The reaction of stabilized carbanions with cationic (η^6-arene)tricarbonylmanganese complexes gives, as expected, neutral mononuclear tricarbonyl(η^5-cyclohexadienyl)manganese complexes. But, depending on the amount of carbanion, these reactions can also lead to dinuclear tricarbonyl(η^5-cyclohexadienyl)manganese complexes. With a primary carbanion, it was even possible to isolate a "caroussel-like" trinuclear tricarbonyl(η^5-cyclohexadienyl)manganese complex, whose formation, as well as that of the dinuclear complex, was easily explained.

We have extended this reaction to the synthesis of heterodinuclear complexes with η^5 and η^6 hapticities by using other electrophiles, such as tricarbonyl(halogenoarene)chromium derivatives. In one case, we have observed a spectacular cleavage of the bond between an (η^5-cyclohexadienyl)manganese unit and a benzylic carbon atom of an arene-tricarbonylchromium entity.

An alternative method to these heterodinuclear complexes involves the reaction of electrophilic Mn complexes with nucleophilic benzylic carbanions of Cr complexes.

Experimental Section

General: All reactions were carried out under dry nitrogen. All experiments were always protected from exposure to light and oxygen. Workup procedures were done in air. Tetrahydrofuran (THF) and dibutyl ether (DBE) used were distilled from sodium benzophenone ketyl under dry nitrogen. − ^{1}H- and ^{13}C-NMR spectra were obtained with Bruker AC 200 and ARX 400 spectrometers. Infrared spectra were recorded with Perkin-Elmer 1420 and Bruker FT spectrometers. Elemental analyses were performed by Le Service de Microanalyses de l′Université P. et M. Curie. Melting points were measured with a Reichert apparatus.

Preparation of (η^6-Arene)manganese and -chromium Complexes

Tricarbonyl(η^6-1,2,3-trimethoxybenzene)manganese Tetrafluoroborate (2): Prepared according to a literature method, yield: 95%, ref.[5]: 95%. − IR ($CHCl_3$): $\tilde{\nu}$ = 2058 cm^{-1}, 1997 (CO). − ^1H NMR (200 MHz, [D_6]acetone): δ = 7.00 (t, J = 7 Hz, 1 H, H^5), 6.25 (t, J = 7 Hz, 2 H, H^4 and H^6), 4.27 (s, OCH_3 at C^1 and C^3), 4.08 (s, OCH_3 at C^2). − ^{13}C NMR (50 MHz, [D_6]acetone): δ = 217.6 (CO), 146.6 (C^1 and C^2), 120 (C^2), 74.1 (C^4 and C^6), 65.2 (OCH_3 at C^2), 59.3 (OCH_3 at C^1 and C^3). − $C_{12}H_{12}BF_4MnO_6$ (392.07): calcd. C 36.58, H 3.07; found C 36.54, H 2.99.

(η^6-Benzene)tricarbonylmanganese Hexafluorophosphate Complex 5: Prepared according to a literature method, yield: 92%; ref.[26] 72%.

(η^6-Benzene)dicarbonylphosphitomanganese Hexafluorophosphate Complex $5P_1$: Prepared according to a literature method, yield: 54%, ref.[28a] 88%.

(η^6-Benzene)carbonyldiphosphitomanganese Hexafluorophosphate Complex $5P_2$: Prepared according to a modified literature method[28a] from complex **5**. Yield: 54%, yellow solid. − IR ($CHCl_3$): $\tilde{\nu}$ = 1940 cm^{-1} (CO). − ^1H NMR (200 MHz, [D_6]acetone): δ = 5.00 (t, J = 2.1 Hz, 6 H), 4.15 (m, 12 H), 1.34 (t, J = 7.1 Hz, 18 H). − ^{13}C NMR (50 MHz, [D_6]acetone): δ = 227.0 (d, J_{CP} = 37.5 Hz), 94.7 (CH), 63.1 (CH_2), 16.2 (CH_3). − ^{31}P NMR (162 MHz, [D_6]acetone): δ = 181.5. − $C_{19}H_{36}F_6MnO_7P_3$ (638.34): calcd. C 35.75, H 5.68; found C 35.85, H 5.71.

(η^6-Anisole)tricarbonylmanganese Hexafluorophosphate Complex 26a: Prepared according to a literature method, yield 70%; ref.[27] 56%.

(η^6-Anisole)dicarbonylphosphitomanganese Hexafluorophosphate Complex 26b: In a typical procedure[28b] cationic complex **26a** (500 mg, 1.27 mmol) was dissolved in freshly distilled acetone (50 mL). $P(OEt)_3$ (430 μL, 2.50 mmol), then Me_3NO (a pinch) were added and mixed at room temperature for 3 h. Solvents were removed under reduced pressure. The crude oil was washed with ether and the complex was recrystallised in an acetone/diethyl ether mixture to give orange-yellow needles of complex **26b** (457 mg, 0.86 mmol, 68% yield). − IR ($CHCl_3$): $\tilde{\nu}$ = 1960 cm^{-1}, 2005 (CO). − ^1H NMR (200 MHz, $CDCl_3$): δ = 6.32 (t, J = 5.6 Hz, 2 H, H^3 and H^5), 5.71 (d, J = 5.6 Hz, 2 H, H^2 and H^6), 5.58 (t, J = 5.6 Hz, 1 H, H^4), 4.02 [m, 6 H, $P(OCH_2CH_3)$], 3.92 (s, 3 H, CH_3), 1.35 [t, J = 7.0 Hz, 9 H, $P(OCH_2CH_3)$]. − ^{13}C NMR (100 MHz, $CDCl_3$): δ = 219.9 (CO−Mn), 146.1 (C^1), 101.4 (C^3 and C^5), 87.5 (C^4), 80.5 (C^2 and C^6), 63.6 [d, J = 7.0 Hz, $P(OCH_2CH_3)$], 57.3 (CH_3), 16.0 [d, J = 7.0 Hz, $P(OCH_2CH_3)$]. − ^{31}P NMR (162 MHz, $CDCl_3$): δ = 176.0. − $C_{15}H_{23}F_6MnO_6P_2$ (530.20): calcd. C 31.16, H 4.01; found C 31.51, H 4.42.

Tricarbonyl(η^6-*p*-fluorotoluene)chromium Complex 13: Prepared according to literature methods described for tricarbonyl(*o*- and *m*-fluorotoluene)chromium complexes.[29] Yield: 42%. − IR (CCl_4): $\tilde{\nu}$ = 1910 cm^{-1}, 1980 (CO). − ^1H NMR (200 MHz, [D_6]acetone): δ = 5.81 (d, J = 4.1 Hz, 4 H, H^2, H^3, H^5, and H^6), 2.11 (s, 3 H, CH_3). − ^{13}C NMR (50 MHz, [D_6]acetone): δ = 233.7 (Cr−CO), 145.8 (C^1, d, J = 260.4 Hz), 105.5 (C^4), 95.9 (C^3 and C^5, d, J = 7.1 Hz), 82.2 (C^2 and C^6, d, J = 20.4 Hz), 19.6 (CH_3). − $C_{10}H_7CrFO_3$ (246.16): calcd. C 48.79, H 2.87, N 21.13; found C 48.83, H 2.85, N 21.19.

(η^6-Benzyl methyl ether)tricarbonylchromium Complex 23: Prepared according to a literature method, yield 62%, ref.[30] 84%.

Syntheses of Complexes 3a, 3b, 3c, 4, 6a, 7a, 6b, 7b, 8b, 6c, 7c

Typical Procedure. − Complex 3a: To a solution of $LiN(CHMe_2)_2$ (1.2 mmol) [obtained by addition of *n*BuLi (755 μL, 1.2 mmol) in a solution of $HN(CHMe_2)_2$ (154 μL, 1.2 mmol) in THF at −78°C] in THF (10 mL) were added $(iPr)_3SiCH_2CN$ (220 μL, 1.2 mmol) and TMEDA (905 μL, 6 mmol). The mixture was stirred for 5 min at −78°C, then added, through a canula, to a solution of complex **2** (394 mg, 1 mmol) in THF (5 mL). The resulting solution was stirred for 3 min at −78°C then treated with distilled water, then with Et_2O. After extraction, the organic phase was washed with brine and dried with $MgSO_4$. Concentration of the organic layer gave a yellow solid. Flash chromatography on basic alumina gave compound **3a** (yield 38%). m.p. 113°C. − IR ($CHCl_3$): $\tilde{\nu}$ = 2010 cm^{-1}, 1935 (CO), 2210 (CN). − ^1H NMR (200 MHz, $CDCl_3$): δ = 4.02 (s, 3 H, OCH_3 at C^2), 3.58 (s, 3 H, OCH_3 at C^1 or C^3), 3.43 (s, 3 H, OCH_3 at C^3 or C^1), 3.14 (dd, J = 6 and 1.9 Hz, 1 H, H^4 or H^6), 2.93 (q, J = 6 Hz, 1 H, H^5), 2.83 (dd, J = 6 and 1.9 Hz, 1 H, H^6 or H^4), 1.44 (d, J = 6 Hz, 1 H, C*H*CN), 1.22 [m, 3 H, $Si(CH-Me_2)$], 1.09 {d, 18 H, $[(CH_3)_2CH]_3Si$}. − ^{13}C NMR (100 MHz, $CDCl_3$): δ = 219.3 (CO), 136.9 (C^1 or C^3), 136.2 (C^3 or C^1), 119.8 (CN or C^2), 115.8 (C^2 or CN), 66.3 (OCH_3 at C^2), 55.3 (OCH_3 at C^1 or C^3), 54.7 (OCH_3 at C^3 or C^1), 36.4 (C^4 or C^6), 35.8 (C^5), 35.7 (C^6 or C^4), 29.2 (CH), 18.6 (CH_3), 11.9 (CH). − $C_{23}H_{34}MnNO_6Si$ (503.54): calcd. C 54.86, H 6.80, N 2.78; found C 54.91, H 6.79, N 2.72.

Crystal Structure of 3a: $[Mn(CO)_3(C_{20}H_{34}O_3NSi)]$, M = 503.5, μ = 0.548 mm^{-1}, $F(000)$ = 1064, ρ = 1.24 $g.cm^{-3}$, monoclinic, $P2_1/n$, Z = 4, a = 13.264(3), b = 12.120(4), c = 17.246(6) Å, β = 104.41(2)°, V = 2685(15) $Å^3$, from 25 reflections (30° < 2θ < 30.5°). Cell dimensions and intensities were measured at 295 K with a Nonius CAD4 diffractometer with graphite-monochromated Mo-K_α radiation (λ = 0.71069 Å). ω/2θ scans, two standard reflections measured every hour showed no significant variation. 1° < θ < 28° (−17 < h < 16, 0 < k < 15, 0 < l <22); 6984 measured reflections, 6461 unique reflections of which 3385 were observed [$|F_o|^2 > 3\sigma(|F_o|^2)$]; R_{int} = 0.021 for equivalent reflections. Data were corrected for Lorentz and polarization effects and for absorption[31] (transmission factors min. 0.9, max. 1). The structure was solved by direct methods using SHELXS,[32] all other calculations used CRYSTALS.[33] Atomic scattering factors and anomalous dispersion terms were taken from ref.[34] Full-matrix least-squares refinement based on $|F|$ and a Chebychev weighting scheme gave final values R = 0.0576, wR = 0.0707, and s = 1.00 for 301 variables and 3385 contributing reflections. The maximum shift/esd of the last cycle was 1.32. Non-hydrogen atoms were anisotropically refined. Hydrogen atoms were introduced in calculated positions, except for hydrogen atoms of methoxy groups which were located in a difference Fourier map; their coordinates were left in fixed positions, only an overall isotropic thermal parameter was refined. The final difference electron density map showed a maximum of 0.43 and a minimum of −0.34 $eÅ^{-3}$.

Complexes 3b, 3c, and 4: Same method as for complex **3a**. Preparation from $LiN(CHMe_2)_2$ (1.2 mmol), Me_3SiCH_2CN (164 μl, 1.2 mmol), complex **2** (393.96 mg, 1 mmol). Overall yield 60%. After a fast silica gel column chromatography, complexes **3b**, **3c**, and **4** could be isolated in a 82:12:4 ratio (50.4%, 7.2%, 2.4% yield, respectively).

Complex 3b: M.p.103°C. − IR ($CHCl_3$): $\tilde{\nu}$ = 2210 cm^{-1} (CN), 2010,1930 (CO). − ^1H NMR (200 MHz, $CDCl_3$): d = 4.06 (s, 3 H, OCH_3 at C^2), 3.58 (s, 3 H, OCH_3 at C^1 or C^3), 3.47 (s, 3 H, OCH_3 at C^3 or C^1), 3.09 (d, J = 6.2 Hz, 1 H, H^4), 2.84 (m, 2 H, H^6, H^4 and H^5), 2.77 (q, J = 6.3 Hz, 1 H, H^5), 1.28 (d, J = 6.2

Hz, 1 H, C*H*CNSiMe$_3$), 0.19 [s, 9 H, (CH$_3$)$_3$Si]. − ^{13}C NMR (CDCl$_3$, 100 MHz): δ = 219.3 (CO), 136.7 (C^1 or C^3), 136.3 (C^3 or C^1), 119.5 (CN or C^2), 116.5 (C^2 or CN), 66.4 (OCH$_3$ at C^2), 55.4 (OCH$_3$ at C^1 or C^3), 54.8 (OCH$_3$ at C^3 or C^1), 36.2 (C^4 or C^6), 36 (C^5), 35.5 (C^6 or C^4), 34.3 (C*H*CNSiMe$_3$), − 2.06 (CH$_3$ at SiMe$_3$). − $C_{17}H_{22}MnNO_6Si$ (419.4): calcd. C 48.68, H 5.28, N 3.33; found C 48.83, H 5.32, N 3.37.

Complex 3c: M.p. 91°C. − IR (CHCl$_3$): $\tilde{\nu}$ = 2242 cm^{-1} (CN), 2010, 1935 (CO). − ^{1}H NMR (200 MHz, CDCl$_3$): δ = 4.06 (s, 3 H, OCH$_3$ at C^2), 3.48 (s, 6 H, OCH$_3$ at C^1 and C^3), 2.90 (m, 3 H, H^4, H^5 and H^6), 1.67 (d, *J* = 5.8 Hz, 2 H, CH$_2$CN). − ^{13}C NMR (50 MHz, CDCl$_3$,): δ = 212.1 (CO), 137.1 (C^1 and C^3), 116.4 (CN or C^2), 115.4 (C^2 or CN), 66.8 (OCH$_3$ at C^2), 55.3 (OCH$_3$ at C^1 and C^3), 34.4 (C^5), 33.8 (C^4 or C^6), 29.9 (CH$_2$CN). − $C_{14}H_{14}MnNO_6$ (347.2): calcd. C 48.43, H 4.06, N 4.03; found C 49.68, H 4.58, N 4.05.

Crystal Structure of 3c: [Mn(CO)$_3$(C$_{11}$H$_{14}$O$_3$N)], *M* = 347.2, μ = 0.811 mm^{-1}, *F*(000) = 712, ρ = 1.43 g cm^{-3}, monoclinic, *P*2$_1$/*n*, *Z* = 4, *a* = 13.198(6), *b* = 12.691(6), *c* = 9690(2) Å, (= 97.17(3)°, *V* = *1*610 Å^3, from 25 reflections (30° < 2θ < 32°). Cell dimensions and intensities were measured at 295 K with a Philips PW1100 diffractometer with graphite-monochromated Mo-K_α radiation (λ = 0.71069Å). ω/2θ scans, two standard reflections measured every two hours showed no significant variation. 2° < θ < 25° (−15 < *h* < 15, 0 < *k* < 15, 0 < *l* <11); 3134 measured reflections, 2804 unique reflections of which 1124 were observed [$|F_o|^2 > 2.5\sigma(|F_o|^2)$]; R_{int} = 0.025 for equivalent reflections. Data were corrected for Lorentz and polarization effects and for absorption[31] (transmission factors min = 0.75, max = 1). The structure was solved by direct methods using SHELXS,[32] all other calculations used CRYSTALS.[33] Atomic scattering factors and anomalous dispersion terms were taken from ref.[34] Full-matrix least-squares refinement based on |*F*| and a Chebychev weighting scheme gave final values *R* = 0.0666, *wR* = 0.0627, and *s* = 1.13 for 200 variables and 3385 contributing reflections. The maximum shift/esd of the last cycle was 0.26. Non-hydrogen atoms were anisotropically refined. Hydrogen atoms were located in a difference Fourier map; their coordinates were left in fixed positions, only an overall isotropic thermal parameter was refined. The final difference electron density map showed a maximum of 0.31 and a minimum of − 0.39 eÅ^{-3}.

Complex 4: M.p. 191°C. − IR (CHCl$_3$): $\tilde{\nu}$ = 2225 cm^{-1} (CN), 2010,1935 (CO). − ^{1}H NMR (200 MHz, CDCl$_3$): δ = 3.99 (s, 6 H, 2 OCH$_3$ at C^2), 3.59 (s, 6 H, 2 OCH$_3$ at C^1 or C^3), 3.50 (s, 6 H, 2 OCH$_3$ at C^3 or C^1), 2.76 (dd, *J* = 6.1 and 1.4 Hz, 2 H, 2 H^4 or 2 H^6), 2.66 (dd, *J* = 6.1 and 1.4 Hz, 2 H, 2 H^6 or 2 H^4), 2.52 (q, *J* = 6.1 Hz, 2 H, 2H^5), 0.98 (t, *J* = 6.1 Hz, 1 H, CHCN). − ^{13}C NMR (100 MHz, CDCl$_3$,): δ = 218.5 (CO), 137.5 (C^1 or C^3), 137.2 (C^3 or C^1), 117.8 (CN or C^2), 115.1 (C^2 or CN), 66.2 (OCH$_3$ at C^2), 55.6 (OCH$_3$ at C^1 or C^3), 55.4 (OCH$_3$ at C^3 or C^1), 55.1 (*C*HCN), 35.2 (C^5), 33.2 (C^4 or C^6), 32.3 (C^6 or C^4). − $C_{26}H_{25}Mn_2NO_{12}$ (653.35): calcd. C 47.75, H 3.82, N 2.14; found C 47.95, H 3.95, N 2.19.

Complexes 6b, 7b and 8b:

Typical Procedure: To a solution of LiN(CHMe$_2$)$_2$ (1.1 mmol) [obtained by addition of *n*BuLi (687 μL, 1.1 mmol) in a solution of HN(CHMe$_2$)$_2$ (140μL, 1.1 mmol) in THF at −78°C] in THF (10 mL) was added acetonitrile (55 μL, 1.05 mmol). The mixture was stirred for 5 min at −78°C , then added, through a canula, to a solution of complex **5** (362 mg, 1 mmol) in THF (5 mL). The resulting solution was stirred for 3 min at −78°C then treated with distilled water followed by Et$_2$O. After extraction, the organic phase was washed with brine and dried with MgSO$_4$. Concentration of the organic layer gave a yellow oil. Flash chromatography on basic alumina gave compounds **8b** (the less polar), then **7b** and **6b** (overall yield: 58%) in a 2:18:80 ratio.

Complex 6b: M.p. 95°C. − IR (CCl4): $\tilde{\nu}$ = 2240 cm^{-1} (CN), 1945, 2005 (CO). − ^{1}H NMR (200 MHz, CDCl3): δ = 5.84 (t, *J* = 6.0 Hz, 1 H, H^3), 4.94 (t, *J* = 6.0 Hz, 2 H, H^2 and H^4), 3.23 (t, *J* = 6.0 Hz, 2 H, H^1 and H^5), 2.94 (m, 1 H, H^6), 1.69 (d, *J* = 6.7 Hz, 2 H, CH$_2$). − ^{13}C NMR (50 MHz, [D$_6$]acetone): δ = 221.7 (Mn−CO), 116.7 (CN), 96.9 (C^2 and C^4), 80.7 (C^3), 53.2 (C^1 and C^5), 31.7 (C^6), 29.0 (CH$_2$). − $C_{11}H_8MnNO_3$ (257.13) calcd. C 51.38, H 3.14, N 5.45; found C 51.42, H 3.30, N 5.43.

Complex 7b: M.p. 201°C. − IR (CHCl$_3$): $\tilde{\nu}$ = 2230 cm^{-1} (CN), 1940, 2100 (CO). − ^{1}H NMR (400 MHz, [D$_6$]acetone): δ = 6.04 (tt, *J* = 6.5 and 1.2 Hz, 2 H, 2 H^3), 5.17 (m, 4 H, 2 H^2 and 2 H^4), 3.42 (tdd, *J* = 6.5, 3.3 and 1.2 Hz, 2 H, 2 H^1 or 2 H^5), 3.33 (tdd, *J* = 6.5, 3.3 and 1.2 Hz, 2 H, 2 H^5 or 2 H^1), 2.85 (q, *J* = 6.5 and 6.7 Hz, 2 H, 2 H^6), 1.32 (t, *J* = 6.5 Hz, 1 H, H^7). − ^{13}C NMR (100 MHz, [D$_6$]acetone): δ = 224.5 (Mn−CO), 119.7 (CN), 99.0 and 99.2 (C^2 and C^4), 83.5 (C^3), 55.4 (C^7), 54.3 and 56.4 (C^1 and C^5), 34.6 (C^6). − $C_{20}H_{13}Mn_2NO_6$ (473.21) calcd. C 50.77, H 2.77, N 2.96; found C 50.90, H 2.71, N 3.02.

Complex 8b: M.p. 204°C. − IR (CCl4): $\tilde{\nu}$ = 2330 cm^{-1} (CN), 2020, 1950 (CO). − ^{1}H NMR (200 MHz, [D$_6$]acetone): δ = 6.01 (t, *J* = 5.8 Hz, 3 H, H^3), 5.26 (t, *J* = 5.8 Hz, 6 H, H^2 and H^4), 3.46 (t, *J* = 5.8 Hz, 6 H, H^1 and H^5), 2.93 (t, *J* = 5.8 Hz, 3 H, H^6). − ^{13}C NMR (50 MHz, [D$_6$]acetone): δ = 222.9 (Mn−CO), 120 (CN), 98 (C^2 and C^4), 81.7 (C^3), 66.2 (*C*-CN), 55.4 (C^1 and C^5), 36.7 (C^6). − $C_{29}H_{18}Mn_3NO_9$ (689.27) calcd. C 50.53, H 2.63, N 2.03; found C 50.95, H 2.77, N 3.16.

Complexes 6a and 7a: Same method as for complexes **6b**, **7b**, and **8b**: Starting from 1 equiv. of complex **5**, 1 equiv. of CH$_3$CH$_2$CN and 1 equiv. of LDA, complexes **6a** and **7a** were obtained (overall yield: 87%) in a 87:13 ratio. Starting from 2 equiv. of complex **5**, 1 equiv. of CH$_3$CH$_2$CN and 2 equiv. of LDA, complexes **6a** and **7a** were obtained (overall yield 85%) in a 28:72 ratio.

Complex 6a: M.p. 139°C. − IR (CCl$_4$): $\tilde{\nu}$ = 2240 cm^{-1} (CN), 1950, 2010 (CO). − ^{1}H NMR (200 MHz, CDCl$_3$): δ = 5.80 (t, 1 H, *J* = 6.1 Hz, H^3), 4.97 (t, *J* = 6.1 Hz, 1 H, H^2 or H^4), 4.92 (t, *J* = 6.1 Hz, 1 H, H^4 or H^2), 3.34 (tt, *J* = 6.1 and 1.5 Hz, 1 H, H^1 or H^5), 3.15 (tt, *J* = 6.1 and 1.5 Hz 1 H, H^5 or H^1), 2.64 (m, 1 H, H^6), 1.69 (q, *J* = 7.2 Hz, 1 H, H^7), 1.01 (d, *J* = 7.2 Hz 3 H, CH$_3$). − ^{13}C NMR (50 MHz, [D$_6$]acetone): δ = 225.4 (Mn−CO), 124.8 (CN), 99.9 (C^2 and C^4), 84.0 (C^3), 54.3 (C^1 and C^5), 38.9 (C^6), 38.7 (C^7), 14.9 (CH$_3$). − $C_{12}H_{10}MnNO_3$ (271.16): calcd. C 53.16, H 3.72, N 5.07; found C 53.06, H 3.81, N 5.17.

Complex 7a: M.p. 194°C. − IR (CCl4): $\tilde{\nu}$ = 2240 cm^{-1} (CN), 1945, 2005 (CO). − ^{1}H NMR (200 MHz, [D$_6$]acetone): δ = 5.98 (tt, *J* = 5.7 and 1.3 Hz, 2 H, H^3), 5.25 (m, 4 H, 2 H^2 and 2 H^4), 4.78 (tt, *J* = 5.7 and 1.3 Hz, 2 H, 2 H^1 or 2 H^5), 3.35 (tt, *J* = 5.7 and 1.3 Hz, 2 H, 2 H^5 or 2 H^1), 2.84 (m, 2 H, 2 H^6), 0.74 (s, 3 H, CH$_3$). − ^{13}C NMR (50 MHz, [D$_6$]acetone): δ = 225.5 (Mn−CO), 124.7 (CN), 101.1 (C^2 and C^4), 84.0 (C^3), 56.0 and 57.4 (C^1 and C^5), 40.9 (C^6), 39.6 (C^7), 18.1 (CH$_3$). − $C_{21}H_{15}Mn_2NO_6$ (487.23): calcd. C 51.77, H 3.10, N 2.87; found C 52.15, H 3.09, N 2.84.

Crystal Structure of 7a: [(CO)$_3$Mn(C$_{15}$H$_{15}$N)Mn(CO)$_3$], *M* = 487.21, μ = 0.126 mm^{-1}, *F*(000) = 492, ρ = 1.26 g.cm^{-3}, triclinic, *P*$\bar{1}$, *Z* = 2, *a* = 6.735(6), *b* = 12.779(8), *c* = 13.425(12) Å, α = 116.11(6), β = 92.21(1), γ = 103.94(8)°, *V* = 993 Å^3, from 25 reflections (20° < 2θ < 22°). Cell dimensions and intensities were measured at 295 K with a Philips PW1100 diffractometer with graphite-monochromated Mo-K_α radiation (λ = 0.71069 Å). ω/2θ scans, two

standard reflections measured every two hours showed no significant variation. $2° < \theta < 20°$ ($-6 < h < 6$, $-12 < k < 11$, $0 < l < 12$); 1960 measured reflections, 1816 unique reflections of which 1232 were observed [$|F_o|^2 > 1.5\sigma(|F_o|^2)$]; $R_{int} = 0.035$ for equivalent reflections. Data were corrected for Lorentz and polarization effects and for absorption[31] (transmission factors min = 0.8, max = 1). The structure was solved by direct methods using SHELXS,[32] all other calculations used CRYSTALS.[33] Atomic scattering factors and anomalous dispersion terms were taken from ref.[34] Full-matrix least-squares refinement based on $|F|$ and a Chebychev weighting scheme gave final values $R = 0.0591$, $Rw = 0.0616$, and $s = 1.18$ for 207 variables and 1232 contributing reflections. The maximum shift/esd in the last cycle was 0.22. $Mn(CO)_3$, CN, and methyl C atoms were anisotropically refined, other C atoms were left isotropic in order to reduce the number of variables. Hydrogen atoms were introduced in calculated positions; their coordinates were left in fixed positions, only an overall isotropic thermal parameter was refined. The final difference electron density map showed a maximum of +0.52 and a minimum of −0.45 eÅ^{-3}.

Crystallographic data (excluding structure factors) have been deposited with the Cambridge Crystallographic Data Center as supplementary publication no. CCDC-101517 (**3a**), -101518 (**3c**), -101519 (**7a**). Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1 EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Complexes 6c and 7c: Same method as for complexes **6b**, **7b**, and **8b**: prepared from $LiN(CHMe_2)_2$ (1.2 mmol), Me_3SiCH_2CN (164 µL, 1.2 mmol), and complex **5** (362.04 mg, 1 mmol). Overall yield: 66%. A fast silica gel chromatography gave complexes **6c**, **7c**, **6b**, and **7b** in a 64:28:7:1 ratio.

Complex 6c: M.p. 93°C. − IR ($CHCl_3$): $\tilde{\nu}$ = 2205 cm^{-1} (CN), 2015 and 1945 (CO). − ^{1}H NMR (400 MHz, $CDCl_3$): δ = 5.86 (t, J = 6.2 Hz, 1 H, H^3), 5.00 (t, J = 6.2 Hz, 1 H, H^2 or H^4), 4.93 (t, J = 6.2 Hz, 1 H, H^4 or H^2), 3.40 (t, J = 6.2 Hz, 1 H, H^1 or H^5), 3.16 (t, J = 6.2 Hz, 1 H, H^5 or H^1), 2.85 (q, J = 6.2 Hz 1 H, H^6), 1.33 (d, J = 6.2 Hz, 1 H, C*H*CNSiMe$_3$), 0.19 (s, 9 H, $(CH_3)_3Si$). − ^{13}C NMR (100 MHz, $CDCl_3$): δ = 222.3 (CO), 120.1 (CN), 96.6 (C^2 or C^4), 96.3 (C^4 or C^2), 81.3 (C^3), 55.1 (C^1 or C^5), 55.0 (C^5 or C^1), 33.5 (*C*HCNSiMe$_3$), 33.4 (C^6), −1.72 (CH_3 of $SiMe_3$). − $C_{14}H_{16}MnNO_3Si$ (329.31): calcd. Addition of α-Sulfonyl Carbanions to Benzenetricarbonylmanganese Complex 5: Typical procedure: *n*BuLi (692 µL of a solution 1.6 M in hexane; 1.1 mmol) was added under nitrogen to a solution of chloromethyl *p*-toluenesulfonate (204.6 mg; 1.0 mmol) in THF (10 mL). After 30 min of stirring, this solution was transferred at −78°C under nitrogen through a canula into a flask containing benzenetricarbonylmanganese complex **5** (364.5 mg; 1 mmol) and THF (10 mL). After 30 min, the reaction temperature was increased progressively to room temperature. The mixture was extracted with water and diethyl ether, the organic layer was washed with brine, and dried with $MgSO_4$. Concentration of the ether layer gave a yellow oil. After chromatography on a silica gel column, two fractions were obtained: the first one was a yellow powder consisting of a 2:1 mixture of complex **9a** (149.5 mg; 0.35 mmol; yield 35%) and starting sulfone (eluent: petroleum ether/diethyl ether, 80:20); dinuclear complex **10a** (241.9 mg; 0.38 mmol; yield 38%) was obtained from the second fraction.

Complex 9a: IR (CCl_4): $\tilde{\nu}$ = 1940 cm^{-1}, 1950, and 2010 (CO), 1150 and 1350 (SO_2). − ^{1}H NMR (400 MHz, $CDCl_3$): δ = 7.86 (d, J = 9.3 Hz, 1 H, H^9 or H^{13}), 7.54 (d, 1 H, J = 9.3 Hz, H^{13} or H^9), 7.18 (m, 2 H, H^{10} and H^{12}), 5.83 (t, J = 5.4 Hz, 1 H, H^3), 4.99 (m, 2 H, H^2 and H^4), 3.65 (d, J = 9.3 Hz, 1 H, H^7), 3.49 (m, 1 H, H^1 or H^5), 3.30 (m, 1 H, H^6), 3.12 (m, 1 H, H^5 or H^1), 2.46 (s, 3 H, CH_3). − ^{13}C NMR (50 MHz, $CDCl_3$): δ = 221.8 (Mn−CO), 145.9 (C^8), 133.1 (C^{11}), 130.1 (C^{10} and C^{12}), 129.5 (C^9 and C^{13}), 96.5 (C^2 and C^4), 81.2 (C^7), 78.1 (C^3), 48.9 and 53.9 (C^1 and C^5), 36.2 (C^6), 21.8 (CH_3). − MS (CI) (NH_3); *m*/*z*: 438 [MNH_4]$^+$.

Complex 10a: IR (CCl_4): $\tilde{\nu}$ = 1945 cm^{-1} and 2005 (CO), 1140 and 1325 (SO_2). − ^{1}H NMR (400 MHz, $CDCl_3$): δ = 7.74 (d, J = 9.5 Hz, 2 H, H^9 and H^{13}), 7.38 (m, 2 H, H^{10} and H^{12}), 5.78 (t, J = 5.3 Hz, 2 H, 2 H^3), 5.09 (m, 2 H, 2 H^2 or 2 H^4), 4.89 (t, J = 5.3 Hz, 2 H, 2 H^4 or 2 H^2), 3.34 (m, 4 H, 2 H^1 and 2 H^5), 3.15 (m, 2 H, 2 H^6), 2.48 (s, 3 H, CH_3). − ^{13}C NMR (50 MHz, $CDCl_3$): δ = 222.0 (Mn−CO), 146.1 (C^8), 133.0 (C^{11}), 130.6 (C^{10} and C^{12}), 129.7 (C^9 and C^{13}), 97.7 and 97.9 (2 C^2, 2 C^4), 93.1 (C^7), 80.1 (C^3), 54.5 (2 C^1, 2 C^5), 39.8 (C^6), 21.8 (CH_3). − $C_{26}H_{19}ClMn_2O_8S$ (636.83): calcd. C 49.01, H 2.98; found C 49.00, H 2.96.

Complexes 9b and 10b: Same method as for **9a** and **10a**: starting from *n*BuLi (692 µL; 1.1 mmol), fluoromethyl benzenesulfonate (174.2 mg; 1 mmol), and complex **5** (364.5 mg; 1 mmol). A fast silica gel column chromatography gave complexes **9b** (43%) and a mixture of complex **10b** (5%) and some starting sulfone. If 2 equiv. of *n*BuLi and 2 equiv. of complex **5** were used, after chromatography, complexes **11** (16%), **9b** (3%), and a mixture of **10b** (52%) and starting sulfone were obtained.

Complex 9b: IR (CCl_4): $\tilde{\nu}$ = 1905 cm^{-1}, 1945, 1975, and 2005 (CO), 1155 and 1347 (SO_2). − ^{1}H NMR (400 MHz, $CDCl_3$): δ = from 7.42 to 7.92 (several m, H^9, H^{10}, H^{11}, H^{12}, and H^{13}), 5.78 (t, J = 5.6 Hz, 1 H, H^3), 4.90 (m, 2 H, H^2 and H^4), 3.91 (dd, J_{HF} = 47.5 Hz, J_{HH} = 7.5 Hz, 1 H, H^7), 3.44 (m, 1 H, H^6), 3.06 (m, 1 H, H^1 or H^5), 2.95 (t, J = 5.6 Hz, 1 H, H^5 or H^1). − ^{13}C NMR (50 MHz, $CDCl_3$): δ = 222.4 (Mn−CO), 134.8 (C^8), 129.6 (C^{11}), 129.4 (C^{10} and C^{12}), 129.2 (C^9 and C^{13}), 97.3 and 97.6 (C^2 and C^4), 99.9 and 104.3 (C^7), 80.8 (C^3), 47.8 and 48.6 (C^1 and C^5), 33.5 and 33.9 (C^6). − MS (CI) (NH_3); *m*/*z*: 408 [MNH_4^+], 391 [MH^+].

Complex 10b: IR (CCl_4): $\tilde{\nu}$ = 1905 cm^{-1}, 1945, 1975, and 2005 (CO), 1155 and 1347 (SO_2). − ^1H NMR (400 MHz, $CDCl_3$): δ = 7.42−7.92 (several m, H^9, H^{10}, H^{11}, H^{12} and H^{13}), 5.71 (t, *J* = 6.0 Hz, 2 H, $2H^3$), 4.90 (m, 2 H, H^2 and H^4), 4.58 (t, *J* = 6.0 Hz, 2 H, H^2 and H^4), 3.29 (t, *J* = 6.0 Hz, 1 H, H^6), 3.24 (t, *J* = 6.0 Hz, 1 H, H^6), 3.06 (m, 2 H, H^1 and H^5), 2.76 (t, *J* = 6.0 Hz, 2 H, H^1 and H^5). − ^{13}C NMR (50 MHz, $CDCl_3$): δ = 222.4 (Mn−CO), 134.9 (C^8), 129.4 (C^{11}), 129.2 (C^{10} and C^{12}), 129.0 (C^9 and C^{13}), 97.5 and 97.7 (C^2 and C^4), 93.1 (C^7), 80.5 (C^3), 49.9 and 50.7 (C^1 and C^5), 36.7 and 37.2 (C^6). − MS(CI)(NH_3); *m*/*z*: 624 [MNH_4^+], 607 [MH^+].

Complex 15: $LiN(CHMe_2)_2$ (1.1 mmol) was added at −78°C, under nitrogen to a solution of complex **6a** (388.8 mg; 1.43 mmol) in 5 mL of THF. After 15 min, this red solution was transferred through a canula to another flask containing a solution of tricarbonyl(*p*-fluorotoluene)chromium complex **13** (369.2 mg; 1.50 mmol) in 5 mL of THF. After 30 min of stirring at room temperature, the mixture was extracted with water and diethyl ether. The ether layer was washed with brine, dried with $MgSO_4$, concentrated, and purified by chromatography on a silica gel column. Eluting with a mixture of diethyl ether/petroleum ether (2:98) gave tricarbonyl(*p*-fluorotoluene)chromium complex **13** (160.6 mg, 0.65 mmol, 43% yield); elution with a mixture of diethyl ether/petroleum ether (60:40) gave complex **15** (157.3 mg, 0.56 mmol, 40% yield). M.p. 123°C. − IR ($CHCl_3$): $\tilde{\nu}$ = 1900 cm^{-1} and 1945 (CO), 2220 (CN). − ^1H NMR (400 MHz, [D_6]acetone): δ = 5.89 (d, *J* = 6.2 Hz, 2 H, H^3 and H^5), 5.58 (d, *J* = 6.2 Hz, 1 H, H^2 or H^6), 5.55 (d, *J* = 6.2 Hz, 1 H, H^6 or H^2), 4.01 (q, *J* = 7.2 Hz, 1 H, H^7), 2.24 (s, 3 H, CH_3), 1.66 (d, *J* = 7.2 Hz, 3 H, CH_3). − ^{13}C NMR (50 MHz, [D_6]acetone): δ = 233.8 (Cr−CO), 120.5 (CN), 111.3 (C^1), 106.8 (C^4), 94.5 and 95.5 (C^3 and C^5), 93.8 and 94.0 (C^2 and C^6), 28.6 (C^7), 21.4 (CH_3), 20.2 (CH_3). − $C_{13}H_{11}CrNO_3$ (281.23): calcd. C 55.52, H 3.94, N 4.98; found C 55.74, H 3.75, N 4.31.

Complex 14: $LiN(CHMe_2)_2$ (1.1 mmol) was added at −78°C under nitrogen to a solution of complex **15** (39.6 mg; 0.14 mmol) in 10 mL of THF. After 10 min, this solution was transferred through a canula to a suspension of benzenetricarbonylmanganese complex **5** (57.9 mg; 0.16 mmol) in 5 mL of THF. After 5 min at room temperature, the mixture was extracted with water and diethyl ether, the organic layer was washed with brine and concentrated to give 52.3 mg of a yellow powder, consisting of a mixture of compounds **14** (yield 37%) and **15** (yield 63%). Chromatography of this mixture on silica gel 15 μ column, leads only to the recovery of complex **15**. − IR ($CHCl_3$): $\tilde{\nu}$ = 1905 cm^{-1} and 1920 (Cr−CO), 1945 and 2010 (Mn−CO), 2240 (CN). − ^1H NMR (200 MHz, [D_6]acetone): δ = 5.84 (dd, *J* = 6.8 and 1.6 Hz, 1 H, H^{10} or H^{12}), 5.76 (dd, *J* = 6.8 and 1.6 Hz, 1 H, H^{12} or H^{10}), 5.50 (dd, *J* = 6.8 and 1.6 Hz, 1 H, H^9 or H^{13}), 5.43 (d, *J* = 6.8 Hz, 1 H, H^{13} or H^9), 5.30 (m, 2 H, H^2 and H^4), 3.54 (t, *J* = 5.9 Hz, 1 H, H^3), 3.40 (m, 1 H, H^1 or H^5), 3.32 (t, *J* = 5.9 Hz, 1 H, H^5 or H^1), 3.12 (t, *J* = 5.9 Hz, 1 H, H^6), 2.33 (s, 3 H, CH_3), 1.47 (s, 3 H, CH_3). − ^{13}C NMR (50 MHz, [D_6]acetone): δ = 233.8 (Cr−CO), 223.2 (Mn−CO), 124.5 (CN), 112.5 (C^8), 106.1 (C^{11}), 99.3 and 99.4 (C^2 and C^4), 97.0 (C^{10} and C^{12}), 92.4 and 92.5 (C^9 and C^{13}), 54.7 (C^3), 54.1 (C^1 and C^5), 47.1 (C^6), 21.4 (C^7), 20.6 (CH_3), 20.2 (CH_3). − MS(CI)(NH_3); *m*/*z*: 515 [MH_4^+], 498 [MH^+].

Reaction of the Anion of (Benzyl methyl ether)tricarbonylchromium Complex 23 with Complexes 5, $5P_1$, $5P_2$. − Typical Procedure: 750 μl of *n*BuLi (1.2 mmol) was added at −40°C to a solution of (benzyl methyl ether)tricarbonylchromium complex **23** (258.2 mg; 1.00 mmol) in THF (20 mL). After 1 h, this solution was transferred under nitrogen through a canula to a suspension of benzenetricarbonylchromiummanganese complex **5** (434.4 mg; 1.2 mmol) in 5 mL of THF. The mixture was extracted with water and diethyl ether. The organic phase was washed with brine, dried with $MgSO_4$ and concentrated to give an oil which was purified by chromatography on a silica gel (15 μ) column. Elution with a mixture of petroleum ether/diethyl ether (92:8) gave complex **25** (96.4 mg; 0.285 mmol, 29% yield); with a mixture of petroleum ether/diethyl ether (78:22), complex **24a** (193.5 mg; 0.408 mmol, 41% yield) was isolated.

Complex 24a: Yellow oil. − IR ($CHCl_3$): $\tilde{\nu}$ = 1940 cm^{-1} and 2010 (Mn−CO), 1895 and 1970 (Cr−CO). − ^1H NMR (200 MHz, $CDCl_3$): δ = 5.79 (t, *J* = 6.0 Hz, 1 H, H^3), 5.39 [m, 2 H, H^{10} and H^{12} (or H^9 and H^{13})], 5.23 (t, *J* = 6.3 Hz, 1 H, H^{11}), 5.11 [m, 2 H, H^9 and H^{13} (or H^{10} and H^{12})], 4.91 (m, 2 H, H^2 and H^4), 3.44 (s, 3 H, OMe), 3.30 (t, *J* = 6.0 Hz, 1 H, H^1 or H^5), 3.03 (s, 1 H, H^7), 2.83 (t, *J* = 6.0 Hz, 1 H, H^5 or H^1), 2.60 (m, 1 H, H^6). − ^{13}C NMR (50 MHz, $CDCl_3$): δ = 232.7 (Cr−CO), 222.2 (Mn−CO), 107.1 (C^8), 96.8 and 97.0 (C^2 and C^4), 90.7 (C^{11}), 89.8, 90.9, 93.1 and 94.1 (C^9, C^{10}, C^{12} and C^{13}), 87.0 (C^6), 80.4 (C^3), 59.9 (OMe), 56.7 (C^7), 51.7 and 54.6 (C^1 and C^5). − $C_{20}H_{15}CrMnO_7$ (474.27) calcd. C 50.65; H 3.19; found C 51.09, H 3.45.

Complex 25: Yellow oil. − IR ($CHCl_3$): $\tilde{\nu}$ = 1940 cm^{-1} and 2010 (CO). − ^1H NMR (200 MHz, $CDCl_3$): δ = from 7.08 to 7.37 (several m, H^9, H^{10}, H^{11}, H^{12} and H^{13}), 5.78 (tt, 1 H, H^3, *J* = 5.9 and 1.1 Hz), 4.89 [tt, 1 H, H^2 (or H^4), *J* = 5.9 and 1.1 Hz], 4.80 [tt, 1 H, H^4 (or H^2), *J* = 5.9 and 1.1 Hz], 3.48 [m, 1 H, H^1 (or H^5)], 3.05 (s, 3 H, OMe), 3.01 (d, 1 H, H^7, *J* = 8.7 Hz), 2.76 (m, 1 H, H^6), 2.52 [tt, 1 H, H^5 (or H^1), *J* = 5.9 and 1.1 Hz]. − ^{13}C NMR (50 MHz, $CDCl_3$): δ = 222.8 (Mn−CO), 137.8 (C^8), 127.6 and 128.4 (C^9, C^{10}, C^{12} and C^{13}), 128.0 (C^{11}), 96.4 and 96.7 (C^2 and C^4), 90.5 (C^7), 80.0 (C^3), 56.7 (OMe), 52.5 and 56.8 (C^1 and C^5), 41.6 (C^6). − $C_{17}H_{15}MnO_4$ (338.21): calcd. C 60.37, H 4.47; found C 59.80, H 4.90.

Complex 24b: Same method as for **24a** (yield 55%), yellow oil. − IR ($CHCl_3$): $\tilde{\nu}$ = 1965 cm^{-1}, 1945, 1880 (CO). − ^1H NMR (400 MHz, $CDCl_3$): δ = 5.53 (t, *J* = 3.6 Hz, 1 H, H^3), 5.40 (m, 2 H, H^{10}, H^{12} or H^9, H^{13}), 5.26 (t, J = 6.6 Hz, 1 H, H^{11}), 5.18 (m, 2 H, H^9, H^{13} or H^{10}, H^{12}), 4.73 (m, 2 H, H^2 and H^4), 3.92 [m, 6 H, $P(OCH_2CH_3)$], 3.47 (s, 3 H, OCH_3), 3.04 (m, 1 H, H^5 or H^1), 2.62 (m, 2 H, H^6 and H^7), 2.54 (m, 1 H, H^1 or $H^{5)}$, 1.27 [t, *J* = 7.0 Hz, 9 H, $P(OCH_2CH_3)$]. − ^{13} C NMR (100 MHz, $CDCl_3$): δ = 233.1 (CO−Cr), 229.0 (d, *J* = 31.1 Hz, CO−Mn), 108.3 (C^8), 95.3 and 95.5 (C^2 and C^4), 93.6, 94.1, 91.1, 90.0 (C^9, C^{10}, C^{11}, C^{12}, C^{13}), 87.0 (C^6), 79.5 (C^3), 60.3 [$P(OCH_2CH_3)_3$], 59.8 (OCH_3), 48.5 and 51.4 (C^1 and C^5), 42.7 (C^7), 16.2 and 16.5 [$P(OCH_2CH_3)_3$]. − $C_{25}H_{30}CrMnO_9P$ (612.43): calcd. C 49.03, H 4.94; found C 48.81, H 4.85.

Complex 24c: Same method as for **24a** (yield 47%), yellow oil. − IR ($CHCl_3$): $\tilde{\nu}$ = 1950 cm^{-1}, 1850, 1810. − ^1H NMR (200 MHz, $CDCl_3$): δ = 5.33, 5.18 (2 m, 6 H, H^9, H^{10}, H^{11}, H^{12}, H^{13}, and H^3), 4.53 (m, 2 H, H^2 and H^4), 3.92 [m, 12 H, $P(OCH_2CH_3)$], 3.41 (s, 3 H, OCH_3), 2.61 (m, 1 H, H^5 or H^1), 2.51 (m, 1 H, H^6), 2.15 (m, 1 H, H^7), 2.05 (m, 1 H, H^1 or H^5), 1.20 [t, *J* = 7.0 Hz, 18 H, $P(OCH_2CH_3)$]. − ^{13}C NMR (50 MHz, $CDCl_3$): δ = 233.4 (CO−Cr), 230.4 (m, CO−Mn), 109.6 (C^8), 93.2 and 93.7 (C^2 and C^4), 89.9, 91.0, 91.2, 93.9, 94.1 (C^9, C^{10}, C^{11}, C^{12}, C^{13}), 87.2 (C^6), 76.8 (C^3), 59.7 [$P(OCH_2CH_3)$ and OCH_3], 45.2 and 47.8 (C^1 and C^5), 42.3 (C^7), 16.4 [$P(OCH_2CH_3)_3$]. − $C_{30}H_{45}CrMnO_{11}P_2$ (750.58): calcd. C 48.01, H 6.04; found C 48.06, H 6.09.

Reaction of the Anion of (Benzyl methyl ether)tricarbonylchromium Complex 23 with Anisolemanganese Complexes 26a and 26b. − Typical Procedure: To a solution of complex **23** (258 mg, 1 mmol)

in THF (20 mL) at −78° C was added *n*BuLi (1.2 mmol). After stirring for 1 h at −40°C, this solution was added through a canula to cationic complex **26a** (470 mg, 1.2 mmol), dissolved in freshly distilled THF (5 mL). The reaction mixture turned orange and was stirred at room temperature for 15 min, then treated with distilled water and Et_2O. After extraction, the organic phase was washed with brine and dried with $MgSO_4$. Concentration of the organic phase under a nitrogen flow gave a yellow oil which was separated by chromatography. Dinuclear complex **27a** (2 diastereoisomers in a 1:1 ratio) was isolated first by eluting with an Et_2O/petroleum ether (15:100) mixture (239 mg, 0.47 mmol, 47% yield). Then starting complex **23** (123 mg, 0.26 mmol, 26% yield) was obtained by eluting with an Et_2O/petroleum ether (20:100) mixture.

Complex 27a: Yellow oil. − IR ($CHCl_3$): $\tilde{\nu}$ = 2005 cm^{-1}, 1930 (CO−Mn), 1970, 1890 (CO−Cr). − ^1H NMR (200 MHz, $CDCl_3$): δ = 5.67 (m, 2 H, H^3), 5.38 (m, 4 H, H^9 and H^{13}), 5.20 (m, 4 H, H^{10} and H^{12}), 5.07 (t, *J* = 6.0 Hz, 2 H, H^{11}), 4.92 (m, 2 H, H^4), 3.51 and 3.49 (s, 6 H, OCH_3 at C_2), 3.44 (s, 6 H, OCH_3 at C^7), 4.19 (m, 4 H, H^1 or H^7), 2.72 (m, 8 H, H^1, H^5, H^6 and H^{11}). − ^{13}C NMR (100 MHz, $CDCl_3$): δ = 232.9 (CO−Cr), 222.2 (CO−Mn), 143.5 (C^2), 110.8 (C^8), 94.2 (C^9 and C^{13}), 93.3 and 93.7 (C^4) 93.0 (C^{11}) 90.9 (C^9, C^{13}, C^{10}, C^{12}), 90.0 (C^{10}, C^{12}), 87.0 and 87.3 (C^6), 67.9 and 68.5 (C^3), 59.9 (OCH_3 at C^7), 55.0 (C^7), 54.4 (OCH_3 at C_2), 52.4 (C^7), 45.1 (C^5), 38.3 and 40.0 (C^1). − $C_{21}H_{17}CrMnO_8$ (504.30): calcd. C 50.02, H 3.40; found C 50.09, H 3.35.

Complex 27b: Same procedure as for **27a**. Yield: 64% of **27b** (2 diastereoisomers in a 1:1 ratio), yellow oil. − IR ($CHCl_3$): $\tilde{\nu}$ = 1965 cm^{-1}, 1870 (CO−Cr), 1940, 1880 (CO−Mn). − ^1H NMR (400 MHz, $CDCl_3$): δ = 5.33 (m, 5 H, 2 H^3, 2 H^9 and 1 H^{13}), 5.13 (m, 7 H, 2 H^{10} 2 H^{11}, 2 H^{12}, and 1 H^{13}), 4.67 (m, 2 H, H^4), 3.85 [m, 12 H, $P(OCH_2CH_3)$], 3.39 (s, 6 H, OCH_3 at C^7), 3.38 (s, 3 H, OCH_3 at C^2), 3.37 (s, 3 H, OCH_3 at C^2: the other diast.), 3.04 (m, 1 H, H^1) 2.75 (m, 1 H, H^7), 2.65 (m, 2 H, H^5), 2.54 (m, 3 H, H^2 and H^6), 2.27 (m, 1 H, H^7), 1.27 [m, 18 H, $P(OCH_2CH_3)$]. − ^{13}C NMR (100 MHz, $CDCl_3$): δ = 232.0 (CO−Cr), 223.3 and 230.4 (m, CO−Mn), 139.5 (C^2), 107.2 (C^8), 93.0 (C^9, C^{13}), 92.5 and 92.7 (C^4) 92.4 (C^{11}), 89.9 and 90.1 (C^9 and C^{13}), 88.8, 89.0 and 89.8 (C^{10} and C^{12}), 86.0 and 86.4 (C^6), 66.7 and 67.1 (C^3), 59.2 [$P(OCH_2CH_3)$], 58.7 (OCH_3 at C^7), 53.1 and 52.8 (OCH_3 at C^2), 48.1 and 50.9 (C^7), 43.8 and 43.9 (C^5), 34.4 and 36.6 (C^1), 15.2 [$P(OCH_2CH_3)$]. − ^{31}P NMR (162 MHz, $CDCl_3$): δ = 196.7, 198.0. − $C_{26}H_{32}MnCrO_{10}P$ (642.45): calcd. C 48.61, H 5.02; found C 48.66, H 5.16.

Complex Catalysis 55[+]

Oxidative Addition Reactions of Organorhodium(I) Complexes Containing the Tridentate Ligand 2,6-Bis(diphenylphosphanylmethyl)pyridine [Rh(PNP)R] ($R = CH_3$, C_6H_5) with Iodine and Methyl Iodide and Investigation of the Reductive Elimination

Christine Hahn,[a] Michael Spiegler,[b] Eberhardt Herdtweck,[b] and Rudolf Taube*[b]

Dedicated to Professor Helmut Werner on the occasion of his 65th birthday

Keywords: Rhodium(III) complexes / Tridentate ligand / Oxidative addition / Reductive elimination / C–C coupling

As part of studies aimed at delineating the mechanism of the rhodium complex-catalyzed hydroamination of olefins, the model complexes [Rh(PNP)R] (R = CH_3 **1a**, C_6H_5 **1b**) have been investigated with regard to oxidative addition reactions. The reaction of I_2 with **1a** leads to both *trans*- and *cis*-[Rh(PNP)(CH_3)I_2] (*trans*: **2a**, *cis*: **2a′**), whereas with **1b** only *trans*-[Rh(PNP)(C_6H_5)I_2] (**2b**) is obtained. The rhodium(III) complexes [Rh(PNP)(CH_3)RI] (**3a**,**b**) are formed by the reaction of **1a**,**b** with CH_3I. The new organorhodium(III) complexes **2a**,**b** and **3a**,**b** have been characterized by ^{31}P-, ^{1}H-, and ^{13}C-NMR spectrometry, as well as by EI mass spectrometry. The hydrocarbons RCH_3 are reductively eliminated in the reaction of [Rh(PNP)(CH_3)RI] (**3a**,**b**) with $TlBF_4$ in acetone, while the reaction of **3b** and $TlBF_4$ in THF/CH_3CN leads to the stable rhodium(III) complex [Rh(PNP)(CH_3)(C_6H_5)(CH_3CN)]BF_4 (**5**). Complex **5** has been characterized by X-ray crystallography.

Introduction

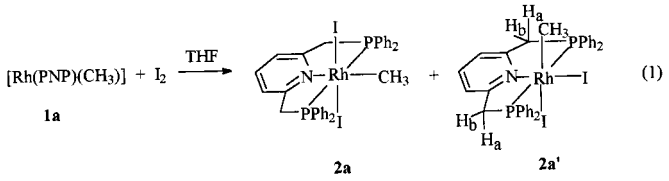
Detailed model studies have been initiated aimed at elucidating the reaction mechanism of the rhodium complex-catalyzed hydroamination of ethylene.[1] For the first time, the process was shown to be catalyzed by a cationic ethylene rhodium(I) complex under normal conditions.[2] For these studies, model complexes containing the 2,6-bis(diphenylphosphanylmethyl)pyridine-rhodium(I) fragment [Rh(PNP)]$^+$ as a stable structural unit were synthesized and characterized.[3]

Since the formation and cleavage of an Rh−C σ-bond is expected to play an essential role in this catalytic cycle, organorhodium(I) complexes [Rh(PNP)R] (R = CH_3, C_6H_5) were synthesized and investigated with regard to the coordination of ethylene and protolysis. It was found that with protic acids such as HSO_3CF_3 and [$HN(CH_3)_3$]Cl, these organorhodium(I) complexes react by immediate release of the hydrocarbon HR, presumably via reductive elimination from an initially formed hydrido organorhodium(III) complex.[4]

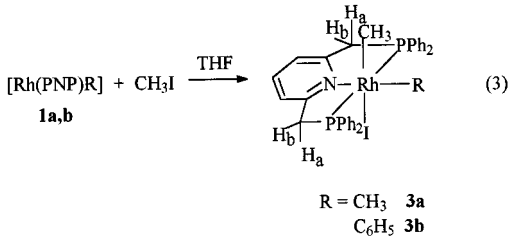
While a hydrido organorhodium(III) complex, which might have been expected to be formed by oxidative addition of the protic acid, could not be isolated or detected in these cases, a stable monohydrido chloro rhodium(III) complex [Rh(PNP)HCl(CH_3CN)]SO_3CF_3 is accessible by oxidative addition of HSO_3CF_3[4] to the related chloro rhodium(I) complex [Rh(PNP)Cl].[3b,5] Since the oxidative addition and the reductive elimination involved in numerous other rhodium-complex catalyzed processes are of general importance[6] it seemed therefore interesting to study these reaction steps at the [Rh(PNP)]$^+$ fragment.

In this paper, we report on oxidative addition reactions of the organorhodium(I) complexes [Rh(PNP)R] (R = CH_3, C_6H_5) with I_2 and CH_3I, as well as on the conditions under which the obtained diorganorhodium(III) complexes [Rh(PNP)(CH_3)RI] undergo reductive elimination.

Results and Discussion



Oxidative Addition Reactions of [Rh(PNP)R] ($R = CH_3$, C_6H_5) with I_2 and CH_3I



In order to show that stable PNP-organorhodium(III) complexes are accessible, the reactivity of organorhodium(I) complexes **1a**,**b** with iodine and methyl iodide, which are known as suitable reagents for oxidative addition to rhodium(I) complexes,[7] was investigated. Both organorhodium(I) complexes **1a**,**b** were found to react smoothly with iodine to give the corresponding rhodium(III) complexes [Rh(PNP)I_2R] **2** [Eqs. (1) and (2)], which were isolated as brown, air-stable solids.

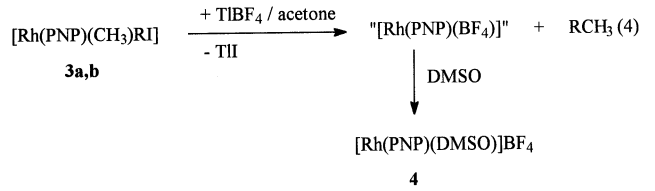
In the case of the methyl complex, the formation of the *trans* as well as of the *cis* addition product (**2a** and **2a′**, respectively) was established by NMR spectrometry. The two isomers constantly crystallize as a mixture, however, no further attempts were made to separate **2a** and **2a′** by other methods. In the ^{31}P-NMR spectrum, two doublets are observed at δ = 14.3 (J_{P-Rh} = 99 Hz) for **2a** and at δ = 23.3 (J_{P-Rh} = 106 Hz) for **2a′**, in an intensity ratio of 3:2. The phosphorus-rhodium coupling constants are markedly lower in comparison to those in the organorhodium(I) complexes **1a**,**b**, indicating the Rh^{III} oxidation state.[8] Accordingly, in the ^{1}H-NMR spectrum, two discrete methyl group signals are observed at δ = 1.99 for **2a** and at δ = 0.43 for **2a′**, with the same relative intensities of 3:2. The corresponding characteristic signal patterns of the methylene protons of the PNP ligand, a pseudo triplet at δ = 4.84 for **2a** and two doublets of pseudo triplets at δ = 4.49 and 4.80 for **2a′**, are consistent with the symmetry of these *trans* and *cis* isomers. In the ^{13}C-NMR spectrum, two discrete signals at δ = −18.4 and δ = 8.7 are observed for the methyl groups, while for the methylene groups of the PNP ligand, two signals appear at δ = 44.7 and δ = 46.7, showing slightly different intensities.

The phenyl complex **1b** forms exclusively the *trans* addition product **2b** on reaction with iodine [Eq. (2)]. The ^{31}P-NMR spectrum exhibits only one doublet at δ = 18.8 (J_{P-Rh} = 105 Hz). The pseudo triplet for the methylene group is seen at δ = 4.90 in the ^{1}H-NMR spectrum, consistent with the C_2 symmetry of the *trans*-diiodo complex **2b**. The ^{1}H-NMR signals of the phenyl moiety in **2b** are slightly downfield shifted compared to those found for **1b**, appearing at δ = 6.88 and 7.96.

In the mass spectra of **2a**,**a′** (analyzed as an isomeric mixture) and of **2b**, peaks are observed corresponding to the fragments $[M - I]^+$, $[M - R]^+$, $[M - I - R]^+$, $[M - I - I]^+$, and $[M - I - I - R]^+$. Additionally in the mass spectrum of **2a**,**a′**, a peak at *m*/*z* = 142 is found, which can be assigned to $[CH_3I]^+$ as the product of reductive elimination.

The reactions of **1a**,**b** with methyl iodide [Eq. (3)] led to the diorganorhodium(III) complexes [Rh(PNP)(CH_3)RI] **3a**,**b**, which were isolated as pale-yellow air-stable solids and characterized by ^{31}P-, ^{1}H-, and ^{13}C-NMR spectrometry, as well as by mass spectrometry.

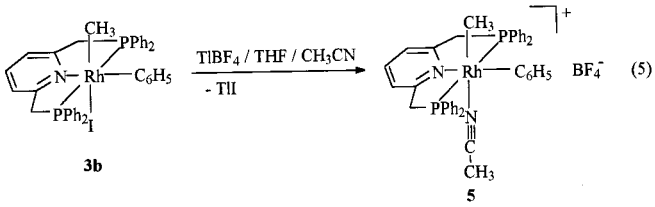
The ^{31}P-NMR signals observed at δ = 26.5 (J_{P-Rh} = 120 Hz) for **3a** and at δ = 30.5 (J_{P-Rh} = 119 Hz) for **3b** are downfield shifted in comparison to the signals of the corresponding diiodo complexes **2a** and **2b**. The increased phosphorus-rhodium coupling constants in **3a**,**b** in comparison to those in **2a**,**b** may be arised by coordination of the more basic methyl ligand instead of one iodo ligand, respectively. In the ^{1}H-NMR spectrum of the dimethyl complex **3a**, two discrete methyl signals are observed at δ = −0.35 and δ = 1.02, suggesting the coordination of two distinct methyl groups in a mutual *cis*-arrangement. This is confirmed by the resonances of the methylene protons of the PNP ligand, which appear as two doublets of pseudo triplets at δ = 4.31 and 4.66, consistent with the inequivalence of the methylene protons arising from the *cis* orientation of the methyl groups. Accordingly, in the ^{13}C-NMR spectrum, two discrete signals for the methyl groups are observed at δ = −14.5 and 6.9.



The ^{1}H-NMR signal of the methyl group in the methyl phenyl complex **3b** appears at δ = 0.35, while the phenyl group gives rise to multiplets at δ = 6.90 and 7.68. The typical signal pattern for the non-equivalent methylene protons, as observed for **3a**, is seen in the spectrum of **3b** at δ = 4.34 and 4.80. The ^{13}C-NMR signal for the methyl group in **3b** appears at δ = 8.8, while the phenyl group signals are seen at δ = 121.5, 125.9, and 142.3.

In the mass spectra of **3a** and **3b**, peaks are observed corresponding to the fragments $[M - CH_3]^+$, $[M - CH_3 - R]^+$, and $[M - CH_3 - R - I]^+$. Additionally, in the mass spectrum of **3b**, a peak at *m*/*z* = 91 can be observed, attributable to $[C_7H_7]^+$. This suggests that toluene is reductively eliminated from the methyl phenyl complex **3b** following C−C bond formation.

Investigation of the Reductive Elimination of Hydrocarbons by C−C Bond Formation from [Rh(PNP)(CH_3)RI]BF_4 3a,b



In a manner analogous to the reductive elimination of the hydrocarbon from the proposed hydrido organorhodium(III) intermediates by formation of a C−H bond,[4,9] the reactivity of the diorganorhodium(III) complexes **3a**, **b** was investigated. The aforementioned mass spectral observation of toluene generation from **3b** gave a prior indication of C−C bond formation between the two organo moieties. After addition of $TlBF_4$ to a solution of **3a** or **3b** in acetone, TlI precipitated while the solution changed colour from pale yellow to dark-red during 1−2 days indicating the

change of the oxidation state from Rh^{III} to Rh^{I}. Indeed, the hydrocarbon which is formed by reductive elimination from **3a** and **3b**, respectively [Eq. (4)], has been proved. Carrying out the reaction of **3a** and $TlBF_4$ in [D_6]acetone in a sealed NMR tube the singlet of the liberated ethane could be observed in the ^{1}H-NMR spectrum while the signals of complex **3a** disappeared. Whereas the toluene reductively eliminated from **3b** was detected in the filtrate of the reaction solution by gas chromatography. The dark colour of the solutions indicated a decomposition reaction, most likely as a consequence of the weak coordination of the acetone, which does not have sufficient donor strength to stabilize the remaining $[Rh^{I}(PNP)]^+$ fragment. In order to prove that the rhodium was present in the +I oxidation state, some DMSO was added to the solution. The corresponding stable rhodium(I) complex $[Rh(PNP)(DMSO)]BF_4$ **4** was obtained, which was identified by comparison of its ^{31}P-NMR spectrum with that of an authentic sample (cf. ref.[3b]).

Clearly, the cleavage of the iodo ligand from the octahedral diorganorhodium(III) complex **3a**,**b** leads to a kinetically unstable five-coordinate complex, which cannot be stabilized by the weakly coordinating acetone used as solvent. This confirms the dissociative mechanism of the reductive elimination.[9]

However, when the reaction of **3b** with $TlBF_4$ was carried out in the presence of the more strongly coordinating acetonitrile, a stable six-coordinate methyl phenyl acetonitrile rhodium(III) complex $[Rh(PNP)(CH_3)(C_6H_5)(CH_3CN)]BF_4$ **5** was obtained [Eq. (5)], which was isolated as an air-stable, white, crystalline solid and characterized by ^{31}P-, ^{1}H-, and ^{13}C-NMR spectrometry, as well as by X-ray crystal structure analysis.

In the ^{31}P-NMR spectrum of **5**, the doublet at $\delta = 32.7$ ($J_{P-Rh} = 117$ Hz) is somewhat downfield shifted compared to the corresponding signal in the iodo complex **3b**. While the ^{1}H- and ^{13}C-NMR signals of the phenyl moiety appear at approximately the same chemical shifts as found for **3b**, the signals for the methyl moiety of **5** are somewhat upfield shifted in both the ^{1}H- ($\delta = 0.09$) and the ^{13}C-NMR spectra ($\delta = 2.0$), compared to those in **3b**. This may be interpreted in terms of the differential *trans* influence of the respective *trans*-coordinated ligands (I^- **3b**; CH_3CN **5**).

For the coordinated acetonitrile in **5**, a singlet is observed at $\delta = 1.45$ in the ^{1}H-NMR spectrum, while in the ^{13}C-NMR spectrum, two signals are observed at $\delta = 2.0$ and 128.5. In the IR spectrum, the two bands characteristic of end-on coordinated acetonitrile[9] are seen at $\tilde{\nu} = 2281$ and 2376 cm^{-1}. The coordination of the pyridine of the PNP ligand is indicated by two bands at $\tilde{\nu} = 1574$ and 1606 cm^{-1},[11] while a strong band at $\tilde{\nu} = 1062$ cm^{-1} is characteristic of the non-coordinated BF_4^- anion.[12]

Single crystals of **5** of X-ray quality were obtained from a solution of the complex in acetone overlayered with diethyl ether. X-ray crystal structure analysis confirmed the *cis*-arrangement of the organo moieties in the octahedral complex cation of **5**, which is an essential structural prerequisite for the reductive elimination of toluene. The molecular structure of the complex cation $[Rh(PNP)(CH_3)(C_6H_5)(CH_3CN)]^+$ is shown in Figure 1.

Comparing the rhodium-carbon distances of the σ-bonded methyl and phenyl groups [Rh−C(3) 2.085(3), Rh−C(11) 2.049(3)], only a very slight difference is apparent. The small difference in bond lengths of the two types of Rh−C bond may be viewed as reflecting the differential *trans* influence of the N(sp^2) and N(sp) atoms of the coordinated pyridine moiety and acetonitrile ligand, respectively, which gives rise to an extension of the Rh−C(sp^2) bond and a shortening of the Rh−C(sp^3) bond. However, it may also be viewed as merely following the expected trend that the sp^2 carbon atom has a shorter distance to the rhodium atom than the sp^3 carbon atom.

Furthermore, it is interesting to compare the molecular structure of **5** with that of the related cationic Rh^{III} complex $[Rh(PNP)ClH(CH_3CN)]SO_3CF_3$,[4] which contains the same structural unit $[Rh^{III}(PNP)(CH_3CN)]^+$, but with the hydrido ligand coordinated *trans* to the acetonitrile ligand. In both complexes, the N atom of the coordinated acetonitrile shows an identical distance to the rhodium atom of 2.14 Å, as a result of the comparable *trans* influence of the methyl and hydrido ligands. However, the distance of the pyridine N atom to the rhodium atom in **5** is significantly longer [Rh−N(2) 2.152(2) Å] than the corresponding Rh−N(py) distance in the hydrido chloro Rh^{III} complex [Rh−N(2) 2.0656(17) Å].[4] This is consistent with the expected stronger *trans* influence of the phenyl group, which has a lower electronegativity than the chloro ligand coordinated *trans* to the pyridine. The end-on coordinated acetonitrile shows an almost linear arrangement of Rh−N(1)−C(1)−C(2) [C(1)−N(1)−Rh 172.0(2)°, N(1)−C(1)−C(2) 178.4(4)°], as was also found in the cationic Rh^{III} complex $[Rh(PNP)ClH(CH_3CN)]SO_3CF_3$,[4] as well as in the cationic rhodium(I) complex $[Rh(PNP)(CH_3CN)]BF_4$.[3b]

Conclusions

The organorhodium(I) complexes [Rh(PNP)R] smoothly undergo oxidative addition reactions with I_2 and CH_3I to give the stable organorhodium(III) complexes $[Rh(PNP)RI_2]$ and $[Rh(PNP)(CH_3)RI]$, respectively.

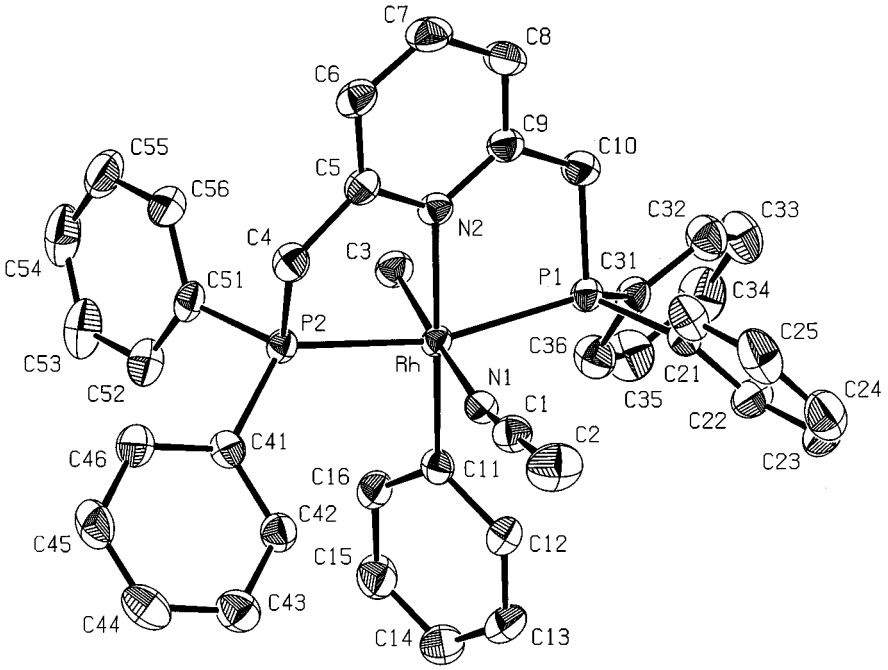


Figure 1. PLATON[13] drawing of the structure of the complex cation of $[Rh(PNP)(C_6H_5)(CH_3)(CH_3CN)]BF_4$ **5**. Selected bond lengths [Å] and angles [°]: Rh−N(1) 2.142(3), Rh−N(2) 2.152(2), Rh−C(3) 2.082(3), Rh−C(11) 2.049(3), Rh−P(1) 2.2913(9), Rh−P(2) 2.3098(8), P(1)−C(10) 1.848(5), P(2)−C(4) 1.835(3); P(1)−Rh−P(2) 164.58(3), N(1)−Rh−P(1) 93.92(7), N(1)−Rh−P(2) 89.55(7), N(1)−Rh−N(2) 88.56(9), C(3)−Rh−C(11) 91.77(12), N(1)−Rh−C(3) 176.65(11), N(2)−Rh−C(11) 179.9(2), C(1)−N(1)−Rh 172.0(2), N(1)−C(1)−C(2) 178.4(4).

It was shown that the diorganorhodium(III) complexes $[Rh(PNP)(CH_3)RI]$, in which the organo moieties are coordinated in a *cis* arrangement, C−C bond formation leading to the reductive elimination of the hydrocarbons RCH_3 is possible. This was realized by cleavage of the iodo ligand with $TlBF_4$ in the presence of acetone. Acetone is too weakly coordinating as a ligand to stabilize the resulting five-coordinate diorganyl rhodium(III) complex. However, when the reaction is carried out in the presence of the more strongly coordinating CH_3CN, the stable six-coordinate acetonitrile complex $[Rh(PNP)(CH_3)(C_6H_5)(CH_3CN)]BF_4$ is formed, confirming the dissociative mechanism of the reductive elimination.

The smooth oxidative addition reactions of the model compounds [Rh(PNP)R], and the stability as well as the reactivity of the Rh-C σ-bond in the rhodium-PNP complexes suggests that rhodium(I) has the potential to catalyze the hydroamination of olefins according to the proposed catalytic reaction mechanism.[4]

Experimental Section

All reactions were carried out under dry argon. Acetone, [D$_6$]acetone, CD_2Cl_2, and $CDCl_3$ were refluxed over 4-Å molecular sieves and purged of oxygen by bubbling argon. THF and diethyl ether were refluxed over Na/benzophenone. Acetonitrile, DMSO, and methyl iodide were dried over 4-Å molecular sieves and distilled prior to use.

Infrared spectra were recorded from KBr pellets on a Perkin-Elmer FT-IR 16 spectrometer. − The ^{1}H-, ^{13}C{^{1}H}-, and ^{31}P{^{1}H}-NMR spectra were recorded at 300, 75, and 121 MHz, respectively, on a Varian Gemini 300 NMR spectrometer. The ^{1}H- and ^{13}C-NMR shifts were referenced to the solvent signals, while the ^{31}P-NMR shifts were referenced to external 85% H_3PO_4. − A Chrompack CP 9000 gas chromatograph was used for the identification of liquid organic compounds. − EI mass spectra were recorded on an AMD 402 spectrometer (AMD Intectra) at 70 eV. − C,H,N elemental analyses were carried out on a LECO CHN 932 analyzer, while Rh was determined using a photometric method.[14]

Synthesis of $[Rh(PNP)RI_2]$ (R = CH_3 *trans:* 2a, *cis*: 2a′; C_6H_5 2b): 237 mg of I_2 (0.93 mmol) in 2 mL of THF was added to a solution of 552 mg (0.93 mmol) of **1a** in 4 mL of THF. After a few seconds, a brown, microcrystalline solid precipitated, and the reaction mixture was stirred for 10 min. After a further 30 min (without stirring), the solid was filtered off and washed with THF and diethyl ether. The crude product was recrystallized from refluxing THF. The recrystallized product was washed twice with THF and twice with diethyl ether and dried in vacuo.

The synthesis of **2b** was carried out in the same manner as described for **2a/a′**, starting from 572 mg (0.87 mmol) of **1b** in 4 mL of THF and 222 mg of I_2 dissolved in 2 mL of THF. Yield: 565 mg (0.62 mmol, 71%); m.p. 293°C (dec.). − $C_{37}H_{32}I_2NP_2Rh$ (909.33): calcd. C 48.87, H 3.55, N 1.54, Rh 11.32; found C 49.05, H 3.95, N 1.31, Rh 11.42. − ^{31}P NMR (CD_2Cl_2): δ = 18.8 (d, J_{P-Rh} = 105 Hz). − ^{1}H NMR (CD_2Cl_2): δ = 4.90 (ps. t, N_{H-P} = 4.7 Hz, 4 H, CH_2), 6.88 (m, 3 H, Ph), 7.26−7.38 (m, 20 H, PPh), 7.60 (d, J_{H-H} = 7.7 Hz, 2 H, 3,5-py), 7.82 (t, J_{H-H} = 7.7 Hz, 1 H, 4-py), 7.96 (m, 2 H, Ph). − ^{13}C NMR (CD_2Cl_2): δ = 48.1 (ps. t, N = 15.7 Hz, *C*H_2), 121.5 (ps. t, N = 5.3 Hz, $C_{3,5\text{-py}}$), 122.7 (s, Ph), 125.9 (s, Ph), 127.7 (ps. t, N = 5.0 Hz, PC_{meta}), 130.3 (s, PC_{para}), 134.3 (ps. t, N = 4.7 Hz, PC_{ortho}), 135.9 (ps. t, N = 24.5 Hz, PC_{ipso}), 138.8 (s, $C_{4\text{-py}}$), 147.2 (ps. t, N = 4.3 Hz, Ph), 160.4 (ps. t, N < 3 Hz, $C_{2,6\text{-py}}$). − EI-MS: *m/z* (%): 832 (0.4) $[M - C_6H_5]^+$, 781 (12.5) $[M - I]^+$, 705 (100) $[M - I - C_6H_5]^+$, 655 (1.4) $[M - I - I]^+$, 578 (27) $[M - I - I - C_6H_5]^+$.

Synthesis of [Rh(PNP)(CH$_3$)RI] (R = CH_3 **3a**, C_6H_5 **3b**): To a solution of 571 mg (0.96 mmol) of **1a** in 6 mL of THF was added 60 µl of CH_3I (Rh/CH_3I = 1:1). After a few seconds, a pale-yellow microcrystalline solid precipitated and the reaction mixture was stirred for 10 min. After a further 30 min (without stirring), the solid was filtered off and washed with THF and diethyl ether. The crude product was recrystallized by extraction with refluxing THF. The recrystallized product was washed twice with THF, twice with diethyl ether, and dried in vacuo.

3a: Yield: 390 mg (0.53 mmol, 55%); m.p. 214−220°C (dec.). − $C_{33}H_{33}INP_2Rh$ (735.39): calcd. Reactivity of 3a and 3b Toward TlBF$_4$: (a) A mixture of 20 mg (0.027 mmol) of **3a** and 8 mg (0.027 mmol) of $TlBF_4$ in 0.7 mL of [D_6]acetone was shaken in a sealed NMR tube over 2 days. While TlI precipitated the solution changed colour to dark-red. In the ^{1}H-NMR spectrum a singlet is found at δ = 0.82 for ethane, whereas the signals of **3a** completely disappeared.

78 mg (0.27 mmol) of $TlBF_4$ was added to a solution of 215 mg (0.27 mmol) of **3b** in 5 mL of acetone. After stirring overnight, a yellow precipitate of TlI was filtered off. Toluene was detected in the dark-red filtrate by means of gas chromatography. Upon addition of 0.5 mL of DMSO, the solution became orange-red in colour. The DMSO−rhodium(I) complex [Rh(PNP)(DMSO)]BF_4 (**4**) was detected by ^{31}P-NMR spectroscopy (in acetone/external C_6D_6: δ = 40.2, J_{P-Rh} = 148 Hz). This was consistent with an authentic sample, which was prepared from [Rh(PNP)(C_2H_4)]BF_4 and DMSO.[3b]

(b) In the Presence of CH$_3$CN: 322 mg (0.4 mmol) of **3b** was suspended in a mixture of 7 mL of THF and 1 mL of acetonitrile. To this was added 120 mg of $TlBF_4$ and the mixture was stirred overnight. A yellow precipitate of TlI was deposited, which was filtered off. Diethyl ether was added dropwise to the pale-yellow filtrate, resulting in the precipitation of a white, crystalline solid. This was filtered off, washed with diethyl ether, and dried in vacuo. The solid was characterized as [Rh(PNP)(CH_3)(C_6H_5)(CH_3CN)]BF_4 (**5**): Yield: 271 mg (0.34 mmol, 85%); m.p. 146°C (dec.). − $C_{40}H_{38}BF_4N_2P_2Rh$ (798.41): calcd. C 60.17, H 4.80, N 3.51, Rh 12.89; found C 60.30, H 5.28, N 3.75, Rh 12.57. − ^{31}P NMR ($CDCl_3$): δ = 32.7 (d, J_{P-Rh} = 117 Hz). − ^{1}H NMR ($CDCl_3$): δ = 0.09 (td, J_{H-P} = 6.6 Hz, J_{H-Rh} = 1.5 Hz, 3 H, CH_3), 1.45 (s, 3 H, NCH_3), 4.30 (d ps. t, J_{Ha-Hb} = 17.5 Hz, N_{H-P} = 4.3 Hz, 2 H, CH_a), 4.47 (d ps. t, J_{Ha-Hb} = 17.5 Hz, N_{H-P} = 4.2 Hz, 2 H, CH_b), 6.95 (m, 3 H, Ph), 7.07−7.40 (m, 22 H, PPh, Ph), 7.75 (d, J_{H-H} = 7.7 Hz, 2 H, 3,5-py), 7.99 (t, J_{H-H} = 7.7 Hz, 1 H, 4-py). − ^{13}C NMR ($CDCl_3$): δ = 2.03 (s, N*C*H_3), 2.03 (m, overlapped with the N*C*H_3 signal, *C*H_3), 44.7 (ps. t, N = 13.7 Hz, *C*H_2), 120.4 (s, Ph), 122.5 (ps. t, N = 5.6 Hz, $C_{3,5\text{-py}}$), 127.2 (s, Ph), 128.5 (br, *C*N), 128.7 (br, PC_{meta}), 130.7 (s, PC_{para}), 130.8 (s, PC_{para}), 131.7 (ps. t, N = 18.3 Hz, PC_{ipso}), 132.7 (ps. t, N = 5.7 Hz, PC_{ortho}), 132.9 (ps. t, N = 5.6 Hz, PC_{ortho}), 138.1 (ps. t, N < 4.0 Hz, Ph), 139.6 (s, $C_{4\text{-py}}$), 159.1 (ps. t, N < 3 Hz, $C_{2,6\text{-py}}$). − IR (KBr): $\tilde{\nu}$ = 2281, 2376 cm^{-1} (CH_3CN); 1574, 1606 (py); 1062 (BF_4).

Crystal Structure Determination of Compound 5: *Crystal Data:* $C_{40}H_{38}BF_4N_2P_2Rh \cdot (C_4H_{10}O)_{0.8}$, formula weight 857.79 g mol^{-1}, monoclinic, $P2_1/n$ (No. 14), a = 12.6065(6), b = 24.5689(10), c = 13.5059(9) Å, β = 102.356(6)°, V = 4086.3(4) Å^3, Z = 4, d_{calc} = 1.394 g cm^{-3}, F(000) = 1767. − *Data Collection:* STOE-IPDS,[14] Mo-K_α radiation (graphite monochromator, λ = 0.71073 Å), crystal size 0.34 × 0.30 × 0.26 mm^3, T = 193(2) K, scan range 2.0 < θ < 25.7°; intensities were measured for 31092 reflections with 7411 unique reflections, of which 5469 were considered observed [$I \geq 2\sigma(I)$]. The reflections were corrected for Lorentz and polarization effects; μ = 0.55 mm^{-1}, no absorption correction. − *Structural Analysis and Refinement:* Preliminary positions of heavy atoms

were found by direct methods,[16] while positions of the other non-hydrogen atoms were determined from subsequent difference Fourier synthesis coupled with initial isotropic least-squares refinement.[17] An additional diethyl ether solvent molecule was located in the asymmetric unit and refined with 80% partial occupancy. With the exception of those of the solvent molecule, all hydrogen atoms were found in a difference Fourier map and refined with individual isotropic temperature parameters. Refinement: Full-matrix least-squares on F^2; 7070 reflections; 649 refined parameters; final $R_1 = 0.0333$, $wR_2 = 0.0806$, goodness-of-fit on $F^2 = 1.040$.

Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre (CCDC-100736). Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, U.K. [Fax: (internat.) + 44-1223/336033; E-mail: deposit@ccdc.cam.ac.uk].

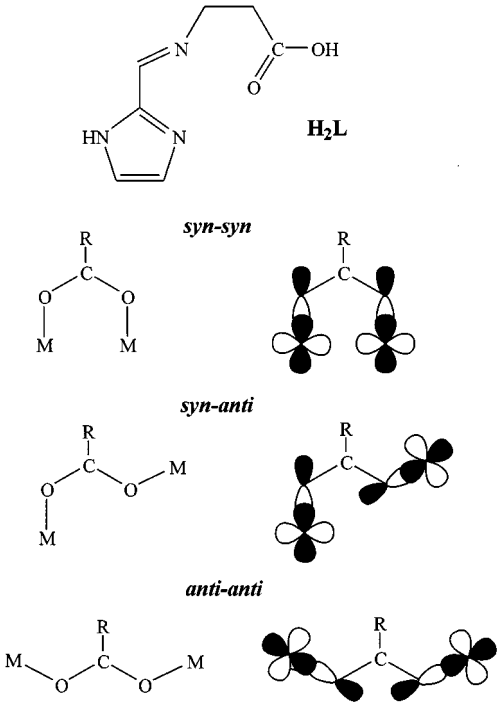
Singly *anti-anti* Carboxylate-Bridged Zig-Zag Chain Complexes from a Carboxylate-Containing Tridentate Schiff Base Ligand and $M(hfac)_2$ [M = Mn^{II}, Ni^{II}, and Cu^{II}]: Synthesis, Crystal Structure, and Magnetic Properties



Enrique Colacio,*[a] Jose M. Domínguez-Vera,[a] Mustapha Ghazi,[a] Raikko Kivekäs,[b] Martti Klinga,[b] and José M. Moreno[a]

Keywords: Copper / Nickel / Manganese / Carboxylate bridge / Metal complexes / Magnetic properties

The reaction of $M(hfac)_2$ with the tridentate Schiff base H_2L (where H_2L stands for the 1:1 condensation product of 2-imidazolecarboxaldehyde with β-alanine) leads to the complexes $[M(HL)(hfac)]_n$ [M = Mn^{II}, Ni^{II}, and Cu^{II}; hfac = hexafluoroacetylacetonate anion] (**1**–**3**). The structures of the complexes **1** and **3** have been solved by X-ray crystallographic methods. The structures are very similar and consist of infinite zig-zag chains, running parallel to the *b* axis, in which the metal ions are bridged sequentially by *anti-anti* carboxylate groups with intrachain metal–metal distances of 6.134 Å for **1** and 6.239 Å for **3**. Each monodeprotonated HL ligand acts as a tridentate one to a metal(II) ion and as a monodentate one to a neighbouring metal(II) centre. Metal atoms exhibit distorted octahedral coordination spheres comprised of two oxygen atoms from the hexafluoroacetylacetonate ligand, three donor atoms from the HL ligand and the oxygen atom belonging to the carboxylate group of an adjacent molecule. The complexes **1–3** have been confirmed to be isomorphous and isostructural on the basis of X-ray powder diffraction and IR spectra. The magnetic properties of the three compounds were studied by susceptibility measurements as a function of the temperature and successfully analyzed in terms of the isotropic spin Hamiltonian for one-dimensional infinite chain systems to give the coupling parameters J = –0.91 cm^{-1}, g = 2.03 (**1**); J = –13.2 cm^{-1}, g = 2.24 (**2**); and J = 0.40 cm^{-1}, g = 2.11 (**3**). The magnetic behaviour for all three complexes can be satisfactorily explained in terms of the conformation of the bridge and the interaction between the d orbitals of the metal centre and the bridge.

Polynuclear complexes containing bridging carboxylate groups are of current interest due to the fact that the carboxylate ions play a key role as a ligand in many biochemical systems involving mono- and polymetallic active sites.[1,2] In addition, polynuclear metal carboxylates are good candidates for the investigation of exchange-coupling interaction between adjacent metal ions.[3–6] Carboxylate is a versatile anion that can assume many types of bridging conformations, the most important being monoatomic and triatomic *syn-syn*, *syn-anti*, and *anti-anti*[5,6] (see Scheme 1). Copper(II) complexes with monoatomic or *syn-anti* triatomic conformations exhibit very weak magnetic exchange interactions,[5,7] whereas triatomic *syn-syn* and *anti-anti* conformations mediate large and weak to medium antiferromagnetic interactions, respectively.[8,9] Among metal(II) carboxylate polymers, structurally and magnetically characterized singly carboxylate-bridged chain complexes are rare[4,10–12] and those adopting the *anti-anti* conformation are rarer still. To our knowledge, they are limited to three Mn^{III} Schiff base chain complexes[11,13,14] and one Fe^{II}[15] and one Cu^{II}[9] two-dimensional complex.

Polydentate ligands with carboxylate groups are good candidates to undergo self-assembly processes based on complexation reactions. In fact, we have previously shown that the tridentate ligand 1,3-dimethyl-5-[(2-carboxyphen-

yl)azo]barbituric acid reacts with copper(II) leading to a *syn-anti* carboxylate-bridged helix chain copper(II) complex through a self-assembly reaction.[4] Following a similar strategy we succeeded in obtaining a series of *anti-anti* singly carboxylate-bridged chain complexes from the reaction of the precursors $M(hfac)_2$ [M = Mn^{II}, Ni^{II}, and Cu^{II}, hfac = hexafluoroacetylacetonato anion] with the tridentate Schiff base H_2L, where H_2L stands for the 1:1 condensation product of 2-imidazolecarboxaldehyde and β-alanine (see Scheme 1). The present paper is devoted to the structural and magnetochemical studies of these complexes.

When the square-planar complexes $M(hfac)_2$ [M = Mn^{II}, Ni^{II}, and Cu^{II}] react with the tridentate Schiff base H_2L, the ligand loses the carboxylic proton and replaces one of the hfac ligands of the precursor complex to give rise, in principle, to a pentacoordinated complex. Because the metal ion is able to additionally receive the non-coordinated oxygen atom of the carboxylate group belonging to another pentacoordinated molecule, a spontaneous self-assembly reaction occurs leading to singly carboxylate-bridged chain complexes $[M(HL)(hfac)]_n$. It should be pointed out that chemical analyses, IR spectra and powder X-ray data confirm that compounds **1**−**3** are isomorphous and isostructural.

Crystal Structures

Complexes **1** and **3** are isostructural and consist of infinite zig-zag chains, running parallel to the *b* axis, in which the metal ions are bridged sequentially by *anti-anti* carboxylate groups. A perspective view of the zig-zag chain for **3**, together with the corresponding atom labelling scheme, is given as an example in Figure 1. Selected bond lengths and angles are listed in Table 1.

Each monodeprotonated HL ligand acts as a tridentate one to a metal(II) ion and as monodentate one to a neighbouring metal(II) centre. Metal atoms exhibit distorted octahedral coordination spheres comprised of two oxygen atoms from the hexafluoroacetylacetonate ligand, three donor atoms from the HL ligand, and the oxygen atom belonging to the carboxylate group of an adjacent molecule. As expected, the three donor atoms of HL occupy in-plane coordination positions and then the carboxylate bridges have to be oriented in a mutually *cis* fashion. The tridentate behaviour of the HL ligand results in the formation of one five- and one six-membered rings having the M−N(7) bond in common. For **3**, the *anti-anti* carboxylate group bridges two Cu^{II} ions in equatorial-axial positions and the surrounding of each copper ion is (4+2), the octahedron being elongated along the O(17)−Cu(1)−$O(12)^{ii}$ axis (*ii* = 1 − *x*, 0.5 + *y*, 1.5 − *z*). In the M−O−C−O−M fragment of **3**, the metal ions are pushed out of the COO plane by 0.214 and 0.806 Å. In **1** the metal ions are also out of the COO plane by 0.620 and 0.652 Å. For both compounds large deviations from the idealized orthogonal geometry are found at the metal atom in the five-membered M−N(1)−C(2)−C(6)−N(7)−M rings [N(1)−Mn−N(7) = 74.33(18)° for **1** and N(1)−Cu−N(7) = 81.45° for **3**]. Such deviations are expected to be due to the small bite distance of this part of the HL ligand. Bond lengths of M(hfac) moieties are in agreement with those reported for other hfac-

containing Mn^{II} and Cu^{II} complexes.[16] The *anti-anti* bridging mode for **3** affords an intrachain metal−metal distance of 6.239 Å, whereas for **1** the metal−metal distance is 6.134 Å; they are similar to those found for singly *anti-anti* carboxylate-bridged Mn^{III}[11,13,14] and Fe^{III}[15] complexes. The shortest interchain metal separations are 7.412 and 6.854 Å for **1** and **3**, respectively. The polymeric chains are held together by pairs of complementary hydrogen bonds between the N(3)−H group and the carboxylate oxygen atoms of a neighbouring chain.

Magnetic Properties

The EPR spectrum of complex **1** at 100 K exhibits a featureless broad resonance at $g = 2.00$ with a half-height width of 400 G. The broadness of this EPR signal is characteristic of polynuclear manganese(II) complexes. The frozen methanol solution spectrum at 100 K exhibits an allowed hyperfine sextuplet centred at $g = 2.0$ ($A = 88.10^{-4}$ cm^{-1}) with forbidden hyperfine lines corresponding to transitions between levels with different nuclear magnetic quantum numbers. This spectrum is typical of electronically isolated Mn^{II} species, thus suggesting either that the chain structure of complex **1** is not retained in solution or that the small antiferromagnetic interaction operating between the Mn^{II} ions does not modify appreciably the EPR spectrum of the complex. Neither polycrystalline powder nor solution EPR spectra could be detected for complex **2**. At 100 K the spectrum of a polycrystalline sample of **3** looks like that expected for a copper(II) ion in a d(x^2-y^2) ground state. Two main features are attributable to paralell ($g_{||} = 2.24$) and perpendicular ($g_{\perp} = 2.11$) components of an axially symmetrical spectrum. In addition, signals of low intensity are observed between these two features. The spectrum is devoid of any hyperfine structure or half-field signal and does not show any appreciable temperature dependence. Analogous spectra have also been observed for other ferromagnetic chain copper complexes with oxalate[17] and *syn-anti* carboxylate bridges.[4] The frozen methanol solution spectrum of **3** at 100 K is typical of electronically isolated Cu^{II} species, thus suggesting that the chain structure is not retained in dilute methanol solution or that the magnetic exchange interaction does not appreciably affect the EPR spectrum.

The magnetic properties of the complexes **1**−**3** are given in Figure 2 in the form $\chi_M T$ versus T. The $\chi_M T$ products per metal atom at 290 K for complexes **1**−**3** are 4.41, 1.15, and 0.425 cm^3·mol^{-1}·K, respectively, which correspond well with those expected for isolated metal ions. For complexes **1** and **2**, $\chi_M T$ continuously decreases upon cooling and reaches values, at 4.2 K, of 1.225 and 0.056 cm^3·mol^{-1}·K, respectively, thus revealing the existence of an antiferromagnetic exchange interaction between metal ions through the carboxylate bridging group. The occurrence of susceptibility maximum around 5 and 25 K for **1** and **2**, respectively, is the signature of the antiferromagnetic interaction. The absence of a Curie-like tail at the lowest temperatures allows one to assume the absence of impurities in these products. For **3**, the $\chi_M T$ product steadily increases when the temperature decreases to a value of 0.63 cm^3·mol^{-1}·K at 2 K, thus suggesting a weak ferromagnetic interaction between the copper(II) ions. The experimental magnetization values as a function of the applied field at 5 K are higher than those predicted by the Brillouin function for $S = 1/2$, thus confirming the existence of weak ferromagnetic interaction between copper(II) ions.

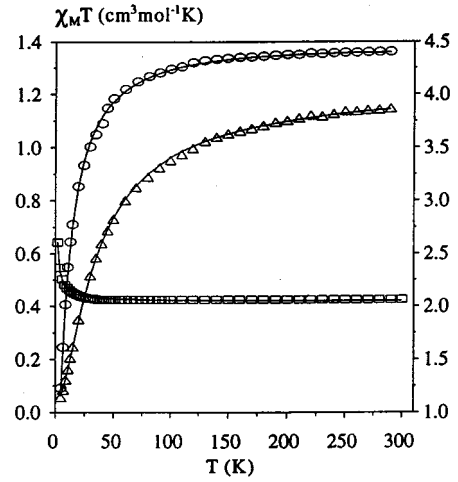

Figure 2. Magnetic plots ($\chi_M T$ vs T) of complexes: **1** (○) (right axis), **2** (△) (left axis) and **3** (□) (left axis)

We fitted the data of **1** using the analytical expression derived by Fisher for an infinite chain of classical spin scaled to $S = 5/2$;[18] for **2** we used the expression derived by Weng from calculations performed on ring systems of increasing lengths, where the nickel ion is assumed to be magnetically isotropic;[18] while the expression used to fit the magnetic data of **3** was that of Baker et al.,[18] which is based on the high-temperature Padé expansion technique.

Very good fits of the data of the complexes **1**−**3** to the corresponding theoretical equations can be obtained with $J = -0.91$ cm^{-1}, $g = 2.03$ (**1**); $J = -13.2$ cm^{-1}, $g = 2.24$ (**2**); $J = 0.40$ cm^{-1}, $g = 2.11$ (**3**).

The difference in the magnitude and sign of the magnetic exchange interactions found for **1**, **2**, and **3** can be satisfactorily explained in terms of the conformation of the bridge and the interaction between the d orbitals of the metal centre and the bridge. It is noteworthy that despite the larger separations found in complexes containing *anti-anti* bridges this configuration is more favourable for transmitting the interaction through the carboxylate bridge than the *syn-anti* one. The reason of these different magnetic behaviours lies in the fact that the contributions of the 2p oxygen orbitals belonging to the magnetic orbital centred on the metal ions are much more favourably oriented to give an effective overlap in the *anti-anti* than in the *syn-anti* configuration (see Scheme 1), thus leading to stronger magnetic exchange couplings.

In good accord with this, complexes **1** and **2** exhibit significant antiferromagnetic couplings with J values that are larger than those observed for singly bridged *syn-anti* car-

boxylate Mn^{II}[19] and alternating *syn-anti* and *anti-anti* carboxylate chain Mn^{II} and Ni^{II} complexes.[20] The *J* value for complex **1** is much smaller than that of complex **2**. Nevertheless, to deal with comparable values, the $n^2|J|$ relation (*n* is the number of unpaired electrons on each paramagnetic centre) should be taken into account. From the *J* values of **1** and **2** and the $n^2|J|$ relation we see that $|J_{Ni}|$ (13.2 cm^{-1}) >> 25/4 $|J_{Mn}|$ (5.7 cm^{-1}), thus illustrating the ability of Ni^{II} as compared to Mn^{II} to yield antiferromagnetic interactions, everything being equal. Similar *J* values have been reported for Mn^{II} (−1.1 cm^{-1}) and Ni^{II} (14 cm^{-1}) complexes with 2,2′-bipyrimidine,[21,22] a ligand that has been shown to transmit intermediate magnetic exchange couplings. Several reasons may contribute to the higher efficiency of the superexchange for the nickel(II) complex: (i) the larger spin delocalization on the bridge in the case of the Ni^{II}, since the energies of the $3d_{Ni}$ orbitals are lower and the M−O distances generally shorter than those of the Mn^{II}; (ii) small structural differences affecting either the carboxylate bridges or M^{II}−N,O bond lengths, and (iii) the possibility of more ferromagnetic contributions in the case of Mn^{II}.

In the case of **3**, the copper(II) ion exhibits a tetragonal elongated geometry, in which the unpaired electron is adequately described by a $d(x^2-y^2)$ orbital pointing toward the nitrogen and oxygen atoms of the basal equatorial plane, O(11)N(1)O(13)N(7). In light of the structural features of **3**, it is evident that these copper(II) orbitals are mismatched for interaction to take place between them through the carboxylate group, since the exchange pathway Cu−O−C−O−Cu involves an equatorial position on one copper [$d(x^2-y^2)$ direction] and an axial position on the other copper atom [$d(z^2)$ direction]. Departures from the idealized symmetry might allow some mixture with the $d(z^2)$ orbital, but in any case the overlap would be very weak. This would lead to a negligible antiferromagnetic contribution so that the ferromagnetic one becomes predominant. It should be noted that other carboxylate-bridged copper complexes having similar topology of the bridges also exhibit weak ferromagnetic interactions.[17]

Experimental Section

General: Elemental analyses were carried out with a Fisons-Carlo Erba analyzer, model EA 1108. − IR: Perkin−Elmer 983 G (KBr pellets). − Variable-temperature magnetic susceptibility data of **1** and **2** were collected on powdered samples of the compounds with the use of a pendulum-type magnetometer (MANICS DSM8) equipped with a helium continuous-flow cryostat working in the 300−4.2 K range and a Drusch EAF 164E electromagnet, whereas those of **3** (2−290 K) were obtained with a SQUID-based sample magnetometer using a Quantum Design Model MPMS instrument. Data were corrected for the diamagnetism of the ligands using Pascal′s constants. − EPR: Bruker ESP 300E (solid state: 300 and 100 K, methanol solution: 110 K).

Preparation of [M(HL)(hfac)] (1−3): These complexes were all prepared using the same method as described in detail for complex **1** as an example. This complex was prepared by refluxing 2-imidazolecarboxaldehyde (0.15 g, 1.56 mmol) and β-alanine (0.14 g, 1.56 mmol) for 1 h in 30 mL of an MeOH/H_2O mixture (4:1, v/v). To the cold, filtered yellow solution was added $Mn(hfac)_2$ (0.73 g, 1.56 mmol) in 30 mL of MeOH dropwise with stirring. The resulting yellow solution was kept at room temperature for 2 d and provided yellow prism-like crystals, which were filtered and air-dried. Yield: 0.60 g (90%). − $C_{12}H_9F_6MnN_3O_4$ (427.93): calcd. C 33.66, H 2.12, N 9.81; found C 33.49, H 1.96, N 10.15. − IR (KBr): $\tilde{\nu}$ = 3141 cm^{-1} (N_{im}−H), 1649, 1602 (C=O), 1257, 1217, 1144 (F−C).

2: Green powder. − Yield: 0.54 g (80%). − $C_{12}H_9F_6N_3NiO_4$ (431.71): calcd. C 33.41, H 2.10, N 9.75; found C 33.79, H 1.91, N 9.45. − IR (KBr): $\tilde{\nu}$ = 3137 cm^{-1} (N_{im}−H), 1649, 1600 (C=O), 1259, 1221, 1144 (F−C). − Powder X-ray diffraction:[23] monoclinic, *Pc*, *a* = 11.900(63), *b* = 8.462(24), *c* = 16.578(104) Å, β = 102.92(44)°.

3: Green plate-like crystals. − Yield: 0.44 g (65%). − $C_{12}H_9CuF_6N_3O_4$ (436.54): calcd. C 33.03, H 2.08, N 9.64; found C 32.98, H 2.09, N 9.53. − IR (KBr): $\tilde{\nu}$ = 3142 (N_{im}−H), 1664, 1625 (C=O), 1259, 1209, 1141 (F−C).

X-ray Crystallographic Study: Crystallographic data are listed in Table 2. The unit-cell parameters were determined and the data collected with a Rigaku AFC7S diffractometer at −80°C for complex **1** and with a Siemens P4 diffractometer at 20°C for **3**. The data were corrected for Lorentz polarisation effects and for dispersion, and an empirical absorption correction, using the programs TEXSAN[24a] and SHELXTL V5[24b] for **1** and **3**, respectively. The structures were solved by Direct methods using the SHELXS-86 program[24c] and refined (full-matrix least squares on F^2) by using the SHELX-97 and SHELXL-93 programs.[24d] For **1**, all non-hydrogen atoms were refined anisotropically, while for **3**, all non-hydrogen atoms were refined anisotropically except the F atoms, which were disordered and refined isotropically. In both cases, H atoms were included in calculated positions and treated as riding atoms using the SHELX-97 (for **1**) and SHELXL-93 (for **3**) default parameters.

Multistep Oxidation Kinetics of [Fe^{II}(cdta)] [cdta = *N,N′,N′′,N′′′*-(1,2-Cyclohexanediamine)tetraacetate] with Molecular Oxygen

Sabine Seibig[a] and Rudi van Eldik*[a]

Keywords: Kinetics / Oxidations / Iron / Oxygen / High pressure

The complicated oxidation kinetics of the reaction of [Fe^{II}(cdta)] [cdta = 1,2-(*N,N′*- cyclohexanediamine)tetraacetate] with molecular oxygen was investigated as a function of [Fe^{II}], [O_2], pH, temperature and pressure. In the presence of an excess of [Fe^{II}(cdta)] three steps could be observed, for which the following rate constants were found at 25°C; k_1 = 1080 ± 16 M^{-1} s^{-1}, k_2 = 103 ± 4 M^{-1} s^{-1} and k_3 = 59 ± 5 M^{-1} s^{-1}. These reaction steps can be accounted for in terms of the following mechanism: (1) [Fe^{II}(cdta)H_2O]$^{2-}$ reacts with O_2 by a substitution process to form [Fe^{II}(cdta)O_2]$^{2-}$; (2) electron-transfer to form an Fe^{III}-superoxo species; (3) subsequent bridge formation followed by electron-transfer to give [(cdta)Fe^{III}-O_2^{2-}-Fe^{III}(cdta)]$^{4-}$; and (4) a fast decomposition of the peroxide intermediate yielding the monomeric [Fe^{III}(cdta)] and H_2O_2. Rate and activation parameters for these steps are reported and discussed in terms of the postulated mechanism and in reference to available literature data.

Introduction

During the past decades there has been a continued interest in the study of oxidation reactions of [Fe^{II}(aminopolycarboxylato)] complexes, especially with dioxygen or hydrogen peroxide.[1−12] Of particular interest in the present context was their importance in several biochemical processes, for example the cleavage of DNA, the decomposition of H_2O_2 or the dismutation of superoxide.[13−20] Many investigators have tried to solve these complicated reactions before, but in most cases they could only observe a single reaction step spectroscopically, even when more than one step was postulated in the mechanism.[1−12,21]

We recently reported a detailed kinetic study of the oxidation kinetics of [Fe^{II}(edta)] with molecular oxygen.[22] For the first time we could observe three steps spectroscopically and could investigate two of them in detail. The first step was so fast that we were not able to analyse it systematically on the stopped-flow time scale. We have therefore searched for a ligand, which would tune the reactivity of the complex in such a way, that this first step would become slower. Since the cdta ligand (cdta = *N,N′*-(1,2-cyclohexanediamine)tetraacetate) is known to stabilize its metal complexes, we thought that it would also affect their reactivity.[23−27] Moreover, it is known from several kinetic investigations that the cdta complex always reacts slower than the corresponding edta complex.[28−30] We, therefore, performed detailed kinetic measurements on the rather complicated oxidation reactions of [Fe^{II}(cdta)] with dioxygen.

The present work describes how the selected chelate can tune the reactivity of the complex. We were now able to investigate three reaction steps in detail. A mechanism is presented that accounts for all spectroscopic and kinetic observations, and is discussed in reference to our earlier work on the [Fe^{II}(edta)] system[22] and work reported in the literature.[4,6,7,10,12,21]

Results and Discussion

Spectral Observations

A number of test experiments on the [Fe^{II}(cdta)] system showed that its spectroscopic behavior is very similar to the [Fe^{II}(edta)] system, which we investigated recently.[22] Typical spectra indicate that both [Fe^{II}(cdta)] and [Fe^{III}(cdta)] exhibit an absorbance maximum at 260 nm and that the molar extinction coefficient for [Fe^{III}(cdta)] is significantly higher than for the [Fe^{II}(cdta)] complex. Since the overall oxidation reaction is accompanied by a significant decrease in [H^+], it was necessary to use buffers for pH ≥ 3 throughout the study.[31] The reaction of [Fe^{II}(cdta)] with molecular oxygen can best be followed at 370 nm in the presence of an excess of [Fe^{II}(cdta)] and at 260 nm in the presence of an excess of O_2 using a 1 cm cuvette. All kinetic traces were measured over more than 5 half-lives.

Kinetic Measurements

Kinetic traces measured in the presence of an excess of [Fe^{II}(cdta)] showed a complicated multistep process. In contrast to the [Fe^{II}(edta)] system, we could now fit the kinetic traces in most cases to three exponential functions (see Figure 1). This means we were able to confirm our earlier observations, where we only had limited evidence for the first

fast step.[22] For the present system the fast step was only about a factor of ten faster than the subsequent steps. According to the data analysis this step is accompanied by a small decrease in absorbance which results in the non-linear increase in absorbance seen in Figure 1b. The two subsequent steps differ by a factor of ca. two, which is in good agreement with the data we obtained for the [Fe^{II}(edta)] system. However, in comparison, the rate constants for the [Fe^{II}(edta)] system are two times faster than for the [Fe^{II}(cdta)] system. The values of k_{obs} for all three reaction steps vary linearly with [Fe^{II}(cdta)] over the investigated concentration range (see Figure 2). The dependence for the first step shows a significant intercept, whereas the two other lines go through the origin. At pH = 6.0, the three reaction steps have the following second-order rate constants, $k_1 = 1080 \pm 16$ M^{-1} s^{-1}, $k_2 = 103 \pm 4$ M^{-1} s^{-1} and $k_3 = 59 \pm 5$ M^{-1} s^{-1} at 25°C, which are assigned to the reaction steps outlined in (2), (4), and (6), respectively (see further Discussion).

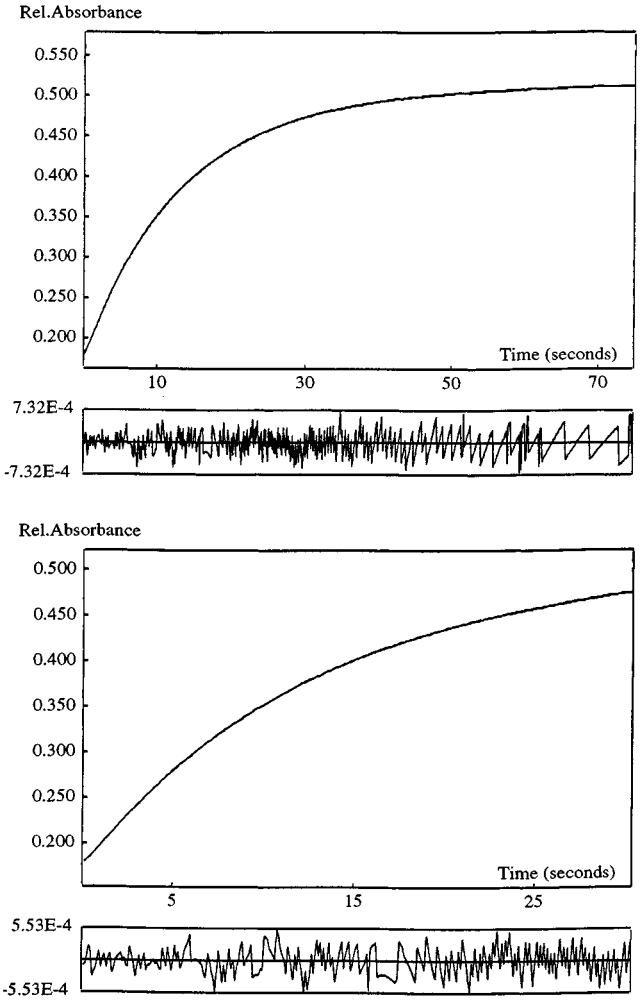

Figure 1. Typical absorbance time trace obtained in an excess of [Fe^{II}(cdta)] fitted with three exponential functions. – Experimental conditions: [Fe^{II}(cdta)] = $2.5 \cdot 10^{-3}$ M, [O_2] = $1.25 \cdot 10^{-4}$ M, ionic strength = 0.5 M, [acetate buffer] = 0.1 M, pH = 6, T = 25°C, λ = 370 nm

The pH dependence of the reaction in the presence of an excess [Fe^{II}(cdta)] was studied in the range pH = 2 to 7 (see

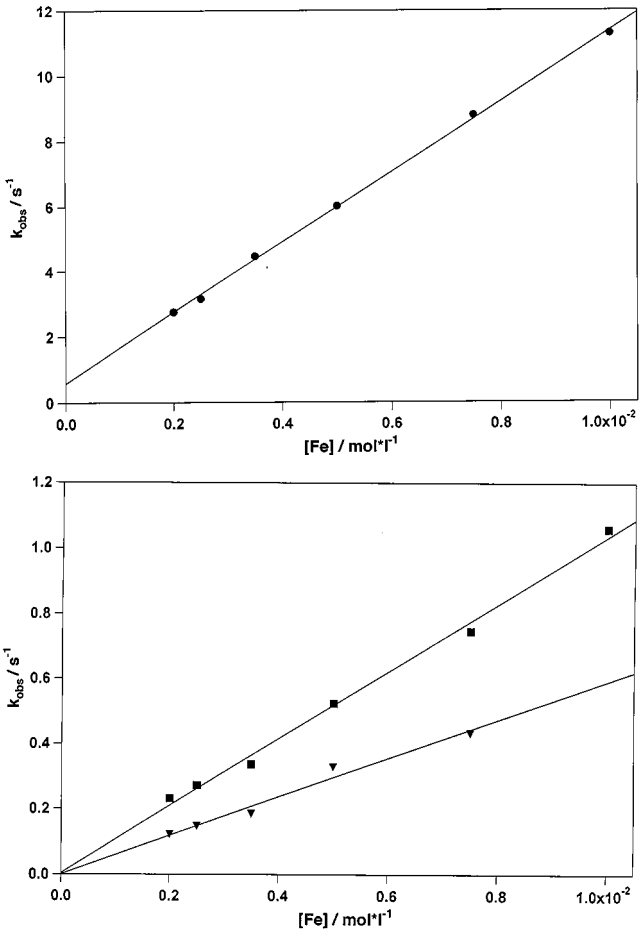

Figure 2. a: k_{obs1} (•) as a function of [Fe^{II}(cdta)] for the oxidation of [Fe^{II}(cdta)]. – b: k_{obs2} (■) as a function of [Fe^{II}(cdta)] for the oxidation of [Fe^{II}(cdta)]. – c: k_{obs3} (▼) as a function of [Fe^{II}(cdta)] for the oxidation of [Fe^{II}(cdta)]
Experimental conditions: [O_2] = $1.25 \cdot 10^{-4}$ M, ionic strength = 0.5 M, [acetate buffer] = 0.1 M, pH = 6, T = 25°C, λ = 370 nm.

Figure 3). The resolution of the time traces at a pH > 4 showed a more complicated kinetic behavior, but we were able to analyze the three main steps. All three steps show a bell-shaped pH dependence with a maximum around pH = 2.5. The maximum rate of all three observed steps corresponds quite well to the distribution of species in solution (see Figure 4). The kinetic pH dependence indicates that the monoprotonated species in solution is the most reactive one. This behavior was also observed for different [Fe^{II}(edta)] reactions before. For example, the oxidation kinetics of [Fe^{II}(edta)] with molecular oxygen showed the same pH dependence.[21,22] But, moreover, kinetic studies of the reaction of [Fe^{II}(edta)] with HONO or NO_2^- also showed the same pH dependence,[35,36] which supports our suggestion that the observed bell-shaped curves are due to the distribution of species in solution and not due to an acid-catalyzed process, as suggested in an earlier study.[21]

The increase in rate at pH > 6 (see Figure 3a) is not expected on the basis of the distribution of species in solution. This may be an effect of the selected buffer and we therefore selected other buffers. This, however, did not solve the problem. It was noticed that a precipitate occurred at

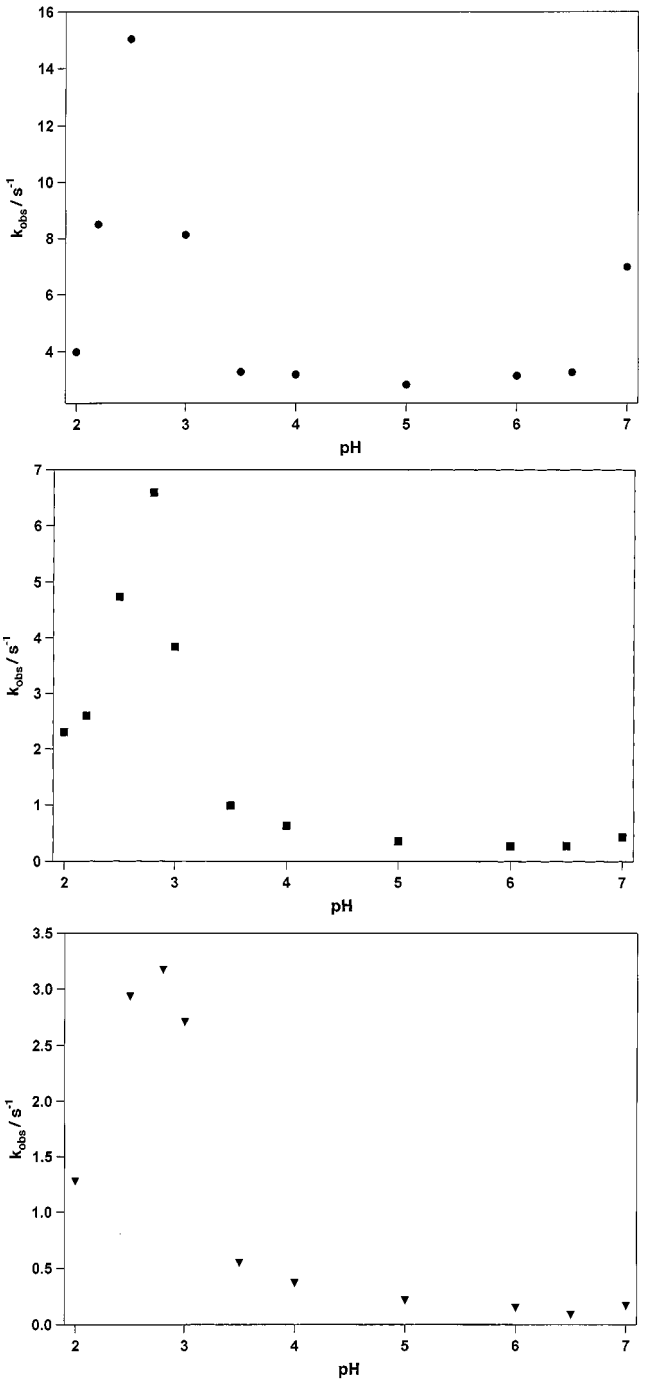

Figure 3. a: pH dependence of k_{obs1} (●) for the oxidation of [Fe^{II}(cdta)] in the presence of an excess of [Fe^{II}(cdta)]. – b: pH dependence of k_{obs2} (■)for the oxidation of [Fe^{II}(cdta)] in the presence of an excess of [Fe^{II}(edta)]. – c: pH dependence of k_{obs3} (▼) for the oxidation of [Fe^{II}(cdta)] in the presence of an excess of [Fe^{II}(cdta)]
Experimental conditions: [Fe^{II}(cdta)] = $2.5 \cdot 10^{-3}$ M, [O_2] = $1.25 \cdot 10^{-4}$ M, ionic strength = 0.5 M, [acetate buffer] = 0.1 M for pH > 3, [Tris buffer] = 0.1 M or [MOPS buffer] = 0.1 M for pH > 6 , T = 25°C, λ = 370 nm.

pH = 7.5, which prevented measurements in a higher pH range. The precipitate suggested that the investigated [Fe^{II}(cdta)] complex is not as stable as reported in the literature[38] and that some free Fe^{II} may be present in solution.

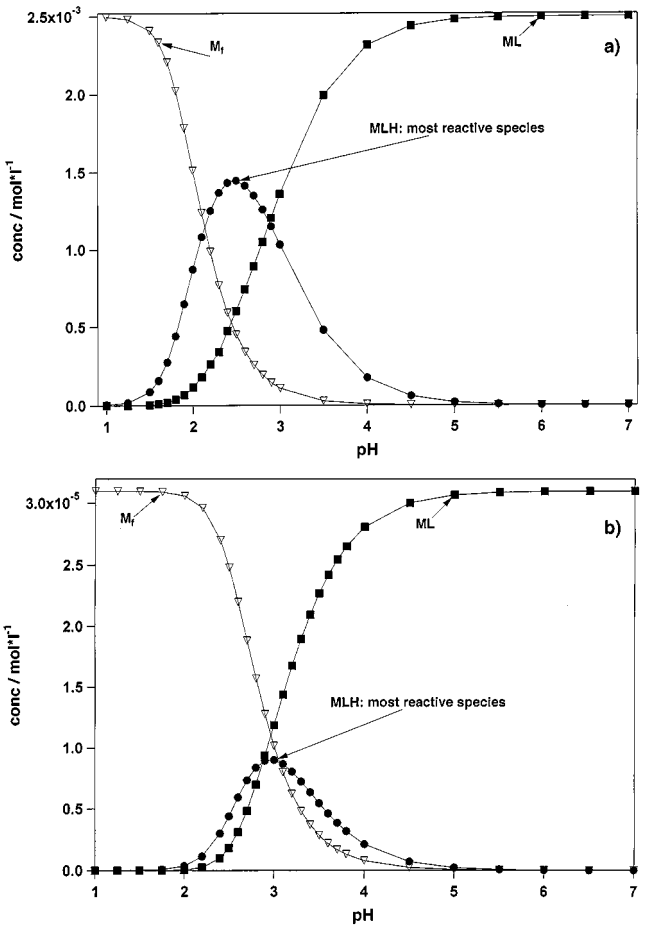

Figure 4. a: Distribution of [Fe^{II}(cdta)] species in solution, [Fe^{II}(cdta)] = 2.5×10^{-3} M. – b: Distribution of [Fe^{II}(cdta)] species in solution, [Fe^{II}(cdta)] = 3.0×10^{-5} M; M_f = free Fe_2+, ML = [Fe^{II}(cdta)$(H_2O)]^{2-}$, MLH = [Fe^{II}(cdtaH)$(H_2O)^-$

The addition of $FeSO_4 \cdot 7\ H_20$ to the test solution accelerated the observed reactions with dioxygen, and the presence of free Fe^{II} can therefore account for the unexpected increase in rate at pH > 6.

Reactions in the presence of an excess of oxygen could in most cases be fitted to two exponential functions between pH = 6.0 and pH = 2.0. However, near the maximum reactivity, the kinetic behavior was even more complicated, so that it was sometimes necessary to fit the kinetic traces to three exponential functions. In these cases we only report rate constants for the two main reaction steps for reason of comparison with the other pH data. The complicated kinetic behavior in more acidic medium is also reflected by the difficulties encountered to fit our data in the presence of an excess of [Fe^{II}(edta)] in that pH region (vide supra). The studied pH dependence exhibits a maximum at pH = 3 (see Figure 5), which is in good agreement with the data obtained for the pH dependence in an excess of [Fe^{II}(cdta)] (see Figure 3) and corresponds also quite well to the distribution of species in solution at the appropriate concentration of [Fe^{II}(cdta)] (see Figure 4b).

Various efforts were made to study the oxygen concentration dependence under these conditions, especially to

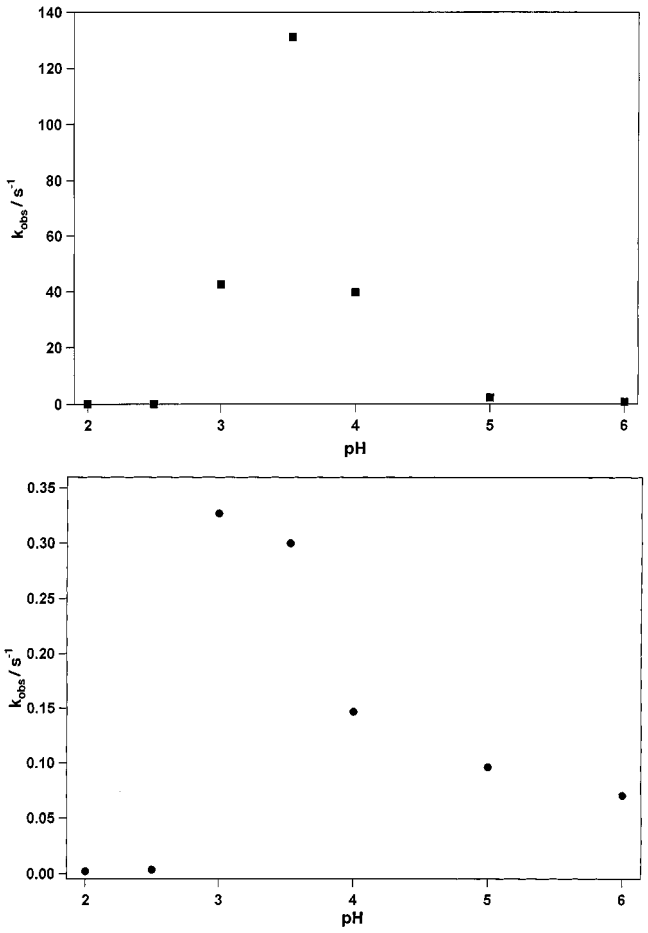

Figure 5. a: pH dependence of k_{obs1} (■) for the oxidation of [Fe^{II}(cdta)] in the presence of an excess of O_2. – b: pH dependence of k_{obs2} (•) for the oxidation of [Fe^{II}(cdta)] in the presence of an excess of O_2
Experimental conditions: [O_2] = $6.25 \cdot 10^{-4}$ M, [Fe^{II}(cdta)] = $3.0 \cdot 10^{-5}$ M, ionic strength = 0.5 M, [acetate buffer] = 0.1 M for pH > 3, T = 25°C, λ = 260 nm

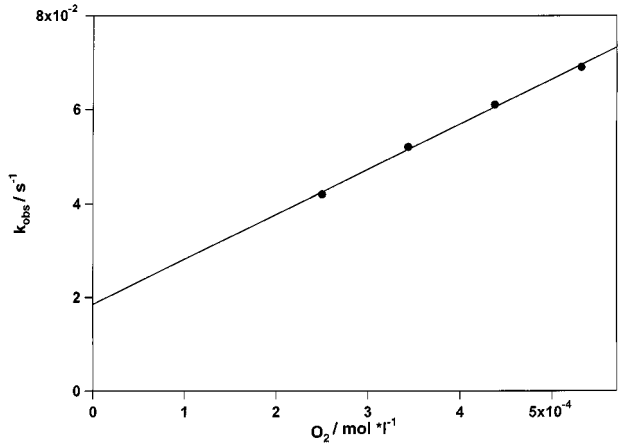

Figure 6. k_{obs2} (•) as a function of [O_2] for the oxidation of [Fe^{II}(cdta)]
Experimental conditions: [Fe^{II}(cdta)] = $3.0 \cdot 10^{-5}$ M, ionic strength = 0.5 M, [acetate buffer] = 0.1 M, pH = 6, T = 25°C, λ = 260 nm

analyse the mentioned additional faster reaction step, which could also be observed in the case of the [Fe^{II}(edta)] system.[22] First we used a concentration range where we worked in a 10- to 20-fold excess of oxygen. We could fit the obtained traces quite well to two exponential functions. The k_{obs} values for the second step observed under these conditions varied linearly with the O_2 concentration at pH = 6.0 (see Figure 6). The slope of the line, viz. 96 ± 3 M^{-1} s^{-1}, is in very close agreement with that observed for the second reaction step in the presence of an excess of [Fe^{II}(cdta)], viz. k_2 = 103 ± 4 M^{-1} s^{-1} under similar conditions.

In general the obtained kinetic traces were of a too poor quality to allow analysis of the fast step, due to the relatively low [Fe^{II}(cdta)] concentration that had to be selected in order to have the oxygen in a large enough excess. We, therefore, tried to increase the concentration of [Fe^{II}(cdta)] and measured in a 6- to 10-fold excess of oxygen. Under these conditions the data could best be fitted to three exponential functions. The initial fast rate constant showed, within experimental error limits, no meaningful dependence on the oxygen concentration. In principle such a reaction step could involve ring-opening of the cdta ligand prior to or following the binding of dioxygen. Unfortunately, it was not possible to determine within reasonable accuracy the thermal activation parameters for this reaction. The second subsequent step exhibited a decrease in absorbance comparable to the first fast step observed in the presence of an excess of [Fe^{II}(cdta)]. The determined second order rate constant for this step is k_1 = 611 ± 234 M^{-1} s^{-1} , which is of the same order as k_1 = 1080 ± 16 M^{-1} s^{-1} determined in the presence of an excess of [Fe^{II}(cdta)]. It follows that the data obtained in the presence of an excess of oxygen, despite their relatively poor quality, do support the overall trends observed in the presence of an excess of [Fe^{II}(cdta)].

Mechanistic Interpretation

pH titrations for the [Fe^{II}(cdta)] complex[37] show a similar behavior as reported for the [Fe^{II}(edta)] complex.[38] As these complexes are very similar, it is reasonable that [Fe^{II}(cdta)] shows a similar behavior like [Fe^{II}(edta)] in solution and in the solid state. It is known from X-ray data for the [Fe^{II}(edta)] complex, which was crystallized from neutral solution, that it exists as a seven coordinate [Fe^{II}-(edta)H_2O]$^{2-}$ species with a mono-capped trigonal-prismatic geometry (MCP).[39] The edta chelate can be protonated when the solution is acidified.[4,40,41] This results in a monoprotonated species [Fe^{II}(edtaH)(H_2O)]$^-$, which has a pentagonal bipyramidal geometry (PB) in the solid state.[41] Although such X-ray data are not available for the [Fe^{II}(cdta)] complex, it is quite realistic to expect that [Fe^{II}(cdta)] behaves in a similar way, and that the structure in solution is comparable to the structure in the solid state. For example, from NMR and Raman studies,[42–46] it is known for the [Fe^{III}(edta)] complex, that the structure in solution is the same as in the crystalline state.[47–49]

The increase in k_{obs} with increasing [H^+] at pH < 5 could result from the protonation of the cdta ligand which is ac-

companied by a change in geometry from MCP to PB. The PB geometry has a higher reactivity due to the greater bite angle in the PB form such that the incoming oxygen molecule has more space to enter the coordination sphere and to substitute the coordinated water. On further acidification, another changeover in geometry occurs which is associated with the diprotonation of the complex as shown in (1). This diprotonated form of the complex results again in a mono-capped trigonal-bipyramidal geometry.[41] Here the $Fe-OH_2$ bond of the $[Fe^{II}(edta)(H_2O)]^{2-}$ complex is shortened as a result of protonation of two acetate arms. The decrease in reactivity can therefore also be due to a shortening of the $Fe-OH_2$ bond of the corresponding $[Fe^{II}(cdtaH_2)(H_2O)]$ complex at pH < 2.5.

For the deprotonation of the monoprotonated complex a pK_a of 2.88 was reported in the literature.[37] The resulting distribution diagramms (see Figure 4) correlate very well with the found kinetic pH dependencies, such that these titration data strongly support our assumption that the monoprotonated form of the complex is the reactive one.

$$\underset{\text{MCP}}{[Fe^{II}(cdta)(H_2O)]^{2-}} + H^+ \overset{K_{a1}}{\rightleftharpoons} \underset{\text{PB}}{[Fe^{II}(cdtaH)(H_2O)]^-} \quad (1)$$

$$\underset{\text{PB}}{[Fe^{II}(cdtaH)(H_2O)]^-} + H^+ \overset{K_{a2}}{\rightleftharpoons} \underset{\text{MCP}}{[Fe^{II}(cdtaH_2)(H_2O)]}$$

All three complexes can react with O_2 to produce $[Fe^{II}(cdta)(O_2)]^{2-}$, $[Fe^{II}(cdtaH)(O_2)]^-$, and $[Fe^{II}(cdtaH_2)(O_2)]$, respectively, as shown in (2). We believe that these reactions account for the first fast step, especially because they correlate with the pH-dependent profile (see Figure 3a). Moreover, the substitution of coordinated H_2O by O_2 on the $[Fe^{II}(cdta)]$ complexes is not expected to cause a significant UV-Vis spectral change. The concentration dependence in Figure 2a suggests that the process is reversible. From the slope and the intercept an apparent equilibrium constant was calculated to be $K_1 = 1862\ M^{-1}$. However, this is based on the assumption that the intercept in Figure 2a is entirely due to the back reaction, which does not have to be the case.

$$[Fe^{II}(cdta)(H_2O)]^{2-} + O_2 \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} [Fe^{II}(cdta)(O_2)]^{2-} + H_2O$$

$$[Fe^{II}(cdtaH)(H_2O)]^- + O_2 \underset{k'_{-1}}{\overset{k'_1}{\rightleftharpoons}} [Fe^{II}(cdtaH)(O_2)]^- + H_2O \quad (2)$$

$$[Fe^{II}(cdtaH_2)(H_2O)] + O_2 \underset{k''_{-1}}{\overset{k''_1}{\rightleftharpoons}} [Fe^{II}(cdtaH_2)(O_2)] + H_2O$$

The reactions in (2) are reversible substitution processes in which the protonated pentagonal bipyramidal species can bind O_2 more rapidly than the nonprotonated and diprotonated mono-capped trigonal-prismatic species.

The following rate law for the forward reactions can account for the bell shaped pH dependence at pH = 2.0:

$$k_{obs1} = \left\{ \frac{k_1 + k'_1 K_{a1}[H^+] + k''_1 K_{a1}K_{a2}[H^+]^2}{1 + K_{a1}[H^+] + K_{a1}K_{a2}[H^+]^2} \right\} [Fe^{II}(cdta)] \quad (3)$$

The subsequent redox reactions (4) to produce superoxo complexes of $[Fe^{III}(cdta)]$ will induce a significant spectral change and are suggested to account for the first slower reaction step. Thus electron transfer is the rate-determining step following the rapid coordination of O_2 in (2). The observed rate constants, k_{obs2}, are expected to depend on pH since the different species produced in (2) are expected to undergo oxidation at different rates.

$$[Fe^{II}(cdta)(O_2)]^{2-} \xrightarrow{k_2} [Fe^{III}(cdta)(O_2^-)]^{2-}$$

$$[Fe^{II}(cdtaH)(O_2)]^- \xrightarrow{k'_2} [Fe^{III}(cdtaH)(O_2^-)]^- \quad (4)$$

$$[Fe^{II}(cdtaH_2)(O_2)] \xrightarrow{k''_2} [Fe^{III}(cdtaH_2)(O_2^-)]$$

The given rate law (5), derived under conditions that $[Fe^{II}(cdta)] >> [O_2]$, can account for the bell shaped pH dependence observed at pH = 2.0 in Figure 3b. Furthermore, this rate law is also in agreement with the linear dependence on the concentration of $[Fe^{II}(cdta)]$ as found in Figure 2b.

$$k_{obs2} = \left\{ \frac{k_2K_1 + k'_2 K'_1 K_{a1}[H^+] + k''_2 K'_1 K_{a1}K_{a2}[H^+]^2}{1 + K_{a1}[H^+] + K_{a1}K_{a2}[H^+]^2} \right\} [Fe^{II}(cdta)] \quad (5)$$

The subsequent reaction step, k_{obs3}, exhibits a similar pH profile (Figure 3c) and is on the average ca. two times slower than k_{obs2}. Since these experiments are performed in the presence of an excess of $[Fe^{II}(cdta)]$, we suggest that equilibrium (1) must also account for the pH dependence found for this reaction step. Thus the superoxo species produced in (4) may react further as shown in (6). The rate law for these reactions will be similar to that in (5), as summarized in (7).

$$[Fe^{III}(cdta)(O_2^-)]^{2-} + [Fe^{II}(cdta)(H_2O)]^{2-} \xrightarrow{k_3} [(cdta)Fe^{III}(O_2^{2-})Fe^{III}(cdta)]^{4-} + H_2O$$

$$[Fe^{III}(cdtaH)(O_2^-)]^- + [Fe^{II}(cdtaH)(H_2O)]^- \xrightarrow{k'_3} [(cdtaH)Fe^{III}(O_2^{2-})Fe^{III}(cdtaH)]^{2-} + H_2O \quad (6)$$

$$[Fe^{III}(cdtaH_2)(O_2^-)] + [Fe^{II}(cdtaH_2)(H_2O)] \xrightarrow{k''_3} [(cdtaH_2)Fe^{III}(O_2^{2-})Fe^{III}(cdtaH_2)] + H_2O$$

$$k_{obs3} = \left\{ \frac{k_3 + k'_3 K_{a1}[H^+] + k''_3 K_{a1}K_{a2}[H^+]^2}{1 + K_{a1}[H^+] + K_{a1}K_{a2}[H^+]^2} \right\} [Fe^{II}(cdta)] \quad (7)$$

The temperature and pressure dependence of the reactions were also studied in the presence of an excess of [Fe^{II}(cdta)]. As the concentration dependence of the first fast step exhibits a significant intercept, it was neccessary to measure the temperature dependence as a function of concentration in order to separate the contribution of the intercept from the slope (see Supplementary Table S1). The volumes of activation could only be obtained for the second and the third step (see Supplementary Figure S1). Since the first fast step exhibits only very small absorbance changes and is ca. ten times faster in comparison to the subsequent steps, our instrumentation did not allow a determination of the associated volume of activation. All obtained rate and activation parameters are summarized in Table 1.

Table 1. Rate constants and activation parameters determined in the presence of an excess of [Fe^{II}(cdta)] for the oxidation by dioxygen

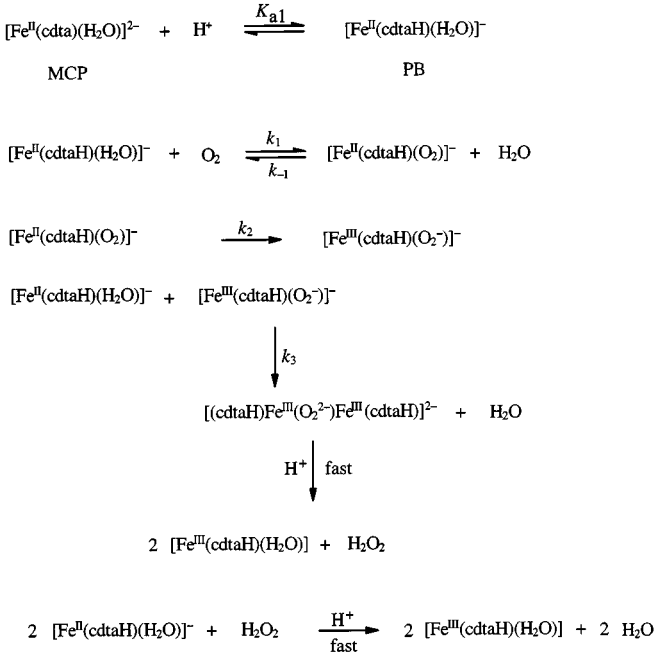
	1. Reaction	2. Reaction	3. Reaction
rate constant ($M^{-1} s^{-1}$)	1080 ± 16	103 ± 4	59 ± 5
$\Delta H^{\#}$ (kJ mol^{-1})	44.1 ± 2.3	66.5 ± 0.9	67.1 ± 0.8
$\Delta S^{\#}$ (J $mol^{-1} K^{-1}$)	−236 ± 8	18.7 ± 2.4	18.0 ± 2.7
$\Delta V^{\#}$ (cm^3 mol^{-1})	not determined	−20.2 ± 2.3	−23.0 ± 3.9

Experimental conditions: [Fe^{II}(cdta)] = $2.5 \cdot 10^{-3}$ M, [O_2] = $1.25 \cdot 10^{-4}$ M, ionic strength = 0.5 M, [acetate buffer] = 0.10 M, pH = 6.0, λ = 370 nm.

Overall Suggested Mechanism

All three reaction steps could be resolved during the interaction of dioxygen with an excess of [Fe^{II}(cdta)]. These include at first substitution of a coordinated water molecule by dioxygen, where this process probably follows an associative mechanism as a result of the strongly negative entropy of activation (see Table 1). This step is then followed by an intramolecular electron-transfer reaction to produce an Fe^{III}-superoxo complex, which in the third step reacts with another [Fe^{II}(cdta)] species to produce a dimeric [$Fe^{III}-O_2^{2-}-Fe^{III}$] complex, which is postulated to dissociate rapidly to form the monomeric [Fe^{III}(cdta)] complex and H_2O_2. The latter species was shown to react considerably faster with [Fe^{II}(cdta)] than dioxygen (typical rate constants of $k_1 = 1.9 \cdot 10^4$ $M^{-1}s^{-1}$ and $k_2 = 1.6 \cdot 10^3$ $M^{-1}s^{-1}$ were found at $T = 25°C$ and pH = 6). In principle, it should be possible to observe four reaction steps of which two are associated with substitution and electron-transfer of the first [Fe^{II}(cdta)] complex, and two associated with similar reactions of the second [Fe^{II}(cdta)] complex. With the aid of a Global Analysis Program it could be shown that the fit with a three-step mechanism is not perfect. But due to the similarity of the two postulated substitution processes, we were not successful to separate it into four rate constants. The fact that all three observed concentration dependences are linear means that the substitution equilibria for the first and third steps must be unfavorable in order to result in a linear concentration dependence of the second and fourth reaction steps.

The extinction coefficient of [Fe^{II}(cdta)] at pH = 6 was found to be 743 $M^{-1} cm^{-1}$ at 261 nm, which is much lower than for the corresponding [Fe^{II}(edta)] complex.[22] The extinction coefficient of [Fe^{III}(cdta) H_2O]$^-$ under similar conditions was found to be 7817 $M^{-1} cm^{-1}$ and for [Fe^{III}(cdta) OH]$^{2-}$ to be 7644 $M^{-1} cm^{-1}$. From this data a final spectrum could be calculated. Due to our assumption that only the monomeric [Fe^{III}(cdta)] species is formed, the stoichiometry of the reaction is only between 2:1 and 3:1 (Fe/O_2). That leads to the result that the applied model could be too simple and that a small amount of free Fe^{II} (vide supra) or bridged species affect the final absorbance.



The rate constants clearly show that the substitution processes are very fast and are followed by the rate-determining electron-transfer processes. This is one of the reasons, why we were unable to detect the postulated intermediates as the superoxo or peroxo species, since they immediately react once they are formed. Furthermore, for the related [Fe(edta)] complex it was reported that the characteristic bands for the [Fe^{III}(edta)O_2]$^{2-}$ complex at 287 nm (ε = 6100 $M^{-1} cm^{-1}$) and 520 nm (ε = 530 $M^{-1} cm^{-1}$) show, in comparison to [Fe^{III}(edta)H_2O]$^-$ with ε = 9290 $M^{-1} cm^{-1}$ (256 nm),[15,16,50] low extinction coefficients, such that the spectra of the intermediates would be hidden by the product spectrum. Such data are presently not available for the corresponding [Fe(cdta)] complexes.

The reaction with dioxygen proceeds via a fast substitution process on the [Fe^{II}(cdta)H_2O]$^{2-}$ complex. For this process only $\Delta H^{\#}$ and $\Delta S^{\#}$ could be determined, where $\Delta S^{\#}$ is strongly negative (see Table 1). Our assumption that this first fasty step is a substitution process is strongly supported by these activation parameters. They are rather similar to related substitution processes on corresponding Ru complexes.[51−53] The subsequent slower intramolecular electron-transfer process must be controlled by a reorganization barrier in order to convert [$Fe^{II}-O_2$] to [$Fe^{III}-O_2^-$]. This reaction is characterized by a significantly negative $\Delta V^{\#}$ value (Table 1), which must be related to the oxidation of Fe^{II} to Fe^{III} and the reduction of O_2 to O_2^-. The corresponding value for $\Delta S^{\#}$, however, is small and positive; this apparent discrepancy can be explained by the large experimental error of $\Delta S^{\#}$. Both these processes are expected to involve a significant decrease in partial molar volume and an increase in electrostriction.[54−56] The efficiency of the ligand substitution process is controlled by the nature of the [Fe^{II}(cdta)H_2O]$^{2-}$ complex, which on protonation produces a more labile [Fe^{II}(cdtaH)H_2O]$^-$ species. The latter accounts for the drastic increase in observed rate constant on decreasing the pH in the range from 5 to 3.

The reaction of the second [Fe^{II}(cdta)H_2O]$^{2-}$ species results in very similar concentration, pH, temperature and pressure dependencies, which are once again interpreted in terms of a rapid complex-formation reaction followed by a rate-determining electron-transfer process. This reaction is once again characterized by a significantly negative $\Delta V^{\#}$ value for the same reasons as outlined above. A comparison with the data reported in our last study,[22] indicates that the determined $\Delta V^{\#}$ values are very similar for both com-

plexes, which confirms our assumption that they are due to electron-transfer processes. The very similar activation parameters observed for both oxidation processes indicate that a similar reorganization barrier must exist. When oxygen is used in excess, only one electron transfer reaction is observed since a peroxo-bridged complex cannot be formed under these conditions. This is in good agreement with the second reaction step observed in the presence of an excess of [Fe^{II}(cdta)]. Again the reaction is controlled by electron-transfer and the associated reorganization barrier. The additional fast process which was observed in an excess of [O_2] may be related to ring-opening of the cdta ligand when dioxygen enters the coordination sphere as mentioned above.

The results of this study have shown that a change in the chelate ligand has decelerated the fast substitution process, which could not be studied in detail in our recent paper.[22] The change in reactivity can be due to the different geometry of the here employed ligand,[23−30] which has its acetate arms in the trans position. This seems to lead to a less reactive binding of O_2. We are now able to suggest a detailed multistep mechanism for the reaction in the presence of an excess of [Fe^{II}(cdta)] as shown in Scheme 1. At high pH (pH = 6), mostly the nonprotonated form will react, whereas at low pH (pH = 4) the more reactive monoprotonated form will react. The mechanism in Scheme 1 is given for the more reactive protonated species

Scheme 1. Multistep mechanism for the reaction of [Fe^{II}(cdta)] with molecular oxygen

Experimental Section

Materials: Chemicals of analytical reagent grade and ultrapure water were used throughout this study. [Fe^{II}(cdta)] was prepared in solution from $FeSO_4 \cdot 7\ H_2O$ and H_4(cdta). NaOH, $HClO_4$, and NaOAc were used to adjust the pH of the test solutions.[31] The ionic strength of the medium was adjusted with $NaClO_4$.

Preparation of Solutions: [Fe^{II}(cdta)] is extremely oxygen sensitive and is rapidly oxidized to [Fe^{III}(cdta)].[32] Test solutions were therefore prepared under the exclusion of oxygen as described in our earlier report.[22] The ionic strength was adjusted with $NaClO_4$ to 0.50 M for all solutions. Acetate buffer was employed for 3 < pH < 6 and Tris or MOPS buffer was used for 6 < pH < 7. Test measurements showed that the employed buffers had no significant effect on the observed kinetics. Test solutions were transferred to the stopped-flow unit by using gastight syringes.

Instrumentation: The kinetic experiments were performed on a Applied Photophysics SX.18MV stopped-flow unit, to which an online data acquisition system was connected. Rapid scan spectra were obtained with the Applied Photophysics Instrument by addition of obtained absorbance-time traces over the investigated wavelength range. Kinetic measurements at pressures up to 120 MPa were performed on a homemade high-pressure stopped-flow unit.[3,34] UV-Vis spectra were recorded on a Hewlett-Packard HP 8452A diode array spectrophotometer. The pH of the stock solutions was measured with the aid of a Mettler Delta 340 pH meter. The reference electrode was filled with NaCl instead of KCl in order to prevent precipitation of $KClO_4$. All kinetic traces were analyzed by using OLIS KINFIT (OLIS, Bogart, Georgia, USA) and Applied Photophysics Kinfit (Applied Photophysics Limited, Leatherhead, UK) software. For Global Analysis, spectra were recorded on the Applied Photophysics Instrument and fitted with the aid of the Applied Photophysics Software Package.

Supporting Information

Figure S1 reports pressure dependences obtained in the presence of an excess of [Fe^{II}(cdta)]. Table S1 reports second-order rate constants as a function of temperature. This material is available on the WWW under http://www.wiley-vch.de/home/eurjic or from the authors.

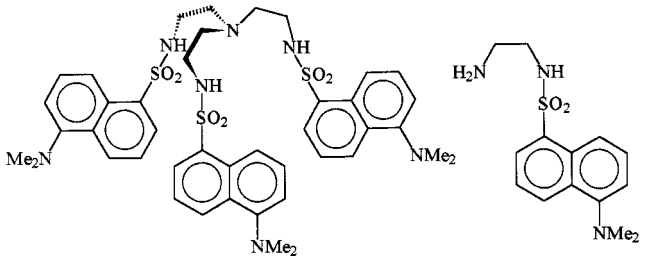
Searching for New Luminescent Sensors: Synthesis and Photophysical Properties of a Tripodal Ligand Incorporating the Dansyl Chromophore and of Its Metal Complexes

Luca Prodi,*[a] Fabrizio Bolletta,[a] Marco Montalti,[a] and Nelsi Zaccheroni[a]

Keywords: Chemosensors / Fluorescence / Tripodal ligands



The new tripodal ligand **1** containing the dansyl chromophore has been synthesized and characterized. The intense luminescence characteristic of the chromophore is maintained in the ligand structure, showing that no intramolecular interactions are present. This ligand has been shown to complex in acetonitrile/water solutions only with Cu^{2+}, Co^{2+}, Zn^{2+}, and Cd^{2+} ions, with concomitant pronounced changes in the fluorescence spectra. The complexation is controlled by pH conditions: at neutral pH this ligand shows a remarkable selectivity towards Cu^{2+} ions, suggesting a possible use for **1** as a luminescent chemosensor for this ion.

Photoluminescence spectroscopy has recently attracted increasing attention in the scientific community as it has been finding applications in growing fields of great economic and social impact, such as medical diagnostics, environmental sciences, cell biology and molecular electronics.[1−5] In particular, the synthesis, characterization, and application of many luminescent sensors has opened up many opportunities for solving complex analytical problems. The sensitivity and versatility of luminescence spectroscopy make it a particularly suitable technique for analytical applications, giving for example the possibility of monitoring analyte concentrations in real-time and real-space.[2−5]

Of particular interest is the measurement of the concentrations of transition-metal ions, since many of these are also pollutants in environmental systems and essential trace elements in biological systems. For these reasons, many fluorescent sensors for these metal ions have been synthesized and characterized.[3−5] In this context, we have synthesized the ligand tris[2-(5-dimethylamino-1-naphthalenesulphonamido)ethyl]amine (**1**), a new tripodal ligand incorporating the dansyl chromophore. Its luminescent properties have been widely used in order to obtain fluorescent sensors and labels,[6−15] especially in the field of biochemistry for peptides and amino acids. We report here the synthesis and the luminescence properties of this ligand and its metal complexes, as well as luminescence studies of (dansylethylenediamine)metal complexes **2** to provide a more in-depth investigation of the photophysics of such a widely used chromophore.

Results

All the photophysical experiments were carried out in acetonitrile/water (1:1, v/v) solutions. The absorption spectrum of **1** (Figure 1) was very similar in shape to the absorption spectrum of **2**, but it was three times more intense, as would be expected given the presence of three chromophoric groups in **1**. As far as the fluorescence properties are concerned, as can be seen from Table 1, compounds **1** and **2** have very similar spectra and exhibit similar lifetimes and quantum yields. The absorption spectra and fluorescence properties of **1** and **2** do not depend on the pH conditions in the range 3−11.

1 2

Scheme 1

As can be seen from Figure 2 and Table 1, strong changes in the luminescence properties of **1** were indeed observed upon addition of Cu^{2+}, Co^{2+}, Zn^{2+}, and Cd^{2+} at pH = 9.5. In particular, for the first two metal ions, a strong quenching (I_{rel} = 1%, Table 1) of the fluorescence intensity was observed, while for Zn^{2+} and Cd^{2+} a blue shift, accompanied by an enhancement of the quantum yield, could be detected.

Smaller, but non-negligible changes could also be observed at these pH conditions in the absorption bands of **1** upon addition of Co^{2+}, Zn^{2+}, Cd^{2+}, and Cu^{2+} (Figure 1). A blue shift of the fluorescence band of **1** was also observed upon addition of Ag^{+} and Hg^{2+} metal ions; however, precipitation of the metal ions before reaching complete complexation prevented further investigations. Similar effects caused by addition of Cu^{2+} ions were observed in the absorption and luminescence spectra of compound **2**, while

[a] This residual luminescence can be ascribed to an impurity of a luminescent dansyl derivative present in the sample. For more details, see text.

addition of Co^{2+} ions did not cause any change in its photophysical properties. An increase in the luminescence intensity of **2** was observed upon addition of Zn^{2+} and Cd^{2+}, but the formation of the metal hydroxide prevented the formation of the complex.

Addition to a 5×10^{-5} M solution of **1** and **2** of up to 10 molar equiv. of Na^+, K^+, Ca^{2+}, Sr^{2+}, Ba^{2+}, Eu^{3+}, Ni^{2+}, Mn^{2+}, Pb^{2+}, Fe^{2+}, Fe^{3+}, and Cr^{3+} did not lead to any change in the absorption and emission spectra of the dansyl derivatives in all the pH range examined (3−11). Furthermore, no effects were found on the absorption and luminescence spectra upon addition of up to 10 equiv. of the aforementioned metal ions to a solution containing equimolar amounts of **1** and Zn^{2+} or Cu^{2+} ions.

The observed changes for **1** and **2**, as can be seen from Figures 3 and 4, respectively, were very sensitive to the pH conditions: They were almost negligible at pH values lower than 4, and reached a plateau at higher pH, the pattern being characteristic for the ligand and the metal ion. This behavior is fully reversible; superimposable titration profiles have been obtained starting from pH = 11 upon addition of acid.

Titration experiments were performed in order to investigate the stoichiometry of the complexes formed, by adding

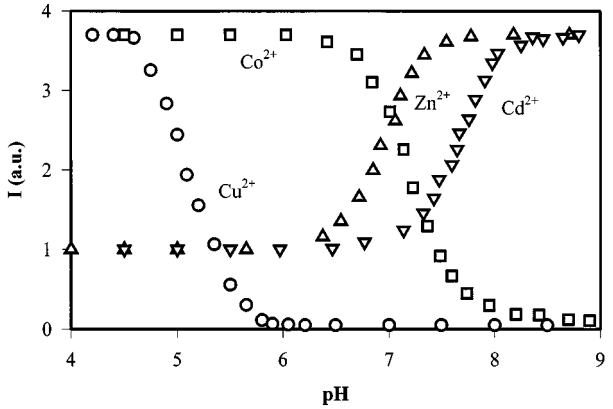

Figure 3. pH dependence of the fluorescence intensity (λ_{exc} = 340 nm) for solutions containing equimolar amounts (8×10^{-5} M) of **1** and (i) Cu^{2+} ions (λ_{em} = 540 nm), (ii) Co^{2+} ions (λ_{em} = 540 nm), (iii) Zn^{2+} ions (λ_{em} = 500 nm), and (iv) Cd^{2+} ions (λ_{em} = 500 nm); superimposable titration profiles have been obtained starting from pH = 11 upon addition of acid

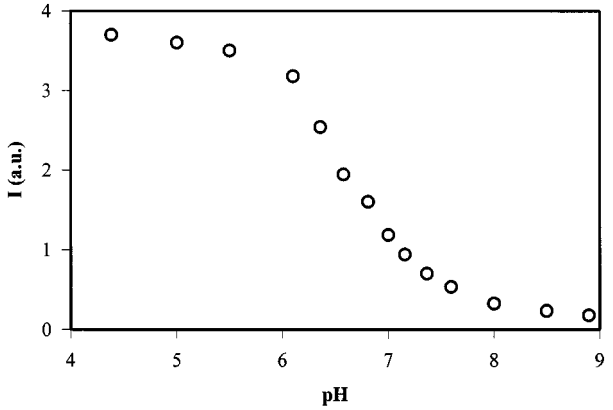

Figure 4. pH dependence of the fluorescence intensity (λ_{exc} = 340 nm, λ_{em} = 540 nm) for a solution containing equimolar (8×10^{-5} M) amounts of **2** and Cu^{2+}; superimposable titration profiles have been obtained starting from pH = 11 upon addition of acid

the metal ion to a basic (pH = 9.5) solution of the ligand. Titrations of **1** and **2** with Cu^{2+} are shown in Figure 5. These experiments always indicate a 1:1 (metal/ligand) stoichiometry for **1**, while for **2** there is evidence of a 1:2 (metal/

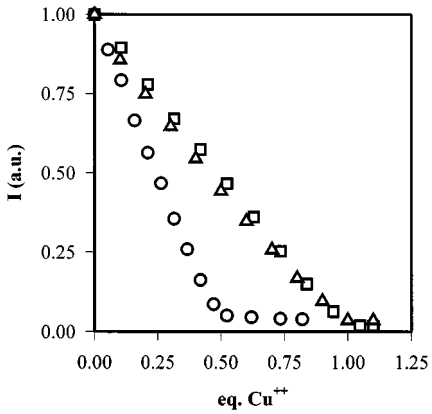

Figure 5. Dependence of the fluorescence intensity (λ_{exc} = 340 nm, λ_{em} = 540 nm) of a solution (i) containing **2** (8×10^{-5} M) at pH = 9.5 (open circles), (ii) containing **1** (8×10^{-5} M) at pH = 9.5 (open triangles), and (iii) containing **1** (8×10^{-5} M), Zn^{2+}, Co^{2+}, and Cd^{2+} (1.6×10^{-4} M) at pH = 6.5 (open squares) upon addition of Cu^{2+}

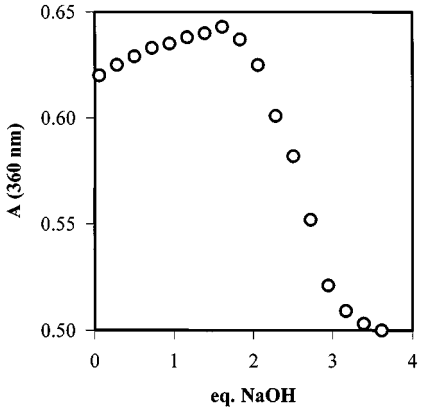

Figure 7. Dependence of the absorbance at 360 nm of a solution containing **1** and Cu^{2+} (8×10^{-5} M) upon addition of NaOH

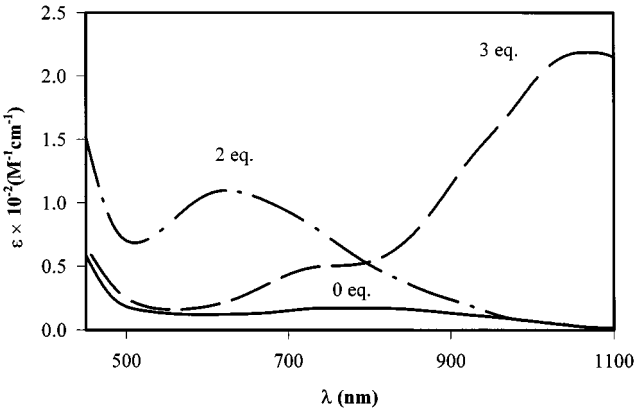

Figure 8. Cu^{2+}-centered absorption bands in the presence of one equiv. of **1** in acetonitrile/water (1:1, v/v) after the addition of various amounts of NaOH

ligand) stoichiometry. On adding up to 2 equiv. of Co^{2+}, Zn^{2+}, and Cd^{2+} ions to a solution of **1** at pH = 6.5 no changes in the luminescence properties of the ligand were observed. Titration of the same solution containing the aforementioned ions with Cu^{2+} ions led to the same pattern as shown for the titration at pH = 9.5 (Figure 5). These results clearly indicate that under these conditions only the copper ions can induce changes in the luminescence properties of **1**, and no interferences come from the other metal ions.

Addition of NaOH to a solution containing an equimolar amount of metal ion and ligand **1** (Figure 6) showed that for Co^{2+}, Zn^{2+}, and Cd^{2+} the plateau of the luminescence intensity vs. added base is reached after addition of 3 equiv. of base. For Cu^{2+}, the complete quenching of the luminescence was observed after addition of 2 equiv. of base while further changes were observed in the absorption bands of the dansyl chromophores until the addition of 3 equiv. (Figure 7). Strong changes were also observed for the metal-centered absorption bands of the copper ion in the 450−1100 nm region (Figure 8). Addition of up to 2 equiv. of base to an equimolar (1×10^{-3} M) solution of **1** and Cu^{2+} led to the appearence of a band with maximum at 620 nm, while addition of a third equivalent caused the disappearence of such a band with the concomitant formation of a band centered at 1050 nm.

By contrast, for **2** and Cu^{2+} complete quenching of the luminescence was observed after addition of 1 equiv. of base relative to the ligand.

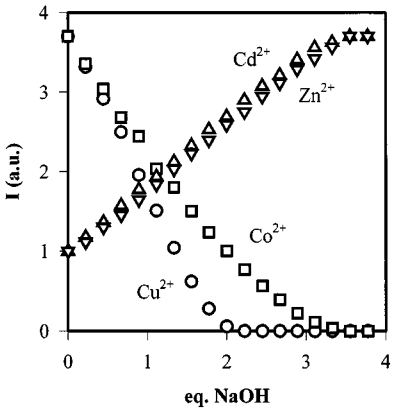

Figure 6. Dependence of the fluorescence intensity (λ_{exc} = 340 nm) for solutions containing equimolar amounts (8×10^{-5} M) of **1** and (i) Cu^{2+} ions (λ_{em} = 540 nm), (ii) Co^{2+} ions (λ_{em} = 540 nm), (iii) Zn^{2+} ions (l_{em} = 500 nm), and (iv) Cd^{2+} ions (λ_{em} = 500 nm) upon addition of NaOH

Discussion

Dansylamide and its derivatives typically show intense and large luminescence bands in the 400−600-nm region. These bands are very sensitive to the polarity of the solvent and have considerable charge-transfer character, caused by mixing of the ^1L_a and ^1L_b states of naphthalene with a charge-transfer state arising from the promotion of a lone-pair electron on the amino group into a π antibonding orbital of the naphthalene ring.[16] The photophysical behavior of **1** and **2** is in agreement with the data obtained with other dansyl derivatives.[6−16] The constancy of the

photophysical properties on passing from compound **1** to dansylamide and the ligand **2** shows that intramolecular interactions between the three chromophores in **1** are negligible.

Complexes with Cu^{2+}

Addition of Cu^{2+} ions to a neutral water/acetonitrile (1:1, v/v) solution of **1** and **2** caused a strong decrease in the fluorescence intensity and lifetime of the ligands. The quenching observed for **2** has been explained, as already reported for other dansyl derivatives, as being due to the complex formation by the amino group, followed by abstraction of the sulphonamide hydrogen atom.[9−10,17] For compound **2** (Figure 5) evidence for the formation of a complex with a 2:1 (ligand/metal ion) stoichiometry could be seen, although a 1:1 stoichiometry at higher metal concentration cannot be ruled out.[11] The observation of a plateau after addition of an equimolar amount of base in respect to the ligand is further evidence for the mechanism involving the deprotonation of the sulphonamide group for obtaining the quenched species.

A similar complexation/deprotonation mechanism can also be invoked for **1**, but with some differences. The first one is the evidence, from titration experiments, of the formation of a complex with 1:1 stoichiometry between **1** and Cu^{2+}. In addition, the pattern shown by the fluorescence spectra clearly indicates that an almost complete quenching is reached after addition of two equiv. of base (Figure 6), i.e. with the formation of a neutral complex obtained with the deprotonation of only two dansyl moieties. Under these conditions a residual luminescence with a relative intensity of 1% is observed that has an unquenched lifetime. This residual luminescence can be ascribed to an impurity of a luminescent dansyl derivative present in the sample. The further deprotonation of the third side arm, demonstrated by the changes in the absorption spectra (Figures 7 and 8), is obtained only in a second step at pH > 7.5 with the addition of the third equivalent of base.

In principle, the quenching effect after the formation of the complex can be ascribed for both **1** and **2** to either a dansyl-to-metal energy-transfer (ET) or a metal-to-dansyl electron-transfer (eT) mechanism. From the intensity data obtained, lower limits of the quenching rate constants at room temperature and at 77 K can be calculated for **1** by using Equation 1, and are 1×10^{-10} s^{-1} and 5×10^{-9} s^{-1}, respectively. The high value of the estimated quenching rate constant at 77 K suggests at least a contribution from the ET mechanism.

$$k_q = 1/\tau^\circ(I^\circ/I - 1) \quad (1)$$

The almost complete quenching of **1** after deprotonation of only two dansyl derivatives suggests that under these conditions the third side arm lies in close contact to the metal ion.

It is important to note that the formation of the Cu complex occurs at lower pH values for **1** than for **2**. This observation, together with the different stoichiometry observed for the two ligands, confirms the co-operative effect of the three side arms of the tripodal ligand **1**.

Complexes with Co^{2+}

As reported above, no changes in absorption and fluorescence spectra were observed on adding Co^{2+} ions to a solution of **2**. In contrast, at pH values higher than 7, a quenching (I_{rel} = 1%, Table 1) of the fluorescence intensity of **1** is observed, and titration experiments revealed a 1:1 (ligand/metal) stoichiometry of the complex. In this case, a simultaneous deprotonation of all the three dansyl moieties is observed from titration experiments (Figure 6). As discussed previously, a dansyl-to-Co energy-transfer (ET) or a Co-to-dansyl electron-transfer (eT) mechanism can be invoked to explain the observed fluorescence quenching, although its high efficiency at 77 K (Table 1) again suggests a contribution from the energy-transfer mechanism. As proposed for the Cu^{2+} complex, a co-operative effect of the three arms of the ligand **1** has to be invoked in order to explain the different behaviour of the two ligands examined.

Complexes with Zn^{2+} and Cd^{2+}

As reported above, addition of Zn^{2+} and Cd^{2+} ions to basic water/acetonitrile solutions of **1** caused a noticeable blue-shift in their fluorescence bands, with a concomitant increase in the quantum yield and lifetime. This effect can also be explained in terms of the formation of a complex by the amino group, followed by the deprotonation of the sulphonamide hydrogen atoms. As already known, complexation with d^{10}-Zn^{2+} and -Cd^{2+} ions does not usually introduce low-energy metal-centered or charge-separated excited states into the molecule, so that ET and eT processes cannot usually occur. However, the deprotonation/complexation process increases the electronic density on the naphthalene ring, moving towards higher energy the amine-to-naphthalene charge-transfer state present in the dansyl chromophore. A hypsochromic shift with a concomitant increase of the luminescence intensity is also observed for dansyl derivatives upon raising the energy of this excited state using low-polar solvents.[16] Complexes with a 1:1 (ligand/metal ions) stoichiometry are obtained for **1** with both Zn^{2+} and Cd^{2+}, and as observed for the Co^{2+} ions, a simultaneous deprotonation of all the three dansyl groups takes place (Figure 6). For ligand **2**, formation of the complexes occurs at higher pH values, but the competitive formation and precipitation of the metal hydroxide prevents the complete formation of the complexes.

The results obtained with Na^+, K^+, Ca^{2+}, Sr^{2+}, Ba^{2+}, Eu^{3+}, Ni^{2+}, Mn^{2+}, Pb^{2+}, Fe^{2+}, Fe^{3+}, and Cr^{3+}, both by direct and by competition experiments, indicate that these metal ions do not interfere with the complexation of Cu^{2+}, Co^{2+}, Zn^{2+} and Cd^{2+} ions. Finally, it is worth noting that among the latter ions, **1** shows a remarkable affinity and selectivity towards the Cu^{2+} ions, as can be seen from the

titration experiment performed in the presence of the other possible interfering metal ions (Figure 5). The pH window in which the complete quenching occurs is quite large (Figure 3) compared with that of other chemosensors for Cu^{2+}.[18−20] All these features make **1** a good candidate for a possible use as chemosensor for copper ions.

Conclusions

Tris[2-(5-dimethylamino-1-naphthalenesulphonamido)-ethyl]amine (**1**), a new tripodal ligand, has been synthesized and characterized, and the results compared with dansylethylenediamine (**2**), a compound that has been widely used as a reference for many other dansyl derivatives. The fluorescence properties of **1** are not unexpected considering the presence of three non-interacting dansyl moieties. Strong changes were observed upon addition of Cu^{2+}, Co^{2+}, Zn^{2+}, and Cd^{2+}, indicating a strong complexation leading to deprotonation of the sulphonamide groups of the dansyl moieties for all of them. For Cu^{2+} and Co^{2+}, a strong quenching was observed both at room temperature and at 77 K, that can be ascribed to energy- or electron-transfer processes, although the first possibility seems to be the most likely. For Zn^{2+} and Cd^{2+}, a shift of the fluorescence band toward lower wavelengths was observed with a concomitant increase of fluorescence quantum yield and lifetime. This phenomenon can be explained by a higher electronic density on the naphthalene ring of the dansyl groups after the deprotonation/complexation process. For all the metal ions, **1** was found to form stronger complexes than **2**, indicating a co-operative effect of the three arms of the tripodal ligand. Furthermore, **1** shows a remarkable affinity and selectivity towards the Cu^{2+} ions at pH > 4, suggesting a possible use of this ligand as luminescent chemosensor for these ions.

Experimental Section

General: The following materials were used: dansyl chloride (Aldrich), tris(2-aminoethyl)amine, "TREN" (Aldrich), triethylamine (Aldrich); sodium hydroxide, copper(II) nitrate hemipentahydrate, cobalt(II) and zinc(II) hexahydrate, and cadmium(II) nitrate tetrahydrate were obtained from Fluka. − Dansylethylenediamine (**2**) was a gift from Prof. Marchelli and Dr. Corradini of the University of Parma, and was available from previous work.[9] − Thin-layer-chromatographic analysis was performed using precoated TLC silica gel plates (60 F-254, Merck). − ^{1}H-NMR and ^{13}C-NMR spectra were recorded at 20°C with a Varian 500 FT spectrometer.

Tris[2-(5-dimethylamino-1-naphthalenesulphonamido)ethyl]amine (1): To a stirred solution of dansyl chloride (0.2 g, 0.74 mmol) in anhydrous $CHCl_3$ (8 ml) was added triethylamine (0.1 ml, 0.75 mmol) and TREN (35 ml, 0.25 mmol); the solution turned from dark yellow to fluorescent in less than 2 min. After stirring for another 2 h, the reaction mixture was quenched (ethyl acetate, 0.1 M in water) and extracted (CH_2Cl_2, 3 × 30 ml). Purification by flash chromatography on silica gel (CH_2Cl_2/diethyl ether, 1:1) allowed the isolation of **1** (120 mg, 59%) as a highly fluorescent yellow dense oil. − ^{1}H NMR (500 MHz, $CDCl_3$): δ = 8.51 (d, 3 H, J = 8.5 Hz), 8.44 (d, 3 H, J = 8.5 Hz), 8.26 (d, 3 H, J = 7.0 Hz), 7.52 (m, 6 H), 7.05 (d, 3 H, J = 7.5 Hz), 6.56 (br. s, 3 H, NH), 2.84 (m, 24 H, NCH_3, NCH_2CH_2NH), 2.42 (br. s, 6 H, NCH_2CH_2NH). − ^{13}C NMR ($CDCl_3$): δ = 152.19, 130.58, 130.31, 130.07, 129.55, 129.06, 123.74, 119.98, 115.75, 53.14 (NCH_2CH_2NH), 45.93 (NCH_3), 42.02 (NCH_2CH_2NH).

Spectroscopic Measurements: The solvents used for photophysical measurements were acetonitrile (Merck UVASOL) and Millipore grade water, both without further purification. The solutions of the ligands were prepared in a concentration range between 4×10^{-5} M and 1×10^{-4} M unless otherwise noted. Absorption spectra were recorded with Perkin−Elmer lambda 16 and lambda 40 spectrophotometers. Corrected emission and excitation spectra were obtained with a Perkin−Elmer LS50 spectrofluorimeter. The fluorescence lifetimes (uncertainty, ± 5%) were obtained with an Edinburgh single-photon-counting apparatus (D_2-filled flash lamp). Luminescence quantum yields (uncertainty ± 15%) were determined using quinine sulphate (Φ = 0.546[21] in 1 N H_2SO_4 aqueous solution) as standard. Emission spectra in a rigid matrix at 77 K were recorded using quartz tubes immersed in a quartz Dewar filled with liquid nitrogen. In order to allow comparison of emission intensities, corrections for instrumental response, inner filter effects, and phototube sensitivity were performed.[22]

Metal-Ion Binding: Titration experiments of **1** and **2** with the different metal ions were carried out on 3 ml of 5×10^{-5} M solutions, adding 10 ml each time of a 2.5×10^{-3} M solution of the metal ion. These experiments were performed at pH = 6.5 using a 10^{-2} M lutidine buffer and at pH = 9.5 using a 10^{-2} M borate buffer. The pH dependence of the complexation processes were followed by adding 10 ml each time of a 5×10^{-3} M solution of NaOH to a solution containing **1** or **2** (5×10^{-5} M) and the metal ion (5.2×10^{-5} M).

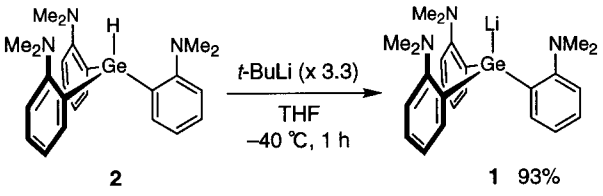
Distorted Germyllithium Induced by Intramolecular Coordination of an Amino Group: Synthesis and Structures of {Tris[2-(dimethylamino)phenyl]germyl}lithium

Atsushi Kawachi,*[a] Yoko Tanaka,[a] and Kohei Tamao*[a]

Keywords: Germyllithium / 2-(Dimethylamino)phenyl ligand / Chelates / Solid-state structures / Solution structures



{Tris[2-(dimethylamino)phenyl]germyl}lithium (**1**) has been prepared. The X-ray analysis shows that **1** exists as a monochelated monomer in the solid state, where the lithium atom is coordinated to one of the amino groups and two THF molecules. The interaction between the lithium atom and the amino group induces the distortion of the geometry around the germanium atom. In solution, however, two species exist as evidenced by ^{1}H-, ^{7}Li-, and ^{13}C-NMR spectra. The temperature-dependent behavior of these two species has been analyzed by variable-temperature NMR studies.

Introduction

Among a variety of Group-14 element−alkali metal compounds, germyllithium compounds have been well studied from the synthetic point of view,[1] but structural studies are still scarce; only six structures of germyllithium compounds have been determined by X-ray analysis[2] and the substituents have been limited to the tris(trimethylsilyl)silyl group and germole skeletons. We report here the preparation of {tris[2-(dimethylamino)phenyl]germyl}lithium (**1**) and its structure in the solid state and in solution, focusing on the interaction between the lithium atom and the amino group[3] as well as on the germanium−lithium bonding character.

Results and Discussion

The germyllithium **1** was prepared by deprotonation of the hydrogermane[4] **2** with *tert*-butyllithium (3.3 equiv.) in THF at −40°C in 93% yield, as shown in Scheme 1; the yield was estimated by quenching with D_2O. When **2** was treated with a deficient amount of *tert*-butyllithium (1.2 equiv.), **1** could be isolated as pale yellow crystals in 33% yield after recrystallization from toluene at −20°C.

Structure in the Solid State

X-ray analysis of the crystal reveals that **1** has a monomeric structure in the solid state, as shown in Figure 1. The selected bond lengths, bond angles, and torsion angles are listed in Table 1. The most striking feature is the highly distorted geometry around Ge(1) due to the unsymmetrical interaction of Li(1) with the amino group. Li(1) bonded to Ge(1) is coordinated to N(1) of one of the three NMe_2 groups, forming a five-membered chelate ring consisting of Li(1), Ge(1), C(1), C(2), and N(1). Li(1) is also coordinated to O(1) and O(2) of two THF molecules arising from the reaction solvent. The Li(1)−Ge(1) bond length [2.598(9) Å] is the shortest among those of the characterized germyllithium compounds [2.613(3)−2.759(24) Å].[2] The Li(1)−N(1) bond length [2.15(1) Å] is longer than the sum of the covalent radii (Li 1.23 Å; N 0.70 Å),[5] but normal as coordinative Li−N bonds (2.01−2.17 Å).[3] The intramolecular coordination of N(1) to Li(1) reduces the angle of Li(1)−Ge(1)−C(1) to 83.9(3)°. As a result, Li(1), Ge(1), C(9), and C(17) are almost coplanar; the sum of the three angles of Li(1)−Ge(1)−C(9), Li(1)−Ge(1)−C(17), and C(9)−Ge(1)−C(17) is 359.5°. In spite of the distorted geometry, however, there are no significant differences among the three Ge−C bonds [2.042(6), 2.030(5), and 2.054(5) Å] and the three C−Ge−C angles [96.8(2), 99.2(2), and 98.4(2)°]. It is also noted that the sum of the latter (294.4°) is strongly reduced from the sp^3 tetrahedral value (328°). Thus, the geometry of **1** may be designated pyramidal rather than distorted tetrahedral.

In order to obtain information about the electronic structure, we performed an ab initio calculation of **1**·$(THF)_2$ at HF level using the 6-311+G* basis set on Li and Ge atoms and the 6-31G basis set on H, C, N, and O atoms,[6] based on the geometry of the crystal structure. The natural bond orbital analysis reveals that the anionic electrons on Ge(1) have a considerably higher s character (s 57.3%; p 42.6%; d 0.1%) than the sp^3-hybrid orbitals,[7] whereas the three Ge−C bonds have a higher p character [Ge(1)−C(1), 86.7%; Ge(1)−C(9), 84.0%; Ge(1)−C(17), 85.2%]. These p

Ge(1)−C(17)−C(18)−N(3)	−5.8(7)

characters are almost equivalent to each other, in agreement with the similarity of the Ge−C bond lengths. The molecular orbital analysis of the anionic electrons (HOMO) indicates that the lithium atom is located not along the vector of the anionic electrons but aside from it, as shown in Figure 2. This may be represented as an intramolecular separated ion pair, which is not unusual if the Ge−Li interaction is weak while the N−Li coordinative interaction is relatively strong.

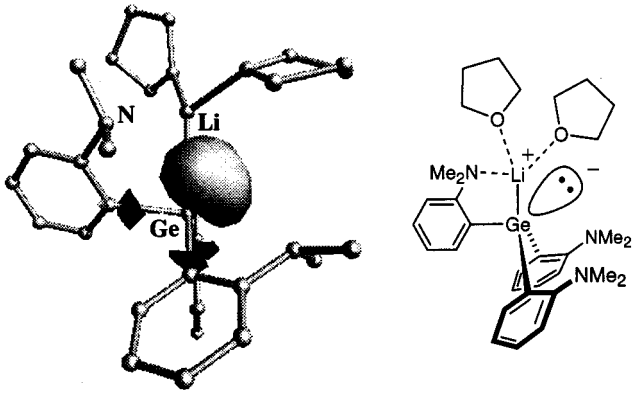

Figure 2. HOMO of **1**·$(THF)_2$ calculated at HF level using the 6-311+G* basis set on Li and Ge atoms and the 6-31G basis set on H, C, N, and O atoms; geometry is based on the crystal structure; its schematic representation is also shown

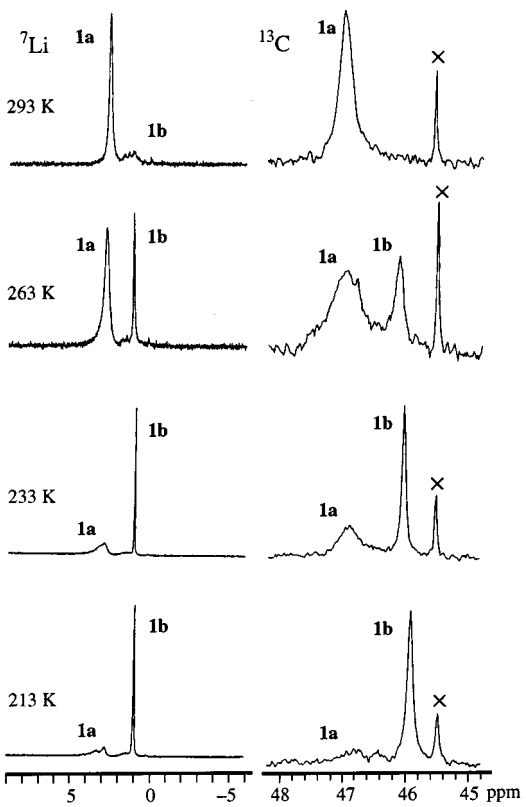
Structures in Solution

In contrast to the single structure in the solid state, the structure of **1** in solution is not simple. Crystalline **1** involving two solvated THF molecules was dissolved in $[D_8]$toluene, and the behavior was examined by variable-temperature ^{1}H-, ^{7}Li-, and ^{13}C-NMR spectroscopy. The results of the latter two analyses are shown in Figure 3. The analysis of the spectra reveals that **1** exists as a mixture of two species in the solution and their integral ratio reversibly changes as the temperature changes. Thus, the ^{7}Li-NMR spectra display two distinct signals at $\delta = 1.20$ and $\delta = 2.88$. The ^{13}C-NMR spectra show two kinds of signals at $\delta = 46.1$ and $\delta = 47.0$ for the NMe_2 carbon atoms. The ^{1}H-NMR spectra also show two kinds of signals at $\delta = 2.31$ and $\delta = 2.59$ for the NMe_2 protons, analogously to the ^{13}C-NMR signals.

Based on the temperature-dependent behavior of these two species, we assumed that the monomer **1a**, arising from the crystals, dimerizes to the dimer **1b** and they are in equilibrium in the solution, as shown in Scheme 2. Whereas the monomer **1a** is favored at higher temperatures in terms of the entropy effect,[3g] the dimer **1b** is favored at lower temperatures in terms of the electrostatic interaction,[8] through which the anionic electrons are efficiently stabilized by the two lithium cations. Based on this assumption, the thermodynamic parameters for the monomer−dimer equilibrium between **1a** and **1b** were estimated from a series of ^{1}H-NMR spectra. The equilibrium is described as $K_{eq} = [\mathbf{1b}]/[\mathbf{1a}]^2$ according to Scheme 2. From a van′t Hoff plot of $\ln(K_{eq})$ vs $1/T$, we obtained $\Delta H° = -34.5 \pm 1.7$ kJ/mol, $\Delta S° = -135 \pm 7$ J/mol·K, $\Delta G°_{293} = 5.1 \pm 3.8$ kJ/mol, and $\Delta G°_{213} = -5.8 \pm 3.2$ kJ/mol. These thermodynamic data, especially the large negative entropy, strongly support the proposed monomer−dimer equilibrium and formation of the dimer at lower temperatures.

To confirm the monomer/dimer assignment and rule out other assignments for the higher aggregate, we performed a variable concentration study.[9] A plot of log[dimer] vs log[monomer] (integration of ^{1}H-NMR spectra at 233 K) has a slope of 2.1 ± 0.2, confirming that the two species



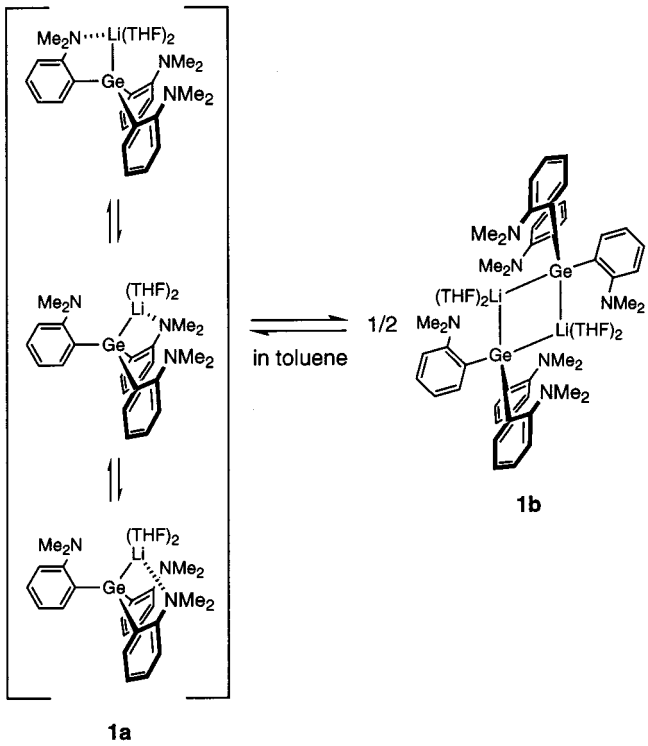


Figure 3. ^{7}Li- and ^{13}C-NMR spectra of **1** in [D_8]toluene at different temperatures; peaks marked with × are due to the hydrogermane **2**

Scheme 2

differ in aggregation state by a factor of 2. It is also found that the ^{7}Li-chemical shift of **1a** (δ = 2.88) is consistent with the GIAO calculated shift of **1**·$(THF)_2$ (δ = 3.06), based on the geometry of the crystal structure.[6,10,11] Thus, the two species **1a** and **1b** are represented as monomer and dimer, respectively.

Accordingly, the signals at δ = 2.88 (^{7}Li) and δ = 47.0 (^{13}C) can be attributed to **1a** while the signals at δ = 1.20 (^{7}Li) and δ = 46.1 (^{13}C) can be attributed to **1a** at 263 K in Figure 3. Some aspects require a comment: (i) In the hydrocarbon solvent, the monomer **1a** is expected to be chelated by the NMe_2 group(s), as observed in the crystal structure. However, the NMe_2 groups might equilibrate on the NMR time scale, because they appear as a broad ^{13}C resonance upon cooling to 213 K. (ii) In the dimer **1b**, the NMe_2 groups may not interact with the lithium atom, because they appear as a sharp ^{13}C resonance upon cooling to 213 K. (iii) The smaller line width of the ^{7}Li resonance[3g,12] of **1b** than that of **1a** may reflect the more symmetrical environment around the lithium atom in the former.

In conclusion we have revealed the structure of the germyllithium **1** in the solid state and in solution. While in the solid state the intramolecular coordination of the amino group induces the distorted geometry of the monomeric **1a**, **1a** tends to dimerize in solution.

Experimental Section

General: ^{1}H (270 MHz), ^{7}Li (105.01 MHz), and ^{13}C (67.94 MHz) NMR spectra were recorded with a JEOL EX-270 spectrometer. ^{1}H- and ^{13}C-chemical shifts were referenced to internal [D_8]toluene (^{1}H: δ = 2.10; ^{13}C: δ = 20.40), [D_6]benzene (^{1}H: δ = 7.20), and $CDCl_3$ (^{13}C: δ = 77.00). ^{7}Li-chemical shifts were referenced to external lithium chloride (δ = 0) in methanol. − Mass spectra were measured at 70 eV with a JEOL JMS-700 mass spectrometer equipped with an MS-SEPU data processing system. − Melting points were measured with a Yanaco-MP-S3 apparatus and are uncorrected. − Infrared spectra were recorded with a JASCO IR-810 spectrophotometer. − *tert*-Butyllithium in pentane was purchased from Kanto Chemical Co., Inc. THF was distilled under nitrogen from sodium benzophenone ketyl and then lithium aluminium hydride or sodium potassium alloy. Toluene was distilled under nitrogen from sodium. All reactions were carried out under an inert atmosphere.

Preparation of {Tris[2-(dimethylamino)phenyl]germyl}lithium (1) and Trapping with D_2O. − Formation of Tris[2-(dimethylamino)phenyl]-deuteriogermane (3): To a solution of tris[2-(dimethylamino)phenyl]hydrogermane (**2**)[4] (217 mg, 0.50 mmol) in THF (1.0 mL) was added *tert*-butyllithium in pentane (1.64 M, 1.0 mL, 1.64 mmol) at −40°C. The reaction mixture was stirred at −40°C for 1 h to give a yellow suspension of **1**. To the suspension was added deuterium oxide (0.3 mL, 17 mmol) at −40°C and the mixture was stirred at room temperature for 4 h. After the solvent was removed under reduced pressure, the residue was diluted with benzene (10 mL) and filtered. The filtrate was concentrated to give **3** as a solid. The yield was estimated by means of NMR analysis (93%) using mesitylene as the internal standard. Recrystallization of the solid from hexane (0.4 mL) gave **3** as colorless crystals (178 mg, 82% yield based on **2**), m.p. 96.5−97.0°C. − ^{1}H NMR ([D_6]benzene): δ = 2.57 (s, 18 H), 6.94−6.99 (m, 3 H), 7.07−7.10 (m, 3 H), 7.20−7.25 (m, 3 H), 7.40−7.43 (m, 3 H). − ^{13}C NMR ($CDCl_3$): δ = 45.68, 119.30,

123.40, 129.49, 135.53, 136.57, 159.44. − IR (KBr): $\tilde{\nu}$ = 1530 cm^{-1} (Ge−D). − MS (70 eV); *m/z* (%): 436 (2) [M^+], 434 (1) [M^+ − D], 314 (85) [$(Me_2NC_6H_4)_2Ge$], 194 (56) [$Me_2NC_6H_4Ge$], 120 (100) [$Me_2NC_6H_4$].

Crystals of 1·$(THF)_2$: To a solution of **2** (210 mg, 0.49 mmol) in THF (1.4 mL) was added *tert*-butyllithium in pentane (1.56 M, 0.38 mL, 0.59 mmol) at −40°C. The reaction mixture was stirred at −40°C for 1 h. The solvent was removed under reduced pressure at 0°C to give a yellow solid. Recrystallization of the solid from toluene (0.5 mL) at −20°C gave **1**·$(THF)_2$ as pale yellow crystals (92 mg, 33% yield based on **2**), m.p. 270.0−271.0°C (sealed tube, decomp.).

X-ray Structure Determination for 1·$(THF)_2$: All crystal data and refinement parameters are summarized in Table 2. The crystal was sealed in a capillary tube under argon. Data were collected with a Rigaku RAXIS-IV imaging plate area detector with filtered Mo-K_α radiation. The structure was solved by direct methods (SIR92)[13] and expanded using Fourier techniques (DIRDIF94)[14] and refined on $|F|^2$. Empirical absorption corrections based on azimuthal scans of several reflections were applied**.** The non-hydrogen atoms were anisotropically refined. All hydrogen atoms were located at the expected positions by a geometrical calculation and fixed at these positions. Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary no. CCDC-102693. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: int. code + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Bis(dipeptide ester–H^+) Complexes of Palladium(II) – Precursors for the Formation of Cyclotetrapeptides

Katharina Haas,[a] Eva-Maria Ehrenstorfer-Schäfers,[a] Kurt Polborn,[a] and Wolfgang Beck*[a]

Dedicated to Professor Peter Jutzi on the occasion of his 60th birthday

Keywords: Dipeptide ester / Cyclic tetrapeptides / Palladium complexes / Coordination chemistry

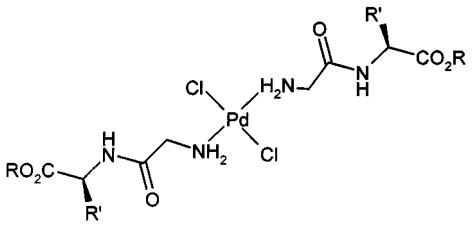
trans-Bis(dipeptide ester)palladium **1**–**6** complexes with a deprotonated amide group were obtained by dehydrochlorination of *trans*-Cl_2Pd(dipeptide ester)$_2$ or by direct reaction of Na_2PdCl_4 with dipeptide ester in the presence of sodium methoxide. The structure of $Pd(NH_2CH_2CONCH_2CH_2CO_2CH_3)_2$ (**3**) was determined by X-ray diffraction. Addition of $NaOCH_3$ to $Pd[NH_2C(H)(R)NCH_2CH_2CO_2CH_3]_2$ [R = $CH(CH_3)_2$ **4**, CH_2Ph **5**] results in the formation of the corresponding complexes **7**, **8** with cyclic tetrapeptides which also can be directly synthesized from the dipeptide ester and Na_2PdCl_4.

Introduction

Palladium(II) and platinum(II) complexes of amino acids and peptides have found considerable attraction due to their potential antitumor activity. Amino acid and peptide ligands may act as carriers for cyctotoxic metal fragments.[2] The chemistry of palladium(II)[3−5] and platinum(II)[3,6] with α-amino acids and peptides has been reviewed. Palladium(II) has many attractive features as a Lewis acid due to its fixed coordination number 4, its high Lewis acidity, its high formation constants with N,O donor ligands and its intermediate kinetic lability.[7] A particular feature of palladium(II) is its ability to deprotonate peptide NH groups, which in free peptides have pK_a values of ca. 15. The pK_a value of the Pd^{II}-induced ionization of peptide NH bonds is about 3.5[8], which is much lower than that of other metal ions such as Cu^{2+}, Ni^{2+} and Zn^{2+}.[9−11] Thus, Pd^{2+} ions show a nonspecific binding to the peptide backbone involving a destabilization of the secondary structure of peptides, i.e. α-helices.[12] The palladium ion promoted hydrolysis of peptides[13−15] and esters[7,15] has attracted attention due to the relevance of these systems to the function of metalloenzymes.[16] Ternary palladium complexes with peptides and nucleic acids were synthesized as models for the interaction between proteins and nucleic acids with the intervention of metal ions.[5,17,18] Several palladium complexes of peptides have been structurally characterized.[19−21]

Mogilevkina et al.[22] reported the synthesis of platinum(II) complexes $Pt(NH_2CH_2CONCH_2COOH)_2$ and $[Pt(NH_2CH_2CONCH_2CO_2)_2]^{2-}$ from Cl_2Pt(gly−glyOH)$_2$[23]. Margerum et al. studied the formation of (tripeptide)platinum complexes in solution.[24] From IR data a structure with N,N′ chelate rings was derived, like that found for the structurally characterized (Cl)Pt(gly−L-met).[25]

Results and Discussion



Recently we reported the metal-assisted formation of cyclic tetrapeptides from dipeptide esters.[26] In the course of our continuing studies on the formation of peptides at metal centres,[27−29] including the use of platinum(II) and palladium(II) as amino protecting group [6,30,31] we describe the synthesis and characterization of bis(dipeptide ester) complexes of palladium(II), which are precursors for the formation of cyclic peptides. The *trans*-bis(dipeptide ester) complexes of palladium(II) were obtained by two routes: a) by dehydrochlorination of *trans*-dichlorobis(dipeptide ester)palladium(II) with NEt_3 in dichloromethane to give **1** and **2** and b) by direct reaction of the dipeptide ester hydrochloride, consisting of α- and β-amino acids, with Na_2PdCl_4 in the presence of two equivalents of NaOMe in methanol to give **3**−**6**.

In the IR spectra the intensive absorptions at 1559−1580cm^{-1} and at 1722−1731 cm^{-1} are characteristic for the deprotonated and coordinated amide group and the ester group. The ^{1}H- and ^{13}C-NMR spectra show the expected signals. In accordance with *trans* configuration (C_2 symmetry) of **1**−**6** the peptide ligands show only one set of signals in the ^{1}H- and ^{13}C-NMR spectra. All compounds contain two supramolecularly bound equivalents of water

which can be observed in the ^{1}H-NMR spectra by a broad signal at $\delta \approx 4.6$.

Crystals of **3** were obtained by slow cooling of a saturated solution in methanol. The environment of the palladium atom is strictly planar (sum of the angles around the Pd atom is 360°). The X-ray crystal structure analysis of **3** × 4 H_2O shows the expected *trans* configuration with

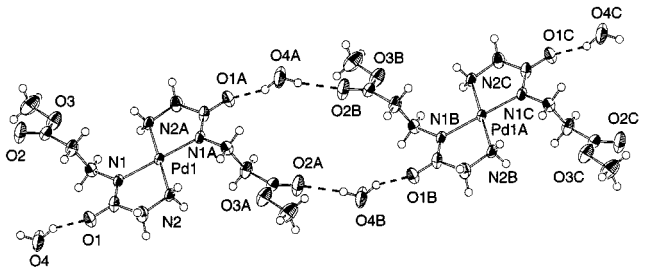

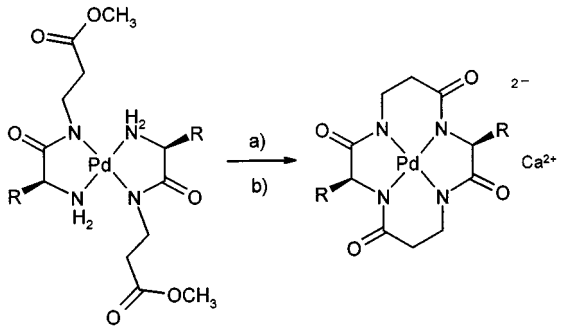

Figure 2. Part of the chain structure formed by the molecules of **3**

coordination of the amino and the deprotonated amide groups and with palladium as inversion centre (Figure 1). In the crystal lattice the molecules of **3** form chains via hydrogen bonds between the water molecules and the carbonyl groups of the amide and the ester groups (distance O1B···HO4B 1.856 Å, O2A···HO4B 2.023 Å, Figure 2). Similar hydrogen bonds between water molecules and carbonyl groups have been observed in the palladium complex [cyclo(gly−ß-ala)$_2$Pd](PPN)$_2$ × 8 H_2O × 3 CH_3CN which lead to the formation of layers.[26]

Addition of two equivalents of NaOMe to **4** and **5** results in the formation of the palladium complexes of cyclic tetrapeptides **7** and **8** which can also be directly obtained from a dipeptide ester and Na_2PdCl_4 (Scheme 3). Thus, the suggested mechanism[26] for the formation of cyclic tetrapeptides at some metal centres from dipeptide esters is proven.

The IR spectra of **7** and **8** show the characteristic intensive absorption for the amide group at 1560−1670 cm^{-1}. The ^{1}H-NMR spectra of **7** and **8** reveal broad signals according to a coordination of the calcium cation to the cyclic tetrapeptide.

A similar chelate complex of platinum(II) with two deprotonated tripeptide ligands **10** has been obtained by dehydrochlorination of *trans*-Cl_2Pt(gly−gly−glyOH)$_2$ (**9**) with

Experimental Section

The *trans*-dichlorobis(dipeptide ester)Pd^{II} complexes were prepared as previously described.[33] Dipeptide ester hydrochlorides were prepared according to standard methods.[34,35] All operations were carried out under nitrogen using Schlenk techniques. Solvents were dried by distillation from Mg (MeOH), calcium hydride (CH_2Cl_2) or Na (Et_2O). − NMR spectra: Jeol EX 400 (^1H: 399.78 MHz; ^{13}C: 100.53 MHz). − IR: Perkin Elmer 841, Nicolet 520 FT-IR. − X-ray: NONIUS CAD4 diffractometer.

General Procedure for the Synthesis of 1 and 2: To a solution of *trans*-dichlorobis(dipeptide ester)palladium(II) (0.2 mmol) in 10 mL of dichloromethane NEt_3 (0.4 mmol) was slowly added. The solution was stirred for 3 d at room temperature, while the colour changed to light yellow. After concentration, the solid residue was washed twice with a small amount of water. The precipitate was centrifuged off and dried in vacuo.

1: Light yellow powder, yield 42%; m.p. 176°C (dec). − IR (KBr, cm^{-1}): $\tilde{\nu}$ = 3280 s, 3230 s (NH_2), 1730 vs (ester), 1673 m, 1570 vs, br. (amide I). − $C_{16}H_{30}N_4O_6Pd$ (480.9): calcd. C 39.96, H 6.29, N 11.65; found C 39.70, H 6.39, N 10.41.

2: Light yellow powder, yield 25%; m.p. 110°C (dec). − IR (KBr, cm^{-1}): $\tilde{\nu}$ = 3280 s, 3240 s (NH_2), 1720 vs (ester), 1670 m, 1570 vs, br. (amide I). − $C_{26}H_{34}N_4O_6Pd$ (605.0): calcd. C 51.61, H 5.66, N 9.26; found C 51.28, H 5.68, N 8.37.

General Procedure for the Synthesis of 3−6: In a typical experiment the dipeptide ester hydrochloride (0.2 mmol) and Na_2PdCl_4 (0.1 mmol) were dissolved in methanol (5 mL) and NaOMe (0.4 mmol) was slowly added to the solution. The light yellow reaction mixture was stirred for 1 h at room temperature. Then the solvent was evaporated in vacuo and the residue was dissolved in 10 mL of absolute dichloromethane. To achieve complete dissolution a minimum volume of absolute methanol was added. After centrifugation, the solution was concentrated to a volume of approximately 2 mL and the *trans*-bis(dipeptide ester)palladium(II) complexes were precipitated by addition of 40 mL of Et_2O as colourless powders, which were dried in vacuo.

3: Light yellow platelets, yield 76%; m.p. 165°C (dec.). − IR (KBr, cm^{-1}): $\tilde{\nu}$ = 3332.5 vs, 3299.2 s (NH_2), 1731.3 vs (ester), 1564.1 vs, br. (amide I). − ^1H NMR (400 MHz, CD_3OD/D_2O): δ = 3.73 (s, 3 H, CO_2H_3), 3.35 (s, 2 H, CH_2), 3.04 (pseudo t, $^2J = {}^3J$ = 6.64 Hz, 2 H, NCH_2CH_2CO), 2.52 (pseudo t, $^2J = {}^3J$ = 6.64 Hz, 2 H, NCH_2CH_2CO). − ^{13}C NMR (100 MHz, CD_3OD/D_2O): δ = 183.00 (CONR), 176.86 (CO_2CH_3), 53.30 (CH_2), 42.46 (NCH_2CH_2CO), 35.65 (NCH_2CH_2CO). − $C_{12}H_{22}N_4O_6Pd \times H_2O$ (442.77): calcd. C 32.55, H 5.46, N 12.65; found C 33.35, H 5.47, N 12.04.

4: Colourless powder, yield 67%; m.p. 125°C (dec.). − IR (KBr, cm^{-1}): $\tilde{\nu}$ = 3230 s, 3125 s (NH_2), 1728.8 vs (ester), 1559.4 vs, br. (amide I). − ^1H NMR (300 MHz, CD_3OD): δ = 3.63 (s, 6 H, CO_2CH_3), 3.47 [pseudo quint, ^2J = 5 Hz, ^3J = 7 Hz, 2 H, $CHCH(CH_3)_2$], 3.11−3.16 (m, 4 H, $NCH_2CH_2CO_2CH_3$), 2.53−2.46 [m, 2 H, $CHCH(CH_3)_2$], 2.36−2.30 (m, 4 H, $NCH_2CH_2CO_2CH_3$), 1.10 [d, ^3J = 7 Hz, 6 H, $CHCH(CH_3)_2$]. − ^{13}C NMR (300 MHz, CD_3OD): δ = 183.16 (CONR), 174.72 (CO_2CH_3), 66.09 [$CHCH(CH_3)_2$], 52.31 (CO_2CH_3), 41.93, 36.83 (CH_2CH_2), 32.59 [$CHCH(CH_3)_2$], 20.01, 18.09 [$CHCH(CH_3)_2$]. − $C_{18}H_{34}N_4O_6Pd \times 3\ H_2O$ (562.96): calcd. C 38.40, H 7.16, N 10.16; found C 37.99, H 6.40, N 9.95.

5: Colourless powder, yield 68%; m.p. 158°C (dec.). − IR (KBr, cm^{-1}): $\tilde{\nu}$ = 3385.0 s, 3274.8 s, 3232.9 s (NH_2), 1721.7 vs (ester), 1568.9 vs, br. (amide I). − ^1H NMR (300 MHz, CD_3OD): δ = 7.36−7.17 (m, 10 H, Ph), 3.53 (dd, ^3J = 3.59 Hz, ^3J = 9.34 Hz, 2 H, $CHHCH$), 3.23 (dd, ^3J = 3.59 Hz, ^2J = 14.23 Hz, 2 H, $CHHCH$), 3.15 (pseudo t, $^3J = {}^2J$ = 7.48 Hz, 4 H, NCH_2CH_2CO), 3.03 (dd, ^3J = 9.34 Hz, ^2J = 14.23 Hz, 2 H, $CHHCH$), 2.46 (pseudo t, $^3J = {}^2J$ = 7.48 Hz, 4 H, NCH_2CH_2CO). − ^{13}C NMR (300 MHz, CD_3OD): δ = 182.38 (CONR), 174.52 (CO_2CH_3), 138.27, 130.68, 129.90, 128.14 (Ph), 62.02 ($CHCH_2$), 42.03, 41.08, 36.68 ($CHCH_2$ and CH_2CH_2). − $C_{26}H_{34}N_4O_6Pd \times 2.5\ H_2O$ (650.04): calcd. X-ray Structure Determination of 3:[36] $C_{12}H_{22}O_6N_4Pd \times 2\ H_2O$, M = 460.77, T = 21(2)°C, NONIUS CAD4 diffractometer, crystal size, 0.17 × 0.27 × 0.50 mm, monoclin $P2_1/c$ (no. 14), a = 11.939(5), b = 7.814(3), c = 10.250(4), β = 96.38(2)°, V = 950.3(7) Å^3, Z = 2, d(calcd.) = 1.620 g/cm^3, λ(Mo-K_α) = 0.71073 Å, μ(Mo-K_α) = 1.021 mm^{-1}, F(000) = 472, 2θ range: 3.12−22.96°, index ranges: $-13 \le h \le 13$, $0 \le k \le 8$, $-11 \le l \le 0$, reflections collected: 1219, independent reflections: 1144 [R(int) = 0.0401], observed reflections: 941, semiempirical absorption correction from ψ scans, max./min. transmission: 0.9594/0.5076, data/restraints/parameters: 1144/0/116, refinement method: full-matrix least squares on F^2, goodness-of-fit on F^2: 1.077; final R indices [$I > 2\ \sigma(I)$]: $R1$ = 0.0491, $wR2$ = 0.1379; R indices (all data): $R1$ = 0.0579, $wR2$ = 0.1506, largest diff. peak/hole: 0.833/−0.787 eÅ^{-3}.

General Procedure for the Synthesis of 7 and 8: The *trans*-bis(dipeptide ester)Pd^{II} complex **4** or **5** (0.1 mmol) is dissolved in 10 mL of methanol. A solution of NaOMe (0.2 mmol) in methanol is added and the solution is heated to 65°C for 24 h, after which $CaCl_2$ (0.1 mmol) is added. Upon the addition of acetone the white precipitate is collected and for purification recrystallized from water/acetone (1/5), twice washed with acetone and dried in vacuo.

7: White powder, yield 89%. − IR (KBr, cm^{-1}): ṽ = 1560 vs, br. (amide I), 1417 s (amide II). − ^{1}H NMR (400 MHz, D_2O/CD_3OD): δ = 3.62−3.75 [m, br., 2 H, C*H*CH$(CH_3)_2$], 3.53−3.59 (m, br., 2 H, N*H*CHHCHCO), 3.5−2.92 (m, br., 4 H, NHC*HH*CHCO), 2.86−2.69 [m, br., 2 H, CHC*H*$(CH_3)_2$], 2.55−2.22 (m, br., 2 H, NHCHHC*H*CO), 1.10−1.14 [m, br., 12 H, CHCH$(CH_3)_2$]. − $C_{24}H_{24}CaN_4O_4Pd \times 8\ H_2O$ (683.025): calcd. C 39.86, H 5.58, N 7.75; found C 39.19 H 4.66, N 7.45.

8: White powder, yield 92%. − IR (KBr, cm^{-1}): ṽ = 1569 vs, br. (amide I), 1448 s, 1428 s, 1413 s (amide II). − ^{1}H NMR (400 MHz, D_2O/CD_3OD): δ = 6.98−7.45 (m, 10 H, C_6H_5), 4.20−4.45 (m, br., 2 H, C*H*CH_2Ph), 3.18−2.63 (m, br., 6 H, N*H*CHCH$_2$CO, CHC*H*$_2$Ph), 2.44−1.87 (m, br., 6 H, NHC*HCH*$_2$CO). − $C_{16}H_{24}CaN_4O_4Pd \times 3\ H_2O$ (536.938): calcd. C 35.79, H 5.63, N 10.43; found C 35.83 H 5.59, N 9.98.

9: The synthesis of **9** was accomplished according to Mogilevkina et al.[32] K_2PtCl_4 (420 mg, 1 mmol) and gly−gly−glyOH (760 mg, 4 mmol) were dissolved in 10 mL of 0.25 N NaOH (4 mmol) and the mixture was stirred for 40 min at 60°C in a water bath, while the colour of the solution changed from red to light yellow. After ice cooling the solution was combined with 2.5 mL of concentrated HCl and stirred for another 3 d at room temperature. The light yellow precipitate was collected and washed with HCl (2 N), ethanol and diethyl ether and dried in vacuo. − Light yellow powder, yield 34%; m.p. 196°C (dec.). − IR (KBr, cm^{-1}): ṽ = 3330 s, 3270 sh, 3230 sh (NH_2), 1720 m (COOH), 1650 vs (amide I), 1535 s (amide II). − $C_{12}H_{22}Cl_2N_6O_8Pt$ (644.3): calcd. C 22.27, H 3.44, N 13.04; found C 21.91, H 3.90, N 12.96.

10: A solution of 215 mg (0.33 mmol) of **9** in 1.33 mL of 0.5 N KOH (0.66 mmol) was stirred for 3.5 h at 70°C using a water bath. After stirring for 24 h at room temperature, the white precipitate was collected, washed with water, ethanol and diethyl ether and dried in vacuo. − Colourless powder, yield 21%; m.p. 206°C (dec.). − IR (KBr, cm^{-1}): ṽ = 3340 s, 3260 s (NH_2), 1700 vs (COOH), 1633 m, 1575 vs (amide I). − $C_{12}H_{20}N_6O_8Pt \times 2\ H_2O$ (607.5): calcd. Metal Complexes of Biologically Important Ligands, CXIII[+]

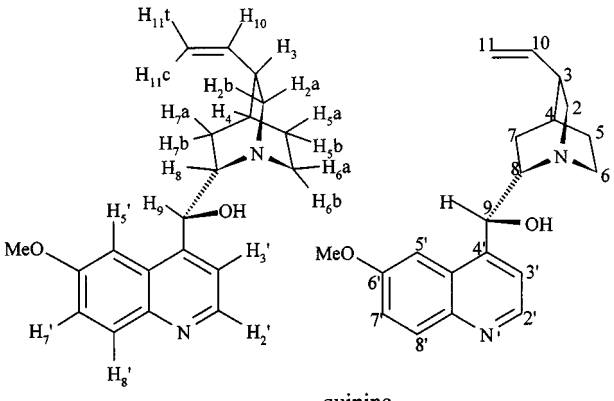
Cinchona Alkaloids as Versatile Ambivalent Ligands – Coordination of Transition Metals to the Four Potential Donor Sites of Quinine

Roland Hubel,[a] Kurt Polborn,[a][2] and Wolfgang Beck*[a]



Dedicated to Professor Helmut Werner on the occasion of his 65th birthday

Keywords: Quinine / Cinchonine / Palladium / Platinum / Silver / Gold

A series of metal complexes in which quinine (L^1) and cinchonine (L^2) are coordinated via the four possible donor atoms was prepared and characterized. Coordination of the tertiary N atom of quinine is observed in $[L^1MPPh_3]^+NO_3^-$ [M = Au (**1**), Ag (**2**)], $[L^1Pd(COD)(Cl)]^+$ NO_3^- (**3**) and $L^1Pd(Cl)(allyl)$ (**4**). The mono anion of quinine functions as N,O chelate ligand in $(L^1–H^+)M(Cl)(PR_3)$ (M = Pd, Pt, **5**–**10**), $[(L^1–H^+)Pd(en)]^+NO_3^-$ (**11**) and $(L^1–H^+)_2TiCl_2$ (**12**). Protection of the tertiary N atom of quinine by methylation or protonation allows the synthesis of the quinoline complexes $[(L^1CH_3^+)M(Cl)_2(PR_3)]^+$ BF_4^- (M = Pd, Pt, **14**–**18**), $[(L^1CH_3^+)Ir(Cl)_2(Cp^*)]^+$ BF_4^- (**19**), $[(L^1+H^+)M(Cl)_2(PR_3)]^+$ $CF_3SO_3^-$ (M = Pd, Pt, **20**–**22**) and $(L^2+H^+)(ZnCl_3^-)$ (**23**). Quinine and cinchonine act as N,O–N bridge in the complexes $(R_3P)(Cl)M(\mu\text{-}L^1–H^+)M(Cl)_2(PR_3)$ (M = Pd, Pt, **24**, **25**, **27**, **28**), $(Cp^*)(Cl)Ir(\mu\text{-}L^1–H^1)Ir(Cl)_2(Cp^*)$ (**29**), $(EtP_3)(Cl)Pd(\mu\text{-}L^2–H^+)Pd(Cl)_2(PEt_3)$ (**26**), and as N–N bridge in the complexes $[(Ph_3P)Au(\mu\text{-}L^1)Au(PPh_3)]^+NO_3^-$ (**30**) and $(allyl)(Cl)Pd(\mu\text{-}L^1)Pd(Cl)(allyl)$ (**31**). Coordination of quinine via the C=C double bond occurs in $[(L^1+2\ H^+)PtCl_3]^+Cl^-$ (**32**). The structures of **11**, **13**, **19**, **23**, **26** and **32** were determined by X-ray diffraction. In most cases the coordination mode and the conformation of quinine can also be derived from the ^{1}H-NMR spectra.

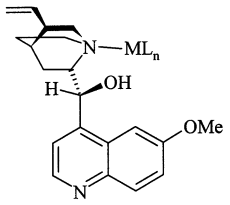
Quinine is a widely used antimalaria drug and its derivatives are applied as optically active auxiliaries in asymmetric synthesis.[3] Most important is the Sharpless asymmetric dihydroxylation of olefins with osmium tetroxide and cinchona alkaloids.[4]

Recently, the interesting mechanism of this reaction was extensively analysed by Sharpless[5] and Corey.[6] The mechanism involves coordination of the tertiary N atom of the quinuclidine residue and the structure of the OsO_4 complex with the tertiary *N*-coordinated dihydroquinidine derivative was established by Sharpless et al.[7] To our knowledge only few metal complexes of cinchona alkaloids have been described.[8] In our group several organometallic compounds of cinchona alkaloids were synthesized and the first N,O-chelate complexes of cinchonidine and cinchonine were characterized by X-ray crystallography.[9] In continuation of these studies we now report on the synthesis of quinine complexes using all four potential donor sites of quinine (OH group, tertiary N and pyridine N atoms, olefinic C=C bond). In most cases analysis of the ^{1}H-NMR spectra of the various complexes gives information which donor atom is involved in coordination. The ^{1}H-NMR spectra of the free ligands have been previously interpreted.[10,11]

quinine

Results and Discussion

1. Coordination at the Quinuclidine N Atom



The most basic donor site of quinine is the quinuclidine N atom and coordination at this donor occurs in the reaction of quinine with in situ prepared Ph_3PAuNO_3, Ph_3PAgNO_3, $(COD)Pd(Cl)(NO_3)$ and with $(\eta^3\text{-}C_3H_5)Pd(\mu\text{-}Cl)_2Pd(\eta^3\text{-}C_3H_5)$ to give the complexes **1**–**4**.

The mode of coordination can be unambiguously derived from the ^{1}H-NMR spectra. The signals (which were assigned by 2D-COSY experiments) of the hydrogen atoms situated near the tertiary N atom show a considerable

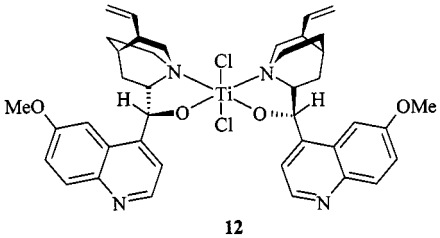
downfield shift in comparison to those of the free quinine. A detailed study of the conformations of cinchona alkaloides has been carried out by Wynberg and Sharpless[11] and four conformers were defined ("closed conformation 1 and 2, open conformation 3 and 4"). The "open conformation 3" in **1**−**4** which was also found for the OsO_4 complex[7] and some complexes of Ru, Ir, and Au[9] follows from the downfield shift of the signal of 7b-H as a consequence of the change of the position of 7b-H relative to the aromatic system: In the "open conformation 3" the 7b-H atom lies in the same plane with the quinoline ring and is no longer shielded by the anisotropic cone of the heteroaromatic ring. Hydrogen 7a-H, which is positioned above the quinoline ring, suffers a small upfield shift. In contrast to **5**−**10** (see below) the signals of the aromatic protons are almost not shifted which means that they do not interact with the d_{z^2} orbital of Pd^{II},[12] a further hint for the "open conformation 3".

2. N,O-Chelate Complexes



From the chloro-bridged complexes $(R_3P)(Cl)M(\mu\text{-}Cl)_2M(Cl)(PR_3)$ (M = Pd, Pt) and quinine in the presence of NaOMe in methanol the compounds **5**−**10** are obtained.

12

In order to avoid coordination of the pyridine N atom the reaction was carried out at −78 °C. We assume that the *trans*-P−M−N isomers are formed as main products. Presumably the reaction proceeds stepwise as was found, for example, for the reaction of $[PtCl_3(C_2H_4)]^-$ with α-amino carboxylates.[13] The first step is the opening of the chloro bridge by the quinuclidine N atom and building of the M−N bond. This step is followed by the closure of the chelate ring with displacement of the *cis*-chloride by the oxy group. The P−M−N isomer was also found e.g. for $(Cl)(Ph_3P)Pt[NH_2C(Me)_2CO_2]$.[14] Two further ^{31}P-NMR signals of low intensity (< 5%) which were only observed for the Pd^{II} complexes may indicate formation of the *cis* isomer and of a complex with quinine coordinated via the pyridine N atom as minor products.

The reaction of $[(en)Pd(OH_2)_2]^{2+}(NO_3^-)_2$ with quinine affords the N,O-chelate complex **11**. The formation of the five-membered chelate ring in **5**−**11** is confirmed by the downfield shift of the ^{1}H-NMR signal of 9-H and by the disappearance of the ν(OH) absorption in the IR spectrum.

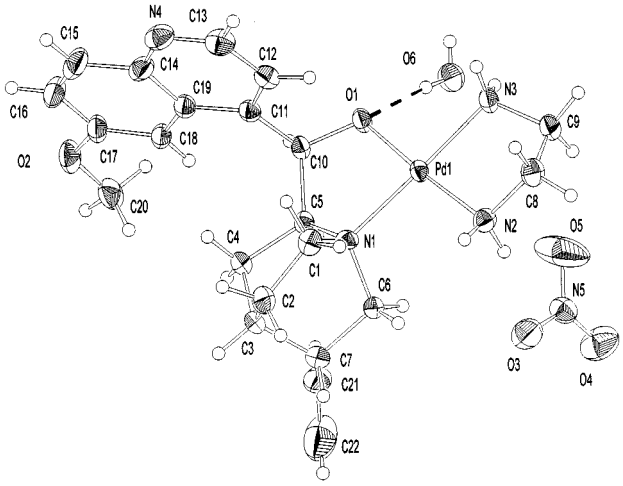

Figure 1. Molecular structure of **11** in the crystal; selected bond lengths [Å] and angles [°]: Pd1−O1 1.982(3), Pd1−N1 2.040(3), Pd1−N3 2.043(3), Pd1−N2 2.041(4), O1−C10 1.406(5), N1−C1 1.485(8), N1−C5 1.505(5) N1−C6 1.518(7), N2−C8 1.474(6), N3−C9 1.481(6), C8−C9 1.505(7), C5−C10 1.543(6), C10−C11 1.525(7); O1−Pd1−N1 85.30(13), O1−Pd1−N3 92.84(13), N1−Pd1−N3 178.0(2), O1−Pd1−N2 175.05(14), N1−Pd1−N2 98.79(15), N3−Pd1−N2 83.11(15), N1−C5−C10 111.2(4), N1−Pd1−O1−C10 6.8(3), N1−Pd1−N2−C8 −163.0(4), N1−C5−C10−O1 40.7(6), N1−C5−C10−C11 −86.9(5)

The conformation of quinine in **5**−**11** can be described as "open conformation 4".[11] The signal of the 3′-H atom in **5**−**11** suffers a downfield shift up to 1.8 ppm which is due to interaction with the d_{z^2} orbital.[12] This is ascertained by the X-ray structure determination of **11**.

Reaction of $TiCl_4$ and quinine in CH_2Cl_2 afforded a complex **12** for which − from analytic and ^{1}H-NMR data − we assume the shown structure.

3. Coordination at the Quinoline N Atom

The quinuclidine N atom of quinine was selectively protected by alkylation with Me_3O^+ BF_4^- [15] and from the reaction of the methylquininium tetrafluoroborate **13** with chloro-bridged complexes $(Cl)(R_3P)M(\mu\text{-}Cl)_2M(Cl)(PR_3)$ (M = Pd, Pt) and $(Cl)(Cp^*)Ir(\mu\text{-}Cl)_2Ir(Cl)(Cp^*)$ the compounds **14**−**19** were isolated.

23

obtained ammonium salt (which was not isolated) reacted with the chloro-bridged Pd and Pt complexes to give compounds **20**−**22**. Attempts to deprotonate **20**−**22** in order to yield neutral complexes gave mixtures which were not separated.

In the ^{1}H-NMR spectra of **14**−**19** and **20**−**22** a downfield shift is observed for the signals of 2′-H and 8′-H, which indicates coordination of the metal center to the quinoline N atom. For **14**, **15** and **20**−**22** a ^4J(2′-H,P) coupling can be detected. The "open-conformation 3" of coordinated quinine is found for **14**−**22**, like in **1**−**4**. In the IR spectra of **20**−**22** the ν(NH) absorption at 2600−2700 cm^{-1} and the ν(OH) band at ca. 3400 cm^{-1} are characteristic.

A zwitterionic structure is found for the product **23** from cinchonine and $ZnCl_2$ in methanol. Complex **23** may be compared with a molecular L-histidinium trichlorozincate (L-histidineH^+) $ZnCl_3$.[16]

4. Dinuclear Complexes

The bimetallic complexes **24**−**29** were obtained in two steps using first a stoichiometric ratio of 1/1/0.5 of NaOMe,

Figure 4. 	ML_n
30	$AuPPh_3^+NO_3^-$
31	PdCl(allyl)

Heterobimetallic complexes could only be obtained as mixtures by this route. The "open conformation 4" of quinine and cinchonine in **24**−**29** is analogous to that in **5**−**10**. The downfield shift of the 2′-H and 8′-H ^{1}H-NMR signals caused by the interaction with the d_{z^2} orbital of the metal ion[12] indicates that the chloro ligands in **24**−**29** as in **14**−**19** lie perpendicular to the quinoline plane.

In the dinuclear complexes **30**−**31** quinine functions as a bis(monodendate) bridge. The characteristic ^{1}H-NMR signals of **30**−**31** are consistent with an "open conformation 3" of the ligand.

Figure 5. 5. Coordination at the Olefinic Group

Finally we proved the coordination of a metal ion at the C=C double bond of quinine using the general method[17] for preparing (olefin)platinum complexes.

The reaction of double protonated quinine with K_2PtCl_4 in aqueous hydrochloride acid gives the (also thermally) stable complex **32**, which is an analogue of the Zeise salt $K[PtCl_3(C_2H_4)]$. As a consequence of complexation of the C=C double bond an upfield shift is observed for the three ^{1}H-NMR signals of the olefinic protons. In the ^{1}H-NMR spectrum of **32** two sets of signals in the ratio 1:1 are observed. By coordination of the prochiral C=C double bond the C-10 atom becomes a stereogenic centre, and two diastereoisomers are formed. In contrast to various Pt^{II} complexes with coordinated olefins and optically active amino acids[18] or amines[19] no diastereoselectivity is observed in our case.

Metal complexes of C=C-coordinated quinine may be useful for the derivativization of quinine at the C=C double bond.

Figure 6. 6. X-ray Structural Determinations of 11, 13, 19, 23, 26 and 32[28]

Of interest is the conformation of the coordinated cinchona alkaloid in the various complexes which can be derived from the torsion angle C4′−C9−C8−N. The "open conformation 3" is found in the complexes **19**, **23**, **32** and in **13** according to the ^{1}H-NMR spectra. The torsion angles of these compounds are in the range of 161−176°. For the "free" cinchonidine a torsion angle of 158° was reported.[20] The formation of the N,O-chelate in **11** and **26** affords a torsion angle C4′−C9−C8−N of 81−85° ("open conformation 4").

In the Pd^{II} complexes **11** and **26** the Pd atoms have a strictly planar environment with distortion of the square. The ligands at the Zn^{2+} ion of **23** form a distorted tetrahedron.

The analysed crystal of **32** contained the diastereoisomer [*S*(C10), *S*(C8), *R*(C9), *S*(C4), *R*(C3)]. The olefinic C=C double bond lies perpendicular to the $PtCl_3$ plane as in $K[PtCl_3(C_2H_4)]$. Also the C=C, Pt−C and Pt−Cl lengths are similar to that of the Zeise salt.[21]

Experimental Section

Where appropriate, the reactions were carried out in dry solvents under nitrogen. − NMR: Jeol GSX 270 or Jeol EX 400, using the solvent as internal standard. − IR: Nicolet 520 FT-IR. − The starting materials were prepared according to literature procedures: Ph_3PAuCl,[22] $[(C_3H_5)PdCl]_2$,[23] $(COD)PdCl_2$,[24] $[R_3PPtCl_2]_2$,[25] $[R_3PPdCl_2]_2$,[24] $(en)PdCl_2$,[26] $[Cp^*IrCl_2]_2$.[27] Quinine and cinchonine were used as supplied (Fluka). $ZnCl_2$ was dried for 2 d at 80°C. PE = polyethylene.

1: To a solution of 49.5 mg (0.1 mmol) of PPh_3AuCl in 3 mL of CH_2Cl_2 a solution of 17 mg (0.1 mmol) of $AgNO_3$ in 3 mL of methanol was added. After 1 h of vigorous stirring with exclusion of light, AgCl was centrifuged off and 32.4 mg (0.1 mmol) of quinine was added. The light yellow solution was stirred for another 1 h to give a clear colourless solution which was concentrated to about 1 mL and added to 20 mL of pentane. The white precipitate was washed twice with Et_2O and dried in vacuo for a few days. − IR (KBr): $\tilde{\nu}$ = 3379 cm^{-1} m br. (OH), 3074 w (CH_{arom}), 2935 m (CH_{aliph}). − ^{1}H NMR (400 MHz, $CDCl_3$): δ = 8.71 (d, 1 H, $^3J_{3'}$ = 4.61 Hz, 2′), 8.10 (d, 1 H, $^3J_{7'}$ = 9.37 Hz, 8′), 7.74 (d, 1 H, $^3J_{2'}$ = 4.35 Hz, 3′), 7.57−7.43 [m. 16 H, $P(C_6H_5)_3$, 5′], 7.35 (dd, 1 H, $^3J_{8'}$ = 9.31 Hz, $^4J_{5'}$ = 2.45 Hz, 7′), 6.02 (s, br., 1 H, 9), 5.77 (ddd, 1 H, $^3J_{11c}$ = 17.47 Hz, $^3J_{11t}$ = 10.15 Hz, $^3J_3$ = 7.32 Hz, 10), 5.02 (d, 1 H, $^3J_{10}$ = 17.43 Hz, 11*c*), 4.98 (d, 1 H, $^3J_{10}$ = 10.03 Hz, 11*t*), 4.0−3.6 (m, 1 H, 6b*), 3.75 (s, 3 H, OCH_3), 3.37 (m, 1 H, 2b), 2.93 (m, 1 H, 8), 2.43−1.20 (5m, 8 H, 2a, 6a, 3, 4, 5b, 7b, 5a, 7a). − ^{31}P NMR (109.3 MHz): δ = 29.8. − $C_{38}H_{39}AuN_3O_5P \times CH_2Cl_2$ (866.9): calcd. C 52.99, H 4.59, N 4.85; found C 52.87, H 5.02, N 4.40.

2: To a solution of 34 mg (0.2 mmol) of $AgNO_3$ in 10 mL of methanol a solution of 65 mg (0.2 mmol) of quinine in 5 mL of CH_2Cl_2 was added with exclusion of light. After 1 h of vigorous stirring at room temperature, a white precipitate was obtained which was dissolved again by the addition of 52.5 mg (0.2 mmol) of PPh_3. The colourless solution was stirred for another 1 h, concentrated to about 0.5 mL and added to 20 mL of Et_2O to give the product as white light-sensitive solid which was washed twice with Et_2O and dried in vacuo for 2 d. − IR (KBr): $\tilde{\nu}$ = 3397 cm^{-1} m br. (OH), 3071 w (CH_{arom}), 2939 s (CH_{aliph}). − ^{1}H NMR (400 MHz, $CDCl_3$): δ = 8.75 (d, 1 H, $^3J_{3'}$ = 4.38 Hz, 2′), 7.82 (d, 1 H, $^3J_{7'}$ = 9.36 Hz, 8′), 7.68 (d, 1 H, $^3J_{2'}$ = 4.76 Hz, 3′), 7.52−7.30 [m, 15 H, $P(C_6H_5)_3$], 7.07 (dd, 1 H, $^3J_{8'}$ = 9.19 Hz, $^4J_{5'}$ = 2.04 Hz, 7′), 6.99 (s, 1 H, 5′), 6.06 (s, 1 H, 9), 5.57 (ddd, 1 H, $^3J_{11c}$ = 17.33 Hz, $^3J_{11t}$ = 10.53 Hz, $^3J_3$ = 6.80 Hz, 10), 5.05 (d, 1 H, $^3J_{10}$ = 10.12 Hz, 11*t*), 5.02 (d, 1 H, $^3J_{10}$ = 17.85 Hz, 11*c*), 4.35 (m, 1 H, 6b), 3.77 (s, 3 H, OCH_3), 3.56 (dd, 1 H, *J* = 10.66 Hz, *J* = 13.19 Hz, 2b), 3.40 (m, 1 H, 8), 3.23 (m, 2 H, 2a, 6a), 2.70 (m, 1 H, 3), 2.24−2.10 (m, 3 H, 4, 5b, 7b), 1.90- 1.79 (m, 1 H, 5a), 1.42 (m, 1 H, 7a). − ^{31}P NMR (109.3 MHz): δ = 12.4. − $C_{38}H_{39}AgN_3O_5P \times 0.5\ CH_2Cl_2$ (799.1): calcd. C 57.87, H 5.05, N 5.28; found C 57.93, H 5.15, N 5.63.

3: To a solution of 86 mg (0.30 mmol) of $(COD)PdCl_2$ in 10 mL of CH_2Cl_2 a solution of 51 mg (0.30 mmol) of $AgNO_3$ in 15 mL of methanol was added. After 1 h of vigorous stirring with exclusion of light, AgCl was centrifuged off and 97 mg (0.30 mmol) of quinine was added. The solution was stirred for another 1 h to give a clear colourless solution which was concentrated to about

General Procedure for the Preparation of 5−10: A solution of quinine in 10 mL of CH_2Cl_2 and the appropriate amount of a solution of NaOMe in methanol was cooled to −78°C. After the addition of $[R_3PMCl_2]_2$, the solution was allowed to warm up to room temperature for 16 h and stirred for another 2 h. The solvent of the light yellow suspension was removed in vacuo and the residue was dissolved again in CH_2Cl_2 and stirred for 10 min. The suspension was filtered through Celite to remove NaCl and the resulting clear yellow solution was concentrated to dryness. The yellow solid was washed twice with pentane and once with 10 mL of cold Et_2O and dried in vacuo for 2 d.

