compounds **7**, complex **8** exhibits signals in the ^{1}H and ^{13}C NMR spectra of a static cot-derived subunit. By a combination of pertinent 1D and 2D NMR experiments the structure of the $C_8H_8B(C_6F_5)_3$ ligand was established as being of the bicyclo[5.1.0]octadienyl type. The ^{1}H/^{13}C NMR spectroscopic assignments (including their very characteristic $^1J_{CH}$ coupling constants) are as follows (see Scheme 4 for the atom numbering scheme): δ = 1.23/39.4 ($^1J_{CH}$ = 165 Hz, C1/7−H), 6.66/158.7 (157 Hz, C2/6−H), 3.30/91.8 (155 Hz, C3/5−H), 3.86/71.4 (167 Hz, C4−H), 3.33/(^{13}C signal not observed, C8−H). The newly formed ligand is probably η^5-coordinated to tantalum. Addition of the B(C$_6$F$_5$)$_3$ Lewis acid has apparently occurred at the central carbon atom of the open, noncoordinated π^5-pentadienyl anion section of the cot ligand in **7a**, which resulted in a rapid subsequent disrotatory ring closure to give the bicyclic cot-B(C$_6$F$_5$)$_3$-derived ligand in **8**. In principle four different diastereoisomers of **8** could have been formed in this reaction, depending on whether B(C$_6$F$_5$)$_3$ had attacked from "inside" or from "outside" the complex framework of **7a**, each attack being followed by two possible modes of disrotatorial ring closure. Apparently, one of these electrophilic addition/ring closure combinations has prevailed here, leading to a single observed diastereoisomer **8** of the [Cp*(η^4-C$_4$H$_6$){8-B(C$_6$F$_5$)$_3$-η^5-bicyclo[5.1.0]-octadienyl}Ta] system. We assume that the structure depicted in Scheme 4 is favored, with the B(C$_6$F$_5$)$_3$ substituent *endo* to the bicyclic framework (the observed ^3J(1-H/8-H) coupling constant of ca. 8 Hz would be in accord with the *cis* substitution pattern at the three-membered ring), and the Cp*(η^4-C$_4$H$_6$)Ta "metallocene" η^5-coordinated from the *exo*-face, as was observed for a remotely related example

in the early (cot)Nb chemistry described by Schrock et al.[5b]

Scheme 4. Reaction of **7a** with $B(C_6F_5)_3$ and atom numbering scheme for **8**

Conclusion

Our study has shown that [^{R}Cp(η^4-butadiene)$TaCl_2$] complexes react cleanly with the cot dianion to yield the [^{R}Cp(η^4-butadiene)(η^3-cot)Ta] complexes **7**. These complexes exhibit a slightly greater σ^2,π-character of the (η^4-butadiene) ligand than their niobium analogues. Most of the complexes **7** exhibit a *supine*-oriented butadiene ligand, but for the [Cp(η^4-butadiene)(η^3-cot)Ta] system we have for the first time observed the *prone* isomer as a minor equilibrium component in solution. This probably indicates that steric factors dominate this equilibrium situation. In the complexes **7** the ^{R}Cp(η^4-diene)Ta subunit seems to function structurally and chemically in a similar manner to the Cp_2M bent metallocene unit in group 4 metal chemistry:[19] treatment of **7a** with $B(C_6F_5)_3$ leaves the bent metallocene surrogate intact; the attack occurs exclusively at the adjacent cot ligand. This ligand system seems to be chemically active in these complexes. It serves as a carbon nucleophile at the center of its uncomplexed pentadienyl moiety to yield the addition product **8**. Further chemical reactions and the catalytic potential of the complexes **7** will be investigated in our laboratory

Experimental Section

All reactions were carried out under argon using Schlenk-type glassware or in a glovebox. Solvents were dried and distilled under argon prior to use. For additional general information including a list of instruments used for the spectroscopic and physical characterization of the compounds see ref.[20] The [^{R}Cp(η^4-diene)$TaCl_2$] complexes **6** were prepared analogously as described by Yasuda et al.[8][21] The [(cot)Li_2] reagent was prepared according to a literature procedure.[9]

Synthesis of (η^4-Butadiene)(η^3-cyclooctatetraene)(η^5-pentamethylcyclopentadienyl)tantalum (7a): A solution of **6a** (1.00 g, 2.70 mmol) in toluene (20 mL) was added to a suspension of [(cot)Li_2] (330 mg, 2.80 mmol) in 20 mL of toluene. The mixture was stirred for 15 h at 50°C, then filtered and the solvent removed from the filtrate in vacuo. The crude reaction product was stirred for 10 h in 10 mL of pentane, then the product was collected by filtration to give 653 mg (54%) of **7a** as a black solid. Single crystals of **7a** suitable for an X-ray crystal structure analysis were obtained from a solution containing 100 mg of **7a** in 3 mL of toluene and 8 mL of pentane. − M.p. 185°C (decomp.). − IR (KBr): $\tilde{\nu}$ = 3050, 2984, 2904, 1547, 1496, 1422, 1375, 1229, 1159, 1147, 1054, 1041, 1023, 902, 840, 805, 797, 686, 614 cm^{-1}. − ^{1}H NMR ([D$_8$]toluene, 599.8 MHz, 298 K): δ = 5.16 (s, 8 H, cot-H), 4.40 (m, 2 H, 2-H), 3.04 (m, 2 H, 1-H′), 1.46 [s, 15 H, $C_5(CH_3)_5$], −0.93 (m, 2 H, 1-H). − ^{1}H NMR [$CDClF_2$/$CDCl_2F$ (2:1), 599.8 MHz, 143 K]: δ = 5.18 (s, 8 H, cot-H), 3.97 (m, 2 H, 2-H), 3.08 (m, 2 H, 1-H′), 1.86 [s, 15 H, $C_5(CH_3)_5$], −0.97 (m, 2 H, 1-H). − 1D TOCSY ([D$_8$]toluene, 599.8 MHz, 298 K): irradiation at δ = 4.45 (2-H): response at 3.05 (1-H′) and −0.92 (1-H). − GCOSY ([D$_8$]toluene, 599.8 MHz, 298 K): δ = 4.45/3.05, −0.92 (2-H/1-H′, 1-H), −0.92/4.45, 3.05 (1-H/2-H, 1-H′). − ^{13}C NMR ([D$_8$]toluene, 599.8 MHz, 298 K): δ = 127.0 (C2), 109.7 [$C_5(CH_3)_5$], 102.5 (C-cot), 46.9 (C1), 10.6 [$C_5(CH_3)_5$]. − GHSQC ([D$_8$]toluene, 150.8/599.8 MHz, 298 K): δ = 127.0/4.45 (C2, 2-H), 102.5/5.16 (C-cot/cot-H), 46.9/3.05 (C1/1-H′), 46.9/−0.92 (C1/1-H), 10.6/1.93 $C_5(CH_3)_5$/$C_5(CH_3)_5$. − $C_{22}H_{29}Ta$ (474.4): calcd. Preparation of (η⁴-Butadiene)(η³-cyclooctatetraene)(η⁵-methylcyclopentadienyl)tantalum (7d): The reaction between **6d** (1.00 g, 2.60 mmol) and [(cot)Li_2] (337 mg, 2.85 mmol) was performed as described above to yield 720 mg (66%) of **7d** as a dark-brown solid. − m.p. 148°C (decomp.). − IR (KBr): $\tilde{\nu}$ = 3097, 3074, 2990, 2956, 2942, 1547, 1493, 1456, 1438, 1429, 1305, 1230, 1054, 1029, 857, 825, 807, 689, 613 cm^{-1}. − ^1H NMR ([D_8]toluene, 599.8 MHz, 298 K): δ = 5.24 (s, 8 H, cot-H), 4.83 (d, J_{HH} = 2.5 Hz, 2 H), 4.35 (pt, J_{HH} = 2.5 Hz, 6 H, C_5H_4), 4.24 (m, 2 H, 2-H), 3.48 (m, 2 H, 1-H′), 1.74 (s, 3 H, CH_3), −0.98 (m, 2 H, 1-H). − ^{13}C NMR ([D_8]toluene, 150.8 MHz, 298 K): δ = 126.0 (C2), 113.4, 103.0, 99.7 (C_5H_4), 101.0 (C-cot), 46.6 (C1), 14.3 (CH_3). − GHSQC ([D_8]toluene, 150.8/599.8 MHz, 298 K): δ = 126.0/4.24 (C2/2-H), 113.5/4.83 (C_5H_4/C_5H_4), 101.0/5.24 (C-cot/cot-H), 99.7/4.35 (C_5H_4/C_5H_4), 46.6/3.48 (C1/1-H′), 46.6/−0.98 (C1/1-H). − $C_{18}H_{21}Ta$ (418.31): calcd. C 51.68, H 5.06; found C 52.16, H 5.32.

Preparation of the (η⁴-Butadiene)(η³-cyclooctatetraene)(η⁵-cyclopentadienyl)tantalum Isomers 7e and 7e′: The reaction between **6e** (1.50 g, 4.04 mmol) and [(cot)Li_2] (525 mg, 4.45 mmol) was performed as described above to yield 902 mg (55%) of a 95:5 mixture of **7e** and **7e′**. − m.p. 147°C (decomp.). − IR (KBr): $\tilde{\nu}$ = 3098, 3085, 2998, 2947, 1437, 1429, 1367, 1236, 1070, 1020, 1011, 817, 844, 822, 690, 612, 430 cm^{-1}. − ^1H NMR ([D_8]toluene, 599.8 MHz, 298 K): **7e** (major isomer): δ = 5.22 (s, 8 H, cot-H), 4.79 (d, 5 H, Cp-H), 4.20 (m, 2 H, 2-H), 3.56 (m, 2 H, 1-H′), −1.04 (m, 2 H, 1 H). **7e′** (minor isomer): δ = 5.22 (s, 8 H, cot-H, under signal of the major isomer), 4.81 (d, 5 H, Cp-H), 4.78 (m, 2 H, 2-H, under **7e** resonance), 2.45 (m, 2 H, 1-H′), 1.50 (m, 2 H, 1-H). − 1D TOCSY ([D_8]toluene, 599.8 MHz, 298 K): **7e**: irradiation at δ = 3.56 (1-H′): response at δ = 4.20 (2-H) and −1.05 (1-H). **7e′**: irradiation at δ = 1.50 (1-H): response at δ = 4.79 (2 H) and 2.45 (1-H′). − GCOSY ([D_8]toluene, 599.8 MHz, 298 K): **7e**: δ = 4.20/3.56, −1.05 (2-H/1-H′, 1-H), 3.56/4.20, −1.05 (1-H′/2-H, 1-H), −1.05/4.20, 3.56 (1-H/2-H, 1-H′). **7e′**: δ = 4.79/2.45, 1.50 (2-H/1-H′, 1-H), 2.45/4.79, 1.50 (1-H′/2-H, 1-H), 1.50/4.79, 2.45 (1-H/2-H,1-H′). − ^{13}C NMR ([D_8]toluene, 150.8 MHz, 298 K): **7e**: δ = 125.4 (C2), 100.7 (C-cot), 100.6 (C−Cp), 45.3 (C1). **7e′**: δ = 122.8 (C2), 100.4 (C-cot), 99.6 (C−Cp), 45.4 (C1). − GHSQC ([D_8]toluene, 150.8/599.8 MHz, 298 K): **7e**: δ = 125.4/4.20 (C2/2-H), 100.5/5.22 (C-cot/cot-H), 100.6/4.74 (C−Cp/Cp-H). 45.3/3.56 (C1/1-H′), 45.3/−1.05 (C1/1-H). **7e′**: δ = 122.8/4.79 (C2/2-H), 100.4/5.22 (C-cot/cot-H), 99.6/4.81 (C-Cp/Cp-H), 45.4/2.45 (C1/1-H′), 45.4/−1.50 (C1/1-H). − $C_{17}H_{19}Ta$ (404.29): calcd. C 50.51, H 4.74; found C 50.12, H 4.73.

Reaction of Complex 7a with $B(C_6F_5)_3$. − Generation of 8: (The reaction was carried out in deuterated solvent and the product was not isolated. At room temperature complex **8** starts to decompose after about 2 h; therefore some NMR experiments had to be carried out at low temperature.) An NMR tube was charged with a sample of **7a** (50 mg, 54.1 μmol) and a solution of $B(C_6F_5)_3$ (81.0 mg, 158 μmol) in 0.8 mL of [D_2]dichloromethane was added at −78°C. The sample was warmed to +10°C inside the NMR spectrometer. After ca. 1 h, the addition reaction to give **8** was complete and the sample was cooled to −30°C to collect the NMR spectroscopic data. − ^1H NMR ([D_2]dichloromethane, 599.8 MHz, 223 K, bco = bicyclo[5.1.0]octadienyl): δ = 6.66 (m, 2 H, bco-2/6-H), 5.42 (m, 2 H, butadiene-2-H), 3.86 (m, 1 H, bco-4-H), 3.33 (m, 1 H, bco-8-H), 3.30 (m, 2 H, bco-3/5-H), 2.86 (m, 2 H, butadiene-1-H′), 1.94 [s, 15 H, $C_5(CH_3)_5$], 1.23 (m, 2 H, bco-1/7-H), 0.17 (m, 2 H, butadiene-1-H). − 1D TOCSY ([D_2]dichloromethane, 599.8 MHz, 223 K): (i) irradiation at δ = 5.42 (butadiene-2-H): response at δ = 2.86 (1-H′), 0.17 (1-H). (ii) irradiation at δ = 6.66 (bco-2/6-H): response at δ = 3.86 (4-H), 3.33 (8-H), 3.30 (3/5-H), 1.23 (1/7-H). − GCOSY ([D_2]dichloromethane, 599.8 MHz, 223 K): δ = 6.66/3.30, 1.23 (bco-2/6-H//3/5-H, 1/7-H), 5.42/2.86, 0.17 (butadiene-2-H/1-H, 1-H′), 3.86/3.30 (bco-4-H//3/5-H), 3.33/1.23 (bco-8-H//1/7-H), 3.30/3.86, 6.66 (bco-3/5-H//4-H, 2/6-H), 2.86/5.42, 0.17 (butadiene-1-H′//2-H, 1-H), 1.23/3.33 (bco-1/7-H//8-H), 0.17/5.42, 2.86 (butadiene-1-H//2-H, 1−1H′). − ^{13}C NMR ([D_2]dichloromethane, 150.8 MHz, 223 K): δ = 158.7 ($^1J_{CH}$ = 157 Hz, bco-C2/6), 148.2 [$^1J_{CF}$ = 249 Hz, *o*-$B(C_6F_5)_3$], 144.7 [$^1J_{CF}$ = 260 Hz, *p*-$B(C_6F_5)_3$], 137.1 [$^1J_{CF}$ = 251 Hz, *m*-$B(C_6F_5)_3$], 113.2 (butadiene-C2), 110.1 [$C_5(CH_3)_5$], 91.8 ($^1J_{CH}$ = 155 Hz, bco-C3/5), 71.4 ($^1J_{CH}$ = 167 Hz, bco-C4), 39.4 ($^1J_{CH}$ = 165 Hz, bco-C1/7), 10.6 [$C_5(CH_3)_5$], *ipso*-C of $B(C_6F_5)_3$ and bco-C8 not observed, butadiene-C1 hidden by solvent. − GHSQC ([D_2]dichloromethane, 150.8 MHz, 223 K): δ = 158.7/6.66 (bco-C2/6//2/6-H), 113.3/5.42 (butadiene-C2/2-H), 91.8/3.30 (bco-C3/5//3/5-H), 71.4/3.86 (bco-C4//4-H), 65.1/3.33 (bco-C8//8-H), 54.1/2.86, 0.17 (butadiene-C1//1-H/H′), 39.4/1.23 (bco-C1/7//1/7-H), 10.6/1.94 (Cp*). − ^{11}B NMR ([D_2]dichloromethane, 64.2 MHz, 243 K): δ = −14.0. − ^{19}F NMR ([D_2]dichloromethane, 564.3 MHz, 243 K): δ = −130.4 [m, 6 F, *o*-$B(C_6F_5)_3$], −161.7 [m, 3 F, *p*-$B(C_6F_5)_3$], −165.6 [m, 6 F, *m*-$B(C_6F_5)_3$].

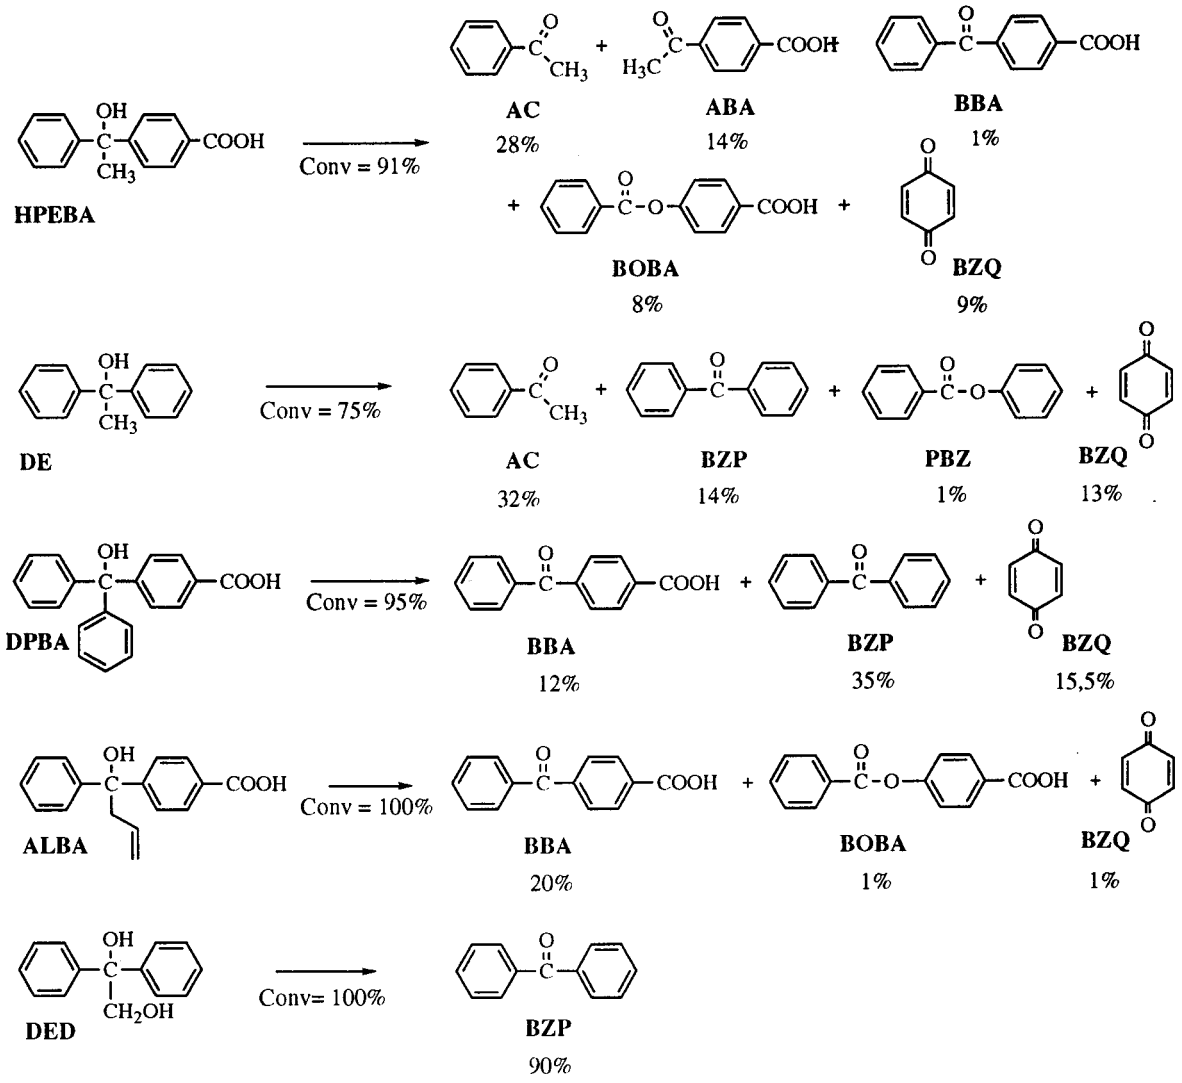
Mechanism of the Catalytic Oxidation of Tertiary Alcohols by the Water-Soluble Mn-TMPyP/$KHSO_5$ System: β-Fragmentation versus *O*-Neophyl Rearrangement

Karine Wietzerbin,[a] Jean Bernadou,*[a] and Bernard Meunier*[a]

Keywords: Oxidations / Tertiary alcohol / Porphyrins / Neophyl rearrangement / Cleavage reactions / β-Scission

Oxidation of 4-(1-hydroxy-1-phenylethyl)benzoic acid HPEBA with a water-soluble metalloporphyrin as catalyst and $KHSO_5$ as oxygen atom donor gives the major products, acetophenone AC and acetylbenzoic acid ABA, by a C_{aliph}–C_{Ar} bond cleavage, but a minor product, benzoyloxybenzoic acid BOBA, requires the insertion of an oxygen atom to form the ester. This compound becomes the main oxidation product on increasing the amount of acetonitrile in the reaction medium, and its formation is oxygen-dependent. The conversion is drastically lowered by using D_2O instead of H_2O, suggesting that an alkoxyl radical is formed in the rate-determining step. Labeling experiments using $^{18}O_2$ or $H_2{}^{18}O$ under different reaction conditions show that the carbonyl oxygen atoms of AC and ABA originate either from substrate, water or dioxygen. However, the carbonyl oxygen atom in the ester group of BOBA originates from dioxygen while the other oxygen atom of the ester remains unlabeled. These results can be explained by an *O*-neophyl rearrangement of the initial alkoxyl radical to afford a carbon-based radical which then reacts with dioxygen or Mn^{IV}-OH/water. In a competitive reaction pathway, direct β-scission of the alkoxyl radical leads to unlabeled products. The oxidation of other tertiary diaryl alcohols is also discussed.



Introduction

Little is known about the oxidative C–C bond cleavage by biomimetic catalysts, although it is a key step in several reactions catalyzed by cytochrome P-450 in steroidal hormone biosynthesis such as estrogen biosynthesis or the side chain cleavage of cholesterol.[1] In the latter case, the cleavage is achieved by three successive oxidations; two hydroxylation steps at C-20 and C-22 produce a vicinal diol which is then oxidatively cleaved in the third step into two carbonyl compounds. With the aim of simulating this last scission step, the oxidation of aryl-substituted ethane-1,2-diols by chromium(III) tetraphenylporphyrin/4-cyano-*N,N*-dimethylaniline *N*-oxide without[2] and under photocatalysis,[3] or by iron(III) tetraphenylporphyrin/O_2/dihydropyridine[4][5] was shown to induce C–C bond cleavage selectively to give aldehydes and ketones. The photochemical cleavage of 1,2-diphenylethane-1,2-diols has also been observed with water-soluble iron porphyrin complexes to produce benzaldehyde and small amounts of benzoic acid, in which experimental yields and bleaching of the catalyst depend on the presence of O_2.[6][7] Aromatization of a synthetic androgen analogue by a peroxo iron(III) porphyrin complex results in C–C bond cleavage and allows the authors to mimic the third step of aromatase, the enzyme responsible for the conversion of androgens to estrogens in humans, which involves loss of the C-19 aldehyde and aromatization of the A ring of the steroid.[8]

As part of our mechanistic studies on the biomimetic Mn-TMPyP/$KHSO_5$ system – a water-soluble manganese porphyrin complex as catalyst with potassium monopersulfate as oxygen atom donor – we show here how some intermediate tertiary alcohol models can give ketones through cleavage of a C–C bond. As opposed to primary and secondary alcohols, tertiary alcohols are usually resistant to oxidation, and examples of such oxidative conversions are rather unusual and generally related to some structural peculiarity. Chromium(VI) can oxidize allylic- or α-cyclopropyl tertiary alcohols to give rearrangements,[9–11] δ- or γ- unsaturated tertiary alcohols to afford cyclization products,[12][13] and tertiary cycloalkanols to produce fragmentations.[14] Cerium(IV) salts and cobalt(III) complexes can also induce C–C bond cleavage by oxidation of tertiary alcohols, leading mainly to fragmentation reactions.[15][16] Synthetic metalloporphyrins, used as models for cytochrome P-450, are highly efficient catalysts for the oxidation of various substrates but only some rare examples of oxidation of tertiary alcohols are described in the literature. Recently, we have shown that the biomimetic water-soluble Mn-TMPyP/$KHSO_5$ system gives mainly C_{aliph}–C_{aliph} and C_{aliph}–C_{Ar} bond cleavage through a β-fragmentation mechanism in the course of the oxidation of aryl and diaryl tertiary alcohol derivatives.[17][18] We now report a mechanistic study based on a careful examination of the oxidation products of tertiary alcohols, and labeling experiments, which emphasizes, besides the initial observation of β-fragmentation as a possible mechanism to explain the observed product distribution, the role of *O*-neophyl rearrangement. This latter mechanism allows us to understand not only the partial incorporation of oxygen from water and dioxygen in oxidation products but also the formation of an unexpected

Scheme 1. Identified products and yields from oxidation of HPEBA, DE, DPBA, ALBA and DED with the Mn-TMPyP/$KHSO_5$ system

ester derivative which is characteristic of such a reaction pathway.

Results

Oxidation of HPEBA With Mn-TMPyP/$KHSO_5$

The metalloporphyrin-catalyzed oxidation of 4-(1-hydroxy-1-phenylethyl)benzoic acid HPEBA was performed in air at pH 5 in aqueous phosphate buffer containing 10% acetonitrile, with the manganese(III) *meso*-tetrakis(1-methylpyridinium-4-yl)porphyrin (Mn-TMPyP) as catalyst and $KHSO_5$ as oxidant. Final concentrations of substrate, catalyst and oxidant were 500 μM, 10 μM and 10 mM, respectively. The reaction was monitored by HPLC. After 10 min, the substrate conversion was 90%. Products (Scheme 1) were identified by HPLC co-injection of authentic samples (benzoyloxybenzoic acid, BOBA, which is not commercially available, was synthesized) and by GC-MS analysis of a reaction sample after esterification of the carboxylic groups with diazomethane.

In the case of benzoquinone BZQ, which is not easily detectable by GC-MS, it should be noted that its HPLC peak disappeared after addition of a small amount of sodium dithionite ($Na_2S_2O_4$), which is a specific reductant of benzoquinones. Product yields and selectivities are given in Table 2. The major products, acetophenone AC and *p*-acetylbenzoic acid ABA, are derived from a $C_{aliph}-C_{ar}$ bond cleavage, while a very small amount of *p*-benzoylbenzoic acid BBA resulting from a $C_{aliph}-C_{aliph}$ bond cleavage was obtained. The formation of the unexpected ester BOBA requires the loss of a methyl group and the insertion of an oxygen atom. Surprisingly, the isomeric ester monophenylterephthalate MPTP, corresponding to insertion of the oxygen atom on the phenyl side of the carbonyl ester function, was not detected. This fact was confirmed by preparing an authentic sample of this compound, which proved to have almost the same HPLC elution time as BOBA, but different GC behavior and different NMR and EI-MS spectra. MPTP was not observed, either by GC-MS analysis of the reaction mixture or by NMR spectroscopic analysis of the

collected HPLC peak (the NMR spectrum corresponded to that of BOBA only). When replacing $KHSO_5$ by the same molar amount of H_2O_2, no conversion was observed, and the use of methanol instead of acetonitrile inhibited the oxidation, probably through trapping of the high valent metal-oxo species.[19] We also checked that no reaction occurred in the absence of catalyst and that ABA, BBA, AC and BZQ were stable under the catalytic oxidation conditions. However, in the case of BOBA, 70% conversion was obtained after 10 min, the only identified product being a small amount of benzoquinone. The same behavior was observed with MPTP but, in this case, conversion was 90%. We then decided to study the competitive oxidation of a mixture of substrate and one of the two esters. For a mixture of HPEBA and BOBA, the conversion of HPEBA was almost 100%, while only 10−15% of BOBA was converted. Therefore, the yield of BOBA resulting from the catalytic oxidation is barely affected by further oxidation. The same experiment with MPTP revealed an 85% conversion of the ester. These observations led us to conclude that MPTP was not detected among the reaction products because either: (i) it was further oxidized under the reaction conditions, or (ii) it was not formed during the catalytic reaction. These two possibilities will be discussed later.

Influence of the Acetonitrile/Buffer Ratio

Increasing the acetonitrile content from 10% to 45% in the buffered medium resulted in a decrease in the conversion, from 90% to 35%, and also in a significant change in the product distribution. Figure 1 shows that, with more than 40% acetonitrile, BOBA becomes the main product, while the selectivity in the other four products is slightly lowered. In fact, acetonitrile seems to favor the formation of BOBA. These results highlight the peculiar behaviour of BOBA over that of the other products, and suggest that there are several reaction pathways operating at the same time (at least two), one of them leading only to BOBA.

Influence of Dioxygen

In order to assess the influence of the reaction atmosphere, we carried out the oxidation under different pressures of dioxygen (to avoid leaks, we always added nitrogen to maintain a pressure of 1 atm). For these experiments we used 10% catalyst so that, in each case, the conversion was close to 100%. Figure 2 indicates the evolution of product selectivities as the amount of dioxygen is raised. Once again, the yield of BOBA increases while the yield of the other products is lowered indicating that formation of BOBA is oxygen-dependent. Furthermore, Figure 2 also shows that the yields of BOBA and AC are inversely correlated. In other words, as the yield of BOBA increases, the yield of AC decreases by the same amount, so that the value ([BOBA] + [AC]) remains constant (see also Table 1). This suggests that AC and BOBA have a common intermediate in their formation pathway. This intermediate is able to react with molecular oxygen to give BOBA, or to follow an alternative route leading to AC.

ABA	16	16
BOBA	16	4

Labeling Experiments

In order to obtain more information about the reaction mechanism, we performed labeling experiments. To this end, we prepared the trideuteriated substrate CD_3-HPEBA, where the CH_3 has been replaced by a CD_3, and subjected it to the Mn-TMPyP/$KHSO_5$ system. Substrate conversion, product yields and selectivities are shown in Table 2. First of all, we observed that the conversion rate is almost the same as the oxidation rate of HPEBA. The absence of an isotope effect allows us to conclude that the rate-determining step of the oxidation does not involve an H-abstraction

Table 2. Yields and selectivities of products obtained from Mn-TMPyP/$KHSO_5$ oxidation of HPEBA in H_2O or D_2O and CD_3-HPEBA in H_2O[a]

Substrate Products	HPEBA in H_2O Yield (%)[b]	Selectivity (%)[b,c]	CD3-HPEBA in H_2O Yield (%)[b]	Selectivity (%)[b,c]	HPEBA in D_2O Yield (%)	Selectivity (%)[c]
AC	28 ± 1	31 ± 1	28 ± 1	34 ± 1	6	19
ABA	14 ± 0.5	15.3 ± 0.4	15.2 ± 0.3	19 ± 0.5	9	21
BBA	0.8 ± 0.1	0.9 ± 0.1	2.6 ± 0.3	3.2 ± 0.4	0.5	1
BOBA	7.7 ± 0.3	8.7 ± 0.3	6.8 ± 0.2	8.0 ± 0.1	2	6
BZQ	9.2 ± 0.4	10.6 ± 0.2	8.0 ± 0.4	9.8 ± 0.3	2	6
Conversion (%)	*91 ± 4*		*83 ± 3*		*37*	

[a] Experiments were performed under the same conditions, with 10% acetonitrile (substrate, $KHSO_5$ and Mn-TMpyP concentrations were respectively 500 μM, 10 mM and 10 μM). – [b] Experimental errors were obtained from three independent experiments. – [c] Selectivity is defined as the ratio of product yield divided by substrate conversion.

from the methyl group. No major changes in product selectivity were observed, except for BBA, whose selectivity, although it remained very low, increased significantly by a factor of 3.5. Thus replacing CH_3 by CD_3 in HPEBA influences only the formation of BBA. The reaction mixture resulting from the oxidation of CD_3-HPEBA was also analyzed by GC-MS. The mass spectra of AC and derivatized ABA showed a unique molecular peak at M + 3 (*m*/*z* 123 and *m*/*z* 181, respectively). These data clearly demonstrate that during the formation of ABA and AC, the methyl group remains unchanged since the three deuterium atoms are still present in the oxidation products.

Another experiment was performed in D_2O instead of H_2O, using HPEBA. An important isotopic effect was detected: the product distribution was not really affected, but the conversion decreased to 37% instead of the 91% observed in H_2O over the same reaction time (Table 2). When the substrate was placed in D_2O, its alcoholic hydrogen was exchanged for a deuterium. The decreased conversion indicates the major role played by the alcoholic hydrogen in the reaction mechanism. Additionally, we checked that with a substrate without exchangeable hydrogen, no such isotopic effect was observed. For example, the epoxidation of carbamazepine with Mn-TMPyP/$KHSO_5$, performed in D_2O, gave 97% conversion, the value obtained in H_2O being 95% in the same reaction conditions.[20] We can therefore conclude that the isotope effect observed with HPEBA is not a solvent isotope effect, but must be related to an isotope effect of the substrate itself.

In order to investigate the origin of the oxygen incorporated in the oxidation products, we performed experiments in the presence of ^{18}O-labeled water or dioxygen. The reactions were carried out with 10% catalyst and 20% acetonitrile for 10 min, so that the conversion was almost complete, and the yield of BOBA was optimized to provide suitable conditions for GC-MS analyses. In control experiments, we checked that HPEBA, AC, BBA and BOBA did not exchange their oxygen with water under these reaction conditions. A small exchange (7%) was found in the case of ABA. Also, $KHSO_5$ itself does not exchange its oxygen with water.[21] The labeling of BZQ was not studied since it was not detected by GC-MS under our conditions. Experiments were performed under air or under 1 atm of nitrogen or dioxygen either labeled or not. The dependence of the amount of labeled oxygen incorporated into each product on the reaction conditions is indicated in Table 3. The percentages were determined by calculating the relative abundances of molecular ions at M, M + 2 and M + 4, corresponding to the incorporation of none, one or two heavy oxygen atoms (the latter case concerns only BOBA). For BOBA, the relative abundances of the peaks at *m*/*z* 105 and 107 ($[Ph-C=O]^+$) provided the separate labeling of the carbonyl oxygen.

These results give us several key data. First, the oxygen incorporated in BOBA comes only from dioxygen, and is selectively introduced at the carbonyl position (no M + 4 peak was detected, and M + 2/M and 107/105 relative abundances were both close to 100% when the reaction was performed under $^{18}O_2$). In other words, 100% of the carbonyl oxygen atom of BOBA originates from dioxygen, while the oxygen atom of the ester remains unlabeled. This is consistent with the fact that BOBA formation is oxygen-dependent (see Figure 2). In contrast, the other three products incorporate labeled-oxygen atoms either from water or dioxygen. With AC and ABA, the labeling depends on the reaction conditions: as the quantity of dioxygen decreases, the amount of oxygen atoms from water increases (runs 2–4, Table 3). Interestingly, when the reaction was performed under 1 atm of dioxygen, AC was found to contain 24% of water-derived oxygen atoms and 65% of dioxygen-derived oxygen atoms. The total contribution of both water and dioxygen is thus 89%, which nearly corresponds to the amount of oxygen atoms incorporated from water when the reaction is performed under nitrogen (*i.e.* 85%). The same observation can be made with ABA. This suggests that there are two competitive pathways leading to AC and ABA, one involving a reaction with water, and the other involving a reaction with dioxygen. As the amount of dioxygen decreases, the preferred pathway become the water-dependent one. In the case of BBA, the labeling does not depend on the reaction conditions, since the amount of oxygen atoms from water remains unchanged whether the reaction is performed under nitrogen or under dioxygen (runs 2 and 4, Table 3).

Oxidation of Other Tertiary Alcohols

For a better understanding of the reactivity of HPEBA we decided to study the catalytic oxidation of some other tertiary alcohols. 1,1-Diphenylethan-1-ol DE (Scheme 1) was chosen to study the influence of the carboxylic group. Under the same experimental conditions as with HPEBA, the conversion was 75% and the oxidation products were the same as those resulting from oxidation of HPEBA, but without the carboxylic group, *i.e.* AC, BZQ, benzophenone BZP and the phenylbenzoate ester PBZ. The small amount of PBZ detected (Scheme 1) may be due to its poor stability in the reaction medium, since a control experiment showed that PBZ is completely oxidized by Mn-TMPyP/$KHSO_5$ in 10 min. The more striking fact is the large amount of BZP formed relative to the very low quantity of BBA obtained from HPEBA. This suggests that removal of the carboxylic group influences the rate of the $C_{aliph}-C_{aliph}$ bond cleavage pathway.

4-(Diphenylhydroxymethyl)benzoic acid DPBA and 4-(1-hydroxy-1-phenylbut-3-en-1-yl)benzoic acid ALBA (Scheme 1), analogous to HPEBA but with a phenyl or an allyl group instead of the methyl susbstituent, were also prepared and oxidized by Mn-TMPyP/$KHSO_5$ under the same conditions as HPEBA. The reactions were followed by HPLC and GC-MS. In both cases, the conversion was almost complete. The identified products and yields are indicated in Scheme 1. In the case of DPBA, the products are formed from the three possible $C_{aliph}-C_{ar}$ bond cleavages. Despite the fact that the loss of the phenyl group is statistically favored, the major product is BZP, resulting from the loss of the *p*-carboxyphenyl group. This is consistent with the selectivity observed for oxidation of HPEBA, where AC, deriving from the loss of the *p*-carboxyphenyl, is formed preferentially over ABA, resulting from the loss of the phenyl group. In contrast, no product deriving from the loss of one of the aromatic rings was detected by GC-MS analysis of the reaction mixture obtained from catalytic oxidation of ALBA. Instead, the major product is formed by loss of the allyl substituent, and we found a small amount of BZQ and BOBA. These observations suggest that the nature of the substituents of the carbinol plays a crucial role in the cleavage selectivity.

The last compound studied was 1,1-diphenylethane-1,2-diol DED (Scheme 1). In the presence of Mn-TMPyP/$KHSO_5$, substrate conversion was complete, and the only identified product was BZP, which was obtained in 90% yield. We also performed the oxidation with labeled water or dioxygen. In both cases, no labeled oxygen was found in the BZP, indicating that the carbonyl oxygen atom of BZP comes from the oxygen of the tertiary alcohol.

Discussion

Formation of Unlabeled Products

In a previous communication,[17] we suggested, based on product distribution from catalytic oxidation of HPEBA, that ABA, BBA, and AC are formed from the β-scission of the alkoxyl radical intermediate **1** by abstraction from the substrate of either H·, or an electron followed by H^+ loss (Scheme 2). Either type of abstraction may be performed by the high-valent $Mn^V=O$ species, generated by $KHSO_5$ with Mn-TMPyP, which is the active species operating in this catalytic system.[20][22] Taking into consideration the present labeling results, we now know that the pathway leading to these products must involve, at least in part, molecular oxygen and water. Since some products remain unlabeled, a β-scission must occur, but it is not the only reaction pathway operating. The experiments performed with CD_3-HPEBA demonstrate that, during the formation of AC and ABA, the methyl group is not modified, allowing us to discard any mechanism involving an oxidative attack on this group. On the other hand, the important role of the alcoholic hydrogen atom is shown by the experiment in D_2O where the conversion is significantly lowered. All these data are consistent with the formation of an alkoxy radical in a rate-determining step, as initially proposed. This radical can undergo β-fragmentation in competition with alternative pathways involving water and/or dioxygen. Thus, we can attribute the formation of the unlabeled fraction of AC, ABA and BBA to the β-scission of the alkoxy radical intermediate **1** (Scheme 2): the three products originate from the three possible cleavages, producing phenyl, *p*-carboxyphenyl and methyl radicals but the loss of the aryl groups is highly preferred, since very small amounts of BBA are formed. Previous studies on the decomposition of the cumyloxyl radical[23][24] and its derivative bearing a *p*-COOH substituent on the phenyl ring[18] revealed a predominent elimination of the methyl group, leading to acetophenone derivatives. Actually, β-scission is a process involving a late tran-

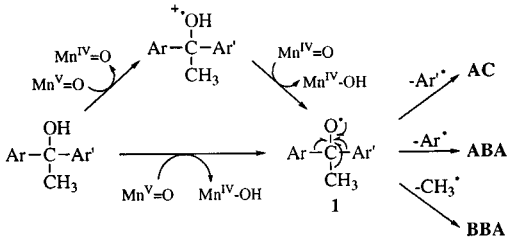

Table 3. ^{18}O-incorporation in AC, ABA, BBA and BOBA during the oxidation of HPEBA by Mn-TMPyP/$KHSO_5$ with $H_2{}^{18}O$ or $^{18}O_2$ (● = ^{18}O-labeled oxygen atom)

Run	Conditions	AC C=●	ABA C=●	BBA C=●	BOBA −C=●	−●−

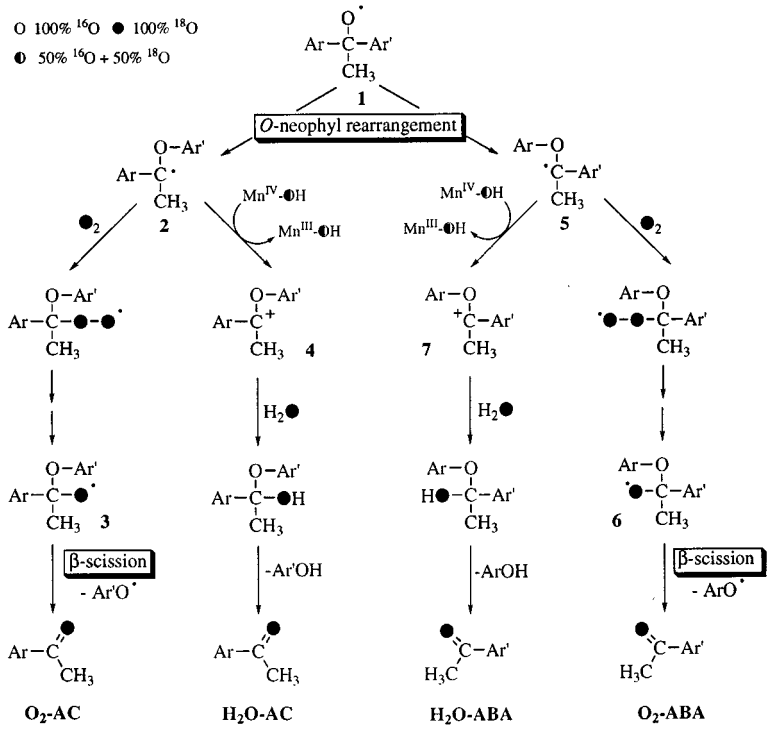
2	$H_2●/O_2$	24%	14%	22%	0	0
3	$H_2●$/Air	46%	19%	13%[a]	0	0
4	$H_2●/N_2$	85%	38%	22%	0	0

[a] The GC peak corresponding to BBA was too small in this experiment (yield of BBA from oxidation of HPEBA was 1%) to afford an accurate value.

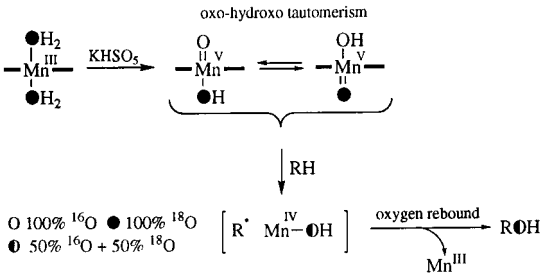
sition state.[25] Consequently, the reaction rate depends on the stability of the generated radical and also of the carbonyl product formed. In our case, and in the case of cumyloxyl radicals, very unstable radicals are released (methyl or aryl radicals), so the orientation of the C−C bond cleavage should be controlled by the stability of the carbonyl products. Thus, the cleavage orientation can be rationalized by the enhanced stability of acetophenone derivatives over benzophenone derivatives (or acetone in the case of loss of a phenyl group from cumyloxyl radicals).[24] Furthermore, other factors such as diminution of the steric strain by expulsion of bulky groups can also influence a β-scission reaction.[24]

In contrast with HPEBA, none of the aryl groups were cleaved during the oxidation of ALBA (see Scheme 1). Instead, the only product detected results from cleavage of the allyl group. Assuming that the β-scission is the only pathway, we propose that, in this case, the much higher stability of the allyl radical[26] over the phenyl and *p*-carboxyphenyl radicals is the driving force for the reaction. Thus, the release of the allyl radical is highly favored, and there is only a minor influence of the stability of the carbonyl products formed concomitantly, or of any other factor.



Scheme 2. Formation of unlabeled AC, ABA and BBA through β−scission of the alkoxyl radical **1**; Ar = phenyl and Ar′ = *p*-carboxyphenyl.

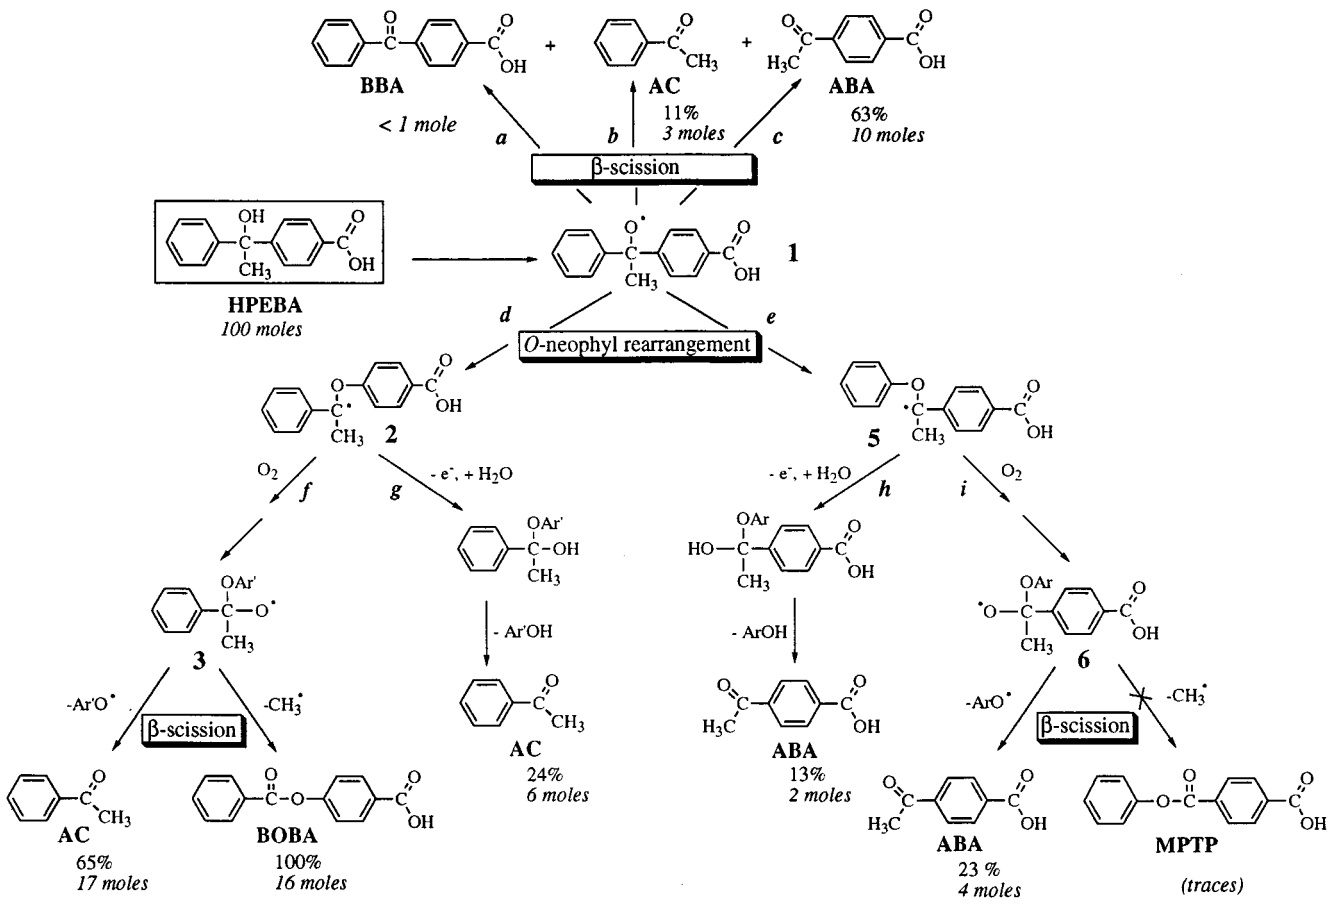
Formation of Labeled AC, ABA and BOBA



Following the idea that the alkoxy radical is the key intermediate in the oxidation reaction, we decided to investigate how this alkoxy radical can lead to AC, ABA, and BOBA with incorporation of oxygen atoms from water and dioxygen in the carbonyl function (in the case of AC and ABA) or from dioxygen only (in the case of BOBA). Obviously, the observed ^{18}O-incorporation and, more importantly, the formation of the ester BOBA require the involvement of a rearrangement. Aryl-substituted alkoxyl radicals are known to undergo an *O*-neophyl rearrangement, consisting of a 1,2 migration of an aryl group from the carbon to the oxygen, which gives rise to a new, more stable, carbon-centred radical (see for example Scheme 3).[27][28]

Usually, this rearrangement occurs on alkoxy radicals substituted by three α-aryl groups, generating an efficiently stabilized carbon radical, although the 1,1-diphenylethoxyl radical is also known to rearrange in such a way.[29−32] Considering that: (i) the structure of the 1-*p*-carboxyphenyl-1-phenylethoxyl radical **1** is very close to that of 1,1-diphenylethoxyl radical, and (ii) that 1,1-diphenylethanol exhibits a similar reactivity to HPEBA under the present oxidative conditions (see above), we can reasonably suppose that the alkoxyl radical **1** may also undergo an *O*-neophyl rearrangement (Scheme 3). Thus, if either phenyl (Ar) or *p*-carboxyphenyl (Ar′) migrates, two new carbon-centred radicals **2** and **5** are formed, which may escape from the solvent cage and react with dioxygen or Mn^{IV}-OH/water to provide AC and ABA, with a carbonyl oxygen atom from either dioxygen or water. Clearly, if the *p*-carboxyphenyl group migrates to the oxygen, the carbon-centred radical **2** is formed. This radical can react with dioxygen to produce a peroxy radical which can dimerize and provide a new alkoxy radical **3** after a Russell fragmentation. The β-scission of **3** releases a *p*-carboxyphenoxy radical and acetophenone, with a dioxygen-derived carbonyl oxygen atom (O_2-AC). Such a process was shown to occur with the 1,1-diphenylethoxy radical by Ingold *et al.*[29] Alternatively, the *O*-neophyl-rearranged radical can suffer electron abstraction by Mn^{IV}-OH. Reaction of the resulting cation **4** with water produces a hemiacetal, which can subsequently be hydrolysed to form acetophenone containing a water-derived carbonyl oxygen atom (H_2O-AC). Another possible pathway leading to H_2O-AC could be that the radical **2** gives the hemiacetal by a classical oxygen rebound route with Mn^{IV}-OH. However, it has been established that, in water, the active species Mn^{V}=O undergoes an oxo-hydroxo tautomerism,[20][22] leading to a 50% labeled active species Mn^{V}=O if ^{18}O-labeled water is used (Scheme 4).

Thus, after H-abstraction, a 50% labeled Mn^{IV}-OH species is generated. Therefore an oxygen rebound mechanism should lead to a 50% incorporation of labeled oxygen from water in the resulting product. In our case, since there are other pathways operating, there should be less than 50% incorporation of water-derived oxygen atoms in AC, and we should obtain at least the same amount of nonlabeled AC. However, the incorporation of labeled oxygen from water was found to be 85% under a nitrogen atmosphere (run 4, Table 3), and 24% under a dioxygen atmosphere (run 2) but with only 11% of nonlabeled H_2O-AC (runs 1 and 2: 11% = 100% − 65% − 24%). Thus, an oxygen rebound mechanism to explain the incorporation of water-derived oxygen atoms can be ruled out, at least as a main mechanism. A similar pathway, involving an initial migration of the phenyl group instead of the *p*-carboxyphenyl of the alkoxyl radical **1**, leads to O_2-ABA and H_2O-ABA. This mechanism explains why the incorporation of oxygen from water increases as the amount of dioxygen in the reaction atmosphere decreases. Indeed, the carbon-centred radicals **2** and **5** can follow two competitive routes, one involving water and the other involving dioxygen. The importance of each route depends on the amount of dioxygen (or water) available and, when the reaction is performed under nitrogen, the only pathway operating must be the water-dependent one. This is in agreement with the fact that, when the reaction is performed under nitrogen, the number of oxygen atoms from water is equal to the total number of oxygen atoms coming from water + dioxygen when the reaction is performed under dioxygen (run 4 and runs 1, 2, respectively, Table 3).



Scheme 3. Formation of ^{18}O-labeled AC and ABA after an *O*-neophyl rearrangement of intermediate **1**, using $H_2{}^{18}O$ or $^{18}O_2$ (direct β-scission from radical **1** generates unlabeled products); Ar = phenyl, Ar′ = *p*-carboxyphenyl

Scheme 4. Oxo-hydroxo tautomerism and oxygen rebound in $KHSO_5$ hydroxylation reaction catalyzed by Mn-TMPyP and performed in $H_2{}^{18}O$

A study of the influence of dioxygen showed that AC and BOBA probably have a common intermediate since, when the amount of dioxygen increases, the quantity of BOBA produced increases as well, but at the expense of AC formation. In addition, BOBA does not derive from a Baeyer-Villiger reaction on BBA because we checked that BBA is stable under the catalytic oxidation conditions. Furthermore, BOBA must incorporate a dioxygen-derived oxygen atom exclusively on the carbonyl position, the other ester oxygen atom being substrate-derived. According to these data, we propose that BOBA is formed through the β-scission of the alkoxy radical **3** (Scheme 5) with loss of a methyl radical. This C-β-scission pathway is in competition with the O-β-scission leading to acetophenone with loss of *p*-carboxyphenoxyl radical. It should be noted that, as far as we are aware, such an alternative between O- and C-β-scission has not previously been reported. A small difference between the bond dissociation energy of a C−C bond or a C−O bond in radical **3** would explain the formation of BOBA and AC from the same radical intermediate. The O_2-dependent pathway to BOBA formed at the expense of AC can now be explained as follows: under anaerobic conditions, the carbon-centred radical **2** (Scheme 3 and 5) follows a water-dependent route leading to AC containing a water-derived carbonyl oxygen atom, but under aerobic conditions, an oxygen-dependent pathway competes with this, leading to AC and BOBA both containing dioxygen-derived carbonyl oxygen atoms.

In a similar manner, the loss of a methyl radical from the oxygen-centred radical **6** (Scheme 5) could lead to MPTP with the same labeling as BOBA. However, MPTP was not detected among the reactions products, but careful analysis of the GC-MS spectra obtained from the labeling experiments showed traces of MPTP with a dioxygen-derived carbonyl oxygen atom. Since it is not stable under the reaction conditions, we wonder whether MPTP is formed and further oxidized, or whether only traces are formed. Our view is that if MPTP is formed, like BOBA, in significant amounts, then the production of ABA should be influenced in the same way as AC by the increase in acetonitrile or dioxygen concentrations. Since ABA proved to be indifferent to these changes of reaction conditions (see Figure 1 and 2), this fact precludes a competitive route leading to MPTP at the expense of ABA formation. Thus, we propose that MPTP is not formed in significant amounts during the reaction. However, we have presently no explanation to rationalize this particular difference in selectivity between C- and O-β-scissions of radicals **3** and **6**.

Scheme 5. Formation pathway of AC, ABA, BOBA and unlabeled BBA; the percentages indicate the part of the product formed through the considered route under a dioxygen atmosphere; the number of mols is the amount of each product formed if the initial amount of HPEBA is 100 mols

Formation of Labeled BBA

The reaction pathways presented in Scheme 5 do not explain the production of partially labeled BBA in the experiments performed in $H_2{}^{18}O$ or under $^{18}O_2$ (Table 3). Although BBA represents only 1% of the products, some additional experimental data were collected to try to understand the role of dioxygen and water in its formation, besides the direct β-fragmentation process. A conceivable pathway which could lead to BBA, after an initial hydroxylation of the methyl group and further oxidation of the resulting 1,1-diarylethane-1,2-diol, can be discarded since: (i) the catalytic oxidation of the related compound 1,1-diphenylethane-1,2-diol DED by Mn-TMPyP/$KHSO_5$ only produces unlabeled products in experiments performed in $H_2{}^{18}O$ or under $^{18}O_2$, and (ii) BBA is more efficiently produced when the methyl group of the substrate is trideuterated (see Table 2), this inverse deuterium isotope effect allows us to eliminate the possibility of an initial hydroxylation of the methyl group. In addition, this isotope effect is different from that observed for the loss of $CD_3^\bullet$ or $CH_3^\bullet$ from $C_6H_6C(CH_3)(CD_3)O^\bullet$ by β-scission (k_H/k_D = 1.15).[25] A carbon-centred radical such as Ar−C·(OH)-Ar′ is a possible intermediate since analogous radicals have been proposed in oxidations catalyzed by cytochrome P-450 or chemical models.[33][34] At present, these results do not allow us to propose a convincing mechanism to explain the available data on this minor reaction product.

Overall Mechanism for HPEBA Oxidation

An overall mechanism, presented in Scheme 5, can now be established with the involvement of two possible evolution pathways for the alkoxy radical **1**: direct β-scission or *O*-neophyl rearrangement. Both AC and ABA can form from **1** through either a direct β-scission (top of Scheme 5) or an *O*-neophyl rearrangement followed (bottom, on the left and on the right) or not (bottom, in the middle) by a β-scission in the ultimate step. BOBA is only produced from **1** through a *O*-neophyl rearrangement followed, after dioxygen addition, by a β-scission in the last step of the reaction (bottom, on the left). BBA is partially produced by direct β-scission of **1** (top) but other pathway(s) remain unidentified at the moment. In Scheme 5, the percentages under the products indicate the part of each product formed through the considered route under 1 atm of dioxygen. Assuming a starting quantity of 100 mols of HPEBA, we obtained for each product the quantities indicated below the percentages. These calculations afford an additional demonstration that

the proposed mechanism is coherent. Indeed, according to this scheme, if the reaction is performed under nitrogen instead of O_2 (according to Table 1, 4 mols of BOBA were still produced under N_2, probably due to the presence of traces of residual dioxygen), routes d + g should lead to 35 mols of AC (17 + 16 + 6 − 4 mols of residual BOBA) containing a water-derived oxygen atom. Adding the 3 mols of AC generated by β-scission gives a total number of 38 mols of AC produced. This quantity is consistent with the 44% yield experimentally observed under nitrogen (see Table 1). In addition, the fact that formation of BOBA was favored by increase in acetonitrile concentration (see Figure 1) can be explained by the decreasing polarity of the medium, which disfavors the β-scission pathway.[35]

Formation of Benzoquinone

Benzoquinone probably derives from the further oxidation of the aryl radicals (phenyl, *p*-carboxyphenyl, phenoxy and *p*-carboxyphenoxy radicals) released in the different β-scission processes. We have checked that phenol, benzoic acid and *p*-hydroxybenzoic acid, three putative evolution products of the aryl radicals (phenol and *p*-hydroxybenzoic acid are also formed through the water-dependent route, see Scheme 5), are quickly oxidized to BZQ by the catalytic system. An additional argument is that the oxidation of ALBA and DED, where almost no aryl radicals are released, gives only 1% of benzoquinone (Scheme 1). In contrast, a significant amount of BZQ is obtained from oxidation of HPEBA, DE and DPBA, for which the oxidation products are derived mainly from a $C_{aliph}-C_{ar}$ bond cleavage with release of aryl radicals (Scheme 1). Consequently, the formation of BZQ can be considered as proof of formation of aryl radicals during the oxidation process.

Conclusions

The catalytic oxidation of several tertiary diaryl alcohols has been achieved with $KHSO_5$ in the presence of Mn-TMPyP. The use of this biomimetic catalytic system represents an alternative and efficient process for oxidative conversion of tertiary alcohols, which are resistant to conventional oxidants. Interestingly, the reaction led to acetophenone and benzophenone derivatives, and also to an unexpected ester. This product distribution, and additional labeling experiments, provide useful insights into the mechanism of the C−C bond cleavage by this cytochrome P-450 model system. The key intermediate in this catalytic oxidation is an alkoxy radical which follows a β-scission route or, alternatively, undergoes an *O*-neophyl rearrangement. This latter route explains the formation of products containing dioxygen- or water-derived oxygen atoms. In addition the unprecedented formation of an ester derivative during the catalytic oxidation of tertiary diaryl alcohols can be considered as a proof of the involvement of an *O*-neophyl rearrangement in the reaction mechanism

Experimental Section

Materials: Potassium monopersulfate (the triple salt $[KHSO_5]_2[KHSO_4][K_2SO_4]$, Curox®) was kindly donated by Peroxid Chemie GmbH. Mn-TMPyP (pentaacetate form) was prepared according to ref.[36] AC, ABA, BBA, BZQ, BZP, PBZ and DE were purchased from Aldrich. $H_2{}^{18}O$ (96.5 atom%) was supplied by Eurisotop (Gif sur Yvette, France) and $^{18}O_2$ (96.8 atom%) was supplied by Leman (Saint Quentin en Yvelines, France).

Instrumentation: HPLC analyses were performed on a Waters Millipore chromatograph equipped with a U6 K injector, a diode array detector (Kontron Instrument) and a 10 μm Nucleosil C18 column (Interchrom). The eluent was a mixture of acetonitrile/triethylammonium acetate buffer 0.1M (pH = 6.5) in proportions 35:65 or 25:75 (v/v) for oxidation of HPEBA, DPBA and ALBA and 45:55 (v/v) for oxidation of DE and DED. The flow rate was 1 mL/min Detection was performed at 240 nm. GC-MS analyses were performed on a Hewlett Packard HP 6890 instrument coupled with a MSD 5973 mass spectrometer, using electron impact ionization at 70 eV. The GC column used was a non polar capillary column [25 m × 0.2 mm HP-5MS, cross-linked diphenyl (5%) and dimethylpolysiloxane (95%)] and the carrier gas was helium. The injector temperature was 250°C, and analyses were performed at 80°C for 2 min, then up to 200°C (10°C/min) where the temperature was maintained for 15 min. MS spectra were obtained on a Nermag R10/10H instrument. ^{1}H NMR spectra were recorded with a Bruker WM 250 spectrometer.

Preparation of HPEBA: The three-step procedure was adapted from ref.[37] and improved in terms of solvent used, purification and yields. *p*-Benzoylbenzoic acid (1 g, 4.4 mmol), (−)-menthol (2.8 g, 18 mmol) and *p*-toluenesulfonic acid (42 mg, 0.2 mmol) were heated for 8 h at 180°C. The crude product was dissolved in 50 mL ether/toluene 1/1 (v/v) and washed three times with a saturated solution of sodium carbonate. After addition of water, the organic layer was steam distilled up to 140°C in order to remove the excess menthol. The aqueous residue was then extracted with toluene, and the extracts were dried with sodium sulfate. After removal of solvent under vacuum, menthyl *p*-benzoylbenzoate was obtained as a brown oil (1.52 g, yield = 94%). − ^{1}H NMR ([D$_6$]DMSO): δ = 0.88 [d, ^3J(H,H) = 6.9 Hz, 3 H, CH_3], 1.02 (m, 7 H, $2CH_3$ + CH), 1.25 (m, 2 H, CH_2), 1.56−1.88 (m, 4 H, 2 CH_2), 2.00 (m, 1 H, CH), 2.13 (m, 1 H, CH), 5.01 (m, 1 H, CH), 7.70 [t, ^3J(H,H) = 7.3 Hz, 2 H, 2 aromatic CH], 7.79−7.92 (m, 3 H, 3 aromatic CH), 7.97 [d, ^3J(H,H) = 8.5 Hz, 2 H, 2 aromatic CH], 8.23 [d, ^3J(H,H) = 8.5 Hz, 2 H, 2 aromatic CH].

Methylmagnesium iodide (3.7 mmol) was added dropwise to a stirred solution of menthyl *p*-benzoylbenzoate (674 mg, 1.8 mmol) in 9 mL anhydrous toluene under nitrogen at room temperature. After hydrolysis with 2 M aqueous hydrochloric acid, the organic layer was washed with water, dried over sodium sulfate and concentrated under vacuum. A brown solid was obtained and identified as menthyl *p*-(1-hydroxy-1-phenylethyl)benzoate (562 mg, yield = 82%). − ^{1}H NMR ([D$_6$]DMSO): δ = 0.84 [d, ^3J(H,H) = 6.9 Hz, 3 H, CH_3], 0.99 (m, 7 H, $2CH_3$ + CH), 1.21 (m, 2 H, CH_2), 1.64 (m, 2 H, CH_2), 1.79 (m, 2 H, CH_2), 1.97 (m, 4 H, CH+CH_3), 2.08 (m, 1 H, CH), 4.93 (m, 1 H, CH), 6.01 (s, 1 H, OH), 7.33−7.48 (m, 3 H, 3 aromatic CH), 7.54 [d, 2 H, ^3J(H,H) = 7.2 Hz, 2 aromatic CH], 7.68 [d, ^3J(H,H) = 8.4 Hz, 2 H, 2 aromatic CH], 7.98 [d, ^3J(H,H) = 8.5 Hz, 2 H, 2 aromatic CH].

Menthyl-*p*-(1-hydroxy-1-phenylethyl)benzoate (474 mg, 1.3 mmol) was dissolved in 30 mL aqueous ethanol containing 2.5 M KOH. The solution was refluxed for 4 hours. After removal of ethanol

under vacuum, menthol was extracted with ether. The aqueous layer was then acidified with hydrochloric acid until a brown oil precipitated, which was extracted with dichloromethane. The organic phase was washed with water saturated in sodium chloride until neutral pH and dried over sodium sulfate. Solvent was removed under vacuum. The resulting product was recrystallized from a dichloromethane/hexane mixture to yield pure HPEBA as a white powder (177 mg, yield = 58%). − ^{1}H NMR ([D$_6$]DMSO): δ = 1.96 (s, 3 H, CH$_3$), 5.97 (s, 1 H, OH), 7.29 [t, ^3J(H,H) = 7.3 Hz, 1 H, aromatic CH], 7.40 [t, ^3J(H,H) = 7.3 Hz, 2 H, 2 aromatic CH], 7.54 [d, ^3J(H,H) = 7.0 Hz, 2 H, 2 aromatic CH], 7.64 [d, ^3J(H,H) = 8.4 Hz, 2 H, 2 aromatic CH], 7.96 [d, ^3J(H,H) = 8.4 Hz, 2 H, 2 aromatic CH], 12.97 (br s, 1 H, COOH). − $C_{15}H_{14}O_3$(242.28): calcd. C 74.36, H 5.82; found C 74.12, H 5.74. − MS (DCI/NH$_3$): *m/z*: 260 [$M^+ + NH_4^+$], 242 [M^+], 225 [$(M - OH)^+$].

Preparation of CD$_3$-HPEBA: The procedure was the same as for HPEBA except that in the second step, methylmagnesium iodide was replaced by trideuterated methylmagnesium iodide (3 mmol). Reaction with menthyl *p*-benzoylbenzoate (727 mg, 2 mmol) followed by saponification gave CD$_3$-HPEBA as a white powder (277 mg, yield = 56% for the two steps). − ^{1}H NMR ([D$_6$]DMSO): δ = 5.97 (s, 1 H, OH), 7.29 [t, ^3J(H,H) = 7.3 Hz, 1 H, aromatic CH], 7.40 [t, ^3J(H,H) = 7.3 Hz, 2 H, aromatic CH], 7.54 [d, ^3J(H,H) = 7.0 Hz, 2 H, 2 aromatic CH], 7.64 [d, ^3J(H,H) = 8.4 Hz, 2 H, 2 aromatic CH], 7.96 [d, ^3J(H,H) = 8.4 Hz, 2 H, 2 aromatic CH], 12.97 (br s, 1 H, COOH); − $C_{15}D_3H_{11}O_3$(245.29): calc. C 73.47, H 5.71; found C 73.24, H 5.55. − MS (DCI/NH$_3$): *m/z*: 263 [$M^+ + NH_4^+$], 245 [M^+], 228 [$(M - OH)^+$].

Preparation of DPBA: The procedure was the same as for HPEBA except that in the second step, methylmagnesium iodide was replaced by phenylmagnesium iodide (3.2 mmol) and hydrolysis was performed with 2M aqueous NH_4Cl instead of 2N HCl. Reaction with menthyl *p*-benzoylbenzoate (787 mg, 2.2 mmol) followed by saponification gave DPBA as a cream-colored solid (330 mg, yield = 48% for the two steps). ^{1}H NMR ([D$_6$]DMSO): δ = 6.74 (s, 1 H, OH), 7.29−7.50 (m, 12 H, aromatic H), 8.00 [d, ^3J(H,H) = 8.4 Hz, 2 H, 2 aromatic CH], 12.96 (br s, 1 H, COOH) − $C_{20}H_{16}O_3 \cdot 0.2\ H_2O$ (307.95): calcd. C 78.00, H 5.37; found C 77.94, H 5.13.

Preparation of ALBA: The procedure was the same as for HPEBA except that in the second step, methylmagnesium iodide was replaced by allylmagnesium bromide (7 mmol) and hydrolysis was performed with 2M aqueous NH_4Cl instead of 2M HCl. Reaction with menthyl *p*-benzoylbenzoate (768 mg, 2.1 mmol) followed by saponification and purification by chromatography on silica gel (eluent used was CH_2Cl_2/MeOH 96/4, v/v) gave ALBA as a yellow oil which solidified under vacuum (79 mg, yield = 14% for the two steps). ^{1}H NMR ([D$_6$]DMSO): δ = 3.19 [d, ^3J(H,H) = 6.7 Hz, 2 H, CH$_2$], 4.95−5.20 (m, 2 H, CH$_2$), 5.78 (m, 1 H, CH), 5.93 (s, 1 H, OH), 7.28 [t, ^3J(H,H) = 7.4 Hz, 1 H, aromatic CH], 7.40 [t, ^3J(H,H) = 7.4 Hz, 2 H, 2 aromatic CH], 7.57 [d, ^3J(H,H) = 8.0 Hz, 2 H, 2 aromatic CH], 7.67 [d, ^3J(H,H) = 8.3 Hz, 2 H, 2 aromatic CH], 7.95 [d, ^3J(H,H) = 8.2 Hz, 2 H, 2 aromatic CH], 12.95 (br s, 1 H, COOH). − MS (DCI/NH$_3$): *m/z*: 303 [$(M^+ + N_2H_7^+$], 286 [$(M^+ + NH_4^+$], 268 [$(M - OH + NH_3)^+$], 251 [$(M - OH)^+$].

Preparation of DED: Phenylmagnesium bromide (3.6 mmol) was added dropwise to a stirred solution of ethyl glycolate (110 mg, 1.06 mmol) in anhydrous toluene (10 mL) under nitrogen at room temperature. After hydrolysis with 2M aqueous NH_4Cl, the organic layer was washed with water, dried over sodium sulfate and concentrated under vacuum. The resulting product was recrystallized from a dichloromethane/hexane mixture to yield pure DED as a white solid (141 mg, yield = 62%). − ^{1}H NMR ($CDCl_3$): δ = 1.8 (br s, 1 H, OH), 3.15 (br s, 1 H, OH), 4.17 (s, 2 H, CH$_2$), 7.25−7.45 (m, 10 H, aromatic H). − $C_{14}H_{14}O_2$ 0.2 H_2O (214.26): calc. C 78.48, H 6.59; found C 78.25, H 6.26.

Preparation of BOBA: Benzoyl chloride (1.3 mL, 10.8 mmol) was added dropwise to a stirred solution of *p*-hydroxybenzoic acid (1 g, 7.2 mmol) and triethylamine (2.6 mL, 18 mmol) in 45 mL of acetonitrile under nitrogen at room temperature. After stirring for 3 h, the mixture was poured into 35 mL diethyl ether and washed with water. The aqueous layer was acidified with hydrochloric acid to precipitate the product, which was extracted with diethyl ether. The organic layer was dried over sodium sulfate and the solvent removed under vacuum. The resulting solid was recrystallized from hot ethanol to give a white powder identified as BOBA (262 mg, yield = 15%). − ^{1}H NMR ([D$_6$]DMSO): δ = 7.55 [d, ^3J(H,H) = 8.6 Hz, 2 H, 2 aromatic CH], 7.74 [t, ^3J(H,H) = 7.7 Hz, 2 H, 2 aromatic CH], 7.89 [t, ^3J(H,H) = 7.4 Hz, 1 H, aromatic CH], 8.16 [d, ^3J(H,H) = 8.5 Hz, 2 H, 2 aromatic CH], 8.27 [d, ^3J(H,H) = 7.2 Hz, 2 H, 2 aromatic CH], 13.1 (br s, 1 H, COOH). − $C_{14}H_{10}O_4 \cdot 0.2H_2O$ (242.23): calc. C 69.42, H 4.16; found C 69.25, H 3.97. − MS (DCI/NH$_3$): *m/z:* 277 [$M^+ + N_2H_7^+$], 260 [$M^+ + NH_4^+$].

Preparation of MPTP: A solution of phenol (100 mg, 1.06 mmol) in 5 mL acetonitrile was added dropwise to a stirred solution of terephthaloyl chloride (1.08 g, 5.3 mmol) and triethylamine (500 μL, 3.6 mmol) in 25 mL of acetonitrile under nitrogen at room temperature. After stirring for 1 h, the mixture was poured into water and extracted with dichloromethane. The organic layer was dried over sodium sulfate and solvent was removed under vacuum. The product was purified by chromatography on silica gel (the eluent was dichloromethane/ethanol 95:5, v/v) as it was found to contain terephthalic acid as a by-product of the reaction. **MPTP** (62 mg, yield = 24%) was obtained as a white powder. ^{1}H NMR ([D$_6$]DMSO): δ = 7.40−7.49 (m, 3 H, 3 aromatic CH), 7.61 [t, ^3J(H,H) = 7.5 Hz, 2 H, 2 aromatic CH], 8.25 [d, ^3J(H,H) = 8.4 Hz, 2 H, 2 aromatic CH], 8.36 [d, ^3J(H,H) = 8.5 Hz, 2 H, 2 aromatic CH], 13.6 (br s, 1 H, COOH).

General Catalytic Oxidation Conditions: Unless otherwise stated, the reaction medium (1 mL of water/acetonitrile 9:1, v/v) contained 66 mM phosphate buffer pH 5, 500 μM substrate (introduced as a 25 mM solution in CH_3CN), 10 mM $KHSO_5$ (introduced as a 250 mM solution in water) and 200 μM *p*-diacetylbenzene (used as internal standard). Mn-TMPyP (10 μM) was introduced as a 1 mM solution in water in five consecutive 2 nmol additions, every two min. The first addition initiated the reaction. Reactions were performed at room temperature and monitored by HPLC. Yields were calculated after 10 min from the initial amount of substrate by comparison with calibration curves. For the oxidation of carbamazepine, a previously reported procedure was used.[19]

Competitive Oxidation of HPEBA with BOBA or MPTP: The reaction was carried out as described above, but with addition of 150 μM of BOBA or MPTP. After 10 min, the products were analyzed by HPLC. The amount of ester coming from the catalytic oxidation was estimated from the substrate conversion, so that the conversion of BOBA or MPTP initially introduced could be calculated.

Experiments Under Different Pressures of Dioxygen: In this case, the mixture contained 20% acetonitrile instead of 10%, and the Mn-TMPyP concentration was 50 μM. The reaction medium was placed in a Schlenk tube connected to a pressure captor and degassed by three consecutive freeze-thaw cycles under vacuum. It was then repressurized with the desired pressure of dioxygen, and nitrogen was added to maintain a final pressure of 1 atm. Mn-

TMPyP (previously degassed) was added in five consecutive additions by gas-tight syringe. HPLC analysis was performed after 10 min.

Experiments with D_2O: Solutions of the required concentrations and volume of buffer plus $KHSO_5$ on the one side, and Mn-TMPyP on the other side, were prepared and lyophilized using a Speed-Vac. Substrate and internal standard in CH_3CN and appropriate volumes of D_2O were added (in this case the total volume was 500 μL). The reaction was then carried out as described above.

Experiments with $H_2{}^{18}O$: In this case, the mixture contained 20% acetonitrile instead of 10%, and the Mn-TMPyP concentration was 50 μM. Solutions of the required concentration and volume of buffer plus $KHSO_5$ on the one side, and Mn-TMPyP on the other side, were prepared and lyophilized using a Speed-Vac. Substrate in CH_3CN and appropriate volumes of $H_2{}^{18}O$ were added (in this case the total volume was 500 μL). In the case of the reaction under dioxygen or nitrogen, the reaction medium was placed in a Schlenk tube connected to a pressure captor and degassed by three consecutive freeze-thaw cycles under vacuum. It was then repressurized with 1 atm of dioxygen or nitrogen. Mn-TMPyP (previously degassed) was added in five consecutive additions by gastight syringe. After 10 min, the mixture was saturated with NaCl and extracted with three 1 mL portions of dichloromethane. The organic phase was concentrated, and a solution of diazomethane in dichloromethane (prepared with an Aldrich MNNG diazomethane generation apparatus) was added to convert the carboxylic functions into methyl esters. After concentration, the sample was analysed by GC-MS (to analyze AC, which does not require prior derivatization, a 30 μL sample was taken after the first extraction and analyzed by GC-MS without further treatment). The percentage of ^{18}O incorporated in each product was determined by the relative abundances of the peaks at: *m/z* 120 and 122 [M^+], and *m/z* 105 and 107 [$(M - CH_3)^+$] for **AC**, *m/z* 178 and 180 [M^+], and *m/z* 163 and 165 [$(M - CH_3)^+$] for ABA methyl ester, *m/z* 240 and 242 [M^+], and *m/z* 209 and 211 [$(M - OCH_3)^+$] for BBA methyl ester, *m/z* 256, 258 and 260 [M^+], and *m/z* 105 and 107 [$(M - OC_6H_4COOCH_3)^+$] for BOBA methyl ester. The values obtained were corrected considering the ^{18}O content of the labeled water. Since BOBA and HPEBA methyl esters had the same mass and almost the same elution time, it was necessary to add 10% catalyst instead of 2% to ensure a complete conversion. In addition, a peak at *m/z* 241 [$(M - CH_3)^+$] corresponding only to HPEBA methyl ester allowed us to check the possible presence of small amounts of nonconverted substrate and to calculate its contribution to the molecular peak. Control experiments to check if the products exchanged their oxygen with $H_2{}^{18}O$ were performed under the same conditions using 200 μM AC, ABA, BBA or BOBA instead of HPEBA.

Experiments with $^{18}O_2$: The reaction conditions were the same as for experiments under different pressures of dioxygen, but in this case the Schlenk tube was repressurized with 1 atm of $^{18}O_2$ and the total volume was 500 μL. After 10 min, the sample was treated and analyzed as described for the $H_2{}^{18}O$ experiments. The values obtained from ^{18}O incorporations were corrected considering the ^{18}O content of the labeled dioxygen.

Acknowledgments

We thank Dr. Massimo Bietti (University of Rome) for fruitful discussions on the neophyl rearrangement.

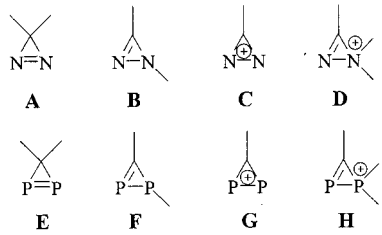
Tungsten Carbonyl Complexes of 1*H*-Diphosphirenes and Diphosphirenylium Salts

Didier Bourissou,[a] Yves Canac,[a] Heinz Gornitzka,[a] Colin J. Marsden,[b] Antoine Baceiredo,[a] and Guy Bertrand*[a]

Keywords: Phosphorus heterocycles / Cations / Tungsten complexes / Coordination modes / Phosphaalkenes



The 1,1,3-tris(diisopropylamino)diphosphirenium salt **1** reacts with lithium aluminium hydride leading to the *P*-hydrogeno-*C*-phosphinophosphaalkenes **2**, which on treatment with a catalytic amount of $BF_3{\cdot}OEt_2$ afford the 1,3-bis(diisopropylamino)-1*H*-diphosphirene **3**. The corresponding η^1-coordinated 1*H*-diphosphirene **6** can be prepared by treatment of **2** or **3** with one equivalent of $[W(CO)_5(thf)]$. Alternatively, the diphosphirenium salt **1** reacts with an excess of $[W(CO)_5(thf)]$, affording the corresponding η^1-coordinated diphosphirenium salt complex **4**, which is converted into the *P*-hydrogenophosphaalkene complex **5** with lithium aluminium hydride. The dinuclear tungsten complexes **7** and **8** are obtained by treatment of the free 1*H*-diphosphirene **3** with two equivalents of $[W(CO)_5(thf)]$ or one equivalent of $[W(CO)_4(thf)_2]$, respectively. Compound **6** reacts with two equivalents of hydrogen chloride, giving the 1-chloro-3-diisopropylamino-1*H*-diphosphirene **9**, which can be subsequently converted into the 1-diisopropylamino-, 1-azido, or 1-phenyl-3-diisopropylamino-1*H*-diphosphirenes **6**, **10** and **11** by nucleophilic substitution with diisopropylamine, azidotrimethylsilane or sodium tetraphenylborate, respectively. The [η^2-(3-diisopropylaminodiphosphirenylium salt)·$W(CO)_5$] complexes **12a-c** can be prepared by reaction of **9** with silver trifluoromethanesulfonate, aluminium or gallium trichloride or, alternatively, by treatment of **6** with two equivalents of trifluoromethanesulfonic acid. Reaction of **12a** with diisopropylamine, water, bis(triphenylphosphoranylidene)-ammonium chloride or tetrabutylammonium fluoride gives the corresponding 1*H*-diphosphirene complexes **6**, **13**, **9**, or **14**, respectively. Compound **12a** also reacts with one or two equivalents of $[W(CO)_5(thf)]$, leading to the di- and trinuclear complexes **15** and **16**, respectively.

Introduction

Three-membered rings, in particular the dinitrogen- and diphosphorus-containing unsaturated heterocycles **A**−**H** (Scheme 1), are not only fascinating species for scientists because of their inherent ring strain, but also valuable starting materials. The chemistry of the 3*H*-diazirines **A**, which are good precursors for transient carbenes, has been extensively explored,[1] whereas only one anti-aromatic 1*H*-diazirine **B** has been spectroscopically characterized.[2] In contrast, for the analogous phosphorus-containing series, one 1*H*-diphosphirene, **F**, has been isolated,[3] while no 3*H*-diphosphirenes **E**, which feature a weak P=P bond,[4] have been characterized.[5] As far as cationic derivatives are concerned,[6] none of the nitrogen-containing systems **C** or **D** has been observed and even the postulated involvement[7] of diazirinium salts, **C**, in the exchange reaction of nucleophiles with halodiazirines has been refuted.[8] The replacement of nitrogen atoms by phosphorus centres decreases the ring strain, and a diphosphirenium salt **H**[9] has been isolated.[10]

Although no complexes featuring 1*H*-diazirines **B** or diazirinium salts **C** and **D** as ligands are known, the coordination chemistry of 3*H*-diazirines **A** constitutes a well-established field in organometallic chemistry.[1c] It is important to note that the cyclic diazirine moiety is retained when bound to group VI metal carbonyls; the diazirine adopts an end-on coordination mode and both mono- and dimetallic complexes have been obtained.

For the diphosphorus-containing series, only two complexes of 1*H*-diphosphirenes **F** have been reported.[11] Here we report experimental and theoretical results concerning the coordination chemistry of heterocycles **F**−**H**. We have evidence for various coordination modes of the 1*H*-diphosphirenes **F** and diphosphirenylium salt **G** to the $W(CO)_5$ fragment.

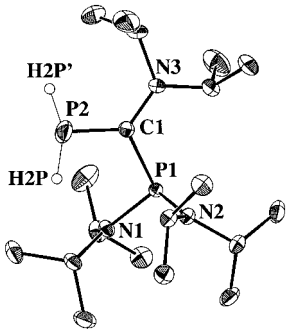
Results and Discussion

Synthesis of Free and Coordinated 1*H*-diphosphirenes

We have already[12] shown that the 1*H*-diphosphirene **3** is readily available (52% yield) from the diphosphirenium salt **1**[9] via the *P*-hydrogeno phosphaalkenes **2** (Scheme 2). Single crystals of **2**, suitable for an X-ray diffraction study, were obtained from a pentane solution at −20°C (Figure 1, Table 1). The asymmetric unit contains two independent molecules of **2**. Although Fourier synthesis reveals a disorder for the phosphorus-bonded hydrogen atom positions, it is quite clear that both *cis* and *trans* isomers are present in the solid state. The P1−C1−N3−P2−H fragment is nearly planar (average torsion angle: 10°). The planar geometry around N3 (sum of the angles 359.7°), along with the shortness of the C1−N3 bond [1.368(2) Å], suggests an interaction between the nitrogen lone pair and the π system of the P−C bond. This is corroborated by the value of the central C1−P2 bond length [1.713(2) Å], which is at the upper limit for localized C=P double bonds (1.71 Å)[13] although significantly shorter than in HP=C(NMe$_2$)$_2$ [1.740(1) Å].[14] Finally, probably due to severe steric constraints around C1, the C1−P1 bond is elongated [1.899(2) Å] relative to the expected value for a P−C single bond (1.83−1.84 Å).[15]



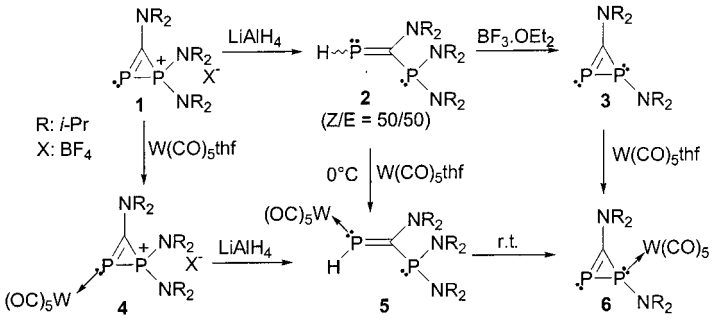


Figure 1. Thermal ellipsoid diagram (30% probability) of **2** showing the atom numbering scheme. Both positions for the disordered hydrogen atom are represented. Selected bond lengths (A) and bond angles (°): P1−C1 1.899(2), P1−N1 1.685(2), P1−N2 1.687(2), C1−N3 1.368(2), C1−P2 1.713(2), P2−H2P 1.226, P2−H2P′ 1.206; P1−C1−N3 114.5(1), P1−C1−P2 118.7(1), N3−C1−P2 126.5(1), C1−P2−H2P 103.2, C1−P2−H2P′ 110.0.

The coordinated 1*H*-diphosphirene **6** can be easily obtained in 65% yield by treatment of **3** with [W(CO)$_5$(thf)]. The end-on coordination of the σ^3-phosphorus centre to the pentacarbonyltungsten fragment was clearly established from the characteristic[16] ^1J(P,W) coupling constant of 295 Hz. Interestingly, **6** can also be prepared directly from phosphaalkenes **2** in 80% yield (Scheme 2). In this case, evidence for the transient formation of the phosphaalkene complex **5** (*E* isomer) has been provided by ^{31}P NMR spectroscopy at 0°C.[12] The metal fragment can even be introduced at the σ^2-phosphorus atom of the diphosphirenium salt **1**. Indeed, treatment of **1** with an excess of [W(CO)$_5$(thf)] in THF at room temperature quantitatively leads to complex **4**. Due to the lability of the P-W bond, this compound was only characterized by ^{31}P NMR spectroscopy [δ = −33.9 (d, *J*(P,P) = 130 Hz, P$^+$), +39.9 (d, *J*(P,P) = 130 Hz, ^1J(P,W) = 249 Hz, σ^{2}P)]. It is noteworthy that the reduction of the coordinated diphosphirenium salt **4** with lithium aluminium hydride affords the coordinated *P*-hydrogeno phosphaalkene **5** (Scheme 2).

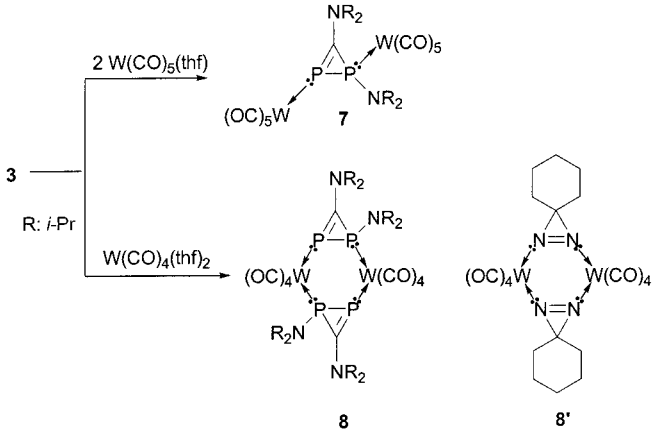
Clearly, the reduction/cyclisation sequence can be achieved with free compounds or in the coordination sphere of the tungsten, and the diphosphirenium salt **1** can thereby be converted into the corresponding 1*H*-diphosphirene complex **6**. Moreover, these new synthetic routes can be used on multi-gram scales allowing for the development of the chemistry of 1*H*-diphosphirenes.



Scheme 2. Synthesis of the mononuclear diphosphirene complex **6**

In **6**, the tungsten is coordinated to the σ^3-phosphorus atom.[17] However, the σ^2-phosphorus atom can also be implicated in the coordination of a transition metal. Indeed, the dinuclear complex **7** is obtained in near quantitative yield when a two-fold excess of [W(CO)$_5$(thf)] is used (Scheme 3). Derivative **7** has been isolated as yellow crystals (mp. 128−129°C) and fully characterized. The coordination of both phosphorus centres is clearly established by ^{31}P NMR spectroscopy {δ = −86.9 [d, *J*(P,P) = 111 Hz, ^1J(P,W) = 296 Hz, P−NR$_2$], −6.3 [d, *J*(P,P) = 111 Hz,

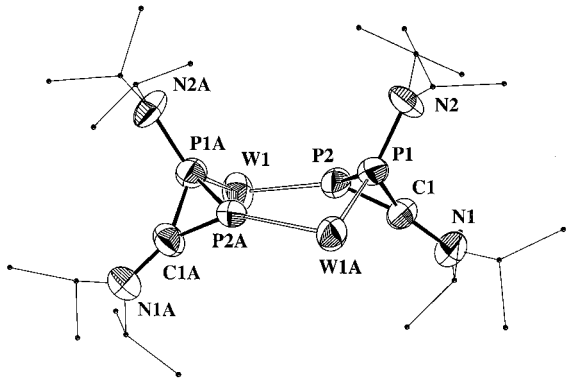
^1J(P,W) = 209 Hz, P=C]}. The IR spectrum features characteristic $\tilde{\nu}_{CO}$ absorption bands at 1934, 1972, 2067 and 2079 cm^{-1}. Among them, the band at 2067 cm^{-1} can be assigned to the $(R_2N)P-W(CO)_5$ fragment by comparison with that observed for the mononuclear complex **6** (2069 cm^{-1}). The absorption at 2079 cm^{-1} can similarly be assigned to the $W(CO)_5$ moiety bonded to the σ^2-phosphorus atom, which suggests a stronger π back donation.[18]

In the nitrogen-containing series, the related 3*H*-diazirines have been used as "structurating" 1,2-bidentate ligands to prepare an original dinuclear double-bridged complex **8′**.[19] This derivative, in which two 3*H*-diazirines coordinate two $W(CO)_4$ fragments, is organised around a *planar* six-membered dimetallacycle. The free 1*H*-diphosphirene **3** was analogously treated with one equivalent of $[W(CO)_4(thf)_2]$.[20] After displacement of the two labile ligands, the dinuclear double-bridged complex **8** was isolated as yellow crystals (M.p. 166−167°C) in 60% yield (Scheme 3). The dimeric structure of **8** was indicated by an A_2B_2 spin system present in the ^{31}P NMR spectrum [δ = −129.4 (P−NR_2), −28.6 (P=C)]. Single crystals of **8**, suitable for an X-ray diffraction study, were grown from a dichloromethane/pentane solution at −20°C. In the solid state (Figure 2), complex **8** is organised around a twofold axis, the six-membered ring adopts an unusual slightly distorted *boat conformation*, and the two three-membered rings occupy equatorial positions. The geometry of the 1*H*-diphosphirene fragment is very similar to that previously observed for the only known free derivative.[3] Interestingly, the boat conformation induces an unusual twist (ca. 42.5°) of the P=C double bond. In most η^1-coordinated complexes the phosphaalkene moiety is nearly planar,[21] whereas twisted P=C bonds have only been reported in sterically congested systems.[22]

Scheme 3. Synthesis of the dinuclear diphosphirene complexes **7** and **8**

Synthesis and Reactivity of Coordinated Diphosphirenylium Salts

Halogenophosphane complexes are very good precursors for coordinated functionalised phosphanes and coordinated



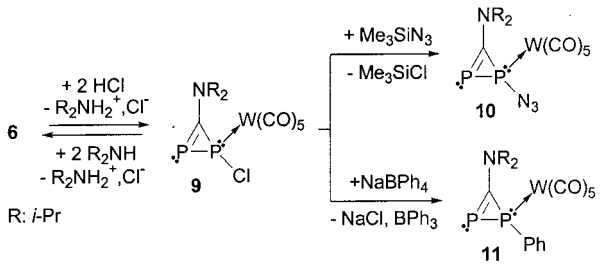


Figure 2. Thermal ellipsoid diagram (30% probability) of **8** showing the atom numbering scheme. All the carbonyl groups have been omitted, and the isopropyl groups have been simplified. Selected bond lengths (Å) and bond angles (°): P1−C1 1.798(15), P1−N2 1.680(11), C1−N1 1.327(18), C1−P2 1.686(15), P1−P2 2.130(5), P2−W1 2.508(3), P1−W1A 2.529(4); P1−C1−N1 138.1(12), P2−C1−N1 146.6(13), P1−C1−P2 75.3(6), C1−P1−P2 49.9(5), C1−P1−N2 113.7(7), P2−P1−N2 113.0(4), C1−P1−W1A 117.4(5), N2−P1−W1A 122.0(5), P2−P1−W1A 120.17(18), C1−P2−P1 54.7(5), C1−P2−W1 150.3(5), P1−P2−W1 143.5(2), P2−W1−P1A 82.6(12).

phosphenium salts, by nucleophilic exchange of the halogen atom and heterolytic cleavage of the P−X bond,[23] respectively. Therefore, *P*-halo-1*H*-diphosphirene complexes seemed to be ideal precursors for coordinated *P*-functionalised-1*H*-diphosphirenes as well as coordinated diphosphirenylium salts. Reaction of **6** with two equivalents of hydrogen chloride[24] in pentane gives the *P*-chloro-1*H*-diphosphirene **9** as a yellow oil in 69% yield (Scheme 4). Although the solubility of **9** in pentane leaves no doubt about the covalent nature of the P−Cl bond, it is interesting to note that the mass spectrum features fragment peaks corresponding to both complexed and uncomplexed diphosphirenylium salts {CI, CH_4, *m/z* = 534 MH^+, 498 $(M - Cl)^+$ and 174 $[M - Cl - W(CO)_5]^+$}.

The chlorine atom of derivative **9** can easily be substituted for an amino substituent, an azido or a phenyl group. Indeed, complex **6** was isolated (85% yield) after treatment of **9** with two equivalents of diisopropylamine in pentane. On addition of a THF solution of azidotrimethylsilane at 45°C, **9** afforded the *P*-azido-1*H*-diphosphirene complex **10** in 40% yield.[25] The replacement of the chlorine atom by an azido group at the λ^3-phosphorus centre was apparent from the mass (CI, $CH_{4,\ m/z}$ = 540), the IR ($\tilde{\nu}_{N3}$ 2130 cm^{-1}) and the ^{31}P NMR spectra [δ = −96.6 (d, J(P,P) = 210 Hz, ^1J(P,W) = 310 Hz, P−N_3), −5.0 (d, J(P,P) = 210 Hz, P=C)]. Finally, treatment of **9** with sodium tetraphenylborate in dichloromethane at room temperature afforded the *P*-phenyl-1*H*-diphosphirene **11** (60% yield) (Scheme 4, Table 2). The formation of **11** probably results from the ionization of the P−Cl bond of **9** leading to a transient diphosphirenylium salt, which abstracts a phenyl group from the tetraphenylborate counterion.[26]

In order to prevent nucleophile transfer, ionization of **9** was carried out in dichloromethane solution at −78°C with either silver trifluoromethanesulfonate,[27] or aluminium or gallium trichloride. The corresponding coordinated diphos-

phirenylium salts **12a**−**c** were isolated as highly air- and moisture-sensitive brown oils in high yields (90−95%). Note that the heterolytic cleavage of the P−N bond of complex **6** with 2 equivalents of trifluoromethanesulfonic acid directly afforded the diphosphirenylium cation **12a** in near quantitative yield (Scheme 5). The structure of derivatives **12a**−**c** and, in particular, the η^2-coordination of the heterocycle (through the P=P bond), has been clearly established by multinuclear NMR and IR spectroscopy, and mass spectrometry.[12] The stability of **12a**−**c** (stable for weeks in solution at room temperature) is almost certainly due to the presence of the metal fragment, but also to the effective π-donation of the nitrogen: **12′** is likely to be the major contributing resonance structure.

Scheme 5. Synthesis of the mononuclear diphosphirenylium salt complexes **12**

Computational Studies

In order to gain more of an insight into the role of the amino substituent and to rationalize the η^2-coordination mode, theoretical calculations were performed on model derivatives **G1**,**2** and **12d**−**g** at the SCF/DZP and B3LYP/DZP levels. The optimized geometric data and atomic charges of derivatives **G1** and **G2** (R = H and NH_2, respectively) are listed in Table 3. Both cations adopt perfectly planar geometries with C_{2v} symmetry. Amino-substitution induces a significant shortening of the P−P bond while the P−C bonds are slightly elongated. The C−N bond length in **G2** is typical for C=N double bonds and comparable with the value found in the tris(dimethylamino)cyclopropenium salt.[28] These data, along with the values of Mulliken and π-charges calculated for **G2**, strongly suggest that the positive charge is shifted outside the ring toward the nitrogen atom. Therefore, the well-established[29] effect of amino substituents on the stability of cyclopropenium salts is also effective for the related diphosphorus-containing species **G**.

It is of further interest to analyse the frontier orbital systems in **G1**,**2**. A detailed listing of the orbitals HOMO-2, HOMO-1, and HOMO is presented in Table 4. It must be noted that as all orbital energies are taken from the results of the energy-optimized RHF calculation of the geometries, orbital energies are meaningful only for the occupied orbitals. In the parent system **G1**, the HOMO and HOMO-1 refer to symmetric and antisymmetric combinations of the two phosphorus lone pairs (a_1 and b_2 orbitals, respectively) while the HOMO-2 corresponds to a π_{PP}-orbital (b_1) which is perpendicular to the ring. The situation is totally different for the amino-substituted cation **G2**. Indeed, the HOMO now refers to the π_{PP}-orbital (b_1) whereas the HOMO-1 and HOMO-2 are almost degenerate and correspond to the a_1 and b_2 orbitals (Figure 3). Thus, the frontier orbital system of **G2** is in agreement with the observed η^2-coordination mode and, in order to complete the theoretical study, the geometry of the isomeric η^1- and η^2-complexes **12d** and **12e** (R = NH_2) were optimized at the B3LYP/DZ(P) level (Figure 4). It is interesting to note that the geometries of the three-membered rings are very similar to those calculated for the free derivative **G2**. The only noticeable difference is the entirely understandable elongation of the P−P bond for the η^1-complex **12d** (**G2** 2.11 Å; **12d** 2.23 Å) and to an even greater extent for the η^2-complex **12e** (2.31 Å). As expected, the η^2-complex **12e** is the more stable isomer, but it is interesting to note that it lies only 16 kJ mol^{-1} below the corresponding η^1-complex **12d**. The influence of the amino group on the coordination mode is shown by the calculations performed for the related complexes **12f,g** featuring the parent cation **G1** as ligand. Indeed, geometry optimization of an η^2-complex of type **12e** results in the η^3-complex **14g**. The tungsten interacts with all the atoms of the three-membered ring of **14g**, as shown by the deviation of the C−H bond from the ring plane (21°) and by the W−P and W−C bond lengths (2.72 and 2.39 Å, respectively, relative to 2.73 and 3.06 Å for **12e**). This η^3-coordination mode results in a reinforced diphosphirenylium salt-metal binding energy (240 kJ mol^{-1} compared to 166 kJ mol^{-1} for **12e**), and thus, the corresponding η^1-complex **12f** is substantially higher in energy (57 kJ mol^{-1}). As far as we are aware, there are no previous examples in which the $W(CO)_5$ fragment is η^3-coordinated.

In the hope of preparing hitherto unknown 3*H*-diphosphirenes **E**, the diphosphirenylium salt complex **12a** was

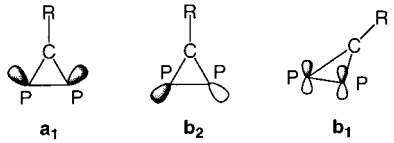

Figure 3. Schematic representation of the molecular orbitals calculated for the model diphosphirenylium salts **G1** and **G2**.

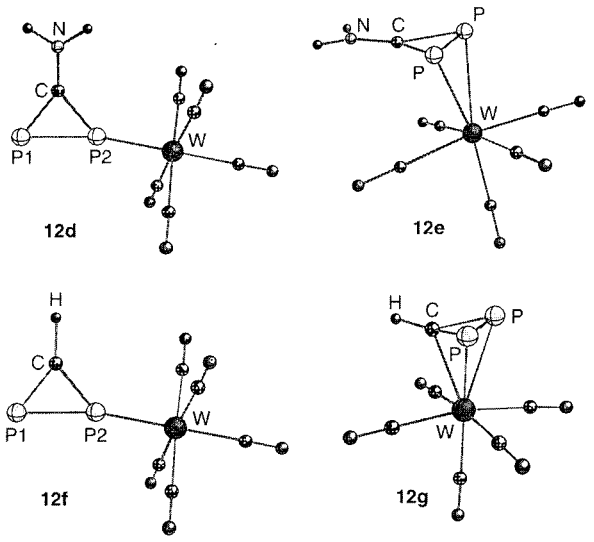

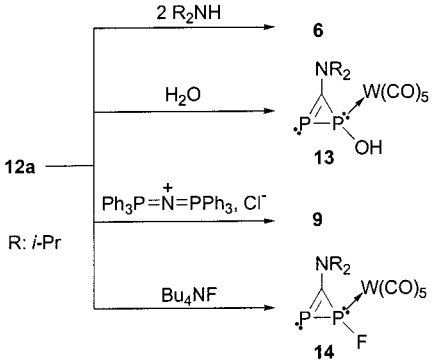

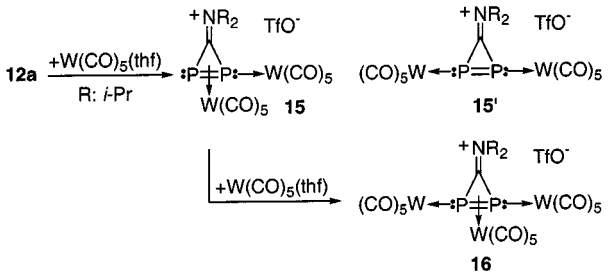

Figure 4. Ball-and-stick views of the calculated structures (at the B3LYP/DZP level) of the η^1-, η^2- and η^3-diphosphirenylium salt complexes **12d−g**. Selected bond lengths (Å): **12d**: N−C 1.33, C−P1 1.78, C−P2 1.77, P2−W 2.40; **12e**: N−C 1.32, C−P1 1.80, P1−P2 2.20, P1−W 2.73; **12f**: H−C 1.09, C−P1 1.73, C−P2 1.75, P2−W 2.37; **12g**: H−C 1.32, C−P 1.79, P−P 2.20, P−W 2.72, C−W 2.39.

then treated with various nucleophiles. However, using diisopropylamine (two equivalents), water, bis(triphenylphosphoranylidene)ammonium chloride (PPNCl) or tetrabutylammonium fluoride, the corresponding 1*H*-diphosphirene complexes **6**, **13**,[30] **9** and **14** were, according to ^{31}P-NMR spectroscopy, formed quantitatively (Scheme 6). In all cases, the presence of the 1*H*-diphosphirene moiety was evidenced by the typical AX spin system observed in the ^{31}P-NMR spectra (Table 2). The presence of the hydroxy or fluoro functionality was deduced from the mass spectrum of **13** (CI, CH_4, m/z = 544), and the ^{31}P and ^{19}F NMR spectra of **14** {^{31}P: δ = −12.1 [dd, J(P,P) = 238 Hz, ^1J(P,W) 323 Hz, J(P,F) = 1116 Hz, P−F], 43.2 [dd, J(P,P) = 238 Hz, J(P,H) = 121 Hz, P=C]; ^{19}F: δ = −14.1 [dd, J(P,F) = 1116 and 121 Hz]}.

Scheme 6. Reaction of the diphosphirenylium salt complex **12a** with various nucleophiles

We then studied the coordination chemistry of the diphosphirenylium salt **12a**, since it can potentially act as a 2-, 4- or 6-electron ligand. The reaction of **12a** with [W(CO)$_5$(thf)] in dichloromethane solution was monitored by ^{31}P NMR spectroscopy. On addition of one equivalent of [W(CO)$_5$(thf)], the sharp singlet corresponding to **12a** (δ = −157.4) disappears to give a broad signal centred at δ = −130. Addition of an excess of [W(CO)$_5$(thf)] subsequently converts the broad signal into a sharp singlet at δ = −74.1.

Scheme 7. Synthesis of the di- and trinuclear diphosphirenylium salt complexes **15** and **16**

This chemical shift, in the range expected for a three-membered phosphorus heterocycle,[32] and the presence of three different *J*(P,W) coupling constants (176, 61 and 45 Hz)[33] strongly support the trinuclear structure **16** (Scheme 7). In addition, the ^{13}C NMR spectrum of **16** reveals the presence of two types of $W(CO)_5$ fragment {δ = 193.6 [t, *J*(P,C) < 1 Hz, ^1J(C,W) = 127 Hz, CO_e], 194.5 (s, CO_a) and 213.6 (s, CO_e), 214.7 (s, CO_a)}. By comparison with those observed for **12a** {δ = 189.3 [t, *J*(P,C) = 4 Hz, ^1J(C,W) = 122 Hz, CO_e], 194.4 [t, *J*(P,C) < 1 Hz, CO_a]}, the signals at δ = 193.6 and 194.5 can be assigned to the η^2-$PW(CO)_5$ moiety while the deshielding of the other two signals (Δδ ≈ 20 ppm) can be classically[34] attributed to the η^1-coordination mode of the corresponding $W(CO)_5$ fragments. Taking into account the trinuclear structure of **16**, the intermediate broad signal detected by ^{31}P NMR spectroscopy is probably due to the dinuclear tungsten complex, for which an equilibrium between the structures **15** and **15′** is likely to occur. Indeed, calculations have clearly shown a small energy difference between η^1- and η^2-coordination modes for the model compounds **12d** and **12e** (see above). The formation of the mono-, di- and trinuclear diphosphirenylium complexes **12**, **15** and **16**, respectively, shows that the coordination chemistry of diphosphirenylium salts **G** shows some resemblance to that of diphosphenes RP=PR.[35]

Conclusion

We have shown that the 1*H*-diphosphirene **3**, which is easily available from the corresponding diphosphirenium salt **1**, can act as a 2- or 4-electron ligand to afford mono- and dinuclear tungsten complexes. Furthermore, not only can this ligand be modified in the coordination sphere of tungsten, but several coordinated diphosphirenylium salts have been prepared and isolated.[36]

These results as a whole clearly demonstrate that diphosphirenylium salts **G** merit further study, and that the synthesis of a noncomplexed derivative remains an exciting challenge. Moreover, the reactivity of these cations has up to now been governed by the electrophilicity of the phosphorus centres, and it would be particularly interesting to attempt to force the system to react at the carbon atom, which should lead to the hitherto unknown 3*H*-diphosphirenes **E**.

Experimental Section

All manipulations were performed under argon with standard Schlenk techniques. Dry, oxygen-free solvents were employed. ^1H, ^{13}C, and ^{31}P NMR spectra were recorded on Bruker AC80, AC200, WM250 or AMX400 spectrometers. Chemical shifts are reported in ppm relative to Me_4Si as external standard (^1H and ^{13}C) or with a positive sign, in ppm, relative to external 85% H_3PO_4 (^{31}P). Infrared spectra were recorded on a Perkin−Elmer FT-IR Spectrometer 1725 X. Mass spectra were obtained on a Ribermag R10 10E instrument.

***C*-Diisopropylamino-*C*-[bis(diisopropylamino)phosphino]phosphaalkenes (2)**: To a THF solution (5 mL) of the diphosphirenium salt **1** (0.46 g, 1 mmol) was added, at −78°C, 1 equiv. of $LiAlH_4$ (38 mg, 1 mmol). The solution was warmed to room temp., the solvent removed in vacuo, and the residue extracted with pentane (15 mL). After filtration and evaporation of pentane, compound **2** (as a 50:50 mixture of *Z* and *E* isomers) was obtained as a yellow powder (0.30 g, 80%). − M.p. 25−30°C. − ^1H NMR (C_6D_6): δ = 1.20−1.35 (m, 72 H, CH_3), 3.7−4.0 (m, 12 H, CHN), 4.66 (dd, ^1J(P,H) = 174 Hz, ^3J(P,H) = 1.0 Hz, 1 H, P−H, isomer 1), 4.96 (dd, ^1J(P,H) = 138 Hz, ^3J(P,H) = 7.4 Hz, 1 H, P−H, isomer 2). − $^{13}C\{^1H\}$ NMR (C_6D_6): δ = 205.1 (dd, ^1J(P,C) = 97.6 and 40.1 Hz, PCP), 212.3 (dd, ^1J(P,C) = 65.4 and 58.8 Hz, PCP). − ^{31}P NMR (C_6D_6): δ = 23.8 (dd, ^2J(P,P) = 40 Hz, ^1J(P,H) = 138 Hz, P−H, isomer 1), 34.3 (d, ^1J(P,H) = 174 Hz, P−H, isomer 2), 53.7 (d, ^2J(P,P) = 40 Hz, P−N*i*Pr_2, isomer 1), 55.9 (s, P−N*i*Pr_2, isomer 2). − $C_{19}H_{43}N_3P_2$ (375.3): calcd. C 60.77, H 11.54, N 11.19; found C 60.52, H 11.38, N 11.00.

1,3-Bis(diisopropylamino)-1*H*-diphosphirene (3): To a THF solution (5 mL) of phosphinophosphaalkenes **2** (0.37 g, 1 mmol) was added, at −78°C, a catalytic amount of $BF_3{\cdot}Et_2O$ (14 mg, 0.1 mmol). The solution was warmed to room temp., and stirred for 1 h (the reaction being monitored by ^{31}P NMR spectroscopy). The solvent was then removed in vacuo and the residue extracted with pentane (15 mL). After filtration and evaporation of pentane, compound **3** was obtained as a yellow oil (0.17 g; 62%). − ^1H NMR (C_6D_6): δ 0.95 (d, ^3J(H,H) = 6.6 Hz, 6 H, CH_3), 1.13 (d, ^3J(H,H) = 6.7 Hz, 6 H, CH_3), 1.15 (d, ^3J(H,H) = 6.6 Hz, 6 H, CH_3), 1.32 (d, ^3J(H,H) = 6.7 Hz, 6 H, CH_3), 3.60 (sept, ^3J(H,H) = 6.7 Hz, 2 H, CHN), 4.19 (sept d, ^3J(H,H) = 6.6 Hz, ^3J(P,H) = 1.8 Hz, 2 H, CHN). − $^{13}C\{^1H\}$ NMR (C_6D_6): δ = 19.1 (d, *J*(P,C) = 4.9 Hz, CH_3), 20.1 (d, *J*(P,C) = 2.7 Hz, CH_3), 21.6 (d, *J*(P,C) = 2.1 Hz, CH_3), 21.8 (s, CH_3), 24.2 (d, *J*(P,C) = 12.2 Hz, CH_3), 24.5 (d, *J*(P,C) = 5.2 Hz, CH_3), 43.4 (d, *J*(P,C) = 5.6 Hz, CHN), 51.3 (s, CHN), 58.4 (t_{like}, *J*(P,C) = 4.2 Hz, CHN), 191.2 (dd, *J*(P,C) = 82.2 and 77.9 Hz, PCP). − $^{31}P\{^1H\}$ NMR (C_6D_6): δ = −121.7 (d, *J*(P,P) = 121 Hz, P−N*i*Pr_2), −23.7 (*J*(P,P) = 121 Hz, σ^2-P). − MS (NH_3, CI); *m*/*z*: 275 (MH^+). − $C_{13}H_{28}N_2P_2$ (274.2): calcd C 56.92, H 10.29, N 10.21; found C 57.04, H 10.43, N 9.87.

[1,1,3-Tris(diisopropylamino)diphosphirenium Salt][$W(CO)_5$] (4): To a THF solution (30 mL) of the diphosphirenium salt **1** (0.46 g, 1 mmol) was added, at −78°C, an excess of [$W(CO)_5$(thf)] (10 mL, 0.3 M solution in THF, 3 mmol). The solution was warmed to room temp. and stirred for 1 h at room temp. Complex **4** was characterized in solution without further purification. − ^{31}P NMR (THF): δ = −33.9 (d quint, *J*(P,P) = 130 Hz, ^3J(P,H) = 20 Hz, P−N*i*Pr_2), 39.9 (d, *J*(P,P) = 130 Hz, ^1J(P,W) = 249 Hz, P=C).

{*C*-Diisopropylamino-*C*-[bis(diisopropylamino)phosphino]phosphaalkene}[$W(CO)_5$] (5): To a THF solution (5 mL) of phosphinophosphaalkenes **2** (0.37 g, 1 mmol) was added, at −78°C, 1 equiv. of [$W(CO)_5$(thf)] (5 mL, 0.2 M solution in THF, 1 mmol). The solu-

tion was warmed to 0°C, the solvent removed in vacuo, the residue redissolved in deuterated toluene and complex **5** characterized in solution at 0°C. – ^{1}H NMR (C_7D_8): δ = 1.10–1.60 (m, 36 H, CH_3), 3.30–4.20 (m, 6 H, CHN), 4.95 (d, 1 H, ^1J(P,H) = 267 Hz, P–H); ^{13}C{^{1}H} NMR (C_7D_8): δ = 20.0–25.0 (m, CH_3), 50.2 (s, CHN), 55.7 (d, J(P,C) = 45.9 Hz, CHN), 58.7 (d, J(P,C) = 29.7 Hz, CHN), 199.9 (s, ^1J(C,W) = 126.1 Hz, CO_e), 203.3 (d, ^2J(P,C) = 7.7 Hz, CO_a), 233.3 (dd, ^1J(P,C) = 72.3 and 50.3 Hz, PCP). – ^{31}P NMR (C_7D_8): δ = –71.0 (d, ^1J(P,H) = 267 Hz, ^1J(P,W) = 129 Hz, P–H), 66.5 (s, P–N*i*Pr$_2$). – Complex **5** was also obtained by adding an excess of lithium aluminium hydride to a THF solution of the diphosphirenium salt complex **4** at –78°C.

[1,3-Bis(diisopropylamino)-1*H*-diphosphirene][W(CO)$_5$] (6): To a THF solution (5 mL) of 1*H*-diphosphirene **3** (0.27 g, 1 mmol) was added, at –78°C, 1 equiv. of [W(CO)$_5$(thf)] (5 mL, 0.2 M solution in THF, 1 mmol). The solution was warmed to room temp., the solvent removed in vacuo and the residue extracted with pentane (15 mL). After filtration and evaporation of pentane, complex **6** was obtained as a yellow oil (0.39 g; 65%). – ^{1}H NMR (C_6D_6): δ = 1.18 (d, ^3J(H,H) = 6.9 Hz, 6 H, CH_3), 1.25 (d, ^3J(H,H) = 6.9 Hz, 6 H, CH_3), 1.29 (d, ^3J(H,H) = 6.7 Hz, 3 H, CH_3), 1.37 (d, ^3J(H,H) = 6.6 Hz, 3 H, CH_3), 1.39 (d, ^3J(H,H) = 6.6 Hz, 3 H, CH_3), 1.51 (d, ^3J(H,H) = 6.7 Hz, 3 H, CH_3), 3.63 (sept d, ^3J(H,H) = 6.9 Hz, ^3J(P,H) = 13.8 Hz, 2 H, CHNP), 3.97 (sept, ^3J(H,H) = 6.6 Hz, 1 H, CHN), 4.51 (sept, ^3J(H,H) = 6.7 Hz, 1 H, CHN). – ^{13}C{^{1}H} NMR (C_6D_6): δ = 18.3 (d, J(P,C) = 5.6 Hz, CH_3), 19.0 (d, J(P,C) = 3.5 Hz, CH_3), 20.7 (s, CH_3), 23.8 (s, CH_3), 48.8 (s, CHN), 49.2 (d, J(P,C) = 7.7 Hz, CHNP), 62.4 (dd, J(P,C) = 5.8 and 3.8 Hz, CHN), 195.9 (dd, J(P,C) = 80.6 and 48.4 Hz, PCP), 197.6 (d, ^2J(P,C) = 8.7 Hz, ^1J(C,W) = 126.9 Hz, CO_e), 200.2 (d, ^2J(P,C) = 33.1 Hz, ^1J(C,W) = 149.9 Hz, CO_a). – ^{31}P{^{1}H} NMR (C_6D_6): δ = –123.0 (d, J(P,P) = 164 Hz, ^1J(P,W) = 295 Hz, P–N*i*Pr$_2$), 15.0 (J(P,P) = 164 Hz, σ^2-P). – IR (THF): $\tilde{\nu}$ = 1930 (vs), 1938 (vs) and 2069 (s) cm^{-1} (CO). – $C_{18}H_{28}N_2O_5P_2W$ (598.1): calcd C 36.14, H 4.72, N 4.68; found C 36.35, H 4.53, N 4.62.

[1,3-Bis(diisopropylamino)-1*H*-diphosphirene][W(CO)$_5$]$_2$ (7): To a THF solution (5 mL) of 1*H*-diphosphirene **3** (0.27 g, 1 mmol) was added, at –78°C, 2 equiv. of [W(CO)$_5$(thf)] (5 mL, 0.4 M solution in THF, 2 mmol). The solution was warmed to room temp., the solvent removed in vacuo and the residue extracted with pentane (15 mL). After filtration, complex **7** crystallized from the pentane solution as a yellow, microcrystalline powder (0.85 g; 92%). – M.p. 128–129°C (dec). – ^{1}H NMR (C_6D_6): δ = 0.86 (d, ^3J(H,H) = 6.7 Hz, 3 H, CH_3), 1.08 (d, ^3J(H,H) = 6.7 Hz, 3 H, CH_3), 1.10 (d, ^3J(H,H) = 6.9 Hz, 6 H, CH_3), 1.19 (d, ^3J(H,H) = 6.9 Hz, 6 H, CH_3), 1.21 (d, ^3J(H,H) = 6.8 Hz, 3 H, CH_3), 1.32 (d, ^3J(H,H) = 6.8 Hz, 3 H, CH_3), 3.39 (sept, ^3J(H,H) = 6.8 Hz, 1 H, CHN), 3.66 (sept d, ^3J(H,H) = 6.9 Hz, ^3J(P,H) = 15.5 Hz, 2 H, CHNP), 4.27 (sept, ^3J(H,H) = 6.7 Hz, 1 H, CHN). – ^{13}C{^{1}H} NMR (C_6D_6): δ 20.0 (d, J(P,C) = 3.2 Hz, CH_3), 20.3 (d, J(P,C) = 2.1 Hz, CH_3), 20.4 (d, J(P,C) = 2.5 Hz, CH_3), 20.9 (d, J(P,C) = 2.1 Hz, CH_3), 24.4 (s, CH_3), 24.6 (d, J(P,C) = 3.1 Hz, CH_3), 49.7 (d, J(P,C) = 1.7 Hz, CHN), 50.4 (d, J(P,C) = 9.0 Hz, CHN), 61.5 (d, J(P,C) = 8.0 Hz, CHN), 188.3 (dd, J(P,C) = 46.4 and 37.5 Hz, PCP), 195.7 (d, ^2J(P,C) = 6.2 Hz, ^1J(C,W) = 126.4 Hz, CO_e), 197.6 (dd, J(P,C) = 7.8 and 1.7 Hz, ^1J(C,W) = 127.0 Hz, CO_e), 199.4 (d, ^2J(P,C) = 34.9 Hz, CO_a), 199.7 (d, ^2J(P,C) = 35.2 Hz, CO_a). – ^{31}P{^{1}H} NMR (C_6D_6): δ = –86.9 (d, J(P,P) = 111 Hz, ^1J(P,W) = 296 Hz, P–N*i*Pr$_2$), –6.3 (J(P,P) = 111 Hz, ^1J(P,W) = 209 Hz, P=C). – IR (THF): $\tilde{\nu}$ = 1934 (vs), 1972 (vs), 2067 (s) and 2079 (s) cm^{-1} (CO). – $C_{23}H_{28}N_2O_{10}P_2W_2$ (922.0): calcd C 29.96, H 3.06, N 3.04; found C 30.12, H 2.88, N 2.92.

{[1,3-Bis(diisopropylamino)-1*H*-diphosphirene][W(CO)$_4$]}$_2$ (8): To a THF solution (5 mL) of 1*H*-diphosphirene **3** (0.27 g, 1 mmol) was added, at –78°C, 1 equiv. of [W(CO)$_4$(thf)$_2$] (2.5 mL, 0.4 M solution in THF, 1 mmol). The solution was warmed to room temp., the solvent removed in vacuo and the residue extracted with pentane (15 mL). After filtration, complex **8** crystallized from a pentane/dichloromethane solution at –20°C as yellow crystals (0.26 g; 60%). – M.p. 166–167°C (dec). – ^{1}H NMR (C_6D_6): δ = 1.24 (d, ^3J(H,H) = 6.7 Hz, 6 H, CH_3), 1.33 (d, ^3J(H,H) = 6.7 Hz, 6 H, CH_3), 1.35 (d, ^3J(H,H) = 6.7 Hz, 12 H, CH_3), 1.37 (d, ^3J(H,H) = 6.7 Hz, 12 H, CH_3), 1.39 (d, ^3J(H,H) = 6.7 Hz, 6 H, CH_3), 1.45 (d, ^3J(H,H) = 6.7 Hz, 6 H, CH_3), 3.40 (m, 2 H, CHN), 3.86 (m, 2 H, CHN), 4.04 (sept, ^3J(H,H) = 6.7 Hz, 2 H, CHN), 4.42 (sept, ^3J(H,H) = 6.7 Hz, 2 H, CHN). – ^{13}C{^{1}H} NMR (C_6D_6): δ = 19.3 (s, CH_3), 19.7 (s, CH_3), 20.6 (s, CH_3), 20.8 (s, CH_3), 23.8 (s, CH_3), 24.4 (s, CH_3), 47.8 (s, CHN), 50.1 (s, CHN), 61.7 (d, J(P,C) = 5.7 Hz, CHN), 194.3 (dd, J(P,C) = 52.6 and 37.7 Hz, PCP), 198.2 (s, ^1J(C,W) 129.3 Hz, CO_a), 201.0 (d, ^2J(P,C) = 6.7 Hz, ^1J(C,W) = 130.6 Hz, CO_a), 204.2 (d, ^2J(P,C) = 35.6 Hz, ^1J(C,W) = 158.2 Hz, CO_e), 207.3 (dd, J(P,C) = 37.3 and 6.5 Hz, CO_e). – ^{31}P{^{1}H} NMR (C_6D_6): A_2B_2 system δ –129.4 (P–N*i*Pr$_2$), –28.6 (P=C). – $C_{34}H_{56}N_4O_8P_4W_2$ (1140.2): calcd C 35.81, H 4.95, N 4.91; found C 36.05, H 4.80, N 4.82.

[1-Chloro-3-diisopropylamino-1*H*-diphosphirene][W(CO)$_5$] (9): To an ether solution (6 mL) of complex **6** (0.12 g, 0.2 mmol) was added, at –78°C, 400 μL of a 1 M Et_2O solution of HCl (2 equiv). The solution was warmed to room temp., the solvent removed in vacuo and the residue extracted with pentane (20 mL). After filtration and evaporation of pentane, complex **9** was obtained as a yellow oil (0.07 g; 69%). – ^{1}H NMR (C_6D_6): δ 0.86 (d, ^3J(H,H) = 6.7 Hz, 3 H, CH_3), 1.03 (d, ^3J(H,H) = 6.7 Hz, 3 H, CH_3), 1.04 (d, ^3J(H,H) = 6.7 Hz, 3 H, CH_3), 1.12 (d, ^3J(H,H) = 6.7 Hz, 3 H, CH_3), 3.27 (sept, ^3J(H,H) = 6.7 Hz, 1 H, CHN), 4.71 (sept, ^3J(H,H) = 6.7 Hz, 1 H, CHN). – ^{13}C{^{1}H} NMR (C_6D_6): δ = 19.3 (d, J(P,C) = 4.2 Hz, CH_3), 19.5 (d, J(P,C) = 4.6 Hz, CH_3), 20.4 (s, CH_3), 20.5 (s, CH_3), 50.2 (d, J(P,C) = 3.3 Hz, CHN), 63.4 (dd, J(P,C) = 7.3 and 4.8 Hz, CHN), 189.0 (dd, J(P,C) = 88.6 and 34.7 Hz, PCP), 196.7 (d, ^2J(P,C) = 8.6 Hz, ^1J(C,W) = 127.1 Hz, CO_e), 199.5 (d, ^2J(P,C) = 46.8 Hz, CO_a). – ^{31}P{^{1}H} NMR (C_6D_6): δ = –78.5 (d, J(P,P) = 218 Hz, ^1J(P,W) = 308 Hz, P–Cl), 34.6 (d, J(P,P) = 218 Hz, σ^2-P). – IR (pentane): $\tilde{\nu}$ = 1949 (vs), 1959 (vs) and 2079 (s) cm^{-1} (CO). – MS (CH_4, CI); *m*/*z*: 534 (MH^+), 498 [(M–Cl)$^+$], 442 [(M–Cl-*i*Pr)$^+$], 174 {[M–Cl-W(CO)$_5$]$^+$}. – $C_{12}H_{14}ClNO_5P_2W$ (532.9): calcd C 27.02, H 2.65, N 2.63; found C 26.75, H 2.50, N 2.42.

Reaction of complex 9 with *i*Pr$_2$NH: To a THF solution (5 mL) of complex **9** (0.36 g, 0.7 mmol) was added, at room temp., 2 equiv. of diisopropylamine (0.14 g, 1.4 mmol). The solution was warmed to room temp., the solvent removed in vacuo and the residue extracted with pentane (15 mL). After filtration and evaporation of pentane, complex **6** was obtained as a yellow oil (0.40 g; 95%).

[1-Azido-3-diisopropylamino-1*H*-diphosphirene][W(CO)$_5$] (10): To a THF solution (5 mL) of complex **9** (0.36 g, 0.7 mmol) was added, at room temp., 1 equiv. of Me_3SiN_3 (0.08 g, 0.7 mmol). The solution was warmed to 45°C and stirred for 1 h (the reaction was monitored by ^{31}P NMR spectroscopy). The solvent was then removed in vacuo and the residue extracted with pentane (20 mL). After filtration and evaporation of pentane, complex **10** was obtained as a brown oil (0.15 g; 40%). – ^{1}H NMR (C_6D_6): δ = 0.86 (d, ^3J(H,H) = 6.8 Hz, 3 H, CH_3), 1.02 (d, ^3J(H,H) = 6.8 Hz, 3 H, CH_3), 1.06 (d, ^3J(H,H) = 6.8 Hz, 3 H, CH_3), 1.12 (d, ^3J(H,H) = 6.8 Hz, 3 H, CH_3), 3.30 (sept, ^3J(H,H) = 6.8 Hz, 1 H, CHN), 4.71

(sept, ^3J(H,H) = 6.8 Hz, 1 H, CHN). − $^{13}C\{^1H\}$ NMR (C_6D_6): δ = 19.1 (d, J(P,C) = 4.5 Hz, CH_3), 19.5 (d, J(P,C) = 4.2 Hz, CH_3), 20.4 (s, CH_3), 20.7 (s, CH_3), 51.3 (d, J(P,C) = 3.3 Hz, CHN), 62.5 (dd, J(P,C) = 36.4 and 4.3 Hz, CHN), 196.4 (d, ^2J(P,C) = 8.8 Hz, ^1J(C,W) = 109.3 Hz, CO_e), 199.0 (d, ^2J(P,C) = 41.9 Hz, CO_a), PCP was not observed. − $^{31}P\{^1H\}$ NMR (C_6D_6): δ = −96.6 (d, J(P,P) = 210 Hz, ^1J(P,W) = 310 Hz, P−N_3), −5.0 (d, J(P,P) = 210 Hz, σ²-P). − IR (THF): $\tilde{\nu}$ = 2130 (vs) cm^{-1} (NN). − MS (CH_4, CI) *m/z*; 540 (MH^+), 498 [(M-N_3)$^+$]. − $C_{12}H_{14}N_4O_5P_2W$ (540.0): calcd C 26.69, H 2.61, N 10.37; found C 26.83, H 2.74, N 10.23.

[1-Phenyl-3-diisopropylamino-1*H*-diphosphirene][W(CO)$_5$] (11): To a CH_2Cl_2 solution (2 mL) of complex **9** (0.07 g, 0.14 mmol) was added, at −78°C, a CH_2Cl_2 solution (2 mL) of 1 equiv. of $NaBPh_4$ (0.05 g, 0.14 mmol). The solution was warmed to room temp., the solvent removed in vacuo and the residue extracted with pentane (15 mL). After filtration and evaporation of pentane, complex **11** was obtained as a yellow oil (0.05 g; 60%). − ^1H NMR (C_6D_6): δ 0.82 (d, ^3J(H,H) = 6.7 Hz, 3 H, CH_3), 1.30 (d, ^3J(H,H) = 6.7 Hz, 3 H, CH_3), 1.38 (d, ^3J(H,H) = 6.7 Hz, 3 H, CH_3), 1.47 (d, ^3J(H,H) = 6.7 Hz, 3 H, CH_3), 3.88 (sept d, ^3J(H,H) = 6.7 Hz, J(P,H) = 2.1 Hz, 1 H, CHN), 4.28 (sept, ^3J(H,H) = 6.7 Hz, 1 H, CHN), 6.9−7.1 (m, 3 H, $H_{m,p}$), 7.65 (ddd, ^3J(H,H) = 8.0 Hz, ^4J(H,H) = 1.5 Hz, J(P,H) = 13.2 Hz, 2 H, H_o). − $^{13}C\{^1H\}$ NMR (C_6D_6): δ = 19.0 (d, J(P,C) = 3.2 Hz, CH_3), 19.2 (d, J(P,C) = 4.0 Hz, CH_3), 20.2 (s, CH_3), 20.3 (s, CH_3), 49.4 (d, J(P,C) = 3.2 Hz, CHN), 63.2 (dd, J(P,C) = 7.3 and 4.3 Hz, CHN), 129.0 (d, J(P,C) = 10.2 Hz, C_{arom}), 130.5 (d, J(P,C) = 2.0 Hz, C_{arom}), 132.5 (d, J(P,C) = 15.8 Hz, C_{arom}), 197.7 (d, ^2J(P,C) = 8.0 Hz, ^1J(C,W) = 126.3 Hz, CO_e), 199.1 (d, ^2J(P,C) = 30.4 Hz, CO_a), C_i and PCP were not observed. − $^{31}P\{^1H\}$ NMR (C_6D_6): δ = −177.5 (d, J(P,P) = 148 Hz, ^1J(P,W) = 257 Hz, P−Ph), −60.0 (d, J(P,P) = 148 Hz, σ²-P). − IR (THF): $\tilde{\nu}$ = 1935 (vs), 1943 (vs) et 2071 (s) cm^{-1} (CO). − MS (NH_3, CI) *m/z*; 576 (MH^+), 498 [(M−Ph)$^+$].

