COVER PICTURE

The cover picture shows the structure of an unusual dinuclear $Rh^{I}-Rh^{III}$ complex obtained in the reaction of the tetradentate ligand 3,6-bis(2-pyridyl)pyridazine with cationic (diene)Rh^{I} precursors. Initially, the expected N,N-bidentate Rh^{I} complex is formed, which upon further reaction with the Rh^{I} precursor undergoes C–H bond activation of the pyridazine ring, forming a C,N-bidentate Rh^{III} center. This is followed by a unique rearrangement of the diene, which is dependent on the metal precursor and on the ligand used. Details are discussed in the article by D. Milstein et al. on p. 70ff. We thank Relli Mahager (Graphics Department, WIS) for producing the colour picture.

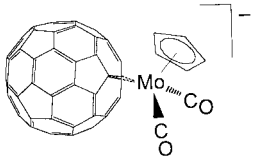
Anionic Cyclopentadienyl C_{60} Complexes of Molybdenum and Tungsten; The Strange Case of Iron



Keywords: Fullerenes / Molybdenum / Tungsten / Iron

Sandwich and Half-Sandwich (Imido)niobium Complexes

Antonio Antiñolo,[a] Mariano Fajardo,[b] Antonio Otero,*[a] and Sanjiv Prashar[b]

Keywords: Niobium / Imido ligands / Cyclopentadienyl ligands / *ansa*-Niobocene complexes

This review discusses the study we have carried out towards the synthesis, structure and reactivity of (imido)niobium complexes, which contain at least one cyclopentadienyl ligand. The following families of niobium complexes are described: (i) half-sandwich imido complexes; (ii) metallocene imido compounds; (iii) imido complexes containing *ansa*-cyclopentadienyl ligands; (iv) dinuclear imido complexes such as $[\{Nb(\eta^5\text{-}C_5H_4SiMe_3)_2Cl\}_2(\mu\text{-}1,3\text{-}N_2C_6H_4)]$. In addition we describe spectroscopic and structural features of the (imido)niobium complexes.

1. Introduction

The interest arising from the use of imido groups as ligands in the organometallic chemistry of the group 5 elements has experienced a rapid increase in the past decade. Half-sandwich complexes are well known in (imido)niobium chemistry.[1−25] Their metallocene counterparts have also been studied but to a lesser degree.[24−30]

The attention dedicated to imido-containing niobium complexes can be attributed firstly to the isoelectronic relationship that this ligand shares with the cyclopentadienyl moiety. Thus, the half-sandwich imido fragment Nb(=NR)Cp is isoelectronic with MCp_2 (M = Ti, Zr, Hf). Secondly, the imido group can also be bound to the metal atom in differing fashions acting either as a two- or four-electron donor.

Antonio Antiñolo (top, left) was born in Cartagena, Spain in 1956. He obtained his graduate degree in 1978 from the University of Murcia and his Doctorate in 1982 with Prof. Pascual Royo at the University of Alcalá de Henares. After his postdoctoral appointment with Prof. Michael F. Lappert in 1984 at the University of Sussex, Antonio Antiñolo took up a lectureship position at the University of Alcalá de Henares in 1984. In 1990 he moved to the University of Castilla-La Mancha and became a Full Professor in 1999. His current research interests are centred on metallocene and ansa-metallocene derivatives of early transition metals as possible stereoselective catalysts in olefin polymerization and the activation of small molecules in polyhydride chemistry.

Mariano Fajardo (top, right) was born in Cartagena, Spain in 1956. He obtained his graduate degree in 1978 from the University of Murcia and his Doctorate in 1982 with Prof. Pascual Royo at the University of Alcalá de Henares. From 1982 to 1984 he worked as a postdoc with Prof. Jack Lewis at the University of Cambridge. On his return to Spain he took up a lectureship post at the University of Alcalá de Henares. In the year 2000 he was appointed Full Professor at the University Rey Juan Carlos in Madrid. His current research interests are centred on complexes of early transition metals as possible stereoselective catalysts in olefin polymerization and epoxidation processes and the role of metal complexes in environmental chemistry.