5: 65 mg (0.2 mmol) of quinine, 0.2 mmol of NaOMe in MeOH and 77 mg (0.1 mmol) of $[(PEt_3)PtCl_2]_2$ were used. − IR (KBr): $\tilde{\nu}$ = 3076 cm^{-1} m (CH_{arom}), 2963 s, 2935 s (CH_{aliph}). − IR (PE): $\tilde{\nu}$ = 333 cm^{-1} m (M−Cl). − ^{1}H NMR (400 MHz, $CDCl_3$): δ = 9.30 (d, 1 H, $^3J_{2'}$ = 4.53 Hz, 3′), 8.89 (d, 1 H, $^3J_{3'}$ = 4.52 Hz, 2′), 8.06 (d, 1 H, $^3J_{7'}$ = 9.16 Hz, 8′), 7.37 (dd, 1 H, $^3J_{8'}$ = 9.16 Hz, $^4J_{5'}$ = 2.69 Hz, 7′), 7.12 (d, 1 H,$^4J_{7'}$ = 2.71 Hz, 5′), 5.97 (ddd, 1 H, $^3J_{11c}$ = 17.21 Hz, $^3J_{11t}$ = 10.31 Hz, $^3J_3$ = 6.87 Hz, 10), 5.76 (dd, 1 H, ^4J_P = 9.78 Hz, $^3J_8$ = 6.67 Hz, 9), 5.24 (d, 1 H, $^3J_{10}$ = 10.37 Hz, 11*t*), 5.20 (d, 1 H, $^3J_{10}$ = 17.12 Hz, 11*c*), 4.09 (m, 1 H, 8), 3.92 (s, 3 H, OCH_3), 3.79 (d, 1 H, *J* = 12.99 Hz, 2b), 3.52 (m, 1 H, 2a), 3.25 (m, 1 H, 6b), 2.94 (pt, 1 H, ^3J = 12.09 Hz, 6a), 2.41 (m, 1 H, 3), 2.26−2.16 (m, 1 H, 7b), 2.10−1.84 [m, 6 H, P(CH_2CH_3)$_3$], 1.81 (m, 1 H, 4), 1.29 [dt, 9 H, ^3J_P = 16.44 Hz, $^3J_{CH2}$ = 7.58 Hz, P(CH_2CH_3)$_3$], 1.41−1.21 (m, 3 H, 5b*, 7a*, 5a*). − ^{31}P NMR (109.3 MHz): δ = −4.12 ($^1J_{P\text{-}Pt}$ = 3430 Hz). − $C_{26}H_{38}ClN_2O_2PPt \times 0.5\ CH_2Cl_2$ (714.6): calcd. General Procedure for the Preparation of 24−29: A solution of quinine in 10 mL of CH_2Cl_2 and the equivalent amount of a solution of NaOMe in methanol was cooled to −78°C. After the addition of 0.5 equivalents of [R_3PMCl_2]$_2$ or of [Cp*$IrCl_2$]$_2$, the solution was allowed to warm up to room temp. for 16 h and stirred for another 2 h. To the yellow solution again 0.5 equivalents of [R_3PMCl_2]$_2$ or of [Cp*$IrCl_2$]$_2$ were added. After 16 h of stirring, the solvent was removed in vacuo, the residue was dissolved in CH_2Cl_2 and the mixture was filtered through Celite to remove NaCl. The solvent was removed again in vacuo and the residue was washed twice with 5 mL of cold Et_2O to give a yellow powder which was dried in vacuo for several days.

24: 59 mg (0.182 mmol) of quinine, 0.182 mmol of NaOMe in MeOH and 140 mg (0.182 mmol) of [(PEt_3)$PtCl_2$]$_2$ were used. − IR (KBr): $\tilde{\nu}$ = 3073 cm^{-1} w (CH_{arom}), 2962 s, 2935 m (CH_{aliph}). − IR (PE): $\tilde{\nu}$ = 340 cm^{-1} s, 331 s sh (M−Cl). − ^{1}H NMR (400 MHz, $CDCl_3$): δ = 9.40 (d, 1 H, $^3J_{7'}$ = 9.65 Hz, 8′), 9.27 (d, 1 H, $^3J_{2'}$ = 5.11 Hz, 3′), 8.99 (dd, 1 H, $^3J_{3'}$ = 5.52 Hz, ^4J_P = 3.42 Hz, 2′), 7.49 (dd, 1 H, $^3J_{8'}$ = 9.44 Hz, $^4J_{5'}$ = 2.54 Hz, 7′), 7.05 (d, 1 H, $^4J_{7'}$ = 2.48 Hz, 5′), 5.96 (ddd, 1 H, $^3J_{11c}$ = 17.22 Hz, $^3J_{11t}$ = 10.37 Hz, $^3J_3$ = 6.85 Hz, 10), 5.22−5.15 (m, 3 H, 9, 11*c*, 11*t*), 3.94−3.75 (m, 2 H, 8*, 2b*), 3.81 (s, 3 H, OCH_3), 3.45−3.41 (m, 1 H, 2a), 3.27−3.21 (m, 1 H, 6b), 3.01−2.92 (m, 1 H, 6a), 2.44 (m, 1 H, 3), 2.20−2.09 (m, 1 H, 7b), 2.09−1.20 (4*, 5b*, 7a*, 5a*) 2.05−1.98 [m, 6 H, N′PtP(CH_2CH_3)$_3$], 1.92−1.83 [m, 6 H, (N,O)PtP(CH_2CH_3)$_3$], 1.37−1.23 (m, 18 H, N′PtP(CH_2CH_3)$_3$, (N,O)PtP(CH_2CH_3)$_3$]. − ^{31}P NMR (109.3 MHz): δ = 6.18 (N′PtP, $^1J_{P\text{-}Pt}$ = 3636 Hz), −0.20 [(N,O)PtP, $^1J_{P\text{-}Pt}$ = 3382 Hz]. − $C_{32}H_{53}Cl_3N_2O_2P_2Pt_2$ × 0.5 CH_2Cl_2 (1098.7): calcd. Synthesis and Nonlinear Optical Properties of Carbonylrhenium Bromide Complexes with Conjugated Pyridines

Oliver Briel,[a] Karlheinz Sünkel,[a][+] Ingo Krossing,[a][+] Heinrich Nöth,[a][+] Elmar Schmälzlin,[b][++] Klaus Meerholz,[b][++] Christoph Bräuchle,[b][++] and Wolfgang Beck*[a]

Dedicated to Professor Klaus-Jürgen Range on the occasion of his 60th birthday

Keywords: Rhenium / N Ligands / Nonlinear optics

Carbonylrhenium bromide complexes *fac*-$Br(OC)_3ReL_2$ (**3a**,**b**, **4a**,**b**) and *cis*-$Br(OC)_4ReL$ (**5a**,**b**) with conjugated pyridines L = Fc–CH=CH–*p*-C_5H_4N (**1a**), Fc–CH=CHC-(CH_3)=CHCH=CHCH=C(CH_3)CH=CH–*p*-C_5H_4N (**1b**), 1,1′-Fc(–CH=CH–*p*-$C_5H_4N)_2$ (**1c**), *p*-Me_2N–C_6H_4–CH=CHCH= CH–*p*-C_5H_4N (**2a**), and *p*-Me_2N–C_6H_4–CH=CHC(CH_3)= CHCH=CHCH=C(CH_3)–CH=CH–*p*-C_5H_4N (**2b**) have been synthesized. The structures of **4a** and **5a** have been determined by X-ray diffraction analysis. Compound **4a** exhibits a remarkable quadratic hyperpolarizability.

1. Introduction

Following the discovery of a marked first hyperpolarizability of *cis*-[1-ferrocenyl-2-(4-nitrophenyl)ethylene] by Green et al.[1] in 1987, organometallic materials with nonlinear optical properties have attracted increasing attention. Compared to organic substances, metal complexes have some definitive advantages such as tunability of the polarizability by changing the oxidation state of the metal atom or by variation of the ligands.[2a] In a recent article by Whittall et al.,[2b] the scope of various nonlinear optical organometallic complexes was reviewed.

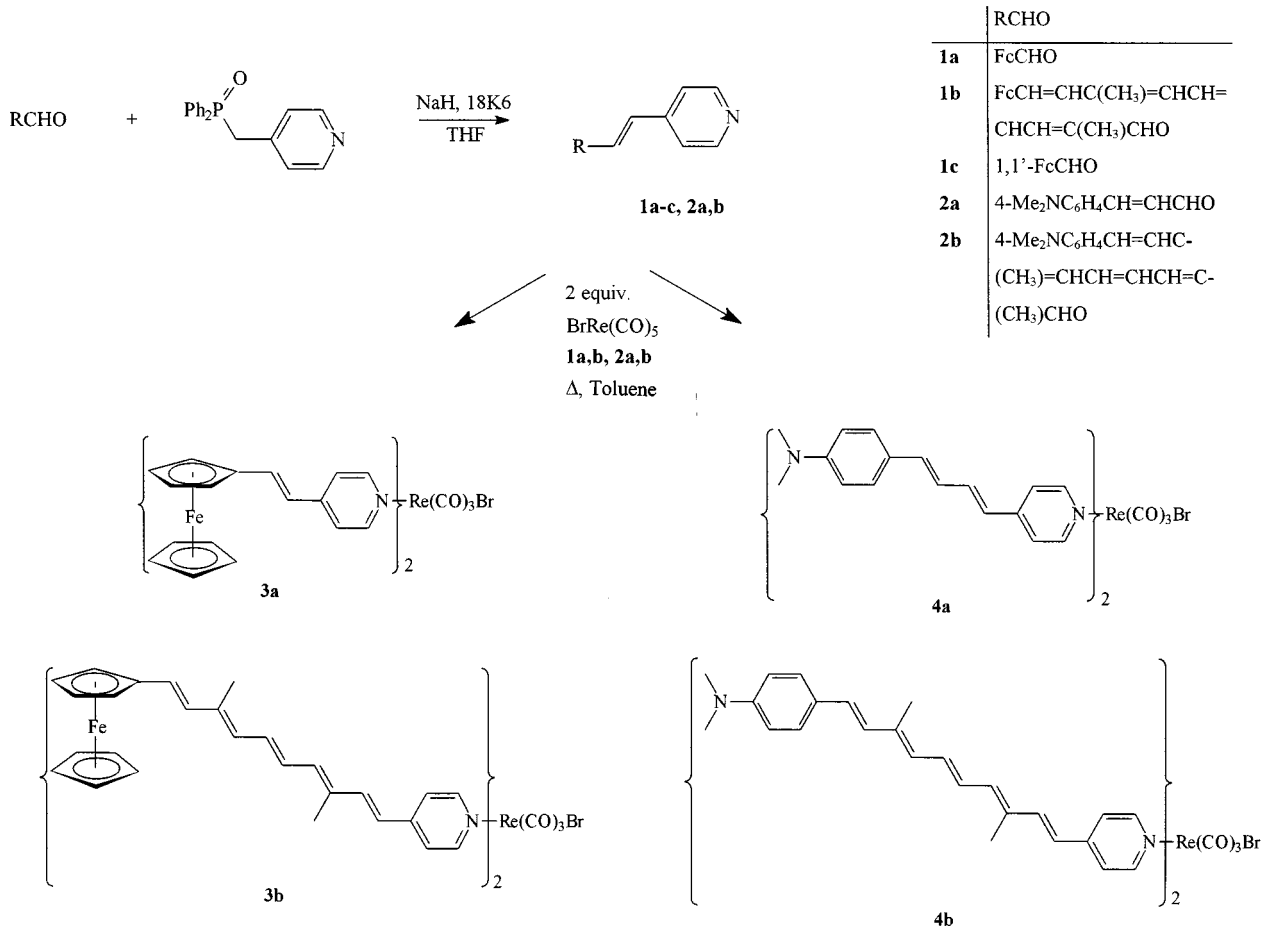
Kanis et al.[3] have performed ZINDO-SOS calculations for substituted pyridine complexes of the type (py)ML_5 (py = substituted pyridine derivative; ML_5 = d-metal fragment) in order to determine their hyperpolarizabilities β. They found that the metal fragments in complexes bearing donor-substituted pyridines as ligands contribute as inductive acceptors to the β response of the materials. A series of conjugated pyridine-containing nonlinear optical (NLO) metal complexes have been reported.[3–5] Furthermore, some carbonylrhenium compounds $X(OC)_3ReL_2$ incorporating aromatic N-donors have been studied as NLO materials.[6] Carbonylrhenium compounds,[7] including those of the type $X(OC)_3ReL_2$[8] and $[(OC)_3ReL_2L']^+$, have frequently been used in investigations of other photophysical or electron-transfer processes.

In continuation of our studies of metal complexes with polyene-containing ligands,[9] we have used new pyridine-containing ligands with an olefinic backbone and electron-donating organic or organometallic substituents to construct and investigate complexes of the type $(R-py)_nRe(CO)_{5-n}Br$ (n = 1, 2). We chose to prepare complexes of this type because of their stability and ease of handling.

As the molecular structures of our complexes fulfilled the basic requirements for NLO active materials, HRS measurements were performed.

Complexes of the type *cis*/*trans*-$LRe(CO)_4X$ have been investigated by several research groups, with L being some kind of phosphane.[10] To the best of our knowledge, only one complex of this type has been reported with an N-donor.[11] We have obtained new stable complexes of the type $(R-py)Re(CO)_4Br$ by reaction of $Re(CO)_5Br$ with pyridyl ligands.

2. Results and Discussion



2.1 Synthesis

Pyridine derivatives bearing extended conjugated olefinic substituents **1a–c**, **2a**,**b** in all-*trans* configuration were obtained by Wittig–Horner reaction of aldehydes with diphenyl(4-picolyl)phosphane oxide in yields of up to 70% according to the procedure of Effenberger et al.[12] We used formylferrocene, 1,1′-diformylferrocene, 9-ferrocenyl-2,7-dimethylnonatetraenal,[13] *p*-(dimethylamino)cinnamaldehyde, and 9-(*p*-dimethylaminophenyl)-2,7-dimethylnonatetraenal[13] as aldehyde components. The new compounds were purified by column chromatography on grade-III Al_2O_3 using dichloromethane as eluent. The ligand **1a** has previously been synthesized by other routes[5] and complexes $[(\mathbf{1a})M(CO)_5]$ (M = Cr, W, Mn^+, Re^+) have been prepared as NLO materials.

By reaction of $Re(CO)_5Br$ with two equivalents of the pyridine-containing ligands **1a**,**b** and **2a**,**b** in boiling tolu-

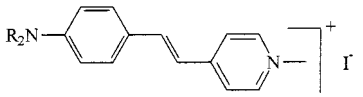
ene, two carbonyl ligands were substituted to give the *fac*-tricarbonylrhenium complexes **3a**,**b** and **4a**,**b**. These complexes were isolated by column chromatography of the crude reaction mixtures on silica gel using dichloromethane as eluent. Upon reaction of **1c** with $Re(CO)_5Br$, a red powder was obtained, presumably of the polymeric structure $[Re(CO)_3BrL]_n$.

Reaction of only one equivalent of the pyridine derivatives **1a** and **2a** with $Re(CO)_5Br$ led to the formation of a mixture of monosubstituted *cis*-(R−py)$Re(CO)_4Br$ (**5a**,**b**) and disubstituted complexes (R−py)$_2Re(CO)_3Br$ (**3a**, **4a**), which could be separated by column chromatography.



2.2 Characterization

For the complexes **3a**−**c** and **4a**,**b**, three CO absorptions of similar intensity are observed in the IR spectra, which is typical for *fac*-$L_2Re(CO)_3X$ complexes.[10] The CO band at the highest frequency is the one most sensitive to the nature of the ligand L. This absorption appears at lower energies compared with existing data for similar substituted pyridyl complexes.[6,10c] This indicates that the π-donor strength of our pyridine ligands is larger. For the complexes (R−py)Re(CO)$_4$Br (**5a** and **5b**), four CO absorptions are detected, in accordance with their *cis* configuration.

7a : R= CH_3; **7b**: R= $C_{16}H_{33}$

8

In agreement with the results of McCleverty et al.,[5b] the pyridyl protons H^2 and H^6 as well as H^3 and H^5 in **3**−**5** are equivalent and thus each pair gives rise to just one signal in the room-temperature ^{1}H-NMR spectra. This implies rapid rotation of the pyridyl rings in relation to the vinyl group to which they are attached; if the pyridyl ring were coplanar with the rest of the conjugated system, it could not have two-fold symmetry.

Several intense absorption bands are seen in the UV/Vis spectra in CH_2Cl_2. For the ferrocene-containing compounds, the following transitions are expected: two ferrocene-based MLCT absorptions between 350 and 500 nm and an intense π→π* absorption around 300 nm.[5a] Furthermore, π→π* or intense ILCT absorptions for the olefinic backbones, as well as MLCT bands of d(Re)→π* (py−R) around 340 nm are observed. The intense π→π* absorption of **1a**[5a] (313 nm) is red-shifted upon complexation (**3a**: 342 nm) and becomes superimposed by the expected MLCT band. A further weaker absorption appears at 501 nm. The principal absorption band of compound **3b** is a π→π* absorption of the olefinic backbone at 443 nm. Weaker absorptions of **3b** give bands at 334 nm and as a shoulder at 521 nm. Compounds **4a** (438 nm) and **5b** (444 nm) show strong and broad ILCT absorptions, which cover the MLCT [d(Re)→π*(py−R)] absorptions.

For compound **2a**, an emission spectrum is observed. The fluorescence band may be attributed to a long-distance intramolecular charge transfer (ICT).[14] This emission band is red-shifted in complexes **4a** and **5b**, in accordance with the inductive electron-accepting effect of the complex fragment.[3] For the other compounds, no fluorescence could be observed at $\lambda_{em} \leq 630$ nm with excitation between 350 and 450 nm.

2.3 X-ray Crystallography

X-ray quality crystals of **4a** and **5a** were obtained by diffusion of *n*-pentane into solutions of the complexes in CH_2Cl_2. The structures are essentially as expected and confirm the expected structures of the complexes. Crystal parameters are given in Table 2.[15]

Both compounds crystallize in centrosymmetric space groups (**4a** in *C*2/*c* and **5a** in *R*−3). Both crystal structures contain relatively large channels, which extend along the C_2 (in **4a**) or C_3 axes (in **5a**), and which constitute 17% and 5.4% of the respective cell volumes. The cavities in **4a** are surrounded by bromine atoms with distances of 3.89 Å, while in **5a** they are surrounded by the oxygen atoms of two carbonyl ligands with distances of 3.68 Å (O1) and 3.20 Å

(O2).[16] In compound **4a**, a molecule of CH_2Cl_2 was found to be localized in the "void channel" and could be refined (besides a further CH_2Cl_2 molecule in a general position). No solvent molecules were found in the crystal structure of **5a**, which might in part be due to the incompatibility of

Figure 2. CH_2Cl_2 symmetry with the trigonal symmetry of the void.

In both compounds, the rhenium atoms are very close to ideal octahedral geometry, with Re−Br and Re−N distances in the expected ranges.[6c]

In **4a**, the pyridine ligands are mutually *cis* oriented, with an interplanar angle of 72°. In both compounds, the pyridine ligands are in a staggered orientation with respect to the $Re(CO)_2BrN$ fragments: The interplanar angles are 38° and 50° in **4a**, and 49° in **5a**. This indicates that minimization of steric interactions prevails over electronic π-delocalization.[5b]

The π-system in compound **5a** is less twisted than that in compound **4a**. The angle between the cp ligand and the pyridyl ring is only 4°, which results from two mutually cancelling torsions at the double bond (C6−C7−C10−C11 −9.3°/C10−C11−C12−C13 −170.3°). In **4a**, however, the torsions are additive and lead to interplanar angles of 17° between the terminal planes containing N1, and of 7° between the termini in the second pyridyl ligand (C5−C6−C9−C10 −174.8°/C9−C10−C11−C12 −173.0° and C22−C23−C26−C27 −178.4°/C26−C27−C28−C29 −177.8°).

The small twist in the ferrocenyl derivative **5a** permits additional intermolecular interactions between a cyclopentadienyl ring and a pyridine ring of a neighbouring molecule. The distance between the ring centroids is 3.68 Å, and with a vertical plane distance of 3.42 Å; this leads to a β angle of 18°, indicative of effective π-stacking of the molecules.[16]

2.4 NLO Properties of 3a and 4a

The first hyperpolarizabilities of **3a** and **4a** were determined by hyper Rayleigh scattering (HRS)[17] To circum-

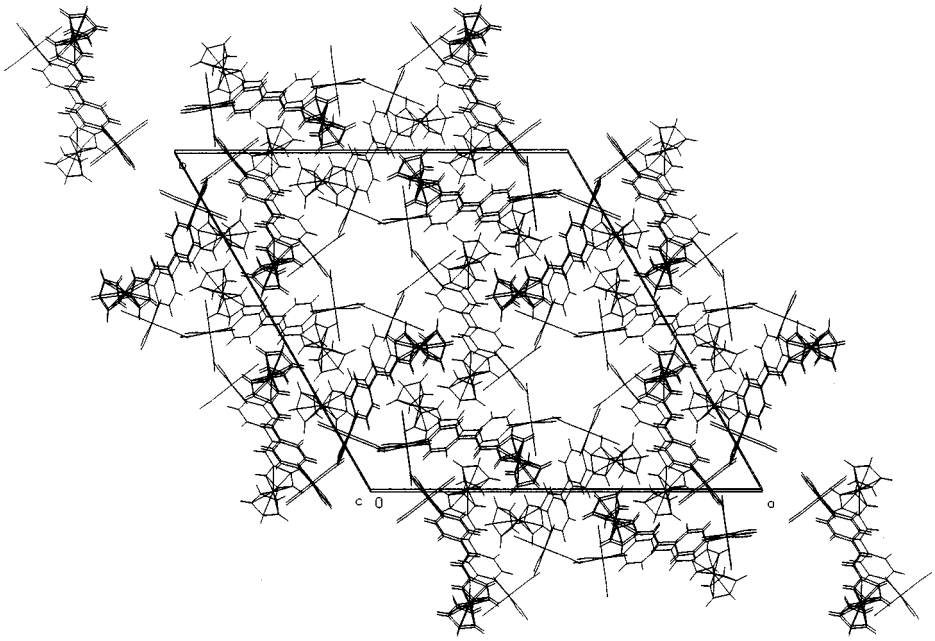

Figure 3. Crystal structure of complex **5a** view down the *c* axis

vent problems associated with reabsorption of the second harmonic and enhancement of β by multiphoton-induced fluorescence,[18] the measurements were carried out at fundamental wavelengths of 1300 nm (**3a**) and 1500 nm (**4a**), respectively. Descriptions of the HRS apparatus and of the method of data analysis have been given previously,[19,20] thus we describe here in brief only the key features. As an external standard, *p*-dimethylaminocinnamaldehyde (DMAZ) was used ($\beta_{zzz} = 41 \times 10^{-30}$ esu at 1300 nm, and 35×10^{-30} esu at 1500 nm in $CHCl_3$).[21] A plot of $I(2\omega)$, the intensity of the measured second harmonic, versus the number density for both sample and reference leads to the ratio $<\beta_{HRS}^2>_{sample}/<\beta_{HRS}^2>_{reference}$, from which specific components of the β tensor may be determined. Depending on the molecular symmetry, only some tensor elements contribute to $\langle\beta_{HRS}^2\rangle$. For 1D molecules such as DMAZ:

$$\langle\beta_{HRS}^2\rangle = \frac{6}{35}\beta_{zzz}^2 \qquad (1)$$

3a and **4a** have approximate C_2 symmetry, therefore:

$$\langle\beta_{HRS}^2\rangle = \frac{6}{35}\beta_{zzz}^2 + \frac{4}{7}\beta_{xyz}^2 + \frac{38}{105}\left(\beta_{xxz}^2 + \beta_{yyz}^2\right) + \frac{16}{105}\left(\beta_{xxz}\beta_{yyz} + \beta_{xxz}\beta_{zzz} + \beta_{yyz}\beta_{zzz}\right) \qquad (2)$$

Since it is not possible to deduce β_{xxz}, β_{xyz}, β_{yyz} and β_{zzz} of **3a** and **4a** from the measured $<\beta_{HRS}^2>$ value, a theoretical ratio $\beta_{xxz}/\beta_{xyz}/\beta_{yyz}/\beta_{zzz}$ was calculated by tensor addition.[20,22] For the sake of simplicity, **3a** and **4a** were assumed to consist of two non-interacting 1D subunits. From X-ray crystallography measurements on **4a**, a 90° angle between the subunits was derived. For **3a**, the same angle was assumed. Electron transitions within the Re complex were neglected. As a result, β_{xyz} and β_{yyz} vanish, and β_{xxz} and β_{zzz} were found to be equal. Together with Eq. 2, this yields:

$$\langle\beta_{HRS}^2\rangle = \frac{24}{35}\beta_{zzz}^2; \quad \beta_{zzz} = \beta_{xxz} \qquad (3)$$

The results of the HRS measurements and the β values of the subchromophores **6** and **8** given in the literature are summarized in Table 2. The modulus

$$\|\beta\| = \sqrt{\sum_{ijk}\beta_{ijk}^2}$$

was used to compare the hyperpolarizabilities of molecules with different specific components of the β tensor.

Table 3. First hyperpolarizabilities of **3a**, **4a**, **6**−**8**; hyperpolarizabilities are given in 10^{-30} esu; 1×10^{-30} esu = 3.713×10^{-51} Cm^3V^{-2}; the HRS measurements were carried out in $CHCl_3$

	λ_{max} [nm]	β_{xxz}	β_{zzz}	$\|\beta\|$	fundamental wavelength [nm]
3a	501[e]	12	12	24	1300

[a] ZINDO-derived value, ref.[23] – [b] HRS measurement at 1500 nm,[25] converted to 1910 nm by the two-level model.[26] – [c] ZINDO-derived value, ref.[24] – [d] In $CHCl_3$. – [e] In CH_2Cl_2.

Taking the β values of the 1D molecules **6** and **8** as starting points, the theoretical moduli $\|\beta\|$ of angled clusters consisting of two equal 1D subchromophores were calculated by tensor addition. For a 90° angle, this yielded $\|\beta\| = 96 \times 10^{-30}$ esu (subchromophore **8**) and $\|\beta\| = 485 \times 10^{-30}$ esu (subchromophore **6**), respectively, at 1910 nm. Although comparison of the calculated and experimental data for **7a** and **7b** indicates an overestimation of the β values by ZINDO, the hyperpolarizabilities of the complexes **3a** and **4a** are much smaller than those calculated for the angled clusters consisting of the corresponding subchromophores **6** and **8**, respectively. Therefore, replacement of the methyl

moiety by the Re complex leads to a noticeable reduction of the acceptor properties of the pyridinium moiety. Nevertheless, **4a** shows a remarkably high first hyperpolarizability. Even higher quadratic hyperpolarizabilities have recently been reported for the complexes $[(\mathbf{1a})M(CO)_5]^+$ (M = Mn, Re).[5d]

Experimental Section

All operations were carried out under nitrogen using the Schlenk technique. $Re(CO)_5Br$ was synthesized according to a literature procedure.[27] Solvents were dried by distillation from sodium/benzophenone, $LiAlH_4$, or CaH_2 as appropriate. − NMR spectra were recorded with a Jeol GSX 270 (^1H: 270.17 MHz; ^{13}C: 67.94 MHz; ^{31}P: 109.38 MHz) or a Jeol EX 400 spectrometer (^1H: 399.78 MHz; ^{13}C: 100.53 MHz). − IR: Perkin−Elmer 841, Nicolet 520 FT-IR. − UV/Vis: Philips PU 8710. − Luminescence: Perkin−Elmer Luminescence Spectrometer LS 50B.

Ligands 1a−c, 2a,b: Essentially the same procedures were followed to synthesize **1a−c** and **2a**,**b**. Thus, only the preparation of **1a** is described here in detail.

***trans*-Fc−CH=CH−C_5H_4N (1a):** A mixture of 275 mg (0.94 mmol) of diphenyl(4-picolyl)phosphane oxide, 200 mg (0.94 mmol) of ferrocene aldehyde, 250 mg (0.96 mmol) of 18-crown-6, and 55 mg (1.2 mmol; 55% in paraffin; washed twice with pentane) of NaH was stirred in 40 mL of THF at room temperature for 3 h. At the beginning of the reaction, 25 μL of H_2O was added to activate the NaH. The resulting red suspension was then filtered through a G3 glass funnel. The solvent was removed from the filtrate in vacuo, and the crude product was chromatographed on grade-III Al_2O_3. The first fraction (R_f = 0.5) was identified as the product, and furnished a red powder upon evaporation of the solvent. Yield 136 mg (50%). − IR (KBr): ṽ(C=C, C=N) = 1632 (s), 1594 cm^{-1} (vs). − ^1H NMR (270 MHz, $CDCl_3$): δ = 8.53 (d, 2 H, ^3J = 6.2 Hz, NC*H*), 7.28 (d, 2 H, ^3J = 6.0 Hz, NCHC*H*), 7.13 (d, 1 H, ^3J = 15.7 Hz, H_{ol}), 6.60 (d, 1 H, ^3J = 16.1 Hz, H_{ol}), 4.51 (t, 2 H, ^3J = 1.9 Hz, C_5H_4), 4.36 (t, 2 H, ^3J = 2.2 Hz, C_5H_4), 4.16 (s, 5 H, C_5H_5). − UV/Vis (CH_2Cl_2) (lg ε): λ_{max} = 313 (4.47), 374 (3.67), 464 nm (3.47). − $C_{17}H_{15}FeN$ (289.1): calcd. Complexes 3a−c, 4a,b, 5a,b: All the compounds were found to be moderately stable as solids and did not decompose significantly upon exposure to air for several days. Essentially the same procedures were followed to synthesize **3a−c** and **4a**,**b**, thus only the preparation of **4a** is described here in detail.

[all-*trans*-($H_3C)_2N(C_6H_4$)CH=CHCH=CHC_5H_4N]$_2$Re(CO)$_3$Br (4a): 100 mg (0.4 mmol) of **2a** and 80 mg (0.2 mmol) of $Re(CO)_5Br$ were allowed to react in refluxing toluene for 1 h. The solvent was then evaporated from the resulting orange solution. The crude product was chromatographed on silica gel using CH_2Cl_2 as eluent. The first fraction was found to contain the product. Bright-orange powder, yield 85 mg (77%). − IR (KBr): ṽ(C=O) = 2019 (vs), 1919 (vs), 1878 cm^{-1} (vs). − ^1H NMR (270 MHz, $CDCl_3$): δ = 8.63 (d, 4 H, ^3J = 6.9 Hz, NC*H*), 7.37 (d, 4 H, ^3J = 9.2 Hz, C_6H_4), 7.21 (d, 4 H, ^3J = 6.9 Hz, NCHC*H*), 7.16 (m, 2 H, H_{ol}), 6.79−6.77 (m, 4 H, H_{ol}), 6.69 (d, 4 H, ^3J = 9.0 Hz, C_6H_4), 6.42 (d, 2 H, ^3J = 15.3 Hz, H_{ol}), 3.00 [s, 12 H, ($H_3C)_2N$]. − ^{13}C NMR (68 MHz, $CDCl_3$): δ = 195.39/192.20 (CO), 154.04, 147.59, 138.95, 137.85, 130.67, 129.11, 128.51, 124.96, 121.73, 112.30 (C_{ar}, C_{ol}), 40.31 [$N(CH_3)_2$]. − UV/Vis (CH_2Cl_2) (lg ε): λ_{max} = 438 nm (5.11). − Emission spectrum (CH_2Cl_2, λ_{ex} = 350 nm): $\lambda_{em,max}$ = 564 nm. − $C_{37}H_{36}BrN_4O_3Re$ (850.7): calcd. C 52.23, H 4.27, N 6.59; found C 51.85, H 3.92, N 6.45.

(*trans*-Fc−CH=CH−$C_5H_4N)_2$Re(CO)$_3$Br (3a): Red powder, yield 60 mg (67%). − IR (KBr): ṽ(C=O) = 2021 (vs), 1914 (vs), 1884 cm^{-1} (vs). − ^1H NMR (270 MHz, $CDCl_3$): δ = 8.66 (d, 4 H, ^3J = 6.6 Hz, NC*H*), 7.30 (m, 2 H, H_{ol}), 7.22 (d, 4 H, ^3J = 8.2 Hz, C_6H_4), 7.21 (d, 4 H, ^3J = 6.9 Hz, NCHC*H*), 6.56 (d, 2 H, ^3J = 15.6 Hz, H_{ol}), 4.53 (t, 4 H, ^3J = 1.9 Hz, C_5H_4), 4.43 (t, 4 H, ^3J = 1.9 Hz, C_5H_4), 4.16 (s, 10 H, C_5H_5). − UV/Vis (CH_2Cl_2) (lg ε): λ_{max} = 343 (4.72), 501 nm (3.99). − $C_{37}H_{30}BrFe_2N_2O_3Re$ (928.0): calcd. C 47.85, H 3.26, N 3.02; found C 47.80, H 3.43, N 2.87.

[(C_5H_5)Fe(C_5H_4)CH=CHC(CH_3)=CHCH=CHCH=C(CH_3)-CH=CHC_5H_4N]$_2$Re(CO)$_3$Br (3b): Dark-red powder, yield 80 mg (67%). − IR (KBr): ṽ(C=O) = 2021 (vs), 1916 (vs), 1882 cm^{-1} (vs). − ^1H NMR (270 MHz, $CDCl_3$): δ = 8.64 (d, 4 H, ^3J = 6.4 Hz, NC*H*), 7.23 (d, 4 H, ^3J = 6.8 Hz, NCHC*H*), 7.11 (d, 2 H, ^3J = 15.8 Hz, H_{ol}), 6.86−6.25 (m, 12 H, H_{ol}), 6.43 (d, 2 H, ^3J = 16.3 Hz, H_{ol}), 4.46 (t, 4 H, ^3J = 1.8 Hz, C_5H_4), 4.30 (t, 4 H, ^3J = 1.9 Hz, C_5H_4), 4.12 (s, 10 H, C_5H_5), 2.02/2.01 (each s, each 6 H, CH_3). − UV/Vis (CH_2Cl_2) (lg ε): λ_{max} = 443 (4.98), 521 nm (sh, 4.69). − $C_{57}H_{54}BrFe_2N_2O_3Re$ (1192.2): calcd. C 57.37, H 4.57, N 2.35; found C 57.51, H 4.39, N 2.19.

{trans-Fe[(C_5H_4)CH=CHC_5H_4N]$_2$Re(CO)$_3$Br}$_n$ (3c): Dark-red powder, washing with CH_2Cl_2 furnished the product; yield 30 mg (23%). − IR (KBr): $\tilde{\nu}$(C=O) = 2020 (vs), 1912 (vs), 1884 cm^{-1} (vs). − ^{1}H NMR (270 MHz, $CDCl_3$): δ = 8.70−8.60 (m, 4 H, NC*H*), 7.37−7.15 (m, 6 H, NCHC*H*, H_{ol}), 6.58−6.42 (m, 2 H, H_{ol}), 4.55−4.35 (m, 8 H, C_5H_4). − ($C_{27}H_{20}BrFeN_2O_3Re)_n$ (1/*n* M = 741.96): calcd. C 43.67, H 2.72, N 3.77; found C 42.79, H 2.89, N 3.65.

[($H_3C)_2$N(C_6H_4)CH=CHC(CH_3)=CHCH=CHCH=C(CH_3)CH=CHC_5H_4N]$_2$Re(CO)$_3$Br (4b): Dark-red powder, yield 40 mg (67%). − IR (KBr): $\tilde{\nu}$(C=O) = 2019 (vs), 1915 (vs), 1880 cm^{-1} (vs). − ^{1}H NMR (270 MHz, $CDCl_3$): δ = 8.65 (d, 4 H, ^3J = 6.7 Hz, NC*H*), 7.37 (d, 4 H, ^3J = 8.7 Hz, C_6H_4), 7.23 (d, 4 H, ^3J = 6.5 Hz, NCHC*H*), 7.12 (d, 1 H, ^3J = 15.8 Hz, H_{ol}), 6.88−6.32 (m, 14 H, H_{ol}), 6.71 (d, 4 H, ^3J = 8.6 Hz, C_6H_4), 3.00−2.99 [m, 12 H, ($H_3C)_2$N], 2.05/2.02 (each s, each 6 H, CH_3). − UV/Vis (CH_2Cl_2) (lg ε): λ_{max} = 328 (4.49), 485 nm (5.01). − $C_{53}H_{56}BrN_4O_3Re$ (1062.3): calcd. C 59.87, H 5.31, N 5.27; found C 59.53, H 5.81, N 5.63.

***trans*-Fc−CH=CH−C_6H_4N−*cis*-Re(CO)$_4$Br (5a):** 58 mg (0.2 mmol) of *trans*-Fc−CH=CH−C_6H_4N was added to 81 mg (0.2 mmol) of $Re(CO)_5Br$ in toluene and the mixture was heated until a solution was obtained. The solvent was then evaporated and the residue was subjected to column chromatography on silica gel using CH_2Cl_2 as eluent. Two main fractions were collected, the first containing **5a** (32 mg, 25%) and the second **4a** (52 mg, 28%). Dark-red powder. − IR (KBr): $\tilde{\nu}$(C=O) = 2105 (m), 2002 (vs), 1988 (vs), 1946 cm^{-1} (vs). − ^{1}H NMR (270 MHz, $CDCl_3$): δ = 8.84 (d, 2 H, ^3J = 7.0 Hz, NC*H*), 7.39 (d, 2 H, ^3J = 8.9 Hz, C_6H_4), 7.30 (d, 2 H, ^3J = 6.8 Hz, NCHC*H*), 7.26−7.20 (m, 1 H, H_{ol}), 6.83 (m, 2 H, H_{ol}), 6.70 (d, 2 H, ^3J = 8.7 Hz, C_6H_4), 6.45 (d, 1 H, ^3J = 15.6 Hz, H_{ol}), 3.03 [s, 6 H, ($H_3C)_2$N]. − ^{13}C NMR (109 MHz, $CDCl_3$): δ = 195.47, 192.17 (CO), 154.07, 147.27, 136.73 (C_{ar}), 121.44/120.92 (C_{ol}), 80.47, 70.64, 69.55, 67.93 (Fc). − UV/Vis (CH_2Cl_2) (lg ε): λ_{max} = 341 (4.66), 508 nm (3.89). − $C_{21}H_{15}BrFeNO_4Re$ (666.9): calcd. C 37.79, H 2.27, N 2.10; found C 38.15, H 2.49, N 2.13.

[all-*trans*-($H_3C)_2$N(C_6H_4)CH=CHCH=CHC_5H_4N]−*cis*-Re(CO)$_4$-Br (5b): Orange powder, yield 55 mg (22%). − IR (KBr): $\tilde{\nu}$(C=O) = 2108 (m), 2024 (vs), 1990 (vs), 1938 cm^{-1} (vs). − ^{1}H NMR (270 MHz, $CDCl_3$): δ = 8.87 (d, 2 H, ^3J = 6.8 Hz, NC*H*), 7.34 (d, 2 H, ^3J = 6.9 Hz, NCHC*H*), 7.30 (d, 1 H, ^3J = 16.1 Hz, H_{ol}), 6.59 (d, 1 H, ^3J = 16.1 Hz, H_{ol}), 4.56 (t, 2 H, ^3J = 1.8 Hz, C_5H_4), 4.46 (t, 2 H, ^3J = 1.9 Hz, C_5H_4), 4.18 (s, 5 H, C_5H_5). − UV/Vis (CH_2Cl_2) (lg ε): λ_{max} = 307 (4.59), 444 nm (5.00). − Emission spectrum (CH_2Cl_2, λ_{ex} = 350 nm): $\lambda_{emi,max}$ = 573 nm. − $C_{21}H_{18}BrN_2O_4Re$ (628.0): calcd. C 40.13, H 2.89, N 4.46; found C 39.53, H 2.90, N 4.27.

Acknowledgments

Generous support by the Fonds der Chemischen Industrie is gratefully acknowledged. We thank the BASF AG, Ludwigshafen, and the F. Hoffmann-LaRoche AG, Basel, for gifts of carotenoid dialdehydes.

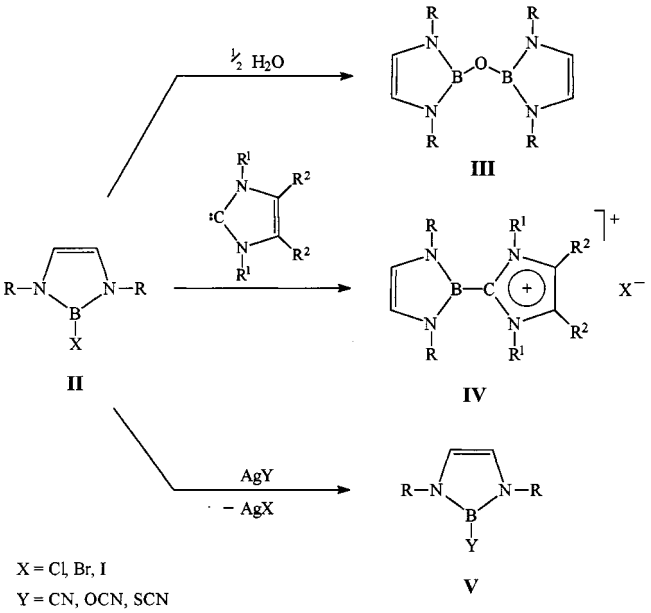
Synthesis and Structure of 2-Hydro-, 2-Alkyl-, 2-Alkynyl-, and 2-Stannyl-2,3-dihydro-1*H*-1,3,2-diazaboroles

Lothar Weber,*[a] Eckhard Dobbert,[a] Hans-Georg Stammler,[a] Beate Neumann,[a] Roland Boese,[b] and Dieter Bläser[b]

Dedicated to Professor Dietmar Seyferth on the occasion of his 70th birthday

Keywords: Boron / Diazaboroles / Hydrides / Tin / Heterocycles

1,3-Di-*tert*-butyl-2,3-dihydro-1*H*-1,3,2-diazaborole (**4a**) and 1,3-bis(2,6-dimethylphenyl)-2,3-dihydro-1*H*-1,3,2-diazaborole (**4b**) were formed by the reaction of the corresponding 2-bromo or 2-iodo derivatives **1a** and **2b** with $LiAlH_4$. Treatment of **1a** with *n*-butyllithium afforded 2-*n*-butyl-1,3-di-*tert*-butyl-2,3-dihydro-1*H*-1,3,2-diazaborole (**5a**), whereas 1,3-di-*tert*-butyl-2-cyano-2,3-dihydro-1*H*-1,3,2-diazaborole (**3a**) was converted into the 2-*tert*-butyl derivative **6a** or the 2-ethynyl-1,3,2-diazaborole **7a** by means of *tert*-butyllithium or by the ethylenediamine adduct of lithium acetylide. Similarly, 1,3-di-*tert*-butyl-2-trimethylstannyl-2,3-dihydro-1*H*-1,3,2-diazaborole (**8a**) and 1,3-bis(2,6-dimethylphenyl)-2-trimethylstannyl-2,3-dihydro-1*H*-1,3,2-diazaborole (**8b**) were accessible from **1a** or **2b** and trimethylstannyllithium. In the complex **9a** the compound **3a** serves as an η^1 ligand towards the $[Cr(CO)_5]$ unit via the cyano group. These novel compounds were characterized by ^1H-, ^{11}B-, ^{13}C-, and ^{119}Sn-NMR spectroscopy, as well as by X-ray structure analyses of **4b**, **8a**, and **9a**.



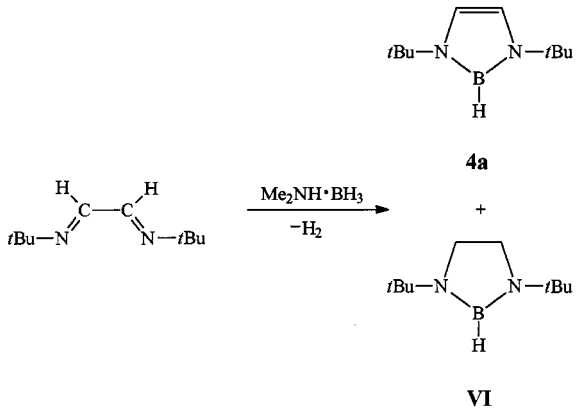
The synthesis of the first 2,3-dihydro-1*H*-1,3,2-diazaboroles **I** dates back to the early 1970s,[1,2] and since then a series of papers concerned with the synthesis, structure, and bonding of such heterocycles has been published.[3,4] A thorough investigation of the chemical reactivity of 2,3-dihydro-1*H*-1,3,2-diazaboroles was primarily hampered by the lack of functionalities at the core of the molecules.[5,6]

Recently, we started a program for the synthesis of the 2-halo-2,3-dihydro-1*H*-1,3,2-diazaboroles **II** as starting materials for further chemical transformations.[7] Treatment of **II** with water, imidazol-2-ylidenes, AgCN, AgOCN, and AgSCN afforded a series of novel 1,3,2-diazaboroles **III**–**V**.[7,8]

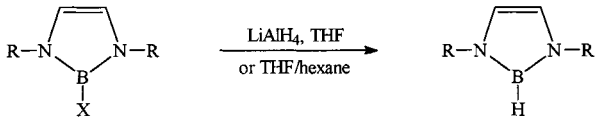
The intention of the work described herein is to provide efficient syntheses for 2-hydro-, 2-alkyl-, 2-alkynyl-, and 2-stannyl-2,3-dihydro-1*H*-1,3,2-diazaboroles.

Results and Discussion

One general route to 2,3-dihydro-1*H*-1,3,2-diazaboroles involves the formation of borolium salts from suitable 1,4-diazabutadienes and organoboron halides prior to reduction with sodium amalgam.[2,3,7,8] Accordingly, in the early attempts to synthezise 2,3-dihydro-1*H*-1,3,2-diazaboroles a 1,4-diazabutadiene derivative was treated with $Me_2NH \cdot BH_3$, which led to an inseparable 1:4 mixture of the desired diazaborole **4a** and the corresponding saturated 2-bora-1,3-diazacyclopentane **VI**.[9]



Scheme 1. Chemical transformations of **II**



However, the availability of 2-halo-functionalized 2,3-dihydro-1*H*-1,3,2-diazaboroles provides an alternative approach to 2,3-dihydro-1*H*-1,3,2-diazaboroles. Thus, the treatment of the 2-bromo derivative **1a** and the 2-iodo derivative **2b** with equimolar amounts of $LiAlH_4$ in a hexane/THF mixture or in THF, led cleanly to the 2,3-dihydrodiazaboroles **4a** and **4b**, respectively, in high yields and within a few min.

Scheme 3. Formation of **4a,b**

The crude products were purified by sublimation at 50°C and 10^{-3} Torr (**4a**) or 210°C and 10^{-4} Torr (**4b**) to give colorless air- and moisture-sensitive solids. In the proton-coupled ^{11}B-NMR spectra (C_6D_6 solution) compounds **4a** and **4b** exhibit doublets at δ = 18.9 ($^1J_{B,H}$ = 149 Hz) and 21.9 ($^1J_{B,H}$ = 158 Hz). The former value compares well with results given in Schulze′s thesis for **4a** (δ = 18.9, d, $^1J_{B,H}$ = 152 Hz), which was dissolved in the four-fold amount of the corresponding saturated compound **VI** (δ = 26.1, d, $^1J_{B,H}$ = 136 Hz).[9] Niedenzu et al. observed for the 1,3,2-diazaboracyclopentane (Me)N^{a}CH$_2$CH$_2$N^b(Me)BH(*N*^{a}−B) and the diazaboracyclohexane (Me)N^{a}CH$_2$CH$_2$CH$_2$N^b-(Me)BH(*N*^{a}−B) ^{11}B-NMR signals at δ = 28.3 (d, $J_{B,H}$ = 131 Hz) and 26.0 (d, $J_{B,H}$ = 132 Hz).[10,11]

The ^{1}H-NMR spectrum of **4a** shows a quadruplet resonance at δ = 4.78 ($^1J_{B,H}$ = 150 Hz) for a boron-ligated hydrogen atom. A medium intense band at $\tilde{\nu}$ = 2594 cm^{-1} and a weak band at $\tilde{\nu}$ = 2623 cm^{-1} in the IR spectrum of **4a** are attributed to the stretching vibrations ν(^{11}B−H) and ν(^{10}B−H). The IR spectrum of **4b** shows a medium intense band at $\tilde{\nu}$ = 2607 cm^{-1} for this mode of vibration. Alkyl substituents at the boron atom of diazaboroles were usually introduced with the organodihaloborane in the condensation step of the synthesis. With 2-halo- and 2-pseudohalo-1,3,2-diazaboroles an inverse approach to such species, namely the replacement of the halide (pseudohalide) by carbanions is now available.

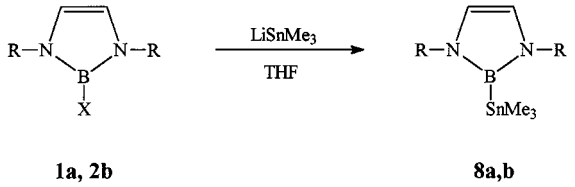


Scheme 4. Nucleophilic substitutions at the B atom of **1a,3a**

The reaction of 2-bromo-1,3,2-diazaborole **1a** with an equimolar amount of *n*-butyllithium in hexane at ambient temp. cleanly afforded **5a** as a colorless hygroscopic solid after distillation at 200−250° and 10^{-3} Torr (84%).

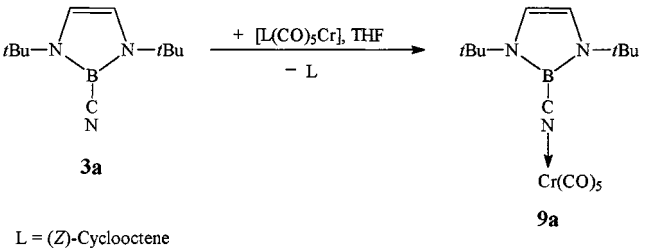
Similarly the 2-cyano-1,3,2-diazaborole **3a** was converted in high yield into the 2-*tert*-butyl- and the 2-ethynyl-1,3,2-diazaboroles **6a** and **7a**, respectively, by treatment with *t*BuLi or the ethylenediamine adduct of lithium acetylide. In the case of **7a** the employment of the 2-cyano-1,3,2-diazaborole as a starting material was crucial since the bromo derivative and the organolithium component gave rise to the formation of (*t*Bu)N^{a}CH=CHN^b(*t*Bu)B^a−N^c(H)CH$_2$-CH$_2$N^d(H)B^{b}N^e(*t*Bu)CH=CH−N^f(*t*Bu)(*N*^{a}−B^a)(*B*^{b}−N^f) instead of **7a**.[12] The ^{11}B{^{1}H}-NMR signals of **5a** (δ = 26.4) compare well with those of (*t*Bu)N^a−CH=CHN^b(*t*Bu)B−CH$_3$(*N*^{a}−B) (δ = 26.2),[3,9] whereas the ^{11}B-NMR resonance of the *tert*-butyl derivative **6a** appeared slightly deshielded (δ = 30.1). In a series of bis(aminoboryl-)acetylenes, the ^{11}B-NMR resonances were registered in the narrow range of δ = 23.8−24.9 regardless of the remaining substituents at the C≡C triple bond.[13] In comparison to this the ^{11}B-NMR signal of **7a** (δ = 15.7) is shielded markedly. This observation may be explained by the aromaticity of the heterocyclic system under discussion. In the ^{1}H-NMR spectrum of **7a** the chemical shift of the ethynyl proton (δ^{1}H = 2.72, s) is identical with those in ($R_2N)_2$B(C≡CH) (R = Me or Et).[13]

The resonance for the α-C atom of the ethynyl unit could not be located in the ^{13}C{^{1}H}-NMR spectrum of the compound. The signal of C_β was registered as a singlet at δ = 96.2, and thus this carbon atom is more deshielded than the corresponding ^{13}C nuclei in Et_2N−B(C≡CH)$_2$ (δ = 85.0), whereas the signal of C_β in (*n*BuO)$_2$B−C≡CH (δ = 91.4) is better comparable with that of **7a**.

The first stannylated 2,3-dihydro-1*H*-1,3,2-diazaboroles were synthesized from **1a** and **2b** and equimolar amounts of trimethylstannyllithium in a THF/hexane mixture at ambient temp.

Comp.	R
1a, 8a	*t*Bu
2b, 8b	2,6-$Me_2C_6H_3$

Scheme 5. Stannylation of **1a,2b**



Purification of the colorless solid **8a** was achieved by distillation at 190°C and 10^{-3} Torr and subsequent crystallization of the distillate from *n*-hexane at −30°C (89% yield). The colorless crystalline **8b** precipitated from a hexane solution at −10°C (60% yield).

The $^{11}B\{^1H\}$-NMR spectrum of **8a** is characterized by a singlet at δ = 25.8, with ^{119}Sn satellites ($^1J_{Sn,B}$ = 1031 Hz). In accordance to this, a quadruplet at δ = 152 ($^1J_{Sn,B}$) was encountered in the $^{119}Sn\{^1H\}$-NMR spectrum of the compound. Similarly, the ^{11}B chemical shift of **8b** (δ = 28.2) shows a ^{119}Sn-^{11}B coupling of ^1J = 960 Hz. The $^{119}Sn\{^1H\}$-NMR resonance of **8b** is observed as a quadruplet at δ = 146 with $^1J_{Sn,B}$ = 960 Hz. The saturated compound (Me)-$N^a-CH_2CH_2N^b$(Me)B($SnMe_3$)(N^a−B) displayed a ^{11}B signal at markedly lower field (δ = 36.5, $^1J_{Sn,B}$ = −930 Hz) and a ^{119}Sn-NMR resonance at δ = 152.[14]

The mass spectra of **8a** and **8b** showed, in addition to the peak of the molecular ion, peaks of high intensity at *m*/*z* = 194 (80%) and *m*/*z* = 290 (100%), respectively, which are attributed to the corresponding 2-methyl-2,3-dihydro-1*H*-1,3,2-diazaboroles.

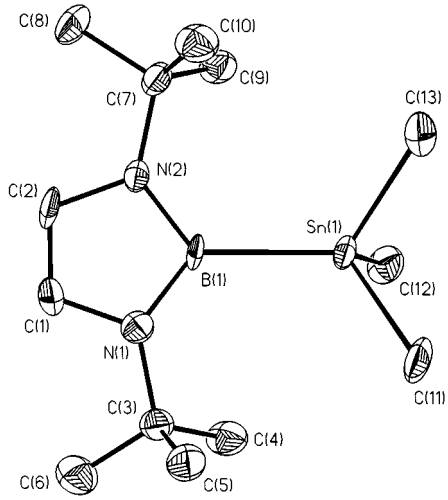
Principally, the 2-cyano-2,3-dihydro-1*H*-1,3,2-diazaborole **3a** is a polyfunctional ligand with different donor sites. Formation of the complex **9a** featuring η^1 coordination of the ligand via the cyano group was achieved by treatment of **3a** with an equimolar amount of [(*Z*)-cyclooctene]$Cr(CO)_5$ in THF at room temp. The product was isolated as yellow needles after crystallization from *n*-hexane at −10°C (83% yield). The ^{11}B-NMR signal of the complex is shielded by Δδ = 2.5 with respect to that of the free ligand. Four ν(CO) bands in the IR spectrum of **9a** ranging from $\tilde{\nu}$ = 2053 to 1888 cm^{-1}, and singlets in the $^{13}C\{^1H\}$-NMR spectrum at δ = 214.4 (CO_{eq}) and 218.9 (CO_{ax}), are consistent with the presence of a $Cr(CO)_5$ group and thus clearly point to a η^1 coordination of **3a**.

In addition to the significant high-field shifts of the ^{11}B-NMR signals of the 2,3-dihydro-1*H*-1,3,2-diazaboroles presented here, in comparison to their saturated analogs, the ^1H- and ^{13}C-NMR resonances of the CH=CH building block (δ^1H = 6.00−6.39 and $\delta^{13}C$ = 112.7−115.5 in **4a−9a**) sustain the argument for the heteroaromatic nature of the rings under discussion.

Scheme 6. Formation of complex **9a**

X-ray Structural Analysis of 8

The molecular structure of **8a** (Figure 1) features a planar 1,3,2-diazaborole ring with a trimethylstannyl substituent which is linked to the boron atom via a B−Sn single bond of 2.274(5) Å. Structurally documented atomic distances between tricoordinate boron and tetravalent tin atoms are rare. The Sn−B bond lengths in the 1,2-bis(organostannylboryl)ethenes **VII** and **VIII** amount to 2.305(7)−2.323(7) and 2.286(17), and 2.277(17) Å, respectively.[15]



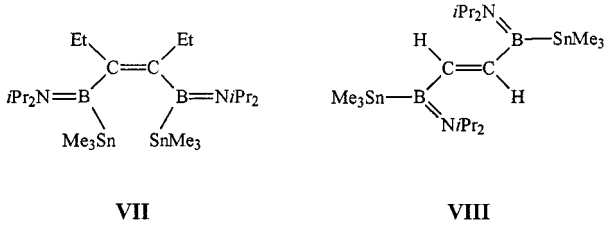


Figure 1. Molecular structure of **8a** in the crystal; selected bond lengths [Å] and angles [°]: B(1)−Sn(1) 2.274(5), B(1)−N(1) 1.439(7), N(1)−C(1) 1.379(7), C(1)−C(2) 1.344(8), N(2)−C(2) 1.399(7), B(1)−N(2) 1.450(7), N(1)−C(3) 1.500 (7), N(2)−C(7) 1.497(7); N(1)−B(1)−N(2) 105.0(4), N(1)−B(1)−Sn(1) 127.5(4), N(2)−B(1)−Sn(1) 127.5(4), B(1)−N(1)−C(1) 108.1(4), B(1)−N(2)−C(2) 107.1(4), B(1)−N(1)−C(3) 131.1(5), B(1)−N(2)−C(7) 130.7(4), N(1)−C(1)−C(2) 110.2(5), N(2)−C(2)−C(1) 109.7(5), B(1)−Sn(1)−C(11) 116.7(2), B(1)−Sn(1)−C(12) 111.7(3), B(1)−Sn(1)−C(13) 119.2(3)

VII **VIII**

Scheme 7. Stannylboranes **VII** and **VIII**

A boron−tin bond length of 2.237(5) Å was measured in the boratobenzene complex (C_5Me_5)Fe(C_5H_5B−$SnMe_3$).[16] In the anion $[B_{11}H_{11}SnMe]^-$ boron−tin con-

tacts of comparable lengths [2.288(3)−2.306(3) Å] were encountered.[17]

Atomic distances and valence angles within the diazaborole ring are in good agreement with the equivalent data for the borolylimidazolium cation **IV**.[7] In **8a** the B−N bond lengths [1.439(7), 1.450(7) Å] indicate multiple bond character. In a series of diazaboroles the B−N bond lengths range from 1.407(3) to 1.450(2) Å. The atomic distance C(1)−C(2) [1.344(8) Å] and the N−C(sp^2) bond lengths [1.379(7) and 1.399(7) Å] also indicate multiple bonding. For the N(sp^2)−C(sp^3) single bonds N(1)−C(3) and N(2)−C(7) bond lengths of 1.500(7) and 1.497(7) Å are measured. The endocyclic angles in **8a** N(1)−B(1)−N(2) [105.0(4)°], B(1)−N(1)−C(1) [108.1(4)°], B(1)−N(2)−C(2) [107.1(4)°], N(1)−C(1)−C(2) [110.2(5)°], and N(2)−C(2)−C(1) [109.7(5)°] resemble those in **2b**:[8] N−B−N [106.9(4)°], B−N−C [107.5(3)°], and N−C−C [109.1(2)°] and **IV** [107.1(6), 105.9(4) and 110.5(3)°]. This also applies to the exocyclic angles N(1)−B(1)−Sn(1) and N(2)−B(1)−Sn(1) [127.5(4)°] in **8a**, and the corresponding angle in **2b** [126.6(2)°]. The angles B(1)−Sn(1)−C(13) [119.2(3)°] and B(1)−Sn(1)−C(11) [116.7(2)°] are significantly widened as compared to the angle B(1)−Sn(1)−C(12) [111.7(3)°], which reflects steric interactions between the *tert*-butyl substituents and methyl groups C(11)H_3 and C(13)H_3.

X-ray Structural Analysis of 4

The molecular structure of **4b** (Figure 2) features a planar 1,3,2-diazaborole ring with two nearly orthogonally oriented *ortho*-xylyl substituents at the nitrogen atoms (interplanar angles between the heterocycle and the arene rings: ψ = 85.9 and 86.5°). Atomic distances and valence angles within the diazaborole ring (see caption of Figure 2) are in excellent agreement with those of **8a**, **2b**, and **IV**.

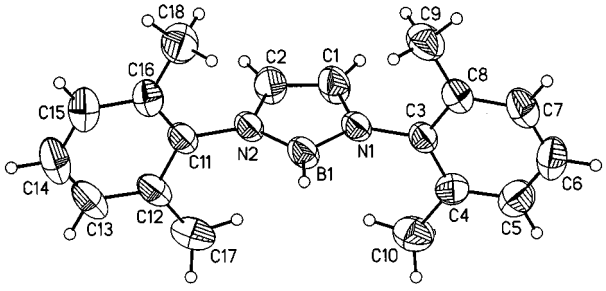

Figure 2. Molecular structure of **4b** in the crystal; selected bond lengths [Å] and angles [°]: B(1)−H(1A) 1.04(3), B(1)−N(1) 1.395(4), N(1)−C(1) 1.377(3), N(1)−C(3) 1.427(3), B(1)−N(2) 1.398(4), N(2)−C(2) 1.374(3), N(2)−C(11) 1.421(3), C(1)−C(2) 1.323(4); N(1)−B(1)−N(2) 106.8(2), N(1)−B(1)−H(1A) 124(2), N(2)−B(1)−H(1A) 129(2), B(1)−N(1)−C(1) 106.9(2), B(1)−N(1)−C(3) 130.9(2), N(1)−C(1)−C(2) 109.8(3), C(1)−N(1)−C(3) 122.1(2), B(1)−N(2)−C(2) 107.3(2), B(1)−N(2)−C(11) 130.6(2), C(2)−N(2)−C(11) 122.1(2), N(2)−C(2)−C(1) 109.2(3)

X-ray Structural Analysis of 9

The molecular structure determination of the pentacarbonylchromium adduct **9a** reveals a nearly undistorted octahedron, one apex of which is occupied by the η^1-2-cyano-2,3-dihydro-1*H*-1,3,2-diazaborole. Thus the atoms B(1), C(1), N(1), Cr(1), C(14), and O(14) are in a linear arrangement. The plane of the heterocycle is staggered with respect to the plane defined by the metal center and the four equatorial carbonyl groups. The bond Cr(1)−C(14) in *trans* disposition to the ligand [1.825(7) Å] is markedly shortened as compared to the remaining Cr(1)−C(CO) bond lengths [1.899(6)−1.917(6) Å], which reveals the 2-cyanodiazaborole as a donor ligand without appreciable π-back bonding. The bond Cr(1)−N(1) of 2.051(5) Å is close to sum of the covalent radii of Cr^0 (1.48 Å)[18] and sp-hybridized N (0.55 Å)[19a]. The C(1)−N(1) bond length of 1.140(6) Å resembles that in cyanogen (1.15 Å).[19b] Due to the presence of an sp-hybridized carbon atom, the bond length B(1)−C(1) [1.547(8) Å] is shorter than the B(sp^2)−C(sp^2) bond in the borolylimidazolium ion **IV** [1.580(11) Å], and it is comparable with the C(sp^2)−B(sp) distance in Li^+-[2,4,6-$Me_3C_6H_2$−B=C−B(2,4,6-$Me_3C_6H_2$)CH($SiMe_3$)$_2$]$^-$ [1.543(6) Å].[20] The bonding parameters within the 1,3,2-diazaborole ring largely resemble those of **4b**, **IV**, and **2b**, and merit no further discussion.

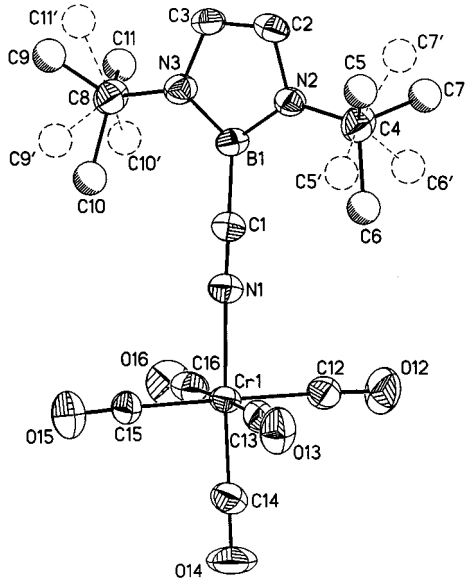

Figure 3. Molecular structure of **9a** in the crystal; selected bond lengths [Å] and angles [°]: B(1)−N(2) 1.416(7), N(2)−C(2) 1.389(7), N(2)−C(4) 1.477(5), B(1)−N(3) 1.433(7), N(3)−C(3) 1.373(6), N(3)−C(8) 1.478(5), C(2)−C(3) 1.312(8), B(1)−C(1) 1.547(8), C(1)−N(1) 1.140(6), Cr(1)−N(1) 2.051(5), Cr(1)−C(12) 1.906(7), Cr(1)−C(13) 1.899(6), Cr(1)−C(14) 1.825(7), Cr(1)−C(15) 1.906(6), Cr(1)−C(16) 1.917(6); N(2)−B(1)−N(3) 107.5(4), B(1)−N(2)−C(4) 133.5(4), B(1)−N(3)−C(8) 132.9(4), B(1)−N(2)−C(2) 105.6(4), C(2)−N(2)−C(4) 120.9(4), B(1)−N(3)−C(3) 105.1(4), C(3)−N(3)−C(8) 122.0(4), N(2)−C(2)−C(3) 110.2(5), N(3)−C(3)−C(2) 111.5(5), B(1)−C(1)−N(1) 178.2(5), C(1)−N(1)−Cr(1) 177.5(5), N(1)−Cr(1)−C(12) 89.0(2), N(1)−Cr(1)−C(13) 90.4(2), N(1)−Cr(1)−C(14) 177.5(3), N(1)−Cr(1)−C(15) 91.7(2), N(1)−Cr(1)−C(16) 92.0(2), Cr(1)−C(14)−O(14) 177.9(6)

Experimental Section

General: All manipulations were performed under dry argon. Solvents were rigorously dried with an appropriate drying agent and freshly distilled before use. − The following compounds were prepared as described in the literature: (*t*Bu)N^a−CH=CH−N^b(*t*Bu)-BBr(*N*^{a}−B) (**1a**),[7] (*t*Bu)N^a−CH=CH−N^b(*t*Bu)BCN(*N*^{a}−B) (**3a**),[8] (2,6-Me$_2$C$_6$H$_3$)N^a−CH=CH−N^b(2,6-Me$_2$C$_6$H$_3$)BI(*N*^{a}−B) (**2b**),[8] [(*Z*)-cyclooctene]Cr(CO)$_5$.[21] LiAlH$_4$, Me$_3$SnCl, Li(H$_2$NCH$_2$CH$_2$NH$_2$)C≡CH, Li metal, *n*-butyllithium, *tert*-butyllithium were purchased. − IR spectra: Bruker FTIR IFS66. − ^{1}H-, ^{11}B-, ^{13}C-, and ^{119}Sn-NMR spectra: C$_6$D$_6$ at room temp.; Bruker AC 100 (^{1}H, 100.13 MHz); Bruker Avance DRX 500 (^{1}H, 500.13 MHz, ^{11}B, 160.46 MHz, ^{13}C, 125.75 MHz, ^{119}Sn, 186.51 MHz); references: SiMe$_4$ (^{1}H, ^{13}C), BF$_3$ · OEt$_2$ (^{11}B), SnMe$_4$ (^{119}Sn). − Mass spectra (EI): VG Autospec sector-field mass spectrometer (Micromass) 70 eV.

(*t*Bu)N^a−CH=CH−N^b(*t*Bu)BH(*N*^{a}−*B*) (4a): A sample of solid LiAlH$_4$ (0.114 g, 3.0 mmol) was added to a solution of **1a** (0.777 g, 3.0 mmol) in a mixture of *n*-hexane (20 mL) and THF (20 mL). After 2 min of stirring at 20°C, the solution was decanted from the solid components and concentrated to dryness. The residue was taken up in *n*-pentane (30 mL) and filtered. The filtrate was freed from solvent, and the colorless residue was sublimed (40−45°C, 10^{-3} Torr) to afford 0.475 g (88%) of colorless solid **4a**. M.p. 51−53°C. − IR (nujol): $\tilde{\nu}$ = 2623 cm^{-1} w [ν(^{10}B−H)], 2594 m [ν(^{11}B−H)], 1410 s, 1366 s, 1316 m, 1290 m, 1282 m, 1247 s, 1221 w, 1147 m, 1092 w, 922 m, 818 w, 664 s, 633 w, 553 m. − ^{1}H NMR: δ = 1.30 (s, 18 H, *t*Bu), 4.78 (q, $^1J_{B,H}$ = 150 Hz, 1 H, BH), 6.39 (s, 2 H, CH). − ^{13}C{^{1}H} NMR: δ = 31.9 [s, C(*C*H$_3$)$_3$], 51.4 [s, *C*(CH$_3$)$_3$], 114.2 (s, CH). − ^{11}B NMR: δ = 18.9 (d, $^1J_{B,H}$ = 149 Hz). − MS/EI: *m*/*z* (%) = 180 (67) [M$^+$], 165 (100) [M$^+$ − CH$_3$]. − C$_{10}$H$_{21}$BN$_2$ (180.12): calcd. (*t*Bu)N^a−CH=CH−N^b(*t*Bu)BCN→Cr(CO)$_5$(*N*^{a}−*B*) (9a): A solution of [(*Z*)-cyclooctene]Cr(CO)$_5$ (0.440 g, 14.5 mmol) in 5 mL of THF was added dropwise at room temp. to a stirred solution of **3a** (0.300 g, 14.6 mmol) in 30 mL of THF. After 1 h, the brown reaction mixture was concentrated to dryness. The residue was dissolved in 30 mL of hexane. It was filtered, and the filtrate was stored at −10°C. Product **9a** was isolated as yellow needles. Yield: 0.480 g (83%). M.p. 45−50°C (dec.). − IR (KBr): $\tilde{\nu}$ = 2975 cm^{-1} m, 2206 w, 2120 w, 2053 m [ν(CO)], 1987 sh [ν(CO)], 1927 vs [ν(CO)], 1888 sh [ν(CO)], 1632 m, 1529 w, 1467 w, 1432 w, 1404 w, 1369 m, 1305 w, 1262 w, 1208 w, 1170 w, 1067 m, 1027 m, 803 m, 697 m, 663 s, 552 w, 449 w. − ^{1}H NMR: δ = 1.11 (s, 18 H, *t*Bu), 6.00 (s, 2 H, CH). − ^{13}C{^{1}H} NMR: δ = 31.2 [s, C(CH_3)$_3$], 53.8 [s, $C(CH_3)_3$], 115.5 (s, CH), 214.4 (s, CO_{eq}), 218.9 (s, CO_{ax}). − ^{11}B{^{1}H} NMR: δ = 9.4 s. − MS/EI: *m*/*z* (%) = 397 (0.2) [M^+], 285 (0.4) [M^+ − 4 CO], 257 (5) [M^+ − 5 CO], 205 (30) [M^+ − Cr(CO)$_5$]. − $C_{16}H_{20}BCrN_3O_5$ (397.16): calcd. C 48.39, H 5.08, N 10.58; found: C 48.39, H 5.02, N 10.60.

X-ray Crystallography: For **4b** and **9a** crystallographic data were collected with a Siemens CCD-Smart three-axis goniometer using graphite-monochromated Mo-K_α radiation with a full-sphere scan covering more than 98% of the data. An empirical absorption correction (Siemens-SADABS) was applied, for structure solution with Direct Methods and refinements on F^2; Siemens SHELTL-Plus software (Vers. 5.01) was used. Hydrogen atoms were treated as riding groups with U values at the 1.2 fold (1.5 fold for methyl groups) of the corresponding C atoms. − For **8a** the data were collected with a Bruker P2$_1$ four-circle diffractometer. Crystallographic programs used for structure solution and refinement were from SHELXTL PLUS and SHELXL-97. The structure was solved by using Direct Methods and was refined by using full-matrix least squares on F^2 of all unique reflexions with anisotropic thermal parameters for all non-hydrogen atoms. Hydrogen atoms were included at calculated positions with U(H) = 1.2 U_{eq} for groups, U(H) = 1.5 U_{eq} for CH_3 groups. Crystal data of the compounds are listed in Table 1.[22]

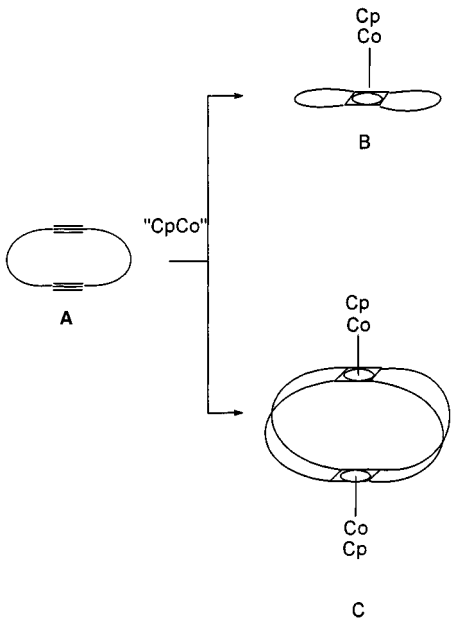
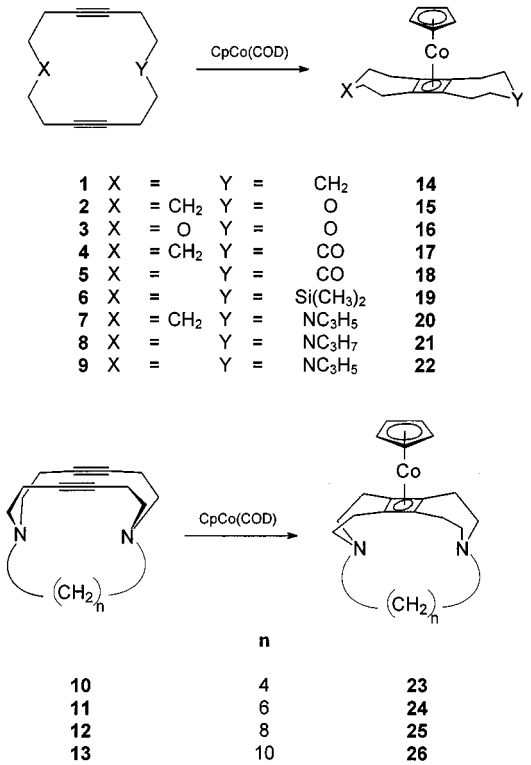
Reactions of 1,8-Diheterocyclotetradeca-4,11-diynes with (η^4-Cycloocta-1,5-diene)(η^5-cyclopentadienyl)cobalt



Volker Wolfart,[a] Matthias Ramming,[a] Rolf Gleiter,*[a] Bernhard Nuber,[b] Hans Pritzkow,[b] and Frank Rominger[a]

Keywords: Alkynes / Heterocycles / Cyclizations / Cobalt



The following monocyclic and bicyclic 14-membered diynes were treated with [CpCo(cod)]: 1-oxacyclotetradeca-4,11-diyne (**2**), 1,8-dioxacyclotetradeca-4,11-diyne (**3**), cyclotetradeca-4,11-diynone (**4**), cyclotetradeca-4,11-diyne-1,8-dione (**5**), 1,1,8,8-tetramethyl-1,8-disilacyclotetradeca-4,11-diyne (**6**), 1-allyl-1-azacyclotetradeca-4,11diyne (**7**), 1,8-dipropyl-1,8-diazacyclotetradeca-1,11-diyne (**8**), 1,8-diallyl-1,8-diazacyclotetradeca-4,11-diyne (**9**), 1,8-diazabicyclo[6.6.4]-octadeca-4,11-diyne (**10**), 1,8-diazabicyclo[6.6.6]eicosa-4,11-diyne (**11**), 1,10-diazabicyclo[8.6.6]docosa-13,19-diyne (**12**) and 1,12-diazabicyclo[10.6.6]tetracosa-15,21-diyne (**13**). In all cases we obtained an intramolecular cyclobutadiene complex stabilized with a CpCo fragment (**15**–**26**). For **3** we could isolate, besides the cyclobutadiene complex **16**, the trimerization product **28**. In the cases of **15**, **16**, **18**, **20**, **23**, **25**, and **26** the structure of the cylobutadiene complexes could be confirmed by X-ray studies. Common to all structures is a boat-like conformation of the tricyclic unit containing the cyclobutadiene ring. The two cycloheptene units adopt a chair conformation in which the heteroatom is removed from the metal center.

The cobalt-mediated cycloaddition of alkynes proceeds either in a [2+2] fashion to yield cyclobutadiene (Cbd) complexes or in a [2+2+2] fashion to give aromatic systems.[1−7] In the case of cyclic diynes the cyclobutadiene complexes dominate.[5−7] Depending on the length of the chain between the triple bonds one obtains either the tricyclic intramolecular cyclobutadiene complexes **B** or the superphanes **C** which are generated in an intermolecular pathway.[6,7] The latter path was preferred in the case of 1,6-cyclodecadiyne and in disilabridged cyclic diynes, while larger rings favored the intramolecular path.[6,7]

In order to extend our knowledge to the 14-membered rings we synthesized a number of hetero derivatives of 1,8-

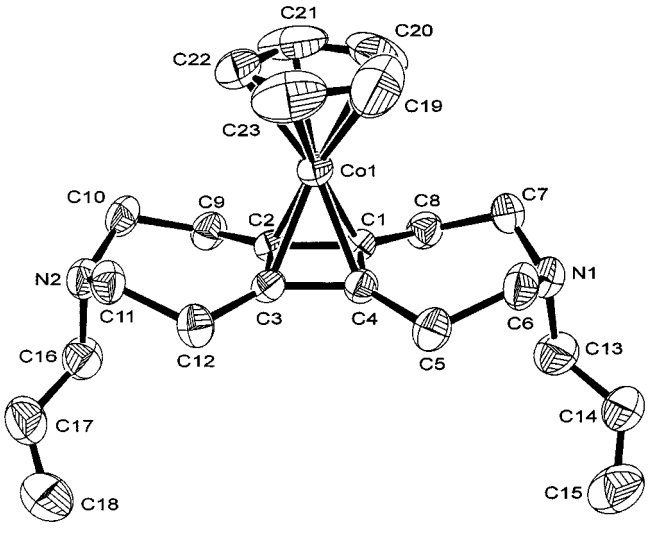
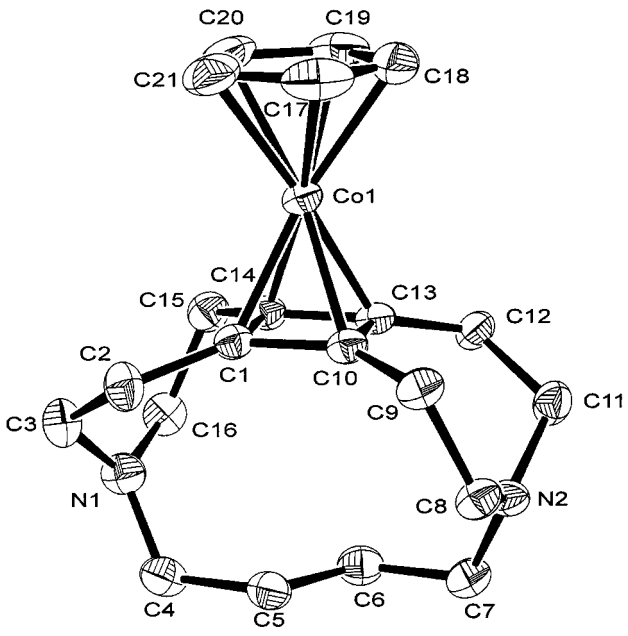
cyclotetradecadiyne (**1**) and explored their reaction with (η^4-cycloocta-1,5-diene)(η^5-cyclopentadienyl)cobalt ([CpCo(cod)]). As model systems we either chose monocyclic systems with O and NR as electron-donating heteroatoms and dimethylsilyl groups as bulky substituents, or we chose bicyclic 1,8-diaza-substituted systems. By varying the chain length we were able to influence the conformation of the 14-membered ring system.



We chose the following congeners of **1**: 1-oxacyclotetradeca-4,11-diyne (**2**),[8] 1,8-dioxacyclotetradeca-4,11-diyne (**3**),[8] cyclotetradeca-4,11-diynone (**4**),[8] cyclotetradeca-4,11-diyne-1,8-dione (**5**),[8] 1,1,8,8-tetramethyl-1,8-disilacyclotetradeca-4,11-diyne (**6**),[9] 1-allyl-1-azacyclotetradeca-4,11-diyne (**7**),[10] 1,8-dipropyl-1,8-diazacyclotetradeca-4,11-diyne (**8**),[10] 1,8-diallyl-1,8-diazacyclotetradeca-4,11-diyne (**9**),[10] 1,8-diazabicyclo[6.6.4]octadeca-4,4-diyne (**10**),[10] 1,8-diazabicyclo[6.6.6]eicosa-4,11-diyne (**11**),[10] 1,10-diazabicyclo[8.6.6]docosa-13,19-diyne (**12**)[10] and 1,12-diazabicyclo[10.6.6]tetracosa-15,20-diyne (**13**)[10] (see Scheme 2).

Results and Discussion



The reactions of **2**−**13** were carried out by heating the diynes in nonane with [CpCo(cod)] until no starting material could be detected. In most cases we could only observe the corresponding intramolecular products **15**−**26** in yields

Molecular structure of **16**, **22** and **23**; selected bond lengths [Å] and angles [°]: **16**: Co−C6 1.980(2), Co−C7 1.991(2), Co−C1 2.058(2), Co−C3 2.082(2), C6−C7 1.462(2), C7−C12 1.463(2); C7−C8 1.485(2), C9−O1 1.433(2), C9−O1−C10 115.2(2), C8−C9−O1 113.4(2); **22**: Co−C1 1.977(3), Co−C2 1.983(3), Co−C19 2.035(5), Co−C20 2.041(5), C1−C2 1.466(4), C2−C3 1.452(4), C1−C8 1.477(4), C7−N1 1.459(5), N1−C13 1.448(5), C13−C14 1.493(6), C14−C15 1.298(6); C6−N1−C7 116.9(3), C6−N1−C13 115.0(3), C13−C14−C15 125.6(5); **23**: Co−C1 1.983(3), Co−C10 1.978(3), Co−C19 2.058(3), Co−C20 2.065(4), C1−C10 1.465(5), C1−C14 1.448 (5), C1−C2 1.495(5), C3−N1 1.441(4), N1−C4 1.448(4); C3−N1−C16 118.8(2), C3−N1−C4 119.0(3)

between 3 and 70% (see Table 1). The exceptions were the parent system **1**, in which besides the intramolecular product **14** a superphane **27** could be observed in 7% yield,[11] and **3**, for which in addition to **16** the trimer **28** was obtained in 6% yield. In the case of **15**, **16**, **18**, **22**, **23**, **25**, and **26** we were able to grow single crystals which allowed the study of the molecular structure of these molecules in the solid state. In Figure 1 we show the X-ray-structures of **16**, **22**, and **23** as examples. In all cases we observed that together with the two carbon atoms of the cyclobutadiene unit the bridges with five main-group atoms between the former triple bonds adopt a chair conformation in which the heteroatom is removed from the metal center. This holds whether the heteroatoms are tethered with a short (C_4 in **23**), a long (C_{10} in **26**) or no chain (**15**, **16**, **18**, **22**). The substituents at the nitrogen atoms adopt the axial position whether they are tethered (**23**, **25**, **26**) or not (**22**).

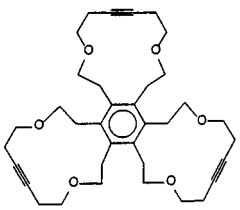

Table 1. Yields of the intramolecular cyclobutadiene complexes **14**−**26** by treating **1**−**13** with [CpCo(cod)]

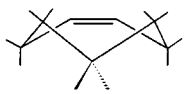
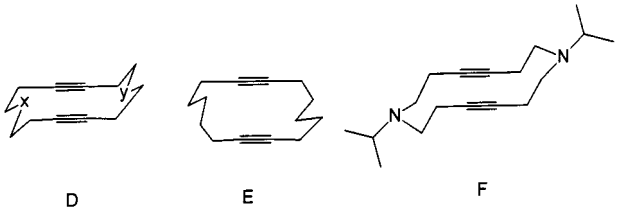
starting material		**1**	**2**	**3**	**4**	**5**	**6**
product		**14**	**15**	**16**	**17**	**18**	**19**
yield (%)		29	11	14	48	60	68
starting material	**7**	**8**	**9**	**10**	**11**	**12**	**13**
product	**20**	**21**	**22**	**23**	**24**	**25**	**26**
yield (%)	5	39	3	71	25	38	50



The chair conformation is expected because for cycloheptene systems a chair conformation **29** is reported in the literature.[12] The axial position of the allylic groups in **22** we ascribe to packing effects in the crystal because there are clearly two 1,3 interactions in the chair form.

27



28

29

The uniformity of the conformations of the products is contrasted by a variety of conformations of the starting diynes. The structures of **1**, **3**−**5**,[8] 1,8-diisopropyl-1,8-diazacyclotetradeca-4,11-diyne (**30**),[10] **10**,[10] and **12**[10] have been studied in the solid state by means of X-ray techniques. For **3**−**5** the 14-membered ring adopts a chair conformation with a zig-zag arrangement of the chains between the triple bonds. This gives rise to two *anti* and two *gauche* interactions in the chain (**D**). In the case of **1**[8,13] an arrangement of the methylene groups with three *gauche* and one *anti* interaction is found (**E**). AM1[14] and MNDO[15] calculations show only a small energy difference (2 kcal/mol) between the two conformations. In the case of **30** a chair conformation was found in which the chains adopt a half-envelope conformation (**F**). In this conformation there are two *gauche* and two *eclipsed* interactions. The energy difference between conformations **F** and **D** was calculated (AM1, MNDO) to be 20 kcal/mol. In the cases of the bicyclic diynes **10** and **12** a twist-boat conformation was encountered.

D E F

X = Y = O
X = Y = CO
X = CO Y = O

The different conformations provide different transannular distances between the triple bonds: **1**: 4.64 Å; **3**: 4.71 Å; **5**: 5.20 Å; **29**: 3.85 Å; **10**: 4.19 Å; **12**: 3.77 Å. Our experiments provide no correlation between conformations of the starting material and yield of the products. This can be interpreted by assuming either that steric effects are important at a later stage of the multi-step reaction, or that at the reaction temperature all conformations mentioned above interconvert rapidly.

Experimental Section

General Methods: Reactions were conducted in oven-dried (150°C) glassware under argon. Solvents were distilled and dried under argon before use: *n*-nonane and cyclooctane from sodium, DME from potassium. − Melting points: Dr. Tottoli apparatus (Büchi), uncorrected values. − Materials used for column chromatography: Neutral alumina (Aldrich, Macherey-Nagel), Kieselgel 60 (Merck, Macherey-Nagel), Florisil (Acros). GLC: HP 5890A instrument connected to a Shimadzu C-R3A integrator. A capillary column Ultra 2 (PhMeSilicone, 25 m × 0.32 mm × 0.52 μm) was used with nitrogen carrier gas and a flame-ionization detector (FID). − ^{1}H and ^{13}C NMR: Bruker WH 300 (^{1}H at 300 MHz and ^{13}C at 75.47 MHz) and Bruker WH 200 (^{1}H at 200 MHz and ^{13}C at 50.33 MHz) by using the solvent as internal standard. If not otherwise mentioned spectra were determined at 300 MHz and 75.47 MHz, respectively. − IR: Perkin Elmer 580B, Bruker IFS 66, Bruker IFS 88 and Bruker Vector 22. − UV: Hewlett Packard HP 8452A. − High-resolution MS: ZAB high-resolution mass spectrometer (Fa. Vacuum Generators). − Elemental analyses were carried out by the Mikroanalytisches Laboratorium der Universität Heidelberg.

General Procedure for the Reactions of the Cyclic and Bicyclic Diynes 2−13 with [CpCo(cod)]: If not otherwise mentioned the diynes and [CpCo(cod)] were dissolved in *n*-nonane and the mixtures were heated under reflux. When the diyne could not be detected any more by TLC the mixture was cooled. In the case of the carbocyclic cobalt complexes **17** and **18** the solvent was removed under vacuum. The residue was dissolved in CH_2Cl_2, adsorbed on Al_2O_3 (neutral, 6% H_2O) and chromatographed on Al_2O_3 (neutral, 6% H_2O). For the other cobalt complexes excess [CpCo(cod)] and *n*-nonane were removed by flash chromatography on Al_2O_3 (neutral, 6% H_2O) with petroleum ether as solvent. Afterwards the cobalt complex was eluted with petroleum ether or petroleum ether/diethyl ether mixtures as eluent.

(η^5-Cyclopentadienyl){(η^4-1,2,8,9)-5-oxatricyclo[7.5.0.0^{2,8}]tetradeca-1,8-diene}cobalt (15): To a refluxing solution of 800 mg (5.0 mmol) of 1-oxacyclotetradeca-4,11-diyne (**2**) in 80 mL of *n*-nonane 1.66 g (10.0 mmol) of [CpCo(cod)] in 20 mL of *n*-nonane was added within 60 min and refluxing was continued for 4 h. Column chromatography of the cooled mixture with petroleum ether/pentane (5:1) as eluent yielded 330 mg, (21%) of **15** as orange crystals, m.p. 143°C. − ^{1}H NMR ($CDCl_3$): δ = 4.72 (s, 5 H, H_{Cp}), 4.19 (m, ^2J = 12.5 Hz, 2 H, CH_2−O), 3.42 (m, 2 H, CH_2−O), 1.97 (m, 4 H, C_{Cbd}−CH_2, 1.58 (m, 5 H, CH_2). − ^{13}C NMR ($CDCl_3$): δ = 79.9 (C_{Cbd}), 78.8 (C_{Cp}), 76.8 (C_{Cbd}), 74.4 (CH_2−O), 30.4, 30.2, 30.0, 27.8 (CH_2). − IR (KBr): $\tilde{\nu}$ = 3436 cm^{-1}, 3094, 2922, 2860, 2811, 1112, 1002, 809. − UV (CH_2Cl_2): λ_{max} (lg ε) = 292 nm (3.09), 272 (4.35), 222 (4.05). − $C_{18}H_{23}CoO$ (314.31): calcd. C 68.78, H 7.38; found C 68.67, H 7.45.

(η^5-Cyclopentadienyl){(η^4-1,2,8,9)-5,12-dioxatricyclo-[7.5.0.0^{2,8}]tetradeca-1,8-diene}cobalt (16): Starting material: 800 mg (4.2 mmol) of 1,8-dioxacyclotetradeca-4,11-diyne (**3**) and 966 mg (4.2 mmol) of [CpCo(cod)] in 50 mL of *n*-nonane. Reaction time: 4 h. The warm reaction mixture was chromatographed with petroleum ether/diethyl ether (1:1) to yield the intramolecular complex **16** (180 mg, 14%). Afterwards the trimerization product **28** (51 mg, 6%) could be isolated by using diethyl ether as eluent. − **16**: Yellow-orange crystals, m.p. 193°C. − ^{1}H NMR (CD_2Cl_2): δ = 4.70 (s, 5 H, H_{Cp}), 4.15 (m, 4 H, CH_2−O), 3.63 (m, 4 H, CH_2−O), 1.94 (m, 8 H, C_{Cbd}−CH_2). − ^{13}C NMR (CD_2Cl_2): δ = 79.3 (C_{Cp}), 30.6 (C_{Cbd}−CH_2), 77.8 (CH_2−O), 74.5 (C_{Cbd}). − IR (KBr): $\tilde{\nu}$ = 3440 cm^{-1}, 2938, 2866, 2816, 1632, 1108. − UV (CH_2Cl_2): λ_{max} (lg ε) = 386 nm (2.35), 298 (2.87), 266 (4.37), 222 (4.04). − HRMS (EI, 70 eV): $C_{17}H_{21}CoO_2$: calcd. 316.0874, found 316.0841. − **28**: Colorless needles. − ^{1}H NMR ($CDCl_3$): δ = 3.71 (t, 12 H, CH_2−O), 3.62 (t, 12 H, CH_2−O), 3.08 (t, 12 H, CH_2−Ph), 2.40 (t, 12 H, CH_2−C≡). − ^{13}C NMR ($CDCl_3$): δ = 135.5 (C_{ar}), 79.5 (C≡C), 20.8 (CH_2−C≡C), 71.4 (CH_2−O), 69.0 (CH_2−O), 31.5 (CH_2−Ph). − IR (KBr): $\tilde{\nu}$ = 3441 cm^{-1}, 2864, 1632, 1483, 1365, 1131, 799. − UV (CH_2Cl_2): λ_{max} (lg ε): 232 nm (3.3). − HRMS (EI, 70 eV): $C_{36}H_{48}O_6$: calcd. 576.3451, found 576.3465.

(η^5-Cyclopentadienyl){(η^4-1,2,8,9)-tricyclo[7.5.0.0^{2,8}]tetradeca-1,8-dien-5-one}cobalt (17): Starting material: 400 mg (2.0 mmol) of cyclotetradeca-4,11-diynone (**4**) and 504 mg (2.2 mmol) of [CpCo(cod)] in 30 mL of *n*-nonane. Reaction time: 3 d. The reaction mixture was chromatographed with *n*-hexane/diethyl ether (8:1). For elemental analysis it was necessary to subject **17** to further column chromatography on silica gel with the solvent mixture mentioned above. Yield: 314 mg (48%) of **16** as yellow crystals, m.p. 124°C. − ^{1}H NMR ($CDCl_3$): δ = 4.80 (s, 5 H, H_{Cp}), 2.98 (td, ^2J = $^3J_1$ = 11.3, $^3J_2$ = 5.2 Hz, 2 H, O=C−CH_2), 2.54 (d, 2 H, O=C−CH_2, ^2J = 11.3 Hz), 2.12−1.80 (m, 10 H, CH_2), 1.58 (m, 4 H, CH_2). − ^{13}C NMR ($CDCl_3$): δ = 214.4 (CO), 80.7 (C_{Cbd}), 79.2 (C_{Cp}), 76.4 (C_{Cbd}), 44.1, 30.4, 30.3, 27.5, 22.4 (CH_2). − IR (KBr): $\tilde{\nu}$ = 2920 cm^{-1}, 2821, 2812, 1701, 1444, 1321, 1295, 798. − UV/Vis (CH_2Cl_2): λ_{max} (lg ε) = 224 nm (4.05), 266 (4.29). − $C_{19}H_{23}CoO$ (326.32): calcd. C 69.93, H 7.11; found C 69.84, H 7.10.

(η^5-Cyclopentadienyl){(η^4-1,2,8,9)-tricyclo[7.5.0.0^{2,8}]tetradeca-1,8-diene-5,12-dione}cobalt (18): Starting material: 500 mg (2.3 mmol) of cyclotetradeca-4,11-diyne-1,8-dione (**5**) and 580 mg (2.5 mmol) of [CpCo(cod)] in 35 mL of *n*-nonane. Reaction time: 5 d. The reaction mixture was chromatographed with $CHCl_3$/ethyl acetate (20:1). For elemental analysis it was necessary to subject **18** to further column chromatography on silica gel with the solvent mixture mentioned above. Yield: 470 mg (60%) of **18** as yellow crystals, m.p. 177°C. − ^{1}H NMR (200 MHz, $CDCl_3$): δ = 4.85 (s, 5 H, H_{Cp}), 2.95 (td, ^2J = $^3J_1$ = 11.6, $^3J_2$ = 5.2 Hz, 4 H, O=C−CH_2,), 2.57 (m, 4 H, O=C−CH_2), 2.12 (ddd, 4 H, C_{Cbd}−CH_2, ^2J = 15.9, $^3J_1$ = 5.2, $^3J_2$ = 4.2 Hz), 1.88 (ddd, 4 H, C_{Cbd}−CH_2, ^2J = 15.9, $^3J_1$ = 11.6, $^3J_2$ = 4.3 Hz). − ^{13}C NMR (50.33 MHz, $CDCl_3$): δ = 208.7 (CO), 79.8 (C_{Cp}), 77.7 (C_{Cbd}), 44.0, 22.1 (CH_2). − IR (KBr): $\tilde{\nu}$ = 1695 cm^{-1}, 1321, 1295, 1165, 1104, 803. − UV/VIS (CH_2Cl_2): λ_{max} (lg ε) = 224 nm (4.03), 268 (4.26). − $C_{19}H_{21}CoO_2$ (340.31): calcd. C 67.06, H 6.22; found C 66.75, H 6.25.

(η^5-Cyclopentadienyl){(η^4-1,2,8,9)-5,5,12,12-tetramethyl-5,12-disilatricyclo[7.5.0.0^{2,8}]tetradeca-1,8-diene}cobalt (19): Starting material: 106 mg (0.38 mmol) of 1,1,8,8-tetramethyl-1,8-disilacyclotetradeca-4,11-diyne (**6**) and 159 mg (0.69 mmol) of [CpCo(cod)] in 25 mL of *n*-nonane. Reaction time: 130 h. The reaction mixture was poured on a column, which was filled with 5 cm of Al_2O_3 (neutral, 6% water) and SiO_2 on top. Quick flash chromatography, with petroleum ether as eluent, yielded **19** (105 mg, 68%) as yellow crystals, m.p. 120°C (dec.). − ^{1}H NMR (C_6D_6): δ = 4.92 (s, 5 H, H_{Cp}), 2.25−1.86 (m, 8 H, C_{Cbd}−CH_2), 1.07−0.88 (m, 8 H, Si−CH_2), 0.12 (s, 6 H, Si−CH_3), −0.02 (s, 6 H, Si−CH_3). − ^{13}C NMR (C_6D_6): δ = 81.4 (C_{Cbd}), 79.2 (C_{Cp}), 21.0 (CH_2), 16.9 (Si−CH_2), −1.6 (Si−CH_3), −6.2 (Si−CH_3). − IR (KBr): $\tilde{\nu}$ = 3449 cm^{-1}, 3101, 3080, 2947, 2915, 2893, 2874, 2821, 1622, 1439, 1394, 1246, 1001, 834, 679. − UV (CH_2Cl_2): λ_{max} (lg ε) = 224 nm (4.01), 266 (4.29), 296 (3.15), 362 (2.60). − HRMS (EI, 70 eV): $C_{21}H_{33}CoSi_2$: calcd. 400.14527, found 400.14529.

{(η^4-1,2,8,9)-*N*-Allyl-5-azatricyclo[7.5.0.0^{2,8}]tetradeca-1,8-diene}-(η^5-cyclopentadienyl)cobalt (20): Starting material: 800 mg (3.5 mmol) of *N*-allyl-1-azacyclotetradeca-4,11-diyne (**7**) and 810 mg (3.5 mmol) of [CpCo(cod)] in 40 mL of *n*-nonane were heated at reflux for 4 h. After 10 h of additional stirring at room temperature (r.t.), the mixture was subjected to column chromatography with petroleum ether/diethyl ether (3:1) as eluent. Yield: 60 mg (5%) of **20** as orange crystals, m.p. 102°C. − ^{1}H NMR ($CDCl_3$): δ = 5.83 (m, 1 H, CH_2=C*H*−), 5.13 (m, 2 H, C*H*$_2$=CH−), 4.78 (s, 5 H, H_{Cp}), 3.28−2.95 (m, 4 H, CH_2−N), 2.13−1.57 (m, 8 H, C_{Cbd}−CH_2, CH_2). − ^{13}C NMR ($CDCl_3$): δ = 136.6 (CH_2=*C*H), 116.7 (*C*H_2=CH−), 79.5 (C_{Cbd}), 78.9 (C_{cp}), 78.0 (C_{Cbd}), 55.5, 54.7 (CH_2−N), 30.6, 30.4, 28.0, 26.9, 26.2, 24.6 (CH_2). − IR (KBr): $\tilde{\nu}$ = 3440 cm^{-1}, 3074, 2913, 1636, 1442, 1351, 1112, 1000, 803, 566. − UV (CH_2Cl_2): λ_{max} (lg ε) = 222 nm (4.1), 266 (4.37), 300 (3.07). − $C_{20}H_{28}CoN$ (353.39): calcd. C 71.37, H 7.99; N 3.96; found C 71.42, H 7.86, N 3.77.

(η^5-Cyclopentadienyl){(η^4-1,2,8,9)-*N*,*N*′-di-*n*-propyl-5,12-diazatricyclo[7.5.0.0^{2,8}]tetradeca-1,8-diene}cobalt (21): Starting material: 850 mg (3.7 mmol) of [CpCo(cod)] in 50 mL of *n*-nonane, which was refluxed for 45 min; 945 mg (3.45 mmol) of *N*,*N*′-di-*n*-propyl-1,8-diazacyclotetradeca-4,11-diyne (**8**) was added. The mixture was heated to 160°C for 20 h. After cooling to r.t., column chromatography of the reaction mixture on Al_2O_3 [neutral, 6% water, petroleum ether/diethyl ether (5:1)] gave 537 mg, (39%) of **21** as orange crystals, m.p. 40°C. − ^{1}H NMR ($CDCl_3$): δ = 4.75 (s, 5 H, H_{Cp}), 3.24−3.00 (m, 8 H, CH_2−N), 2.44 (m, 4 H, CH_2−N), 2.04 (m, 4 H, C_{Cbd}−CH_2), 1.75−1.70 (m, 4 H, C_{Cbd}−CH_2),1.44 (m, 4 H, CH_2), 0.86 (t, ^3J = 7.4 Hz, 6 H, CH_3). − ^{13}C NMR ($CDCl_3$): δ = 79.0 (C_{Cp}), 77.9 (C_{Cbd}), 55.4 (CH_2−N), 52.4 (CH_2−N), 26.1, 20.6 (CH_2), 11.9 (CH_3). − IR (KBr): $\tilde{\nu}$ = 3440 cm^{-1}, 3094, 3066, 2952, 2899, 2869, 2828, 1624, 1449, 1348, 1117, 1091, 1024, 999, 807, 587, 438. − UV (CH_2Cl_2): λ_{max} (lg ε) = 222 nm (4.3), 266 (4.4), 294 (3.5), 358 (3.2). − HRMS (EI, 70 eV): $C_{23}H_{36}CoN_2$: calcd. 398.2148, found 398.2132.

X-ray Crystallographic Studies: Crystal data are given in Table 2. Intensity data were collected for **16** at −73°C with a Siemens CCD system, for all other compounds with a Syntex R3 diffractometer (Mo-K_α radiation, graphite monochromator, ω scan). Intensities were corrected for Lorentz and polarization effects. An empirical absorption correction was applied. All structures were solved by direct methods (SHELXS-86)[16] and refined by least-squares methods based on F^2 with all measured reflections (SHELXL-97).[17] All non-hydrogen atoms were refined anisotropically, hydrogen atoms were located in difference Fourier maps and refined isotropically. The cyclopentadienyl rings in **18** and **25** were disordered. The positions of the Cp hydrogen atoms in the latter compounds and in **26** were calculated and not refined. Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-103160 (**15**), -103161 (**16**), -103162 (**18**), -103163 (**22**), -103164 (**23**), -103165 (**25**), -103166 (**26**). Copies of the data can be obtained free of charge on application to the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: int. code + 44-1223/336-0335, E-mail: deposit@ccdc.cam.uc.uk].

A Dimeric Tetranuclear Copper(II) Compound Assembled through Pentacoordinating Carbonate Anions

Richard H. Bode,[a] Willem L. Driessen,*[a] Frans B. Hulsbergen,[a] Jan Reedijk,[a] and Anthony L. Spek[b]

Keywords: Macrocycle / Pyrazole / N-Heterocycle / Carbonate / Copper

The 22-membered macrocycle, spanning four endocyclic pyrazole groups, viz. 1,4,9,14,17,22,27,28,29,30-decaaza-5,13,18,26-tetramethylpentacyclo[24.2.1.1^{4,7}.1^{11,14}.1^{17,20}]-triacontane-5,7(28),11(29),12,18,20(30),24(27),25-octaene (**22Pz**), rendered the tetranuclear compound [Cu_4(22Pz)$_2$-(CO_3)$_2$($MeOH$)$_2$](ClO_4)$_4$($MeOH$)$_4$. The copper(II) ions are in distorted octahedral N_3O_3 environments. All four pyrazole groups of each macrocycle participate in the coordination of the copper(II) ions. The cationic part of this compound is in fact a dimer of two macrocyclic ligands, each containing two copper(II) ions bridged by two carbonate ions in the highly unusual pentacoordinating fashion.

Introduction

In the course of our investigations towards model compounds[1−4] for type-3 site copper proteins, like the important dioxygen processing enzymes hemocyanin and tyrosinase,[5−7] the macrocyclic ligand 9,22-di(pyridin-2-ylmethyl)-1,4,9,14,17,22,27,28,29,30-decaaza-5,13,18,26-tetramethylpentacyclo[24.2.1.1^{4,7}.1^{11,14}.1^{17,20}]triacontane-5,7(28),11(29),12,18,20(30),24(27),25-octaene (**MePy22Pz**) which contains four endocyclic pyrazole groups and two exocyclic pyridine groups, has been synthesised in an eleven-step procedure.[8,9] Several dinuclear coordination compounds have been prepared with this macrocyclic ligand, notably some copper(I) complexes which were found to bind one equivalent of dioxygen between the two copper ions as an O_2^{2-} anion in an end-on *trans*-μ-1,2-peroxo fashion inside the 22-membered cavity.[10] This appeared to be the first example of a dinuclear copper complex capable of binding dioxygen at room temperature in a protic solvent.

While processing a solution of this ligand with a copper(II) salt and sodium carbonate, with the objective to obtain a carbonate-bridged dinuclear copper(II) compound, the pendent pyridine arms were hydrolysed and a unique tetranuclear copper(II) compound resulted in which the carbonate groups indeed bridge the copper ions, but in an uncommon pentacoordinating fashion. The present paper reports the structure of this unusual carbonate-bridged tetranuclear copper compound.

Results and Discussion

Synthetic Aspects

The tetranuclear copper(II) compound [Cu_4(22Pz)$_2$-(CO_3)$_2$($MeOH$)$_2$](ClO_4)$_4$($MeOH$)$_4$ has been obtained by treating a solution of MePy22Pz and copper(II) perchlorate in methanol/water with a solution of sodium carbonate in water. During this process hydrolysation at the tertiairy nitrogen of the macrocycle resulted in the loss of the pendent pyridine groups and the formation of the "bare" 22-membered macrocycle **22Pz**. Vapor diffusion with diethylether resulted in the growth of single crystals of the coordination compound suitable for X-ray diffraction. The ligand field spectrum of this compound shows an asymmetric band at 16500 cm^{-1} in compliance with the distorted N_3O_3 environments of the copper(II) ions (vide supra). NMR spectra of the compound in solution could not be obtained due to linebroadening paramagnetism.

Description of the Structure

A PLUTON[11] plot of the cationic part is given in Figure 1. The asymmetric unit comprises half a molecule [Cu_4-(22Pz)$_2$(CO_3)$_2$($MeOH$)$_2$](ClO_4)$_4$($MeOH$)$_4$, the other half of the molecule is generated through a center of symmetry.

Firstly it is to be remarked that the ligand in this tetranuclear compound is a derivative of the macrocycle MePy22Pz,[8−10] viz. 1,4,9,14,17,22,27,28,29,30-decaaza-5,13,18,26-tetramethylpentacyclo[24.2.1.1^{4,7}.1^{11,14}.1^{17,20}]triacontane-5,7(28),11(29),12,18,20(30),24(27),25-octaene (**22Pz**) as during the synthesis of the coordination compound the pyridine groups and spacers were lost through hydrolysis. Also, all pyrazole groups are involved in the coordination of the copper ions, which appeared not to be the

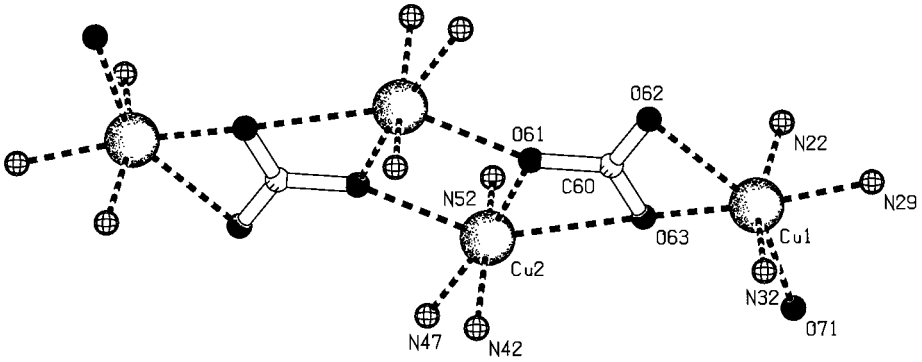

Figure 2. A PLUTON[11] projection of the coordination environments of the four copper(II) ions in the tetranuclear dimeric cation, showing the pentacoordination of the carbonate ions

case with the parent ligand MePy22Pz.[12] The most remarkable feature, however, is the penta-coordination mode of the carbonate ions (see Figure 2) with regular copper to oxygen bonds of 1.934(5) and 1.905(5) Å between respectively Cu(1) and O(63) and between Cu(2) and O(61), while the Cu(1) to O(62), the Cu(2) to O(61)a, and the Cu(2) to O(63) distances of respectively 2.589(8), 2.453(6), and 2.668(5) Å are regarded as *semi*-bonding distances (see Table 1).

O(62) binds to Cu(1), O(63) bridges between Cu(1) and Cu(2) in the same macrocyclic ring, while O(61) bridges between Cu(2) and Cu(1) in different macrocyclic rings. So, the two carbonate ions are bridging both intramolecularly and intermolecularly, thereby effecting that the tetranuclear cation is in fact a dimer of two dinuclear parts, viz. $[\{Cu_2(22Pz)(CO_3)(MeOH)\}^{2+}]_2$. Multiple bridging of carbonate groups in coordination compounds is not a rare phenomenon,[13,14] but only one compound has been reported so far,[13] viz. a trinuclear nickel compound,[15] in which the carbonate ion also bridges in a pentacoordinating fashion, in this case with five regular nickel to oxygen bonding distances (varying between 2.14 and 2.22 Å).

The coordination geometries of both copper ions are roughly the same. Each copper(II) ion is in a distorted, more or less elongated, octahedral N_3O_3 environment, with N(22), N(29), N(32), and O(63) equatorial and O(71) and O(62) axial for Cu(1) and with N(42), N(47), N(52), and O(61) equatorial and O(63) and O(61)a axial for Cu(2). The largest distortion from regular octahedral symmetry is of course caused by the didentate carbonate oxygens, imposing O−Cu−O angles of about 55° (see Table 1 and Figure 2).

The three-bond ligand bites contribute also to the deviation from regular octahedral symmetry. The two copper ions in the same macrocyclic ring, viz. Cu(1) and Cu(2), are at a distance of 4.601(2) Å, a distance suitable for the binding of a small molecule like dioxygen in a bridging fashion between the two copper ions. Two of the copper ions in different macrocyclic rings, viz. Cu(2) and Cu(2)a, are even

Experimental Section

Synthesis of $[Cu_4(22Pz)_2(CO_3)_2(MeOH)_2](ClO_4)_4(MeOH)_4$: To a solution of 25.0 mg of 9,22-di(pyridin-2-ylmethyl)-1,4,9,14,17,22,27,28,29,30-decaaza-5,13,18,26-tetramethylpentacyclo-[24.2.1.1^{4,7}.1^{11,14}.1^{17,20}]triacontane-5,7(28),11(29),12,18,20(30),24(27),25-octaene (**MePy22Pz**)[9][12] (38.8 mmol) in 5 mL of MeOH and 1 mL of H_2O, two equivalents (1.3 mL) of a solution of $Cu(ClO_4)_2 \cdot 6\ H_2O$ in MeOH (59 mmol) were added. A clear green solution was obtained after gentle warming and subsequent filtration. Addition of one equivalent Na_2CO_3 (77.6 mmolar solution in H_2O) invoked a blue colorisation for only a few seconds. After filtration a clear green solution was obtained. Vapour diffusion with Et_2O at 298 K resulted after three weeks in light-blue crystals, suitable for X-ray diffraction, of $[Cu_4(22Pz)_2(CO_3)_2(MeOH)_2](ClO_4)_4(MeOH)_4$, with **22Pz** being 1,4,9,14,17,22,27,28,29,30-decaaza-5,13,18,26-tetramethylpentacyclo[24.2.1.1^{4,7}.1^{11,14}.1^{17,20}]triacontane-5,7(28),11(29),12,18,20(30),24(27),25-octaene.

Materials and Methods: FT-IR spectra were recorded on a Perkin Elmer paragon 1000 FT-IR spectrometer as KBr disks (4000−400 cm^{-1}). Ligand field spectra were registered on a Perkin Elmer lambda 900 UV/Vis/NIR spectrometer.

X-ray Structure Analysis of $[Cu_4(22Pz)_2(CO_3)_2(MeOH)_2](ClO_4)_4(MeOH)_4$: $C_{51}H_{84}Cl_4Cu_4N_{20}O_{30}$, M = 1901.39, light-blue prismatic crystal (0.12 × 0.37 × 0.37 mm), Enraf-Nonius CAD4T diffractometer with rotating anode, λ(Mo-*K*α) = 0.71073 Å, T = 290 K, monoclinic, $P2_1/c$, a = 12.419(3), b = 23.058(4), c = 14.743(4) Å, β = 109.98(2)°, V = 3968(2) Å^3, Z = 2, D_c = 1.592 gcm^{-3}, μ(Mo-*K*α) = 12.8 cm^{-1}, F(000) = 1956, θ max = 26.5°, h, k, l range = −14/14, −27/27, 0/17, a total of 15281 reflections, of which 7462 unique, with R_{int} = 0.139 (poor crystal quality) and 3263 observed [I>2σ(I)], R = 0.087 (*wR* 0.23, *S* 0.89), ρ min/max = −0.47/1.05 e/Å^3, n(pars) = 561, correction for Lorentz and polarization, no absorption correction. Structure solved with automated Patterson techniques (DIRDIF/PATT[16]), refined on F^2, full-matrix least-squares (SHELXL-97.[17,18]) All non-hydrogen atoms refined with anisotropic displacement parameters, hydrogen atoms introduced on calculated positions and refined riding on their carrier atoms. The disordered perchlorate anions were isotropically refined with the oxygens on partly occupied positions, as were the non-hydrogens of the lattice solvent molecules without calculated hydrogens. Geometric calculations and molecular graphics were performed with PLATON.[11] Table 1 contains selected bond lengths and angles.

Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-103045. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (Fax: +44-1223/ 336-033; E-mail: deposit@ccdc.cam.ac.uk).

Isomerism in Copper(I)-Induced Folding of Homoditopic Macrocyclic Ligands with Bis(dithiadiimine) Donor Sets

Peter Comba*[a] and Andreas Kühner[a]

Keywords: Macrocyclic ligands / Molecular modeling / Schiff bases / Helical structures / Copper

The structural properties of the dicopper(I) compounds of the two large macrocyclic Schiff base ligands *para*-222 and *meta*-222 with two dithiadiimine coordination sites, where the two sites are linked by two *para*- or two *meta*-xylylene spacer groups and all bridges between the donors of each site are ethylene groups (32- and 30-membered macrocycles for the *para*- or *meta*-xylylen-bridged *para*-222 and *meta*-222 species, respectively) are studied, in solution and by computer modeling. Solid-state structural data have been reported elsewhere. The coordination of the 32-membered macrocycle *para*-222 to two copper(I) centers leads to a helical figure-of-eight-shaped structure. Two diastereomeric pairs of enantiomers have been observed for this type of compound in solution. The crystallized form is more stable than the second isomer by approximately 6–10 kJ/mol (solution-NMR spectroscopy and force-field calculations). Both experimentally detected isomers are more than 15 kJ/mol more stable than the other five possible configurations (force-field calculations). For the *meta*-222 macrocycle (30-membered ring) an achiral structure has been observed in the solid while two of the 21 possible isomers have been detected in solution (3:1, NMR spectroscopy). The computed structures and isomer distributions (force-field calculations) are compared with the solid-state structures and with observed isomer distributions from NMR experiments, and dynamic processes are analyzed in detail.

Introduction

The coordination of the paracyclophane-based preorganized double-helical $(N_2S_2)_2$ bis(dithiadiimine) ligand (phane-222, see Figure 1) to copper(I) yields a dicopper(I) complex that, based on the observed structure, is not much strained.[1] Indeed, the coordination of copper(I) to analoguous macrocyclic ligands, where the two $(N_2S_2)_2$ donor sites are linked by two *para*-xylylene groups (*para*-222, see Figure 1) leads to a very similar figure-of-eight-shaped structure.[2–4] That is, copper(I) induces an identical folding, and this indicates that phane-222 is highly preorganized for copper(I).[5–7] The isomer with *meta*-xylylene-bridged donor groups (30- instead of 32-membered macrocyclic ring, *meta*-222, see Figure 1) leads to an achiral dicopper(I) compound but the overall shape of the structure ("squeezed" instead of "twisted" figure-of-eight shape) and, in particular, the geometry of the chromophores are very similar.[3] Plots of the observed structures of the three dicopper(I) compounds are shown in Figure 1 and relevant parameters are assembled in Table 1.

From solid-state structural studies of an extended series of dicopper(I) compounds of Schiff base $(N_2S_2)_2$ ligands of the general type shown in Figure 1 (variation of the aromatic spacer groups, variation of the chelate ring sizes) it emerges that, for the chiral compounds with *para*-substituted spacer groups (e.g. *para*-222), only one of seven possible diastereoisomeric pairs of enantiomers is observed, that is, one of the two forms that have identical configuration for all four coordinated thioether-S donors (see below and Figure 1); for the *meso* form (*meta*-222) the thioether-S configurations are (*R*)(*R*)(*S*)(*S*) and only one of three theoretically possible isomers with respect to the orientation of the xylylene spacer groups is observed in the crystal structural analysis (see Figure 1).[3,4]

Solution-NMR studies indicate that the geometries in solution are identical to those observed in the solid, that is figure-of-eight-shaped ("twisted" or "squeezed" for *para*- and *meta*-substituted xylylene spacer groups, respectively), and that dynamic processes occur. The dicopper(I) compounds of *para*-222 and of derivatives with larger chelate ring sizes have been studied in detail by solution-NMR spectroscopy.[4] An intramolecular dynamic process leads to helix inversion (epimerization, that is, retention of the configuration of the S donors), and a solvent-dependent intermolecular process leads to full racemization.[4] For the derivative of *para*-222 with two seven-membered chelate rings (*para*-242) there is spectroscopic evidence for an equilibrium with a less stable isomer, and this is attributed to the helix inversion (epimerization) product.[4] The solution chemistry of *meta*-222 is addressed here. We also present a full conformational analysis of the two isomers $[Cu_2(para\text{-}222)]^{2+}$ and $[Cu_2(meta\text{-}222)]^{2+}$, based on force-field calculations, and these are compared to observed solid-state and solution data.

Results and Discussion

Isomerism

The helical dinuclear compounds, that is, the dicopper(I) compounds of phane-222 and *para*-222, have the same shape and the same idealized symmetry (D_2) while the achiral dicopper(I) compound, that is, that of *meta*-222 has ide-

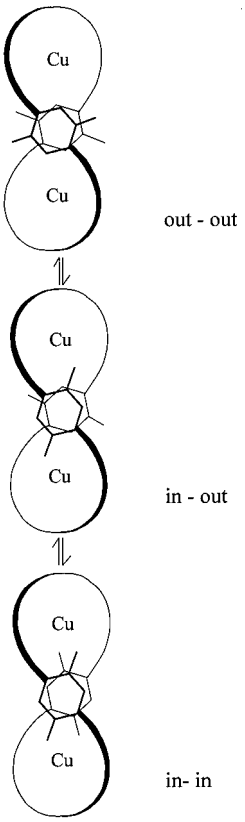
alized C_{2h} symmetry (see Scheme 1). For $[Cu_2(para\text{-}222)]^{2+}$ there are eleven elements of asymmetry, the helix, the four thioether-S donors and the six five-membered chelate rings. The experimentally determined structure has Λ-(*S*)(*S*)(*S*)(*S*)-λλλλλλ geometry (the order of the thioether-S configurations and of the five-membered chelate ring conformations is based on the numbering scheme given in Figure 1; the same conformation is observed in all other structurally determined derivatives[4]). There are seven diastereomeric pairs of enantiomers with different sequences of thioether-S configurations [Λ-helices: (*S*)(*S*)(*S*)(*S*), (*S*)(*S*)(*S*)(*R*), (*S*)(*S*)(*R*)(*R*), (*S*)(*R*)(*R*)(*S*), (*S*)(*R*)(*S*)(*R*), (*R*)(*R*)(*R*)(*S*) and (*R*)(*R*)(*R*)(*R*)]. For each there is a number of possible sequences of the five-membered chelate ring conformations, leading to 350 non-degenerate isomers.

The $[Cu_2(meta\text{-}222)]^{2+}$ ion has twelve stereochemical elements, the four thioether-S donors, the six five-membered chelate ring conformations and the orientation of the two *meta*-xylylene spacer groups. The crystallized molecule has

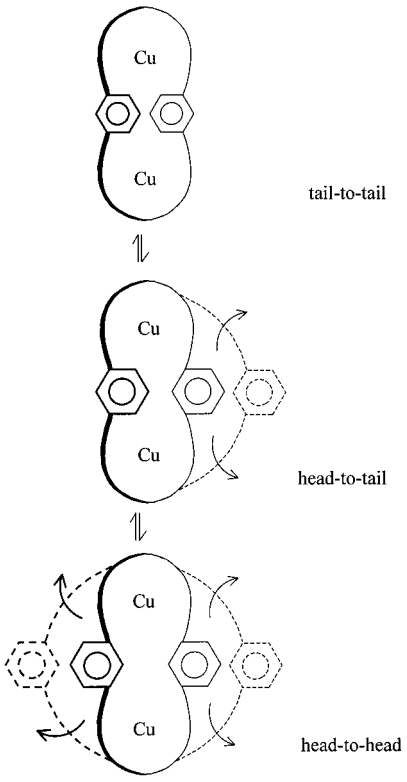


Scheme 1

tail-to-tail-(*S*)(*S*)(*R*)(*R*)-λλλδδδ geometry (the nomenclature follows the numbering scheme given in Figure 1; tail-to-tail refers to the orientation of the *meta*-xylylene bridges, see Scheme 3, below). There are 72 non-degenerate isomers in this system.

Dynamics − Experimental Observations

High-resolution ^{1}H-NMR spectroscopy indicates that, for both structural types, the figure-of-eight-shaped geometry is retained in solution.[1−4] For the helical dicop-



per(I) compounds (e.g. $[Cu_2(para\text{-}222)]^{2+}$) there is evidence for two independent dynamic processes.[4] The first is helix inversion with full retention of the thioether-S configuration (epimerization). This is observed at low temperature in solvents with little affinity to copper(I) (intramolecular reaction, observed in nitromethane) in the low-field region of the ^{1}H-NMR spectrum (non-equivalent aromatic protons, see Scheme 2).[4] For a derivative of *para*-222 (i.e. *para*-242) there is spectroscopic evidence for the second diastereoisomer that emerges from helix inversion [Δ-(*S*)(*S*)(*S*)(*S*) versus Λ-(*S*)(*S*)(*S*)(*S*)]. For *para*-222 the helix inversion has a lower energy barrier and the spectra were therefore not fully resolved at the lowest temperature available in nitromethane.[4] The comparison of the temperature-dependent ^{1}H-NMR data of the dicopper(I) compounds of *para*-222 with those of ligands with substituted benzene spacer groups (e.g. Me-*para*-222, see Scheme 2, dimethylated spacer group) suggests that along the helix inversion mode there is rotation of the xylylene groups around the C1···C4 axes (in/out isomerism, see Scheme 2).[4] The rate of this rotation depends on the size of the xylylene substituents.

Scheme 2

The second dynamic process leads to full racemization, that is, it involves inversion of the helix *and* inversion at each of the four thioether-S donors [Λ-(*S*)(*S*)(*S*)(*S*) versus Δ-(*R*)(*R*)(*R*)(*R*)]. This reaction is only observed in acetonitrile for which copper(I) has a strong affinity. It occurs at significantly higher temperatures than the helix inversion, and it was assigned on the basis of temperature-dependent ^{1}H-NMR spectra in the high-field region (methylene protons).[4] The solvent dependence and the fact that inversion at the thioether-S donors involves copper(I)−S bond breaking suggest that full racemization is an intermolecular process. This was supported by crystallization and the structural analysis of a putative intermediate with two coordinated acetonitrile molecules.[4]

The solution ^{1}H-NMR spectroscopic behavior of the achiral $[Cu_2(meta\text{-}222)]^{2+}$ cation is strikingly different. In both solvents, acetonitrile and nitromethane, there are, in dependence of the temperature, two types of spectra: a well-resolved low-temperature spectrum (for the region of aromatic and imine protons, see Figure 2) and a high-temperature spectrum that has coupling patterns identical to those of the metal-free ligand but chemical shifts (methylene protons, high-field region) that indicate copper(I) coordination. In analogy to the observations and interpretations with the helical compounds[4] (see above), the high-temperature spectrum is attributed to a species, where a dynamic process leads to full scrambling which may involve a "stack-and-slip" process (Scheme 1), reorientation of the *meta*-xylylene spacer groups (Scheme 3) and inversion at the thioether-S centers.

Scheme 3

In contrast to observations with the "twisted" geometries (helical compounds, e.g. $[Cu_2(para\text{-}222)]^{2+}$, see above[4]) with the "squeezed" geometry ($[Cu_2(meta\text{-}222)]^{2+}$) this process occurs in acetonitrile *and* in nitromethane {$[Cu_2(meta\text{-}222)]^{2+}$: coalescence temperatures for the aromatic protons: 330 K (nitromethane), 300 K (nitromethane/acetonitrile, 10:1), 250 K (acetonitrile); $[Cu_2(para\text{-}222)]^{2+}$, aromatic pro-

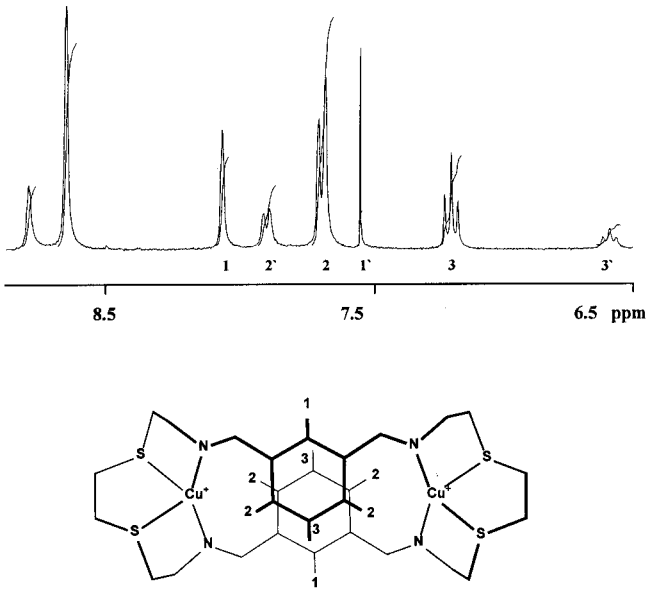


Figure 2. Region of the signals of the aromatic protons in the ^{1}H-NMR spectrum (200 MHz, 290K, CD_3NO_2) of $[Cu_2(meta\text{-}222)]^{2+}$; the numbering of the protons of the *meta*-xylylene groups is given in the sketch

tons: < 230 K, solvent-independent; methylene protons (only in acetonitrile): 300 K}. This suggests that intramolecular processes for $[Cu_2(meta\text{-}222)]^{2+}$ have significantly higher activation barriers. Based on the structural features of the "squeezed" geometry this is not unexpected: The stack-and-slip process (Scheme 1) must lead to a significant amount of unfolding and strain in the copper(I)−donor bonds, especially for the experimentally observed tail-to-tail rotamer; the reorientation of the *meta*-xylylene spacer groups (tail-to-tail/head-to-tail/head-to-head isomerization) involves a rotation around the C1···C3 axis, and this is sterically less favorable than the corresponding rotation of the *para*-xylylene spacer groups (C1···C4 axis). The fact that the high-temperature dynamic process is only moderately dependent on the solvent for $[Cu_2(meta\text{-}222)]^{2+}$ suggests that Cu^I-S bond breaking has a more dissociative activation than for $[Cu_2(para\text{-}222)]^{2+}$, and this is supported by the higher activation barrier of the low-temperature dynamics, that is, these processes involve highly strained transition states. Further support for this interpretation emerges from the observation that the air stability of the $[Cu_2(meta\text{-}222)]^{2+}$ species is considerably lower than that of $[Cu_2(para\text{-}222)]^{2+}$, that is, oxygenation of the dicopper(I) compound is probably also activated along the intramolecular dynamic process.

In the region of the aromatic and imine proton signals one expects a singlet for the imine protons and three signals for the aromatic protons (singlet, doublet, triplet) in the ratio 2:1:2:1. The experimetal ^{1}H-NMR spectrum at 298 K (Figure 2) suggests that two isomeric $[Cu_2(meta\text{-}222)]^{2+}$ species in the ratio of approximately 3:1 are present in solution. There is only one set of signals in the region of aliphatic protons, suggesting that the coordination geometries of the two isomers are close to identical [the sum of the integrals of the signals in the aromatic region (both isomers) corresponds to that expected from the sum of integrals of the aliphatic protons]. Possible isomeric forms [tail-to-tail (observed in the solid state, see Figure 1), head-to-tail, head-to-head] are shown in Scheme 3. The experimental spectrum suggests that only two species are stable in solution. Also, the head-to-tail isomer has a lower symmetry, and additional splitting in the aromatic region would be expected for this species, unless a fast dynamic exchange occured.

Further structural information emerges from a qualitative analysis of the chemical shifts in the aromatic region (Table 2; see structural sketch in Figure 2 for proton numbering). Based on the solid-state structure (Figure 1; the *meta*-xylylene rings are stacked with a xylylene···xylylene distance of 3.39 Å and a horizontal displacement of the two rings by 1.06 Å[3]) one expects that signals of protons 2 and especially 3 are shifted to higher field due to dipole-dipole interactions with the other aromatic ring, while there is less interaction with protons 1. The observed signals of the major species are in agreement with these expectations (shift with respect to the chemical shift of the metal-free ligand of $\Delta\delta = +0.07, -0.11, -0.31$ for signals 1, 2, 3, respectively). In the less abundant isomer (primed resonances in Figure 2), the signals for proton 1′ and 3′ are shifted to higher field with respect to those in the major isomer ($\Delta\delta = -0.53$ and -1.52), indicating that there is a very strong interaction with the other aromatic ring. For protons 2′ there is a decreasing interaction ($\Delta\delta = +0.21$). This behavior may be interpreted by a tilt of the two aromatic planes with respect to each other (see rotation of the xylylene rings above). The relative symmetry (number of symmetry-related protons) suggests that a fast equilibrium between various sites must be involved, that is, in average, both *meta*-xylylene rings are equivalent.

Modeling Studies

Empirical force-field calculations in combination with experimental data (isomer distributions, reduction potentials, EPR, NMR and electronic spectra) have been used extensively to determine structures of transition metal compounds in solution.[8−11] The MOMEC program[12] and force field[13] have been tested successfully in this field, and in various areas they have demonstrated to lead also to accurate predictions of conformational equilibria and energy barriers for conformer interconversions.[14] This is not necessarily expected since the force field is primarily based on solid-state structural data.[14] However, the parameter sets used for the ligand backbones are transferable, and from the fact that some of these parameters were fitted to thermodynamic observables it emerges that the steepnesses of the potentials are approximately realistic. Published studies, primarily in the fields of (hexaamine)cobalt(III) and -nickel(II) compounds support this suggestion.[8−11,14] The new parameters necessary to model the conformational

Table 2. ^{1}H-NMR data of *meta*-222 and $[Cu_2(meta\text{-}222)]^{2+}$ [200 MHz, CD_3NO_2, 290 K (and 350 K), low-field region, δ (ppm)]; for atom numbering, see Figure 2

		$[Cu_2(meta\text{-}222)]^{2+}$

imine proton	8.3	8.68	8.82	8.70
aromatic proton 1	8.0	8.07	7.54	8.01
aromatic proton 2	7.8	7.69	7.90	7.75
aromatic proton 3	7.5	7.19	5.57	7.05

space of $[Cu_2(para\text{-}222)]^{2+}$ and $[Cu_2(meta\text{-}222)]^{2+}$ include copper(I)−thioether-S interactions and a few parameters involving the substituents of the thioether and Schiff base donors (see Experimental Section). These were fitted to the published experimental structures in this series.[1−4] Thus, the expectation was that, together with the experimental data discussed above, a full conformational analysis of the two isomers $[Cu_2(para\text{-}222)]^{2+}$ and $[Cu_2(meta\text{-}222)]^{2+}$ would lead to some insight into the dynamic processes in these systems.

$[Cu_2(para\text{-}222)]^{2+}$

The conformation observed in the solid {Λ-(*S*)(*S*)(*S*)(*S*)-λλλλλλ-$[Cu_2(para\text{-}222)]^{2+}$} is the most stable structure (U_{strain} = 28 kJ/mol). Inversion of a five-membered chelate ring costs approximately 5 kJ/mol and inversion of a coordinated thioether-S center leads to a destabilization of approximately 16 kJ/mol. These effects are not additive but the next lowest energy structure (five-membered ring inversions alone excluded; these have activation barriers of approximately 25 kJ/mol,[15,16] i.e. their interconversion will not be frozen at the low-temperature limits of our experimental studies) is that of the helix inversion product, i.e. Δ-(*S*)(*S*)(*S*)(*S*)-λλλλλλ-$[Cu_2(para\text{-}222)]^{2+}$ with U_{strain} = 34 kJ/mol. The strain energy minimization of structures with constrained pseudo-torsional angles ϕ around the centroids of the two *para*-xylylene rings (helix inversion; ϕ = 80° to ϕ = −80°) was not as straight forward as one might anticipate. Without any further constraints there was a considerable distortion in the stacking of the *para*-xylylene rings that lead to intermediate structures at the transition state (pseudo-torsional angle ϕ = 0°) with horizontal translations or tilts of the two *para*-xylylene rings. This supports the interpretation based on the solution ^{1}H-NMR studies that, along the helix inversion, there is a low-energy rotation of the *para*-xylyene rings (see above). Also, with constrained stacking, the distance between the *para*-xylylene rings increases at the transition state (ϕ = 0°) from approximately 3.3 Å to approximately 4.9 Å.The energy barrier of the helix inversion process with constrained stacking of the *para*-xylylene rings is approximately 50 kJ/mol (see Figure 3). This upper limit of the activation energy for the helix inversion process is in good qualitative agreement with the temperature-dependent ^{1}H-NMR data.[4]

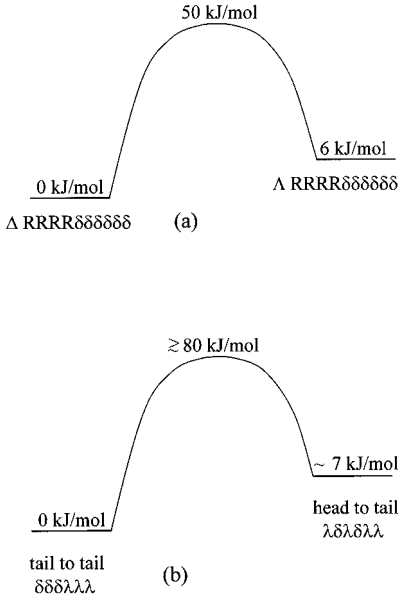

Figure 3. Energy profile of the dynamic processes of (a) $[Cu_2(meta\text{-}222)]^{2+}$ and (b) $[Cu_2(para\text{-}222)]^{2+}$

$[Cu_2(meta\text{-}222)]^{2+}$

Only two of the three putative rotamers of $[Cu_2(meta\text{-}222)]^{2+}$ (Scheme 3) converged to a stable structure. The experimentally observed geometry {tail-to-tail-(*R*)(*R*)(*S*)(*S*)-δδδλλλ-$[Cu_2(meta\text{-}222)]^{2+}$} was that with the lowest strain energy (U_{strain} = 40 kJ/mol; that is, the isomer with *meta*-xylylene spacer groups is approximately 12 kJ/mol less stable than that with *para*-xylylene spacer groups). The energy differences to species with inverted five-membered chelate rings and inverted thioether-S donor groups are similar to those of the *para* isomer (see above). Optimization of the head-to-tail isomer leads to a structure with one of the two aromatic rings tilted with respect to the other (see Figure 4). Optimization of the third rotamer (head-to-head) converged to either of the two other structures (head-to-tail or tail-to-tail), that is, this is not a minimum on the energy surface. The most stable head-to-tail conformer is head-to-tail-(*R*)(*R*)(*S*)(*S*)-λδλδλλ-$[Cu_2(meta\text{-}222)]^{2+}$ with U_{strain} = 47 kJ/mol.[17] The strain energy difference between the two rotamers (7 kJ/mol) is in good agreement with the isomer distribution observed in the ^{1}H-NMR spectrum (3:1, Figure 2). The optimized structure of the less abundant head-to-tail isomer is of particular interest since it is as expected

from the solution ^{1}H-NMR spectroscopic data, that is, the two aromatic spacer groups are tilted with respect to each other (see above). The sketches shown in Scheme 3 indicate that this might be due to the relieve of some strain related to the geometry around the C-1 and C-3 bridgehead carbon atoms of the *meta*-xylylene spacer group.

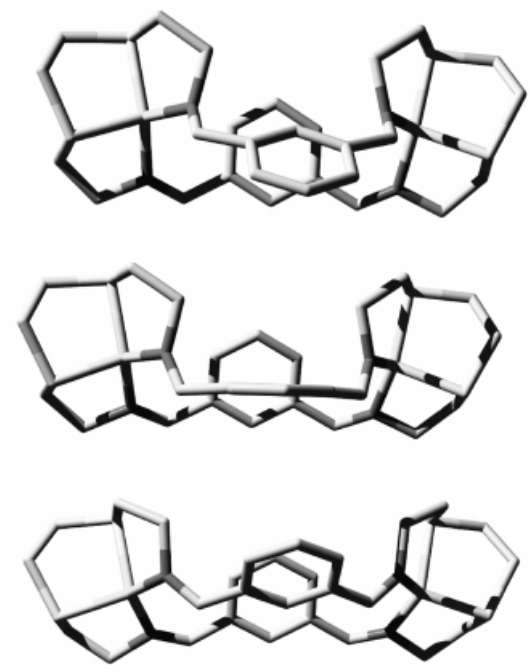

Figure 4. Visualization of the low-temperature dynamic process of the head-to-tail isomer of $[Cu_2(meta\text{-}222)]^{2+}$

Constraints were used to map the interconversion of the two rotamers of $[Cu_2(meta\text{-}222)]^{2+}$. The qualitative picture (see Figure 3) is that there is an activation energy between the two isomers of at least 80 kJ/mol. This is consistent with the observation that, at low temperature (< 300 K) there is no fast interconversion of the two isomers. Especially interesting is the observation that, for the tilted head-to-tail isomer there is a very shallow energy surface with at least three minima where the tilt angle between the two xylylene planes varies from approximately 30° to approximately 120° (see Figure 4). In the enforced structure of the head-to-tail isomer with parallel aromatic rings (transition state) the two *meta*-xylylene rings are symmetry-related, that is, there is a wagging mode of the two rings with an energy barrier of less than approximately 25 kJ/mol, and this is consistent with the observed ^{1}H-NMR spectra (see above). That is, the observed chemical shifts are due to the tilt of one of the xylylene planes with respect to the other and the shallow energy minima with various structural modes is in agreement with the observed high symmetry averaged structure.

Experimental Section

The syntheses have been described before.[1−4] − NMR spectra were obtained with a Bruker AS200 instrument at 200 MHz. − MOMEC97[12,13] with a published force field[12] was used to compute the optimized structures and minimized strain energies. Parameters not published before are given in Table 3.

Table 3. MOMEC force-field parameters[a]

[17] Detailed studies that involved the reported structures and isomer distributions of all figure-of-eight-shaped dicopper(I) compounds indicate that some of the force-field parameters need some further tuning. One of the critical parameters was the torsional angle force constant for the $C_{xylylene}-C_{imine}$ bond. The steepness of this potential is probably overestimated, and an optimum fit was obtained when this parameter was reduced from $k = 0.025$ mdyn·A by a factor of up to 5. This observation is based on the very restricted class of compounds discussed here, and future studies with other types of compounds are needed to establish this parameter on a more general basis.

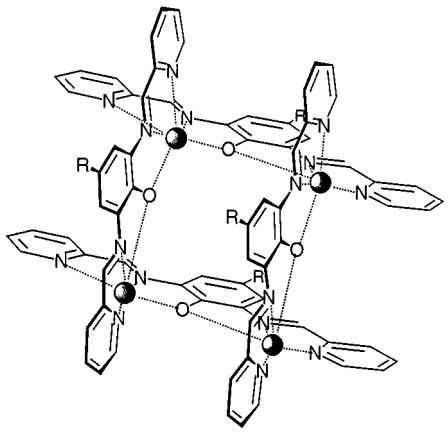
Self-Assembly, Crystal Structure, and Magnetic Properties of a Phenoxo-Bridged Tetranuclear Cu^{II} Complex of the [2 × 2] Grid Type

Javier Rojo,[a] Jean-Marie Lehn,*[a] Gerhard Baum,[b] Dieter Fenske,*[b] Oliver Waldmann,[c] and Paul Müller[c]



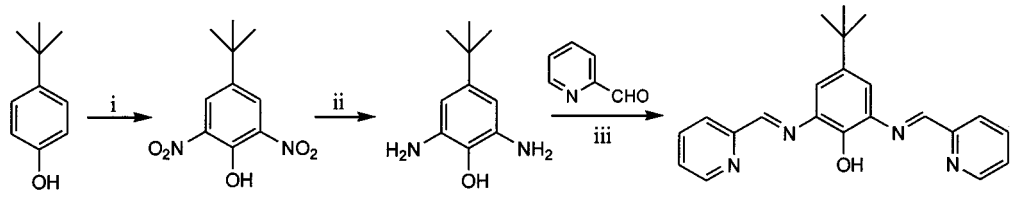
Keywords: Self-assembly / Tetranuclear Cu^{II} complex / [2 × 2] grid-type complex / Crystal structure / Magnetic properties

The ditopic ligand **3** has been synthesized. In its deprotonated form, it reacts with copper(II) ions to form a tetranuclear complex **1** of the [2 × 2] Cu^{II}_4 grid type, the structure of which has been confirmed by X-ray crystallography. Magnetic studies of complex **1** indicate a very weak antiferromagnetic coupling between the phenoxo-bridged Cu^{II} ions.

Self-assembly of suitably designed ligands with transition-metal ions allows the creation of inorganic architectures with well-defined structures in a spontaneous but directed manner.[1] One of the aims of supramolecular chemistry is the formation of assemblies that may possess interesting physical properties.

Previously, we have reported the self-assembly of metal complexes of rack-[2] and grid-type[3] geometries, where the metal ions are bridged by pyrimidine rings. The metallic centers in these arrays are located at appropriate distances (6.16−6.50 Å) such as to allow electronic interaction, which is manifested in the physical properties of the complexes such as redox potentials,[2,3] optical,[4] and magnetic[5] features. In order to enhance the coupling between the metal-ion centers compared to that provided by a pyrimidine group, and to obtain inorganic architectures exhibiting new properties, we have explored the use of ligands that introduce oxygen bridges between the coordination binding sites.

Oxo-bridged binuclear copper(II) complexes have been extensively studied as a result of the magnetic properties arising from ferromagnetic or antiferromagnetic spin-coupling between the copper ions,[6] which depend strongly on the geometry of the Cu−O−Cu bridge (Cu−Cu distances and bridge angles). While a linear correlation of the magnetic exchange parameter J with bridge angle Φ is well-established for dihydroxo-bridged copper(II) complexes with square-pyramidal $d_{x^2-y^2}$ electronic ground states, this might not be the case for monohydroxo-bridged complexes with a different electronic ground state (i.e. trigonal-bipyramidal, d_{z^2}).[7] The antiferromagnetic coupling observed for most monohydroxo-bridged complexes is larger than that found for di-μ-hydroxocopper(II) complexes and normally occurs through a super-exchange mechanism, with the hydroxo bridge acting as the primary pathway for exchange.[8] Most hydroxo-bridged copper(II) complexes are pentacoordinated and typically exhibit square-pyramidal or trigonal-bipyramidal geometries. Here, we report the synthesis, structural details, and magnetic properties of **1**, $[\mathbf{L}Cu]_4(CF_3SO_3)_4$, a tetrametallic copper(II) complex of the [2 × 2] grid type, where the copper atoms adopt a distorted bipyramidal geometry and are bridged by the phenolate oxygen atom of the ionized form $\mathbf{L}^-$ of ligand **3**. Recently, an Mn^{2+} complex of the [2 × 2] grid type with a ligand similar to **3**, but where the metal centers are bridged by non-conjugated alkoxide-type oxygen atoms, has been reported.[9]



1

Results and Discussion

Ligand **3** was prepared by condensation of two equivalents of 2-pyridinecarboxaldehyde with one equivalent of 2,6-diamino-4-*tert*-butylphenol in methanol solution in the

presence of 4-Å molecular sieves. The latter was obtained by dinitration of 4-*tert*-butylphenol[10] to give **2** and subsequent reduction of the nitro groups to amino groups[11] (Scheme 1). Reaction of ligand **3** with one equivalent of sodium methoxide in anhydrous methanol at ambient temperature led to the immediate formation of a deep-red colour, characteristic of the ligand anion $\mathbf{L}^-$, which consists of two tridentate coordination subunits. One equivalent of copper triflate was then added, resulting in a colour change to purple, indicating complex formation (Scheme 2). After 3 h, the copper complex was precipitated by adding a saturated methanolic solution of ammonium hexafluorophosphate, isolated by centrifugation, purified by recrystallization from acetonitrile/diethyl ether, and characterized by its spectral and analytical properties. Its structure was confirmed by X-ray crystallography.

Crystal Structure of Complex 1

Single crystals of complex **1** were obtained by slow vapor diffusion of diethyl ether into an acetonitrile solution of the complex. Crystal structure determination by X-ray diffraction analysis (Figure 1) revealed that the complex consists of a metallic core composed of four copper(II) atoms, four ligands placed in an orthogonal orientation defining a distorted square, and four counteranions (PF_6^-) delocalized in the unit cell, along with two CH_3CN solvent molecules. The arrangement of the metal ions shows approximate C_4 symmetry and is of the [2 × 2] grid type, analogous to the recently described Co_4 grids.[3]

Each copper atom has a distorted bipyramidal geometry and is bound to two pyridine nitrogen atoms, two imine nitrogen atoms, and two phenoxo oxygen atoms belonging to two orthogonal ligands. The Cu−O distances in the complex correspond to those in other Cu^{II}−O(phenolate) complexes, amounting to 2.29 Å for the phenolate in the apical position and 1.98 Å for the phenolate in the equatorial position. Cu−N bond lengths are between 2.06 and 1.96 Å for the equatorial nitrogen atoms and 2.38 Å for the apical nitrogen atoms (Table 1). The tetranuclear center is characterized by metal−metal separations of 4.04 Å for the μ-phenoxo-bridged copper atoms Cu(1)−Cu(2) and of 5.35 Å for Cu(1)−Cu(3), and a bridge angle Cu−O−Cu of 140.58°.

The metal−metal separations and the oxygen bridge angle are larger than those typically found in bridged bimetallic copper(II) complexes.[6] However, there are other cases where longer distances of 4.09 and 4.13 Å have been reported.[7c,7d]

Electronic Absorption Spectrum of Complex 1

The electronic absorption spectrum of complex **1** in acetonitrile solution shows two maxima centered at 224 nm ($\varepsilon = 5.6 \times 10^4$ $M^{-1}cm^{-1}$) and 328 nm ($\varepsilon = 6.1 \times 10^4$ $M^{-1}cm^{-1}$), corresponding to ligand-centered (LC) π-π* transitions. An absorption band in the visible region at 521 nm ($\varepsilon = 4.7 \times 10^4$ $M^{-1}cm^{-1}$) can be ascribed to a metal−ligand charge-transfer transition (MLCT). The strong intensity of this MLCT band suggests a good overlap between the phenolate and the metal orbitals. It is known that charge-transfer transitions of phenolate−Cu^{II} groups are more intense when the phenolate oxygen orbital overlaps with the copper $d_{x^2-y^2}$ orbital.[7c]

Magnetic Studies

Figure 2 depicts the temperature dependence of the susceptibility of **1** plotted as χT (Figure 2a) and the field dependence of the magnetic moment at $T = 2$ K (Figure 2b).

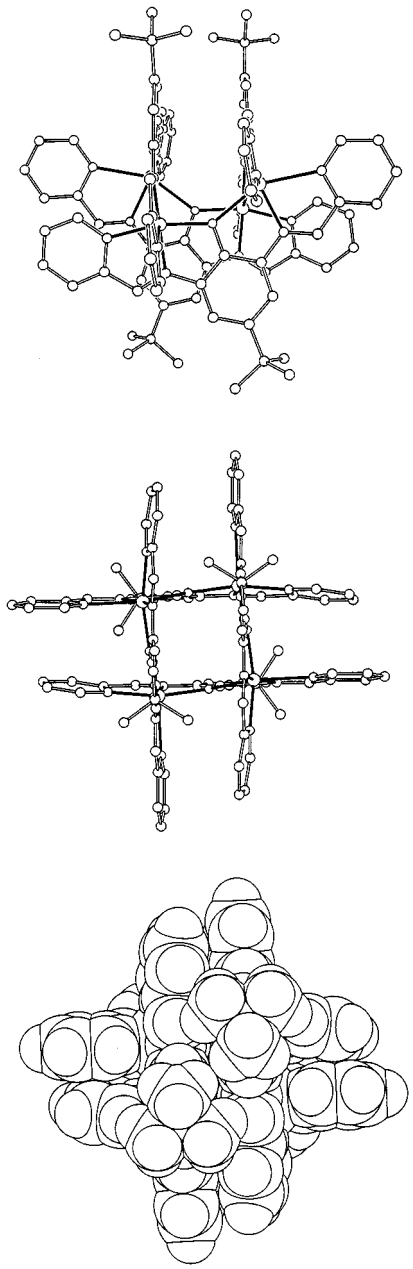

Figure 1. X-ray structure of the [2 × 2] Cu^{II}_4 grid-type complex **1**: (top) side view, (center) top view, (bottom) top view in space-filling representation

The data can be characterized by the following three features:

1. χT decreases slightly with decreasing temperature. The effective moment per copper ion is determined to be μ_{eff} = 1.913 at 250 K and μ_{eff} = 1.786 at 30 K, corresponding to g = 2.21 and g = 2.06, respectively. However, this decrease in χT cannot simply be ascribed to a temperature-independent paramagnetic contribution μ_0 as the decrease is not linear, as can be seen in Figure 2a. Furthermore, the value of μ_0 would have to be of the order of 10^{-3} cm^3 mol^{-1}, a value which is far beyond the scope of experimental uncertainty.

		N(2)−Cu−N(1)	79.96

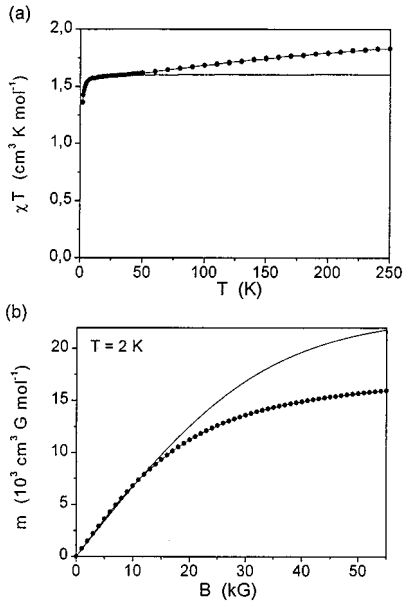

Figure 2. (a) Temperature dependence of the susceptibility of **1** plotted as χT and (b) field dependence of the magnetic moment at T = 2 K; the solid lines represent the curves calculated for the hamiltonian (Equation 1) with parameters J = −0.4 cm^{-1} and g = 2.07

2. Below ca. 10 K, the onset of a sharp decrease of χT can be seen (Figure 2a), indicating a weak antiferromagnetic coupling of the copper ions. In order to obtain an estimate of the coupling strength, we fitted the data below 25 K to the susceptibility given by the spin hamiltonian:

$$H = -J(S_1 \cdot S_2 + S_2 \cdot S_3 + S_3 \cdot S_4 + S_4 \cdot S_1) + \mu_B g B \cdot S \quad (1)$$

The parameters were determined to be J = −0.4 cm^{-1} and g = 2.07. The calculated susceptibility is drawn as a solid line in Figure 2a.

3. The magnetic moment at T = 2 K exhibits a strong field dependence, resulting in unusually low values of the magnetic moment at high fields (Figure 2b). This can clearly be seen if the data are compared to the curve calculated for the hamiltonian (Equation 1) using the above parameters. However, the field dependence is paramagnetic-

like, indicating that the magnetic coupling of the copper ions is at best of the order of -0.1 to -1 cm^{-1}.

As yet, we have been unable to provide a satisfactory interpretation of the magnetic data that would explain both the slight decrease of χT and the unusually strong magnetic field dependence. Nevertheless, although these two peculiarities of the data obviously necessitate further investigation, it can be unambiguously concluded that the exchange coupling in **1** is very weak.

Considering the coupling strengths, monohydroxo-bridged copper(II) dimers may be roughly divided into two classes. The systems belonging to the first class exhibit strong antiferromagnetic coupling of the order of several -100 cm^{-1}. This can be attributed to the arrangement of the square-pyramidal coordination spheres of the copper ions, which leads to $d_{x^2-y^2}$ ground states with the orbital lobes directed towards each other, thereby providing a good σ-type exchange pathway.[7a,8b,12,13] Dimers of the second class are characterized by very weak ferro- or antiferromagnetic couplings of just a few cm^{-1}. In these systems, several coordination geometries are realized, e.g. two square pyramids with the bridging oxygen atom in the apical position,[7c] two trigonal bipyramids with the oxygen atom in the equatorial planes,[13] or a combination of a square pyramid and a trigonal bipyramid with the oxygen atom in the equatorial planes,[12] which lead to negligible overlap and thus to weak coupling.

In the [2 × 2] grid **1** a new situation is seen, which leads to negligible exchange coupling. The coordination geometries of the copper ions can be described as distorted bipyramidal, with the equatorial planes lying perpendicular to the plane of the grid. The ground state of the copper ions is thus $d_{x^2-y^2}$, with the lobes directed towards N_1, N_2, N_3 and the equatorial phenoxy oxygen atom (Figure 3). However, in view of the approximate C_4 symmetry of the grid, the bipyramids of neighboring copper ions are rotated by 90°, such that the overlap of the orbitals is negligible (Figure 3). This accounts for the almost zero exchange coupling found for the present Cu^{II}_4 grid complex **1**. On this basis, we predict that exchange coupling in the analogous nickel grid should be quite strong, as in this case both $d_{x^2-y^2}$ and d_{z^2} would be occupied and thus a $d_{x^2-y^2}$ – d_{z^2} exchange path would exist.

Conclusions

A [2 × 2] Cu^{II}_4 grid-type complex **1** has been synthesized and characterized. The crystal structure data reveal a complex of C_4 symmetry, where the copper centers adopt a distorted bipyramidal geometry. Cu−N bond lengths and Cu−O−Cu bridge angles are typical for complexes of this type, which usually exhibit antiferromagnetic spin coupling. However, in the present case, magnetic measurements indicate only a very weak antiferromagnetic coupling of the copper ions due to insufficient overlap of the orbitals, which can be rationalized by considering the crystal structure of this grid complex.

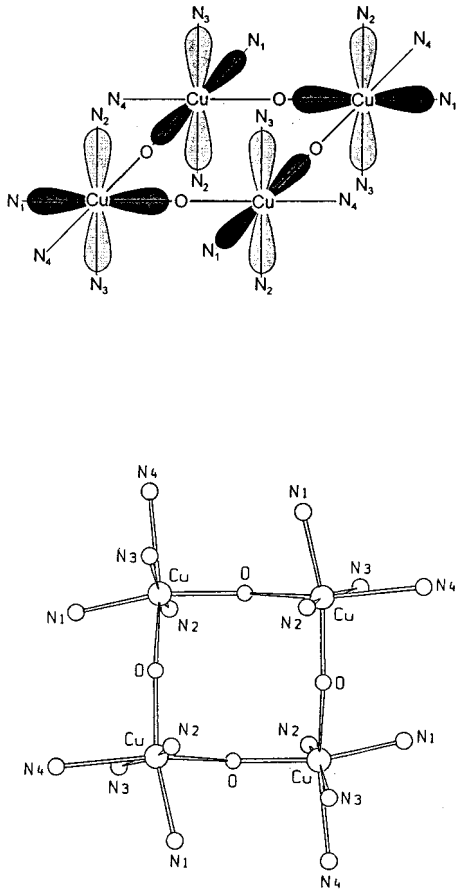

Figure 3. Schematic representation of the orientation of the magnetic $d_{x^2-y^2}$ orbitals in the [2 × 2] grid **1** (top) and X-ray structure of the metallic core of complex **1** and the N,O heteroatoms coordinated to the Cu^{II} ions (bottom)

Experimental Section

Unless otherwise noted, ^{1}H-NMR spectra were recorded in $CDCl_3$ solution with respect to the residual solvent peak at 200 MHz with a Bruker AC 200 spectrometer. − Melting points were obtained with a digital Thomas Hoover (Electrotherma) apparatus and are uncorrected. − Infrared absorption spectra were recorded with a Perkin-Elmer 1600 series FT-IR spectrometer and electronic absorption spectra with a Cary 219 spectrometer in acetonitrile; λ_{max} in nm and ε in M^{-1} cm^{-1}. − Fast-atom bombardment (FAB) mass spectrometry was performed with a ZAB-HF VG spectrometer with *m*-nitrobenzyl alcohol as the matrix; electronic impact (EI) was performed with a Fisons Instruments VG trio 2000 spectrometer, and electrospray (ES) mass spectrometry with a ZAB-HF VG spectrometer. All spectroscopic studies were performed in spectroscopic-grade solvents. All other solvents were reagent grade and were used without further purification.

Magnetic Measurements: Magnetic moments of powdered samples of complex **1** were measured with a commercial SQUID magnetometer (Quantum Design). Measurements were made over the temperature range 2−250 K at a maximum field of 5.5 T. Susceptibility was determined on the basis of measurements made at fields of 10 KG. The powder samples were fixed with apiezon grease on a plastic straw. The background signal of the plastic straw was found to be below the resolution of the magnetometer. The signal of the grease was measured independently and the data were corrected accordingly. The data were also corrected for a diamagnetic contri-

bution of -1.5×10^{-3} cm^3 mol^{-1}, taking into account the contribution of the ligands, which was estimated using Pascal's constants and the TIP of the copper(II) ions. The weight of the powder sample used was typically 1.2 mg. The magnetization of the hamiltonian (Equation 1) was calculated in the following way. The well-known formula for the susceptibility of the hamiltonian $-\Sigma J_{ij} S_i \cdot S_j + \mu_B g B \cdot S$[14] can be easily generalized to

$$m = N\mu_B g \frac{\sum_s \Omega(S) \sinh[(2S+1)y] S B_S(Sy) \exp[-\beta E(S)]}{\sum_s \Omega(S) \sinh[(2S+1)y] \exp[-\beta E(S)]}$$

for the magnetization at arbitrary magnetic field. Here $y = g\mu_B B/(k_B T)$, $B_S(Sy)$ is the Brillouin function,[15] $\beta = 1/(k_B T)$, $\Omega(S)$ denotes the degeneracy of the states E(S), and other symbols have their usual meanings. For the hamiltonian (Equation 1), the energies E(S) and degeneracies $\Omega(S)$ can be easily calculated using Kambe's vector coupling model.[15,16] The final result for the magnetization is

$$m = N\mu_B g \frac{\sinh(3/2y)\, B_1(y)\,(x + 2x^2) + \sinh(5/2y)\, B_2(2y) 2x^3}{\sinh(1/2y)\,(1 + x^2) + \sinh(3/2y)\,(x + 2x^2) + \sinh(5/2y)\, 2x^3}$$

with $x = \exp(\beta J)$.

4-*tert*-Butyl-2,6-dinitrophenol (2): A solution of 4-*tert*-butylphenol (0.1797 mol, 27 g) in glacial acetic acid (60 mL) was added dropwise with constant stirring to a mixture of nitric acid 65% (40 mL) and glacial acetic acid (75 mL) cooled to −15°C. After the addition, the mixture was allowed to slowly warm to room temperature over a period of 30 min and then poured onto crushed ice. The resulting yellow solid was filtered off, redissolved in chloroform, and this solution was washed several times with water. The organic phase was dried (Na_2SO_4) and the solvent was removed under reduced pressure. The residue was chromatographed on silica gel, eluting with ethyl acetate/hexane (1:6), to give **2** as a yellow solid (30 g, 70% yield); m.p. 96−97°C (ref.[10] 95°C). − IR (KBr): $\tilde{\nu}$ = 3448, 3173, 2961, 1640, 1533, 1368, 1309, 1266, 922, 729, 651 cm^{-1}. − ^{1}H NMR: δ = 8.32 (s, 2 H, Ar), 1.37 (s, 9 H, *t*Bu). − ^{13}C NMR: δ = 147.2, 143.0, 137.2, 34.7, 30.8. − MS (EI); *m/z* (%): 239.9 (40) [M$^+$], 224.9 (100) [M$^+$ − Me]. − $C_{10}H_{12}N_2O_5$ (240.22): calcd. C 50.00, H 5.04, N 11.66; found C 50.18, H 5.09, N 11.79.

Ligand LH 3: To 4-*tert*-butyl-2,6-dinitrophenol (**2**, 4.2 mmol, 1.0 g) in ethyl acetate (10 mL) and dry methanol (20 mL), 5% Pd/C (0.4 g) and 9 equiv. of anhydrous ammonium formate (37.5 mmol, 2.36 g) were added. The resulting mixture was stirred at room temperature under argon for 15 min, according to the standard literature procedure.[11] The catalyst was then removed by filtration through a Celite pad and washed with dry methanol. The combined filtrate and washings were concentrated to dryness, the resulting residue was triturated with water (10 mL), and extracted with chloroform (3 × 50 mL). The combined organic extracts were dried (Na_2SO_4) and the solvent was removed under reduced pressure to leave a dark solid (670 mg). This solid was redissolved in dry THF (10 mL), two equivalents of 2-pyridinecarboxaldehyde (7.4 mmol, 0.7 mL) were added, and the resulting mixture was stirred in the presence of 4-Å molecular sieves for 7 h. The solvent was then removed and the residual oil was triturated with hexane to give **3** as a brownish-yellow solid, which was filtered off and washed with further hexane. Ligand **3** (1.01 g, 81% yield, m.p. 103−105°C) was used without further purification for the complexation studies. − IR (KBr): $\tilde{\nu}$ = 3354, 2954, 1629, 1586, 1467, 1435, 1362, 1288, 1247, 989, 778, 550, 406 cm^{-1}. − ^{1}H NMR: δ = 8.87 (s, 2 H, CH=N), 8.72 (d, 2 H, *J* = 4.3 Hz, Ar), 8.28 (d, 2 H, *J* = 8.0 Hz, Ar), 7.89 (dt, 2 H, *J* = 7.7, 1.4 Hz, Ar), 7.39 (ddd, 2 H, *J* = 7.4, 4.9, 1.0 Hz, Ar), 7.28 (s, 2 H, Ar), 1.35 (s, 9 H, *t*-Bu). − ^{13}C NMR: δ = 159.5, 154.3, 149.5, 143.5, 136.9, 136.6, 136.1, 125.1, 121.6, 115.2, 34.4, 31.3. − MS (FAB): *m/z* (%) = 359.1 (100) [M$^+$ + 1]. − HRMS ($C_{22}H_{23}N_4O$): calcd. 359.1867; found 359.1872. − UV/Vis: λ_{max} (ε × 10^4) = 226 (0.13), 282 (0.12), 500 nm (0.05).

$(LCu)_4(PF_6)_4$ 1: To ligand LH **3** (0.2789 mmol, 100 mg) in anhydrous methanol (15 mL), 1 equiv. of NaOMe (0.2789 mmol, 15 mg) was added at room temperature. To the deep-red solution obtained, 1 equiv. of $Cu(CF_3SO_3)_2$ (0.2789 mmol, 100 mg) was added, resulting in a color change to purple. The mixture was stirred for 3 h and then filtered through cotton. Addition of a saturated methanolic solution of ammonium hexafluorophosphate led to the precipitation of a solid, which was collected by centrifugation and recrystallized from acetonitrile/diethyl ether to give complex **1** as a deep-purple solid (158 mg, 80% yield); m.p. 240°C (calcination). − IR (KBr): $\tilde{\nu}$ = 3142, 1598, 1484, 1400, 1281, 1248, 838, 559 cm^{-1}. − MS (ES); *m/z*: 2119.3 [M − PF_6], 987 [M − 2 PF_6]. − $C_{88}H_{84}Cu_4F_{24}N_{16}O_4P_4$ (2263.78): calcd. C 46.69, H 3.74, N 9.90; found C 46.68, H 3.82, N 9.73. − UV/Vis: λ_{max} (ε × 10^4) = 224 (5.6), 328 (6.1), 521 nm (4.7).

Crystal Structure Determination: Crystal data for $C_{88}H_{84}Cu_4F_{24}N_{16}O_4P_4 \cdot (MeCN)_2$, M_r = 2592.18, tetragonal, space group *I*4(1)/*a* (no. 88), *a* = *b* = 26.325(4), *c* = 16.980(3) Å, *V* = 11767(3) Å^3, *Z* = 4, D_c = 1.463 Mg m^{-3}, *F*(000) = 5296, *T* = 200 K, crystal dimensions 0.3 × 0.2 × 0.2 mm, purple; 28039 reflections, of which 5952 were unique (R_{int} = 0.0457), were recorded with an Enraf−Nonius CAD4 diffractometer. Final *R* indices: R_1 = 0.0451, wR_2 = 0.1195; (all data) R_1 = 0.0554, wR_2 = 0.1260 for 463 parameters. Goodness of fit on F^2 = 1.020. Largest diff. peak and hole 0.750 and −0.599 Å^{-3}. Crystallographic data for complex **1** have been deposited at the Cambridge Crystallographic Data Centre (CCDC) as supplementary publication CCDC-112945. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, U.K. [Fax: (internat.) + 44-1223/336033; E-mail: deposit@ccdc.cam.ac.uk].

Characterization of Palladium(II) Azide and Crystal Structure of Bis(azido)bis(pyridine)palladium(II) and Tetramminepalladium Tetraazidopalladate(II)

Wolfgang Beck,[a] Thomas M. Klapötke,*[a] Jörg Knizek,[a][+] Heinrich Nöth,[a][+] and Thomas Schütt[a]

Keywords: Palladium / Azide / Pyridine

Palladium(II) azide **(1)** was synthesized by reaction of palladium nitrate and sodium azide. **1** was characterized by AAS, IR, and ^{14}N-NMR spectroscopy. Bis(azido)bis(pyridine)-palladium(II) (**2**) and tetramminepalladium tetraazidopalladate(II) (**3**) were synthesized by a high-yield reaction. Both were characterized by X-ray structural analysis, IR, Raman, and NMR spectroscopy.

Introduction

In the early 1960s Sherif et al. examined the first palladium azide complexes in solution photometrically. The existence of $[Pd(N_3)_2Cl_2]^{2-}$, $[Pd(N_3)_4]^{2-}$, and $Pd(N_3)^+$ was postulated in accordance with absorption measurements.[1] Palladium(II) azide was first synthesized by Clem et al.[2] Spectroscopic studies failed because the compound exploded. In this work palladium(II) azide has been characterized by AAS, IR, and ^{14}N-NMR spectroscopy. Beck et al. synthesized some interesting palladium azide compounds in the late 1960s.[3−5] Tetraphenylarsonium tetraazidopalladate(II) has been synthesized as shown in Equation 1. In this study the structure of the tetraazidopalladate(II) anion has been determinated by X-ray structure investigation.

$$Pd(NO_3)_2 + 4\,NaN_3 + 2\,As(C_6H_5)_4Cl \xrightarrow[-\,2\,NaNO_3\ -\,2\,NaCl]{H_2O} [As(C_6H_5)_4]_2[Pd(N_3)_4] \quad (1)$$

Results and Discussion

Synthesis of 1

Palladium(II) azide (**1**) can be synthesized by reaction of two equivalents of sodium azide with palladium nitrate in water (Equation 2). A black-brown compound precipitates which is highly explosive if dried in air. Attempts to dry the product in the desiccator failed because of the explosivity of **1**. The compound detonates at 117°C. The palladium determination with AAS spectroscopy shows a result of 46.55% of palladium. For coordinated water the calculated palladium percentage is 46.98%, so it can be expected that there is water coordinated. The IR spectrum of the explosion gases shows a weak absorption at 3650 cm^{-1} for OH streching vibrations. An IR spectrum has been measured on a KBr plate. It was not possible to measure in Nujol because of the explosivity of the compound. The IR spectrum shows five absorptions at 3450 cm^{-1} for OH streching vibrations, at 2067 cm^{-1} for the antisymmetric stretching vibration of the azide group, 1205 cm^{-1} for the symmetric stretching vibration of the azide group, 559 cm^{-1} for the deformation vibration of the azide group and at 438 cm^{-1} for the palladium−nitrogen stretching vibration. The strong intensity of the symmetric stretching vibration which is not allowed for the azide ion, points to a covalent palladium−azide bond.[3] The fact that there is only one signal for the antisymmetric streching vibration of the azide group concludes that the palladium atom is surrounded by chemically equivalent azide groups as shown in Figure 1.

$$Pd(NO_3)_2 + 2\,NaN_3 \xrightarrow[-\,2\,NaNO_3]{H_2O} Pd(N_3)_2 \quad (2)$$

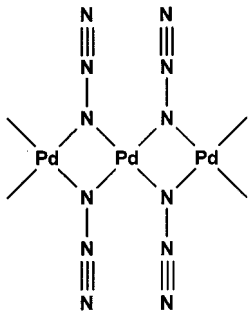

Figure 1. Structure model of **1**

Compound **1** crystallizes probably in chains in which the palladium atom is surrounded in a square-planar fashion by bridging azide groups. The ^{14}N-NMR spectrum of **1** shows the expected signals for covalently bonded azides. The N2 atom shows a resonance at $\delta = -129$, the N3 atom at $\delta = -226$, and the N1 atom a very weak resonance at $\delta = -328$. The solution of **1** in pyridine shows the same

resonances as for **2** in the ^{14}N-NMR spectrum. Probably pyridine coordinates at the palladium center to form **2**.

Synthesis of 2

Palladium nitrate reacted with an excess of pyridine and sodium azide to form orange-yellow prisms of bis(azido)-bis(pyridine)palladium(II) (Equation 3). The compound is not explosive. At a temperature of 165°C the compound decomposes.

$$Pd(NO_3)_2 + 2\,py + 2\,NaN_3 \xrightarrow[-\,2\,NaNO_3]{H_2O} Pd(py)_2(N_3)_2 \qquad (3)$$

Crystal Structure of 2

Crystals of **2** (Figure 2) are monoclinic, space group *C*2/*c* with 4 molecules in the unit cell. The palladium atom is surrounded by four nitrogen atoms, two of the azide group and two of the pyridine rings. All eight nitrogen atoms lie in plane. The pyridine rings are out of this plane. The distance between two palladium atoms is 3.86 Å. The crystals form chains in which all molecules are congruent. The plane of the nitrogen atoms of the next chain is twisted 90° to the nitrogen plane of the other chain. Bond lengths and bond angles are compiled in Table 1.

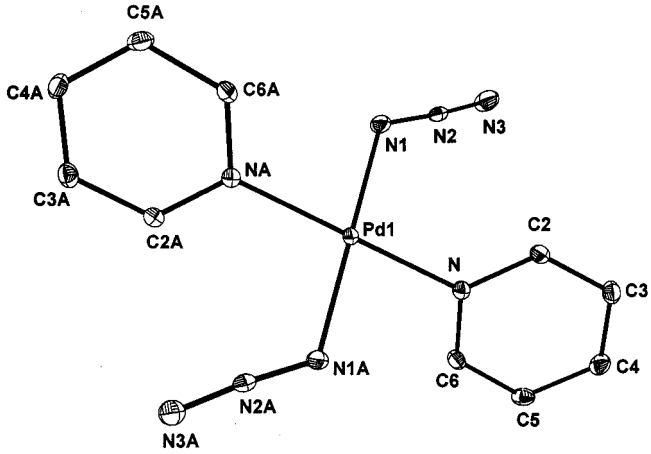

Figure 2. Molecular structure of **2** (the thermal ellipsoids represent a 25% probability)

Table 1. Selected bond lengths [Å] and angles [°] for **2**

Pd(1)−N(1)	2.037(2)	N(1)−N(2)	1.203(2)
Pd(1)−N(A)	2.0417(18)	N(2)−N(3)	1.150(3)
Pd(1)−N(1A)	2.037(2)	C(2)−C(3)	1.387(4)
Pd(1)−N	2.0417(18)	C(3)−C(4)	1.378(4)
N−C(6)	1.334(3)	C(4)−C(5)	1.384(4)
N−C(2)	1.356(4)	C(5)−C(6)	1.388(3)
N(1)−Pd(1)−N(1A)	180	N(1)−Pd(1)−N(A)	85.78(8)
N(1A)−Pd(1)−N(A)	94.21(8)	N(1)−Pd(1)−N	94.21(8)
N(1A)−Pd(1)−N	85.79(8)	N(A)−Pd(1)−N	180
C(6)−N−C(2)	118.6(2)	C(6)−N−Pd(1)	120.0(2)
C(2)−N−Pd(1)	121.3(2)	N(2)−N(1)−Pd(1)	125.5(2)
N(3)−N(2)−N(1)	175.2(2)	N−C(2)−C(3)	121.6(3)
C(4)−C(3)−C(2)	119.5(3)	C(5)−C(4)−C(3)	118.8(2)
C(4)−C(5)−C(6)	119.0(2)	N−C(6)−C(5)	122.5(2)

The N1−N2 bond length is 1.203(2) Å; thus, the bond order is between one and two. The covalent radius[6] for a single-bonded nitrogen atom is r_{cov} = 0.7 Å, 0.6 Å for a double-bonded nitrogen atom, and 0.55 Å for a triple-bonded nitrogen atom. The bond order for the N2−N3 [1.150(3) Å] is between two and three. The angle of the azide group (N1−N2−N3) is 175.2(2)°, the angle between the palladium atom and the azide group (Pd1−N1−N2) is 125.5(2)°.

Synthesis of 3

Compound **3** was synthesized by reaction of $Pd(NH_3)_4Cl_2$ with sodium azide in water (Equation 4). The compound can be handled, but it detonates by shock or by friction. It has been fully characterized by IR, Raman, and ^{14}N-NMR spectroscopy. An X-ray structure determination was also performed for this compound.

$$2\,Pd(NH_3)_4Cl_2 + 4\,NaN_3 \xrightarrow[-\,4\,NaCl\\-\,4\,NH_3]{H_2O} [Pd(NH_3)_4][Pd(N_3)_4] \qquad (4)$$

The ^{14}N-NMR spectrum shows the expected signals for covalently bonded azides.[7−9] But two signals can be seen for the N3 nitrogen atom at δ = −231 and −234. The crystal structure determination shows only equivalent N3 nitrogen atoms, so that only one signal for the N3 atom is expected. Consequently, there are no equivalent N3 nitrogen atoms in solution. There may be a coordination between half of the N3 nitrogen atoms and the electrophilic center of the tetramminepalladium cation. This coordination would lead to different N3 nitrogen atoms.

Crystal Structure of 3

Compound **3** crystallizes in the othorhombic space group *I*4/*m* with two molecules in the unit cell (Figure 3). The crystallographic data and refinement details for compound **3** are summarized in the Experimental Section. The bond lengths and bond angles are compiled in Table 2.

Compound **3** displays a salt-like structure with a Pd−Pd interaction between cation and anion. The Pd−Pd distance is 3.0420 Å. The dihedral angle between the ammine and the azide ligands is 45°. The cation and anion are both ideal square-planar. The N1−N2 distance of the azide group is 1.211(4) Å. This corresponds with a bond order between one and two. The N2−N3 distance is 1.143(4) Å. The bond order of this bond lies between two and three. The azide group is nearly linear with an N1−N2−N3 angle of 178.3(3)°. The angle between the palladium atom and the N2 atom of the azide group is 116.8(2)°. Therefore the structure of the anion looks like a "wind wheel" (Figure 4). The bond lengths and angles are similar to the valence-isoelectronic $[Au(N_3)_4]^-$ anion which shows the same wind-wheel-like structure. This compound crystallizes even with

Synthesis and Structural Study by Wide-Angle X-ray Scattering (WAXS) of Polymeric $\{Ln_2[M(opba)]_3\}\cdot S$ Compounds Containing 4f Ln^{III} and 3d M^{II} $\{Ln_2[M(opba)]_3\}\cdot S$ Ions [opba = *ortho*-Phenylenebis(oxamato), S = Solvent Molecules]

Keywords: Lanthanides / WAXS / Ladder polymers / Rare-earth compounds / Supramolecular chemistry

The compounds of formula $Ln_2[M(opba)]_3\cdot xH_2O\cdot yDMSO$ containing 4f Ln^{III} and 3d M^{II} ions have been synthesized; opba stands for *ortho*-phenylenebis(oxamato). These compounds crystallize poorly, and hence structural information has been obtained from the wide angle X-ray scattering (WAXS) technique. It has been shown that the compounds present the same ladder-like motif as that previously described for $Tm_2[Cu(opba)]_3\cdot 4H_2O\cdot 10DMF$. Changing the Ln^{III} and/or M^{II} ions results in more or less pronounced distortions of the ladders. For a given M^{II} ion, changing the Ln^{III} ion from La^{III} to Lu^{III} results in a decrease of the Ln–M distance parallel to the lanthanide contraction. In the same way, for a given rare earth, changing the M^{II} ion from Cu^{II} to Ni^{II} and Zn^{II} ions also results in the decrease of the Ln–M distance in accord with the decreasing radii of the M^{II} ions. The structural details have been analyzed and discussed.

Introduction

For one decade or so, we have been concerned with the chemistry and physics of molecular compounds containing both 4f and 3d metal ions. We first focused on the $Ln^{III}-[Cu(pba)]^{2-}$ systems where Ln^{III} stands for a trivalent lanthanide ion and pba for the bisbidentate ligand 1,3-propylenebis(oxamato). Depending on the $Ln^{III}/[Cu(pba)]^{2-}$ stoichiometry and the synthetic conditions, three structures have been found, namely tube-like motifs, double sheet layers, and ladder-like motifs. Subsequently, we used the $[Cu(opba)]^{2-}$ precursor where opba stands for *ortho*-phenylenebis(oxamato). So far, one- and two-dimensional compounds have been characterized, some of them exhibiting a long-range magnetic ordering at low temperature.[1]

It is now well established that the interaction between Gd^{III} and Cu^{II} ions is ferromagnetic. On the other hand, the nature of the interaction when Gd^{III} is replaced by another magnetic Ln^{III} ion is still an open question. The presence of an orbital momentum makes the theoretical approach very difficult. Recently, we decided to tackle this problem, and to utilize a chemical approach.[2] Let us consider a compound involving both 4f Ln^{III} and 3d M^{II} magnetic ions. The magnetic behavior of such a system is governed by two factors, namely the coupling between Ln^{III} and M^{II} magnetic centres on the one hand, and the thermal population of the Stark levels of Ln^{III} on the other hand. Our approach consists of replacing the magnetic 3d M^{II} ion by a diamagnetic one, such as Zn^{II}. The magnetic behavior of a $Ln^{III}Zn^{II}$ compound is governed only by the thermal population of the Stark levels. Comparing the magnetic properties of the $Ln^{III}M^{II}$ and $Ln^{III}Zn^{II}$ compounds results in a qualitative estimation of the nature of the $Ln^{III}-M^{II}$ interaction, provided that the $Ln^{III}M^{II}$ and $Ln^{III}Zn^{II}$ compounds have similar structures.

In this paper we describe the synthesis and the structural characterization of polymeric compounds of formula $Ln_2[M(opba)]_3\cdot xH_2O\cdot yDMSO$ where M^{II} may be Cu^{II}, Ni^{II} or Zn^{II} and DMSO is dimethyl sulfoxide. Most of these compounds crystallize poorly, and we used the wide-angle X-ray scattering (WAXS) technique to obtain structural information. Even if the WAXS technique cannot give the exact structure as an X-ray diffraction study in principle does, it has been successfully utilized to structurally characterize inorganic polymers.[3] Furthermore, for one of our compounds, a structure determined from X-ray diffraction is available. This structure may be utilized as a starting guess to interpret the WAXS data for the other compounds.

Results

First Approach

Figure 1 (top) shows the reduced intensities for three selected compounds, and Figure 1 (bottom) shows the RDFs. The reduced intensity represents the structural part of the scattering phenomenon after the full correction procedure. The Fourier transform of this spectrum gives the RDF which can be considered as a histogram of ordered distances weighted by the distance multiplicity and the

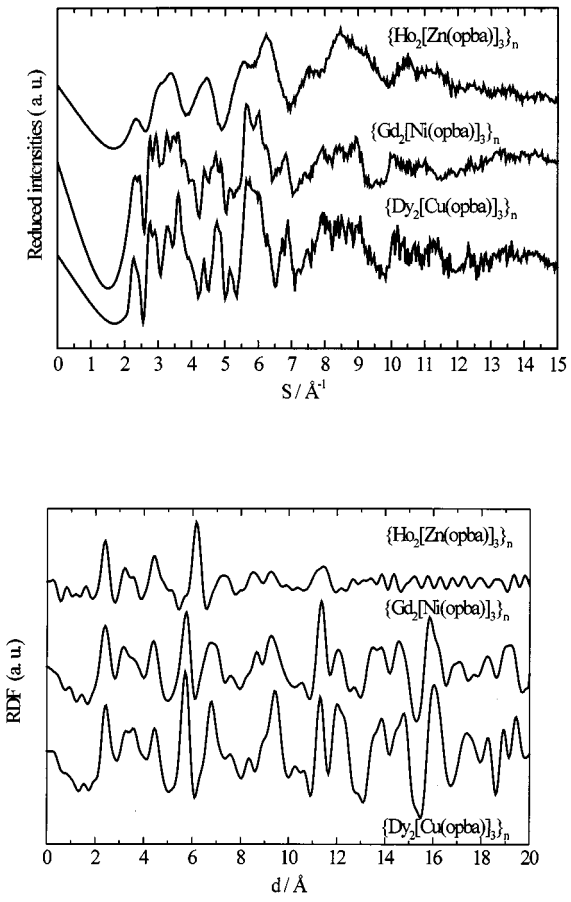

Figure 1. Overview of the experimental reduced intensities (top) and the Radial Distribution Function (RDF, bottom) for three selected samples

number of electrons engaged in these distances. Thus, an intense peak on the RDF indicates a frequent distance between two atoms.

A first qualitative look shows that the spectra are very similar to each other. The spectra of nickel- and copper-containing compounds are almost identical. The few small differences which can be detected will be discussed below. The spectra of the zinc-containing compounds differ a little bit more. This is mainly due to two factors: First, the $\{Ln_2[Zn(opba)]_3\}\cdot S$ compounds are more poorly crystallized; second, a systematic shift of each RDF peak towards longer distances is observed. The coherence length is limited to approximately 12 Å, as revealed by the collapse of ordered distances beyond this limit in the RDF of $\{Ho_2[Zn(opba)]_3\}\cdot S$.

The structures of a few oxamato-bridged $Ln^{III}Cu^{II}$ compounds were determined by X-ray diffraction on single crystals: $Gd_2[Cu(pba)]_3[Cu(H_2O)_5]\cdot 20H_2O$ presents a layered structure,[1] $Sm_2[Cu(pba)]_3\cdot 23H_2O$ shows infinite tube-like motifs,[1] and $Dy_2[Cu(pba)]_3\cdot 23H_2O$[1] and $Tm_2[Cu(opba)]_3\cdot 4H_2O\cdot 10DMF$[4] adopt a ladder-type structure. The theoretical RDFs were calculated for these three different architectures and compared to the experimental RDFs. In all cases, the best fit was obtained for the ladder-type structure. As shown in Figure 2, the uprights are made of Ln[M(opba)] units, with M = Cu, Ni or Zn, and the rungs are made of [M(opba)] units bridging Ln atoms from each upright. When seen along the direction of a rung, the two edges of the ladder are in an eclipsed conformation. Each Ln^{III} ion is surrounded by three $[M(opba)]^{2-}$ groups, its coordination sphere being completed by solvent molecules. Let us consider a specific example: $Dy_2[Cu(opba)]_3\cdot 3H_2O\cdot 9DMSO$. Figure 3 compares the experimental RDF for $Dy_2[Cu(opba)]_3\cdot 3H_2O\cdot 9DMSO$ with the RDF calculated from the X-ray diffraction data for $Tm_2[Cu(opba)]_3\cdot 4H_2O\cdot 10DMF$. The fit is fairly good up to 18 Å, which strongly suggests that $Dy_2[Cu(opba)]_3\cdot 3H_2O\cdot 9DMSO$ also has a ladder-type structure. The main difference between experimental and calculated RDFs is the shift of the peak centred at 9.85 Å in $Tm_2[Cu(opba)]_3\cdot 4H_2O\cdot 10DMF$ which is located around 9.40 Å in $Dy_2[Cu(opba)]_3\cdot 3H_2O\cdot 9DMSO$. In $Tm_2[Cu(opba)]_3\cdot 4H_2O\cdot 10DMF$ this peak corresponds to the *a* lattice parameter, i.e. to the distance between two ladders [see Figure 2 (bottom)]. Apparently, this distance is smaller in $Dy_2[Cu(opba)]_3\cdot 3H_2O\cdot 9DMSO$ than in $Tm_2[Cu(opba)]_3\cdot 4H_2O\cdot 10$ DMF, suggesting that the packing distance between two ladders is smaller in $Dy_2[Cu(opba)]_3\cdot 3H_2O\cdot 9DMSO$ than in $Tm_2[Cu(opba)]_3\cdot 4H_2O\cdot 10DMF$. This difference may be attributed to the fact that the volume of 4 H_2O and 10 DMF molecules is larger than that of 3 H_2O and 9 DMSO molecules. Beyond 18 Å the quality of the fitting decreases somewhat, but for such long distances inter-ladder packing interactions involving non-coordinated solvent molecules become important.

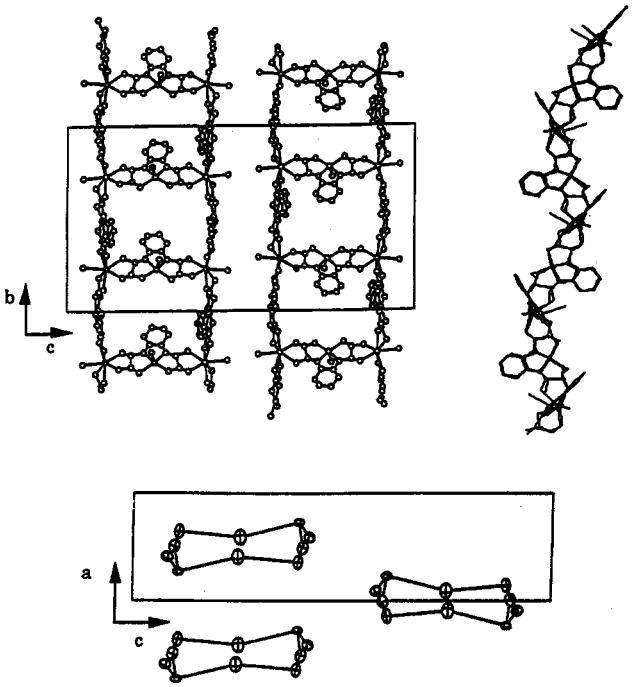

Figure 2. Structure of $Tm_2[Cu(opba)]_3\cdot 4H_2O\cdot 10DMF$ determined from X-ray diffraction; top left: view of two neighboring ladders in the *bc* plane; top right: view of one of the ladders rotated by 90°; bottom: schematic view of the ladders projected in the *ac* plane

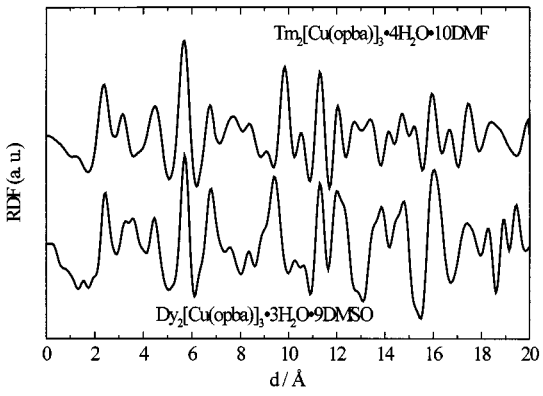

Figure 3. Comparison of the experimental RDF for $Dy_2[Cu(opba)]_3\cdot 3H_2O\cdot 9DMSO$ and the theoretical RDF for $Tm_2[Cu(opba)]_3\cdot 4H_2O\cdot 10DMF$ calculated from the structural data of ref.[4]: space group $P2_12_12_1$, a = 9.864 Å, b = 20.855 Å, c = 39.101 Å

Modeling of the $Dy_2[Cu(opba)]_3$ Ladder

Even if the structures of $Dy_2[Cu(opba)]_3\cdot 3H_2O\cdot 9DMSO$ and $Tm_2[Cu(opba)]_3\cdot 4H_2O\cdot 10$ DMF appear to be very similar, systematic shifts around 0.1 to 0.2 Å can be detected on the RDF peaks, and we decided to go further in the interpretation of the WAXS data. The starting model is a single ladder of $Tm_2[Cu(opba)]_3$ generated from crystallographic data, in which the inter-ladder contributions are obviously ignored. It follows that some slight distortions are imposed on the model in order to obtain a perfect agreement between theoretical and experimental RDF's. The final model is shown in Figure 4. Figure 5 shows the reduced intensities (top) and the RDF (bottom) computed from both experimental data and the model of Figure 4. We can notice that the Ln−Cu distances through the oxamato bridge are found to be slightly larger in $Dy_2[Cu(opba)]_3\cdot 3H_2O\cdot 9DMSO$ than in $Tm_2[Cu(opba)]_3\cdot 4H_2O\cdot 10DMF$ (Dy−Cu = 5.74 Å and Tm−Cu = 5.59 Å).

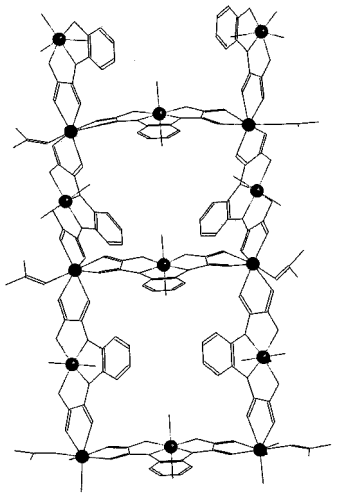

Figure 4. Structure of $Dy_2[Cu(opba)]_3\cdot 3H_2O\cdot 9DMSO$ as deduced from the WAXS study (see text); main distances: Cu−O and Cu−N: 1.95 to 2.1 Å; Dy−O: 2.27 to 2.38 Å; Dy−S: 3.55 Å; Dy−Cu: 5.72 to 5.76 Å; Dy−Dy: 11.21 to 11.36 Å

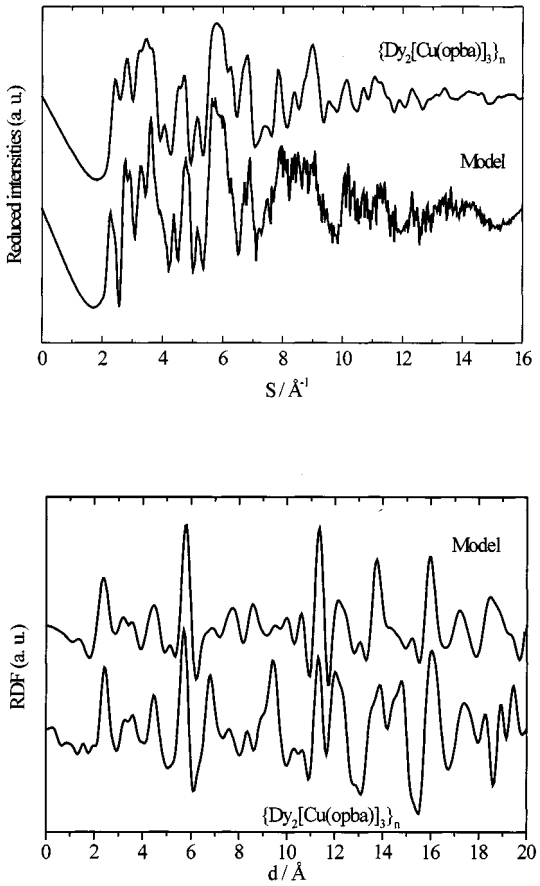

Figure 5. Reduced intensities (top) and experimental and theoretical RDFs (bottom) for $Dy_2[Cu(opba)]_3\cdot 3H_2O\cdot 9DMSO$

An interesting feature is the presence of a RDF peak centered around 3.55 Å in all the compounds containing DMSO molecules. This peak does not appear in the RDF calculated from the crystallogaphic data for $Tm_2[Cu(opba)]_3\cdot 4H_2O\cdot 10DMF$ (compare Figures 3 and 5). A simulation suggests that this distance could correspond to a Ln−S separation associated with a DMSO molecule coordinated to the Ln^{III} ion through an oxygen atom. This hypothesis is strengthened by the fact that the intensity of this peak corresponds approximately to one sulfur atom per lanthanide atom.

The agreement between experimental and calculated RDFs suggests that our model is essentially valid. However, two peaks, at 9.4 Å and 14.7 Å, are not expected in our model. These two peaks arise from intermolecular distances which are not at all modeled. Probably, the peak centred around 9.4 Å is due to the a cell parameter whereas the second one centered at 14.7 Å is the packing distance between two ladders in a same cell (see Figure 2). This hypothesis is strengthened by the fact that these two distances are equal to 9.86 Å and 14.75 Å, respectively, in $Tm_2[Cu(opba)]_3\cdot 4H_2O\cdot 10DMF$.

Ladder Distortions Induced by Metal-Ion Substitutions

Performing the modeling-distortion-fitting procedure for all the compounds would be extremely cumbersome. Such a work was carried out in one case (DyCu compound) in order to demonstrate that the compound has the ladder-type structure found for $Tm_2[Cu(opba)]_3 \cdot 4H_2O \cdot 10DMF$, with some weak distortions of the ladders. Precise assignment of the RDF peaks was also one of our goals. It is possible to determine accurately some structural characteristics such as the Ln−M (5.74 Å for the DyCu compound) and Ln−Ln (11.3 Å for the DyCu compound) distances through the opba bridge as Ln and M are changed. The results are shown in Figure 6. The two curves of Figure 6 confirm that the nickel- and copper-containing compounds have very similar structures. For a same Ln^{III} ion, the width of the ladders is slightly smaller in the copper derivatives, which is in line with the difference in ionic radius between Cu^{II} and Ni^{II} (0.72 and 0.78 Å, respectively). The width of the ladders is even larger in the zinc derivatives, in agreement with an ionic radius of 0.83 Å for Zn^{II}. In a similar way, for a same M^{II} ion the width of the ladders decreases as the atomic number of Ln increases. This observation is obviously in line with the contraction of the atomic radius from the left to the right of the lanthanide series, from 1.22 Å for La^{III} to 0.85 Å for Lu^{III}. It can be noticed that in the LnZn series two compounds, GdZn and TbZn, show larger Ln−Ln distances, 11.65 and 11.75 Å, respectively, than those for the other LnZn compounds (11.45 Å in average). This might result from the relative flexibility of the Ln−Zn−Ln alignment, i.e. the deviation of ρ (the angle between the two Ln−Zn bonds) from 180° (see below).

To obtain further information on the linearity of the Ln−[M(opba)]−Ln network in the various compounds, we calculated the ratios of the distances, ρ = Ln−Ln/Ln−M. If this network is strictly planar, ρ should be equal to 2; a ρ value smaller than 2 reveals a distortion of the network. For the compounds with M = Ni and Cu, ρ is in the range 1.96−1.98, i.e. very close to 2. On the other hand, for the compounds with M = Zn, ρ ranges between 1.80 and 1.85. Probably, the ladders in the zinc-containing compounds are more distorted than in the nickel- and copper-containing derivatives. However, as shown in Figure 6, two compounds of the Zn series (GdZn and TbZn) seem to deviate from linearity less than the other compounds of this series. In any case, this distortion would explain why the zinc derivatives are less crystalline than the nickel and copper ones. In these zinc compounds, this distortion probably induces a statistical disorder which reduces the coherence length to about 12 Å.

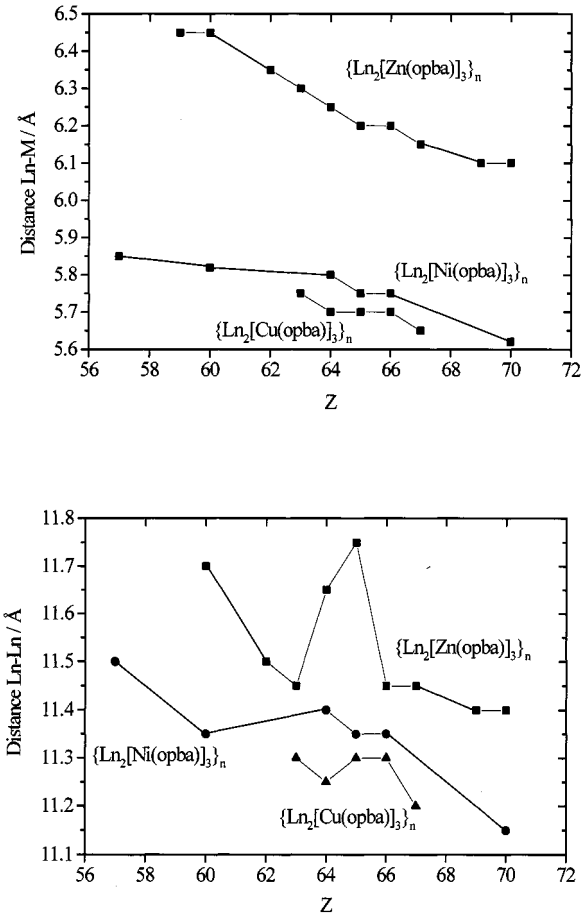

Figure 6. Evolution of M−Ln (top) and Ln−Ln (bottom) distances as a function of the atomic number of the Ln and M elements

Conclusion

This WAXS study on a new series of 4f−3d compounds proves without doubt that all the $\{Ln_2[M(opba)]_3\} \cdot S$ compounds have similar structures. These compounds crystallize poorly. However, the coherence length is important enough to strongly suggest that the structures consist of ladder-like motifs, very similar to those found in $Tm_2[Cu(opba)]_3 \cdot 4H_2O \cdot 10DMF$. These WAXS studies allow us not only to confirm the ladder-type structure but also to determine precisely important distances such as Ln−M, Ln−Ln and Ln−S. The Ln−M separations across the oxamato bridge range from 5.60 to 6.45 Å, and the separation between two Ln^{III} ions connected in the transverse direction range from 11.15 to 11.75 Å depending on the nature of the Ln^{III} and M^{II} ions. The packing distances between two ladders range from 9.0 to 9.5 Å (*a* lattice parameter) and is around 14.7 Å between two ladders in the same cell. For a given M^{II} ion, changing Ln^{III} from La^{III} to Lu^{III} ion results in the decrease of the Ln−M distance in accord with the lanthanide contraction. In the same way, for a given rare earth, changing the M^{II} ion from Cu^{II} to Ni^{II}, and then Zn^{II} results also in the decrease of the Ln−M distance in accord with the decreasing radii of the M^{II} ions. These studies confirm that the determination of the structure of polymeric compounds is possible with the WAXS technique and that precise structural information can be obtained.

Systematic magnetic measurements are in progress and will be published in a subsequent paper. This structural

study was a prerequisite to discussing and interpreting the magnetic data.

Experimental Section

Syntheses. – Starting Materials: $Ln(NO_3)_3\cdot xH_2O$,[5] Et_2H_2opba and $(NMe_4)_2[Cu(opba)]$,[6] were synthesized according to described procedures. The Zn^{II} precursor, $(NBu_4)_2[Zn(opba)]$, was synthesized as follows: A solution of Et_2H_2opba (1.545 g, 5 mmol) and NBu_4OH (2.62 ml, 40 wt.-% sol. in water, 4 mmol) in MeOH was stirred at 60°C for 30 min. A methanolic solution of $Zn(Ac)_2\cdot 2H_2O$ (0.219 g, 1 mmol) was added dropwise. A white precipitate was immediately formed. The solid was collected by centrifugation of the mixture, washed three times with MeOH and dried under vacuum (2.8 g, yield 70%). – ^{1}H NMR [D$_6$]DMSO: δ = 7.94 (br. s, 2 H, *aromatic*); 6.57 (br. s, 2 H, *aromatic*); 3.16, 1.55, 1.29 [3 br. m, 48 H, $N(CH_2)_3CH_3$]; 0.91 (br. m, 24 H, CH_3). – IR (principal vibrations; KBr; cm^{-1}): $\tilde{\nu}$ = 2961.7 (w), 2874.0 (w): ν(C–H); 1598.1 (s), 1572.5 (s): ν(C=O); 753.5 (w): aromatic ring. – $C_{42}H_{96}N_4O_{16}Zn$ (978.6): calcd. C 51.5, H 9.9, N 5.7, Zn 6.7; found C 50.8, H 8.9, N 5.4, Zn 7.3.

Ni^{II} Precursor $(NMe_4)_2[Ni(opba)]$: A solution of Et_2H_2opba (1.545 g, 5 mmol) and NMe_4OH (7.18 ml, 25 wt.-% sol. in water, 20 mmol) in MeOH was stirred at 60°C for 30 min. A methanolic solution of $Ni(ClO_4)_2\cdot 6H_2O$ (1.828 g, 5 mmol) was added dropwise. The solution was filtered and the solvent was removed. The addition of a small amount of distilled MeOH gave a precipitate of $(NMe_4)(ClO_4)$. The reaction mixture was then kept at –18°C for 12 h, then filtered. The solvent was removed under reduced pressure to give an orange oil which crystallized by addition of diethyl ether (3.4 g, yield 85%). – ^{1}H NMR ([D$_6$]DMSO): δ = 7.80 (br. s, 2 H, *aromatic*); 6.55 (br. s, 2 H, *aromatic*); 3.10 (s, 24 H,CH_3). – IR (principal vibrations; KBr; cm^{-1}): $\tilde{\nu}$ = 3018.9 (w): ν(C–H); 1663.8 (s), 1636.1 (s): ν(C=O); 618.5 (w) aromatic. – $C_{22}H_{44}N_4NiO_{10}$ (583.3): calcd. C 45.3, H 7.6, N 9.6, Ni 10.0; found C 45.6, H 7.1, N 11.8, Ni 9.6.

$\{Ln_2[M(opba)]_3\}\cdot S$: All the $\{Ln_2[M(opba)]_3\}\cdot S$ compounds were synthesized by using the same general procedure. Here is described the general procedure. A solution of $Ln(NO_3)_3\cdot xH_2O$ (33 mmol), dissolved in 5 mL of DMSO, was added dropwise to a solution of $(Cat^+)_2[M(opba)]$ (50 mmol), dissolved in 10 mL of DMSO solution. A precipitate was formed and the mixture was stirred for 3 h. The solid was collected by centrifugation, washed three times with DMSO and three times with ether, then dried under vacuum. – IR (principal vibrations; KBr; cm^{-1}): $\tilde{\nu}$ = $\{Dy_2[Cu(opba)]_3\}\cdot S$: 1626.4 (s), 1596.1 (s), 1572.5 (s): ν(C=O); 1014.5 (s), 951.1 (m): ν(S=O). $\{Ho_2[Zn(opba)]_3\}\cdot S$: 1590.4 (s), 1560.4 (s): ν(C=O); 1016.8 (s), 954.3 (m) ν(S=O). $\{Gd_2[Ni(opba)]_3\}\cdot S$: 1618.0 (s), 1572.5 (s): ν(C=O); 1014.8 (s), 953.0 (m): ν(S=O). – $C_{48}H_{72}Cu_3Dy_2N_6O_{30}S_9$ (2017.3): calcd C 28.6, H 3.6, Cu 9.4, N 4.2, S 14.3; found C 28.3, H 2.8, Cu 8.5, N 5.8, S 14.5; $C_{31}H_{45}Gd_2N_6Ni_3O_{33.5}S_{0.5}$ (1544.3): calcd C 24.1, H 2.9, Gd 20.4, N 5.4, S 1.0, Ni 11.4; found C 25.3, H 2.9, Gd 20.0, N 5.3, S 0.4, Ni 10.5; $C_{44}H_{64}Ho_2N_6O_{30}S_7Zn_3$ (1907.5): calcd C 27.7, H 3.4, Ho 17.3, N 4.4, S 11.8; found C 29.6, H 3.9, Ho 17.4, N 4.3, S 11.7.

WAXS Studies: A typical experiment was performed as follows: The sample was sealed in a Lindeman capillary. The diffusion spectrum scattered by the sample irradiated with graphite-monochromatized molybdenum K_α radiation (λ = 0.71069 Å) was obtained using a LASIP diffractometer.[7] 457 intensities corresponding to equidistant points [$s = 4\pi(\sin\theta/\lambda)$; Δs = 0.035 Å^{-1}] were collected in the 0° < θ < 65° range. Measurements of air and Lindeman capillary diffusion were carried out exactly under the same conditions. The raw sample scattered intensity (sample + air + capillary) was corrected for air and capillary contributions by spectra subtraction taking into account absorption from sample, then corrected for polarization and self absorption effects. Normalization was performed using Norman and Krogh-Moe's method.[8] The atomic scattering factors were taken from Cromer and Waber.[9] The reduced experimental Radial Distribution Function (RDF) was calculated similarly as described in ref.[10] Theoretical structural models were built up using the CERIUS2 program.[11] The theoretical RDF was computed from the structural models by Fourier transform of the theoretical intensities calculated according to the Debye formula[12] using the KURVLR program.[13] Debye–Waller factors commonly observed in related crystalline structures were used for the computation.

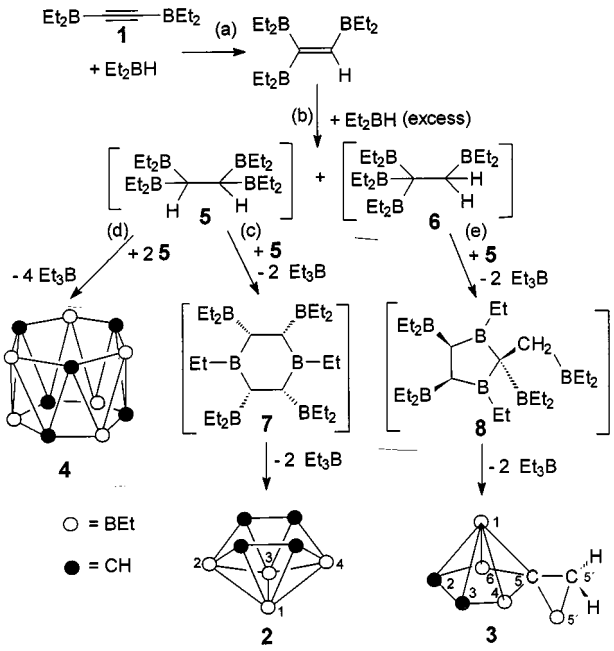
The Structures of a Tetracarba-*nido*-octaborane(8) and a Novel Spiro Derivative of a 2,3,5-Tricarba-*nido*-hexaborane(7)

Bernd Wrackmeyer,*[a] Hans-Jörg Schanz,[a] Matthias Hofmann,[b] Paul von R. Schleyer,[b] and Roland Boese[c]

Keywords: Ab initio calculations / Carboranes / NMR / X-ray analysis



Hydroboration of bis(diethylboryl)ethyne (**1**) with tetraethyldiborane(6) leads to a *B*-ethyl-substituted tetracarba-*nido*-octaborane **2**, a spiro-carborane **3**, which belongs to the 2,3,5-tricarba-*nido*-carborane family, and a hexacarba-*arachno*-dodecaborane(12) **4**, along with polymeric material. The X-ray structure analysis of carborane **2**, determined here, is fully consistent with the structure deduced earlier from NMR data. The structure of **3** in solution was established by theoretical analysis of its NMR data. Ab initio calculations of the structures of **2b** and **3b** (**b** denotes the *B*-metyhl-substituted derivatives) and the comparison of calculated with experimental NMR data support the suggested structures of **2** and **3** in solution. The calculated structure of the carborane cage of **2a** also agrees with the experimental geometry of **2**.

Introduction

Tetracarba-*nido*-octaboranes(8) are reported to result from transition metal complex promoted reactions[1,2] or from the reduction of organo-substituted 1,2,5-thiadiborolenes with potassium.[3] However, the evidence for structural assignments is not firm, and the chemistry of these carboranes has not been explored. We prepared the *B*-ethyl-substituted tetracarba-*nido*-octaborane(8) **2** by hydroboration of bis(diethylboryl)ethyne (**1**); the structure was inferred from NMR data in solution along with an X-ray structural analysis of the hexacarbonyldiiron complex of **2**.[4] The hydroboration of **1** (Scheme 1) also leads to other products, e.g. the hexacarba-*arachno*-dodecaborane(12) derivative **4**,[5] and **3**, a spiro-carborane isomer of **2**.[5] We now report the first X-ray-structural analysis of the *nido*-C_4B_4 cage, and our finding of an isomer of **2** with a carborane cage different from that of **2**. We employ the ab initio/GIAO-IGLO/NMR method[6] to elucidate the structures.

Results and Discussion

The routes to the carboranes **2**−**4** are shown in Scheme 1. The mechanism is speculative. The suggested intermediates **5**−**8** were not detected, but are inferred [as associated diborane(6) species due to the excess of tetraethyldiborane(6)] from the products. The formation of polymeric material is suggested if the diethylboryl groups in **7** or **8** are not in the correct positions for BH-catalyzed intramolecular elimination of Et_3B (these isomers of **7** or **8** are not shown in Scheme 1). In the case of **8** intramolecular elimination of Et_3B from the $Et_2BCH-CHBEt_2$ moiety leads to the apical BEt group and therefore, it can be predicted that a second intramolecular elimination of Et_3B, forming the spiro compound, should give the three-membered ring with an endocyclic C5−B5′ bond as in **3**. The proposed structure of **3** is unique in carborane chemistry and therefore, extensive NMR studies and ab initio MO calculations were per-

formed to prove its existence, in particular in the absence of direct structural evidence.

In contrast to **2** and **4**, the carborane **3** is extremely sensitive towards oxygen. It is therefore not observed when the usual work-up procedures are used. However, if the reaction mixtures are not oxidized or hydrolyzed, **3** can be obtained in a mixture with **2** by fractional distillation, and a complete set of NMR data of **3** can be recorded. The ^{11}B-NMR signal at $\delta = -28.9$ with relative intensity 1 indicates the presence of a boron atom (B1) in apical position, and the signal at $\delta = +23.3$ with relative intensity 2 is typical of boron atoms B4,6 in basal positions. A third ^{11}B-NMR signal at rather low field ($\delta = +64.0$), much more typical of triorganoboranes than of carboranes is assigned to the boron atom in the three-membered ring. The connectivity between the ^{11}B4,6 and ^{13}C2,3 nuclei is evident from the sharpening of relevant ^{13}C-NMR signals as the result of selective ^{11}B decoupling experiments (see Figure 1). Irradiation of the ^{11}B resonance at $\delta = +64.0$ sharpens two $^{13}C(CH_2)$ signals, one due to the BEt group and the other to the unique CH_2 moiety in the three-membered ring. The carborane **3** is the first 2,3,5-tricarba-*nido*-hexaborane derivative[7,8] without an *endo*-C5−H bond. For the parent carborane a hyperconjugative interaction of the *endo*-C5−H bond with B4 (or B6) was found computationally.[9] This participation in the cluster bonding satisfies the electron counting rules.[10] In comparison with the δ^{11}B data of hexaethyl-2,3,5-tricarba-*nido*-hexaborane(7) **9** (Table 1) the apical ^{11}B nucleus in **3** is deshielded by 8 ppm. This can be the result of the different substituents linked to C5 (vide infra), and it can also be caused (however, less likely) by the missing ethyl groups at C2,3 in **3**.

Two reactions of **3** (Scheme 2) provide further evidence for its unique structure. If γ-picoline is added to the mixture of **2** and **3**, the ^{11}B-NMR signal at $\delta = +64.0$ disappears, and a new broad signal at $\delta = +13.5$ is observed. The spiro cage structure of **3** appears to be retained, since the effect on all other ^{11}B and ^{13}C(cage) signals is small. The carborane **2** does not react. Treatment of the mixture of **2** and **3** with BuLi also does not affect **2**, but **3** reacts by ring opening to give the 2,3,5-tricarba-*nido*-hexaborate(1−) derivative **11**. The reaction can be controlled by using slightly less then one equivalent of BuLi. The ^{11}B-NMR spectrum shows signals with correct integral intensities for B(1) and B(4,6) at $\delta = -38.5$ and $+21.7$, respectively, and a signal at $\delta = +86.7$ for the Et(Bu)B group in the typical range of non-cyclic trialkylboranes.[11] The δ^{11}B(1,4,6) values are close to those determined for corresponding 2,3,5-tricarba-*nido*-hexaborates(1−) [e.g. *nido*-Et_6-2,3,5-C_3B_3-hexaborate(1−): δ^{11}B1 = −44.2 and δ^{11}B(4,6) = +17.2.[8]]

Scheme 2. Reactivity of the spiro-carborane **3** towards γ-picoline and BuLi

The NMR data of **2** in solution discussed previously,[4] are fully consistent with the molecular structure of **2** in the solid state.[12] The X-ray data of **2** confirm the proposed[4,13] hexagonal open face formed by the four carbon atoms, linked in pairs, and two boron atoms (Figure 2). In

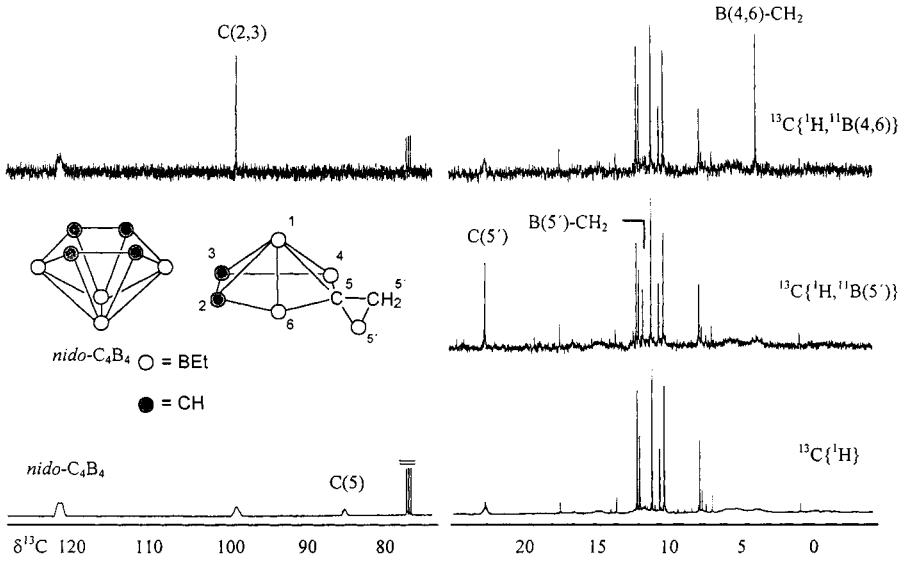

Figure 1. 125.8-MHz ^{13}C-NMR spectra of a mixture of **2** and **3** (ca. 10 mg in 0.5 mL of $CDCl_3$); **A**: normal $^{13}C\{^1H\}$-NMR spectrum spectrum; **B**: the selective heteronuclear $^{13}C\{^1H,^{11}B(4,6)\}$ triple-resonance experiment shows sharpening of the B(4,6)-$^{13}CH_2$, and ^{13}C(2,3) signals; **C**: the selective heteronuclear $^{13}C\{^1H,^{11}B(1)\}$ triple-resonance experiment only gives rise to sharpening of the $^{13}CH_2$-B(1) signal

the cage, the short distances d_{CC} [138.0(3), 138.5(3) pm] and rather short distances d_{B4C} and d_{B2C} [157.7(4), 159.0(4), 158.4(4), 158.6(4) pm] characterize the bonding situation in the open face. In particular, d_{B4B1} = 189.5(4) and d_{B2B3} = 190.5(4) pm are long when compared with the short d_{B1B3} = 171.0(4) pm separation. The other d_{BC} distances in the cage are similar to the known deltahedral B−C bond lengths. Variations of bond lengths in the hexacarbonyldiiron complex of **2** are less significant. The B−C−C angles in the BEt groups are 116.0(3)° (mean value), in the same range as in pentaethyl-1,5-dicarba-*closo*-pentaborane,[14] in which the B−C−C angles were interpreted in terms of hyperconjugational effects.[15]

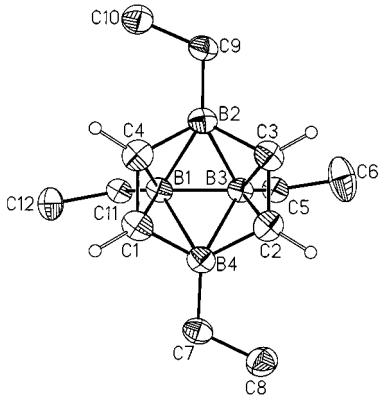

Figure 2. Presentation of the molecular structure of **2** with 50% thermal ellipsoids (ethyl hydrogen atoms are omitted for clarity); selected bond lengths [pm] and angles [°]: B1−C1 172.5(3), B1−C4 172.6(3), B1−B3 171.0(4), B1−B4 189.5(4), B1−C11 157.6(3), B2−C3 158.4(4), B2−C4 158.6(4), B2−C9 159.6(4), B2−B3 190.5(4), C1−C4 138.0(3), C2−C3 138.5(3); C1−B4−C2 109.9(2), C3−B2−C4 110.2(2), C10−C9−B2 115.4(2), C12−C11−B1 116.5(2)

Geometries were optimized at the MP2(fc)/6-31G* level of theory using the Gaussian 94 program.[16] Chemical shifts were evaluated from GIAO-SCF/6-31G* computations of chemical shieldings employing B_2H_6 (σ = 107.0) as a primary reference. Reported values are converted to the experimental standard, $BF_3 \cdot OEt_2$ using $\delta(B_2H_6)$ = 16.6.[17]

The parent $C_4H_8B_4$ spiro-carborane, optimized assuming a classical C_2B three-membered ring attached to a C_2B_3 cluster by two C−B connections, gave a C_s-symmetric geometry **12**. This was characterized as a transition structure at RHF/6-31G*. (Optimization without symmetry constraints converged to a spirocyclic structure with a six- and a three-membered ring.) Computed ^{11}B-NMR-chemical shifts for **12** of +32.5 (B1), +3.2 (B4,5) and +84.6 ppm are in gross disagreement with experimental data (−28.9, +23.3, +64.0 ppm). An alternative starting geometry whose larger B4−B5 separation allows the spiro carbon atom to become part of the cluster optimized to structure **3a**, 63.9 kcal mol^{-1} lower in energy than **12**. Chemical shifts computed for **3a** (B1: −34.0, B4,6: 8.7, B5′: 40.2; C2,3: 108.6, C5: 93.6, C5′: 10.4) are in acceptable agreement with measured values (see Table 1) when substituent effects are

[a] Solution of a mixture of **2** and **3** in $CDCl_3$ (25°C); solutions of mixtures of **2** and **9** and **2** and **10** in C_6D_6 (25°C); n.m.: not measured. − [b] **2b** and **3b** are the *B*-methyl-substituted analogs of **2** and **3**. − [c] Hexaethyl-2,3,5-tricarba-*nido*-hexaborane(7).[8]

taken into account. A model better than **3a**, the tetrakis(*B*-methylated) structure **3b**, gives satisfactory overall agreement although the B5′ chemical shift is 14.2 ppm too low. We compute a B4,6−B5′ separation of 206.2 pm for the parent **3a**. But this distance is increased to 211.6 pm for the better per(*B*-methylated) model (and probably is even larger with ethyl substitution). The $C_4B_4H_8$ tetracarba-*nido*-octaborane structure **2a** is 28.9 kcal mol^{-1} more stable than **3a**. The difference between the tetrakis(*B*-methyl) derivatives **2b** and **3b** is 26.2 kcal mol^{-1} (//MP2(fc)/6-31G*).

Compound **3a** is a derivative of 2,3,5-tricarbahexaborane(7), for which the *endo*-C5−H bond was shown to be asymmetrically bent towards one neighboring boron atom (partially bridging).[9] For **3a**, no evidence for a similar bending of the *endo*-C5−B5 bond was found; the C_s structure is a minimum and the C5−B5 distance is not significantly elongated (150.9 pm). However, the *endo*-B atom does interact with the cage: Hyperconjugative donation from the cage results in a 0.34-electron population of the formally empty p(B5′) orbital according to an NBO analysis (0.31 for **3b**).[18] As a consequence, the NLMO/NPA[18] bond order between the *exo*-B5′ atom and the basal B4,6 atoms is 0.23 (0.31 for **3b**). This compares with 0.73 and 0.87 (0.62 and 0.70 for **3b**) between B5′ and C5 and the methylene C5′ atom, respectively. This hyperconjugation confers considerable stabilization. Thus, **13**, where B5′ is in *exo* position, is 35.3 kcal mol^{-1} less stable than **2a**. The B4,6−B5′ bond order in **3** is only 0.06 and the p(B5′) orbital has a population of only 0.06 electrons. (The *exo*-B5′ isomer related to **12** is only 4.9 kcal mol^{-1} higher in energy than **12**.)

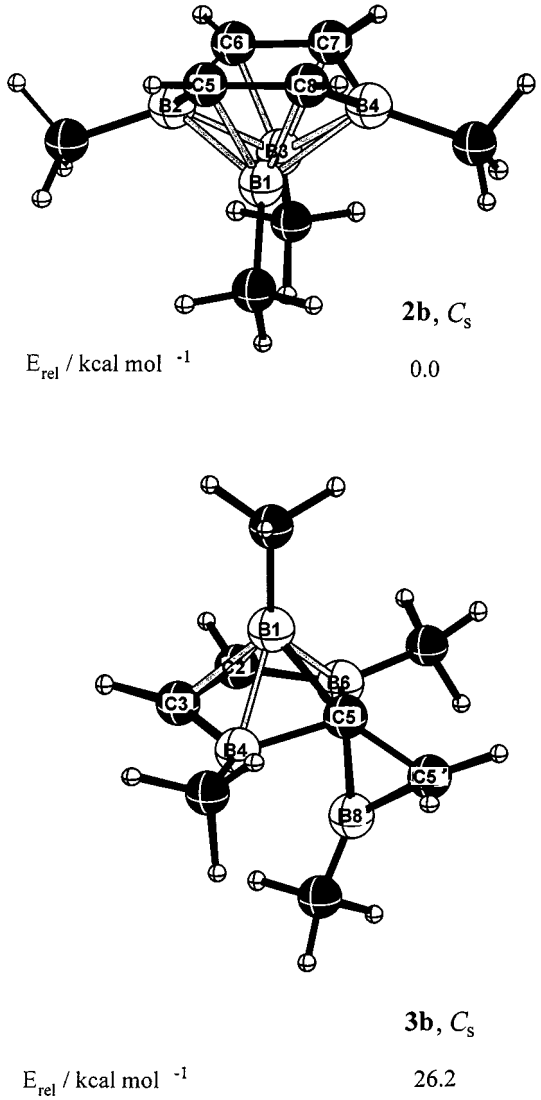

Figure 4. Geometries (bond lengths in pm) of model compounds **2b** (B1−C2 172.8, B1−B4 184.9, B1−C5 161.0, C2−C3 144.5, C2−B6 152.0, B4−C5 161.4, C5−C5′ 150.8, C5−B5 151.1, C5′−B5 158.3) and **3b** (B1−B2 186.5, B1−B3 172.9, B1−C5 170.7, B2−C4 158.5, C5−B8 139.3), optimized at MP2(fc)/6-31G*

Experimental Section

General: The preparation and the handling of samples was carried out under N_2 or Ar, observing all necessary precautions to exclude traces of oxygen or moisture. Commercial starting materials were employed (γ-picoline, BuLi in hexane (1.6 M)] or were prepared as described [Et_2BH,[19] $Et_2B-C\equiv C-BEt_2$[4]]. − NMR spectra: Bruker ARX 250 and DRX 500 spectrometers; the latter was equipped with a triple-resonance probehead for $^{13}C\{^1H,^{11}B\}$ experiments; chemical shifts are given with respect to Me_4Si [δ^1H ($CHCl_3/CDCl_3$) = 7.24; δ^1H ($C_6C_5CD_2H$) = 2.03; $\delta^{13}C$ ($CDCl_3$) = 77.0; $\delta^{13}C$ ($C_6D_5CD_3$) = 20.4] and $Et_2O \cdot BF_3$ [$\delta^{11}B$ = 0 for $\Xi(^{11}B)$ = 32.083971 Mhz].

1,2,3,4-Tetraethyl-5,6,7,8-tetracarba-*nido*-octaborane(8) (2) and Its Spiro Isomer 3: After heating of a solution of 3.57 g (21.7 mmol) of bis(diethylboryl)ethyne in 5.0 mL of Et_2BH (57.1 mmol hydride[20]) at 80°C for a period of 24 h, it was saturated with ethene (reactive B−H are converted into B−Et bonds). Fractional distillation under reduced pressure first gave 0.97 g (21%) of a mixture (65:35) of compounds **2** and **3** (b.p. 75−85°C/10^{-4} Torr). The residue contained polymeric material and **4** which could be isolated as described.[5] Repeated distillation did not lead to further separation of **2** and **3**, and a small amount of this mixture was used to obtain the NMR data of **3** and to carry out the reactions of **3** with γ-picoline and BuLi (by adding the γ-picoline and BuLi to the carborane mixture at −78°C, warming to room temperature and removing all volatile material in vacuo). Treatment of 0.9 g (4.2 mmol) of the carborane mixture with a solution of Na[Et_3BH] in hexane (6 M; 0.5 mL; 3 mmol of hydride) at room temperature gave, after filtration and washing of the insoluble material with hexane (15 mL), a colorless solution containing only Et_3B and the carborane **2** (^{11}B NMR). Compound **2** (0.41 g; 9% relative to **1**; b.p. 82°C/10^{-4} Torr) was obtained as a colorless liquid in high purity (suitable for growing single crystals for X-ray analysis; vide infra) after threfold fractional distillation (see ref.[4] for NMR and MS data of **2**).

3: ^1H NMR (500.1 MHz, 25°C, $CDCl_3$): δ = 5.24 (s, 2 H, C2,3-H), 1.64 (s, 2 H, C5−CH_2), 0.19, 0.56 (q, t, 5 H, B1−Et), 0.83, 0.69, 1.06 (m, m, t, 10 H, B4,6−Et), 1.20, 1.01 (m, t, 5 H, C5−BEt). − ^{11}B NMR (80.3 MHz, 25°C, $CDCl_3$): δ = −28.9 (B1), 23.3 (B4,6), 64.0 (B5′). − ^{13}C NMR (125.8 MHz, 25°C, $CDCl_3$): δ = 98.9 (br., C2,3), 85.1 (br., C5), 22.5 (br., CH_2), −0.4 (br.), 10.6 (B1−Et), 4.0 (br.), 11.2 (B4,6−Et), 11.7 (br.), 12.0 (BEt).

Structure Determination of 2: Compound **2**, $C_{12}H_{24}B_4$, formula weight 211.55, crystallized from the colorless neat liquid by cooling

to 168 K and application of a miniature zone-melting procedure using a CO_2 laser beam[21] as a cylindrical crystal (diameter 0.3 mm) which was measured at 120 K with a Nicolet R3 diffractometer with graphite-monochromized Mo-K_α radiation. Cell dimensions of the triclinic system: a = 8.044(4), b = 9.114(4), c = 10.557(5) Å, α = 71.89(3), β = 88.79(4), γ = 70.13(3)°, V = 688.7(5) Å^3, Z = 2, space group $P\bar{1}$, $\rho_{calcd.}$ = 1.020 gcm^{-3}, μ = 0.052 mm^{-1}, ω-scan data collection of 2567 intensities ($2\Theta_{max}$ = 50°), 2422 independent (R_{merg} = 0.0388), 1756 observed [$F_o \geq 4\sigma(F)$], structure solution with direct methods and refinement on F^2 with Siemens SHELXTL-Plus program package (version 5.03), $R1$(obsd. data) = 0.0577, $wR2$(all data) = 0.1866, GOF = 1.060, $w^{-1} = \sigma^2(F_o^2) + (0.0558 \cdot P)^2 + 0.55 \cdot P$), where $P = [(\max F_o^2) + (2\ F_c^2)]/3$, maximum/minimum residual electron density 0.208/−0.196 e Å^{-3}.