[η^2-(3-Diisopropylaminodiphosphirenylium Salt)][W(CO)$_5$] (12): To a CH_2Cl_2 solution (3 mL) of complex **9** (0.15 g, 0.28 mmol) was added, at −78°C, 1 equiv. of $AgCF_3SO_3$ (0.07 g, 0.28 mmol). The solution was warmed to room temp., and silver salts were removed by filtration. Evaporation of CH_2Cl_2 gave the complex **12a** as a yellow oil (0.16 g; 90%). − ^1H NMR ($CDCl_3$): δ = 1.39 (d, ^3J(H,H) = 6.7 Hz, 6 H, CH_3), 1.44 (d, ^3J(H,H) = 6.7 Hz, 6 H, CH_3), 4.34 (sept, ^3J(H,H) = 6.7 Hz, 2 H, CHN). − $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ 20.2 (s, CH_3), 20.9 (s, CH_3), 63.2 (s, CHN), 119.7 (q, ^1J(C,F) = 319 Hz, CF_3), 189.3 (t, ^2J(P,C) = 4.3 Hz, ^1J(C,W) = 121.5 Hz, CO_e), 194.4 (t, ^2J(P,C) < 1 Hz, CO_a), 205.1 (t, ^1J(P,C) = 90.9 Hz, PCP). − $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = −157.4. − IR (CH_2Cl_2): $\tilde{\nu}$ = 1950 (vs) and 2055 (s) cm^{-1} (CO). − MS (CH_4, CI) *m/z*; 498 (M^+), 470 [(M−CO)$^+$], 442 {[M-2(CO)]$^+$}. − The same salt **12a** was obtained in near quantitative yield (95%) by adding, at −78°C, 2 equivalents of CF_3SO_3H to a CH_2Cl_2 solution of complex **6**. Starting from complex **9** and using $AlCl_3$ or $GaCl_3$ as Lewis acids, complexes **12b** and **12c** could also be obtained in 90% yield. − $C_{12}H_{14}Cl_4GaNO_5P_2W$ (707.6): calcd C 20.31, H 1.99, N 1.97; found C 19.60, H 2.39, N 2.10.

Reactivity of Complex 12a:

− *i*Pr_2NH: To a CH_2Cl_2 solution (4 mL) of complex **14a** (0.14 g, 0.22 mmol) was added, at −78°C, 2 equiv. of *i*Pr_2NH (0.04 g, 0.44 mmol). The solution was warmed to room temp., the solvent removed in vacuo and the residue extracted with pentane (15 mL). After filtration and evaporation of pentane, complex **6** was obtained as a yellow oil (0.12 g; 95%).

− H_2O: A CH_2Cl_2 solution (4 mL) of complex **12a** (0.08 g, 0.13 mmol) was stirred in contact with air for 1 h. Compound **13** (obtained in quantitative yield according to ^{31}P NMR spectroscopy) was analyzed without further purification. − $^{31}P\{^1H\}$ NMR (C_6D_6): δ = −67.4 (d, J(P,P) = 199 Hz, ^1J(P,W) = 305 Hz, P−OH), 33.7 (d, J(P,P) = 199 Hz, σ²-P). − MS (CH_4, CI); *m/z*: 544 (M+29), 516 (M+1), 498 [(M−OH)$^+$].

− $Ph_3P{=}N{=}PPh_3^+,Cl^-$: To a CH_2Cl_2 solution (4 mL) of complex **12a** (0.14 g, 0.22 mmol) was added, at −78°C, 1 equiv. of $Ph_3P{=}N{=}PPh_3^+.Cl^-$ (0.13 g, 0.22 mmol). The solution was warmed to room temp., the solvent removed in vacuo and the residue extracted with pentane (15 mL). After filtration and evaporation of pentane, complex **9** was obtained as a yellow oil (0.11 g; 94%).

− Bu_4NF: To a CH_2Cl_2 solution (4 mL) of complex **12a** (0.14 g, 0.22 mmol) was added, at −78°C, 1 equiv. of Bu_4NF (0.06 g, 0.22 mmol). The solution was warmed to room temp. and compound **14** (obtained in quantitative yield according to ^{31}P NMR spectroscopy) was analyzed without further purification. − ^{19}F NMR (C_6D_6): δ = −14.1 (dd, ^1J(P,F) = 1116 Hz, ^2J(P,F) = 121 Hz) − $^{31}P\{^1H\}$ NMR (CH_2Cl_2): δ = −12.1 (dd, J(P,P) = 238 Hz, ^1J(P,F) = 1116 Hz, ^1J(P,W) = 323 Hz, P−F), 43.2 (dd, J(P,P) = 238 Hz, ^2J(P,F) = 121 Hz, σ²-P).

[η^2-(3-Diisopropylaminodiphosphirenylium Salt)][W(CO)$_5$]$_2$ (15): To a $C_2H_4Cl_2$ solution (4 mL) of complex **12a** (0.19 g, 0.3 mmol) was added, at −78°C, 1 equiv. of [W(CO)$_5$(thf)] (3 mL, 0.1 M solution in THF, 0.3 mmol). The solution was warmed to room temp., stirred for 1 h, and compound **15** was analyzed without further purification. − $^{31}P\{^1H\}$ NMR ($C_2H_4Cl_2$): δ = −130 (broad).

[η^2-(3-Diisopropylaminodiphosphirenylium Salt)][W(CO)$_5$]$_3$ (16): To a CD_2Cl_2 solution (4 mL) of complex **12a** (0.19 g, 0.3 mmol) was added, at −78°C, 2 equiv. of [W(CO)$_5$(thf)] (6 mL, 0.1 M solution in THF, 0.6 mmol). The solution was warmed to room temp., stirred for 1 h, the solvent removed in vacuo, and the compound **16** (obtained in quantitative yield according to ^{31}P NMR spectroscopy) was analyzed without any further purification. − ^1H NMR (CD_2Cl_2): δ = 1.60 (d, ^3J(H,H) = 6.8 Hz, 6 H, CH_3), 1.63 (d, ^3J(H,H) = 6.8 Hz, 6 H, CH_3), 4.48 (sept, ^3J(H,H) = 6.8 Hz, 2 H, CHN). − $^{13}C\{^1H\}$ NMR (CD_2Cl_2): δ = 20.1 (s, CH_3), 21.3 (s, CH_3), 59.3 (s, CHN), 118.5 (q, ^1J(C,F) = 318 Hz, CF_3), 193.6 (t, J(P,C) < 1 Hz, ^1J(C,W) = 127.1 Hz, CO_e), 194.5 (s, CO_a), 213.6 (s, CO_a), 214.7 (s, CO_e), PCP was not observed. − $^{31}P\{^1H\}$ NMR (CD_2Cl_2): δ = −74.1 (J(P,W) = 176, 61 and 45 Hz).

X-Ray Crystal Structure Determination of 2 and 8: Crystal data for all structures are presented in Table 1. Data for **2** and **8** were collected at low temperatures using an oil-coated, shock-cooled crystal[37] on a Stoe-IPDS with Mo-*Kα* (λ = 0.71073 Å) radiation. The structures were solved by direct methods using SHELXS-97[38] and refined with all data on F^2 using SHELXL-97.[39] All non-hydrogen atoms were refined anisotropically. The hydrogen atoms of the molecules were geometrically idealized and refined using a riding model. A numerical absorption correction was employed for structure **8**,[40] the min./max. transmissions are 0.4325/0.568. Refinement of an inversion twin parameter[41] [x = 0.49(2), where × = 0 for the correct absolute structure and +1 for the inverted structure] confirmed a racemic twinning of **8**. The two positions for the disordered hydrogen atoms in **2** were localized by Fourier synthesis and refined by using distance restraints. In **8** two half molecules of CH_2Cl_2 located on the twofold axis are refined anisotropically. 80 ADP and distance restraints were used for the refinement of **8**.

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cam-

bridge Crystallographic Data Centre as supplementary publications nos. CCDC-121633 (2) and −121634 (8). Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44(1223)336−033; E-mail: deposit@ccdc.cam.ac.uk].

Computational details. We have used standard, well-calibrated computational methods incorporated into the Gaussian 92 program.[42] In view of the size of the molecules concerned, typical approximations were made so that the computations were actually performed on model compounds, in which the diisopropylamino substituent was replaced by an hydrogen atom, or an amino group. Geometries were optimized with the complete DZP basis set[43] at both SCF and B3LYP[44] levels. For the free species, vibrational frequencies were calculated for the various stationary points located, to check that these are true minima. Pseudo-potentials were adopted for W[45] and P[46] atoms in calculations on complexes **12d−g**; the use of these pseudopotentials was shown to lead to trivial differences relative to all-electron results for the ligands G1,2. Geometries for **12d−g** were fully optimized under C_s symmetry at the B3LYP level, employing a basis with polarisation functions on P atoms only. Final binding energies (B3LYP) were obtained with a basis containing polarisation functions on all atoms (f-type exponent 0.5 for W).

Keywords: Peroxo complexes / Vanadium / Mass spectrometry / ^{51}V-NMR spectroscopy / Vanadium dependent bromoperoxidases

ESI mass spectrometry and ^{51}V-NMR spectroscopy have been used to study the reactions occurring between bisperoxo vanadates and a number of histidine and histidine-like ligands, in aqueous alcoholic solutions. Coordination of one and two molecules of ligand is observed with all the compounds investigated affording $[VO_5L]^-$ and $[VO_52L]^-$, respectively. Characterization of these species has been achieved by MS^n experiments, which have allowed specific fragmentations of the peroxidic moiety to be distinguished. In particular, with $[VO_52L]^-$, two distinct modes of decomposition were observed, depending on the presence in the ligand of a free carboxylic function. – Possible biochemical implications related to vanadium haloperoxidase enzymes are discussed.

Introduction

Haloperoxidase enzymes catalyze the oxidation of halides by hydrogen peroxide.[1][2] The presence of vanadium in the oxidation state 5+ in vanadium-dependent chloro- and bromoperoxidases has been firmly established by using a variety of techniques. The binding of hydrogen peroxide to the metal, to yield a peroxo species as active intermediate, has been established as the initial step in the catalytic cycle. The oxidized halide is likely formed upon nucleophilic attack of X^- on the protonated peroxide group. In the absence of an organic halogen acceptor, the halogenating intermediate reacts with a second molecule of hydrogen peroxide thus producing halide, water and dioxygen, in its singlet state.

On the basis of several mechanistic studies, the catalytic cycle of the haloperoxidase enzymes can be outlined as it follows in Figure 1.[1][2]

Recently the X-ray structures of the native and peroxide form of V^V containing chloroperoxidase (V-ClPO) from the fungus *Curvularia inaequalis*[3] have been solved and possible implications for the catalytic mechanism have also been offered.[4][5] These recent crystallographic studies confirmed that the apical nitrogen donor bound to the metal center in the active site of the enzyme is an histidine imidazole. The other interactions of the prosthetic group with the proteic residues are hydrogen bonds to surrounding, positively charged or hydrophilic protein functions. A second molecule of histidine (His 404) is close to the active site. A very similar environment around the vanadium atom has been detected in the peroxide form of the enzyme.[4][5]

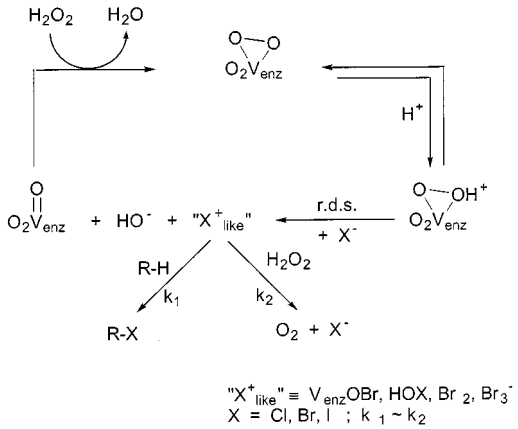

Figure 1. Mechanism for halides oxidation with hydrogen peroxide catalyzed by V-HalPO enzymes

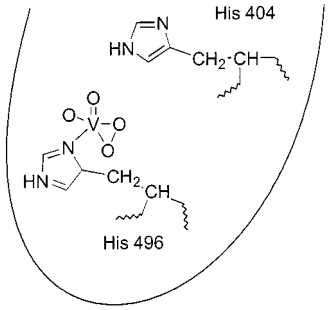

Figure 2. Schematic representation of the vanadium containing active site in the peroxide form of V-ClPO from *Curvularia inaequalis* taken from ref.[5]; hydrogen bonds network with water molecules has been removed for clarity

The occurrence of a protonation step in the catalytic cycle, see Figure 1, is strongly supported from mechanistic

studies both on the enzyme and on model systems.[2][6] In the enzyme such a role appears to be played by protonated histidine 404, which is in the appropriate position to activate, by protonation, the peroxidic complex through hydrogen bonding interactions.

Several functional models for vanadium dependents HalPO have been reported,[2] the simplest one being *cis*-dioxovanadium(V), VO_2^+, in acidic conditions in the presence of hydrogen peroxide.[7] It is well-known that depending on the acidity of the medium and on the concentration of precursors both mono- and bisperoxovanadium species can be formed.[8][9] We have recently proposed as functional models for V-BrPO a two-phase procedure, the oxidation of bromide is carried out, in the aqueous acidic phase, by either monoperoxo- or bisperoxovanadium derivatives which are formed from NH_4VO_3 and H_2O_2.[10–12] Subsequently, the reactive intermediate can brominate the substrate in the organic phase. The vanadium bisperoxo complex appears to be reactive toward bromide ions only when it is protonated.[6][13]

In almost neutral conditions, bisperoxovanadium complexes are quite stable species,[14] therefore we envisaged the possibility of using such complexes, in the presence of histidine-like ligands,[15] as simple models for the analysis of structural features in solution of peroxovanadium complexes in order to collect information related the behavior of the enzyme. The idea of studying a bisperoxovanadate species as a model of the enzyme is based on the knowledge of the crystal structure of V-ClPO,[5] see Figure 2. In fact, the prosthetic group of the enzyme is a monoperoxo-metavanadate moiety[5] bound to the protein only through histidine 496. Therefore, there is significant correspondence between the structure of a bisperoxovanadate[15] eventually containing an imidazole ring and the prosthetic group of V-ClPO from *C. inaequalis*.

We report here a study on the chemistry in solution of histidine-containing bisperoxovanadium compounds, by using ^{51}V-NMR and ESI-MS analyses. The latter technique has been already successfully used for the analysis of cationic mono-peroxovanadium compounds in acid conditions.[16]

Results and Discussion

Speciation of Bisperoxovanadates

Ammonium vanadate ($4\cdot10^{-3}$ mol L^{-1}), dissolved in water at pH ca. 6.8 shows in ^{51}V-NMR the known distribution pattern of mono- and oligomeric vanadate species.[17] In particular the prevailing species are monomeric, dimeric and tetrameric metavandates, respectively, indicated by the resonances at $\delta = -559$, -572, and -577, in agreement with literature data. When the same solution is diluted with ethanol, signals appear at $\delta = -552$, -556, -561, and -571, thus showing the possible formation also of the pentameric derivative. The addition of alcohol results in downfield shifts of the resonances and a broadening of the signals. This latter behavior can be assigned to fast exchange between water and alcohol molecules in the coordination sphere of the metal.[18]

The analysis of the same solutions by ESI-MS, in negative ion mode, shows the occurrence of the following species: $[VO_3]^-$ (*m*/*z* 99, relative abundance 3%), $[VO_3(H_2O)]^-$ (*m*/*z* 117, 14%), $[VO_3(EtOH)]^-$ (*m*/*z* 145, 44%), $[OV(O)(OEt)_2]^-$ (*m*/*z* 173, 100%), the dimeric $[\{OV(O)\}_2O(OH)]^-$ (*m*/*z* 199, 2%) and $[\{OV(O)\}_2O(OEt)]^-$ (*m*/*z* 227, 28%), as well as the less intense trimeric and tetrameric ions $[\{OV(O)\}_3O(OEt)(OH)]^-$ (*m*/*z* 327, 3%), $[\{OV(O)\}_3O(OEt)_2]^-$ (*m*/*z* 355, 8%), $[\{OV(O)\}_4O(OH)_3]^-$ (*m*/*z* 399, 2%).

When hydrogen peroxide is added to vanadate solutions in water/ethanol, a number of peroxovanadates are formed.[8,9,19] The relative abundance of the different species depends on the ratio H_2O_2/vanadate, pH, and on vanadium concentration. Under acidic conditions, in the presence of equimolar amounts of H_2O_2 with respect to vanadium, the predominant species are cationic monoperoxo complexes with different coordination sphere, whose ESI-MS behavior has been already reported.[16]

Aqueous solutions of peroxovanadium species were initially analyzed by employing mixtures of water and methanol. However, the presence in the coordination sphere of the metal of both the peroxo O_2^{2-} moiety and the methanol molecule having the same molecular weight (32 Da) caused difficulties in assigning some of the fragmentation patterns. Therefore, water and water/ethanol mixtures have been used as solvent. See Experimental Section for details regarding the preparation of the solutions. The preferential formation of bisperoxovanadium monoanion complexes was monitored by increasing the amount of hydrogen peroxide up to a 2.4:1 ratio with respect to vanadium, for pH values of 1.3, 6.9, 8.2. ^{51}V-NMR spectra at pH 1.3 revealed the presence of similar concentration of mono- and bisperoxo complexes, as indicated by signals at $\delta = -521$ ($W_{1/2}$ 501 Hz) and -681 ($W_{1/2}$ 468 Hz), respectively. On the other hand, in ESI-MS experiments, carried out both in positive and negative ion mode, the absence of any detectable species suggests that in these conditions, mono- and protonated bisperoxo compounds do not survive to the electrospray ionization conditions. In agreement with this observation, we have found that the decomposition reaction of bisperoxovanadium solutions at various pHs is faster as the concentration of $HClO_4$ increases, see Figure 3.

^{51}V-NMR experiments at almost neutral pH indicate the presence of a single species at $\delta = -689$ ($W_{1/2}$ 270 Hz) identified as the bisperoxovanadium compound. When the same solution is analyzed by ESI-MS, most of the observed peaks can be attributed to bisperoxo species containing different solvent molecules in the coordination sphere: $[VO_5]^-$ (*m*/*z* 131, 100%), the solvent bound species $[VO_5(EtOH)]^-$ (*m*/*z* 177, 55%) and $[VO_5(EtOH,H_2O)]^-$ (*m*/*z* 195, 5%), see Figure 4.

Other peroxidic compounds are observed at higher *m*/*z* values such as the dimeric species $[\{VO(OO)_2\}_2(H)]^-$ (*m*/*z* 263, 5%) and the water containing $[\{VO(OO)_2\}_2(H,H_2O)]^-$

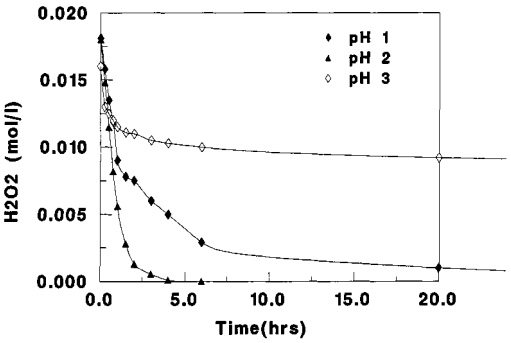

Figure 3. Disappearance of H_2O_2 (0.0.2 mol L^{-1})as a function of the time in the presence of NH_4VO_3 (0.01 mol L^{-1}) in water at 25 °C, at various pH ($HClO_4$); ▲ = pH 1.1 ($[VO(O_2)]^+ \sim [VO(O_2)_2]^-$ as measured by ^{51}V-NMR), ◆ = pH 2.0; (only $[VO(O_2)_2]^-$), ◇ = pH 3.0 (only $[VO(O_2)_2]^-$)

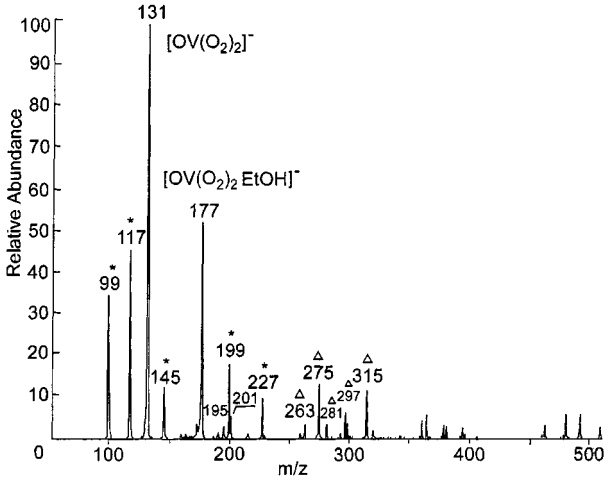

Figure 4. ESI mass spectrum of VO_3^- ($2\cdot10^{-3}$ mol L^{-1}) in the presence of 2.4 equivalents of H_2O_2 in ethanol/water 1:1, pH 6.9; (*) non-peroxidic species, (Δ) peroxospecies with a ratio $O_2^{2-}/V \geq 2$

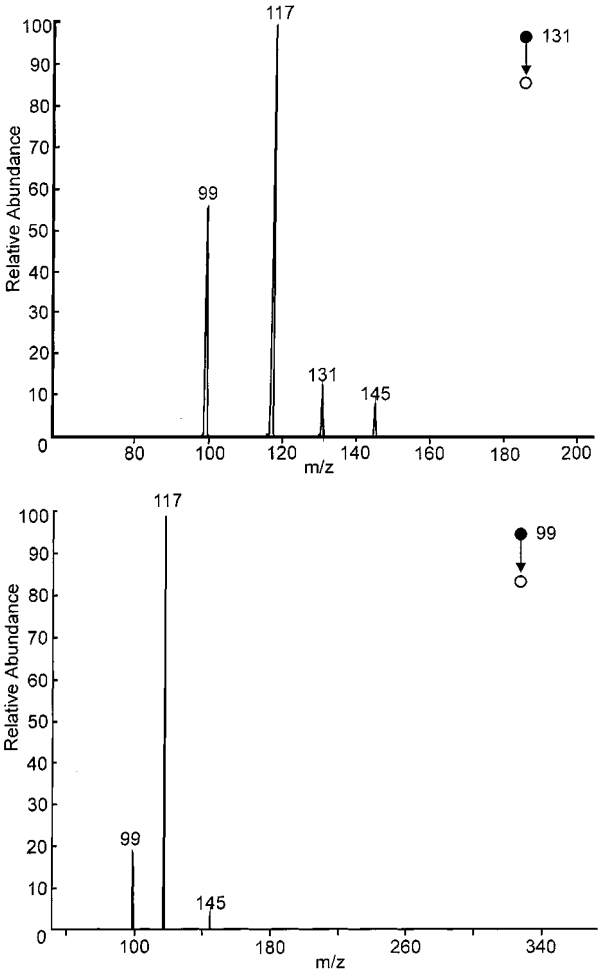
ion (*m/z* 281, 5%). It is worth of noting that very recently the crystal structure of this latter dimeric compound has been solved.[20] Furthermore, species having a peroxo-to-vanadium ratio higher than two have been detected at *m/z* 315 and 361. As far as the possibility of observing the formation of the previously reported[19] triperoxo compound is concerned, under such experimental conditions even though a small peak is detected at the correct *m/z* value corresponding to $[OV(O_2)_3(H_2O)_2(H)_2]^-$ (*m/z* 201, < 5%), we could not confirm its nature with collision induced-decomposition experiments (MS^n) because of the low intensity of the signal.

MS^n mass spectra were used to identify some of the above-mentioned species. The "naked" bisperoxovanadium compound, at *m/z* 131, fragments to the non-peroxidic species $[VO_3]^-$ (*m/z* 99). This decomposition is followed by the coordination of water or ethanol to $[VO_3]^-$ affording ions at *m/z* 117 and 145, respectively, Figure 5a. Support for this behavior was obtained by independent experiments on the isolated $[VO_3]^-$ which showed addition of water or ethanol, see Figure 5b. $[VO_5]^-$ with an ethanol molecule in the coordination sphere, is more prone to add neutrals, as found in the MS/MS mass spectrum of $[VO_5(EtOH)]^-$ (*m/z* 177) where coordination of water and ethanol is observed, affording the ions $[VO_5(EtOH,H_2O)]^-$ *m/z* 195 and $[VO_5(EtOH)_2]^-$ *m/z* 223, the latter in much lower relative intensity. An increase of the pH of the medium promotes the formation of oligomeric vanadium peroxo compounds in most cases having a peroxo-to-vanadium ratio higher than two.[19] As expected, also the increase of the concentration of vanadium favors the oligomerization process.



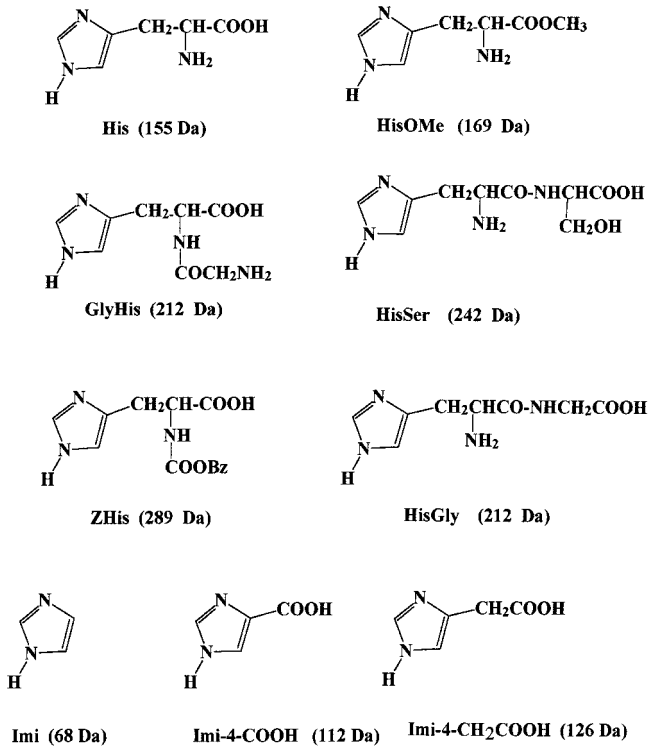


Figure 5. MS/MS mass spectrum of (a) the bisperoxovanadium $[VO_5]^-$ and of (b) the non-peroxidic species $[VO_3]^-$, in ethanol/water, 1:1, pH 6.9

We recently reported[16] that the tandem use of ^{51}V-NMR and ESI-MS analyses allows a better characterization of rapidly exchanging monoperoxovanadium species with different coordination sphere composition. Analogously, in the present study, the evidence that the line width of the NMR signals related to bisperoxocompounds significantly increases in passing from water to water/alcohol mixtures suggests the occurrence of new equilibria, regardless, a detailed snapshot of the equilibrating species, not feasible on NMR time scale, is accessible with the ESI-MS technique.

Histidine-Like Ligands for Bisperoxovanadates

Vanadium imidazole complexes have recently received significant attention in connection with the evidence that haloperoxidases contain histidine residues coordinated to vanadium.[3−5] Taking advantage of the results reported above we analyzed bisperoxo vanadium compounds at neutral pH in the presence of histidine and histidine-like ligands, i.e. methyl histidine (HisOMe), carbobenzoxy histidine (ZHis); dipeptides: GlyHis, HisSer, HisGly; imidazole (Imi), and carboxyimidazole derivatives (Imi−4-COOH) and (Imi−4-CH_2COOH), see Scheme 1. For example, upon addition of 2 to 6 equivalents of histidine to the bisperoxovanadium solution, at pH 6.9, together with the ^{51}V-NMR signal located at ca. $\delta = -690$, two new peaks are observed at $\delta = -729$ ($W_{1/2}$ not measured due to low intensity) and $\delta = -742$ ($W_{1/2} = 291$ Hz). This latter value is very close to the chemical shift ($\delta = -744$) reported by Crans et al.[15] for the bisperoxovanadium imidazole monoanion thus confirming that the coordination of histidine to $[VO_5]^-$ occurs via the imidazole moiety. The former signal has been assigned by Tracey et al.[21], even though with no firm evidence, to a species containing histidine bound to vanadium through the second imidazole nitrogen.

Scheme 1

The coordination properties of all the ligands used, see Scheme 1, were tested via ^{51}V-NMR technique in aqueous solution (pH ca. 6.9) and in water-ethanol mixture, by changing the [ligand]/$[VO_5]^-$ ratio from 1 to 6. In all cases the main peak observed is located between $\delta = -738$ and -750, depending from the ligand and from the solvent, thus indicating that the binding to the bisperoxovanadium complex always occurs through the imidazole sp^2 nitrogen. In agreement with previous data, ^{51}V-NMR analysis of solutions containing Imi and Imi−4-CH_2COOH as ligands shows the occurrence of bisperoxovanadates (at δ ca. -700) and $[VO_5L]^-$ (at δ ca. -740) species. On the other hand, by using Imi−4-COOH, three signals were detected pertaining to bisperoxovanadate ($\delta = -690$), $[VO_5$Imi−4-COOH$]^-$ ($\delta = -740$) and to a new species, located at $\delta = -770$. As far as its nature is concerned, we suggest the formation a dimeric bisperoxovanadate, possibly containing one or two molecules of Imi−4-COOH. Characterization of such species is currently in progress. Solutions of bisperoxovanadates in the presence of two equivalents of histidine were analyzed by ESI-MS, and additional signals are observed at *m/z* 286 and 441, corresponding to $[VO_5$His$]^-$ and $[VO_5$2His$]^-$, respectively, see Figure 6.

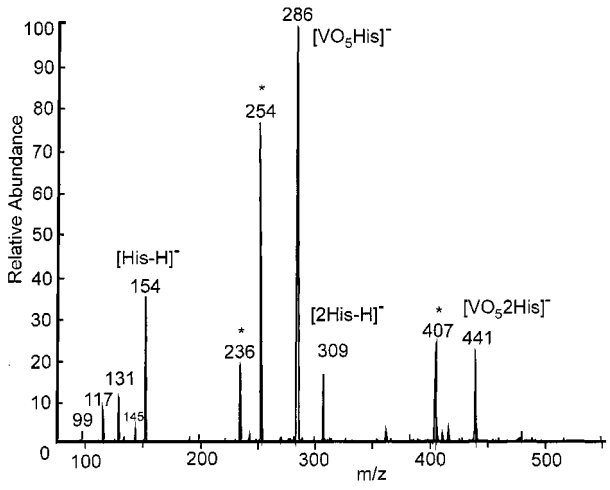

Figure 6. ESI mass spectrum of VO_3^- ($2\cdot10^{-3}$ mol L^{-1})/H_2O_2 (2.4 equivalents) in ethanol/water, 1:1, pH 6.9. in the presence of histidine (2 equivalents); (*) signals due to fragmentation of $[VO_5$His$]^-$ and $[VO_5$2His$]^-$, respectively, see text

It is important to emphasize that both *m/z* values correspond to the insertion of intact histidine molecule(s), although at this point we shall not specifically address where the protons are located. As will be discussed later on in the paper, this is a crucial point in the reactivity of the species. MS^n mass spectra of $[VO_5$His$]^-$ and $[VO_5$2His$]^-$ were also collected and the relevant data are inserted in Table 1. In particular, the different behavior of $[VO_5$His$]^-$ with respect to $[VO_5$2His$]^-$ deserves comments. The collision-induced decomposition (MS^2) of the $[VO_5$His$]^-$ complex shows a new peak at *m/z* 254 corresponding to the loss of 32 Da. On the other hand, $[VO_5$2His$]^-$ under the same CID conditions, shows formation of peaks at *m/z* 407 and 286 related to the loss of 34 and 155 Da. The $[VO_5$2His -155 Da$]^-$ ion is easily attributed to the release of a neutral histidine molecule. In order to better understand the nature of the 32 and 34 Da fragments observed in the decomposition of $[VO_5$His$]^-$ and $[VO_5$2His$]^-$ respectively, we have extended the analysis to the other ligands listed in Scheme 1, see Table 1.

Table 1. Relative abundances of $[VO_5L]^-$ and $[VO_52L]^-$ ionic species in ESI mass spectra of bisperoxovanadium compounds in the presence of histidine and histidine-like ligands and related MS/MS fragmentations[a]

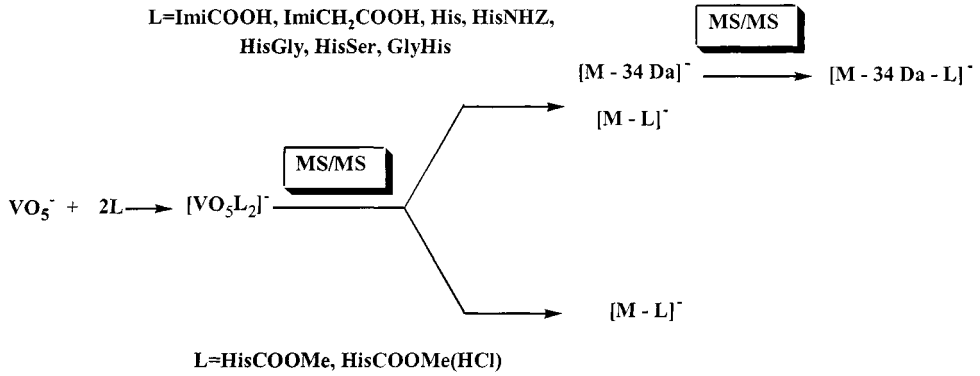
[a] MS/MS fragmentations of the selected $[M]^-$ and $[M']^-$ ions, respectively. − [b] These signals are due to the use as ligand of the commercially available HisOMe(HCl).

The overall picture obtained with these ligands by ESI-MS is very close to that observed for histidine. The data reported in the Table show that all the vanadium bisperoxo species containing one heteroligand in the coordination sphere are prone to release the 32 Da fragment, whereas the presence of two heteroligands on $[VO_5]^-$ appears to favor the expulsion of 34 Da only when a carboxy group is present in the framework of the ligand. The loss of 32 Da fragment from $[VO_5L]^- \equiv [M]^-$ has been attributed to the decomposition of both peroxidic moieties, which gives rise to the formation of the non-peroxidic species $[VO_3L]^-$ on the basis of the identical decomposition pattern of $[M - 32\ Da]^-$ ions and the isobaric ions obtained from ligands containing vanadates solutions, see Scheme 2. On the other hand, the loss of 34 Da fragment from $[VO_52L]^- \equiv [M']^-$, observed when L has a free carboxylic function, has been attributed to the release of H_2O_2. In fact upon isolation of the $[M' - 34]^-$ ion, loss of an intact L molecule is observed, thus proving that fragmentation of the ligands is not taking place, Scheme 3. Furthermore, the $[M' - 34]^-$ ions have to have an intact "side on" peroxidic group otherwise they would not be monoanions and therefore observed at a different *m/z* value.

A plausible explanation for the above-reported data takes into account the protonation a peroxidic oxygen by the carboxylic function of the ligands. When two ligands are involved in the coordination, the loss of hydrogen peroxide is made possible. Protonation of a peroxidic moiety likely results in an opening of the three-membered ring.[14] Such a process may allow a direct coordination to the metal of a second molecule of ligand. The resulting species has the peculiar ESI-MS fragmentation pattern discussed above, i.e. 34 Da loss. In the absence of a free carboxy group, as it is the case of HisOMe, HisOMe(HCl), and IMI, the second molecule of ligand in $[VO_5L_2]^-$, can be seen as external to the first coordination sphere of the metal, as it is in the crystal structure of $[VO_5Imi]^-(ImiH)^+$, where the imidazolium cation acts as counterion. Ab initio calculations are currently in progress in order to obtain further support to this hypothesis.



Conclusion

In summary, this study shows that the correct choice of the model for V-HalPO enzymes and its analysis with appropriate techniques allows the collection of significant structural and mechanistic data. In this respect, we have obtained direct[6] and independent evidence that the protonation of the peroxidic moiety is a crucial step in the activation of vanadium peroxocompounds. Such a mechanism of activation is also involved in the reactivity of V-HalPO enzymes.[5] The role of two different molecules of histidine and histidine-like ligands as proton donors has been also directly observed.

Experimental Section

General Remarks: The ESI-MS measurements were obtained using a Finnigan MAT LCQ instrument (San Jose, CA) by using the following parameters: solution flow rate 8 μL min^{-1}, capillary temperature 120−140 °C, spray voltage 3.4 kV, capillary voltage comprised between −5 and −20 V, nebulizing gas N_2 (40 units flow rate). Parameters related to octapoles and detector were those achieved by the automatic set-up procedure. Collision induced decompositions of selected ions (MS^n, n = 2, 3) were obtained by applying a supplementary r.f. voltage (tickle voltage) to the end cap electrodes of the ion trap (resonance activation). Typical tickle voltage values for fragmentation were 3−5 V. The vanadate and peroxovanadate solutions were introduced into the instrument by direct injection. The vanadate solutions at pH 6.9 are prepared by dissolving NH_4VO_3 ($2\cdot10^{-3}$ mol L^{-1}), in CH_3CH_2OH/H_2O, 1:1. The peroxovanadium solutions are prepared by dissolving NH_4VO_3 ($4\cdot10^{-3}$ mol L^{-1}) in water. 2.4 equivalents of H_2O_2 are subsequently added and pH is finally adjusted to the desired value [1.3 ($HClO_4$), 6.9 (natural value), and 8.2 (NH_3)]. The solutions are then diluted 1:1 with ethanol. Ligands are added in due time (1−8 equivalents with respect to V^V) to the aqueous solution of peroxovanadates before pH adjustment.

No significant variation on the qualitative distribution of the species was observed by repeating the measurements. However, the intrinsic nature of the ESI-MS technique does not allow to estimate the relative concentration of the ions detected. This event, nevertheless, does not interfere with the conclusion drawn in the present work.

Decomposition Reactions: The appropriate amount (2 equivalents) of H_2O_2, in water, is added to a aqueous solution of NH_4VO_3 ($1\cdot10^{-3}$ mol L^{-1}), at pH = 1 and 25 °C. When needed, pH adjustment (at values of 2 and 3) is settled with NH_3. Consumption of peroxide content is analyzed at chosen time interval with standard iodometric titration. Reproducibility of the kinetic behavior was checked for each pH with triplicate runs.

NMR experiments were carried out as already described.[9][12]

Keywords: Half-sandwich complexes / Molybdenum / Optically active complexes / Rhenium / Tungsten

The synthesis of (η^5-PinCp*)Re($CO)_3$ [PinCp* = tetramethyl(pinanyl)cyclopentadienyl] is described. Successive substitution of two CO ligands by NO^+ and PPh_3 generates a 1:1 diastereomeric mixture of chiral-at-metal [(S_{Re})/(R_{Re})-(PinCp*)Re(CO)(NO)(PPh_3)]BF_4. The diastereomers are converted with sodium methoxide into the derivative "esters" (S_{Re})/(R_{Re})-(PinCp*)Re($COOCH_3$)(NO)(PPh_3), and then with (+)-(*R*)-(1-naphthylethyl)amine to the "amides" (S_{Re})/(R_{Re})-(PinCp*)Re(NO)(PPh_3)[$CONHCH(CH_3)C_{10}H_7$] [(S_{Re})/(R_{Re}) = 1:1]. Fractional crystallisation separates the (S_{Re}) isomer with an optical purity of > 98%. The latter compound has been characterized by X-ray structure analysis. By treating the (S_{Re})-amide with CF_3CO_2H and $NaBF_4$, (S_{Re})-(PinCp*)Re(CH_3)(NO)(PPh_3) can be generated. Protolysis of this compound with HBF_4/Et_2O in CD_2Cl_2 at –78 °C leads to the solvent-stabilized complex (S_{Re})-[(PinCp*)Re(NO)(PPh_3)($ClCD_2Cl$)]$^+BF_4^-$. The thermal and configurational stability of this chiral Lewis acid is investigated at various temperatures. The syntheses of [PinCp*$RhCl_2]_2$, PinCp*$TiCl_3$ and PinCp*$M(CO)_2$(NO) (M = Mo, W) are also described. Starting with PinCp*$M(CO)_2$(NO), the relatively stable 16-VE complexes PinCp*MCl_2(NO) and PinCp*$W(CH_2SiMe_3)_2$(NO) are synthesized.

Introduction

Chiral Lewis acids, derived from transition-metal complexes, play an increasingly important role in enantioselective organic synthesis.[1–4] Both their thermal as well as their configurational stability are essential for their application as catalysts in asymmetric synthesis. While Gladysz et al.[4] have investigated the stability of the chiral-at-metal Lewis acid (S_{Re})-[(η^5-C_5H_5)Re(NO)(PPh_3)($ClCD_2Cl$)]$^+$ BF_4^-, our group has studied the behaviour of a chiral Lewis acid incorporating an optically active cyclopentadienyl ligand, namely (S_{Re})-[(η^5-PCp)Re(NO)(PPh_3)-($ClCD_2Cl$)]$^+$-BF_4^- (PCp = "pinene-fused cyclopentadienyl").[5][6] Gladysz determined the configurational stability of (S_{Re})-[(η^5-C_5H_5)Re(NO)(PPh_3)($ClCD_2Cl$)]$^+BF_4^-$ by either investigating the optical purity of the decomposition products formed after warming above −20°C, or by analysing the products generated when nucleophiles are added at low temperatures. The configurational stability of (S_{Re})-[(η^5-PCp)Re(NO)(PPh_3)($ClCD_2Cl$)]$^+BF_4^-$, on the other hand, was determined by low-temperature ^{31}P-NMR spectrocopy, where the optically active cyclopentadienyl ligand served as an internal spectroscopic probe of diastereomeric purity. Both systems show no inversion of configuration at the stereogenic metal centre up to their decomposition points at −20°C.

Recently, Gladysz et al.[7] have extended their studies to the peralkylated derivative (S_{Re})-[(η^5-C_5Me_5)Re(NO)-(PPh_3)($ClCD_2Cl$)]$^+BF_4^-$, under the assumption that peralkylated ligands should enhance the thermal and configurational stability of the chiral Lewis acid by either shielding the central metal atom through the bulk of the ligand, or by stabilizing the cationic centre through the electron-donating effect of the five alkyl groups. Surprisingly, they found that decomposition of (S_{Re})-(η^5-C_5Me_5)Re(NO)(PPh_3)-($ClCD_2Cl$)]$^+BF_4^-$ seems to occur even below −35°C. They also noticed that products formed by addition of nucleophiles at lower temperatures were only recovered with a maximum enantiomeric purity of 90%. Because spectroscopic methods for directly determining the conformational stability of enantiomers are limited, Gladysz et al. were not able to fully rationalize their observations.

As our previous work[6] had shown that the fate of a stereogenic metal centre could be easily monitored by low-temperature NMR spectroscopy when an optically active cyclopentadienyl ligand is present, we also investigated the synthesis and stability of a chiral Lewis acid derived from a peralkylated, optically active ligand such as PinCp* [PinCp* = tetramethyl(pinenyl)cyclopentadienyl], a ligand that has been first introduced by Lai et al.[8] This ligand, like PCp used by us before, should serve as an internal chiral probe to directly determine the stability of peralkylated derivatives of Gladysz' chiral Lewis acids. We also wanted

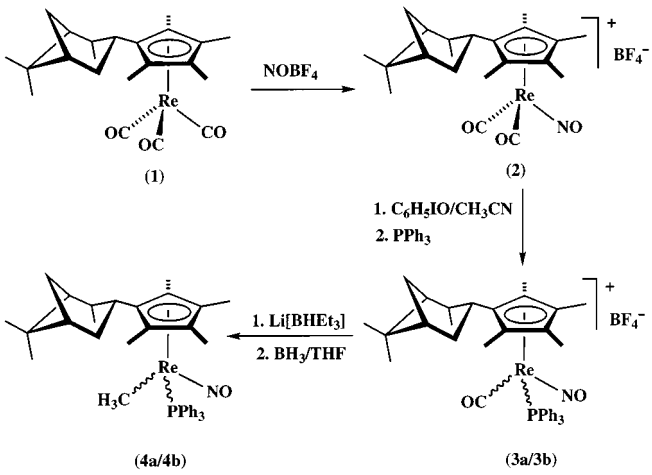
to show that this ligand could be universally used as a chiral replacement for Cp* by incorporating it into a series of other organometallic compounds.

Results and Discussion



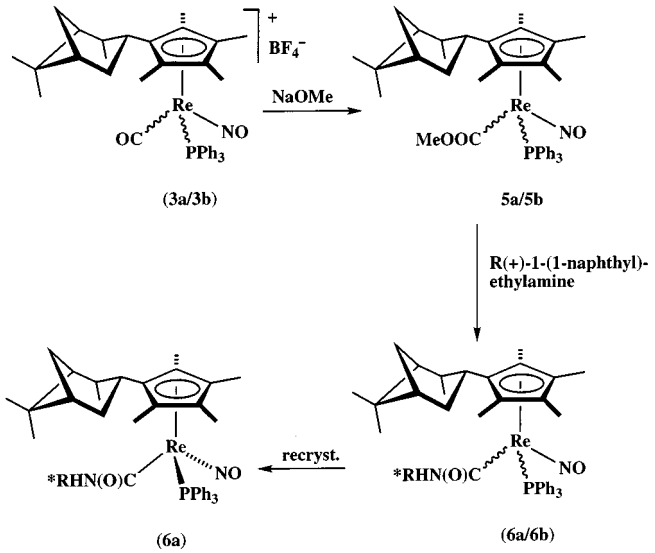
1. Synthesis of a Diastereomeric Mixture of (S_{Re})/(R_{Re})-(η^5-PinCp*)Re(CH_3)(NO)(PPh_3)

The ligand PinCp* was prepared from optically active (+)-pinanaldehyde,[9] which was oxidized to the (+)-carboxylic acid and then converted in several steps into a peralkylated cyclopentadiene ligand, as described by Lai for the other enantiomer[8] (Scheme 1).

Scheme 1

Following the same method as before,[6] (η^5-PinCp*)-Re($CO)_3$ (**1**) was synthesized in good yield by reaction of [Re($CO)_3$($THF)_2$]Cl with PinCp*Li in THF (Scheme 2). Because the peralkylated ligand has homotopic faces, only one product is generated and no separation step is required. In line with the work of Gladysz et al.,[10] the tricarbonyl complex was treated with freshly prepared $NOBF_4$ in CH_2Cl_2 at 0°C to form [(η^5-PinCp*)Re($CO)_2$(NO)]$^+$ (**2**) as yellow crystals after workup. The two diastereotopic CO groups could now be distinguished in the ^{13}C-NMR spectrum as two singlets. Because PPh_3 is less π-accepting than CO, the second CO ligand could not be substituted directly. In a first step, one of the CO groups had to be oxidized with iodosobenzene in acetonitrile. The intermediate acetonitrile complex was then treated with an excess of PPh_3 to give a diastereomeric mixture of (S_{Re})/(R_{Re})-[(η^5-PinCp*)-Re(CO)(NO)(PPh_3)]$^+BF_4^-$ (**3a/3b**), which was obtained in excellent yield and purity. The IR spectrum contains two bands for the CO and NO ligands. The ^{1}H- and ^{13}C-NMR spectra each have two sets of signals due to the two diastereomers. The signals of the diastereomeric CO ligands are quite interesting, because they appear as two doublets at δ = 202, each with a coupling constant of 8.3 Hz. There was, unexpectedly, only one signal for both diastereomers in the ^{31}P-NMR spectrum, both in [D_6]acetone and in [D_3]nitromethane.

Scheme 2



The reduction of the CO ligand to a methyl group was achieved in a two-step reaction with Li(C_2H_5)BH_3 and BH_3·THF.[11] After workup, (S_{Re})/(R_{Re})-(η^5-PinCp*)-Re(CH_3)(NO)(PPh_3) (**4a/4b**) was obtained as a red powder. The IR spectrum had one characteristic band for the NO ligand, while the ^{1}H- and ^{13}C-NMR spectra again contained two sets of signals for the two diastereomers. In the ^{1}H-NMR spectrum, the four methyl groups of the five-membered ring and the three methyl groups of the pinanyl part of each diastereomer overlapped. These signals therefore cannot be assigned unambiguously. Two signals, one at δ = 25.7 and one at δ = 23.4, appeared in the ^{31}P-NMR spectrum of the diastereomeric complexes. Because one of these signals is sharp and the other one is broad, it appears as if one of the two diastereomers is undergoing hindered ligand rotation. Measurements at low temperature confirmed that the broadened signal disappears below 0°C; two new signals, at a 3.5:1 ratio, appeared below −25°C. The sharp signal for the other diastereomer is retained throughout this experiment. That the original spectrum was observed again after the NMR sample was warmed up, confirms that hindered ligand rotation is a likely explanation for this phenomenon. It is interesting, but not yet explained why the two diastereomers should show such disparate behaviour and which type of rotation is involved.

The two signals of **4a/4b** appeared in a ratio of 1:1 in the ^{31}P-NMR spectrum, at room temp. The optically active PinCp* ligand therefore caused no asymmetric induction at the rhenium stereogenic centre. A reason for this may be the high temperature required for the substitution of the second CO group.

2. Resolution of Optically Active (S_{Re})-(PinCp*)Re(CH_3)(NO)(PPh_3) (4a)

Usually, mixtures of diastereomers can be separated by fractional crystallization or by chromatography. In our case, fractional crystallization was not possible because of the poor crystallinity of the mixture of (S_{Re})/(R_{Re})-(η^5-PinCp*)-Re(CH_3)(NO)(PPh_3). Also, no solvent mixture could be found to separate the diastereomers by preparative MPLC. We therefore followed the route of Gladysz et al. for the separation of (S_{Re})/(R_{Re})-(η^5-C_5Me_5)Re(CH_3)(NO)(PPh_3)[7] by using a suitable derivative.

The starting material for the separation was the complex (S_{Re})/(R_{Re})-[(η^5-PinCp*)Re(CO)(NO)(PPh_3)]$^+BF_4^-$ (**3a/3b**), which was treated with sodium methoxide in methanol to give the methyl ester (S_{Re})/(R_{Re})-[(η^5-PinCp*)Re(COOMe)(NO)(PPh_3) (**5a/5b**) in excellent yield (Scheme 3). The ^{31}P-NMR spectrum contained two sharp singlets in a ratio of 1:1. We could determine the ratio of the two diastereomers by using the two singlets of the methoxy groups at $\delta = 3$ in the ^{1}H-NMR spectrum. The CO groups appear in the ^{13}C-NMR spectrum as two doublets at $\delta = 203$ and 202, with $J_{C-P} = 13.8$ Hz.

Scheme 3

The methyl ester complexes were then treated with commercially available (+)-(*R*)-(1-naphthyl)ethylamine in CH_2Cl_2 to obtain the amide complexes **6a/6b**. The solvent was evaporated and the residual orange oil was stirred in *n*-hexane. An orange solid separated, which was collected by filtration, and recrystallized from benzene/*n*-hexane as crystals of one single diastereomer in an optical purity of > 98%, as determined by ^{1}H- and ^{31}P-NMR spectra (Scheme 3).

This less soluble diastereomer was identified by a crystal-structure determination to be (S_{Re})-(η^5-PinCp*)Re(NO)(PPh_3)[CONHCH(CH_3)$C_{10}H_7$] (**6a**) (Figure 1). These observations agree with Gladysz′ findings for (η^5-C_5Me_5)Re(NO)(PPh_3)[CONHCH(CH_3)$C_{10}H_7$], where the symmetrical products (S_{Re},S_{amid}) and (R_{Re},R_{amid}) were also more soluble than the mixed products (S_{Re},R_{amid}) and (R_{Re},S_{amid}).[7] The pinanyl substituent in **6a** adopts a conformation in which the methyl group points away from the metal centre and the dimethylmethylene bridge lies parallel to the plane of the cyclopentadienyl ring. This is very similar to the stereochemistry found in Lai′s molybdenum compound.[8]

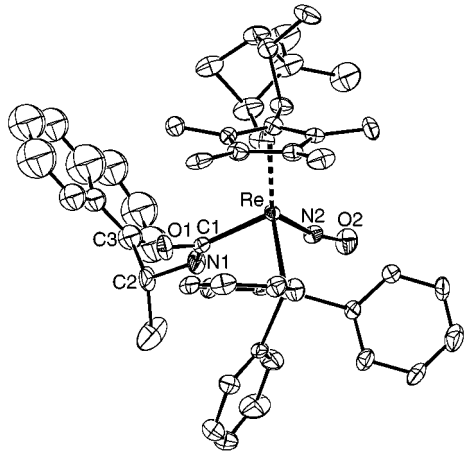


Figure 1. Crystal structure of (S_{Re})-(η^5-PinCp*)Re(NO)(PPh_3)-[CONHCH(CH_3)$C_{10}H_7$] (**6a**)

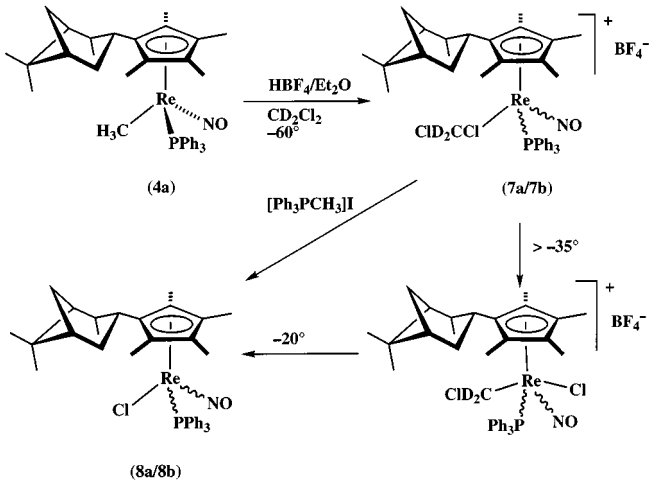
The enantiomerically pure amide was treated with trifluoroacetic acid at 0°C, which recovered the cationic, optically pure carbonyl complex, which was then isolated as the tetrafluoroborate salt (S_{Re})-[(η^5-PinCp*)Re(CO)-NO(PPh_3)]$^+BF_4^-$ (**3a**). By following this procedure with the other diastereomer, recovered by concentration of the mother liquor of the resolution step, the (R_{Re})-carbonyl complex could also be obtained in 80% optical purity. The reduction of pure **3a** to the methyl complex **4a** was carried out as described above for the diastereomeric mixture. The ^{31}P-NMR spectrum of (S_{Re})-(η^5-PinCp*)Re(CH_3)(NO)-(PPh_3) (**4a**) shows the broadened signal of the diastereomer undergoing hindered rotation. This signal, upon cooling, underwent the same changes as described before.

3. Formation and Stability of the Diastereomeric Mixture of (S_{Re})/(R_{Re})-[(η^5-PinCp*)-Re(NO)(PPh_3)($ClCD_2Cl$)]$^+BF_4^-$ (7a/7b) and Its Optically Pure (S_{Re}) Isomer

The chiral Lewis acid (S_{Re})/(R_{Re})-[(η^5-PinCp*)-Re(NO)(PPh_3)($ClCD_2Cl$)]$^+BF_4^-$ (**7a/7b**) was generated as described before.[5][12] The diastereomers were dissolved in CD_2Cl_2 in an NMR tube and treated with HBF_4 at −78°C. The ^{31}P-NMR spectrum, measured directly after shaking the reaction mixture, had three sharp signals of different intensity at $\delta = 14$, assignable to the two diastereomeric cations where one cation is a mixture of two rotamers. Additional signals appeared at $\delta = 15$ and 11 and seem to be decomposition products. When the solution was warmed, one of the three signals of the chiral Lewis acid remained unchanged, while the two others became broad. This behav-

iour is similar to that of the diastereomeric mixture of the complex (S_{Re})/(R_{Re})-[(η^5-PinCp*)Re(CH_3)(NO)(PPh_3) described above. Warming to −20°C resulted in a rapid decrease in the intensity of the three signals and a concomitant growth of the signals at δ = 11 and 15. The signal at δ = 11 appeared as two singlets in a ratio of 1:1, one of them sharp, the other one broadened.



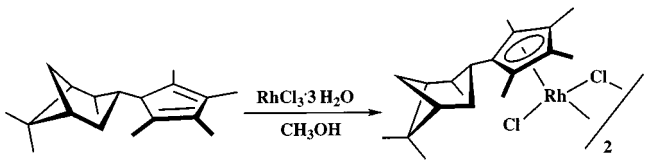
We then repeated the same experiment with optically pure (S_{Re})-[(η^5-PinCp*)Re(CH_3)(NO)(PPh_3). We expected to see only the two signals of the (S_{Re}) isomer, but surprisingly we also immediately observed the third signal due to the second diastereomer. This indicates that inversion at the metal centre starts taking place directly after mixing the compounds at −80°C. A noticeable amount of decomposition products was also observed at this temperature. At −60°C, the two diastereomers approached a ratio of 1:1, which was reached at −40°C. At −20°C, the cation had completely disappeared and the two signals at δ = 11 were again apparent as one sharp and one broadened signal. The IR spectrum of the reaction mixture, measured at room temperature, contained two NO signals, one at 1746 cm^{-1}, and one at 1641 cm^{-1}; they are assigned to the main decomposition products at δ = 11 and 15.

These results clearly show that the chiral Lewis acid (S_{Re})-[(η^5-PinCp*)Re(NO)(PPh_3)($ClCD_2Cl$)]$^+BF_4^-$ has an extremely low configurational stability. Even at −80°C, a small amount of the inversion product can be detected and at −40°C complete inversion has occurred. These conclusions could be drawn solely on the basis of low-temperature ^{31}P-NMR spectroscopy and they confirm the results obtained by Gladysz et al. for the Cp* complex. Gladysz′ observations, that the optically purity of the Lewis acid diminishes on reaction with another nucleophile can now be explained: Inversion at the metal centre already starts occurring shortly before the CD_2Cl_2 ligand is exchanged for a new nucleophile.

To find an explanation for the thermal and configurational instability of the complex [(η^5-Cp*)-Re(NO)(PPh_3)($ClCD_2Cl$)]$^+BF_4^-$, Gladysz et al. examined the products formed on warming the solution. They found that oxidative addition of the dichloromethane fragment takes place to give the cationic complex [(η^5-PinCp*)-Re(NO)(PPh_3)(CD_2Cl)Cl]$^+BF_4^-$. This Re^{III} species gives rise to a singlet at δ = 11 in its ^{31}P-NMR spectrum and an NO band at 1739 cm^{-1} in its IR spectrum. It was rationalized that the electron-rich permethylated complex confers stability to this unexpected Re^{III} species; this favours the formation of a higher oxidation species, which, contrary to expectations, lowers the stability of the chiral Lewis acid.

As we also saw two signals at δ = 11 in the ^{31}P-NMR spectra and a signal at 1746 cm^{-1} in the IR spectra, we tried to isolate [(η^5-PinCp*)Re(NO)(PPh_3)(CD_2Cl)Cl]$^+$-BF_4^- by dissolving the dried residue of the NMR sample in a small amount of THF and precipitating it with ether. A solid appeared, which dissolved again after being stirred for a short time. If this precipitate was in fact the Re^{III} species, of which we are sure, it must be quite unstable in the case of the PinCp* complex.

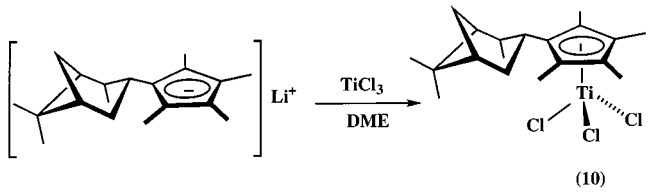
The chiral Lewis acid decomposition products whose signals were observed at δ = 15 appeared to be more stable. By comparing[12][13] the ^{31}P-NMR and IR data of the analogous PCp and Cp* complexes, we deduced this species to be a diastereomeric mixture of (S_{Re})/(R_{Re})-(η^5-PinCp*)-ReCl(NO)(PPh_3) (**8a/8b**). This could have formed directly by nucleophilic substitution of the stabilizing solvent molecule by a chloride anion, available from a small amount of DCl in the solvent. On the other hand, it could have formed by loss of CD_2Cl^+ from the Re^{III} species. We favour the second pathway because the signal at 1746 cm^{-1} disappears in favour of the signal at 1641 cm^{-1} (Scheme 4).



Scheme 4

To confirm this, we synthesized the chloride complex independently, following the route that Gladysz used for the Cp* complex.[13] After formation of the chiral Lewis acid, methyltriphenylphosphonium iodide was added. The solution turned red and the product could be identified by IR, ^{1}H-, ^{13}C-, ^{31}P-NMR, and MS data to be the expected chloride species (**8a/8b**). The IR and ^{31}P-NMR signals were identical to those of the previous NMR experiments. The ^{31}P-NMR spectrum of **8a/8b** contained a sharp and a broad signal. The broadened signal disappeared upon cooling below 0°C and two new signals appeared upon further cooling. The sharp signal does not change during this time. The same behaviour was previously observed for (S_{Re})/(R_{Re})-[(η^5-PinCp*)Re(CH_3)(NO)(PPh_3). Again, a hindered ligand rotation associated most likely with the bulky PinCp* ligand occurs within the (S_{Re}) isomer, but not in the case of the (R_{Re}) isomer. It remains unclear why this phenomenon should so persistently be restricted to only one of the two diastereomers.

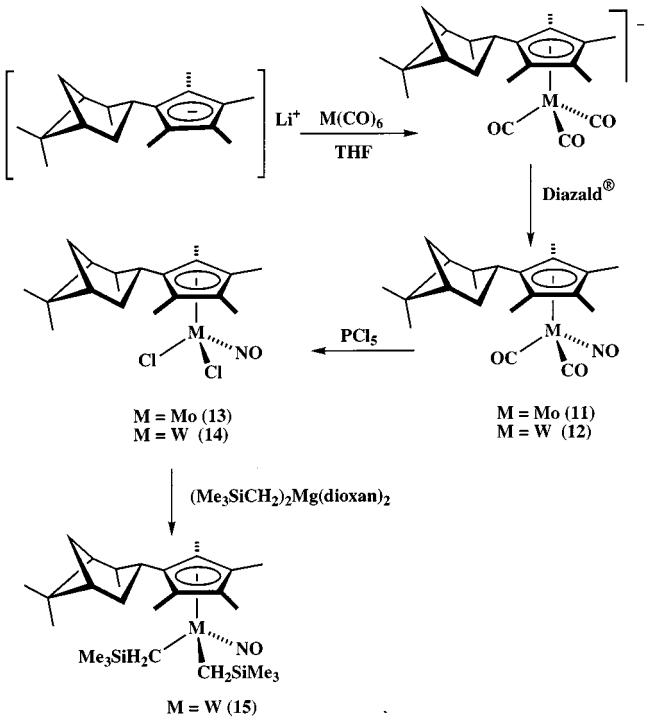
4. Synthesis of Other Metal Complexes of the Chiral Cyclopentadienyl Ligand PinCp*



As rhodium complexes with a chiral cyclopentadienyl ligand are known to be useful in asymmetric hydrogenations,[14] we also synthesized a corresponding PinCp* complex. We prepared [PinCp*$RhCl_2$]$_2$ (**9**) by heating

$RhCl_3 \cdot 3H_2O$ and PinCp*H in methanol under reflux for a few days (Scheme 5). After the solvent was evaporated, a red solid was collected in reasonable yields, which was characterized by ^1H- and ^{13}C-NMR spectroscopy and elemental analysis. We are currently trying to perform these experiments in the presence of zeolites to prepare a corresponding "ship-in-the-bottle" complex and to test **9** as a catalyst precursor in enantioselective hydrogenation.

Scheme 5



Chiral cyclopentadienyl ligands are also often attached to early transition metals like Ti, Zr, and Hf.[15] Such complexes may be efficient Ziegler-Natta polymerization catalysts, or catalyse enantioselective synthesis. We prepared the complex (PinCp*)$TiCl_3$ (**10**) by treating $TiCl_3 \cdot 3THF$ with PinCp*Li in DME under reflux.[16] After workup, a red solid was isolated and characterized by ^1H- and ^{13}C-NMR and MS data to be PinCp*$TiCl_3$. Extraction of the remaining solid with CCl_4 did not lead to the isolation of the expected doubly substituted product (PinCp*)$_2TiCl_2$. The reaction with PinCp* therefore takes a different route from that with Cp*, where Cp*$_2TiCl_2$ is the major product under the same reaction conditions (Scheme 6).

Scheme 6

Legdzins et al. have prepared many complexes with the 14-VE backbone Cp′M(NO) [M = Mo, W; Cp′ = C_5H_5 or C_5Me_5].[17] Their aim was to synthesize stable 16-VE complexes of the type Cp′M(NO)(R)(R′), where the alkyl or aryl substituents could be equivalent or different from each other. To synthesize such a complex with the chiral ligand PinCp* we followed the procedure published for Cp*.[18] [(η^5-PinCp*)M$(CO)_3$]$^-$ was synthesized by treating $M(CO)_6$ with PinCp*Li in THF. The anion was then directly converted into the neutral, coordinatively saturated complexes (η^5-PinCp*)M$(CO)_2$(NO) (**11**,**12**) without further purification by treating the tricarbonyl complex with Diazald. The product was purified by sublimation and excess Diazald was separated by column chromatography (hexane/ether, 4:1). The reaction of the nitrosyl complexes with PCl_5 in ether yielded the 16-VE complexes (PinCp*)MCl_2(NO) (**13**,**14**) as poorly soluble, green solids (Scheme 7).

The nitrosyl dichloride complex was alkylated with $(Me_3SiCH_2)_2Mg \cdot (dioxane)_2$ at very low temperatures.[19] As the Cp* tungsten complex was more stable than the corresponding molybdenum compounds,[20] we restricted our investigations to the former. The NO group of the dialkylated product (PinCp*)W(NO)$(CH_2SiMe_3)_2$ (**15**) has an IR absorption at 1582 cm^{-1} which agrees with a weakening of the N−O bond as found by Legdzins et al. in crystal structures. The ^1H- and ^{13}C-NMR spectra contain two signals for the diastereotopic $SiMe_3$ groups. The compound does not appear to be as stable in solution as the corresponding Cp* complex, but it can be stored at room temperature as a solid. We could also obtain a monoalkylated product as a red oil by using only half an equivalent of the magnesium reagent and strict temperature control, but this product was too unstable to be isolated and fully characterized in analytically pure form.

Scheme 7

We also tried to generate a new stereogenic centre at the metal atom by a thermal or photochemical substitution of one of the CO groups in (PinCp*)W$(CO)_2$(NO). Brunner[21] had reported an efficient substitution of PPh_3 for CO to generate the complex CpMo(CO)(NO)(PPh_3) in refluxing toluene. He obtained quantitative yields, while another group[22] claimed that this substitution does not take place even at very high temperatures. We treated (PinCp*)Mo$(CO)_2$(NO) with PPh_3 in refluxing toluene over several hours. No substitution could be observed, which may be either because the PinCp* ligand is more electron-donating or because of steric hindrance. A photochemical ligand exchange also did not occur by irradiation in toluene, where after one hour the starting material had completely decomposed.

PinCpH* also reacts with carbonyliron and -ruthenium complexes to form dimeric carbonyl complexes. These will be described elsewhere.

Conclusion

The optically active peralkylated ligand PinCp*H can be introduced into a series of metal complexes of titanium, molybdenum, tungsten, rhenium and rhodium. In most cases, these new complexes have properties similar to those of the corresponding Cp* complexes. The PinCp* ligand can serve as an internal spectroscopic probe for the configurational stability of the chiral-at-metal Lewis acid [PinCp*ReNO(PPh_3)($ClCD_2Cl$)]$^+$.

Experimental Section

General Remarks: All experiments were performed under purified nitrogen using standard vacuum-line and Schlenk-tube techniques. Diethyl ether and THF were distilled from sodium benzophenone ketyl. Acetonitrile and dichloromethane were distilled from calcium hydride. Dimethoxyethane (DME) and *n*-hexane were dried with molecular sieves. [$Re(CO)_3(THF)_2$]Cl,[23] $NOBF_4$,[24] iodosobenzene,[25] [$(Me_3Si)CH_2Mg$]·(dioxane)$_2$[26] and PinCp*[8] were prepared as described in the literature. (+)-3-Formylpinane was a gift from BASF. − Infrared spectra were recorded with a Perkin−Elmer 1750 FT spectrophotometer as solutions in *n*-hexane, CH_2Cl_2, or DME in NaCl cells. − NMR spectra were recorded with either a Varian VXR 300 or a Varian Unity 500 spectrometer in $CDCl_3$ or C_6D_6 unless otherwise stated. ^{1}H- and ^{13}C-NMR spectra were referenced to tetramethylsilane (TMS) or from internal solvent peaks; ^{31}P-NMR spectra were referenced to H_3PO_4 (external). All ^{13}C- and ^{31}P-NMR data are of proton-decoupled (broadband) spectra.

(+)-(1*S*,2*S*,3*S*,5*R*)-Pinane-3-carboxylic Acid: (+)-3-Formylpinane (49.8 g, 0.30 mol) was dissolved in acetone and treated slowly with a cold saturated aqueous solution of $KMnO_4$ (31.6 g, 0.2 mol). The solution was stirred for 2 h at room temperature and the precipitate of MnO_2 was filtered off with a Buchner funnel, and through Celite/cotton wool. The solution was treated with solid KOH to an approximate pH value of 12 and extracted 3 times with ether. After acidification with concd. HCl, the aqueous solution was again extracted 3 times with ether. The organic phases were combined and dried with $MgSO_4$. The solvent was evaporated under reduced pressure in a rotary evaporator, leaving a pale-yellow oil, yield 52.8 g (0.29 mol, 98%). This product was used for the further synthesis of PinCp*.[8]

[(η^5-PinCp*)Re(CO)$_3$ (1): PinCp*H (5.16 g, 20.0 mmol) was dissolved in 80 mL of THF and cooled to −78°C. *n*BuLi (1.6 M in hexane, 20 mmol, 12.5 mL) was added by syringe while the solution was stirred. The mixture was allowed to warm to room temperature and was then refluxed for 14 h. PinCp*Li precipitated as a white solid. The solvent was removed by vacuum distillation and the product was washed twice with 100 mL of *n*-hexane. The white solid was dissolved in 50 mL of THF, cooled to 0°C, and a solution of 20.0 mmol of [$Re(CO)_3(THF)_2$]Cl in THF was added dropwise. The solution was then refluxed for 12 h and, after cooling to room temperature, the solvent was removed by vacuum distillation. The residue was extracted with hot *n*-hexane and filtered hot through Celite. After concentrating the solution, the product precipitated at −30°C as an off-white solid; yield: 10.00 g (19.0 mmol, 95%). − IR (*n*-hexane): $\tilde{\nu}_{(CO)}$ = 2014 (s), 1923 (s) cm^{-1}. − ^{1}H NMR ($CDCl_3$): δ = 2.94 (q, J_{H-H} = 9.5 Hz, 1 H, H-4), 2.38 (m, 1 H), 2.27 (s, 3 H, C_5Me_4), 2.21 (s, 3 H, C_5Me_4), 2.17 (d, J_{H-H} = 7.3 Hz, 6 H, C_5Me_4), 2.08 (m, 3 H, H-9), 1.90 (t, J_{H-H} = 5.5 Hz, 2 H), 1.26 (s, 3 H, H-9), 1.19 (s, 1 H), 1.16 (s, 3 H, H-8), 1.02 (d, J_{H-H} = 7.0 Hz, 2 H). − ^{13}C NMR ($CDCl_3$): δ = 198.1 (CO), 105.5, 100.9, 98.4, 96.9 (C_5Me_4), 49.2 (C-5), 43.2 (C-1), 39.42, 34.4 (C-2/6/10), 39.1 (br., C-3), 33.9 (C-4), 28.7, 23.5 (C-8/9), 21.2 (C-7), 12.0, 10.9, 10.8 (C_5Me_4). − $C_{22}H_{29}O_3Re$ (527.66): calcd. C 50.08, H 5.54; found C 50.08, H 5.52.

[(η^5-PinCp*)Re(CO)$_2$(NO)]$^+$BF$_4^-$ (2): Compound **1** (2.30 g, 4.36 mmol) was dissolved in 100 mL of CH_2Cl_2 and cooled to 0°C. Freshly prepared $NOBF_4$ (0.79 g, 6.77 mmol) was added in small portions and CO started to evolve immediately. After 3 h of stirring, the solution was poured into 300 mL of diethyl ether and a light yellow precipitate formed. The solid was collected by filtration and washed with diethyl ether. Recrystallisation from CH_2Cl_2/*n*-hexane gave a yellow compound **2**; yield: 2.63 g (4.27 mmol, 98%). − IR (hexane): $\tilde{\nu}_{(CO)}$ = 2093 (s), 2040 (s); $\tilde{\nu}_{(NO)}$ = 1799 (m) cm^{-1}. − ^{1}H NMR ([D$_6$]acetone): δ = 3.37 (q, *J* = 9.5 Hz, 1 H, H-4), 2.64 (s, 3 H, C_5Me_4), 2.57 (s, 3 H, C_5Me_4), 2.50 (d, J_{H-H} = 2.8 Hz, 6 H, 2∞ C_5Me_4), 2.47 (m, 1 H), 2.35 (m, 2 H), 2.12 (m, 1 H), 1.99 (m, 2 H), 1.30 (s, 3 H, H-9), 1.28 (s, 1 H), 1.22 (s, 3 H, H-8), 1.12 (d, J_{H-H} = 7.0 Hz, 3 H, H-7). − ^{13}C NMR ([D$_6$]acetone): δ = 187.0, 186.9 (CO), 112.1, 109.2 (C_5Me_4), 49.9 (C-5), 43.8 (C-1/3), 40.1, 38.3, 34.9 (C-2/6/10), 35.2 (C-4), 29.0, 23.7 (C-8/9), 21.4 (C-7), 11.9, 11.7, 10.5, 10.3 (C_5Me_4). − $C_{21}H_{29}BF_4NO_3Re$ (616.47): calcd. C 40.91, H 4.74, N 2.27; found C 40.56, H 2.25, N 2.25.

(*S*$_{Re}$)/(*R*$_{Re}$)-[(η^5-PinCp*)Re(CO)(NO)(PPh_3)]$^+$BF$_4^-$ (3a/3b): The nitrosyl complex **2** (2.56 g, 4.16 mmol) was dissolved in 50 mL of acetonitrile and freshly prepared iodosobenzene (1.05 g, 4.78 mmol) was added at 0°C. CO_2 evolution started immediately and the solution was stirred until the solid had dissolved (about 1.5 h). The solution was filtered through 2 cm of silica gel and after evaporation of the solvent (*S*$_{Re}$)/(*R*$_{Re}$)-[(η^5-PinCp*)Re(CH_3CN)(NO)(PPh_3)]$^+$BF$_4^-$ was obtained as a brown oil. − IR (CH_3CN): $\tilde{\nu}_{(CO)}$ = 2010 (s), $\tilde{\nu}_{(NO)}$ = 1743 cm^{-1}. − The oil was dissolved in 2-butanone and PPh_3 (1.33 g, 5.09 mmol) was added in small portions while stirring. The dark-brown mixture was refluxed for 12 h and the solvent was removed afterwards by vacuum distillation. The residue was recrystallized from acetone/Et_2O; yield of yellow **3a/3b**: 3.18 g (3.74 mol, 90%). − IR (CH_2Cl_2): $\tilde{\nu}_{(CO)}$ = 2005 (s), $\tilde{\nu}_{(NO)}$ = 1747 (s) cm^{-1}. − ^{1}H NMR ([D$_6$]acetone): δ = 7.70−7.50 (m, 30 H, PPh_3), 3.45 (q, J_{H-H} = 9.46 Hz, 1 H, H-4), 3.40 (q, J_{H-H} = 7.02, 1 H, H-4′), 2.85 (s, 3 H), 2.50 (s, 3 H), 2.46 (m, 1 H), 2.38 (m, 3 H), 2.31 (s, 3 H), 2.27 (s, 3 H), 2.16 (m, 3 H), 2.00 (m, 2 H), 1.86 (s, 3 H), 1.71 (s, 3 H), 1.51 (s, 3 H), 1.33(s, 1 H), 1.30 (m, 6 H), 1.27 (s, 3 H), 1.24 (s, 3 H), 1.12 (m, 6 H). − ^{13}C NMR ([D$_6$]acetone): δ = 201.8 (d, J_{C-P} = 12.6 Hz, CO), 201.4 (d, J_{C-P} = 12.6 Hz, CO′), 134.3 (d, J_{C-P} = 11.4 Hz, C-b), 134.1 (d, J_{C-P} = 11.4 Hz, C-b′), 133.3 (dd, J_{C-P} = 6.6 Hz, C-d/d′), 131.2 (d, J_{C-P} = 12.6 Hz, C-a/a′), 130.7 (d, J_{C-P} = 11.4 Hz, C-c), 130.6 (d, J_{C-P} = 11.4 Hz, C-c′), 115.5, 114.7, 109.7, 107.5, 106.0 (C_5Me_4), 50.2 (C-5/5′), 44.4 (br. s, C-3/3′), 43.9, 43.7 (C-1/1′), 40.2, 40.1 (C-10/10′), 37.8, 36.3 (C-4/4′), 35.9, 35.6, 34.9 (C-2/2′/6/6′), 29.4, 29.0, 23.9, 23.7 (C-8/8′/9/9′), 21.8, 21.7 (C-7/7′), 15.1, 11.8, 11.6, 10.2, 10.0, 9.8, 9.4 (C_5Me_4). − ^{31}P NMR ([D$_6$]acetone): δ = 12.9. − $C_{38}H_{44}BF_4NOPRe$ (834.71): calcd. C 53.65, H 5.21, N 1.65; found C 52.98, H 5.22, N 1.64.

(*S*$_{Re}$)/(*R*$_{Re}$)-(η^5-PinCp*)Re(CH_3)(NO)(PPh_3) (4a/4b): The diastereomeric mixture of **3** (1.56 g, 1.83 mmol) was suspended in 50 mL of THF and 3.7 mL of Li(C_2H_5)$_3$BH in THF (1 M in THF, 3.7 mmol) was injected. The precipitate dissolved slowly, while the colour of the solution became honey-brown. Then 9.2 mL of 0.776 M BH_3·THF in THF (7 mmol) was added. H_2 evolution occurred immediately and the solution was stirred for 30 min. The

solvent was then removed and the residue extracted with toluene and passed through a short silica gel column. The solvent was evaporated to give complex **4a/4b** as a red powder; yield 1.31 g (1.74 mmol, 95%). − IR (hexane): $\nu_{(NO)}$ = 1634 (s) cm^{-1}. − ^1H NMR ($CDCl_3$): δ = 7.50−7.32 (m, 30 H, PPh_3), 3.22 (q, J_{H-H} = 9.46 Hz, 1 H, H-4), 3.13 (q, J_{H-H} = 9.46 Hz, 1 H, H-4′), 2.38 (m, 2 H), 2.28 (m, 2 H), 2.21 (m, 2 H), 2.06 (s, 3 H), 2.00(m, 1 H), 1.90 (m, 4 H), 1.82 (s, 3 H), 1.80 (s, 3 H), 1.53(s, 3 H), 1.50 (s, 3 H), 1.29−1.23 (6 s, 18 H), 1.11 (d, J_{H-H} = 7.02 Hz, 3 H), 1.06 (d, J_{H-H} = 7.02 Hz, 3 H), 0.84 (d, J_{H-P} = 7.02, 3 H, Re−Me), 0.79 (d, J_{H-P} = 7.02 Hz, 3 H, Re−Me′), 0.68 (s, 3 H), 0.5 (s, 3 H). − ^{13}C NMR ($CDCl_3$): δ = 136.4, 136.0 (d, J_{C-P} = 47.7 Hz, C-a), 136.0, 135.6 (d, 47.7 Hz, C-a′), 134.08, 134.01 (d, J_{C-P} = 9.8 Hz, C-b), 134.04, 133.96 (d, 10.4 Hz, C-b′), 129.5 (C-d/d′), 128.1, 128.0 (C-c/c′), 107.5, 105.9, 103.7, 103.6, 100.4, 96.6, 95.6, 94.7 (C_5Me_4), 49.6, 49.5 (C-5/5′), 43.8 (br., C-3/3′), 43.2, 43.1 (C-1/1′), 39.6, 39.5 (C-10/10′), 35.7, 35.4, 34.8, 34.6,34.4 (C-4/4′/2/2′/6/6′), 28.9, 23.6, 23.5 (C-8/8′/9/9′), 21.6, 21.5 (C-7/7′), 11.9,11.8, 10.8, 10.7, 10.6, 7.6, 7.3 (C_5Me_4), −22.7 (d, J_{C-P} 7.0 Hz, Re−Me), −24.7 (d, J_{C-P} = 7.2 Hz, Re−Me). − ^{31}P NMR (C_6D_6): δ = 25.7 (br.), 23.4. − $C_{38}H_{47}NOPRe$ (750.92): calcd. (S_{Re})/(R_{Re})-[(η⁵-PinCp*)Re(NO)(PPh_3)($ClCD_2Cl$)]$^+BF_4^-$ (7a/7b) (NMR Experiment): A 5-mm NMR tube was filled with a solution of **4a/4b** (60.0 mg, 0.08 mmol) in 0.7 mL of CD_2Cl_2. The NMR tube was cooled to −78 °C and 11 μL of HBF_4·Et_2O (54% in Et_2O, 0.081 mmol) was added by syringe. The tube was sealed, shaken

quickly and a ^{31}P-NMR spectrum was measured at −80°C immediately. − ^{31}P NMR (CD_2Cl_2): δ = 14.7, 14.3, 14.2 (−80°C); 14.6, 14.1, 14.0 (−60°C); 14.5 (v br.), 14.0, (br.), 13.9 (−40°C); 13.9 (v br.), 13.8 (−20°C).

(S_{Re})-[(η^5-PinCp*)Re(NO)(PPh_3)($ClCD_2Cl$)]$^+BF_4^-$ (7a) (NMR Experiment): Optically pure **4a** was treated the same way as the diastereomeric mixture. − ^{31}P NMR (CD_2Cl_2): δ = 14.7, 14.3 (−80°C); 14.6, 14.1 (−60°C); 14.5 (v br.), 14.0, (br.) (−40°C); 13.9 (v br.) (−20°C).

(S_{Re})/(R_{Re})-(η^5-PinCp*)ReCl(NO)(PPh_3) (8a/8b): Complexes **4a/4b** (60 mg, 0.08 mmol) were dissolved in 10 mL of CH_2Cl_2 and cooled to −78°C. 11.8 µL HBF_4·Et_2O (54% in Et_2O, 0.087 mmol) was added by syringe and the mixture was stirred at this temperature for 10 min. Then $[Ph_3PCH_3]^+I^-$ (39.5 mg, 0.098 mmol) was added and the cooling bath was removed. The solution was warmed to room temperature, passed through 3 cm of silica gel and dried. Yield of a red solid **8a/8b**: 49.3 mg (0.06 mmol, 80%). − IR (CH_2Cl_2) $\tilde{\nu}_{(NO)}$ = 1641 cm^{-1}. − ^{1}H NMR ($CDCl_3$): δ = 7.60−7.52 (m, 6 H, H-b), 7.37 (m, 9 H, H-c/d), 3.14 (q, J_{H-H} = 9.46 Hz, 1 H, H-4), 3.06 (q, J_{H-H} = 9.46 Hz, 1 H, H-4′), 2.49 (m, 1 H), 2.34 (m, 2 H), 2.29 (m, 1 H), 2.20 (m, 2 H), 2.05 (m, 4 H), 1.96 (s, 1 H), 1.92 (m, 1 H), 1.89 (m, 2 H), 1.75 (s, 3 H), 1.73 (s, 3 H), 1.65 (s, 3 H), 1.3 (s, 3 H), 1.28−1.16 (6s, 18 H), 1.14 (d, J_{H-H} = 6.7 Hz, 3 H), 1.11 (d, 7.0 Hz, 3 H), 0.85 (m, 3 H), 0.78 (s, 3 H). − ^{13}C NMR ($CDCl_3$): δ = 134.32, 134.24 (d, J_{C-P} = 10.4 Hz, C-b), 134.29, 134.21 (d, J_{C-P} = 9.9 Hz, C-b′), 130.0 (C-d/d′), 128.3, 128.2 (C-c/c′), 115.9, 115.5, 107.9, 105.3, 103.8, 97.3, 95.7, 93.2, 90.7 (C_5Me_4), 49.5, 49.3 (C-5/5′), 43.3 (br., C-3/3′), 43.0, 42.9 (C-1/1′), 39.5 (C-10/10′), 36.4, 34.7, 34.5, 34.3 (C-2/2′/6/6′), 34.9 (C-4/4′), 28.8, 28.7, 23.5, 23.4 (C-8/8′/9/9′), 21.6, 21.4 (C-7/7′), 12.1, 11.6, 11.4, 10.9, 10.7, 10.6, 8.4, 7.0 (C_5Me_4/C_5Me_4′). − ^{31}P NMR ($CDCl_3$): δ = 17.0 (br.), 15.2 (25°C); 17.5 (v br.), 15.4 (0°C); 18.1 (br.), 16.3 (v. br.), 15.5 (−25°C); 18.4, 16.6, 15.6 (−50°C). − MS (EI); *m*/*z* (%): 771 (10) [M$^+$].

[(η^5-PinCp*)$_2$$RhCl_2$]$_2$ (9): PinCp*H (2.00 g, 7.70 mmol) was dissolved in 50 mL of methanol and Rh_3·$3H_2O$ (0.96 g, 37.4% Rh, 3.50 mmol) was added. The light red solution was refluxed for 5 d and the solvent was concentrated to 10 mL afterwards. Storage at 5°C for several hours gave a red solid, which was filtered, washed with diethyl ether and dried. Compound **9** can be recrystallized from CH_2Cl_2/Et_2O. Yield of the red solid **9**: 1.52 g (1.76 mmol, 50%). − ^{1}H NMR ($CDCl_3$): δ = 2.82 (q, J_{H-H} = 9.46 Hz, 1 H, H-4), 2.49 (m, 1 H), 2.35 (m, 1 H), 2.06 (m, 2 H), 1.90 (m, 2 H), 1.83 (s, 3 H), 1.80 (s, 3 H), 1.65 (s, 3 H), 1.61 (s, 3 H), 1.24 (s, 3 H), 1.14 (s, 3 H), 0.95 (d, J_{H-H} = 10.1 Hz), 0.98 (d, J_{H-H} = 6.7 Hz). − ^{13}C NMR ($CDCl_3$): δ = 100.1, 98.2, 96.3, 93.1, 90.8 (C_5Me_4), 48.8 (C-5), 42.2 (C-1), 41.3 (br., C-3), 39.6, 34.3 (C-2/6), 32.7 (C-4), 32.5 (C-10), 28.8, 23.5 (C-8/9), 21.6 (C-7), 11.6, 11.1, 10.0, 9.2 (C_5Me_4). − $C_{38}H_{58}Cl_4Rh_2$ (862.5): calcd.: C 52.92, H 6.78; found C 53.41, H 6.75.

(η^5-PinCp*)$TiCl_3$ (10): PinCp*Li (0.86 g, 3.46 mmol) was dissolved in DME and $TiCl_3$·3THF (0.43 g, 1.15 mmol) was added at −78°C. The solution was warmed to room temp. and refluxed for 2 d. Concd. HCl (2.7 mL) was added carefully at −30°C, followed by 10 mL of chloroform. The layers were separated and the organic layer was dried with $NaSO_4$. The solvent was removed and the nearly dry residue was transferred to a Soxhlet extractor. The extraction was performed with pentane saturated with HCl gas. The red solution, obtained after 30 min, was dried and a red solid was obtained. Yield of the red solid **10**: 0.13 g (0.32 mmol, 28%). − ^{1}H NMR ($CDCl_3$): δ = 3.63 (q, J_{H-H} = 9.46 Hz, 1 H, H-4), 2.67 (s, 3 H), 2.47 (s, 3 H), 2.46 (s, 3 H), 2.43−2.34 (m, 1 H), 2.27 (s, 3 H), 2.22−2.17 (m, 1 H), 2.13 (m, 1 H), 1.90 (m, 1 H), 1.80 (m, 1 H), 1.28 (s, 3 H), 1.26 (m, 2 H), 1.23 (s, 3 H), 0.95 (d, J_{H-H} = 7.02 Hz, 3 H). − ^{13}C NMR ($CDCl_3$): δ = 148.8, 141.2, 137.9, 137.1, 134.3 (C_5Me_4), 49.4 (C-5), 43.8 (br., C-3), 42.6 (C-1), 39.6 (C-10), 37.6 (C-4), 34.4, 33.5 (C-2/6), 28.8, 23.5 (C-8/9), 21.7 (C-7), 16.6, 15.6, 15.2, 14.0 C_5Me_4). − MS (EI): *m*/*z* (%): 375 (7) [M$^+$ − Cl], 256 (80) [PinCp*$^+$]. − $C_{19}H_{29}Cl_2Ti$ (411.7): calcd.: C 55.43, H 7.10; found C 56.18, H 7.21.

(η^5-PinCp*)$Mo(CO)_2(NO)$ (11): PinCp*Li (3.54 g, 13.41 mmol) was dissolved in THF and, after addition of $Mo(CO)_6$ (3.33 g; 13.41 mmol), the reaction mixture was heated under reflux for 12 h. After cooling the solution, Diazald (2.7 g, 12.60 mmol), dissolved in 10 mL of THF, was added dropwise, so that the temperature did not exceed room temp. Stirring was continued for 3 h, with a continuous slight flow of nitrogen over the solution. The solvent was distilled off and the residue was sublimed at 140°C and 10^{-3} bar. The sublimed product was then purified by chromatography (Al_2O_3; hexane/ether, 4:1) to give red crystals after evaporation of the solvent. Yield: 3.60 g (8.19 mmol, 65%). − IR (hexane): $\tilde{\nu}_{(CO)}$ = 2004 (s), 1930 (s), $\tilde{\nu}_{(NO)}$ = 1667 cm^{-1}. − ^{1}H NMR ($CDCl_3$): δ = 3.03 (q, J_{H-H} = 9.77 Hz, 1 H, H-4), 2.37 (m, 1 H) 2.17 (s,3 h), 2.12 (m, 3 H), 2.07 (s, 3 H), 2.03 (s, 3 H), 2.03 (s, 3 H), 1.85 (m, 2 H), 1.26 (s, 3 H), 1.21 (m, 1 H), 1.17 (s, 3 H) 1.02 (d, J_{H-H} = 7.02 Hz, 3 H). − ^{13}C NMR ($CDCl_3$): δ = 230.7, 230.6 (CO), 114.8, 108.2, 106.0, 105.1 (C_5Me_4), 49.2 (C-5), (43.5 (br., C-3) 43.1 (C-1) 39.5 (C-2/6), 38.0 (C-10), 34.5 (C-4), 28.8, 23.5 (C-8,9), 21.5 (C-7), 12.1, 12.0, 10.9, 10.8 (C_5Me_4). − $C_{21}H_{29}NO_3Mo$ (439.4): calcd.: C 57.40, H 6.65, N 3.19; found: C 57.62, H 6.72, N 3.15.

(η^5-PinCp*)$W(CO)_2NO$ (12): (η^5-PinCp*)$W(CO)_2NO$ (**12**) was prepared in a similar way to **11** from PinCp*Li (3.00 g 11.40 mmol) and $W(CO)_6$ (4.05 g, 11.50 mmol) after 5 d of reflux. Diazald (2.44 g, 11.4 mmol) was added as before. Yield: 3.61 g (6.84 mmol, 60%), red crystals. − IR (hexane): $\tilde{\nu}_{(CO)}$ = 1995 (s), 1918 (s), $\tilde{\nu}_{(NO)}$ = 1661 cm^{-1}. − ^{1}H NMR ($CDCl_3$): δ = 3.03 (q, J_{H-H} = 9.2 Hz, 1 H, H-4), 2.35 (m, 1 H) 2.27 (s, 3 H), 2.18 (s, 3 H), 2.14 (s, 3 H), 2.10 (s, 3 H), 1.89 (m, 2 H), 1.25 (s, 3 H), 1.19 (m, 1 H), 1.16 (s, 3 H) 0.99 (d, J_{H-H} = 7.0 Hz, 3 H). − ^{13}C NMR ($CDCl_3$): δ = 222.4 (2CO), 113.4, 106.4, 104.6, 104.0 (C_5Me_4), 49.4 (C-5), (43.4 (C-3) 43.2 (C-1) 39.4 (C-10))34.8 (C-2/6), 34.5 (C-4), 28.8, 23.4 (C-8,9), 21.1 (C-7), 11.8, 10.7, 10.6 (C_5Me_4). − $C_{21}H_{29}NO_3W$ (527.31): calcd.: C 47.83, H 5.54, N 2.66; found C 48.51, H 5.61, N 2.70.

(η^5-PinCp*)$MoCl_2(NO)$ (13): Compound **11** (0.85 g, 1.94 mmol) was dissolved in ether and treated slowly at 0°C with solid PCl_5 (0.40 g, 1.94 mmol). Stirring was continued for 12 h at room temp.; the solution turned a vivid green with a green solid precipitate. After addition of 30 mL of hexane, the volume was reduced to 10 mL under vacuum. The green solid was filtered, washed with a small amount of cold ether and dried. Yield 0.75 g (1.65 mmol, 85%). − IR (THF): $\tilde{\nu}_{(CO)}$ = 1660 cm^{-1}. − ^{1}H NMR ($CDCl_3$): δ = 3.13 (q, J_{H-H} = 9.46 Hz, 1 H, H-4), 2.38 (m, 1 H), 2.23 (s, 3 H), 2.19 (m, 3 H), 2.10 (s, 3 H), 2.06 (m, 3 H) 1.95 (s, 3 H) 1.86 (m, 2 H), 1.26 (s, 3 H), 1.18 (m, 1 H) 1.14 (s, 3 H) 1.00 (d, J_{H-H} = 7.02 Hz), 3 H). − ^{13}C NMR ($CDCl_3$): δ = 127.0, 125.8, 124.6, 119.1 (C_5Me_4), 49.2 (C-5), 43.1 (br., C-3) 42.4 (C-1), 39.5, 34.5 (C-2/6), 34.9 (C-4). 33.2 (C-10) 28.8, 23.4 (C-8/9), 21.8 (C-7), 12.9, 12.6, 10.7, 10.3 (C_5Me_4). − MS: *m*/*z* (%): 455 (20) [M$^+$], 425 (95) [M$^+$ − NO], 385 (25) [M$^+$ − 2 Cl]. − $C_{19}H_{29}Cl_2NOMo$ (454.27): calcd.: C 48.88, H 6.60; found C 48.63, H 6.49.

(η^5-PinCp*)$WCl_2(NO)$ (14): Compound **12** (1.07 g, 2.03 mmol) was dissolved in ether and was treated slowly at 0°C with solid PCl_5 (0.42 g, 2.03 mmol). Reaction and workup as above. Yield

0.95 g(1.75 mmol, 86%). − IR (THF): $\tilde{\nu}_{(CO)}$ = 1632 cm^{-1}. − ^1H NMR ($CDCl_3$): δ = 3.15 (q, J_{H-H} = 9.53 Hz, 1 H, H-4), 2.42 (s, 3 H), 2.25 (s, 3 H), 2.21 (s, 3 H), 2.15 (m, 2 H), 2.04 (m, 3 H) 2.02−1.78 (m, 4 H) 1.86 (m, 2 H), 1.26 (s, 3 H), 1.21 (m, 1 H) 1.16 (s, 3 H) 1.00 (d, J_{H-H} = 7.02 Hz, 3 H). − ^{13}C NMR ($CDCl_3$): δ = 124.2, 123.2, 119.3, 117.3 (C_5Me_4), 49.9 (C-5), 43.4 (br., C-3) 43.1 (C-1), 39.9, 35.5 (C-2/6), 34.4 (C-4). 33.2 (C-10) 29.0, 23.6 (C-8/9), 21.8 (C-7), 12.5, 12.3, 10.8, 10.3 (C_5Me_4). − MS: *m*/*z* (%): 543 (40) [M^+], 490 (70) [M^+ − Cl, − NO], 385 (30) [M^+ − 2 Cl, − NO]. − $C_{19}H_{29}Cl_2NOW$ (542.18): calcd.: C 40.78, H 5.51; found C 40.52, H 5.39.

(η⁵-PinCp*)W(CH_2SiMe_3)$_2$NO (15): Compound **14** (346.9 mg, 0.64 mmol) and [$(CH_3)_3Si(CH_2)_2Mg$]·(dioxan)$_2$ (246.1 mg, 0.64 mmol) were mixed as solids in a Schlenk tube. After cooling to −196°C, 20 mL of THF was slowly condensed into the tube under vacuum. After waiting for 10 min, the Schlenk tube was transferred into a Dewar cooled to −78°C. The temperature was allowed to rise to −50°C and kept at this temperature for 12 h. The solution assumed a deep purple colour. The solvent was evaporated at 0°C, the residue taken up in cold ether and filtered at −20°C through Celite. A purple residue was obtained after evaporating the solvent at 0°C, yield 315.9 mg (0.51 mmol, 80%). − IR (hexane): $\tilde{\nu}_{(CO)}$ = 1582 (s) cm^{-1}. − ^1H NMR (C_6D_6): δ = 3.03 (q, J_{H-H} = 9.15 Hz, 1 H, H-4), 2.28 (m, 2 H), 2.13 (m, 1 H), 1.90 (s, 3 H), 1.82 (s, 3 H), 1.78 (m, 1 H), 1.71 (d, J_{H-H} = 11.58, 1 H, H-a1), 1.68 (S, 3 H), 1.66 (d, J_{H-H} = 11.29 Hz, 1 H, H-b1), 1.49 (s, 3 H), 1.33−1.22 (m, 2 H), 1.17 (s, 3 H), 1.10 (m, 1 H), 1.08 (s, 3 H), 0.93 (d, J_{H-H} = 7.01 Hz, 3 H), 0.38 (2 s, 18 H, $SiMe_3$), −1.21 (d, J_{H-H} = 11.29 Hz, 1 H, H-b2), −1.29 (d, J_{H-H} = 11.58 Hz, 1 H, H-a2). − ^{13}C NMR (C_6H_6): δ = 119.2, 117.2, 113.6, 112.2 (C_5Me_4), 65.2, 63.4, (2 × C-11), 49.6 (C-5), 43.0 (br., C-3), 42.8 (C-1), 39.5, 35.0 (C-2/6), 34.9 (C-4), 30.1 (C-10), 28.9, 23.5 (C-8/9) 21.8 (C-7), 14.3, 12.0, 9.7, 9.5 (C_5Me_4), 1.41, 1.37 ($SiMe_3$). − $C_{27}H_{51}NOSi_2W$ (645.72): calcd. C 49.28, H 8.11; found C 49.64, H 8.23.

X-ray Crystallographic Study: (S_{Re})-[(η⁵-PinCp*)Re(COOMe)NO-(PPh_3) (**5a**) crystallizes in the orthorhombic space group $P2_12_12_1$ (no. 19). Crystal data: $C_{50}H_{56}N_2O_2PRe$, formula mass 934.19 g mol^{-1}, *a* = 11.522(5), *b* = 18.789(2), *c* = 20.116(6) Å, *V* = 4355(2) $Å^3$, *Z* = 4, $d_{calcd.}$ = 1.425 g cm^{-3}, μ(Mo-K_α) = 29.02 cm^{-1}, *F*(000) = 1904. Intensity data were collected at 203 K on an orange rod of approximate dimensions 0.47 × 0.18 × 0.15 mm with an ENRAF-Nonius CAD4 diffractometer in the ω mode up to θ_{max} = 26°. A total of 11726 reflections were corrected for Lorentz and polarization effects and for absorption (numerical by Gaussian integration;[28] min. transmission 0.5339, max. transmission 0.6826). After averaging symmetry-equivalent data, the structure was solved[29] by Patterson and subsequent Fourier difference synthesis. Full-matrix least-squares refinement on *F*[29] of 428 variables for 7010 independent observations with $I > 1.0\ \sigma(I)$ converged at *R* = 0.057, R_w = 0.058 [$w^{-1} = \sigma^2(F_o)$], *GOF* = 1.338. During refinement the naphtyl moiety was treated as a rigid group, all other non-hydrogen atoms were assigned anisotropic displacement parameters, and hydrogen atoms were included as riding in calculated positions [C−H = 0.98 Å, U_{iso}(H) = 1.3 U_{eq}(C)]. A final Fourier difference synthesis showed a residual electron density of ca. 3 $eÅ^{-3}$ in the region of the disordered naphtyl moiety. Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data centre as supplementary publication no. CCDC-114499. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

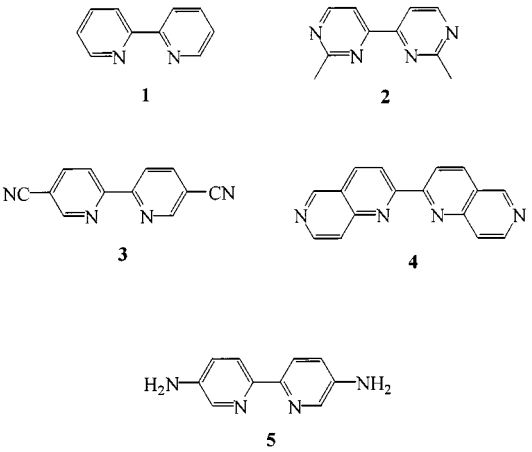
Modified Bipyridines: 5,5′-Diamino-2,2′-bipyridine Metal Complexes Assembled into Multidimensional Networks via Hydrogen Bonding and π–π Stacking Interactions

Christoph Janiak,*[a] Stephan Deblon,[a] He-Ping Wu,[a] Mario J. Kolm,[a] Peter Klüfers,*[b] Holger Piotrowski,[b] and Peter Mayer[b]



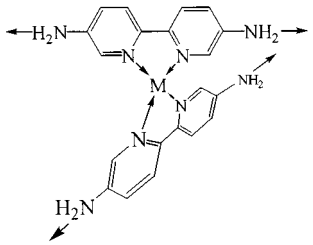
Keywords: 2,2′-Bipyridines / Chelate complexes / Hydrogen bonding / π–π stacking / Crystal structure

A new synthetic route for the synthesis of 5,5′-diamino-2,2-bipyridine (**5**) based on the coupling of 2-chloro-5-aminopyridine in the presence of $NiCl_2 \times 6\ H_2O/PPh_3/Zn$ in dimethylformamide is described. The reactions of the potentially ambidentate ligand **5** with salts of the transition metals Mn, Fe, Ni, Cu, Zn, Ag, and Cd gave a variety of 13 metal–ligand complexes depending on the anion, the crystallization conditions and the metal-to-ligand ratio. The complexes obtained were characterized by thermal analyses, NMR including ^{113}Cd-NMR, IR, and for the iron complex ^{57}Fe-Mößbauer spectroscopy. The structure of eight of the compounds was elucidated by X-ray crystallography. All of these metal complexes show a bipyridine–metal coordination. The amino functionality was never involved in metal coordination. The intermolecular arrangement is dictated by hydrogen bonding from the amino functionality and by π–π stacking of the bipyridine rings.

Introduction

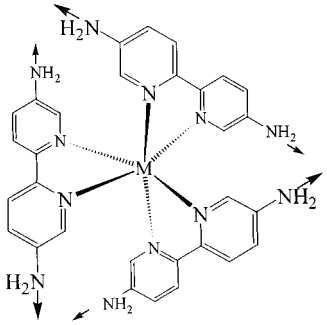
Metal complexes of chelating 2,2′-bipyridine (bipy, **1**) and secondary terminal or chelating amines are of constant and general interest in metal-coordination chemistry.[1] We have recently engaged into a program to study the coordination behavior of modified 2,2′-bipyridine ligands such as 2,2′-dimethyl-4,4′-bipyrimidine (**2**),[2] 5,5′-dicyano-2,2′-bipyridine (**3**),[3] 2,2′-bi-1,6-naphthyridine (**4**),[4] and modified tris(pyrazolyl)borate ligands.[5] As part of this program we report here the coordinating properties of ambidentate 5,5′-diamino-2,2′-bipyridine (**5**). The idea behind the use of such ambidentate ligands is to have tetrahedral (**6**) or octahedral building blocks (**7**) for supramolecular assemblies based on the chelation of two or three ligands, respectively with an appropriate metal center. The intermolecular connectivity should then be controlled through an NH_2→metal coordination or through hydrogen bonding.[6][7] The amino group on the aromatic ring is a good candidate for hydrogen bonding as has been exploited in the self-assembly of supramolecular entities with 2,4,6-triaminopyrimidine units, for example.[8] The related ligand 2,2′-bipyridine-5,5′-dicarboxylate forms tris(chelate) complexes which are then connected by hydrogen bonding.[9]

Rigid bridging ligands have recently gained considerable interest in the synthesis of (rectangular) two-dimensional network structures.[10] The generation of such frameworks is a promising path in the search for stable microporous metal-organic networks that exhibit reversible guest exchange and possibly selective catalytic activity.[11]



Results and Discussion

Ligand Synthesis



The synthesis of **5** has been achieved according to a route suggested by Whittle (Scheme 1):[12] 5,5′-Dimethyl-2,2′-bipyridine (**9**) is obtained in medium yield by a Raney nickel catalyzed coupling reaction from β-picoline (**8**).[13][14] Oxidation with $KMnO_4$ and esterification of the acid then yields the 5,5′-diester **10**.[15] Hydrazinolysis of the ester group and hydrazine-azide transformation gives the acyl azide **11**. In a Curtius rearrangement this acyl azide is converted by pyrolysis to the isocyanate (R−N=C=O) from which in the presence of ethanol the dicarbamate **12** is derived. Alkaline hydrolysis and sublimation leads to the final

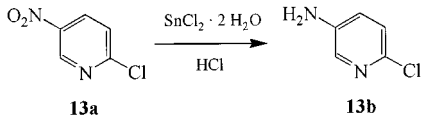
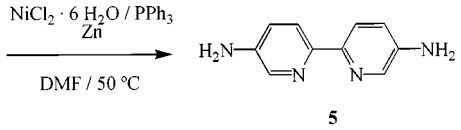
product **5** in an overall yield of 38% based on 5,5′-dimethyl-2,2′-bipyridine.



8 9 10 11 12 5

Scheme 1. Synthesis of **5** starting from 3-aminopyridine (**8**)



In order to shorten the synthesis of **5** and to improve the yield, we also tried a new method, namely the coupling of 5-amino-2-chloropyridine (**13**). It was reported in the literature that the coupling of haloaryl or halopyridine compounds in the presence of a catalytic system consisting of $NiCl_2 \times 6\ H_2O$/L/reducing agent could lead to the formation of bipyridine and biaryl derivatives. Such *ni*ckel-containing *c*omplex-*r*educing *a*gents are generally abbreviated as NiCRALs, L representing PPh_3 or 2,2′-bipyridine. Reducing agents can be zinc[16] or a mixture of sodium hydride and sodium *tert*-butoxide.[17][18] Zerovalent nickel complexes for the coupling of aryl halides were initially introduced by Semmelhack and co-workers.[19]

For the coupling of 5-amino-2-chloropyridine the use of sodium hydride as a reducing agent for the nickel complex to give the NiCRAL was unsuccesful. The necessary excess of NaH apparently deprotonates the amino function of the pyridine, which then coordinates to the nickel center so that the reaction is slowed down considerably. After 5 d under reaction conditions, the starting compound was still present and only traces of **5** were found. This is remarkable, since under the same conditions 2-amino-3-chloropyridine is coupled to the 2,2′-diamino-3,3′-bipyridine in 44% yield in 17 h.[17]

The use of zinc powder as a reducing agent for the NiCRAL was eventually successful: A solution of nickel(II) chloride hexahydrate and triphenylphosphane in DMF was reduced with zinc and was subsequently treated with a stoichiometric amount of 5-amino-2-halopyridine. No pyridine compound could be detected anymore after 2−2.5 h and workup yielded the coupling product **5** in over 60% yield (Scheme 2). The starting compound for the coupling reaction, the amino-substituted 2-halopyridine **13b** was obtained from the commercially available 2-chloro-5-nitropyridine (**13a**).[20]

Syntheses of Metal Complexes of 5

Different methods were used for the syntheses of metal complexes of **5**. An overview of the prepared metal compounds is provided in Scheme 3.

In the case of the manganese complexes $[Mn(\mathbf{5})_3]Cl_2$ (**14**) and $[Mn(N_3)_2(\mathbf{5})_2]$ (**15**) it was sufficient to combine the reactands in solution and let them stand for some time. For the d^5-high-spin Mn^{2+} ion ligand substitution results only in a small gain of energy because of the theoretically zero ligand field stabilization energy (LFSE). Hence, the thermodynamic driving force for the formation of the manganese chelate complexes from the hexaaquametal ions is small and the reaction proceeds much slower than for iron, nickel and copper which have larger LFSE contributions.[21]

Heating an aqueous suspension or an ethanolic solution of **5** with a solution of the metal salt in water gave upon cooling the tris(5,5′-diamino-2,2′-bipyridine)metal complexes $[M(\mathbf{5})_3]^{2+}$ of iron as the sulfate (**16**), nickel as the chloride (**17**), zinc as the nitrate (**22**), and cadmium as the chloride (**26**). Furthermore, the mono(5,5′-diamino-2,2′-bipyridine)diaqua(μ-sulfato)copper compound **19** and a

Scheme 3. The metal complexes of 5,5′-diamino-2,2′-bipyridine (**5**)

mono(5,5′-diamino-2,2′-bipyridine)silver derivative (see **23**) was obtained by such a hydrothermal reaction. Also $[Zn(NO_3)_2(\mathbf{5})]$ (**21**) and $[Cd(\mu\text{-}Cl)_2(\mathbf{5})]$ (**25**) react with two equivalents of **5** under reflux to form the homoleptic tris(chelate) complexes $[Zn(\mathbf{5})_3](NO_3)_2$ (**22**) and $[Cd(\mathbf{5})_3]Cl_2$ (**26**), respectively. This observation agrees with the complexation behavior found for 2,2′-bipyridine.[22]

A different synthetic route was chosen for complexes where the coordination sphere was not completely constructed by the diaminobipyridine chelate ligand **5**. Such was the case for the compounds $[CuCl_2(\mathbf{5})]$ (**20**), $[Cd(\mu\text{-}Cl)_2(\mathbf{5})]$ (**24**), and the presumable silver complex $[Ag(NO_3)(\mathbf{5})]$ (**23**). Here the synthesis was carried out at room temperature mostly by overlayering the aqueous metal salt solution with an ethanolic solution of **5**. To slow down the diffusion of both solvents a layer of ethyl acetate was brought in between the water and the ethanol phase. In three cases it could be shown that the above heteroleptic complexes may be viewed as thermodynamically unstable intermediates along the reaction coordinate to the homoleptic compounds. The 1:1 ligand/metal complexes **21** and **25** react with two equivalents of **5** under reflux to the thermodynamically apparently more stable tris(chelate) complexes $[Zn(\mathbf{5})_3](NO_3)_2$ (**22**) and $[Cd(\mathbf{5})_3]Cl_2$ (**26**), respectively. A 1:1 ligand/silver complex (as **23**) is initially obtained from the reaction of two equivalents of **5** with one equivalent of Ag^+. This complex dissolves in concentrated aqueous ammonia and upon slow evaporation produces the 2:1 ligand/metal complex $[Ag(\mathbf{5})_2]NO_3$. Such a recrystallization involves formation of the intermediate $[Ag(NH_3)_2]^+$ complex and slow ligand exchange of the stronger, yet more volatile ammine ligand with **5**.[23] A similar ligand exchange was used in the synthesis of the complex $[Ni(\mathbf{5})_3](SCN)_2$ (**18**) which was obtained from mixing the reactands $NiCl_2$, **5**, and KSCN and adding concentrated ammonia, so that the rather stable amminenickel complex $[Ni(NH_3)_6]^{2+}$ is formed. In addition to the synthetic procedures described in the Experimental Section, the reactions were carried out with different concentrations and different ratios of ligand to metal salt (varied in a wide range between 1:1 and 5:1). In all cases the 3:1 ligand/metal complexes were obtained, though. The deep-red iron complex **16** was formed even in the case of a hundred-fold metal excess. The special stability of iron(II) complexes with 2,2′-bipyridine is well known[24] so that the unsubstituted bipyridine is applied as a test reagent for iron(II).

All of the above metal complexes are insoluble in aliphatic and aromatic solvents and in acetonitrile. The heteroleptic silver and cadmium complexes **23** and **25** are little water- but easily DMSO-soluble. The heteroleptic Cu^{2+} complexes **19** and **20** show a good solubility in water, but they do not dissolve in alcohol or THF. The homoleptic compounds **14** (Mn), **22** (Zn), and **26** (Cd) dissolve well in hot water and DMSO, the tris(chelate)iron and -nickel complexes **16** and **17** are well water-soluble but little in DMSO. Many of the crystalline metal complexes with **5** incorporate water of crystallization which is easily lost upon drying in air, so that the crystals have to be stored in water. The silver complexes **23** and **24** are light-sensitive and have to be stored in the dark.

An attempt was made to use the homoleptic tris(chelate) complexes as building blocks in the reaction with silver nitrate and to achieve the coordination through the amino function (to the silver atom) to give a heterobimetallic coordination polymer. However, a simple ligand exchange was observed when the zinc complex **22** was used (Equation 1) and a redox reaction occurred when the iron complex **16** was employed (Equation 2).

$$[Zn(\mathbf{5})_3]^{2+} + 2\,Ag^+ \xrightarrow{H_2O/EtOH\ (1:1)} [Zn(\mathbf{5})]^{2+} + 2\,[Ag(\mathbf{5})]^+ \quad (1)$$

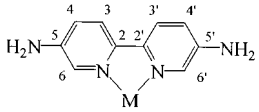
Thermal Analyses

Some complexes were studied by thermogravimetry (TG) and differential scanning calorimetry (DSC) to gain information on the amount of the incorporated crystal water, the temperature of water loss and other phase transitions. The TG data on the water loss show good agreement with values from NMR experiments (see Table 1) and fit the elemental analyses data. For **16** and **17** the water content from the X-ray structural analyses is different. This may indicate a varying water content for each single crystal.



After the loss of solvent water, the manganese complex **14** looses a ligand molecule at 290°C and possibly forms a neutral complex of composition $[MnCl_2(\mathbf{5})_2]$, which in turn shows another phase transition at 361°C. Investigations on solvated tris(2,2′-bipyridine)iron complexes have shown that upon heating the loss of water of crystallization is followed by sequential loss of ligands.[25]

NMR Spectroscopy

Nuclear magnetic resonance spectroscopy is a valuable tool to judge the electronic effects in ligands, including bipyridinemetal chelate complexes.[26] Usually, the d^{10} ions Ag^+ and Cd^{2+} only cause a small down-field shift of the proton signals with respect to those of the free ligand ($\Delta\delta \approx 0.0-0.2$ ppm). A comparison of the chemical shift data for **5** and **22**–**26** in Table 2 confirms this statement. The small shift is due to the weak Lewis acidity and the small diamagnetic interaction of the ring current with the relatively large cations.[27] This is different for zinc and iron complexes. Since the iron compound **16** was not soluble enough in DMSO, it had to be measured in D_2O and the zinc complex **22** was investigated in both solvents to allow comparison between iron and silver complexes, and the free ligand.

A comparison between the two different solvents for **22** shows the effect of hydrogen bonding from water to the amino functions. This decreases the electron-donating (positive) inductive effect of the amino function to the heterocycle so that especially the signals of the protons in the 4- and 6-position experience a low-field shift compared to signals in DMSO. The significant high-field shift of 0.8−1 ppm of the signal of the proton in 6-position or α to the metal center in **22**/DMSO and **16**/D_2O versus the silver and cadmium complexes is due to the smaller ionic radii of the zinc and iron metal centers. This improves the diamagnetic interaction of the metal center with the ring current.[22][27]

Table 2. ^{1}H-NMR data of diamagnetic metal complexes of **5**

Compound	Solvent	H3, H3′	H4, H4′	H6, H6′
Free ligand **5**	$[D_6]$DMSO	7.92	6.95	7.84
$[Ag(NO_3)(\mathbf{5})]$ (**23**)	$[D_6]$DMSO	7.92	7.15	7.91
$[Ag(\mathbf{5})_2]NO_3$ (**24**)	$[D_6]$DMSO	7.91	7.12	7.90
$[CdCl_2(\mathbf{5})]$ (**25**)	$[D_6]$DMSO	7.92	7.14	7.98
$[Cd(\mathbf{5})_3]Cl_2$ (**26**)	$[D_6]$DMSO	7.90	7.09	7.88
$[Zn(\mathbf{5})_3](NO_3)_2$ (**22**)	$[D_6]$DMSO	8.08	7.19	7.08
	D_2O	8.43	7.84	7.79
$[Fe(\mathbf{5})_3]SO_4$ (**16**)	D_2O	7.99	7.28	6.85

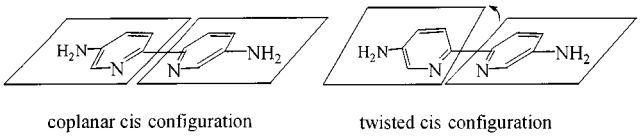
The trends in the shifts in carbon-13 spectroscopy are less straightforward. The signals of the carbon atoms 2, 3, and 6 show only little chemical-shift difference to those of the free ligand (−0.5 to +0.8 ppm), the C4 signal experiences a slight down-field shift (1 to 7 ppm) and the C5 signal an up-field shift (2.8 to 4.2 ppm). These trends stem from two superimposing effects: The negative inductive effect of the coordinated metal ion leads in 2- and 6- (*ortho*) position to the nitrogen atom to a down-field shift and to a lesser extent also in the 4- (*para*) position. The interaction of the paired metal d electrons with the diamagnetic ring current, on the other hand, enhances the shielding and consequently induces an upfield shift, which weakens with increasing distance from the metal center.[27][28]

The ligand effect on a metal center was studied with the help of ^{113}Cd-NMR-spectroscopy. The Cd^{II} ion has a rather high relaxation time of 0.1−50 s. Labile complexes which experience rapid ligand exchange, including aqua ligands, then give a broad time-averaged signal. In the building block $[Cd(\mu\text{-}Cl)_2(\mathbf{5})]$ of the heteroleptic complex **25**, the coordination sphere can be concluded by aqua ligands so that the species $[CdCl_2(\mathbf{5})(H_2O)]$ and $[CdCl_2(\mathbf{5})(H_2O)_2]$ also exist in solution with a rapid interchange among them.[29][30]

Table 1. Thermogravimetic data on the crystal water content in **14**, **16**, and **17**

Compound	Temperature for H_2O loss [°C]	Mass loss [mass%]	ΔH [kJ/g]	Water content [1/formula unit] from TG	from NMR	from X-ray
$[Mn(\mathbf{5})_3]Cl_2 \times 6\ H_2O$ (**14**)	101−150	14.3	34.6	6.3	6.5	–
$[Fe(\mathbf{5})_3]SO_4 \times 6\ H_2O$ (**16**)	162−166	14.1	59.9	6.5	–[a]	9.0
$[Ni(\mathbf{5})_3]Cl_2 \times 6\ H_2O$ (**17**)	145−168	12.3	51.6	5.6	6.0	2.5

[a] Due to the low solubility in $[D_6]$DMSO the water content could not be verified by NMR.



Hence, the signal for **25** was very broad and could not be clearly assigned. Whereas the tris(chelate) complex **26** gave a rather narrow singlet, which is indicative of the stable nature of $[Cd(\mathbf{5})_3]^{2+}$ in solution. The chemical shift of $\delta = 253$ for **26** [versus 2 M $Cd(ClO_4)_2$ as a standard] falls right in the range observed for other tris(bipyridine) and tris(phenanthroline) complexes: $[Cd(bipy)_3](ClO_4)_2$ ($\delta = 243$), $[Cd(4,4'\text{-}Me_2bipy)_3](ClO_4)_2$ ($\delta = 254$), and $[Cd(phen)_3](ClO_4)_2$ ($\delta = 254$ ppm) [all against 0.1 M $Cd(ClO_4)_2$ solution].[29]

Mößbauer Spectroscopy

The iron complex **16** is an exception with respect to its thermodynamic stability in the series of the analogous $[M(\mathbf{5})_3]^{2+}$ derivatives. It forms directly even at high metal excess. A possible explanation is the $3d^6$ low-spin configuration of the Fe^{II} ion which possesses a maximal ligand field stabilization energy.[31] Some bipyridineiron(II) complexes are known, e.g. $[Fe(bipy)_3](BF_4)_2 \times 2\ H_2O$[32][33] or $[Fe(3,3'\text{-}Me_2\text{-}bipy)_3](ClO_4)_2$[34] which exhibit a thermally induced low-spin to high-spin crossover. Such a spin crossover changes the spin state from singlet-$^1A_{1g}$ to quintuplet-$^5T_{2g}$ and as a consequence leads to an increase in ligand−metal bond length.[35] Mößbauer spectroscopy allows to discern the spin state of the iron complex. For $[Fe(\mathbf{5})_3]SO_4$ (**16**) in the solid state a pronounced doublet with an isomer shift $\delta(\alpha\text{-Fe}) = 0.30$ mm/s (at 293 K) and a half-width Γ of 0.25 mm/s was found. The quadrupole splitting ΔE_Q was 0.27 mm/s. These values are typical for tris(2,2′-bipyridine) complexes of iron in the low-spin state. The isomer shifts measured, for example, for $[Fe(bipy)_3](ClO_4)_2$, $[Fe(bipy)_3]Cl_2$, and $[Fe(bipy)_3]SO_4$ are 0.30, 0.33, and 0.24 mm/s, respectively.[25,33,36] The small quadrupole splitting in **16** indicates at the most a weak distortion from the octahedral $Fe-N_6$ coordination geometry. The DSC data for **16** exclude the existence of a thermally induced spin transition up to the decomposition temperature of 350 °C, because no reversible phase transition could be observed.[5][37] Another indication along the same lines is the deep-red color of **16** which stems from the $^1A_{1g} \rightarrow {}^1T_{1g}$ d-d transition. Upon heating, this color does not fade as would be expected from a spin crossover, because the smaller d-d splitting in the high-spin state shifts the absorption from the visible into the infrared regime.[5][38] Both negative indicators for a spin crossover behavior precluded a temperature-variable Mößbauer study.

Infrared Spectroscopy

Metal complexes with 2,2′-bipyridine ligands were the subject of intense IR-spectroscopical investigations.[39−41] All bands are now clearly assigned. Some of the many ring vibrations are sensitive to metal coordination and experience an hypsochromic shift (to higher wavenumbers or energy) of 10 to 20 wavenumbers.[40] The influence of the metal coordination on the vibrations of the amino function has been elucidated with the 2- and 3-aminopyridine ligand.[42][43] The in-plane ring-stretch vibrations of **5** are found at 1568, 1478 and 656 cm^{-1}.[44] The first two show in all metal complexes the aforementioned hypsochromic shift to 1579−1590 cm^{-1} and 1486−1497 cm^{-1}, respectively. The band at 656 cm^{-1} either remains almost unshifted (in **15**, **16**, **17**, **18**, **22**, **24**, and **25**) or is split into two bands (as in **14**, **19**, **23**, and **26**). Similarly, the corresponding band in $[Mn(bipy)_3](ClO_4)_2$ is split.[40][41] The explanation is sought in a substantial twist (over 10°) of the pyridine ring planes around the connecting C2−C2′ bond away from the almost coplanar to a twisted *cis* configuration (**27**).

coplanar cis configuration twisted cis configuration

27

To the extent of a few degrees the ring planes in a bipyridine pair are always twisted (see below).[45] An X-ray structure analysis of $[Mn(bipy)_3](ClO_4)_2$ confirmed the substantial twist, the dihedral angles between each pair of pyridine rings in all three bipyridine ligands lay between 13 and 25°.[46]

The structures collected here do not reveal a substantial twist in any case. The dihydral angles between the pyridine ring planes were 9.7° in **15**, 5.3, 5.7, and 11.3° in **18**, 3.3° in **19**, 2.3° in **20**, 5.2, 8.9, and 9.1° in **22**, and 0.1° in **25**. This finding coincides with the non-splitting of the band at around 656 cm^{-1} but does not agree with the splitting found for **19**. Hence, the IR analysis with respect to a twisted configuration should be applied with caution.

From aqueous solutions the ligand **5** crystallizes as the monohydrate. The IR spectrum of $\mathbf{5} \times H_2O$ then shows two sharp bands at 3425 and 3340 cm^{-1}, which are assigned to the symmetric and asymmetric NH stretch. Three additional and broader bands at 3376, 3315, and 3205 cm^{-1} are due to the formation of amino hydrogen bonds to the water oxygen atom. The NH deformation is found at 1632 cm^{-1}. In all metal complexes the position of this bending vibration remains rather unchanged, different to what would be expected in case of amino−metal complexation.[42]

X-ray Structural Studies

Generally, all of the metal complexes of **5** which are structurally elucidated here show a bipyridine−metal coordination of the potentially ambidentate diaminobipyridine ligand. The amino functionality was never involved in metal coordination, yet, could play a substantial role in hydrogen bonding (see below). Specific distances and angles and some figures for the hydrogen bonding networks which are not given here, can be found in the supporting information. The specific structures are described in some more detail in the following.

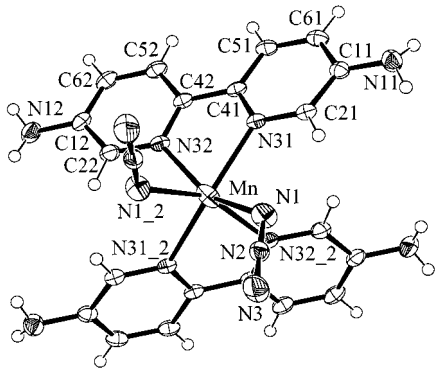


Figure 1. Molecular structure of $[Mn(N_3)_2(\mathbf{5})_2]$ (**15**); selected distances [Å] and angles [°]: Mn−N1 2.211(1), Mn−N31 2.265(1), Mn−N32 2.286(1), N1−N2 1.171(2), N2−N3 1.168(2); N1−Mn−N1#2 86.58(8), N1−Mn−N31#2 113.66(4), N1−Mn−N31 89.19(4), N31−Mn−N31#2 149.14(5), N1−Mn−N32 154.51(5), N1−Mn−N32#2 86.07(5), N31#2−Mn−N32#2 71.61(4), N31−Mn−N32#2 90.61(4), N32−Mn−N32#2 110.09(6), N1−N2−N3 178.1(1) (symmetry equivalent position #2 = 0.5 − *x*, *y*, −*z*)

$[Mn(N_3)_2(\mathbf{5})_2]$ (15)

Figure 1 illustrates the structure of this molecular complex. The two azide ligands are *cis*-coordinated, terminally bound and do not bridge between metal centers. The bonding mode is not unusual for coordinated azides.[47] The pseudooctahedral structure of **15** is similar to *cis*-$[Mn(NCS)_2(bipy)_2]$.[48] The M−N(bipy) bond lengths *trans* to the azide (or NCS) ligand show some lengthening. The crystal structure is stabilized by stacking interactions involving bipyridine ligands of adjacent molecules (π−π contacts down to 3.2 Å). Intermolecular hydrogen bonding from the amino functions to the N3 atom of the azide ligand is observed.

$[Fe(\mathbf{5})_3]SO_4 \times 9\ H_2O$ (16)

The tris(chelate) structure (cf. Figure 3) of the $[Fe(\mathbf{5})_3]^{2+}$ moiety is unremarkable (Table 3). Recent examples of $[Fe(bipy)_3]^{2+}$ complexes include the counterions $[Fe(NO)_2Cl_2]^-$,[49] $[Fe_2OCl_6]^{2-}$,[50] $[Fe_2(ox)_3]^{2-}$,[51] and

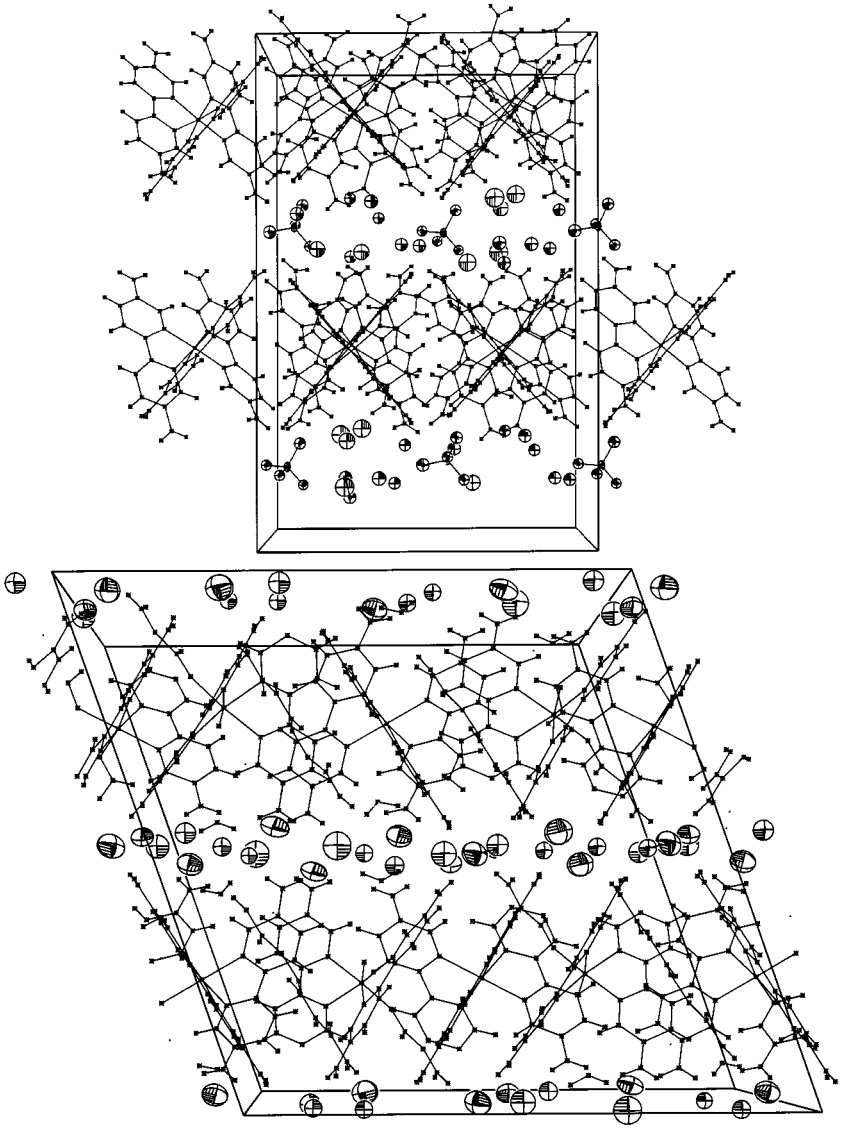

Figure 2. Layer arrangement of the $[M(\mathbf{5})_3]^{2+}$ cations and the anions (SO_4^{2-} or Cl^-) together with the water of crystallization in the structures of (a, top) $[Fe(\mathbf{5})_3]SO_4 \times 9\ H_2O$ (**16**) and (b, bottom) $[Ni(\mathbf{5})_3]Cl_2 \times 2.5\ H_2O$ (**17**); view along *a* (a) and *b* (b)

$[MC(ox)_3]^{2-}$,[52][53] (ox = oxalate, M = Ag, Na, Li). We just note that **16** is constructed from alternating layers of the tris(chelate) cations and layers of the sulfate anions together with the water of crystallization (Figure 2a). The interaction between the layers occurs through hydrogen bonding from the amino group to the oxygen centers.