Antonio Otero (bottom, left) was born in Minglanilla (Cuenca), Spain in 1949. He obtained his graduate degree in 1973 from the University of Murcia and his Doctorate in 1976 with Prof. Pascual Royo. From 1978−1979, he worked as a postdoctoral fellow at the University of Oxford with Prof. Malcolm Green researching C−H bond activation processes from cyclopentadienylmolybdenum and -tungsten organometallic complexes. From 1979 to 1989 he was a lecturer at the University of Alcalá. In December 1989, he was appointed Full Professor in Inorganic Chemistry at the University of Castilla-La Mancha. He has authored more than 130 publications in reviewed journals. His current research interests include organometallic chemistry of early transition metals, particularly of group 4 and 5 elements, homogeneous catalytic processes of olefin polymerization with group 4 metallocene catalysts, and heterogeneization of homogeneous catalysts on different inorganic supports.

Sanjiv Prashar (bottom, right) was born in London, United Kingdom in 1966. He obtained his B.Sc. in 1987 and his D.Phil. in 1992 with Prof. Michael F. Lappert from the University of Sussex. His first postdoctoral appointment took him to Spain where he worked with Prof. Pascual Royo at the University of Alcalá de Henares. In 1995 he moved to Ciudad Real in the Spanish Mancha and for more than 6 years he worked at the University of Castilla-La Mancha in collaboration with Professors Antonio Antiñolo and Antonio Otero. It was here that the majority of this study of (imido)niobium compounds was carried out. In October 2001 he took up a lectureship position at the University Rey Juan Carlos in Madrid where his current research interests are centred on ansa-metallocene derivatives of early transition metals as possible stereoselective catalysts in olefin polymerization.

MICROREVIEWS: This feature introduces the readers to the author's research through a concise overview of the selected topic. Reference to important work from others in the field is included.

Imido ligands, are common ligands in high-oxidation-state transition-metal chemistry. An (imido)metal complex has the general form M=NR where there is a double bond between the metal centre and the nitrogen atom. In addition, the lone pair on the nitrogen atom usually donates electron density to the metal centre, providing a triple-bond interaction with the metal atom.

In high-valent complexes the imido unit is usually considered to be RN^{2-} whereas in low-valent complexes it tends to be considered as a neutral ligand. When specifying how many electrons an imido ligand donates it is therefore necessary to state which electron formalism one is using and to consider how the nitrogen atom is participating in the bonding (Scheme 1). It should be noted that the imido and oxo ligands are isoelectronic.

	$L_nM{=}N{-}R$	$L_nM{\leftarrow}N{\equiv}C$
Hybridization at nitrogen:	sp^2	sp
Idealized bond angle:	120°	180°
Isoelectronic to:	$L_nM{=}O$	$L_nM{\leftarrow}O$
Electron donation:		
NR^{2-}	$4e^-$	$6e^-$
neutral	$2e^-$	$4e^-$

Scheme 1. Hybridization and electron counting in imido compounds

The M−N−R bond angle can, in most cases be regarded as an indicator of the degree of π-donation from the nitrogen atom. Imido ligands are very good π-donors and thus the overwhelming majority of imido complexes are linear or near-linear (bond angles from 150 to 180°).

The imido ligand can act as a spectator ligand similar to the role played by cyclopentadienyl or can directly participate in the reactivity namely in protonation processes. Imido ligands are of interest not only for their role as ancillary ("spectator") ligands, but for the potential group transfer of the imido unit to an organic moiety.

2. Discussion

2.1 (Imido)niobium Precursors

The complexes [Nb(=NAr)Cl_3(DME)] [Ar = C_6H_4Me-4 (**1**), C_6H_4OMe-4 (**2**)][31] [Equation (1)] were prepared by a modification of the synthetic methods reported for other (imido)niobium halide complexes.[32,33] The synthesis of [Nb(=N*t*Bu)Cl_3(py)$_2$] was reported by Sundermeyer et al.[34] These complexes have been employed in the synthesis of the cyclopentadienyl-containing niobium complexes discussed hereafter.

$$NbCl_5 + ArNH_2 + DME + 2py + 2ZnCl_2 \xrightarrow{CH_2Cl_2} [Nb(=NAr)Cl_3(DME)] + 2[pyH][ZnCl_3] \quad (1)$$

Ar = C_6H_4Me-4 (**1**), C_6H_4OMe-4 (**2**)

The ^{1}H NMR spectra of **1** and **2** show clearly the inequivalence of the methyl and methylene groups of the DME adduct suggesting, for an octahedral disposition, that this ligand is bonded to the metal centre by two Nb−O links in which one oxygen atom is located *cis* to the imide group and the other oxygen atom *trans*. This has been confirmed by X-ray crystal diffraction studies (Figure 1).[35]