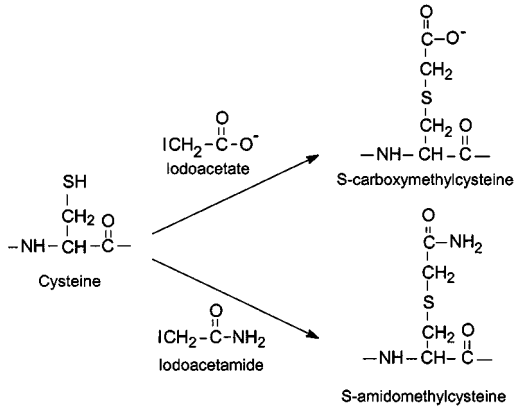
Models for Terminal Ni(S-Cysteine) Modification in [NiFe]Hydrogenases by Iodoacetamide and Iodoacetate

Jason J. Smee,[a] Dawn C. Goodman,[a] Joseph H. Reibenspies,[a] and Marcetta Y. Darensbourg*[a]



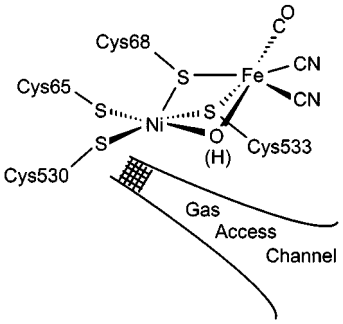
Keywords: Nickel / Sulfur ligands / Hydrogenases / Bioinorganic chemistry

The *cis*-dithiolate complex [*N*,*N*′-bis(2-mercaptoethyl-2-methylpropyl)-1,5-diazacyclooctane]nickel(II) (**Ni-1***) **reacts with stoichiometric amounts of iodoacetamide to yield *S*-alkylated, mono- and diacetamide complexes, [(AA)Ni-1*][I] and [$(AA)_2$Ni-1*][$I]_2$. Their molecular structures are established by X-ray crystallography and find the former in pseudo-square planar geometry with no additional coordination of the amide functionality, while the latter is an octahedral $N_2S_2O_2Ni^{II}$ complex. The assignment of the axial coordination ligands as amide oxygen atoms is consistent with IR-spectroscopic ν(C=O) results both in the solid and solution states. The complexes are further characterized by UV/Vis spectroscopy, conductance measurements, and electrochemical studies. Comparisons are drawn between the alkylation of these simple dithiolate complexes and the loss of [NiFe]hydrogenase activity upon addition of alkylating agents.**

Introduction

Cysteine modification reagents such as sodium iodoacetate ($ICH_2CO_2^-Na^+$) and iodoacetamide [$ICH_2C(=O)NH_2$] are widely used to probe the involvement of cysteine residues in enzymatic systems.[1] S_N2 attack by the nucleophilic cysteinate sulfur atom produces *S*-(carboxymethyl)cysteine and *S*-(amidomethyl)cysteine, respectively (Scheme 1), which typically results in loss of catalytic activity. While Scheme 1 represents the reactive S as sulfhydryl, it is well known that deprotonated cysteines are more reactive towards alkylating agents. In some cases, the modified cysteine unit has been tracked by radiolabelling, thus permitting identification of the active site position in the protein. For example, the zinc metalloenzyme cobalamin-independent methionine synthase (MetE) contains a reactive zinc cysteinate residue at position 726 that is required for enzymatic activity.[2]

Iodoacetamide and acetylene were shown to inhibit the catalysis of H/D exchange of H_2/D_2O by the [NiFe]hydrogenase enzyme of *Thiocapsa roseopersicina*, the former irreversibly.[3] Inhibition by acetylene is reversible; upon removal of the acetylene, nearly maximal activity is restored. On placing the enzyme under acetylene and subsequently treating it with iodoacetamide, the H/D exchange was inhibited, but the activity could be partially restored by removing both the iodoacetamide and the acetylene. Notably, the irreversible inhibition by iodoacetamide occurs only in the reduced, active form of the enzyme. Alkylation with iodoacetamide in the oxidized, inactive form followed by reductive activation of the enzyme showed maximal H/D exchange activity. Although the alkylated residues were not identified, experiments which monitored the levels of ^{14}C-labeled *S*-(amidomethyl)cysteine indicated that the reduced enzyme contained a greater amount of cysteine modification in the portion of the protein containing the active site. These results suggest the possibility of active site modification.[3]



Scheme 1. Products resulting from alkylation of the cysteine sulfhydryl groups with iodoacetate and iodoacetamide; the other product, HI, is not shown

The X-ray crystal structure of an analogous [NiFe]H_2ase, isolated from *Desulfovibrio gigas* was recently solved[4a] and contains an $Ni(S-Cys)_4$ unit comprised of two terminal cysteines and two cysteines which bridge to an $Fe(CN)_2(CO)$ unit.[4b,4c] The oxidized state also contains a bridging ligand tentatively assigned as an oxo or hydroxo species, which is expected to be absent in the reduced or active form of the enzyme.[4b] Analysis of the X-ray crystal structure of *D. gigas* also reveals that the active site is buried ca. 30 Å from the protein surface with several cavities that converge on a unique entrance to the active site.[4b] In a separate study, xenon pressurization of crystals derived from *Desulfovibrio fructosovorans*, a [NiFe]H_2ase with sig-

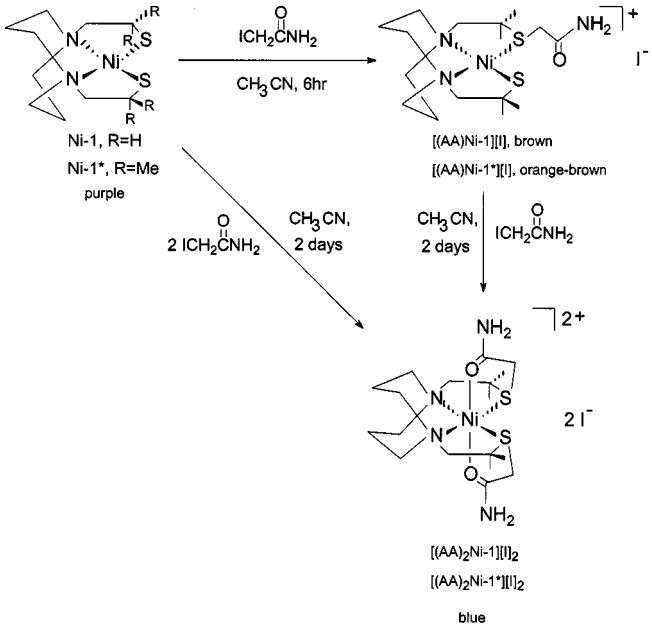
nificant homology to *D. gigas*, confirmed the cavities to be a gas access channel.[5] It is thus tempting to conclude that the channel provides a means for H_2 molecules, as well as acetylene or iodoacetamide, to reach the active site. Experimentally, i.e., by the location of the Xe atoms, this channel was found to approach the active site at the terminal Ni(S−Cys) ligands, specifically $Ni-S-Cys_{530}$, to within 4 to 5 Å (Scheme 2). Electron density maps suggest that there are protein residues or water molecules which prevent closer contact. Molecular dynamics calculations find that H_2 molecules can, however, penetrate to within 1.4 and 1.8 Å of the nickel and iron atoms, respectively.[5] Since EPR and IR spectroscopies of [NiFe]H_2ases derived from various bacteria[4b,6,7] are similar to one another, it is reasonable to expect a similar active site composition, although gas access routes to the active site could differ.

Scheme 2. A representation of the hydrophobic channel leading to the active site of *D. fructosovorans* [NiFe]H_2ase

Thus, the structural studies on [NiFe]H_2ases suggest some, and at most, limited, access to the active-site metal-bound cysteine. Indeed the specific residues alkylated by iodoacetamide in *T. roseopersicina* [NiFe]H_2ase have not been identified. Nevertheless there are examples of metal-bound cysteine modification at the active sites of other metalloproteins such as the zinc-containing MetE protein described above.[2] A fundamental question to be addressed by small molecule biomimics is, assuming active site access, will nickel-bound cysteines be alkylated by iodoacetamide or iodoacetate, and, if so, what are the structural, spectroscopic and electrochemical consequences?

One appropriate study, designed for other purposes, used the N_2S_2Ni square planar complex, *N*,*N*′-bis(mercaptoethyl)-1,5-diazacyclooctanenickel(II) (**Ni-1**).[8] The *cis*-dithiolate sulfur atoms of **Ni-1** are highly reactive with alkylating reagents, and in the case of sodium haloacetate salts, the **Ni-1** species yielded the octahedral $N_2S_2O_2$ complex shown in Equation 1.[8]



Given the relevance of these results to the [NiFe]H_2ase cysteine modification described above, we have explored similar reactions of **Ni-1** as well as the sterically more hindered *N*,*N*′-bis(2-mercapto-2-methylpropane)-1,5-diazacyclooctanenickel(II) (**Ni-1***) with iodoacetamide. Described below are the fully characterized products of **Ni-1*** reactions with one and two equivalents of iodoacetamide. The X-ray crystal structures will show the two possibilities of S-modification, i.e., with and without additional coordination of functional groups.

Results and Discussion

Syntheses and Solution Properties

In contrast to the reactions[8] of $XCH_2CO_2^-Na^+$ (X = Cl, I) with the parent (bme-daco)Ni (**Ni-1**) complex for which a monoalkylated complex could not be isolated (Equation 1), both the mono- and dialkylated species of **Ni-1** and the sterically encumbered **Ni-1*** have been isolated using iodoacetamide as the alkylating agent. Scheme 3 summarizes the synthetic procedures and stick-drawn structures resulting from structural characterization in the solid state (vida infra).

Scheme 3. Reactions of **Ni-1** and **Ni-1*** with one and two equivalents of iodoacetamide

As depicted in Scheme 3, the monoacetamide derivative of **Ni-1***, **[(AA)Ni-1*][I]**, is a four-coordinate pseudo-square planar complex and is soluble in most polar solvents including H_2O, MeOH and MeCN, all of which result in green solutions. In contrast, the brown solid **[(AA)Ni-1][I]** yields brown solutions in the same solvents. Minor differences in color are also seen for the **[(Me)Ni-1*][I]**[9] and **[(Me)Ni-1][I]**[10] species and are reflected in the d-d transitions as seen in Table 1 (see entries 3, 5, 7 and 9). The molar conductivities of **[(AA)Ni-1*][I]** and **[(AA)Ni-1][I]**,

measured in MeCN, are 166 and 161 S/cm·mol respectively, extrapolated to infinite dilution; these values fall in the range of uni-uni electrolyte solutions in CH_3CN[13] and indicate complete ionization of iodide in solution. Thus, we conclude that both **[(AA)Ni-1*][I]** and **[(AA)Ni-1][I]** are four-coordinate monocations in solution and the difference in color results from differences in ligand fields (see below).

The dialkylated products **[$(AA)_2$Ni-1*][I_2]** and **[$(AA)_2$Ni-1][I_2]** were isolated as blue solids with UV/Vis-spectral properties similar to those of **[$(Ac)_2$Ni-1]** (see entries 4, 6 and 11 of Table 1). For comparison, the dimethylated, four-coordinate derivatives **[$(Me)_2$Ni-1*][I_2]** and **[$(Me)_2$Ni-1][I_2]** have significantly different UV/Vis properties (entries 8 and 10 in Table 1) consistent with the conclusion that **[$(AA)_2$Ni-1*][I_2]** and **[$(AA)_2$Ni-1][I_2]** are six-coordinate complexes with Ni^{2+} in an $N_2S_2O_2$ coordination environment. **[$(AA)_2$Ni-1*][I_2]** and **[$(AA)_2$Ni-1][I_2]** are only slightly soluble in MeCN and are quite soluble in H_2O and MeOH, all of which yield blue solutions.

Table 1. UV/Vis[a] and IR[b] spectroscopic data (AA = *S*-acetamide; Ac = *S*-acetate; sh = shoulder)

Infrared Spectroscopy

Table 1 also lists the ν(C=O) stretching frequencies for acetamide, $CH_3C(=O)NH_2$, and for the complexes derivatized with iodoacetamide. The monoacetamide derivatives exhibit ν(C=O) values similar to free acetamide (entries 3, 5 and 12 in Table 1) whereas the diacetamide derivatives (entries 4 and 6 in Table 1) show a decrease of ca. 35 cm^{-1} in ν(C=O) relative to the monoacetamide complexes. This is consistent with the UV/Vis-spectroscopic results which suggest that oxygen binds to the nickel only in the case of the dialkylates **[$(AA)_2$Ni-1][I_2]** and **[$(AA)_2$Ni-1*][I_2]**. Thus, ν(C=O) is diagnostic for amide oxygen coordination to a metal center. Such shifts in the carbonyl stretching frequencies have been observed for other complexes with ligating amido groups.[14]

Electrochemistry

The cyclic voltammogram of **[(AA)Ni-1*][I]**, Figure 1, shows an irreversible cathodic event at $E_{pc} = -1.30$ V (vs NHE) and two oxidations ascribed to iodide electrochemistry. Figure 2, the cyclic voltammogram of **[$(AA)_2$Ni-1*][I_2]**, shows a quasi-reversible cathodic event at $E_{1/2} = -0.89$ V as well as a quasi-reversible anodic event at $E_{1/2} = +1.44$ V; two oxidations and one reduction due to iodide (or I_3^-) are also present.

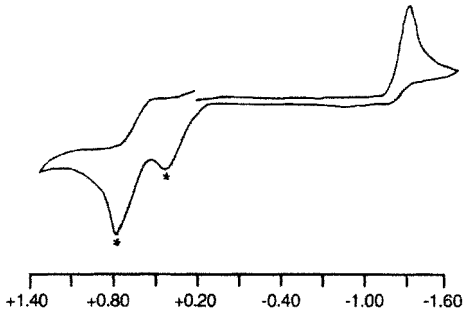

Figure 1. Cyclic voltammogram of **[(AA)Ni-1*][I]** in CH_3CN; all potentials referenced to NHE (* = peaks arising from iodide counterion)

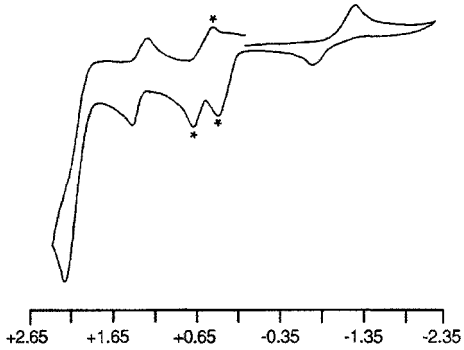

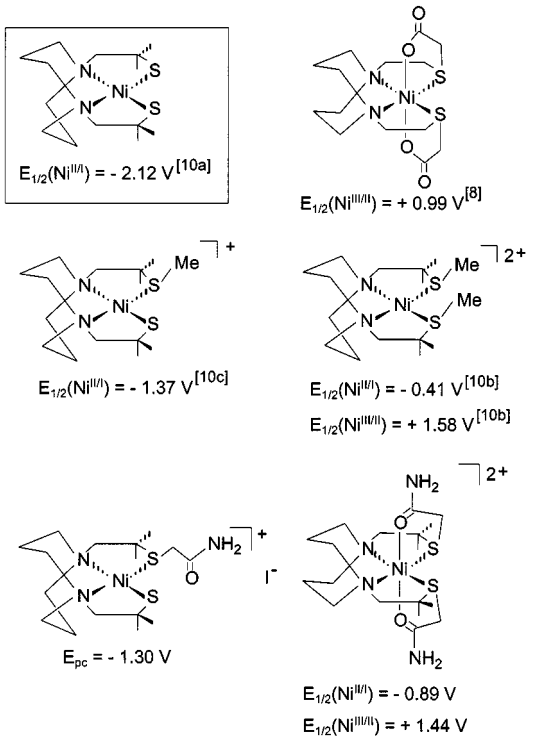

Figure 2. Cyclic voltammogram of **[$(AA)_2$Ni-1*][I_2]** in CH_3CN; all potentials referenced to NHE (* = peaks arising from iodide counterion)

Scheme 4 presents the previously well-defined redox couples of the four-coordinate methyl thioether derivatives **[(Me)Ni-1*][I]**[9] and **[$(Me)_2$Ni-1*][I_2]**[12] and the six-coordinate diacetate derivative **[$(Ac)_2$Ni-1]** for comparison to those of the acetamide complexes **[(AA)Ni-1*][I]** and **[$(AA)_2$Ni-1*][I_2]**.[15] The square planar monomethyl derivative has an $Ni^{II/I}$ redox couple ca. 750 mV more positive than that of the **Ni-1*** dithiolate precursor, while the dimethyl derivative, the dication, shows an additional positive gain of +960 mV. The enhanced accessibilities of the $Ni^{II/I}$ redox couples are attributed mainly to the positive charge resulting from successive *S*-methylations and the transformation of anionic thiolates into neutral thioether donors.[10] Consistent with this is the observation that the $Ni^{II/I}$ reduction of the neutral **[$(Ac)_2$Ni-1]** complex is not observed

when scanned to −2.0 V in CH_3CN. The increased electron density on the nickel center provided by the two anionic axial donors accounts for the negative shift.

Scheme 4. Comparison of the $Ni^{II/I}$ reduction potentials ($E_{1/2}$ vs. NHE) of **[(AA)Ni-1*][I]** and **$[(AA)_2$Ni-1*$][I]_2$** with those of **[(Me)Ni-1*][I]**, **$[(Me)_2$Ni-1*$][I]_2$**, and **$[(Ac)_2$Ni-1]**

The similarity in reduction potentials of **[(AA)Ni-1*][I]** and the $Ni^{II/I}$ redox couple of **[(Me)Ni-1*][I]** suggests that the ligand environments, geometries, and charges are nearly the same in the two complexes. The dialkylated compounds differ. The increased electron density on the nickel center in the octahedral complex accounts for the relative difficulty (by ca. 480 mV) in the reduction of **$[(AA)_2$Ni-1*$][I]_2$** as compared to the four-coordinate **$[(Me)_2$Ni-1*$][I]_2$**, Scheme 4. Nevertheless, the $Ni^{II/I}$ couple of the dication is at minimum 1.1 V more positive than that of the neutral **$[(Ac)_2$Ni-1]** complex.

The anodic events for the **$[(Me)_2$Ni-1*$][I]_2$**, **$[(AA)_2$Ni-1*$][I]_2$** and **$[(Ac)_2$Ni-1]** complexes, Scheme 4, are assigned as metal-based oxidation, presumably $Ni^{II/III}$. The quasi-reversible oxidation wave for **$[(AA)_2$Ni-1*$][I]_2$** is closer in value to **$[(Me)_2$Ni-1*$][I]_2$** (ca. 140 mV more accessible) than to **$[(Ac)_2$Ni-1]** (ca. 440 mV less accessible). These results indicate that both the $Ni^{II/I}$ and the $Ni^{II/III}$ redox potentials are predominantly determined by the charge of the complex, with the addition of axial donor groups providing a lesser perturbation. The greater difference in the $E_{1/2}$ of the $Ni^{II/I}$ couples in **$[(Me)_2$Ni-1*$][I]_2$** and **$[(AA)_2$Ni-1*$][I]_2$** as compared to the difference in $E_{1/2}$ of the $Ni^{II/III}$ couples may be attributed to the following: 1) unlike the hexadentate ligand, the tetradentate N_2S_2 ligand has some capability to distort toward tetrahedral which eases the $Ni^{II/I}$ reduction; and 2) little, if any, ligand distortion is required to accommodate Ni^{3+}.

Molecular Structures

A portion of the crystal packing for **[(AA)Ni-1*][I]** is given in Figure 3 to highlight the intermolecular N···H···O interactions. Each complex cation is H-bonded to an adjacent cation via the carbonyl oxygen atoms and amide hydrogen atoms with N···O distances of 2.60(1) Å. These cations are stacked such that the pseudo six-membered cyclic structures form a channel through the lattice. The cyclic structure itself bonds externally to two iodide ions as seen in the N···I distance of 3.365(1) Å.

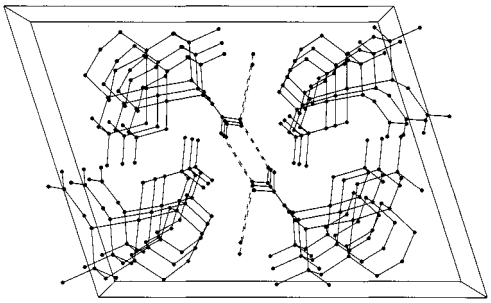

Figure 3. A portion of the crystal packing diagram of **[(AA)Ni-1*][I]** showing intermolecular hydrogen bonding; the hydrogen atoms have been omitted for clarity

Two iodide counterions and one CH_3CN solvent molecule co-crystallize with the complex cation **$[(AA)_2$Ni-1*$]^{2+}$**. The packing diagram for this salt indicates that a weak hydrogen bonding array exists between the amide hydrogen atoms and the iodide ions [I···N distances of 3.55(1) and 3.53(1) Å]; the solvent of crystallization does not appear to be involved in H-bonding.

Figures 4 and 5 display the molecular structures of the coordination complex cations of **[(AA)Ni-1*][I]** and **$[(AA)_2$Ni-1*$][I]_2$**; selected bond lengths and angles for each complex are given in Table 2. The singly alkylated compound, **[(AA)Ni-1*][I]** is four-coordinate and greatly distorted from the regular square planar geometry of the parent dithiolate complex, **Ni-1***. Despite the rigidity of the bme*-daco ligand, this distortion, a 13.6° tetrahedral twist (see Table 2 footnote), is among the largest observed for the collection of **Ni-1** and **Ni-1*** four-coordinate derivative complexes.[10−12,16] The Ni−S(2) (thioether S) distance is only slightly elongated from the Ni−S(1) (thiolate S) distance and from the average Ni−S distance [2.152(1) Å] in **Ni-1***.[11] There is no significant difference in the average Ni−N distances between **[(AA)Ni-1*][I]** and **Ni-1*** [1.995(3) Å]. Like most four-coordinate **Ni-1** and **Ni-1*** derivatives, the diazacyclooctane backbone in **[(AA)Ni-1*][I]** adopts a chair-boat configuration.

The expansion in the coordination sphere of the octahedral **$[(AA)_2$Ni-1*$][I]_2$** relative to the four-coordinate **[(Me)Ni-1*][I]** complex is seen primarily in the Ni−S dis-

N_2S_2 plane distortion[a]	13.6	6.5

[a] The N_2S_2 plane distortion angles are measured as the angle of intersection of the normals of the S(1)−X−S(2) and N(1)−X−N(2) planes, where X is the centroid of the N_2S_2 plane. As the nickel atom is not necessarily equidistant from the nitrogen and sulfur atoms, the centroid rather than Ni is used to define the planes.

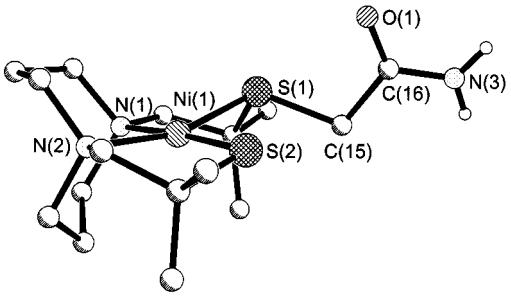

Figure 4. Ball-and-stick structure of **[(AA)Ni-1*][I]**; the iodide counterion and hydrogen atoms bonded to carbon atoms are omitted

tances (lengthened by ca. 0.3 Å). The axial atom that is bound to the nickel center also forms the shortest bond to the amide carbon atom and is thus assumed, consistent with the IR assignment above, to be O. In both **[$(AA)_2$Ni-1*][I]$_2$** and **[$(Ac)_2$Ni-1]** the diazacyclooctane framework adopts the chair-chair configuration commonly seen in other six-coordinate **Ni-1** and **Ni-1*** derivatives in which the central methylene carbon atoms are oriented towards each other and away from the $N_2S_2O_2Ni$ coordination sphere.[8,16b,17−19]

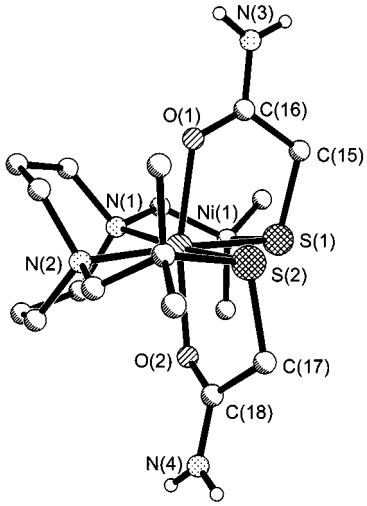

Figure 5. Ball-and-stick structure of **[$(AA)_2$Ni-1*][I]$_2$**; the iodide counterions, the solvent of crystallization and hydrogen atoms bonded to carbon atoms are omitted

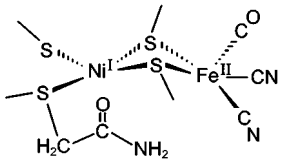
Exposure to Acetylene

There are several reports of reactions of metal sulfides with acetylene to produce enedithiolates.[20] Thus, acetylene was bubbled through a CH_3CN solution of **Ni-1*** and the resultant mixture was monitored by UV/Vis spectroscopy. After 25 minutes, the spectrum of the solution was nearly identical to that of a solution containing only **Ni-1***. At that point, the addition of one equivalent of iodoacetamide caused a color change from purple to brown; the UV/Vis spectrum was found to be identical to that of **[(AA)Ni-1*][I]**. The implication is that acetylene does not inhibit or block alkylation by iodoacetamide in the Ni^{II} dithiolate complex.



Conclusion

The *cis*-dithiolates **Ni-1** and **Ni-1*** demonstrate S-nucleophilicity with iodoacetate and iodoacetamide, forming S−C bonds and at least the potential for extending the denticity of the modified N_2S_2 ligand. In all cases the thioether S-donors remain coordinated to the nickel center. Both acetamide derivatives of **Ni-1*** show positive $Ni^{II/I}$ redox couple shifts relative to the parent dithiolate, accountable mainly to increased positive charge on the complexes. In the diacetamide derivatives of **Ni-1** and **Ni-1*** the identity of the axial donor atoms as the amide oxygen atoms was suggested by X-ray crystallography and confirmed by IR spectroscopy.

Despite the excellent nucleophilicity of the *cis*-dithiolates of **Ni-1***, the presence of acetylene did not inhibit alkylation by iodoacetamide. Two possible explanations for the reported[3] protection by acetylene of the nickel-iron heterometallic site of *T. roseopersicina* [NiFe]H_2ase from iodoacetamide deactivation are as follows: 1) acetylene might serve as a molecular block which prevents iodoacetamide access to the active site; or 2) in the reduced state of the enzyme,

presumably containing Ni^{I}, acetylene might reversibly bind to the cysteine thiolates or the nickel center to prevent alkylation.

The model study above finds that terminal thiolates bound to nickel(II) are reactive with alkylating agents and maintain Ni−S(thioether) coordination. It is expected that thiolates bound to Ni^{I}, the presumed oxidation state of Ni in the reduced active form, will show similar if not enhanced reactivity. It should be noted that the structural and molecular dynamics studies[5] of the [NiFe]H_2ase enzyme were performed on coordinates derived from the oxidized, inactive form. The active, reduced form of the enzyme could have a modified access channel, one that is more accessible to larger molecules. Thus, *assuming* the iodoacetamide moiety can reach the active site Ni(S−Cys)$_2$ unit, a possible structure of the iodoacetamide-alkylated, heterobimetallic site is depicted in Scheme 5. Amide-O coordination to the nickel center forming a distorted square pyramid (not shown), could be another possible consequence of alkylation. Additionally, the open site of the d^6 iron center expected in the reduced form of the enzyme (i.e., the μ-OH group is lost)[4] could present another amide-O binding site. In any case, *S*-alkylation would disrupt the 4 to 5 Å segment which blocks access to the active site from the gas access channel. The fact that the H/D exchange reaction of H_2/D_2O is lost in the chemically modified protein is consistent with proposals that hydrogen activation takes place at the terminal Ni(S−Cys)$_2$ unit,[21] or at the open site on the iron center. On the other hand, our studies have shown that a dramatic change in redox potentials occurs upon conversion of a thiolate to a thioether by iodoacetamide alkylation. Such a redox change is expected to overwhelm the entire range of [NiFe]H_2ase activity, influencing whatever site and mechanism is operative for H_2/H^+ catalysis.

Scheme 5. One possible structural consequence of iodoacetamide alkylation at a terminal Ni(S-Cys) residue in [NiFe]H_2ase

It is noteworthy that the iodoacetamide deactivation of the zinc-metalloenzyme MetE occurs at a particular cysteine unit (Cys726), known to be bound to zinc.[2] In this case a similar chemical process of *S*-alkylation undoubtedly blocks the transfer of the methyl group from 5-methyltetrahydrofolate to homocysteine. That is, changes in redox properties are not mechanistic options.

While the Vignais study[3] suggests the possibility of active-site cysteine modification, the identity of the modified residues was not determined in the [NiFe]H_2ase examined. Histidine and carboxylate residues, reasonably good nucleophiles, are known to be somewhat reactive with alkylating agents. The modification of these and/or cysteine residues far remote from the active site could cause structural changes in the protein which might severely disrupt the active site or prevent substrate from binding. Thus, despite the clear-cut evidence offered above and elsewhere for nickel-bound thiolate reactivity, there may be factors other than active-site modification which can lead to enzyme deactivation.

Experimental Section

General Procedures: Although the products are air-stable, they are somewhat hygroscopic and should be handled using standard Schlenk or syringe techniques using N_2 (passed through a drying tube of $CaSO_4$, molecular sieves and NaOH) or an Ar-filled glovebox (Vacuum Atmospheres). Solvents were dried according to published procedures[22] and distilled under N_2. Acetonitrile was distilled once from CaH_2 and twice from P_2O_5 and freshly distilled from CaH_2 immediately before use. Reagent grade iodoacetamide (Aldrich) was used as received.

Physical Measurements: UV/Vis spectra were measured with a Hewlett-Packard 8452A diode array spectrophotometer and quartz cells of path length 1.00 cm. Infrared spectra were recorded as KBr pellets (unless otherwise specified) using an IBM IR/32 Fourier transform single-beam spectrophotometer. Elemental analyses were performed by Canadian Microanalytical Services, Delta, British Columbia, Canada. Conductance measurements were performed with an Orion Model 160 conductance meter. − Cyclic voltammograms were recorded with a BAS-100A electrochemical analyzer using $Ag^0/AgNO_3$ reference and glassy carbon working electrodes with 0.1 M tetra-*n*-butylammonium hexafluorophosphate (TBAHFP) supporting electrolyte in CH_3CN with a platinum wire auxiliary electrode. The potentials were referenced to NHE using ferrocene (+400 mV vs NHE).

Syntheses: The **Ni-1*** and **Ni-1** complexes were synthesized and purified according to published procedures.[23] Iodoacetamide was stored inside a glovebox refrigerator (−30°C) and weighed out in the glovebox immediately before use. Unless otherwise stated all reactions were performed under N_2 and at ambient temperature (22°C).

[(AA)Ni-1*][I]: Iodoacetamide (10 mg, 0.054 mmol) was dissolved in dry CH_3CN (5 mL) and transferred to a purple 5-mL acetonitrile solution containing one equivalent of **Ni-1*** (19 mg, 0.055 mmol). A color change from purple to green was immediately observed. The solution was stirred for 6 h during which time no further color change occurred. The reaction mixture was transferred via cannula to a double test tube for ether diffusion. Red brown crystals of suitable for X-ray diffraction were obtained (yield 34%). − $C_{16}H_{32}IN_3NiOS_2$ (532.18): calcd. (found) C 36.1 (36.1), H 6.06 (5.89), N 7.90 (7.85). − FT IR (KBr): ν [$^{-1}$] = 3304, 3140, 1684. − UV/Vis (MeOH): λ_{max} [nm] (ε) = 224 (20626), 264 (7967), 308 (7262), 456 (124), 604 (51).

1,5-Diazacyclooctane-1,5-diylbis(2,2-dimethyl-3-thiapentanamide)-nickel(II) Iodide {[(AA)$_2$Ni-1*][I]$_2$}: As described above, iodoacetamide (20 mg, 1.08 mmol) in 5 mL of CH_3CN was transferred to a 5-mL CH_3CN solution containing 1/2 equivalent of **Ni-1*** (19 mg, 0.055 mmol). A color change from purple to green was observed and the solution was stirred for 48 h to assure complete reaction. The green solution was transferred via cannula to a double test tube for ether diffusion. Dark blue crystals suitable for X-ray diffraction were obtained (yield 27%). − $C_{18}H_{36}I_2N_4NiO_2S_2 \cdot CH_3CN$ (758.19): calcd. (found) C 31.7 (31.7), H 5.18 (5.10), N 9.23 (9.08). − FT IR (KBr): ν [$^{-1}$] = 3236, 3100, 1645, 1591. − UV/Vis

(MeOH): λ_{max} [nm] (ε) = 220 (19914), 258 (7158), 356 (29), 580 (23).

[(AA)Ni-1][I]: As described above a 10-mL CH_3CN solution of iodoacetamide (140 mg, 0.76 mmol) was transferred to a 40-mL CH_3CN solution of **Ni-1** (220 mg, 0.76 mmol). A color change from purple to dark brown was observed and the solution was stirred for 6 h. The solvent was removed in vacuo. The remaining brown solid was dissolved in dry MeOH (ca. 10 mL) and orange-brown crystals were formed from diethyl ether diffusion (yield 5.6%). − $C_{12}H_{24}IN_3NiOS_2$ (476.07): calcd. (found) C 30.3 (30.5), H 5.08 (5.05), N 8.83 (8.73). − FT IR (KBr): ν [$^{-1}$] = 3362, 3244, 3167, 1676, 1604. − UV/Vis (MeOH): λ_{max} [nm] (ε) = 224 (20048), 304 (7970), 472 (137), 592 (53).

1,5-Diazacyclooctane-1,5-diylbis(3-thiapentamide)nickel(II) Iodide {[$(AA)_2$Ni-1][$I]_2$}: Similarly, a 10-mL CH_3CN solution of iodoacetamide (195 mg, 1.05 mmol) was transferred to a solution of **Ni-1** (153 mg, 0.525 mmol) in 40 mL of CH_3CN. An immediate color change from purple to dark brown was followed by development of a blue color and then a precipitate formed over the course of 12 h. The supernatant was removed via cannula and the precipitate washed twice with dry acetonitrile (2 × 10 mL). The product was dissolved in dry MeOH (ca. 10 mL) and dark blue crystals were formed upon diethyl ether diffusion (yield 49%). − $C_{14}H_{28}I_2N_4NiO_2S_2 \cdot CH_3OH$ (693.08): calcd. (found) C 26.0 (25.8), H 4.65 (5.10), N 8.08 (8.16). − FT IR (KBr): ν [$^{-1}$] = 3240, 3125, 1649, 1590. − UV/Vis (MeOH): λ_{max} [nm] (ε) = 220 (18836), 254 (7182), 362 (51), 580 (36).

Iodoacetamide Addition to Ni-1 in the Presence of Acetylene: A 2.5-mL aliquot of a 5 mM MeCN solution of **Ni-1*** (4.3 mg, 12.5 μmol) was transferred via cannula to a UV/Vis cell. The cell was stoppered with a rubber septum and acetylene was bubbled through the solution for 25 min and the UV/Vis spectrum was recorded; it was identical to that of **Ni-1***. A 0.2-mL portion of a 62.5 mM MeCN solution of iodoacetamide (2.3 mg, 12.5 μmol) was added to the cell via syringe; the acetylene purge was resumed. After ca. 20 min, the solution color had changed from purple to brown; the acetylene bubbling was discontinued and the UV/Vis spectrum was taken. The final UV/Vis spectrum of the **Ni-1***, acetylene and iodoacetamide mixture was identical with that of isolated **[(AA)Ni-1*][I]**.

X-ray Crystallography and Structure Solution: The X-ray crystal structure analyses were carried out at the Crystal & Molecular Structure Laboratory Center for Chemical Characterization and Analysis at Texas A&M University. Crystallographic data for the complexes **[(AA)Ni-1*][I]** and **[$(AA)_2$Ni-1*][$I]_2$** are listed in Table 3; selected parameters are listed in Table 2. Preliminary examinations and data collections were performed with a Siemens P4 X-ray diffractometer. The structures were solved by direct methods [SHELXS, SHELXTL-93].[24] Both compounds crystallize in the monoclinic space group $P2_1/c$. **[(AA)Ni-1*][I]** crystallizes with two orthogonal orientations of the Ni complex relative to the iodide positions in the asymmetric unit. This produces a disordered structure. The Ni position is common to both disordered structures. The disordered portions of the Ni complex are related by a pseudo two-fold axis parallel to the a^* axis and running through the Ni atoms. Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Center as supplementary publication nos. CCDC-102633 and -102634. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: int. code + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

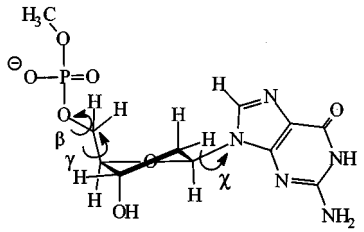
Multinuclear NMR Study of the Conformational Changes in Me*p*dG and dG*p*Me upon Interaction with Mg^{2+}, Zn^{2+} and Hg^{2+} Ions Reveals the Strengthening of the Anomeric Effect by Soft M^{2+} Ions

Matjaž Polak[a] and Janez Plavec*[a]

Keywords: Nucleotides / Conformation analysis / NMR spectroscopy / Pseudorotational equilibrium / Anomeric effect

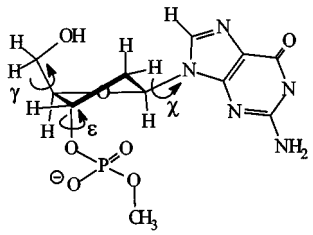
A conformational study is reported on 2′-deoxyguanosine 5′-methylmonophosphate [Me*p*dG (**1**)] and 2′-deoxyguanosine 3′-methylmonophosphate [dG*p*Me (**2**)] and their interactions with Mg^{2+}, Zn^{2+} and Hg^{2+} ions. The conformation of Me*p*dG (**1**) and dG*p*Me (**2**) in D_2O solution was inferred from vicinal proton-proton, proton-phosphorus and carbon-phosphorus NMR coupling constants and nuclear Overhauser effects (NOE). The chemical shift changes showed that hard Mg^{2+} ions interact preferentially with the phosphate oxygen atoms in Me*p*dG (**1**), whereas in the case of dG*p*Me (**2**) the interaction with the phosphate oxygen atoms competes with the interaction to the C6=O carbonyl group. Softer Zn^{2+} and Hg^{2+} ions were found to show strong binding affinity towards N7 in both Me*p*dG (**1**) and dG*p*Me (**2**). Analysis of *J* coupling constants and NOEs measured as a function of metal ion concentration revealed that: (i) N $\rightleftarrows$ S pseudorotational equilibria are biased towards C2′-*endo* pseudorotamers in M^{2+}-free Me*p*dG (**1**) and dG*p*Me (**2**) by 68% and 75% at 298K, respectively. Titration of Me*p*dG (**1**) and dG*p*Me (**2**) with Mg^{2+} ions caused no observable changes in N $\rightleftarrows$ S pseudorotational equilibrium, whereas the interactions of Zn^{2+} and Hg^{2+} ions with N7 resulted in the shift towards N-type pseudorotamers which can be explained by the strengthening of the anomeric effect as softer metal ions bind to N7 and make the imidazole moiety less electron-rich. (ii) The binding of divalent metal ions to Me*p*dG (**1**) and dG*p*Me (**2**) causes a shift of the *syn* $\rightleftarrows$ *anti* equilibrium towards *anti*, which is larger for softer Zn^{2+} than for harder Mg^{2+} ions. (iii) The conformational equilibrium across the C4′–C5′ bond (γ torsion) in dG*p*Me (**2**) is not affected by the increased concentration of M^{2+} ions. (iv) β^t conformers are preferred by ca. 77% in aqueous solution of Me*p*dG (**1**) and only small changes of ca. 1 percentage point in β^t population have been found upon metal ion binding to Me*p*dG (**1**). (v) The two-state $\varepsilon^t \rightleftarrows \varepsilon^-$ conformational equilibrium is biased towards ε^t rotamers by 63.5% in dG*p*Me (**2**). Interaction of hard Mg^{2+} and softer Zn^{2+} or Hg^{2+} ions with dG*p*Me (**2**) resulted in the minor increase (< 3 percentage points) in the population of ε^t conformers.

Introduction



The structure and function of nucleic acids depend on metal ions. A knowledge of the effects of metal species on DNA structures is important in understanding the natural role of metal species.[1] Monovalent alkaline cations and divalent alkaline-earth metal cations interact preferentially with the phosphate groups, which stabilizes the DNA double duplex by neutralizing the negatively charged sugar-phosphate backbone, and to a lesser extent with the bases.[2] Interactions of divalent cations with nucleobases are involved in many biophysical processes and can cause polarization of nucleobases associated with the stabilization of certain hydrogen bonds between A=T and G≡C Watson-Crick base pairs as well as Hoogsteen base pairs in triplex DNA. Little is, however, known in the literature about how the interaction of metal ions with particular nucleotide in oligomeric fragment affects its conformation and how this local conformational change is transmitted into reorganization of the three-dimensional structure. In order to study local conformational changes induced by metal ions we have prepared two simple mononucleotide models of DNA, Me*p*dG (**1**) and dG*p*Me (**2**), which consist of all the essential structural elements of DNA to which metal ions can interact: β-D-2′-deoxyribofuranose, the phosphodiester fragment and the heterocyclic moiety.

The phosphodiester groups in Me*p*dG (**1**) and dG*p*Me (**2**) carry one negative charge at neutral pH and are expected not to overestimate the effect of electrostatic association of metal ions and a nucleotide on the structural change of nucleic acids. With the use of high-field multinuclear ^{1}H-, ^{13}C-, ^{15}N- and ^{31}P-NMR spectroscopy we were able to identify the binding sites for the individual metal ions on Me*p*dG (**1**) and dG*p*Me (**2**), and to examine the conformational changes along the glycosyl bond (*syn* $\rightleftarrows$ *anti* equilibrium, torsion angle χ), pseudorotational equilibrium of sugar moiety between North- and South-type conformers, reorientation along C4′−C5′ bond (torsion angle γ) and the conformational equilibria along phosphodiester fragments with torsion angles β[P−O5′−C5′−C4′] and ε[C4′−C3′−O3′−P] in Me*p*dG (**1**) and dG*p*Me (**2**), respectively.



According to the pseudorotation concept[3] the furanosyl ring in nucleosides and nucleotides[4,5] is involved in interconversions of puckered envelope and twist forms. The puckering mode can be defined by Altona−Sundaralingam parameters[4,5] which are the phase angle of pseudorotation (*P*) and the maximum puckering amplitude (Ψ_m). *P* defines

Figure 1. Structural formula of MepdG (**1**) and dGpMe (**2**)

the part of the ring which is most puckered and Ψ_m indicates the extent of the puckering. In a survey of X-ray crystal structures[6] of nucleosides and nucleotides sugar moieties were found in both North (N) and South (S) conformations. The former range ($0° < P < 36°$) is centered around $P = 18°$ (C3′-*endo*), whereas the latter ($144° < P < 180°$) is centered around $P = 162°$ (C2′-*endo*). The values of Ψ_m were found in a range from 30° to 46°.[6] A large collection of NMR data is consistent with the conformational equilibrium between two distinctly identifiable N and S conformations which are dynamically interconverting in solution. Two-state N $\rightleftharpoons$ S pseudrotational equilibrium is controlled by the competing anomeric and *gauche* effects.[7] The 3′-OH or 3′-phosphate groups in 2′-deoxynucleos(t)ides drive the N $\rightleftharpoons$ S equilibrium towards S-type conformation through the tendency to adopt a *gauche* orientation of the [O4′−C4′−C3′−O3′] torsion angle.[7,8] The heterocyclic bases are involved in the anomeric effect which results in the energetic preference of N-type (pseudoaxial nucleobase) over S-type (pseudoequatorial nucleobase) conformation in terms of the anomeric effect alone. The anomeric effect in nucleosides involves the interaction between the non-bonded lone pairs of O4′ and the antibonding σ* orbital of the glycosyl bond (*i.e.* $n_{O4'} \rightarrow \sigma^*_{C1'\text{-}N}$ orbital overlap) and its strength is closely related to the electronic nature of the aglycone.[7,9−15] The protonation of the nucleobase facilitates the $n_{O4'} \rightarrow \sigma^*_{C1'\text{-}N}$ interactions, thereby resulting in the increased population of N-type conformers.[12−14,16] We have already shown in our preliminary study on the conformational changes induced by metal ion binding to 2′-dG that Zn^{2+} and Hg^{2+} bind to N7 and shift the N $\rightleftharpoons$ S pseudorotational equilibrium towards N by 0.8 percentage points ($R = 2.0$) and 4.1 percentage points ($R = 0.2$), respectively.[17] In the present study we have chosen three divalent metal ions (Mg^{2+}, Zn^{2+} and Hg^{2+}) which differ in their soft-hard nature and are known to have distinct binding modes to nucleic acids. Hard metal ions like Mg^{2+} are expected to bind to phosphate oxygen atoms in MepdG (**1**) and dGpMe (**2**), which would alter the strength of the [O4′−C4′−C3′−O3′] *gauche* effect in dGpMe (**2**) in particular and should change the population of S-type conformers in dGpMe (**2**). On the other hand, possible binding of Mg^{2+} to C6=O of guanine ring[18] would change the electron distribution in the purine moiety and thus specifically affect the N $\rightleftharpoons$ S pseudorotational equilibrium through the modulation of the anomeric effect. Soft metal ions like Hg^{2+} will bind to N7 of the guanine ring which is expected to increase the population of the N-type conformers due to the strengthening of the anomeric effect. It is, however, hard to predict how the increase in the steric bulk due to soft metal ion binding to N7 of MepdG (**1**) and dGpMe (**2**) would additionally shift the N $\rightleftharpoons$ S pseudorotational equilibrium towards S. Zn^{2+} is expected to have affinities for both the nucleobase and the phosphate groups and is therefore expected to change both the anomeric effect as well as the strength of the [O4′−C4′−C3′−O3′] *gauche* effect.

Results and Discussion

Binding Sites

The affinity of metal ions towards the specific electron-rich sites in MepdG (**1**) and dGpMe (**2**) has been studied by monitoring the changes in their ^1H, ^{13}C, ^{15}N and ^{31}P NMR chemical shifts as the concentration of Mg^{2+}, Zn^{2+} and Hg^{2+} ions was gradually increased to 0.1, 0.2, 0.5, 1.0 and 2.0 molar equivalents. Titration of MepdG (**1**) and dGpMe (**2**) with two molar equivalents of Mg^{2+} ions resulted in a very small chemical shift change of a few ppb for the H8 signal (Figure 2), which indicates the absence, or possibly very weak interaction of Mg^{2+} with N7 of the guanine moiety.[19] In addition, the small ^1H-, ^{13}C- and ^{15}N-NMR$\Delta\delta$ values reported in Table 1 for MepdG (**1**) indicate a very weak interaction of Mg^{2+} ions with the pentofuranose moiety, phosphodiester or the heterocyclic ring in MepdG (**1**). On the other hand, the addition of two molar equivalents of Mg^{2+} ions to dGpMe (**2**) caused a downfield shift of 0.143 ppm for the C6 signal, which suggests an interaction of Mg^{2+} ions with the C6=O carbonyl oxygen atom under neutral pH. We have furthermore detected changes of 0.4 Hz in $^2J_{PC5'}$ and $^2J_{PCH3}$ coupling constants for MepdG (**1**), which indicate that Mg^{2+} ions interact with oxygen atoms of the phosphate group and possibly influence rotamer population across β (vide infra).

Titration of MepdG (**1**) and dGpMe (**2**) with up to two molar equivalents of Zn^{2+} ions resulted in the progressive downfield shift of the H8 signal (Figure 2). The affinity of Zn^{2+} aqua ions to bind to N7 of the nucleobase[20] has been independently confirmed with ^{13}C- and ^{15}N-NMR data (Table 1). The ^{31}P chemical shifts of MepdG (**1**) and

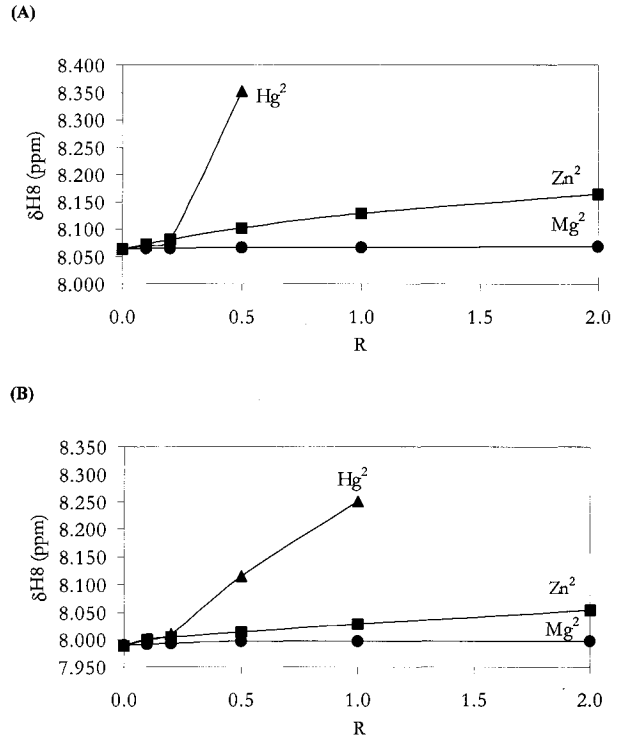

Figure 2. Changes of H8 chemical shifts as a function of increasing metal ion concentration in D_2O solution of Me*p*dG (**1**) (panel A) and dG*p*Me (**2**) (panel B); in the case of Hg^{2+} ions the precipitation precludes the extraction of NMR chemical shifts above R = $[M^{2+}]$/[nucleotide] = 1.0

dG*p*Me (**2**) moved upfield by 0.095 ppm and 0.018 ppm, respectively, upon addition of two molar equivalents of Zn^{2+} ions which suggests that the coordinative interaction between Zn^{2+} and phosphate oxygen atoms is negligible. It is noteworthy that chelation[21−26] of N7 and α-PO_4 monoester in 6-oxopurine nucleotide monophosphates by Pt^{2+} resulted in a downfield Δδ(^{31}P) shift of 3.5 ppm.[21] The ^{31}P chemical shifts are, however, sensitive[27] to bond angle changes, conformational changes along α and ζ and environmental effects, and are therefore difficult to correlate with the strength of binding of metal ions with phosphate groups. The addition of more than 0.2 molar equivalents of Hg^{2+} ions to the aqueous solutions of Me*p*dG (**1**) or dG*p*Me (**2**) resulted in the broadening of ^{1}H-NMR signals probably due to macrochelation, which was followed by precipitation after the addition of one molar equivalent of Hg^{2+} ions. The downfield shifts of H8 resonances upon addition of Hg^{2+} ions were much larger than in the case of Zn^{2+} (Figure 2) which is in agreement with the softer nature of Hg^{2+} ions and indicates strong binding affinity towards N7 (Table 1).

North ⟺ South Pseudorotational Equilibrium

The analysis of the solution conformation of the 2′-deoxy-β-D-ribofuranosyl moiety in Me*p*dG (**1**) and dG*p*Me (**2**) is based on five ($^3J_{1'2'}$, $^3J_{1'2''}$, $^3J_{2'3'}$, $^3J_{2''3'}$ and $^3J_{3'4'}$) proton-proton coupling constants (Table 2) which have been interpreted in terms of a two-state N ⟺ S pseudorotational equilibrium, as is normal for 2′-deoxyribose rings (see Experimental Section).[4,5,29−31] The titration of both Me*p*dG (**1**) and dG*p*Me (**2**) with Mg^{2+} ions caused no observable changes in $^3J_{HH}$ coupling constants (Table 2). In the case of Zn^{2+} and Hg^{2+} ions, we observed considerable changes in $^3J_{HH}$ coupling constants, which indicated that the N ⟺ S pseudorotational equilibrium were perturbed

Table 1. The comparative effects of Mg^{2+}, Zn^{2+} and Hg^{2+} ions on the ^{1}H-, ^{13}C-, ^{31}P- and ^{15}N-NMR chemical shifts[a] of Me*p*dG (**1**) and dG*p*Me (**2**)

[a] Coupling constants are listed only at two limiting concentrations ($R = 0$ and $R = 2.0$ or 0.2), whereas they have been collected as a function of increasing R. The coupling constants at all concentrations of metal ions ($0.0 < R < 2.0$) have been used in the conformational analysis. The signals for H5′ and H5" were isochronous for Me*p*dG (**1**). $^2J_{2'2''}$ was 14.0 and 14.2 Hz for Me*p*dG (**1**) and dG*p*Me (**2**), respectively. $^2J_{5'5''}$ was 12.5 Hz for dG*p*Me (**2**). $^2J_{2'2''}$ and $^2J_{5'5''}$ did not change by increasing the concentration of metal ions.

as the softer metal ions interacted with Me*p*dG (**1**) and dG*p*Me (**2**).

In the elaboration of the experimental $^3J_{HH}$ coupling constants at various metal ion concentrations we have used the computer program PSEUROT,[31] which calculates the least-squares fit of the five parameters defining the two-state N $\rightleftharpoons$ S pseudorotational equilibrium (P_N, $\Psi_m{}^N$, P_S, $\Psi_m{}^S$ and x_S) to the set of experimental $^3J_{HH}$ coupling constants. Our analysis incorporated 30 (i.e. 6×5) $^3J_{HH}$ coupling constants in the case of Mg^{2+} and Zn^{2+} ions, 15 (i.e. 3×5) $^3J_{HH}$ coupling constants in the case of Hg^{2+} ions and five $^3J_{HH}$ coupling constants for metal-free aqueous solutions of Me*p*dG (**1**) and dG*p*Me (**2**). As $^3J_{HH}$ coupling constants in Me*p*dG (**1**) and dG*p*Me (**2**) indicated a bias of N $\rightleftharpoons$ S pseudorotational equilibrium towards S-type conformers, the maximum puckering amplitude of the minor N-type component ($\Psi_m{}^N$) was constrained in the iterative procedure to find the best fit between experimental and calculated coupling constants. All other parameters were freely optimized (see the Experimental Section for details). The final convergence resulted in the global minima for each metal ion data set with root-mean-square error below 0.3 Hz and the maximum discrepancy between experimental and calculated coupling constants (ΔJ_{max}) below 0.5 Hz. The results in Table 3 show that the geometry of the minor N conformer is characterized by C2′-*exo* puckering ($-32.1° < P_N < -22.0°$, $37.3° < \Psi_m{}^N < 38.2°$), whereas the major S conformer is characterized by C2′-*endo* puckering ($161.5° < P_S < 166.5°$, $37.3° < \Psi_m{}^S < 38.2°$). Two important conclusions can be drawn from the data in Table 3. First, the interaction of Me*p*dG (**1**) and dG*p*Me (**2**) with divalent metal ions results in only a minute variation in the geometry of the pseudorotamers in both N and S regions of conformational space. The differences in the pseudorotational parameters P and Ψ_m are certainly a matter of degree, not of kind. Second, the gradual increase in the concentration of metal ions has direct influence on the population of N- and S-type conformers in Me*p*dG (**1**) and dG*p*Me (**2**) (Figure 3). The largest shift of N $\rightleftharpoons$ S pseudorotational equilibrium towards N-type conformers was 5 percentage points upon addition of two molar equivalents of Zn^{2+} to Me*p*dG (**1**). The binding of metal ions to N7 makes the imidazole moiety less electron-rich which strengthens the anomeric effect of the heterocyclic nucleobase in Me*p*dG (**1**) and dG*p*Me (**2**). Note that the changes in the N $\rightleftharpoons$ S pseudorotational equilibrium are smaller than changes caused by N7 protonation.[12] The smaller drive towards N-type sugar conformation due to the interaction of divalent metal ions with N7 of guanine in Me*p*dG (**1**) and dG*p*Me (**2**) relative to that due to protonation could be explained by the solvation of the metal ions. Water molecules, which mediate M^{2+} interactions with nucleotides reduce the effect of the metal ion on the redistribution of electron density in guanine. The increase in the population of N-type conformers upon interaction with two molar equivalents of Zn^{2+} is larger for Me*p*dG (**1**) than for dG*p*Me (**2**). The interaction of Zn^{2+} with the 5′-phosphodiester in Me*p*dG (**1**) is not expected to affect the N $\rightleftharpoons$ S pseudorotational equilibrium directly. The N7-phosphate chelation in Me*p*dG (**1**) could, however, affect its N $\rightleftharpoons$ S pseudorotational equilibrium and result in higher conformational purity. On the other hand, the interaction of Zn^{2+} ions with the 3′-phosphodiester group in dG*p*Me (**2**) changes the strength of the [O4′−C4′−C3′−O3′] *gauche* effect which should be observed through the specific shift of the N $\rightleftharpoons$ S pseudorotational equilibrium towards the S-type conformers. It is, however, clear from the $\Delta\delta$ values given in Table 1 that Zn^{2+} ions interact predominantly with N7 in dG*p*Me (**2**) which strengthens the anomeric effect and drives the N $\rightleftharpoons$ S pseudorotational equilibrium towards N-type pseudorotamers. As the [O4′−C4′−C3′−O3′] *gauche* effect and the anomeric effect counteract each other in the drive of the N $\rightleftharpoons$ S pseudorotational equilibrium, the overall increase in the population of N-type pseudorotamers is larger in Me*p*dG (**1**) than in dG*p*Me (**2**).

The ^{1}H-NMR chemical shift changes of the H8, H1′ and H2′ resonances for Me*p*dG (**1**) at seven concentrations in the range from 60 mM to 1 mM afforded the average association constant ($K_{av} = 3.5 \pm 1.6$ M^{-1}) which suggested the presence of 94% (±3) of unstacked molecules at a 10 mM concentration. Similar evaluation of self-association of Me*p*dG (**1**) after titration with Mg^{2+} ions ($R = 1.0$) with the use of the chemical shift changes of the H8, H1′, H2′ and H2″ signals gave a K_{av} value of 3.0 ± 1.5 M^{-1} corresponding to 94% (±3) of unstacked molecules at a 10 mM concentration. The interpretation of the chemical shifts of

[a] Phase angle of pseudorotation and maximum puckering amplitude for N-(P_N and $\Psi_m{}^N$) and S-type (P_S and $\Psi_m{}^S$) pseudorotamers are in degrees, root-mean-square error (r.m.s.) and the maximum individual discrepancy between experimental and calculated coupling constants (ΔJ_{max}) are in Hz.

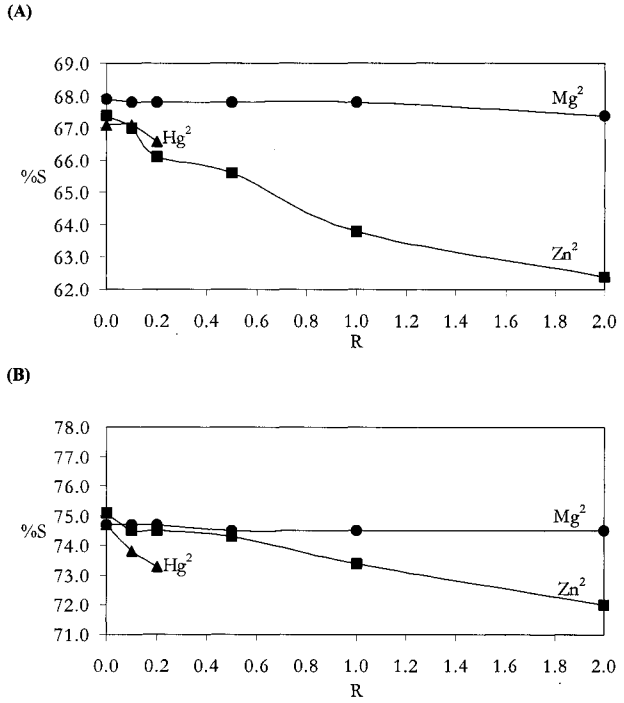

Figure 3. The N ⇌ S pseudorotational equilibrium in Me*p*dG (**1**) (panel A) and dG*p*Me (**2**) (panel B) as a function of increasing metal ion concentration

the H8, H2′ and H2″ signals in Me*p*dG (**1**) in the presence of Zn^{2+} ions (R = 1.0) resulted in a K_{av} value of 27.2 ± 17.0 M^{-1} which corresponds to 67% (± 14) of unstacked species at a 10 mM concentration of Me*p*dG (**1**). The additional titration of Me*p*dG (**1**) with Zn^{2+} ions from R = 0.0 to R = 2.0 was performed at a 1 mM concentration, where 95% (±3) of species was found to be unstacked. The comparison of the results at the two concentrations showed that the geometries of both major and minor conformers and their respective populations differed only slightly (for 1 mM: P_N = −24.9°, $\Psi_m{}^N$ = 37.4°, P_S = 165.3°, $\Psi_m{}^S$ = 37.4°,%S_{free} = 68.1 and %$S_{Zn^{2+}}$ = 65.5 at R = 2.0, r.m.s. error = 0.217 Hz, ΔJ_{max} = 0.4 Hz; for 10 mM see Table 3). Although the fraction of unstacked species decreases from 95% at 1 mM to 67% at 10 mM concentration, the Zn^{2+}-promoted drive of the N ⇌ S pseudorotational equilibrium towards N changes by only 2 percentage points which is within the error limits. There is therefore a definite M^{2+}-promoted drive of the N ⇌ S pseudorotational equilibrium towards N which is not affected considerably by the extent of self-association and the conclusions on the tuning of the N ⇌ S equilibrium by M^{2+} interactions with N7 of the nucleobase at a 10 mM concentration remain unchanged.

The comparison of the temperature-dependent shift of the N ⇌ S pseudorotational equilibrium from 278 K to 338 K at 1 and 10 mM Me*p*dG (**1**) upon interaction with Zn^{2+} (R = 1.0) has shown the following: (i) the geometries of the interconverting N and S conformers are nearly identical [for 1 mM: (P_N = −28.0°, $\Psi_m{}^N$ = 37.5°) ⇌ (P_S = 166.0°, $\Psi_m{}^S$ = 37.5°); for 10 mM: (P_N = −25.2°, $\Psi_m{}^N$ = 37.3°) ⇌ (P_S = 166.5°, $\Psi_m{}^S$ = 37.3°)], and (ii) the decrease in the population of S-type pseudorotamers with the increase of temperature is smaller at a 10 mM than at a 1 mM concentration (for 1 mM: $\%S^{278K}$ = 68.5, $\%S^{338K}$ = 64.0 and for 10 mM: $\%S^{278K}$ = 66.8, $\%S^{338K}$ = 63.8). The increase in temperature from 278 K to 338 K caused the upfield shift of the H8 signal from δ = 8.125 to δ = 8.069 at 10 mM, and from δ = 8.097 to δ = 8.043 at 1 mM Me*p*dG (**1**). The ^{1}H-NMR Δδ values between 278K and 338K are indeed very similar for all resonances at 1 and 10 mM Me*p*dG (**1**). The shift of the N ⇌ S pseudorotational equilibrium is slightly different, which indicates that as more nucleotide becomes unstacked with the increase of temperature, the Zn^{2+}-promoted drive towards N-type sugar conformation becomes comparable at the two concentrations. The temperature-dependent population changes, however, do not allow us to dissect the effect of enthalpy and entropy contributions to the Zn^{2+}-promoted drive towards N-type sugar conformation from the drive of the

N ⟷ S equilibrium due to the variation of the stability constant of labile M^{2+}−nucleotide species with temperature.

syn ⟷ *anti* Equilibrium

The semiquantitative information about the conformational equilibrium across the glycosyl bond (χ) in Me*p*dG (**1**) and dG*p*Me (**2**) upon the interactions with metal ions has been calculated from H8 ↔ H1′ NOEs.[32] Me*p*dG (**1**) showed a preference of 62% for *anti* conformation, whereas dG*p*Me (**2**) showed a preference of 69% for *syn* conformation (Figure 4). The higher tendency for *anti* conformation in Me*p*dG (**1**) relative to that in dG*p*Me (**2**) can be explained by the unfavorable steric interactions between the 5′-phosphodiester group and the nucleobase which are both on the β side in Me*p*dG (**1**). The binding of divalent metal ions to Me*p*dG (**1**) and dG*p*Me (**2**) caused a shift of the *syn* ⟷ *anti* equilibrium towards *anti*, except in the case of Mg^{2+} interactions with dG*p*Me (**2**) which caused a slight shift of 2 percentage points (within experimental error) towards *syn* (Figure 4). The steric bulk of the phosphate group on the β side of the furanosyl moiety in Me*p*dG (**1**) increases with the (electrostatic) interaction of Mg^{2+} ions with the phosphate oxygen atoms, which forces the nucleobase to adopt an *anti* conformation where the steric hindrance is reduced.

It is interesting to note that the shift of the *syn* ⟷ *anti* equilibrium in both Me*p*dG (**1**) and dG*p*Me (**2**) towards *anti* upon binding of Zn^{2+} ions is correlated with the increased population of N-type pseudorotamers. Similar correlations have already been reported.[16,33]

Conformational Equilibrium Across the C4′−C5′ Bond (γ)

The isochronicity of H5′ and H5′′ in Me*p*dG (**1**) prevented the measurement of individual $^3J_{4'5'}$ and $^3J_{4'5''}$ coupling constants. Analysis of the experimental $^3J_{4'5'}$ and $^3J_{4'5''}$ coupling constants (Table 2) in dG*p*Me (**2**) has shown 56% population of γ^+, 28% of γ^t and 16% of γ^- rotamers. Note, that the small changes in the experimental $^3J_{4'5'}$ and $^3J_{4'5''}$ coupling constants of 0.1 Hz (Table 2) upon interaction of M^{2+} ions with dG*p*Me (**2**) indicate negligible redistribution of the conformational equilibrium across γ.

Conformational Equilibrium Across the C5′−O5′ (β) and C3′−O3′ (ε) Bonds

The conformational equilibrium across the torsion angle β[C4′−C5′−O5′−P] has been assessed on the basis of experimental $^3J_{C4'P}$ coupling constants[34] alone as the isochronicity of H5′ and H5′′ protons in Me*p*dG (**1**) prevented the determination of the individual $^3J_{H5'P}$ and $^3J_{H5''P}$ coupling constants. It turned out that β^t conformers are preferred by 76.7% in M^{2+}-free solution of Me*p*dG (**1**). The

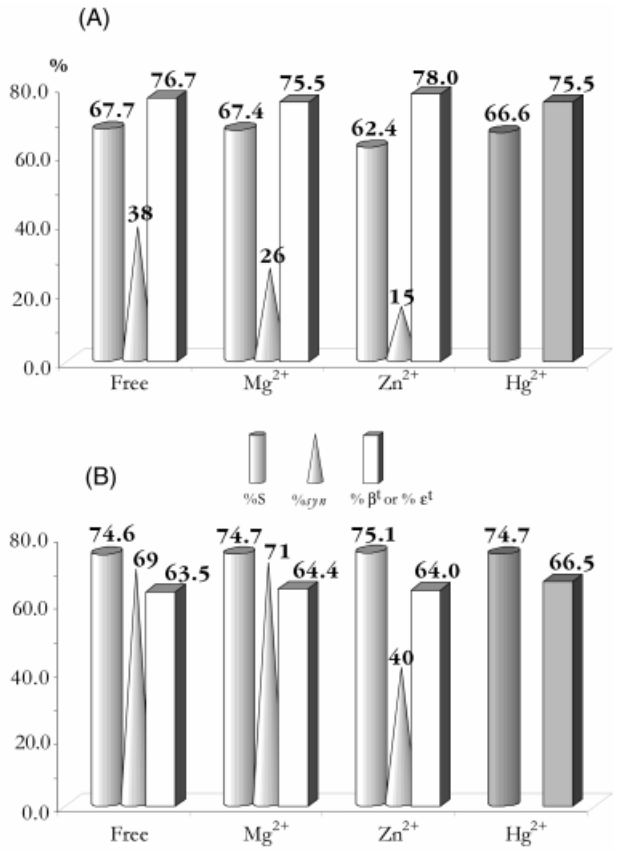

Figure 4. Changes in the conformational equilibria upon interaction of Mg^{2+}, Zn^{2+} and Hg^{2+} ions with Me*p*dG (**1**) (panel A) and dG*p*Me (**2**) (panel B); the population of S-type conformers (% S) is represented with cylinders, population of *syn* conformers (% *syn*) with cones, and population of β^t rotamers (% β^t) in Me*p*dG (**1**) and ε^t rotamers (% ε^t) in dG*p*Me (**2**) with square blocks; note that different levels of shading illustrate that data for Mg^{2+} and Zn^{2+} correspond to the addition of two molar equivalents ($R = 2.0$) of metal ions, whereas data for Hg^{2+} ions correspond to $R = 0.2$

increase in metal ion concentration showed only small changes of ca. 1 percentage point in β^t population, which is well within the range of experimental error (Table 4), and suggests that the conformation along the torsion angle β is not affected by metal ion binding to Me*p*dG (**1**).

Table 4. The effect of metal ions on the conformational equilibria across the C5′−O5′ bond (β torsion) in Me*p*dG (**1**) and across the C3′−O3′ bond (ε torsion)[a] in dG*p*Me (**2**)

	Me*p*dG (**1**)			dG*p*Me (**2**)		
	% β^t	ε^t	ε^-	% ε^t	ΔJ_{max}	r.m.s.
M^{2+}-free	76.7	209.5	270.8	63.5	0.44	0.39
Mg^{2+}	75.5	209.0	270.9	64.4	0.29	0.31
Zn^{2+}	78.0	209.4	270.7	64.0	0.81	0.52
Hg^{2+}	75.5	209.6	270.7	66.5	0.53	0.42

[a] Torsion angles ε^t and ε^- are in degrees, root-mean-square error (r.m.s.) and maximum discrepancy between the experimental and calculated $^3J_{C4'P}$, $^3J_{C2'P}$ and $^3J_{H3'P}$ coupling constants (ΔJ_{max}) are in Hz.

The experimental $^3J_{H3'P}$, $^3J_{C4'P}$ and $^3J_{C2'P}$ coupling constants (Table 2) have been used for the determination of the conformational equilibrium across the C3′−O3′ bond

(torsion angle ε[C4′−C3′−O3′−P]) in dG*p*Me (**2**) in terms of a two-state $\varepsilon^t \rightleftharpoons \varepsilon^-$ conformational equilibrium.[35−38] The ε^t rotamer is preferred by 63.5% in M^{2+}-free dG*p*Me (**2**) (Table 4). Interaction of hard Mg^{2+} and softer Zn^{2+} or Hg^{2+} ions with dG*p*Me (**2**) resulted in the minor increase (< 3 percentage points) in the preference for ε^t conformers which is not correlated with the relatively higher affinity of Mg^{2+} ions for the interaction with phosphate oxygen atoms (Table 4). Additionally, $^4J_{H2'P}$ coupling constants have been used for the qualitative assessment of the population of ε^- rotamers[39] and the results from both methods are in nice agreement (Table 4).

Conclusions

Me*p*dG (**1**) and dG*p*Me (**2**), which consist of all three structural elements of single-stranded DNA, have been chosen as simple model compounds for the evaluation of metal ion binding sites and related conformational changes in the absence of intermolecular interactions. The metal ion concentrations have been gradually increased by titration of aqueous solutions of Me*p*dG (**1**) and dG*p*Me (**2**). Multinuclear ^{1}H-, ^{13}C-, ^{15}N- and ^{31}P-NMR spectroscopy has been used to evaluate all rotational degrees of freedom across the sugar-phosphate backbone and glycosyl torsion angles.

The chemical shift changes showed that hard Mg^{2+} ions interact preferentially with the phosphate oxygen atoms in Me*p*dG (**1**), whereas in the case of dG*p*Me (**2**) the interaction of Mg^{2+} ions with the phosphate oxygen atoms competes with the interaction to the C6=O carbonyl group. Softer Zn^{2+} and Hg^{2+} ions were found to show a strong binding affinity for N7 in both Me*p*dG (**1**) and dG*p*Me (**2**).

The interpretation of $^3J_{HH}$ coupling constants in Me*p*dG (**1**) and dG*p*Me (**2**) has shown the bias of their N $\rightleftharpoons$ S pseudorotational equilibria towards S-type conformers. At 298 K the population of C2′-*endo* pseudorotamers in M^{2+}-free aqueous solutions of Me*p*dG (**1**) and dG*p*Me (**2**) were 68% and 75%, respectively. Titration of Me*p*dG (**1**) and dG*p*Me (**2**) with Mg^{2+} ions caused no observable changes in the N $\rightleftharpoons$ S pseudorotational equilibrium. On the other hand, the interaction of Zn^{2+} and Hg^{2+} ions with N7 strengthens the anomeric effect which is apparent from the increase in the population of N-type pseudorotamers. The shift of the N $\rightleftharpoons$ S pseudorotational equilibrium towards N-type conformers upon addition of two molar equivalents of Zn^{2+} was 5 percentage points for Me*p*dG (**1**) and 3 percentage points for dG*p*Me (**2**). The changes in the N $\rightleftharpoons$ S pseudorotational equilibrium are small compared to the changes caused by protonation which can be explained by the solvation of metal ions with water molecules, which mediate the interaction and thus reduce the effect of labile metal ion interaction on the redistribution of π-electron density of the guanine residue in Me*p*dG (**1**) and dG*p*Me (**2**).

The binding of divalent metal ions to Me*p*dG (**1**) and dG*p*Me (**2**) causes a shift of the *syn* $\rightleftharpoons$ *anti* equilibrium towards *anti*, which is larger for softer Zn^{2+} than harder Mg^{2+} ions. The increase in the population of *anti* conformers in both Me*p*dG (**1**) and dG*p*Me (**2**) upon binding of Zn^{2+} ions is correlated with the increased population of N-type pseudorotamers.

The small changes in the experimental $^3J_{4'5'}$ and $^3J_{4'5''}$ coupling constants in dG*p*Me (**2**) upon interaction with M^{2+} ions indicate negligible redistribution of the conformational equilibrium across C4′−C5′ bond (γ torsion).

The interpretation of $^3J_{C4'P}$ coupling constant has shown that β^t conformers are preferred by ca. 77% in M^{2+}-free aqueous solution of Me*p*dG (**1**). Only small changes of ca. 1 percentage point in the β^t population have been found upon metal ion binding to Me*p*dG (**1**).

The two-state $\varepsilon^t \rightleftharpoons \varepsilon^-$ conformational equilibrium is biased towards ε^t rotamers by 63.5% in dG*p*Me (**2**). The interaction of hard Mg^{2+} and softer Zn^{2+} or Hg^{2+} ions with dG*p*Me (**2**) resulted in the minor increase below 3 percentage points in the population of ε^t conformers.

Experimental Section

Synthesis: The synthesis of Me*p*dG (**1**) and dG*p*Me (**2**) has been carried out by procedures reported by Khorana[48,49] and Marzilli.[20] 2′-Deoxyguanosine-3′-monophosphate and 2′-deoxyguanosine-5′-monophosphate have been suspended in dry methanol. After addition of three molar equivalents of dicyclohexylcarbodiimide (DCC), the suspension was stirred at room temperature for 72 h. The solvent was evaporated under reduced pressure and water was added to precipitate DCC and its byproducts. The filtrate was extracted with petroleum ether and water removed by lyophilization.

NMR Measurements: ^{1}H- and ^{31}P-NMR spectra were recorded with a Varian Unity-plus 300 at 299.858 MHz and at 121.384 MHz, respectively. ^{13}C- and ^{15}N-NMR were acquired at 150.909 MHz and 60.817 MHz, respecitvely, with a Varian Unity Inova 600 NMR spectrometer at the National NMR Center of Slovenia. Spectra were acquired in D_2O (99.9% deuterium) at neutral pH (pH* = 7.5) at a 10 mM concentration, which is a compromise between the extent of self-association and the sensitivity of NMR measurements of rare nuclei like ^{15}N. Trimethylsilylpropionic acid was used as internal standard for ^{1}H- and ^{13}C-NMR (δ = 0) spectra, MeCN (δ = −135.8) as external reference for ^{15}N-NMR spectra, and 85% aq. H_3PO_4 (δ = 0) as external reference for ^{31}P-NMR spectra. The sample temperature was 298K ± 0.5K. Metal ion concentration was gradually increased by simple titration of nucleotides with 0.1, 0.2, 0.5, 1.0 and 2.0 molar equivalents of nitrate salts of Mg^{2+}, Zn^{2+} and Hg^{2+} ions. 1D-^{1}H measurements were performed under identical spectral and processing conditions: 9 ppm sweep width, 32K time domain, zero filling to 128K, and slight Gaussian apodization to give enhanced resolution. In order to obtain accurate *J* coupling data and chemical shifts ^{1}H-NMR spectra were simulated with a standard computer simulation algorithm, which is integrated into the Varian software package (VNMR rev. 5.3B).[28] The error in $^3J_{HH}$ is 0.1 Hz as estimated from the comparison of the experimental and simulated spectra. 1D-NOE experiments were run with 5 s irradiation time and with saturation of individual lines within the multiplet. NOE difference spectra were obtained by internal subtraction of on- and off-resonance spectra. Proton-decoupled ^{13}C-NMR spectra were recorded with 220 ppm sweep, 96K time domain, zero filling to 512K. Proton-

decoupled ^{31}P-NMR spectra were acquired with 100 ppm sweep, 56K time domain, zero filling to 64K. ^{15}N-NMR chemical shifts were obtained from 2D-HMBC experiments using gradients for coherence selection; 4096 (ω2) × 128 (ω1) data points, 320 scans per FID, 16 dummy scans, appropriate delays were calculated according to $^{1}J_{NH}$ = 90 Hz and $^{n}J_{NH}$ = 4 Hz, 6 kHz (ω2) × 15 kHz (ω1) spectral width, transformed after multiplication with a sine bell filter shifted by π/2 in both ω2 and ω1 to give an 8K × 1K matrix. Digital resolutions were 0.05 Hz in ^{1}H-NMR spectra, 0.1 Hz in ^{13}C-NMR spectra, 0.3 Hz in ^{31}P-NMR spectra and 30 Hz along the ^{15}N(*f*1) axis of 2D-HMBC spectra. − The chemical shift measurements at seven concentrations in the range from 60 mM (solubility limit) to 1 mM were employed to study self association with the isodesmic model.[53] In this model, the assumption is made that all the equilibrium constants for the $N_n + N \rightleftarrows N_{n+1}$ equilibria are equal. The observed chemical shift (δ_{obs}) is defined by Equation 1 where *c* is the total concentration of a nucleotide, δ_0 represents the chemical shift at infinite dilution, δ_∞ is the chemical shift at infinitely long stack, and *K* is the association constant.

$$\delta_{obs} = \delta_\infty + \frac{(\delta_\infty - \delta_0)\cdot(1-\sqrt{4Kc+1})}{2Kc} \quad (1)$$

Conformational Analysis: The conformational analysis of the sugar moiety was performed by the computer program PSEUROT[31] with the use of λ electronegativities for the substituents along H−C−C−H fragments and the six-parameter set from 1994 for the generalized Karplus-type equation.[29] The following λ electronegativity values were used: 0.0 for H, 0.58 for heterocycle, 1.26 for OH, 0.62 for C1′, C3′ and C4′, 0.74 for C2′, 1.27 for O4′ and 0.68 for C5′. The analysis of $^{3}J_{HH}$ coupling constants consists of three standard translation steps. First step translates experimental proton−proton coupling constants to proton-proton torsion angles and is covered by the generalized Karplus−Altona equation. Second step is the translation of proton−proton torsion angles into the corresponding endocyclic torsion angles and is formulated with the set of linear equations $\Phi_{HH} = A\nu_j + B$. Φ_{HH} is the torsion angle between two vicinal protons and ν_j is the corresponding endocyclic torsion angle. Parameters A and B were determined from a large collection of X-ray data. Third translational step of endocyclic torsion angles into the pseudorotational parameters is described by a simple cosine function $\nu_j = \Psi_m \cdot \cos[P + (j - 2) \cdot 4\pi/5]$, where *P* is the phase angle of pseudorotation and Ψ_m is the maximum puckering amplitude. In the following optimization procedure the geometries and populations of N and S pseudorotamers are varied to obtain the best fit between experimental and calculated coupling constants. Our optimization procedure was started with the following input values: P_N = 18°, $\Psi_m{}^N$ = 36°, P_S = 156°, $\Psi_m{}^S$ = 36°. The puckering amplitude of the minor N conformer ($\Psi_m{}^N$) was kept frozen during individual iterative least-squares optimization, while all other parameters were freely optimized. The best fits are given in Table 3 together with error evaluation in terms of maximum individual Δ*J* and root-mean-square error. − The population of the β^t rotamers was calculated with the following equation: $x_{\beta t} = [^3J_{C4'P}(expt) - {}^3J_{C4'P}(60°)]/[^3J_{C4'P}(180°) - {}^3J_{C4'P}(60°)] = (^3J_{PC4'}(expt) - 0.7)/10.3$, where the values of 11.0 Hz and 0.7 Hz have been used as the limiting coupling constants for $^3J_{C4'P}(180°)$ and $^3J_{C4'P}(60°)$, respectively.[34] − The population across the C4′−C5′ bond was evaluated on the basis of experimental $^3J_{4'5'}$ and $^3J_{4'5''}$ coupling constants which were interpreted with the assumption of the conformational equilibrium between three staggered conformers.[50] The limiting coupling constants were calculated[29] with the use of the torsion angles γ from a survey of X-ray crystallographic data (*gauche*-plus, γ = 53° ⇌ *gauche*-trans, γ = 180° ⇌ *gauche*-minus, γ = −70°).[50] The limiting coupling constants and populations of the three rotamers are related with the following equations: $^3J_{4'5'} = 1.64\ x_{\gamma+} + 2.86\ x_{\gamma t} + 10.40\ x_{\gamma-}$ and $^3J_{4'5''} = 1.84\ x_{\gamma+} + 10.78\ x_{\gamma t} + 2.71\ x_{\gamma-}$. − The interpretation of the experimental $^3J_{C4'P}$, $^3J_{C2'P}$ and $^3J_{H3'P}$ coupling constants has been performed with the assumption of a two-state $\varepsilon^t \rightleftarrows \varepsilon^-$ conformational equilibrium across the C3′−O3′ bond in dG*p*Me (**2**). The three-parameter Karplus equations[37,38] for $^3J_{CP} = 9.1 \cdot \cos^2\Phi - 1.9 \cdot \cos\Phi + 0.8$ and $^3J_{HP} = 15.3 \cdot \cos^2\Phi - 6.2 \cdot \cos\Phi + 1.5$ have been used in the calculation of $^3J_{CP}$ and $^3J_{HP}$ from ε^t and ε^- torsion angles and their respective populations, which were iterated to find the best fit with the experimental $^3J_{C4'P}$, $^3J_{C2'P}$ and $^3J_{H3'P}$ coupling constants. An additional semiquantitative estimation of the population of ε^- rotamers was done with the equation $x_{\varepsilon^-} = {}^4J_{H2'P}(expt)/2.3$,[39] which showed that population of ε^- rotamers is in the range from 30 to 35 percentage points. − The populations of *syn* and *anti* conformers could be estimated with the use of 1D-NOE difference spectroscopy by saturating H8 and measuring the NOE at H1′ for *syn*, and the sum of NOEs at H2′ and H3′ for the *anti* conformers.[32] As the signal for H3′ is overlapping with the signal of residual HOD for both Me*p*dG (**1**) and dG*p*Me (**2**) and its suppresion could introduce considerable error in our evaluation of *syn* ⇌ *anti* equilibrium we have only used H8 ↔ H1′ NOEs. Nuclear Overhauser enhancements upon saturation of H8 were 4.3% and 7.8% for free Me*p*dG (**1**) and dG*p*Me (**2**), respectively, 2.9% and 8.1% for Mg^{2+} (*R* = 2.0) and 1.7% and 4.5% for Zn^{2+} (*R* = 2.0). The NOE enhancements were used to calculate the population of *syn* conformers with the following equation: %*syn* = 100 · ηH1′/11.3.[32]

Synthesis of Two Acridine Conjugates of the Bis(phenanthroline) Ligand "Clip-Phen" and Evaluation of the Nuclease Activity of the Corresponding Copper Complexes

Steven A. Ross,[a] Marguerite Pitié,[a] and Bernard Meunier*[a]

Keywords: Bioinorganic chemistry / Copper / DNA cleavage / Intercalation

The synthesis of three novel derivatives [*N*-acetyl-Clip-Phen (**1**), Clip-Phen-hexylaminoacridine (**4**) and Clip-Phen-hexylchloromethoxyaminoacridine (**5**)] of the bis(phenanthroline) ligand "**Clip-Phen**", are described. Complexation of these ligands with copper(II) afforded the 1:1 complexes as hexafluorophosphate salts. The relaxation of ϕX 174 DNA was used as a DNA cleavage assay, with the following results. $[Cu(\mathbf{1})]^{2+}$ was found to show a diminished activity relative to the parent complex $[Cu(\mathbf{Clip\text{-}Phen})]^{2+}$. However, the acridine-containing complexes $[Cu(\mathbf{4})H]^{3+}$ and $[Cu(\mathbf{5})H]^{3+}$ exhibited significantly enhanced cleavage efficiencies, which has been attributed to increased affinity of the complexes for DNA. UV/Vis-spectral data of the complexes in the presence of calf-thymus DNA was consistent with an intercalative mode of binding.

Introduction

The artificial nuclease capability of redox-active copper complexes of the chelating ligand 1,10-phenanthroline (Phen) is well established.[1][2] Single-strand cleavage of nucleic acids is observed in the presence of dioxygen and a reductant, by oxidative attack on deoxyribose units from the DNA minor groove.[1] The reactive species $(Phen)_2Cu^{I}$ is significantly more active than the $(Phen)Cu^{I}$ species,[3] although the association constant for the second Phen ligand[4] is only $10^{5.5}$ M^{-1}. Competitive binding of copper can thus be a problem in cleavage experiments, and may hamper the use of (Phen)copper compexes in vivo. With these concepts in mind, we recently reported the synthesis of the novel bis(phenanthroline) ligand "Clip-Phen", whereby two Phen ligands are linked at the 2′ position by a serinol bridge.[5] The artificial nuclease activity of this new ligand was found to be higher than Phen itself (by a factor of 2) and, in addition, the serinol bridge contains an exogenous amine group, which allows further functionalisation.

Attachment of the natural polyamine spermine to Clip-Phen also afforded a new conjugate with even greater nuclease efficiency.[6] This was attributed to the high affinity of the spermine moiety for nucleic acids, through electrostatic interactions with the anionic phosphate backbone.[7] Cleavage reactions on restriction fragment DNA showed that there was very little sequence specificity of this Clip-Phen-spermine bioconjugate.

Attachment of an intercalating agent to Clip-Phen was the motivation for the current work. DNA binding by intercalation of polyaromatic species between adjacent base pairs was first proposed by Lerman[8] in 1961. Efficient intercalators must be planar and often contain three fused six-membered rings. The presence of a positive charge usually aids in the binding process.[9] Although intercalation has been studied by various groups, the overall binding process is complex, partly due to ambiguities in the actual binding mode (intercalation, minor-groove binding, or electrostatic interactions) and difficulties in measuring association constants.[10] Certain intercalators, such as daunomycin, adriamycin, and *m*-AMSA exhibit anti-tumour activity, in a process which is believed to involve the disruption of topoisomerase activity in vivo.[11] Association constants for intercalation are broadly comparable, normally between 10^5 and 10^6 M^{-1}, and there is a general lack of correlation between affinity and pharmacological efficacy. Overall, there is little sequence specificity observed in the interactions of intercalators with DNA.[9]

We wished to quantify the nuclease efficiency of an intercalator−Clip-Phen hybrid, such that the reactive Clip-Phen fragment would be anchored to the DNA. We chose to attach acridine derivatives for several reasons. Firstly, acridines are one of the most studied of the intercalating groups. Secondly, acridines are known to rapidly enter cells and accumulate in the nucleus,[12] which is an important consideration with regard to in vivo activity. For example, a netropsin−acridine hybrid has been reported to accumulate in the cell nucleus, using the acridine moiety as the cell-penetration vector,[13] whereas netropsin itself exhibits slow kinetics of cell penetration and poor uptake by the nucleus.[14] Finally, conjugation to acridines was considered to be the most straightforward and least expensive synthetic route available. Synthetic strategies to oligonucleotide-intercalator hybrids[15] and minor-groove binder-intercalator hybrids[16] have been reviewed recently in the literature.

Results and Discussion

Ligand Synthesis

Clip-Phen was readily prepared according to the previously reported procedure.[5] The primary amine of Clip-Phen presents a convenient site for further functionalisation. However, previous reports[17] have suggested that the reactive fragments in intercalator hybrids show greater efficacy if separated by a polymethylene linker. We chose, therefore, to protect the amine function of 6-aminohexanoic acid (with the BOC group) allowing facile attachment of the carboxylate to Clip-Phen by amide bond formation. Deprotection of Clip-Phen-hexyl-BOC (**2**) proceeded smoothly to afford Clip-Phen-hexylamine (**3**) in 80% yield (see Scheme 1).

Scheme 1. Synthesis of ligands **4** and **5**, and their corresponding Cu^{II}/PF_6^- complexes; conditions: (i) 6-BOC-amino-1-hexanoic acid, EtOCOCl; (ii) 25% CF_3COOH in CH_2Cl_2; (iii) appropriate 9-phenoxyacridine, CH_3CN, 10 equiv. CH_3COOH; (iv) $Cu(OAc)_2 \cdot 2\,H_2O$, MeOH, then NH_4PF_6

Primary amines are known to react with 9-chloroacridine derivatives in hot phenol (by in situ 9-phenoxyacridine formation) to give the 9-amino acridines in high yield.[18] We encountered several problems with this reaction, only being able to isolate products in very low yield after chromatographic separation. ^{1}H-NMR data from side-products obtained suggested that this was due to decomposition of the Clip-Phen fragment in hot phenol, possibly due to nucleophilic attack of phenol at the C-2′ position of the phenanthroline. We chose, therefore, to isolate the 9-phenoxyacridine derivatives prior to reaction with **3**. Reaction of 9-phenoxyacridine with **3** in refluxing acetonitrile afforded the Clip-Phen-hexylaminoacridine (**4**) in 30−40% yield after chromatography. However, the corresponding reaction between 6-chloro-9-phenoxy-2-methoxyacridine and **3** proceeded in very poor yield. Addition of 5−10 equivalents of acid (usually acetic acid) was found to greatly improve the yield by increasing the electrophilicity of the C-9′′ carbon atom.[19] Subsequent addition of acid to the reaction between 9-phenoxyacridine and **3** also led to a significant enhancement in yield (to 74%). Products **4** and **5** (see Scheme 1) were bright yellow, fluorescent solids, which made chromatographic purification simple, and gave satisfactory ^{1}H-NMR and mass spectra and analytical data.

Since the Clip-Phen fragments of both **4** and **5** contain an amide function in place of the primary amine, we also wished to prepare an analogous Clip-Phen amide derivative (without an intercalating group) to allow direct comparison of reactivities. This was readily achieved by reaction of acetic anhydride with Clip-Phen in CH_2Cl_2, to afford *N*-acetyl Clip-Phen (**1**) (see Figure 1) in 94% yield. The DNA cleavage reactivity of (phenathroline)Cu^{II} derivatives necessitates reduction to Cu^{I}, and thus formation of a tetrahedral intermediate. By converting the amine of Clip-Phen to the amide in **1**, we would thus avoid any differences in the coordination sphere or any steric constraints upon reduction.

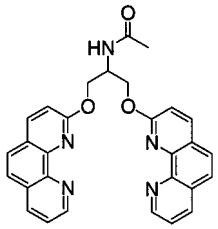

Figure 1. *N*-Acetyl Clip-Phen (**1**)

Complex Formation with Cu^{II} Salts

The coordination chemistry of the Clip-Phen family of ligands (L) with Cu^{II} is not straightforward.[20] The 5-atom bridge between the two phenanthrolines leads to little thermodynamic stability of the mononuclear species $[Cu(L)]^{2+}$, with respect to higher nuclearity species $[Cu_n(L)_n]^{2n+}$, in a process that may be dependent upon concentration and solvent. Complexes with a Cu/L ratio of 2:1 have also been observed when the Cu^{II} concentration is higher than that of the ligand. In general, we found that isolation of solid products of overall stoichiometry 1:1 (L/Cu) was problematic when $CuCl_2 \cdot 2\,H_2O$ or $Cu(SO_4) \cdot 4\,H_2O$ were used as the starting copper salts (data not

shown). We found that a reproducible procedure for complex formation with **1**, **4**, and **5** was to treat one equivalent of $Cu(OAc)_2 \cdot H_2O$ with one equivalent of ligand in warm methanol for two hours. Addition of an excess of NH_4PF_6 gave a precipitate which was redissolved by addition of acetone. Upon concentration of this solution, the products precipitated and could be isolated by centrifugation. Analytical data and mass spectra were consistent with the formation of L/Cu^{II} 1:1 complexes. The pK_a of the acridine fragment (> 10) is sufficiently high to allow proton transfer from the ammonium ion of NH_4PF_6 ($pK_a = 9.3$), such that the intercalator is present as an acridinium hexafluorophophate in the complexes of both **4** and **5** (see Scheme 1). This did not present a problem, however, since the intercalators are also protonated under biological conditions, and under the conditions used for the DNA experiments described (phosphate buffer, pH = 7.2). The UV/Vis spectra of the complexes exhibited the expected ligand absorptions between 200 and 450 nm, in addition to a broad Cu^{II} d-d band at circa 810 nm ($\varepsilon \approx 150\ M^{-1}\ cm^{-1}$).

The 1:1 copper complex of Clip-Phen was prepared by using the previously reported synthesis of [Cu(Clip-Phen]Cl_2.[5] After equimolar quantities of Clip-Phen and anhydrous $CuCl_2$ were stirred in DMF for 4 h, the chloride salt was precipitated with ether. This was redissolved in MeOH and an excess of NH_4PF_6 was added to afford a green precipitate, which was isolated by centrifugation. The analytical data was consistent with the overall stoichiometry [Cu(Clip-Phen)]$(PF_6)_2$. The absence of a third hexafluorophosphate anion in this complex indicates that the exogenous primary amine of Clip-Phen is not protonated.

DNA Cleavage Activity

Relaxation of supercoiled circular Φx 174 DNA (form I) into relaxed circular (form II) and linear (form III) conformations was the assay used to assess the relative cleavage efficiency of the four complexes. The redox activity of the Cu^{II} centres was initiated by the addition of 5 mM mercaptopropionic acid (MPA) in the presence of air.

Reactions were carried out by using either the isolated hexafluorophosphate salts described, or by premetallating the ligands with $CuCl_2$ in DMF/H_2O (40:60, 1 mM in ligand, 1 mM in $CuCl_2$) for 2 h prior to dilution and addition to DNA. The DNA/complex mixtures were allowed to equilibrate for 30 min at room temperature prior to addition of MPA. Several reactions were also carried out by pre-equilibration of the ligand (1 μM, 15 min) with DNA, followed by $CuCl_2$ (1 μM, 15 min), or by pre-equilibration of $CuCl_2$ (1 μM, 15 min) with DNA, followed by ligand (1 μM, 15 min). The choice of counterion (chloride or hexafluorophosphate) or order of addition was found to have a negligible effect upon the degree of reactivity (within experimental error). Since stock solutions of the hexafluorophosphate salts appeared to decompose over time (becoming an orange-brown colour), we chose to freshly prepare our complexes by metallation with $CuCl_2$ prior to reaction.

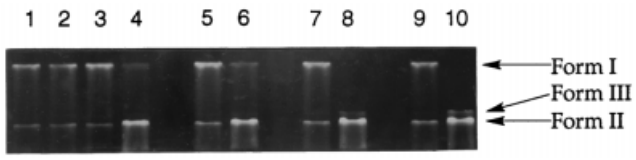

Figure 2. Comparison of Φx 174 cleavage efficiency between Clip-Phen, **1**, **4**, and **5** (1 μM) in the presence of $CuCl_2$ (1 μM) and MPA (5 mM); lane 1: control, no complex, no MPA; lane 2: control, no complex, with MPA; lanes 3, 5, 7, and 9: Clip-Phen, **1**, **4**, and **5**, respectively, without addition of Cu; lanes 4, 6, 8, and 10: Clip-Phen, **1**, **4** and **5**, respectively, in the presence of Cu

Figure 2 shows a representative gel illustrating the relative reactivities of the 4 complexes at 1 μM concentration. The reactivity of Clip-Phen-copper (1.4 ± 0.1 strand breaks per plasmid) is consistent with the previously reported data,[5] showing a cleavage activity which is approximately twice that of phenanthroline itself. However, *N*-acetyl Clip−Phen−copper shows a diminished reactivity (0.9 ± 0.1 strand breaks per plasmid), either due to the lack of a primary amine to coordinate or due to the steric effects of the bulkier amide group. The lack of protonation of the primary amine in the [Cu(Clip-Phen)]$(PF_6)_2$ complex is consistent with coordination to the Cu^{II} centre, although it is unlikely to be coordinated upon reduction to Cu^{I}. The copper complexes of the acridine-containing ligands **4** and **5** both exhibit cleavage activities of circa 4 ± 1, which is significantly higher than the two non-acridine-containing ligands. A direct comparison between **1** and **4** suggests an approximate fourfold increase in reactivity. Since the estimation of cleavage efficiency is less accurate after the disappearance of form 1, the variation in reactivity with concentration was also measured for **1** and **4**, this data being presented in Figure 3. Enhanced reactivity is thus observed at all concentrations.

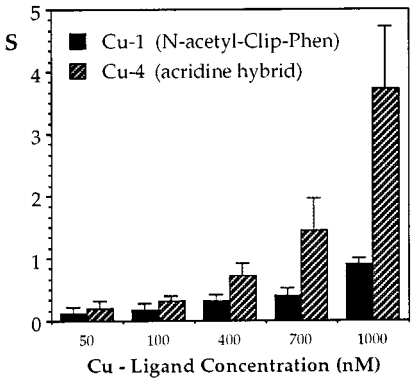

Figure 3. Concentration dependence of Φx 174 cleavage efficiency for **1** (solid) and **4** (hatched) in the presence of equimolar $CuCl_2$

Spectrophotometric Studies of DNA Binding

The binding of the complexes and ligands described herein to DNA is expected to be complex, since both moieties (the acridine fragment and the Cu−Clip-Phen frag-

ment) each have a separate affinity for DNA. Intercalative binding of acridine derivatives is well established, and gives rise to small (but significant) bathochromic and hypochromic shifts in the visible spectrum.[21] This technique was therefore used as a guide to whether intercalation was taking place with derivatives **4** and **5**. The alkylamino derivatives 9-(3-methoxyprop-1-ylamino)acridine (**6**) and 6-chloro-2-methoxy-9-(3-methoxyprop-1-ylamino)acridine (**7**) (see Figure 4) were also prepared and studied, since these analogues should have the same chromophores as **4** and **5**, without containing the clip-phen fragment.

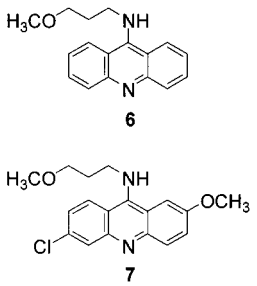

Figure 4. Alkylaminoacidire derivatives **6** and **7**

The spectrophotometric studies were carried out under identical buffer and salt conditions to the DNA cleavage experiments. Spectral shifts were recorded for DNA base-pair ratios of 0, 1, 4, 12, and 20 equivalents. We did not attempt to interpret this data in terms of binding constants, since the Cu−Clip-Phen fragment may also be binding in the minor groove.

Compounds **4**, **4** + $CuCl_2$, and **6** all gave bathochromic shifts of around 4 nm and hypochromic shifts of around 30% upon the addition of calf-thymus DNA (see Table 1), which were in good agreement with data previously reported in the literature.[21] We conclude from these results that the binding process of the free ligand (**4**), its copper complex (**4** + $CuCl_2$) and a related alkylaminoacridine (**6**) all involve intercalative binding of the acridine fragment. The spectral shifts of **4** + $CuCl_2$ and **6** upon titration with calf-thymus DNA are shown in Figure 5.

The data obtained from the 9-amino-6-chloro-2-methoxyacridine derivatives was more complex, as can be evidenced from the data in Table 1. Compounds **5**, **5** + $CuCl_2$, and **7** all show similar λ_b and ε_b in the presence of excess DNA, suggesting that the acridine fragment is in a similar environment for all three upon DNA binding. However, in the absence of DNA, whilst the free acridine compound **7** exhibits the expected behaviour, **5** and its copper complex show anomalous behaviour. This is probably due to stacking interactions of the acridine fragment with the phenanthroline rings in the absence of DNA, particularly with free **5**, which shows a 12-nm red-shift, relative to its Clip-Phen-free analogue **7**.

The in vivo activity of compounds **4** and **5** is currently being investigated and will be reported in due course.

Table 1. UV/Vis data in the region 370−470 nm for **4**, **5**, **4** + $CuCl_2$, **5** + $CuCl_2$, **6**, and **7** (10 μM) in phosphate buffer (pH = 7.2): ε_f and λ_f are the values in the absence of calf-thymus DNA; ε_b and λ_b are the values in the presence of 20 base-pair equivalents of calf-thymus DNA

	λ_f (ε_f)	λ_b (ε_b)
4	396 (7000) 415 (8600) 437 (8100)	398 (4400) 419 (5700) 440 (5400)
4 + $CuCl_2$	394 (4200) 414 (6800) 437 (5500)	397 (2700) 417 (4100) 440 (3700)
6	395 (4500) 410 (8100) 432 (6900)	398 (2900) 416 (5800) 436 (5000)
5	433 (7800) 455 (7700)	428 (9700) 450 (9500)
5 + $CuCl_2$	426 (2900) 444 (2700)	427 (8100) 451 (7700)
7	420 (13300) 443 (12700)	429 (6800) 451 (6900)

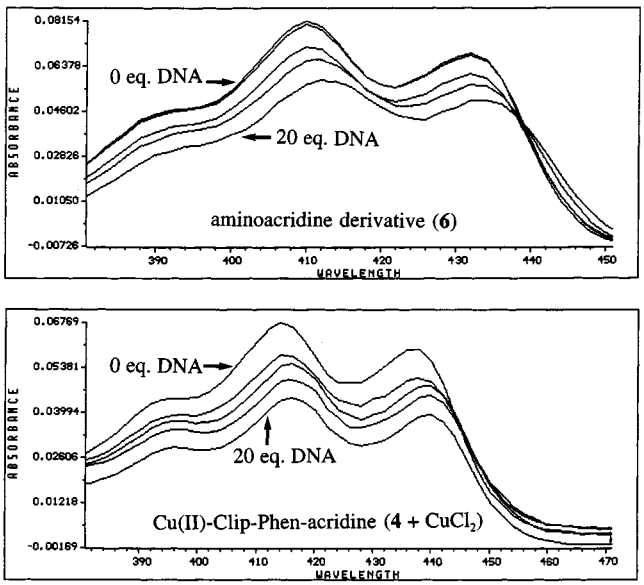

Figure 5. UV/Vis titration of **6** (top) and **4** + $CuCl_2$ (bottom) (all 10 μM) against calf-thymus DNA (0, 1, 4, 12, and 20 base-pair equivalents) in phosphate buffer (pH = 7.2) in the presence of NaCl (50 mM) and $MgCl_2$ (10 mM)

Conclusions

We have described the synthesis of two novel conjugate ligands (**4** and **5**) and their copper(II) complexes, which contain a reactive DNA cleavage unit attached to an intercalating DNA recognition unit. The presence of the intercalator has been shown to significantly enhance the DNA cleavage activity, in spite of the diminished activity which is found upon blockage of the exogenous primary amine of

the parent Clip-Phen from which they are derived. Thus, these species are of potential interest for in vivo applications.

Experimental Section

Warning: Acridines and ethidium bromide are mutagenic and should always be handled with appropriate precautions.

General: Reactions were monitored by thin-layer chromatography using Macherey-Nagel Alugram Sil G/UV 254 plates and spots were visualized with UV light. − Proton NMR spectra were recorded with a Bruker 250 MHz instrument and referenced to deuterated solvent. Aromatic proton signals due to phenanthroline are denoted by a single prime (′), those due to acridine are denoted by double prime (′′). − UV/Vis spectra were recorded with a Hewlett-Packard 8452A diode-array spectrophotometer in cuvettes of 1 cm path length. − Electrospray mass spectra were recorded with a Perkin-Elmer SCIEX API 100 instrument. − Ligand metallation and DNA reactions were carried out in Nanopure deionized water. DMF was dried with calcium sulfate. Other commercial reagents were used without purification.

Syntheses

2-Amino-1,3-bis(1′,10′-phenanthrolin-2′-yloxy)propane (Clip-Phen) was prepared by reaction of 2-chloro-1,10-phenathroline with serinol according to the method described previously.[5]

6-(Butoxycarbonylamino)-1-hexanoic Acid: 6-Aminohexanoic acid (1 g, 7.6 mmol), MgO (296 mg, 7.6 mmol), and NaOH (305 mg, 7.6 mmol) were added to 40 mL of dioxane/H_2O (6:1). Di-*tert*-butyl dicarbonate (1.83 g, 8.39 mmol) was then added in portions over 20 min, the solution was stirred for 18 h at room temperature, filtered, and concentrated in vacuo. The residue was dissolved in H_2O (20 mL), washed with diethyl ether (20 mL), acidified to pH = 3 with acetic acid (10%), and extracted with ethyl acetate (2 × 50 mL). The organic was then dried ($MgSO_4$) and concentrated to afford the product as a colourless oil (1.56 g, 89%). − ^{1}H NMR (CD_2Cl_2): δ = 1.41 [s, 9 H, C(CH_3)$_3$], 1.3−1.5 (m, 4 H, CH_2CH_2), 1.59 (m, 2 H, CH_2), 2.34 (t, 2 H, *J* = 7.5 Hz, CH_2COOH), 3.06 [m, 2 H, CH_2NHC(O)O], 4.67 (br. s, 1 H, CH$_2$N*H*). − DCI MS; *m*/*z* (%): 232 (63) [MH$^+$], 249 (56) [MNH$_4^+$]. − $C_{11}H_{21}NO_4$ (231.3): calcd. (+ 0.5 H_2O) C 54.9, H 9.15, N 5.82; found C 55.5, H 8.91, N 5.84.

***N*-Acetyl Clip-Phen (1):** Clip-Phen (447 mg, 1 mmol) was dissolved in CH_2Cl_2, to which was added Et_3N (1 mL) and acetic anhydride (1 mL). Upon standing for 2 h at room temperature, the solvent was removed in vacuo, the residue redissolved in CH_2Cl_2 (10 mL), washed with aqueous NaOH (10 mL, 1 M), and dried ($MgSO_4$). The solution was then concentrated to ca. 2 mL, and hexane was added to precipitate the product as a white solid (460 mg, 94%), which was filtered off and dried in vacuo. − ^{1}H NMR (CD_2Cl_2): δ = 2.03 (s, 3 H, CH_3), 4.84 (m, 3 H, serinol bridge), 5.04 (m, 2 H, serinol bridge), 7.15 (d, 2 H, *J* = 8.5 Hz, 3′-H), 7.59 (dd, 2 H, *J* = 8, 4.25 Hz, 8′-H), 7.70 (d, 2 H, *J* = 8.75 Hz, 6′-H), 7.77 (d, 2 H, *J* = 8.75 Hz, 5′-H), 8.14 (d, 2 H, *J* = 8.5, 4′-H), 8.27 (dd, 2 H, *J* = 1.5, 8 Hz, 7′-H), 9.07 [br. s, 1 H, CH_3C(O)N*H*], 9.07 (dd, 2 H, *J* = 1.5, 4.25 Hz, 9′-H). − DCI MS; *m*/*z* (%): 490 (100) [MH$^+$]. − $C_{29}H_{23}N_5O_3$ (489): calcd. (+ 0.33 $CHCl_3$, 0.5 H_2O) C 65.4, H 4.43, N 13.1; found C 65.4, 4.49, N 13.4.

Clip-Phen-hexyl-BOC (2): 6-Butoxycarbonylamino-1-hexanoic acid (1.3 g, 5.62 mmol) was dissolved in CH_2Cl_2 (10 mL) at 0°C, to which was then added Et_3N (567 mg, 5.62 mmol) and EtOC(O)Cl (609 mg, 5.62 mmol). After stirring for 30 min, the solvent was removed in vacuo, the residue dissolved in CH_2Cl_2, Clip-Phen (1 g, 2.23 mmol) added, and the solution stirred at room temperature for 3 h. The solvent was removed in vacuo, the residue redissolved in CH_2Cl_2 (50 mL), and the solution was washed with aqueous $KHCO_3$ (5%, 3 × 50 mL), H_2O (3 × 50 mL), dried ($MgSO_4$), and concentrated in vacuo to afford the product as an oily solid (1.22 g, 83%). − ^{1}H NMR (CD_2Cl_2): δ = 1.0−1.2 (m, 4 H, CH_2CH_2), 1.38 [s, 9 H, C(CH_3)$_3$] 1.41 (m, 2 H, CH_2), 2.24 [t, 2 H, *J* = 7.5 Hz, CH_2C(O)NH], 2.88 [m, 2 H, CH_2NHC(O)O], 4.55 [br. s, 1 H, OC(O)N*H*], 4.84 (m, 3 H, serinol bridge), 5.06 (m, 2 H, serinol bridge), 7.14 (d, 2 H, *J* = 8.5 Hz, 3′-H), 7.62 (dd, 2 H, *J* = 8, 4.25 Hz, 8′-H), 7.71 (d, 2 H, *J* = 8.75 Hz, 6′-H) 7.77 (d, 2 H, *J* = 8.75 Hz, 5′-H), 8.14 (d, 2 H, *J* = 8.5 Hz, 4′-H), 8.27 (dd, 2 H, *J* = 1.5, 8 Hz, 7′-H), 8.69 [d, 1 H, *J* = 5.8 Hz, CH$_2$C(O)N*H*], 9.10 (dd, 2 H, *J* = 1.5, 4.25 Hz, 9′-H). − DCI MS; *m*/*z* (%): 661 (72) [MH$^+$]. − $C_{38}H_{40}N_6O_5$ (660).

Clip-Phen-hexylamine (3): 2 (1 g, 1.52 mmol) was dissolved in 25% (v/v) of CF_3COOH/CH_2Cl_2 (40 mL) and the solution stirred for 1 h at room temperature. The solvent was then removed in vacuo, the residue dissolved in H_2O, and the pH adjusted to 12 (1 M NaOH). Extraction of this solution with CH_2Cl_2, followed by drying ($MgSO_4$) and concentration in vacuo afforded the product as a pale yellow solid (823 mg, 97%). − ^{1}H NMR (CD_2Cl_2): δ = 1.0−1.2 (m, 4 H,CH_2CH_2), 1.41 (m, 2 H, CH_2), 2.05 (br. s, 2 H, CH$_2$NH_2), 2.21 [t, 2 H, *J* = 7.8 Hz, CH_2C(O)NH], 2.44 (t, 2 H, *J* = 6.5 Hz, CH_2NH$_2$), 4.85 (m, 3 H, serinol bridge), 5.06 (m, 2 H, serinol bridge), 7.14 (d, 2 H, *J* = 8.5 Hz, 3′-H), 7.58 (dd, 2 H, *J* = 8, 4.25 Hz, 8′-H), 7.69 (d, 2 H, *J* = 8.75 Hz, 6′-H), 7.76 (d, 2 H, *J* = 8.75 Hz, 5′-H), 8.13 (d, 2 H, *J* = 8.5 Hz, 4′-H), 8.26 (dd, 2 H, *J* = 1.5, 8 Hz, 7′-H), 8.69 [d, 1 H, *J* = 5.8 Hz, CH$_2$C(O)N*H*], 9.06 [dd, 2 H, *J* = 1.5, 4.25 Hz, 9′-H]. − DCI MS; *m*/*z* (%): 561 (100) [MH$^+$].

9-Chloroacridine: Acridone (2 g, 10.3 mmol) and $POCl_3$ (20 mL) were placed in a round-bottomed flask and heated at reflux for 1 h. The unused $POCl_3$ was then removed by distillation under vacuum, the residue cooled to 50°C, diluted with $CHCl_3$ (20 mL), and poured into aqueous ammonia (30%, 10 mL) and ice (25 g). After the organic layer was separated and the aqueous further extracted with $CHCl_3$ (3 × 50 mL), the organic layers were combined, dried ($MgSO_4$), and concentrated to 10 mL, and then hexane was added. Filtration afforded the product as a yellow solid (1.99 g, 91%). − ^{1}H NMR (CD_2Cl_2): δ = 7.67 (dd, 2 H, *J* = 9.9 Hz, 2′′-H or 3′′-H), 7.82 (dd, 2 H, *J* = 9.9 Hz, 2′′-H or 3′′-H), 8.20 (d, 2 H, *J* = 9 Hz, 1′′-H or 4′′-H), 8.44 (d, 2 H, *J* = 9 Hz, 1′′-H or 4′′-H). − DCI MS; *m*/*z* (%): 214 (100) [MH$^+$]. − $C_{13}H_8ClN$ (213): calcd. C 73.0, H 3.77, N 6.56; found C 72.7, H 3.35, N 6.41.

9-Phenoxyacridine: 9-Chloroacridine (680 mg, 3.2 mmol) was added to a solution of NaOH (200 mg, 5 mmol) in phenol (3 g, 32 mmol), the mixture was stirred at 100°C for 2 h, then poured into NaOH solution (2 M, 50 mL). The solution was then extracted with $CHCl_3$ (3 × 50 mL) and the solution dried ($MgSO_4$) and concentrated in vacuo. Recrystallisation of the residue from hot MeOH/H_2O (50:50) afforded the product as pale yellow needles (770 mg, 89%). − ^{1}H NMR (CD_2Cl_2): δ = 6.87 (m, 2 H, phenoxy 2-H), 7.05 (m, 1 H, phenoxy 4-H), 7.27 (m, 2 H, phenoxy 3-H) 7.47 (dd, 2 H, *J* = 9.9 Hz, 2′′-H or 3′′-H), 7.78 (dd, 2 H, *J* = 9, 9 Hz, 2′′-H or 3′′-H), 8.11 (d, 2 H, *J* = 9 Hz, 1′′-H or 4′′-H), 8.25 (d, 2 H, *J* = 9 Hz, 1′′-H or 4′′-H). − DCI MS; *m*/*z* (%): 272 (100) [MH$^+$]. $C_{19}H_{13}NO$ (271).

6-Chloro-2-methoxy-9-phenoxyacridine: 6,9-Dichloro-2-methoxyacridine (2 g, 7 mmol) was added to a solution of NaOH (400 mg, 10 mmol) in phenol (10 g, 106 mmol), the mixture was stirred at

100°C for 2 h and then poured into NaOH solution (2 M, 50 mL). After this solution had been extracted with $CHCl_3$ (3 × 50 mL), the combined organic layers were dried ($MgSO_4$) and concentrated in vacuo. Recrystallisation of the residue from hot MeOH afforded the product as yellow needles (2.02 g, 84%). − ^{1}H NMR (CD_2Cl_2): δ = 3.79 (s, 3 H, OC*H*$_3$), 6.86 (d, 2 H, *J* = 12 Hz, phenoxy 2-H), 7.06 (t, 1 H, *J* = 7 Hz, phenoxy 4-H), 7.16 (d, 1 H, *J* = 2.75 Hz, 1′′-H or 5′′-H), 7.26 (m, 2 H, phenoxy 3-H), 7.37 (dd, 1 H, *J* = 9.25, 2 Hz, 3′′-H or 7′′-H), 7.45 (dd, 1 H, *J* = 2.75, 9.5 Hz, 3′′-H or 7′′-H), 7.97 (d, 1 H, *J* = 9.25 Hz, 4′′-H or 8′′-H), 8.08 (d, 1 H, *J* = 9.5 Hz, 4′′-H or 8′′-H), 8.17 (d, 1 H, *J* = 2 Hz, 1′′-H or 5′′-H). − DCI MS; *m*/*z* (%): 336 (100) [MH$^+$].

Clip-Phen-hexylaminoacridine (4): Compound **3** (200 mg, 0.36 mmol), 9-phenoxyacridine (195 mg, 0.72 mmol), and acetic acid (216 mg , 3.6 mmol) were added to CH_3CN (15 mL) and the solution was heated at reflux for 18 h. The solvent was then removed in vacuo, the residue was dissolved in H_2O and the pH adjusted to 12 (1 M NaOH). The solution was extracted with $CHCl_3$ (2 × 50 mL), the combined organic layers dried ($MgSO_4$), concentrated in vacuo, and the residue was purified by column chromatography (CH_2Cl_2/MeOH/Et_3N, 92:7:1) on silica gel to afford the product (R_f = 0.3) as a bright yellow solid (194 mg, 74%). − UV/Vis (phosphate buffer, pH = 7.2): λ_{max} (ε M^{-1}cm^{-1}) = 226 (87500), 268 (90600), 396 (7000), 415 (8600) and 437 (8100). − ^{1}H NMR (CD_2Cl_2): δ = 1.23 (m, 2 H, NHCH$_2$CH$_2$C*H*$_2$CH$_2$CH$_2$), 1.51 (m, 4 H, NHCH$_2$C*H*$_2$CH$_2$C*H*$_2$CH$_2$), 2.31 (t, 2 H, *J* = 7.25 Hz, NHCH$_2$CH$_2$CH$_2$CH$_2$C*H*$_2$), 3.57 (t, 2 H, *J* = 7 Hz, NHC*H*$_2$-CH$_2$CH$_2$CH$_2$CH$_2$), 4.84 (m, 3 H, serinol bridge), 4.99 (m, 3 H, serinol bridge), 7.08 (d, 2 H, *J* = 8.5 Hz, 3′-H), 7.25 (m, 2 H, 2′′-H or 3′′-H), 7.51 (dd, 2 H, *J* = 8, 4.25 Hz, 8′-H), 7.58 (d, 2 H, *J* = 8.75 Hz, 6′-H), 7.59 (m, 2 H, 2′′-H or 3′′-H), 7.65 (d, 2 H, *J* = 8.75 Hz, 5′-H), 7.96 (d, 2 H, *J* = 8.75 Hz, 1′′-H or 4′′-H), 8.04 (d, 2 H, *J* = 8.5 Hz, 4′-H), 8.06 (d, 2 H, *J* = 8.75 Hz, 1′′-H or 4′′-H), 8.16 (dd, 2 H, *J* = 1.5, 8 Hz, 7′-H), 8.92 (br. d, 1 H, *J* = 5.75 Hz, N*H*CO), 9.02 (dd, 2 H, *J* = 1.5, 4.25 Hz, 9′-H). − DCI MS; *m*/*z* (%): 738 (18) [MH$^+$], 542 (38) [MH$^+$ − phenanthrolyloxy], 197 (100) [hydroxyphenathrolineH$^+$]. − $C_{46}H_{39}N_7O_3$ (737): calcd. 9-(3-Methoxyprop-1-ylamino)acridine (6): 3-Methoxypropylamine (50 mg, 0.56 mmol), 9-phenoxyacridine (140 mg, 0.52 mmol), and acetic acid (100 mg) were added to CH_3CN (5 mL) and the solution was heated at reflux for 1 h. The solvent was then removed in vacuo and the residue purified by column chromatography (CH_2Cl_2/MeOH/NH_4OH, 90:9:1) on silica gel to afford the product as a bright yellow solid (104 mg, 76%). − ^{1}H NMR (CD_2Cl_2): δ = 2.15 (m, 2 H, C*H*$_2$), 3.41 (s, 3 H, C*H*$_3$), 3.62 (t, 2 H, *J* = 5.5 Hz, C*H*$_2$), 3.99 (t, 2 H, *J* = 7 Hz, C*H*$_2$), 7.09 (dd, 2 H, *J* = 9, 9 Hz, 2′′-H or 3′′-H), 7.41 (dd, 2 H, *J* = 9, 9 Hz, 2′′-H or 3′′-H), 7.72 (d, 2 H, *J* = 9 Hz, 1′′-H or 4′′-H), 8.09 (d, 2 H, *J* = 9 Hz, 1′′-H or 4′′-H). − DCI MS; *m*/*z* (%): 331 (100) [MH$^+$].

6-Chloro-2-methoxy-9-(3-methoxyprop-1-ylamino)acridine (7): 3-Methoxypropylamine (50 mg, 0.56 mmol), 6-chloro-2-methoxy-9-phenoxyacridine (100 mg, 0.30 mmol), and acetic acid (100 mg) were added to CH_3CN (5 mL) and the solution was heated at reflux for 1 h. The solvent was then removed in vacuo and the residue was purified by column chromatography (CH_2Cl_2/MeOH/NH_4OH, 90:9:1) on silica gel to afford the product as a bright yellow solid (80 mg, 81%). − ^{1}H NMR (CD_2Cl_2): δ = 1.97 (m, 2 H, C*H*$_2$), 3.45 (s, 3 H, C*H*$_3$), 3.67 (t, 2 H, *J* = 5.5 Hz, C*H*$_2$), 3.88 (t, 2 H, *J* = 6 Hz, C*H*$_2$), 3.93 (s, 3 H, OC*H*$_3$), 7.27 (dd, 1 H, *J* = 2, 9 Hz, 3′′-H or 7′′-H), 7.30 (d, 1 H, *J* = 2 Hz, 1′′-H or 5′′-H), 7.38 (dd, 1 H, *J* = 2, 9 Hz, 3′′-H or 7′′-H), 7.92 (d, 1 H, *J* = 9 Hz, 4′′-H or 8′′-H), 7.99 (d, 1 H, *J* = 2 Hz, 1′′-H or 5′′-H) and 8.12 (d, 1 H, *J* = 9 Hz, 4′′-H or 8′′-H). − DCI MS; *m*/*z* (%): 267 (100) [MH$^+$].

[(Clip-Phen)Cu^{II}](PF$_6$)$_2$: $CuCl_2$ (3 mg, 0.022 mmol) and Clip-Phen (10 mg, 0.022 mmol) were dissolved in DMF (2 mL) and the solution was stirred for 4 h. Diethyl ether was then added and the solution left at −20°C for 18 h. The green precipitate which had formed was isolated by centrifugation, washed with ether, and dried. This solid was then dissolved in MeOH (2 mL) and a solution of NH_4PF_6 (15.9 mg, 0.1 mmol) in MeOH/H_2O (2 mL, 50:50) was added to give immediately a green precipitate. This was isolated by centrifugation, washed with H_2O and dried in vacuo (11.8 mg, 78%). − UV/Vis (CH_3CN): λ_{max} (ε M^{-1}cm^{-1}) = 226 (71800), 272 (49800), 810 (132). − ES MS; *m*/*z* (%): 510 (26) [Cu(Clip-Phen)]$^+$. − $C_{27}H_{21}CuF_{12}N_5O_2P_2$ (800.5): calcd. (+ 2 H_2O) C 38.7, H 2.98, N 8.37; found C 38.7, H 2.61, N 8.21.

Complex Formation with Ligands 1, 4, and 5: Molar equivalents of ligand and $Cu(OAc)_2 \cdot 2\ H_2O$ were dissolved separately in a small volume (1−2 mL) of warm methanol, then the solutions were mixed and left to stand for 2 h. A fivefold excess of NH_4PF_6 was then added as an aqueous solution to afford a precipitate. Acetone was slowly added until the solid dissolved and the solution was left open to the air for 24−48 h. Evaporation of the acetone afforded the product as a precipitate, which was isolated by centrifugation, washed with water and dried in vacuo.

[(1)Cu^{II}](PF$_6$)$_2$: Reaction of **1** and $Cu(OAc)_2 \cdot H_2O$ on a 0.024-mmol scale afforded 14.9 mg (74%) of product as a pale green solid. − UV/Vis (CH_3CN): λ_{max} (ε M^{-1}cm^{-1}) = 226 (55900), 276 (44400), 818 (135). − ES MS; *m*/*z* (%): 550.9 (100) [Cu(**1**)]$^+$. − $C_{29}H_{23}CuF_{12}N_5O_3P_2$ (842.5): calcd. (+ 0.5 CH_3COCH_3) C 41.9, H 2.97, N 8.03; found C 42.2, H 3.00, N 8.31.

[(4)Cu^{II}](PF$_6$)$_2$ · HPF$_6$: Reaction of **4** and $Cu(OAc)_2 \cdot H_2O$ on a 0.025-mmol scale afforded 17.0 mg (55%) of product as a bright

yellow solid. − UV/Vis (phosphate buffer, pH = 7.2): λ_{max} (ε $M^{-1}cm^{-1}$) = 226 (97600), 274 (89900), 394 (4200), 414 (6800), 437 (5500) and 814 (180). − ES MS; *m/z* (%): 799.3 (73) $[Cu(\mathbf{4})]^+$. − $C_{46}H_{40}CuF_{18}N_7O_3P_3$ (1236.5): calcd. C 44.6, H 3.23, N 7.88; found C 45.0, H 3.22, N 7.92.

$[(5)Cu^{II}](PF_6)_2 \cdot HPF_6$: Reaction of **5** and $Cu(OAc)_2 \cdot H_2O$ on a 0.025-mmol scale afforded 20.2 mg (62%) of product as a bright yellow solid. − UV/Vis (phosphate buffer, pH = 7.2): λ_{max} (ε $M^{-1}cm^{-1}$) = 226 (122000), 274 (122000), 426 (2900), 444 (2700) and 818 (146). − ES MS; *m/z* (%): 865.3 (100) $[Cu(\mathbf{5})]^+$. − $C_{47}H_{41}ClCuF_{18}N_7O_4P_3$ (1301): calcd. (+ CH_3COCH_3) C 44.2, H 3.45, N 7.21; found C 44.2, H 3.30, N 7.46.

DNA Cleavage Experiments: Reactions were carried out in a total volume of 20 μL (10 μL DNA and buffer + 5 μL complex + 5 μL MPA) containing 250 ng of Φx174 viral DNA (7nM, 19 μM in base pairs) in 40 mM sodium phosphate (pH = 7.2), 50 mM NaCl and 10 mM $MgCl_2$ (final concentrations). Complexes were prepared as 1mM stock solutions in DMF, which were then diluted to 4 μM with water, prior to being added to DNA solutions for 30 min at room temperature. DNA cleavage was initiated by addition of mercaptopropionic acid (5 μL, 20mM, final concentration 5mM) and samples were incubated at 37°C for 1 h. 7.5 μL of a solution of 50% (v/v) glycerol/40 mM Tris. HCl buffer (pH = 8) and 0.05% bromophenol blue (w/v) was then added and the samples were immediately loaded on agarose gel (0.8%) containing 1 μg/mL of ethidium bromide. Electrophoresis was carried out at constant current (25 mA) for 15 h in TBE buffer. Bands were located by UV light, photographed, and quantified by microdensity, rates being averaged from at least 3 different sets of experimental data. The correction coefficient 1.47 was used for the decrease in stainability of form I DNA versus forms II and III.[22] The average number of single-strand scissions per DNA molecule, expressed as μ, was considered to be equal to −ln(fraction of form I) according to a Poisson distribution.[23]

UV/Vis-Spectrophotometric Titrations: Solutions were prepared with the appropriate acridine derivative (4 μL of a 2.5 mM solution in DMF), calf-thymus DNA (diluted from a 1 mg/mL solution), NaCl (final concentration 50 mM), $MgCl_2$ (final concentration 10 mM) and phosphate buffer (pH = 7.2, final concentration 40 mM) and diluted with H_2O to a total volume of 1 mL. After equilibration for 24 h, spectra were recorded against an analogous blank solution containing the same concentration of DNA/NaCl/$MgCl_2$ and phosphate buffer. The $CuCl_2$ complexes of **4** and **5** were preformed for 30 min (4 μL of 2.5 mM ligand solution and 1 μL of 10 mM $CuCl_2$ solution) prior to dilution with the appropriate salts and DNA.

Transition Metal Ions in Microporous Crystalline Aluminophosphates: Isomorphous Substitution

Bert M. Weckhuysen,*[a] R. Ramachandra Rao,[a] Johan A. Martens,[a] and Robert A. Schoonheydt[a]

Keywords: Microporous crystalline aluminophosphates / Isomorphous substitution / Synthesis / Spectroscopy / Heterogeneous catalysis / Transition metal ion

Microporous crystalline metalloaluminophosphates (MeAPO-*n*) represent an important group of molecular sieves because of their potential catalytic and adsorptive properties. Many transition metal ions are claimed to incorporate in the framework of these molecular sieves. Here, the concept of isomorphous substitution, and the different indirect and direct tools available to verify this substitution process for Co, Cr, V, Fe and Mn are reviewed taking the $AlPO_4$-5 structure as an example. In addition, it will be shown that transition metal ions can be used as a probe to follow the hydrothermal synthesis process of microporous aluminophosphates.

Bert M. Weckhuysen was born in Aarschot, Belgium in 1968. In 1991 he received his M.S. degree from the Faculty of Agronomy and Applied Biological Sciences, Catholic University of Leuven, Belgium. From 1991 to 1995 he was employed as a doctoral student at the Center for Surface Chemistry and Catalysis under the supervision of Professor Robert A. Schoonheydt. There he gained experience in spectroscopic techniques, zeolite synthesis, catalyst design, and characterization. After obtaining his Ph.D. in Applied Biological Sciences in 1995, he has worked as a visiting research scientist with Professor Israel E. Wachs at the Zettlemoyer Center for Surface Studies of Lehigh University, USA. From 1996 to 1997 he has worked as a postdoc with Professor Jack H. Lunsford in the Chemistry Department of Texas A&M University, USA. Presently, he is a postdoctoral research fellow of the National Fund of Scientific Research at the Catholic University of Leuven. He is author of more than 50 scientific papers.

Ramachandra R. Rao was born in Kanigiri, India in 1968. In 1991 he received his M.S. degree from the A.P.S. University, Rewa, India. After obtaining his Ph.D. in Chemistry from the Osmania University, Hyderabad, India under the supervision of Dr. S. J. Kulkarni in 1996, he moved to the Catholic University of Leuven, Belgium. Presently, he is a postdoctoral fellow at the Department of Interphase Chemistry. His research interests are in the synthesis, characterization and applications of zeolite-based materials. He has authored more than 15 scientific publications.

Johan A. Martens was born in Jette, Belgium in 1958. He obtained his Ph.D. in Applied Biological Sciences at the Catholic University of Leuven, Belgium in 1985. After a research career at the National Fund of Scientific Research, he became full professor in environmental catalysis at the Department of Interphase Chemistry of the Catholic University of Leuven. His teaching assignments are in the fields of "Synthesis of the highly divided solids", "Adsorption" and "Catalysts, adsorbents and colloids for industry and environment". He is author of the book "Synthesis of high-silica aluminosilicate zeolites", editor of two conference proceedings and has published 120 scientific papers. In 1995, he was granted the Exxon Chemical Biannual Science and Engineering Award, for "pioneering research in heterogeneous catalysis for hydrocarbon and natural feedstocks". His current research themes are environmental catalysis, surface chemistry, sol-gel processes, synthesis of oxides, zeolites, adsorption and separation processes, petroleum refining and DeNOx processes.

Robert A. Schoonheydt received his M.S. degree in 1966 and his Ph.D. in 1970, both under the supervision of Professor Jan B. Uytterhoeven at the Catholic University of Leuven, Belgium. After one year as a postdoc with Professor Jack H. Lunsford in the Chemistry Department of Texas A&M University, USA, he returned to the Catholic University of Leuven as a National Fund of Scientific Researchresearcher. He became full professor in 1989. His teaching responsibilities include physical chemistry, analytical chemistry, and general thermodynamics for engineering students at the Faculty of Agricultural and Applied Biological Sciences. His research is concentrated in three areas: (1) spectroscopy and chemistry of surface transition metal ions; (2) molecular organization on clay surfaces, and (3) theoretical modeling of molecule-surface interactions. He has authored more than 170 scientific papers, and is the editor of the book "Developments in the theory of chemical reactivity and heterogeneous catalysis". Presently, he is secretary-general of AIPEA and dean of the Faculty of Agricultural and Applied Biological Sciences. He also serves on the editorial board of Microporous and Mesoporous Materials, Applied Clay Science and European Journal of Inorganic Chemistry.

MICROREVIEWS: This feature introduces the readers to the authors' research through a concise overview of the selected topic. Reference to important work from others in the field is included.

1. Introduction

Material scientists usually subdivide the family of microporous crystalline oxides into silicate-based and phosphate-based materials[1] (Figure 1). Although this distinction has a historical origin because phosphate-based molecular sieves have been discovered after their silicate-based counterparts, it is often very arbitrary, as some molecular sieves contain both silicon and phosphorus; i.e., the silicoaluminophosphates (SAPO′s). In addition, two other classes of materials recently emerged, which includes the family of e.g. octahedral molecular sieves.

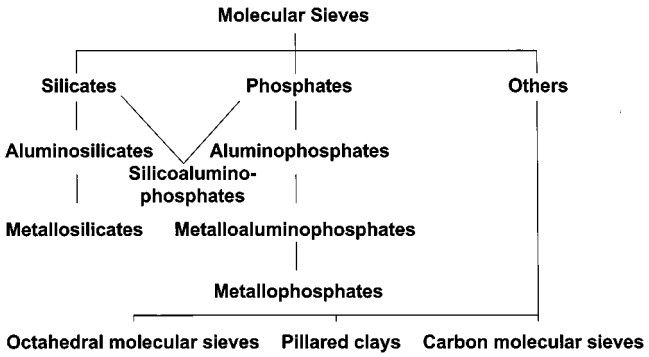

Figure 1. Molecular sieves can be split into three main families, the silicate-based materials containing the aluminosilicates or zeolites and the metallosilicates; the phosphate-based materials containing the aluminophosphates, silicoaluminophosphates, metalloaluminophosphates, and metallophosphates; and finally a remaining group of materials, such as the octahedral molecular sieves

Aluminophosphates consist of tetrahedra of Al^{3+} and P^{5+}, which are corner-sharing an oxygen atom, and building up a three-dimensional framework with channels and/or pores of molecular dimensions.[2,3] This is schematically illustrated in Figure 2. A well-known example is $AlPO_4$-5 (Figure 3), which has one-dimensional channels with 12-ring apertures of 7.3 Å diameter. The acronym $AlPO_4$-*n* is usually used for denoting the different framework structures, and actually more than 35 different topologies of $AlPO_4$-*n* materials are known in the literature.[1−3] All these materials are crystallized from aqueous or non-aqueous solutions at temperatures up to 473 K in the presence of organic structure-directing agents, called templates. Since the first publication on microporous crystalline aluminophosphates in 1982,[4] these materials have attracted a lot of attention mainly because of the promising catalytic and adsorptive properties. Recently, the family of phosphate-based molecular sieves has been further expanded towards mesoporous materials with channel dimensions up to 50 Å.[5]

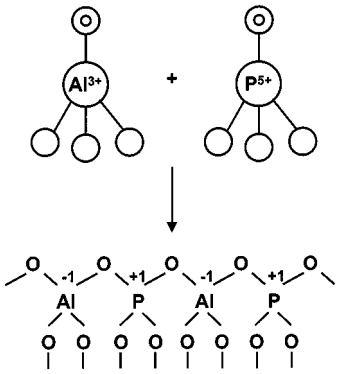

Figure 2. Assembly of a microporous aluminophosphate material (after ref.[1])

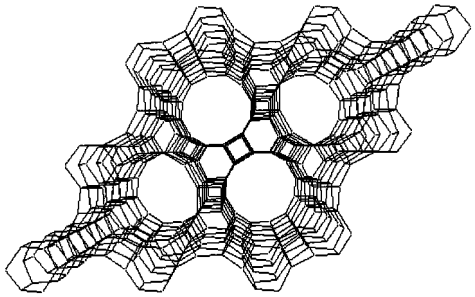

Figure 3. Pictorial representation of the $AlPO_4$-5 structure

In topological models of $AlPO_4$-*n* materials, Al^{3+} and P^{5+} are mostly considered to be both in tetrahedral coordination (Figure 2). This is generally true for dehydrated materials, but important framework distortions or coordination changes may occur in actual $AlPO_4$-*n* crystals in the presence of adsorbed molecules. Indeed, NMR experiments have revealed the formation of five- or six-fold coordinated Al^{3+} in $AlPO_4$-*n* (with n = 5, 11, 21, and 25) materials by interaction with water, ammonia, methanol and acetonitrile.[6] The adsorption of e.g. water may also result in the hydrolysis of Al−O−P bonds with the formation of hydroxy groups. Thus, interrupted frameworks can be formed, in which Al−O−P bonds are systematically missing. These aspects of crystal chemistry of microporous crystalline aluminophosphates seem to be essential in understanding the concept of isomorphous substitution.

Isomorphous substitution in dense oxides is defined as the replacement of an element in the crystalline framework by another element with similar cation radius and coordination requirements.[1c,1d] The concept of isomorphous substitution can be handled for molecular sieves as well, and is

very important because it may result in novel materials with special redox and catalytic properties. Although isomorphous substitution in $AlPO_4$-*n* materials is generally considered as a complex phenomenon, currently 17 elements are reported to replace Al^{3+} and/or P^{5+}; i.e., Be, B, Mg, Si, Ti, V, Cr, Mn, Fe, Co, Ni, Cu, Zn, Zr, Ge, Ga, and As.[1,7] Furthermore, the synthesis of multi-element phases containing up to six different elements has also been claimed.[12]

The only experimental limitation up to now was the substitution degree, which was set to about 38% of the Al^{3+} sites replaced by a particular transition metal ion (TMI).[8] However, very recently Stucky and co-workers were able to increase the substitution degree up to 90% by applying novel synthesis routes.[9] These results suggest that there exists no upper limit to the amount of a particular TMI incorporating in the framework of MeAPO-*n* materials. Indeed, the synthesis of microporous metallophosphates containing no aluminum is also reported in the literature. Some examples are UCSB-6GaCo, a microporous $Co_xGa_{1-x}PO_4$ material synthesized at the University of California at Santa Barbara,[9] DAF-2, a microporous $CoPO_4$ material discovered in the Davy Faraday Research Laboratory[10] and a microporous $ZnPO_4$.[11]

The aim of this review is to give an overview of the evidence currently available in the literature whether a TMI is isomorphously substituted in the framework of MeAPO-*n* materials or not. We will limit ourselves to CoAPO-5 (Co), CrAPO-5 (Cr), VAPO-5 (V), FAPO-5 (Fe), and MnAPO-5 (Mn) because of their well-documented literature. The paper starts with a brief review of the general concepts of isomorphous substitution. These concepts will then be applied to the different TMIs under study, and the obtained information will be compared with the available spectroscopic data. Both indirect and direct tools to verify isomorphous substitution will be discussed. In a third part, it will be shown that TMIs can be used as a probe to monitor the synthesis process of microporous crystalline aluminophosphates. In a final part, the application of microporous crystalline aluminophosphates in the field of heterogeneous catalysis will be briefly discussed. Special emphasis will be placed on possible leaching and mobility of the TMI. The review closes with some concluding remarks, and an outlook into the future.

2. Isomorphous Substitution

As mentioned above, isomorphous substitution in microporous crystalline aluminophosphates is complex, and two different substitution mechanisms can be envisaged for TMIs.[1] This is schematically illustrated in Figure 4. Substitution mechanism (SM) I involves the substitution of an Al atom for a TMI with valence +1 (Ia), +2 (Ib), or +3 (Ic), whereas SM II consists of the replacement of a P atom by a TMI with valence +4 (IIa) or +5 (IIb). Other types of substitutions not mentioned in Figure 4 seem to be very unlikely because they would lead either to positively charged frameworks or to a too high negative charge density. In the case of Si^{4+}, both P^{5+} and Al^{3+} are simultaneously replaced, and, as a consequence, silicon islands are formed in SAPO-5 materials. It is also clear from Figure 4 that SM Ia, Ib, and IIa lead to negatively charged frameworks, which must be balanced by an equivalent number of positively charged extra-framework species such as quaternary ammonium cations, protonated amines, hydroxonium ions or TMIs. On the other hand, SM Ic and IIb lead to electroneutral frameworks, and no charge balancing ions are involved. Finally, it is important to notice that TMI occurring in the synthesis medium under different oxidation states may be simultaneously incorporated according to different substitution mechanisms.

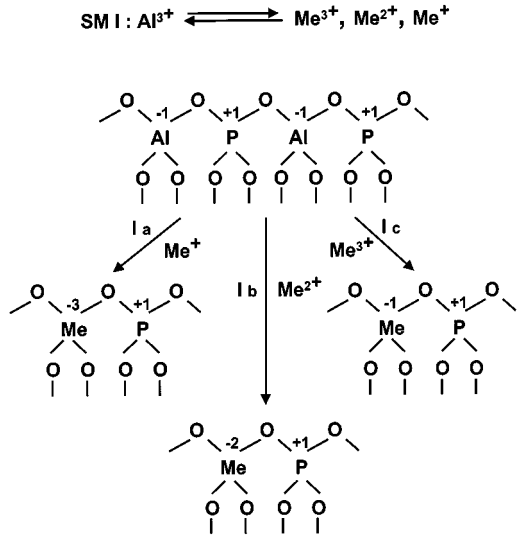

Figure 4A. Isomorphous substitution mechanism I (denoted as SM I) of $AlPO_4$-*n* molecular sieves (after ref.[1])

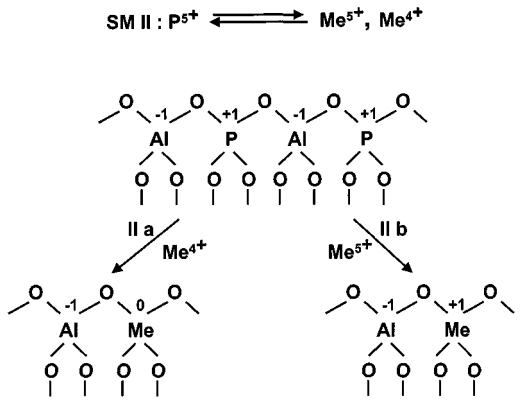

Figure 4B. Isomorphous substitution mechanism II (denoted as SM I) of $AlPO_4$-*n* molecular sieves (after ref.[1])

Four criteria are important for isomorphous substitution of a TMI in $AlPO_4$-5 materials:

(1) The formal charge and the ionic radius of the TMI to be incorporated. In the ionic bonding theory the limited ratios r_+/r_- for tetrahedral and octahedral coordination are

0.225 and 0.414, respectively, [with $r_- = r(O^{2-}) = 1.33$ Å and $r_+ = r$(cation) = 0.299 or 0.551 Å for tetrahedral or octahedral substitution, respectively]. According to Table 1, divalent transition metal ions are too large; trivalent cations are on the limit of tetrahedral coordination, while higher valency would in principle lead to isomorphous substitution.

(2) The solution chemistry of the TMI as a function of the pH of the synthesis gel. Here, it is crucial to avoid precipitation of insoluble transition metal hydroxides or oxides during the synthesis process because they may prevent that the TMI becomes available for isomorphous subsitution.

(3) The ligand field stabilization energy (LFSE) of the TMI. In the cases under study octahedral coordination is always the preferred one.

(4) The thermodynamic stability of the resulting microporous aluminophosphate framework.

Table 1. Ionic cation radii [Å] for different coordination geometries of P, Al, and transition metal ions

Cation	4	5	6	Cation	4	5	6
P^{5+}	0.17	–	–	Mn^{4+}	–	–	0.54
Al^{3+}	0.39	–	0.53	Mn^{3+}	–	0.58	0.65
Co^{2+}	0.57	–	0.74	Mn^{2+}	–	–	0.82
Co^{3+}	–	–	0.61				
Fe^{2+}	0.63	–	0.78				
Fe^{3+}	0.49	–	0.65	Cr^{6+}	0.30	–	–
V^{5+}	0.355	0.46	0.54	Cr^{5+}	0.35	–	–
V^{4+}	–	–	0.59	Cr^{3+}	–	–	0.615
V^{3+}	–	–	0.64	Cr^{2+}	–	–	0.82

Based on the cation radii and valence states it is then likely to assume that Co^{2+}, Fe^{2+}, and Fe^{3+} are substituting for Al^{3+} in the $AlPO_4$-5 framework according to SM Ib or Ic, whereas for example V^{5+} may replace P^{5+}. In any case, the possible incorporation of e.g. octahedrally coordinated Cr^{3+} and Mn^{2+} ions can only be explained by the flexibility of the aluminophosphate framework, and specific interactions with e.g. the organic template molecule. An additional explanation can be found in the unique possibility to increase the coordination number from four to five or six by interaction with additional ligands not being part of the framework; e.g., H_2O or OH groups, as was already discussed above for framework aluminum in $AlPO_4$-5 materials.[6] In addition, TMIs may also exist as oxides or extra-framework cations at the surface of the molecular sieves. Thus, the goal is then to develop direct and indirect tools which are able to verify isomorphous substitution.

3. Indirect Tools to Verify Isomorphous Substitution

The incorporation of TMIs into the framework of $AlPO_4$-5 materials would lead to an increase in unit cell volume of the crystal structure, all other factors remaining invariant (symmetry, etc.). This is expected because the radii of high-spin tetrahedral TMI, in a *T*-O matrix, is larger than that of Al^{3+} or P^{5+} (Table 1), and this expansion can be directly measured by X-ray diffraction techniques (XRD), according to

$$4/3\ [(h^2 + hk + k^2)/a^2] + l^2/c^2 = (4 \sin^2\theta)/\lambda^2$$

with *a* and *c*, the cell parameters of the unit cell of a hexagonal system; θ, the diffraction angle; and λ, the wavelength of the incident X-rays. An example of such a lattice expansion is shown for VAPO-5 materials in Figure 5.[12] However, such lattice expansions are not always observed, and no lattice expansions or even lattice contractions are reported in the literature for MeAPO-5 systems.[13] One of the explanations is that the amount of TMI is not sufficient to change the unit cell dimensions within the experimental error of the system.

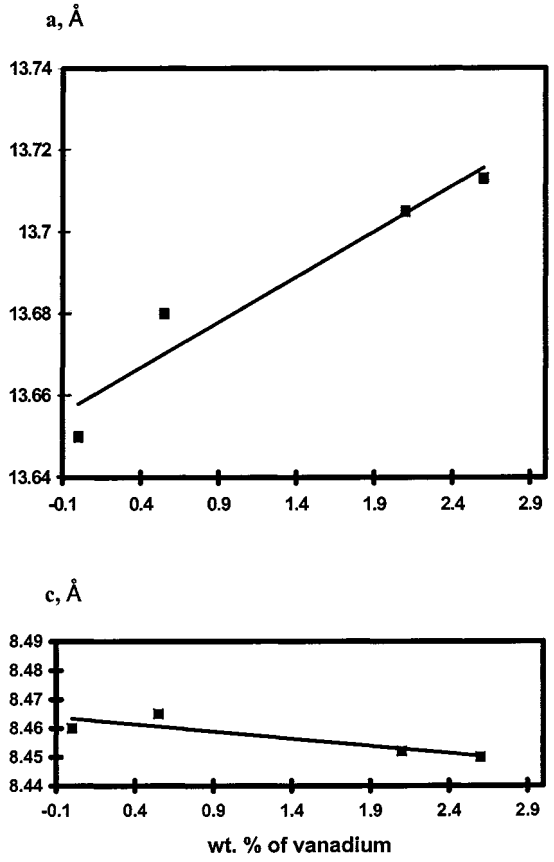

Figure 5. Lattice expansion as observed for VAPO-5 materials: variation of the *a* and *c* cell parameters as a function of the vanadium content (after ref.[12])

Isomorphous substitution can also be verified by chemical analysis. One expect then that the molar ratio of ([TMI] + [Al])/[P] (if the TMI is replacing Al) or ([TMI] + [P])/[Al] (if the TMI is replacing P) is equal to 1. Although this method is still very useful, it is very arbitrary and often inaccurate. Indeed, unreasonable values will be obtained if extra-framework TMI is present or if different substitution mechanisms simultaneously occur in the synthesis medium.

Another method to verify isomorphous substitution is by measuring the weight loss, associated with the burning of the template molecule. In the case of the template molecule Et_3NH^+, one can write the following combustion reaction:

$Et_3NH^+ + 11\ O_2 \rightarrow 6\ CO_2 + 8\ H_2O + NO_2$. It is then assumed that for every TMI^{n+} ($n = 2$) substituting for Al in the lattice, one template molecule is needed to compensate for the negative charge of the framework. It is important to notice that the combustion process of an occluded and positively charged template molecule usually occurs at a higher temperature than that of an adsorbed neutral template molecule.

The formation of extra-framework TMI can be indirectly probed by comparing the volume of intrachannel void space of MeAPO-5 and $AlPO_4$-5. Indeed, the generation of extra-framework species in channels and cavities would reduce the available void space of the $AlPO_4$-5 crystals.

Finally, if Me^{2+} (e.g., Co^{2+}, Fe^{2+}, and Mn^{2+}) substitute for Al^{3+}, one expects the formation of Brønsted acid sites in a concentration equal to that of Me^{2+}. The amount of Brønsted acid sites can be measured by performing TPD with e.g. a secondary amine, such as isopropylamine. Another interesting method is IR spectroscopy in conjunction with ammonia and acetonitrile as probe molecules. One of the problems here is to distinguish between the different forms of acidity (Lewis vs. Brønsted acidity).

The results of the application of these indirect measurements for isomorphous substitution to MeAPO-5 materials (with Me = Co, Cr, V, Fe, and Mn) are summarized in Table 2. It is clear that there is indirect evidence for the isomorphous substitution of Co^{2+}, $Fe^{2+/3+}$, and Mn^{2+} into the framework of $AlPO_4$-5 molecular sieves. Another problem with indirect methods, besides that they being indirect, is the lack of sensitivity. As a consequence, relatively high amounts of framework TMI are necessary to observe characteristic changes with the techniques mentioned.

4. Direct Tools to Verify Isomorphous Substitution

It can be concluded from the previous section that other more direct − preferably spectroscopic − techniques have to be called in to distinguish between framework and extra-framework TMI. Because each spectroscopic technique has its own sensitivity and application domain, a whole battery of complementary spectroscopic techniques has been applied to obtain detailed information of the coordination environment of TMI. Another disadvantage is the occurrence of complex and overlapping spectra, and chemometrical techniques have to be called in to obtain fingerprint spectra of framework and extra-framework TMI.

4.1. Cobalt

CoAPO-5 is probably the most studied MeAPO-*n* system ever. This can be easily explained by the fact that almost all scientists agree that Co^{2+} is substituting − at least partially − for Al^{3+} in the framework. This has been evidenced by applying a combination of DRS, ES, and EXAFS spectroscopies.

As mentioned above, the TMI content that can be incorporated into the $AlPO_4$-5 structure is still limited, and attempts to synthesize CoAPO-5 with high Co content usually lead to low-crystalline products contaminated with impurities.[15] An explanation for the failure in obtaining a pure CoAPO-5 phase from Co-rich gels can be the more favorable crystallization of other competing crystalline phases, such as the chabazite structure of CoAPO-34.[16,17] In addition, when attempting to incorporate large amounts of Co^{2+} in the framework, some of the Co^{2+} is present as octahedral Co^{2+}, clustered CoO and/or a $CoAl_2O_4$ phase.[18]

CoAPO-5 materials have been studied in detail by DRS spectroscopy, and an example of a set of DRS spectra is shown in Figure 6. The absorption bands for the blue, as-synthesized CoAPO-5 are typical for a perfect tetrahedron $[CoO_4]$ with two triplets centered at $\nu_2 = 6700\ cm^{-1}$ and $\nu_3 = 17300\ cm^{-1}$. This observation, together with the linear dependency of the band intensities with the Co^{2+} content are taken as proof of incorporation of Co^{2+} in the lattice. This is surprising because (1) the Co^{2+} radius of 0.57 Å is on the limit of tetrahedral and octahedral coordination and (2) the Co^{2+} radius is significantly larger than that of Al^{3+} (Table 1). As a consequence, a distortion of the $[CoO_4]$ tetrahedron is expected, and this strain is relieved in the lattice by interaction with adsorbed molecules in the 12-ring channels of the $AlPO_4$-5 structure.

This is proven by the DRS spectra taken after calcination in O_2 (Figure 6). A yellow-green sample is obtained with a distorted Co^{2+} species with two triplets centered at $\nu_2 = 5500\ cm^{-1}$ and $\nu_3 = 15150\ cm^{-1}$. These frequencies are indicative of a weaker ligand field, too. The distortion and strain of the zeolite lattice is reflected by the instability of the framework Co^{2+}. Indeed, part of the Co^{2+} is expelled from the lattice to give extra-framework pseudo-tetrahedral Co^{2+} ($\nu_2 = 5500$ and $\nu_3 = 16500\ cm^{-1}$) and octahedral Co^{2+} ($\nu_2 = 8100$ and $\nu_3 = 19550\ cm^{-1}$). A fraction of the Co remaining in the lattice is oxidized to high-spin tetrahedral Co^{3+} with its characteristic d-d transition at around

Table 2. Indirect criteria to verify isomorphous substitution of TMI in $AlPO_4$-5 molecular sieves

TMI	Lattice expansion	Chemical analysis	Template burning	Void space	Brønsted acidity
Co^{2+}	+	+	+	+	+/−
Cr^{3+}	nd	+/−	nd	nd	ne
V^{4+}	+/−	+/−	+	+	nd
$Fe^{2+/3+}$	+	+	nd	nd	−, ne (Fe^{3+})
Mn^{2+}	+	+	nd	nd	+

+: positive evidence; −: negative evidence; +/−: mixed opinions in the literature; nd: not determined; ne: not expected.

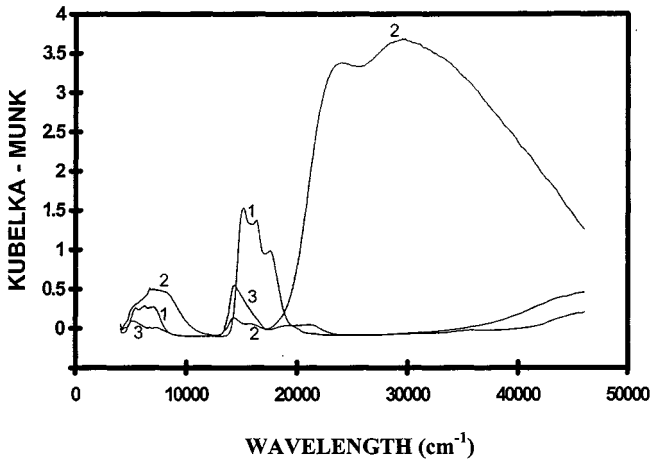

Figure 6. DRS spectra of CoAPO-5 materials as a function of the pretreatment: (1) in as-synthesized form; (b) after calcination overnight at 773 K and (3) after reduction with H_2 at 623 K (after ref.[16])

9000 cm^{-1}, and very intense $O \rightarrow Co^{3+}$ charge transfer transitions around 25000 and 31500 cm^{-1}.

The redox chemistry of Co is reversible. Co^{3+} is quantitatively reduced to Co^{2+} by H_2 at high temperatures, but also by CO, NO, methanol, acetone, and toluene.[16,19–25] The overall scheme of this reaction is given in Figure 7. Additional evidence comes from the observation of a weak OH stretching band at 3540 cm^{-1} after reduction and its disappearance upon oxidation. Whether the presence of a DRS spectrum of tetrahedral Co^{2+} is still a sufficient proof of lattice-substituted Co^{2+} is questionable. Indeed, one might envisage octahedral lattice Co^{2+} by analogy with Al^{3+}, or the presence of extra-framework Co oxides in different forms.

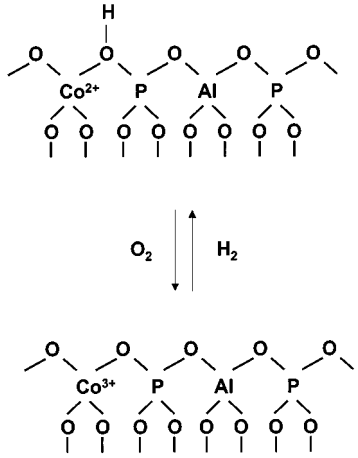

Figure 7. Schematic representation of the oxidation/reduction cycle of CoAPO-5 molecular sieves

Further evidence for the oxidation of Co^{2+} to Co^{3+} during calcination is found by ESR. A significantly reduced ESR signal in calcined CoAPO-5 was explained by a partial oxidation of Co^{2+} to the ESR invisible Co^{3+}.[20,21] Lee and Chon proved the oxidative abilities of CoAPO-5 with ESR by the formation of radicals upon interaction with alkenes.[26] However, this interpretation has been challenged by Kurshev et al.[27] These authors propose a distortion of the tetrahedral Co^{2+} environment to a dihedral symmetry resulting from the interaction of Co^{2+} with two O_2 molecules. Finally, Co K-edge EXAFS studies of CoAPO-5 recorded after synthesis and during calcination and reduction have only revealed small changes in bond lengths and coordination numbers of $Co^{2+/3+}$, suggesting an incomplete oxidation of the Co^{2+}.[28]

4.2. Chromium

The synthesis of CrAPO-5 molecular sieves has also been extensively studied in the literature, but the question remains if Cr^{3+} really substitutes for Al^{3+} in the framework, and to what extent.[29] Indeed, tetrahedral Cr^{3+} is difficult to obtain as evidenced by the scarcity of tetrahedral Cr^{3+} complexes and the absence of reported inorganic structures with tetrahedral Cr^{3+}.[30]

Figure 8 shows the DRS spectra of the green colored as-synthesized CrAPO-5 samples with increasing Cr content, which are characterized by two absorption bands at 15900 and 21800 cm^{-1}.[29][31] The intensities of both bands almost linearly increase with increasing Cr content, and they are assigned to the ν_1 and ν_2 transitions of octahedral Cr^{3+}. In addition, the 15900 cm^{-1} band has two weak shoulders, which are both spin-forbidden transitions. It is important to notice that during synthesis there is no indication for a transformation of Cr^{3+} (O_h) to Cr^{3+} (T_d). A similar conclusion can be made from dehydration experiments in vacuo of as-synthesized CrAPO-5 taking into account that dehydrated $AlPO_4$-5 does not possess octahedral Al^{3+} in the framework (vide supra). Thus, there is no unambiguous experimental evidence to propose an octahedral lattice Cr^{3+} species. Nevertheless, some authors have proposed such lattice Cr^{3+} (O_h) with two H_2O molecules completing its first coordination sphere:[32] $Cr^{3+}(O)_4(H_2O)_2$.

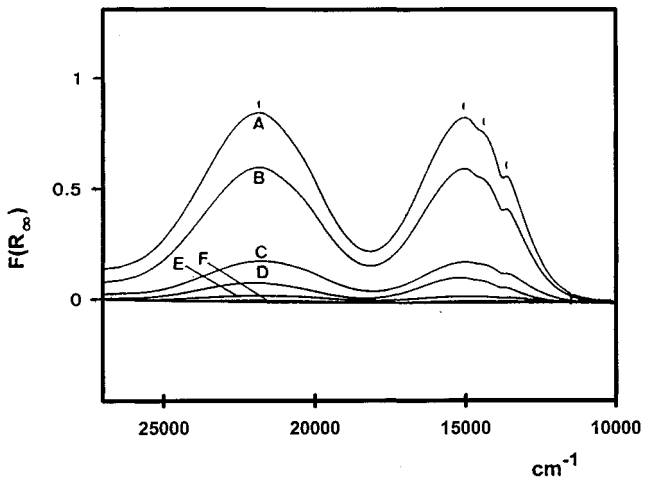

Figure 8. DRS spectra of as-synthesized CrAPO-5 materials as a function of the chromium content: 0.75 $R.(Cr_xAl_yP_z)O_4 \cdot 20\ H_2O$ with x = (A) 0.08; (B) 0.04; (C) 0.02; (D) 0.004; (E) 0.002, and (F) 0.0 (after ref.[29a])

Evidence for the presence of extra-framework Cr^{3+} comes from ESR experiments. The ESR spectra of as-synthesized CrAPO-5 are dominated by two characteristic signals: (1) a broad isotropic signal with $g = 2$ and (2) a rhombic signal with a positive lobe at $g_{eff} = 4.3$ and a weaker isotropic contribution at $g_{eff} = 2$. The zero-field parameters D and E are equal to 0.490 and 0.163 cm^{-1}, respectively. The former signal is typical for clustered Cr^{3+} in octahedral symmetry, which are most probably located as small oxidic particles at the outer surface or in the channels or pores of the molecules sieve. The latter signal is typical for Cr^{3+} in a strongly distorted environment, and because this signal is also observed for Cr^{3+} ions at the surface of amorphous supports (Al_2O_3, ...), one can assign it to distorted Cr^{3+} at the surface of $AlPO_4$-5.[33] By using other techniques, such as photoluminescence and single-crystal UV/Vis spectroscopy, others came to similar conclusions.[34−37]

Calcination in O_2 results in a color change from green to yellow-green. Both DRS and ESR spectroscopies indicate an incomplete oxidation of Cr^{3+} to Cr^{6+} with traces of Cr^{5+}. This suggests that some of the oxidic/isolated Cr^{3+} in the channels or pores of $AlPO_4$-5 resists oxidation. The formed Cr^{6+} is most probably attached to the surface of $AlPO_4$-5 as a chromate species with two extra-framework oxygen ions.[29,31]

4.3. Vanadium

VAPO-5 can be synthesized hydrothermally with different vanadium sources and template molecules, although the final oxidation state of vanadium largely depends on the vanadium source used.[12,13,38]. If V_2O_5 is used, some V^{5+} will be reduced to V^{4+} during hydrothermal synthesis, and a mixture of V^{4+} and V^{5+} is observed in the final solid products. The nature and properties of these vanadium sites are still a subject of debate. Up to now, it has not been proven unambiguously that vanadium really incorporates in the framework of $AlPO_4$-5 crystals, and the incorporation mechanism of $V^{4+/5+}$ is considered to be more complex than in the case of Co^{2+}.[39] This is not only due to the charge difference (proposal of substitution by SM II), but also because vanadium is prone to condensation reactions in solution, which lead to a variety of oligomeric species.

According to Montes et al.[13] and Jhung et al.[38] V^{4+} substitutes for P^{5+}, whereas Rigutto and van Bekkum[40] suggested the replacement of Al^{3+} by V^{4+}. Substitution of P^{5+} by V^{4+} is mainly proposed in view of a priori arguments such as the similarities between vanadium and phosphorus chemistry, and the existence of the mineral Schoderite, which contains both VO_4^{3-} and PO_4^{3-}.[41] The replacement of Al^{3+} by a $V{=}O^{2+}$ cation seems to be more convincing since the presence of the latter species is supported by spectroscopic evidence,[39,40,42] and no tetrahedral V^{4+} was ever detected by spectroscopic means. Indeed, combined DRS-ESR measurements have shown that V^{4+} is always present as a (pseudo-)octahedral species in VAPO-5.[39]

The above-mentioned models have in common that the vanadium sites are considered as monomeric. The key argument used for this assumption is that highly resolved ESR spectra are observed for as-synthesized VAPO-5 materials. However, clustered V^{4+} ions may be invisible due to line broadening as caused by spin-spin coupling of strongly interacting V^{4+} ions. If the vanadium ions tend to cluster one would expect that the amount of isolated V^{4+} ions as determined by quantitative ESR is lower than that expected from chemical analysis. This is indeed the case, and only 10% of the vanadium contributes to the ESR spectrum of VAPO-5.[39] Thus, V^{4+} is present as both isolated and clustered species, but it is uncertain whether both species substitute in the lattice. Finally, it is important to stress that two slightly different ESR signals are observed, which suggest the presence of two distinct V^{4+} ions, most probably located at defect sites.

Upon calcination in O_2, V^{4+} is almost completely oxidized to V^{5+} as evidenced by the weak V^{4+}-ESR signal and the observation of tetrahedrally coordinated V^{5+} (vanadate) by DRS and ^{51}V-NMR spectroscopies.[39,40,43] Reduction with CO or H_2 results in a partial regeneration of V^{4+}, and most probably lower oxidation states, such as V^{3+}, are formed.

4.4. Iron

FAPO-5 molecular sieves, discovered by Messina et al. in 1985,[44] can be synthesized using a variety of template molecules, typically amines or quaternary ammonium hydroxides, and either a Fe^{2+} or Fe^{3+} salt may be used as iron source. Regardless of the iron salt used, mostly both Fe^{2+} and Fe^{3+} are observed in the as-synthesized samples. Two reasons have to be invoked: (1) The oxidation of Fe^{2+} to Fe^{3+} in the initial synthesis gel. Indeed, by flushing the synthesis gel with nitrogen the oxidation to Fe^{3+} could be suppressed; and (2) the reduction of Fe^{3+} to Fe^{2+} by reaction with the amine template, according to $2\ Fe^{3+} + R_3N + H_2O \rightarrow 2\ Fe^{2+} + R_3NO + 2\ H^+$. The same reaction is responsible for the reduction of V^{5+} to V^{4+} during hydrothermal synthesis (vide supra). At low metal content, more than 90% of the iron is reduced, and with increasing iron content, the amount of reduced iron decreases only slowly. The reduction of Fe^{3+} can only be minimized by hydrothermal synthesis at lower temperature using e.g. tetraethylammonium hydroxide as template.

Several papers have appeared in the literature on the spectroscopic characterization of FAPO-5 molecular sieves.[45−55] The main techniques used were DRS, ESR, XPS, and Mössbauer spectroscopy. Especially ESR and Mössbauer spectroscopy seem to be very powerful, although their spectral interpretation is still a matter of debate.

As-synthesized FAPO-5 samples are characterized by a weak absorption at 23500 cm^{-1}, and an intense shoulder at around 26500 cm^{-1} in DRS. The former band is the spin-forbidden transition ν_3 of high-spin Fe^{3+} in tetrahedral coordination, while the latter is a charge-transfer transition of the type $O{\rightarrow}Fe^{3+}$.[46] It is assumed that the band at 23500

cm^{-1} is typical for Fe^{3+} in framework positions. No absorption bands of Fe^{2+} are detected. After calcination in O_2, the material turned from white to off-white, and the corresponding spectrum has characteristic absorption bands at 20800, 23000, 24400, and 26500 cm^{-1}. The transitions at 20800 and 23000 cm^{-1} are assigned to the spin-forbidden transitions ν_1 and ν_2, respectively, of high-spin Fe^{3+} in tetrahedral coordination.[46] Reduction with H_2 does not result in any spectral changes.

The co-existence of Fe^{2+} and Fe^{3+} in as-synthesized samples was unambiguously revealed by XPS. The binding energies of $Fe2p_{3/2}$ at 712.3 and 708.4 eV are assigned to framework Fe^{3+} and Fe^{2+}, respectively, while the presence of non-framework Fe^{3+} was evidenced by the $Fe2p_{3/2}$ peak at 710.5 eV. Calcination results in a total oxidation of Fe^{2+} to Fe^{3+}, and as a consequence, the disappearance of the $Fe2p_{3/2}$ peak at 708.4 eV. More detailed information can be obtained by Mössbauer spectroscopy. Four characteristic quadrupole doublets are observed, which are assigned to framework $Fe^{3+}(T_d)$; extra-framework $Fe^{3+}(O_h)$; framework $Fe^{2+}(T_d)$ and extra-framework $Fe^{2+}(T_d)$, their relative amounts depending on the treatment condition and the preparation method. For example, Schubert et al. found that as-synthesized FAPO-5 contains about 70% of Fe^{3+} and 30% of Fe^{2+}, and the amount of Fe^{3+} gradually increases with increasing calcination temperature.[51b]

Finally, ESR spectroscopy has been used to characterize the state of Fe^{3+} in FAPO-5 materials, and an example of an X-band ESR spectrum is given in Figure 9. Five different ESR signals can be observed: $g_1 = 2.0$; $g_2 = 2.2-2.3$; $g_3 = 4.3$; $g_4 = 5.2$ and $g_5 = 8.4$.[45] The two most intense signals are g_1 and g_2, and their assignments are still controversial. The traditional assignment is that g_1 is due to extra-lattice oxidic Fe^{3+}, whereas g_2 is due to framework Fe^{3+}. The three other signals would then be due to extra-lattice Fe^{3+} in various forms, although no detailed assignments have been given up to now. In light of recent work of Goldfarb et al.,[50] g_1 is due to both framework and extra-framework Fe^{3+}, whereas g_2 is typical for Fe^{3+} in a distorted tetrahedral coordination at defect sites. Thus, ESR alone will not be able to discriminate between framework and extra-framework Fe^{3+}.

It is important to notice that the relative intensity of g_2 decreases with increasing Fe loading, suggesting that Fe^{3+} will first coordinate to defect sites of the $AlPO_4$-5 crystals, while at higher loading, Fe^{3+} will incorporate in the framework or is present as small oxide particles. Upon calcination, the five ESR signals remain visible, suggesting that Fe^{3+} is relatively stable in the FAPO-5 material. Reduction results in a relative increase of the intensity of the g_1 signal, which can be explained by the formation of oxidic Fe^{3+}, and thus a migration and clustering of iron.

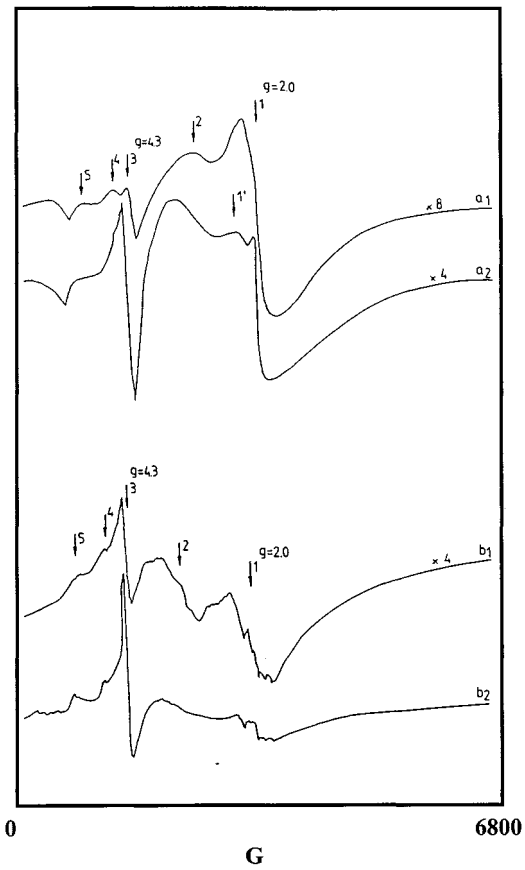

Figure 9. ESR spectra of FAPO-5 materials as a function of the pretreatment: (a) in as-synthesized form and (b) after calcination overnight at 773 K and helium flushing for 15 min at room temperature; the samples were measured at room temperature (1) and at 120 K (2) (after ref.[45])

4.5. Manganese

The evidence for the incorporation of Mn^{2+} into the framework of $AlPO_4$-5 is scarce. One of the reasons is the current discrepancy between the results obtained by indirect and direct tools to verify isomorphous substitution (Table 2). In addition, only ESR and its pulsed variant ESEEM have been applied to probe Mn^{2+} in $AlPO_4$-5 systems.[56–62] Thus, there is clearly a need to use other characterization techniques, such as DRS.

ESR spectroscopy of MnAPO-5 with a low manganese content shows six resolved hyperfine lines ($I = 5/2$) with a hyperfine coupling constant A of 90 G and a small zero-field splitting parameter D. Such ESR spectrum is typical for a slightly distorted octahedral Mn^{2+} species. In addition, ESEEM experiments showed that the isolated Mn^{2+} species interact through weak dipolar interactions with an average of six ^{31}P nuclei at a distance of 5 Å.[56][57] All these observations do not agree with a model in which Mn^{2+} is substituting for framework Al. As a consequence, it was concluded that the majority of Mn^{2+} in MnAPO-5 systems was present as extra-framework Mn^{2+}.

Dehydration of MnAPO-5 systems stimulates migration of the Mn^{2+} cations, resulting in an increase in spin exchange interaction, and only a single ESR line is observed. X-band and Q-band ESR spectra reveal that the 6-line hyperfine splitting is superimposed on a broader ESR signal, which has been assigned to transitions other than $-1/2 \rightarrow$

1/2 of Mn^{2+} with $I = 5/2$ or to another Mn^{2+} species by Levi et al.[57] Removal of water at increasing temperatures up to 400°C significantly broadens the hyperfine line and finally the resolution is completely lost and only one broad line is observed. Rehydration usually restores the 6-lines ESR spectrum of the hydrated MnAPO-5 sample completely.

The redox behavior of Mn^{2+} in MnAPO-5 materials has been investigated by Katzmarzyk et al.[59] Calcination in O_2 changes the color from white to deep blue or violet, and this color change is associated with an overall decrease of the Mn^{2+} ESR intensity. This decrease in signal intensity is attributed by the same authors to a partial oxidation of Mn^{2+} to the ESR inactive Mn^{3+}. Oxidation to Mn^{4+} can be ruled out because new ESR signals cannot be detected at the low measurement temperature (93 K). Addition of polar molecules, such as water and ammonia, causes a color change from blue to pink or even gray. Reduction of the sample with H_2 at temperatures below 450 K does not change the ESR spectrum, while after reduction at 475 K the ESR signal becomes narrower and more intense. A possible explanation is that reduction of Mn^{3+} to Mn^{2+} under these conditions leads to more ESR active spins.

Although the above-described ESR interpretations are challenged by several authors (e.g., the presence of cluster-like arrangements of the type $Mn^{2+}-O-P-O-Mn^{2+}$),[62,63] it is obvious that clear spectroscopic evidence of framework Mn^{2+} is still lacking in the literature.

5. Probing the Early Stages of the Crystallization Process

The synthesis of microporous crystalline aluminophosphates generally starts with a gel phase which is digested during synthesis at high temperatures. Several attempts have been made to elucidate the chemistry of this gel, and its hydrothermal digestion. A whole variety of characterization techniques, such as liquid-phase NMR, IR and Raman spectroscopy, have been applied. For example, the existence of aluminum phosphate entities in solution has been demonstrated by NMR.[64–66]

Another approach is to probe the coordination geometry of TMI during hydrothermal synthesis. Indeed if the TMI is incorporated in the lattice, the synthesis gel with octahedral $TMI(H_2O)_6^{n+}$ ions will be transformed during synthesis into a solid material containing tetrahedral framework and/or non-framework TMI. One way to study this synthesis process is to use spectroscopy to probe the TMI during synthesis. In this respect, DRS has been used to characterize the synthesis of CoAPO-5 from its early precursors to the formation of a crystalline phase.[67–69] This is possible because: (1) Co^{2+} is, as discussed above, relatively easily incorporated in the $AlPO_4$-5 framework during hydrothermal synthesis, and a distinction between tetrahedral and octahedral Co^{2+} can be made; (2) the DRS spectra have excellent quality; and (3) the DRS technique is applicable to both wet gels and dried solids, amorphous and crystalline as well.

Figure 10 shows the XRD and DRS intensities of the solid materials versus synthesis time. The DRS intensities of tetrahedral Co^{2+} increase concomitantly with the XRD intensities. Thus, as crystallization proceeds, Co^{2+} is incorporated in the structure. In the nucleation stage of the synthesis, the nuclei are too small to be detected by XRD, and DRS can then be used to probe the coordination of Co^{2+}. This is illustrated in Figure 11, where the DRS spectra of four distinct gel stages as a function of synthesis time are given.

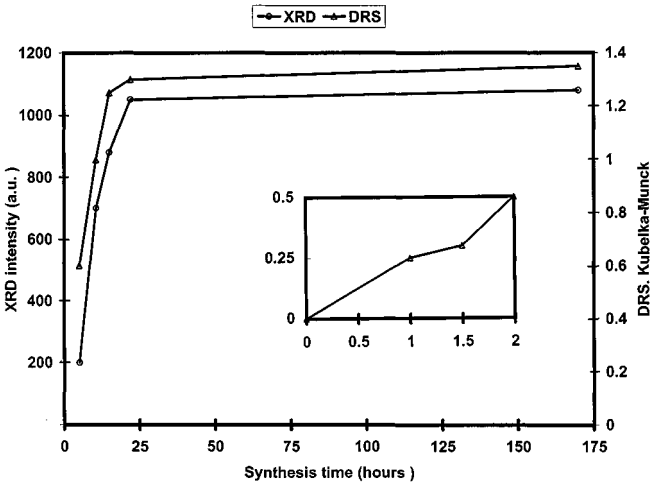

Figure 10. XRD and DRS intensities of the solid materials versus the synthesis time for CoAPO-5 materials (after ref.[67])

These gels were isolated from the autoclaves, and measured at room temperature. S_1 is the hydration-gelation phase, and nucleation has not yet started. Co^{2+} is octahedrally coordinated and not yet incorporated. It can be washed off by centrifugation. The DRS spectrum of gel S_2 consists of a weak triplet of tetrahedral Co^{2+}, superimposed on a broad band of (pseudo-)octahedral Co^{2+}. The latter is interpreted as cobalt with two water molecules in the first coordination sphere; i.e., $[CoO_4(H_2O)_2]$ taken up in the solid gel. Stage 3, which is attained after two hours of synthesis, is characterized by a dramatic increase of the band intensities of tetrahedral Co^{2+} at the expense of octahedral Co^{2+}. This means that Co^{2+} is being taken up by the CoAPO-5 material as $Co(OP)_4$. Further evidence for this transformation process comes from the decrease of the water bands in the NIR region. In stage S_4, the sample contains no water peak, indicating a full transformation of the gel into a crystalline phase. The peaks of tetrahedral cobalt are very intense and well resolved, which is indicative for Co^{2+} in identical crystallographic sites. The overall picture of the uptake of Co^{2+} can then schematically be shown as:

$$Co(H_2O)_6^{2+}\ \text{(liquid phase)} \rightarrow [CoO_4(H_2O)_6]\ \text{(gel phase)} \rightarrow [CoO_4]\ \text{(crystalline)}$$

This scheme is valid for CoAPO-5, but not for all structure types. Thus, CoAPO-34 synthesis is favoured at high template and Co contents; i.e., less water. This means that

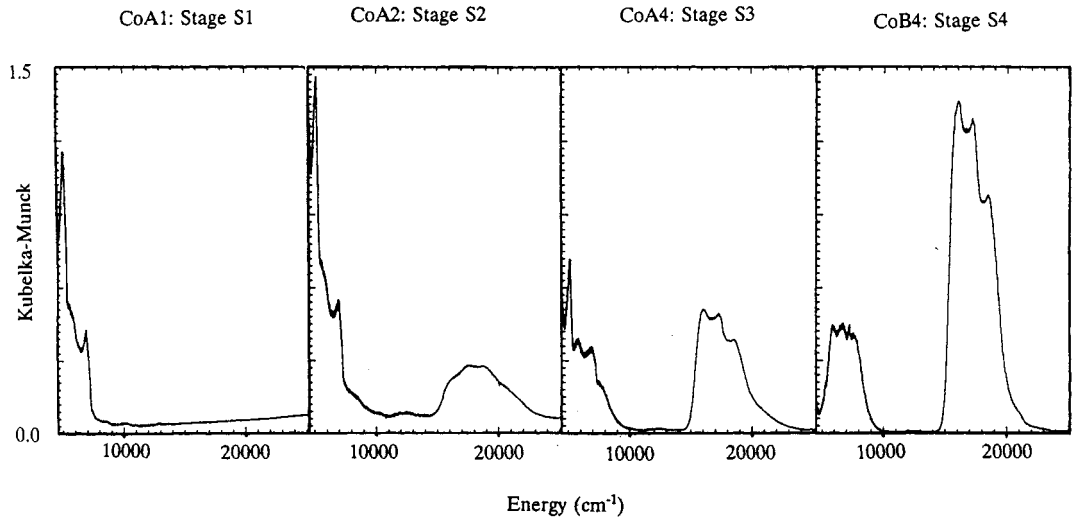

Figure 11. Four distinct gel stages for the synthesis of CoAPO-5, as recorded by DRS (after ref.[67])

upon interaction with the gel phase Co^{2+} is immediately transformed into a tetrahedral species:

$$Co(H_2O)_6^{2+}\ (\text{liquid phase}) \rightarrow [CoO_4]\ (\text{gel}) \rightarrow [CoO_4]\ (\text{crystal})$$

One observes that the template does not intervene directly in both schemes, but through its pH-regulating role it certainly influences indirectly the chemistry going on in the synthesis mixture.

6. Heterogeneous Catalysis

As mentioned above, MeAPO-5 molecular sieves have been explored as promising heterogeneous catalysts for both liquid-phase and gas-phase reactions. Their applications have been recently reviewed by Bellussi and Rigutto[70] and Arends et al.[71] Rather than summarizing the main results described, we would like to focus on the potential problems associated with their use in catalytic applications.

The catalytic activity of MeAPO-5 materials originates from the (co-)presence of Brønsted acid sites and/or redox centers, and thus in principle both acid- and redox-catalyzed reactions can be performed. Indeed, the activation of e.g. CoAPO-5 involves the calcination to remove template molecules. Simultaneously, part of the lattice TMI is oxidized to higher oxidation states (vide supra):

$$\text{CoAPO-5-}(Et)_3NH^+ \rightarrow (Co^{2+}{}_x,Co^{3+})H_x\text{-APO-5}$$

Protons are necessary for charge balance, and thus two catalytic functions are formed (Figure 7). If both Co^{2+} and Co^{3+} are in the lattice, they are expected to be in high-spin and in tetrahedral coordination. Redox catalysis requires free coordination sites, and this is impossible in such an ideal situation. Therefore, such type of catalysis can only be explained by (1) the presence of less than four lattice oxygen atoms around the TMI; (2) the lattice oxygen atoms, which are indirectly involved in redox chemistry or (3) the presence of extra-lattice TMI.

In addition, shape selectivity can be introduced in these molecular sieves because reactive substrates with a kinetic diameter larger than the pore size of the molecular sieve cannot react, whereas the reaction with a smaller molecule may proceed within the pore system. Another important advantage of such materials over their homogeneous counterparts is that the TMI is embedded in an inorganic microporous structure, which prevents or suppresses catalyst deactivation. Indeed, the most common deactivation mechanisms of homogeneous catalysts are the degradation of the (organic) ligands, and oligomerization of the active TMI.

Although the concept "reaction in micropores" generally leads to less catalyst deactivation, it is important to mention that other deactivation mechanisms may come into play; i.e., leaching of the active TMI and blocking of the microporous structure by a strong adsorption of reactants or products. Leaching of the active TMI is often severe, especially in the case of V and Cr, and several authors have attributed their observed catalytic activity solely to the presence of TMI leached in the reaction mixture.[72,73] In this respect, the composition of the reaction mixture is critical. Indeed, for CoAPO-5 molecular sieves it is proven that the molecular sieve dissolves during the oxidation of organic compounds in strong alkaline medium. On the other hand, in a strong apolar solvent (e.g. cyclohexane) an extremely low concentration of Co could be detected in solution, and the autoxidation activity of CoAPO-5 could not be attributed to this dissolved cobalt.[72] Another striking observation was recently found by Haanepen et al.[73] They observed that the leaching process of VAPO-5 molecular sieves only occurred in the beginning of the catalytic reaction, and that the heterogeneous contribution steadily stopped due to a strong adsorption of organic molecules in the pore system of $AlPO_4$-5. Removal of the VAPO-5 material from the reaction mixture after a short reaction time showed an ongo-

ing reaction in the filtrate. Similar results were obtained for CrAPO-5 molecular sieves.[74] Surely, the most promising direction for heterogeneous catalysis seems to be gas-phase reactions.[75] In this respect, the oxidative dehydrogenation of alkanes has received the most attention, and both VAPO-5 and MnAPO-5 are efficient catalysts for this type of reaction.[12,76,77]

7. Concluding Remarks and Look into the Future

The chemistry of TMIs in microporous aluminium phosphates is complex. The synthesis conditions of the materials do not favour incorporation of TMI in the lattice. In addition, the size of the TMI with respect to that of Al or P is such that substitution introduces strain in the structure. The following conclusions can be drawn from this microreview:

(1) Even at low metal loading, TMIs seem to be present under different coordination geometries; i.e.:

(a) Truly isomorphous substituted TMI possessing a (pseudo-)tetrahedral coordination. This has been spectroscopically proven for Co^{2+}, and to a lesser extent for $Fe^{2+/3+}$. It is important to notice that the presence of framework TMI with a higher coordination number (5 or 6) cannot be excluded (e.g., Cr^{3+}). Indeed, NMR studies have clearly shown the presence of octahedrally coordinated Al^{3+} in the framework of $AlPO_4$-*n* materials.

(b) Defect sites, which originate from interrupted frameworks in which Al−O−P bonds are missing. It is anticipated that Co^{2+}, Cr^{3+}, V^{4+}, $Fe^{2+/3+}$, and Mn^{2+} may coordinate to these defects, which will give rise to a (pseudo-)octahedral coordination. In this respect, it is remarkable to see that the overall crystallinity of the MeAPO-5 materials decreases with increasing metal loading. This suggests a continuous creation of defect sites in the framework with increasing incorporation of TMI.

(c) Extra-framework transition metal oxides, which are most probably located at the outer surface or occluded within the micropores of the molecular sieve. Spectroscopic evidence is available that Cr_2O_3, Fe_2O_3, and V_2O_4 clusters are formed during the synthesis of MeAPO-5 materials.

(2) More advanced synthesis procedures have to be developed which selectively increase the amount of framework TMI. The synthesis of nanosized transition metal oxides within the micropores could be another scientific challenge because of their possible quantum size properties.

(3) Both indirect and direct criteria to evaluate isomorphous substitution have been established. It is obvious that positive evidence via indirect criteria is not sufficient to claim a truly isomorphous substituted TMI. There is clearly a need to develop more refined spectroscopic tools to discriminate between framework and extra-framework TMI.

(4) Co^{2+} can be used as a probe for the synthesis mechanisms of microporous aluminium phosphates. Other TMIs, for which there is still no direct spectroscopic proof of lattice substitution, cannot be used as synthesis probes. Another approach, the in situ spectroscopy, might be a useful additional tool to extend this research direction.

(5) Only for Co^{3+}/Co^{2+} in the lattice has a clear redox chemistry been achieved, not yet for the other TMIs. Whether this is indicative for no incorporation of Fe, V, Cr, Mn in the lattice has still to be proven.

(6) The creation of Brønsted acid sites and redox centers makes MeAPO-5 interesting heterogeneous catalysts. However, the careful choice of the catalytic conditions is of paramount importance for the development of a successful catalytic application. In this respect, gas-phase catalysis seems to be a promising new direction.

The authors anticipate that the above-described remarks are also applicable to the isomorphous substitution of TMI in other molecular sieves.

Compounds of Germanium, Tin, and Lead, 30[+]

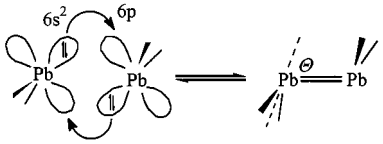
A Heteroleptic Diplumbene and a Magnesium Dibromide Stabilized Plumbylene Dimer

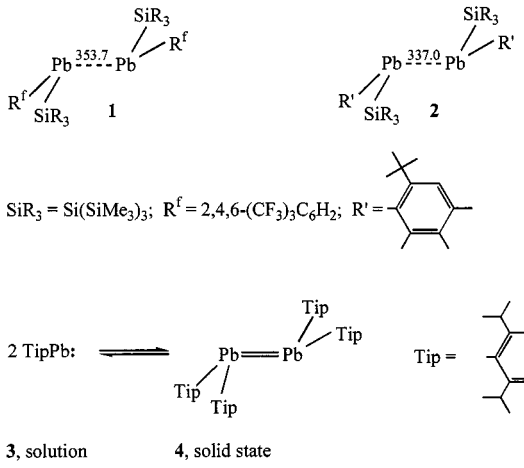
Martin Stürmann,[a] Wolfgang Saak,[a] Manfred Weidenbruch,*[a] and Karl W. Klinkhammer[b]

Keywords: Lead / Plumbylenes / Plumbanediyles / Diplumbene / Plumbylene dimers / Double-bond systems

Treatment of the diarylplumbylene R_2Pb**:** (R = 2,4,6-*i*$Pr_3C_6H_2$) with the disilylplumbylene R'_2Pb**:** [R′ = $Si(SiMe_3)_3$] furnishes the heteroleptic plumbylene RR′Pb**:** which exists as the diplumbene RR′Pb=PbRR′ (**7**) in the solid state. The X-ray structure analysis of **7** reveals a *trans*-bent angle of 42.7° and a Pb–Pb bond length of 298.99(5) pm, the shortest observed so far for diplumbenes with a lead–lead double bond. Reaction of mesitylmagnesium bromide with $PbCl_2$ yielded black crystals of an $MgBr_2$ stabilized dimesitylplumbylene dimer with a large *trans*-bent angle of 71°, a lead–lead separation of 335.49(6) pm, and long Pb···Br contacts of 315.71(8) pm.

Dialkyl-[1][2] and diarylplumbylenes[3−5] without intra- or intermolecular donor stabilization have become known and their structures have been elucidated only in the past few years.[6] They predominantly exist as V-shaped molecules without any contacts between the lead atoms of neighboring plumbylene molecules. The low tendency for dimerization (Figure 1) is probably a consequence of the available mechanism for bond formation which, unlike that for carbon, for example, is through donor-acceptor interactions between the doubly occupied 6s orbitals and the empty 6p orbitals of two singlet plumbylene molecules. This is corroborated by the low bond-dissociation energy, which was calculated to be merely 24 kJ mol^{-1}.[7]





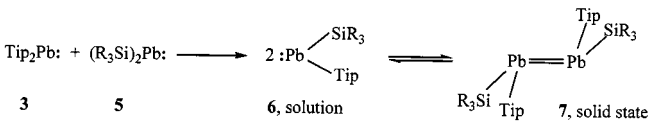


Figure 1. Formation of a diplumbene from two singlet plumbylenes

The first advances in the direction of lead−lead interactions were realized with the syntheses of compounds **1**[7] and **2**[5] which exhibited the theoretically required *trans*-bent arrangements. However, the observed Pb···Pb separations of 353.7(1) pm in **1** and 337.0(1) pm in **2** were markedly larger than the calculated values of around 295 pm for the parent compound $H_2Pb{=}PbH_2$ with a Pb−Pb double bond. Values of about 55° were determined for the corresponding *trans*-bent angles θ.[7−9] With the preparation of compound **4** we recently obtained the first diplumbene with a Pb−Pb bond length [305.15(3) pm] and *trans*-bent angles θ [43.9° and 51.2°] in good agreement with the theoretical predictions.[10]

We now describe the first heteroleptic diplumbene with a Pb−Pb bond even shorter than that of **4** as well as a plumbylene dimer stabilized by magnesium dibromide.

In the syntheses of the plumbylene dimers **1** and **2** the diarylplumbylene was allowed to react with the disilylplumbylene[11] to furnish the heteroleptic molecules **1** and **2** by substituent exchange. An analogous reaction of the plumbylene **3**, existing in solution, with the disilylplumbylene **5** also proceeded through rapid substituent exchange to afford a greenish-blue solution of the plumbylene **6** from

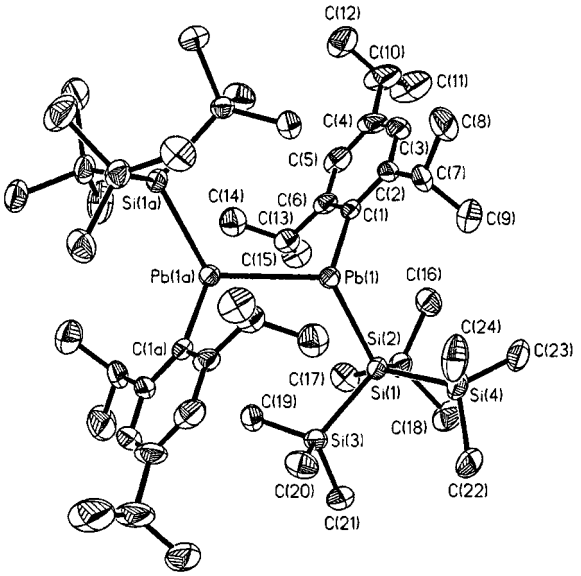
which reddish-brown crystals of the diplumbene **7** were isolated.



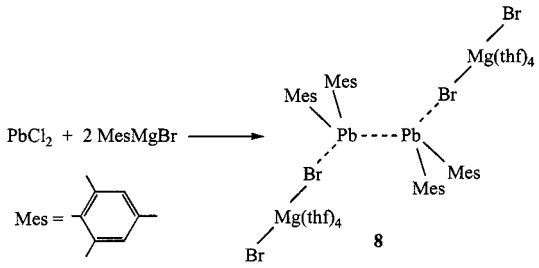


Figure 2. Molecular structure of **7** in the crystal (hydrogen atoms omitted); ellipsoids are drawn at 50% probability; selected bond lengths [pm] and angles [°]: Pb(1)−Pb(1a) 298.99(5), Pb(1)−C(1) 229.6(4), Pb(1)−Si(1) 271.7(1); C(1)−Pb(1)−Si(1) 108.8(1), C(1)−Pb(1)−Pb(1a) 109.5(1), Si(1)−Pb(1)−Pb(1a) 120.72(3)

An X-ray crystal-structure analysis of compound **7** (Figure 2) revealed the existence of a centrosymmetrical molecule having a lead−lead bond length of 298.99(5) pm, a value even shorter than that of **4** and very close to the theoretically calculated value for the parent compound. The *trans*-bent angle θ in **7** of 43.7° (see Figure 1) is somewhat smaller than those of **4**, presumably as a consequence of the different substitution pattern. Thus, compound **7** is not only the second diplumbene ever to be prepared but is also the first heteroleptic molecule of this type.

It has been found for disilenes, digermenes, and distannenes that the steric requirements of the substituents must increase with increasing length of the element−element double bond in order to effectively shield the compounds from further reactions.[12][13] Thus, for example, the compounds $Tip_2Si{=}SiTip_2$ and $Tip_2Ge{=}GeTip_2$ (Tip = 2,4,6-iPr$_3$C$_6$H$_2$) are thermally stable while $Tip_2Sn{=}SnTip_2$, although it can be generated thermally or photochemically from the cyclotristannane $(Tip_2Sn)_3$, reverts to the three-membered ring compound at room temperature.[14] The existence of compounds **4** and **7**, however, seems to suggest that steric shielding of the Pb−Pb double bond does not play such a dominating role. We have thus examined whether the use of smaller aryl groups would also permit the formation of this structural element or whether subsequent reactions would occur.

Reaction of the Grignard reagent MesMgBr with solid lead(II) chloride at low temperature in THF furnished a red-brown solution from which, among other products, black crystals of a very sensitive, thermolabile compound

were isolated. Satisfactory characterization of this product by spectroscopic methods was not possible on account of its properties.

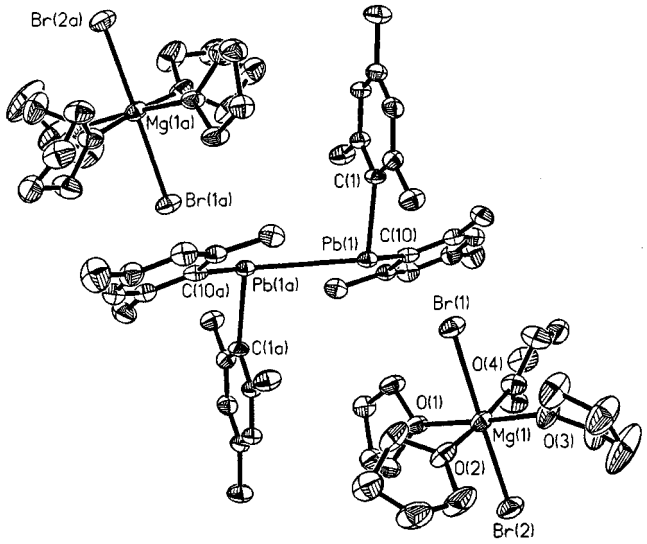

Figure 3. Molecular structure of **8** in the crystal (hydrogen atoms omitted); ellipsoids are drawn at 50% probability; selected bond lengths [pm] and angles [°]: Pb(1)···Pb(1a) 335.49(6), Pb(1)−C(1) 232.2(5), Pb(1)−C(10) 230.4(6), Mg(1)−Br(2) 262.6(2), Mg(1)−Br(1) 279.7(2), Pb(1)···Br(1) 315.71(8); C(1)−(Pb1)−Pb(1a) 99.6(2), C(10)−Pb(1)−Pb(1a) 118.0(2), Br(1)−Pb(1)−Pb(1a) 133.44(2), Br(2)−Mg(1)−Br(1) 178.04(9)

However, a low-temperature X-ray crystallographic analysis of these black crystals revealed that a magnesium bromide stabilized plumbylene dimer **8** had been formed (Figure 3). The Pb···Pb separation of 335.49(6) pm is in the same range as that for compound **2**. The *trans*-bent angle θ of 71° is unusually large. A further surprising feature is that a bromine atom of an $MgBr_2(thf)_4$ molecule experiences a weak interaction with each lead atom and not the THF present in a large excess. Although the respective Pb···Br separations are about 50 pm larger than those of a Pb−Br single bond,[15] these interactions are characterized not only by a large *trans* arrangement but also by the Mg−Br bond lengths within the almost linear Br−Mg−Br units. Thus, the Br−Mg bond weakly coordinated to the lead atom is around 17 pm longer than the other Mg−Br bond.

The novel molecules **7** and **8** described here indicate that further interesting and unexpected results may be expected in the field of low-coordinated lead compounds.

Experimental Section

General: All manipulations were performed by using standard Schlenk techniques under dry argon. − ^{1}H and ^{13}C NMR: Bruker AM 300. − MS: Finnigan MAT 212. − UV/Vis: ComSpec with fiber optics. − Elemental analyses: Analytische Laboratorien, D-51789 Lindlar, Germany.

(2,4,6-Triisopropylphenyl)[tris(trimethylsilyl)silyl]plumbylene (6) and (*E*)-1,2-Bis(2,4,6-triisopropylphenyl)-1,2-bis[tris(trimethylsilyl)silyl]diplumbene (7): A solution of the plumbylenes **3** (0.34 g, 0.55 mmol) and **5** (0.39 g, 0.55 mmol) in 15 mL of *n*-pentane was stirred in the dark for 20 min at room temperature. The greenish-blue solution was concentrated to a volume of 15 mL and cooled at −65°C for 24 h. After this time, 0.53 g (73% yield) of reddish-brown crystals (green in thin layers) of **7** were isolated. M.p. 90°C (decomp.). − Spectroscopic data for **6** in solution: ^{1}H NMR ([D$_8$]toluene, 298 K): δ = 0.44 (s, 27 H), 1.34 (d, 6 H, ^3J = 6.85 Hz), 1.35 (d, 12 H, ^3J = 6.7 Hz), 2.15 (m, 2 H), 2.86 (m, 1 H), 7.29 (s, 2 H). − ^{13}C NMR ([D$_8$]toluene, 298 K): δ = 7.07, 24.50, 24.99, 33.81, 35.52, 124.74, 125.39, 127.58, 147.33, 158.53, 259.12. − ^{29}Si NMR ([D$_8$]toluene, 298 K): δ = −16.4 [*Si*(SiMe$_3$)$_3$], −4.3 (*Si*Me$_3$). − The ^{207}Pb-NMR signal could not be observed. − MS (CI, isobutane); *m*/*z* (%): 660 (5) [**6**$^+$]. − UV/Vis: λ_{max}(ε) = 350 (670), 591 (80), 770 (175) nm. − $C_{48}H_{100}Pb_2Si_8$ (**8**) (1316.4): calcd. C 43.79, H 7.64; found C 43.48, H 7.43.

Bis(2,4,6-trimethylphenyl)plumbylene Dimer·2 MgBr$_2$(thf)$_4$ (8): At −110°C, solid PbCl$_2$ (4.7 g, 16.8 mmol) was added to the Grignard compound, prepared in turn from 1-bromo-2,4,6-trimethylphenylbenzene (6.8 g, 34 mmol) and magnesium turnings (3.2 g, 120 mmol) in 100 mL of THF. The mixture was allowed to warm to room temperature over a period of 30 min with vigorous stirring. THF was distilled off and the residue extracted with 10 mL of *n*-hexane in order to remove small amounts of 1,3,5-trimethylbenzene. The remaining residue was extracted with two portions of toluene (50 mL each), and the magnesium salts were filtered off. Concentration of the reddish-brown toluene solution to a volume of 60 mL and cooling at −50°C furnished 3.72 g (18% yield) of thermally unstable, black crystals of **8**. − ^{1}H NMR (C$_6$D$_6$, 298 K): δ = 2.15 (s, 6 H), 2.62 [s, 12 H, ^4J(^{1}H,^{207}Pb) = 5 Hz], 6.78 (s, 4 H); minor signals for THF at δ = 1.38 (m), 3.69 (m).

Solubility and Solvation of Carbon Dioxide in the Molten $Li_2CO_3/Na_2CO_3/K_2CO_3$ (43.5:31.5:25.0 mol-%) Eutectic Mixture at 973 K I. Experimental Part

Paul Claes,*[a] Dominique Moyaux,[a] and Daniel Peeters[b]

Keywords: Dicarbonate ion / Autodissociation constant / Electrochemistry / Potentiometric titration / Acidity / Basicity / Anions

The solubility of CO_2 in the molten ternary eutectic mixture Li_2CO_3–Na_2CO_3–K_2CO_3 (43.5, 31.5, 25.0 mol.%) at 973 K has been determined by a titration technique. From the obtained titration curve, the solubility has been found to amount to $9.5\cdot10^{-2}$ mol·L^{-1} (σ = 1.0) under a pressure of CO_2 of 1 atm and the pK_d value of the carbonate melt has been evaluated to 5.37 (σ_5 = 0.24) if the concentrations of the solutes are expressed in mol·L^{-1}. This pK_d value is in good agreement with literature data but the solubility value reported in this work is much higher than most of those reported in the literature. A chemical dissolution of CO_2 as $C_2O_5^{2-}$ is proposed and the consequences of the occurrence of this species on the acidobasic properties of molten carbonates are discussed. It appears from the experimental results that the $CO_2/C_2O_5^{2-}$ equilibrium in the carbonate melt is a slow process.

1. Introduction

The use of molten carbonates as reaction media for chemical or electrochemical applications needs a deep understanding of their chemical properties and particularly of their acidobasic and redox behaviour. Carbonate melts are amphoteric oxoacidobasic liquids whose autodissociation equilibrium is generally written as follows:[1]

$$CO_3^{2-} \rightleftharpoons CO_2 + O^{2-}{}_{solv} \quad (1)$$

where $O^{2-}{}_{solv}$ represents a solvated oxide ion.

The corresponding autodissociation constant (K_d) is then written:

$$K_d = a(O^{2-}{}_{solv}) \cdot P(CO_2) \quad (2)$$

where $a(O^{2-}{}_{solv})$ and $P(CO_2)$ are the activity of solvated oxide ions in the melt and the partial pressure of carbon dioxide in the gas phase in equilibrium with the liquid phase. According to this, the solvated oxide ion is the strongest base available in the melt, while CO_2 is the strongest acid.

Acidity scales may be based on pO^{2-} values [$pO^{2-} = -\log a(O^{2-}{}_{solv})$] or on $-\log P(CO_2)$ values. The two scales are, of course, related:

$$pK_d = pO^{2-} - \log P(CO_2) \quad (3)$$

These scales extend from $pO^{2-} = pK_d$ or $-\log P(CO_2) = 0$ for the most acidic media to $pO^{2-} = 0$ or $-\log P(CO_2) = pK_d$ for the most basic media.

The scales described in this way are quite satisfactory from a thermodynamic point of view but fail to give a sound and complete explanation of chemical or electrochemical behaviours. The concentration of CO_2 physically dissolved in a melt is indeed related to its partial pressure according to Henry's law:

$$C(CO_2) = k_H \cdot P(CO_2) \quad (4)$$

where k_H is the Henry's constant. For a given partial pressure of carbon dioxide, depending on the value of Henry's constant, significant differences might occur in the kinetics of chemical and electrochemical reactions whose rates are limited by the diffusion of CO_2.

Surprisingly, solubility data for CO_2 in carbonate melts are scarce and scattered as shown in Table 1 which presents some literature data for Henry's constant in three carbonate melts. Nevertheless, the knowledge of the correct value of the solubility of carbon dioxide is essential to a complete understanding of phenomena occurring in molten carbonates.

Table 1. Henry's constant for CO_2 in carbonate melts

Melt	T [K]	k_H [mol·L^{-1}·atm^{-1}]	Ref.
Na_2CO_3	1153	$9.6\cdot10^{-3}$	[2]
$(NaK)_2CO_3$	1073	$1.83\cdot10^{-1}$	[3]
$(LiNaK)_2CO_3$	973	$3.6\cdot10^{-3}$	[4]
	973	$1.19\cdot10^{-2}$	[5]
	833	10^{-1}	[6]

The aim of this work is to determine the Henry's constant of CO_2 in a carbonate melt (its solubility under a partial pressure of carbon dioxide of 1 atmosphere) by carrying out a potentiometric titration of a saturated carbonate melt at high temperature. This kind of experiment is probably

the most direct way to the determination of the solubility of carbon dioxide; it does not need any assumption nor any calibration nor any change of temperature or physical state of the system and gives thus, in our opinion, the best confidence about the accuracy of the results.

2. Titration Procedure

The principle of the method is very simple. An accurately known amount of carbonate melt previously saturated with carbon dioxide under a pressure of 1 atmosphere is neutralized by adding to the liquid weighed portions of sodium oxide. The potential of an oxygen electrode dipped into the molten salt is measured after the complete dissolution and reaction of the added sodium oxide. The titration curve is obtained by plotting the measured potentials as a function of the amount of added sodium oxide. The end point of the titration allows to calculate the solubility of carbon dioxide and the pK_d value may be computed from the experimental solubility and from the amplitude of the titration curve.

The melt contained in an alumina crucible was saturated with carbon dioxide by flowing pure CO_2 through the cell for 24 hours. The time needed to reach equilibrium conditions after the addition of a given amount of Na_2O was about 6 hours. On the other hand, the potential difference underwent a slight potential shift which precluded to carry out a complete titration in one continuous experiment by adding successive amounts of Na_2O to one carbonate sample and by measuring the potential difference after each addition. An example of the evolution of the potential difference after addition of a given amount of sodium oxide to a CO_2 saturated melt is shown in Figure 1. The first part of the graph shows the effect of the neutralization reaction which is followed by a regular shift of the potential.

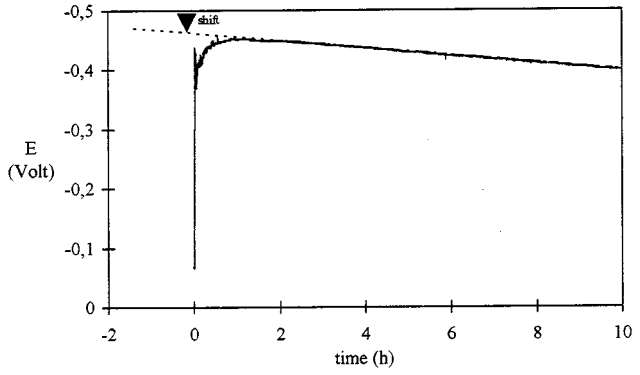

Figure 1. Evolution of the potential difference between the working and the reference electrodes as a function of the time elapsed from the addition of Na_2O to an acidic melt (1.1739 g of Na_2O added to 170.4 ml of melt)

In order to prevent too long observation times, each point of the titration curve was the result of one experiment where a given amount of sodium oxide was added to a freshly saturated sample. By increasing the amount of added Na_2O from one experiment to another, it was possible to construct the complete titration curve.

The neutralization reaction consumed not only the carbon dioxide dissolved in the melt but also the carbon dioxide contained in the free volume of the cell. Each titration point must thus be corrected for this extra consumption. Therefore, the amount of carbon dioxide contained in the cell was accurately measured in the following way. The cell containing an empty crucible was filled with carbon dioxide under a pressure of 1 atmosphere. The gas was then flushed out of the cell by a stream of pure nitrogen and allowed to bubble through a given volume of a standard solution of sodium hydroxide. The amount of absorbed carbon dioxide was determined by titration of the excess sodium hydroxide with a standard solution of hydrogen chloride. Three independent determinations have been carried out. The number of moles of CO_2 contained under a pressure of 1 atmosphere in the cell containing an empty crucible was found to be 0.0290 mol with a standard deviation of $2.9 \cdot 10^{-4}$ mol.

When the experimental results were plotted in order to construct the titration curve, the amounts of sodium oxide added to the melt were corrected for the number of moles of CO_2 contained in the gas phase at equilibrium $n(CO_2)_{gas}$ calculated according to:

$$n(CO_2)_{gas} = 0.0290 - \frac{PV_{melt}}{RT} \quad (5)$$

where P and V_{melt} are the pressure at equilibrium (1 atm) and the volume of the carbonate melt. Due to this procedure, the number of moles of Na_2O is plotted on a scale where it remains negative as long as the total amount of Na_2O added to the system is lower than the quantity required to neutralize the CO_2 contained in the free volume of the cell. The number of moles of sodium oxide calculated in this way was further divided by V_{melt} expressed in liters in order to normalize all the data to 1 liter of carbonate melt. This number $n_{norm}(Na_2O)$ was finally plotted as abscissa.

With the experimental set-up used in this investigation, the number of moles of CO_2 dissolved in the melt amounted to about 20% of the total number of moles introduced into the cell for each experiment.

Another procedure, less accurate than the preceding one, was also used. In this case, when the melt was saturated with CO_2, the cell was connected to the vacuum device for a short time (10 sec) in order to remove the carbon dioxide contained in the free volume. After that time, the residual pressure in the cell was about 1 cm Hg. It is of course impossible to state whether the extraction time was correctly choosen or not. It seems however highly probable that some positive (incomplete exhaustion of the CO_2 from the free volume) or negative (degassing of the melt) occurred in this procedure.

3. Results

Figures 2 and 3 show respectively a titration curve obtained by the first and by the second procedure. From the first graph, the solubility of carbon dioxide at 700°C in the

ternary eutectic under a pressure of 1 atmosphere is found to be 9.5 $10^{-2} \pm 1.0 \times 10^{-2}$ mol·L^{-1}atm^{-1} (this value was obtained by fifth-order polynomial fit with a correlation factor of 0.95). The equivalent point of the titration curve of the second graph corresponds to a solubility of $5.5 \cdot 10^{-2}$ mol·L^{-1}atm^{-1}. The agreement between these two values is reasonable if the difference between the two experimental procedures is taken into account. The observed difference may be attributed to a partial degassing of the melt during the emptying of the free volume.

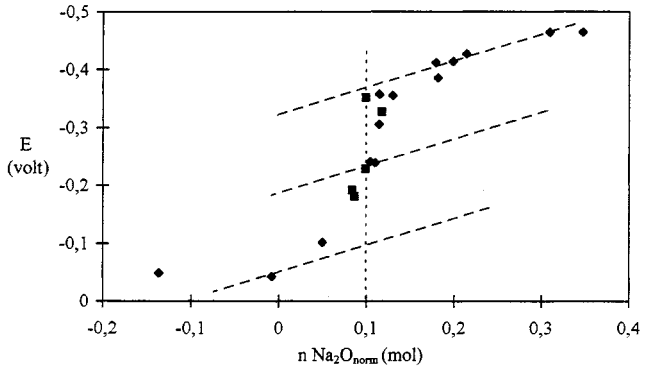

Figure 2. Titration curve obtained after correction for the neutralization of the amount of CO_2 contained in the free volume of the cell

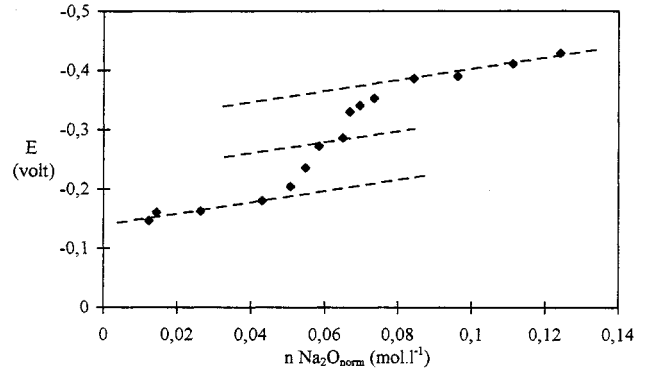

Figure 3. Titration curve obtained after the possibly incomplete removal of the CO_2 contained in the free volume of the cell

The pK_d value of the ternary eutectic at 700°C can be calculated from the value of the potential of the working electrode characteristic of the melt saturated with CO_2 under a pressure of 1 atm on the one hand and from the potential obtained for equilibrium conditions when an excess of sodium oxide has been added to the liquid on the other hand. The excess concentration of sodium oxide must of course be lower than the solubility of sodium oxide in the ternary eutectic at 700°C. According to White and Twardoch, this concentration limit amounts to 0.054 mol·L^{-1} [7].

Equations (6) and (7) describe the electrode reactions of the oxygen redox system respectively in basic and in acidic conditions:

$$O_2 + 4\ e^- \rightleftharpoons 2\ O^{2-} \quad (6)$$
$$O_2 + 2\ CO_2 + 4\ e^- \rightleftharpoons 2\ CO_3^{2-} \quad (7)$$

The corresponding Nernst equations are written:

$$E = E^\circ_{O2/O^{2-}} + (RT/4F)\ \ln P(O_2) - (RT/4F)\ \ln a(O^{2-}) \quad (8)$$
$$E = E^\circ_{O2/O^{2-}} + (RT/4F)\ \ln P(O_2) - (RT/4F)\ \ln K_d + (RT/4F)\ \ln P(CO_2) \quad (9)$$

If the partial pressure of oxygen, which is the residual pressure of oxygen, is considered as a constant, Equations (7) and (8) may be rewritten:

$$E = A - (RT/4F)\ \ln a(O^{2-}) \quad (10)$$
$$E = A - (RT/4F)\ \ln K_d + (RT/4F)\ \ln P(CO_2) \quad (11)$$

The potential value for the excess Na_2O concentration was corrected for the potential shift which occurred in basic media. Therefore, the electrodes were allowed to rest in the melt after the neutralization of the carbon dioxide by the introduced sodium oxide and the potential difference was measured as a function of the time. Using this shift per unit time measured experimentally for each neutralization experiment, the value of the potential obtained for the basic melt was corrected considering the time elapsed between the introduction of sodium oxide and the end of the experiment. Taking into account Equations (10) and (11) as well as the correction for the potential drift $[(\Delta E)_{drift}]$ and assuming that the activity of oxide ions in Equation (10) may be replaced by the excess concentration of sodium oxide $[C(Na_20)_{exc}]$ (the concentration corresponding to the amount of Na_2O introduced in the saturated melt less the solubility of carbon dioxide), one finds for the difference between the initial and the final potentials (ΔE):

$$\Delta E = -(RT/4F)\ \ln K_d - (RT/4F)\ \ln C(Na_2O)_{exc} - (\Delta E)_{drift} \quad (12)$$

The pK_d values were determined from five independent experiments whose results are shown in Table 2. This table gives successively the normalized amount of sodium oxide introduced into the saturated melt $[n_{norm}(Na_2O)]$, the excess concentration of sodium oxide $[C(Na_2O)_{exc}]$, the potential of the gold electrode measured at the beginning of the experiment ($E_{t=0}$) and 8 hours later ($E_{t=8}$), the experimental drift correction $[(\Delta E)_{drift}]$, the potential difference (ΔE) and the calculated pK_d value.

The mean value is pK_d = 5.37 with a standard deviation of σ_5 = 0.24

4. Discussion

4.1. Comparison with the Literature

The Henry's constant determined in this work is one order of magnitude higher than those measured by Appleby[4] and by Broers[5] but it agrees with the value given by Dubois.[6] This disagreement might be due to differences between experimental techniques used in these investigations. Appleby deduced his solubility data using a melt-chilling method based on the measurement of the quantity of dissolved gas released on freezing of the melt. This technique is certainly suitable for the determination of physical solu-

Table 2. Determination of the pK_d value

$n_{norm}(Na_2O)$ [mol·L^{-1}]	$C(Na_2O)_{exc}$ [mol·L^{-1}]	$E_{t=0}$ [Volt]	$E_{t=8h}$ [Volt]	$(\Delta E)_{drift}$ [Volt]	ΔE [Volt]	pK_d
0.179	0.084	0.043	0.412	0.033	0.402	5.24
0.115	0.020	0.043	0.357	0.056	0.370	5.53
0.114	0.019	0.043	0.306	0.096	0.359	5.44
0.130	0.035	0.043	0.355	0.031	0.343	5.01

bilities but might lead to underestimations in the case of chemical solubilities if the chemical reactions which take place in the dissolution process are slow. Broers used a procedure based on impedance determinations at a stationary $CO,CO_2/CO_3^{2-}$/Au electrode over a range of $P(CO)/P(CO_2)$ ratios which allows the CO_2/CO solubility ratio to be calculated. The CO_2 solubility is then deduced from the solubility of CO measured by an amperometric titration method. The interpretation of impedance spectroscopy determinations is much more complex than our measurements and needs that dissolved CO_2 and CO both occur in the melt as definite species reacting at the electrode at a well defined potential.

The pK_d value obtained in this work ($pK_d = 5.37 \pm 0.24$) is in reasonable agreement with the result obtained by Andersen ($pK_d = 5.8$)[8]. A small lack of accuracy might occur in our determinations due to the fact that the residual partial pressures of oxygen in the carbon dioxide and in the nitrogen used to generate the gaseous atmosphere in equilibrium respectively with the acidic and basic melts are not exactly the same. The accuracy might probably be improved by adding a small constant partial pressure of oxygen to the gaseous atmospheres successively imposed above the melt during the determinations in place of using "pure" carbon dioxide and "pure" nitrogen.

4.2. Comparison with the Electrochemical Behaviour of Carbon Dioxide

Earlier results have shown that CO_2 is electroactive in molten carbonates and that the corresponding CO_2/CO redox system exhibits a reversible behaviour[3,9−11]. The proposed electrochemical reaction is:

$$2\ CO_2 + 2\ e^- \rightleftharpoons CO + CO_3^{2-} \quad (13)$$

This was indeed confirmed in this work since a cathodic peak occurs at about −0.8 V versus the reference electrode in the linear sweep voltammograms of CO_2 saturated melts. Such a voltammogram is shown in Figure 4. The current density of this signal was allways very small, of the order of magnitude of 1 mA·cm^{-2}.

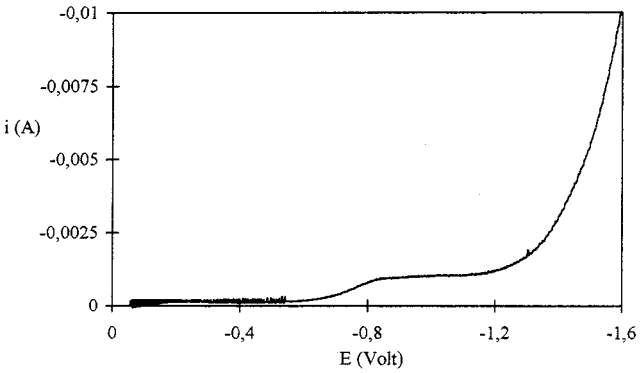

Figure 4. Voltammogram of a CO_2 saturated carbonate melt. ($\nu = 1$ V·s^{-1})

$$i_p = 0.4463(\nu D/RT)^{1/2}(nF)^{3/2}\ SC \quad (14)$$

From the Randles−Sevcikc Equation (14) in which $i_p = 10^{-3}$ A, $n = 1$, $S = 1$ cm^2, $T = 973$ K, $\nu = 1$ Vs^{-1} and $D = 10^{-5}$ cm^{2}s^{-1}, which is the order of magnitude of diffusion coefficients in molten carbonates in the temperature range 873−973 K[3,7,11−13], a concentration value of $2\cdot10^{-3}$ mol·L^{-1} is calculated. This calculation is in agreement with the results of Peelen[11] who reports a value of $0.95\cdot10^{-8}$ mol·cm^{-2}s$^{-1/2}$ for the product $s \times D^{1/2}$ (where s is the solubility) relative to CO_2 in a molten Li/K carbonate mixture at 848 K. From this, with the same diffusion coefficient, the value of the solubility s is found to be $3\cdot10^{-3}$ mol·L^{-1}. These solubilities are lower by about two orders of magnitude than the Henry's constant measured by the titration technique.

In order to make the experimental solubility compatible with the electrochemical observations, it may be assumed that most of the carbon dioxide dissolved in the carbonate melt is so strongly solvated that it should react at the cathode at a potential at which the reduction of carbonate ions still occurs. The formation of dicarbonate ions may be proposed:

$$CO_2 + CO_3^{2-} \rightleftharpoons C_2O_5^{2-} \quad (15)$$

with an equilibrium constant:

$$K = \frac{a(C_2O_5^{2-})}{P(CO_2)} \quad (16]$$

According to this assumption, a small proportion of CO_2 dissolves physically in the melt, yielding "free" CO_2 responsible for the observed electrochemical reduction. As calculated above, this physical dissolution accounts for only about 2% of the dissolved CO_2. The largest part of the dissolution occurs chemically yielding dicarbonate ions. Furthermore, these dicarbonate ions have to be inactive in the electrochemical window. The "complexation" of CO_2 by CO_3^{2-} or the overpotential for the reduction of $C_2O_5^{2-}$ must therefore be strong enough to shift that reaction to potential values where the reduction of CO_3^{2-} still occurs. In order to explain the weakness of the cathodic signal due to the reduction of CO_2, it must also be assumed that the production of CO_2 through equilibrium (15) is slow enough that the consumption of CO_2 in the electrochemical reduction is not compensated by the equilibrium. The sluggishness of the formation−dissociation kinetics of pyrocarbonate ions applies to all phenomena consuming carbon dioxide and the unexpected high solubility of CO_2 contributes little, for instance, to enhance CO_2 mass transfer in MCFC cathodes. The occurrence of a physical and a chemical solubility might also explain, at least partly, the discrepancies between solubility determinations by different techniques.

Unfortunately, we are unable at the moment to propose any experimental evidence for the occurrence of dicarbonate ions in acidic carbonate melts. However, the quantum chemical approach proposed in the second part of this work provides good arguments for the formation of that species.

4.3. Acidobasic Properties of Carbonate Melts

The occurrence of a chemical solubility of carbon dioxide besides its physical solubility leads to a second autodissociation reaction of carbonates, which would be written as Equation (17) and which would occur in the melt besides equilibrium (1).

$$2\ CO_3^{2-} \rightleftharpoons C_2O_5^{2-} + O^{2-} \quad (17)$$

The corresponding autodissociation constant is:

$$K_d' = a(C_2O_5^{2-}) \cdot a(O^{2-}) \quad (18)$$

For practical purposes, this is written:

$$K_d' = [C_2O_5^{2-}]\cdot[O^{2-}] \quad (19)$$

Taking into account equilibrium (16), one finds:

$$K_d' = KP(CO_2)[O^{2-}] = K_dK \quad (20)$$

The neutrality condition for autodissociation, which is a relationship between the concentrations of basic and acidic species in a pure carbonate melt should then be written:

$$[O^{2-}] = [CO_2] + [C_2O_5^{2-}] \quad (21)$$

The titration carried out in this work does not allow the direct measurement of Henry′s constant, which accounts only for the physical solubility. The measured constant is in fact ($k_H + K$) since both chemically and physically dissolved carbon dioxide react with Na_2O:

$$[CO_2] + [C_2O_5^{2-}] = (K+ k_H)\cdot P(CO_2) = 9.5\cdot10^{-2} \pm 1.0\cdot10^{-2}\ mol\cdot L^{-1} \quad (22)$$

The ratio of the concentration of physically and chemically dissolved carbon dioxide depends only on the temperature of the melt:

$$\frac{[CO_2]}{[C_2O_5^{2-}]} = \frac{k_H}{K} \quad (23)$$

An approximative value of this ratio may be proposed from the results obtained in this work: $[CO_2]$ has been evaluated to be $2\cdot10^{-3}$ mol·L^{-1} from the peak current density for the electrochemical reduction of carbon dioxide in a saturated melt and $[C_2O_5^{2-}]$ may be considered as the experimental solubility since, taking into account the level of approximation, the physical solubility may be neglected in comparison with the chemical solubility. The value of $2\cdot10^{-2}$ is thus a good approximation of the ratio of the physical to the chemical solubility.

$C_2O_5^{2-}$ is a weak acid relative to CO_2, which is the strongest acid available in carbonate melts. The respective strengths of these acids are measured by the equilibrium constants (K_1 and K_2) of the reactions of these acids with oxide ions:

$$C_2O_5^{2-} + O^{2-} \rightleftharpoons 2\ CO_3^{2-} \quad (24)$$

$$CO_2 + O^{2-} \rightleftharpoons CO_3^{2-} \quad (25)$$

$$\frac{K_1}{K_2} = \frac{[CO_2]}{[C_2O_5^{2-}]} \quad (26)$$

$C_2O_5^{2-}$ is thus a weaker acid than CO_2 by a factor of about $2\cdot10^{-2}$.

5. Conclusions

The experimental value of the solubility of carbon dioxide in carbonate melts depends on the technique used for the determination. The solubility measured in this work by a titration technique is much higher than those reported in the literature for the same melt at the same temperature. These differences may be explained by the occurrence of a physical and a chemical solubility due to the formation of dicarbonate ions. This chemical solubility is about 50 times more important than the physical solubility. The simultaneous occurrence of CO_2 and $C_2O_5^{2-}$ in carbonate melts means that the autodissociation of carbonate ions occurs in two different ways producing two different conjugated acids of the solvent. The comparison of these two acids from a thermodynamic point of view shows that the strength of the dicarbonate ion is about 50 times lower than that of carbon dioxide, which is the strongest acid available in molten carbonates. Our results do not allow the deduc-

tion of any information about the kinetic properties of these two species, but the occurrence of $C_2O_5^{2-}$ offers a convenient explanation for the slowness of the neutralization reaction of oxide ions in acidic carbonate melts as demonstrated by Lu and Selman[15]. This is a rather speculative consideration but it seems important to pay some attention to this point in the future.

Experimental Section

Chemicals: Lithium-, sodium-, and potassium carbonates were analytical grade reagents from Merck. The lithium salt was dried at 200°C for 24 hours under vacuum before use.

200 g of a dry homogeneous mixture of salts with the composition of the ternary eutectic $Li_2CO_3-Na_2CO_3-K_2CO_3$ (43.5%, 31.5% and 25.0% mol. respectively) was used for each experiment. The sample was progressively heated up to 400°C under a nitrogen pressure of 1 atmosphere in order to remove residual water. After melting, nitrogen was replaced by carbon dioxide and the temperature of the liquid was raised to 700°C.

The gases were supplied by Air Liquide; their purities are certified to be at least 99.999% for nitrogen, 99.99% for O_2, and 99.995% for CO_2. The water content of all these gases is lower than 5 ppm.

When mixtures of gases were needed (reference electrode), the expected proportions were obtained by adjusting the streams of the components with precision valves and flowmeters to a buffer vessel, where the gases were allowed to mix together.

Experimental Set-up: The carbonate melt was contained in an alumina (Al23 Degussa) crucible setted in an alumina (Al23 Degussa) cell located in a vertical furnace whose temperature was regulated to ±2°C. The cell was provided with an airtight cover which allowed to introduce into the melt a working and a reference electrode and with alumina tubings intended to introduce sodium oxide, carbon dioxide and nitrogen into the cell.

Addition of Na_2O was carried out without changing the composition of the gaseous atmosphere in the cell by means of a lock chamber.

During the titration procedure, nitrogen was progressively introduced to compensate for the consumption of carbon dioxide in order to keep constant the total pressure in the cell.

Electrochemical Device: The working electrode used in potentiometric determinations is a 0.5 mm diameter gold wire which acts as an oxygen electrode. The reference electrode is an oxygen electrode in an acidic melt contained in a pythagoras tubing dipped into the investigated melt. The electrochemical arrangement is thus:

Au / CO_2 (0.66 atm), O_2 (0.33 atm) / CO_3^{2-} / pythagoras / CO_3^{2-} sample / CO_2 or O^{2-}, O_2 (res.) / Au

The electrochemical determination have been carried out with a Princeton Applied Research potentiostat/galvanostat model 273.

Keywords: Ab initio calculations / Dicarbonate anion $C_2O_5^{2-}$ / Dicarbonate structure / Dicarbonate stability

A theoretical study of the structure and stability of the dicarbonate ion has been performed at the Hartree–Fock, MP2, and QCI/SD levels. A flexible 6-31+G(d) basis set was used to allow for the diffuse electron density appearing in the anions. A stable anion corresponding to two CO_2 entities covalently bound to a central oxygen has been found. The formation reaction starting from the carbonate anion and carbon dioxide has also been studied. Its thermodynamic features favour the formation of the dicarbonate anion, which in turn may account for the impressive solubility of carbon dioxide in carbonate melts.

Introduction

In the first part of this work[1] we described the measurement of the solubility of carbon dioxide in the ternary $Li_2CO_3/Na_2CO_3/K_2CO_3$ molten eutectic mixture under a pressure of 1 atm of CO_2. The experimentally determined value amounted to 0.995×10^{-1} mol L^{-1}, which is much higher than the values reported in the literature for the same melt at the same temperature. This solubility value is also 50 times higher than that deduced from the voltammetric peak current density measured for the electrochemical reduction of CO_2 dissolved in the melt under a pressure of 1 atm. In order to rationalize these data, it was suggested that CO_2 might combine with the carbonate ions to yield a strongly stabilized solvated species. The formation of dicarbonate ions has been proposed (Equation 1).

$$CO_2 + CO_3^{2-} \rightleftharpoons C_2O_5^{2-} \quad (1)$$

The free energy change for this reaction was assumed to be sufficiently large to shift the cathodic reaction at potentials where the reduction of carbonate ions yet occurs. Unfortunately, however, the previous investigation did not provide any direct experimental evidence for the occurrence of dicarbonate ions.

The main goal of this study is to analyse by theoretical means the structure, stability and properties, especially thermodynamic properties, of the relevant species. A quantum chemical approach to such a problem remains difficult, even though current computer technology permits access to an explicit and extensive treatment of such systems.

These experiments are carried out by considering a condensed, globally neutral, liquid medium. In such a model approach, the carbonate ions are assumed to be able to move freely through the medium of the molten salt phase while interacting with their neighbours. With this assumption, the study may be reduced to that of a particular molecular event; a single carbonate ion and a single carbon dioxide molecule may be considered in isolation and their mutual interaction can be studied as if they were isolated in the gas phase. We thus explicitly neglect the bulk behaviour as well as the nature of the counterion at this level. These should, of course, be introduced in condensed-phase simulations, but we shall concentrate our study on the most elementary chemical process accessible by quantum chemical means.

At the level used, the main difficulty involved lies in obtaining an adequate description of the behaviour of electrons in anions, especially when multiple excess charges are present. To treat this problem with a suitable degree of accuracy, two criteria need to be fulfilled:

1. As the excess electrons may be delocalized over large domains in space, the basis sets needed to simulate their distribution must offer sufficient flexibility to allow for such a large extension. Theoretical calculations must therefore be based on large basis sets, including polarization functions as well as extra diffuse functions.

2. As the correlation between electrons within the molecular domain is more important than in the case of neutral molecules, theoretical calculations must go beyond the Hartree−Fock level and explicitly include electron correlation.

In the next section, we shall briefly describe the methodology used in this work. The results of our simulation will then be presented. Finally, we shall discuss the chemical properties obtained and their relation to the macroscopic problem of interest.

Method

Owing to the size of the system, we chose to start our calculations at the valence split 6-31G basis set of Pople

and co-workers, which was augmented by a set of 6 Cartesian "d" polarization functions.[2] An additional set of diffuse sp functions[3] completed the basis. This led to the 6-31+G(D) basis set, containing some 133 atomic orbitals for the $C_2O_5^{2-}$ system. The ab initio molecular orbital calculations were then performed at restricted Hartree−Fock (RHF) level using the GAUSSIAN series of programs.[4] Post-SCF level computations were subsequently performed to introduce the electron correlation. In these, the inner cores were frozen, but all single and double excitations of the valence orbitals were considered using one of two different approaches: In the first, second-order Moller−Plesset perturbation theory computations (MP2) were performed. Such calculations remain affordable for carrying out a full optimization of the geometry. The second approach involved quadratic configuration interaction (QCI/SD). This latter method was in fact adopted, since it provides, within the variation principle, size-consistent results. This is a prerequisite for obtaining reliable reaction energies.

The geometric structures were derived from a full geometry optimization of all $3N - 6$ internal coordinates, thereby relaxing any a priori symmetry constraints. A conventional gradient technique was used to perform the optimization process.

Analytical computation of the first and second derivatives of the energy hypersurface was completed at the SCF level in order to verify the good behaviour of the minima and maxima found and to obtain a vibrational analysis within the harmonic approximation. This provided some information regarding the ways in which the molecules may be distorted. Knowledge of the geometrical structure and of the related rotational and vibrational frequencies allows further thermodynamic insight into the problem by applying the relationships of conventional statistical thermodynamics. From such an analysis, a simulation of the IR spectrum may even be obtained. At this point, we should mention that the theoretical vibrational frequencies needed to evaluate the zero-point energy and thermal corrections were scaled to adjust theoretical frequencies to experimental ones (Equation 2).[5]

$$\nu(\mathrm{sc}) = 0.9\ \nu(\mathrm{th}) \qquad (2)$$

At post-SCF MP2 level, the analytical gradient was used in conjunction with the analytical SCF Hessian matrix. The same approach was used at the QCI level, although this was not possible for the dicarbonate ion as in this case computation of the analytical gradient remains beyond our computational facilities. For the latter, a single-point energy was obtained at QCI/SD level using the MP2-optimized geometry.

Considering the results obtained for some other systems, we suspect that a correctly optimized structure would induce a further modification of some 0.003 Å in the bond lengths while the energy might be lower by about 2−3 kcal mol^{-1}.

Results

The reactants and product of the reaction were fully optimized as described in the preceding section. The resulting structures and energies for CO_2 and CO_3^{2-} are given in Table 1. Corresponding results for $C_2O_5^{2-}$ are given in Table 2 and its structure is depicted in Figure 1. It is noteworthy that for the latter the potential energy surface around the minimum is very flat and allows a considerable degree of freedom with regard to the position of the central oxygen atom. The absolute minimum has a C_2-symmetric structure at both the RHF and MP2 levels, but an asymmetric adjustment of the central C−O bonds by 0.005 Å leaves the energy almost unchanged.

With regard to the charge distribution, it is meaningless to use a conventional Mulliken population analysis with polarized and diffuse atomic basis sets, as their spatial extension and overlap is far too great. Mulliken charges ob-

tained using a 6-31G basis set computation are listed in Table 3.

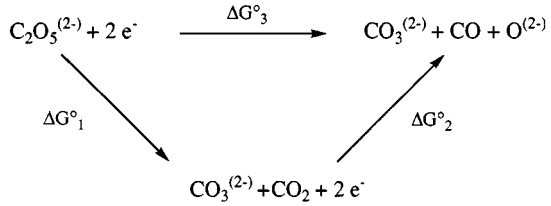
Discussion

The collected results offer an insight into the general behaviour of the studied system.



1. From a thermodynamic point of view, starting from the force constants obtained at Hartree−Fock level, one may compute the vibrational frequencies of the reactants and products. Furthermore, the computed energy, the moment of inertia, and scaled frequencies allow us to estimate, using statistical relationships, the reaction enthalpy, the entropy, and the Gibbs′ free energy at various temperatures. The results obtained at 298.15 K are presented in Table 4, along with those at the higher temperatures of 698.15 K and 973.15 K, which are closer to those of molten salts.