$[Ni(5)_3]Cl_2 \times 2.5\ H_2O$ (17) and $[Ni(5)_3](SCN)_2$ (18)

The tris(chelate) structure around the nickel centers (Figure 3, Table 3) is common in a sizable number of tris(bipyridine)metal complexes which are described in the literature. Recent examples are $[Ni(bipy)_3][Mn_2(ox)_3]$,[53] $[Ni(bipy)_3]$-$NaAl(ox)_3]$,[54] $[Ni(bipy)_3][Ni(CN)_4] \times bipy \times 6\ H_2O$,[55] and $[Ni(bipy)_3]_2[Ag(CN)_2]_3Cl \times 9\ H_2O$.[56] The structure of **17** contains an analogous layer arrangement as seen before in **16** (Figure 2b). Noteworthy in **18** is the hydrogen bonding from the amino groups to both the sulfur and the nitrogen end of the SCN anions.

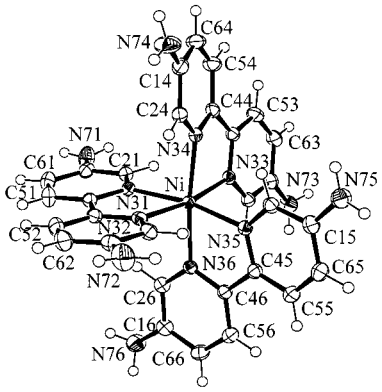

Figure 3. Exemplified view of the molecular structure of the tris-chelate)metal cations in $[Fe(5)_3]SO_4 \times 9\ H_2O$ (**16**), $[Ni(5)_3]Cl_2 \times 2.5\ H_2O$ (**17**), $[Ni(5)_3](SCN)_2$ (**18**, shown here), and in $[Zn(5)_3](NO_3)_2$ (**22**); selected distances and angles are given in Table 3

$^1{}_\infty[Cu(\mu\text{-}SO_4)(5)(H_2O)_2] \times 3\ H_2O$ (19)

Figure 4a shows a section of the 1-dimensional coordination polymer and Figure 4b displays the stabilizing π−π interaction (about 3.4 Å)[57] of adjacent strands. The chains

[a] Two symmetically independent molecules in the unit cell.

are formed through the bridging action of the sulfato ligand, two of which are arranged *trans* around the copper center with Jahn−Teller-elongated Cu−O contacts. The aqua and sulfato ligands on the metal center and the water molecules of crystallization form a three-dimensional hydrogen-bonding network surrounding the π-interacting double strands from Figure 4.

[$CuCl_2$(5)] (20)

The structure of this molecular complex is displayed in Figure 5. The copper atom is four-coordinate with a coordination polyhedron between square-planar and tetrahedral. The dihedral angle between the plane of the five-membered chelate ring and the Cl−Cu−Cl plane is 41.1°. In the complex (3-amino-6,6′-dimethyl-2,2′-bipyridine)dichlorocopper(II) a (Jahn−Teller-)compressed tetrahedral structure is found since the methyl groups *ortho* to the coordinating nitrogen atom apparently prevent a more planar ligand arrangement.[58] An approximately square-planar coordination around Cu is observed in (2,2′-bipyridine-3,3′-dicarboxylic acid)dichlorocopper(II) monohydrate.[59] However, weak intermolecular interactions with a Cl atom (3.117 Å) and an O atom (2.678 Å away) on adjacent molecules complete an octahedral donor arrangement around the metal center. In **20** no such intermolecular interactions can be found; the next chlorine contact to a neighboring molecule is 5.28 Å. The absence of bridging chlorine atoms in **20** is unusual as in the related compounds dichloro(4,4′-dimethyl-2,2′-bipyridine)copper(II) hemihydrate[60] and in dichloro(2,2′-bipyridine)copper(II)[61] such intermolecular interactions are present leading to five- and six-coordinate copper centers in dimeric and polymeric structures, respectively. The chlorine atoms in **20** are involved in hydrogen bonding to the amino group (H···Cl 2.799 and 2.858 Å, see Figure 8a), yet, it is unclear if this is sufficient to prevent coordination to the copper atom (see below). That such intermolecular interaction are feasable is demonstrated with the structure of $^1{}_\infty$[Cd(μ-Cl)$_2$(**5**)] × 2 H_2O (**25**). The packing of the molecules of **20** (π−π distances around 3.4 Å) is discussed in combination with the related structure of **25** below.

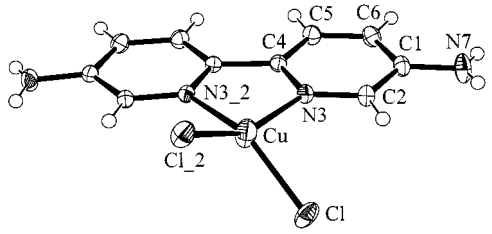

Figure 5. Molecular structure of [$CuCl_2$(**5**)] (**20**); selected distances [Å] and angles [°]: Cu−N3 1.981(1), Cu−Cl 2.2346(4); N3−Cu−N3#2 82.28(8), N3−Cu−Cl 97.41(4), N3−Cu−Cl#2 150.80(4), Cl−Cu−Cl#2 96.61(2) (symmetry equivalent position #2 = $-x + 1$, y, $-z + 0.5$)

[$Zn(5)_3$]$(NO_3)_2$ × 2 H_2O (22)

The unspectacular tris(chelate) structure is again found in **22** (cf. Figure 3, Table 3). We refer to [$Zn(bipy)_3$]$(SCN)_2$ × 7 H_2O[62] and to the various structures of [$Zn(bipy)_3$]-$ClO_4)_2$[63] as recent examples. Of more interest is an extended, two-dimensional hydrogen-bonded network formed by the nitrate anions, the water molecules of crystallization and the amino functions of the bipyridine ligands (Figure 6). These hydrogen-bonded grids separate and sandwich the layers build from the tris(chelate) complex molecules (and vice versa). Within such a network the amino groups hydrogen-bond either to one (N56) or two nitrate ions (N53, N54, N55) or bridge with their hydrogen atoms between a nitrate anion and a water molecule (N52) or between two water molecules (N51). One of the hydrogen atoms from N54 thereby forms a 3-center or bifurcated bridge to two oxygen atoms (O1 and O2) of a nitrate ion. One of the water molecules (O92) bridges between two nitrate anions and accepts a hydrogen bond from the other solvent water (O91). The latter forms hydrogen bonds between a nitrate ion and a water molecule and the oxygen atom accepts three hydrogen bonds from amino groups to become five-coordinate. Each of the nitrate ions is anchored by five or six hydrogen bonds, four of which are derived from the amino groups and the remaining one or two from water molecules. Figure 6 illustrates the hydrogen-bonded network and Table 4 provides further details.

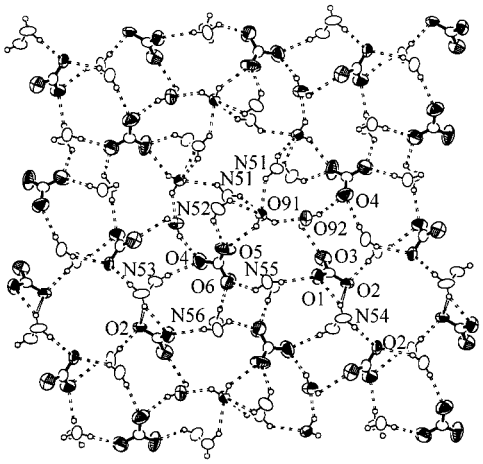

Figure 6. Two-dimensional hydrogen bonding network in [$Zn(5)_3$]$(NO_3)_2$ (**22**) in the *ab* plane; the nitrogen atoms of the amino groups are drawn as empty ellipsoids only; due to space requirements only part of the atom positions are labelled and symmetry operations are not shown

$^1{}_\infty$[Cd(μ-Cl)$_2$(5)] × 2 H_2O (25)

The building block for this one-dimensional coordination polymer is drawn in Figure 7a. At first sight, the structure is similar to the copper complex **20**. The dihedral angle between the plane of the five-membered chelate ring and the Cl−Cd−Cl plane is 17.8°. However, unlike **20** the cadmium compound forms 1D strands (Figure 7b). Polymer formation is based on the bridging action of the chloro ligands as is evident from Figure 7b. The distorted octahedral coordination sphere of cadmium thus consists of the two bipyridine nitrogen atoms and four bridging chlorine atoms. The cadmium−chlorine (2.561, 2.781 Å) and cadmium−cad-

mium (4.04 Å) distances found here are typical for chloro-bridged cadmium compounds.[64] The amino groups are not involved in metal coordination but take part in the hydrogen bonding network build up by the water of crystallization.

The packing and strand formation in **25** by chlorine bridging can be compared to the packing of the molecular complexes of **20**. Figure 8 contrasts similar views of the unit cells of both compounds. It can be seen that the bipyridine π−π stacking (both from 3.4 Å on in **20** and in **25**)[57] is an important motif to control the intermolecular arrangement, as was also pointed out in Figure 4 for the copper complex **19**; π strands are formed with the MCl_2 moieties alternatingly facing to the left and right of these stacks. These π interactions may be more important in **20** than in **25**, since the ring overlap is larger in the copper than in the cadmium compound. On the basis of the molecular copper complex in Figure 8a, the metal−chlorine bridging in **25** (Figure 8b) can be developed by stretching the *a* axis and shortening the *b* axis. Cadmium−chlorine bridging can then occur along *b* between the $CdCl_2$ moieties which face each other. Starting from the complete ring overlap in **20** the bridging in **25** is enhanced at the cost of the bipyridine π overlap by moving the (bipy)$CdCl_2$ moieties to the left and right in the *b* direction, so that the ring overlap is greatly diminished.

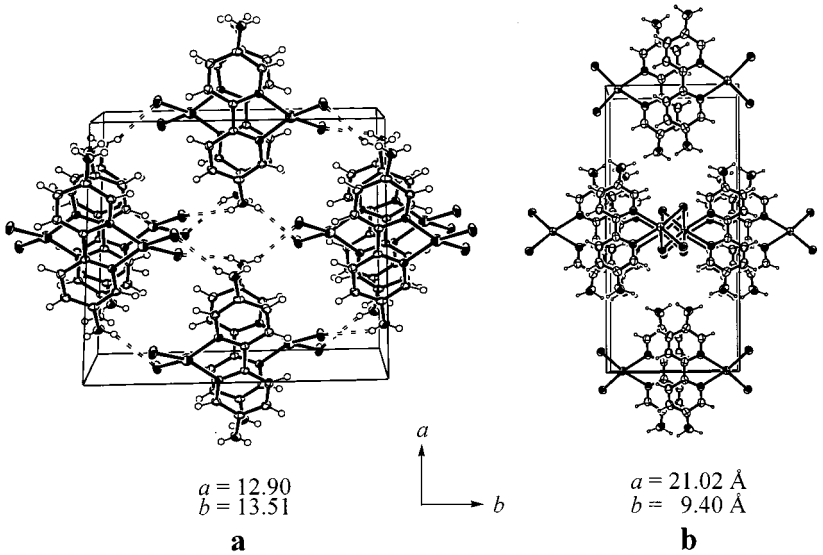

Figure 8. (a, left) unit cell of $[CuCl_2(\mathbf{5})]$ (**20**) and (b, right) unit cell of $^1{}_\infty[Cd(\mu\text{-}Cl)_2(\mathbf{5})] \times 2\ H_2O$ (**25**), both viewed approximately along *c*, to compare the relationship between the unbridged and chlorine-bridged packing; hydrogen−chlorine bonding is indicated in **20**; the water molecules of crystallization in **25** have been omitted for clarity

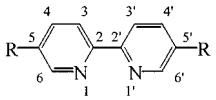
Conclusions



The expectation that the potentially ambidentate group 5,5′-diamino-2,2′-bipyridine (**5**) could function as a bridging and/or chelating bi- to tetradentate ligand in the coordination of transition metals has not been fulfilled. This may be traced to the delocalization of the amine lone-pair into the electron-deficient pyridine ring. The structural studies showed a well-developed coplanarity of the amino group with the aromatic ring. However, the amino function takes part in hydrogen bonding to the anions and to incorporated water molecules of crystallization. From this a two- to three-dimensional hydrogen-bonding network was created which was one of the factors in the packing of the molecular or extended ligand−metal complexes. The other key factor responsible for the supramolecular arrangement of the 5,5′-diamino-2,2′-bipyridine−metal entities is a face-to-face π−π stacking interaction between bipyridine ligands of neighboring ligand−metal fragments. The importance of such a π−π stabilization[57] for the ligand−metal packing has also been elucidated in the structures of the metal complexes with 2,2′-dimethyl-4,4′-bipyrimidine (**2**),[2] 5,5′-dicyano-2,2′-bipyridine (**3**),[3] and 2,2′-bi-1,6-naphthyridine (**4**).[4] These last three ligands also exhibit the sought for bridging and/or chelating bi- to tetradentate metal coordination.

Experimental Section

General: NMR: Bruker ARX 200 (200.1 MHz for ^{1}H, 50.3 MHz for ^{13}C) or Varian O-300 (300.0 MHz for ^{1}H, 75.4 MHz for ^{13}C); calibrated against the solvent signal ([D$_6$]DMSO: ^{1}H NMR: δ = 2.53; ^{13}C NMR: δ = 39.5; $CDCl_3$: ^{1}H NMR: δ = 7.26; ^{13}C NMR: δ = 77.0; C_6D_6: ^{1}H NMR: δ = 7.19; ^{13}C NMR: δ = 128.0). − Thermogravimetric analyses: simultaneous thermoanalysis apparatus STA 429 from Netsch. − IR spectra: Perkin−Elmer 783 infrared spectrophotometer as KBr disks or as Nujol mulls. − Mass spectra: GC/MS Finnigan MAT in solid-probe EI mode at an ionization energy of 70 eV. − Elemental analyses: Perkin−Elmer elemental analyzer E 240 C. − Commercial triphenylphosphane was dried for 24 h in vacuo at 50°C. Distilled water was carefully degassed prior to use. Dimethyl formamide (DMF) was of technical grade and was fractionally distilled with 10 vol-% of toluene and 2 vol-% of water. This prepurified DMF was stirred for 2 h over CaH_2 under argon and then distilled under vacuum. 5-Amino-2-chloropyridine (**13b**) was prepared as described in ref.[20] from 2-chloro-5-nitropyridine (**13a**) in 92% yield.

Synthesis of 5 from 3-Methylpyridine (8) (Scheme 1)

5,5′-Dimethyl-2,2′-bipyridine (9): ***CAUTION:*** Dry Raney nickel is highly pyrophoric! In a 250-mL three-necked flask 20 g of nickel/aluminum alloy were added under inert gas and ice-cooling in portions within 30 min to a solution of 25.6 g (0.64 mol) of NaOH in 100 mL of water. The temperature increased quickly to 80°C. After complete addition, stirring was continued at 80°C for 1 h. Then 100 mL of water was added and the solution was decanted from the Raney nickel. The latter was washed 20 times with 100 mL of H_2O each, which was decanted each time after 2 min of stirring. Afterwards the three-necked flask was fitted with a reflux condenser and a dropping funnel. The remaining water was first removed with a water aspirator at 60°C, eventually the Raney nickel was dried at 0.05 mbar at 80°C for 3 h. Then, 30 mL (0.29 mol) of 3-methylpyridine (**8**) was slowly added dropwise under ice-cooling and the reaction mixture was kept for 5 d at an oil-bath temperature of 180°C. The product was filtered hot through a D3 frit and the Raney nickel residue washed twice with hot toluene. (The Raney nickel was slowly dissolved with water, medium concentrated HCl and conc. HNO_3.) The filtrate was freed from the starting compound and toluene by vacuum distillation. The product was sublimed twice and obtained in colorless needle-shaped crystals (yield 9.5 g, 36%; ref.[13][14] 17%). − The procedure could easily scaled up six-fold: From 125 g of nickel/aluminum alloy, 160 g of NaOH, two times 600 mL of degassed water and 188 mL of 3-methyl-pyridine was obtained 55 g of **9** (31%). A 2-l flask was used as the reaction vessel and the reaction mixture was kept for 4 d at 180°C. The Raney nickel residue was washed three times with 80 mL of hot toluene, each. − M.p. 114°C (ref.[13] 114.5−115°C. − ^{1}H NMR ($CDCl_3$): δ = 8.41 (d, 2 H, J = 1.5 H, H6, H6′), 8.17 (d, 2 H, J = 9.0 Hz, H4, H4′), 7.52 (dd, 2 H, J_1 = 8.0 Hz, J_2 = 2.0 Hz, H3, H3′), 2.29 (s, 6 H, CH_3). − ^{13}C NMR ($CDCl_3$): δ = 153.7 (C2, C2′), 149.5 (C6, C6′), 137.3 (C4, C′), 132.9 (C5, C5′), 120.2 (C3, C3′), 18.2 (methyl-C). − The numbering for the NMR notation for **5**, **9−12** is as in Scheme 4.

Scheme 4. Numbering scheme for bipyridines

Diethyl 2,2′-Bipyridine-5,5′-dicarboxylate (10): 9.45 g (51 mmol) of **9** were added to a solution of 50.0 g (317 mmol) of $KMnO_4$ in 600 mL of water. The mixture was refluxed until decolorization had occurred. The solution was filtered from precipitated MnO_2 and the filtrate acidified with half-concentrated HCl. A fine colorless powder of 2,2′-bipyridine-5,5′-dicarboxylic acid precipitated. This intermediate (M.p. > 280°C) was separated by filtration, dried in vacuo and suspended in 200 mL of dried ethanol. After careful addition of 50 mL of conc. H_2SO_4, the reaction mixture was refluxed for 16 h to give a clear solution. The warm solution was poured onto ice. The hitherto obtained precipitate was filtered, washed several times with water, dried and recrystallized from ethanol to give **10** as colorless needles (yield 9.8 g, 64%). − M.p. 145°C (ref.[12]: 147°C) − ^{1}H NMR ([D$_6$]DMSO): δ = 9.18 (d, 2 H, J = 2.5 Hz, H6, H6′), 8.54 (dd, 2 H, J_1 = 8.6 Hz, J_2 = 2.5 Hz, H4, H4′), 8.44 (d, 2 H, J = 8.6 Hz, H3, H3′), 4.38 (q, 4 H, J = 7.1 Hz, OCH_2), 1.36 (t, 6 H, J = 7.1 Hz, CH_3). − ^{13}C NMR ($CDCl_3$): δ = 164.2 (*C*OOEt), 157.3 (C2, C2′), 149.8 (C6, C6′), 137.9 (C4, C4′), 126.2 (C5, C5′), 121.0 (C3, C3′), 61.0 (OCH_2), 13.8 (CH_3).

2,2′-Bipyridine-5,5′-dicarboxylic Diazide (11): 50 mL of an 80% hydrazine hydrate solution was added to a slurry of 8.20 g (27.3 mmol) of **10** in 50 mL of ethanol. The mixture was heated for 3 h at an oil-bath temperature of 120°C to give a viscous mass which was filtered, washed with hot ethanol and dried in vacuo. The intermediate dihydrazide (6.5 g) thus obtained was suspended at 0°C in 150 mL of conc. HCl. A solution of 3.88 g (56 mmol) of $NaNO_2$ in 30 mL of water was added dropwise to this slurry with the temperature kept always below 10°C. After a few hours, a clear yellow solution was obtained. Upon dilution with 750 mL of water a colorless precipitate was produced which was filtered, washed several times with water, twice with 30 mL of hot ethanol and dried in vacuo to yield 6.72 g (84%) of a white powder. − M.p. > 300°C. − IR (Nujol): $\tilde{\nu}$ = 3076 cm^{-1} w, 2730 w, 2182 w, 2143 w, 1728 w,

1696 s, 1595 m, 1556 w, 1560 w, 1467 s, 1380 m, 1290 m, 1282, 1238 m, 1182 m, 1238 w, 1182 w, 1160 w, 1130 w, 1120 w, 1058 w, 1034 w, 1000 w, 895 w, 870 w, 860 w, 751 w, 722 w.

5,5′-Bis(ethoxycarbonylamino)-2,2′-bipyridine (12): 6.00 g (20.4 mmol) of the diazide **11** was suspended in a mixture of 150 mL of *p*-xylene and 150 mL of dried ethanol and refluxed for 18 h to give a clear yellow solution. Upon cooling yellowish crystals were obtained which after filtration were recrystallized from ethanol. The yield of the now colorless product was 6.5 g (97%). − M.p. > 300°C. − ^{1}H NMR ([D$_6$]DMSO): δ = 9.92 (s, 2 H, NH), 8.67 (d, 2 H, *J* = 2.2 Hz, H6, H6′), 8.20 (d, 2 H, *J* = 8.8 Hz, H3, H3′), 7.97 (dd, 2 H, J_1 = 8.8 Hz, J_2 = 2.4 Hz, H4, H4′), 4.14 (q, 4 H, *J* = 7.1 Hz, OC*H*$_2$CH$_3$), 1.24 (t, 6 H, *J* = 7.1 Hz, CH$_2$C*H*$_3$). − ^{13}C NMR ([D$_6$]DMSO): δ = 159.3 (EtO*C*ONH), 155.0 (C2, C2′), 144.9 (C6, C6′), 141.5 (C4, C4′), 131.5 (C3, C3′), 125.6 (C5, C5′), 66.4 (OCH$_2$), 20.2 (CH$_3$).

5,5′-Diamino-2,2′-bipyridine (5): 5.00 g (15.2 mmol) of the diurethane **12** was refluxed for 24 h in a mixture of 200 mL of ethanol and 200 mL of 2 N NaOH. After cooling to room temperature, the solution was carefully neutralized and the alcohol distilled of at normal pressure. Upon cooling the hydrate of the diamine **5** crystallized as long needles which may be weakly pink colored due to traces of iron. Further purification was achieved by sublimation at 0.2 mbar and an oil-bath temperature of 190°C. Yield 1.97 g (70%). Analytical data are given after the following procedure.

Synthesis of 5 by Coupling of 5-Amino-2-chloropyridine (Scheme 2): In a 250-mL three-necked flask was placed 2.37 g (10 mmol) of nickel dichloride hexahydrate and 10.5 g (40 mmol) of triphenylphosphane. The flask was evacuated and refilled with argon for three times. 100 mL of dried dimethyl formamide was added under inert gas and the solution rapidly turned blue. After PPh_3 and $NiCl_2 \times 6\ H_2O$ had completely dissolved in DMF, 0.7 g (11 mmol) of zinc powder was added to the solution under inert gas at 50°C and the solution slowly turned brown-red. After stirring this mixture for 1 h, 10 mL of a DMF solution with 1.28 g (10 mmol) of 5-amino-2-chloropyridine was added dropwise to the mixture. Stirring was continued for 4 h at 50°C at which time the starting material could not be detected anymore by thin-layer chromatography (eluent ethyl acetate). The reaction mixture was then concentrated in vacuo to half of its volume. After adding 250 mL of water, the mixture was carefully poured into 150 mL of conc. ammonia and stirred for 18 h. The solution turned blue because of the formation of hexaamminenickel(II) complexes. The PPh_3 precipate was removed by filtration and the filtrate was extracted three times with 50 mL of dichloromethane each. The combined organic phases were treated with 50 mL of half-concentrated HCl for three times each to separate the diaminobipyridine from PPh_3. During this procedure strongly colored aminohydrochlorides of **5** were formed. The combined acidic aqueous phases were carefully neutralized with a 10% Na_2CO_3 solution. The product **5** separated as a yellowish solid and was sublimed as described above to give a colorless powder (yield 1.11 g, 60%). − M.p. 205°C (ref.[12] 205−206°C). − ^{1}H NMR ([D$_6$]DMSO): δ = 7.92 (d, 2 H, *J* = 2.8 Hz, H6, H6′), 7.84 (d, 2 H, *J* = 8.6 Hz, H3, H3′), 6.95 (dd, 2 H, J_1 = 8.6 Hz, J_2 = 2.5 Hz, H4, H4′), 5.30 [s (br.), 4 H, NH_2]. − ^{13}C NMR ($CDCl_3$): δ = 144.7 (C2, C2′),143.6 (C5, C5′), 134.9 (C6, C6′), 120.5 (C3, C3′), 119.0 (C4, C4′); ([D$_6$]DMSO): δ = 147.1, 145.5, 136.6, 123.5, 122.2. − IR (KBr): $\tilde{\nu}$ = 3424 cm^{-1} w, 3338 m, 3310 m, 3207 m, 3062 w, 3057 w, 3005 w, 1632 w, 1600 m, 1568 m, 1478 s, 1412 m, 1289 m, 1248 w, 1137 w, 1108 w, 1088 w, 1060 w, 1024 w, 920 w, 897 w, 846 m, 832 m, 737 w, 656 m, 552 m, 517 m, 509 w, 418 w.

Syntheses of Transition Metal Complexes

[Tris(5,5′-diamino-2,2′-bipyridine)manganese(II)] Chloride Hydrate (14): To a solution of 76.2 mg (0.38 mmol) of $MnCl_2 \times 4\ H_2O$ in 20 mL of distilled water was given a solution of 192.5 mg (1.03 mmol) of **5** in 25 mL of ethanol. The pale red solution was allowed to stand several days at room temperature. The bright red cubic crystals were separated by filtration. Upon standing in air the crystals slowly lose water of crystallization and turn opaque (yield 222 mg, 82%). − A thermogravimetric analysis shows the complete loss of crystal water at 101−145°C. At 290°C the loss of one diaminobipyridine ligand takes place with possible formation of [$MnCl_2$(**5**)$_2$]. Above 360°C decomposition is observed. − IR (Nujol): $\tilde{\nu}$ = 3420 cm^{-1} w (br.), 3305 m (br.), 3200 w (br.), 1632 m, 1598 s, 1585 m, 1487 m, 1430 m, 1325 w (br.), 1319 m, 1300 m, 1272 w (br.), 1262 w (br.), 1162 w, 1055 w, 1030 m, 1019 w, 965 w (br.), 890 w, 862 w, 852 w, 827 m, 758 w, 740 w, 728 m, 656 w, 650 w. − Tetrahydrate $C_{30}H_{38}Cl_2MnN_{12}O_4$ (756.56): calcd. C 47.62, H 5.06, N 22.21; found C 47.56, H 4.05, N 22.31.

[Diazidobis(5,5′-diamino-2,2′-bipyridine)manganese(II)] (15): 15 mL of an ethanolic solution of **5** (100 mg, 0.54 mmol) was added to 15 mL of an aqueous solution of $MnCl_2 \times 4\ H_2O$ (110 mg, 0.54 mmol) and stirred for 15 min. To this solution was added 5 mL of an aqueous solution of NaN_3 (88 mg, 1.35 mmol). The resulting yellow solution was left standing for 36 h at room temperature. Then some undissolved solid was filtered and the filtrate was then placed at ambient temperature. One month later, a yellow precipate had formed on the bottom of the flask. Two months later, the yellow precipate had transformed into well-formed red-orange crystals which were collected by filtration and washed with water and ethanol to give 123 mg of product (69%, based on **5**). − IR (KBr): $\tilde{\nu}$ = 3430 cm^{-1} w, 3372 s, 3304 s, 3207 s, 2078 s ν(N_3), 2020 s ν(N_3), 1620 s, 1604 s, 1588 s, 1485 s, 1438 s, 1350 w, 1328 m, 1311 s, 1295 m, 1275 s, 1165 m, 1125 w, 1060 w, 1030 m, 1025 m, 960 w, 934 m, 892 m, 865 w, 849 m, 838 s, 728 m, 698 w, 653 m, 630 m, 620 w, 592 w, 545 s, 520 m. − $C_{20}H_{20}N_{14}Mn$ (511.40): calcd. C 46.96, H 3.91, N 38.36; found C 46.76, H 3.92, N 38.33.

[Tris(5,5′-diamino-2,2′-bipyridine)iron(II)] Sulfate Hydrate (16): To a hot solution (90°C) of 532 mg (2.86 mmol) of **5** in 30 mL of distilled water was added dropwise a solution of 280 mg (1.01 mmol) of $FeSO_4 \times 7\ H_2O$ in 10 mL of distilled water. A red color immediately developed. After complete addition, the solution was allowed to cool and the precipitated crystals were washed with a few mL of ice-cooled water, then with dried ethanol and finally with diethyl ether. The crystals were briefly dried in air. Single crystals could best be obtained by cooling a saturated solution from room temperature to 0°C (yield 720 mg, 92%). − A thermogravimetric analysis shows the complete loss of water of crystallization at 166°C and decomposition above 350°C. − ^{1}H NMR (D_2O): δ = 7.99 (d, *J* = 8.8, H3, H3′), 7.29 (dd, J_1 = 8.8 Hz, J_2 = 2.4 Hz, H4, H4′), 6.85 (d, *J* = 2.4 Hz, H6, H6′). − ^{13}C NMR (D_2O): δ = 149.6 (C2, C2′), 144.7 (C5, C5′), 139.3 (C6, C6′), 123.1 (C4, C4′), 121.4 (C3, C3′). − IR (Nujol): $\tilde{\nu}$ = 3420 cm^{-1} w, 3340 w, 3205 w, 1632 s, 1602 s, 1580 m, 1575 w, 1488 s, 1429 m, 1368 s, 1352 m, 1328 m, 1310 s, 1292 m, 1268 m, 1206 m, 1165 m, 1028 w, 1019 w, 904 w, 860 w, 838 w, 832 w, 728 w, 655 w. − Hexahydrate $C_{30}H_{42}FeN_{12}O_{10}S$ (818.65): calcd. C 44.01, H 5.17, N 20.53; found C 44.16, H 4.20, N 20.50.

[Tris(5,5′-diamino-2,2′-bipyridine)nickel(II)] Chloride Hydrate (17): A solution of 158 mg (0.66 mmol) $NiCl_2 \times 6\ H_2O$ in 30 mL of distilled water was combined with a solution of 383 mg (2.05 mmol) of **5** in 25 mL of ethanol. The mixture was heated to reflux and a pale red solution formed. After cooling to room

temperature, the precipitate was filtered, washed with little cold water, ethanol, and diethyl ether and air-dried (yield 150 mg, 85%). Single crystals could be obtained by slow cooling of a saturated solution from room temperature to 0°C. The product crystallizes in bright red cubes, which slowly loose water of crystallization in air. − A thermogravimetric analysis shows the complete loss of water of crystallization at 168°C and decomposition above 280°C. − IR (Nujol): $\tilde{\nu}$ = 3420 cm^{-1} w (br.), 3320 w (br.), 3200 m (br.), 1630 m, 1602 s, 1579 m, 1486 s, 1432 m, 1321 m, 1300 m, 1272 m, 1260 w, 1161 w, 1060 w, 1054 w, 1031 w, 1019 w, 960 w (br.), 888 w, 868 w, 852 w, 828 m, 722 w, 654 m, 596 w, 532 w, 428 w. − Hexahydrate $C_{30}H_{42}Cl_2N_{12}NiO_6$ (796.34): calcd. C 45.25, H 5.31, N 21.11; tetrahydrate $C_{30}H_{38}Cl_2N_{12}NiO_4$ (760.31): calcd. C 47.39, H 4.99, N 22.10; 2.5-hydrate $C_{30}H_{35}Cl_2N_{12}NiO_{2.5}$ (733.28): calcd. C 49.13, H 4.81, N 22.92; found C 47.64, H 4.08, N 22.39.

[Tris(5,5′-diamino-2,2′-bipyridine)nickel(II)] Thiocyanate (18): To an aqueous solution (100 mL) of $NiCl_2 \times 6\ H_2O$ (0.64 g, 2.69 mmol or 0.32 g, 1.35 mmol) was added a DMF solution (10 mL) of **5** (0.50 g, 2.69 mmol). After stirring for 2 h, 50 mL of conc. ammonia was added and stirring was continued for 20 h. During this time the solution changed color from yellow to brown. 20 mL of the aforementioned solution (containing 80 mg/0.34 mmol or 40 mg/0.17 mmol of nickel and 62 mg/0.34 mmol of **5**) was used to overlayer 5 mL of an aqueous solution of 33 mg (0.34 mmol) of KSCN in a test tube. The solution was allowed to stand for 15 d at ambient temperature. The resulting orange-brown crystals were collected by filtration, washed with water and ethanol and dried under vacuum (yield 66−76 mg, 54−66% based on **5**). − $C_{32}H_{30}N_{14}NiS_2$ (733.50): calcd. C 52.41, H 4.09, N 26.75; found C 51.45, H 4.11, N 26.41. − IR (KBr): $\tilde{\nu}$ = 3438 cm^{-1} m, 3300 m, 3190 m, 2076 s ν(SCN), 2048 s ν(SCN), 1630 s, 1602 s, 1580 s, 1460 s, 1443 s, 1318 m, 1310 m, 1300 m, 1275 m, 1170 m, 1163 m, 1148 w, 1060 w, 1035 m, 1021 w, 858 w, 840 m, 825 m, 744 w, 725 m, 700 w, 660 s, 550 m. − $C_{32}H_{30}N_{14}NiS_2$ (733.50): calcd. C 52.41, H 4.09, N 26.75; found C 51.56, H 4.19, N 26.57.

$^1{}_\infty$[Diaqua(5,5′-diamino-2,2′-bipyridine)(μ-sulfato)copper(II)] Hydrate (19): A 25-ml flask was charged with mixture of $CuSO_4 \times 5\ H_2O$ (135 mg, 0.54 mmol), **5** (100 mg, 0.54 mmol) and 10 mL of water, sealed and heated in an oil bath to 120°C for 48 h. After cooling, the dark-green crystals formed were collected by filtration and washed with water and ethanol. Concentration of the filtrate by slow evaporation of the solvent at room temperature for 8 d gave another crop of well-formed dark-green crystals. A total yield of 183 mg (89%) was obtained. − IR (KBr): $\tilde{\nu}$ = 3420 cm^{-1} m, 3340 m, 3220 m, 1650 m, 1606 m, 1590 m, 1495 s, 1446 w, 1332 w to m, 1324 w, 1280 w, 1210 w, 1140 m, 1115 m, 1040 w, 955 w, 925 w, 850 w, 839 w, 718 w, 660 w, 550 w. − $C_{10}H_{14}CuN_4O_6S$ (381.86): calcd. C 31.45, H 3.67, N 14.68; found C 31.32, H 3.84, N 14.70.

[Dichloro(5,5′-diamino-2,2′-bipyridine)copper(II)] (20): 10 mL of an aqueous solution of $CuCl_2 \times 2\ H_2O$ (92 mg, 0.54 mmol) was carefully overlayered in a test tube with 10 mL of an ethanolic solution of **5** (100 mg, 0.54 mmol). The solution was allowed to stand for 7 d at room temperature. After this time, the well-formed rod-shaped dark-green crystals were collected by filtration and washed with cold water and ethanol to give 14 mg of product (82%). − IR (KBr):$\tilde{\nu}$ = 3448 cm^{-1} s, 3346 s, 3210 w, 1615 s, 1603 s, 1580 m, 1510 w, 1492 s, 1435 m, 1350 w to m, 1332 m, 1310 w, 1278 m, 1220 m, 1161 w, 1156 w, 1064 w, 1038 m, 1022 w, 968 w, 885 w, 836 s, 715 m, 665 w, 660 w, 550 m, 530 w. − $C_{10}H_{10}Cl_2CuN_4$ (322.66): calcd. C 37.44, H 3.12, N 17.47; found C 36.45, H 3.12, N 17.15. − The reaction of **5** in ethanol (or THF) with $CuCl_2 \times 2\ H_2O$ in water in the molar ratio of 1:2 also gave **20**.

[(5,5′-Diamino-2,2′-bipyridine)dinitratozinc(II)] (21): A solution of 64 mg (0.22 mmol) of $Zn(NO_3)_2 \times H_2O$ in 5 mL of distilled water was overlayered in a test tube first with 2 mL of ethyl acetate and then with a solution of 35 mg (0.19 mmol) of **5** in 4 mL of ethanol. After standing for several days, colorless rhombohedra had formed at the boundary layer, which were carefully separated, washed with little THF and air-dried (yield 55 mg, 77%). − When **21** was heated with two equivalents of **5** in water crystals formed upon cooling which were shown by analysis to have a 3:1 ligand/metal ratio as in **22**.

[Tris(5,5′-diamino-2,2′-bipyridine)zinc(II)] Nitrate Hydrate (22): To a solution of 167.5 mg (0.56 mmol) $Zn(NO_3)_2 \times 6\ H_2O$ in 20 mL of distilled water was added 332.8 mg (1.79 mmol) of **5** and the mixture heated to reflux for 30 min which led to a clear solution. After cooling to room temperature, the crystals formed were separated by filtration, washed with little ice-cooled water, ethanol and diethyl ether. After drying in air, the complex was obtained as a light yellow fine crystalline powder. Single crystals were obtained by slow cooling of a saturated solution from room temperature to 0°C (yield 320 mg, 69%). − A thermogravimetric analysis shows complete loss of the water of crystallization at 179°C and decomposition above 335°C. − ^{1}H NMR (D_2O):δ = 8.43 (d, J = 8.6, H3, H3′), 7.84 (dd, J_1 = 8.6 Hz, J_2 = 2.6 Hz, H4, H4′), 7.79 (d, J = 2.6 Hz, H6, H6′); ([D_6]DMSO): δ = 8.08 (d, J = 8.7, H3, H3′), 7.19 (dd, J_1 = 8.7 Hz, J_2 = 2.5 Hz, H4, H4′), 7.08 (d, J = 2.5 Hz, H6, H6′). − ^{13}C NMR (D_2O):δ = 145.5 (C2, C2′), 140.8 (C5, C5′), 134.4 (C6, C6′), 126.1 (C4, C4′), 122.2 (C3, C3′). − IR (Nujol): $\tilde{\nu}$ = 3430 cm^{-1} w (br.), 3325 w (br.), 3210 w (br.), 1630 m, 1602 s, 1582 m, 1488 m, 1378 m, 1342 m, 1320 m, 1316 m, 1272 m, 1160 w, 1152 w, 1142 w, 1080 w, 1060 w, 1031 w, 1019 w, 898 w, 892 w, 867 w, 850 w, 838 w, 828 m, 722 m, 658 w. − Dihydrate $C_{30}H_{34}N_{14}O_8Zn$ (784.07): calcd. C 45.94, H 4.37, N 25.00; found C 45.61, H 3.32, N 25.05.

[(5,5′-Diamino-2,2′-bipyridine)nitratosilver(I)] Hydrate (23): A solution of 122 mg (0.72 mmol) of $AgNO_3$ in 10 mL of distilled water was overlayered in a test tube first with 3 mL of dried ethyl acetate and then with a solution of 104 mg (0.56 mmol) of **5** in 15 mL of dried ethanol. After standing for several weeks at room temperature in the dark, yellowish fiber clusters had formed at the layer boundary. They were separated by filtration, washed with some cold water, ethanol and finally diethyl ether. Drying in air gave light yellow fibers (yield 1.66 mg, 76%). − M.p. > 195°C (dec.). − ^{1}H NMR ([D_6]DMSO): δ = 7.92 (d, J = 2.6 Hz, H6, H6′), 7.91 (d, J = 8.8 Hz, H3, H3′), 7.15 (dd, J_1 = 8.6 Hz, J_2 = 2.6 Hz, H4, H4′). − ^{13}C NMR ([D_6]DMSO): δ = 145.2 (C2, C2′), 140.4 (C5, C5′), 136.2 (C6, C6′), 121.9 (C4, C4′), 121.2 (C3, C3′). − IR (Nujol): $\tilde{\nu}$ = 3450 cm^{-1} w (br.), 3325 m (br.), 3210 w (br.), 1628 s, 1604 s, 1574 m, 1488 s, 1422 m, 1350 s, 1326 s, 1296 m, 1271 m, 1252 w, 1153 w, 1062 w, 1043 w, 1022 w, 1018 w, 879 w, 862 w, 843 w, 819 w, 722 m, 652 m, 646 m. − $C_{10}H_{14}AgN_5O_5$ (392.12): calcd. C 30.63, H 3.60, N 17.86; found C 30.22, H 3.18, N 17.63.

[Bis(5,5′-diamino-2,2′-bipyridine)silver(I)] Nitrate (24): A slurry of 225 mg (1.21 mmol) of **5** in 20 mL of distilled water was heated until complete dissolution. Then a hot solution of 110 mg (0.65 mmol) of $AgNO_3$ in 10 mL of water was added which immediately gave a colorless precipitate. This was shown by elemental analysis to have a 1:1 ligand/metal composition. Conc. aqueous ammonia was added dropwise until the precipitate had completely dissolved. The solution was kept at room temperature open to the air and after a few days thin platelets with a mother-of-pearl shine had formed. The crystals were collected by filtration, washed with diethyl ether and dried in vacuo (yield 171 mg, 52%). − M.p. >

230°C. – ^{1}H NMR ([D$_6$]DMSO): δ = 7.91 (d, J = 8.6 Hz, H3, H3′), 7.90 (d, J = 2.3 Hz, H6, H6′), 7.12 (dd, J_1 = 8.6 Hz, J_2 = 2.6 Hz, H4, H4′), 5.68 [s (br.), NH$_2$]. – ^{13}C NMR ([D$_6$]DMSO): δ = 145.1 (C2, C2′), 140.7 (C5, C5′), 136.0 (C6, C6′), 121.8 (C4, C4′), 121.0 (C3, C3′). – IR (Nujol): $\tilde{\nu}$ = 3420 cm^{-1} w, 3340 w, 3205 w, 1632 s, 1602 s, 1582 m, 1575 w, 1488 s, 1429 m, 1368 s, 1352 m, 1328 m, 1310 s, 1292 m, 1268 m, 1206 m, 1165 m, 1028 w, 1019 w, 904 w, 860 w, 838 w, 832 w, 728 w, 655 w. – $C_{20}H_{20}AgN_9O_3$ (542.31): calcd. C 44.30, H 3.70, N 23.25; found C 44.73, H 3.95, N 23.46.

$^1_\infty$[Di(μ-chloro)(5,5′-diamino-2,2′-bipyridine)cadmium(II)] Hydrate (25): A solution of 175 mg (0.87 mmol) $CdCl_2 \times H_2O$ in 10 mL of distilled water was overlayered in a test tube first with 3 mL of ethyl acetate and then with a solution of 130 mg (0.70 mmol) of **5** in 15 mL of ethanol. After standing for several days, colorless rhombohedra had formed at the boundary layer, which were carefully separated, washed with little THF and air-dried (yield 160 mg, 56%). – M.p. > 225°C. – ^{1}H NMR ([D$_6$]DMSO): δ = 7.98 [s (br.), H6, H6′], 7.92 (d, J = 8.7, H3, H3′), 7.14 (dd, J_1 = 8.7 Hz, J_2 = 2.7 Hz, H4, H4′), 5.85 [s (br.), NH$_2$]. – ^{13}C NMR ([D$_6$]DMSO): δ = 145.5 (C2, C2′), 138.0 (C5, C5′), 134.7 (C6, C6′), 122.8 (C4, C4′), 120.8 (C3, C3′). – IR (Nujol): $\tilde{\nu}$ = 3510 cm^{-1} w, 3338 m (br.), 3204 m (br.), 1638 m (br.), 1602 s, 1590 s, 1487 s, 1435 m, 1326 w, 1315 w, 1300 m, 1272 m, 1266 m, 1160 m, 1130 w (br.), 1064 w (br.), 1030 m, 918 m, 862 msh, 845 s, 827 m (br.), 727 m, 700 w, 655 w. – $C_{10}H_{14}CdCl_2N_4O_2$ (405.56): calcd. C 29.59, H 3.48, N 13.80; found C 30.55, H 3.22, N 13.23. – When **25** was heated with two equivalents of **5** in water crystals formed upon cooling which were shown by analysis to have a 3:1 ligand/metal ratio as in **26**.

[Tris(5,5′-diamino-2,2′-bipyridine)cadmium(II)] Chloride Hydrate (26): In 20 mL of an aqueous solution of 117.5 mg (0.58 mmol) of $CdCl_2 \times H_2O$ was suspended 336.0 mg (1.80 mmol) of **5** and heated under reflux for 30 min. From the bright yellow solution fine crystals formed upon cooling, which were filtered, washed with little ethanol and diethyl ether and air-dried. Upon storage in air the crystals slowly lost incorporated solvent water (yield 350 mg, 76%). – M.p. > 225°C. – ^{1}H NMR ([D$_6$]DMSO): δ = 7.90 (d, J = 8.6, H3, H3′), 7.88 (d, J = 2.6 Hz, H6, H6′), 7.09 (dd, J_1 = 8.6 Hz, J_2 = 2.6 Hz, H4, H4′). – ^{13}C NMR ([D$_6$]DMSO): δ = 144.9 (C2, C2′), 139.4 (C5, C5′), 134.6 (C6, C6′), 122.2 (C4, C4′), 120.4 (C3, C3′). – ^{113}Cd NMR (66.0 MHz, ([D$_6$]DMSO), standard is a 2.0 M cadmium perchlorate solution in D$_2$O): δ = 254 (s), half width 30 ppm. – IR (Nujol): $\tilde{\nu}$ = 3425 cm^{-1} w, 3310 w, 3205 w, 1628 s, 1604 m, 1586 w, 1495 s, 1440 s, 1330 m, 1322 w, 1280 w, 1269 w, 1172 w, 1168 w, 1130 w (br.), 1036 w, 1028 w, 970 w, 905 w, 888 w, 870 w, 833 m, 728 w, 668 w, 660 w. – Dihydrate $C_{30}H_{34}CdCl_2N_{12}O_2$ (778.00): calcd. C 46.29, H 4.40, N 21.59; found: C 45.59, H 3.85, N 21.48.

X-ray Structure Determinations: Data were collected with Mo-K_α radiation (λ = 0.71073 Å) and the use of a graphite monochromator. Structure solution was performed by direct methods using SHELXS-97.[65] Refinement: Full-matrix least-squares on F^2 [SHELXL-97 (version 97–2)];[65] all non-hydrogen positions found and refined with anisotropic temperature factors. Crystal data are

[a] Largest difference peak and hole. – [b] Largest difference peak and hole. – [c] $R1 = (\Sigma\ F_o - F_c)/\Sigma\ F_o$; $wR2 = \{\Sigma[w(F_o^2 - F_c^2)^2] / \Sigma[w(F_o^2)^2]\}^{1/2}$. – [d] Goodness-of-fit, Gof = $\{\Sigma\ [w(F_o^2 - F_c^2)^2]/(n - p)\}^{1/2}$. – [e] $w = 1/[\sigma^2(F_o^2) + (a{\cdot}P)^2 + b{\cdot}P]$ where $P = [\max(F_o^2 \text{ or } 0) + 2{\cdot}F_c^2]/3$. – [f] Two independent molecules in the unit cell. – [g] Structure refinement was hampered by the disorder in the anion-water layer.

listed in Table 5. The structure of compound **22** was refined as an axis twin (twin axis [010]). The volume fraction of the twin component from refinement was 0.5118(10), i.e. there is almost 1:1 twinning. Graphics were computed with ORTEP3 for Windows.[66] Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Center as supplementary publication no. CCDC-119339 (**15**), -119340 (**16**), -119341 (**17**), -119342 (**18**), 119343 (**19**), -119344 (**20**), -119345 (**22**), and -119346 (**25**). Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: int. code + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk]. − Additional information (distances and angles) on hydrogen bonding which is not described in detail here can be found in the Supporting Information.

Boryl and Bridged Borylene Complexes of Iron and Ruthenium

Holger Braunschweig,*[a] Carsten Kollann,*[a] and Karl W. Klinkhammer[b]

Keywords: Boron / Iron / Ruthenium / Boryl Complexes / Borylene Complexes

The reactivity of aminodihaloboranes R_2NBX_2 (R = Me, $SiMe_3$; X = Cl, Br) towards transition metal complexes of the type $Na[(\eta^5\text{-}C_5R'_5)M(CO)_2]$ (M = Fe, Ru; R′ = H, Me) was investigated. In the case of Me_2NBBr_2 and M = Fe the borylcomplexes $[(\eta^5\text{-}C_5R'_5)(CO)_2Fe\{BBr(NMe_2)\}]$ ($C_5R'_5$ = C_5H_5 **9a**; $C_5R'_5$ = C_5H_4Me **9b**; $C_5R'_5$ = C_5Me_5 **10**) were obtained. The compounds **9a** and **9b** were formed together with the corresponding bridged borylene complexes $[\mu\text{-}BNMe_2(\mu\text{-}CO)\{(\eta^5\text{-}C_5R'_5)Fe(CO)\}_2]$ ($C_5R'_5$ = C_5H_5 **11a**; $C_5R'_5$ = C_5H_4Me **11b**) in a 1:1 ratio, the latter, however, could be isolated from these mixtures as pure materials. In addition the novel boryl and borylene ruthenium complexes $[(\eta^5\text{-}C_5H_5)(CO)_2Ru\{BX(NMe_2)\}]$ (X = Cl **12a**; X = Br **12b**), $[(\eta^5\text{-}C_5H_5)(CO)_2Ru\{BCl\{NSiMe_3\{BClN(SiMe_3)_2\}\}\}]$ (**13**) and $[\mu\text{-}BN(SiMe_3)_2(\mu\text{-}CO)\{(\eta^5\text{-}C_5H_5)Ru(CO)\}_2]$ (**14**) were obtained by similar methods. All compounds were characterized by multinuclear NMR and IR spectroscopy. The structure of **13** in the solid state was determined by a single-crystal X-ray diffraction study.

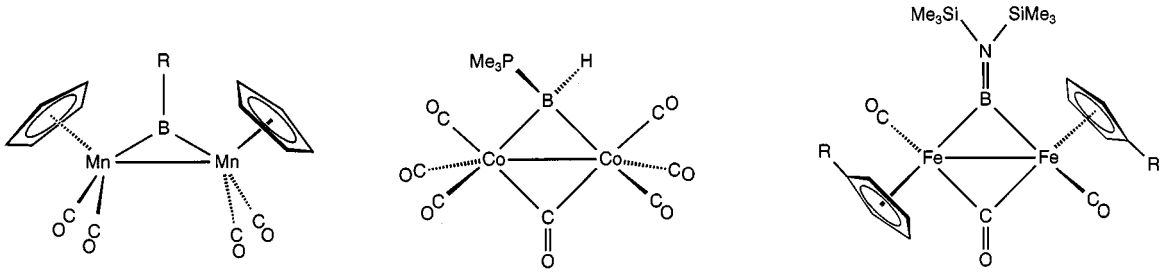
Introduction

Transition metal complexes of boron, especially boryl and borylene complexes, have attracted considerable interest over the last decade.[1][2] The synthesis of boryl complexes, which are known to be versatile compounds for the functionalization of hydrocarbons,[3a−3c,4] is achieved mainly by the use of 1,2-dioxobenzo- or catecholborane and its derivatives.[5a−5j] More recently, however, nitrogen-substituted boranes have also proved to be well suited for the synthesis of such compounds. Examples include aminoboryl complexes,[6a,6b] diborane(4)yl complexes[7a,7b] and η^1-borazine complexes.[8]

In contrast to numerous reports on boryl complexes, only very few bridged[9−11] and terminal[12][13] borylene complexes are known. The first compounds of this class, bridged borylene complexes of the type $[\mu\text{-}BR\{(\eta^5\text{-}C_5H_5)Mn(CO)_2\}_2]$ (R = NMe_2 **1a**; R = *t*Bu **1b**), were obtained by an unprecedented reaction of diboranes(4) with cleavage of the boron boron bond[9a,9b] and, recently, the corresponding dinuclear cobalt complex $[\mu\text{-}BH(PMe_3)(\mu\text{-}CO)\{Co(CO)_3\}_2]$ (**2**) was obtained by a similar cleavage reaction of 1,2-bis(trimethylphosphane)diborane(4) (Scheme 1).[10] In the case of compounds **1** the range of bridged borylene complexes was broadened by utilizing substitution reactions at the metal-coordinated boron with preservation of the central Mn_2B core.[11] Both synthetic methods, however, are very specific and are restricted to the examples mentioned above. In order to open a more general access to bridged borylene complexes we investigated the reactions of aminodihaloboranes with anionic transition metal complexes. The compounds $[\mu\text{-}BN(SiMe_3)_2(\mu\text{-}CO)\{(\eta^5\text{-}C_5R'_5)Fe(CO)\}_2]$ ($C_5R'_5$ = C_5H_5 **3a**; $C_5R'_5$ = C_5H_4Me **3b**) represent the first borylene complexes obtained by this method (Scheme 1).[6b]

In the first part of the present paper we describe the synthesis of boryl and bridged borylene complexes from the reaction of Me_2NBBr_2 with $Na[(\eta^5\text{-}C_5R_5)Fe(CO)_2]$ (R = H, Me) and point out some differences with respect to the corresponding reactions of Me_2NBCl_2.[6b]

The second part of the paper reports on novel ruthenium complexes of boron, including the synthesis and spectroscopic characterization of the first bridged borylene complex of this transition metal.



Results and Discussion

Iron Complexes

A number of iron complexes of boron were obtained by salt elimination reactions employing the strongly nucleophilic compound $Na[(\eta^5\text{-}C_5R_5)Fe(CO)_2]$ (R = H, Me) and suitable haloboranes. Examples include boryl complexes such as $[(\eta^5\text{-}C_5H_5)Fe(CO)_2)BCat]$ (Cat = 1,2-$O_2C_6H_4$) (**4**) and $[(\eta^5\text{-}C_5H_5)Fe(CO)_2)BPh_2]$ (**5**)[5a], the diborane(4)yl complex $[(\eta^5\text{-}C_5H_5)Fe(CO)_2\{B(NMe_2)BCl(NMe_2)\}]$ (**6**)[7a] and the η^1-borazine complexes $[\{(C_5R_5)(CO)_2Fe\}_n\text{-}Cl_{3-n}B_3N_3H_3]$ (*n* = 1, C_5R_5 = C_5Me_5 **7a**; *n* = 2, C_5R_5 = C_5H_4Me **7b**; *n* = 3, C_5R_5 = C_5H_5 **7c**).[8] In the case of aminodichloroboranes, corresponding reactions with the sterically less demanding Me_2NBCl_2 always resulted in the formation of monosubstituted boryl complexes $[(\eta^5\text{-}C_5R_5)(CO)_2Fe\{BCl(NMe_2)\}]$ (C_5R_5 = C_5Me_5 **8a**; C_5R_5 = C_5H_4Me **8b**; C_5R_5 = C_5H_5 **8c**) regardless of the iron to boron ratio.[6b] The more bulky, albeit more electrophilic $(Me_3Si)_2NBCl_2$, however, reacts with substitution of both the chloride ligands yielding the bridged borylene complexes $[\mu\text{-}BN(SiMe_3)_2(\mu\text{-}CO)\{(\eta^5\text{-}C_5R'_5)Fe(CO)\}_2]$ ($C_5R'_5$ = C_5H_5 **3a**; $C_5R'_5$ = C_5H_4Me **3b**).[6b]

Scheme 1. Examples for bridged borylene complexes

Due to the weaker boron halide bonds,[14a,14b] Me_2NBBr_2 proves to be more reactive than the corresponding aminodichloroborane and reacts with $Na[(\eta^5\text{-}C_5R_5)Fe(CO)_2)]$ in benzene at ambient temperature to form a 1:1 mixture of the boryl complexes $[(\eta^5\text{-}C_5R'_5)(CO)_2Fe\{BBr(NMe_2)\}]$ ($C_5R'_5$ = C_5H_5 **9a**; $C_5R'_5$ = C_5H_4Me **9b**) and the corresponding bridged borylene complexes $[\mu\text{-}BNMe_2(\mu\text{-}CO)\{(\eta^5\text{-}C_5R'_5)Fe(CO)\}_2]$ ($C_5R'_5$ = C_5H_5 **11a**; $C_5R'_5$ = C_5H_4Me **11b**) according to Scheme 2. These mixtures were obtained as dark red solids from hexane at −30°C and attempts to seperate the boryl and borylene complexes by crystallisation or sublimation failed. The multinuclear NMR spectra of these mixtures, however, show no significant impurities and it was possible to assign all signals by comparison with the related compounds **8b**, **c** and **3a**, **b**, respectively. The boryl complexes **9a**, **b** are characterized by low-field-shifted signals in the ^{11}B-NMR spectra at δ = 54.5 (**9a**) and 55.0 (**9b**), and show the expected double sets of signals for the Me_2N groups in both ^{1}H- and ^{13}C-NMR spectra, indicating a hindered rotation of this group with respect to the boron nitrogen double bond. Interestingly, treatment of the obtained mixtures with water in diethyl ether under air (Scheme 2) resulted in a selective hydrolysis of the boryl complexes and the borylene complexes **11a**, **b** could subsequently be isolated as dark red crystals. The stability of **11a**, **b** towards air and water is in sharp contrast

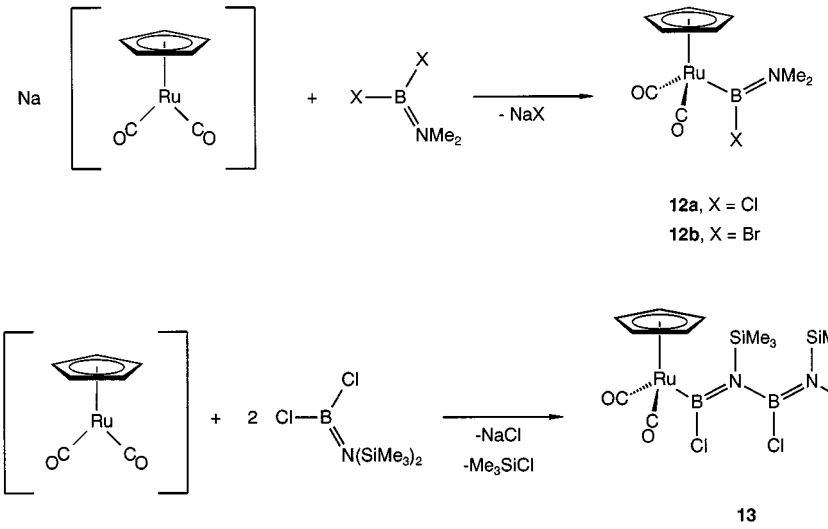
Scheme 2. Syntheses of the bridged borylene complexes **11a**, **b**

10

to the known reactivity of $[\mu\text{-}BN(SiMe_3)_2(\mu\text{-}CO)\{(\eta^5\text{-}C_5R'_5)Fe(CO)\}_2]$ ($C_5R'_5 = C_5H_5$ **3a**; $C_5R'_5 = C_5H_4Me$ **3b**),[6b] which decompose under these conditions, whereas the related dimethylaminoborylene complex $[\mu\text{-}BNMe_2\{(\eta^5\text{-}C_5H_5)Mn(CO)_2\}_2]$ (**1a**)[9a,9b] exhibits a very similar stability. One might expect the electron-withdrawing effect of the nitrogen bound $SiMe_3$ groups and, hence, the enhanced electrophilicity of the boron atom in **3a**, **b** to be responsible for this different reactivity. The molecular structure of **11a**, **b** in solution can be deduced from the NMR and IR spectra. Due to the formation of two iron boron bonds these borylene complexes show highly deshielded signals in their ^{11}B-NMR spectra at $\delta = 103.5$ (**11a**) and 104.5 (**11b**). The presence of a bridging carbonyl group, which has already been found for **3a**, **b** is established by ^{13}C-NMR and IR spectroscopic data (**11a,** $\delta = 275.8$, $\tilde{\nu} = 1942$ cm^{-1}, 1776 cm^{-1}; **11b,** $\delta = 277.0$, $\tilde{\nu} = 1946$ cm^{-1}, 1778 cm^{-1}).



Similar reactions of Me_2NBBr_2 with the sterically demanding $Na[(\eta^5\text{-}C_5Me_5)Fe(CO)_2]$ result in the selective substitution of only one bromide and formation of the boryl complex $[(\eta^5\text{-}C_5Me_5)(CO)_2Fe\{BBr(NMe_2)\}]$ (**10**), which is isolated as a brown crystalline solid in 34% yield after recrystallization from hexane (Equation 1). The structure of **10** in solution is derived from the NMR and IR spectra, which resemble those of the related compounds **8a**−**c** and **9a**, **b**, e.g. the signal in the ^{11}B-NMR spectrum at $\delta = 57.2$ and the characteristic double sets of signals for the Me_2N group in both ^{1}H- and ^{13}C-NMR spectra. The CO stretching frequencies in the IR spectrum at 1991 cm^{-1} and 1933 cm^{-1} give no evidence for any iron-boron π-backbonding in solution, which corresponds to the findings for other nitrogen-substituted boryl complexes of iron.[6b,7a,8]

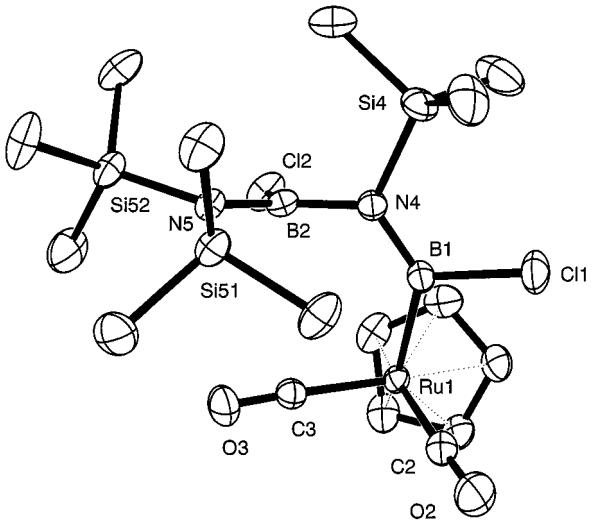
Ruthenium Complexes

Ruthenium complexes of boron, which are characterized by two-centre, two-electron bonds between ruthenium and boron are extremely rare. The few examples known, include the boryl complexes $[(\eta^5\text{-}C_5Me_5)Ru(CO)_2\{B(1,2\text{-}O_2\text{-}3,5\text{-}Me_2C_6H_2)\}]$[4] and $[Ru(BR_2)Cl(CO)(PPh)_3]$ (R = various ligands),[15] as well as the diborane(4)yl complex $[(\eta^5\text{-}C_5H_5)Ru(CO)_2\{B(NMe_2)BCl(NMe_2)\}]$.[7b] The latter represents the only structurally characterized compound of this type.

The anionic ruthenium moiety $[(\eta^5\text{-}C_5H_5)Ru(CO)_2]^-$ was reported to be less nucleophilic than the corresponding iron anion $[(\eta^5\text{-}C_5H_5)Fe(CO)_2]^-$ and hence one might expect a reduced, and probably more selective, reactivity with respect to salt eliminations.[16] Indeed, the reaction of $Na[(\eta^5\text{-}C_5H_5)Ru(CO)_2]$ with Me_2NBX_2 (X = Cl, Br) results in the selective formation of the borylcomplexes $[(\eta^5\text{-}C_5H_5)(CO)_2Ru\{BX(NMe_2)\}]$ (X = Cl **12a**; X = Br **12b**) with substitution of only one halide according to Equation 2. Both compounds can be isolated as dark yellow crystalline materials from hexane in yields of 77% (**12a**) and 41% (**12b**), respectively. These boryl complexes are stable at ambient temperature in hydrocarbon solution under nitrogen but decompose rapidly on contact with air or water. The structure of **12a, b** in solution is derived from multinuclear-NMR and IR spectroscopy. The signals in the ^{11}B-NMR spectra at $\delta = 50.3$ (**12a**) and 48.1 (**12b**) are considerably shifted to lower field with respect to the signals of the starting aminoboranes ($\delta \approx 30$),[17] thus appearing in the expected region for aminoboryl complexes. The double sets of signals for the Me_2N groups in the NMR spectra are again consistent with a hindered rotation of this group with respect to the boron nitrogen double bond. A variable temperature ^{1}H-NMR spectroscopic study of **12a** shows a coalescence of the two resonances at 98 °C from which a value of $\Delta G^{\neq} = 75.4$ kJ/mol for the rotation barrier can be calculated. This figure is in agreement with a value of $\Delta G^{\neq} = 72.3$ kJ/mol for the related iron complex $[(\eta^5\text{-}C_5R_5)(CO)_2Fe\{BCl(NMe_2)\}]$ ($C_5R_5 = C_5H_4Me$ **8b**).[6b] The IR spectra of both compounds show no evidence for a metal boron π-interaction, since the CO stretching frequencies (**12a**, 2019 cm^{-1}, 1956 cm^{-1}; **12b**, 2022 cm^{-1}, 1960 cm^{-1}) closely resemble those of the corresponding methyl ruthenium complex (2028 cm^{-1}, 1960 cm^{-1}).[18]

The compound $Na[(\eta^5\text{-}C_5H_5)Ru(CO)_2]$ exhibits a markedly different reactivity towards $(Me_3Si)_2NBCl_2$ and the nature of the reaction products depends on the reaction conditions and stoichiometry employed. According to Equation 3, $Na[(\eta^5\text{-}C_5H_5)Ru(CO)_2]$ reacts with two equivalents of $(Me_3Si)_2NBCl_2$ to form the boryl complex **13**, which can be isolated in 30% yield as a yellow crystalline material. This compound contains the unusual boryl ligand $-BCl(NSiMe_3)-BCl[N(SiMe_3)_2]$, which was formed by an intramolecular elimination of $ClSiMe_3$. The solution spectroscopic data indicate a structure for compound **13** similar to the ruthenium boryl complexes **12a**, **b**. This is indicated by a lowfield-shifted signal in the ^{11}B-NMR spectrum at $\delta = 60.3$ for the metal-coordinated boron atom ($\delta = 35.0$ for NBN) and the CO stretching frequencies at 2018 cm^{-1} and 1955 cm^{-1} in the IR spectrum. Crystals of **13** suitable

for an X-ray structure analysis were obtained after several days from hexane solutions at −30°C (Scheme 1). The complex crystallizes in the spacegroup $P\bar{1}$ and the molecule adopts C_1 symmetry in the crystal. The ruthenium-boron distance of 211.5(2) pm is 6 pm shorter than in the compound $[(\eta^5\text{-}C_5H_5)Ru(CO)_2\{B(NMe_2)BCl(NMe_2)\}]$,[7b] but still exceeds the sum of the covalent radii of both elements, thus giving no evidence for a ruthenium-boron π-interaction in the solid state. In the BNBN chain, two short boron-nitrogen distances of 141.5(2) pm (B1−N4) and 140.5(3) pm (B2−N5) are found, together with a significantly longer distance of 147.0(2) pm (B2−N4). These values, together with the dihedral angles between the bonding planes of B1/N4 (17.5°), B2/N4 (96.2°) and B2/N5 (17.7°), indicate boron nitrogen double bonds between B1 and N4, and between B2 and N5, and a single bond between B2 and N4.



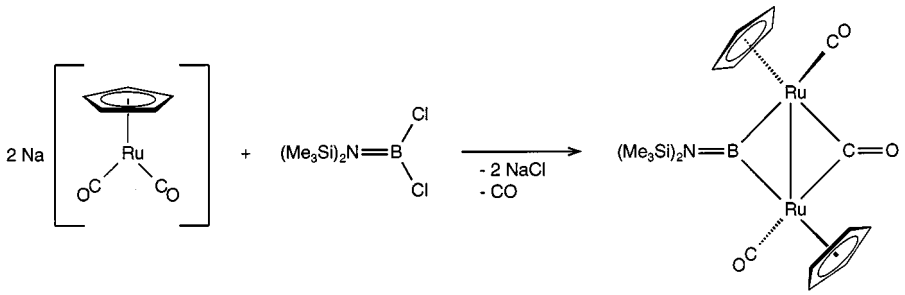


Figure 1. X-ray crystal structure of **13**. Selected bond lengths (pm) and angles (deg): Ru1−B1 211.5(2); B1−N4 141.5(2); B1−Cl1 185.4(2); N4−B2 147.0(2); B2−Cl2 182.2(2); B2−N5 140.5(2); Ru1−B1−Cl1 112.54(9); Ru1−B1−N4 133.29(12); Cl1−B1−N4 114.01(12); B1−N4−B2 120.90(14); N4−B2−Cl2 114.18(12); Cl2−B2−N5 118.76(13); N4−B2−N5 126.97(15).

The bridged borylene ruthenium complex $[\mu\text{-}BN(SiMe_3)_2(\mu\text{-}CO)\{(\eta^5\text{-}C_5H_5)Ru(CO)\}_2]$ (**14**) can be obtained from the reaction of $(Me_3Si)_2NBCl_2$ with two equivalents of $Na[(\eta^5\text{-}C_5H_5)Ru(CO)_2)]$, according to Equation 4, with elimination of one CO group. In order to prevent the formation of **13** as a by-product, the aminodichloroborane has to be added very slowly to a suspension of an excess of the anionic ruthenium complex. The borylene complex **14** can be isolated as a moderately air- and water-sensitive yellow amorphous solid from hexane at −30°C in 20% yield. The molecular structure of **14** in solution can be deduced from NMR and IR spectroscopic data and resembles that for the analogous iron compounds. The strongly deshielded signal at δ = 105.9 in the ^{11}B-NMR spectrum is in the expected region for aminobridged borylene complexes and the presence of a bridging CO group is established by the characteristic signal at δ = 250.2 in the ^{13}C-NMR spectrum and by a CO stretching frequency of 1776 cm^{-1} in the IR spectrum.

Conclusion

This study provides some insight into the reactivity of transition metal complexes of the type $Na[(\eta^5\text{-}C_5R_5)M(CO)_2)]$ (M = Fe, Ru) towards aminodihaloboranes. In the case of the strong nucleophiles $[(\eta^5\text{-}C_5R_5)Fe(CO)_2)]^-$ (C_5R_5 = C_5H_5, C_5H_4Me) the formation of bridged borylene complexes may be achieved not only by the use of electrophilic aminoboranes, such as $(Me_3Si)_2NBCl_2$, but also by employing dibromoboranes, which contain a more reactive boron halide bond. This is illustrated by the formation of $[\mu\text{-}BNMe_2(\mu\text{-}CO)\{(\eta^5\text{-}C_5R_5)Fe(CO)\}_2]$ (C_5R_5 = C_5H_5 **11a**; C_5R_5 = C_5H_4Me **11b**) from Me_2NBr_2. The reaction of Me_2NBr_2 with the very bulky $Na[(\eta^5\text{-}C_5Me_5)Fe(CO)_2)]$, however, results in the substitution of only one bromide and formation of the boryl complex $[(\eta^5\text{-}C_5Me_5)(CO)_2Fe\{Br(NMe_2)\}]$ (**10**).

The less nucleophilic ruthenium analogue $[(\eta^5\text{-}C_5H_5)Ru(CO)_2)]^-$ reacts with both Me_2NBCl_2 and Me_2NBBr_2 with selective substitution of only one halide

14

and formation of the boryl complexes $[(\eta^5\text{-}C_5H_5)(CO)_2Ru\{BX(NMe_2)\}]$ (X = Cl **12a**; X = Br **12b**). The first bridged borylene complex of ruthenium $[\mu\text{-}BN(SiMe_3)_2(\mu\text{-}CO)\{(\eta^5\text{-}C_5H_5)Ru(CO)\}_2]$ (**14**) was obtained from the reaction of $(Me_3Si)_2NBCl_2$ with two equivalents of $Na[(\eta^5\text{-}C_5H_5)Ru(CO)_2]$.

The reactivity of aminobridged borylene complexes of the type $[\mu\text{-}BNR_2\{ML_x\}_2]$ with respect to hydrolysis and oxidation depends on the electronic nature of the amino-group NR_2 and, to a lesser extent, on steric factors or on the transition metal. In the case where $NR_2 = N(SiMe_3)_2$, the electron-withdrawing effect of the silyl groups enhances the reactivity of the borylene complexes. The sterically less demanding, albeit stronger electron donating, Me_2N group, however, makes the corresponding borylene complexes rather unreactive towards air and/or water.

Experimental Section

All manipulations were carried out under dry nitrogen using standard Schlenk techniques, unless otherwise stated. Solvents and reagents were dried by standard procedures, distilled and stored under nitrogen over molecular sieves. Me_2NBCl_2,[19] Me_2NBBr_2,[19] $(Me_3Si)_2NBCl_2$,[20] $Na[(\eta^5\text{-}C_5R_5)Fe(CO)_2]$[21] and $Na[(\eta^5\text{-}C_5H_5)Ru(CO)_2]$[22] were synthesized according to literature procedures. − NMR: Varian Unity 500 at 499.843 MHz (^1H, standard TMS internal), 150.364 MHz (^{11}B, standard $BF_3{\cdot}OEt_2$ in C_6D_6 external), 125.639 MHz ($^{13}C\{^1H\}$, APT, standard TMS internal); all NMR spectra were recorded in C_6D_6 as solvent. − Mass spectra were recorded on a Finnigan MAT 95 (70 eV) and elemental analyses (C, H, N) were obtained from a Carlo−Erba elemental analyzer, model 1106. − IR: Perkin−Elmer FT-IR 1720x.

Reaction of $Na[(\eta^5\text{-}C_5H_5)Fe(CO)_2]$ with Me_2NBBr_2: $Na[(\eta^5\text{-}C_5H_5)Fe(CO)_2]$ (0.80 g, 4.00 mmol) was suspended in 25 mL of benzene and Me_2NBBr_2 (0.43 g, 2.00 mmol) was added dropwise at ambient temperature. After stirring for 15 min, all volatiles were removed in vacuo and the residue was treated with 20 mL of hexane, filtered and the remaining solid rinsed with 5 mL of hexane. The dark red filtrate was concentrated in vacuo to 15 mL and stored at −30°C for a period of 7 d. The dark red precipitate thus formed was found to be a 1:1 mixture of the boryl complex **9a** and the bridged borylene complex **11a**. − ^1H NMR: δ = 2.72 (s, 3 H, NMe, **9a**), 2.87 (s, 3 H, NMe, **9a**), 2.98 (s, 6 H, NMe_2, **11a**), 4.10 (s, 5 H, C_5H_5, **9a**), 4.39 (s, 10 H, C_5H_5, **11a**). − ^{11}B NMR: δ = 54.5 (s, 1 B, Fe−B−Br, **9a**), 103.5 (s, 1 B, Fe−B−Fe, **11a**). − ^{13}C NMR: δ = 35.3 (NMe, **9a**), 37.9 (NMe, **9a**), 43.1 (NMe_2, **11a**), 83.1 (C_5H_5, **9a**), 87.0 (C_5H_5, **11a**), 213.6 (CO, **11a**), 216.9 (CO, **9a**), 275.8 (μ-CO, **11a**).

Isolation of μ-Carbonyl-[μ-(dimethylamino)boranediyl]bis[carbonyl-(η^5-cyclopentadienyl)iron](*Fe−Fe*) (11a): The mixture of **9a/11a** was dissolved in 15 mL of raw diethyl ether and 10 mL of water were added without employing an inert gas atmosphere. After vigorously shaking the mixture for 3 min, the red organic layer was separated from the turbid, brownish aqueous phase and evaporated to dryness. The remaining red solid was recrystallized from 10 mL of hexane, yielding pure **11a** (0.08 g, 10.5%) as a dark red, crystalline solid. − ^1H NMR: δ = 2.98 (s, 6 H, NMe_2), 4.39 (s, 10 H, C_5H_5). − ^{11}B NMR: δ = 103.5 (s). − ^{13}C NMR: δ = 43.1 (NMe_2), 87.0 (C_5H_5), 213.6 (CO), 275.8 (μ-CO). − IR (toluene): $\tilde{\nu}$ = 1942 cm^{-1}, 1776 (CO). − $C_{15}H_{16}BFe_2NO_3$ (380.79): calcd. C 47.31, H 4.24; N 3.68; found C 46.85; H 4.39; N 3.80.

Reaction of $Na[(\eta^5\text{-}C_5H_4Me)Fe(CO)_2]$ with Me_2NBBr_2: This compound was prepared as described above, using $Na[(\eta^5\text{-}C_5H_4Me)Fe(CO)_2]$ (2.42 g, 11.31 mmol) and Me_2NBBr_2 (0.97 g, 4.53 mmol). The dark red solid obtained is a 1: 1 mixture of the boryl complex **9b** and the bridged borylene complex **11b**. − ^1H NMR: δ = 1.79 (s, 3 H, C_5H_4Me, **9b**), 1.86 (s, 6 H, C_5H_4Me, **11b**), 2.68 (s, 3 H, NMe, **9b**), 2.76 (s, 3 H, NMe, **9b**), 3.06 (s, 6 H, NMe_2, **11b**), 3.95−4.03 (m, 4 H, C_5H_4Me, **9b**), 4.08−4.48 (m, 8 H, C_5H_4Me, **11b**). − ^{11}B NMR: δ = 55.0 (s, 1 B, Fe−B−Br, **9b**), 104.5 (s, 1 B, Fe−B−Fe, **11b**). − ^{13}C NMR. δ = 12.9 (C_5H_4Me, **11b**), 13.1 (C_5H_4Me, **9b**), 34.7 (NMe, **9b**), 37.5 (NMe, **9b**), 43.2 (NMe_2, **11b**), 83.1, 85.2 (C_5H_4Me, **9b**), 83.7, 84.7, 86.2, 90.2 (C_5H_4Me, **11b**), 102.4 (*ipso*-C, C_5H_4Me, **9b**), 103.8 (*ipso*-C, C_5H_4Me, **11b**), 214.0 (CO, **11b**), 218.5 (CO, **9b**), 277.0 (μ-CO, **11b**).

Isolation of μ-Carbonyl-[μ-(dimethylamino)boranediyl]bis[carbonyl-(η^5-methylcyclopentadienyl)iron](*Fe−Fe*) (11b): The mixture of **9b/11b** was treated in the same way as described above. After recrystallisation from hexane, pure **11b** (0.19 g, 12.0%) was recovered at −30°C as a red, crystalline solid. − ^1H NMR: δ = 1.86 (s, 6 H, C_5H_4Me), 3.06 (s, 6 H, NMe_2), 4.08−4.48 (m, 8 H, C_5H_4Me). − ^{11}B NMR: δ = 104.5 (s). − ^{13}C NMR: δ = 12.9 (C_5H_4Me), 43.2 (NMe_2), 83.7, 84.7, 86.2, 90.2 (C_5H_4Me), 103.8 (*ipso*-C, C_5H_4Me), 214.0 (CO, **11b**), 277.0 (μ-CO). − IR (toluene): $\tilde{\nu}$ = 1946 cm^{-1}, 1778 (CO). − $C_{17}H_{20}BFe_2NO_3$ (408.84): calcd. C 49.94, H 4.93; N 3.43; found C 49.79; H 4.99; N 3.51.

[Bromo(dimethylamino)boryl]dicarbonyl(η^5-pentamethylcyclopentadienyl)iron (10): $Na[(\eta^5\text{-}C_5Me_5)Fe(CO)_2]$ (1.64 g, 6.07 mmol) was suspended in 30 mL of benzene and Me_2NBBr_2 (1.29 g,5.92 mmol) was added dropwise from a syringe at ambient temperature. After stirring for 15 min, all volatiles were removed in vacuo and the dark brown, solid residue was treated with 20 mL of hexane, filtered and the remaining solid rinsed with 10 mL of

hexane. The dark red filtrate was concentrated in vacuo to 15 mL and stored at −30°C overnight. Compound **10** (0.77 g, 33.7%) was obtained as red-brown needles. − ^{1}H NMR: δ = 1.52 (s, 15 H, C_5Me_5), 2.87 (s, 3 H, NMe), 3.06 (s, 3 H, NMe). − ^{11}B NMR: δ = 57.2. − ^{13}C NMR δ = 9.8 (C_5Me_5), 44.4 (NMe), 44.8 (NMe), 95.5 (C_5Me_5), 217.4 (CO). − IR (toluene): $\tilde{\nu}$ = 1991 cm^{-1}, 1933 (CO). − $C_{14}H_{21}BBrFeNO_2$ (381.89): calcd. C 44.03, H 5.54, N 3.67; found C 43.97, H 5.82, N 3.60.

[Chloro(dimethylamino)boryl]dicarbonyl(η^5-cyclopentadienyl)-ruthenium (12a): As described for **10**, Na[(η^5-C_5H_5)Ru(CO)$_2$] (0.65 g, 2.65 mmol) was treated with Me_2NBCl_2 (0.33 g, 2.65 mmol). Compound **12a** (0.64 g, 77.4%) was obtained as a brown-yellow, crystalline solid. − ^{1}H NMR: δ = 2.70 (s, 3 H, NMe), 2.91 (s, 3 H, NMe), 4.61 (s, 5 H, C_5H_5). − ^{11}B NMR: δ = 50.3. − ^{13}C NMR: δ = 40.7 (NMe), 44.4 (NMe), 87.4 (C_5H_5), 201.9 (CO). − IR (toluene): $\tilde{\nu}$ = 2019 cm^{-1}, 1956 (CO). − $C_9H_{11}BClNO_2Ru$ (312.51): calcd. C 34.59; H 3.55, N 4.48; found C 34.03, H 3.59, N 4.30.

[Bromo(dimethylamino)boryl]dicarbonyl(η^5-cyclopentadienyl)-ruthenium (12b): As described for **10**, 1.86 g (7.65 mmol) of Na[(η^5-C_5H_5)Ru(CO)$_2$] was treated with 1.64 g (7.65 mmol) Me_2NBBr_2. Compound **12b** (1.12 g, 40.1%) was obtained as brown-yellow crystals. − ^{1}H NMR: δ = 2.72 (s, 3 H, NMe), 2.99 (s, 3 H, NMe), 4.59 (s, 5 H, C_5H_5). − ^{11}B NMR: δ = 48.1. − ^{13}C NMR: δ = 43.5 (NMe), 45.0 (NMe), 87.8 (C_5H_5), 201.9 (CO). − IR (toluene): $\tilde{\nu}$ = 2022 cm^{-1}, 1960 (CO). − $C_9H_{11}BBrNO_2Ru$ (356.96): calcd. C 30.28; H 3.11, N 3.92; found C 30.19, H 3.34, N 4.08.

Dicarbonyl(chloro{chlorobis(trimethylsilylamino)boryl](trimethylsilyl)amino}boryl)(η^5-cyclopentadienyl)ruthenium (13): Na[(η^5-C_5H_5)Ru(CO)$_2$] (0.87 g, 3.55 mmol) was suspended in 25 mL of benzene and $(Me_3Si)_2NBCl_2$ (1.72 g, 7.10 mmol) was added all at once at ambient temperature. After stirring for 20 min, all volatiles were removed in vacuo and the brown, solid residue was treated with 25 mL of hexane, filtered and the remaining solid was rinsed with hexane (2 × 5 mL). The brown filtrate was concentrated in vacuo to 15 mL and stored at −30°C. After 72 h, **13** (0.60 g, 30.1%) was obtained as dark yellow crystals. − ^{1}H NMR: δ = 0.44 [s, 18 H, N(SiMe$_3$)$_2$], 0.49 (s, 9 H, NSiMe$_3$), 4.80 (s, 5 H, C_5H_5). − ^{11}B NMR: δ = 35.0 (s, 1 B, NBN), 60.3 (s, 1 B, NBRu). − ^{13}C NMR: δ = 3.8 [N(SiMe$_3$)$_2$], 5.3 (NSiMe$_3$), 89.3 (C_5H_5), 202.3 (CO). − IR (toluene): $\tilde{\nu}$ = 2018 cm^{-1}, 1955 (CO). − MS; *m/z* (%): 547 (5) [M$^+$ − Me], 534 (4) [M$^+$ − CO], 439 (6) [M$^+$ − Me − ClSiMe$_3$], 339 (40) [M$^+$ − (C_5H_5)Ru(CO)$_2$], 231 (100) [M$^+$ − ClSiMe$_3$ − (C_5H_5)Ru(CO)$_2$], 98 (75) [BNSiMe$_3^+$], 73 (90) [SiMe$_3^+$]. − $C_{16}H_{32}B_2Cl_2N_2O_2RuSi_3$ (562.29): calcd. C 34.17; H 5.74; N 4.98; found C 34.26; H 5.89; N 4.93.

{μ-[Bis(trimethylsilyl)amino]boranediyl}-μ-carbonylbis[carbonyl-(η^5-cyclopentadienyl)ruthenium](*Ru−Ru*) (14): A solution of $(Me_3Si)_2NBCl_2$ (0.38 g, 1.58 mmol) in 5 mL of benzene was added dropwise over a period of 10 min to a suspension of Na[(η^5-C_5H_5)Ru(CO)$_2$] (1.55 g, 6.32 mmol) in 20 mL of benzene at ambient temperature. The colour of the reaction mixture turned from dark yellow to brown during the addition. After stirring the mixture for another 10 min, all volatiles were removed in vacuo. The light brown residue was suspended in 20 mL of hexane and filtered. Compound **14** (0.18 g, 19.6%) was recovered from the filtrate at −30°C as an orange, amorphous solid. − ^{1}H NMR: δ = 0.29 (s, 18 H, SiMe$_3$), 4.90 (s, 10 H, C_5H_5). − ^{11}B NMR: δ = 105.9. − ^{13}C NMR: δ = 5.0 (SiMe$_3$), 90.2 (C_5H_5), 203.6 (CO), 250.2 (μ-CO). − IR (toluene): $\tilde{\nu}$ = 1932 cm^{-1}, 1776 (CO). − $C_{19}H_{28}BNO_3Ru_2Si_2$ (587.55): calcd. C 38.84, H 4.80; N 2.38; found C 38.26, H 4.58, N 2.08.

Crystal Structure Data Determination of 13: X-ray-quality crystals were removed from a Schlenk tube and immediately covered with a layer of viscous hydrocarbon oil (Paratone N, Exxon). A suitable crystal was selected, attached to a glass fiber and instantly placed in a low-temperature N_2 stream of a $P2_1$ four-circle diffractometer (Siemens). M_r = 562.30, triclinic, space group $P\bar{1}$, a = 911.6(2), b = 1133.7(2), c = 1465.4(3), α = 103.09(2), β = 102.72(2), γ = 111.000(15)°, V = 1.2994(5) mm^3, Z = 2, $\rho_{calc.}$ = 1.437 M gm^{-3}, $F(000)$ = 576, λ = 71.073 pm, T = 173 K, μ(MoK_α) = 0.962 mm^{-1}, crystal size: 0.4 × 0.4 × 0.3 mm, 3.02° < 2θ < 60°; of the 8516 reflections collected 7562 were unique and 7561 were used for refinement of 263 parameters; max./min. difference electron density: −866/744 e nm^{-3}. $R1$ = 0.027 [$F > 4\sigma(F)$] and wR_2 = 0.075 (all data) with $R1 = \Sigma||F_o| - |F_c||/\Sigma|F_o|$ and $wR2 = \{\Sigma w(F_o^2 - F_c^2)^2/\Sigma w(F_o^2)^2\}^{0.5}$. Calculations were carried out with the SHELXTL PC 5.03[23] and SHELXL-97[24] program system installed on a local PC. The phase problem was solved by direct methods and the structures were refined on F_o^2 by full-matrix least-squares refinement. An extinction correction was applied, extinction coefficient: 0.0115(7). Anisotropic thermal parameters were included for all non-hydrogen atoms. H atoms were placed geometrically and refined using a riding model, including free rotation of methyl groups. Their isotropic thermal parameters were constrained to 1.2 (cyclopentadienyl H) or 1.5 (methyl groups) times U_{eq} of the bonded carbon. Crystallographic data (excluding structure factors) have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-116235. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: + 44-1223/336−033; E-mail: deposit@ccdc.cam.ac.uk].

The Detection of $O{=}SiCl_2$ as an Intermediate During the Combustion Process of $SiCl_4$ with O_2

Markus Junker,[a] Andreas Wilkening,[b] Michael Binnewies,[b] and Hansgeorg Schnöckel*[a]

Dedicated to Professor G. Fritz on the occasion of his 80th birthday

Keywords: $SiCl_4$ Combustion / $OSiCl_2$ / Matrix isolation / Thermodynamic data / DFT calculations

During the technical important combustion of $SiCl_4$ with oxygen [$SiCl_4(g) + O_2(g) = SiO_2(s) + 2{\cdot}Cl_2(g)$] many intermediates have been detected in the past. However, the presence of the primary species $O{=}SiCl_2$ has been discussed controversially until today. With the help of matrix isolation technique we have now been successful to monitor $O{=}SiCl_2$ via its IR spectrum. With the help of quantum chemical calculations the thermodynamic data have been calculated first. On this basis it was possible to find the optimal conditions to trap $OSiCl_2$ from the high-temperature equilibrium. Furthermore it could be shown via IR spectroscopy and quantum chemical calculations, that the radical OSiCl does not play a significant role within this combustion process.

Introduction

The reaction of silicontetrachloride with oxygen at temperatures far above 1000 °C ends up with solid SiO_2, which can be obtained as an industrial produced fine grained aerosil, if special reaction conditions are applied. At temperatures of about 1000 °C a great variety of chlorosiloxanes have been isolated, which can be regarded as metastable intermediates of this reaction.[1] The large number of products − the reaction yields hundreds of different molecules − allows the conclusion, that there must be an high reactive species involved in a primary step of the reaction.

Some time ago we did the presumption that this reactive intermediate is $OSiCl_2$.[2] Assuming its existence, most resultant products can easily be elucidated, for example Si_2OCl_6 can be regarded as a reaction product between $OSiCl_2$ and $SiCl_4$. A reaction of $OSiCl_2$ with a catenasiloxan $Si_nO_{n-1}Cl_{2n+2}$ yields chain prolongation, an oligomerisation leads to cyclosiloxanes $Si_nO_nCl_{2n}$. The formation of higher condensed siloxanes [$n(O) > n(Si)$] can be explained via elimination of $SiCl_4$ from siloxanes containing a smaller amount of oxygen.

In order to prevent consecutive reactions yielding higher condensed siloxanes and to detect $OSiCl_2$, the reaction of $SiCl_4$ and O_2 was performed at very low pressure. Performing the reaction first in the inlet system of a mass spectrometer, only a significant increase of the signal at m/z = 44 (SiO) and no signal, that could be assigned to $OSiCl_2$, was found. Therefore we tried to detect this molecule via matrix IR-spectroscopy. These investigations are mainly reported in the following paper.

However, first of all we want to discuss the results of DFT calculations on OSiCl and $OSiCl_2$ and their thermodynamic data, which are the basis for the high-temperature gas-phase equilibrium calculations, which will presented further on.

Results and Discussion

Quantum Chemical Calculations

Though we have described matrix isolated $OSiCl_2$, generated via a photoinduced reaction between Cl_2 and SiO in solid argon, some years ago,[3] literature provides no direct information about the thermodynamic stability of this species. Though we have published some quantum chemical SCF calculations on the structure and energetic relation of this molecule, the results have not been analysed with respect to a possible gas-phase stability.[4] In order to test the reliability of our DFT-calculations presented here,[5] we first applied the similar method to get the well-known values of $\Delta H_f^0(298)$ and $S^0(298)$ of Cl_2CO. Due to the excellent agreement between both couples of values [$\Delta H_f^0(298)$: (exp.) −220.078 kJ/mol[17]/(theor.) −227.2 kJ/mol and $S^0(298)$: (exp.) 283.852 J/(mol·K)[17]/(theor.) 283.84 J/(mol·K)], we assessed the calculated data for $OSiCl_2$ as reliable too. First we determined the enthalpy and entropy of the following reaction (1) to be $\Delta H_R^0(298) = -336$ kJ/mol and $\Delta S_R^0(298) = -137$ J/(mol·K).

$$Cl_2(g) + SiO(g) = OSiCl_2(g) \quad (1)$$

On the basis of the experimental data of $Cl_2(g)$ and SiO(g),[17] the $\Delta H_f^0(298)$ and $S^0(298)$ values for $OSiCl_2$ can be calculated to be:

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1999 1434−1948/99/0909−1529 $ 17.50+.50/0

$$\Delta H_f^0(298) = -440.0\ \text{kJ·mol}^{-1}$$
$$S^0(298) = 302.4\ \text{J·(mol·K)}^{-1}$$

The geometry of $OSiCl_2$, which is a further result of these calculations, shows the expected differences to the former SCF calculation, e.g. the bond lengths are shortened [Si−O: 148.4 pm (SCF)/152.5 pm (DFT) and Si−Cl: 200.8 pm (SCF)/203.4 pm (DFT)], while the bond angles obtained by both methods are nearly identical: 109.1° (SCF)/ 108.9°(DFT). In order to calculate the thermodynamic data and to check the assignment of the matrix spectra, the following vibration frequencies (IR intensities [km/mol] in brackets) for $OSiCl_2$ have been determined.

Table 1. Calculated vibrational frequencies for $OSiCl_2$ (IR intensities [km/mol] in brackets)

Character	Frequencies in cm^{-1} (IR intensities in km/mol)		
A_1	1257.7 (99.4)	485.7 (24.1)	200.7 (2.8)
B_1	625.8 (249.2)	271.4 (25.3)	
B_2	274.7 (38.6)		

The excellent agreement between these calculated frequencies and the experimental values of the argon matrix isolated $OSiCl_2$ we published some years ago.[3]

[A_1: 1239.9/501.1 (200 estimated); B_1: 637.5/269.0; B_2: 279.9] confirms the reliability of the calculations about the high-temperature equilibrium presented further on.

During the combustion of $SiCl_4$ in principle one must also expect the radical species OSiCl, which recently has been characterised by our group.[6] The following thermodynamic values for OSiCl which are also the basis for the equilibrium calculations presented in the next chapter have been determined: $\Delta H_f^0(298) = -167.2\ \text{kJ·mol}^{-1}$; $S^0(298) = 279.1\ \text{J·(mol·K)}^{-1}$ [6]

Equilibrium State Considerations

To answer the question what should happen in the first steps of the considered reaction between $SiCl_4$ and O_2 we have carried out thermodynamic calculations of an equilibrium between the atoms and molecules given in Table 2. The computation was performed under the restriction, that no solid SiO_2 and higher molecular chlorosiloxanes are formed, that means only a homogeneous gas phase reaction is assumed.

The total pressure in the reaction tube cannot be measured exactly, therefore it is fixed to be 10^{-7} bar, which seems to be a realistic value, according to our experiments.

These data together with the presumed molar ratios 7:3, 5:5, and 3:7 of the species $SiCl_4$ and O_2 are the basis of our calculation. The results are shown in the diagrams Figure 1 to Figure 3, in which the partial pressures versus temperature are plotted.

Table 2. Thermodynamic data of those molecules which are involved in the equilibrium state calculations

Compound	$\Delta H°_{298}$/kJ/mol	$S°_{298}$/J/(K·mol)	Ref.
$SiCl_4$	−662.8	330.9	[17]
$SiCl_3$	−390.4	318.2	[17]
$SiCl_2$	−168.6	281.3	[17]
SiCl	198.3	237.8	[17]
Cl_2	0	223.1	[17]
Cl	121.3	165.2	[17]
O_2	0	205.1	[17]
O	249.2	161.1	[17]
SiO	−100.4	211.6	[17]
$OSiCl_2$	−440.0	302.4	cf. text
OSiCl	−167.2	279.1	cf. text

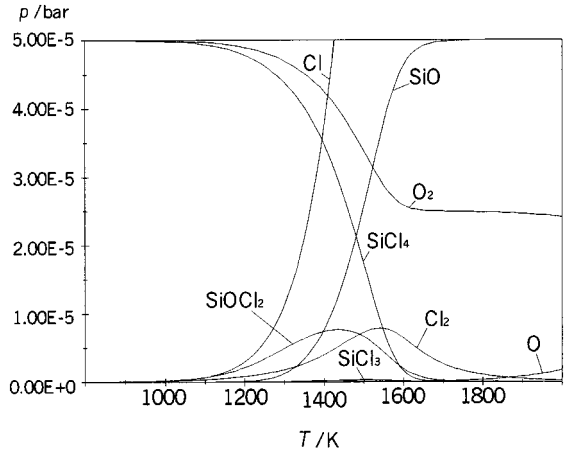

Figure 1. Equilibrium state partial pressures of the gaseous species in the system O/Si/Cl at a total pressure of 10^{-4} mbar; $SiCl_4$/ O_2 = 1:1

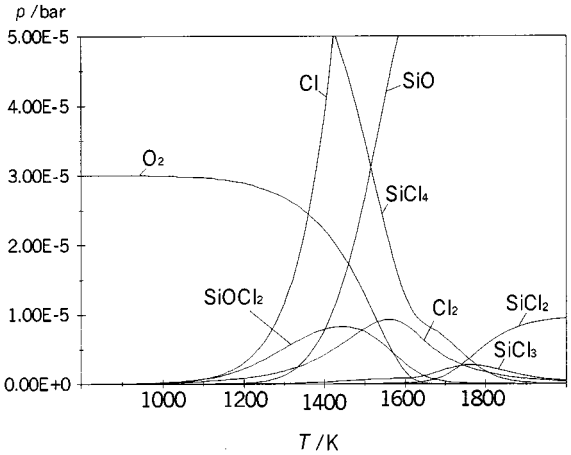

Figure 2. Equilibrium state partial pressures of the gaseous species in the system O/Si/Cl at a total pressure of 10^{-4} mbar; $SiCl_4$/ O_2 = 7:3

Although we cannot be sure that the system has been equilibrated all results of the computations are in good

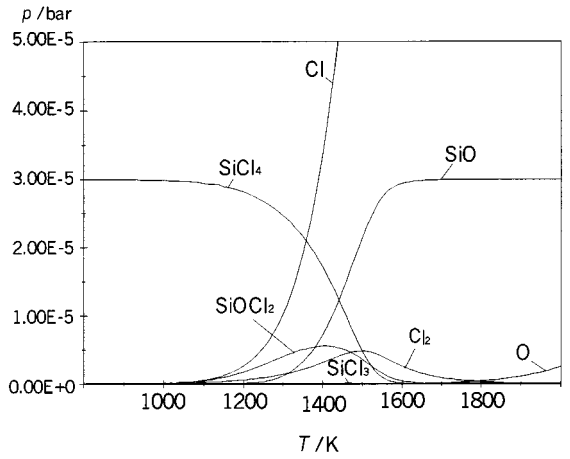

Figure 3. Equilibrium state partial pressures of the gaseous species in the system O/Si/Cl at a total pressure of 10^{-4} mbar; $SiCl_4$/O_2 = 3:7

agreement with experimental observations. It is evident that the reaction should start at a temperature of about 1000 K since the partial pressures of the starting materials $SiCl_4$ and O_2 begin to decrease there. Preparative and spectroscopic observations confirm this prediction. The formation of the oxygen containing species (e.g. $OSiCl_2$) is nearly completed at a temperature of 1400 K. Above this temperature mainly the dissociation of $SiCl_4$ and O_2 occurs. From all three diagrams it can be concluded that only two molecules containing Si and O appear at temperatures above 1000 K: SiO and $OSiCl_2$.[7]

The highest partial pressure of SiO is about one order of magnitude above that of $OSiCl_2$. The existence of the latter one is coupled to a rather narrow temperature range ΔT of about 300 to 400 K with a maximum of the partial pressure at about 1400 K. Based on these equilibrium state calculations the detection of $OSiCl_2$ via matrix IR spectroscopy should be possible without problems, because at a temperature of 1200 °C only SiO and $SiCl_4$ should be present in addition to $OSiCl_2$ and the IR-absorptions of the former ones are well-known and separated from those of $OSiCl_2$.

IR-Spectroscopic Investigations on Matrix-Isolated $OSiCl_2$

Matrix IR spectroscopy seemed to be the proper technique in order to investigate the combustion of $SiCl_4$ with O_2, since the starting materials as well as the products have already been studied by this method: $SiCl_4$,[8] SiO,[9] OSiCl,[6] and $OSiCl_2$.[3] Some time ago the $OSiCl_2$ molecule has been produced in the following way:[3] The high-temperature species SiO was cocondensed together with chlorine and a hundredfold excess of argon. The IR spectrum after cocondensation exhibited only the bands of SiO and its oligomers. Subsequently $OSiCl_2$ was generated from of SiO and Cl_2 in the matrix after irradiation with UV light of 254 nm. The IR spectrum of $OSiCl_2$ was analysed with the help of its isotopic shifts (^{16}O – ^{18}O/^{35}Cl – ^{37}Cl) and by means of a normal coordinate analysis.

In order to perform matrix investigations of the combustion process of $SiCl_4$ the gaseous components $SiCl_4$ and O_2 were first mixed in a ratio of 1:1. This gaseous mixture was passed under high-vacuum conditions through a high-temperature reactor at 1240 °C with a molar flow rate of 10^{-3} mmol/h. The mixture of gases leaving the high-temperature furnace was diluted with a hundredfold amount of gaseous argon and then was condensed onto a copper block of 15 K. The IR spectrum of a matrix after 30 minutes of condensation time of this gaseous mixture is shown in Figure 4.

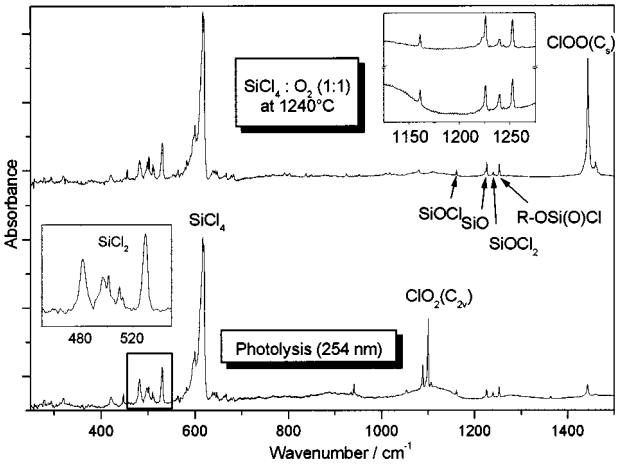

Figure 4. Top: argon matrix IR spectrum of the reaction products of the 1:1 $SiCl_4$/O_2-mixture at 1240 °C; below: following photolysis of the matrix with 254 nm for 10 min

The absorption bands of $OSiCl_2$ (1240 cm^{-1}, 637.5 cm^{-1}, 501.1 cm^{-1}), $SiCl_4$ (616.1 cm^{-1}), OSiCl (1161 cm^{-1}, 509.4 cm^{-1}), SiO (1226 cm^{-1}), $SiCl_2$ (512.0 cm^{-1}, 510.1 cm^{-1}, 501.4 cm^{-1}, 498.0 cm^{-1}), and ClO_2 (1100 cm^{-1}) can be observed. The molecule ClOO is formed spontaneously in the matrix by a reaction of chlorine atoms from the high-temperature equilibrium and O_2 molecules. The band at 1442 cm^{-1} can be assigned to the ClOO isomer (C_s symmetry).[10] After irradiation (254 nm) of the matrix the ClOO-molecule rearranges to the more stable C_{2v} isomer ClO_2 (1100 cm^{-1}). A spectrum over the whole range after photolysis is shown in Figure 4.

Starting with a molar ratio between $SiCl_4$ and O_2 of 5:1 a much smaller amount of ClO_2 is formed. This observation is plausible since no free O_2 molecules are present in the matrix due to the fact, that they have already reacted with the Si species which are present in large excess.

The most unexpected observation in Figure 4 is the larger intensity of the bands belonging to OSiCl, compared to those of $OSiCl_2$. Based on theoretical investigated integral extinction coefficients[14] of the "SiO absorption bands" (in [km/mol] SiO: 52.1; OSiCl: 56.8; $OSiCl_2$: 114) an OSiCl/$OSiCl_2$ ratio of about ten, averaged over eight experiments

is observed, whereas SiO and $OSiCl_2$ are produced in nearly equimolar amounts (with an light weight excess of SiO). While the molar ratio of SiO/$OSiCl_2$ roughly corresponds to our expectations of a high-temperature equilibrium at 1500 K, there is by far too much OSiCl in the matrix compared to the amount of $OSiCl_2$. This discrepancy can only be understood if OSiCl is not formed in the gas phase but in the matrix from SiO molecules and Cl atoms. To confirm this hypothesis some experiments have been performed, in which exclusively SiO and Cl atoms from two separate high-temperature reactors were cocondensed with an excess of argon.[6] The resulting spectra exhibited unchanged SiO and only OSiCl as a Si-containing species. No $OSiCl_2$ was formed. Even after a subsequent photolysis (254 nm) no $OSiCl_2$ is observed, i.e. in the high-temperature equilibrium nearly no Cl_2 was present, because, if it would be present, $OSiCl_2$ should be obtained after irradiation.[3]

The conclusion of all these experiments is, that the observed $OSiCl_2$ species during the matrix experiments are unambiguously formed in the high-temperature equilibrium. The observation of the first matrix experiments showing an OSiCl amount to be one or two orders of magnitude too high do not correspond to the equilibrium conditions at 1240 °C, for OSiCl is nearly exclusively produced by the spontaneous reaction of chlorine atoms and SiO in the matrix. However the higher concentrations of $OSiCl_2$ and SiO, concluded from the analysis of these matrix spectra after correction for spontaneously formed OSiCl, are in good agreement with the presented equilibrium calculations.

In the spectrum presented in Figure 4 a SiO valence band appears at 1250 cm^{-1}. It is only observed in those experiments starting with a molar ratio of $SiCl_4$ and O_2 of 1:1. With respect to the intensity of this band in several experiments it must be assigned to a different species than these discussed so far. Due to the high frequency range a −O(Cl)Si=O group can be expected, since ν(Si−O) in $OSiF_2$ is observed at 1309.4 cm^{-1}.[11] This estimation is confirmed by DFT calculations[12] from which the following SiO frequencies of the molecules under discussion result: SiO (1245 cm^{-1}), OSiCl (1149 cm^{-1}), $OSiCl_2$ (1258 cm^{-1}), and $Cl_3SiOSi(O)Cl$ (1299 cm^{-1},[13]). This variation in the frequency range reflects to a certain degree the variation in the SiO bond strength. However, for entropy reasons the species $Cl_3SiOSi(O)Cl$ should not exist in the high-temperature equilibrium, that means it should be formed in the matrix. However it is astonishing, that $Cl_3SiOSi(O)Cl$ and not the molecule $Cl_2SiO_2SiCl_2$ (with an central SiO_2Si four-membered ring) is formed, though according to analogous DFT calculations[12] the latter one is expected to be more stable by about 162 kJ/mol.

After the combustion of $SiCl_4$ we have also pyrolysed hexachlorodisiloxan (Figure 5) and octachlorotrisiloxan (Figure 6) at temperatures of 1240 °C.

These experiments clearly show the formation of the molecules SiO and $SiCl_4$. The species OSiCl and especially $OSiCl_2$ are only produced in small portions, that means the observed band intensities are below the limit of detection of this spectroscopic method.

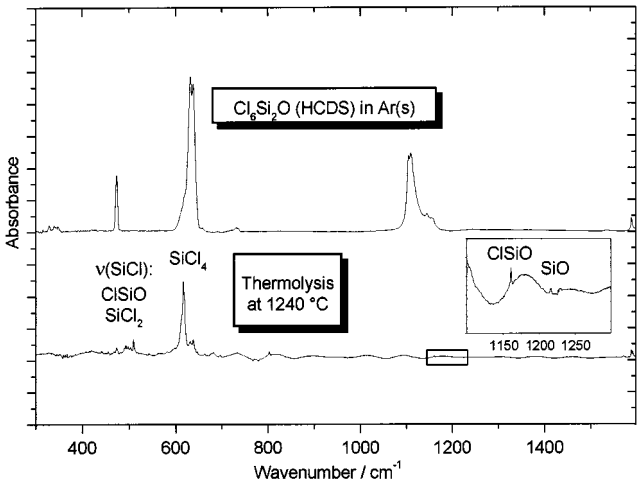

Figure 5. Top: argon matrix IR spectrum of hexachlordisiloxane, below: matrix IR spectrum of the thermolysis products (1240 °C)

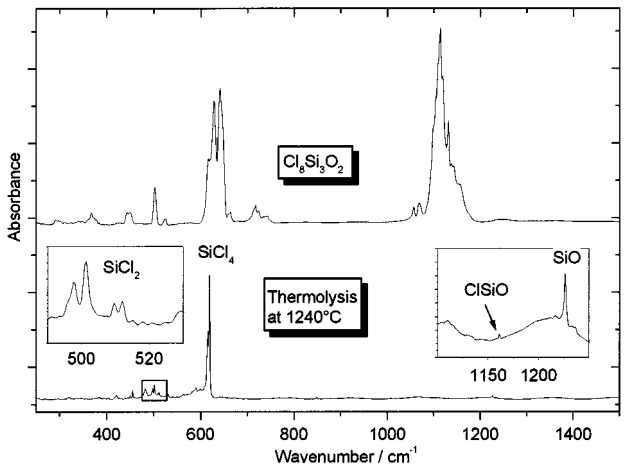

Figure 6. Top: matrix IR spectrum of octachlortrisiloxane in solid argon, below: matrix IR spectrum of the thermolysis products (1240 °C)

Conclusion

The quantumchemical calculations about the thermodynamic stability of OSiCl and $OSiCl_2$ and the equilibrium calculations based on these data are in good agreement with the experimental results of the matrix IR spectra. That means theory as well as experiments show that $OSiCl_2$ is an essential reactive intermediate in the combustion process of $SiCl_4$ with O_2. Therefore the presented results may be important as well for further synthetic investigations as for every kind of high-temperature processes, in which chlorine containing species are in a thermodynamic equilibrium with SiO containing species (e.g. chemical processes in quartz vessels). Since similar relations are expected for the reaction

between $SiBr_4$/SiI_4 and O_2, the analogous species $OSiBr_2$/$OSiI_2$ may also be important for the understanding of the gas phase reactions in halogen lamps.

Experimental Section

$SiCl_4$ (> 99 %, MERCK GaA, Darmstadt) and O_2 (4.8, MESSER-GRIESHEIM, Krefeld) were mixed in a glass vessel and the pressure was measured by means of a capacity instrument (MKS Instruments Deutschland GmbH). The same instrument was used in order to monitor the flow rate (10^{-5} mol/h) passing the reaction vessel (quartz) of the high-temperature furnace (alumina).

The relative amount of argon (4.8, MESSER-GRIESHEIM, Krefeld) mixed with the gaseous species after passing the high-temperature area to the Si/O/Cl species was estimated to be about 200:1. After a condensing period of 30 min, IR absorptions were recorded. The IR absorptions were recorded by means of a reflection unit, in which the copper plate for deposition of the matrix gases was cooled by a closed-cycle refrigerator (RGD 510, LEYBOLD Köln).

All spectra were recorded with a BRUKER IFS 113v FT-IR Spectrometer (BRUKER GmbH, Karlsruhe). A MCT detector and a Ge/KBr beamsplitter have been applied in order to obtain the spectra presented.

The DFT calculations were carried out on IBM RS 6000/390 workstations using the B3-LYP functional and a TZVPP basis. The program packages GAUSSIAN 94[14] and TURBOMOLE[15] have been used. Contour line diagrams have been realised using the program MOLDEN[16].

Photochemical activation has been performed with the help of a low-pressure Hg lamp (Gräntzel, Karlsruhe, Germany).

Atom	Basis	Contraction pattern	Exponent of the polarisation function
H	TZVPP	(5s2p1d) / [3s2p1d] {311/11/1}	η_p = 1.407; 0.388 η_d = 1.057

Structural and Functional Investigations on Diiron Complexes: Catalase-Like Activity and Mechanistic Studies on the Formation of (μ-Peroxo)diiron(III) Adducts

Roberto Than,[a] Antje Schrodt,[b] Lars Westerheide,[a] Rudi van Eldik,*[b] and Bernt Krebs*[a]

Dedicated to Professor Dirk Walther on the occasion of his 60th birthday

Keywords: Iron(III) / Peroxo Complexes / Kinetics / Hydrogen Peroxide / Catalase

The new diiron complex $[Fe_2(tbpo)\{O_2As(CH_3)_2\}(CH_3O)(CH_3OH)](ClO_4)_3 \cdot 5\ CH_3OH \cdot 2\ H_2O$ (**1**) containing a (μ-alkoxo)(μ-dimethylarsinato)diiron(III) core was synthesized using the heptadentate ligand *N*,*N*,*N*′,*N*′-Tetrakis(2-benzimidazolylmethyl)-1,3-diamino-2-propanol (Htbpo). The complex was characterized structurally by X-ray crystallography. **1** reproduces the coordination mode and the stoichiometry of the proposed purple acid phosphatase-arsenate inhibitor complex. More importantly, **1** is a good functional model for the activation of small molecules, since the solvent molecule in the coordination sphere of each iron ion can be substituted very easily by a small substrate molecule. This is confirmed by the comparatively high pH-dependent catalase-like activity of **1**. In order to study the influence of the cacodylate bridge on the formation of the metastable adduct with hydrogen peroxide, the analogous hydroxo-bridged complex $[Fe_2(tbpo)(OH)(NO_3)_2](NO_3)_2 \cdot CH_3OH \cdot 2\ H_2O$ (**2**) was employed. The reactions of **1** and **2** with H_2O_2 were studied as a function of $[H_2O_2]$, pH, temperature, and pressure, and the kinetic results including the activation parameters are reported. In the case of compound **2** the reaction proceeds in one step, and the observed first order rate constant, k_{obs}, shows a linear dependence on the hydrogen peroxide concentration with a zero intercept. For complex **1** the kinetic traces could be fitted to two exponential functions. One of the observed pseudo-first-order rate constants, k_{obs1}, exhibits a linear dependence on the hydrogen peroxide concentration with a zero intercept, whereas the other rate constant, k_{obs2}, was independent of the hydrogen peroxide concentration. A mechanistic interpretation is presented.

Introduction

Bridged diiron complexes can be regarded as structural and functional models for non-heme iron proteins.[1−5] Proteins belonging to this class include hemerythrin (Hr), ribonucleotide reductase (RR), methane monooxygenase (MMO), and purple acid phosphatase (PAP), whose X-ray structures are all available.[6−9] The spectroscopic and structural properties of the diiron centres of the metalloproteins have been modelled successfully by using various ligand systems.[10−16] There has been a particular interest in the oxygen activation at these diiron active sites in the last few years.[17−20] Therefore, the reaction of diiron complexes with either dioxygen or hydrogen peroxide has been studied very intensively.[21−24]

Recently, the structures of three dinuclear peroxo bridged iron complexes have been published, which were all generated by the reaction of dioxygen and the diferrous precursor compounds: $[Fe_2(O_2)(C_6H_5CH_2COO)_2\{(HB(pz')_3\}_2]$, $[Fe_2(N\text{-Et-tbpo})(O_2)(Ph_3PO)_2]^{3+}$, and $[Fe_2(Ph\text{-bimp})(C_6H_5COO)(O_2)]^{2+}$.[25−27] These peroxo complexes all show a μ-1,2-binding mode of the introduced peroxo ligand. The (1:1) peroxo adduct of $[Fe_2(tbpo)(OH)(NO_3)_2](NO_3)_2$ was described earlier in the literature,[28] but no X-ray structure was determined. The spectroscopic, magnetic and electrochemical investigations revealed a similar μ-1,2 coordination of the peroxide.

In this work we report the X-ray structure and catalase-like activity of the new μ-arsinato bridged diiron(III) complex $[Fe_2(tbpo)\{O_2As(CH_3)_2\}(CH_3O)(CH_3OH)](ClO_4)_3 \cdot 5\ CH_3OH \cdot 2\ H_2O$ (**1**) containing the heptadentate ligand *N*,*N*,*N*′,*N*′-Tetrakis(2-benzimidazolylmethyl)-1,3-diamino-2-propanol (Htbpo). In order to understand the rapid formation of the μ-peroxo complexes we carried out detailed kinetic studies on the reaction of species **1** and the related, well characterized species $[Fe_2(tbpo)(OH)(NO_3)_2](NO_3)_2 \cdot CH_3OH \cdot 2\ H_2O$ (**2**) with hydrogen peroxide in aqueous solution. The activation parameters for this reaction were determined and plausible mechanisms are postulated.

Results and Discussion

Structural Studies on 1

The structure of **1** confirms a (μ-alkoxo)(μ-dimethylarsinato)diiron(III) core. **1** reproduces the coordination mode and the stoichiometry of the proposed purple acid phosphatase-oxoanion interaction.[31] Therefore **1** can be regarded as a model complex for the proposed structure of the oxidized arsenate complex of uteroferrin.

The cation of **1** is shown in Figure 1, while relevant bond lengths are collected in Table 1. Each iron ion is four-coordinated by the heptadentate ligand $tbpo^-$.

The metal ions are bound by two benzimidazole moieties, one tertiary non-aromatic nitrogen atom and the bridging oxygen atom. The metal centre in **1** exhibits a μ-alkoxo bridged diiron(III) unit with an additional dimethylarsinato bridge. The environments of the ions are completed by the coordination of one methanol and one methanolate ligand. The distance between the methanolic oxygens O4 and O5 (2.452 Å) indicates a strong "hydrogen bridge bond". The proton is assumed to be positioned between O4 and O5 at the same distance to each oxygen atom, so that it can be considered to be delocalized.

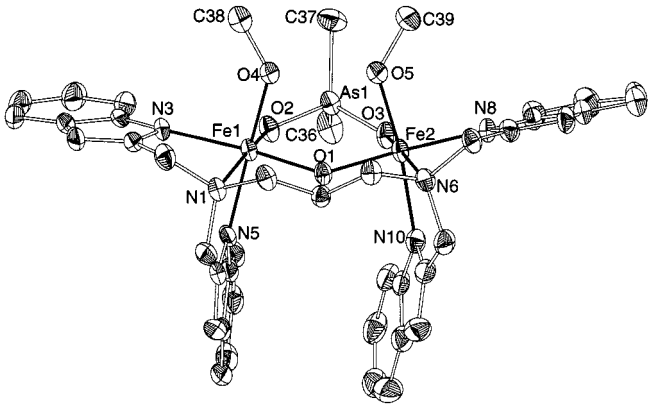

Figure 1. Structure of the cation in **1** showing 50% probability ellipsoids; hydrogen atoms have been omitted for clarity

Table 1. Selected bond lengths [Å] in **1**

Fe(1)···Fe(2)	3.445(1)	O(4)···O(5)	2.452(4)
Fe(1)···As	3.290(1)	Fe(2)···As	3.209(1)
Fe(1)−O(1)	1.941(3)	Fe(2)−O(1)	1.985(3)

As−C(36)	1.887(5)	As−C(37)	1.901(5)

Only two complexes containing a (μ-alkoxo)(μ-dimethylarsinato)diiron(III) core are known.[23] The Fe···Fe distance in **1** of 3.445 Å is shorter than the metal-metal separation in $[Fe_2(tbpo)\{O_2As(CH_3)_2\}(Cl)(H_2O)]^{3+}$ (3.58 Å)[23b] and $[Fe_2(mtbpo)\{O_2As(CH_3)_2\}(Cl)_2\ (CH_3OH)]^{2+}$ (3.54 Å)[23a]. The average Fe···As separation in **1** (3.25 Å) is in accordance with the Fe···As distances in $[Fe_2(tbpo)\{O_2As(CH_3)_2\}(Cl)(H_2O)]^{3+}$ and $[Fe_2(mtbpo)\{O_2As(CH_3)_2\}(Cl)_2(CH_3OH)]^{2+}$ with 3.31 Å and 3.28 Å, respectively.

Functional Studies on 1 and 2

The evolution of dioxygen was measured to investigate the hydrogen peroxide decomposition by complexes **1** and **2**. Figure 2 shows the initial decomposition rate after addition of the complexes **1**, **2**, or iron(III) salts (blind) to buffered aqueous hydrogen peroxide solutions. Both complexes exhibit only very little activity at pH 5 to 7 and no activity at pH 3 to 4, which is consistent with a completely protonated form of the substrate under these conditions. A little increase is observed at pH 8. The initial rate for the peroxide decomposition (0.90% O_2 per second) of complex **1** at pH 9 shows a significant increase in catalase-like activity at this pH. **2** has also a comparably high activity at pH 9 (0.48% O_2 per second). A solution containing iron(III) perchlorate instead of a complex shows no or very little activity at pH 3 to 9, which is also consistent with low solubility. Logarithm plots of the initial rates versus complex and peroxide concentrations, respectively, indicate that the reaction of **1** and **2** at pH 9 is first order in complex and peroxide concentration.

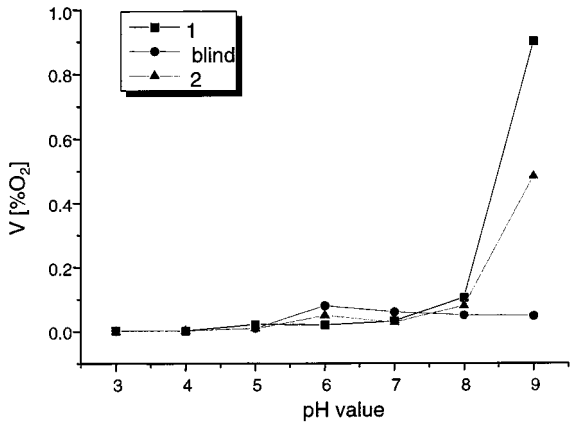

Figure 2. pH-dependence of the catalase-like activity of **1** and **2**

These experiments show that the decomposition of hydrogen peroxide is strongly pH dependent. **1** has approximately twice the activity than **2** to decompose hydrogen peroxide. Both complexes have a significantly higher catalase-like activity than iron(III) at pH 8 and 9. Activity at higher pH values could not be investigated due to solubility problems. **1** and **2** form metastable peroxide adducts at lower pH values. This adduct formation was investigated using kinetic methods.

Kinetic Measurements on the $[Fe_2(tbpo)(OH)(NO_3)_2](NO_3)_2$ Complex 2

A typical series of time resolved spectra observed during the reaction of the $[Fe_2(tbpo)(OH)(NO_3)_2](NO_3)_2$ complex **2** with an excess of hydrogen peroxide is shown in Figure 3.

The formation of the intensively blue coloured and metastabile peroxo species is accompanied by the formation of a new broad absorbance band at 550 nm, which strongly depends on the selected solvent[28] and is assigned to the iron–peroxo charge transfer. All subsequent kinetic measurements were performed at this wavelength.

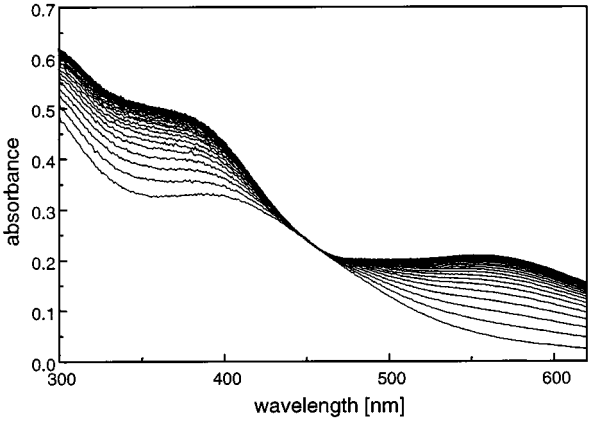

Figure 3. Typical time resolved spectra (10 ms) for the reaction of the hydroxo-bridged complex with a ten fold excess of H_2O_2. Experimental conditions: $[Fe_2(tbpo)(OH)] = 9.45 \cdot 10^{-5}$ M, ionic strength = 0.1 M, pH = 4.0, $T = 25.0$°C.

The reactions were followed for at least 5 half-lives and the kinetic traces, recorded in the presence of an excess of hydrogen peroxide, could all be fitted to a single exponential function under all experimental conditions. The observed pseudo-first-order rate constant, k_{obs}, exhibits a linear dependence on the hydrogen peroxide concentration with a zero intercept (Figure 4). An Eyring analysis of the kinetic data collected over the temperature range 5 to 35°C (Figure 5) allowed the estimation of the activation parameters listed in Table 2.

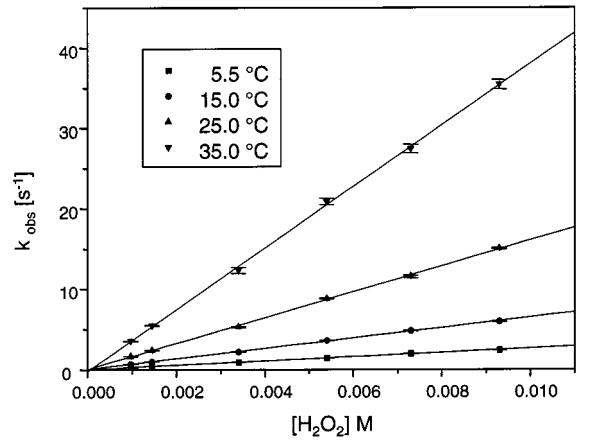

Figure 4. k_{obs} as a function of $[H_2O_2]$ and temperature. Experimental conditions: $[Fe_2(tbpo)(OH)] = 9.45 \cdot 10^{-5}$ M, ionic strength = 0.1 M, pH = 3.0, $T = 5.5–35.0$°C, $\lambda = 550$ nm

Stopped-flow measurements under high pressure showed that the reaction was practically independent of pressure, and the plot of ln k_{obs} vs. pressure gave a zero volume of activation. A preliminary pH dependence study of the reaction was performed in the range 2.0 to 4.0, since the complex showed its lowest catalase-like activity in this pH range. The pH range was limited by the decomposition of the complex occurring at lower pH and the formation of a precipitate at higher pH under the conditions selected for the kinetic measurements. The data showed an increase in the rate constant with increasing pH.

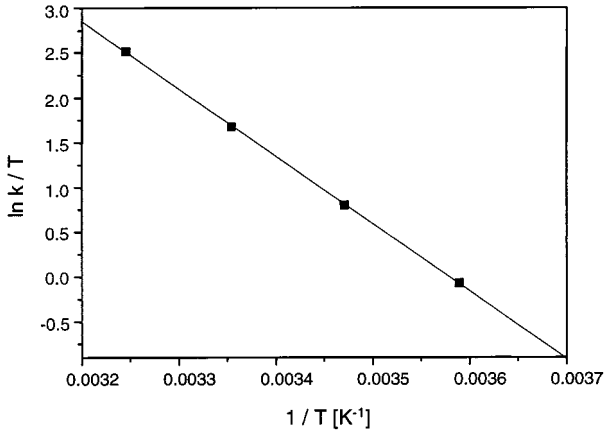

Figure 5. Eyring plot for the reaction of $[Fe_2(tbpo)(OH)]$ ($9.45 \cdot 10^{-5}$ M) with H_2O_2 based on the second-order rate constant determined from the kinetic measurements in the temperature range 5.5–35.0°C

Kinetic Measurements on the $[Fe_2(tbpo)\{O_2As(CH_3)_2\}(OCH_3)(HOCH_3)](ClO_4)_3$ Complex 1

Figure 6 shows a typical series of time resolved spectra observed during the reaction of the $[Fe_2(tbpo)\{O_2As(CH_3)_2\}(OCH_3)(HOCH_3)](ClO_4)_3$ complex with an excess of hydrogen peroxide.

The formation of the intensively blue coloured and metastable peroxo species is accompanied by the formation of a typical broad band at 550 nm, again assigned to the iron–peroxo charge transfer. This wavelength was selected for the kinetic investigations. The reactions were followed for at least 5 half-lives, but in contrast to complex **2** the kinetic traces recorded in the presence of an excess of hydrogen peroxide could not be fitted to a single, but rather to the sum of two exponential functions under all experimental conditions. One of the observed pseudo-first-order rate constants, k_{obs1}, exhibits a linear dependence on the hydrogen peroxide concentration with a zero intercept (Figure 7a), whereas the other rate constant, k_{obs2}, remains independent of the hydrogen peroxide concentration (Figure 7b). An Eyring analysis of the kinetic data collected over the temperature range 5 to 35°C (Figure 8a, b) afforded the activation parameters for k_1 and k_2 listed in Table 2.

The activation volume determined from the pressure dependence studied in the range 5 to 125 MPa is zero within the experimental error limits. The pH dependence was also studied in a preliminary way in the limited range 2.5 to 4.0, for the same reasons as outlined for complex **2**. Both k_{obs1} and k_{obs2} increased with increasing pH.

Table 2. Summary of rate and activation parameters for the reaction of **1** and **2** with H_2O_2 at pH 3.0.

complex	k_2 (s^{-1}) T = 25.0°C	k_1 (M^{-1} s^{-1}) T = 25.0°C	$\Delta H^{\#}$ (kJ mol^{-1})	$\Delta S^{\#}$ (J $mol^{-1}K^{-1}$)	$\Delta V^{\#}$ (cm^3 mol^{-1})
2		1600 ± 40	62.5 ± 0.5	26 ± 17	0 ± 2
1		1820 ± 40	57 ± 2	2 ± 9	0.2 ± 3
1	0.190 ± 0.010		79 ± 4	8 ± 13	−0.3 ± 0.9

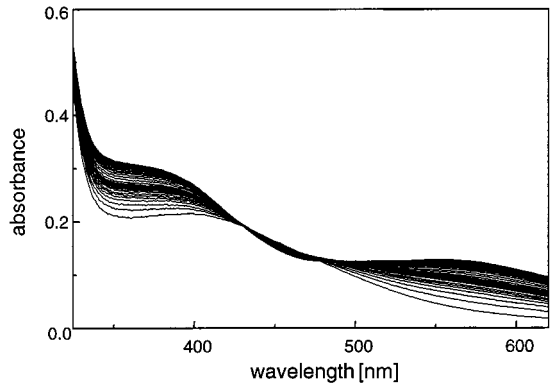

Figure 6. Typical time resolved spectra (10 ms) observed during the reaction of the $[Fe_2(tbpo)\{O_2As(CH_3)_2\}(OCH_3)(HOCH_3)](ClO_4)_3$ **1** complex with a ten fold excess of H_2O_2. Experimental conditions: $[Fe_2(tbpo)(OH)] = 9.45\cdot10^{-5}$ M, ionic strength = 0.1 M, pH = 3.0, T = 25.0°C.