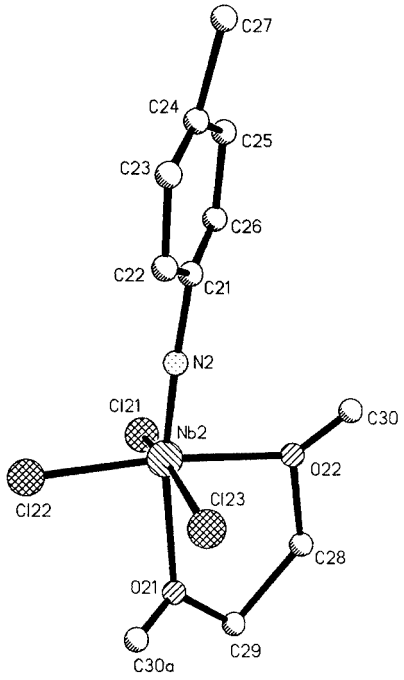

Figure 1. Molecular structure of [Nb(=NC_6H_4Me-4)Cl_3(DME)] (**1**)

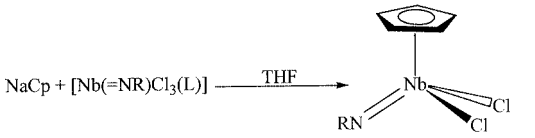
2.2 Half-Sandwich (Imido)niobium Complexes

2.2.1 Synthesis

The principal synthetic routes, reported previously in the literature, for the preparation of half-sandwich (imido)niobium complexes involved the reaction of [Nb(η^5-C_5R_5)Cl_4] with the appropriate amine H_2NR' or $NR'(SiMe_3)_2$.[20,23] However, [Nb(=N*t*Bu)$CpCl_2$] (**3**) and [Nb(=NC_6H_4Me-4)$CpCl_2$] (**4**) were prepared by the straightforward reaction of 1 mol-equiv. of NaCp with [Nb(=N*t*Bu)Cl_3(py)$_2$] or **1**, respectively [Equation (2)].[31]

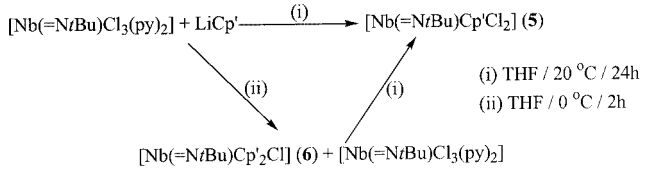


(2)

When the same reaction was carried out between [Nb(=N*t*Bu)Cl_3(py)$_2$] and LiCp′ (Cp′ = η^5-$C_5H_4SiMe_3$) both the monosubstituted [Nb(=N*t*Bu)Cp′Cl_2] (**5**) and disubstituted [Nb(=N*t*Bu)Cp′$_2$Cl] (**6**) complexes were shown to be present (Scheme 2).[31]

2.2.2 Structural Characterization

Complexes containing the unsubstituted cyclopentadienyl ligand show a unique signal in their ^{1}H NMR

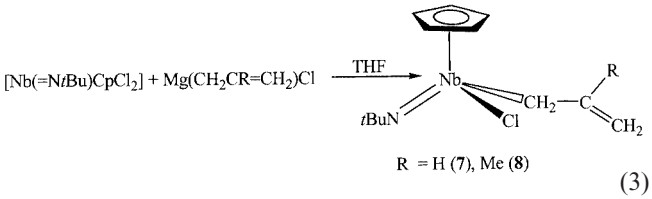


Scheme 2

spectra regardless of the surrounding symmetry for this moiety. However, when a substituent is introduced in the cyclopentadienyl ring, the resulting ring protons give signals directly related to the symmetry of the complex. Thus for **5**, an AA′BB′ system for the ring protons is observed in the ^{1}H NMR spectrum.

2.2.3 Reactivity with Allyl Grignard Reagents

The allyl(imido)niobium complexes [Nb(=N*t*Bu)Cp(η^1-$CH_2C(R)CH_2$]Cl] [R = H (**7**), Me (**8**)] were prepared by the reaction of **3** with the corresponding allylmagnesium chloride [Equation (3)].[36] In the ^{1}H NMR spectrum for **7** and **8** the signals associated with η^1-allyl systems, namely three signals corresponding to the CH_2 moiety bonded to the metal centre, the central group C(R) and the olefinic protons for the terminal CH_2, were observed. The values of the coupling constants and those of other η^1-allyl complexes discussed in this review are given in Table 1.