Table 4. Thermodynamic reaction properties derived from the theoretical results at 6-31+G(D) level

Method	$\Delta H(T)$ [kcal mol^{-1}]	$\Delta S(T)$ [cal K^{-1}mol^{-1}]	$\Delta G(T)$ [kcal mol^{-1}]
$T = 298.15$ K			
RHF	−56.09	−27.90	−47.77
MP2	−52.05	–	−43.73
QCI/SD	−54.83	–	−46.51
$T = 698.15$ K			
RHF	−55.382	−26.50	−36.87
MP2	−51.342	–	−32.83
QCI/SD	−54.123	–	−35.61
$T = 973.15$ K			
RHF	−54.62	−25.60	−29.71
MP2	−50.58	–	−25.67
QCI/SD	−53.36	–	−28.45

It can readily be seen that the product of this reaction has appreciable thermodynamic stability at any considered temperature. On the one hand, since the structure is not totally optimized at the QCI level, the reaction energies must still be more negative. On the other hand, the theoretical reaction energy of such systems may still be subject to some errors (basis set limitations, electronic correlation). However, we feel that with the presented methodology, especially at QCI level, further sophistication will not lead to a modification of the results by more than a few kcal mol^{-1}, which would be negligible compared to the −54 kcal mol^{-1} enthalpy variation. The reaction entropy is of course negative, but the overall Gibbs′ free energy remains negative, confirming the stability of the dicarbonate species. We may add to the argument that the reaction medium modifies the reaction entropy, generally leading to slightly less negative entropy contributions due to the bulk properties of condensed phase media.[6] This further confirms the thermodynamic stabilization of the dicarbonate ion in the molten medium.

As stated in the introduction, the free energy change for the production of dicarbonate ions from carbon dioxide and carbonate ions must be sufficient to shift the electrochemical reduction at potentials where the reaction of carbonate ions yet occurs. The reduction potential of dicarbonate ions may be calculated from the free energy change associated with reaction according to Equation 1. From the thermodynamic cycle shown in Scheme 1, Equation 3 may be derived.

Scheme 1. Thermodynamic cycle involving $C_2O_5^{2-}$

$$\Delta G^\circ_3 = \Delta G^\circ_1 + \Delta G^\circ_2$$
or
$$\Delta E^\circ_3 = -\Delta G^\circ_1/n\mathrm{F} + \Delta E^\circ_2 \quad (3)$$

Here, ΔG°_1 is the calculated free energy change associated with reaction according to Equation 1, which is given in Table 4 (−28.45 kcal.mol^{-1}); ΔE°_3 and ΔE°_2 are the standard potentials of the $C_2O_5^{2-}$/CO and CO_2/CO redox systems, respectively, and $-\Delta G^\circ_1/n$F is the difference between these two standard potentials. The latter thus represents the difference between the reduction potentials of CO_2 and $C_2O_5^{2-}$.

The value calculated in this way amounts to 617 mV, which is close to the difference between the reaction potential of CO_2 and the cathodic limit of the accessible electrochemical window in the molten ternary eutectic mixture of carbonates, which is of the order of 600 mV. Although the result obtained by our theoretical approach must be treated with caution as no medium effects are taken into consideration, the trend indicated by this estimation is in reasonably good agreement with the assumption made in the first part of this work.

2. From a structural point of view, the association of a CO_2 molecule with a CO_3^{2-} anion does not lead to a molecule−ion complex, as might have been expected, but to a well-defined dicarbonate molecular species. The distances between the C and O atoms correspond to those of covalent bonds. The symmetry of the system indicates that the two CO_2 moieties are equivalent. The integrity of an incoming CO_2 molecule is lost in the formation of the product, in which the central oxygen atom is trapped between two CO_2 units. It is readily conceivable that at the surface of the condensed molten carbonate medium, CO_2 may be absorbed from the gaseous environment forming a $C_2O_5^{2-}$ species,

which will then be able to diffuse inside the molten salt. A possible mechanism for the diffusion could be described in terms of the interchange of oxygen atoms with neighbouring CO_3^{2-} ions (Equation 4).

$$O_2C^* + O'CO_2^{2-} \rightleftharpoons O_2C^*O'CO_2^{2-} \rightleftharpoons O_2C^*O'^{2-} + CO_2 \rightleftharpoons \text{etc.} \quad (4)$$

This description is further supported by the presence in the IR spectrum of a low-energy asymmetric stretch of the central C−O bonds and by the aforementioned observation that the potential energy surface remains almost constant under deformation of the C−O−C arrangement.

Of course, our description only relates to an ideal "gas phase" level, which may indeed be appropriate close to the interface between the gaseous and liquid phases, justifying the solubility of CO_2. However, one must be cautious in generalizing such a mechanism to the bulk, where the nature of the counterions and the existence of high electric fields will presumably modify this mechanism.

Indeed, it was concluded in the first part of this work that the regeneration of CO_2 from the dicarbonate ion should be a slow process, since the electrochemical reduction of CO_2 appears to be restricted to free CO_2. With regard to the proposed transport mechanism, this slowness is unexpected and may highlight an inconsistency.

General Conclusions

We have shown herein that CO_2 interacts with the carbonate anion to produce a stable dicarbonate ion. The latter exhibits C_2 symmetry, the central oxygen atom being covalently bonded by two equivalent CO_2 moieties. Analysis of the potential energy surface, completed by a vibrational analysis, shows that the central oxygen atom has sufficient freedom of motion to undergo ready exchange with the CO_2 species. This leads to the assumption that carbon dioxide should be highly soluble in the molten mixture of carbonates and consequently points to the existence of dicarbonate ions in this medium.

Metal–Metal Interactions in Dinuclear (triphos)Cobalt Complexes Exhibiting Mixed Valency

Katja Heinze,[a] Gottfried Huttner,*[a] and Olaf Walter[a]

In memoriam Dr. L. Zsolnai

Keywords: Tripodal ligands / Cobalt / Bridging ligands / Mixed-valence compounds

The spectroscopic and electrochemical properties of a series of dinuclear mixed-valence complexes containing two (triphos)Co units are reported: $[(triphos)Co(L)Co(triphos)]^+$ (L = $C_6O_4X_2$; X = H, Cl, Br, I, Me: **2a–e$^+$**; L = $C_{14}H_4O_4Me_2$: **4$^+$**). Complexes **2a–e$^+$** are bridged by tetraoxybenzene ligands and exhibit very strong metal–metal interaction leading to delocalized class-III behaviour while in **4$^+$** the extended tetraoxoanthracence bridging ligand leads to a partial electron localization. Additionally, the different oxidation behaviour of the parent dicationic complexes **1a–e^{2+}** and **3^{2+}** have been investigated and are explained on the basis of a qualitative MO model.

Introduction

In the frame of a general study of magnetic[1][2] and electronic[3] interactions between two cobalt centres connected through a bridging ligand we have been interested in the investigation of complexes of the type $[(triphos)Co(L)Co(triphos)]^{n+}$. The tridentate terminal ligand triphos [1,1,1-tris(diphenylphosphanylmethyl)ethane] induces a five-fold coordination around each cobalt centre providing two free *cis* coordination sites[4–6] and thus allowing a bis(bidentate) coordination mode of the bridging ligand L within the dinuclear complex. The phosphorus donor set usually splits the metal d orbitals such that low-spin configurations (d^6-Co^{III}; d^7-Co^{II}) with zero or one unpaired electron, respectively, are obtained.[4][5] Antiferromagnetic exchange coupling is observed between the unpaired electrons of two $[(triphos)Co^{II}]$ entities in the complexes $[(triphos)Co(L)Co(triphos)]^{2+}$ with L = di-μ-X (X = Cl,[7][8] Br,[7] OH,[7] NH_2,[9] SMe[10]), 1,4,5,8-tetraoxonaphthalene, 1,4,9,10-tetraoxoanthracene,[1] fumarate and terephthalate.[2] Strong metal−bridging ligand interaction occurs within the dinuclear $[(triphos)Co^{III}]$ complexes $[(triphos)Co(L)Co(triphos)]^{2+}$ with L = 3,6-disubstituted 1,2,4,5-tetraoxybenzenes resulting in unusually intense, low-energy LMCT absorption bands.[3] In all cases the π system of the bridge proved to be essential for the interaction. In the latter complexes a further manifestation of the interaction is the separation of the two metal-centered reduction potentials which is due to the efficient overlap of the metal d(π) orbitals with the π orbitals of the bridging ligand.

We therefore attempted to prepare, isolate and characterize cationic mixed-valence complexes of the type $[(triphos)Co(L)Co(triphos)]^+$ with L = 3,6-disubstituted 1,2,4,5-tetraoxybenzenes in order to address the question of electron delocalization and electron transfer within the dinuclear unit. As the length of the bridging ligand has a remarkable influence on the communication between metal centres, analogous complexes with the extended bridging ligand 1,2,6,7-tetraoxy-9,10-dimethylanthracene are also reported.

Results and Discussion

Preparation of Complexes 1a−e^{2+}, 2a−e$^+$; Thermodynamic Stability and Reactivity of 2a−e$^+$

The complexes $[(triphos)Co(C_6O_4X_2)Co(triphos)]^{2+}$ (X = H, Cl, Br, I, Me), **1a−e^{2+}**, were prepared according to the literature.[3] Their CV data have already been reported but are repeated here for completeness (Table 1). The exceptionally large separation of the two reversible reduction steps shows that the mixed-valence species are thermodynamically stable towards disproportionation into the neutral and dicationic complexes. The green dicationic complexes can be reduced with one equivalent of cobaltocene to the blue cationic complexes **2a−e$^+$** (Figure 1; equation 1) which can be characterized in solution by spectroscopic methods. Reoxidation is possible by reaction with ferrocenium tetrafluoroborate (70−80% recovery).

All attempts to isolate **2a−e$^+$** as pure and crystalline materials failed as the complexes **2a−e$^+$** rapidly decompose on removing the solvent. Furthermore the mixed-valence complexes are highly reactive towards dioxygen leading to decomposition of the complexes (rapid colour change to red-brown yielding the free bridging ligand and phosphane oxides[11]). The reduction of **1a−e^{2+}** to **2a−e$^+$** was also carried out by the reaction with primary and secondary sodium alkoxides (NaOR; R = Me, Et, *i*Pr, CH_2Ph, allyl) yielding the corresponding aldehydes and ketones, respectively (isolated as their 2,4-dinitrophenylhydrazones). No carboxylic acids were detected in the reaction mixture. Ti-

equation 1

equation 2

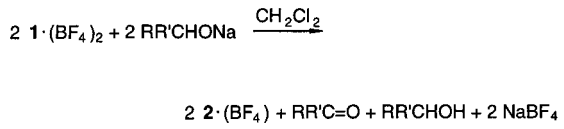

Figure 1. Reduction of **1a−e**$^{2+}$ to **2a−e**$^+$

trations with NaO*i*Pr, monitored by UV/Vis spectroscopy, showed clearly that one equivalent of base is necessary for complete conversion of **1a−e**$^{2+}$ to **2a−e**$^+$ (Table 1). The UV/Vis spectra obtained for the titration of **1c**$^{2+}$ with NaO*i*Pr are shown in Figure 2 as an example.

The intensity of the characteristic LMCT absorption band of **1c**$^{2+}$ at 1195 nm decreases with increasing base concentration, and simultaneously the band pattern of the cationic complex **2c**$^+$ emerges. Three isosbestic points are visible (304, 434 and 923 nm) which show that no UV/Vis-detectable intermediates are present. The net reaction can therefore be written as shown in Figure 1 (equation 2). These solutions are somewhat more stable than solutions of

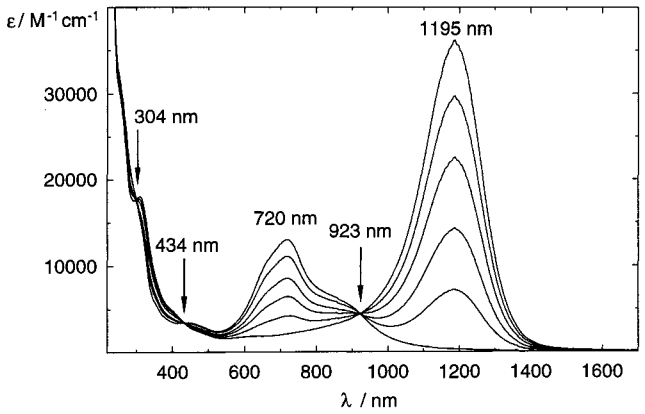

Figure 2. UV/Vis spectra during the titration of **1c**$^{2+}$ with NaO*i*Pr

2a−e$^+$ in pure CH_2Cl_2 and/or THF as long as an excess alcoholate is present.

Spectroscopic Properties of 2a−e$^+$

The isotropic EPR spectra of **2a−e**$^+$ in CH_2Cl_2 at 295 K show a broad, poorly resolved signal at *g* factors of around 2.11 (Table 1). The *g* factor and the width (half width at full height ca. 140 G) of the signal exclude the possibility of a significant spin density located on the bridging ligand. In a THF/CH_2Cl_2 matrix at 100 K the EPR spectrum exhibits a complex line pattern centered around $g = 2.10$. Figure 3 (left) shows the EPR spectrum of **2e**$^+$ as an example.

A 3 × 8 signal pattern would be expected if the unpaired electron were localized at one cobalt centre ($I_{Co} = {}^7/_2$), whereas a coupling with two equivalent cobalt centres should result in a 3 × 15 line pattern. Attempts to simulate the obtained spectra with a coupling to one metal centre failed; on the other hand a satisfactory approximation of the spectra was possible with the assumption of a coupling with two metal centres (Figure 3, right). This leads to the conclusion that the unpaired electron is delocalized over both metal centres, at least on the EPR time scale (10^{-9} s).

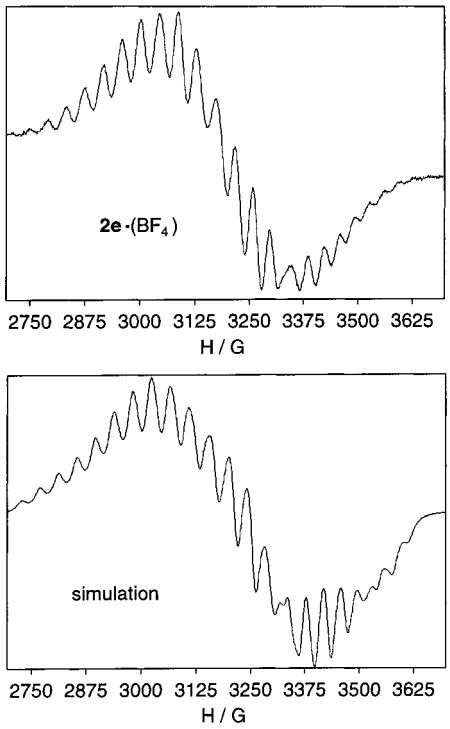

Figure 3. EPR spectrum of $\mathbf{2e}^+$ in THF/CH_2Cl_2 at 100 K and simulated spectrum

The obtained hyperfine coupling constants of $A_x \approx 40$ G, $A_y \approx 40$ G and $A_z \approx 34$ G further corroborate this interpretation. The coupling is significantly smaller than that found in the related mononuclear Co^{II} complexes [(triphos)-Co(L)] (L = substituted catecholate) with the unpaired electron inevitably localized on one metal centre ($A_x \approx 68-74$ G, $A_y \approx 58-60$ G and $A_z \approx 48-53$ G[12][13]).

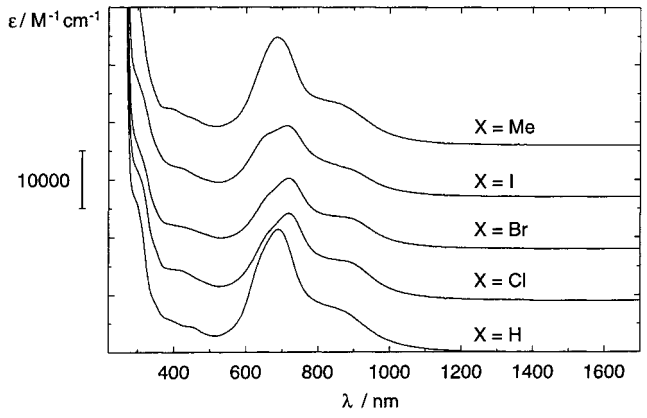

Figure 4. UV/Vis spectra of $\mathbf{2a-e}^+$

In accord with this interpretation of a delocalized system no absorption band which could be assigned to an intervalence transition could be detected up to 1700 nm in the UV/Vis/NIR spectra (Figure 4). In the visible part of the spectra a three-band pattern is observed (Table 1; $\lambda_4-\lambda_6$). The energy of the band maxima depends slightly on the substituents at the central bridge: Halides induce a red shift ($\mathbf{2a-d}^+$), alkyl residues a blue shift ($\mathbf{2e}^+$). This trend was also observed for the parent compounds $\mathbf{1a-e}^{2+}$.[3] The low-energy shoulder λ_6 has a half width at full height of only ca. 1630 cm^{-1} which is more than three times smaller than expected for a partly localized class-II system according to the Hush theory (5150−5260 cm^{-1}[14][15]). This transition might therefore better be described as a $\pi-\pi^*$ transition between delocalized states. Based on the CV, EPR, and UV/Vis data we therefore formulate the complex cations $\mathbf{2a-e}^+$ as delocalized class-III systems.

Crystal Structure of $(\mathbf{2b})_2\cdot(CoCl_4)$

Crystals of the complex salt $(\mathbf{2b})_2 \cdot (CoCl_4)$ were obtained as described in the Experimental Section. $(\mathbf{2b})_2 \cdot (CoCl_4)$ crystallizes in the tetragonal space group *P*4/*n*. The cation possesses crystallographic inversion symmetry, the $CoCl_4^{2-}$ counterion crystallographic S_4 symmetry. The results of the structural analysis are presented in Figure 5 and Table 2. In addition selected bond lengths and angles of the parent dicationic complex $(\mathbf{1b}) \cdot (BF_4)_2$[3] are shown for comparison.

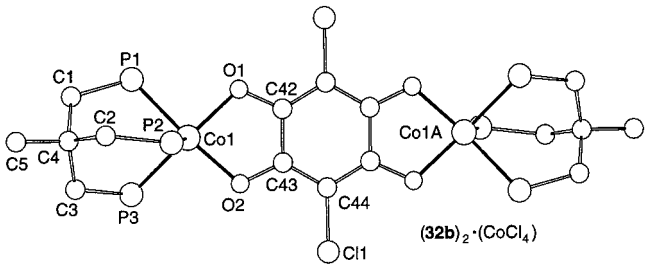

Figure 5. View of the structure of $\mathbf{2b}^+$; phenyl rings of the triphos ligand are omitted for clarity reasons

Neither a ligand dissociation nor a significant distortion of the coordination geometry relative to the structure of $\mathbf{1b}^{2+}$ is observed (maximum angle deviation X−Co−Y is observed for P3−Co1−O2 with 4.4°). Likewise the intraligand bond lengths (C−C, C−O, C−Cl) remain identical within the 2σ limit. Significant changes of the bond lengths are observed for the Co−O and Co−P bonds. The Co1−P2 (Δx = 0.073 Å) and the Co1−O1,2 bonds (Δx = 0.045, 0.053 Å) especially are elongated. As mainly bond lengths and only to a minor extent bond angles are affected by the additional electron the Franck−Condon barrier for the electron transfer can be estimated via $E_{in} = {}^1/_2\, N \Sigma\, k_i\, (\Delta x_i/2)^2$[16] [with k(Co−P) = 200 N m^{-1}; k(Co−O) = 440 N m^{-1}] resulting in about 2.5 kJ mol^{-1} per cobalt centre (i.e. 5 kJ mol^{-1} per complex). For the redox couple $[Co(tacn)_2]^{2+/3+}$ (tacn = 1,4,7-triazacyclononane) E_{in} is calculated as 25 kJ mol^{-1} [k(Co−N) = 170 N m^{-1}; Δx = 0.181 Å].[17] The very low activation barrier for the self-exchange reaction is due to the extremely small changes of the cobalt−ligand bond lengths Δx which might be the result of two effects: first the fact that the electron is delocalized over two metal centres and second that the cobalt centres retain their low-spin state as opposed to the $[Co(tacn)_2]^{2+/3+}$ case (hs-Co^{II}/ls-Co^{III}).

			φ_6	16.6	11.0

[a] Estimated standard deviations of the least significant figures are given in parentheses. − [b] The torsion angles τ_x are defined as follows: C4−C_x−P_x−Co (x = 1−3). The torsional arrangement of the six phenyl groups (φ_1−φ_6) is defined with respect to auxiliary vectors Hz_x−P_x (Hz_x is a dummy atom above P_x orthogonal to the plane spanned by the three phosphorus atoms) (x = 1−3): Hz_x−P_x−C_{ipso}−C_{ortho}.

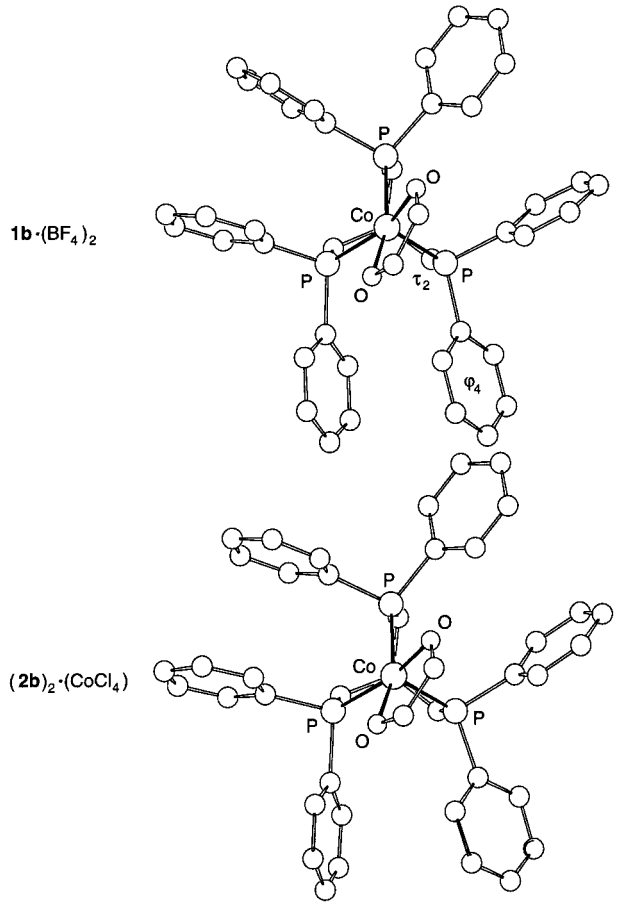

Figure 6. View of one (triphos)Co(O_2C_2) fragment of $\mathbf{1b}^{2+}$ and $\mathbf{2b}^{+}$[3] perpendicular to the plane spanned by the three phosphorus atoms

The conformation of the triphos ligand in the complex cations $\mathbf{1b}^{2+}$ and $\mathbf{2b}^{+}$ as decribed by the torsion angles of the chelate cage τ_{1-3} and the rotational position of the six phenyl rings φ_{1-6}[6] is shown in Figure 6 and Table 2. The only significant changes involve the backbone torsion angle τ_2 ($\Delta\tau_2 \approx 7°$) and the orientation of the fourth phenyl ring ($\Delta\varphi_4 \approx 14°$) both associated with the phosphorus atom P2.

In summary the structural data show that the additional electron in $\mathbf{2b}^{+}$ is neither localized on the bridging ligand nor on the triphos ligand, but on the metal centres. Of course, the X-ray structural analysis does not allow a decision between a localized or delocalized electronic description.

MO Calculations

The results of a molecular orbital calculation on the model compound $[\{(PH_3)_3Co\}_2(C_6H_2O_4)]^{2+}$ by the INDO method are presented in Figure 7,[18] which shows the relative energies and symmetries of the frontier orbitals. Here it suffices to note that in accordance with the EPR results the additional electron occupies a (68%) molecular orbital of b_u symmetry (C_{2h}) centered mainly on both metal atoms and that a filled ligand-centered (99% ligand) MO of b_g symmetry lies *below* the essentially ligand-centered MO of a_g symmetry (70% ligand).

Preparation of Complexes 3^{2+}, 4^{+}, 5^{3+}

The dicationic complex **3** · $(PF_6)_2$ may be obtained from $CoCl_2$, triphos, the bridging ligand 2,3,6,7-tetrahydroxy-9,10-dimethylanthracene and $NaPF_6$ as an analytically pure

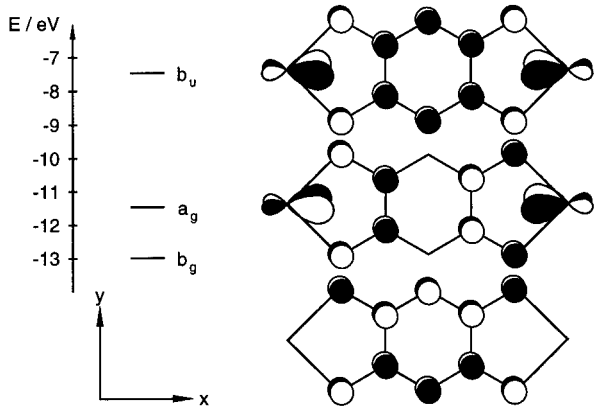

Figure 7. Orbital splitting and orbital symmetry of the model complex $[\{(PH_3)_3Co\}_2(C_6H_2O_4)]^{2+}$; the symmetry labels for the orbitals assume C_{2h} symmetry; the x axis is the Co−Co axis, and the z axis is perpendicular to the plane of the bridging ligand

blue powder. The FAB mass spectrum shows a typical fragmentation pattern[1−3] of dinuclear dicationic (triphos)cobalt complexes (see Experimental Section). The ^{1}H-NMR spectrum of **3** · $(PF_6)_2$ in CD_2Cl_2 shows signals for the CH_3, CH_2 and CH groups of the triphos ligand and signals for the CH and CH_3 groups of the bridging ligand in the correct intensity ratio. The phosphorus atoms of the triphos ligand give rise to a singlet at $\delta = 31.1$ in the ^{31}P-NMR spectrum. The signal of the ^{31}P nucleus of the hexafluorophosphate counterion is observed at $\delta = -144.2$ with the correct intensity ratio[19] of P(PF_6)/P(triphos) = 1:3. Due to the low solubility of **3** · $(PF_6)_2$ no ^{13}C-NMR spectrum could be obtained.

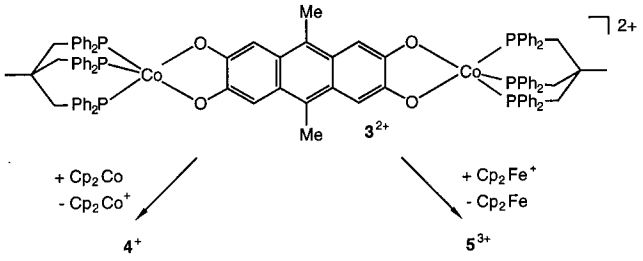

Figure 8. Synthesis of 4^+ and 5^{3+}

The dicationic complex 3^{2+} can be reduced in two reversible steps at −170 mV (Figure 9; 1) and −355 mV (Figure 9; 2), reversibly oxidized at +335 mV (Figure 9; 3) and irreversibly oxidized at $E_p \approx +935$ mV (vs. SCE). The reversible character of both reduction steps and the first oxidation wave precludes any significant structural rearrangement during the redox processes, i.e. all species 3^{2+}, 4^+ and 5^{3+} can be described by the same structure. The reduction to the mixed-valence complex 4^+ can be accomplished with cobaltocene; the oxidation to the trication 5^{3+} with ferrocenium tetrafluoroborate (Figure 8). With the separation of the two reduction potentials of 185 mV the conproportionation constant K_C for 4^+ is estimated to be 1.3×10^3 which is 15 orders of magnitude smaller than K_C of the complex $2e^+$.

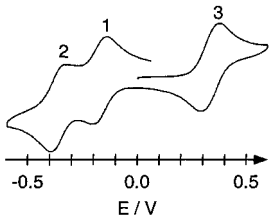

Figure 9. Cyclic voltammogram of **3** · $(PF_6)_2$ in CH_3CN

The UV/Vis spectrum of 3^{2+} (Figure 10, Table 3) shows two intense LMCT bands at 610 and 909 nm and intraligand absorptions around 400 nm as well as a weak absorption at 1250 nm which might have also LMCT character (vide supra).

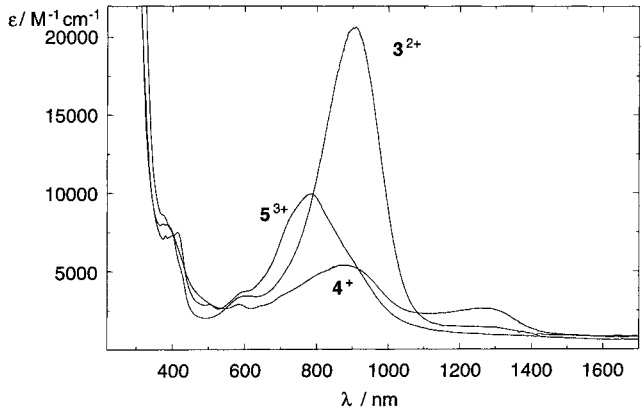

Figure 10. UV/Vis spectra of 3^{2+}, 4^+ and 5^{3+}

Spectroscopic Properties of 4^+

Reduction of 3^{2+} to 4^+ with one equivalent of cobaltocene leads to an orange-brown solution. The UV/Vis spectrum is depicted in Figure 10. Analogous to the mixed-valence complexes **2a**−**e**$^+$ it shows a three-band pattern in the Vis/NIR region. The low-energy absorption is red shifted compared to the corresponding bands of **2a**−**e**$^+$ (Tables 1 and 3). This absorption band might be a candidate for an intervalence transition although its half width at full height (1785 cm^{-1}) is lower than expected for a class-II mixed-valence system according to the Hush theory.[14][15] The characteristic features of this absorption band are quite similar to those of the well-known Creutz−Taube ion.[14] Therefore 4^+ might well be considered a borderline case between a class-II and a class-III system[20] which is also in accord with the thermodynamic data obtained by cyclic voltammetry (Table 3).

Spectroscopic Properties of 5^{3+}

One-electron oxidation of 3^{2+} gives the green tricationic complex 5^{3+}. The stability of 5^{3+} towards dispro-

portionation can only be estimated as the oxidation of $\mathbf{5}^{3+}$ is not reversible. Using the peak potential E_p instead of $E_{1/2\ KC}$ can be estimated to be of the order of 10^8. The UV/Vis spectrum of $\mathbf{5}^{3+}$ is similar to that of $\mathbf{3}^{2+}$ (Figure 10); the charge-transfer bands at 598 and 784 nm are shifted to higher energy and are less intense compared to those of $\mathbf{3}^{2+}$ (Tables 1 and 3). The isotropic EPR spectrum of a CH_2Cl_2 solution of $\mathbf{5}^{3+}$ is shown in Figure 11. The sharp signal centered at $g = 2.0056$ is without observable hyperfine splitting (half width at full height 24 G). This signal is characteristic for organic radicals, showing that the organic part of the dinuclear complex is oxidized.

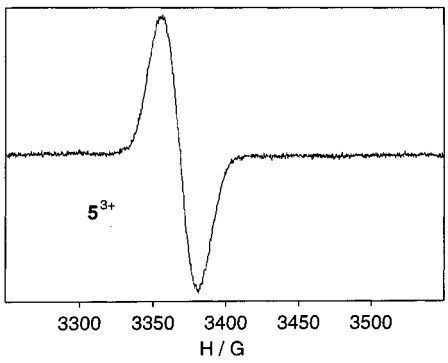

Figure 11. EPR spectrum of $\mathbf{5}^{3+}$ in CH_2Cl_2 at 295 K

MO Calculations

The frontier orbitals of the model complex $[\{(PH_3)_3Co\}_2(C_{14}H_6O_4)]^{2+}$ calculated by the INDO method are shown in Figure 12. As in the case of the complexes $\mathbf{1}^{2+}$ (Figure 7) interaction of the metal fragments with π orbitals of the bridging ligand results in two Co−O π-bonding MOs with large ligand character (b_u: 85%, not shown and a_g: 81% ligand, Figure 12) and in two Co−O π-antibonding MOs which are essentially metal-localized (b_u: 63%, and a_g: 57% metal, not shown, Figure 12). A non-bonding ligand-centered filled π orbital (b_g: 99% ligand) is located energetically between these occupied and empty orbitals. By analogy with the complexes $\mathbf{1a-e}^{2+}$ the intense absorption band at 909 nm can be assigned to the $a_g \rightarrow b_u$ transition and the additional low-energy absorption at 1250 nm to a $b_g \rightarrow b_u$ LMCT transition.

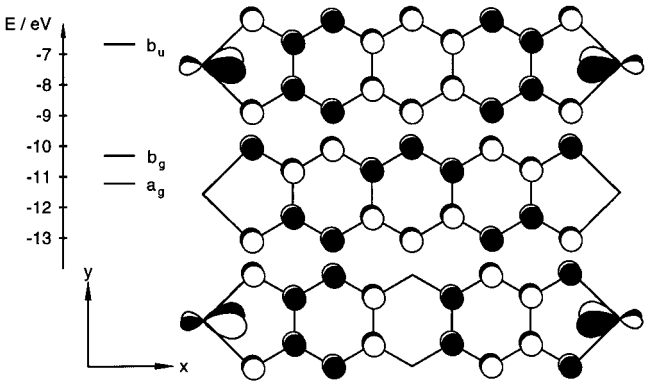

Figure 12. Orbital splitting and orbital symmetry of the model complex $[\{(PH_3)_3Co\}_2(C_{14}H_6O_4)]^{2+}$; the symmetry labels for the orbitals assume C_{2h} symmetry; the x axis is the Co−Co axis, and the z axis is perpendicular to the plane of the bridging ligand

With this MO scheme in mind the interpretation of the redox processes is straightforward: Reduction occurs, as in the case of the redox couple $\mathbf{1}^{2+}/\mathbf{2}^{+}$, at the metal centres leading to mixed-valence species. A reversible oxidation of $\mathbf{3}^{2+}$ which is not observed for $\mathbf{1}^{2+}$, is possible due to the energetically higher Co−O non-bonding ligand-centered b_g molecular orbital. For the complexes $\mathbf{1}^{2+}$ the HOMO of the complexes is Co−O π bonding (Figure 7) and oxidation would weaken the Co−O π bonds.

Concluding Remarks

The mixed-valence (triphos)cobalt complexes $\mathbf{2a-e}^{+}$ with a benzoic system as a bridging ligand ($d_{Co-Co} \approx 7.7$ Å) are shown to belong to class III of the Robin−Day classification, i.e. exhibit complete electron delocalization. In complex $\mathbf{4}^{+}$ with an extended bridging ligand of the anthracence type ($d_{Co-Co} \approx 13$ Å) the delocalization decreases towards a borderline class-II/class-III case. The assignments are corroborated by spectroscopic and theoretical means. In addition, the unexpected oxidation of the dicationic complex $\mathbf{3}^{2+}$ to $\mathbf{5}^{3+}$ leading to a ligand-centered radical is also interpreted in terms of the MO level ordering.

Experimental Section

Computational Details: Calculations were performed with an Apple Macintosh IIfx using the CACHe/ZINDO program Version 3.6 (M. C. Zerner 1990−1994) with INDO/1 parameters. Orbital energies were obtained from an SCF calculation. The geometry of the molecules was idealized to a square-pyramidal polyhedron around the metal centre and a planar bridging ligand. The triphos ligand was replaced by three isoelectronic PH_3 groups. Distances and angles were as follows: Co−P_{eq} 2.14 Å, Co−P_{ax} 2.22 Å, Co−O 1.89 Å, P−H 1.41 Å, O−Co−O 82.8°, P−Co−P 87.5°.

General Methods: Unless noted otherwise all manipulations were carried out under an inert gas by means of standard Schlenk techniques. All solvents were dried by standard methods and distilled under inert gas. − NMR: Bruker AC 200 at 200.13 MHz (^{1}H), 50.323 MHz (^{31}P). − IR: Bruker FTIR IFS-66, as CsI disks. − UV/Vis/NIR: Perkin Elmer Lambda 19. − MS: Finnigan MAT 8230. − EPR: Bruker ESP 300 E, X-band, standard cavity ER 4102, temperature control unit Eurotherm B-VT 2000, external standard diphenylpicrylhydrazyl (DPPH). − Elemental analyses: Microanalytical Laboratory of the Organisch-Chemisches Institut, University of Heidelberg. − Melting points: Gallenkamp MFB-595 010, melting points are not corrected. − Cyclic voltammetry: Metrohm "Universal Meß- und Titriergefäß", Metrohm GC electrode RDE 628, platinum electrode, SCE electrode, Princeton Applied Research potentiostat Model 273, 10^{-3} M in 0.1 M nBu$_4$NPF$_6$/CH_3CN. − Chemicals: 1,1,1-tris(diphenylphosphanylmethyl)-ethane, $CH_3C(CH_2PPh_2)_3$,[21] **1a−e** · $(BF_4)_2$,[3] 2,3,6,7-tetrahydroxy-9,10-dimethylanthracene,[22] (triphos)CoCl.[8,23,24]

Crystallographic Structure Determination: The measurement was carried out with a Siemens P4 (Nicolet Syntex) R3m/v four-circle diffractometer with graphite-monochromated Mo-K_α radiation. All calculations were performed using the SHELXT PLUS software package. The structure was solved by direct methods with the SHELXS-86 program and refined with the SHELX93 program.[25] Graphics were prepared using XPMA and ZORTEP.[26] An absorption correction (ψ scan, Δψ = 10°) was applied to all data. Atomic coordinates and anisotropic thermal parameters of the non-hydrogen atoms were refined by a full-matrix least-squares calculation. $C_{88}H_{78}Cl_4Co_{2.5}P_6O_4$ (· 0.8 Et_2O, 0.5 THF), M = 1674.6 g mol^{-1}, crystal dimensions 0.30 × 0.35 × 0.25 mm, tetragonal, Z = 4, space group $P4/n$ (no. 85), a = 23.773(6) Å, b = 23.776(6) Å, c = 16.301(4) Å, V = 9213(4) Å^3, $\rho_{calcd.}$ = 1.292 g cm^{-3}, T = 293 K, 2θ range = 2.4−54.0°, 25 reflections used for cell parameter refinement, scan speed 4.0−60.0° min^{-1}, 7672 measured reflections, 7198 unique reflections, 3637 observed reflections [$I > 2\,\sigma(I)$], 531 parameters, R_1 = 0.07, $R_w(F^2)$ = 0.224. Further details of the crystal structure determination may be obtained from the Fachinformationszentrum Karlsruhe, D-76344 Eggenstein-Leopoldshafen (Germany), on quoting the depository number CSD-410110.

2a−e · (BF_4): (a) Reduction with cobaltocene: To a dark green solution of the complexes **1a−e** · $(BF_4)_2$ in 20 mL of CH_2Cl_2 [**1a** · $(BF_4)_2$: 8.4 mg; **1b** · $(BF_4)_2$: 8.7 mg; **1c** · $(BF_4)_2$: 9.2 mg; **1d** · $(BF_4)_2$: 9.7 mg; **1e** · $(BF_4)_2$: 8.5 mg; 5 × 10^{-3} mmol] were added 0.5 mL of a Cp_2Co solution (10^{-2} M in CH_2Cl_2). The colour changed to bright blue. This solution was analysed by UV/Vis and EPR spectroscopy. For the low-temperature EPR measurements a mixture of 14 mL of THF and 6 mL of CH_2Cl_2 was used instead of 20 mL of CH_2Cl_2. − (b) Reduction with sodium isopropoxide: To a dark green solution of the complexes **1a−e** · $(BF_4)_2$ in 30 mL of CH_2Cl_2/10 mL of iPrOH [**1a** · $(BF_4)_2$: 16.8 mg; **1b** · $(BF_4)_2$: 17.4 mg; **1c** · $(BF_4)_2$: 18.4 mg; **1d** · $(BF_4)_2$: 19.4 mg; **1e** · $(BF_4)_2$: 17.0 mg; 1 × 10^{-2} mmol] was added 0.5 mL of a solution of iPrONa in CH_2Cl_2 (2 × 10^{-2} M) in 0.1-mL steps. After each addition, a UV/Vis spectrum was recorded. All attempts to isolate crystals from these solutions failed as they rapidly decompose on removing the solvent. Changing the solvents or the counter ions (BF_4^-, PF_6^-, BPh_4^-) was just as unsuccessful. − (c) Crystals of **2b$_2$** · $(CoCl_4)$: To a suspension of (triphos)CoCl (560 mg, 0.78 mmol) in THF (15 mL) was added a solution of 3,6-dichloro-2,5-dihydroxy-1,4-benzoquinone (81 mg, 0.39 mmol) in EtOH (5 mL). The (triphos)CoCl dissolved completely and the solution turned bright blue. After stirring for 30 min, the progress of the reaction was checked by UV/Vis spectroscopy and a solution of $NaBPh_4$ (133.5 mg, 0.39 mmol) in 5 mL of EtOH was added. After filtration and concentration of the solution to approximately 7−8 mL the solution was layered with Et_2O (10 mL). Bright blue crystals of **2b$_2$** · $(CoCl_4)$ suitable for X-ray-crystallographic analysis were obtained within one week.

3 · $(PF_6)_2$: A solution of $CoCl_2$ (130 mg, 1 mmol) in EtOH (15 mL) was added to a solution of the triphos ligand (624 mg, 1 mmol) in THF (15 mL). Addition of solid 2,3,6,7-tetrahydroxy-9,10-dimethylanthracene (135 mg, 0.5 mmol) resulted in a colour change to blue. After the addition of solid $NaPF_6$ (168 mg, 1 mmol), the solution was stirred for 1 h and concentrated to approximately 10 mL. The resulting precipitate was separated by filtration, washed with Et_2O (2 × 10 mL), EtOH (2 × 7 mL) and again with Et_2O (2 × 10 mL). To remove NaCl the blue powder was dissolved in CH_2Cl_2 and filtered through 2 cm of Kieselgur. Addition of Et_2O precipitated **3** · $(PF_6)_2$ in 59% yield (567 mg). − M.p. 240 °C (decomp.). − IR (CsI): $\tilde{\nu}$ = 829 (br., PF). − MS (FAB); m/z (%): 1778 (5) [M^+ + PF_6], 1632 (15) [M^+], 1027 (15) [M^+ − triphos − Co + Ph + 1], 950 (25) [M^+ − triphos − Co], 816 (10) [M^{2+}]. − UV/Vis (CH_2Cl_2): λ_{max} (ε) = 376 nm (9450 M^{-1} cm^{-1}), 404 (6360, sh), 610 (3540), 909 (19140), 1250 (1440, sh). − CV (CH_3CN): $E_{1/2}$ = −0.170 V (rev.), −0.355 V (rev.), +0.335 V (rev.), E_p = +0.935 (irr.). − ^{1}H NMR (CD_2Cl_2): 1.75 (br. s, 3 H, triphos-CH_3), 2.63 (br. s, 6 H, triphos-CH_2), 3.10 (s, 3 H, ligand-CH_3), 7.0−7.5 (m, 30 H, triphos-CH_{ar}), 9.2 (s, 2 H, ligand-CH). − ^{31}P NMR (CD_2Cl_2): 31.1 (s, 3 P, triphos-P), −144.2 (sept., 1 P, PF_6, $^1J_{PF}$ = 713 Hz). − $C_{98}H_{88}Co_2F_{12}O_4P_8$ (1922.3): calcd. for **3** · $(PF_6)_2$ · 0.5 · CH_2Cl_2 C 60.18, H 4.56; found C 60.06, H 5.04.

Reduction of 3 · $(PF_6)_2$ with Cobaltocene to Obtain 4 · (PF_6): To a blue solution of **3** · $(PF_6)_2$ (9.6 mg; 5 × 10^{-3} mmol) in CH_2Cl_2 (20 mL) was added 0.5 mL of a Cp_2Co solution (10^{-2} M in CH_2Cl_2). The colour changed to orange-brown. This solution was analysed by UV/Vis and EPR spectroscopy. Addition of a second equivalent of the Cp_2Co solution (0.5 mL) resulted in a colour change to yellow.

Oxidation of 3 · $(PF_6)_2$ with Ferrocenium Tetrafluoroborate to Obtain 5^{3+}: To a blue solution of **3** · $(PF_6)_2$ (9.6 mg; 5 × 10^{-3} mmol) in CH_2Cl_2 (20 mL) was added 0.5 mL of a $[Cp_2Fe](BF_4)$ solution (10^{-2} M in CH_2Cl_2). The colour changed to green. This solution was analysed by UV/Vis and EPR spectroscopy.

N-Thiophosphorylated and *N*-Phosphorylated Iminophosphoranes [$R_3P{=}N{-}P(X)R'_2$; X = O, S] as Models for Dendrimers: Synthesis, Reactivity and Crystal Structures

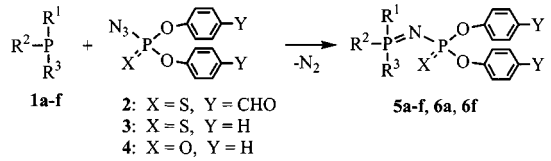
Christophe Larré,[a] Bruno Donnadieu,[a] Anne-Marie Caminade,*[a] and Jean-Pierre Majoral*[a]

Keywords: Phosphorus / Ferrocenes / Phosphorylated iminophosphoranes / Dendrimers / Cations

Several $R_3P{=}N{-}P(X)R'_2$ and $Fe[C_5H_4Ph_2P{=}N{-}P(X)R'_2]_2$ derivatives (X = S, O) are readily obtained from Staudinger reactions between phosphanes and $N_3{-}P(X)R'_2$. The P=N–P=X groups are easily alkylated on the X atom with methyl or isopropyl triflates. The alkylation induces a lengthening of the P–X bond, as shown by X-ray diffraction studies. This corresponds to a weakening of the P–X bond which can be cleaved with $P(NMe_2)_3$ to yield [P=N–P:] linkages. The presence of tricoordinated phosphorus atoms opens the way to a versatile reactivity, including the reaction with alkyl iodides and functionalized azides. These molecules are good models for screening which types of reagents and reactions could be used with macromolecules possessing also P=N–P=X linkages, such as dendrimers.

Introduction

N-Thiophosphorylated iminophosphoranes are known since more than 40 years, but have only attracted a moderate interest up to now as illustrated by the relative small number of $R_3P{=}N{-}P(S)R'_2$ compounds already described[1] (approximately 100). However, we have recently demonstrated the great synthetic interest of the P=N−P=S linkage for the building of very complex hyperbranched nanosized macromolecules, namely dendrimers.[2] Furthermore, the P=N−P=S linkages included in phosphorus-containing dendrimers[3] display a versatile and chemoselective reactivity[4] which leads to the unprecedented grafting of various functional groups[5] or new branches[6] within the dendritic architecture when and where desired.



The chemistry of dendrimers is fascinating but generally suffers from two drawbacks: the synthesis requires multistep procedures which are time-consuming, and the reactivity (as well as the synthesis) necessitates to use only reactions with quantitative yields. Thus, it is highly desirable to have models for dendrimers, in order to study the reactivity on small molecules easy to synthesize and to characterize, and to choose the type of reactions and reagents which could be used later with dendrimers. In this paper, we describe the synthesis of various *N*-thiophosphorylated iminophosphoranes, their reactivity toward strong electrophiles such as alkyl triflates, their desulfurization reactions leading to [P=N−P:] linkages, and Staudinger reactions of these linkages with functionalized azides. A few *N*-phosphorylated iminophosphoranes (P=N−P=O linkages) are also described to be compared with their thiophosphorylated analogues. The structure of four derivatives of ferrocene possessing two P=N−P=X or two [P−N−P−X−Me]$^+$ (X = S, O) groups determined by X-ray diffraction is also presented.

Results and Discussion

Syntheses

The method of synthesis we have used to obtain the P=N−P=X (X = S, O) linkages is the Staudinger reaction between phosphanes **1a−f** and phosphorylated azides **2−4** (Scheme 1). In all cases, the reaction proceeds rapidly at room temperature with evolution of nitrogen as sole by-product, and leads to compounds **5** (X = S) and **6** (X = O) in quantitative yields as crude products and in very good yields after work up, with the exception of compound **5d** which is isolated only in 70% yield. This lower yield is presumably due to the presence of two C≡C groups in compound **1d**, which are known to undergo cycloaddition reac-

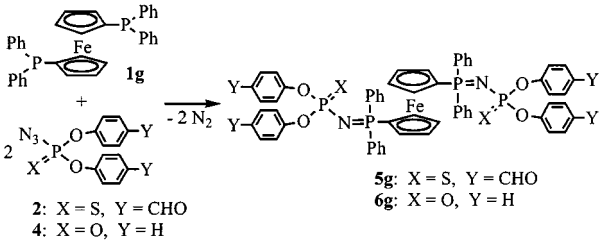
tions with azides,[7] lowering the amount of the desired product **5d**.



The occurrence of the Staudinger reaction is characterized in the ^{31}P-NMR spectra by the appearance of a system of two doublets, with $^2J_{PP} \approx 30$ Hz for all compounds except for **5d** (Table 1). The chemical shift is $\delta \approx 51$ for the P=S groups, and $\delta \approx -7$ for the P=O groups, for all compounds. The chemical shift of the $R^1R^2R^3P{=}N$ groups strongly depends on the $R^1R^2R^3$ substituents linked to this phosphorus atom, but is almost insensitive to the presence of sulfur or oxygen double bonded to the other phosphorus atom, as shown by the comparison between **5a** [X = S; δ(P=N) = 14.9] and **6a** [X = O; δ(P=N) = 13.7].

[a] In $CDCl_3$. – [b] In CD_3COCD_3. – * In these cases, the assignment of the chemical shift to P=N or P–S–R is ambiguous.

Analogous reactions applied to the 4,4′-bis(diphenylphosphanyl)ferrocene **1g** and compounds **2** and **4** lead to the quantitative formation of derivatives **5g** (X = S, Y = CHO) and **6g** (X = O, Y = H) possessing two P=N–P=X linkages (Scheme 2). These compounds display characteristic ^{31}P-NMR data (Table 1).

Scheme 2. Synthesis of bis[*N*-(thio)-phosphorylated iminophosphoranyl]ferrocenes

The structure of both compounds was also determined by X-ray diffraction studies (Table 2). Selected bond lengths and bond angles are gathered in Table 3. Figures 1 and 2 show the molecular structure of compounds **5g** and **6g**, respectively. The dihedral angle between the substituents of the Cp rings is 142.73° for compounds **5g** and 180° for compound **6g**. This position favors a large distance between the "branches", thus compound **5g** has been used as a tetrafunctional core for the synthesis of dendrimers.[8] The P=N–P moieties of the P=N–P=X linkage is very similar for both compounds **5g** and **6g**. Furthermore, the P–N bond lengths are almost equal {*d*[P(1)–N(1)] = 1.559(4) Å and *d*[N(1)–P(2)] = 1.569(4) Å for **5g**; 1.568(2) Å and 1.578(2) Å, respectively, for **6g**}. The P=S [1.918(2) Å] and P=O [1.450(2) Å] bond lengths are classical.

Reactivity

A few alkylations of the sulfur atom of P=N–P=S linkages have already been reported,[9] for instance with methyl iodide,[9a] but this reagent does not react neither with compounds **5**, nor with compounds **6**, so stronger electrophiles are needed. For this purpose, methyl trifluoromethanesulfonate is first used as alkylating agent. The reaction carried out with compounds **5a–g**, **6a**, **6f**, and **6g** leads immediately, and in quantitative yield except for compound **7d**, to the formation of cationic compounds possessing one (**7a–f**, **8a**, **8f**) or two (**7g**, **8g**) $[P{-}N{=}P{-}X{-}Me]^+$ linkages (Scheme 3).

Two different behaviors are observed in the ^{31}P-NMR spectra, depending on the nature of the X atom. The alkylation of the thiophosphoryl groups induces a large shielding of the signal corresponding to the P=S group, from $\delta \approx 51$ to $\delta \approx 25$, while the signal corresponding to the P=N group is deshielded (Table 1). In several cases, the chemical-shift values corresponding to the P=N and P–S–Me groups are very close, but their attribution is unambiguous, on the basis of ^{31}P-NMR spectra with proton couplings, except for compound **7f**. On the other hand, the alkylation of the phosphoryl groups induces only a slight shielding of the signal corresponding to the P=O groups ($\Delta\delta_{max} = 3$) and a deshielding of the signal corresponding to the P=N groups ($\Delta\delta \approx 10$). The value of the $^2J_{PP}$ coupling constant is lowered when X = S (for the transformation **5** → **7**), and slightly increased when X = O (**6** → **8**) (Table 1).

To ascertain the occurrence of the alkylation reaction on the sulfur or oxygen and not on the nitrogen atom or on the aldehyde groups, the structure of compounds **7g** and **8g** was determined by X-ray diffraction (Table 2). Figures 3 and 4 show the molecular structure of the cationic moieties of compounds **7g** and **8g**, respectively. These drawings confirm without any ambiguity that alkylation took place on the sulfur (**7g**) and oxygen atom (**8g**). Selected bond lengths and bond angles for both compounds are gathered in Table 3. The alkylation induces in both cases a lengthening of the P=N [P(1)–N(1)], P=X [P(2)–S(2) or P(2)–O(3)], and O–C(Ar) bond lengths and a shortening of the N–P [N(1)–P(2)] and P–O [P(2)–O(1) and P(2)–O(2)] bond lengths; the six P–O bond lengths are equivalent for compound **8g**. All these phenomena, as well as the deshielding observed for the signal of the P=N groups in the ^{31}P-NMR spectra, indicate that the positive charge is partly localized on this phosphorus atom.

Other triflates can react with the P=N–P=X linkages, for instance isopropyl trifluoromethanesulfonate. The reaction proceeds in the same conditions than with methyl triflate, to afford compounds **9a** and **10a**, from **5a** and **6a**,

respectively (Scheme 4, Table 1). An analogous behavior is observed with trimethylsilyl triflate. The oxophilicity of silicon induces the formation of the cationic compound **11f** from **6f** (Scheme 5). The ^{31}P-NMR spectrum displays the expected shielding of the signal corresponding to the PO groups from δ = −6.2 to −18.6 (Table 1). However, it must be noted that this compound is much more sensitive to moisture than the corresponding methylated analogue, thus for practical purposes, the use of trimethylsilyl triflate has not been extended to other compounds, and only the reactivity of cationic compounds **7** and **8** has been explored.

In fact, we have focused our attention on the reactivity of compounds **7**, because the methylation reaction of compounds **5** is more easily monitored by ^{31}P-NMR spectroscopy than that of compounds **6**. The lengthening of the P=S bond after methylation [1.918(2) Å for **5g**, 2.034(5) and 2.040(5) Å for **7g**] should induce a weakening of this bond which could be cleaved, leading to the formation of [P=N−P:] linkages incorporating a tricoordinated phosphorus atom. First experiments are conducted with compound **7f** which is the best model for dendrimers. The desulfurization reaction occurs easily at room temperature when tris(dimethylamino)phosphane is added to a solution of **7f** in CH_2Cl_2.[10] The reaction proceeds with a transfer of the S−Me$^+$ group from **7f** to $P(NMe_2)_3$, leading to compound **12f** and $[MeS-P(NMe_2)_3]^+$ (Scheme 6).

The reaction is monitored by ^{31}P-NMR spectroscopy, which shows the appearance of two doublets at δ = 143.9 (P:) and 9.9 (P=N) ($^2J_{PP}$ = 32 Hz) for **12f** and one singlet at δ = 68 for $[MeS-P(NMe_2)_3]^+$. These data indicate that only the P−S bond is cleaved, and not the P−O or P−N bonds. Compound **12f** is very sensitive toward oxidation, therefore it is not really isolated but only cleared of $[MeS-P(NMe_2)_3][CF_3SO_3]$. The presence of a tricoordinated phosphorus atom in compound **12f** should lead to a versatile reactivity. For instance, compound **12f** can react with electrophiles such as allyl iodide (Scheme 6). The formation of the phosphonium salt **13f** is characterized by ^{31}P-NMR spectroscopy, with the appearance of two doublets at δ = 27.3 and 28.9 ($^2J_{PP}$ = 20 Hz). This reaction, which allows the grafting of functional groups, has been extended to the reactivity of the internal layers of dendrimers.[5b]

Compound **12f** also reacts with azides, such as 4-azidophenyl isothiocyanate. The Staudinger reaction occurs readily to give compound **14f**, characterized in the ^{31}P-NMR spectrum by the presence of two doublets at δ = 15.3 (P=N) and −7.7 (N−P=N) ($^2J_{PP}$ = 16 Hz). This compound can be isolated to be characterized also by ^{1}H- and ^{13}C-NMR spectroscopy, but it decomposes within a few days when left in solution, to give compound **5f** as the sole phosphorus-containing compound. The decomposition probably proceeds by an aza Wittig reaction between the P=N and

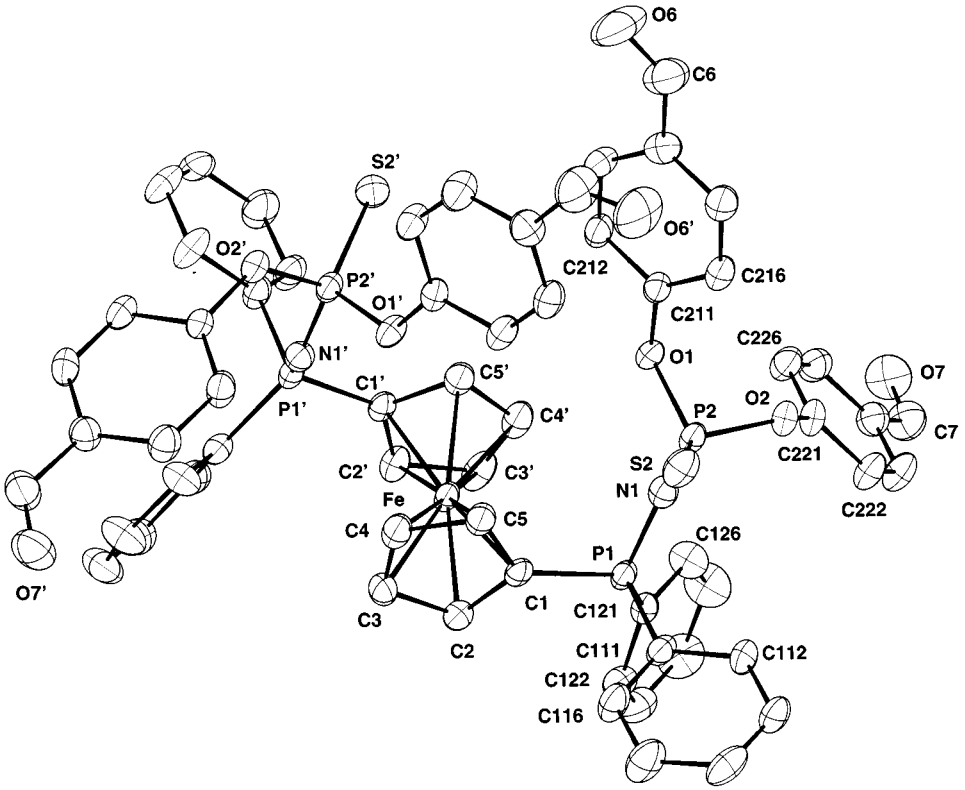

Figure 1. Molecular structure of compound **5g**

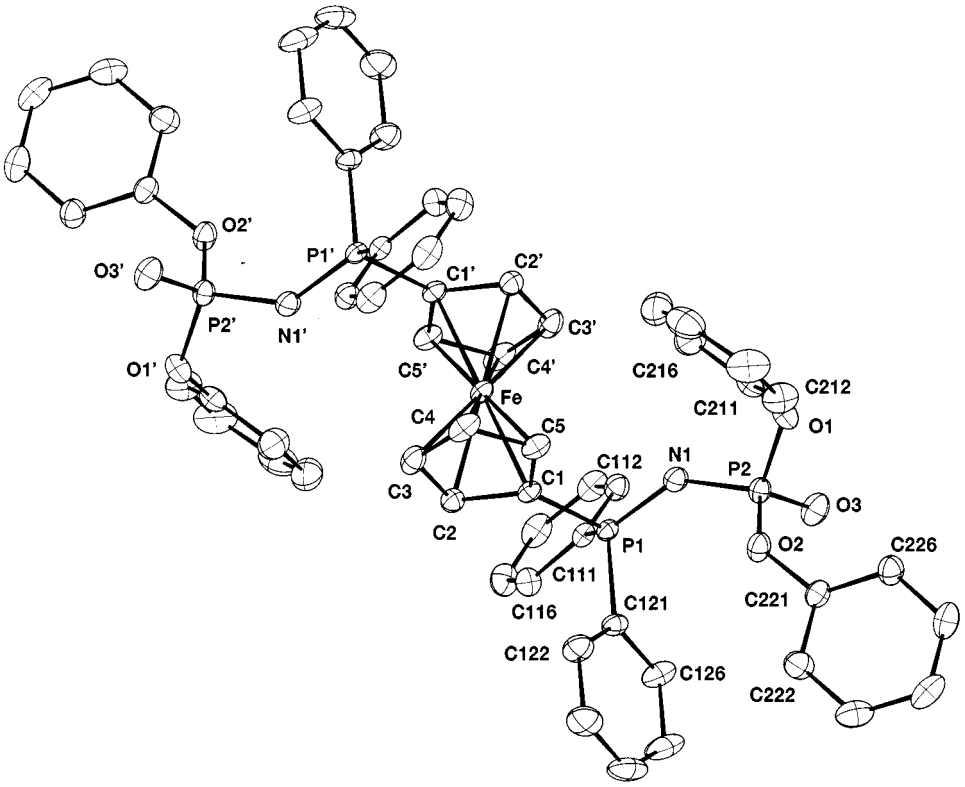

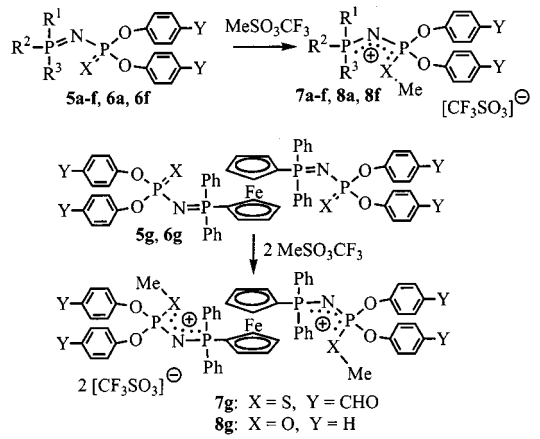

Figure 2. Molecular structure of compound **6g**

C=S bonds. This reaction is presumably intermolecular; indeed, the intramolecular reaction is unlikely from a geometric point of view. Furthermore, the use of the same azide in the internal layers of dendrimers gives stable com-

Scheme 3. Methylation of P=N−P=X linkages

(δ = 17.9, $^2J_{PP}$ = 23 Hz, *P*=N−P=N−P=S; δ = 45.9, $^2J_{PP}$ = 63 Hz, P=N−P=N−*P*=S) and one doublet of doublet (δ = −14.3, P=N−*P*=N−P=S) in the ^{31}P-NMR spectrum. The sequence of reactions **5g** → **7g** → **12g** → **15g** which allows the grafting of aldehyde groups is of crucial importance for the growing of new branches within a dendritic framework.[6]

The P=S group of the P=N−P=N−P=S linkage possesses the same properties than those included in P=N−P=S linkages. Indeed, methylation with $MeSO_3CF_3$ occurs on the sulfur atom, as shown by the large shielding of the doublet corresponding to the P=S groups in the ^{31}P-NMR spectrum from δ = 45.9 ($^2J_{PP}$ = 63.5 Hz) for **15g** to δ = 20.0 ($^2J_{PP}$ = 51 Hz) for **16g**. The slight deshielding observed for the doublet corresponding to the *P*=N−P=N−P=S groups from δ = 17.9 ($^2J_{PP}$ = 23.2 Hz) for **15g** to δ = 21.5

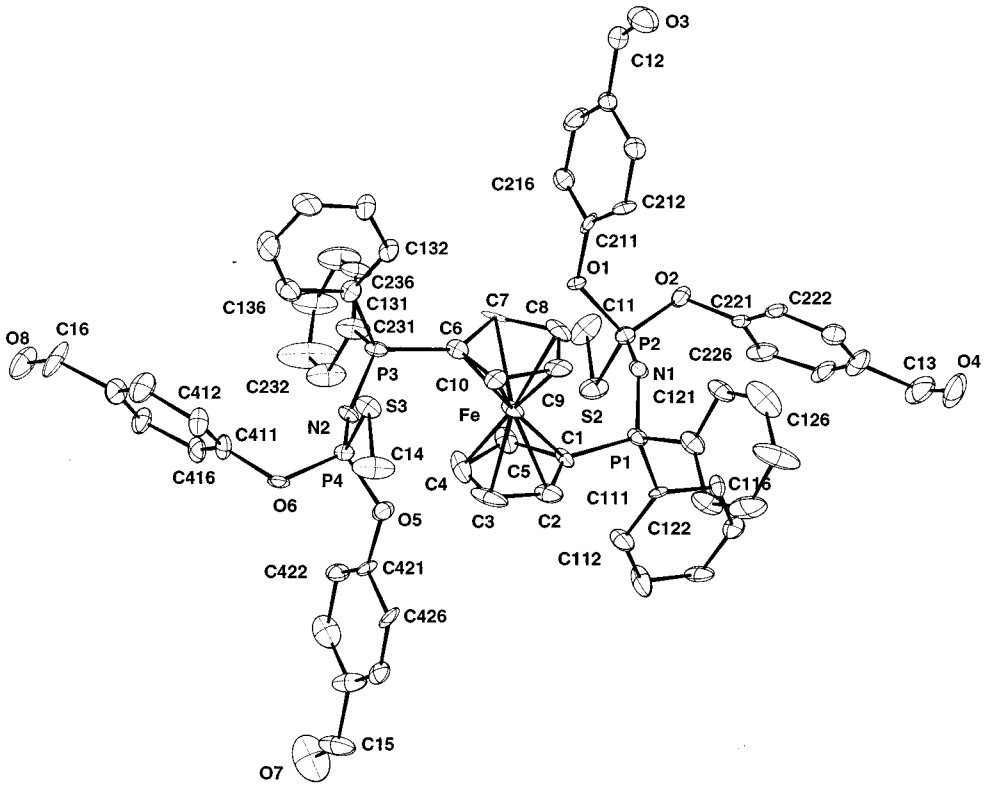

Figure 3. Molecular structure of compound **7g**; the anionic counterion is omitted for clarity

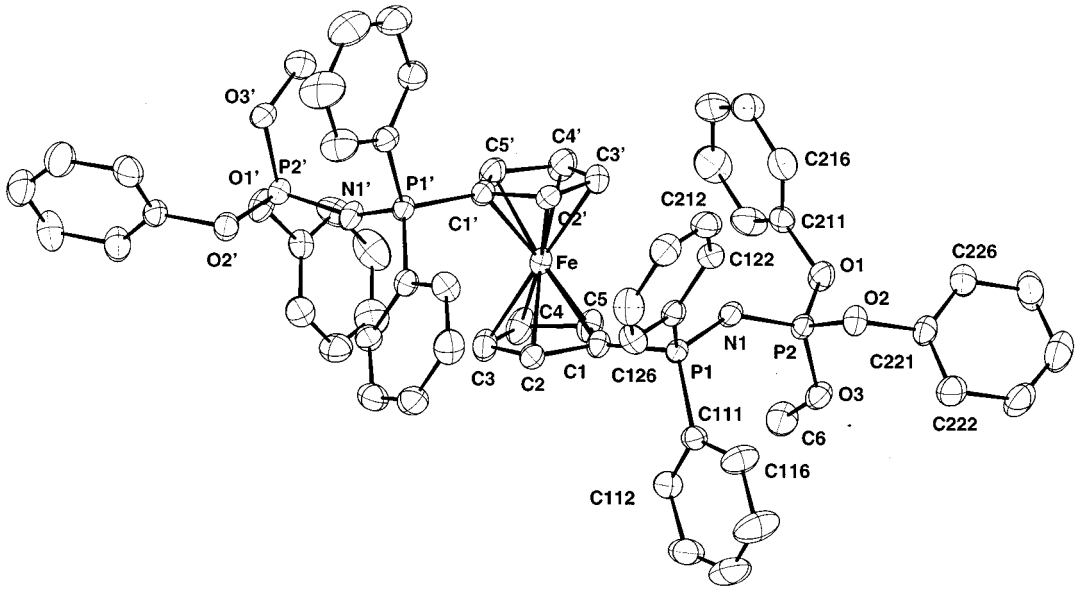
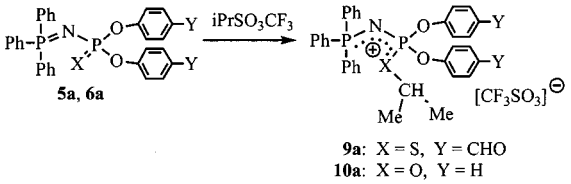
pounds which do not decompose within several days in solution. One can presume that the P=N and C=S bonds of the internal layers of two molecules of dendrimer cannot interact for steric reasons, and that the reaction between two branches of one dendrimer is also unlikely for geometric and topographic reasons.[5b]

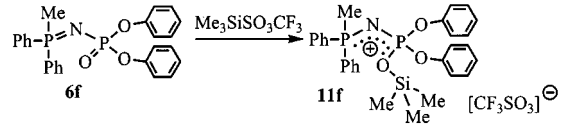
The desulfurization reaction can be applied also to the dicationic ferrocene derivative **7g**, leading to the formation of compound **12g** (Scheme 7). The Staudinger reaction of two equivalents of the azide **2** with the ferrocene derivative **12g** affords compound **15g** in quantitative yield. The formation of both P=N−P=N−P=S linkages induces the appearance of a very characteristic system of two doublets ($^2J_{PP}$ = 30 Hz) for **16g**, indicates a delocalization of the positive charge all along this linkage. The chemical shift of the doublet of doublet corresponding to P=N−*P*=N−P=S is almost insensitive to this reaction (δ = −14.3 for **15g**, δ = −16.9 for **16g**).

Conclusion

Various compounds possessing P=N−P=X (X = S, O) linkages have been prepared and their reactivity toward various electrophiles has been tested, leading in all cases to the alkylation of the X atom of this linkage, as shown by







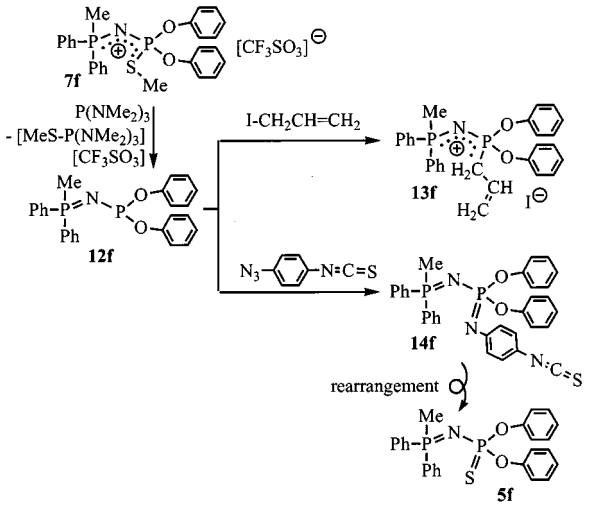


Figure 4. Molecular structure of compound **8g**; the anionic counterion is omitted for clarity

Scheme 4. Alkylation of P=N−P=X lnkage with $iPr_2SO_3CF_3$

Scheme 6. Desulfurization of a P−N−P−S−Me linkage and subsequent reactions

^{31}P-NMR and X-ray diffraction studies. These compounds, particularly $Ph_2MeP{=}N{-}P(S)(OPh)_2$ (**5f**), and $Fe[C_5H_4P\text{-}Ph_2{=}NP(S)(OC_6H_4CHO)_2]_2$ (**5g**) are interesting models to check what type of reactions and reagents could be applied later to dendrimers possessing also P=N−P=S linkages. In this perspective, the desulfurization leading to tricoordinated phosphorus atoms has a great synthetic interest, and has opened the way to a very original field of the chemistry of dendrimers: the grafting of various functional groups and branches in the internal layers of dendrimers after their construction.[5][6]

Scheme 7. Desulfurization of compound **7g** and subsequent reactions

Experimental Section

General: All manipulations were carried out with standard high-vacuum and dry-argon techniques. – ^{1}H-, ^{13}C-, ^{31}P-, and ^{19}F-NMR spectra were recorded with Bruker AC200, AC250 or AMX 400 spectrometers. References for NMR chemical shifts are: $SiMe_4$ for ^{1}H and ^{13}C NMR, 85% H_3PO_4 for ^{31}P NMR, CF_3COOH for ^{19}F NMR. The numbering used for NMR assignments is depicted in Figure 5. – Melting points are uncorrected. – Compounds $N_3P(S)(OC_6H_4CHO)_2$,[11] *t*BuP(C≡CPh)$_2$,[11] Ph(C_4H_6P)[12] and CF_3SO_3*i*Pr,[13] were synthesized according to published procedures. – CF_3SO_3*i*Pr was freshly prepared each time.

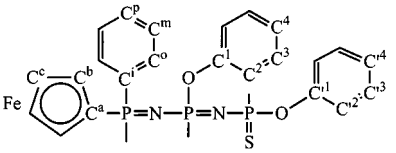

Figure 5. Numbering used for NMR

General Procedure for 5a, 5b, 5d, 5e, 5f, 6a, 6f: To a solution of 3 mmol of compound **2**, **3**, or **4** in THF (10 mL) was added at room temperature a solution of 3 mmol of phosphane **1a,b,d–f** in THF (5 mL). The resulting solution was stirred at room temperature (or at 55°C for **5d**) until the evolution of nitrogen ceases. The solution was concentrated to dryness under vacuum. The residue was washed with ether, then with pentane to afford **5a**, **5b**, **5f**, **6a**, **6f** as powders and **5d**, **5e** as oils.

Synthesis of Compound 5c: The procedure is analogous to the previous one, using CH_3CN instead of THF. Compound **5c** was isolated as an oil.

General Procedure for 5g and 6g: To a solution of 3 mmol of compound **2** or **4** in THF (10 mL) was added at room temperature a solution of 1.5 mmol of 4,4′-bis(diphenylphosphanyl)ferrocene **1g** in THF (10 mL). The resulting solution was stirred at room temperature until the evolution of nitrogen ceased. The solution was concentrated to dryness under vacuum. The residue was washed with ether, then with pentane to give **5g**, **6g** as orange powders. Crystallization at −30°C in CH_2Cl_2 for **5g** and in CH_2Cl_2/pentane (1:1) for **6g** afforded single crystals suitable for X-ray diffraction.

Compound 5a: 97% yield, white powder, m.p. 131°C. – ^{31}P{^{1}H} NMR ($CDCl_3$): δ = 14.9 (d, $^2J_{PP}$ = 30.0 Hz, P=N), 50.1 (d, $^2J_{PP}$ = 30.0 Hz, P=S). – ^{1}H NMR ($CDCl_3$): δ = 7.27–7.78 (m, 23 H, C_6H_4, C_6H_5), 9.90 (s, 2 H, CHO). – ^{13}C{^{1}H} NMR ($CDCl_3$): δ = 121.8 (d, $^3J_{CP}$ = 5.5 Hz, C^2), 128.0 (dd, $^1J_{CP}$ = 106.5 Hz, $^3J_{CP}$ = 3.8 Hz, C^i), 128.5 (d, $^3J_{CP}$ = 13.0 Hz, C^m), 130.9 (s, C^3), 132.4 (d, $^2J_{CP}$ = 10.5 Hz, C^o), 132.6 (br. s, C^4, C^p), 156.6 (d, $^2J_{CP}$ = 9.6 Hz, C^1), 190.8 (s, CHO). – IR (KBr): $\tilde{\nu}$ = 1701 cm^{-1} (C=O). – $C_{32}H_{25}N_1O_4P_2S$ (581.6): calcd. C 66.09, H 4.33, N 2.41; found C 66.30, H 4.49, N 2.36.

Compound 5b: 95% yield, white powder, m.p. 102°C. – ^{31}P{^{1}H} NMR (CD_3COCD_3): δ = 12.9 (d, $^2J_{PP}$ = 32.0 Hz, P=N), 50.5 (d, $^2J_{PP}$ = 32.0 Hz, P=S). – ^{1}H NMR (CD_3COCD_3): δ = 7.56–8.04 (m, 20 H, C_6H_4), 10.10 (s, 2 H, CHO). – ^{13}C{^{1}H} NMR (CD_3COCD_3): δ = 122.2 (d, $^3J_{CP}$ = 5.0 Hz, C^2), 129.3 (d, $^3J_{CP}$ = 14.0 Hz, C^m), 131.0 (s, C^3), 133.2 (s, C^4), 134.0 (dd, $^1J_{CP}$ = 58.3 Hz, $^3J_{CP}$ = 12.0 Hz, C^i), 134.4 (d, $^2J_{CP}$ = 12.5 Hz, C^o), 139.4 (d, $^4J_{CP}$ = 4.8 Hz, C^p), 156.5 (d, $^2J_{CP}$ = 8.5 Hz, C^1), 190.7 (s, CHO). – IR (KBr): $\tilde{\nu}$ = 1696 cm^{-1} (C=O). – $C_{32}H_{22}Cl_3N_1O_4P_2S$ (684.9): calcd. C 56.09, H 3.21, N 2.04; found C 56.39, H 3.31, N 1.97.

Compound 5c: 94% yield, white viscous oil. – ^{31}P{^{1}H} NMR (CD_3COCD_3): δ = 30.5 (d, $^2J_{PP}$ = 28.0 Hz, P=N), 50.5 (d, $^2J_{PP}$ = 28.0 Hz, P=S). – ^{1}H NMR (CD_3COCD_3): δ = 2.68–3.00 (m, 12 H, CH_2–CH_2), 7.57 (m, 4 H, C_6H_4), 8.97 (m, 4 H, C_6H_4), 10.0 (s, 2 H, CHO). – ^{13}C{^{1}H} NMR (CD_3COCD_3): δ = 21.5 (d, $^1J_{CP}$ = 3.0 Hz, *C*H$_2$P), 22.7 (s, *C*H$_2$CH$_2$P), 118.7 (s, C≡N), 122.1 (d, $^3J_{CP}$ = 4.7 Hz, C^2), 131.1 (br. s, C^3), 133.3 (s, C^4), 156.2 (d, $^2J_{CP}$ = 8.4 Hz, C^1), 191.0 (s, CHO). – IR (THF): $\tilde{\nu}$ = 2210 (C≡N), 1701 (C=O) cm^{-1}. – $C_{23}H_{22}N_4O_4P_2S$ (512.5): calcd. C 53.91, H 4.33, N 10.93; found C 53.67, H 4.43, N 10.81.

Compound 5d: 70% yield, yellow viscous oil. – ^{31}P{^{1}H} NMR ($CDCl_3$): δ = −8.9 (d, $^2J_{PP}$ = 6.0 Hz, P=N), 52.2 (d, $^2J_{PP}$ = 6.0 Hz, P=S). – ^{1}H NMR ($CDCl_3$): δ = 1.30 (d, $^3J_{HP}$ = 21.0 Hz, 9 H, CH_3), 7.24–7.94 (m, 18 H, C_6H_4, C_6H_5), 9.83 (s, 2 H, CHO). – ^{13}C{^{1}H} NMR ($CDCl_3$): δ = 22.7 (d, $^2J_{CP}$ = 1.9 Hz, CH_3), 34.1 (dd, $^1J_{CP}$ = 103.1 Hz, $^3J_{CP}$ = 7.0 Hz, *C*-CH_3), 76.7 (d, $^1J_{CP}$ = 186.9 Hz, ≡C–P), 106.4 (d, $^2J_{CP}$ = 31.5 Hz, *C*≡C–P), 118.7 (d, $^3J_{CP}$ = 4.4 Hz, C^i), 121.9 (d, $^3J_{CP}$ = 5.1 Hz, C^2), 128.4 (s, C^m), 130.8 (s, C^3), 131.4 (s, C^p), 132.4 (br. s, C^4, C^o), 156.5 (d, $^2J_{CP}$ = 8.3 Hz, C^1), 190.7 (s, CHO). – IR (THF): $\tilde{\nu}$ = 2170 (C≡C), 1701 (C=O) cm^{-1}. – $C_{34}H_{29}N_1O_4P_2S$ (609.6): calcd. C 66.99, H 4.79, N 2.30; found C 66.93, H 4.59, N 2.24.

Compound 5e: 90% yield, white viscous oil. – ^{31}P{^{1}H} NMR ($CDCl_3$): δ = 47.9 (d, $^2J_{PP}$ = 29.0 Hz, P=N), 52.6 (d, $^2J_{PP}$ = 29.0 Hz, P=S). – ^{1}H NMR ($CDCl_3$): δ = 2.34 (md, $^2J_{HP}$ = 136.0 Hz, 2 H, CH_2P), 2.73 (m, 2 H, CH_2CH$_2$P), 6.14 (ddt, $^3J_{HP}$ = 26.7 Hz, $^3J_{HH}$ = 8.1 Hz, $^3J_{HH}$ = 1.7 Hz, 1 H, C*H*=CH–P), 7.08 (ddt, $^2J_{HP}$ = 45.9 Hz, $^3J_{HH}$ = 8.1 Hz, $^4J_{HH}$ = 1.3 Hz, 1 H, =CH–P), 7.27–7.81 (m, 13 H, C_6H_4, C_6H_5), 9.80 (s, 2 H, CHO). – ^{13}C{^{1}H} NMR ($CDCl_3$): δ = 22.2 (d, $^1J_{CP}$ = 68.9 Hz, CH_2P), 30.5 (d, $^2J_{CP}$ = 9.5 Hz, *C*H$_2$CH$_2$P), 121.4 (d, $^3J_{CP}$ = 4.8 Hz, C^2), 121.6 (d, $^1J_{CP}$ = 90.9 Hz, =CH–P), 128.4 (d, $^3J_{CP}$ = 13.5 Hz, C^m), 128.6 (dd, $^1J_{CP}$ = 110.3 Hz, $^3J_{CP}$ = 9.7 Hz, C^i), 130.2 (d, $^2J_{CP}$ = 11.7 Hz, C^o), 130.7 (s, C^3), 132.1 (s, C^4), 132.2 (s, C^p), 154.9 (d, $^2J_{CP}$ = 23.8 Hz, *C*H=CH-P), 156.1 (d, $^2J_{CP}$ = 9.0 Hz, C^1), 190.4 (s, CHO). – IR (THF): $\tilde{\nu}$ = 1701 cm^{-1} (C=O). – $C_{24}H_{21}N_1O_4P_2S_1$ (481.5): calcd. C 59.87, H 4.40, N 2.91; found C 60.01, H 4.55, N 2.85.

Compound 5f: 88% yield, white viscous oil. – ^{31}P {^{1}H} NMR (THF): δ = 15.5 (d, $^2J_{PP}$ = 32.1 Hz, P=N), 53.0 (d, $^2J_{PP}$ = 32.1 Hz, P=S). – ^{1}H NMR ($CDCl_3$): δ = 2.20 (d, $^3J_{HP}$ = 13.3 Hz, 3 H, CH_3), 7.00–7.65 (m, 20 H, C_6H_5). – ^{13}C {^{1}H} NMR ($CDCl_3$): δ 14.6 (d, $^2J_{CP}$ = 67.9 Hz, CH_3), 121.7 (d, $^3J_{CP}$ = 4.3 Hz, C^2), 124.2 (s, C^4), 128.8 (d, $^3J_{CP}$ = 13.1 Hz, C^m), 129.1 (s, C^3), 130.6 (dd, $^1J_{CP}$ = 108.0 Hz, $^3J_{CP}$ = 5.1 Hz, C^i), 131.1 (d, $^2J_{CP}$ = 10.9 Hz, C^o), 132.3 (d, $^4J_{CP}$ = 3.5 Hz, C^p), 152.1 (d, $^2J_{CP}$ = 8.7 Hz, C^1). – $C_{25}H_{23}NO_2P_2S$ (463.5): calcd. C 64.79, H 5.00, N 3.02; found C 64.98, H 4.95, N, 2.97.

Compound 5g: 97% yield, orange powder, m.p. 211°C. – ^{31}P {^{1}H} NMR ($CDCl_3$): δ = 16.1 (d, $^2J_{PP}$ = 32.0 Hz, P=N), 49.2 (d, $^2J_{PP}$ = 32.0 Hz, P=S). – ^{1}H NMR ($CDCl_3$): δ = 4.35 (dd, $^3J_{HH}$ = 1.8 Hz, $^3J_{HP}$ = 3.7 Hz, 4 H, C^{b}H), 4.55 (dd, $^3J_{HH}$ = 1.8 Hz, $^3J_{HP}$ = 3.5 Hz, 4 H, C^{c}H), 7.24–7.82 (m, 36 H, C_6H_4, C_6H_5), 9.90 (s, 4 H, CHO). – ^{13}C{^{1}H} NMR ($CDCl_3$): δ = 71.8 (dd, $^1J_{CP}$ = 122.0 Hz, $^3J_{CP}$ = 3.4 Hz, C^a), 74.1 (d, $^2J_{CP}$ = 13.4 Hz, C^b), 74.1 (d, $^3J_{CP}$ = 11.3 Hz, C^c), 121.6 (d, $^3J_{CP}$ = 5.8 Hz, C^2), 128.3 (d, $^3J_{CP}$ = 13.4 Hz, C^m), 129.1 (dd, $^1J_{CP}$ = 108.6 Hz, $^3J_{CP}$ = 4.0 Hz, C^i), 131.1 (s, C^3), 131.8 (d, $^2J_{CP}$ = 10.9 Hz, C^o), 132.5 (s, C^4), 132.6 (d, $^4J_{CP}$ = 2.3 Hz, C^p), 156.7 (d, $^2J_{CP}$ = 9.3 Hz, C^1), 190.8 (s, CHO). – IR (KBr): $\tilde{\nu}$ = 1699 cm^{-1} (C=O). – $C_{62}H_{48}FeN_2O_8P_4S_2$ (1193.0): calcd. C 62.42, H 4.06, N 2.35; found C 62.60, H 4.19, N 2.25.

Compound 6a: 97% yield, white powder, m.p. 145°C. – ^{31}P {^1H} NMR ($CDCl_3$): δ = −7.9 (d, $^2J_{PP}$ = 32.0 Hz, P=O), 13.7 (d, $^2J_{PP}$ = 32.0 Hz, P=N). – ^1H NMR ($CDCl_3$): δ = 7.01−7.62 (m, 25 H, C_6H_5). – ^{13}C {^1H} NMR ($CDCl_3$): δ = 120.4 (d, $^3J_{CP}$ = 4.4 Hz, C^2), 123.4 (s, C^4), 128.4 (d, $^3J_{CP}$ = 12.9 Hz, C^m), 128.8 (s, C^3), 129.1 (dd, $^1J_{CP}$ = 107.3 Hz, $^3J_{CP}$ = 3.6 Hz, C^i), 132.1 (s, C^p), 132.3 (d, $^2J_{CP}$ = 11.6 Hz, C^o), 152.1 (d, $^2J_{CP}$ = 7.7 Hz, C^1). – $C_{30}H_{25}N_1O_3P_2$ (509.5): calcd. C 70.73, H 4.95, N 2.75; found C 70.90, H 5.03, N 2.68.

Compound 6f: 96% yield, white powder, m.p. 72°C. – ^{31}P {^1H} NMR ($CDCl_3$): δ = −6.2 (d, $^2J_{PP}$ = 31.0 Hz, P=O), 15.2 (d, $^2J_{PP}$ = 31.0 Hz, P=N). – ^1H NMR ($CDCl_3$): δ = 2.07 (d, $^2J_{HP}$ = 13.3 Hz, 3 H, CH_3), 7.02−7.58 (m, 20 H, C_6H_5). – ^{13}C {^1H} NMR ($CDCl_3$): δ = 15.4 (d, $^1J_{CP}$ = 67.9 Hz, CH_3), 120.4 (d, $^3J_{CP}$ = 5.2 Hz, C^2), 123.4 (s, C^4), 128.5 (d, $^3J_{CP}$ = 12.9 Hz, C^m), 128.9 (s, C^3), 130.2 (dd, $^1J_{CP}$ = 107.7 Hz, $^3J_{CP}$ = 5.5 Hz, C^i), 130.5 (d, $^2J_{CP}$ = 10.7 Hz, C^o), 132.0 (s, C^p), 152.0 (d, $^2J_{CP}$ = 7.9 Hz, C^1). – $C_{25}H_{23}N_1O_3P_2$ (447.4): calcd. C 67.11, H 5.18, N 3.13; found C 67.33, H 5.22, N 2.98.

Compound (6g): 96% yield, orange powder, m.p. 174°C. – ^{31}P {^1H} NMR ($CDCl_3$): δ = −8.6 (d, $^2J_{PP}$ = 37.0 Hz, P=O), 14.5 (d, $^2J_{PP}$ = 37.0 Hz, P=N). – ^1H NMR ($CDCl_3$): δ = 4.21 (br. s, 4 H, C^bH), 4.56 (br. s, 4 H, C^cH), 7.02−7.46 (m, 40 H, C_6H_5). – ^{13}C {^1H} NMR ($CDCl_3$): δ = 72.0 (dd, $^1J_{CP}$ = 120.7 Hz, $^3J_{CP}$ = 3.4 Hz, C^a), 73.7 (d, $^2J_{CP}$ = 13.7 Hz, C^b), 75.0 (d, $^3J_{CP}$ = 11.0 Hz, C^c), 120.2 (d, $^3J_{CP}$ = 5.2 Hz, C^2), 123.4 (s, C^4), 128.2 (d, $^3J_{CP}$ = 13.1 Hz, C^m), 128.8 (dd, $^1J_{CP}$ = 50.0 Hz, $^3J_{CP}$ = 4.2 Hz, C^i), 129.0 (s, C^3), 131.5 (d, $^2J_{CP}$ = 11.4 Hz, C^o), 132.0 (d, $^4J_{CP}$ = 1.9 Hz, C^p), 152.3 (d, $^2J_{CP}$ = 7.7 Hz, C^1). – $C_{58}H_{48}FeN_2O_6P_4$ (1048.8): calcd. C 66.42, H 4.61, N 2.67; found C 66.63, H 4.73, N 2.53.

General Procedure for 7a-f, 8a, 8f: To a solution of 1 mmol of compounds **5a**−**f**, **6a**, **6f** in CH_2Cl_2 (10 mL) was added at room temperature 1.05 mmol (slight excess) of $MeSO_3CF_3$. The solution was stirred for 15 min, then concentrated to dryness. The residue was washed twice with ether/pentane (1:1) to afford **7a**−**f**, **8a**, **8f** as oils.

General Procedure for 7g, 8g, and 16g: To a solution of 1 mmol of compound **5g**, **6g** or **15g** in CH_2Cl_2 (10 mL) was added at room temperature 2.1 mmol (slight excess) of $MeSO_3CF_3$. The solution was stirred for 15 min, then concentrated to dryness. The residue was washed twice with ether/pentane (1:1) to afford **7g**, **8g** or **16g** as a powder. Crystallization at −30°C in CH_2Cl_2/pentane (1:1) afforded single crystals of **7g** and **8g** suitable for X-ray diffraction.

Compound 7a: 95% yield, orange viscous oil. – ^{31}P {^1H} NMR ($CDCl_3$): δ = 22.8 (d, $^2J_{PP}$ = 20.0 Hz, P=N), 23.4 (d, $^2J_{PP}$ = 20.0 Hz, P−S−Me). – ^{31}P NMR ($CDCl_3$): δ = 22.8 (m, P=N), 23.4 (qd, $^2J_{PP} \approx {}^3J_{HP} \approx$ 19 Hz, P−S−Me). – ^1H NMR ($CDCl_3$): δ = 2.59 (d, $^3J_{HP}$ = 19.0 Hz, 3 H, CH_3-S), 7.24−7.92 (m, 23 H, C_6H_4, C_6H_5), 9.96 (s, 2 H, CHO). – ^{13}C {^1H} NMR ($CDCl_3$): (CF_3SO_3 not detected) δ = 13.7 (d, $^2J_{CP}$ = 5.5 Hz, CH_3−S), 121.3 (d, $^3J_{CP}$ = 5.5 Hz, C^2), 124.0 (d, $^1J_{CP}$ = 110.9 Hz, C^i), 130.2 (d, $^3J_{CP}$ = 13.1 Hz, C^m), 131.9 (d, $^2J_{CP}$ = 11.0 Hz, C^o), 132.0 (s, C^3), 134.6 (br. s, C^4, C^p), 153.1 (d, $^2J_{CP}$ = 10.1 Hz, C^1), 190.6 (s, CHO). – ^{19}F NMR ($CDCl_3$): δ = −2.2 (s, CF_3SO_3). – IR (KBr): $\tilde{\nu}$ = 1699 (C=O) cm^{-1}. – $C_{34}H_{28}F_3N_1O_7P_2S_2$ (745.7): calcd. C 54.76, H 3.78, N 1.88; found C 54.83, H 3.82, N 1.85.

Compound 7b: 91% yield, red viscous oil. – ^{31}P {^1H} NMR (CD_3COCD_3): δ = 26.2 (d, $^2J_{PP}$ = 23.0 Hz, P=N), 31.4 (d, $^2J_{PP}$ = 23.0 Hz, P−S−Me). – ^{31}P NMR (CD_3COCD_3): δ = 26.2 (m, P=N), 31.4 (qd, $^2J_{PP} \approx {}^3J_{HP} \approx$ 20 Hz, P−S−Me). – ^1H NMR (CD_3COCD_3): δ = 2.95 (d, $^3J_{HP}$ = 18.5 Hz, 3 H, CH_3-S), 7.74−8.19 (m, 20 H, C_6H_4), 10.18 (s, 2 H, CHO). – ^{13}C {^1H} NMR (CD_3COCD_3): δ = 13.6 (d, $^2J_{CP}$ = 4.6 Hz, CH_3−S), 121.4 (q, $^1J_{CF}$ = 319.9 Hz, CF_3SO_3), 122.0 (d, $^3J_{CP}$ = 4.5 Hz, C^2), 123.1 (br. d, $^1J_{CP}$ = 109 Hz, C^i), 130.3 (d, $^3J_{CP}$ = 14.1 Hz, C^m), 132.1 (s, C^3), 134.4 (d, $^2J_{CP}$ = 14.0 Hz, C^o), 135.3 (s, C^4), 141.0 (s, C^p), 153.3 (d, $^2J_{CP}$ = 9.6 Hz, C^1), 190.9 (s, CHO). – ^{19}F NMR (CD_3COCD_3): δ = 2.7 (s, CF_3SO_3). – IR (KBr): $\tilde{\nu}$ = 1698 (C=O) cm^{-1}. – $C_{34}H_{25}Cl_3F_3N_1O_7P_2S_2$ (849.0): calcd. C 48.07, H 2.94, N 1.64; found C 48.13, H 3.00, N 1.58.

Compound 7c: 92% yield, orange viscous oil. – ^{31}P {^1H} NMR (CD_3COCD_3): δ = 28.9 (d, $^2J_{PP}$ = 10.0 Hz, P−S−Me), 45.7 (d, $^2J_{PP}$ = 10.0 Hz, P=N). – ^{31}P NMR (CD_3COCD_3): δ = 28.9 (qd, $^2J_{PP}$ = 10.0 Hz, $^3J_{HP}$ = 19.0 Hz, P−S−Me), 45.7 (m, P=N). – ^1H NMR (CD_3COCD_3): δ = 2.83 (d, $^3J_{HP}$ = 19.0 Hz, 3 H, CH_3-S), 2.84−2.98 (m, 12 H, CH_2−CH_2), 7.78−8.17 (d, $^3J_{HH}$ = 12.0 Hz, 8 H, C_6H_4), 10.09 (s, 2 H, CHO). – ^{13}C {^1H} NMR (CD_3COCD_3): δ = 13.6 (d, $^2J_{CP}$ = 5.3 Hz, CH_3-S), 21.1 (s, CH_2P), 22.4 (s, CH_2CH_2P), 118.7 (s, C≡N), 121.2 (q, $^1J_{CF}$ = 320.7 Hz, CF_3SO_3), 121.9 (d, $^3J_{CP}$ = 4.8 Hz, C^2), 132.1 (s, C^3), 135.3 (s, C^4), 153.6 (d, $^2J_{CP}$ = 11.0 Hz, C^1), 191.1 (s, CHO). – ^{19}F NMR (CD_3COCD_3): δ = 2.5 (s, CF_3SO_3). – IR (THF): $\tilde{\nu}$ = 2211 (CN), 1700 (C=O) cm^{-1}. – MS [FAB$^+$ (MNBA/CH_2Cl_2)]; *m/z* (%): 527 (100) [$M^+ - CF_3SO_3$]. – $C_{25}H_{25}F_3N_4O_7P_2S_2$ (676.6): calcd. C 44.38, H 3.72, N 8.28; found C 44.47, H 3.73, N 8.24.

Compound 7d: 79% yield, orange viscous oil. – ^{31}P {^1H} NMR ($CDCl_3$): δ = −4.7 (d, $^2J_{PP}$ = 5.5 Hz, P=N), 28.5 (d, $^2J_{PP}$ = 5.5 Hz, P-S-Me). – ^{31}P NMR ($CDCl_3$): δ = −4.7 (dec d, $^2J_{PP}$ = 5.2 Hz, $^3J_{HP}$ = 24.0 Hz, P=N), 28.5 (br. q, $^3J_{HP}$ = 18.5 Hz, P−S−Me). – ^1H NMR ($CDCl_3$): δ = 1.25 (d, $^3J_{HP}$ = 22.5 Hz, 9 H, C−CH_3), 2.79 (d, $^3J_{HP}$ = 18.5 Hz, 3 H, CH_3−S), 7.38−7.95 (m, 18 H, C_6H_4, C_6H_5), 9.85 (s, 2 H, CHO). – ^{13}C {^1H} NMR ($CDCl_3$): δ = 13.5 (d, $^2J_{CP}$ = 5.1 Hz, CH_3−S), 22.3 (d, $^2J_{CP}$ = 2.3 Hz, C−CH_3), 35.0 (dd, $^1J_{CP}$ = 94.9 Hz, $^3J_{CP}$ = 6.0 Hz, C−CH_3), 73.2 (d, $^1J_{CP}$ = 201.7 Hz, ≡C−P), 110.5 (d, $^2J_{CP}$ = 36.0 Hz, C≡C-P), 116.7 (d, $^3J_{CP}$ = 4.6 Hz, C^i), 120.7 (q, $^1J_{CF}$ = 320.8 Hz, CF_3SO_3), 121.3 (d, $^3J_{CP}$ = 4.9 Hz, C^2), 129.0 (s, C^m), 132.0 (s, C^3), 132.6 (s, C^p), 132.8 (d, $^4J_{CP}$ = 1.7 Hz, C^o), 134.6 (d, $^5J_{CP}$ = 1.3 Hz, C^4), 152.9 (d, $^2J_{CP}$ = 10.8 Hz, C^1), 190.3 (s, CHO). – ^{19}F NMR ($CDCl_3$): δ = −2.0 (s, CF_3SO_3). – IR (THF): $\tilde{\nu}$ = 2170 (C≡C), 1699 (C=O) cm^{-1}. – $C_{36}H_{32}F_3N_1O_7P_2S_2$ (773.8): calcd. Compound 8g: 96% yield, orange powder, m.p. 169°C. − $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = −9.7 (d, $^2J_{PP}$ = 34.5 Hz, P−O−Me), 25.2 (d, $^2J_{PP}$ = 34.5 Hz, P=N). − ^{31}P NMR ($CDCl_3$): δ = −9.7 (dq, $^2J_{PP}$ = 34.5 Hz, $^3J_{HP}$ = 12.9 Hz, P−O−Me), 25.2 (m, P=N). − ^1H NMR ($CDCl_3$): δ = 4.03 (br. s, 4 H, C^bH), 4.13 (d, $^3J_{HP}$ = 12.4 Hz, 6 H, CH_3−O), 4.39 (br. s, 4 H, C^cH), 7.00−7.64 (m, 40 H, C_6H_5). − $^{13}C\{^1H\}$ NMR ($CDCl_3$): (CF_3SO_3 not detected) δ = 58.1 (d, $^2J_{CP}$ = 9.1 Hz, CH_3−O), 68.5 (dd, $^1J_{CP}$ = 126.8 Hz, $^3J_{CP}$ = 4.7 Hz, C^a), 73.6 (d, $^2J_{CP}$ = 15.1 Hz, C^b), 76.2 (d, $^3J_{CP}$ = 11.8 Hz, C^c), 119.7 (d, $^3J_{CP}$ = 4.3 Hz, C^2), 126.3 (dd, $^1J_{CP}$ = 107.9 Hz, $^3J_{CP}$ = 4.7 Hz, C^i), 126.8 (s, C^4), 129.4 (d, $^3J_{CP}$ = 13.8 Hz, C^m), 130.5 (s, C^3), 131.4 (d, $^2J_{CP}$ = 11.8 Hz, C^o), 134.1 (s, C^p), 149.4 (d, $^2J_{CP}$ = 9.2 Hz, C^1). − ^{19}F NMR ($CDCl_3$): δ = −2.0 (s, CF_3SO_3). − MS [FAB^+ (MNBA/CH_2Cl_2)]; *m/z* (%): 512 (100) [(M^{2+} − Fe − 2 CF_3SO_3)/2]. − $C_{62}H_{54}F_6FeN_2O_{12}P_4S_2$ (1377.0): calcd. C 54.06, H 3.92, N 2.03; found C 54.10, H 3.95, N 2.00.

General Procedure for 9a, 10a: To a solution of 1 mmol of compound **5a** or **6a** in CH_2Cl_2 (10 mL) was added at room temperature a solution of 1.05 mmol (slight excess) of *i*$PrSO_3CF_3$ generated in situ in CCl_4 at 0°C. The resulting solution was allowed to reach room temperature under stirring for 30 min, then concentrated to dryness. The residue was washed twice with ether/pentane (1:1) to afford **9a** or **10a** as oils.

Compound 9a: 90% yield, red viscous oil. − $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 21.5 (d, $^2J_{PP}$ = 17.3 Hz, P−S−*i*Pr), 22.4 (d, $^2J_{PP}$ = 17.3 Hz, P=N). − ^1H NMR ($CDCl_3$): δ = 1.43 (d, $^3J_{HH}$ = 6.8 Hz, 6 H, CH_3), 3.83 (septd, $^3J_{HH}$ = 6.8 Hz, $^3J_{HP}$ = 13.6 Hz, 1 H, C*H*Me_2), 7.01−7.96 (m, 23 H, C_6H_4, C_6H_5), 9.91 (s, 2 H, CHO). − $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 24.7 (d, $^3J_{CP}$ = 7.4 Hz, CH_3), 42.6 (d, $^2J_{CP}$ = 5.3 Hz, *C*HMe_2), 120.5 (q, $^1J_{CF}$ = 321.4 Hz, CF_3SO_3), 121.1 (d, $^3J_{CP}$ = 5.1 Hz, C^2), 124.0 (dd, $^1J_{CP}$ = 103.6 Hz, $^3J_{CP}$ = 7.2 Hz, C^i), 129.6 (d, $^3J_{CP}$ = 13.3 Hz, C^m), 131.8 (d, $^2J_{CP}$ = 10.7 Hz, C^o), 131.9 (s, C^3), 134.4 (br. s, C^4, C^p), 153.1 (d, $^2J_{CP}$ = 11.7 Hz, C^1), 190.5 (s, CHO). − ^{19}F NMR ($CDCl_3$): δ = −2.0 (s, CF_3SO_3). − IR (KBr): $\tilde{\nu}$ = 1700 (C=O) cm^{-1}. − $C_{36}H_{32}F_3N_1O_7P_2S_2$ (773.8): calcd. C 55.88, H 4.17, N 1.81; found C 55.83, H 4.09, N 1.86.

Compound 10a: 91% yield, colorless viscous oil. − $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = −12.1 (d, $^2J_{PP}$ = 21.5 Hz, P−O−*i*Pr), 21.7 (d, $^2J_{PP}$ = 21.5 Hz, P=N). − ^1H NMR ($CDCl_3$): δ = 1.33 (d, $^3J_{HH}$ = 6.2 Hz, 6 H, CH_3), 5.04 (septd, $^3J_{HH}$ = 6.2 Hz, $^3J_{HP}$ = 12.6 Hz, 1 H, C*H*Me_2), 6.91−7.69 (m, 25 H, C_6H_5). − $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 23.1 (d, $^3J_{CP}$ = 5.2 Hz, CH_3), 79.7 (d, $^2J_{CP}$ = 9.2 Hz, *C*HMe_2), 119.7 (d, $^3J_{CP}$ = 5.4 Hz, C^2), 120.8 (q, $^1J_{CF}$ = 321 Hz, CF_3SO_3), 125.0 (dd, $^1J_{CP}$ = 108.9 Hz, $^3J_{CP}$ = 3.7 Hz, C^i), 126. 6 (s, C^4), 129.5 (d, $^3J_{CP}$ = 13.1 Hz, C^m), 130.2 (s, C^3), 131.9 (d, $^2J_{CP}$ = 12.0 Hz, C^o), 134.2 (s, C^p), 149.3 (d, $^2J_{CP}$ = 9.4 Hz, C^1). − ^{19}F NMR ($CDCl_3$): δ = −2.3 (s, CF_3SO_3). − $C_{34}H_{32}N_1O_6F_3P_2S$ (701.7): calcd. C 58.20, H 4.60, N 2.00; found C 58.32, H 4.69, N 2.05.

Synthesis of Compound 11f: To a solution of 1 mmol of compound **6f** (450 mg) in CH_2Cl_2 (10 mL) was added at room temperature 1.05 mmol (slight excess) of $Me_3SiSO_3CF_3$. The solution was stirred for 15 min, then concentrated to dryness. The residue was not washed, it was directly used for NMR characterization. − 90% yield, colourless viscous oil. − $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = −18.6 (d, $^2J_{PP}$ = 33.1 Hz, P−O−Si), 23.2 (d, $^2J_{PP}$ = 33.1 Hz, P=N). − ^1H NMR ($CDCl_3$): δ = 0.25 (br. s, 9 H, CH_3Si), 2.12 (d, $^2J_{HP}$ = 12.9 Hz, 3 H, CH_3P), 7.02−7.62 (m, 20 H, C_6H_5). − $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 0.0 (s, CH_3Si), 14.6 (d, $^1J_{CP}$ = 73.7 Hz, CH_3P), 119.6 (s, C^2), 119.8 (q, $^1J_{CF}$ = 319.4 Hz, CF_3SO_3), 126.3 (dd, $^1J_{CP}$ = 112.7 Hz, $^3J_{CP}$ = 4.9 Hz, C^i), 126.4 (s, C^4), 129.2 (d, $^3J_{CP}$ = 13.9 Hz, C^m), 130.1 (s, C^3), 130.3 (d, $^2J_{CP}$ = 14.5 Hz, C^o), 133.6 (s, C^p), 149.2 (d, $^2J_{CP}$ = 7.6 Hz, C^1). − ^{19}F NMR ($CDCl_3$): δ = −1.9 (s, CF_3SO_3).

General Procedure for 12f, and 12g: To a solution of 1 mmol of compound **7f**, or 0.5 mmol of compound **7g** in CH_2Cl_2 (10 mL) was added at room temperature 1.1 mmol (slight excess) of $P(NMe_2)_3$. The solution was stirred for 1 hour, then concentrated to dryness. The residue was extracted with toluene (10 mL) and the solution was filtered under argon to give **12f** or **12g** which were

used without further purification, due to their high sensitivity toward air and moisture.

Compound 12f: Not isolated. − $^{31}P\{^1H\}$ NMR (CH_2Cl_2): δ = 9.9 (d, $^2J_{PP}$ = 32 Hz, P=N), 143.9 (d, $^2J_{PP}$ = 32 Hz, P^{III}).

Compound 12g: Not isolated. − $^{31}P\{^1H\}$ NMR (CH_2Cl_2): δ = 12.8 (d, $^2J_{PP}$ = 63 Hz, P=N), 144.4 (d, $^2J_{PP}$ = 63 Hz, P^{III}).

Synthesis of Compound 13f: To a solution of 0.5 mmol of compound **12f** in toluene (10 mL) was added at room temperature 1 mmol (100% excess) of allyl iodide. The solution was stirred for 1 h. The phosphonium salt **13f** precipitated progressively. This precipitate was recovered by filtration, and washed with pentane to afford **13f** as a powder. − 85% yield, white powder. − $^{31}P\{^1H\}$ NMR (CD_3COCD_3): δ = 27.3 (d, $^2J_{PP}$ = 20.3 Hz, P=N), 28.9 (d, $^2J_{PP}$ = 20.3 Hz, P-allyl). − ^{31}P NMR (CD_3COCD_3): δ = 27.3 (m, P=N), 28.9 (dt, $^2J_{PP} \approx {}^2J_{PH} \approx$ 20 Hz, P-allyl). − ^1H NMR (CD_3COCD_3): δ = 2.57 (d, $^2J_{HP}$ = 13.4 Hz, 3 H, CH_3P), 3.87 (dddd, $^2J_{HP}$ = 20.1 Hz, $^3J_{HHA}$ = 7.3 Hz, $^4J_{HHB} \approx {}^4J_{HHC} \approx$ 1.1 Hz, 2 H, CH_2), 5.52 (dddt, $^3J_{HBHA}$ = 10.2 Hz, $^4J_{HBP}$ = 5.1 Hz, $^2J_{HBHC} \approx {}^4J_{HBCH2} \approx$ 1.2 Hz, 1 H, H_B), 5.64 (dddt, $^3J_{HCHA}$ = 16.8 Hz, $^4J_{HCP}$ = 6.1 Hz, $^2J_{HCHB} \approx {}^4J_{HCCH2} \approx$ 1.3 Hz, 1 H, H_C), 6.03 (dddt, $^3J_{HAHC}$ = 16.8 Hz, $^3J_{HAHB}$ = 10.2 Hz, $^3J_{HACH2} \approx {}^3J_{HAP} \approx$ 7.3 Hz, 1 H, H_A), 7.20−7.90 (m, 20 H, C_6H_5). − $^{13}C\{^1H\}$ NMR (CD_3COCD_3): δ = 15.8 (d, $^1J_{CP}$ = 68.0 Hz, CH_3P), 33.2 (d, $^1J_{CP}$ = 133.6 Hz, -CH_2-), 121.6 (d, $^3J_{CP}$ = 4.2 Hz, C^2), 123.3 (d, $^3J_{CP}$ = 16.2 Hz, CH_2=), 125.4 (d, $^2J_{CP}$ = 12.9 Hz, CH_A), 126.9 (s, C^4), 128.2 (dd, $^1J_{CP}$ = 108.0 Hz, $^3J_{CP}$ = 4.5 Hz, C^i), 129.7 (d, $^2J_{CP}$ = 12.2 Hz, C^m), 130.9 (s, C^3), 131.4 (d, $^3J_{CP}$ = 12.0 Hz, C^o), 133.7 (d, $^4J_{CP}$ = 2.7 Hz, C^p), 149.9 (d, $^2J_{CP}$ = 11.6 Hz, C^1). − $C_{28}H_{28}INO_2P_2$ (599.4): C 56.11, H 4.71, N 2.34; found C 55.98, H 4.63, N 2.27.

Synthesis of Compound 14f: A solution of 0.5 mmol of compound **12f** in toluene (10 mL) was added at room temperature to 0.5 mmol of 4-azidophenyl isothiocyanate. Evolution of nitrogen occurred rapidly. After 1 h, the solution was concentrated to dryness, and the residue was washed twice with THF/pentane (1:5) to afford compound **14f** as a viscous oil. This compound is not stable when left in solution. − 91% Yield, orange viscous oil. − $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = −7.7 (d, $^2J_{PP}$ = 16 Hz, N=P−O), 15.3 (d, $^2J_{PP}$ = 16 Hz, N=P−C). − ^1H NMR ($CDCl_3$): δ = 1.95 (d, $^3J_{HP}$ = 13.3 Hz, 3 H, CH_3), 6.80−7.80 (m, 24 H, C_6H_5, C_6H_4). − $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 15.0 (d, $^1J_{CP}$ = 69 Hz, CH_3), 121.0 (d, $^3J_{CP}$ = 4.7 Hz, C^2), 123.3 (d, $^3J_{CP}$ = 21.0 Hz, C'^o), 124.2 (s, C^4), 126.3 (s, C'^m), 126.9 (s, C'^p), 128.7 (d, $^3J_{CP}$ = 13.5 Hz, C^m), 129.3 (s, C^3), 130.6 (dd, $^1J_{CP}$ = 107 Hz, $^3J_{CP}$ = 5 Hz, C^i), 130.8 (d, $^2J_{CP}$ = 10.3 Hz, C^o), 132.3 (br. s, C^p), 133.7 (s, C=S), 149.8 (br. s, C'^i), 151.7 (d, $^2J_{CP}$ = 8.6 Hz, C^1). − $C_{32}H_{27}N_3O_2P_2S$ (579.6): C 54.40, H 3.85, N 5.95; found C 54.29, H 3.80, N 5.84.

Synthesis of Compound 15g: To a solution of 0.5 mmol of compound **12g** in toluene (10 mL) was added at room temperature a solution of 1 mmol of the azide **2** in toluene (10 mL). Evolution of nitrogen occurred rapidly. After 1 h, the solution was concentrated to dryness, and the residue was washed with dichloromethane/pentane (1:5) to afford compound **15g** as a powder. 95% yield, orange powder, m.p. 237°C. − $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = −14.3 (dd, $^2J_{PP}$ = 63.5 Hz, $^2J_{PP}$ = 23.2 Hz, N−P=N), 17.9 (d, $^2J_{PP}$ = 23.2 Hz, C−P=N), 45.9 (d, $^2J_{PP}$ = 63.5 Hz, P=S). − ^1H NMR ($CDCl_3$): δ = 4.14 (br. s, 4 H, C^bH), 4.53 (br. s, 4 H, C^cH), 7.02−7.69 (m, 52 H, C_6H_4, C_6H_5), 9.86 (s, 8 H, CHO). − $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 70.7 (dd, $^1J_{CP}$ = 126.8 Hz, $^3J_{CP}$ = 4.6 Hz, C^a), 73.6 (d, $^2J_{CP}$ = 13.8 Hz, C^b), 75.5 (d, $^3J_{CP}$ = 11.3 Hz, C^c), 121.0 (d, $^3J_{CP}$ = 4.5 Hz, C^2), 121.5 (d, $^3J_{CP}$ = 4.5 Hz, C'^2), 128.5 (dd, $^1J_{CP}$ = 108.5 Hz, $^3J_{CP}$ = 4.3 Hz, C^i), 128.6 (d, $^3J_{CP}$ = 13.5 Hz, C^m), 130.9 (s, C^3), 131.1 (s, C'^3), 131.8 (d, $^2J_{CP}$ = 11.6 Hz, C^o), 132.4 (s, C'^4), 132.9 (d, $^4J_{CP}$ = 5.0 Hz, C^p), 133.0 (s, C^4), 155.6 (d, $^2J_{CP}$ = 9.1 Hz, C^1), 156.5 (d, $^2J_{CP}$ = 9.1 Hz, C'^1), 190.5 (s, CHO), 190.7 (s, CHO). − IR (KBr): $\tilde{\nu}$ = 1699 cm^{-1} (C=O). − $C_{90}H_{68}FeN_4O_{16}P_6S_2$ (1767.4): calcd. C 61.16, H 3.88, N 3.17; found C 61.25, H 3.95, N 3.14.

Synthesis of Compound 16g: To a solution of 0.4 mmol of compound **15g** in CH_2Cl_2 (10 mL) was added at room temperature 0.81 mmol (slight excess) of $MeSO_3CF_3$. The solution was stirred for 30 min, then concentrated to dryness. The residue was washed twice with ether/pentane (1:1) to afford compound **16g** as a powder. − 96% yield, orange powder. − $^{31}P\{^1H\}$ NMR (CD_3COCD_3): δ = −16.9 (dd, $^2J_{PP}$ = 51 Hz, $^2J_{PP}$ = 29 Hz, N−P=N), 20.0 (d, $^2J_{PP}$ = 51 Hz, P−S−Me), 21.5 (d, $^2J_{PP}$ = 29 Hz, C−P=N). − ^1H NMR (CD_3COCD_3): δ = 2.73 (d, $^3J_{PP}$ = 18.4 Hz, 6 H, CH_3−S), 4.00 (br. s, 4 H, C^bH), 4.40 (br. s, 4 H, C^cH), 7.18−8.00 (m, 52 H, C_6H_4, C_6H_5), 10.0 (s, 8 H, CHO). − $^{13}C\{^1H\}$ NMR (CD_3COCD_3): δ = 13.3 (d, $^2J_{CP}$ = 4.6 Hz, CH_3), 70.4 (dd, $^1J_{CP}$ = 126.4 Hz, $^3J_{CP}$ = 6.8 Hz, C^a), 73.9 (d, $^2J_{CP}$ = 14.1 Hz, C^b), 76.0 (d, $^3J_{CP}$ = 11.4 Hz, C^c), 121.5 (d, $^3J_{CP}$ = 4.9 Hz, C^2 or C'^2), 121.6 (d, $^3J_{CP}$ = 4.9 Hz, C'^2 or C^2), 121.7 (q, $^1J_{CF}$ = 321.1 Hz, CF_3SO_3), 127.5 (dd, $^1J_{CP}$ = 108.0 Hz, $^3J_{CP}$ = 4.0 Hz, C^i), 129.7 (d, $^3J_{CP}$ = 13.6 Hz, C^m), 132.0 (d, $^2J_{CP}$ = 11.1 Hz, C^o), 132.1 (s, C'^3, C^3), 134.3 (br. s, C^p), 134.7 (s, C'^4), 135.3 (s, C^4), 153.5 (d, $^2J_{CP}$ = 9.9 Hz, C^1), 154.6 (d, $^2J_{CP}$ = 9.5 Hz, C'^1), 191.0 (s, CHO). − IR (KBr): $\tilde{\nu}$ = 1699 cm^{-1} (C=O). − $C_{94}H_{74}F_6FeN_4O_{22}P_6S_4$ (2095.6): calcd. C 53.87, H 3.56, N 2.67; found C 54.01, H 3.61, N 2.64.

X-ray Structure Determination for Compounds 5g ($C_{62}H_{48}FeN_2O_8P_4S_2$), 6g ($C_{58}H_{48}FeN_2O_6P_4$), 7g {$[C_{64}H_{54}N_2O_8P_4S_2Fe][CF_3SO_3]_2$ 3/2CH_2Cl_2}, and 8g {$[C_{60}H_{54}N_2O_6P_4Fe][CF_3SO_3]_2$}: The data were collected on a Stoe Imaging Plate Diffraction System (I.P.D.S) equipped with an Oxford Cryosystems Cooler Device, for the four compounds. The structures were solved by direct methods (SIR92)[14] and refined by least-squares procedures on F_o. All hydrogen atoms were located on a difference Fourier map, but they were introduced in calculation in idealized positions [d(C−H) = 0.96 Å], their atomic coordinates were recalculated after each cycle of refinement. They were given isotropic thermal parameters 20% higher than those of the carbon atoms to which they were connected. All non-hydrogen atoms were anisotropically refined. Models were easily located and refined for **5g**, **6g** and **8g**; concerning the structure **7g**, the molecule appears as relatively disordered. Moreover, around the molecules of solvent (CH_2Cl_2) the electron density seems to be spread and diffuse. Finally, the difference Fourier synthesis still shows some residual electron density in these regions, which could not be fitted to any model. Least-squares refinement was carried out by minimizing the function $\Sigma w(||F_o| - |F_c||)^2$, where F_o and F_c are the observed and calculated structure factors. A weighting scheme was used in the last refinement cycles, where weights are calculated from the following expression: w = [weight] × [1 − Δ(F)/6 × σ(F)]^2.[15] Models reached convergence with R = $\Sigma(||F_o| - |F_c||)/\Sigma|F_o|$ and Rw = $[\Sigma w(||F_o| - |F_c||)^2/\Sigma w(|F_o|)^2]^{1/2}$. The calculations were performed with CRYSTALS programs[16] running on a PC. The drawing of the molecules was realized with the aid of CAMERON[17] and the atomic scattering factors were taken from International Tables for X-Ray Crystallography.[18] Crystallographic data (excluding structure factors) for the structure(s) reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-103861 (**5g**), -103862 (**6g**), -103863 (**7g**), -103864 (**8g**). Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: int. code + 44(1223)336-033; E-mail: deposit@ccdc.cam.ac.uk].

Vinylidene Transition-Metal Complexes, 48[+]
A Novel Route to Cationic Four-Coordinate Rhodium(I) Complexes with Rh=C Bonds

Bettina Windmüller,[a] Oliver Nürnberg,[a] Justin Wolf,[a] and Helmut Werner*[a]

Dedicated to Professor Michael F. Lappert on the occasion of his 70th birthday

Keywords: Rhodium / Ketone complexes / Vinylidene complexes / Allenylidene complexes / Ligand substitution reactions

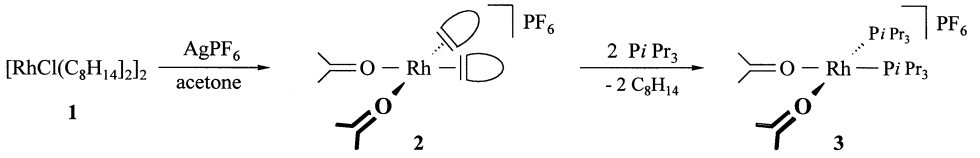
The complex $[Rh(acetone)_2(C_8H_{14})_2]PF_6$ (**2**), which is prepared from $[RhCl(C_8H_{14})_2]_2$ and $AgPF_6$ in acetone, reacts with P*i*Pr$_3$ to afford the PF_6 salt **3** of the cation $[Rh(acetone)_2(PiPr_3)_2]^+$ containing the ketone and phosphane ligands in *cis* dispositions. Treatment of **3** with MeC≡CPh leads to the displacement of one acetone ligand and the formation of the corresponding π-alkyne complex **4**. In contrast, from **3** and terminal alkynes such as HC≡CC_6H_4–4-Me or HC≡CCPh_2OH the cationic vinylidenerhodium(I) compounds **5** and **6** are obtained. The latter, with C=CHCPh_2OH as the ligand, is rather labile and even at room temperature eliminates water to give the cationic four-coordinate rhodium allenylidene **7**. The molecular structure of this compound has been determined by X-ray crystallography. In the presence of pyridine or ammonia, the acetone ligand of **5** and **7** is readily displaced and the substitution products **8**–**10** are formed almost quantitatively. Anions such as acetate or hydroxide also displace the ketone unit of **7** and yield the neutral allenylidenerhodium(I) complexes *trans*-$[RhX(=C=C=CPh_2)(PiPr_3)_2]$ with X = OAc (**11**) and OH (**12**).

Following the synthesis of the first square-planar allenylidenerhodium(I) complex *trans*-[RhCl(=C=C=CPh_2)(P*i*Pr$_3$)$_2$],[1] we have recently shown that rhodium allenylidenes of this particular type are useful tools for the generation of metal bound species that are hardly accessible by other preparative routes.[2] After having characterized a series of compounds of the general composition *trans*-[RhX(=C=C=CRR′)(P*i*Pr$_3$)$_2$] (X = Cl, I, CN, OH, OPh, OAc, OTos),[3] we became interested to find out whether also four-coordinate *cationic* allenylidenerhodium(I) complexes $[Rh(L)(=C=C=CRR')(PiPr_3)_2]^+$ (L = two-electron donor ligand) can be obtained. Recent attempts from our laboratory with the aim to prepare the cation *trans*-$[Rh(=C=C=CPh_2)_2(PiPr_3)_2]^+$ unexpectedly led, via a novel C–C coupling, to the formation of two isomeric hexapentaenerhodium(I) compounds of which the isomer having the polyene coordinated in an unsymmetrical fashion is the thermodynamically more stable.[4] However, after we found that carbonyl-, ethene- and even vinylidenerhodium derivatives such as *trans*-$[Rh(py)(L)(PiPr_3)_2]^+$ and *trans*-$[Rh(NH_3)(L)(PiPr_3)_2]^+$ (L = CO, C_2H_4, C=CHR) are accessible and, with BF_4^- or PF_6^- as counterion, stable under ambient conditions,[5] we felt encouraged to prepare also the corresponding species with L = C=C=CRR′.

In this paper we report the synthesis of complexes *trans*-$[Rh(L')(=C=C=CPh_2)(PiPr_3)_2]PF_6$, the first X-ray crystal structure analysis of a *cationic* rhodium compound with Rh=C=C=CPh_2 as a molecular unit, and an alternative preparative route to neutral species with X^- instead of L′ as ligands coordinated to rhodium(I).

Precursors of the General Composition *cis*-$[Rh(acetone)_2(L)_2]^+$

The procedure which we recently used for the synthesis of the above-mentioned compounds *trans*-[Rh(py)(L)-(P*i*Pr$_3$)$_2$]X with L = CO, C_2H_4 and C=CHR[5] turned out to be not the method of choice for L = C=C=CPh_2. Treatment of the mixture of $[Rh(\eta^3\text{-}C_3H_5)(PiPr_3)_2]$ and $[pyH]BF_4$ with the propargylic alcohol HC≡CCPh_2OH in acetone at room temperature led, within a short period of time, to the formation of a deep red solution from which a red, moderately air-sensitive solid was obtained after removal of the solvent. According to the NMR spectra it consisted mainly of our target, the allenylidene complex *trans*-$[Rh(py)(=C=C=CPh_2)(PiPr_3)_2]BF_4$ but also contained some impurities. Despite several attempts these could not be completely separated from the dominating species.



Therefore, we developed an alternative route to the cations $[Rh(L')(=C=C=CPh_2)(PiPr_3)_2]^+$ by using the dimeric bis(cyclooctene)rhodium(I) complex **1** as the starting material. If a suspension of **1** in acetone is treated with a solution of $AgPF_6$ in the same solvent at 0°C, a brownish yellow solution is formed from which the PF_6 salt **2** can be isolated in 74% yield. The yellow microcrystalline solid

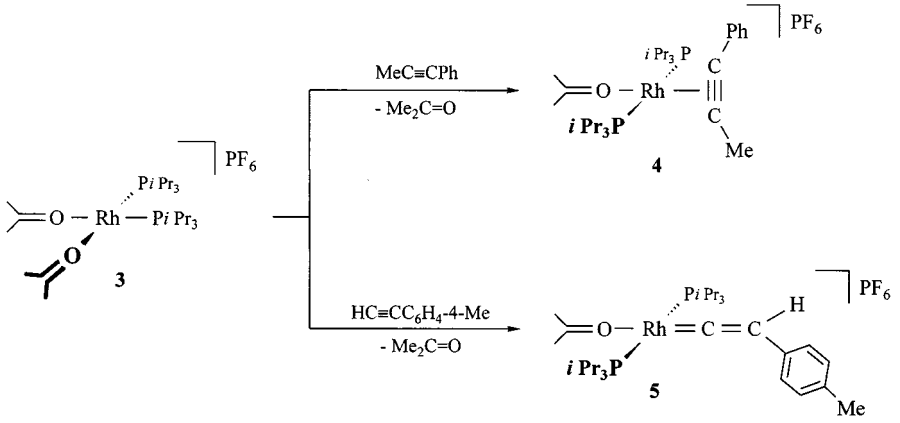
(which decomposes at 58°C) has been characterized by elemental analysis, conductivity measurements and spectroscopic techniques. Although the ^{1}H-NMR data cannot decide whether the structure proposed in Scheme 1 is correct, in analogy to the related cation $[Rh(acetone)_2(C_8H_{12})]^+$ the *cis* arrangement of the acetone ligands seems most likely.[6] the ^{13}C-NMR spectrum at δ = 75.0 (≡CPh) and 64.5 (≡CMe) and also the IR band at 1885 cm^{-1} assigned to ν(C≡C). The Rh−P coupling of the single ^{31}P-NMR resonance of **4** (116.3 Hz) is considerably smaller than that of **3** (204.9 Hz) which also supports the *trans* position of the two P*i*Pr$_3$ groups.

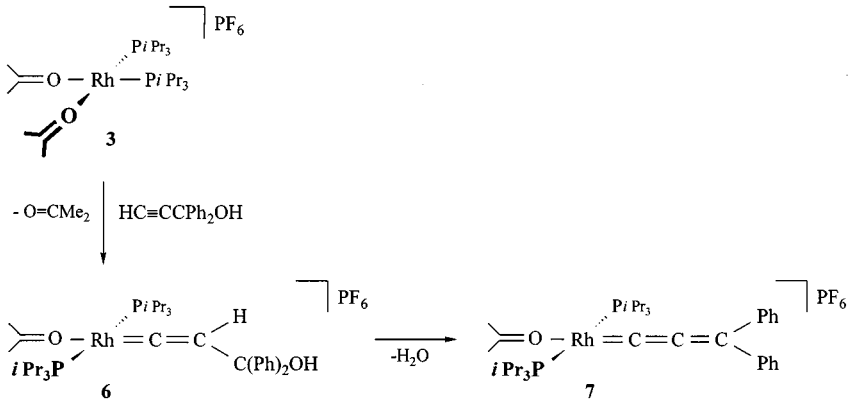
Scheme 1



After the isolation of the cationic compound **2** the interesting question arose whether the acetone or the cyclooctene ligands are more weakly bound to the metal center. The experiment revealed that upon treatment of a suspension of **2** in ether/acetone with two equivalents of P*i*Pr$_3$ the olefinic groups are preferentially displaced. Upon recrystallization from acetone/diethyl ether the bis(phosphane) complex **3** was isolated as a violet air-sensitive solid in 98% yield. The ^{31}P-NMR spectrum of **3** displays a doublet at δ = 60.3 with a large Rh−P coupling that is typical for a *cis*-disposed $[Rh(PiPr_3)_2]$ unit.[7]

Cationic Complexes with Rh=C Bonds

The bis(acetone)rhodium(I) complex **3** proved to be an ideal precursor for the preparation of cationic vinylidene and allenylidene rhodium(I) derivatives. In order to test whether one of the metal bound ketones can be selectively replaced by an alkyne ligand, we first carried out the reaction of **3** with MeC≡CPh. It leads to the alkyne complex **4** (Scheme 2) as an orange air-sensitive solid in 75% yield. In contrast to **3**, the ^{1}H-NMR spectrum of **4** displays two resonances for the CH_3 protons of the isopropyl moieties, the virtual coupling of both points to a *trans* arrangement of the phosphane ligands.[8] Typical features of the π-bonded unsymmetrical alkyne unit are the two signals in



Treatment of compound **3** with HC≡CC_6H_4−4-Me as a representative of a *terminal* acetylene derivative affords instead of an alkyne complex the vinylidene isomer **5** almost quantitatively. If the 1-alkyne is added to a solution of **3** in diethyl ether/acetone at −78°C, a rapid change of color from violet to orange takes place indicating (see: compound **4** is orange) that in the initial step the cation $[Rh(O{=}CMe_2)(HC{\equiv}CR)(PiPr_3)_2]^+$ (R = *p*-tolyl) is probably formed. However, even at −78°C after a few minutes the color of the solution changes again to violet and a violet solid precipitates. Upon warming to room temperature, removal of the solvent and recrystallization of the residue from acetone/diethyl ether the product was obtained in 95% yield. In agreement with the spectroscopic data of other vinylidenerhodium(I) complexes,[5][9][10] the ^{13}C-NMR spectrum of **5** displays two signals (both doublets of triplets) in the low-field region at δ = 309.3 and 113.3 which are assigned to the α- and β-carbon atoms of the vinylidene ligand, respectively.

The course of the reaction of the bis(acetone)rhodium(I) compound **3** with the propargylic alcohol HC≡CCPh_2OH in diethyl ether/acetone is at least in the initial stage quite similar to that of **3** with HC≡CC_6H_4−4-Me (see Scheme 3). If the solution, after it was stirred at −78°C for 2 min and then warmed to 0°C, was quickly worked up an orange-red solid was isolated which based on the NMR spec-

Scheme 2

tra consists of a mixture of the functionalized vinylidene compound **6** and the allenylidene complex **7**, the first being the dominating species. Attempts to obtain **6** as an analytically pure solid failed since the crude product upon dissolution, e.g., in acetone or dichloromethane smoothly converted completely to **7**. In acetone at room temperature, the formation of **7** is completed in ca. 15 min. Removal of the solvent and recrystallization of the residue from acetone/diethyl ether gave orange crystals which were characterized by elemental analysis, conductivity measurements and spectroscopic means. In contrast to the neutral compounds *trans*-[RhCl{=C=C=C(Ph)R}(P*i*Pr$_3$)$_2$],[1][11] in the ^{13}C-NMR spectrum of **7** the resonances of the α-and β-carbon atoms of the Rh=C=C=C moiety could not be observed, even if a saturated solution of **7** in [D$_6$]acetone was used. The signal of the respective γ-carbon atom appears at δ = 150.8 as a singlet.

Scheme 3

In order to confirm the structure proposed for **7** [which is the first *cationic* allenylidenerhodium(I) complex], an X-ray crystal structure analysis was carried out. The result is shown in Figure 1. The coordination geometry around the rhodium center is almost exactly square-planar with bond angles P1−Rh−P2 and O1−Rh−C1 of 176.78(2)° and 178.67(9)°. The Rh−C1 distance is 1.822(2) Å and thus somewhat shorter than in *trans*-[RhCl{=C=C=C(Ph)C$_6$H$_4$−2-Me}(P*i*Pr$_3$)$_2$] [1.855(5) Å].[11] The shortening is surprising insofar as in *cationic* rhodium(I) species the degree of π-back bonding should be smaller compared to structurally related *neutral* derivatives. The bond length C1−C2 [1.267(3) Å] is slightly longer and the bond length C1−C3 [1.343(3) Å] slightly shorter than in the above-mentioned allenylidene(chloro)rhodium(I) compound [C1−C2 = 1.239(8) Å, C2−C3 = 1.370(9) Å], indicating that for the bonding situation the resonance structure **B** (Figure 2) is less important in the cationic complex than in the neutral analog. The Rh−C−C−C chain is nearly linear, with only a slight bending at the carbon atom C2. The planes of the two phenyl groups are not perpendicular to each other like the aryl rings in *trans*-[RhCl{=C=C=C(Ph)C$_6$H$_4$−2-Me}(P*i*Pr$_3$)$_2$] but form a dihedral angle of 68.31(8)°. The atoms O1, C34, C35 and C36 of the acetone ligand lie in a plane which is orthogonal to the central plane [P1, P2, Rh, O1, C1] and we assume that this minimizes the steric repulsion between the O=CMe$_2$ and the P*i*Pr$_3$ ligands.

Ligand Substitution Reactions of Compounds 5 and 7

The observation that in the starting material **3** one of the ketone ligands could be easily replaced by an alkyne, vinylidene or allenylidene unit, led us to try to substitute also the remaining acetone moiety in the cations *trans*-[Rh(O=CMe$_2$)(L)(P*i*Pr$_3$)$_2$]$^+$ by an olefin, alkyne or even a more typical π-acceptor ligand such as CO. However, all these attempts failed. Nevertheless, the displacement of acetone in the vinylidene and allenylidene complexes **5** and **7** can be achieved with *N-donors* such as pyridine or ammonia under very mild conditions. After workup the substitution products **8**−**10** were isolated in 85−90% yield (Scheme 4). The properties of the pyridine- and ammonia-containing cationic compounds are very similar to those of the acetone derivatives **5** and **7** and thus deserve no further comment. It should be mentioned, however, that since for the preparation of **10** aqueous ammonia was used as the substrate, the C=C=CPh$_2$ ligand is *not* attacked by OH$^-$ or H$_2$O as a nucleophile as was observed with a variety of cationic *six-coordinate* allenylidenemetal complexes.[12] The ^{13}C-NMR spectrum of **9** displays the three expected signals for the α-, β- and γ-carbon atoms of the Rh−C−C−C chain at δ = 270.4, 229.6 and 150.9, of which those at lowest fields (assigned to α-C and β-C) are split into doublets of triplets.

In order to illustrate that the acetone ligand of compound **7** can also be displaced by coordinating anions, the known acetato- and hydroxorhodium(I) derivatives **11** and **12** were prepared by this route (Scheme 5). From **7** as the starting material and with CH$_3$CO$_2$Na or KOH as the substrate, the isolated yield of **11** and **12** is ca. 80%. The neutral allenylidene complex **12** with OH in *trans* position to the C$_3$Ph$_2$ unit was originally prepared from the chloro compound *trans*-[RhCl(=C=C=CPh$_2$)(P*i*Pr$_3$)$_2$] and KO*t*Bu in C$_6$H$_6$/*t*BuOH and upon treatment with acetic acid trans-

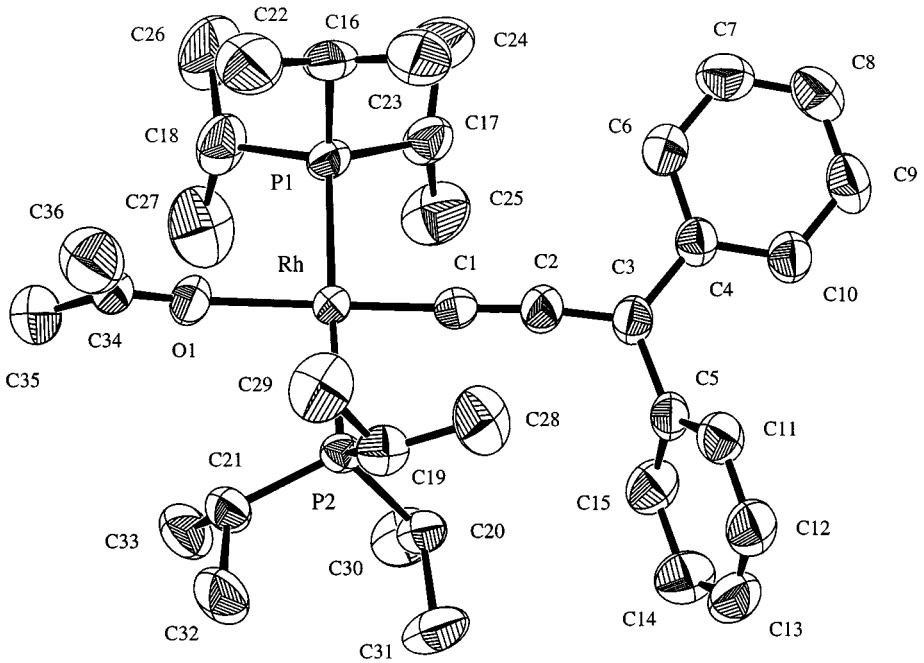


Figure 1. Molecular structure (ORTEP plot) of the cation of compound **7**; the hydrogen atoms are omitted for clarity; selected bond lengths (Å) and angles [°]: Rh−P1 2.3557(6), Rh−P2 2.3513(6), Rh−O1 2.078(2), Rh−C1 1.822(2), C1−C2 1.267(3), C2−C3 1.343(3), C3−C4 1.472(3), C3−C5 1.491(3), O1−C34 1.216(3); P1−Rh−P2 176.78(2), P1−Rh−O1 90.08(5), P1−Rh−C1 90.11(6), P2−Rh−O1 92.41(5), P2−Rh−C1 87.45(6), O1−Rh−C1 178.67(9), Rh−C1−C2 178.1(2), C1−C2−C3 172.6(2), C2−C3−C4 122.8(2), C2−C3−C5 118.2(2), O1−C34−C35 119.1(3), O1−C34−C36 122.4(3)

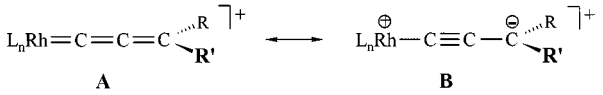

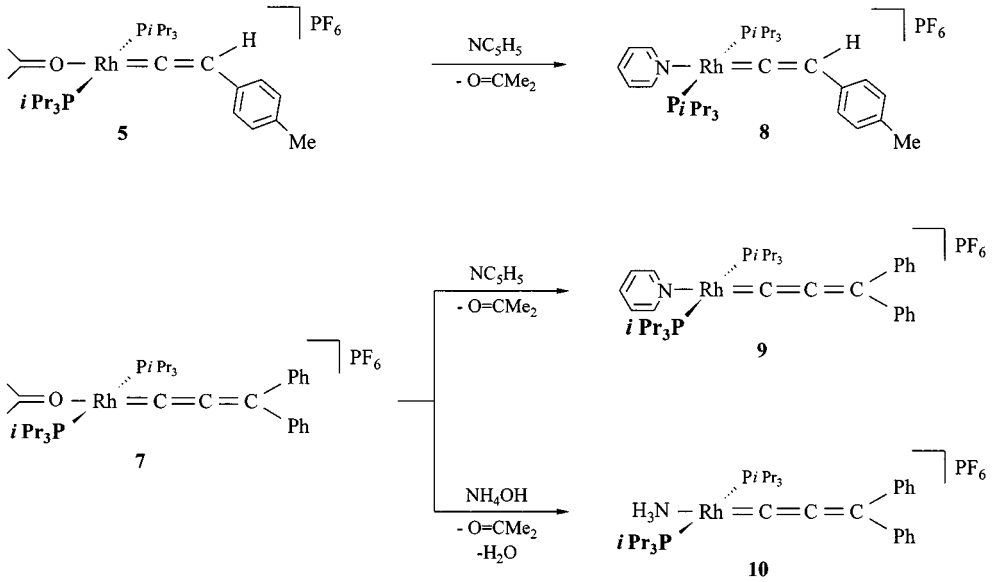

Figure 2. Resonance structures for allenylidenemetal complexes

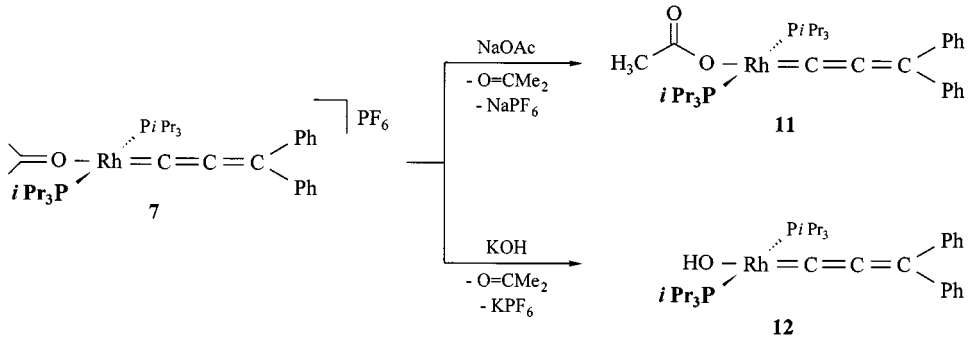

formed to the acetato derivative.[2b][3] Some exploratory studies indicate that it is possible to substitute the acetone ligand of **7** also by C-nucleophiles such as $CH(CN)_2^-$ or CN^- and thus the reaction of **7** with X^- could be an alternative route for the preparation of allenylidenerhodium(I) complexes of the general composition *trans*-[RhX(=C=C=CPh$_2$)(P*i*Pr$_3$)$_2$].

Concluding Remarks

The present investigation has shown that in addition to the well-known neutral rhodium allenylidenes *trans*-[RhX(=C=C=CRR′)(P*i*Pr$_3$)$_2$] structurally related *cationic* complexes *trans*-[Rh(=C=C=CPh$_2$)(L)(P*i*Pr$_3$)$_2$]$^+$ with L = acetone, pyridine or ammonia are also accessible. The

Scheme 4

Scheme 5

method of choice for preparing these compounds (as the PF_6 salts) is the "alkynol route", which was developed by Selegue[13] and later used by us[3][14] and several other groups as well.[15][16] The most remarkable feature is that the starting material **3** (which despite the lability of the acetone-metal bonds has been isolated and fully characterized) reacts with terminal alkynes HC≡CR, including the propargylic alcohol $HC{\equiv}CCPh_2OH$, almost instantaneously to give cationic vinylidene compounds with Rh=C=CHR as the central unit. Since all attempts to detect the corresponding *alkyne*rhodium(I) derivatives assumed to be formed in the initial step failed, we conclude that the metal-assisted isomerization of HC≡CR to C=CHR takes place considerably *faster* in the coordination sphere of a four-coordinate *cationic* than of a related *neutral* d^8 metal center. With regard to the subsequent conversion of the Rh=C=$CHCPh_2OH$ to the Rh=C=C=CPh_2 unit we note that in the case of the *cationic* species the elimination of water also occurs much more readily than for the analogous neutral derivative and that neither the presence of Al_2O_3 nor of Brønsted acids HX is necessary for this process.

Experimental Section

General: All operations were carried out under argon using Schlenk techniques. The starting material $[RhCl(C_8H_{14})_2]_2$ (**1**)[17] and the propargylic alcohol $HC{\equiv}CCPh_2OH$[18] were prepared as described in the literature. The other alkynes were commercial products from ABCR and Aldrich. − IR: Perkin-Elmer 1420. − NMR: Bruker AC 200 and AMX 400 [dvt = doublet of virtual triplets; $N = {}^3J(PH) + {}^5J(PH)$ or ${}^2J(PC) + {}^4J(PC)$, respectively]. − Conductivity measurements in nitromethane with a Schott Konduktometer CG 851. − Melting and decomposition points determined by DTA.

1. Preparation of *cis*-[Rh(O=CMe_2)$_2$(C_8H_{14})$_2$]PF_6 (2): A suspension of 404 mg (0.56 mmol) of **1** in 30 mL of acetone was treated dropwise at 0°C with a solution of 276 mg (1.09 mmol) of $AgPF_6$ in 2 mL of acetone. Under continuous stirring the reaction mixture was slowly warmed to room temp. (ca. 20 min) and after it was stored for 1 h the solution was filtered. The filtrate was concentrated to ca. 5 mL in vacuo and 20 mL of diethyl ether was added. A yellow microcrystalline solid precipitated which was separated from the mother liquor, washed three times with 2-mL portions of diethyl ether and dried; yield 471 mg (74%); dec. temp. 58°C; Λ = 80 $cm^2\Omega^{-1}mol^{-1}$. − ^1H NMR (200 MHz, CD_3NO_2): δ = 2.97 (m, 4 H, =CH of C_8H_{14}), 2.42 (s, 12 H, O=CMe_2), 2.25, 1.62, 1.42 (all m, 24 H, CH_2 of C_8H_{14}). − $C_{22}H_{40}F_6O_2PRh$ (584.4): calcd. C 45.21, H 6.90; found C 44.98, H 6.61.

2. Preparation of *cis*-[Rh(O=CMe_2)$_2$($PiPr_3$)$_2$]PF_6 (3): A suspension of 90 mg (0.15 mmol) of **2** in 10 mL of diethyl ether/acetone (9:1) was treated at −78°C with 62 μL (0.31 mmol) of P*i*Pr_3. Under continuous stirring the reaction mixture was slowly warmed to room temp. (ca. 30 min) which led to a change of color from yellow to dark violet. Moreover, a small amount of a violet solid precipitated. The solution was concentrated to ca. 1 mL in vacuo and then 10 mL of diethyl ether was added. After the mixture was stored for 2 h, the violet precipitate was separated from the mother liquor, washed three times with 2-mL portions of diethyl ether and dried; yield 103 mg (98%); dec. temp. 83°C; Λ = 110 $cm^2\Omega^{-1}mol^{-1}$. − IR (CH_2Cl_2): $\tilde{\nu}$ = 1705, 1653 cm^{-1} (C=O). − ^1H NMR (200 MHz, $(CD_3)_2CO$): δ = 2.08 (s, 12 H, O=CMe_2), 2.03 (m, 6 H, PC*H*CH_3), 1.40 [dd, J(PH) = 13.1, J(HH) = 7.3 Hz, 36 H, PCHC*H*$_3$]. − ^{31}P NMR (81.0 MHz, $(CD_3)_2CO$): δ = 60.3 [d, J(RhP) = 204.9 Hz]. − $C_{24}H_{54}F_6O_2P_3Rh$ (684.5): calcd. C 42.11, H 7.95; found C 42.62, H 7.84.

3. Preparation of *trans*-[Rh(O=CMe_2)(MeC≡CPh)($PiPr_3$)$_2$]PF_6 (4): A suspension of 103 mg (0.15 mmol) of **3** in 10 mL of diethyl ether/acetone (9:1) was treated at −78°C with 19 μL (0.15 mmol) of MeC≡CPh. After the reaction mixture was slowly warmed to room temp. (ca. 30 min), it was worked up analogously as described for **3**. Orange microcrystalline solid; yield 84 mg (75%); dec. temp. 44°C; Λ = 77 $cm^2\Omega^{-1}mol^{-1}$. − IR (CH_2Cl_2): $\tilde{\nu}$ = 1885 (C≡C), 1707 cm^{-1} (C=O). − ^1H NMR (400 MHz, $(CD_3)_2CO$): δ = 7.68 (m, 5 H, C_6H_5), 2.50 (br. s, 3 H, ≡CMe), 2.08 (s, 6 H, O=CMe_2), 1.94 (m, 6 H, PC*H*CH_3), 1.37 [dvt, N = 13.5, J(HH) = 7.0 Hz, 18 H, PCHC*H*$_3$], 1.12 [dvt, N = 13.1, J(HH) = 6.8 Hz, 18 H, PCHC*H*$_3$]. − ^{13}C NMR (100.6 MHz, $(CD_3)_2CO$): δ = 206.2 (s, O=*C*Me_2), 130.9, 129.1, 128.8, 127.7 (all s, C_6H_5), 75.0 (br. m, ≡*C*Ph), 64.5 (br. m, ≡*C*Me), 30.4 (s, O=C*C*H_3), 23.5 (vt, N = 17.7 Hz, P*C*HCH_3), 20.8, 19.6 (both s, PCH*C*H_3), 13.2 (s, ≡C*C*H_3). − ^{31}P NMR (81.0 MHz, $(CD_3)_2CO$): δ = 33.9 [d, J(RhP) = 116.3 Hz]. − $C_{30}H_{56}F_6OP_3Rh$ (742.6): calcd. C 48.52, H 7.60; found C 48.42, H 7.33.

4. Preparation of *trans*-[Rh(O=CMe_2)(=C=CHC_6H_4−4-Me)($PiPr_3$)$_2$]PF_6 (5): A suspension of 103 mg (0.15 mmol) of **3** in 10 mL of diethyl ether/acetone (9:1) was treated at −78°C with 19 μL (0.15 mmol) of $HC{\equiv}CC_6H_4$−4-Me. A rapid change of color from violet to orange occurred which after ca. 5 min was followed by a reverse change of color from orange to violet. Upon continuous stirring a violet solid precipitated. The reaction mixture was slowly warmed to room temp. (ca. 30 min), and after it was stirred for 8 h the solvent was removed in vacuo. The residue was dissolved in 1 mL of acetone and 20 mL of diethyl ether was added to the

solution. Violet crystals were formed which were washed three times with 2-mL portions of diethyl ether and dried; yield 106 mg (95%); dec. temp. 98°C; Λ = 92 $cm^2\Omega^{-1}mol^{-1}$. – ^1H NMR [400 MHz, $(CD_3)_2CO$]: δ = 6.65 (m, 4 H, C_6H_4), 2.46 (m, 6 H, PC*H*CH_3), 2.30 (s, 3 H, C_6H_4C*H*$_3$), 2.08 (s, 6 H, O=CMe_2), 1.38 [dvt, *N* = 14.0, *J*(HH) = 7.0 Hz, 36 H, PCHC*H*$_3$]; signal of =CH proton probably covered by signal of PCHC*H*$_3$ protons. – ^{13}C NMR [100.6 MHz, $(CD_3)_2CO$]: δ = 309.3 [dt, *J*(RhC) = 61.4, *J*(PC) = 17.6 Hz, Rh=C], 206.3 (s, O=*C*Me_2), 136.2, 129.8, 126.8, 120.6 (all s, C_6H_4), 113.3 [dt, *J*(RhC) = 16.1, *J*(PC) = 6.0 Hz, =CH], 30.3 (s, O=C*C*H_3), 24.3 (vt, *N* = 20.9 Hz, P*C*HCH_3), 20.8 (s, C_6H_4*C*H_3), 20.1 (s, PCH*C*H_3). – ^{31}P NMR (162.0 MHz, $(CD_3)_2CO$): δ = 42.5 [d, *J*(RhP) = 135.1 Hz]. – $C_{30}H_{56}F_6OP_3Rh$ (742.6): calcd. C 48.52, H 7.60; found C 48.56, H 7.62.

5. Generation of *trans*-[Rh(O=CMe_2)(=C=CHCPh_2OH)-($PiPr_3$)$_2$]PF_6 (6): A suspension of 103 mg (0.15 mmol) of **3** in 10 mL of diethyl ether/acetone (9:1) was treated at −78°C with 31 mg (0.15 mmol) of HC≡CCPh_2OH. A rapid change of color from violet to orange occurred. After the solution was stirred for 2 min and then warmed to 0°C, it was concentrated to ca. 1 mL in vacuo. Upon dropwise addition of diethyl ether and subsequently of pentane (ca. 10 mL) an orange-red solid precipitated which was separated from the mother liquor, washed three times with 2-mL portions of diethyl ether, then with 2 mL of pentane, and dried. The ^1H- and ^{31}P-NMR spectra revealed that besides **6** also compound **7** was formed. – IR (CH_2Cl_2): $\tilde{\nu}$ = 3410 (OH), 1642 cm^{-1} (C=C). – ^1H NMR [400 MHz, $(CD_3)_2CO$]: δ = 7.57 (m, 10 H, C_6H_5), 3.05 (br. s, 1 H, OH), 2.41 (m, 6 H, PC*H*CH_3), 2.08 (s, 6 H, O=CMe_2), 1.30 [dvt, *N* = 13.9, *J*(HH) = 6.8 Hz, 36 H, PCHC*H*$_3$]; signal of =CH proton probably covered by signal of PCHC*H*$_3$ protons. – ^{13}C NMR [100.6 MHz, $(CD_3)_2CO$]: δ = 206.3 (s, O=*C*Me_2), 130.2, 128.4, 125.9 (all s, C_6H_5), 117.8 [dt, *J*(RhC) = 17.1, *J*(PC) = 6.0 Hz, =CH], 72.0 (s, *C*Ph_2OH), 30.2 (s, O=C*C*H_3), 23.9 (vt, *N* = 20.7 Hz, P*C*HCH_3), 19.8 (s, PCH*C*H_3); signal of Rh=C not exactly located. – ^{31}P NMR [162.0 MHz, $(CD_3)_2CO$]: δ = 42.3 [d, *J*(RhP) = 135.9 Hz].

6. Preparation of *trans*-[Rh(O=CMe_2)(=C=C=CPh_2)($PiPr_3$)$_2$]PF_6 (7): A suspension of 103 mg (0.15 mmol) of **3** in 10 mL of diethyl ether/acetone (9:1) was treated at −78°C with 31 mg (0.15 mmol) of HC≡CCPh_2OH, and upon warming to room temp. was stirred for 15 h. The solvent was removed, the residue was dissolved in 1 mL of acetone and the solution was layered with 20 mL of diethyl ether. Orange crystals were formed which were separated from the mother liquor, washed three times with 2-mL portions of diethyl ether, once with 2 mL of pentane, and dried; yield 93 mg (76%); dec. temp. 62°C; Λ = 87 $cm^2\Omega^{-1}mol^{-1}$. – IR (KBr): $\tilde{\nu}$ = 1873 cm^{-1} (C=C=C). – ^1H NMR [400 MHz, $(CD_3)_2CO$]: δ = 7.73 (m, 10 H, C_6H_5), 2.49 (m, 6 H, PC*H*CH_3), 2.18 (s, 6 H, O=CMe_2), 1.41 [dvt, *N* = 13.8, *J*(HH) = 7.1 Hz, 36 H, PCHC*H*$_3$]. – ^{13}C NMR [100.6 MHz, $(CD_3)_2CO$]: δ = 206.3 (s, O=*C*Me_2), 150.8 (s, Rh=C=C=*C*), 130.5, 130.3, 126.5 (all s, C_6H_5), 30.2 (s, O=C*C*H_3), 24.8 (vt, *N* = 20.6, P*C*HCH_3), 20.0 (s, PCH*C*H_3); signals of α- and β-carbon atoms of Rh=C=C=C unit not exactly located. – ^{31}P NMR [162.0 MHz, $(CD_3)_2CO$]: δ = 41.8 [d, *J*(RhP) = 132.7 Hz]. – $C_{36}H_{58}F_6OP_3Rh$ (816.7): calcd. C 52.94, H 7.16, Rh 12.60; found C 52.51, H 6.87, Rh 13.00.

7. Preparation of *trans*-[Rh(=C=CHC$_6$H$_4$−4-Me)(py)($PiPr_3$)$_2$]PF_6 (8): A suspension of 111 mg (0.15 mmol) of **5** in 10 mL of diethyl ether was treated at −78°C with an excess (ca. 0.5 mL) of pyridine which led to the precipitation of a red-violet solid. After the reaction mixture was warmed under continuous stirring to room temp. (ca. 30 min), it was stored for 1 h. The red-violet solid was separated from the mother liquor, washed three times with 2-mL portions of diethyl ether and dried; yield 86 mg (91%); dec. temp. 96°C. – ^1H NMR (200 MHz, CD_3NO_2): δ = 8.03 (m, 5 H, NC_5H_5), 6.63 (m, 4 H, C_6H_4), 2.42 (m, 6 H, PC*H*CH_3), 2.28 (s, 3 H, C_6H_4C*H*$_3$), 1.39 [dvt, *N* = 14.0, *J*(HH) = 7.0 Hz, 36 H, PCHC*H*$_3$]; signal of =CH proton probably covered by signal of PCHC*H*$_3$ protons. – ^{13}C NMR (50.3 MHz, CD_3NO_2): δ = 309.2 [dt, *J*(RhC) = 61.2, *J*(PC) = 17.4 Hz, Rh=C], 151.8, 140.5, 136.2, 129.7, 127.3, 126.8, 121.5 (all s, NC_5H_5 and C_6H_4), 114.3 [dt, *J*(RhC) = 16.0, *J*(PC) = 6.1 Hz, =CH], 24.6 (vt, *N* = 20.9 Hz, P*C*HCH_3), 21.1 (s, C_6H_4*C*H_3), 20.1 (s, PCH*C*H_3). – ^{31}P NMR [162.0 MHz, $(CD_3)_2CO$]: δ = 40.3 [d, *J*(RhP) = 134.9 Hz]. $C_{32}H_{55}F_6NP_3Rh$ (763.6): calcd. C 50.33, H 7.62, N 1.83; found C 49.56, H 7.62, N 1.50.

8. Preparation of *trans*-[Rh(=C=C=CPh_2)(py)($PiPr_3$)$_2$]PF_6 (9): Analogously as described for **8**, by using 123 mg (0.15 mmol) of **7** and ca. 0.5 mL of pyridine as starting materials. Red-violet solid; yield 109 mg (87%); dec. temp. 98°C. – IR (CH_2Cl_2): $\tilde{\nu}$ = 1916 cm^{-1} (C=C=C). – ^1H NMR (400 MHz, CD_3NO_2): δ = 8.38, 7.48, 7.27 (all m, 5 H, NC_5H_5), 7.92, 7.59, 7.37 (all m, 10 H, C_6H_5), 2.16 (m, 6 H, PC*H*CH_3), 1.24 [dvt, *N* = 13.7, *J*(HH) = 6.6 Hz, 36 H, PCHC*H*$_3$]. – ^{13}C NMR (100.6 MHz, CD_3NO_2): δ = 270.4 [dt, *J*(RhC) = 56.0, *J*(PC) = 19.0 Hz, Rh=C], 229.6 [dt, *J*(RhC) = 15.0, *J*(PC) = 9.0 Hz, Rh=C=*C*], 153.2, 140.3, 131.1, 129.7, 128.1, 127.3, 126.5 (all s, NC_5H_5 and C_6H_5), 150.9 (s, =*C*Ph_2), 26.4 (vt, *N* = 20.0 Hz, P*C*HCH_3), 20.5 (s, PCH*C*H_3). – ^{31}P NMR (162.0 MHz, CD_3NO_2): δ = 38.2 [d, *J*(RhP) = 134.0 Hz]. – $C_{38}H_{57}F_6NP_3Rh$ (837.7): calcd. C 54.99, H 6.86, N 1.67; found C 54.87, H 7.20, N 1.79.

9. Preparation of *trans*-[Rh(=C=C=CPh_2)(NH_3)($PiPr_3$)$_2$]PF_6 (10): A solution of 123 mg (0.15 mmol) of **7** in 10 mL of CH_2Cl_2 was treated at −20°C with 2.8 mL of a 0.55 M solution of NH_4OH (0.15 mmol) in water. The solution was slowly warmed to room temp. and, after it was continuously stirred for 1 h, concentrated to ca. 1 mL in vacuo. The solution was then layered with 10 mL of diethyl ether and upon storing for 6 h at room temp. red crystals were formed. The crystals were separated from the mother liquor, washed three times with 2-mL portions of diethyl ether and pentane and dried; yield 116 mg (85%); dec. temp. 134°C. – IR (CH_2Cl_2): $\tilde{\nu}$ = 1905 cm^{-1} (C=C=C). – ^1H NMR (400 MHz, CD_3NO_2): δ = 7.89, 7.31 (both m, 10 H, C_6H_5), 2.52 (m, 6 H, PC*H*CH_3), 1.32 [dvt, *N* = 13.4, *J*(HH) = 6.7 Hz, 36 H, PCHC*H*$_3$]. – ^{13}C NMR (100.6 MHz, CD_3NO_2): δ = 269.1 (br. m, Rh=C), 230.5 [dt, *J*(RhC) = 19.0 *J*(PC) = 7.0 Hz, Rh=C=*C*], 151.8 (s, =*C*Ph_2), 152.4, 130.7, 130.1, 127.0 (all s, C_6H_5), 25.5 (vt, *N* = 20.0 Hz, P*C*HCH_3), 20.4 (s, PCH*C*H_3). – ^{31}P NMR (162.0 MHz, CD_3NO_2): δ = 41.6 [*J*(RhP) = 131.0 Hz]. – $C_{33}H_{55}F_6NP_3Rh$ (775.6): calcd. C 51.10, H 7.15, N 1.81; found C 50.87, H 7.12, N 1.78.

10. Preparation of *trans*-[Rh(OAc)(=C=C=CPh_2)($PiPr_3$)$_2$] (11): A suspension of 123 mg (0.15 mmol) of **7** in 10 mL of diethyl ether/acetone (9:1) was treated at −78°C with 12 mg (0.15 mmol) of sodium acetate. A rapid change of color from deep orange to green occurred. Under continuous stirring the reaction mixture was warmed to room temp. and then brought to dryness in vacuo. The residue was extracted with 20 mL of diethyl ether, and the solvent was removed from the extract. The residue was dissolved in 2 mL of acetone and the solution was stored at −20°C for 8 h. Green crystals were formed which were separated from the mother liqour, washed three times with 2-mL portions of acetone (−20°C) and dried; yield 82 mg (81%). Compound **11** was identified by comparison of the IR and NMR data with those of an authentic sample.[2b][19]

11. Preparation of *trans*-[Rh(OH)(=C=C=CPh$_2$)(PiPr$_3$)$_2$] (12): Analogously as described for **11**, by using 123 mg (0.15 mmol) of **7** and 8 mg (0.15 mmol) of KOH as starting materials. Green solid; yield 76 mg (79%). Compound **12** was identified by comparison of the IR and NMR data with those of an authentic sample.[2b][19]

12. Determination of the X-ray Crystal Structure of 7:[20] Single crystals were grown from acetone/diethyl ether at room temp. Crystal data (from 23 reflections, $10° < \Theta < 13°$): triclinic; space group P-1 (No. 2); a = 9.074(6), b = 14.42(1), c = 16.16(1) Å, α = 85.50(5), β = 87.16(5), γ = 77.61(5)°; V = 2057(3) Å^3, Z = 2; $d_{calcd.}$ = 1.32 gcm^{-3}; μ(Mo-K_α) = 5.7 cm^{-1}; crystal size 0.15 × 0.15 × 0.40 mm; Enraf-Nonius CAD-4 diffractometer, Mo-K_α radiation (λ = 0.71073 Å), graphite monochromator, zirconium filter (factor 16.4); T = 293(1) K; ω/Θ-scan, max. 2Θ = 48°; 6904 reflections measured, 6442 independent ($R_{int.}$ = 0.0091), 5779 with $F_o > 2\sigma(F_o)$. Intensity data were corrected for Lorentz and polarization effects and an empirical absorption correction (Ψ-scan method) was applied (min. transmission 96.1%). The structure was solved by direct methods (SHELXS-86).[21] Atomic coordinates and the anisotropic thermal parameters of non-hydrogen atoms were refined by full-matrix least squares on F^2 (SHELXS-93).[22] The PF_6^- anion is disordered. The positions of 18 fluorine atoms (3 × 6) could be located around the central phosphorus atom P3 and refined anisotropically with a weighting factor of 1/3. The positions of all hydrogen atoms could be located in a final difference Fourier synthesis and refined isotropically. Conventional R = 0.0216 [for 5779 reflections with $F_o > 2\sigma(F_o)$], and weighted wR_2 = 0.0612 for all 6442 located reflections; reflection/parameter ratio 10.1; residual electron density +0.20/-0.27 eÅ^{-3}.

Acknowledgments

This work was supported by the Deutsche Forschungsgemeinschaft (SFB 347) and the Fonds der Chemischen Industrie (Promotionsstipendium to O. N.). We are grateful to Mrs. R. Schedl and Mr. C. P. Kneis for performing the elemental analyses and DTA measurements, to Dr. B. Stempfle and Dr. W. Buchner for NMR spectra, and in particular to Mrs. A. Spenkuch for valuable technical assistance. Degussa AG generously supported this work by gifts of chemicals.

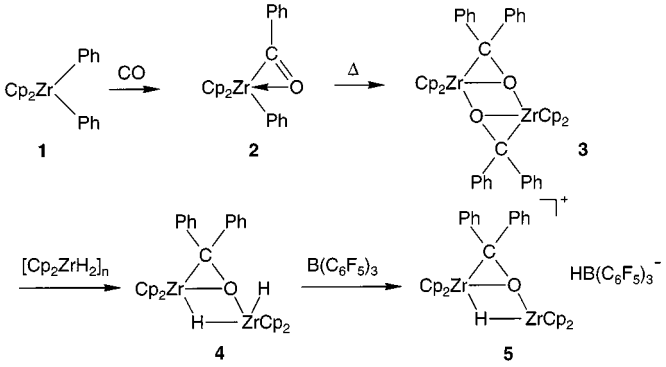
Syntheses and Insertion Reactions of (η^2-Aldehyde)zirconocene-Supported (Hydrido)zirconocene Cation Systems

Ulrich Blaschke,[a] Frederik Menges,[a] Gerhard Erker,*[a] and Roland Fröhlich[a]

Keywords: (η^2-Aldehyde)zirconocene complexes / Metallaoxirane-stabilized group 4 metallocene hydride cations / Nitrile insertion / Isocyanate insertion



Treatment of the $[Cp_2Zr(\eta^2\text{-acetaldehyde})/H(CH_3)ZrCp_2]$ adduct **8** with $B(C_6F_5)_3$ yields the dimetallabicyclic salt $[Cp_2Zr(\mu\text{-}\eta^1\text{-}O{:}\eta^2\text{-}C,O\text{-}OCHMe)(\mu\text{-}H)(ZrCp_2)]^+[CH_3B(C_6F_5)_3]^-$ **18b**. Similarly, hydride abstraction from the related neutral dimetallabicyclic $[Cp_2Zr(OCHR)/H_2ZrCp_2]$ adducts **11** (R = CH_3) or **14** (R = C_2H_5) with $B(C_6F_5)_3$ yields the systems $[Cp_2Zr(\mu\text{-}\eta^1\text{-}O{:}\eta^2\text{-}C,O\text{-}OCHR)(\mu\text{-}H)(ZrCp_2)]^+[HB(C_6F_5)_3]^-$ (**18a**, **c**) and the reaction of $B(C_6F_5)_3$ with $[Cp_2Zr(OCHCH_2Ph)/H(PhCH_2)ZrCp_2)]^+$ **17** gives $[Cp_2Zr(\mu\text{-}\eta^1\text{-}O{:}\eta^2\text{-}C,O\text{-}(OCHCH_2Ph)(\mu\text{-}H)ZrCp_2]^+[PhCH_2B(C_6F_5)_3]^-$ **18d**. A variety of nitriles $R^2\text{–}C{\equiv}N$ (R = CH_3, CMe_3, *p*-tolyl, or ethyl) cleanly reacts with the cations **18** by addition of the $Zr_2(\mu\text{-}H)$ moiety to the nitrile functionality to yield the respective aldiminium-bridged cations $[Cp_2Zr(\mu\text{-}\eta^1\text{-}O{:}\eta^2\text{-}C,O\text{-}(OCHR^1)(\mu\text{-}N{=}CHR^2)\text{-}ZrCp_2]^+$ (**21**–**24**). Complex **24d** (R^1 = $PhCH_2$, R^2 = C_2H_5) was characterized by an X-ray crystal structure analysis. Similarly, treatment of the systems **18a**–**d** with isocyanates RN=C=O (R = CMe_3, $SiMe_3$, *p*-tolyl, or adamantyl) gave the related μ-formamidato complexes **27**–**30**.

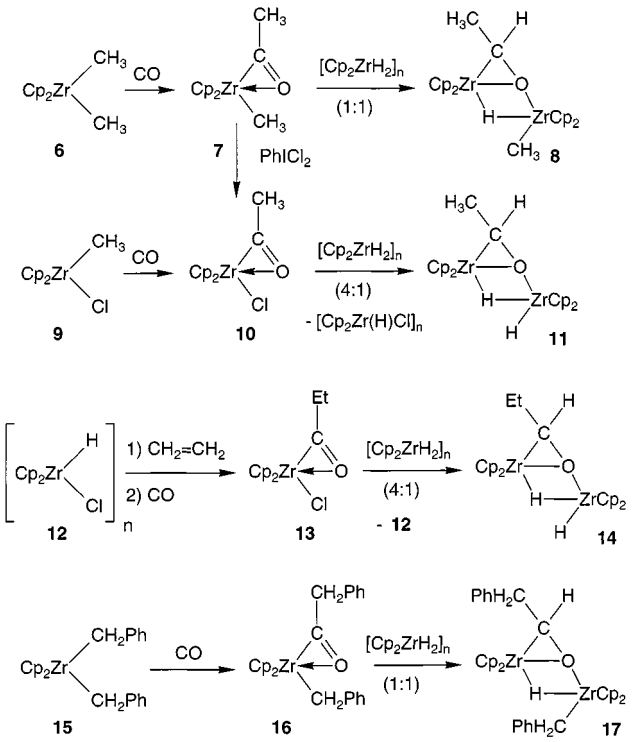
Introduction

It has been shown that (η^2-ketone)- and (η^2-aldehyde)zirconocene complexes structurally and chemically behave as metallaoxiranes.[1] The three-membered metallacycles have a tendency of binding a variety of reactive organometallic species in a specific way by using the nucleophilic character of the metallaoxirane oxygen atom and the strongly electrophilic group 4 metal center in combination. In this way the metallaoxirane template may behave like a molecular metal-oxide model.[2] It has, for instance, been used to bind and stabilize the Cp_2ZrH_2 moiety,[3] that is not persistent as a monomer in solution.[4] The reactivity of the metallaoxirane-template stabilized zirconocene dihydride towards carbon monoxide has been used to devise molecular Fischer–Tropsch models.[5]

Recently we have succeeded in generating a (hydrido)zirconocene cation at a (η^2-diarylketone)zirconocene template.[6] The monomeric $[Cp_2ZrH]^+$ cation is probably an elusive species in solution; but stabilized at this specific metallaoxirane matrix it can readily be generated, characterized and handled. The $[Cp_2Zr(OCPh_2)/(Cp_2Zr{-}H)]^+$ adduct (see Scheme 1) even reacts with ethene to form polyethylene.[6][7]

Unfortunately, we have not been able to experimentally observe and characterize any intermediate insertion products starting from the system **5** so far. Therefore, we have begun to prepare a variety of similarly structured (hydrido)-zirconocene cation systems that are bonded to and stabilized by similar metallaoxirane template frameworks that bear less bulky and sterically demanding substituents at the organometallic three-membered ring. We have succeeded to obtain a number of such systems derived from differently substituted (η^2-aldehyde)zirconocene complexes, and in these cases it was possible to form stable monomeric insertion products by treatment with nitriles and with isocyanates. A series of examples is described in this article.

Scheme 1



Results and Discussion

Preparation of the (η^2-Aldehyde)zirconocene-Stabilized (Hydrido)zirconocene Cation Systems

Starting materials for the preparation of the $[(\eta^2\text{-aldehyde})ZrCp_2/Cp_2ZrH]^+$ complexes investigated in the course of this study were several neutral metallaoxirane adducts of Cp_2ZrH_2 and of $Cp_2Zr(H)R$ complexes. Three different metallaoxirane templates were used, namely (η^2-acetaldehyde)-, (η^2-propionaldehyde)-, and (η^2-phenylacetaldehyde)zirconocene. The starting materials for the preparation of the dinuclear $[(\mu\text{-}\eta^1\text{-}O{:}\eta^2\text{-}C,O\text{-aldehyde})(\mu\text{-}H)(ZrCp_2)_2]^+$ cations were synthesized as follows (see also Scheme 2).

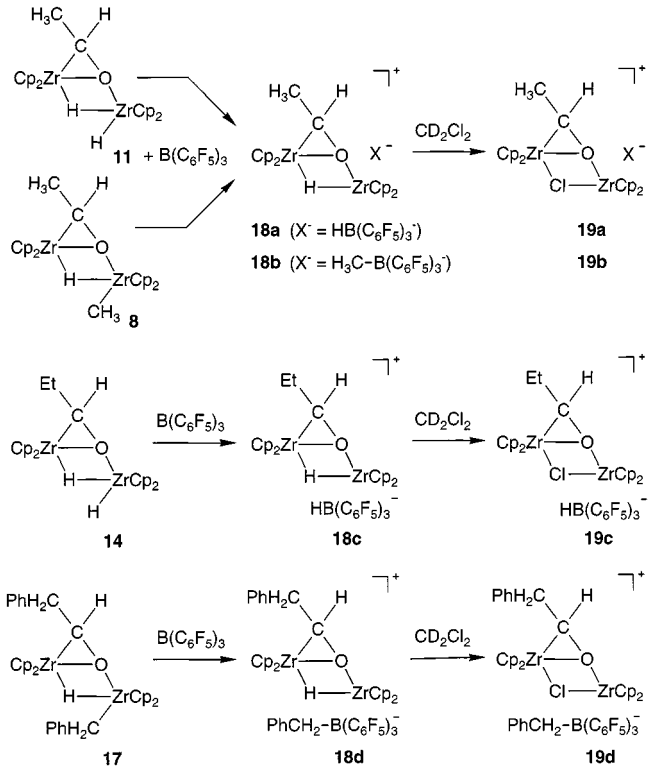
Scheme 2

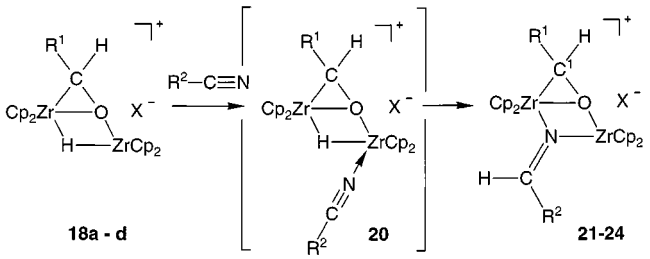
As previously described by us,[8] the $[Cp_2Zr(OCHMe)/Cp_2Zr(H)Me]$ adduct **8** was prepared by Cp_2ZrH_2 addition to (η^2-acetyl)methyl zirconocene (**7**). The corresponding $[Cp_2Zr(OCHMe)/Cp_2ZrH_2]$ adduct (**11**) was prepared by treatment of (η^2-acetyl)zirconocene chloride (**10**) with excess $[Cp_2ZrH_2]_n$ (4:1 ratio). Under these optimized literature conditions[8] hydride addition to the (η^2-acyl)metallocene moiety is observed and a subsequent chloride vs. hydride exchange reaction is effectively achieved (for details see the Experimental Section). The $[Cp_2Zr(OCHEt)/Cp_2ZrH_2]$ adduct (**14**) was prepared analogously. We have used as an additional starting material the [Cp_2Zr(OCH-benzyl)/Cp_2Zr(H)benzyl] adduct (**17**) that to our knowledge was prepared here for the first time. The reaction sequence employed started from dibenzylzirconocene (**15**). Carbonylation yields the (η^2-phenylacetyl)benzylzirconocene complex **16**. Addition of a stoichiometric quantity of dihydridozirconocene (employed as the oligomeric $[Cp_2ZrH_2]_n$ reagent[4]) then furnished the dinuclear (μ-hydrido)bis(zirconocene) complex **17**.



Complex **11** was treated with the organometallic Lewis acid tris(pentafluorophenyl)borane[9] in toluene solution. The reaction between the zirconium hydride and $B(C_6F_5)_3$ takes place instantaneously under these conditions at ambient temperature. The product separates from the solution as a dark colored oil. It dissolves in a [D_8]THF/[D_6]benzene mixture and can thus be characterized spectroscopically. The reaction between **11** and $B(C_6F_5)_3$ has led to abstraction[10] of the terminal hydride ligand at zirconium with formation of the adduct salt $[Cp_2Zr(OCHMe)/Cp_2ZrH]^+[HB(C_6F_5)_3]^-$ (**18a**). The borohydride anion is characterized by its ^{11}B-NMR doublet at δ −24.6 ($^1J_{BH}$ = 82 Hz). The ^{1}H-NMR spectrum of the cation of **18a** shows only a single residual hydride resonance (at δ −1.79) that is very typical of a hydride ligand bridging between two zirconium atoms[11] [see for a comparison: ^{1}H NMR of the bis(zirconocene)dihydride complex **11**: δ 4.32 (terminal Zr−H), δ −1.51 (μ-H), $^2J_{HH}$ = 13.9 Hz].[8] In the complex **18a** the metallaoxirane framework is still intact [^{1}H-NMR signals at δ 3.69 (q, 1 H), 1.48 (d, 3 H, $^3J_{HH}$ = 6.3 Hz); ^{13}C-NMR signals at δ 90.1 (C^1H) and 23.7 (C^1-CH_3)], and both bent metallocene units show diastereotopic splitting of their pairs of Cp-resonances (^{13}C NMR: δ 112.4, 112.1, 106.7, 106.6) due to the adjacent metallaoxirane chirality center (C^1HMeO[Zr]). These NMR features indicate that the chiral dimetallabicyclic framework has remained intact upon treatment of **11** with $B(C_6F_5)_3$. We conclude that this reaction has cleanly resulted in abstraction of the terminal hydride ligand at zirconium by the boron Lewis acid with formation of the dimetallic (η^2-acetaldehyde)zirconocene-template stabilized (hydrido)zirconocene cation complex **18a** (see Scheme 3). Complex **18a** can be dissolved in a halogenated solvent such as [D_2]dichloromethane at low temperature. Its NMR spectra could be recorded at 243 K, but a rather selective reaction with this solvent took place at temperatures above 255 K to replace the μ-hydride ligand by chloride from the solvent to generate **19a**. Surprisingly, dideuteromethane (CD_2H_2) was the only organic product that was detected ^{1}H-NMR spectroscopically (quintett at δ 0.17). The mechanism of this apparently selective double chloride vs. hydride exchange remains to be clarified. An analogous series of reactions was observed upon treatment of the [(η^2-propanal)$ZrCp_2$/H_2ZrCp_2] adduct **14** with $B(C_6F_5)_3$ to yield the cations **18c** and **19c**, subsequently (see Scheme 3).

The salt **18b** was prepared by treatment of **8** with $B(C_6F_5)_3$. In this case, the terminal methyl ligand at the "south-east" zirconocene moiety is selectively removed. The same cation (i.e. $[Cp_2Zr(OCHMe)/Cp_2ZrH]^+$) is obtained from the reaction of **11** with $B(C_6F_5)_3$, only that **18b** contains the $[CH_3B(C_6F_5)_3]^-$ counteranion. Its formation is evident from the respective ^{1}H-NMR (δ 1.03, CH_3B) and ^{11}B-NMR signals (singlet at δ −14.5). The remaining signals of **18a** and **18b** must be considered equivalent, taking into account the pronounced sensitivity of the actual NMR chemical shifts of this charged metallocene system to small changes in solvent polarity (for details see the Experimental Section).

Similarly, treatment of the dinuclear benzyl-substituted metallocene hydride complex **17** with $B(C_6F_5)_3$ results in selective transfer of the σ-benzylligand from zirconium to boron to yield **18d**. Exposure to CD_2Cl_2 at 265 K also leads to H^- vs. Cl^- exchange to generate **19d** and CD_2H_2 (see Scheme 3).



Reaction of the $[Cp_2Zr(OCHR)/Cp_2ZrH]^+$ Cations with Nitriles

The [(μ-acetaldehyde)(μ-hydrido)bis(zirconocene)]$^+$ cation [**18a**, with $HB(C_6F_5)_3^-$ anion] reacts readily with added

Scheme 3

acetonitrile.[12][13] Usually the reaction was carried out by treating a suspension of e.g. **18a** in toluene with $CH_3-C\equiv N$. The addition reaction takes place very rapidly in the two-phase system. After ca. five minutes the oil, that remains separated from the toluene solution, is collected and is shown to consist of the product **21a**. The $HB(C_6F_5)_3^-$ anion is not affected by the treatment with acetonitrile. The cation of **18a** has added its hydride to the acetonitrile $-C\equiv N$ carbon atom with formation of a dimetallated acetaldiminium moiety.[14] In **21a** the iminium nitrogen atom bridges between the two zirconium centers. This leads to the formation of a dimetallabicyclic framework, part of which is the intact (μ-η^1-O:η^2-C,O-acetaldehyde)metallocene template. Consequently, complex **21a** exhibits the typical NMR signals of the metallaoxirane moiety [^{1}H NMR in a [D_8]THF/[D_6]benzene mixture: δ 3.65 (q, 1 H), 1.52 (d, 3 H), $^3J_{HH}$ = 6.1 Hz; ^{13}C NMR: δ 88.5 (C^1-H), 23.9 (C^1-CH_3)]. The presence of the chiral center (C^1) inside the metallaoxirane ring systems results in the observation of the NMR signals of two pairs of diastereotopic Cp ligands at the zirconium centers in complex **21a** (^{13}C NMR in [D_8]THF/[D_6]benzene: δ 113.6, 113.5, 108.8, 108.7). The bridging acetaldiminium moiety shows very typical NMR features; the *H*(Me)*C*=N ^{1}H-/^{13}C-NMR resonances are located at δ 8.67 (^{1}H; q, $^3J_{HH}$ = 4.7 Hz) and δ 187.2 (^{13}C). At such a structural framework two geometrical isomers could in principle be formed that are characterized by having the aldiminium alkyl substituent oriented (*Z*) or (*E*) relative to the metallaoxirane zirconium center. Treatment of **18a** with acetonitrile yielded only a single isomer. In view of an X-ray crystal structure of a related example (see below) we tentatively assign to it the structure of the (*E*)-isomer (see Scheme 4).

R^1	X^-	R^2	CH_3	CMe_3	p-tolyl	Et
CH_3	$HB(C_6F_5)_3^-$	**21**	**a**	**b**	**c**	-
CH_3	$MeB(C_6F_5)_3^-$	**22**	**a**	**b**	**c**	**d**
Et	$HB(C_6F_5)_3^-$	**23**	**a**	**b**	**c**	-
$PhCH_2$	$PhCH_2B(C_6F_5)_3^-$	**24**	**a**	**b**	**c**	**d**

Scheme 4

We have treated most of the complexes **18a−d** (see Scheme 3) with the nitrile reagents R−C≡N with R groups being methyl, ethyl, *tert*-butyl, or *p*-tolyl. In each case a clean 1:1 addition reaction with formation of the respective [(μ-aldiminium)bis(zirconocene)]$^+$ cation complexes (**21−24**) was observed. In each of these cases single isomerically pure products were obtained, that always contained the intact respective metallaoxirane moieties as a part of the dimetallabicyclic framework. Single crystals were obtained of the propionitrile addition product to **18d**. The [(μ-phenylacetaldehyde)(μ-propionaldiminium)bis(zirconocene)]$^+$ cation complex **24d** was characterized by X-ray diffraction. In the crystal there is an enantiomeric disorder at C1 (for details see the Experimental Section). The X-ray crystal structure analysis of complex **24d** shows the presence of a planar dimetallabicyclic framework of the cation. Both zirconium atoms, the C−O part of the μ-aldehyde ligand and the N=CH(R) core are located in the central molecular plane. The (η^2-aldehyde)zirconocene moiety exhibits a very pronounced σ-complex character.[1a,15] Both the Zr1−C1 [2.228(20) Å] and the Zr1−O [2.26(10) Å] linkages are in the σ-bond range. The bond angles inside the Zr1−O−C1 three-membered ring are 71.8(9)° (O−C1−Zr1), 36.2(5)° (C1−Zr1−O) and 72.0(9)° (C1−O−Zr1) (see Figure 1). The C1−O bond length is 1.384(18) Å. The adjacent Zr2−O linkage is very short at 2.007(8) Å. The C1−O−Zr2 angle amounts to 168.7(13)° and Zr1−O−Zr2 angle is at a very typical value of 107.4(5)°. The aldiminium nitrogen bridges between the two zirconium centers [bond lengths Zr2−N 2.187(12) Å, Zr1−N 2.377(11) Å, angle Zr1−N−Zr2 96.7(5)°]. The coordination geometry around the iminium nitrogen atom is trigonally planar. The N−C41 double bond [1.235(19) Å][16] is almost symmetrically arranged in the σ-ligand plane between Zr1 and Zr2 [angles Zr2−N−C41 137.9(11)°, Zr1−N−C41 125.3(12)°], taking into account the rather different coordination environments at Zr2 [angle

O−Zr2−N: 82.2(4)°] and Zr1 [angle O−Zr1−N: 73.6(4)°].[14] Again, there is only a single geometric aldiminium isomer observed in the crystal. It is characterized by having the ethyl substituent ($C^{42}H_2-C^{43}H_3$) at the aldiminium N=C^{41} double bond placed in the (*E*)-orientation relative to the metallaoxirane zirconium center Zr1.

Figure 1. Reactions with Isocyanates

It is mechanistically feasible that an incoming unsaturated reagent may first coordinate to one of the zirconium atoms in the [(μ-aldehyde)(μ-hydride)bis zirconocene]$^+$ cations (**18**) to form an adduct. We assume that coordination probably occurs preferentially at the four-coordinate zirconium and not the five-coordinate zirconium center that is part of the metallaoxirane ring system. Thus, alkyl- or arylnitrile coordination to **18** would be expected to preferentially lead to the reactive intermediate **20** (see Scheme 4). Subsequent hydride shift to the nitrile carbon atom of the activated R−C≡N reagent would in this case directly result in the formation of the (*E*)-stereoisomeric insertion product type that is actually only observed experimentally. It is expected that other unsaturated reagents may follow a similar course when treated with the dinuclear group 4 metallocene hydrido cations **18**. This was in fact observed when the complexes **18** were treated with a series of alkyl or aryl isocyanates RN=C=O (with R being *tert*-butyl, trimethylsilyl, *p*-tolyl, or adamantyl). In each case a single reaction product is formed that was isolated in high yield.

The reaction of **18a** with *tert*-butylisocyanate is a typical example. A single product (**27a**) is obtained, that was isolated as a pale yellow solid in 75% yield. The NMR spectra show that the metallaoxirane moiety inside the dimetallabicyclic framework is retained [^{1}H NMR: δ 3.41 (q, 1 H, C^1-H), 1.53 (d, 3 H, C^1-CH_3), $^3J_{HH}$ = 6.3 Hz; ^{13}C NMR: δ 85.8(C^1), 23.8 (C^1-CH_3)]. Consequently, the signals of two pairs of diastereotopic cyclopentadienyl ligands are registered (^{13}C NMR: δ 114.2, 114.0, 110.0, 109.5 in [D_8]THF/[D_6]benzene solution). The added isocyanate has selectively reacted with the zirconium hydride of the starting material to form a formamidate ligand [^{1}H/^{13}C NMR: δ 7.45/165.1 (O=CH−)].

Scheme 5

It is likely that the zirconium hydride addition reaction to the heterocumulene is also initiated by pre-coordination to the more electrophilic four-coordinate zirconium center in **18** (see Scheme 5). The *tert*-butylisocyanate addition to zirconium probably takes place preferentially by means of the heterocumulene oxygen (to generate **25**). Subsequent hydride addition to the sp-carbon atom of the activated RN=C=O reagent then may lead to the formation of the intermediate **26**. In view of the preferred 1,3-κ^2-bonding mode of many related mononuclear amidate or amidinate ligands at the group 4 metallocenes[18] subsequent stabilizing rearrangement of **26** to yield the final [(μ-amidate)bis(zirconocene)]$^+$ cation systems **27**−**30** must be assumed. Unfortunately, we have not been able to characterize any of the RN=C=O reaction products of **18** by X-ray diffraction. Therefore, we cannot definitively decide whether the isomers **27**−**30A** or **B** were formed in the reactions. In each of the examples listed in Scheme 5 a single differently substituted regioisomer of **27**−**30** was formed selectively. From the mechanistic course, preferred formation of the isomers **27**−**30A** would be expected, if the observed reactions are kinetically controlled.

Conclusions

Our study has shown that (η^2-aldehyde)zirconocene moieties are very well suited to serve as templates to accommodate the elusive Cp_2Zr-H^+ cation reagent. Selective σ-ligand abstraction from the readily available dinuclear $[Cp_2Zr(OCHR^1)/Cp_2Zr(H)R^2]$ (R^2 = alkyl or hydride) precursors provides a reliable synthetic entry to the $[Cp_2Zr(OCHR^1)/Cp_2ZrH]^+$ cation systems. The metallaoxirane template seems ideally suited to accommodate the (hydrido)zirconocene cation species since it contains both a strongly electrophilic zirconocene unit and a pronouncedly nucleophilic metallaoxirane oxygen center. This bifunctional characteristic probably results from the pronounced three-membered ring σ-complex properties of the (η^2-aldehyde)$ZrCp_2$ unit, which makes oxygen to zirconium π-backbonding extremely unfavorable.[19] What remains is the inductive effect of the group 16 element that serves to further decrease the electron deficiency at the formally 16 electron metallocene center of the metallaoxirane subunit.

Formal addition of the $[Cp_2Zr-H]^+$ unit to the bifunctional metallaoxirane 1,2-chelate serves to stabilize both the nucleophilic hydride and the electrophilic metallocene of the formally 14-electron cationic reagent. However, binding the (hydrido)metallocene cation to the bifunctional template preserves the principal reactivity pattern of the $[Cp_2Zr-H]^+$ reagent, only in a moderated form. This becomes evident from the course taken in the polar RC≡N or RN=C=O addition reactions, that still follow the typical reaction pattern expected for cationic zirconocene-hydride addition.[12][13] It is remarkable that the 1:1 addition reactions at the template adducts are taking place with very high regioselectivities. Although it is well known that (η^2-aldehyde)$ZrCp_2$ complexes can insert a variety of polar reagents into their zirconium-carbon σ-bond,[17][20] the reactions of the $[Cp_2Zr(OCHR)/Cp_2ZrH^+]$ template adducts selectively involve only the 1,2-coordinated zirconium hydride under the conditions applied in this study. Thus it seems that (η^2-ketone)- and (η^2-aldehyde)zirconocenes serve as very suitable templates for studying otherwise extremely reactive, or even elusive organometallic species, such as the $[Cp_2Zr-H]^+$ cation, stabilized by attachment to the metallaoxirane matrix and moderated in their reactivity, but not completely changed with regard to their typical reactivity pattern. We are hopeful that the favorable template effect of the group 4 metallaoxiranes can be used for accommodating and investigating the typical properties of a variety of other highly reactive organometallic species as well.

Experimental Section

General Information: All reactions were carried out under argon using Schlenk-type glassware or in a glovebox. Solvents, including deuterated solvents, were dried and distilled under argon prior to use. − The following instruments were used for spectroscopic and physical characterization of the compounds: Bruker AC 200P (^{1}H: 200.13, ^{13}C: 50.3 MHz, ^{11}B: 64.2 MHz), Bruker ARX 300 (^{19}F: 282.4 MHz), and Varian Unity Plus (^{1}H: 599.9, ^{13}C: 150.8 MHz) NMR spectrometers (assignments in the ^{1}H- and ^{13}C-NMR spectra were in some example cases confirmed through GCOSY, GHSQC, and GHMBC spectra[21]); Nicolet 5 DXC FT-IR spectrometer; melting points: DSC 2910 (Thermo Analysis/DuPont); elemental analyses: Foss-Heraeus CHN-Rapid. − Tris(pentafluorophenyl)-borane[9], $[Cp_2ZrH_2]_n$[4], $Cp_2ZrMeCl$ **8**[22], bis(η^5-cyclopentadienyl)(η^2-phenylacetyl)benzylzirconium **16**[23], μ-(η^1-O:η^2-C,O-acetaldehyde)-μ-hydrido[bis(η^5-cyclopentadienyl)hydridozirconium][bis(η^5-cyclopentadienyl)zirconium] **11**, μ-(η^1-O:η^2-C,O-acetaldehyde)-μ-hydrido[bis(η^5-cyclopentadienyl)methylzirconium][bis(η^5-cyclopentadienyl)zirconium] **8**, and μ-(η^1-O:η^2-C,O-propionaldehyde)-μ-hydrido[bis(η^5-cyclopentadienyl)hydridozirconium][bis(η^5-cyclopentadienyl)zirconium] **14**[8] were prepared according to literature procedures. In addition, $Cp_2Zr(COMe)Cl$ (**10**) used for the preparation of **8**, was synthesized according to the procedure reported below.

Preparation of Bis(η^5-cyclopentadienyl)(η^2-acetyl)zirconiumchloride (10): 3.15 g (11.6 mmol) of $Cp_2ZrMeCl$ **9** was loaded into a Schlenk tube and dissolved in 60 mL of toluene. Argon was removed by shortly evaporating the Schlenk tube and then the solution was exposed to carbon monoxide under rapid stirring at 0 °C. After two hours the yellow precipitate was isolated by filtration, twice washed with 10 mL of pentane and dried in vacuo, yield 2.60 g (75%).

Preparation of μ-(η^1-O:η^2-C,O-Phenylacetaldehyde)-μ-hydrido-[bis(η^5-cyclopentadienyl)benzylzirconium][bis(η^5-cyclopentadienyl)zirconium] (17): 1.77 g (4.10 mmol) of **16** and 0.90 g (4.03 mmol) of dihydridozirconocene were weighed in a Schlenk vessel, 100 mL of toluene was added and the suspension was stirred for 5 days at room temperature. From the resulting clear yellow solution all volatiles were removed in vacuo. The remaining yellow powder was suspended in 60 mL of a 5:1 mixture of pentane/toluene, the precipitate collected by filtration and washed three times with 20 mL of pentane. After drying in vacuo, **17** was obtained as a slightly yellow solid, yield 1.20 g (46%), mp 146 °C (DSC, decomp.). − $C_{35}H_{36}OZr_2$ (655.1): calcd. C 64.17, H 5.54, found C 62.51, H 5.49. − ^{1}H NMR (599.9 MHz, [D$_6$]benzene): δ = 7.39 (m, 4 H, *o, m*), 7.06 (pst, 1 H, *p*-Zr-CH_2Ph), 7.31 (pst, 2 H, *m*), 7.26 (psd, 2 H, *o*), 7.20 (pst, 1 H, *p*-$CHCH_2$Ph), 5.40, 5.38, 5.37, 5.26 (each s, each 5 H, Cp), 3.11 (dd, 1 H, $^2J_{HH}$ = 14.9 Hz, $^3J_{HH}$ = 3.4 Hz, CHCH_2), 2.83 (dd, 1 H, $^3J_{HH}$ = 9.9 Hz, $^3J_{HH}$ = 3.4 Hz, 1-H), 2.60 (d, 1 H, $^2J_{HH}$ = 9.7 Hz, Zr-CH_2), 2.41 (dd, 1 H, $^2J_{HH}$ = 14.9 Hz, $^3J_{HH}$ = 9.9 Hz, CHCH_2), 2.18 (d, 1 H, $^2J_{HH}$ = 9.7 Hz, Zr-CH_2), −0.61 (br., 1 H, μ-H). − ^{13}C NMR (150.8 MHz, [D$_6$]benzene): δ = 145.0, 128.8, 128.6, 126.0 (*ipso*, *m*, *o*, *p*-$CHCH_2$Ph), 155.2, 127.7, 127.6, 120.7 (*ipso*, *o*, *m*, *p*-Zr-CH_2Ph), 110.5, 110.4, 104.1, 104.1 (each Cp), 82.8 (C1), 45.8 (Zr-CH_2), 44.6 (CHCH_2) .

Generation of the Hydrido Zirconocene Cations 18a−d: General Procedure: A solution of 210 mg (410 μmol) of tris(pentafluorophenyl)borane in 2 mL of toluene was added to a Schlenk flask containing a solution of 293 μmol dimetallic hydride **11**, **8**, **14**, or **17** in 2 mL of toluene. A dark brown oil precipitated immediately. The reaction mixture was stirred for one minute, the oil allowed to settle and then the toluene phase was decanted. The oil was washed with 2 mL of toluene, followed by 2 mL of pentane and then solidified by stirring with 3 mL of pentane. After decanting the solvent and drying the solid in vacuo, the hydrido zirconocene cations were isolated as red-brown powders. Reported below are the quantities of reagents used and yields of products obtained.

Reaction of 11 with Tris(pentafluorophenyl)borane, Preparation of 18a: 200 mg (410 μmol) of **11** was treated with 210 mg (410 μmol) of $B(C_6F_5)_3$ to yield 341 mg (83%) of **18a**, mp 147°C (DSC, decomp.). − $C_{40}H_{26}BF_{15}OZr_2$ (1000.9): calcd. C 48.00, H 2.62, found C 48.46, H 2.74. − ^{1}H NMR (200.1 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = 5.78, 5.77, 5.54, 5.46 (each s, each 5 H, Cp), 3.58 (q, 1 H, $^3J_{HH}$ = 6.3 Hz, 1-H), 1.33 (d, 3 H, $^3J_{HH}$ = 6.3 Hz, CHC*H*$_3$), −1.98 (s, 1 H, μ-H), B-*H* resonance not observed. − ^{13}C NMR (50.3 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = 149.0, 138.0, 137.1 [each d, each $^1J_{CF}$ = 240 Hz, *o*, *p*, *m*-$B(C_6F_5)_3$], 112.4, 112.1, 106.7, 106.6 (each Cp), 90.1 (C1), 23.7 (CH*C*H$_3$), *ipso*-$B(C_6F_5)_3$ resonance not located. − ^{11}B NMR (64.2 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = −24.6 (d, $^1J_{BH}$ = 82 Hz). − ^{19}F NMR (282.4 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = −132.0, −163.5, −166.3 [each m, *o*, *p*, *m*-$B(C_6F_5)_3$].

Reaction of 8 with Tris(pentafluorophenyl)borane, Preparation of 18b: 206 mg (410 μmol) of **8** was treated with 210 mg (410 μmol) of $B(C_6F_5)_3$ to yield 320 mg (77%) of **18b**, mp 140°C (DSC, decomp.). − $C_{41}H_{28}BF_{15}OZr_2$ (1014.9): calcd. Reaction of 18a−d with [D$_2$]Dichloromethane, Generation of 19a−d. − General Proceedure: 78.1 μmol of dimetallic hydride **11**, **8**, **14**, or **17** and 40 mg (78.1 μmol) of tris(pentafluorophenyl)borane were mixed as solids in a NMR tube, the tube sealed with a septum and cooled to −78°C. Using a syringe, 1 mL of −78°C cold CD_2Cl_2 was added through the septum. The solids slowly dissolved to form a dark red solution which was allowed to warm to room temperature. Above −20°C, gas evolution took place and the color changed to red-orange. NMR spectra were then collected and in all cases CH_2D_2 was observed by ^{1}H NMR at 0.17 (quint.). Reported below are the quantities of reagents used.

Characterization of 19a: 38.1 mg (78.1 μmol) of **11** was treated with 40.0 mg (78.1 μmol) of $B(C_6F_5)_3$ in CD_2Cl_2. − ^{1}H NMR (200.1 MHz, [D$_2$]dichloromethane): δ = 6.47, 6.41, 6.00, 5.96 (each s, each 5 H, Cp), 4.33 (q, 1 H, $^3J_{HH}$ = 6.0 Hz, 1-H), 1.83 (d, 3 H, $^3J_{HH}$ = 6.0 Hz, CHC*H*$_3$), B-*H* resonance not observed. − ^{13}C NMR (50.3 MHz, [D$_2$]dichloromethane): δ = 148.2, 137.9, 136.9 [each d, each $^1J_{CF}$ = 240 Hz, *o*, *p*, *m*-$B(C_6F_5)_3$], 116.5, 116.4, 109.7, 109.6 (each Cp), 91.0 (C1), 24.9 (CH*C*H$_3$), *ipso*-$B(C_6F_5)_3$ resonance not located. − ^{11}B NMR (64.2 MHz, [D$_2$]dichloromethane): δ = −25.6 (d, $^1J_{BH}$ = 82 Hz). − ^{19}F NMR (282.4 MHz, [D$_2$]dichloromethane): δ = −130.6, −163.0, −165.4 [each m, *o*, *p*, *m*-$B(C_6F_5)_3$].

Characterization of 19b: 39.2 mg (78.1 μmol) of **8** was treated with 40.0 mg (78.1 μmol) of $B(C_6F_5)_3$ in CD_2Cl_2. − ^{1}H NMR (200.1 MHz, [D$_2$]dichloromethane): δ = 6.50, 6.42, 6.02, 5.98 (each s, each 5 H, Cp), 4.36 (q, 1 H, $^3J_{HH}$ = 6.0 Hz, 1-H), 1.86 (d, 3 H, $^3J_{HH}$ = 6.0 Hz, CHC*H*$_3$), 0.53 (br, 3 H, B-C*H*$_3$). − ^{13}C NMR (50.3 MHz, [D$_2$]dichloromethane): δ = 149.0, 138.0, 137.1 [each d, each $^1J_{CF}$ = 240 Hz, *o*, *p*, *m*-$B(C_6F_5)_3$], 116.8, 116.7, 110.0, 109.9 (each Cp), 91.7 (C1), 25.4 (CH*C*H$_3$), *ipso*-$B(C_6F_5)_3$ and B-*C*H$_3$ resonances not located. − ^{11}B NMR (64.2 MHz, [D$_2$]dichloromethane): δ = −15.3. − ^{19}F NMR (282.4 MHz, [D$_2$]dichloromethane): δ = −130.5, −162.7, −165.4 [each m, *o*, *p*, *m*-$B(C_6F_5)_3$].

Characterization of 19c: 39.2 mg (78.1 μmol) of **14** was treated with 40.0 mg (78.1 μmol) of $B(C_6F_5)_3$ in CD_2Cl_2. − ^{1}H NMR (200.1 MHz, [D$_2$]dichloromethane): δ = 6.48, 6.43, 6.03, 5.98 (each s, each 5 H, Cp), 4.08 (dd, 1 H, 1-H), 2.2−1.6 (m, 2 H, C*H*$_2$), 1.10 (pst, 3 H, CH$_2$C*H*$_3$), B-*H* resonance not observed. − ^{13}C NMR (50.3 MHz, [D$_2$]dichloromethane): δ = 148.2, 137.9, 136.9 [each d, each $^1J_{CF}$ = 240 Hz, *o*, *p*, *m*-$B(C_6F_5)_3$], 116.7, 116.5, 109.7, 109.5 (each Cp), 98.0 (C1), 32.3 (*C*H$_2$), 13.3 (CH$_2$*C*H$_3$), *ipso*-$B(C_6F_5)_3$ resonance not located. − ^{11}B NMR (64.2 MHz, [D$_2$]dichloromethane): δ = −25.6 (d, $^1J_{BH}$ = 82 Hz). − ^{19}F NMR (282.4 MHz, [D$_2$]dichloromethane): δ = −130.6, −163.0, −165.4 [each m, *o*, *p*, *m*-$B(C_6F_5)_3$].

Characterization of 19d: 51.2 mg (78.1 μmol) of **17** was treated with 40.0 mg (78.1 μmol) of $B(C_6F_5)_3$ in CD_2Cl_2. − ^{1}H NMR (599.9 MHz, [D$_2$]dichloromethane): δ = 7.49 (pst, 2 H, *m*), 7.40 (pst, 1 H, *p*), 7.29 (psd, 2 H, *o*-CH$_2$Ph), 6.88 (pst, 2 H, *m*), 6.80 (pst, 1 H, *p*), 6.76 (psd, 2 H, *o*-B-CH$_2$Ph), 5.76, 5.57, 5.56, 5.46 (Cp), 4.47 (dd, 1 H, $^3J_{HH}$ = 10.6 Hz, $^3J_{HH}$ = 2.8 Hz, 1-H), 3.60 (dd, 1 H, $^2J_{HH}$ = 15.0 Hz, $^3J_{HH}$ = 2.8 Hz, CHC*H*$_2$), 2.92 (dd, 1 H, $^2J_{HH}$ = 15.0 Hz, $^3J_{HH}$ = 10.6 Hz, CHC*H*$_2$), 2.84 (br, 2 H, B-C*H*$_2$). − ^{13}C NMR (150.8 MHz, [D$_2$]dichloromethane): δ = 147.8, 137.5, 135.8 [each d, each $^1J_{CF}$ = 240 Hz, *o*, *p*, *m*-$B(C_6F_5)_3$], 140.6, 128.7, 127.7, 126.8 (*ipso*, *m*, *o*, *p*-CH$_2$Ph), 148.3, 128.3, 126.4, 122.1 (*ipso*, *o*, *m*, *p*-B-CH$_2$Ph), 116.4, 115.9, 109.6, 109.2 (each Cp), 94.8 (C1), 44.4 (CH*C*H$_2$), 30.2 (br, B-*C*H$_2$), *ipso*-$B(C_6F_5)_3$ resonance not located.

– ^{11}B NMR (64.2 MHz, [D$_2$]dichloromethane): δ = −12.9. – ^{19}F NMR (282.4 MHz, [D$_2$]dichloromethane): δ = −128.7, −163.8, −165.4 [each m, *o*, *p*, *m*-B(C_6F_5)$_3$].

Reaction of 18a–d with Nitriles and Isocyanates. – General Procedure: Cation **18** was formed in situ by addition of 4 mL of toluene to a Schlenk flask containing 293 μmol of the dimetallic hydride complex **11**, **8**, **14**, or **17** and 210 mg (293 μmol) of B(C_6F_5)$_3$. The two compounds dissolved and within a few seconds, compound **18** precipitated as a dark brown oil. The solution was decanted and the oil washed with 2 mL of toluene. Then 1.1 equiv. of the respective nitrile or isocyanate reagent was added and the reaction mixture was stirred for five minutes. The resulting yellow or orange oil was washed with 2 mL of toluene, followed by 2 mL of pentane, and then solidified by stirring with 3 mL of pentane. After decanting the solvent and drying the solid in vacuo, the insertion products were isolated as yellow or orange powders. Reported below are the quantities of reagents actually used and the yields of products obtained.

Reaction of 18a with Acetonitrile: Preparation of 21a: Reaction of 200 mg (410 μmol) of **11** with 210 mg (410 μmol) of B(C_6F_5)$_3$ and subsequent reaction of the such in situ prepared **18a** with 23.9 μL (18.5 mg, 450 μmol) of acetonitrile gave **21a** as a yellow powder, yield 320 mg (75%), mp 184°C (DSC, 213°C decomp.). – $C_{42}H_{29}BF_{15}NOZr_2$ (1039.0): calcd. C 48.42, H 2.81, N 1.34, found C 48.40, H 3.00, N 1.52. – ^{1}H NMR (200.1 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = 8.67 (q, 1 H, $^3J_{HH}$ = 4.7 Hz, N=C*H*), 5.88, 5.81, 5.44, 5.43 (each s, each 5 H, Cp), 3.65 (q, 1 H, $^3J_{HH}$ = 6.1 Hz, 1-H), 1.81 (d, 3 H, $^3J_{HH}$ = 4.7 Hz, N=CHCH_3), 1.52 (d, 3 H, $^3J_{HH}$ = 6.1 Hz, CHCH_3), B-*H* resonance not observed. – ^{13}C NMR (150.8 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = 187.2 (N=*C*H) 149.0, 138.0, 136.9 [each d, each $^1J_{CF}$ = 240 Hz, *o*, *p*, *m*-B(C_6F_5)$_3$], 113.6, 113.5, 108.8, 108.7 (each Cp), 88.5 (C1), 33.3 (N=CH*C*H$_3$), 23.9 (CH*C*H$_3$), *ipso*-B(C_6F_5)$_3$ resonance not located. – ^{11}B NMR (64.2 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = −24.6 (d, $^1J_{BH}$ = 82 Hz). – ^{19}F NMR (282.4 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = −132.0, −163.5, −166.3 [each m, *o*, *p*, *m*-B(C_6F_5)$_3$].

Reaction of 18a with *tert*-Butyl Cyanide: Preparation of 21b: Reaction of 200 mg (410 μmol) of **11** with 210 mg (410 μmol) of B(C_6F_5)$_3$ and subsequent reaction of the in situ prepared **18a** with 49.7 μL (37.4 mg, 450 μmol) *tert*-butyl cyanide gave **21b** as a yellow powder, yield 342 mg (77%), mp 170°C (DSC, decomp.). – $C_{45}H_{35}BF_{15}NOZr_2$ (1084.0): calcd. C 49.86, H 3.25, N 1.29, found C 48.99, H 3.53, N 1.35. – ^{1}H NMR (200.1 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = 8.87 (s, 1 H, N=C*H*), 5.91, 5.84, 5.44, 5.43 (each s, each 5 H, Cp), 3.55 (q, 1 H, $^3J_{HH}$ = 6.0 Hz, 1-H), 1.49 (d, 3 H, $^3J_{HH}$ = 6.0 Hz, CHCH_3), 0.85 [s, 9 H, C(CH_3)$_3$], B-*H* resonance not observed. – ^{13}C NMR (50.3 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = 197.5 (N=*C*H), 149.0, 138.0, 136.9 [each d, each $^1J_{CF}$ = 240 Hz, *o*, *p*, *m*-B(C_6F_5)$_3$], 114.0, 113.8, 109.2 (double intensity) (each Cp), 90.0 (C1), 41.6 [*C*(CH$_3$)$_3$], 25.3 [C(*C*H$_3$)$_3$], 23.4 (CH*C*H$_3$), *ipso*-B(C_6F_5)$_3$ resonance not located. – ^{11}B NMR (64.2 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = −24.6 (d, $^1J_{BH}$ = 82 Hz). – ^{19}F NMR (282.4 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = −132.0, −163.5, −166.3 [each m, *o*, *p*, *m*-B(C_6F_5)$_3$].

Reaction of 18a with *p*-Tolunitrile: Preparation of 21c: Reaction of 200 mg (410 μmol) of **11** with 210 mg (410 μmol) of B(C_6F_5)$_3$ and subsequent reaction of the in situ prepared **18a** with 52.7 mg (450 μmol) of *p*-tolunitrile gave **21c** as a yellow powder, yield 325 mg (71%), mp 169°C (DSC, decomp.). – $C_{48}H_{33}BF_{15}NOZr_2$ (1118.0): calcd. Reaction of 18c with *p*-Tolylisocyanate: Preparation of 29c: Reaction of 206 mg (410 μmol) of **14** with 210 mg (410 μmol) of B(C_6F_5)$_3$ and subsequent reaction of the in situ prepared **18c** with 56.6 μL (59.9 mg, 450 μmol) of *p*-tolylisocyanate gave **29c** as a yellow powder, yield 353 mg (75%), mp 170°C (DSC, decomp.). – $C_{49}H_{35}BF_{15}NO_2Zr_2$ (1148.1): calcd. C 51.26, H 3.07, N 1.22, found C 50.90, H 3.32, N 1.52. – ^{1}H NMR (200.1 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = 7.75 (s, 1 H, O=C*H*), 7.16, 6.78 (each psd, each 2 H, *m*, *o*-PhCH$_3$), 6.16, 5.96, 5.92, 5.90 (each s, each 5 H, Cp), 3.37 (dd, 1 H, 1-H), 2.28 (s, 3 H, PhCH_3), 1.9-1.6 (m, 2 H, CH_2), 0.98 (pst, 3 H, CH_2CH_3), B-*H* resonance not observed. – ^{13}C NMR (50.3 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = 166.0 (O=*C*H), 149.0, 138.1, 137.2 [each d, each $^1J_{CF}$ = 240 Hz, *o*, *p*, *m*-B(C_6F_5)$_3$], 139.8, 138.0, 130.8, 121.4 (*ipso*, *p*, *m*, *o*-PhCH$_3$), 114.5, 114.3, 110.1, 109.6 (each Cp), 94.7 (C1), 31.9 (CH_2), 24.8 (Ph*C*H$_3$), 14.5 (CH_2CH_3), *ipso*-B(C_6F_5)$_3$ resonance not located. – ^{11}B NMR (64.2 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = −24.6 (d, $^1J_{BH}$ = 82 Hz). – ^{19}F NMR (282.4 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = −131.9, −164.3, −166.6 [each m, *o*, *p*, *m*-B(C_6F_5)$_3$].

Reaction of 18d with *tert*-Butylisocyanate: Preparation of 30a: Reaction of 269 mg (410 μmol) of **17** with 210 mg (410 μmol) of B(C_6F_5)$_3$ and subsequent reaction of the in situ prepared **18d** with 52.8 μL (44.6 mg, 450 μmol) of *tert*-butylisocyanate gave **30a** as a yellow powder, yield 358 mg (69%), mp 180°C (DSC, decomp.). – $C_{58}H_{45}BF_{15}NO_2Zr_2$ (1266.3): calcd. C 55.02, H 3.58, N 1.11, found C 55.59, H 3.87, N 1.50. – ^{1}H NMR (599.9 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = 7.26 (s, 1 H, O=C*H*), 7.34 (pst, 2 H, *m*), 7.22 (pst, 1 H, *p*), 7.18 (m, 2 H, *o*-CH_2Ph), 6.98 (pst, 2 H, *m*), 6.84 (pst, 1 H, *p*-B-CH_2Ph), 5.85, 5.77, 5.69, 5.52 (each s, each 5 H, Cp), 3.68 (dd, 1 H, $^3J_{HH}$ = 9.9 Hz, $^3J_{HH}$ = 3.1 Hz, 1-H), 3.41 (br, 2 H, B-CH_2), 3.01 (dd, 1 H, $^2J_{HH}$ = 14.7 Hz, $^3J_{HH}$ = 3.1 Hz, CHCH_2), 2.67 (dd, 1 H, $^2J_{HH}$ = 14.7 Hz, $^3J_{HH}$ = 9.9 Hz, CHCH_2), 0.98 (s, 9 H, C(CH_3)$_3$). – ^{13}C NMR (150.8 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = 165.3 (O=*C*H), 149.0, 138.1, 137.2 [each d, each $^1J_{CF}$ = 240 Hz, *o*, *p*, *m*-B(C_6F_5)$_3$], 143.8, 129.0, 128.7, 126.8 (*ipso*, *m*, *o*, *p*-CH_2Ph), 149.2, 129.3, 127.4, 123.1 (*ipso*, *o*, *m*, *p*-B-CH_2Ph), 114.1, 114.0, 109.8, 109.5 (each Cp), 91.8 (C1), 56.1 [*C*(CH_3)$_3$], 45.0 (CH*C*H$_2$), 32.4 (br, B-*C*H$_2$), 31.0 [C(*C*H$_3$)$_3$], *ipso*-B(C_6F_5)$_3$ resonance not located. – ^{11}B NMR (64.2 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = −12.3. – ^{19}F NMR (282.4 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = −128.1, −164.2, −166.8 [each m, *o*, *p*, *m*-B(C_6F_5)$_3$].

Reaction of 18d with Trimethylsilylisocyanate: Preparation of 30b: Reaction of 269 mg (410 μmol) of **17** with 210 mg (410 μmol) of B(C_6F_5)$_3$ and subsequent reaction of the in situ prepared **18d** with 59.8 μL (51.8 mg, 450 μmol) of trimethylsilylisocyanate gave **30b** as a yellow-orange powder, yield 342 mg (65%), mp 167°C (DSC, decomp.). – $C_{57}H_{45}NBF_{15}O_2SiZr_2$ (1282.3): calcd. C 53.39, H 3.54, N 1.09, found C 53.36, H 3.85, N 1.13. – ^{1}H NMR (599.9 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = 7.30 (s, 1 H, O=C*H*), 7.28 (pst, 2 H, *m*), 7.17 (pst, 1 H, *p*),7.16 (psd, 2 H, *o*-CH_2Ph), 7.09 (psd, 2 H, *o*), 6.90 (pst, 2 H, *m*), 6.76 (pst, 1 H, *p*-B-CH_2Ph), 5.81, 5.77, 5.68, 5.46 (each s, each 5 H, Cp), 3.71 (dd, 1 H, $^3J_{HH}$ = 9.9 Hz, $^3J_{HH}$ = 3.1 Hz, 1-H), 3.32 (br, 2 H, B-CH_2), 2.98 (dd, 1 H, $^2J_{HH}$ = 14.8 Hz, $^3J_{HH}$ = 3.1 Hz, CHCH_2), 2.64 (dd, 1 H, $^2J_{HH}$ = 14.8 Hz, $^3J_{HH}$ = 9.9 Hz, CHCH_2), 0.01 [s, 9 H, Si(CH_3)$_3$]. – ^{13}C NMR (150.8 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = 170.4 (O=*C*H), 149.0, 138.1, 137.2 [each d, each $^1J_{CF}$ = 240 Hz, *o*, *p*, *m*-B(C_6F_5)$_3$], 144.0, 129.0, 128.8, 126.8 (*ipso*, *m*, *o*, *p*-CH_2Ph), 149.2, 129.3, 127.3, 123.0 (*ipso*, *o*, *m*, *p*-B-CH_2Ph), 114.1, 114.0, 109.9, 109.6 (each Cp), 92.7 (C1), 45.0 (CH*C*H$_2$), 32.4 (br, B-*C*H$_2$), −0.1 [Si(*C*H$_3$)$_3$], *ipso*-B(C_6F_5)$_3$ resonance not located. – ^{11}B NMR (64.2 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = −12.3. – ^{19}F NMR (282.4 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = −128.1, −164.2, −166.8 [each m, *o*, *p*, *m*-B(C_6F_5)$_3$].

Reaction of 18d with *p*-Tolylsilylisocyanate: Preparation of 30c: Reaction of 269 mg (410 μmol) of **17** with 210 mg (410 μmol) of B(C_6F_5)$_3$ and subsequent reaction of the in situ prepared **18d** with 56.6 μL (59.9 mg, 450 μmol) of *p*-tolylisocyanate gave **30c** as a yellow-orange powder, yield 341 mg (64%), mp 168°C (DSC, decomp.). – $C_{61}H_{43}BF_{15}NO_2Zr_2$ (1300.3): calcd. C 56.35, H 3.33, N 1.08, found C 56.08, H 3.46, N 1.44. – ^{1}H NMR (599.9 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = 7.27 (s, 1 H, O=C*H*), 7.27 (pst, 2 H, *m*), 7.16 (pst, 1 H, *p*), 7.14 (psd, 2 H, *o*-CH_2Ph), 7.09 (psd, 2 H, *o*), 6.85 (pst, 2 H, *m*), 6.75 (pst, 1 H, *p*-B-CH_2Ph), 7.04, 6.63 (each psd, each 2 H, *m*, *o*-PhCH$_3$), 5.90, 5.81, 5.71, 5.37 (each s, each 5 H, Cp), 3.75 (dd, 1 H, $^3J_{HH}$ = 10.1 Hz, $^3J_{HH}$ = 2.7 Hz, 1-H), 3.31 (br, 2 H, B-CH_2), 2.97 (dd, 1 H, $^2J_{HH}$ = 14.7 Hz, $^3J_{HH}$ = 2.7 Hz, CHCH_2), 2.62 (dd, 1 H, $^2J_{HH}$ = 14.7 Hz, $^3J_{HH}$ = 10.1 Hz, CHCH_2), 2.13 (s, 3 H, PhCH_3). – ^{13}C NMR (150.8 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = 165.6 (O=*C*H), 149.0, 138.1, 137.2 [each d, each $^1J_{CF}$ = 240 Hz, *o*, *p*, *m*-B(C_6F_5)$_3$], 139.8, 138.3, 130.9, 121.5 (*ipso*, *p*, *m*, *o*-PhCH$_3$), 144.0, 129.0, 128.8, 126.8 (*ipso*, *m*, *o*, *p*-CH_2Ph), 149.2, 129.3, 127.4, 123.0 (*ipso*, *o*, *m*, *p*-B-CH_2Ph), 114.5, 114.3, 110.1, 109.7 (each Cp), 93.7 (C1), 45.1 (CH*C*H$_2$), 31.8 (br, B-*C*H$_2$), 20.7 (Ph*C*H$_3$), *ipso*-B(C_6F_5)$_3$ resonance not located. – ^{11}B NMR (64.2 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = −12.3. – ^{19}F NMR (282.4 MHz, [D$_6$]benzene/[D$_8$]tetrahydrofuran, ca. 4:1): δ = −128.1, −164.2, −166.8 [each m, *o*, *p*, *m*-B(C_6F_5)$_3$].

Hard Acid and Soft Base Stabilisation of Di- and Trimercury Cations in Benzene Solution – A Spectroscopic, X-ray Scattering, and Quantum Chemical Study

Stefan Ulvenlund,[a] Jan Rosdahl,[b] Andreas Fischer,[b] Peter Schwerdtfeger,[c] and Lars Kloo*[b]

Dedicated to Prof. Warren R. Roper on the occation of his 60th birthday

Keywords: Mercury cations / Subvalent compounds / Ab initio calculations / Liquid X-ray scattering

Hg_2Cl_2 dissolves in $GaCl_3$/benzene solution to yield Hg_2^{2+} and chlorogallate(III) ions, $Ga_nCl_{3n+1}^-$. In such solutions, Hg_2^{2+} can be reduced to Hg_3^{2+} by metallic mercury. Solubility measurements show that one mol of Hg is oxidised per mol of Hg_2^{2+}. The Hg_3^{2+} ion gives a strong band at 110 cm^{-1} in the Raman spectrum and Hg–Hg correlations at about 2.60 and 5.15 Å in the radial distribution function obtained by liquid X-ray scattering. – Hg_3^{2+} can also be synthesised in high yield by direct oxidation of metallic mercury by Ga^{III} in $GaCl_3$/benzene solution. In contrast, mercury is insoluble in neat liquid $GaCl_3$ and only sparingly soluble in $GaCl_3$/KCl melts. It therefore seems likely that the thermodynamic stabilisation of subvalent mercury species in benzene solution not only relies on the traditional acid stabilisation provided by the hard Lewis acid $GaCl_3$, but also on a "soft-base stabilisation" provided by interactions between the aromatic molecules and the cations. Evidence for such specific interactions between Hg_m^{2+} cations and C_6H_6 are observed in the Raman spectra: The totally symmetric C_6H_6 band at 991 cm^{-1} is found to split in the presence of Hg_m^{2+} ions and to give new peaks at 978 (m = 2) and 982 (m = 3) cm^{-1}. – In order to further elucidate the cluster–arene interactions, ab initio and density functional calculations were performed for the model compounds $Hg_m(C_6H_6)_2^{2+}$ and $Hg_mCl_2(C_6H_6)_2$, m = 2 and 3. The calculations show that both models represent coordinations modes which are feasible for Hg_m^{2+} ions. However, the calculated vibrational frequencies for the $Hg_m(C_6H_6)_2^{2+}$ models with η^1/*quasi*-η^3 coordination of the benzene molecules along the Hg–Hg vector are most consistent with the body of experimental and literature data. The counterions are thus suggested to occupy secondary coordination sites.

Introduction

Mercury displays a rich and unusual subvalent chemistry. In addition to the well-known dimer Hg_2^{2+}, previously reported metal−metal-bonded, subvalent mercury species include the linear cations Hg_3^{2+} and Hg_4^{2+}, which have been structurally characterised as salts of the weakly coordinating anions $AlCl_4^-$,[1] AsF_6^-,[2−4] $Ta_2F_{11}^-$,[5] and $[(MF_5)_2SO_4]^{2-}$ (M = Nb, Ta).[5] Mercury also forms infinite, one-dimensional chains in the non-stoichiometric compounds Hg_xTiS_2[6][7] and $Hg_{3-\delta}MF_6$ (M = As,[8−10] Sb,[11] Nb or Ta[12]), some of which transform into stoichiometric, layered compounds $Hg_3(MF_6)$ under appropriate conditions.[13] The fascinating physical properties of these anisotropic compounds have been investigated in considerable detail,[14−19] and are highlighted by the recent assignment of the well-known orange luminescence of calomel to Hg_3^{2+}, presumably formed by disproportionation of Hg_2Cl_2.[20]

As is the case with the vast majority of subvalent post-transition element species (apart from the anomalously stable Hg_2^{2+} cation), the traditional synthetic routes to subvalent mercury cations are based on molten-salt solutions, superacid media, or solutions of strongly oxidising fluorides in liquid SO_2. These highly Lewis-acidic solvent systems have been considered necessary in order to impede the disproportionation of the subvalent cations to higher, more acidic oxidation states and the parent metal.[21] However, triangular Hg_3^{4+} and $AgHg_2^{3+}$ species have recently been stabilised by diphosphanes in the direct reduction of divalent mercury in the presence of the phosphane ligand.[22−24] This route involves reaction media which are immensly more Lewis-basic than the traditional ones. In addition, it comprises *soft*, rather than hard, donors.

In recent publications we have described the syntheses of bismuth clusters and subvalent gallium species by a novel route employing solutions of $GaCl_3$ in organic (aromatic) solvents as reaction media.[25−28] The spectroscopic data for these systems suggest substantial interactions between subvalent metal species and aromatic donors. These donors have, of course, a pronounced soft character. Considering the recent success of stabilising subvalent mercury species in systems comprising other soft donors (i.e. diphosphanes), the $GaCl_3$/arene route is thus of great potential interest for

the synthesis of such mercury species. In addition, the interaction between the mercury species and the solvent, i.e. gallates and arene, is of interest because of the unusual coordination chemistry displayed by the previously investigated metal−metal-bonded bisarene compounds $[Pd_2(AlCl_4)_2](C_6H_6)_2$, $[Pd_2(Al_2Cl_7)_2](C_6H_6)_2$,[29−31] and $[Hg_2(C_9H_{12})_2](AlCl_4)_2$ (C_6H_6 = benzene; C_9H_{12} = mesitylene).[32] In the Pd compounds, the aluminates occupy the primary coordination site along the Pd−Pd bond vector and the benzene molecules sandwich the Pd_2^{2+} core. Surprisingly, the opposite is true for the dimercury compound, where mesitylene occupies the primary coordination site. In the case of mercury, this site is normally occupied by anionic, hard bases with donor atoms such as oxygen, nitrogen, and halogens.[33−35] Nevertheless, the compound $[Hg_2(CO)_2](Sb_2F_{11})_2$ has recently been studied by vibrational spectroscopy and seems to provide another example of linear C−Hg−Hg−C coordination.[36] However, the only isolated, solid compound containing Hg_2^{2+} ions and benzene is $[Hg_2(AlCl_4)_2](C_6H_6)_2$.[37] Unfortunately, this compound has never been completely structurally characterised and thus does not shed any light on the Hg_2^{2+}−benzene interaction and the competition between benzene and chloroaluminate ions for the primary coordination sites of the cation.

The aim of the present work is twofold: firstly, to investigate the stability of subvalent mercury species in aromatic solvents and, secondly, to elucidate the coordination of aromatic molecules by such species.

Experimental Results and Discussion

Throughout this work the abbreviation X°(A;B) will be used to denote the mol fraction of component A with respect to component B in ternary or higher order systems; i.e. $X°(A;B) = n_A/(n_A + n_B)$.

The $Hg_2Cl_2/GaCl_3$/Benzene System

The solubility of Hg_2Cl_2 in a 30 mol-% $GaCl_3$/benzene solution approximately corresponds to $X°(Hg_2Cl_2;GaCl_3) = 0.15$. Solutions saturated with Hg_2Cl_2 consist of two liquid phases in equilibrium with solid Hg_2Cl_2. The less dense, colourless phase constitutes only a minor part of the total volume and Raman and NMR spectra indicate that it essentially consists of pure benzene. The Raman spectrum of the denser, faintly yellow liquid phase is more informative (Figure 1, Table 1) and the bands are readily assigned. The strong band at 154 cm^{-1} coincides with the Hg−Hg stretch frequency of Hg_2Cl_2 in Hg−$HgCl_2$ melts.[38] In addition, the band at 368 cm^{-1} (the symmetrical, terminal $GaCl_3$ stretch in $Ga_nCl_{3n+1}^-$)[25] and the lack of bands belonging to Ga_2Cl_6 unambigously show that $GaCl_3$ acts as a chloride acceptor in the dissolution of Hg_2Cl_2 in $GaCl_3$/benzene solution (Equation 1).

$$Hg_2Cl_2 + 2n\ GaCl_3 \rightarrow Hg_2^{2+} + 2\ Ga_nCl_{3n+1}^- \quad (1)$$

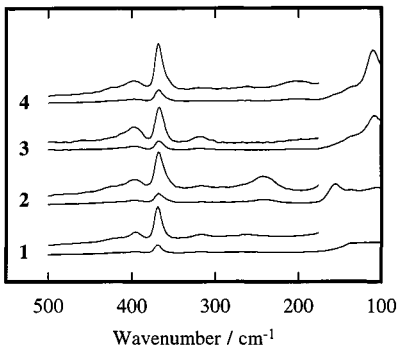

Figure 1. The Raman spectra of (1) the $Ga/GaCl_3/C_6H_6$ system, $X°(Ga;GaCl_3) = 0.191$; (2) the denser liquid phase of the $Hg_2Cl_2/GaCl_3/C_6H_6$ system saturated with Hg_2Cl_2; (3) the $Hg/GaCl_3/C_6H_6$ system saturated with mercury metal; (4) the denser liquid phase of the $Hg/Hg_2Cl_2/GaCl_3/C_6H_6$ system saturated with Hg_2Cl_2 and metallic mercury; $X°(GaCl_3;C_6H_6) = 0.300$ in all systems; the top spectrum of each pair is shown on an expanded scale

The band at 368 cm^{-1} is markedly skew-symmetric relative to the corresponding band observed in $Ga/GaCl_3$/benzene solutions,[25] which suggests a lowering of the local symmetry of the terminal $GaCl_3$ groups in the presence of Hg_2^{2+}. Such a lowering of the $GaCl_3$ symmetry is presumably caused by an interaction between the anions and Hg_2^{2+}. Further inspection of the Raman spectra reveals other indications of strong interactions between Hg_2^{2+} and chlorogallate ions. Thus, the band at 241 cm^{-1} is found near the position of the Ga−Cl−Ga stretch frequency of $Ga_2Cl_7^-$ in $Ga(Ga_2Cl_7)$/benzene solutions (264 cm^{-1}),[25] but the intensity of the 241 cm^{-1} band is much higher relative to that of the symmetrical, terminal $GaCl_3$ stretch vibration. It therefore seems reasonable to assume that this region of the spectrum contains contributions from modes other than the Ga−Cl−Ga stretch. The Hg−Cl stretch vibration (ν_2, Σ_g^+) in Hg_2Cl_2 has been reported at 260 cm^{-1} in $Hg/HgCl_2$ melts and at 279 cm^{-1} in solid Hg_2Cl_2.[38] A shift of the Hg−Cl band towards lower wavenumbers is to be expected when Cl^- is substituted for the more weakly coordinating $Ga_nCl_{3n+1}^-$ ions. It is therefore plausible that the band at 241 cm^{-1} contains contributions also from Hg−Cl modes. Indeed, a distinct Hg−Cl interaction between Hg_2^{2+} and $Ga_nCl_{3n+1}^-$ is expected since Hg_2^{2+} has previously been shown to form Hg−X bonds with weak Lewis bases such as trifluoroacetate and perchlorate.[39][40] However, it has to be remembered that $Ga_nCl_{3n+1}^-$ ions are not the only Lewis bases present in the $Hg_2Cl_2/GaCl_3$/benzene system; the solvent itself, benzene, is a Lewis base and must be accounted for when discussing the coordination of Hg_2^{2+} in this system. Evidence for an interaction between benzene and Hg_2^{2+} are also found in the Raman data. The totally symmetric, ring-breathing mode (of A_{1g} symmetry in the D_{6h} point group) of C_6H_6 at 993 cm^{-1} is split in the spectra of the $Hg_2Cl_2/GaCl_3$/benzene system and a new band is observed at 978 cm^{-1} (Figure 2). This spectral effect could be the result of a symmetry-lowering of C_6H_6 coordinated to Hg_2^{2+} in a $(Hg_2^{2+})(C_6H_6)_k$ complex, but an activation of the most probable candidate, the C−H bending mode of E_{2u} symmetry, is unlikely to produce such a strong Raman

Table 1. Comparison of Raman bands observed in the $Hg_2Cl_2/GaCl_3$/benzene, $Hg/Hg_2Cl_2/GaCl_3$/benzene and $Hg/GaCl_3$/benzene systems with literature data on the molten Hg-$HgCl_2$ system;[38] the intensity and appearance of the bands are indicated by the following abbreviations: s = strong, m = medium, w = weak, v = very, br = broad, sh = shoulder; the assignments for bands of Ga_2Cl_6 and $Ga_nCl_{3n+1}^-$ are based on data from the $Ga/GaCl_3$ system[25][42]

$Hg_2Cl_2/GaCl_3/C_6H_6$	$Hg/Hg_2Cl_2/GaCl_3/C_6H_6$	$Hg/GaCl_3/C_6H_6$	$Hg/HgCl_2$ (melt)	Assignment

band. Instead, the new peak shifted about 15 cm^{-1} to lower wavenumbers is interpreted as arising from the benzene breathing mode of molecules coordinated to the Hg_2^{2+} core, thus reflecting the difference in C−C bonding between coordinated and noncoordinated benzene molecules.