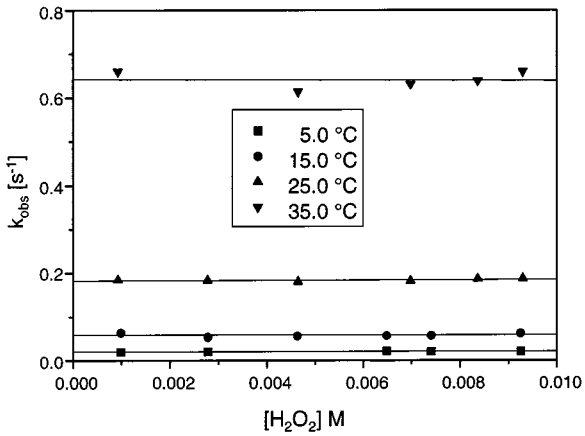

Figure 7b. k_{obs2} as a function of $[H_2O_2]$ and temperature. Experimental conditions: $[Fe_2(tbpo)\{O_2As(CH_3)_2\}] = 9.45\cdot10^{-5}$ M, ionic strength = 0.1 M, pH = 3.0, T = 5.0−35.0°C, λ = 550 nm

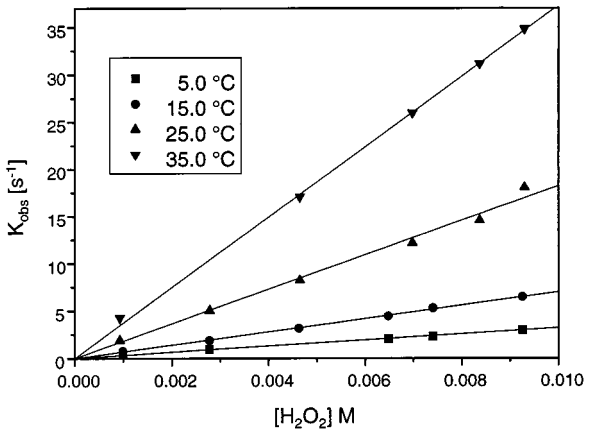

Figure 7a. k_{obs1} as a function of $[H_2O_2]$ and temperature. Experimental conditions: $[Fe_2(tbpo)\{O_2As(CH_3)_2\}] = 9.45\cdot10^{-5}$ M, ionic strength = 0.1 M, pH = 3.0, T = 5.0−35.0°C, λ = 550 nm

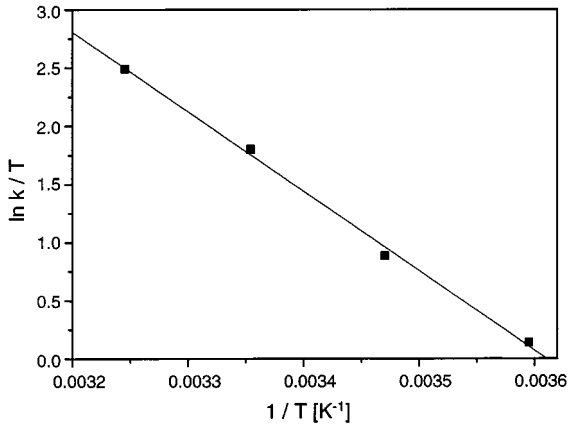

Figure 8a. Eyring plot for the reaction of $[Fe_2(tbpo)\{O_2As(CH_3)_2\}]$ ($9.45\cdot10^{-5}$ M) with H_2O_2 based on the second-order rate constant determined from the kinetic measurements in the temperature range 5.0−35.0°C at pH 3.0

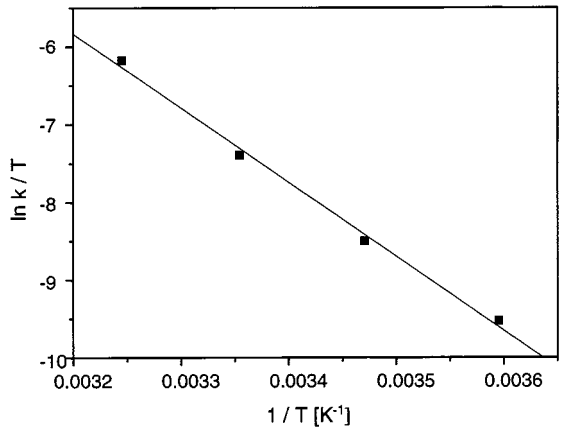
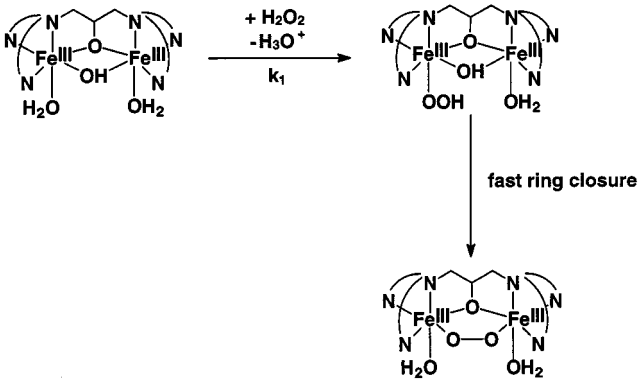
Conclusion

At present no structural information is available on the peroxo products of both complexes **1** and **2.** From the literature[21][28] and our own spectroscopic investigations[32] we know that both complexes form a 1:1 adduct with H_2O_2. For the hydroxo-bridged complex the displacement of the hydroxo bridge during the formation of the peroxo complex is suggested in the literature,[28] whereas for the related benzoate-bridged complex $\{[Fe_2(tbpo)(OBz)](BF_4)_2\}$ no displacement of the benzoate bridge seems to occur.[21] In the X-ray structure of $[Fe_2(tbpo)(OH)(NO_3)_2](NO_3)_2$[33] two nitrates are coordinated to the iron centres, but in aqueous solution it is reasonable to expect that these will be displaced by water molecules. Similarly, in the cacodylate-bridged complex, two water molecules are coordinated to the iron centres, thereby replacing the methanol molecules. pH measurements after addition of two stoichiometrical amounts of acid to the complex solution showed that no protonation of the bridge occurs under these conditions. Spectrophotometric titrations could not be resolved in detail due to the complexity of the system.

The suggested reaction mechanisms for both complexes are shown in Schemes 1 and 2. For both complexes the first step is suggested to be the addition of H_2O_2 to one of the iron centres, which involves substitution of a more labile bond (e.g. coordinated water). In the case of the hydroxo-





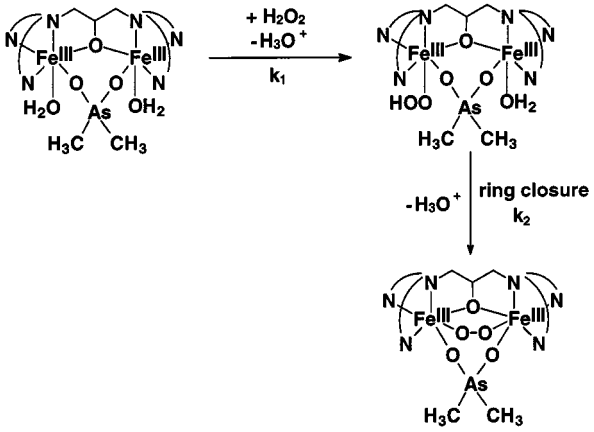


Figure 8b. Eyring plot for the reaction of $[Fe_2(tbpo)\{O_2As(CH_3)_2\}]$ ($9.45 \cdot 10^{-5}$ M) with H_2O_2 based on the first-order rate constant determined from the measurements in the temperature range 5.0−35.0°C at pH 3.0

bridged complex, a very fast ring closure follows which most probably involves the release of the hydroxo-bridge, which can be observed by magnetic and conductivity measurements.[28] In the other case the first reaction is the same, but the subsequent ring-closure reaction is much slower, and so it can be observed in the kinetics as k_2, a $[H_2O_2]$ independent rate constant. Due to the more stable binding of the cacodylate bridge it is not released during the formation of the peroxo adduct. This bulky bridge causes a steric hindrance during the ring-closure reaction, such that this reaction becomes much slower. The rate constant for the first step is similar to the rate constant for the hydroxo-bridged complex (see Table 2).

Scheme 1. Suggested mechanism for the reaction of the hydroxo-bridged complex with H_2O_2

The difference between the two complexes concerns the second step of the reaction, i.e. the bridge formation by the hydroperoxo ligand. In the case of the hydroxo-bridged complex the distance between the Fe^{III} centres (3.177 Å) is significantly shorter than in the case of the cacodylate-bridged complex.[33] This is consistent with the rapid bridge-formation step in the former complex and the much slower step in the latter complex.

Scheme 2. Suggested mechanism for the reaction of the cacodylate-bridged complex with H_2O_2

For both systems studied, preliminary data showed that the rate constants exhibit an increase with increasing pH over the limited pH range accessible. This can be related to the partial deprotonation of H_2O_2 (pK_a = 11.6), since HO_2^- will be orders of magnitude more nucleophilic than the fully protonated form. In a recent study[34] of the oxidation of hydrogen peroxide by different Ni^{III}, Fe^{III}, and Ru^{III} complexes, the authors also found an increase in the observed rate constants with increasing pH over a similar limited pH range. The data could be fitted to a model in which HO_2^- is up to 7 orders of magnitude more reactive than the fully protonated H_2O_2. A similar explanation can account for our observations, even in the case of the second reaction step observed for the cacodylate complex, since coordinated HO_2^- is expected to have a significantly lower pK_a value than the free ion. Alternatively, it is also possible that another ligand in the coordination sphere undergoes deprotonation at higher pH and results in an increase in reactivity.

The reactions are all characterised by almost zero entropies and volumes of activation. This is typical for a pure interchange substitution mechanism, where coordinated water is displaced during the first step, or by HO_2^- during the second bridge formation step. The similarity in the nature of the donor group and the associated partial molar volumes, can account for the zero volume change observed during the interchange of these ligands in the transition state. Thus the formation of the bridged peroxo complex is controlled by the displacement of the coordinated water molecules in both systems. The similarity in rate constants for the first reaction step indicates that the lability of the coordinated water molecules must be very similar in both complexes. This result also clearly supports the suggested displacement of the nitrate and the methanol/methanolate ligands, respectively, in aqueous solution.

Experimental Section

General Remarks: The heptadentate ligand Htbpo was synthesized as published previously,[23b] while all other chemicals were

purchased commercially and used as received. Chemicals of analytical reagent grade and ultrapure water were used throughout this study. **Caution!** The perchlorate salts in this study are potentially explosive and should be handled with care.

Compound **1:** The reaction of equimolar amounts of Htbpo (100 mg) and the sodium salt of cacodylic acid with two equivalents of $Fe(ClO_4)_3 \cdot 9\,H_2O$ in 10 mL of a methanol/ethanol (5:2) solution leads to the formation of red crystals of $[Fe_2(tbpo)\{O_2As(CH_3)_2\}(CH_3O)(CH_3OH)](ClO_4)_3 \cdot 5\,CH_3OH \cdot 2\,H_2O$ (**1**).

Compound **2:** The complex $[Fe_2(tbpo)(OH)(NO_3)_2](NO_3)_2 \cdot CH_3OH \cdot 2\,H_2O$ **2** was synthesized according to literature procedures.[28] The complexes were checked by elemental analysis (CHN-O Rapid, Heraeus). − **1** ($C_{44}H_{70}AsCl_3Fe_2N_{10}O_{24}$): calcd. C 38.39, H 5.31, N 10.17; found C 38.18, H 5.10, N 10.31. − **2** ($C_{36}H_{43}Fe_2N_{14}O_{17}$): calcd. C 41.04, H 3.92, N 18.61; found: C 41.01, H 3.86, N 18.38.

For the kinetic studies both complexes **1** and **2** were dissolved in water and the ionic strength was adjusted with $NaClO_4$ or with $NaNO_3$. The pH of the solution was adjusted with NaOH, $HClO_4$, or HNO_3 and HEPES(I) was used as non-coordinating buffer. Hydrogen peroxide solutions were prepared from 30% hydrogen peroxide and standardized by titration with $KMnO_4$.

Crystallographic Studies:[35] The crystallographic data were collected on a Siemens P3/V diffractometer using monochromated Mo-K_α (λ = 0.71073 Å) radiation by the ω-scan method at 170 K. The crystal of **1** had approximate dimensions of 0.20 × 0.18 × 0.15 mm. Two standard reflections were measured every 99 reflections and remained constant throughout the data collection. The structure was solved using Patterson methods without absorption correction. All non-hydrogen atoms of the cation were refined anisotropically with the SHELX program suite.[36] Refinement was carried out on F^2 using full-matrix least-squares procedures. Hydrogen atoms were included with fixed distances and isotropic temperature factors 1.2 times those of their attached atoms. The R values are defined as $R_1 = \Sigma|F_o - F_c|/\Sigma F_o$ and $wR_2 = [\Sigma[w(F_o^2 - F_c^2)^2/\Sigma[w(F_o^2)^2]]^{1/2}$. Pertinent crystallographic details for **1** are collected in Table 3, and selected bond lenghts are tabulated in Table 1.

Functional Studies: The catalase-like activity measurements were done using a fiberoptical sensor (MOPS, microprocessor-controlled, optical, and portable oxygen sensor), which is based on fluorescence quenching of tris(4,7-diphenyl-1,10-phenanthroline)ruthenium(II) chloride by oxygen. The MOPS indicates dioxygen evolution as percent dioxygen in solution based on calibrations with saturated and unsaturated solutions. 5 mL of aqueous buffer solutions were saturated with nitrogen and different hydrogen peroxide solutions with concentrations between 0.16 and 0.28 mmol·dm^{-3} were added. The decomposition of hydrogen peroxide starts after the addition of a dioxygen-free methanolic complex solution (between 0.003 and 0.01 mmol·dm^{-3}). All reactions were carried out under nitrogen at room temperature in a 10 cm^3 reactor containing a stirring bar at pH values between 3 and 9 and observed over a 5 minute time periode.

Kinetic Studies: The kinetic experiments were performed on Biologic SFM-3 and Applied Photophysics SX.18MV (Leatherhead, UK) stopped-flow instruments, to which an online data acquisition system was connected. Time resolved spectra were recorded on an Applied Photophysics SX.18MV stopped flow (Leatherhead, UK) equipped with a J&M TIDAS 16−500 diode array spectrophotometer (Aalen, Germany). The kinetic measurements at pressures up to 150 MPa were carried out on a homemade high-pressure stopped-flow unit.[29][30] Data fitting was carried out using OLIS KINFIT (OLIS, Bogart, Georgia, USA) and Applied Photophysics (Leatherhead, UK) software. Complete tables of all rate constants (2 pages) are provided in the Supporting Information.

Crystal Structure, Infrared, and Polarized Raman Spectra of $K_3Sm(PO_4)_2$

Mohamed Toumi,[a] Leila Smiri-Dogguy,[a] and Alain Bulou*[b]

Keywords: Phosphates / Structure / IR spectroscopy / Raman spectroscopy

The low-temperature form of $K_3Sm(PO_4)_2$ crystallizes in the monoclinic system [a = 7.4347(5) Å, b = 5.6270(5) Å, c = 9.4919(5) Å, β = 90.870(6)°, Z = 2, space group $P2_1/m$]. The structure has been determined using 1263 independent reflections (R = 0.045, R_w = 0.11) and is found to be of the glaserite type. The Raman and infrared spectra have been investigated: they are consistent with the proposed space group and an assignment of the observed frequencies is given.

Introduction

Compounds of the type $A_3M(TO_4)_2$ (M = Sc, Fe, Cr, rare earth; A = Na, K; T = P, V, As, S)[1−11] have structures built-up of isolated tetrahedra linked only by cations and exhibit pseudohexagonal symmetries. Their structures can be related to that of glaserite, $K_3Na(SO_4)_2$, which exhibits an ideal highly symmetrical arrangement (trigonal, $P\bar{3}\,m1$ space group, Z = 1, with a_0 = 5.547 Å c_0 = 7.070 Å in a hexagonal cell).[12] The latter consists of tetrahedral units separated by cavities, which are occupied by two kinds of atomic sequences (denoted E1 and E2) extending parallel to the c_0 axis. The E1 sequence involves potassium and sodium ions with coordination numbers of 12 and 6, respectively, while the E2 sequence involves ten-coordinated potassium ions.

In this work, we describe a new compound belonging to this structural family, namely $K_3Sm(PO_4)_2$. Such systems offer the possibility of doping by various rare earth ions, the luminescent properties of which can be useful in the field of lasers. The experimental conditions of preparation are given, along with details of the X-ray diffraction structure determination and the results of infrared and Raman investigations.

Results and Discussion

Structural Description and Discussion

Figure 1 shows a projection of the crystal structure in the [100] plane.[13] This arrangement is characterized by the presence of isolated $P(1)O_4$ and $P(2)O_4$ tetrahedra linked only by cations. All PO_4 tetrahedra have a mirror plane (a,c) and present a face almost parallel to the (b,c) plane.

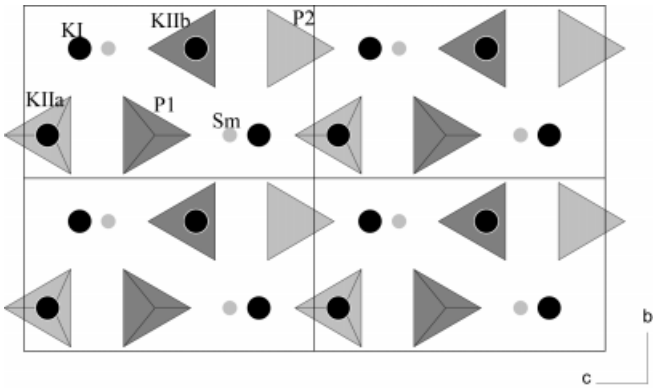

Figure 1. Projection of the $K_3Sm(PO_4)_2$ structure in the [001] plane

$P(1)O_4$ Tetrahedra: The average P(1)−O distance in the tetrahedra (1.542 Å; values range from 1.532 to 1.548 Å) is in good agreement with the value of 1.539 Å calculated by Baur and Khan.[14] The variance in the O−P−O bond angles, σ_1^2 = 2.37, is, however, larger than the value of 0.109 observed in $K_3Na(SO_4)_2$ [the variance σ^2 is defined as $\sigma^2 = 1/6\ \Sigma(\theta_i - 109.47)^2$, where θ_i represents the O−P−O bond angle and 109.47° is the ideal O−P−O bond angle in the PO_4 tetrahedron].

$P(2)O_4$ Tetrahedra: Again, the average P(2)−O distance (1.539 Å; range from 1.513 to 1.552 Å) is in good agreement with the calculated value. The variance σ_2^2 = 1.07 is much smaller than σ_1^2. The short P(2)−O(5) distance (1.513 Å) relates to the oxygen only bonded to potassium ions.

This structure can be described as comprising two types of sequences of atoms extending parallel to the a axis. The first sequence (E1) is formed by a regular succession of isolated PO_4 tetrahedra and potassium ions K(IIa) and K(IIb). The coordination numbers of K(IIa) and K(IIb) are 10 and 11, respectively. The second sequence (E2) consists of a regular succession of samarium and potassium ions. The coordination numbers are seven for samarium ions and nine for the potassium ions [K(I)].

The relationship between the $K_3Na(SO_4)_2$, β-K_2SO_4,[15] and $K_3Sm(PO_4)_2$ structures can easily be established by

considering the coordination numbers (given in square parentheses) and the cell parameters:

$K_3Na(SO_4)_2$	$[K^{[12]}Na^{[6]}][K^{[10]}(SO)_4]_2$	(a_0, c_0, $P\bar{3}$ $m1$)
β-K_2SO_4	$[K^{[9]}K^{[9]}][K^{[10]}(SO_4)]_2$	($a = c_0$; $b = a_0\sqrt{3}$; $c = a_0$; *Pnma*
$K_3Sm(PO_4)_2$	$[K^{[9]}Sm^{[7]}][K^{[10]}(PO)_4]$-$[K^{[11]}(PO_4)]$	($a = c_0$; $b = a_0$; c = $a_0\sqrt{3}$; β = 90.870°; $P2_1/m$)

The structure of β-K_2SO_4 is derived from the glaserite type through a reorientation of the tetrahedra as well as a disordering of the K^+ ions of the E2 sequence. The structure of $K_3Sm(PO_4)_2$ is similar to this β-K_2SO_4 arrangement, with only a slight distortion. The variation in the coordination numbers of the cations can be attributed to a slight rotation and distortion of PO_4 tetrahedra.

The greater distortion of $P(1)O_4$ compared to that of $P(2)O_4$ may be explained by considering the nearest neighbors: in the former case, only three samarium and four potassium ions are found at distances less than 3.6 Å, while seven potassium ions are present in the latter case.

Spectroscopic Analysis

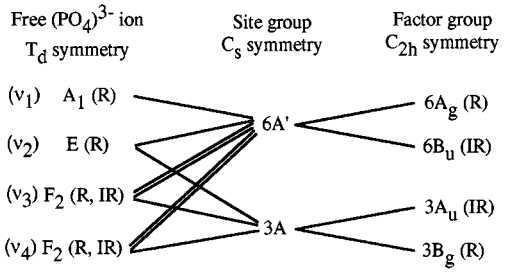
Group Theory Analysis

In accordance with the space group $P2_1/m$, the normal modes of vibration can be classified in the following irreducible representations of C_{2h} as:

$\Gamma_{optic} = 26A_g + 16B_g + 15A_u + 24B_u$

$\Gamma_{acoustic} = 1A_u + 2B_u$.

The A_g and B_g modes are Raman-active, while the A_u and B_u modes are infrared (IR)-active.



Vibrations of the PO_4 Groups

The free PO_4^{3-} tetrahedron exhibits T_d symmetry and so possesses four normal modes of vibration having A_1 (ν_1 mode), E (ν_2) and F_2 (ν_3 and ν_4) symmetries with average wave numbers of 938, 420, 1017, and 567 cm^{-1}, respectively.[16] All of these modes are Raman active, whereas only the triply-degenerate ν_3 and ν_4 modes are IR-active. The ν_1 and ν_2 modes represent the symmetric stretching and deformation vibrations, while ν_3 and ν_4 represent the corresponding asymmetric stretching and deformation vibrations. Since the other PO_4^{3-} ions occupy sites of lower symmetry than that of the free ion, anisotropic crystal fields may remove degeneracies in the normal modes and allow inactive modes to become active.

In the crystal cell, the two PO_4^{3-} ions occupy C_s-symmetric sites. The site method[17] can be applied in the analysis of the internal modes of the PO_4 groups. Table 1 shows the correlation diagram between the free PO_4^{3-} group vibrations in T_d symmetry and the lattice PO_4^{3-} internal vibrations in C_{2h} symmetry through the C_s symmetry of one PO_4 in the crystal. The correlation shows that 18 Raman and 18 IR lines are predicted:

Raman:
8 stretching modes: 2 ν_1 ($2A_g$); 6 ν_3 ($4A_g$, $2B_g$)
10 deformation modes: 4 ν_2 ($2A_g$, $2B_g$); 6 ν_4 ($4A_g$, $2B_g$)
IR:
8 stretching modes: 2 ν_1 ($2B_u$); 6 ν_3 ($4B_u$, $2A_u$)
10 deformation modes: 4 ν_2 ($2A_u$, $2B_u$); 6 ν_4 ($4B_u$, $2A_u$)

Table 1. Correlation scheme for the internal vibrations of the PO_4 group

Analysis of IR Spectra

In view of the paucity of infrared data in the frequency range below 300 cm^{-1}, only assignment of the internal modes of the PO_4 will be discussed.

In the IR spectrum (Figure 2) the bands in the 970−1100 cm^{-1} region can be assigned to the asymmetric stretching (ν_3) mode.

The two nondegenerate symmetric stretching (ν_1) modes, observed at 936 and 964 cm^{-1}, confirm the presence of two crystallographically distinct PO_4 groups. The IR bands are strongly influenced by the cation environments.

Only three bands are observed (410, 414, and 466 cm^{-1}) for the doubly-degenerate symmetric bending (ν_2).

The triply-degenerate asymmetric bending mode (ν_4) gives four bands at 545, 574, 585, and 601 cm^{-1}.

Analysis of Raman Spectra:

According to group theory analysis, of the 81 optical modes, 42 are Raman-active. With reference to the Raman tensors (Table 2), they can be distinguished by polarization investigations.

Polarized Raman spectra were recorded for different orientations of the crystal. The A_g modes were obtained in the $z(xx)\bar{z}$, $z(yy)\bar{z}$, $y(zz)\bar{y}$, and $y(zx)\bar{y}$ geometries, the B_g modes in the $x(zy)\bar{x}$ and $z(xy)\bar{z}$ geometries. The spectra are shown in Figure 3.

PO_4 Vibrations

A_g Modes

The two high-intensity bands at 938 and 970 cm^{-1} can be assigned to A_g components of the nondegenerate ν_1 mode corresponding to phosphates in sites 1 and 2.

Group theory analysis predicts four bands for the asymmetric bending mode ν_3 (A_g). Four bands at 989, 1026, 1050, and 1100 cm^{-1} are indeed observed for this mode in the $z(xx)\bar{z}$, $z(yy)\bar{z}$, and $y(zx)\bar{y}$ orientations of the Raman

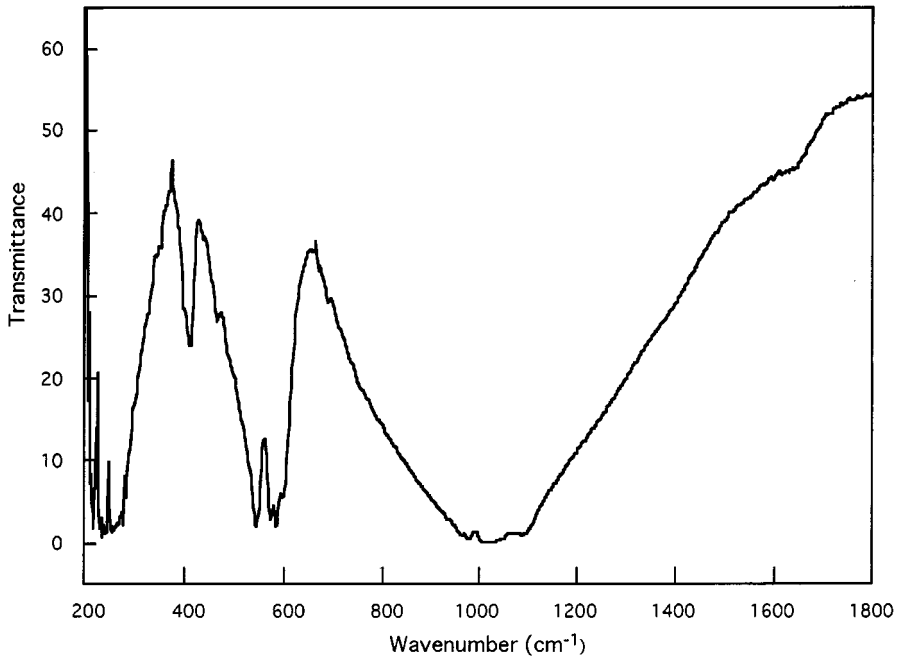


Figure 2. Infrared spectra of $K_3Sm(PO_4)_2$

Table 2. Raman tensors for the C_{2h} point group

	xx	0	*zx*		0	*yx*	0
A_g	0 xz	yy 0	0 zz	B_g	xy 0	0 yz	zy 0

spectra. In the $y(zz)\bar{y}$ orientation, only three bands at 989, 1050, and 1101 cm^{-1} are visible.

The polarized Raman bands observed at 561, 572, 589, and 609 cm^{-1} in the $z(xx)\bar{z}$, $z(yy)\bar{z}$, and $y(zz)\bar{y}$ spectra correspond to the asymmetric bending ν_4 (A_g) vibrations of the PO_4 group.

Factor group analysis predicts two bands for the symmetric bending ν_2 (A_g). Two bands at 415 and 450 cm^{-1} are indeed observed for this mode in the $z(yy)\bar{z}$ and $y(zx)\bar{y}$ orientations. In the $z(xx)\bar{z}$ and $y(zz)\bar{y}$ orientations, only one band at 450 cm^{-1} is seen.

B_g Modes

In the $x(zy)\bar{x}$ and $z(xy)\bar{z}$ geometries, 9 and 11 bands are observed, respectively.

$x(zy)\bar{x}$ 425, (450), 562, (572), (589), (938), (973), (988), 1009.

$z(xy)\bar{z}$ (416), 425, 447, 563, (573), 578, (589), (938), (972), (989), 1007.

According to group theory, only six lines are to be expected. In fact, detailed analysis shows that several lines correspond to A_g lines (frequencies in parentheses) and can be attributed to a contaminant that is difficult to completely eliminate for measurements under a microscope.

The bands at 425 and 447 cm^{-1} can be assigned to the $\nu_2(B_g)$ symmetric bending mode, those at 563 and 578 cm^{-1} to the $\nu_4(B_g)$ asymmetric bending mode, and those at 1007 and 1009 cm^{-1} to $\nu_3(B_g)$, the asymmetric bending mode.

In conclusion, the number of internal modes of the PO_4^{3-} anion observed in the Raman and IR spectra is consistent with predictions based on the proposed space group. The loss of symmetry compared to $K_3Na(SO_4)_2$[18] is clearly evident since the D_{3d} space group would lead to a much smaller number of Raman lines (Table 3).

External Modes

14 A_g and 10 B_g lines can be expected in the Raman low-frequency range, corresponding to external modes. In the absence of coupling, they would result from:

12 modes ($6A_g$ and $6B_g$) associated with the vibrations and translations of the PO_4 tetrahedra;

6 translational modes ($4A_g$ and $2B_g$) due to K^+ in K(IIa) and K(IIb) sites;

3 translational modes ($2A_g$ and $1B_g$) due to K^+ in a K(I) site;

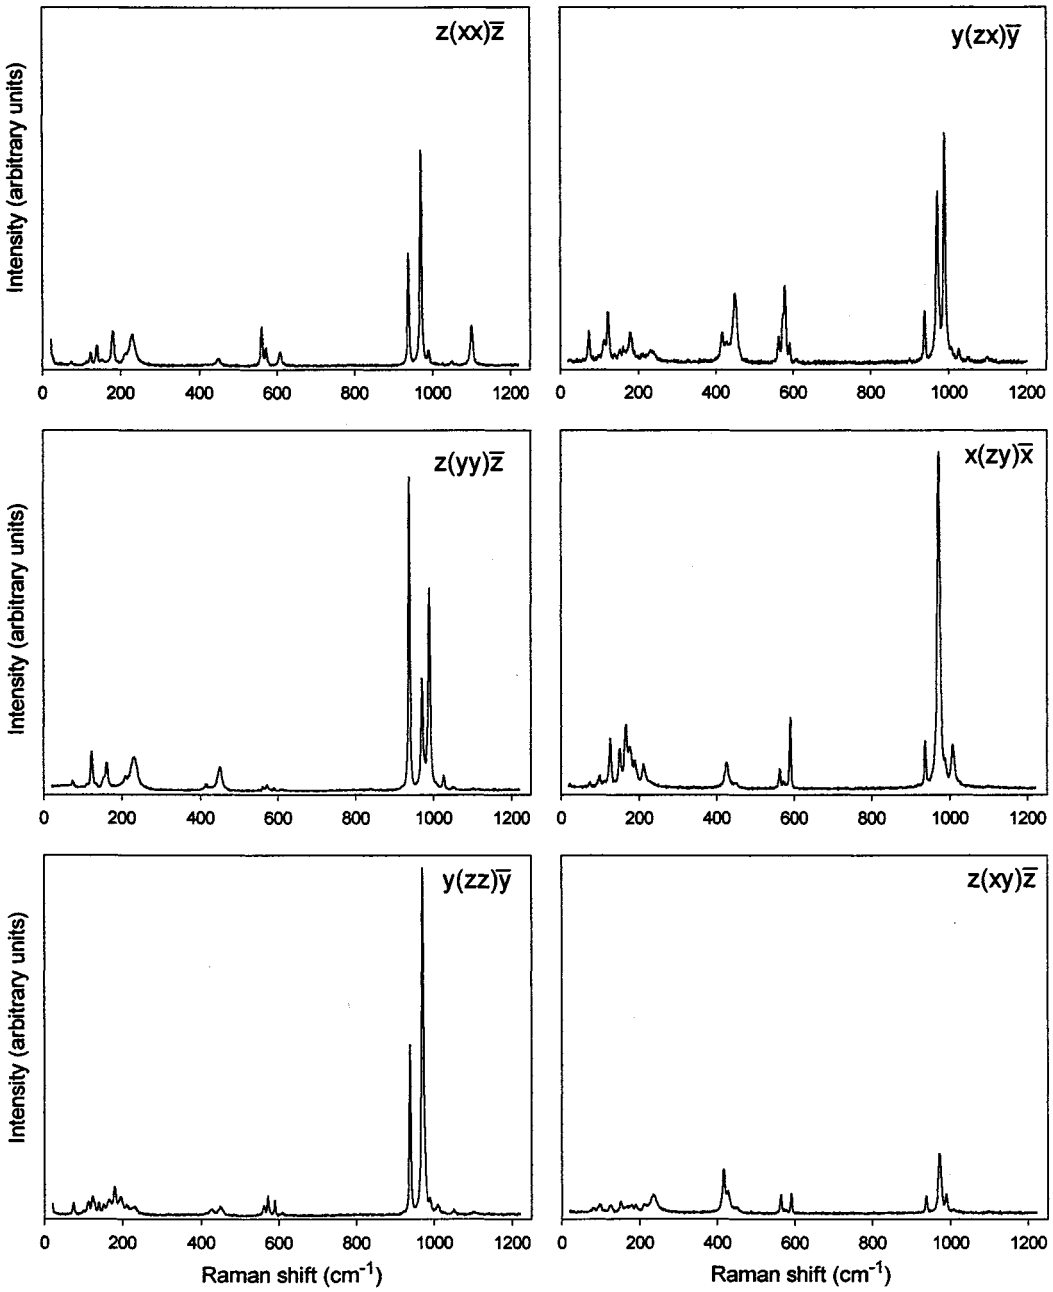
3 translational modes ($2A_g$ and $1B_g$) due to Sm^{3+}.

Experimentally, 14 A_g modes and 10 B_g modes are indeed observed at the following wave numbers (cm^{-1}):

A_g mode: 73, 111, 121, 137, 151, 153, 161, 164, 179, 194, 209, 210, 228, 231,

B_g mode: 74, 82, 98, 126, 150, 165, 177, 188, 211, 234.

These modes are, as expected, well out of the frequency range of the internal modes of PO_4. However, it is very difficult to make assignments since the frequencies are al-



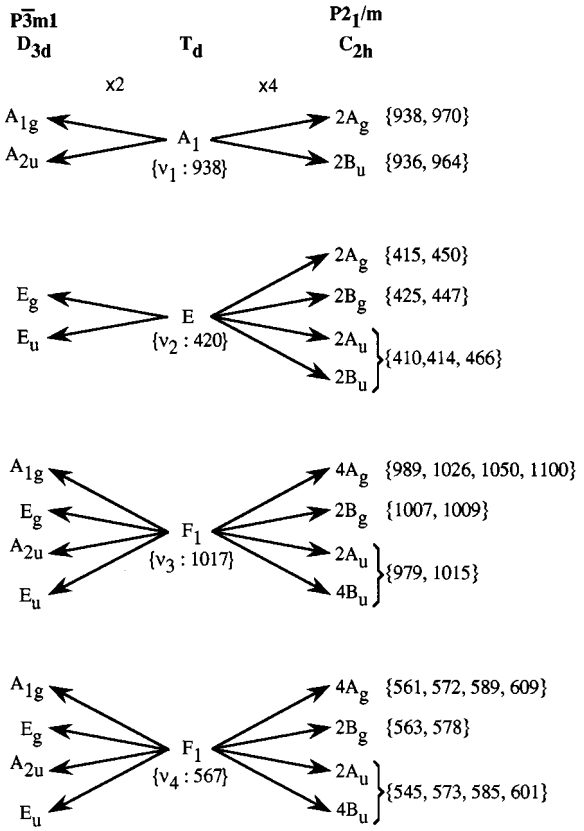


Figure 3. Raman spectra of $K_3Sm(PO_4)_2$ recorded in the various geometries indicated at the top right of each plot (the spectra recorded in cross-polarization mode are plotted with double scale)

most regularly spread and the various ionic displacements are presumably strongly coupled. Moreover, the compounds derived from glaserite[19] (space group $P\bar{3}\,m1$, $Z = 1$) that have so far been subjected to vibrational investigations,[20] such as $M^IM^{III}(XO_4)_2$ (M^I = K, Rb, Cs; M^{III} = In, Sc; X = Mo, W), do not possess the same ionic charges as in the present compound, neither for the cations nor for the molecular ions. Thus, it is not possible to extrapolate the frequencies merely from mass effects. A similar problem arises in the case of the Nasicon-type compounds Na_2-$M^{IV}(PO_4)_2$ (M^{IV} = Ti, Zr, Hf), also derived from glaserite, since the charge on samarium is just 3. However, with regard to the investigations of Barj et al.,[21] who assigned the translational modes of Ti, Zr, and Hf [setting on the K(I) site] at 195, 150, and 105 cm^{-1}, the modes involving samarium, with a lower charge, can be expected to appear at a lower frequency than 115 cm^{-1}. Indeed, several modes appear in this frequency range.

Conclusion

The crystal structure of $K_3Sm(PO_4)_2$ has been determined from single-crystal X-ray diffraction data. This structure is a derivative of the glaserite type.

Table 3. Relationship between the normal modes of vibration of the free PO_4 ions (center), those of $K_3Sm(PO_4)_2$ in the real $P2_1/m$ space (right), and those in the case of the ideal highly symmetrical glaserite (left)

The infrared and Raman spectra of single crystals of $K_3Sm(PO_4)_2$ have been measured and studied in detail on the basis of group theory analysis and by reference to other compounds derived from glaserite. The internal vibrations of the PO_4^{3-} anion could all be identified. The Raman and infrared spectra confirm the structural distortions deduced from the X-ray diffraction study.

Experimental Section

Preparation: Single crystals of $K_3Sm(PO_4)_2$ were obtained by solid-state reaction of K_2CO_3, $(NH_4)_2HPO_4$, Sm_2O_3, and KF in a 3:4:1:10 molar ratio. After grinding, the mixture was heated at 400°C for 4 h, then at 900°C for 6 h, and was finally allowed to

cool to room temperature at a rate of 10°C/h. Small needles were separated from the flux by repeated washing in hot water.

X-ray Data Collection: The X-ray diffraction intensities from a single crystal ($0.05 \times 0.1 \times 0.12$ mm^3) were collected using a Nonius CAD4 four-circle diffractometer with graphite-monochromated Mo-K_α radiation ($\lambda = 0.7107$ Å). The unit cell parameters were determined by a least-squares fit of 25 randomly located reflections between 22° and 32° in 2 θ. The total sphere of reflection with index ranges $-10 \leq h \leq 10$, $-7 \leq k \leq 1$, $-3 \leq l \leq 0$ was measured and one standard reflection (−4 1 1) was monitored hourly. No absorption correction was applied ($R_\mu = 0.65$).

The experimental details are given in Table 4. The structure calculations were performed with the SHELXS-86[22] and SHELXL-93[23] programs. The atomic positions, selected bond lengths and angles are reported in Tables 5 and 6, respectively.

Raman Spectroscopy: The Raman spectra were recorded with a DILOR Z24 spectrometer. An argon laser (Coherent Innova 90.3) was used for the excitation: radiation of the wavelength 514.5 nm was chosen since the possible luminescence lines from samarium are weak and appear outside of the spectral range where the Raman signals appear. The spectral width (full-width at half-maximum) was less than 6 cm^{-1} and the error in the line positions was less than 1 cm^{-1}. The measurements were made at room temperature under a microscope (in the back-scattering geometry) with a × 50 objective with a long working distance. This was performed on micrometric samples (typically less than 0.1 mm in length) fixed on a goniometer head and suitably orientated for polarization analysis. The orientations were deduced from the growth faces of the crystals, which were needle-shaped with diamond-shaped bases. For the structure deriving from trigonal glaserite, the needle axis corresponds to the *c* direction and so to [100] of the monoclinic cell of $K_3Sm(PO_4)_2$.

Infrared Spectroscopy: The infrared absorption spectra in KBr pellets were obtained on a Perkin−Elmer FT-IR 1000 PC spectrophotometer in the range 4000−200 cm^{-1} with 4 cm^{-1} spectral resolution.

Synthesis of Tumor-Inhibiting Complex Salts Containing the Anion *trans*-Tetrachlorobis(indazole)ruthenate(III) and Crystal Structure of the Tetraphenylphosphonium Salt

Wolfgang Peti,[a] Thomas Pieper,[a] Martina Sommer,[a] Bernhard K. Keppler,*[a] and Gerald Giester[b]

Dedicated to Prof. Dirk Walther on the occasion of his 60th birthday

Keywords: Ruthenium / Coordination chemistry / Paramagnetic complexes / Magnetic properties / Ion exchange / Antitumor agents / Colon tumors

Indazolium *trans*-tetrachlorobis(indazole)ruthenate(III) exhibits excellent results against different tumor models in vitro and in vivo. To improve the water solubility necessary for the introduction of this tumor-inhibiting compound into clinical trials, we synthesized the corresponding sodium salt in a two-step ion exchange via the tetramethylammonium salt. The sodium salt shows a 35-fold higher solubility in water relative to the indazolium salt. We also synthesized the *n*-butylammonium, *n*-octylammonium, and tetraphenylphosphonium salts, all of which showed improved solubility in organic solvents. The X-ray crystal structure of the latter could be solved, proving the *trans* configuration of the complex anion. In spite of the paramagnetic Ru^{III} center an assignement of the coordinated indazole protons could be made with the help of a COSY experiment.

Introduction

The development of ruthenium complexes as an alternative to platinum-based tumor inhibitors is of special interest. Antitumor and antimetastatic activity was found for different Ru^{II} and Ru^{III} complexes.[1–7] Ruthenium(III) complexes of the general formula $HL[RuCl_4L_2]$, where L is a heterocyclic ligand bound to ruthenium through nitrogen and HL the protonated ligand, show remarkable activity against different tumor models in vitro and in vivo. They exhibit excellent activity especially against autochthonous colorectal tumors in rats, with a tumor reduction of 70% to 90%.[8][9] This autochthonous tumor induced by intrarectal application of acetoxymethylnitrosamine (AMMN) is comparable to human colon tumors in its histological appearance and behavior toward chemotherapeutics. The metal-based antitumor drug *cisplatin* is completely inactive in this model. Furthermore, the Ru^{III} complexes show antiproliferative activity in two human colon cancer cell lines (SW707 and SW948).[10] The most promising complex contains two *trans*-standing indazole (L = ind) ligands. It exhibits antineoplastic effects on proliferation of clonogenic cells from freshly explanted human tumors in a capillary soft agar cloning system.[11] The problem with compound **1**, $HInd[RuCl_4ind_2]$ (see Figure 1),[12] is its poor water solubility, making a formulation for clinical trials difficult. To solve this problem, we synthesized new complex salts by ion exchange of the indazolium cation against a variety of cations. The complex anion, responsible for antitumor activity, remains unchanged. Especially the sodium salt **2** shows a much better water solubility, while the corresponding tetraphenylphosphonium salt, of which the crystal structure could be resolved, and the tetraalkylammonium salts are much more soluble in organic solvents, which might be of interest for further reactions with these complex salts.

Results and Discussion

Exchange of the indazole cation in the complex salt **1**, $HInd[RuCl_4ind_2]$, against a tetraalkylammonium or tetraphenylphosphonium cation can be achieved by adding the corresponding chloride salt to a nearly saturated solution of **1** in water (see Figure 1). Immediate precipitation of the complex salts **4**, **5**, or **6**, even less soluble in water than **1**, occurs. In the case of the tetramethylamonium salt **3** methanol is used as solvent instead of water because **3** is more soluble in water than **1**.

The more hydrophobic the substituents of the cation, the more soluble in organic solvents are the corresponding Ru-complex salts. Not surprisingly the tetraoctylammonium salt **5** exhibits the best solubility in less polar solvents like chloroform.

These solubility characteristics can be used in synthesizing the sodium salt **2**, $Na[RuCl_4ind_2]$, that cannot be obtained directly from **1**. Addition of sodium tetraphenylbo-

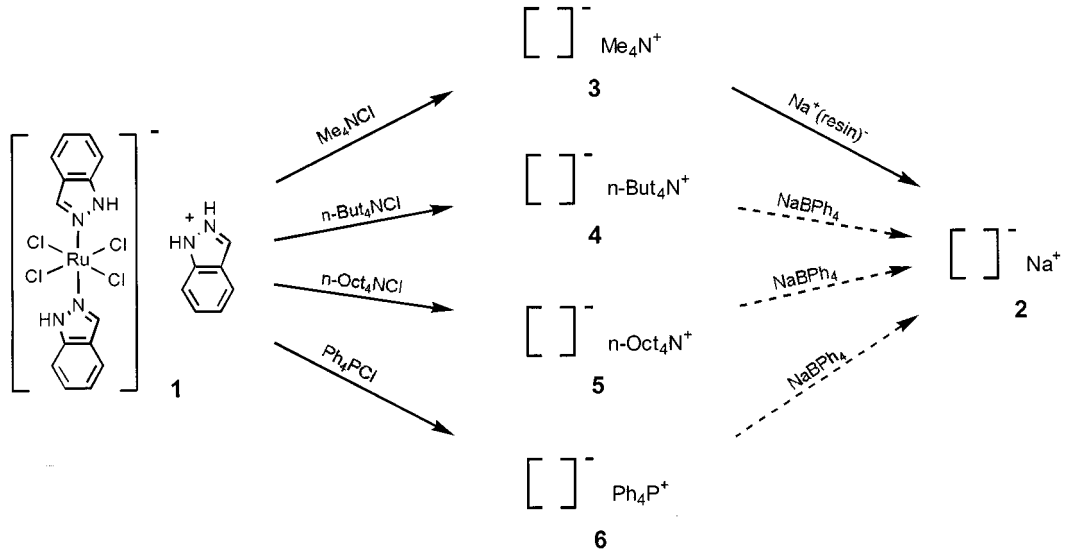

Figure 1. Synthesis of the complex salts **3**, **4**, **5**, and **6** ([ ]$^-$ represents the complex [$RuCl_4ind_2$]$^-$) and synthesis pathways from **1**, HInd[$RuCl_4ind_2$], to **2**, Na[$RuCl_4ind_2$]

rate to a solution of the complex salts **3**, **4**, **5**, or **6** in solvents like methanol, acetone or acetonitrile leads to precipitation of the corresponding tetraphenylborate salts, for example tetraphenylphosphonium tetraphenylborate in the case of **6**. The sodium salt **2** stays in solution and can be precipitated by addition of diethyl ether. Unfortunately, pure products cannot be obtained reproducibly. The best results were obtained with the tetraphenylphosphonium salt **6** in acetonitrile.

A more advantageous method of synthesizing the sodium salt **1** makes use of cation exchange resins. This method was only successful when the tetramethylammonium salt **3**, already more soluble in water than the indazolium salt **1**, was used. The sodium salt could not be prepared directly from the indazolium salt. Thus, a solution of **3** in water was mixed with a Dowex cation exchange resin preloaded with sodium. To avoid hydrolysis of the complex, the solution was frozen immediately after ion exchange, and water was removed under vacuum. After this lyophilization process the product **2**, sodium *trans*-tetrachlorobis(indazole)ruthenate(III), is obtained as a trihydrate. Its solubility in water (0.018 mol/l) is about 35 times higher than that of **1**.

The ^{1}H-NMR spectra of the complex salts show high-field shifts and peak broadening for the protons of the coordinated indazole ligands, because of the paramagnetic Ru^{III} center. In a [D_3]acetonitrile solution of the sodium salt **2** the signals for the protons at position 1 and 3 of the heterocycle, nearest to the Ru^{III} center, can be detected at a chemical shift of about $\delta = -7$ and -12, respectively. The signal at $\delta = -7$ can be assigned to the protons at N1 of the indazole rings, because it disappears due to rapid exchange upon addition of water. The other signals at $\delta = 2.45$ (2 H, at C4 or C7), 2.63 (2 H, at C7 or C4), 3.18 (2 H, at C5 or C6), and 4.32 (2 H, at C6 or C5), represent the protons at a greater distance from the paramagnetic Ru^{III} center. They were assigned in pairs with the help of a COSY experiment (see Figure 2).

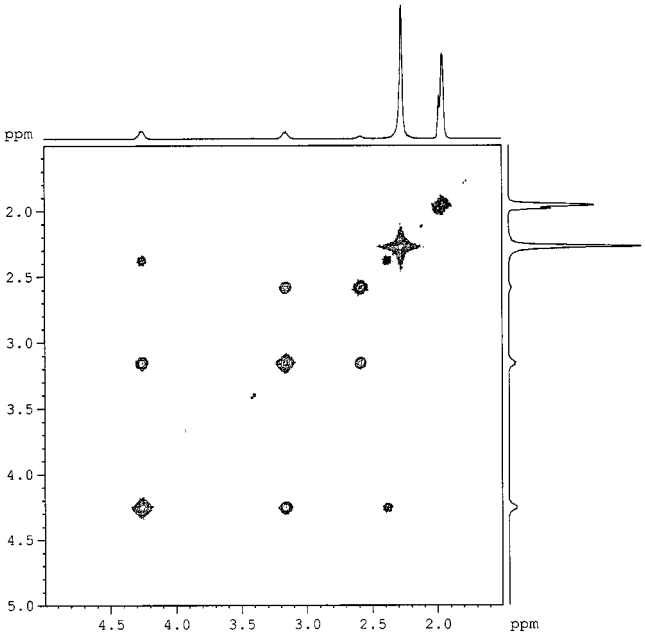

Figure 2. Detail of the COSY spectrum of **2**, Na[$RuCl_4ind_2$], in [D_3]acetonitrile, showing the signals at $\delta = 2.45$, 2.63, 3.18, and 4.32 that represent the indazole protons further from the paramagnetic Ru^{III} center (the signal at $\delta = 2.45$ in the projections is overlapped by the water signal of the solvent) than the two nearest protons, which cannot be detected in the COSY experiment.

In ^{13}C-NMR measurements the signals of the two quaternary carbons and the carbon beneath the coordinated nitrogen of each indazole ligand could not be detected. The detectable carbons at $\delta = 118.07$ (C5 or C6), 114.72 (C6 or C5), 98.29 (C4 or C7), and 97.77 (C7 or C4) could also be assigned in pairs because of the corresponding cross peaks in a H,C-correlated spectrum (HMQC, spectrum not shown).

The X-ray crystal structure of the tetraphenylphosphonium salt was solved, proving the *trans* configuration of

the complex anion $[RuCl_4ind_2]^-$ (see Figure 3, crystallographic data are collected in Table 1). The Ru atom is in the center of an octahedron. The two planes of the *trans* indazole ligands, bound through the N2 nitrogen, are twisted. The longest Ru−Cl bond is formed between Cl(2) and the Ru center [2.3723(8) Å], whereas the Ru−Cl(1) [2.3627(7) Å], Ru−Cl(3) [2.3618(7) Å] and especially the Ru−Cl(4) [2.3586(8) Å] bonds are slightly, but significantly shorter. The longer Ru−Cl(2) bond is due to hydrogen bonding between the Cl(2) and the N(4) of one indazole ligand. The N(4)−Cl(2) distance is 3.105 Å. The distance between Cl(2) and the hydrogen at the N(4) of the indazole ring, H(2), is 2.441 Å [N(4)−H(2): 1.094 Å]. Cl(2), Ru, N(3), N(4), and H(2) are nearly in a plane.

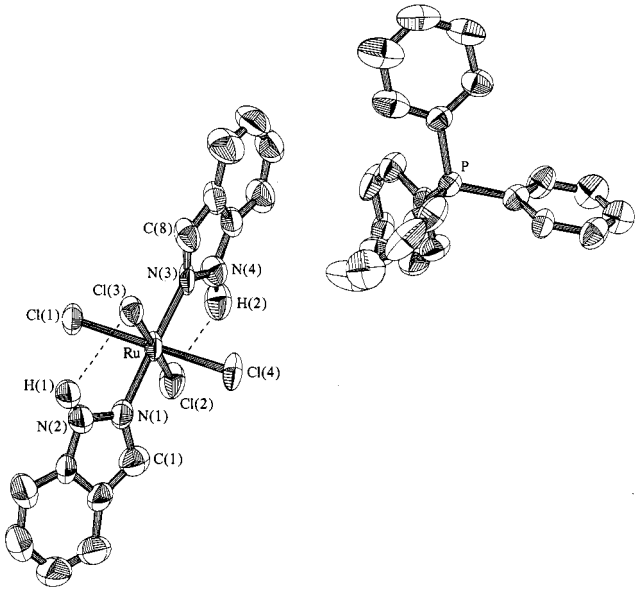

Figure 3. Perspective view of the crystal structure of **6**, $Ph_4P[RuCl_4ind_2]$. Selected bond lengths [Å] and angles [deg]: Ru−Cl(1) 2.3627(7), Ru−Cl(2) 2.3723(8), Ru−Cl(3) 2.3618(7), Ru−Cl(4) 2.3586(8), Ru−N(1) 2.0517(21), Ru−N(3) 2.0711(22), N(1)−N(2) 1.3498(31), N(3)−N(4) 1.3466(29), N(1)−C(1) 1.3338(36), N(3)−C(8) 1.3065(39), N(1)−Ru−N(3) 178.33(8), N(1)−Ru−Cl(1) 90.33(6), N(1)−Ru−Cl(2) 89.81(6), N(1)−Ru−Cl(3) 89.80(6), N(1)−Ru−Cl(4) 89.63(6), N(3)−Ru−Cl(1) 90.89(6), N(3)−Ru−Cl(2) 89.07(7), N(3)−Ru−Cl(3) 91.37(6), N(3)−Ru−Cl(4) 89.20(6), Cl(1)−Ru−Cl(2) 89.85(3), Cl(1)−Ru−Cl(3) 87.96(3), Cl(1)−Ru−Cl(4) 177.44(2), Cl(2)−Ru−Cl(3) 177.78(2), Cl(2)−Ru−Cl(4) 92.71(3), Cl(3)−Ru−Cl(4) 89.48(3)

In contrast, N(2) of the other indazole ligand exhibits only weak interactions with the chlorine Cl(3) through its H(1) atom [N(2)−Cl(3): 3.212 Å, Cl(3)−H(1): 2.750 Å, N(2)−H(1): 0.853 Å]. The N(2)−Cl(1) distance is 3.426 Å. Cl(4) is not involved in any hydrogen bonding and therefore exhibits the shortest Ru−Cl bond length.

In general, the Ru−Cl and Ru−N [Ru−N(1): 2.0517(21) Å, Ru−N(3): 2.0711(22) Å] bond lengths, as well as the bond lengths of the indazole rings, lie in the same range as those of the corresponding 1-methylindazole complex, the crystal structure of which has already been published[12]. The phosphorus of the tetraphenylphosphonium counterion is tetrahedrally coordinated by the phenyl rings, as could be expected

Experimental Section

Materials: All solvents and reagents were used as received and were of analytical grade. Indazolium *trans*-tetrachlorobis(indazole)ruthenate(III), $HInd[RuCl_4ind_2]$, was prepared as described previously[12].

Infrared Spectra: Infrared spectra were recorded on a Perkin−Elmer FTIR 2000 IR spectrophotometer.

NMR Spectra: The ^1H-, ^{13}C-, and 2D NMR experiments were performed at 400.13 MHz (^1H) and 100.61 MHz (^{13}C) on a Bruker DPX 400 spectrometer at 24 °C.

The gradient selected COSY and the HMQC (inverse H,C-correlation with BIRD selection and GARP decoupling in phase-sensitive mode using TPPI) experiments were performed with standard Bruker pulse programs.

X-ray Structure Determination: A single crystal of the tetraphenylphosphonium salt with the approximate dimensions of 0.30 × 0.25 × 0.15 mm was used for X-ray measurement on a Nonius KappaCCD diffractometer (Mo-*Kα* radiation) at room temperature. Denzo-SMN software was utilized for the data evaluation. The structure was solved by direct methods (SHELXS-97)[13] and refined (SHELXL-97)[14] including the positions of all hydrogen atoms. A summary of the crystal data and of the refinement procedures is given in Table 1. Atomic coordinates and displacement parameters are deposited in the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-112417.

Elemental Analyses: C,H,N analysis were carried out on a Perkin−Elmer 2400 CHN Elemental Analyzer. Cl was analyzed by argentometry.

Preparation of Compounds. Sodium *trans*-Tetrachlorobis(indazole)ruthenate(III) Trihydrate, $Na[RuCl_4ind_2] \cdot 3\ H_2O$ (2): A solution of $Me_4N[RuCl_4ind_2]$ (**3**; 100 mg, 0.18 mmol) in water (200 mL) was mixed with a Dowex 50WX2 acidic cation-exchange resin preloaded with sodium for 20 minutes. After filtration, the solution was immediately frozen with liquid nitrogen and lyophilized. The sodium salt was obtained as a voluminous, brown powder. Yield: 80 mg (89%). − $C_{14}H_{12}Cl_4N_4NaRu \cdot 3\ H_2O$ (556.19): calcd. C 30.23, H 3.26, Cl 25.50, N 10.07; found: C 30.20, H 2.62, Cl 25.47, N 9.80. − ^1H NMR (400 MHz, [D$_3$]acetonitrile): δ = 4.32 (2 H), 3.18 (2 H), 2.63 (2 H), 2.45 (2 H), −7.1 (2 H), −12.9 (2 H). − ^{13}C NMR (100 MHz, [D$_3$]acetonitrile): δ = 118.07, 114.72, 98.29, 97.77. IR (CsI): $\tilde{\nu}$ = 3459 s, 3316 s, 2925 w, 1627 vs, 1511 m, 1439 w, 1382 m, 1356 vs, 1280 w, 1241 s, 1154 m, 1124 m, 1085 s, 1004 m, 967 m, 900 w, 868 w, 838 m, 782 w, 750 vs, 667 s, 616 w, 435 m, 321 s, 291 m, 215 m cm^{-1}. − Thermogravimetric analysis (Mettler-Toledo TGA 850): The loss of one mol equivalent of water was achieved by heating up to 130 °C (nitrogen atmosphere). Further weight loss is observed at temperatures above 200 °C, resulting in decomposition of the complex.

Sodium *trans*-Tetrachlorobis(indazole)ruthenate(III), $Na[RuCl_4ind_2]$: $NaB[C_6H_5]_4$ (600 mg, 1.75 mmol) was added to a solution of **6** ($Ph_4P[RuCl_4ind_2]$, 500 mg, 0.61 mmol) in acetonitrile (25 mL). The precipitated $Ph_4PB[C_6H_5]_4$ was filtered off after stirring for five minutes. The sodium salt was precipitated by addition of diethyl ether to the filtrate. After standing at 4 °C for 30 minutes, $Na[RuCl_4ind_2]$ was filtered and dried in vacuum over P_2O_5. Yield: 266 mg (87%). − $C_{14}H_{12}Cl_4N_4NaRu$ (502.15): calcd. C, 33.49, H 2.41, N 11.16, Cl 28.24; found: C 33.09, H 2.67, N 11.04, Cl 26.79. − ^1H NMR (400 MHz, [D$_3$]acetonitrile): δ(cation) = 7.94 (4 H), 7.71 (m, 16 H); δ(anion) = 4.55 (2 H), 3.27 (2 H), 2.84 (2 H), 2.59 (2 H), −7.0 (2 H), −12.5 (2 H).

Table 1. Crystallographic data for $Ph_4P[RuCl_4ind_2]$ (**6**)

Crystal−detector distance: 28 mm, 180 frames with 2° φ scan range and 2 × 150 s exposure time per frame.

Tetramethylammonium *trans*-Tetrachlorobis(indazole)ruthenate(III), $Me_4N[RuCl_4ind_2]$ (3): Tetramethylammonium chloride (368 mg, 3.36 mmol) was added to $HInd[RuCl_4ind_2]$ (500 mg, 0.84 mmol) in methanol (150 mL). After stirring for 30 min, the formed precipitate was filtered, washed with water and dried under vacuum over phosphorus pentaoxide. Yield: 326 mg (70%). − $C_{18}H_{24}Cl_4N_5Ru$ (553.1): calcd. C 39.07, H 4.37, Cl 25.63, N 12.66; found: C 38.90, H 4.29, Cl 25.52, N 12.36. − ^{1}H NMR (400 MHz, [D$_3$]acetonitrile): δ(cation) = 3.16 (s, 12 H); δ(anion) = 4.54 (2 H), 3.27 (2 H), 2.83 (2 H), 2.58 (2 H), −5.81 (2 H), −10.89 (2 H). − ^{13}C NMR (100 MHz, [D$_3$]acetonitrile): δ(cation) = 59.24; δ(anion) = 118.12, 113.91, 98.12, 97.81. − IR (CsI): $\tilde{\nu}$ = 3460 m, 3293 s, 3013 m, 1627 s, 1560 w, 1509 m, 1483 s, 1438 w, 1380 w, 1356 vs, 1276 w, 1239 s, 1149 w, 1119 w, 1082 m, 1002 m, 945 vs, 866 w, 836 w, 750 vs, 669 s, 522 m, 455 w, 435 m, 336 m, 321 s, 291 m, 266 w, 218 m cm^{-1}.

Tetra(*n*-butyl)ammonium *trans*-Tetrachlorobis(indazole)ruthenate(III), $(n\text{But})_4N[RuCl_4ind_2]$ (4): $HInd[RuCl_4ind_2]$ (200 mg, 0.34 mmol) was suspended in water (100 mL) and acetonitrile (5 mL) by ultrasonic treatment and then dissolved in water (400 mL). Tetra(*n*-butyl)ammonium chloride (186 mg, 0.69 mmol) was added to this solution and precipitation occurred immediately. To complete the reaction, the mixture was stirred overnight. The precipitate was filtered, washed with water, and dried under vacuum over phosphorus pentaoxide. Yield: 216 mg (89%). − $C_{30}H_{48}Cl_4N_5Ru$ (721.63): calcd. C 49.93, H 6.70, Cl 19.65, N 9.71; found: C 49.57, H 6.46, Cl 19.67, N 9.53. − ^{1}H NMR (400 MHz, [D$_3$]acetonitrile): δ(cation) = 3.20 (8 H), 1.76 (8 H), 1.40 (8 H), 1.01 (12 H); δ(anion) = 4.55 (2 H), 3.26 (2 H), 2.83 (2 H), 2.57 (2 H), −7.0 (2 H), −12.3 (2 H). − ^{13}C NMR (100 MHz, [D$_6$]DMSO): δ(cation) = 59.36, 24.39, 20.26, 14.53; δ(anion) = 118.39, 114.69, 99.79, 96.28. − IR (CsI): $\tilde{\nu}$ = 3307 s, 2960 s, 2874 m, 2360 m, 1626 s, 1506 w, 1478 vs, 1442 m, 1381 m, 1354 vs, 1275 w, 1243 s, 1152 s, 1089 m, 1002 m, 963 m, 838 m, 749 vs, 670 s, 628 s, 556 s, 434 m, 333 m, 320 s, 289 m, 217 m cm^{-1}.

Tetra(*n*-octyl)ammonium *trans*-Tetrachlorobis(indazole)ruthenate(III), $(n\text{Oct})_4N[RuCl_4ind_2]$ (5): To a solution of $HInd[RuCl_4ind_2]$ (250 mg, 0.42 mmol) in water (800 mL), prepared analogously to the above-mentioned procedure, were added tetra(*n*-octyl)ammonium chloride (420 mg, 0.84 mmol) in water (30 mL) and ethyl acetate (1 mL) to aid solution. After stirring for three days a green agglutinated precipitate formed and was filtered, washed with methanol, and dried under vacuum over phosphorus pentaoxide. Yield: 234 mg (59%). − $C_{46}H_{80}Cl_4N_5Ru$ (946.06): calcd. C 58.39, H 8.52, Cl 14.99, N 7.40; found: C 57.85, H 8.11, Cl 14.42, N 7.69. − ^{1}H NMR (400 MHz, $CDCl_3$): δ(cation) = 2.91 (8 H), 1.47 (16 H), 1.19 (32 H), 0.83 (12 H); δ(anion) = 4.11 (2 H), 3.11 (2 H), 2.40 (2 H), 2.27 (2 H), −7.7 (2 H), −14.3 (2 H). − ^{13}C NMR (100 MHz, $CDCl_3$): δ(cation) = 32.13, 30.19, 29.56, 29.02, 28.38, 23.04, 21.81, 14.55; δ(anion) = 116.88, 116.22, 99.40, 95.33. − IR (CsI): $\tilde{\nu}$ = 3296 s, 3096 w, 2955 s, 2926 vs, 2856 s, 1626 m, 1504 w, 1466 s, 1375 m, 1353 s, 1269 w, 1242 m, 1149 w, 1114 w, 1083 m, 998 w, 954 w, 830 w, 746 s, 671 m, 547 w, 442 w, 433 w, 328 s, 283 m, 218 m cm^{-1}.

Tetraphenylphosphonium *trans*-Tetrachlorobis(indazole)ruthenate(III), $Ph_4P[RuCl_4ind_2]$ (6): Tetraphenylphosphonium chloride (190 mg, 0.5 mmol) was added to a solution of $HInd[RuCl_4ind_2]$ (150 mg, 0.25 mmol) in water (500 mL), prepared analogously to the above-mentioned procedure, which resulted in immediate precipitation. After stirring overnight the precipitate was filtered and washed with water. Afterwards the crude product was dissolved in acetone and reprecipitated by addition of diethyl ether. The ocher-yellow precipitate was washed with diethyl ether/acetone (1:1) and dried under vacuum over phosphorus pentaoxide. Yield: 82 mg (40%). − $C_{38}H_{32}Cl_4N_4PRu$ (818.56): calcd. C 55.76, H 3.94, Cl 17.32, N 6.84; found: C 55.55, H 3.77, Cl 17.19, N 6.65. − ^{1}H NMR (400 MHz, [D$_3$]acetonitrile): δ(cation) = 7.94 (4 H), 7.71 (m, 16 H); δ(anion) = 4.54 (2 H), 3.26 (2 H), 2.82 (2 H), 2.58 (2 H), −7.1 (2 H), −12.5 (2 H). − ^{13}C NMR (100 MHz, [D$_6$]DMSO): δ(cation) = 136.88, 135.60 (d), 131.86 (d), 118.88 (d); δ(anion) = 118.42, 114.71, 99.82, 96.26. − IR (CsI): $\tilde{\nu}$ = 3475 s, 3351 s, 3057 m, 1626 s, 1584 m, 1508 m, 1482 m, 1437 vs, 1380 m, 1358 s, 1277 m, 1164 m, 1108 vs, 1087 w, 996 s, 962 m, 837 m, 764 vs, 723 vs, 690 vs, 666 s, 528 vs, 440 w, 435 w, 336 m, 321 s, 282 m, 216 m cm^{-1}. − Crystals for X-ray diffraction were obtained by slowly evaporating an acetonitrile solution.

Acknowledgments

The assistance of Mrs. Rosa Strobl in preparing the manuscript is gratefully acknowledged.

Synthesis and Metal-Ion Extraction Properties of *para-tert*-Butylcalixareneglycine Ester Acetamides

Burkhard König,*[a] Tom Fricke,[a] Karsten Gloe,*[b] and Christine Chartroux[b]

Dedicated to Professor Dirk Walther (Jena) on the occasion of his 60th birthday

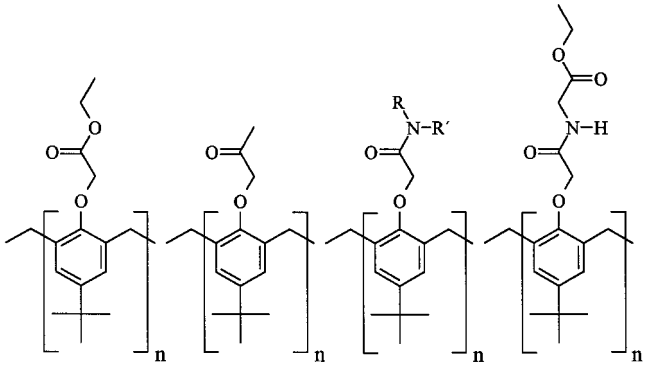
Keywords: Calixarenes / Macrocycles / Silver / Radiotracer technique / Metal-ion extraction / Radiochemistry

Calixareneglycine ester acetamides **4a–c** have been synthesized from calixareneacetyl chlorides **5a–c** and glycine ethyl ester (**6**). Their ion-binding properties have been investigated by liquid-liquid extraction with radiotracer techniques. The experiments reveal a moderate affinity towards silver(I) ions, which increases with calixarene ring size.

Introduction

Calixarenes are most suitable precursors for the synthesis of selective ionophores.[1] As illustrated by many examples their unique molecular structure allows the arrangement of functional groups in space for the coordination of metal cations.[2] Receptor molecules with remarkable selectivities in cation binding have been developed, e.g. from calix[4]arene, which was anchored in a particular conformation of the macrocycle by suitable derivatization[1] and functionalized with crown ethers.[3] But even the introduction of much simpler functional groups, such as ethers, esters, amides or ketones has a profound effect on the binding ability of calixarenes. It has been well established that the phenolic functions of calixarenes can be alkylated with alkyl bromoacetates to form alkyl calixarene acetates **1** with significant ion-binding potential for mainly alkali metal cations.[4] The series has been extended to calixarene ketones **2**,[5] amides **3**,[6] thioamides and carboxylic acids,[7] and their alkali and alkaline earth cation binding properties have been determined. The principal findings of these studies were that calix[4]arene esters **1a**, ketones **2a** and *tert*-amides **3a**[8] show a clear preference for Na^+ ions, the pentamer series (**1d**, **2d**, **3d**), reflecting the larger receptor volume than the tetramers, favors the larger cations K^+, Rb^+ and Cs^+ over Na^+, and calix[6]arene (**1b**, **2b**, **3b**) and calix[8]arene derivatives (**1c**, **2c**, **3c**) are characterized by lower extraction ability and low levels of discrimination among the alkali cations. The *tert*-amides **3a** and **3b** also bind the alkaline earth metal ions Ca^{2+}, Sr^{2+} and Ba^{2+} with high efficiency, but without clear size preference. This was confirmed by stability-constant measurements and solvent-extraction studies.[2a] In contrast to the behavior of tertiary amides (R = R′ = alkyl) the related secondary amides **3a**, **3b**, **3c** (R = H; R′ = *n*Bu) extract alkali metal ions only very weakly.[9] With the alkaline earth metals the same compounds give size-dependent extractabilities, which are furthermore graduated in the order **3b > 3c > 3a**. Less data have been reported on the complexation of transition-metal cations in solution, with the exception of Ag^+, for which a broad range of stability constants in methanol is available.[2a,2b] With *para-tert*-butylcalixarene tetra- (**1a**), penta- (**1d**) and hexaesters (**1b**) log β values range between 3.1 and 4.3, and no size selectivity is observed. The stability of complexes is slightly higher for the tetraketone **2a** and much higher for the tetraamide **3a**. In the amide series there is a size effect: Compound **3d** shows a higher log β value than **3a** or **3b**.[2a,8] The calix[4]arene-*tert*-amide **3a** is a useful extractant for Ag^I from strongly acidic medium.[10]

In order to investigate the effect of functional groups simultaneously present in each arene moiety,[11] we have synthesized a series of new calixareneglycine ester acetamides **4**, which represent examples of simple calixarenes that bear both secondary amide *and* ester groups as potential coordination sites for metal ion binding. Their binding properties have been investigated by liquid-liquid extraction of aqueous solutions of metal picrates. A first example of this type, calix[4]areneglycine tetra-*tert*-butyl ester acetamide, was recently reported by Reinhoudt et al.[12]



Results and Discussion

Synthesis

The synthesis of the *para-tert*-butylcalixareneglycine ester acetamides **4a–c** was achieved analogously to previously reported procedures for the synthesis of calixarene acetamides. The reaction of the *para-tert*-butylcalixareneacetyl chlorides **5a–c**[13] with glycine ethyl ester (**6**)[14] under standard conditions enabled the isolation of the glycine es-

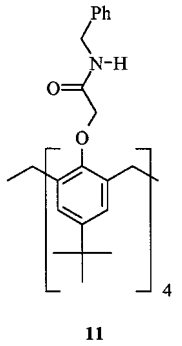
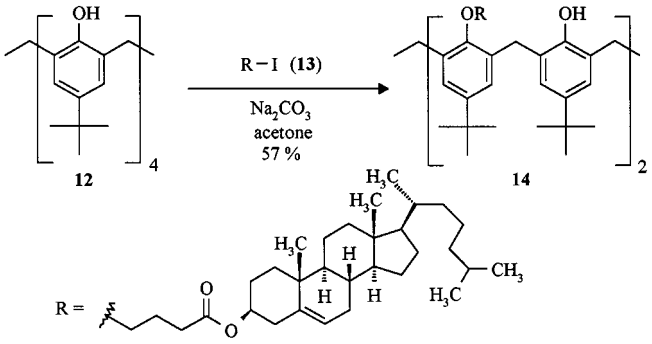
ter acetamides **4a–c** in 59–79% yields. As indicated by the broad resonance signals in the NMR spectra of **4b**, the compound has a restricted conformational mobility on the NMR time scale. Obviously, compound **4a** is, like **5a**, fixed in the cone conformation, whereas the macrocyclic ring of **4c** is large enough to allow rotation of the substituted arene units. The reaction of **5a** with heterocyclic amino acid esters, such as **7** and **8**, proceeds analogously, but is much less efficient for **8**.[15] Surprisingly, amides **9** and **10** show significant decomposition in chloroform solution at room temperature, which renders them unsuitable for extraction studies. *N*-Benzylamide **11** and compound **14** were synthesized from **5a** and benzylamine, and alkylation of **12** with **13**,[16] respectively, for comparison of their extraction properties with compound **4a**.



Scheme 2. Synthesis of *para-tert*-butylcalixareneglycine ester acetamides

Metal-Ion Extraction Properties



The binding properties of the new compounds were investigated by liquid-liquid extraction experiments. Aqueous solutions of the metal salts ($c = 1 \cdot 10^{-4}$ mol/l) and picric acid ($5 \cdot 10^{-3}$ mol/l), buffered to pH = 5.2 by NaOAc/HCl,[17] were extracted with chloroform solutions of the calixarene derivatives ($c = 1 \cdot 10^{-3}$ mol/l). The determination of the metal concentrations in both phases was carried out by measurement of the radiation of the corresponding

radionuclides.[18] As metal ions Na^+, Ba^{2+}, Tl^+, Pd^{2+}, Cu^{2+}, Zn^{2+}, Hg^{2+}, Eu^{3+} and Ag^+ were employed to obtain information about extraction properties towards alkali, alkaline earth and transition metal ions. Figure 1 summarizes the results. All glycine ester acetamides extract Ag^+, and the efficiency increases drastically from **4a** (1.8%) to **4b** (15%) and **4c** (57%).[19] For the large glycine ester acetamide **4c** some extraction of Cu^{2+} (7.1%), Hg^{2+} (5.5%), Eu^{3+} (3%) and Ba^{2+} (1.8%) was noted. Compound **4b** shows, besides Ag^+ binding, some uptake of Tl^+ (3.5%) but very low Hg^{2+}, Cu^{2+}, Eu^{3+} and Ba^{2+} extraction (< 2%). Extraction of Na^+ or Zn^{2+} was not observed in any case. The importance of the ester groups for extraction is illustrated by comparison with the *N*-benzylamide-substituted calix[4]arene **11**: None of the tested metal salts were ex-

tracted under the selected experimental conditions and only a small affinity towards Pd^{2+} could be detected.[20] Compound **14**, lacking ester and amide groups, did not show any extraction of metal salts within the error of the experiment.

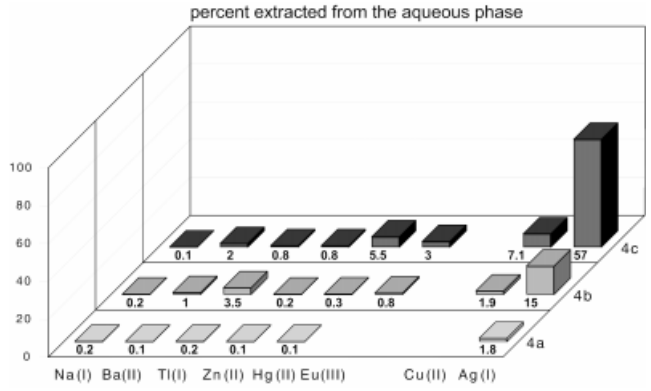

Figure 1. Extraction of metal picrates with compounds **4a**, **4b** and **4c**; $c_M = 1 \cdot 10^{-4}$ M; $c_{HPic} = 5 \cdot 10^{-3}$ M; pH = 5.2; $c_L = 1 \cdot 10^{-3}$ M/$CHCl_3$ a stoichometry of 1:1 for Hg^{2+}, Tl^+, Eu^+ complexes, and 1:1, 1:2 stoichometries for Ag^+ and Ba^{2+} complexes

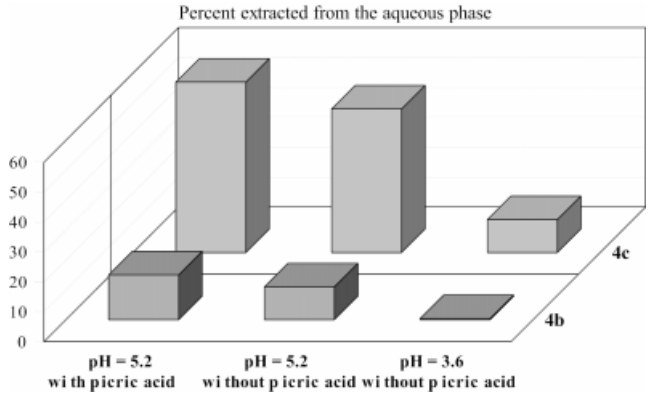

Figure 2. Influence of the pH value on the extraction of Ag^+ with **4b** and **4c**; $c_{Ag} = 1 \cdot 10^{-4}$ M; $c_L = 1 \cdot 10^{-3}$ M/$CHCl_3$

The extractability of Ag^+ with **4b** and **4c** strongly depends on the pH value of the aqueous phase. As it is shown in Figure 2 a decreasing pH value (from 5.2 to 3.6) led to a significant lower extraction (from 57% to 11% for **4c**; from 15% to 0.4% for **4b**). In contrast to this, amazingly, the influence of the picrate anion on the Ag^+ extraction is weak (see Figure 2). The extractability for **4c** in the absence of picrate is only 9%, and for **4b** 4% lower than with picrate present.

Some additional information about the stoichiometry of the calixarene metal complexes in the organic phase was derived from double log plots of distribution ratios of the metals versus ligand concentrations (Figure 3). The analysis suggests that **4b** and **4c** form 1:1 complexes with Hg^{2+}. The same composition is also obtained from **4b** with Tl^+ and Eu^{3+}; 1:1 and 1:2 complexes (M/L) are identified for Ag^+[21] with the calixarenes **4a** and **4b** and for Ba^{2+} with **4b**. The calculated extraction constants are summarized in Table 1. Preliminary molecular modeling studies give some evidence for the binding of the metal ion by ether and carbonyl oxygen donor atoms inside the cavity, similar to the known structures with tertiary amides.[2e] The limited extraction power of the novel compounds in comparison with *tert*-amides might be rationalized by a specific hydrogen-bonding pattern between the secondary amide and carbonyl oxygen functions in the molecule, as it is observed for compounds with related structure.[22] The interaction of the secondary amide with the solvent chloroform might also be taken into account.

Conclusion

In summary, calixarene derivatives that bear a secondary amide moiety and an ester group on each arene unit were obtained by reaction of calixareneacetyl chlorides **5** with glycine ethyl ester (**6**). The investigation of the binding

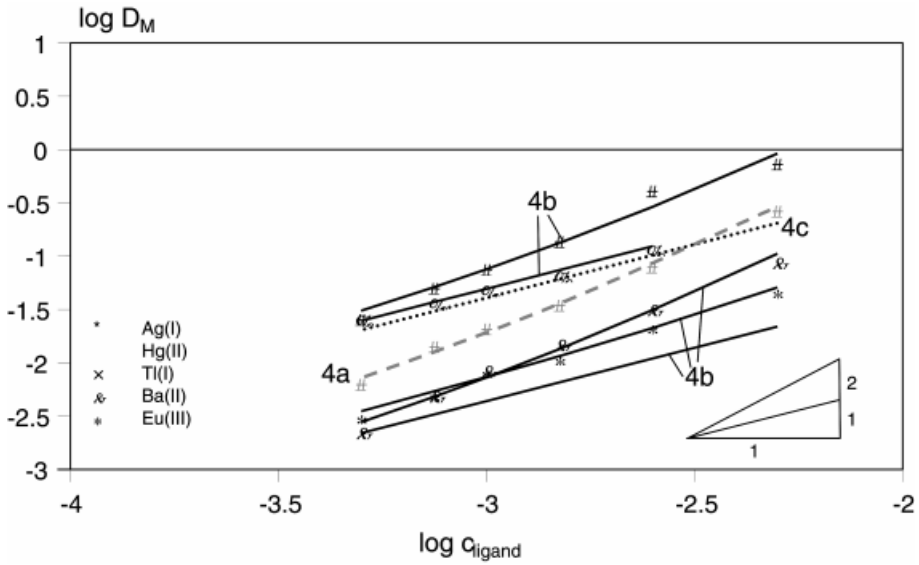

Figure 3. The double logarithmic plot suggests a stoichiometry of 1:1 for Hg^{2+} complexes in the organic phase, and 1:1, 1:2 or higher stoichiometries for Ag^+ complexes; $c_M = 1 \cdot 10^{-4}$ M; $c_{HPic} = 5 \cdot 10^{-3}$ M; pH = 5.2; $c_L = 5 \cdot 10^{-4} - 5 \cdot 10^{-3}$ M/$CHCl_3$

properties of the new potential ionophores by liquid-liquid extraction of picrate salts revealed poor to moderate extraction of mainly silver(I) salts, in which the calix[8]arene derivative **4c** shows the largest extraction ability. For calixarenes bearing secondary amides on the lower rim efficient extraction of alkaline earth cations has been reported, and a little of this characteristic remains in compounds **4b** and **4c**. However, the affinity of calixareneacetates towards alkali cations[2a,8] is completely lost in **4**, where the ester is placed further away from the calixarene core and separated from it by an amide group. The ability of *para-tert*-butylcalixareneglycine ester acetamides **4** to bind Ag^+ ions is clearly surpassed by calixarene-*tert*-amides,[8] and in particular, -*tert*-thioamides.[23] In conclusion, calix[6]- and calix[8]areneglycine acetamides **4b** and **4c** show some affinity in metal ion extraction, but their efficiency and selectivity is inferior to other known calixarene ionophores.

Experimental Section

General Remarks: Melting points were taken with a hot-plate microscope apparatus and are not corrected. − NMR spectra were recorded at 400 MHz (^{1}H) and 100 MHz (^{13}C) in [D]chloroform solutions unless otherwise stated. The multiplicity of the ^{13}C signals was determined with the DEPT technique and quoted as: (+) for CH_3 or CH, (−) for CH_2 and (C_{quat}) for quaternary carbon atoms. CC means column chromatography on silica gel unless otherwise stated. PE means petroleum ether with a boiling range of 60−70°C, EA means ethyl acetate.

Determination of Metal-Ion Binding Properties by Liquid-Liquid Extraction: All extractions were performed at 25°C in agitated microreactors (2 cm^3). To reach the equilibrium of distribution the organic and aqueous phase of equal volumes were shaken for 30 min for all investigated metal ions. Only in the case of palladium was 2 h of shaking necessary to reach the equilibrium. The phases were separated, centrifuged and the concentration of metal ions in both phases was determined by the emission of the radionuclides which were used. The γ-radiation (^{203}Hg, ^{133}Ba, ^{110m}Ag, ^{109}Pd, ^{65}Zn, ^{64}Cu, ^{22}Na) was measured with an NaI(Tl) scintillation counter (Cobra II, Canberra Packard) and β-emission (^{204}Tl) was determined with a liquid scintillation counter (Tricarb 2500, Canberra Packard).

Calix[4]arene 4a: To a solution of the acyl chloride **5a** (0.24 g, 0.25 mmol) in 10 mL of CH_2Cl_2 was added glycine ethyl ester (**6**; 0.31 g, 3.0 mmol) in 10 mL of CH_2Cl_2 at 0°C, the reaction mixture was stirred at room temp. for 16 h, washed with saturated aqueous NH_4Cl solution, dried with $MgSO_4$ and the solvent was removed in vacuo. CC (Et_2O/EA, 5:1; R_f = 0.49) of the crude product gave 0.24 g (79%) of **4a** as a white solid, m.p. 230°C. − IR (KBr): $\tilde{\nu}$ = 3380 cm^{-1}, 1750, 1680, 1190. − UV/Vis (CH_3CN): λ_{max} (lg ε) = 194 nm (5.046), 216 (4.796). − ^{1}H NMR: δ = 7.92 (t, ^3J = 5.7 Hz, 4 H), 6.83 (s, 8 H), 4.58 (s, 8 H), 4.56 (d, ^2J = 13.9 Hz, 4 H), 4.19 (q, ^3J = 7.1 Hz, 8 H), 4.12 (s, 8 H), 3.31 (d, ^2J = 13.0 Hz, 4 H), 1.28 (t, ^3J = 7.1 Hz, 12 H), 1.09 (s, 36 H). − ^{13}C NMR: δ = 170.3 (C_{quat}), 170.1 (C_{quat}), 152.5 (C_{quat}), 146.1 (C_{quat}), 132.6 (C_{quat}), 125.9 (+), 74.1 (−), 61.2 (−), 41.0 (−), 33.9 (C_{quat}), 31.3 (+), 31.1 (−), 14.1 (+). − MS (MALDI-TOF); *m/z* (%): 1244.4 (100) [M + Na]$^+$. − C68H92N4O16·H2O (1239.5): calcd. C 65.89, H 7.64, N 4.52; found C 66.25, H 7.78, N 4.20.

Calix[6]arene 4b: To a solution of the acyl chloride **5b** (1.4 g, 1.0 mmol) in 30 mL of CH_2Cl_2 was added at 0°C glycine ethyl ester (**6**; 1.9 g, 18 mmol) in 30 mL of CH_2Cl_2; the mixture was stirred for 16 h at room temp. and was worked up as described for compound **4a**. The crude product was recrystallized from ethyl acetate (5 mL) and petroleum ether (30 mL) at −20°C overnight to yield 1.26 g (69%) of **4b** (R_f = 0.38 in Et_2O/EA, 5:1) as a white solid, m.p. 116−118°C. − IR (KBr): $\tilde{\nu}$ = 3410 cm^{-1}, 1750, 1680, 1190. − UV/Vis (CH_3CN): λ_{max} (lg ε) = 196 nm (5.264), 218 (4.995). − MS (MALDI-TOF); *m/z* (%): 1854.0 (100) [M + Na]$^+$. − $C_{102}H_{138}N_6O_{24}$ (1832.2): calcd. C 66.85, H 7.60, N 4.59; found C 66.53, H 7.66, N 4.29.

Calix[8]arene 4c: To a solution of the acyl chloride **5c** (1.4 g, 0.73 mmol) in 30 mL of CH_2Cl_2 was added at 0°C glycine ethyl ester (**6**; 1.9 g, 18 mmol), dissolved in 30 mL of CH_2Cl_2; the reaction mixture was stirred for 16 h at room temp. and worked up as described for **4c**. The crude product was recrystallized from CH_2Cl_2 (5 mL) and *n*-heptane (30 mL) at −20°C overnight to give 1.06 g (59%) of **4c** (R_f = 0.27 in Et_2O/EA, 5:1) as a white solid, m.p. 224−226°C. − IR (KBr): $\tilde{\nu}$ = 3430 cm^{-1}, 1750, 1690, 1200. − UV/Vis (CH_3CN): λ_{max} (lg ε) = 196 nm (5.366), 222 (5.075). − ^{1}H NMR: δ = 7.92 (t, ^3J = 5.7 Hz, 4 H), 6.83 (s, 8 H), 4.58 (s, 8 H), 4.56 (d, ^2J = 13.9 Hz, 4 H), 4.19 (q, ^3J = 7.1 Hz, 8 H), 4.12 (s, 8 H), 3.31 (d, ^2J = 13.0 Hz, 4 H), 1.28 (t, ^3J = 7.1 Hz, 12 H), 1.09 (s, 36 H). − ^{13}C NMR: δ = 169.9 (C_{quat}), 169.0 (C_{quat}), 151.9 (C_{quat}), 147.0 (C_{quat}), 132.0 (C_{quat}), 125.9 (+), 71.4 (−), 61.2 (−), 40.7 (−), 34.2 (C_{quat}), 31.3 (+), 31.2 (−), 14.0 (+). − MS (MALDI-TOF); *m/z* (%): 2466.1 (100) [M + Na]$^+$. − $C_{136}H_{184}N_8O_{32}$·H_2O (2461.0): calcd. C 66.38, H 7.62, N 4.55; found C 66.19, H 7.73, N 4.35.

Calix[4]arene 9: A mixture of methyl 1-methyl-4-nitropyrrole-2-carboxylate (0.5 g, 2.7 mmol) and Pd/C (0.15 g) in 200 mL of ethyl acetate and 100 mL of methanol was hydrogenated at an H_2 pressure of 4 bar for 16 h at room temp., the catalyst was removed by filtration and the solvent was removed in vacuo. The resulting amino acid **7** was dissolved in 30 mL of CH_2Cl_2, triethyl amine (2 mL, 14 mmol) and the acyl chloride **5a** (0.5 g, 0.52 mmol) were added at 0°C, the reaction mixture was stirred for 16 h at room temp., washed with saturated aqueous NH_4Cl solution, dried with Na_2SO_4 and the solvent was removed in vacuo. CC (CH_2Cl_2/MeOH, 97:3, R_f = 0.33) of the crude product gave 0.66 g (89%) of **9** as a white solid. − IR (KBr): $\tilde{\nu}$ = 3310 cm^{-1}, 1710, 1690, 1450, 1200. − UV/Vis (CH_3CN): λ_{max} (lg ε) = 204 nm (5.016), 228 (4.978), 284 (4.525). − ^{1}H NMR: δ = 9.56 (s, 4 H), 7.32 (d, ^4J = 1.9 Hz, 4 H), 6.85 (d, ^4J = 1.9 Hz, 4 H), 6.79 (s, 8 H), 4.57 (s, 8 H), 4.52 (d, ^2J = 12.9 Hz, 4 H), 3.75 (s, 12 H), 3.71 (s, 12 H), 3.23 (d, ^2J = 13.1 Hz, 4 H), 1.07 (s, 36 H). − ^{13}C NMR: δ = 167.4 (C_{quat}), 161.4 (C_{quat}), 153.4 (C_{quat}), 145.7 (C_{quat}), 132.8 (C_{quat}), 125.8 (+), 121.7 (+), 121.1 (C_{quat}), 119.8 (C_{quat}), 109.0 (+), 74.8 (−), 50.9 (+), 36.5 (+), 33.8 (C_{quart}), 31.4 (−), 31.3 (+). − MS (ESI); *m/z* (%): 1448.4 (90) [M + Na]$^+$, 732.4 (100) [M + K]$^{2+}$.

Calix[4]arene 10: A solution of ethyl 1-methyl-4-nitroimidazol-2-carboxylate (0.5 g, 2.5 mmol) in 200 mL of ethyl acetate and 100 mL of methanol was hydrogenated for 16 h at room temp. on Pd/C (0.15 g) at an H_2 pressure of 4 bar. The catalyst was removed by filtration, the solvent was distilled off in vacuo, CH_2Cl_2 (30 mL) and triethylamine (2 mL, 14 mmol) were added. The acyl chloride **5a** (0.5 g, 0.52 mmol) was added at 0°C, the reaction mixture was stirred for 16 h at room temp. and worked up as described for **9**. CC (CH_2Cl_2/MeOH, 97:3, R_f = 0.26) gave 70 mg (9%) of **10** as a solid. – ^{1}H NMR: δ = 9.91 (s, 4 H), 7.43 (s, 4 H), 6.75 (s, 8 H), 4.80 (s, 8 H), 4.58 (d, ^2J = 13.1 Hz, 4 H), 4.22 (q, ^3J = 7.1 Hz, 8 H), 3.85 (s, 12 H), 3.23 (d, ^2J = 13.3 Hz, 4 H), 1.22 (t, ^3J = 7.1 Hz, 12 H), 1.01 (s, 36 H). – ^{13}C NMR (100 MHz, $CDCl_3$): δ = 167.4 (C_{quat}), 158.8 (C_{quat}), 153.0 (C_{quat}), 145.6 (C_{quat}), 136.8 (C_{quat}), 132.7 (C_{quat}), 131.4 (C_{quat}), 129.3 (+), 125.7 (+), 74.7 (–), 61.1 (–), 35.8 (+), 33.8 (C_{quat}), 31.4 (–), 31.3 (+), 14.1 (+). – MS (ESI); *m/z* (%): 1507.6 (100) $[M + Na]^+$.

Calix[4]arene 11: To a solution of the acyl chloride **5a** (0.4 g, 0.42 mmol) and triethylamine (1.2 mL, 8.4 mmol) in 30 mL of CH_2Cl_2 was added benzylamine (0.2 mL, 1.8 mmol) at 0°C; the reaction mixture was stirred for 16 h at room temp. and worked up as described for **4a**. CC (CH_2Cl_2/MeOH, 49:1, R_f = 0.30) yielded 50 mg (10%) of **11** as a white solid, m.p. 277–278°C. – IR (KBr): $\tilde{\nu}$ = 3280 cm^{-1}, 1660, 1480, 1200. – UV/Vis (CH_3CN): λ_{max} (lg ε) = 194 nm (5.306), 202 (5.166), 276 (3.546). – ^{1}H NMR: δ = 7.81 (t, ^3J = 5.9 Hz, 4 H), 7.23 (m, 20 H), 6.75 (s, 8 H), 4.40 (m, 20 H), 3.14 (d, ^2J = 13.1 Hz, 4 H), 1.07 (s, 36 H). – ^{13}C NMR: δ = 169.5 (C_{quat}), 152.8 (C_{quat}), 145.8 (C_{quat}), 138.3 (C_{quat}), 132.6 (C_{quat}), 128.5 (+), 127.6 (+), 127.2 (+), 125.8 (+), 74.4 (–), 42.9 (–), 33.8 (C_{quat}), 31.4 (–), 31.3 (+). – MS (ESI); *m/z* (%): 1259.8 (100) $[M + Na]^+$, 1237.6 (40) $[M + H]^+$. – $C_{80}H_{92}N_4O_8$ (1236.7): calcd. C 77.64, H 7.49, N 4.53; found C 77.34, H 7.78, N 4.43.

Calix[4]arene 14: To a suspension of *para-tert*-butylcalix[4]arene (**12**; 0.5 g, 0.77 mmol) and Na_2CO_3 (0.5 g, 4.7 mmol) in 70 mL of acetone was added 2.7 g (4.6 mmol) of **13** and the reaction mixture was refluxed for 10 d. The solvent was removed, the solid residue was extracted with 20 mL of CH_2Cl_2 and the resulting suspension was filtered. The organic phase was washed with sat. aqueous NH_4Cl solution, dried with Na_2SO_4, and the solvent was removed in vacuo. CC (PE/EA, 20:1; R_f = 0.37) of the crude product yielded 0.68 g (57%) of **14**, as a white solid, m.p. 210°C. – IR (KBr): $\tilde{\nu}$ = 3430 cm^{-1}, 1730, 1470, 1170. – UV/Vis (CH_3CN): λ_{max} (lg ε) = 192 nm (5.553), 230 (4.006), 286 (3.618). – ^{1}H NMR: δ = 7.65 (s, 2 H), 7.03 (s, 4 H), 6.83 (s, 4 H), 5.34 (d, ^3J = 3.8 Hz, 2 H), 4.62 (m, 2 H), 4.24 (d, ^2J = 12.9 Hz, 4 H), 4.03 (t, ^3J = 5.9 Hz, 4 H), 3.31 (d, ^2J = 12.9 Hz, 4 H), 2.83 (t, ^3J = 7.2 Hz, 4 H), 1.67 (m, 60 H), 1.27 (s, 18 H), 1.00 (s, 6 H), 0.99 (s, 18 H), 0.92 (d, ^3J = 6.5 Hz, 6 H), 0.87 (d, ^3J = 6.6 Hz, 6 H), 0.86 (d, ^3J = 6.6 Hz, 6 H), 0.68 (s, 6 H). – ^{13}C NMR: δ = 172.7 (C_{quat}), 150.7 (C_{quat}), 149.5 (C_{quat}), 146.9 (C_{quat}), 141.3 (C_{quat}), 139.7 (C_{quat}), 132.7 (C_{quat}), 127.6 (C_{quat}), 125.5 (+), 125.1 (+), 122.5 (+), 75.1 (–), 74.0 (+), 56.7 (+), 56.1 (+), 50.0 (+), 42.3 (C_{quat}), 39.7 (–), 39.5 (–), 38.1 (–), 37.0 (–), 36.6 (C_{quat}), 36.2 (–), 35.8 (+), 33.9 (C_{quat}), 33.8 (C_{quat}), 31.9 (–), 31.8 (+), 31.7 (+), 31.0 (+), 28.2 (–), 28.0 (+), 27.7 (–), 25.5 (–), 24.3 (–), 23.8 (–), 22.8 (+), 22.5 (+), 21.0 (–), 19.3 (+), 18.7 (+), 11.8 (+). – MS (ESI); *m/z* (%): 1580.9 (55) $[M + Na]^+$, 524.2 (100). – $C_{106}H_{156}O_8$ (1558.4): calcd. C 81.70, H 10.09; found C 81.44, H 10.21.

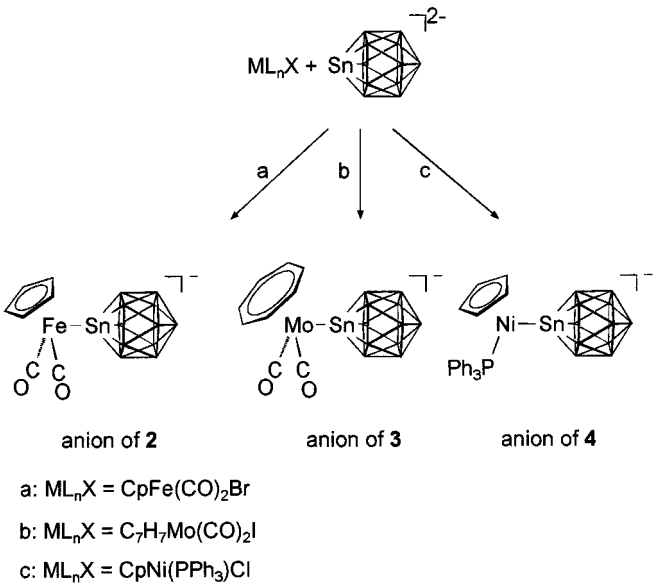
Stanna-*closo*-dodecaborate: A Nucleophile in Transition Metal Chemistry

Lars Wesemann,*[a] Thiemo Marx,[a] Ulli Englert,[a] and Michael Ruck[b]

Keywords: Stannaborate cluster / Transition metal complexes / Tin / Coordination modes / Clusters / Boron



Reactions of the stannaborate salt $[NBu_4]_2[SnB_{11}H_{11}]$ (**1**) with the organometallic electrophiles $[CpFe(CO)_2Br]$, $[(C_7H_7)Mo(CO)_2I]$, and $[CpNi(PPh_3)Cl]$ resulted in substitution of the halide to give the stannaborate coordination products $[NBu_4][CpFe(CO)_2(SnB_{11}H_{11})]$ (**2**), $[NBu_4][(C_7H_7)Mo(CO)_2(SnB_{11}H_{11})]$ (**3**), and $[NBu_4][CpNi(PPh_3)(SnB_{11}H_{11})]$ (**4**) in high yields. Single crystals of the air- and moisture-stable products have been characterized by X-ray crystal structure analyses.

The incorporation of transition metals into the skeletons of boranes and heteroboranes has been extensively studied.[1] However, the direct coordination of a *closo* cluster at a transition metal centre has been realized in only a few cases.[2]

Recently, as part of a study on the chemistry of weakly coordinating anions, Strauss reported on the first structurally characterized example of a *closo*-monocarborane with an *exo* carbon−transition metal bond $\{[NBu_4]_2[CuCl(CB_{11}F_{11})]\}$.[3] The dianion $[CB_{11}F_{11}]^{2-}$ can be regarded as a new ligand in transition metal chemistry, offering the possibility of synthesizing complexes with zwitterionic structures incorporating weakly coordinating anions.

In our approach to this field, we set out to explore the synthetic potential of the *closo*-stannaborate dianion $[NBu_4]_2[SnB_{11}H_{11}]$ (**1**). This stannaborate was first synthesized by Todd starting from the readily accessible undecaborate cluster $[Me_3NH][B_{11}H_{14}]$.[4] Deprotonation with *n*-butyllithium and treatment with tin dichloride resulted in the formation of the *closo* cluster dianion **1**.

Although Todd has shown previously that the stannaborate reacts as a nucleophile with methyl iodide, the nucleophilic power of the dianion towards transition metal electrophiles has remained unexplored. In order to investigate the nucleophilicity of the cluster $[SnB_{11}H_{11}]^{2-}$, we studied its reaction with several transition metal halides. The stannaborate salt **1** was treated with $[CpFe(CO)_2Br]$, $[(C_7H_7)Mo(CO)_2I]$, and $[CpNi(PPh_3)Cl]$ in CH_2Cl_2. In all three cases the substitution product was straightforwardly obtained, in almost quantitative yield on the basis of ^{11}B-NMR spectroscopy. Besides the cluster coordination product, one equivalent of $[NBu_4]$[halide] was formed, which could be separated by extraction with water. The air- and moisture-stable transition metal complexes were crystallized by slow diffusion of hexane into a dichloromethane solution of the respective salt. Each transition metal complex was characterized by elemental analysis, NMR spectroscopy, and X-ray diffraction analysis of single crystals. In the ^{11}B-NMR spectrum of the cluster dianion **1** in solution, three signals in an intensity ratio of 1:5:5 for the eleven boron atoms indicate C_{5v} symmetry. The ^{11}B-NMR signals of the substitution products **2**, **3**, and **4** appear at higher field and the signals for the two B_5 groups are isochronic (Scheme 1). Thus, ^{11}B-NMR spectroscopy is an appropriate tool for monitoring the progress of the reactions. ^{119}Sn-NMR spectra were recorded in all three cases, although for the nickel derivative no resonance was observed. The ^{119}Sn-NMR spectra of **2** and **3** feature a single resonance at $\delta = -208$ ($W_{1/2} = 112$ Hz) and $\delta = -257$ ($W_{1/2} = 124$ Hz), respectively. The ^{119}Sn chemical shift depends on the oxidation state, the coordination number, and the solvent.[5] For the two oxidation states, the chemical shift ranges overlap markedly, thereby making impossible any assessment of the oxidation state on the basis of the observed chemical shifts. The measured chemical shifts can be compared with that of the methyl-substituted derivative $[MeSnB_{11}H_{11}]^-$ ($\delta = -196.5$).[4]

In each case, crystals suitable for X-ray diffraction analysis were obtained by slow diffusion of hexane into a dichloromethane solution of the respective salt. Views of the cluster anions of **2**, **3**, and **4** are depicted in Figures 1, 2, and 3, respectively. Selected interatomic lengths are listed in Table 1. In all three cases, the interatomic lengths between the cluster atoms indicate a close resemblance to the structure of $[MePPh_3][MeSnB_{11}H_{11}]$. The observed bond lengths between the tin atoms and the transition metal atoms [Fe−Sn 2.479(1) Å, Mo−Sn 2.711(1) Å, Ni−Sn 2.412(1) Å] fall within the ranges of known M−Sn lengths in related organometallic compounds [$CpFe(CO)_2SnBr_3$: Fe−Sn 2.462(2) Å, $CpFe(CO)_2SnCl_3$: Fe−Sn 2.467(2) Å, $CpFe(CO)_2SnPh_3$: Fe−Sn 2.536(2) Å],[6] [$(C_7H_7)Mo(CO)_2SnCl_3$: Mo−Sn 2.720(1) Å, $Cp_2Mo(Br)(SnBr_3)$: Mo−Sn 2.691(4) Å],[7] [$(CpNiPEt_3)_2SnCl_2$: Ni−Sn 2.468(1) Å, $(CpNiPEt_3)_3SnCl$: Ni−Sn 2.531(1) Å].[8]

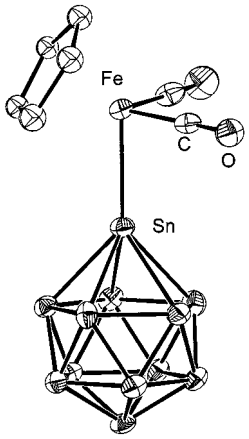

Figure 1. Molecular structure of the anion of **2**

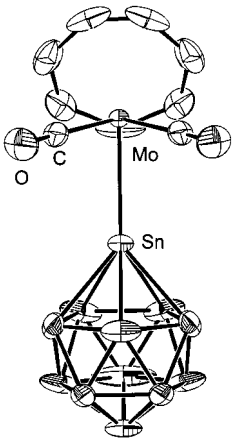

Figure 2. Molecular structure of the anion of **3**

The salts **2** and **4** crystallize in lattices built up of $[NBu_4]^+$ cations and $[L_nM(SnB_{11}H_{11})]^-$ anions. In the anion lattice, the charge-bearing stannaborates are directed towards the cation lattice.

In summary, the stannaborate cluster reacts as a nucleophile towards organometallic electrophiles and installs a negative charge in the complex, which is localized on the cluster atoms. The substitution products show remarkable stability towards air and moisture.

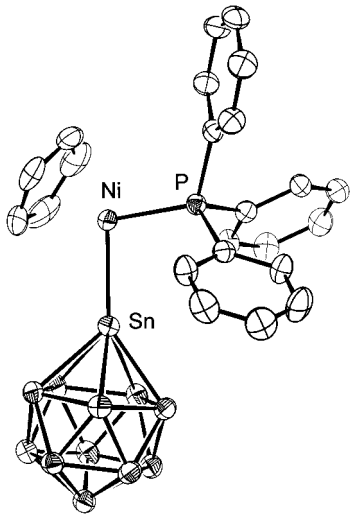

Figure 3. Molecular structure of the anion of **4** (the ellipsoids represent 50% probability)

Table 1. Selected interatomic distances [Å] in **2**, **3**, and **4**

Experimental Section

General: All manipulations were carried out under dry N_2 in Schlenk glassware. Solvents were dried and purified by standard methods and were stored under N_2. − NMR: Varian Unity 500 (^{1}H: 500 MHz, int. TMS; ^{13}C{^{1}H}: 126 MHz, int. TMS; ^{31}P: 202 MHz, ext. H_3PO_4; ^{11}B: 160 MHz, ext. $BF_3{\cdot}OEt_2$; ^{119}Sn: 186 MHz, ext. Me_4Sn). − MS: Finnigan MAT 95. − Elemental analysis: Institut für Anorganische Chemie RWTH Aachen, Carlo−Erba model 1106 elemental analyser.

$[NBu_4][CpFe(CO)_2SnB_{11}H_{11}]$ (2): A solution of 230 mg (257.1 g/mol, 0.89 mmol) of $CpFe(CO)_2Br$ in 10 mL CH_2Cl_2 was added at room temperature to a solution of 600 mg (733.8 g/mol, 0.82 mmol) of $[NBu_4]_2[SnB_{11}H_{11}]$ in 20 mL CH_2Cl_2. After stirring for 30 min, the solvent was evaporated in vacuo and the resulting brown waxy residue was stirred in 80 mL H_2O for 4 h. The remaining solid was filtered off, dried in vacuo, and crystallized from 20 mL CH_2Cl_2 by slow diffusion of hexane at +8°C to give 370 mg (67% yield) of **2** as orange-brown crystals. − ^{1}H{^{11}B} NMR (CD_2Cl_2): δ = 1.02 (t, 12 H, ^3J = 7.3 Hz, CH_2CH_3), 1.44 (m, 8 H, ^3J = 7.3 Hz, $CH_2CH_2CH_3$), 1.63 (m, 8 H, $CH_2CH_2CH_2$), 3.14 (m, 8 H, NCH_2CH_2), 5.32 (m, 5 H, C_5H_5). − ^{11}B{^{1}H} NMR (CD_2Cl_2): δ = −10.8 (s, B12), −15.1 (s, B2−6 and B7−11). − ^{13}C{^{1}H} NMR (CD_2Cl_2): δ = 12.7 (CH_2CH_3), 19.0 ($CH_2CH_2CH_3$), 23.2 ($CH_2CH_2CH_2$), 58.2 (NCH_2CH_2), 82.3 (C_5H_5), 210.4 (M−CO). − ^{119}Sn NMR (CD_2Cl_2): δ = −208.4. − MS (70 eV) SIMS; *m/z* (%):

248.0 (100) [M^- − $CpFe(CO)_2$]. − $C_{23}H_{52}B_{11}FeNO_2Sn$ (668.1): calcd. C 41.35, H 7.84, N 2.10; found C 41.11, H 7.93, N 1.93.

X-ray Crystallographic Study of 2: $C_{23}H_{52}B_{11}NO_2FeSn$; formula mass 668.13 g/mol; triclinic, space group $P\bar{1}$ (no. 2); a = 11.493(4), b = 11.852(6), c = 14.39(1) Å, α = 95.62(6), β = 90.55(6), γ = 120.44(3)°, V = 1678(2) Å^3, Z = 2, $d_{calcd.}$ = 1.322 g cm^{-3}, $\mu_{lin.}$ = 1.20 mm^{-1}. Enraf−Nonius CAD4 diffractometer; Mo-K_α radiation (λ = 0.71073 Å); graphite monochromator. Data collection at 203 K on a crystal of dimensions ca. 0.35 × 0.35 × 0.2 mm using ω scans in the range 2° ≤ θ ≤ 27° yielded 7197 reflections. The data were corrected for Lorentz and polarization effects, and an empirical absorption correction based on azimuthal scans[9] was applied. After merging symmetry equivalent data, 4856 unique observations with $I > 1.0\ \sigma(I)$ remained for structure solution[10] by Patterson and subsequent Fourier difference syntheses. Orientational disorder of the Cp ring was encountered. Least-squares refinement on structure factors[10] was performed with isotropic displacement parameters for the Cp carbon atoms, anisotropic displacement parameters for all other nonhydrogen atoms, and hydrogen atoms placed in calculated positions (C−H = 0.98 Å, B−H = 1.1 Å). Convergence was obtained for 349 variables, 4856 data, and R = 0.078, R_w = 0.068, GoF = 1.523. A final difference Fourier map showed fluctuations of less than 1.5 eÅ^{-3} close to the Sn atom.[11]

$[NBu_4][(C_7H_7)Mo(CO)_2SnB_{11}H_{11}]$ (3): A solution of 352 mg (371.0 g/mol, 0.95 mmol) of $(C_7H_7)Mo(CO)_2I$ in 10 mL CH_2Cl_2 was added to a solution of 696 mg (733.8 g/mol, 0.95 mmol) of $[NBu_4]_2[SnB_{11}H_{11}]$ in 20 mL CH_2Cl_2 at room temperature. After stirring for 30 min, the solvent was removed in vacuo and then the red waxy residue was treated with 80 mL H_2O for 4 h. The remaining dark-red solid was separated by filtration, dried in vacuo, and recrystallized from 20 mL CH_2Cl_2 by slow diffusion of hexane at +8°C to give 455 mg (65% yield) of **3** as dark-red needles. − $^1H\{^{11}B\}$ NMR (CD_2Cl_2): δ = 1.00 (t, 12 H, ^3J = 7.3 Hz, CH_2CH_3), 1.45 (m, 8 H, ^3J = 7.3 Hz, $CH_2CH_2CH_3$), 1.61 (m, 8 H, $CH_2CH_2CH_2$), 3.15 (m, 8 H, NCH_2CH_2), 5.73 (m, 7 H, C_7H_7). − $^{11}B\{^1H\}$ NMR (CD_2Cl_2): δ = −9.2 (s, B12), −14.4 (s, B2−6 and B7−11). − $^{13}C\{^1H\}$ NMR (CD_2Cl_2): δ = 13.8 (CH_2CH_3), 20.1 ($CH_2CH_2CH_3$), 24.3 ($CH_2CH_2CH_2$), 59.3 (NCH_2CH_2), 93.4 (C_7H_7), 215.1 (M−CO). − ^{119}Sn NMR (CD_2Cl_2): δ = −257.2. − $C_{25}H_{54}B_{11}MoNO_2Sn$ (735.3): calcd. C 40.89, H 7.41, N 1.91; found C 39.58, H 7.45, N 1.78.

X-ray Crystallographic Study of 3: $C_{25}H_{54}B_{11}MoNO_2Sn$; formula mass 734.27 g/mol; orthorhombic, space group *Pnma* (no. 62); a = 28.941(3), b = 10.684(4), c = 11.703(3) Å, V = 3619(2) Å^3, Z = 4, $d_{calcd.}$ = 1.348 g cm^{-3}, $\mu_{lin.}$ = 1.05 mm^{-1}. Enraf−Nonius CAD4 diffractometer; Mo-K_α radiation (λ = 0.71073 Å); graphite monochromator. Data collection at 293 K on a crystal of dimensions ca. 0.3 × 0.3 × 0.2 mm using ω-2θ scans in the diffraction range 3° < θ < 25° resulted in 13384 reflections. The data were corrected for Lorentz and polarization effects, and an empirical absorption correction based on azimuthal scans[9] was applied. After merging symmetry equivalent data, 3133 unique reflections remained for structure solution by direct methods.[12] The structure model was completed by Fourier difference synthesis: the cation was found to be disordered with respect to the crystallographic mirror plane. Tentative refinements in the noncentrosymmetric subgroup did not give satisfactory results and no Bijvoet differences could be detected, even though this subgroup should exhibit polarity. Least-squares refinement on structure factors[10] was performed with anisotropic displacement parameters for all nonhydrogen atoms except for the nitrogen atom in the cation close to the symmetry element. Hydrogen atoms were placed in calculated positions (C−H = 0.98 Å; B−H = 1.05 Å). Convergence was obtained for 266 variables, 2513 observed data with $I > 1.0\ \sigma(I)$ and R = 0.055, R_w = 0.055, GoF = 1.225. A final difference Fourier map showed fluctuations of less than 0.9 eÅ^{-3} close (0.8 Å) to B9.[11]

$[NBu_4][CpNi(PPh_3)SnB_{11}H_{11}]$ (4): A solution of 383 mg (421.6 g/mol, 0.91 mmol) of $CpNi(PPh_3)Cl$ in 10 mL CH_2Cl_2 was added at room temperature to a solution of 666 mg (733.8 g/mol, 0.91 mmol) of $[NBu_4]_2[SnB_{11}H_{11}]$ in 20 mL CH_2Cl_2. The reaction mixture was stirred for 30 min and then the solvent was evaporated in vacuo. The brown waxy residue was stirred in 80 mL H_2O. After filtration, the collected solid was dried and then recrystallized from 20 mL CH_2Cl_2 by slow diffusion of hexane at +8°C to give 574 mg (72% yield) of **4** as small golden-brown crystals. − $^1H\{^{11}B\}$ NMR (CD_2Cl_2): δ = 0.98 (t, 12 H, ^3J = 7.3 Hz, CH_2CH_3), 1.41 (m, 8 H, ^3J = 7.3 Hz, $CH_2CH_2CH_3$), 1.62 (m, 8 H, $CH_2CH_2CH_2$), 3.22 (m, 8 H, NCH_2CH_2), 5.32 (m, 5 H, C_5H_5), 7.50 (m, 5 H, C_6H_5). − $^{11}B\{^1H\}$ NMR (CD_2Cl_2): δ = −10.7 (s, B12), −15.2 (s, B2−6 and B7−11). − $^{13}C\{^1H\}$ NMR (CD_2Cl_2): δ = 14.0 (CH_2CH_3), 20.1 ($CH_2CH_2CH_3$), 24.3 ($CH_2CH_2CH_2$), 59.3 (NCH_2CH_2), 92.3 (C_5H_5), 128.7 (C_{meta}, C_{para}), 130.8 (C_{ortho}), δ = 134.2 (P−C). − ^{31}P NMR (CD_2Cl_2): δ = 42.3 (s, PPh_3). − $C_{40}H_{69}B_{11}Cl_2NNiPSn$ (877.3 + CH_2Cl_2): calcd. C 49.93, H 7.23, N 1.46, found C 48.55, H 7.26, N 1.35.

X-ray Crystallographic Study of 4: $C_{40}H_{69}B_{11}Cl_2NNiPSn$; formula mass 877.3 g/mol + CH_2Cl_2; monoclinic space group $P2_1/c$ (no. 14); a = 16.192(6), b = 15.000(8), c = 19.689(9) Å, α = 96.21(3)°, V = 4754(4) Å^3, Z = 4, $d_{calcd.}$ = 1.344 g cm^{-3}, $\mu_{lin.}$ = 1.10 mm^{-1}. Siemens/Stoe AED2 diffractometer; Mo-K_α radiation (λ = 0.71073 Å); graphite monochromator; data collection at 200(2) K on a single crystal of dimensions 0.2 × 0.3 × 0.6 mm, 1.5° ≤ θ ≤ 25°; 8106 independent reflections measured, 6634 "observed" [$I > 2\ \sigma(I)$]; Lorentz and polarization factors; structure solution by direct methods and difference Fourier synthesis,[13] F^2 refinement; anisotropic parameters for nonhydrogen atoms, CH_2Cl_2 disordered, hydrogen atoms placed in calculated positions (C−H = 0.98 Å; B−H = 1.12 Å). Convergence was obtained for 516 variables with wR_2 = 0.057, R_1 = 0.028, GoF = 1.031. Max./min residual density +1.12/−0.52 eÅ^{-3}.[14]

Chemistry of 2*H*-Azaphosphirene Complexes, 16[+]

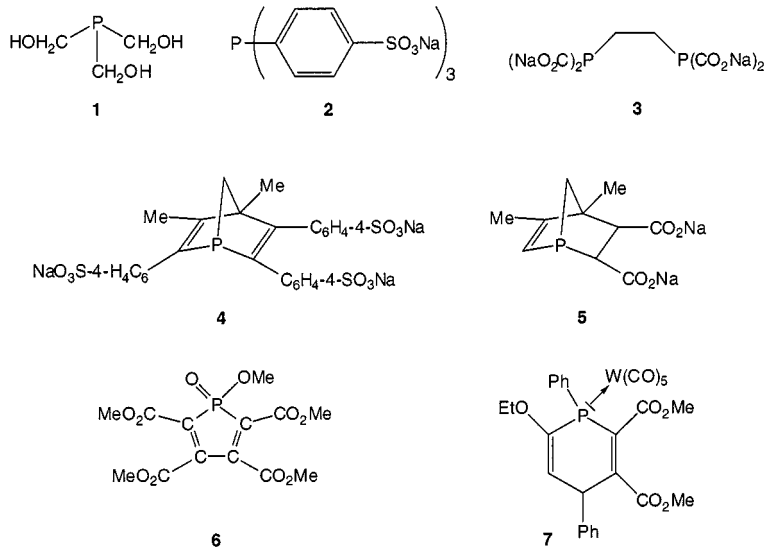
Syntheses, Structures, and Reactions of *C*-Methoxycarbonyl-Functionalized Small- and Medium-Sized P-Heterocycle Complexes

Rainer Streubel,*[a] Hendrik Wilkens,[a] Udo Rohde,[a] Annette Ostrowski,[a] Jörg Jeske,[a] Frank Ruthe,[a] and Peter G. Jones[a]

Dedicated to Professor Reinhard Schmutzler on the occasion of his 65th birthday

Keywords: Phosphorus heterocycles / 2*H*-Azaphosphirene complexes / Water-soluble P ligands / Tungsten / Cyclizations

Thermal ring-opening of [{2-bis(trimethylsilyl)methyl-3-phenyl-2*H*-azaphosphirene-κ*P*}pentacarbonyltungsten(0)] (**8a**) in the presence of dimethyl acetylenedicarboxylate (DMAD) led to the 2,3-bifunctionalized 1*H*-phosphirene complex **9a** and the 4-phenyl-substituted 2*H*-1,2-azaphosphole complex **10a**, the latter as a by-product. If a small amount of benzonitrile was added, complex **10a** was obtained as the main product, along with a small amount of the decomplexed 2*H*-1,2-azaphosphole **11**, which could not be isolated. Reaction of complex **10a** with elemental sulfur furnished the corresponding P^V sulfide **13**. When the ring-opening of complex **8a** was performed in the presence of two equivalents of DMAD and two equivalents of dimethyl cyanamide, we obtained the 4-dimethylamino-substituted 2*H*-1,2-azaphosphole complex **10b**, together with the diastereomeric Δ^3-1,3,2-oxazaphospholene complexes **14a**,**b**. On reaction of [{2-pentamethylcyclopentadienyl-3-phenyl-2*H*-azaphosphirene-κ*P*}pentacarbonyltungsten(0)] (**8b**) and DMAD in toluene, the corresponding 1*H*-phosphirene complex **9b** was only formed as a transient species and the *P*-coordinated P,C-cage compound **15** was the final product. Using benzonitrile as solvent, the 4-phenyl-substituted 2*H*-1,2-azaphosphole complex **10c** was obtained, together with the 7-aza-1-phosphanorbornadiene complex **16**, the latter through partial decomposition of **10c** coupled with rearrangement and a Diels–Alder reaction; the ratio **10c/16** was found to depend strongly on the molar ratio of complex **8b** to DMAD. A cycloaddition reaction of the 2,3-bifunctionalized 1*H*-phosphirene complex **9a** with 2,3-dimethylbutadiene furnished the bicyclic phosphirane complex **19**, along with a small amount of the noncoordinated bicyclic phosphirane **20**. Reaction of complex **9a** with diethylamine yielded the phosphirane complex **21** as a 1,2-addition product, the diorganophosphane complex **22** through ring-opening of **9a**, and the 3,4-functionalized 1,2-dihydro-1-phosphet-2-one complex **23** through an unprecedented ring-expansion reaction; the products **21**, **22**, **23** were formed in a ratio of ca. 1:1:1. The structures of the 1*H*-phosphirene complex **9a**, the 4-dimethylamino-substituted 2*H*-1,2-azaphosphole complex **10b**, the bicyclic phosphirane complex **19**, the phosphirane complex **21**, and the 1,2-dihydro-1-phosphet-2-one complex **23** have been determined by single-crystal X-ray diffraction analysis.



Introduction

The success of biphasic homogeneous catalytic reactions currently being achieved[2] using transition metals with triorganophosphane ligands has led to a great demand for ligands with enhanced water solubility.[3] Various concepts have been developed to satisfy this prerequisite, e.g. phosphanes bearing hydroxy-functionalized organic substituents such as the well-known tris(hydroxymethyl)phosphane **1**,[4] phosphanes bearing sodium *p*-phenylsulfonate groups as in triphenylphosphane trisodium sulfonate (TPPTS) **2**,[5] or sodium carboxylate groups as in **3**.[6] Moreover, water-soluble derivatives of P-heterocycles such as the 1-phosphanorbornadiene NORBOS **4**[7] have been successfully employed in catalytic processes, while others, such as the 1-phosphanorbornene **5**, seem likely to follow suit.[8] Apart from a very recent report on the catalytic use of complexes with polycyclic phosphane ligands having a phosphirane subunit,[9] knowledge of applications of small- and medium-sized P-heterocycle complexes as catalysts is still very limited. Equally apparent is the fact that unsaturated P^{III} heterocycles of different ring size with one or more *C*-methoxycarbonyl groups attached to the ring system are accessible only with difficulty,[10] although such systems are promising precursors for the respective carboxylic acid derivatives. This is in contrast to the situation for P^V phospholes such as **6**, which is accessible by reaction of trimethyl phosphite with dimethyl acetylenedicarboxylate (DMAD).[11] Unfortunately, the corresponding P^{III} derivative is still unknown. Apart from reactions of triorgano-

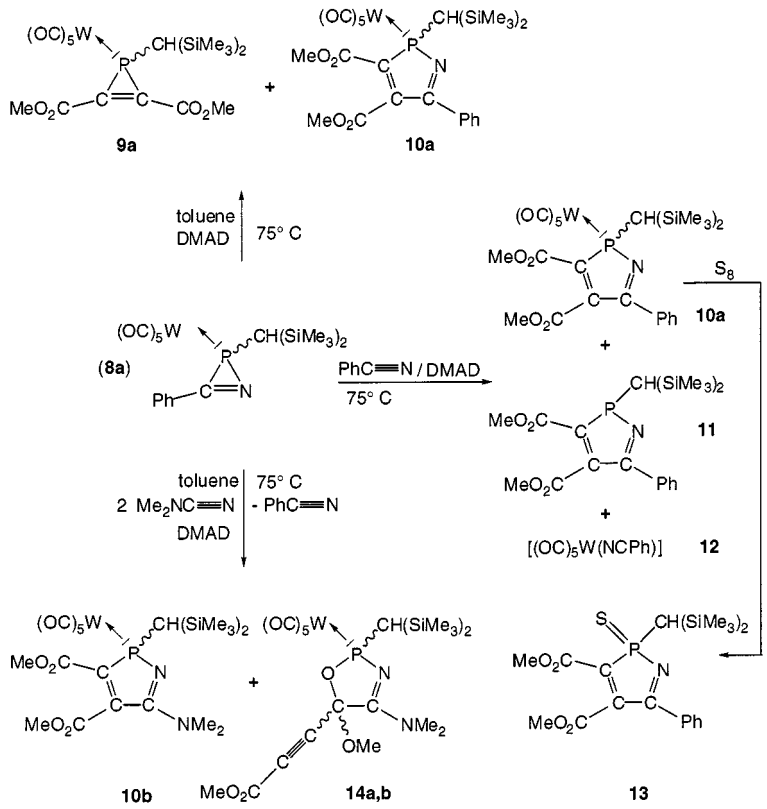
Scheme 1. Water-soluble phosphanes (**1**−**5**) and phosphorus heterocycles bearing methoxycarbonyl groups (**6**,**7**)

phosphanes with DMAD, which are often unselective,[12] some more useful reactions exist, relying on DMAD as trapping reagent and leading, e.g., to complexes such as **7** with six-membered P^{III} heterocyclic ring systems.[13]

In view of the aforementioned factors, and bearing in mind that ring size variations could be a valuable additional instrument for tuning the attributes of the ligands, we decided to seek new routes to small- and medium-sized P-heterocycle complexes having *C*-methoxycarbonyl groups attached to the ring system. These, in turn, could give rise to the uncoordinated P-heterocycles by applying standard decomplexing methodologies.



Recently, we demonstrated that ring-opening reactions of 2*H*-azaphosphirene complexes offer access to a wide variety of small- and medium-sized P-heterocycle complexes.[14−16] We also briefly reported on the syntheses of mono-,[17][18] bi-, and polycyclic P-heterocycles[1] with *C*-methoxycarbonyl-functionalized ring systems, using this methodology with dimethyl acetylenedicarboxylate (DMAD) as the trapping reagent.

In this paper, we show that the general reaction course to such *C*-methoxycarbonyl-functionalized heterocycle complexes depends largely on the solvent employed, and that the formation of the final products depends on the phosphorus substituent. Additionally, preliminary investigations of the reactivity of a 2,3-bifunctionalized 1*H*-phosphirene complex towards 2,3-dimethylbutadiene and diethylamine are presented. The latter reaction demonstrates how initial nucleophilic attack on the 1*H*-phosphirene ring system can give rise to three different reaction pathways, namely 1,2-addition to the C,C-double bond, ring-opening, and ring-expansion. The latter represents the first access to a ring-functionalized 1,2-dihydro-1-phosphet-2-one complex.

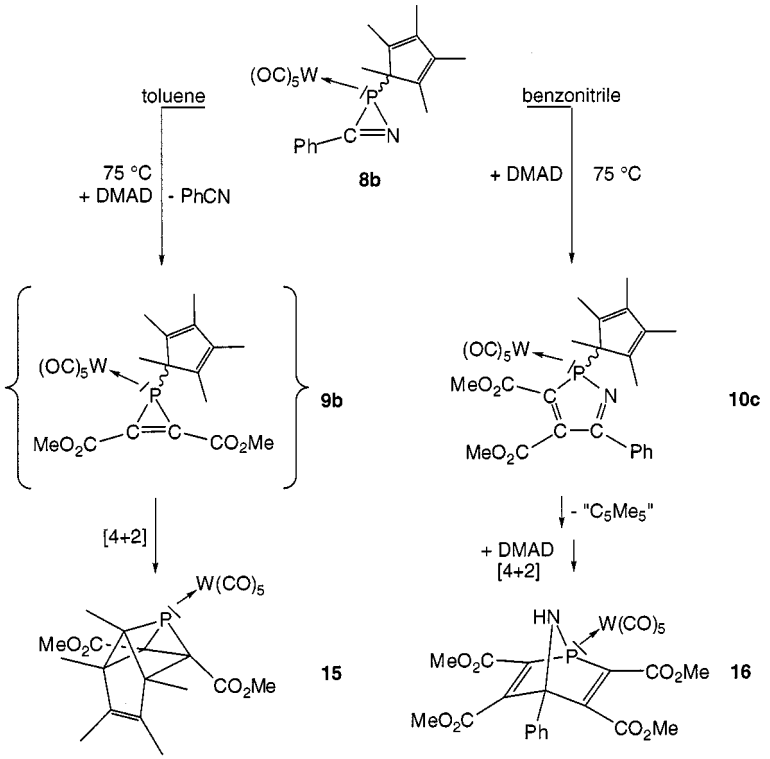
Results

A. Syntheses of *C*-Methoxycarbonyl-Functionalized Mono-, Bi-, and Polycyclic P-Heterocycles by Ring Opening of 2*H*-Azaphosphirene Complexes and Subsequent Trapping Reactions with DMAD

Apart from P^{V} phosphole derivatives such as **6**[11] and related compounds,[12] little is known about five-membered unsaturated P-heterocycles with one or more carboxylate groups bonded to the ring system.[13] Therefore, we became interested in developing a new synthetic methodology leading to such heterocycles. As we have already described in brief, thermally induced ring-opening of the 2*H*-azaphosphirene complex **8a**[19] in toluene and in the presence of DMAD leads to the 1*H*-phosphirene complex **9a** along with minor amounts of the 2*H*-1,2-azaphosphole complex **10a**.[17,18a] The yield of complex **10a** is significantly increased if the reaction is carried out in a mixture of toluene and benzonitrile. Under these reaction conditions, complex **10a** undergoes partial decomplexation leading to the benzonitrile−tungsten complex **12** and two other uncharacterized products exhibiting ^{31}P-NMR resonances at $\delta = 85.5$ and $\delta = 42.1$. Because of the $\Delta\delta$ value of the order of 25,[20] the former resonance would seem to be indicative of the 2*H*-1,2-azaphosphole **11**. Upon heating in benzonitrile with elemental sulfur, complex **10a** reacted selectively to give the 2*H*-1,2-azaphosphole *P*-sulfide **13**. When **8a** was heated in toluene in the presence of DMAD and two equivalents of dimethyl cyanamide, the reaction course was significantly altered; under these conditions the 2*H*-1,2-azaphosphole complex **10b**, along with the two diastereomeric Δ^3-1,3,2-oxazaphospholene complexes **14a**, **b** were formed.[18b] In this case, the transient formation of the nitrilium betaine-type complex

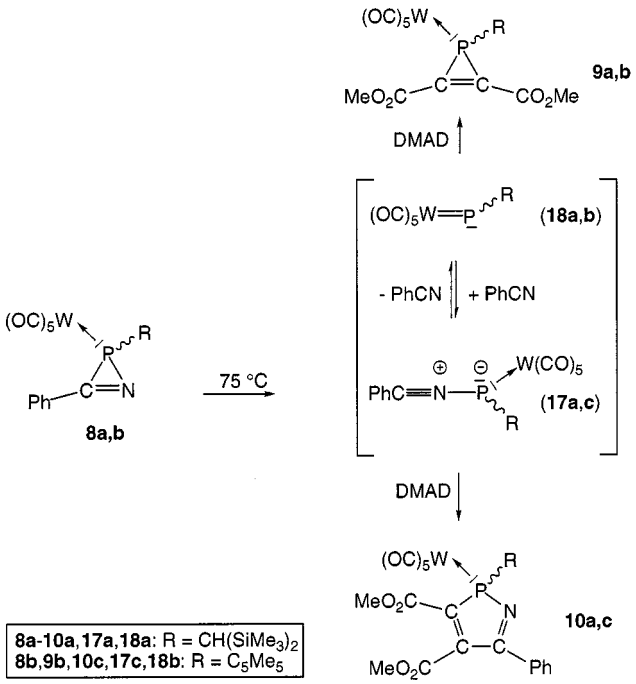
Scheme 2. Thermal ring-opening of 2*H*-azaphosphirene tungsten complex **8a** under various conditions in the presence of DMAD

$\{Me_2NCNP[CH(SiMe_3)_2]W(CO)_5\}$ via transylidation of **17a** seems to be operative (cf. Scheme 4).