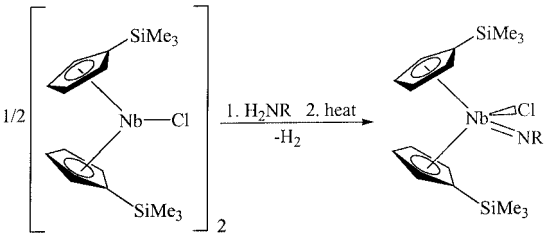


R = H (**7**), Me (**8**) (3)

2.3 (Imido)niobocene Complexes

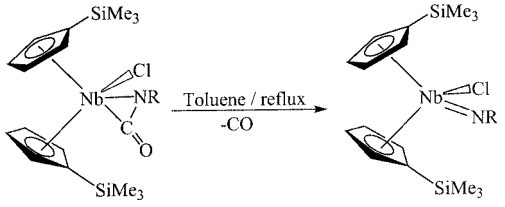
2.3.1 Synthesis

Although the chemistry of monocyclopentadienyl(imido) complexes of niobium is well documented[1−25] far fewer examples of bent (imido)niobocene complexes can be found in the literature.[24−30] Our initial studies in this field led to the synthesis of [Nb(=NR)Cp′$_2$Cl] [R = *t*Bu (**6**), Ph (**9**), *n*Pr (**10**), *i*Pr (**11**)] along two distinctive preparative routes.[37,38] The first involved the reaction of RNH_2 with [{NbCp′$_2$Cl}$_2$] in accordance with a sequence involving initial oxidative addition of the amine, giving rise presumably to an amido intermediate which on subsequent thermolytic expulsion of H_2 affords the imido derivative [Equation (4)].[37] The second route consisted of the thermal treatment of [NbCp′$_2$(RNCO)Cl] to give the desired imido complex [see Equation (5)].[37,38]



(4)

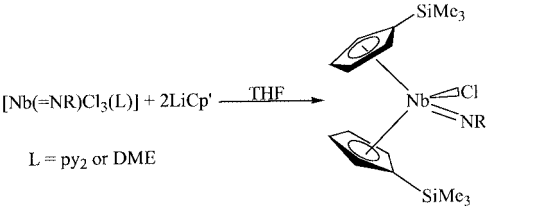
R = *t*Bu (**6**), Ph (**9**), *n*Pr (**10**), *i*Pr (**11**)



(5)

R = *t*Bu (**6**), Ph (**9**), *n*Pr (**10**), *i*Pr (**11**)

A more straightforward preparative method, by the reaction of 2 equiv. of LiCp′ with the corresponding (imido)niobium halide precursor [Equation (6)], was used in the synthesis of [Nb(=NR)Cp′$_2$Cl] [R = *t*Bu (**6**), C_6H_4Me-4 (**12**), C_6H_4OMe-4 (**13**)].[31] In a similar manner the imido complex [Nb(=NC_6H_4Me-4)Cp$_2$Cl] (**14**) was synthesized.[39] The mixed sandwich complex [Nb(=N*t*Bu)-CpCp′Cl] (**15**) was prepared by the addition of LiCp′ to a THF solution of [Nb(=N*t*Bu)CpCl$_2$] (**3**) [Equation (7)].[31]



(6)

R = *t*Bu (**6**), C_6H_4Me-4 (**12**), C_6H_4OMe-4 (**13**)

2.3.2 Structural Characterization

The ^{1}H NMR spectra of the $(Cp')_2$(imido) complexes **6**, **9**−**13** all give similar signal patterns reflecting the C_s symmetry of the molecules. Thus, there is inequivalency between the cyclopentadienyl ring protons in the same system but equivalency between the two rings. An ABCD system is therefore observed.

The molecular structures of **9** and **13**, determined by single-crystal X-ray diffraction studies are depicted in Figures 2 and 3.

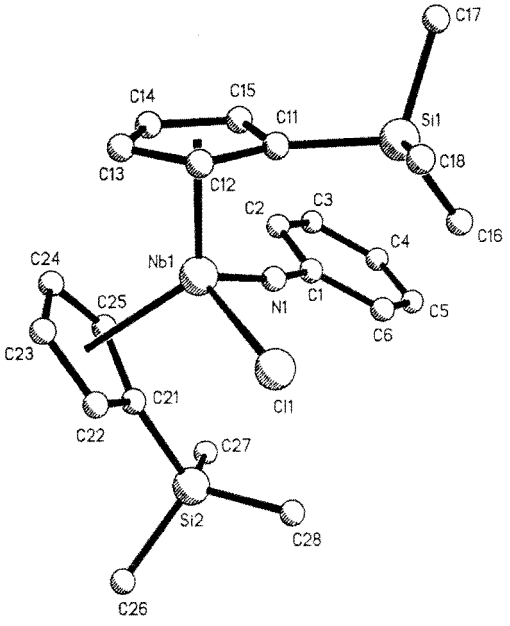

Figure 2. Molecular structure of [Nb(=NPh)Cp′$_2$Cl] (**9**)