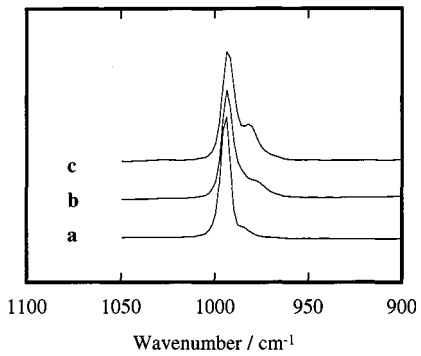

Figure 2. The Raman-spectroscopic effect of Hg_m^{2+} ions on the totally symmetric C_6H_6 ring breathing mode: (a) neat benzene; (b) Hg_2^{2+} in $Hg_2Cl_2/GaCl_3/C_6H_6$ saturated with Hg_2Cl_2; (c) Hg_3^{2+} in $Hg/Hg_2Cl_2/GaCl_3/C_6H_6$ saturated with Hg and Hg_2Cl_2. $X°(GaCl_3;C_6H_6) = 0.300$ in b and c

The IR-active, all-in-phase, out-of-plane C−H bending mode (A_{2u} symmetry) observed at 673 cm^{-1} in benzene, is a sensitive indicator of benzene substitution[41] and, as we will see, coordination. In $GaCl_3$/benzene solution two peaks at 672 and 697 cm^{-1} appear in the IR spectra. The former is identified as the pure benzene A_{2u} band, and the latter is consistent with a shift (+25 cm^{-1}) in frequency of the same vibration mode when benzene is $^1\pi$-coordinated to Ga_2Cl_6.[42] The dissolution of Hg_2Cl_2 in the $GaCl_3$/benzene reaction medium follows Equation 1, where the predominant gallate species formed are $Ga_2Cl_7^-$ and $Ga_3Cl_{10}^-$. In the $Hg_2Cl_2/GaCl_3$/benzene system, we thus expect a strong band at 672 cm^{-1} from noncoordinated benzene, a weak peak at 697 cm^{-1} from benzene coordinated to a small amount of remaining Ga_2Cl_6 and finally a peak from benzene coordinated to Hg_2^{2+}. These expectations are verified and a new band, assigned to benzene in a complex with Hg_2^{2+}, appears at 721 cm^{-1} (shift: +48 cm^{-1} relative to neat benzene).

In ^{13}C-NMR spectra of $Hg_2Cl_2/GaCl_3$/benzene solutions the effects of the inferred complex formation are small and amount to a minor (0.7 ppm in solutions saturated with Hg_2Cl_2) downfield shift of the ^{13}C resonance of C_6H_6 relative to neat benzene. The interaction between aromatic molecules and Hg_2^{2+} has previously been studied by ^{13}C-NMR and Raman spectroscopy in SO_2 solution and a few $(Hg_2^{2+})(arene)_k$ complexes have been isolated from such solution as their hexafluoroarsenate(V) salts.[43][44] No direct structural data were derived, but the results were interpreted in terms of a localized η^2 coordination of C_6H_6 by Hg_2^{2+}. However, the trends in ^{13}C-NMR shifts cannot unambigously be interpreted as coordination effects.

In order to shed further light on the structure of $Hg_2Cl_2/GaCl_3$/benzene solutions, a liquid X-ray scattering investigation (LXS) was performed. Due to the high linear absorptivity of the systems, the data do not allow for a full refinement of a structure model, but the reduced radial distribution function (rRDF, Figure 3) can be evaluated semiquantitatively. The most prominent feature of the rRDF is a strong peak at 2.58 Å which can be assigned to the Hg−Hg correlation. This strong Hg−Hg peak probably overlaps and hides any Hg−Cl or Hg−C correlations. In solid Hg_2Cl_2 the two shortest Hg−Cl distances are found at 2.43 Å,[45] but these can be expected to be somewhat longer for the $Hg_2^{2+}-Ga_nCl_{3n+1}^-$ contacts because of the weaker Lewis basicity of the gallates. The Hg−Hg bond length inferred by the rRDF (2.58 Å) is somewhat longer than in solid Hg_2Cl_2 (2.53 Å)[46] and in aqueous solutions of Hg^I perchlorate (2.52 Å).[47] Unfortunately, the suggested overlap between the Hg−Hg and Hg−Cl (or Hg−C) correlations in the rRDF makes the determination of the Hg−Hg distance uncertain. A detailed interpretation of the inferred bond elongation in terms of coordination effects on Hg_2^{2+} is therefore difficult.

On the basis of the known structural data for the $[Pd_2(AlCl_4)_2](C_6H_6)_2$ and $[Hg_2(C_9H_{12})_2](AlCl_4)_2$ compounds,[29−32] two structural models can be constructed that realistically rationalize the peaks in the rRDF for r values smaller than 5 Å. The two models are depicted schematically in Figures 4a and 4b and are compared with ex-

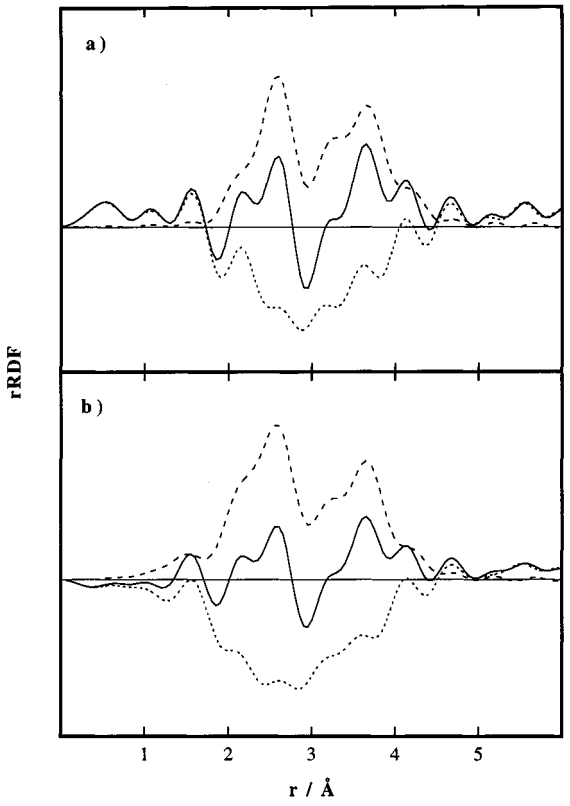

Figure 3. The rRDFs of the $Hg_2Cl_2/GaCl_3/C_6H_6$ (saturated with Hg_2Cl_2) system; X°($GaCl_3$;C_6H_6) = 0.300; the experimental functions are shown as solid lines. The sum of the calculated peak shapes of the two models shown in Figure 4a and 4b are shown as dashed and the difference curves (between experimental data and structural model) as dotted lines in the (a) and (b) figures, respectively

perimental data in the corresponding Figures 3a and 3b. In addition to Hg−Hg and Hg−Cl distances, the models include Ga−Ga, Cl···Cl, terminal Ga−Cl distances, and interaromatic C−C contacts, in agreement with those in benzene solutions of $Ga(Ga_2Cl_7)$.[25] As seen in the Figures 3a and 3b, X-ray scattering alone or in conjunction with spectroscopic data cannot be used to unambigously distinguish between the two structural models. Therefore, we also have to consider the results from quantum-chemical calculations before arriving at a conclusion. These results are reported below, together with those for the Hg_3^{2+} ion.

The $Hg/Hg_2Cl_2/GaCl_3$/Benzene System

The reduction of a $Hg_2Cl_2/GaCl_3$/benzene solution with an excess of metallic mercury yields a dark brown solution. $Hg/Hg_2Cl_2/GaCl_3$/benzene systems saturated with both Hg and Hg_2Cl_2 display two liquid phases, of which the less dense one consists of virtually pure benzene as is evident from its Raman and NMR spectra. The spectral characteristics of the denser liquid phase differ from the corresponding one of the $Hg_2Cl_2/GaCl_3$/benzene solution in several ways:

1. The Hg−Hg Raman band of Hg_2^{2+} at 154 cm^{-1} is replaced by a very strong band at 110 cm^{-1}. This band

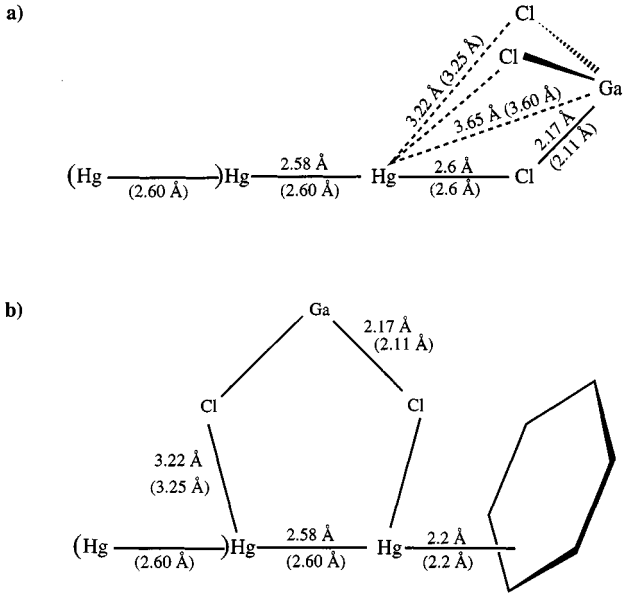

Figure 4. General structural models for (a) the $Hg_m^{2+}-Ga_nCl_{3n+1}^-$ coordination, and (b) the $Hg_m^{2+}-C_6H_6$ coordination compatible with LXS data; distances shown in brackets are those for $m = 3$; those without brackets are for $m = 2$; all distances correspond to peaks in the rRDFs

nearly coincides with that of the Hg_3^{2+} ion in SO_2 solution, reported at 113 cm^{-1}.[2]

2. The band at 241 cm^{-1} is replaced by a less intense band at 201 cm^{-1}. Considering the assignment of this band to Hg−Cl modes, the shift to lower wavenumbers and the decreased intensity suggest a weaker coordination of $Ga_nCl_{3n+1}^-$ to Hg_3^{2+} as compared to Hg_2^{2+}.

3. The ^{199}Hg-NMR resonance at δ = −2103 (relative to $HgMe_2$) observed in $Hg_2Cl_2/GaCl_3$/benzene solutions disappears upon reduction with an excess of metallic Hg. The same NMR-spectroscopic characteristics of Hg_2^{2+} and Hg_3^{2+} have been reported from studies in fluorosulphuric acid and liquid SO_2 solution at room temperature. In these studies, the observation of mercury signals from Hg_3^{2+} was complicated by the enormous Hg−Hg coupling constant and low-temperature experiments were needed to indentify the coupling satellites.[48] Due to the relatively high melting point of benzene, such experiments cannot be performed in this study.

The rRDF of the dense liquid phase from a $GaCl_3$/benzene solution equilibrated with an excess of Hg_2Cl_2 and Hg (Figure 5) is very similar to that of the $Hg_2Cl_2/GaCl_3$/benzene solution at $r < 4$ Å and thus suggests a very similar coordination of the benzene and chlorogallate ions and a nearest neighbour Hg−Hg distance of 2.60 Å. However, a notable feature which is not present in the rRDF of the $Hg_2Cl_2/GaCl_3$/benzene system is the strong peak at 5.15 Å. This value is in good agreement with what should be expected for the correlation between the terminal Hg atoms in a linear Hg_3^{2+} cation with a nearest neighbour Hg−Hg distance of about 2.60 Å. The two alternative general structure models for the rRDF are shown in Figures 4a and 4b, and they are compared with the experimental data in Figures 5a and 5b.

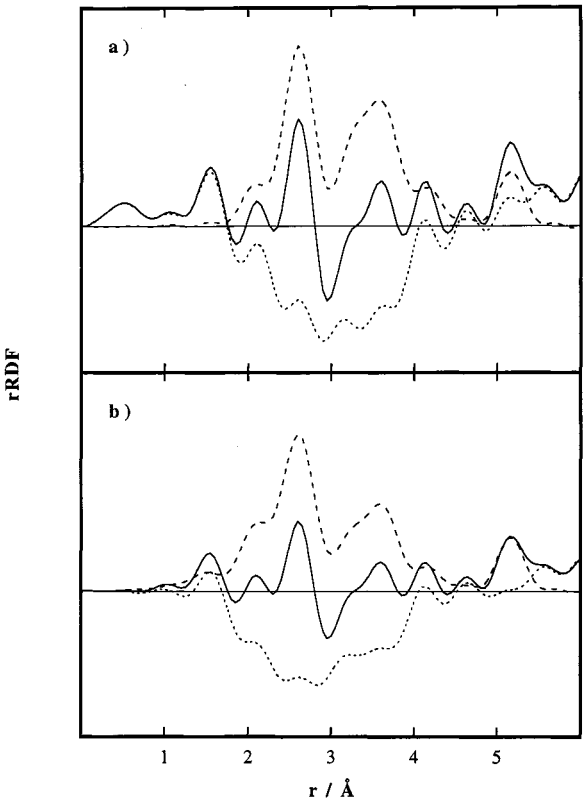

Figure 5. The rRDFs of the $Hg/Hg_2Cl_2/GaCl_3/C_6H_6$ (saturated with Hg and Hg_2Cl_2) systems; $X°(GaCl_3;C_6H_6) = 0.300$; the experimental functions are shown as solid lines; the sum of the calculated peak shapes of the two models shown in Figures 4a and 4b are shown as dashed and the difference curves (between experimental data and structural model) as dotted lines in the (a) and (b) figures, respectively

In the solid state, the Hg_3^{2+} ion has been found to be linear[2] (or very nearly so)[1][5] with Hg−Hg distances ranging between 2.551 and 2.562 Å. The Hg−Hg distance of Hg_3^{2+} in benzene solution (2.60 Å) is thus implied to be somewhat longer than in the solid state and the data therefore parallels the results for the Hg_2^{2+} ion in benzene solution. The $Hg_3^{2+}-C_6H_6$ interaction also seems to parallel that of the Hg_2^{2+} ion. The splitting of the C_6H_6 band at 993 cm^{-1} gives rise to a new band at 982 cm^{-1} in the $Hg/Hg_2Cl_2/GaCl_3$/benzene system (Figure 2), whereas the ^{13}C-NMR resonance in $GaCl_3$/benzene solutions saturated with Hg_2Cl_2 and Hg occurs 0.6 ppm downfield relative to neat benzene. In the IR spectra, the all-in-phase C−H out-of-plane bending mode is shifted to 713 cm^{-1} (shift: +40 cm^{-1}). The spectrum also contains the previously discussed peaks from benzene (673 cm^{-1}) and remaining Ga_2Cl_6−benzene complexes (697 cm^{-1}).

Solubility measurements substantiate the conclusion that Hg_3^{2+} is formed by the oxidation of mercury by Hg_2^{2+}. The solubility measurements were performed in systems where Hg_2Cl_2 was added to transfer essentially all Ga^{III} into $Ga_2Cl_7^-$, according to Equation 1. The only oxidising agent present is thus Hg_2^{2+}, and the solubility was found to be $X°(Hg;Hg_2Cl_2) = 0.958\pm0.005$, thus supporting the interpretation of the spectroscopic data in terms of the reaction $Hg(l) + Hg_2^{2+} \rightarrow Hg_3^{2+}$.

The $Hg/GaCl_3$/Benzene and $Hg/GaCl_3$ Systems − Experimental Evidence for "Soft-Base Stabilisation" of Subvalent Mercury Species

In previous investigations of the reaction between bismuth metal and $GaCl_3$, it transpired that the reactions taking place in $GaCl_3$/benzene solution at room temperature paralleled those in the liquid $GaCl_3$ and $NaCl/GaCl_3$ systems at elevated temperatures.[26][27] In all these solvents, the oxidation of excess bismuth was found to yield concentrated solutions of Bi_5^{3+}, Ga^+, and chlorogallate(III) ions. In stark contrast, the reaction between mercury metal and $GaCl_3$ seems to be thermodynamically dependent on the presence of benzene. Thus, mercury is very soluble in $GaCl_3$/benzene [$X°(Hg;GaCl_3) = 0.226$; $X°(GaCl_3;C_6H_6) = 0.300$], but is insoluble in neat, liquid $GaCl_3$ and only sparingly soluble in liquid $KCl/GaCl_3$ [$X°(Hg;GaCl_3) = 0.024$; $X°(KCl;GaCl_3) = 0.10$]. If an excess of mercury metal is added to a $GaCl_3$/benzene solution, a single, brown liquid phase in equilibrium with mercury metal rapidly is obtained. The Raman spectrum of this solution at low wavenumbers (Figure 1) is very similar to that of the $Hg/Hg_2Cl_2/GaCl_3$/benzene system and confirms the formation of Hg_3^{2+}. In addition, the Raman band at 322 cm^{-1} and the observation of a $^{71}Ga^I$-NMR signal at $\delta = -994$ (relative aqueous $GaCl_4^-$) reveal the concomitant formation of Ga^+ and $Ga_3Cl_{10}^-$ ions, in analogy with the results from $Bi/GaCl_3$/benzene solutions.[26][27] Taken together, these observations strongly suggest Equation 2 to be the predominant reaction between mercury metal and $GaCl_3$ in benzene solution. Assuming a complete reaction between mercury and $GaCl_3$ according to Equation 2, mercury would be soluble to $X°(Hg;GaCl_3) = 0.231$ in the $Hg/GaCl_3$/benzene system. This is in excellent agreement with the experimental value (0.226). In solutions not saturated with Hg metal also Hg_2^{2+} can be synthesised in an analogous manner.

$$3\ Hg + 10\ GaCl_3 \rightarrow Hg_3^{2+} + Ga^+ + 3\ Ga_3Cl_{10}^- \quad (2)$$

It is not feasible to assign the low solubility of mercury metal in liquid $GaCl_3$ and $KCl/GaCl_3$ to a thermal instability of Hg_3^{2+}, since this species has been detected in the chloroaluminate melts at temperatures around 200°C and isolated as tetrachloroaluminate salt from such systems.[1][44] It is therefore tempting to assign the efficient formation of Hg_3^{2+} in $GaCl_3$/benzene solution and the lack of such in liquid $GaCl_3$ and $KCl/GaCl_3$ to stabilising interactions between the arene and the mercury cation. Such interactions, together with those between Ga^+ and benzene, clearly have the potential to push Equation 2 to the right through a formation of $(Hg_3^{2+})(C_6H_6)_k$ complexes and would provide a "base stabilisation" of the subvalent mercury cation. However, Hg_3^{2+} is of course still to be regarded as "acid-stabilised" in the sense that the strongly Lewis-acidic environment ensured by the coordinatively unsaturated $Ga_nCl_{3n+1}^-$ anions prohibits the stabilisation of the Hg^{II} oxidation state through complex formation with chloride and therefore hinders disproportionation. This fact infers a superficially contradictory notion of base stabilis-

ation acting side by side with acid stabilisation. However, the concept of acid stabilisation, as it is normally formulated, is applicable *only* to acid−base equilibria involving hard or intermediate donors and acceptors. This, in turn, is a consequence of the fact that most of the work previously done has involved fluoride and chloride systems. In the present system, the presence of the pronounced *soft* donor C_6H_6 must also be taken into account.

Theoretical Calculations on the Coordination of Hg_m^{2+} Ions

Theoretical calculations were used in an attempt to resolve the experimental ambiguities regarding the coordination of the Hg_m^{2+} ions in $GaCl_3$/benzene media and to substantiate the indications that the subvalent mercury ions are to be regarded as "soft-base-stabilised" in such media. The benzene coordination to the Hg_m^{2+} (m = 2, 3) cores were theoretically investigated in two types of models. In the first type, only interactions between Hg_m^{2+} and two benzene molecules were included; in the second type, also interactions with two chloride ions (as models for gallates/aluminates in the primary coordination site along the Hg−Hg bond vector) were considered. In addition, the separate Hg_m^{2+} and Hg_mCl_2 (m = 2, 3) units where investigated. Models for the coordination of gallates in the secondary site were not considered. The reason is both the ambiguous potential coordination mode and the calculationally huge systems that would emerge.

The quantum-chemical calculations were performed with the GAUSSIAN94 program package.[49] Several potential coordination models for $Hg_m(C_6H_6)_2^{2+}$ and $Hg_mCl_2(C_6H_6)_2$, m = 2 and 3, were optimised at Hartree-Fock level using basis sets of double-zeta quality, viz. LANL2DZ for Hg and 3-21G for the lighter elements. The geometries shown in Figures 6 and 7 represent points of zero gradients on the hypersurface and were identified using the LANL2DZ basis sets (only used for pre-optimisation), later optimised using larger basis sets. The more extended basis sets used for the lighter elements were of augmented 3-21G type; (10s7p)/[5s4p] for Cl, (7s4p)/[4s3p] for C, and (3s)/[2s] for H. The valence space of Hg was optimized at both HF and MP2 level, employing a 60-electron ARECP for Hg,[50] and contracted to (9s9p6d2f)/[6s6p3d1f], where the original f function was omitted because of the lack of gradients for f functions in the combination with ECPs in all common theoretical program packages. Although these basis sets are of moderate size for an atom, the calculations for the molecules were elaborate in computer time and disk space requirements for the full geometry optimisations and frequency calculations, which were performed for all systems at Hartree−Fock (HF) and hybrid density-functional (B3LYP) levels.[51] All systems, except the trimercury ones, were also studied at MP2 level. The HF-optimised basis sets were used for the HF calculations. However, for the correlated calculations the Hg basis set was re-optimised by minimising the MP2 total energy. This has the advantage that basis set superposition errors (BSSE) are suppressed and the bonding involving Hg atoms therefore better described.

The structures in Figure 6 display the $Hg_m(C_6H_6)_2^{2+}$ models in which the chloride ions were not explicitly included and benzene occupies the primary coordination site along the Hg−Hg bond vector. As can be seen from the summary in Tables 2, the energy differences between the η^6, η^2, and η^1/*quasi*-η^3 coordination modes are small but significant. The most stable configuration is the η^1/*quasi*-η^3 one, in good agreement with the crystal structure of $[Hg_2(C_9H_{12})_2](AlCl_4)_2$ (C_9H_{12} = mesitylene).[32] For the $Hg_2(C_6H_6)_2^{2+}$ complex the η^2 mode is 18 kJ mol^{-1} and the η^6 mode 119 kJ mol^{-1} higher in energy (B3LYP level), and the corresponding values for the $Hg_3(C_6H_6)_2^{2+}$ complex are 23 and 99 kJ mol^{-1}. Furthermore, as is obvious from a study of the Hessians, the optimised structures of $Hg_m(\eta^2\text{-}C_6H_6)_2^{2+}$ and $Hg_m(\eta^6\text{-}C_6H_6)_2^{2+}$ (Figure 6) are somewhat too restricted to be considered as proper minima in the strict sense. Negative eigenvalues of the Hessian for these structures correspond to distortions towards the η^1/(*quasi*-η^3) structures. The Hg−Hg bonds are slightly elongated upon coordination to the benzene molecules, and the elongation seems to increase as the hapticity decreases. The charge transfer in the $Hg_m(C_6H_6)_2^{2+}$ complexes is small; the terminal Hg atoms have a formal charge close to +2/m, according to an NBO population analysis. The electron density donation to the terminal Hg atoms seems to be smaller in the trimer than in the dimer, and also the Hg−C distances longer.

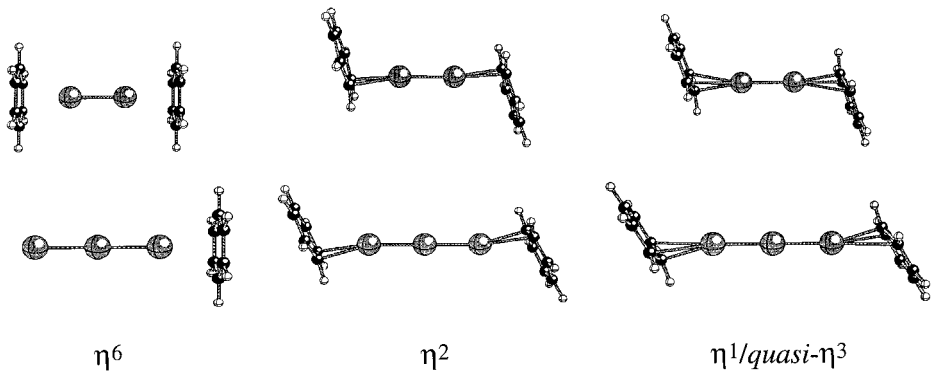

Figure 6. Optimised structures (B3LYP level) of the η^6-, η^2- and η^1/*quasi*-η^3-benzene coordination models for Hg_2^{2+} and Hg_3^{2+}

[a] bz = benzene. − [b] Charge on central Hg atom (first value) and terminal ones (second value). − [c] Average value for all six Hg−C correlations. − [d] Shortest two Hg−C distances and the corresponding average bond order. − [e] Shortest Hg−C distance and the corresponding bond order. − [f] Shortest two Hg−C distances from the central Hg atom and the corresponding average bond order.

In the optimized $Hg_mCl_2(C_6H_6)_2$ models (with chlorides in the primary coordination sites, Figure 7), the electron donation to Hg is substantially larger than in $Hg_m(C_6H_6)_2^{2+}$ (Table 2). Also, the Hg−C bonds are considerably longer, and the benzene coordination is best characterised as η^2 for both $m = 2$ and $m = 3$. In $Hg_2Cl_2(C_6H_6)_2$, the two Hg atoms coordinate in an identical manner, whereas in $Hg_3Cl_2(C_6H_6)_2$ the main benzene coordination is to the central atom of lowest positive charge. In both cases, the coordination mode and distances are very similar to the arene complexes of Pd_2^{2+}, Cu^+, and Ag^+ ions.[29−31,52−54] Inclusion of benzene molecules to the Hg_mCl_2 structures causes a weakening of the Hg−Cl interaction, and a substantial elongation of the Hg−Hg bonds to about 2.6 Å. Furthermore, in $Hg_3Cl_2(C_6H_6)_2$, the charge transfer from benzene to the central Hg atom is substantial, giving the central atom almost the same positive charge as the terminal ones.

According to the calculations, the energy changes for the Equations 3a and 3b are all strongly favourable. At B3LYP level the changes in energy are −789 ($m = 2$) and −688 kJ mol^{-1} ($m = 3$) for Equation 3a, and −236 ($m = 2$) and −432 kJ mol^{-1} ($m = 3$) for Equation 3b.

$$Hg_m^{2+} + 2\ C_6H_6 \rightarrow Hg_m(\eta^1\text{-}C_6H_6)_2^{2+} \quad (3a)$$

$$Hg_mCl_2 + 2\ C_6H_6 \rightarrow Hg_mCl_2(\eta^2\text{-}C_6H_6)_2 \quad (3b)$$

From the calculations, a few general trends regarding the benzene coordination can be discerned: The coordination of benzene to Hg_2^{2+} is more favourable than to Hg_3^{2+}, but this trend is reversed for Hg_mCl_2 (with chlorides in the primary coordination sites). As indicated by the Hg−C bond

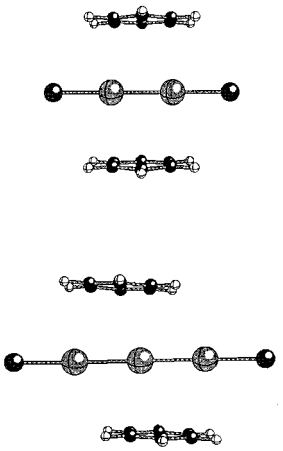

Figure 7. Optimised structures (B3LYP level) of the benzene/gallate coordination models for Hg_2^{2+} and Hg_3^{2+}

lengths, the interaction seems to be energetically stronger between the Hg_m^{2+} ions and benzene, than between the Hg_mCl_2 units and benzene. However, this is a highly simplified analysis, totally disregarding the difference in direct gallate/aluminate−mercury interaction.

Conclusions Based on the Conjunction of Experimental and Theoretical Results

The LAXS data for the Hg_m^{2+} cores in $GaCl_3$/benzene media indicate an elongation of the Hg−Hg distance in such media relative to that in the solid state and molten-salt systems. This evidence finds support in the theoretical calculations, in so far as the calculations suggest that the coordination of benzene to both Hg_m^{2+} and Hg_mCl_2 increase the Hg−Hg distance by a magnitude in good agreement with the experimental results. The calculated Hg−Hg stretch frequencies of the model compounds $Hg_mCl_2(\eta^2\text{-}C_6H_6)_2$ are close to those observed experimentally (Table 3). This is also true for the $Hg_m(C_6H_6)_2^{2+}$ models, irrespective of hapticity, and the influence of benzene coordination on the Hg−Hg stretch frequency thus cannot be used to elucidate the preferred coordination of benzene and chloride by the Hg_m cores.

According to the calculations, the inclusion of benzene molecules to the Hg_mCl_2 structures causes a weakening of the Hg−Cl interaction, consistent with the experimentally observed shift of the Hg−Cl stretch frequencies in benzene media as compared with Hg_mCl_2 melts. The calculated Hg−Cl stretch frequencies (Table 3) are slightly too high at all levels relative to the experimental ones, indicating that the current level of approximation overbind the Hg−Cl interaction. This is expected and unavoidable in the present models, since $Ga_nCl_{3n+1}^-$ ions are weaker Lewis bases than chlorides.

The LAXS and NMR data cannot distinguish between the benzene coordination modes in Figures 6 and 7, although the lack of distinct Hg−C correlations in the rRDFs can be taken as a primitive indication for a low hapticity of the benzene coordination. Nevertheless, the relatively small energy differences between the different coordination modes may indicate a fluxional behavior in solution, consistent with the lack of detailed NMR-spectroscopic data for the benzene interaction. A frontier orbital analysis is consistent with the experimentally observed shift in frequency of the benzene ring breathing mode to lower wavenumbers, assuming an electron-density donation from the bonding benzene π system to the s-dominated, Hg−Hg-antibonding LUMO of the Hg_m^{2+} units. However, of most interest are the calculated shifts in C−C breathing and C−H all-in-phase, out-of-plane mode frequencies of the coordinated benzene molecules for the eight structure models in Figures 6 and 7 (Table 3). It seems clear from the calculations that *only* the end-on coordination of benzene (Figure 6) produces a shift in the C−C mode of a magnitude comparable to the experimental values. The strong and clear effect for the benzene ring breathing mode is a rather convincing evidence for a benzene coordination in the Hg−Hg direction. Also the shift in C−H bending frequencies is best in agreement with the experimental results for the $Hg_m(C_6H_6)_2^{2+}$ models. However, the calculations suggest that the energy of two monomeric $Hg(\eta^2\text{-}C_6H_6)^+$ complexes has about the same energy as $Hg_2(\eta^2\text{-}C_6H_6)_2^{2+}$ at both HF and B3LYP level (Table 2). This indicates that the benzene-coordinated dimer requires the extra stabilisation provided by gallates in the secondary (sandwiching) coordination site. Consequently, it seems that both the presence of benzene *and* gallate anions are important for the stabilisation of subvalent mercury species in benzene solution. This is in good agreement with our experimental data, which are consistent with a strong interaction between both the anionic, hard gallates and the neutral, soft benzene molecules, of which the latter clearly is a fundamental prerequisite for the formation of subvalent mercury ions in the Hg/$GaCl_3$/benzene system.

To conclude, both coordination models proposed for Hg_2^{2+} and Hg_3^{2+} are theoretically feasible, and the current systems are thus highly interesting in terms of the competition between hard and soft donor ligands for the primary coordination site. However, in view of the experimental and quantum-chemical results we are inclined to favour the coordination model with η^1/*quasi*-η^3-benzene along the Hg−Hg bond vector and the gallates confined to a secondary coordination site (Figure 6). The possible "base stabilisation" of subvalent clusters by aromatics definitely deserves further experimental and theoretical investigation since interactions with hetero groups (carbonyl transition metal compounds) recently have been shown to be a way to stabilise new and unprecedented clusters of the post-transition elements.[55−58] However, results derived for the subvalent Hg_m^{2+} ions must be applied with considerable care on other subvalent post-transition element clusters, since the mercury species are unique in their strong interaction with the counterions.

Experimental Section

General: All sample preparations were performed in a glove box under dried, deoxygenated nitrogen (< 1 ppm H_2O). All glassware

[a] The average benzene ring breathing mode (ν_2). In the mercury compounds, the two benzene rings can vibrate in and out of phase, thus giving rise to two modes with frequencies that normally only differ by a few wavenumbers. Formally, only the A-symmetry mode is Raman-active, but in order to minimise the effect of extensive mixing with other modes in the lower symmetries the average of the two are used. − [b] The all-in-phase C−H bending mode perpendicular to the benzene plane, normally sensitive to ring substitution and coordination. In the mercury complexes, the H atoms in the two benzene rings can vibrate in and out of phase, giving rise to two bands with very similar frequencies. − [c] The difference with respect to the corresponding calculated frequency for free benzene. − [d] bz=benzene.

was dried at 300°C in vacuo prior to use. After sample preparation all sample cells were sealed under vacuum. Hg_2Cl_2 (Merck, p.A. grade) was dried at 150°C for several weeks prior to use. Benzene was distilled and stored over sodium. $GaCl_3$ (ALFA, 99.999%) and mercury metal (Merck, p.A. grade) were used as received. KCl (Merck. p.A.) was dried for several days at 130°C before use. The solubility measurements were made gravimetrically, monitoring the amount of dissolved mercury metal at equilibrium with known amounts of Hg_2Cl_2, $GaCl_3$, and benzene.

Liquid X-ray Scattering (LXS): The LXS experiments were performed at room temperature using Mo-K_α radiation and a Seifert GSD θ−θ diffractometer equipped with a liquid-nitrogen-cooled solid-state detector (Ortec EG&G). The samples were enclosed in sealed Lindemann capillaries with an outer diameter of 1 mm. The experimental procedure and data evaluation have previously been described in detail.[62] The nominal composition of the solvent was $X°(GaCl_3;C_6H_6)$ = 0.29 and the samples were saturated with Hg_2Cl_2 or Hg/Hg_2Cl_2 in order to maximise the contributions from mercury species to the intensity function $s{\cdot}i(s)$ ($s = 4\pi\sin\theta/\lambda$). Data were collected in the s range 0.200−13.00 $Å^{-1}$. In the data evaluation, corrections for spurious peaks in the reduced radial distribution function were applied for $r < 1.0$ Å and the value of k in the damping function $\exp(-ks^2)$ was set to 0.012.

Vibrational Spectroscopy: Raman spectra were recorded with a Bruker IFS-66/FRA-106 FT Raman spectrometer equipped with a low-power Nd:YAG laser (λ = 1064 nm) and a liquid-nitrogen-cooled, solid-state Ge diode detector. The samples were contained in 5-mm NMR tubes sealed under vacuum. The IR spectra were recorded with a Bio-Rad FTS 6000 FT-IR spectrometer, using a Globular radiation source and KBr beamsplitter and DTGS detector, and 6.25 μm Mylar beamsplitter and PE-DTGS detector for the mid-IR and far-IR spectra, respectively. The resolution in both

Raman and IR spectra was 4 cm^{-1}. The samples were prepared in a glove box (vide supra) and contained in polyethylene bags in the far-IR and between Teflon-coated KBr pellets in mid-IR experiments.

NMR Spectroscopy: The NMR measurements were performed with a Varian Unity 300-MHz spectrometer. TMS was used as a reference for the ^{13}C-NMR spectra, whereas ^{199}Hg- and ^{71}Ga-NMR shifts were determined relative to $HgMe_2$ and $GaCl_4^-$ in hydrochloric acid, respectively.

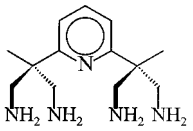
Kinetics and Mechanism of Base Hydrolysis in Cobalt(III) Complexes − The Case of a Complex $CoLCl^{2+}$ where L has the Novel Topology of a Square-Pyramidal NN_4 Coordination Cap

Tilo Poth,[a] Helmut Paulus,[a][+] Horst Elias,*[a] Rudi van Eldik,[b] and Andreas Grohmann*[b]



Keywords: Cobalt(III) complexes / Tetrapodal pentadentate ligand / Hydrolysis / Kinetics / Mechanism

Multi-wavelength stopped-flow spectrophotometry was used to study the kinetics of base hydrolysis of the octahedral cobalt(III) complex $CoLCl^{2+}$ (**2**), in which the tetrapodal pentadentate ligand L has an NN_4 donor set and forms a square-pyramidal coordination cap [L = 2,6-bis(1′,3′-diamino-2′-methylprop-2′-yl)pyridine, **1**]. The kinetic investigation, carried out at different temperatures, pressures and ionic strengths I, led to second-order kinetics, rate = k_{OH} [**2**][OH^-], with $k_{OH} = 0.139 \pm 0.001$ $M^{-1}s^{-1}$ (I = 0.1 M) and $k_{OH} = 0.0570 \pm 0.0004$ $M^{-1}s^{-1}$ (I = 1.0 M) at 298 K. The temperature and pressure dependence of k_{OH} resulted in $\Delta H^{\ddagger} = 119 \pm 3$ kJmol^{-1} (I = 0.1 M) and $\Delta H^{\ddagger} = 123 \pm 3$ kJmol^{-1} (I = 1.0 M), $\Delta S^{\ddagger} = +130 \pm 13$ Jmol^{-1}K^{-1} (I = 0.1 M) and $\Delta S^{\ddagger} = +151 \pm 15$ Jmol^{-1}K^{-1} (I = 1.0 M) and $\Delta V^{\ddagger} = +27.6 \pm 0.6$ cm^{3}mol^{-1} (I = 1.0 M). The kinetic results support the operation of the conjugate base mechanism, D_{cb}, with intermediate deprotonation occuring *cis* to the leaving chloride ion. The observed inertness of complex **2** towards base hydrolysis is discussed on the basis of the special structural features of the ligand L. The pK_a of the coordinated water in the aqua species $CoL(H_2O)^{3+}$(**3**) was determined to be pK_a = 6.0 ± 0.1 at I = 0.1 M. The X-ray crystal structure analysis of the hydroxo complex $[CoL(OH)](ClO_4)_2$ (**4**) shows a mononuclear terminal (hydroxo)Co^{III} complex, in which the ligand provides a regular square-pyramidal NN_4 donor cap for the octahedrally six-coordinate Co^{III} ion [**4**, monoclinic, space group $C2/m$, a = 16.841(6) Å, b = 8.541(3) Å, c = 15.112(5) Å, β = 109.13(1)°, Z = 4]. Coordination of L is accompanied by the formation of 6 six-membered chelate rings, all of which adopt a boat conformation. In the crystal lattice, pairs of cations are associated via four (hydroxo)O···H–N(primary amine) hydrogen bonds and related through an inversion center. Full spectroscopic data for **4** (^{1}H-, ^{13}C-NMR, IR, MS) are presented.

Introduction

Tetrapodal pentadentate ligands designed to provide a square-pyramidal coordination cap for octahedrally coordinating transition metal ions were until recently unknown.[1−3] This coordination mode requires a ligand to have an apical donor atom with a lone pair oriented towards the center of the octahedron, while four donor groups are juxtaposed to occupy the equatorial positions. The interest in ligands of this type arises from their potential stabilization of free coordination sites in otherwise octahedrally coordinated complexes. Suitable derivatization of the equatorial positions may then provide an environment for a monodentate substrate or reagent (such as metal-coordinated hydroxide) in which it shows modulated reactivity.[4]

The coordination behavior of the prototypical NN_4 coordination cap **1** (≡ L) towards nickel(II) and cobalt(III) has been the subject of recent work.[2,5,6] The ligand acts as a podand in all cases (including a $Co^{III}-CH_3$ complex), and

1 (≡ L)

a polynuclear coordination mode has not been observed. Given the similarity of pyridine and ammine ligands with respect to their position in the spectrochemical series, **1** may be considered a highly symmetrical chelating analogue of the classical pentaammine donor set, and complexes of **1** are expected to show similar reactivity, e.g. with respect to ligand exchange. In order to substantiate this assumption and obtain mechanistic data relevant to future use of the ligand as a mononucleating head group in functional metal complexes, we chose to study the kinetics of a classical exchange reaction of cobalt(III), viz. the base-assisted hydrolysis of $CoLCl^{2+}$ (**2**).

Base-assisted hydrolysis of the octahedral Werner-type complex $Co(NH_3)_5Cl^{2+}$ according to Equation 1, following the simple rate law of Equation 2, has initiated an impressive number of kinetic studies on reactions of Equation 3.[7]

$$Co(NH_3)_5Cl^{2+} + OH^- \rightarrow Co(NH_3)_5(OH)^{2+} + Cl^- \quad (1)$$

$$\text{rate} = k_{OH}[Co^{III}][OH^-] \quad (2)$$

$$Co(\text{'}N_5\text{'})Cl^{2+} + OH^- \rightarrow Co(\text{'}N_5\text{'})(OH)^{2+} + Cl^- \quad (3)$$

These reactions are now commonly agreed to proceed by the so-called "conjugate base mechanism", D_{cb} (formerly S_N1CB), which involves the intermediate formation of a substitutionally labile amide complex.[8,9] The symbol 'N_5' in Equation 3 stands for a set of five N donor atoms in the form of either five monodentate ligands or combinations of monodentate and chelate ligands, such as ($N + N_2 + N_2$), ($N_2 + N_3$), ($N + N_4$), and (N_5).

Such variations in the 'N_5' set of ligands were made in order to allow meaningful conclusions concerning, for example, the question of deprotonation and amide bond formation *cis* or *trans* to the leaving group. An interesting outcome of these studies was that the nature of the ligands making up 'N_5' has a pronounced effect on the magnitude of the second-order rate constant k_{OH}, which reflects the kinetic significance of the structural features in the 'N_5' coordination sphere.

The NN_4 topology of L in the octahedral chlorocobalt complex $[CoLCl]Cl(ClO_4) \cdot H_2O$[2] represents a novel type of 'N_5' unit. In view of the individual steps associated with the D_{cb} mechanism, the situation in this complex is remarkable for several reasons. Firstly, the nitrogen atom *trans* to the leaving group is tertiary, hence cannot be deprotonated. Since pyridine donors coordinated *cis* to the leaving group were found to increase the rate of base hydrolysis markedly,[10] species in which pyridine is coordinated *trans* to the leaving group have long been called for for the purpose of comparison.[11,12] Secondly, the ligand L enforces a rigid square-pyramidal coordination cap containing four equivalent $Co-NH_2R$ bonds, which raises the question whether the internal steric strain associated with the deprotonation of one of the NH_2 groups is possibly too high to allow intermediate amide bond formation at all.

The present contribution provides the kinetic data obtained for the reaction according to Equation 3 at different temperatures, pressures and ionic strengths, as well as spectroscopic and X-ray structural data for the hydroxo complex $[CoL(OH)](ClO_4)_2$ (**4**). The pK_a value of the aqua complex $CoL(H_2O)^{3+}$ (**3**) is also reported.

Results and Discussion

Properties of the Complexes

Table 1 summarizes the UV/Vis absorption data of the cations **2**, **4**, and **3**. The spectra show two absorption maxima, which can be assigned to the transitions $^1T_{1g} \leftarrow {}^1A_{1g}$ and $^1T_{2g} \leftarrow {}^1A_{1g}$, commonly observed in Co^{III} complexes of this type. The variation of the sixth ligand ($Cl^- \rightarrow OH^- \rightarrow H_2O$) causes a blue shift of both maxima ($\lambda_{max} = 356 \rightarrow 343 \rightarrow 335$ nm and $\lambda_{max} = 512 \rightarrow 480 \rightarrow 480$ nm), which is in accord with the position of the ligands in the spectrochemical series.

Table 1. Visible absorption {λ_{max} [nm] (ε_{max} [$M^{-1}cm^{-1}$])} of the complex cations in aqueous solution at 293 K

$CoL(Cl)^{2+}$ (**2**)	356(101)	512(67)
$CoL(OH)^{2+}$ (**4**)	343(128)	480(95)
$CoL(H_2O)^{3+}$ (**3**)	335(100)	480(56)

Figure 1 shows the spectral changes following the stepwise deprotonation of the species **3** according to Equation 4 and, as an example, the plot of A_{483} vs pH. Multi-wavelength fitting of the (A, [H^+]) data (350−600 nm) with Equation 5 leads to $pK_a = 6.0 \pm 0.1$. The pK_a found for complex **3** is very similar to the pK_a reported for other (amine)(monoaqua)cobalt(III) complexes.[13] From its magnitude it follows that even at pH = 5−6 appreciable amounts of the hydroxo species **4** are present.

$$CoL(H_2O)^{3+} \overset{K_a}{\rightleftharpoons} CoL(OH)^{2+} + H^+ \quad (4)$$

$$A = \{A_{H_2O} + A_{OH}(K_a)^{-1}[H^+]\}/\{1 + (K_a)^{-1}[H^+]\} \quad (5)$$

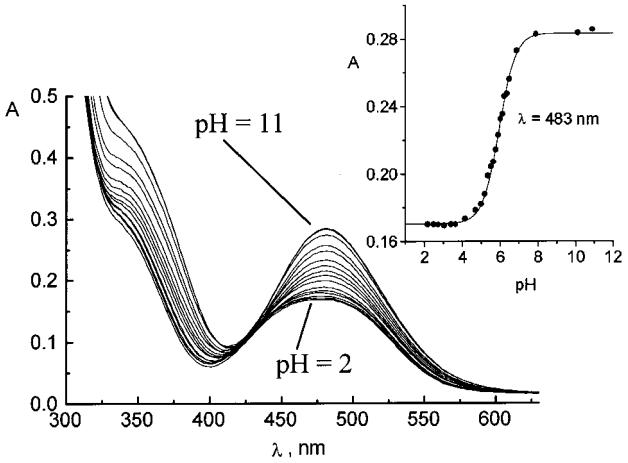

Figure 1. Spectral changes associated with the titration of complex **3** ($3 \cdot 10^{-3}$ M) with 0.1 M NaOH at 298 K and $I = 0.1$ M ($NaNO_3$); insert: plot of A_{483} vs. pH and fit (solid line) with Equation 5

The ^1H- and ^{13}C-NMR spectra of **4** (r.t.; amount of sample: 20 mg; solvent: anhydrous [D_6]DMSO; amount of solvent: 0.6 mL) largely resemble those of the parent chloro complex $[CoLCl]Cl(ClO_4) \cdot H_2O$ in terms of chemical shift and signal multiplicity.[2] A few features deserve special mention. In the ^1H-NMR spectrum of **4**, the resonances of the diastereotopic amine protons ($\delta = 4.52$ and 4.70) are shielded by ca. 0.8 ppm and 1.2 ppm, respectively, relative to the corresponding resonances in $[CoLCl]Cl(ClO_4) \cdot H_2O$ ($\delta = 5.29$ and 5.85). There is a broad singlet at high field, viz. −2.60 (sweep width −20 to +30 ppm; $W_{1/2} = 7.1$ Hz), which we assign to the proton of the hydroxo ligand. The observed high-field shift is presumably a consequence of the OH proton being solitary, i.e. not involved in hydrogen bonding under the given conditions. Hydrogen bonding, if present, as well as the electronegative nature of the heteroatom carrying this proton, would lead one to expect a significant *downfield* shift of its resonance. The signal disappears owing to exchange when water is allowed to diffuse into the sample. We are not aware of reliable previous NMR data of structurally characterised Co^{III} complexes containing a terminal hydroxo ligand. In a structurally characterised monomeric terminal hydroxo complex of zinc, the $Zn-OH$ resonance is observed at similarly high field ($\delta = -0.06$; solvent: [D_6]benzene).[14] In the ^{13}C-NMR spectrum of **4**, the resonance assigned to the methylene carbon atoms

shows fine structure. An asymmetric three-line signal is observed (J = 7.8 Hz), of which the line towards low field is not well resolved but is visible as a shoulder. We attribute this splitting to partially resolved coupling with the ^{14}N nucleus (I = 1), which is usually only observable in highly symmetric species such as tetraalkylammonium ions, in which the electric field gradient at ^{14}N is zero or sufficiently small.[15]

In the IR spectrum of **4**, there is a sharp ν(OH) str band of medium intensity at 3578 cm^{-1}. A band below 1200 to 700 cm^{-1}, characteristic of a hydroxo complex and due to the M−O−H bending vibration,[16] cannot be assigned with certainty as this region is obscured by the very broad absorption of the ClO_4^- counterions.

Structure of the Complex $[CoL(OH)](ClO_4)_2$ (4)

The X-ray structure analysis unequivocally confirms the presence of a mononuclear terminal (hydroxo)Co^{III} complex, making **4** one of the very few examples of such complexes that have been structurally characterised.[17] The molecular structure of the cation, which has crystallographically imposed mirror symmetry, is shown in Figure 2. Selected bond lengths and angles are given in Table 2. The mirror plane contains the pyridine ring, the quaternary and methyl carbon atoms of the pentaamine ligand backbone, one of the protons on each exocyclic methyl group, the cobalt atom, and the oxygen and hydrogen atoms of the hydroxo ligand. All hydrogen atoms have been located in the difference Fourier map. Specifically, the location of electron density corresponding to *one* proton bound to the hydroxo oxygen atom is clearly discernible at a reasonable distance and angle relative to that atom [d(O−H) = 0.863(2) Å, ∠Co−O−H = 109.9(2)°]. There is no residual electron density in the vicinity of the hydroxo ligand.

The pentaamine ligand coordinates to cobalt(III) in pyramidal fashion, with the pyridine nitrogen atom occupying an axial position of the overall coordination octahedron, while the four equivalent amino nitrogen atoms take the equatorial positions. This mode of coordination leads to the formation of 6 six-membered chelate rings, all of which adopt a boat conformation. The hydroxo ligand occupies the remaining axial position. The coordination octahedron is close to regular, with angles N_{ax}−Co−N_{eq} and N_{eq}−Co−N_{eq} ranging from 84.91(10)° to 93.16(7)°. The arrangement of atoms along the principal axis of the octahedron (N11, Co1, O1) is linear [179.77(8)°], and the angles between diametrically disposed pairs of NH_2 substituents (N12, N13′; N12′, N13) at Co are close to 180° [175.94(7)°]. The cobalt atom is displaced from the plane defined by the four equatorial amino nitrogen atoms towards the pyridine N atom by only 0.044(1) Å. The pyridine ring is a regular hexagon. Thus, the tetrapodal pentadentate amine ligand provides a square-pyramidal coordination cap for the metal center in the same way as in a related chloro[2] and methyl complex.[6] The cobalt−pyridine bond length in **4** [1.934(2) Å] is the same within experimental error as that in the chloro complex $[CoLCl]Cl(ClO)_4 \cdot H_2O$ [1.928(3) Å],[2] as opposed to a value of 2.018(2) Å for the corresponding bond in the methyl complex $[CoL(CH_3)]S_2O_6$.[6] This reflects *trans* influences of comparable magnitude for OH^- and Cl^-, as opposed to the significantly larger *trans* influence exerted by the CH_3^- ligand.[18] The Co1−O1 distance in **4** [1.897(2) Å] is comparable to the value obtained for another terminal Co^{III}−OH complex [1.894(10) Å],[17b] while the value determined for a third complex [2.190(3) Å] is so large as to have been considered at odds with the formulation as a hydroxo species.[17a]

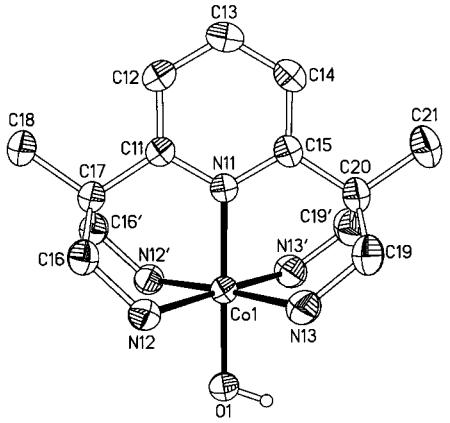

Figure 2. Molecular structure of **4** with thermal ellipsoids drawn at the 50% probability level; the position of the hydroxo hydrogen atom H1 is indicated by a sphere of arbitrary diameter; all other hydrogen atoms have been omitted for clarity

In the crystal lattice, pairs of cations are associated via (hydroxo)O···H−N(primary amine) hydrogen bonds and related through an inversion center as follows: Both lone pairs on the hydroxo ligand of cation 1(2) receive hydrogen bonds from one proton each on two adjacent amino groups in cation 2(1). The distance O1···N12 is 2.874(2) Å, and the angle at H12A is 151.8(1)° (sum of the van der Waals radii of O and N: 3.07 Å[19]). The hydroxo protons of cation 1 and 2 point away from each other and do not participate

in hydrogen bonding. The crystallographic inversion center is located at the midpoint of the vector connecting the hydroxo oxygen atoms of cation 1 and 2. The other non-bonded distances in the crystal packing fall outside the range where significant hydrogen bonding may be inferred. The two perchlorate counterions show rotational disorder which has been resolved, but otherwise have normal structural parameters. The residual electron density in the overall structure is located at ClO_4^-.

Kinetics of Base Hydrolysis

As shown in Figure 3 for pH ≈ 12, base hydrolysis of complex **2**, as obtained by dissolving $[CoLCl]Cl(ClO_4) \cdot H_2O$ in water, is associated with substantial spectral changes and occurs with a half-life of several minutes (T = 298 K). The (A, t) data can be fitted very satisfactorily to one exponential (Equation 6) for the whole wavelength range. Experiments carried out in the presence of a thirtyfold excess of NaCl guaranteed that non-coordinated chloride ions, as introduced with the complex $[CoLCl]Cl(ClO_4) \cdot H_2O$, have no effect on the magnitude of the experimental rate constant k_{obsd}.

$$A = (A_0 - A_\infty)[\exp(-k_{obsd}t)] + A_\infty \quad (6)$$

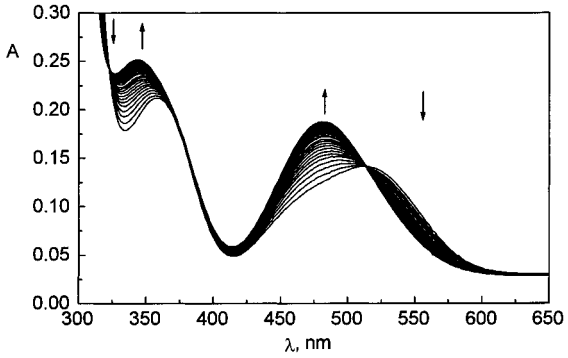

Figure 3. Spectral changes associated with the base hydrolysis of complex **2** ($2.2 \cdot 10^{-3}$ M) at pH ≈ 12 and 293 K (the spectra, taken at time intervals of 19.8 s, cover a reaction time of 990 s)

Figure 4 shows that the dependence of k_{obsd} on $[OH^-]$ is linear, which leads to the rate law of Equation 7 and second-order rate constant k_{OH}.

$$\text{rate} = -d[CoLCl^{2+}]/dt = d[CoL(OH)^{2+}]/dt = k_{OH}[CoLCl^{2+}][OH^-] \quad (7)$$

In addition, Figure 4 documents that the rate of base hydrolysis increases with decreasing ionic strength, as expected for the reaction between species of opposite charge.[20] The observed ratio for k_{OH} (I = 0.1 M)/k_{OH} (I = 1.0 M) = 2.4 is in accord with the averaged value k_{OH} (I = 0.1 M)/k_{OH} (I = 1.0 M) = 2.2, as reported earlier for a number of $Co'N_5'X^{2+}$ complexes.[11]

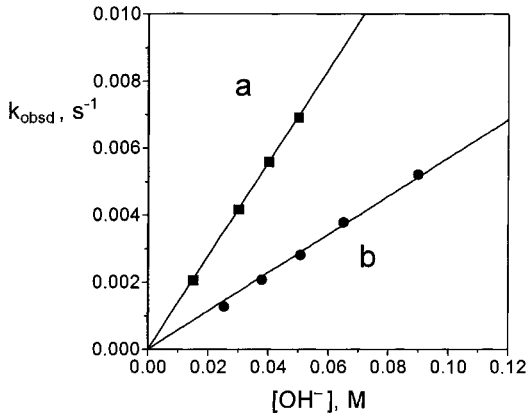

Figure 4. Plot of the experimental rate constant k_{obsd} vs. $[OH^-]$ for base hydrolysis of complex **2** ($2.2 \cdot 10^{-3}$ M) according to Equation 7 at I = 0.1 M $NaClO_4$ (a) and I = 1.0 M $NaNO_3$ (b), (T = 298 K)

Least-squares fitting of the data shown in Figure 3 leads to k_{OH} = 0.139 $M^{-1}s^{-1}$ (I = 0.1 M) and k_{OH} = 0.0570 $M^{-1}s^{-1}$ (I = 1.0 M). These rate constants are amongst the lowest ever reported for base hydrolysis reactions of Equation 3.[21]

The D_{cb} mechanism is based on the reaction sequence of Equations 8a–8c, with Equation 8a being a fast deprotonation/protonation equilibrium and Equation 8b being the rate-determining step which, as pointed out, is very slow in the present system (the symbol L_{-H} stands for the ligand L, mono-deprotonated at one of the four primary amino groups).

$$CoLCl^{2+} + OH^- \overset{K}{\rightleftharpoons} CoL_{-H}Cl^+ + H_2O \quad (8a)$$

$$CoL_{-H}Cl^+ \xrightarrow[\text{rds}]{k} CoL_{-H}^{2+} + Cl^- \quad (8b)$$

$$CoL_{-H}^{2+} + H_2O \xrightarrow{\text{fast}} CoL(OH)^{2+} \quad (8c)$$

Assuming the equilibrium according to Equation 8a to be established and $[complex]_o << [OH^-]$, one can derive the rate law of Equation 9 which suggests that the dependence $k_{obsd} = f([OH^-])$ should come to saturation for $K[OH^-] >> 1$.

$$d[CoL(OH)^{2+}]/dt = \{k \cdot K[OH^-]/(1 + K[OH^-])\} \cdot [CoLCl^{2+}] = k_{obsd}[CoLCl^{2+}] \quad (9)$$

As shown in Figure 4, k_{obsd} increases linearly with $[OH^-]$ up to $[OH^-]$ = 0.09 M. This means that the estimate $K[OH^-] << 1$ can be made, for which condition the rate law of Equation 9 takes the simple form of Equation 10 which corresponds to the experimentally found rate law of Equation 2 with $k_{OH} \equiv k \cdot K$.

$$d[CoL(OH)^{2+}]/dt = k \cdot K[OH^-] \cdot [CoLCl^{2+}] \quad (10)$$

It is noteworthy that a linear dependence of k_{OH} on $[OH^-]$ is generally observed for the base hydrolysis of cobalt(III) complexes.[9]

[a] $\Delta H^{\neq}$ and $\Delta S^{\neq}$ were obtained from the temperature dependence of k_{OH} at five temperatures in the range T = 285– 318 K. $\Delta V^{\neq}_{exptl}$ was obtained from the pressure dependence of the first-order rate constant k_{obsd} in the range 10–150 MPa at 308 K. – [b] en = 1,2-Diaminoethane ($NH_2[CH_2]_2NH_2$). – [c] tren = Tris(2-aminoethyl)amine [$N(CH_2CH_2NH_2)_3$]; *t* isomer: tertiary nitrogen atom *trans* to coordinated chloride, *p* isomer: tertiary nitrogen atom *cis* to coordinated chloride. – [d] tmd = 1,3-Diaminopropane ($NH_2[CH_2]_3NH_2$); dien = 3-azapentane-1,5-diamine ($NH_2[CH_2]_2NH[CH_2]_2NH_2$); *a* isomer: "flat" nitrogen atom of dien *cis* to coordinated chloride; *d* isomer: "bent" nitrogen atom of dien *cis* to coordinated chloride; *h* isomer: "bent" nitrogen atom of dien *trans* to coordinated chloride. – [e] tacn = 1,4,7-Triazacyclononane; amp = 2-aminomethylpyridine.

It has been shown that anion competition experiments[22,23] and the determination of reaction volume profiles[24] can provide experimental evidence for the validity of the commonly accepted D_{cb} mechanism. In order to substantiate the operation of the D_{cb} mechanism for the base hydrolysis of **2**, experiments at different temperatures (see Table 4) and pressures (see Figure 5) were carried out. The resulting activation parameters $\Delta H^{\neq}$, $\Delta S^{\neq}$, and $\Delta V^{\neq}_{exptl}$ are listed in Table 3, together with the corresponding data reported for other Co'N_5'Cl^{2+} complexes.

[a] [$CoLCl^{2+}$] = 2.5·10^{-3} M. – [b] [OH^-] = 0.025 M. – [c] [OH^-] = 0.065 M.

The $\Delta H^{\neq}$ and $\Delta S^{\neq}$ values obtained for **2** are conspicuously close to those of the "parent complex" $Co(NH_3)_5Cl^{2+}$, which undergoes base hydrolysis at a similarly low rate.[25] The large positive entropy of activation of ca. 150 $Jmol^{-1}K^{-1}$ has often been discussed as a mechanistic proof for the equilibrium according to Equation 8a.[26] The value of $\Delta V^{\neq}_{exptl}$ = 27.6 ± 0.6 cm^3mol^{-1} (cf. Experimental Section) provides strong evidence that base hydrolysis of complex **2** follows the D_{cb} mechanism. By way of comparison, the average base hydrolysis volume of activation of 11 different dipositive (amine)cobalt(III) complexes is 29.7 cm^3 mol^{-1},[24] and thus close to the value found in the present study. In the same way as $k_{OH} \equiv kK$, $\Delta V^{\neq}_{exptl}$ is a composite parameter, involving the contribution of the pressure dependence of the equilibrium of Equation 8a, $\Delta \bar{V}(K)$, and that of the rate-determining dissociation step of Equation 8b, $\Delta V^{\neq}(k)$, according to Equation 11. For Co^{III} complexes with an overall 2+ charge, the magnitude of $\Delta \bar{V}(K)$ can be estimated[24,27] to be + 19.3 ± 1.5 cm^3 mol^{-1}, resulting in an activation volume $\Delta V^{\neq}(k)$ of 8.3 cm^3 mol^{-1} for the reaction step of Equation 8b.

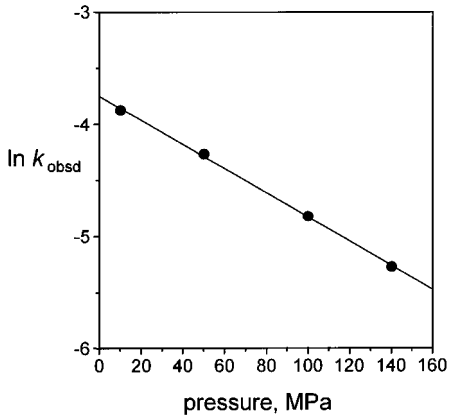

Figure 5. Plot of ln k_{obsd} vs. pressure for base hydrolysis of complex **2** according to Equation 12 at 308 K ([complex] = 2.5·10^{-3} M; [OH^-] = 0.1 M; I = 1.0 M $NaNO_3$)

$$\Delta V^{\neq}_{exptl} = \Delta \bar{V}(K) + \Delta V^{\neq}(k) \quad (11)$$

This value is smaller when compared to $\Delta V^{\neq}(k)$ = 14.5 cm^3 mol^{-1} for the complex $Co(NH_3)_5Cl^{2+}$,[28a] but within the experimental error limits not small enough to indicate convincingly an I_d-controlled reaction of the deprotonated intermediate $CoL_{-H}Cl^+$ (see Equation 8b) as opposed to a D-controlled one.[28b] The overall $\Delta V^{\neq}_{exptl}$ value therefore favors the operation of a D_{cb} mechanism. The difference in $\Delta V^{\neq}(k)$ found for **2** and $Co(NH_3)_5Cl^{2+}$ probably reflects the rigidity of the tetrapodal ligand L, which makes the

formation of a five-coordinate intermediate very unfavorable and hinders the dissociation of the intermediate amide complex according to Equation 8b.

Conclusions Concerning the D_{cb} Mechanism

There has been a lot of controversy as to whether deprotonation in the step of Equation 8a, leading to the conjugate base, occurs at the most acidic amino proton. ^{1}H-NMR studies provided strong evidence that this is not necessarily so.[12,23] It was therefore repeatedly concluded that the differences in the rate of base hydrolysis are mainly governed by the lability of the conjugate base rather than by differences in proton labilities of the parent complex. Questions of this sort need not to be considered for **2**, where the *trans* position is occupied by a 2,6-disubstituted pyridine. Deprotonation can thus occur only at one of the four equivalent amino groups *cis* to the leaving chloride ion.

It is well established that the lability of the amido conjugate base depends significantly on the constraints imposed by the geometry and structure of the ligand(s):

1) A meridional or "flat" secondary nitrogen atom (such as the central nitrogen atom in the ligand dien), *cis* to the leaving group, leads to high base hydrolysis rates. In the case of facial coordination (resulting in a "bent" secondary nitrogen atom), hydrolysis occurs at a notably lower rate.[21]
2) Five-membered chelate rings on either side of a "flat" nitrogen atom favor rapid hydrolysis, especially in the presence of additional six-membered chelate rings.[21]
3) A pyridine ligand *cis* to the leaving group increases the rate of base hydrolysis markedly.[10,11]
4) The geometry and structure of the chelating ligand determine how readily the complex will form a five-coordinate amide intermediate of trigonal bipyramidal geometry, which is considered to be the most favorable geometry.[12,21]

When the first two of these conditions are fulfilled, base hydrolysis can indeed be extraordinarily fast, as in the case of the complex cation Co(tmd)(dien)Cl^{2+}, which has a secondary "flat" nitrogen atom *cis* to the chloride ligand as well as five-membered chelate rings on either side (k_{OH} = $5\cdot10^5$ $M^{-1}s^{-1}$; see Table 3). When the ligand dien in this complex is coordinated facially, with the secondary "bent" nitrogen atom *trans* to chloride, the reaction rate constant is reduced to k_{OH} = 10.6 $M^{-1}s^{-1}$.

According to the four requirements mentioned above, base hydrolysis of complex **2** is expected to be slow, because (i) there are no secondary NH protons at all, (ii) the pyridine ligand is not *cis* to the leaving group, and (iii) the rigid ligand L does not favor the formation of an intermediate of trigonal bipyramidal geometry.

It is interesting to note that base hydrolysis of the complex *t*-Co(tren)$(NH_3)Cl^{2+}$ is also especially slow (k_{OH} = 0.02 $M^{-1}s^{-1}$; see Table 3). The ligand tren in this complex is a tripodal ligand of the type $N(NH_2)_3$ with its tertiary nitrogen donor coordinated *trans* to chloride, whereas in **2** the ligand **L** is tetrapodal and of the type $N(NH_2)_4$. One may argue, therefore, that it is the tripod or tetrapod structural element that causes reduced flexibility and, as a consequence, low base hydrolysis rates. The comparison of the complexes $Co(NH_3)_5Cl^{2+}$ and **2** shows, however, that this argument is of limited value. Both complexes show similarly low base hydrolysis rates and have virtually the same values of $\Delta H^{\neq}$ and $\Delta S^{\neq}$ (see Table 3), while the difference in ligand flexibility could not possibly be greater. Compared to **2**, $Co(NH_3)_5Cl^{2+}$ should easily form the trigonal bipyramidal amide conjugate base. Still, base hydrolysis is practically as slow as in the case of **2**. This may suggest that the rate at which cobalt(III) complexes of the type Co'N_5'Cl^{2+} follow the D_{cb} mechanism will also be affected by the symmetry of the species Co'N_5'Cl^{2+}. In contrast to most of the other complexes listed in Table 3, both $Co(NH_3)_5Cl^{2+}$ and **2** are highly symmetrical in the ground state and deprotonation reduces this high degree of symmetry substantially.

A pseudo-base mechanism has been discussed to account for the rate enhancement which is observed when a pyridine ligand is coordinated *cis* to the leaving group, but there is little experimental evidence to substantiate this assumption.[12,29] A pyridine ligand *trans* to the leaving group is a structural element which had so far been lacking in the chemistry of Co'N_5'Cl^{2+} complexes, despite a number of attempted syntheses.[11,12] The present results clearly prove that a *trans*-coordinated pyridine ligand does not have any significant labilizing effect on the leaving group, and reinforce the analogy between the tetrapodal pentadentate ligand L and the classical pentaammine donor set.

Experimental Section

$AgClO_4$ and $NaClO_4 \cdot H_2O$ (Fluka; reagent grade) were used without further purification. (***CAUTION:*** Perchlorate salts are potentially explosive; they should be handled with caution and in small quantities only!). [CoLCl]$Cl(ClO_4) \cdot H_2O$ was prepared as described.[2] Deionized water was doubly distilled in a quartz apparatus before use.

[CoL(OH)]$(ClO_4)_2$ (4): In non-basic aqueous solution, the removal of coordinated chloride from [CoLCl]$Cl(ClO_4) \cdot H_2O$ by addition of two equivalents of $AgClO_4$ and heating to 80°C for 1 h was not complete. Complex **4** was therefore prepared by keeping a basic aqueous solution of [CoLCl]$Cl(ClO_4) \cdot H_2O$ (110 mg, 0.22 mmol, 10 mL 0.3 M NaOH, pH = 13−14) at 80°C for 1 h. The solution was neutralized with $HClO_4$ (pH = 6−8), and 2 equivalents of $AgClO_4$ were added to remove chloride by precipitation of AgCl, which was separated by filtration. Addition of one equivalent of $NaClO_4 \cdot H_2O$ to the filtrate induced crystallization. Within a few days, **4** separated from solution in the form of orange-red crystals, suitable for X-ray structure analysis (88 mg, 76% yield). − ^{1}H NMR ([D$_6$]DMSO, r.t.): δ = 8.21 [t, ^3J(HH) = 7.9 Hz, 1 H, H^4], 7.73 [d, ^3J(HH) = 7.9 Hz, 2 H, H^{3,5}], 4.70 (m, br., N*H*H), 4.52 (m, br., NH*H*), 2.67 (m, C*H*HNH$_2$, 4 H), 2.26 (m, CH*H*NH$_2$, 4 H), 1.47 (s, 6 H, CH_3), −2.60 [s (br.), $W_{1/2}$ = 7.1 Hz, OH]. − ^{13}C NMR ([D$_6$]DMSO, r.t.): δ = 165.32 (s, C2/6), 140.46 (s, C4), 120.48 (s, C3/5), 46.51 (s, >C<), 44.83 (m, 3 lines, J = 7.8 Hz, CH_2), 21.17 (s, CH_3). − MS (FAB$^+$); *m/z* (relative intensity): 409 (48) [M − OH + ClO_4], 79 (100), C_5H_5N. − MS (ESI$^+$): 326 (100) [M − H], 308 (76) [M − H_2O − H], correct isotope patterns in both cases.

− IR (KBr): $\tilde{\nu}$ = 3578 cm^{-1} (m), 3294 (s), 2972 (m), 1610 (m), 1471 (m), 1093 (vs), 624 (m). − $C_{13}H_{26}Cl_2CoN_5O_9$ (526.22): calcd. C 29.67, H 4.98, N 13.31; found C 29.42, H 4.95, N 13.18.

Instrumentation: UV/Vis spectra, diode array spectrophotometer (Zeiss Specord S10); NMR spectra, FT-NMR spectrometer (JEOL JNM-EX 270); mass spectra, Micromass ZabSpecE spectrometer; IR spectra, FT-IR spectrometer (Nicolet, Impact 400); pH measurements, glass electrode (Schott) in combination with a potentiometer (Metrohm 691), calibrated at I = 0.1 M ($NaNO_3$) and 25°C to yield $-\log[H^+]$ = pH − 0.09; kinetics of base hydrolysis, multi-wavelength stopped-flow spectrophotometer[30] and stopped-flow spectrophotometer in combination with a high-pressure cell.[31]

Spectrophotometric Titration: The acid dissociation constant K_a of **3** according to Equation 4 was determined by spectrophotometric titration of an acid solution of **3** with 0.1 M NaOH. Least-squares fitting of Equation 5 to the (absorbance, $[H^+]$) data led to K_a (A_{H2O} and A_{OH} refer to the absorbance of **3** and **4**, respectively, at the concentration of $[Co]_{tot}$).

Kinetic Measurements: Base hydrolysis of **2** according to Equation 3 in freshly prepared solutions of $[CoLCl]Cl(ClO)_4 \cdot H_2O$ in water was followed by stopped-flow spectrophotometry in the wavelength range 300−600 nm under pseudo-first-order conditions ($[OH^-]$ >> $[complex]_o$) at variable temperature (285−318 K) and variable pressure (10−150 MPa). The reactions were followed for t = 6−8 half-lives. Monitoring at high pressure was done at 480 nm. The ionic strength was set to I = 0.1 M or 1.0 M ($NaClO_4$ or $NaNO_3$). Least-squares fitting of the (absorbance, time) data with Equation 6 led to the experimental rate constant k_{obsd}. The volume of activation was obtained from the pressure dependence of k_{obsd} according to Equation 12. A correction for the pressure dependence of the activity coefficients (less than 0.6 cm^3 mol^{-1} under the given conditions[32]) was not applied.

$$\Delta V^{\neq}_{exptl} = -RT\,(\partial \ln k_{obsd}/\partial P)_T \qquad (12)$$

Crystallography: The crystal of **3** (orange-red platelet, 0.45 × 0.40 × 0.17 mm) was grown as stated above. The measurement was made with a four-circle diffractometer (Stoe-Stadi-4) using graphite-monochromatized Mo-K_α radiation (λ = 0.71069 Å); scan 2θ/ω = 1:1). Cell constants were determined by the least-squares method from the 2θ angles of 50 reflections. The structure was solved by direct methods with SHELXS-86 and refined by least squares to the R values given in Table 5 using the program package SHELXL-93. The non-hydrogen atoms were refined anisotropically. All hydrogen atoms, including that in the hydroxo ligand, were located in the difference Fourier map. The hydrogen atom positions and a uniform isotropic displacement parameter were kept fixed during refinement. An empirical absorption correction was applied (T_{min} = 0.693/T_{max} = 0.799). The residual electron density was +0.624/−0.409 e $Å^{-3}$. Crystal data and data collection parameters are listed in Table 5, and selected distances and angles are given in Table 2. Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-103018. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: int. code + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

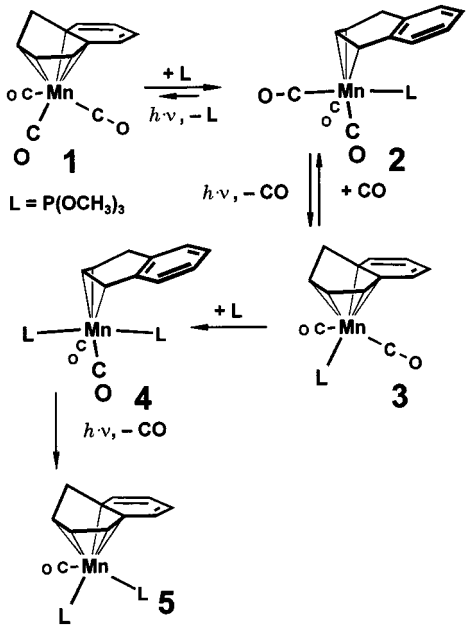
Hindered Ligand Movements in Transition-Metal Complexes, 46[+]

Facile Hapticity Changes in (1-Hydronaphthalene)manganese Complexes, Ligand Addition and Photochemical Ligand Cleavage

Andreas Georg[a] and Cornelius G. Kreiter*[a]



Keywords: Manganese / Coordination modes / 1-Hydronaphthalene complexes / Trimethylphosphite addition / Photochemistry

Tricarbonyl(2–4,4a,8a-η-1-hydronaphthalene)manganese (**1**) reacts readily with trimethyl phosphite to afford tricarbonyl(2–4-η-1-hydronaphthalene)(trimethyl phosphite)-manganese (**2**), by a simultaneous η^5-η^3-hapticity change. Upon UV irradiation, one carbonyl ligand is preferentially cleaved from **2** to yield dicarbonyl(2–4,4a,8a-η-1-hydronaphthalene)(trimethyl phosphite)manganese (**3**), with a η^5-coordinated 1-hydronaphthalene ligand. In a similar fashion **3** also reacts with trimethyl phosphite and forms dicarbonyl(2–4-η-1-hydronaphthalene)bis(trimethyl phosphite)manganese (**4**), which loses carbon monoxide upon UV irradiation to afford carbonyl(2–4,4a,8a-η-1-hydronaphthalene)bis(trimethyl phosphite)manganese (**5**). All compounds were characterized by IR and NMR spectroscopy. The η^5-1-hydronaphthalene complexes **1**, **3** and **5** show hindered 1,4-H shifts of 1-H^{endo}. Considerable energy barriers were also found for the rotation of the 1-hydronaphthalene ligand in **2**–**5**.

Recently, the authors reported the formation of an η^5-1-hydronaphthalene manganese complex as a byproduct of the photochemical reaction of pentacarbonyl(μ-$\eta^{4:6}$-1,4-dimethylnaphthalene)dimanganese with 2-butyne.[2][3] Meanwhile it was found[4] that 1-hydronaphthalene complexes are also formed in high yields by the treatment of cationic tricarbonyl(η^6-naphthalene)manganese complexes[5] with $Li[BEt_3H]$. An analogous behaviour was already known in the case of the corresponding reaction of cationic (η^6-benzene)tricarbonylmanganese complexes.[6–11] In this work the reaction of tricarbonyl(2,3,4,4a,8a-η-1-hydronaphthalene)manganese (**1**) with potential ligands, such as trimethyl phosphite, has been studied in order to learn how the partially weakly coordinated 1-hydronaphthalene ligand influences the reactivity. Even at 203 K **1** adds one equiv. of trimethyl phosphite within seconds to form tricarbonyl(2−4-η-1-hydronaphthalene)(trimethyl phosphite)-manganese (**2**).

The reaction can be carried out in coordinating solvents such as THF or ether, as well as in non-polar hydrocarbon solvents such as *n*-hexane or *n*-pentane. Simultaneously with the coordination of trimethyl phosphite, the C4a−C8a bond is decomplexed and the hapticity of the 1-hydronaphthalene ligand changes from η^5 to η^3.

The π or side-on bonding of unsaturated hydrocarbons to transition metals is described according to the Dewar−Chatt−Duncanson model[12][13] with a so called σ-donor and π-acceptor part. In Lewis formulas of π complexes the interaction between the π system of an unsaturated hydrocarbon and the metal center is normally characterized by an arrow or a (dotted) line from double bonds, circles or circular arches, which symbolize the π system, to the metal center. An alternative formalism, which seems to us more meaningful, uses thin lines between the coordinated carbon atoms and the metal center. It is justified by the bonding model in which each coordinated sp^2-carbon atom donates one electron to the metal center, which then contributes the same number of electrons for back donation. The thin lines in our formulae mark bonding interactions between carbon and metal atoms and do not symbolize localised σ bonds.

Scheme 1

Photolysis of **2** in hexane or THF at room temp. yields 78% of dicarbonyl(2−4,4a,8a-η-1-hydronaphthalene)(trimethyl phosphite)manganese (**3**), in addition to 8% of **1**.

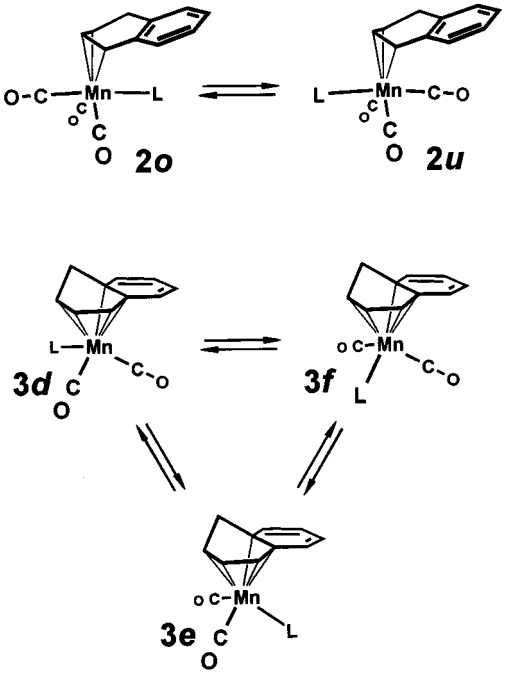
The main reaction is the photochemical cleavage of one carbonyl ligand and the recoordination of the C4a−C8a bond, to afford complex **3**. Byproduct **1** is formed in a back reaction of the addition of trimethyl phosphite to **1**.

The reaction of **3** with CO effects the quantitative back reaction to **2** with decomplexation of the C4a−C8a bond. Treatment of **3** in ether with trimethyl phosphite yields dicarbonyl(2−4-η-1-hydronaphthalene)bis(trimethyl phosphite)manganese (**4**). Due to the steric bulk of the two trimethyl phosphite ligands, this bright yellow complex is only stable at temperatures below 268 K.

By photolysis of **4** one CO ligand is cleaved. The C4a−C8a bond is coordinated again to form the dark red carbonyl(2−4,4a,8a-η-1-hydronaphthalene)bis(trimethyl phosphite)manganese (**5**).

For the η^5-1-hydronaphthalene complexes **1**, **3** and **5** hindered 1,4-H shifts of 1-H^{endo} are observed in the temperature-dependent ^{1}H-NMR spectra. The activation parameters were determined by line-shape analysis (**1**: $\Delta H^{\neq}$ = 78.6 kJ·mol^{-1}, $\Delta S^{\neq}$ = 14.9 J·mol^{-1}·K^{-1}; **3**: $\Delta H^{\neq}$ = 66.7 kJ·mol^{-1}, $\Delta S^{\neq}$ = 0.1 J·mol^{-1}·K^{-1}; **5**: $\Delta H^{\neq}$ = 43.7 kJ·mol^{-1}, $\Delta S^{\neq}$ = 26.9 J·mol^{-1}·K^{-1} with maximum errors of ± 3 kJ·mol^{-1}, and ± 20 J·mol^{-1}·K^{-1}, respectively).



Scheme 2

The low-temperature ^{1}H- and ^{31}P-NMR spectra of **2** show the presence of two isomers with populations of 81:19. They differ due to the position of the trimethyl phosphite ligand in the pseudo-trigonal-bipyramidal coordination sphere of manganese. In [Mn(η^3-enyl)L(CO)$_3$] complexes donor ligands occupy exclusively axial positions from which the *o*-position relative to the enyl ligand is normally more favoured than the *u*-position. In case of sterically demanding enyl ligands the preference of the isomers is inverted. For the η^3-1-hydronaphthalene ligand such a sterical hindrance has to be expected as the trimethyl phosphite ligand is in the *o*-position. For that reason we assign the predominant isomer to ***2u***, and the other to ***2o***, with the trimethyl phosphite close to C-8a of the aromatic ring. In the predominant isomer the trimethyl phosphite shows no sterical interaction with the 1-hydronaphthalene ligand. This assignment is supported by a $^3J_{H,P}$ coupling of 3-H of 15.5 Hz in ***2u***. The isomer ***2o*** shows only a small, unresolved H,P coupling of 3-H. The interconversion of ***2u*** and ***2o*** affords an activation energy of $\Delta H^{\neq}$ = 65.0 kJ·mol^{-1} with $\Delta S^{\neq}$ = 36.0 J·mol^{-1}·K^{-1}.

A comparable ligand movement is found for **4**. The two trimethyl phosphite ligands both occupy axial positions. At 183 K the rotation of the η^3-1-hydronaphthalene ligand is slowed down and two ^{31}P-NMR signals appear. The activation energy was determined to be $\Delta H^{\neq}$ = 51.1 kJ mol^{-1}, $\Delta S^{\neq}$ = 15.5 J K^{-1} mol^{-1}.

The η^5-1-hydronaphthalene complexes **3** and **5** also show a hindered rotation. The ^{31}P-NMR of **3** shows an intense signal at 183 K which is assigned to the less hindered isomer ***3d*** (0.92), a weaker signal is assigned to ***3f*** (0.08). Although a separate signal for the third, strongly hindered isomer is not observed, it can not be excluded with certainty. The activation parameters for the ***3d***/***3f*** isomerization were found to be $\Delta H^{\neq}$ = 47.7 kJ mol^{-1} and $\Delta S^{\neq}$ = 21.0 J K^{-1} mol^{-1}. For **5** all three possible isomers give separate ^{31}P-NMR signals, from which the relative populations 0.89:0.06:0.05 are determined. They were assigned according to the sterical interactions between the trimethyl phosphite ligands and the 1-hydronaphthalene. The activation parameters for the isomerization are $\Delta H^{\geq}$ = 37.6 kJ mol^{-1} and $\Delta S^{\geq}$ = −37.0 J K^{-1} mol^{-1}.

A similar hindered H-shift and ligand rotation was already detected for dicarbonyl($\eta^{4:(2)}$-1,5-*H*-benzocycloheptene)(trimethyl phosphite)chromium(0).[14]

Scheme 3

Experimental Section

All reactions were carried out under dry nitrogen using common Schlenk techniques. THF was dried with potassium, diethyl ether with sodium, *n*-pentane with P_4O_{10} and *n*-hexane with CaH_2. Silica gel for column chromatography was heated to 413 K in vacuo, deactivated with 4% of degassed water and stored under nitrogen. A high-pressure mercury lamp TQ 150 (Heraeus-Noblelight, Kleinostheim) was used for the photolysis reaction. It was immersed in a 120-mL photoreactor of Duran® with a cooling jacket, wrapped with aluminium foil. The photoreactor and the chromatography column were cooled with a cryostat RUL 80 (Lauda), with methanol as the coolant. − IR: Perkin Elmer FT-IR 16 PC. − NMR: Bruker AMX 400 (^{1}H, 400.13 MHz, ^{13}C, 100.62 MHz, ^{31}P, 162.12 MHz), ^{1}H and ^{13}C chemical shifts are given relative to TMS, using

the solvent signals as internal reference ($C_6D_5CHD_2$: δ_H = 2.03, $C_6D_5CD_3$: δ_C = 20.40 , C_6HD_5: δ_H = 7.20, C_6D_6: δ_C = 128), ^{31}P chemical shifts are relative to external 85% phosphorous acid. − Elemental analyses: Perkin Elmer microanalyser 240. − Tricarbonyl(2−4,4a,8a-η-1-hydronaphthalene)manganese (**1**) was synthesized according to the literature[4] using $Li[BEt_3H]$ instead of $Na[BH_3CN]$ as the reducing agent. The activation parameters for the hindered 1,4-H shift of 1-H^{endo} in **1** were determined from the temperature dependence of the ^{1}H-NMR signals of 1-H−4-H; *T* [K], *k* [s^{-1}]: 328, 2; 348, 15; 358, 40; 368, 70; 378, 100. The trimethyl phosphite (Fluka) was used as purchased.

Tricarbonyl(2−4-η-1-hydronaphthalene)(trimethyl phosphite)manganese (2): 175 mg (0.66 mmol) of tricarbonyl(2−4,4a,8a-η-1-hydronaphthalene)manganese (**1**) was dissolved in THF (20 mL). When 0.1 mL (0.85 mmol) of trimethyl phosphite was added dropwise to the orange-red solution the color changed immediately to bright yellow. After 2 min of stirring, $MgSO_4$ (2 g) was added to the solution and the solvent removed in vacuo. Chromatography of the residue on a column packed with silica gel gave two fractions. An orange fraction was eluted with hexane/diethyl ether (50:1). It contained only a small amount of the starting material. **2** was eluted as a bright yellow fraction with *n*-hexane/diethyl ether (20:1). Removal of the solvent and crystallization from *n*-hexane at 243 K gave 158 mg (62%) of **2** as yellow crystals. − IR (*n*-hexane): $\tilde{\nu}$ = 2010 (s) cm^{-1} (CO), 1950 (s), 1944 (sh), 1918 (sh), 1911 (s). The shoulders of the ν_{CO} bands are probably due to the rotamer **2o**. − ^{1}H NMR ([D$_8$]toluene, 333 K): δ = 6.85 (dd, *J* = 7.3, 0.9 Hz, 1 H, 5-H), 6.78 (dd, *J* = 7.3, 6.8 Hz, 1 H, 6-H), 6.70 (ddd, *J* = 7.3, 6.8, 1.3 Hz, 1 H, 7-H), 6.55 (d, 7.3 Hz, 1 H, 8-H), 4.73 (ddd, *J* = 9.5, 6.8, 5.8 Hz, 1 H, 3-H,), 4.15 (d, *J* = 5.8 Hz, 1 H, 4-H), 4.05 (dddd, *J* = 6.8, 4.9, 1.6, 1.6 Hz, 1 H, 2-H), 3.31 (dd, *J* = 21.1, 4.9 Hz, 1 H, 1-H^{endo}), 3.17 [d, *J* = 11.2 Hz, 9 H, $P(OCH_3)_3$], 3.17 (d, *J* = 21.1 Hz, 1 H, 1-H^{exo}) . − ^{1}H NMR ([D$_8$]toluene, 233 K): **2*u*** (81%): δ = 6.90 (d, *J* = 7.5 Hz, 1 H, 5-H), 6.83 (dd, *J* = 7.5, 6.8 Hz, 1 H, 6-H), 6.77 (dd, *J* = 7.3, 6.8 Hz, 1 H, 7-H), 6.60 (d, 7.3 Hz, 1 H, 8-H), 4.76 (ddd, *J* = 15.5, 6.7, 6.1 Hz, 1 H, 3-H,), 4.27 (d, *J* = 6.1 Hz, 1 H, 4-H), 4.02 (br. m, 1 H, 2-H), 3.31 (dd, *J* = 21.8, 7.4 Hz, 1 H, 1-H^{endo}), 3.17 (d, *J* = 21.8 Hz, 1 H, 1-H^{exo}), 3.05 [d, *J* = 10.7 Hz, 9 H, $P(OCH_3)_3$]; **2*o*** (19%): δ = 6.72 (dd, *J* = 6.9, 6.9 Hz, 1 H, 6-H), 6.58 (dd, *J* = 6.9, 6.9 Hz, 1 H, 7-H), 6.52 (d, *J* = 7.1 Hz, 1 H, 8-H), 4.65 (br. dd, *J* = 6.6, 5.6 Hz, 1 H, 3-H), 4.16 (d, *J* = 5.6 Hz, 1 H, 4-H), 3.14 [d, *J* = 10.1 Hz, 9 H, $P(OCH_3)_3$]. − The activation parameters for the hindered interconversion of **2*u*** and **2*o*** were determined from the temperature dependence of the ^{1}H-NMR signals of 3-H of both isomers; *T* [K], *k* [s^{-1}]: 233, 1; 243, 5; 253, 15; 273, 100; 283, 500; 293, 1000; 313, 10000; 333, 30000. − ^{13}C NMR ([D$_8$]toluene, 293 K): δ = 225 (s, 3 C, CO), 143.10 (s, C-4a), 129.01 (s, C-8a), 127.77 (d, *J* = 153 Hz, C-5), 126.54 (d, *J* = 158 Hz, C-6), 125.65 (d, *J* = 158 Hz, C-8), 125.09 (d, *J* = 145 Hz, C-7), 83.84 (d, *J* = 168 Hz, C-3), 61.81 (d, *J* = 180 Hz, C-4 or -2), 59.91 (br. d, *J* = 160 Hz, C-2 or -4), 51.96 (dq, $^1J_{C,H}$ = 147, $^2J_{C,P}$ = 5 Hz, O*C*H$_3$), 34.32 (t, *J* = 127 Hz, C-1) . − ^{31}P NMR ([D$_8$]toluene, 233 K): δ = 194.4 (s, 0.81 P), 185.4 (s, 0.19 P). − $C_{16}H_{18}MnO_6P$ (392.23): calcd. C 49.00, H 4.63; found C 48.9, H 4.4.

Photoreaction of Tricarbonyl(2−4-η-1-hydronaphthalene)(trimethyl phosphite)manganese (2): 106 mg (0.27 mmol) of **2** was dissolved in 100 mL of *n*-hexane in a photoreactor. The yellow solution was irradiated with UV light at room temp. After 10 min, the carbon monoxide bands of **2** had disappeared and the color of the solution turned to orange. The irradiation was stopped, 2 g of $MgSO_4$ added and the solvent removed in vacuo. The orange residue was separated into three fractions by column chromatography on silica gel at 253 K. A bright yellow fraction was obtained with *n*-pentane/toluene (10:1) as eluent. It contained 6 mg (0.02 mmol, 8%) of **1**. The second fraction was eluted with *n*-pentane/diethyl ether (20:1) from which 73 mg (0.21 mmol) of dicarbonyl(2−4,4a,8a-η-1-hydronaphthalene)(trimethyl phosphite)manganese (**3**) was obtained (78%). − IR (*n*-hexane): $\tilde{\nu}$ = 1947 (s) cm^{-1} (CO), 1889 (s). − ^{1}H NMR ([D$_8$]toluene, 293 K): δ = 7.03 (d, *J* = 7.3 Hz, 1 H, 5-H), 6.78 (dd, *J* = 7.5, 7.3 Hz, 1 H, 6-H), 6.72 (d, *J* = 8.2 Hz, 1 H, 8-H), 6.64 (dd, *J* = 8.2, 7.5 Hz, 1 H, 7-H), 5.93 (d, *J* = 5.0 Hz, 1 H, 4-H), 4.85 (ddd, *J* = 5.0, 5.5, 7.0 Hz, 1 H, 3-H), 3.2 [d, *J* = 11.4 Hz, 9 H, $P(OCH_3)_3$], 3.13 (dd, *J* = 13.6, 5.6 Hz, 1 H, 1-H^{endo}), 2.83 (ddd, *J* = 5.8, 5.5, 2.7 Hz, 1 H, 2-H), 2.50 (dd, *J* = 13.6, 2.7 Hz, 1 H, 1-H^{exo}) . − The activation parameters for the hindered 1,4-H shift of 1-H^{endo} in **3** were determined from the temperature dependence of the ^{1}H-NMR signals of 1-H−4-H; *T* [K], *k* [s^{-1}]: 303, 20; 313, 50; 323, 100; 343, 500; 353, 1000. − ^{13}C NMR ([D$_8$]toluene, 293 K): δ = 232.1 (s, CO), 224.5 (s, CO), 134.0 (d, *J* = 161 Hz, C-5), 129.9 (d, *J* = 162 Hz, C-6), 128.3 (d, *J* = 169 Hz, C-7), 126.6 (d, *J* = 162 Hz, C-8), 109.3 (s, C-4a), 96.6 (d, *J* = 164 Hz, C-4), 90.7 (s, C-8a), 72.4 (d, *J* = 173 Hz, C-3), 51.2 [dd, $^1J_{C,H}$ = 145, $^3J_{C,P}$ = 4 Hz, $P(OCH_3)_3$], 46.3 (d, *J* = 165 Hz, C-2), 30.6 (t, *J* = 131 Hz, C-1) . − ^{31}P NMR ([D$_8$]toluene, 183 K): **3*d***: δ = 212.3 (s, 0.92 P), **3*f***: δ = 207.4 (s, 0.08 P). − The activation parameters for the hindered isomerization of **3*d*−3*f*** were determined from the temperature dependence of the ^{31}P-NMR signals of **3*d*** and **3*f***; *T* [K], *k* [s^{-1}]: 183, 1; 203, 30; 223, 500; 233, 1000; 253, 10000; 273, 50000. − $C_{15}H_{18}MnO_5P$ (364.22): calcd. C 49.47, H 4.98; found: C 49.2, H 4.9. − A third red fraction could be eluted with diethyl ether. Removal of the solvent yielded less than 1 mg of a red oil. − IR (*n*-pentane, 293 K): $\tilde{\nu}$ = 1970 (m) cm^{-1},1948 (s), 1889 (m), 1868 (vs).

Reaction of Dicarbonyl(2−4,4a,8a-η-1-hydronaphthalene)(trimethyl phosphite)manganese (3) with Carbon Monoxide: 20 mg of dicarbonyl(2−4,4a,8a-η-1-hydronaphthalene)(trimethyl phosphite)manganese (**3**) was dissolved in 50 mL of diethyl ether. While stirring, carbon monoxide was bubbled through the solution for 5 min, then the reaction solution stirred for another 5 min. The original orange-colored solution changed to bright yellow. In the control IR spectra a quantitative reaction of **3** to **2** was observed. ^{1}H-NMR-spectroscopic measurements confirmed this observation.

Reaction of Dicarbonyl(2−4,4a,8a-η-1-hydronaphthalene)(trimethyl phosphite)manganese (3) with Trimethyl Phosphite: 200 mg (0.55 mmol) of dicarbonyl(2−4,4a,8a-η-1-hydronaphthalene)(trimethyl phosphite)manganese (**3**) was dissolved in 20 mL of *n*-hexane at 243 K. With a syringe 0.2 mL of $P(OMe)_3$ was slowly added dropwise to the solution. Within 10 min the color of the reaction solution changed to a lemon yellow. From the IR control spectra it was seen that **3** had reacted to a dicarbonyl complex nearly quantitatively. This was very temperature-sensitive and decomposed in solution even at 268 K. The solution was concentrated in vacuo at 243 K to about 5 mL and stored for 48 h at 198 K. Bright yellow dicarbonyl(2−4-η-1-hydronaphthalene)bis(trimethyl phosphite)-manganese (**4**) separated as a microcrystalline powder. At 233 K the solvent was removed with a pipette and the residue washed with *n*-pentane (5 ×) and cooled to 233 K. The solid was dried for several days at 243 K in high vacuum. − IR (diethyl ether): $\tilde{\nu}$ = 1947 (s) cm^{-1}, 1848 (vs). − ^{1}H NMR ([D$_8$]toluene, 233 K): δ = 6.99 (d, *J* = 8.3 Hz, 1 H, 5-H), 6.92 (d, *J* = 8.1 Hz, 1 H, 8-H), 6.81 (dd, *J* = 8.3, 6.2 Hz, 1 H, 6-H), 6.74 (dd, *J* = 8.1, 6.2 Hz, 1 H, 7-H), 4.97 (dd, *J* = 6.2, 6.0 Hz, 1 H, 3-H), 4.17 (m, 1 H, 4-H), 4.04 (m,

1 H, 2-H), 3.36 (d, J = 12.4 Hz, 1 H, 1-H^{endo}), 3.32 [d, J = 11.0 Hz, 18 H, P(OCH$_3$)$_3$], 3.18 (d, J = 12.4 Hz, 1 H, 1-H^{exo}). − ^{31}P NMR ([D$_8$]toluene, 183 K): δ = 200.45 (s), 198.25 (s). − $C_{18}H_{27}MnO_8P_2$ (488.30): calcd. C 44.28, H 5.57; found C 45.0, H 5.5.

Photolysis of Dicarbonyl(2−4,4a,8a-η-1-hydronaphthalene)bis-(trimethyl phosphite)manganese (5): In a photolysis vessel 100 mg (0.02 mmol) of dicarbonyl(2−4-η-1-hydronaphthalene)bis(trimethyl phosphite)manganese (**4**) was dissolved at 223 K in 120 mL of diethyl ether. The bright yellow solution was irradiated for 60 min with UV light. One CO ligand was cleaved and an orange-colored monocarbonyl complex formed. The crude product was absorbed at 253 K on 2 g of Na_2SO_4 and placed on a column filled with silica gel. First an orange-colored fraction was eluted with *n*-pentane/diethyl ether (25:1) which contained 10 mg of **1**. A red-brown fraction was eluted with *n*-pentane/diethyl ether (10:1) into a precooled Schlenk tube at 253 K. Removal of the solvent in vacuo at the same temp. yielded carbonyl(2−4-η-1-hydronaphthalene)bis-(trimethyl phosphite)manganese (**5**) as a dark, red-brown oil. − IR (*n*-pentane): $\tilde{\nu}$ = 1869 cm^{-1}. − ^{1}H NMR ([D$_8$]toluene, 183 K): δ = 7.26 (br. s, 1 H, 5-H), 6.91 (br. s, 1 H, 6-H), 6.79 (br. s, 1 H, 8-H), 6.65 (br. s, 1 H, 7-H), 5.88 (br. s, 1 H, 4-H), 5.22 (br. s, 1 H, 3-H), 3.38 [m, 18 H, P(OCH$_3$)$_3$], 3.17(br. s, 1 H, 1-H^{endo}), 3.05 (br. s, 1 H, 2-H), 2.62 (br. s, 1 H, 1-H^{exo}). − ^{31}P NMR ([D$_8$]toluene, 183 K): ***5d,f***: δ = 215.3 (d, J = 82 Hz, 0.89 P), 214.1 (d, J = 82 Hz, 0.89 P); ***5d,e***: δ = 206.7 (br. s, 0.06 P), 193.7 (br. s, 0.06 P); ***5e,f***: δ = 201.5 (br. s, 0.05 P), 198.8 (br. s, 0.05 P). − The activation parameters for the hindered isomerization of ***5d,f***, ***5d,e***, ***5e,f*** were determined from the temperature dependence of the ^{31}P-NMR signals of **5*d***, ***5d,e***, and ***5e,f***; T [K], k [s^{-1}]: 183, 1; 233, 150; 273, 1000. − $C_{17}H_{27}MnO_7P_2$ (460.28): calcd. C 44.36, H 5.91; found C 45.4, H 6.1.

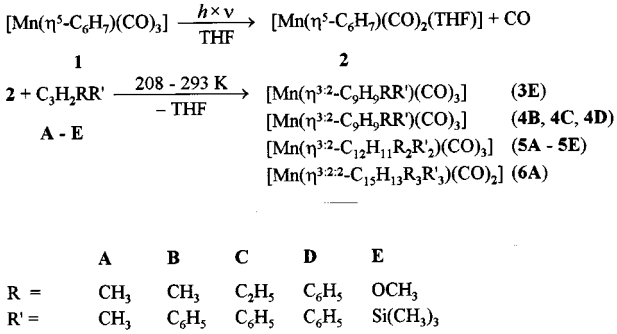
Photochemical Reactions of Transition Metal Organyl Complexes with Olefins, 21[+]

Photolysis of Tricarbonyl(η⁵-cyclohexadienyl)manganese in Tetrahydrofuran, Reactions with Cumulated Dienes

Cornelius G. Kreiter,*[a] Norbert K. Wachter,[a] and Guido J. Reiß[a]

Keywords: Manganese complexes / Organyl complexes / C–C coupling / [5+2] Cycloaddition / Cumulenes / Photochemistry

$[Mn(\eta^5\text{-}C_6H_7)(CO)_3]$ (**1**) forms highly reactive $[Mn(\eta^5\text{-}C_6H_7)(CO)_2(THF)]$ (**2**) upon UV irradiation in THF at 208 K. Solvent complex **2** reacts between 208 and 293 K with 1,1-disubstituted allenes C_3H_2RR' [R, R′ = CH_3, CH_3 (**A**); CH_3, C_6H_5 (**B**); C_2H_5, C_6H_5 (**C**); C_6H_5, C_6H_5 (**D**); OCH_3, $Si(CH_3)_3$ (**E**)] to four different types of complexes: The [5+2] cycloadduct $[Mn(\eta^{3:2}\text{-}C_9H_9RR')(CO)_3]$ (**3E**), rearranged [5+2] cycloadducts $[Mn(\eta^{3:2}\text{-}C_9H_9RR')(CO)_3]$ (**4B**, **4C**, **4D**), 1:2 adducts $[Mn(\eta^{3:2}\text{-}C_{12}H_{11}R_2R'_2)(CO)_3]$ (**5A**–**5E**), and the 1:3 adduct $[Mn\{\eta^{3:2:2}\text{-}C_{15}H_{13}(CH_3)_6\}(CO)_2]$ (**6A**). The constitutions of the products were established by IR and NMR spectroscopy, as well as by C,H elemental analysis and mass spectrometry. The crystal and molecular structure of **6A** was determined by X-ray structure analysis. A formation mechanism for the complexes is proposed.



Introduction

Coordination of unsaturated hydrocarbons to transition metals allows pericyclic reactions, that are not allowed for the free hydrocarbons by the Woodward−Hoffmann rules.[2][3] Thus transition-metal-mediated cycloadditions of higher order play an important role in the synthesis of medium-sized carbocyclic and heterocyclic systems. Within the scope of our studies on photochemical reactions of transition metal organyl complexes with olefins we have already reported about light-induced [6+4] cycloadditions of conjugated dienes to tricarbonyl(η⁶-1,3,5-cycloheptatriene)chromium(0)[4−9] and [6+2] cycloadditions of dienes to tricarbonyl(η⁶-cycloocta-1,3,5,7-tetraene)chromium(0).[10]

Further significant advances have been made in recent years.[11−15] The related [6+2] cycloadditions of alkynes to trienes at chromium have also been described by different authors.[16−19] Furthermore we have shown that tricarbonyl(η⁵-pentadienyl)manganese and its derivatives react with conjugated dienes to give tricarbonyl(η$^{3:2}$-cyclonona-2,6-dienyl)manganese complexes in a photochemically induced formal [5+4] cycloaddition.[20−23] Also, photo-assisted cycloadditions of alkynes to η⁵-dienyl ligands have been reported by us[24−28] and others.[29,30] In this respect, the role of cumulenes and heterocumulenes as partners in transition-metal-promoted cycloadditions has so far been described only in a few papers.[31,32] In the following we will discuss our studies upon the reactions of photochemically generated dicarbonyl(η⁵-2,4-cyclohexadienyl)(tetrahydrofuran)manganese (**2**) with selected 1,1-disubstituted cumulenes.

Preparative Results

UV irradiation of tricarbonyl(η⁵-2,4-cyclohexadienyl)-manganese (**1**) at 208 K in THF generates in situ the thermally labile, solvent stabilized dicarbonyl(η⁵-2,4-cyclohexadienyl)(tetrahydrofuran)manganese (**2**). After addition of 3-methyl-1,2-butadiene (**A**), 3-phenyl-1,2-butadiene (**B**), 3-phenyl-1,2-pentadiene (**C**), 1,1-diphenyl-1,2-propadiene (**D**), or 1-methoxy-1-trimethylsilyl-1,2-propadiene (**E**) to the THF solution of **2** at 208 K, the reaction mixture is allowed to warm up slowly to room temperature. Four different types of complexes are formed under these conditions depending on the substituents of the 1,1-disubstituted allenes. Only for **E** is the [5+2] cycloadduct $[Mn\{\eta^{3:2}\text{-}C_9H_9(OCH_3)Si(CH_3)_3\}(CO)_3]$ (**3E**) obtained. Dienes **B**, **C**, and **D** also yield 1:1 adducts with the general formula $[Mn(\eta^{3:2}\text{-}C_9H_9RR')(CO)_3]$ (**4B**, **4C**, **4D**) which are formed from the primary [5+2] cycloadduct by a 1,3 H-shift. All cumulenes used in this study generate 1:2 adducts $[Mn(\eta^{3:2}\text{-}C_{12}H_{11}R_2R'_2)(CO)_3]$ (**5A−5E**), and with **A** a 1:3 adduct $[Mn\{\eta^{3:2:2}\text{-}C_{15}H_{13}(CH_3)_6\}(CO)_2]$ (**6A**) is also obtained.

The reaction mixtures were separated by column and/or HPL chromatography. The complexes are isolated as yellow to red crystals (**4B**, **4C**, **4D**, **6A**) or oils (**3E**, **5A**−**5E**) in moderate to low yields depending upon the substituents R, R′.

^{1}H-NMR and ^{13}C-NMR Spectra

The ^{1}H-NMR-spectroscopic data of the products **3E**−**6A** are given in the Experimental Section. The assignments of the signals to the corresponding protons are based upon homo-decoupling experiments and H,H-COSY-90 spectra. The ^{1}H-NMR spectrum of the [5+2] cycloadduct **3E** shows 11 well-separated signals with the relative intensities 1:1:1:3:1:1:1:1:1:1:9 that prove the addition of one 1-methoxy-1-trimethylsilyl-1,2-propadiene (**E**) to the cyclohexadienyl ligand. The δ,*J* diagram (Figure 1) is in accord with a 6-methylenebicyclo[3.2.1]oct-3-en-2-yl ligand with methoxy and trimethylsilyl groups at the exocyclic sp^2-methylene carbon atom, formed by a [5+2] cycloaddition of the unsubstituted double bond of the cumulene **E** to the cyclohexadienyl ligand of **1**.

The ^{13}C-NMR spectrum of **3E** shows the expected 14 signals. IR, ^{1}H-NMR and ^{13}C-NMR data of **3E** fit well with a tricarbonyl{$\eta^{3:2}$-6-(1-methoxy-1-trimethylsilyl-methylene)bicyclo[3.2.1]oct-3-en-2-yl}manganese complex.

The reactions of **2** with 3-phenyl-1,2-butadiene (**B**), 3-phenyl-1,2-pentadiene (**C**) and 1,1-diphenyl-1,2-propadiene (**D**) yield the 1:1 adducts **4B**, **4C** and **4D**. The ^{1}H-NMR spectra of these complexes are similar with the exception of the substituent signals. The δ-*J* diagram (Figure 1) is in accordance with a 7-methylenebicyclo[3.2.1]oct-2-en-6-yl ligand with methyl and phenyl groups at the exocyclic sp^2-methylene carbon. Like in **3E** it is formed by a [5+2] cycloaddition of the unsubstituted double bond of the cumulene **B** to the cyclohexadienyl ligand followed by a H shift from position 7 to 2.

The ^{13}C-NMR data of **4B** supplement the information from the ^{1}H-NMR spectrum. The ^{1}H-NMR and ^{13}C-NMR spectra of **4C** and **4D** differ from those of **4B** only due to the signals of the substituents. Therefore related structures have to be considered.

All cumulenes used in this study form 2:1 adducts with **1**. The tricarbonyl complexes **5A**−**5E** show similar NMR spectra which differ only in the signals of the respective substituents. The δ,*J* diagram (Figure 1) is closely related to that of **4B** and it is in accordance with a 7-methylenebicyclo[3.2.1]oct-2-en-6-yl ligand with two methyl groups at the exocyclic sp^2-methylene carbon atom and a 3-methyl-2-butenyl group in 4^{endo} position.

The ^{13}C-NMR-spectroscopic data are also in accord with a $\eta^{3:2}$-4-(3-methyl-2-butenyl)-7-(1-methyl-ethylidene)bicyclo[3.2.1]oct-2-en-6-yl-ligand in **5A**.

The ^{1}H-NMR and ^{13}C-NMR spectra of **5B**−**5E** are, with the exception of the signals of the substituents, closely related to those of **5A**. Therefore, in all of them $\eta^{3:2}$-4-(2-propenyl)-7-(methylene)bicyclo[3.2.1]oct-2-en-6-yl-ligands, correspondingly substituted, are present.

The ^{1}H-NMR spectrum of **6A** shows the expected thirteen signals with single and six methyl signals with threefold intensities for a 1:3 adduct of **1** and **A**. Chemical shifts and signal patterns are closely related to those of **5A**, but due

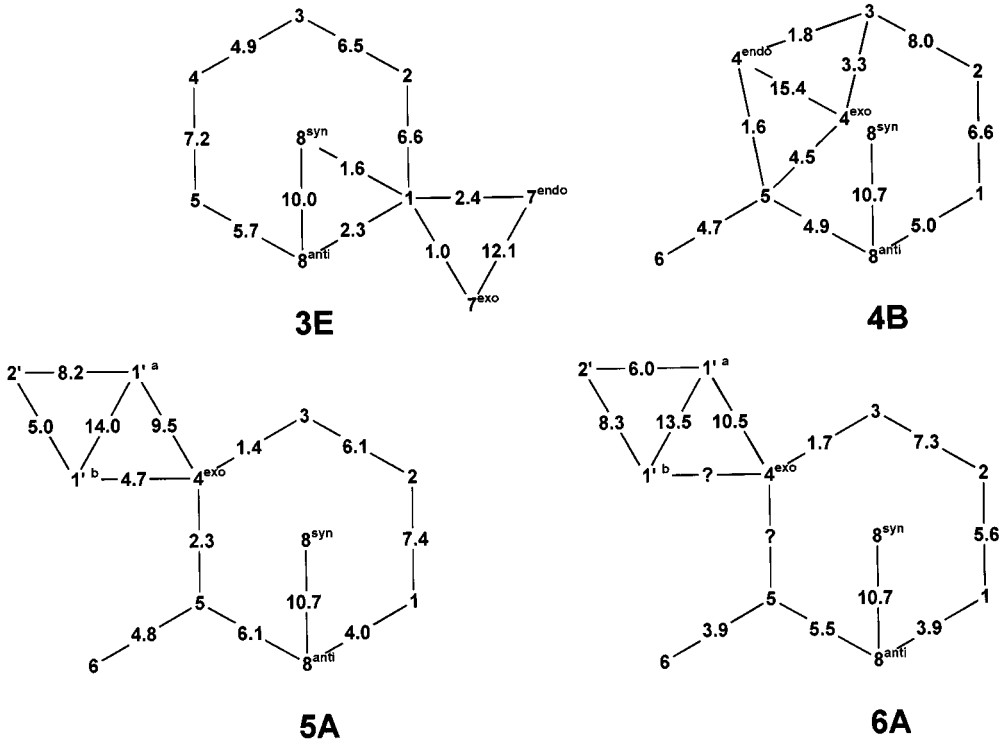

Figure 1. δ,*J* diagrams, showing geminal and vicinal coupling constants, of **3E**, **4B**, **5A** and **6A**

to the overlap of some signals it was not possible to determine all coupling constants. The assignment of the signals was facilitated by a $^1H,^1H$ COSY-90 NMR spectrum, and by the molecular structure of **6A** which was determined by X-ray structure analysis. Two doublets of an AB system at $\delta = 1.00$ and 0.56 ($J = 4.1$ Hz) are due to 1′′*E*-H and 1″*Z*-H of the 2,4-dimethyl-3-methylenepenta-2,4-diyl group. The δ,*J* diagram (Figure 1) of the remaining 11 signals of single intensity is in accord with a 4-(3-methyl-2-butenyl)bicyclo[3.2.1]octa-2,6-dien-7-yl system.

The ^{13}C-NMR spectrum is also consistent with the structure of **6A**.

Crystal and Molecular Structure of 6A

Recrystallization of [Mn{$\eta^{3:2:2}$-$C_{15}H_{12}(CH_3)_6$}$(CO)_2$] (**6A**) from *n*-pentane at 243 K yields red, rhombic crystals. The complex crystallizes in the triclinic space group $P\bar{1}$ with unit cell of $a = 804.8(2)$ pm, $b = 1201.5(4)$ pm, $c = 1222.1(3)$ pm, $\alpha = 61.01(2)°$, $\beta = 81.12(2)°$, $\gamma = 87.47(2)°$. Figure 2 shows an ORTEP projection of the molecule (selected bond lengths and angles are given in the caption). If the coordination sphere of complex **6A** is considered a distorted trigonal bipyramid, the centre of C6, C7 (M2) and C9 occupy the two axial positions. In the equatorial sites the centre of C2, C3 (M1), the centre of gravity of C14−C16 (M3), and C10 are located. The mean value of the six angles between axial and equatorial positions is 90.3° with an msd of 9.0°. For the three angles between equatorial sites the mean value is 119.9° with an msd of 9.5°. Alternatively the coordination sphere can be described as a distorted octahedron with C14−C16 occupying two coordination sites. However, the angle M1−Mn1−C10 with 111.7(5)° makes this description less suited for **6A**.

The plane defined by Mn1, M1, M3, C10 (rmsd 2.69 pm) is cut by M2−Mn1 with 72.6° and by C9−Mn1 with 82.5°. While C2−C3 are virtually parallel to that plane (2.8°), C15−C16 are turned by 28.0° with respect to it. The

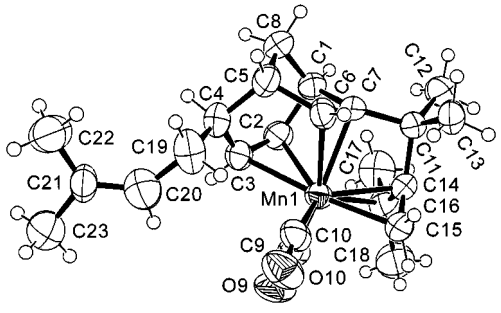

Figure 2. ORTEP projection of dicarbonyl{2,3,6,7,3″,4″,1‴-η-7-(2,4-dimethyl-3-methylenepenta-2,4-diyl)-4-(3-methyl-2-butenyl)-bicyclo[3.2.1]octa-2,6-diene}manganese (**6A**); selected bond lengths [pm] and bond angles [°]: Mn1−C2 213.4(3), Mn1−C3 217.8(3), Mn1−C6 237.2(3), Mn1−C7 226.1(3), Mn1−C9 176.8(3), Mn1−C10 177.9(4), Mn1−C14 212.2(3), Mn1−C15 214.6(3), Mn1−C16 236.5(3), C2−C3 140.4(4), C6−C7 137.4(4), C14−C15 142.6(4), C14−C16 141.5(4), O9−C9 116.2(3), O10−C10 116.3(3); C9−Mn1−C10 84.72(15), O9−C9−Mn1 175.7(3), O10−C10−Mn1 170.6(3), C16−C14−C15 116.3(3)

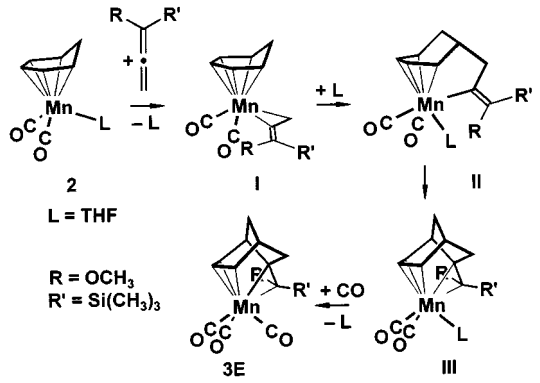
Mn−C bond lengths of the hydrocarbon chelate ligand differ over a considerable range. For the coordinated sp^2-carbon atoms in the equatorial plane the distances lie between 212.2(3) pm (Mn1−C14) and 217.8(3) pm (Mn1−C3). For Mn1−C16 the distance is distinctly larger [236.5(3) pm] as a result of the steric bulk of the two methyl groups. The C−C double bond in axial position is less tightly coordinated according to Mn1−C6 237.2(3) pm and Mn1−C7 226.1(3) pm. As a consequence of the different extent of coordination the elongation of C2−C3 140.4(4) pm is larger than for C6−C7 with 137.4 (4). A comparable bonding situation has been already found for [$\eta^{3:2:2}$-1-(3-butene-1,2-diyl)-1,3-dimethyl-2,6-cyclononadiene]dicarbonylmanganese with even larger Mn−C distances for the axially coordinated C−C double bond.[20]



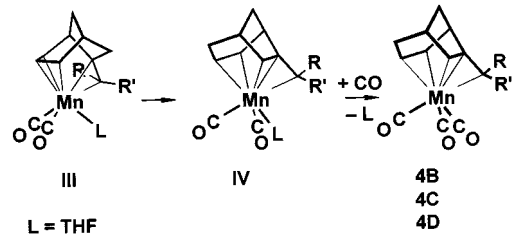
Discussion

Tricarbonyl(η^5-penta-2,4-dienyl)manganese complexes react photochemically with 1,3-dienes in a formal [5+4] cycloaddition to tricarbonyl($\eta^{3:2}$-cyclonona-2,6-dienyl)-manganese complexes. The expected analogous photochemical [5+2] cycloaddition of alkynes to tricarbonyl(η^5-penta-2,4-dienyl)manganese is not observed experimentally.[26] At 208 K in THF, photochemically generated, very reactive dicarbonyl(η^5-2,4-dimethylpenta-2,4-dienyl)(tetrahydrofuran)manganese adds diphenylacetylene or dimethyl butynedioate to yield in a first step the [5+2] cycloadducts with accordingly substituted $\eta^{3:2}$-cyclohepta-2,4-dienyl ligands. These unstable intermediates rearrange by manganese-mediated 1,4-H shifts and form substituted tricarbonyl(η^5-cyclohepta-2,4-dienyl)manganese complexes.

Similarly, irradiation of tricarbonyl(η^5-cyclohexa-2,4-dienyl)manganese (**1**) at 208 K in *n*-pentane in the presence of the cumulenes **A**−**E** causes within 30 minutes only complete decomposition of **1**. The IR spectra, measured during the UV irradiation in regular intervals show no new bands in the region of 2200−1600 cm^{-1} due to the formation of manganese complexes.

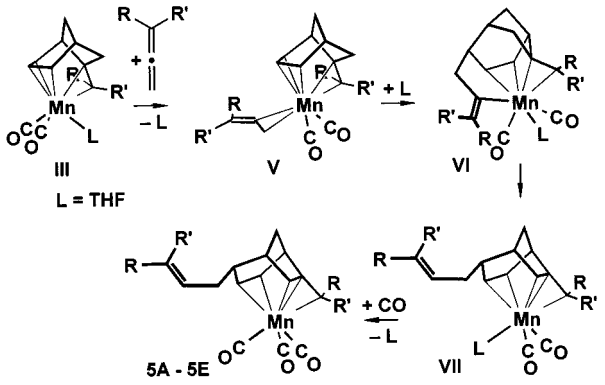
Dicarbonyl(η^5-cyclohexa-2,4-dienyl)(tetrahydrofuran)-manganese (**2**), photochemically generated at 208 K, reacts with the 1,2-dienes **A**−**E** when the solution is allowed to warm up to room temperature to four types of complexes. From the constitution of these products their formation can be proposed taking into account the results of other cycloadditions of higher order at metal centres. Prerequisite for a C−C bond formation is the simultaneous presence of reactive hydrocarbon ligands in the coordination sphere. Stable complexes are only formed when one of the ligands is endowed with uncoordinated π-bonds. Each C−C bond formation is accompanied by a loss of two metal−carbon bonds, and produces electronically and coordinatively unsaturated intermediates. Saturation is accomplished by coordination of n-donor or σ-donor-π-acceptor ligands. Metal-mediated C−C bond formation is closely related to reductive elimination, and coordination of olefins to metals centres, by which two metal−carbon bonds are generated, to oxidative addition reactions.

First step of the reaction between **2** and the cumulene **A**−**E** is the substitution of the weakly coordinated THF ligand (**I**) by the cumulene. For stereochemical reasons the hydrocarbons are coordinated through the unsubstituted double bond to the manganese centre. C−C bond formation between C-1 of the cyclohexadienyl and the terminal carbon atom of the coordinated cumulene leads to the dicarbonyl{$\eta^{4:1}$-1-(2-propen-1,2-diyl)cyclohexa-2,3-diene}-manganese intermediates **II** probably stabilized by THF. The second C−C bond is formed between 5-C of the ring and 2-C of the 2-propen-1,2-diyl side chain, and the exocyclic, substituted double bond is coordinated to manganese (**III**). The result of the two C−C bond formations is a formal [5+2] cycloadduct of a cumulene to the cyclohexadienyl ligand. Substitution of the THF ligand by carbon monoxide, dissolved in the solution, completes the reaction of **2** with 1-methoxy-1-trimethylsilyl-1,2-propadiene (**E**) to give **3E**.



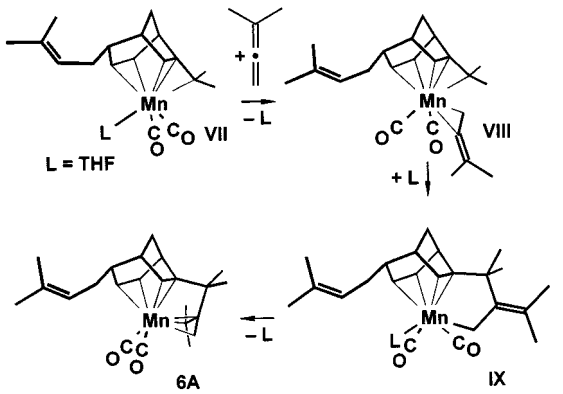
Scheme 1. Proposed formation of tricarbonyl{$\eta^{3:2}$-6-(1-methoxy-1-trimethylsilylmethylene)bicyclo[3.2.1]oct-3-en-2-yl}manganese (**3E**) via intermediates **I**−**III**

With regard to the substituents at the coordinated exocyclic double bond two isomers (*E*, *Z*) are possible. The spectroscopic data of **3E**, however, prove only the formation of one isomer. For stereochemical reasons the bulky $Si(CH_3)_3$ group is proposed to be in *E* position relative to C-5.



In case of cumulenes with phenyl substituents (**B**, **C**, **D**) from **III** a manganese-mediated 1,3-H shift takes place which results in the THF stabilized dicarbonyl($\eta^{3:2}$-7-methylenebicyclo[3.2.1]oct-2-en-6-yl)manganese complexes **IV**. The exchange of THF by CO completes the reactions to **4B**, **4C** and **4D**. Again, only one regioisomer with the phenyl group in *Z* position relative to C-5 is observed for **4B**, and **4C**.

The formation of the 1:2 adducts **5A**−**5E** is explained by an analogous reaction sequence as for **3E** starting from **III**. Substitution of the THF ligand by a cumulene affords the intermediate **V**. C−C bond formation between C-4 of the 6-methylenebicyclo[3.2.1]oct-3-en-2-yl and the terminal carbon atom of the coordinated cumulene leads to the accordingly substituted dicarbonyl{$\eta^{2:2:1}$-4-(2-propen-1,2-diyl)-6-methylenebicyclo[3.2.1]oct-2-en}(tetrahydrofuran)manganese intermediates **VI**. By a 1,5-H shift (**VII**) and addition of carbon monoxide the tricarbonyl{2,3,6,7,1″-η-7-methyl-



Scheme 2. Proposed formation of tricarbonyl{$\eta^{3:2}$-7-methylenebicyclo[3.2.1]oct-2-en-6-yl}manganese complexes **4B**, **4C**, **4D** by 1,3-H shift in intermediate **III**

ene-4-(2-propenyl)bicyclo[3.2.1]oct-2-en-6-yl}manganese complexes **5A**−**5E** result. Only one regioisomer is obtained for the products from unsymmetrically substituted 1,1-allenes (**5B**, **5C**, **5E**).

Scheme 3. Proposed formation of tricarbonyl{2,3,6,7,1″-η-7-methylene-4-(2-propenyl)bicyclo[3.2.1]oct-2-en-6-yl}mangemese complexes **5A**−**5E** via intermediates **III** and **V**−**VII**

The ligand of **6A** consists of three cumulenes and cyclohexadienyl. A reasonable reaction sequence for **6A** starts from intermediate **VII**. Substitution of THF by **A** gives the cumulene complex **VIII** which rearranges by C−C bond formation between C-1 of the 1-methylethylidene group and C-2 of the 3-methyl-1,2-butadiene unit to intermediate **IX**, stabilized with THF. Finally the 2,4-dimethyl-3-methylenepenta-2,4-diyl side chain is η^3-coordinated to the manganese centre.

Scheme 4. Proposed formation of dicarbonyl{2,3,6,7,3″,4″,1′″-η-7-(2,4-dimethyl-3-methylenepenta-2,4-diyl)-4-(3-methyl-2-butenyl)-bicyclo[3.2.1]octa-2,6-diene}manganese (**6A**)

Experimental Section

All operations and reactions were carried out under dry, oxygen-free nitrogen by common Schlenk techniques. All solvents were purified by standard methods (*n*-pentane, *n*-hexane with CaH_2, THF with potassium, diethyl ether with sodium/benzophenone and CH_2Cl_2 with P_4O_{10}) and stored under nitrogen. Alumina, neutral (Macherey-Nagel GmbH and CO KG, Düren) for column chromatography was degassed under vacuum, deactivated with 4% of water and saturated with nitrogen. UV irradiations were carried out in a 180-mL Duran flask with cooling jacket, wrapped with aluminium foil, with a 150-W mercury lamp TQ 150 (Heraeus-Noblelight, Kleinostheim). The irradiation flask was cooled by a cryostat SK 80 D (Lauda) with methanol as cooling liquid. During the irradiation, nitrogen was bubbled through the solutions to ensure mixing and to remove some of the carbon monoxide from the solutions. HPLC was performed with an Abimed/Gilson appliance consisting of three pumps (type 303), a dynamic mixer (type 811), a high-grade steel column with pre-column (Abimed/Gilson, type Dynamax, l = 25 cm, d = 21.4 mm, silica gel Si 60, 8 μm) and a UV detector (type 116). − IR: Perkin-Elmer FT-IR 16 PC. − NMR: Bruker AC 200 (200.13 MHz for ^{1}H, 50.32 MHz for ^{13}C), Bruker AMX 400 (400.13 MHz for ^{1}H, 100.63 MHz for ^{13}C). Chemical shifts are given relative to TMS, calculated from the solvent as internal standard (C_6HD_5: δ_H = 7.20, C_6D_6: δ_C = 128.0 and CD_2Cl_2: δ_C = 54.0). − C, H elemental analyses: Perkin−Elmer microanalyzer 240. The starting material tricarbonyl(η^5-cyclohexa-2,4-dienyl)manganese (**1**) was prepared from $[Mn(CO)_5Br]$ according to a literature procedure.[33][34] 3-Methyl-1,2-butadiene (**A**), 3-phenyl-1,2-butadiene (**B**), 3-phenyl-1,2-pentadiene (**C**), 1,1-diphenyl-1,2-propadiene (**D**) and 1-methoxy-1-trimethylsilyl-1,2-propadiene (**E**) were also prepared as described in literature.[35]

1. Photoreaction of Tricarbonyl(η^5-cyclohexadienyl)manganese (1) in Tetrahydrofuran: The irradiation flask was loaded with 250 mg (1.15 mmol) of $[Mn(\eta^5\text{-}C_6H_7)(CO)_3]$ (**1**), dissolved in 180 mL of THF. The pale yellow solution was cooled to 208 K and irradiated with UV light. After a few minutes, the colour of the solution turned to red. After 45 minutes, the CO bands of **1** had nearly disappeared and the irradiation was stopped. Dicarbonyl(η^5-cyclohexa-2,4-dienyl)(tetrahydrofuran)manganese (**2**) was identified by IR spectroscopy according to two νCO bands at 1930 (s) und 1861 (s) cm^{-1}.

2. Reaction of Dicarbonyl(η^5-cyclohexa-2,4-dienyl)(tetrahydrofuran)-manganese (2) with 3-Methyl-1,2-butadiene (A): To a THF solution of $[Mn(\eta^5\text{-}C_6H_7)(CO)_2THF]$ (**2**), freshly prepared from 250 mg (1.15 mmol) of $[Mn(\eta^5\text{-}C_6H_7)(CO)_3]$ (**1**), 0.2 mL (3 mmol) of 3-methyl-1,2-butadiene (**A**) was added at 208 K. The reaction mixture was allowed to warm up to room temperature while a slight stream of nitrogen was bubbled through it. During this procedure the colour of the solution changed from carmine to yellow. The solvent was removed in vacuo and the brown, oily residue was dissolved in *n*-pentane and chromatographed at 253 K on alumina with *n*-pentane.

1st Fraction: $[Mn(\eta^5\text{-}C_6H_7)(CO)_3]$ (**1**).

2nd Fraction: Yellow zone, tricarbonyl{2,3,6,7,1″-η-4-(3-methyl-2-butenyl)-7-(1-methylethylidene)bicyclo[3.2.1]oct-2-en-6-yl}manganese (**5A**) with traces of other carbonyl complexes. After purification by HPL chromatography with *n*-hexane as eluent, 105 mg (26%) of **5A**, yellow oil. − IR (*n*-pentane): $\tilde{\nu}$ (CO) = 2005 (s), 1932 (vs), 1922 (vs) cm^{-1}. − ^{1}H NMR (400.13 MHz, C_6D_6, 298 K): δ = 5.32 (m, J = 8.2, 5.0, 1.4, 1.4 Hz, 1 H, 2′-H), 3.82 (ddd, J = 6.1, 2.3, 1.4 Hz, 1 H, 3-H), 2.94 (ddd, J = 14.0, 9.5, 8.2 Hz, 1 H, 1′^{A}-H), 2.89 (d, J = 4.8 Hz, 1 H, 6-H), 2.72 (ddd, J = 14.0, 5.0, 4.7 Hz, 1 H, 1′^{B}-H), 2.64 (dddd, J = 9.5, 4.7, 2.3, 1.4 Hz, 1 H, 4-H), 2.45 (dd, J = 7.4, 4.0 Hz, 1 H, 1-H), 2.30 (dd, 7.4, 6.1 Hz, 1 H, 2-H), 1.99 (s, 3 H, 1″E-CH_3), 1.97 (dddd, J = 6.1, 4.8, 2.3, 2.3 Hz, 1 H, 5-H), 1.76 (d, J = 1.4 Hz, 3 H, 3′-CH_3), 1.69 (d, J = 1.4 Hz, 3 H, 3′-CH_3), 1.57 (ddd, J = 10.7, 6.1, 4.0 Hz,1 H, 8^{anti}-H), 1.28 (s, 3 H, 1″Z-CH_3), 1.21 (d, J = 10.7 Hz, 1 H, 8^{syn}-H). − ^{13}C NMR (50.32 MHz, C_6D_6, 298 K): δ = 226.0 (s, *C*O), 225.3 (s, *C*O), 224.5 (s, *C*O), 133.2 (s, C-3′), 122.9 (d, J = 157 Hz, C-2′), 99.4 (d, J = 158 Hz, C-3), 90.4 (s, C-7 or C-1″), 88.0 (s, C-7 or C-1″), 66.6 (d, J = 166 Hz, C-2), 59.0 (d, J = 119 Hz, C-4), 49.6 (d, J = 165 Hz, C-6), 42.7 (t, J = 132 Hz, C-1′), 39.7 (d, J = 141 Hz, C-1), 35.1 (t, J = 131 Hz, C-8), 33.5 (d, J = 154 Hz, C-5), 27.3 (q, J = 129 Hz, 1″E-*C*H$_3$), 25.9 (q, J = 126 Hz, 3′-*C*H$_3$), 25.6 (q, J = 126 Hz, 3′-*C*H$_3$), 18.1 (q, J = 125 Hz, 1″Z-*C*H$_3$). − $C_{19}H_{23}MnO_3$ (354.33): calcd. C 64.41, H 6.54; found C 64.02, H 6.52.

3rd Fraction: Yellow solution, dicarbonyl{2,3,6,7,3″,4″,1‴-η-7-(2,4-dimethyl-3-methylenepenta-2,4-diyl)-4-(3-methyl-2-butenyl)-bicyclo[3.2.1]octa-2,6-diene}manganese (**6A**). Removal of the solvent and crystallization from *n*-pentane at 243 K yielded 55 mg (12%) of **6A**. Red, rhombic crystals, suitable for X-ray diffraction analysis. − IR (*n*-pentane): $\tilde{\nu}$ (CO) = 1956 (vs), 1900 (vs) cm^{-1}. − ^{1}H NMR (200.13 MHz, C_6D_6, 298 K): δ = 5.56 (m, J = 8.3, 6.0, 1.4, 1.4 Hz, 1 H, 2′-H), 3.54 (dd, J = 3.9, 1.5 Hz, 1 H, 6-H), 3.44 (ddd, J = 7.3, 2.3, 1.7 Hz, 1 H, 3-H), 3.16 (ddd, J = 13.5, 10.5, 6.0, Hz, 1 H, 1′^{A}-H), 2.95 (ddd, J = 13.5, 8.3, ? C 72.80, H 5.69; found C 71.0, H 6.09.

4. Reaction of Dicarbonyl(η^5-cyclohexa-2,4-dienyl)(tetrahydrofuran)-manganese (2) with 3-Phenyl-1,2-pentadiene (C): To a THF solution of [Mn(η^5-C_6H_7)(CO)$_2$THF] (**2**), freshly prepared from 250 mg (1.15 mmol) of [Mn(η^5-C_6H_7)(CO)$_3$] (**1**), 0.2 mL (1.5 mmol) of 3-phenyl-1,2-pentadiene (**C**) was added at 208 K. After warming up to room temperature, the solvent was removed in vacuo and the residue was separated by HPLC with *n*-hexane.

1st Fraction: [Mn(η^5-C_6H_7)(CO)$_3$] (**1**).

2nd Fraction: Yellow solution, tricarbonyl{η$^{3:2}$-7-(1-phenylpropylidene)bicyclo[3.2.1]oct-2-en-6-yl}manganese (**4C**). After crystallization from *n*-pentane, 25 mg (6%) of **4C**, orange red crystals. − IR (*n*-pentane): ν̃ (CO) = 2006 (vs), 1934 (s), 1923 (vs) cm^{-1}. − ^{1}H NMR (200.13 MHz, C_6D_6, 298 K): δ = 7.59 (d, J = 7.0 Hz, 2 H, *o*-Ph), 7.23 (t, J = 7.0 Hz, 2 H, *m*-Ph), 7.10 (t, J = 7.0 Hz, 1 H, *p*-Ph), 3.67 (m, J = 8.0, 3.4, 2.0, 1.8 Hz, 1 H, 3-H), 3.03 (ddd, J = 6.3, 5.6, 1.3 Hz, 1 H, 1-H), 2.79 (dd, J = 4.9, 1.3 Hz, 1 H, 6-H), 2.65 (m, J = 15.4, 4.5, 3.4, 1.5 Hz, 1 H, 4^{exo}-H), 2.32 (dd, J = 8.0, 6.6 Hz, 1 H, 2-H), 2.23 (dq, J = 14.4, 7.2 Hz, 1 H, CH_2), 2.10 (m, J = 15.4, 2.0, 1.5 Hz, 1.5 Hz, 1 H, 4^{endo}-H), 2.02 (m, J = 4.9, 4.8, 4.5, 1.8, 1.5 Hz, 1 H, 5-H), 1.59 (m, J = 10.7, 5.6, 4.8, 1.5, 1.5 Hz, 1 H, 8^{anti}-H), 1.17 (dq, J = 14.4, 7.2 Hz, 1 H, CH_2), 0.97 (d, J = 10.7 Hz, 1 H, 8^{syn}-H), 0.80 (t, J = 7.2 Hz, 3 H, CH_3). − MS (70 eV); *m*/*z* (%): 362.0 (0.94) [M$^+$], 334.0 (6.90) [M$^+$ − CO], 306.0 (9.37) [M$^+$ − 2 CO], 278.0 (100) [M$^+$ − 3 CO], 223.0 (10.11) [M$^+$ − 3 CO, − Mn]. − $C_{20}H_{19}MnO_3$ (362.31): calcd. C 66.30, H 5.29; found C 66.38, H 5.27.

3rd Fraction: Yellow solution, tricarbonyl{2,3,6,7,1″-η-4-(3-phenyl-2-pentenyl)-7-(1-phenylpropylidene)bicyclo[3.2.1]oct-2-en-6-yl}-manganese (**5C**), 60 mg (10%), yellow oil. − IR (*n*-pentane): ν̃(CO) = 2008 (vs), 1940 (vs), 1920 (vs) cm^{-1}. − ^{1}H NMR (200.13 MHz, C_6D_6, 298 K): δ = 7.12−7.20 (m, 5 H, Ph-H), 7.00−6.90 (m, 5 H, Ph-H), 5.58 (dd, J = 9.5, 5.5 Hz, 1 H, 2′-H), 3.64 (ddd, J = 7.8, 2.0, 1.5 Hz, 1 H, 3-H), 3.29 (dq, J = 14.3, 7.2 Hz, 1 H, CH_2) 2.98 (ddd, J = 13.9, 9.5, 9.0 Hz, 1 H, $1'^{A}$-H), 2.98 (d, J = 4.9 Hz, 1 H, 6-H), 2.53−2.68 (m, 2 H, $1'^{B}$-H and 4-H), 2.26−2.48 (m, 5 H, 1-H, 2-H, CH_2), 1.98 (ddd, J = 5.5, 4.9, 2.0 Hz, 1 H, 5-H), 1.71 (ddd, J = 10.7, 5.5, 5.0 Hz, 1 H, 8^{anti}-H), 1.23 (d, J = 10.7 Hz, 1 H, 8^{syn}-H), 1.03 (t, J = 7.2 Hz, 3 H, CH_3), 0.90 (t, J = 7.2 Hz, 3 H, CH_3). − $C_{31}H_{31}MnO_3$ (506.53): calcd. C 73.51, H 6.17.

5. Reaction of Dicarbonyl(η^5-cyclohexa-2,4-dienyl)(tetrahydrofuran)-manganese (2) with 1,1-Diphenyl-1,2-propadiene (D): To a THF solution of [Mn(η^5-C_6H_7)(CO)$_2$THF] (**2**), freshly prepared from 250 mg (1.15 mmol) of [Mn(η^5-C_6H_7)(CO)$_3$] (**1**), 0.3 mL (1.5 mmol) of 1,1-diphenyl-1,2-propadiene (**D**) was added at 208 K. After warming up to room temperature, the solvent was removed in vacuo and the residue was separated by HPLC with *n*-hexane/CH_2Cl_2 (50:1).

1st Fraction: [Mn(η^5-C_6H_7)(CO)$_3$] (**1**).

2nd Fraction: Yellow solution, tricarbonyl{η$^{3:2}$-7-(1,1-diphenylmethylene)bicyclo[3.2.1]oct-2-en-6-yl}manganese (**4D**). After crystallization from *n*-pentane/CH_2Cl_2 (5:1), 15 mg (3%) of **4D** was isolated as red crystals. − IR (*n*-pentane): ν̃ (CO) = 2010 (s), 1945 (vs), 1921 (vs) cm^{-1}. − ^{1}H NMR (400.13 MHz, C_6D_6, 298 K): δ = 7.81 (d, br, 2 H, *o*-Ph), 7.20 (m, 4 H, *o*-, *m*-Ph), 7.10 (t, J = 7.2 Hz, 1 H, *p*-Ph), 6.97 (t, J = 7.2 Hz, 2 H, *m*-Ph), 6.87 (t, J = 7.2 Hz, 1 H, *p*-Ph), 3.80 (dd, J = 8.2, 3.4 Hz, 1 H, 3-H), 3.57 (d, J = 4.8, 1 H, 6-H), 2.97 (dd, J = 8.2, 6.1 Hz, 1 H, 2-H), 2.71 (m, J = 14.7, 3.4, 3.4, 1 H, 4^{exo}-H), 2.21 (ddd, J = 6.1, 4.8, 1 H, 1-H), 2.15 (m, J = 5.5, 4.8, 3.4 Hz, 1 H, 5-H), 2.12 (d, J = 14.75 Hz, 1 H, 4^{endo}-H), 1.60 (ddd, J = 10.8, 5.5, 4.8 Hz, 1 H, 8^{anti}-H), 0.90 (d, J = 10.8 Hz, 1 H, 8^{syn}-H). − MS (70 eV); *m*/*z* (%): 409.8 (< 1) [M$^+$], 381.9 (4.21) [M$^+$ − CO], 353.9 (4.51) [M$^+$ − 2 CO], 325.9 (100) [M$^+$ − 3 CO], 272.0 (23.29) [M$^+$ − 3 CO, − Mn]. − $C_{24}H_{19}MnO_3$ (410.35): calcd. C 70.25, H 4.67.

3rd Fraction: Yellow solution, tricarbonyl{2,3,6,7,1″-η-4-(3,3-diphenyl-2-propenyl)-7-(1,1-diphenyl-methylene)bicyclo[3.2.1]oct-2-en-6-yl}manganese (**5D**). After crystallization from *n*-hexane at 243 K, 35 mg (5%) of **5D**, red needles.− IR (*n*-pentane): ν̃ (CO) = 2010 (s), 1942 (vs), 1920 (vs) cm^{-1}. − ^{1}H NMR (400.13 MHz, C_6D_6, 298 K): δ = 7.79 (d, J = 7.2 Hz, 2 H, *o*-Ph), 7.44 (d, J = 7.2 Hz, 3 H, *o*-Ph), 7.32 (d, J = 7.2 Hz, 3 H, *o*-Ph), 7.28−7.01 (m, 8 H, *m*-Ph), 6.98 (t, J = 7.2 Hz, 3 H, *p*-Ph), 6.90 (t, J = 7.2 Hz, 1 H, *p*-Ph), 6.24 (dd, J = 9.0, 5.8 Hz,1 H, 2′-H), 3.83 (ddd, J = 8.0, 2.5, 1.5 Hz, 1 H, 3-H), 3.26 (dd, J = 6.1, 3.8 Hz, 1 H, 6-H), 3.25 (ddd, J = 14.1, 10.0, 9.0 Hz, 1 H, $1'^{A}$-H), 2.83 (dd, J = 8.0, 6.1 Hz, 1 H, 2-H), 2.80 (ddd, J = 14.1, 5.8, 4.1 Hz, 1 H, $1'^{B}$-H), 2.68 (m, J = 10.0, 4.1, ? Hz, 1 H, 4-H), 2.32 (dd, J = 6.1, 3.4, Hz, 1 H, 1-H), 2.18 (m, J = 6.1, 2.5, ? Hz, 1 H, 5-H), 1.66 (ddd, J = 10.9, 3.4, ? Hz, 1 H, 8^{anti}-H), 1.10 (d, J = 10.9 Hz, 1 H, 8^{syn}-H). − MS (70 eV); *m*/*z* (%): 518.2 (58.17) [M$^+$ − 3 CO], 464.2 (29.77) [M$^+$ − 3 CO, − Mn], 271.1 (76.81) [M$^+$ − 3 CO, − Mn, − $C_3H_3(C_6H_5)_2$], 193.0 (100) [M$^+$ − 3 CO, − Mn, − $C_3H_2(C_6H_5)_2$, − C_6H_5]. − $C_{39}H_{31}MnO_3$ (602.61): calcd. C 77.73, H 5.19; found C 77.07, H 5.07.

6. Reaction of Dicarbonyl(η^5-cyclohexa-2,4-dienyl)(tetrahydrofuran)-manganese (2) with 1-Methoxy-1-trimethylsilyl-1,2-propadiene (E): To a THF solution of [Mn(η^5-C_6H_7)(CO)$_2$THF] (**2**), freshly prepared from 250 mg (1.15 mmol) of [Mn(η^5-C_6H_7)(CO)$_3$] (**1**), 0.3 mL (1.5 mmol) of 1-methoxy-1-trimethylsilyl-1,2-propadiene (**E**)

was added at 208 K. After warming up to room temperature, the solvent was removed in vacuo and the residue was separated by HPLC with *n*-hexane as eluent.

1st Fraction: [Mn(η^5-C_6H_7)(CO)$_3$] (**1**).

2nd Fraction: Yellow solution, tricarbonyl{$\eta^{3:2}$-6-(1-methoxy-1-trimethylsilylmethylene)bicyclo[3.2.1]oct-3-en-2-yl}manganese (**3E**). After removal of the solvent, 50 mg (12%) of **3E**, yellow oil. − IR (*n*-pentane): $\tilde{\nu}$ (CO) = 2006 (w), 1999 (s), 1924 (w), 1912 (vs) cm^{-1}. − ^{1}H NMR (200.13 MHz, C_6D_6, 298 K): δ = 4.71 (ddd, *J* = 6.5, 4.9, 1.1 Hz, 1 H, 3-H), 4.39 (m, *J* = 6.6, 6.5, 2.7, 1.0 Hz, 1 H, 2-H), 4.01 (ddd, *J* = 7.2, 4.9, 2.7 Hz, 1 H, 4-H), 3.59 (s, 3 H, OC*H*$_3$), 3.28 (dddd, *J* = 7.2, 5.7, 1.3, 1.0 Hz, 1 H, 5-H), 2.31 (m, *J* = 6.6, 2.4, 2.3, 1.6 Hz, 1 H, 1-H), 1.73 (ddd, *J* = 12.1, 2.7, 1.3 Hz, 1 H, 7^{exo}-H), 1.35 (dddd, *J* = 12.1, 2.4, 1.1, 1.0 Hz, 1 H, 7^{endo}-H), 0.98 (ddd, *J* = 10.0, 2.7, 1.6 Hz, 1 H, 8^{syn}-H), 0.54 (m, *J* = 10.0, 5.7, 2.3, 1.0 Hz, 1 H, 8^{anti}-H), 0.43 [s, 9 H, Si(C*H*$_3$)$_3$]. − ^{13}C NMR (50 MHz, C_6D_6, 298 K): δ = 229.1 (s, *C*O), 225.2 (s, *C*O), 223.2 (s, *C*O), 128.3 (s, 6-C), 97.0 (d, *J* = 163 Hz, 3-C), 79.2 (s, 1′-C), 73.3 (d, *J* = 161 Hz, 2-C), 57.8 (q, *J* = 144 Hz, O*C*H$_3$), 56.7 (d, *J* = 168 Hz, 4-C), 47.2 (t, *J* = 136 Hz, 7-C), 37.6 (t, *J* = 131 Hz, 8-C), 37.46 (d, *J* = 140 Hz, 1-C or 5-C), 37.3 (d, *J* = 140 Hz, 1-C or 5-C), 1.6 [q, *J* = 120 Hz, 3 C, Si(*C*H$_3$)$_3$]. − $C_{16}H_{21}MnO_4Si$ (360.37): calcd. C 53.33, H 5.87; found C 53.93, H 6.04.

3rd Fraction: Yellow solution, tricarbonyl{2,3,6,7,1″-η-4-(3-methoxy-3-trimethylsilyl-2-propenyl)-7-(1-methoxy-1-trimethylsilylmethylene)bicyclo[3.2.1]oct-2-en-6-yl}manganese (**5E**). After crystallization from *n*-pentane at 243 K 75 mg (13%) of **5E**, yellow crystals. − IR (*n*-pentane): $\tilde{\nu}$ (CO) = 2000 (s), 1920 (vs, br.) cm^{-1}. − ^{1}H NMR (200.13 MHz, C_6D_6, 298 K): δ = 5.15 (dd, *J* = 9.6, 5.4 Hz, 1 H, 2′-H), 4.01 (ddd, *J* = 7.8, 2.2, 1.6 Hz, 1 H, 3-H), 3.80 (s, 3 H, OC*H*$_3$), 3.52 (ddd, *J* = 5.5, 4.6, 2.2 Hz, 1 H, 1-H), 3.35 (s, 3 H, OC*H*$_3$), 3.09 (ddd, *J* = 14.3, 9.8, 9.6 Hz, 1 H, 1′^{A}-H), 2.81 (ddd, *J* = 14.3, 5.4, 3.5 Hz, 1 H, 1′^{B}-H), 2.75 (dd, *J* = 7.8, 5.5 Hz, 1 H, 2-H), 2.65 (m, *J* = 9.8, 3.5, 1.6, 1.4 Hz, 1 H, 4-H), 2.56 (d, *J* = 5.1 Hz, 1 H, 6-H), 2.21 (dd, *J* = 6.0, 5.1 Hz, 1 H, 5-H), 1.73 (m, *J* = 11.1, 6.0, 4.6, 1.4 Hz, 1 H, 8^{anti}-H), 1.34 (d, *J* = 11.1 Hz, 1 H, 8^{syn}-H), 0.47 [s, 9 H, Si(C*H*$_3$)$_3$], 0.28 [s, 9 H, Si(C*H*$_3$)$_3$]. − MS (70 eV); *m*/*z* (%): 501.6 (4.12) [M$^+$], 417.7 (100) [M$^+$ − 3 CO], 385.7 (69.23) [M$^+$ − 3 CO, − OCH$_3$], 355.7 (10.02) [M$^+$ − 3 CO, − 2 OCH$_3$], 281.8 (12.99) [M$^+$ − 3 CO, − 2 OCH$_3$, − Si(CH$_3$)$_3$]. − $C_{23}H_{35}MnO_5Si_2$ (502.64) calcd. C 54.96, H 7.02; found C 55.20, H 6.94.

7. X-ray-Structural Analysis of Dicarbonyl{2,3,6,7,3″,4″,1‴-η-7-(2,4-dimethyl-3-methylenepenta-2,4-diyl)-4-(3-methyl-2-butenyl)-bicyclo[3.2.1]octa-2,6-diene}manganese (6A):[36] $C_{23}H_{31}MnO_2$, *M* = 394.42 g × mol^{-1}, triclinic space group $P\bar{1}$, *a* = 804.8(2), *b* = 1201.5(4), *c* = 1222.1(3) pm, α = 61.01(2), β = 81.12(2), γ = 87.47(2)°, *V* = 1.0206(5) nm^3, *Z* = 2, ρ(calcd.) = 1.283 g × cm^{-3}. Crystal size 0.01 × 0.45 × 0.45 mm. Using a P4 diffractometer (Siemens), radiation Mo-K_α, graphite monochromator, wavelength λ = 71.073 pm, ω-scan type, 5259 reflections were collected in the θ range 4.16° to 26.50° at *T* = 293 K. After data reduction, 4157 unique reflections (R_{int} = 0.0123) were obtained. The structure was solved by direct methods using SHELXS-97[37] and refined by full-matrix least squares against F^2 with SHELXL-97.[38] 271 parameters were refined to R_1 [$I > 2\sigma(I)$] 0.0547, wR_2 [$I > 2\sigma(I)$] 0.0811.

Electron-Sink Behaviour of the Carbonylnickel Clusters $[Ni_{32}C_6(CO)_{36}]^{6-}$ and $[Ni_{38}C_6(CO)_{42}]^{6-}$: Synthesis and Characterization of the Anions $[Ni_{32}C_6(CO)_{36}]^{n-}$ (n = 5–10) and $[Ni_{38}C_6(CO)_{42}]^{n-}$ (n = 5–9) and Crystal Structure of $[PPh_3Me]_6[Ni_{32}C_6(CO)_{36}] \cdot 4$ MeCN

Keywords: Nickel / Carbonyl complexes / Carbides / Structure elucidation / Electrochemistry

The hexacarbide clusters $[H_{6-n}Ni_{38}C_6(CO)_{42}]^{n-}$ (n = 3, 4, 5, or 6) have been directly obtained from the reaction of $[Ni_6(CO)_{12}]^{2-}$ with C_3Cl_6, whereas the related anions, $[H_{6-n}Ni_{32}C_6(CO)_{36}]^{n-}$ (n = 5 or 6), have been obtained by degradation under carbon monoxide of $[Ni_{38}C_6(CO)_{42}]^{6-}$, or upon thermal treatment at ca. 110 °C of $[Ni_{10}C_2(CO)_{16}]^{2-}$ salts. The compound $[PPh_3Me]_6[Ni_{32}C_6(CO)_{36}] \cdot 4$ MeCN is triclinic, space group $P\bar{1}$ (No 2), with a = 15.974(3), b = 17.474(3), c = 18.200(4) Å, α = 61.37(2), β = 69.31(2), γ = 72.35(2)° and Z = 1; final R = 0.033. The structure of $[Ni_{32}C_6(CO)_{36}]^{6-}$ has an idealised O_h symmetry and is based on a truncated octahedral $Ni_{32}C_6$ framework, with all edges spanned by bridging carbonyl groups. The six interstitial carbide atoms are lodged in square-antiprismatic cavities. The overall geometry of the $Ni_{32}C_6$ core is very similar to that found previously in $[HNi_{38}C_6(CO)_{42}]^{5-}$, and shows very close interatomic separations. Both $[Ni_{32}C_6(CO)_{36}]^{6-}$ and $[H_{6-n}Ni_{38}C_6(CO)_{42}]^{n-}$ (n = 5 or 6) display electron-sink behaviour. Thus, they have been chemically and electrochemically reduced to their corresponding $[Ni_{32}C_6(CO)_{36}]^{n-}$ (n = 7–10), $[Ni_{38}C_6(CO)_{42}]^{n-}$ (n = 7–9) and $[HNi_{38}C_6(CO)_{42}]^{n-}$ (n = 6–8) derivatives, and several of the involved redox changes show features of electrochemical reversibility. In contrast, both $[Ni_{32}C_6(CO)_{36}]^{6-}$ and $[H_{6-n}Ni_{38}C_6(CO)_{42}]^{n-}$ (n = 5 or 6) support only one partially reversible oxidation step. Their different behaviour upon protonation or oxidation is an indirect, but unambiguous, proof of the hydride nature of $[HNi_{32}C_6(CO)_{36}]^{5-}$ and $[H_{6-n}Ni_{38}C_6(CO)_{42}]^{n-}$ (n = 3, 4, or 5), which could not be validated by ^{1}H-NMR spectroscopy.

Introduction

Homoleptic carbonyl transition metal clusters show little propensity for multiple redox changes.[1−3] Only some exceptional compounds feature different (three or more) oxidation states which are stable, or sufficiently long-lived, to permit isolation or spectroscopic characterisation of the species. Among these exceptions there are examples of both homo-, e.g. $[Ir_{14}(CO)_{27}]^{n-}$ (n = 0, 1, 2),[4] and heterometallic clusters, e.g. $[Fe_3Pt_3(CO)_{15}]^{n-}$ (n = 0, 1, 2),[5,6] $[Ag_{13}Fe_8(CO)_{32}]^{n-}$ (n = 3, 4, 5),[7] and $[AuFe_4(CO)_{16}]^{n-}$ (n = 1, 2, 3);[8] a few more associate group 14−16 elements, e.g. $[Co_{13}C_2(CO)_{30}]^{n-}$ (n = 3, 4, 5, 6),[9,2c] $[Co_9Si(CO)_{23}]^{n-}$ (n = 2, 3, 5),[10] $[Ni_{11}Bi_2(CO)_{18}]^{n-}$ (n = 2, 3, 4),[11] $[Ni_{13}Sb_2(CO)_{24}]^{n-}$ (n = 2, 3, 4),[12] and $[Fe_5S_2(CO)_{14}]^{n-}$ (n = 0, 1, 2),[13] in their cluster cores. EHMO[6,7b,8] as well as LDF[14] calculations suggest that the redox aptitude of some clusters descends from ad hoc electronic conditions such as the presence within the HOMO-LUMO gap of a low-lying delocalised orbital, non-bonding or slightly antibonding in character; this can be filled or depleted of electrons without significant destabilisation of the cluster. In other cases, such as $[Co_{13}C_2(CO)_{30}]^{n-}$ and $[Co_9Si(CO)_{23}]^{n-}$, a synergy between steric (good fit of the cavity) and electronic (extra-stabilisation arising from Co−C or Co−Si bonds) effects seems to be operative.

Only very few homoleptic carbonyl clusters, viz. $[Pt_{19}(CO)_{22}]^{4-}$,[15,2c] $[Pt_{24}(CO)_{30}]^{2-}$,[16] and $[HFe_6Pd_6(CO)_{24}]^{3-}$[17] display a wider redox aptitude. In particular the former two homometallic clusters undergo two consecutive pairs of close-spaced one-electron reductions, as well as two close-spaced one-electron oxidations. Several of the above redox changes display features of electrochemical reversibility, even if most electrogenerated species are only stable on the timescale of cyclic voltammetry.

Multivalent carbonyl metal clusters are of interest for several reasons. First of all, the knowledge of their structural parameters and/or spectroscopic behaviour can validate their theoretical analysis (a procedure defined by L. F. Dahl as 'experimental quantomechanics'). Secondly, the intrinsically paramagnetic odd-electron species are molecular quantum dots.[14] Finally, anionic multivalent clusters in conjunction with cationic multivalent counterparts may give rise to ionic materials, hopefully with interesting electronic and magnetic behaviour. Ionic solids in which both

the cation and the anion are organometallic clusters have already been prepared.[18]

In the search for new multivalent anionic systems we re-investigated the chemistry of the nickel carbido-carbonyl clusters.[19] As a result, we report the synthesis and chemical and structural characterisation of the $[Ni_{32}C_6(CO)_{36}]^{6-}$ and $[HNi_{32}C_6(CO)_{36}]^{5-}$ clusters. The study of the electrochemical redox behaviour of both $[Ni_{32}C_6(CO)_{36}]^{6-}$ and $[H_{6-n}Ni_{38}C_6(CO)_{42}]^{n-}$ (n = 5 or 6) points out that these clusters show electron-sink features. Both compounds withstand several reversible electrochemical and chemical reduction steps. In contrast, they feature only a single one-electron oxidation step and the resulting species of this exhibits a limited stability. This lack of propensity for oxidation provides indirect but unambiguous proof of the hydride nature of $[HNi_{32}C_6(CO)_{36}]^{5-}$ and $[H_{6-n}Ni_{38}C_6(CO)_{42}]^{n-}$ (n = 3, 4, or 5), which could not be validated by proton NMR experiments.

Preliminary reports on the synthesis and structure of $[Ni_{32}C_6(CO)_{36}]^{6-}$ and $[HNi_{38}C_6(CO)_{42}]^{5-}$ have already appeared.[20][21]

Results and Discussion

Synthesis, Chemical Reactivity, and Spectroscopic Behaviour of $[HNi_{32}C_6(CO)_{36}]^{5-}$, $[Ni_{32}C_6(CO)_{36}]^{n-}$ (n = 5−8), $[H_{6-n}Ni_{38}C_6(CO)_{42}]^{n-}$ (n = 3−5), and $[Ni_{38}C_6(CO)_{42}]^{n-}$ (n = 5−8)

Previous work carried out showed that the reaction of the $[Ni_6(CO)_{12}]^{2-}$ dianion with C_3Cl_6 in THF or acetone as solvent leads to the formation of the $[HNi_{38}C_6(CO)_{42}]^{5-}$ hexacarbide cluster in low yields.[20] A re-investigation of the above reaction has shown that slight modifications of the reaction procedure have beneficial effects on the yields. In particular, the changes include: i) the use of a dild. THF solution of C_3Cl_6 which is slowly added in small portions to a THF solution of $[NEt_4]_2[Ni_6(CO)_{12}]$ up to a 1:2 molar ratio, ii) the continuous removal of the reaction atmosphere with a slow stream of nitrogen to avoid the build-up of a carbon monoxide partial pressure, and iii) the cooling of the reaction solution at ca. −15°C to minimise the stripping of $Ni(CO)_4$ vapour. Under these conditions, IR monitoring of the reaction shows that $[Ni_6(CO)_{12}]^{2-}$ is initially oxidised by C_3Cl_6 to $[Ni_7(CO)_{15}]^{2-}$ and $[Ni_9(CO)_{18}]^{2-}$; this step requires ca. 0.3 moles of C_3Cl_6 per mol of $[Ni_6(CO)_{12}]^{2-}$. The subsequent addition of a similar amount of C_3Cl_6 gives rise to a solution containing $Ni(CO)_4$, a yet uncharacterised brown species [ν_{CO} in THF at 2019 (s), 1856 (mw), and 1829 (sh) cm^{-1}] and a dark precipitate. At this stage the reaction mixture is left to stand for 24−48 hours at room temp. under a static nitrogen atmosphere. During this period it precipitates further. Extraction of the precipitate with acetone, acetonitrile, and DMSO sequentially affords three fractions containing $[H_2Ni_{38}C_6(CO)_{42}]^{4-}$, $[HNi_{38}C_6(CO)_{42}]^{5-}$, and $[Ni_{38}C_6(CO)_{42}]^{6-}$ respectively. Formation of the $[H_{6-n}Ni_{38}C_6(CO)_{42}]^{n-}$ (n = 4, 5) hydrides, in addition to the parent $[Ni_{38}C_6(CO)_{42}]^{6-}$ hexaanion, can probably be ascribed to the intrinsic acidity of the reaction solution owing to formation of Ni^{2+} salts during the reaction, and the presence of humidity. The above mixture can be converted into pure $[NEt_4]_6[Ni_{38}C_6(CO)_{42}]$ by direct extraction of the residue in DMSO and precipitation with water. Other quaternary ammonium or phosphonium salts of $[Ni_{38}C_6(CO)_{42}]^{6-}$ have been isolated by metathesis with their corresponding halides in DMSO and precipitation with water.

Addition of stoichiometric amounts of acids yields further products, e.g. dild. H_2SO_4, to an acetonitrile solution of $[Ni_{38}C_6(CO)_{42}]^{6-}$ sequentially, affords $[HNi_{38}C_6(CO)_{42}]^{5-}$ and $[H_2Ni_{38}C_6(CO)_{42}]^{4-}$, as shown by a progressive shift to higher wavenumbers of the carbonyl absorptions. The latter is obtained in a spectroscopically pure form only on switching to acetone as solvent. In this latter solvent addition of a further amount of acid leads to the formation of $[H_3Ni_{38}C_6(CO)_{42}]^{3-}$, which slowly decomposes to an (as yet) uncharacterised species. The $[H_{6-n}Ni_{38}C_6(CO)_{42}]^{n-}$ (n = 3−5), as well as the related $[Ni_{38}C_6(CO)_{42}]^{n-}$ (n = 5−8) species (see below), share a common characteristic infrared pattern consisting of three equally intense bands, one in the terminal and two in the edge bridging region; the absorptions wavenumbers of all above compounds are collected in Table 1. We have been unable to directly and unambiguously demonstrate the presence of hydride atoms by ^1H NMR spectroscopy in any of the $[H_{6-n}Ni_{38}C_6(CO)_{42}]^{n-}$ (n = 3−5) derivatives, probably as a result of the too low molar concentrations which can be obtained in both acetone and acetonitrile. However, as previously reported, the apparent partial or quantitative reduction occurring on dissolving the $[H_{6-n}Ni_{38}C_6(CO)_{42}]^{n-}$ (n = 3−5) salts in organic solvents with increasing dielectric constants can only be reasonably interpreted as due to the occurrence in solution of protonation-deprotonation equilibria, such as those reported in Eq. (1) and (2).

Table 1. Infrared carbonyl absorptions (± 2 cm^{-1}) of the $[H_{6-n}Ni_{38}C_6(CO)_{42}]^{n-}$ (n = 3−6) and $[Ni_{38}C_6(CO)_{42}]^{n-}$ (n = 5−8) derivatives

$$[H_2Ni_{38}C_6(CO)_{42}]^{4-} \xrightleftharpoons{MeCN} [HNi_{38}C_6(CO)_{42}]^{5-} + H^+ \quad (1)$$

$$[HNi_{38}C_6(CO)_{42}]^{5-} \xrightleftharpoons{DMSO} [Ni_{38}C_6(CO)_{42}]^{6-} + H^+ \quad (2)$$

Moreover, the presence of hydride atoms has now been indirectly, but unambiguously, proved by the electrochemical experiments (see below).

The $[Ni_{38}C_6(CO)_{42}]^{6-}$ hexaanion in DMF is sequentially reduced by the addition of a sodium/naphthalene solution to the corresponding $[Ni_{38}C_6(CO)_{42}]^{7-}$ and $[Ni_{38}C_6(CO)_{42}]^{8-}$ polyanions. Both these two new derivatives show the characteristic IR pattern of the parent compound and are apparently stable in solution under a nitrogen atmosphere for several hours. Nevertheless, their attempted isolation by precipitation with quaternary ammonium or phosphonium salts failed owing to their partial or complete reoxidation to the hexaanion. Addition of a further amount of the reducing agent to $[Ni_{38}C_6(CO)_{42}]^{8-}$ causes a further shift of the carbonyl absorptions to lower wavenumber; however, the IR pattern appears less distinctive and this can probably be attributed to a $[Ni_{38}C_6(CO)_{42}]^{9-}$ species, as in this instance the band due to the stretching of edge bridging carbonyls is too close to the carbonyl infrared band of DMF.

The $[Ni_{38}C_6(CO)_{42}]^{8-}$ is sequentially oxidised by stoichiometric amounts of tropylium tetrafluoroborate to $[Ni_{38}C_6(CO)_{42}]^{7-}$, $[Ni_{38}C_6(CO)_{42}]^{6-}$, and $[Ni_{38}C_6(CO)_{42}]^{5-}$. The $[Ni_{38}C_6(CO)_{42}]^{5-}$ pentaanion shows infrared carbonyl absorptions practically coincident with those of $[HNi_{38}C_6(CO)_{42}]^{5-}$; however, the different nature of the two is pointed out by the fact that the former is observed in a highly ionising medium such as DMF, where the latter undergoes a ready deprotonation. Addition of one further equiv. of tropylium tetrafluoroborate to $[Ni_{38}C_6(CO)_{42}]^{5-}$ results in its complete decomposition to $Ni(CO)_4$ and an insoluble amorphous black material. The failure to obtain infrared spectroscopic evidence for the possible existence of $[Ni_{38}C_6(CO)_{42}]^{n-}$ ($n = 3, 4$) upon oxidation with tropylium tetrafluoroborate can also be taken as circumstantial evidence of the hydride nature of the $[H_{6-n}Ni_{38}C_6(CO)_{42}]^{n-}$ ($n = 3, 4, 5$) derivatives resulting upon addition of protonic acids to $[Ni_{38}C_6(CO)_{42}]^{6-}$. The enhanced stability of $[H_{6-n}Ni_{38}C_6(CO)_{42}]^{n-}$ ($n = 3-5$) with respect to their corresponding $[Ni_{38}C_6(CO)_{42}]^{n-}$ ($n = 3-5$) anions can probably be ascribed to the fact that protonation, in contrast to oxidation, leaves unchanged the number of valence electrons of the cluster.

The $[H_{6-n}Ni_{38}C_6(CO)_{42}]^{n-}$ ($n = 4$ and 5) derivative is unstable with respect to carbon monoxide at atmospheric pressure and decomposes principally to a mixture of $Ni(CO)_4$ and an insoluble black material. Only minor amounts of the new $[Ni_{32}C_6(CO)_{36}]^{6-}$ hexaanion could be recovered. For $n = 4$, the decomposition above is probably favoured by the instability of the corresponding $[H_2Ni_{32}C_6(CO)_{36}]^{4-}$ species (vide infra). In contrast, the $[Ni_{38}C_6(CO)_{42}]^{6-}$ hexaanion affords $[Ni_{32}C_6(CO)_{36}]^{6-}$ almost quantitatively according to Eq. (3).

$$[Ni_{38}C_6(CO)_{42}]^{6-} + 18\ CO \underset{CO\ (1\ atm)}{\overset{MeCN,}{\rightleftharpoons}} [Ni_{32}C_6(CO)_{36}]^{6-} + 6\ Ni(CO)_4 \quad (3)$$

The equilibrium (Eq. 3) is shifted to the right by removal of $Ni(CO)_4$ under vacuum and re-exposure of the solution to a carbon monoxide atmosphere. IR monitoring of the reaction initially shows the appearance of $Ni(CO)_4$ and a change in the pattern of the carbonyl absorptions. As the reaction proceeds, the absorption attributed to the terminal carbonyl groups progressively weakens and the two bands attributed to the edge bridging carbonyls collapse into a single absorption centred at slightly higher wavenumber. The intermediate IR patterns are suggestive of the possible formation of $[Ni_{38-x}C_6(CO)_{42-x}]^{6-}$ ($x = 1-5$) species by stepwise loss of Ni(CO) moieties. It should be noted that members of the $[Ni_{38-x}C_6(CO)_{42-x}]^{6-}$ ($x = 0-6$) series of compounds would always have $6N + 19$ filled cluster valence orbitals; therefore each one of them is sterically and electronically feasible. Previously reported examples of such behaviour include the $[Ni_{10}C(CO)_{18}]^{2-}$–$[Ni_8C(CO)_{16}]^{2-}$,[19a] $[Ni_{12}C_2(CO)_{16}]^{4-}$–$[Ni_{11}C_2(CO)_{15}]^{4-}$,[19e] $[Ni_{12}Ge(CO)_{22}]^{2-}$–$[Ni_{10}Ge(CO)_{20}]^{2-}$,[22] and $[Ni_{35}C_4(CO)_{39}]^{6-}$–$[Ni_{34}C_4(CO)_{38}]^{6-}$[19d] sets of compounds. The resulting $[Ni_{32}C_6(CO)_{36}]^{6-}$ hexaanion shows a single sharp carbonyl absorption in the region of edge-bridging carbonyls (see Table 2). Although the $[Ni_{32}C_6(CO)_{36}]^{6-}$ hexaanion is also not indefinitely stable under a carbon monoxide atmosphere, its decomposition is slow. As a result, it has been isolated in yields of ca. 80% by monitoring the reaction with IR, and removal of the carbon monoxide atmosphere and $Ni(CO)_4$ as soon as the equilibrium (Eq. 3) has shifted to the right.

Table 2. Infrared carbonyl absorptions (± 2 cm^{-1}) of the $[HNi_{32}C_6(CO)_{36}]^{5-}$ and $[Ni_{32}C_6(CO)_{36}]^{n-}$ ($n = 5-8$) derivatives

Compound	Solvent	ν_{CO} [cm^{-1}]
$[HNi_{32}C_6(CO)_{36}]^{5-}$	acetone	1911 (s)
$[Ni_{32}C_6(CO)_{36}]^{5-}$	DMF	1905 (s)
$[Ni_{32}C_6(CO)_{36}]^{6-}$	acetonitrile	1888 (s)
$[Ni_{32}C_6(CO)_{36}]^{6-}$	DMF	1889 (s)
$[Ni_{32}C_6(CO)_{36}]^{7-}$	DMF	1872 (s)
$[Ni_{32}C_6(CO)_{36}]^{8-}$	DMF	1851 (s)

Formation of small amounts of $[Ni_{32}C_6(CO)_{36}]^{6-}$ often occurs upon thermal treatment of the majority of nickel carbide clusters, including monocarbides such as $[Ni_9C(CO)_{17}]^{2-}$. However, the best results have been obtained by using the $[Ni_{10}C_2(CO)_{16}]^{2-}$ dicarbide as the starting material.[19b] Thermal decomposition of this dicarbide in diglyme affords $[Ni_{32}C_6(CO)_{36}]^{6-}$, approximately according to Eq. 4.

$$5\ [Ni_{10}C_2(CO)_{16}]^{2-} \xrightarrow{110\ °C} [Ni_{16}C_4(CO)_{23}]^{4-} + [Ni_{32}C_6(CO)_{36}]^{6-} + 2\ Ni(CO)_4 + 13\ CO \quad (4)$$

The salts of $[Ni_{32}C_6(CO)_{36}]^{6-}$ separate out from the reaction solution, together with some insoluble inorganic material, owing to their very low solubility in diglyme. Their tetrasubstituted ammonium and phosphonium salts have been purified by extraction in MeCN and precipitated by layering di-isopropyl ether.

The chemical reactivity of $[Ni_{32}C_6(CO)_{36}]^{6-}$ is similar but not coincident with that of the parent $[Ni_{38}C_6(CO)_{42}]^{6-}$.

The major difference is represented by the decreased propensity of $[Ni_{32}C_6(CO)_{36}]^{6-}$ to partially substitute its free negative charge with hydrogen atoms upon protonation. Thus, addition of acid to an acetonitrile solution of $[Ni_{32}C_6(CO)_{36}]^{6-}$ gives rise only to trace amounts of $[HNi_{32}C_6(CO)_{36}]^{5-}$. This arises from the fact that in acetonitrile the equilibrium (Eq. 5) is shifted to the right, and can be moved to the left only on using acetone as the solvent.

$$[HNi_{32}C_6(CO)_{36}]^{5-} \overset{MeCN}{\rightleftharpoons} [Ni_{32}C_6(CO)_{36}]^{6-} + H^+ \quad (5)$$

In this solvent $[HNi_{32}C_6(CO)_{36}]^{5-}$ is stable and has been isolated in the solid state by precipitation with isopropyl alcohol. Attempts to further protonate $[HNi_{32}C_6(CO)_{36}]^{5-}$ only resulted in decomposition to $Ni(CO)_4$ and as yet uncharacterised materials. The instability of the $[H_{6-n}Ni_{32}C_6(CO)_{36}]^{n-}$ ($n = 3-5$) hydrides is in keeping with the reported failures above to degrade the corresponding $[H_{6-n}Ni_{38}C_6(CO)_{42}]^{n-}$ salts with carbon monoxide.

As with $[Ni_{38}C_6(CO)_{42}]^{6-}$, the $[Ni_{32}C_6(CO)_{36}]^{6-}$ hexaanion is progressively reduced by a solution of sodium/naphthalene in DMF to the corresponding $[Ni_{32}C_6(CO)_{36}]^{7-}$ and $[Ni_{32}C_6(CO)_{36}]^{8-}$ polyanions, as shown by a concomitant shift to lower wavenumber of their unique carbonyl absorption (see Table 2). IR monitoring shows that both species are stable at room temp. for at least several hours. The reaction is perfectly reversible upon addition of a DMF solution of tropylium tetrafluoroborate. The $[Ni_{32}C_6(CO)_{36}]^{7-}$ intermediate and the parent $[Ni_{32}C_6(CO)_{36}]^{6-}$ hexaanion are regenerated quantitatively. So far, all attempts to isolate the $[Ni_{32}C_6(CO)_{36}]^{7-}$ and $[Ni_{32}C_6(CO)_{36}]^{8-}$ salts have met with little success owing to their partial or complete reoxidation to $[Ni_{32}C_6(CO)_{36}]^{6-}$ during the workup. Addition of a further equiv. of tropylium tetrafluoroborate to $[Ni_{32}C_6(CO)_{36}]^{6-}$ causes the appearance of an infrared absorption practically coincident with that of $[HNi_{32}C_6(CO)_{36}]^{5-}$; however, this is assigned to $[Ni_{32}C_6(CO)_{36}]^{5-}$, in view of the fact that Eq. 5 is already shifted to the right in acetonitrile. Furthermore, $[HNi_{32}C_6(CO)_{36}]^{5-}$ salts obtained as above are instantaneously and completely deprotonated to the parent hexaanion once dissolved in DMF.

All $[Ni_{32}C_6(CO)_{36}]^{n-}$, as well as $[Ni_{38}C_6(CO)_{42}]^{n-}$ species with an odd n value contain an odd number of electrons and should, therefore, be paramagnetic. However their solutions in organic solvents such as DMF and *N*-methylpyrrolidinone do not display any significant EPR signal at any temperature (150−300 K). It is worth mentioning that such an unfortunate behaviour is featured by several previously reported odd-electron clusters, e.g. $Ni_3Cp_3S_2$[23] and $[Ni_{11}Bi_2(CO)_{18}]^{3-}$;[11] the latter does exhibit an enormously broad EPR signal but only in the solid state. As a result, their formulation is based exclusively upon their chemical and electrochemical behaviour.

X ray Crystal Structure of $[PPh_3Me]_6[Ni_{32}C_6(\mu\text{-}CO)_{36}]\cdot 4$ MeCN

The unit cell of $[PPh_3Me]_6[Ni_{32}C_6(\mu\text{-}CO)_{36}]\cdot 4$ MeCN contains one molecular anion located on a crystallographic inversion centre, six cations, and four acetonitrile molecules. A view of the structure of the $[Ni_{32}C_6(CO)_{36}]^{6-}$ hexaanion is reported in Figure 1. Selected interatomic distances and angles are given in Table 3. The truncated octahedral $Ni_{32}C_6$ framework of $[Ni_{32}C_6(CO)_{36}]^{6-}$, which shows an overall idealized O_h symmetry (Figure 2), is identical to the corresponding fragment previously found in $[HNi_{38}C_6(CO)_{42}]^{5-}$,[20] with very close interatomic separations. A formal stepwise construction of the metal skeletons of the two is shown in Figure 3. The inner part of both clusters constitutes a Ni_8 empty cube ($Ni-Ni_{av}$ = 2.397 Å, vs. 2.402 Å in $[HNi_{38}C_6(CO)_{42}]^{5-}$) with all six faces capped by carbon atoms, which describe a nonbonded C_6 octahedron. This inner Ni_8C_6 moiety is surrounded by a truncated-octahedral Ni_{24} shell {$Ni-Ni_{av}$ = 2.461 Å vs. 2.459 Å in $[HNi_{38}C_6(CO)_{42}]^{5-}$} in such a way as to generate six square-antiprismatic cavities lodging the six carbide atoms ($Ni-C_{av}$ = 2.062 Å). Each nickel atom of the inner cube lies ca. 0.93 Å underneath the centre of each hexagonal face of the outer Ni_{24} shell {av. $Ni_{inner}-Ni_{outer}$ = 2.634 Å vs. 2.633 Å in $[HNi_{38}C_6(CO)_{42}]^{5-}$} and is 12-coordinate being at a bond distance from 6 nickel atoms of the outer shell, 3 nickel atoms of the inner cube and 3 carbide atoms.

In the solid state, $[Ni_{32}C_6(CO)_{36}]^{6-}$ shows the presence of edge-bridging carbonyl groups only ($Ni-C_{av}$ = 1.917; $C-O_{av}$ = 1.152 Å), which span all Ni−Ni edges of the outer Ni_{24} shell. The above carbonyl stereochemistry is also retained in solution, as shown by the infrared spectrum of $[Ni_{32}C_6(CO)_{36}]^{6-}$, which only consists of one strong absorption in the bridging region.

An interesting structural feature of $[Ni_{32}C_6(CO)_{36}]^{6-}$ is represented by the presence of eight distorted hexagonal cups formed by subsequent concentric rings of oxygen, carbon, and nickel atoms, and ending with a unique nickel atom belonging to the inner cube. Addition of six Ni(CO) fragments to six of the above eight cups generates $[Ni_{38}C_6(CO)_{42}]^{6-}$. It may be questioned as to why two opposite cups have been left empty and whether a $[Ni_{40}C_6(CO)_{44}]^{6-}$ species could be possible or not. It is conceivable that the existence of the latter is unlikely owing to the shrinking of the carbonyl groups on those two empty cups, which releases the steric pressure brought about by the progressive entrance of the six Ni(CO) fragments in the others.

Electrochemical Behaviour of $[Ni_{38}C_6(CO)_{42}]^{6-}$ and $[Ni_{32}C_6(CO)_{36}]^{6-}$

The high redox aptitude of $[Ni_{32}C_6(CO)_{36}]^{6-}$ in acetonitrile solution is illustrated in Figure 4. The cyclic voltammogram displays five sequential electron transfer steps possessing features of chemical reversibility. Voltammetry at a platinum electrode with periodical renewal of the diffusion

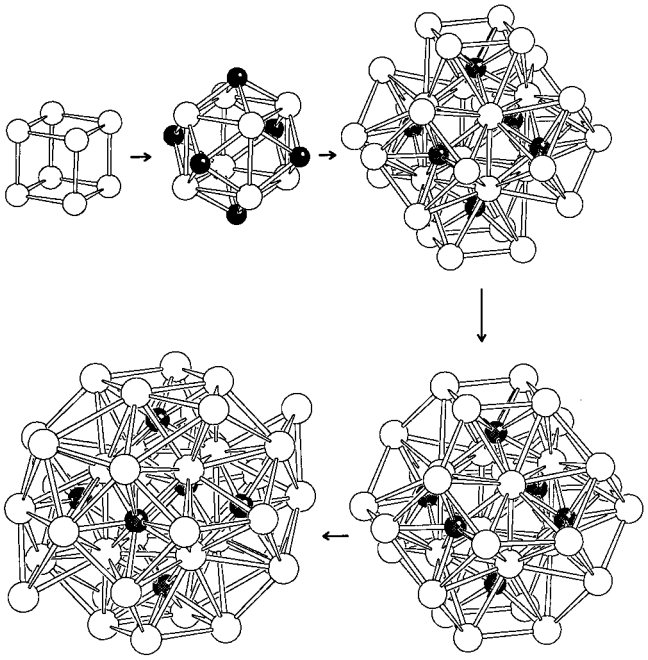

Figure 3. Formal construction of the metal skeletons of $[Ni_{32}C_6(CO)_{36}]^{6-}$ and $[HNi_{38}C_6(CO)_{42}]^{5-}$

performed in correspondence to the first reduction process ($E_w = -0.9$ V) show that it consumes one electron/molecule. The resulting solution displays a cyclic voltammetric profile complementary to the original one, thus testifying to the chemical reversibility of the $[Ni_{32}C_6(CO)_{36}]^{6-/7-}$ redox change. Further exhaustive reduction at the potential of the second reduction process ($E_w = -1.2$ V) also consumes one electron/molecule, but the subsequent cyclic voltammetric monitoring already indicates the partial occurrence of some degradation of the electrogenerated $[Ni_{32}C_6(CO)_{36}]^{8-}$. Based on these results we assume that all the electron transfer processes exhibited by $[Ni_{32}C_6(CO)_{36}]^{6-}$ are one-electron steps generating the corresponding redox congeners (namely $[Ni_{32}C_6(CO)_{36}]^{5-}$, $[Ni_{32}C_6(CO)_{36}]^{7-}$, $[Ni_{32}C_6(CO)_{36}]^{8-}$, $[Ni_{32}C_6(CO)_{36}]^{9-}$, $[Ni_{32}C_6(CO)_{36}]^{10-}$), which are stable under the short times of cyclic voltammetry, but under the longer times of macroelectrolysis only $[Ni_{32}C_6(CO)_{36}]^{7-}$ appears perfectly stable.

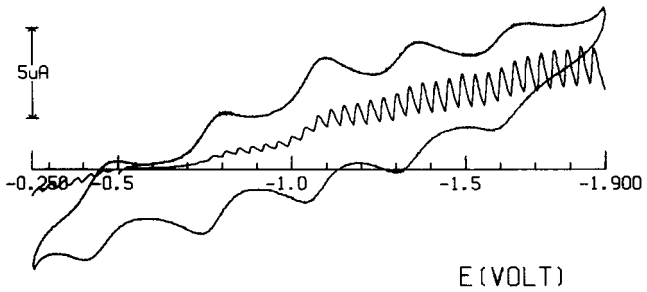

Figure 4. Cyclic and d.c. voltammograms recorded at a platinum electrode on a MeCN solution containing $[Ni_{32}C_6(CO)_{36}]^{6-}$ ($6\cdot10^{-4}$ mol dm^{-3}) and $[NEt_4][ClO_4]$ (0.1 mol dm^{-3}). Scan rates: cyclic voltammogram, 0.2 Vs^{-1}; d.c.voltammogram, 0.02 Vs^{-1}

Figure 5 compares the electrochemical response of $[Ni_{38}C_6(CO)_{42}]^{6-}$ in acetonitrile solution with that of its protonated species $[HNi_{38}C_6(CO)_{42}]^{5-}$. The hexaanion gives rise to four well-defined redox processes, all of which possess features of chemical reversibility in the cyclic voltammetric timescale. In this case too, direct-current voltam-

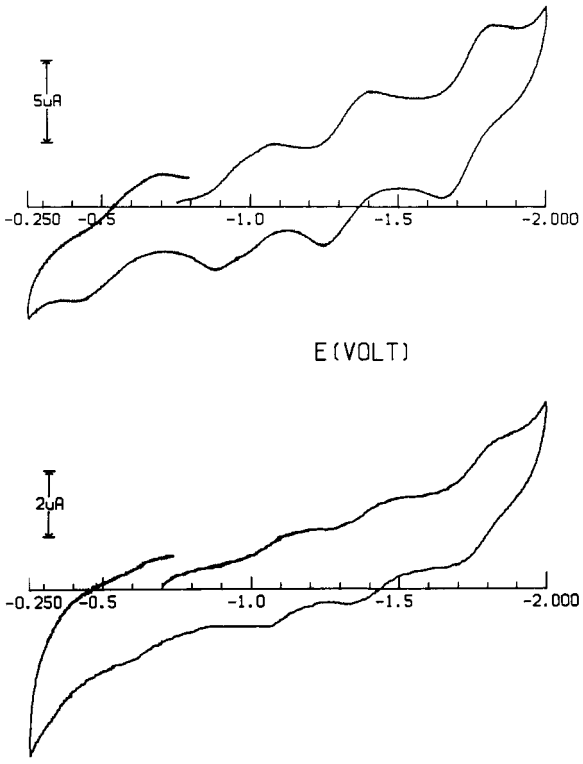

Figure 5. Cyclic voltammograms recorded at a mercury electrode on MeCN solutions containing $[NEt_4][ClO_4]$ (0.1 mol dm^{-3}). Top: $[Ni_{38}C_6(CO)_{42}]^{6-}$ ($4\cdot10^{-4}$ mol dm^{-3}). Bottom: $[HNi_{38}C_6(CO)_{42}]^{5-}$ ($5\cdot10^{-4}$ mol dm^{-3}). Scan rate 0.2 Vs^{-1}

metry shows the occurrence of one oxidation and three subsequent reduction processes. The protonated pentaanion also exhibits an analogous sequence of redox processes, encompassing the $[HNi_{38}C_6(CO)_{42}]^{4-/8-}$ oxidation states; they are, however, less well defined and shifted by about 400 mV towards more negative potential values. To our knowledge, the highest nuclearity clusters which have been previously studied to determine the influence of hydride incorporation on the electrochemical redox behaviour are $[Ru_{10}C(CO)_{24}]^{2-}$ and $[HRu_{10}C(CO)_{24}]^{-}$.[25] These, however, only exhibit a two-electron electrochemically irreversible reduction.

Step-by-step controlled potential coulometry shows that both $[Ni_{38}C_6(CO)_{42}]^{7-}$ and $[Ni_{38}C_6(CO)_{42}]^{8-}$ are stable, whereas $[Ni_{38}C_6(CO)_{42}]^{5-}$ tends to decompose slowly.

Finally, as illustrated in Figure 6, the redox change $[Ni_{38}C_6(CO)_{42}]^{8-/9-}$ in DMF solution is probably masked by the solvent discharge, because of the shift of the redox processes of $[Ni_{38}C_6(CO)_{42}]^{6-}$ towards negative potential values. Furthermore, one more anodic process becomes detectable, even if the instantaneously generated $[Ni_{38}C_6(CO)_{42}]^{4-}$ species is very unstable.

The formal electrode potentials of the redox changes exhibited by the present complexes are compiled in Table 4. From the electrochemical viewpoint it is noteworthy that all the redox changes concerned with the Ni_{38} species exhibit peak-to-peak separations which largely depart from the value of 60 mV, which is the theoretical prediction for electrochemically reversible one-electron processes. It could be speculated that the quasi-reversibility of such redox processes, i.e. their rather slow electron transfer rate, suggests that the Ni_{38} electron exchanges are accompanied by some geometric reorganisations, which are more significant than those accompanying the Ni_{32} redox processes.[2d]

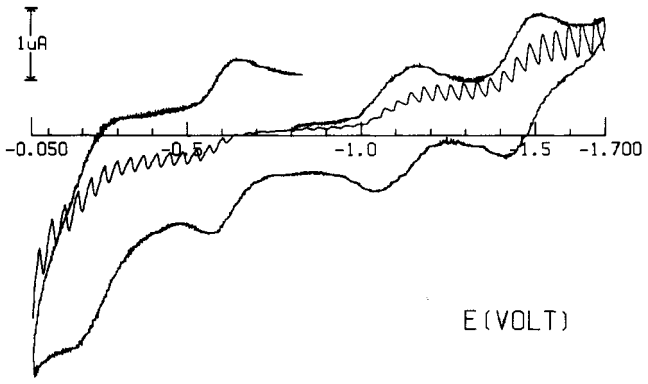

Figure 6. Cyclic and d.c. voltammograms recorded at a mercury electrode on a DMF solution containing $[Ni_{38}C_6(CO)_{42}]^{6-}$ ($3\cdot10^{-4}$ mol dm^{-3}) and $[NEt_4][ClO_4]$ (0.1 mol dm^{-3}). Scan rates: cyclic voltammogram, 0.2 Vs^{-1}; d.c.voltammogram, 0.02 Vs^{-1}.

Conclusion

The most notable property of the $[H_{6-n}Ni_{32}C_6(CO)_{36}]^{n-}$ (n = 5, 6) and $[H_{6-n}Ni_{38}C_6(CO)_{42}]^{n-}$ (n = 4, 5, 6) derivatives is represented by their electron-sink behaviour encompassing up to six different electrochemically reversible oxidation states. Their redox features resemble those of higher valent clusters such the Fe−S cubanes,[2] or fullerenes.[26] In the nickel clusters mentioned above such behaviour probably arises from the presence of highly connected nickel atoms belonging to the inner cube and the extra-stability of the metal core granted by the interstitial carbide atoms. Indeed, the nickel atoms of the inner cubic core of $[Ni_{32}C_6(CO)_{36}]^{6-}$ display coordination number 12, being coordinated to 9 nickel and 3 carbide atoms, whereas the coordination number of six out of eight corresponding nickel atoms of $[Ni_{38}C_6(CO)_{42}]^{6-}$ increases to 13 by intervention of the additional six Ni(CO) fragments. LDF calculations, carried out on $[Ni_{32}C_6(CO)_{36}]^{6-}$ prior to its isolation and characterisation, indicate that its electronic structure begins to bear some qualitative resemblance to that of a metal. In particular, almost degenerate t_{1u}, a_{2g}, and t_{2g} levels, holding a total of ten electrons, were found close to the Fermi energy.[27] This finding is in perfect agreement with the redox behaviour of $[Ni_{32}C_6(CO)_{36}]^{6-}$. Indeed, the progressive one-electron reduction of the latter to the corresponding decaanion corresponds to complete filling of the energy levels mentioned above. Moreover, the differences between the formal electrode potentials of consecutive redox couples of $[Ni_{32}C_6(CO)_{36}]^{6-}$ (range 0.26−0.33 V) is indicative of the presence in the frontier region of almost equally spaced one-electron energy levels with an average energy separation of ca. 0.3 eV. It may be concluded therefore that a metalisation process begins to emerge due to the presence of eight highly-connected nickel atoms.

Experimental Section

General Remarks: All reactions including sample manipulations were carried out under a well ventilated hood with standard Schlenk techniques under nitrogen and in carefully dried solvents.

Table 4. Formal electrode potentials (in V, vs. S.C.E.) and peak-to-peak separations (in mV) for the redox changes exhibited by $[Ni_{32}C_6(CO)_{36}]^{6-}$, $[Ni_{38}C_6(CO)_{42}]^{6-}$, and $[HNi_{38}C_6(CO)_{42}]^{5-}$

[a] Measured at 0.2 Vs^{-1} − [b] Difficult to be measured.

The $[Ni_6(CO)_{12}]^{2-}$ salts were prepared according to literature.[28] – Elemental analyses: atomic absorption on a Pye-Unicam instrument (Ni), gravimetrically as BPh_4^- salts for the tetrasubstituted ammonium cations. – IR: Perkin-Elmer 1605 interferometer using CaF_2 cells. Materials and apparatus for the electrochemical measurements have been described elsewhere.[29] Potential values are referred to the saturated calomel electrode (SCE).

Synthesis of $[NEt_4]_6[Ni_{38}C_6(CO)_{42}]$: $[NEt_4]_2[Ni_6(CO)_{12}]$ (2.58 g, 2.72 mmol) was dissolved in THF (40 mL) in a 100 mL three-necked round-bottomed flask cooled at −15°C and equipped with a microburette charged with C_3Cl_6 (0.51 g, 2.05 mmol) in THF (5 mL). The C_3Cl_6 solution (4 mL) was added dropwise over a period of six h into the stirred $[NEt_4]_2[Ni_6(CO)_{12}]$ solution while continuously removing the reaction atmosphere with a slow stream of nitrogen. The resulting dark brown suspension was left standing for 2 d at room temp. and under a static nitrogen atmosphere, and then evaporated to dryness under vacuum. The residue was washed in portions with water (30 mL), methanol (20 mL), and THF (20 mL) and extracted with DMSO (30 mL). $[NEt_4]_6[Ni_{38}C_6(CO)_{42}]$ was precipitated from the DMSO solution by addition of a solution of $[NEt_4]Cl$ (1.5 g) in water (30 mL) with stirring, it was then filtered, and washed with methanol (20 mL). The resulting dark brown material was extracted with acetonitrile (20 mL) and filtered. Precipitation by layering of diisopropyl ether (40 mL) gave black crystals of $[NEt_4]_6[Ni_{38}C_6(CO)_{42}]\cdot x$ MeCN (0.61 g). The salt is soluble in acetonitrile, DMF and DMSO, and sparingly soluble or insoluble in acetone, THF, alcohols, and nonpolar solvents. – $[NEt_4]_6[Ni_{38}C_6(CO)_{42}]$: calcd. $[NEt_4]^+$ 18.31, Ni 52.38; found $[NEt_4]^+$ 16.9, Ni 49.07. – Ni/$[NEt_4]^+$ calcd 6.33; found 6.43.

The corresponding $[NBu_4]^+$, $[NMe_3CH_2Ph]^+$, $[PPh_3Me]^+$, $[PPh_3CH_2Ph]^+$, and $[PPh_4]^+$ salts of $[Ni_{38}C_6(CO)_{42}]^{6-}$ have been similarly prepared by metathesis in DMSO with the appropriate quaternary salt.

Synthesis of $[PPh_3Me]_6[Ni_{32}C_6(CO)_{36}]$: A solution of $[PPh_3Me]_6[Ni_{38}C_6(CO)_{42}]$ (0.35 g, 0.067 mmol) in acetonitrile (20 mL) was stirred under a carbon monoxide atmosphere for 15 min and evaporated under vacuum to dryness. The residue was dissolved in acetonitrile (20 mL) and stirred under a carbon monoxide atmosphere for 10 min and dried under vacuum. The resulting dark brown residue was extracted with acetonitrile (20 mL) and filtered. Precipitation by layering of diisopropyl ether (40 mL) gave black crystals of $[PPh_3Me]_6[Ni_{32}C_6(CO)_{36}]\cdot 4$ MeCN (210 mg, 0.043 mmol). The salt is soluble in acetone, acetonitrile, DMF, and DMSO, and insoluble in THF, alcohols, and nonpolar solvents. – $[PPh_3Me]_6[Ni_{32}C_6(CO)_{36}]\cdot 4$ MeCN: calcd. $[PPh_3Me]^+$ 34.74, Ni 39.26; found $[PPh_3Me]^+$ 34.12, Ni 38.87. – Ni/$[PPh_3Me]^+$: calcd 5.33, found 5.37.

The corresponding $[NEt_4]^+$, $[NBu_4]^+$, $[NMe_3CH_2Ph]^+$, $[PPh_3CH_2Ph]^+$, and $[PPh_4]^+$ salts have been similarly prepared using the appropriate starting material.

Synthesis of $[NBu_4]_5[HNi_{38}C_6(CO)_{42}]$: $[NBu_4]_6[Ni_{38}C_6(CO)_{42}]$ (0.91 g) was dissolved in acetonitrile (30 mL), treated with 2.5 mL of a solution obtained by diluting 1 mL of H_2SO_4 (20% in aqueous solution) in acetonitrile (25 mL), and evaporated to dryness under vacuum. The resulting residue was extracted in acetone (20 mL) and precipitated by layering with isopropyl alcohol (45 mL) to give black crystals of $[NBu_4]_5[HNi_{38}C_6(CO)_{42}]$. Yields 0.64 g. The salt is soluble in acetone, sparingly soluble in THF, and insoluble in alcohols and nonpolar solvents. $[NBu_4]_5[HNi_{38}C_6(CO)_{42}]$ is very soluble in acetonitrile, DMF, and DMSO with partial or complete conversion into the corresponding $[Ni_{38}C_6(CO)_{42}]^{6-}$ hexaanion. – $[NBu_4]_5[HNi_{38}C_6(CO)_{42}]$: calcd. $[NBu_4]^+$ 25.80, Ni 47.57; found $[NBu_4]^+$ 25.12, Ni 47.2. – Ni/$[NBu_4]^+$: calcd. 7.6, found 7.74.

Synthesis of $[PPh_3Me]_5[HNi_{32}C_6(CO)_{36}]$: $[PPh_3Me]_6[Ni_{32}C_6(CO)_{36}]$ (0.31 g) was dissolved in acetonitrile (10 mL), treated with 1 mL of a solution obtained by diluting 1 mL of H_2SO_4 (20% in aqueous solution) in acetonitrile (25 mL) and evaporated to dryness under vacuum. The resulting residue was extracted in acetone (15 mL) and precipitated by layering with isopropyl alcohol (30 mL) to give black crystals of $[PPh_3Me]_5[HNi_{32}C_6(CO)_{36}]$. Yields 0.24 g. The salt is soluble in acetone, sparingly soluble in THF, and insoluble in alcohols and nonpolar solvents. $[PPh_3Me]_5[HNi_{32}C_6(CO)_{36}]$ is also soluble in acetonitrile, DMF, and DMSO with complete conversion into the parent $[Ni_{32}C_6(CO)_{36}]^{6-}$ hexaanion. – $[PPh_3Me]_5[HNi_{32}C_6(CO)_{36}]$: calcd. $[PPh_3Me]^+$ 31.88, Ni 43.24; found $[PPh_3Me]^+$ 30.79, Ni 41.57. – Ni/$[PPh_3Me]^+$: calcd 6.4, found 6.37.

X-ray Data Collection and Crystal Structure Determination: Crystal data for $[PPh_3Me]_6[Ni_{32}C_6(CO)_{36}]\cdot 4$ MeCN: triclinic, space group $P\bar{1}$ (No. 2), $a = 15.974(3)$, $b = 17.474(3)$, $c = 18.200(4)$ Å, $\alpha = 61.37(2)$, $\beta = 69.31(2)$, $\gamma = 72.35(2)°$, $V = 4115(1)$ Å^3, $Z = 1$, $D_c = 1.93$ gcm^{-3}, Mo-K_α radiation ($\lambda = 0.71073$ Å), μ (Mo-K_α) = 37.1 cm^{-1}, $T = 298$ K. 14585 reflections with $3° < \theta < 25°$ were measured on a CAD4 diffractometer at room temp. using a crystal with approximate dimensions $0.20 \times 0.15 \times 0.35$ mm. Data were corrected for Lorentz polarisation and absorption effects (empirical absorption, transmission factors in the range 0.56−1.00[30]). The structure was solved by direct methods (SIR 89) and refined using 10639 independent reflections having $I > 3\sigma(I)$, minimising the function $\Sigma w(|Fo|-|Fc|)^2$. Scattering factors were taken from Cromer and Waber.[31] Anomalous dispersion corrections were included.[32] Anisotropic displacement parameters were assigned to all non-hydrogen atoms.The hydrogen atoms were placed at calculated positions (C−H 0.95 Å). The final R value was 0.033 (R_w = 0.043). All the calculations were performed using Personal SDP software.[33]

Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-179-79 Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44 (1223) 336-033; E-mail: deposit@ccdc.cam.ac.uk].

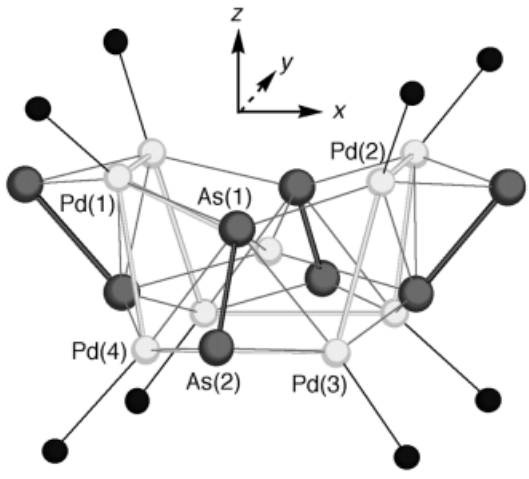
Bonding Analysis in Inorganic Transition-Metal Cubic Clusters, 4[+] The Distorted $Pd_9(\mu:\eta^5,\eta^2\text{-}As_2)_4(PPh_3)_8$ Architecture

Régis Gautier,[a] Jean-François Halet,*[a] and Jean-Yves Saillard*[a]

Keywords: Electron counting / Electronic structure / Density functional calculations / Extended Hückel calculations / Cluster compounds / Cluster compounds



Extended Hückel and density functional calculations were carried out on the title compound **1**. Results indicate that the bonding of the interstitial Pd_i atom with the D_{2d} distorted $(Pd_s)_8(As_2)_4$ cubic host differs from that found in the related metal-centered cubic species $M_9(\mu_4\text{-}E)_6L_8$. Species **1** can be described as an approximate square-planar 16-electron Pd_iL_4 center bound through Pd_i–As rather than Pd_i–Pd_s contacts to a distorted cubic fragment composed of four 30-electron bimetallic Pd_2L_8 units. Although a substantial gap is computed between the highest occupied molecular orbital and the lowest unoccupied molecular orbital for the observed electron count of 130 MVEs, calculations indicate that such an architecture should be observed for different electron counts close to that count. The incorporation of the central Pd atom does not seem to be essential to ensure the stability of the distorded $Pd_8(As_2)_4(PH_3)_8$ cluster. Such empty clusters, with formally four M–M bonds and eight planar 16-electron Pd_s centers, should exist for electron counts close to 120 MVEs.

Introduction

Because of potential applications in nanoelectronics, the miniaturization of solids to cluster size is an area of active research.[1] Initially restricted to metals, this field has rapidly been extended to ligated metal clusters. Among the latter, systems where a metal cube is bridged by different heavy main group atoms constitute now an important and fascinating family, which can be regarded as nanoscaled cutouts of bulk transition metal pnictides and chalcogenides. These cubic arrays may be empty or centered by an interstitial atom.[2−18] Theoretical calculations performed on empty $M_8(\mu_4\text{-}E)_6L_8$ clusters[19] and metal-centered $M_9(\mu_4\text{-}E)_6L_8$[20] (M = transition metal, E = group 14, 15, and 16 element, L = two-electron donor ligand) have shown that such compounds are characterized by an electronic structure which is either "molecular" (closed-shell electron configuration) or "metallic" (open-shell electron configuration) in nature, depending upon the electron count and the nature of the capping ligands.[21]

When omnicapped, such clusters depict generally a rather regular cubic arrangement. Expanding or shrinking of the cube is observed upon variation of the number of metal valence electrons (MVE), which ranges from 99 to 120 MVEs for empty $M_8(\mu_4\text{-}E)_6L_8$ species and from 121 to 130 MVEs for metal-centered $M_9(\mu_4\text{-}E)_6L_8$ clusters so far.[19−21] On the other hand, distorted cubic architectures are encountered when the ligand environment of the metallic cage is nonsymmetrical. This is observed for instance in the 127-MVE species $[Co_9(\mu_5\text{-}Bi)_4(CO)_{16}]^{2-}$, characterized by Eveland and Whitmire.[22] Being viewed as a metal-centered elongated Co_8 cube with four Bi atoms capping the four rectangular faces, such a cluster bears some structural resemblance to the hexacapped cubic $M_9(\mu_4\text{-}E)_6L_8$ compounds. A theoretical analysis of the bonding in this tetracapped compound and in related compounds has been recently published.[21,23]

An alternative distortion of a metal-centered M_9 cube is encountered in the related cluster $Pd_9(\mu:\eta^5,\eta^2\text{-}As_2)_4(PPh_3)_8$ (**1**), characterized by Fenske and Persau some years ago.[14] In this compound, the nine Pd atoms build up an approximate body-centered cube of D_{2d} symmetry, with four short [average Pd(1,2)−Pd(4,3) = 2.88 Å], four long [average Pd(3)−Pd(4) = 3.16 Å], and four very long [average Pd(1)−Pd(2) = 4.45 Å] distances between surface Pd (Pd_s) centers. This D_{2d} distortion of an M_8 cube is sketched in

Figure 1. Rather long separations, ca. 3.00−3.09 Å are also observed between Pd_s atoms and the interstitial Pd (Pd_i) atom. Four faces of this highly distorted cube are asymmetrically capped by (μ:η^5,η^2-As_2) dumb-bells. The central Pd_i atom is bound to four As atoms (Pd_i−As = 2.57 Å) in an approximate square-planar arrangement, somewhat distorted toward tetrahedral. The As−As separation is rather short (2.36 Å) suggesting some π-bonding. The atoms constituting each As_2 units have a different environment. The As(1) atoms are connected to five metal atoms, one of them being Pd_i. Among the four As(1)−Pd_s bonds, two of them are shorter [average Pd(1,2)−As(1) = 2.49 Å] while the remaining two are quite long [average Pd(3,4)−As(1) = 2.61 Å]. The pyramidally tricoordinated As(2) atom is bonded to two Pd_s atoms [average Pd(3,4)−As(2) = 2.44 Å].

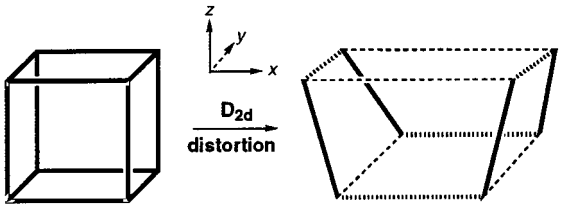

Figure 1. Conceptual formation of the D_{2d} distorted cubic $Pd_8(PH_3)_8$ fragment present in model **1**-H. Dashed lines and dotted lines correspond to long (ca. 3.15 Å) and very long (ca. 4.45 Å) metal−metal contacts, respectively.

Leaving a non-bonding lone pair on As(2), one can count the neutral (μ:η^5,η^2-As_2) units as six-electron donor ligands, which leads to a total of 130 MVEs for **1**. This renders this cluster isoelectronic to the regular cubic $Pd_9(\mu_4\text{-Te})_6(PEt_3)_8$ species.[16] Extended Hückel Theory (EHT) and Density Functional Theory (DFT) calculations were undertaken on the model compound $Pd_9(\mu:\eta^5,\eta^2\text{-}As_2)_4(PH_3)_8$ (**1**-H) to understand the unusual bonding situation in this compound (see the Appendix for the computational details). We discuss the results in this paper.

The Empty Distorted $Pd_8(As_2)_4(PH_3)_8$ Cube

The electronic structure of compound **1**-H can be formally analyzed as resulting from the interaction between the interstitial Pd_i atom and its $Pd_8(As_2)_4(PH_3)_8$ host. On the other hand, the molecular orbital (MO) diagram of the D_{2d} $Pd_8(As_2)_4(PH_3)_8$ fragment itself can be derived from the interaction of the four noninteracting $[As_2]^{4-}$ units (As−As single bonds are assumed) with the distorded $[Pd_8(PH_3)_8]^{16+}$ fragment. The frontier molecular orbitals (FMO) of the latter itself descend from those of a regular cubic cage. Indeed, starting with a regular cube, the metal framework found for **1** can be generated according to a D_{2d} distortion by elongating parallel metal−metal edges of the top and bottom faces of the cube as illustrated in Figure 1. Therefore, it is important to evaluate first the effects of the D_{2d} distortion on the skeletal MOs of an idealized $Pd_8(PH_3)_8$ cube. The qualitative analysis developped below is based on EHT calculations (see Appendix for details).

The MO diagram of the idealized $Pd_8(PH_3)_8$ cube of O_h symmetry (Pd−Pd = 2.88 Å) can be qualitatively obtained by combining the FMOs of the eight $Pd(PH_3)$ units.[19a,21] Such a fragment, as shown on the far left-hand side of Figure 2, presents a block of five d-type orbitals (one, two, and two of σ, π, and δ symmetry, respectively) below a radial σ-type sp hybrid and a set of two tangential π-type orbitals of Pd 5p parentage.[19a] When the cube is built, the three upper diffuse FMOs (sp_σ and p_π) of the eight $Pd(PH_3)$ groups overlap strongly and generate a set of 12 bonding MOs, largely separated from a set of 12 antibonding MOs. The more contracted d-type FMOs give rise to a band of 40 combinations which spreads out over a range of about 1 eV. Unlike for the s and p orbitals, the d-type overlap is not strong enough to create an energy gap separating the in-phase combinations from the out-of-phase ones. In our chosen fragment charge partitioning, the eight upper orbitals of the d-band are formally vacant. The derivation of the MO level ordering of the regular $[Pd_8(PH_3)_8]^{16+}$ cube from the $Pd(PH_3)$ FMOs is sketched in Figure 2a.

Upon D_{2d} distortion which leads to four long and four very long metal−metal separations (see Figure 1), the MO diagram of $[Pd_8(PH_3)_8]^{16+}$ is perturbed as shown in Figure 2b. Because of the lengthening of eight edges of the cube, some antibonding and bonding metal−metal MOs become nonbonding. EHT calculations indicate that the overlap between the s and p Pd FMO's is cancelled along the four 4.45 Å very long edges while it is still significant along the four 3.16 Å long Pd−Pd edges. As a result, four s and p-type antibonding combinations are significantly stabilized, leading to a set of eight antibonding orbitals and a set of 16 bonding/nonbonding orbitals. The overlap between the more contracted d-type orbitals remains significant only on the four 2.88 Å short edges. Whithin the d-band, this leads to the concentration of most of the Pd−Pd bonding character over a set of four orbitals of a_1, b_1, and e symmetry. These four orbitals lie at the very bottom of the band. They are preponderantly localized on the short edges of the distorted cube and have the proper symmetry to be considered as holding four localized Pd−Pd bonding pairs.

With formally a single bond between the As atoms, the seven occupied MOs of an isolated $(As_2)^{4-}$ unit separate into one low-lying σ-bonding orbital and six more or less nonbonding MOs which can be associated with the six lone pairs of the saturated $(As_2)^{4-}$ species. Four of these six orbitals are the in-phase (weakly bonding) and out-of-phase (weakly antibonding) combinations of the 4p(π) As orbitals, the remaining 2 being of σ-type. Because of the large energy separation between the 4s and 4p shells in As, one of the σ-nonbonding combinations, being largely 4s in character, lies at very low energy. Considering that the empty antibonding σ* level is situated at a very high energy, one is left for each $(As_2)^{4-}$ unit with 5 MOs (4 of π-type, 1 of σ-type) lying at a moderate energy and consequently susceptible to significantly interact with the $[Pd_8(PH_3)_8]^{16+}$ cube. These orbitals, all occupied, are sketched on the far right-hand side of Figure 2. When brought together, the frontier orbitals of the $(As_2)^{4-}$ groups give rise to a set of

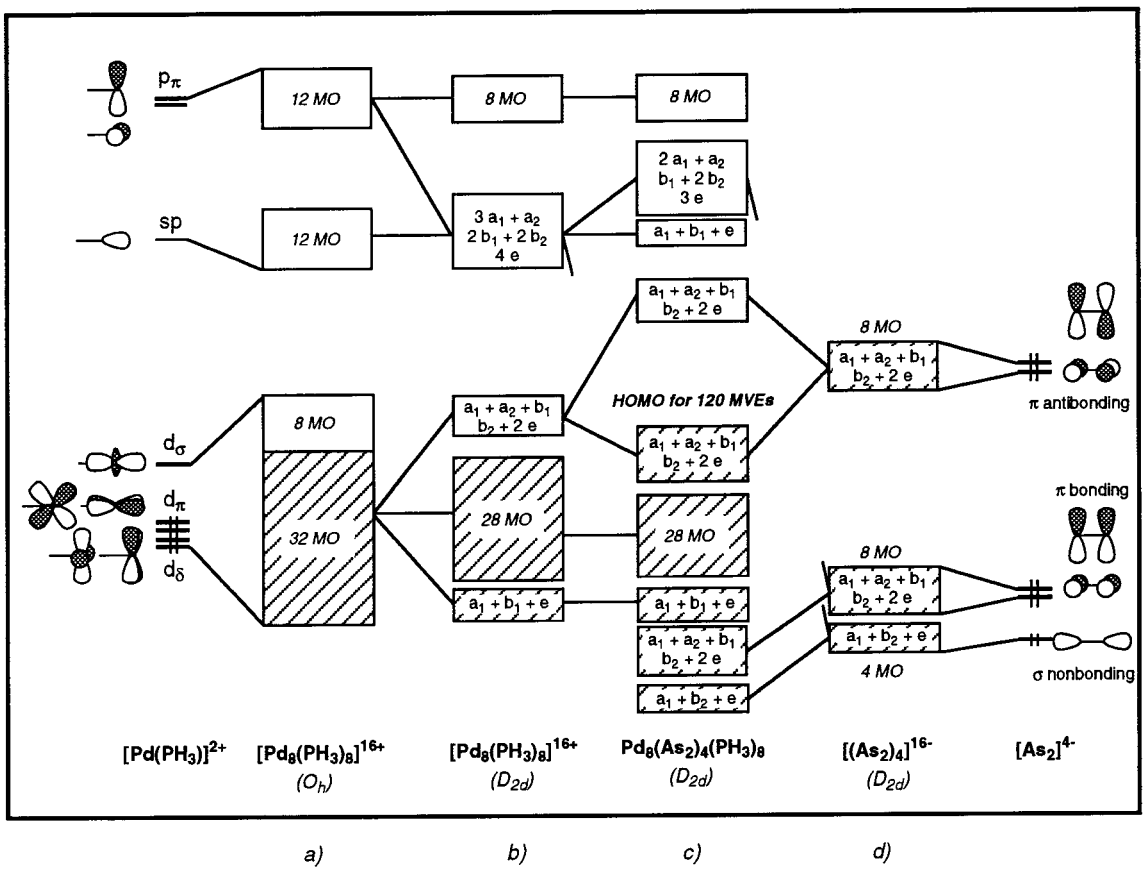

Figure 2. Qualitative MO diagrams based on EHT calculations for the idealized (12 M−M bonds) (a) and distorted (4 M−M bonds) (b) $[Pd_8(PH_3)_8]^{16+}$ fragment, the empty distorted $Pd_8(PH_3)_8(As_2)_4$ cluster (c), and the $[(As_2)_4]^{16-}$ fragment (d). The FMOs of the $Pd(PH_3)$ and As_2 moieties are shown on the far left- and far right-hand sides, respectively.

four combinations of the σ FMOs, lying close to a set of 8 combinations of the π FMOs, separated from the 8 π* combinations, as shown in Figure 2d.

The MO diagram showing the major bonding interactions between the two $[(As_2)_4]^{16-}$ and $[Pd_8(PH_3)_8]^{16+}$ fragments is given in Figure 2c. The twenty occupied FMOs of the former need to find vacant metallic counterparts of the same symmetry in the latter. These twenty metallic FMO's originate from two groups. One of them is made of the 8 d-type vacant orbitals, of symmetry $a_1 + a_2 + b_1 + b_2 + 2\times$ e. The second group, of symmetry $2\times a_1 + a_2 + b_1 + 2\times b_2 + 3\times$ e, is made of 12 among the sixteen s- and p-type bonding/nonbonding combinations. The interaction between the two fragments leads to the formation of twenty bonding and twenty antibonding combinations, as illustrated in Figure 2. Applying the closed-shell requirement to the hypothetical $Pd_8(PH_3)_8(As_2)_4$ model leads to the favored 120-MVE count. For this peculiar electron count, EHT calculations give a gap of 0.90 eV between the highest occupied molecular orbital (HOMO) and the lowest unoccupied molecular orbital (LUMO). The computed overlap population corresponding to the short Pd−Pd distances is rather weak [Pd(1,2)−Pd(3,4) = 0.03], whereas those corresponding to the long and very long Pd−Pd separations are nearly equal to zero. The significant participation to vacant levels of the π* FMOs of the $(As_2)^{4-}$ units provide the As−As single bonds with some additional π-bonding character, as shown by the increase of the As-As overlap population relative to an isolated $(As_2)^{4-}$ unit [0.92 in $Pd_8(PH_3)_8(As_2)_4$ vs 0.53 for the free $(As_2)^{4-}$ group]. The Pd−As overlap populations [Pd(1,2)−As(1) = 0.30, Pd(3,4)−As(1) = 0.18, and Pd(3,4)−As(2) = 0.38] suggest that the As atoms are firmly bonded to the eight Pd atoms.

To gain some confidence in the EHT results, DFT calculations were undertaken on the 120-MVE $Pd_8(PH_3)_8(As_2)_4$ model. Full optimization was made under the D_{2d} symmetry constraint. The optimized bond lengths for this model are given in Table 1 along with those obtained for the 130-MVE metal-centered $Pd_9(\mu{:}\eta^5,\eta^2\text{-}As_2)_4(PH_3)_8$ species. Remarkably, the computed distances are similar overall in the empty and the metal-centered clusters. We shall come back to this point in the next section. A HOMO-LUMO gap of 0.73 eV (comparable to that obtained from EHT calculations) is computed. These results suggest that empty clusters such as $Pd_8(As_2)_4(PH_3)_8$ with a D_{2d} distorted cubic framework may exist.

The fact that each $(As_2)^{4-}$ ligand uses only five FMOs for making six Pd−As "bonds" is typical of hypervalency.[24] However, as for the diamagnetic 120-MVE $M_8(\mu_4\text{-}E)_6L_8$ clusters, it is possible to describe $Pd_8(PH_3)_8(As_2)_4$ with a

simple 2-electron/2-center localized bonding scheme in which the number of bonding electron pairs is necessarily larger than the number of bonding combinations appearing in the delocalized MO diagram.[19] Assuming four Pd−Pd bonds, 24 Pd−As bonds, and four As−As bonds, the triconnected As(2) atoms hold a lone pair and satisfy the octet rule while the hypervalent As(1) atoms are 10-electron centers. Interestingly, within this bonding scheme, the Pd atoms are 16-electron centers, a typical configuration for the planar coordination mode.[24] As a matter of fact, a careful structural analysis of **1** indicates a not-far-from planar ligand environment around the Pd_s atoms. In the $Pd_8(PH_3)_8(As_2)_4$ model, the geometry of which is taken from the idealized geometry of **1**, the two strongest Pd−As bonds and the Pd−P bond are almost in the same plane for each metal center, whereas the weaker Pd−As bond is about 10° away from this plane. From this point of view, the hypothetical 120-MVE $Pd_8(As_2)_4(PH_3)_8$ cluster can be considered as the assemblage of four 30-electron $L_4Pd-PdL_4$ units, made of two 16-electron centers and linked to each other via bridging As_2 ligands (i.e. $4 \times (2 \times 16 - 2) = 120$ MVEs). It is related to a series of 128-MVE Cu_8 clusters which can be described as resulting from the assemblage of eight 16-electron square-planar systems, with no formal metal−metal bonding (except perhaps some $d^{10}-d^{10}$bonding).[26] Adding formally 8 electrons to $Pd_8(PH_3)_8(As_2)_4$ would break the four Pd−Pd bonds, making the system isoelectronic to the Cu_8 species.

Encapsulation of the Interstitial Metal Atom

The qualitative MO diagram of the metal-centered $Pd_9(\mu:\eta^5,\eta^2\text{-}As_2)_4(PH_3)_8$ cluster (**1**-H) illustrating the major interactions between Pd_i and its metallic host is shown in Figure 3. According to EHT calculations, only four among the 9 Pd_i atomic orbitals interact with the empty cage. The 5s and 5p(*x,y*) orbitals (of symmetry a_1 and e, respectively) are strongly destabilized by occupied counterparts of the $Pd_8(PH_3)_8(As_2)_4$ cage. After interaction, the occupation of the 5s and 5p(*x,y*) orbitals is 0.33 and 0.24, respectively. The fourth Pd_i orbital which is involved in the bonding is the low-lying and occupied x^2-y^2 orbital, of b_2 symmetry, which is stabilized by the lowest unoccupied b_2 level of the cage which has a large As−As π* character. After interaction, the x^2-y^2 population is 1.72. The other d-type orbitals of Pd_i do not interact, as well as the 5p(*z*) orbital which remains almost unperturbed with an occupation close to zero (0.03). It is noteworthy that the FMOs of the host which interact with Pd_i are mainly localized on the As(1) atoms overall and rather poorly on the As(2) and Pd_s atoms. This was expected owing to the short Pd_i−As(1) distances (ca. 2.57 Å). Since Pd_i is situated in an approximately square-planar environment of As(1) atoms, it is thus not surprising that it uses its s, *x*,*y*, and x^2-y^2 orbitals for bonding. Four Pd_i−As(1) bonding pairs can be identified. Three of them, of a_1 and e symmetry, are provided by the empty cage and donated to the metal. The fourth bonding pair, of b_2 symmetry, is provided by the metal x^2-y^2 orbital and donated to the cage (mainly to the As−As π* orbitals). Therefore, Pd_i can be described as a d^{10} square-planar 16-electron center. From the point of view of total cluster electron count, it is important to note that the three electron pairs, which are donated by the cage to Pd_i, are already involved in the bonding within the cage. Since they cannot be counted twice, the total MVE count can be formulated as 120 (empty cage) + 16 (Pd_i) − 6 (delocalized bonding electrons) = 130 MVEs.

As expected from the above discussion, the Pd_s-Pd_i overlap population is very weak. On the other hand, the Pd_i−As(1) overlap populations are strong, ca. 0.22, comparable to the Pd_s−As overlap populations which are 0.27 on average. As in the empty $Pd_8(As_2)_4(PH_3)_8$ parent cluster, the overlap populations corresponding to the long and very long Pd_s-Pd_s separations are nearly zero, whereas those corresponding to the short Pd_s-Pd_s contacts are ca. 0.02. The different Pd_s−As overlap populations [Pd(1,2)−As(1) = 0.30, Pd(3,4)−As(1) = 0.16, and Pd(3,4)−As(2) = 0.36] and As−As OP (0.91) are comparable to those computed for the empty parent cluster (vide supra). DFT calculations were carried out on **1**-H in order to support the EHT orbital analysis. The Pd_s-Pd_s and Pd_s−As separations obtained from a full optimization of **1**-H under the D_{2d} symmetry constraint indicate, as suggested from the EHT calculations, that the insertion of the central Pd atom hardly modifies the geometry of the distorted $Pd_8(As_2)_4(PH_3)_8$ cube. The geometries are highly similar

Table 1. Comparison of the calculated and experimental distances [Å] for empty and metal-centered distorted cubic models

Compound	$Pd_8(As_2)_4(PH_3)_8$[a]	$Pd_9(\mu:\eta^5,\eta^2\text{-}As_2)_4(PH_3)_8$[a]	$Pd_9(\mu:\eta^5,\eta^2\text{-}As_2)_4(PPh_3)_8$[b]
Pd_i-Pd_s	−	3.06	3.04

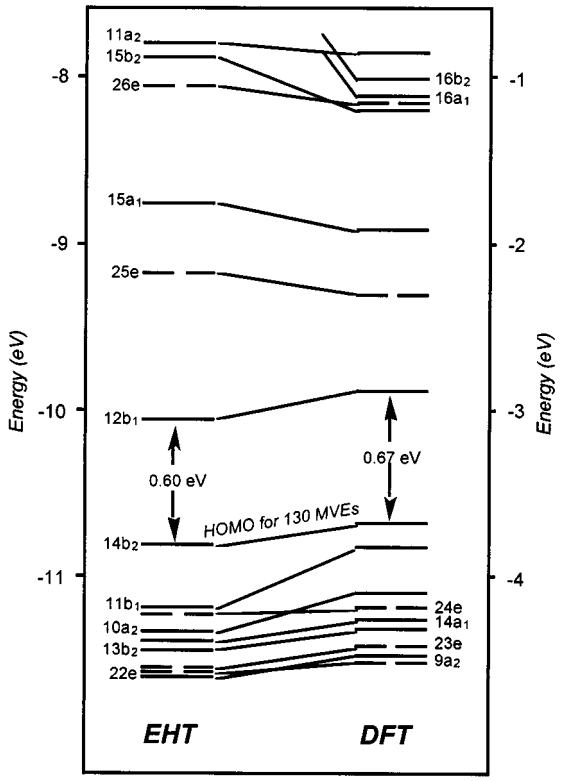

Figure 4. EHT (left) and DFT (right) MO diagrams for **1**-H

(see Table 1). The potential energy surface is particularly flat around the energy minimum, indicating that such an arrangement is rather flexible. A rather good agreement is observed between the optimized geometry of **1**-H and the experimental geometry of **1**. The largest deviation concerns the short Pd_s-Pd_s distance, computed to be 0.09 Å longer than the experimental value. This provides compelling evidence that the DFT approach is reliable for predicting the bond lengths of large inorganic transition metal systems.

The DFT and EHT MO diagrams of **1**-H are compared in Figure 4. They are similar overall, exhibiting the same ground-state electronic configuration. Both calculations predict a closed-shell configuration for the count of 130 MVEs. Note that a single-point DFT calculation on compound **1**, that is in which the PH_3 ligands were replaced by PPh_3 ligands, lead to similar results.

According to Figure 4, several empty MOs lie in the middle of a large energy gap separating the HOMO $14b_2$ from the high-lying 26e MO. One may ask whether reduced species would be stable. EHT calculations indicate that populating the $12b_1$ LUMO hardly changes the nature of the bonding in the cluster. Mono- or di-anionic species should be possible. Conversely, oxidation of compound **1** may be possible since the $14b_2$ HOMO is somewhat Pd_s-Pd_i antibonding. Its complete or partial depopulation should lead to some shrinking of $Pd_8(As_2)_4$ and enhance the Pd_s-Pd_i bonding. In other words, in comparison with other cubic M_8 and M_9 architectures which are observed for a large range of electron counts,[19–21,23] arrangements such as **1** should be observed for different electron counts with either closed- or open-shell electron configurations.

Conclusion

The theoretical analysis of $Pd_9(\mu{:}\eta^5,\eta^2\text{-}As_2)_4(PPh_3)_8$ shows that the bonding of the interstitial Pd atom with the D_{2d} distorded $Pd_8(As_2)_4$ cubic host differs from that found in its related metal-centered cubic species $M_9(\mu_4\text{-}E)_6L_8$ in which the bonding was ensured by strong bonding interactions between the central and surface metal atoms. Indeed, in compound **1** the central atom can be described as a roughly square-planar 16-electron center, bound through Pd_i-As rather than Pd_i-Pd_s contacts to a distorted cubic fragment made of four 30-electron bimetallic Pd_2L_8 units, each Pd_2L_8 unit being made of two approximately planar PdL_4 16-electron centers linked by a Pd–Pd bond. Since six metal-ligand bonding electrons are shared by the cage and the Pd_i center, the cluster electron count can be decomposed as follow: $8 \times (2 \times 16 - 2) + 16 - 6 = 130$ MVEs. A strongly different bonding picture was computed for the isoelectronic 130-MVE $Ni_9Te_6(PEt_3)_8$ species.[20] A substantial HOMO–LUMO gap is computed for the observed electron count of 130 MVEs, a situation generally encountered in stable molecular compounds. However, our calculations indicate that such an architecture should be observed for a range of allowed electron counts around 130 MVEs, a common situation encountered in extended structures.

Appendix

a) Extended Hückel Calculations: Calculations have been carried out within the extended Hückel formalism[26] using the weighted H_{ij} formula[27] with the program CACAO.[28] The exponents (ζ) and the valence shell ionization potentials (H_{ii} in eV) were (respectively): 1.3, −13.6 for H 1s; 1.6, −18.6 for P 3s; 1.6, −14.0 for P 3p; 2.23, −16.22 for As 4s; 1.89, −12.16 for As 4p; 2.19, −7.32 for Pd 5s; 2.152, −3.75 for Pd 5p. H_{ii} value for Pd 4d was set equal to −12.02. A linear combination of two Slater-type orbitals of exponents $\zeta_1 = 5.983$ and $z_2 = 2.613$ with the weighting coefficients $c_1 = 0.5264$ and $c_2 = 0.6373$ was used to represent the Pd 4d atomic orbitals. The different molecular models used were based on the averaged idealized (D_{2d}) experimental structure of **1**. The following bond distances [Å] were used in the $Pd_8(As_2)_4(PH_3)_8$ and $Pd_9(As_2)_4(PH_3)_8$ models: Pd_i-Pd_s = 3.05, Pd(1,2)−Pd(4,3) = 2.88 Å, Pd(3)−Pd(4) = 3.16 Å, Pd(1)−Pd(2) = 4.45 Å, Pd_i−As(1) = 2.57 Å, Pd(1,2)−As(1) = 2.51 Å, Pd(1,2)−As(2) = 2.61 Å, Pd(3,4)−As(2) = 2.43 Å, and Pd−P = 2.26 Å.

b) Density Functional Calculations: Density Functional calculations[29] were carried out on the empty $Pd_8(As_2)_4(PH_3)_8$ and metal-centered $Pd_9(As_2)_4(PH_3)_8$ models using the Amsterdam Density Functional (ADF) program.[30] Electron correlation was treated within the local density approximation (LDA).[31] The numerical integration procedure applied for the calculations was developed by te Velde et al.[29c] The atom electronic configurations were described by a triple-ζ Slater-type orbital (STO) basis set for H 1s, P 2s and 2p, As 3s and 3p, Pd 5s and 4d, and single-z STO function for H 2p, P 3d, As 4d, and Pd 5p. A frozen-core approximation[32] was used to treat the core electrons of P, As, and Pd.