That the reaction course depends not only on the solvent, but also on the phosphorus substituent, was impressively demonstrated by investigations of the ring-opening of the 2*H*-azaphosphirene complex **8b**[20] in toluene and benzonitrile, both with DMAD as the trapping reagent (Scheme 3). In the first case, complex **15** was obtained as final product, whereas in the second case, the 7-aza-1-phosphanorbornadiene complex **16** was obtained.[1] The thermal instabilities of the transiently formed 1*H*-phosphirene complex **9b** and the 2*H*-1,2-azaphosphole complex **10c** were quite unexpected. Whereas the existence of the former is merely a plausible assumption, complex **10c** could be obtained using a different stoichiometry.

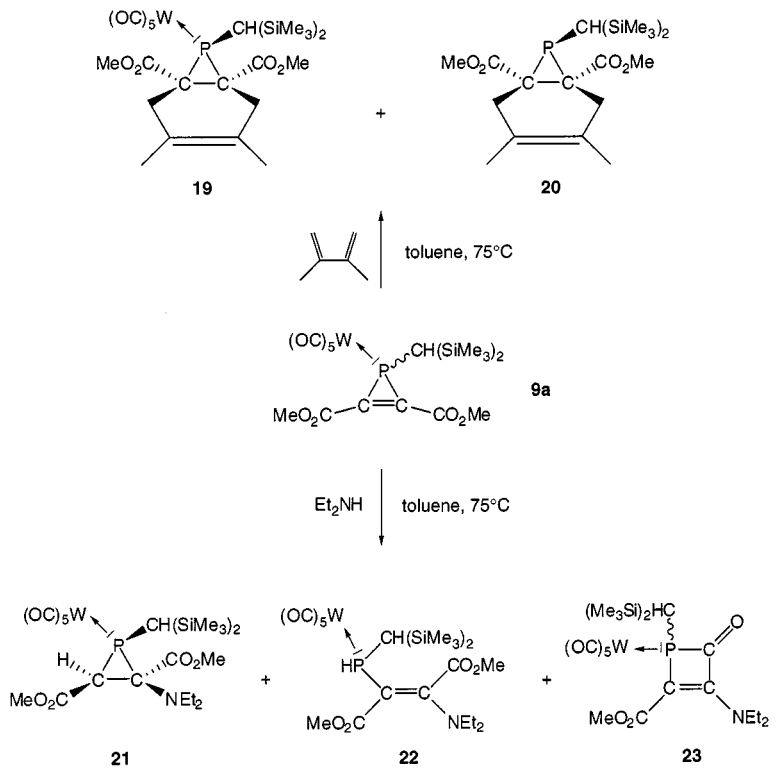
An explanation of these reaction pathways should take into account the roles of $[PhCNP(C_5Me_5)W(CO)_5]$ (**17c**) and the terminal phosphanediyl complex $[(OC)_5WPC_5Me_5]$ (**18b**) as intermediates (cf. Scheme 4). The fate of such intermediates seems to depend mainly on the solvent used for the reactions. The 1*H*-phosphirene complex **9b**, formed by [2+1] cycloaddition of **18b** to DMAD, undergoes rapid intramolecular [4+2] cycloaddition leading to the tungsten-coordinated P,C-cage compound **15**. In benzonitrile, complex **17b** reacts with the C,C π-system of DMAD to form the 2*H*-1,2-azaphosphole complex **10c** through a [3+2] cycloaddition. The next step could be an exocyclic P−C bond cleavage in complex **10c** with subsequent proton addition (the origin of which is still under investigation), to give a short-lived 1*H*-1,2-azaphosphole complex. This could then undergo rapid [4+2] cycloaddition with a second equivalent of DMAD, thereby yielding the 7-aza-1-phosphanorbornadiene complex **16**. Such a hypothesis of the intermediacy of a short-lived 1*H*-1,2-azaphosphole complex is further supported by an earlier observation by Mathey and co-workers that transiently formed 2*H*-phospholes undergo rapid [4+2] cycloaddition reactions leading to 1-phosphanorbornadienes[22] or 1-phosphanorbornenes[23] depending on the trapping reagent used.



The main aspects of the aforementioned ring-opening reactions can be summarized as shown in Scheme 4. In all cases, the first step seems to be the transient formation of nitrilium phosphane−ylide complexes **17a**, **c**, which can decompose to give benzonitrile and the terminal phosphanediyl complexes **18a**, **b**. In toluene, complexes **18a**, **b** undergo subsequent [2+1] cycloaddition reactions to give complexes **9a**,**b**. In benzonitrile, however, reversion to the nitrilium phosphane−ylide complexes **17a**, **c** occurs preferentially, which show a tendency to undergo [3+2] cycloaddition reactions leading to the formation of 2*H*-1,2-azaphosphole complexes **10a**, **c**.

B. Cycloaddition, 1,2-Addition, Ring-Opening, and Ring-Expansion Reactions of *C*,*C*′-Methylcarboxylate-Functionalized 1*H*-Phosphirene Complex 9a

It has been demonstrated by Mathey and co-workers that a monofunctionalized *C*-carboxylate 1*H*-phosphirene com-

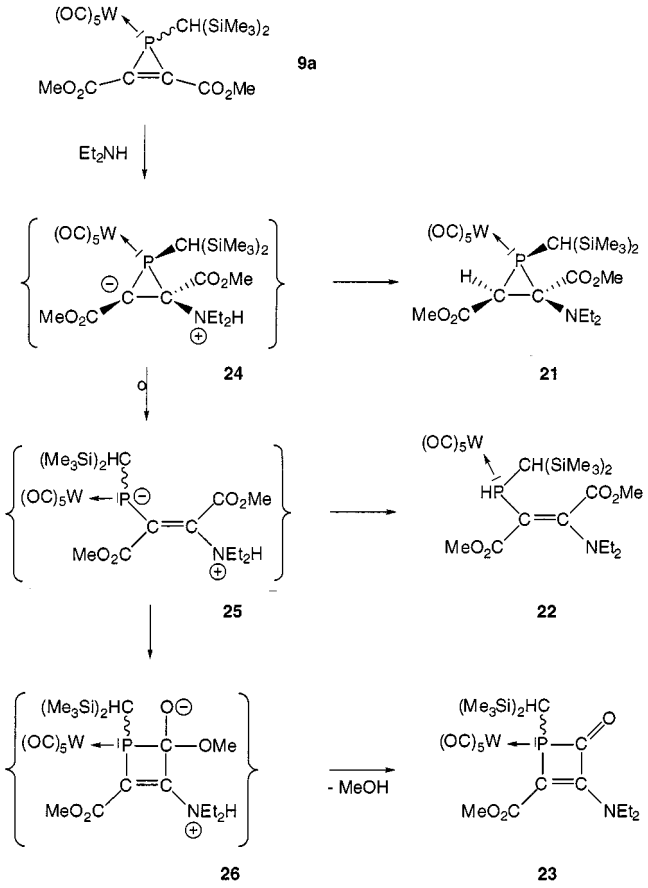


Scheme 3. Thermal ring-opening of 2*H*-azaphosphirene tungsten complex **8b** in various solvents in the presence of DMAD

Scheme 4. Proposed explanation for the generation and reactions of transiently formed nitrilium phosphane−ylide complexes

plex may react either with 1,3-dimethylbutadiene to give a bicyclic phosphirane complex through [4+2] cycloaddition, or with a secondary amine such as morpholine to yield a secondary vinylphosphane complex through ring-opening of the phosphirane ring.[24] These observations prompted us to investigate the reactivity of the bifunctionalized 1*H*-phosphirene complex **9a** towards 1,3-dimethylbutadiene and diethylamine. At 75°C, complex **9a** underwent a diastereoselective reaction with 1,3-dimethylbutadiene to give the [4+2] cycloadduct **19** together with a small amount of the bicyclic phosphirane **20**, the latter probably arising from partial decomplexation of complex **19** (Scheme 5). In both compounds, the six-membered ring moiety and the bis(trimethylsilyl)methyl substituent reside on the same side of the phosphirane ring plane, implying that the cycloaddition reaction is sterically controlled. In contrast to this relatively unsurprising reaction, the outcome of the reaction of complex **9a** with diethylamine at ambient temperature was unexpected: three phosphorus-containing products in a ratio of ca. 1:1:1 were formed, namely the 1,2-addition product **21**, the secondary vinylphosphane complex **22**, and the 1,2-dihydro-1-phosphet-2-one complex **23** (Scheme 5). In comparison to the other example mentioned above (PR = PPh),[24] the greater steric demand of the substituent at phosphorus in this case seems to increase the lifetime of the various intermediates, thus making possible three competing reaction pathways. Although the first 1,2-dihydro-1-phosphet-2-one complex[25] was also obtained by means of an insertion reaction (of carbon monoxide), the present example represents an unprecedented ring-expansion reaction in 1*H*-phosphirene chemistry.[26] A related ring-expansion has been reported for the reaction of a cyclopropene carboxylic acid derivative with $SOCl_2$.[27]

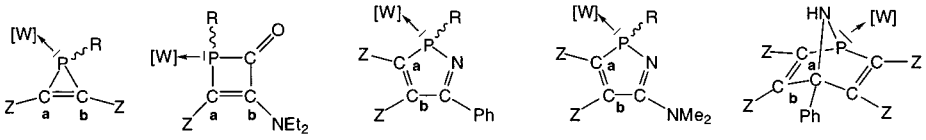
This reaction of complex **9a** can be rationalized by assuming the initial step to be a nucleophilic attack of the diethylamine nitrogen lone-pair on one carbon atom of the 1*H*-phosphirene ring, leading to the zwitterionic phosphir-



Scheme 5. Reactions of 1*H*-phosphirene tungsten complex **9a** with dimethylbutadiene and with diethylamine

ane complex **24**, which can either give rise to the 1,2-addition product **21** or undergo ring-opening to give **25** (Scheme 6). The latter can add a proton to furnish **22** or undergo ring-closure to yield **26** through an intramolecular attack of the phosphorus anion on the methoxycarbonyl carbon atom; the transient complex **26** subsequently eliminates methanol to give the 1,2-dihydro-1-phosphet-2-one complex **23**. The first step of this reaction cascade, i.e. the nucleophilic attack, also proceeds under steric control, leading exclusively to the phosphirane complex **21** with the pentacarbonyltungsten and diethylamino groups in a *trans* arrangement. The stereochemistry of the C−C double bond in **22** has not been determined but is expected to be *trans* (cf. ref.[25]). It should also be noted that no transformation of complex **21** into **22** (and vice versa) via prototropic rearrangement was observed.

C. Discussion of Selected NMR-Spectroscopic Data



All of the reported complexes have been characterized by heteronuclear NMR experiments, IR spectroscopy, and mass spectrometry (see Experimental Section). Selected NMR data of the complexes are collected in Tables 1 and 2 and are discussed here; for X-ray data see Section D, Tables 1−3, and the Experimental Section.

A comparison of selected NMR data of the variously sized heterocycles of complexes **9a**, **10a**, **b**, **16**, and **23** (Table 1) shows, in all cases, significant resonances of the carbon nuclei of the C−C double bond units. Thus, the resonances of the carbons directly bonded to phosphorus appear at

Scheme 6. Proposed reaction course for the formation of complexes **21**−**23**

higher field, while for the vicinal carbon atoms the opposite is true. All of the C_a carbons of **9a**, **10a**, **b**, **16**, and **23** exhibit absolute values of the carbon−phosphorus coupling constants in excess of 17 Hz, which depend specifically on the different scalar couplings (**9a** and **23**: $|^1J + {}^2J|$; **10a**, **b** and **16**: $|^1J + {}^4J|$). According to the ring size, the situation concerning the C_b carbons of **10a**, **b** and **16** is quite different from that in **23**; the former have absolute coupling constant values between 1.1 and 5.3 Hz ($|^2J + {}^3J|$), whereas for the latter the value is 56.2 Hz ($|^2J + {}^2J|$). Because of the approximately constant substitution pattern at phosphorus [with the exception of complex **16**, which has no $CH(SiMe_3)_2$ group] and the only slight variations at the other neighbouring atoms, the influence of the ring size on the phosphorus resonance can be delineated. The fact that the phosphorus nucleus becomes deshielded with increasing ring size has been widely documented for other P-heterocycles with different substitution patterns.[28] The magnitudes of the phosphorus−tungsten coupling constants show a marked dependence on the electronegativities of the phosphorus substituents[29] and, more surprisingly, on the ring size as well.

The 7-aza-1-phosphanorbornadiene complex **16** exhibits a phosphorus resonance δ = 63.0 with a large phosphorus−tungsten coupling constant of 294.8 Hz, indicating that the nitrogen fragment is directly bonded to the phosphorus. Compared to [pentacarbonyl(1,3,4-triphenyl-1,2-dihydro-1-phosphet-2-one)tungsten(0)][25a] [**27**; δ(^{31}P) = 86.9, ^1J(P,W) = 231.9 Hz], complex **23** shows similar ^{31}P-NMR data [δ = 71.7, ^1J(P,W) = 241.2 Hz]. Nevertheless, the π-donation of the diethylamino group is quite apparent throughout the ^{13}C-NMR resonances of the four-membered ring {δ = 119.4, [$^{(1+3)}J$(P,C) = 41.6 Hz, P*C*CO_2Me], 152.9 [$^{(2+2)}J$(P,C) = 56.2 Hz; PC*C*NEt_2]}, although the P*C*O carbon resonance seems to be largely unaffected {δ = 198.7, [$^{(1+3)}J$(P,C) = 35.7 Hz]; cf. **27:** δ = 190.72, [$^{(1+3)}J$(P,C) = 34.2 Hz]}. A comparison of the NMR data of the five-membered heterocycles **10a**, **b** and **13** reveals some noteworthy details. The phosphorus nuclei of **10a**, **b** and **13** exhibit resonances in the range δ = 85.6 to 103, whereas that in **10c** is significantly more deshielded (δ = 119.6). In these 2*H*-1,2-azaphosphole derivatives, the magnitudes of the phosphorus−tungsten coupling constants show a marked dependence on the nature of the substituents at phosphorus and the C^5-carbon; those in **10b** (J = 249.7 Hz) and **10c** (J = 248.1 Hz) are thus considerably greater than that in **10a** (237.9 Hz). Considering further the phosphorus−tungsten coupling constants, the effect of the oxygen atom directly bonded to phosphorus in the diastereoisomeric Δ^3-1,3,2-oxazaphospholene complexes **14a**, **b** is dominant (J = 303.1 and 305.9 Hz). Astonishingly, the imino carbon resonances of **10a**−**c**, **13**, and **14a**, **b** are hardly affected by variations in the bonding situation at the phosphorus atom. A comparison of selected NMR data of the three-membered heterocycle complexes having a mono- or polycyclic ring system (Table 2) shows that the phosphirane complexes **15**, **19**, and **21** exhibit phosphorus resonances in the same region as the 1*H*-phosphirene complex **9a**, which is not unexpected.[30] Complexes **9a**, **19**, and **21** show only slightly different phosphorus−tungsten coupling constants, whereas that of complex **15** is markedly smaller. Moreover, the nuclei of the three-membered ring of **15** are more deshielded. Taken together, the above results point to the dominating effect of the electronegativity of the phos-

phorus substituents (especially with regard to the hybridization of the carbon atoms) on the phosphorus−tungsten coupling constants. In this context, the very small bond angle sums of these complexes are of particular interest (see Section D).

D. Discussion of Selected X-ray Structural Data

The molecular structures of the complexes **9a**, **10b**, **19**, **21**, and **23** were confirmed in the solid state by X-ray crystallography (Figures 1−5); further details of the crystal data and structure refinement are given in Table 3.[31] Comparison of the structure of complex **9a** (Figure 1) with that of other 1*H*-phosphirene complexes[17b] having the same phosphorus fragment, [{$(Me_3Si)_2HCP$}$W(CO)_5$], reveals slightly shortened endo- and exocyclic carbon−carbon and phosphorus−carbon distances and a significantly shortened tungsten−phosphorus distance of 2.4749(11) Å (vs. ca. 2.50 Å)[17b] as the most interesting features. The latter is combined with a widened W−P−C(12) angle of 121.27(24)° (vs. ca. 118−119.5°)[17b] and an increased W−C(5) distance [2.001(5) Å] of the *trans* CO ligand, thus indicating weaker W−C and stronger W−P π-back bonding. The fact that there are no extended P−C distances (bonds) within the *P*-ligand is quite remarkable and is inconsistent with the current π-acceptor orbital bonding model, for which a substantial participation of σ*-orbitals has been proposed.[32][33]

For complex **10b**, the asymmetric unit contains two independent molecules, which are not significantly different from one another. The structure consists of discrete molecules with no unusual intermolecular distances. The heterocyclic ring of complex **10b** (Figure 2) is approximately planar, with the dimethylamino group subtending an interplanar angle to the five-membered ring of 11.4°. Apart

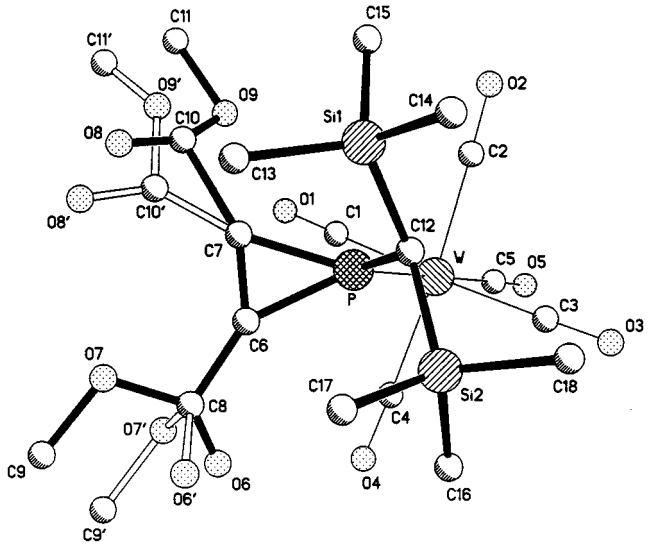

Figure 1. Molecular structure of **9a** in the crystal (both positions of the two disordered methoxycarbonyl groups are shown; hydrogen atoms are omitted for clarity); selected bond lengths [Å] and angles [°]: W−C(5) 2.001(5), W−C(4) 2.054(6), W−P 2.4749(11), P−C(12) 1.808(4), P−C(6) 1.791(5), P−C(7) 1.795(5), C(6)−C(7) 1.294(7); W−P−C(12) 121.27(14), C(6)−P−C(7) 42.3(2), C(6)−C(7)−P 68.7(3), C(7)−C(6)−P 69.0(3)

from localized endocyclic nitrogen−carbon and carbon−carbon double-bond lengths of 1.312(5) and 1.338(6) Å, respectively, the ring also has a substantially shortened exocyclic nitrogen−carbon bond length of 1.346(5) Å (cf. ref.[34]). Together with the angle sum of 360° at the N(2) nitrogen atom, this provides evidence for a $p_\pi-p_\pi$ electron interaction of the nitrogen lone-pair and the C−N π-bond. It is also noteworthy that this also affects the W−P distance, which amounts to 2.5237(11) Å in **10b** and 2.505(12) Å in **10a**.[18a]

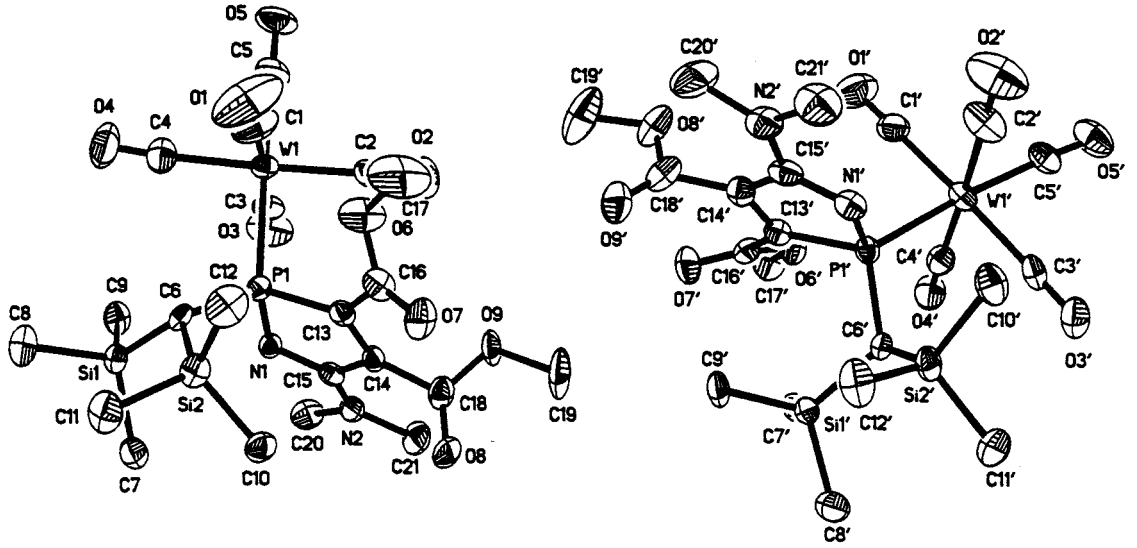

Figure 2. Two independent molecules of **10b** in the crystal (only one data set is given; ellipsoids represent 30% probability levels, hydrogen atoms are omitted for clarity); selected bond lengths [Å] and angles [°]: W(1)−C(5) 1.999(5), W(1)−C(1) 2.019(6), W(1)−C(2) 2.053(5), W(1)−P(1) 2.5237(11), P(1)−C(6) 1.836(4), P(1)−N(1) 1.674(4), N(1)−C(15) 1.312(5), N(2)−C(15) 1.346(5), C(15)−C(14) 1.492(6), C(14)−C(18) 1.338(6), C(13)−P(1) 1.839(4); W(1)−P−C(6) 119.26(14), C(13)−P(1)−N(1) 92.51(19), P(1)−N(1)−C(15) 112.1(3), N(1)−C(15)−C(14) 114.9(4), C(15)−C(14)−C(13) 111.6(4), C(14)−C(13)−P(1) 108.0(3)

Comparison of the structures of complexes **19** and **21** (Figures 3 and 4) with that of **9a** shows that the former have both significantly lengthened endocyclic bond lengths and slightly widened W−P−C(6) angles of 122.62(9) and 124.10(10)°, respectively. Detailed comparison between **19** and **21** cannot be made as the $CH(SiMe_3)_2$ groups adopt opposite orientations with respect to the $W(CO)_5$ fragment, which is very unusual in such P-heterocycle complexes. All three complexes have comparable angle sums [$\Sigma°(P_{PR3})$ values, Table 2] of ca. 264°, but distinctly different W−P distances. This finding most probably stems from different cone angles[35] of these P-ligands; unfortunately, much less data is currently available for such P-heterocycle ligands than for acyclic triorganophosphane ligands.[32][33] Comparing these findings to those for complex **15**,[1] for which a smaller bond angle sum [$\Sigma°(P_{PR3})$ value] and W−P distance were observed [ca. 195° and 2.4569(8) Å], this situation seemingly results from a reduction in the steric strain and an increase in the pyramidalization of the PR_3 ligand, as shown by the increasing distance of the phosphorus atom from the plane defined by the α-atoms of the three substituents (cf. Tables 2 and 3).[32][33] The latter aspect in particular merits further study. Although complexes **15**, **19**, **21** (and even **9a**) are quite similar, it is noteworthy that there is no simple correlation between X-ray structural parameters such as the $\Sigma°(P_{PR3})$ value and the W−P distance on one hand, and an NMR parameter such as the magnitude of the phosphorus−tungsten coupling constant on the other (cf. Table 2).

The molecular structure of the 1,2-dihydro-1-phosphet-2-one complex **23** (Figure 5) is characterized by an unsymmetrical, planar, four-membered ring system. Compared to the structure of complex **27**,[25a] the carbon−carbon bond length of the double bond unit is longer in **23** [1.399(5) vs. 1.36(1) Å (**27**)]. Moreover, it forms part of a

Experimental Section

General Procedures: All reactions and manipulations were carried out under an atmosphere of deoxygenated dry nitrogen, using standard Schlenk techniques with conventional glassware. Solvents were dried according to standard procedures. − NMR spectra were recorded on a Bruker AC-200 spectrometer (200 MHz for ^{1}H; 50.3 MHz for ^{13}C; 81.0 MHz for ^{31}P) with [D]chloroform and [D_6]benzene as solvents and internal standards; shifts are given relative to ext. tetramethylsilane (^{1}H, ^{13}C) and 85% H_3PO_4 (^{31}P). − Mass spectra were recorded on a Finnigan MAT 8430 (70 eV); apart from the *m*/*z* values of the molecular ions, only those peaks having intensities > 20% of the base-peak are listed. − Infrared spectra were recorded on a Biorad FT-IR 165 spectrometer (selected data given). − Melting points were measured on a Büchi 535 capillary apparatus. − Elemental analyses were performed using a Carlo Erba analytical gas chromatograph. − The κ*P* notation in the nomenclature is intended to differentiate between *P*- and *N*-coordination of the relevant heterocycle to the metal.

Pentacarbonyl[2-bis(trimethylsilyl)methyl-3,4-bis(methoxycarbonyl)-5-phenyl-2*H*-1,2-azaphosphole-κ*P*]tungsten(0) (10a): To a solution of the 2*H*-azaphosphirene tungsten complex **8a** (1.5 g, 2.4 mmol) in toluene (7.5 mL) and benzonitrile (2 mL) was added dimethyl acetylenedicarboxylate (0.6 mL, 5 mmol) and the mixture was heated at 75°C for 1.5 h under slow stirring. The solvent was then removed in vacuo and the product was separated by low-temperature column chromatography (SiO_2, −20°C, 10 × 4 cm, hexane/diethyl ether, 90:10). Evaporation of the solvent from the second fraction yielded **10a** as dark-red crystals. Data Collection, Structure Solution, and Refinement of 9a, 10b, 19, 21, and 23: Crystal data for all the structures are presented in Table 3. Structure determination of **9a**, **10b**, and **19**: A yellow prism (**9a**), a yellow tablet (**10b**), or a pale-yellow block (**19**) was mounted in inert oil and measured by ω-scans using Mo-K_α radiation (graphite monochromator) on a Siemens P4 diffractometer. After an absorption correction (ψ-scans), all unique data were used for the calculations (**9a**, **19**: program SHELXL-93;[37] **10b**: program SHELXL-97[38]). The structures were solved by direct methods (**9a**, **10b**) or the heavy-atom method (**19**) and refined anisotropically by full-matrix least-squares on F^2. All hydrogen atoms (except rigid methyl groups) were refined as a riding model. Structure determination of **21** and **23**: A colourless tablet (**21**) or an orange tablet (**23**) was mounted in inert oil and measured by ω/θ-scans using Mo-K_α radiation (graphite monochromator) on a Stoe STADI-4 diffractometer. Structure solution: heavy-atom method. Other details were as for **10b** above.

Acknowledgments

Support by the Deutsche Forschungsgemeinschaft and the Fonds der Chemischen Industrie, and MS measurements by Dr. Hans-Martin Schiebel (Technische Universität Braunschweig) are gratefully acknowledged.

Diversity in Complexation of $[Rh^I(cod)]^+$ and $[Ir^I(cod)]^+$ by Pyridine-Amine-Pyrrole Ligands

Bas de Bruin,[a] Reinout J. N. A. M. Kicken,[a] Nicolaas F. A. Suos,[a] Maurice P. J. Donners,[a] Carolien J. den Reijer,[a] Albertus J. Sandee,[a] René de Gelder,[a] Jan M. M. Smits,[a] Anton W. Gal,*[a] and Anton L. Spek[b]

Keywords: Rhodium / Iridium / N ligands / Coordination modes / Polymerizations

Complexation of $[Rh^I(cod)]^+$ and $[Ir^I(cod)]^+$ by the new pyridine-amine-pyrrole ligands Py–CH_2–N(R)–CH_2–Pyr–H (HL_R; R = H, Bzl, Bu) and the corresponding pyridine-amine-pyrrolate ligands $[Py–CH_2–N(R)–CH_2–Pyr]^-$ (L_R^-; R = H, Bzl, Bu, CH_2Py) has been investigated. The neutral ligands HL_R (R = H, Bu, Bzl) give $[(HL_R)M^I(cod)]^+$ (M = Rh, Ir) in which HL_R acts as a didentate ligand via the pyridine nitrogen (N_{Py}) and the amine nitrogen (N^R_{amine}). The crystal structures of $[(HL_H)M^I(cod)]PF_6$ (M = Rh: **[1]**PF_6 and M = Ir: **[2]**PF_6) have been determined. Deprotonation of $[(HL_R)M^I(cod)]^+$ (M = Rh, Ir; R = H, Bzl, Bu) results in the neutral complexes $[(L_R)M^I(cod)]$ (M = Rh, Ir) of the mono-anionic ligands L_R^- (R = H, Bzl, Bu). In square-planar $[(L_H)M^I(cod)]$ (M = Rh: **3**, M = Ir: **4**), L_H^- is didentate via N^H_{amine} and the pyrrolate nitrogen (N_{Pyr}). The X-ray structures of **3** and **4** reveal that in both cases the uncoordinated N_{Py} accepts a hydrogen bond from N^H_{amine}. The X-ray structures of $[(L_{Bzl})M^I(cod)]$ (M = Rh: **5**, M = Ir: **6**), show that L_{Bzl}^- is didentate via N_{amine} and N_{Pyr} for M = Rh and tridentate for M = Ir. In solution L_{Bzl}^- is tridentate for both M = Rh and M = Ir. The neutral complexes $[\{Py–CH_2–N(R)–CH_2–Pyr\}M^I(cod)]$ (M = Rh, Ir) cannot be oxidised selectively with H_2O_2. This is in marked contrast to the previously observed selective oxidation of the corresponding cationic complexes $[\{Py–CH_2–N(R)–CH_2–Py\}Rh^I(cod)]^+$. Rhodium complex **5** is an active catalyst for the stereoregular polymerisation of phenylacetylene, whereas iridium complex **6** is inactive.

Introduction

Multidentate N-donor ligands ("N_x" ligands) have thusfar found limited application in the organometallic chemistry of rhodium(I) and iridium(I). Interesting reactivity has, however, been reported for triazacyclononane,[1][2] trispyrazolylborate,[2] and pyridine-2,6-diimine[3] complexes. We recently described the fast and selective mono-oxygenation of $[Rh^I(cod)]^+$ to $[Rh^{III}(oxabicyclononadiyl)]^+$ with aqueous hydrogen peroxide.[4] In this reaction $[Rh^I(cod)]^+$ is stabilised by the neutral tridentate pyridine-amine-pyridine ligands Py−CH_2−N(R)−CH_2−Py (R = H, Bu, Bzl). As part of our investigation into the tolerance of the observed oxygenation to changes in the nitrogen donor ligands, we have prepared and characterised a series of neutral complexes $[\{Py−CH_2−N(R)−CH_2−Pyr\}M^I(cod)]$ (M = Rh, Ir). In these, $[M^I(cod)]^+$ is stabilised by the potentially tridentate pyridine-amine-pyrrolate ligands $[Py−CH_2−N(R)−CH_2−Pyr]^-$ ($[L_R]^-$; R = H, Bzl, Bu). The complexes were obtained by deprotonation of the cationic complexes $[\{Py−CH_2−N(R)−CH_2−Pyr−H\}M^I(cod)]^+$ which result from reaction of $[\{(cod)M^I(\mu\text{-}Cl)\}_2]$ (M = Rh, Ir) with the neutral didentate ligands Py−CH_2−N(R)−CH_2−Pyr−H (HL_R;R = H, Bu, Bzl).

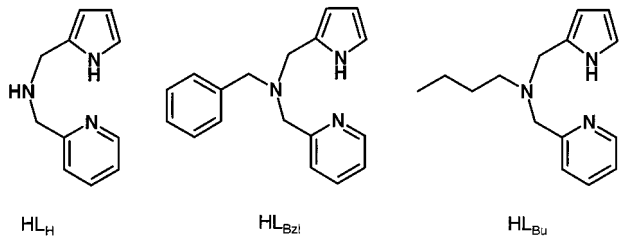
Results and Discussion

Synthesis of the Ligands HL_R

The neutral ligands HL_R (R = H, Bzl, Bu; see Figure 1) were prepared via the synthesis routes shown in Scheme 1.



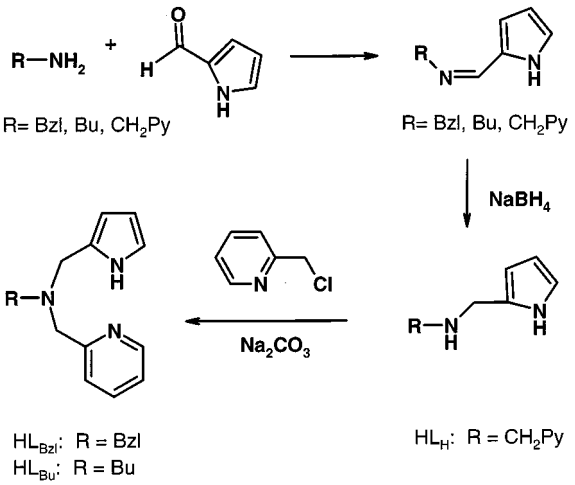


Figure 1. Pyridine-amine-pyrrole ligands HL_H, HL_{Bzl}, and HL_{Bu}

N-(2-pyridylmethyl)-*N*-(1*H*-2-pyrrolylmethyl)amine (HL_H) was prepared in two steps: condensation of 2-pyridylmethylamine and pyrrole-2-carboxaldehyde to the corresponding imine and subsequent reduction of the imine with $NaBH_4$. *N*-benzyl-*N*-(2-pyridylmethyl)-*N*-(1*H*-2-pyrrolylmethyl)-amine (HL_{Bzl}) and *N*-butyl-*N*-(2-pyridylmethyl)-*N*-(1*H*-2-pyrrolylmethyl)amine (HL_{Bu}) were prepared in three steps: *N*-benzyl-*N*-(1*H*-2-pyrrolylmethylidene)amine and *N*-butyl-*N*-(2-pyrrolylmethylidene)amine were obtained by condensation of pyrrole-2-carboxaldehyde with benzylamine and *n*-butylamine, respectively. The imines were reduced to the corresponding amines with $NaBH_4$. Alkylation of the amines with 2-picolyl chloride in a suspension of Na_2CO_3 in CH_3CN gave HL_{Bzl} and HL_{Bu}, respectively.

Scheme 1. Synthesis of the ligands HL_H, HL_{Bzl}, and HL_{Bu}

Structure of HL_H

Colourless crystals of compound HL_H were obtained by crystallisation from a hot saturated toluene solution. The structure of HL_H was determined by single-crystal X-ray diffraction (Figure 2).

In the crystal, the enantiomers (*R*) and (*S*) of HL_H occur as hydrogen-bridged dimers (*R*,*R*) and (*S*,*S*) in which the pyrrole N−H (N_{Pyr}−H) acts as a hydrogen bond donor, and the amine nitrogen (N_{amine}) as a hydrogen bond acceptor [N_{Pyr}−N_{amine} distance: 3.02(1) Å, H−N_{amine} distance: 2.09(6) Å, N_{Pyr}−H−N_{amine} angle: 169(4)°]. Selected bond lengths and angles are given in Tables 1 and 2. Crystallographic data are given in Table 4.

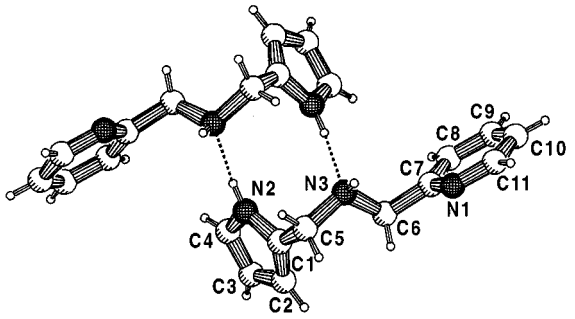

Figure 2. X-ray structure of ligand HL_H [the crystal contains the dimers (*R*,*R*) and (*S*,*S*) of the enantiomers (*R*) and (*S*); only (*R*,*R*) is shown]

Complexation of $[Rh^I(cod)]^+$ and $[Ir^I(cod)]^+$ by HL_H

Reaction of HL_H with $[\{(cod)Rh(\mu\text{-}Cl)\}_2]$ in methanol, followed by addition of an excess of NH_4PF_6, resulted in precipitation of $[(HL_H)Rh^I(cod)]PF_6$, [**1**]PF_6. Crystals of [**1**]PF_6 were obtained by cooling of a hot saturated solution of [**1**]PF_6 in methanol. The analogous reaction of HL_H with $[\{(cod)Ir(\mu\text{-}Cl)\}_2]$ in $MeOH/CH_2Cl_2$, followed by addition of excess KPF_6, led to precipitation of [**2**]PF_6. Crystals of [**2**]PF_6, were obtained by cooling of a saturated solution of [**2**]PF_6 in $MeOH/H_2O$ to 5 °C. The structures of [**1**]PF_6 and [**2**]PF_6 were determined by X-ray diffraction. The X-ray structure of $\mathbf{1}^+$ is shown in Figure 3. $\mathbf{2}^+$ was found to be isostructural. Selected bond lengths and angles for $\mathbf{1}^+$ and $\mathbf{2}^+$ are given in Tables 1 and 2.

Complexes $\mathbf{1}^+$ and $\mathbf{2}^+$ have the expected square-planar geometry. The ligand HL_H is didentate via the pyridine (N_{Py}) and amine (N_{amine}) nitrogens. No interaction is observed between the metal centre and the pyrrole N−H bond (N_{Pyr}−H). In both structures, the N_{Pyr}−H and N^H_{amine} protons are hydrogen bonded to two different PF_6^- counterions ($\mathbf{1}^+$: N_{amine}−F6 distance: 3.165(6) Å, H30−F6 distance: 2.33(7) Å, N_{amine}−H30−F6 angle: 173(6)°, N_{Pyr}−F3 distance: 3.118(6) Å, H20−F3 distance: 2.57(6) Å, N_{Pyr}−H20−F3 angle: 141(6)°; $\mathbf{2}^+$: N_{amine}−F6 distance: 3.098(7) Å, H30−F6 distance: 2.33(7) Å, N_{amine}−H30−F6 angle: 159(6)°, N_{Pyr}−F3 distance: 3.133(7) Å, H20−F3 distance: 2.54(7) Å, N_{Pyr}−H20−F3 angle: 152(8)°). In $[\mathbf{1}]^+$ the Rh−N_{Py} distance [Rh1−N1: 2.101(4) Å] and the Rh−N_{amine} distance [Rh1−N3: 2.144(4) Å] fall within the ranges of Rh−N_{sp2} (2.007−2.140 Å)[5] and Rh−N_{sp3} (2.111−2.178 Å)[5f,6] distances observed for other square planar "N_2"Rh^I(cod) complexes. The observed Rh−C and cod double bond lengths are also normal for "N_2"Rh^I(cod) complexes (Table 1).

The NMR data for [**1**]PF_6 and [**2**]PF_6 in [D_6]acetone are very similar, and are in accordance with their X-ray structure. The largest shift difference between $\mathbf{1}^+$ and $\mathbf{2}^+$ is observed for the *olefinic* cod fragment $(-CH=CH-)_{cod}$ (see Table 3). In the ^{1}H-NMR spectrum of [**1**]PF_6 the pyrrole signals appear at almost the same position as for the free HL_H, whereas the N^H_{amine} proton has shifted 2.75 ppm downfield (HL_H: δ = 2.24, [**1**]PF_6: δ = 4.99). The pyridine-H^6 signal has shifted 0.53 ppm upfield (HL_H: δ = 8.49, [**1**]PF_6: δ = 7.96) as a result of anisotropic shielding by η^4-cod. The N−CH_2−Pyr− and N−CH_2−Py signals appear as singlets at room temp. due to rapid dissociation, pyramidal inversion, and recoordination of N^H_{amine}. Combination of this inversion with rapid rotation of the η^4-cod fragment results in only one signal each for the vinylic, the allylic *exo* and the allyllic *endo* protons of cod. At −80 °C the pyramidal inversion at N_{amine} and rotation of cod are both frozen out. This results in two AB-type doublets for both N−CH_2−Pyr and N−CH_2−Py, each with an additional coupling to the N^H_{amine} proton. At this temperature each cod proton appears as a separate signal, with the exception of two overlapping allylic *exo* protons and two sets of two overlapping allylic *endo* protons.

Complexation of $[Rh^I(cod)]^+$ and $[Ir^I(cod)]^+$ by L_H^-

Reaction of HL_H with $[\{(cod)M^I(\mu\text{-}Cl)\}_2]$ (M = Rh, Ir) in methanol resulted in a solution of $[(HL_H)M^I(cod)]Cl$ M = Rh, Ir). The neutral complexes $[(L_H)M(cod)]$ (M = Rh: **3**; M = Ir: **4**) precipitated upon deprotonation of the uncoordinated pyrrole nitrogen (N_{Pyr}−H) by excess aqueous Na_2CO_3. Cooling of a saturated solution of rhodium

[a] For atom labelling see Figure 2−6. Superscripts A and B refer to crystallographically independent molecules.

complex **3** in toluene resulted in crystals suitable for single-crystal X-ray diffraction. The analogous procedure for iridium complex **4** gave micro-crystalline material with a PXRD-pattern different from that of crystalline **3**. Single crystals of **4**, suitable for X-ray diffraction, could not be obtained from toluene. However X-ray quality crystals of $\mathbf{4} \cdot 1/2\ CH_2Cl_2$ were obtained by cooling a saturated solution in CH_2Cl_2. In the crystal of $\mathbf{4} \cdot 1/2\ CH_2Cl_2$, two independent iridium complexes $\mathbf{4^A}$ and $\mathbf{4^B}$, with geometries slightly different from rhodium complex **3** and from each other, are found in the asymmetric unit. The X-ray structure of **3** is given in Figure 4. Selected bond lengths and angles of **3** and **4** are given in Tables 1 and 2.

Both **3** and **4** have a square planar coordination geometry in which $[L_H]^-$ is didentate via N_{amine} and N_{Pyr}. Thus, deprotonation of $N_{Pyr}-H$ in $[\mathbf{1}]^+$ and $[\mathbf{2}]^+$ to a pyrrolate nitrogen (N_{Pyr}) results in a shift of $[M(cod)]^+$ (M = Rh, Ir) from the $N_{amine}-N_{Py}$ compartment to the $N_{amine}-N_{Pyr}$ compartment (Scheme 2).

In both **3** and $\mathbf{4} \cdot 1/2\ CH_2Cl_2$, N_{Py} accepts an intramolecular hydrogen bond from $N_{amine}-H$ (**3**: $N_{amine}-N_{Py}$ distance: 2.833(4) Å, $H-N_{Py}$ distance: 2.48(4) Å $N_{amine}-H-B_{Py}$ angle 105(3)°; $\mathbf{4^A}$: $N_{amine}-N_{Py}$ distance: 2.815(7) Å, $H-N_{Py}$ distance: 2.43 Å, $N_{amine}-H-N_{Py}$ angle: 104°, $\mathbf{4^B}$: $N_{amine}-N_{Py}$ distance: 2.824(8) Å, $H-N_{Py}$ distance: 2.46 Å, $N_{amine}-H-N_{Py}$ angle: 104°). Whereas in **3** the (*R*) and (*S*) enantiomers occur as monomers, in **4** they dimerise to (*R*,*R*) and (*S*,*S*) via additional intermolecular hydrogen-bonding interactions between $N_{amine}-H$ and N_{Py} (see $\mathbf{4^A}$ and $\mathbf{4^B}$ in Figure 5). [Intermolecular $N_{amine}-N_{Py}$ distances: 3.269(8) Å, 3.216(7) Å; intermolecular $H-N_{Py}$ distances: 2.47 Å, 2.41 Å intermolecular $N_{amine}-H-N_{Py}$ angles: 145°, 145°].

The additional intermolecular hydrogen bonding on going from **3** to **4**, could well reflect that the N^H_{amine} proton of iridium compound **4** is slightly more acidic than the N^H_{amine} proton of rhodium compound **3**, in accordance with its down-field ^{1}H-NMR shift on going from **3** (δ = 4.5) to **4** (δ = 5.3). This might also explain the difference in PXRD-pattern of crystalline **3** and **4** from toluene.

The $M-N_{Pyr}$ distances in **3** and **4** are approx. 0.06 Å shorter than the corresponding $M-N_{Py}$ distances in **[1]**PF_6 and **[2]**PF_6, respectively. This demonstrates the stronger interaction of the anionic pyrrolate nitrogen (N_{Pyr}) with the M^I center. The observed $M-N_{amine}$, $M-C_{olefin}$ and olefinic C−C distances in **3** and **4** are not significantly different from those in **[1]**PF_6 and **[2]**PF_6, respectively. As for $[\mathbf{1}]^+$, the Rh−N, Rh−C and olefinic C−C distances in **3** fall within the normal range for square planar "N_2"Rh^I(cod) complexes.[5][6]

The NMR spectra of **3** and **4** are very similar and correspond well with their solid state structure. As for $[\mathbf{1}]^+$and $[\mathbf{2}]^+$, the largest shift differences between **3** and **4** are observed for $(-CH=CH-)_{cod}$ signals (Table 3). In the ^{1}H-NMR spectrum of rhodium complex **3** at room temp. the pyramidal inversion at N_{amine} is frozen out (AB type signals with additional coupling to the N^H_{amine} proton for $N-CH_2-Py$ and $N-CH_2-Pyr$). Rapid rotation of the η^4-cod fragment results in one signal for the vinylic, two for the allylic *exo* and two for the allylic *endo* protons. The pyridine signals appear at almost the same position as in free HL_H. The N^H_{amine} proton (δ_{NH} = 4.50) has shifted

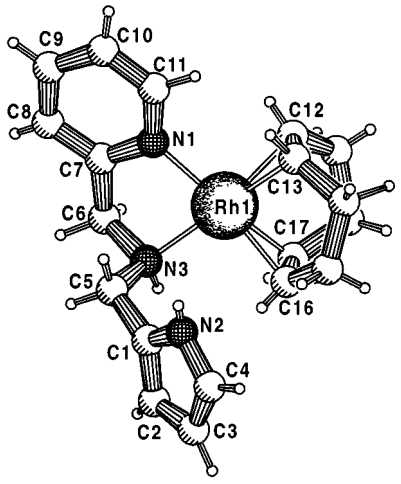

Figure 3. X-ray structure of $[\mathbf{1}]^+$ [only the (*S*) enantiomer is shown]

2.09 ppm downfield from that in the free ligand (δ_{NH} = 2.41). The pyrrole signals have all shifted up-field relative to HL_H. The chemical shift difference is most pronounced for Pyr−H^5 (Pyr−H^5: 0.42 ppm, Pyr−H^4: 0.13 ppm and Pyr−H^3: 0.26 ppm), probably due to anisotropic shielding by the η^4-cod fragment.

Complexation of $[Rh^I(cod)]^+$ and $[Ir^I(cod)]^+$ by $[L_{Bzl}]^-$ and $[L_{Bu}]^-$

Reaction of HL_{Bzl} with $[\{(cod)M^I(\mu\text{-}Cl)\}_2]$ (M = Rh, Ir) in methanol results in a solution of $[(HL_{Bzl})M^I(cod)]Cl$ (M = Rh, Ir). Subsequent addition of an excess of aqueous Na_2CO_3 results in deprotonation of N_{Pyr}−H and precipitation of the neutral complexes $[(L_{Bzl})M^I(cod)]$ (M = Rh: **5**, M = Ir: **6**). $[(L_{Bu})Rh^I(cod)]$, **7**, was obtained analogously. Crystals of **5** and **6** were obtained by cooling of a saturated solution in toluene. Their structures were determined by single-crystal X-ray diffraction (Figure 6). Selected bond lengths and angles are given in Tables 1 and 2.

In the crystal, complex **5** has a square planar geometry with didentate L_{Bzl}^- via N^{Bzl}_{amine} and N_{Pyr}, analogous to L_H^- in **3**. N_{Py} in **5** is not involved in any bonding interaction, whereas N_{Py} in **3** accepts a hydrogen bond from N^H_{amine}. The Rh−N_{Pyr} distances (N2−Rh1) in **5** and **3** are equal within experimental error, but the Rh−N^{Bzl}_{amine} dis-

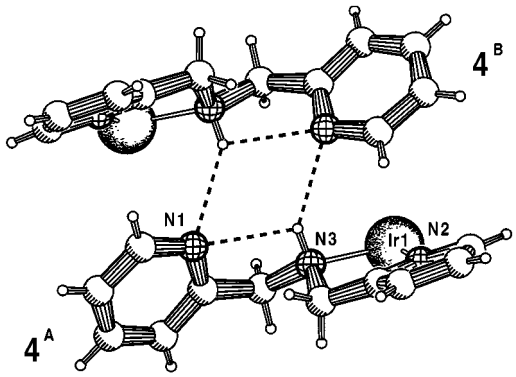

Figure 5. Hydrogen-bonding pattern in the X-ray structure of **4** · 1/2 CH_2Cl_2 [the crystal contains the dimers (*R,R*) and (*S,S*) of the enantiomers (*R*) and (*S*); only *R,R*) is shown]

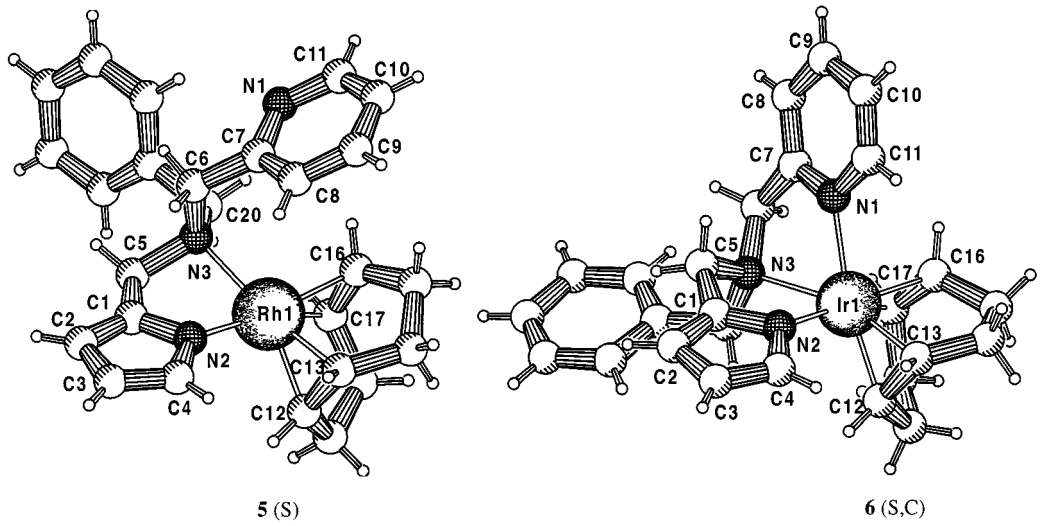
tance in **5** [N3−Rh1 = 2.231(2) Å] is 0.07 Å longer than the Rh−N^H_{amine} distance in **3** [N3−Rh1 = 2.164(3) Å] and longer than Rh−N_{sp3} distances for square-planar "N_2"-ligand Rh^I complexes (2.111−2.178 Å) known so-far.[5][6] In accordance with this, the Rh−C distances *trans* to N^{Bzl}_{amine} in **5** are approx. 0.04 Å shorter than those trans to N_{Pyr}, whereas the corresponding distances in **3** are not significantly different. These effects all seem to indicate a substantial weakening of the Rh−N^R_{amine} interaction upon substitution of H by Bzl.

In contrast to the four-coordinate rhodium complex **5**, iridium complex **6** is five-coordinate. Complex **6** has a pseudo trigonal-pyramidal geometry with tridentate $[L_{Bzl}]^-$ (Figure 6). N_{Pyr} and one double bond of cod occupy the axial positions, whereas N_{Py} and N_{amine} together with the other double bond of cod occupy the equatorial positions.

Complex **6** contains two chiral centres; N^{Bzl}_{amine} and Ir. Nevertheless only the enantiomeric pairs *S,C* and *R,A*, and not their diastereomers *S,A* and *R,C* are observed. Because of the short "arms" of the ligand, the chiral centre on the amine nitrogen dictates the chirality at the iridium centre during complexation. The *S,A* and *R,C* forms are not accessible due to the geometrical constraints in the ligand.

For d^8-metals in a trigonal-bipyramidal geometry, theoretical and experimental results by Rossi and Hoffmann indicate that the strongest σ-donor prefers the axial position and that olefins are more strongly bound in the equatorial plane.[7] The axial position of the strongest σ-donor,



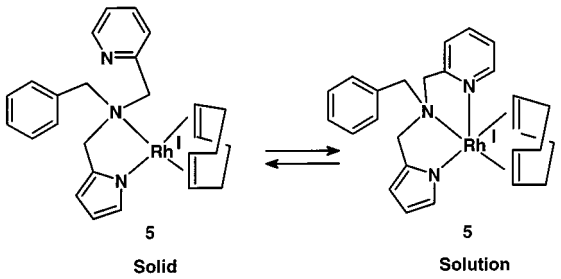


Figure 6. X-ray structures of **5** (*S* enantiomer) and **6** (*S,C* enantiomer), corresponding with enantiomer (*S*) of **3** in Figure 4

N_{Pyr}, at the shortest Ir−N distance (Ir−N2: 2.066 Å) and the shorter Ir−C distances for the equatorial double bond [Ir1−C12: 2.068(8) Å, Ir1−C13: 2.055(8) Å] relative to the axial double bond [Ir1−C16: 2.136(11) Å, Ir1−C17: 2.129(10) Å] are in accordance with theoretical and experimental results by Rossi and Hoffmann. In accordance with its "unfavourable" equatorial position, the $M-N^{Bzl}_{amine}$ distance (M1−N3) in the five-coordinate iridium complex **6** exceeds the $M-N^{Bzl}_{amine}$ distance in four-coordinate rhodium complex **5** by 0.17 Å, whereas the $M-N_{Pyr}$ distance (M−N2) in the "favourable" axial position is not significantly longer than in **5** (Table 1). Interestingly, **5** undergoes $\kappa^2-\kappa^3$ isomerisation on going from the solid state to solution (Scheme 3).

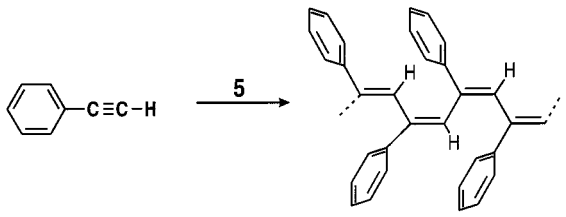
Scheme 3. $\kappa^2-\kappa^3$ isomerism for L_{Bzl}^- in **5**

In the ^{1}H-NMR solution spectrum of **5**, Py-H^6 of L_{Bzl}^- has shifted 0.69 ppm downfield relative to Py-H^6 of free HL_{Bzl} (HL_{Bzl}: δ = 8.56, HL_{Bzl}^- in **5**: δ = 9.25). This is in marked contrast with the situation for **3**, where we observed no significant shifts for Py-H^6 of the uncoordinated pyridine group of L_H^- compared to free HL_H (HL_H: δ = 8.48, L_H^- in **3**: δ = 8.55). Also, the Py-H^6 signal in **5** shows clear NOE contacts (counter phase to diagonal) with Pyr-H^5, and the two vinylic and the two allylic *exo* signals of cod. This shows that the structure of **5** in solution is predominantly five-coordinate. As was the case for $[\mathbf{1}]^+$ and **3**, the ^{1}H-NMR spectrum of **5** shows rapid rotation of the η^4-cod fragment. Two signals are observed for the vinylic protons, one for the allylic *exo* protons, and one for the allylic *endo* protons. At room temperature pyramidal inversion at N^{Bzl}_{amine} is slow on the ^{1}H-NMR time-scale (two AB-type doublets for each, $N-CH_2-Py$, $N-CH_2-Pyr$, and $N-CH_2-Ph$), but fast on the NOESY/EXSY time scale (exchange correlation peaks were observed for the two vinylic proton signals and for H_a and H_b of the three AB-patterns). On the basis of its ^{1}H-NMR spectrum, the solution structure of butylamine derivative **7** is similar to that of benzylamine derivative **5** (Table 3). As for **5**, the significant downfield shift of Py-H^6 (Δδ = 0.58 ppm) indicates that L_{Bu}^- is tridentate in solution.

Complex **6**, the iridium analogue of **5**, is also five-coordinate in solution. However **6** does not show N^{Bzl}_{amine} inversion on the ^{1}H-NOESY/EXSY time-scale. This seems to indicate the stronger preference of iridium for five-coordination.[8] Apart from the chemical shift differences for $(-HC=CH-)_{cod}$ (Table 3), the NMR spectra of **5** and **6** are very similar.

Thus, substitution of the N^H_{amine} proton in **3/4** by benzyl in **5/6** or butyl in **7** induces N_{Py} coordination in solution. This appears to be triggered by a weaker $N_{amine}-Rh$ interaction resulting from steric repulsions, and by the loss of stabilisation of the uncoordinated N_{Py} through hydrogen bonding with $N_{amine}-H$.

The ^{13}C-NMR signals for $(-CH=CH-)_{cod}$ of the iridium complexes appear at significant lower values than their corresponding rhodium analogues (Table 3), indicating stronger π-back donation for iridium.[8] Both for rhodium and for iridium, significant upfield shifts are observed for the $(-CH=CH-)_{cod}$ NMR signals on going from four-coordination to five-coordination (Table 3). The average NMR signals of $(-CH=CH-)_{cod}$ of four-coordinate **3** and **4** in CD_2Cl_2 [**3**: δ(^{1}H) = 4.1 and δ(^{13}C) = 79; **4**: δ(^{1}H) = 3.8 and δ(^{13}C) = 62] appear at significantly higher values than those of five-coordinate **5** and **6** [**5**: δ(^{1}H) = 3.6 and δ(^{13}C) = 77−74 (br); **6**: δ(^{1}H) = 3.2 and δ(^{13}C) = 57−54(br)]. For **7**, δ(^{1}H) = 3.7, which is close to the value



of **5**. This situation parallels that for 3,5-disubstituted tris(pyrazolyl)borate (Tp^{R2}) rhodium(I) cod complexes, where in $CDCl_3$ $\delta(^1H) = 4.1$ and $\delta(^{13}C) = 80$ for four-coordinate $[(\kappa^2\text{-}Tp^{R2})Rh^I(cod)]$ and $\delta(^1H) = 4.0$ and $\delta(^{13}C) = 73$ for five-coordinate $[(\kappa^3\text{-}Tp^{H2})Rh^I(cod)]$.[12e]

Reactivity towards H_2O, O_2, and H_2O_2

Solutions of the pyridine-amine-pyrrolate complexes **3**, **4**, **5**, **6**, and **7** show no reactivity towards water, but are oxidised in a nonselective way by air and aqueous H_2O_2. Sparingly soluble precipitates result, which have complex ^1H-NMR spectra with very broad lines.

Catalytic Polymerisation of Phenylacetylene

Complexes **5** and **7** are neutral "N_3"$Rh^I(cod)$ complexes that show $\kappa^2-\kappa^3$ isomerism, similar to tris(pyrazolyl)borate rhodium(I) cod complexes. Isomerisation of $[(\kappa^3\text{-}Tp^{R2})Rh^I(cod)]$ to $[(\kappa^2\text{-}Tp^{R2})Rh^I(cod)]$ has been suggested to be essential for its catalytic activity in the polymerisation of phenylacetylene.[9] In accordance with this we observed that rhodium complex **5**, but not iridium complex **6,** is an active catalyst for the polymerisation of phenylacetylene (Scheme 4).

Scheme 4. Polymerisation of phenylacetylene by **5**

Reaction of phenylacetylene in MeOH in the presence of 0.1 mol-percent of **5** resulted in precipitation of yellow poly(phenylacetylene) in 24% yield within 20 min. The molecular mass (M_n) and the high stereoregularity (head-to-tail cis-transoidal structure) of the obtained poly(phenylacetylene) are similar to those of poly(phenylacetylene) prepared with $(Tp^{R2})Rh^I(cod)$[9] and other rhodium catalysts.[10] The broad molecular weight distribution ($M_w/M_n = 4.7$) could be the result of partial precipitation during polymerisation.

Discussion

The pyridine-amine-pyrrolate complexes **3**−**7** are not oxidised selectively by H_2O_2 or O_2. Oxidation of the negatively charged pyrrolate group is probably responsible for these aselective oxidations. The new pyridine-amine-pyrrole and pyridine-amine-pyrrolate ligands display a diverse coordination chemistry towards $[Rh^I(cod)]^+$ and $[Ir^I(cod)]^+$.

The neutral pyridine-amine-pyrrole ligand HL_H in $[\mathbf{1}]^+$ and $[\mathbf{2}]^+$ is didentate via N^H_{amine} and N_{Py}. Deprotonation of the pyrrole group results in the potentially tridentate pyridine-amine-pyrrolate ligands L_H^-, L_{Bzl}^- and L_{Bu}^-. In both **3** (M = Rh) and **4** (M = Ir), L_H^- is didentate via N^H_{amine} and N_{Pyr} in the solid state *and* in solution. The observed difference between **3** and **4** in the solid state could well reflect that the N^H_{amine} proton of iridium compound **4** is slightly more acidic than the N^H_{amine} proton of rhodium compound **3**, in accordance with the down-field shift of the N^H_{amine} proton in the ^1H-NMR spectrum on going from **3** to **4**. The higher acidity is probably the result of stronger metal−ligand interaction for iridium(I) than for rhodium(I). In accordance with this, the ^{13}C-NMR olefinic cod signals of the iridium complexes are observed at higher field than those of their rhodium analogues (see Table 3).

L_{Bzl}^- in **5** (M = Rh) is predominantly tridentate via N_{Pyr}, N_{amine}, and N_{Py} in solution, but didentate via N_{Pyr} and N_{amine} in the solid state. Apparently, the free energy increase on going from κ^3-L_{Bzl} to κ^2-L_{Bzl} can easily be overcome by packing forces. The ^1H-NMR spectrum of **5** shows the occurrence of another mode of $\kappa^2-\kappa^3$ isomerism in solution, involving dissociation, pyramidal inversion and recoordination of N^{Bzl}_{amine}. The activity of **5** in polymerisation of phenylacetylene also reflects the occurrence of $\kappa^2-\kappa^3$ isomerism. L_{Bzl}^- in **6**, the Ir-analogue of **5**, shows no sign of pyramidal inversion of N^{Bzl}_{amine} via $\kappa^2-\kappa^3$ isomerism in solution, and is tridentate in the solid state. The observed differences between **5** and **6** in solution and in the solid state both appear to reflect the higher tendency of iridium for five coordination.[8]

Previously, $\kappa^2-\kappa^3$-isomerism has been observed for 3,5-disubstituted tris(pyrazolyl)borate[11] (Tp^{R2}) complexes $[(Tp^{R2})Rh^I(L_2)]$ (L_2 = diolefin or $(olefin)_2$).[12][13] Whereas a bulky R at the pyrazolyl-3-position in $[(Tp^{R2})Rh^I(cod)]$ favours four-coordination over five-coordination ($\kappa^2 > \kappa^3$), a bulky R at N^R_{amine} in $[(L_R^-)Rh^I(cod)]$ favours five-coordination over four-coordination ($\kappa^3 > \kappa^2$). Increased steric repulsion at N^R_{amine} in $[(L_R^-)Rh^I(cod)]$ induces a weaker $Rh-N^R_{amine}$ interaction. This is compensated by additional coordination of N_{Py}, and thus results in five coordination.

Experimental Section

General Methods: All reactions were performed under a nitrogen atmosphere using standard schlenk techniques, unless mentioned otherwise. Solvents (p. a.) were deoxygenated by bubbling through a stream of N_2 or by the freeze-pump-thaw method. The temperature indication room temp. corresponds to ca. 20 °C. $[\{(cod)Rh(\mu\text{-}Cl)\}_2]$[14] and $[\{(cod)Ir(\mu\text{-}Cl)\}_2]$[15] were prepared according to a literature procedure. All other chemicals are commercially available and were used without further purification. − IR spectra were measured on a Perkin−Elmer 1720X. − NMR experiments were carried out on a Bruker DPX200 (200 MHz and 50 MHz for ^1H and ^{13}C respectively), a Bruker AC300 (300 MHz and 75 MHz for ^1H and ^{13}C respectively) and a Bruker AM500 (500 MHz and 125 MHz for ^1H and ^{13}C respectively). Solvent shift reference for ^1H NMR: $[D_6]$acetone $\delta_H = 2.05$, THF-$[D_8]$ $\delta_H = 1.72$, CD_2Cl_2 $\delta_H = 5.31$, $CDCl_3$ $\delta_H = 7.28$. For ^{13}C NMR: $[D_6]$acetone $\delta_C = 29.50$, CD_2Cl_2 $\delta_C = 54.20$. Abbreviations used are s = singlet, d = doublet, dd = doublet of doublets, ddd = doublet of doublets of

doublets, t = triplet, m = multiplet and br = broad. − Elemental analysis (C,H,N) were carried out on a Carlo Erba NCSO-analyser. − Mass Spectra were recorded on a VG 7070 Mass spectrometer (FAB/EI) or on a JEOL JMS SX/SX102A four sector mass spectrometer (FD).

X-ray Diffraction: Crystals of [**1**]PF_6 and [**2**]PF_6 suitable for X-ray diffraction studies were obtained by cooling a saturated solution of the corresponding compound in MeOH to −20 °C. Crystals of HL_H, **3**, **5**, and **6** suitable for X-ray diffraction studies were obtained from hot saturated toluene solutions. Crystals of **4** suitable for X-ray diffraction studies were obtained by slow crystallisation from a saturated CH_2Cl_2 solution at −20°C. Single crystals were mounted in air on glass fibres. For [**1**]PF_6, [**2**]PF_6, **4**, **5**, and **6** an Enraf−Nonius CAD4 single-crystal diffractometer was used, graphite monochromatised Cu-*Kα* radiation, θ-2θ scan mode. The X-ray diffraction data for **3** were collected on a Enraf−Nonius CAD4T rotating anode diffractometer, graphite monochromatised Mo-*Kα* radiation, ω-scan mode. Semi-empirical absorption correction (*ψ*-scan) was applied.[16]

For HL_H an Enraf−Nonius CAD4 single-crystal diffractometer was used, graphite monochromatised Mo-*Kα* radiation, θ-2θ scan mode. No absorption correction was applied. Structures [**1**]PF_6, [**2**]PF_6, **3**, **4**, **5**, and **6** were solved by the program system DIRDIF[17] using the program PATTY[18] to locate the heavy atoms. The structure of HL_H was solved using the program CRUNCH.[19] All structures were refined with standard methods (refinement against F^2 of all reflections with SHELXL97[20]) with anisotropic parameters for the nonhydrogen atoms. Intensity data were corrected for Lorentz and polarisation effects. All hydrogen atoms were placed at calculated positions and were subsequently freely refined, however, for **4** and **6**, the hydrogen atoms were placed at calculated positions and were refined riding on the parent atoms. Details of the crystal parameters, data collections and structure refinements are given in Table 4. Crystallographic data (tables of structure determinations summaries, lists of anisotropic displacement parameters, lists of atom coordinates and full lists of bond lengths and angles, excluding structure factors) have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-115640 ([**1**]PF_6), 115641 (**3**), 115642 (**5**), 115643 (HL_H), 115644 ([**2**]PF_6), 115645 (**6**), and 115646 (**4**). Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: Int. Code +44 (1223) 336-033; E-mail: deposit@chemcrys.cam.ac.uk)

Syntheses

***N*-(2-Pyridylmethyl)-*N*-(1*H*-2-pyrrolylmethyl)amine (HL_H):** 6.8 g (0.064 mol) of 1*H*-pyrrole-2-carboxaldehyde was dissolved in 60 mL of EtOH and 6.0 g (0.063 mol) of picolylamine was added dropwise. The solution was heated to reflux for 10 min. Evaporation of the solvent under vacuum results in a yellow powder, from which *N*-(2-pyridylmethyl-*N*-(1*H*-pyrrolylmethylidene)amine was obtained as a white solid by recrystallisation from a hot saturated Et_2O solution. Yield 11.5 g (0.062 mol, 98%). − 11.3 g (0.061 mol) of *N*-(2-pyridylmethyl-*N*-(1*H*-pyrrolylmethylidene)amine was then dissolved in 200 mL of deoxygenated methanol. The solution was cooled to −10°C, and 2.9 g (0.076 mol) of $NaBH_4$ was added and some gas evolved from the solution. The solution was heated to 50°C for 3 h after which the solvent was partially evaporated. To this solution 50 mL water was added to destroy the excess $NaBH_4$. The water layer was extracted three times with 30 mL of Et_2O, and the combined Et_2O-fractions were dried with 10 g of $MgSO_4$. Filtration and evaporation of the solvent results in *N*-(2-pyridylmethyl)−*N*-(1*H*-2-pyrrolylmethyl)amine (HL_H) as a yellow powder, and was recrystallised from a hot saturated Et_2O solution. Yield 10.3 g (0.055 mol, 90%). Colourless crystals suitable for X-ray diffraction were obtained by crystallisation from toluene. − Mp: 59.0°C. − ^{1}H NMR (200 MHz, CD_2Cl_2, 298 K): δ = 9.40 (s, b, 1 H, Pyr−H1), 8.54 [d,1 H, ^3J(H,H) = 4.1 Hz, Py−H6], 7.65 [t, 1 H, ^3J(H,H) = 7.6 Hz, Py−H4], 7.26 [d, 1 H, ^3J(H,H) = 7.6 Hz, Py−H3], 7.16 [dd, 1 H, ^3J(H,H) = 7.6 Hz, ^3J(H,H) = 4.1 Hz, Py−H5], 6.67 (m, Pyr−H5), 6.05 (m, 1 H, Pyr−H4), 5.98 (m, 1 H, Pyr−H3), 3.86 (s, 2 H, N−CH_2−Py), 3.78 (s, 2 H, N−CH_2−Pyr), 2.41 (s, br, 1 H, NH). − ^{13}C {^{1}H} (75 MHz, [D$_6$]acetone, 298 K): δ = 161.4 (Py−C2), 149.9 (Py−C6), 137.2 (Py−C4), 131.6 (Pyr−C2), 122.9 (Pyr−C5), 122.2 (Py−C5), 117.8 (Py−C3), 108.7 (Pyr−C4), 106.9 (Pyr−C3), 54.9 (N−CH_2−Pyr), 46.8 (N−CH_2−Py). − EI-MS (*m*/*z*): 185 $[M]^+$, 118 $[M - Pyr + H]^+$, 107 $[M - CH_2Py]^+$, 93 $[CH_2Py + H]^+$. − $C_{11}H_{13}N_3$ (187.24): calcd. C 70.56, H 7.00, N 22.44; found C 70.55, H 7.03, N 21.95.

***N*-Benzyl-*N*-(2-pyridylmethyl)-*N*-(1*H*-2-pyrrolylmethyl)amine (HL_{Bzl}):** 9.5 g (0.09 mol) of 1*H*-pyrrole-2-carboxaldehyde was dissolved in 50 mL of freshly distilled THF and cooled to 0°C. 10.7 g (0.10 mol) of benzylamine was added drop wise. After 15 min the solution was allowed to warm up to room temp. and was stirred for 10 h. Evaporation of the solvent under vacuum results in a yellow powder, from which *N*-benzyl-*N*-(1*H*-pyrrolylmethylidene)-amine was obtained as a white solid by recrystallisation from a hot saturated Et_2O solution. Yield 17.7 g (0.085 mol, 96%). 9.2 g (0.049 mol) of *N*-benzyl-*N*-(1*H*-pyrrolylmethylidene)amine was then dissolved in 60 mL of deoxygenated methanol. The solution was cooled to 0°C, and 2.0 g (0.053 mol) of $NaBH_4$ was added and some gas evolved from the solution. The solution was heated to 50°C for 10 h after which the solvent was partially evaporated. To this solution 50 mL of water was added to destroy the excess $NaBH_4$. The water layer was extracted three times with 30 mL of Et_2O, and the combined Et_2O fractions were dried with 10 g of $MgSO_4$. Filtration and evaporation of the solvent results in 1*H*-pyrrol-2-ylmethylbenzylamine as a yellow oil, sufficiently pure for further reaction. Yield 7.87 g (0.061 mol, 71.3%). 100 mL of methanol was cooled to 0°C and 12 g of Na_2CO_3, dissolved in 20 mL of water, was added. To the resulting suspension 6.89 g (0.042 mol) of picolyl chloride hydrochloride and 7.9 g (0.042 mol) of (1*H*-pyrrol-2-ylmethyl)benzylamine were added. The pink solution was stirred for 10 h and gradually changed its colour to orange. The mixture was filtered and the filtrate was evaporated yielding a crude red solid. *N*-benzyl-*N*-(2-pyridylmethyl)-*N*-(1*H*-2-pyrrolylmethyl)amine (HL_{Bzl}) was obtained as a white solid by recrystallisation from a saturated Et_2O solution at −20°C. Yield 4.46 g (0.016 mol, 38%). − Mp: 86.0°C. − ^{1}H NMR (200 MHz, CD_2Cl_2, 298 K): δ = 9.84 (s, br, 1 H, Pyr−H1), 8.56 (m,1 H, Py−H6), 7.70 (m, 1 H, Py−H4, Py−H3), 7.8−7.2 (m, 6 H, Ph−H, Py−H4, Py−H5), 6.79 (m, Pyr−H5), 6.08 (m, 1 H, Pyr−H4), 5.99 (m, 1 H, Pyr−H3), 3.65 (s, 2 H, N−CH_2−Py), 3.62 (s, 2 H, N−CH_2−Pyr), 3.52 (s, 2 H, N−CH_2−Ph). − ^{13}C {^{1}H} (75 MHz, [D$_6$]acetone, 298 K): δ = 161.1 (Py−C2), 149.9 (Py−C6), 141.0 (Pyr−C2), 137.6 (Py−C4), 130.0 (Ph−C2, Ph−C3), 129.4 (Ph−C4), 128.1 (Ph−C1), 124.3 (Pyr−C5), 123.2 (Py−C5), 118.5 (Py−C3), 108.8 (Pyr−C4), 108.6 (Pyr−C3), 59.9 (N−CH_2−Ph), 58.9 (N−CH_2−Pyr), 51.1 (N−CH_2−Py). − EI-MS [*m*/*z* (%)]: 277 $[M]^+$ (0.13), 211 $[M - Pyr]^+$ (0.10), 197 $[M - CH_2Pyr]^+$ (37.10), 185 $[M - CH_2Py]^+$ (75.34), 93 $[CH_2Py + H]^+$ (100). − $C_{18}H_{19}N_3$ (277.37): calcd. C 77.95, H 6.90, N 15.15; found C 77.81, H 6.90, N 14.75.

***N*-Butyl-*N*-(2-pyridylmethyl)-*N*-(1*H*-2-pyrrolylmethyl)amine (HL_{Bu}):** *N*-Butyl-*N*-(2-pyridylmethyl)-*N*-(1*H*-2-pyrrolylmethyl)am-

ine (HL_{Bu}) was obtained as a red oil by a procedure similar to that of *N*-benzyl-*N*-(2-pyridylmethyl)-*N*-(1*H*-2-pyrrolylmethyl)amine (HL_{Bzl}), starting from *n*-butylamine instead of benzylamine. The compound was purified by column chromatography over silica-60H with 10% MeOH/$CHCl_3$. Yield 0.64 g (2.63 mmol, 15.5%). − ^{1}H NMR (200 MHz, $CDCl_3$, 298 K): δ = 9.83 (s, br, 1 H, Pyr−H1), 8.52 [d, 1 H, ^3J(H,H) = 3.2 Hz, Py−H6], 7.61 (m, 1 H, Py−H4), 7.45 (m, 1 H, Py−H3), 7.15 (m, 1 H, Py−H5), 6.78 (m, 1 H, Pyr−H5), 6.11 (m, 1 H, Pyr−H4), 6.01 (m, 1 H, Pyr−H3), 3.69 (s, 2 H, N−CH_2−), 3.59 (s, 2 H, N−CH_2−), 2.48 [t, 2 H, ^3J(H,H) = 7.4 Hz, N−CH_2−C_3H_7], 1.51 (m, 2 H, N−CH_2−CH_2−C_2H_5), 1.31 (m, 2 H, N−C_2H_4−CH_2−CH_3), 0.85 [t, 3 H, ^3J(H,H) = 7.1 Hz, N−C_3H_6−CH_3]. − EI-MS [*m*/*z* (%)]: 244 $[M]^+$ (3), 186 $[M - Bu]^+$ (4), 163 $[M - Py]^+$ (39), 151 $[M - Bu - Pyr]^+$ (84), 107 $[M - Bu - Py]^+$, 93 $[CH_2Py + H]^+$ (100).

(η^4-Cycloocta-1,5-diene)[*N*-(2-pyridylmethyl)-*N*-(1*H*-2-pyrrolylmethyl)amine]rhodium(I) Hexafluorophosphate ([1]PF_6): 30.0 mg (0.16 mmol) of *N*-(2-pyridylmethyl)-*N*-(1*H*-2-pyrrolylmethyl)amine (HL_H) was dissolved in 5 mL of MeOH and 39.5 mg (0.08 mmol) of $[\{(cod)Rh(\mu\text{-}Cl)\}_2]$ was added, and stirred at room temp. for 1 h. Addition of 32.6 mg of NH_4PF_6 resulted in the precipitation of $[(HL_H)Rh^{I}(cod)]PF_6$ ([**1**]PF_6) as a yellow solid, which was collected by filtration, washed with small portions of water and MeOH and was vacuum-dried. Crystals suitable for X-ray diffraction were obtained by slow crystallisation from a saturated MeOH solution at −20°C. Yield 54 mg (62%). − ^{1}H NMR (500 MHz, [D$_6$]acetone, 298 K): 10.22 (s, br, 1 H, Pyr−H1), 8.10 [ddd, 1 H, ^3J(H,H) = 7.83 Hz, ^3J(H,H) = 7.10 Hz, ^4J(H,H) = 1.46 Hz, Py−H4], 7.96 [d, 1 H, ^3J(H,H) = 5.88 Hz, Py−H6], 7.76 [d, 1 H, ^3J(H,H) = 7.83 Hz, Py−H3], 7.54 [dd, 1 H, ^3J(H,H) = 7.10 Hz, ^3J(H,H) = 5.88 Hz, Py−H5], 6.80 (m, 1 H, Pyr−H5), 6.29 (m, 1 H, Pyr−H3), 6.06 (m, 1 H, Pyr−H4), 4.99 (s, br, 1 H, NH), 4.46 (m, br, 4 H, −HC=CH−), 3.98 (s, 2 H, N−CH_2−), 3.95 (s, 2 H, N−CH_2−), 2.47 (m, br, 4 H, −C=C−$CH_{2\ exo}$), 1.98 (m, br, 4 H, −C=C−$CH_{2\ endo}$). − ^{1}H NMR (500 MHz, [D$_6$]acetone, 193 K): δ = 10.65 (s, br, 1 H, Pyr−H1), 8.12 [ddd, ^3J(H,H) = 7.4 Hz, ^3J(H,H) = 7.4 Hz, ^4J(H,H) = 1.5 Hz, Py−H4], 7.98 [d, 1 H, ^3J(H,H) = 5.5 Hz, Py−H6], 7.79 [d, 1 H, ^3J(H,H) = 7.4 Hz, Py−H3], 7.56 [dd, 1 H, ^3J(H,H) = 7.4 Hz, ^3J(H,H) = 5.5 Hz, Py−H5], 6.87 [d, 1 H, ^3J(H,H) = 1.5 Hz, Pyr−H5], 6.25 (m, 1 H, Pyr−H3), 6.06 (m, 1 H, Pyr−H4), 5.16 (s, br, 1 H, NH), 4.74 (s, br, 1 H, −*HC*=*CH*−), 4.57 {dd[AB], 1 H, ^2J(H,H) = 16.0 Hz, ^3J(H,H) = 4.8 Hz, N−CH_2−}, 4.51 (s, br, 1 H, −*HC*=*CH*−), 4.30 {dd[AB], 1 H, ^2J(H,H) = 16.0 Hz, ^3J(H,H) = 2.9 Hz, N−CH_2−}, 3.95 {dd[AB], 1 H, ^2J(H,H) = 14.0 Hz, ^3J(H,NH) = 6.6 Hz, N−CH_2−}, 3.86 {dd[AB], 1 H, ^2J(H,H) = 14.0 Hz, ^3J(H,NH) = 6.6 Hz, N−CH_2−}, 3.64 (s, br, 1 H, −*HC*=*CH*−), 2.58 (m, br, 1 H, −C=C−$CH_{2\ exo}$), 2.46 (m, br, 1 H, −C=C−$CH_{2\ exo}$), 2.30 (m, br, 2 H, −C=C−$CH_{2\ exo}$), 2.02 (m, br, 2 H, −C=C−$CH_{2\ endo}$), 1.85 (m, br, 2 H, −C=C−$CH_{2\ endo}$). − ^{13}C NMR (50 MHz, [D$_6$]-acetone, 298 K): δ = 161.5 (Py−C2), 147.8 (Py−C6), 139. 8 (Py−C4), 124.8 (Pyr−C2), 124.0 (Py−C3), 122.9 (Py−C5), 118.6 (Pyr−C5), 109.6 (Pyr−C4), 108.2 (Pyr−C2), 82.2 (br., *C*=*C*), 56.5 (d, ^2J(C,Rh) = 4.6 Hz, N−CH_2−), 47.7 (N−CH_2), 29.8 (C=C−CH_2−). − FT-IR (KBr): $\tilde{\nu}$ = 3297 (NH), 1655 (C=C), 840 $[(PF_6)^-]$, 558 $[(PF_6)^-]$. − FAB-MS (*m*/*z*): 941 $[2\ M - PF_6]^+$, 398 $[M - PF_6]^+$. − $C_{19}H_{25}F_6N_3PRh$ (543.30): calcd. Polymerisation of Phenylacetylene: 0.82 g of Phenylacetylene was dissolved in 20 mL of MeOH. 5 mg of catalyst $[(L_{Bzl}^-)Rh^I(cod)]$ (**5**) was added to this solution. Almost immediate formation of poly(phenylacetylene) as a yellow/orange precipitate can be observed, and a gradual colour change of the solution from pale yellow to deep red. After 20 min the poly(phenylacetylene) precipitate was collected by filtration, washed with MeOH and dried under vacuum. Yield 0.20 g (24%). − IR (KBr): ṽ = 3053, 1596, 1488, 1444, 1073, 1028, 884, 756, 737, 696 cm^{-1}. − ^{1}H NMR (200 MHz, $CDCl_3$, 298 K): δ = 6.98 (s, br. Ph), 6.67 (m, br., Ph), 5.86 (s, br., vinyl). − GPC analysis (polystyrene standard): M_n = 14000, M_w = 65000, M_z = 137000, M_w/M_n = 4.7, M_z/M_w = 2.1, $[\eta]_{dv}$ = 0.292.

Main Group Metal Directed Self-Assembly in a Tetrameric Trimethyltin(IV) *N*-nitroso-*N*-phenylhydroxylaminato Complex Containing an Unprecedented 20-Membered Inorganic (Carbon-Free) Metallamacrocycle

Andrea Deák,[a,b] Ionel Haiduc,*[b] László Párkányi,[a] Monica Venter,[b] and Alajos Kálmán*[a]

Keywords: Metallamacrocycles / Structure elucidation / Supramolecular chemistry / Tin(IV) compounds / Vibrational spectroscopy

Tetrakis[trimethyl(*N*-nitroso-*N*-phenylhydroxylaminato)tin(IV)] was synthesized by reaction of cupferron ([PhN(O)NO]NH_4) with trimethyltin(IV) chloride. The complex was characterized by X-ray diffraction analysis, FT-IR and FT-Raman spectroscopy. An X-ray structural analysis of the title complex $[Me_3Sn(O_2N_2Ph)]_4$ reveals the first example of a bridging coordinated cupferronato ligand. This coordination pattern leads to an unprecedented inorganic 20-membered (carbon-free) metallamacrocycle $Sn_4O_8N_8$ in which four Me_3Sn and four PhN_2O_2 subunits are self-assembled.

Introduction

The rational design and construction of inorganic and organometallic metallamacrocycles by transition metal directed multicomponent self-assembly has had a major impact on supramolecular chemistry.[1−3] The incorporation of metal centres into supramolecular systems gives rise to novel electronic and/or magnetic properties[1] as well as fascinating structural features. Metallamacrocycles have been widely used in host-guest chemistry to understand self-assembly phenomena in natural systems.[3][4] Transition metal centres present a large variety of preferred coordination geometries (square-planar, tetrahedral or octahedral) which have been systematically used in the construction of supramolecular assemblies such as molecular racks,[5] ladders,[5] grids,[6] cylinders,[7] metallamacrocycles,[4][8] metallacyclic polygons[9] and helicates.[10] In contrast, the use of main group metals in supramolecular chemistry has been less well explored. Tin(IV) complexes are also known to display a wide range of coordination geometries around the metal centre, the most common being the penta- and hexacoordinate environments.[11] In the case of pentacoordination, the trigonal-bipyramidal (TBP) configuration is more common than square-pyramidal (SP). For example, the axial connections of nearly planar Me_3Sn(IV) units, with suitable bridging ligands, offer ready access to the preferred TBP coordination and may generate metallamacrocycles. This can be seen in the tetranuclear complexes $[Me_3Sn(O_2PPh_2)]_4$[12] and $\{Me_3Sn[C_5Me_5W(O)(\mu\text{-}O)_2]\}_4$[13] which contain 16-membered inorganic metallamacrocycles $Sn_4O_8E_4$ (E = P and/or W). In addition, the ligand subunits must have two binding sites in a correct arrangement and must be as rigid as possible in order to predispose the coordinating groups to the desired geometry.

The aim of this work is to design new metallamacrocycles exploring the structural features of the cupferronato ligand as well as the ability of the Me_3Sn(IV) unit to exhibit TBP geometry in inorganic ring systems.[12][13] We report an unprecedented 20-membered inorganic (carbon-free)[14][15] metallamacrocycle in the trimethyltin(IV) cupferronato complex $[Me_3Sn(O_2N_2Ph)]_4$. The compound was characterized by analytical and spectroscopic (FT-IR, FT-Raman) methods.[16] To elucidate the three dimensional structure of the macrocycle, X-ray diffraction analysis was performed.[16] The ammonium salt of *N*-nitroso-*N*-phenylhydroxylamine, [PhN(O)NO]NH_4 (cupferron) is a well-known analytical reagent for the quantitative determination of several metal ions.[17] The *N*-nitroso-*N*-phenylhydroxylaminato (cupferronato) anion, [PhN(O)NO^-] has been extensively used as a ligand in transitional metal chemistry behaving as a μ^3-bridging or, in most cases, as a bidentate chelating ligand.[18] In all cases, the X-ray diffraction analysis of the investigated cupferronato metal complexes has revealed a rigid and planar structure of the N(O)NO unit.[18] To the best of our knowledge, however, no bidentate bridging coordination pattern of the cupferronato ligand has been described.

Results and Discussion

Reaction of the cupferron with Me_3SnCl (1:1 ratio) in water yields the new tetranuclear trimethyltin(IV) cupferronato complex, $[Me_3Sn(O_2N_2Ph)]_4$ as a colourless crystalline solid. Single crystals suitable for an X-ray diffraction analysis were obtained by slow concentration of an *n*-heptane solution at ambient temperature.

[a] Equivalent atom generated by $1 - x, -1 + y, 2 - z$.

The molecular structure of $[Me_3Sn(O_2N_2Ph)]_4$ consists of a novel 20-membered macrocyclic inorganic ring system $Sn_4O_8N_8$, self-assembled from four Me_3Sn units, connected by four bridging *N*-nitroso-*N*-phenylhydroxylaminato anions. It provides the first example of the bridging coordination pattern of the cupferronato ligand. Each metal centre occupies an almost perfect TBP coordination site defined by the oxygen atoms of two cupferronato ligands in a *trans* axial array [O(1a)−Sn(1)−O(2) = 175.75(7)°] and three methyl groups in the equatorial plane [average C−Sn−C = 119.91(12)°]. The distortion from the idealized TBP geometry can be quantified by the τ factor, where the limits of τ = 0 or 1 are indicative[19] of perfect SP or TBP geometries, respectively. The calculated value of τ = 0.81 reveals a strong TBP character of the Sn(IV) coordination environment. The Sn(1)−O(1) bond length is shorter by 0.089 Å than that of Sn(1)−O(2), but both are significantly longer than the normal Sn−O covalent bond.[11] The intramolecular nonbonded Sn(1)···O(2a) distance of 3.273(2) Å suggests a weak secondary interaction.

In each cupferronato anion the N(O)NO moieties are essentially planar [r.m.s. deviation from the best plane is 0.0127 Å; torsion angle: O(1)−N(1)−N(2)−O(2) = 4.0(3)°] and nearly coplanar with that of the phenyl ring [O(1)−N(1)−C(1)−C(2) = 5.6(3)°]. These structural features reveal a rigid arrangement of all the atoms in the cupferronato moieties. A significant electron delocalisation along the N(O)NO group can be predicted, all N−N and N−O bond lengths being intermediate between that of the corresponding single and double bond lengths.[16]

The title complex with $P\bar{4}2_1$ symmetry consists of a 20-membered cup-shaped metallamacrocycle $Sn_4O_8N_8$ (see Figure 2) in which the four Sn(1)−O(2) bonds lie in the best plane of the symmetry related Sn(1) and O(2) atoms [r.m.s. deviation from the best plane is 0.212 Å; torsion angles: Sn(1)−O(2)−Sn(1a)−O(2a) = 1.12(7)°, O(2)−Sn(1)−O(2b)−Sn(1b) = 20.68(9)°, Sn(1a)−O(2a)−Sn(1b)−O(2b) = 1.12(7)°, O(2c)−Sn(1c)−O(2a)−Sn(1a) = 20.68(9)°]. The bridging ligands are placed alternatively above and below this plane. In the same manner, two of the three methyl groups on each tin atom protrude alternately above and below the $\{\cdots Sn(1)-O(2)\cdots\}_4$ plane. This arrangement leads to two narrow rings defined by the C(7), C(7a), C(7b), C(7c) and C(8,) C(8a), C(8b), C(8c) atoms, which are concentric with the 20-membered metallamacrocycle. There are weak intramolecular hydrogen bonds such as C−H···O [C(8)···O(2), O(2)···H(8A) distances, 3.368(3), 2.899(12) Å, C(8)−H(8A)···O(2) angle 115.04°] and C−H···N [C(7)···N(1), N(1)···H(7A) distances 3.282(3), 2.732(10) Å, C(7)−H(7A)···N(1) angle 122.60°; C(7)···N(2), N(2)···H(7A) distances 3.412(3), 2.874(14) Å, C(7)−H(7A)···N(2) angle 121.88°] between the methyl hydrogen atoms and an adjacent cupferronato group and weak Me···Ph [C(8)···π, H(8A)···π distances 3.793, 3.054 Å, C(8)−H(8A)···π angle 142.63°] interactions between neighbouring groups.

The molecules self-organise in the solid state leading to a column arrangement along the shortest unit cell edge of 7.383(1) Å, analogous to the β-type packing observed in crystalline aromatic hydrocarbons (see Figure 3). If we rescale the short axis ranges given by Desiraju and Gavezotti for crystalline aromatic hydrocarbons[20] by the ratio of the covalent radii of Sn/C (1.82), the short axis for a β-packing must be less than 7.6 Å.[21] Indeed, the shortest axis of the title compound falls in this range in agreement with the β-packing assumed by the cup-shaped metallamacrocycles. These symmetry-related columns then interact with each other through weak C−H···π contacts [C(4)···π, H(4)···π distances 3.854, 3.150 Å, C(4)−H(4)···π angle 133.36°].

The spectral data are consistent with the determined structure of the title compound. The FT-IR and Raman spectra were recorded for the $[Me_3Sn(O_2N_2Ph)]_4$ complex and its corresponding neutral ligand $[PhN(O)NO]NH_4$ (cupferron) in the 3500−100 cm^{-1} range. Selected bands and assignments are listed in Table 2.

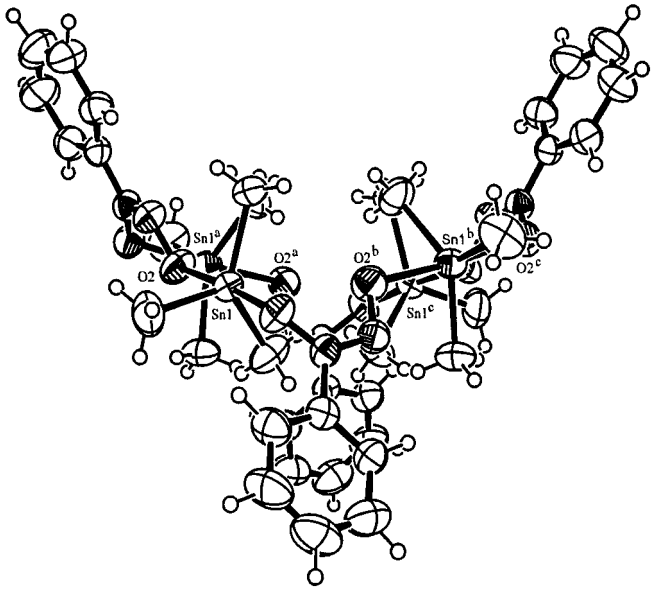

Figure 2. The side view of the molecular structure in $[Me_3Sn(O_2N_2Ph)]_4$; equivalent atoms are generated by: [a]: $1-x, -1+y, 2-z$; [b]: $-x, 2-y, z$; [c]: $1+x, 1-y, 2-z$

Table 2. Selected FT-IR/Raman data and vibrational assignments for cupferron and $[Me_3Sn(O_2N_2Ph)]_4$[a]

		542 m	546 mw	ν(Sn−C)
		520 w	516 s	$\nu_s(SnC_3)$
		387 vs		ν(Sn−O)
		142 s	141 m	$\delta(SnC_3$

[a] vw: very weak, w: weak, m: medium, mw: medium weak, s: strong, vs: very strong.

The assignments of the N−N and N=O stretching as well as ONNO bending modes − specific for the neutral ligand − in the 1500−800 cm^{-1} range of the IR and Raman spectra of the cupferron are in good agreement with similar IR data already published.[22][23] A comparison of IR and Raman spectra of the title complex with that of cupferron reveals significant changes in the position of the mentioned bands due to electron delocalisation over the coordinated ONNO unit. Thus, the ν(N−N) and δ(ONNO) modes are shifted to higher frequencies by 9 (IR)/14 (Raman) and 9 (IR)/8 (Raman) cm^{-1}, respectively, while the ν(N=O) mode is shifted to lower frequencies by 46/34 (IR) and 49/39 (Raman) cm^{-1}.

The vibrational modes specific to the coordination environment of tin may be assigned in the 800−100 cm^{-1} spectral range. The Me rocking vibration (779 cm^{-1} in the IR)[24] and the Sn−C stretching mode (542 in IR and 546 cm^{-1} in Raman)[24] are characteristic. Furthermore, the assignment of the three vibrational modes of the SnC_3 group (ν_{as}, ν_s and δ) in the IR spectrum of the complex are in good agreement with the vibrational behaviour proposed for a trigonal-plane arrangement of the Me groups about the tin(IV) centre.[24] The presence of the $\nu_s(SnC_3)$ − as a strong band − and $\delta(SnC_3)$ modes in the Raman spectrum support this structural feature.

Taking into account the coordination of the anionic cupferronato ligand to the metal centres through the oxygen atoms, the Sn−O stretching vibration, tentatively assigned at 565−560 cm^{-1},[22] was not found in the IR spectrum of the title complex. It is probably found at 387 cm^{-1}, as a very strong band.[23]

Experimental Section

General Remarks: All reagents and solvents were purchased from commercial suppliers and used without further purification. Elemental analyses were carried out in the laboratory of the University of Santiago de Compostela (Spain). FT-IR spectra were recorded on a Perkin−Elmer 2000 spectrometer. FT-Raman spectra

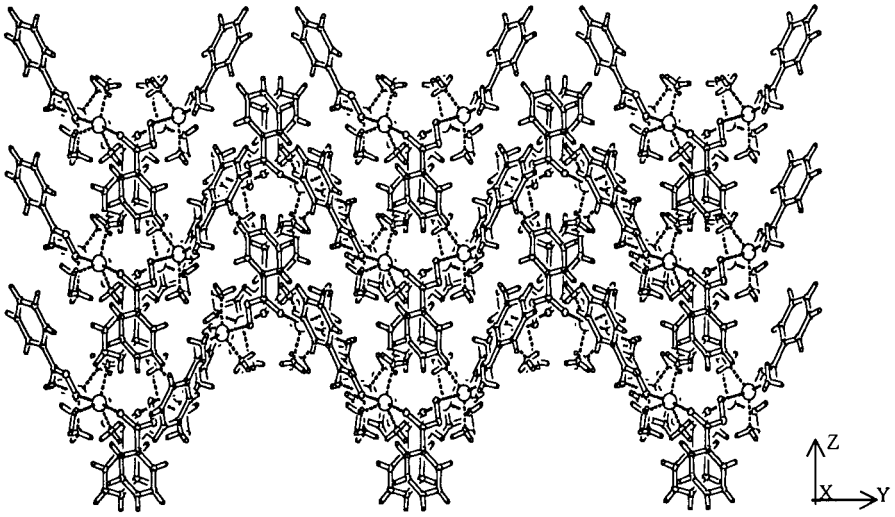

Figure 3. Crystal packing in $[Me_3Sn(O_2N_2Ph)]_4$; the molecules are stacked along the *c* axis

were recorded on a Bruker FT Raman spectrometer (IFS model 66).

Tetrakis[trimethyl(*N*-nitroso-*N*-phenylhydroxylaminato)tin(IV)]: NH_4[PhN(O)NO] (0.20 g, 1.29 mmol) was dissolved in 10 mL water and this solution was added to a solution of Me_3SnCl (0.26 g, 1.30 mmol) in 10 mL water. The product was formed immediately as a pale yellow precipitate. After stirring for 20 minutes at room temperature, the mother liquor was removed and the product was dried. Recrystallisation from n-heptane gave the title compound as colourless crystals. Yield: 0.24 g (62%); m.p. 81−85°C. − FT-IR (KBr): $\tilde{\nu}$ = 1594 cm^{-1} (C−H), 1487 (C−H), 1463 (C−H), 1344 (N−N), 1299 (C−H), 1224 (N=O), 1186 (N=O), 919 (ONNO), 779 (C−H), 755 (C−H), 689 (C−H), 555 (SnC_3), 542 (Sn−C), 520 (SnC_3), 387 (Sn−O), 280 (C−H), 230 (C−H), 142 (SnC_3). − FT-Raman: $\tilde{\nu}$ = 1594 cm^{-1} (C−H), 1491 (C−H), 1346 (N−N), 1288, 1221 (N=O), 1187 (N=O), 1003 (C−H), 918 (ONNO), 546 (Sn−C), 516 (SnC_3), 141 (SnC_3). − $C_{36}H_{56}N_8O_8Sn_4$ (1203.73): calcd. X-ray Crystallographic Study: Crystal data for $[Me_3Sn(O_2N_2Ph)]_4$: $C_{36}H_{56}N_8O_8Sn_4$, M = 1203.73, tetragonal, space group $P\bar{4}2_1c$ (No. 114), with $a = b$ = 18.084(3), c = 7.383(1) Å, $\alpha = \beta = \gamma$ = 90°, V = 2414.5(7) $Å^3$, Z = 8, ρ_{calcd} = 1.656 Mg/m^3, $F(000)$ = 1184, λ = 0.71073 Å, T = 293(2) K, μ(Mo-K_α) = 2.096 mm^{-1}, crystal size 0.45 × 0.25 × 0.24 mm. Intensity data of 11745 reflections were measured (2.25 ≤ 2Θ ≤ 34.98°) on an Enraf−Nonius CAD-4 diffractometer (ω-2Θ scans) of which 5245 were independent (R_{int} = 0.0197). The intensities of the standard reflections indicated a crystal decay of 28% which was corrected. A semi-empirical (ψ-scan) absorption correction was also applied (min/max transmission: 0.933/0.974). The structure was solved by direct methods (SHELXS-97)[25a] and refined by full-matrix least squares (SHELXL-97).[25b] 5245 reflections were employed in the structure refinement (138 parameters, 0 restraints). The final R values were $R1$ = 0.0238 [$I \geq 2\sigma(I)$] and $wR2$ = 0.0486 (all data); min/max residual electron density −0.467/0.262 $eÅ^{-3}$. All non-hydrogen atoms were refined anisotropically. Hydrogen atomic positions were generated from assumed geometries. A riding model refinement was applied for the hydrogen atoms. Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-114414. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: int. code +44−1223/336−033; E-mail: deposit@ccdc.cam.ac.uk].

[21] In principle *mutatis mutandis* the tin macrocycles may adopt one of the four packing types characterized by the rescaled ranges β [$sa \leq$ 7.6 Å], γ [8.4 ≤ sa ≤ 9.8 Å], herringbone [9.8 ≤ sa ≤ 14.5 Å] and sandwich herringbone [$sa \leq$; 14.5 Å] (sa: the shortest crystal axis). The applicability of the empirical rescaling was tested on a 16-membered inorganic tin macrocycles. The $[Me_3Sn(O_2PPh_2)]_4$[12] complex crystallizes in an orthorhombic system (space group *Pnma*) with a short crystal axis of 14.501 Å which suggests a herringbone or sandwich-herringbone packing. Indeed, in this complex a sandwich-herringbone packing can be recognized. In contrast, in the oblique unit cell (space group $P\bar{1}$) of $[Me_3Sn(C_5Me_5W(O)(\mu\text{-}O)_2)]_4$[13] complex no such packing rules can be realised.

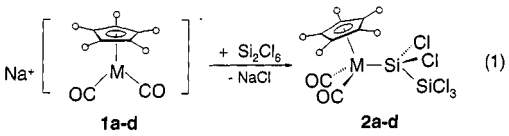
Dedicated to Professor Helmut Werner on occasion of his 65th birthday

Keywords: Metallo-disilanes / Ligand exchange at silicon / Transition metal effect / Raman spectroscopy / Density functional theory

Reaction of the sodium metalates $Na[M(CO)_2C_5R_5]$ [M = Fe, R = H (**1a**), Me (**1b**); M = Ru, R = H (**1c**), Me (**1d**)] with an equimolar amount of hexachlorodisilane yields the metallo-pentachlorodisilanes $C_5R_5(OC)_2M–SiCl_2–SiCl_3$ (**2a–d**), which can be converted into the pentahydrido analogues $C_5R_5(OC)_2M–SiH_2–SiH_3$ (**3a–c**) via Cl/H exchange with $LiAlH_4$. Due to the activating effect of the transition metal fragment chlorination of **3a–c** with CCl_4 or $HCCl_3$ occurs at the α-silicon to give $C_5R_5(OC)_2M–SiCl_2–SiH_3$ (**4a–c**). The metallo-disilanes were characterised by ^1H-, ^{13}C-, ^{29}Si-NMR, IR and especially Raman spectroscopy. The structures of $C_5H_5(OC)_2Fe–Si_2Cl_5$ (**2a**) and $C_5Me_5(OC)_2Fe–Si_2H_5$ (**3b**) have been determined by X-ray analysis; **2a,b**, **3a,b** were theoretically described by DFT calculations.



Introduction

Iron-substituted disilanes $Cp(OC)_2Fe–SiR_2–SiR_3$[1][2] have preferentially been the subject of studies concerning the photoinduced rearrangement to silyl(silylene) complexes $Cp(OC)Fe(=SiR_2)SiR_3$.[3] If organic substituents are attached to the silicon atoms this species represent a short-lived intermediate which is confirmed only by IR matrix studies[4] or by the isolated photolysis product $Cp(OC)_2Fe–SiR_3$.[3a–d] However, introduction of alkoxy groups at the β-silicon leads to oxygen stabilised cyclic (bis)silylene complexes $R_2Si^a–Cp(OC)Fe–SiR_2\cdots O^aR'(Si^a–O^a)$.[3e,f]

A limited number of investigations have been reported concerning complexes containing "inorganic" substituents at the silicon atoms, for instance hydrogen or halogen.[5][6] Therefore, we have undertaken efforts to establish efficient routes for the synthesis of metallo-pentachloro- and -pentahydridodisilanes.[6] These ligands offer the possibility to study the influence of the transition metal fragment on the exchange reactivities of the silicon atoms in α- or β-position as well as on the stability of the M–Si–Si bonding arrangement with respect to fragmentation. Support for the interpretation of the findings is expected from a detailed vibrational analysis using especially Raman spectroscopy combined with DFT calculations.

I. Preparative Results

In accordance with former experiments[6] a suspension of the sodium metalates **1a–d** in cyclohexane is combined with hexachlorodisilane in a molar ratio of 1:1 and the reaction mixture stirred at room temperature under exclusion of light for 3 to 48 hours to give the metallo-pentachlorodisilanes **2a–d** (Equation 1).

1a-d **2a-d** (1)

	a	b	c	d
M	Fe	Fe	Ru	Ru
—○	H	Me	H	Me

2a–d are isolated as pale yellow microcrystalline solids in good yields, which show considerable solubility in *n*-pentane and aromatic solvents. **2a–d** can be stored as solids under an atmosphere of nitrogen for months without decomposition.

Heterogeneous "salt elimination" according to Equation (1) is the only way to guarantee controlled mono-metallation of Si_2Cl_6 as analogous experiments with

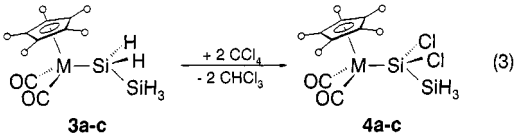
$Na[Fe(CO)_2Cp]$ (**1a**) performed by Hengge et al. proved using THF as a solvent.[5] In this case homogeneous reaction yields a mixture of **2a** and the bis(iron)disilane $[Cp(OC)_2Fe-SiCl_2]_2$ which makes separation necessary giving rise to a reduced yield of **2a** (41%).

The stability of the iron−silicon or ruthenium−silicon bonds of **2a−c** allows exchange reactions at the silicon atoms without Fe−Si bond cleavage. An attractive example in this context is the Cl/H exchange of the silicon bound chlorine atoms which is achieved by treatment of a solution of **2a−c** at −78°C in diethyl ether with $LiAlH_4$. For a molar ratio of 1:5 after 2 h of stirring at room temperature both silicons were fully hydrogen substituted (Equation 2).



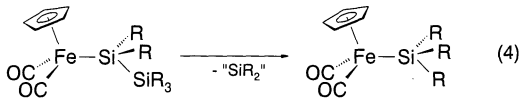
(2)

	a	b	c
M	Fe	Fe	Ru
R	H	Me	H

The metallo-disilanes **3a−c** are obtained after crystallisation from pentane at −78°C (**3b**) or sublimation in high vacuum (**3a,c**), respectively, as light yellow (**3a,b**) to colorless (**3c**) waxy solids, which show a good solubility in *n*-pentane and benzene.[7]

The pronounced electron releasing capacity of the transition metal fragment induces a highly hydridic character of the hydrogens at the α-silicon compared with that at the β-position, a fact that is clearly deduced from IR- and ^{29}Si-NMR data (see below).

As a consequence, the hydrogens of the metallo-pentahydridodisilanes **3a−c** next to the metal are selectively substituted by chlorine at room temperature after 3 hours using CCl_4 to give exclusively the metallo-dichlorodisilanes **4a−c** (Equation 3).



(3)

	a	b	c
M	Fe	Fe	Ru
—○	H	Me	H

The same procedure can be realised with $HCCl_3$, but more severe reaction conditions are necessary (40°C, 12 h). **4a−c**, which represent the first complexes bearing a dichloro-disilanyl ligand, are obtained as yellow solids in good yields, which are purified by crystallisation from pentane at −78°C. Solubility is comparable to that of **3a−c**.

A characteristic of ferrio-disilanes $Cp(OC)_2Fe-SiR_2-SiR_3$ (R = alykl) is the photoinduced rearrangement with elimination of the SiR_2 group to give the monosilyl complex $Cp(OC)_2Fe-SiR_3$ via oxidative addition of the Si−Si bond to the metal atom.[3] A comparable reaction, at least concerning the final product, is observed for the pentachloro- and pentahydridodisilanyl complexes **2a**,**c** and **3**.

In accordance with these results photolysis of **2a**/**3a** in benzene/cyclohexane at room temperature leads to the silyl iron complexes **5**[8] or **6**,[9] respectively, after 120 h. **2a** additionally shows this behaviour in the solid state (Equation 4).

(4)

The thermal stability of the metallo-disilanes **2, 3** decreases on going from the pentachloro- to the pentahydrido derivatives. Heating **2a** in cyclohexane to 65°C for 32 h does not result in any decomposition, while in the case of **3a** under these conditions $Cp(OC)_2Fe-SiH_3$ (**6**) is isolated quantitatively. A detailed examination of the silylene elimination involved in the photodegradation as well as trapping experiments concerning the silylenes SiH_2[10] and $SiCl_2$[11] are currently under way.

II. Spectroscopic Data

NMR Spectroscopy

Substantial information concerning the electronic character of the silicon atoms of **3a−c** is given by the ^1J(SiH) coupling. It is generally accepted that this parameter can be correlated with the s-electron density in the Si−H bond.[12] The SiH_2 units next to the transition metal give rise to a low value of the ^1J(SiH) coupling constants [179.5 Hz (**3a**), 172.4 Hz (**3b**), 181.0 Hz (**3c**)] compared to Si_2H_6[13] characterising the transition metal ligand as an efficient electron releasing group. The ^1J(SiH) value of the SiH_3 moiety is higher (184−186 Hz), but still below that of Si_2H_6 indicating a reduced "transition metal effect" on the β-silicon.

The difficulties of correlating the ^{29}Si-NMR shifts of organosilicon compounds on the basis of purely inductive effects have been pointed out in the literature.[14] Due to this fact only some empirical regularities of the ^{29}Si-NMR data will be discussed.

1.) The signals for **2** at low field (δ = −2 to +76) and **3** at high field (δ = −45 to −95) appear in the range characteristic of the corresponding disilanes Si_2R_6 [R = Cl (δ = −6.14);[15a] H (δ = −104.1)[15b]]. The metallo-dichlorodisilane **4a** with differing substituents at the silicon atoms follows these trends (**4a**: δ = +93 and −83). In each case the resonance of the metal-substituted silicon is characterised by an enormous low-field shift with the maximum for **4a** compared to the silicon in the β-position.

2.) The δ-value of the SiX_3 moiety is approximately identical for all species [δ = +1 to −2 (**2,** X = Cl), δ = −93 to −95 (**3,** X = H)]. In comparison to Si_2R_6 (R = Cl, H) the small low-field shift of this resonance of ca. 5−10 ppm indicates a minor influence of the transition metal fragment on the β-silicon of **2** and **3**. The largest difference (21 ppm)

is obtained for the SiH_3 resonance of the ferrio-dichlorodisilane **4a** ($\delta = -83$).

3.) Exchange of the iron against the ruthenium group causes a high-field shift of approximately 20 ppm for the α-silicon resonance. The chemical shift of the SiX_3 moieties remains unaffected.

Vibrational Spectroscopy and Density Functional Theory Calculations

Among the methods that can be used for the simulation of vibrational spectra, density functional methods are known to give very good results for vibrational wavenumbers compared to *ab initio* methods.[16]

a) Comparison of measured and calculated Raman bands of **2a**, **3a,b**:

The former assignments of the complex **3a** were based on normal coordinate analysis (NCA).[17] They agree with the results of DFT calculations. The simulation of vibrational spectra with NCA is based on a purely mechanical model, where an initial force constant matrix is chosen with a limited number of force constants [$(3N - 6)(3N - 5)/2$ in non-redundant internal coordinates for a nonlinear molecule], and then a force constant refinement is carried out.

Table 1. Comparison of measured (Raman spectra) and calculated wavenumbers of **3a** and **3b**

3a Measured [cm^{-1}]	**3a** Calculated [cm^{-1}]	**3b** Measured [cm^{-1}]	**3b** Calculated [cm^{-1}]	Mode description
2141	2177	/	2174	$\nu_{asym}(SiH_3)$
2132	2163	2135	2161	$\nu_{asym}(SiH_3)$
	2141		2141	$\nu_{sym}(SiH_3)$
2098	2126	2063	2108	$\nu_{asym}(SiH_2)$
2087	2098	2076	2082	$\nu_{sym}(SiH_2)$
2008	1906	2008	1887	$\nu_{sym}(CO)$
1959	1865	1959	1846	$\nu_{asym}(CO)$
1114	1102	594	575	Cp-ring breathing
606	611	606	617	$\nu_{asym}(FeC)$
441	425	449	425	ν(SiSi)
373	359	412	401	ν_{sym}(Fe-Cp)[a]

[a] Also partly a $C-CH_3$ out-of-plane bending vibration in Cp* compound.

Quantum mechanical calculations like DFT use another approach to obtain a force field: here, all necessary force constants are calculated by the second derivative of the energy with respect to the coordinates ($\partial^2 E/\partial q_i \partial q_j$). This method is more satisfying because of the avoidance of the empirical force constant refinement. Compared to conventional *ab initio*-methods, DFT has the advantage that an empirical scaling of force constants giving a *Scaled Quantum Mechanical* (SQM) force field of Pulay *et al.*[18] is not necessary to account for the lack of correlation energy. However, a scaling is often introduced to account for the anharmonicity. But we favoured to compare measured anharmonic wavenumbers with calculated *un*scaled harmonic wavenumbers rather than to introduce an empirical scaling procedure, because scaling does not change the fact we can get from the second derivatives only harmonic wavenumbers.

In comparison to NCA, the wavenumbers for the CH stretching vibrations obtained from DFT calculation and partly the SiH stretching vibrations were calculated to be too high.

Significant is the lowering of the ring breathing vibration to 575 cm^{-1}, according to the higher mass of the ring substituents.

Difficulties in the assignment of the pentamethylcyclopentadienyl complex **3b** arise from the great number of additional bands especially in the ν(C−C) and δ(CH) region due to the five methyl groups. Most of these vibrations are not summarized in Table 1.

Further complications originate from coupling of different internal coordinates: some formerly ″pure″ vibrations are coupled with vibrations of the substituent, e.g. the ν_{sym}-(Fe−Cp) is in the case of the pentamethylcyclopentadienyl complex also partly a $C-CH_3$ out-of-plane bending vibration. This gives the explanation for the unexpected shift in the calculations and in the spectra (because of the higher mass of the Cp*) towards higher wavenumbers [from 359 to 401 cm^{-1} (calc.), from 373 to 412 cm^{-1} (exp.)]. Consequently, the wavenumber shift in this case *cannot* be taken as a direct measure of bond strength. However, for the ν(CO) value, such an interpretation is possible, because this vibration is only coupled with the other CO stretching vibration. Both vibrations ν_{sym}(CO) and ν_{asym}(CO) are shifted by 35 cm^{-1} to lower wavenumbers switching from a cyclopentadienyl (Cp) to a pentamethylcyclopentadienyl (Cp*) ligand in the iron compounds **2a,b** and **3a,b**, respectively, which is in accordance with the higher electronic density in the case of **3b** causing a stronger back bonding from the metal to the carbonyl carbon and, consequently, a weaker CO bond. This shift is confirmed by the DF calculation, although the absolute value of ν_s(CO) and ν_{as}(CO) differ by nearly 100 cm^{-1} from the experimental data. In addition, the change of substituents at the silicon from H (**3a,b**) to Cl (**2a**) causes a shift of the ν(CO) band to higher wavenumbers. The identical spectral position of the carbonyl modes in **2b** and **3a** shows, that the difference in the −I-effect between the Cl atoms of **2b** and the H atoms of **3a** is compensated by the different electronic donor capacities of the Cp* and Cp ligands. Characterisation of the SiH stretching modes is an effective way to get information about the electronic structure of the Si atom and how it is influenced by the metal fragment. The IR spectra of **3a** show two weak bands at 2071 and 2133 cm^{-1}, which are assigned to the SiH stretching modes of the silylene and the silyl fragment.[19] In this case the signal at 2133 cm^{-1} can be assigned to an overlap of the symmetric and antisymmetric stretching modes of the silyl group.[20] Compound **3b**, with the better electron donating ligand C_5Me_5, shows the stretching modes of the silylene group at 2063 cm^{-1} [ν_{as}-(SiH_2)] and at 2076 cm^{-1} [ν_s(SiH_2)]. The symmetric and the antisymmetric stretching modes of the silyl group overlap in their spectral position and appear at 2135 cm^{-1}.

The SiSi stretching mode is found in a narrow spectral range around 445 cm^{-1} and its position is primarily independent from all the other ligands. The DFT calculations show that this vibration is indeed a pure SiSi stretching, and no other internal coordinates are involved. So, we can conclude that changes in the electronic density of the metal atom have no influence on this bond.

Table 2. Comparison of measured (FT Raman spectrum) and calculated wavenumbers of **2a**

Measured [cm^{-1}]	Calculated [cm^{-1}]	Mode description
2022	1937	ν_{sym}(CO)
1991	1901	ν_{asym}(CO)
1120	1102	Cp ring breathing
607	600	ν_{asym}(FeC)
528	523	ν(SiSi) + ν(SiCl)
493	496	ν(SiCl) + ν(SiSi) +
386	345	ν_{asym}(Fe-Cp)
290	321	ν_{asym}(Fe-Cp)
233	249	ν(FeSi) + δ(SiCl)
213	200	($SiCl_3$) in phase def. + ($SiCl_2$) bending
202	182	($SiCl_3$) in phase def.

The measured spectrum in Table 2 is a Fourier transform Raman spectrum with excitation in the NIR (1064 nm), because in the visible region decomposition in the laser focus occurred. The CO stretching vibrations appear at 2022 and 1991 cm^{-1}, indicating a higher CO stretching force constant than in the case of $Cp(OC)_2Fe-SiH_2SiH_3$ (2008 and 1959 cm^{-1}) which is in accordance with the higher electronegativity of the chlorine atom. The CC stretching vibrations of the coordinated cyclopentadienyl anion as well as the significant Cp ring breathing vibration do not change compared to $Cp(OC)_2Fe-SiH_2SiH_3$. For many other vibrations, the internal coordinates are more coupled than in $Cp(OC)_2Fe-SiH_2SiH_3$. This is an effect of the higher mass of chlorine, which is much closer to the mass of the other atoms compared to hydrogen. In contrast, for **3a,b** no band exists that can be assigned to be a pure Si−Si stretching vibration.

III. X-ray Analysis of $C_5H_5(OC)_2Fe-SiCl_2SiCl_3$ (2a), $C_5Me_5(OC)_2Fe-SiH_2SiH_3$ (3b) and Comparison to DFT Calculations

Final verification of the structures of **2a** and **3b** came from X-ray crystallographic studies (Figures 1−3). **3b** is to our knowledge the first structurally characterized metalloderivative of Si_2H_6.

The octahedral coordination sphere at the iron centre is in both cases indicated by the ligand-metal-ligand angles close to 90°. Larger angles are found between the carbonyl carbon atoms [94.2(11)° (**2a**); 96.0 (11)° (**3b**)] while the angles between the silicon atom and the CO ligands [88.4(8)°/88.3(8)° (**2a**); 85.5(8)°/88.5(8)° (**3b**)] are smaller. The Fe−Si bond length with a value of 2.224(7) Å (**2a**), 2.298(9) Å (**3b**) lies within the range of known iron silicon compounds[21a−h] with the usual trend of a bond shortage due to electronegative substituents like chlorine.[21c] The Si1−Si2 distance of 2.333(9) Å (**2a**), 2.335(11) Å (**3b**) is close to that of known disilanes (e. g. Me_6Si_2: 2.340 Å[22])

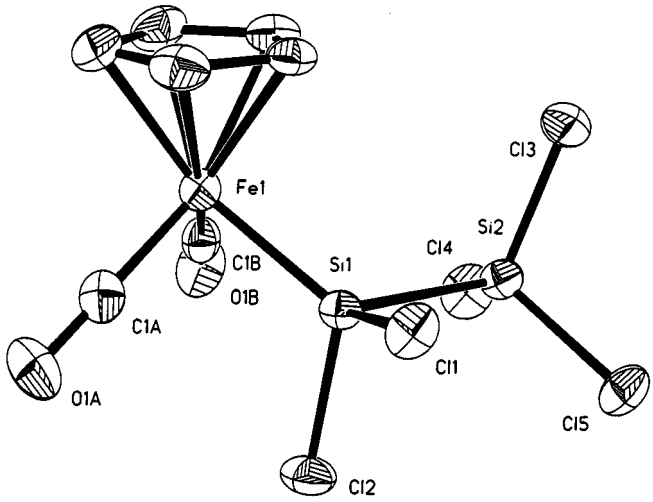


Figure 1. ORTEP view of $C_5H_5(OC)_2Fe-SiCl_2-SiCl_3$ (**2a**). Selected bond lenghts [Å], angles [°] and torsion angles [°]: Fe−Si1 2.2239(7), Si1−Si2 2.3333(9), Si1−Cl1 2.0859(8), Si1−Cl2 2.0811(9), Si2−Cl3 2.0410(9), Si2−Cl4 2.0421(9), Si2−Cl5 2.0358(9), Fe−C1a−O1a 178.9(3), Fe−C1b−O1b 178.8(9), Cl1−Si1−Si2 99.53(3), Cl3−Si2−Si1 111.60(4), Fe−Si1−Si2 119.20(3), C1a−Fe1−Si1 88.27(8), Fe1−Si1−Si2−Cl5 175.05(3), Fe1−Si1−Si2−Cl4 −63.76(5), Fe1−Si1−Si2−Cl3 55.53(4), Cl1−Si1−Si2−Cl5 46.59(5), C1a−Fe1−Si1−Cl1 −80.11(8), C1b−Fe1−Si1−Cl1 −174.37(8), Cp(Z)−Fe1−Si1−Si2 68.2, Cp(Z)−Fe1−Si1−Cl1 51.7, Cp(Z)−Fe1−Si1−Cl2 6.2.

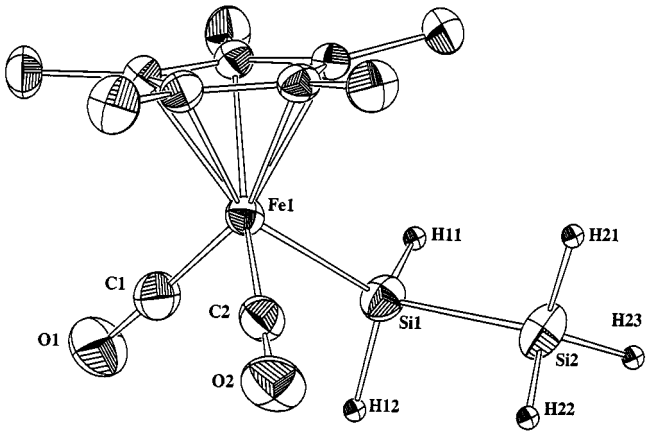

Figure 2. ORTEP view of $C_5Me_5(OC)_2Fe-SiH_2-SiH_3$ (**3b**). Selected bond lenghts [Å], angles [°] and torsion angles [°]: Fe−Si1 2.2980(9), Si1−Si2 2.3355(11), Si1−H11 1.43(2), Si1−H12 1.47(2), Si2−H21 1.41(3), Si2−H22 1.37(3), Si2−H23 1.42(3); C1−Fe1−Si1 85.46(8), C2−Fe1−Si1 88.52(8), H11−Si1−H12 102.7(12),H11−Si1−Fe 114.7(9), H12−Si1−Fe 113.4(9), H11−Si1−Si2 106.6(9), Si2−Si1−Fe 115.15(5), H21−Si2−H22 106.0(16), H21−Si2−Si1 111.4(12), H23−Si2−Si1 113.2(12), C1−Fe−C2 95.96(11), Fe−C1−O1 178.6(2), Fe−C2−O2 177.9(2); C2−Fe−Si1−Si2 −50.50(8), C1−Fe−Si1−Si2 −146.60(8), H11−Si1−Si2−H21 83.0(16), H11−Si1−Si2−H22 −159.3(14), H11−Si1−Si2−H23 −38.3(15), H12−Si1−Si2−H21 −169.3(16), H12−Si1−Si2−H22 −51.6(15), H12−Si1−Si2−H23 69.4(16), Fe−Si1−Si2−H21 −45.4(13), Fe−Si1−Si2−H22 −72.3(11), Fe−Si1−Si2−H23 −166.7(13), Cp(Z)−Fe1−Si1−Si2 82.56, Cp(Z)−Fe1−Si1−H11 41.72, Cp(Z)−Fe1−Si1−H12 159.25.

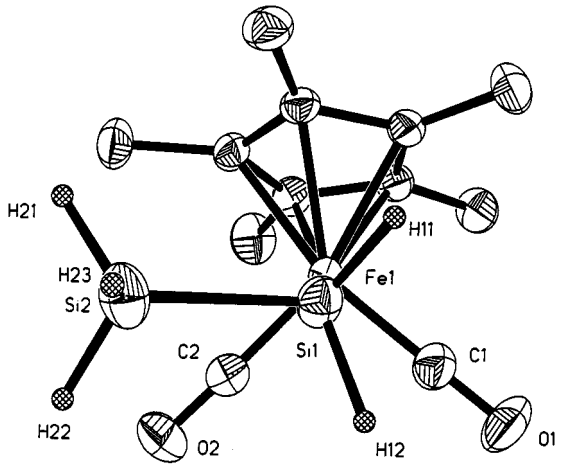

Figure 3. Newman like projection along the Fe−Si bond of **3b**

as well as to other disilanyl-metal-complexes[21f] including the tungsten derivative $C_5Me_5(OC)_2(Me_3P)W-SiCl_2-SiCl_3$ (Si1−Si2: 2.350 Å).[6] While Si−Cl distances of **2a** at Si2 (Si2−Cl3 2.0410(9), Si2−Cl4 2.0421(9), Si2−Cl5 2.0358(9) Å) are in the range of chlorosilanes,[21i] the analogous distances at the metal bound silicon exhibit a significant elongation (Si1−Cl1 [2.086(8) Å], Si1−Cl2 [2.081(9) Å]) due to the electron releasing capacity of the transition metal fragment. The Newman projection along the Fe−Si bond (Figure 3) reveals a staggered pseudo-ethane conformation with the following pairs of *"trans"*-arranged substituents: Cp*/X, CO/X, CO/SiX_3 (X = Cl, H).The gauche position of the SiX_3 group (X = H, Cl) with respect to the cyclopentadienyl unit found for **2a**, **3b** is typical for pseudo-tetrahedral halfsandwich iron complexes of the type $C_5R_5(OC)_2Fe-Si_2X_5$ (X = H, Cl, alkyl);[21h] at the metal centre more crowded complexes like the pseudo tetragonal monopyramidal tungsten compound$C_5Me_5(OC)_2(Me_3P)W-SiCl_2-SiCl_3$ prefer the trans arrangement.[6] Distorsion with respect to the ideal conformation of about 20° (**3b**)/ 8° (**2a**) for all the substituents at Si1 deduced from the dehedral angles Cp(Z)−Fe1−Si1−Si2 (82.6°)/(68.2°), Cp(Z)−Fe1−Si1−H11 (41.7°)/ Cp(Z)−Fe1−Si1−Cl1 (51.7°) and Cp(Z)−Fe1−Si1−H12 (159.3°)/ Cp(Z)−Fe1−Si1−Cl2 (6.2°) indicates the higher sterical demand of the SiX_3 group compared to the hydrogen or chlorine atoms.

The octahedral coordination sphere is also found in the calculation, and the corresponding bond angles show a very good agreement between the measured and calculated structures. In our calculations, the Si−Cl bond lengths of **2a** are somewhat overestimated, but they show the same behaviour concerning the effect of the iron fragment close to Si1, where the Si−Cl bonds are longer than those at Si2. Comparison of X-ray data of **3b** and the calculated structural data obtained by DFT method reveals a slightly different conformation, which is deduced from bond and torsion angles. The Si_2H_5 moiety is turned clockwise about 10° around the Fe−Si bond. However, the structural parameters reproduce reasonably the experimental values. An interesting aspect of the calculation are the Si−H bond lengths, which cannot be determined by X-ray structure analysis with satisfying accuracy. In the DFT calculation, the bond lengths at Si1 (next to the iron fragment) are elongated compared to the SiH_3-group, a result that parallels

Table 3. Comparison of selected structural parameters from X-ray data and DFT calculations for $C_5H_5(OC)_2FeSiCl_2-SiCl_3$ (**2a**), $C_5Me_5(OC)_2Fe-SiH_2-SiH_3$ (**3b**)

the finding for the Si_2Cl_5 derivative (*vide supra*) and offers a reasonable explanation for the higher reactivity of the SiH_2-group compared to the SiH_3 moiety. This difference is in addition established in the measured as well as in the calculated vibrational spectrum of **3b**.

Experimental Section

NMR: Bruker AMX 400 (400.1 MHz, 100.6 MHz and 79.5 MHz for ^1H, ^{13}C and ^{29}Si, respectively). [D_6]benzene as a solvent (used unless otherwise stated) $\delta_H = 7.15$, $\delta_C = 128.0$; for ^{29}Si ^2H-Lock internal, rel. TMS external. − IR: Perkin−Elmer 283. − MS: Varian MAT 112 S (70 eV). All reactions were performed under an atmosphere of purified nitrogen. Solvents were dried according to conventional procedures, distilled and saturated with N_2 prior to use. − DTA: Du Pont 9000. − Starting Materials: Na[Fe(CO)$_2$C$_5$R$_5$] (R = H,[23a] Me[23b]), Na[Ru(CO)$_2$C$_5$R$_5$] (R = H,[24a] Me[24]).