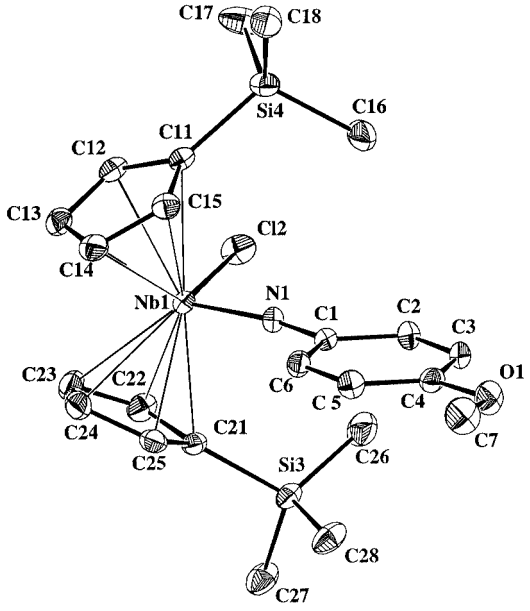

Figure 3. Molecular structure of [Nb(=NC$_6$H$_4$OMe-4)Cp′$_2$Cl] (**13**)

The structural features of **9** and **13** are nearly identical and thus for reasons of simplicity, reference is only made to the former complex.

Compound **9** is a monomer in the solid state and shows a typical bent-metallocene structure. Interestingly, the chlorine atom and the phenyl group lie practically in the equatorial plane, in a similar disposition to that found previously for [Ta(=NPh)(η^5-$C_5Me_5)_2$H] and [Ta(=NH)(η^5-$C_5Me_5)_2$Cl].[40,41] Using a frontier-orbital approach Jørgensen[42] explained why the phenyl group in this type of complexes lies in the equatorial plane and not perpendicular to it in an alternative arrangement. The Nb−N bond length is 1.792(2) Å, indicating that probably a bond order halfway between two (Nb=N) and three (Nb≡N) is present. However, the interesting structural parameter is the value of 165.1(2)° found for the Nb−N−C_{ipso} moiety. In the structures reported linear M−N−C geometries are observed for virtually all metallocene complexes (see Table 4). However, for **9** a deviation in this angle of about 15° is observed. The bent arrangement may indicate that the imido nitrogen atom is sp^2-hybridized, but in such a case the phenyl substituent should be orientated out of the equatorial plane towards one of the cyclopentadienyl ligands.[40] Therefore, in spite of the low angle for Nb−N−C_{ipso}, we propose that the nitrogen atom is sp-(not sp^2-)hybridized and that the two limiting descriptions, Nb≡N−R and Nb=N−R, proposed by Bercaw and co-workers for (η^5-$C_5Me_5)_2$Ta(=NPh)(H) may explain the true bonding situation.[40]

In order to gain more insight into the nature of the Nb−N bond, extended-Hückel molecular-orbital calculations have been performed.[43−46] Figure 4 shows an interaction diagram for the frontier orbitals of [Nb(=NPh)Cp_2Cl] from [$NbCp_2Cl]^{2+}$ to the left and NPh^{2-} to the right.[37] The results are in agreement with those found previously by Jørgensen[42] for [Ta(=NPh)(η^5-$C_5Me_5)_2$H].

A Walsh diagram for five of the frontier orbitals for bending of the phenyl group in the equatorial plane between 180 and 120° is illustrated in Figure 5, and shows that the highest occupied molecular orbital (HOMO) is unaffected by this bending in contrast to the bending out of the equatorial plane where an increase in energy similar to that described for [Ta(=NPh)(η^5-$C_5Me_5)_2$H] is observed.[37] However, the Walsh diagram shows that the second and third HOMO increase in energy upon bending the phenyl group (θ = 140°) and a change in total energy from −1717.63 eV for θ = 180° to 1714.54 eV for θ = 120° is observed. However, no significant changes in energy between θ = 180 and 140° are observed, indicating that in complex **9**, with Nb−N−C_{ipso} of 165°, electronic effects are not responsible for this deviation from linear. The Nb−N and N−C_{ipso} overlap populations decrease as a result of the bending and the charge at the niobium atom decreases as the charge at the nitrogen atom increases (see Table 2). The phenyl substituent arranges itself so as to maximize the overlap with the nitrogen p-orbital, but slight modifications of this overlap are observed in the range θ = 180−160°. We have established that the imido bond angles for "linear imide" in this class of complexes can vary to 140° with little effect on the M−N bonding.[37]