Cage-Structured Triplatinacyclophanes

Ekkehard Lindner,*[a] Christian Hermann,[a] Gerhard Baum,[b][++] and Dieter Fenske[b][++]

Dedicated to Professor Jochen Ellermann on the occasion of his 65th birthday

Keywords: Cage compounds / Metallacyclophanes / P ligands / Platinum / Supramolecular chemistry

The synthesis of the tris(triflate) **4** (Scheme 1) has been achieved by means of a straightforward three-step reaction sequence. After initial lithiation of mesitylene, treatment of the obtained trilithium compound $C_6H_3(CH_2Li)_3$ (**2**) with oxirane results in the formation of 1,3,5-tris(3-hydroxypropyl)benzene (**3**), which is then transformed to **4** by reaction with $(CF_3SO_2)_2O$ in the presence of pyridine. Whereas **4** reacts with $Na_2[Os(CO)_4]$ in a somewhat complicated manner, similar reactions with $Na[Re(CO)_5]$ and $LiPPh_2$ give the hydrocarbon-bridged tris(rhenium) complex $C_6H_3[(CH_2)_3Re(CO)_5]_3$ (**5**) and the tris(phosphane) $C_6H_3[(CH_2)_3PPh_2]_3$ (**6**), respectively. Employing the high-dilution method, from **6** and $Cl_2Pt(NCPh)_2$ the nanoscaled tri- and hexaplatinacyclophanes **7** and **9** are available. Owing to the optimal geometry and flexibility of the cage in **7**, 1,2-dichloroethane can be reversibly encapsulated. The molecular structure of **7** · 7 1,2-$Cl_2C_2H_4$ was determined by an X-ray structure analysis. The utility of the reactive metal centers in **7** has been demonstrated by replacing the chloro ligands by acetonitrile to give the cationic platinacyclophane **8**, in which, according to NMR studies, the cage-like structure is preserved.

Introduction

Cage-like molecules containing a macrobicyclic skeleton play an important role in host/guest chemistry[1] and as nanoscaled building blocks for the construction of supramolecular assemblies.[2] Attempts to construct such molecules through threefold carbon−carbon couplings necessitate multi-step procedures and high-dilution conditions, and ultimately give only low yields.[3] An attractive alternative, however, is the dimerization of trifunctional molecular precursors. Based on this method, several syntheses of three-dimensional cyclophanes have be realized.[1c,3a,4] Although these cage molecules also incorporated either transition or main-group metal centers, which could serve as anion receptors, they did not possess the classical threefold bridged cyclophane structure with aromatic units at the bottom and the top of the molecule, and where the metal atoms are located in the center of the aliphatic bridges.[5] Since the first typical metallaphanes appeared in the literature in 1994,[6] investigations have been mainly focused on two-dimensional systems.[7] The introduction of tetracarbonyliron and -osmium fragments into the cyclophane framework has a marked effect on the structures of these macrocycles. Moreover, these new reactive centers also permit the insertion of small molecules, such as carbon monoxide, into the metal−carbon σ bonds.

Unlike two-dimensional systems, *bona fide* three-fold bridged metallacyclophanes conforming to the classical cyclophane structure remain rather rare. Of the limited number of examples, most are not suited for host/guest chemistry owing to their rigid structures and/or the absence of an intramolecular cavity.[8] Recently, Fujita et al. introduced a remarkable template synthesis of a palladium-containing cyclophane with the ability to incorporate anions of aromatic carboxylic and sulfonic acids.[9] The same group,[10] as well as Steel[11] and Stang,[12] have also reported on six-fold bridged metallacyclophanes with tetrahedral symmetry. The rigidity of the employed triply functionalized ligands and palladium or platinum complex fragments is an essential prerequisite for this self-assembly. Some of these palladium-containing "nanometer-scale molecular container compounds" are also capable of encapsulating guest molecules.[10,11]

The present investigation relates to a synthetic route recently exploited by Balch et al.[8a] for the synthesis of novel three-fold bridged platinacyclophanes. The objective was to create a flexible ligand system based on an aromatic nucleus with three methylene groups as spacers, functionalized with tertiary phosphane end groups. It is envisaged that two of these ligands should be capable of assembly via three platinum atoms to furnish an elastic, three-dimensional molecular cage, in which the kinetics are sufficiently fast for host/guest complexation and decomplexation.[4c] To meet this re-

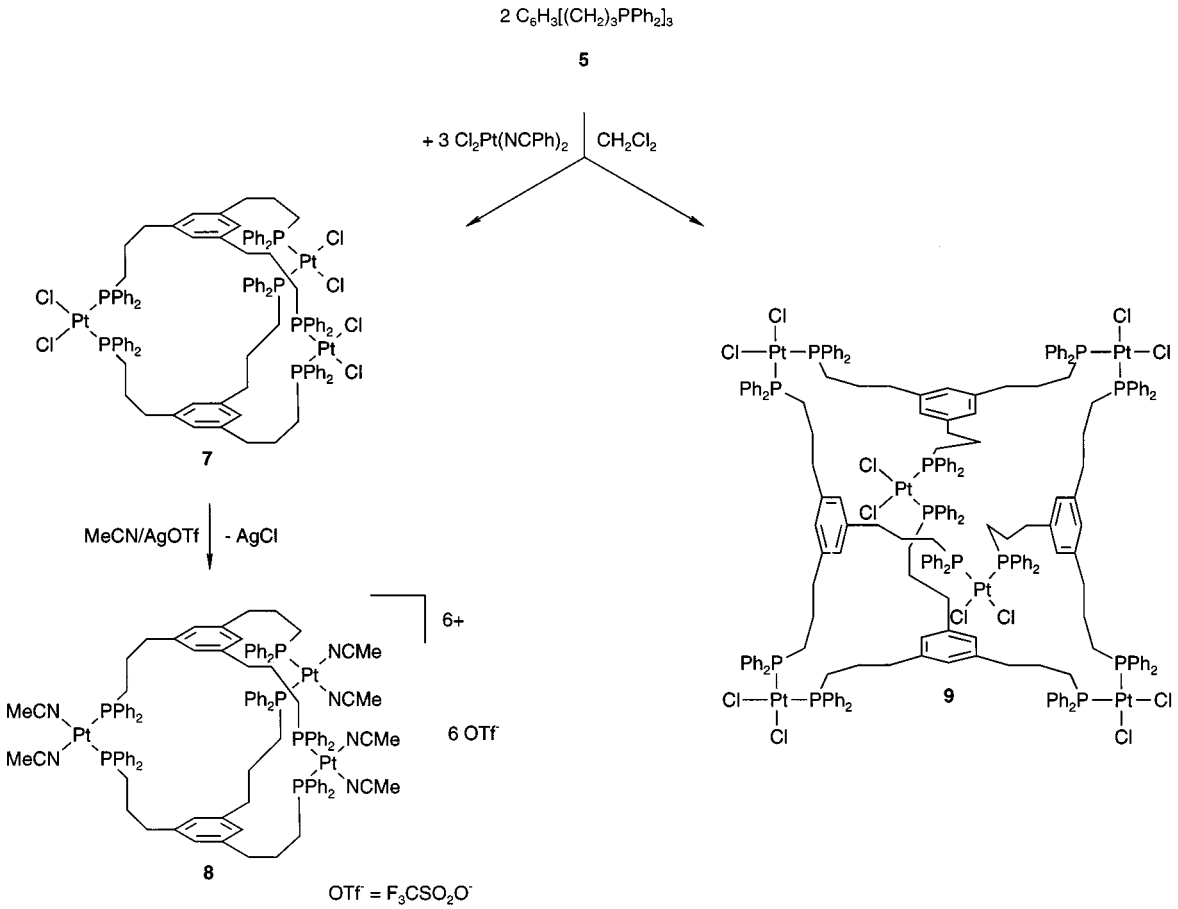
quirement, a symmetrically substituted tris(diphenylphosphanylpropyl)benzene has been synthesized from a suitable tris(triflate).

Results and Discussion

Synthesis of Ligands and Reactions with Metal Lewis Bases

In analogy to previous studies on the generation of osma- and ferracyclophanes,[6,7c,7d] our strategy was to treat the tris(triflate) **4** (Scheme 1) with a suspension of the organometallic Lewis base, $[Os(CO)_4]^{2-}$ or $[Fe(CO)_4]^{2-}$, in dimethyl ether at −25°C, so as to obtain the corresponding triosma- and triferracyclophane species. The tris(triflate) **4** could be obtained by treatment of the triol **3** with $(CF_3SO_2)_2O$[13] in the presence of pyridine at −30°C.[14] In turn, the triol **3**[15] was conveniently prepared by a two-step reaction starting from mesitylene (**1**). Lithiation of **1** with *n*BuLi/TMEDA afforded the trilithium derivative **2**,[16] and subsequent treatment of a suspension of **2** in diisopropyl ether with an equivalent amount of oxirane led directly to the triol **3** (Scheme 1). After purification by column chromatography, the tris(triflate) **4** was obtained as a colorless, viscous, moisture-sensitive, thermally labile oil, which could be stored without any decomposition below −35°C. It was found to be freely soluble in common organic solvents. The molecular composition of **4** was determined from its FD mass spectrum, which showed the molecular ion peak at *m/z* = 647.6.



Scheme 1. Synthesis of the rhenium complex **5** and the tris(phosphane) **6**

Reaction of the tris(triflate) **4** with $Na_2[Os(CO)_4]$ in boiling dimethyl ether[6,7c,7d,14] did not lead to the expected triosmacyclophane with D_3 symmetry. Only oligo- or polymeric species precipitated from the reaction mixture. The yellow solid collected exhibited four terminal carbonyl absorptions in its IR spectrum (in KBr: $\tilde{\nu}$ = 2124 cm^{-1}, 2040, 2038, 2009), which are characteristic of *cis*-$Os(CO)_4$ units. The failure of this attempt to gain access to a triosmacyclophane cannot be attributed to any lack of reactivity of the tris(triflate) **4**. When a THF solution of $Na[Re(CO)_5]$ was treated with **4** at −20°C, the colorless, rather stable tris(pentacarbonylrhenium) complex **5** was formed in satisfactory yields. A similar trinuclear rhenium complex with an aromatic unit in the center of the molecule was reported by Beck et al. several years ago.[17] The ^{1}H-NMR spectrum of complex **5** exhibits three complex multiplets at δ = 0.9, 2.0, and 2.5, corresponding to AA′XX′, AA′MM′XX′, and AA′MM′ spin systems for the α-, β-, and γ-methylene protons. This suggests a hindered rotation about the $C_\alpha-C_\beta$ bonds due to the bulky $Re(CO)_5$ fragments at the α-methylene groups.[18]

In our quest to find an alternative approach for the construction of three-dimensional, triply bridged metallaphanes, we considered a cage structure incorporating metal−phosphorus bonds instead of metal−carbon σ linkages. In order to assess this possibility, a prerequisite was the synthesis of the tris(phosphane) **6**, which was achieved by reaction of **4** with $LiPPh_2$ in diethyl ether at −30°C (Scheme 1). After column-chromatographic work-up of the reaction mixture, the phosphane **6** was isolated as a rather air-sensitive, viscous oily liquid, which was found to be freely soluble in common organic solvents. In the FD mass spectrum, the molecular ion peak was observed at *m/z* = 756.9. Such phosphanes represent suitable starting materials for the reaction with substitution-labile platinum complexes to give access to cage-like molecules.[8a]

Platinacyclophanes

Since the discovery of crown ethers by Pedersen[19] in 1967, the chemistry of synthetic hosts for specific complexation of organic and inorganic guest molecules has developed rapidly. In particular, investigations on the use of cyclophanes as hosts have contributed to an understanding of the complexation of neutral organic guest molecules such as arenes or chlorinated hydrocarbons in aqueous and organic media.[20] The introduction of transition metal units into the framework of a cyclophane has an effect on the geometric properties of the cavity formed by the resulting metallacyclophane. In order to achieve the generation of a three-fold bridged metallaphane, the platinum complex $Cl_2Pt(NCPh)_2$ was treated with the tris(phosphane) **6** according to the high-dilution method.[21] Indeed, the hexachlorotriplatinacyclophane **7** was obtained in rather good yields (Scheme 2). Because of entropic factors, the formation of oligomeric and polymeric species was suppressed. The energy cost associated with the loss of several

Scheme 2. Synthesis of the platinacyclophanes **7**–**9**

degrees of freedom for the components of the assembly is not so large for a system with a smaller number of units.[12,22]

The $^{31}P\{^1H\}$-NMR spectrum of **7** reveals a singlet for the six chemical equivalent phosphorus atoms at $\delta = 8.8$ and a doublet for the ^{195}Pt satellites, which is typical for *cis*-$PtCl_2$ fragments. This assignment is confirmed by the ^{195}Pt-NMR spectrum, which displays a triplet at $\delta = -4414$ with a coupling constant of $^1J_{PtP} = 3660$ Hz. Most characteristic for the $^{13}C\{^1H\}$-NMR spectrum of **7** are three complex multiplets with AXX′ spin systems at $\delta = 127.9$, 38.0, and 30.6 which are assigned to the *o*-carbon atoms of the $(C_6H_5)_2P$ units and to the carbon atoms of the α- and β-methylene groups of the hydrocarbon chains, respectively.[5a] To the best of our knowledge, **7** is the first metallacyclophane which is able to encapsulate a lipophilic guest molecule like dichloroethane. In contrast to the cage-like palladium-containing system of Fujita,[9] **7** is also obtainable without a guest (template). The complexation/decomplexation process is reversible, which was proved by microelemental analyses and ^1H- as well as $^{13}C\{^1H\}$-NMR spectra of the complex **7** · 7 $C_2H_4Cl_2$, which in addition to the signals of **7** exhibit the ^{13}C peaks for $C_2H_4Cl_2$. The integration of the ^1H signals in the ^1H-NMR spectrum and the crystal structure analysis corroborate the stoichiometry of **7** · 7 $C_2H_4Cl_2$.[23] One of the dichloroethane molecules is located in the cavity, the others are positioned at the exterior of the cage in interstices of the crystal. In the case of the complexation of exolipophilic guests no specific linkages between guests and hosts are present, but the guests have to fit geometrically into the cavity.[4c] Owing to its alkylene units, the cage **7** is sufficiently flexible to exhibit satisfactorily fast kinetics for complexation and decomplexation reactions. The hexachlorotriplatinacyclophane **7** exhibits an L_2M_3 composition (L = ligand, M = transition metal fragment) with C_3 symmetry of the ring skeleton. In view of the bulky phenyl substituents at the *cis*-platinum-coordinated phosphorus atoms, the trigonal-prismatic cavity of the cage containing the encapsulated 1,2-dichloroethane molecule is well-shielded from the exterior (Figure 1). The length of the edges of this cavity is approximately 8 Å and its height is about 4.8 Å.

Owing to the C_3 axis passing through the phenylene rings of the cyclophane, the embedded dichloroethane had to be refined at three split positions. The centers of both phenylene groups, which are arranged almost parallel, are located approximately one upon the other. All three distorted square-planar coordinated platinum atoms of **7** lie within a circular area, midway between the aromatic rings of the two ligands. The Pt–Cl and Pt–P connections are arranged

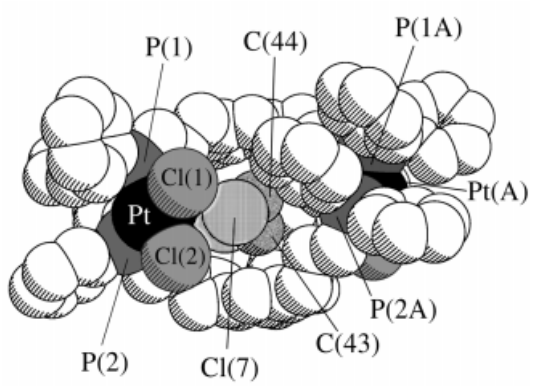


Figure 1. Molecular structure of **7**·7 1,2-$Cl_2C_2H_4$ (space-filling representation); the complete envelopment of 1,2-dichloroethane [gray spheres in center: C(43), C(44), Cl(7)], which is located in one of three possible split positions, is evident

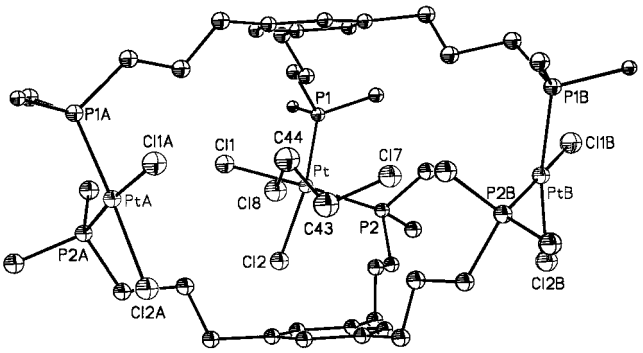

Figure 2. Molecular structure of **7**·7 1,2-$Cl_2C_2H_4$ in the crystal; ORTEP plot with thermal ellipsoids at 20% probability; hydrogen atoms and phenyl groups at the phosphorus atoms are omitted for clarity; selected distances [Å]: Pt−PtA = Pt−PtB = PtA−PtB 9.91(3), P1−P1A = P1−P1B = P1A−P1B 10.94(3), P2−P2A = P2−P2B = P2A−P2B 10.15(2), P1−P2 = P1A−P2A = P1B−P2B 3.44(3), Cl7−Pt 5.98(5), Cl7−PtB 4.30(4), Cl8−Pt 4.03(6), Cl8−PtA 6.12(4), distance between the centers of the phenylene groups of the ligands 8.01(2); torsion angle between the phenylene groups of the ligands 20.0(2)°

above and below this area. The distance between each platinum atom and the center of the circular area is 5.721(3) Å (Figure 2).

According to the considerations of Stang et al.,[12] supramolecular systems containing palladium or platinum complex fragments as that described above are able to form even higher units with the compositions L_4M_6, L_8M_{12}, and $L_{20}M_{30}$ with *T*, *O*, and *I* symmetry, respectively. In fact, in addition to the expected triplatinacyclophane (L_2M_3) **7**, traces of the hexaplatinacyclophane **9** (Scheme 2) with the composition L_4M_6 were also formed in the reaction of **6** with $Cl_2Pt(NCPh)_2$. This system, with a cavity formed by six platinum atoms, was detected in the FAB mass spectrum, which featured the [M^+ − Cl] peak at m/z = 4589. Ideally, such molecules adopt an adamantanoid structure with *T* symmetry.[11,12] Whereas the aromatic rings are placed at the vertices of a tetrahedron, the metal atoms are located at the vertices of an octahedron.

In a subsequent experiment, the triplatinacyclophane **7** was employed as a starting compound in order to obtain a modified cyclophane in which the cage-like structure was preserved, but which exhibited different properties. Thus, by treatment of **7** with silver trifluoromethanesulfonate in a mixture of acetonitrile/dichloromethane (1:1), all the chloro ligands were replaced by acetonitrile and the six-fold positively charged triplatinacyclophane **8** was isolated as a thermally stable white solid (Scheme 2). The composition of this three-fold bridged, cationic macrocycle was confirmed by elemental analysis and by its FAB mass spectrum. In agreement with symmetry requirements, the $^{31}P\{^1H\}$-NMR spectrum of **8** displays a singlet, with appropriate ^{195}Pt satellites, for the six equivalent phosphorus atoms. From the size of the ^1J(Pt,P) couplings, it can be concluded that the phosphorus donors still occupy *cis* positions. The presence of the triflate anions is confirmed by a singlet at δ = −78.8 in the ^{19}F-NMR spectrum of **8**. Although complex, the ^1H- and $^{13}C\{^1H\}$-NMR spectra are not only diagnostic of the proposed structure of **8**, but they are also consistent with the corresponding NMR data of the chloro derivative **7**, the structure of which was elucidated by an X-ray structural determination.[23]

A brief discussion of the $^{13}C\{^1H\}$-NMR spectrum is restricted to the ring skeleton. Two singlets at δ = 141.1 and 126.8 can be assigned to the quaternary (DEPT-135 experiment) and tertiary carbon atoms bonded to the phosphorus atoms of the cage. At higher field (δ = 36.4), an AXX′ pattern can be ascribed to the carbon atoms of the methylene groups adjacent to the phenyl rings. Complex multiplets at δ = 26 are attributable to the remaining methylene functions. Two further singlets at δ = 117.9 and 2.0 are attributable to the nitrile and methyl carbon atoms of the acetonitrile ligands attached to the platinum centers.

Conclusion

Cyclophane chemistry has made a valuable contribution in the field of molecular recognition, since it has led to the development of a multitude of architecturally impressive molecules, with various structural features and functionalities, in which guest molecules can be embedded.[1e,20] The incorporation of transition metals into the aliphatic framework of cyclophanes offers an ingenious means of controlling the inclusion of potential host systems[9−11] and of creating new reactive centers.[7c,7d] Trimetalla- (L_2M_3, L = tripodal ligand, M = transition metal fragment) and even hexametallacyclophanes (L_4M_6), with cavities suitable for the encapsulation of neutral molecules or anions of aromatic carboxylic and sulfonic acids, have hitherto only been prepared by self-assembly, employing nitrogen-containing ligands.[9−12] However, Balch recently succeeded in synthesizing a cage-like molecule composed of aromatic tris(phosphane) ligands,[8a] although due to its rigid structure and limited solubility in nearly all common solvents, this system was not suited for host-guest chemistry. By constructing such a tridentate phosphane around an additional flexible alkane backbone, we have prepared the three-dimensional platinacyclophane **7**, which, by virtue of its size, is able to

reversibly encapsulate 1,2-dichloroethane.[23] Remarkably, in the same reaction, the dodecachlorohexaplatinacyclophane (L_4M_6) **9** was also formed in trace amounts. The ligands attached to the platinum atoms in **7** can easily be exchanged with preservation of the cage-like structure, enabling adaptation of the cyclophane molecules to specific conditions. In this context, the new cationic hexakis(acetonitrile)triplatinacyclophane **8** was prepared, which exhibited quite different properties.

Experimental Section

General: All reactions and manipulations were carried out under dry argon using standard Schlenk techniques. Solvents were dried with appropriate reagents and stored under argon. − Column chromatography: Activated silica gel, 0.063−0.200 mm (Merck); column dimensions are reported in the specific sections describing the synthesis of the compounds. − Elemental analyses: Carlo Erba 1106. − F and S analyses were carried out according to Schöniger[24] and determined as described by Brunisholz and Michod[25], and by Wagner[26], respectively. − Rhenium and platinum were determined with a Varian AA20 spectrometer. − FD and FAB MS: Finnigan 711A (8 kV), modified by AMD. − IR: Bruker IFS 48 FT-IR. − ^{1}H, ^{13}C{^{1}H}, ^{31}P{^{1}H}, ^{19}F, and ^{195}Pt NMR: Bruker DRX 250 spectrometer operating at 250.13, 62.90, 101.26, 235.33, and 53.55 MHz, respectively. ^{1}H chemical shifts were referenced to the residual proton peaks of the solvents and are quoted in ppm downfield from TMS. ^{13}C chemical shifts were calibrated against the deuterated solvent multiplet and referenced to TMS. ^{31}P chemical shifts were measured relative to external 85% H_3PO_4 with downfield values being taken as positive. ^{19}F chemical shifts were measured relative to external 0.05% 1,3,5-trifluorotoluene. ^{195}Pt chemical shifts were measured relative to external 37.5% $Na_2[PtCl_6] \cdot 6\ H_2O$. Oxirane was of commercial grade and was used without further purification; 1,3,5-tris(lithiomethyl)benzene,[16] $(CF_3SO_2)_2O$,[13] $LiPPh_2$,[27] and $Cl_2Pt(NCPh)_2$[28] were synthesized according to literature methods.

1,3,5-Tris(3-hydroxypropyl)benzene (3): Pyrophoric 1,3,5-tris(lithiomethyl)benzene (**2**), prepared from 500 mL of a solution of *n*-butyllithium (1.6 M in *n*-hexane), 92.97 g (800.0 mmol) of TMEDA, and 16.03 g (133.4 mmol) of mesitylene, was filtered off from the reaction mixture (P3) and washed with *n*-pentane until the washings were almost colorless. After drying in vacuo, **2** was suspended in 500 mL of diisopropyl ether and the suspension was cooled to −30°C. Then, 17.62 g (400.0 mmol) of oxirane was condensed into the reaction vessel over a period of 2 h. The resulting mixture was stirred at −30°C for 1 h and then allowed to warm to room temperature. The orange suspension obtained was then rapidly poured into 150 mL of iced water, and 2 N H_2SO_4 was added until pH = 2 was attained. The organic layer was separated and the aqueous phase was washed with diethyl ether (3 × 150 mL). The combined organic phases were dried with Na_2SO_4 and the solvent was evaporated. The product was purified by column chromatography (CH_2Cl_2/MeOH/*n*-hexane, 15:2:1, diameter/length of column 7/50 cm). Yield 7.82 g (24.6%), colorless oil. − ^{1}H NMR ([D$_6$]acetone): δ = 6.87 (s, 3 H, aromatic H), 3.56 (t, $^3J_{HH}$ = 6.4 Hz, 6 H, CH_2OH), 2.61 (t, $^3J_{HH}$ = 7.7 Hz, 6 H, CH_2CH$_2$CH$_2$OH), 1.79 (m, 6 H, CH_2CH$_2$OH). − ^{13}C{^{1}H} NMR ([D$_6$]acetone): δ = 142.7 (s, aromatic C), 126.4 (s, aromatic CH), 61.5 (s, CH$_2$OH), 35.2 (s, *C*H$_2$CH$_2$CH$_2$OH), 32.4 (s, *C*H$_2$CH$_2$OH). − MS (FD, 35°C); *m*/*z*: 252.5 [M$^+$]. − $C_{15}H_{24}O_3$ (252.4): calcd. C 71.39, H 9.59; found C 70.95, H 9.56.

1,3,5-Tris[3-(trifluoromethylsulfonyloxy)propyl]benzene (4): To a suspension of 3.43 g (13.58 mmol) of **3** in 100 mL of dichloromethane, 3.38 g (42.78 mmol) of pyridine was added dropwise. The resulting clear solution was cooled to −30°C and $(CF_3SO_2)_2O$ (12.64 g, 44.81 mmol) was added over a period of 1 h. The reaction mixture was stirred for a further 1 h at −30°C, then filtered (P 3), and washed with water (3 × 50 mL). The organic layer was dried with Na_2SO_4 and then concentrated to a volume of 20 mL under reduced pressure. The product was purified by column chromatography (CH_2Cl_2, diameter/length of column 2/10 cm). Yield 5.92 g (67.2%), colorless oil. − IR (film): $\tilde{\nu}$ = 1412 cm^{-1}, 1246, 1211, 1146, 931 (CH$_2$, CF$_3$, SO$_2$, SOC). − ^{1}H NMR ($CDCl_3$): δ = 6.86 (s, 3 H, aromatic H), 4.49 (t, $^3J_{HH}$ = 6.1 Hz, 6 H, CH$_2$O), 2.70 (t, $^3J_{HH}$ = 7.5 Hz, 6 H, CH_2CH$_2$CH$_2$O), 2.10 (m, 6 H, CH_2CH$_2$O). − ^{13}C{^{1}H} NMR ($CDCl_3$): δ = 141.0 (s, aromatic C), 127.3 (s, aromatic CH), 119.2 (q, $^1J_{FC}$ = 317.7 Hz, CF$_3$), 77.2 (s, CH$_2$O), 31.4 (s, *C*H$_2$CH$_2$CH$_2$O), 31.0 (s, *C*H$_2$CH$_2$O). − MS (FD, 35°C); *m*/*z*: 647.6 [M$^+$]. − $C_{18}H_{21}F_9O_9S_3$ (647.5): calcd. C 33.34, H 3.26, F 26.36, S 14.83; found C 33.49, H 3.62, F 25.94, S 14.59.

1,3,5-Tris[3-(pentacarbonylrhenio)propyl]benzene (5): A solution of $Na[Re(CO)_5]$ in 20 mL of THF, prepared from 502.3 mg (0.77 mmol) of Re_2CO_{10} and sodium amalgam, was added to a solution of 316.8 mg (0.49 mmol) of the tris(triflate) **4** in 50 mL of THF at −20°C. After stirring for 4 h at −20°C, the reaction mixture was allowed to warm to room temperature and the solvent was removed in vacuo. The residue was suspended in 10 mL of a mixture of CH_2Cl_2/*n*-pentane (2:1) and the solid material was filtered off (P4). The filtrate was then purified by column chromatography (CH_2Cl_2/*n*-pentane, diameter/length of column 2/10 cm). The collected product was finally washed with *n*-pentane (5 × 3 mL). Yield 272 mg (47.3%), white solid, m.p. 97°C. − IR (CH_2Cl_2): $\tilde{\nu}$ = 2125 cm^{-1}, 2008, 1981 (CO). − ^{1}H NMR ($CDCl_3$): δ = 6.77 (s, 3 H, aromatic H), 2.49 (m,[29] *N* = 7.7 Hz, 6 H, CH_2CH$_2$CH$_2$Re), 2.00 (m,[30] 6 H, CH_2CH$_2$Re), 0.95 (m,[31] *N* = 17 Hz, 6 H, CH$_2$Re). − ^{13}C{^{1}H} NMR ($CDCl_3$): δ = 186.2 (s, equatorial CO), 181.7 (s, axial CO), 142.7 (s, aromatic C), 126.3 (s, aromatic CH), 44.4 (s, *C*H$_2$CH$_2$CH$_2$Re), 41.7 (s, *C*H$_2$CH$_2$Re), −9.0 (s, CH$_2$Re). − MS (FD, 30°C); *m*/*z*: 1180.0 [M$^+$]. − $C_{30}H_{21}O_{15}Re_3$ (1180.1): calcd. C 30.53, H 1.79, Re 47.34; found C 30.70, H 1.98, Re 47.46.

1,3,5-Tris[3-(diphenylphosphanyl)propyl]benzene (6): To a suspension of $LiPPh_2$ in 50 mL of *n*-pentane, prepared from 2.071 g (11.12 mmol) of $HPPh_2$ and 6.95 mL of a solution of *n*-butyllithium (1.6 M in *n*-hexane), a solution of 2.004 g (3.09 mmol) of **4** in 30 mL of diethyl ether was added at −35°C. The reaction mixture was stirred for 12 h at −35°C and then the LiOTf formed was filtered off by passage through a short silica-gel column (1 cm). After evaporation of the solvent, the product **6** was redissolved in 15 mL of a mixture of *n*-pentane/diisopropyl ether (2:1) and purified by column chromatography (*n*-pentane/diisopropyl ether, 2:1, diameter/length of column 2/20 cm). Yield 1.028 g (44.0%), colorless oil. − ^{1}H NMR ($CDCl_3$): δ = 7.6−7.4 (m, 30 H, C_6H_5), 6.95 (s, 3 H, C_6H_3), 2.85 (t, $^3J_{HH}$ = 7.2 Hz, 6 H, CH_2CH$_2$CH$_2$P), 2.26, 1.97 (m, 12 H, CH$_2$CH$_2$P). − ^{13}C{^{1}H} NMR ($CDCl_3$): δ = 142.5 (s, *quat*-C_6H_3), 139.6 (d, $^1J_{PC}$ = 12.6 Hz, *ipso*-C_6H_5), 133.5 (d, $^2J_{PC}$ = 18.9 Hz, *o*-C_6H_5), 129.3 (s, *m*-C_6H_5), 129.1 (s, *p*-C_6H_5), 127.0 (s, *tert*-C_6H_3), 37.8 (d, $^3J_{PC}$ = 12.6 Hz, *C*H$_2$CH$_2$CH$_2$P), 28.6−28.3 (m, CH$_2$CH$_2$P). − ^{31}P{^{1}H} NMR ($CDCl_3$): δ = −15.0 (s). − MS (FD, 30°C); *m*/*z*: 756.9 [M$^+$]. − $C_{51}H_{51}P_3$ (756.9): calcd. C 80.93, H 6.79; found C 80.77, H 7.11.

5,5,20,20,35,35-Hexachloro-4,4,6,6,19,19,21,21,34,34,36,36-dodecaphenyl-4,6,19,21,34,36-hexaphospha-5,20,35-triplatina[9$_3$](1,3,5)-cyclophane (7): Solutions of $Cl_2Pt(NCPh)_2$ (1.040 g, 2.202 mmol;

−30°C) and of **6** (1.111 g, 1.468 mmol) in 200 mL each of dichloromethane were *simultaneously* added dropwise during 12 h into 500 mL of stirred dichloromethane. Then the solvent was evaporated in vacuo and the residue was extracted with 150 mL of dichloromethane. After concentration of the solvent under reduced pressure to a volume of 20 mL and addition of 100 mL of CCl_4, oligomeric and polymeric fractions were precipitated. The product **7** was precipitated from the remaining solution by addition of diethyl ether. After filtration (P3) the residue was washed three times with 10 mL of diethyl ether to give the pure product. Yield 645.3 mg (38%), white solid, m.p. > 230°C (dec.). − IR (CsCl): $\tilde{\nu}$ = 316 cm^{-1}, 291 (*cis*-$PtCl_2$). − ^1H NMR (CD_2Cl_2): δ = 7.4−7.1 (m, 60 H, C_6H_5), 6.77 (s, 6 H, C_6H_3), 2.49 (t, $^3J_{HH}$ = 7.7 Hz 12 H, $CH_2CH_2CH_2P$), overlapping with 2.38 (br. s, 12 H, CH_2P), 2.11 (br. s, 12 H, CH_2CH_2P). − $^{13}C\{^1H\}$ NMR (CD_2Cl_2): δ = 141.4 (s, *ipso*-C_6H_5), 132.7 (s, *m*-C_6H_5), 130.7 (s, *p*-C_6H_5), 129.8 (s, *quat*-C_6H_3), 127.9 (m[32], *N* = 13 Hz, *o*-C_6H_5), 126.1 (s, *tert*-C_6H_3), 38.0 (m[32], *N* = 17 Hz, CH_2P), 30.6 (m[32], *N* = 44 Hz, CH_2CH_2P), 28.8 (s, $CH_2CH_2CH_2P$). − $^{31}P\{^1H\}$ NMR (CD_2Cl_2): δ = 8.8 (s, d, $^1J_{PtP}$ = 3660 Hz). − ^{195}Pt NMR (CD_2Cl_2): δ = −4414 (t, $^1J_{PtP}$ = 3660 Hz). − MS (FAB, 30°C, positive ions); *m*/*z*: 2331.4 [M^+ + Na], 2274.5 [M^+ − Cl], 2238.6 [M^+ − 2 Cl], 2203.2 [M^+ − 3 Cl]. − MS (FAB, 30°C, negative ions); *m*/*z*: 2344.1 [M^- + Cl], 2311.0 [M^-], 2272.9 [M^- − Cl]. − $C_{102}H_{102}Cl_6P_6Pt_3$ (2311.8): calcd. X-ray Structure Determination of 5,5,20,20,35,35-Hexachloro-4,4,6,6,19,19,21,21,34,34,36,36-dodecaphenyl-4,6,19,21,34,36-hexaphospha-5,20,35-triplatina[9$_3$](1,3,5)cyclophane (7) · 7 1,2-$Cl_2C_2H_4$:[23] Single crystals of **7** · 7 $C_2H_4Cl_2$ were obtained from a 1,2-dichloroethane/*n*-octane solution. Diffractometer STOE IPDS, Mo-K_α radiation, λ = 0.71069 Å. No absorption correction was applied. The structure was solved by direct methods (SHELXS) and refined by last-square methods with the full matrix, based on F_o^2 (SHELXL). Hydrogen atoms bound to carbon atoms are located at calculated positions. − Crystallographic data: $C_{102}H_{102}Cl_6P_6Pt_3 \cdot 7\ C_2H_4Cl_2 \cdot 1.5\ Et_2O$, M_r = 3115.5, $d_{calcd.}$ = 1.242 gcm^{-3}, crystal dimension 0.2 × 0.2 × 0.1 mm^3, trigonal, space group *P*31*c*, *a* = *b* = 22.596(3), *c* = 18.842(4) Å, *V* = 8331(2) $Å^3$, *Z* = 2, *T* = 200 K, μ(Mo-K_α) = 2.928 mm^{-1}, *F*(000) = 3106. − Data collection: 2Θ = 4.68−51.88° in $-26 \le h \le 27$, $-20 \le k \le 27$, $-20 \le l \le 22$. 16498 measured reflections, of which 7922 were symmetry-independent and 7441 were observed with $I > 2\ \sigma(I)$. − Solution of the structure: An LP correction was applied with $R_{int.}$ = 0.0470. The applied absolute structural parameter was −0.012(9).[33] Parts of the host lattice are refined isotropically with a disorder (first order). The diethyl ether molecules are refined without hydrogen atoms at half-occupied positions. Maximum and minimum peaks in the final synthesis were 1.435 and −0.704 $eÅ^{-3}$. 13 geometrical restraints, 335 parameters, *R*1 = 0.0487, *wR*2 = 0.1437 (all data, $w = 1/[s^2(F_o^2) + [0.1019[(F_o^2 + 2\ F_c^2)/3]^2 + 8.6742[(F_o^2 + 2\ F_c^2)/3]]$), GOF = *S* = 1.093; residual electron density min./max. = −0.704/1.435 e $Å^{-3}$.[23]

Acknowledgments

Support of this research by the Deutsche Forschungsgemeinschaft and the Fonds der Chemischen Industrie is gratefully acknowledged. Degussa AG are thanked for supplying starting materials. We are also indebted to Priv.-Doz. Dr. H. A. Mayer and M. Steimann, Institut für Anorganische Chemie II, University of Tübingen, for helpful discussions regarding the interpretation of the NMR spectra and X-ray structural analyses, respectively. Dipl.-Chem A. Hagenbach, Institut für Anorganische Chemie I, University of Tübingen, is gratefully thanked for the determination of the cell constants.

Structural Characterization and Magnetic Behaviour of the Ferro-Antiferromagnetic Alternating Manganese–Azido Chain $[Mn(3\text{-Et,4-Mepy})_2(\mu\text{-}N_3)_2]_n$ (3-Et,4-Mepy = 3-Ethyl-4-methylpyridine)

Morsy A. M. Abu-Youssef,[a] Albert Escuer,*[b] Mohamed A. S. Goher,*[c] Franz A. Mautner,[a] and Ramon Vicente*[b]

Keywords: Bridging ligands / Manganese / Azido bridge / Alternating chain / Magnetic properties

The ligands 3-ethyl-4-methylpyridine (3-Et,4-Mepy) and azide coordinate to Mn^{II} forming an alternating chain with the formula $[Mn(3\text{-Et,4-Mepy})_2(\mu\text{-}N_3)_2]_n$. This compound crystallizes in the space group $P-1$. The compound consists of chains of octahedrally coordinated manganese atoms alternately bridged by double end-to-end ($\mu_{1,3}$) and double end-on ($\mu_{1,1}$) azido bridges, which results in a structurally and magnetically alternating chain. The 3-ethyl-4-methylpyridine ligands are arranged *trans*, completing the six-fold coordination spheres of the manganese atoms. The Mn–Mn distances are distinctly different: Mn(1)–Mn(1A) = 5.149(3) Å (double end-to-end azido bridge) and Mn(1)–Mn(1B) = 3.402(2) Å (double end-on azido bridge). The magnetic properties of the compound, as studied in the temperature range 300–4 K, show bulk antiferromagnetic interaction. Fitting of the magnetic data by using an equation for alternating ferro-antiferromagnetic $S = 5/2$ 1-D systems gives the parameters $J_{AF} = -13.7(1)$ cm^{-1}, $J_F = 2.4(1)$ cm^{-1}, $g = 2.036(2)$.

The chemistry of the manganese(II)−(L)−azido-bridged system, L = N-aromatic ligand, affords habitually high-dimensional compounds: 3-D for L = pyridine (py)[1][2] and 2,2′-bipyrimidine (bipym),[3][4] 2-D for the substituted pyridines L = 3- and 4-acetylpyridine (3-Acpy[5] and 4-Acpy[6]), methyl- and ethyl isonicotinate (Meinc[7] and Etnic[2]), and 4-cyanopyridine (4-CNpy[5]), or 1-D for 2,2′-bipyridine,[8] 3-ethylpyridine, and 2-hydroxypyridine.[9] A 3-D network with a distorted perovskite structure has also been found for $[N(CH_3)_4][Mn(N_3)_3]$.[10] In contrast, only in the case of L = 2,2′:6′,2′′-terpyridine has a dinuclear compound been obtained.[11] The coordination mode of the azido bridge is commonly found to be $\mu_{1,3}$-N_3 (end-to-end, EE), although in some cases it is $\mu_{1,1}$-N_3 (end-on, EO), and even alternating 1-D or 2-D systems in which the two kinds of coordination mode coexist in the same compound have been found. No correlation has been identified between the properties of the ligand L and the coordination mode of the azido bridge, and from a synthetic point of view, the manganese(II)−azido system shows unpredictable behaviour, analogous to that observed for azido-bridged polynuclear copper(II) and nickel(II) systems. The magnetic behaviour of these compounds follows the same general trends as seen for copper and nickel(II) systems, i.e. end-to-end azido bridges lead to antiferromagnetic interaction, while end-on bridges give rise to ferromagnetic coupling. The main difference between these systems is the higher dimensionality shown by the manganese derivatives.

In continuation of our research on compounds of this kind, we report herein on a new system of the pyridine series, using L = 3-ethyl-4-methylpyridine to obtain the one-dimensional system $[Mn(3\text{-Et,4-Mepy})_2(\mu\text{-}N_3)_2]_n$ (**1**). This compound constitutes the second example of an alternating chain in which the manganese atoms are bridged alternately by two coplanar end-to-end and two end-on azido ligands, but is the first case with a *trans* arrangement of the EO and EE azido bridges. In the previously published alternating chain $[Mn(bipy)(\mu\text{-}N_3)_2]_n$, the EO and EE azido bridges have a *cis* arrangement.[8] The experimental magnetic susceptibility vs. T data for **1** have been fitted by using a recently published equation for $S = 5/2$ alternating F/AF-coupled 1-D systems.[8]

Results and Discussion

Infrared Spectra

The IR spectrum of the title complex $[Mn(3\text{-Et,4-Mepy})_2(N_3)_2]_n$ shows bands attributable to the 3-Et,4-Mepy ligand at the normal frequencies. In the 2000−2100 cm^{-1} region, the complex shows a very intense split band that can be assigned to the asymmetric stretching vibrations of the azide group [$\nu_{as}(N_3)$], centred at 2056 and 2080 cm^{-1}. In the region 1280−1360 cm^{-1}, no band was observed that could be attributed to the $\nu_s(N_3)$ mode, while the two bands at 2056 and 2080 cm^{-1} indicate the presence of two different symmetric and asymmetric azido groups. This was tentatively rationalized in terms of the coexistence of both μ(1,1)-EO and μ(1,3)-EE bridging azido groups, which was supported by the X-ray structural data. In the far infrared

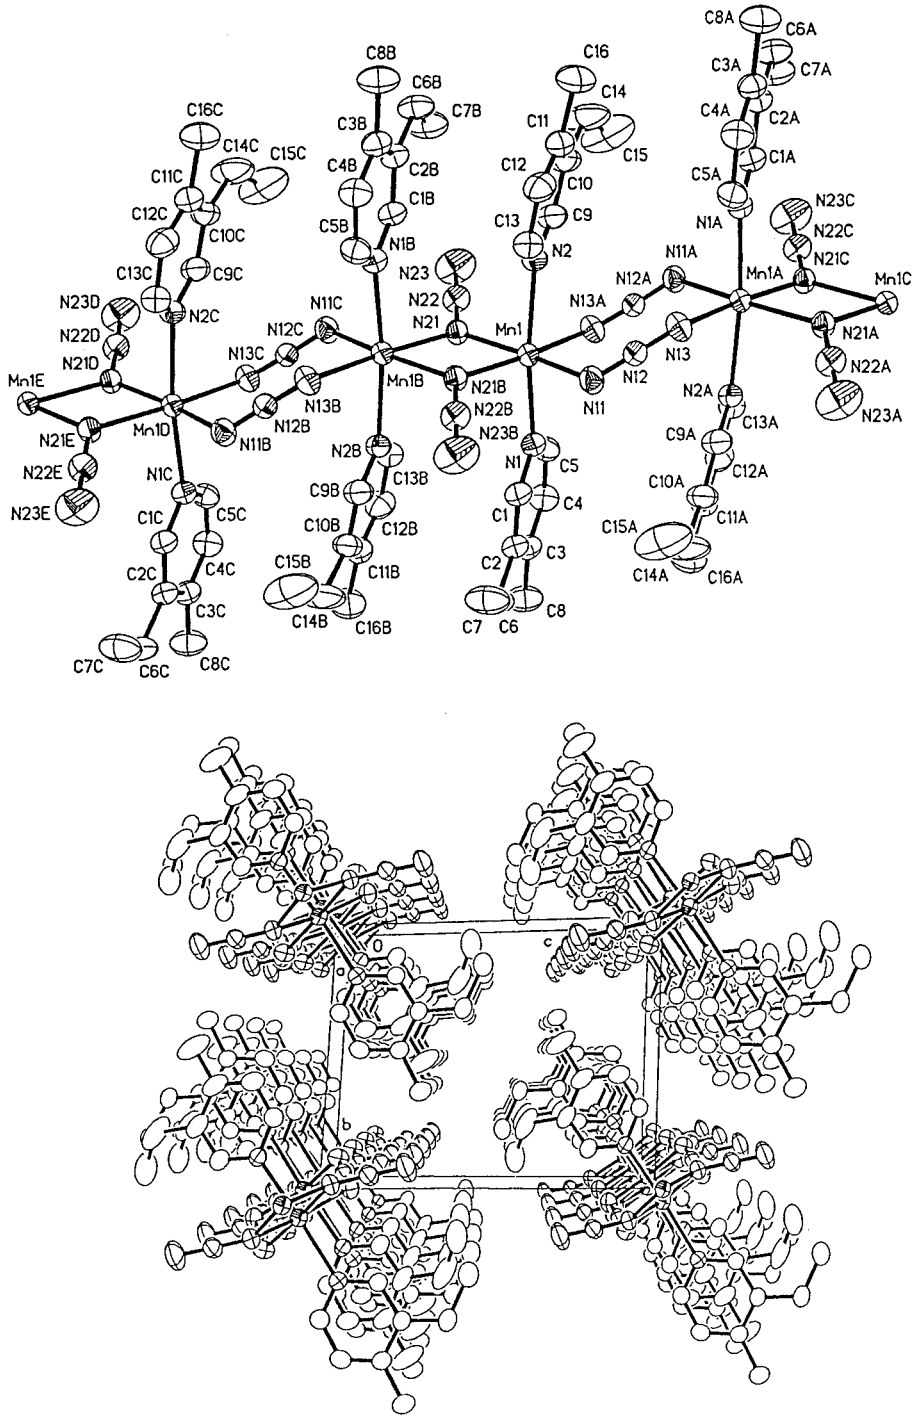
region, one band attributable to the $\nu(Mn-N_3)$ mode around 310 cm^{-1} and two bands due to the $\nu[Mn-N(L)]$ mode around 254 and 230 cm^{-1} were observed.

Crystal Structure of $[Mn(3\text{-Et},4\text{-Mepy})_2(\mu\text{-}N_3)_2]_n$ (1)

The labelled diagram for **1** is shown in Figure 1. The structure consists of octahedrally coordinated manganese atoms, about which the coordination sites are occupied by two 3-ethyl-4-methylpyridine ligands in a *trans* arrangement and four coplanar azido ligands. Two azido groups act as end-to-end bridging ligands with a neighbouring manganese atom, while the other two act as end-on bridging ligands with another neighbouring manganese atom, giving a one-dimensional system with alternating $\mu_{1,3}$ and $\mu_{1,1}$ bridges extending along the *a* axis of the unit cell. The bond parameters relating to the end-on bridges are Mn(1)−N(21) = 2.209(2) Å, Mn(1)−N(21B) = 2.240(2) Å, N(21)−N(22)−N(23) = 178.2(4)°, Mn(1)−N(21)−



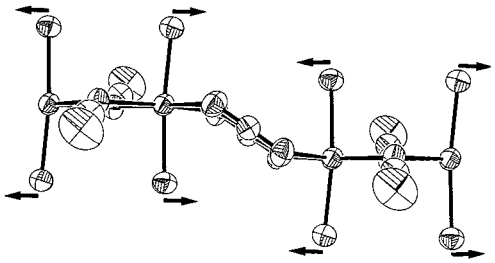


Figure 1. ORTEP drawing (thermal ellipsoids drawn at 40% probability) with atom labelling scheme and packing plot viewed along the *a* axis of the unit cell of $[Mn(3\text{-Et},4\text{-Mepy})_2(\mu\text{-}N_3)_2]_n$ (**1**)

Mn(1B) = 99.75(10)°, while those relating to the end-to-end bridges are Mn(1)−N(11) = 2.225(3) Å, Mn(1)−N(13A) = 2.256(3) Å, Mn(1)−N(11)−N(12) = 124.8(2) Å, Mn(1)−N(13A)−N(12A) = 123.2(2)°, N(11)−N(12)−N(13) = 177.9(3)°. The Mn(1)−Mn(1A) and Mn(1)−Mn(1B) distances amount to 5.149(3) Å and 3.402(2) Å, respectively. The degree of distortion of the $Mn_2(\mu_{1,3}\text{-}N_3)_2$ ring from planarity towards a chair form may be quantified by means of the acute angle δ between the normal to the planes defined by the six N atoms of the azido bridges and the corresponding N−Mn−N planes: δ in this case is 31.7(1)° [torsion Mn(1)−N(11)−N(12)−N(13)−Mn(1A) 51.2(2)°]. The neutral chains of **1** are well-isolated by the ligands, the minimum Mn−Mn interchain distance being 9.258(4) Å.

The alternation of $\mu_{1,3}$ and $\mu_{1,1}$ bridges along the *a* axis of the unit cell may be due to the effects of steric hindrances: In the $[Mn_2(\mu_{1,1}\text{-}N_3)_2(L_4)]$ unit the L rings are not oriented exactly perpendicular to the $[Mn_2(\mu_{1,1}\text{-}N_3)_2]$ mean plane, but are inclined out of this plane along the chain direction, resulting in an N(1)−Mn(1)−N(2) angle of 172.61(8)°.

For this reason, it is not possible to repeat the $[Mn_2(\mu_{1,1}\text{-}N_3)_2(L_4)]$ unit, which would necessitate short Mn−Mn distances. The structural solution to have a one-dimensional system is to add the $[Mn_2(\mu_{1,3}\text{-}N_3)_2(L_4)]$ unit, with longer Mn−Mn distances.

Magnetic Properties

The $\chi_M{\cdot}T$ product and the molar magnetic susceptibilities of $[Mn(3\text{-Et},4\text{-Mepy})_2(\mu\text{-}N_3)_2]_n$ (**1**) vs. *T* in the range 300−4 K are plotted in Figure 2. The overall behaviour of **1** corresponds to a bulk antiferromagnetically coupled system. The $\chi_M{\cdot}T$ value, which amounts to 3.75 $cm^3{\cdot}K{\cdot}mol^{-1}$ at 290 K, decreases on cooling and tends to zero at low temperatures. The χ_M vs. *T* plot shows an increase in χ_M from 1.29×10^{-2} $cm^3{\cdot}mol^{-1}$ at 290 K to a broad maximum between 60 and 20 K. On further cooling, this plot quickly tends to zero. The magnetic data were analysed by means of the expression recently published[8] by Cortés et al. for alternating ferro-antiferro one-dimensional *S* = 5/2 compounds, which was derived from the spin Hamiltonian:

$$H = -J_1\Sigma S_{2i}S_{2i+1} - J_2\Sigma S_{2i+1}S_{2i+2}$$

The best fit parameters obtained were $J_1 = -13.7(1)$ cm^{-1}, $J_2 = 2.4(1)$ cm^{-1} and $g = 2.036(2)$. No other local minima in the fitting process were found. J_1 and J_2 correspond to the double EE and the double EO superexchange pathways, respectively.

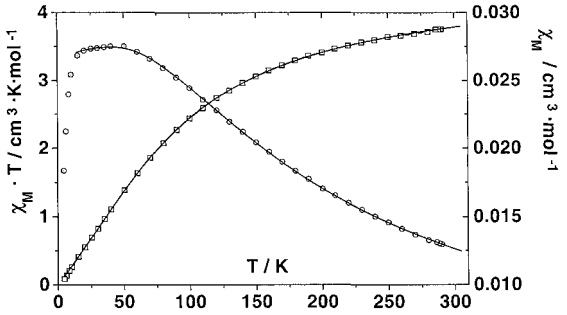

Figure 2. χ_M vs. *T* (○) and $\chi_M{\cdot}T$ vs *T* (□) plots for $[Mn(3\text{-Et},4\text{-Mepy})_2(\mu\text{-}N_3)_2]_n$ (**1**); the solid line shows the best fit theoretical curve

EPR spectra recorded on powdered samples at room temperature show an isotropic signal centred at $g = 2.020$ with a linewidth of 320 G. This signal is temperature-dependent; the spectrum at 4 K shows a signal centred at $g = 2.038$ with linewidth 541 G, as well as a weak signal at half-field. This linewidth is much larger than that of the sharp signals (linewidth 35 G at room temperature) recently reported for the related compounds $[Mn(pyOH)_2(\mu\text{-}N_3)_2]_n$ and $[Mn(3\text{-Etpy})_2(\mu\text{-}N_3)_2]_n$, where pyOH and 3-Etpy denote 2-hydroxypyridine and 3-ethylpyridine, respectively.[9]

This behaviour may be explained by considering the main factors[12] that influence the linewidth for an isotropic Heisenberg one-dimensional system, i.e. exchange narrowing, due to the superexchange interactions along the chain, and dipolar interactions, which induce broadening of the signal. Adequate characterization of these effects requires well-isolated chains in order to reduce the interchain interactions. This condition reduces the number of suitable systems and the well-known compound $[(CH_3)_4][MnCl_3]$, abbreviated as TMMC,[13] remains the standard reference compound 25 years after the first studies in this field. In the three $[Mn(R)_2(\mu\text{-}N_3)_2]_n$ complexes (R = 3-Et,4-Mepy; pyOH, and 3-Etpy), the chains are neutral and are well-isolated by the large pyridyl ligands (see Figure 1). Moreover, the interchain distances are slightly shorter than the 9.15 Å found in TMMC and compare well with the 7.60 Å reported for $Cs[MnBr_3]$[14] or the 7.5 Å reported for $[Mn(py)_2Cl_2]_n$.[15] The sharp signals reported for the pyOH and 3-ethyl derivatives may be attributed to exchange narrowing, taking into account the $-J$ values larger than 10 cm^{-1} and the negligible dipolar contribution (Mn···Mn distances larger than 5.4 Å in the EE bridges). In contrast, although $[Mn(3\text{-Et},4\text{-Mepy})_2(\mu\text{-}N_3)_2]_n$ has comparable superexchange interactions, it shows alternating Mn···Mn distances of 5.149 and 3.402 Å and thus the dipolar broadening mechanism becomes active in the Mn_2N_2 rings with double EO azide bridges. The same explanation may account for the large linewidth (close to 500 G) observed for the EPR signal of the alternating system $[Mn(bipy)(\mu\text{-}N_3)_2]_n$, which shows comparable superexchange parameters

J, interchain packing, and alternating Mn···Mn intrachain distances.[8]

Experimental Section

General: Infrared spectra (4000−400 cm^{-1}) were recorded using KBr pellets with a Nicolet 520 FT-IR spectrophotometer. Magnetic measurements were carried out with a DSM8 pendulum susceptometer, operating in the temperature range 300−4 K. The applied external magnetic field was 1.5 T. Diamagnetic corrections were estimated from Pascal tables. EPR spectra were recorded at X-band frequency with a Bruker ES200 spectrometer equipped with an Oxford liquid helium cryostat for variable-temperature work.

Synthesis of the Compound: The title complex $[Mn(3\text{-Et},4\text{-Mepy})_2(N_3)_2]_n$ was synthesized by mixing ca. 50 mL of a pure methanolic solution of manganese perchlorate hexahydrate (1.00 g, 2.7 mmol) and a solution of 0.61 g (ca. 5 mmol) of 3-ethyl-4-methylpyridine in 20 mL of methanol, with subsequent dropwise addition of a concentrated aqueous solution of sodium azide (0.65 g, 10 mmol). The solution became turbid and a gelatinous precipitate was produced, which was filtered off. By slow evaporation of the solvent from the clear filtrate, colourless transparent plates of the title complex, suitable for X-ray analysis, were formed within 6 d; yield: 0.60 g (ca. 65%). − $C_{16}H_{22}MnN_8$ (381.36): calcd. C 50.4, H 5.8, Mn 14.4, N 29.4; found C 50.6, H 5.9, Mn 14.3, N 29.2.

Crystal Structure Determination and Refinement of the Structure: Single-crystal X-ray data for $[Mn(3\text{-Et},4\text{-Mepy})_2(N_3)_2]_n$ were collected with a modified STOE four-circle diffractometer. Crystal size: 0.60 × 0.50 × 0.24 mm. The crystallographic data, conditions maintained for the intensity data collection, and some features of the structure refinement are listed in Table 1. Graphite-monochromated Mo-K_α radiation (λ = 0.71069 Å) was used to collect the data set, employing the ω-scan technique. The accurate unit cell parameters were determined from automatic centering of 40 reflections (9.2° < θ < 14.9°) and refined by least-squares methods. 5167 reflections (4539 independent reflections, R_{int} = 0.0275) were collected in the range 2.76° < θ < 27.99°. An intensity decay of 12% for control reflections, measured after every set of 100 reflections, was observed during the data collection. Corrections were applied for Lorentz and polarization effects, for intensity decay, as well as for absorption, using the DIFABS[16] computer program. The structure was solved by direct methods using the SHELXS-86[17] program, and refined by full-matrix least-squares methods on F^2 using the SHELXL-93[18] program, as incorporated in the SHELXTL/PC V 5.03[19] program library, and the graphics program PLUTON.[20] All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were geometrically fixed with the HFIX utility[19] (i.e.: hydrogen atoms riding with idealized geometrical values on their parent carbon atoms with fixed distances: CH = 0.93 Å, CH_2 = 0.97 Å and CH_3 = 0.96 Å; for each methyl group the torsion angle was set which maximizes the sum of the electron density at the three calculated hydrogen positions). Selected bond parameters are given in Table 2.

Atomic positional and thermal parameters, lists of bond lengths and angles, and F_o/F_c values are available as supplementary material from one of the authors (F. A. M.). Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication No. CCDC-103250. Copies of the data can be obtained free of charge on application to CCDC,

Synthesis and Diels–Alder Reactions of Some New (Phthalocyanine)nickel Complexes

Bernd Hauschel,[a] Reiner Jung,[a] and Michael Hanack*[a]

Keywords: (Phthalocyanine)nickel complexes / Unsymmetrical phthalocyanines / Isobenzofurans / Diels–Alder reactions / Ladder-type molecules

The octasubstituted (phthalocyanine)nickel complexes **4a**,**b**, soluble in common organic solvents, bearing four dienophilic functionalities were synthesized from the corresponding phthalodinitriles **3a**,**b** and nickel(II) acetate. Reaction of **4a** with tetracyclone **5** led to the phthalocyanine–tetracyclone adduct **6** which is a precursor for an intermediate phthalocyanine **7** containing four isobenzofuran moieties. The capability of **7** to react as tetrakis(diene) was demonstrated by its reaction with naphthoquinone. Furthermore, the unsymmetrical phthalocyanines **13** and **16a**,**b**,**c** containing one dienophilic functionality were synthesized using a statistical approach. Their tetracyclone adducts **17**, **18a**,**b**,**c** can be used for the synthesis of ladder-type phthalocyanine dimers. The dimer **22** was synthesized from **18c** and *p*-benzoquinone via the isobenzofuran intermediate **19** and the benzoquinone adduct **21**. For dehydration experiments the naphthoquinone monoadduct **23** was synthesized from **18c**. Dehydration of **22** and **23** was carried out successfully with *p*-toluenesulfonic acid. The Diels–Alder reactions are discussed with respect to the occurring *exo*/*endo* ratio.

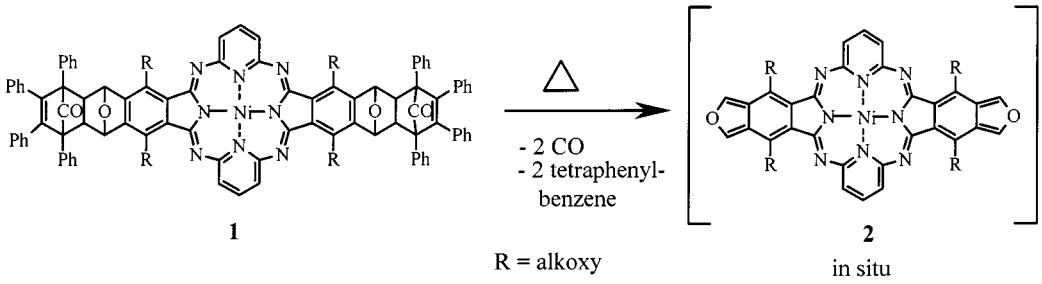
Introduction

We are involved in the synthesis of ladder-type oligomers and polymers consisting of metallomacrocycles (e. g. metallohemiporphyrazines and metallophthalocyanines) as repeating units.[1] Especially conjugated ladder polymers with phthalocyanine (Pc) subunits are expected to show − besides a high thermal and chemical resistance − remarkable properties like nonlinear optical behaviour and low band gaps.[2]

We already reported on the successful synthesis of ladder-type oligomers and polymers starting from hemiporphyrazine (Hp) building blocks,[3] whereby a Diels−Alder strategy[4] was used. Hp intermediates with isobenzofuran moieties (**2**) were generated from convenient precursors (**1**, compare Scheme 1) and used as bis(dienes) in repetitive Diels−Alder (DA) reactions.[3b,5] These diene moieties gave the best results regarding yields and the suppression of side reactions. In this paper, similar Pc intermediates are described.

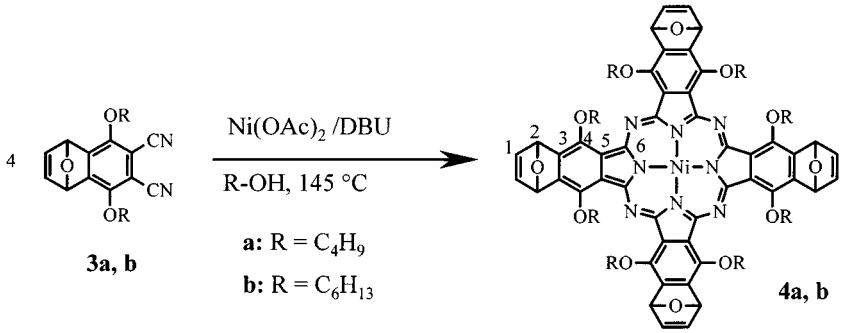
Results and Discussion

In a previous work, we already reported the synthesis of unsubstituted PcM complexes bearing four diene or dienophilic functionalities (M = H_2, Ni, Zn).[6] Due to the poor solubility of these compounds, DA reactions with e.g. 2,3-dimethylbutadiene proceeded with unsatisfactory conversion rates. Therefore, we now attempted the synthesis of the tetrakis(dienophilic), octaalkoxy-substituted PcNi complexes **4a**,**b** (Scheme 2) showing an enhanced solubility in organic solvents. The reaction of the phthalodinitriles **3a,b**[7] in the presence of nickel(II) acetate and a catalytic amount of DBU in 1-butanol (**3a**) or *n*-hexanol (**3b**) at elevated temperatures furnished the PcNi complexes **4a**,**b** after several hours (24−36 h, the nucleophilic alkoxide ions generated from an *n*-alcohol and DBU may attack the phthalodinitriles **3a**,**b** and replace the alkoxy substituents; therefore, we chose the solvents in a way that the replacement led to identical molecules). Chromatographic work up on silica gel gave pure, deep green compounds in isolated yields of ca. 30%. **4a**,**b** proved to be well soluble in e.g. toluene or $CHCl_3$.



Attempts to synthesize similar octaalkyl-substituted PcNi (instead of octaalkoxy-substituted compounds) from 5,8-dialkyl-6,7-dicyano-1,4-dihydro-1,4-epoxynaphthalenes failed, probably due to the bigger steric interactions of the alkyl groups.

PcNi **4a,b** are unequivocally characterized by their NMR and FD-MS spectra (see Experimental Section). In the ^{1}H-NMR spectra of both compounds, only two slightly broadened singlets (at $\delta \approx 6.4$ and 7.3) appear besides the resonances of the aliphatic protons. These singlets are assigned to the two different kinds of protons on the oxo-brigded ring [**4a**: δ = 6.38 (2-H), 7.33 (1-H), **4b**: δ = 6.37 (2-H), 7.32 (1-H)].



Due to the relative orientations of the epoxy bridges, the molecules **4a,b** can exist in four isomeric forms (C_{4v}, C_s, C_{2h}, D_{2d}). The NMR spectra do not allow the distinction between the single isomers. The separation of the mixture (e.g. by HPLC) was not furthermore pursued. Therefore, the relative amounts of the isomers in the mixture are not known.

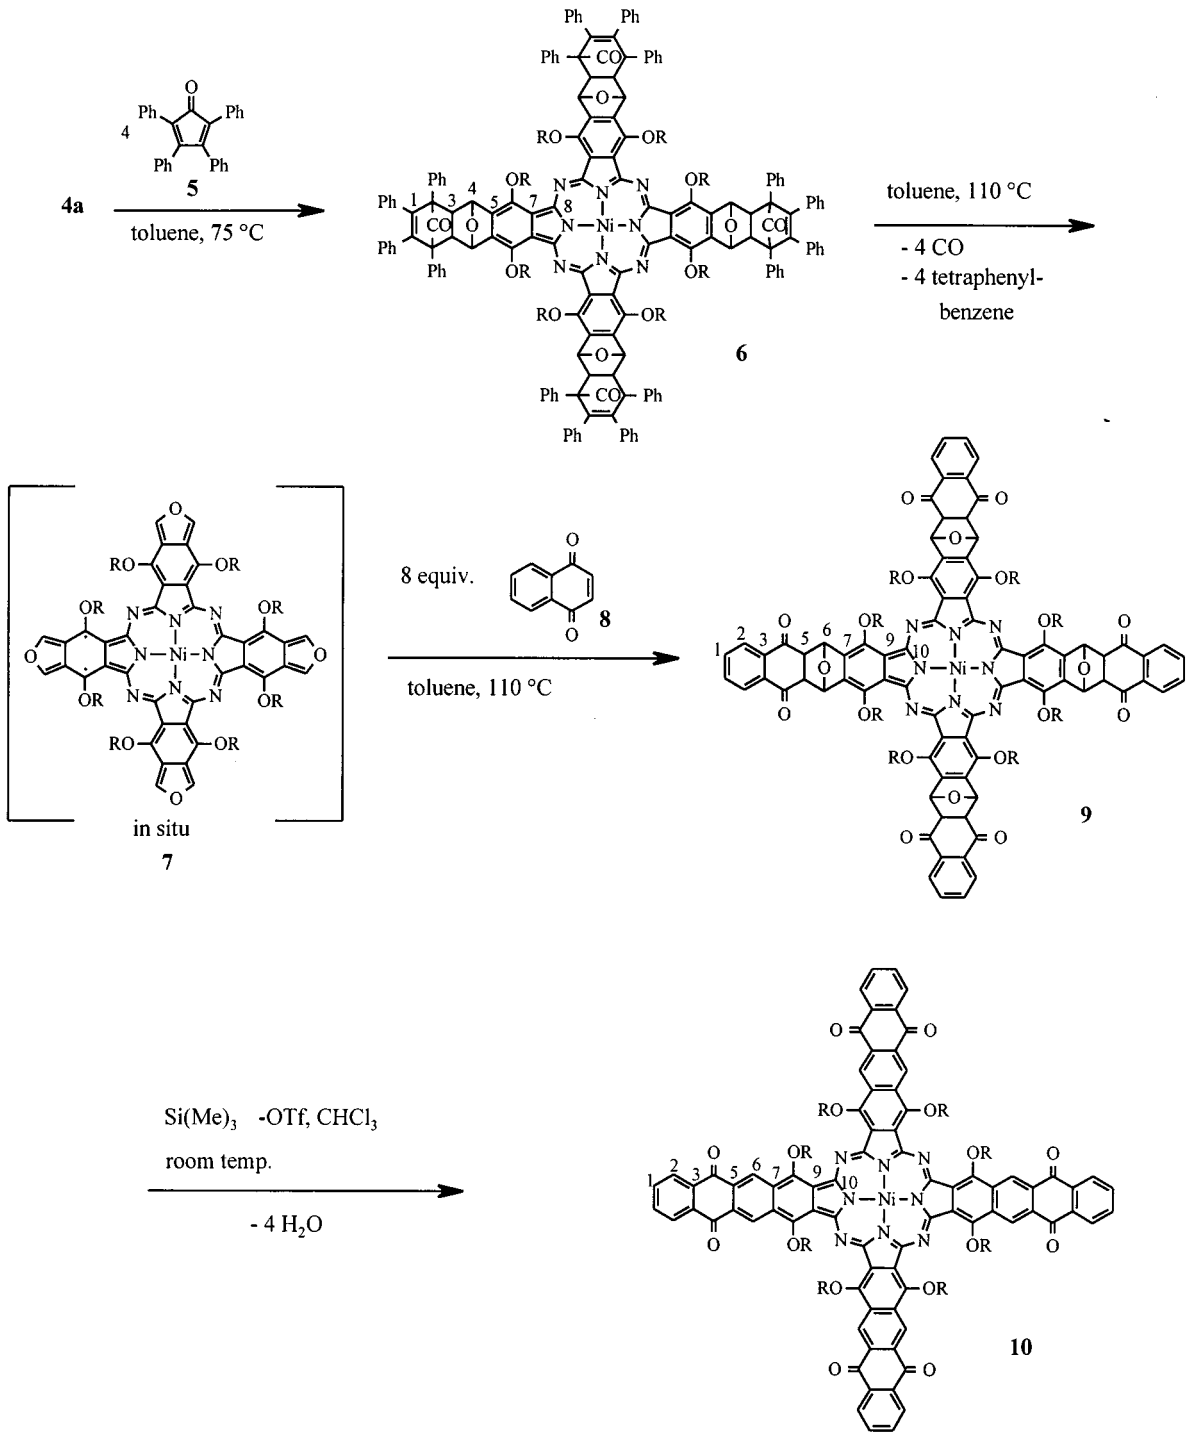
Scheme 1. Generation of the reactive isobenzofuran intermediate

Scheme 2. Synthesis of **4a,b** bearing four dienophilic groups

The UV/Vis spectra of the compounds **4a,b** (recorded from $CHCl_3$ solutions) do not show a remarkable influence of the side-chain length on the wavelength values of the electronic transitions. The $Q_{0\text{-}0}$ bands appear at 713 (**4a**) and 714 nm (**4b**), respectively. The $Q_{0\text{-}0}$ transition of the corresponding unsubstituted compound, namely [2,5,11,14,20,23,29,32-octahydro-2,5:11,14:20,23:29,32-tetraepoxynaphthalocyaninato]nickel(II) is found at 668 nm.[6] As expected, the introduction of eight auxochromic alkoxy substituents leads to a bathochromic shift of the Q band of ca. 45 nm. The comparison of the values of **4a,b** with the $Q_{0\text{-}0}$ transitions found for [1,4,8,11,15,18,22,25-octaalkoxyphthalocyaninato]nickel(II) complexes (which contain the same π-conjugated system as **4a,b**) shows a significant hypsochromic shift of ca. 30 nm [compare the $Q_{0\text{-}0}$ transition of the 1,4-substituted $(PentO)_8PcNi$ appearing at 742 nm[8]]. This shift seems to be caused by the electronic influence of the four epoxybenzo units attached to the phthalocyanine core.



As already mentioned, the unsubstituted [2,5,11,14,20,23,29,32-octahydro-2,5:11,14:20,23:29,32-tetraepoxynaphthalocyaninato]nickel(II) complex underwent a DA reaction when heated with an excess of 2,3-dimethylbutadiene in toluene for several days.[6] However, this reaction proceeded with unsatisfactory conversion rates. The well-soluble compounds **4a,b** should give much better conversions when allowed to react with dienes.

In the next synthetic step, we therefore envisaged the addition of four molecules of 1,2,3,4-tetraphenylcyclopentadienone (tetracyclone, **5**) to the tetrafunctional PcNi **4a** (Scheme 3).[9] This was accomplished in a single reaction by stirring **4a** with a fourfold excess of **5** in toluene at 75°C over 48 h. Chromatographic workup (silica gel; *n*-hexane/ethyl acetate, 6:1) afforded the deep green compound **6** in 66% isolated yield. PcNi **6** is the precursor of the intermediate **7** exhibiting four isobenzofuran moieties.

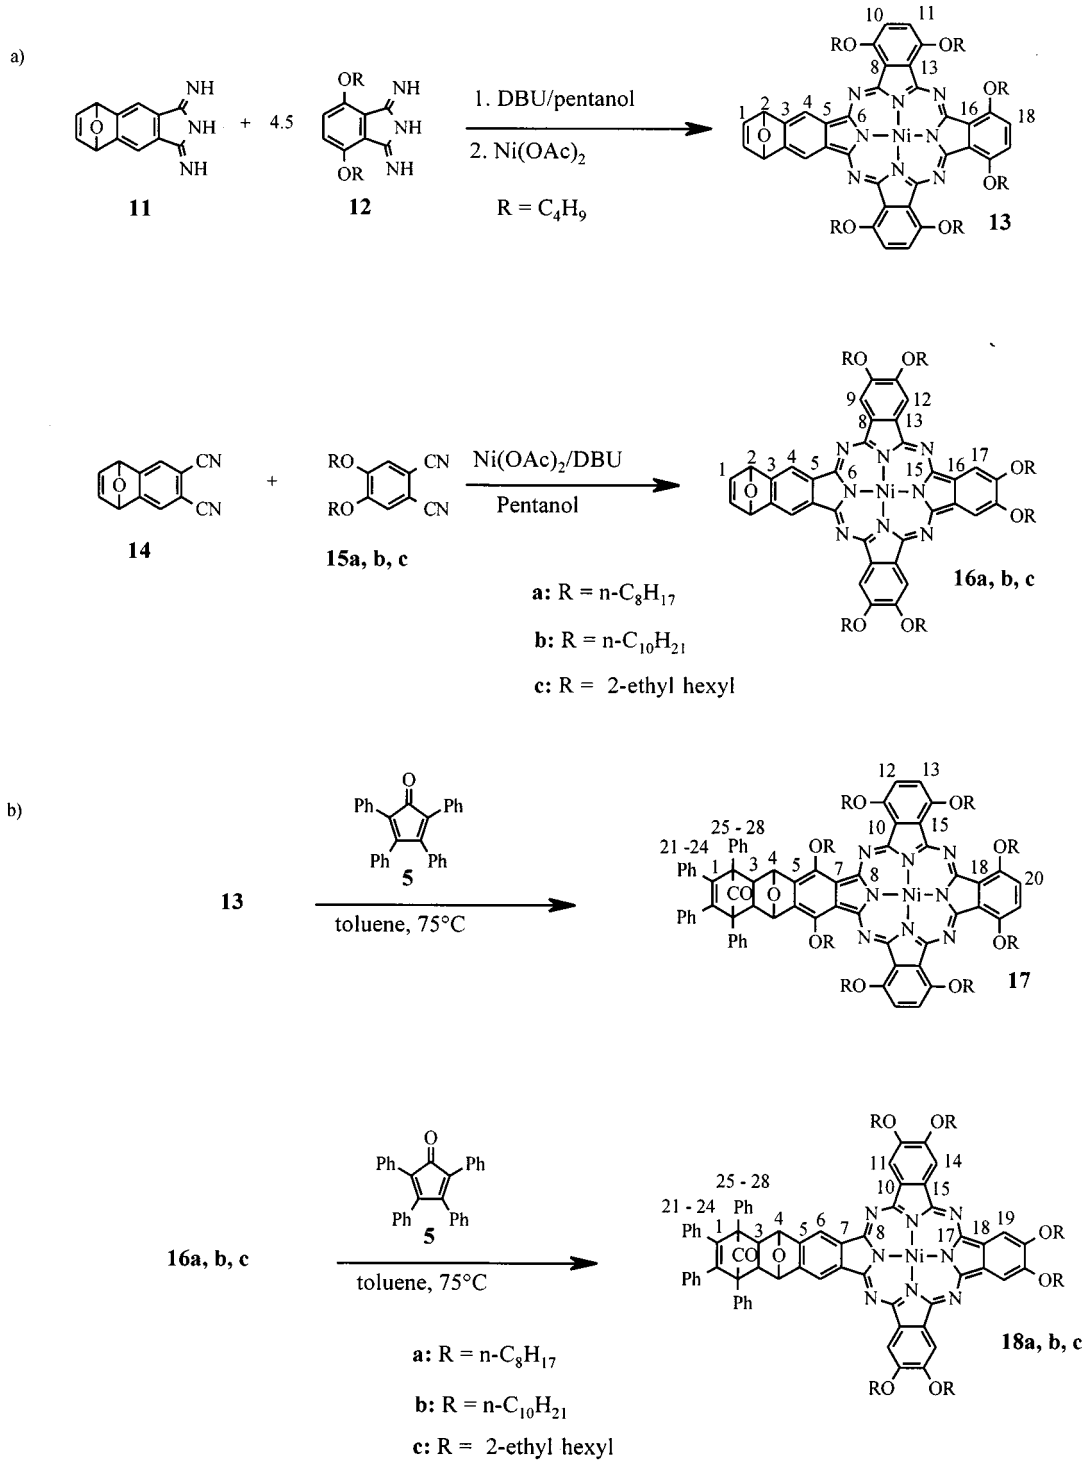
The ability of **7** to react as a tetrafunctional diene was tested with excess naphthoquinone (**8**) as trapping dienophile (Scheme 3) in the following procedure: The precursor **6** and naphthoquinone (8 equiv.) were stirred in refluxing toluene for 24 h. Subsequent flash chromatography (*n*-hexane/ethyl acetate, 3:2) allowed the separation of 1,2,3,4-tetraphenylbenzene and of unreacted quinone as the first and second fraction. The third, deep green fraction proved to be the desired compound **9**. The PcNi **9** was obtained in a yield of 70%.

In previous work, exclusive *exo* orientation was observed during the DA addition of tetracyclone to 1,4-epoxynaphthalenes.[5a,b] Since the isomeric mixture of **4a** (vide infra) was used as starting material to prepare **6**, the tetracyclone adduct **6** is present as a mixture of at least four isomers. The NMR spectra of **6** are in agreement with exclusive *exo* addition, since two clearly separated resonances should appear for e.g. 3-H in the case of *endo* and *exo* addition. The resonances of 3-H and 4-H appear as signal groups of alleged singlets at $\delta = 3.49-3.66$ and at $6.44-6.50$. The appearance of several singlets arises from the magnetic non-equivalence of 3-H and 4-H even in a single all-*exo* isomer of **6** (with exception of the C_{4v} isomer). This non-equivalence and the presence of at least four isomers also complicates the ^{13}C-NMR spectrum (see Experimental Section).

The completeness of the tetracyclone addition is clearly demonstrated by the integration values obtained from the ^1H-NMR spectrum of **6** which are in excellent agreement with the expected values. Moreover, in the DEPT-135 spectrum of **6**, no signal is found downfield from $\delta = 131$. A

Scheme 3. Synthesis of the dehydrated naphthoquinone adduct **10**

remaining vinylic carbon signal (C-1 in structure **4a**) should appear at $\delta \approx 143$.



The Q-band transitions in the electronic spectrum of **6** ($CHCl_3$ solution) are bathochromically shifted compared to the "parent" compound **4a**. The $Q_{0\text{-}0}$ transition appears at 724 nm (**4a**: 713 nm, vide infra), thus indicating that the electronic influence of the epoxybenzo units on the Pc core decreases during the DA addition to the dienophilic double bonds in **4a**.

exo and *endo* attack was expected for the DA addition of naphthoquinone (**8**) to the isobenzofuran moieties of **7**.[3c,10] The fact that both orientations are present in compound **9** is reflected by two clearly separated broad signals for 5-H at $\delta = 3.51$ (*exo*) and 4.09 (*endo*) in the corresponding ^{1}H-NMR spectrum. The *exo*/*endo* assignments given in the Experimental Section are in agreement with the chemical shifts and with an additionally performed H,C-COSY experiment. Comparison of the integrals of the mentioned

5-H signals allowed the determination of the overall *exo*/*endo* ratio (*exo*/*endo* ≈ 2.5:1). Similar reactions of mono- and bifunctional hemiporphyrazine intermediates with *p*-benzoquinone proceeded with the same ratio.[3c]

The $Q_{0\text{-}0}$ transition in the electronic spectrum of compound **9** is found at 728 nm. In comparison to the "parent" molecule **4a**, the same tendency (bathochromic shift) as found for the above described DA adduct **6** occurs.

Full dehydration and therefore planarization of PcNi **9** was attempted next to obtain first informations about the behaviour of phthalocyanine–quinone adducts against dehydrating agents. Treatment with *p*-toluenesulfonic acid (toluene, reflux, 1 h) led to complete decomposition of **9**. The use of the Lewis acid trimethylsilyl triflate was more successful. When **9** was allowed to react with $SiMe_3OTf$ in dry $CHCl_3$ (room temp., 36 h), the reddish-brown naphtha-

Scheme 4. Synthesis of the unsymmetrical Pcs **13**, **16a–c** and their tetracyclone adducts **17**, **18a–c**

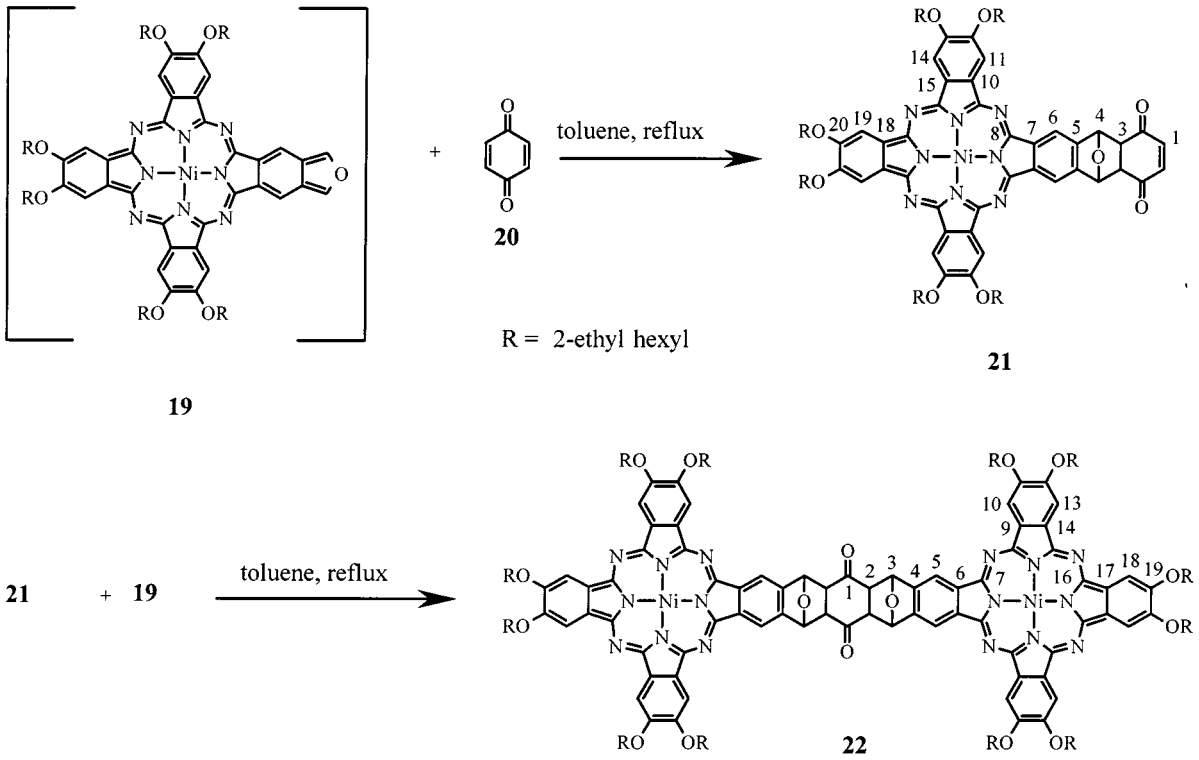
locyanine (Nc) **10** was formed (Scheme 3). **10** was isolated after quenching of the reaction and chromatographic workup (silica gel, toluene/ethyl acetate 8:1) in 12% yield. The low yield is due to partial decomposition of **10** during the reaction. The acid stability of substituted Ncs is generally lower than the one of Pcs. Overall 1,4-substitution on the Pc core additionally raises the lability to hydrolysing agents by causing a slight deviation from the perfect planarity of the macrocyclic plane. In air, compound **10** slowly decomposes over days.

Complete dehydration is clearly demonstrated by the absence of any residual signals from the starting compound **9** in the ^{1}H-NMR spectrum of **10**. A strongly downfield-shifted broad singlet at $\delta = 9.95$ is observed for 6-H. Characteristic of 1,6,10,15,19,24,28,33-octaalkoxy-substituted NcNi complexes, the $Q_{0\text{-}0}$ transition appears in the near IR region at 855 nm.

As described above, the overall substitution in the 1,4-positions on a Pc core decreases its hydrolytic stability. Therefore, the target molecules **13** and **16a,b,c** (having one DA functionality and a lower number of or even no 1,4-substituents) were chosen next to test DA building blocks with an increased hydrolytic stability (Scheme 4a). The synthesis of such AAAB-Pcs, composed of three subunits A and one subunit B, is possible by a statistical condensation of two differently substituted phthalodinitriles or diiminoisoindolines A and B,[11] whereby the desired compounds are formed besides other combinations. In order to obtain a relatively large amount of the AAAB-Pc, an excess of the starting compound A is generally used.

The 1,4-substituted PcNi **13** was obtained by the reaction of 1 equiv. of 5,8-dihydro-1,3-diimino-5,8-epoxybenz[*f*]isoindoline (**11**)[6] with 4.5 equiv. of 4,7-dibutoxy-1,3-diiminoisoindoline (**12**)[8][12] in refluxing *n*-pentanol and in the presence of catalytic amounts of DBU (72 h). Metallation was achieved by adding 1.2 equiv. of nickel(II) acetate to the reaction mixture and refluxing for further 6 h. The desired product **13** was separated from other Pcs formed by flash chromatography, whereby two subsequent separations with different eluents were performed (first column: $CHCl_3$/ethyl acetate, 2:1, **13** is contained in the 1st fraction; second column: toluene/ethyl acetate, 10:1, the pure blue-green compound **13** is eluted as the 2nd fraction in a yield of 9%).

The preparation of the 2,3-substituted PcNi **16a,b,c** was realized by the condensation reaction of 1 equiv. of 6,7-dicyano-1,4-dihydro-1,4-epoxynaphthalene (**14**)[6] with 8 equiv. of 1,2-dicyano-4,5-dioctyloxybenzene (**15a**), 1,2-dicyano-4,5-didecyloxybenzene (**15b**) and 1,2-dicyano-4,5-bis(2-ethylhexyloxy)benzene (**15c**),[13] respectively in *n*-pentanol at 145°C (18 h, catalytic amounts of DBU). To minimize the separation problems arising from the strong aggregation in a statistical mixture of 2,3-substituted PcNi molecules, we chose an 8-fold excess of the phthalodinitriles **15a,b,c** in order to obtain a product mixture mainly consisting of the AAAA-Pc besides the AAAB-Pcs **16a,b,c**. The blue-green compound **16a,b,c** was separated from other Pcs formed by flash chromatography starting with CH_2Cl_2 and later using CH_2Cl_2/ethyl acetate, 4:1 as the mobile phase (see Experimental Section). We obtained **16a,b** and **c** in average yields of 14%.



The hydrolytic stability of the PcNi dienophiles **13** and **16a** was tested by treating them with *p*-toluenesulfonic acid (200-fold excess) over a period of 1 h in a toluene solution (room temp.). **13** partially decomposed while **16a** showed no reaction at all (TLC control). The epoxy bridge in **13** and **16a** was not affected under these conditions.

The compounds **13** and **16a,b,c** could be converted to the corresponding PcNi–tetracyclone adducts **17**, **18a,b,c** in moderate to good yields (Scheme 4b). In a typical procedure, the corresponding PcNi (**13**, **16a,b,c**) was stirred with 1 equiv. of tetracyclone in toluene at 75°C (several days). In contrast to a similar addition reaction starting from hemiporphyrazines,[3b,14] the reaction could not be driven to completion within 7 days for **13** and **16a,b**. The isolated yields were 69% (**17**) and 55% (**18a,b**), respectively, whereas the reaction with HpNi complexes proceeded almost quantitatively within 24 h and gave isolated yields of ca. 90%.[3b,14] The hindered reactivity of the PcNi dienophiles **13** and **16a,b** during this DA addition may be due to aggregation phenomena in the corresponding reaction mixture. One possibility to suppress aggregation is the introduction of bulky or branched substituents on the Pc core.[15] Therefore, **16c** was expected to give better yields under identical reaction conditions. As expected, the reaction proceeded almost quantitatively and yields of 90% were obtained.

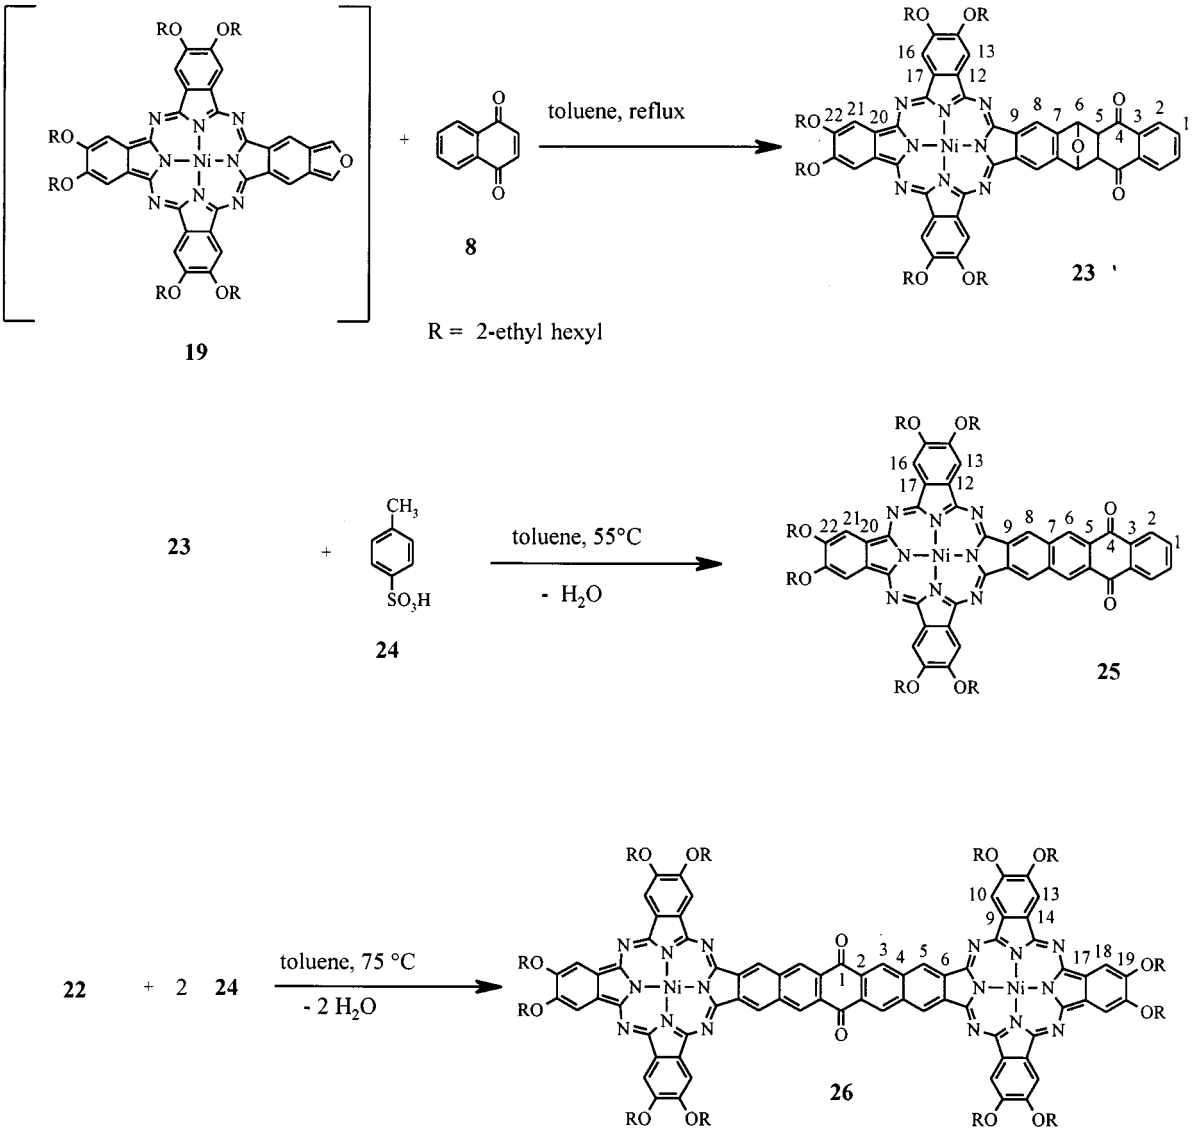
The purified compounds **13**, **16a,b,c**, **17** and **18a,b,c** were identified on the basis of their NMR and FD- or FAB-MS spectra (see Experimental Section). Characteristic for the epoxybenzo units in **13** and **16a,b,c** are three singlets in the ^{1}H-NMR spectra arising from 1-H, 2-H, and 4-H. In the case of compound **13**, these signals are sharp and appear at $\delta = 6.13$ (2-H), 7.24 (1-H) and 8.93 (4-H), while the stronger aggregation in $CDCl_3$ solutions of **16a,b,c** leads to broadened resonances. For **16a** these resonances appear at $\delta = 6.14$ (2-H), 7.23 (1-H) and 8.20 (4-H). All other NMR data are in agreement with the proposed structures.

By the addition of tetracyclone to the isolated double bonds in **13**, **16a,b,c**, the signals of the vinylic protons 1-H disappear and singlets for the methine protons 3-H are found at $\delta = 3.44$ (**17**) and 3.24 (**18a**), respectively. The appearance of singlets for 3-H, 4-H is in agreement with the expected *exo* orientation of the tetracyclone addition (vide infra). The *exo* orientation causes a dihedral angle between the two mentioned protons which is close to 90°. Therefore, a small coupling constant results.

The DA reaction of the isobenzofuran intermediate **19** (generated from **18c**) with *p*-benzoquinone **20** furnished the benzoquinone monoadduct **21** which (after removal of unreacted **20** by sublimation) was treated (without further purification) with a second equiv. of **19** to form the ladder-type phthalocyanine dimer **22** in a yield of 55%. **18a** was also treated with *p*-benzoquinone according to the same sequence, but the formed dimer could not be identified by spectroscopic means due to heavy aggregation (see below).

Scheme 5. Synthesis of Pc dimer **22**

A small amount of the benzoquinone adduct **21** was isolated and purified by flash chromatography (silica gel; CH_2Cl_2/ethyl acetate, 8:1). As described for compound **9**, *exo* and *endo* orientation is present in compound **21**. The ^{1}H-NMR spectrum shows two clearly separated broad signals for 3-H at δ = 3.24 (*exo*) and 3.88 (*endo*). The *exo*/*endo* assignments given in the Experimental Section are in agreement with the chemical shifts and comparison of the integrals of the mentioned 3-H signals allowed the determination of the overall *exo*/*endo* ratio (*exo*/*endo* ≈ 1:2).



Due to aggregation phenomena and the fact that six isomers can be formed, the full spectroscopic characterization of the ladder-type PcNi dimer **22** was difficult. The resolution of the NMR spectra is only moderate, therefore a discussion of the *exo*/*endo* ratio is not possible. Yet all the signals found in the ^{1}H-NMR and the ^{13}C-NMR spectrum verify the proposed structure. The ^{1}H-NMR spectrum shows broad resonances for the methine proton 2-H at δ = 2.93, 3.48, and 3.74 and at δ = 6.11, 6.36, and 6.58 for 3-H. The corresponding carbon signals appear at δ = 53.7, 55.1, 55.3 (C-2) and at δ = 84.1, 85.1 (C-3), respectively. The IR spectrum shows the carbonyl band at 1701 cm^{-1}. If the DA addition of a second equiv. of isobenzofuran **19** had failed, the carbonyl band should still appear at 1676 cm^{-1} (**21**). The shift to higher wavelengths also indicates that the two carbonyl groups in the molecule are no longer conjugated.

In order to prepare a model compound for dehydration experiments we treated **18c** with a 7-equiv. excess of naphthoquinone (**8**, toluene, 110°C, 24 h,). The naphthoquinone monoadduct **23** was obtained in a yield of 70%. Again, the NMR spectra indicate *exo* and *endo* orientation. Two signals appear for 5-H at δ = 3.42 (*exo*), 4.14 (*endo*) and 6-H at 6.30 (*exo*), 6.38 (*endo*) The *exo* and *endo* isomers are formed in a ratio of 1:2.5 and can be separated by preparative TLC with CH_2Cl_2 as eluent. For further dehydration reactions the isomers were not separated because both isomers form the same product during the dehydration reaction.

Since **16a** proved to be stable against strong proton acids, **23** was expected to undergo acid-promoted dehydration easily to give the corresponding planarized and fully unsaturated naphthoquinone adduct **25** without decomposition.

By treating **23** with a 4-fold excess of *p*-toluenesulfonic acid (**24**) dehydration was carried out successfully and **25** was obtained in a yield of 85% after isolation by flash chromatography with CH_2Cl_2 as eluent. During the whole reaction time no decomposition was observed. Complete dehydration is clearly demonstrated by the absence of any residual signals from the methine proton 5-H in its ^{1}H-NMR spectrum.

A downfield-shifted singlet at δ = 8.17 is observed for 6-H. All NMR data are in agreement with the proposed structure and with an additionally performed H,C-COSY experiment. In the IR spectrum the carbonyl band has been shifted from 1680 cm^{-1} (**23**) to 1672 cm^{-1} in **25**. This shows an increased conjugation of the two carbonyl functions in the molecule. As expected the Q-band transitions in the electronic spectrum of **25** are bathochromically shifted compared to the precursor molecule **23**. The $Q_{0\text{-}0}$ transition appears at 708.5 nm (**23**: 668 nm).

Scheme 6. Synthesis of the dehydrated naphthoquinone adduct **25** and the fully unsaturated Pc dimer **26**

By an identical treatment of **22** with a 6-fold excess of toluenesulfonic acid (**24**) in toluene at 75°C the completely unsaturated dimer **26** was obtained in a yield of 68% after purification by flash chromatography with CH_2Cl_2 as eluent. Compared to the dehydration of **21** slightly higher reaction temperatures and longer reaction times were necessary to obtain optimized yields. During the reaction also the monodehydrated dimer was observed during TLC control. A small amount was isolated and identified by ^{1}H NMR. Further identification was not pursued.

The NMR spectra of **26** show that dehydration was successful although **26** has a strong tendency to form aggregates and the resolution of the ^{1}H-NMR spectrum is only moderate. The methine proton signals of **22** (2-H) have completely vanished and the 3-H signal now appears at δ = 8.1. Moreover, in the DEPT-135 spectrum no signal is found between δ = 40 and 60. A remaining methine carbon signal should appear at $\delta \approx 55$. In the IR spectrum the carbonyl band has been shifted to lower wavelengths (1695 cm^{-1}) compared with **23**. The Q transitions in the electronic spectrum of **26** are bathochromically shifted (730, 681 nm) compared to **22** (659, 628 nm).

Experimental Section

The following compounds were prepared as described in the literature: 5,8-dibutoxy-6,7-dicyano-1,4-dihydro-1,4-epoxynaphthalene (**3a**),[7] 6,7-dicyano-5,8-dihexyloxy-1,4-dihydro-1,4-epoxynaphthalene (**3b**),[7] 5,8-dihydro-1,3-diimino-5,8-epoxybenz[*f*]isoindoline (**11**),[6] 4,7-dibutoxy-1,3-diiminoisoindoline (**12**),[8][12] 6,7-dicyano-1,4-dihydro-1,4-epoxynaphthalene (**14**),[6] 1,2-dicyano-4,5-dioctyloxybenzene (**15a**), 1,2-dicyano-4,5-didecyloxybenzene (**15b**), 1,2-dicyano-4,5-bis(2-ethylhexyloxy)benzene (**15c**).[13] – FT IR: Bruker IFS 48. – UV/Vis: Shimadzu UV-2102 PC. – NMR: Bruker AC 250, Bruker ARX 250 (^{1}H: 250.1 MHz, ^{13}C: 62.9 MHz). – MS: Finnigan ISQ 70; Varian MAT 711A (modified by AMD Intectra). – Elemental analyses were performed with Carlo Erba Elemental Analyzer 1104, 1106. All chemical shifts are referenced to the signals of $CDCl_3$ (except for **16c**). All chromatographic sep-

arations (column chromatography or TLC) with "$CHCl_3$" as eluent or as part of the eluent were performed with $CHCl_3$ containing 1% of EtOH.

General Procedure for the Preparation of the PcNi 4a,b: The corresponding phthalodinitrile (**3a,b**), 1.2 equiv. of $Ni(OAc)_2 \cdot 4\ H_2O$ and a catalytic amount of DBU were suspended in the convenient *n*-alcohol (**3a**: *n*-butanol, **3b**: *n*-hexanol) under nitrogen. The mixture was then heated for several hours (**3a**: reflux, 36 h; **3b**: 145°C, 24 h). After cooling, the solvent was stripped from the butanol solution in a rotatory evaporator. The crude product was purified by column chromatography on silica gel. The hexanol solution was cooled down and poured into a mixture of $MeOH/H_2O$, 2:1. The precipitate was collected by centrifugation and washed several times with MeOH. The crude product was then dried and purified by column chromatography (silica gel). Both deep green solids were furthermore extracted with MeOH and dried in vacuo.

1,6,10,15,19,24,28,33-Octabutoxy-2,5,11,14,20,23,29,32-octahydro-2,5:11,14:20,23:29,32-tetraepoxynaphthalocyaninato]nickel(II) (4a): 550 mg (1.62 mmol) of **3a** and 121 mg (0.49 mmol) of $Ni(OAc)_2 \cdot 4\ H_2O$ were allowed to react in 30 ml of *n*-butanol according to the general procedure (36 h). Column chromatography was performed using *n*-hexane/ethyl acetate, 2:1 as eluent and afforded 172 mg (30%) of **4a**. R_f (SiO_2; toluene/ethyl acetate, 10:1) = 0.50. − IR (KBr): $\tilde{\nu}$ = 2957 cm^{-1}, 2928, 2858, 1591, 1518, 1493, 1466, 1362, 1288, 1246, 1178, 1124, 1111, 1076, 988, 870, 710. − UV/Vis ($CHCl_3$): λ_{max} = 713 nm, 642, 383, 338, 311. − ^1H NMR ($CDCl_3$): δ = 1.01 (t, *J* = 7.3 Hz, 24 H, CH_3), 1.51−1.66 (m, 16 H, CH_2), 1.89−2.02 (m, 16 H, CH_2), 4.72−5.03 (m, 16 H, OCH_2), 6.38 (s, 8 H, 2-H), 7.33 (s, 8 H, 1-H). − ^{13}C NMR ($CDCl_3$): δ = 14.1 (CH_3), 19.4 (CH_2), 32.6 (CH_2), 75.4 (OCH_2), 81.3 (C-2), 130.0 (C-5), 143.0 (C-1), 143.1, 144.9, 145.6 (C-3, C-4, C-6). − MS (FD); *m/z* (%): 1412.6 (100) [M^+]. − $C_{80}H_{88}N_8NiO_{12}$ (1412.3): calcd. Tetrakis(tetracyclone) Adduct PcNi 6: 117 mg (82.8 μmol) of **4a** and 128 mg (332.9 μmol) of tetracyclone **5** were dissolved in 30 ml of toluene under nitrogen and stirred for 48 h at 75°C. After cooling and evaporation of the solvent, the raw product was purified using column chromatography (silica gel) with *n*-hexane/ethyl acetate, 6:1 (1st fraction: tetracyclone; 2nd fraction: **6**; 3rd fraction: incompletely converted products). After evaporating the solvent from the 2nd fraction, it was extracted several times with *n*-hexane to remove remaining traces of **5**. Drying in vacuo gave 162 mg (66%) of **6** as a deep green powder. R_f (SiO_2; *n*-hexane/ethyl acetate, 3:1) = 0.44. − IR (KBr): $\tilde{\nu}$ = 3057 cm^{-1}, 3028, 2957, 2932, 2872, 1778 (C=O), 1605, 1587, 1497, 1447, 1356, 1340, 1298, 1250, 1223, 1198, 1115, 1074, 1026, 982, 949, 897, 820, 752, 698. − UV/Vis ($CHCl_3$): λ_{max} = 724 nm, 651, 422 (sh), 360, 339, 306. − ^1H NMR ($CDCl_3$): δ = 0.96−1.11 (m, 24 H, CH_3), 1.59−1.88 (m, 16 H, CH_2), 2.05−2.44 (m, 16 H, CH_2), 3.49−3.66 (m, 8 H, 3-H), 4.57−5.57 (m, 16 H, OCH_2), 6.44−6.50 (m, 8 H, 4-H), 7.07 (br., 40 H, 10-H, 11-H, 12-H), 7.37−7.75 (m, 40 H, 14-H, 15-H, 16-H). − ^{13}C NMR ($CDCl_3$): δ = 14.1, 14.2 (CH_3), 19.4, 19.5 (CH_2), 32.5, 32.6 (CH_2), 46.9, 47.2 (C-3), 64.6 (C-2), 75.9 (OCH_2), 80.4 (C-4), 126.9, 127.7, 128.4, 129.74, 129.83, 129.95, 130.02 (C-10-12, C-14-16), 130.5 (C-7), 135.2, 135.27, 135.33, 135.6 (C-9, C-13), 138.8, 138.87, 138.90, 139.0 (C-1), 142.1, 142.2, 142.3, 142.5, 144.30, 144.34, 144.46, 144.52, 144.65, 144.74, 145.01, 145.07 (C-5, C-6, C-8), 196.6 (CO). − MS (FAB); *m/z* (%): 2949.0 (18) [M^+], 2538.7 (5) [M^+ − CO − $C_{30}H_{22}$], 2127.5 (5) [M^+ − 2 × CO − 2 × $C_{30}H_{22}$], 1717.9 (12) [M^+ − 3 × CO − 3 × $C_{30}H_{22}$], 1305.9 (90) [M^+ − 4 × CO − 4 × $C_{30}H_{22}$ − 1]. − $C_{196}H_{168}N_8NiO_{16}$ (2950.2): calcd. C 79.80, H 5.74, N 3.80; found C 79.10, H 5.92, N 4.07.

Tetrakis(naphthoquinone) Adduct PcNi 9: 155 mg (52.5 μmol) of **6** and 266 mg (1.68 mmol) of 1,4-naphthoquinone (**8**) were dissolved in 30 ml of toluene (under nitrogen) and heated under reflux for 24 h. The solvent was removed and the residue was separated by flash chromatography (*n*-hexane/ethyl acetate, 3:2), whereby 1,2,3,4-tetraphenylbenzene and unreacted naphthoquinone were eluted in front of the green fraction containing **9**. Drying in vacuo furnished 71 mg (70%) of **9** as a deep-green solid. R_f (SiO_2; *n*-hexane/ethyl acetate, 1:1) = 0.50. − IR (KBr): $\tilde{\nu}$ = 3071 cm^{-1}, 2959, 2934, 2872, 1682 (C=O), 1593, 1495, 1358, 1294, 1267, 1223, 1153, 1113, 989, 949, 750. − UV/Vis ($CHCl_3$): λ_{max} = 728 nm, 655, 425 (sh), 360, 308. − ^1H NMR ($CDCl_3$): δ = 1.02−1.13 [m, *exo*], 1.16−1.29 [m, *endo*] (24 H, CH_3), 1.58−1.95 (m, 16 H, CH_2), 2.07−2.25 (m, 16 H, CH_2), 3.46−3.56 [m, *exo*], 4.09 [br., *endo*] (8 H, 5-H), 4.30−5.50 (m, 16 H, OCH_2), 6.49 (m, 8 H, 6-H), 7.50−7.81 [m, *endo*, 1-H, 2-H], 7.85−7.89 [m, *exo*, 1-H], 8.26−8.30 [m, *exo*, 2-H] (16 H). − ^{13}C NMR ($CDCl_3$): δ = 14.2 (CH_3), 19.5 (CH_2), 32.3, 32.8 (CH_2), 50.8 [*endo*], 52.1 [*exo*] (C-5), 75.4, 75.8 (OCH_2), 82.4 [*endo*], 84.3 [*exo*] (C-6), 125.9 [br., *endo*], 127.5 [*exo*] (C-2), 129.8 [br.] (C-9), 132.6 [br., *endo*], 134.7 [*exo*] (C-1), 134.3, 135.7 (C-3), 139.1, 139.5 [br.] (C-7), 144.8 [br.], 145.0 [br.] (C-8, C-10), 193.4, 194.7 (CO). − MS (FAB); *m/z* (%): 1939.4 (55) [M^+], 1781.5 (35) [M^+ − $C_{10}H_6O_2$], 1623.3 (20) [M^+ − 2 × $C_{10}H_6O_2$], 1464.0 (30) [M^+ − 3 × $C_{10}H_6O_2$ − 1], 1307.4 (70) [M^+ − 4 × $C_{10}H_6O_2$]. − $C_{112}H_{104}N_8NiO_{20}$ (1940.7): calcd. [1,4,8,11,15,18-Hexabutoxytribenzo[*b*,*g*,*l*]-23,26-dihydro-23,26-epoxynaphtho[*q*]porphyrazinato]nickel(II) (13): 300 mg (1.42 mmol) of the diiminoisoindoline **11** and 1.85 g (6.39 mmol) of the diiminoisoindoline **12** were suspended in 50 ml of *n*-pentanol (under nitrogen) and a catalytic amount of DBU was added. The mixture was kept under reflux for 72 h. 582 mg (2.34 mmol) of $Ni(OAc)_2 \cdot 4\ H_2O$ was added to the hot reaction mixture and it was heated for further 6 h. The mixture was allowed to cool down and poured into 200 ml of MeOH/H_2O, 3:1, whereby a green solid precipitated. This was collected by centrifugation and washed several times with MeOH. The crude statistical mixture was dried and separated using flash chromatography by doing two subsequent separations. The first column was performed with $CHCl_3$/ethyl acetate, 2:1 as the mobile phase. The desired PcNi **13** was contained in the 1st fraction. The second column was eluted with toluene/ethyl acetate, 10:1, whereby **13** was contained in the second blue-green fraction. After evaporation of the solvent, the residue was extracted several times with MeOH and dried in vacuo. Yield: 189 mg (9%) of **13**. R_f (SiO_2; $CHCl_3$/ethyl acetate, 3:2) = 0.63. − IR (KBr): $\tilde{\nu}$ = 2957 cm^{-1}, 2932, 2870, 1607, 1522, 1502, 1466, 1385, 1312, 1275, 1254, 1232, 1198, 1178, 1107, 1074, 926, 870, 852, 793, 760. − UV/Vis ($CHCl_3$): λ_{max} = 725 nm, 651, 448, 332, 305. − ^{1}H NMR ($CDCl_3$): δ = 1.06 (t, *J* = 7.4 Hz, 12 H, 4 CH_3), 1.30 (t, *J* = 7.3 Hz, 6 H, 2 CH_3), 1.54−1.70 (m, 8 H, 4 CH_2), 2.02−2.22 (m, 12 H, 6 CH_2), 2.29−2.40 (m, 4 H, 2 CH_2), 4.50−4.59 (m, 4 H, 2 OCH_2), 4.69−4.78 (m, 8 H, 4 OCH_2), 6.13 (s, 2 H, 2-H), 7.24 (s, 2 H, 1-H), 7.34 (m [AB], 4 H, 10-H, 11-H), 7.49 (s, 2 H, 18-H), 8.93 (s, 2 H, 4-H). − ^{13}C NMR ($CDCl_3$): δ = 14.1, 14.4 (CH_3), 19.4, 20.0 (CH_2), 31.5, 31.6, 32.4 (CH_2), 69.3, 71.2, 71.4 (OCH_2), 82.7 (C-2), 113.6 (C-4), 116.5, 117.0 (C-10, C-11, C-18), 125.8, 127.0, 127.5 (C-8, C-13, C-16), 136.1 (C-5), 143.0 (C-1), 145.37, 145.44, 145.9, 146.3 (C-3, C-9, C-12, C-17), 149.8, 150.0, 150.2, 150.5 (C-6, C-7, C-14, C-15). − MS (FD); *m*/*z* (%): 1068.3 (100) [M^+]. − $C_{60}H_{66}N_8NiO_7$ (1069.9): calcd. General Procedure for the Preparation of the PcNi 16a,b,c: 4.40 mmol of the corresponding phthalodinitrile **15a,b,c** (A), 0.55 mmol of the phthalodinitrile **14** and 1.49 mmol of $Ni(OAc)_2 \cdot 4\ H_2O$ were suspended in 50 ml of *n*-pentanol and a catalytic amount of DBU was added (under nitrogen). The mixture was heated to 145°C and stirred for 18 h. It was allowed to cool down and poured into 200 ml of MeOH. The formed precipitate was isolated using centrifugation and washed several times with MeOH. The raw mixture of PcNi complexes was separated by flash chromatography starting with CH_2Cl_2 as the mobile phase. After complete elution of the 1st fraction (AAAA-PcNi) a mixture of CH_2Cl_2/ethyl acetate, 4:1 was used as eluent to obtain **16a,b,c** as the 2nd fraction. The solvent was removed and the blue-green solid was extracted several times with acetone to achieve further purification. Drying in vacuo furnished average yields of 14% of **16a,b,c**.

General Procedure for the Preparation of the Mono(tetracyclone) Adducts 18a,b,c: 100 μmol of **16a,b,c** and 102 μmol of **5** were dissolved in 30 ml of toluene and stirred at 70−75°C (5−7 d; TLC control: SiO_2, $CHCl_3$). The solvent was evaporated and the residue was separated by flash chromatography (CH_2Cl_2; 1st fraction: tetracyclone; 2nd fraction: **18a,b,c**). Evaporation of the solvent and drying in vacuo gave average yields of 55% of **18a,b** and 90% of **18c** as a blue-green solid.

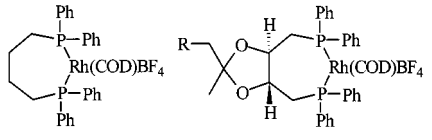
Conformational Analysis of Seven-Membered Ring Chelates, 1

Conformations and Dynamic Behaviour of Rhodium Complexes with 1,4-Bis(diphenylphosphanyl)butane, DIOP and Its HO Analogue

Renat Kadyrov,*[a] Armin Börner,[a] and Rüdiger Selke[a]

Keywords: Conformation analysis / Molecular modelling / NMR spectroscopy / Seven-membered chelates / Rhodium / Ab initio calculations



The temperature dependence of NMR spectra of $[(L)Rh(cod)]BF_4$ complexes with L = dppb (**1**), (*R*,*R*)-diop (**2**) and (*R*,*R*)-HO-diop (**3**) has been examined. Molecular mechanics and ab initio calculations on the [{1,4-bis(dimethylphosphanyl)butane}Rh^+(diolefin)] complex predict local energy minima for all twist-chair (TC_1, TC_2 = TC_7, TC_3 = TC_6, TC_4 = TC_5) and two boat (B_3 = B_6 and TB_1) conformations. Furthermore, ab initio calculations at the B3LYP/6-31G(d)/LANL2DZ level show that two minima are located in the wide-open region between the TC_7 and C_4 conformations. Relative B3LYP/6-31G(d) energies of the B_3, TC_1 and {C_4-TC_7} conformations are 0.0, 0.71 and 0.97–1.08 kcal mol^{-1}, respectively. Analysis of crystallographic data contained in the Cambridge Structural Database shows that the majority of structures are concentrated in the region {C_4-TC_7} and close to B_3. The symmetrical doublet in the ^{31}P-NMR spectra is assigned to the fast equilibrium {TC_7-C_4} ⇌ TC_1 ⇌ {C_5-TC_2}. The resonances of the other species are consistent with B_3 = B_6 geometry. A fused dioxolane ring forces the chelate in diop complexes to adopt the B_4 = B_5 conformation. For both types of ligand the chair-like conformation is enthalpically preferred at low temperatures ($\Delta H°$ = 0.45–0.46 kcal mol^{-1}), whereas the boat-shaped structure predominates at temperatures above 200 K ($\Delta S°$ = 0.9–1.3 cal K^{-1} mol^{-1}). Line-shape analysis provides a boat pseudorotation barrier for complex **1** of $\Delta G^{\neq}$ = 5.9 kcal mol^{-1} and for **2** $\Delta G^{\neq}$ = 5.3 kcal mol^{-1} at 184 K. The free energy of activation at this temperature for the boat–chair interconversion is $\Delta G^{\neq}$ = 8.6 kcal mol^{-1} for complex **1** and $\Delta G^{\neq}$ = 8.0 kcal mol^{-1} for complex **2**.

Introduction

Chelating bis(phosphane) ligands play a dominant role in metal-catalyzed stereoselective syntheses.[1] The relationship between catalyst conformation and the product configuration is well established. In general, the observed asymmetric induction is attributed to discriminatory interactions between substrate and bulky phosphane substituents adjusted by the chiral conformation of the chelate.[2] In particular, asymmetric hydrogenation catalyzed by cationic rhodium complexes containing chiral phenyl-substituted five-membered bis(phosphane) chelates is one of the most intensively investigated stereoselective reactions. The generally accepted basis for the enantioselectivity is the concept of pseudo axial−equatorial arrangement of the *P*-phenyl groups based on the "edge-to-face" model.[3] The configuration of the hydrogenation product is determined by the δ or the λ conformation of the five-membered ring.[4]

Complexes based on seven-membered bis(phosphane) chelates hydrogenate with higher reaction rates. The enhanced catalytic activity is associated with the high degree of conformational flexibility of the chelate ring. Only very few solution-NMR studies on seven-membered chelate conformations have been performed.[5] Although the crystallographic data show that these chelates may adopt some non-symmetrical conformations,[6] recent NMR results have been interpreted in terms of C_2-symmetrical geometries.[5a,7] Accordingly, idealized C_2-symmetrical twist-chair and twist-boat conformations were involved in mechanistic considerations on the origin of the stereoselectivity.[4b,8]

We examined the conformations and dynamic behaviour of seven-membered chelate rings of three complexes $[(L)Rh(cod]BF_4$ with L = 1,4-bis(diphenylphosphanyl)butane (**1**), (*R*,*R*)-diop (**2**) and (*R*,*R*)-HO-diop (**3**); cod = 1,5-*cis*-cyclooctadiene (Scheme 1).

1 (dppb) **2** R = H (diop) **3** R = OH (HO-diop)

Scheme 1

First, we calculated all basic conformations of the chelate ring by applying a simple MMX force field. The results of these calculations were used as input for ab initio calculations at the B3LYP/6-31G(d)/LANL2DZ level. X-ray data available from the Cambridge Structural Database were analyzed to verify the predicted favoured conformers. Low-temperature NMR spectroscopy was used to obtain infor-

mation about the conformers present in solution and their dynamic properties.

Results

Conformations of the Seven-Membered Chelate Rings — Computed versus Experimental Structures

Molecular mechanics calculations have been used to establish the main conformational features of cycloheptane and some seven-membered heterocycles.[9] Calculations based on empirically determined potential functions were also successfully applied to the solution of structural problems of the coordination chemistry[10] especially of square-planar transition-metal complexes.[11] Recently, some reports demonstrated the utility of the molecular modeling program PCMODEL for determining minimum-energy structures of a variety of flexible complexes.[12] For the following discussion we use the notation for conformations introduced by Hendrickson,[13] labelling the position of the metal as 1.

In order to reduce the independently varied parameters, we have involved the corresponding dimethylphosphanyl derivative in the calculations. The structure of [{1,4-bis(dimethylphosphanyl)butane}Rh^+(cod)] = [(dmpb) Rh^+(cod)] was constructed by use of PCMODEL 4.0 with the parameter set and interactions described in the Experimental Section. At first, we carried out a series of calculations to search all relative low-energy local minima. For identification the conformations were analyzed in terms of ring-puckering coordinates. These coordinates (q_2, q_3, ϕ, ψ) were calculated from the Cartesian coordinates according to the original Cremer−Pople method.[14] The puckering amplitudes q_i were replaced by the total puckering amplitude Q and the angle θ:

$$q_2 = Q \cos \theta$$
$$q_3 = Q \sin \theta$$

The angle θ specifies the relative contribution of boat- and chair-like conformations. The chair-twist-chair family has for cycloheptane a θ value of about 66°. Boat-twist-boat conformers are characterized by $\theta \approx 0°$.[15] The minimization procedures gave four different twist-chair conformations (TC_1, $TC_7 = TC_2$*, $TC_6 = TC_3$*, $TC_5 = TC_4$*) and two boat forms (TB_1 and distorted $B_3 = B_6$*), where $TC_7 = TC_2$* means that TC_2 is enantiomeric to TC_7. The calculated energies and geometries of conformers are summarized in Table 1. The twist-chair conformations are connected by a pseudorotation pathway as are the twist-boat conformations. Figures 1 and 2 display the energy profiles in the course of pseudorotation. The calculation of the energy variation along the pseudorotation pathways is detailed in the Appendix.

The geometries determined using MMX force fields for these conformers were used as starting points for the ab initio calculations of the [(dmpb) $Rh^+(C_2H_4)_2$]. For all six conformers, full geometry optimizations were done at the B3LYP/6-31G(d)/LANL2DZ level. The calculated energies and geometries of conformers are given in Table 1. These calculations also indicate the B_3 structure to be of lowest energy with the TC_1 structure only 0.71 kcal mol^{-1} higher in energy. Since the pseudorotation $TC_7 \rightleftharpoons C_4 \rightleftharpoons TC_1$ changes mainly the P−Rh torsion angle (see Appendix), it is expected that the behaviour of the potential energy curve in this region is affected by electronic interactions of the phosphane moiety with the metal centre. Therefore, we examined the potential energy surface along the TC_7 to TC_1 pseudorotation at the B3LYP/6-31G(d) level. At first, partial geometry optimization was performed for C_4 (at ϕ = 50°) conformation with fixed cyclic Rh−P torsion angle. Full optimization, in the next step, led to the additional minimum at ϕ = 30° (distorted C_4). Furthermore, the spline interpolation gave a nearly flat potential-energy curve for the $TC_7 \rightleftharpoons C_4 \rightleftharpoons TC_1 \rightleftharpoons C_5 \rightleftharpoons TC_2$ pseudorotation.

Table 1. Puckering coordinates[a] of optimized molecular geometries and calculated relative energies[b] for [(dmpb)Rh^+(cod)] at the MMX level and for [(dmpb) $Rh^+(C_2H_4)_2$] at the B3LYP/6-31G(d)/LANL2DZ level

Conformation	Method	Q	θ	ϕ	ψ	ΔE
Distorted B_3	MMX	1.51	9.1	29.1	10.5	0
	B3LYP	1.47	8.6	30.1	9.5	0
TB_1	MMX	1.15	11.1	90	90	5.69
	B3LYP	1.17	4.1	90	90	6.38
TC_7	MMX	1.19	49.5	13.2	49.2	2.22
	B3LYP	1.12	48.4	12.4	50.9	1.08

	B3LYP	1.00	31.5	-142.0	8.8	1.85

[a] Q in Å and θ, ϕ, ψ in°. − [b] In kcal mol^{-1}.

MMX and B3LYP calculations indicate that the most stable conformer is boat-shaped, and is represented in the energy hypersurface by a large well between canonical B_3 and TB_4 geometries. For clarity, we define this conformer as distorted B_3. The C_2-symmetrical TB_1 form, mostly mentioned in the literature, is 6.4 kcal mol^{-1} above. Pseudorotation $B_3 \rightleftharpoons B_6$ proceeds via B_1 and requires, according to the MMX molecular mechanics model, an activation energy of 5.5 kcal mol^{-1}. In the next family three low-energy chair forms, TC_7, distorted C_4 and TC_1, are separated by very low barriers. The barrier to the succeeding TC_6 at the molecular mechanics level is not as high as 3 kcal mol^{-1}, whereas TC_6 and TC_5 are separated by a barrier of approximately 7 kcal mol^{-1}. Therefore, conformation $TC_5 = TC_4$ should be distinguishable in the low-temperature NMR spectra from the fast equilibrium $TC_6 \rightleftharpoons TC_7 \rightleftharpoons TC_1 \rightleftharpoons TC_2 \rightleftharpoons TC_3$. Note that barrier calculations using the MMX model reflect exclusively steric and electrostatic influences of the inorganic unit of the molecule and give large deviations from those calculated by ab initio methods if substantial electronic interactions with the metal centre come into play.

We have analyzed the conformational preferences of the seven-membered chelate rings with 1,4-diphosphanylbutane fragments using crystallographic data collected in the Cambridge Structural Database (CSD).[16] There are 51 structures containing M(dpb) and M(diop) fragments, where M = transition metal of group VI−VIII and dpb = 1,4-diphosphanylbutane. Crystallographic data for these structures were saved in FDAT format and then the Cartesian coordinates of the chelating seven-membered ring were extracted. Puckering coordinates (Q, θ, ϕ, ψ) were calculated according to the procedure outlined above. 37 unique fragments present in the crystal structures are characterized by θ = 45−67° and can be identified as chair-like structures. Figure 1b displays scatter plots of phase angles ϕ, ψ for these fragments and projections of a pseudorotation map for the chair-twist-chair forms of cycloheptane. The majority of structures are concentrated in the region between two neighbouring cycloheptane conformations {C_4-TC_7} and only one of them exists in the TC_1 conformation.[28] The most obvious consequence is that the preferred chair-like conformation of the metal chelates with a diphosphanylbutane fragment located between the C_4 and TC_7 forms. Evidently, the shape of this conformation depends on the metal and nature of the co-ligands. Several structures were found in TC_5 and TC_6 conformations indicating the stabilization of these conformations in accordance with the theoretical calculations.

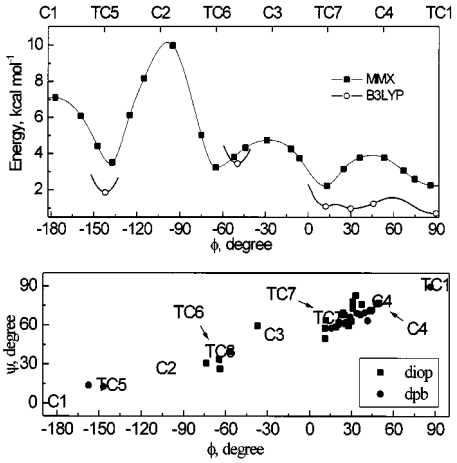

Figure 1. (a) (top) Relative MMX energy as a function of chair ⇌ twist-chair pseudorotation phase ϕ for [(dmpb)Rh^+(cod)] and relative energies of the B3LYP/6-31G(d)/LANL2DZ optimized geometries for [(dmpb) $Rh^+(C_2H_4)_2$]; (b) (bottom) scatter plot of pseudorotation phases ϕ, ψ for transition metal complexes bearing 1,4-diphosphanylbutane (●) or diop (■) fragments contained in CSD and projection of pseudorotation map for the chair ⇌ twist-chair forms of cycloheptane

The next 25 fragments are specified by θ = 3−11° and, therefore, may be assigned to the boat-like conformation. The structures on the scatter plot (Figure 2) are distributed in the regions of B_5−TB_6 conformations for the diop chelates and between B_3−TB_4 canonical forms for the chelates without rigid backbone. In this case, the calculations show satisfactory agreement with the structural information obtained by X-ray analysis. Since θ ≈ 0°, only ϕ defines the conformations in the boat family and the pseudorotation path is just a function of ϕ. Thus, one has to expect only one stable boat-shaped form for the seven-membered ring chelates, which can be represented as distorted B_3 for dpb. Although the twist-boat is more stable than the boat, introduction of the heteroatomic P−M−P fragments into the cycloheptane ring avoids some H/H bond eclipsing in the B_3 conformation. On the other hand, a large difference in the bond lengths forces the heterocyclic seven-membered ring out of its canonical boat and twist boat forms.

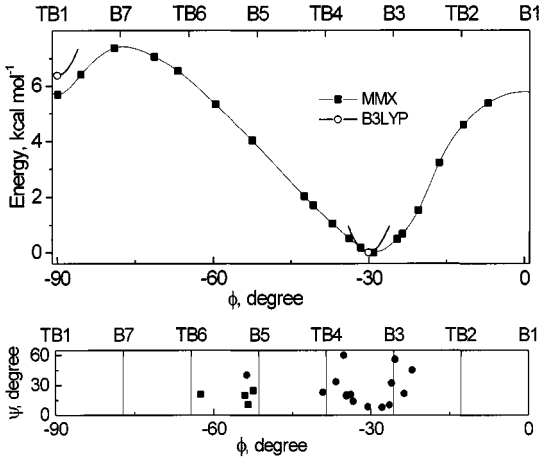

Figure 2. (a) (top) Relative MMX energy as a function of twist-boat ⇌ boat pseudorotation phase ϕ for [(dmpb)Rh^+(cod)] and relative energies of the B3LYP/6-31G(d)/LANL2DZ optimized geometries for [(dmpb) $Rh^+(C_2H_4)_2$]; (b) (bottom) scatter plot of pseudorotation phases ϕ, ψ for transition metal complexes bearing 1,4-diphosphanylbutane (●) , diop (■) fragments contained in CSD and projection of pseudorotation map for the twist-boat ⇌ boat forms of cycloheptane

Complexes bearing chiral diop-type ligands provide an interesting example of the *trans* fusion of a dioxolane ring to a seven-membered chelate ring. According to Hendrickson,[9a] *trans* fusion of cyclopentane to cycloheptane should be most favoured at either 2e-3e or 3e-4e of the twist chair that correspond to the 4e-5e-TC_6 and 4e-5e-TC_7 conformations in our definition. In fact, most structures examined by X-ray analysis reveal a 4e-5e-{C_4-TC_7} conformation and several structures were found in a 4e-5e-TC_6 conformation, as illustrated in Figure 1. The *trans* fusion across the 4−5 bond to the B_3 = B_6* conformation requires 4a-5e or 4e-5a orientation with a fusion angle of approximately 120° and, thus, would strain the system. On the contrary, the B_4 = B_5* conformation allows an energetically more favourable fusion at the 4e-5e position. This conformer is likely to be the most stable boat-shaped form of the diop chelates (Figure 2).

Variable-Temperature NMR Studies of Complexes

The Rh^I complexes with dppb (**1**), (*R*,*R*)-diop (**2**) and (*R*,*R*)-HO-diop (**3**) exhibit temperature-dependent NMR spectra. The sharp doublet in the $^{31}P\{^1H\}$-NMR spectrum of **2** in a mixture of $CHCl_2F/CD_2Cl_2$ (3:1) at 250 K (Figure 3) undergoes coalescence at approximately 188 K as the

sample is cooled. Two doublets separate below 179 K in a 1:0.45 intensity ratio, similar to those briefly described by Brown and Chaloner.[7]

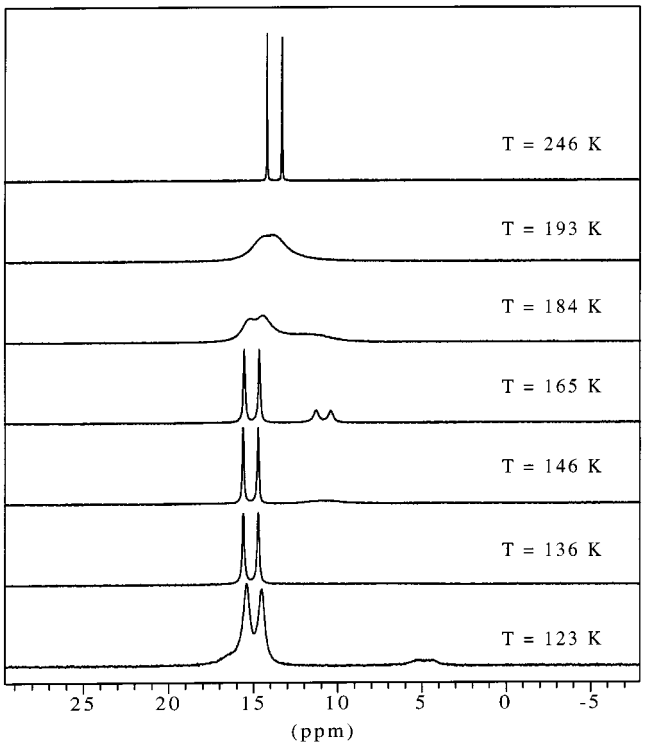

Figure 3. Variable-temperature $^{31}P\{^1H\}$-NMR spectra of complex **2** in $CD_2Cl_2/CHFCl_2$

While the downfield doublet at a chemical shift of δ = 14.7 due to the major isomer **A** sharpens as the temperature is lowered further, the upfield signals at δ = 10.5 of isomer **B** broaden and then separate below 123 K into two broad signals with Rh coupling at $\delta \approx 5.2$ and 15.9. The variable-temperature spectra of the complexes **1** and **3** show the same behaviour as for **2**, if one takes into account that the phosphorus atoms in **3** are diastereotopically not equivalent. The low-temperature ^{31}P-NMR data are included in Table 2. It is noteworthy that the resonances of the major species **A** in complex **1** are shifted to lower field compared to that in **2** and **3**. However, those of the minor species **B** in complex **1** exhibit significantly larger differences in chemical shifts than those in compounds **2** and **3**.

Structural Assignment of the Exchanging Sites in Solution

Detailed variable-temperature NMR studies of [(diop-4NMe$_2$)PtCl$_2$] confirmed that the species characterized at low temperature by a downfield phosphorus resonance has a rigid conformation with C_2 symmetry.[5a] The upfield signal broadens significantly as the temperature is lowered further. This indicates the flexibility of this species and that the C_2 symmetry is time-averaged.[5a] These results are in accordance with our observations of ^{31}P-NMR spectra of complexes **2** and **3**. Inspection of the X-ray data for [(HO-diop)Rh(cod)]BF$_4$ reveals two conformations for the seven-membered chelate in the solid state.[17] One of the ring conformations can be described as C_4 chair and the other as distorted B_5 boat (Figure 4).

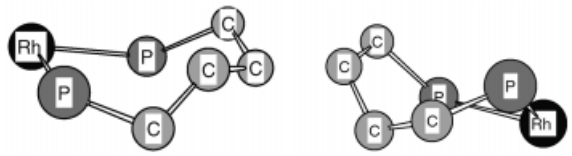

Figure 4. View of two chelate ring conformations as present in crystalline complex **3**: C_4 (left) and distorted B_5 (right)

Therefore, we assign the AMX pattern of the isomer **B** in the spectra of **2** and **3** at 123 K to the dissymmetric distorted B_5 structure which undergoes pseudorotation with an appreciable barrier to give a symmetrized doublet above 155 K. Note that the pseudorotation segment $C_5 \rightleftharpoons TC_1 \rightleftharpoons C_4$ connects two enantiomeric chair forms. According to the consideration in the first section this pseudorotation should be almost completely free. The symmetrical doublet at δ = 15 of the isomer **A** may be assigned to this fast equilibrium, because two phosphorus atoms remain equivalent just at very low temperatures. The dynamic phenomenon observed in the ^{31}P-NMR spectra between 210 K and 180 K is caused by the interconversion of two families of conformations. These assignments are consistent with recent solution-NMR investigations of similar compounds.[5a]

By analogy, it appears reasonable to assign the twist-chair conformation to the species **A** in the conformational equilibrium of the complex without a rigid backbone. The low-field shift of the **A** resonances in the case of complex **1** in comparison with those of complexes **2** and **3** is caused by other twist-chair conformations being appreciably popu-

Table 2. $^{31}P\{^1H\}$-NMR data of the complexes in $CD_2Cl_2/CHFCl_2$[a,b]

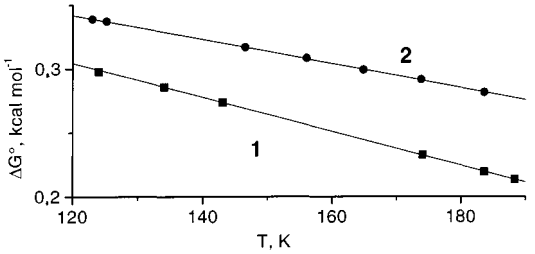
lated in the fast conformational equilibrium. According to X-ray data the chelate ring in complex **1** has a B_3-shaped structure in the solid state.[18] Based on these data we assign the B_3-like conformer to the species **B** in solution. Evidently, this B_3-shaped moiety exhibits a much larger difference in chemical shifts than the B_5-like geometry.

Thermodynamic and Kinetic of Exchange

The equilibrium constants $K = [\mathbf{B}]/[\mathbf{A}]$ for the $\mathbf{A} \rightleftharpoons \mathbf{B}$ interconversion for the complexes **1** and **2** have been calculated at different temperatures by ^{31}P-NMR integration. The evaluated energy differences $\Delta G^\circ = -RT \ln K$ have been plotted against T giving a satisfactory linear least-squares fit (Figure 5). Linear-regression analysis of these data allows calculation of the enthalpy and entropy values which are shown in Table 3. The obtained values for ΔS° suggest that the boat-shaped conformation has a substantially higher entropy than the chair-like and is predominant at higher temperatures.



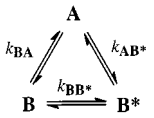


Figure 5. Plots of ΔG° vs. temperature obtained by $^{31}P\{^1H\}$-NMR integration for complexes **1** (■) and **2** (●)

Table 3. Thermodynamic and kinetic data for the complexes[a,b]

Complex	**1**	**2**
ΔG°_{AB}	0.22	0.28
ΔH°_{AB}	0.45 ± 0.02	0.46 ± 0.02
ΔS°_{AB}	1.3	0.9
$\Delta G^{\neq}_{AB}$	8.6	8.0
$\Delta H^{\neq}_{AB}$	8.4 ± 0.1	7.6 ± 0.2
$\Delta S^{\neq}_{AB}$	1.5 ± 1	3 ± 1
$\Delta G^{\neq}_{BB'}$	5.9	5.3
$\Delta H^{\neq}_{BB'}$	6.0 ± 0.1	5.9 ± 0.1
$\Delta S^{\neq}_{BB'}$	−1 ± 1	−3 ± 1

[a] ΔG and ΔH in kcal mol^{-1}, ΔS in cal mol^{-1} K^{-1}. – [b] All ΔG are given at 184 K.

By application of WIN-DYNAMICS,[19] spectra were simulated and iteratively fitted to the experimental spectra in order to evaluate the rate constants at various temperatures. The line-shape analysis was performed on the basis of the three-site exchange model (Scheme 2).

Scheme 2. Three-site exchange

The resulting rate constants as a function of the temperature were used to construct an Eyring plot (Figure 6). The activation parameters obtained from linear regression analysis are given in Table 3. The activation entropies are close to zero. The values of activation energy $\Delta G^{\neq}$ for complex **2** are lower than those found for complex **1**.

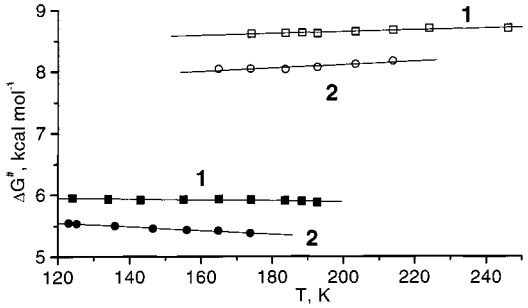

Figure 6. Eyring plots of $\Delta G^{\neq}$ vs. temperature from the kinetic data for compexes **1** (□, ■) and **2** (○, ●); the open symbols are the data for the $\mathbf{B} \rightleftharpoons \mathbf{A}$ exchange and the closed ones for the $\mathbf{B} \rightleftharpoons \mathbf{B}$ exchange

Discussion

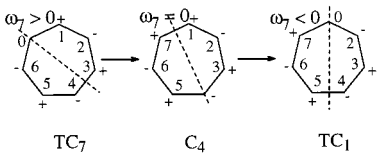
NMR investigations by Brown and Chaloner[7] show the conformational flexibility of the seven-membered diop chelate ring. A dynamic equilibrium between at least two different basic conformers was manifested. Activation energies between 9.6 to 11.7 kcal mol^{-1} were obtained for Pt, Pd and Ni complexes at 220−250 K.[7][20] We have found activation energy values $\Delta G^{\neq}$ of the boat-to-chair interconversion of 8.6 kcal mol^{-1} in complex **1** and 8.0 kcal mol^{-1} in **2** at 184 K. These values are comparable with the barrier for chair-to-boat interconversion of about 8.5 kcal mol^{-1} in cycloheptane.[9c,21] The lower inversion barrier in the diop complex is in accordance with the diminished cyclohexane interconversion barrier by fusion with a cycloheptane ring and reflects increasing strain energy in the ground state.[22]

Nevertheless, the experimentally observed C_2 symmetry of the chair conformation is apparently time-averaged. The ab initio calculations show that part of a family of flexible conformers $TC_7 \rightleftharpoons C_4 \rightleftharpoons TC_1 \rightleftharpoons C_5 \rightleftharpoons TC_2$ form a large potential well with minima separated by very low barriers. This explains why X-ray studies show in most cases an unsymmetrical C_4 or TC_7 conformation,[6] but low-temperature NMR studies reveal C_2-symmetrical species. The pseudorotation in the boat family proceeds with higher activation energy. The observed barriers are 5.9 kcal mol^{-1} for **1** and 5.3 kcal mol^{-1} for **2**. These are much higher than calculated for cycloheptane (0.5 kcal mol^{-1}),[15] but are in surprisingly good accordance with that calculated using a simple MMX model for [(dmpb)Rh$^+$(cod)] (5.5 kcal mol^{-1}). Note that for diop-type chelates pseudorotation $B_4 \rightleftharpoons B_5$ proceeds via TB_1.

In fact, entropy favours the boat form, whereas the chair-like conformation is enthalpically stabilized and predominates at 124 K by only $\Delta G^\circ = 0.30$ kcal mol^{-1} in complex **1** and by $\Delta G^\circ = 0.34$ kcal mol^{-1} in **2**. Because of the coun-

tertrend of $\Delta H°$ and $\Delta S°$ there is a cross-over of the equilibrium constant K = [**B**]/[**A**] at about 180−200 K. Above that temperature the boat conformation is more stable. The relatively large magnitude of the entropy difference $\Delta S°$ = 0.9−1.3 cal K^{-1} mol^{-1} comes as somewhat of a surprise. On the other hand, the error in the $\Delta S°$ determination consists of the inaccuracy in temperature determination and the error of integration of the broadened lines in the NMR spectra at low temperatures. We could not ascertain the exact source of the error. Thus, the given values of ΔS should be taken with care.

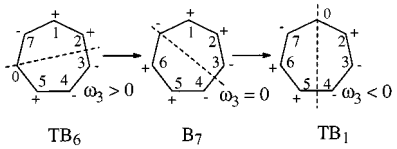
We can conclude that seven-membered diphosphane chelates exist in two conformations, chair- and boat-like, with the position of equilibrium depending on the temperature. The $\{TC_2\text{-}C_5\}$ = $\{TC_7\text{-}C_4\}$ structure represents the enthalpically most stable conformation and undergoes pseudorotation readily. The other conformer has the distorted B_3 = B_6 geometry for dppb and distorted B_4 = B_5 arrangement for diop chelates. This moiety undergoes a conformational inversion with a higher barrier.



Experimental Section

General Remarks: All solvents were freeze-pump-thaw-degassed using a vacuum line and stored under argon. The diolefin complexes [(dppb)Rh(cod)]BF_4 and [(diop)Rh(cod)]BF_4 were prepared by standard methods from ligand and [(acac)Rh(cod)] by treatment with HBF_4.[23] The preparation of [(HO-diop)Rh(cod)]BF_4 has been previously described.[24] The NMR samples were prepared under an inert gas and the solvents were transferred under vacuum. The solution was degassed with one freeze-pump-thaw cycle and then the tube was sealed. − The NMR spectra were recorded with a Bruker ARX400 spectrometer. The ^{31}P chemical shifts are reported in δ units relative to H_3PO_4. The temperature of the NMR probe was calibrated using a methanol temperature standard and the low-temperature range by extrapolation of the difference in chemical shifts of CHF_2OH in ^1H-NMR spectra.

Molecular Mechanics Calculations: Except where noted, the molecular mechanics parameters were set to the PCMODEL[25] default values. The force field about the metal ion was designed so that the metal−ligand distances and the ligating atom−ligating atom interactions determined the shape of the coordination sphere. Default bending force constant for ideal P−Rh−P angle of 90° in a square-planar geometry was used. All other metal-dependent interactions were treated exactly as in a points-on-a-sphere approach.[26] This was accomplished by setting the L−Rh−L angle parameters, and L−Rh−L−A and Rh−L−A−B torsional parameters to zero.



Ab Initio Calculations: All calculations were performed using the B3LYP hybrid functional. The full geometry optimizations have been carried out with LANL2DZ basis for rhodium, associated with the relativistic effective core potential, and the 6-31G(d) basis set for all other atoms. The calculations were performed with the program GAUSSIAN 94.[27]

Appendix: To calculate the energy along a pseudorotation path note that the sequence $TC_i \rightarrow C_{i-3} \rightarrow TC_{i+1}$ represents the elementary steps in the chair pseudorotation. Moreover, bond dihedral angles ω_i in one TC_i conformation change sign going on to the next TC_{i+1} conformation in the pseudorotation sequence as shown in Scheme 3.

Scheme 3. Sequence of the elementary steps in the chair pseudorotation

In addition, signs of the out-of-plane displacements (z coordinates) of each cyclic atom are drawn here for visual representation of conformation. The sequence $TB_i \rightarrow B_{i+1} \rightarrow TB_{i+2}$ constructs a pseudorotation in a boat family (Scheme 4).

Scheme 4. Sequence of the elementary steps in the boat pseudorotation

Therefore, each intermediate form between two twisted forms is unequivocally defined by a corresponding torsional angle. That is ω_i for the $TC_i \rightarrow TC_{i+1}$ movement and ω_{i+4} for the $TB_i \rightarrow TB_{i+2}$ conversion. Starting at the value of the initial twisted form the magnitude of ω was incremented (decremented) in 5° or 10° steps until the next twisted conformation was reached and the conformation of minimum energy was found for each given value of ω. The Cartesian coordinates of the optimized (by keeping ω constant) geometries were transformed into the puckering coordinates. The energies thus obtained for each value of ω were plotted against a phase angle ϕ and connected by an interpolation curve to give cuts of the energy surface along the pseudorotation tracks between two of each twisted forms. These cuts were combined in common plots for chair and boat pseudorotations, as shown in Figures 1 and 2.

Catalytic Transfer Hydrogenation of Ketones with $KHCr(CO)_5/HCO_2H/Et_3N$ Systems[+]

Jean-Jacques Brunet,*[a] Remi Chauvin,[a] and Pascale Leglaye[a]

Keywords: Chromates / Catalytic transfer hydrogenation / Hydrogenations / Reductions / α,β-Unsaturated ketones / Asymmetric synthesis

In the presence of a HCO_2H/Et_3N (1:1) mixture, $KHCr(CO)_5$ is an efficient catalyst precursor for the transfer hydrogenation of ketones in THF at room temperature. $KHCr(CO)_5$ is also a stoichiometric reagent for the selective reduction of the carbon–carbon double bond of α,β-unsaturated ketones.

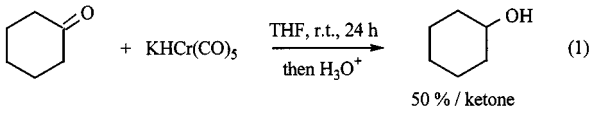
Introduction

Main-group hydrides, such as the well-known boron and aluminium hydrides, are widely used in organic synthesis as reducing agents for a large range of functional groups and derivatives have been designed which exhibit very useful chemoselectivities.[1] These reagents must be used in stoichiometric quantities. In contrast, transition-metal hydrides are much less widely used, even though a large number of easily accessible derivatives are available. These compounds are interesting alternatives because of the possibility of using them in catalytic amounts in the presence of molecular hydrogen or of a hydrogen transfer agent.[2] As an extension of our work on carbonylhydridoferrates,[3,4] we recently became interested in the chromium series, and we developed a very easy and reproducible preparation of $K^+[HCr(CO)_5]^-$.[5]

The reactivity of $[PPN]^+[HCr(CO)_5]^-$ {$[PPN]^+$ = bis(triphenylphosphoranylidene)ammonium} has been previously investigated by Darensbourg et al.[6–8] This reagent has been shown to reduce selectively acid chlorides into aldehydes without further reduction to alcohols.[7] $[PPN]^+[HCr(CO)_5]^-$ itself is also inactive towards ketones, but becomes an efficient reducing agent in the presence of one equivalent of acetic acid (H^+ assistance and in situ protonolysis).[8]

Two catalytic systems involving carbonylchromates and molecular hydrogen have also been reported for the hydrogenation of ketones. Firstly, the system $Cr(CO)_6$/MeONa in methanol is active at 100–120°C under 100 bar of H_2.[9] Secondly, the complex $[PPN]^+[Cr(CO)_5(OAc)]^-$ is an active catalyst precursor for the hydrogenation of ketones in THF at 125°C under 40 bar of H_2.[10] In these catalytic reactions, $[HCr(CO)_5]^-$ is believed to be the active species.

To the best of our knowledge, no report has been published of the use of carbonylchromium complexes as catalyst precursors for the reduction of ketones by hydrogen transfer from easy-to-handle hydrogen donors.[11] Such reactions do not require the use of high-pressure reactors.



We report here that $K^+[HCr(CO)_5]^-$ (**1**) does react with ketones in THF at room temperature under *mild* conditions. Moreover, in the presence of the HCO_2H/Et_3N combination as a hydrogen transfer agent, *catalytic* reduction to the corresponding alcohols is achieved under atmospheric pressure at room temperature.

Results and Discussion

Stoichiometric Experiments

We have previously reported that $K^+[HFe(CO)_4]^-$ does not reduce normal ketones in the absence of a Brønstedt acid, either in THF or in methanol.[12] In contrast, we have now found that the chromium analogue **1** reacts with ketones to give the corresponding alcohol *in the absence of any Brønstedt acid*.

Treating cyclohexanone with **1** in THF at room temperature for 24 h resulted in 50% reduction (GC analysis) to cyclohexanol after hydrolysis of the reaction medium.

(1)

There is thus a significant difference in reactivity between $K^+[HCr(CO)_5]^-$ and $[PPN]^+[HCr(CO)_5]^-$ (vide supra). This phenomenon may be ascribed to K^+ assistance, as previously demonstrated for the hydrogenation of ketones with potassium hydrido(phosphane)ruthenate complexes.[13] From a more general point of view, and as previously observed for $[HFe(CO)_4]^-$,[4] the reactivity of $[HCr(CO)_5]^-$ seems to be strongly dependent on the associated cation, due to ion-pairing effects.[14] For example, it has been reported that $[PPN]^+[HCr(CO)_5]^-$ exchanges with MeOD (or D_2O) in THF at room temperature to give the corresponding deuteride $[PPN]^+[DCr(CO)_5]^-$[8] whereas $[Et_4N]^+[HCr(CO)_5]^-$ has been reported to react vigorously with MeOH at room temperature with H_2 evolution and formation of the dinuclear complex $[HCr_2(CO)_{10}]^-$[9] (however,

the reaction with 1-phenylethanol requires heating to 75°C). Similarly, we observed that, at room temperature, $K^+[HCr(CO)_5]^-$ slowly reacts with cyclohexanol in THF with formation of the dinuclear $[HCr_2(CO)_{10}]^-$ species.

If the reaction of **1** with cyclohexanone is conducted for longer reaction times (120 h), the reduction yield is not increased. After 24 h of reaction, ^{1}H-NMR analysis of the reaction medium (after evaporation of the solvent and redissolution in [D$_8$]THF) indicates that the starting complex **1** ($\delta_{CrH} = -7.05$) had been consumed and that the dinuclear hydrido anion $[HCr_2(CO)_{10}]^-$ ($\delta_{CrH} = -19.56$) is the only detectable hydride species. ^{13}C-NMR spectroscopy confirms the presence of $[HCr_2(CO)_{10}]^-$ ($\delta_{CO} = 222.4$ and 227.3) and suggests the presence of $[Cr_2(CO)_{10}]^{2-}$ ($\delta_{CO} = 243.8$ and 244.1).[15] The IR spectrum mainly exhibits the characteristic bands of $KHCr_2(CO)_{10}$ [2030 cm^{-1} (w), 1940 (vs) and 1882 (br.)], but also less intense bands at 2050 cm^{-1} (vw), 1919 (m), 1880 (br.) and 1766 (m) which may be ascribed to $[Cr_2(CO)_{10}]^{2-}$ or mixture of the latter with $[ROCr(CO)_5]^-$ (R = cyclohexyl) on the basis of literature data.[8][9] Unexpectedly, a ν_{OH} band corresponding to free cyclohexanol was also observed *before* hydrolysis of the reaction medium.

Control experiments indicated that the dinuclear hydride $KHCr_2(CO)_{10}$ reduces cyclohexanone in less than 5% yield after 72 h at room temperature in THF. It is thus reasonable to propose that **1** is the active species for the reduction. The first step of the reaction could occur by hydride transfer, generating an alkoxocarbonylchromate species (Equation 2).[9]

$$[HCr(CO)_5]^- + R^1R^2C{=}O \rightleftharpoons [R^1R^2CHOCr(CO)_5]^- \quad (2)$$

According to literature data, alkoxocarbonylchromates may further react with $[HCr(CO)_5]^-$, to give $[Cr_2(CO)_{10}]^{2-}$ (Equation 3)[9] and/or $[HCr_2(CO)_{10}]^-$ (Equation 4).[8]

$$[R^1R^2CHOCr(CO)_5]^- + [HCr(CO)_5]^- \longrightarrow R^1R^2CHOH + [Cr_2(CO)_{10}]^{2-} \quad (3)$$

$$[R^1R^2CHOCr(CO)_5]^- + [HCr(CO)_5]^- \longrightarrow [R^1R^2CHO]^- + [HCr_2(CO)_{10}]^{2-} \quad (4)$$

Quantitative conversion of the ketone thus requires another in situ evolution of the alkoxochromium complex, for example by protonation by HX (Equation 5) under conditions where $[HCr(CO)_5]^-$ does not decompose.

$$[R^1R^2CHOCr(CO)_5]^- + HX \longrightarrow R^1R^2CHOH + [XCr(CO)_5]^- \quad (5)$$

For a catalytic version, the carbonylhydridochromate $[HCr(CO)_5]^-$ has to be regenerated from $[XCr(CO)_5]^-$. This could be expected from the formato complex $[HCO_2Cr(CO)_5]^-$ which has been shown to undergo a rapid decarboxylation process according to Equation 6.[16]

$$[HCO_2Cr(CO)_5]^- \rightleftharpoons [HCr(CO)_5]^- + CO_2 \quad (6)$$

Formic acid itself cannot play the role of HX for the introduction of the formate moiety. Indeed, reaction of cyclohexanone with stoichiometric amounts of $KHCr(CO)_5$ in the presence of 1 equiv. of formic acid in THF resulted in less than 5% reduction to cyclohexanol after 24 h at room temperature (the same result was obtained by using acetic acid). These results are in contrast to the reported 95% yield reduction of cyclohexanone with $[PPN]^+[HCr(CO)_5]^-$/AcOH for 4 h in THF.[8] Both formic and acetic acids are too strong for the $KHCr(CO)_5$ base in THF, and preferentially lead to $KHCr_2(CO)_{10}$. However, when the strength of formic acid is moderated by the presence of triethylamine, the stoichiometric reduction of cyclohexanone (ketone/$KHCr(CO)_5$/HCO_2H/Et_3N in a 1:1:1:1 ratio) leads to a reduction yield of up to 65% after 24 h at room temperature. Using a 1:1:5:5 ratio of reagents resulted in a quantitative reduction to cyclohexanol after 6 h. By comparison, Noyori et al. recently reported the use of a different HCO_2H/Et_3N combination (5:2 azeotropic mixture[17]) for the ruthenium(II)-catalysed asymmetric transfer hydrogenation of ketones.[18]

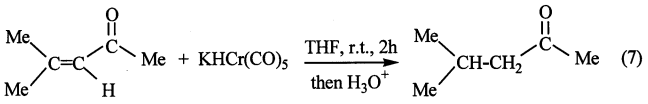
Control experiments indicated that the formate ion alone [which could have been useful for displacing the unsaturated "Cr(CO)$_5$" moiety from the alkoxochromate, thus preventing $[HCr(CO)_5]^-$ consumption (Equations 3 and 4)] is not sufficient to promote the observed reactivity. Indeed, the association $KHCr(CO)_5/HCO_2K$ reduces cyclohexanone in the same yield than **1** alone (50%, 24 h at room temperature).

Catalytic Experiments

The system $KHCr(CO)_5/HCO_2H/Et_3N$ (1:5:5 ratio) was tested for the catalytic reduction of cyclohexanone. In the presence of stoichiometric amounts of HCO_2H/Et_3N as a hydrogen transfer agent, cyclohexanone is almost quantitatively (95%) reduced to cyclohexanol with 20% $KHCr(CO)_5$ after 24 h at room temperature in THF. Using lower amounts of **1** is also possible (10% $KHCr(CO)_5$: 83% yield after 24 h; 5% $KHCr(CO)_5$: 70% yield after 24 h) but complete conversion of cyclohexanone is achieved only after several days.

Performing the catalytic reaction at 0°C resulted in a decrease in reaction rate. However, if after 24 h at 0°C the temperature is raised to room temperature, the expected catalytic activity is restored. For reactions conducted at 60°C, the cyclohexanol yield is lower than 50% (24 h) and no longer evolves, suggesting that the catalytically active species have been destroyed competitively.

The above system was tested for the catalytic reduction of some representative ketones at room temperature (Table 1). For comparison, the experiments were stopped after 24 h.



As expected from literature data on the reduction of ketones with hydridometallates,[8,9,19] cyclohexanones are more rapidly reduced than methyl ketones. In the case of 4-*tert*-butylcyclohexanone, the preponderant formation of the *trans* alcohol has previously been explained by the steric demand of the "$OCr(CO)_5$" group of the alkoxocarbonylchromate formed in the first step of the reaction (Equation 2).[9] This explanation also stands for the present system.

Table 1. Catalytic reduction of ketones with 20% $KHCr(CO)_5$ in the presence of HCO_2H/Et_3N[a,b]

	conversion (%)[c]	products[d] (yield%)[c]
2-hexanone	38	2-hexanol (38)
acetophenone	25	1-phenyl ethanol (25)
3-methyl-2-butanone	45	3-methyl-2-butanol (45)
cyclohexanone	95	cyclohexanol (95)
4-*tert*-butylcyclo-hexanone	80	4-*tert*-butylcyclohexanol (80)[e]
mesityl oxide	20	4-methyl-2-pentanone (20)

[a] Reactions conducted with 100 mg of $KHCr(CO)_5$ (0.43 mmol) in THF (10 mL) for 24 h at room temp. – [b] Ketone/$KHCr(CO)_5$/HCO_2H/Et_3N = 1:0.2:1:1. – [c] Determined by GC analysis with internal standards. – [d] Identified by GC retention times and GC-MS analysis. – [e] *cis*/*trans* ratio = 33:67.

The selective reduction of the carbon–carbon double bond of mesityl oxide to give 4-methyl-2-pentanone (Table 1) is noteworthy. This specificity of $KHCr(CO)_5$ has been confirmed by a stoichiometric experiment (*in the absence the HCO_2H/Et_3N combination*) leading to 4-methyl-2-pentanone in > 95% yield after 2 h at room temperature (Equation 7).

(7)

For this reaction, $KHCr(CO)_5$ is more reactive than $KHFe(CO)_4$ but exhibits the same chemoselectivity. Indeed, it has been shown that *under the same conditions*, $KHFe(CO)_4$ reduces mesityl oxide to give 4-methyl-2-pentanone in less than 25% yield after 24 h [literature data indicate that, in the presence of excess $Fe(CO)_5$, $NaHFe(CO)_4$ reduces mesityl oxide to 4-methyl-2-pentanone in 96% yield after 24 h *at 60°C* in MeOH[20]].

In control experiments, it has been shown that $KHCr_2(CO)_{10}$ (1 equiv.) also selectively reduces mesityl oxide under the conditions of Equation 7, but 4-methyl-2-pentanone was formed in less than 10% after 2 h. Thus, for this reaction, $KHCr(CO)_5$ is also much more reactive than $KHCr_2(CO)_{10}$. This order of reactivity between the mono- and dinuclear carbonylhydridochromates is in contrast to what has been reported in the iron series where $NaHFe_2(CO)_8$ is at least 26 times more reactive than mononuclear $NaHFe(CO)_4$ for the reduction of α,β-unsaturated ketones.[2,20,21]

Finally, exploratory experiments were conducted on a possible enantioselective catalytic system based on the chiral amine, quinine, instead of Et_3N. The system $KHCr(CO)_5$/(–)-quinine/HCO_2H (1:5:5 ratio.) reproducibly reacts with acetophenone (5 equiv.) in a catalytic manner to yield 1-phenylethanol in 45% yield and 10% ee (120 h in THF at room temperature).

Work is in progress to obtain a better mechanistic understanding of the observed reactivity of $KHCr(CO)_5$ (in particular, a catalytic cycle is to be sought) and to extend its use as reagent or catalyst in organic synthesis.

Experimental Section

General: All reactions were performed under argon using standard Schlenk tube techniques. THF was distilled under argon from Na/benzophenone. – NMR: Bruker AC 200 or AMX 400 apparatus. – IR: Perkin–Elmer 1725X FT-IR spectrometer with CaF_2 windows (0.5 mm). – GC: Hewlett–Packard HP 5890 apparatus equipped with a 30-m capillary Rt-β-DEXm chiral column. – GC MS: Hewlett–Packard HP 6890 apparatus (EC Wax, 30-m capillary column) equipped with an HP 5973 M ion detector. – $KHCr(CO)_5$[5] and $KHFe(CO)_4$[22] were prepared from the corresponding $Cr(CO)_6$ or $Fe(CO)_5$ and technical KOH, according to the reported procedures. $KHCr_2(CO)_{10}$ was prepared as follows. A solution of 86% KOH (0.290 g, 4.55 mmol) in 7.5 mL of absolute ethanol was added to 20mL of a CH_2Cl_2 solution of $Cr(CO)_6$ (0.500 g, 2.27 mmol). After stirring for 10 min, the solution was concentrated to 4 mL. Water (5 mL) was added and the solution stirred for 0.5 h at room temp. THF (2 × 10 mL) was added and each time concentrated to dryness to remove any trace of water. The resulting solid was dissolved in THF (20 mL), the solution filtered under argon, and concentrated to dryness to leave an orange solid (0.434 g, 90% yield). – IR (THF) $\tilde{\nu}$ = 2030 cm^{-1} (w), 1940 (s) and 1878 (vs). – ^1H NMR (CD_3CN, 200 MHz): δ = –19.56 (s).

Stoichiometric Reductions of Ketones: The general procedure is exemplified for the reduction of cyclohexanone. A solution of cyclohexanone (223 μL, 2.16 mmol) and nonane (138 mg, 1.08 mmol) in THF (10 mL) was cannulated to solid $KHCr(CO)_5$ (500 mg, 2.16 mmol). After stirring for 24 h at room temp., the solution was treated with 1 N HCl (10 mL) and diethyl ether (10 mL) was added. The aqueous phase was then extracted with diethyl ether (2 × 10 mL) and the ethereal phase analysed by GC. For complementary experiments (see text), additives (HCO_2H, AcOH, HCO_2K, or HCO_2H/Et_3N mixtures) were dissolved in the THF solution containing cyclohexanone before it was cannulated to solid $KHCr(CO)_5$.

Catalytic Reduction of Ketones: The general procedure is exemplified in the case of cyclohexanone. Triethylamine (300 μL, 2.16 mmol) and technical (95–97%) formic acid (82 μL, 2.16 mmol) were added to a solution of cyclohexanone (223 μL, 2.16 mmol) and nonane (138 mg, 1.08 mmol) in THF (10 mL). The resulting solution was then cannulated into a Schlenk flask containing solid $KHCr(CO)_5$ (100 mg, 0.43 mmol) and a stirring bar. The flask was closed with a glass stopper and the solution magnetically stirred at room temp. Aliquots (0.5 mL) were hydrolysed with dilute HCl (0.5 mL), extracted with diethyl ether (0.5 mL) and analysed by GC.

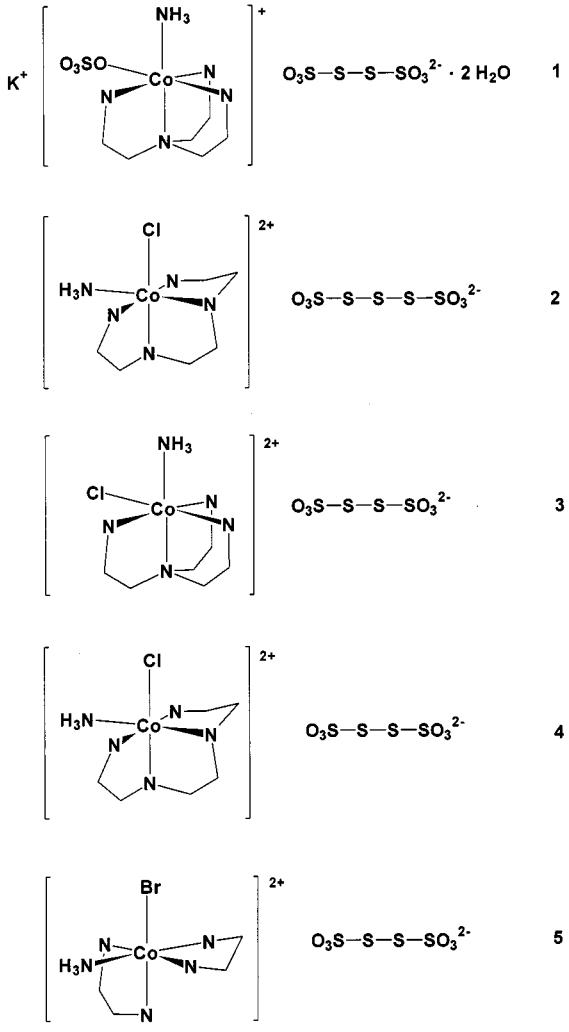
Syntheses of $K[Co(tren)(NH_3)(SO_4)](S_4O_6)\cdot 2(H_2O)$ and of $[cis\text{-}\alpha\text{-}Co(trien)(NH_3)Cl](S_5O_6)$ – Compounds Produced by Hydrolytic Cleavage of Sulfur–Sulfur Bonds of the Tetrathionate Anion



Hyungphil Chun[a] and Ivan Bernal*[a]

Keywords: Tetrathionates / Pentathionates / Sulfato ligands / Cobalt(III) complexes / *Thiobacillus ferrooxidans*

$K[Co(tren)(NH_3)(SO_4)](S_4O_6)\cdot 2(H_2O)$ (**1**) and $[cis\text{-}\alpha\text{-}Co(trien)(NH_3)Cl](S_5O_6)$ (**2**) have been prepared unexpectedly while attempting to obtain crystals suitable for X-ray diffraction of $[Co(tren)(NH_3)Cl](S_4O_6)$ (**3**) and of $[cis\text{-}Co(trien)(NH_3)Cl](S_4O_6)$ (**4**), respectively. **1** is derived from **3** by hydrolysis of the tetrathionate anion resulting in a sulfato moiety which displaces the chloro ligand from the coordination sphere of the metal center. **2** is derived from **4** by hydrolysis of the tetrathionate anion followed by reformation into pentathionate anion and H_2S, as described in previous chromatographic work by Steudel. Compounds **1** and **2** have been characterized by elemental analyses and by single-crystal X-ray diffraction studies.

Some time ago, we discovered that the compound $[cis\text{-}Co(en)_2(NH_3)Br](S_4O_6)$ (**5**) crystallizes as a conglomerate, as we had hoped.[1,2] (Conglomerate crystallization is the phenomenon whereby a racemic solution produces a mechanical mixture of enantiomorphically pure single crystals of both handedness.) By a crystal structure determination, we also demonstrated that the parent compound, $[cis\text{-}Co(en)_2(NH_3)Br]Br_2$, from which **5** was prepared was a racemate[2]. At the time, we argued that crystallization as a conglomerate was justified since both cation and anion are chiral, as one could expect for chiral recognition to occur giving rise to specificity and, indeed, that was the purpose of using the tetrathionate anion to begin with.[1] Interestingly, we found that the $S_4O_6^{2-}$ anion is hydrogen-bonded to the cations, via the SO_3 fragments, in exactly the same fashion as the $-SO_3$ of bromocamphorsulfonate when used as resolving agent for the same Co^{III} cation.[3,4] Finally, the sodium salt of the $S_4O_6^{2-}$ anion crystallizes as a conglomerate.[5]

At the time, we indicated[1] that we planned to examine a series of polythionates of the *cis*-amminehalo cations in order to establish whether the chirality of the countercation played a role in the selection of the crystallization pathway. In this report, we detail the results of our studies using tetrathionate with two different Co^{III} cations, results which produced novel and unexpected chemical products. Moreover, these results are in revealing and interesting agreement with the pioneering work of Steudel and associates,[6] who reached similar conclusions to ours using totally different sources of information.

Results and Discussion

As indicated by the results listed in Table 3, the structures are well behaved, that of **1** being a of a little higher quality than that of **2** caused by larger number of weak data present in the crystals of the latter substance and by a small amount of disorder present in C(6) of **2**; for details of the disorder, see below.

Upon solving the structures of the two compounds, we realized that marked changes from the expected compounds had occurred. This is evident from Figures 1, 2 (see also Tables 1, 2) which, to our great surprise, show the true molecular and stereochemical nature of the two compounds – a fact that was later verified by elemental analyses.

What those results demonstrate is that a $S-SO_3$ bond had been broken and that the terminal sulfur atom had been oxidized to S^{6+} creating a sulfato moiety. At the same time the chloro ligand, initially present in the Co^{III} substrate, has been eliminated and a sulfato ligand has replaced it using a single oxygen atom to coordinate the metal center. At a later time, the solubility limit of **1** was reached and crystals began to be deposited. A check of the literature revealed the following facts:

(a) the Cambridge Structural Database (CSD)[7] lists no mononuclear 3-d metal complex in the 3+ charge state containing a monodentate sulfato ligand. There are some 3-d metal complexes carrying such ligands; however, they are all 2+ complexes. Among them, the majority are Cu^{2+} complexes, some Zn^{2+} and three Co^{2+} examples. A large

number of sulfato complexes are known in which the ligand bridges two or more metal centers or acts as a bidentate ligand to a single metal center. We also examined the Inorganic Crystal Sturucture Database(ICSD)[8] which does not list a single example of a trivalent metal center bearing a monodentate sulfato ligand. These facts make compound **1** an interesting rarity.

(b) A check in the literature revealed the presence of a seminal paper by Steudel and colleagues[6] detailing their chromatographic separation experiments during the equilibration of polythionates in carefully controlled media. They reported detecting $S_nO_6^{2-}$ species, where $n = 2\ldots22$. Two equations of the equilibria they proposed are particularly relevant to the results we are reporting. They are:

$$S_4O_6^{2-} + H_2O \rightarrow HS_2SO_3^- + HSO_4^- \quad (1)$$

$$2\ HS_2SO_3^- \rightleftharpoons S_5O_6^{2-} + H_2S \quad (2)$$

All those species were detected in their chromatographic work and, now, we have trapped the sulfate as a ligand to the metal center in **1** and the pentathionate in Equation 2 is the counteranion to the metal center in compound **2**. Thus, the two studies are mutually reinforcing and it is specially pleasing that we were able to obtain the structures of the relevant moieties proposed by Steudel, et al.[6]

The Stereochemistry of 1 and 2

As shown in Figure 1, the cation of **1** consists of a Co^{III} cation surrounded by the four nitrogen atoms of the ligand tren [tris(2-aminoethyl)amine]. The ammine ligand is *trans* to the central nitrogen atom of tren (so-called *p*-mode of binding) and the sulfato ligand is *cis* to the ammine and bound to the metal center by a single oxygen atom. There are two waters of crystallization which are hydrogen-bonded to terminal $-NH_2$. The potassium cation is bonded to oxygen atoms of a terminal $-SO_3$ fragment of the tetrathionate anion (see Figure 4 for further details); finally, the $-SO_3$ fragment at the opposite end of the tetrathionate anion is hydrogen-bonded to the $-NH_3$ hydrogen atoms, as shown in Figure 1.

An interesting stereochemical result is that the S−O bond of the metal-bound sulfate is noticeably longer than those of the other three oxygen atoms which is to be expected since the bound oxygen atom is donating its electron density to the Co^{III} ion. The average value of the S−O distances in the tetrathionate anion is 1.435(4) Å which is significantly shorter than those in the bound sulfato ligand. Finally, the S−S distances within the tetrathionate differ in that the central S−S bond is significantly shorter than the outer two. This result is in close agreement with the values published earlier for compound **5**[1] where the central S−S bond was found to be 2.019(2) Å and the outer ones were 2.111(2) and 2.133(2) Å. The remaining stereochemistry of this molecule is normal and it does not require further comment. Its main importance is the fact that the postulated formation of the sulfate anion has been verified by the accident of trapping it into the cation of **1**.

The stereochemistry of **2** is shown in Figure 2 in which the trien (1,4,7,10-tetraazadecane) ligand is in the *cis*-α configuration. Figure 3 shows that C(6) is disordered (50:50) into its two alternate positions, making that ring either λ or δ, the former being the lowest energy conformation and it is the one shown in Figure 2.

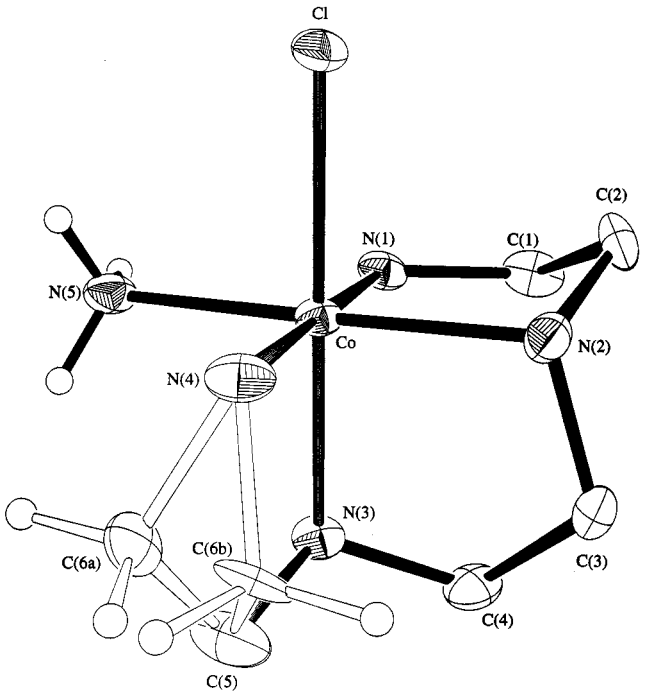

Figure 3. A view of the cation of **2** showing the disorder of the ring containing C(6)

This disorder contributes to the somewhat higher *R* factors listed in Table 3 since occupancy factors and anisotropic thermal parameters are correlated, as is widely known. Also, the partial disorder at C(6) is probably the result of steric hindrance with O(1) which is held in that position by hydrogen bonding to the $-NH_3$ hydrogen atoms, as is clear from Figures 2 and 5. The O(1)−C(6a) contact is 3.804 Å and the O(1)−H(6a2) is 3.282 Å while the hydrogen bond O(1)−H(5g) is 2.201 Å and these contacts are the likely source of the disorder we discovered. We also note that the $-NH_3$ hydrogen atoms were readily found in the structural analysis and were located at very reasonable positions indicating that the disorder problem is strictly localized at C(6). Figure 5 depicts the association of pentathionate anions with the cations in the crystal structure. Its S−O distances are fairly uniform, the longest being 1.444(6) Å and the shortest 1.418(6) Å, with an average of 1.433(7) Å. The small differences are probably due to differences in extents of hydrogen bonding of the two ends of the anion.

Mechanism of the Reactions Observed in 1 and 2

First, let us emphasize the fact that not every *cis*-amminehalo compound of a (polyamine)cobalt complex causes the fragmentation of the tetrathionate anion since we deter-

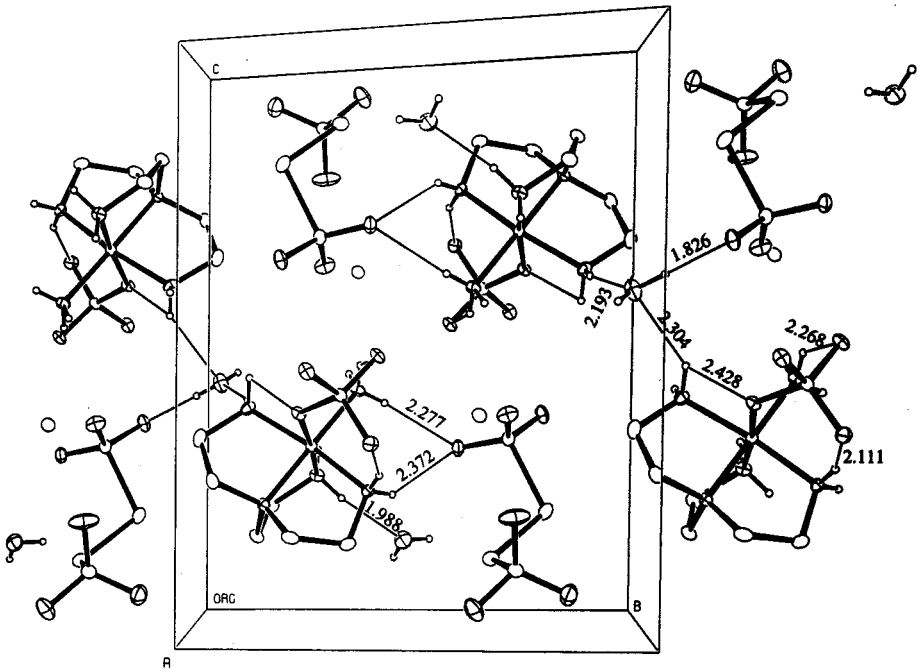

Figure 4. The packing of the ions and waters of crystallization of compound **1**; note the hydrogen bonds holding the pieces together; only the shortest ones are drawn (light lines) and their distances are given; the tetrathionate anions are bonded by a single oxygen atom to only two hydrogen atoms of a cation; in those cases of conglomerate crystallization (see ref.[1]) there were strong hydrogen bonds of the three oxygen atoms of one $-SO_3$ moiety to three hydrogen atoms of a *fac* face of its cation

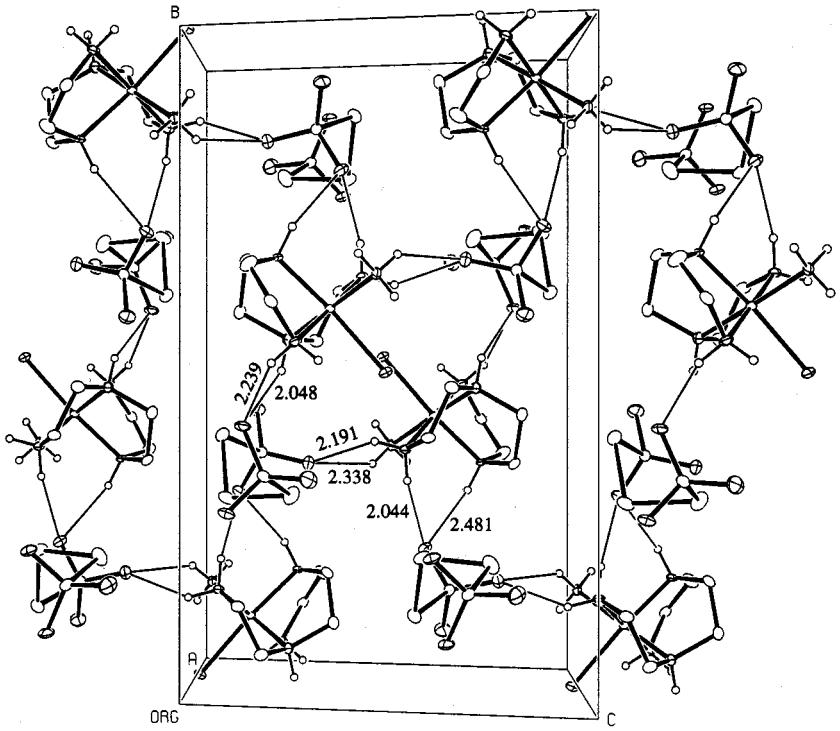

Figure 5. The packing of the ions of compound **2**; only the shortest hydrogen bonds are drawn (light lines) and their distances are given; note that the pentathionate anions are also bonded by two oxygen atoms to two hydrogen atoms of a pair of adjacent cations

mined[1] the crystal structure of [*cis*-Co(en)$_2$(NH$_3$)Br](S$_4$O$_6$) (**5**; conglomerate) and of pre-resolved (+)$_{589}$[*cis*-Λ(δλ)-Co(en)$_2$(NH$_3$)Br](S$_4$O$_6$) (**6**); we saw no evidence of the formation of either sulfate or of pentathionate with those compounds. These observations are the more interesting when viewed against the fact that the spectrochemical series classifies a chloro ligand as being stronger than a bromo ligand. Consequently, if sulfate were formed by cleavage of $S-SO_3$ in **5** and **6** it should more readily displace the bromo ligand from the coordination sphere of the cobalt center in

those cations; however, this is not the experimental result. Therefore, the suggestion is that only specific combinations of polythionates and *cis*-ammine(halo)cobalt cations are capable of giving rise to S−S cleavage reactions. As a matter of fact, we have recently determined the structure of [*cis*-$Co(en)_2(NH_3)Br](S_3O_6)$ and observed no evidence of S−S bond fragmentation, either.[9]

The $-NH_3$ ligands of **1** and **2** have remained bound to their cobalt centers and we note that in the latter the chloro ligand has also remained bound to its metal atom. This is a puzzling result in view of the fact that Equation 1 of the mechanism proposed by Steudel, et al.[6] requires the formation of $HS_2SO_3^- + HSO_4^-$ in order to use the former for the creation of the pentathionate found on **2**. This suggests that the first stage of the reaction (Equation 1; sulfate formation) happens without chloride elimination, concerted or otherwise. The suggestion is, then, that after the formation of the sulfate anion, the chloro ligand of **1** is replaced by a sulfato ligand which loses then its proton − an example of highly charged metal induction of proton elimination, as in the classical case of:

$$[M(H_2O)_6]^{3+} \rightarrow [M(H_2O)_5(OH)]^{2+} + H^+$$

We observed experimentally that such a process of halide elimination and sulfato substitution does not occur in the case of **2**. What could be the possible reason it does not do so?

First, we note that the chloro ligand in **1** is *trans* to a primary (terminal) $-NH_2$ ligand whereas in **2** it is *trans* to a secondary −NH− ligand, the latter being a better Lewis base; and, thus, a better σ donor to the metal center. It is fair to assume that in both compounds the chloro ligand is an equally good σ donor and π acceptor and is not the root of any differences in bonding. However, if more σ-electron density is donated to the metal center of **2**, one would expect a stronger (shorter) Co−Cl bond in the case of **2**. The structures of three different salts of $[Co(tren)(NH_3)Cl]^{2+}$ (the parent cation for **1**) were precisely determined by Buckingham et al.[10] who found Co−Cl bonds of 2.301(2), 2.288(2) and 2.291(4) Å. In compound **2**, the Co−Cl bond length is 2.266(2) Å, the difference from the average value of Buckingham′s results [2.293(3) Å] is 0.027 Å, which is greater than ca. 10 times the esds given. Thus, the difference is significant and may be the reason why the chloro ligand was not expelled by sulfato in the case of **2**.

The Connection with *Thiobacillus ferrooxidans* (*T. f.*)

It was pointed out by Steudel et al.[6] that *T. f.* is "a chemolithotrophic bacterium which participates in the sulfur cycle in nature and plays an important role in the bacterial leaching of mineral ores." Fe^{2+} is present in these bacterial cultures and the energy driving these systems is the oxidation of Fe^{2+} to Fe^{3+} and/or the oxidation of low-valent sulfur compounds to sulfate. Since we generated, and trapped, sulfate in the case of **1** and, presumably, we also formed sulfate in the case of **2** (see above arguments), our compounds may have some value as bio-inorganic models for such reactions, despite the fact that they are Co^{III} derivatives.

Experimental Section

Pure samples of $K_2S_4O_6$ and $Na_2S_4O_6·2H_2O$ were purchased from SIGMA Chemical Company. $[Co(tren)(NH_3)Cl]Cl(ClO_4)$ was prepared by a literature method[11] and $[Co(trien)(NH_3)Cl]Cl_2$ was prepared by the same method using trien instead of tren. The elemental analyses described were performed by Galbraith Laboratories.[12]

Synthesis of K[Co(tren)(NH_3)(OSO_3)](S_4O_6)·2(H_2O) (1): A solution of partially dissolved $[Co(tren)(NH_3)Cl]Cl(ClO_4)$ (1.46 g, 3.72 mmol) in 30mL of water was filtered and added slowly to 30 mL of an aqueous solution containing $K_2S_4O_6$ (1.35 g, 4.46 mmol). A small amount (35 mg) of single crystals suitable for X-ray diffraction study was obtained by liquid diffusion with acetone. − $C_6H_{25}CoKN_5O_{12}S_5$ (617.64): calcd. C 11.67, H 4.09, Co 9.54, N 11.34; found C 11.33, H 3.62, Co 9.26, N 11.06.

Synthesis of [*cis*-α-Co(trien)(NH_3)Cl](S_5O_6) (2): 1.0 g (3.21 mmol) of $[Co(trien)(NH_3)Cl]Cl_2$ was dissolved in 15 mL of water and was filtered directly into 10 mL of an aqueous solution of 1.0 g (3.27 mmol) of $Na_2S_4O_6·2H_2O$. Red crystalline products were formed and collected after 6 d (90 mg). − $C_6H_{21}ClCoN_5O_6S_5$ (513.96): calcd. C 14.02, H 4.12, N 13.63; found C 14.07, H 4.27, N 13.63.

Crystallography: Crystals of **1** and **2** were obtained directly from the reaction media and were mounted onto a goniometer head and

Table 3. Crystal data and structure refinement for K[Co(tren)-(NH_3)(OSO_3)](S_4O_6)·2(H_2O) (**1**) and [*cis*-α-Co(trien)(NH_3)Cl]-(S_5O_6) (**2**)

transferred to an Enraf-Nonius CAD4 diffractometer. For both compounds the intensity data were collected with the Enraf-Nonius data-collection package for PC-driven diffractometers.[13] The crystals were centered with data in the range $14° \leq 2\theta \leq 36°$ and examination of the cell constants, systematic absences, and Niggli matrix[14] showed **1** to crystallize in the space group $P\bar{1}$ (no. 2) while **2** crystallizes in the space group $P2_1/c$ (no. 14). The intensity data were corrected for absorption using empirical curves derived from φ scans of suitable reflections. The solutions and refinements of the structures were carried out using SHELXS-86[15a] and SHELXL-93.[15b] The scattering curves were taken from Cromer and Waber's compilation.[16] During data collection three intensity and orientation standards were monitored and showed no significant deviations from the initial values. A summary of data collection and refinements for both compounds is given in Table 3. Selected bond lengths and angles for **1** and **2** are given in Tables 1 and 2, respectively. Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC-1018665 and -101866. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: int. code + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Acknowledgments

We thank the Robert A. Welch Foundation for support of this research (Grant E-592 to I. B.) and for a fellowship granted to H. C.; I. B. also thanks the National Science Foundation for the funds used in purchasing the diffractometer.

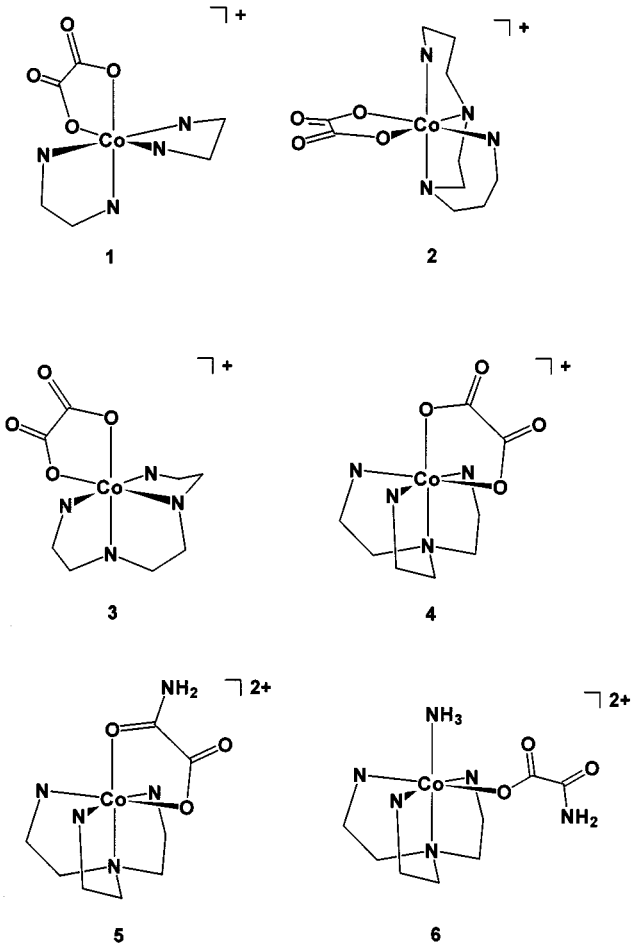
Crystal Structures of Oxalato and Oxamido Polyaminecobalt(III) Complexes Produced by Hydrolysis of Monooxamide

Hyungphil Chun,[a] Bobby J. Salinas,[a] and Ivan Bernal*[a]



Keywords: Monooxamide / Amide hydrolysis / Cobalt(III)

The reactions of sodium monooxamide (H_2NCOCO_2Na) with *trans*-[Co(en)$_2$Cl$_2$]Cl, *trans*-[Co(3,2,3-tet)Cl$_2$]Cl (3,2,3-tet = 1,5,8,12-tetraazadodecane), *cis*-α-[Co(trien)Cl$_2$]Cl and [Co(tren)Cl$_2$]Cl result in the formation of [Co(en)$_2$(ox)]Cl · 4H_2O (**1**), *cis*-β-[Co(3,2,3-tet)(ox)]Cl· 4 H_2O (**2**), *cis*-α-[Co(trien)(ox)]Cl · 2 H_2O (**3**), and [Co(tren)(ox)](ClO_4) · 0.5 H_2O (**4**) respectively, implying a hydrolytic cleavage of the amide bond. [Co(tren)(*O*,*O*′-oxam)]Cl$_2$ · 2 H_2O (**5**) (oxam = $H_2NCOCO_2^-$) and *p*-[Co(tren)(NH_3)(*O*-oxam)]Cl$_2$ (**6**) have also been prepared in order to give mechanistic information for the hydrolysis of monooxamide. Crystal structures of the products are reported and possible pathways for the hydrolysis reactions are discussed.

Since we discovered[1] that compounds of composition [Co(en)$_2$(ox)]X · **n** H_2O (X = Cl^-, *n* = 4; X = Br^-, *n* = 1; X = I^-, *n* = 0) crystallize as conglomerates (conglomerate crystallization is a spontaneous resolution of a racemic solution by crystallization), we have decided to explore the effect of substituting the oxalato ligand with monooxamide ($H_2NCOCO_2^-$) in order to know whether it will displace *cis*- or *trans*-dichloro ligands of Co^{III} to act as a bidentate ligand as oxalate does, and whether additional hydrogen atoms of the NH_2 group will play a major role in their crystallization modes. Much to our surprise, the original purpose in designing this study has not been accomplished since the reaction products we isolated are not monooxamides; instead, they are oxalates obtained by the hydrolysis of the amide bond of the monooxamide anion.

Realizing that this hydrolysis occurs by dichlorocobalt(III) complexes with various types of multidentate polyamine ligands, such as (en)$_2$, 3,2,3-tet, or trien, we thought that we could obtain more detailed information about the hydrolysis of monooxamide including the reaction pathway if a Co^{III} compound with monodentate or bidentate monooxamide could be isolated and characterized unequivocally. *p*-[Co(tren)(NH_3)Cl]$^{2+}$ (the prefix *p*- denotes that the chloro ligand is *trans* to the primary nitrogen atom of the tren ligand) and [Co(tren)Cl$_2$]$^+$ ions were used for that purpose and *O*-bound monodentate and *O*,*O*′-bound bidentate monooxamidecobalt(III) complexes were obtained, respectively.

Although several studies describing the "catalytic" effects of Co^{III} complexes such as *cis*-[$CoN_4(OH_2)(OH)$]$^{2+}$, where N_4 is trien,[2] two ethylenediamines,[3] and tren,[4] and [Co(dien)X][5] (X = tripeptides) on the hydrolysis of amides and peptides have been reported, an amide hydrolysis has not previously been observed with *cis*- or *trans*-dihalo compounds of Co^{III} as in the case of **1**−**4**. Also the formation of oxamido compounds **5** and **6** is unique in that no trivalent transition metal compound containing monooxamide as a monodentate or bidentate ligand has been structurally characterized.

Results and Discussion

In an attempt to probe the effect of exchanging monooxamide for oxalate ligands and recording its crystallization behavior we found that we had not prepared the desired $[Co(en)_2(O,O'\text{-oxam})]Cl_2$. Instead, we isolated the known conglomerate of oxalato compound **1** which suggests that the monooxamide anion had undergone hydrolysis at the amide bond. These results are reproducible and it makes no difference whether one uses the *cis* or *trans* isomer of the dichloro derivative. The structure of the resulting oxalato compound is identical with the published one[1] (see crystallography section).

In order to test the generality of the above observation, we treated the *trans*-$[Co(3,2,3\text{-tet})Cl_2]^+$ ion with sodium monooxamide, which resulted in the formation of the new compound **2**. Its structure (Figure 1) shows that the Co(3,2,3-tet) moiety displays the *cis*-β configuration and that the oxalato ligand faces an asymmetric surface in which one carbonyl group faces two chelate rings (a five- and a six-membered ring) and the other carbonyl group faces a single, six-membered ring, leading to two separate peaks for the carbonyl carbon atoms in the ^{13}C-NMR spectrum (see Experimental Section).

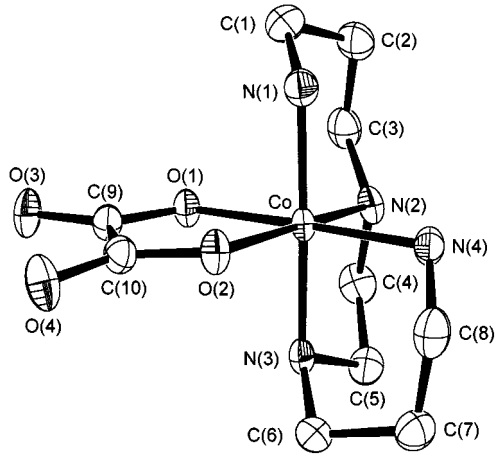

Figure 1. Structure of the cation of **2** drawn at 50% probability level; hydrogen atoms have been omitted for clarity; selected bond lengths and angles: Co−N(1) 1.968(2), Co−N(2) 1.959(2), Co−N(3) 1.961(2), Co−N(4) 1.963(2), Co−O(1) 1.912(2), Co−O(2) 1.921(2) Å; O(1)−Co−O(2) 85.21(7), O(1)−Co−N(2) 89.00(8), O(2)−Co−N(4) 91.86(8), O(1)−Co−N(4) 176.99(8), O(2)−Co−N(2) 173.44(8), N(1)−Co−N(3) 178.66(10)°

Compound **3** whose structure is shown in Figure 2 is the product of the reaction of the *cis*-α-$[Co(trien)Cl_2]^+$ ion with sodium monooxamide and indicates the generality of the reaction of *cis*- and *trans*-dichloropolyaminecobalt(III) with monooxamide.

Interestingly, a compound of composition $\{cis\text{-}\alpha\text{-}[Co(trien)(ox)]Cl\}_2 \cdot 9\ H_2O$ was prepared by rational methods and its structure has been reported by this group.[6] The only difference between the two is the number of waters of hydration, a phenomenon which seems to be common in coordination compounds as observed earlier and discussed in some detail.[7] It also would be interesting to note that

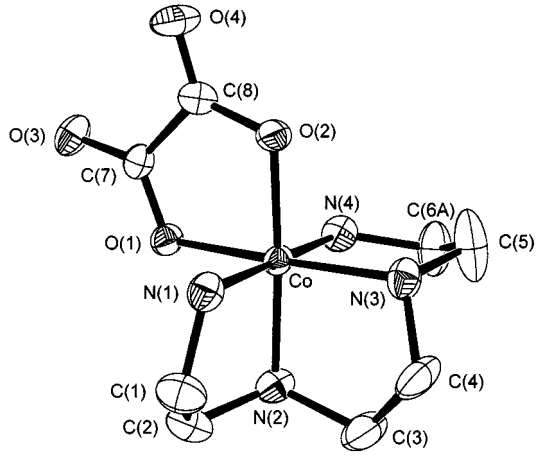

Figure 2. Structure of the cation of **3** drawn without hydrogen atoms; note that C(6) is disordered over two positions corresponding δ and λ conformations and only the former is shown; selected bond lengths and angles: Co−N(1) 1.958(3), Co−N(2) 1.940(3), Co−N(3) 1.943(3), Co−N(4) 1.949(3), Co−O(1) 1.908(2), Co−O(2) 1.906(2) Å; O(1)−Co−O(2) 85.60(10), O(1)−Co−N(2) 93.50(11), O(2)−Co−N(3) 93.80(11), O(1)−Co−N(3) 175.33(11), O(2)−Co−N(2) 174.93(11), N(1)−Co−N(4) 178.65(12)°

the crystal structure of the same compound as **3** but with *cis*-β configuration has been reported.[8]

Compound **4** whose crystal structure has not been reported was prepared by simple ligand displacement of chlorides with oxalate or by base hydrolysis of monooxamide with $[Co(tren)Cl_2]Cl$. As the structure of the cation shown in Figure 3 implies, only one peak is observed for the carbonyl carbon atoms in the ^{13}C-NMR spectrum. The crystallographic asymmetric unit of compound **4** contains two independent molecules and the two molecules are different only in that the five-membered chelate ring which is *trans* to the oxalato ligand has δ and λ conformations in Co(1a) and Co(1b) cations, respectively.

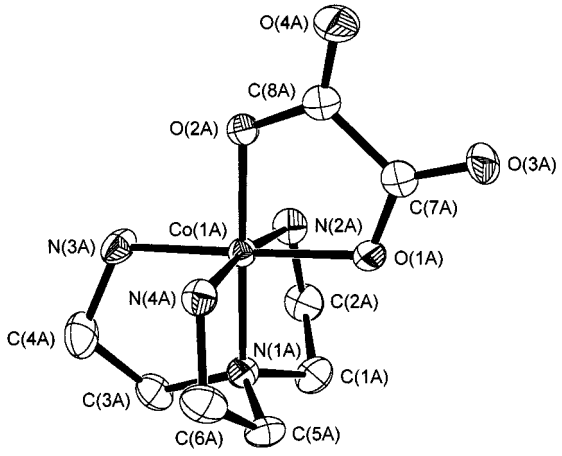

Figure 3. Structure of one of the two cations of **4**; the three chelate rings of tren ligand have (λδδ) conformation; the Co(1b) cation which is not shown here has (λλδ) conformation; selected bond lengths and angles: Co(1a)−N(1a) 1.936(4), Co(1a)−N(2a) 1.954(4), Co(1a)−N(3a) 1.938(4), Co(1a)−N(4a) 1.951(4), Co(1a)−O(1a) 1.925(3), Co(1a)−O(2a) 1.906(3) Å; O(1a)−Co(1a)−O(2a) 85.18(14), O(1a)−Co(1a)−N(1a) 94.2(2), O(2a)−Co(1a)−N(3a) 93.2(2), O(1a)−Co(1a)−N(3a) 177.9(2), O(2a)−Co(1a)−N(1a) 179.4(2), N(2a)−Co(1a)−N(4a) 171.9(2)°

When $[Co(tren)Cl_2]Cl$ was allowed to react with monooxamide in a neutral aqueous solution in a temperature range of 20−45°C, the hydrolysis does not occur and both chloro ligands are replaced by *O*,*O*′-bound monooxamide to give compound **5**. The structure of the cation is shown in Figure 4 and two separate peaks for the carbonyl carbon atoms are observed in the ^{13}C-NMR spectrum, as expected.

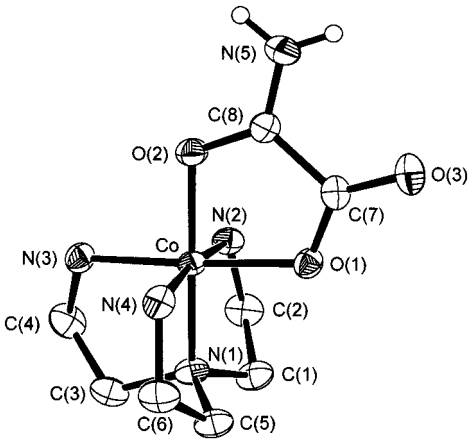

Figure 4. Structure of the cation of **5** showing the bidentate monooxamide ligand; hydrogen atoms of the tren ligand have been omitted for clarity; selected bond lengths and angles: Co−N(1) 1.918(3), Co−N(2) 1.957(3), Co−N(3) 1.931(3), Co−N(4) 1.957(3), Co−O(1) 1.929(2), Co−O(2) 1.917(3) C(8)−N(5) 1.299(5) Å; O(1)−Co−O(2) 85.00(11), O(1)−Co−N(1) 94.80(13), O(2)−Co−N(3) 92.51(13), O(1)−Co−N(3) 177.01(13), O(2)−Co−N(1) 179.63(12), N(2)−Co−N(4) 172.53(13)°

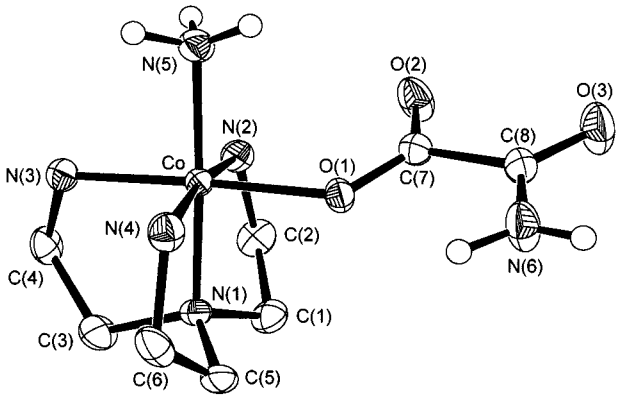
The Cambridge Structural Database[9] lists three transition metal compounds which contain bidentate *O*,*O*′-bound monooxamide ligands. They are of the structure type $[M(O,O'\text{-oxam})_2(H_2O)_x] \cdot n\ H_2O$ (M = Co^{2+}, $x = 2$, $n = 2$[10]; M = Zn^{2+}, $x = 2$, $n = 0$[11]; M = Cd^{2+}, $x = 4$, $n = 0$[12]). Note that all of them bore divalent metal cations.

Finally, the *p*-$[Co(tren)(NH_3)Cl]^{2+}$ ion was treated with monooxamide to give compound **6**. The structure of the cation (Figure 5) shows that only the chloro ligand has been replaced, as expected, by a monodentate *O*-bound monooxamide whose amide bond is still intact, which suggests that an unactivated amide bond of monooxamide would not easily be hydrolyzed, if at all.



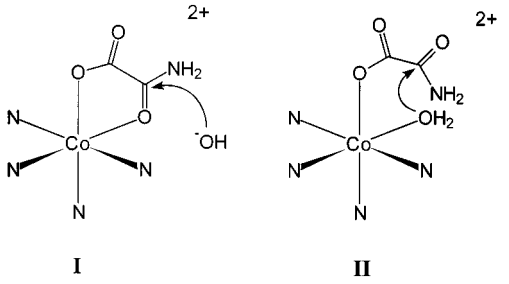


Figure 5. Structure of the cation of **6** showing the dangling NH_2 group of the monodentate monooxamide ligand; hydrogen atoms of the tren ligand have been omitted for clarity; selected bond lengths and angles: Co−N(1) 1.949(2), Co−N(2) 1.970(2), Co−N(3) 1.927(3), Co−N(4) 1.960(3), Co−O(1) 1.949(2), Co−N(5) 1.943(2) C(8)−N(6) 1.321(4) Å; O(1)−Co−N(2) 92.47(10), O(1)−Co−N(4) 83.24(10), O(1)−Co−N(5) 91.13(10), O(1)−Co−N(3) 175.53(10), N(5)−Co−N(1) 177.36(11), N(2)−Co−N(4) 171.19(11)°

As far as we know, a transition metal compound containing a monodentate monooxamide ligand has never been structurally characterized.

As reviewed earlier,[13] two reaction pathways, the so-called "direct activation" and "intramolecular attack", have been postulated for the hydrolysis of amide bonds by Co^{III} complexes. Although a detailed discussion concerning the hydrolysis mechanism can not be made without kinetic data obtained under pH-controlled condition, two key intermediates can be considered for this work according to the above concepts (Scheme 2).

Scheme 2. Key step for direct activation (**I**) and intramolecular attack (**II**)

Species **I** and **II** correspond to the direct activation and intramolecular attack, respectively. For compounds **1**−**3**, the possibility of hydrolysis through intermediate **I** can be excluded for the following reasons. First, relatively flexible binding modes of $(en)_2$, 3,2,3-tet, or trien coupled with labile chloro ligands would allow coordination of a solvent water molecule before monooxamide became a bidentate ligand. This is especially true for **1** and **2** which undergo *trans*/*cis* isomerization at raised temperature. Second, "neutral", deionized, solvent water used in this work was in fact slightly acidic (pH = 5.40) due to atmospheric CO_2, which makes the attack of HO^- ion to the amide carbon atom less likely to occur. The possibility of attack of solvent water to bidentate monooxamide can also be removed as the presence of compound **5** implies. Therefore, we cautiously adopt the intramolecular attack of a coordinated water molecule as the correct mechanism for the hydrolysis of monooxamide by Co^{III} complexes with configurationally versatile multidentate amine ligands.

The behavior of monooxamide with $[Co(tren)Cl_2]Cl$ also supports this argument. That is, when the multidentate amine ligand of a Co^{III} complex is configurationally rigid and chloro ligands are relatively stable with respect to the substitution by solvent water molecules, monooxamide coordinates as a bidentate ligand as in compound **5** and the hydrolysis of the amide bond does not occur. Once monooxamide is coordinated as a bidentate ligand, an additional source of HO^- ions is necessary in order to hydrolyze the amide bond.

In conclusion, monooxamide was found to be hydrolyzed by Co^{III} complexes containing various types of polyamine tetradentate ligands, such as $(en)_2$, 3,2,3-tet, trien, or tren to give their corresponding oxalato compounds **1**, **2**, **3**, and **4**, respectively. In compounds **1**, **2**, and **3**, intramolecular attack of coordinated water molecule is the likely pathway for the hydrolysis reactions. In compound **4**, the hydrolysis reaction seems to occur by attack of HO^- ions to the amide carbon atom of the bidentate monooxamide ligand. Compounds **5** and **6** are also important not only from their structural point of view, but also because of their implications in the hydrolysis mechanism.

Experimental Section

General: H_2NCOCO_2Na (Aldrich Chemical Company) and $(NH_4)_2C_2O_4 \cdot H_2O$ (Fisher Scientific Company) were used as received. *trans*-$[Co(en)_2Cl_2]Cl$,[14] *trans*-$[Co(3,2,3\text{-tet})Cl_2]Cl$,[15] *cis*-α-$[Co(trien)Cl_2]Cl \cdot 2\ H_2O$,[7] $[Co(tren)Cl_2]Cl$,[16] and *p*-$[Co(tren)(NH_3)Cl]Cl(ClO_4)$[17] were prepared using known methods. Elemental analyses were carried out by the Galbraith laboratories.[18] ^{13}C-NMR spectra were recorded with a GE QE-300 instrument using TMSPA as the internal standard.

$[Co(en)_2(ox)]Cl \cdot 4\ H_2O$ (1): 30 mL of an aqueous solution of 2.00 g (18 mmol) of H_2NCOCO_2Na was slowly added to a greenish solution of 4.08 g (14 mmol) of *trans*-$[Co(en)_2Cl_2]Cl$ in 30 mL of water. While heating the solution at 60°C, the color changed to purple and finally to red. When the volume was reduced to about 15 mL, it was allowed to stand at room temperature. After 10 d, red crystals were obtained which effloresce upon removal from the mother liquor. The compound was analyzed after drying to constant weight. − $C_6H_{16}ClCoN_4O_4$ (302.64): calcd. C 23.81, H 5.34, N 18.52; found C 22.55, H 5.59, N 17.90.

***cis*-β-[Co(3,2,3-tet)(ox)]Cl · 4 H_2O (2):** The same procedure as in the case of **1** was employed using *trans*-$[Co(3,2,3\text{-tet})Cl_2]Cl$. Red crystals were obtained after 10 d at room temperature. − $C_{10}H_{30}ClCoN_4O_8$ (428.76): calcd. C 28.01, H 7.07, N 13.07; found C 27.95, H 6.98, N 13.20. − ^{13}C NMR (300 MHz, D_2O): δ = 168.38 and 168.44 (2 C=O), 20.97, 26.01, 37.69, 38.22, 44.74, 47,49, 48.45, and 53.37 (8 CH_2).

***cis*-α-[Co(trien)(ox)]Cl · 2 H_2O (3):** The same procedure as in the case of **1** was used by treating equimolar amounts of *cis*-α-$[Co(trien)Cl_2]Cl \cdot 2\ H_2O$ and H_2NCOCO_2Na. Red crystals were collected after 3 weeks. − $C_8H_{22}ClCoN_4O_6$ (364.67): calcd. C 26.35, H 6.08, N 15.36; found C 25.80, H 6.08, N 15.46.

$[Co(tren)(ox)]ClO_4 \cdot 0.5\ H_2O$ (4): ***Warning: Metal amine perchlorates may be explosive!*** A solution of ammonium oxalate (0.46 g, 3.24 mmol) in 11 mL of water was added to a solution of $[Co(tren)Cl_2]Cl$ (1.00 g, 3.21 mmol) in 12 mL of water. The initially formed purple precipitate dissolved and the solution turned a clear red color after heating for 10 min; 0.40 g (3.27 mmol) of $NaClO_4$ was then added and the solution was filtered. Red crystals were formed upon standing and collected after 2 weeks (0.99 g, 77%). − $C_8H_{19}ClCoN_4O_{8.5}$ (401.65): calcd. C 23.92, H 4.77, N 13.95; found C 23.70, H 4.87, N 13.90. − ^{13}C NMR (300 MHz, D_2O):

[a] $R_1 = \Sigma||F_o| - |F_c||/\Sigma|F_o|$, $wR_2 = [\Sigma w(F_o^2 - F_c^2)^2/\Sigma w(F_o^2)^2]^{1/2}$ and $w = 1/[\sigma^2F_o^2 + (a \cdot P)^2]$, where $P = (F_o^2 + 2\ F_c^2)/3$.

δ = 166.57 (2 C=O), 43.38, 44.12, 59.47, and 61.56 (6 CH_2). − The same product was obtained by adding 0.21 g (5.25 mmol) of NaOH to a solution containing 1.00 g (3.21 mmol) of [Co(tren)Cl_2]Cl and 0.36 g (3.24 mmol) of H_2NCOCO_2Na in 15 mL of water. The resulting dark red solution was filtered after stirring for 30 min; 0.4 g (3.27 mmol) of $NaClO_4$ was added to the solution after 5 d and the solution was filtered. The solution was filtered off frequently whenever a powdery precipitate was formed until red single-crystals suitable for X-ray diffraction study were obtained. The unit cell parameters [a = 11.1569(21), b = 11.5038(22), c = 11.5904(117) Å, α = 97.377(35), β = 90.782(31), γ = 97.974(14)°] and the Laue class of the unit cell were identical, within experimental error, with those of the compound prepared from ammonium oxalate, and therefore X-ray data were not collected. − calcd. C 23.92, H 4.77, N 13.95; found C 23.64, H 5.03, N 13.91.

[Co(tren)(O,O′-oxam)]Cl_2 · 2 H_2O (5): A mixture of 0.18 g (1.62 mmol) of H_2NCOCO_2Na in 3 mL and 0.50 g (1.61 mmol) of [Co(tren)Cl_2]Cl in 10 mL of water was stirred for 30 min at room temperature and then filtered. Red plate crystals were obtained upon standing and collected after 8 d (0.58 g, 90%). − $C_8H_{24}Cl_2CoN_5O_5$ (400.15): calcd. C 24.01, H 6.05, N 17.50; found C 22.75, H 5.68, N 16.21. Although duplicate analyses were carried out due to the disagreement between calculated and experimental results, all the experimental values were consistently smaller than calculated values. Because there is no doubt in the crystal structure and because the ratio of the number of each element to the other showed good agreement with calculated values, the apparent disagreement was ignored. − ^{13}C NMR (300 MHz, D_2O): δ = 166.53 [C(=O)O], 170.67 [C(=O)NH_2], 43.72, 44.13, 60.68, and 62.91 (6 CH_2). − In a separate experiment, the initial reaction mixture was warmed at 45°C for 30 min and then filtered. The purple solution turned red within 4 h. Red plate crystals were obtained upon standing and examined on a X-ray diffractometer to give the same unit cell parameters [a = 11.2172(45), b = 22.4952(76), c = 12.8525(120) Å, α = β = γ = 90°] and Laue symmetry as the compound obtained from the room-temperature reaction, and therefore X-ray data were not collected. − ^{13}C NMR (300 MHz, D_2O): δ = 166.50 [C(=O)O], 170.69 [C(=O)NH_2], 43.55, 43.96, 60.47, and 62.73 (6 CH_2).

***p*-[Co(tren)(NH_3)(O-oxam)]Cl_2 (6):** A partly dissolved solution containing 1.12 g (2.85 mmol) of *p*-[Co(tren)(NH_3)Cl]Cl(ClO_4) in 20 mL of water was directly filtered into a solution of H_2NCOCO_2Na (0.32 g, 2.88 mmol) in 10 mL of water. Small amounts of red crystals suitable for X-ray diffraction were obtained by liquid diffusion with acetone and collected after 10 d. − $C_8H_{23}Cl_2CoN_6O_3$ (381.15): calcd. C 25.21, H 6.09, N 22.05; found C 25.18, H 6.19, N 21.95.

Crystallography: For all six compounds the intensity data were collected with an Enraf-Nonius CAD4 diffractometer. Although the crystal of **1** was mounted inside a sealed capillary tube in order to prevent decay, it completely lost its crystallinity after collecting 1267 reflections with a total X-ray exposure time of 82387 s (22.87 h). The unit cell was orthorhombic with a = 6.340(3), b = 11.976(3), and c = 20.290(6). The limited data set showed only three systematic absences, $h \neq 2n$ for (h00), $k \neq 2n$ for (0k0) and $l \neq 2n$ for (00l), implying the unique space group $P2_12_12_1$ (no. 19). It was then noticed that the symmetry and unit cell dimensions agree with [Co(en)$_2$(ox)]Cl · 4 H_2O of ref.[1], which is orthorhombic, $P2_12_12_1$, a = 6.349(3), b = 11.969(4), and c = 20.311(5), and isotropic refinement of the structure using the atomic coordinates from the reference gave an R factor of 16% for 413 observed reflections [$I > 2\sigma(I)$]. For the compounds **2**−**6** routine procedures were used to collect data and solve the structures. Hydrogen atoms of **3**, **4**, and **5** were placed in their geometrically ideal positions with isotropic temperature factors 1.2 times of those of the attached non-hydrogen atoms. However, hydrogen atoms of water molecules and monooxamide ligand of those compounds along with all hydrogen atoms of **2** and **6** were located from difference maps and refined isotropically. SHELXS-86[19] and SHELXL-93[20] were used for solution and refinement, respectively. Parameters for data collection and structure refinements are summarized in Table 1 and 2. Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre[9] as supplementary publication no. CCDC-111984 to CCDC-111988.

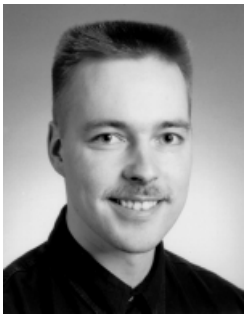
New Rare-Gas-Containing Neutral Molecules

Mika Pettersson,[a] Jan Lundell,[a] and Markku Räsänen*[a]

Keywords: Ab initio calculations / Matrix isolation / Rare-gas compounds / Solid-state chemistry / Photochemistry



The synthesis of novel neutral rare-gas-containing molecules of type HXY, where X = Xe or Kr and Y is an electronegative atom or fragment, is discussed. The molecules are characterised experimentally by their vibrational spectra and computationally by extensive ab initio calculations. They are formed in low-temperature rare-gas solids from neutral reagents and their bonding consists of both covalent and ionic contributions. Our recent studies add to the previously known class of rare-gas chemical bonds in neutral ground-state molecules the new bonds Xe–H, Xe–I, Xe–Br, Xe–S, Kr–H, Kr–C, and Kr–Cl.

Introduction

The rare gases form one of the most abundant classes of constituents of our Universe. The beautiful octet rule led scientists to accept the nonreactivity of rare gases until 1933, when Linus Pauling suggested[1] from considerations of ionic radii of different elements that molecules like XeF_6 and KrF_6, and perhaps unstable compounds XeF_8 and H_4XeO_6, should be preparable. However, attempts to synthesize rare-gas-containing molecules were not successful at that time.[2]

It took about 30 years until the first rare-gas-containing chemical compound was found. Neil Bartlett reported[3a] first a solid compound with a structure $Xe^+[PtF_6]^-$, which was later shown to consist most probably of a mixture of $XeF^+PtF_6^-$ and $XeF^+Pt_2F_{11}^-$.[3b] The key idea for this discovery was the similar ionisation potentials of O_2 and Xe. Almost simultaneously independently of Bartletts results, Hoppe et al.[4] synthesized XeF_2, and slightly later, Claassen et al.[5] reported XeF_4. After these first findings a number of compounds, where Xe is bound to fluorine and/or oxygen, were characterised. The extent of rare-gas chemistry in its early stages accounted, in addition to the species

Mika Pettersson (left, top), born in 1969, received his Ph.D. in 1998 from the laboratory of Physical Chemistry, University of Helsinki. The topic of his thesis was novel rare-gas compounds. At the moment he is continuing his investigations at the University of Helsinki. His research interests cover spectroscopy and computations on weakly bound and reactive species, photochemistry and IR-induced processes in low-temperature matrices.

Jan Lundell (left, bottom), born in 1966, received his Ph.D. in 1995 from the Laboratory of Physical Chemistry, University of Helsinki. After his Ph.D. he spent a postdoctoral year at the Fritz Haber Research Institute for Molecular Dynamics, The Hebrew University of Jerusalem with professor Robert B. Gerber. In 1996 he returned to University of Helsinki, where he is now as a postdoctoral researcher of the Academy of Finland. He focuses his interest on hydrogen-bonded complexes, weak chemical interactions, and photochemical processes of small molecules in low-temperature matrices.

Markku Räsänen (right), born in 1949, received his Ph.D. in 1983 from the Laboratory of Physical Chemistry, University of Helsinki. After this he spent a postdoctoral year at the AT&T Bell Laboratories, Murray Hill, NJ with professor Vladimir E. Bondybey. He was a senior researcher of the Academy of Finland and received in 1992 the position of Associate Professor in Physical Chemistry, University of Helsinki (the title was changed to Professor in 1998). His general interests are in spectroscopy (vibrational and time-resolved luminescence) and photochemistry of small impurity molecules in simple solids, e.g. rare gases at low temperatures. The light-induced processes of interest are bond dissociation with UV/Vis photons and conformational changes induced by vibrational excitations.

MICROREVIEWS: This feature introduces the readers to the authors' research through a concise overview of the selected topic. Reference to important work from others in the field is included.

mentioned above, for example molecules XeF_6, $XeOF_4$ and XeO_2F_2, $XeF_2 \cdot 2\,SbF_5$ and $XeF_6 \cdot AsF_5$ salts, and the XeF radical.[6−11] These species have been reviewed by several authors.[12−16] In addition, the theory of binding in the Xe compounds has been authoritatively reviewed by Coulson.[17]

These findings promoted an active search for the extent of chemical bonds between rare gases and other elements. In this search, carbon played an important role and the first reports on Xe−C bonds date in the early 1970s when the bond strength of CH_3Xe^+ was measured[18] (its value is 231.0 ± 10.5 kJ mol^{-1}[19]). Also, an unstable $FXeCF_3$[20] species has been suggested as a reaction intermediate and for $Xe(CF_3)_2$ a lifetime of ca. 30 min has been reported[21] even though the compound has not been characterised spectroscopically. A stable Xe−C-bonded molecule, pentafluorophenylxenon(II) fluoroborate, was found almost simultaneously by two groups in 1989.[22][23] After this, a number of novel organoxenonium compounds have been synthesized.[24][25]

Before the advent of Xe−C chemistry, some other elements were found to bond chemically to Xe. In an Xe matrix, Nelson and Pimentel[26] prepared $XeCl_2$ and also compound $FXeBF_2$ was reported.[27] In addition, in condensed phases xenon is found to form readily a dixenon cation (Xe_2^+).[28] The first Xe−N bond was found in fluoro-[imidobis(sulphuryl fluoride)]xenon, $FXeN(SO_2F)_2$.[29] After this, a number of xenon−nitrogen bonds were characterised in complex molecules.[30−38]

Chemistry related to the lighter rare gases is naturally much more sparse than that of Xe. The first reports dealt with fluorine−krypton compounds, molecules KrF_4[39] and KrF_2[40−42] being analogous to the fluorinated xenon compounds. Discoveries of Kr bonding to N and O have been done especially by the Schrobilgen group.[43−46]

The only serious candidate for Ar compounds, ArBeO, was prepared in low-temperature matrices by Thompson and Andrews.[47] The considerable spectral shifts suggested rather strong binding between Ar and BeO, and computational results give 0.29 eV for the interaction energy,[48] which is caused by induced dipole interactions. Various possible bonds between rare-gas atoms and other elements have been extensively studied theoretically by Frenking and Cremer.[49]

As referenced above, the early stages of rare-gas chemistry benefitted also of low-temparature matrix-isolation studies.[26,40,42,47] This method was originally developed for trapping unstable species and reaction intermediates at low temperatures.[50−52] The novel compounds described in this microreview have been up to now prepared in solid rare gases. In brief, the starting point for the preparation is the selection of a suitable hydrogen-containing precursor followed by photodissociative generation of hydrogen atoms and electronegative fragments and trapping them in the low-temperature solid for further reactions. The typically used precursors include hydrogen halides, HCN, H_2S etc. In solid rare gases, the photodissociation is often prevented by the strong cage effect.[53−58] However, the barrier for cage exit of hydrogen atoms during photodissociation in solid rare gases is relatively low, 1−2 eV[59][60], allowing photogeneration and isolation of H atoms. After preparation of the neutral reactants, hydrogen atoms are selectively mobilised by annealing the matrix at a suitable temperature (ca. 30 K for Kr and ca. 50 K for Xe). HXY-type rare-gas compounds (X = Kr or Xe; Y = Cl, Br, I, CN, ...) are then formed in a concerted reaction H + X + Y → HXY.

In this article we describe the solid-state synthesis of several HXY-type rare-gas molecules shown in Figure 1. It is to be noted that the present species *are not* van der Waals systems but truly chemically bound molecules. We give the spectral characteristics of these new compounds, describe their formation mechanism from neutral constituents as well as their stabilities. This review is based on original articles and a PhD Thesis during years 1995−1998.[61−67] Additionally, we connect ab initio results with the experimental data to aid the understanding of the bonding and charge distribution of the new molecules.

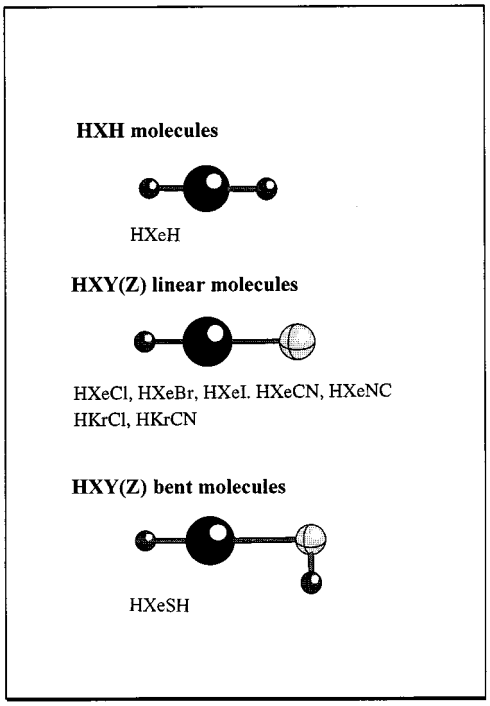

Figure 1. The HXH, HXY, and HXY(Z) molecules

Preparation of the HXY Molecules

In the following we describe shortly the solid-state experiments for preparing the new rare-gas-containing molecules. Solid rare gases (5−50 K) are used as the medium for synthesis and for spectroscopic identification of the formed species. The precursor molecules HY (hydrogen halides, HCN, H_2S, etc) are mixed with rare gases in the gas phase and isolated in a typical 1000-fold excess of the host atoms in a polycrystalline solid deposited onto an optically transparent substrate. The isolated species and their photoprod-

ucts can be monitored by measuring their infrared absorption spectra or by measuring the time-resolved luminescence spectra.

In order to promote the isolated precursor to photodissociative repulsive states different light sources can be used. The dissociation energies (D_0) of the hydrogen halides HCl, HBr, and HI are 4.43, 3.75, and 3.05 eV, respectively,[68] and various UV lamps work well for decomposing these precursors. For H_2S, photodissociation at 193 nm (ArF laser) is very efficient,[69] since the absorption maximum of the precursor is near this wavelength. Also HCN can be photodissociated at 193 nm in solid Kr and Xe even though the efficiency is low. Additionally, water, which is always present as an impurity, produces H atoms into the solid host upon 193 nm excitation.

Upon photolysis the IR absorptions of the precursor disappear and isolated H atoms and electronegative fragments Y are formed. This can be seen for instance from the appearance of the spin-orbit ($^2P_{1/2} \leftarrow {}^2P_{3/2}$) absorption at ca. 7600 and 3600 cm^{-1} for iodine and bromine atoms, respectively.[66] Both the H atoms and Y fragments are stable below the mobilisation temperature of hydrogen atoms (30−50 K). In very diluted matrices (M/A ratio > 1000), it is possible to convert a major part of the precursor molecules into hydrogen atoms and Y fragments. In more concentrated matrices, other processes like clusterization and photoinduced reactions of hydrogen atoms produce more complicated products and hydrogen molecules.[66,70]

The next step in the synthesis is the raising of the temperature to the point at which the photogenerated hydrogen atoms start to diffuse. In solid Xe, several separate experiments have shown that hydrogen atoms diffuse at around 45 K.[59,70−73] Randomly distributed hydrogen atoms diffuse until they find a Xe atom which has a fragment Y as a nearest neighbour. At this stage, these three fragments H, Xe, and Y react and form an HXY molecule. This process is described in Figure 2. Another possibility is a reaction of two hydrogen atoms with an Xe atom between them. This reaction produces xenon dihydride (HXeH) and it happens in any Xe matrix which contains hydrogen atoms. Most importantly, since HXY molecules are formed from H and Y which are too far from each other to be able to re-form the precursor HY, species HXY and HXeH are the major trapping sites for H atoms and Y fragments in solid rare gases after the mobilisation of hydrogen atoms.[67]

The formed HXY molecules are easily detected by IR spectroscopy since they have extremely intensive X−H stretching absorptions,[61,62,64,65] and the position of the stretching band is very characteristic for each Y. The Xe−H stretching bands of different HXeY molecules are presented in Figure 3. In addition to these absorptions, weaker bending absorptions can be detected for some of the compounds. Characteristic for HXeNC is also an intensive N−C stretching absorption. All vibrational bands of the HXY compounds observed thus far are collected in Table 1 including the deuterated compounds.

As can be seen from Table 1 and Figure 3, the position of the Xe−H stretching band (or more generally the X−H stretching band) changes considerably by varying the Y fragment. This property is rationalised in the following sections where the origin of the bonding is discussed. It will be shown that the position of the stretching band reflects both the Xe−H bond length as well as the charge distribution of the compounds. A striking example of this sensitivity of the ν_{Xe-H} absorption can be found by comparing the two isomers of HXeCN. For the more stable HXeCN the ν_{Xe-H} absorption is at 1624 cm^{-1} and it shifts +227

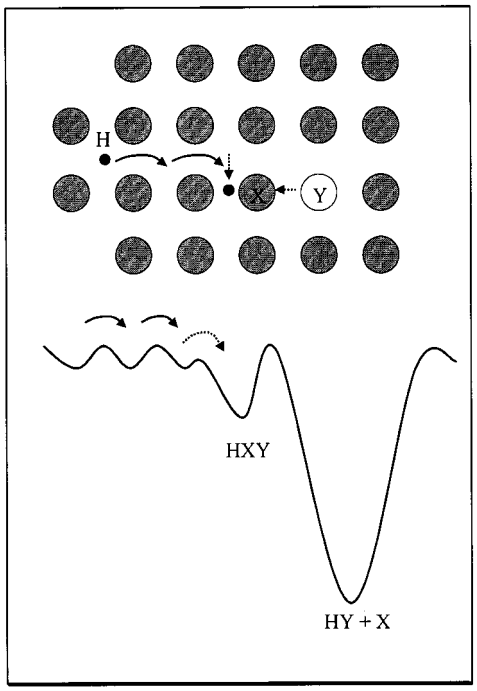

Figure 2. A schematic picture of the generation of the HXY (X = Kr, Xe; Y = Cl, Br, I, CN, ...) molecules in solid rare gases; the lower curve describes the potential energy

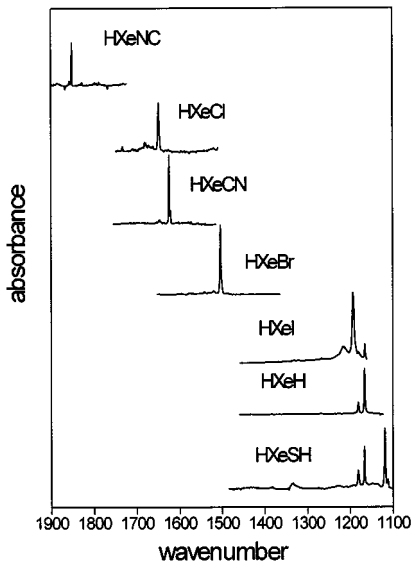

Figure 3. The Xe−H stretching absorptions of different HXeY compounds in solid Xe; note that the absorptions of HXeH at 1166 and 1181 cm^{-1} appear in the spectra of HXeI and HXeSH as well

cm^{-1} for HXeNC to 1851 cm^{-1}. This also measures the anisotropicity of the CN pseudohalogen.

The data in Table 1 also collects the observed overtones. At first it can be noted that HXeI, HXeBr, and HXeH show measurable intensity in the first overtone of Xe−H stretching vibration originating from anharmonic effects. Furthermore, this anharmonicity influences the fundamental wavenumber by several percent, which must be kept in mind while comparing the experimental and calculated (harmonic) wavenumbers.