1. 1-[Dicarbonyl(η^5-cyclopentadienyl)ferrio]-1,1,2,2,2-pentachlorodisilane (2a): A suspension of 2150 mg (10.8 mmol) of Na[Fe(CO)$_2$Cp] (**1a**) in 50 mL of cyclohexane is treated with 3190 mg (12.0 mmol) of hexachlorodisilane and the mixture is stirred for 3 d at room temperature in the absence of light. After filtration of insoluble material (unreacted **1a** and formed NaCl), removal of the solvent and excess of hexachlorodisilane in vacuo the dark red residue is treated 6 times with 30 mL of pentane. The combined extracts are evaporated in vacuo to 15 mL and cooled to −78°C. Crystallised **2a** is filtered off, washed with 10 mL of cold pentane and dried in vacuo. − Yield 3800 mg (86%). − Pale yellow microcrystalline powder. − M.p. 63−64°C. − ^1H NMR: δ = 4.16 (s, H_5C_5). − ^{29}Si NMR ($CDCl_3$): δ = 76.81 (s, α-Si), −2.37 (s, β-Si). − IR (pentane): $\tilde{\nu}$ = 2035 cm^{-1} (vs), 1998 (vs) [ν(CO)]. − MS (rel. to ^{28}Si, ^{35}Cl and ^{56}Fe, 70 eV, 30°C): *m/z* (%) = 408 (3, $[M]^+$), 380 (8, $[M - CO]^+$), 352 (30, $[M - 2CO]^+$), 275 (55, $[M - SiCl_3]^+$), 254 (77, $[M - 2CO, - SiCl_2]^+$), 247 (11, $[M - CO, - SiCl_3]^+$), 156 (87, $[CpFeCl]^+$), 121 (44, $[CpFe]^+$), 93 (100, $[CpSi]^+$), 91 (22, $[FeCl]^+$). − $C_7H_5Cl_5FeO_2Si_2$ (410.40): calcd. C 20.48, H 1.23, Cl 43.19; found C 20.10, H 1.51, Cl 43.50.

2. 1-[Dicarbonyl(η^5-pentamethylcyclopentadienyl)ferrio]-1,1,2,2,2-pentachlorodisilane (2b): According to **1.** from 1880 mg (6.96 mmol) of Na[Fe(CO)$_2$C$_5$Me$_5$] (**1b**) and 2058 mg (7.65 mmol) of hexachlorodisilane in 60 mL of cyclohexane after 18 h. The obtained residue is stirred for 1 h with 35 mL of benzene, insoluble material filtered off and the clear filtrate evaporated in vacuo to 10 mL. After addition of 40 mL of *n*-pentane **2b** precipitates, is filtered off, washed with 20 mL of cold pentane and dried in vacuo. − Yield 2100 mg (63%). − Pale yellow microcrystalline powder. − M.p. 165°C. − ^1H NMR: δ = 1.50 [s, $(H_3C)_5C_5$]. − ^{13}C NMR: δ = 212.7 (s, CO), 97.76 [s, $C_5(CH_3)_5$], 9.16 [s, $(CH_3)_5C_5$]. − ^{29}Si NMR: δ = 75.65 (s, α-Si), −0.20 (s, β-Si). − IR (pentane): $\tilde{\nu}$ = 2013 cm^{-1} (s), 1981 (sh), 1975 (vs) [ν(CO)]. − MS (rel. to ^{28}Si, ^{35}Cl and ^{56}Fe, 70 eV, 80°C): *m/z* (%) = 478 (2, $[M]^+$), 450 (3, $[M - CO]^+$), 422 (15, $[M - 2CO]^+$), 345 (58, $[M - SiCl_3]^+$), 324 (12, $[M - 2CO, - SiCl_2]^+$), 289 (26, $[M - 2CO, - SiCl_3]^+$), 226 (100, $[C_5Me_5FeCl]^+$), 191 (83, $[C_5Me_5 - Fe]^+$), 163 (80, $[C_5Me_5Si]^+$). − $C_{12}H_{15}Cl_5FeO_2Si_2$ (480.55): calcd. C 29.99, H 3.15, Cl 36.89; found C 30.46, H 3.20, Cl 37.10.

3. 1-[Dicarbonyl(η^5-cyclopentadienyl)ruthenio]-1,1,2,2,2-pentachlorodisilane (2c): According to **1.** from 520 mg (2.12 mmol) of Na[Ru(CO)$_2$Cp] (**1c**) and 720 mg (2.90 mmol) of hexachlordisilane in 20 mL of cyclohexane after 14 h. − Yield 561 mg (58%). − Yellow microcrystalline powder. − M.p. 72°C (DTA). − ^1H NMR: δ = 4.44 (s, H_5C_5). − ^{13}C NMR: δ = 196.8 (s, CO), 87.84 (s, C_5H_5). − ^{29}Si NMR: δ = 58.31 (s, α-Si), −1.19 (s, β-Si). − IR (pentane): $\tilde{\nu}$ = 2043 cm^{-1} (vs), 1997 (vs) [ν(CO)]. − $C_7H_5Cl_5O_2RuSi_2$ (455.62): calcd. C 18.45, H 1.11, Cl 38.91; found C 19.14, H 1.23, Cl 38.46.

4. 1-[Dicarbonyl(η^5-pentamethylcyclopentadienyl)ruthenio]-1,1,2,2,2-pentachlorodisilane (2d): According to **1.** from 780 mg (2.35 mmol) of K[Ru(CO)$_2$C$_5$Me$_5$] (**1d**) and 760 mg (2.82 mmol) of hexachlorodisilane in 60 mL of cyclohexane after 18 h. − Yield 1005 mg (85%). − Yellow microcrystalline powder. − M.p. 62°C (decomp., DTA). − ^1H NMR: δ = 1.45 [s, $(H_3C)_5C_5$]. − ^{13}C NMR: δ = 199.5 (s, CO), 101.4 [s, $C_5(CH_3)_5$], 9.5 [s, $(CH_3)_5C_5$]. − ^{29}Si NMR: δ = 56.69 (s, α-Si), 1.29 (s, β-Si). − IR (pentane): $\tilde{\nu}$ = 2024 cm^{-1} (vs), 1980 (vs) [ν(CO)]. − $C_{12}H_{15}Cl_5RuO_2Si_2$ (525.76): calcd. C 27.41, H 2.88; found C 28.46, H 3.20.

5. 1-[Dicarbonyl(η^5-cyclopentadienyl)ferrio]disilane (3a): A suspension of 347 mg (9.14 mmol) $LiAlH_4$ in 40 mL of diethyl ether is cooled to −78°C and 750 mg (1.83 mmol) of Cp(OC)$_2$Fe−$SiCl_2$−$SiCl_3$ (**2a**), dissolved in 30 mL of diethyl ether, are added within 15 min. After 30 min of stirring the reaction mixture is warmed up to room temperature and stirred for another 2 h. Insoluble materials are filtered off, the solvent removed in vacuo and the oily residue extracted with 35 mL of petroleum ether (boiling range 50−70°C). After reducing the volume of the extract in vacuo to 6 mL and cooling to −78°C **3a** precipitates, is separated, washed with 5 mL of cold pentane and dried in vacuo. Further purification is achieved by sublimation at 80−85°C/10^{-2} Torr. − Yield 310 mg (71%). − Yellow, microcrystalline powder. − M.p. 16−17°C. − ^1H NMR: δ = 4.10 (s, 5 H, H_5C_5), 3.95 [q, ^1J(HSi) = 179.5 Hz, ^2J(HSiSi) = 4.6 Hz, ^3J(HSiSiH) = 3.2 Hz, 2 H, H_2Si], 3.66/3.30 [t, ^1J(HSi) = 186.1 Hz, ^{2}J(HSiSi) = 7.7 Hz, ^3J(HSiSiH) = 3.2 Hz, 3 H, H_3Si]. − ^{29}Si NMR: δ = −53.92 (SiH_2), −93.81 [^1J(SiSi) = 67.3 Hz, SiH_3]. − IR (pentane): $\tilde{\nu}$ = 2133 cm^{-1} (w, SiH_3), 2087 (w, SiH_2) [ν(SiH)]; 2007 (s), 1968 (vs) [ν(CO)]. − MS (rel. to ^{28}Si and ^{56}Fe, 70 eV, 35°C): *m/z* (%) = 238 (22, $[M]^+$), 210 (11, $[M - CO]^+$), 182 (19, $[M - 2CO]^+$), 179 (39, $[M - CO, - SiH_3]^+$), 151 (31, $[M - 2CO, - SiH_3]^+$), 149 (68, $[CpFe-Si]^+$), 121 (100, $[CpFe]^+$), 93 (71, $[CpSi]^+$). − $C_7H_{10}FeO_2Si_2$ (238.20): calcd. C 35.29, H 4.24; found C 35.84, H 4.51.

6. 1-[Dicarbonyl(η^5-pentamethylcyclopentadienyl)ferrio]disilane (3b): According to **5.** from 1010 mg (2.10 mmol) of $C_5Me_5(OC)_2Fe-SiCl_2-SiCl_3$ (**2b**) and 395 mg (10.5 mmol) of $LiAlH_4$ in 80 mL of diethyl ether after stirring for 4 h. **3b** is purified by recrystallisation from 15 mL of *n*-pentane. − Yield 630 mg (97%). − Deep yellow crystals. − M. p. 64°C. − ^1H NMR: δ = 3.75 [m, 5 H, ^1J(HSi) = 172.4 Hz (SiH_2), ^1J(HSi) = 184.4 Hz (SiH_3), H_5Si_2], 1.40 [s, 15 H, $(H_3C)_5C_5$]. − ^{13}C NMR: δ = 215.68 (s, CO), 95.12 [s, $C_5(CH_3)_5$], 9.42 [s, $(CH_3)_5C_5$]. − ^{29}Si NMR: δ = −45.19 (SiH_2), −95.61 (SiH_3). − IR (petroleum ether): $\tilde{\nu}$ = 2127 cm^{-1} (w, SiH_3), 2071 (w, SiH_2) [ν(SiH)]; 1994 (vs), 1947 (vs) [ν(CO)]. − MS (rel. to ^{28}Si and ^{56}Fe, 70 eV, 35°C): *m/z* (%) = 308 (15, $[M]^+$), 280 (60, $[M - CO]^+$), 252 (7, $[M - 2CO]^+$), 250 (55, $[M - CO, - SiH_2]^+$), 249 (23, $[M - CO, - SiH_3]^+$), 248 (100, $[M - Si_2H_5]^+$), 247 (24, $[M - Si_2H_6]^+$), 219 (87, $[C_5Me_5FeSi]^+$), 191 (48, $[C_5Me_5Fe]^+$), 163 (83, $[C_5Me_5Si]^+$). − $C_{12}H_{20}FeO_2Si_2$ (308.35): calcd. C 46.74, H 6.55; found C 47.05, H 6.68.

7. 1-[Dicarbonyl(η^5-cyclopentadienyl)ruthenio]disilane (3c): According to **5.** from 91 mg (2.39 mmol) of $LiAlH_4$ and 210 mg (0.47 mmol) of Cp(OC)$_2$Ru−$SiCl_2$−$SiCl_3$ (**2c**) in 30 mL of diethyl ether after stirring for 2 h at room temperature, extraction of the residue with 10 mL of petroleum ether (40−60) and sublimation at 40°C/10^{-5} Torr. − Yield 112 mg (82%). − Colorless waxy solid. −

M.p. −12 to −14)°C. − ^{1}H NMR: δ = 4.41 (s, 5 H, H_5C_5), 3.73 [q, ^3J(HSiSiH) = 3.36 Hz, 2 H, H_2Si], 3.66 [t, ^3J(HSiSiH) = 3.36 Hz, 3 H, H_3Si]. − ^{29}Si NMR: δ = −76.6 [dq, ^1J(SiH) = 181.0 Hz, ^2J(SiSiH) = 5.0 Hz, SiH_2], −94.0 [dt, ^1J(SiH) = 186.1 Hz, ^2J(SiSiH) = 6.6 Hz, SiH_3]. − IR (pentane): $\tilde{\nu}$ = 2129 cm^{-1} (w, SiH_3), 2084 (w, SiH_2) [ν(SiH)]; 2022 (vs), 1978 (vs) [ν(CO)]. − $C_7H_{10}O_2RuSi_2$ (283.39): calcd. C 29.67, H 3.56; found C 29.54, H 3.51.

8. 1-[Dicarbonyl(η^5-cyclopentadienyl)ferrio]-1,1-dichlorodisilane (4a): A solution of 175 mg (0.73 mmol) of $Cp(OC)_2Fe-SiH_2-SiH_3$ (**3a**) in 5 mL of cyclohexane is combined with 566 mg (3.68 mmol) of CCl_4 and the reaction mixture stirred for 3 h at room temperature and monitored by ^{1}H NMR. After removing volatile components (solvent, formed chloroform and excess of CCl_4) in vacuo the orange residue is extracted twice with 7 mL each of petroleum ether (50−70) and the volume of the extract is reduced in vacuo to 5 mL. **4a** crystallises after cooling for 3 h to −78°C, is filtered off and dried in vacuo at 10°C. − Yield 205 mg (91%). − Yellow microcrystalline powder. − M.p. 23−24°C. − ^{1}H NMR: δ = 4.07 (s, 5 H, H_5C_5), 3.83 (s, 3 H, HSi). − ^{13}C NMR: δ = 211.5 (s, CO), 85.07 (s, C_5H_5). − ^{29}Si NMR: δ = 93.6 (s, α-Si), −83.23 (s, β-Si). − IR (pentane): $\tilde{\nu}$ = 2150 cm^{-1} [w, ν(SiH)]; 2028 (s), 2021 (m), 1989 (vs), 1981 (s) [ν(CO)]. − MS (rel. to ^{28}Si, ^{35}Cl and ^{56}Fe, 70 eV, 35°C): *m/z* (%) = 306 (8, $[M]^+$), 278 (41, $[M - CO]^+$), 250 (7, $[M - 2CO]^+$), 247 (49, $[M - CO, - SiH_3]^+$), 219 (86, $[M - 2CO, - SiH_3]^+$), 149 (18, $[CpFeSi]^+$), 121 (37, $[CpFe]^+$), 93 (100, $[CpSi]^+$). − $C_7H_8Cl_2FeO_2Si_2$ (307.08): calcd. C 27.32, H 2.49, Cl 22.81; found C 27.38, H 2.63, Cl 23.00.

9. 1-[Dicarbonyl(η^5-pentamethylcyclopentadienyl)ferrio]-1,1-dichlorodisilane (4b): According to **8.** from 210 mg (0.68 mmol)/90 mg (0.29 mmol) of $C_5Me_5(OC)_2Fe-SiH_2-SiH_3$ (**3b**) and 7 mL of CCl_4/ 2 mL of $CHCl_3$ after 80 min at room temperature/12 h at 40°C. The brown residue obtained is extracted with 10 mL of a 1:1 mixture of petroleum ether (50−70)/methylcyclohexane, the extract evaporated in vacuo to dryness and the residue dissolved in 4 mL of pentane. **4b** crystallises on cooling to −78°C. − Yield 200 mg (77%)/ 98 mg (89%). − Yellow microcrystalline powder. − M.p. 119−120°C. − ^{1}H NMR: δ = 3.97 (s, 3 H, H_3Si), 1.49 [s, 15 H, $(H_3C)_5C_5$]. − ^{13}C NMR: δ = 215.6 (s, CO), 94.9 [s, $C_5(CH_3)_5$], 9.41 [s, $(CH_3)_5C_5$]. − IR (pentane): $\tilde{\nu}$ = 2141 cm^{-1} [w, ν(SiH)]; 2008 (s), 2001 (m), 1970 (vs), 1961 (s) [ν(CO)]. − MS (rel. to ^{28}Si, ^{35}Cl and ^{56}Fe, 70 eV, 60°C): *m/z* (%) = 376 (4, $[M]^+$), 348 (14, $[M - CO]^+$), 320 (8, $[M - 2CO]^+$), 289 (8, $[M - 2CO, - SiH_3]^+$), 226 (4, $[C_5Me_5FeCl]^+$), 191 (13, $[C_5Me_5Fe]^+$), 163 (100, $[C_5Me_5Si]^+$), 135 (19, $[C_5Me_5]^+$). − $C_{12}H_{18}Cl_2FeO_2Si_2$ (377.23): calcd. C 38.21, H 4.82, Cl 18.80; found C 38.33, H 4.92, Cl 18.55.

10. 1-[Dicarbonyl(η^5-cyclopentadienyl)ruthenio]-1,1-dichlorodisilane (4c): According to **8.** from 105 mg (0.37 mmol) of $Cp(OC)_2Ru-SiH_2-SiH_3$ (**3c**) in 15 mL of benzene and 550 mg (3.60 mmol) of CCl_4 after 15 h. After dissolving the beige residue in 1 mL of benzene and addition of 10 mL of pentane **4c** precipitates, is filtered off and dried in vacuo. − Yield 85 mg (65%). − Light beige powder. − M.p. 68°C (decomp.). − ^{1}H NMR: δ = 4.48 (s, 5 H, H_5C_5), 3.71 (s, 3 H, H_3Si). − IR (benzene): $\tilde{\nu}$ = 2151 cm^{-1} [w, ν(SiH)]; 2025 (s), 2017 (m), 1979 (vs), 1970 (s) [ν(CO)]. − $C_7H_8Cl_2O_2RuSi_2$ (352.29): calcd. C 23.87, H 2.29, Cl 20.13; found C 24.79, H 1.49, Cl 19.87.

11. Photolysis of $Cp(OC)_2Fe-SiCl_2-SiCl_3$ (2a): A solution of 100 mg (0.24 mmol) of $Cp(OC)_2Fe-SiCl_2-SiCl_3$ (**2a**) in 5 mL of benzene is irradiated for 120 h with UV-light (quartz lamp TQ 718, 700 W, Hanau). Insoluble materials are filtered off and the yellow filtrate is evaporated in vacuo to dryness. The residue is extracted with 10 mL of pentane, and the volume of the extract is reduced to 3 mL. After cooling to −78°C $Cp(OC)_2Fe-SiCl_3$ (**5**)[9a] precipitates. − Yield 43 mg (59%). − Light beige, microcrystalline powder.

12. Photolysis of $Cp(OC)_2Fe-SiH_2-SiH_3$ (3a): A solution of 93 mg (0.39 mmol) of $Cp(OC)_2Fe-SiH_2-SiH_3$ (**3a**) in 5 mL of cyclohexane is irridiated for 120 h with UV light (quartz lamp TQ 718, 700 W, Hanau). A white unidentified precipitate is separated and the filtrate evaporated in vacuo to dryness, yielding $Cp(OC)_2Fe-SiH_3$ (**6**).[8][21] − Yield 43 mg (53%).

13. Thermolysis of $Cp(OC)_2Fe-SiH_2-SiH_3$ (3a): A solution of 146 mg (0.61 mmol) of $Cp(OC)_2Fe-SiH_2-SiH_3$ (**3a**) in 8 mL of cyclohexane is heated to 65°C for 32 h. Workup according to **12.** yields $Cp(OC)_2Fe-SiH_3$ (**6**).[8][21] − Yield 93 mg (73%).

14. X-ray Crystal Structure Determination of 2a: Suitable single crystals of $Cp(OC)_2FeSi_2Cl_5$ were obtained from a saturated *n*-pentane solution at −20°C. Crystal data for $Cp(OC)_2FeSi_2Cl_5$**:** $C_7H_5Cl_5FeO_2Si_2$, M = 410.39, triclinic, space group P-1 (No. 2), yellow crystals, dimensions 0.20 × 0.20 × 0.30 mm^3, a = 12.1711(4), b = 8.7557(4), c = 13.9851(6) Å, α = 90°, β = 100.589(2)°, γ = 90°, V = 1465.0(2) Å^3, D_c = 1.861 Mg m^{-3}, Z = 4, μ (Mo-$K\alpha$) = 2.088 mm^{-1}, T = 123(2) K, F(000) = 808; 17118 reflections were collected on a Nonius Kappa CCD diffractometer ($2\theta_{max.}$ = 56.6°, $-16 \le h \le 16$, $-11 \le k \le 11$, $-17 \le l \le 16$), 3292 symmetry independent reflections (R_{int} = 0.1011) were used for the structure solution (Patterson methods)[1] and refinement (full-matrix least-squares on F^2,[2] 155 parameters, 0 restraints), non-hydrogen atoms were refined anisotropically, $wR2$ = 0.0572 [R_1 = 0.037 for 3292 $I > 2\ \sigma(I)$].Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-114922. Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambrigde CB2 1EZ, UK (Fax: int. code +(1223)336−033; E-mail: teched@ccdc.cam.ac.uk).

15. X-ray Crystal Structure Determination of 3b: Yellow crystals of **3b**, suitable for X-ray diffraction were grown by slow diffusion of pentane into a saturated toluene solution of **3b** at −30°C. Crystal data: $C_{12}H_{20}FeO_2Si_2$, M = 308.31, triclinic, space group: P-1 (No. 2), a = 7.739(3) Å, b = 8.233(5) Å, c = 13.875(6) Å, α = 77.795(8)°, β = 84.945(8)°, γ = 63.262(9)°, V = 771.7(6) Å^3, Z = 2, $d_{calcd.}$: 1.327 gcm^{-3}, CAD4-diffractometer (Enraf−Nonius), radiation type: Mo-K_α, wavelength: λ = 0.71073 Å, graphite monochromator, crystal size: 0.55 × 0.50 × 0.50 mm, temperature: 173(2) K, ω/Θ-scan, scale range: 1.50° < Θ < 24.92°, F(000): 324, total reflections: 5300, independant reflections: 2691, observed reflections: 2310 with $I > 2\sigma(I)$, absorption coefficient: μ = 1.121 mm^{-1}, semi-empirical absorption correction (T_{min}/T_{max}: 0.9716/0.9983), structure solution: SHELXS-96[25a] with patterson methods, structure refinement: SHELXL-96[25b] (234 parameters), R_1 = 0.0249, wR_2 = 0.0614. The absorption correction was conducted semi-empirically with the help of of the SDP-program.[26] All atoms were determined by Fourier-transformation, the non-hydrogens refined anisotropically by the method of the smallest mean-square-errors (full-matrix least-squares) while the hydrogen atoms were refined isotropically.

Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-101420. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: int. Code + 44(1223)336−033; E-mail: deposit@ccdc.cam.ac.uk].

16. Matrix Isolation Raman Spectra of $Cp(OC)_2Fe-SiH_2-SiH_3$ (3a): For the Raman spectroscopic investigations of **3a** the sample was isolated in a krypton matrix at 20 K by using the ″slow-spray-on″ technique.[27] The matrix isolation apparatus consisted of a cryocooler (CTI Cryogenics, model 22C) and a turbo-pumping unit (Pfeiffer/Balzers, TPH 170).[28] The sample material was sublimated in a Knudsen cell at 308 K and a pressure of $10^{-7} - 10^{-8}$ mbar. Afterwards the gas was directly mixed with the matrix gas (krypton) in a heated nozzle, from where it was deposited on a highly polished gold plated copper cold head at 20 K. For excitation of the Raman spectra we used the 647 nm line of a krypton ion laser (Spectra Physics, model 2025). The laser beam was focussed on the matrix layer in a 30° angle to the target. The scattered light was dispersed by means of a double monochromator (Spex, model 1404) and the signal was detected by a CCD camera system (Photometrics, Spectra 9000). For the spectrum a resolution of 3 cm^{-1} was chosen. Data acquisition and spectra analyses were performed by a commercial software package (MAPS, Photometrics).

17. Density Functional Calculations of 2a, 3a: The quantum mechanical calculations were performed using Gaussian94.[29] For the best combination of exchange and correlation functionals concerning vibrational frequencies[30] we used Becke′s 1988 exchange functional[31] in combination with the Perdew-Wang 91 gradient-corrected correlation functional[32] (BPW91). As basis sets we tested the Los Alamos effective core potential (ECP) plus double zeta[33] on iron, silicon and chlorine, whereas for the rest of the atoms (all first-row elements) the Dunning/Huzinaga full double zeta basis set[34] was applied. All calculations were performed on DEC alphastations 500 [400 MHz]). Wavenumber calculations are only valid at a stationary point,so in every calculation a full geometry optimization had to be done first.

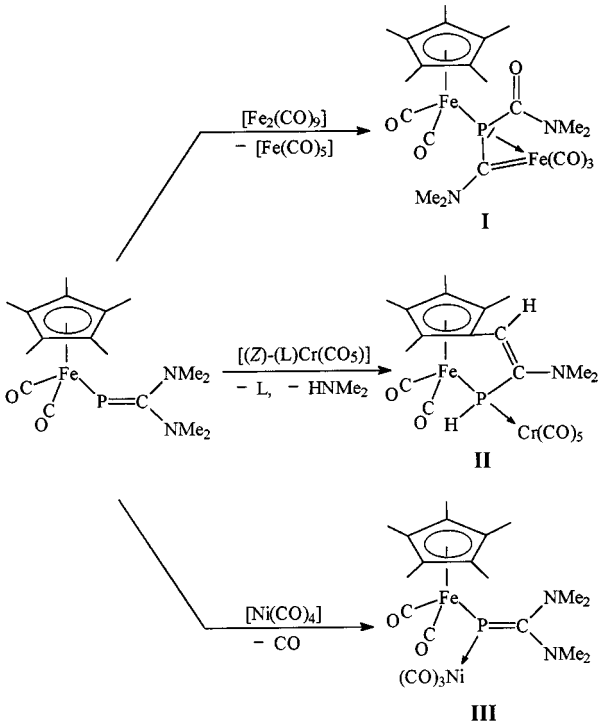
Transition Metal Substituted Phosphaalkenes, 40[+] Transition Metal Substituted Arsaalkenes, 6[+]

Reactivity of Ferriophosphaalkene $[(\eta^5\text{-}C_5Me_5)(CO)_2Fe\text{–}P{=}C(NMe_2)_2]$ and Ferrioarsaalkene $[(\eta^5\text{-}C_5Me_5)(CO)_2Fe\text{–}As{=}C(NMe_2)_2]$ Towards Trimethylaluminium, -gallium and -indium

Lothar Weber,*[a] Matthias H. Scheffer,[a] Hans-Georg Stammler,[a] and Anja Stammler[a]

Dedicated to Professor Reinhard Schmutzler on the occasion of his 65th birthday



Keywords: Arsaalkenes / Phosphaalkenes / Aluminium / Gallium / Indium

Reaction of equimolar amounts of the ferriophosphaalkene $[(\eta^5\text{-}C_5Me_5)(CO)_2FeP{=}C(NMe_2)_2]$ (**1a**) or the ferrioarsaalkene $[(\eta^5\text{-}C_5Me_5)(CO)_2FeAs{=}C(NMe_2)_2]$ (**1b**) with trimethylaluminium, trimethylgallium and trimethylindium afforded the adducts $[(\eta^5\text{-}C_5Me_5)(CO)_2FeE\{MMe_3\}C(NMe_2)_2]$ with E = P; M = Al (**2a**), Ga (**3a**), In (**4a**) and E = As; M = Al (**2b**), Ga (**3b**), and In (**4b**). These compounds feature η^1-coordination of the phosphaalkene or the arsaalkene ligand towards the Lewis acid via the pnictogen atom. The molecular structures of **2a** and **3a** were elucidated by X-ray diffraction analyses.

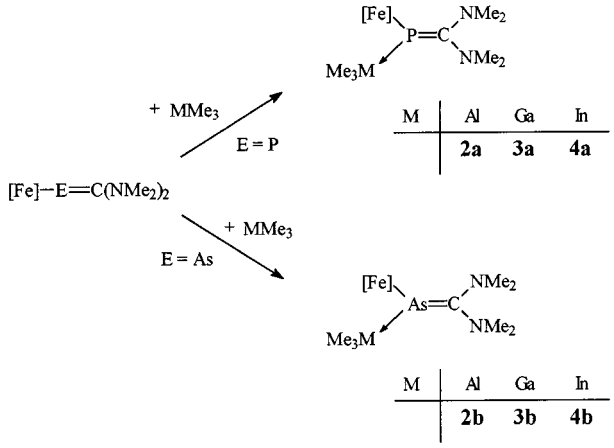
Introduction

During the course of our investigations on the chemical properties of metallophospha- and metalloarsaalkenes $[(\eta^5\text{-}C_5Me_5)(CO)_2FeE{=}C(NMe_2)_2]$ (E = P, As)[1][2] we have studied their reactivity towards transition metal carbonyls. Whereas the treatment of the arsalkene with $[Ni(CO)_4]$, $[Fe_2(CO)_9]$ or [(*Z*)-cyclooctene$Cr(CO)_5$] afforded adducts of the type $[(\eta^5\text{-}C_5Me_5)(CO)_2FeAs\{M(CO)_n\}C(NMe_2)_2]$ ($[M(CO)_n$ = $[Ni(CO)_3]$, $[Fe(CO)_4]$, $[Cr(CO)_5]$)[3] the corresponding phosphaalkene and $[Fe_2(CO)_9]$ or [(*Z*)-cyclooctene$Cr(CO)_5$] gave rise to the formation of complexes **I** and **II**.[4]

With nickel carbonyl adduct **III** was obtained.[4] Moreover, the metallophosphaalkene was converted by $[(\eta^5\text{-}C_5H_5)(CO)_2Rh]$ into a complex analogous to **II** ($[(\eta^5\text{-}C_5H_5)(CO)Rh]$ instead of $[Cr(CO)_5]$) the arsaalkene was disintegrated to the η^2-diarsene complex $[\{(\eta^5\text{-}C_5Me_5)(CO)_2Fe\text{-}As\}_2Rh(CO)(\eta^5\text{-}C_5H_5)]$.[5] In view of these results it was obvious to extent our studies on the reactivity of the title compounds to electrophiles derived from main group metals.

Scheme 1

Results and Discussion



Treatment of **1a** and **1b** with equimolar amounts of $AlMe_3$, $GaMe_3$ and $InMe_3$ in *n*-pentane in the temperature range −78 °C to 20 °C afforded the trimethylmetal adducts **2a,b**, **3a,b** and **4a,b** as air- and moisture sensitive solids, whereas **1a** and **1b** appeared to be inert towards $Al(iPr)_3$. Solutions of compound **2b** in benzene completely decomposed at 20 °C within a few hours. The stability of the remaining adducts in solution was sufficient to provide satisfactory NMR spectra. Purification of the obtained compounds was achieved by recrystallization from *n*-pentane at −28 °C. In the IR spectra (KBr) of adducts **2a**,**b, 3a,b** and

[+] Part 39; part 5: L. Weber, M. H. Scheffer, H.-G. Stammler, B. Neumann, *Inorg. Chim. Acta*, in the press.

4a,b intense bands at $\tilde{\nu}$ = 1991−2000 and 1931−1951 cm^{-1} were assigned to the stretching modes of the terminal carbonyls of the $[Fe(CO)_2]$ unit. Hypsochromic shifts of 10−27 cm^{-1} of these bands with respect to **1a** and **1b** indicate a significant withdrawal of electron density from the organophosphorus or the organoarsenic ligand by the Lewis acids.

Scheme 2

The $^{13}C\{^1H\}$-NMR spectra of the phosphaalkene and arsaalkene adducts showed resonances at δ = 219.4−220.8 for the carbonyl carbon atoms, which are only slightly shielded when compared to the starting materials **1a** and **1b**. The resonance for the methylene carbon atom in the phosphaalkene adducts appeared as doublet at δ = 203.0−204.5, and thus is slightly shifted to low-field relative to **1b** (δ = 202.4). Adduct formation was accompanied by a decrease of the $^1J_{PC}$ coupling constant from 97.0 Hz in **1a** to 75.8−80.6 Hz in **2a**-**4a**. In a corresponding $[Ni(CO)_3]$ adduct a similar $^1J_{PC}$ coupling was measured ($^1J_{PC}$ = 77.7 Hz),[4] whereas smaller coupling constants ranging from 59.0 to 67.4 Hz were registered upon protonation, alkylation and silylation of **1a**.[6] The methylene carbon atom of **1b** (δ = 214.8) is shifted upfield to δ = 211.7 (**3b**) and 211.9 (**4b**) upon adduct formation. The $^{31}P\{^1H\}$-NMR spectra of the adducts **2a**, **3a** and **4a** are characterized by singlets at δ = −12.1, 14.5 and 22.2, which are strongly deshielded with respect to **1a** (δ = 135.5).

X-ray Structural Analysis of 2a

To ensure that the metallophosphaalkene is bonded to the metal through the phosphorus atom and to establish the stereochemistry within the ligand an X-ray structural determination of **2a** was undertaken.

An ORTEP drawing of **2a** is shown in Figure 1, also selected bond lengths and angles . The analysis shows that η^1-coordination of the ferriophosphaalkene to trimethylaluminium by virtue of the phosphorus lone pair results in a significant distortion of the organophosphorus ligand. Thus, the phosphorus atom is now trigonal-pyramidally coordinated (sum of angles 340.0°). This value is between those of the corresponding adducts of **1a** to the $[Ni(CO)_3]$ (335.8°)[4] and to the $[Cr(CO)_5]$ units (346.1°).[7] The phosphorus atom forms single bonds to the atoms Fe, Al and C(16). In comparison to **1a** [1.709(5) Å] the PC bond is elongated to 1.779(3) Å, a situation which was also evident in the $[Ni(CO)_3]$ adduct [1.770(5) Å].[4] The iron−phosphorus bond length [2.3174(9) Å] is similar to the one in **1a** [2.325(2) Å].[1] The P−Al bond length of 2.5077(12) Å may be compared to the P−Al distances in the number of adducts of phosphanes and $AlMe_3$ such as $Me_3Al-PH(t\text{-}Bu)CH_2CH_2(t\text{-}Bu)HP-AlMe_3$ [2.533(3) Å],[8] $Me_3Al-P(Ph)_2CH_2CH_2(Ph_2)P-AlMe_3$ [2.544(4) Å][9] and $Me_3Al-P(Ph)_2CH_2CH_2P(Ph)[AlMe_3]CH_2CH_2(Ph)_2P-AlMe_3$ [2.504(6) and 2.535(7) Å].[8]

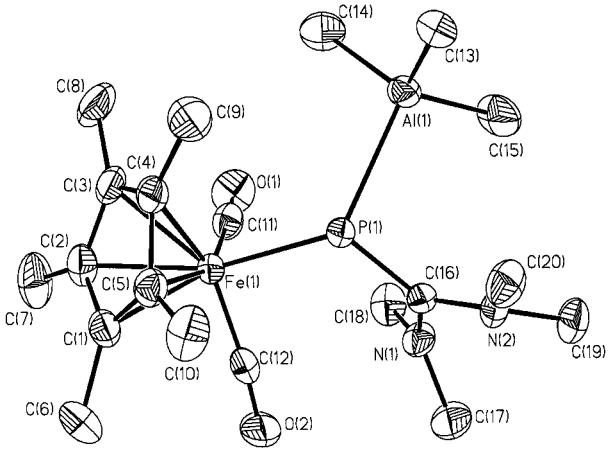

Figure 1. Molecular structure of **2a** in the crystal. Selected bond lengths [Å] and angles [deg]: Fe(1)−C(12) 1.754(3), Fe(1)−C(11) 1.761(3), Fe(1)−P(1) 2.3174(9), Al(1)−C(15) 1.980(4), Al(1)−C(14) 1.984(4), Al(1)−C(13) 1.988(4), Al(1)−P(1) 2.5077(12), P(1)−C(16) 1.779(3), O(1)−C(11) 1.142(4), O(2)−C(12) 1.151(4), N(1)−C(16) 1.358(4), N(1)−C(18) 1.447(4), N(1)−C(17) 1.470(4), N(2)−C(16) 1.363(4), N(2)−C(20) 1.457(4), N(2)−C(19) 1.465(4); C(12)−Fe(1)−C(11) 97.01(16), C(12)−Fe(1)−P(1) 92.08(11), C(11)−Fe(1)−P(1) 92.84(10), C(15)−Al(1)−C(14) 111.87(19), C(15)−Al(1)−C(13) 111.33(18), C(14)−Al(1)−C(13) 112.71(16), C(15)−Al(1)−P(1) 107.58(12), C(14)−Al(1)−P(1) 107.04(12), C(13)−Al(1)−P(1) 105.90(11), C(16)−P(1)−Fe(1) 116.45(10), Fe(1)−P(1)−Al(1) 124.13(4), C(16)−N(1)−C(18) 122.5(3), C(16)−N(1)−C(17) 122.5(3), C(18)−N(1)−C(17) 114.9(3), C(16)−N(2)−C(20) 122.5(3), C(16)−N(2)−C(19) 121.7(3), C(20)−N(2)−C(19) 113.5(3), O(1)−C(11)−Fe(1) 175.6(3), O(2)−C(12)−Fe(1) 174.6(3), N(1)−C(16)−N(2) 115.2(3), N(1)−C(16)−P(1) 126.0(2), N(2)−C(16)−P(1) 118.8(2)

The methylene carbon atom C(16) of **2a** is trigonal planar (sum of angles 360.0°). The same is true for nitrogen atom N(1) (sum of angles 359.9°), whereas atom N(2) slightly deviates from planarity (sum of angles 357.7°). Relatively short carbon−nitrogen bonds C(16)−N(1) [1.358(4) Å] and C(16)−N(2) [1.363(4) Å] indicate effective π-coordination of the lone pair of electrons on the nitrogen atoms with C(16).

In the crystal molecule **2a** adopts a conformation with an orthogonal orientation of the bond P(1)−Al(1) and the vector Cp*−Fe (where Cp* is the centre of the C_5Me_5 ring [torsion angle Cp*−Fe(1)−P(1)−Al(1) = −90.1°]. According to a Newman projection of **2a** (Figure 2) the lone pair at the phosphorus atom is presumably directed towards the

C_5Me_5 ring, leading to a nearly eclipsed position of the vectors Fe(1)−C(12)−O(2) and P(1)−C(16) [torsion angle C(12)−Fe(1)−P(1)−C(16) = 14.5°].

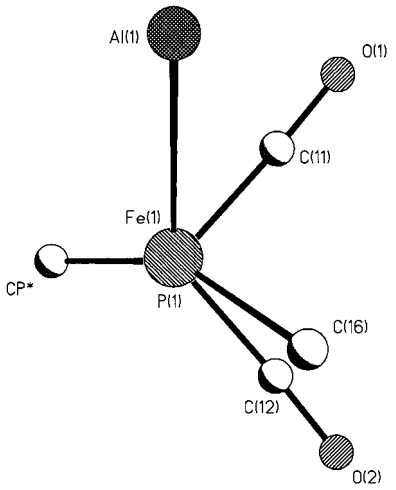

Figure 2. Newman projection of **2a** with view along the P(1)−Fe(1) vector

X-ray Structural Analysis of 3a

The molecular structure in the crystal of the $GaMe_3$ adduct of **1a**, as determined by X-ray diffraction analysis (Figure 3), is closely related to the structure of **2a**. The trigonal-pyramidal phosphorus atom (sum of angles = 340.3°) and the single bond lengths P(1)−C(16) of 1.780(4) Å and Fe(1)−P(1) of 2.3233(17) Å are well comparable in **3a** and **2a**. The Ga−P and Al−P atomic distances are the same within experimental error, which was also observed in the bis-adducts of diphos with $AlMe_3$ and $GaMe_3$. Thus, in $[Me_3GaP(Ph)_2CH_2CH_2P(Ph)_2GaMe_3]$ the Ga−P bond lengths were determined to 2.546(4) Å.[9] Generally, Ga−P bonds in molecules with tetra-coordinate gallium and phosphorus range from 2.347(5) Å in $[(Me_3Si)_3P-GaI_3]$[10] up to 2.683(5) Å in $[Ph_2(H)P\text{-}Ga\{CH_2(t\text{Bu})\}_3]$.[11][12]

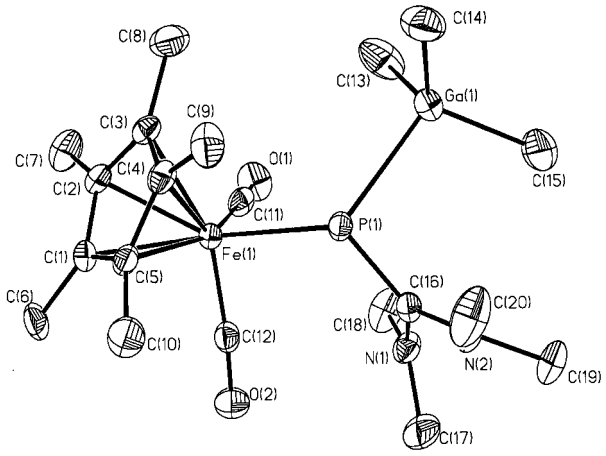

Figure 3. Molecular structure of **3a** in the crystal. Selected bond lengths [Å] and angles [deg]: Ga(1)−C(13) 1.976(6), Ga(1)−C(14) 1.990(5), Ga(1)−C(15) 1.996(5), Ga(1)−P(1) 2.5027(16), Fe(1)−C(12) 1.754(5), Fe(1)−C(11) 1.756(5), Fe(1)−P(1) 2.3233(17), P(1)−C(16) 1.780(4), O(1)−C(11) 1.147(5), O(2)−C(12) 1.151(5), N(1)−C(16) 1.363(5), N(1)−C(18) 1.459(6), N(1)−C(17) 1.462(6), N(2)−C(16) 1.354(5), N(2)−C(20) 1.455(6), N(2)−C(19) 1.473(5); C(13)−Ga(1)−C(14) 112.2(2), C(13)−Ga(1)−C(15) 114.1(3), C(14)−Ga(1)−C(15) 112.6(3), C(13)−Ga(1)−P(1) 107.68(16), C(14)−Ga(1)−P(1) 103.75(17), C(15)−Ga(1)−P(1) 105.67(17), C(12)−Fe(1)−C(11) 97.5(2), C(12)−Fe(1)−P(1) 90.07(15), C(11)−Fe(1)−P(1) 93.83(15), C(16)−P(1)−Fe(1) 117.14(16), C(16)−P(1)−Ga(1) 100.63(15), Fe(1)−P(1)−Ga(1) 122.55(7), C(16)−N(1)−C(18) 122.5(4), C(16)−N(1)−C(17) 122.4(4), C(18)−N(1)−C(17) 115.0(4), C(16)−N(2)−C(20) 123.1(4), C(16)−N(2)−C(19) 122.2(4), C(20)−N(2)−C(19) 113.4(4), O(1)−C(11)−Fe(1) 175.4(4), O(2)−C(12)−Fe(1) 174.7(4), N(2)−C(16)−N(1) 115.0(4), N(2)−C(16)−P(1) 117.9(3), N(1)−C(16)−P(1) 127.1(3)

Experimental Section

All operations were performed under dry, oxygen-free dinitrogen using standard Schlenk techniques. Solvents were dried by standard methods and freshly distilled under argon prior to use. − Infrared spectra were recorded on a Bruker FT-IR IFS66 spectrometer. − ^1H, ^{13}C, and ^{31}P-NMR spectra were recorded at 22 °C by using a Bruker AC 100 (^1H, 100.13 MHz, ^{31}P, 40.53 MHz), Bruker Avance DRX 500 (^1H, 500.13 MHz, ^{13}C, 125.75 MHz, ^{31}P, 202.46 MHz); references: $SiMe_4$ (^1H, ^{13}C) and 85% H_3PO_4 (^{31}P). − Elemental analyses were performed in the microanalytical laboratory of the University of Bielefeld. − The metallophosphaalkene $[\eta^5\text{-}Cp^*(CO)_2Fe-P=C(NMe_2)_2]$ (**1a**)[1] and the metalloarsaalkene $[\eta^5\text{-}Cp^*(CO)_2Fe-As=C(NMe_2)_2]$ (**1b**)[2] were synthesized according to the literature. $AlMe_3$, $GaMe_3$ and $InMe_3$ were purchased commercially (Strem).

$[(\eta^5\text{-}C_5Me_5)(CO)_2FeP\{AlMe_3\}C(NMe_2)_2]$ (2a): A chilled solution (−78 °C) of **1a** (0.39 g, 1.03 mmol) in 50 mL of *n*-pentane was combined with 0.42 mL of a 2.39 M solution of $AlMe_3$ in toluene. Stirring was continued for a period of 1.5 h, during which the mixture was allowed to warm-up to room temp. It was filtered, and the filtrate was diluted with 100 mL of *n*-pentane. Storing at −28 °C for 20 h afforded **2a** (0.19 g, 43%) as a dark brown, air and moisture sensitive solid. − IR (KBr): $\tilde{\nu}$ = 2000 (s, CO), 1951 (s, CO). − ^1H NMR (C_6D_6): δ = −0.14 (s, 9 H, $AlMe_3$), 1.51 (s, 15 H, C_5Me_5), 2.70 (s, br, 12 H, NMe_2). − $^{13}C\{^1H\}$ NMR (C_6D_6): δ = −2.98 (s, $AlCH_3$), 9.31 [s, $C_5(CH_3)_5$], 43.45 (s, NCH_3), 96.25 [s, $C_5(CH_3)_5$], 202.95 (d, $^1J_{PC}$ = 75.8 Hz, PC), 219.38 (s, CO). − $^{31}P\{^1H\}$ NMR (C_6D_6): δ = −12.12 s. − $C_{20}H_{36}AlFeN_2O_2P$ (419.35): calcd. C 53.34, H 8.06, N 6.22; found C 50.89, H 7.91, N 6.03. The C,H,N elemental analysis was repeated several times with crystalline samples, however, no better C-values were obtained.

$[(\eta^5\text{-}C_5Me_5)(CO)_2FeAs\{AlMe_3\}C(NMe_2)_2]$ (2b): To a chilled solution (−78 °C) of **1b** (0.32 g, 0.76 mmol) in *n*-pentane (50 mL) was added 0.33 mL of a 2.39 M solution of $AlMe_3$ (0.79 mmol) in toluene. An orange precipitate spontaneously occurred, which was redissolved upon warming up the mixture to 20 °C. Stirring was continued for 1 h, and then it was filtered. The filtrate was diluted with 50 mL of *n*-pentane and stored at −28 °C to afford 0.15 g (41%) of thermolabile orange-red crystalline **2b**. Solutions in benzene completely decomposed at 20 °C within a few hours which prevented the registration of a reliable $^{13}C\{^1H\}$ NMR spectrum. − ^1H NMR (C_6D_6): δ = −0.09 (s, 9 H, $AlMe_3$), 1.57 (s, 15 H, C_5Me_5), 2.73 (s, br, 12 H, NMe_2). − $C_{20}H_{36}AlAsFeN_2O_2$ (494.26): calcd. C 48.60, H 7.34, N 5.67; found C 48.31, H 6.94, N 5.60.

$[(\eta^5\text{-}C_5Me_5)(CO)_2FeP\{GaMe_3\}C(NMe_2)_2]$ (3a): A *n*-pentane solution (50 mL) of **1a** (0.47 g, 1.24 mmol) was combined at −78 °C with 0.54 g (1.24 mmol) of a 2.3 M solution of $GaMe_3$ in *n*-hexane.

The stirred mixture was allowed to warm to 20 °C within a period of 2 h. Filtration, addition of *n*-pentane (50 mL) to the filtrate and storage at −28 °C for 20 h afforded 0.36 g (59%) of black crystalline **3a**. − IR (KBr): ṽ = 2000 (s, CO), 1947 (s, CO). − ^{1}H NMR (C_6D_6): δ = 0.20 (s, 9 H, $GaMe_3$), 1.51 (s, 15 H, C_5Me_5), 2.71 (s, 12 H, NMe_2). − $^{13}C\{^1H\}$ NMR (C_6D_6): δ = 0.32 (s, $GaCH_3$), 9.24 [s, $C_5(CH_3)_5$], 43.33 (s, NCH_3), 96.23 [s, $C_5(CH_3)_5$], 203.76 (d, $^1J_{PC}$ = 80.6 Hz, PC), 219.62 (s, CO). − $^{31}P\{^1H\}$ NMR (C_6D_6): δ = 14.52 s, br. − $C_{20}H_{36}FeGaN_2O_2P$ (493.06): calcd. C 48.72, H 7.36, N 5.68; found C 47.88, H 6.91, N 5.56.

[(η^5-C$_5$Me$_5$)(CO)$_2$FeAs{GaMe$_3$}C(NMe$_2$)$_2$] (3b): Analogously, the reaction of equimolar amounts of **1b** (0.15 g, 0.36 mmol) and $GaMe_3$ (0.16 g of a 2.3 M solution in *n*-hexane) in *n*-pentane gave 0.10 g (51%) of **3b** as red-black needles. − IR (KBr): ṽ = 1991 (s, CO), 1932 (s, CO). − ^{1}H NMR (C_6D_6): δ = 0.24 (s, 9 H, $GaMe_3$), 1.57 (s, 15 H, C_5Me_5), 2.68 (s, 12 H, NMe_2). − $^{13}C\{^1H\}$ NMR (C_6D_6): δ = −0.46 (s, $GaCH_3$), 9.31 [s, $C_5(CH_3)_5$], 44.50 (s, NCH_3), 95.00 [s, $C_5(CH_3)_5$], 211.7 (s, AsC), 220.8 (s, CO). − $C_{20}H_{36}AsFeGaN_2O_2$ (537.00): calcd. C 44.73, H 6.76, N 5.22; found C 44.30, H 6.50.

[(η^5-C$_5$Me$_5$)(CO)$_2$FeP{InMe$_3$}C(NMe$_2$)$_2$] (4a): A chilled solution (−78 °C) of **1a** (0.53 g, 1.40 mmol) in *n*-pentane (50 mL) was treated with 0.7 mL of a 2 M solution of $InMe_3$ (1.40 mmol) in *n*-pentane. After the usual work up black crystalline **4a** (0.44 g, 58%) was isolated. − IR (KBr): ṽ = 1999 (s, CO), 1946 (s, CO). − ^{1}H NMR (C_6D_6): δ = 0.18 (s, 9 H, $InMe_3$), 1.50 (s, 15 H, C_5Me_5), 2.70 (s, 12 H, NMe_2). − $^{13}C\{^1H\}$ NMR (C_6D_6): δ = −4.56 (s, $InCH_3$), 9.13 [s, $C_5(CH_3)_5$], 43.28 (s, NCH_3), 96.14 [s, $C_5(CH_3)_5$], 204.5 (d, $^1J_{PC}$ = 80.5 Hz, PC), 219.53 (s, CO). − $^{31}P\{^1H\}$ NMR (C_6D_6): δ = 22.2 s, br. − $C_{20}H_{36}FeInN_2O_2P$ (538.16): calcd. C 44.64, H 6.74, N, 5.21; found C 44.64, H 6.80, N 5.12.

[(η^5-C$_5$Me$_5$)(CO)$_2$FeAs{InMe$_3$}C(NMe$_2$)$_2$] (4b): Black crystalline **4b** (0.37 g, 59%) was synthesized analogously from **1b** (0.46 g, 1.09 mmol) and 1.10 mmol (0.55 mL of a 2 M solution in *n*-pentane) of $InMe_3$. − IR (KBr): ṽ = 1993 (s, CO), 1931 (s, CO). − ^{1}H NMR (C_6D_6): δ = 0.21 (s, 9 H, $InMe_3$), 1.54 (s, 15 H, C_5Me_5), 2.66 (s, 12 H, NMe_2). − $^{13}C\{^1H\}$ NMR (C_6D_6): δ = −4.82 (s, $InCH_3$), 9.20 [s, $C_5(CH_3)_5$], 44.20 (s, NCH_3), 95.1 [s, $C_5(CH_3)_5$], 211.9 (s, AsC), 220.5 (s, CO). − $^{31}P\{^1H\}$ NMR (C_6D_6): δ = 14.52 s, br. − $C_{20}H_{36}AsFeInN_2O_2$ (582.10): calcd. C 41.27, H 6.23, N 4.81; found C 41.10, H 6.06, N 4.62.

X-ray Structural Solution and Refinement: The same general procedures were employed to collect the X-ray diffraction data for complexes **2a** and **3a**. Crystal data collection and refinement parameters are given in Table 1. ORTEP drawing of the solid state structure of **2a** and **3a** are shown in Figures 1,2 and 3, respectively.[13] For **2a** and **3a** the data were collected with a Siemens $P2_1$ four-circle diffractometer (Mo-K_α radiation λ = 0.71073 Å). Crystallographic programs used for structure solution and refinement were from SHELXTL PLUS and SHELXL-97. The structure was solved by using Direct Methods and was refined by using full-matrix least squares on F^2 of all unique reflections with anisotropic thermal parameters for all non-hydrogen atoms.

Two New Carbon-Free Indium(III) Asymmetric Chelates – Synthesis and X-ray Crystal Structures of $[In\{Ph_2P(O)NP(S)Ph_2\text{-}O,S\}_3]\cdot 3/4\ C_6H_6$ and $[InCl\{Ph_2P(S)NP(Se)Ph_2\text{-}S,Se\}_2]$

Keywords: Indium / Chalcogens / Chelates / Phosphazenes / Metallacycles

The ligands $[Ph_2(S)PNHP(X)Ph_2]^-$ (X = O, Se) react with $InCl_3$ in a 3:1 ratio to give a tris-chelate $[In\{Ph_2P(O)NP(S)Ph_2\text{-}O,S\}_3]\cdot 0.75\ C_6H_6$ (**2**) and the unexpected pentacoordinate derivative $[InCl\{Ph_2P(Se)NP(S)Ph_2\text{-}Se,S\}_2]$ (**3**). These compounds have been characterized by means of IR, ^1H- and ^{31}P-NMR spectroscopy, positive-ion FAB mass spectrometry and elemental analysis. The molecular structures have been determined by single-crystal X-ray diffraction analysis. The coordination geometry in **2** resembles that observed in the three analogous tris-chelates incorporating the corresponding symmetrical oxygen, sulfur and selenium ligands. Compound **3** exhibits a very distorted trigonal-bipyramidal geometry at indium, where both the selenium and chlorine atoms are in equatorial positions, while the sulfur atoms are in axial positions.

Introduction

Inorganic chelate rings have been the subject of increasing interest in recent years, since they constitute a bridge between traditional inorganic heterocycles (containing mainly non-metallic elements) and classical coordination compounds.[1,2] The anions of the ligands $[R_2(X)PNHP(X')R_2]$ (**1**: R = Ph, Me, *i*-Pr, and OPh, but not all permutations) are excellent chelating agents, which form stable phosphazene metallacycles. They have also found important use as metal extracting agents.[2,3] Compounds containing the symmetric ligands **1a**−**c** have been extensively studied.[4] In contrast, chelate complexes with the asymmetric ligands (**1d**−**f**) have been less well studied, with only few examples known to date.[2,5,6] This is in part due to the long absence of a simple synthetic procedure for such systems. However, more convenient synthetic methods have been reported in the last few years.[2][5]

	X	X′
1a	O	O
1b	S	S
1c	Se	Se
1d	O	S
1e	O	Se
1f	S	Se

In the course of our studies on the coordination chemistry of the imidobis(diphenylphosphanechalcogenide) ligands (**1**) with heavy main group elements, we synthesized some heavier Group 13 complexes [In(III) and Ga(III)] with the symmetric anions **1a**−**c**.[4b−4d] In order to explore possible changes that might be induced by asymmetric ligands (**1d** and **1f**), we decided to synthesize indium(III) derivatives with these ligands.

We report herein on the synthesis and spectroscopic characterization of the indium(III) tris-chelate $[In\{Ph_2P(O)NP(S)Ph_2\text{-}O,S\}_3]$ (**2**) and the unexpected pentacoordinate indium(III) complex $[InCl\{Ph_2P(S)NP(Se)Ph_2\text{-}S,Se\}_2]$ (**3**).

Results and Discussion

The compounds were prepared from $InCl_3$ and the appropriate $K(Ph_2PSNPXPh_2)$ salt (X = O or Se) in a 1:3 molar ratio. In the reaction with the ligand **1f**, only the bis-chelate $[InCl\{Ph_2P(Se)NP(S)Ph_2\text{-}Se,S\}_2]$ (**3**) was obtained, even on employing different molar proportions. There was no evidence for the formation of the expected tris-chelate.

Both complexes were obtained as air-stable, colourless, crystalline solids, and were found to be soluble in some organic solvents (e.g. $CHCl_3$, CH_2Cl_2, benzene, THF), but not in others (hexane, ethanol). They were characterized by partial elemental analyses (C, H, N), IR, ^1H- and ^{31}P-NMR spectroscopy, and positive-ion FAB mass spectrometry. The crystal and molecular structures of both compounds (**2** and **3**) were determined by means of single-crystal X-ray diffraction analysis.

Characteristic infrared bands of the new compounds were assigned by comparison with the spectra of reported compounds containing the $[Ph_2PSNPXPh_2]^-$ ligand.[2, 4−7] The FAB mass spectrum of **2** exhibits a low intensity signal for the molecular ion, but rather intense ion fragments containing ^{115}In, e.g. $[S_2O_2(PPh_2)_4N_2{}^{115}In^+]$ [*m*/*z* (%): 979

(100)], $[SO(PPh_2)_2N^{115}In^+]$ [*m/z* (%): 546 (45)]. In the case of compound **3**, the base peak corresponds to the expected first fragmentation, i.e. $[M^+ - Cl]$ (*m/z*: 1107). All of the observed signals exhibit the expected isotopic pattern.

The $^{31}P\{^1H\}$-NMR spectra each feature two signals attributable to two non-equivalent phosphorus nuclei P_S and P_X. Upon chelation to In(III), there is a small change in δP and a reduction in ^1J(PSe) for the bonded $[Ph_2P(S)NP(X)Ph_2]^-$ ligand [**2**: δ(P) = 33.6, 23.3; **3**: δ(P) = 40.53, 28.24; ^1J(PSe) = 738 Hz] in comparison to $K[Ph_2P(S)NP(X)Ph_2]$ [X = O: δ(P) = 35.3, 13.9; X = Se: δ(P) = 37.6, 26.7; ^1J(PSe) = 682 Hz].[5]

Structural Description

The structures of the compounds are built-up from discrete $[In\{Ph_2P(O)NP(S)Ph_2\text{-}O,S\}_3]$ (**2**) and $[InCl\{Ph_2P(S)NP(Se)Ph_2\text{-}S,Se\}_2]$ (**3**) molecules. Compound **2** crystallizes with benzene molecules in a 4:3 ratio. The molecular structures of **2** and **3** are shown in Figures 1 and 2, respectively.

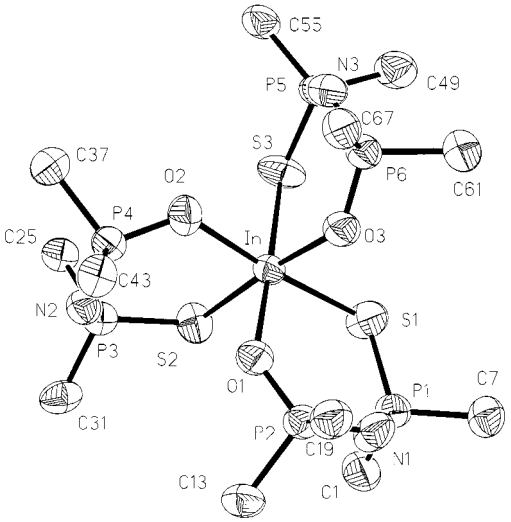

Figure 1. ORTEP view of $[In\{Ph_2P(O)NP(S)Ph_2\text{-}O,S\}_3]\cdot 3/4\ C_6H_6$; **2**; phenyl groups are omitted for clarity; selected bond lengths [Å] and angles [°]: In−O(1) 2.121(4), In−O(2) 2.144(4), In−O(3) 2.125(4), In−S(1) 2.591(1), In−S(2) 2.611(1), In−S(3) 2.595(1), S(1)−P(1) 2.009(3), S(2)−P(3) 2.010(3), S(3)−P(5) 2.021(2), O(1)−P(2) 1.505(5), O(2)−P(4) 1.533(5), O(3)−P(6) 1.507(5), P(1)−N(1) 1.566(6), P(2)−N(1) 1.594(6), P(3)−N(2) 1.582(5), P(4)−N(2) 1.587(5), P(5)−N(3) 1.578(6), P(6)−N(3) 1.592(6); O(1)−In−O(2) 87.8(1), O(1)−In−O(3) 85.4(1), O(1)−In−S(1) 97.2(1), O(1)−In−S(2) 92.1(1), O(1)−In−S(3) 178.3(1), O(2)−In−S(1) 174.6(1), O(2)−In−S(2) 95.9(1), O(2)−In−S(3) 91.1(1), O(3)−In−O(2) 87.8(1), O(3)−In−S(1) 91.0(1), O(3)−In−S(2) 175.4(1), O(3)−In−S(3) 95.9(1), S(1)−In−S(3) 83.73(7), S(1)−In−S(2) 85.45(7), S(3)−In−S(2) 86.60(6), In−S(1)−P(1) 106.42(9), In−S(2)−P(3) 104.61(9), In−S(3)−P(5) 105.69(9), In−O(1)−P(2) 134.3(3), In−O(2)−P(4) 127.7(3), In−O(3)−P(6) 132.1(3), P(1)−N(1)−P(2) 133.6(4), P(3)−N(2)−P(4) 128.8(3), P(5)−N(2)−P(6) 128.8(4), N(1)−P(1)−S(1) 119.7(2), N(2)−P(3)−S(2) 118.5(2), N(3)−P(5)−S(3) 119.7(2), N(1)−P(2)−O(1) 117.9(3), N(2)−P(4)−O(2) 118.1(3), N(3)−P(6)−O(3) 118.2(3)

In **2**, the coordination geometry at indium is similar to that observed in the three analogous compounds incorporating the corresponding symmetrical ligands, $[In\{Ph_2P(X)NP(X')Ph_2\text{-}X,X'\}_3]$ [X = X′ = O (**4**), S (**5**), Se (**6**)].[4b−4d] The indium atom is bonded to three ligands through the sulfur and oxygen atoms, leading to a very distorted octahedron. This may be largely attributed to the asymmetry of the ligand. The molecule corresponds to the facial isomer. The In−X bond lengths [av. In−O 2.13(4), In−S 2.599(2) Å] agree well with the values found for the corresponding bonds in **4** [av. In−O 2.127(9) Å] and **5** [av. In−S 2.63(3) Å],[4a] as well as those found in previous structure determinations.[8−10] The O−In−S bite angles [av. 96.3(2)°] are larger than the corresponding O−In−O [**4**: av. 89.5(7)°] and S−In−S [**5**: av. 91.9(16)°] bite angles observed in the two analogous compounds. The inter-ligand angles fall in the range 83.73(7)° to 92.1(1)°.

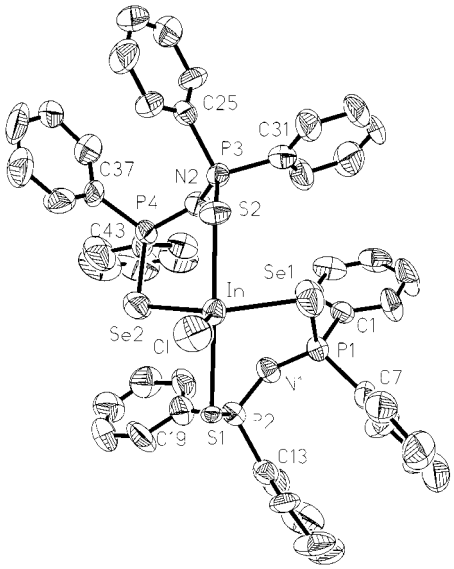

Figure 2. ORTEP view of $[InCl\{Ph_2P(Se)NP(S)Ph_2\text{-}Se,S\}_2]$, **3**; selected bond lengths [Å] and angles [°]: In−Cl 2.422(3), In−Se(1) 2.570(2), In−Se(2) 2.583(2), In−S(1) 2.693(3), In−S(2) 2.642(3), Se(1)−P(1) 2.160(4), Se(2)−P(4) 2.184(4), S(1)−P(2) 2.088(4), S(2)−P(3) 2.048(4), P(1)−N(1) 1.582(10), P(2)−N(1) 1.591(10), P(3)−N(2) 1.597(9), P(4)−N(2) 1.603(10); Cl−In−Se(1) 115.5(1), Cl−In−Se(2) 114.4(1), Cl−In−S(1) 84.0(1), Cl−In−S(2) 84.6(1), Se(1)−In−Se(2) 129.98(7), S(1)−In−S(2) 168.53(8), Se(1)−In−S(2) 85.55(9), Se(2)−In−S(2) 98.37(9), Se(1)−In−S(1) 97.76(7), Se(2)−In−S(1) 87.96(7), In−Se(1)−P(1) 101.8(1), In−Se(2)−P(4) 102.4(1), In−S(1)−P(2) 99.1(1), In−S(2)−P(3) 103.7(1), P(1)−N(1)−P(2) 130.9(6), P(3)−N(2)−P(4) 127.7(6), N(1)−P(1)−Se(1) 116.2(4), N(1)−P(2)−S(1) 115.8(4), N(2)−P(4)−Se(2) 118.0(4), N(2)−P(3)−S(2) 117.4(4)

The pentacoordinate geometry found in $[InCl\{Ph_2P(S)NP(Se)Ph_2\text{-}S,Se\}_2]$ (**3**) was completely unexpected since all of the previously studied indium(III) complexes with the analogous $[R_2(X)PNHP(X')R_2]^-$ ligands are tris-chelates.[4b−4d] This structure is also interesting in view of the fact that many of the known pentacoordinate indium structures result from intermolecular associations[9] and only a few examples correspond to discrete pentacoordinate molecules.[10] In complex **3**, only two of the ligands are attached to the indium atom through the sulfur and selenium atoms. The resulting arrangement can be described as a very distorted trigonal bipyramid (TP), where Se(1), Se(2), and a chlorine atom are equatorially positioned, while S(1) and

S(2) are axially positioned. The diaxial angle is 168.53(8)°, while the average equatorial angle is 119.9(10)°. Four of the remaining In−donor atom angles are less than 90°. The S−In−Se bite angles [98.37(9)° and 97.76(7)°] are larger than the corresponding S−In−S [**5**: av. 91.9(16)°] and Se−In−Se [**6**: av. 96.9(9)°] bite angles in the octahedral compounds with the symmetrical ligands.[4c−e]

The axial In−S bond lengths resemble those found in the analogous sulfur tris-chelate [av. **5**: 2.63(3) Å],[4b] while the In−Se distances [In−S 2.583(2) and 2.570(2) Å] are shorter than the corresponding bonds in the analogous selenium tris-chelate [**6**: av. 2.75(3) Å].[4d] These In−Se lengths are closer to those measured for the less crowded [In{Se(2,4,6-*t*-$Bu_3C_6H_2$)}$_3$] derivative.[8b] The In−Cl bond length [2.422(3) Å] is similar to the equatorial In−Cl distance in the pentacoordinate [$(n$-$C_4H_9)_4N]_2$[InCl{$S_2C_2(CN)_2$}$_2$], 2.418(2) Å,[10a] and the axial In−Cl length in [$Et_4N]_2$[$InCl_5$], 2.415(2) Å.[10b] The average In−Cl equatorial bond length in the trigonal-bipyramidal adduct $InCl_3$·$2PPh_3$ is 2.383(5) ± 0.05 Å.[10d]

In both compounds **2** and **3**, the resulting $InSXP_2N$ (X = O, Se) chelate rings may be considered as having a very distorted boat conformation with the indium and nitrogen atoms at the apices. A similar arrangement was found for asymmetric $PbOSP_2N$ rings[6b] as well as for the symmetric InO_2P_2N rings in **4**, which also exhibit a boat conformation.[4c] The symmetric InS_2P_2N chelate rings adopt a twisted boat conformation (**5**).[4b] In contrast, the $InSe_2P_2N$ ring in **6** displays both conformations (boat and twisted boat), but with the selenium and phosphorus atoms at the apices.[4d] Average P−S [**2**: 2.013(4); **3**: 2.068(4) Å], P−O [**2**: 1.515(5); **3**: 2.172(4) (X = Se) Å], and P−N [**2**: 1.582(6); **3**: 1.586(10) Å] bond lengths are consistent with a delocalized π-bond structure involving the five ligand atoms of the chelate ring, as has been noted for cyclic phosphazene.[11]

The packing in the crystal structures is largely determined by van der Waal′s forces. There are no particularly short intermolecular contacts.

Experimental Section

Chemicals of commercial grade were purchased from Aldrich and were used as supplied. Solvents were distilled prior to use. The asymmetric [R_2(X)PNHP(X′)R_2] ligands **1d** [12] and **1f**[5] were prepared by published methods. They were converted to the corresponding potassium salts by treatment with KO*t*Bu according to a previously described procedure.[13] The ^{1}H- and ^{31}P{^{1}H}-NMR spectra were obtained at room temperature in $CDCl_3$ on a Varian Unity spectrometer operating at 299.94 MHz and 121 MHz, respectively [external references: $Si(CH_3)_4$ and 85% H_3PO_4]. FAB^+ MS (3-nitrobenzyl alcohol matrix) were measured on a Jeol JMS-SX102A instrument. The IR spectrum of **2** (KBr pellet) was recorded on a Nicolet FT-IR Magna 750 spectrometer, while that of **3** (Nujol) was recorded on a Bruker IFS28 spectrometer. Elemental analyses of **2** and **3** were performed with a Galbraith Laboratories (Knoxville, TN) analyzer and a Fison′s Instruments (Italy) EA 1108 apparatus, respectively.

X-ray Diffraction Studies: Crystals suitable for X-ray analysis were obtained by slow diffusion of *n*-hexane into benzene (**2**) or chloroform (**3**) solutions of the corresponding compound. Details of the data collections and refinements are summarized in Table 1. The structures were solved by direct methods and refined by full-matrix least-squares calculations using the program system SHELXL-97.[14] Non-hydrogen atoms were refined anisotropically, while H atoms were refined using a riding model (U = 0.06). The Flack parameter for **3** was η = 0.003(19).[15] A semiempirical (ψ scan) absorption correction was applied for **3** (0.92957/0.62808). The crystal structure data (excluding structure factors) have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC-113996 (**2**) and CCDC-113995 (**3**). Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, U.K. [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

A Universal Two-Parameter Kratzer-Potential and Its Superiority over Morse's for Calculating and Scaling First-Order Spectroscopic Constants of 300 Diatomic Bonds

Guido Van Hooydonk*[a]

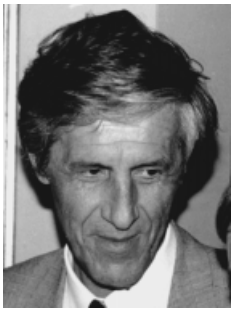
Keywords: Calculations / Bond theory / Electronic structure / Molecular dynamics / Kratzer / Morse / Potential energy curve

After decades of intensive research, the question remains whether or not a universal two- or three-parameter potential exists. For a large number of about 300 bonds, we now critically review the constraints for potentials and asymptotes, involved in three available scaling processes (Varshni, Calder–Ruedenberg, and Graves–Parr). We show that the covalent Sutherland parameter can never be a universal scaling factor. This implies that the usual constraint $U(R) = -D_e$ at $R = \infty$ for potentials is only desirable and that the natural asymptote D_e is not even needed to explain the relations between the constants. We show that ionic potentials of generalized Kratzer-type (Varshni's V^{th} potential) and their ionic Coulomb-like asymptotes Ae^2/R_e (with A close to 1) behave as simple universal two-parameter potentials. For both α_e and $\omega_e x_e$, this potential gives percentage deviations 2 to 3 times smaller than Morse's three parameter potential for hundreds of bonds. We also prove that the Graves–Parr scaling hypothesis is valid, despite these authors' own conclusion. We discuss various new relations between spectroscopic constants.

1. Introduction

Finding a universal two- or three-parameter potential still has considerable theoretical interest not only for molecular spectroscopy and for the theory of the chemical bond but also for a number of practical chemical processes such as metallic adhesion, cohesion and chemisorption, where similar potentials appear.[1]

For decades, considerable efforts were made on scaling potentials and/or spectroscopic constants.[1–15] This ever-continuing search for what Tellinghuisen[10] once called the *Holy Grail of Spectroscopy* remains justified since the spectroscopic constants of a large number of diatomic bonds exhibit an extremely simple, intriguing behavior, not yet accounted for theoretically. Various opinions persist whether or not a universal low parameter function really exists and the matter is certainly not yet solved.[9] Experience shows that even a three-parameter potential cannot be of universal character,[2][3] a thesis we will now reconsider.



In this review, we use a method devoid of two of the common problems in this kind of research, e.g. finding representative sets for

(a) *molecules (and constants)*: the set used here is beyond doubt representative and also large enough, as we collected all readily available spectroscopic data for about 400 bonds and for

(b) *potentials*: here we confront two completely different low-parameter reduced potentials: a reputed covalent one and a less known ionic one. Both stand for a series of related potentials in their category.

The author (born 1944) obtained his Ph.D. in 1971 at the University of Ghent (chemistry). He then moved to the University Library, built in 1935 by the famous Bauhaus co-founder, designer and architect Henry Van de Velde. – In 1990 he became professor and chief librarian. He implemented an integrated library system, one of the first in Europe to focus on a dynamic integration of bibliographic sources with the on-line catalog (http://www.lib.rug.ac.be). He published books and articles on different aspects of the library and on a derivative of library sciences, bibliometrics. – Since 1971, he published about 40 articles on many aspects of the theory of the chemical bond, still his main research interest. Numerous spectroscopic data are used to confront bonding theories with experiment. Recent experimental work is on the analysis of pigments in medieval manuscripts by TXRF- and micro-Raman spectrometry. Prof. Van Hooydonk is a referee for many journals and a member of national and international societies in exact and in library sciences.

MICROREVIEWS: This feature introduces the readers to the authors' research through a concise overview of the selected topic. Reference to important work from others in the field is included.

2. Overview of Scaling Spectroscopic Constants and Potentials: Aim of This Work

The most essential (zeroth order) information about chemical bonding is contained in only *three constants*: the dissociation energy D_e (the natural asymptote), the bond length R_e and the force constant k_e. These determine an important *species-dependent* scale factor, the dimensionless Sutherland[11] parameter Δ, defined as

$$\Delta = 1/2\ k_e R_e^2/D_e = a_0/D_e \quad (1)$$

Herein a_0, the first coefficient in the Dunham expansion[12] near the minimum and representing the asymptote in the harmonic oscillator presentation, is scaled by D_e, the atomic dissociation limit or the natural asymptote. By definition, a_0 is determined by the two *zero*th order spectroscopic constants (see below). D_e can be determined experimentally in various ways.

For the two *first order spectroscopic constants*, Varshni[3] introduced two dimensionless parameters F and G also related to the next coefficients a_1 and a_2 in the Dunham expansion. Both F and G derive from the potential and are numerical functions of Δ. From these two theoretical relations $F(\Delta)$ and $G(\Delta)$, a theoretical $G(F)$ relation follows. The experimental $G(F)$ plot is, in general, roughly in line with the theoretical expectations for empirical potentials.[6] Many inconsistencies, almost like a "spectroscopic gap" between different kinds of bonds,[6] are found both in $F(\Delta)$- and $G(\Delta)$ plots, *meaning that something fundamental must be wrong with the Sutherland parameter as a scaling aid in molecular spectroscopy.*[3][6]

Although 30 years after Varhsni's standard analysis[3] of 23 bonds, Graves and Parr[2] analyzed 150 bonds and argued that the square root of the Sutherland parameter is the better species-dependent scale factor, this new scaling operation did not fit the experimental data any better.[10] Both the Varshni and the Graves and Parr analyses are essentially similar and lead to the same conclusions. Scaling by the Sutherland parameter (Δ or even $\Delta^{1/2}$) is not effective, which is correct. Their next conclusion that, therefore, a universal three-parameter potential cannot exist, is probably not correct, as we intend to demonstrate in this study and did so already some time ago on a smaller scale.[6][7]

Later, Jhung and co-workers[9] proved theoretically that a universal three-parameter function exists, but, unfortunately enough, they were unable to identify its analytical form. The best candidate, to their opinion, would be the Morse potential.[13] However, this popular (overworked[3]) potential is known to be bad for ionic bonds, a class of molecules not studied by Jhung.[9] Smith et al.[14] suggested to include an ionic term in the potential, a procedure that gave good results.

Graves and Parr in their analysis of the scaling problem[2] concluded that a three-parameter potential must always make some compromise on D_e, R_e, or k_e. This seems like an invitation to question the universal character of Δ, where these three constants are united, see Equation (1). Looking for such a compromise is one of the challenges of this work. In fact, we suggested some time ago,[6] even before Graves and Parr, that an alternative Sutherland parameter should be used and that a universal potential might be of ionic type, an hypothesis to be reviewed now in the context of scaling on a much larger set of bonds.

This thesis is in line with the alternative scaling (Sutherland-like) parameter t, introduced for ionic bonds by Varshni and Shukla[4] many years ago and used by Van Hooydonk[6] as a universal scaling parameter for both ionic and non-ionic bonds. Ionic potentials[4] use an asymptote D_x, different from D_e, leading to an alternative Sutherland parameter a_0/D_x. This shift in asymptotes seems a solution for the compromise, suggested by Graves and Parr.[2]

Recently, and in line with our earlier work,[6] also Von Szentpaly[15] suggested another alternative asymptote D_x: the valence state energies of the atoms, which refers to a rather classical Atoms In Molecules (AIM) approach. This asymptote consists of two separated atoms, frozen in the same valence state they have at the equilibrium distance. In this terminology, an ionic approach is an IIM (Ions In Molecules) method, which freezes ions instead of atoms. Both our results with the IIM method[6] and Von Szentpaly's with AIM method[15] remove several problems with $F(\Delta)$- and $G(\Delta)$ plots, due to the use of the covalent Sutherland parameter.

Very recently and partly because of these latter two approaches, Freeman, March, and Von Szentpaly[16] argued that an empirical power relation between G and F would be evidence for chaotic/fractal behavior in anharmonicities. As one can never underestimate the impact of (inverse-) power-laws, such as Coulomb's, in chemistry and physics, this problem is now reviewed also.

We now collected constants of 400 diatomic (*inorganic*) molecules, with bonds between zero-, mono-, and polyvalent atoms, of molecular ions, of isotopomers, and of excited states. Scaling based upon alternative asymptotes and simple potentials is critically examined by three related scaling methods available in the literature (Varhsni,[3] Graves−Parr,[2] and Calder−Ruedenberg[5]).

Except for the data collection (section 3), the paper is divided in 4 main sections: (4) theoretical constraints for potentials; (5) extensions and consequences of earlier results on scaling properties of the covalent Sutherland parameter; (6) the search for a universal two-parameter function: theoretical requirements and (7) the search for a universal two-parameter function: testing the theoretical results with the constants.

3. Data Collection

Data for 402 bonds are taken from Huber and Herzberg[17] and Radzig and Smirnov,[18] without checking for accuracy. Different mass units are used (C = 12 in the first and a.m.u. in the second). For 21 bonds, first order constants are not simultaneously available. For 76 bonds, D_e is not available, which leaves about 300 bonds for a one-by-

one comparison between covalent and other scaling approaches.

4. Theoretical Constraints for Potentials

4.1 Universality of Potentials

Two methods can be used to decide whether or not a function is universal: (a) PECs, potential energy curves (RKR method) fall within ± 5%, of the function and/or (b) calculated spectroscopic constants fall ± 5%, of the experimental values. In either case, the number of a variety of bonds must be large. Method (a) can be used in combination with (b). However, since the number of bonds in this study is very large, we can only use method (b). A perfect result for (b) does not warrant the same result for (a) in the complete range $0 \leq R \leq \infty$ (Steele et al.[8]).

4.2 The Dunham Expanion

The Dunham expanion[12] around the minimum is:

$$U(\rho) = a_0\rho^2(1 + a_1\rho + a_2\rho^2 + ...) - D_e \quad (2a)$$

where a_n are constants and where the variable is

$$\rho = (R - R_e)/R_e \quad (2b)$$

The first term is the well-known harmonic oscillator equation and the first constant (the well depth or the Dunham asymptote) is given by [see also Equation (1)]:

$$a_0 = \omega_e^2/4\ B_e \quad (2c)$$

Since a_0 is solely determined by zeroth order spectroscopic constants, the Dunham asymptote is a *mathematical* asymptote. The next Dunham coefficients are related to the first-order constants: a_1 to α_e, the rotation-vibration constant, and a_2 to $\omega_e x_e$, the anharmonicity constant. Dividing all terms in (2a) by D_e shows why the covalent Sutherland parameter is an important scaling aid. Conversely, accounting for the higher Dunham coefficients is also a major test for the universal character of a potential.

4.3 Constraints for Potentials and Asymptotes

Although constraints for potentials can be divided in two classes: necessary and desirable (Varshni[3]), we will restrict ourselves here to some general constraints. As remarked by Von Szentpaly,[15] one global constraint is that an A/R^x-law is preferential for *attraction*

− A should allow for interacting charges: the concept of *valences* (as in the Calder−Ruedenberg Column classification,[5] also used by Graves and Parr[2]), for *charge-transfer* between partially charged atoms, as argued by Smith, Schlosser, Leaf, Ferrante, and Rose[14]

− $1/R^x$ should allow for the idea of forces *getting smaller with distance* (reflected in the Herschbach and Laurie Row classification[19])

(a) with $x = 1$, this is in line with *Coulomb's fundamental law*, and in the next instance, with ionic bonding (see Berzelius,[20] Kossel,[21] Van Hooydonk[6][7]), although also covalent bonding calls for a $1/R$-law (Borkman and Parr,[22] Sanderson[23])

(b) with $x \neq 1$, a number of other possibilities are open (Varshni[3]), among which the idea of (inverse) *power- laws* (see Freeman, March and Von Szentpaly[16]).

For *repulsion*, a large number of solutions are available (see Varshni[3] for a review).

More detailed constraints for potentials are not repeated here (see for instance Varhsni,[3] Calder and Ruedenberg,[5] Jenc[8]). Basic constraints for any potential $U(R)$ are

(i) $U(0) = \infty$ (or very large) *and* $U(\infty) = 0$

(ii) $U(R_e) = -D_e$

(iii) $U'(R_e) = 0$ and

(iv) $U''(R_e) = 4\pi^2\mu\omega_e^2 = k_e$ (the force constant or the curvature at the minimum), where μ is the reduced mass. The force constant and R_e determine the first coefficient in the Dunham expanion a_0, see Equation (1) and (2c). Replacing condition (ii) by $U(R_e) = -D_x$ instead of D_e does not alter any of the next mathematical steps required to arrive at Varhsni's parameters F and G. Scaling the higher derivatives $U'''(R_e)$, $U^{IV}(R_e)$, ... by the force constant $k_e = U''(R_e)$, leads the parameters X and Y, related to F and G and to the next coefficients in the Dunham expansion a_1 and a_2 and to the first order constants. At this stage, Sutherland's parameter comes in as a scaling factor, called so by Varshni[3] to honor Sutherland's work.

The question is whether constraint (ii) is either necessary or only desirable. We know of no simple (low parameter) analytical function that accounts for the atomic dissociation limit, whereas a large number of simple analytic potentials are available, leading to well defined but different asymptotes. Also Von Szentpaly[15] gave arguments for replacing the atomic dissociation limit as a scaling factor and retraced earlier arguments to do so (see also below). We will consider constraint (ii) as *desirable*, since exactly this condition expresses our *desires* and expectations about a perfect universal function. Modifying constraint (ii) is also a way of interpreting the empirical fact that, after decades of intensive research by numerous researchers all over the world, a really universal (low parameter) function has not yet been found.

All other constraints mentioned above *must remain valid* for a universal function (mainly for reasons of *internal* consistency). However, if *any* two or three-parameter function can be found that produces an asymptote D_x with a simple chemical meaning and which scales the Dunham coefficients efficiently, the question of scaling is probably solved. How to reach the atomic dissociation limit with that potential, would lead to a different, more transparent, situation.

The Dunham expansion itself does not require the atomic dissociation limit. It is limited to the situation around the equilibrium internuclear distance in the first place and to a consistent reproduction of the spectroscopic constants by

means of a relatively simple series expansion in terms of an harmonic oscillator model (see below).

5. Previous Results on the Scaling Properties of the Sutherland Parameter

5.1 The Zeroth Order Spectroscopic Constants (the Dunham Asymptote) and Scaling

Scaling has much to do with the relations between the constants determining a_0, as scaling is essentially a two-dimensional operation (Graves and Parr[2]).

The two zeroth order constants (the vibrational constant ω_e and the rotational constant B_e) are known to have a very intimate relationship, which made $1/R$ potentials so popular in the past, since $B_e = 1/(\mu R_e^2)^{1/2}$.

An ω_e (B_e) plot shows two basic characteristics: (a) a Row dependency (Herschbach–Laurie[19]) and (b) a Column dependency (Calder–Ruedenberg[5]).

Figure 1a on the Row dependency and Figure 1b on the Column dependency represent some of the results obtained from our data. The almost parallel lines combining molecules in the same Row have an intercept at the x-axis (B_e), whereas the parallel lines representing the Column classification have an intercept at the y-axis (ω_e). Taking two parallel lines in Figure 1b (Column dependency) together with two parallel lines in Figure 1a (Row dependency) would always result in a (scaled and oblique) replica of the Periodic Table. A similar scattering is observed when a plot (not shown) is made for the two first order constants: $\omega_e x_e$ (or x_e) and α_e. Figure 1c gives the normal (i.e. non-logarithmic) plot between the two zeroth order constants.

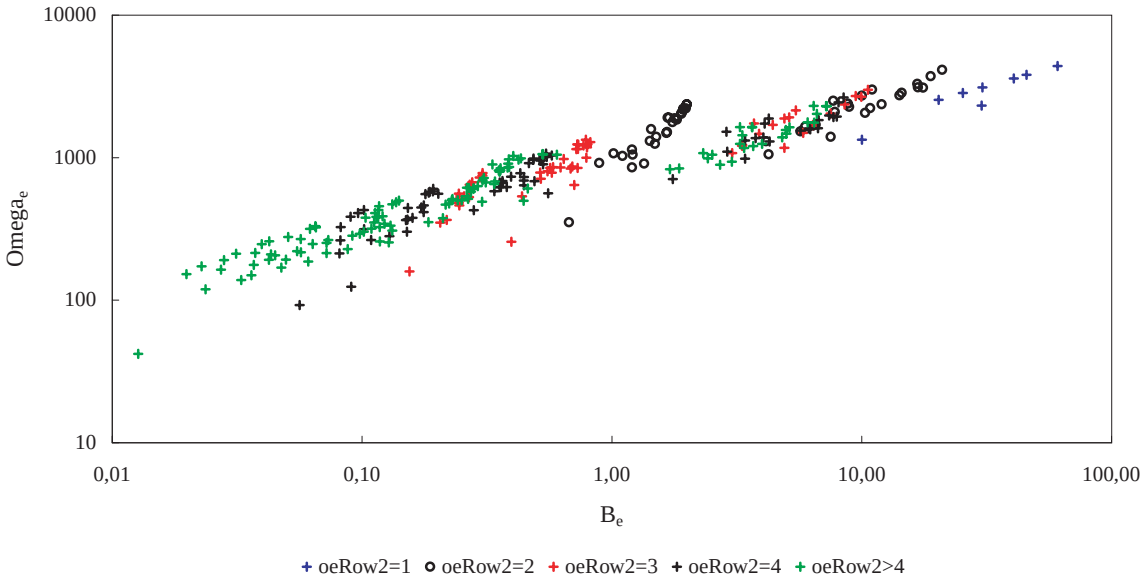

Figure 1a. Omega$_e$ versus B$_e$ for 300 bonds (Row-classification) (log-scale)

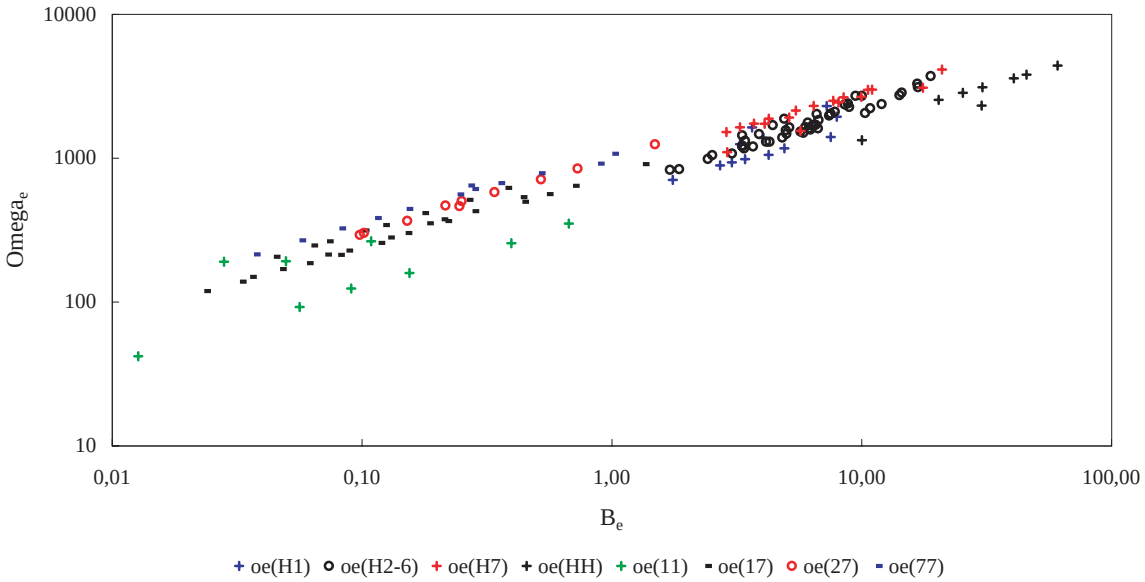

Figure 1b. Omega$_e$ versus B$_e$ for 300 bonds (Column-classification) (log-scale)

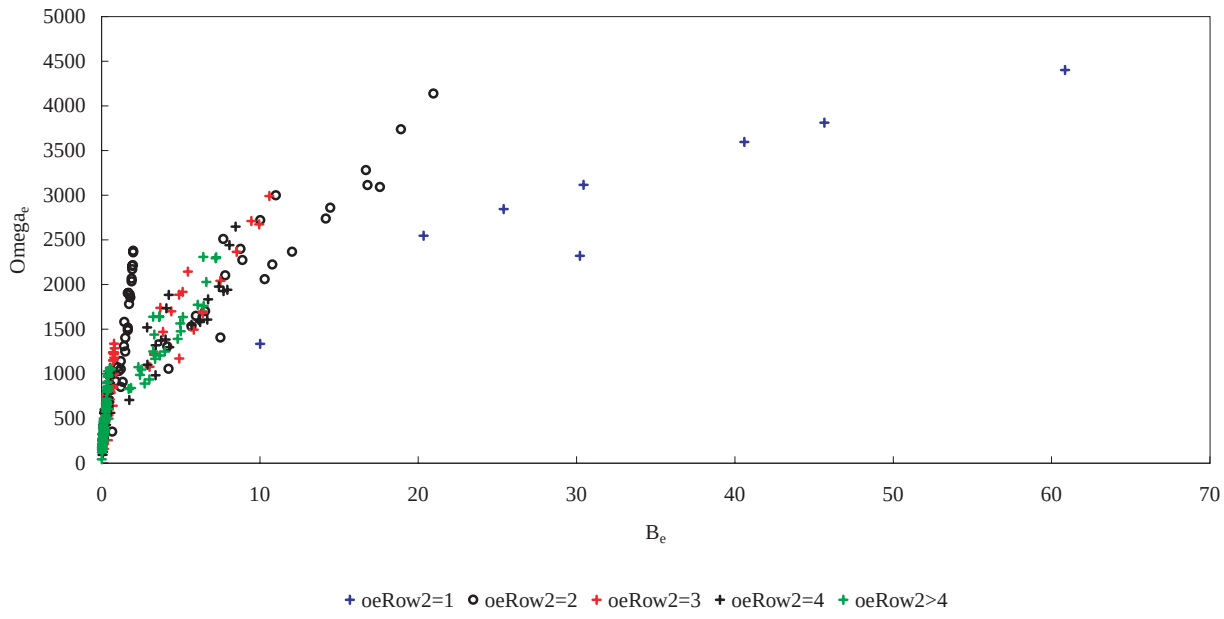

Figure 1c. Omega$_e$ versus B$_e$ (Row-classification) (normal scale)

Perfect scaling seems to consist in reducing these replicas of the two-dimensional table to a one-dimensional version. For *atomic spectroscopy*, this would not be a problem, since either the atomic number Z or the atom mass M can be used (both are rather simply related to one another). The H atom is the prototype in atomic bonding: its energy and its spectroscopic behavior are easily computed from first principles. But, if perfect scaling in *molecular spectroscopy* can be achieved, a similar solution must exist: using first principles, a universal potential will determine the energy and the spectroscopic behavior of a universal bond, which can then be considered as the equivalent of the H atom in atomic spectroscopy. To arrive at a situation analogous to that found in atomic spectroscopy, a scaling system must be found which brings the scattering in the data-points in Figure 1a−c down to almost a single smooth line.

Since the two zeroth order constants completely determine the Dunham asymptote, such a relation would be extremely valuable for scaling this asymptote. In second order, scaling a_0 has immediate consequences for the first order constants also, according to Varshni's analysis[3] and its Graves−Parr variant.[2] Despite the fact that a $1/R$ law seems to interfere with the two constants that determine a_0, scaling the Dunham asymptote is almost invariantly done by means of D_e, the atomic dissociation limit (the covalent Sutherland parameter).

5.2 Relations Between First-Order Constants (Varhsni Functions *F* and *G*) and Scaling by the Covalent Sutherland Parameter: Early Observations

In addition to a re-appraisal of the Sutherland parameter, Varshni[3] showed that two dimensionless parameters F and G relate to the first order spectroscopic constants:

$$F = \alpha_e\omega_e/6\ B_e^2 \quad (3)$$

$$G = \omega_e x_e \mu R_e^2/2.1078\cdot 10^{-10} \quad (4)$$

However, already 40 years ago, Varshni remarked that $F(\Delta)$- and $G(\Delta)$ plots for 23 bonds seemed to generate two sets of different molecules, for which he could hardly give an explanation.[3] Therefore, he *had* to conclude that a universal three-parameter potential probably could not exist. Varshni's early observation was later referred to as a *spectroscopic gap*[6] between different types of bonds as it leads to a conflict between the Morse potential and the covalent Sutherland parameter. In fact, we now made a plot (see Figure 2a) of the Varshni function F (related to a_1) against the square root of the covalent Δ for 91 bonds between monovalent atoms. The theoretical result[3] of a Morse potential is $F = \Delta^{1/2} - 1$ and is represented by a solid line in Figure 2a. If the Morse potential is the most likely candidate for being a universal function (Jhung et al.[9]) and if $\Delta^{1/2}$ is the best scaling factor (Graves and Parr[2]), something very elementary must be wrong: only 22 out of 91 data-points (25%) are on or close to the line theoretically predicted by the Morse potential.

To make things worse, a $G(\Delta)$ plot leads to the same situation (Varshni,[3] Van Hooydonk[6]). In this case,[3] the Morse potential predicts that $G = 8\Delta$. Figure 2b gives the corresponding plot for the same 91 bonds. We can only conclude again either (a) that the Morse potential can never reach the status of a universal potential or (b) that the covalent Sutherland parameter can never be a perfect universal scaling aid.

Strangely enough, most of these discrepancies disappear when G is plotted directly as a function of F, whereby the intermediary step involving the covalent Sutherland parameter Δ is avoided. This illustrates the intriguing relations,

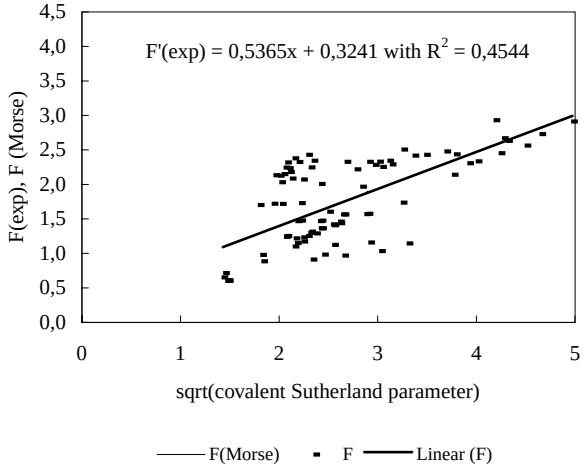

Figure 2a. F(exp) and F(Morse) versus sqrt(covalent Sutherland parameter) for 91 single bonded diatomics

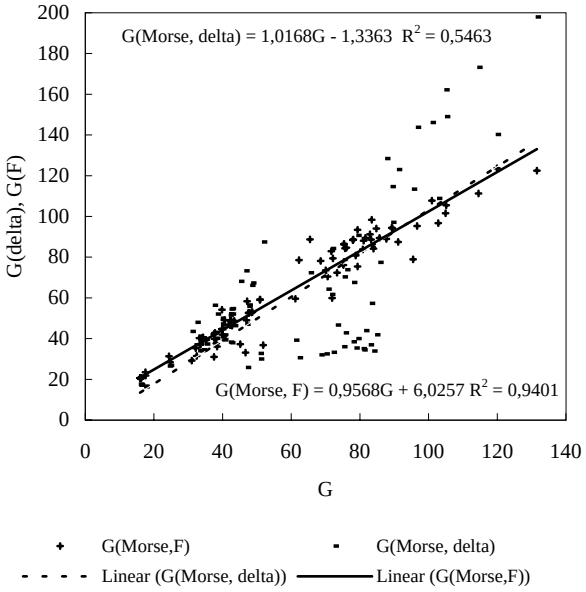

Figure 2b. G(Morse, delta) and G(Morse, F) versus G for 91 single bonded diatomics

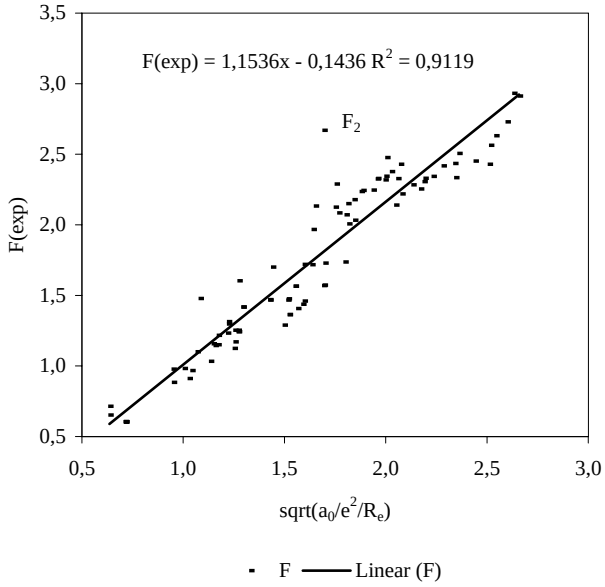

Figure 2c. F(exp) versus sqrt($a_0/e^2/R_e$) for 91 single bonded diatomics

that exist between the spectroscopic constants and shows that, in reality, there is no spectroscopic gap at all.[6]

This effect is also shown in Figure 2b by the data-group G(Morse F). If we use the prediction of the Morse potential that $\Delta = (1 + F)^2$ and calculate G from $G = 8(1+F)^2$, i.e. without the interference of Δ values, the Morse′s three-parameter potential almost behaves like a universal function (Jhung[9]).

Consequently, the covalent Sutherland parameter is not at all a good scaling factor. This answers our dissatisfaction with the last conclusion by Varshni[3] and Graves and Parr[2] that a universal *three*-parameter potential (like Morse′s) does not exist, if this conclusion is based on the fact that scaling with the covalent Sutherland parameter does not work.

We see that things go wrong as soon as an external parameter D_e, not simply related to the zeroth order constants, is introduced as a scaling parameter for a_0, which is completely and solely determined by these zeroth order constants. And although attempts were made to correlate D_e with some constants, such a correlation has no universal validity (probably on account of the very same reason: we refer to the linear Birge−Spooner extrapolation, discussed by Varshni,[3] which is ultimately also based upon the usefulness of a covalent Δ for scaling).

It appears that F and G would both be independent of D_e. The Morse potential is not a universal potential in the whole range of R values (0 to ∞) but appears to be a good approximation to a universal function around R_e. This is not a surprise, when one looks at the analytical form of and the variable in the Morse function: both are very similar to Dunham′s.

5.3 An Alternative Sutherland Parameter

Having to re-scale Δ, the most important species dependent scaling factor in molecular spectroscopy, may seem a drastic measure. We discuss the two asymptotes involved.

5.3.1 The Dunham Asymptote a_0

This mathematical asymptote is determined by the zeroth order constants alone. Hence, only mathematical re-scaling can be allowed. At least theoretically, re-scaling the Dunham asymptote is not that strange after all, since Dunham used the variable $(R - R_e)/R_e$ in his harmonic oscillator model.[12] For small deviations around the equilibrium distance, this variable refers to energies varying with R, which is not in line with observation on the molecular level and in physics and chemistry. The resulting well depth a_0 is difficult to understand in terms of a bonding model and it always leads to a completely wrong and too large a dissociation limit at $R = \infty$. This asymptote is not a natural atomic or molecular state but a mathematical artifact. It results from forcing Hooke′s law to apply to chemical bonding, in an attempt to recover mathematically all lower order spectroscopic constants in the harmonic oscillator

model. However, *this limitation of Dunham's asymptote is at the same time also its major advantage:* it provides us with a true, i.e. mathematical, reflection of the situation at the minimum, without any interference of external or higher order effects.

Now, the very similar variable $(R - R_e)/R$ would almost give the same oscillator behavior around R_e. In addition, this variable refers to an attractive energy varying with $1/R$, much more plausible in physical and chemical processes and the potential would not behave badly at $R = \infty$, as it will always converge to a finite limit (Van Hooydonk;[7] Simons, Parr, and Finlan[24]). This variable is well-known in physics and chemistry and was introduced by Kratzer,[25] more than 10 years before Dunham published his analysis.

The mathematical re-scaling for a_0 consists in a change of variable in Dunham's series. A change in the variable has a consequence for the asymptote, equal to

$D_x = D_{ion} = e^2/R_e$

corresponding with an (ionic) Coulomb energy between two point charges (attraction through a $1/R$-law) and with an ionic bonding model. Experiment shows that very often $D_e < D_x < a_0$, which is important for other reasons (see below). For 40 bonds, the performance of Kratzer potentials is good, even for higher order spectroscopic constants,[6][7] not under review now.

5.3.2 The Atomic Dissociation Limit D_e

Like constraint (ii), this limit seems untouchable, as it is experimentally and consistently reproduced in various ways. Yet, it is not closely bound to the low order constants as is a_0 at $R = R_e$.

Indeed, a number of effects can interfere between R_e and ∞ before the atomic dissociation limit is actually reached (see Varshni[3]). We give two examples. First, if the non-crossing rule interferes between the minimum and ∞, a fundamental change in the potential or in its parameters must have occurred. Consequently, the atomic dissociation limit D_e is then not a true reflection of the bonding situation at R_e (Varshni[3]). Second, if the atoms are *charged* at R_e, as in ionic bonds, a dissociation into *neutral* atoms is not a true reflection of the bonding state either. However, these two disturbing situations can never occur for the (artificial) Dunham-dissociation process, leading to a_0, which is, by definition, always and only, a true reflection of the bonding characteristics at R_e. If in some cases the atomic dissociation limit D_e is an n^{th} order asymptote, it has been subjected to effects, which are not included in the zeroth order potential describing the situation at the minimum. Then, we are in need of another alternative asymptote (and potential) that can be used to scale a_0 accordingly.

5.3.3 Constraints for an Alternative Sutherland Parameter

A possible solution would consist in leaving out the atomic dissociation limit as a scaling energy-level and a change of the variable in the Dunham potential, which entrains a different asymptote automatically (an ionic one in the case of the Kratzer variable).

The *necessary* constraints for an alternative asymptote D_x remain stringent: it should

− have a simple relation with zeroth order spectroscopic constants, very much like a_0

− derive from a two or three parameter universal potential

− have a simple chemical meaning (bonding model)

− reproduce correctly the first order spectroscopic constants (i.e. distinctively better than the results presented in Figure 2a and 2b using the Morse potential) and

− be situated between a_0 and D_e, in order that the non-crossing rule can interfere to obtain the correct dissociation limit D_e. $D_x - D_e$, would then determine the critical distance.

We realize that skipping condition (ii) opens the way for other potentials with possibly universal characteristics.[15] However, using a priori another dissociation limit to account for the observed PE curves, also a priori introduces an apparent error: this should constantly be kept in mind when comparing the performances of different potentials and asymptotes.

5.3.4 Scaling *F* and *G* by Ionic Sutherland Parameters

In principle, one could imagine various potentials with alternative asymptotes. We suggested that the ionic dissociation limit (and an ionic potential) is a good alternative,[6] as it is almost as good a *natural* dissociation limit as the atomic one and, it is usually situated between a_0 and D_e. The alternative (AIM-) asymptote of Von Szentpaly[15] seems to meet these constraints too, although his potential is not that transparent as an ionic one, it is not a reduced potential and the bonding model it relies upon is not that simple either (AIM-approach). A fairly good reason for choosing an ionic asymptote is that most of the aberrations showing in $F(\Delta)$- and $G(\Delta)$ plots, when a covalent Δ is used (see Figure 2a−b), disappear, *in agreement with experiment*, when the covalent bond energy is replaced by the ionic bond energy *for both ionic and non-ionic molecules.*[6][7] But, in general, two kinds of ionic asymptotes can be distinguished, depending on their D_e dependency.

5.3.4.1 Ionic Sutherland Parameter Depending on D_e

Only for dissociation in $A^+ + B^-$, a good approximation for the ionic Sutherland parameter is

$$\Delta_{ion} = 1/2\ k_e R_e^2/D_{ion} = a_0/D_{ion} \quad (5a)$$

where

$$D_{ion} = IE_B - EA_A + D_e \quad (5b)$$

in which IE_X is the ionization energy and EA_X the electron affinity. However, this is a poor approximation for the ionic

asymptote of bonds with intermediate polarity. In addition, it will always depend upon D_e (for a general D_{ion}, valid for all types of bonds, see below).

5.3.4.2 Ionic Sutherland Parameter not depending on D_e

For ionic molecules, with a spectroscopic behavior rationalized by ionic functions, Varhsni and Shukla[4] already suggested another scaling parameter t, defined as

$$t = 2 + k_e R_e^3/e^2 \quad (6)$$

independent of D_e and which relies upon an eigenvalue

$$D_x = e^2/R_e \quad (7a)$$

corresponding with a different ionic (Coulomb) Sutherland parameter

$$\Delta'_{ion} = 1/2\ k_e R_e^2/D'_{ion} = a_0/e^2/R_e \quad (7b)$$

This is the most natural ionic asymptote imaginable in chemistry (Coulomb attraction between two point charges) and it is exactly the asymptote generated by a Kratzer potential. This asymptote can, when generally valid, be extended to all types of bonds without exception (for which R_e is known) and can even be applied to bonds for which D_e is not known, which is the case for many of the 400 bonds, inventoried in the present study.

5.3.5 Results with Ionic Sutherland Parameters − Discussion

For 40 bonds, the constants of non-ionic (i.e. covalent or homonuclear) molecules can be brought in line with ionic bonds just using an ionic Sutherland parameter.[6] In addition, the RKR curves are correctly reproduced for different kinds of bonds.[6] Not only $F(\Delta_{ion})$ and $G(\Delta_{ion})$ plots but also $F(t)$ and $G(t)$ plots show very smooth relations, not too far away from the ones theoretically expected by ionic potentials.[6] Figure 2c illustrates these earlier findings on a larger scale for *91* single bonds, whereby experimental F values are plotted against the *square root* of the ionic Coulomb Sutherland parameter, simply related to the Varshni −Shukla parameter t:

$$\Delta'_{ion} = a_0/e^2/R_e = (1/2)k_e R_e^3/e^2 = t/2 - 1 \quad (8)$$

We cannot but conclude from Figure 2c, in which no *gap* appears at all, that our suggestion to change the variable in the Dunham expansion and to use the alternative asymptote generated for scaling turns out to be very satisfactory. The slope of the trend line is almost *unity*, the intercept is almost *zero* and most data-points are on or very close to the empirical fit. The goodness of fit is over *0.9*, including the data point for F_2, which is the most notable exception. This is also an exception in the Von Szentpaly scheme[15] and in many other instances.

In comparison with Figure 2a, Figure 2c represents a significant improvement, both practically and theoretically. We are now justified to elaborate the theoretical predictions of ionic potentials and to see whether or not they can be considered as universal (low parameter) potentials.

6. Universal Two-Parameter Functions: Theoretical Requirements

6.1 Ionic Potentials

Born,[26] Pauling,[27] and Mulliken[28] all had a special interest for ionic potentials, which remain an important part of the chemical heritage (see Varshni and Shukla′s review[4] for alkali-halides, dissociating nearly into ions, with $D_e \approx D_{ion}$). The choice of empirical ionic potentials is very large[4] and it is impossible to give a full overview here. However, since all ionic potentials are similar, we give two functions, bearing a direct relationship with Coulomb′s law.

6.1.1 The Born−Landé Potential[25]

$$U(R) = -e^2/R + B/R^n \quad (9)$$

is one of the oldest ionic potentials and it is a simplified version of the general Mecke[29]−Sutherland[11] function, used by Grüneisen[30] and Mie[31] in solid state physics. The potential was discussed by Varshni and Shukla.[4] Their results for F and G in function of Δ are given in Table 1 below. Its asymptote equals

$$D_x = e^2(1 - 1/n)/R_e \quad (10)$$

and is, in general, larger than D_e. Values for n are obtained using ionization energies, electron affinities and D_e, which is always needed. In general $n \approx 9$, but $n = 2$ is a special case.

6.1.2 The Kratzer[25]−Fues[32] Potential

With $n = 2$ in (9), a Kratzer-type potential is generated, of the general form

$$U(R) = -2Ae^2/R + B/R^2 \quad (11)$$

which is a very attractive potential[6,7,33,34]. This Coulomb function also generates a simple asymptote, comparable in magnitude with (10), and equal to

$$D_x = Ae^2/R_e \quad (12).$$

The Kratzer variable

$$\lambda = (R_e - R)/R \quad (13)$$

behaves almost exactly as the Dunham variable ρ around R_e (see above). With $A = 1$, this is even a *one parameter potential*.

In reduced form, the potential can be *forced* towards the atomic dissociation limit at infinite separation instead of to its natural asymptote (12), leading to

$$U(R) = D_e(1 - R_e/R)^2 \quad (14)$$

and then becomes a *two parameter potential*. Since we proposed the variable (13) to replace Dunham's ρ, an expansion of (14) in terms of ρ generates (ideal) ionic Dunham coefficients[7]:

$$a_n = (-1)^n (n + 1) \quad (15)$$

Even these simple values are of the correct order of magnitude in a number of cases. With a deviation of ± 25%, these *mathematical* coefficients are obeyed by about 1/5 of 381 bonds:

- for $-a_1 = 2 \pm 0.50$: 108 bonds
- for $a_2 = 3 \pm 0.75$: 76 bonds.

In his analysis of the Kratzer potential, Varshni[3] argued that this *two* parameter potential always gives $\Delta = 1$ (see Table 1), a value reserved exclusively for $D_x = a_0$. He remarked that this Δ value (= 1) did not occur in practice with a_0/D_e values and he had to reject the potential. In our set of over 300 bonds, we found 2.040 as the lowest value for the *covalent* Sutherland parameter (for T_2^+). Applying constraint (ii), Varhsni could not try a different asymptote, although for ionic asymptotes, the situation $\Delta_{ion} < 1$ also occurs. Instead, he introduced a generalization, expected to yield better results, when coupled to D_e (see next section).

Although they did not mention Kratzer's work, Simons, Parr, and Finlan[24] also attempted to remedy the convergence problem of the Dunham series, i.e. its wrong behavior at $R = \infty$, by using the Kratzer variable λ, leading to a function known as the SPF potential. Despite the advantages the SPF potential certainly has, we showed[7] a long time ago that this can never be an appropriate solution. In the SPF theory λ remains coupled with (if not to say forced to) the atomic dissociation energy, which is not its natural eigenvalue.

6.1.3 Generalized Kratzer Potentials

The Varshni-V potential[3]

$$U(R) = D_e[1 - (R_e/R)^m]^2 \quad (16)$$

is a straightforward generalization of the Kratzer potential (14), although the asymptote should be e^2/R_e, and not D_e. The corresponding *reduced* generalized function is

$$U(R)/D_e = [1 - (R_e/R)^m]^2 = (1 - r^{-m})^2 \quad (17)$$

with $R = rR_e$, r being a number, obeying $0 \le r \le \infty$. This potential was applied to a variety of bonds with satisfactory results, only after replacing D_e with D_{ion}.[6][7] This generalization leads to the F and G expressions, collected in Table 1, where the potential is denoted by *Kratzer I-Varshni V*. Reminding Figure 2c, the identity $F = m = \Delta^{1/2}$ is intriguing. We will test here

$$U(R) = Ae^2/R_e[1 - (R_e/R)^m]^2 \quad (18)$$

With $A = 1$, this is a *two parameter (R_e and m) ionic potential:* just two parameters, R_e and k_e, suffice to reach a first order solution for the spectroscopic constants. The third parameter, available for further fitting, is A in Equation (18), as the only practical further scaling element is the Coulomb interaction. Here, parameterization in terms of the Calder−Ruedenberg idea of a Column classification (ionicity, charge-effects, ...) can logically be considered (see Figure 1). Only if the results obtained with $A = 1$ are acceptable for bonds with one or two monovalent atoms, we can allow other A values (for instance for multiple bonds). In cases where $A \neq 1$, we deal with a *three*-parameter potential.

Other generalizations of the Kratzer potential are possible[7]: a ratio $(R_e + a)/(R + a)$ leads to

$$U(R) = D_x [1 - (R_e + a)/(R + a)]^2$$
$$= D_x (1 - R_e/R)^2 [1/(1 + a/R_e)]^2 \quad (19)$$

in which the original Kratzer potential is multiplied by the square of a normalizing or scaling factor $y = 1/(1 + a/R_e)$. Expanding this alternative generalized Kratzer function in ρ, we get $F = 2\Delta^{1/2} - 1$ (see Table 1) as the Dunham coefficients will now be given by[7]

$$a_n = (-\Delta^{1/2})^n (n + 1) \quad (20)$$

These are scaled coefficients with respect to the ideal ionic ones given in Equation (15), where $\Delta^{1/2} = 1$. Results are collected in Table 1 under the potential *Kratzer II*. If D_x is an ionic dissociation limit computed from atomic data or computed directly from R_e, *ionic functions remain two parameter potentials.*

6.2 Ionic Dissociation Energy and the Ground State of Molecules

6.2.1 The Born−Landé Asymptote

To avoid the cumbersome procedure to obtain the n values needed for the Born−Landé asymptote (10), we want to replace it with a simpler variant, also independent of D_e.

Normally, ionic bond energies (asymptotes) are either given by $IE_A - EA_B + D_e$ for dissociation into A^+ and B^- or $IE_B - EA_A + D_e$ for dissociation into A^- and B^+ and, in both cases, D_e is needed. For bonds of intermediate polarity, the situation is less clear. If B has the higher electronegativity and *if both ionic forms are present in the ground state in a ratio* b^2/a^2 with $a^2 + b^2 = 1$, this virtual ionic dissociation energy would not be available experimentally. We can try to calculate it by putting

$$e^2(1 - 1/n)/R_e = a^2[(IE_B - EA_A) + D_e] + b^2[(IE_A - EA_B) + D_e]$$
$$= [IE_A + a^2(IE_B - IE_A)] - (a^2EA_A + b^2EA_B) + D_e \quad (21a)$$
$$\approx IE_A + a^2(IE_B - IE_A) \quad (21b)$$

In going from Equation (21a) to (21b), we used the intermediate result,[34] that, in first approximation,

$$D_e = a^2EA_A + b^2EA_B \quad (22)$$

and this might remove D_e from the ionic bond energies in a systematic way.

With the definition of the bond polarity $I = b^2 - a^2$, this ionic asymptote will further reduce to

$$e^2(1 - 1/n)/R_e \approx IE_A + (1 - I)(IE_B - IE_A)/2 \quad (23)$$

$$\approx 1/2(IE_A + IE_B)(1 - I^2) \quad (24)$$

if $I = (IE_B - IE_A)/(IE_A + IE_B)$ is used as a first order approximation for the bond polarity I.

Strictly spoken, I should depend on electronegativities, according to Wilmshurst.[35] Using IE_X as an approximation for either the Pauling[36] electronegativity χ_P or Mulliken's[37] $\chi_M = (IE_X + EA_X)/2$ is acceptable, especially if Mulliken's definition is taken as a guideline (in general $IE_X >> EA_X$). The only theoretical advantage of these deductions is a simplification of the ionic bond energy (21), which can now be computed from available atomic quantities (ground state ionization energies of atoms), as intended. Using Pauling χ_P values would not alter much to the result for the asymptote (except in a few cases).

The asymptote for a virtual dissociation in $a^2(A^- + B^+) + b^2(A^+ + B^-)$ gives an idea of the bonding situation at R_e, since the bonding partners, isolated at $R = \infty$, are frozen in the same (*charged*) states they had at the equilibrium distance (IIM method).

Developing (23) further shows that

$$e^2(1 - 1/n)/R_e \approx 2\ IE_AIE_B/(IE_A + IE_B) \quad (25)$$

For homonuclear bonds XX, we get

$$e^2(1 - 1/n)/R_e \approx (IE_X - EA_X) + D_e \approx IE_X \quad (26)$$

if the difference between EA_X and D_e is not too large.

Using this approximation would again lead to a *two-parameter* potential, at least for bonds between monovalent atoms, whereby just k_e and R_e will be needed to compute F and G. Additional refinements are possible using valence state ionization energies instead of ground state values, similar an approach as suggested by Von Szentpaly in his AIM approximation.[15]

Rewriting Equation (25) in function of effective charges q_X and covalent radii r_X of atoms X and using $IE_X = q_X e^2/2r_X$, where q_X and r_X are respectively the effective nuclear charge (for the valence electron) and the covalent radius of atom X, we obtain

$$e^2(1 - 1/n)/R_e = e^2(1 - I^2)(q_Ar_B + q_Br_A)/r_Ar_B.$$

If both q_A and q_B are not too different from 1, a standard relation results for the bond length

$$R_e \approx r_A + r_B$$

since the two polarity terms will cancel in first approximation. This brings ionic bond energies in line with the Kratzer asymptote, as intended by eliminating D_e in the Born−Landé asymptote.

6.2.2 The Kratzer Asymptote

Whether or not the Kratzer asymptote e^2/R_e is (or must be) the same as the Born−Landé asymptote is not clear. The predictions of these two ionic potentials will therefore be tested as such. We notice the dependence of the theoretical ionic bond energies upon $(1 - I^2)$ in Equation (23), which also suggests an alternative Kratzer I asymptote equal to

$$D_x = e^2(1 - I^2)/R_e \quad (27)$$

This corresponds with A in (18) equal to $(1 - I^2)$, a correction for charge transfer in the bond. If valid, this means that for two interacting charges at equilibrium the following Equation applies

$$A = q_Aq_B = A'(1 - I)(1 + I) = A'(1 - I^2) \quad (28)$$

if $q_X \approx 1 \pm I$, a strange formula for ionic bonds anyhow ($I = 1$ would mean $A = 0$), to be tested below with the spectroscopic constants. $A' = 1$ in Equation (28) would still give rise to two parameter Kratzer potentials, since I can be calculated from atomic quantities. It must be noticed that A will not only be determined by the atom's partial *charge* ($\pm I$) but also by its *valence* (which is a Column classification effect, as noticed by Calder and Ruedenberg[5]).

6.3 Relations Between the First-Order Parameters *F* and *G* and the Scaling Factor Δ for Some Standard Potentials

According to Varshni's procedure,[3] the higher derivatives of potentials, scaled by the second, result in relations between F and G and the Sutherland parameter Δ, shown in Table 1. Most potentials can be considered as two *or* three parameter functions (see above), only Morse's function is always a *three*-parameter potential. First order-zeroth order relations like $F(\Delta)$ allow a computation of D_x values, the intermediate asymptotes, directly from the spectroscopic constants for each of the potentials mentioned in Table 1.

For the same Δ values, large differences are expected for $F(\Delta)$ and $G(\Delta)$. Leaving out the Kratzer potential, the following F values are respectively obtained for $\Delta = 9$: 6.33, 3.00, 5.00, and 2.00 (difference > 300%). Differences (in%) for $\Delta = 1$ would be larger, as the respective F values are equal to 1.00, 1.00, 1.00, and 0.

Translating this into D_x values gives for $F = 2$ values ranging from $a_0/2.666$ to $a_0/0.41$, a ratio of 1/6.5, which must be clearly visible. Since, in theory, there are no differences between the Δ's in Table 1 (in a standard theory, they all equal the *covalent* Sutherland parameter), this would lead to conflicts, when the relative merits of potentials are to be compared, and universal scaling would become practically impossible (see Figure 2).

The resulting $G(F)$ relations and the G/F ratios, are similar, as they all start with a scaling factor $(1 + F)^2$. This factor relates to $a_1 = -(1 + F)$. Comparing the potentials

Table 1. $F(\Delta)$, $G(\Delta)$, and $G(F)$ relations according to some potentials

Potential	$F =$	$G =$	$G(F)$	G/F value	
				for $F = 1$	$F = 3$
Born−Landé	$2\Delta/3 + 1/3$	$(8\Delta^2 + 38\Delta + 26)/3$	$3 + 15F + 6F^2$ $= 6(1 + F)^2 + 3(F - 1)$	24	34
Kratzer	1	24	24 $(= 6(1 + F)^2)$	24	24
Kratzer I (= Varhsni V)	$\Delta^{1/2}$	$8\Delta + 12\Delta^{1/2} + 4$	$4 + 12F + 8F^2$ $= 8(1 + F)^2 - 4(1 + F)$	28	39
Kratzer II	$2\Delta^{1/2} - 1$	24Δ	$6 + 12F + 6F^2$ $= 6(1 + F)^2$	24	32
Morse	$\Delta^{1/2} - 1$	8Δ	$8 + 16F + 8F^2$ $= 8(1 + F)^2$	32	43

shows that, theoretically, Morse's potential gives the highest G values, followed by Kratzer I, Born−Landé, and Kratzer II in that order.

6.4 The *G*/*F* Ratio

Table 1 shows that theoretical G/F ratios obey equations of the general form

$$G/F = aF + b + c/F \ldots \quad (29)$$

where a, b, and c are constants and where the exponent of F [equal to 1 in Equation (29)] depends on the potential. Predictions about G/F values are roughly comparable with observed values.

In terms of the constants and according to Varshni's definition,[3] the G/F ratio obeys

$$G/F \approx (\omega_e x_e/\omega_e)\,(B_e/\alpha_e)$$
$$\approx (B_e/\omega_e)\,(\omega_e x_e/\alpha_e)$$
$$\approx \omega_e x_e B_e/\alpha_e\omega_e \quad (30)$$

independent of Δ and in which all lower order constants are pair-wise coupled in a symmetrical (vibrational/rotational or first order/zeroth order) or in an anti-symmetrical way. The normalizing factor for G, to distinguish between potentials, should rather be a_1^2 or $(1+F)^2$ (as in the Graves−Parr scheme[2]), but this would destroy part of the relation of the G/F ratio with the four constants in Equation (30). The G/F ratio plays an important role in other scaling schemes, although this is not always apparent in the original publications.

6.4.1 The *G*/*F* Ratio and the Calder−Ruedenberg Constant *C*

In the first large-scale analysis on constants of 160 diatomics, Calder and Ruedenberg[5] concluded 30 years ago that the G/F ratio is a constant C and that it is equal to

$$C = 4(1+a_1)/(a_2 - 5a_1^2/4) \approx 1.39\ (\pm\ 5\%) \quad (31)$$

The reported error of 5% for 160 bonds sounds impressive. They did not mention, however, that this constant C bears an intimate numerical relation with the G/F ratio:

$$G/F = 48/C \quad (32)$$

This follows from the relations between F and G and the lower order Dunham coefficients:

$$a_1 = -(1 + F) \quad (33a)$$
$$a_2 = (5/4)\,a_1^2 - G/12 \quad (33b)$$

since substituting (33a) and (33b) in (31) immediately gives (32). Very unfortunately, Calder and Ruedenberg did not at all discuss *potentials*: they restricted their analysis to the constants.

Translating their analysis to potentials and predicted G/F values [Table 1 and Equation (29)] leads to a contradiction: C can never be a constant as it will always depend upon F in a particular way for each of the potentials in Table 1 (see also Varshni[3] for other examples).

In the case of the Kratzer II potential, $C = 8F/(1 + F)^2$ leads to $C = 0$ for $F = 0$, with a maximum of 2 for $F = 1$ and then gradually decreasing with increasing F to 1.33 for $F = 4$. These predictions are roughly in line with observation, even Calder and Ruedenberg's: C values in general decrease with increasing F (or $-a_1$) values. Even the reputed Morse potential gives a similar result for C. With the ideal ionic coefficients (15), the constant C is equal to 2, of the correct order of magnitude.[7]

We showed some time ago how the difference between the asymptote D_x and the atomic asymptote D_e can influence quantitatively C values,[7] which, if true, might also point towards an external influence on G/F values (see further below).

Calder−Ruedenberg's idea of a constant C arose from classifying molecules in function of the position of the atoms in the columns of the Periodic Table (which might be a very rough intuitive measure for *valence* and for *bond ionicity* too, see above). This classification is justified by relations found between constants, whereby a clustering was observed for bonds between atoms in the same Columns of the Table (as illustrated in Figure 1b). Graves and Parr[2] also used the Column classification. However, these authors concluded that it did not help *significantly* to reveal scaling trends, in clear contradiction with the Calder−Ruedenberg analysis, its claimed accuracy and its conclusion.

The Graves−Parr conclusion is in line with our discussion about scaling given above (see Figure 1a−b) and we

will discuss the matter more fully below in another context. Despite this negative conclusion of Graves and Parr, the idea for a possible grouping of molecules in the spirit of Calder and Ruedenberg remains important in the context of Coulomb attraction

$$q_A q_B e^2/R \tag{34}$$

We refer to the discussion of A values in Equation (28), in terms of *charge* and *valence* effects. Strictly spoken, the Calder−Ruedenberg classification invokes an additional (hidden) parameter, not yet quantified. In line with the remarks by Graves and Parr, we will show that several of the Calder−Ruedenberg groups overlap (see also Figure 1b).

6.4.2 The *G*/*F* Ratio and the Graves−Parr Scaling System

In addition, in the Graves−Parr scaling system, the G/F ratio plays a dominant role, although this is not apparent in their paper.[2] They showed that the Dunham coefficients a_1 and a_2 should both be scaled by the *covalent* Sutherland parameter. With perfect scaling, the ratio of a_1^2/Δ and a_2/Δ should theoretically be a constant. However, statistical effects, not mentioned by Graves and Parr, will also increase the goodness of fit with respect to the unscaled coefficients. Table 2 gives some results.

Table 2. Graves−Parr scaling procedure

Potential	$a_1^2 =$	$a_2 =$	$a_1^2/a_2 =$
Kratzer	4	3	4/3 = 1.333
Kratzer I − Varshni V	$(1+\Delta^{1/2})^2$	$7/12(1 + \Delta^{1/2})^2 + (1/3)(1 + \Delta^{1/2})$	$1.714/(1 + 4/[7(1 + \Delta^{1/2}))]$
Kratzer II	4Δ	3Δ	4/3 = 1.333
Morse	Δ	$(7/12)\Delta$	12/7 = 1.714

The relations between the Dunham coefficients and the Varshni parameters F and G in Equation (33) show that a_1^2/a_2 is also determined by the G/F ratio. Whereas 3 potentials lead to a constant, only the Kratzer-I−Varshni-V function predicts that a_1^2/a_2 should be a function of $\Delta^{1/2}$ (or of F).

6.4.3 The *G*/*F* Ratio: Chaotic/Fractal Behavior

Freeman, March and Von Szentpaly[16] argued that an empirical power $G(F)$ relation exists

$$G = 27.4F^{4/3} \tag{35}$$

This, in their opinion, suggests chaotic/fractal behavior. Equation (35) leads to the ratio

$$G/F = 27.4F^{1/3} \tag{36}$$

resulting in the values 27 and 40 for F equal to 1 and 3, comparable with those in Table 1.

If this relation were reliable, this would probably complicate the search for a universal potential.

7. Universal Two-Parameter Functions: Theory versus Experiment

7.1 Lower-Order Constants

The spectroscopic constants ω_e, $\omega_e x_e$, B_e, and α_e exhibit intriguing relations, some of which were discussed already above and also by Calder and Ruedenberg[5] in order to justify the Column classification and by Herschbach and Laurie[19] for the Row classification. These will not be repeated here, although we discuss 100 bonds containing H, of which only 10 were included in the Calder−Ruedenberg analysis (one relation was extended to H bonds in Figure 1a and 1b).

We first present the results for the last identity in Equation (30) for 381 diatomic molecules in Figure 3. The empirical *power* relation (logarithmic scale), valid for differences of the order of 10^7 in the two axes, combined with a high R^2 value, is not significantly better than the empirical *linear* relation. Since these also determine the G/F ratio, chaotic/fractal behavior[16] may be put in doubt. The accuracy for the computed product of a pair of two constants is 10% for 381 bonds, which illustrates the overall quality of the relations between the constants. Various other relations are found. In some cases, an empirical power relation gives a goodness of fit of (over) 0.9, as can be seen from the results in Table 3. It is not always clear, however, whether or not this is due to large-scale differences or to a basic relation between the constants. We believe this is a matter of further research.