Mechanism of Formation

Before going into the details of bonding it is important to discuss the mechanism of formation of the rare-gas molecules. UV photolysis of halogen-doped rare gases may induce permanent charge separation as was shown by Fajardo and Apkarian,[74−76] which results in trapped ionic centers like X_2H^+, Y_2H^-, and X_n^+ (X = rare gas, Y = halogen).[77−80] Thus, thermal activation of the photolysed solids may also induce ionic reaction channels, which should not be neglected when considering the mechanism of formation of the HXY molecules. However, for HXeI we could experimentally show that the molecule originates from neutral atoms. The ν_{Xe-H} frequency of HXeI is 1193 cm^{-1}, $2\nu_{Xe-H}$ is 2190 cm^{-1}, and around energies $3\nu_{Xe-H} \approx$ 3000 cm^{-1} the molecule decomposes (see Figure 4). The HXeI photodissociation experiment[63] also yields the absorption profile for the $3\nu_{Xe-H}$ transition with an onset at 2950 cm^{-1} which can be taken as an approximate value for the D_0 dissociation energy of HXeI. After this IR decomposition the molecular form can be restored *quantitatively*. Important is that the quantitative restoration of the molecular form occurs at considerably lower temperatures than the global mobilisation of H atoms after initial UV photodissociation of the precursor. This means that the IR decomposition of HXeI produces atoms, which are in a dissociated form in close contact with each other and HXeI can be recovered by slight warming or even at the lowest temperatures by tunneling.[63] The low energy of the $3\nu_{Xe-H}$ infrared photons is not sufficient to produce ionic centers into the crystal and the only effect is bond breaking with the resulting neutral atoms being located at their van der Waals distances from each other. The final proof in favour of the formation of the HXeI molecule from neutral atoms was obtained by following the concentrations of HXeI and I atoms simultaneously by IR measurements. The increase of the spin-orbit absorption ($^2P_{1/2} \leftarrow {}^2P_{3/2}$) of I atoms[66] at 7457 cm^{-1} correlated with the decrease of HXeI and vice versa.[63]

In addition to this direct evidence on formation of HXeI from neutral atoms supporting information is available from Feldman and co-workers.[81,82] By combined infrared and ESR-spectroscopic studies on electron-irradiated hydrocarbon-containing Xe matrices these authors found that the decrease of hydrogen atoms correlated with the growth of HXeH. Also, addition of electron scavengers which enhanced the ion formation decreased the yield of xenon dihydride.[81,82] It can also be mentioned that these authors found indications of possible reactions of HXeH with hydrocarbons.

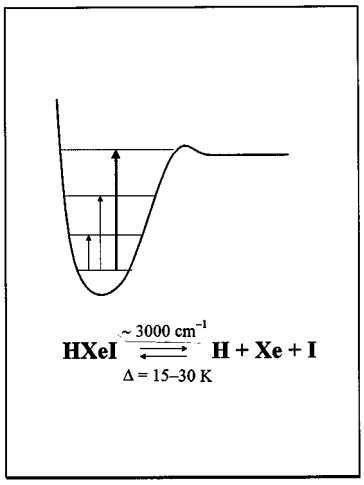

Figure 4. Photodissociation of the HXeI molecule with infrared light at ca. 3 μm

The result that the HXY compounds are formed from neutral atoms is very important because neither ions nor complex intermediates are needed to synthesize these molecules. Solid rare gases form an ideal environment for synthesis since one of the reactants is present as a solvent. Additionally, one needs only to find a suitable precursor molecule which can be photodissociated to hydrogen atoms and Y fragments. In most cases, hydrogen atoms can be selectively mobilised after photolysis, the Y fragments being immobile. This reduces the number of unwanted side reactions and only HXeH is a major "side product".

Considering the possible preparation of HXY in the gas phase, the major requirement appears to be the simultaneous production of H and X atoms, and the Y fragments. This can be achieved, for example, by microwave discharge. In preliminary attempts we have obtained HXeCl directly in the matrix by depositing a mixture of HCl and Xe through a discharge.[83] Unfortunately, it was impossible to determine whether HXeCl was produced in the gas phase or on the surface of the matrix. In any case, this positive result prompts for further gas-phase experiments.

A Simple Model for the Bonding

The origin of bonding in the HXY compounds can be understood on the basis of a simple ionic model. In this model, the HXY molecule is best described as an ion pair HX^+Y^-, which contains a covalently bound HX^+ interacting with Y^- mainly due to Coulombic attraction. This idea was presented by Last and George predicting the existence of HXe^+Cl^- in 1988 by their semiempirical DIIS method.[84] It is also interesting to note that the ionic $(HXe)^+$ and $(HKr)^+$ constituents of the new rare-gas molecules are isoelectronic with HI and HBr, respectively.

On the basis of this charge-transfer model it is informative to determine the main factors which affect the existence and stability of HXY. Figure 5 explains the model of HXY compounds in a simple manner. According to this model, HXY has ionic nature at the equilibrium structure which originates from the ionic $HX^+ + Y^-$ diabatic surface. However, when the bonds are stretched the system dissociates to the neutral H + X + Y limit due to the avoided crossing between the two diabatic surfaces. The ionization potential (*IP*) of X, electron affinity (*EA*) of Y and the dissociation energy (D_e) of XH^+ determine the energetics between the ionic and neutral limits. Low ionization potential of X and large electron affinity of Y are favourable with respect to the stability of HXY. The D_e values of XeH^+ and KrH^+ are about 4.05 and 4.8 eV, respectively.[85–88] These large values tend to bring the ionic limit low in energy and this explains partially the existence of the HXY compounds. Moreover, small Y^- fragments stabilise HXY more than the larger ones because they can approach closer to the HX^+ fragment and thus produce larger Coulombic stabilisation. Altogether, there is rather subtle balance between different factors affecting the energetics of HXY compounds and their properties depend strongly on Y as observed in experiments from the position of the X–H stretching band.

In terms of resonance structures, HXY should be described as a resonance hybrid between several possible structures from which the most important is HX^+Y^-. Other important structures are neutral H–X–Y and ionic H^-X^+Y. The ionic structures tend to stabilise the compound and the neutral structure destabilises it. HXeH is best described similarly as a resonance hybrid between HXe^+H^- and H^-Xe^+H.

The bonding of the HXeH molecule can be considered qualitatively within the Molecular Orbital (MO) theory also

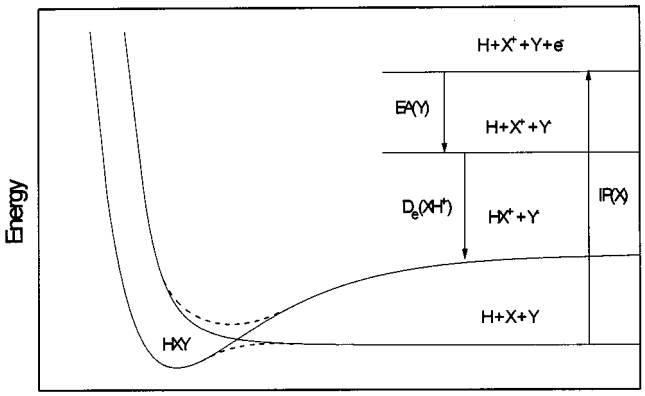

Figure 5. Schematic picture of the origin of bonding in the HXY molecules; the *x* axis describe the sum of the X–H and X–Y distances in a linear geometry

by a three-center four-electron model[12,17,89,90] in accordance to the fluorinated Xe compounds. The highest occupied orbital (σ_g) of HXeH is practically centered around the H atoms, being non-bonding.[90] The lowest σ_u molecular orbital, responsible for the covalent bonding, consists of a collinear set comprising one 5p orbital of Xe and the hydrogen 1s orbitals, being occupied by the two other electrons. Similar simple linear model should be valid also for other HXY molecules by replacing the other 1s hydrogenic orbital by the proper orbital of the Y fragment.

Computational Properties of the HXY Compounds

In order to understand the nature of bonding and spectral characteristics of the rare-gas molecules, ab initio methods have been applied extensively.[61,62,64,65,67,90] The computational results support strongly the bonding model presented above and they corroborate the experimental spectroscopic features as well as give insight to the stabilities of these molecules. The basis set and electron-correlation dependencies of the various properties are discussed separately in the following.

Selection of Computational Methods

From the computational point of view the HXY(Z) molecules are a challenging task. The ion-pair nature of these compounds, interaction of different neutral and ionic configurations, as well as relatively weak bonds and relativistic effects establish a test for the performance of the standard computational approaches. All-electron basis sets become unfeasibly large when rare-gas atoms are considered. Therefore, most of the studies on the HXY molecules have applied effective core potentials (ECP) to describe the rare-gas atoms while first- and second-row atoms are dealt with standard all-electron Gaussian-type basis sets. The use of ECPs diminishes the size of the calculation by the accounted number of electrons, for example, reducing the number of electrons in Xe from 54 to 8 or 18 in the valence

space. This enables also application of higher level correlation in the calculations. As an example, the calculated bond lengths and spectra of HXeH have been collected at various levels of theory in Table 2. Most of these calculations would not be feasible using all-electron basis sets on xenon.

Aiding the first observations of the HXY molecules HXeI, HXeBr, HXeCl, HKrCl, and HXeH the MP2/LANL1DZ level was used as the preliminary theoretical method.[61][62] This very inexpensive approach was observed to give a stable minimum for all the observed 5 molecules, whereas the HKrI and HKrBr molecules were unstable computationally and have, in fact, despite attempts, never been experimentally observed. The failure of the MP2/LANL1DZ calculations was that they predicted the HXY molecules to be energetically *above* the atomic dissociation limit. However, these calculations were able to predict the properties around the equilibrium structure reasonably well and the harmonic vibrational frequencies of the new HXY molecules were satisfactory. As can be seen in Table 2, the discrepancy between the MP2/LANL1DZ-calculated and the observed wavenumbers is quite small especially when taking into account the anharmonic effects. This is actually accidental as pointed out by Runeberg and co-workers.[90] These authors showed that increasing the level of correlation requires also a larger and more flexible basis set to work properly for the HXY molecules. Increasing only the basis set using the perturbation theory (MPn) shortens the Xe−H bond length thereby also increasing the harmonic vibrational frequency. If higher correlation levels are used the Xe−H bond length increases decreasing the harmonic frequencies. The most appropriate levels of theory seem to be the CCSD(T) and multireference-CI (MR-CI) levels when connected with extensive basis sets.[90] It must be noted, however, that even though the CCSD(T) theory, coupled with large basis sets and taking into account BSSE and spin-orbit effects, results in a qualitatively correct picture, it failed to reproduce a deep enough potential well to be consistent with the observed overtone/combination band of HXeH. Therefore, in most cases the low-level calculations are sufficient to help the interpretation of experimental data while obtaining an accurate potential energy surface is very demanding.

Computed Structures of the HXY Molecules

The observed new rare-gas molecules can roughly be divided into three groups: the centrosymmetric HXH molecule, the linear HXY(Z) molecules, and the bent HXYZ molecules (see Figure 1). In all of these cases, linear bonding around the rare-gas atom is found. The only new centrosymmetric molecule HXeH resembles its fluorine analog FXeF. Concerning the structures of these novel rare-gas molecules we have to rely on calculated values, experimental data being nonexistent so far. The calculated structural parameters, Mulliken charges and dipole moments of the various HXY(Z) molecules, are collected in Table 3. For comparison the experimental bond lengths of XeH^+ and KrH^+ are included.

It can be noted that the calculated parameters follow a general trend. The H−Xe bond length decreases with the increasing partial positive charge on xenon. The positive charge residing on xenon is largest (+0.88) for the HXeNC molecule resulting in the shortest H−Xe bond length (1.659 Å). This trend finally approaches the XeH^+ cation at the limit of complete ionic bonding. Similarly, in the Kr compounds the larger charge on Kr results in a shorter bond length converging towards the KrH^+ cation. It is also worth mentioning that these molecules have very large dipole moments due to the extent of charge separation.

To rationalize the difference of the HXY molecules from the van der Waals geometries of the constituents we can inspect the HXeI system. Figure 6 displays the molecular and van der Waals distances showing that chemical bond formation between the atoms results in more than two-fold decrease of the Xe−H distance and in almost 30% contraction of the Xe−I distance.

HXeSH is an interesting bent molecule representing the first example of an Xe−S bond. The Xe−S−H angle of ca. 91 degrees is very close to the angle of H_2S. Also the S−H bond length of HXeSH (calculated 1.334 Å) is almost the same as the experimental value for H_2S (1.336 Å).[91] Therefore it seems that the rare-gas atom is inserted into the covalent hydrogen−sulphur bond and has a negligible effect on the residing molecule. Also, for the linear HXeCN, HXeNC, and HKrCN molecules the rare-gas molecules restore the precursor structure, the novel molecules being linear and having C≡N bond lengths close to the HCN precursor.

Vibrational Spectra of the HXY Molecules

The Xe−H stretching motion is an essential part of the vibrational calculation of the HXY molecules. As discussed above, highly correlated calculations with large basis sets

[a] For Kr and Xe 18-VE ECPs and for I 17-VE ECP (denoted as LJ18, see ref.[93]) were used while the standard 6−311++G(2d,2p) basis set was applied for the first- and second-row atoms. − [b] This is the only bent molecule of the HXY(Z) molecules with the H−S−Xe angle being 91.02°. − [c] Experimental value 1.603 Å, ref.[94]. − [d] Experimental value 1.421 Å, ref.[85].

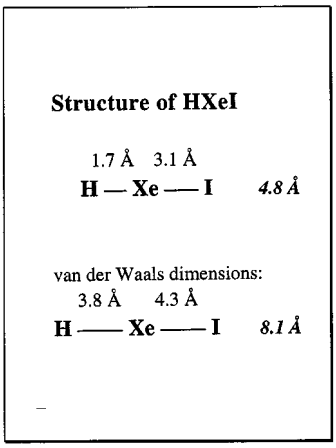

Figure 6. Structure of HXeI; the molecular bond lengths are taken from MP2/LJ18 calculations; the van der Waals dimensions are deduced from Xe−H[95] and Xe−I[96] pair potential minima

result in a good agreement with the experimental values.[90] This is especially important when the HXY molecule is relatively weakly bound, and the potential energy surface near the dissociation limit is not described accurately with modest computational methods like the perturbation theory. For instance, such examples are HKrCN[64] and HXeSH.[65] For HKrCN the MP2/LJ18-calculated Kr−H stretching wavenumber is 2011 cm^{-1}, while the largest correlation level, CCSD(T)/LJ18, gives a harmonic ν_{Kr-H} frequency of 1781 cm^{-1} for HKrCN, still being ca. 300 cm^{-1} above the experimental value of 1497 cm^{-1}.[64] As discussed previously, anharmonic effects explain partially the difference. In addition, the solid host red-shifts the observed wavenumber from its gas-phase value and the remaining discrepancy can mostly be attributed to the underestimated basis set used. For HXeSH the situation is similar: The MP2/LJ18 calculations predict the Xe−H stretching at 1521 cm^{-1}, while the CCSD(T)/LJ18 calculation reduces this value to 1148 cm^{-1}, the experimental value being 1119 cm^{-1}.

Increasing the size of the HXY molecules beyond three-atomics makes the use of state-of-art computational methods unfeasible. In the course of our work with the HXY-type molecules we have found that even the moderate MP2/LJ18 level gives reasonable qualitative results for structures, charge separation, and vibrational frequencies. In addition, the extreme intensities of the X−H stretching absorptions are well predicted. Therefore, we have collected the MP2/LJ18-calculated characteristic X−H bond lengths and vibrational frequencies, including IR intensities in Table 4 for comparison. Also the Becke3-LYP/LJ18-calculated values are included, since the DFT methods are becoming more attractive for larger molecular systems due to their computational efficiency.

The experimental Xe−H stretching wavenumbers shift to higher values when going from the HXeSH molecule to HXeNC. Even though the computational vibrational frequencies are generally overestimated the systematic trend among the present HXY molecules is correctly predicted as discussed in more details in ref.[67] Therefore, using a low-level, economical computational approach, quite useful approximations on the structures and especially on the ν_{X-H} wavenumbers and intensities of new HXY molecules can be done.

Energetics of the HXY Molecules

Even though the structure and vibrational frequencies appear to be reachable also with low-level computational methods, the energetics of the new HXY molecules is more challenging. As demonstrated in the simple bonding model derived earlier (see Figure 5), the HXY molecules possess both neutral (HXY) and ionic (HX^+Y^-) character. This means also that the closer the ionic surface lies to the neutral molecular surface, the larger interaction between the two surfaces is expected. The preliminary MP2/LANL1DZ calculations indicated that the H + X + Y atomic dissociation limit would be *below* the HXY molecular en-

Table 4. The calculated harmonic H−Xe stretching frequencies [cm^{-1}] of HXY(Z) molecules at the MP2 and Becke3-LYP levels; the numbers in the parentheses are the calculated intensities [km mol^{-1}], and the bond lengths are given in Å

ergy[61][62] However, increasing the basis set *and* the correlation level the situation is reversed and the HXY configuration becomes *lower* in energy than the atomic dissociation limit. A dissociation energy of 0.32 eV was estimated for HXeH according to the dissociation limit Xe + 2 H.[90] This result was obtained at the CCSD(T) level, using a large 18-VE ECP basis for Xe and all-electron basis for hydrogen, and correcting the value for both BSSE and spin-orbit coupling effects. However, taking into account the observed overtone/combination transition at 2003 cm^{-1} and assuming this vibrational level to lie below the dissociation limit, and estimating the symmetric stretch wavenumber from the calculations (ca. 1100 cm^{-1}) we end up with a value of at least 0.48 eV for the experimental dissociation energy (D_e) of HXeH. The origin of the present discrepancy ($\geq$ 0.16 eV) between the calculated and experimental dissociation energies may be technical since also the stabilising role of the solid host has been estimated to be small (0.033 eV for quadrupole interaction of HXeH in Xe[90]).

For HXeI an experimental D_e value of about 0.42 eV has been deduced from IR pumping experiments.[63] These molecules together with HXeSH are the weakest bound of all the HXY molecules found up to now. They also have the lowest lying Xe−H stretching bands. The ν_{Xe-H} for HXeCl at 1648 cm^{-1} suggests a larger binding energy than for HXeH, HXeSH, and HXeI. Indeed, a preliminary high-level computational study at the CISD level estimates the binding energy of HXeCl to be 0.9 eV.[92] The computationally strongest bound molecule is HXeCN, which has a D_e of 1.43 eV[64] with respect to the dissociation limit H + Xe + CN. In general, the observed HXY molecules feature dissociation energies between 0.4 and 1.4 eV, and the corresponding fluorine compound HXeF is expected to be much more strongly bound but it has not yet been experimentally observed.

An additional interesting aspect of the calculation of the stabilization energy of the HXY molecules is that all calculations are performed for molecules in vacuo whereas the experimental evidence up to now is from low-temperature solid rare gases. This rises the question of the role of the rare gas lattice in stabilizing the HXY molecules. First, as found out in the IR pumping experiments on HXeI, the lattice traps the atomic fragments. Secondly, except HXeH, the HXY molecules possess strong dipole moments which could induce long-range interactions with the surrounding rare gases. Especially the xenon environment could be an important, additional stabilizing factor due to its large polarizability compared to argon and krypton. Anyhow, as was shown experimentally in ref.[61], HXeCl can be easily produced also in Kr surroundings and in this case the Xe−H stretch was shifted only by 16 cm^{-1} from its value in pure Xe. Corresponding shifts for HXeBr and HXeCN are 26 and 20 cm^{-1}, respectively,[61][64] indicating a relatively small environmental effect.

Conclusions

Rare-gas atoms X (Xe and Kr) are shown to react with a hydrogen atom and a neutral electronegative fragment Y in a concerted reaction to produce neutral ground-state HXY molecules. The very strong X−H stretching absorption is the most characteristic spectral feature of these molecules, its wavenumber reflecting sensitively the electron distribution in the HXY molecule. The present ab initio calculations show that the bonding comprises both covalent and ionic contributions. A bonding model based on avoided crossing of the neutral H + X + Y and ionic $(HX)^+ + Y^-$ surfaces is presented. This model is applicable for qualitative understanding of bonding in all of the new compounds: HXeI, HXeBr, HXeCl, HXeH, HXeCN, HXeNC, HXeSH, HKrCl, and HKrCN. At the present time these species are produced in solid rare gases by photodissociation of the HY precursor and thermal mobilisation of the fragments. The dissociation energies vary from 0.4 to over 1 eV, and warrant observation of these molecules also in the gas phase. Future computational studies will deepen our understanding in the bonding details as well as suggest the existence of further similar compounds.

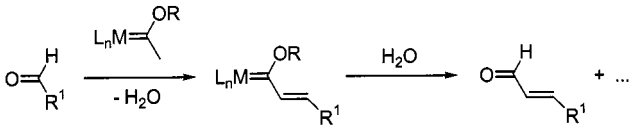
Synthesis and Hydrolysis of [Alkenyl(alkoxy)carbene]manganese Complexes: Evidence for a Transient Allylic Intermediate on the Way to α,β-Unsaturated Aldehydes



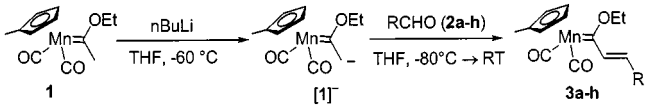
Carole Mongin,[a] Yannick Ortin,[a] Noël Lugan,*[a] and René Mathieu[a]

Keywords: Manganese / Carbenes / Hydrolyses / Aldehydes / Vinylogation

A variety of alkenylcarbene complexes [Cp′(CO)$_2$Mn=C(OEt)CH=CHR] (**3**) (Cp′ = η^5-MeC$_5$H$_4$) was obtained in a straightforward manner upon aldol condensation of [Cp′(CO)$_2$Mn=C(OEt)CH$_3$] (**1**) with aromatic and α,β-unsaturated aldehydes RC(H)O (**2**). The reaction is totally stereoselective, giving (*E*)- or (*all-E*)-alkenylcarbenes only. The protonation of **3** at low temperature followed by reaction with water affords the α,β-unsaturated aldehyde complexes [Cp′(CO)$_2$Mn(η^2-RCH=CHCHO] (**5**), from which the aldehydes RC(H)=C(H)C(H)O (**6**) were displaced by acetonitrile. The intermediate aldehyde complexes are shown to result from the hydrolysis of a transient cationic π-allyl species [Cp′(CO)$_2$Mn(η^3-RCHCHC(OEt)H]$^+$ ([**4**]$^+$) formed upon protonation of **3**.

Introduction

Alkenyl-alkoxy-substituted Fischer carbene complexes have been shown in some cases to release α,β-unsaturated aldehydes upon hydrolysis, with optimum efficiency at high pH values.[1,2] Though mechanistically clear under such conditions,[2b] the reaction has received little attention as a synthetic procedure. Yet, if we keep in mind that alkenyl-alkoxy-substituted Fischer carbenes can be obtained upon aldol condensation of alkyl(alkoxy)carbene complexes with aldehydes,[3,4] their hydrolysis can be regarded as part of a potential process for the homologation of aldehydes into α,β-unsaturated aldehydes (Scheme 1).



Scheme 1

The vinylogation of aldehydes is of special interest for the synthesis of molecular materials[5] and natural products.[6] Though several procedures derived from general olefination reactions have been devised,[7] the search for easy-to-handle, selective, and versatile reagents is still of current interest.[7e,8] As part of an ongoing effort to develop synthetically useful reactions employing cheap and readily available group-7 Fischer carbene complexes obtained from [Cp′Mn(CO)$_3$] (Cp′ = η^5-MeC$_5$H$_4$),[9] we were challenged to examine the scope of [Cp′(CO)$_2$Mn=C(OEt)CH$_3$] (**1**) for the above reaction. The present paper deals with the results of our investigation and provides insight into the mechanism of the hydrolysis of alkenyl-substituted Fischer carbene complexes under acidic conditions.[10]

Results and Discussion

The carbenemanganese anion [Cp′(CO)$_2$Mn=C(OEt)-CH$_2$]$^-$ ([**1**]$^-$), generated in situ by addition of *n*BuLi to a THF solution of [Cp′(CO)$_2$Mn=C(OEt)CH$_3$] (**1**) cooled at −60°C,[11] was treated at low temperature with one molar equivalent of various aromatic and α,β-unsaturated aldehydes RCHO (**2a**−**h**, Table 1). An aldol/elimination reaction subsequently occurred upon return to room temperature, giving the corresponding alkenyl(alkoxy)carbenes [Cp′(CO)$_2$Mn=C(OEt)CH=CHR] (**3a**−**h**) in valuable yields (Scheme 2, Table 1, entries 1−8).

Scheme 2. Aldol condensation of **1** with aldehydes **2a**−**h**

This sequence was reproduced with a dialdehyde, namely 1,1′-bis(formyl)ferrocene. Depending on the stoichiometry, the reaction could be directed toward either [{η^5-(Cp′(CO)$_2$Mn=C(OEt)CH=CHC$_5$H$_4$)}Fe{η^5-C$_5$H$_4$CHO}] (**3i$_1$**), or [{η^5-(Cp′(CO)$_2$Mn=C(OEt)CH=CHC$_5$H$_4$}$_2$Fe] (**3i$_2$**) (Scheme 3, Table 1, entries 9−10).

Complexes **3a**−**i** were characterized by ^{1}H-, ^{13}C-, and (when necessary) HMQC ^{1}H-^{13}C NMR analysis.[12] Their formation is totally stereoselective, giving (*E*) (for **3a**−**b**, **f**, **i**) or (*all-E*) (for **3c**−**e**, **g**−**h**) isomers only, as indicated by $^3J_{HH}$ coupling constants of ca. 15 Hz for the protons adjacent to the carbon−carbon double bonds.

In a first attempt to release α,β-unsaturated aldehydes from the above alkenyl(alkoxy)carbenes upon hydrolysis in

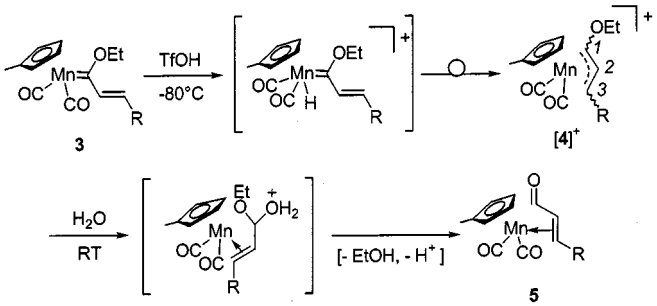


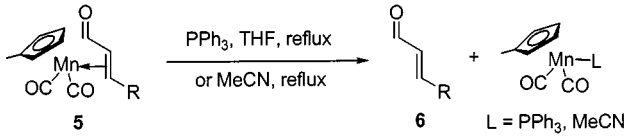
Scheme 3. Aldol condensation of **1** with 1,1′-diformylferrocene (**2i**)

basic conditions, **3c** was treated with urotropine in the presence of water according to a procedure Aumann et al. described for group-6 analogs.[1] No reaction was observed after 24 hours. This may be attributed to the insufficient electrophilic character of the carbene carbon atom that disfavors the required nucleophilic attack of hydroxide ions.[1,2b]

Keeping in mind that Fischer carbene complexes can be protolytically cleaved to form the corresponding aldehydes,[10] we next treated complexes **3** with one equivalent of TfOH at −80 °C in CH_2Cl_2 (but two equivalents in the case of **3f**[13] and in the case of the dialkenylcarbene $\mathbf{3i_2}$). An instantaneous reaction occurred, leading to a fairly stable species, whose IR spectra displayed two bands at ca. 2015 and 1970 cm^{-1} characteristic of $[Cp'(CO)_2MnLX]^+$-type complexes.[14,15] These were indeed identified as the π-allyl species $[Cp'(CO)_2Mn(\eta^3\text{-RCHCHC(OEt)H}]^+$ ([**4**]$^+$) on the basis of ^{1}H-, ^{13}C-, and HMQC ^{1}H-^{13}C NMR spectroscopy for [**4a**−**c**]$^+$.[12] In particular, the signals of the protons H^1, H^2, and H^3 within the π-allyl moiety (see Scheme 4) in [**4c**]$^+$ were observed at δ = 6.12, 5.55, and 3.41, respectively, in the ^{1}H dimension, and they correlate with the signals observed at δ = 138.1, 77.3, and 62.2 in the ^{13}C dimension. The proton H^1 clearly originates from TfOH, since the NMR spectrum of [D-**4c**]$^+$, generated from **3c** upon treatment with TfOD, does not show any resonance in the area around δ = 6.12. Within the $^{13}C\{^1H\}$-NMR sensitivity and resolution limits, the formation of [**4a**−**c**]$^+$ is quantitative and stereoselective. However, due to the systematic formation of paramagnetic impurities, their stereochemistry could not be determined by ^{1}H NMR.

When an excess of water was added to CH_2Cl_2 solutions of [**4a**−**i**]$^+$, IR monitoring showed the gradual disappearance of the bands due to [**4a**−**i**]$^+$ whereas three new bands grew at ca. 1965, 1905, and 1670 cm^{-1} indicative of the formation of the α,β-unsaturated aldehyde complexes $[Cp'(CO)_2Mn(\eta^2\text{-RCH=CHCHO})]$ (**5a**−**i**) (Scheme 3, Table 1).[16] The NMR data of **5a**−**i** clearly indicate that the α,β-unsaturated aldehyde ligand is coordinated in an η^2 fashion through the carbon−carbon double bond adjacent to the aldehyde function, and that the (*E*) or (*all-E*) arrangement of the alkenyl moieties in **3a**−**i** is maintained through their conversion into **5a**−**i**.[12] Finally, when [D-**4c**]$^+$ was treated with water, the deuterium label on C^1 was totally retained in the aldehyde function of $[Cp'(CO)_2Mn(\eta^2\text{-PhCH=CHCH=CDO})]$ [D-**5c**].[17]

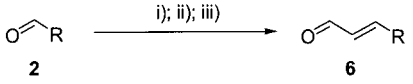
The overall transformation of the alkenyl(alkoxy)carbene complexes **3** into the α,β-unsaturated aldehyde complexes **5** is depicted in Scheme 4.



Scheme 4. Proposed mechanism for the formation of **5**

Though no intermediate hydride species could be observed, the context of chemistry and the results of previous studies on protonation reactions of electron-rich carbene complexes suggest that [**4**]$^+$ is likely to result from a protonation of **3** at the metal center followed by hydride migration to the carbene carbon atom,[18,19] and concomitant stabilization of the resulting 16e$^-$ species by coordination of the pendant alkenyl moiety.[20] Upon addition of water, hydrolysis of the highly electrophilic π-allyl ligand in [**4**]$^+$[15c] would then take place through initial nucleophilic addition of water (or hydroxide ions) at the carbon atom bearing the ethoxy group to give the final aldehyde complexes **5**.

Finally, the α,β-unsaturated aldehydes RCH=CHCHO (**6**, Table 1) could be released in nearly quantitative yields by displacement by triphenylphosphane in THF, or by



acetonitrile in neat acetonitrile, under refluxing conditions (Scheme 5).

5 6

Scheme 5. Demetalation of the α,β-unsaturated aldehydes **6**

Considering the satisfactory yields of the individual steps, as well as the efficient demetalation of the newly formed α,β-unsaturated aldehydes from the final complex, we logically became interested in a possible application of the above sequence to the vinylogation of aldehydes. A one-vessel procedure was thus developed (Scheme 6) giving the α,β-unsaturated aldehydes **6** in synthetically useful yields.

2 6

Scheme 6. Reagents and reaction conditions: i) $[\mathbf{1}]^-$, −78°C → 20°C, THF; ii) HCl (aq.), MeCN; iii) reflux

The best performances were recorded with formylferrocene (**2b**) and 4-(dimethylamino)benzaldehyde (**2f**) giving the corresponding vinylogated aldehydes **6b** and **6f** in 75%, and 68% yield, respectively. A practical limitation of the procedure is still the need of chromatographic workup to separate the newly formed aldehyde **6** from its precursor **2**.

In conclusion, whereas a recurrent problem with organometallic synthons is the difficulty to establish the mechanism of their participation in organic reactions, the carbenemanganese system disclosed here appears to be both synthetically useful and amenable to mechanistic studies due to the relative stability of the intermediates. In particular, we suggest that the mechanism established here for the hydrolysis of the (alkenylcarbene)manganese complexes under acidic conditions may serve as a model for parallel transformations occurring in related systems.[2b,10d]

Experimental Section

General Remarks: All synthetic manipulations were carried out using standard Schlenk techniques under dry N_2. THF used for the synthesis was distilled under N_2 from Na/benzophenone ketyl just before use. Other solvents were purified according to standard procedures, and stored under N_2. A liquid N_2/2-propanol slush bath was used to maintain samples at the desired low temperature. − Chromatographic separations were performed on alumina. − $[Cp'(CO)_2Mn{=}C(OEt)CH_3]$ (**1**) was prepared by modifications of literature procedures for related complexes.[21] 1,1′-Diformylferrocene (**2i**) was synthesized according to a published procedure.[22] − Solution-IR spectra were recorded with Perkin−Elmer 225 or Perkin−Elmer 983 spectrophotometers with 0.1-mm cells equipped with CaF_2 windows. − ^{1}H- and ^{13}C-NMR spectra were obtained with Bruker AC200, WM250, DPX300, or AMX400 spectrometers and were referenced to the residual signals of the solvents. − Mass spectra were recorded with a Nermag R10−10 mass spectrometer. − Microanalyses were performed with a Perkin−Elmer 2400 CHN analyzer.

1. Typical Procedure for the Synthesis of the Alkenyl(alkoxy)carbene Complexes $[Cp'(CO)_2Mn{=}C(OEt)CH{=}CHR]$ (3) as Illustrated for 3c [R = (*E*)-PhCH=CH]: The carbene anion $[\mathbf{1}]^-$ was generated in situ by addition of *n*BuLi (0.630 mL of a 1.6 M solution in hexanes, 1.1 mmol) to a solution of $[Cp'(CO)_2Mn{=}C(OEt)CH_3]$ (**1**, 0.260 g, 1.0 mmol) in THF (15 mL) at −60°C. After stirring for 20 min, the solution was cooled to −80°C and (*E*)-cinnamaldehyde (**2c**, 0.125 mL, 1.0 mmol) was added. The cooling bath was removed to allow the reaction medium to reach room temperature gradually. After stirring for an additional 1 h, the solvents were removed under vacuum. The brown oily residue was extracted with pentane (ca. 20 mL), and applied on top of an alumina column. Elution with pentane afforded a yellow band which was discarded. Elution with a diethyl ether/pentane (1:10) mixture gave a brown band containing $[Cp'(CO)_2Mn{=}C(OEt)CH{=}CHCH{=}CHPh]$ (**3c**), which was isolated as a brown solid after removal of the solvents under vacuum (0.245 mg, 0.65 mmol, 65% yield). − $C_{21}H_{21}MnO_3$ (376.33): calcd. C 67.02, H 5.58; found C 67.13, H 5.65. − Mp 94−96°C. − IR (ν_{CO}, THF): $\tilde{\nu}$ = 1940, 1876 cm^{-1}. − NMR ^{1}H (C_6D_6, 250 MHz, 298 K): δ = 7.27−7.09 (Ph), 7.00 (m, 1 H, H^2, J_{H2H3} = 15 Hz), 6.73 (m, 1 H, H^3, J_{H3H4} = 11 Hz), 6.63 (m, 2 H, H^4 and H^5, J_{H3H4} = 11 Hz, J_{H5H4} = 15 Hz), 4.82 (q, 2 H, OCH_2CH_3, J_{HH} = 7 Hz), 4.55−4.35 (m, 4 H, Me*Cp*), 1.71 (s, 3 H, *Me*Cp), 1.29 (t, 3 H, OCH_2CH_3). − NMR $^{13}C\{^1H\}$ (C_6D_6, 63 MHz, 298 K): δ = 316.1 (C^1), 233.9 (MnCO), 143.4 (C^2), 139.4 (C^5), 137.2−126.8 (Ph), 128.6 (C^3), 123.4 (C^4), 104.1, 87.7, 86.5 (Me*Cp*), 71.6 (OCH_2CH_3), 14.8 (OCH_2CH_3), 13.4 (*Me*Cp). − MS (EI); *m*/*z*: 376 [M$^+$].

2. In Situ Formation of the π-Allyl Complexes $Cp'(CO)_2Mn(\eta^3$-RCHC)C(OEt)H]$^+$ ([4][TfO]) as Illustrated for [4c][TfO] [R = (*E*)-PhCH=CH]: TfOH (0.018 mL, 0.2 mmol) was added to a solution of $[Cp'(CO)_2Mn{=}C(OEt)CH{=}CHCH{=}CHPh]$ (**3c**, 0.080 mg, 0.2 mmol) in CD_2Cl_2 (1 mL) at −80°C. The brown solution instantaneously turned red. The reaction mixture was allowed to reach room temperature, and the solution was filtered through a plug of celite directly into an NMR tube for analysis. Complex [D-**4c**][TfO] was generated in a similar manner from **3c** and TfOD. − IR (ν_{CO}, CH_2Cl_2): $\tilde{\nu}$ = 2010, 1970 cm^{-1}. − ^{1}H NMR (CD_2Cl_2, 300 MHz, 223 K): δ = 7.7−7.3 (m, 5 H, Ph), 7.2−6.7 (m, 2 H, H^4 and H^5), 6.12 [s (br.), 1 H, H^1], 5.55 [s (br.), 1 H, H^2], 5.3−4.9 (m, 4 H, Me*Cp*), 4.30 [s (br.), 2 H, OCH_2CH_3], 3.41 [s (br.), 1 H, H^3], 1.73 (s, 3 H, *Me*Cp), 1.29 [s (br.), 3 H, OCH_2CH_3]. − $^{13}C\{^1H\}$ NMR (CD_2Cl_2, 75 MHz, 223 K): δ = 227.5, 226.4 (MnCO), 138.1 (C^5), 132.2 (C^1), 134.8, 128.8, 128.4, 126.9 (Ph), 125.4 (C^4), 105.9, 90.9, 90.8, 89.5, 89.2 (Me*Cp*), 77.3 (C^2), 72.6 (OCH_2CH_3), 62.2 (C^3), 14.1 (OCH_2CH_3), 12.2 (*Me*Cp).

3. Typical Procedure for the Synthesis of the Aldehyde Complexes $[Cp'(CO)_2Mn(\eta^2$-RCH=CHCHO)] (5) as Illustrated for 5c [R = (*E*)-PhCH=CH]: TfOH (0.180 mL, 2.0 mmol) was added to a solution of $[Cp'(CO)_2Mn{=}C(OEt)CH{=}CHCH{=}CHPh]$ (**3c**, 0.750 g, 2.0 mmol) in dichloromethane (15 mL) at −80°C. The cooling bath was removed to allow the reaction medium to reach room temperature. An excess of water (5 mL) was added. After stirring for 30 min, the organic phase was separated and the volatiles were removed under vacuum. The brownish oily residue was purified by column chromatography on alumina. Elution with a diethyl ether/pentane (1:1) mixture gave a brown band, which was discarded. Elution with pure dichloromethane released $[Cp'(CO)_2Mn(\eta^2$-PhCH=CHCH=CHCHO) (**5c**), isolated as an orange solid after evaporation of the solvent (0.610 mg, 1.76 mmol, 88% yield). − $C_{19}H_{17}MnO_3$ (348.28): calcd. C 65.51, H 4.88; found C 65.68, H 4.81. − Mp 136°C (dec.). − IR (ν_{CO}, CH_2Cl_2): $\tilde{\nu}$ = 1965, 1904, 1675 cm^{-1}. − ^{1}H NMR (C_6D_6, 250 MHz, 298 K): δ = 8.32 (d, 1

H, H[1], J_{H1H2} = 7 Hz), 7.26−7.05 (Ph), 6.67 (d, 1 H, H[5], J_{H5H4} = 16 Hz), 5.55 (dd, 1 H, H[4], J_{H4H3} = 10 Hz), 3.83, 3.79, 3.75, 3.60 (m, 4 H, Me*Cp*), 4.05 [AB(X) pattern, 2 H, H[2] and H[3], J_{H2H3} = 11 Hz], 1.47 (s, 3 H, *Me*Cp). − $^{13}C\{^1H\}$ NMR (C_6D_6, 63 MHz, 298 K): δ = 233.0, 229.8 (MnCO), 192.2 (C[1]), 131.9 (C[5]), 131.8−125.0 (Ph), 129.9 (C[4]), 103.2, 86.2, 85.8, 85.5, 84.3 (Me*Cp*), 67.8 (C[3]), 60.5 (C[2]), 12.8 (*Me*Cp). − MS (EI); *m*/*z*: 348 [M^+].

4. Typical Procedure for the Demetallation of α,β-Unsaturated Aldehydes RCH=CHCHO (6) as Illustrated for (*E*,*E*)-PhCH=CHCH=CHCHO [6c (≡ 2h)]: Complex [Cp′$(CO)_2$Mn(η[2]-PhCH=CHCH=CHCHO)] (**5c**, 0.610 g, 1.76 mmol) was dissolved in degassed acetonitrile (15 mL) and then heated under reflux for 1 h. After cooling, acetonitrile was removed under vacuum. The oily yellow residue was chromatographed on an alumina column. Elution with a pentane/diethyl ether (1:1) mixture afforded a yellow band containing [Cp′$(CO)_2$Mn(NCMe)]. A second elution with pure diethyl ether afforded (*E*,*E*)-5-phenyl-2,4-pentadienal [**6c** (≡ **2h**)], which was isolated as a yellow solid (0.255 g, 1.62 mmol, 95% yield).

5. One-Vessel Vinylogation of Aldehydes as Illustrated for Formylferrocene (2b) To Give (3-Oxo-1-propenyl)ferrocene [6b (≡ 2g)]: The carbene anion [Cp′$(CO)_2$Mn=C(OEt)CH_2]$^-$ [**1**]$^-$ was generated in situ by addition of *n*BuLi (1.25 mL of a 1.6 M solution in hexanes, 2.0 mmol) to a solution of [Cp′$(CO)_2$Mn=C(OEt)CH_3] (**1**, 525 mg, 2.0 mmol) in THF (15 mL) at −60 °C in a two-necked flask fitted with a reflux condenser. After stirring for 20 min, the solution was cooled to −80°C and formylferrocene was added as a powder (430 mg, 2.0 mmol). The cooling bath was removed to allow the reaction medium to reach room temperature gradually, and the solution was stirred for an additional 1 h. THF was evaporated under vacuum and replaced by degassed acetonitrile (30 mL). Hydrochloric acid (0.330 mL of a 10 M solution in water) was added dropwise, and the mixture was heated under reflux for 1 h. After cooling, the volatiles were removed under vacuum. The oily residue was purified by column chromatography on alumina. Elution with a pentane/diethyl ether (1:1) mixture afforded a yellow band containing traces of [Cp′$(CO)_3$Mn], traces of **1**, and [Cp′$(CO)_2$Mn(NCMe)], which was discarded. A second elution with pure diethyl ether gave a purple band followed by an orange one. The first one contained (3-oxo-1-propenyl)ferrocene [**6b** (≡ **2g**)], isolated as a microcrystalline purple material (360 mg, 1.5 mmol, 75% yield), whereas the second one contained traces of unchanged formylferrocene.

Acknowledgments

We wish to thank the CNRS for financial support, the French Ministère de l'Education Nationale, de la Recherche et de la Technologie for a fellowship to C. M. and Y. O., and Dr. Guy Lavigne for helpful discussions.

Synthesis and Homomolecular Metalation of Trialkylsilylphosphanides of Calcium and Barium

Matthias Westerhausen,*[a] Matthias H. Digeser,[a] Mathias Krofta,[a] Nils Wiberg,[a] Heinrich Nöth,[a][+] Jörg Knizek,[a][+] Werner Ponikwar,[a][+] and Thomas Seifert[a][+]

Keywords: Arsenic / Barium / Calcium / Metalations / NMR spectroscopy / Phosphorus

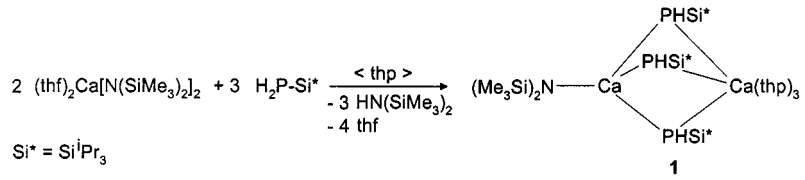
Metalation of triisopropylsilylphosphane with bis(tetrahydrofuran-*O*)calcium bis[bis(trimethylsilyl)amide] in tetrahydropyran (thp) in a molar ratio of 3:2 yields $(Me_3Si)_2NCa[\mu\text{-}P(H)Si\mathit{i}Pr_3]_3Ca(thp)_3$ (**1**) containing a trigonal-bipyramidal Ca_2P_3 core, the metal atoms occupying apical positions. Reaction of two equivalents of triisopropylsilylphosphane or -arsane with bis(tetrahydrofuran-*O*)barium bis[bis(trimethylsilyl)amide] in tetrahydrofuran gives the corresponding bis(phosphanide) **2** and bis(arsanide) **3**, compounds of the type $(thf)_3Ba[\mu\text{-}E(H)Si\mathit{i}Pr_3]Ba(thf)_2E(H)Si\mathit{i}Pr_3$ with E = P, As. The equimolar reaction of (tri-*tert*-butylsilyl)phosphane with $(thf)_2Ba[N(SiMe_3)_2]_2$ in toluene yields heteroleptic dimeric $(thf)_2Ba[N(SiMe_3)_2][P(H)Si\mathit{t}Bu_3]$ (**4**). Addition of a further equivalent of $H_2PSi\mathit{t}Bu_3$ leads to the formation of homoleptic $(thf)_nBa[P(H)Si\mathit{t}Bu_3]_2$ (**5**). Dissolution of the latter in aromatic hydrocarbons leads to the elimination of $H_2PSi\mathit{t}Bu_3$, yielding dimeric $(thf)Ba_3(PSi\mathit{t}Bu_3)_2[P(H)Si\mathit{t}Bu_3]_2$ (**6**). The inner core of **6** consists of the tetramer $(BaPSi\mathit{t}Bu_3)_4$ based on a Ba_4P_4 heterocubane unit, two opposite faces being capped with $(thf)Ba[P(H)Si\mathit{t}Bu_3]_2$ molecules.

Introduction

The bis(trialkylsilyl)amides and -phosphanides of the heavier alkaline earth metals calcium, strontium, and barium are gaining interest not only due to their unexpected solid-state and solution structures, but also due to their high reactivity.[1] Addition reactions of alkaline earth metal bis[bis(trimethylsilyl)amides] and the corresponding phosphanides with benzonitrile are followed by 1,3-trimethylsilyl group shifts, as is seen in the syntheses of the alkaline earth metal bis[*N*,*N*′-bis(trimethylsilyl)benzamidinates][2] and bis[1,3-bis(trimethylsilyl)-2-phenyl-1-aza-3-phosphapropenides].[3] Addition reactions of $M[P(SiMe_3)_2]_2$ (M = Ca, Sr, Ba) with diphenylbutadiyne yield the alkaline earth metal phospholides by a 1,3-trimethylsilyl group migration from the phosphorus to a carbon atom.[4]

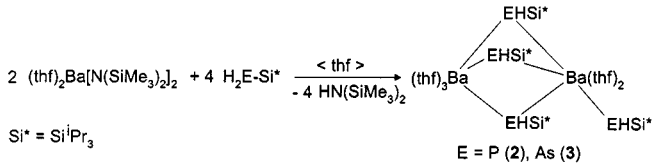
Another type of reactivity stems from the pK_s values of compounds $HE(SiMe_3)_2$ (E = N, P). Metallations of substrates with more acidic hydrogen atoms such as alcohols,[1] thiols,[5] selenols,[1,6,7] and tellurols[7,8] are well known. The IR spectra of mono(trialkylsilyl)-substituted phosphanides such as tetrakis(tetrahydrofuran-*O*)calcium bis(triisopropylsilylphosphanide)[9] reveal a reduced force constant of the P−H bond compared with the corresponding bonds in the phosphanes $H_2PSi\mathit{i}Pr_3$ and $HP(Si\mathit{i}Pr_3)_2$.[9,10] This enhanced reactivity leads to slow decomposition of these compounds when they are dissolved in hydrocarbons such as toluene or benzene, but as yet we have been unable to determine the structures of the products thus formed. Because phosphanediides tend to be polymeric, insoluble, and poorly characterized materials, the synthesis of such compounds has remained a challenge and hence there are relatively few examples. Driess and co-workers prepared oxygen-centered Li_2O-containing oligomers[11] and R_3SiF adducts of a dimer[12] of dilithium triorganylsilylphosphanediide and -arsanediide. Monomeric bis[tris(trimethylsilyl)methylzinc] triisopropylsilylphosphanediide[13] displays a pyramidal coordination sphere at the phosphorus atom. Hexameric tin(II) triisopropylsilylphosphanediide crystallizes as a hexagonal Sn_6P_6 prism.[14]

The structures of dimeric alkaline earth metal bis(phosphanides) show an energetic minimum for the bicyclic derivatives $M(\mu\text{-}PH_2)_3MPH_2$ with M = Ca, Sr, and even for the tricyclic isomer $Ba(\mu\text{-}PH_2)_4Ba$, as shown by ab initio calculations.[1,9] The steric demand of the substituents at the phosphorus atom forces the adoption of a monocyclic dimeric structure, with two bridging and two terminally bonded phosphanide substituents.[15] The bicyclic nature of $(Me_3Si)_2NCa[\mu\text{-}P(H)Si\mathit{i}Pr_3]_3Ca(thf)_3$ has been deduced by NMR spectroscopy,[9] although we were unable to obtain single crystals to allow corroboration of this by an X-ray structure determination.



Results and Discussion

Synthesis



Metalation of triisopropylsilylphosphane with calcium bis[bis(trimethylsilyl)amide][16,17] in a 3:2 stoichiometric ratio in tetrahydropyran (thp) yields almost quantitatively bicyclic $(Me_3Si)_2NCa[\mu\text{-}P(H)Si\mathit{i}Pr_3]_3Ca(thp)_3$ (**1**). This compound exhibits somewhat surprising NMR data (vide infra).

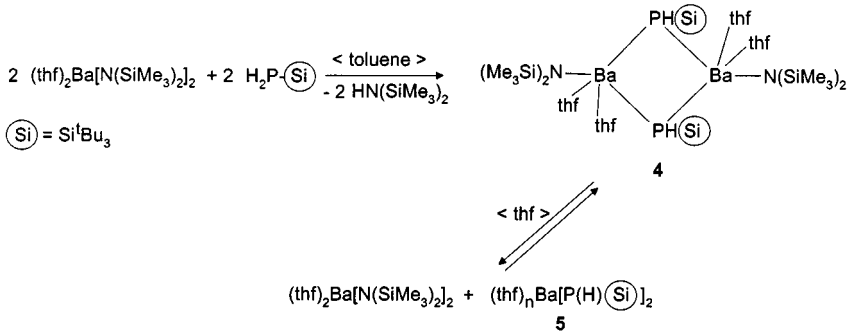
Scheme 1. Synthesis of **1**

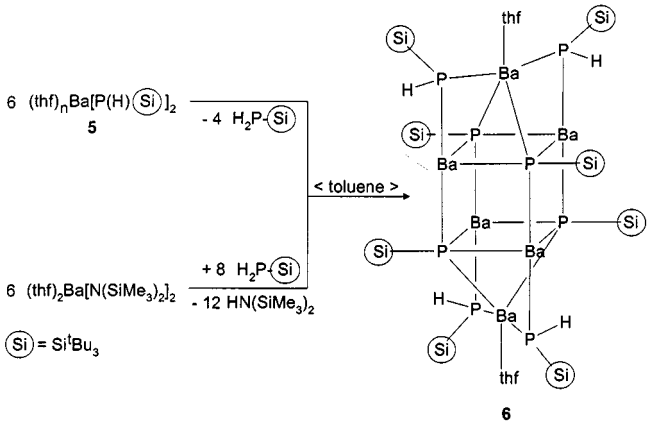
Scheme 2. Synthesis of **2** and **3**

Barium bis[bis(trimethylsilyl)amide][16,18] metalates triisopropylsilylphosphane in thf to give the dimeric barium bis(triisopropylsilylphosphanide) **2** in a good yield. In contrast to the alkaline earth metal phosphanides characterized to date, **2** shows a monomer−dimer equilibrium in thf. Analogous investigations of a toluene solution were not possible since **2** undergoes immediate decomposition upon removal of the neutral coligand in vacuo or after dissolution in toluene. The corresponding arsanide H_2AsSi-iPr_3[19] displays a similar reactivity towards $(thf)_2Ba[N(SiMe_3)_2]_2$, the metalation resulting in the formation of barium bis(triisopropylsilylarsanide) **3**, although we were unable to obtain single crystals of this material. All these colorless compounds were found to be extremely air- and moisture-sensitive.



Compounds **1** and **2** decompose in toluene solution within a few days. The decomposition products show a 1:1 ratio of triisopropylsilylphosphanide and triisopropylsilylphosphanediide substituents, but all efforts to obtain a pure crystalline product were unsuccessful. Therefore, we metalated tri-*tert*-butylsilylphosphane[20] with barium bis[bis(trimethylsilyl)amide]. Reaction of equimolar amounts of $(thf)_2Ba[N(SiMe_3)_2]_2$ and $H_2PSitBu_3$ in toluene quantitatively affords heteroleptic dimeric bis(tetrahydrofuran-*O*)-barium bis(trimethylsilyl)amide tri-*tert*-butylsilylphosphanide (**4**), featuring a central Ba_2P_2 ring. Only the centrosymmetric isomer crystallizes from toluene, although numerous isomers were observed in solution. Assignment of the NMR data to specific isomers was not possible. Dissolution of **4** in thf leads to dismutation reactions and the formation of homoleptic derivatives, namely barium bis[bis(trimethylsilyl)amide] and barium bis(tri-*tert*-butylsilylphosphanide) **5**. Reaction of **4** with a further equivalent of $H_2PSitBu_3$ also quantitatively yields compound **5**, which decomposes with elimination of $H_2PSitBu_3$. Therefore, no monomer−dimer equilibrium could be investigated.

Decomposition of **5** yields colorless $\{(thf)Ba_3(\mu_4\text{-}PSitBu_3)_2[\mu_2\text{-}P(H)SitBu_3]_2\}_2$ (**6**) with a 1:1 molar ratio of $tBu_3SiP(H)^-$ and tBu_3SiP^{2-} anions. This complex can be regarded as a Ba_4P_4 heterocubane with two opposite sides capped by $(thf)Ba[P(H)SitBu_3]_2$ molecules, although the mechanism of its formation might well proceed via a polyhedron best described as a dimer of two pentagonal bipyramids with a common MP_2 face. Although heterocubane structures with heavier alkaline earth metals are only known for heterobimetallic tin(II)-containing molecules such as $[(thf)_3Ca]_2Sn_2(PSiMe_3)_4$[21] and $(toluene)BaSn_3(PSitBu_3)_4$,[22] the trigonal-bipyramidal M_2P_3 core seems to be more common.[1,21,23] Similar findings were published by Rabe et al.[24] in relation to the arylphosphanides of Rb (tetrameric, Rb_4P_4 heterocubane core) and Cs {dimeric, $Cs^+[Cs(\mu\text{-}PHR)_3Cs]^-$ with a trigonal Cs_2P_3 bipyramid}, whereas $NaP(H)SitBu_3$ crystallizes as a dimer with a central Na_2P_2 ring.[20c] The constitution of complex **6** was further proven by an X-ray structure determination (vide infra). Although the central Ba_6P_8 moiety is shielded by eight tri-*tert*-butylsilyl substituents, derivative **6** proved to be air- and moisture-sensitive.



Metalations of $H_2PSiiPr_3$, $H_2AsSiiPr_3$, and $H_2PSitBu_3$ lead to shifts of the P−H stretching vibrations of approximately 70 cm^{-1} towards lower wavenumbers. The large reduction of the P−H force constant explains the increased reactivity with regard to the metalation reaction and accounts for the fact that compounds of the type $M[P(H)SiR_3]_2$ decompose so readily. In complex **6**, the remaining P−H fragments are shielded by the sterically demanding tri-*tert*-butylsilyl groups, which prevent further metalation, even in refluxing toluene.

NMR Spectroscopy

The ^{31}P-NMR spectrum of compound **1** (Figure 1) displays a coupling pattern of the AA′A′′XX′X′′ type with remarkably large $^2J(P,P)$ and $^3J(P,H)$ coupling constants of 92.3 and 11.7/2.1 Hz, respectively, which were verified by simulation. The $^1J(P,H)$ coupling constant of 186.1 Hz lies within the characteristic range. An explanation for these observations could be the close contact of the phosphanide anions due to the formation of the bicyclic Ca_2P_3 bipyramid. The barium complex **2** with a similar Ba_2P_3 core is dynamic in thf solution, with even the terminal and bridging substituents being indistinguishable by NMR. Only very broad signals with half-height widths between 15 (at

Scheme 3. Synthesis of **4** and dismutation reaction in thf

Scheme 4. Synthesis of **6**

−30°C, δ = −291.7) and 1060 Hz (at +50°C, δ = −280.2) are observed. Corresponding investigations of a toluene solution were not possible due to the decomposition of **2**. Similar results were obtained for **5**, which do not merit special comment.

In contrast to the NMR data of **1**, the ^2J(P,P) coupling constants of **6** are smaller than 3 Hz and are not resolved. With a ^1J(P,H) coupling constant of 149 Hz, however, the signal at δ = −222.9 can clearly be assigned to the phosphanide ligands. The tri-*tert*-butylsilylphosphanediide substituents show a remarkable low-field shift of δ = −25.0. This chemical shift may be explained by the rather high coordination number of five at the phosphorus atoms and might be taken as an indication that these molecules do not dissociate in solution.

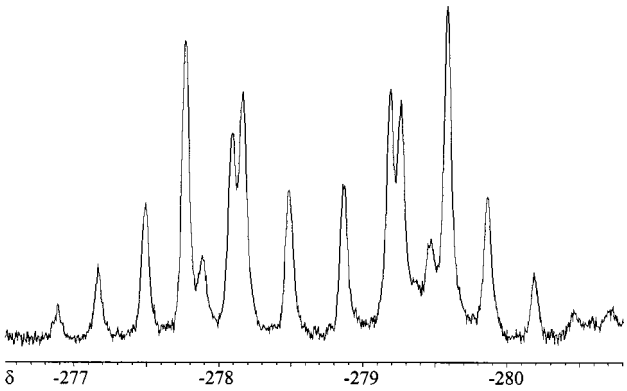


Figure 1. ^{31}P-NMR spectrum of $(Me_3Si)_2NCa[\mu\text{-}P(H)Si\textit{i}Pr_3]_3Ca(thp)_3$ (**1**) at δ = −278.68 ([D_8]toluene, 25°C, 109.365 MHz; coupling constants see text)

Molecular Structures

The molecular structure of **1**, showing the numbering scheme, is depicted in Figure 2. Ca1 is surrounded by three phosphorus atoms and an amide ligand in a distorted tetrahedral arrangement, whereas Ca2 has a coordination number of six and a distorted octahedral coordination sphere with a facial arrangement of the phosphorus and oxygen atoms. The thp coligands adopt chair conformations. The Ca2−O(*n*) distances are between 235 and 241 pm and thus lie within the characteristic range.[1]

The terminally bonded bis(trimethylsilyl)amide substituent exhibits a trigonal-planar coordination sphere at the nitrogen atom, the Ca1−N1 bond length of 228 pm matching the corresponding bond lengths in the calcium bis[bis(trimethylsilyl)amides].[1][25]

The triisopropylsilylphosphanide substituents occupy bridging positions. Due to the higher coordination number of Ca2, the Ca2−P(*n*) bonds (mean value 297.7 pm) are approximately 6 pm longer than the Ca1−P(*n*) bonds (mean distance 291.3 pm). These bond lengths are consistent with the Ca−P distances observed in other calcium bis-

Figure 2. (phosphanides).[1] The distortion of the tetrahedral environments of the phosphorus atoms is best illustrated by the angle sums at these centers, neglecting the hydrogen atoms [M, M′ = Ca1, Ca2, Si(*n*); ΣMP1M′ = 351.1°; ΣMP2M′ = 358.7°; ΣMP3M′ = 345.2°]. Compared to those in HP(Si*i*Pr$_3$)$_2$ (P−Si 226.5 pm[9]), the P(*n*)−Si(*n*) bonds are approximately 4 pm shorter due to the negative charge on the phosphorus atoms. Furthermore, the higher coordination number of four at the phosphorus atoms leads to elongated P−Si bonds compared with those in tetrakis(tetrahydrofuran-*O*)calcium bis[bis(trimethylsilyl)phosphanide] (P−Si 219 pm[21]) and tetrakis(tetrahydrofuran-*O*)bis(triisopropylsilylphosphanide) (P−Si 219.6 pm[9]). Moreover, the elongation of bond lengths within the ESi*i*Pr$_3$ fragment is a well-known consequence of the steric strain.[26]

Figure 3 shows the molecular structure and the numbering scheme of (thf)$_5$Ba$_2$[P(H)Si*i*Pr$_3$]$_4$ (**2**). The central moiety is a trigonal-bipyramidal Ba$_2$P$_3$ core with the barium atoms in apical positions. Both alkaline earth metal centers have a distorted octahedral coordination sphere. The asymmetric unit contains two virtually identical molecules with the barium atoms labelled Ba(*mn*), where *m* = 1 or 2 denotes the molecule number and *n* is a digit to distinguish between different atoms. Here, the discussion is limited to the molecule with *m* = 1.

Ba11 is bonded to four phosphanide anions and two thf molecules, whereas Ba12 is surrounded by three phosphanide substituents and three thf molecules. The Ba11−P(*n*) bond lengths vary over the narrow range of 331 ± 3 pm regardless of whether the phosphanide ligand is in a bridging or terminal position. The Ba12−P(*n*) distances have a mean value of 323.4 pm and are clearly smaller. These findings are consistent with an electrostatic viewpoint, where the size of the ions largely determines the intramolecular distances between the cations and anions, but not the coordination number at the phosphorus atoms. All the aforementioned Ba−P distances lie within the broad range of Ba−P values found in barium bis(phosphanides).[1]

As described for **1**, a flattening of the coordination spheres about the bridging phosphorus atoms is observed [M, M′ = Ba11, Ba12, Si(1*n*); ΣMP11M′ = 347.8°; ΣMP12M′ = 348.5°; ΣMP13M′ = 359.1°]. The smallest Ba−P(1*n*)−Si(1*n*) angle is realized within the terminal phosphanide substituent (*n* = 4), with a value of 115.5°. Due to the intramolecular strain, the Si*i*Pr$_3$ groups are pushed to the periphery of the molecule, thereby widening the Ba−P−Si angles and flattening the coordination spheres of the P atoms.

Figure 4 shows the molecular structure as well as the numbering scheme of dimeric heteroleptic **4**. The apostrophes indicate symmetry-related atoms. The bis(trimethylsilyl)amide ligand is in a terminal position, while the tri-*tert*-butylsilylphosphanide substituent adopts a bridging position. A coordination number of five at the alkaline earth metal center is achieved by the coordination of two thf coligands. In this case, we were able to locate the phosphorus-bonded hydrogen atoms. The Ba−N (260.1 pm) and Ba−P bond lengths (330 pm) have values in the expected

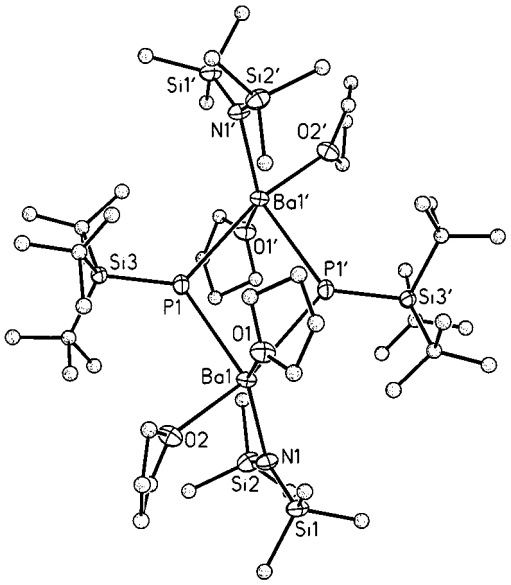

Figure 4. Molecular structure of **4**; thermal ellipsoids are drawn at a 40% probability level; C atoms are shown with arbitrary radii and H atoms are omitted for clarity; symmetry-related atoms ($-x + 1, -y, -z$) are marked with an apostrophe; selected bond lengths [pm] and angles [°]: Ba1−N1 260.1(2), Ba1−P1 330.27(7), Ba1−P1′ 329.25(7), Ba1−O1 275.4(2), Ba1−O2 278.9(2), N1−Si1 168.5(2), N1−Si2 167.5(2), P1−Si3 222.96(9); P1−Ba1−P1′ 73.25(2), Ba1−P1−Ba1′ 106.75(2), Ba1−P1−Si3 127.92(3), Ba1′−P1−Si3 124.45(3), Ba1−N1−Si1 117.6(1), Ba1−N1−Si2 115.3(1), Si1−N1−Si2 127.1(2)

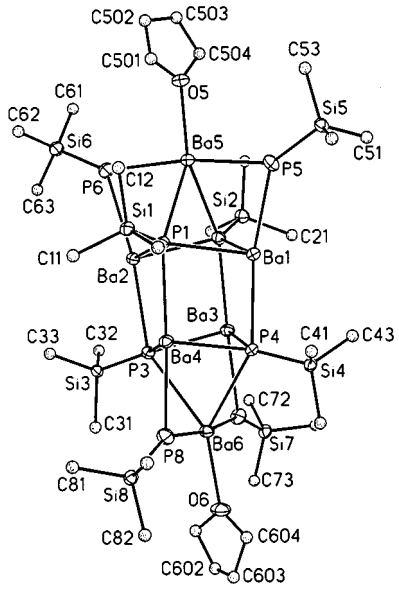

Figure 5. Molecular structure of **6**; the methyl groups of the Si*t*Bu$_3$ substituents and the H atoms are omitted for clarity; the remaining C atoms are shown with arbitrary radii; ellipsoids are drawn at a 40% probability level; selected bond lengths [pm] and angles [°]: see Table 1

ranges[1] and are essentially similar to those found in $\{(Me_3Si)_2NBa[\mu\text{-}P(SiMe_3)_2]\}_2$.[23] Neglecting H1, the coordination sphere about P1 is almost planar, having an angle sum of 359.1°.

Figure 5 displays the molecular structure and the numbering scheme of **6**. This molecule is built-up of four inner tri-*tert*-butylsilylphosphanediide ligands (P1 to P4) and four outer tri-*tert*-butylsilylphosphanide ligands (P5 to P8), held together by six barium atoms. The central Ba_6P_8 core is depicted in Figure 6 in a stereoscopic view. Whereas the phosphanide ligands contain quadruply coordinated phosphorus atoms, the inner P atoms are surrounded by four barium centers and one silicon atom. The Ba−P bond lengths are spread over a wide range from 311 to 347 pm (Table 1). The shortest Ba−P bond lengths are found within the four-membered rings Ba1−P1−Ba2−P2 and Ba3−P3−Ba4−P4. The Ba−P distances between these Ba_2P_2 cycles as well as the Ba−P values to the P(H)Si*t*Bu$_3$ substituents are significantly longer. All the barium atoms are bonded to four phosphorus atoms. Their coordination spheres are completed by the coordination of a thf molecule (Ba5 and Ba6) or by agostic interactions with *tert*-butyl groups (Ba1 to Ba4). The Ba−O bond lengths of 273 pm lie within the characteristic range.[1,18b] The close contacts between Ba5 and Ba6, respectively, and the neighboring metal centers are a consequence of the rather low coordination numbers of these barium atoms and the strong electrostatic attraction between the dianions and dications. The coordination polyhedra of Ba5 and Ba6 are trigonal-bipyramids with the phosphanide ligands in apical positions [P5−Ba5−P6 170.30(7)°, P7−Ba6−P8 172.73(7)°].

The angle sums ΣMPM′ at P5 (359.7°), P6 (359.7°), P7 (358.7°), and P8 (356.9°) indicate an almost planar environment at the phosphorus atoms. The hydrogen atoms at these P atoms were not located and due to the planar Ba_2PSi fragments the H atoms could be bonded on either side and several isomers are possible. However, the ^{31}P-NMR data show only one resonance for the PH groups. The P−Si bond lengths have values of approximately 222 pm, irrespective of whether mono- or dianions are considered. Due to shielding by the *tert*-butyl groups, the P−H moieties are not metalated by the still present barium bis[bis(trimethylsilyl)amide], not even at elevated temperatures such as in boiling toluene.

Conclusion

Metalations of H_2PSiR_3 (R = *i*Pr, *t*Bu) with bis(tetrahydrofuran-*O*)calcium and bis(tetrahydrofuran-*O*)barium bis[bis(trimethylsilyl)amide] yield the corresponding alkaline earth metal bis(trialkylsilylphosphanides) of the type $(L)_nM[P(H)SiR_3]_2$. These phosphanides show a weakening of the P−H bond compared to the phosphane and hence an increased reactivity. Consequently, these compounds react as metalating reagents and as metalation substrates. The elimination of H_2PSiR_3 yields a product of the type $(L)_nM[P(H)SiR_3]_2(PSiR_3)_2$. With R = *t*Bu, an X-ray structure determination has revealed a dimer of this formula unit. The central M_6P_8 core can be considered as two trigonal bipyramids with a common MP_2 face; this polyhedron dimerizes via the square-planar M_2P_2 plane.

Scheme 5. Metalation of $H_2P - Si\mathit{i}Pr_3$ and formation of **6**

Experimental Section

General Remarks: All experiments and manipulations were carried out under argon or nitrogen that had been purified by passage through BTS catalyst and P_4O_{10}. Reactions were performed using standard Schlenk techniques and dried, thoroughly deoxygenated solvents. The starting materials $(thf)_2Ca[N(SiMe_3)_2]_2$,[16][17] $(thf)_2Ba[N(SiMe_3)_2]_2$,[16][18] $H_2PSi\mathit{i}Pr_3$,[9] and $H_2PSi\mathit{t}Bu_3$[20] were prepared according to literature procedures. − NMR spectra were recorded with Jeol GSX270 and EX400 spectrometers. − A Perkin-Elmer Paragon 1000 PC spectrophotometer was used to record the IR spectra; solid substances were examined as Nujol mulls between CsBr plates (vs very strong, s strong, m medium strong, w weak, vw very weak, sh shoulder). The frequencies in the region of the Nujol vibrations are not listed. − The low carbon values obtained in the elemental analyses can be attributed to carbide and carbonate formation, as well as to the loss of neutral coligands during handling and combustion of the compounds.

$(Me_3Si)_2NCa[\mu\text{-}P(H)Si\mathit{i}Pr_3]_3Ca(thp)_3$ (1): To 2.78 g of $(thf)_2Ca[N(SiMe_3)_2]_2$ (5.50 mmol), dissolved in 12 mL of thp, 1.33 mL of triisopropylsilylphosphane (8.25 mmol) was added at −60°C. After warming to room temp., this solution was stirred for a further 12 h. All volatiles were then removed at room temp. in vacuo. Addition of toluene and storage at −30°C led to the deposition of 0.93 g of crystalline **1** (0.87 mmol; 32%); dec. above 110°C. − NMR ([D_8]toluene, 30°C); ^{1}H: δ = −0.49 (m, PH), 0.50 (s, $SiMe_3$), 1.25 (m, CH), 1.31 (s, Me), 1.31, 1.39 and 3.77 (thp); $^{31}P\{^1H\}$: δ = −278.68; ^{31}P: δ = −278.63 [AA′A″XX′X″, simulation: ^1J(P,H) = 186.1(1) Hz, ^2J(P,P) = 92.3(1) Hz, ^3J(P,H′) = 11.7(6) Hz, ^3J(P,H″) = 2.1(6) Hz]. − IR: $\tilde{\nu}$ = 2274 m, 1462 s, 1442 m, 1384 w, 1379 w, 1362 w, 1357 w, 1328 vw, 1310 m, 1277 w, 1248 s, 1240 s, 1194 s, 1181 sh, 1125 sh, 1098 m, 1077 s, 1048 vs, 1033 vs, 1015 s, 992 s, 966 m, 931 m, 918 m, 881 vs, 865 s, 833 s, 820 s, 812 s, 767 m, 747 w, 708 sh, 683 sh, 664 sh, 652 s, 639 s, 626 m, 609 m,

[a] Definition of the *R* values: $R_1 = (\Sigma||F_o| - |F_c||)/\Sigma|F_o|$; $wR_2 = \{\Sigma[w(F_o^2 - F_c^2)^2]/\Sigma[w(F_o^2)^2]\}^{1/2}$ with $w^{-1} = \sigma^2(F_o^2) + (aP)^2$. − [b] $s = \{\Sigma[w(F_o^2 - F_c^2)^2]/(N_o - N_p)\}^{1/2}$.

tion was reduced to a volume of a few mL. At 4°C, 508 mg of light-brown crystals of **6** (0.19 mmol; 76%) precipitated; m.p. 378°C (dec.). – NMR (30°C); ^{1}H ([D$_6$]benzene): δ = 1.31 (PHSi*t*Bu$_3$), 1.53 (PSi*t*Bu$_3$), 1.36 and 3.56 (thf), PH signal was not observed; ^{13}C{^{1}H}: δ = 24.06 (PHSiC), 26.82 (PSiC), 31.83 (PHSiC*Me*$_3$), 33.90 (PSiC*Me*$_3$), 25.09 and 68.48 (thf); ^{31}P ([D$_8$]toluene): δ = −25.0 (s, PSi*t*Bu$_3$), −222.9 [d, PHSi*t*Bu$_3$, ^1J(P,H) = 149 Hz]. – IR: $\tilde{\nu}$ = 2234 w, 1251 m, 1180 m, 1064 m, 1037 m, 1013, 932 s, 881 m, 842 s, 816 vs, 803 s, 757 w, 729 vw, 694 vw, 685 vw, 664 vw, 594 m, 569 s, 511 vs, 478, 456 m, 389 vw, 360 vw, 331 vw. – $C_{96}H_{220}Ba_6P_8Si_8$ (2671.24): calcd. C 43.17, H 8.30; found C 43.15, H 7.31.

Structure Determinations:[27] Single crystals were covered with Nujol, sealed in thin-walled capillaries, mounted on a Siemens P4 diffractometer, and examined with graphite-monochromated Mo-K_α radiation (λ = 71.073 pm). A Siemens SMART-CCD area detector was used to monitor the reflections of **1**, **2**, **4**, and **6**. Crystallographic parameters and details of the data collection are summarized in Table 2.

All structures were solved by direct methods and refined with the software packages SHELXL-93 and SHELXL-97.[29] Neutral atom scattering factors were taken from Cromer and Mann,[30] and for the hydrogen atoms from Stewart et al.[31] The non-hydrogen atoms were refined anisotropically. The H atoms were considered as a riding model under restriction of ideal symmetry at the atoms to which they were attached. The disordering of *i*Pr groups in **1** and **2** is not shown in Figures 2 and 3. The methyl groups of the *t*Bu$_3$Si substituent of **4** show a two-site disorder. The structure of **6** contains two toluene molecules and a thf molecule between the barium phosphanide complexes. The carbon and oxygen atoms of these solvent molecules were refined isotropically.

Acknowledgments

We are grateful to the Deutsche Forschungsgemeinschaft, Bonn, and the Fonds der Chemischen Industrie, Frankfurt/Main, for the generous financial support. We would also like to thank Dr. H.-W. Lerner and Dr. K. Karaghiosoff for their helpful advice.

Synthesis and Structures of *cisoid* and *transoid* Bis(1,2-dimethoxyethane)bis(η²-pyrazolato)lanthanoid(II) Complexes

Glen B. Deacon,*[a] Ewan E. Delbridge,[a] Brian W. Skelton,[b] and Allan H. White[b]

Keywords: Lanthanide(II) complexes / Ytterbium / Europium / Samarium / Redox transmetallation / Thallium / Diphenylmercury

The complexes $[Yb(bind)_2(DME)_2]$, $[Yb(MePhpz)_2(DME)_2]$, $[Yb(azin)_2(DME)_2]$, and $[Eu(Ph_2pz)_2(DME)_2]$ (bindH = 4,5-dihydro-2*H*-benz[*g*]indazole; MePhpzH = 3-methyl-5-phenylpyrazole; azinH = 7-azaindole; Ph_2pzH = 3,5-diphenylpyrazole; DME = 1,2-dimethoxyethane) have been prepared by redox transmetallation between ytterbium or europium metal and the corresponding thallium(I) pyrazolate in tetrahydrofuran (THF) in the presence of mercury metal, followed by work up with DME. The thallium reagents were obtained by treatment of the appropriate pyrazole with thallium(I) ethoxide. Both $[Yb(Ph_2pz)_2(DME)_2]$ and $[Sm(Ph_2pz)_2(DME)_2]$ have been prepared by metathesis from $LnI_2(THF)_2$ and $K(Ph_2pz)$ in THF, whilst the former has also been obtained by redox transmetallation from $[Hg(Ph_2pz)_2]$ and ytterbium metal and by reaction of 3,5-diphenylpyrazole with $Yb(C_6F_5)_2$, and the latter from protolysis of $[Sm\{N(SiMe_3)_2\}_2(THF)_2]$ with Ph_2pzH, followed in each case by crystallisation of the crude product from DME. Europium(II) 3,5-di-*tert*-butylpyrazolate was synthesised by a redox transmetallation/ligand exchange reaction between europium metal chunks, diphenylmercury(II), and 3,5-di-*tert*-butylpyrazole (tBu_2pzH) in the presence of mercury metal in THF, and $[Eu(tBu_2pz)_2(DME)_2]$ was isolated on crystallisation of the crude product from DME. The X-ray crystal structures of $[Ln(L)_2(DME)_2]$ (Ln =Yb, L = bind or azin; Ln = Eu or Sm, L = Ph_2pz; Ln = Eu, L = tBu_2pz), each of a different crystallographic form, reveal eight-coordinate lanthanoid complexes with two η²-pyrazolate and two chelating DME ligands, but the structures differ in the relationship (*cisoid* or *transoid*) between the pyrazolate ligands. Thus cen–Ln–cen (cen = centre of the N–N bond) angles of 106.7° $[Yb(bind)_2(DME)_2]$ (**3a**), 141.4° $[Yb(azin)_2(DME)_2]$ (**3c**), 142.2° $[Eu(Ph_2pz)_2(DME)_2]$ (**4a**), 107.4° $[Eu(tBu_2pz)_2(DME)_2]$ (**4b**), and 102.1° $[Sm(Ph_2pz)_2(DME)_2]$ (**5**) are observed.

Introduction

Pyrazolate ligands have had an extensive role as bridging ligands particularly between d-block metals, and as chelating ligands, particularly to f-block metals.[2] This chemistry is now being enlivened by a range of new features, such as the first homoleptic η²-pyrazolates,[3a] the first η²-d block[3a,3b] and main-group[3c] pyrazolates, the use of pyrazolates in semiconductor doping,[3d] and new modes of pyrazolate coordination (μ-η²:η²[3e] and combined η² and μ-η¹:η¹[3f]). Recent investigations have provided synthetic routes to a range of lanthanoid(III) pyrazolates.[4–7] Structures of initially prepared compounds revealed cages and dimers with both bridging (μ-η¹:η¹) and chelating (η²) ligands.[4][5] However, lanthanoid(III) complexes of bulky 3,5-disubstituted pyrazolates $[Ln(R_2pz)_3(L)_n]$ (R = *t*Bu or Ph; L = tetrahydrofuran (THF), 1,2-dimethoxyethane (DME), or Ph_3PO; n = 1–3) are monomeric with exclusively η²-bonding.[6][7] Moreover, the preferred arrangements of the three η²-pyrazolate ligands, can induce unexpected coordination modes of the co-ligands, e.g. bridging DME ligands in $[Nd(tBu_2pz)_3(DME)]_\infty$, and novel unidentate DME in $[Er(Ph_2pz)_3(DME)_2]$.[7] Lanthanoid(II) pyrazolates appear less favoured since the redox transmetallation/ligand exchange reaction between Yb metal, $Hg(C_6F_5)_2$, and 3,5-di-*tert*-butylpyrazole yields $[Yb(tBu_2pz)_3(THF)_2]$ even when an excess of the highly reducing metal is used.[6a,6c] However, recently we have prepared the first lanthanoid(II) pyrazolate complex $[Yb(Ph_2pz)_2(DME)_2]$ by redox transmetallation between Yb metal and thallium(I) 3,5-diphenylpyrazolate, and also by redox transmetallation/ligand exchange between the lanthanoid element, $HgPh_2$, and 3,5-diphenylpyrazole.[8] Subsequently, use of 3,5-di-*tert*-butylpyrazole in the latter synthetic method and crystallisation of the product from petroleum ether gave $[Yb(tBu_2pz)_2(THF)]_2$, which contained the first example of a μ-η²:η²-bonded pyrazolate.[3e] We now report a detailed study of the synthesis and structures of a range of bis(1,2-dimethoxyethane)bis(pyrazolato)lanthanoid(II) complexes, as well as the preparation and structure of the closely related $[Yb(azin)_2(DME)_2]$ (azinH = 7-azaindole).

Results and Discussion

Synthesis

A key step in the route to lanthanoid(II) pyrazolates was the synthesis of the thallium(I) pyrazolates, Tl(bind) (**1a**) (bindH = 4,5-dihydro-2*H*-benz[*g*]indazole), Tl(MePhpz) (**1b**) (MePhpzH = 3-methyl-5-phenylpyrazole), Tl(azin) (**1c**), Tl(Ph_2pz)[8] (**1d**), and Tl($MePh_2pz$) (**1e**) ($MePh_2pzH$ = 4-methyl-3,5-diphenylpyrazole).

$$Tl(OEt) + R_2R'pzH \rightarrow Tl(R_2R'pz) + EtOH \quad (1)$$

However, Tl(tBu$_2$pz) could not be prepared by this method and appeared thermally unstable. Consistent with pyrazolate formation, no ν(NH) absorption was observed in the infrared spectra of the complexes, which were additionally characterized by parent ions in their mass spectra and/or satisfactory ^{1}H-NMR spectra. Another possible redox transmetallation reagent, mercury(II) 3,5-diphenylpyrazolate (**2a**), was prepared both by metathesis (Equation 2),

$$HgCl_2 + 2\ K(Ph_2pz) \rightarrow 2\ KCl + Hg(Ph_2pz)_2 \quad (2)$$

and by mercuration of diphenylpyrazole under alkaline conditions.

$$HgBr_4^{2-} + 2\ OH^- + 2\ Ph_2pzH \rightarrow Hg(Ph_2pz)_2 + 4\ Br^- + 2\ H_2O \quad (3)$$

The complex could not be obtained analytically pure, but the identity was clear from an MH^+ ion in the electrospray mass spectrum and the product was a viable source of $Yb(Ph_2pz)_2$ (below).

Several thallium(I) pyrazolates and Tl(azin) were found to undergo redox transmetallation with ytterbium and europium in tetrahydrofuran to give the corresponding divalent pyrazolates.

$$Ln + 2\ Tl(R_2pz) \rightarrow Ln(R_2pz)_2 + 2\ Tl\downarrow \quad (4)$$

Crystallisation of the crude products from DME gave the complexes [Yb(bind)$_2$(DME)$_2$] (**3a**), [Yb(MePhpz)$_2$(DME)$_2$] (**3b**), [Yb(azin)$_2$(DME)$_2$] (**3c**), and [Eu(Ph_2pz)$_2$(DME)$_2$] (**4a**). The reported [Yb(Ph_2pz)$_2$(DME)$_2$], previously prepared by Equation 4 and by redox transmetallation/ligand exchange from Yb metal, $HgPh_2$, and Ph_2pzH,[8] was prepared in modest to good yields by three further methods, viz. metathesis from ytterbium diiodide (Equation 5, Ln = Yb), redox transmetallation from impure Hg(Ph_2pz)$_2$ (Equation 6), and protolysis of bis(pentafluorophenyl)ytterbium(II) (Equation 7).

$$LnI_2 + 2\ K(Ph_2pz) \rightarrow Ln(Ph_2pz)_2 + 2\ KI \quad (5)$$

$$Yb + Hg(Ph_2pz)_2 \rightarrow Yb(Ph_2pz)_2 + Hg\downarrow \quad (6)$$

$$Yb(C_6F_5)_2 + 2\ Ph_2pzH \rightarrow Yb(Ph_2pz)_2 + 2\ C_6F_5H \quad (7)$$

Only, a short reaction time was needed for successful isolation of Yb(Ph_2pz)$_2$ from Equation 7, otherwise a black unidentified solid was obtained, similar to the unsuccessful outcome of an attempted synthesis by redox transmetallation/ligand exchange from Yb metal, Hg(C_6F_5)$_2$, and 3,5-diphenylpyrazole. Because of the failure to prepare Tl(tBu$_2$pz), an alternative to Equation 4 was needed for Eu(tBu$_2$pz)$_2$, and this was achieved by redox transmetallation/ligand exchange between europium metal, diphenylmercury, and 3,5-di-*tert*-butylpyrazole (Equation 8),

$$Eu + HgPh_2 + 2\ tBu_2pzH \rightarrow Eu(tBu_2pz)_2 + 2\ PhH + Hg\downarrow \quad (8)$$

followed by isolation as [Eu(tBu$_2$pz)$_2$(DME)$_2$] (**4b**). This synthetic method has previously been used for [Yb(Ph_2pz)$_2$(DME)$_2$] (**3d**)[8] and [Yb(tBu$_2$pz)$_2$(THF)]$_2$.[3e] Since an attempt to prepare Sm(Ph_2pz)$_2$ by Equation 4 yielded instead Sm(Ph_2pz)$_3$ (Equation 9),[8]

$$Sm + 3\ Tl(Ph_2pz) \rightarrow Sm(Ph_2pz)_3 + 3\ Tl\downarrow \quad (9)$$

two alternative approaches were used to give the divalent target compound, viz metathesis (Equation 5) (Ln = Sm), and protolysis of bis[bis(trimethylsilyl)amido]samarium(II) by 3,5-diphenylpyrazole.

$$Sm[N(SiMe_3)_2]_2 + 2\ Ph_2pzH \rightarrow Sm(Ph_2pz)_2 + 2\ HN(SiMe_3)_2 \quad (10)$$

After workup with DME a much higher yield of [Sm(Ph_2pz)$_2$(DME)$_2$] (**5**) was obtained by the former method.

Equation 4 opens the use of thallium-based redox transmetallation as a route to lanthanoid organoamides. Redox transmetallation with thallium(I) reagents was a source of only cyclopentadienyls[9] and phenolates,[10] prior to our preliminary report.[8] Mercury-based redox transmetallation (e.g. Equation 6) has previously been used for lanthanoid amides,[9c,11] whilst use of diphenylmercury in redox transmetallation/ligand exchange (e.g. Equation 8), is a recent development[11] by contrast with the extensive use of Hg(C_6F_5)$_2$.[9a−9c]

The different outcomes of the reactions of ytterbium and samarium with thallium 3,5-diphenylpyrazolate (Equation 4; Ln = Yb; R = Ph and Equation 9) are explicable by the observation (Experimental Section) that samarium metal does not reduce Sm(Ph_2pz)$_3$ whereas ytterbium metal reduces Yb(Ph_2pz)$_3$.

$$2\ Yb(Ph_2pz)_3 + Yb \rightarrow 3\ Yb(Ph_2pz)_2 \quad (11)$$

Formation of Yb(Ph_2pz)$_2$, rather than a trivalent complex from redox transmetallation/ligand exchange between ytterbium metal, diphenylmercury, and 3,5-diphenylpyrazole,[8] is guaranteed both by reduction (Equation 11), and also by the current finding that Yb(Ph_2pz)$_2$ does not undergo oxidation/ligand exchange with diphenylmercury and Ph_2pzH.

$$2\ Yb(Ph_2pz)_2 + HgPh_2 + 2\ Ph_2pzH \not\rightarrow 2\ Yb(Ph_2pz)_3 + 2\ PhH + Hg$$

This further illuminates the contrasting formation of Yb(tBu$_2$pz)$_3$ from synthesis with Hg(C_6F_5)$_2$[6a,6c] but Yb(t-Bu$_2$pz)$_2$ with $HgPh_2$.[3e] Synthetic consequences of the dif-

fering oxidising capacity of these mercurials have been previously observed in that $YbCp_2$ is converted by $Hg(C_6F_5)_2$ into $YbCp_2(C_6F_5)$, but is inert to diphenylmercury,[12a] and electrochemical reduction is more facile for $Hg(C_6F_5)_2$ than for $HgPh_2$.[12b,12c]

Despite the high air and moisture sensitivity of $[Ln(R_2pz)_2(DME)_2]$ complexes and $[Yb(azin)_2(DME)_2]$, all complexes were obtained with acceptable C, H, N, and Ln analyses. No ν(NH) absorptions were observed in the spectra, consistent with the formation of pyrazolatolanthanoid complexes. The ^{1}H-NMR spectra of the diamagnetic Yb^{II} complexes and of $[Sm(Ph_2pz)_2(DME)_2]$ were consistent with the proposed compositions, except for **3a** where the bind integrations were approximately half the expected intensity, and where all resonances, *especially* those of bind, were surprisingly broadened. This may be the source of the low integrations. A spectrum of a cooled solution showed the same features. No Yb^{III} impurities could be detected by electronic spectroscopy (Experimental Section), and the oxidation state is clear from spectroscopy, analysis and the X-ray crystallography. Not only was the ^{1}H-NMR spectrum of the paramagnetic Sm^{II} complex **5** clearly resolved and assigned (Experimental Section), but it was clearly distinguishable from that of the Sm^{III} analogue, $[Sm(Ph_2pz)_3(DME)_2]$.[8] The ^{171}Yb resonance of the azin complex **3c** (Experimental Section) was very close to that (δ = 480) of $[Yb(Ph_2pz)_2(DME)_2]$,[8] consistent with our view of the azin ligand as a pseudo-pyrazolate. It is also at lower frequencies than the ^{171}Yb chemical shift of seven-coordinate $[Yb(tBu_2pz)_2(THF)]_2$ (δ = 536).[3e] There is some evidence that a higher frequency shift accompanies a decrease in coordination number *in complexes with similar ligands*,[11][13] as in these examples, but **3c** and **3d** necessarily were examined in DME and $[Yb(tBu_2pz)_2(THF)]_2$ in PhMe. The visible/near-IR spectra of the complexes show moderately intense (for Ln complexes) features attributable to Ln→L charge transfer (Experimental Section). More notably near-infrared absorptions characteristic[14] of Yb^{III} and Sm^{III} were absent from the spectra of the Yb^{II} and Sm^{II} compounds.

X-ray Structure Determinations

Single-crystal X-ray structure determinations have been carried out for **3a**, **3c**, **4a**, **4b**, and **5**. No complexes, including the analogous **3d** of the preliminary report,[8] are isostructural, and all show crystallographically independent forms. These are displayed in Figures 1−6, attention being drawn to crystallographically significant features in the Figure captions and in the Experimental Section. Selected bond lengths and angles are in Tables 1 and 2. All $[Ln(R_2pz)_2(DME)_2]$ complexes have eight-coordinate monomeric structures with two chelating DME and two chelating (η^2)-pyrazolate or azin ligands. In each case the two nitrogen atoms bind nearly symmetrically to the metal centre such that the metal is approximately coplanar with the ligand plane (Figures 1−6). There are two different stereochemical types. Thus, the cen−Ln−cen angles (cen = centre of N−N bonds or, for azin, the centre of the N···N distance) (Table 3) are either in the range 101−108° (**3a**, **3d**, **4b**, **5**; Figures 1−4) giving a *cisoid* disposition of the pyrazolate ligands, or 141−143° (**3c**, **4a**; Figure 5, 6) giving a *transoid* array of Ph_2pz or azin ligands. A similar relationship is shown by the cen′−Ln−cen′ angles (cen′ = midpoint of the O···O distance) (Table 3), with **3a**, **4b**, **5**, and **3d** having values of 85−98° and a *cisoid* disposition of DME ligands. By contrast **3c** and **4a** have values of 138−143° respectively, arising from *transoid* DME ligands, where the four oxygen donor atoms are nearly coplanar. All single crystals were obtained from concentrated DME solutions, hence the difference in arrangement seen in the Ph_2pz complexes **3d**, **4a**, and **5**, and especially between the complexes of the adjacent metals Ln = Eu or Sm, is striking.

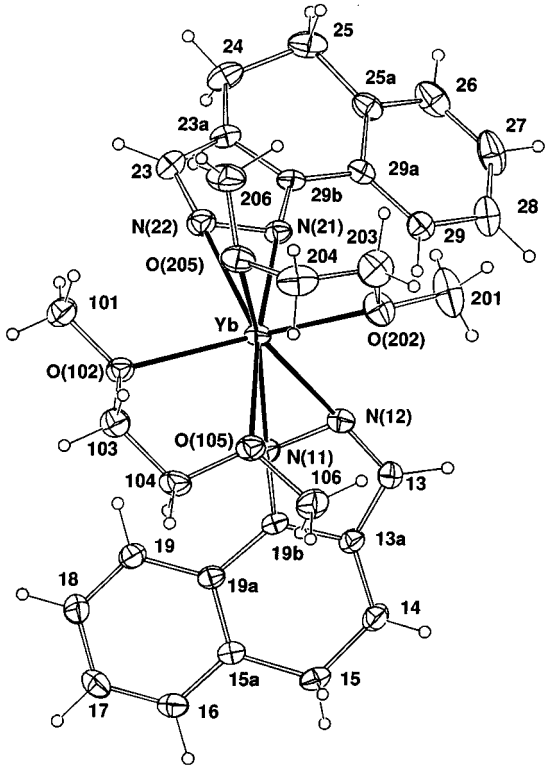

Figure 1. Molecular projection of $[Yb(bind)_2(DME)_2]$ (**3a**) down the quasi-*2* axis; no disorder is present

Amongst the *cis* complexes, **4b**, **5**, and **3d** differ from **3a** in that the $Ln(R_2pz)_2$ arrays have potential *mm* symmetry, one *m* bisecting the ligand and relating the two substituents. By contrast, the $Yb(bind)_2$ array in **3a** is disposed as approaching *2* symmetry. In the *transoid* complexes, **3c** and **4a**, the Ph_2pz and azin ligand pairs are closely coplanar with each other and with the metal atom. In the diphenylpyrazolate complexes **4a**, **5**, and **3d**, each pyrazolate ring is almost coplanar with its phenyl substituents, regardless of whether the Ph_2pz groups are *cisoid* or *transoid*.

In **3a**, one molecule devoid of crystallographic symmetry, and of any complicating factors such as different bind ligand orientations (possible by reversal of the inequivalent

Table 1. Metal atom environments in *cisoid* **5**, **4b** (molecules 1 and 2), **3d**, **3a**; connectivity to (*r* [Å]) or via the metal centre (angles [°]); * values are for the disordered/symmetry-related O component

N donor atoms), comprises the asymmetric unit. However, in **3c**, isomeric diversity arising from alternative azin orientations is manifested as disorder, although one of the four possible combinations is dominant, as is displayed in Figure 3a.

The pyrazolate and azin ligands are symmetrically coordinated with differences in Ln−N bond pairs ≤ 0.06 Å for all ligands and ≤ 0.03 Å for all but two. Even the largest differences, which, not surprisingly, are found for the unsymmetrical ligands bind and azin, are observed for only *one* ligand in each of **3a** and **3c**, respectively. Moreover, the maximum difference (0.06 Å) is less than those (0.07−0.10 Å) in some Ln^{III} complexes with Ph_2pz and tBu_2pz.[6b,7a] There is more asymmetry in the DME chelation with the largest pair of differences (0.10, 0.06 Å) in **3d** which has highly symmetrical Ph_2pz coordination, but different conformations of the (non-disordered) DME ligands. Further, no unusual asymmetry in the DME coordination is found in complexes of the unsymmetrical ligands bind and azin. In **3a**, the two DME ligands have different conformations whilst in **3c** they are the same. When appropriate allowance is made for the differences in the ionic radii of eight coordinate Eu^{2+}, Sm^{2+}, and Yb^{2+} [15], the <Ln−N> bond distances of all complexes are very similar with sole exception of **3c**, where <Yb−N> is ca. 0.13 Å longer than values for the other two Yb^{II} complexes, **3a** and **3d**. Given that the 7-azindolate ligand is not a pyrazolate, it would be unwise at this stage to attach too much significance to this difference, but it can be argued that azin has more steric stress in the immediate vicinity of the donor atoms than R_2pz ligands

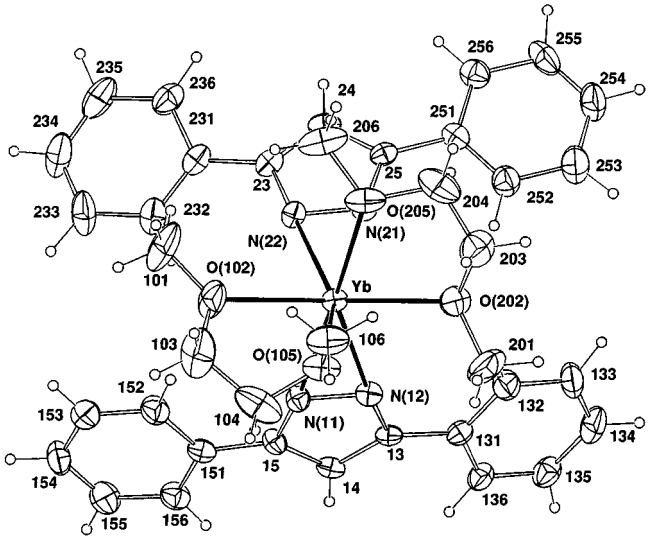

Figure 2. Molecular projection of $[Yb(Ph_2pz)_2(DME)_2]$ (**3d**) down the quasi-*2* axis; no disorder is present

and the "bite" is also larger. Greater uniformity is seen in ionic radius adjusted <Ln−O> values (despite greater individual variation than for Ln−N), with a slight deviation in <Eu−O> of **4b**, which is ca. 0.05 Å longer than for other complexes. This may be a consequence of the bulky *tert*-butyl substituents of the tBu_2pz ligand. For the azin complex **3c**, the Yb−O distances are similar to those of **3a** and **3d**, despite the longer Yb−N lengths. Comparison of bond lengths in *cisoid* and *transoid* Ph_2pz complexes **3d**, **5**, and **4a** reveals no significant differences after allowance for ionic radii differences. Subtraction of eight-coordinate Ln^{3+} radii[15] from <Ln−N> values gives a residue of 1.28−1.32 Å, for all complexes except for the anomalous **3c** (1.42 Å), and these are at the low end of the range, 1.26−1.38 Å, for $[Ln(R_2pz)_3L_n]$ (L = THF, n = 2 or 3; L = DME, n = 1 or 2) complexes.[6,7a] The uniqueness of the azin coordination is further illustrated by the subtraction value, which lies outside the normal pyrazolatolanthanoid range. Similar subtraction from <Ln−O> gives 1.38−1.40 Å with the exception of 1.45 Å for the tBu_2pz complex **4b**. Values for Ln^{III} complexes $[Ln(R_2pz)_3(THF)_n]$ (n = 2 or 3) cover the range 1.35−1.38 Å,[6] whilst $[Er(Ph_2pz)_3(\eta^2\text{-DME})(\eta^1\text{-DME})]$ gives 1.35 Å for the η^1-DME and 1.42 Å for the chelating DME.[7a] These subtraction residues suggest that the $[Ln(R_2pz)_2(DME)_2]$ structures are not greatly crowded, especially given that analogous values for Ln−O(THF) in crowded, bulky aryloxides lie in the range 1.49−1.59 Å.[10b,10c,16]

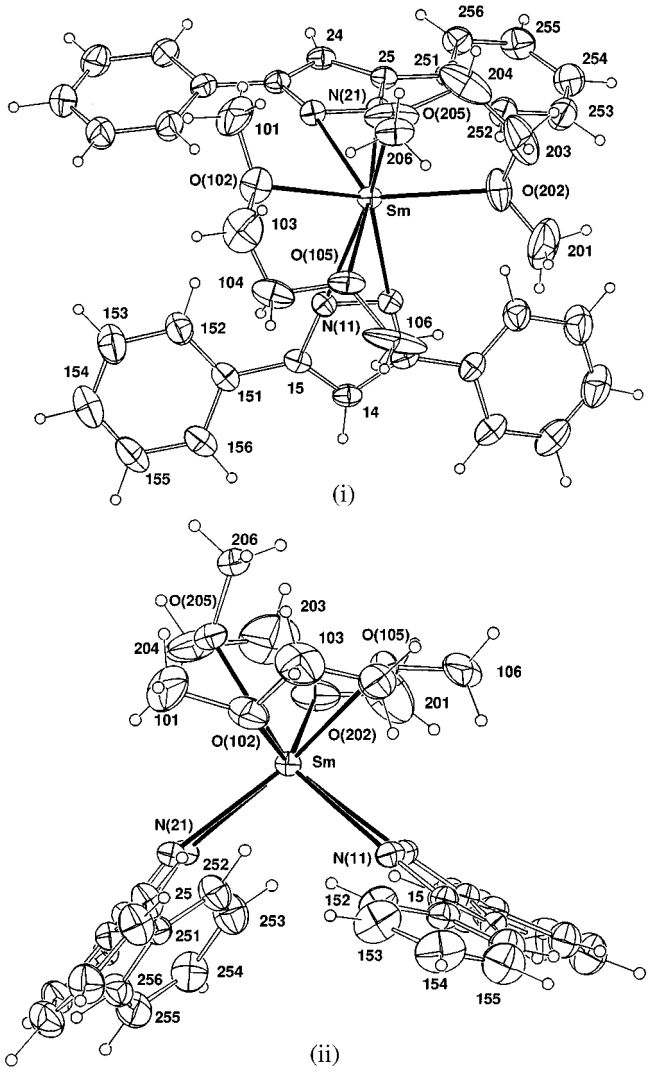

Figure 3. Molecular projections of $[Sm(Ph_2pz)_2(DME)_2]$ (**5**) (i) down and (ii) normal to the quasi-*2* axis; as modelled, the molecule lies disposed to either side of a crystallographic mirror plane, passing through samarium and the mid-points of the N−N bonds of the pyrazolate ligands, i.e. normal to and vertical in the page in (i) and in the plane of the page in (ii); the DME ligands are necessarily disordered to either side of that plane, the two components having different conformations, only one of each type being shown

Experimental Section

General: The compounds described here are extremely air- and moisture-sensitive and consequently all operations were carried out in an inert atmosphere (purified argon or nitrogen). Unless indicated otherwise, handling methods and solvent purification were as described previously.[17] Petroleum ether refers to the fraction boiling between 40 and 60°C. − IR data (4000−650 cm^{-1}) were obtained for Nujol mulls sandwiched between NaCl plates with a Perkin Elmer 1600 FTIR spectrometer. − Mass spectra were obtained with a VG Trio-1 GC mass spectrometer (Ln, Tl compounds) or a Micromass Platform Electrospray mass spectrometer $[Hg(Ph_2pz)_2]$. Each listed *m/z* value for metal-containing ions (where the metal has more than one isotope) is the most intense peak of a cluster with an isotope pattern in good agreement with the calculated pattern. − Room-temperature (20°C) NMR spectra were recorded with a Bruker AC 200 MHz (^1H, ^{13}C) or AM 300 MHz (^1H, ^{171}Yb) spectrometer. The chemical shift references were the residual solvent signals ([D_6]benzene: δ_H = 7.15, δ_C = 128.0; [D_8]THF: δ_H = 1.73, 3.58, δ_C = 25.3, 67.4; [D_8]toluene: δ_H = 2.09) or external $[Yb(C_5Me_5)_2(THF)_2]$ (0.15 M solution in THF) (^{171}Yb: δ = 0.0).[13] Degrees of substitution for ^{13}C nuclei were determined using $^1H/^{13}C$ *J*-modulation pulse sequences. [D_6]benzene (Cambridge Isotopes) was dried with sodium/potassium alloy and [D_8]THF (Cambridge Isotopes) was dried with CaH_2. The deuterated solvents were then vacuum-transferred to greaseless Schlenk tubes and stored under purified argon. − Lanthanoid analyses were by

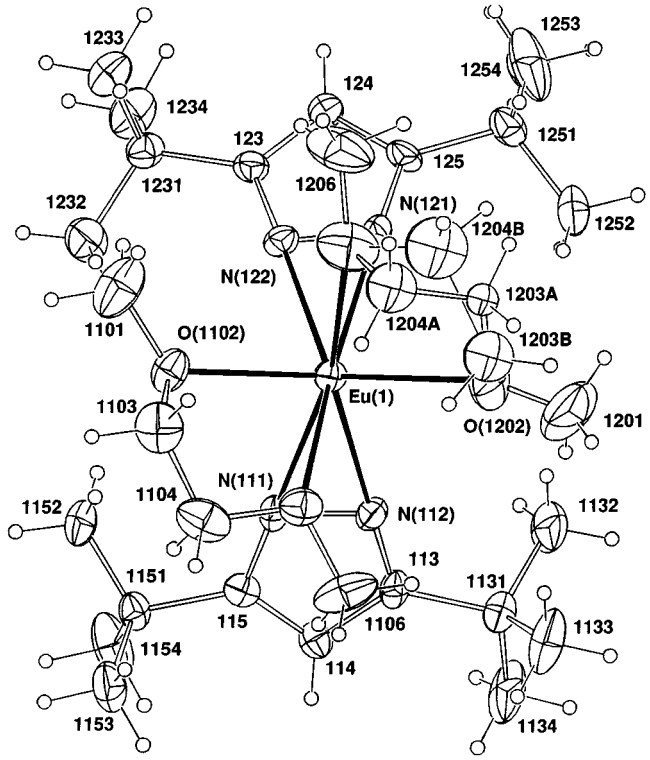

Figure 4. Molecular projection of $[Eu(tBu_2pz)_2(DME)_2]$ (**4b**) down the quasi-*2* axis (molecule 1 only is shown, molecule 2 being pseudo-symmetrically related and therefore similar); one of the DME ligands is disordered over two conformations, the two components of the relevant atoms of the CH_2CH_2 group being shown

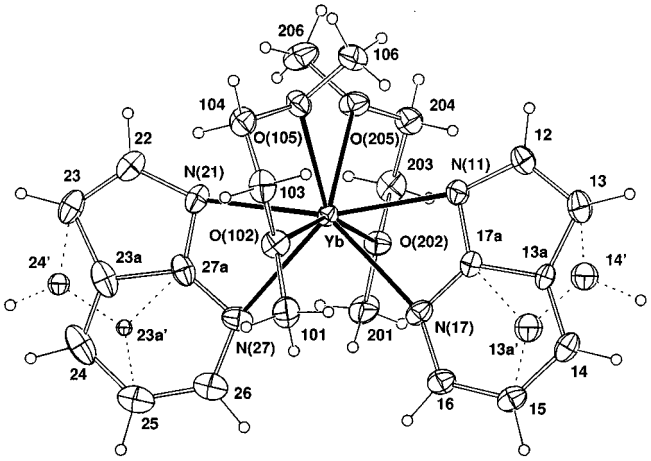

Figure 5. Molecular projection of $[Yb(azin)_2(DME)_2]$ (**3c**) normal to the the quasi-*2* axis; minor disordered azin components beeing shown

EDTA titration[18] with xylenol orange indicator of solutions prepared by digestion of accurately weighed samples in concentrated HNO_3/2% concentrated H_2SO_4 followed by dilution with water and buffering with hexamine. Thallium analyses were by potassium iodate titration[19] of solutions prepared by digestion of accurately weighed samples in concentrated HNO_3/2% concentrated H_2SO_4. Once the HNO_3 was removed by heating, the residue was treated with excess Na_2SO_3 to reduce Tl^{3+} to Tl^+, and the solution was boiled to expel excess SO_2. – Microanalysis samples were sealed in glass ampoules under purified argon and were determined either by the Campbell Microanalytical Service, University of Otago, New

Zealand or by Chemical and Microanalytical Services Pty. Ltd, Belmont, Australia. − Lanthanoid elements as either powders or distilled metal ingots were obtained from Rhône-Poulenc. Thallium(I) ethoxide was purchased from Fluka or Merck and was filtered under argon to remove any thallium metal and stored at −20°C in the dark. 7-Azaindole and $HgPh_2$ were purchased from Aldrich. 4,5-Dihydro-2*H*-benz[*g*]indazole was synthesised by a reported method[20]. Other pyrazoles were synthesised[21] by treating the appropriate commercially available β-diketone with an equimolar amount of hydrazine hydrate in refluxing ethanol. These pyrazoles were then recrystallised from an acetone/petroleum ether mixture. Lanthanoid(II) diiodides[22], bis[bis(trimethylsilyl)amido]bis-(tetrahydrofuran)samarium(II),[23] bis(pentafluorophenyl)mercury-(II),[24] and bis(pentafluorophenyl)ytterbium(II)[24] were synthesised by the indicated reported method.

(4,5-Dihydro-2*H*-benz[*g*]indazolato)thallium(I) (1a): Thallium(I) ethoxide (0.35 mL, 1.25 g, 5.0 mmol) was added to a diethyl ether solution (30 mL) of 2*H*-benz[*g*]-4,5-dihydroindazole (0.85 g, 5.0 mmol) giving a white precipitate, which was filtered from solution and washed twice with petroleum ether (2 × 20 mL) yielding 1.62 g (87%) of a white crystalline solid. − IR: $\tilde{\nu}$ = 1608 cm^{-1} w, 1531 w, 1508 w, 1340 w, 1315 m, 1298 w, 1272 m, 1213 m, 1156 w, 1098 m, 1052 s, 1036 s, 1019 s, 1011 s, 960 s, 931 m, 887 m, 850 s, 762 vs, 732 s, 706 vs, 685 m, 659 w. − ^{1}H NMR (200 MHz, [D$_8$]THF): δ = 2.75 (t, 2 H, 4-H), 2.85 (t, 2 H, 5-H), 6.99−7.05 (m, 2 H, 6-H and 9-H), 7.15 (t, 1 H, 7-H), 7.44 (s, 1 H, 3-H), 7.62 (t, 1 H, 8-H). − ^{13}C{^{1}H} NMR (200 MHz, [D$_8$]THF): δ = 21.0 (C-4), 31.7 (C-5), 118.0 (C-3a), 123.0 (C-9), 126.5 (C-8), 127.2 (C-7), 128.9 (C-3 and C-6), 132.5 (C-9a), 137.3 (C-5a), 151.7 (C-10a). − MS (70 eV, EI); *m*/*z* (%): 374 (20) [(^{205}Tl)M$^+$], 205 (85) [^{205}Tl$^+$], 170 (100) [$C_{11}H_{10}N_2^+$]. − $C_{11}H_9N_2Tl$ (373.6): calcd. Tl 54.71; found Tl 55.26.

(3-Methyl-5-phenylpyrazolato)thallium(I) (1b): Thallium(I) ethoxide (0.35 mL, 1.25 g, 5.0 mmol) was added to a THF solution (30 mL) of 3-methyl-5-phenylpyrazole (0.79 g, 5.0 mmol) giving a pale yellow solution. The THF was removed under vacuum giving **3** as an off-white solid which was recrystallised from CH_2Cl_2 and petroleum ether [1.40 g (77%)]. − IR: $\tilde{\nu}$ = 1599 cm^{-1} m, 1292 w, 1261 m, 1154 vw, 1092 m, 1070 m, 1019 s, 962 m, 866 vw, 791 w, 759 vs, 716 s, 696 vs. − ^{1}H NMR (300 MHz, [D$_8$]THF): δ = 2.37 (s, 3 H, Me), 6.41 (s, 1 H, 4-H) 7.08−7.13 (m, 1 H, *p*-H), 7.17−7.23 (t, 2 H, *m*-H), 7.59 (d, 2 H, *o*-H). − MS (70 eV, EI); *m*/*z* (%): 362

(7-Azaindolato)thallium(I) (1c): Thallium(I) ethoxide (2.56 mL, 9.01 g, 36.1 mmol) was added to an ether solution (30 mL) of 7-azaindole (4.26 g, 36.1 mmol) giving a white precipitate and a pale yellow solution. The white precipitate was filtered from solution and washed with petroleum ether (2 × 30 mL) giving **1c** [11.61 g (65%)]. − IR: $\tilde{\nu}$ = 1582 cm^{-1} w, 1534 w, 1333 w, 1278 m, 1257 w, 1150 m, 1092 m, 1044 w, 898 m, 798 s, 766 vs, 746 s, 721 vs, 622 m. − ^{1}H NMR (200 MHz, [D$_8$]THF): δ = 6.39 (s, 1 H, 3-H), 6.90 (dd, 1 H, 5-H) 7.30 (s, 1 H, 2-H), 7.87 (d, 1 H, 4-H), 8.05 (d, 1 H, 7-H). − $C_7H_5N_2Tl$ (321.5): calcd. Tl 63.57; found Tl 64.11.

(3,5-Diphenylpyrazolato)thallium(I) (1d): The preparation and properties have been given in a preliminary report.[8]

(4-Methyl-3,5-diphenylpyrazolato)thallium(I) (1e): Thallium(I) ethoxide (0.35 mL, 1.25 g, 5.0 mmol) was added to a THF solution (30 mL) of 4-methyl-3,5-diphenylpyrazole (1.17 g, 5.0 mmol) giving a deep yellow solution. This was reduced in volume to ca. 5 mL and petroleum ether was added causing deposition of **1e** as a white solid, which was filtered off and dried under vacuum [1.80 g (82%)]. − IR: $\tilde{\nu}$ = 1601 cm^{-1} m, 1528 w, 1516 w, 1292 w, 1248 w, 1225 w, 1145 w, 1117 s, 1070 s, 1011 s, 994 w, 966 w, 916 m, 847 w, 771 vs, 718 s, 700 vs. − ^{1}H NMR (300 MHz, [D$_8$]THF): δ = 2.26 (s, 3 H, CH_3), 7.20−7.26 (m, 2 H, *p*-H), 7.29−7.31 (m, 4 H, *m*-H), 7.44 (t, 4 H, *o*-H). − ^{13}C{^{1}H} NMR (400 MHz, [D$_8$]THF): δ = 12.2 (Me), 111.9 (C-4, pz), 127.2 (C-4, Ph), 129.1 (C-2,C-6 and C-3,C-5, Ph), 136.2 (C-1, Ph), 153.1 (C-3,C-5, pz). − MS (70 eV, EI); *m*/*z* (%): 438 (40) [(^{205}Tl)M$^+$], 234 (90) [$C_{16}H_{14}N_2^+$], 205 (15) [^{205}Tl$^+$], 130 (100) [$C_9H_8N^+$]. − $C_{16}H_{13}N_2Tl$ (437.7): calcd. C 43.90, H 2.99, N 6.40; found C 44.00, H 3.08, N 6.21.

Bis(3,5-diphenylpyrazolato)mercury(II) (2)

Method A: 3,5-Diphenylpyrazole (1.00 g, 4.5 mmol) was treated with a THF solution (30 mL) of potassium hydride (0.18 g, 4.5 mmol) at 0°C. Gas evolution was observed and a slightly pale yellow solution formed. $HgCl_2$ (0.62 g, 2.3 mmol) was added causing formation of a white precipitate. The reaction mixture was stirred for 1 h and then was treated with water. The precipitated mercurial **2** was filtered off, washed with water, ethanol, and ether, and then dried under vacuum for 30 min giving 1.10 g (76%) of impure **2** as a white powder. − IR: $\tilde{\nu}$ = 1604 cm^{-1} m, 1542 w, 1400 m, 1236 w, 1321 w, 1296 w, 1274 m, 1236 m, 1157 m, 1128 m, 1074 s, 1026 m, 1001 w, 986 m, 958 w, 914 m, 844 w, 800 w, 758 vs, 696 vs. − MS (electrospray); *m*/*z* (%): 641 (100) [(^{202}Hg)MH$^+$], 549 (100) [$^{202}HgC_{23}H_{15}N_4^+$], 467 (76) [$^{202}HgC_{17}H_{19}N_3^+$]. − $C_{30}H_{22}N_4Hg$ (639.1): calcd. C 56.38, H 3.47, N 8.77; found C 54.57, H 3.77, N, 8.07.

Method B: $HgBr_2$ (1.80 g, 5.0 mmol) and NaBr (2.05 g, 20 mmol) were dissolved in *t*BuOH (80 mL). 3,5-Diphenylpyrazole (2.20 g, 10 mmol) and NaOH (0.80 g, 20 mmol) were added and the reaction mixture was refluxed for 4 h. The cream-coloured solution was poured into distilled H_2O (150 mL) giving bis(3,5-diphenylpyrazolato)mercury as a cream precipitate which was filtered from the solution and dried under vacuum. The infrared spectrum of this compound was in good agreement with that of the product from Method A and a yield of > 90% was obtained.

Bis(2*H*-benz[*g*]-4,5-dihydroindazolato)bis(1,2-dimethoxyethane)-ytterbium(II) (3a): A mixture of ytterbium powder (0.69 g, 4.0 mmol) and (2*H*-benz[*g*]-4,5-dihydroindazolato)thallium(I) (0.74 g, 2.0 mmol) in THF (30 mL) was subjected to ultrasonication for 24 h. The resulting deep red solution with grey suspended solids was allowed to stand for several hours, when a filter cannula was employed to separate the red solution from the deposited grey solids. The THF was removed under vacuum yielding a red solid which was dissolved in DME (40 mL) and allowed to stand for several days at room temperature during which time 0.54 g (78%) of large red crystals formed. − IR: $\tilde{\nu}$ = 1605 cm^{-1} m, 1528 w, 1509 w, 1297 w, 1275 w, 1240 w, 1224 w, 1210 w, 1191 w, 1121 m, 1097 s, 1073 s, 1045 w, 1028 w, 1009 m, 977 m, 954 m, 943 m, 884 m, 855 s, 818 s, 766 vs, 734 m, 716 vs, 686 m, 673 m. − ^{1}H NMR (300 MHz, [D$_8$]THF): δ = 2.73 and 2.79 (br. d, overlapping signals, total integration 4 H, 4-H,5-H), 3.31 (br. s, 12 H, MeO, DME), 3.48 (br. s, 8 H, CH_2 DME), 7.00 (br. m, 3 H, 6-H,7-H,9-H), 7.55 (br. s, 1 H, 3-H), 7.85 (br. s, 1 H, 8-H). Integration of the indazolate protons showed approximately half the expected intensity. − Visible/near IR (THF): λ_{max} (ε): 430 (415) nm. − $C_{30}H_{38}N_4O_4Yb$ (691.7): calcd. C 52.09, H 5.54, N 8.10, Yb 25.02; found C 51.91, H 5.66, N 7.27, Yb 25.14.

Bis(1,2-dimethoxyethane)bis(3-methyl-5-phenylpyrazolato)-ytterbium(II) (3b): A mixture of ytterbium powder (1.73 g, 10.0 mmol), mercury metal (ca. 0.20 mL), and (3-methyl-5-phenylpyrazolato)thallium(I) (1.20 g, 2.31 mmol) in THF (30 mL) was subjected to ultrasonication for 48 h. The resulting deep red solution with grey suspended solids was allowed to stand for several hours until the suspension settled out. The reaction mixture was then filtered using a filter cannula. The filtrate was concentrated to dryness under vacuum yielding a red solid which was dissolved in DME which was subsequently removed under vacuum giving **3b** [0.48 g (62%)]. − IR: $\tilde{\nu}$ = 1602 cm^{-1} m, 1527 w, 1491 m, 1413 m, 1298 w, 1190 w, 1155 w, 1099 m, 1054 s, 1016 m, 964 m, 912 w, 888 m, 858 m, 762 vs, 712 m, 695 vs. − Visible/near IR (THF): λ_{max} (ε) = 389 nm (586). − ^{1}H NMR (300 MHz, [D$_8$]THF): δ = 2.22 (br. s, 6 H, 3-Me), 3.20 (s, 12 H, MeO DME), 3.36 (s, 8 H, CH_2 DME), 6.30 (br. s, 2 H, 4-H), 6.96 (br. s, 2 H, *p*-H), 7.14 (br. s, 4 H, *m*-H), 7.72 (br. s, 4 H, *o*-H). − $C_{28}H_{38}N_4O_4Yb$ (667.7): calcd. Yb 25.92; found Yb 25.82.

Bis(7-azaindolato)bis(1,2-dimethoxyethane)ytterbium(II) (3c): A mixture of ytterbium powder (1.73 g, 10.0 mmol), mercury metal (ca. 0.20 mL), and (7-azaindolato)thallium(I) (0.64 g, 2.0 mmol) in THF (30 mL) was subjected to ultrasonication for 16 h. The resulting deep red solution with grey suspended solids was allowed to stand for several hours until the suspension settled out. The reaction mixture was then filtered using a filter cannula. The filtrate was concentrated to dryness under vacuum yielding a red solid which was recrystallised from DME giving **3c** [0.41 g (70%)]. − IR: $\tilde{\nu}$ = 1581 cm^{-1} m, 1542 m, 1402 w, 1335 w, 1321 m, 1295 s, 1258 m, 1193 m, 1153 s, 1118 m, 1060 m, 1020 m, 984 m, 951 w, 907 w, 896 w, 857 vs, 795 s, 771 s, 744 s, 718 vs, 617 m, 598 m. − Visible/near IR (THF): λ_{max} (ε) = 480 nm (259). − ^{1}H NMR (300 MHz, [D$_6$]benzene): δ = 2.79 (s, 12 H, MeO DME), 2.83 (s, 8 H, CH_2 DME), 6.74 (m, 4 H, 2-H,5-H), 7.88 (s, 2 H, 2-H), 7.97 (m, 4 H, 4-H,7-H). − ^{171}Yb NMR (52.5 MHz, 0.04 M in DME): δ = 489 ($\Delta\nu_{1/2}$ = 54 Hz). − $C_{22}H_{30}N_4O_4Yb$ (587.6): calcd. C 44.97, H 5.15, N 9.54, Yb 29.45; found C 43.85, H 4.82, N 10.01, Yb 29.41.

Bis(1,2-dimethoxyethane)bis(3,5-diphenylpyrazolato)ytterbium(II) (3d)

Method A: A mixture of ytterbium powder (0.83 g, 4.8 mmol) and $Hg(Ph_2pz)_2$ (1.00 g, 2.4 mmol) in THF (30 mL) was subjected to ultrasonication for 6 d. The resulting deep red solution with grey suspended solids was allowed to stand for several hours, and was then filtered. The THF was removed under vacuum giving a deep red sticky solid which was recrystallised from DME affording 1.10 g (58%) of large red crystals. − IR: identical with that reported.[8] − $C_{38}H_{42}N_4O_4Yb$ (791.8): calcd. Yb 21.85; found Yb 22.28, 22.04.

Method B: $Yb(C_6F_5)_2$, generated in situ from ytterbium metal (1.73 g, 10.0 mmol) and $Hg(C_6F_5)_2$ (1.07 g, 2.0 mmol) was treated with 3,5-diphenylpyrazole (0.88 g, 4.0 mmol) in THF (30 mL). After stirring at room temerature for 15 min, the THF was removed and the red solid was recrystallised from DME [0.34 g, (22%)]. − IR and visible/near IR (THF): identical with those reported.[8]

Method C: 3,5-Diphenylpyrazole (0.59 g, 2.7 mmol) was treated with a THF solution (30 mL) of potassium hydride (0.11 g, 2.7 mmol) at 0°C. To the resulting solution $YbI_2(THF)_2$ (0.77 g, 1.35 mmol) was added causing an formation of a red solution and a white precipitate. After stirring for 12 h, removal of THF gave a sticky orange solid which was extracted with in toluene (80 mL) giving a red/brown solution and a white precipitate. After filtration, the toluene solution was concentrated to dryness giving a red solid which was recrystallised from DME [0.40 g (37%)]. − IR: identical with that reported.[8] − $C_{38}H_{42}N_4O_4Yb$ (791.8): calcd. Yb 21.85; found Yb 21.52.

Bis(1,2-dimethoxyethane)bis(3,5-diphenylpyrazolato)europium(II) (4a): A mixture of europium metal chunks (0.61 g, 4.0 mmol), mercury metal (ca. 0.20 mL) and (3,5-diphenylpyrazolato)thallium(I) (0.85 g, 2.0 mmol) in THF (30 mL) was subjected to ultrasonication for 48 h. The resulting deep yellow solution with grey suspended solids was allowed to stand for several hours. Filtration, and evaporation of the THF yielded a yellow solid, which was recrystallised from DME giving 0.69 g (90%) of **4a** as large yellow crystals. − IR: $\tilde{\nu}$ = 1602 cm^{-1} m, 1157 w, 1120 w, 1193 w, 1115 m, 1096 m, 1069 s, 1057 s, 1025 m, 1016 m, 980 m, 968 s, 907 w, 852 s, 832 w, 794 w, 770 m, 750 vs, 697 s, 682 s. − $C_{38}H_{42}EuN_4O_4$ (770.7): calcd. C 59.22, H 5.49, Eu 19.72, N 7.27; found C 59.06, H 5.67, Eu 19.68, N 7.59.

Bis(3,5-di-*tert*-butylpyrazolato)bis(1,2-dimethoxyethane)europium(II) (4b): A mixture of europium metal chunks (1.52 g, 10.0 mmol), mercury metal (ca. 0.20 mL), diphenylmercury(II) (0.98 g, 2.78 mmol) and 3,5-di-*tert*-butylpyrazole (1.00 g, 5.56 mmol) in THF (30 mL) was heated (60 °C) for 24 h. The resulting deep yellow solution with grey suspended solids was allowed to stand for several hours. Filtration, and evaporation of the THF yielded a yellow solid, which was recrystallised from DME giving 0.57 g (59%) of **4b** as large yellow crystals. − IR: $\tilde{\nu}$ = 1509 cm^{-1} m, 1404 w, 1354 m, 1318 w, 1248 s, 1218 m, 1195 m, 1158 w, 1123 m, 1103 m, 1078 s, 1032 m, 1010 s, 996 m, 860 vs, 769 vs, 722 vs. − Visible/near IR (THF): λ_{max} (ε) = 345 nm (477). − $C_{38}H_{42}EuN_4O_4$ (690.8): calcd. C 52.16, H 8.46, Eu 22.00, N 8.11; found C 51.28, H 8.39, Eu 22.02, N 8.88.

Bis(1,2-dimethoxyethane)bis(3,5-diphenylpyrazolato)samarium(II) (5)

Method A: 3,5-Diphenylpyrazole (0.27 g, 1.2 mmol) was treated with a THF solution (30 mL) of bis[bis(trimethylsilyl)-amido]bis(tetrahydrofuran)samarium(II) (0.38 g, 0.60 mmol). The resulting purple solution was stirred for 30 min, and the THF was then removed under vacuum yielding a purple solid which was washed twice with petroleum ether (2 × 30 mL). The purple solid was recrystallised from DME (30 mL) giving 0.12 g (25%) of **5** as dark purple crystals. − IR: $\tilde{\nu}$ = 1602 cm^{-1} m, 1509 w, 1243 w, 1220 w, 1156 w, 1121 w, 1101 m, 1073 s, 1026 m, 1014 w, 967 s, 913 w, 860 m, 849 m, 793 w, 758 vs, 697 s, 685 s. − Visible/near IR (THF) λ_{max} (ε): ca. 600 br. (900) nm. − ^1H NMR (300 MHz, [D_8]THF): δ = −11.76 (s, 2 H, H-4), 2.93 (d, 8 H, *o*-H), 3.48 (s, 12 H, MeO, DME), 3.54 (s, 8 H, CH_2, DME), 5.84 (t, 4 H, *p*-H), 6.73 (t, 8 H, *m*-H). − $C_{38}H_{42}N_4O_4Sm$ (769.2): calcd. C 59.34, H 5.50, N 7.28, Sm 19.55; found C 59.42, H 5.63, N 7.51, Sm 19.26.

Method B: $SmI_2(THF)_2$ (0.54 g, 1.0 mmol) was added to a THF solution (30 mL) of (3,5-diphenylpyrazolato)potassium(I) (2.0 mmol) (generated in situ as described above in the synthesis of **3d**) causing formation of a dark purple solution and a white precipitate. This reaction mixture was stirred for 12 h followed by removal of THF to give a sticky purple solid, which was extracted with toluene (30 mL) giving a red/brown solution and a white precipitate. The toluene solution was filtered and concentrated to dryness yielding dark purple **5** which was recrystallised from DME [0.48 g (62%)]. − IR: identical with that of the product from Method A. − $C_{38}H_{42}N_4O_4Sm$ (769.2): calcd. Sm 19.55; found Sm 19.90.

Reaction between 3d and $HgPh_2$ and Ph_2pzH: 3d (0.40 g, 0.50 mmol), $HgPh_2$ (0.89 g, 0.25 mmol) and Ph_2pzH (0.55 g, 0.25 mmol) were stirred in DME (30 mL) at room temperature for 2 d. The reaction mixture remained red and there were no signs of precipitated metal. A visible/near-IR spectrum of the reaction mixture was indentical to that reported[8] for **3d**.

Reaction between (1,2-Dimethoxyethane)tris(3,5-diphenylpyrazolato)ytterbium(III) and Ytterbium Metal: A mixture of (1,2-dimethoxyethane)tris(3,5-diphenylpyrazolato)ytterbium(III)[25] (0.46 g, 0.50 mmol), ytterbium metal (1.73 g, 10.0 mmol), and mercury metal (ca. 0.20 mL) in DME (30 mL) were subjected to ultrasonication for 24 h. The initially colourless solution turned deep red after sonication for 12 h. Separation of excess ytterbium and mercury followed by removal of DME yielded a red solid. Visible/near-IR and IR spectra were indentical with those reported[8] for **3d**.

Reaction between Bis(1,2-dimethoxyethane)tris(3,5-diphenylpyrazolato)samarium(III) and Samarium Metal: A mixture of bis(1,2-dimethoxyethane)tris(3,5-diphenylpyrazolato)samarium(III)[8] (0.99 g, 1.0 mmol), samarium metal (1.50 g, 10.0 mmol), and mercury metal (ca. 0.20 mL) in DME (30 mL) were subjected to ultrasonication for 2 d. The initially colourless solution remained colourless after sonication for 2d. A visible/near IR spectrum of the reaction mixture was indentical with that reported[8] for $[Sm(Ph_2pz)_3(DME)_2]$.

Attempted Reaction of Ytterbium Metal with $Hg(C_6F_5)_2$ and 3,5-Diphenylpyrazole: A mixture of ytterbium powder (1.73 g, 10.0 mmol), mercury metal (ca. 0.20 mL), bis(pentafluorophenyl)mercury(II) (0.53 g, 1.0 mmol), and 3,5-diphenylpyrazole (0.44 g, 2.0 mmol) in THF (40 mL) was stirred at room temperature for 4 d. On addition of THF an orange solution formed. This progressively darkened to a black solution over the course of the reaction. The resulting black solution with grey suspended solids was allowed to stand for several hours. Filtration and removal of THF under vacuum revealed a black solid which was insoluble in DME. The infrared spectrum of this black material was significantly different from that obtained for compound **3d**. − IR: $\tilde{\nu}$ = 1365 cm^{-1} m, 1303 w, 1246 m, 1193 m, 1112 br. s, 1028 m, 983 m, 940 m, 852 s, 763 vw, 723 vw.

Structure Determinations: Room-temperature single-counter/four-circle diffractometer data sets were measured on capillary-mounted specimens (2θ/θ-scan mode; graphite-monochromated radiation, λ = 0.7107_3 Å; $T \approx 295$ K), in most cases with symmetry equivalences, yielding N_{total} reflections, these being merged (R_{int} as specified) after absorption correction, yielding N (unique) data, N_o with $I > 2\sigma(I)$ being considered "observed" and used in the full-matrix least-squares refinement (n_v variables). Anisotropic thermal parameters were refined for the non-hydrogen atoms, (x, y, z, $U_{iso})_H$ being included constrained at estimated values. Conventional residuals R, R_w [statistical weights, derivative of $\sigma^2(I) = \sigma^2(I_{diff}) + 0.0004\ \sigma^4(I_{diff})$] on $|F|$ are quoted at convergence. Neutral atom complex scattering

factors were employed, the Xtal 3.4 program system[26] being used. Individual abnormalities, variations in procedure and idiosyncrasies are noted as "variata"; in no case was there difference-map evidence for occluded solvent, although ligand disorder was evident in some cases (see below). In Figures 1−6, 20% thermal ellipsoids are shown for the non-hydrogen atoms, hydrogen atoms having arbitrary radii of 0.1 Å. In the case of **5** and **4a** pairs of molecular projections (Figures 3 and 6) are shown and provide views (i) down the actual or putative *2* axis of the molecule, so as to display that symmetry, and (ii) normal to that axis. The latter is provided to display better (a) any difference in conformation among the pair of DME ligands, (b) any ligand disorder, (c) any tendency to dodecahedral coordination about the metal atom [the $(N_2)_2$ ligand pair comprising one of the two intersecting planes and the $(O_2)_2$ the other]. Crystallographic data (excluding structure factors and including torsion angles describing the DME conformations) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC-101118 (**3d**)[8] and -109937−109941. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: int. code + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Crystal/Refinement Data

3a [Yb(bind)$_2$(DME)$_2$]: $C_{30}H_{38}N_4O_4Yb$, M = 691.7. Monoclinic, space group $P2_1/c$ (C_{2h}^5, no. 14), a = 15.570(2), b = 23.434(5), c = 8.052(3) Å, β = 94.98(2)°, V = 2927 Å^3. $D_{calcd.}$ (Z = 4) = 1.570 g cm^{-3}; F(000) = 1392. μ_{Mo} = 32.4 cm^{-1}; specimen: 0.45 × 0.30 × 0.45 mm; $A^*_{min,max}$ = 2.28, 3.85 (analytical correction). $2\theta_{max}$ = 55°; N = 6476, N_o [$I > 3\sigma(I)$] = 4954; R = 0.026, R_w = 0.029; n_v = 333. $|\Delta\rho_{max}|$ = 1.13 e Å^{-3}.

3c [Yb(azin)$_2$(DME)$_2$]: $C_{22}H_{30}N_4O_4Yb$, M = 587.6. Orthorhombic, space group *Pbca* (D_{2h}^{15}, no. 61), a = 18.183(4), b = 16.567(6), c = 15.855(9) Å, V = 4776 Å^3. $D_{calcd.}$ (Z = 8) = 1.634 g cm^{-3}; F(000) = 2336. μ_{Mo} = 39.5 cm^{-1}; specimen: 0.12 × 0.40 × 0.45 mm; $A^*_{min,max}$ = 1.60, 4.2 (analytical correction). $2\theta_{max}$ = 55°; N_{total} = 11095, N = 5483 (R_{int} = 0.028), N_o = 3229; R = 0.034, R_w = 0.038; n_v = 299. $|\Delta\rho_{max}|$ = 0.80 e Å^{-3}.

Variata: Each azin ligand is capable of coordinating in two modes involving interchange of nitrogen atoms with various associated possibilities of isomerism; these modes are both observed for each ligand, C(4,4′) [Figure 5: C(14), C(14′) and C(24), C(24′) of the respective ligands] of each being the only constituent atoms sufficiently displaced from overlap to permit meaningful refinement of the alternate fragments. Site occupancies (x, 1 − x) for the two ligands refined to x = 0.83, 0.77(3), isotropic thermal parameter forms being used for the minor fragments.

[M(Ph$_2$pz)$_2$(DME)$_2$] (M = Yb, Eu, Sm): $C_{38}H_{42}MN_4O_4$.

[**3d (M = Yb)** has been recorded elsewhere;[8] a redeposition has been made, with atoms relabelled as shown in Figure 2, in conformity with present arrays, which conform to the quasi-*2* symmetry of the system.]

4a (M = Eu): **M** = 770.7. Monoclinic, space group $P2/c$ (C_{2h}^4, no. 13), a = 19.746(3), b = 12.635(2), c = 15.396(2) Å, β = 110.12(1), V = 3607 Å^3. $D_{calcd.}$ (Z = 4) = 1.419 g cm^{-3}; F(000) = 1572. μ_{Mo} = 17.8 cm^{-1}; specimen: 0.55 × 0.30 × 0.30 mm; $A^*_{min,max}$ = 1.50, 1.82 (gaussian correction). $2\theta_{max}$ = 50°; N = 6328, N_o = 4823; R = 0.046, R_w = 0.049; n_v = 427. $|\Delta\rho_{max}|$ = 0.85 e Å^{-3}.

5 (M = Sm): **M** = 769.1. Orthorhombic, space group *Pnma* (D_{2h}^{16}, no. 62), a = 7.9941(6), b = 24.263(3), c = 19.080(3) Å, V = 3701 Å^3. $D_{calcd.}$ (Z = 4) = 1.380 g cm^{-3}; F(000) = 1568. μ_{Mo} = 16.3 cm^{-1}; specimen: 0.25 × 0.35 × 0.55 mm; $A^*_{min,max}$ = 1.47, 1.72 (gaussian correction). $2\theta_{max}$ = 60°; N_{total} = 8395, N = 3650 (R_{int} = 0.029), N_o = 2240; R = 0.042, R_w = 0.037; n_v = 270. $|\Delta\rho_{max}|$ = 1.04 e Å^{-3}.

Variata: As modelled in the present space group, the DME moieties are disordered across the crystallographic mirror plane; meaningful refinement could not be achieved in a lower symmetry space group. An ordered component is shown in the Figures and Tables and has a crystallographic mirror plane passing through the metal atom and relating the two halves (including substituents) of each Ph$_2$pz ligand. Despite similar Ln sizes, the M = Eu, Sm adducts **4a**, **5** are not isomorphous with each other, or with the Yb adduct **3d**.

4b [Eu(*t*Bu$_2$pz)$_2$(DME)$_2$]: $C_{30}H_{58}EuN_4O_4$, M = 690.8. Triclinic, space group $P\bar{1}$ (C_i^1, no. 2), a = 22.791(4), b = 15.709(4), c = 10.289(3) Å, α = 89.38(2), β = 82.31(2), γ = 84.49(2)°, V = 3634 Å^3. $D_{calcd.}$ (Z = 4) = 1.263 g cm^{-3}; F(000) = 1444. μ_{Mo} = 17.6 cm^{-1}; specimen: 0.40 × 0.50 × 0.50 mm; $A^*_{min,max}$ = 1.60, 2.12 (gaussian correction). $2\theta_{max}$ = 50°; N_{total} = 19495, N = 12765 (R_{int} = 0.047), N_o [$I > 3\sigma(I)$] = 6027; R = 0.057, R_w = 0.064; n_v = 700. $|\Delta\rho_{max}|$ = 1.45 e Å^{-3}.

Variata: One of the DME groups is conformationally disordered in each molecule, discrete $(CH_2)_2$ carbon atoms being resolvable and refined (C thermal parameters isotropic) with site occupancies set at 0.5 after trial refinement. Crystal decomposition of 55% was evident during data collection (isotropic) and compensated by scaling.

Acknowledgments

We are grateful to the Australian Research Council for financial support and for the award of an Australian Postgraduate Award to E. E. D.

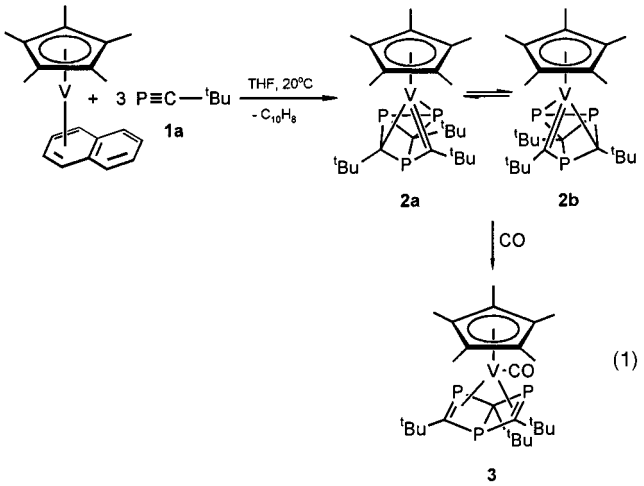
1,3,5-Triphosphabicyclo[3.1.0]hexene-η^3,η^1-diyl Hafnium Complexes: Structure and Reactivity



Paul Binger,*[a,b] Stefanie Stutzmann,[a] Jörg Stannek,[a] Klaus Günther,[b] Petra Phillips,[a] Richard Mynott,[a] Joachim Bruckmann,[a] and Carl Krüger[a]

Keywords: 1,3,5-Triphosphabicyclo[3.1.0]hexene-η^3,η^1-diyl hafnium complexes / 1,3,5-Triphosphabicyclo[3.1.0]hexene / 1,3,5-Triphosphacyclohexa-1,4-diene / Cyclotrimerization / Phosphaalkyne

It is shown that the $(P{\equiv}C{-}t\mathrm{Bu})_3$ ligand found in the hafnium complex (COT)Hf$(P{\equiv}C{-}t\mathrm{Bu})_3$ **5** (COT = cyclooctatetraene), which we reported recently,[3] is also present in the new hafnium complex **12**, prepared by reaction of hexachloroethane with complex **5** in pentane, as well as in its trimethylphosphane adduct **14**. The structures of complexes **12** and **14** have been determined by X-ray crystallography and that of **5** by comparing its ^{1}H-, ^{13}C-, and ^{31}P-NMR spectra with those of the complexes **12** and **14**. The organophosphorus ligand in all three complexes is a 2,4,6-tri-*tert*-butyl-1,3,5-triphosphabicyclo[3.1.0]hexene-η^3,η^1-diyl. Hydrolysis of complexes **5** and **12** with water gives the new phosphorus heterocycle **15**, whereas the new heterocycles **16** and **17** are formed in an approximately 1:1 mixture using either silica gel containing 2% H_2O or $Na_2SO_4 \cdot 10\ H_2O$.

Introduction

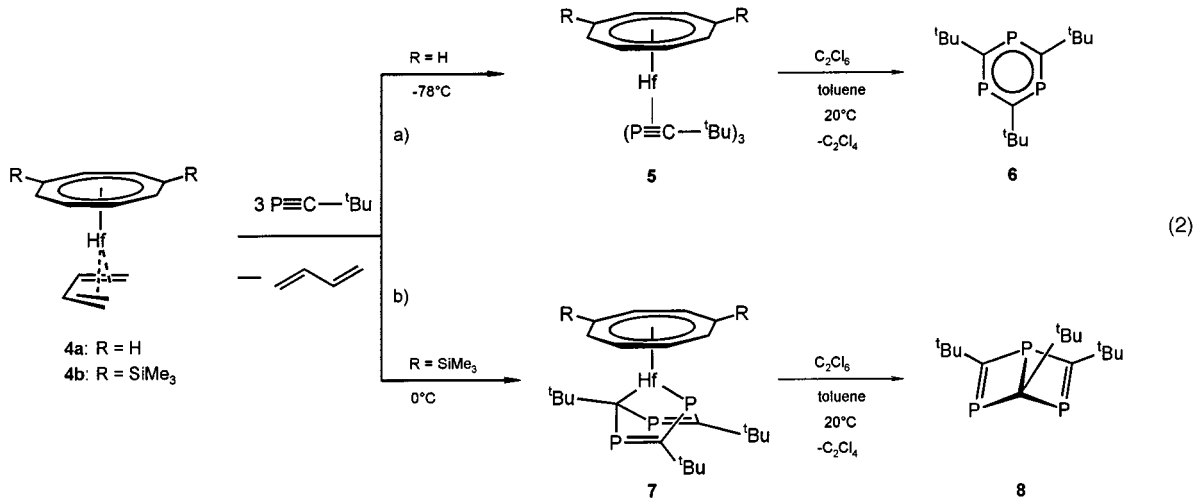
Although numerous reactions are known where phosphaalkynes (**1**), e.g. *tert*-butylphosphaalkyne (**1a**), are cyclodimerized in the coordination sphere of a transition metal, the corresponding cyclotrimerizations are rare.[1] Until recently, the only example reported where it has been established unambiguously that **1a** is cyclotrimerized is the reaction to give the stable vanadium complexes **2** and **3**.[2]

(1)

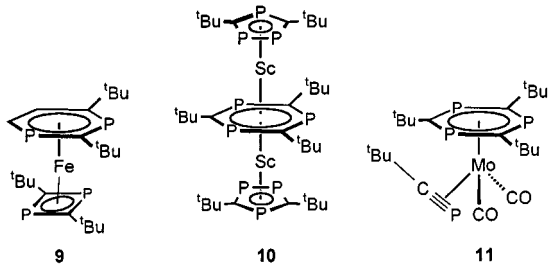
Recently, we succeeded in preparing an η^8-cyclooctatetraene hafnium$-(PC-t\mathrm{Bu})_3$ complex **5** from **1a** and η^8-cyclooctatetraene-η^4-butadiene hafnium **4a** in high yield. Subsequent reaction of **5** with hexachloroethane afforded the new cyclotrimer 2,4,6-tri-*tert*-butyl-1,3,5-triphosphabenzene **6** (Eq. 2a).[3] An extensive NMR study of complex **5** showed that the trimeric phosphaalkyne unit in this hafnium complex is not bonded to the metal as a triphosphabenzene **6**, even though this species is liberated in subsequent displacement reactions. However, the NMR experiments did not permit a full description of the bonding situation.[3]

Slight modification of the cyclooctatetraene ligand in complex **4** (introduction of trimethylsilyl substituents → **4b**) led to another hafnium$-(PC-t\mathrm{Bu})_3$ complex (**7**), in which a 7-hafna-1,3,5-triphosphanorbornadiene appears to be formed. Free 1,3,5-triphospha-Dewar-benzene **8** could be obtained by displacement of the $(PC-t\mathrm{Bu})_3$ unit from **7**[3] (Eq. 2b).

In the last few years, two transition metal complexes have been reported where a 1,3-diphosphabenzene[4] (**9**) and a 1,3,5-triphosphabenzene[5] (**10**) are incorporated as η^6-coordinated ligands. However, it would seem very unlikely that the η^6-phosphabenzene molybdenumdicarbonyl complex **11** published much earlier[6] does indeed have the claimed structure.[7]



In this publication, we show that the $(P{\equiv}C-t\mathrm{Bu})_3$ ligand bonded to the hafnium in complex **5** as well as in the two new complexes **12** and **14** is a new type with a 1,3,5-triphosphabicyclo[3.1.0]hexene skeleton. This has been established by determining the structures of complexes **12** and **14** by X-ray crystallography. Supporting evidence comes from the observation that hydrolysis of complexes **5** and **12** yields the same phosphorus heterocycles **15**–**17**, indicating that the $(P{\equiv}C-t\mathrm{Bu})_3$ unit has the same structure in all three complexes **5**, **12**, and **14**.



Results and Discussion

As described previously,[3] triphosphabenzene **6** can be generated from the hafnium complex **5** in 53% yield by a redox reaction with hexachloroethane (Eq. 2). The "(COT)-

hafnium(II)" fragment (COT = cyclooctatetraene) is oxidized to $(COT)HfCl_2$ and the hexachloroethane is reduced to tetrachloroethene. Unexpectedly, further studies revealed that the course of this reaction can be influenced by variation of the solvent. In our original experiments we had used toluene,[3] but replacing this by pentane led to an almost complete change in the reaction products. In the latter medium, the aforementioned redox reaction becomes merely a side reaction giving **6** only in ca. 16% yield, while the main product, 2,4,6-tri-*tert*-butyl-1,3,5-triphosphabicyclo[3.1.0]-hexene-η^3,η^1-diylhafnium dichloride **12** is formed in ca. 44% yield. The fate of the cyclooctatetraene ligand is unknown.

The new hafnium complex **12** is a red solid. Crystals suitable for X-ray analysis could be obtained from pentane at −20°C.

X-ray structural analysis of **12** revealed that it is dimeric in the solid state and contains a μ-Cl_2 bridge. Molecular weight measurements showed the complex to be monomeric in solution, e.g. in toluene. The $(PC-tBu)_3$ moiety in **12** possesses a hitherto unknown structure for this ligand: it is linked to the metal as a 1,3,5-triphosphabicyclo[3.1.0]hexenediyl via a C1−Hf σ-bond and an η^3-allyl bond (C6, C11, and P1). The bicyclic ligand adopts a chair conformation, with an interplanar angle P2−C1−P3 and C6−C11−P2−P3 of 77.9°; P1 is bent away from the metal by 24.1°. The P−C and P−P σ-bond lengths in the bicyclic system lie in the normal ranges,[8] e.g. P2−C1 = 1.924(6), P3−C1 = 1.893(6), P3−C6 = 1.950(6), P2−C11 = 1.851(6) Å. The η^3-allylic nature of the C6−P1−C11 moiety is evident from the typical bond lengths Hf−C6 = 2.442(6), Hf−C11 = 2.358(6), Hf−P1 = 2.727(2) Å and from the P−C distances P1−C6 = 1.729(6) and P1−C11 = 1.752(6), which lie between those known for P−C single and P−C double bonds.[8] Similar P−C distances have been found in η^3-P−C−C and η^3-C−P−C allylic complexes of cobalt,[9] nickel,[10] and molybdenum.[11] The Hf−C1 σ-bond is reflected in a short distance of 2.081(6) Å.

As mentioned above, the hafnium complex **12** is monomeric in solution and is therefore electronically and coordinatively unsaturated. Thus, it can be expected to react readily with electron-donating ligands such as isocyanides and phosphanes. Indeed, even at −78°C, complex **12** takes up one equivalent of *tert*-butyl isocyanides or trimethylphosphane to give the new hafnium complexes **13** and **14**, respectively. No further reactions, e.g. displacement of the $(PC-tBu)_3$ unit, are observed when these ligands are use in excess.

Both complexes were isolated as dark-red microcrystals. Only those of **14** proved to be stable at room temperature and both complexes were found to be unstable in solution above 0°C. The trimethylphosphane complex **14** dissociates into complex **12** and free trimethylphosphane, while the isonitrile complex **13** rearranges into a complex of unknown structure that gives rise to two new signals in the

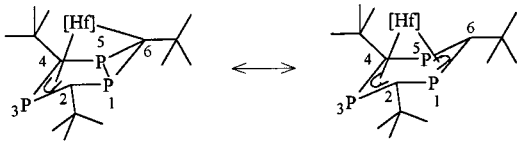
^{31}P-NMR spectrum at δ = −163.8 and −100.4 in a 2:1 ratio.

X-ray analysis of crystals of **14**, obtained from pentane solution at −78°C, revealed that the complex is monomeric and contains a (PC−*t*Bu)$_3$ unit isostructural with that found in complex **12**. However, in view of the rather poor quality of the crystal structure analytical data, no further details will be discussed, neither here nor in the Experimental Section.

To gain insight into the structure of the [P_3C_3tBu$_3$] ligand of the complexes **5**, **12**, and **14** in solution, we examined their NMR spectra (^{1}H, ^{13}C, ^{31}P) in detail. In each case, the NMR spectra recorded at −30°C showed that a single complex of high symmetry was present. The similarity of the characteristic features of the spectra shows that the structure of the [P_3C_3tBu$_3$] ligand is the same in all three cases. For the three P and three C atoms of the [P_3C_3] unit, two signals are found in a 1:2 ratio in the ^{31}P- and ^{13}C-NMR spectra, respectively. In the ^{1}H-NMR spectra, two signals are observed in the same ratio due to the protons of the *tert*-butyl groups (see Table 1).



Although the ^{31}P-NMR spectra of the complexes are broadly similar, the positions of the signals differ somewhat depending on the nature of the other ligand bonded to the metal (e.g. **5**: δ = 357.1 and 17.3; **12**: δ = 410.2 and −45.6). Nevertheless, the P,P coupling constants remain almost unchanged (41.9−43.8 Hz). While the ^{13}C-chemical shifts of the three ring-carbon atoms of complexes **5**, **12**, and **14** differ considerably from compound to compound, the appearance of the multiplets and the magnitude of the coupling constants remains essentially the same.

For complex **12**, a detailed analysis of the ^{13}C multiplet at δ = 169.1 (C2 and C4) reveals that these carbon atoms constitute the X part of an AA′MX spin system (A, M = ^{31}P, X = ^{13}C). It consists of two AA′X subspectra, each of five signals, where the outer combination lines, just detectable above the noise, are split by $^1J_{P,C}$ = 73.4 Hz. Although an exact analysis is not possible, the spectrum allows adequately accurate estimates of $^1J_{P1,P5}$ (74 Hz), $^1J_{P3,C2}$ (73 Hz), $^1J_{P2,C2}$ (70 Hz), and $^3J_{P5,C2}$ (13 Hz) to be made. These values were confirmed by computer simulation. The interpretation of the magnitude of $J_{P1,P5}$ (74 Hz) is ambiguous: it appears to be rather small for a $^1J_{P,P}$ coupling, but large for a $^2J_{P,P}$ coupling (e.g. $^1J_{P,P}$ in complex **2a**, **b** = 219 Hz). On the basis of these NMR studies, we propose that the structure of the (P_3C_3tBu$_3$) ligand in complexes **5**, **12**, and **14** is best represented by the two canonical forms **a** and **b** (see Table 1).

Support for this interpretation of the NMR spectra is provided by the products of hydrolysis of complexes **5** and **12**. When the hafnium complex **5** is treated with an excess of water, the only metal-free reaction products obtained are the new bicyclic phosphorus heterocycle **15** (yield 55%) together with 10% of 1,3,5-triphosphabenzene **6**. Under milder and more controlled conditions, the addition of the second equivalent of water can be suppressed and the two new phosphorus heterocycles **16** and **17** are formed in almost equal amounts. Suitable reagents for this purpose are silica gel with a water content of 2% and the hydrate $Na_2SO_4 \cdot 10\ H_2O$. With these two reagents, both hafnium complexes **5** and **12** react to give 1,3,5-triphosphabicyclo[3.1.0]hex-2-ene **16** and 1,3,5-triphosphacyclohexa-1,4-diene **17** in yields of 83% and 90%, respectively. It is likely that **16** is an intermediate in the formation of **15** from complex **5**. The NMR spectra of **15**, **16**, and **17** indicate that only one isomer is formed in each case.

The structure determination of compounds **15**−**17** is based mainly upon their NMR data. The IR and mass spectra, as well as elemental analysis data support the proposed structures. The presence of a diphosphirane unit in compounds **15** and **16** is evident from the high field shifts of P1 and P5 [δ = −222.8 (s) in **15**; δ = −117.4 and −128.6

($^1J_{P,P}$ = 167.2 Hz) in **16**].[12] The proposed conformation of **15** shown in Eq. 5a is supported by the small magnitudes of the coupling constants between P1, P5 and 2-H and 4-H ($^3J_{P,H}$ = 3.5 Hz) and the high value of 16 Hz between P3 and 2,4-H, as well as by NOESY experiments. The presence of the PHO unit in **15** is indicated by its ^{31}P-NMR signal at δ = 39.4 with $^1J_{P,H}$ = 454.6 Hz and its IR absorptions at 2320 and 1183 cm^{-1}, which are typical for P−H and P=O bonds, respectively.[13] The small coupling constants between 4-H and the two adjacent P atoms reveal its *trans* orientation with respect to the lone pairs of these P atoms in compound **16**.[12] The high symmetry of 1,3,5-triphosphacyclohexa-1,4-diene **17** is reflected in its simple ^{31}P- and ^{13}C-NMR spectra, which feature only two sets of signals for the three P and C atoms of the six-membered ring and the three *tert*-butyl groups (^{31}P: δ = 241.3 and −24.9; ^{13}C: δ = 213.5 and 66.1) in a 2:1 ratio. The ^{1}H-, ^{13}C-, and ^{31}P-NMR chemical shifts are also consistent with the structure proposed for **17**. Analysis of the multiplets in the ^{13}C-NMR spectrum provides additional evidence for this structure. The signals attributable to C2, C4 and those of the *tert*-butyl groups linked to C2 and C4 all analyse as the X part of an AA′MX spin system (A, A′, M = ^{31}P, X = ^{13}C). The magnitude of the P1,P5 coupling constant, estimated as 10.5 Hz by simulation of the C2 multiplet, shows that P1 and P5 are not directly bonded.

The only difficulty in the interpretation of the ^{13}C-NMR spectrum of **17** was the finding that the signal of C6 at δ = 66.1 is a first-order triplet of doublets with a triplet splitting of $^1J_{P,C}$ = 51.5 Hz and a doublet splitting of $^3J_{P,C}$ = 42.2 Hz. While the value of $^1J_{P,C}$ is unremarkable, the magnitude of $^3J_{P,C}$ is unexpectedly large. In related organophosphorus compounds, a ^{31}P,^{13}C coupling constant of this order is more consistent with a one-bond coupling and we have not found any example of such a large coupling over three bonds in the literature. In order to show that P3 and C6 are not directly bonded and to confirm the connectivities in **17**, we determined the ^{13}C isotope shifts on the phosphorus chemical shifts. Analysis of the ^{13}C satellites in the ^{31}P-NMR spectrum showed that $^1\Delta^{31}P_1(^{13/12}C_6)$ amounts to −30.0 ppb, but that $^3\Delta^{31}P_3(^{13/12}C_6)$ is just −4.6 ppb. The latter is of a much smaller magnitude than is usually observed for $^1\Delta^{31}P(^{13/12}C)$ in similar compounds, confirming that P-3 and C-6 are not directly connected.[14] The observed ^{31}P,^{13}C and ^{31}P,^{1}H coupling constants are consistent with the electron pair on phosphorus and 6-H being *cis* to one another. The magnitude of ^3J(P-3,C-6) in compound **17** (42.2 Hz) is a further example illustrating the strong stereochemical dependence of $^3J(^{31}P,^{13}C)$[15,16] (for a full listing of NMR data, see Experimental Section).

As far as we are aware, the 1,3,5-triphosphabicyclo[3.1.0]hexane **15** and -hexene **16**, as well as the 1,3,5-triphosphacyclohexa-1,4-diene **17**, are the first examples of such phosphorus heterocycles to be reported. Their synthesis from the hafnium complexes **5** and **12** can be rationalized in terms of the hydrolysis of the two mesomeric forms **5c/12c** and **5d/12d**, which contain one P−M and one C−M σ-bond (see Scheme 2). In the presence of pure water, the

phosphorus heterocycle **16** adds a second equivalent of water to give compound **15**. In all these reactions, the hafnium part of the complexes **5** and **12** should be displaced as the corresponding hafnium dihydroxide, species that are known to be unstable.[17]

Scheme 2

In summary, we have determined the solid-state structures of the hafnium complexes **12** and **14** by X-ray analysis and have shown by extensive NMR studies and by hydrolysis of **5**, **12**, and **14** that all these hafnium complexes have the same structure in solution. By hydrolysis of **5** and **12** we have also been able to synthesize the new phosphorus heterocycles **15**, **16**, and **17**.

Experimental Section

General: All experiments were carried out under argon in anhydrous solvents. − MS: EI; Finnigan MAT 311 ADF. − ^{1}H- and ^{13}C-NMR: Bruker AC 200, AC 300, AMX 400, and DMX 600; chemical shifts were determined relative to solvent signals and converted to the TMS scale [$\delta(^1H)$ of C_6D_5H at 7.15; $\delta(^{13}C)$ of C_6D_6 at 128.0]. The ^{13}C multiplicities were confirmed by means of DEPT spectra. − ^{31}P-NMR: Bruker AC 200 (81.1 MHz) and AC 300 (121.5 MHz), external standard H_3PO_4. − Elemental analysis: Microanalytical laboratory, Dornis and Kolbe, Mülheim a.d. Ruhr. − Commercial chemicals: hexachloroethane, *tert*-butyl isocyanide (Aldrich); sodium sulfate decahydrate (Reininghaus). − (η^8-Cyclooctatetraene)(P≡C−*t*Bu)$_3$hafnium (**5**)[3] and trimethylphosphane[18] were prepared according to published procedures.

(2,4,6-Tri-*tert*-butyl-1,3,5-triphosphabicyclo[3.1.0]hexene-η^3,η^1-diyl)hafnium Dichloride (12): Hexachloroethane (230 mg, 0.97 mmol) was added to a suspension of the hafnium complex **5** (480 mg, 0.82 mmol) in pentane (10 mL). The reaction mixture was stirred at room temperature for 12 h, in the course of which the colour changed from green to red and a brown precipitate was formed. After filtration through Celite and washing the solid with pentane (2 × 3 mL), the filtrate was concentrated to a volume of ca. 4 mL and cooled to −78°C. Red-violet crystals of complex **12** (210 mg, 44%) precipitated, which were isolated by filtration. Triphosphabenzene **6** (40 mg, 16%) could be isolated from the filtrate by column chromatography. Complex **12**: m.p. 172°C (dec.). − ^{1}H and ^{31}P NMR: See Table 1. − ^{13}C{^{1}H} NMR (100.6 MHz, [D$_8$]THF, −30°C): δ = 176.3 (A_2X spin system, A = ^{31}P, X = ^{13}C, t, $^1J_{C,P}$ = 67.7 Hz, C-6), 169.1 (AA′MX spin system, AA′ = ^{31}P-1 and ^{31}P-5, M = ^{31}P-3, X = ^{13}C-2,4, $J_{M,X}$ = 73.4, $J_{A,A}$ = 73.7, $|J_{A,X}$ = 70|, $J_{A',X}$ = 13 Hz , values checked by simulation, C-2 and C-4), 42.8 [t, $^2J_{C,P}$ = 7.6 Hz, *C*(CH$_3$)$_3$ at C-6], 33.2 [C(*C*H$_3$)$_3$ at C-6], 41.8 [*C*(CH$_3$)$_3$ at C-2 and C-4], 36.4 [C(*C*H$_3$)$_3$ at C-2 and C-4]. − MS (EI, 70 eV); *m/z* (%): 550 (28) [M$^+$], 450 (17) [M − PC*t*Bu$^+$], 300 (12) [(PC*t*Bu)$_3^+$], 169 (31) [PC$_2$(*t*Bu)$_2^+$], 41 (100). − $C_{15}H_{27}P_3Cl_2Hf$ (549.7): calcd. C 32.78, H 4.95; found C 32.75, H 4.90.

***tert*-Butyl Isocyanide Adduct 13 of Complex 12:** *tert*-Butyl isocyanide (0.8 g, 9.6 mmol) was added to a cooled (−78°C) solution of the hafnium complex **12** (300 mg, 0.55 mmol) in pentane (5 mL) and the reaction mixture was stirred for 12 h. The solvent and excess isocyanide were then evaporated off at 0.5 bar and the residue was taken up in pentane (2 mL). At −78°C, dark-red microcrystals separated, which were collected by filtration and dried at −78°C and 0.5 bar to yield 150 mg (44%) of the isocyanide adduct **13**. Complex **13** was found to be unstable at room temperature and thus had to be stored at −78°C. − ^{1}H NMR (200.1 MHz, [D$_8$]toluene, 30°C): δ = 1.52 (s, 27 H, *t*Bu at C2, C4 and C6), 0.77 (s, *t*Bu at N). − ^{13}C{^{1}H} NMR (50.1 MHz, [D$_8$]toluene, 30°C): δ = 188.5−187.0 (br. m, C-2, C-4, C-6), 150.1 (m, C=N), 54.6 [br. s, *C*(CH$_3$) at N], 33.9 [dt, $J_{C,P}$ = 10.7 and 9.8 Hz, *C*(CH$_3$) at C-2, C-4 and C-6], 33.3 [t, $J_{C,P}$ = 7.9 Hz, C(*C*CH$_3$) at C-6], 30.3 [d, $J_{C,P}$ = 7.8 Hz, C(*C*H$_3$) at C-2 and C-4], 27.6 [s, C(*C*H$_3$) at N]. − ^{31}P NMR (81.1 MHz, [D$_8$]toluene, 30°C): δ = 315.1 (t, $J_{P,P}$ = 5.0 Hz, P-3), −24.1 (d, $J_{P,P}$ = 5.0 Hz, P-1 and P-5).

Trimethylphosphane Adduct 14 of Complex 12: Trimethylphosphane (0.1 mL, 0.8 g, 10.5 mmol) was added to a solution of the hafnium complex **12** (300 mg, 0.55 mmol) in pentane (5 mL), cooled to −78°C. After stirring for 2 h, all volatile components were removed at 0°C and 0.5 mbar and the red oily residue was redissolved in pentane (2 mL) at −10°C. At −78°C dark-red crystals of complex **14** (250 mg, 73%) suitable for X-ray analysis were obtained. The product was isolated by filtration and dried at 0.5 mbar. − ^{1}H and ^{31}P NMR: See Table 1. − ^{13}C{^{1}H} NMR (100.6 MHz, [D$_8$]THF, −30°C): δ = 168.1 (m, C-6), 165.1 (m, C-2 and C-4), 40.6 [t, $^2J_{P1,C}$ = $^2J_{P5,C}$ = 7.9 Hz, *C*(CH$_3$) at C-6], 40.1 [td, $^2J_{P3,C}$ = 16.6 Hz, $^2J_{P1,C}$ = $^3J_{P5,2}$ = 10.4 Hz, *C*(CH$_3$) at C-2 and C-4], 36.1 [s, C(*C*H$_3$) at C-2 and C-4], 32.4 [s, C(*C*H$_3$) at C-6], 13.0 [d, $^1J_{P,C}$ = 10.4 Hz, P(*C*H$_3$)$_3$].

2,4,6-Tri-*tert*-butyl-1,3,5-triphospha-3-oxobicyclo[3.1.0]hexane (15) from Hydrolysis of Hafnium Complex 5: To a green solution of complex **5** (300 mg, 0.51 mmol) in diethyl ether (5 mL) at 0°C was added water (1 mL, 5.56 mmol). After stirring for 10 h at room temperature, a brownish solid precipitated from the yellow solution. The precipitate was removed by filtration through Celite and all volatiles were distilled off from the filtrate at 20°C and 0.5 mbar.

Chromatographic separation of the solid residue on silica gel gave triphosphabenzene **6** (15 mg, 10%) as a first fraction on eluting with pentane, followed by compound **15** (90 mg, 55%) on eluting with THF. The latter was isolated by concentrating the THF fraction to 5 mL, adding pentane (5 mL), and cooling to −78°C, whereupon **15** precipitated as colourless needles; m.p. 198°C. − ^{1}H NMR ([D$_8$]THF, 400 MHz, 30°C): δ = 6.10 (dtt, $^1J_{P3,H}$ = 454.6 Hz, $^3J_{P1,H}$ = $^3J_{P5,H}$ = 2.0 Hz, $^3J_{2\,H,H}$ = $^3J_{4\,H,H}$ = 9.2 Hz, 3-H), 1.94 [t(d), $^2J_{P1,H}$ = $^2J_{P5,H}$ = 4.1 Hz, $^4J_{P3,H}$ ≈ 1.4 Hz, 6-H], 1.73 (dd/pseudo t, $^2J_{P3,H}$ = 16.0 Hz, $^2J_{P1,H}$ + $^3J_{P5,H}$ = 6.8 Hz, $^3J_{3\,H,H}$ = 9.2 Hz, 2-H and 4-H), 1.30 [s, 18 H, C(CH$_3$)$_3$ at C-2 and C-4], 0.94 [t, 9 H, $^4J_{P1,H}$ = $^4J_{P5,H}$ < 1 Hz, C(CH$_3$)$_3$ at C-6]. − ^{13}C NMR ([D$_8$]THF, 100.1 MHz, 30°C): δ = 51.1 [dtd(A$_2$MX), $^1J_{C,H}$ = 155, $^1J_{P1,C}$ = $^1J_{P5,C}$ = 47.3, $^3J_{P3,C}$ = 6.5 Hz, C-6], 47.3 [tdd(AA′MX), $^1J_{C,H}$ = 140, $^1J_{P3,H}$ = 54.9, $J_{P1,C}$ + $J_{P5,C}$ = 52.0 Hz, C-2 + C-4], 34.1 [dt(AA′MX), $J_{P1,C}$ + $J_{P5,C}$ = 17.6, $^2J_{P3,C}$ = 0.9 Hz, *C*(CH$_3$)$_3$ at C-2 and C-4], 33.5 [dt(A$_2$MX), $^2J_{P1,C}$ = $^2J_{P5,C}$ = 11.8, $^4J_{P3,C}$ = 6.0 Hz, *C*(CH$_3$)$_3$ at C-6], 30.3 [tq(A$_2$MX), $^1J_{C,H}$ = 126, $^3J_{P1,C}$ = $^3J_{P5,C}$ = 5.9 Hz, C(*C*H$_3$)$_3$ at C-6], 30.1 [dtt(AA′MX), $^1J_{C,H}$ = 126, $J_{P1,C}$ + $J_{P5,C}$ = 10.7, $^3J_{P3,C}$ = 5.6 Hz, C(*C*H$_3$)$_3$ at C-2 and C-4]. − ^{31}P NMR ([D$_8$]THF, 30°C, 81.1 MHz): δ = 39.4 (s, P-3), −222.8 (s, P-1 and P-5). − IR (KBr): $\tilde{\nu}$ = 2961 (*t*Bu), 2320 (P−H), 1393, 1363 (*t*Bu), 1138 cm^{-1} (P=O). − MS (EI, 70 eV): *m/z* (%): 320 (100) [M$^+$], 305 (47) [M − CH$_3^+$], 263 (72) [(M − *t*Bu$^+$], 251 (60), 57 (50) [*t*Bu$^+$]. − $C_{15}H_{31}OP_3$ (320.3): calcd. C 56.24, H 9.75; found C 56.18, H 9.68.

2,4,6-Tri-*tert*-butyl-1,3,5-triphosphabicyclo[3.1.0]hex-2-ene (16) and 2,4,6-Tri-*tert*-butyl-1,3,5-triphosphacyclohexa-1,4-diene (17): (a) By Hydrolysis of Hafnium Complex 5 with Hydrated Silica Gel: Silica gel (63−100 μm, Merck AG, dried at 150°C for 12 h and then deactivated with 2% water) was added to a suspension of complex **5** (300 mg, 0.55 mmol) in pentane (10 mL). Immediately, a colour change from green to yellow was observed. After stirring for 15 min, the reaction mixture was extracted with pentane. The combined extracts were concentrated to one-third of the original volume and crystallization at −78°C yielded **17** (60 mg, 40%) as a pale-yellow powder. Column chromatography (glass column, ∅ = 2 cm, 15 cm silica gel, argon pressure) of the mother liquor and evaporation of pentane from the appropriate fraction furnished **16** (67 mg, 43%) as a pale-yellow powder.

(b) By Hydrolysis of Hafnium Complex 12 with $Na_2SO_4 \cdot 10\ H_2O$: $Na_2SO_4 \cdot 10\ H_2O$ (156 mg, 1.10 mmol) was added to a solution of hafnium complex **12** (300 mg, 0.55 mmol) in diethyl ether (5 mL). After stirring the mixture for 12 h at room temperature, its colour changed from red-violet to yellow and a brownish precipitate was formed. Pentane (5 mL) was then added to complete the precipitation. The reaction mixture was filtered through Celite and compounds **16** and **17** were separated from the filtrate as described above. **16** (77 mg, 46%) and **17** (72 mg, 44%) were obtained as pale-yellow powders.

Compound 16: ^{1}H NMR (C$_6$D$_6$, 300.1 MHz, 30°C): δ = 2.92 (dd, $^2J_{P,H}$ = 4.2 and 1.1 Hz, 4-H), 2.57 (dd, ^2J = 9.3, 6.9 Hz, 6-H), 1.51 [d, $^4J_{P3,H}$ = 1.8 Hz, C(CH$_3$)$_3$ at C-2], 1.15 [s, C(CH$_3$)$_3$ at C-4], 0.95 [t, $^4J_{P,H}$ = 0.8 Hz, C(CH$_3$)$_3$ at C-6]. − ^{13}C{^{1}H} NMR (C$_6$D$_6$, 75.5 MHz, 30°C): δ = 230.8 (ddd, $^1J_{P3,C}$ = 74.5, $^1J_{P1,C}$ = 58.8, $^2J_{P5,C}$ = 2.5 Hz, C-2), 70.6 (t, $^1J_{P,C}$ = 53.0 Hz, C-6), 61.4 (ddd, $^1J_{P,C}$ = 48.5, 44.1, $^2J_{P,C}$ = 6.4 Hz, C-4), 43.1 [dd, $^2J_{P,C}$ = 20, 18 Hz, *C*(CH$_3$)$_3$ at C-2], 34.2 [dd, $^2J_{P,C}$ = 15.2, $^4J_{P,C}$ = 2.0 Hz, *C*(CH$_3$)$_3$ at C-6], 36.0 [dd, $J_{P,C}$ = 15.3, 2.8 Hz, *C*(CH$_3$)$_3$ at C-4], 33.6 [dd, $^3J_{P,C}$ = 14.6, 9.0 Hz, C(*C*H$_3$)$_3$ at C-2], 30.6 [t, $^3J_{P,C}$ = 5.5 Hz, C(*C*H$_3$)$_3$ at C-6], 30.0 [dd, $^3J_{P,C}$ = 10.5, 8.5 Hz, C(*C*H$_3$)$_3$ at C-4]. − ^{31}P NMR (C$_6$D$_6$, 121.5 MHz, 30°C): δ = 311.8 (dd, $^2J_{P1,P3}$ = 36.5, $^2J_{P3,P5}$ = 13.0 Hz, P-3), −117.4 (dd, $^1J_{P1,P5}$ = 167.2, $^2J_{P1,P3}$ = 36.5 Hz, P-1), −128.6 (dd, $^1J_{P1,P5}$ = 167.2, $^2J_{P3,P5}$ = 13.0 Hz, P-5). − MS (EI, 70 eV): *m/z* (%): 302 (96) [M$^+$], 245 (12) [M − *t*Bu$^+$], 231 (14), 175 (100) [M − CH*t*Bu$^+$], 162 (29), 131 (53) [P$_2$C*t*Bu$^+$], 113 (21), 100 (19) [PC*t*Bu$^+$], 69 (29), 57 (38) [*t*Bu$^+$]. − $C_{15}H_{29}P_3$ (302.3): calcd. C 59.60, H 9.67; found C 59.87, H 9.61.

Compound 17: ^{1}H NMR (C$_6$D$_6$, 400.1 MHz, 30°C): δ = 6.40 (dt, $^1J_{P,H}$ = 227.7, $^3J_{P,H}$ = 6.4 Hz, 3-H), 1.98 (dt, $^2J_{P,C}$ = 9.6 Hz, $^4J_{P,C}$ = 5.2 Hz, 6-H), 1.41 [s, C(CH$_3$)$_3$ at C-6], 1.35 [br. s, C(CH$_3$)$_3$ at C-2 and C-4]; structure established by NOESY. − ^{13}C{^{1}H} NMR (C$_6$D$_6$, 100.6 MHz, 30°C): δ = 213.5 (AA′MX spin system, $^1J_{P,C}$ = 40.8 and 50.0 Hz, C-2 and C-4), 66.1 (dt, $^1J_{P,C}$ = 51.5, $^3J_{P,C}$ = 42.2 Hz, C-6), 43.2 [AA′MX spin system, *J* not resolved, *C*(CH$_3$)$_3$ at C-2 and C-4], 34.2 [dt, $^2J_{P,C}$ = 15.3, $^4J_{P,C}$ = 2.5 Hz, *C*(CH$_3$)$_3$ at C-6], 32.7 [AA′MX spin system, $^3J_{P,C}$ = 14.1 and 3.5 Hz, $^5J_{P,C}$ = 0.8 Hz, C(*C*H$_3$)$_3$ at C-2 and C-4], 31.2 [td, $^3J_{P,C}$ = 9.5 Hz, $^5J_{P,C}$ = 0.9 Hz, C(*C*H$_3$)$_3$ at C-6]. − ^{31}P{^{1}H} NMR (C$_6$D$_6$, 162.0 and 243.0 MHz, 30°C): δ = 241.3 (t, $^2J_{P,P}$ = 5.5 Hz, P-1 and P-5), −249 (t, P-3). − IR (KBr): $\tilde{\nu}$ = 2957, 2898 (*t*Bu), 2329 cm^{-1} (P−H). − MS (EI, 70 eV): *m/z* (%): 302 (22) [M$^+$], 211 (11), 231 (5), 175 (23), 155 (21), 131 (22), 113 (7), 99 (100), 69 (33), 57 (84). − $C_{15}H_{29}P_3$ (302.3): calcd. C 59.60, H 9.67; found C 59.55, H 9.63.

X-ray Crystal Structure Analysis of 12:[19] Siemens SMART diffractometer (Mo-K_α radiation), T = 100 K; structure solution by heavy atom method (SHELXS-86[20]) and refinement by SHELXL-93;[21] monoclinic, space group *C*2/*c*; lattice constants a = 9.943(2), b = 18.315(4), c = 22.456(5) Å; β = 90.66(3)°, V = 4089.1(14) Å^3, Z = 8, μ(Mo-K_α) = 5.591 mm^{-1}, crystal size 0.46 × 0.39 × 0.21 mm, θ_{max} = 33.16°; 7591 independent reflections (R_{int} = 0.0680); 22971 measured reflections, of which 5300 were considered observed with $I > 2\sigma(I)$; empirical absorption correction; min./max. transmission 0.168/0.318; max./min. residual electronic density −5.883 and −3.151 e/Å^3 (less then 1 Å from Hf). 190 parameters [C, Cl, Hf, and P anisotropic; the positions of the H atoms were calculated for idealized distances (d_{C-H} = 0.980 Å)]; R_1 = 0.0590; wR^2 = 0.1340.

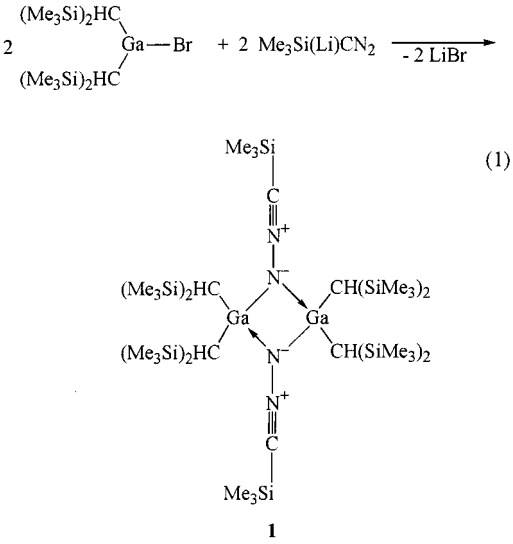
Diazomethane Derivatives Bearing Dialkylaluminium or Dialkylgallium Substituents – The Isomeric Diazomethane and Nitrile Imine Structures Realized by the Different Coordination Behavior of Aluminium and Gallium

Werner Uhl,*[a] Frank Hannemann,[a] Wolfgang Saak,[a] and Rudolf Wartchow[b]

Keywords: Aluminium / Gallium / Diazo compounds / Dimerization / Coordination modes

Lithium trimethylsilyldiazomethanide $Li(SiMe_3)CN_2$ reacted with the dialkylaluminium or -gallium halides R_2AlCl and R_2GaBr [$R = CH(SiMe_3)_2$] by the elimination of lithium halide and the formation of the corresponding aluminium or gallium diazo compounds. As shown by a crystal structure determination, the gallium derivative **1** adopts the nitrile imine structure, in which the gallium atom is coordinated by the terminal nitrogen atom of the diazo group. The N–N–C–Si moiety is almost ideally linear with N–N and C–N bond lengths of 125.5 and 115.9 pm on average. In contrast, the diazomethane structure was formed with dialkylaluminium chloride, and the aluminium atom in **2** is attached to the carbon atom of diazomethane. The almost linear N–N–C group (174.1°) has N–N and N–C distances of 120.0 and 126.4 pm, respectively, inverse to that of the gallium derivative. The bonding situations can best be described by the resonance structures $R–C{\equiv}N^+–N^––GaR_2$ for **1** and $R_2Al–(R)C{=}N^+{=}N^–$ for **2**. The nitrile imine isomer of the aluminium compound could be detected by NMR spectroscopy as a by-product. Both compounds gave dimers in the solid state, a Ga_2N_2 four-membered heterocycle was formed of **1**, while an eight-membered $Al_2C_2N_4$ heterocycle resulted with **2**.

Diazomethane and its derivatives form a group of fascinating compounds due to their bonding situation and their singular chemical reactivity.[1] In many cases, they are used as a facile source of carbenes and for the synthesis of carbon−nitrogen heterocycles. As shown for the first time in 1933,[2] the methylene hydrogen atoms of diazomethane can be replaced by alkali metals, and those metalated diazomethane derivatives are very useful reagents for the syntheses of numerous diazomethane compounds containing main-group or transition-metal elements.[3−8] The lithiated compounds $Li–(H)CN_2$ and $Li–(Me_3Si)CN_2$ were theoretically investigated by the group of Boche.[8] By intramolecular rearrangements four isomeric structures are possible: $Li–(H)C{=}N^+{=}N^–$ (diazomethane), $C^–{\equiv}N^+–N(Li)H$ (*N*-isocyanoamine), $Li–C{\equiv}N^+–N^––H$ and $H–C{\equiv}N^+–N^––Li$ (nitrile imine), of which the second one was found to give the global minimum. The diazomethane formulation was intermediate, and both nitrile imine isomers were highest in energy. The energies of dimers were also calculated, and some aspects of their structures will be discussed below. Lithiated trimethylsilyldiazomethane was observed as a part of a complicated crystal structure by the same group.[8] Remarkably, it adopted the nitrile imine structure with the silyl group bound to the carbon atom and the lithium atom bound to the terminal nitrogen atom. The influence of the silyl group on the energy of the isomers could also be verified by theoretical calculations.[8] Previously, only one diazomethane compound of an element of the third main group was reported in literature, which has a tetracoordinated boron atom bound to the carbon atom of the CN_2 group.[6] The nitrile imine structure was found in two aluminium derivatives,[9] which have a phosphanyl group attached to the carbon atom and the terminal nitrogen atom coordinated by two alkylaluminium groups. We became interested in aluminium, gallium, or indium diazomethane derivatives for two reasons: (i) The nitrile imine molecular center is isosteric to an azido group. We recently succeeded in isolating a dialkylaluminium azide sterically highly shielded by bulky substituents, which formed a trimer with the unexpected head-to-tail coordination of the azido groups and a twelve-membered Al_3N_9 heterocycle.[10] Thus, we supposed that an unusual coordination behavior may be observed with the diazomethane derivatives, too. (ii) We hoped to use the reactivity of the diazomethane derivatives for the synthesis of novel organoaluminium or -gallium compounds. For instance, silylated diazomethane compounds inserted into the Al−Al bond of tetrakis[bis(trimethylsilyl)methyl]dialan(4), while a fragmentation reaction was observed with the corresponding gallium derivative.[11]



Reaction of Lithium Trimethylsilylmethyldiazomethanide with R_2AlCl and R_2GaBr [$R = CH(SiMe_3)_2$]

The reactive intermediate $Li–(Me_3Si)CN_2$ was obtained according to a literature procedure[3] by treating trimethylsilyldiazomethane with *n*-butyllithium at −100°C. The alkylgallium and -aluminium halides were added at this temperature, and the reaction mixtures were warmed slowly

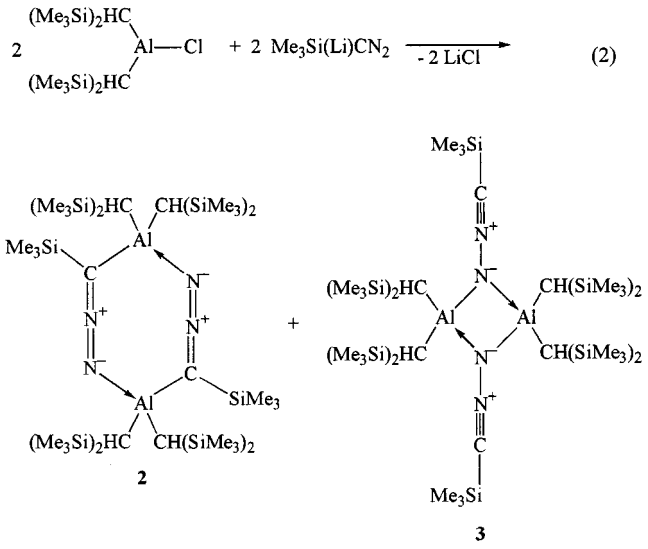
to room temperature. Dialkylgallium bromide gave a mixture of compounds, from which the diazomethane product **1** was isolated in a yield of 38% (Equation 1). Compound **1** was identified by elemental analysis and a crystal structure determination (see below) as the nitrile imine isomer of diazomethane, in which the alkylgallium group is attached to the terminal nitrogen atom. The main component of the mother liquor was identified by NMR spectroscopy as the trialkylgallium derivative $Ga[CH(SiMe_3)_2]_3$,[12] which due to its high solubility in organic solvents could, however, not be isolated in a pure form. Three resonances were observed in the ^{1}H-NMR spectrum of **1**, which could be assigned to the methyl protons of the bis(trimethylsilyl)methyl groups, the protons of the $SiMe_3$ groups of diazomethane and the methine protons. The latter have a chemical shift of $\delta = -0.22$, which is just intermediate between the characteristic ranges of bis(trimethylsilyl)methyl compounds with coordination numbers of three and four at the central gallium atoms.[13–15] The IR spectrum showed an intensive absorption at 2120 cm^{-1}, which was attributed to the stretching vibration of the C–N group with a high π-bond order.[16] The molar mass of **1** cryoscopically determined in benzene is intermediate between those calculated of the monomer and the dimer, thus an equilibrium may exist between the monomeric and dimeric formula units, which is shifted in dilute solutions to the monomer.



(1)

1

The reaction with dialkylaluminium chloride was different from that of the gallium analogue. Two compounds were formed. Only one could be isolated by recrystallization in a pure form (**2**): The second one (**3**) could be enriched by repeated recrystallization to a maximum concentration of only 70% besides **2** (Equation 2). The impure compound **3** crystallizes as colorless needles similar to **1** and has the resonances of the trimethylsilyl group attached to the carbon atom of diazomethane in the ^{1}H- and ^{13}C-NMR spectra at $\delta = 0.11$ and -0.8, respectively, which is similar to the chemical shifts observed for the corresponding group in **1**. In addition, two singlets are observed in each spectrum for the methine and methyl protons of the bis(trimethylsilyl)methyl group. Due to these strong similarities, we assume that compound **3** is the aluminium analogue of the gallium derivative **1** with the nitrile imine structure. Compound **2** was characterized by a crystal structure determination and has another constitution derived from the diazomethane isomer with the aluminium atom bound to the carbon atom of the CN_2 group. The compound is a dimer in the solid state (see below) and in solution, as shown by the cryoscopic determination of its molar mass in benzene. Due to the coordination of the central aluminium atom by two $CH(SiMe_3)_2$ groups and one carbon and one nitrogen atom of the diazomethane fragment, the trimethylsilyl groups become diastereotopic and, in contrast to **1** and **3**, give two resonances in the ^{1}H- and ^{13}C-NMR spectra. The protons of the N_2CSiMe_3 group shows a resonance at $\delta = 0.32$. It is shifted to lower field than the corresponding signals of **1** and **3**, which are part of the linear $Me_3Si-C\equiv N^+-N^-$ moieties. In the IR spectrum of **2**, three absorptions are observed between 2135 and 2220 cm^{-1}, which can be assigned to the stretching vibrations of both C=N=N groups of the heterocycle.[16] Remarkably, the ratio between both aluminium compounds in the mixture remains constant in solution, and no rearrangement by the 1,3 shift of the dialkylaluminium group to form a thermodynamically more favored product was observed even in hot benzene. Thus, the formation of the mixture may not be caused by the migration of alkylaluminium groups in any stage of the reaction, but may reflect the distribution of the lithiated diazomethane species in their complicated equilibrium in solution. With gallium, only the nitrile imine isomer was isolated in a low yield of 38%, and we observed the formation of the corresponding trialkylgallium derivative besides some further minor by-products. A diazomethane isomer similar to compound **2** could not be detected. This isomer may be formed as an intermediate, but possibly it is not stabilized by the formation of a strong dimer due to the lower Lewis acidity of gallium than of aluminium and decomposes by the release of nitrogen, for instance. A following redistribution reaction may yield GaR_3 as the main product. The lower stability of the gallium compounds due to the formation of only weak dimers is in agreement with the partial dissociation of **1** in benzene and its low decomposition point as discussed below.

Both products **1** and **2** were heated and irradiated with UV light, in order to investigate their stability and to prove their ability to lose nitrogen and to form carbene intermediates. Solutions in benzene can be stored at 60°C for many hours without any detectable secondary reaction. The crystals of compound **1** completely decomposed at temperatures as low as 117°C by the formation of a gaseous product, while the aluminium compound **2** was more stable and did not decompose below 200°C. But in each case the thermal decomposition yielded mixtures of many unknown products, from which none could be isolated in a pure form. A similar result was obtained upon irradiation of solutions with UV light, which led to the formation of oily residues with many unknown products.

Crystal Structures of 1 and 2

The molecular structure of compound **1** is depicted in Figure 1. The ligand derived from the starting diazomethane compound adopts the almost linear nitrile imine form, and with their terminal nitrogen atoms two of these ligands bridge two dialkylgallium fragments to yield a dimer with a Ga_2N_2 heterocycle. The geminal coordination of the terminal nitrogen atoms by two gallium atoms is similar to the situation in trimeric diisobutylaluminium nitrile imide[9] or to the structures of dialkylaluminium and -gallium azides,[17] which were derived from their IR-spectroscopic characterization. Further examples of a geminal bridging by azido groups could be verified by crystal structure determinations.[17] A different coordination was, however, found for the sterically highly shielded trimer of $[(Me_3Si)_2CH]_2AlN_3$, for which a 1,3 coordination of the azido group by the formation of a twelve-membered heterocycle was observed.[10] This unusual structure may be caused by the electrostatic repulsion between the positively charged aluminium atoms and a steric interaction between the bulky substituents. The electrostatic repulsion should be lower in the case of the more electronegative gallium. The formation of dimers with Al_2N_2 or Ga_2N_2 heterocycles comparable to compound **1** has not been observed before for this type of ambident ligands.

The angles N−N−C and N−C−Si in both independent molecules of **1** are on average 178.7° and 176.5°, respectively. The C−Si bonds to the terminal trimethylsilyl group of the ligand (184.5 pm on average) are not shorter than the expected value. The C−N bond lengths (115.9 pm) correspond to a normal C≡N triple bond[18], and the N−N bonds (125.5 pm on average) are a little longer than typical N=N double bonds,[19] which may indicate some π character of the bond or an electrostatic contribution to the N−N bond strength. These results are in excellent agreement with the theoretically obtained parameters of 114.6 and 127.8 pm for hydrogen-substituted nitrile imine or 114.6 and 121.4 pm for dimeric LiN_2CH with a central Li_2N_2 heterocycle.[8] They impressively confirm the formulation of compound **1** as a nitrile imine derivative with a main contribution of the resonance structure $R-C\equiv N^+-N^--GaR_2$, which gives a dimer by the interaction of a lone electron pair at the negatively charged nitrogen atom with a second gallium atom. The nitrogen atoms in the heterocycles have almost ideally planar surroundings, and the sum of the bond angles are between 358.6° and 360.0°. The heterocycles are slightly folded, and the angles between the normals of the planes GaN_2 are 12.3 and 12.1°. Similar to other compounds with a four-membered heterocycle like $R_4Ga_2(\mu\text{-}OH)_2$[14] or a $R_4Ga_2(\mu\text{-}F)_2$,[15] the most acute angles in the ring are observed at the gallium atoms (76.3°); the inner ring angles at the nitrogen atoms are 102.9°.

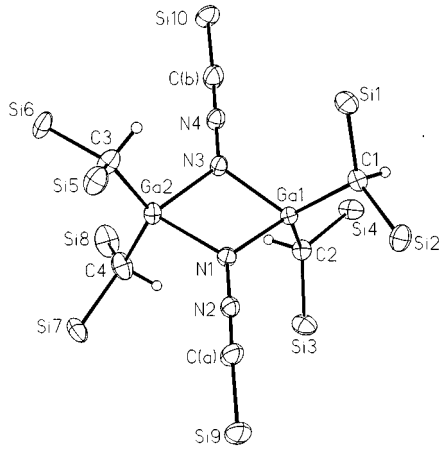


Figure 1. Molecular structure and numbering scheme of compound **1**; the thermal ellipsoids are drawn at the 40% probability level; methyl groups are omitted for clarity; only one of both independent molecules is shown; selected bond lengths [pm] and angles [°] (values of the second molecule in square brackets): Ga1−N1 200.7(3) [200.3(3)], Ga1−N3 202.5(3) [203.0(3)], Ga1−C1 200.5(4) [201.3(4)], Ga1−C2 202.2(4) [199.7(4)], Ga2−N1 202.9(3) [202.2(3)], Ga2−N3 202.6(3) [201.3(3)], Ga2−C3 200.0(4) [201.2(4)], Ga2−C4 201.9(4) [201.6(4)], N1−N2 126.0(4) [125.8(4)], N2−C(a) 115.3(5) [114.8(5)], N3−N4 124.2(4) [125.9(5)], N4−C(b) 117.2(5) [116.3(6)], C(a)−Si9 185.0(4) [185.7(4)], C(b)−Si10 183.5(4) [183.8(5)]; Ga1−N1−Ga2 103.0(1) [103.3(1)], Ga1−N3−Ga2 102.5(1) [102.7(1)], N1−Ga1−N3 76.7(1) [76.2(1)], N1−Ga2−N3 76.2(1) [76.2(1)], Ga1−N1−N2 128.5(3) [128.4(2)], Ga1−N3−N4 129.4(3) [126.4(3)], Ga2−N1−N2 127.1(2) [127.0(2)], Ga2−N3−N4 128.1(3) [129.5(3)], N1−N2−C(a) 178.4(4) [178.6(4)], N3−N4−C(b) 179.5(4) [178.3(4)], N2−C(a)−Si9 176.9(4) [175.8(4)], N4−C(b)−Si10 174.9(4) [178.4(5)]

The nitrile imine structure has been observed before in the complicated lithium compound $(LiN_2CSiMe_3)_6[LiC_2N_3(SiMe_3)_2]_2(Et_2O)_7$[8] and in two aluminium compounds, $(R_2PCN_2AliBu_2)_3$ and $[R_2PCN_2(AlCltBu_2)_2]^-$ (R = NMe_2).[9] While the nitrile imine fragments of the aluminium compounds have structural parameters similar to **1**, the C−N and N−N bonds are almost equally long in the lithium derivative. Furthermore, few nitrile imine derivatives of non-metals are known.[20] Their bond lengths and angles (C−N 117.2 pm and N−N 125.6 pm on average) resemble those observed for compound **1**. But their X−CN_2 groups with X the central atom of the terminal ligand deviate more significantly from linearity and show angles X−C−N between 137.3 and 165.1°.

Although compound **2** (Figure 2) also forms dimers in the solid state, a completely different structure is found, which is not derived from the nitrile imine, but from the diazomethane skeleton. The aluminium atom is bound to the diazomethane carbon atom, and an eight-membered centrosymmetric $Al_2C_2N_4$ heterocycle is formed by the interaction of the terminal diazomethane nitrogen atom with the aluminium atom of a second molecule. The Al−C bonds (Al−C3) within the ring have a length of 196.1(4) pm, which is in the range usually observed. The diazomethane group is almost linear with an angle C−N−N of 174.1°. The ratio of the C−N and N−N bond lengths in this group is inverted relative to those of **1**. The N−N bond is shorter than in **1** [120.0(6) pm] corresponding to an N=N double bond[19] and the C−N bond is longer [126.4(5) pm] indicating the formation of a C=N double bond.[18] Thus, the bonding in this part of the molecule is best described by the resonance structure $R_2Al-(R)C=N^+=N^-$. Usually, diazomethane[21] and its *C*-metalated, monomeric derivatives[5−7] show larger differences between their C−N and N−N bond lengths with longer C−N distances and very short N−N bonds, which are in the characteristic range of N≡N triple bonds. The exocyclic bond Si5−C3 [177.2(4) pm] is much shortened relative to the corresponding Si−C bond in compound **1** (184.5 pm), which may indicate some additional hyperconjugative interaction between the trimethylsilyl group and the carbon atom. The terminal nitrogen atom of the diazomethane group is coordinated to the aluminium atom of a second fragment with a long[22] Al−N distance of 208.4(6) pm. The angle Al−N1−N2 approaches linearity with 158.9°. All Al−C distances are, however, in the expected range. The eight-membered heterocycle is almost planar, and the largest deviation of an atom from the mean plane is observed for N2 with only 6.5 pm.

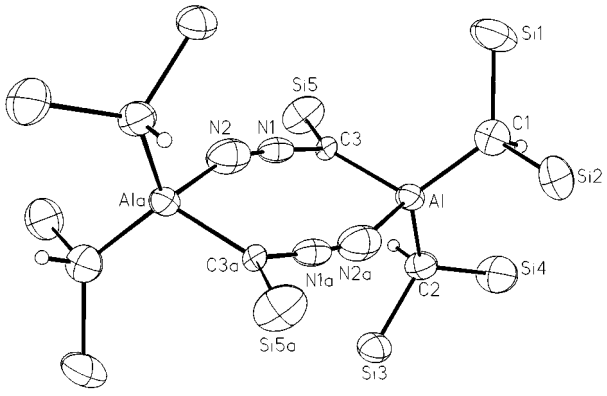

Figure 2. Molecular structure and numbering scheme of compound **2**; the thermal ellipsoids are drawn at the 40% probability level; methyl groups are omitted for clarity; selected bond lengths [pm] and angles [°]: Al−C3 196.1(4), Al−N2*a* 208.4(6), Al−C1 197.4(8) and 203.5(6) (disordered), Al−C2 198.8(5), C3−Si5 177.2(4), C3−N1 126.4(5), N1−N2 120.0(6); C3−Al−N2*a* 92.0(2), Al−C3−Si5 133.5(2), Al−C3−N1 113.7(3), N1−C3−Si5 112.2(3), C3−N1−N2 174.1(4), N1−N2−Al*a* 158.9(4); the atoms labeled *a* are generated by $-x + 2, -y, -z + 2$

Experimental Section

General: All procedures were carried out under purified argon in dried solvents (diisopropyl ether from Na/benzophenone, *n*-hexane and cyclopentane with $LiAlH_4$, pentafluorobenzene over molecular sieve). Bis[bis(trimethylsilyl)methyl]gallium bromide was synthesized as described in ref.[23] The corresponding aluminium chloride was obtained according to ref.[24] Commercially available solutions of trimethylsilyldiazomethane and *n*-butyllithium in *n*-hexane were used without further purification.

Synthesis of the Gallium Diazomethane Derivative 1: 0.9 mL (1.79 mmol) of a 2 M solution of trimethylsilyldiazomethane in hexane was diluted with 10 mL of hexane and cooled to −100°C. A cooled (−60°C) mixture of 1.12 mL (1.79 mmol) of a 1.6 M solution of *n*-butyllithium in hexane and 10 mL of the same solvent was added over a period of 10 min. After stirring for 15 min at −100°C, the lithium trimethylsilyldiazomethanide intermediate was treated with a cooled (−50 to −60°C) solution of 0.837 g (1.79 mmol) of $[(Me_3Si)_2CH]_2GaBr$ in 25 mL of hexane over a period of 20 min. The mixture was slowly warmed to room temperature and filtered. The solvent was removed in vacuo, and the residue was recrystallized twice from diisopropyl ether (20/−50°C). Yield 0.341 g (38%), colorless needles, which usually include small quantities of diisopropyl ether (less than 0.2 mol each monomeric formula unit of **1**), m.p. (argon, sealed capillary): 117°C (dec). − ^{1}H NMR (C_6D_6, 300 MHz): δ = 0.39 [36 H, $SiMe_3$ of $CH(SiMe_3)_2$], 0.15 (9 H, $SiMe_3$ of diazomethane), −0.22 (2 H, $GaCHSi_2$). − ^{13}C NMR (C_6D_6, 75.5 MHz): δ = 9.6 ($GaCSi_2$), 5.3 [$SiMe_3$ of $CH(SiMe_3)_2$], −0.3 ($SiMe_3$ of diazomethane); the carbon atom signal of the CN_2 group was not detected. − IR (CsBr, paraffin): $\tilde{\nu}$ = 2120 vs cm^{-1} νCN; 1464 vs, 1377 vs paraffin; 1335 vs, 1285 vs, 1248 vs δCH_3; 1169 vw, 1157 w, 1127 w, 1111 w diisopropyl ether; 1017 vs δCH; 963 m, 843 vs, 775 s, 758 s, 725 m ρCH_3(Si); 671 s ν_{as}SiC; 631 s ν_sSiC; 519 m, 478 vs, 405 m νGaC, νGaN; 347 vw δSiC. − $C_{18}H_{47}GaN_2Si_5$ (501.7 of the monomer): calcd. Ga 13.9, found Ga 14.1. − Mol. mass: 650 (cryoscopically in benzene).

Synthesis of the Aluminium Diazomethane Derivative 2: A cooled (−60 to −70°C) solution of *n*-butyllithium (2.07 mL, 1.6 M, 3.31 mmol) in hexane, diluted with 20 mL of same solvent, was added to a cooled (−100°C) mixture of 20 mL of hexane and 1.66 mL of a solution (2 M) of trimethylsilyldiazomethane in hexane (3.31 mmol) over a period of 40 min. The mixture was stirred at −100°C and treated with a cooled (−40 to −50°C) solution of 1.26 g (3.31 mmol) of $[(Me_3Si)_2CH]_2AlCl$ in 70 mL of hexane. The mixture was slowly warmed to room temperature and filtered. The solvent was removed in vacuo, and the residue was recrystallized from hexane (20/0°C) to isolate colorless crystals of compound **2**. Further fractions contain mixtures of **2** and the by-product **3**, which could not completely be separated even after repeated recrystallization. Yield: 0.32 g (21%). − M. p. (argon, sealed capillary): 200−204°C (dec.). − ^{1}H NMR (C_6D_6, 300 MHz): δ = 0.36 and 0.35 [each 36 H, $SiMe_3$ of $CH(SiMe_3)_2$], 0.32 (18 H, $SiMe_3$ of diazomethane), −0.90 (4 H, $AlCHSi_2$). − ^{13}C NMR (C_6D_6, 75.5 MHz): δ = 98.0 (C=N), 5.45 and 5.38 [$SiMe_3$ of $CH(SiMe_3)_2$], 3.0 ($AlCSi_2$), 0.7 ($SiMe_3$ of diazomethane). − IR (CsBr, paraffin): $\tilde{\nu}$ = 2220 m cm^{-1}, 2184 m, 2135 s νCNN; 1462 vs, 1377 vs paraffin; 1248 vs δCH_3; 1109 m, 1086 m; 1007 vs δCH; 959 w, 937 m, 843 vs, 775 s, 750 s, 727 s ρCH_3(Si); 671 s ν_{as}SiC; 638 w, 629 m, 613 w ν_sSiC; 505 s, 484 s, 455 s, 442 s νAlC, νAlN; 392 w, 382 w, 374 w, 361 w, 343 vw, 320 w δSiC. − $C_{36}H_{94}Al_2N_4Si_{10}$ (918.0): calcd. Al 5.9, found Al 5.9. − Mol. mass: 865 (cryoscopically in benzene).

[a]Programs: SHELXTL, SHELXL-93;[26] solutions by direct methods; full-matrix refinement with all independent structure factors. − [b]Numerical absorption correction. − [c]Near the solvent molecules.

NMR Characterization of 3: ^{1}H NMR (C_6D_6, 300 MHz, mixture with **2**): δ = 0.40 [72 H, $SiMe_3$ of $CH(SiMe_3)_2$], 0.11 ($SiMe_3$ of diazomethane), −0.73 (4 H, $AlCHSi_2$). − ^{13}C NMR (C_6D_6, 75.5 MHz): δ = 5.7 [$SiMe_3$ of $CH(SiMe_3)_2$], 4.9 ($AlCHSi_2$), −0.8 ($SiMe_3$ of diazomethane); the carbon atom signal of the diazomethane component could not be detected.

Crystal Structure Determinations: Single crystals of the compounds **1** and **2** were obtained by recrystallization from a mixture of pentafluorobenzene and cyclopentane (**1**) and from *n*-hexane (**2**). Crystal data and structure refinement parameters are given in Table 1.[27] The crystals of **1** include one molecule of pentafluorobenzene per formula unit. Two independent molecules were observed in the asymmetric unit, which have similar bond lengths and angles, but differ in the orientation of the bis(trimethylsilyl)methyl groups. Two trimethylsilyl groups (Si6 and Si7) showed a disorder, their atoms were isotropically refined by restrictions of bond lengths and angles with occupation factors of 0.75 and 0.25. The heterocycle of **2** is located on a crystallographic inversion center. One bis(trimethylsilyl)methyl group showed a disorder caused by different orientations of the methine C−H bond with a partial overlap of the atoms (Si1 and C11). All other atoms (C1, C12, C13) were isotropically refined with restrictions of bond lengths and angles using occupation factors of 0.52 and 0.48.

Solid-State and Solution Structural Properties of Copper(I) Compounds with Bidentate Phosphane Ligands

Peter Comba,*[a] Charis Katsichtis,[a] Bernd Nuber,[a] and Hans Pritzkow[a]

Keywords: Copper / Phosphane / Solution structure / P ligands / NMR spectroscopy / Coordination chemistry

The copper(I) compounds $[Cu(dppe)_2]X$ [X = BF_4^-, I^-; dppe = 1,2-bis(diphenylphosphanyl)ethane], $[Cu(dppp)_2]X$ [X = BF_4^-, I^-; dppp = 1,3-bis(diphenylphosphanyl)propane], $[Cu_2(dppe)_3I_2]$, and $[Cu_2(dppe)_2I_2]$ have been prepared and their structural properties in solution and in the solid state have been determined. ^1H-, ^{13}C-, and ^{31}P-NMR spectra in solution [variable temperature and anion (I^-) concentrations] and analyses of solids (mass spectra, elemental analyses, and CPMAS ^{31}P-NMR spectra) are interpreted with equilibria in solution that involve two mono- and two dinuclear species. The structures of $[Cu(dppe)_2]ClO_4$, $[Cu(dppp)_2]BF_4$, and $[Cu_2(dppe)_3I_2] \cdot 2\ CHCl_3$ have been analyzed by X-ray crystallography. In all three structures the copper(I) center adopts a distorted tetrahedral geometry.

Introduction

Detailed structural studies and the understanding of solution equilibria and dynamics of copper(I) compounds of bidentate phosphanes are of importance due to their potential application as potent antitumor agents[1] and as free radical scavengers in industrial processes.[2][3] There are a number of published studies of solution equilibria and structures that involve copper(I) compounds with phosphane ligands with variable copper(I)-to-ligand ratios.[4] Similar equilibria have also been observed for silver(I) compounds of bidentate phosphane ligands.[5] Mononuclear[4e,4g,4i–4j,4l,4m,4p] and dinuclear phosphanecopper(I) compounds[4a–4d,4k,4n,4o,4q] with coordinated and bridging halide anions and with phosphane ligands in various coordination modes have been isolated and characterized. There is spectroscopic evidence that some of the structurally characterized solids lead to complex equilibria in solution. However, so far there is only relatively little thorough information on structures and dynamics in solution.[1,4f] Here we report our results from studies on the structural properties of copper(I) compounds of dppe and dppp in the solid state and in solution.

Results and Discussion

Syntheses and Properties of the Solids

Reaction of $[Cu(CH_3CN)_4]BF_4$ with dppe in CH_2Cl_2 in a 1:2 ratio yields $[Cu(dppe)_2]BF_4$ (**1**). $[Cu(dppe)_2]I$ (**2**), $[Cu_2(dppe)_3I_2]$ (**3**), and $[Cu_2(dppe)_2I_2]$ (**4**) are prepared under similar conditions from CuI and dppe in CH_2Cl_2 or $CHCl_3$ (1:2, 2:3, and 1:1 Cu^I-to-ligand ratios). Reaction of dppp with $[Cu(CH_3CN)_4]BF_4$ and CuI in a 2:1 ratio in CH_2Cl_2 yields the compounds $[Cu(dppp)_2]BF_4$ (**5**) and $[Cu(dppp)_2]I$ (**6**), respectively. X-ray quality crystals of **1** (as the perchlorate salt), **3** (with two disordered chloroform molecules in the lattice), and **5** were obtained by vapor diffusion of diethyl ether into a solution of the complexes in CH_2Cl_2 or $CHCl_3$. The solids were studied by X-ray diffractometry, mass spectrometry, elemental analysis, CPMAS ^{31}P-NMR and IR spectroscopy. ^1H, ^{13}C, and ^{31}P NMR was used to establish the solution structures of the compounds.

ORTEP[6] plots of the experimentally determined structures of $[Cu(dppe)_2]ClO_4$ (**1**), $[Cu_2(dppe)_3I_2]$ (**3**), and $[Cu(dppp)_2]BF_4$ (**5**) are presented in Figure 1, and selected structural parameters are given in Table 1. As expected, the copper(I) center adopts a distorted tetrahedral geometry in these structures. The copper(I)–phosphane distances are in the range expected from other known structures[4b,4e,4g,4r] but there is a rather large variation in the individual distances, also within each complex. The degree of distortion from tetrahedral geometry depends primarily on the chelate ring size (dppe vs. dppp), with bite angles of the five-membered chelate rings of approximately 90° and bite angles of the six-membered rings of approximately 98°, and this leads to a flattening of the tetrahedral chromophores (deviation of the angles θ in Table 1 from 90°). All chelate rings are puckered, and the six-membered rings have the expected chair conformations.

There is no crystal structural analysis of $[Cu_2(dppe)_2I_2]$ (**4**). The structural assignment given in Scheme 1 is based on the reported structures of $[Cu_2(dppf)_2I_2]$[7] [dppf: 1,1′-bis(diphenylphosphanylferrocene)] and $[Cu_2(PhPH_2)_4I_2]$[8] ($PhPH_2$: phenylphosphane). The signals in the CPMAS ^{31}P-NMR spectra of the copper(I) complexes are rather broad, due to distortion from tetrahedral symmetry, unresolved coupling to the copper nuclei, quadrupole interactions involving the copper centers and the presence of two isotopes (^{63}Cu, ^{65}Cu);[9] nevertheless, the observed spectra (see Table 2 for chemical shift data) are qualitatively in good agree-

Equilibria in Solution

dppe Compounds

A broad signal at $\delta = 2.46$ is observed in the ^{1}H-NMR spectrum of $[Cu(dppe)_2]BF_4$ (**1**) in CD_2Cl_2. It is assigned to the methylene protons of the coordinated dppe ligands. The line broadening suggests unresolved ^{31}P-^{1}H coupling (relevant chemical shift data are assembled in Table 2). The ^{31}P-NMR spectrum of **1** in CD_2Cl_2 consists of a very broad signal centered at $\delta = +7.5$. It is assigned to the four phosphorus atoms coordinated to the copper(I) center. Lowering of the temperature leads to a significant decrease of $\Delta\nu_{1/2}$ (2500 Hz at 298 K vs. 250 Hz at 193 K) and a small upfield shift ($\Delta\delta \approx 0.9$) of this signal. This variation as a function of temperature is similar to that reported for $[Cu(dppey)_2]^+$[4p] [dppey = *cis*-bis(diphenylphosphanyl)-ethene] and consistent with the line shapes that have been calculated for fast quadrupolar relaxation[10] of a CuP_4 complex. No splitting is observed over the whole temperature range and the ^{31}P-NMR chemical shifts in the solid state and in solution are similar (Table 2). This suggests that only one species is present in solution, that is, the structure of **1** (see Figure 1) is conserved.

The high-field region of the ^{1}H-NMR spectrum of $[Cu(dppe)_2]I$ (**2**) is presented in Figure 2. There are three broad signals at $\delta = 2.56$, 2.46, and 2.26, the latter is split into two signals at $\delta = 2.27$ and 2.24. Three broad resonances at $\delta \approx +7.5$, -5, and -12.5 are observed in the ^{31}P-NMR spectrum of **2** (Figure 3a). The signals at $\delta = 2.46$ (^{1}H NMR) and +7.5 (^{31}P NMR) are due to the molecular cation observed in the solids of **1** and **2**, that is, to the structure that is conserved from the solid state; the other signals must be due to other species in solution, which is indicative of a chemical exchange process.

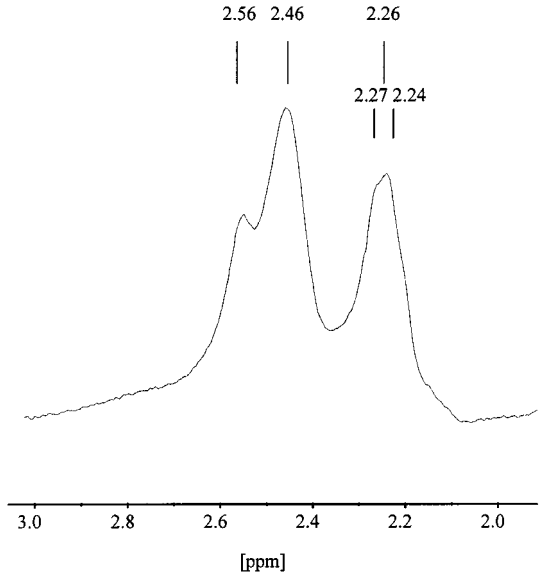

Figure 2. ^{1}H-NMR spectrum (200 MHz) of $[Cu(dppe)_2]I$ (**2**) (298 K; $CDCl_3$)

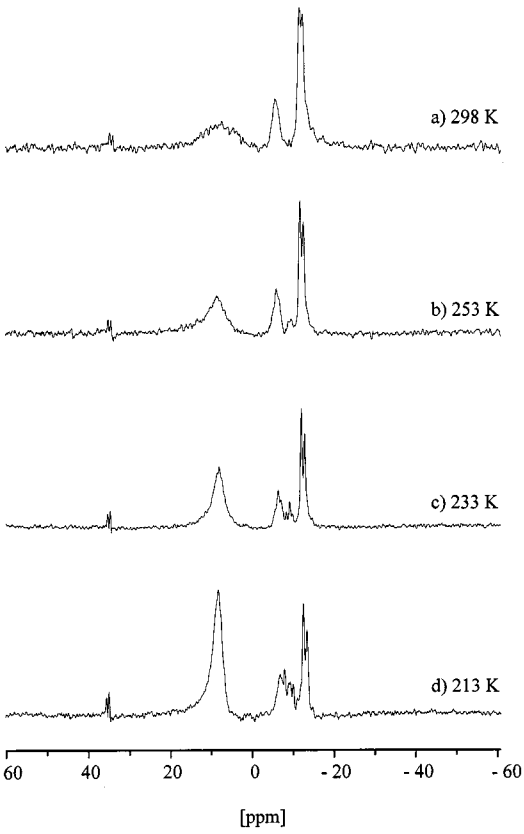
From variable-temperature ^{31}P-NMR spectra of **2** (Figure 3) it emerges that (i) there is a significant decrease in the line width and a small upfield shift of the signal at $\delta = +7.5$, assigned to $[Cu(dppe)_2]^+$ (see above); (ii) there is an additional multiplet at $\delta = -9.5$ which has maximum relative intensity around 240 K; (iii) at lower temperatures the relative intensity of the signal at $\delta = +7.5$ increases. The multiplet at $\delta = -9.5$ is tentatively assigned to a mononuclear intermediate with one bidentate and one monodentate dppe ligand, that is, a species that results from substitution of one phosphane donor by I^-. This is consistent with the chemical shift data (see below and Table 2), the concentration profile (relative intensities, see Figure 3 and above) and the NMR titration experiments (see below).

There is a broad signal at $\delta = 2.56$ in the ^{1}H-NMR spectrum of **4** (see Table 2). This is assigned to the methylene protons of the bidentate dppe ligands. A broad resonance at approximately $\delta = -12.5$ (close to that of the metal-free ligand) is observed in the corresponding ^{31}P-NMR spectrum. A similar observation was made in NMR studies of $[Cu_2(dppf)_2I_2]$, which was characterized by an X-ray crystal structure.[7] Addition of metal-free dppe to a solution of **4** in $CDCl_3$ leads to additional signals at $\delta = 2.27$ and -5 in the ^{1}H- and ^{31}P-NMR spectra, respectively (Figure 4). These new signals are tentatively assigned to a species with



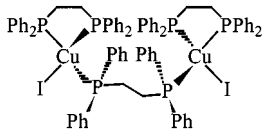


Figure 3. Temperature-dependent ^{31}P-NMR spectra (81 MHz) of $[Cu(dppe)_2]I$ (**2**) ($CDCl_3$; 85% H_3PO_4)

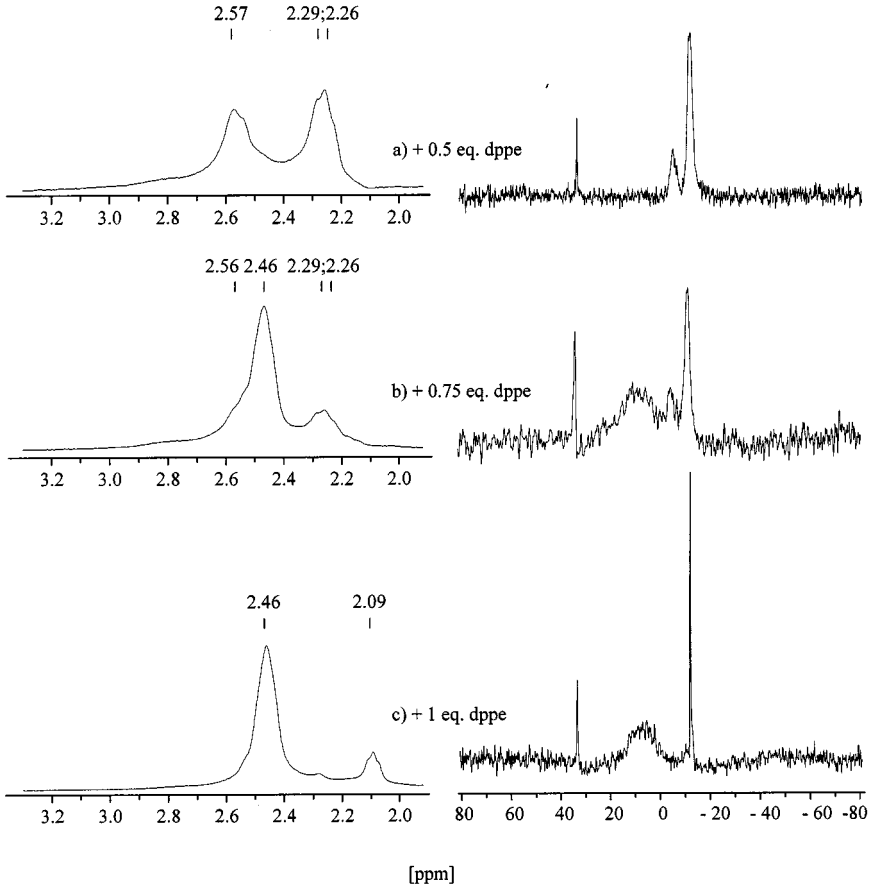
two chelated and one bridging phosphane ligand (Scheme 2). Further addition of dppe leads to decreasing intensity of the signal at $\delta = 2.56$ (^{1}H NMR), a sharpening of the signal at $\delta = -12.5$ (^{31}P NMR) and two additional signals at $\delta = 2.46$ (^{1}H NMR) and $\delta = +7.5$ (^{31}P NMR). That is, addition of dppe to $[Cu_2(dppe)_2I_2]$ produces $[Cu(dppe)_2]^+$ via $[Cu_2(dppe)_3I_2]$.

Scheme 2. Solution structure of $[Cu_2(dppe)_3I_2]$ based on ^{1}H- and ^{31}P-NMR spectroscopy

In a similar experiment ^{1}H- and ^{31}P-NMR spectra of $[Cu_2(dppe)_3I_2]$ (**3**) were measured in dependence of the concentration of added dppe. The two signals in the ^{1}H-NMR spectrum of **3** at $\delta = 2.46$ and 2.27 are assigned to the complexes $[Cu(dppe)_2]I$ and $[Cu_2(dppe)_3I_2]$, respectively. In the ^{31}P-NMR spectra there are signals at $\delta = +7.5$ and -5.0, respectively. Addition of excess dppe results in the disappearance of the resonances at $\delta = 2.27$ (^{1}H NMR) and -5.0 (^{31}P NMR). That is, as expected, the equilibrium is shifted towards $[Cu(dppe)_2]^+$. Hence, the signals at $\delta =$



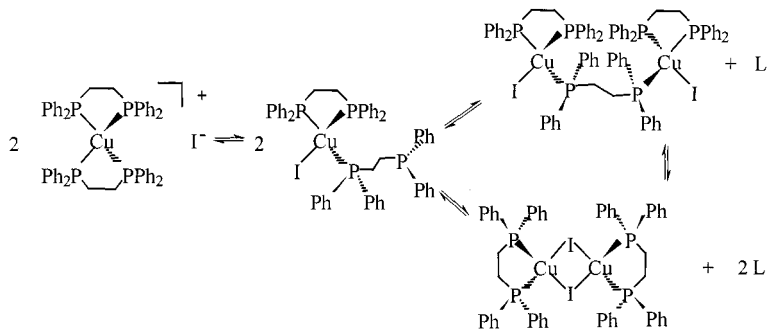


Figure 4. ^{1}H- and ^{31}P-NMR spectra (200 MHz, 81 MHz) of $[Cu_2(dppe)_2I_2]$ (**4**) with different concentrations of added ligand [$CDCl_3$; 298 K; a small amount of impurity at $\delta(^{31}P) \approx 33$ is due to phosphane oxide]

2.27 (^{1}H NMR) and −5.0 (^{31}P NMR) are assigned to the same compound, that is, to $[Cu_2(dppe)_3I_2]$.

The observations from temperature-dependent and ligand-concentration-dependent ^{1}H-NMR and ^{31}P-NMR data, and observations based on the solid-state samples are assembled in Scheme 3. The mononuclear compound $[Cu(dppe)_2]I$ is in equilibrium with the putative intermediate [Cu(dppe)(*P*-dppe)I], which only is observed at low temperature. Dissociation of one or two ligand molecules leads to the dinuclear compounds $[Cu_2(dppe)_3I_2]$ and $[Cu_2(dppe)_2I_2]$, respectively, which have been observed in the solid.

dppp Compounds

Two broad signals for $[Cu(dppp)_2]BF_4$ (**5**) with an intensity ratio of 2:1 are observed in the ^{1}H-NMR spectrum at $\delta = 2.29$ and 1.62 (methylene groups of the coordinated dppp ligands). A broad signal at $\delta = -8.5$ (upfield shift of approximately 8.7 ppm with respect to the metal-free ligand) is observed in the ^{31}P-NMR spectrum of **5** in CD_2Cl_2. This is assigned to the four coordinated phosphorus atoms. The ^{31}P-chemical shifts in the solid state and in solution are similar (see Table 2) and thus the structure of **5** (see Figure 1) is conserved in solution.

Scheme 3. Proposal for the solution equilibria of copper(I) compounds of dppe with two mono- and two dinuclear species

In the high-field region of the ^{1}H-NMR spectrum of $[Cu(dppp)_2]I$ (**6**) in CD_2Cl_2 there are multiplets at $\delta = 2.28$ and 1.64 and some signals of lower intensity at $\delta = 2.05$. The ^{31}P-NMR spectrum has a broad signal at $\delta = -8.80$ and a signal at -17.5. The low-intensity signals in the ^{1}H- and ^{31}P-NMR spectra of **6** suggest that chemical exchange processes, similar to those of $[Cu(dppe)_2]I$, take place. Unfortunately, the proximity of the ^{31}P-NMR signals, due to the smaller chemical shift of the six-membered ring bisphosphane compounds, makes an identification of intermediate compounds in the region between $\delta = -8$ and -17.5 difficult. Thus, a thorough investigation of the solution equilibrium was not appropriate.

The low-temperature ^{31}P-NMR spectrum of $[Cu(dppp)_2]BF_4$ (**5**) in CD_2Cl_2 (Figure 5) has features that are significantly different from those of $[Cu(dppe)_2]BF_4$ (**1**) (see Table 2). Below 213 K the signal at $\delta = -8.5$ splits into two signals ($\delta = -5.84$ and -10.36 at 193 K). The iodine salt **6** in CD_2Cl_2 leads to identical spectroscopic results; the signal at $\delta = -17.5$ (room temperature) disappears at low temperature (193 K). An interpretation of these observations emerges from temperature-dependent ^{1}H-NMR spectroscopy. The two signals at $\delta = 2.29$ and 1.62 (CD_2Cl_2, 298 K), assigned to the methylene protons of **5**, are split into five signals at $\delta = 2.85$, 2.53, 2.20, 1.47, and 0.88 (CD_2Cl_2, 193 K) with an intensity ratio of 1:1:2:1:1. The ^{13}C-NMR spectrum (CD_2Cl_2, 193 K) has three signals at $\delta = 26.97$, 25.91, and 16.62. These may be assigned to the three chemically and magnetically nonequivalent methylene groups of the six-membered ring in a frozen chair conformation. This is in agreement with the two signals in the ^{31}P-NMR spectrum, and these may be assigned to the two nonequivalent phosphorus atoms of the bidentate ligand. This interpretation is also supported by the [^{13}C-^{1}H] spectrum of **5** in CD_2Cl_2.

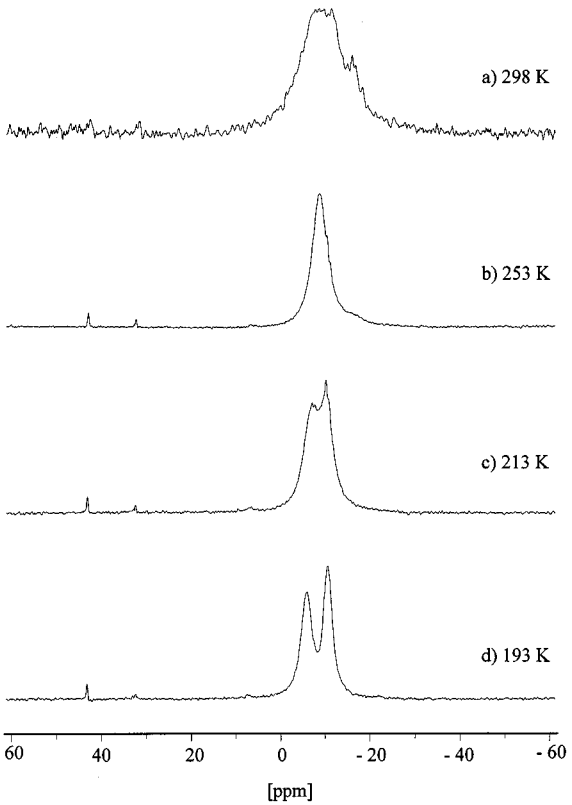

Figure 5. Temperature-dependent ^{31}P-NMR spectra (81 MHz) of $[Cu(dppp)_2]BF_4$ (**5**) (CD_2Cl_2; 85% H_3PO_4)

Experimental Section

Materials: 1,2-Bis(diphenylphosphanyl)ethane (dppe) and 1,3-bis(diphenylphosphanyl)propane (dppp) were purchased from Aldrich; CuI was obtained from Fluka and $Cu(BF_4)_2 \cdot x\ H_2O$ from ABCR Chemicals.

Measurements: ^{1}H-, ^{13}C-, and ^{31}P-NMR spectra at 200.13 or 300.13, 50.32 or 75.47, and 81.03 or 121.5 MHz, respectively, were measured with a Bruker AS 200 or a Bruker WH300 instrument with dichloromethane or chloroform as internal reference. H_3PO_4 (85%) was used as external reference for ^{31}P-NMR spectra. The ^{1}H-COSY and [^{13}C-^{1}H] spectra at 500.13 and 125.77 MHz were obtained with a Bruker Advance 500 instrument. − Infrared spectra (KBr pellets) were measured with a Perkin-Elmer 16PC FT-IR instrument. − Elemental analyses were obtained from the microanalytical laboratory of the chemical institutes of the University of Heidelberg. − Mass spectra (FAB or FD) were measured with a Finnigan 8400 (nitrobenzyl alcohol matrix) or a Jeol JMS-700 instrument.

Syntheses: All manipulations were carried out under Ar, using standard Schlenk techniques. CH_2Cl_2, $CHCl_3$, and diethyl ether were degassed by bubbling Ar through the solutions for 20 min. $[Cu(CH_3CN)_4]BF_4$ was prepared as reported in the literature.[11]

$[Cu(dppe)_2]BF_4 \cdot 0.5\ H_2O$ (1): $[Cu(CH_3CN)_4]BF_4$ (0.395 g, 1.26 mmol) was dissolved in CH_2Cl_2 (4 mL). The ligand dppe (1 g, 2.51 mmol) in CH_2Cl_2 (6 mL) was added (15 min) and the solution was stirred for 15 min at room temperature. After removing approximately 6 mL of the solvent and adding diethyl ether (10 mL), the solution was kept at −15°C over night. The resulting white precipitate was filtered off, recrystallized from methanol/water, and dried in vacuo. Yield (recrystallized): 0.63 g (0.66 mmol; 52%). − $C_{52}H_{48}BCuF_4P_4 \cdot 0.5\ H_2O$ (956.2): calcd. C 65.32, H 5.16, P 12.96; found C 65.43, H 5.13, P 13.03. − IR (KBr): $\tilde{\nu}$ [cm^{-1}] = 3050 (m, C_{ar}−H), 2918 (m, CH_2) 1482 (m, C_{ar}=C_{ar}), 1434 (s, P−Ph), 1054 (s, BF_4^-), 740, 694 (s, C_{ar}−H, 5 H neighboring). − MS (FAB); *m/z* (%): 859 (100) [M − BF_4], 646 (7) [M − BF_4 − $CH_2CH_2PPh_2$], 461 (98) [M − BF_4 − $CH_2CH_2PPh_2$ − PPh_2].

$[Cu(dppe)_2]I \cdot 0.5\ H_2O$ (2): A solution of dppe (1 g, 2.51 mmol) in $CHCl_3$ (6 mL) was slowly added to a suspension of CuI (0.239 g, 1.26 mmol) in $CHCl_3$ (2 mL). After stirring for 45 min, a pale yellow solution was obtained. The volume was reduced to 2 mL and diethyl ether was carefully added, until a white solid started to precipitate. After keeping at −15°C over night, the white precipitate was filtered off, recrystallized from methanol/water, and dried in vacuo. Yield (recrystallized): 0.43 g (0.43 mmol; 34%). − $C_{52}H_{48}CuIP_4 \cdot 0.5\ H_2O$ (996.3): calcd. C 62.69, H 4.96, P 12.44; found C 62.42, H 4.97, P 12.33. − IR (KBr): $\tilde{\nu}$ [cm^{-1}] = 3044 (m, C_{ar}−H), 2924 (m, CH_2) 1480 (m, C_{ar}=C_{ar}), 1432 (s, P−Ph), 740, 700 (s, C_{ar}−H, 5 H neighboring).

$[Cu_2(dppe)_3I_2]$ (3): A solution of dppe (1 g, 2.51 mmol) in CH_2Cl_2 (2 mL) was added to a suspension of CuI (0.319 g, 1.67 mmol) in CH_2Cl_2 (8 mL). The resulting colorless solution was stirred for 15 min, when a white solid started to precipitate. After storage at

−15°C over night, the product was filtered off, recrystallized from methanol/water, and dried in vacuo. Yield (recrystallized): 0.8 g (0.51 mmol; 61%). − $C_{78}H_{72}Cu_2I_2P_6$ (1576.2): calcd. C 59.43, H 4.60, P 11.80; found C 59.72, H 4.77, P 11.63. − IR (KBr): $\tilde{\nu}$ [cm^{-1}] = 3046 (m, $C_{ar}-H$), 2902 (w, CH_2) 1482 (s, $C_{ar}=C_{ar}$), 1432 (s, P−Ph), 747, 705 (s, $C_{ar}-H$, 5 H neighboring). − MS (FD); *m/z* (%): 1449 (5) [M − I, $^{63/65}Cu$], 1051 (17) [M − I − $Ph_2PCH_2CH_2PPh_2$, $^{63/65}Cu$], 859 (100) [M − I − $Ph_2PCH_2CH_2PPh_2$ − CuI, $^{63/65}Cu$], 461 (5) [M − I − $Ph_2PCH_2CH_2PPh_2$ − CuI − $Ph_2PCH_2CH_2$ − PPh_2, $^{63/65}Cu$].