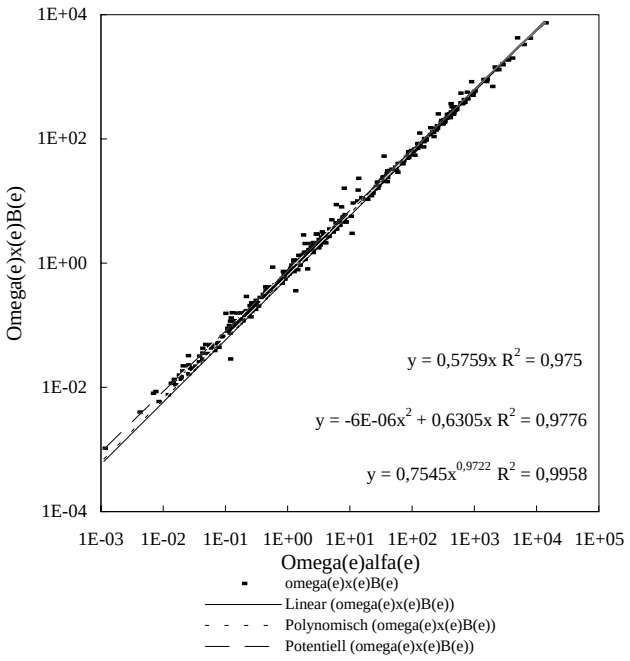

Figure 3. G/F: $\text{omega}_e x_e B_e$ versus $\text{omega}_e\text{alfa}_e$ for 380 bonds

Table 3. Empirical power relations between observed spectroscopic constants ω_e, $\omega_e x_e$, $_{Be}$ and α_e and equivalents for $14.4/R_e$ and a_0 (cm^{-1}) for 381 bonds and D_e(eV) for 300 bonds

$Y(X)$	Empirical $Y(X)$ relation	R^2	Remark
$\omega_e(\alpha_e)$	$3363.4X^{0.2996}$	0.7315	
$\omega_e(\omega_e x_e)$	$304.6\ X^{0.5386}$	0.8086	
$\omega_e(B_e)$	$894.48X^{0.4546}$	0.8336	
$\omega_e x_e(B_e)$	$7.2793X^{0.8044}$	0.9368	important for G, Equation (4)
$\omega_e x_e(\alpha_e)$	$92.138X^{0.5691}$	0.9466	corresponding with a $G(F)$ relation
$B_e(\alpha_e)$	$22.111X^{0.6956}$	0.9769	best fit, important for F, Equation (3)
$\omega_e(14.4/R_e)$	$3.6185X^{2.5694}$	0.8456	
$\omega_e(D_e)$	$391.38X^{0.5584}$	0.2166	for 300 bonds with D_e known
$\omega_e(a_0)$	$41.183X^{0.2372}$	0.0393	

For 381 bonds, the 6 relations between the constants in the upper part of Table 3 are quite reliable, the best being the 6^{th} $B_e(\alpha_e)$ in terms of R^2. This empirical power relation reproduces B_e values from α_e with an average absolute deviation of 10% for most bonds. The 5^{th} corresponds with a $G(F)$ relation (see above). Two other relations with a relative good fit are important for F and G.

The second part of Table 3 gives a confrontation of 3 asymptotes as to their possible relationships with the harmonic frequency, for which the R^2 values are much higher than for the remaining three spectroscopic constants (not shown). For the asymptotes D_e and a_0, there is no significant global relation. The situation is different for the ionic asymptote. However, if the asymptotes (x values) are corrected for reduced masses, the goodness of fit is drastically improved for all asymptotes (for the Kratzer asymptote, even the identity results in the case of B_e). Therefore, the groupings observed in Figure 1a and 1b originate for the larger part from the reduced masses. This is most apparent for H-containing bonds, which seem to form a different spectroscopic group (see Figure 1 and next sections).

7.2 Derived Constants (a_0, k_e, Δ, F, G)

We first confront the asymptotes with the harmonic frequency according to the Column classification (see also Table 3). As remarked by Calder and Ruedenberg,[5] the intuitively sound relation between the two most important constants of a bond, i.e. a_0 and ω_e, can be visualized in the corresponding plot (Figure 4a). Although a_0 depends on the square of ω_e by definition, no straight general relation is observed, except for some classes of bonds. In agreement with the situation in Figure 1a−b, also here we find regularities (Row- or Column classifications). Figure 4a also shows *why* Calder and Ruedenberg excluded most H-containing bonds from their analysis: these distinctly form a different spectroscopic class and the dividing line between H-containing molecules and the other is clearly visible. This line would be situated exactly where a breaking of the symmetry occurs between atom mass M and atom number Z, i.e. at $Z = 1$. Merely using Hooke's law to account for the constants (as in Dunham's oscillator model, where forces depend on masses) is not uniformly applicable throughout the Periodic Table.

Next, substituting a_0 with D_e (Figure 4b) does not improve the picture at all and no new or better global relationship emerges, on the contrary (in agreement with the results in Table 3). The only classes of bonds for which regularities appear (Column-classes 11, 77, and 27) are also grouped or equally regular in Figure 4a. For other groups, the regularities in Figure 4a have disappeared. This seems to justify our suggestion that D_e, the atomic dissociation limit, is only reached in a number of cases, after other effects have been operating between R_e and ∞. Therefore, it seems fair to exclude constraint (ii) in a search for a universal potential (see also Table 3).

Thirdly, substituting a_0 with the ionic dissociation energy (calculated from ionization energies, the Kratzer II asymptote) leads to a better picture (not shown) but which is intermediate with that obtained when one replaces a_0 with the Kratzer I asymptote. Figure 4c gives the plot for e^2/R_e. A similar plot has already been given in Figure 1, since $(B_e)^{1/2}$ can be used as a substitute for e^2/R_e in the x-axis. Figure 1 being an ω_e ($1/\mu R^2$) plot, it is readily concluded that this leads to a completely different picture than the one having a_0 in the x-axis (Figure 4a) both for the H-containing bonds and for other bonds. In fact, and contrary to Figure 4b for D_e, and apart from the scaling and classification effects already discussed above, Figure 4c also shows how well the harmonic frequencies of bonds are correlated with $1/R_e$. This dependence is characteristic for ionic potentials and we remind thereby that multiple bonds were not even excluded from these Figures. As well as the results in Table 3, this strengthens our ideas about the correct variable for the oscillator presentation. Indeed, Figure 4c gives large-scale evidence for the intuitive idea that an ionic Coulomb law seems to govern bond mechanics and that charges and valences are important to account for trends in the harmonic frequencies of bonds.

The details of clustering or classification in Figure 1a and 1b were discussed above. However, we must now remark that, in Figure 1b, the parallel lines are more close to each other and even extend linearly into the H group (points on the right side in Figure 1b). The number of lines that must be drawn in Figure 1b to encompass all data points seems less than in Figure 1a.

In terms of an additional parameter for a potential, it seems that a few values for A in Equation (28) would be sufficient to unify the complete picture in Figure 1b.

Experiment clearly shows, through Figure 4c, that the ionic dissociation limit can indeed be a serious candidate for explaining the relations between the spectroscopic constants. This asymptote seems very suited also for scaling a_0, as it correlates extremely well with the two $zero^{th}$ order constants, which completely determine a_0. These are exactly some of the constraints for the alternative asymptote, given above. The transformation of the Dunham variable into the Kratzer variable for which we gave theoretical arguments

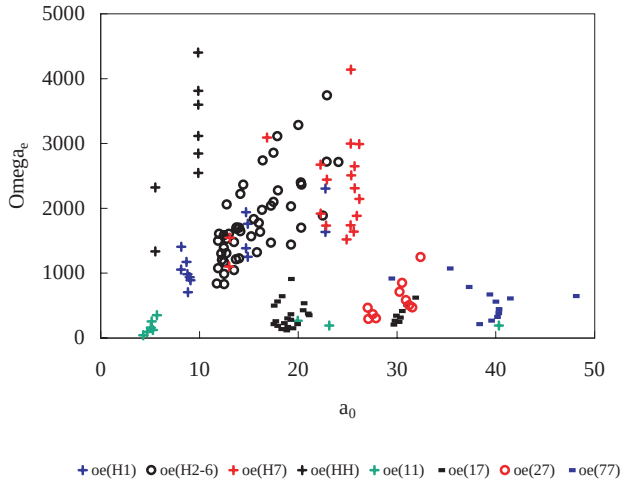

Figure 4a. Omega$_e$ versus a_0 (Column-classification)

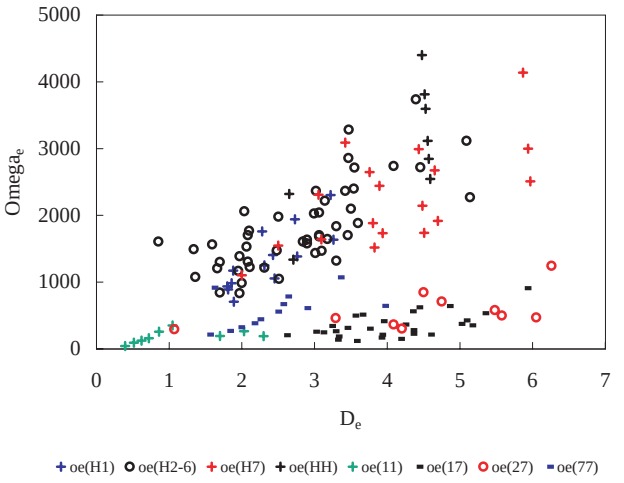

Figure 4b. Omega$_e$ versus D_e (Column-classification)

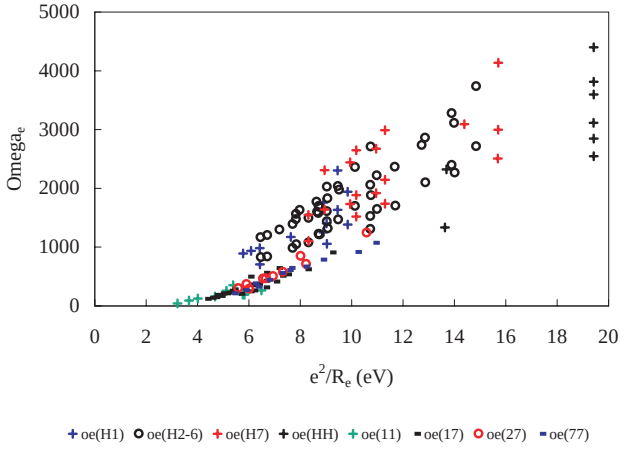

Figure 4c. Omega$_e$ versus e^2/R_e (Column-classification)

above, seems to be very effective indeed and is confirmed by experiment (see Figure 4c and Table 3).

7.3 Atomic Mass-Atomic Charge Symmetry Breaking

If we compare Figure 4c with the corresponding Figure 4a−b, we already notice a significant improvement in the relation between the harmonic frequency and the asymptote. Since Figure 1a and Figure 1b are a justification for the two classification schemes (by Row or by Column), we now find a third effect operating in this correlation: symmetry breaking between atomic masses and atomic charges.

To illustrate this symmetry-breaking effect, we made a plot (Figure 5) of the reduced mass μ versus its equivalent ζ in terms of atom numbers Z, or

$$\zeta = 2Z_AZ_B/(Z_A+Z_B) \quad (37)$$

since, roughly, $M_X = 2Z_X$, especially in the lower part of the Periodic Table ($Z < 50$). Although a linear or a power fit gives R^2 values equal to almost unity, only a log-scale reveals the details of the symmetry-breaking effect at $Z = 1$ (see Figure 5). Only D-containing bonds follow the trend of the general relation. Reduced masses are determined by Rows and by Columns, as well as reduced atomic charges (atom numbers Z).

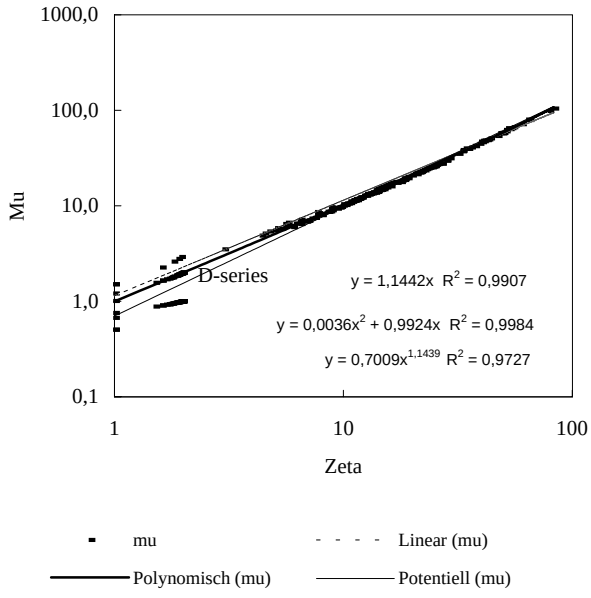

Figure 5. Mu versus Zeta for 300 bonds

In fact, most of the discontinuities between H- and non-H bonds in Figure1a−b disappear if the square root of the harmonic frequency is plotted against an R value, that is corrected for a symmetry breaking effect at $Z = 1$, or

$$R_{corr} = R_e\,(\zeta/\mu)^{1/2} \quad (38)$$

The result is shown in Figure 6a which should be compared with Figure 4c (see above) to notice the global effect. The goodness of fit for a linear relation is 0.93, for a power fit it is 0.95 and for a quadratic one it is over 0.97. This is an improvement over the situation with the Dunham asymptote plotted against the harmonic frequency (Figure 4a) and may even question the validity of the classification schemes, discussed above, as all data-points seem to gather around a *single* line. For instance Row- or Column classifications are hardly visible (see Figure 6b for a log-log plot), and if persistent, hardly quantifiable. A comparison of Fig-

ure 6b with Figure 1 shows the scaling effects we were looking for.

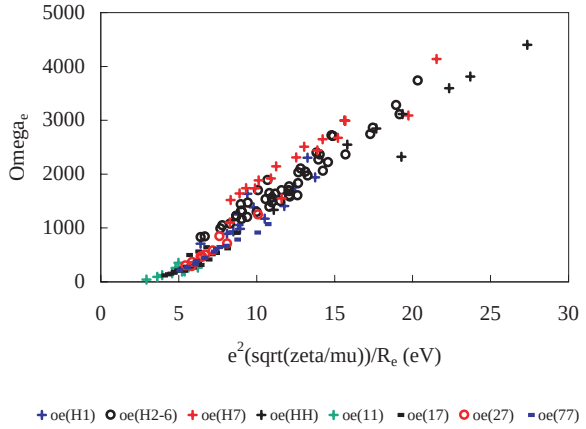

Figure 6a. Omega$_e$ versus e^2(sqrt(zeta/mu))/R$_e$ (Column-classification)

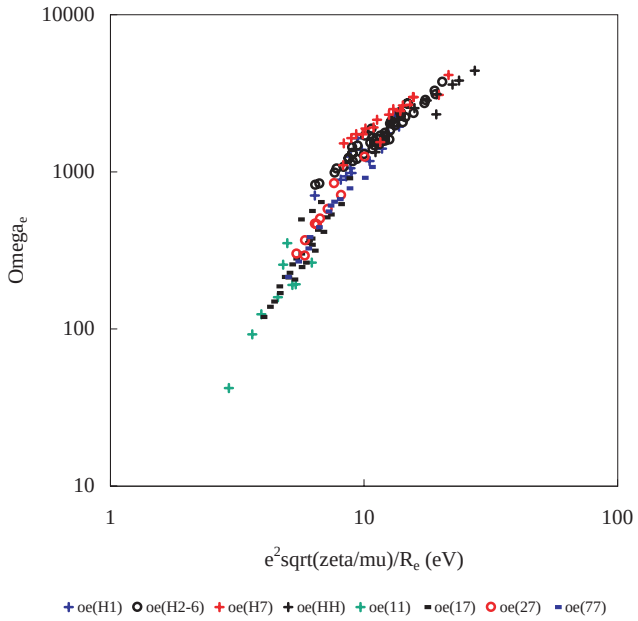

Figure 6b. Omega$_e$ versus e^{2}sqrt(zeta/mu)/R$_e$ (Column-classification) (log-scale)

These results are in agreement with classical dynamics (the dependence of the frequency on the ratio Z/M). This generalization of the ω_e ($1/R_e$) relation provides us with a possibility to achieve universal scaling in terms of charges and Coulomb-like potentials, reminding thereby the spectroscopic definition of a_0, see Equation (2b).

7.4 Experimental and Theoretical $G(F)$ Relations

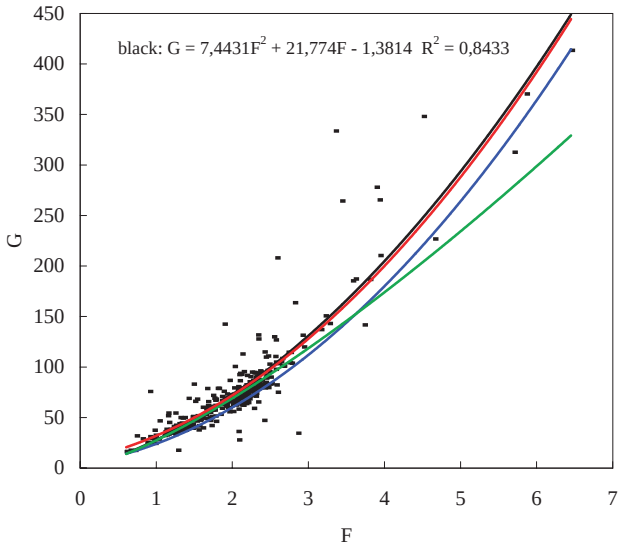
Unlike the $F(\Delta)$- and $G(\Delta)$ relations (see Figure 2a and 2b), the $G(F)$ relation is completely determined by the spectroscopic constants. This relation represents a challenge for potentials and for scaling (see for instance the $\omega_e x_e$ (α_e) dependence in Table 3). We now confront the experimental $G(F)$ relation with the predictions of the potentials in Table 1.

Figure 7a presents the global view for the 381 diatomics with both G and F available. The best fit of a quadratic relation nearly goes through the origin (intercept −1.38), but the coefficients of F are 7.4 for the quadratic and 21.8 for the linear term (see the Equations in Table 1). The power fit gives $28.974F^{1.2978}$, not too far away from the Freeman fit (see Equation 35). Both empirical relations have the same goodness of fit of $R^2 = 0.843$. We observe that the Morse function is closest to the empirical fit, followed by the Kratzer I potential. The goodness of fit is in agreement with that found for the $\omega_e x_e$ (α_e) relation in Table 3.

Nevertheless, there is a strong bias from exotic molecules (Van der Waals molecules, excited states, ...) with anomalous G/F values. Leaving out all excited states and extreme cases gives Figure 7b for some 300 bonds. The empirical quadratic equation is (only) slightly better than the power relation. This empirical quadratic relation gives G ($\approx \omega_e x_e$) from F ($\approx \alpha_e$) within 9.8% of experiment, which is quite accurate given the number and the different kinds of molecules. The empirical fit lies between the Morse and Kratzer curves, but is closer to Morse's. The coefficients compare well with the theoretical ones given in Table 1.

At this stage (Figure 7a and 7b), the enlargement of the data-sample does not favor the conclusion of Freeman et al.[16] about chaotic/fractal behavior, especially not in terms of the goodness of fit. Further material at high F values, where the empirical approaches diverge (Figure 7a), might be decisive in this respect, although this information will be hard to find.

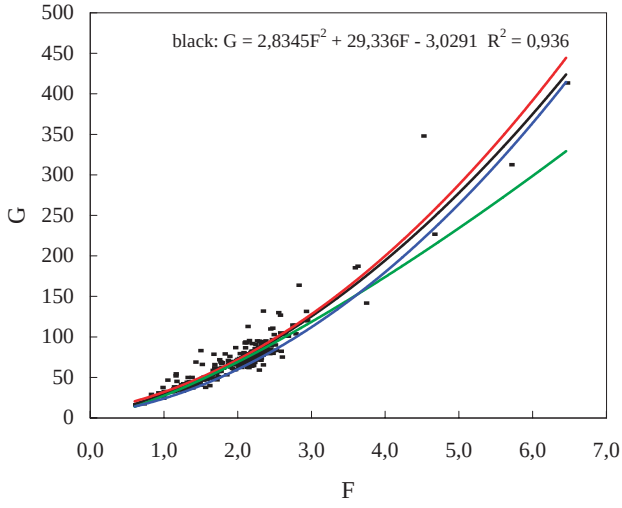
We notice from Figure 7a and 7b that the Morse potential seems to validate Jhung's hypothesis[9] and that the Kratzer I potential is low (see also our discussion of Table 1).



When the set is limited to 91 bonds between monovalent atoms (Figure 7c), different equations are generated. We now have $G = 9.55F^2 + 9.473F + 10.355$ with $R^2 = 0.9439$ and $G = 30.012F^{1.2162}$ with $R^2 = 0.9405$ (not shown), which are again close to the theoretical relations given in Table 1. Comparing the theoretical results of Table 1 with those of empirical quadratic fitting leads us to conclude that the Morse and the Kratzer I potential are the best choices in that order for reproducing the empirical $G(F)$ plot.

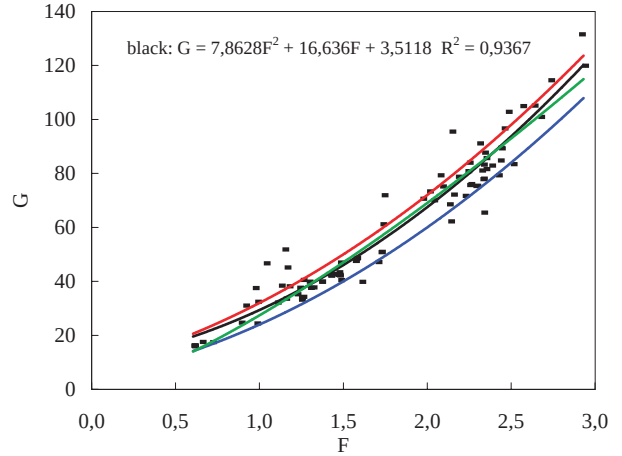
A different situation is found, when the theoretical predictions by the potentials are considered for the $G(\Delta)$ relation (see below). For the 91 bonds between monovalent atoms, the Morse results were already given above (Figure 2b), with a goodness of fit of only 0.5786 and a slope of 1.067 for an intercept of −3.57 in the case of a linear fit.

7.5 Predictions for First-Order Constants α_e and $\omega_e x_e$: Comparing the Performance of Kratzer and Morse Potentials



7.5.1 Ionic Sutherland Parameters for 91 Single Bonds and F

Figure 8a gives a plot of the three ionic Sutherland parameters versus F for 91 bonds between monovalent atoms. Even including F_2 (with $F = 2.667$), the goodness of fit for



red: Morse; blue KratzerI/Varshni V, green Freeman…, empirical

Figure 7a. Plot of G versus F for 381 bonds

red: Morse; blue: Kratzer I/varshni V; green: Freeman, empirical

Figure 7b. G versus F for 300 bonds

red: Morse; blue: Kratzer I/Varshni V; green: Freeman, empirical

Figure 7c. G versus F for 91 single bonded diatomics

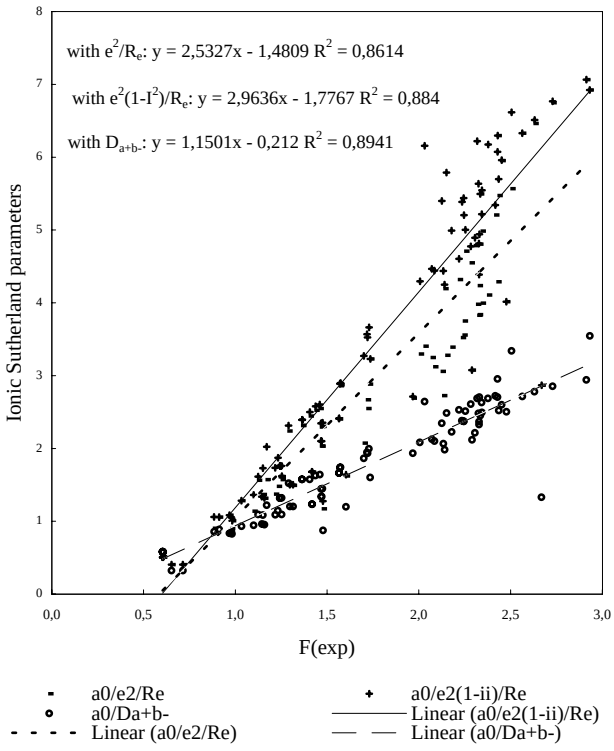


Figure 8a. Plot of 3 ionic Sutherland parameters versus F(exp) for 91 single bonded diatomics

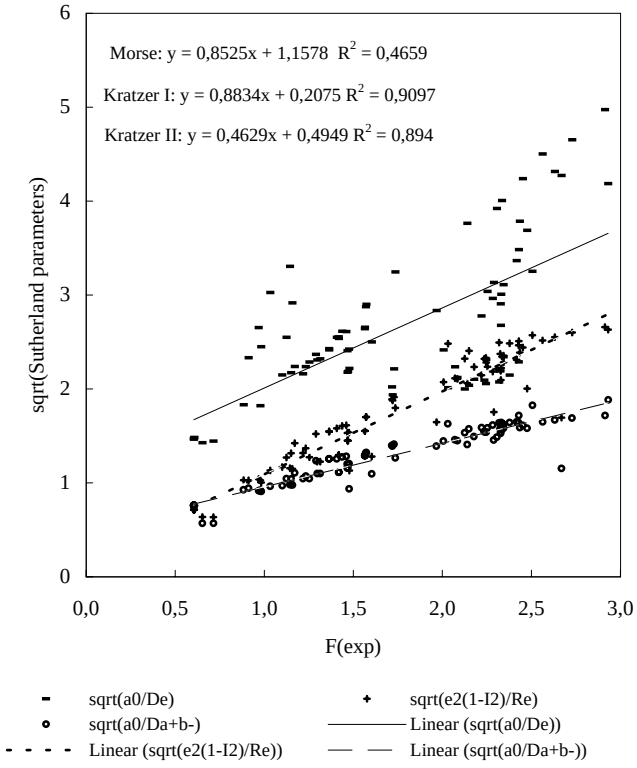

Figure 8b. Square root of different Sutherland parameters versus F for 91 single bonded diatomics

all ionic asymptotes is relatively high. The series, based upon D_{A+B-}, calculated from ionization potentials, has polarity effects ($1 - I^2$) included automatically. The trends observed show that a quadratic dependence might be better (see the Graves−Parr suggestion and see Table 1).

Figure 8b represents the results with $\sqrt{\Delta}$ for the same 91 bonds but now the covalent Sutherland parameter is included for comparison (see also Figure 2). Despite the scale differences, it is readily concluded that *any ionic Sutherland parameter is superior to the covalent one.* Slopes and intercepts are as expected, even for the Morse relation. The covalent Sutherland parameter may be plausible for some (classes of) molecules. About 50 are situated near the theoretical line but 40 are completely out of range (another illustration of Varshni′s earlier observation and of the spectroscopic gap, artificially created by the covalent Sutherland parameter, see above).

The predictions of a Kratzer potential are good. Empirical fitting through the origin yields the theoretically expected coefficient of nearly 1, with a goodness of fit almost identical to a linear fit, with a free intercept (not shown). The other series, based upon D_{A+B-} (also promoting the Born−Landé potential in Figure 8a) practically leads to a relation of the form

$$F = 2\Delta^{1/2} - 1 \text{ or } \Delta^{1/2} = F/2 + 1/2$$

(goodness of fit 0.89). This corresponds with the predictions of the *Kratzer II* potential.

Since the polarity I of the bond is computed from *atomic* quantities, Figure 8b is achieved by means of ionic *two parameter* potentials.

7.5.2 Calculation of α_e and $\omega_e x_e$ for 308 Bonds

A calculation of the constants α_e and $\omega_e x_e$ directly from the potentials gives the results collected in Table 4, given in Supporting Information.

Only for α_e, we tried to present the results graphically (see Figure 9a), using a log scale due to the large differences in α_e values. Two help-lines are drawn at ± 25% of the experimental α_e values. Help-lines at a lower percentage interfere too much with the empirical fittings through the origin (−20% would nearly coincide with the Morse trendline, whereas +10% or +15% would have been too close to the Kratzer trendline). For 308 bonds, the mean deviation for the Kratzer I potential is 18.1% and for Morse′s 20.1% (see also Table 4). This makes the performance of the two comparable but the errors are too large for a universal potential.

We must however divide these 308 bonds in two main series:

– 197 bonds with at least one monovalent atom and a main column element

– 111 other bonds, including bonds between polyvalent atoms, Van der Waals molecules, ...

This distinction is necessary since we can expect that only with A' near or equal to 1, the Kratzer I asymptote can reasonably be calculated without any further assumptions. For these 197 *simple* bonds, it can be expected that also Morse′s function will behave at its best. Part one of Table 4 in the Supporting Information (197 bonds) reveals that the performance of the two parameter Kratzer potential with a *wrong* asymptote is now significantly better than Morse′s three parameter potential, which uses the natural and *correct* asymptote.

Table 5a gives an overview of the spread of the mean deviations (%) in the 197 and 111 series. It is easily verified that the Kratzer potential is superior to Morse′s for pre-

Table 4. Data for 308 bonds (sample for 27 bonds from part one: 197 bonds containing at least one mono-valent atom)[a]

dicting the two constants in 197 series. The number of bonds in the 0−10% range is twice as large for the Kratzer potential, 126 and 86, than for Morse′s, 59 and 54 respectively.

The first row of data in Table 5a shows that up to bond number 85, the average deviation is ±2.38%. Up to number 126, it is ±3.97%, up to 154 ±5.41%, up to 170 ±6.47% and up to 188 ±8.08% (for bond 197 it is 100%). As we pointed out above that an average error of about ±5% can be considered as a reasonable limit for a "universal potential", the Kratzer-I−Varshni-V potential seems to meet this criterion and is certainly superior to Morse′s.

Error ranges derived from the square root of the percentage deviation for α_e times that for $\omega_e x_e$ for the same bond in the same 197 series give

− Kratzer potential deviation ±20% 171 bonds; ±10% 128; ±5% 57

− Morse potential deviation ±20% 109 bonds; ±10% 62; ±5% 20.

With this criterion, Kratzer′s potential is again superior to Morse′s. With Kratzer′s potential, the deviation for 171 bonds (i.e. 87% of 197 bonds) is ±7% for α_e and $\omega_e x_e$ combined.

In order to get an idea of the regularities in these results, we arranged all 308 bonds according to a rough Column classification, e.g. NaK in 11, RbF in 17, BeCl in 27, ... We also computed *C* (the Calder−Ruedenberg constant) and its % deviation from the average value. *F* and *G* values are also given. Table 4 (Supporting Information) gives these additional results for all 308 bonds, divided in the 2 series, ordered by a Column classification and alphabetically by bond.

A global comparison of the performances of the Kratzer and Morse potentials for calculating α_e and $\omega_e x_e$ for the 197 simple bonds is given in Table 5b, using the Column classification as a guideline. The % deviations for the Kratzer potential are smaller than those obtained with the Morse potential. Only rarely, one observes a better score for the Morse potential. The Morse results found here are slightly better than those reported by Varshni, who qualified this potential as not too good.

In the 23 bonds used by Varhsni[3] 17 would belong to the 197 series and his results are ±36.4% for α_e and ±32.9% for $\omega_e x_e$ (for 23 bonds: he found deviations of 33.1% and 31.2% respectively). Varshni′s best results were obtained with an *empirical* potential. The 23-bond set gave errors of ±22.1% for α_e and ±11.1% for $\omega_e x_e$. The figures for the 17 bonds set are nearly the same and comparable with those in Table 5b.

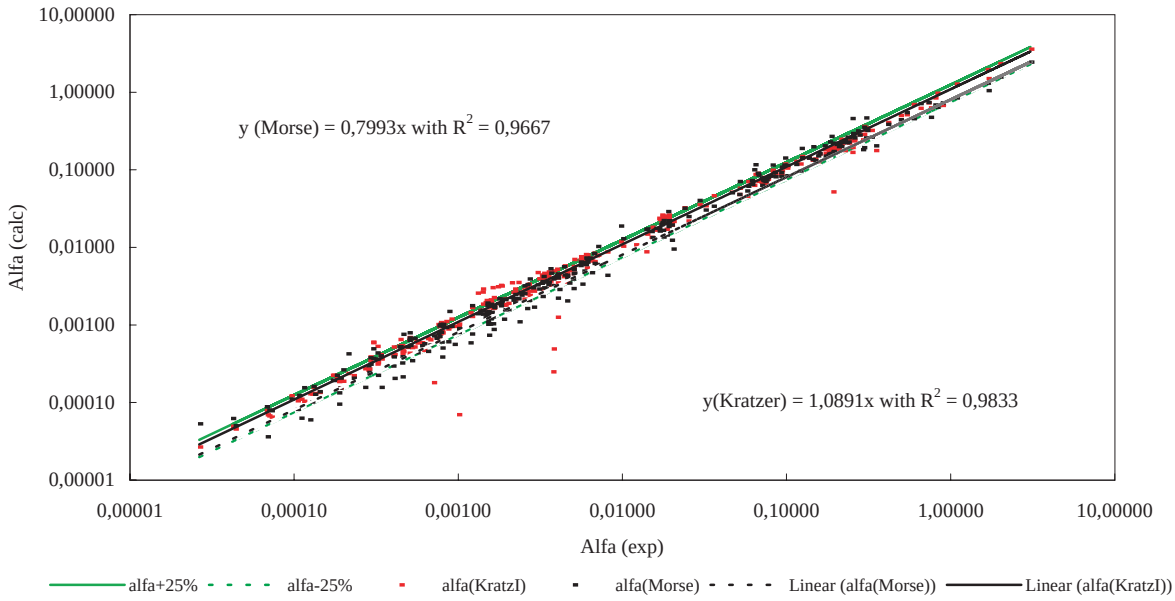

Figure 9a. Alfa for 312 diatomics, computed from Kratzer I/Varshni V and Morse potentials

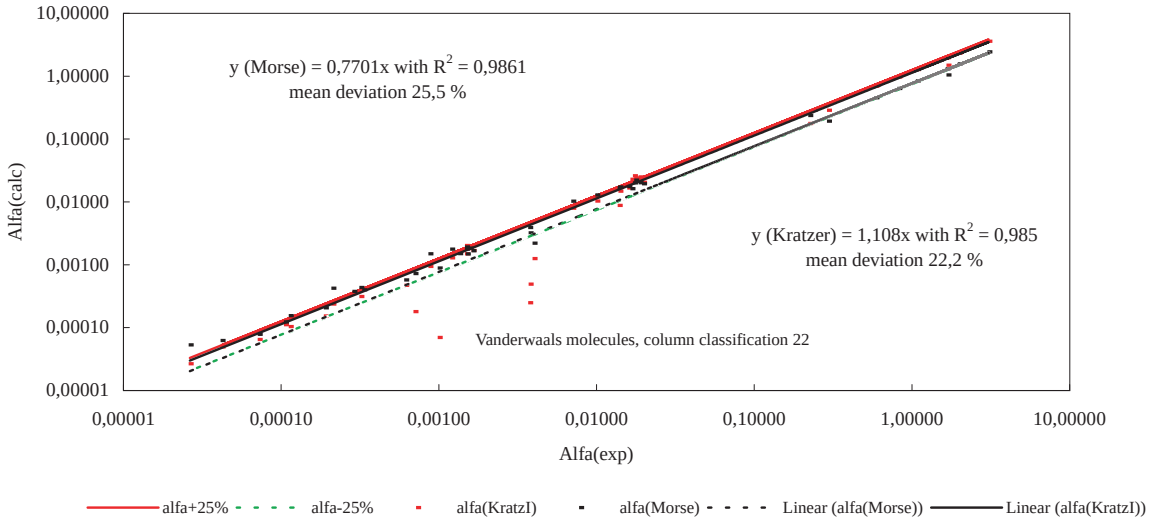

Figure 9b. Alfa for 42 homonuclear bonds, computed from Kratzer I/Varshni V and Morse potentials

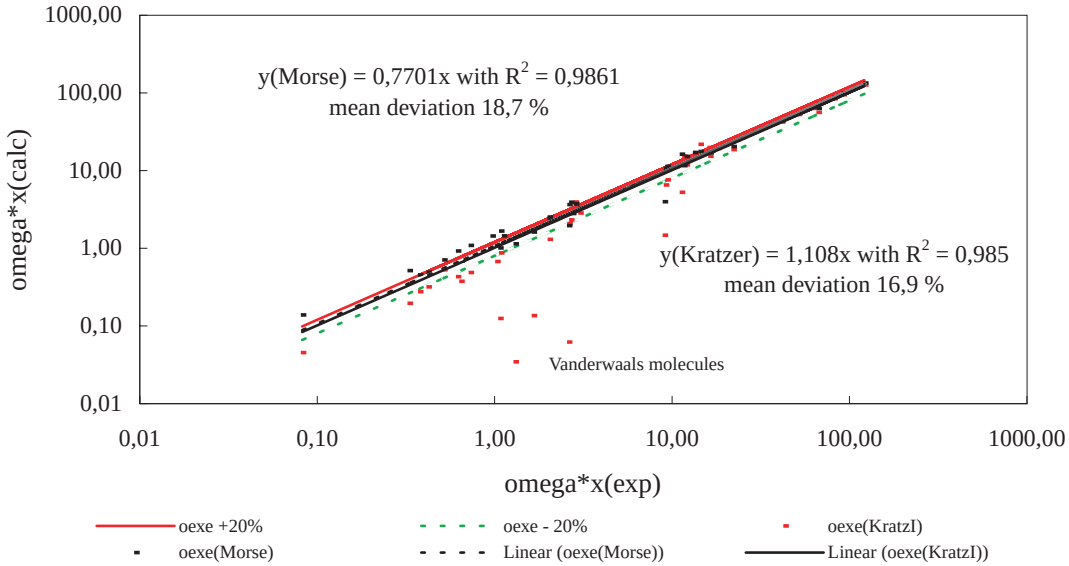

Figure 9c. Omega*x for 42 homonuclear bonds, computed from Kratzer I/Varshni V and Morse potentials

With respect to the Morse results, mean deviations in % are 2 to 3 times smaller for the Kratzer potential (Table 5b). We must keep in mind that many of the compiled constants are uncertain, not all equally accurate and sometimes even in error: the experimental α_e value for YCl (bond Nr. 77 in Table 4) is probably not correct.

Part two of Table 4 reveals interesting further details on this subject. For these 111 bonds, the situation is opposite in terms deviations. Now, Morse′s potential seems superior to Kratzer′s. However, the overall result for the 308 bonds is slightly in favor of the Kratzer potential again. However, this is not straightforward an interpretation.

In fact, the largest deviations for the Kratzer I potential in the 111 bonds set are found

(a) for cases in which $A << 1$ (Van der Waals molecules in group 22 and bonds with noble gas elements in group O): here all deviations are *negative and very large* (between 50 and 100%), meaning that the ionic limit is *overestimated* with an A value around 1

(b) for cases in which $A >> 1$ (multiple bonds): here the opposite situation applies, since all deviations are now *positive and large* (> 20%), as expected. Here the ionic limit is clearly *underestimated*. Numerical results are shown in Tables 4−5.

We did not want an empirical parameterization of the results (for instance using coefficients of empirical trendlines produced in the plots instead of their theoretical values[2][3]). In many cases, this would improve the results empirically (smaller% deviations).

7.5.3 Calculation of α_e and $\omega_e x_e$ for 43 Homonuclear Bonds

With Varshni,[3] we do not understand why the Morse potential has such a good reputation, especially for covalent bonds, as mentioned in many textbooks. Therefore, we selected data for homonuclear diatomics and compared the performances for this type of bond (43 bonds are available, polyvalent atoms, molecular ions, noble gases, ... are all included, see Table 4, Supporting Information).

We present the results in Figure 9b for α_e with the rather surprising conclusion that even here the mean deviations for the ionic Kratzer I potential are smaller than for Morse′s covalent potential. Nevertheless, 5 Van der Waals bonds are included (for which the ionic potential with $A = 1$, $I = 0$, underestimates these asymptotes). These points are indicated in Figure 9a.

In addition, for $\omega_e x_e$ (see Figure 9c) a similar situation applies. Despite the large deviations from $A = 1$ (both > 1 and <1), exactly as in the 111 series and despite the wrong asymptote, the performance of the Kratzer potential is still comparable with that of Morse′s for 43 homonuclear bonds. This is a surprising and unexpected result.

7.5.4 Calculation of α_e and $\omega e x e$ for 91 Single Bonds

For 91 bonds between two monovalent atoms, interesting details show (Table 4, Supporting Information). We refer for this set also to Figure 2, Figure 8, and Figure 7c. The global results are:

− Kratzer potential: mean % deviation for α_e ±8.2, for $\omega_e x_e$ ±13.16%

− Morse potential: mean % deviation for α_e ±25.9, for $\omega_e x_e$ ±26.54%.

These deviations are, as expected, even more pronounced and again in favor of the Kratzer-I−Varshni V potential (see also Tables 5a−b).

7.5.5 Conclusion of This Section

It is difficult to visualize all the results obtained thus far, due to large differences in magnitude, as in Figure 9a−b−c. Nevertheless, we can safely conclude that

(a) an ionic function is better than a covalent one and especially that

(b) the Kratzer-I−Varshni V potential is the most likely candidate, if any, for being a *two-parameter* universal potential.

We will try to illustrate these differences graphically using the Graves−Parr scaling method.[2]

7.6 Scaling 300 Pairs of Dunham Coefficients with an Ionic Sutherland Parameter in the Graves−Parr Scaling Hypothesis

The failure of the Graves−Parr scaling hypothesis led these authors to conclude that this is a deciding step towards the determination of *a four-parameter potential*.[2] Our thesis is to abandon simply the covalent Sutherland parameter as a species dependent scale factor. We can indeed easily demonstrate that the mathematically correct Graves−Parr scaling hypothesis is valid, contrary to their own conclusion, and, hence, that a fourth parameter is not necessary at all.

Let us first give a picture of the unscaled a_1^2 and a_2 values for 381 bonds (Figure 10). Graves and Parr used 150 bonds, leading to a maximum value of the coordinates of 17 for y and 11 for x, considerably lower than those appearing in Figure 10. The empirical fit gives a coefficient of 1.4, within 6% of the coefficient predicted by the Kratzer potentials (Table 2). Even the Kratzer potential, with *ideal* Dunham coefficients (Equation 15), is in line. The most important feature of this Figure 10 is that this scale enlargement to 381 bonds already leads to a rough *clustering*, in agreement with the Graves−Parr scaling hypothesis, and contrary to their own observation, which mentions only *scattering*.[2]

Scaling the coefficients with the covalent Sutherland parameter reduces the number of available data to 303, as D_e must be available. Figure 11 gives the result after scaling with the three parameter Morse potential. The slope is near

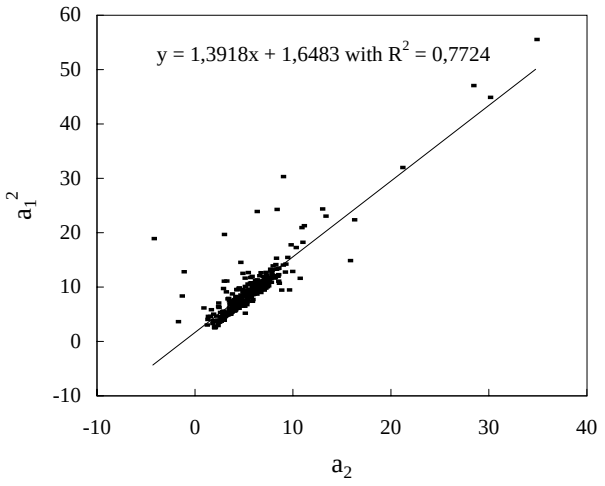

Figure 10. Unscaled a_1^2 versus unscaled a_2 for 381 bonds

unity for a trend line through the origin and the fit of 0.9 is better than in Figure 10 (but this could also be due to a statistical effect, not mentioned by Graves and Parr). Theoretically, at least according to the Graves−Parr[2] scaling hypothesis, the slope should not only be unity but all data points should focus (*cluster*) at a locus near $x = 1$, $y = 1$. This is apparently not the case (see Figure 11).

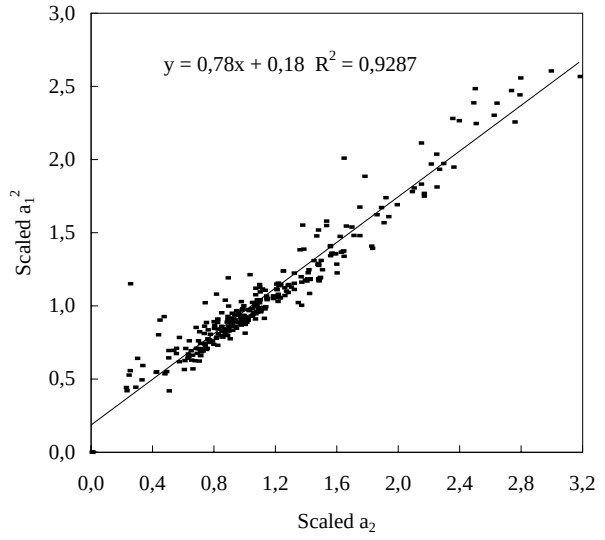

Figure 11. Scaled a_1^2 versus scaled a_2 (covalent Sutherland parameter, D_e) for 312 bonds

We do not show the result for scaling with the Kratzer II potential but immediately give the plot in Figure 12, resulting from scaling with the ionic Sutherland parameter (Kratzer-I−Varshni-V two parameter potential). Since we are no longer dependent on the availability of D_e (just R_e is sufficient), we could at the same time have treated the 381 bonds in Figure 10. However, we wish to compare the two potentials under review by a one by one method. Therefore the same set of 303 bonds is analyzed as in Figure 11 and the same scale is retained to make the differences more pronounced. In comparison with Figure 11, we observe a considerable improvement. This shows above all in the clustering of the data-points in the range $0.8 < x < 1.2$ and $0.8 < y < 1.2$, which is to be expected if the Graves−Parr scaling hypothesis is valid. The slope is near unity but the fit is less than in Figure 11 (which could be a normal consequence of more intensive clustering).

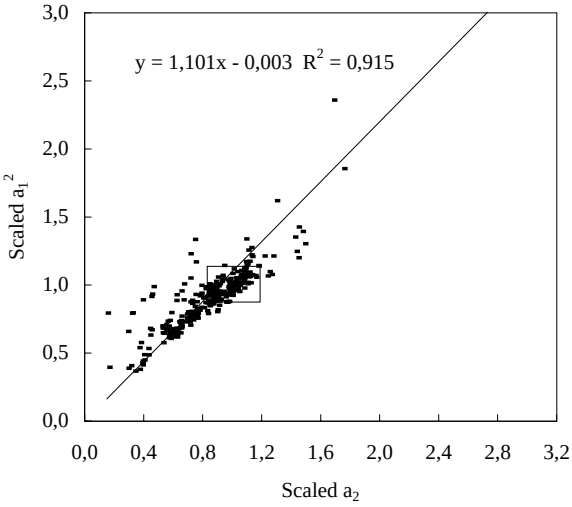

Figure 12. Scaled a_1^2 versus scaled a_2 (ionic Sutherland parameter, e^2/R_e) for 312 bonds

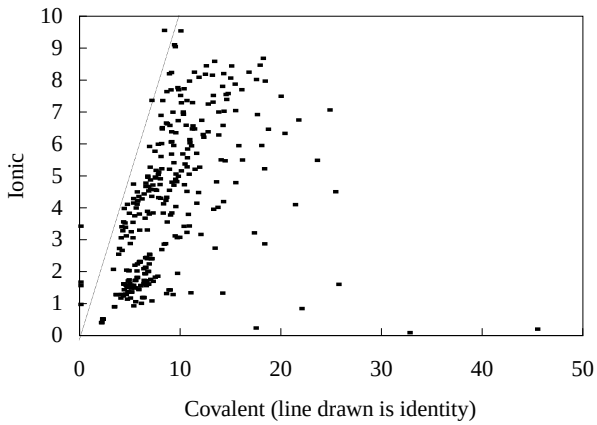

Figure 13. Plot of covalent versus ionic Sutherland parameter for 312 bonds

All this is the more remarkable since the covalent Sutherland parameter values are, on average, *twice as large* than the ionic ones. To illustrate this, we made a plot of the two Sutherland parameters in Figure 13. Scaling by *larger* values should automatically compresses the scaled data to *smaller* values, whereas exactly the opposite effect is observed: the scaling operation is more effective using smaller scaling factors (ionic Sutherland parameters). Considering this shows that the scaling/clustering is even more effective than one could conclude from a simple comparison of the two Figures 11 and 12.

In Figure 14−15, we present the results for the 91 bonds between monovalent atoms. The Morse Graves−Parr plot, Figure 14, does not differ significantly from the general one, Figure 11. For just 22 out of 91 bonds, the data cluster in the critical box. On the contrary for the ionic potential in

Figure 15, the opposite result is obtained: only 21 data points are outside the critical range near $x = 1$, $y = 1$, the most important deviation being found for F_2, indicated in Figure 15. We cannot but conclude that the Graves−Parr scaling hypothesis is indeed valid, contrary to their conclusion. However, this only shows when an alternative asymptote acts as a species dependent scaling factor.

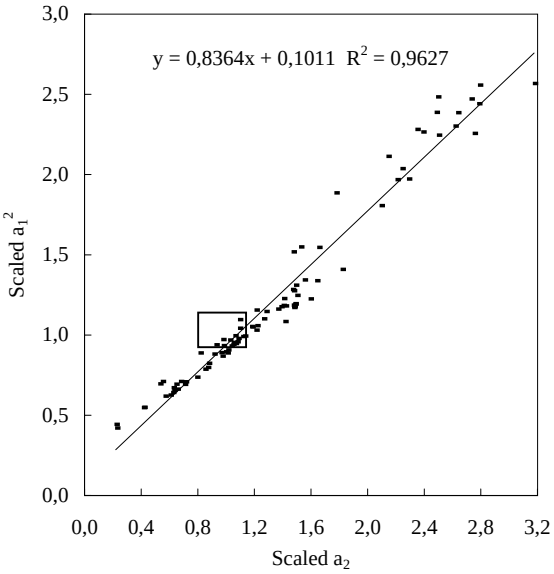

Figure 14. Scaled a_1^2 versus scaled a_2 (covalent Sutherland parameter, D_e) for 91 single bonds

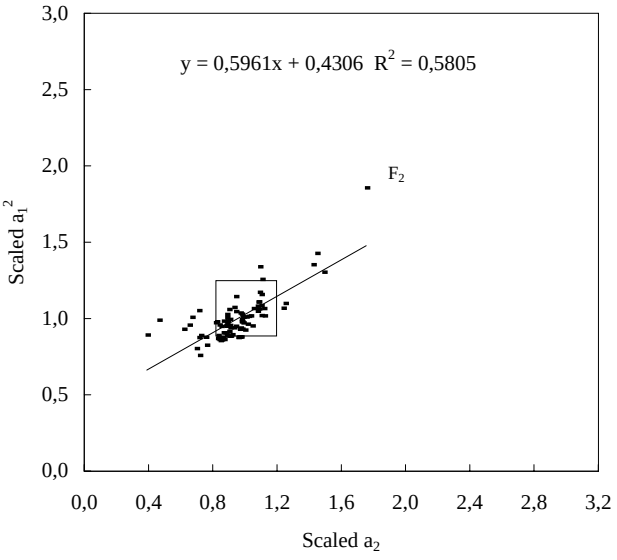

Figure 15. Scaled a_1^2 versus scaled a_2 (ionic Sutherland parameter, e^2/R_e) for 91 single bonds

We had to diverge on this aspect not only for important theoretical but also for practical reasons. Normal graphical procedures are difficult to apply for data, extending to several powers of 10 for a large number of cases (see above, Figure 9a−c and the data in Table 4).

The last figure in this section, Figure 16, represents the scaling results, using the generalized Kratzer-I−Varshni-V potential. This is the only potential giving the theoretical result that $\Delta^{1/2} = F$. This result must be compared with Figure 12.

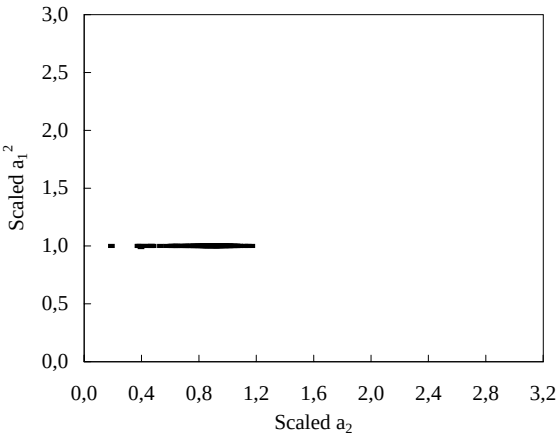

Figure 16. Scaled a_1^2 versus scaled a_2 (Kratzer result, Sutherland parameter = F^2) for 312 bonds

Scaling is now *of course perfect* for a_1^2 but a spread remains for a_2, although 244 data points out of the 303 are still within the critical box (now *line*) near unity. The concentration of 244 data-points in Figure 16 between *0.8 and 1.2 on the x-axis* and an average value for the scaled a_2 of 0.859, i.e. 1 ±14%, for the 303 bonds indicates that the Kratzer-I−Varshni-V potential is quite effective but not completely exact. The spread in the scaled a_2 values is due in the first instance to a scattering in *G*/*F* values. Maybe, the Dunham series is in need of revision (possibly with respect to the truncation of the series for the vibrational energy given the relatively small average deviations on the *x*-axis or, maybe, higher order Dunham coefficients are needed). Maybe also asymptote differences (and hence the critical distance) come into play.[7]

Introducing a third parameter in the Kratzer-I−Varshni-V function might improve the scaling operation and its universal characteristics. Unlike Graves and Parr, we conclude that a four-parameter function is not necessary to obtain better scaling. The large number of data used is an extra argument for this conclusion. Finally, Figure 16 can only be reproduced from ionic potentials as soon as we can show how the identity $F = \Delta^{1/2}$ can be obtained from our scheme for *all* molecules, i.e. those including $A \neq 1$.

7.7 Extension of the Predictions to All Molecules

We now proceed to the necessary, be it totally empirical, extension of the results obtained thus far to all bonds. We can apply a classification scheme (Calder−Ruedenberg[5] or Herschbach−Laurie[19]). A classification in either way is like adding an additional third (but not quantified) parameter. We therefore constructed a pivot table with the Column classification as a guideline and calculated mean *A* factors in Equation (28) using the Kratzer-I−Varshni-V potential and experimental *F* values. We wish to restrict the number of A values to a minimum and require that they should be not too far from 1 in all cases, where at least *one monovalent atom* is present. With two polyvalent atoms in

a bond, larger deviations for A from unity can be expected. These would then have to follow roughly the Calder−Ruedenberg classification,[5] if this makes sense. These authors, with Graves and Parr,[2] used 13 groups (13 values for the additional but hidden parameter) in their analyses of 150 molecules, of which some classes are very similar and nearly coincide (see also *F*igure 1b).

Table 6 gives the results. Only *seven* different (rounded) A values are needed to encompass the results for 269 bonds (in which 27 molecular ions are included, see bottom line of Table 6). The %-deviations of the experimental F values are given, as well as the mean C value for each class. The correlation with the Column classification is roughly followed for polyvalent atoms but we do not discuss the details. We observe that an ionic *three*-parameter potential is largely sufficient. In addition, just 5 A parameters *around unity*, i.e. 0.8; 0.9; 1.0; 1.1, and 1.2 account for more than 220 of the 269 bonds, covering F to within ±3% (and hence also α_e).

Obviously, a three parameter ionic potential is capable of producing Figure 16, which is the best scaling result yet obtainable for the Dunham coefficients a_1 and a_2. This is based upon the identity $F = \Delta^{1/2}$, which is also generated by the generalized Kratzer-I−Varshni-V potential.

7.8 G/F (Calder−Ruedenberg Constant C) and $G/(1 + F)^2$ Values

The C ratio′s in Tables 4−6 reveal that the mean deviation is about the same as for α_e computed with the Kratzer-I−Varshni-V potential. For the corresponding G/F values in function of F, the observed spread (not shown) is 3 times larger than for the $G/(1 + F)^2$ values. This leads us again to conclude that C is far from being constant (see above). However, it is difficult to find any regularity in G/F values (C values) or in $G/(1 + F)_2$ values. This remains the largest stumbling block in achieving a complete picture in the spectroscopic behavior of molecules in terms of ionic potentials or of any kind of potential. The scattering in the G/F ratio is also responsible for the scattering in the scaled a_2 values in Figure 16. Reminding the definition of G/F (or C), in Equation (30), all this must not come as a surprise.

Preliminary analyses point in the direction of a possible relation of the G/F- or similar ratio′s with the critical distance (which corresponds with the asymptote difference). Although this sounds logical[7] and in line with the possible interference of the non-crossing rule (see above), a further discussion of this important question is not given, as more work is needed.

7.9 The Existence of a Universal Two-Parameter Function: Alternative Choices

Against all expectations in the literature, the $F(\Delta)$- and $G(\Delta)$ relations and the scaling effects of an ionic Kratzer-I−Varshni-V potential upon a_1 and a_2 indicate that even a universal ***two***-parameter function does exist for the situation around R_e for a large number and variety of bonds. In addition, its performances for reproducing first order constants are excellent. Using a third parameter for this

function results in an exact fit, as far as F is concerned (see Table 6) and, hence, in almost perfect scaling (as depicted in Figure 16) with a small number (7) of A values for 269 bonds. This corresponds with a really universal three parameter potential.

However, speaking of two or three parameters has become somehow confusing, since we disregarded constraint (ii). But, to put all functions on an equal basis, other functions should be tested upon their relative merits for coping with the constants, using for scaling, instead of D_e, the asymptote generated by the function itself (an example was given by Von Szentpaly[15]).

We cannot predict the outcome of such a review, although we tested here two important *reduced* functions, belonging to two completely different classes of potentials (Morse, exponential and of covalent type versus generalized Kratzer, Coulomb-like and of ionic type). However, a better low parameter potential may appear for scaling purposes. Then, one must review also its capacity (a) to explain chemical bonding (at the minimum) and/or (b) to reproduce the atomic dissociation limit.

In this last respect, any ionic potential will fail by definition as will any other potential with an asymptote $D_x \neq D_e$. In fact, under the rather severe simplifying conditions inherent to ionic potentials and without the condition that D_e should be reproduced, the deviations found in $G(F)$ plots as well as those found in $G/F(F)$ plots indicate that inconsistencies remain with ionic and, most probably, also with a number of other potentials. These can be due either to (a) errors in experimental data (not taken into account), (b) the choice of the potentials (and their analytical form), (c) the Dunham expansion (in which higher order terms in the vibrational part are neglected), (d) higher Dunham coefficients (not considered here[2][24]) or finally to (e) a discontinuous switch between dissociation limits at an R value $\infty > R > R_e$, whereby there is a corresponding shift from one potential to another or from one set of parameters to another in the same potential (non-crossing rule, see next section).

7.10 Obtaining the Correct or Atomic Dissociation Limit, Using an Ionic Two-Parameter Potential

The inconsistencies observed for scaled a_2 values (or in G and in G/F ratios and related ones) indicate that away from the minimum other corrections or additional coefficients are needed for the situation at $R >> R_e$. As the ionic asymptote is situated between a_0 and D_e, the non-crossing rule can interfere.

For large R, interatomic forces are commonly designed as Van der Waals-forces, varying with $1/R^n$, with $n>2$, which are not point charge Coulomb forces[39] as the ones leading to the *ionic* dissociation limit. Very recently, a possible switch from an ionic (Kratzer) potential to a covalent one somewhere between R_e and ∞ was described by Herrick and O′Connor.[40] The problem is not discussed here in detail, as, with Graves and Parr,[2] we remain convinced that the *primary* evidence about the relations between the constants and even about convergence is to be found in the first constants in the Dunham expanion and to the (analytical form of the) potential, wherein R_e, k_e and the asymptote (be it D_e or D_x) will invariantly play a crucial role.

But, these important further details must not distract us from the main conclusion *that a universal two-parameter ionic function exists within reasonable limits.*

7.11 Chaotic/Fractal Behavior

Although we present evidence that Coulomb′s (inverse power) law is important for understanding the relations between the constants of a large number of molecules, this does not fully support fractal/chaotic behavior in anharmonicities.[16] The evidence presented thus far[16] is not yet convincing. We found that power relations in some critical cases are not significantly better than classical linear or quadratic relations. We showed that the use of power laws can be misleading, as fundamental details can get lost (the breaking of the M−Z symmetry). Using log-scales may be an aid when scale differences get large, but they do not change the underlying physical or chemical ideas.

7.12 A Universal Bond, Atomic and Molecular Spectroscopy

Finding a universal function is equivalent to finding a universal bond, a standard for molecular spectroscopy, and the equivalent of H, the standard for atomic spectroscopy.

The Kratzer potential is also applicable in atomic spectroscopy.[34] In molecular spectroscopy, a *one parameter potential* reduces to $U(R) = (e^2/R_e)(1 - R_e/R)^2$ and leads to $\Delta^{1/2} = 1$ (or $F = 1$). Then the most likely candidate for a universal bond should obey almost all of the following constraints to within reasonable limits: $D_x \approx D_{ion} \approx e^2/R_e \approx e^2/2r_X \approx a_0 \approx IE_X$; $F \approx \Delta^{1/2} \approx 1$; $G \approx 24-30$ and, perhaps also $D_{e(XX)} = EA_X$.[34] So we end ultimately with molecules containing Li (with H or other alkali metals), with BeH bonds and, eventually, with the molecule Li_2 (see for instance Table 4). We had, of course, preferred (*desired*) to end with H_2 to make the analogy between atomic and molecular spectroscopy complete, but maybe this is a matter of further scaling (we refer to the breaking of the M−Z symmetry). In addition, the PE curve generated for Li_2 (ground and excited states) computed from a generalized Kratzer potential coincides with the RKR curve.[7] Hence, our search for a simple (two-parameter) potential in molecular spectroscopy, brings us back, at least in a first order approximation around R_e, to atomic spectroscopy and the Bohr-atom model. The fact that ionization potentials appear as the leading term in the global molecular scaling process may contribute to this result. Ionization potentials show a well-known Column and Row dependence, as well as a Z and/or mass dependence, capable of transforming the Periodic Table in a one-dimensional array (see our discussion at Figure 1). This is understandable, when looking

at the analytical form of the Kratzer potential, shaped to be applied in atomic spectroscopy too and used by Fermi[38] in a number of other instances. This now leads to a formal link between atomic and molecular spectroscopy.[34]

The theoretical basis for the universal character of the Kratzer potential is easily recognized. Its quadratic term in R is a generalization of the quantum hypothesis that the angular momentum be constant or that the velocity of a particle varies as $1/R$. The repulsive part in the Kratzer potential corresponds with a kinetic energy term. This secures that, at equilibrium, the ratio between attraction and repulsion terms is always 1/2.

Having in mind that Coulomb′s law is at the hart of this unifying process and that this fundamental law together with a quantum-hypothesis is automatically included in any Kratzer-type potential, it becomes easier to understand

(a) why a universal potential, if it exists in molecular spectroscopy, is also important for a number of other phenomena in *applied* chemistry[1]

(b) that such a potential is very suited for scaling spectroscopic constants and, finally,

(c) that a truly universal potential might indeed have exactly this analytical form.

8. Conclusion

We presented almost conclusive evidence that the Holy Grail of Spectroscopy[10] is an ionic *two-parameter* potential of Kratzer−Varshni-V-type. Bound to a *wrong* asymptote, this simple potential leads to a quantitatively excellent first order approximation for an impressively large number of spectroscopic constants and is superior to a *three-parameter* Morse potential, which uses the *correct* asymptote.

This *wrong* asymptote also gives a smooth picture of the bonding situation at R_e, exactly the only region where Dunham′s analysis (which refers to an asymptote of its own) makes sense. Whether or not the best scaling asymptote is the ionic dissociation limit, could be a matter of further research but the present results reveal that it is certainly a good candidate. Hence, ionic asymptotes can no longer be disregarded in *any* theory of chemical bonding.

Even for homonuclear bonding, the accuracy and consistency of the ionic bonding model, which was the standard by excellence in the early days of theoretical chemistry[6,7,20,21,34] now seems beyond any doubt. Unfortunately, this elementary model was abandoned soon after quantum-mechanical results became available, which led to a new theory of bonding. Ironically enough, exactly the *supposedly poor* performance of ionic potentials in molecular spectroscopy was, at that time, one of the major arguments to abandon the ionic bonding model.[28] Now, our large-scale analysis shows that, on the contrary, ionic potentials are performing very well. Looking at the situation *near the minimum*, we must conclude that covalent or Lewis bonding can be quantitatively rationalized in terms of ionic bonding, which has its roots in Coulomb′s law. The rationale behind the observed simple behavior of spectroscopic constants is that, *at the minimum*, a bond XX is well represented by an equal mixture of two ionic structures $X^+X^- + X^-X^+$. This gives a different but essentially equivalent interpretation of the Lewis concept of valence electron sharing. It appears that we discovered a *trompe l′oeil* in chemistry[41]: the *spectroscopic* behavior of *atoms* in *molecules* is rationalized by the interference of an unobservable (*ionic*) *asymptote*, different from the asymptote we can observe: the *atomic dissociation limit*.

Biomimetic Morphogenesis of Fluorapatite-Gelatin Composites: Fractal Growth, the Question of Intrinsic Electric Fields, Core/Shell Assemblies, Hollow Spheres and Reorganization of Denatured Collagen

Susanne Busch,[a] Hans Dolhaine,[b] Alexander DuChesne,[c] Sven Heinz,[a] Oliver Hochrein,[a] Franco Laeri,[d] Oliver Podebrad,[e] Uwe Vietze,[d] Thomas Weiland,[e] and Rüdiger Kniep,*[a][+]

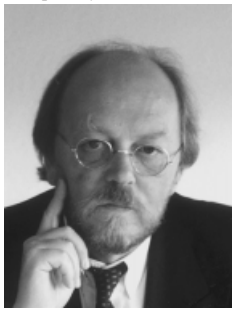
Keywords: Fractals / Materials science / Fluorapatite / Collagen / Intrinsic electric fields / Core/shell assemblies

The biomimetic growth of fluorapatite in gelatin matrices at ambient temperature (double-diffusion technique) starts with elongated hexagonal-prismatic seeds followed by self-similar branching (fractal growth) and ends up with anisotropic spherical aggregates. The chemical system fluorapatite/gelatin is closely related to in vivo conditions for bone or tooth formation and is well suited to a detailed investigation of the formation of an inorganic solid with complex morphology (morphogenesis). The fractal stage of the morphogenesis leads to the formation of closed spheres with diameters of up to 150 μm. The self-assembled hierarchical growth thereby shows immediate parallels to the topological branching criteria of the macromolecular starburst dendrimers. A second growth stage around the closed spheres of the first stage is characterized by the formation of concentric shells consisting of elongated prismatic fluorapatite units with nearly parallel orientation (maximum diameter of the complete core/shell spheres of 1 mm). The specific structure of the core/shell assembly is similar to the dentin/enamel structure in teeth. Together with the idea of the biological significance of electric fields (pyro-, piezoelectricity) during apatite formation under in vivo or biomimetic conditions the present paper considers the composite character of the material and the mechanisms of fractal growth (branching criteria and architecture, the influence of intrinsic electric fields etc.).

Dr. Susanne Busch studied chemistry at Darmstadt University of Technology and received her Ph.D. degree under the supervision of Prof. Dr. R. Kniep in winter 1998. The thesis is entitled "Self-Organization and Morphogenesis of Apatite-Gelatin-Composites under Biomimetic Conditions." At present she is continuing her research on the topic of biomimetic growth of apatite at the Max-Planck-Institute for Chemical Physics of Solids, Dresden.

Dr. Hans Dolhaine studied chemistry at the Universities of Münster, Dortmund and Düsseldorf. He received his Ph.D. degree in 1977. The thesis entitled "NMR-studies on Phosphonates" was performed in Prof Dr. G. Hägele's laboratories at the University of Düsseldorf, supported by a fellowship from the "Studienstiftung des Deutschen Volkes." Currently he is working on various industrial research projects at the Henkel KGaA, Düsseldorf.

Dr. Alexander DuChesne studied chemistry at the Universities of Mersburg and Sofia. In 1991 he started investigations on block copolymer morphologies at the Max-Planck-Institute for Polymer Research in Mainz under the supervision of Prof. Dr. G. Wegner. After receiving his Ph.D. degree in 1993 he went to University College, Dublin to work on conformational transitions of thermoreversible polymer gels with Prof. Dr. K. Dawson. In 1995 he returned to the Max-Planck-Institute at Mainz. He is a specialist in transmission electron microscopy and his current research interests include water-soluble coatings, latex film characterization, polymer morphology, phase transitions, biomineralization and composites.



Dipl. Chem. Sven Heinz studied chemistry at the University of Regensburg where he received his diploma under the supervision of Prof. Dr. R. Andreesen (Dept. of Haematology and Oncology, University Hospital, Regensburg). In 1996, he joined the group of Prof. Kniep at Darmstadt University of Technology to work in the field of gelatin matrix-assisted biomineralization. In 1997, he returned to the group of Prof. Andreesen where he is currently working on his Ph.D. thesis characterising new dendritic cell-specific gene products.

Dipl.-Ing. Oliver Hochrein studied chemistry at Darmstadt University of Technology, where he received his diploma degree in 1996. He is currently working on his Ph.D. thesis about the synthesis and characterization of nitridometalates. In September 1998 he followed Prof. Kniep to the Max-Planck-Institute for Chemical Physics of Solids at Dresden where he continues his work. Furthermore he is interested in the visualization and simulation of growth processes in biomimetic systems.

Dr. Franco Laeri studied at the University of Bern. He received his Ph.D. degree in 1984 from the Institute of Applied Physics at Darmstadt University of Technology . He then went to IBM in San Jose, USA, and returned to Darmstadt in 1984. His current research interest is centered around the optical and electronic properties of ordered porous materials and nanocomposites.

Dipl.-Ing. Oliver Podebrad studied electrical engineering at Darmstadt University of Technology and received his diploma degree in 1994. Since 1995, he has worked as a research assistant in the department of Theory of Electromagnetic Fields at Darmstadt University of Technology. His main research interest is the numerical calculation of electromagnetic fields with a subgrid-formulation of the Finite Integration Method.

Dipl. Phys. Uwe Vietze studied physics at the Institute of Applied Physics at Darmstadt University of Technology and is a Ph.D. candidate. He obtained his diploma degree in 1994 and his current work involves the optical and electronical properties of ordered porous materials and nanocomposites.

Prof. Dr.-Ing. Thomas Weiland studied electrical engineering and mathematics at Darmstadt University of Technology and received his Ph.D. degree in 1977. As a fellow at the European Institute for Nuclear Research (CERN, Switzerland) he continued his work on electromagnetic computing. In 1983, at the DESY in Hamburg, he founded an international collaboration for 3-D electromagnetic simulations. Since 1989, he is a full professor at Darmstadt University of Technology, as head of the department of Theory of Electromagnetic Fields. In 1993, he was elected a full member of the Academy of Science and Literature at Mainz. He received the "Leibniz-Prize" from the German Research Association in 1987 and the "Max Planck Research Prize for International Collaboration" in 1995.

Prof. Dr. Rüdiger Kniep studied chemistry and mineralogy at the Technical University of Braunschweig and received his Ph.D. degree under the supervision of Prof. Dr. A. Rabenau (Max Planck Institute for Solid State Research, Stuttgart) at the Technical University of Braunschweig in 1973. After his habilitation at the University of Düsseldorf in 1978 he was made a professor of inorganic chemistry in 1979. In 1987 he moved as a full professor of inorganic chemistry to the Darmstadt University of Technology (Eduard Zintl Institute). Since 1998 he is a scientific member of the Max Planck Society and director at the Max-Planck-Institute for Chemical Physics of Solids, Dresden.

MICROREVIEWS: This feature introduces the readers to the authors' research through a concise overview of the selected topic. Reference to important work from others in the field is included.

1. Introduction

The basic principles of biomimetic growth of inorganic solids[1][2] include distinct cooperative phenomena between organic and inorganic components. The complex systems assume control of the processes of self-organization, self-similarity, hierarchical arrangements, shape-formation (form-selectivity) and transcription of informations from the microscopic level to the macroscopic range. In cases where the time scale of the biomimetic morphogenesis of an inorganic material is similar to that in biological systems, the development of specific shapes and morphologies can be systematically investigated from the nucleation to the final stage.

In a recent paper[3] the biomimetic growth and self-assembly of fluorapatite spheroids by double diffusion in denatured collagen matrices (gelatin) at 25°C was described phenomenologically. The morphogenesis begins with elongated hexagonal-prismatic seeds. Progressive stages of self-assembled (noncrystallographic) upgrowths of needle-shaped prisms at both ends of the seed lead to dumbbell-shaped aggregates, which complete their shapes by successive branchings to end up with spheres that are notched to a greater or lesser extent. A selected sequence of scanning electron microscopy (SEM) pictures representing the morphogenesis from a needlelike seed to a spherocrystal is shown in Figure 1.[3][4] The surface of a just closed sphere also consists of (small) needlelike units following the general principles of self-similarity.

An investigation of numerous SEM pictures at various stages of the morphogenesis has already led to a *fractal model* for the formation of the (anisotropic) fluorapatite spheres.[3][4] Furthermore, according to the previously postulated hypothesis, the fractal branching of successive generations and the overall symmetry of the self-assembled aggregates may be considered as consequences of *intrinsic electric fields*, which take over control of the growth of the aggregates.[3][4] This interpretation of the specific morphogenesis of the fluorapatite aggregates is broadly based on natural phenomena concerning the biological significance of piezoelectricity,[5] as well as on observations concerning the pyroelectric effect in bone.[6] In addition, the influence of electric polarization on acceleration and deceleration of bonelike crystal growth on hydroxyapatite ceramics was also shown in a recent paper[7] which, in fact, supports the idea that "uniform electric fields, rather than the localized charges usually cited, may determine the sites of crystal nucleation and overgrowth."[8]

This paper now makes a careful attempt at a first approach to the interpretation of the following phenomenological observations:

- **First growth stage**: Fractal growth (branching criteria and architecture, see Section 2).
- **Second growth stage:** Core/shell assemblies (formation of concentric shells around the closed spheres of the first stage, see Section 3).
- **Composite character** of the material (see Section 5).
- Formation of **hollow spheres by** "decalcification" of the composite aggregates (see Section 5).
- **Reorganization of denatured collagen** (gelatin) during morphogenesis (see Section 5).

The specific peculiarities of the chemical system under investigation are caused by numerous preceding stages of selection during evolution. This criterion should be kept in mind when studying and assessing the observations and models given in the present paper. It should also be noted at this point that the formation of morphologies similar to that of dumbbell-shaped aggregates or peanut-type particles, which are found in various chemical systems under various chemical growth conditions,[9] are not necessarily generated by the same mechanism of morphogenesis.

2. Fractal Growth and Architecture

The growth of anisotropic fluorapatite spheres[3][4] by double diffusion in denatured collagen matrices (gelatin) begins with elongated hexagonal-prismatic seeds up to 30 μm in length (critical ratio length/diameter ≈ 5:1). Progressive stages of self-assembled (noncrystallographic) upgrowths of needle-shaped prisms at both ends of the seed (fractal branching) lead to dumbbell-shaped aggregates (Figure 1) which complete their shapes by successive and self-similar upgrowths to give notched spheres after about the 10th fractal generation. The morphogenesis from a needle-shaped seed of about 10 μm in length to a spherocrystal of about 60 μm in diameter takes approximately one week. The fractal growth and architecture is controlled by two noncrystallographic parameters, which were derived from SEM images at different growth stages: i) the maximum aperture angle between the long axis of the seed and the needle-axes of the units of the following generation is 45 ± (5)°; ii) subsequent generations scale down in their lengths by a factor of ≈ 0.7. Based on these two limiting conditions the fractal model[10] of a just closed sphere is shown in Figure 2 (2D-simulation with the umbrella-tree model; crossing of individual crystals suppressed). The simulated surface of the spherocrystal consists of very small needlelike units, an observation which is consistent with the SEM images (mean diameter < 0.1 μm for the surface prisms of a just closed sphere). Inside the spherocrystal a torus-shaped cavity is

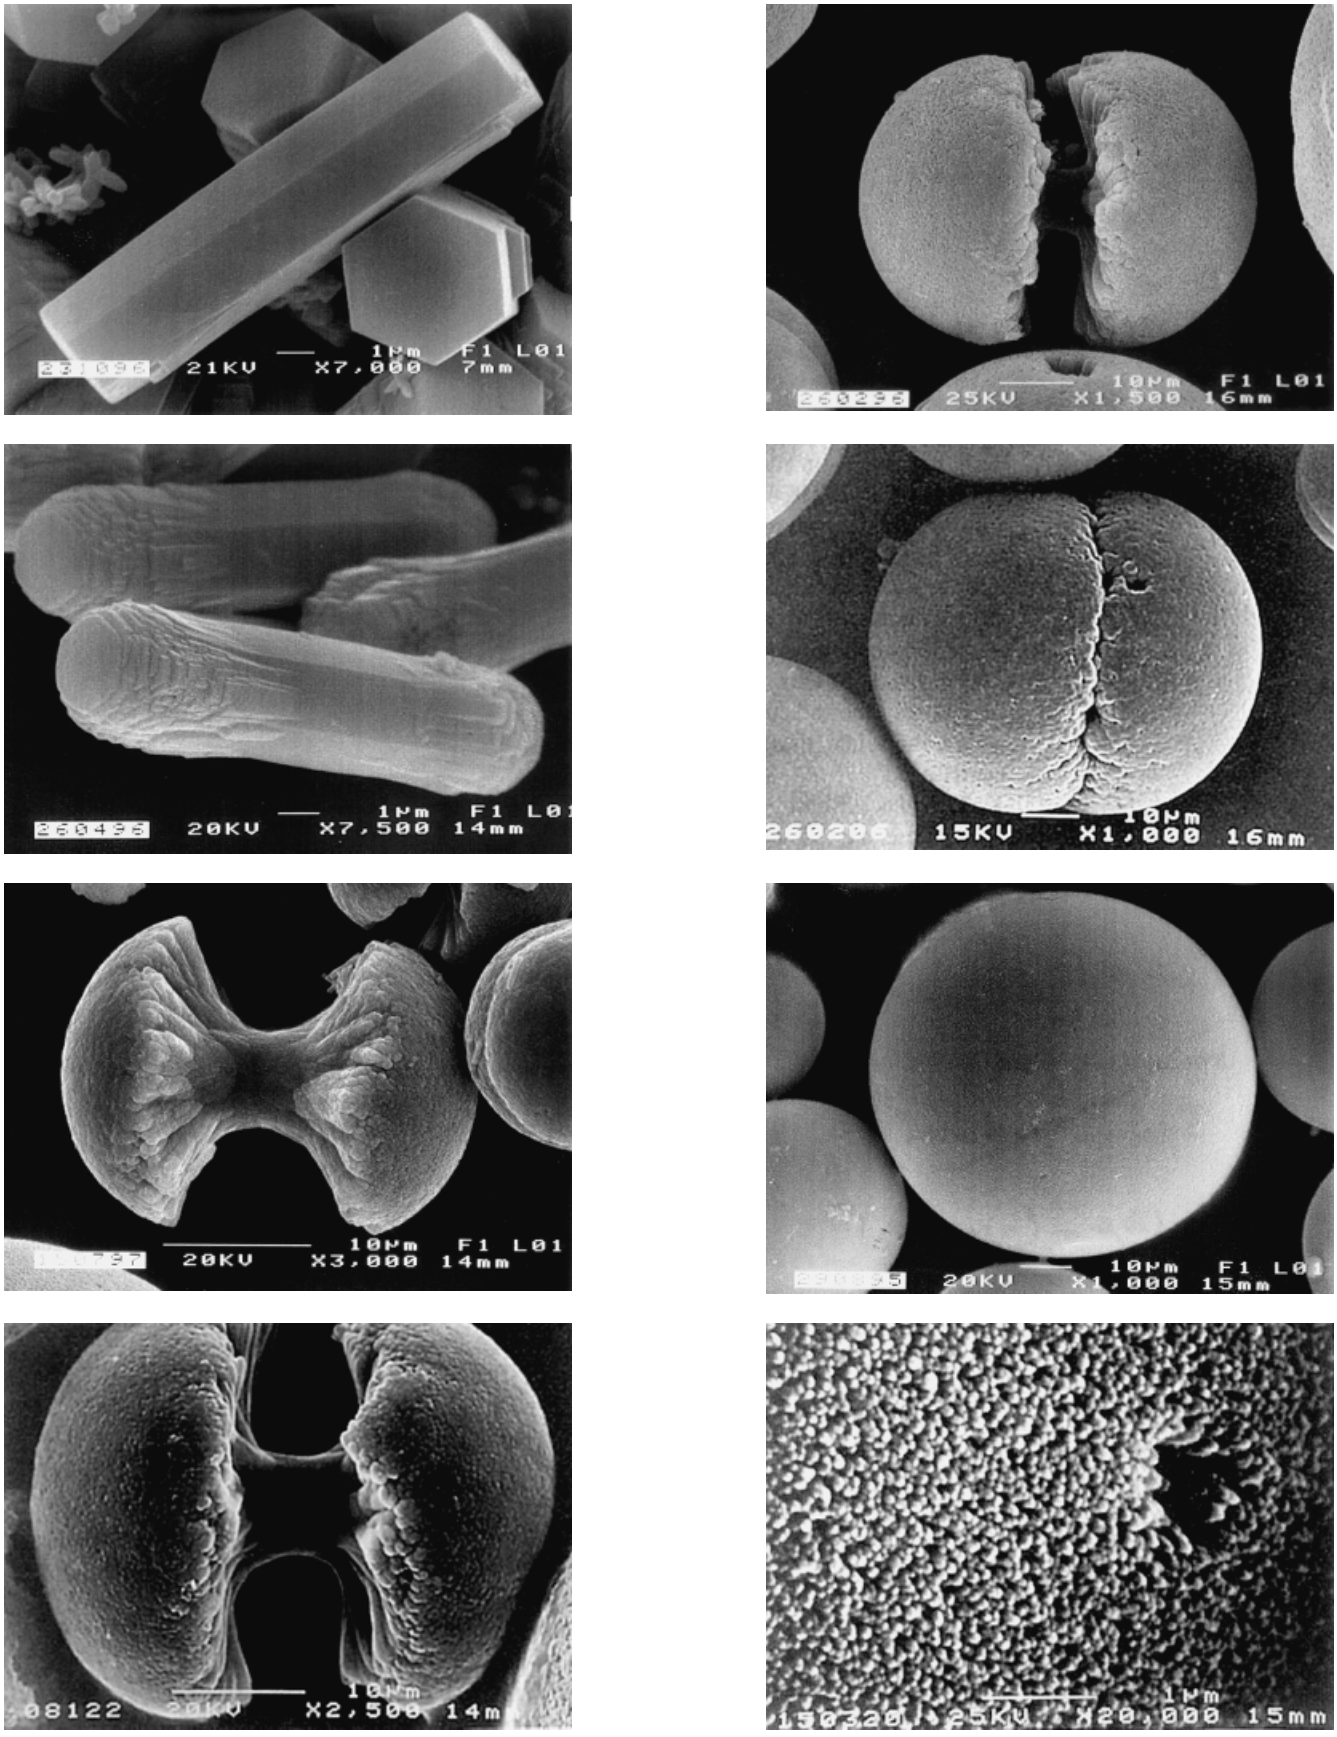

Figure 1. Selected sequence of SEM images of progressive stages of self-assembled (hierarchical) growth of fluorapatite aggregates (morphogenesis): from an elongated hexagonal-prismatic seed (top left) through dumbbell shapes to spheres; the surface of a just closed sphere also consists of needlelike units (bottom right) following the general principles of self-similarity

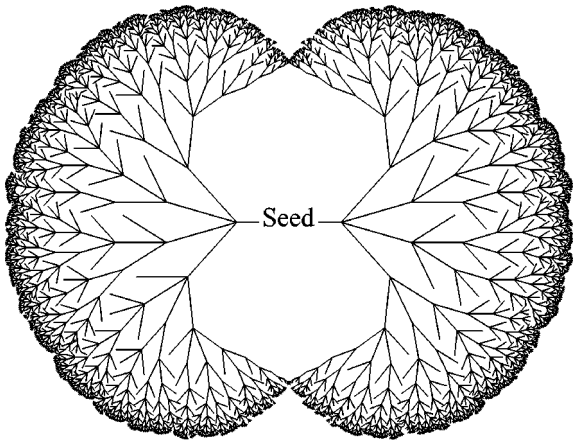

Figure 2. 2D-simulation of a just closed fluorapatite spheroaggregate; fractal model (seed plus 10 generations) assuming a fourfold splitting in each generation (in fact, orders of noncrystallographic branching can be higher); maximum opening angle 48°, scale down factor 0.7; crossing of individuals is suppressed by particular rules following real growth conditions: i. all individuals have the same growing speed; ii. members of higher generations are suppressed, if they cross members of a lower generation; iii. if members of the same generation reach the crossing point at the same time, it is a random decision which one is deleted; if crossing is "nonsymmetric", the individual reaching the crossing point first is favoured; iv. to simulate diffusion-inhibition inside the growing dumbbell area all individuals with an angle greater than 160° relative to the seed are deleted

formed around the elongated seed. A similar architecture is generated by the geometrical model of a splitting needle at constant growth rate and constant splitting rate.[11]

Selected stages of the morphogenesis (SEM images), together with more detailed 3D-simulations,[12] are shown in Figure 3. SEM images of fragments of a spherocrystal are given in Figure 4 and agree very well with the fractal model (Figure 2, Figure 3, Figure 4b). The fragments were produced by breaking spherocrystals perpendicular (Figure 4a) and parallel (in plane; Figure 4d) to the long seed axis. The seed position within a spherocrystal is clearly seen in the centre of the hemisphere (Figure 4a, simulation: Figure 4b). The hexagonal cross-section of the seed and the channel surrounding the seed are shown in Figure 4c. It is interesting to note that the cleavage area of the elongated hexagonal-prismatic seed is characterized by a radial structure starting from the middle, an observation which is in agreement with the idea of nucleation by cylindrical preorientation of macromolecular units ("liquid crystal seed").[13] Figure 4d shows an inner-sphere cross-section parallel to the long seed axis; the two holes represent the torus-shaped cavity around the elongated seed between. The complex but symmetric structure of growth (mirror plane perpendicular to the long seed axis and through the holes) corresponds to the fractal model given in Figures 2−4 and will be discussed in more detail later together with the idea of permanent

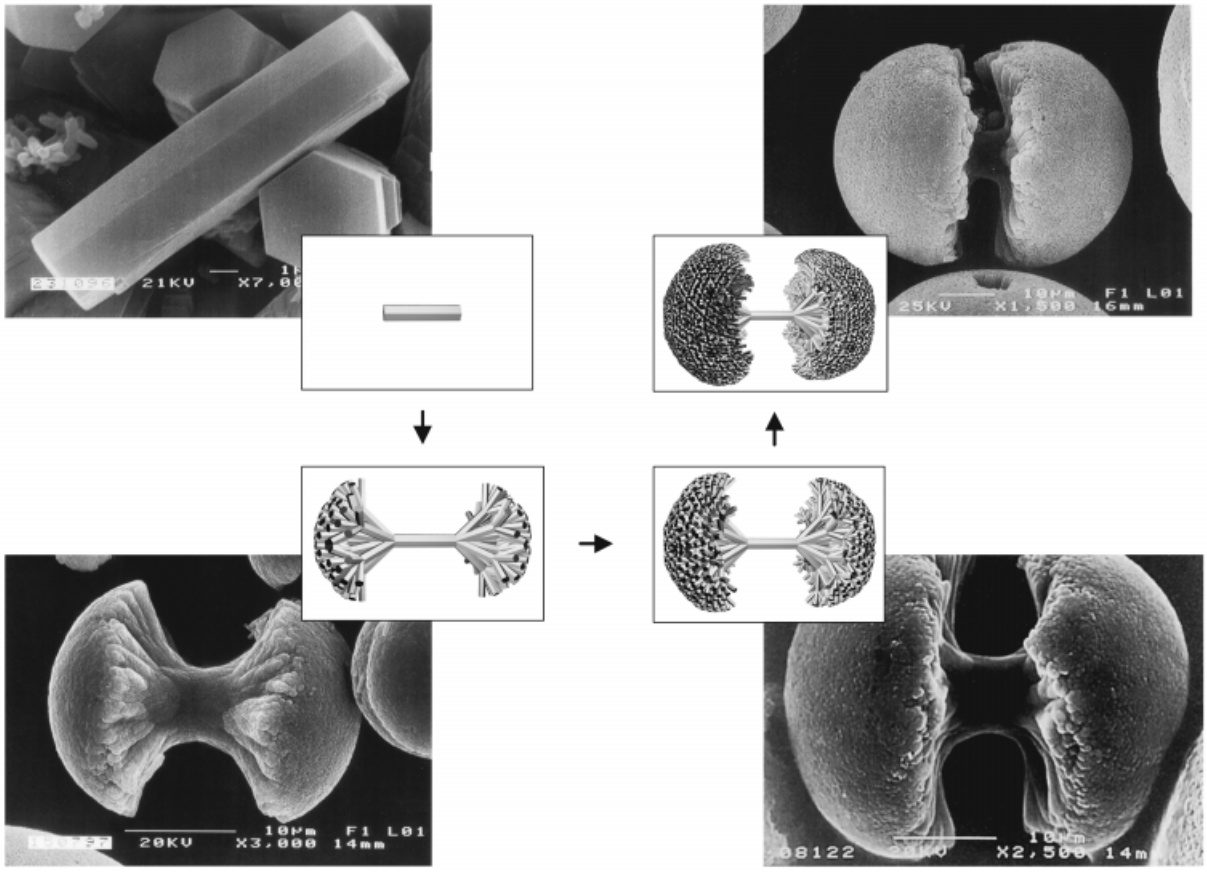

Figure 3. Selected stages of the fractal morphogenesis (SEM images) together with 3D-simulations (from top left anticlockwise: seed, seed + 2, + 3 and + 4 generations)

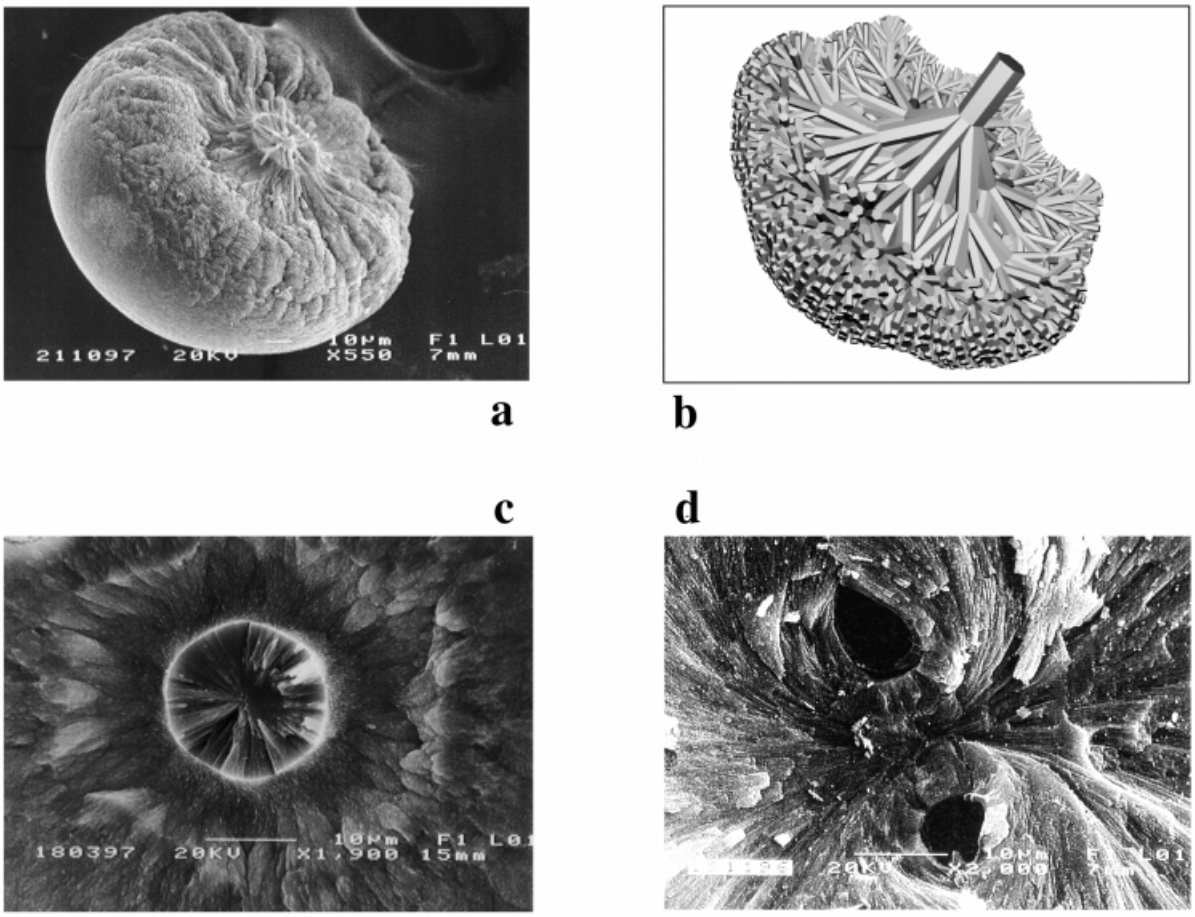

Figure 4. SEM images of specific fragments of a spheroaggregate (fractal model in Figures 2 and 3). **a:** Hemisphere broken perpendicular to the long seed axis; **b:** 3D-simulation[12] of situation **a** (seed + 4 generations); **c:** Hexagonal shaped cross-section of the seed and surrounding channel; **d:** Inner-sphere cross-section parallel (in plane) to the long seed axis

dipoles and their influence on morphogenesis. Here, only a brief comment is given concerning the inner architecture of the spherocrystal (Figure 4d) and the distribution of electric field lines around a given permanent dipole. This situation is demonstrated in Figure 5, in which the growth-orientation within a spherocrystal (section parallel/in plane to the seed) shows a remarkable correspondence to the orientation of electric field lines around a permanent dipole.

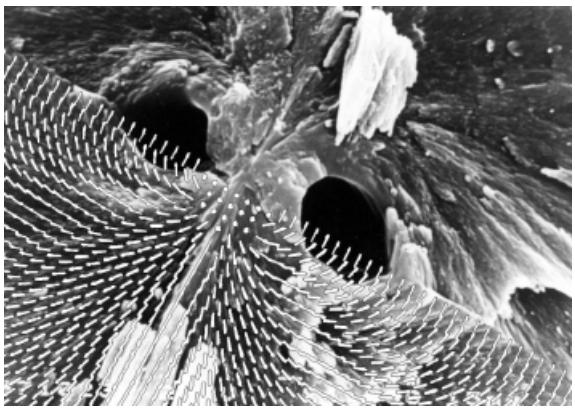

Figure 5. SEM image of a bisectioned spherocrystal broken parallel (in plane) to the long seed axis (Figure 4d) combined with the calculated shape of electric field lines around a permanent dipole (field lines reduced to only one half of the complete area)

3. Core/Shell Assemblies

After the spherocrystals have closed, this special kind of fractal morphogenesis no longer applies and a second, more conventional, growth mechanism by the formation of concentric shells[14] of fluorapatite around the core follows (Figure 6). The shells are built of needle-shaped rods oriented perpendicular to the core-surface and nearly parallel to each other (radial growth). Obviously, the small needle-shaped prisms of the last generation of the fractal core act as nucleation centers for the growing shell. The core/shell interface represents a sphere of decreased stability against thermal and/or mechanical treatment. In fact, the core is easily removed from the shell (Figure 6). Simultaneously, the core and shell assemblies bear a strong resemblance to the complex organisation of teeth (dentin- and enamel).[15] Bundles of needles are combined in bigger assemblies in the same way as the small prisms in enamel are aggregated to enamel rods (Figure 7).

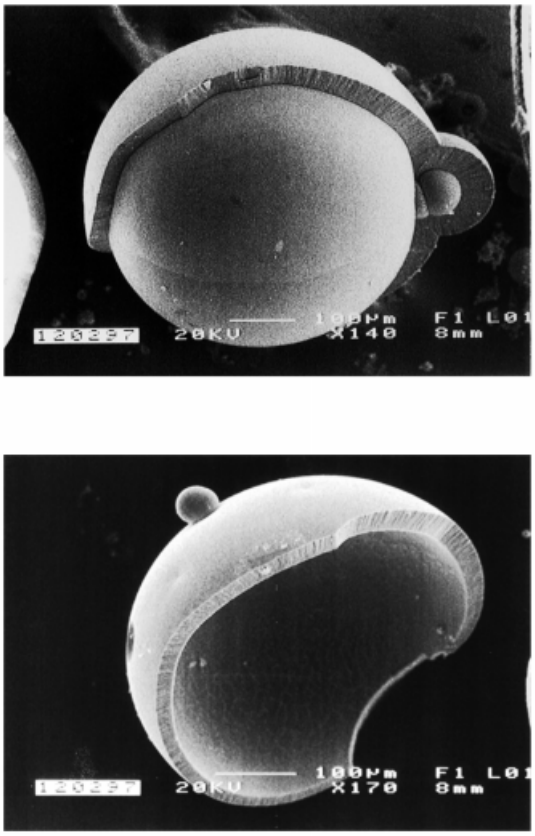

Figure 6. SEM images of a core/shell assembly. **a**: Shell partly removed, free core; **b**: Core removed from the shell

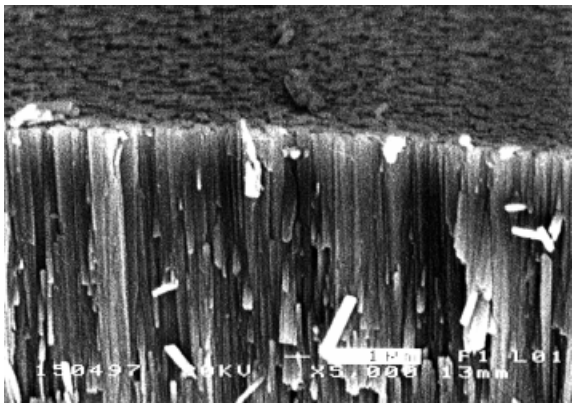

Figure 7. SEM image: Section of a shell area and the surface of a core/shell assembly

4. Intrinsic Electric Fields

Coming back to the core spherocrystal and its architecture, the essential task is to find an interpretation for the noncrystallographic (fractal) splitting of crystal generations and for the overall symmetry ($C_{\infty h}$) of the self-assembled core aggregates. The basic premise in this hypothesis is the presence of intrinsic electric fields which take over control of the growth of the aggregates. This means that the individual "crystals" (actually composite units, see below) − the seeds as well as individuals of the following generations − contain a permanent dipole, an assumption which is consistent with observations on the biological significance of electric fields (pyro-, piezoelectricity) during apatite formation under in vivo or biomimetic conditions.[5−8] The polarity of collagen and the structural peculiarity of the apatite family, varying between centrosymmetric and acentric distribution of the X-species $\{Ca_5(X)[PO_4]_3$, X = F, Cl, OH$\}$[16] support these ideas. We should also bear in mind the extremely mild biomimetic growth conditions, which should favour a high degree of order of the atomic arrangements − partial substitution of F^- by OH^- causes an

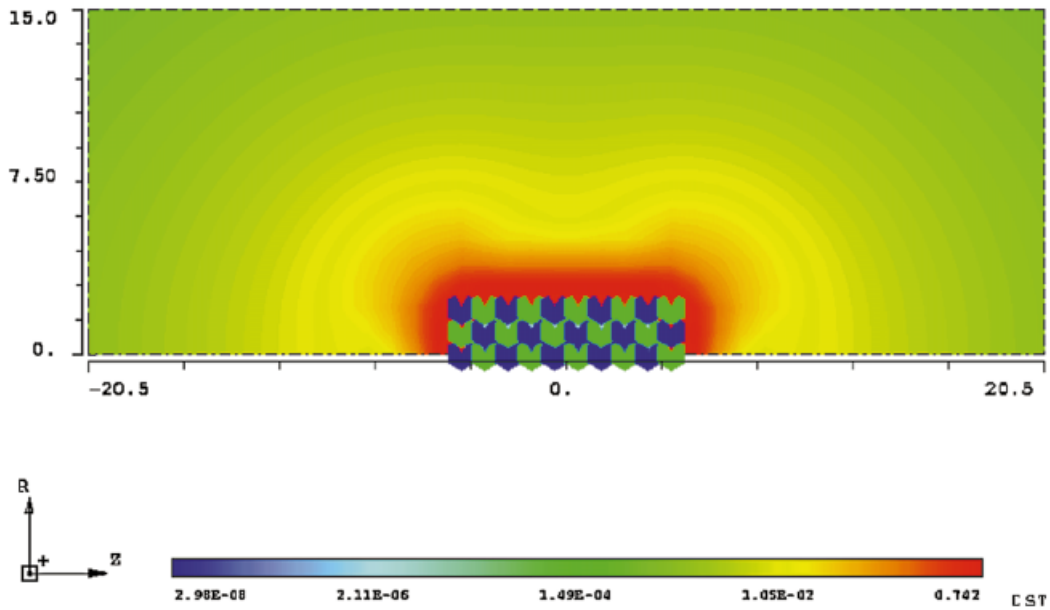

Figure 8. Two-dimensional, logarithmic representation of the distribution of the electric field strengths around an elongated permanent dipole (seed). Elementary dipoles (blue/green graphs = charges +/−; staggered arrangement along the horizontal direction) represent the seed within the coloured area; calculation using the MAFIA program.[19]

asymmetric displacement of the X-species from their "normal" positions (mirror planes)[17] causing a possible reduction of symmetry from the centrosymmetric point group 6/m to the pyroelectric point group 6. Finally, the polar organic component and the inorganic material may act together in the sense of an ordered composite structure, which then gives rise to the formation of a strong (intrinsic) permanent dipole. In this context it is important to note that in vivo nucleation and growth of apatite nanocrystals within a collagen fibril structure leads to an ordered composite system with the *c* axes of the apatite particles oriented parallel to the long axes of the collagen fibrils.[18]

The distribution of the electric field strength around an elongated seed with a permanent dipole (simulation by a set of elementary dipoles; staggered arrangement) was calculated using the MAFIA program[19] and is shown in Figure 8 as a coloured chart of the intensity of the dipole field. Because the field strength is higher at the poles than between them, a bonelike shape results with the maximum field intensities at the edges. The bonelike extension of areas of stronger field strengths starting from the edges of the seed (red/orange in Figure 8) corresponds directly to the self-assembled upgrowths at both ends of the seeds (fractal branching) during progressive growth of the fluorapatite aggregates. Even the maximum aperture angle between the long axis of the seed and the needle axes of prisms of the following generation of about ± 45(5)° is in agreement with the general direction of the extension of higher field strengths around the elongated permanent dipole.

A two-dimensional simulation of the morphogenesis of the overall orientation of electric field lines around a growing spherocrystal is shown in Figure 9 [Permanent dipoles and fractal branching: seed (a); seed + 2 generations (b); seed + 3 generations (c)]. These diagrams give an impression of the possible interactions between the intrinsic electric fields, the charged or polar components in solution, and the growing aggregate within the gelatin matrix. The following points seem to be of significance and, in principle, are consistent with the observed morphogenesis of the fractal solid: i) the transport of ions from the solution to the growing seed (aggregate) and the reorientation of polar organic molecules are influenced by the strength and direction of the electric fields; ii) electric field lines with an orientation between "parallel and perpendicular" to the seed (to the individuals on top of the growing surface of the spherocrystal) do not contribute to a preferred growth rate; iii) the lack of preferred orientation of the electric field lines inside the growing spherocrystal causes reduced growthrates within this area and formation of the torus-shaped cavity.

Experimental indications for the significance of intrinsic electric fields, which assume control of the growth of the fractal spherocrystals, were obtained by using a modified growth-chamber (Figure 10) including an external electric field of 5000 V/1.4 cm (D.C. conditions). The idea was to influence fractal branching of the growing aggregates, and, in fact, splitting of the seeds (area of high field strengths at the edges of an elongated permanent dipole, Figure 8) is predominantly affected by the external field (Figure 11). Instead of similarly shaped polyhedra with definite prism and basal planes, the upgrowing generation under an external

field is characterized by sharpened and bent faces. Moreover, the growing rate of fluorapatite aggregates is significantly diminished by using an external field.

If the spherocrystals (fluorapatite-gelatin composites, see below) represent solid aggregates containing a permanent dipole, a pyroelectric effect similar to that observed in bone and other collagen-containing materials[6] should be expected. We therefore developed an experimental setup for measuring the pyroelectric effect of small aggregates (down to 100 μm in size).[20] The sensitivity of the equipment is already suitable for determining the pyroelectric coefficient of small particles of tourmaline (4.3×10^{-10} coul. $cm^{-2}°C^{-1}$); however, the expected order of about $2-4 \times 10^{-13}$ coul. $cm^{-2}°C^{-1}$ for bonelike materials[6] has not yet been attained. On the other hand, we were able to get an experimental indication for the presence of a permanent dipole in the spherocrystals by placing them in a high-voltage field between two condenser plates. As shown in Figure 12 an applied voltage of 5 kV/cm leads to chainlike arrangements of the spherocrystals. The spherocrystals within the chains are mainly oriented in such a way that the elongated seeds of the spheres (in a direction perpendicular to the equatorial grooves) are in a parallel arrangement, a picture which is consistent with the expected orientation of rod-shaped permanent dipoles between condenser plates.

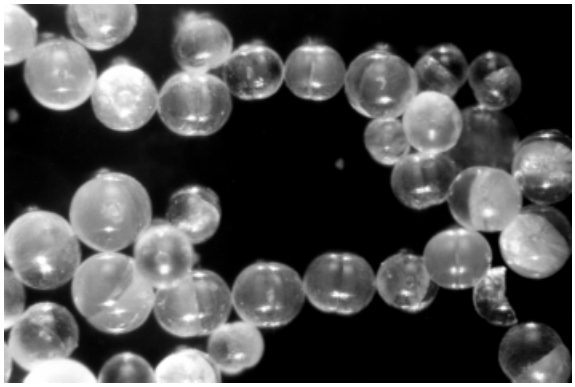

Figure 12. Orientation of fluorapatite spherocrystals exposed to an external high-voltage field of 5 kV/cm (horizontal field); max. sphere-diameter: 400 μm

5. Composite Character, Hollow Spheres and Reorganization of Denatured Collagen during Morphogenesis

The experimental indications for the presence of permanent dipoles and intrinsic electric fields are one of the specific characteristics of the spherocrystals and their morphogenesis. The second essential point is to gain further insight into the composite-nature of the spherocrystals. As already shown by thermogravimetry,[3][4] the biomimetically-grown spherocrystals consist of about 95 wt.-% fluorapatite and about 5 wt.-% organic material and water. A similar ratio of inorganic and organic material is found for human enamel.[21] The composite structure of the spherocrystals is also reflected by dissolution processes in EDTA (0.25 N, pH = 7) as solvent for the inorganic component. Two main observations have been made on treatment of fluorapatite spheres with a neutral EDTA solution at 25°C; they concern firstly the dissolution of the fluorapatite spheres and secondly the structural correlation between apatite and gelatin.

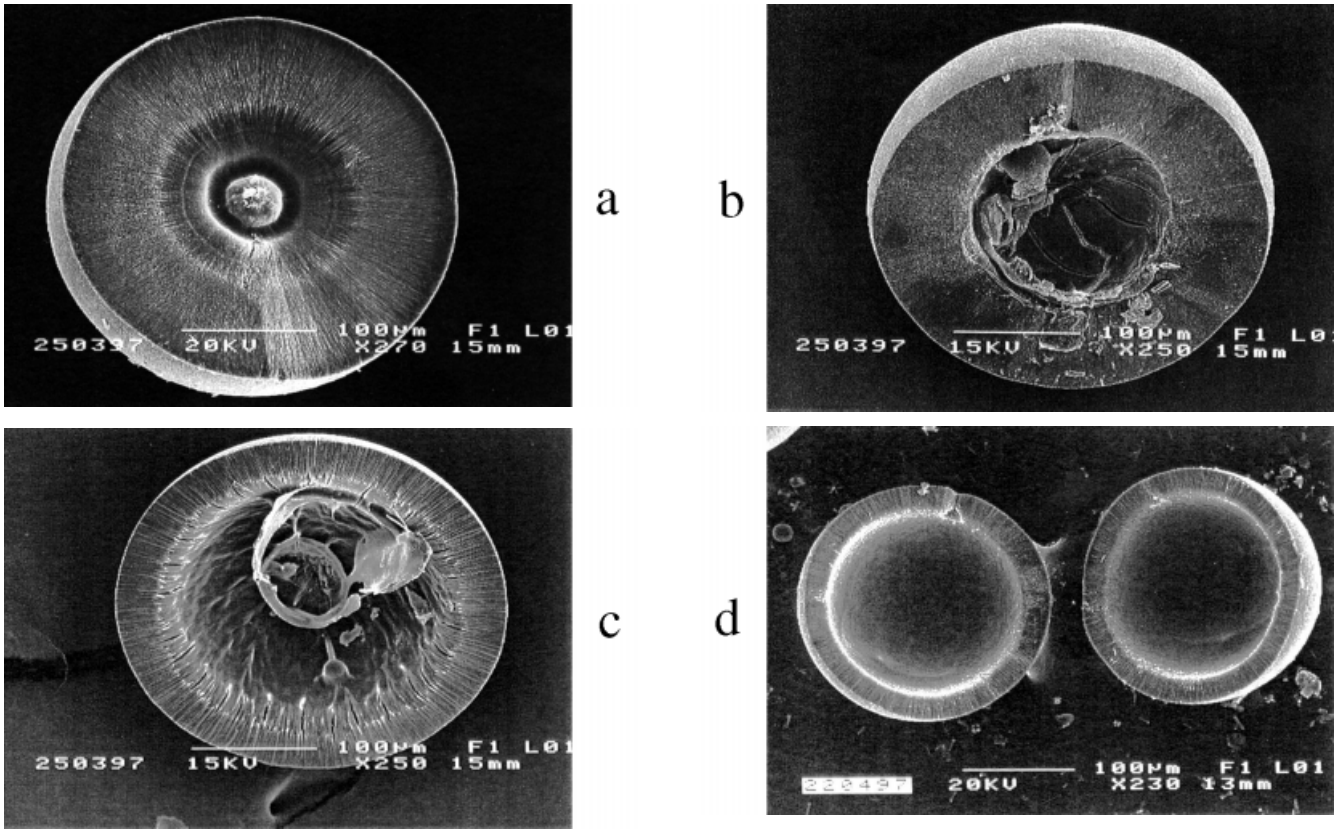

Figure 13. Dissolution of fluorapatite core/shell assemblies in EDTA as solvent; SEM images of hollow hemispheres broken from spheres after treatment with EDTA for 24 h (a), 48 h (b), 72 h (c) and 96 h (d); picture (d) represents the two hollow hemispheres of the same individual; due to shrinking effects during the preparation for SEM investigations (drying) the residual gelatin inside the core loses its original (biomimetic) structure

The first observation is that the dissolution of core/shell assemblies starts within the core and spreads out to the shell, thereby running through continuous stages of apatite hollow-spheres filled with residual gelatin. This situation is shown in Figure 13, which represents hollow hemispheres broken from spheres at different stages of dissolution. In the first stage of the dissolution process the seed within the core is only weakly affected; the later generations of the fractal core spherocrystal are obviously dissolved first (a). After the core has been completely dissolved the attack of the solvent extends to the shell structure and the dissolution progresses leading to a decrease of the wall thickness and an increase of the cavity area (b-d). Decreasing thickness of the "inorganic wall" is consistent with increasing elasticity of the spheres in solution; the consistency of the completely "decalcified" and translucent spheres is similar to that of jellyfish. The early stages of the dissolution process of the fluorapatite core/shell assemblies show close similarities to the early effects of caries:[22] while the surface of a tooth might still be intact, a cavity is formed in the underlying parts. This mechanism occurs in hydroxyapatite-containing teeth as well as in shark teeth (fluorapatite), as was shown by an in vitro study of simulated caries attacks.[23] It was also supposed[24] that the decomposition products of bacteria and their complexing properties are responsible for caries. In the course of these investigations[24] caries-like lesions were obtained by using EDTA as a model reagent.

The second major observation concerning the composite nature of the spherocrystals gives a first answer to the question whether there is a structural correlation between apatite and gelatin. Figure 14 shows images (optical microscope with crossed polarizers) of closed composite core aggregates (a) and of the jellyfish-like spheres (b) obtained

after complete dissolution of the apatite component. The gelatin spheroids show a significant anisotropic optical behaviour (Brewster cross) identical to undissolved spherocystals but without interference colours because of the lack of the inorganic material. Hence there is a strong structural correlation between the orientation of apatite crystallites and the gelatin within the composite spheres, indicating substantial reorganization of the macromolecular matrix within the area of a growing aggregate. Birefringence analyses (λ plate) of partially dissolved and broken specimens show that the directions of the optically denser axes in the apatite crystallites (*c* axes) and the gelatin (chain direction) coincide, as would be expected if the gelatin was preferentially oriented during the process of apatite growth.

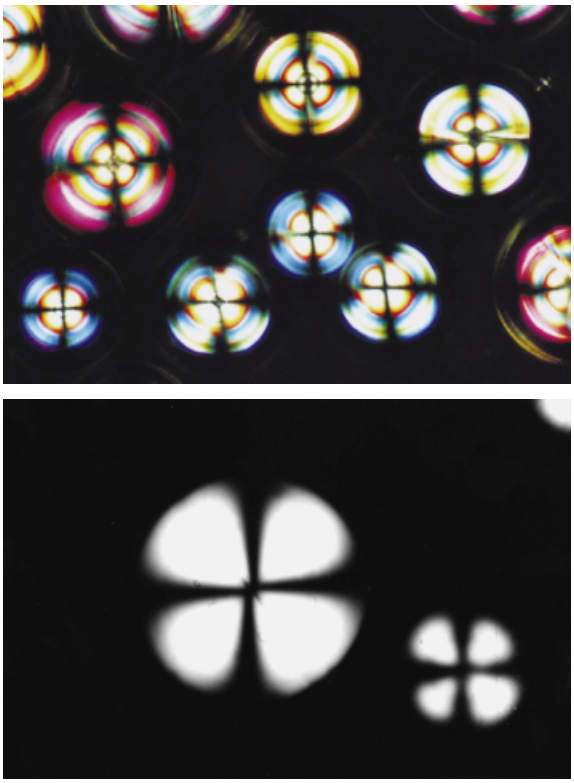

Figure 14. Images from a polarization microscope (crossed polarizers) of just closed composite spheres (apatite/gelatin; a) and of completely "decalcified" spheres (gelatin; b); the gelatin spheroids (b) show significant anisotropic behaviour (Brewster-cross) identical with that of the undissolved spherocrystals (a) but without interference colours because of the lack of inorganic material (apatite); sphere diameters between 100 μm and 150 μm

For transmission electron microscopy (TEM) investigations the composite spherocrystals were first separated from the gelatin matrix by pressing them through a screen and treating them with water. Prior to the dissolution process with EDTA the isolated spheres were immediately fixed with glutardialdehyde and subsequently contrasted with osmium tetraoxide. The water was then extracted by gradual exchange with acetone and the spheres embedded in epoxy resin. Ultrathin sections were prepared at low temperature and subsequently stained with uranyl acetate. In Figure 15 parallel alignments of residual apatite crystallites are visible within a matrix of embedding material and stained gelatin forming a dark network. Within this network stripes are discernible giving the impression of a gelatin structure oriented parallel to the longitudinal axes (*c* axes) of the apatite crystallites. It is thought that the preparation does not change the original gelatin structure of the composite significantly and hence it is assumed that the structure visible in Figure 15 represents the distribution of gelatin within the composite together with apatite. The combination of the TEM observations with the results of optical microscopy leads us to conclude that the stripes (Figure 15) are bundles of gelatin which are stressed and ordered in a parallel orientation together with areas of crystalline apatite. This means that the growth of the aggregates is associated with significant interactions between apatite and gelatin, which cause a reorientation of gelatin from an irregular (amorphous) to an ordered (anisotropic) state.

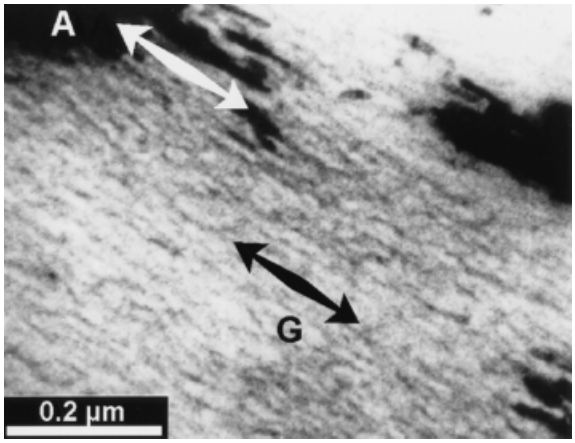

Figure 15. TEM image of an ultrathin section of an apatite/gelatin composite spherocrystal after treatment with EDTA (partial dissolution of the inorganic component, for preparation see text); "A" represents an area of residual apatite crystallites with their longitudinal axes (c axes) parallel to the bright arrow; the stained gelatin region "G" shows an overall orientation (black arrow) parallel to the apatite longitudinal axes

6. Concluding Remarks

In summary, the apatite-gelatin system seems to be well suited for a wide range of interdisciplinary studies to gain further insight into the principles of the morphogenesis of a complex biomimetic material. This story is just beginning and there are still a lot of questions, as can also be seen in the title of the present paper!

Before coming to the end of this contribution only one peculiarity, which may include the key to the deeper understanding of the mechanism of the morphogenesis, should be emphasized in more detail. Though the seed units of the fractal aggregates are formed with a perfect hexagonal-prismatic habit they do not correspond to a single crystal, a fact which is demonstrated by the specific appearance of the fracture area perpendicular to the seed axis (Figure 16). The radial structure of the fracture area indicates that the nucleation of a hexagonal-prismatic unit starts from a central seed which may be formed by fibril-analogous arrange-

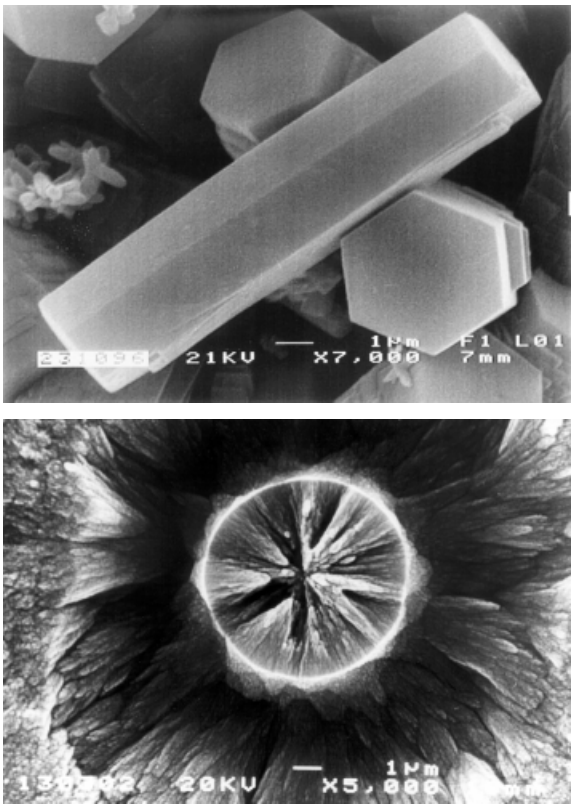

Figure 16. SEM images: Hexagonal prismatic seed (top) and fracture area of a seed (bottom) nearly perpendicular to the seed axis

ments of gelatin molecules able to provide active centres for the nucleation of apatite. The actual size of the apatite crystallites formed is not defined at present and may extend from the nanoscopic to the mesoscopic scale. If this low-scale composite model is valid, the macroscopic hexagonal-prismatic seed is not a single crystal but a hierarchically ordered inorganic/organic composite superstructure. This important question will be the central subject of our future investigations.

Calcium Ions Do Accelerate the DNA Binding of New Antitumor-Active Platinum Aminophosphonate Complexes

Marieke J. Bloemink,[a] Jeroen J. H. Diederen,[a] Jaco P. Dorenbos,[a] Robert J. Heetebrij,[a] Bernhard K. Keppler,[b] and Jan Reedijk*[a]

Keywords: Calcium / Platinum Complexes / Aminophosphonate / Antitumor agents

The presence of Ca^{2+} has a marked effect on the reaction kinetics of platinum phosphonate complexes with d(GpG). Compounds studied are [*cis*-Pt(NH_3)$_2$(bmpaa)] and [Pt(*R*,*S*-dach)(ntmp)]. The formation of GG-*N7*,*N7* chelates and the release of the phosphonate ligand as observed by NMR is significantly accelerated by the presence of Ca^{2+}, which is ascribed to its interaction with the phosphato groups in the ligands.

Introduction

The therapeutic activity of the well-known antitumor drug cisplatin [*cis*-diamminedichloroplatinum(II)] is thought to originate from its interaction with DNA, resulting in inhibition of DNA synthesis.[1] The main reaction product has proven to be the G*N7*,G*N7*-intrastrand crosslink.[2] Numerous analogs of cisplatin have been synthesized and tested in order to improve the therapeutic properties. A rational approach to the development of cytostatics involves the use of carrier functions that cause a specific accumulation of the potential antitumor agents in the target organs or in the target cells. Platinum complexes containing phosphonic acid ligands have been designed for the treatment of bone tumors,[3] since bisphosphonates show a high affinity for bone and other calcified tissues.[4] Four interesting examples of such compounds, i.e. [*cis*-Pt(NH_3)$_2$(bmpaa)] (**a**), [Pt(*R*,*S*-dach)(apmd)] (**b**), [*cis*-Pt(NH_3)$_2$(ntmp)] (**c**), and [Pt(*R*,*S*-dach)(ntmp)] (**d**)[5] are shown in Figure 1, of which [*cis*-Pt(NH_3)$_2$(bmpaa)] (**a**) is expected to enter clinical trials.[6]

Previous work has shown that [*cis*-Pt(NH_3)$_2$(ntmp)] (**c**) and [Pt(*R*,*S*-dach)(ntmp)] (**d**) are capable of forming GG-*N7,N7* chelates (in analogy with cisplatin), concomittant with the release of the phosphonate ligand.[7] Because of the slow reaction kinetics of these platinum complexes, observed at physiological pH, an activation mechanism was supposed to be present in vivo. The principal objective of the work reported here has been to investigate this activation mechanism and, in particular, the influence of the presence of Ca^{2+} on the reaction kinetics.

Results and Discussion

Reaction of [*cis*-Pt(NH_3)$_2$(bmpaa)](**a**) or [Pt(*R*,*S*-dach)(apmd)] (**b**) with d(GpG) [for the structure of d(GpG), see Figure 2] in water, results in the formation of G*N7*,G*N7* chelates, as deduced from the NMR data, in analogy with the Pt phosphonate compounds **c** and **d** (resulting chelates are [*cis*-Pt(NH_3)$_2${d(GpG)-N7(1),N7(2)}] in case of compound **a** and [Pt(*R*,*S*-dach){d(GpG)-N7(1),N7(2)}] in case of compound **b**).[7] In addition free phosphonate ligand is formed. Since the primary amine is a strongly coordinating ligand and usually acts as a non-leaving group it is rather surprising that in the same molecule, i.e. [Pt(*R*,*S*-dach)(apmd)] (**b**), RNH_2 can act as non-leaving group (dach), but also as leaving group (apmd).

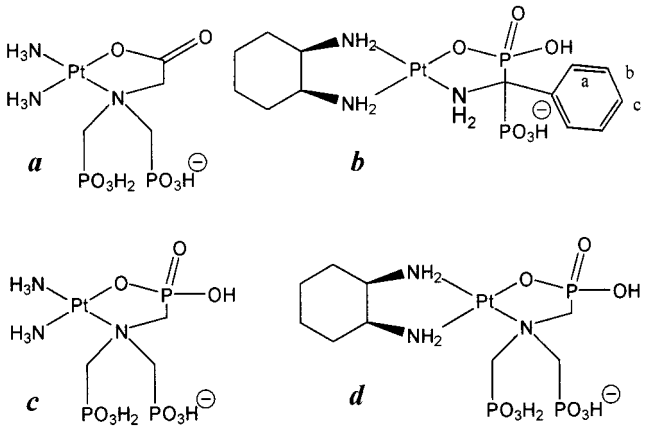

Figure 1. Structures of the platinum phosphonate complexes[*cis*-Pt(NH_3)$_2$(bmpaa)] (**a**), [Pt(*R*,*S*-dach)(apmd)] (**b**), [*cis*-Pt(NH_3)$_2$(ntmp)] (**c**) and [Pt(*R*,*S* dach)(ntmp)] (**d**)

At physiological pH compound **a** is not very reactive towards d(GpG) (see Table 1). The same lack of reactivity towards d(GpG) is observed for compound **d** at physiological pH (see Table 1; see Figure 3). Therefore, an activation mechanism has been proposed to occur in vivo.[7] Initially, it was investigated whether S-containing nucleophiles (cysteine, methionine, gluthatione) could act as activators, because of their known affinity[8] for platinum compounds. However, although initially the reaction of **d** with G bases proceeds faster in the presence of cysteine, methionine or GSH (as determined by UV-Vis spectroscopy), the resulting

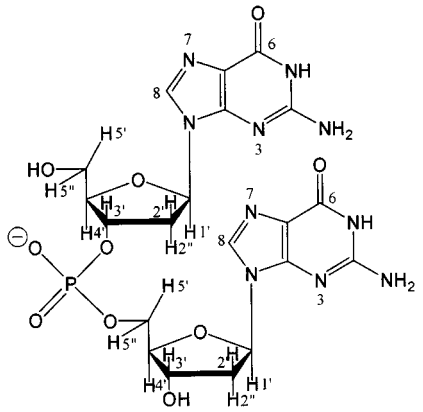

Figure 2. A schematic representation of the dinucleotide anion 2-deoxyguanylyl(3→5′)-2-deoxyguanosine, d(GpG)

product proved to be [Pt(*R*,*S*-dach)(nucl-*S*)(G-*N7*)] (as observed by NMR) and this was found not to be very reactive towards a second G base. Since coordination to a second G base is thought to be necessary for antitumor activity, S-containing nucleophiles are unlikely candidates for an activation mechanism in vivo because they inactivate, rather than activate, platinum phosphonate complexes.

The bmpaa ligand is not released from [*cis*-$Pt(NH_3)_2$(bmpaa)] in the presence of $CaCl_2$, for weeks at 310 K, if no G bases are present. So the above release of bmpaa is not just caused by the $CaCl_2$. Instead the attack of the G base on Pt is significantly enhanced by the presence of Ca^{2+}. The slightly enhanced reactivity in the presence of NaCl could be due to the presence of Na^+ which may also reduce the negative charge on the phosphonate groups, although less pronounced than for Ca^{2+}.

To study the possible effect of (de)protonation, the same experiment has been repeated at slightly acidic pH (pH 6.5) (see Table 1). With these complexes the presence of Ca^{2+} also enhances the reaction, as in the case of pH 7.0. An additional effect, however, must be present under these conditions, since overall the reaction is faster at pH 6.5 than at pH 7. A possible explanation could be that the H^+ ions can also slightly reduce the negative charge on the phosphonate ligand (a similar effect as Na^+, vide supra). Another explanation comes from the known pK_a values of [*cis*-$Pt(NH_3)_2(OH_2)_2$] (pK_{a1} = 5.02, pK_{a2} = 6.93).[9] This implies that at pH 6.5 for the aquated form of cisplatin the predominant species is [*cis*-$Pt(NH_3)_2(OH_2)(OH)]^+$ whereas at pH 7.0 almost all Pt is present as [*cis*-$Pt(NH_3)_2(OH)_2$]

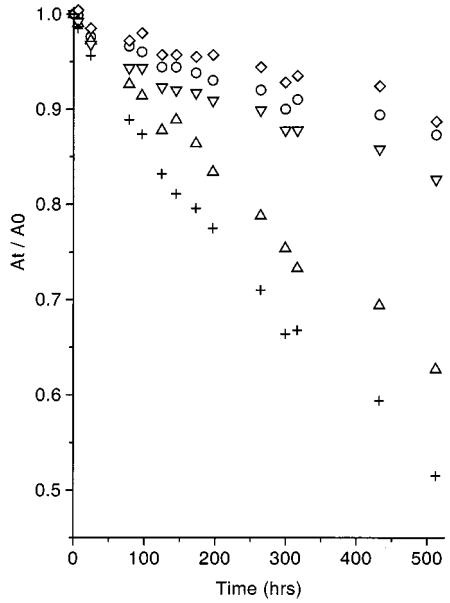

Figure 3. Influence of Ca^{2+} on the reaction of d(GpG) with platinum phosphonate complexes at pH 7 as determined from UV data. ◇ = [Pt(*R*,*S*-dach)(ntmp)]; ○ = [*cis*-$Pt(NH_3)_2$(bmpaa)]; + = [Pt(*R*,*S*-dach)(ntmp)] + Ca^{2+}; ▽ = [*cis*-$Pt(NH_3)_2$(bmpaa)] + Na^+; △ = [*cis*-$Pt(NH_3)_2$(bmpaa)] + Ca^{2+}. A_t/A_o is defined as: $[A_t(\lambda_{max}) - A_t(\lambda_{min})]/[A_o(\lambda_{max}) - A_o(\lambda_{min})]$

which is relatively inert, relative to the aqua species. Although for the Pt phosphonate complexes a direct attack of the G base on the carboxylate is involved (considered to be step 1), it cannot be ruled out that, in case of the subsequent step, the *N*-coordinated phosphonate ligand is hydrolyzed before the second G base will coordinate. This coordination of the second G would occur slower at pH 7.0, due to the presence of coordinated OH, whereas at pH 6.5 relatively more aqua ligand would be present.

The enhanced reactivity of platinum phosphonate complexes in slightly acidic media and in the presence of Ca^{2+} may explain their antitumor properties and selectivity for bone tumors. Since in tumor tissue the pH is known to be (approximately) 0.5 pH units lower than in normal tissues,[10] the reactivity of Pt phosphonates may be enhanced in tumor tissues. In addition, the phenomenon called "bone buffering" may also contribute to the enhanced reactivity of phosphonate compounds in tumors. Bone buffering occurs during prolonged acidosis or other pathological conditions.[11] Calcium phosphate (present as hydroxyapatite in

Table 1. $t_{1/2}$ values (hours) for the several reactions of d(GpG) with [*cis*-$Pt(NH_3)_2$(bmpaa)] and [Pt(*R*,*S*-dach)(ntmp)] (10^{-5} M) as determined from UV data (standard deviations in parentheses)

Compound	pH	$t_{1/2}$	Compound	pH	$t_{1/2}$
[*cis*-$Pt(NH_3)_2$(bmpaa)]	6.5	501 (20)	[Pt(*R*,*S*-dach)(ntmp)]	6.5	479 (20)
+$CaCl_2$	6.5	189 (22)	+ $CaCl_2$	6.5	295 (18)
[*cis*-$Pt(NH_3)_2$(bmpaa)]	7.0	2391 (24)	[Pt(*R*,*S*-dach)(ntmp)]	7.0	2871 (21)
+$CaCl_2$	7.0	685 (7)	+ $CaCl_2$	7.0	521 (10)
+NaCl	7.0	1641(17)			

the inorganic part of the bone) is relatively insoluble; however at lower pH the calcium phosphate can go into solution and the levels of Ca^{2+} and phosphate rise. The increased phosphate concentration is thus able to buffer the H^+ ions, whereas the increased Ca^{2+} level can enhance the reactivity of the platinum phosphonate complexes.

Attack of the G base on Pt does result in release of bmpaa, which is significantly enhanced by the presence of Ca^{2+} The interaction of the calcium ions with the negatively charged phosphonate groups is held responsible for this. This interaction results in less negative charge around the platinum and thus the attack of the incoming G-base is less hindered by electronic repulsion. These observations suggest a possible activation mechanism in vivo induced by calcium and slightly acidic conditions and would nicely explain the antitumor properties of these platinum phosphonate complexes.