$[Cu_2(dppe)_2I_2] \cdot 0.2\ CH_2Cl_2$ (4): A suspension of CuI (0.239 g, 1.26 mmol) in CH_2Cl_2 (2 mL) was treated with a solution of dppe (0.5 g, 1.26 mmol) in CH_2Cl_2 (3 mL). After addition of $CHCl_3$ (5 mL) and stirring for 30 min at room temperature, diethyl ether was layered onto the colorless solution, which was kept over night at −15°C. The white precipitate was filtered off, washed with cold diethyl ether, and dried in vacuo. Yield: 0.85 g (0.72 mmol; 57%). − $C_{52}H_{48}Cu_2I_2P_4 \cdot 0.2\ CH_2Cl_2$ (1194.7): calcd. C 53.03, H 4.11, P 10.52; found C 51.94, H 4.06, P 10.22. − IR (KBr): $\tilde{\nu}$ [cm^{-1}] = 3043 (m, $C_{ar}-H$), 2924 (m, CH_2) 1481 (m, $C_{ar}=C_{ar}$), 1432 (s, P−Ph), 1096 (s, $C_{ar}=C_{ar}$), 739, 692 (s, $C_{ar}-H$, 5 H neighboring). − MS (FAB); *m/z* (%): 1051 (6) [M − I, $^{63/65}Cu$], 859 (100) [M − I − CuI], 653 (39) [M − I − $Ph_2PCH_2CH_2PPh_2$, $^{63/65}Cu$], 461 (70) [M − I − CuI − $Ph_2PCH_2CH_2PPh_2$].

$[Cu(dppp)_2]BF_4$ (5): A pale yellow solution of dppp (1 g, 2.43 mmol) in CH_2Cl_2 (5 mL) was slowly added to a solution of $[Cu(CH_3CN)_4]BF_4$ (0.382 g, 1.21 mmol) in CH_2Cl_2 (4 mL). After stirring for 15 min, the volume was reduced to 5 mL and diethyl ether was layered onto the solution. The resulting gum was solidified by scratching in ice-cold CH_2Cl_2, recrystallized from methanol/water, and dried in vacuo. Yield (recrystallized): 0.91 g, (0.93 mmol; 77%). − $C_{54}H_{52}BCuF_4P_4$ (975.3): calcd. C 66.50, H 5.37, P 12.70; found C 66.03, H 5.34, P 12.61. − IR (KBr): $\tilde{\nu}$ [cm^{-1}] = 3064 (m, $C_{ar}-H$), 2929 (m, CH_2) 1498 (m, $C_{ar}=C_{ar}$), 1439 (s, P−Ph), 1067 (s, BF_4^-), 746, 704 (s, $C_{ar}-H$, 5 H neighboring). − MS (FAB); *m/z* (%): 887 (51) [M − BF_4], 475 (100) [M − BF_4 − $Ph_2P(CH_2)_3PPh_2$].

$[Cu(dppp)_2]I \cdot 0.5\ H_2O$ (6): A white suspension of CuI (0.231 g, 1.21 mmol) in CH_2Cl_2 (2 mL) was added to a solution of dppp (1 g, 2.43 mmol) in CH_2Cl_2 (6 mL). After stirring for 15 min, a colorless solution was obtained. Addition of diethyl ether and storage at −15°C over night resulted in a white precipitate, which was filtered off, recrystallized from methanol/water, and dried in vacuo. Yield (recrystallized): 1.03 g (1.00 mmol; 83%). − $C_{54}H_{52}CuIP_4 \cdot 0.5\ H_2O$ (1824.3): calcd. C 63.32, H 5.21, P 12.09; found C 63.24, H 5.14, P 12.12. − IR (KBr): $\tilde{\nu}$ [cm^{-1}] = 3047 (m, $C_{ar}-H$), 2912 (m, CH_2) 1489 (m, $C_{ar}=C_{ar}$), 1439 (s, P−Ph), 746, 699 (s, $C_{ar}-H$, 5 H neighboring).

Structure Determinations: Intensity-measurement data were obtained with a Syntex R3 diffractometer, using Mo-K_α radiation and operating in the ω-scan mode at room temperature. Data were corrected for Lp and absorption effects (ψ scan). The structures were solved by direct methods (SHELXS 86[12a]) and refined by full-matrix least-squares methods based on F^2 (SHELXL 97[12b]), using anisotropic thermal parameters for all non-hydrogen atoms. Hydrogen atoms were placed in calculated positions, but their parameters were not refined. The $CHCl_3$ solvent molecules in $[Cu_2(dppe)_3I_2] \cdot 2\ CHCl_3$ and the BF_4^- anion in $[Cu(dppp)_2]BF_4$ are disordered. The crystallographic data for $[Cu(dppe)_2]ClO_4$, $[Cu_2(dppe)_3I_2] \cdot 2\ CHCl_3$ and $[Cu(dppp)_2]BF_4$ are summarized in Table 3.

Acknowledgments

We are grateful to Dr. Voelkel (BASF) for the CPMAS ^{31}P-NMR spectra, to Dr. Schilling for the HH- and CH-COSY spectra of $[Cu(dppp)_2]BF_4$ and to the BASF AG, Ludwigshafen, for financial support.

Determination of the Se Atom Distribution in the Layered Compound $Nb_3(Se_{1-x}I_x)I_7$ by Scanning Tunneling Microscopy

Peter J. Schmidt,[a] Gerhard Thiele,*[a] and Myung-Hwan Whangbo*[b]

Keywords: Atom distribution / Mixed crystals / Scanning tunneling microscopy / Layered compounds

The layered compound $Nb_3(Se_{1-x}I_x)I_7$ is obtained when the I atoms at the face-capping sites of the layered compound Nb_3I_8 are replaced by Se atoms. The amount and distribution of the Se atoms in $Nb_3(Se_{1-x}I_x)I_7$ were examined by scanning tunneling microscopy. The analysis shows that the distribution of the Se atoms is completely random.

It is a challenging problem to study how chemical substitution or doping affect the structural and electronic properties of a material at the atomic level. A local-probe technique such as scanning tunneling microscopy (STM)[1][2] provides information about localized defects of a modified material, as demonstrated in a number of STM studies on layered compounds[3−6] and alloys.[7][8] Recently, a number of ternary compounds Nb_3YX_7 (X = halogen, Y = chalcogen) have been prepared.[9] As shown for $Nb_3S_{1-x}I_{7+x}$,[10] a wide range of mixed crystals between Nb_3X_8 and Nb_3YX_7 can be obtained. These compounds are related to the layered halides Nb_3X_8 (X = Cl, Br, I),[11] whose building block is an Nb_3X_{13} cluster (Figure 1a). Nb_3X_8 layers are obtained from these clusters upon sharing their outer octahedral edges (Figure 1b) in such a way that the two surfaces of an Nb_3X_8 layer are different: One surface (surface A) has the triangular face of each Nb_3 trimer capped by the X(4) atom, while the other surface (surface B) has the edges of each Nb_3 trimer capped by the X(1) atoms. The layers of Nb_3X_8 are stacked such that the interface between adjacent layers consists of either surface A or surface B (Figure 1c). Our single-crystal X-ray diffraction analysis of different $Nb_3Se_{1-x}I_{7+x}$ samples shows that only the face-capping site, i.e., I(4), is replaced by Se. When $0 < x < 1$, the face-capping sites of $Nb_3Se_{1-x}I_{7+x}$ are occupied by either I or Se so that each $Nb_3Se_{1-x}I_{7+x}$ layer consists of Nb_3I_{13} and Nb_3SeI_{12} clusters. In this paper, we demonstrate that the amount and distribution of the Se atoms in $Nb_3Se_{1-x}I_{7+x}$ can be determined by STM.

Typical STM images of $Nb_3Se_{1-x}I_{7+x}$ are divided into two groups, A and B, because the surface of the $Nb_3Se_{1-x}I_{7+x}$ sample mounted on the support can be either surface A or surface B. The STM images of group A show patterns of three bright and one less bright spots per unit cell (Figure 2a). This pattern can be readily seen by filtering the observed image by the two-dimensional fast Fourier transform procedure, as illustrated on the upper left part of Figure 2a. The STM images of group A exhibit image defects as dark spots that have the size of approximately one cluster unit. The STM images of group B show one bright spot for each unit cell, with varying degrees of brightness (Figure 2b). The STM images of group A and B recorded for $Nb_3Se_{1-x}I_{7+x}$ refer to the surfaces A and B, respectively. When the image defects are neglected, their unit cell patterns are similar in pattern to the partial density plots $\rho(r_0, E_f)$ calculated for surfaces A and B of Nb_3I_8, respectively.[12]

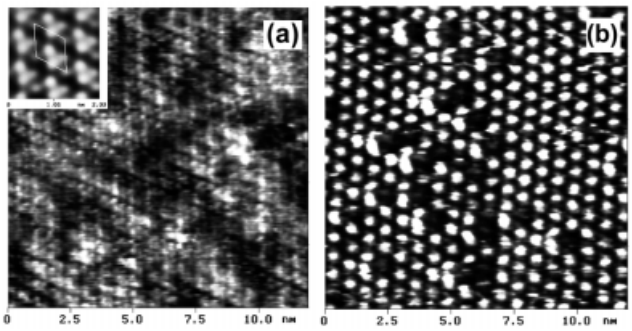

Figure 2. (a) STM current image of $Nb_3Se_{0.36}I_{7.64}$ ($V_{bias} = -164.8$ mV, $I_{set\text{-}point} = 19.89$ nA); (b) STM current image of $Nb_3Se_{0.09}I_{7.91}$ ($V_{bias} = -300$ mV, $I_{set\text{-}point} = 3.48$ nA)

-517.9 mV, and that of Figure 3c with $I_{set\text{-}point} = 15.98$ nA and $V_{bias} = -481.3$ mV. The tip-sample distance in contact-mode STM decreases with decreasing the resistance gap, $R_{gap} = |V_{bias}|/I_{set\text{-}point}$.[2d] Thus, the strength of the tip-sample repulsive interaction, and hence the extent of the sample indentation induced by the tip force, increases with decreasing R_{gap}.[2d] The values of R_{gap} used to obtain the STM images of Figures 3a and 3c are 135.6 and 30.12 MΩ, respectively, so that the tip-sample repulsive interaction leading to the STM image of Figure 3c was much stronger than that leading to the STM image of Figure 3a. To see how often the spot of any given contrast occurs in the STM image of Figure 3a, the contrast of each spot in this image was analyzed. The histogram of Figure 3b shows how many times (in relative number) the spot of a certain contrast occurs as a function of the contrast. The corresponding analysis carried out for the STM image of Figure 3c is summarized in Figure 3d. The bright and less bright spots are more clearly separated in Figure 3d than in Figure 3b. As will be shown below, the concentration ratio [Se]/[I(4)] in $Nb_3Se_{1-x}I_{7+x}$, which is given by $(1 - x)/x$, is equal to the number ratio of the dark spots to the bright spots in the STM images of group B. Thus, the difference between the Nb_3I_{13} and Nb_3SeI_{12} clusters in $Nb_3Se_{1-x}I_{7+x}$ is more clearly distinguished when the tip-sample force interaction is stronger. The reason for this observation will be discussed in our forthcoming paper.[13]

The above discussion shows that the content and distribution of Se in $Nb_3Se_{1-x}I_{7+x}$ can be detected by STM. To examine the nature of the Se atom distribution in $Nb_3Se_{1-x}I_{7+x}$, we analyzed the STM images recorded for the surface B of $Nb_3Se_{1-x}I_{7+x}$. It is easy to assign whether a given spot of the STM image is associated with the Nb_3I_{13} or the Nb_3SeI_{12} cluster; consequently, a given STM image can be converted into a digitized image consisting solely of bright and dark circles representing the Nb_3I_{13} and Nb_3SeI_{12} clusters, respectively. For instance, Figure 4 shows four digitized images obtained from the STM images determined on four different surface regions of $Nb_3Se_{0.24}I_{7.76}$. The amount of Se determined from the digitized images is in good agreement with that determined by wavelength-dispersive X-ray (WDX) analysis. In the digitized images,

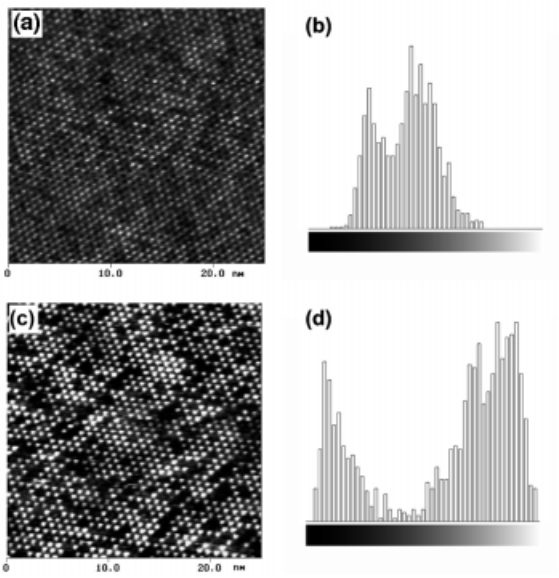

Figure 3. (a) STM current image recorded for surface B of $Nb_3Se_{0.24}I_{7.76}$ ($I_{set\text{-}point} = 3.82$ nA, $V_{bias} = -517.9$ mV); (b) histogram of how often the spot of any given contrast occurs in the STM image of (a); (c) STM current image recorded for surface B of $Nb_3Se_{0.24}I_{7.76}$ ($I_{set\text{-}point} = 15.98$ nA, $V_{bias} = -481.3$ mV); (d) histogram of how often the spot of any given contrast occurs in the STM image of (c); the images of (a) and (c) were obtained from the same sample surface, but the positions are not the same due to the thermal drift during the measurements; the contrast variations in (a) and (c) cover the same range and are proportional to ln I

bright and dark circles form a hexagonal lattice in which each circle is surrounded with six nearest neighbor circles.

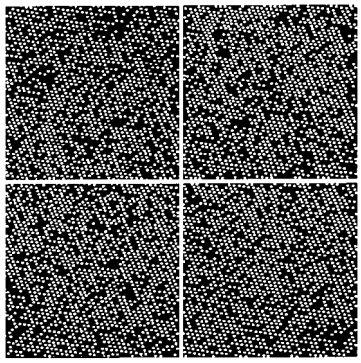

Figure 4. Digitized images derived from analyzing surface B STM images of $Nb_3Se_{0.24}I_{7.76}$ (30 nm × 30 nm); bright and dark spots refer to the Nb_3I_{13} and Nb_3SeI_{12} clusters, respectively

To determine if the distribution of the Se atoms is random, we examined each dark circle of the digitized image and counted how many of its nearest neighbor circles are dark circles. If the distribution of the Se atoms in $Nb_3Se_{1-x}I_{7+x}$ is truly random, then the probability $p(m)$ of finding $m = 0$, 1, 2, 3, 4, 5, or 6 dark circles as nearest neighbors of a given dark circle can be described by a binomial distribution (Equation 1)

$$p(m) = [6!/m!(6 - m)!](1 - x)^m(x)^{6-m} \quad (1)$$

The $p(m)$ values predicted by Equation 1 are compared with the experimental values determined by analyzing the

digitized images of $Nb_3Se_{0.24}I_{7.76}$ in Figure 5, which shows an excellent agreement between the theoretical and experimental $p(m)$ values. The same result is obtained with samples of different Se content. Thus, the distribution of the Se atoms in $Nb_3Se_{1-x}I_{7+x}$ is random.

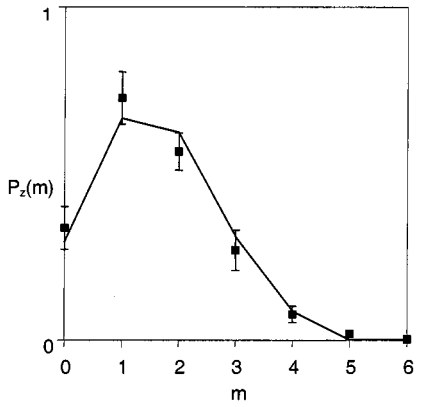

Figure 5. Comparison of the theoretical and experimental $p(m)$ values determined for the distribution of the Se atoms in $Nb_3Se_{0.24}I_{7.76}$

In summary, we determined the content and distribution of Se in $Nb_3Se_{1-x}I_{7+x}$ by carrying out STM experiments. Our work shows that the Nb_3I_{13} and Nb_3SeI_{12} clusters are distinguished by STM, and that the distribution of the Se atoms in $Nb_3Se_{1-x}I_{7+x}$ is random.

Experimental Section

Single crystals of $Nb_3Se_{1-x}I_{7+x}$ were obtained by heating mixtures of the elements in evacuated sealed silica tubes as described in ref.[11b] To avoid the twinning of crystals, the tubes were rapidly quenched at the end of reaction. Higher niobium iodides and niobium selenide iodides were separated from the desired product by sublimation before opening the tubes. The purity and homogeneity of the products were checked by powder X-ray diffraction. The structure and chemical composition of the products were determined by single-crystal X-ray diffraction analysis and by WDX analysis using β-Nb_3I_8 and LT-$NbSe_2I_2$[14] as standards. Samples of $Nb_3Se_{1-x}I_{7+x}$ were examined by STM, as described for Nb_3I_8 elsewhere.[12] Contact-mode STM measurements were carried out on freshly cleaved surfaces of the mounted crystal samples at ambient conditions using a commercial scanning probe microscope Nanoscope II (Digital Instruments, Inc.), mechanically sharpened Pt/Ir 70:30 tips for STM, and commercial cantilevers with Si_3N_4 probes for AFM.

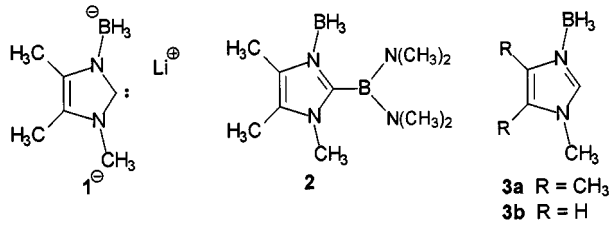
Nucleophilic Substitution Reactions with the 3-Borane-1,4,5-trimethylimidazol-2-ylidene Anion. – Unexpected Formation of an Imidazabole Isomer

Andreas Wacker,[a] Hans Pritzkow,[a] and Walter Siebert*[a]



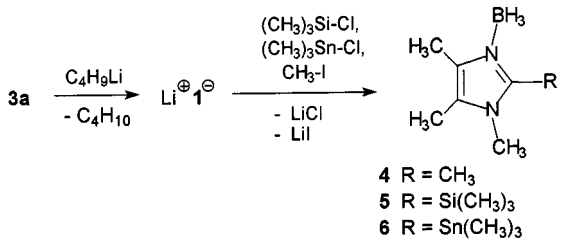
Dedicated to Prof. Bernt Krebs on the occasion of his 60th birthday

Keywords: Boranes / Carbenes / Heterocycles / Imidazoles / X-ray structures

The nucleophilic carbene 3-borane-1,4,5-trimethylimidazol-2-ylidene anion (**1**$^-$) reacts with the electrophiles CH_3I, $(CH_3)_3SiCl$, $(CH_3)_3SnCl$, and the bromodiazaboroline **7** to form the 2-substituted imidazoles **4**, **5**, **6**, and **8**. With triethylborane, the anionic carbene borane adduct **9**$^-$ is obtained. An unexpected result was achieved when chlorodimethoxyborane and $HBCl_2 \cdot S(CH_3)_2$ were used as electrophiles. In both cases only the imidazabole **14a** could be isolated. Imidazole **5**, the imidazole borane adduct **3a** and the imidazabole **14a** were characterized by X-ray structure analyses.

Introduction

Imidazol-2-ylidenes are stable carbenes which have attracted wide attention[1]. Recently, we described the synthesis and characterization of the first anionic imidazol-2-ylidene, the 3-borane-1,4,5-trimethylimidazol-2-ylidene anion (**1**$^-$),[2] and showed that it reacts with bis(dimethylamino)chloroborane to form **2**. We now report further details on the reactivity of **1**$^-$ towards various electrophiles.



Results and Discussion

Formation of Substituted Imidazoles

The anion **1**$^-$ reacts with iodomethane, chlorotrimethylsilane and -stannane to give the expected 2-substituted imidazoles (Scheme 1). The products **4**, **5**, and **6** are obtained as air-stable compounds.

The reaction of **1**$^-$ with iodomethane results in the formation of 3-borane-1,2,4,5-tetramethylimidazole (**4**), which was first prepared[3] from 1,2,4,5-tetramethylimidazole and $BH_3 \cdot SMe_2$. The donor-acceptor compound is isoelectronic with the pentamethylimidazolium ion[3]. **4** is separated from LiI by sublimation which, however, lowers the yield com-

Scheme 1

pared with that of **5** and **6**. In the ^{1}H-NMR spectrum the signal for the methyl group in 2-position is found at δ = 2.45 which is 0.33 ppm at low-field compared with the shift for the CH_3 substituents in 4- and 5-position. The ^{13}C-NMR spectrum shows the expected high-field shift of the C2 carbon atom from δ = 191.3 in **1** to δ = 142.3. In the ^{11}B-NMR spectrum a 1:3:3:1 quartet is observed at δ = −22.4, [^1J(BH) = 82 Hz].

The analogous reaction of **1**$^-$ with chlorotrimethylsilane leads to 3-borane-1,4,5-trimethyl-2-(trimethylsilyl)imidazole (**5**) in quantitative yield. Its NMR data are similar to those of **4**. The trimethylsilyl group shows a resonance in the ^{1}H-NMR spectrum at δ = 0.52 and in the ^{13}C-NMR spectrum at δ = 1.7. As in **4**, the C2 carbon atom again experiences a high-field shift to δ = 146.9 and the ^{11}B-NMR signal is found as a quartet at δ = −19.7. **5** is an isomer of the 1-borane-2,4,5-trimethyl-3-trimethylsilylimidazole adduct (δ^{11}B = −21.8)[3].

Analogously, 3-borane-1,4,5-trimethyl-2-(trimethylstannyl)imidazole (**6**) is quantitatively synthesized from **1**$^-$ and chlorotrimethylstannane. The NMR spectra of **6** are nearly identical with those of **5**: The trimethylstannyl group is found in the ^{1}H-NMR spectrum at δ = 0.49 and in the ^{13}C-NMR spectrum at δ = −5.1. The signal for the C2 carbon atom appears at δ = 151.5 which is five ppm low-field com-

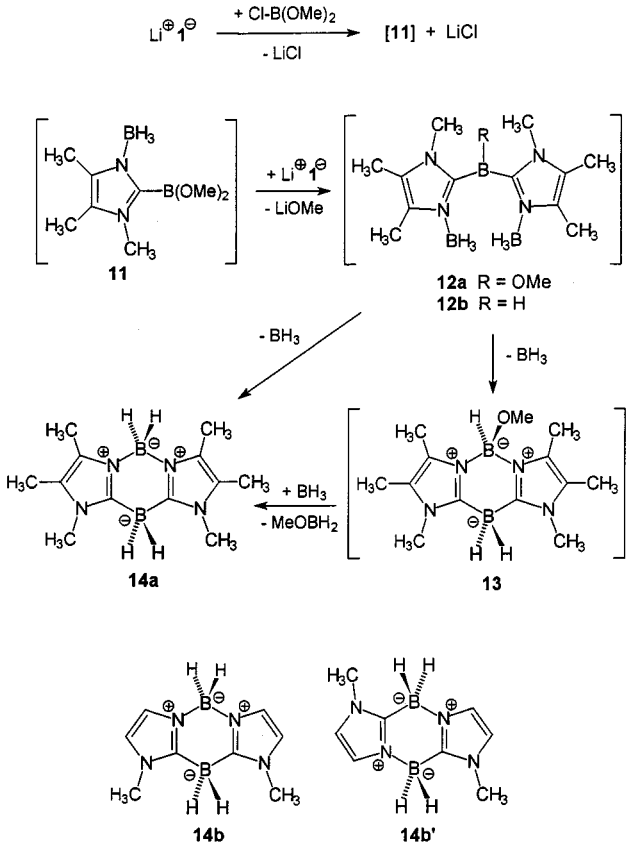
pared to that of **5**. In the ^{11}B-NMR spectrum the signal appears at $\delta = -19.9$.

2-Bromo-1,3-di(*tert*-butyl)-1,3,2-diazaboroline (**7**) reacts with the anion $\mathbf{1}^-$ to give **8** (Scheme 2) which is characterized by NMR and mass spectroscopy. The ^{1}H-NMR spectrum shows three singlets for the methyl groups of the imidazole ring at $\delta = 2.14$, 2.20, and 3.38. The signals for the diazaboroline substituent are found at $\delta = 1.18$ (*tert*-butyl) and 6.46 (C-H). The appearance of only two singlets indicates that the C_2N_2B-ring is orientated perpendicular to the imidazole plane, due to the steric hindrance of the *tert*-butyl substituents. As expected, all signals are shifted to higher field compared with those of a cationic carbene borane adduct, obtained from **7** and 1,3-dimethyl-imidazol-2-ylidene[4].



The ^{13}C-NMR spectrum shows the signals for the diazaboroline ring at $\delta = 31.0$, 53.1, and 114.7 and five more at $\delta = 8.6$, 10.1, 32.8, 123.9, and 132.0 belonging to the imidazole. The C2 atom is not observed. In the ^{11}B-NMR spectrum two signals at $\delta = 19.1$ (C-BN_2) and -20.1 (N-BH_3) are found.

Scheme 2

Reaction of 1^- with Boranes

When $\mathbf{1}^-$ is treated with the Lewis acid triethylborane, the anionic borane adduct $\mathbf{9}^-$ is obtained (Scheme 2). Neutral carbene-borane adducts of 1,3-dialkyl-imidazol-2-ylidenes and BH_3 or BF_3 are already known[5] as well as 1,3,4,5-tetramethyl-2-(triethylborane)imidazoline (**10**), which was recently prepared by a different route[2]. $\mathbf{9}^-$ and **10** are isoelectronic, a formal substitution of CH_3 in **10** by BH_3^- leads to $\mathbf{9}^-$. In its ^{1}H-NMR spectrum the signals for the B-C_2H_5 substituents are found as a broad multiplet ($\delta = 1.1-1.3$) and for the methyl groups at $\delta = 1.68$, 2.24, and 3.55. In the ^{13}C-NMR spectrum the B-C_2H_5 substituents show resonance at $\delta = 12.6$ (CH_3) and 16 (CH_2) of which the latter signal is broadened. The C2 carbon atom in $\mathbf{9}^-$ ($\delta = 175$) exhibits a different chemical shift compared with those of **4**, **5**, and **6**. – As expected, $\mathbf{9}^-$ shows two signals

Scheme 3

in the ^{11}B-NMR spectrum at $\delta = -12.5$ (C-BEt_3) and -21.6 (N-BH_3).

An interesting observation was made, when $\mathbf{1}^-$ was treated with chlorodimethoxyborane. In analogy to the formation of **4**–**6**, and **8**, we expected to find the dimethoxyboryl-substituted imidazole **11** but to our surprise, the only product that could be isolated was the imidazabole **14a** (Scheme 3). It is likely that in the first step **11** is formed, however, it then reacts with additional $\mathbf{1}^-$ to give **12a**. Obviously, ring closure to **13a** occurs with elimination of BH_3 and migration of H^- to the B–R group The methoxy group in **13a** is exchanged for hydrogen to give **14a** and [$(CH_3O)BH_2$] of which the latter was not identified.

To study the influence of boranes on the formation of **14a** the anion $\mathbf{1}^-$ was treated with $BH_3 \cdot$ thf. In the reaction mixture **14a** could be identified in the ^{11}B-NMR spectrum besides other signals that were not assigned. When $\mathbf{1}^-$ was treated with $HBCl_2 \cdot S(CH_3)_3$ in a ratio of 2:1, **14a** was obtained in 48% yield (calculated for $\mathbf{1}^-$). With a 3:1 ratio, the yield increased to 66%. These findings indicate that BH_3, set free in the ring closure process, participates in the reaction with $\mathbf{1}^-$ to give **14a**.

The structure of **14a** follows from the NMR and MS data. The two triplets in the ^{11}B-NMR spectrum at $\delta = -10$ (C_2BH_2) and -32 (N_2BH_2) clearly show that **14a** has been formed. In the ^{1}H-NMR spectrum three signals appear at $\delta = 2.10$, 2.17, and 3.49 and in the ^{13}C-NMR spectrum at $\delta = 9.2$, 10.3, and 31.9. The signals for the ring

carbon atoms are observed at δ = 123.6 and 127.3, that of the C2 atom was not found.

14a is isomeric to the imidazabole **14b′** which was obtained by Contreras, Wrackmeyer et al. in the thermolysis reaction of **3b**[6]. During their investigations they could isolate both isomers **14b** and **14b′**. We did not observe the formation of **14a′**. Thus, a change of the substituents at the boron atom by choosing chlorodimethoxyborane instead of a chlorodiaminoborane leads to a completely different reaction pathway in which the substituted imidazoles **11** and **12b** are postulated intermediates. Different reaction conditions like changing the order in which the starting materials are added as well as carrying out the reaction at elevated temperature have no influence on product formation.

X-ray Structure Analyses of 3a, 5, and 14a

Figure 1 shows the structure of planar **3a**. The B6−N1 distance of **3a** [1.584(3) Å] is similar to that of the trimethylsilyl derivative **5**. Single crystals of **5** were grown from a toluene/hexane solution and the structure is depicted in Figure 2. Comparism of **5** with the carbene anion **1**$^-$ and the imidazole borane adduct **3a** (Figure 1) shows that the structural parameters lie between those of **1**$^-$ and **3a**.

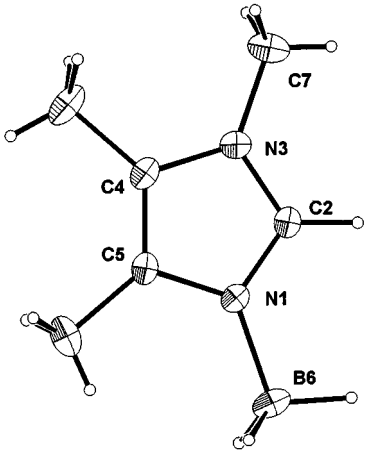


Figure 1. Structure of **3a** in the crystal; bond lenghts and angles are listed in Table 1

Imidazol-2-ylidenes characteristically have smaller N−C−N and larger C−N−C angles than imidazoles. Their C2−N1/2 bonds are equal in contrast to that of imidazole molecules which show single and double bond character[1−3]. In the case of **5**, the following observations are made: First, the C2−N1/2 distances with 1.348(3) and 1.367(3) Å exhibit bond length alternations as in imidazole molecules and they are shorter in comparison with those in **1**$^-$ but are still longer than in **3a** (Table 1). Second, the N−C−N angle of 106.6° has increased compared with that of **1**$^-$ but is still considerably smaller than that of **3a**. The third characteristic structural pattern, the C−N−C angles also show the same tendency: With 109.1° and 109.7° they lie between those found for **1**$^-$ and **3a**. A similar trend is observed in the ^{13}C-NMR shifts of the C2 atoms which

move to higher field [δ = 191.3 (**1**$^-$), 146.9 (**5**), and 135.7 (**3a**)].

The structure of **14a** is shown in Figure 3. Single crystals were obtained from a $CDCl_3$ solution. The molecule is disordered, the structure found is a superposition of two orientations, created by a rotation around the axis through C4 and C4′. Therefore all other positions in the ring are occupied partly by nitrogen and carbon. The distances found are mean values, and the chemically different boron atoms cannot be distinguished. The result of the structure analysis

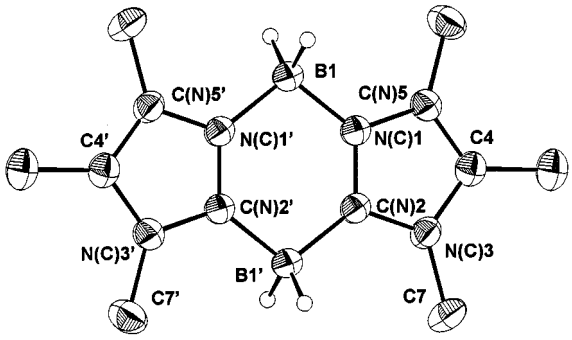

Figure 3. Structure of **14a** in the crystal

does not allow to distinguish **14a** from **14a′** (the analog of **14b′**) in contrast to the ^{11}B-NMR spectrum. A discussion of the angles and distances is therefore not meaningful.

Conclusion

The nucleophilic carbene union $\mathbf{1}^-$ obtained by deprotonation of the imidazole borane adduct **3a** reacts with electrophiles to form the 2-substituted imidazoles **4**, **5**, **6**, and **8**, which are confirmed by NMR and MS data and X-ray structure analyses for **3a** and **5**. With the Lewis acid BEt_3 the carbene addduct $\mathbf{9}^-$ is formed. Surprisingly, the reaction of $\mathbf{1}^-$ with $ClB(OMe)_2$, BH_3, or with $HBCl_2 \cdot SMe_2$ leads to the tricyclic imidazabole **14a**. In the crystal the molecule **14a** is disordered by superposition of two orientations. However, the ^{11}B-NMR spectrum of **14a** proves the presence of one C_2BH_2 and one N_2BH_2 group in the molecule.

Experimental Section

General: The reactions were carried out under dry argon, using standard Schlenk techniques. Solvents were dried, distilled, and saturated with nitrogen. Glassware was dried with a heat-gun in high-vacuum. − ^{1}H-, ^{13}C-, ^{11}B-NMR: Bruker AC 200 or AC 300 spectrometer, NMR references are $(CH_3)_4Si$ and $BF_3 \cdot Et_2O$. − Mass spectra were obtained with a Finnigan MAT 8200 plus spectrometer using EI technique. − Melting points (uncorrected) were obtained with a Büchi apparatus, using a capillary which was filled under argon and sealed. − 3-Borane-1,4,5-trimethylimidazole (**3a**)[2], chlorotrimethylstannane[7a] and 2-bromo-1,3-di(*tert*-butyl)-1,3,2-diazaboroline[7b] were prepared according to literature procedures.

General Procedure for the Preparation of the 2-Substituted Imidazoles 4, 5, and 6: To a suspension of **3a** [0.49 g (4.0 mmol) for **4**; 1.02 g (8.2 mmol) for **5** and 0.87 g (7.0 mmol) for **6**] in 30 mL of thf the equimolar amount of *n*-butyllithium (2.5 N in hexane) was added dropwise at −40°C. The mixture was allowed to warm to room temp. and was stirred for 1 h. Then the corresponding electrophiles [0.75 g (5.3 mmol) of iodomethane; 0.98 g (9.0 mmol) of chlorotrimethylsilane; 1.40 g (7.0 mmol) of chlorotrimethylstannane)] were added at −40°C, the solution again warmed to room temp. and stirred for 1 h. The solvent was removed in vacuo and the white precipitate (**4**) sublimed in vacuo (120−160°C, 10^{-2}−10^{-3} Torr). **5** and **6** were dissolved in toluene and LiCl was separated by filtration. The solution contained the pure product which was isolated by evaporating the solvent or by crystallization from a toluene/hexane solution.

3-Borane-1,2,4,5-tetramethylimidazole (4): Yield: 0.32 g (58%) white powder, m.p.: 140−160°C (decomp.). − ^{1}H NMR (300.1 MHz, $CDCl_3$): δ = 2.08, 2.14 (2s, 6 H, C-CH_3), 2.45 (s, 3 H, C-CH_3), 3.42 (s, 3 H, N-CH_3). − ^{13}C NMR (75.5 MHz, $CDCl_3$): δ = δ = 8.6 (C-*C*H$_3$), 10.5 (C-*C*H$_3$), 11.2 (C-*C*H$_3$), 30.7 (N-CH$_3$), 122.4, 129.5 (C=*C*-N), 142.3 (N=C-N). − ^{11}B NMR (64.2 MHz, C_6D_6): δ = −22.4 (q, $^1J_{B\text{-}H}$ = 82 Hz). − $C_7H_{15}BN_2$ (138.0): calcd. C 60.91, H 10.95, N 20.29; found. C 60.46, H 10.82, N 20.24.

3-Borane-1,4,5-trimethyl-2-trimethylsilylimidazole (5): Yield: 1.48 g (92%) white powder, m.p.: 115−120°C. − ^{1}H NMR (300.1 MHz, $CDCl_3$): δ = 0.52 [s, 9 H, $Si(CH_3)_3$], 2.12, 2.20 (2s, 6 H, C-CH_3), 3.58 (s, 3 H, N-CH_3). − ^{13}C NMR (50.3 MHz, C_6D_6): δ = 1.7 (Si-CH_3), 8.4, 10.7 (C-*C*H$_3$), 32.3 (N-CH$_3$), 126.1, 133.4 (C=*C*-N), 146.9 (N=C-N). − ^{11}B NMR (64.2 MHz, C_6D_6): δ = −19.7 (q, $^1J_{B\text{-}H}$ = 93 Hz). − $C_9H_{21}BN_2Si$ (196.2): calcd. C 55.10, H 10.78, N 14.27; found. C 55.18, H 10.86, N 14.02.

3-Borane-1,4,5-trimethyl-2-trimethylstannylimidazole (6): Yield: 1.91 g (95%) colorless crystals, m.p. 110−115°C. − ^{1}H NMR (200.1 MHz, $CDCl_3$): δ = 0.49 [s, 9 H, $Sn(CH_3)_3$, $^2J_{Sn\text{-}H}$ = 29 Hz],

2-(1-Borane-3,4,5-trimethylimidazolyl)-1,3-di(*tert*-butyl)-1,3,2-diazaboroline (8): To a suspension of 310 mg (2.5 mmol) of **3a** in 25 mL of thf 1.0 mL of *n*-butyllithium (2.5 N in hexane) were added dropwise at −40°C. The mixture was allowed to warm to room temp. and stirred for 1 h. Then a solution of 650 mg (2.5 mmol) of 2-bromo-1,3-(*tert*-butyl)-1,3,2-diazaboroline in 5 mL of thf was added at −78°C. During warming to room temp. the solution became orange colored and was then stirred for 1 h. The solvent was removed in vacuo, the white precipitate dissolved in toluene and LiBr was separated by filtration. After adding hexane to the solution at −30°C the product precipitates. Yield: 170 mg (32%) white powder, sensitive to air and moisture. – ^{1}H NMR (200.1 MHz, $CDCl_3$): δ = 1.18 [s, 18 H, C(CH_3)$_3$], 2.14, 2.20 (2s, 6 H, C-CH_3), 3.38 (s, 3 H, N-CH_3), 6.46 (s, 2 H, C-H). – ^{13}C NMR (50.3 MHz, $CDCl_3$): δ = 8.6, 10.1 (C-*C*H_3), 31.0 [N-C(*C*H_3)$_3$], 32.8 (N-CH_3), 53.1[N-*C*(CH_3)$_3$], 114.7 (C-H), 123.9, 132.0 (C=*C*-N), C2 (imidazole) not observed. – ^{11}B NMR (64.2 MHz, C_6D_6): δ = 19.1 (N-B-N), −20.1 (BH_3). – EI-MS; *m/z* (%) = 302 [M^+] (25), 245 [M^+ − C(CH_3)$_3$] (26), 123 [$C_6H_{12}BN_2^+$] (100).

Lithium 3-Borane-1,4,5-trimethyl-2-(triethylborane)imidazoline (Li^+ 9^-): To a suspension of 500 mg (4.0 mmol) of **3a** in 25 mL of thf 1.65 mL of *n*-butyllithium (2.5 N in hexane) were added dropwise at −40°C. The mixture was allowed to warm to room temp. and stirred for 1 h. Then 390 mg (4.0 mmol) of triethylborane were added at 0°C, then warmed to room temp. and stirred for 1 h. The solvent was removed in vacuo, leaving the product as a yellow oil. Yield: 1.58 g [96% for Li(thf)$_3^+$ 9^-], sensitive to air and moisture. – ^{1}H NMR (200.1 MHz, C_6D_6): δ = 1.1−1.3 (m, 15 H, C_2H_5), 1.4−1.5 (m, 12 H, thf), 1.68, 2.24 (2s, 6 H, C-CH_3), 3.5−3.6 (m, 15 H, N-CH_3 + thf). – ^{13}C NMR (50.3 MHz, C_6D_6): δ = 9.2, 12.6 (C-*C*H_3), 12.6 (CH_2-*C*H_3), 16 (br., *C*$H_2$$CH_3$), 25.5 (thf), 33.1 (N-$CH_3$), 68.4 (thf), 121.8, 128.1 (C=*C*-N), 175 (br., N-C=N). – ^{11}B NMR (64.2 MHz, C_6D_6): δ = −12.5 (C-BEt_3), −21.6 (br., N-BH_3).

Imidazabole 14a: To a suspension of 500 mg (4.0 mmol) of **3a** in 20 mL of thf 1.7 mL of *n*-butyllithium (2.5 N in hexane) were added dropwise at −40°C. The mixture was allowed to warm to room temp. and stirred for 1 h. Then 450 mg (4.2 mmol) of chlorodi(methoxy)borane were added at −70°C, the solution was warmed to room temp. and stirred for 1 h. The solvent was removed in vacuo. The white precipitate was dissolved in toluene and LiCl was separated by filtration. **14a** was allowed to crystallize from a toluene/hexane solution at −30°C. Yield: 200 mg (54%) white, air-stable solid, m.p. > 270°C. – ^{1}H NMR (200.1 MHz, $CDCl_3$): δ = 2.10 (s, 6 H, C-CH_3), 2.17 (s, 6 H, C-CH_3), 3.49 (s, 6 H, N-CH_3). – ^{13}C NMR (50.3 MHz, $CDCl_3$): δ = 9.2, 10.3 (C-*C*H_3), 31.9 (N-CH_3), 123.6, 127.3 (C=*C*-N), 163 (br., N=C-N). – ^{11}B NMR (64.2 MHz, $CDCl_3$): δ = −10.0 (t, C_2-BH_2, $^1J_{B-H}$ = 100 Hz), −31.4 (t, N_2-BH_2, $^1J_{B-H}$ = 87 Hz). – EI-MS: *m/z* (%) 243 (100) [M^+ − H].

Formation of 14a from 1^- and $HBCl_2 \cdot S(CH_3)_2$: To a suspension of 1.00 g (8.1 mmol) [1.05 g (8.5 mmol)] of **3a** in 30 mL of thf 3.5 mL [3.4 mL] of *n*-butyllithium (2.5 N in hexane) were added dropwise at −40°C. The mixture was allowed to warm to room temp. and stirred for 1 h. Then 600 mg (4.2 mmol) [390 mg (2.7 mmol)] of $HBCl_2 \cdot S(CH_3)_2$ were added at −78°C and the solution was allowed to warm to room temp. After stirring for 1 h, the solvent was removed in vacuo and the white precipitate dissolved in toluene. LiCl was separated by filtration. The solvent was evaporated, the residue dissolved in chloroform and allowed to crystallize at −30°C. Yield: 470 mg (48%) [680 mg (66%)] white, air-stable **14a** (analytical data see above).

Crystal Structure Determinations of 3a, 5, and 14a: Crystal data and details of the structure determinations are listed in Table 2. Unique sets of intensity data were collected at −70°C (**5**, **14a**) and at 23°C (**3a**) with a 4-circle diffractometer (Mo-*K*α-radiation λ = 0.71073 Å, graphite monochromator, ω-scan). Empirical absorption corrections (ψ-scans) were applied. The structures were solved by direct methods [SHELXS86][8] and refined by least-squares methods based on F^2 with all measured reflections [SHELXL97][9]. All non-hydrogen atoms were refined anisotropically. The structure of **14a** is disordered. A refinement in $P\bar{1}$ did not converge and gave no reasonable result.

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallograhpic Data Center as supplementary publication no. CCDC 102759 (**3a**), 102760 (**5**), 102761 (**14a**). Copies of the data can be obtained free of charge on application to the Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: int. code +44(1223) 336-001; e-mail: deposit@ccdc.cam.ac.uk.

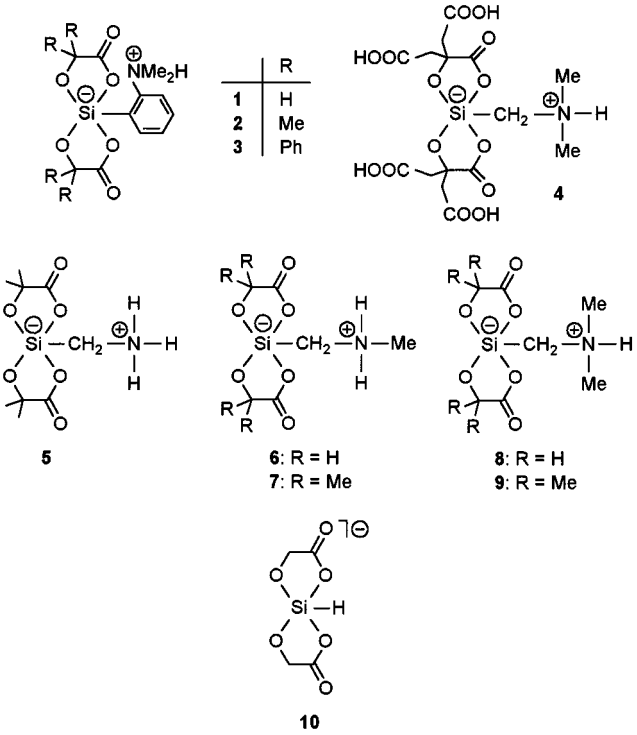
Syntheses, Stereochemistry, and Dynamic Behavior of Chiral Zwitterionic (Ammoniomethyl)bis[glycolato(2–)-O^1,O^2]silicates

Reinhold Tacke,*[a] Rüdiger Bertermann,[a] Andreas Biller,[a] Olaf Dannappel,[a] Melanie Pülm,[a] and Reiner Willeke[a]



Dedicated to Professor Bernt Krebs on the occasion of his 60th birthday

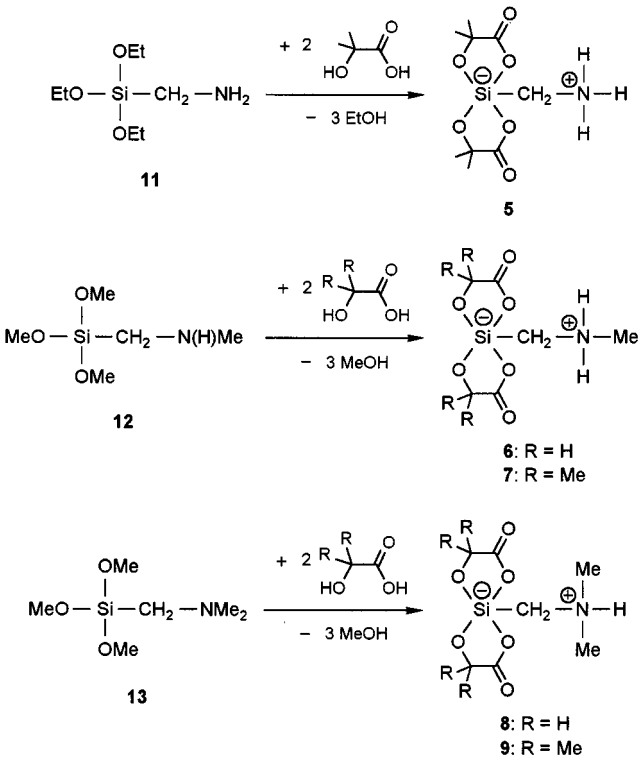
Keywords: Ab initio studies / Chirality / Pentacoordinate silicon / Stereochemistry / Zwitterionic λ^5*Si*-silicates

The syntheses of the zwitterionic (molecular) spirocyclic λ^5*Si*-silicates **5**–**9** are described. These chiral compounds contain a pentacoordinate (formally negatively charged) silicon atom and a tetracoordinate (formally positively charged) nitrogen atom. The stereochemistry and dynamic behavior of **5**–**9** were investigated. For this purpose, compounds **5**–**9** were studied by solution-state NMR spectroscopy (^{1}H, ^{13}C, ^{29}Si; including VT ^{1}H-NMR studies of **9**) and solid-state NMR spectroscopy (^{13}C CP/MAS, ^{29}Si CP/MAS). In addition, compounds **5**·H_2O, **7**, **8**, **9**·H_2O, and **9**·2CH_3CN were structurally characterized by single-crystal X-ray diffraction, and ab initio investigations of the zwitterion **8** and the related anionic model species **10** were carried out.

Introduction

The study of compounds with higher coordinate silicon atoms currently represents one of the main areas of research in silicon chemistry.[1] In context with our systematic investigations on zwitterionic λ^5*Si*-silicates,[1f,1h,1i,2] we have recently reported on the syntheses and crystal structure analyses of the spirocyclic compounds **1**−**3**[2e] and **4**·H_2O[2g]. These molecular pentacoordinate silicon compounds each contain two identical bidentate diolato(2−) ligands that derive from α-hydroxycarboxylic acids. λ^5*Si*-silicates of this particular formula type offer a variety of interesting stereochemical features. In this paper, the results of experimental and theoretical studies concerning the stereochemistry and dynamic behavior of such compounds are described. We report here on the syntheses and characterization of the zwitterionic λ^5*Si*-silicates **5**−**9**, including (i) the crystal structure analyses of **5**·H_2O, **7**, **8**, **9**·H_2O, and **9**·2CH_3CN, (ii) VT ^{1}H-NMR studies of **9**, and (iii) ab initio investigations of **8** and **10**.[3]

Results and Discussion



Syntheses

The zwitterionic λ^5*Si*-silicates **5**−**9** were prepared according to Scheme 1, starting from the trialkoxy(aminomethyl)silanes $(EtO)_3SiCH_2NH_2$ (**11**), $(MeO)_3SiCH_2N(H)Me$ (**12**), and $(MeO)_3SiCH_2NMe_2$ (**13**). Compounds **8** and **9** were synthesized alternatively according to Scheme 2 and 3, starting from the dialkoxy(phenyl)(aminomethyl)silane $Ph(MeO)_2SiCH_2NMe_2$ (**14**) and from the (ammoniomethyl)tetrafluorosilicate $F_4SiCH_2NMe_2H$ (**15**), respectively.

Following the strategy described for the synthesis of **1**−**4**,[2e,2g] compounds **5**−**9** were prepared according to *method a* by reaction of the respective silanes **11**−**13** with two mol equivalents of glycolic acid and 2-methyllactic acid, respectively (Scheme 1). The reactions were performed in acetonitrile at room temperature and the products **5**−**9** were formed spontaneously in precipitation reactions. Com-

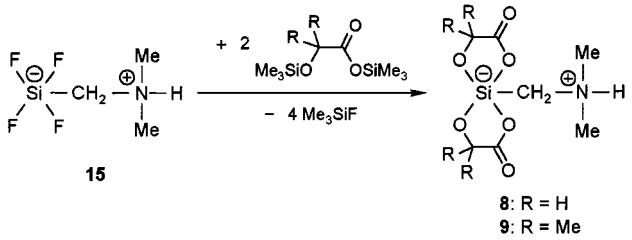
Scheme 1. Syntheses of compounds **5**−**9** according to *method a*



pounds **6**−**9** were isolated, after recrystallization from acetonitrile and drying in vacuo, as colorless crystalline solids (yields: **6**, 77%; **7**, 73%; **8**, 88%; **9**, 79%), whereas compound **5** was obtained as the crystalline hydrate **5**·H_2O (recrystallization from water; yield 78%). Recrystallization of **9** from water also yielded the corresponding hydrate **9**·H_2O which was isolated in almost quantitative yield as a colorless crystalline solid.

Compounds **8** and **9** were synthesized alternatively according to *method b* by reaction of the silane **14** with two mol equivalents of glycolic acid and 2-methyllactic acid, respectively, in acetonitrile at room temperature (Scheme 2). As these syntheses involve a relatively slow Si−C cleavage reaction as rate-determining step, product formation (first crystals formed after several hours) was significantly slower than that observed for *method a*. The syntheses according to *method b* generally yielded directly well-crystallized products which did not need further purification by recrystallization (yields after drying in vacuo: **8**, 98%; **9**, 88%). Crystals of **9**·$2CH_3CN$ (no drying in vacuo) were isolated directly from the reaction mixture.

Scheme 2. Syntheses of compounds **8** and **9** according to *method b*

The third strategy *(method c)* for the preparation of compounds **8** and **9** is based on the reaction of the zwitterionic λ^5*Si*-tetrafluorosilicate **15** with two mol equivalents of $Me_3SiOCH_2C(O)OSiMe_3$ (**16**) and $Me_3SiOCMe_2C(O)OSiMe_3$ (**17**), respectively (Scheme 3). These syntheses were also carried out in acetonitrile at room temperature (first crystals formed after ca. 30 minutes) and the products **8** and **9** were isolated, after recrystallization from acetonitrile and drying in vacuo, as colorless crystalline solids (yields: **8**, 91%; **9**, 79%).

Scheme 3. Syntheses of compounds **8** and **9** according to *method c*

Because of their zwitterionic nature, the high-melting compounds **5**·H_2O, **6**−**9**, **9**·H_2O, and **9**·$2CH_3CN$ are almost insoluble in unpolar organic solvents and also exhibit a very poor solubility in most polar organic solvents. The identity of **5**·H_2O, **6**−**9**, and **9**·H_2O was established by elemental analyses (C, H, N) and solution-state (^1H, ^{13}C, ^{29}Si) and solid-state (^{13}C and ^{29}Si CP/MAS) NMR studies. In addition, the zwitterions **6**−**9** were characterized by mass-spectrometric investigations (FAB MS). Furthermore, crystal structure analyses of compounds **5**·H_2O, **7**, **8**, **9**·H_2O, and **9**·$2CH_3CN$ were performed.

Crystal Structure Analyses

Compounds **5**·H_2O, **7**, **8**, **9**·H_2O, and **9**·$2CH_3CN$ were structurally characterized by single-crystal X-ray diffraction. The structures of the chiral zwitterions **5** and **7**−**9** in the crystal are depicted in Figures 1−5. In all cases the crystals were found to be built up by pairs of Λ- and Δ-enantiomers. The crystal data and the experimental parameters used for these experiments are summarized in Table 6; selected interatomic distances and angles are listed in Table 1.

The *Si*-coordination polyhedra of the zwitterions **5** and **7**−**9** can be described as somewhat distorted trigonal bipyramids, in which each of the axial positions is occupied by the carboxylate oxygen atoms (transition trigonal bipyramid → square pyramid: **5**·H_2O, 4.4%; **7**, 5.4%; **8**, 14.6%; **9**·H_2O, 8.9%; **9**·$2CH_3CN$, 5.1%; pivot atom C1).[4] In all structures the axial Si−O distances [1.7930(12)−1.822(2) Å] are significantly longer than the equatorial ones [1.656(2)−1.6764(8) Å]. The Si−C distances amount to 1.883(2)−1.896(2) Å. Generally, the structural data obtained for the *Si*-coordination polyhedra of the zwitterions **5** and **7**−**9** are very similar to those calculated for **8** and **10** (see ab initio Studies).

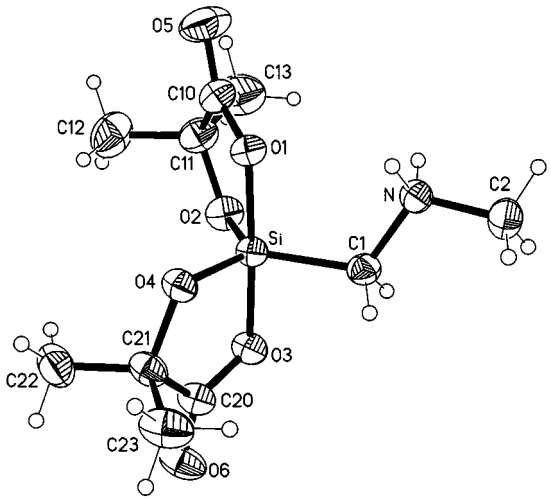

Figure 2. Molecular structure of **7** in the crystal (probability level of displacement ellipsoids 50%), showing the atomic numbering scheme

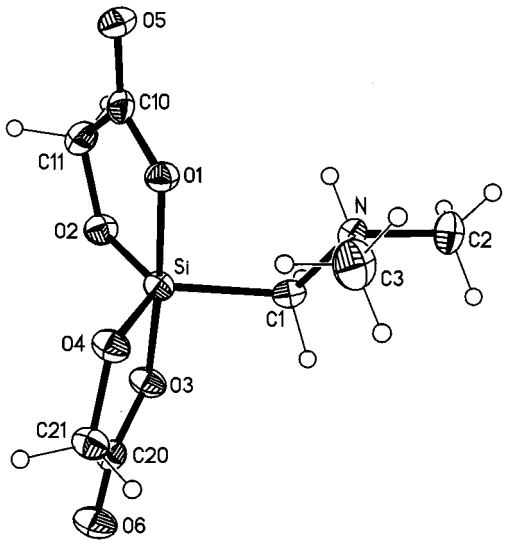

Figure 3. Molecular structure of **8** in the crystal (probability level of displacement ellipsoids 50%), showing the atomic numbering scheme

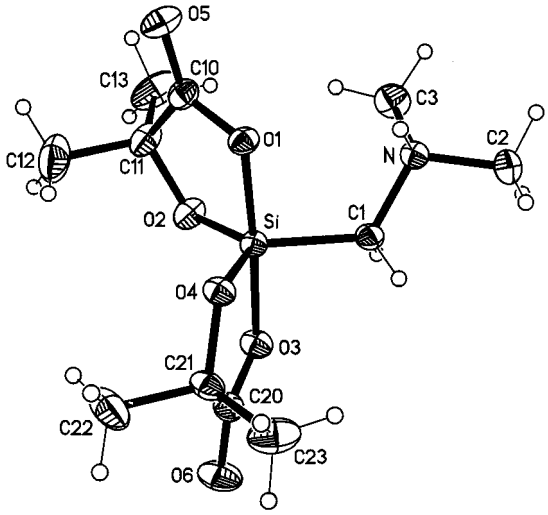

Figure 4. Molecular structure of **9** in the crystal of **9**·H_2O (probability level of displacement ellipsoids 50%), showing the atomic numbering scheme

As would be expected from the presence of the potential NH donor functions and potential oxygen acceptor atoms, intra- and intermolecular N−H···O hydrogen bonds between the zwitterions exist in the crystal of **5**·H_2O, **7**, **8**, **9**·H_2O, and **9**·2CH_3CN. For the hydrates additional intermolecular O−H···O (**5**·H_2O, **9**·H_2O) and N−H···O (**5**·H_2O) hydrogen bonds between the water molecules and the zwitterions were observed. Based on the relevant geometric data, the existence of the hydrogen bonds listed in Table 2 can be assumed.

A bifurcate hydrogen bond [N−H···O1 (intra), N−H···O5 (inter)] leads to the formation of centrosymmetric dimers in the crystal of **8** (Figure 6). These dimers are built up by pairs of enantiomers. The crystal lattices of all the other compounds are characterized by a more complex hydrogen bonding system (Table 2). Although **5**·H_2O, **7**, **9**·H_2O, and **9**·2CH_3CN differ significantly in their hydrogen bonding network, there is at least one common structural feature: in all cases trifurcate hydrogen bonds were observed, each consisting of an intramolecular N−H···O1 interaction and intermolecular N−H···O1 and N−H···O4 interactions.

ab initio Studies

The structure and dynamic behavior of the title compounds were investigated by quantum-chemical methods. For this purpose, computational studies of the anionic model species **10** and the zwitterion **8** were performed. The computational methods used are described in the Experimental Section.

As demonstrated for the model species bis[glycolato(2−)-O^1,O^2]hydridosilicate(1−) (**10**), five different idealized geometries (**10a**−**10e**, Figure 7) have to be considered for the

title compounds. For energetic reasons, trigonal bipyramids with the hydrogen (carbon) atom in an axial site and square pyramids with the hydrogen (carbon) atom in a basal position can be excluded. The trigonal-bipyramidal isomers **10a**–**10c** and the square-pyramidal species **10d** are chiral and therefore exist as pairs of Λ- and Δ-enantiomers, whereas the square-pyramidal species **10e** is achiral. Calculations of the vibrational frequencies for **10a**–**10e** have demonstrated that only the isomers **10a**–**10c** represent local minima, the isomer **10a** being the energetically most favorable one (for selected geometric parameters of **10a**–**10e**, see Table 3).[5] This result is in agreement with the experimentally established crystal structures of **5**·H_2O, **7**, **8**, **9**·H_2O, and **9**·2CH_3CN, indicating that the trigonal-bipyramidal geometry, with the carboxylate oxygen atoms in the axial sites, is indeed the energetically most favorable one. Based on this particular structure, geometry optimizations at the SCF/SVP level were carried out for the zwitterionic λ^5*Si*-silicate **8** (Figure 8).[6] As can be seen from Table 4, the calculated interatomic distances and angles for the *Si*O_4C framework of **8** are in good agreement with the experimentally established values for **5**·H_2O, **7**, **8**, **9**·H_2O, and **9**·2CH_3CN.

These results suggest that the energetically preferred trigonal-bipyramidal *Si*-coordination polyhedra of **5**–**9**, with the carboxylate oxygen atoms in the axial sites, also play the major role in solution, all compounds being expected to exist as pairs of enantiomers. As demonstrated for the model species **10**, an intramolecular isomerization of the antipodes of **5**–**9** should be possible leading to an inversion of absolute configuration of their chiral trigonal-bipyramidal λ^5*Si*-silicate skeletons (Figure 9). According to the results of ab initio studies, the enantiomers Λ-**10a** and Δ-**10a** can be converted into each other along the reaction coordinate Λ-**10a** ⇌ **10**$^{\ddagger 2}$ ⇌ Δ-**10c** ⇌ **10**$^{\ddagger 3}$ ⇌ Λ-**10b** ⇌ **10**$^{\ddagger 1}$ ⇌ Δ-**10b** ⇌ **10**$^{\ddagger 3'}$ ⇌ Λ-**10c** ⇌ **10**$^{\ddagger 2'}$ ⇌ Δ-**10a** (**10**$^{\ddagger 1}$ = **10e**; the pairs **10**$^{\ddagger 2}$/**10**$^{\ddagger 2'}$ and **10**$^{\ddagger 3}$/**10**$^{\ddagger 3'}$ are antipodes) (Figure 9).[7,8] The square-pyramidal species **10**$^{\ddagger 1}$ and the trigonal-bipyramidal species **10**$^{\ddagger 2}$ and **10**$^{\ddagger 3}$ are transition states in this isomerization process.[9] Their relative energies amount to 31.4 kJ mol^{-1} (**10**$^{\ddagger 1}$), 47.1 kJ mol^{-1} (**10**$^{\ddagger 2}$), and 70.8 kJ mol^{-1} (**10**$^{\ddagger 3}$). The hydrogen atoms in these transition states occupy an apical (**10**$^{\ddagger 1}$), equatorial (**10**$^{\ddagger 2}$), or axial (**10**$^{\ddagger 3}$) position (for selected geometric data, see Table 3). The conversions Λ-**10b** ⇌ **10**$^{\ddagger 1}$ ⇌ Δ-**10b** and the conversions Λ-**10a** ⇌ **10**$^{\ddagger 2}$ ⇌ Δ-**10c** (Δ-**10a** ⇌ **10**$^{\ddagger 2'}$ ⇌ Λ-**10c**) can be described in terms of a Berry-type mechanism, with the hydrogen atom as the pivot ligand. In contrast, the conversions Δ-**10c** ⇌ **10**$^{\ddagger 3}$ ⇌ Λ-**10b** (Λ-**10c** ⇌ **10**$^{\ddagger 3'}$ ⇌ Δ-**10b**) differ significantly from a Berry-type mechanism, the transition state being characterized by a distorted trigonal-bipyramidal *Si*-coordination polyhedron with the hydrogen atom in an axial position. As the structure of this transition state is rather twisted [one of the diolato(2–) ligands occupies two equatorial positions], the term "twist mechanism" is suggested for this particular intramolecular isomerization process. The calculated relative energy of the corresponding transition state **10**$^{\ddagger 3}$ (70.8 kJ mol^{-1}) is in good agreement with the experimentally established energy barrier for the isomerization process Λ-**9** ⇌ Δ-**9** (see VT ^{1}H-NMR Studies of **9**).

NMR Studies of 5·H_2O, 6–9, and 9·H_2O

Compounds **5**·H_2O, **6**–**9**, and **9**·H_2O were studied by ^{1}H, ^{13}C, and ^{29}Si solution-state NMR experiments (solvent [D_6]DMSO) and by ^{13}C and ^{29}Si CP/MAS solid-state NMR experiments.[10] All these investigations were performed at room temperature (for VT ^{1}H-NMR studies of **9**, see next chapter).

The isotropic ^{29}Si chemical shifts obtained in the CP/MAS NMR studies of **5**·H_2O, **6**–**9**, and **9**·H_2O (Table 5) clearly characterize the ^{29}Si resonances as arising from pentacoordinate silicon atoms. In the case of **5**·H_2O, **7**, **8**, **9**·H_2O, and **9**·2CH_3CN, pentacoordination of silicon was established independently by single-crystal X-ray diffraction (see Crystal Structure Analyses). As the ^{29}Si chemical shifts obtained in the solid-state NMR experiments are very simi-

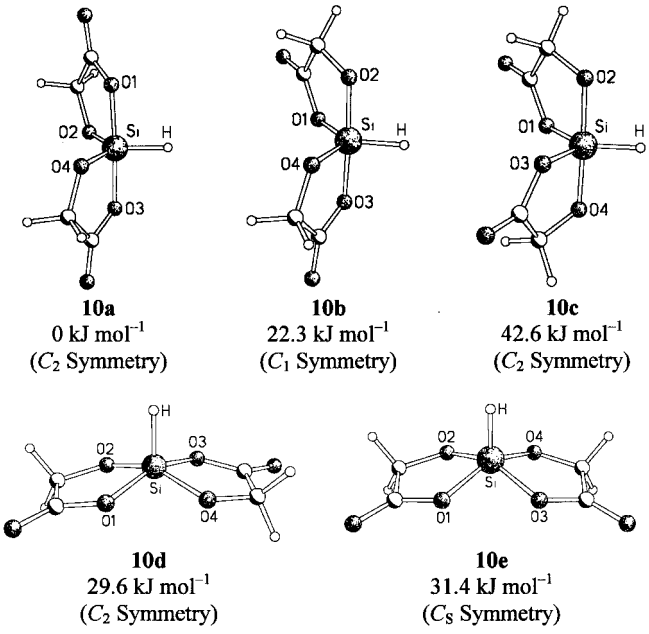

Figure 7. Calculated structures and relative energies of the isomers **10a**−**10e** as obtained by SCF/SVP geometry optimizations

lar to those obtained for the zwitterions **5**−**9** in [D_6]DMSO ($\Delta\delta^{29}Si \leq 2.1$; Table 5), it is concluded that pentacoordination of silicon is also present in solution. In addition, the ^1H chemical shifts observed for the NH protons [δ^1H = 7.2 (**5**·H_2O), 7.9 (**6**), 7.8 (**7**), 8.3 (**8**), 8.4 (**9**, **9**·H_2O)] clearly indicate the presence of ammonium groups in solution. Furthermore, the ^{13}C CP/MAS NMR data of **5**·H_2O, **6**−**9**, and **9**·H_2O are very similar to those obtained for these compounds in solution. Thus, the NMR experiments unequivocally demonstrate that the zwitterions **5**−**9** also exist in [D_6]DMSO.

The solution-state NMR data of the zwitterions **5**−**9** are compatible with the presence of one particular species (such as the trigonal-bipyramidal isomer, with the carboxylate oxygen atoms in the axial positions) or with a rapid low-energy interconversion of different isomers (in this context, see ab initio Studies). As the trigonal-bipyramidal structure, with the carboxylate oxygen atoms in the axial sites, is the energetically most favorable one, it is likely to assume that this particular species is also dominant in solution. The chiral nature of the respective λ^5*Si*-silicate frameworks of **5**−**9** is reflected by the diastereotopism observed for the $SiCH_2N$ (**5**−**9**; AB systems) and $OC(CH_3)_2C$ protons (**5**, **7**, **9**; two separated singlets for the two methyl groups), indicating that the Λ- and Δ-enantiomers of **5**−**9** are configurationally

[a] The isomer **10e** and the transition state $\mathbf{10}^{\neq 1}$ are identical.

stable on the NMR time scale at room temperature. As demonstrated by VT ^{1}H-NMR studies of **9**, the interconversion of the Λ- and Δ-enantiomer is characterized by an energy barrier of 76(1) kJ mol^{-1} ([D$_6$]DMSO), 75(1) kJ mol^{-1} (CD_3CN), and 82(2) kJ mol^{-1} ($CDCl_3$) (see next chapter).

VT ^{1}H-NMR Studies of 9

Compound **9** was studied by solution-state ^{1}H-NMR spectroscopy at 300.1 MHz in the temperature range of 21−118°C ([D$_6$]DMSO), 22−94°C (CD_3CN), and 24−83°C ($CDCl_3$). The concentrations of **9** were 2.5 mmol L^{-1}, 25 mmol L^{-1}, and 250 mmol L^{-1} ([D$_6$]DMSO), 5.0 mmol L^{-1} (CD_3CN), and 2.0 mmol L^{-1} ($CDCl_3$). For all solutions studied, two separated singlets for the diastereotopic methyl groups of the 2-methyllactato(2−) ligands were observed at room temperature, indicating that Λ-**9** and Δ-**9** are configurationally stable on the NMR time scale under these conditions. Upon heating coalescence was observed, indicating a dynamic behavior of the enantiomers of **9** in solution. The temperature dependence of the ^{1}H-NMR spectra of **9** is characterized by complete reversibility (see Figure 10).

For all solutions of **9** in [D$_6$]DMSO (c = 2.5−250 mmol L^{-1}) coalescence was observed at 76°C. The calculated energy barrier (line-shape analysis) for the Λ/Δ-interconversion of the enantiomers of **9** amounts to $\Delta G^{\neq}$ = 76(1) kJ mol^{-1} and is independent on the concentration. The activation free enthalpy is similar in CD_3CN [$\Delta G^{\neq}$ = 75(1) kJ mol^{-1}] and somewhat higher in $CDCl_3$ [$\Delta G^{\neq}$ = 82(2) kJ mol^{-1}]. The coalescence temperature in CD_3CN was 66°C. As coalescence in $CDCl_3$ could not be observed below the boiling point of the solvent, the respective coalescence temperature could not be established directly in these experiments and therefore had to be determined by simulations (calculated coalescence temperature ca. 90°C).

As the coalescence temperature does not depend on the concentration (studies with **9** in [D$_6$]DMSO; c = 2.5−250 mmol L^{-1}), first-order kinetics for the Λ/Δ-isomerization can be assumed suggesting an intramolecular process. This is in accordance with the results obtained by the ab initio

Conclusions

The chiral title compounds exist as pairs of Λ- and Δ-enantiomers in the solid state and in solution. The trigonal-bipyramidal structure of the respective λ^5*Si*-silicate skeletons, with the carboxylate oxygen atoms in the axial sites, is the energetically most stable one. The Λ- and Δ-enantiomers of the zwitterionic λ^5*Si*-silicates **5**−**9** are configurationally stable in solution on the NMR time scale (organic solvents, room temperature) and undergo an intramolecular

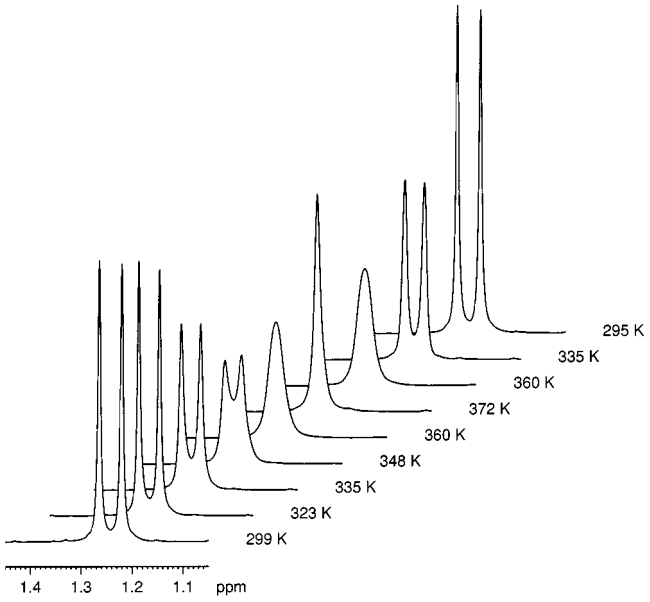

Figure 10. Temperature dependence of the ^{1}H-NMR signals for the two diastereotopic methyl groups of the 2-methyllactato(2−) ligands of **9** (solution in [D_6]DMSO; c = 250 mmol L^{-1}, 300.1 MHz) upon heating from 299 K to 372 K and subsequent cooling to 295 K

Λ/Δ-isomerization with an activation free enthalpy of ca. 75−80 kJ mol^{-1} (experimentally established for **9**; calculated energy barrier for **10**: 70.8 kJ mol^{-1}).

Experimental Section

General Procedures: All syntheses were carried out under dry nitrogen. The organic solvents used were dried and purified according to standard procedures and stored under nitrogen. − Melting points were determined with a Leitz Biomed microscope equipped with a heater (Leitz, Model M 350). − The ^{1}H, ^{13}C, and ^{29}Si solution-state NMR spectra were recorded at room temperature on a Bruker DRX-300 NMR spectrometer (^{1}H, 300.1 MHz; ^{13}C, 75.5 MHz; ^{29}Si, 59.6 MHz). $CDCl_3$, CD_3CN, C_6D_6, and [D$_6$]DMSO were used as solvents. Chemical shifts (ppm) were determined relative to internal $CHCl_3$ (^{1}H, δ = 7.24; $CDCl_3$), CHD_2CN (^{1}H, δ = 1.94; CD_3CN), C_6HD_5 (^{1}H, δ = 7.28; C_6D_6), C_6D_6 (^{13}C, δ = 128.0; C_6D_6), [D$_5$]DMSO (^{1}H, δ = 2.50; [D$_6$]DMSO), [D$_6$]DMSO (^{13}C, δ = 39.43; [D$_6$]DMSO), and external TMS (^{29}Si, δ = 0; C_6D_6, [D$_6$]DMSO). Assignment of the ^{13}C-NMR data was supported by DEPT 135 experiments. ^{13}C and ^{29}Si CP/MAS NMR spectra were recorded at room temperature on a Bruker DSX-400 NMR spectrometer with bottom layer rotors of ZrO_2 (diameter 7 mm) containing ca. 20−300 mg of sample [^{13}C, 100.6 MHz; ^{29}Si, 79.5 MHz; TMS as external standard (δ = 0); spinning rate 5000 Hz; contact time 5 ms; 90° ^{1}H transmitter pulse length 4.0 μs; repetition time 5 s (^{13}C) or 4 s (^{29}Si)]. − Mass spectra were obtained with a Finnigan MAT-8430 mass spectrometer (FAB MS; 3-nitrobenzyl alcohol as liquid matrix, xenon as FAB source) or a Trio-1000 mass spectrometer (ThermoQuest; EI MS, 70 eV). The selected *m*/*z* values given refer to the isotopes ^{1}H, ^{12}C, ^{14}N, ^{16}O, and ^{28}Si. − Elemental analyses were determined by Beller, Mikroanalytisches Laboratorium (Göttingen, Germany).

(Ammoniomethyl)bis[2-methyllactato(2−)-*O*^{1},*O*^{2}]silicate Hydrate (5·H$_2$O): A solution of **11** (967 mg, 5.00 mmol) in acetonitrile (2.5 mL) was added dropwise at room temperature within 2 min to a solution of 2-methyllactic acid (1.04 g, 9.99 mmol) in acetonitrile (22.5 mL). The reaction mixture was stirred for 1 min and then kept undisturbed at room temperature for 24 h (formation of a precipitate ca. 8 min after combining the reactants). The precipitate (compound **5**, crude product) was filtered off, washed with cold acetonitrile (3 × 5 mL), dissolved in water (40 mL), and the solution then kept undisturbed at room temperature for 6 d (slow evaporation of the water). Compound **5**·H$_2$O was isolated in 78% yield (1.10 g) as a colorless crystalline product. Mp 264°C. − ^{1}H NMR ([D$_6$]DMSO, 300.1 MHz): δ = 1.21 (s, 6 H, CCH_3), 1.25 (s, 6 H, CCH_3), 2.01 and 2.19 (AB system, J_{AB} = −16.0 Hz, 2 H, $SiCH_2N$), 3.33 (s, 2 H, H_2O), 7.2 (broad s, 3 H, NH_3). − $^{13}C\{^{1}H\}$ NMR ([D$_6$]DMSO, 75.5 MHz): δ = 26.8 (CCH_3), 27.6 (CCH_3), 28.1 ($SiCH_2N$), 73.7 (OCC_3), 178.5 (C=O). − ^{13}C CP/MAS NMR (36854 transients): δ = 24.7 and 27.3 (CCH_3, $SiCH_2N$), 76.3 (OCC_3), 180.7 (C=O), 182.5 (C=O). − $^{29}Si\{^{1}H\}$ NMR ([D$_6$]DMSO, 59.6 MHz): δ = −98.0. − ^{29}Si CP/MAS NMR (13168 transients): δ = −96.4. − $C_9H_{19}NO_7Si$ (281.3): calcd C 38.42, H 6.81, N 4.98; found C 38.7, H 6.6, N 4.9.

Bis[glycolato(2−)-*O*^{1},*O*^{2}][(methylammonio)methyl]silicate (6): The synthesis was carried out analogously to that of compound **5** by combining a solution of **12** (826 mg, 5.00 mmol) in acetonitrile (2.5 mL) with a solution of glycolic acid (761 mg, 10.0 mmol) in acetonitrile (22.5 mL) (spontaneous formation of a precipitate after combining the reactants). Compound **6** was isolated in 77% yield (852 mg) as a colorless crystalline product. Mp 165°C. − ^{1}H NMR ([D$_6$]DMSO, 300.1 MHz): δ = 2.27 and 2.32 (AB system, J_{AB} = −15.7 Hz, 2 H, $SiCH_2N$), 2.46 (s, 3 H, NCH_3), 3.92 (s, 4 H, OCH_2C), 7.9 (broad s, 2 H, NH_2). − $^{13}C\{^{1}H\}$ NMR ([D$_6$]DMSO, 75.5 MHz): δ = 36.1 (NCH_3), 39.0 ($SiCH_2N$), 62.8 (OCH_2C), 174.0 (C=O). − ^{13}C CP/MAS NMR (3540 transients): δ = 37.2, 38.4, 39.5, and 41.3 (NCH_3, $SiCH_2N$), 62.6 (OCH_2C), 63.3 (OCH_2C), 64.1 (OCH_2C), 174.5 (C=O), 179.2 (C=O), 180.5 (C=O). − $^{29}Si\{^{1}H\}$ NMR ([D$_6$]DMSO, 59.6 MHz): δ = −89.2. − ^{29}Si CP/MAS NMR (215 transients): δ = −88.7. − FAB MS (positive ions): *m*/*z* (%) = 222 (32) [*M* + H$^+$], 154 (100) [matrix]. − $C_6H_{11}NO_6Si$ (221.2): calcd C 32.57, H 5.01, N 6.33; found C 32.5, H 5.2, N 6.2.

[(Methylammonio)methyl]bis[2-methyllactato(2−)-*O*^{1},*O*^{2}]silicate (7): The synthesis was carried out analogously to that of compound **5** by combining a solution of **12** (826 mg, 5.00 mmol) in acetonitrile (2.5 mL) with a solution of 2-methyllactic acid (1.04 g, 9.99 mmol) in acetonitrile (22.5 mL) (spontaneous formation of a precipitate after combining the reactants). Compound **7** was isolated in 73% yield (1.01 g) as a colorless crystalline product. Mp 310°C (dec.) − ^{1}H NMR ([D$_6$]DMSO, 300.1 MHz): δ = 1.21 (s, 6 H, CCH_3), 1.26 (s, 6 H, CCH_3), 2.18 and 2.39 (AB system, J_{AB} = −15.9 Hz, 2 H, $SiCH_2N$), 2.47 (s, 3 H, NCH_3), 7.8 (broad s, 2 H, NH_2). − $^{13}C\{^{1}H\}$ NMR ([D$_6$]DMSO, 75.5 MHz): δ = 26.7 (CCH_3), 27.6 (CCH_3), 36.2 (NCH_3), 39.2 ($SiCH_2N$), 73.8 (OCC_3), 178.4 (C=O). − ^{13}C CP/MAS NMR (109 transients): δ = 25.4 (CCH_3), 27.2 (CCH_3), 27.8 (CCH_3), 28.4 (CCH_3), 38.7 (NCH_3), 41.4 ($SiCH_2N$), 75.3 (OCC_3), 76.6 (OCC_3), 179.6 (C=O), 183.7 (C=O). − $^{29}Si\{^{1}H\}$ NMR ([D$_6$]DMSO, 59.6 MHz): δ = −99.2. − ^{29}Si CP/MAS NMR (293 transients): δ = −98.1. − FAB MS (positive ions): *m*/*z* (%) = 278 (30) [*M* + H$^+$], 154 (100) [matrix]. − $C_{10}H_{19}NO_6Si$ (277.3): calcd C 43.31, H 6.90, N 5.05; found C 43.4, H 6.9, N 5.1.

[(Dimethylammonio)methyl]bis[glycolato(2−)-*O*^{1},*O*^{2}]silicate (8): *Method a:* The synthesis was carried out analogously to that of compound **5** by combining a solution of **13** (896 mg, 5.00 mmol) in acetonitrile (2.5 mL) with a solution of glycolic acid (761 mg, 10.0 mmol) in acetonitrile (22.5 mL) (spontaneous formation of a precipitate after combining the reactants). Compound **8** was isolated in 88% yield (1.04 g) as a colorless crystalline product. Mp 221°C (dec). − ^{1}H NMR ([D$_6$]DMSO, 300.1 MHz): δ = 2.51 and 2.63 (AB system, J_{AB} = −15.9 Hz, 2 H, $SiCH_2N$), 2.73 (s, 6 H, NCH_3), 3.94 (s, 4 H, OCH_2C), 8.3 (broad s, 1 H, NH). − $^{13}C\{^{1}H\}$ NMR ([D$_6$]DMSO, 75.5 MHz): δ = 45.8 (NCH_3), 49.3 ($SiCH_2N$), 62.7 (OCH_2C), 173.9 (C=O). − ^{13}C CP/MAS NMR (1437 transients): δ = 44.3 (NCH_3), 49.0 (NCH_3), 50.8 ($SiCH_2N$), 64.0 (OCH_2C), 64.9 (OCH_2C), 176.6 (C=O), 179.9 (C=O). − $^{29}Si\{^{1}H\}$ NMR ([D$_6$]DMSO, 59.6 MHz): δ = −90.3. − ^{29}Si CP/MAS NMR (20 transients): δ = −88.6. − FAB MS (positive ions): *m*/*z* (%) = 236 (39) [*M* + H$^+$], 154 (100) [matrix]. − $C_7H_{13}NO_6Si$ (235.3): calcd C 35.74, H 5.57, N 5.95; found C 35.2, H 5.6, N 6.1.

Method b: A solution of **14** (1.13 g, 5.01 mmol) in acetonitrile (2.5 mL) was added at room temperature to a solution of glycolic acid (761 mg, 10.0 mmol) in acetonitrile (22.5 mL). The reaction mixture was stirred for 1 min and then kept undisturbed at room temperature for 7 d (formation of a precipitate ca. 18 h after combining the reactants). The precipitate was isolated by filtration, washed with cold acetonitrile (3 × 5 mL), and then dried in vacuo (0.01 Torr, 20°C, 12 h) to give 1.15 g (yield 98%) of colorless crystals. Mp 221°C (dec). − $C_7H_{13}NO_6Si$ (235.3): calcd C 35.74, H 5.57, N 5.95; found C 35.7, H 5.6, N 6.3. For spectroscopic data, see above.

Method c: **16** (1.36 g, 6.17 mmol) was added to a stirred solution of **15** (502 mg, 3.08 mmol) in acetonitrile (20 mL) (formation of a precipitate ca. 20 min after combining the reactants) and the reaction mixture stirred at room temperature for 24 h. The precipitate was filtered off and recrystallized from acetonitrile. The product was isolated by filtration and then dried in vacuo (0.01 Torr, 20°C, 4 h) to give 658 mg (yield 91%) of colorless crystals. Mp 221°C

(dec). – $C_7H_{13}NO_6Si$ (235.3): calcd C 35.74, H 5.57, N 5.95; found C 35.8, H 5.4, N 6.1. For spectroscopic data, see above.

[(Dimethylammonio)methyl]bis[2-methyllactato(2–)-*O*¹,*O*²]silicate (**9**): *Method a:* The synthesis was carried out analogously to that of compound **5** by combining a solution of **13** (896 mg, 5.00 mmol) in acetonitrile (2.5 mL) with a solution of 2-methyllactic acid (1.04 g, 9.99 mmol) in acetonitrile (22.5 mL) (spontaneous formation of a precipitate after combining the reactants). Compound **9** was isolated in 79% yield (1.15 g) as a colorless crystalline product. Mp 242°C. – ^{1}H NMR ([D$_6$]DMSO, 300.1 MHz): δ = 1.21 (s, 6 H, CCH_3), 1.26 (s, 6 H, CCH_3), 2.46 and 2.66 (AB system, J_{AB} = −15.9 Hz, 2 H, $SiCH_2N$), 2.75 (s, 6 H, NCH_3), 8.4 (broad s, 1 H, NH). – ^{13}C{^{1}H} NMR ([D$_6$]DMSO, 75.5 MHz): δ = 26.6 (C*C*H$_3$), 27.5 (C*C*H$_3$), 46.4 (NCH_3), 50.2 ($SiCH_2N$), 73.7 (O*C*C$_3$), 178.3 (C=O). – ^{13}C CP/MAS NMR (912 transients): δ = 24.8–29.7 (C*C*H$_3$), 47.4 (NCH_3), 48.6 (NCH_3), 51.5 ($SiCH_2N$), 52.2 ($SiCH_2N$), 75.7 (O*C*C$_3$), 76.2 (O*C*C$_3$), 177.1 (C=O), 177.7 (C=O), 178.4 (C=O), 182.0 (C=O). – ^{29}Si{^{1}H} NMR ([D$_6$]DMSO, 59.6 MHz): δ = −100.5. – ^{29}Si CP/MAS NMR (54 transients): δ = −100.9, −100.1. – FAB MS (positive ions): *m*/*z* (%) = 292 (100) [*M* + H$^+$]. – $C_{11}H_{21}NO_6Si$ (291.4): calcd C 45.34, H 7.26, N 4.81; found C 45.9, H 7.3, N 4.9.

Method b: The synthesis was carried out analogously to that of **8** *(method b)* by combining a solution of **14** (1.13 g, 5.01 mmol) in acetonitrile (2.5 mL) with a solution of 2-methyllactic acid (1.04 g, 9.99 mmol) in acetonitrile (22.5 mL) (first crystals formed ca. 40 h after combining the reactants). Compound **9** was isolated in 88% yield (1.28 g) as a colorless crystalline product. Mp 242°C. – $C_{11}H_{21}NO_6Si$ (291.4): calcd C 45.34, H 7.26, N 4.81; found C 45.1, H 7.4, N 4.9. For spectroscopic data, see above.

Method c: The synthesis was carried out analogously to that of **8** *(method c)* by combining a solution of **17** (2.51 g, 10.1 mmol) with a solution of **15** (770 mg, 4.72 mmol) in acetonitrile (20 mL) (formation of a precipitate ca. 30 min after combining the reactants). Compound **9** was isolated in 79% yield (1.09 g) as a colorless crystalline product. Mp 242°C. – $C_{11}H_{21}NO_6Si$ (291.4): calcd C 45.34, H 7.26, N 4.81; found C 45.3, H 7.1, N 4.8. For spectroscopic data, see above.

[(Dimethylammonio)methyl]bis[2-methyllactato(2–)-*O*¹,*O*²]silicate Hydrate (**9**·H_2O): Compound **9** (291 mg, 999 μmol) was dissolved in water (10 mL) and the solution kept undisturbed at room temperature for 6 d (slow evaporation of the water). Compound **9**·H_2O was isolated in 99% yield (306 mg) as a colorless crystalline product. Mp 276°C. – ^{1}H NMR ([D$_6$]DMSO, 300.1 MHz): the NMR data were identical with those of **9**, with an additional resonance signal at δ = 3.33 (s, 2 H, H_2O). – ^{13}C{^{1}H} NMR ([D$_6$]DMSO, 75.5 MHz): the NMR data were identical with those of **9**. – ^{13}C CP/MAS NMR (204 transients): δ = 26.2 (C*C*H$_3$), 27.0 (C*C*H$_3$), 28.5 (C*C*H$_3$), 30.4 (C*C*H$_3$), 47.3 (NCH_3), 49.3 (NCH_3), 51.1 ($SiCH_2N$), 75.8 (O*C*C$_3$), 76.3 (O*C*C$_3$), 181.4 (C=O). – ^{29}Si{^{1}H} NMR ([D$_6$]DMSO, 59.6 MHz): the NMR data were identical with those of **9**. – ^{29}Si CP/MAS NMR (200 transients): δ = −98.4 – $C_{11}H_{23}NO_7Si$ (309.4): calcd C 42.70, H 7.49, N 4.53; found C 42.4, H 7.4, N 4.4.

[(Dimethylammonio)methyl]bis[2-methyllactato(2–)-*O*¹,*O*²]silicate–Diacetonitrile (**9**·2CH_3CN): The synthesis was carried out analogously to that of **9** *(method b)*, except for the isolation by filtration and drying of the crystals formed. The crystal used for the X-ray diffraction study was taken directly from the reaction mixture. Attempts to characterize the bulk material after filtration and careful drying gave unsatisfactory results due to the loss of acetonitrile. Drying in vacuo at room temperature resulted in a complete loss of acetonitrile.

(Aminomethyl)triethoxysilane (**11**): Synthesis according to ref.[11]

Trimethoxy[(methylamino)methyl]silane (**12**): A mixture of (chloromethyl)trimethoxysilane (synthesis according to ref.[12]) (17.1 g, 100 mmol) and methylamine (15.5 g, 499 mmol) was heated in an autoclave at 120°C/20 bar for 16 h. After the reaction mixture was cooled to room temperature, the excess methylamine was evaporated and *n*-pentane (100 mL) added to the residue. The resulting precipitate was filtered off and the solvent removed from the filtrate under reduced pressure. The oily residue was distilled in vacuo over a Vigreux column to give 7.60 g (yield 46%) of a colorless liquid. Bp 40°C/6 Torr. – ^{1}H NMR (C_6D_6, 300.1 MHz): δ = 0.8 (broad s, 1 H, NH), 2.27 (s, 2 H, $SiCH_2N$), 2.38 (s, 3 H, NCH_3), 3.60 (s, 9 H, OCH_3). – ^{13}C{^{1}H} NMR (C_6D_6, 75.5 MHz): δ = 36.4 ($SiCH_2N$), 41.0 (NCH_3), 50.5 (OCH_3). – ^{29}Si{^{1}H} NMR (C_6D_6, 59.6 MHz): δ = −47.7. – EI MS: *m*/*z* (%) = 165 (14) [*M*$^+$], 121 (22) [*M*$^+$ – $CH_2N(H)CH_3$], 44 (100) [CH_2=N(H)CH_3^+]. – $C_5H_{15}NO_3Si$ (165.3): calcd C 36.34, H 9.15, N 8.48; found C 36.1, H 8.9, N 8.1.

[(Dimethylamino)methyl]trimethoxysilane (**13**): Synthesis according to ref.[2a]

[(Dimethylamino)methyl]dimethoxy(phenyl)silane (**14**): The synthesis was carried out analogously to that of **12** by treating (chloromethyl)dimethoxy(phenyl)silane (synthesis according to ref.[12]) (12.3 g, 56.8 mmol) with an excess of dimethylamine (6.92 g, 153 mmol). Compound **14** was isolated in 81% yield (10.4 g) as a colorless liquid. Bp 115°C/6 Torr. – ^{1}H NMR (C_6D_6, 300.1 MHz): δ = 2.31 (s, 2 H, $SiCH_2N$), 2.31 (s, 6 H, NCH_3), 3.61 (s, 6 H, OCH_3), 7.3–7.4 and 7.9–8.1 (m, 5 H, SiC_6H_5). – ^{13}C{^{1}H} NMR (C_6D_6, 75.5 MHz): δ = 47.7 ($SiCH_2N$), 49.7 (NCH_3), 50.5 (OCH_3), 128.1 (C-3/C-5, SiC_6H_5), 130.4 (C-4, SiC_6H_5), 133.7 (C-1, SiC_6H_5), 134.9 (C-2/C-6, SiC_6H_5). – ^{29}Si{^{1}H} (C_6D_6, 59.6 MHz): δ = −23.1. – EI MS: *m*/*z* (%) = 225 (2) [*M*$^+$], 210 (6) [*M*$^+$ – CH_3], 167 (8) [*M*$^+$ – $CH_2N(CH_3)_2$] 58 (100) [CH_2=N$(CH_3)_2^+$]. – $C_{11}H_{19}NO_2Si$ (225.4): calcd C 58.63, H 8.50, N 6.22; found C 59.0, H 8.6, N 6.0.

[(Dimethylammonio)methyl]tetrafluorosilicate (**15**): Synthesis according to ref.[2k]

(Trimethylsilyloxy)acetic Acid Trimethylsilyl Ester (**16**): Synthesis according to ref.[13]

2-Methyl-2-(trimethylsilyloxy)propionic Acid Trimethylsilyl Ester (**17**): Synthesis according to ref.[14]

Crystal Structure Analyses: Suitable single crystals of **5**·H_2O and **9**·H_2O were obtained by crystallization of **5** and **9** from water (slow evaporation of the solvent at room temperature), single crystals of **7** and **8** were obtained by crystallization from acetonitrile (slow cooling of a boiling saturated solution to room temperature). A suitable single crystal of **9**·2CH_3CN was isolated directly from the reaction mixture (synthesis according to *method b*). The crystals were mounted on a glass fiber and then transferred to the cold gas stream of the diffractometer [**5**·H_2O, **9**·H_2O: Syntex-R3 diffractometer; **7**: Stoe STADI-4 diffractometer; **8**: Enraf-Nonius CAD4 diffractometer; **9**·2CH_3CN: Stoe IPDS; monochromated Mo-*Kα* radiation (λ = 0.71073 Å)]. For compound **7** a semiempirical absorption correction (ψ scans) was applied. All structures were solved by direct methods.[15] All non-hydrogen atoms were refined anisotropically.[16] For the structures of **7**, **8**, **9**·H_2O, and **9**·2CH_3CN a riding model was employed in the refinement of the CH hydrogen atom positions; for the structure of **5**·H_2O the CH hydrogen atoms were localized in difference Fourier syntheses and

refined freely. In all cases, the positions of the NH and OH hydrogen atoms were localized in difference Fourier syntheses and refined freely.

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-101620 (**5**·H_2O), CCDC-101621 (**7**), CCDC-101622 (**8**), CCDC-101623 (**9**·H_2O), and CCDC-101624 (**9**·$2CH_3CN$). Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [fax: (+44) 1223/336-033; e-mail: deposit@ccdc.cam.ac.uk].

Computational Methods: Geometry optimizations at the SCF/SVP level for the anionic model species **10** and the zwitterion **8** were performed using the TURBOMOLE program system.[17] Stationary geometries and transition states were characterized as local minima (zero imaginary frequencies) and saddle points (one imaginary frequency), respectively, by calculation of the vibrational frequencies. The energies given for **10** include the single point MP2 energy (SVP basis set) and the zero point vibrational energy.

VT ^{1}H-NMR Studies of 9: The experiments were carried out analogously to the standard ^{1}H-NMR measurements using a Bruker DRX-300 NMR spectrometer. [D_6]DMSO, CD_3CN, and $CDCl_3$ were used as solvents. The thermocouple used with the probe was calibrated for high temperatures according to ref.[18] using a 80% solution of 1,2-ethanediol in [D_6]DMSO. Spectra were recorded in the temperature range of 21−118°C ([D_6]DMSO), 22−94°C (CD_3CN), and 24−83°C ($CDCl_3$). The time required for temperature equilibration was 15 min. The data obtained were fitted and simulated by using the Bruker software program WinDyna 1.0b (line-shape analysis). From the simulated spectra the coalescence temperatures T_C and the exchange rates k_C at the coalescence points were extracted and the respective values for the activation free enthalpy $\Delta G^{\neq}$ for the exchange process were calculated by using the Eyring equation:

$$\Delta G^{\neq} = 19.14\ T_C\ [10.32 + \log(T_C/k_C)]\ [\text{J mol}^{-1}]$$[19]

Acknowledgments

We thank the Deutsche Forschungsgemeinschaft and the Fonds der Chemischen Industrie for financial support, and the Bayer AG (Leverkusen and Wuppertal, Germany) and Merck KGaA (Darmstadt, Germany) for various gifts of chemicals. In addition, the authors would like to thank Prof. Dr. R. Ahlrichs and Dr. M. Häser (†) for helpful discussions in context with the ab initio studies.

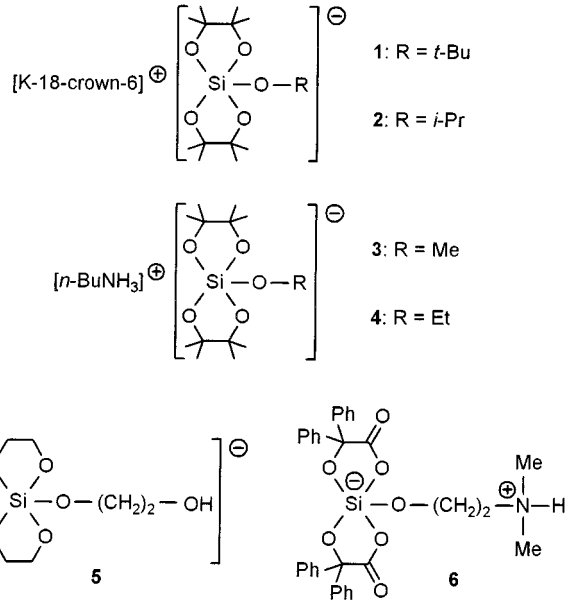
New Chiral Zwitterionic λ^5*Si*-Silicates with an SiO_5 or SiO_4C Framework: Syntheses, Crystal Structures, and Properties

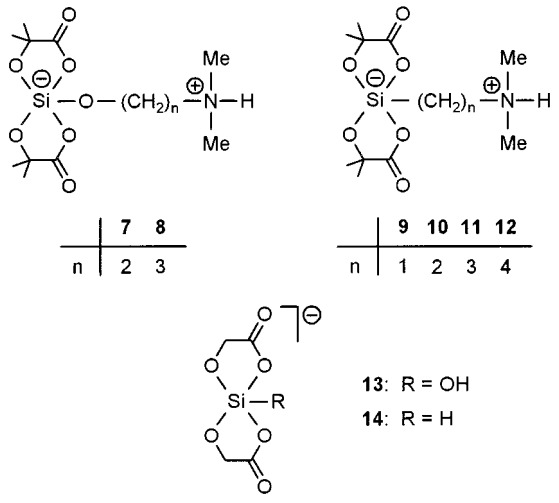
Reinhold Tacke,*[a] Brigitte Pfrommer,[a] Melanie Pülm,[a] and Rüdiger Bertermann[a]



Dedicated to Professor Helmut Werner on the occasion of his 65th birthday

Keywords: Ab initio studies / Chirality / Pentacoordinate silicon / Stereochemistry / Zwitterionic λ^5*Si*-silicates

The syntheses of the zwitterionic (molecular) spirocyclic λ^5*Si*-silicates **7** and **8** (SiO_5 skeletons) and **10**–**12** (SiO_4C skeletons) are described. These chiral compounds contain a pentacoordinate (formally negatively charged) silicon atom and a tetracoordinate (formally positively charged) nitrogen atom. The pairs **7**/**11** and **8**/**12** are isoelectronic O/CH_2 analogues and **10**–**12** represent a series of homologous compounds containing different alkylene spacers that connect the *ate* and *onium* center of these zwitterions. Compound **7**, **8**, and **10**–**12** were studied by single-crystal X-ray diffraction, solution-state (^{1}H, ^{13}C, ^{29}Si) and solid-state (^{29}Si CP/MAS) NMR spectroscopy, and VT ^{1}H-NMR spectroscopy. The experimental investigations were completed by ab initio studies of the related anionic λ^5*Si*-silicate **13**.



Introduction

Numerous pentacoordinate silicon compounds have been described in the literature over the past thirty years.[1] Surprisingly, only a few examples with an SiO_5 skeleton have been reported. To the best of our knowledge, the ionic λ^5*Si*-silicates **1**,[2a] **2**,[2b] **3**·MeOH,[2a] **4**,[2a] and **5**[2c] as well as the zwitterionic λ^5*Si*-silicate **6**·DMF[2d] are the only examples of this particular type of compound that have been structurally characterized by single-crystal X-ray diffraction.[2]

The spirocyclic anions of **1**−**5** contain two bidentate ligands of the ethane-1,2-diolato(2−) type, whereas the spirocyclic zwitterion **6** contains two bidentate benzilato(2−)-O^1,O^2 ligands.

Here we report on the syntheses, crystal structure analyses, and properties of two further zwitterionic λ^5*Si*-silicates with an SiO_5 framework, compounds **7** and **8**.[3] These spirocyclic zwitterions contain two bidentate 2-methyllactato(2−)-O^1,O^2 ligands. In addition, the syntheses, crystal structures, and properties of the related zwitterionic λ^5*Si*-silicates **10**−**12** (SiO_4C skeletons) are described.[3] The zwitterions **11** and **12** formally derive from compounds **7** and **8** by replacement of an oxygen atom by a methylene group. Furthermore, the zwitterions **10**−**12** can be regarded as homologs of compound **9** which has recently been described in the literature.[4] The zwitterionic λ^5*Si*-silicates **9**−**12** differ in their alkylene spacers that connect the *ate* and *onium* centers of these molecules. The experimental investigations

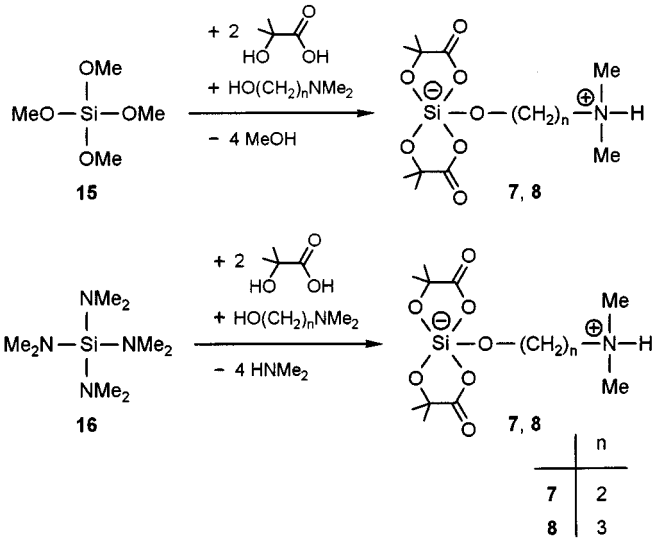
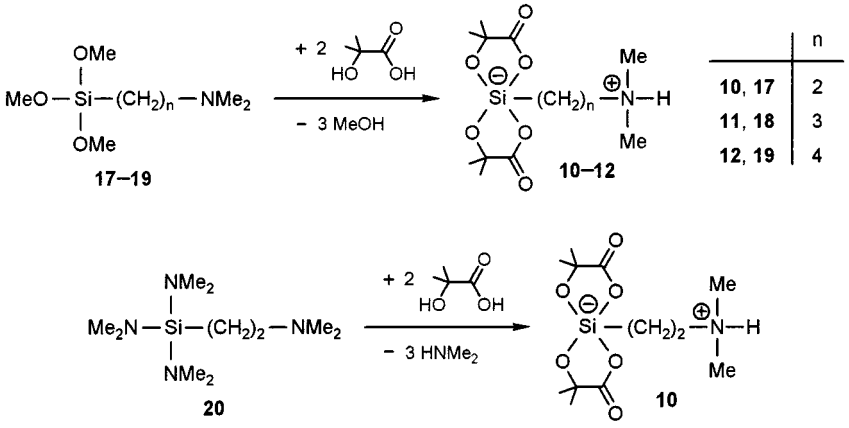
concerning compounds **7** and **8** (SiO_5 skeletons) were completed by ab initio studies of the related anionic λ^5*Si*-silicate **13** (for ab initio investigations of the anion **14**, see ref.[4]).



The main goal of the experimental and computational studies presented here was to contribute to the chemistry of pentacoordinate silicon compounds with an SiO_5 framework. These investigations were carried out with a special emphasis on the comparison of the structures and properties of the O/CH_2 analogues **7/11** and **8/12**. A further concern was to study the influence of the alkylene spacer on the structures and properties of the homologs **9**−**12**.

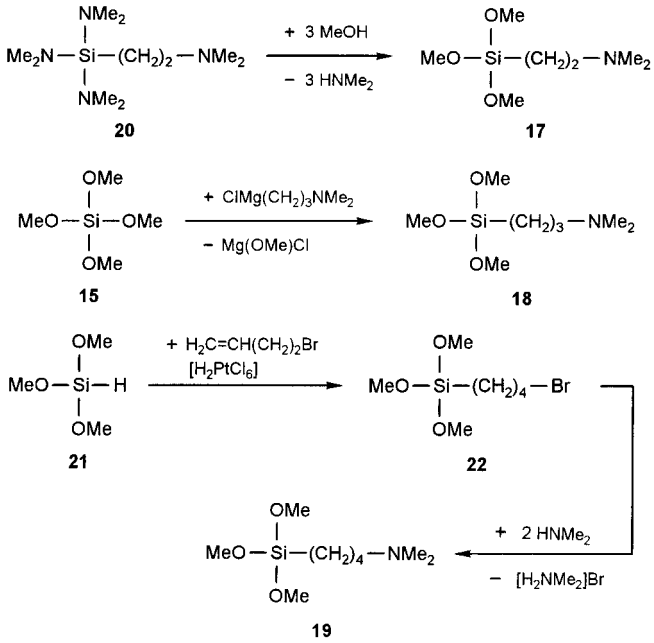
Results and Discussion

Syntheses



The zwitterionic λ^5*Si*-silicates **7** and **8** were prepared according to Scheme 1 using two different synthetic methods each. The first method implies reaction of tetramethoxysilane (**15**) with two mol equivalents of 2-methyllactic acid and one mol equivalent of 2-(dimethylamino)ethanol and 3-(dimethylamino)propanol, respectively. The reactions were carried out in boiling acetonitrile and the resulting methanol, along with part of the solvent, was removed by distillation. After the reaction mixtures were cooled to room temperature, the products precipitated. Compounds **7** and **8** were isolated, after recrystallization from acetonitrile, in 73% (**7**) and 71% yield (**8**). The second method is based on treatment of tetrakis(dimethylamino)silane[5] (**16**) with one mol equivalent of the respective aminoalcohol, followed by treatment with two mol equivalents of 2-methyllactic acid. The syntheses were again carried out in boiling acetonitrile and compounds **7** and **8** were isolated, after recrystallization from acetonitrile, in 62% (**7**) and 53% yield (**8**).

The zwitterionic λ^5*Si*-silicates **10**−**12** were synthesized according to Scheme 2 by reaction of the respective [(dimethylamino)alkyl]trimethoxysilanes **17**−**19** with 2-methyllactic acid (molar ratio 1:2) in acetonitrile at room temperature. Compounds **10**−**12** were isolated, after recrystallization from acetonitrile, in 78% (**10**), 88% (**11**), and 90% yield (**12**). Alternatively, compound **10** was synthesized according to Scheme 2 by treatment of tris(dimethylamino)[2-(dimethylamino)ethyl]silane[6] (**20**) with two mol equivalents of 2-methyllactic acid in acetonitrile and isolated, after recrystallization from acetonitrile, in 82% yield.



Scheme 1. Syntheses of compounds **7** and **8**

The [(dimethylamino)alkyl]trimethoxysilanes **17**−**19** used for the syntheses of **10**−**12** were prepared according to Scheme 3. [2-(Dimethylamino)ethyl]trimethoxysilane (**17**) was synthesized by methanolysis of the corresponding tris(dimethylamino)silane **20** (yield 84%). [3-(Dimethylamino)propyl]trimethoxysilane (**18**) was obtained by reaction of tetramethoxysilane (**15**) with 3-(dimethylamino)prop-1-ylmagnesium chloride in tetrahydrofuran (yield 71%). [4-(Dimethylamino)butyl]trimethoxysilane (**19**) was prepared by a two-step synthesis starting from trimethoxysilane (**21**). Hydrosilylation of 4-bromo-1-butene with **21** in an autoclave (H_2PtCl_6 as catalyst) gave (4-bromobutyl)trimethoxysilane (**22**) (yield 71%) which upon reaction with dimethylamine in an autoclave yielded the corresponding [4-(dimethylamino)butyl]silane **19** (yield 82%). The silanes **17**−**19** and **22** were isolated as colorless liquids. Their identity was established by elemental analyses, NMR studies (^{1}H, ^{13}C, ^{29}Si), and mass-spectrometric investigations (EI MS).

Scheme 2. Syntheses of compounds **10**−**12**

Scheme 3. Syntheses of compounds **17**−**19**

The title compounds **7**, **8**, and **10**−**12** are colorless crystalline solids with melting points in the temperature range between 162°C (**10**) and 298°C (**12**, dec). They are almost insoluble in nonpolar organic solvents and also exhibit a poor solubility in polar organic solvents. The identity of **7**, **8**, and **10**−**12** was established by elemental analyses (C, H, N), solution-state (^{1}H, ^{13}C, ^{29}Si) and solid-state (^{29}Si CP/MAS) NMR studies, and mass-spectrometric investigations (FAB MS). In addition, all compounds were studied by VT ^{1}H-NMR experiments and were structurally characterized by single-crystal X-ray diffraction. All these studies unequivocally established the zwitterionic structure of **7**, **8**, and **10**−**12** in the solid state and in solution.

Crystal Structure Analyses

Compounds **7**, **8**, and **10**−**12** were studied by single-crystal X-ray diffraction. They crystallize in the space group $P2_1/n$ (**11**), $P2_1/c$ (**7**, **8**, **12**), or $P\bar{1}$ (**10**). All crystals are built up by pairs of Λ- and Δ-enantiomers. There are two crystallographically independent zwitterions each in the crystal lattice of **8**, **10**, and **12**. The structures of compounds **7**, **8**, and **10**−**12** in the crystal are depicted in Figures 1−5. The crystal data and the experimental parameters used for these experiments are summarized in Table 7. Selected interatomic distances and angles are listed in Tables 1 and 2. For reasons of comparison, the respective data for compound **9**·H_2O[4] are included in Table 2.

The coordination polyhedra around the silicon atoms of **7**, **8**, and **10**−**12** can be described as distorted trigonal bipyramids, each bidentate 2-methyllactato(2−)-O^1,O^2 ligand spanning one axial (O1, O3) and one equatorial site (O2, O4). In all compounds, the axial sites are occupied by the carboxylate oxygen atoms. In terms of the Berry pseudorotation coordinate, the geometry of the coordination polyhedra is displaced by 6.1% (**7**), 19.4% (**8**, *molecule A*), 19.2% (**8**, *molecule B*), 32.6% (**10**, *molecule A*), 10.2% (**10**, *molecule B*), 9.2% (**11**), 17.2% (**12**, *molecule A*), and 19.6% (**12**, *molecule B*).[7] The atoms O5 (O5′) and C1 (C1′), respectively, are the pivot atoms that best fit to the Berry pseudorotation coordinate. For compound **9**·H_2O a similar structure was determined, the Berry distortion amounting to 8.9%.[4]

The axial Si−O distances in the SiO_5 skeletons of **7** and **8** [1.773(2)−1.810(2) Å] are significantly longer than the

equatorial ones [1.633(2)−1.668(2) Å]. The same holds true for the axial [1.786(3)−1.841(3) Å] and equatorial Si−O distances [1.663(3)−1.685(3) Å] in the *Si*O_4C frameworks of **10**−**12**. Generally, in the case of those oxygen atoms that are involved as acceptor atoms in N−H···O hydrogen bonds (see below), significantly elongated Si−O distances were observed. The Si−C distances for **10**−**12** are very similar [1.868(4)−1.884(2) Å]. Both replacement of oxygen atoms by methylene groups (**7** → **11**; **8** → **12**) and elongation of the $SiO(CH_2)_nN$ and $Si(CH_2)_nN$ chains (**7** → **8**; **9** → **10** → **11** → **12**) do not affect the geometry of the *Si*-coordination polyhedra in a systematic manner. It rather appears that the distortion of the trigonal-bipyramidal coordination polyhedra of the title compounds is mainly influenced by the crystal packing, including hydrogen-bonding interactions between the zwitterions (see below). This is best reflected by the quite different Berry distortions observed for the two crystallographically independent zwitterions in the crystal of **10** (*molecule A*, 32.6%; *molecule B*, 10.2%).

[a] Data taken from ref.[4]

As expected from the presence of their potential NH donor functions and potential oxygen acceptor atoms, all title compounds form N−H···O hydrogen bonds in the crystal. The relevant geometric data for the respective hydrogen-bonding systems are summarized in Table 3.

Table 3. Geometric data for the N−H···O hydrogen bonds in the crystal of **7**, **8**, and **10**−**12**

compd	N−H···O	N···O [Å]	N−H [Å]	H···O [Å]	N−H···O [°]

For compounds **7**, **8**, and **11**, intermolecular bifurcate N−H···O/O hydrogen bonds were observed leading to the formation of infinite chains in the crystal. These chains each are built up by zwitterions with the same (**7**, **8**) or alternating (**11**) absolute configuration. In the case of compound **8**, these chains each contain crystallographically identical molecules. In the crystal of **10** and **12**, centrosymmetric dimers were observed containing zwitterions with opposite absolute configuration. These dimers are built up by intermolecular bifurcate N−H···O/O hydrogen bonds (**10**, *molecules A* and *B*; **12**, *molecule A*) or intermolecular non-furcate N−H···O hydrogen bonds (**12**, *molecule B*). Both axial (**7**, **8**, **10**−**12**) and equatorial oxygen atoms (**10**, **12**) in the *Si*-coordination polyhedra were found to act as acceptor atoms in the above-mentioned hydrogen-bonding systems. In all cases, these intermolecular N−H···O interactions lead to a significant elongation of the respective Si−O distances compared to those of the chemically equivalent SiO moieties that are not involved in hydrogen bonding. Interestingly, the equatorial O5 oxygen atoms of **7** and **8** do not participate in any hydrogen bonding.

NMR Studies

Compounds **7**, **8**, and **10**−**12** were studied by ^{29}Si CP/MAS NMR experiments in the solid state and by ^{1}H-, ^{13}C-, and ^{29}Si-NMR experiments in solution ([D_6]DMSO). All these investigations were performed at room temperature (for VT ^{1}H-NMR studies, see next chapter).

The isotropic ^{29}Si-NMR chemical shifts obtained in the solid-state NMR studies (Table 4) clearly characterize these ^{29}Si resonances as arising from pentacoordinate silicon atoms. For compounds **8** and **10** separated resonance signals for the two crystallographically independent molecules were detected. Replacement of an oxygen ligand atom by a methylene group in **7** (→ **11**) and **8** (→ **12**) leads to a significant change in the isotropic ^{29}Si chemical shift by 24.9 ppm and 27.3 ppm, respectively. In contrast, the length of the spacers between the *ate* and *onium* centers of the zwitterions (comparison of **7**/**8** and **9**/**10**/**11**/**12**) does not significantly affect the ^{29}Si chemical shift.

As the isotropic ^{29}Si chemical shifts for **7**, **8**, and **10**−**12** are very similar to those observed for these compounds in solution [maximum deviation 4.1 ppm (**10**)] (Table 4), it is concluded that pentacoordination is present in solution as well. In addition, the ^{1}H chemical shifts observed for the NCH_3 (δ = 2.71 to 2.78) and NH moieties (δ = 8.7 to 9.2) clearly indicate the presence of ammonium groups in solution. Thus, the NMR experiments unequivocally demonstrate that the zwitterions **7**, **8**, and **10**−**12** also exist in solution.

Table 4. ^{29}Si NMR data for **7**−**12** in the crystal and in solution[a]

compound	δ^{29}Si (crystal)[b]	δ^{29}Si (solution)[c]
7	−115.4	−111.6
8	−115.2/−116.2	−114.8
9[d]	−98.4	−100.5
10	−89.5/−95.2	−93.6
11	−90.5	−90.3
12	−88.4	−89.4

[a] Spectra recorded at room temperature. − [b] Isotropic chemical shifts, ppm values. − [c] Chemical shifts obtained in [D$_6$]DMSO, ppm values. − [d] ^{29}Si CP/MAS NMR studies were performed with **9**·H$_2$O[4].

In all cases the solution-state NMR data are compatible with the presence of one particular species or with a rapid low-energy interconversion of different isomers (in this context, see ab initio Studies). The results of both the crystal structure analyses and the ab initio studies suggest that the trigonal-bipyramidal structure, with the carboxylate oxygen atoms in the axial positions (the energetically most stable structure), dominates in solution. The diastereotopism observed for the two methyl groups of the 2-methyllactato(2−) ligands (two separated singlets in the ^{1}H- and ^{13}C{^{1}H}-NMR spectra) is in accordance with the chiral nature of the respective λ^5*Si*-silicate skeletons of **7**, **8**, and **10**−**12**. In addition, the NMR data obtained indicate that the Λ- and Δ-enantiomers of these species are configurationally stable on the NMR time scale at room temperature.

VT ^{1}H-NMR Studies

Compounds **7**, **8**, and **10**−**12** were investigated by VT ^{1}H-NMR studies at 300.1 MHz in the temperature ranges of 27−116°C (**7**, **10**), 27−124°C (**8**), and 27−128°C (**11**, **12**) (solvent [D$_6$]DMSO). For all solutions studied two separated singlets for the diastereotopic methyl groups of the 2-methyllactato(2−) ligands were observed, indicating that the respective Λ- and Δ-enantiomers of these λ^5*Si*-silicates are configurationally stable on the NMR time scale under these conditions. Upon heating coalescence of the two singlets was observed in all cases, the temperature dependence of the ^{1}H-NMR spectra being completely reversible on subsequent cooling. These results can be interpreted in terms of an intramolecular isomerization process that leads to a conversion of the respective Λ- and Δ-enantiomers into each other (in this context, see ref.[4]). As determined by line-shape analyses, the activation free enthalpies for this process amount to 79.7(4) kJ mol^{-1} (**7**) to 89(2) kJ mol^{-1} (**12**) (Table 5). According to these results, both the O/CH$_2$ exchange (**7** → **11**; **8** → **12**) and the elongation of the SiO(CH$_2$)$_n$N and Si(CH$_2$)$_n$N chains (**7** → **8**; **9** → **10** → **11** → **12**) lead to an increase of the respective $\Delta G^{\neq}$ values for the Λ/Δ-isomerization. The experimentally established activation free enthalpies are comparable with the respective energy barriers calculated for the anionic model species

Table 5. Activation free enthalpies $\Delta G^{\neq}$ for the Λ/Δ-isomerization of **7**−**12** in [D$_6$]DMSO as determined by VT ^{1}H-NMR spectroscopy

compound	$\Delta G^{\neq}$ [kJ mol^{-1}]	compound	$\Delta G^{\neq}$ [kJ mol^{-1}]
7	79.7(4)	**10**	84.6(4)
8	84.6(6)	**11**	88.5(7)
9[a]	76(1)	**12**	89(2)

13 (85.3 kJ mol^{-1}; see next chapter) and **14** (70.8 kJ mol^{-1}; see ref.[4]).

ab initio Studies

The structure and dynamic behavior of compounds **7** and **8** (SiO_5 skeletons) were studied by quantum-chemical methods using the anionic λ^5*Si*-silicate bis[glycolato(2−)-O^1,O^2]hydroxosilicate(1−) (**13**) as a model species. The computational methods used are described in the Experimental Section.

Five different idealized geometries (**13a**−**13e**, Figure 6) for the anion **13** were considered in this study. For energetic reasons, trigonal bipyramids with the hydroxo ligand in an axial site and square pyramids with the hydroxo group in a basal position were excluded. Calculations of the vibrational frequencies demonstrated that the chiral trigonal-bipyramidal isomers **13a**−**13c** represent local minima, whereas the square-pyramidal species **13d** (chiral) and **13e** (**13**$^{\neq 1}$) (achiral) are transition states (for selected geometric parameters of **13a**−**13e**, see Table 6).[8] Isomer **13a**, with the two carboxylate oxygen atoms in the axial sites, was found to be the energetically most favorable one. This is in agreement with the experimentally established crystal structures of **7** and **8**.

Table 6. Calculated interatomic distances [Å] and angles [°] for the local minima **13a**−**13c** and the transition states **13d**, **13e** (= **13**$^{\neq 1}$), and **13**$^{\neq 2}$ as obtained by SCF/SVP geometry optimizations

As shown by further ab initio studies, the enantiomers Λ-**13a** and Δ-**13a** can be converted into each other by an intramolecular isomerization process along the reaction path Λ-**13a** ⇌ Δ-**13c** ⇌ **13**$^{\neq 2}$ ⇌ Λ-**13b** ⇌ **13**$^{\neq 1}$ ⇌ Δ-**13b** ⇌ **13**$^{\neq 2'}$ ⇌ Λ-**13c** ⇌ Δ-**13a** (**13**$^{\neq 1}$ and **13e** are identical; **13**$^{\neq 2'}$ is the antipode of **13**$^{\neq 2}$) (Figure 7).[9−11] The structure of the trigonal-bipyramidal transition state **13**$^{\neq 2}$ is also depicted in Figure 6. The hydroxo groups in the transition states occupy an apical (**13**$^{\neq 1}$) or axial position (**13**$^{\neq 2}$). The species **13**$^{\neq 1}$ can be regarded as a transition state of a Berry-type conversion (OH as pivot ligand), whereas **13**$^{\neq 2}$ (**13**$^{\neq 2'}$) represents the transition state of a "twist-type" mechanism (in this context, see ref.[4]). The highest relative energy was calculated for **13**$^{\neq 2}$ (**13**$^{\neq 2'}$) (85.3 kJ mol^{-1}), the energy being very similar to the experimentally established activation free enthalpies for the isomerization processes Λ-**7** ⇌ Δ-**7** and Λ-**8** ⇌ Δ-**8** (see VT ^{1}H-NMR Studies).

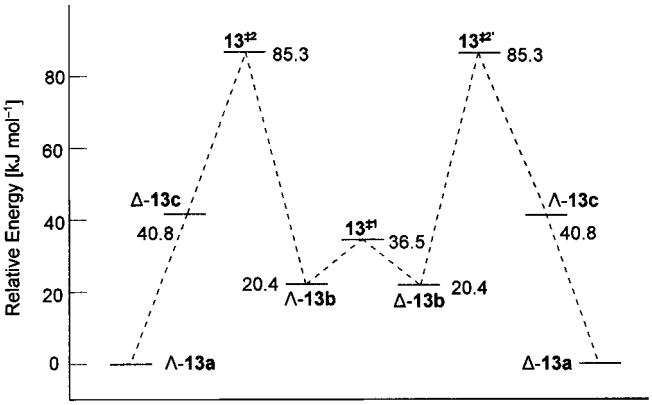

Figure 7. Calculated intramolecular reaction path for the isomerization of **13a** (Λ-**13a** ⇌ Δ-**13a**), showing the relative energies of the local minima **13a**−**13c** and of the transition states **13**$^{\neq 1}$ (= **13e**) and **13**$^{\neq 2}$ (**13**$^{\neq 2'}$)

Experimental Section

General: All syntheses were carried out under dry nitrogen. The organic solvents used were dried and purified according to standard procedures and stored under nitrogen. − Melting points were determined with a Büchi Melting Point apparatus, type B-540. − The ^{1}H, ^{13}C, and ^{29}Si solution-state NMR spectra were recorded at room temperature on a Bruker DRX-300 NMR spectrometer (^{1}H, 300.1 MHz; ^{13}C, 75.5 MHz; ^{29}Si, 59.6 MHz). $CDCl_3$ and [D_6]DMSO were used as solvents. Chemical shifts (ppm) were determined relative to internal $CHCl_3$ (^{1}H, δ = 7.24; $CDCl_3$), $CDCl_3$ (^{13}C, δ = 77.0; $CDCl_3$), [D_5]DMSO (^{1}H, δ = 2.49; [D_6]DMSO), [D_6]DMSO (^{13}C, δ = 39.5; [D_6]DMSO), and external TMS (^{29}Si, δ = 0; $CDCl_3$, [D_6]DMSO). Assignment of the ^{13}C-NMR data was supported by DEPT 135 experiments. ^{29}Si CP/MAS NMR spectra were recorded at room temperature on a Bruker DSX-400 NMR spectrometer with bottom layer rotors of ZrO_2 (diameter 7 mm), containing ca. 200 mg of sample [79.5 MHz, TMS as external standard (δ = 0), spinning rate 5000 Hz, contact time 5 ms, 90° ^{1}H transmitter pulse length 3.6 μs, repetition time 4 s]. − Mass spectra were obtained with a Finnigan MAT-8200 or Finnigan MAT-8430 mass spectrometer (FAB MS, 3-nitrobenzyl alcohol as liquid matrix, xenon as FAB source) and with a Trio-1000 mass spectrometer (ThermoQuest; EI MS, 70 eV). The selected *m*/*z* values given refer to the isotopes ^{1}H, ^{12}C, ^{14}N, ^{16}O, ^{28}Si, and ^{79}Br. − Compounds **15** and **21** were purchased from Aldrich, **16**[5] and **20**[6] were prepared as described in the literature.

[2-(Dimethylammonio)ethoxy]bis[2-methyllactato(2−)-*O*^{1},*O*^{2}]silicate (7) and [3-(Dimethylammonio)propoxy]bis[2-methyllactato(2−)-*O*^{1},*O*^{2}]silicate (8):

Preparation from 15: A solution of **15** (2.04 g, 13.4 mmol) in acetonitrile (20 mL) was added dropwise within 10 min to a stirred boiling solution of 2-methyllactic acid (2.79 g, 26.8 mmol) and the respective aminoalcohol (13.4 mmol) in acetonitrile (35 mL). Subsequently, part of the solvent (30−40 mL) was removed by distillation (760 Torr) and the residue allowed to cool to room temperature (formation of a precipitate after ca. 6 h). The precipitate was filtered off, recrystallized from acetonitrile (slow cooling of a saturated boiling solution to room temperature), and dried in vacuo

(0.01 Torr, 6 h) to give a colorless crystalline product [**7**, 3.14 g (yield 73%); **8**, 3.21 g (yield 71%)].

Preparation from 16: A solution of the respective aminoalcohol (4.80 mmol) in acetonitrile (30 mL) was added within 30 min to a boiling solution of **16** (981 mg, 4.80 mmol) in acetonitrile (50 mL). Subsequently, a solution of 2-methyllactic acid (999 mg, 9.60 mmol) in acetonitrile (50 mL) was added dropwise to this mixture within 2 h and part of the solvent was removed slowly by distillation at the same time. The distillation was continued for a further 2 h until ca. 80 mL of the solvent were removed. The reaction mixture was then kept at 20°C for 24 h (**7**) or at −20°C for 72 h (**8**), and the resulting precipitate was filtered off and dried in vacuo (0.01 Torr, 6 h) to give a colorless crystalline product [**7**, 950 mg (yield 62%); **8**, 860 mg (yield 53%)].

Data for 7: Mp 243°C (dec). − ^{1}H NMR ([D$_6$]DMSO): δ = 1.17 (s, 6 H, CCH$_3$), 1.20 (s, 6 H, CCH$_3$), 2.78 (s, 6 H, NCH$_3$), 3.12−3.14 (m, 2 H, CCH$_2$N), 3.70−3.87 (m, 2 H, CCH$_2$O), 9.2 (broad s, 1 H, NH). − ^{13}C{^{1}H} NMR ([D$_6$]DMSO): δ = 27.2 (C*C*H$_3$), 27.5 (C*C*H$_3$), 42.8 (NCH$_3$), 57.9 and 58.2 (C*C*H$_2$N, O*C*H$_2$C), 73.5 (O*C*C$_3$), 178.4 (C=O). − ^{29}Si{^{1}H} NMR ([D$_6$]DMSO): δ = −111.6. − ^{29}Si CP/MAS NMR (359 transients): δ = −115.4. − FAB MS (positive ions): *m*/*z* 322 (1) [*M* + H$^+$], 90 (100) [HO(CH$_2$)$_2$NH(CH$_3$)$_2^+$]. − FAB MS (negative ions): *m*/*z* 320 (1) [*M* − H$^+$], 249 (100) [{OCMe$_2$C(O)O}$_2$SiOH$^-$]. − $C_{12}H_{23}NO_7Si$ (321.4): calcd C 44.84, H 7.21, N 4.36; found C 44.5, H 7.3, N 4.4.

[2-(Dimethylammonio)ethyl]bis[2-methyllactato(2−)-*O*^{1},*O*^{2}]silicate (**10**):

Preparation from 17: Compound **17** (622 mg, 3.22 mmol) was added to a stirred solution of 2-methyllactic acid (671 mg, 6.44 mmol) in acetonitrile (10 mL) and the reaction mixture kept at room temperature for 4 h. After part of the solvent (ca. 6 mL) was removed by distillation (760 Torr), the boiling solution was cooled slowly to room temperature (formation of a crystalline solid after ca. 3 h). After 24 h the precipitate was filtered off, recrystallized from acetonitrile (slow cooling of a saturated boiling solution to room temperature), and dried in vacuo (0.02 Torr, 6 h) to give 770 mg (yield 78%) of a colorless crystalline product.

Preparation from 20: A solution of **20** (2.00 g, 8.60 mmol) in acetonitrile (30 mL) was added to a stirred solution of 2-methyllactic acid (1.79 g, 17.2 mmol) in acetonitrile (40 mL) and the reaction mixture kept at room temperature for 4 h. After part of the solvent (ca. 40 mL) was removed by distillation (760 Torr), the boiling solution was cooled slowly to room temperature (formation of a crystalline solid after ca. 2 h). After 24 h the precipitate was filtered off, recrystallized from acetonitrile (cooling of a saturated boiling solution to room temperature), and dried in vacuo (0.02 Torr, 6 h) to give 2.15 g (yield 82%) of a colorless crystalline product.

Data for 10: Mp 287°C. − ^{1}H NMR ([D$_6$]DMSO): δ = 0.81−0.98 (m, 2 H, SiCH$_2$C), 1.17 (s, 6 H, CCH$_3$), 1.20 (s, 6 H, CCH$_3$), 2.71 (s, 6 H, NCH$_3$), 2.84−3.04 (m, 2 H, CCH$_2$N), 8.7 (broad s, 1 H, NH). − ^{13}C{^{1}H} NMR ([D$_6$]DMSO): δ = 14.4 (Si*C*H$_2$C), 27.1 (C*C*H$_3$), 27.7 (C*C*H$_3$), 41.2 (NCH$_3$), 55.8 (C*C*H$_2$N), 73.3 (O*C*C$_3$), 178.7 (C=O). − ^{29}Si{^{1}H} NMR ([D$_6$]DMSO): δ = −93.6. − ^{29}Si CP/MAS NMR (109 transients): δ = −89.5, −95.2. − FAB MS (positive ions): *m*/*z* 306 (100) [*M* + H$^+$]. − FAB MS (negative ions): *m*/*z* 304 (100) [*M* − H$^+$]. − $C_{12}H_{23}NO_6Si$ (305.4): calcd C 47.19, H 7.59, N 4.59; found C 46.8, H 7.6, N 4.6.

[3-(Dimethylammonio)propyl]bis[2-methyllactato(2−)-*O*^{1},*O*^{2}]silicate (**11**) **and [4-(Dimethylammonio)butyl]bis[2-methyllactato(2−)-*O*^{1},*O*^{2}]silicate** (**12**): The respective silane (**18**, **19**; 7.62 mmol) was added dropwise within 2 min to a stirred solution of 2-methyllactic acid (1.58 g, 15.2 mmol) in acetonitrile (40 mL) (formation of a precipitate after ca. 10 min). After 48 h the precipitate was filtered off, recrystallized from acetonitrile (slow cooling of a saturated boiling solution to room temperature), and dried in vacuo (0.02 Torr, 6 h) to give a colorless crystalline product [**11**, 2.13 g (yield 88%); **12**, 2.15 (yield 90%)].

The precipitate was filtered off, the solvent removed under reduced pressure, and the residue distilled in vacuo to give 24.9 g (yield 71%) of a colorless liquid. Bp 42°C/0.05 Torr. − ^{1}H NMR ($CDCl_3$): δ = 0.46−0.52 (m, 2 H, $SiCH_2C$), 1.37−1.48 (m, 2 H, CCH_2C), 2.07 (s, 6 H, NCH_3), 2.08−2.13 (m, 2 H, CCH_2N), 3.42 (s, 9 H, OCH_3). − $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 6.9 ($SiCH_2C$), 21.0 (CCH_2C), 45.7 (OCH_3), 50.7 (NCH_3), 62.9 (CCH_2N). − $^{29}Si\{^1H\}$ NMR ($CDCl_3$): δ = −41.5. − EI MS: *m*/*z* 207 (16) [M^+], 176 (6) [$M^+ - OCH_3$], 121 (51) [$M^+ - (CH_2)_3N(CH_3)_2$], 58 (100) [$H_2C{=}N(CH_3)_2^+$]. − $C_8H_{21}NO_3Si$ (207.3): calcd C 46.34, H 10.21, N 6.76; found C 46.3, H 10.2, N 6.8.

[4-(Dimethylamino)butyl]trimethoxysilane (**19**): A mixture of **22** (4.00 g, 15.6 mmol) and dimethylamine (2.16 g, 47.9 mmol) was heated in an autoclave at 60°C/10 bar for 4 h. After the mixture was cooled to room temperature, the excess amine was evaporated and *n*-pentane (25 ml) added to the residue. The precipitate was filtered off, the solvent removed under reduced pressure, and the residue distilled in vacuo to give 2.83 g (yield 82%) of a colorless liquid. Bp 92°C/11 Torr. − ^{1}H NMR ($CDCl_3$): δ = 0.54−0.60 (m, 2 H, $SiCH_2C$), 1.30−1.44 (m, 4 H, CCH_2C), 2.11 (s, 6 H, NCH_3), 2.12−2.17 (m, 2 H, CCH_2N), 3.47 (s, 9 H, OCH_3). − $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 9.5 ($SiCH_2C$), 21.0 (CCH_2C), 31.5 (CCH_2C), 45.9 (OCH_3), 50.8 (NCH_3), 59.9 (CCH_2N). − $^{29}Si\{^1H\}$ NMR ($CDCl_3$): δ = −41.8. − EI MS: *m*/*z* 221 (15) [M^+], 190 (2) [$M^+ - OCH_3$], 121 (34) [$M^+ - (CH_2)_4N(CH_3)_2$], 58 (100) [$H_2C{=}N(CH_3)_2^+$]. − $C_9H_{23}NO_3Si$ (221.4): calcd C 48.83, H 10.47, N 6.33; found C 48.7, H 10.5, N 6.3.

(4-Bromobutyl)trimethoxysilane (**22**): A mixture of 4-bromo-1-butene (5.00 g, 37.0 mmol), **21** (6.78 g, 55.5 mmol), hexachloroplatinic acid hexahydrate (20 mg, 39 μmol), and 2-propanol (0.2 mL) was heated in an autoclave at 140°C/2 bar for 8 h. After the mixture was cooled to room temperature, the solid particles were removed by filtration, and the filtrate was distilled in vacuo to give 6.72 g (yield 71%) of a colorless liquid. Bp 49°C/2 Torr. − ^{1}H NMR ($CDCl_3$): δ = 0.52−0.58 (m, 2 H, $SiCH_2C$), 1.39−1.53 (m, 2 H, CCH_2C), 1.72−1.83 (m, 2 H, CCH_2C), 3.29−3.33 (m, 2 H, CCH_2Br), 3.48 (s, 9 H, OCH_3). − $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 11.2 ($SiCH_2C$), 21.6 (CCH_2C), 33.7 (CCH_2C), 36.1 (CCH_2Br), 50.7 (OCH_3). − $^{29}Si\{^1H\}$ NMR ($CDCl_3$): δ = −42.2. − EI MS: *m*/*z* 256 (1) [M^+], 121 (100) [$M^+ - C_4H_8Br$]. − $C_7H_{17}BrO_3Si$ (257.2): calcd C 32.69, H 6.66; found C 32.2, H 6.7.

Crystal Structure Analyses: Suitable single crystals of **7**, **8**, and **10**−**12** were obtained by crystallization from acetonitrile (slow cooling of saturated boiling solutions to room temperature). The crystals were mounted in inert oil (RS 3000, Riedel-de Haën) on a glass fiber and then transferred to the cold gas stream of the diffractometer [**7**, **8**: Enraf-Nonius CAD4; **10**−**12**: Stoe IPDS; graphite-monochromated Mo-$K\alpha$ radiation (λ = 0.71073 Å)]. The structures were solved by direct methods.[12] All non-hydrogen atoms were refined anisotropically.[13] The positions of the NH hydrogen atoms were localized in difference Fourier syntheses and refined freely (**8**: with one distance restraint). The CH hydrogen atoms were refined freely (**10**, **11**) or a riding model was employed in the refinement of the CH hydrogen atom positions (**7**, **8**, and

12). The maximum residual electron density of 1.447 e $Å^{-3}$ in the crystal of **12** corresponds to a single peak which could be refined to a (hydrogen bonded) oxygen atom (occupation 0.3), but neither the ^{1}H-NMR data nor the elemental analyses confirm any content of water in the crystal of **12** (second residual electron density peak: 0.21 e $Å^{-3}$).

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-102600 (**7**), CCDC-102601 (**8**), CCDC-102602 (**10**), CCDC-102603 (**11**), and CCDC-102604 (**12**). Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [fax: (+44) 1223/ 336-033; e-mail: deposit@ccdc.cam.ac.uk].

VT ^{1}H-NMR Studies: The experiments were carried out analogously to the standard ^{1}H-NMR measurements using a Bruker DRX-300 spectrometer. [D_6]DMSO was used as solvent. The thermocouple used with the probe was calibrated for high temperatures according to ref.[14] using a 80% solution of 1,2-ethanediol in [D_6]DMSO. Spectra were recorded in the temperature ranges of 27−116°C (**7**, **10**), 27−124°C (**8**), and 27−128°C (**11**, **12**). The time required for temperature equilibration was 15 min. The data obtained were fitted and simulated by using the Bruker software program WinDyna 1.0b (line-shape analysis). From the simulated spectra the coalescence temperatures T_C and the exchange rates k_C at the coalescence points were extracted, and the respective values for the activation free enthalpy $\Delta G^{\neq}$ for the exchange process were calculated by using the Eyring equation: $\Delta G^{\neq} = 19.14 \cdot T_C \cdot [10.32 + \log (T_C/k_C)]$ [J mol^{-1}].[15]

Computational Methods: Geometry optimizations at the SCF/SVP level for the anionic model species **13** were performed using the TURBOMOLE program system.[16] Stationary geometries and transition states were characterized as local minima (zero imaginary frequencies) and saddle points (one imaginary frequency), respectively, by calculation of the vibrational frequencies. The energies given for **13** include the single point MP2 energy (SVP basis set) and the zero point vibrational energy.

Contributions to the Chemistry of Boron, 244[+] Preparation and Structural Characterization of Lithium Silylborates

Wolfgang Lippert,[a] Heinrich Nöth,*[a] Werner Ponikwar,[a][§] and Thomas Seifert[a][§]

Dedicated to Prof. Dr. P. Jutzi on the occasion of his 60th birthday

Keywords: Lithium (triphenylsilyl)trihydridoborate / Lithium (*tert*-butyldiphenylsilyl)trihydridoborate / Lithium tris(trimethylsilyl)methylborate / Lithium tetrakis(trimethylsilyl)borate / X-ray structure analysis

Borane triethylamine reacts with lithium triphenylsilanide or lithium *tert*-butyldiphenylsilanide with formation of lithium (triphenylsilyl)trihydridoborate or lithium (*tert*-butyldiphenylsilyl)trihydridoborate. Complexation of the lithium cation with various ligands allows the isolation of compounds **1**, **2a**, and **2b**. Trimethoxyborane reacts with lithium trimethylsilanide to form lithium tetrakis(trimethylsilyl)borate **3** and lithium tris(trimethylsilyl)methylborate **4**. Mixed single crystals of **3** and **4** show an unexpected coordination of the lithium cation due to the lack of any supporting donor molecule. All silylborates exhibit short Si–B bond lengths compared to tricoordinated silylboranes.

Introduction

In 1961, Seyferth et al. described the preparation of the first tetracoordinated borate containing a silicon−boron bond.[2] The addition of triphenylborane to lithium triphenylsilanide leads to the formation of lithium (triphenylsilyl)triphenylborate. In 1982, we reported the synthesis of (trimethylsilyl)borates from alkoxyboranes and trimethylsilyllithium.[3] Although aryl-/alkylsilylborates have been known for some time, as yet no data concerning their molecular structures are available. In 1993, Schmidbaur et al. described the crystal structure of tricyclohexylphosphane-(trimethylsilyl)borane.[4] Nevertheless, to the best of our knowledge, the structures of anionic silylborates have not yet been determined.

Due to their use in organic synthesis, research is ongoing in the field of hydridoborates.[5] This field could be extended by the preparation of silylhydridoborates, which may possess electronic and/or reducing properties different from those of the known and well-investigated alkyl-/arylhydridoborates.[6]

The present report deals with the preparation of new silylhydridoborates, as well as of known (trimethylsilyl)borates. Their molecular structures have been determined by means of X-ray diffraction analysis.

Results and Discussion

One might envisage the most straightforward pathway to monosilyltrihydridoborates as being the addition of BH_3 to alkali metal silanides, $MSiR_3$, with $BH_3 \cdot THF$ as the source of borane, as shown in Eq. 1. However, reactions of $BH_3 \cdot THF$ with various lithium silanides invariably lead to only small amounts (10−20%) of compounds $Li(H_3BSiR_3)$, as shown by ^{11}B-NMR spectroscopy. The main product is $LiBH_4$, which is formed according to Eq. 2. Separation of $Li(H_3BSiR_3)$ from $LiBH_4$ by fractional crystallization has proved impossible.

In order to prevent rapid hydride transfer from $Li(H_3SiBR_3)$ to BH_3, a less reactive BH_3 source was necessary, a requirement that was met by $BH_3 \cdot NEt_3$. In this case, heating the THF solution under reflux was necessary to complete the reaction (Eq. 3) within a few hours. Under these conditions, the formation of $LiBH_4$ could not be completely suppressed. A silylhydridoborate was, however, the main species generated.

$$LiSiR_3 + H_3B{\cdot}THF \xrightarrow{THF} Li(H_3BSiR_3){\cdot}n\,THF \quad (1)$$

$$Li(H_3BSiR_3) + H_3B{\cdot}THF \longrightarrow LiBH_4 + H_2BSiR_3 \quad (2)$$

$$LiSiR_3 + H_3B{\cdot}NEt_3 \xrightarrow[RF]{THF} Li(H_3BSiR_3) + NEt_3 \quad (3)$$

Scheme 1

The triorganylsilyltrihydridoborates **1** and **2** were separated from $LiBH_4$ by crystallization. Compound **2a** was isolated as a THF solvate, while addition of nitrogen-containing ligands to the hexane solution resulted in compounds **1** and **2b**. It is interesting to note that NEt_3 clearly does not coordinate to Li, because **2a** crystallizes from a hexane solution containing NEt_3.

The monosilyltrihydridoborates could not be isolated in the absence of a supporting ligand. In contrast, the tetrasilylborate $LiB(SiMe_3)_4$ (**3**) is known to exist as a ligand-free

compound. It was obtained as described in the literature[3] (Eq. 4). In addition to **3**, $LiMeB(SiMe_3)_3$ (**4**) was formed in approximately 10% yield (^{11}B NMR). Compound **4** is accessible directly from $LiSiMe_3$ and $MeB(OMe)_2$.[3]

$(Ph_3SiBH_3)Li \cdot 3\ TMEDA$ **1**

$(^tBuPh_2SiBH_3)Li \cdot 3\ THF$ **2a**

$(^tBuPh_2SiBH_3)Li \cdot PMDTA$ **2b**

$[(Me_3Si)_4B]Li$ **3**

$[(Me_3Si)_3BMe]Li$ **4**

Scheme 2

$$4\ LiSiMe_3 + B(OMe)_3 \longrightarrow [(Me_3Si)_4B]Li + 3\ LiOMe \quad (4)$$

$$[(Me_3Si)_4B]Li \longrightarrow [(Me_3Si)_3BMe]Li + "SiMe_2" \quad (5)$$

Scheme 3

The 10% contamination of **3** by **4** can be removed by crystallization from hexane. However, a hexane solution of pure **3** shows the presence of **4** after storage for several weeks. Therefore, we suggest that compound **4** is formed according to Eq. 5.

It was of interest to compare the structures of these compounds with those of **1** and **2**.

NMR and IR Spectra

The ^{11}B-NMR spectra of the monosilyltrihydridoborates, recorded in C_6D_6 solution, are almost identical. The chemical shifts δ span the narrow range from δ = −42.5 to −43.8. This is the same region as found for the the ^{11}B resonance of $LiBH_4$ (THF solution, δ = −41.6).[7] A 1:3:3:1 quartet is seen in the proton-coupled ^{11}B-NMR spectra of the silyltrihydridoborates with $^1J(^{11}B,^1H)$ = 78−79 Hz, while $LiBH_4$ is characterized by a quintet with $^1J(^{11}B,^1H)$ = 82.4 Hz.[7] The main differences between the various silyltrihydridoborates lie in the linewidths, which are 22 Hz for **1**, 41 Hz for **2a**, and 20 Hz for **2b**. No $^{29}Si^{11}B$ coupling could be observed, nor any ^{29}Si signal was observed in the ^{29}Si-NMR spectrum. We attribute this to the same relaxation process as that which is operative in CB units, where the ^{13}C resonance is not usually observable due to strong quadrupolar line broadening.

The quartet structures of the ^{11}B-NMR signals suggest that all the hydrogen atoms bonded to the boron atom are magnetically and chemically equivalent, in spite of the fact that this is not the case in the solid state (vide infra). Therefore, free rotation of the BH_3 group about the B−Si bond occurs in solution.

In contrast, the IR spectra of **2a** and **2b** are quite different. **2a** shows two strong BH_3 stretching bands at 2284 and 2257 cm^{-1}, while for **2b** three bands are observed [at 2335 (m), 2266 (vs), and 2237 (s) cm^{-1}]. The two strong bands for **2a** and **2b** are consistent with local C_{3V} symmetry, while the band at 2335 cm^{-1} observed for **2b** most probably results from an overtone of the $\delta(BH_3)$ absorption found at 1167 cm^{-1} (2 × 1167 cm^{-1} = 2334 cm^{-1}). Although the anionic parts of **2a** and **2b** are, at least formally, identical, there is a 20 cm^{-1} difference in the position of the BH_3 stretching bands. We attribute this to the influence of the differently coordinated Li cation.

Molecular Structures in the Solid State

Single crystals of **1**, **2a**, and **2b** were obtained, which allowed the determination of their molecular structures in the solid state. These are depicted in Figures 1−3, and relevant molecular parameters are summarized in Table 1.

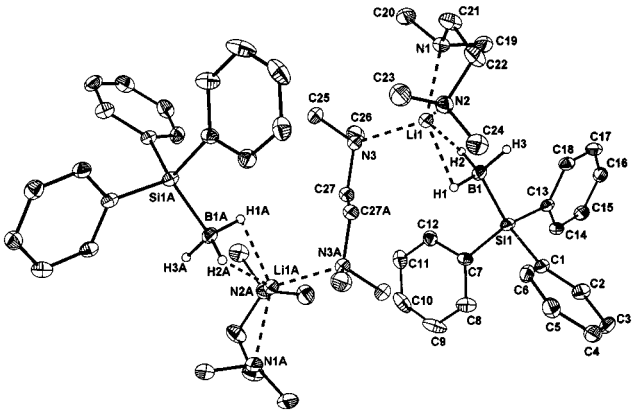

Figure 1. Molecular structure of the TMEDA adduct of lithium (triphenylsilyl)trihydridoborate **1** in the crystal. Thermal ellipsoids are drawn at a 25% probability level; hydrogen atoms (except those on boron) are omitted for the sake of clarity

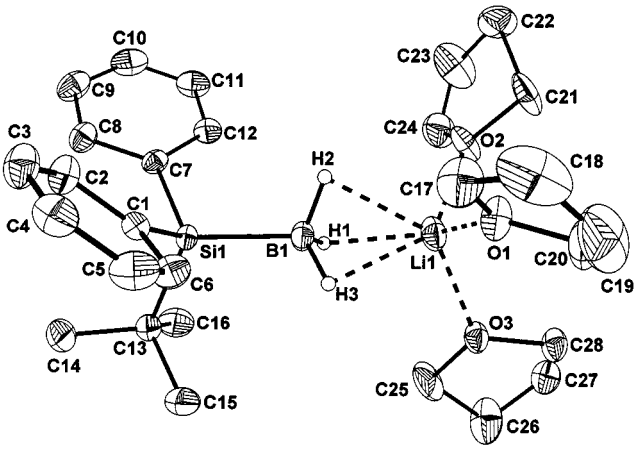

Figure 2. Molecular structure of the THF adduct of lithium (*tert*-butyldiphenylsilyl)trihydridoborate **2a** in the crystal. Thermal ellipsoids are drawn at a 25% probability level; hydrogen atoms (except those on boron) are omitted for the sake of clarity

Lithium (triphenylsilyl)trihydridoborate **1** crystallizes with 1.5 TMEDA ligands per molecule and can be described by the formula $[(Ph_3SiBH_3)Li \cdot TMEDA]_2 \cdot$

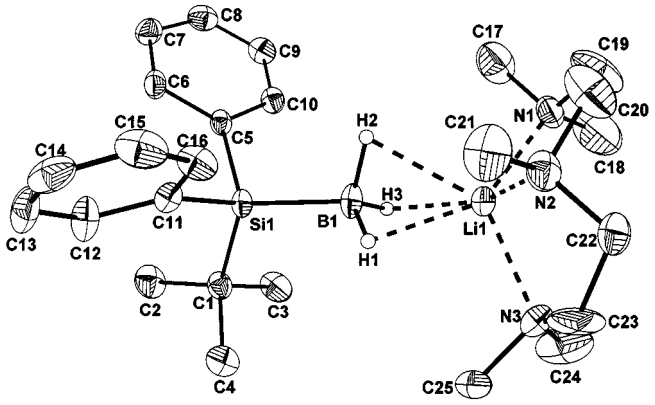

Figure 3. Molecular structure of the PMDTA adduct of lithium (*tert*-butyldiphenylsilyl)trihydridoborate **2b** in the crystal. Thermal ellipsoids are drawn at a 25% probability level; hydrogen atoms (except those on boron) are omitted for the sake of clarity; only one position of the disordered PMDTA ligand is shown

TMEDA. There is one chelating ligand per Li atom, while the third TMEDA molecule binds to the two centers via one N atom each. Moreover, each Li coordinates to two hydrogen atoms of the BH_3 units, making the lithium pentacoordinated. Thus, the $SiBH_3$ unit acts as a $\mu_2{}^1$ ligand with B−H distances of 1.07(3) (H1) and 1.13(3) Å (H2). The molecule has a center of inversion at the midpoint of the C27−C27a bond.

Lithium (*tert*-butyldiphenylsilyl)trihydridoborate · tris(tetrahydrofuran), **2a**, is present as a monomer in the crystal (see Figure 2).[8] In contrast to compound **1**, the Li center in **2a** is hexacoordinated, in this case by three oxygen atoms and three hydrogen atoms. In **2a**, all hydrides of the BH_3 unit are involved in Li−H bonding, with the BH_3 group acting as a $\mu_3{}^1$ ligand. As compound **2b** is also present as a monomeric molecular species (or contact ion pair) in the solid state, it is apparent that the change from oxygen coligands (in **2a**) to nitrogen (in **2b**) has no influence on the molecular structure of **2** in the solid state. The B−H atom distances span a range from 1.02 to 1.19(3) Å.

According to Edelstein et al.,[9] the B−M distance is a function of the bonding mode of the $BH_4{}^-$ ligand, this distance decreasing as we move along the series M···H−BH_3, M···$(H)_2BH_2$, M···$(H)_3BH$, in other words when the BH_4 group acts as a $\mu_1{}^1$, $\mu_2{}^1$, or $\mu_3{}^1$ donor. For geometrical reasons, this of course also holds for $RBH_3{}^-$ groups.

Thus, it can be seen that when the $R_3SiBH_3{}^-$ group acts as a $\mu_2{}^1$ ligand (in compound of type **1**), the Li···B atom distance is 2.377(8) or 2.49(1) Å, whereas in **2a** and **2b**, with $\mu_3{}^1$-R_3SiBH_3 groups, this distance is as short as 2.255(4) or 2.252(8) Å. No influence of the coligands (oxygen in **2a**, nitrogen in **2b**) on the B···Li atom distance was observed. Owing to the different coordination of the Li atom in **1** compared with that in **2a** and **2b**, different Si−B−Li bonding angles are found. While **2a** [175.2(2)°] and **2b** [176.2(4)°] show an almost linear array of the Li, B, and Si atoms, an Si−B−Li angle of 165.2(3)° is found for compound **1**. Irrespective of the degree of association and the different BH_3···Li interactions, the B−Si bond lengths in **1**, **2a**, and **2b** are equal within the margin of the standard deviation, leading to an average Si−B bond length of 1.988 Å. This distance is significantly shorter than the Si−B bond length found in $(c\text{-}C_6H_{11})_3P \cdot H_2BSiMe_3$ [2.007(4) Å[4]]. Surprisingly, the Si−B distances in **1**, **2a**, and **2b** are even shorter than those in trivalent silylboranes,[10] where bond lengths between 2.038 and 2.127 Å have been found. This is a remarkable observation because bond lengths of a certain ligand generally increase with increasing coordination number of the central atom; in this case the B−Si bond length to a tetracoordinated boron atom would be expected to be longer than that to a tricoordinated boron species, but in fact the reverse is found. The shortest B−Si bond length found to date is 1.926(2) Å, observed in the three-membered heterocycle 1-(*tert*-butyl)-3-(diisopropylamino)-2,2-(dimesityl)azasilaboriridine.[11]

Single crystals of the trimethylsilylborates **3** and **4** could not be obtained. However, when these compounds were mixed in a 1:1 ratio, single crystals containing **3** and **4** in this ratio were obtained from hexane solution. Figure 4 shows the molecular structure of **3** and Figure 5 the structure of **4**. The packing of the two species in the unit cell is depicted in Figure 6. Selected structural parameters are summarized in Table 2.

As can be seen in Figure 4, the Li atom of compound **3** resides in a cleft formed by three methyl groups bonded to three different Si atoms, and this imposes an almost C_3 point group symmetry on the molecule. It is particularly surprising that the B−Si bond lengths in **3** are nevertheless all equal [B1 to Si1: 2.025(2), to Si2: 2.027(2), to Si3: 2.025(2), to Si4: 2.025(2) Å], in spite of the fact that the $Si(3)Me_3$ group is not involved in the interaction with Li1.

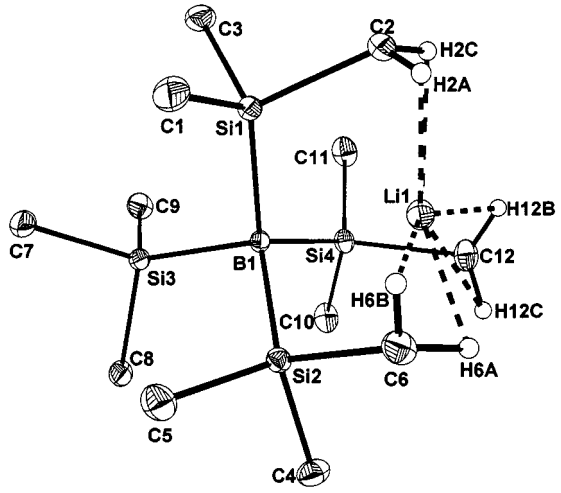

Figure 4. Molecular structure of lithium tetrakis(trimethylsilyl)borate **3** in the crystal. Thermal ellipsoids are drawn at a 25% probability level; hydrogen atoms (except those which show contact to Li) are omitted for the sake of clarity

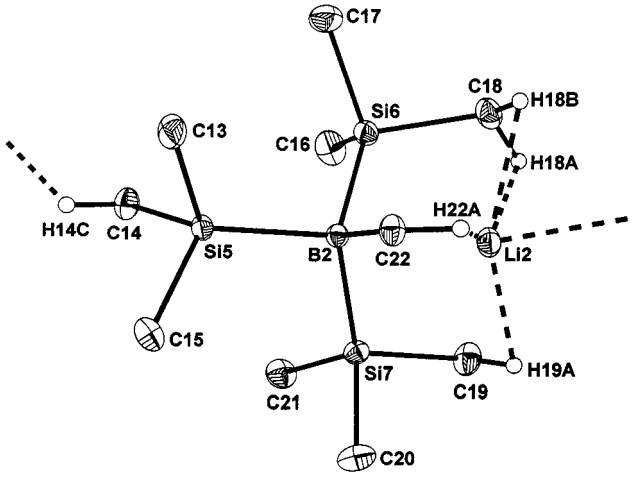

Figure 5. Molecular structure of lithium methyl tris(trimethylsilyl)borate **4** in the crystal. Thermal ellipsoids are drawn at a 25% probability level; hydrogen atoms (except those which show contact to Li) are omitted for the sake of clarity

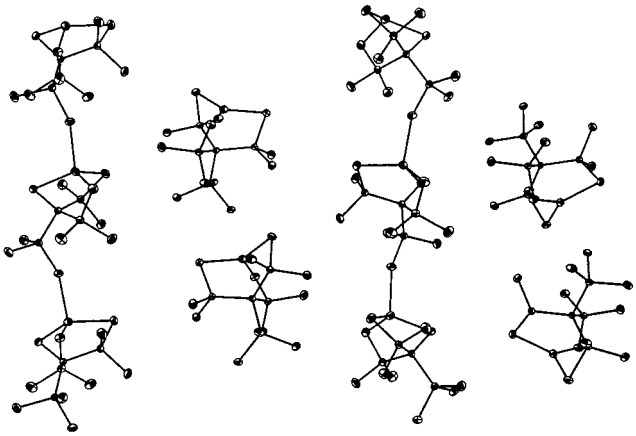

Figure 6. Arrangement of **3** and **4** in the crystal

Table 2. Selected bond lengths [Å] and bond angles [°] of compounds **3** and **4**; estimated standard deviations are given in parentheses

bond lengths	**3**	**4**
aver. $Si_{Li}-B$	2.025	2.032
Si−B	2.025(2)	2.017(2)

bond angles		
Si−B−Li	178.9(1)	173.2(1)
aver. $Si_{Li}-B-Si$	105.6	107.2
aver. $Si_{Li}-B-Si_{Li}$	113.0	113.2

The angle Si3−B1···Li1 is 178.9(1)°. Moreover, the Si−B1−Si angles of the silyl groups orientated towards Li1 are on average 113.0°, while the average of angles Si3−B1−Si is 105.6°. This demonstrates that the Li···H interaction (average Li···H distance 2.17 Å) leads to a widening of the tetrahedral angle.

Lithium methyl tris(trimethylsilyl)borate **4** exhibits an unsymmetrical structure in the solid state. The Li atom is in contact with a total of five hydrogen atoms, four of which are from the same anionic species, while the fifth is from a neighbouring anion. Therefore, the molecules of **4** are associated so as to form a chain structure. Li2−H distances are on average 2.19 Å for the hydrogen atoms of $SiMe_3$ groups, but are as short as 1.87 Å for the contacts with the hydrogens of the BMe group.

In contrast to the structure of the silylborate **3**, two different B−Si bond lengths are found in compound **4**. The Si5−B2 bond measures 2.017(2) Å and is therefore shorter than the Si6−B2 and Si7−B2 bonds [2.034(2), 2.030(2) Å]. Hydrogen atoms of the $Si(6)Me_3$ and $Si(7)Me_3$ groups coordinate intramolecularly to the Li2 center. The Si6−B2−Si7 bond angle is 113.2(1)°, i.e. 3.6° larger than the ideal tetrahedral angle. This deviation, together with the longer Si−C bonds to the $SiMe_3$ groups of Si6 and Si7, indicates that there should be more negative charge on these silyl groups than on that of Si5, and that "hyperconjugation" leads to bond lengthening. Indeed, the Si−C bond lengths of the methyl groups involved in CH···Li interactions are longer [Si6−C18, Si7−C19: 1.920(2) Å] than all the other Si−C distances (average: 1.881 Å). The fact that Li2 is not located between three $SiMe_3$ groups indicates that BCLi "hyperconjugation" is preferred to BSiLi "hyperconjugation". This is also reflected in a rather long BC bond length of 1.679(3) Å, compared with BC bonds of between 1.621(5) and 1.642(4) Å in $LiBMe_4$.[12] In this molecule the Li−B atom distance is 2.541(5) Å, in contrast to **4** where it is only 2.276(4) Å, which is even shorter than that in compound **3** [B1···Li1: 2.387(4) Å].

The packing of the molecules **3** and **4** in the lattice is depicted in Figure 6. There are only van der Waals' contacts

between hydrogen atoms. The chains of molecule **4** are oriented along the *b* axis.

As has been reported previously,[3] all hydrogen atoms of the tetrakis(trimethylsilyl)borate are equivalent on the NMR timescale. The molecule is thus fluxional, and the same holds true for compound **4**. While it can readily be seen from the crystal structures of **3** and **4** that these compounds will be present as molecules in solution, the process that leads to fluxionality is still unknown. We assume that this does not occur by a dissociative process, but rather by a simultaneous movement of the Li centers with rotation of the $SiMe_3$ groups about the B−Si bonds.

Conclusion

Lithium silyltrihydridoborates $Li(R_3SiBH_3)$ are accessible by reacting lithium silanides with $BH_3 \cdot NEt_3$. In contrast to the reaction of lithium organyls with $H_3B \cdot NMe_3$,[13] no deprotonation at the organyl groups of the amine occurs. Depending on the coligand (THF, TMEDA, PMDTA), either bridged dimeric or monomeric molecules are formed. Two different kinds of hydride bridges B−H···Li are observed, corresponding to $\mu_2{}^1$- and $\mu_3{}^1$-BH_3R groups, which are responsible for the association. In contrast, $LiB(SiMe_3)_4$ is monomeric in the solid state, with the Li center "buried" in a cleft between three $SiMe_3$ groups. There are six C−H···Li interactions. Only minor distortion of the $B(SiMe_3)_4{}^-$ anion occurs, the most notable feature being the lengthening of the Si−C bonds when H atoms are involved in C−H···Li interactions. This can be explained in terms of "hyperconjugation". $LiMeB(SiMe_3)_3$ is less symmetrical than **3** because the BMe group is involved in bonding to Li. B−C bond lengthening, which exceeds that observed for $LiBMe_4$, indicates that BCLi "hyperconjugation" is more pronounced than SiCLi "hyperconjugation".

The structures of **3** and **4** are unique for main group organometallic compounds and it would be interesting to compare them with the structures of $LiB(t\mathrm{Bu})_4$ and $LiMeB(t\mathrm{Bu})_3$. However, $LiB(t\mathrm{Bu})_4$ is unstable and decomposes readily with loss of isobutene to give $LiHB(t\mathrm{Bu})_3$, while $LiMeB(t\mathrm{Bu})_3$ ($d^{11}B = -10.4$) has only been observed in THF solution,[14] and has yet to be isolated and characterized, other than by NMR.

Experimental Section

General Remarks: All experiments were performed under anhydrous conditions under N_2 or Ar using Schlenk techniques. All reagents were purified prior to use either by distillation or crystallization. The reactions were monitored by using a Bruker WP 200 PFT NMR spectrometer equipped with a multinuclear probe. − $BH_3 \cdot THF$ was prepared from $NaBH_4$ in diglyme and BF_3; the diborane released was dissolved in pure THF. $BH_3 \cdot NEt_3$ was prepared by adding an equimolar amount of NEt_3 to a solution of $BH_3 \cdot THF$. Lithium silanides were obtained by standard literature procedures.[15] − Elemental analyses, using a Heraeus MX instrument, were performed at the microanalytical laboratory of the Institute. A systematic lack of 1−2% carbon in the analyses is due to the formation of SiC and BC. − IR: Perkin-Elmer FT spectrometer. − NMR: Bruker WP 200 PFT, JEOL GSX 270, and JEOL EX 400 instruments; internal TMS ($^{1\ H,\ 13}C$), external $BF_3{\cdot}OEt_2$ (^{11}B) as standards.

Bis[lithium (triphenylsilyl)trihydridoborate] · Tris(tetramethylethylenediamine) (1): A THF solution (30 mL) of freshly prepared triphenylsilyllithium (10 mmol)[15] was added dropwise to a stirred solution of $BH_3 \cdot NEt_3$ (10 mmol) in THF (20 mL) at −30°C. In the course of the addition, the deep-green colour of the lithium silanide changed to reddish-brown. The mixture was allowed to warm to ambient temperature over a period of 4 h, and was then heated under reflux for 48 h, which resulted in a colourless solution. According to NMR analysis of this solution, $LiBH_4$ and the silyltrihydridoborate **1** were present in a ratio of 1:17. All volatiles were then removed in vacuo, leaving a white powder. **1** was separated from $LiBH_4$ by washing the powder with hexane (3× 30 mL). An attempted crystallization from hexane solution was unsuccessful, a 100% excess of TMEDA (20 mmol) was added. At −20°C, **1** precipitated within 2 weeks as colourless crystals, which were suitable for X-ray diffraction analysis. Yield: 2.90 g (3.2 mmol, 64%), m.p. 110−114°C (decomp.). − $C_{54}H_{84}B_2Li_2N_6Si_2$ (908.97): calcd. C 71.35, H 9.31, N 9.25; found C 70.44, H 8.96, N 8.94. − ^{11}B NMR (64 MHz, C_6D_6): δ = −42.6 [q, ^1J(B,H) = 78 Hz, $h_{1/2}$ = 34 Hz]. − ^1H NMR (400 MHz, C_6D_6): δ = 7.93 (m, Si−C_6H_5), 7.57 (m, Si−C_6H_5), 7.24 (m, Si−C_6H_5), 7.11 (m, Si−C_6H_5), 2.02 (br. s, 12 H, N−CH_2−), 1.98 (br. s, 36 H, N−CH_3), 0.00 [br. q, ^1J(B,H) = 78 Hz]. − ^{13}C NMR (100 MHz, C_6D_6): δ = 136.7 (arom. C_i), 136.2 (arom. C_o), 130.1 (arom. C_p), 128.4 (arom. C_m), 51.6 (N−CH_2−), 46.1 (N−CH_3).

Lithium [(*tert*-Butyldiphenylsilyl)trihydridoborate] · Tris(tetrahydrofuran) (2a): A THF solution (30 mL) of freshly prepared *tert*-butyldiphenylsilyllithium (10 mmol) was added dropwise to a stirred solution of $BH_3 \cdot NEt_3$ (10 mmol) in THF (20 mL) at −30°C. In the course of the addition, the dark-brown colour of the lithium silanide became lighter, but did not disappear entirely. The mixture was allowed to warm to ambient temperature over a period of 4 h, and was then heated under reflux for 48 h, which resulted in a colourless but cloudy solution. According to NMR analysis of this solution, $LiBH_4$ and the silyltrihydridoborate were present in a ratio of 1:9. The volatiles were then removed in vacuo, leaving a white powder. **2a** was separated from $LiBH_4$ by washing the powder with hexane (3× 30 mL). At −20°C, **2a** precipitated from the hexane solution within 2 weeks as colourless crystals, which were suitable for X-ray diffraction analysis. Yield: 2.7 g (5.7 mmol, 57%), m.p. 98−101°C (decomp.). − $C_{28}H_{46}BLiO_3Si$ (476.49): calcd. C 70.58, H 9.73; found C 69.28, H 9.53. − ^{11}B NMR (64 MHz, C_6D_6): δ = −43.8 [q, ^1J(B,H) = 78 Hz, $h_{1/2}$ = 41 Hz]. − ^1H NMR (400 MHz, C_6D_6): δ = 8.11 (m, Si−C_6H_5), 7.31 (m, Si−C_6H_5), 3.52 (m, 12 H, THF: −O−CH_2−), 1.47 [s, 9 H, Si−C(CH_3)$_3$], 1.33 (m, 12 H, THF: −O−CH_2−CH_2−), −0.09 [q, ^1J(B,H) = 78 Hz, 3 H, BH_3]. − ^{13}C NMR (100 MHz, C_6D_6): δ = 137.0 (arom. C_o), 136.1 (arom. C_i), 127.2 (arom. C_p), 127.0 (arom. C_m), 68.3 (O−CH_2−CH_2), 29.5 [Si−C(CH_3)$_3$], 27.7 [Si−C(CH_3)$_3$], 25.4 (O−CH_2−CH_2−). − IR (Nujol): $\tilde{\nu}$ = 2284.3 (br. vs), 2257.2 (br. vs), 1962.4 (vw), 1946.4 (vw), 1483.6 (m), 1467.6 (m), 1459.2 (m), 1425.6 (vs), 1383.0 (m), 1370.0 (w), 1356.1 (m), 1341.6 (w), 1305.3 (w), 1293.8 (w), 1258.4 (m), 1182.2 (m), 1096.1 (vs), 1049.2 (vs), 1010.2 (m), 998.8 (w), 988.8 (vw), 935.2 (w), 916.7 (m), 894.3 (s), 820.8 (s), 738.3 (s), 731.6 (s), 702.5 (vs), 687.7 (s), 636.7 (s), 617.6 (m), 571.8 (m), 490.8 (s), 482.8 (s), 448.3 (m), 397.6 (w), 373.4 (w), 330.8 (w), 323.6 (w), 306.9 (w), 293.5 (m), 250.4 (vw).

Lithium [(*tert*-Butyldiphenylsilyl)trihydridoborate] · Pentamethyldiethylenetriamine (**2b**): A stoichiometric amount of PMDTA was added to a solution of **2a** in hexane. From the resulting solution, colorless crystals grew at −20°C within 7 days; m.p. 106−108°C (decomp.). − $C_{25}H_{45}BLiN_3Si$ (433.48): calcd. C 69.27, H 10.46, N 9.69; found C 68.43, H 9.98, N 8.97. − ^{11}B NMR (64 MHz, C_6D_6): δ = −43.8 [q, ^1J(B,H) = 79 Hz, $h_{1/2}$ = 20 Hz]. − ^{1}H NMR (400 MHz, C_6D_6): δ = 8.27 (m, Si−C_6H_5), 7.35 (m, Si−C_6H_5), 2.00 (br. s, 8 H, −N−CH_2−CH_2−), 1.87 (br. s, 16 H, N−CH_3), 1.54 [s, 9 H, Si−C(CH_3)$_3$], −0.10 [q, 3 H, ^1J(B,H) = 79 Hz, BH_3]. − ^{13}C NMR (100 MHz, C_6D_6): δ = 137.4 (arom. C_o), 136.3 (arom. C_i), 126.9 (arom. C_m), 126.8 (arom. C_p), 57.1 (N−CH$_2$−), 45.9 (N−CH$_3$), 29.9 [Si−C(CH$_3$)$_3$], 28.1 [Si−C(CH$_3$)$_3$]. − IR (Nujol): $\tilde{\nu}$ = 2335.4 (br. m), 2266.4 (br. ss), 2237.5 (br. s), 2008.4 (vw), 1956.5 (vw), 1882.8 (vw), 1826.5 (vw), 1770.2 (vw), 1653.2 (vw), 1588.3 (vw), 1484 (m), 1470.7 (vs), 1463.9 (vs), 1454.9 (vs), 1425.1 (vs), 1410.3 (w), 1390.0 (w), 1379.9 (w), 1361.4 (m), 1351.9 (m), 1324.0 (vw), 1299.3 (m), 1289.1 (m), 1250.4 (w), 1214.8 (vw), 1167.5 (m), 1151.5 (m), 1106.7 (vs), 1094.1 (vs), 1065.0 (m), 1055.7 (m), 1035.6 (s), 1030.1 (s), 1017.7 (m), 999.02 (w), 983.9 (m), 935.0 (m), 897.5 (w), 856.8 (vw), 818.7 (m), 788.3 (w), 773.1 (w), 738.6 (s), 703.7 (vs), 689.3 (s), 645.6 (m), 620.7 (m), 605.5 (vw), 597.9 (vw), 571.6 (m), 509.0 (vw), 482.4 (s), 433.6 (m), 404.9 (w), 3992.2 (w), 343.9 (vw), 316.0 (vw).

Lithium Tetrakis(trimethylsilyl)borate (**3**) and **Lithium Tris(trimethylsilyl)methylborate** (**4**) were prepared as described in the literature.[3]

X-ray Structure Determinations: Single crystals of compounds **1**, **2a**, **2b**, **3**, and **4** were obtained from hexane solutions at −20°C. The selected crystals were covered with perfluoroether oil, mounted on a glass fibre, placed on the goniometer head of the diffractometer, and cooled to −90°C under a flow of N_2. Preliminary dimensions of the unit cells were calculated from the reflections collected at four different settings of the crystal by recording 15 frames each with a CCD area detector. Data collection was performed with a 10 s exposure time per frame by rotating the crystal by 0.3° in φ at two different χ settings. The data from 1350 frames were reduced using the program SAINT[16] and the structures were solved by direct methods using the XS and SHELX97 programs for structure solution and refinement. The structure of compound **2b** showed disorder of one $NC_2H_4NMe_2$ bridge of the PMDTA coligand with an SOF of 0.5. Refinement of this disorder needed restraints in bond length for N−C and C−C distances. Atoms C17, C18, C20, C22, C22a, C24a, and C25a were refined with isotropic thermal parameters. All other non-hydrogen atoms were refined anisotropically, and the positions of hydrogens as found by difference Fourier maps were refined freely. Relevant data are presented in Table 3.

Crystallographic data (excluding structure factors) have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC 105281−105284. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, U.K. [Fax: (internat.) +44 (0)1223/ 336033; E-mail: deposit@ccdc.cam.ac.uk].

[8] Also isolated and characterized by X-ray structure determination was $[(t\mathrm{BuPh_2Si})\mathrm{BH_3} \cdot \mathrm{Li(thf)_2}]_2$. This compound was obtained in an experiment similar to that described for the preparation of **2a**. Its $\mathrm{SiBH_3}$ group acts as a $\mu_2{}^1$, $\mu_1{}^1$-ligand, bridging two Li units, which are pentacoordinated by two O atoms and 3 H atoms (of the THF molecules and two $\mathrm{BH_4}$ units). However, the crystal quality was less than satisfactory since refinement could not be improved beyond $R1 = 10.31$. Furthermore, solution was only possible in the triclinic space proup $P1$bar, whereas the unit cell dimensions showed the presence of a monoclinic crystal system. Crystal data are: $a = 12.2823(6)$, $b = 13.4825(6)$, $c = 15.4181(7)$ Å, $\alpha = 89.996(2)$, $\beta = 86.881(1)$, $\gamma = 89.984(1)°$, $Z = 2$. The data of the structure refinement have also been deposited with the CCDC.

Facile Preparation of Mono- and Bis(tin)-Substituted Niobocenes with Functionalized Stannyl Ligands: The Search for Non-Classical Interligand Interactions

Georgii I. Nikonov,*[a] Lyudmila G. Kuzmina,[b] Jörg Lorberth,[c] and Judith A. K. Howard[d]

Keywords: Niobium / Tin / Hydrides / Group 5 / Group 14

The reaction of niobocene trihydride [Cp_2NbH_3] with one equivalent of an alkyl- or aryltin halide X_nSnR_{4-n} (n = 1, 2) leads to products of the displacement of hydride by tin, i.e. [$Cp_2NbH_2(SnX_{3-n}R_n)$] [R = Me, n = 3 (**1**); R = Me, X = Cl, n = 2 (**3**); R = Ph, n = 3 (**4**); R = Ph, X = Cl, n = 2 (**5**); R = Et, X = Br, n = 2 (**6**)]. Use of an excess of the tin reagent results in a halodealkylation exchange reaction at the tin atom bound to the metal center. Reaction of the mono(silyl) complexes [$Cp_2NbH_2(SiXMe_2)$] (X = Cl, Ph) with organotin halides X_nSnR_{4-n} gives products of the displacement of silicon by tin, whereas the bis(silyl) complex [$Cp_2NbH(SiPhMe_2)_2$] does not undergo this reaction. The bis(tin)-substituted niobocene [$Cp_2NbH(SnMe_3)_2$] has been prepared by the reaction of [$Cp_2NbH_2(SnMe_3)$] with the tin amide Me_3SnNMe_2 under thermal conditions, as well as by the literature method of thermolysis of [$Cp_2NbH(\eta^2\text{-}C_2H_3Ph)$] in the presence of Me_3SnH. Reaction of [$Cp_2NbH(SnMe_3)_2$] with two equivalents of Cl_2SnMe_2 affords the bis(tin)-substituted complex [$Cp_2NbH(SnClMe_2)_2$] (**9**). The possible presence of non-classical hypervalent H···Sn–Cl interactions in this compound has been assessed by means of X-ray structure analysis. The structural data for **9** are in accord with an essentially classical description as a tin-substituted dihydride complex without significant Sn···H interactions.

Introduction

We have been studying the chemistry of trisubstituted Group-5 metallocene complexes bearing hydride and main-group element ligands in the bisecting plane of the metallocene moiety.[1–3] Initially, we focused on the development of convenient synthetic approaches to compounds of this class. These efforts resulted in the introduction of the insertion/deprotonation method based on the interaction of metallocene trihydrides [Cp_2MH_3] (M = Nb, Ta) with Group-15 halides XER_2 (E = P, As, Sb, Bi; X = Cl, Br).[1] This method provides easy access to dihydrides of the general formula [$Cp_2MH_2(ER_2)$]. A very similar approach, namely main-group element displacement of hydride, has recently been used by ourselves in the preparation of a plumbio-substituted niobocene,[2] and previously by Bulychev et al. in the preparation of a tin-substituted tantalocene.[4]

In this paper, we report an extension of these studies to the syntheses of mono- and bis(tin)-substituted niobocenes. Our interest in compounds of this type was intensified following our recent discovery of non-classical H···Si–Cl interligand interactions in the related silicon-substituted niobocene complexes [$Cp_2NbYH(SiR_2X)$] (Y = H, SiR_2X) bearing functionalized silyl ligands SiR_2X.[2] Thus, we were interested in finding analogous H···Sn–Cl interactions in the present systems. The main-group element displacement of hydride and halodealkylation exchange approaches reported herein provide a convenient entry to the chemistry of tin-substituted metallocenes bearing functionalized stannyl substituents SnX_nR_{3-n} (X = Cl, Br; R = Et, Me; n = 1, 2).

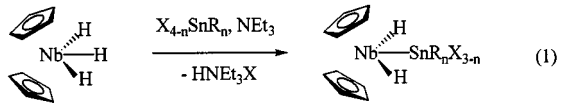
Results and Discussion



Mono(tin)-Substituted Complexes

The first tin-substituted niobocene hydrides [$Cp_2NbH_2(SnMe_3)$] (**1**) and [$Cp_2NbH(SnMe_3)_2$] (**2**), were prepared by Green et al. by means of oxidative addition of $HSnMe_3$ to the 16-electron intermediates [Cp_2NbH] and [$Cp_2NbCH_2CH_2Ph$], which were generated in situ from [Cp_2NbH_3] and the styrene complex [$Cp_2NbH(\eta^2\text{-}C_2H_3Ph)$], respectively.[5] This approach cannot, however, be applied to the syntheses of complexes bearing functionalized stannyl ligands since the parent compounds $XSnR_2H$ are not easily accessible. Green et al. also reported a metathetical reaction leading to **1**, between the anionic complex [Cp_2NbH_2]Li and $ClSnMe_3$, although this reaction proceeds under reducing conditions, thus restricting the use of functionalized tin reagents.[5] In 1986, Bulychev et al. showed that Cl_3SnMe and Cl_2SnMe_2 react with the d^0 complex [Cp_2TaH_3] to give [$Cp_2TaH_2(Cl_nSnMe_{3-n})$] ($n$ = 1, 2), whereas $ClSnMe_3$ does not undergo such a reaction.[4] The highest yields were observed when these reactions were carried out in the presence of an amine, which served to consume the generated HCl. These findings prompted this study of the analogous niobocene chemistry.

[Cp_2NbH_3] reacts readily with one equivalent of a tin halide X_nSnR_{4-n} (n = 1, 2) in diethyl ether in the presence of

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1999 1434–1948/99/0505–0825 $ 17.50+.50/0

NEt_3, to give the mono(tin)-substituted complexes $[Cp_2NbH_2(SnX_{3-n}R_n)]$ [R = Me, n = 3 (**1**); R = Me, X = Cl, n = 2 (**3**); R = Ph, n = 3 (**4**); R = Ph, X = Cl, n = 2 (**5**); R = Et, X = Br, n = 2 (**6**)] (Equation 1). The reactions commence immediately after the reactants are mixed and result in the formation of a flocculent precipitate of $ClH{\cdot}NEt_3$. The mixtures were left to stir overnight to ensure completion of the reactions. Complexes **1**, **3**–**6** could easily be isolated (after filtration and removal of the solvent) and were obtained as pale-yellow, air-sensitive, crystalline materials. The products seemingly showed indefinite thermal stability, as is also the case for the related plumbyl-substituted complex $[Cp_2NbH_2(PbMe_3)]$.[2] In contrast, the related Group-15 substituted complexes $[Cp_2NbH_2(EPh_2)]$ (E = Sb, Bi) exhibit little thermal stability and $Cp_2NbH_2(BiPh_2)$ is also very light-sensitive. Complexes **1**, **3**–**6** were characterized by NMR and IR spectroscopy. Their ^{1}H-NMR spectra are in accord with the formation of only one isomer, specifically that having a centrally positioned tin substituent and lateral hydride ligands. In contrast, the mono(silyl) complex $[Cp_2NbH_2(SiClMe_2)]$ exists in two isomeric forms, one of which, with a lateral silyl group, exhibits non-classical bonding between the hydride and silicon ligands.[3]

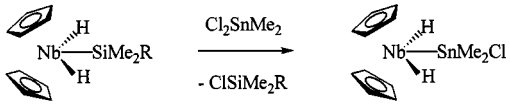
The mechanism of the reaction according to Equation 1 is intriguing. The d^0 complex $[Cp_2NbH_3]$ lacks a metal-centered lone pair of electrons, hence conventional nucleophilic substitution of halide at the tin center is not possible. Although the reaction is carried out in the presence of an amine to consume the HCl released, the amine cannot effect deprotonation of $[Cp_2NbH_3]$ to give a metallocene anion $[Cp_2NbH_2]^-$ amenable to a substitution reaction. It has long been shown by Tebbe that $[Cp_2NbH_3]$ is a basic, rather than an acidic hydride compound.[6] In fact, it can only be deprotonated by bases as strong as BuLi. Moreover, it has been shown that alkyltin halides react with $[Cp_2TaH_3]$ even in the absence of an amine, the yield being decreased as a result of subsequent reactions of the product with the generated HCl.[7] The absence of intermediate $[Cp_2NbH_2]^-$ in the reaction of Equation 1 was further supported by the results of an attempted reaction of $[Cp_2NbH_3]$ with D_2O in the presence of NEt_3. No deuterium incorporation was observed by NMR spectroscopy after stirring the mixture overnight. Therefore, the reaction of $[Cp_2NbH_3]$ with an alkyltin halide must occur through a direct interaction of a basic Nb–H bond with the tin reagent. The most likely mechanism is similar to that proposed by Pasynskii et al. for the reaction of $[Cp_2NbH(CO)]$ with tin halides.[8] It involves coordination of the Sn–Cl bond along the M–H polar bond forming a hydride-bridged bimetallic adduct and a five-coordinated tin center. Proton abstraction and halide dissociation complete the reaction (Scheme 1). At present, it is not clear as to whether dissociation of a halide precedes (this possibility is shown in Scheme 1) or follows the proton abstraction. More detailed studies are required to elucidate this matter.

Scheme 1

Preparation of compound **1** according to Equation 1 has apparent advantages over the reported procedures[5] since it allows for easy isolation of the product and requires only one step rather than two, starting from $[Cp_2NbH_3]$. Moreover, it provides an easy access to complexes with functionalized tin ligands. In order to carry out this reaction successfully, it is necessary to use strictly one equivalent of the tin halide, since excess X_nSnR_{4-n} effects a facile halodealkylation exchange reaction. For example, reaction of Cp_2NbH_3 with two equivalents of $ClSnMe_3$ gives a mixture of **1** and **3**. Similarly, addition of $ClSnMe_3$ to **1** results in the slow replacement of Me by Cl in **1** to give **3**, a process that could be monitored by NMR spectroscopy over a period of several days. In contrast, reaction of **1** with the more electrophilic Cl_2SnMe_2, leading to complex **3** and $ClSnMe_3$, reached completion in the course of overnight monitoring. Analogously, reaction of $[Cp_2NbH_3]$ with two equivalents of Br_2SnEt_2 furnished the dibrominated complex $Cp_2NbH_2(SnBr_2Et)$ (**7**) in high yield (Equation 2). Halodealkylation exchange reactions between transition metal tin complexes and tin halides have previously been observed in some tin-substituted molybdenocenes[9] and tungstenocenes.[10] Moreover, some silyl-substituted molybdenocene compounds have been shown to undergo intramolecular halodealkylation exchange between their coordinated silyl groups.[11] In comparison, in the non-transition metal chemistry of tin, and even more so in the case of silicon, analogous group interchange requires elevated temperatures. Apparently, it is coordination to the transition metal center that facilitates the exchange reaction, probably as a result of weakening of the Sn–C bond of the coordinated stannyl moiety. Bulychev showed that coordination of a stannyl group to a transition metal center effects rehybridization of the tin center,[9][12] in accordance with Bent's rule.[13] Thus, more tin s-orbital character contributes to

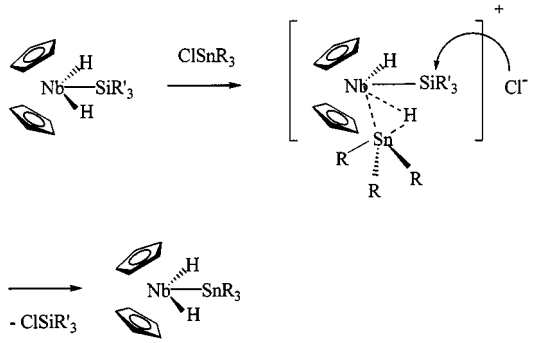


bonding with the metal center and consequently more tin p-orbital character is left for bonding with the alkyl substituents. This also means that the Sn−C bonds become more polar. The increase in p-orbital character also causes lengthening of the Sn−C bonds, which should decrease steric strain in the transition state for exchange. The observation that treatment of $[Cp_2Nb(CO)(SnPh_3)]$ with HCl leads to the formation of $[Cp_2Nb(CO)(SnCl_3)]$[8] rather than to cleavage of the Sn−Nb bond is a further manifestation of the rehybridization effect.

(2)

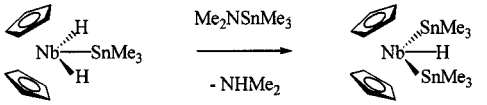
Tin-for-Silicon Exchange

We were interested in employing the hydride by tin displacement reaction for the preparation of mixed silicon/tin-substituted niobocenes of the formula $[Cp_2NbH(SiR'_3)(SnR_3)]$. No compounds of this type have hitherto been prepared. However, we found that the action of $X_{4-n}SnR_n$ on the mono(silyl) complexes $[Cp_2NbH_2(SiPhMe_2)]$ and $[Cp_2NbH_2(SiClMe_2)]$ led to quantitative yields of the corresponding mono(tin) compounds $[Cp_2NbH_2(SnX_{3-n}R_n)]$ (Equation 3). Addition of Cl_2SnMe_2 to the bis(silyl) complex $[Cp_2NbH(SiPhMe_2)_2]$ resulted in no reaction. In the latter case, the central hydride ligand is seemingly sterically too hindered by the silyl ligands to allow interaction with the tin halide. Two mechanisms can, in principle, be invoked to account for the above tin-for-silicon exchange. One implies a direct attack of the tin halide on the metal−silicon bond, while the second involves interaction of X_nSnR_{4-n} with the lateral hydride ligand as discussed above, with subsequent attack of the released halide anion X^- on the silicon substituent, as shown in Scheme 2. We favour the latter possibility, since it necessitates a less hindered transition state. The driving force for this exchange reaction seems to be the formation of a stable Si−Cl bond.



(3)

R = Ph, Cl

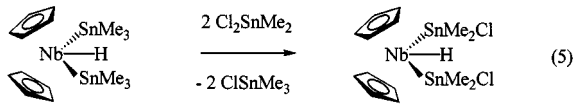


Bis(tin)-Substituted Complexes

The bis(tin)-substituted niobocene $[Cp_2NbH(SnMe_3)_2]$ (**2**) has been prepared by Green et al. by oxidative addition of $HSnMe_3$ to the olefin hydride complex $[Cp_2NbH(\eta^2\text{-}C_2H_3Ph)]$.[5] Reaction of $[Cp_2NbH(SnMe_3)]K \cdot$ (18-crown-6) with $ClSnMe_3$ has also been reported to give **2**.[14] In contrast, we have found the anionic mono(tin)-substituted

Scheme 2

complex $[Cp_2NbH(SnMe_3)]Li \cdot$ (15-crown-5) (**8**) to be incapable of serving as a precursor for bis(tin) derivatives. Attempted reaction of Cl_2SnMe_2 with **8** resulted in a complex mixture of products. The potassium salt appears to have a weakly bound cation and therefore a more nucleophilic metallocene anion, whereas the lack of selectivity in the latter reaction can be explained in terms of effective competition between the metathetical reaction and the facile halodealkylation. This presumably leads to a mixture of mono- and bis(tin)-substituted complexes with variable numbers of alkyl and halogen groups on each tin atom. Also, as mentioned above, due to the facile halodealkylation at the tin center, the hydride-by-tin displacement reaction cannot be employed for the synthesis of bis(tin) derivatives starting from the mono(tin)-substituted compounds. As an alternative approach to complex **2**, we studied Lappert's amine elimination reaction.[15] This method involves interaction of a metal hydride with a tin amide $R_2NSnR'_3$ and requires elevated temperatures (ca. 80−100°C). Lappert et al. used this reaction to prepare $[Cp_2TaH_2(SnMe_3)]$ from $[Cp_2TaH_3]$ and Me_2NSnMe_3, whereas an analogous reaction with $[Cp_2NbH_3]$ led to bis(niobocene) owing to the low thermal stability of niobocene trihydride.[5] By heating a mixture of complex **1** with Me_2NSnMe_3 at 85°C for 8 h, we obtained **2** as the main reaction product (Equation 4).



(4)

1 **2**

Complex **2** was used as a starting material for the synthesis of the functionalized bis(tin)-substituted complex $[Cp_2NbH(SnClMe_2)_2]$ (**9**) by the chlorodemethylation exchange reaction. Thus, overnight stirring of a mixture of two equivalents of Cl_2SnMe_2 with one equivalent of **2** led to complex **9** in high yield (Equation 5). The product was characterized by spectroscopic methods and X-ray diffraction analysis.

As the mono(tin)-substituted niobocenes have centrally positioned tin ligands, they were considered unlikely to show any significant interligand Sn−H interactions.[3c] In contrast, the bis(tin) complex **9** is a structural analogue of the non-classical bis(silyl) complex $[Cp_2NbH-$

(5)

2 9

$(SiClMe_2)_2]$,[3a] and therefore might be expected to show analogous non-classical bonding between Sn and the hydride ligands. To clarify this matter, an X-ray structural investigation of **9** was undertaken. Structures of four tin-substituted niobocenes[5][8] and of one tin-substituted tantalocene[7] have previously been reported, but only one of these, namely the anionic complex $[Cp_2Nb(SnMe_3)_2]^-$, has two tin ligands bound at the metal center.[5a] Crystals of **9** suitable for X-ray analysis were grown from diethyl ether solution. The crystal structure was found to contain two independent molecules of **9** per unit cell. The molecular structure of one of these is shown in Figure 1. Selected bond lengths and angles are given in Table 1. It is noteworthy that in both independent molecules the hydride ligands could be localized from the difference map and refined to the realistic Nb−H distances of 1.76(6) and 1.80(5) Å, in spite of the presence of three heavy atoms. In a neutron diffraction study of $[Cp_2NbH(SiClMe_2)_2]$, the hydride was found at a distance of 1.813 Å from the niobium,[16] while the Nb−H bond lengths in $[Cp_2NbH_3]$, determined by accurate NMR relaxation studies, were found to fall in the range 1.78−1.80 Å.[17] However, the two molecules of **9** are different in that in one of them the hydride is symmetrically positioned in the bisecting plane of the niobocene moiety, while in the second it is shifted closer to one of the tin centers resulting in a short contact of 2.13 Å. An analogous short Sn−H contact of 2.16(4) Å found in the compound $[Cp'Mn(CO)_2HSnPh_3]$ was taken as an indication of complexation of the $H-SnR_3$ bond.[18] Apart from this, the geometries of the four tin centers in the two molecules of **9** are very similar, which rules out any speculation about Sn−H non-classical bonding in the asymmetric structure of **9**. Thus, the observed Nb−Sn σ-bond lengths lie in the range 2.8015−2.8114(6) Å, while the Sn−Cl bonds fall in the range 2.448−2.479(1) Å, but no systematic trends in these parameters are in evidence. Both the Nb−Sn and Sn−Cl bonds are somewhat shorter in the second molecule than the corresponding bonds in the first, which can be attributed to crystal packing effects. This observation suggests that the coordination environments about the tin atoms are very soft. In comparison, the Nb−Sn bond lengths in other tin derivatives of niobocene, bearing SnR_3 (R = alkyl, aryl) ligands, are found in the range 2.817−2.862(1) Å,[5][8] whereas in the trichlorotin derivative $[Cp_2Nb(CO)(SnCl_3)]$[8] a shorter Nb−Sn bond length of 2.764(1) Å is observed due to the electron-withdrawing effect of the chloro substituents. The most compelling evidence in favour of a classical description of **9** and the absence of significant Sn−H interaction is provided by the large values of 109.7(2)° and 108.87(2)° for the Sn−Nb−Sn bond angles in the two independent molecules. In the non-classical complex $[Cp_2NbH(SiClMe_2)_2]$, a noticeably smaller Si−Nb−Si bond angle of 105.57(4)° is found, which reflects the attraction of the lateral Si atoms to the central hydride.[3a] The former values are close to the Si−M−Si bond angles of 110.81(5)° and 109.90(7)° found in the classical complexes $[Cp_2NbH(SiPhMe_2)_2]$[3c] and $[Cp_2TaH(SiHMe_2)_2]$,[19] respectively.

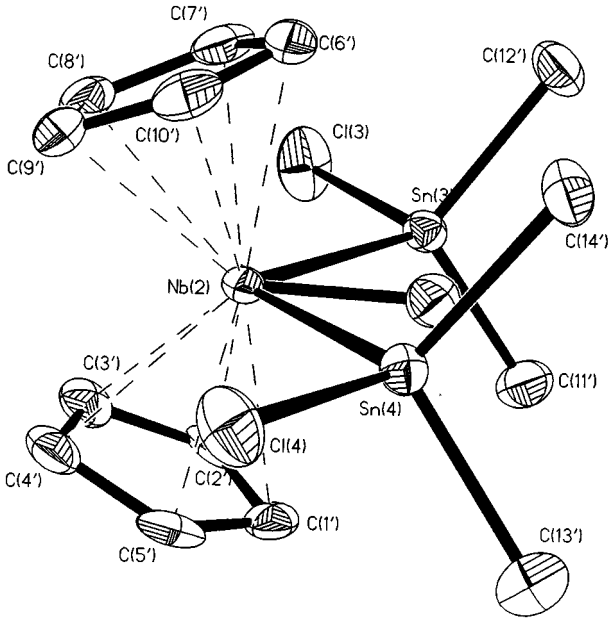


Figure 1. Molecular structure of **9**; hydrogen atoms other than hydride are omitted for the sake of clarity

Conclusions

We have shown herein that reaction of niobocene trihydride with alkyltin halides gives the products of direct displacement of hydride by tin, and thus represents an effective method for the synthesis of niobocene dihydride complexes substituted by functionalized tin ligands. Moreover, we have found that the use of an excess of the tin halide effects a halodealkylation exchange reaction at the coordinated tin center, thus giving products with a larger number of halide substituents at the tin atom. In comparison with the corresponding chemistry in uncoordinated-to-metal tin compounds, this reaction is remarkably facile. This approach has been exploited synthetically in the preparation of the bis(tin)-substituted complex $[Cp_2NbH(SnClMe_2)_2]$ (**9**) from $[Cp_2NbH(SnMe_3)_2]$. At present, it would seem that this halodealkylation exchange reaction represents the only feasible route for preparing compound **9**. Reaction of tin halides with silyl hydride derivatives of niobocene proceeds only for the mono(silyl) dihydride substituted compounds and affords the products of displacement of silicon by tin. Thus, a synthetic approach to the elusive mixed tin/silicon complexes of the formula $[Cp_2NbH(SnR_3)(SiR'_3)]$ has still to be developed. Finally, an X-ray structure determination of compound **9** did not reveal any significant non-classical Sn−H interligand interaction. The reason for this appears

to be the long Nb−Sn bond length, which leads to only minor overlap between the Nb−H bonding and Sn−Cl antibonding orbitals, and therefore precludes the transfer of electron density from the former to the latter.

Experimental Section

General: All manipulations were carried out using conventional Schlenk techniques. − Solvents were dried with sodium or sodium benzophenone ketyl. − NMR: Varian VXR-400 spectrometer (^{1}H: 400 MHz; ^{13}C: 100.4 MHz). − IR: Perkin-Elmer 1600 FT-IR spectrometer. − Tin halides were purchased from Merck. − [Cp_2NbH_3] was prepared by the modified procedure reported in an earlier publication.[1a] Compounds **1** and **2** have been reported previously.[5]

Preparation of $Cp_2NbH_2(SnMe_3)$ (1): 0.502 g (2.22 mmol) of [Cp_2NbH_3] and 0.442 g (2.22 mmol) of Me_3SnCl were mixed in 70 mL of diethyl ether, and then 3 mL of NEt_3 was added. The mixture was stirred overnight, then filtered, and the residue was washed with 50 mL of diethyl ether. All volatiles were then removed in vacuo from the combined filtrate and washings to leave a light-beige powder. Yield: 0.730 g (1.88 mmol, 85%). NMR data are as reported in the literature.[5b]

Preparation of $Cp_2NbH_2(SnMe_2Cl)$ (3). − Method a: The preparation was carried out analogously to that of **1**, to afford **3** in 80% yield.

Method b: [$Cp_2NbH_2SnMe_3$] (0.502 g, 1.72 mmol) and Me_2SnCl_2 (0.386 g, 1.72 mmol) were mixed in 20 mL of diethyl ether, and then 2 mL of NEt_3 was added. The resulting mixture was stirred for 2 d. The solvent was then removed in vacuo and the residue was extracted with toluene. The solution was filtered and all volatiles were removed in vacuo to leave rose-pink crystals. Yield: 0.233 g (0.54 mmol, 32%).

Method c: 0.142 g (1.34 mmol) of [$Cp_2NbH_2SiMe_3$] was added to a solution of 0.098 g (0.45 mmol) of Me_2SnCl_2 in 2 mL of NEt_3 and 10 mL of diethyl ether. The resulting mixture was left overnight, then filtered, and the residue was extracted with 10 mL of diethyl ether. All volatiles were removed in vacuo from the combined fractions, to leave a pale-pink substance. Yield: 0.184 g (0.45 mmol, 100%).

Method d: 0.483 g (0.45 mmol) of [$Cp_2NbH_2SiMe_2Ph$] was added to 0.295 g (1.34 mmol) of Me_2SnCl_2 and 3 mL of NEt_3 in 40 mL of diethyl ether. A bright-red colour soon developed. The mixture was left overnight, whereupon a light-lilac solution was obtained. This solution was filtered, and the residue was extracted with 4× 40 mL of diethyl ether. All volatiles were removed in vacuo from the combined fractions to leave a lilac-coloured substance. Yield: 0.540 g. NMR spectra showed the product to be a mixture of $Cp_2NbH_2SnMe_2Cl$ and $ClSiMe_2Ph$.

Analytically pure material, prepared by Method b, was obtained by recrystallization from diethyl ether. − ^{1}H NMR ([D_6]benzene): δ = 4.82 (s, 10 H, Cp), 1.05 [s + d, ^2J(Sn−H) = 31.6 Hz, 6 H, CH_3], −4.79 [s + 2d, ^2J(Sn−H) = 254.5 and 239.2 Hz, 2 H, Nb−H]. − ^{13}C NMR ([D_6]benzene): δ = 87.4 (s, Cp), 18.0 (s, Me). − $C_{12}H_{18}ClNbSn$ (409.34): calcd. C 35.21, H 4.43; found C 34.95, H 4.01.

Preparation of $Cp_2NbH_2(SnPh_3)$ (4): 0.335 g (1.48 mmol) of [Cp_2NbH_3] and 0.571 g (1.48 mmol) of Ph_3SnCl were mixed in 15 mL of toluene, and then 1 mL of NEt_3 was added. The resulting mixture was stirred overnight, then filtered, and the residue was washed with 15 mL of diethyl ether. All volatiles were removed in vacuo from the combined fractions to leave a white powder. Yield: 0.800 g (1.33 mmol, 90%). − IR (Nujol): $\tilde{\nu}$ = 1682 cm^{-1} (Nb−H). − ^{1}H NMR ([D_6]benzene): δ = 7.98 [d, J(H−H) = 7.6 Hz, 6 H, Ph], 7.32 [t, J(H−H) = 7.4 Hz, 6 H, Ph], 7.22 [t, J(H−H) = 7.4 Hz, 3 H, Ph], 4.48 (s, 10 H, Cp), −4.28 [s + d, ^2J(Sn−H) = 180.8

Hz, 2 H, Nb−H]. − ^{13}C NMR ([D$_6$]benzene): δ = 137.3 (s, Ph), 128.7 (s, Ph), 128.6 (s, Ph), 127.4 (s, Ph), 86.8 (s, Cp). − $C_{28}H_{27}NbSn$ (575.14): calcd. C 58.47, H 4.73; found C 58.58, H 4.96.

Preparation of $Cp_2NbH_2(SnClPh_2)$ (5): 0.448 g (1.98 mmol) of [Cp_2NbH_3] and 0.681 g (1.48 mmol) of Ph_2SnCl_2 were mixed in 15 mL of diethyl ether, and then 1 mL of NEt_3 was added. The resulting mixture was stirred overnight. The supernatant solution was then decanted and the residue was extracted with 5 × 10 mL of toluene. All volatiles were removed in vacuo from the combined toluene fractions to leave a white crystalline material. Yield: 0.388 g (0.727 mmol, 37%). − IR (Nujol): $\tilde{\nu}$ = 1682 cm^{-1} (Nb−H). − ^{1}H NMR ([D$_6$]benzene): δ = 8.60 [d, J(H−H) = 6.8 Hz, 4 H, Ph], 7.32 [t, J(H−H) = 7.6 Hz, 4 H, Ph], 7.18 (t, J_{H-H} = 7.2 Hz, 2 H, Ph), 4.52 (s, 10 H, Cp), −4.18 [s + 2d, J(Sn−H) = 131 Hz and ^2J(Sn−H) = 125 Hz, 2 H, Nb−H]. − ^{13}C NMR ([D$_6$]benzene): δ = 152.8, 135.5, 128.6, 128.3 (s, Ph), 87.7 (s, Cp). − $C_{22}H_{22}ClNbSn$ (533.49): calcd. C 49.53, H 4.16; found C 49.51, H 4.88.

Preparation of $Cp_2NbH_2(SnEt_2Br)$ (6): 3 mL of NEt_3 was added to 0.730 g (3.23 mmol) of [Cp_2NbH_3] in 40 mL of diethyl ether. Then, 1.087 g (3.23 mmol) of Et_2SnBr_2 in 10 mL of diethyl ether was added, resulting in the immediate deposition of white flakes. The mixture was stirred overnight, then filtered, and the residue was washed with 10 mL of diethyl ether. All volatiles were removed in vacuo from the combined fractions to leave a light-yellow powder. Yield: 1.148 g (2.38 mmol, 74%). − IR (Nujol): $\tilde{\nu}$ = 1682 cm^{-1} (Nb−H). − ^{1}H NMR ([D$_6$]benzene): δ = 4.57 (s, 10 H, Cp), 1.56 [t, ^3J(H−H) = 7.8 Hz, 6 H, CH_3], 1.35 (m, 4 H, CH_2), −4.61 [s + d, ^2J(Sn−H) = 247.7 Hz, 2 H, Nb−H]. − ^{13}C NMR ([D$_6$]benzene): δ = 87.2 (s, Cp), 17.3 (s, CH_3), 11.8 (s, CH_2). − $C_{14}H_{22}BrNbSn$ (481.85): calcd. C 34.90, H 4.60; found C 34.54, H 4.37.

Preparation of $Cp_2NbH_2(SnEtBr_2)$ (7): 4 mL of NEt_3 was added to 0.292 g (0.606 mmol) of $Cp_2NbH_2(SnEt_2Br)$ in 25 mL of diethyl ether. Then, 0.204 g (0.606 mmol) of Et_2SnBr_2 was added, resulting in the immediate deposition of white flakes. The mixture was stirred overnight, then filtered, and the residue was washed with 25 mL of diethyl ether. All volatiles were removed in vacuo from the combined fractions to leave a light-yellow powder, which was recrystallized from cold diethyl ether. NMR spectra revealed the product to be **7** contaminated by a minor impurity; complete removal of this impurity could not be achieved. Yield: 0.210 g. − IR (Nujol): $\tilde{\nu}$ = 1728.2 cm^{-1} (Nb−H). − ^{1}H NMR ([D$_6$]benzene): δ = 4.67 (s, 10 H, Cp), 1.52 [t, ^3J(H−H) = 7.8 Hz, 6 H, CH_3], 1.38 (m, 4 H, CH_2), −4.60 [s + d, ^2J(Sn−H) = 247.4 Hz, 2 H, Nb−H]. − ^{13}C NMR ([D$_6$]benzene): δ = 87.33 (s, Cp), 17.46 (s, CH_3), 11.74 (s, CH_2).

Preparation of $Cp_2NbH(SnMe_3)_2$ (2). − Method a: Preparation from [$Cp_2NbH(C_2H_3Ph)$] in 82% yield according to the literature method.[5b]

Method b: A mixture of 0.381 g (0.98 mmol) of [$Cp_2NbH_2(SnMe_3)$] and 0.204 g (0.98 mmol) of Me_3SnNMe_2 in 10 mL of toluene was heated at 85°C for 8 h. All volatiles were then removed in vacuo and the residue was extracted with 20 mL of diethyl ether. Removal of the solvent left 0.250 g (0.45 mmol, 46%) of a brown substance. The obtained product was found to be contaminated by minor amounts of impurities. NMR data are as reported in the literature.[5b]

Preparation of $Cp_2NbH(SnClMe_2)_2$ (8): 0.652 g (2.97 mmol) of Me_2SnCl_2 was added to a suspension of 0.819 g (1.48 mmol) of [$Cp_2NbH(SnMe_3)_2$] in 50 mL of diethyl ether and the resulting mixture was stirred overnight. The supernatant solution was then decanted and the residue was extracted with 30 mL of diethyl ether. All volatiles were removed in vacuo from the combined fractions to leave 0.777 g of a white crystalline substance. This material was washed with 15 mL of petroleum ether to ensure complete removal of Me_3SnCl and then recrystallized from diethyl ether. Yield: 0.547 g (0.92 mmol, 62%). − IR (Nujol): $\tilde{\nu}$ = 1664 cm^{-1} (Nb−H). − ^{1}H NMR ([D$_6$]benzene): δ = 4.58 [s + d, J(Sn−H) = 4.5 Hz, 10 H, Cp], 0.52 [s + d, ^2J(Sn−H) = 35.8 Hz, 12 H, Me], −4.78 [s + d, ^2J(Sn−H) = 280.0 Hz, 1 H, Nb−H]. − ^{13}C NMR ([D$_6$]benzene): δ = 88.0 (s, Cp), 5.2 (s, Me). − $C_{14}H_{23}Cl_2NbSn_2$ (592.77): calcd. C 28.38, H 3.91; found C 28.01, H 3.77.

Crystal Structure Determination of 9: Colourless crystals of **9** were grown from diethyl ether solution. A crystal of **9** of dimensions 0.22 × 0.16 × 0.12 mm was covered with oil and mounted at 150(2) K on a Siemens three-circle diffractometer equipped with an area CCD detector (SMART system). Crystal data: M_r = 592.77; monoclinic, space group $P2(1)/n$; a = 17.0123(3) Å, b = 8.31860(10) Å, c = 27.76540(10), β = 96.82°, Z = 8, V = 3901.48(8) Å^3, $d_{calcd.}$ = 2.018 gcm^{-3}. Data collection: 2θ range from 1.34° to 26.50°, *hkl* range −19 to 21, −10 to 8, −34 to 31; 25550 measured reflections, of which 8085 were considered as unique [R(int) = 0.0527]; analytical absorbtion correction based on Ψ scans (μ = 3.380 mm^{-1}, T_{max} = 0.6872, T_{min} = 0.5235). The structure amplitudes for the 8085 independent reflections were obtained after the usual Lorentz and polarization corrections. The structure was solved by direct methods[20] and refined by full-matrix least-squares procedures[21] against F^2. Only the reflections with $F_o^2 > 2\sigma F_o^2$ were used in the refinements (6371). Hydrogen atoms were found from the difference map and were refined isotropically. In the final cycles of the refinement, all non-hydrogen atoms were refined with anisotropic temperature parameters. $R1$ = 0.0351 and $wR2$ = 0.0553 (only observed reflections), and $R1$ = 0.0574 and $wR2$ = 0.0598 (all data); 528 parameters, $GooF$ = 1.121. The largest peak in the final difference Fourier map had an electron density of 0.704 e·Å^{-3}, while the lowest hole had a value of −0.764 e·Å^{-3}. The location and magnitude of the residual electron density was of no chemical significance. Further details of the crystal structure investigation may be obtained from the Cambridge Crystallographic Data Centre on quoting the depository number (CCDC-105593), the names of the authors, and the full journal citation.

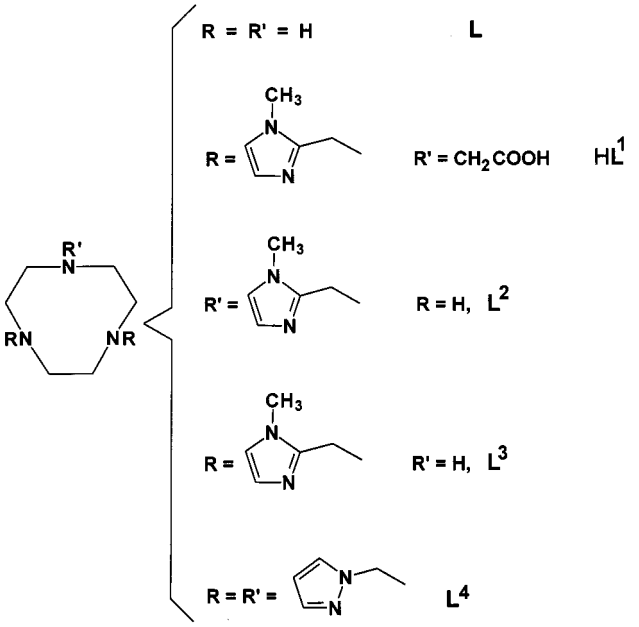
Lead(II) and Bismuth(III) Complexes with Macrocyclic Ligands



Massimo Di Vaira,[a] Fabrizio Mani,*[a] and Piero Stoppioni[a]

Keywords: Lead / Bismuth / Coordination chemistry / Macrocyclic ligands / Tetraphenylborate–lead(II) interaction

The preparation and X-ray characterization of a Pb^{2+} and a Bi^{3+} complex formed with macrocyclic ligands are reported. In the dimeric complex $[\{Pb(CH_3COO)\mathbf{L}BPh_4\}_2]$, where **L** is 1,4,7-triazacyclononane, the metal atoms are chelated by **L** and bridged by an acetate group; moreover, each of the metal atoms is at contact distance from a tetraphenylborate phenyl group, which completes the coordination. The unsymmetrically derivatized macrocycle 1-carboxymethyl-4,7-bis(1-methylimidazol-2-ylmethyl)-1,4,7-triazacyclononane ((AUTHOR: Substituents are alphabetized: c before m!)), $\mathbf{HL^1}$, in its deprotonated ($\mathbf{L^1}$, anionic) form gives the complex of formula $BiCl\mathbf{L^1}BPh_4$ with Bi^{3+}, which contains $[BiCl\mathbf{L^1}]_2^{2+}$ dimeric cations with eight-coodinated Bi^{3+} and bridging acetate groups within the dimer.

Lead is a persistent and ubiquitous toxic metal, and soil contamination by lead is widespread owing to several industrial activities, mainly battery making and recycling, oil refining, and paint manufacturing.[1] Amongst the techniques for lead-contaminated soil remediation that are being investigated, the removal of the contaminant by chelation is apparently the environmentally most sound.[2]

Within the field of the coordination chemistry of lead(II) we are interested in the synthesis and characterization of its complexes with functionalized macrocycles. In the course of these studies we have found that lead(II) coordinated to 1,4,7-triazacyclononane bearing one, two, or three appended groups ($\mathbf{L^2}$, $\mathbf{L^3}$, $\mathbf{L^4}$) (Scheme 1) further interacts in an η^6-C_6H_5 fashion with a phenyl group of a BPh_4^- anion.[3][4] These results show that the contact interaction of BPh_4^- with lead(II), although unprecedented, is not fortuitous as long as functionalized macrocycles of the above nature are employed. With the aim of further investigating the conditions that make the BPh_4^- interaction with a metal ion feasible, we have prepared a lead(II) complex with the unsubstituted macrocycle 1,4,7-triazacyclononane **L** in the presence of $NaBPh_4$. In the course of investigations into an analogous trend in bismuth(III) complexes we have prepared a Bi^{3+} complex of the unsymmetrically substituted 1,4,7-triazacyclononane $\mathbf{HL^1}$ ligand (Scheme 1). Bismuth(III) is isoelectronic with lead(II) and possesses a similar electronegativity value, but has a smaller ionic radius than lead(II): 103 pm and 119 pm for six-coordinate species.[5] Bismuth and its compounds are regarded as less toxic than lead and have been widely used in traditional medicine.[6] More recently, compounds of bismuth(III) have gained considerable importance because of their potential applications in therapy of cancer[7] (^{212}Bi radioactive isotope) and gastric ulcers,[8] as well as in the technology of high-temperature superconductors.[9] For all these reasons the coordination chemistry of lead(II) and bismuth(III) has attracted increasing attention in recent years, particularly in the search for chelating ligands that may function as efficient metal-sequestring agents (Pb^{2+})[10] and for possible applications in biomedical science (Bi^{3+}).[11–13]

Scheme 1. Ligands referred to in the text

We report here the syntheses and X-ray structural characterizations of the two complexes $[Pb(CH_3COO)\mathbf{L}BPh_4]$ (**1**) (**L** = 1,4,7-triazacyclononane) and $[BiCl\mathbf{L^1}BPh_4]$ (**2**) [$\mathbf{L^1}$ is the deprotonated form of the compound 1-carboxymethyl-4,7-bis(1-methylimidazol-2-ylmethyl)-1,4,7-triazacyclononane, $\mathbf{HL^1}$].

Results and Discussion

The reaction of lead(II) acetate with the cyclic triamine 1,4,7-triazacyclononane **L** and $NaBPh_4$ in MeOH/MeCN solution produces colourless crystals of a compound with the formula $Pb(CH_3COO)\mathbf{L}BPh_4$ (**1**) where a BPh_4^- anion has replaced an acetate anion of the starting $Pb(CH_3COO)_2 \cdot 3\,H_2O$ salt. Two lead(II) complexes formed

[a] Dipartimento di Chimica, Università di Firenze, Via Maragliano 77, I-50144 Florence, Italy

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1999 1434–1948/99/0505–0833 $ 17.50+.50/0

by the **L** macrocycle, Pb**L**$(ClO_4)_2$ and Pb**L**$(NO_3)_2$, have been described previously[14] and their X-ray structural characterizations have shown that, in addition to the **L** macrocycle, both anions are coordinated to lead(II) in each complex, giving rise to highly irregular coordination polyhedra. In order to establish the possible role of the BPh_4^- anion in the coordination of the metal atom in complex **1**, the structure of the compound has been determined. Partly for comparison purposes $BiCl_3$ (Bi^{3+} is isoelectronic with Pb^{2+}) was allowed to react with the macrocycles, shown in Scheme 1, in the presence of $NaBPh_4$. A crystalline product was obtained only when the unsymmetrically functionalized macrocycle 1-carboxymethyl-4,7-bis(1-methylimidazol-2-ylmethyl)-1,4,7-triazacyclononane (**HL^1**) containing an appended acetate group in addition to methylimidazoles, was employed. The complex obtained had the formula Bi**Cl**$\mathbf{L^1}BPh_4$ (**2**) (**L^1** is the anionic form of the **HL^1** ligand) and its crystal structure was determined by X-ray diffraction. The affinity of bismuth(III) for nitrogen donors is considered to be significant and, in particular, larger than that of lead(II).[12][15] In agreement with this, in the formation of **2** most bonds within the $BiCl_3$ reactant are broken and the available coordination sites about the metal centre are occupied by the donor atoms of the macrocyclic ligand, which are predominantly nitrogen atoms. On the other hand, when ligands with uncharged oxygen donors, such as the 4,5,6-donor crown ether, are employed,[13] the $BiCl_3$ unit is found to remain intact and neutral complexes are obtained with non-coordinated oxygen atoms.

The structure of complex **1** consists of $[Pb(CH_3COO)\mathbf{L}BPh_4]_2$ dimers where the monometal fractions, related by a twofold symmetry axis, are joined by an acetate anion in a disordered orientation (Figure 1). Each lead(II) atom is coordinated by the three nitrogen atoms of the macrocycle and by three oxygen atoms from the acetate groups, which have fractional occupancies. In addition, the lead(II) atom is approached at contact distance by a tetraphenylborate phenyl group in a similar fashion to that previously detected for lead(II) complexes formed by the **L** macrocycle bearing various substituents.[3][4] The distance of 3.37(1) Å between the metal atom and the phenyl centroid is within the range (3.06−3.44 Å) of the distances previously found. Each of the acetate anions in the dimer is randomly distributed between two positions related by the symmetry axis. As detailed in the Experimental Section, all fractions of the acetate anions have been assigned a population parameter of 0.5. As a consequence of this, and also given the fact that the position of the bridging (fractional) oxygen atom [O(1)] almost coincides with that of its symmetry-related fraction, the lead(II) atom is surrounded by an oxygen site having full occupancy [O(1) + O(1)′; symmetry operation $1 - x$, y, $1/2 - z$] and by two half-occupied sites [O(2) and O(3)]. The acetate group in the bridging position is also chelating the metal atom through O(1) and O(2), whereas the other group is essentially non-chelating, since its O(4) atom lies at a considerably longer distance from the metal centre than the coordinating O(3) atom (Table 1). In agreement with the arrangement found for the four structures previously investigated, which exhibit a close approach of a phenyl group to the metal atom,[3][4] one macrocycle nitrogen, N(1) in **1**, lies almost *trans* to the phenyl ring while the other two N and the fractional O donors are approximately arranged in a plane almost perpendicular to the N(1)−ring centroid direction. As described previously,[3][4] the metal atom is displaced from that plane in the direction of the phenyl group. The Pb−N distances formed by the unsubstituted triazamacrocycle (mean value 2.50 Å) are shorter than those formed by the macrocycle nitrogen atoms when **L** be-

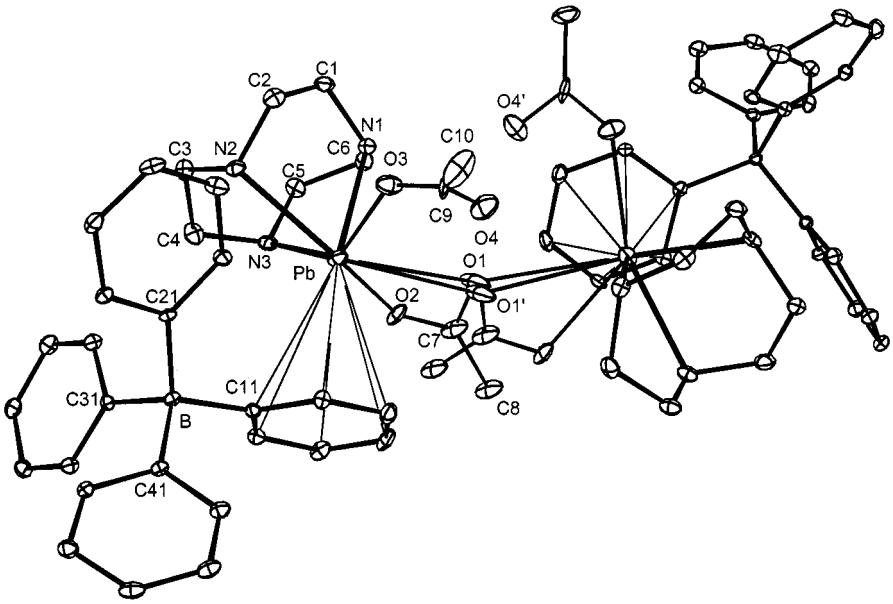


Figure 1. A view of the $[Pb(CH_3COO)\mathbf{L}BPh_4]_2$ dimer in the structure of **1**, showing the atom numbering scheme; all atoms of the acetate groups have a population parameter of 0.5; hydrogen atoms are not shown and only the *ipso*-carbon atoms of phenyl rings are labeled for clarity; primed atoms are related to the corresponding unprimed ones through a twofold symmetry axis

ars substituents (2.52−2.81 Å, range of individual values),[3][4] but are longer than the distances (mean 2.43 Å) found for the two lead(II) complexes formed by the same **L** macrocycle and the coligands with limited space demands ClO_4^- and NO_3^-.[14] The Pb−O distances are in the range of those found for carboxylate complexes.[16]

Table 1. Selected bond lengths [Å] and angles [°] for compound **1**[a−c]

Pb−N(1)	2.423(8)	Pb−O(1)′[b]	2.92(4)
Pb−N(2)	2.558(7)	Pb−O(2)	2.46(1)

O(1)−Pb−N(2)	146.5(1.3)	O(3)−Pb−N(3)	141.8(4)
O(1)−Pb−N(3)	101.3(1.2)	Pb−O(1)−Pb′	149.1(4)

[a] All of the oxygen sites, belonging to the acetate anions, have 0.5 occupancy. Primed atoms are related to the corresponding unprimed ones by a twofold symmetry axis. − [b] The O(1) and O(1)′ sites are almost coincident and together provide one full-occupancy donor atom site in the coordination sphere of each metal atom. − [c] The Pb···C contact distances with the phenyl group carbon atoms are in the range 3.54−3.79 Å.

In agreement with previous results,[3][4] extended Hückel calculations[17][18] on suitable model systems for **1** have shown that the lead(II) lone pair, forming the HOMO of the metal fragment, is neatly oriented away from the region of the "normally" coordinating ligands toward the centre of the phenyl group. This result is practically unaffected by changes to the model aimed at mimicking the partial acetate anion occupancies. Calculations of this type do not account for charge effects and provide rather indirect evidence for the polarization effects that are expected to contribute significantly to the attractive interaction. On the other hand, such calculations stress the repulsive contribution originating from the interaction between the lone pair and the bonding system of the phenyl group. That repulsive contribution is minimized if the lone pair points toward the centre of the phenyl group, as has been shown to occur by the calculations for all five cases investigated. Although the lead(II)/phenyl group interaction under discussion should be considered as a van der Waals interaction augmenting the non-specific ionic component, its surprisingly high strength is revealed by the fact that it appears to be one of the factors that control the packing in the solid state for the compounds in which it has been detected.

Although, in principle, the type of interaction with the tetraphenylborate anion discussed above might be expected to also occur in the bismuth compound **2**, it was found not to be present in that case, probably due to lower extension of the bismuth(III) lone pair compared to that of lead(II) and to the greater importance of ionic interactions in the structure of the bismuth complex. The structure consists of centrosymmetric dimeric $[BiCl\mathbf{L^1}]_2^{2+}$ cations and isolated BPh_4^- anions. Each metal atom is eight-coordinated by the three macrocycle nitrogen atoms and the two methylimidazole nitrogen atoms of the $\mathbf{L^1}$ ligand, by two carboxylate oxygen atoms from different ligands and by the chlorine atom (Figure 2). Each carboxylate group is bridging within the

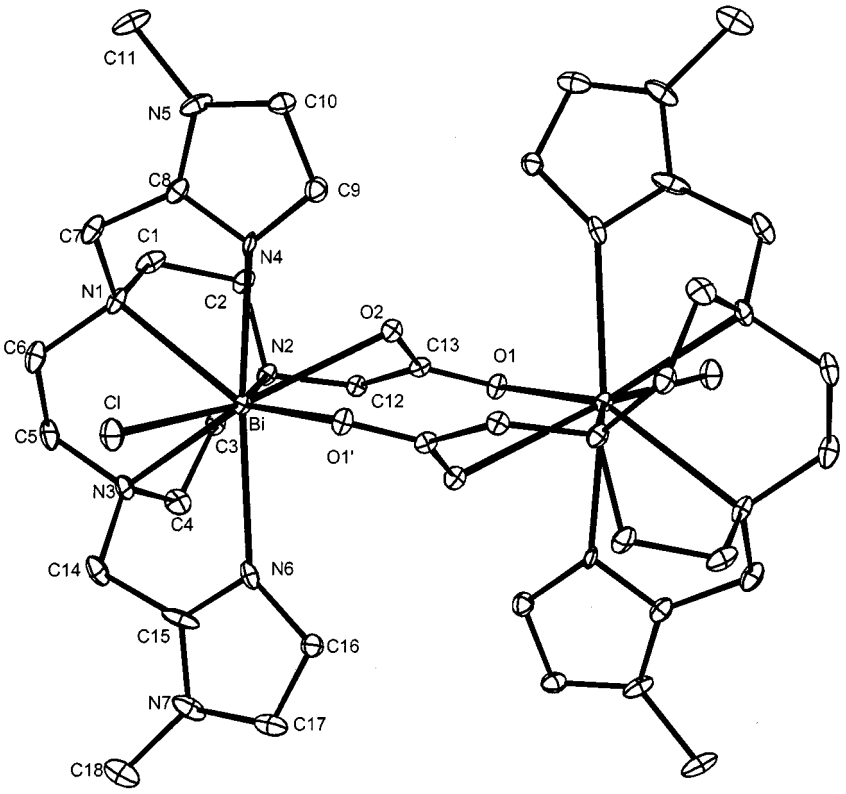

Figure 2. A view of the centrosymmetric $[BiCl\mathbf{L^1}]_2^{2+}$ cation in the structure of **2**; atom O1′ is related to O1 through the inversion centre

dimer, with its two oxygen atoms linked to the different metal atoms. There are five donor atoms [N(1), N(3), N(4), N(6), and O(1)′, symmetry operation $-x, -y, -z$] lying approximately in a plane that also contains the metal atom, with the largest deviations from the plane being < 0.4 Å. The chlorine atom and the midpoint of the two remaining donor atoms N(2) and O(2) define a direction perpendicular to the above plane. Although close comparisons between the present structures are not possible, it is worth noting that the mean value of the distances to the metal centre formed by the macrocycle nitrogen atoms is larger in **2** by 0.22 Å in comparison to **1**, whereas that of the metal−oxygen distances is smaller by 0.14 Å in **2**. These features may again reveal the effect of substituents on the macrocyclic ring, discussed above for the metal−nitrogen interactions in lead(II) compounds, but they may also be due to a higher preference of bismuth(III) for bonds having appreciable ionic character, compared to lead(II). The conformation attained by the $\mathbf{L^1}$ ligand in the bismuth(III) complex differs from the more regular arrangement, approaching threefold symmetry, found for the same ligand in monometal complexes of first-transition-row metal ions.[19] On the other hand, it is not too dissimilar from the arrangement of the pyrazole-trisubstituted macrocycle in the lead(II) complex $Pb\mathbf{L^4}(BPh_4)_2$, where a BPh_4^- phenyl group makes a close approach to the metal atom.[4] By means of extended Hückel calculations on a model of the monometal fraction of the bismuth(III) complex where the environment of the metal atom was schematized in the usual ways,[3][4] with the coordination geometry accurately reproduced, it was verified that the HOMO of the complex essentially consists of the unhybridized metal s orbital, and therefore is without specific directional properties.

Table 2. Selected bond lengths [Å] and angles [°] for compound **2**

Bi−N(1)	2.63(1)	Bi−N(6)	2.54(1)
Bi−N(2)	2.72(1)	Bi−Cl	2.619(4)
Bi−N(3)	2.80(1)	Bi−O(1)′[a]	2.412(8)
Bi−N(4)	2.45(1)	Bi−O(2)	2.601(9)
N(1)−Bi−N(2)	69.0(3)	Cl−Bi−N(1)	81.1(3)
N(1)−Bi−N(3)	65.1(3)	Cl−Bi−N(2)	143.3(2)
N(2)−Bi−N(3)	63.9(3)	Cl−Bi−N(3)	84.7(3)
N(1)−Bi−N(4)	65.5(3)	Cl−Bi−N(4)	88.0(3)
N(3)−Bi−N(6)	62.6(3)	Cl−Bi−N(6)	85.3(3)
N(4)−Bi−N(6)	164.6(3)	Cl−Bi−O(1)′[a]	81.2(2)
O(1)′−Bi−O(2)[a]	75.9(3)	Cl−Bi−O(2)	150.3(2)

[a] The O(1)′ atom is related to O(1) by the inversion centre.

Experimental Section

All reagents were reagent grade. Commercial solvents, when required in the synthetic procedures, were dried according to standard methods and distilled just before use. Hydrated lead(II) acetate (Baker), anhydrous bismuth(III) chloride (Acros), and sodium tetraphenylborate (Baker) were used as received. **L**[20] and $\mathbf{HL^1}$[19] were prepared using procedures reported previously. General experimental methods and measuring techniques were as reported in ref.[19]

$Pb(CH_3COO)LBPh_4$ (1): The salt $Pb(CH_3COO)_2 \cdot 3\,H_2O$ (0.379 g, 1.00 mmol), dissolved in MeOH (20 mL), and a solution of **L** (0.129 g, 1.00 mmol) in MeCN (20 mL) were mixed together at reflux temperature with stirring. Sodium tetraphenylborate (0.684 g, 2.00 mmol) in MeCN (10 mL) was subsequently added to the above mixture and the resulting solution was concentrated nearly to dryness. The residue was redissolved in MeOH and, after addition of EtOH and concentration to a small volume at room temperature, colourless crystals of the complex were obtained. The crystals used for X-ray analysis were obtained by concentration at room temperature of a dilute acetonitrile solution of **1**. − $C_{32}H_{38}BN_3O_2Pb$ (714.65): calcd. C 53.8, H 5.36, N 5.88, found C 53.3, H 5.56, N 5.59. − IR (KBr): $\nu_{asym}(COO^-) = 1590\ cm^{-1}$.

$BiClL^1BPh_4$ (2): $NaBPh_4$ (0.684 g, 2.00 mmol), dissolved in Me_2CO (20 mL), was added with stirring to a boiling solution of anhydrous $BiCl_3$ (0.315 g, 1.00 mmol) and $\mathbf{HL^1}$ (0.376 g, 1.00 mmol) in MeOH (35 mL). On concentrating the resulting solution to a small volume, colourless crystals of **2** were obtained. Recrystallization of the complex from boiling MeCN gave crystals suitable for X-ray diffraction. − $C_{42}H_{48}BBiClN_7O_2$ (938.11): calcd. C 53.8, H 5.16, N 10.5, found C 53.1, H 5.22, N 10.2. − IR (KBr): $\nu_{asym}(COO^-) = 1580\ cm^{-1}$.