Experimental Section

Syntheses: The compounds were synthesized as described elsewhere,[7] and characterized by elemental analysis and IR spectra.

NMR Spectra: The NMR spectra were recorded on a Bruker WM300 spectrometer at 297 K in D_2O (99.95%, Merck). – ^{1}H-NMR data (δ in ppm) were scaled in solution to TMA (tetramethylammonium nitrate, δ = 3.18 downfield TMS), and referenced to TMS and ^{31}P-NMR data were referenced to H_3PO_4 (85%). [*cis*-Pt(NH_3)$_2$(ntmp)] and [Pt(*R*,*S*-dach)(ntmp)] were characterized with ^{1}H- and ^{31}P-NMR spectroscopy as described before.[12] Chemical shift data for the other Pt compounds are: [*cis*-Pt(NH_3)$_2$(bmpaa)]: $\delta H_{CH\text{-}P}$ = 3.56, 3.33; $\delta H_{CH\text{-}COO}$ = 4.30; $\delta^{31}P$ = 10.20. [For comparison: free bmpaa ligand: $\delta H_{CH\text{-}P}$ = 3.60; $\delta H_{CH\text{-}COO}$ = 4.13; $d^{31}P$ = 7.88]. [Pt(*R*,*S*-dach)(apmd)]: δH_a = 7.99, δH_b = 7.43 and δH_c = 7.36; $\delta^{31}P$ = 12.86. [For comparison: free apmd ligand: δH_a = 7.68, δH_b = 7.35 and δH_c = 7.27; $\delta^{31}P$ = 10.55].

Reactions: One equivalent of d(GpG) was allowed to react with one equivalent of complex **a** or complex **d** at 310 K in the dark (10^{-5} M) and the reaction was followed by UV-VIS spectroscopy ((DMS-200 UV-Visible Spectrophotometer, Varian). The pH was kept constant by addition of small amounts (μL) of NaOH (0.1 N) to the reaction mixture. Reactions in the presence of likely activators, such as S-containing nucleophiles, $CaCl_2$ or NaCl, were performed as described above, using the following concentrations: cysteine, methionine, gluthatione, and (*S*)-methylgluthatione ($5\cdot10^{-5}$ M and $5\cdot10^{-6}$ M); $CaCl_2$ ($5\cdot10^{-4}$ M); NaCl (10^{-3} M). After completion of the reaction (no changes in the UV-VIS spectrum can be observed any more) the reaction products were lyophilized and analyzed by NMR. The excess of Ca^{2+} was removed by using oxalic acid and the precipitate was removed by filtration.

Acknowledgments

Support for this work by the Council for Chemical Sciences of the Netherlands Organisation for Scientific Research (CW-NWO) and the foundation of Applied Technical Research (STW) (Grant 349-2293) and a loan of K_2PtCl_4 form Johnson Matthey Ltd. (Reading, England) are greatly appreciated. We acknowledge Pharmachemie BV (Haarlem, the Netherlands) for their financial support. Insights into the Staudinger Reaction: Experimental and Theoretical Studies on the Stabilization of *cis*-Phosphazides

Christoph Widauer,[a] Hansjörg Grützmacher,*[a] Igor Shevchenko,*[b] and Volker Gramlich[c]

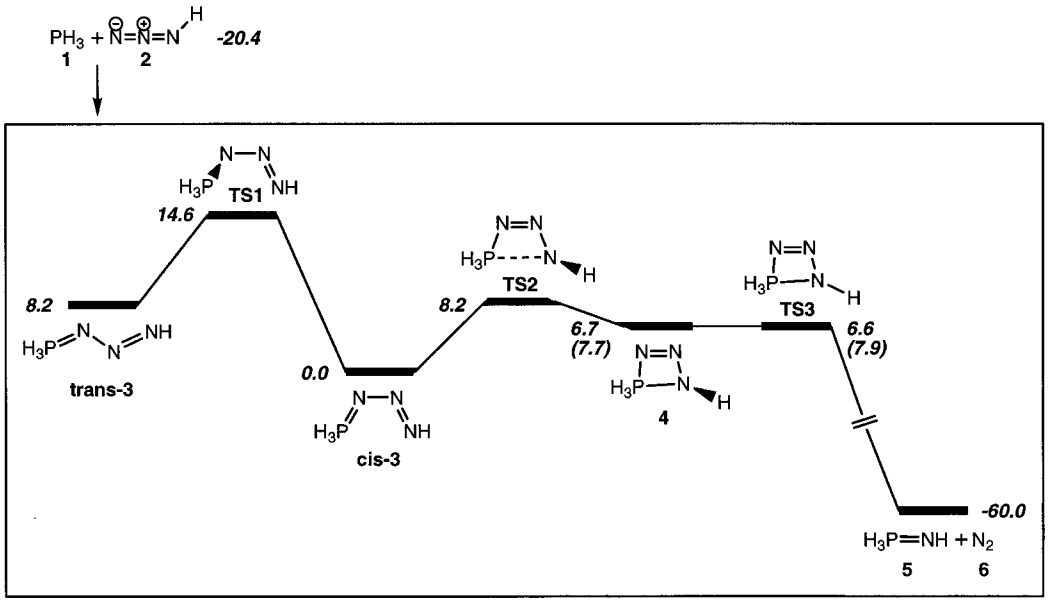
Dedicated to Prof. Dr. Edgar Niecke on the occasion of his 60th birthday

Keywords: Phosphorus / Iminophosphorane / Staudinger reaction / Heterocycles / Ab initio calculations

The Staudinger-model reaction H_3P (**1**) + HN_3 (**2**) → $H_3P{=}NH$ (**5**) + N_2 (**6**) has been investigated at the CCSD(T)/6-31G**//MP2(Full)/6-31G* level. Primary products formed in this reaction are the phosphazides $H_3P{=}N{-}N{=}NH$ (**3**) which exist as *trans* and *cis* isomers. In contrast to some previous assumptions, ***cis*-3** is 8.2 kcal mol^{-1} more stable than ***trans*-3** but decomposes rather easily into the expected products $H_3P{=}NH$ and N_2. This decomposition can be effectively hampered by intramolecular donor–acceptor interactions as shown by calculations on model compounds as well as by experiments. Thus the reaction of a methylene-σ^3,λ^3-phosphanyl-σ^5,λ^5-phosphorane with PhN_3 led to a new four-membered heterocycle containing a thermally remarkable stable *cis*-phosphazide moiety.

Since 1919 the reaction between azides and phosphanes (Staudinger reaction) has been widely used by phosphorus chemists for the preparation of λ^5-iminophosphoranes (phosphazenes).[1] In the course of the reaction the primary imination products, phosphazides, are formed, which are rarely stable under ambient conditions.[2] In a few cases, where R is strongly electron donating, R′ strongly electron withdrawing, or where both R and R′ are sterically bulky, remarkable stable phosphazides $R_3P{=}N{-}N{=}NR'$ have been isolated.[3][4] Here we wish to report on the first detailed ab initio study of the Staudinger reaction and a new possibility to stabilize phosphazides.

The Staudinger-model reaction H_3P (**1**) + HN_3 (**2**) → $H_3P{=}NH$ (**5**) + N_2 (**6**) has been investigated at the CCSD(T)/6-31G**//MP2(Full)/6-31G* level of theory.[5] In the first step of this reaction the *trans*-configured and *cis*-configured phosphazides ***trans*-3** and ***cis*-3** are formed, respectively. Subsequently, decomposition of these intermediates leads to the phosphazene **5** and dinitrogen (**6**) (Scheme 1).



In Figure 1, the geometry-optimized structures of the phosphazides ***trans*-3**, ***cis*-3**, the transition states **TS1**, **TS2**, and **TS3**, the phosphatriazete **4**, and the phosphazene **5** are shown. Calculated total energies of all species are given in Table 1 and atomic charges on P and N of ***trans*-3** and ***cis*-3** obtained by Natural Bond Orbital analyses (NBO) are given in Table 2.

The structures of some phosphazides have been determined experimentally.[3][4] Most of these compounds contain a *trans*-configured phosphazide moiety[3] while the *cis*-conformation[4] has rarely been observed. This led to the assumption that the *trans* conformers are more stable than their corresponding *cis* isomers. However, at least for the parent model system $H_3P{=}N{-}N{=}NH$ our calculations show a different picture: ***cis*-3** is more stable than ***trans*-3** by 8.2 kcal mol^{-1}. The isomerisation of ***trans*-3** to ***cis*-3** proceeds via the transition state **TS1** and requires an activation energy of 6.4 kcal mol^{-1}. Indeed, the *cis* isomer, though thermodynamically more stable, decomposes rather easily into $H_3P{=}NH$ (**5**) and N_2 (**6**). On the reaction coordinate, the transition state **TS2** has to be overcome, which is 8.2 kcal mol^{-1} higher in energy than ***cis*-3**. This reaction can be described as an intramolecular nucleophilic attack of the negatively charged nitrogen centre N3 (−0.55 e) on the positively charged phosphorus centre (+0.95 e). As a result, the P−N3 distance is shortened from 2.402 Å in ***cis*-3** to 1.880 Å in **TS2**. The approach of the N3 centre towards the phosphorus centre is accompanied by a pseudo-rotation at the phosphorus centre. Thereby, the formerly short P=N1 bond (1.673 Å in ***cis*-3**) is lengthened (1.924 Å in **TS2**) and the nitrogen centre N1 takes an axial position within the distorted trigonal-bipyramidal coordination sphere of the phosphorus centre.

The next product encountered on the reaction pathway is the C_1-symmetric λ^5-triazaphosphete **4**. This heterocycle is 6.7 kcal mol^{-1} higher in energy than ***cis*-3**. Molecule **4** is well-prepared for the cycloreversion leading towards the phosphazene **5** and dinitrogen. The P−N1 bond (1.951 Å) and N2−N3 bond (1.434 Å) are even longer than the ones in **TS2** while the N2−N3 bond is shorter. Calculations performed for **4** at higher levels of theory [MP4(Full) and

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1999 1434−1948/99/1010−1659 $ 17.50+.50/0

Scheme 1. Schematic representation of the isomerisation and decomposition pathways of ***cis*-3**; the refined and ZPE-corrected relative energies at the CCSD(T)/6-31G**//MP2(Full)/6-31G* level are given in kcal mol^{-1}; for **4** and **TS3** the refined relative energies at the CCSD(T) level without ZPE-correction are additionally given in parentheses

QCISD(Full)] confirm that triazete **4** is a local minimum on the energy hypersurface. However, without ZPE correction, **4** is only 0.2 kcal mol^{-1} lower in energy than **TS3**. Inclusion of zero-point energies reverses this ordering making **TS3** 0.1 kcal mol^{-1} lower in energy than **4**. This means that ordinary transition-state theory cannot be expected to describe this region of the hypersurface accurately. Therefore, we are not able to distinguish between a stepwise or concerted reaction mechanism at this point.[6] However, we can assume that ***cis*-3** decomposes via **TS2** to form phosphazene $H_3P{=}NH$ (**5**) with loss of dinitrogen.

During the decay of ***cis*-3** to **5** under extrusion of N_2 the valence configuration at N1 and N2 changes from sp^2 to sp. This process may be hampered when the lone pair at one of these nitrogen centres is involved in a donor−acceptor interaction. To test this idea we prepared the methylenephosphanyl phosphorane **7**[7] and reacted it with phenyl azide **8** (Scheme 2).

Scheme 2. Synthesis of trisspirocyclic **9**

The compound **7** contains a (λ^3,σ^3)-phosphorus centre, which can undergo a Staudinger reaction with an azide. To this phosphorus centre, a strongly positively charged (λ^5,σ^5)-phosphorus centre is bonded in the β position which can act as electron-pair acceptor. The reaction of **7** with **8** proceeds smoothly in diethyl ether without evolution of dinitrogen. The product **9** was recrystallized from toluene to afford colorless crystals suitable for an X-ray structure analysis. The result is shown in Figure 2, selected bond lengths and angles are given in the figure caption.

In compound **9** the azide moiety, indeed, takes a bridging position between the two phosphorus centres P1 and P2, thereby forming a planar four-membered ring. The P1−N1−N2−N3 unit shows a *cis* configuration. The P1−N3 distance (2.977 Å) is considerably longer than that calculated for ***cis*-3** (2.402 Å). However, apart from this distance, all other P−N and N−N bond lengths are in good agreement with distances and angles observed in ***cis*-3**. The intramolecular interaction between N1 and P2 augments the coordination number of P2 from five to six and the (λ^5,σ^6)-P2−N1 bond (1.812 Å) is, as expected, considerably longer than the P1=N1 bond (1.626 Å). The heterocycle **9** shows unusual thermal behavior when heated to 100−110°C in toluene. No dinitrogen evolution is observed but the iminophopshorane **10** is obtained which was unequivocally characterized by its NMR spectra. The mechanism leading to its formation is still unclear.

At this stage of our investigation, we returned to theoretical studies. Since the parent phosphazides ***trans*-3** and ***cis*-3**

are rather different from the experimentally obtained structure **9**, we have performed ab initio calculations for ***cis*-11** and ***trans*-11** which are better models. The PF_4 moiety was chosen as substitute for the acceptor group including the hexa-coordinated P2 centre in **9** and the $P(NH_2)_2$ group was chosen to replace the $P1(NEt_2)_2$ unit. The structures of ***cis*-11** and ***trans*-11** were also optimized at the MP2(Full)//6-31G* level and are shown in Figure 3.

The *cis* isomer is again more stable than the *trans* isomer. However, at the MP2(Full)/6-31G* level, the energy difference amounts to only 3.3 kcal mol^{-1} and is 5.6 kcal mol^{-1} smaller than that observed for the parent compounds ***cis*-3** and ***trans*-3**. Thus, the observed *cis*-configuration of the P–N1–N2–N3 unit in **9** might be simply preferred for steric reasons. Generally, the agreement between the calculated structure of ***cis*-11** and that of **9** is acceptable. The four-membered heterocycle which is planar in **9** deviates slightly from planarity in ***cis*-11** and, in an opposite sense, in ***trans*-11**. As was also observed experimentally, the P2–N1 and P2–C bonds pointing away from the hexa-coordinated phosphorus centre P2 are considerably longer than corresponding P1–N1 and P1–C bond lengths. The largest deviation is seen in the intramolecular P1–N3 contact, which is about 0.2 Å longer in ***cis*-11** than the experimental value observed in **9**.

Since the theoretical investigation of the decomposition pathways of **11** is very expensive, we investigated the boromethyl phosphazides **12** and **13**. The decomposition of these compounds is easier to study at the level of theory used throughout this paper and **12** and **13** should serve as reliable models for the study of the effect of intramolecular donor–acceptor interactions. The structures optimized at the MP2(Full)/6-31G* level are shown in Figure 4 including selected bond lengths and angles.

Rotation around the P–C bond interconverts **12** to ***cis*-13**. Intramolecular nucleophilic attack of N1 onto the boron centre leads to the formation of the four-membered B,C,P,N heterocycle. The energy gained by this process amounts to 18.6 kcal mol^{-1} and can be taken as measure of the donor-acceptor stabilization energy of the N1–B interaction. The heterocycle ***cis*-13** is 5.2 kcal mol^{-1} more stable than ***trans*-13**. However, this energy difference is again smaller than that found for the parent compounds ***cis*-3** and ***trans*-3**, respectively (8.2 kcal mol^{-1}). Obviously, the *trans*-isomers become *thermodynamically* more stabilized than the *cis*-isomers by intramolecular donor-acceptor interactions. The latter remain, however, energetically favored. The structure of the *cis*-configured phosphazide moiety P1–N1–N2–N3 does not differ significantly from the one calculated for ***cis*-11** or the one observed in **9**. Note that the P–N3 contact becomes considerably longer (ca. 0.3 Å) in the cyclic compound ***cis*-13** (2.767 Å) while in the acyclic

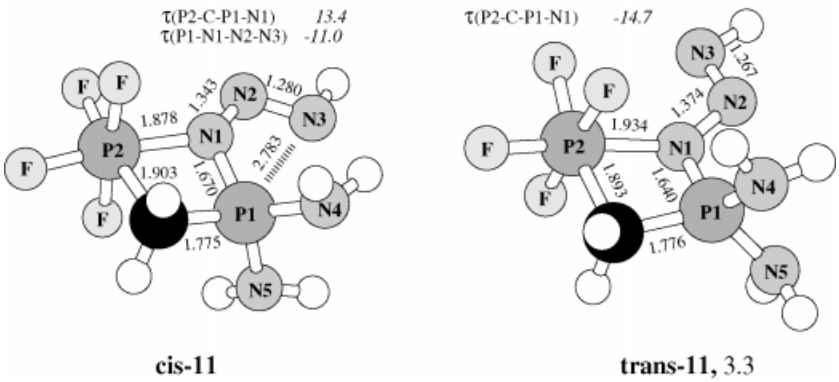

Figure 3. Schematic representation of the isomers ***cis*-11** and ***trans*-11** including bond lengths [Å] and dihedrals τ [°]; the relative energy is given in kcal mol^{-1}

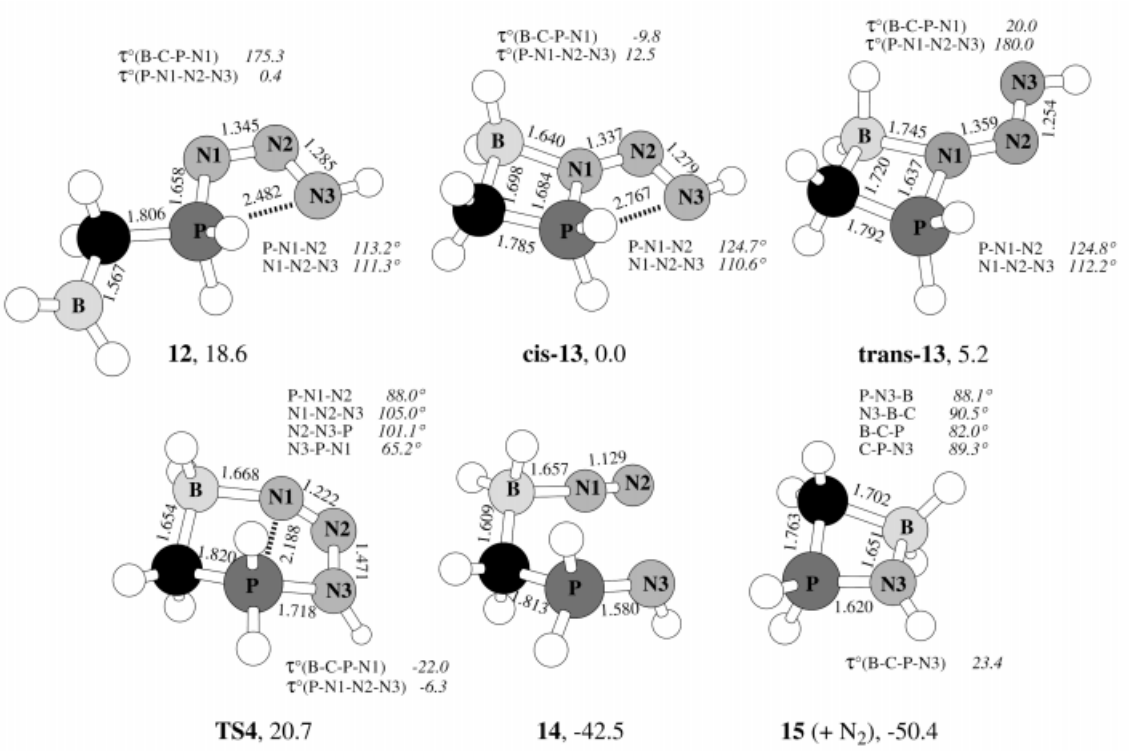

Figure 4. Schematic representation of the fully optimized MP2 structures of the (boromethyl)phosphazides $(H_2BCH_2)H_2P{=}N1{-}N2{=}N_3H$ including selected bond lengths [Å], angles [°], and dihedrals τ [°]; relative energies are given in kcal mol^{-1}

structure **12** this distance (2.482 Å) lies in the same range as has been calculated for the parent compound ***cis*-3** (2.402 Å). The cleavage of dinitrogen from ***cis*-13** proceeds via the bicyclic transition state **TS4** which is 20.7 kcal mol^{-1} higher in energy. This activation barrier is 12.5 kcal mol^{-1} higher than that calculated for the decay of ***cis*-3**. The phosphazene **14** is formed exothermically (−42.5 kcal mol^{-1}) and still contains the dinitrogen N_2 molecule coordinated to the Lewis-acidic boron centre. After dissociation of N_2, the heterocycle **15** is observed as the final product and encloses the thermodynamically highly favored reaction sequence. This example shows that intramolecular donor−acceptor interaction between an electron pair acceptor and the lone pair at the N1 centre may efficiently hamper *kinetically* the decay of *cis*-phosphazides into phosphazenes and dinitrogen.

Experimental Section

Calculations: The calculations were performed with the GAUSSIAN 94 program package.[8] All structures were fully optimized at the MP2(Full) level using the polarized split-valence-shell 6-31G* basis set.[5a,5b] Refined energies were obtained at the CCSD(T) level,[5c−5e] except for ***cis*-11** and ***trans*-11**, in conjunction with the slightly extended basis set 6-31G**,[5b] which also contains p polarization functions on the hydrogen atoms. The vibrational frequency calculations were carried out to characterize all structures as minima or transition states. Relative energies were corrected for zero-point vibrational energy (ZPE) using the unscaled MP2 corrections. Atomic charges were obtained at the MP2(Full)/6-31G* level according to Reed and Weinhold's NBO analysis,[9] which is implemented in GAUSSIAN 94. Selected total and relative energies of all calculated structures are presented in Table 1.

***cis*-Phosphazide 9**: A solution of **7**[7] (150 mg, 0.27 mmol) in 2 mL of diethyl ether was treated with 50 mg (0.42 mmol) of phenylazide and the reaction mixture was allowed to stay at room temperature for 30 min. The bottom of the flask was rubbed by a glass stick to promote the crystallization and after formation of the first crystals the solution was allowed to stay at −18 °C for 12 h. Crystals of **9** were separated and recrystallized from toluene. M.p.: 139−141 °C. An Unusual Reaction of Hexafluoroacetone with Methylenediphosphanes: Facile Synthesis of Carbodiphosphoranes

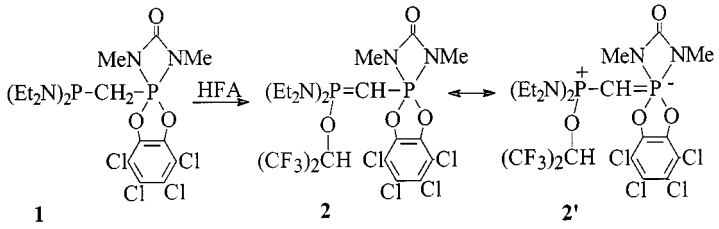
Igor Shevchenko,*[a] Rostislav Mikolenko,[a] Sandra Loss,[b] and Hansjörg Grützmacher*[b]

Keywords: Methylenediphosphane / Hexafluoroacetone / Carbodiphosphorane / Ylides / Carbenes

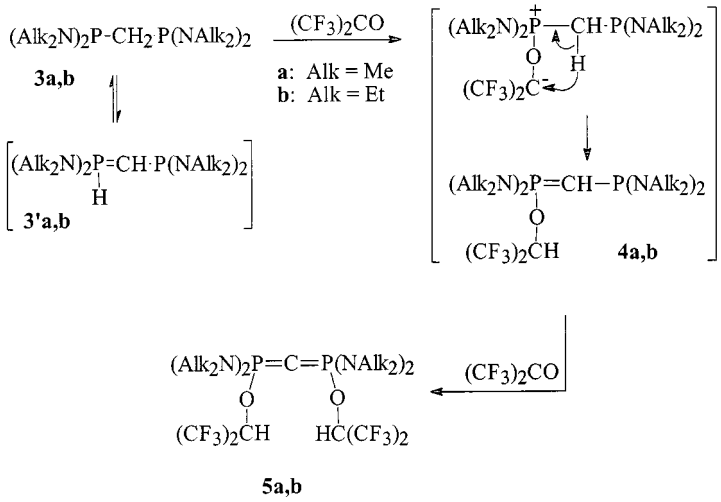
The oxidation of the methylenediphosphanes **3a,b** with hexafluoroacetone does not lead to the expected dioxaphospholane heterocycles, but yields quantitatively the carbodiphosphoranes **5a,b**. Compounds **5a,b** easily add HCl, HF or Cl_2 to the ylidic bonds. The chloro derivative **14b,** and its analogue **17** were used for the synthesis of phosphonium substituted carbenes.

It is well-known that the reaction of phosphanes with two equivalents of hexafluoroacetone (HFA) leads to the formation of phosphoranes in which the phosphorus atom is included in dioxaphospholane heterocycles.[1–4] It turns out that this is not the only possible pathway for this reaction. In one of our previous papers we described the formation of the phosphorus ylide **2** from the reaction of the methylenephosphinophosphorane **1** with one equivalent of HFA.[5] However, we considered this to be an exception to the rule as **1** possesses unique chemical properties due to the ability of the λ^5-phosphorus atom to form zwitterionic structures with tetra- and hexacoordinate phosphorus atoms bearing opposite charges.[6] According to the X-ray data **2** may indeed have the zwitterionic structure **2′**.[5]



It appears, however, that this reaction is not an exception, but has a more common nature. In our preliminary communication[7] we reported an unusual reaction of the bis[bis(dialkylamino)phosphinyl]methanes **3a,b** with two equivalents of hexafluoroacetone, which quantitatively yields the carbodiphosphoranes **5a,b**. The addition of HFA to **3a,b** is accompanied by the migration of two protons from the $P-CH_2-P$ unit to the carbon atoms of HFA. Thus the presence of a methylene group between the two phosphorus atoms is a necessary condition for this reaction.

Formally, the mechanism of the formation of the carbodiphosphoranes **5a,b** can be considered to be an addition of the tautomeric P–H ylide form **3′a,b** to the carbonyl function of HFA. However, it is more likely that the migration of the proton from the $P-CH_2-P$ unit follows an electrophilic attack by HFA on the phosphorus. This reaction probably consists of two steps with the intermediate formation of the monoylides **4a** or **4b**. However, we could not detect these compounds by NMR spectroscopy. If only one equivalent of HFA was added to methylenediphosphanes **3a,b**, the reaction mixture was found to consist of starting material **3** and reaction product **5** in equal proportions. The reaction proceeds smoothly at room temperature by slow bubbling of gaseous HFA through a solution of **3a** or **3b** in hexane. The $^{31}P\{^1H\}$ NMR spectra of the reaction mixtures show the presence of only one compound **5a** or **5b**, respectively (one singlet at $\delta = 33 - 37$). The location of the two equivalent protons in the α-positions to the CF_3 groups is confirmed by the ^{19}F-NMR spectra: all fluorine atoms are equivalent and appear as a doublet at $\delta = -73.0$ with a $^3J_{HF}$ coupling constant of 6.8 Hz. The $HC(CF_3)_2$ protons display the same coupling constant in the ^1H-NMR spectra, showing a characteristic low field multiplet at $\delta = 6.2$. NMR spectroscopic studies revealed an interesting phenomenon: this multiplet of nine slightly broadened lines is a combination of a septet, caused by $^3J_{FH}$coupling, and a triplet caused by $^3J_{PH}$coupling, with approximately equal coupling constants. The two marginal lines are of very low intensity and can only be distinguished at high signal-to-noise ratio and amplification. This unexpected $^3J_{PH}$ triplet was also found in the ^{31}P-NMR spectrum of **5a** or **5b** when measured with the selective decoupling of the protons of the NR_2 group. This means that the protons of the two $HC(CF_3)_2$ units are equivalent for each of the two phosphorus atoms and vice versa. This unusual P–H coupling is probably accounted for by a rapid exchange between the two protons of the $HC(CF_3)_2$ groups, as in **5′a,b**. Derivatives of **5a,b** – the hydrochloride salts **7a,b**, the tetrafluoroborate **16** and the dichloro- and tetrachloro derivatives **13, 14** – exhibit the same spectroscopic phenomenon (see below). It should be noted that the dimethylamino groups of **5a** appear in the ^1H-NMR spectrum not as a doublet, but as a pseudo-triplet, at $\delta = 2.59$, with a broadened central line which is consistent with the NMR spectroscopic data of known compounds. The analogous carbodiphosphorane, which has chlorine atoms instead of HFA groups at the two phosphorus atoms, shows the same pattern for the NMe_2 groups in its ^1H-NMR spectrum.[8]



Theoretically, the reaction of **3a**,**b** with HFA can also lead to compounds **6a**,**b**, which are structural isomers of **5a**,**b** and which would have approximately the same spectral

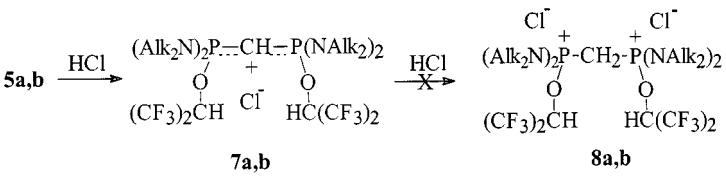
5'a,b



6a,b

data. However, unlike **6a,b**, the carbodiphosphoranes **5a,b** have an ylidic structure which was subsequently confirmed by treating them with HCl to form the stable salts **7a,b**. As strong bases, **5a**,**b** also react with ammonium chlorides. For this reason, small quantities of **7a**,**b** are always formed together with **5a,b** if the starting methylenediphosphanes **3a,b** are contaminated with dialkylammonium chlorides. However, compounds **7a,b** are not soluble in hexane and can easily be separated.

The structures of **7a,b** are entirely consistent with the NMR spectroscopic data obtained. The ^{13}C-NMR spectrum shows a triplet for the P−C−P carbon atom at δ = 7.35. Such an upfield chemical shift is indicative of a carbon atom bearing a negative charge. The ^{1}H-NMR spectrum of **7a** is shown in Figure 1. As in the case for **3a**, the $HC(CF_3)_2$ protons are equivalent towards each phosphorus atom and appear as a multiplet of nine lines at δ = 6.71. This signal, however, is not well resolved due to larger differences between the $^{3}J_{FH}$ and $^{3}J_{PH}$coupling constants. As in **3a,** the NMe_2 units of **7a** appear as pseudo triplets in the ^{1}H- and ^{13}C-NMR spectra. It is important to note that, despite their ylidic character, **7a,b** are very stable towards hydrolysis. With HCl no further reaction occurs and the expected diphosphonium salts **8a,b** cannot be obtained in this way.

The carbodiphosphorane **5a** slowly decomposes in hexane solution at room temperature and its signal in the ^{31}P-NMR spectrum disappears within several hours. Compound **5b,** containing bulkier diethylamino substituents, is more stable and a hexane solution of **5b** can be stored without decomposition for two days. However, subsequent evaporation of the solvent causes **5b** to decompose. The choice of hexane as solvent is very important for the preparation

Scheme 3. Reaction of **5a,b** with HCl

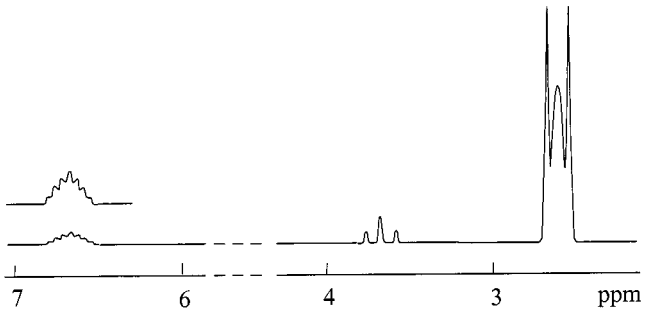


Figure 1. The ^{1}H-NMR spectrum of **7a**

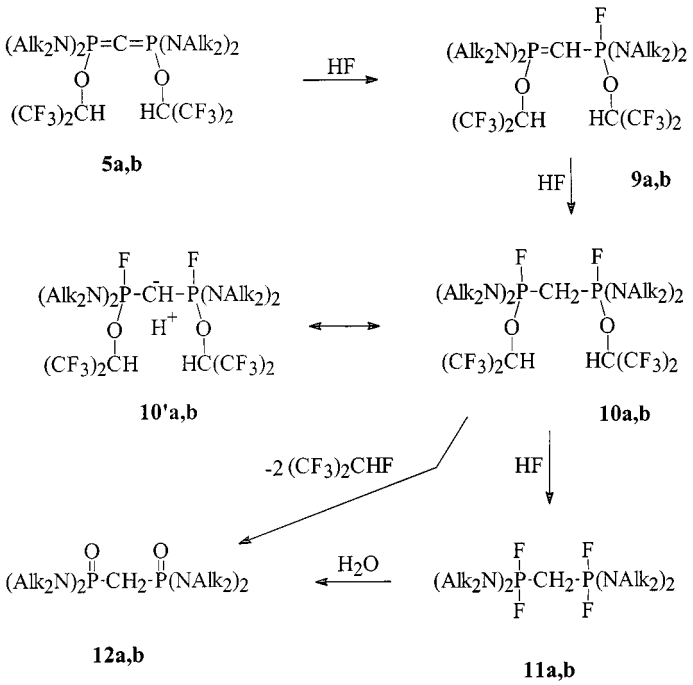

of carbodiphosphoranes **5a,b**. In other solvents they either cannot be obtained (CH_2Cl_2, $CHCl_3$) or are much less stable (C_6H_6, THF).

The decomposition of **5a,b** occurs by several steps (Scheme 4). All the intermediate compounds **9a,b - 12a,b** have been detected in the reaction mixture at different stages of the reaction. Due to the significant basicity of **5a,b** the reaction proceeds by an intermolecular abstraction of HF. In this way, half of the molecules of **5a,b** are used as a source of HF, that is why other compounds are also present in the reaction mixture. For example, small amounts of crystalline diethylammonium hexafluorophosphate (about 1%) can be isolated from the reaction mixture.

The proposed reaction pathway was confirmed by the reaction of **5a,b** with HF. The addition of one equivalent of HF gives the monofluorides **9a,b** which have, unlike their chloride analogues **7a,b,** two inequivalent phosphorus atoms and display two doublets of doublets with characteristic $^2J_{PP}$, $^1J_{FP}$ and $^3J_{FP}$ coupling constants of 45.9 Hz, 950 Hz and 13.7 Hz, respectively, in the ^{31}P-NMR spectra. In contrast to HCl, which does not add to **7a,b,** HF reacts with the monofluorides **9a,b** so readily that it is impossible to obtain **9a,b** without the difluorides **10a,b**. Compounds **10a,b** are also able to react further with HF to give the methylene-bis(difluorophosphoranes) **11a,b**. If a definite amount of HF (2.2 equiv.), or $Et_3N{\cdot}2HF$, is added, the reaction mixture consists only of the difluorides **10** and bis(difluorophosphoranes) **11**, which can easily be separated as compounds **10** are insoluble in hexane and precipitate as a light yellow oil, whereas compounds **11** remain in solution.

The difluorides **10a,b** possess interesting spectral characteristics. Their ^{31}P-NMR spectra display a complex resonance of the AA′XX′ spin system (Figure2) which does not vary in the temperature range from −60 to +60°C. A theoretical calculation of the FPPF system using the experimentally obtained coupling constants gives the same pattern. The carbon atom of the FP−CH_2−PF chain displays the expected triplet of triplets in the ^{13}C-NMR spectra. However, its upfield chemical shift (δ = 10), which is very close to that of the ylides **5a,b** or **7a,b**, shows that it bears a negative charge. The same conclusion can be drawn from the ^{1}H-NMR spectra, as the two acidic methylene protons show a broad signal at δ = 9.5. This indicates that the real structure of these compounds is probably closer to that of **10′a,b**.

The methylenebis(difluorophosphoranes) **11** were isolated as a low-melting crystalline product **11a** or light yellow oil **11b**. Their hydrolysis led to the dioxaderivatives **12a,b**. Interestingly, these compounds were also formed even if the decomposition of the carbodiphosphoranes **5a,b** was carried out under dry conditions. This can probably be explained by the removal of 1,1,1,2,3,3,3-heptafluoropropane from the difluorides **10a,b**. In order to confirm the formation of **12a,b** we tried to obtain them independently

Scheme 4. Reaction of **5a,b** with HF

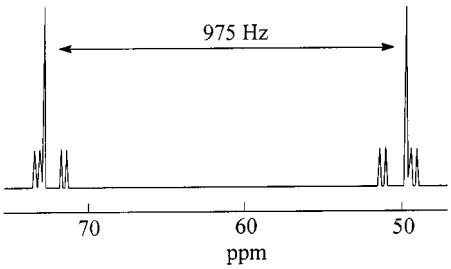

Figure 2. The ^{31}P-NMR spectrum of compounds **10a,b**

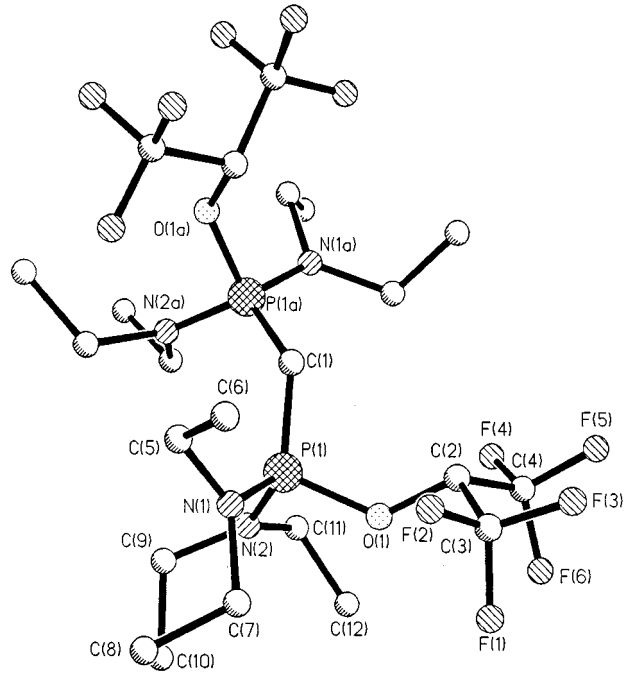
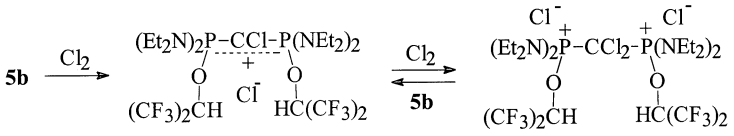
by the reaction of **3a,b** with oxygen. However, even after bubbling gaseous oxygen through a solution of **3a** or **3b** in dichloromethane, at room temperature, over long periods of time no reaction occurred, although it was later found that sulfur reacts very readily with **3a,b**.

The carbodiphosphorane structure of **5** is also confirmed by the rection with chlorine. Thus, **5b** very easily adds two equivalents of chlorine at room temperature to give the tetrachloro derivative **14**. The reaction initially forms the dichloro derivative **13** which, however, cannot be obtained in a pure form in this way, as a further reaction with chlorine occurs. This compound can be prepared by the abstraction of two chlorine atoms from **14** with $SnCl_2$ but, on a preparative scale, the use of the reaction between **14** and the starting carbodiphosphorane **5b** is more convenient. Compounds **13** and **14** were isolated as stable crystalline compounds which are insoluble in nonpolar solvents.

We were interested in dichloride **13,** not only for confirmation of the structure of **5,** but also because of its possible application for the synthesis of carbenes. For this purpose we studied the reaction of **13** with silver tetrafluoroborate. The reaction is carried out in boiling chloroform for 2 hours. However, the phosphonium-substituted carbene **15** turned out to be unstable under these conditions and the only product which could be isolated from the reaction mixture was its derivative **16**. This compound is analogous to the salt **7b** and contains a hydrogen atom attached to the P−C−P carbon atom, which was subsequently confirmed by an X-ray structure analysis (Figure 3). The formation of





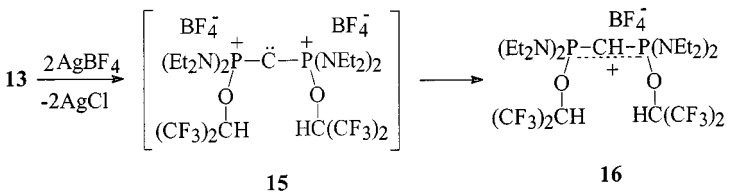


Figure 3. Molecular structure of **16**; selected bond lengths [Å] and angles [°]: P(1)−N(2) 1.618(6), P(1)−N(1) 1.619(6), P(1)−O(1) 1.625(4), P(1)−C(1) 1.681(6), O(1)−C(2) 1.408(6); P(1)#1−C(1)−P(1) 131.5(4); N(2)−P(1)−N(1) 109.27(13), N(2)−P(1)−O(1) 99.4(2), N(1)−P(1)−O(1) 105.5(2), N(2)−P(1)−C(1) 117.6(2), N(1)−P(1)−C(1) 113.66(11), O(1)−P(1)−C(1) 109.9(3), C(2)−O(1)−P(1) 127.5(2)

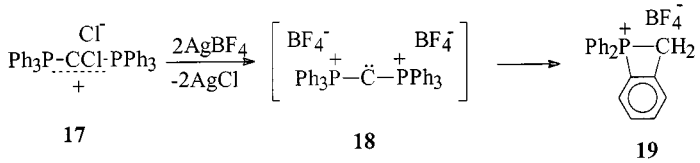
16 probably confirms the formation of the carbene **15** as an intermediate.



As was pointed out above, the tetrafluoroborate **16,** as well as the original carbodiphosphoranes **5a,b** and their derivatives **7a,b**, **13** and **14**, display an interesting spectroscopic phenomenon: the equivalence of the $HC(CF_3)_2$ protons for each of the two phosphorus atoms. This can be explained by a rapid exchange of the protons in solution on the NMR timescale. The crystal structure of **16** shows that these protons point towards the inside of the molecule and, if a rotation around the P−C−P bonds in solution is possible, they should be situated very close to each other thus

Scheme 5. Reaction of **5b** with Cl_2

Scheme 6. Reaction of **13** with $AgBF_4$

17 **18** **19**

Scheme 7. Reaction of **17** with $AgBF_4$

allowing the exchange process. Obviously, this rotation or flip-flop movement around the P−C−P bonds must be possible, as can be seen from the equivalence of the NMe_2 or NEt_2 protons in the NMR spectra, although in the solid state these groups are inequivalent as the molecule of **16** has C2 symmetry.

In order to study the stability of carbenes in such systems, it was interesting to change the substituents at the phosphorus atoms of the P−C−P triad. We chose the dichloro derivative of hexaphenylcarbodiphosphorane[9] **17** as a suitable starting material. Its properties differ remarkably from those of **13**. For example, the chlorination of **17** does not give the tetrachloride but instead leads to the cleavage of a P−C bond.[10]

The reaction of **17** with $AgBF_4$ (Scheme 7) requires milder conditions and works at room temperature. However, the expected carbene **18** is also unstable. It decomposes with the cleavage of one P−C bond to give the cyclic phosphonium salt **19**, which is the main product in this reaction. Compound **19** has a methylene group in the α position to the phosphorus atom and can only be formed from the carbene **18**. It has already been shown that, when the benzene ring at the phosphorus atom has a suitable *ortho* substituent, carbene intermediates can undergo intramolecular reactions often leading to the formation of cyclic products.[11,12,13] Similar results were obtained with diisopropylamino groups attached to a phosphorus atom near the carbene centre.[14] Comparing these data with those known for stable carbenes,[15] one can postulate that the stabilization of a carbene centre requires substituents with σ-accepting and π-donating abilities. Phosphonium groups do not meet one of these conditions.

Experimental Section

All reactions and manipulations were carried out in a nitrogen atmosphere in a dry box or with standard Schlenk techniques, unless otherwise indicated. Solvents were dried by standard procedures and distilled in a nitrogen atmosphere and either used immediately or stored in the dry box prior to use. Glassware was oven-dried at 100°C overnight prior to use. NMR spectra were recorded on JEOL FX-90Q and Bruker WP-200 multinuclear NMR spectrometers. Chemical shifts were measured relative to residual solvent peaks and referenced to Me_4Si (^1H, ^{13}C) or to external 85% H_3PO_4 (^{31}P). Reagents **3a,b**[16] were prepared by standard methods.

Carbodiphosphorane 5a: Gaseous HFA (29.6 mL, 1.32 mmol) from a syringe was slowly bubbled through a solution of **3a** (0.139 g, 0.55 mmol) in 1 mL of hexane at 20°C. If the starting diphosphane is contaminated with dialkylammonium chloride an appropriate amount of salt **7a** is formed which can be easily separated as it is not soluble in hexane. ^1H NMR (200 MHz, [D_8]toluene):[17] δ = 2.59 (pseudo t, $^3J_{PH}$ = 11.6 Hz, 24 H, NCH_3), 6.25 (t of sept, $^3J_{FH}$ = 6.8 Hz, $^3J_{PH}$ = 6.8 Hz, 2 H, $CHCF_3$). − ^{19}F NMR (84.26 MHz, C_6H_{14}): δ = −73.0 (d, $^3J_{HF}$ = 6.8 Hz, 12 F). − ^{31}P NMR (36.2 MHz, C_6H_{14}): δ = 36.7.

Carbodiphosphorane 5b: This compound was obtained as described above from HFA (29.6 mL, 1.32 mmol) and **3b** (0.20 g, 0.55 mmol). − ^1H NMR (200 MHz, [D_8]toluene):[17] δ = 0.98 (t, $^3J_{HH}$ = 7.1 Hz, 24 H, NCH_2CH_3), 3.00 (m, 16 H, NCH_2CH_3), 6.09 (t of sept, $^3J_{FH}$ = 6.8 Hz, $^3J_{PH}$ = 6.8 Hz, 2 H). − ^{19}F NMR (84.26 MHz, C_6H_{14}): δ = −72.9 (d, $^3J_{HF}$ = 6.8 Hz, 12 F). − ^{31}P NMR (36.2 MHz, C_6H_{14}): δ = 33.6.

Phosphonium Chloride 7a: To a solution of **5a** in hexane 1 equiv. of HCl (as a solution in ether) was added at 20°C. The precipitate of **7a** which formed was separated by filtration and recrystallized from CH_2Cl_2/ether at −15°C. Yield 63%. − M.p. 183−185°C (dec.). − ^1H NMR (200 MHz, $CDCl_3$): δ = 2.71 (pseudo t, $^3J_{PH}$ = 10.7 Hz, 24 H, NCH_3), 3.67 (t, $^2J_{PH}$ = 10.0 Hz, 1 H, PCHP), 6.71 (t of sept, $^3J_{FH}$ = 5.9 Hz, $^3J_{PH}$ = 6.8 Hz, 2 H, $CHCF_3$). − ^{13}C NMR (50.3 MHz, $CDCl_3$): δ = 7.4 (t, $^1J_{PC}$ = 209 Hz, PCP), 37.3 (pseudo t, $^2J_{PC}$ = 4.9 Hz, 8 C, NCH_3), 70.3 [sept, $^2J_{FC}$ = 34 Hz, 2 C, $CH(CF_3)_2$], 120.8 (q, $^1J_{FC}$ = 285 Hz, 4 CF_3). − ^{19}F NMR (84.26 MHz, $CDCl_3$): δ = −73.9 (d, $^3J_{HF}$ = 5.9 Hz, 12 F). − ^{31}P NMR (36.2 MHz, $CDCl_3$): δ = 58.6. − $C_{15}H_{27}ClF_{12}N_4O_2P_2$(620.79): calcd. C 29.02, H 4.38; found C 28.77, H 4.32.

Phosphonium Chloride 7b: This compound was prepared as descibed above. Yield 52%. − M.p. 151−153°C. − ^1H NMR (200 MHz, $CDCl_3$): δ = 1.06 (t, $^3J_{HH}$ = 6.8 Hz, 24 H, NCH_2CH_3), 3.05 (m, 16 H, NCH_2CH_3), 3.23 (t, $^2J_{PH}$ = 13.7 Hz, 1 H, PCHP), 6.75 (t of sept, $^3J_{FH}$ = 5.9 Hz, $^3J_{PH}$ = 6.8 Hz 2 H, $CHCF_3$). − ^{13}C NMR (50.3 MHz, $CDCl_3$): δ = 7.3 (t, $^1J_{PC}$ = 209 Hz, PCP), 13.7 (s, 8 C, NCH_2CH_3), 40.6 (s, 8 C, NCH_2CH_3), 70.4 [sept, $^2J_{FC}$ = 34 Hz, 2 C, $CH(CF_3)_2$], 120.8 (q, $^1J_{FC}$ = 285 Hz, 4 CF_3). − ^{19}F NMR (84.26 MHz, $CDCl_3$): δ = −73.0 (d, $^3J_{HF}$ = 5.9 Hz, 12 F). − ^{31}P NMR (36.2 MHz, $CDCl_3$): δ = 59.1. − $C_{23}H_{43}ClF_{12}N_4O_2P_2$(733.01): calcd. C 37.69, H 5.91; found C 28.77, H 4.32.

Methylenebis[bis(diethylamino)difluoro(1,1,1,3,3,3-hexafluoro-2-propoxy)phosphorane] 10b: To a solution of **5b** in hexane, obtained as described above, one molar equivalent of $Et_3N{\cdot}2HF$ was added. The colourless oil separated from the mixture after stirring for 20 min at room temperature was washed with hexane and dried in vacuo. Yield 26.5%. − ^1H NMR (200 MHz, $CDCl_3$): δ = 1.14 (t, $^3J_{HH}$ = 7.07 Hz, 24 H, NCH_2CH_3), 3.13 (m, 16 H, NCH_2CH_3), 4.38 [sept, $^3J_{FH}$ = 6.8 Hz, 2 H, $HC(CF_3)_2$], 9.2 (broad s, 2 H, P−CH_2−P). − ^{13}C NMR (22.5 MHz, $CDCl_3$): δ = 10.32 (tt, $^1J_{PC}$ = 206.1 Hz, $^2J_{FC}$ = 24.4 Hz, FP−CH_2−PF), 13.3 (s, 8 C, NCH_2CH_3), 40.3 (d, $^2J_{PC}$ = 4.9 Hz, 8 C, NCH_2CH_3), 68.6 [sept, $^2J_{FC}$ = 32.2 Hz, 2 C, $CH(CF_3)_2$], 122.3 [q, $^1J_{FC}$ = 284.2 Hz, 4 C, $CHCF_3)_2$]. − ^{19}F NMR (84.26 MHz, $CDCl_3$): δ = −76.4 (d, $^3J_{HF}$ = 6.8 Hz, 12 F, CF_3), −72.5 (d, $^1J_{PF}$ = 975.6 Hz, 2 F, FP−CH_2−PF). − ^{31}P NMR (36.2 MHz, $CDCl_3$): δ = 63.1 [symmetrical multiplet, (see Figure 1), $^1J_{FP}$ = 975.6 Hz, $^2J_{PP}$ = 44.0 Hz, $^3J_{FP}$ = 7.8 Hz, 2 P, FP−CH_2−PF].

Methylenebis[bis(dimethylamino)difluorophosphorane] 11a: To a solution of carbodiphosphorane **5a**, prepared from **3a** (1.2 mmol) and HFA (2.88 mmol), in 4 mL of hexane, was added $Et_3N{\cdot}2HF$ (353 mg, 2.5 mmol). After stirring at room temperature for 30 min the reaction solution was separated from the residue formed. Evaporation of the solvent in vacuo gave 390 mg of a crude product which gave **11a** after recrystallisation from hexane. Yield 120 mg (30%). − M.p. 47−48°C. − ^{1}H NMR (200 MHz, $CDCl_3$): δ = 2.28 (t of quint, $^2J_{HP}$ = 23.4 Hz, $^3J_{HF}$ = 15.8 Hz, P−CH_2−P), 2.69 (dt, $^3J_{PH}$ = 10.5 Hz, $^4J_{FH}$ = 2.6 Hz, 24 H, NCH_3). − ^{13}C NMR (22.5 MHz, $CDCl_3$): δ = 39.6 (t of quint, $^1J_{PC}$ = 182.4 Hz, $^2J_{FC}$ = 44.9 Hz, $F_2P-CH_2-PF_2$), 39.9 (dt, $^2J_{PC}$ = 10.7 Hz, $^3J_{FC}$ = 6.8 Hz 8 C, NCH_3). − ^{19}F NMR (84.26 MHz, $CDCl_3$): δ = −31.4 (dt, $^1J_{PF}$ = 720.2 Hz, $^3J_{HF}$ = 15.8 Hz, 4F). − ^{31}P NMR (36.2 MHz, $CDCl_3$): δ = −53.2 (t, $^1J_{FP}$ = 720.2 Hz, 2 P). − $C_9H_{26}F_4N_4P_2$ (328.28): calcd. C 32.93; H 7.98. found C 32.43; H 8.47.

Methylenebis[bis(diethylamino)difluorophosphorane] (11b): To a solution of carbodiphosphorane **5b**, prepared from **3b** (1.2 mmol) and HFA (2.88 mmol), in 4 mL of hexane, was added $Et_3N{\cdot}2HF$ (353 mg, 2.5 mmol). After stirring the mixture at room temperature for 30 min the reaction solution was separated from the residue formed. Evaporation of the solvent in vacuo gave 390 mg of a crude product from which **11b** was extracted with 1 mL of cold hexane at −15°C. Evaporation of the hexane in vacuo gave 11b as a light yellow oil of about 90% purity. Yield 180 mg (33%). Compound **11b** is thermally stable and can be purified by low-pressure distillation (0.03 Torr) at 110−115°C if prepared on a large scale. − ^{1}H NMR (200 MHz, $CDCl_3$): δ = 1.06 (t, $^3J_{HH}$ = 7.02 Hz, 24 H, NCH_2CH_3), 2.31 (m, broad, 2 H, P−CH_2−P), 2.97 (m, 16 H, NCH_2CH_3) − ^{13}C NMR (22.5 MHz, $CDCl_3$): δ = 15.73 (s, 8 C, NCH_2CH_3), 44.0 (m, $^2J_{PC}$ = 8.7 Hz, $^3J_{FC}$ = 7.8 Hz, 8 C, NCH_2CH_3), 45.2 (t of quint, $^1J_{PC}$ = 182.4 Hz, $^2J_{FC}$ = 43.9 Hz, $F_2P-CH_2-PF_2$) − ^{19}F NMR (84.26 MHz, $CDCl_3$): δ = −38.0 (dt, $^1J_{PF}$ = 728.1 Hz, $^3J_{HF}$ = 14.0 Hz, 4 F) − ^{31}P NMR (36.2 MHz, $CDCl_3$): δ = −52.2 (t, $^1J_{FP}$ = 728.1 Hz, 2 P).

Methylenebis[bis(diethylamino)phosphane oxide] (12b): A solution of **11b** (115 mg, 0.261 mmol) in 0.5 mL of dichloromethane was added to a solution of sodium carbonate (55 mg, 0.52 mmol) in 0.5 mL of water and the reaction mixture stirred at room temperature for 0.5 h. The organic layer was then separated and volatiles evaporated in vacuo. The residue was extracted with 2 mL of hexane. Evaporation of hexane in vacuo gave 54 mg of pure **12b** as a light yellow oil (yield 52%). Compound **12b** is thermally stable and can be purified by low-pressure distillation (0.03 Torr) at 130−135°C if prepared on a large scale. − ^{1}H NMR (200 MHz, $CDCl_3$): δ = 1.10 (t, $^3J_{HH}$ = 7.07 Hz, 24 H, NCH_2CH_3), 2.24 (t, $^3J_{PH}$ = 16.7 Hz, 2 H, P−CH_2−P), 3.08 (dq, $^3J_{PH}$ = 10.7 Hz, $^3J_{HH}$ = 7.07 Hz, 16 H, NCH_2CH_3) − ^{13}C NMR (22.5 MHz, $CDCl_3$): δ = 14.13 (s, 8 C, NCH_2CH_3), 24.75 (t, J_{PC} = 105.3 Hz, P−C−P), 38.88 (m, 8 C, NCH_2CH_3) − ^{31}P NMR (36.2 MHz, $CDCl_3$): δ = 26.7 (s, 2 P). − MS: M_{calc} = 396.5; M_{exp}(EI) = 396; $M_{exp.}$(CI pos.) = 397.

Dichloro Derivative 13: To a solution of **14** (255 mg, 0.304 mmol) in 4 mL of THF at −20°C was added one molar equivalent of the carbodiphosphorane **5b** in hexane. A ^{31}P-NMR spectrum of the reaction mixture showed only one signal at 59.9 ppm. The mixture was allowed to react at this temperature for 15 min. The fine colourless crystals of **13** formed during this time were separated, washed with hexane and dried in vacuo. Yield 391 mg (84%). The product can be recrystallized from dichloromethane-ether. M.p. 160−162°C. − ^{1}H NMR (200 MHz, $CDCl_3$): δ = 1.18 (t, $^3J_{HH}$ = 7.08 Hz, 24 H, NCH_2CH_3), 3.17 (dq, $^3J_{PH}$ = 11.7, $^3J_{HH}$ = 7.08 Hz, 16 H, NCH_2CH_3), 6.71 [m, 2 H, $CH(CF_3)_2$]. − ^{13}C NMR (22.5 MHz, $CDCl_3$): δ = 6.96 (t, $^1J_{PC}$ = 207.73 Hz, P−CCl_2−P), 13.81 (s, 8 C, NCH_2CH_3), 40.72 (s, 8 C, NCH_2CH_3), 70.24 [sept, $^2J_{FC}$ = 33.2 Hz, 2 C $CH(CF_3)_2$], 120.67 [q, $^1J_{FC}$ = 284.78 Hz, 4 C, $CH(CF_3)_2$]. − ^{19}F NMR (84.26 MHz, $CDCl_3$): δ = −72.8 [d, $^3J_{HF}$ = 5.9 Hz, 12 F, $CH(CF_3)_2$]. − ^{31}P NMR (36.2 MHz, $CDCl_3$): δ = 59.9 (s, 2 P). − $C_{23}H_{42}Cl_2F_{12}N_4O_2P_2$ (767.46): calcd. C 36.00, H 5.52; found C 36.68, H 6.17.

Tetrachloro Derivative 14: To a stirred solution of the carbodiphosphorane **5b**, prepared from **3b** (0.42 mmol) and HFA (1.01 mmol), in 1 mL hexane, chlorine (0.84 mmol, as a solution in CCl_4) was added at room temperature. The precipitated yellow oil (257 mg) was separated and recrystallized from dichloromethane-ether. (NB: If the ^{31}P-NMR spectrum of the oil shows a second signal of the intermediate dichloride at 59.9 ppm, more chlorine solution should be added). Yield 138 mg (38%), colourless crystalline product. M.p. 109−113°C. − ^{1}H NMR (200 MHz, $CDCl_3$): δ = 1.19 (t, $^3J_{HH}$ = 6.82 Hz, 24 H, NCH_2CH_3), 3.19 (dq, $^3J_{PH}$ = 11.7, $^3J_{HH}$ = 6.82 Hz, 16 H, NCH_2CH_3), 5.80 [m, 2 H, $CH(CF_3)_2$]. − ^{13}C NMR (22.5 MHz, $CDCl_3$): δ = 13.05 (s, 8 C, NCH_2CH_3), 30.26 (t, $^1J_{PC}$ = 229.2 Hz, P−CCl_2−P), 40.66 (s, 8 C, NCH_2CH_3), 71.12 [sept, $^2J_{FC}$ = 35.1 Hz, 2 C, $CH(CF_3)_2$], 119.91 [q, $^1J_{FC}$ = 285.7 Hz, 4 C, $CH(CF_3)_2$]. − ^{19}F NMR (84.26 MHz, $CDCl_3$): δ = −71.85 [d, $^3J_{HF}$ = 5.9 Hz, 12 F, $CH(CF_3)_2$]. − ^{31}P NMR (36.2 MHz, $CDCl_3$): δ = 55.0 (s, 2 P). − $C_{23}H_{42}Cl_4F_{12}N_4O_2P_2$ (838.38): calcd. C 32.95, H 5.05; found C 33.83, H 5.72.

Phosphonium Tetrafluoroborate 16: To a solution of **13** (300 mg, 0.391 mmol) in 3 mL of $CHCl_3$ was added $AgBF_4$ (90 mg, 0.469 mmol). After refluxing for 3 h the hot reaction mixture was filtered and kept at room temperature for 24 h. The colourless crystals of **16** formed during this time were separated, washed with hexane and dried in vacuo. Yield 69 mg (21%). − M.p. 192−193°C. − ^{1}H NMR (200 MHz, $CDCl_3$): δ = 1.19 (t, $^3J_{HH}$ = 7.08 Hz, 24 H, NCH_2CH_3), 3.18 (dq, $^3J_{PH}$ = 11.7, $^3J_{HH}$ = 7.08 Hz, 16 H, NCH_2CH_3), 5.30 [m, 2 H, $CH(CF_3)_2$]. − ^{19}F NMR (84.26 MHz, $CDCl_3$): δ = −72.9 [d, $^3J_{HF}$ = 5.86 Hz, 12 F, $CH(CF_3)_2$], −151.3 (s, BF_4). − ^{31}P NMR (36.2 MHz, $CDCl_3$): δ = 58.4 (s, 2 P). − $C_{23}H_{43}BF_{16}N_4O_2P_2$ (784.35): calcd. C 35.22, H 5.53; found C 36.82; H 5.63.

Bicyclic Phosphonium Salt 19: To a solution of **17** (300 mg, 0.494 mmol) in 3 mL of CH_2Cl_2, $AgBF_4$ (385 mg, 1.98 mmol) was added and the reaction mixture stirred at room temperature for 48 h. The liquid phase of the reaction mixture was separated and ether was added until it became turbid. The precipitate formed during 24 h at room temperature was separated and dissolved in 1.5 mL of CH_2Cl_2. This solution was washed with 1 mL of water and then ether was added until it became turbid. The crystalline product formed over 24 h at room temperature was separated and dried in vacuo (0.03 Torr). Yield 85 mg (47%). − M.p. 195−197°C. − ^{1}H NMR (200 MHz, $CDCl_3$): δ = 5.22 (d, $^2J_{PH}$ = 5.9 Hz, 2 H, CH_2), 7.76 (m, 14 H, Ar). − ^{19}F NMR (84.26 MHz, $CDCl_3$): δ = −152.4 (s, BF_4). − ^{31}P NMR (36.2 MHz, $CDCl_3$): δ = 22.95 (s). − $C_{19}H_{16}BF_4P$ (362.11): calcd. C 63.02, H 4.45; found C 59.00, H 4.76. Mass spectrum: $M_{calc.}$ = 362.11; $M(cation^+)_{calc.}$ = 275.3; $M(cation^+)_{exp.}$(EI) = 277.

X-ray Crystal Structure Determination of Compound 16: Crystal data: $C_{23}H_{43}BF_{16}N_4O_2P_2$, M_r = 784.36, d = 1.484 Mg/m^3; μ = 0.24 mm^{-1}, orthorhombic, space group *Pbcn*; a = 9.74(4), b = 317.53(7), c = 20.53(8) Å; V = 350(2) Å^3; Z = 4, rhombic colourless crystal 0.8 × 0.7 × 0.6 mm. Data collection and reduction: Data were collected to $2\Theta_{max}$ = 48.1° with a STOE Image plate system using monochromated (graphite monochromator) Mo-K_α

radiation. 17227 reflections were collected (hemisphere), of which 2717 were independent (R_{int} = 0.0700). The structure was solved by direct methods and subjected to full-matrix least-squares refinement based on F^2 with SHELXTL (Version 5.0). R_1 = 4.06%, wR_2 = 9.57% (based on F^2) for 247 parameters and 1570 reflections with $I > 2\sigma(I)$. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were refined using the riding model. The fluorine atoms of the BF_4^- anion were split, resulting in positions having reasonable occupancy factors and B−F bond lengths and F−B−F angles. Crystallographic data (excluding structure factors) have been deposited at the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-112955. Copies of the data can be obtained, free of charge, on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK, (Fax: + 44-1223/336033 or E-mail: deposit@ccdc.cam.ac.uk).

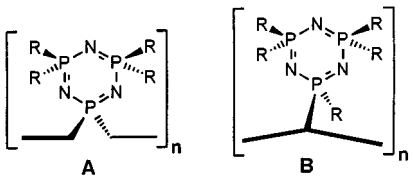
Syntheses of Chiral Cyclotriphosphazenes and Their Use in Cyclolinear Polymers

Isabelle Dez,[a] Joëlle Levalois-Mitjaville,[b] Hansjörg Grützmacher,*[a] Volker Gramlich,[c] and Roger de Jaeger[b]



Keywords: Phosphazenes / Polymers / Chirality / Urethanes / TGA / Thermochemistry / Asymmetric synthesis

The reaction of hexachlorocyclotriphosphazene with two equivalents of the chelating diols 2,2′-dioxybiphenyl and 2′,2′′-dioxy-1′,1′′-bi-2-naphthyl was investigated. Although a mixture of different stereoisomers may be expected, only the formation of the *meso*-compounds [(*R,S*)-$(O,O)_2Cl_2P_3N_3$] is found (O,O stands for the diolate). Interestingly, when the remaining PCl_2 group undergoes reaction with hard nucleophiles like 4-methoxy phenolate, a change of configuration at one phosphorus center is observed and racemic mixtures of chiral [(*R,R*)-$(O,O)_2(RO)_2P_3N_3$] and [(*S,S*)-$(O,O)_2(RO)_2P_3N_3$] phosphazenes are observed. Enantiomerically pure cyclotriphosphazenes were obtaines from either the (*R*)- or (*S*)-form of 2′,2′′-dioxy-1′,1′′-bi-2-naphthyl. Soft nucleophiles like amines, however, do not affect the configuration at the phosphorus centers and allow the synthesis of *meso*-[(*R,S*)-$(O,O)_2(R^1RN)_2P_3N_3$] compounds. the bifunctional cyclotriphosphazenes [$(O,O)_2$(4-OH–$C_4H_4O)_2P_3N_3$] and [(*R,S*)-$(O,O)_2(H_2N)_2P_3N_3$] were used in polyaddition reactions with hexymethylene di(isocyanate) to give cyclolinea polymers of different stereochemical compositions corresponding to the stereochemistry of the phosphazene precursor (i.e. either a racemic mixture of homochiral polymer strands, enantiomerically pure polymers, or the *meso*-form of polymers was obtained). The properties of these polymers are discussed and a mechanism for the change of stereochemistry is proposed.

Introduction

Polyurethanes are generally characterized by poor thermal stability due to the thermally labile urethane group. Their thermal decomposition starts in the region of 150−200°C. Several attempts to increase the thermal stability of polyurethanes by introducing thermally stable groups have been reported.[1−2] Phosphazenes are well-known to impart thermal stability and flame-retardant characteristics to polymer systems[3−6] and cyclomatrix phosphazene polymers containing cyclotriphosphazene rings are known for their excellent fire resistance.[7−12] The modification of different polymers such as polyesters, polyimides, etc. by phosphazenes has been reported previously.[10][11] These polymers may be divided into two groups: in cyclolinear polymers of type **A** the phosphorus centers of the cyclophosphazene moieties are incorporated into the polymer backbone, while in polymers of type **B** the phosphazene rings are attached as pendant groups on the backbone (Scheme 1).

Polymers of types **A** and **B** have commonly been prepared by polycondensation of chloro-substituted cyclotriphosphazenes, $Cl_{6-x}R_xP_3N_3$, with bifunctional substrates. However, these polymerizations are complicated by multiple displacements of chlorine atoms and generally lead to random mixtures of polymers, incorporating both geminally and vicinally substituted phosphazenes.[5,11,13−15] In this respect, the synthesis of spirocyclic cyclotriphosphazenes, $(O,O)Cl_4P_3N_3$ or $(O,O)_2Cl_2P_3N_3$, from sterically congested diols HO,OH (where O,O represents a chelating diol) and $Cl_6P_3N_3$ is interesting, since their preparation permits the selective synthesis of phosphazenes with one or two PCl_2 units.[8,16,17] These monomers should prove useful for the preparation of well-defined cyclolinear polymers of type **A**. Indeed, Kumar and Gupta[9] have reported the synthesis of cyclolinear polyphosphazene polyimides starting from a bis(amino)-bis(spiro)-substituted cyclotriphosphazene $(H_2N)_2(O,O)_2P_3N_3$. Recently, we described the synthesis of new cyclolinear phosphazene polyurethanes from diisocyanates and a bis(spiro)cyclotriphosphazene containing a geminal $P(O-C_6H_4-OH)_2$ unit.[8]

Scheme 1. Depiction of cyclolinear (**A**) and pendant (**B**) phosphazene polymers

The diols 2,2′-dioxybiphenyl and 2′,2′′-dioxy-1′,1′′-bis(2-naphthyl) (abbreviated throughout this paper as biphenoxy and binaphthoxy, respectively) have previously been used for the synthesis of spirocyclic phosphazenes.[8−9,16−19] Tris(2,2′-dioxybiphenylyl)cyclotriphos-

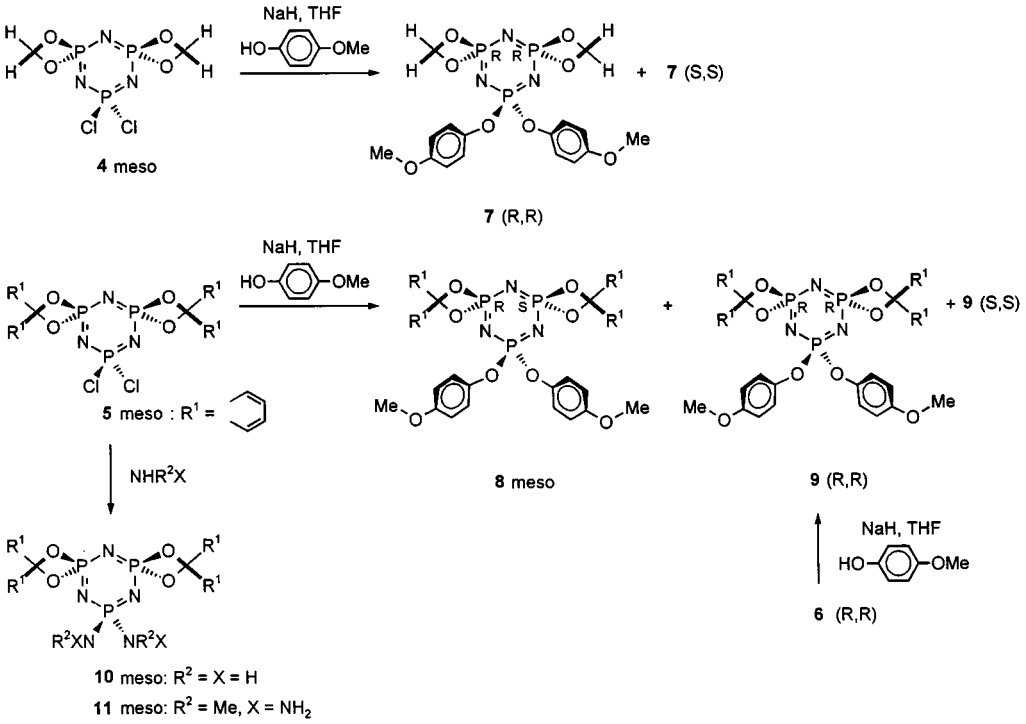
phazene[18] is stable up to at least 350°C and does not undergo polymerization by thermal ring-opening. Hence, increased thermal stability may be expected for polymers incorporating these motifs. Furthermore, binaphthoxy is commercially available in the form of two atropisomers, which do not interconvert at ambient temperature. This offers the possibility of achieving a simple synthesis of enantiomerically pure spirocyclic phosphazenes and hence of chiral polymers. The latter may have interesting properties as supports for catalysts. In this context, it is noteworthy that although the enantiomers of the sterically less hindered biphenoxy rapidly interconvert at ambient temperature, chiral (*R*) or (*S*)-configured phosphorus centers will be formed upon ring-closure by reaction with hexachlorocyclotriphosphazene. In particular, different diastereomers may be formed when racemic mixtures of diols are used and more than one O,O unit is bonded to an oligophosphazene. Thus, cyclotriphosphazenes made up of all (*R*)- or all (*S*)-configured phosphorus centers and/or having different (*R*)- or (*S*)-configured phosphorus centers within one P_3N_3 ring may be anticipated. Remarkably, although multiply-substituted cyclophosphazenes bearing biphenoxy or binaphthoxy groups are known, no particular attention has hitherto been focused on their stereochemistry. We have therefore investigated the synthesis of bis(spirocyclic) phosphazenes of the type $(O,O)_2Cl_2P_3N_3$ in more detail and report here on the somewhat unexpected results obtained. Furthermore, we also describe the incorporation of these phosphazenes into polyurethanes, allowing the synthesis of chiral polymers with improved thermal stabilities.



Results

Synthesis of Bis(spirocyclic) Phosphazenes

Starting from hexachlorocyclotriphosphazene **1** and two equivalents of biphenolate **2**, the bis(spirocyclic) cyclotriphosphazene **4** was obtained as described previously (Scheme 2).[8] Since **2** exists in the form of rapidly interconverting (*R*)- and (*S*)-isomers, the formation of three stereoisomers might have been expected, namely a pair of (*R*,*R*)- or (*S*,*S*)-configured enantiomers and the diastereotopic *meso* form. These diastereoisomers may be distinguished by ^{31}P-NMR spectrometry. However, only one diastereoisomer was formed, as evidenced by the observation of a single set of resonances of an AB_2 spin system in the ^{31}P-NMR spectrum of the crude reaction mixture. X-ray analysis (vide infra) showed that this isomer was, in fact, the *meso* diastereomer, [(*R*,*S*)-$(O,O)_2Cl_2P_3N_3$], containing one (*R*)- and one (*S*)-configured phosphorus center.

Scheme 2. Synthesis of bis(spirocyclic) phosphazenes *meso*-**4**, *meso*-**5**, **6**(*S,S*), and **6**(*R,R*)

Scheme 3. Synthesis of bis(spirocyclic) phosphazenes **7**(*R,R*), **7**(*S,S*), *meso*-**8**, **9**(*R,R*), *meso*-**10**, and *meso*-**11**

In a subsequent experiment, **1** was reacted with a racemic mixture of sodium binaphtholate **3**, consisting of one equivalent of **3**(*S*) and one equivalent of **3**(*R*), which do not interconvert at room temperature. Again only one of the possible stereoisomers of **5** was obtained. By subsequent chemical transformation (vide infra), it was unequivocally shown that here too only the *meso* isomer **5** had been formed. When **1** was reacted with two equivalents of either enantiomerically pure **3**(*S*) or **3**(*R*), the respective chiral cyclotriphosphazenes **6**(*S,S*) or **6**(*R,R*) were obtained. The optical rotation angle α of **6**(*R,R*) was determined as $[\alpha]^{25} = -103°$, which is considerably larger than the value found for unbonded binaphthol ($[\alpha]^{25} = -33°$).

The nonchiral bis(biphenoxy)-substituted cyclotriphosphazene *meso*-**4** was treated with two equivalents of sodium 4-methoxyphenolate in THF at room temperature (Scheme 3) and the reaction was followed by ^{31}P-NMR spectrometry. The resonance of the PCl_2 unit in *meso*-**4** (δ = 30.4) disappeared, while a multiplet at δ = 11.2 was observed constituting the A part of a new AB_2 spin system. After 3 h, quantitative conversion into **7** had been achieved.

Surprisingly, in the ^{1}H- and ^{13}C-NMR spectra of **7**, only one signal for the CH_3 group of the methoxy substituents was observed. If we assume that the (*R,S*)-configuration at the phosphorus centers of the starting material *meso*-**4** is retained in the course of the substitution reaction, then the phenolate substituents are placed *within* the mirror plane and hence cannot be interconverted by this symmetry operation. Therefore, the methyl groups of the 4-methoxy substituents become diastereotopic and should give rise to two resonance signals. On the other hand, if the configuration at one phosphorus center is changed under the reaction conditions from (*R*) to (*S*) − or vice versa − chiral cyclotriphosphazenes **7**(*R,R*) or **7**(*S,S*) with (*R,R*)- and (*S,S*)-configured phosphorus centers will be obtained. In these, the methyl groups are related by a C_2 axis of symmetry and one resonance signal is to be expected. Indeed, X-ray analysis revealed that the configuration at one phosphorus center had changed and that the product corresponded to a racemic mixture of **7**(*R,R*) and **7**(*S,S*). Both enantiomers are present in the unit cell (space group $P\bar{1}$). Stimulated by this finding, we next re-investigated the synthesis of tris(biphenoxy)cyclotriphosphazene[18] by reacting *meso*-**4** with one further equivalent of **2**. Indeed, the sparingly soluble product showed only one ^{31}P-NMR resonance at δ = 22.9 in DMF solution. Evidently, a change of configuration at the phosphorus centers also occurred, leading to a racemic mixture of chiral cyclotriphosphazenes having all (*R,R,R*)- or (*S,S,*S)-configured phosphorus centers.

When the binaphthoxy-substituted compound *meso*-**5** was reacted with 4-methoxyphenolate, a mixture of the stereoisomers *meso*-**8**, **9**(*R,R*), and **9**(*S,S*) was obtained, *meso*-**8** being the major product {ratio *meso*-**8**/[**9**(*R,R*) + **9**(*S,S*)] = 70:30}. As expected, in the ^{1}H-NMR spectrum, the *meso* isomer shows two signals for the magnetically inequivalent methoxy substituents (δ = 3.80 and 3.95), while only one signal (δ = 3.87) is seen for the enantiomers **9**(*R,R*) and **9**(*S,S*). The latter was obtained in enantiomerically pure form by reacting **6**(*R,R*) with 4-methoxyphenolate, which led exclusively to **9**(*R,R*). This cyclotriphosphazene was characterized by X-ray structure analysis (vide infra). It is noteworthy that an equimolar mixture of **6**(*R,R*) and **6**(*S,S*) under identical reaction conditions (THF, room temp., 3 h)

		P(1)−N(16)−P(3)	120.8(4)
		P(1)−N(51)−P(2)	120.9(4)
		P(2)−N(27)−P(3)	123.8(4)

led exclusively to a mixture of **9**(*R*,*R*) and **9**(*S*,*S*) and no *meso*-**8** was observed.

Finally, we investigated the reactions of *meso*-**5** with aqueous ammonia[20] and methylhydrazine[21] in THF solution. Under mild reaction conditions, the replacement of both chlorine centers was observed and the products *meso*-**10** and *meso*-**11** were obtained quantitatively. In *meso*-**11**, the more basic methyl-substituted nitrogen center is bonded to the phosphorus center, as was observed previously.[22] Again, the magnetically inequivalent methyl groups in *meso*-**11** give rise to separate signals (δ = 3.11 and 2.86), proving that the configuration at the phosphorus centers is retained. The presence of the amino groups was also confirmed by the IR spectrum, which featured two bands at $\tilde{\nu}$ = 3340 and 3460 cm^{-1}.

X-ray Structure Analyses

In order to unequivocally determine the stereochemistries of compounds *meso*-**4**, **7**(*R*,*R*), and **9**(*R*,*R*), X-ray crystal structure analyses were performed. Details of the data collections are given in Table 4.

The result obtained for *meso*-**4** is shown in Figure 1 and selected bond lengths and angles are listed in Table 1.

In the crystal, two molecules of *meso*-**4** are aligned in a coplanar fashion (the interplanar angle between the two P_3N_3 planes amounts to 8.3°) by intermolecular π-stacking of two arene moieties of the biphenoxy substituents. The P_3N_3 rings are almost planar [deviations (Å) from best planes: P1(−0.003)−P2(0.005)−P3(−0.004)−N16(0.007)−N27(0.002)−N51(−0.003) and P4(−0.029)−P5(−0.004)−P6(−0.052)−N23(0.005)−N31(0.054)−N41(0.026)] and slightly elongated along the axes running through P1−N27 and P5−N31, respectively. Nevertheless, all P−N and P−O distances, P−N−P (121.8°) and N−P−N (118.0°) angles lie within the expected ranges.[23] The Cl−P−Cl angle (99.4°) is slightly smaller than the O−P−O angles (103.7°). There are no unusually short repulsive intramolecular interactions. The (*R*)-(P2,P6) and (*S*)-(P3,P4) configurations of the two biphenoxy-substituted phosphorus centers within one molecule can clearly

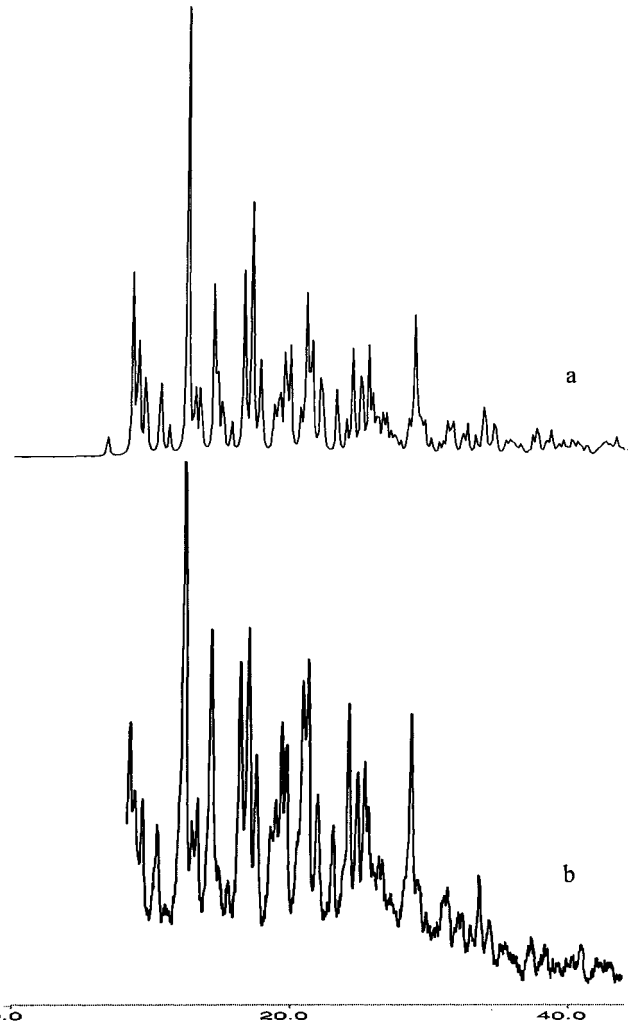

Figure 2. X-ray powder diffraction pattern of *meso*-**4**; a: calculated spectrum; b: experimental spectrum

be seen. In order to verify that the conformer found in the crystal corresponds to that observed in the bulk, we performed a powder diffraction study of microcrystalline material. In Figure 2, the experimental diffraction pattern (bottom) is compared with that calculated using the parameters derived from the single crystal used for the structure determination.

As can be seen, there is an almost perfect fit between the two patterns, which confirms that all synthesized material is of the *meso* form of **4**.

A plot of the molecular structure of the (*R*,*R*)-isomer of **7** is shown in Figure 3. Selected bond lengths and angles are given in Table 2.

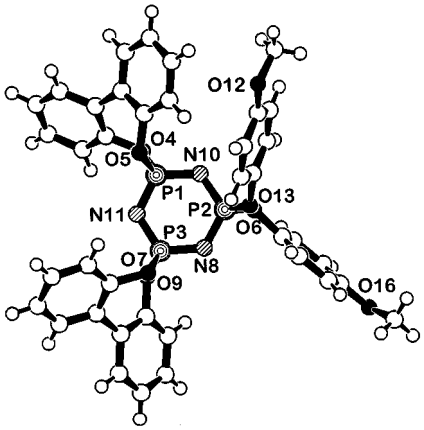

Figure 3. SCHAKAL view of **7**(*R*,*R*)

		P(1)−N(11)−P(3)	121.7(2)
		P(1)−N(10)−P(2)	121.8(2)
		P(2)−N(8)−P(3)	122.0(2)

The other enantiomer is also found in the unit cell (space group $P\bar{1}$), but is not shown. The P_3N_3 ring is almost planar [deviations (Å) from the best plane: P1(−0.053)−P2(−0.025)−P3(0.006)−N8(−0.005)−N10(0.055)−N11(0.022)] and all P−N distances are almost equal (largest variation 0.017 Å), indicating that no unusual steric interactions are involved. An idealized C_2 axis of symmetry runs through P2−N11 and interconverts the methyl groups bonded to O12 and O16.

The chiral cyclotriphosphazene **9**(*R*,*R*) crystallizes in the axial chiral space group $P_2(1)$. The molecule is shown in such a way that the idealized C_2 axis running through P1−N3 lies horizontal in the plane of the paper (Figure 4); selected bond lengths and angles are listed in Table 3.

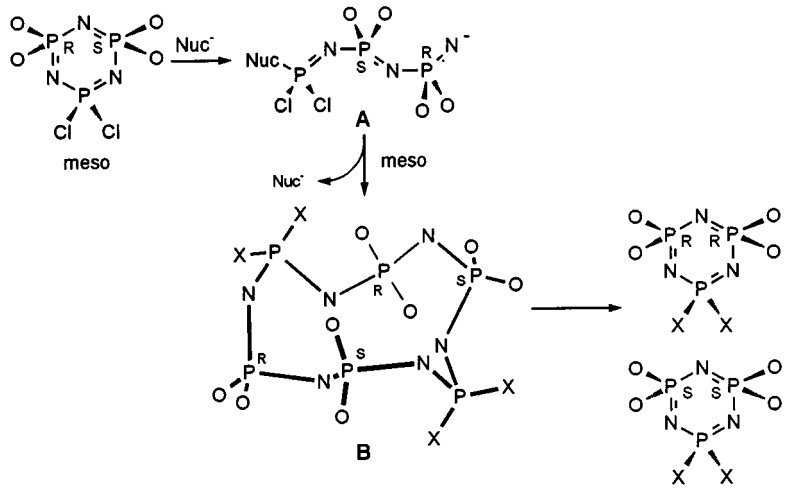
		P(2)−N(3)−P(3)	122.6(4)

Among the phosphazenes investigated in this work, **9**(*R*,*R*) is the most sterically encumbered. This is reflected in a larger variation of the bond lengths (P−N 1.539−1.594 Å; P−O 1.564−1.620 Å) and angles (P−N−P 116.0−118.7°; N−P−N 120.5−124.3°), and in a slight puckering of the P_3N_3 ring [deviations (Å) from the best plane: P1(0.022)−P2(0.024)−P3(−0.02)−N2(−0.38)−N1(0.006)−N3(0.005)]. The internal O5−P2−O6 (101.8°) and O7−P−O8 (102.7°) angles are slightly smaller than the rather open O1−P1−O2 (104.6°). Generally, however, no severe steric interactions leading to unusual distortions are observed.



Discussion

Clearly, the *meso* forms of the 1,1-P-dichloro-substituted cyclotriphosphazenes, *meso*-**4** and *meso*-**5**, respectively, seem to be favored when racemic mixtures of the diols **2** and **3** are used. It is quite remarkable that these are formed exclusively and we cannot offer a straightforward explanation as to why the chiral (*R*,*R*) or (*S*,*S*) forms are not found. On the other hand, an anionic nucleophile converts the *meso* forms either quantitatively, as in the case of *meso*-**4**, or at least partially, as is observed for *meso*-**5**, into the axial chiral isomers. This is even more surprising because the sterically more demanding 4-methoxyphenolate groups should give rise to increased steric interactions, which, at first glance, may be smaller in the *meso* isomers. However, just the opposite may be true and attractive interactions, for example between aromatic hydrogen centers and a π-system of a neighboring arene moiety, may determine the relative stabilities. Such an interaction (< 2.8 Å) is seen in the molecular structure of **7**(*R*,*R*) (Figure 3) between one hydrogen center of a biphenoxy group and the π-cloud of a 4-methoxyphenolate residue. In any case, a plausible mechanism for the change of the configuration at the phosphorus centers within one P_3N_3 unit must be found. While one may speculate about pentacoordinated phosphorus centers undergoing Berry rotation when the biphenoxy-substituted cyclotriphosphazene *meso*-**4** is reacted with an anionic nucleophile, such a possibility is highly unlikely for *meso*-**5**. Instead, a complete intermolecular exchange of (*R*)- or (*S*)-configured (O,O)P units must take place and we propose the mechanism outlined in Scheme 4 to explain this observation.

Nucleophilic attack on the electrophilic PCl_2 group leads to ring-opening and formation of intermediate **A**. This may act as a further nucleophile, attacking a second equivalent of *meso*-configured 1,1-dichlorocyclotriphosphazene. A dimer **B** containing a twelve-membered P_6N_6 ring could thus be formed, although higher oligomers cannot be ruled out. The structures of cyclophosphazenes $(R_2PN)_n$ have been comprehensively determined for $n = 3-12$.[23] It is found that the P−N−P angles in particular widen with ring size [e.g. 133° in $(Me_2PN)_6$]. This may increase the steric interactions between substituents on neighboring phosphorus centers and may be particularly unfavorable for (*R*,*S*)-configured pairs (see Figure 1). Finally, the larger ring **B** collapses into the thermodynamically more stable six-membered chiral phosphazenes. While this mechanism is admittedly highly speculative, it would explain why no *meso*-**8** is obtained when **6**(*R*,*R*) is reacted with 4-methoxyphenolate. It is even conceivable that the substitution of the chlorines by phenolate residues occurs at the stage of the larger-ring phosphazenes. It is noteworthy that no further *meso*-**8** is converted into **9**(*R*,*R*) or **9**(*S*,*S*) when the reaction is carried out for an extended period in the presence of excess phenolate after complete conversion has been already achieved. Raising the temperature to about 100°C led to nonspecific degradation of the reaction products. Thus, it seems that a PCl_2 group is necessary in order to observe the stereochemical phenomena. Furthermore, only hard nucleophiles lead to exchange of the (O,O)P groups, since amine bases do not alter the stereochemistry of the starting materials (cf. the synthesis of *meso*-**10** and *meso*-**11** from *meso*-**5**). Finally, we note that the interconversion of rings of different sizes has been described for anionic cyclosilazanes[24] and it is well-known that cyclosiloxanes, which are isoelectronic with phosphazenes, easily undergo a ring-opening polymerization (ROP) in the presence of base.[25] To the best of our knowledge, equilibria between rings of different sizes, as is

Scheme 4. Syntheses of cyclolinear polymers

Scheme 5. Proposed mechanism for exchange of (O,O)P groups

indirectly evidenced here by an exchange of stereochemically different (O,O)P groups, have not previously been described in cyclophosphazene chemistry.

Syntheses of Polymers

In order to obtain cyclolinear polymers, we converted the racemic mixture of 4-methoxy-substituted phosphazenes **7**(*R*,*R*) and **7**(*S*,*S*) as well as enantiomerically pure **9**(*R*,*R*) into the hydroxylated compounds **12** and **13** by reacting them with BBr_3 and then hydrolyzing the intermediate boron compounds[26] (Scheme 5).

These reactions proceeded with complete retention of the stereochemistry at the phosphorus centers. For instance, using the mixture of isomers *meso*-**8**, **9**(*R*,*R*) and **9**(*S*,*S*) obtained according to Scheme 3, two ^{1}H-NMR signals were observed for the OH groups of the *meso* isomer (δ = 4.05 and 4.11) and one (δ = 4.09) for the enantiomers, in the same ratio as the integrals of the methoxy resonances of the starting material. The enantiomerically pure compound **13**(*R*,*R*) exhibited an optical rotation angle of $[\alpha]^{25} = -119°$. The presence of hydroxyl groups in **12**(*R*,*R*)/**12**(*S*,*S*) and **13**(*R*,*R*) was evident from the IR spectra, which featured a broad band located near 3400 cm^{-1} corresponding to the OH stretching vibration. Furthermore, the complete conversion of **7** and **9** into **12** and **13**, respectively, was evident from the ^{1}H- and ^{13}C-NMR spectra owing to the disappearance of the signals attributable to the methoxy functions.

Polyurethanes incorporating cyclotriphosphazene units were prepared by direct polyaddition of either the bifunctional hydroxylated racemic mixture of **12**(*R*,*R*)/**12**(*S*,*S*) or enantiomerically pure **13**(*R*,*R*) or the bis(amino)-substituted *meso* compound *meso*-**10** with hexamethylenediisocyanate (HDI). The reactions were performed in DMF at 80°C and the polymers **14**(*R*,*R*)/**14**(*S*,*S*), **15**(*R*,*R*), and *meso*-**16** were purified by precipitation and repeated extractions with methanol.[27] The ^{31}P-NMR spectra in [D_6]DMSO solution were very similar to the spectra of the monomers.

The ^{1}H-NMR and IR spectra confirmed the formation of polyurethane structures; the IR spectra of **14**(*R*,*R*)/**14**(*S*,*S*), **15**(*R*,*R*), and *meso*-**16** are given in Figure 5.

The spectra show the characteristic absorptions of the cyclotriphosphazene ring and aromatic groups at around $\tilde{\nu}$ = 1250, 1170, and 960 cm^{-1}, attributable to P=N, (P)−C−O and P−O−(C) stretching vibrations, respectively.[28] These results confirmed that the cyclotriphosphazene units remained unaffected when incorporated into the polymers. The urethane groups present in **14**(*R*,*R*)/**14**(*S*,*S*), **15**(*R*,*R*), and *meso*-**16** are characterized by NH stretching vibrations at $\tilde{\nu} \approx 3350$ cm^{-1} and C=O stretching vibrations at $\tilde{\nu} \approx 1700$ cm^{-1}. In the ^{1}H-NMR spectra of the polymers, a resonance at $\delta \approx 9.6$ can be attributed to the NH proton of the urethane linkage. The molecular weight of **14**(*R*,*R*)/**14**(*S*,*S*) was estimated by steric exclusion chromatography in THF to be $\overline{M}_w$bar = 17000 with a molecular weight distribution $\overline{M}_w$bar/$\overline{M}_n$bar = 1.7. The molecular weights of **15**(*R*,*R*) and *meso*-**16** could not be determined because of the poor solubilities of these polymers in THF.

In terms of the stereochemistries at the phosphorus centers, the polyurethanes prepared in this work are representatives of three different polymer types. Thus, **14**(*R*,*R*)/**14**(*S*,*S*) consists of a racemic mixture of homochiral polymer chains, **15**(*R*,*R*) is the first example of an enantiomerically pure cyclolinear phosphazene polymer (optical rotation angle $[\alpha]^{25} = -111°$), while *meso*-**16** contains (*R*)- and (*S*)-configured phosphorus centers within one polymer strand. The thermal behavior of these three polymers was investigated by dynamic thermogravimetric analysis (TGA) in air. Typical TGA curves for **14**(*R*,*R*)/**14**(*S*,*S*), **15**(*R*,*R*), and *meso*-**16** are shown in Figure 6.

It can be seen that the incorporation of cyclotriphosphazene moieties increases the thermal stability of all polyurethanes. Note that simple "organic" polyurethanes show thermooxidative decomposition starting at ca. 200°C. For **14**(*R*,*R*)/**14**(*S*,*S*), the temperature corresponding to 10%

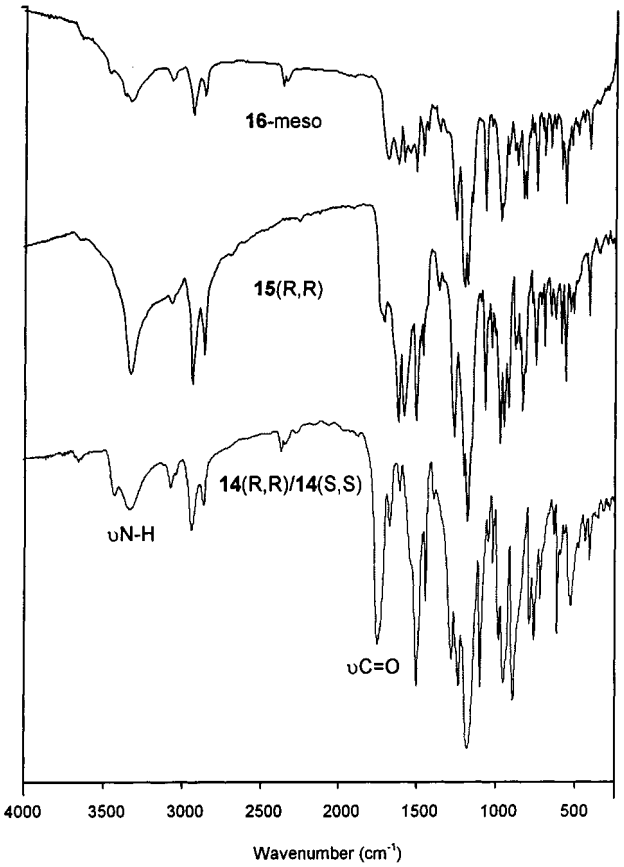


Figure 5. Infrared spectra of polymers **14**(*R*,*R*)/**14**(*S*,*S*), **15**(*R*,*R*), and *meso*-**16**

weight loss (T_{10}) is found to be 325°C. The value of T_{10} is lower for **15**(*R*,*R*) (280°C), but lies in the same range for *meso*-**16** (315°C). At a temperature of 500°C, 72%, 60%, and 70%, respectively, of the original masses of **14**(*R*,*R*)/**14**(*S*,*S*), **15**(*R*,*R*), and *meso*-**16** still remain. This high char yield is characteristic of cyclotriphosphazene-containing polymers[8–10] and accounts for their flame-retardant properties. For comparison, the thermal behavior of a polyurethane synthesized from 1,3-bis(hydroxy)benzene and HDI was investigated. Its T_{10} was found to be low (209°C) and complete decomposition was observed at just 600°C.[3] However, the thermal stability of **15**(*R*,*R*), in which only one stereoisomer of the diol is present, is significantly lower than those of **14**(*R*,*R*)/**14**(*S*,*S*) and *meso*-**16**. In the latter, both atropisomers of the diols are present. As can be deduced from Figure 1, a favorable packing by π-stacking of the arene moieties may be responsible for the enhanced thermal stabilities of these polymers.

Conclusion

Reactions of hexachlorocyclotriphosphazene **1** with two equivalents of the chelating diols 2,2′-dioxybiphenyl, **2**(*S*), **2**(*R*), or 2′,2′′-dioxy-1′,1′′-bis(2-naphthyl), **3**(*S*), **3**(*R*), lead only to the formation of the *meso* compounds [(*R*,*S*)-$(O,O)_2Cl_2P_3N_3$] *meso*-**4** or *meso*-**5**, respectively. Remarkably, when the remaining PCl_2 group is reacted with a hard nucleophile such as 4-methoxyphenolate, either a racemic mixture of chiral [(*R*,*R*)-$(O,O)_2(RO)_2P_3N_3$], **7**(*R*,*R*), and [(*S*,*S*)-$(O,O)_2(RO)_2P_3N_3$], **7**(*S*,*S*), (O,O = 2,2′-dioxybiphenyl) is formed, or at least partial racemization occurs, leading to a mixture of all possible stereoisomers *meso*-**8**, **9**(*R*,*R*) and **9**(*S*,*S*) [O,O = 2′,2′′-dioxy-1′,1′′-bis(2-naphthyl)]. While one may speculate about five-coordinated phosphorus centers undergoing Berry rotation in the case of O,O = biphenoxy, this phenomenon is highly unlikely when O,O = binaphthoxy and does not explain the configurational change at the phosphorus centers. In order to explain the exchange of complete (O,O)P-units within the cycles, we

propose ring-opening and the formation of larger cycles, i.e. cyclohexaphosphazenes, which collapse to reform cyclotriphosphazenes with different stereochemistry. Chiral cyclotriphosphazenes such as **9**(*R*,*R*) and **9**(*S*,*S*) were obtained using either of the enantiomerically pure (*R*)- or (*S*)-forms of 2′,2′′-dioxy-1′,1′′-bis(2-naphthyl) **3** as starting materials. The change of configuration is furthermore related to the presence of a PCl_2 unit in the phosphazene ring, since the stereochemistry of all phenoxy-substituted phosphazenes [$(O,O)_2(RO)_2P_3N_3$] is retained, even when these are reacted with excess phenolate RO^- under harsh conditions. Interestingly, soft nucleophiles such as amines do not affect the configuration at the phosphorus centers and thus allow the synthesis of *meso*-[(*R*,*S*)-$(O,O)_2(R^1RN)_2P_3N_3$] compounds. These observations show that seemingly simple substitution reactions on chloro-substituted phosphazenes are more complex than they might at first appear. The bifunctional cyclotriphosphazenes [(*R*,*R*)-$(O,O)_2$(4-HO−$C_4H_4O)_2P_3N_3$] and/or [(*S*,*S*)-$(O,O)_2$(4-HO−$C_4H_4O)_2P_3N_3$] and [(*R*,*S*)-$(O,O)_2(H_2N)_2P_3N_3$] are suitable monomers for polyaddition reactions with hexamethylenediisocyanate, which furnish cyclolinear polyurethane polymers. Depending on the stereochemistry of the phosphazene precursor, either a racemic mixture of homochiral polymer strands, an enantiomerically pure polymer, or the *meso* form of a polymer was obtained. The latter was found to show the highest thermal stability

Experimental Section

General Methods: ^{31}P-, ^{1}H-, and ^{13}C-NMR spectra were recorded in CD_2Cl_2 and $CDCl_3$ for most compounds, those of *meso*-**10** were recorded in [D_8]THF, while polymers where examined in [D_6]DMSO using Bruker DPX250 and DPX300 NMR spectrometers. Chemical shifts (ppm) are positive in the low-field direction and are quoted relative to external 85% H_3PO_4 (^{31}P) or external TMS (^{1}H, ^{13}C). – Infrared spectra were recorded with a Perkin−Elmer 783 spectrometer. The samples were dispersed in KBr. – Mass spectra were recorded on a Finnigan MAT 8200 spectrometer operating in the EI (70 eV) mode. – Thermogravimetric measurements were performed in air on a Setaram NTB10−8 instrument at a heating rate of 8°C/min. – The optical rotation angles were measured on a Perkin−Elmer 241MC polarimeter [*c* = 1, $CHCl_3$ for **6**(*R*,*R*), **9**(*R*,*R*) and **13**(*R*,*R*); DMF for **15**(*R*,*R*)] using light of the Na D line (λ = 589 nm). – The X-ray powder diffraction pattern of *meso*-**4** was recorded using a Stoe STADIP powder diffractometer equipped with a position-sensitive detector (radiation: Cu-$K_{\alpha1}$).

Tetrahydrofuran (THF), chlorobenzene, dichloromethane, and dimethylformamide (DMF) were obtained from Aldrich. THF, CH_2Cl_2, and DMF were purified by distillation. Sodium hydride, biphenol, binaphthol [(+/−); *R*(+)], sodium hydroxide, 4-methoxyphenol, methylhydrazine, boron tribromide, ammonium hydroxide solution, and 1,6-hexamethylenediisocyanate (HDI) were purchased from Aldrich or Fluka and were used as received. Hexachlorocyclotriphosphazene, $N_3P_3Cl_6$, (Nippon Soda) was

purified by vacuum sublimation. All reactions and manipulations were carried out under inert atmosphere.

Compounds *meso*-**4**, **7**(*RR*)/**7**(*S*,*S*), and **12**(*R*,*R*)/**12**(*S*,*S*) were synthesized according to a procedure reported elsewhere.[8]

Crystallographic Analyses of *meso*-4, 7(*R*,*R*), and 9(*R*,*R*): The data sets for the single-crystal X-ray studies were collected on either a Nonius CAD4 or a fully automated Siemens−Stoe AED2 four-circle diffractometer. All calculations were performed on a Digital Corporation VAX system using the SHELXS-86 and SHELXS-93 program suites.[29][30]

Specific data relating to the crystal structures and refinements are collected in Table 4. The structures were solved by direct methods and refined by full-matrix least-squares on F^2.

The graphical representations of the molecular structures were drawn using the SCHAKAL program.[31]

Synthesis of 2,2-Dichloro-4,4,6,6-bisspiro(2′,2′′-dioxy-1′,1′′-binaphthyl)]cyclotriphosphazene [*meso*-5, 6(*R*,*R*), 6(*S*,*S*)]: A three-necked round-bottomed flask was charged with chlorobenzene (12 mL), water (20 mL), $N_3P_3Cl_6$ (1.13 g, 3.25 mmol), 2,2′-dihydroxy-1,1′-binaphthyl (2.16 g, 6.51 mmol), sodium hydroxide (0.52 g, 13.01 mmol), and TBA (0.10 g, 0.324 mmol). The reaction mixture was stirred rapidly at room temperature for 3 h and then heated at 70°C for a further 3 h. The solvents were then removed under reduced pressure to leave a brown residue, which was washed with chlorobenzene and acetone and dried. A white solid was obtained (2.4 g, 85%); m.p. > 250°C. Spectroscopic data are given in Table 5.

Synthesis of 2,2-Bis(4-methoxyphenyloxy)bisspiro(2′,2′′-dioxy-1′,1′′-binaphthyl)]cyclotriphosphazene [*meso*-8, 9(*R*,*R*), 9(*S*,*S*)]: A solution of 4-methoxyphenol (0.73 g, 5.92 mmol) in THF was added dropwise to a solution of *meso*-**5** [or **6**(*R*,*R*) or **6**(*S*,S)] (2.56 g, 2.96 mmol) in THF containing suspended NaH (0.14 g, 20 mmol). The mixture was stirred at room temperature for 3 h and then the THF was removed under reduced pressure. The residue was redissolved in dichloromethane and the resulting solution was extracted twice with 10% aqueous NaOH, washed with water (three times),

and dried over anhydrous sodium sulfate. After filtration and removal of the solvent under reduced pressure, 2.33 g (83%) of *meso*-**8** [or **9**(*R*,*R*) or **9**(*S*,S)] was obtained; m.p. 199°C. − $C_{54}H_{38}N_3O_8P_3$: calcd. C 67.1, H 4.0, N 4.3; found C 66.8, H 3.8, N 4.3. − Spectroscopic data are given in Table 5.

Synthesis of 2,2-Bis(4-hydroxyphenyloxy)bisspiro(2′,2′′-dioxy-1′,1′′-binaphthyl)]cyclotriphosphazene [13(*R*,*R*)/13(*S*,*S*)]: A solution of 1.07 g (4.26 mmol) of boron tribromide in anhydrous CH_2Cl_2 (10 mL) was added dropwise to a solution of **6**(*R*,*R*) or **6**(*S*,*S*) (2.02 g, 2.13 mmol) in anhydrous CH_2Cl_2 (15 mL). The reaction mixture was stirred at room temperature for 3 h and then poured into water (50 mL). The residue obtained was dissolved in CH_2Cl_2 and the resulting solution was washed with water (three times). The solvent was finally removed under reduced pressure to leave 1.37 g (70%) of **13**(*R*,*R*); m.p. 210°C. − $C_{52}H_{34}N_3O_8P_3$: calcd. C 67.8, H 3.7, N 4.6; found C 67.7, H 3.8, N 4.5. Spectroscopic data are given in Table 5.

Synthesis of 2,2-Bis(amino)-bisspiro(2′,2′′-dioxy-1′,1′′-binaphthyl)]-cyclotriphosphazene (*meso*-10): A solution of 0.605 mL (8.11 mmol) of ammonium hydroxide in THF (10 mL) was added dropwise to a solution of *meso*-**5** (1.57 g, 2.03 mmol) in the same solvent (10 mL). The reaction mixture was stirred at 40°C for 1 h and at room temperature for 2 h and then the THF was removed under reduced pressure. The residue obtained was washed with water (three times) and dried, furnishing 1.16 g (78%) of *meso*-**10**; m.p. >250°C. Spectroscopic data are given in Table 5.

Synthesis of 2,2-Bis(methylhydrazino)bisspiro(2′,2′′-dioxy-1′,1′′-binaphthyl)]cyclotriphosphazene (*meso*-11): To a solution of *meso*-**5** (1.56 g, 2.01 mmol) in THF was added a solution of methylhydrazine (0.43 mL, 8.05 mmol) in THF (4 mL) at 0°C. The resulting mixture was stirred for 2 h at room temperature and then the solvent was evaporated. The residue was taken up in chloroform and the mixture was filtered by passage through Celite. Evaporation of the solvent from the filtrate furnished 1.11 g (70%) of *meso*-**11**. Spectroscopic data are given in Table 5.

Synthesis of Polyurethanes [14(*R*,*R*)/14(*S*,*S*), 15(*R*,*R*), and *meso*-16]: A solution of **12**(*R*,*R*)/**12**(*S*,*S*) or **13**(*R*,*R*) or *meso*-**10** together with HDI (molar ratio, diol or diamine/diisocyanate = 1:1) in DMF was stirred at 80°C for 48 h. The reaction mixture was then poured into cold methanol to precipitate the polymer, which was washed several times with methanol, and finally dried in vacuo at 100°C for 12 h to give a white-yellow solid soluble in DMF and DMSO. − **14**(*R*,*R*)/**14**(*S*,*S*): $C_{44}H_{36}N_5O_{10}P_3$: calcd. C 59.4, H 4.3, N 7.9; found C 58.6, H 4.5, N 8.2. **15**(*R*,*R*): $C_{60}H_{46}N_5O_{10}P_3$: calcd. C 66.1, H 4.2, N 6.4; found C 68.3, H 4.0, N 6.3. *meso*-**16**: $C_{48}H_{40}N_7O_6P_3$: calcd. C 63.8, H 4.4, N 10.8; found C 66.2, H 4.6, N 11.1. Spectroscopic data are given in Table 6.

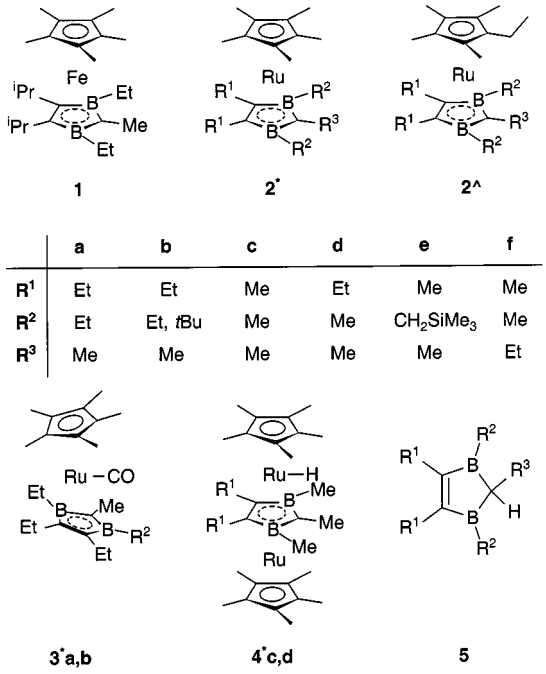
Electron-Poor 2,3-Dihydro-1,3-diborolyl Ruthenium Compounds: Synthesis, Complexation, Oxidative Addition, Capping, and Stacking Reactions

Thomas Müller,[a] Michael Kaschke,[a] Melanie Strauch,[a] Achim Ginsberg,[a] Hans Pritzkow,[a] and Walter Siebert*[a]

Dedicated to Professor Helmut Werner on the occasion of his 65th birthday

Keywords: Boranes / Ruthenium / Sandwich Complexes / Diboroles / Triple-decker



The addition products of lithium alkyls and the pentaalkyl-2,3-dihydro-1,3-diborole derivatives **5a–f** react with $[\{(C_5Me_5)RuCl\}_4]$ and $[\{(C_5Me_4Et)RuCl\}_4]$ to form the violet sandwich compounds **2*c–f** and **2^c**, **f**. These formally 16 VE complexes are in fact electron-poor 18 VE species, because a high-lying combination of σ(B–C) orbitals interacts with the d_{xz} orbital of the Ru atom. Addition of *tert*-butyl isocyanide to **2*a**, or **2*d** leads to the isonitrile complexes **6*a**, and **6*d**, as indicated by the spectroscopic data and X-ray structure analyses. At low temperature the interaction of **2*a**, **c**, or **e** with H_2 yields the classic dihydride complexes **7*a**, **c**, and **e**, respectively, which have been studied by NMR. Oxidative addition of $H_3B{\cdot}THF$ to the ruthenium atom of **2*a** or **c**, followed by a reductive elimination of H_2 and migration of the boranediyl group gives the yellow *closo*-RuC_3B_3 ruthenacarboranes **8*a** and **8*c**, respectively. The reaction of $[(C_2H_4)_2RhCl]_2$ and **2*c** generates the tetranuclear complex **9*c**.

Introduction

Organometallic complexes of the iron triad having less than 18 valence electrons (VE) are of particular interest for catalytic reactions. In the formally 16 VE complexes $[\{(C_5Me_5)Ru(XR)\}_2]$ (X = O, S)[1–3] the Ru atom is coordinatively unsaturated, and the sulfur compounds function as catalysts in the addition of thiols to polar alkynes.[4] Recently, 16 VE $[Ru(C_5Me_5)L_2]^+$ complex cations containing the ligands L_2 = 2,2′-bipyridyl[5a] or a 1,4-diazabutadiene derivative[5b] have been reported.

The formally 16 VE iron complex $[(\eta^5\text{-}C_5Me_5)Fe(\eta^5\text{-}(Ci\text{Pr})_2(BEt)_2CMe)]$ (**1**) has unusual properties.[6] It is thermally stable up to 200°C and shows a folded 1,3-diborolyl ring along the B−B vector by an angle of 41.3°. This unique folding allows a high−lying combination of σ (B−C) orbitals of the 1,3-diborolyl ligand to interact with the empty metal d_{xz} orbital to complete the 18 VE shell.[6] Compound **1** and the isoelectronic Ru complexes **2*a** and **b** are electron-poor, as demonstrated by their reaction with CO. In the case of **1**, a red product of unknown structure is formed, whereas **2*a** and **b** produce the expected monocarbonyl compounds **3*a** and **b**.[6]

Treatment of $[(C_5Me_5)RuCl]_4$ with the less bulky boron heterocycles **5c** and **d** in the presence of an excess of NaH led to the formation of 30 VE triple-decker complexes $[(C_5Me_5)Ru\{\mu,\eta^5\text{-}(CR^1)_2(BR^2)_2CMe\}RuH(C_5Me_5)]$ (**4*c** and **d**) containing a Ru−H bond.[6] The expected sandwich complexes **2*c** and **d** were not obtained. In this paper we describe the synthesis of several ruthenium complexes **2*** (* = pentamethylcyclopentadienyl derivatives) and **2^** (^ = ethyltetramethylcyclopentadienyl derivatives) with less bulky boron heterocycles using lithium methyl as reagent. We report reactions of **2** with *tert*-butylisocyanide, dihydrogen, borane, and the dimer of bisethenerhodium chloride.

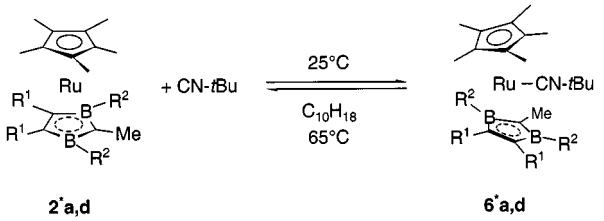
Results and Discussion

Synthesis of Sandwich Complexes 2

The 2,3-dihydro-1,3-diborole derivatives **5c**−**f** are treated with LiMe at −55°C to form addition products, which react with $[(C_5Me_5)RuCl]_4$[7] to give the violet complexes **2*c**, **d**, **e**, and **f** (Scheme 1). In addition to the sandwich compounds **2*c** and **d**, small amounts of the triple-decker compounds **4*c** and **d** are formed, whereas when NaH instead of LiMe is used as base, only the triple-deckers **4*c** and **d** are obtained.[6] The synthesis of the derivatives **2^c** and **f** is achieved by reacting of the boron heterocycle **5c** or **5f** with MeLi and $[(C_5Me_4Et)RuCl]_n$[8] The latter is generated in situ by the reaction of $[(C_5Me_4Et)RuCl_2]_2$ with $[Li(Et_3BH)]$. Isolation and purification of the extremely air-sensitive complexes **2** is achieved by chromatography either on alumina at low temperature or on silica gel at room temperature.

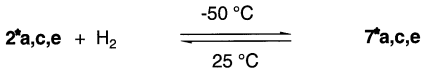


Scheme 1. Formation of complexes **2*** and **2^**

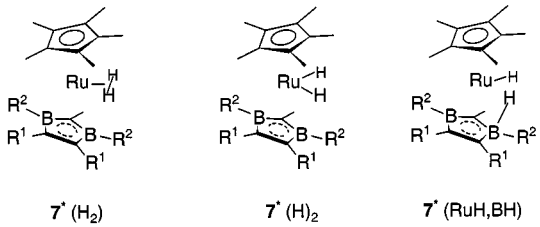
The air-sensitivity of the **2*** and **2** complexes increases with decreasing bulkiness of the ligands. Upon contact with air the color of the complexes changes, and yellow products are formed (see below). Most of the complexes **2*** and **2^** with bulky heterocycle ligands are oily liquids, except for **2*c**, **2*f**, and **2^c**, which are solids. The new compounds are characterized by MS and NMR. In the ^{13}C-NMR spectra, broad signals of the carbon atoms C2 are observed near $\delta = 190$. The following are the C2 shifts for the various complexes: **2*a** $\delta = 191.2$, **2*d** 190.6, **2^f** 190.1, **2^c** 185.8, and **2*c** 185.1. This low-field shift may be the result of a strong interaction between C2 and the ruthenium atom, as it is found in the sandwich **1** [the Fe−C2 distance is 1.899(6) Å, while the Fe−C3,4 distance is 2.116(3) Å][6].

Complexation of 2* with CN*t*Bu

The yellow carbonyl complexes **3*a** and **b** were obtained from the reaction of violet **2*a** and **b** with carbon monoxide.[6] Likewise, with the donor *tert*-butylisocyanide, the yellow complexes **6*a** and **d** are formed (Scheme 2) as crystalline products, which are difficult to purify, because they decompose on a column and during sublimation above 65°C. Their composition was deduced from spectroscopic data and X-ray structure analyses (see below). The ^{13}C-NMR signal for C2 of the isonitrile complex **6*a** appears at $\delta = 70.1$, which is in the range expected for 18 VE compounds. In the ^{11}B-NMR the complexes **6*a**, and **d** exhibit only one signal at $\delta = 29.6$ for **6*a** and 29.4 for **6*d**, whereas **3*b**[6] shows two signals at $\delta = 23.0$ and 36.6. The temperature-dependent ^{11}B-NMR spectra of **6*a** give a relatively sharp signal at 40°C, which gradually broadens at lower temperatures and disappears at −60°C. The ^{1}H- and ^{13}C-NMR spectra of **6*a** and **d** exhibit a double set of signals, which indicates that the isonitrile ligand is not symmetrically bonded with respect to the boron heterocycle, as it is observed for the CO ligand in **3*a** and **b**.[6]



Scheme 2. Addition of CN-*t*Bu to **2*a,d**



The reactions of CO and CN*t*Bu with **2*a** or **d** occur almost quantitatively. No interaction is observed between **2*** and amines (NH_3, isobutylamine), phosphanes (PEt_3, PPh_3), ethylene, or thiophene. There seems to be a weak interaction between THF and **2***, as indicated by ^{1}H- and ^{11}B-NMR spectra (see Experimental Section).

Oxidative Addition of H_2 to 2*

Addition of hydrogen to **2*a**, **c**, or **e** in hexane, tetrahydrofuran, or toluene, leads to the labile complexes **7*a**, **c**, and **e**, which could not be isolated. The color of the solution is violet at room temperature, but reversibly changes to yellow around −50°C. The weakly bonded hydrogen may be easily removed in vacuum. The complexes decompose after a few hours at room temperature, at −80°C they are stable for days. Three isomers for **7*a**, **c**, and **e** seem possible: the non-classic dihydrogen complex **7***(H_2), the classic dihydride complex **7***$(H)_2$, and the complex **7***(RuH,BH) with one hydrogen at the ruthenium and the other at the boron atom.

Scheme 3. Reaction of **2*** with hydrogen

The solution of the complexes **7*a**, **c**, and **e** have been studied by IR and NMR (^{1}H, ^{11}B, and ^{13}C). IR measurements at 20°C show one strong band after 8 scans: 2977 cm^{-1} for **7*a**, 2975 cm^{-1} for **7*c**, and 2979 cm^{-1} for **7*e**. Unfortunately, the complexes decomposed during the measurements. The ^{1}H-NMR spectra exhibit a high-field signal at $\delta = -12.49$ (**7*a**), -12.24 (**7*c**), and -11.91 (**7*e**), which is in the range for compounds with Ru−H or Ru(H_2) bonds [CpRu(CO)(PCy_3)(H_2)]$^+$: -7.91,[10] $RuH_2(H_2)_2(PCy_3)_2$: -9.1,[11] $Ru_2H_4(H_2)(PCy_3)_4$: -12.5,[11] ($\eta^5C_5Me_5$)Ru(μ-$H)_4$Ru($\eta^5C_5Me_5$): -13.99[12]). A temperature-dependent ^{1}H NMR of **7*c** furnished no information about what happened at −50°C, no shift of the high-field signal at $\delta = -12.24$ occurred (Figure 1).

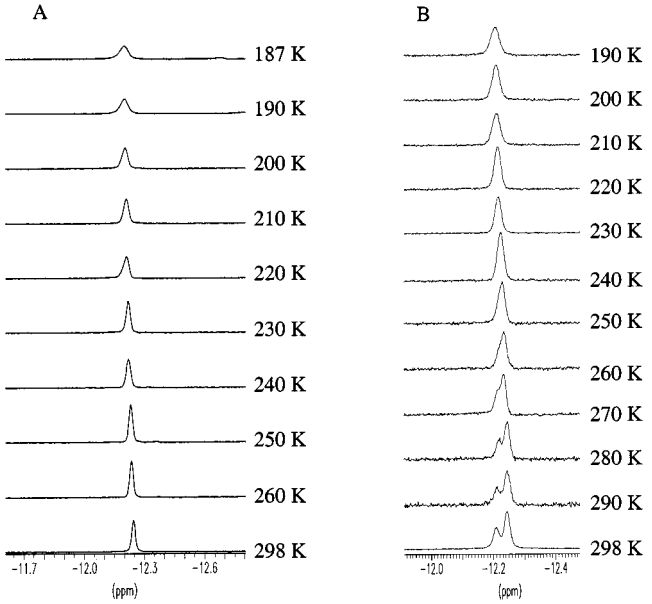


Figure 1. ^{1}H NMR (200.13 MHz, [D_8]THF) at various temperatures after the reaction of **2*c** and H_2 (A) respectively HD (B)

There are two ^{1}H NMR methods to differentiate between the three isomers **7***(H_2), **7***($H)_2$, and **7***(RuH, BH). The first method is the T_1 method, developed by R. H. Crabtree et al.[13] for distinguishing classic hydrides with terminal M−H bonds from non-classic hydrides with H−H as well as M−H bonds. T_1 is a function of the complex structure (dipole−dipole mechanism is the major contributor to this relaxation, a short H−H bond gives small T_1 values down to 3 ms[10]), the magnetic field power, and molecular motion. Molecular motion is dependant on both temperature and solvent, therefore T_1 is measured in dependence of the temperature and a search carried out for the minimum.[14] It is suggested that for $T_{1min} < 40$ ms (250 MHz) a non-classic structure is proposed, and for $T_{1min} > 100$ ms a classic structure is proposed, while values in between are not clearly determinable.[14] Complexes **7*a** and **e** should have small T_{1min} values for a classic and very small T_{1min} values for non-classic structures, because **7*** has a small moment of inertia. In our measurements of **7*a** and **e** no minimum was observed (Figure 2). Unfortunately, the T_1 values (**7*a** = 115 ms and **7*e** = 72) are in the range between a classic and a non-classic complex, therefore we cannot distinguish the two isomers 7*(H_2) and 7*($H)_2$ by this method.

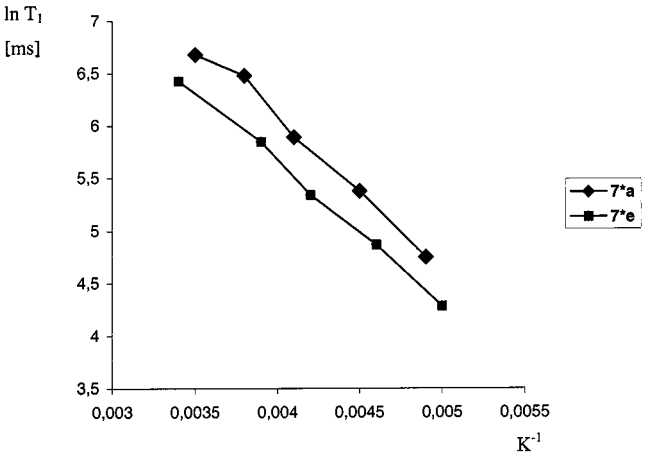

Figure 2. Plot of ln T_1 versus inverse temperature for **7*a**,**e** in [D_8]THF at 200.13 MHz

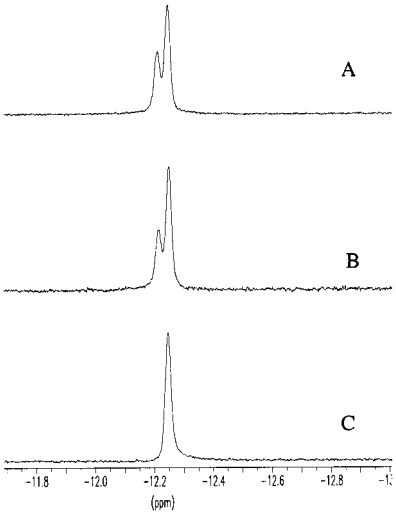
The second method used to differentiate between classic and non-classic complexes is the H/D exchange. The relationship between the H−D distance and the H−D coupling has been discussed.[15] No coupling is observed when **2*c** is treated with HD (Figure 3, **A**). From this we conclude that no H−D non-classic complex is present. Two signals in **A** of Figure 3 appear at $\delta = -12.21$ and -12.24 in a ratio 1: 1.7. The signal at $\delta = -12.24$ is the same as for **2*c** + H_2 (**C** in Figure 3). When H_2 is bubbled into a solution of **7*c**(HD), the signal at $\delta = -12.21$ decreases and disappears after 10 min (Figure 3).



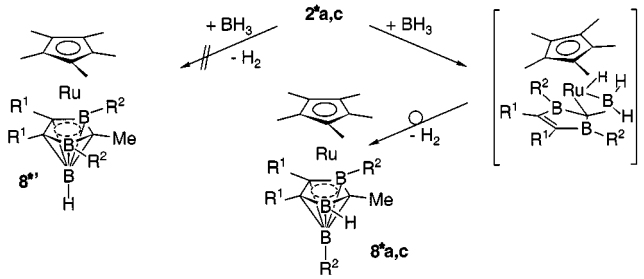


Figure 3. ^{1}H NMR (200.13 MHz, [D_8]THF) of **2*c**, treated with HD and H_2; **A** obtained by bubbling HD into the solution of **2*c**, **B** after H_2 is bubbled for 4 min through the solution of **A**, **C** after H_2 is bubbled for 10 min through the solution of **B**

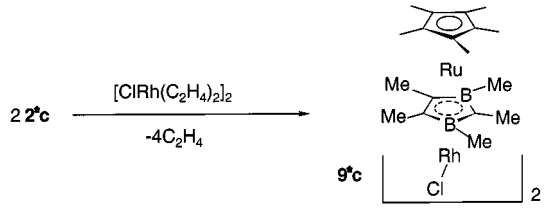
The temperature-dependent ^{1}H NMR of **2*c** + HD shows that the two signals merge into one another around −50°C (Figure 1) which may parallel the change of the color from violet to yellow. At present we are unable to interpret the findings, in which the compounds **7***(H_2) and

7*(RuH,BH) may be involved. The color change at −50°C is agreement with an adduct formation, as it is observed when complexes **2*** react with a 2e donor such as CO and CN−R. Therefore, we assume that H_2 has added to **2*** to give **7***$(H)_2$ (dihydro complex).

Capping and Stacking Reactions of 2



When BH_3·THF is added to **2*a**, or **c** in hexane, the color of the solution changes in a few minutes from violet to yellow, and the tricarbahexaboranyl complexes **8*a** or **8*c** are formed, based on MS, ^{1}H-, ^{11}B-, and ^{13}C-NMR spectra. The isomer **8***′ with BH in the apex position was not detected in the ^{11}B-NMR spectrum as indicated by the absence of a high-field doublet. Three ^{11}B-NMR signals of equal intensity (**8*a**: δ = −0.4, 3.9, 6.6, **8*c**: δ = 1.1, 2.3, 6.0) prove the formation of **8*a** and **8*c**.

Scheme 4. Reaction of **2*a,c** with BH_3

We propose the following mechanism: In the first step an oxidative addition of BH_3 at the ruthenium occurs, followed by the elimination of H_2 to give a transient boranediyl complex, which rearranges with migration of one B−R^2 group into the apex position. Simultaneously, the B−H unit moves into the empty ring position to yield the ruthenacarboranes **8*a** and **c**. According to the cluster rules[16] **8*** has 16 framework electrons and 7 cluster atoms expected for a *closo* structure. Alternatively, **8*** may be described as an 18 VE complex in which the (neutral) 2,3,5-tricarbahexaboranyl ligand supplies 5e for bonding to the metal.[17][18]

When **2*c** is reacted with $[ClRh(C_2H_4)_2]_2$ the diamagnetic tetranuclear complex **9*c** with 56 VE is obtained in 30% yield. The MS and NMR data support the proposed structure of **9*c**, which may be viewed as a pentadecker complex having two bridging chlorine atoms in the central position. It is comparable with the tetranuclear $\{(C_5H_5)Ni[(EtC)_2(BEt)_2CMe]Co(CO)\}_2$ complex having 58 VE.[19]

Scheme 5. Formation of tetranuclear complex **9*c**

Crystal Structures of 6*a, d

The structures of **6*a** and **d** are similar to that of the CO complex **3*b**. The isonitrile group is bonded to the ruthenium, causing a tilt of the Cp* and the 1,3-diborolyl ligands. The best planes through Cp* and 1,3-diborolyl form an angle of 28.6°. The isonitrile is located near one boron atom. The distance B1−C15 is relatively short (2.42 Å) as observed in the CO complex **3*b** (2.41 Å for B1−C17). This weak interaction causes a deviation from linearity of Ru−C≡N*t*Bu (∠ RuCN = 169°), which increases slightly in **3*b** (∠ RuCO = 167°). The 1,3-diborolyl ligand is not planar, but it is less folded along the B1−B3 vector by 16.2° (in **3*a** 19.0°) compared with 41.3° in **1**. The Ru−B distances are significantly larger than those to C, all are in the expected range.

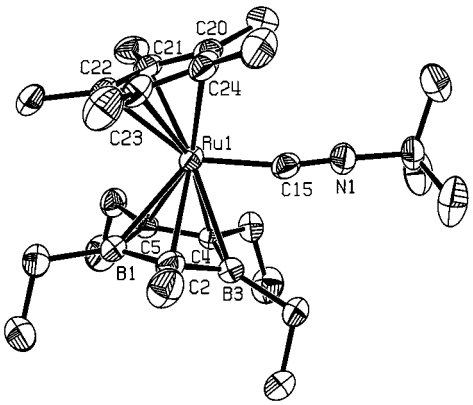


Figure 4. Molecular structure of **6*a** in the crystal