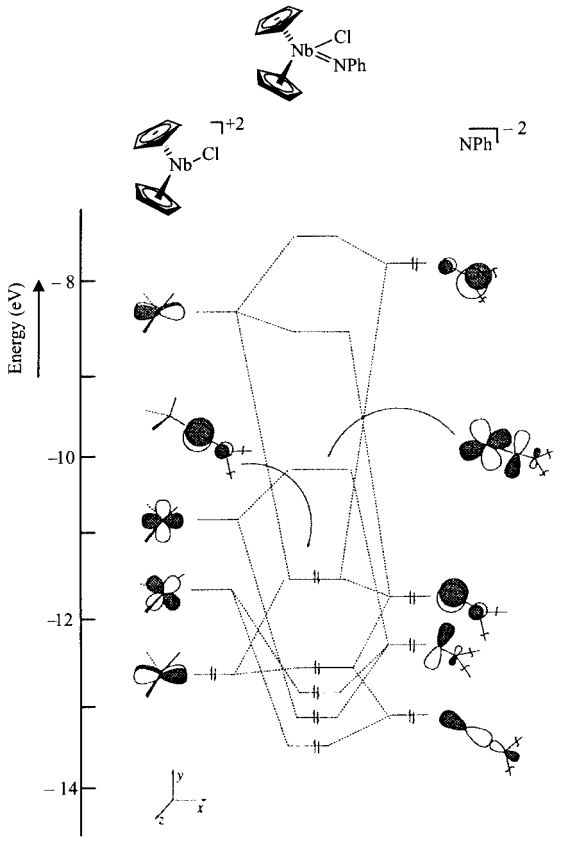

Figure 4. Interaction diagram for the formation of [Nb(=NPh)Cp_2Cl] from $[NbCp_2Cl]^{2+}$ to the left and NPh^{2-} to the right; some of the frontier orbitals are shown in the centre

The formal electron count of **9** is 20 electrons with the excess 2 electrons probably being located in a nonbonding orbital similar to that proposed by Green et al. for [Mo(=N*t*Bu)(η^5-C_5H_5)$_2$].[47] Similar "20-electron" (imido)niobocene complexes [Nb(=NR)(η^5-$C_5H_4SiMe_3$)$_2$Cl] have shown a lengthening of the Nb−centroid distances in comparison with their 18- and 17-electron analogues and this too occurs in **9** (see Table 3). Indeed, such lengthening has also been observed in (imido)metallocene complexes of titanium[48] and molybdenum.[47] The bonding in the "19-electron" vanadium complex [V(=$NC_6H_3Me_2$-2,6)(η^5-C_5Me_5)$_2$] has previously been studied by molecular orbital calculations and led to the proposal that the surplus electrons in these "high-electron" complexes are located in essentially ligand-based orbitals and thus the 18-electron rule is not violated.[49−51] Similar calculations have been carried out for "20-electron" osmium complexes [Os(NR)$_3$].[52]

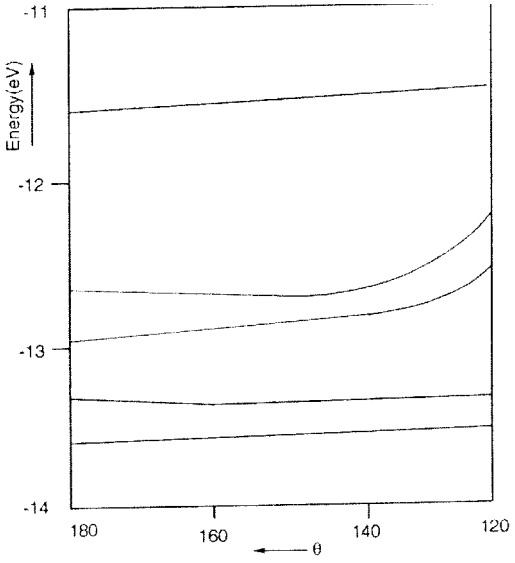

Figure 5. Walsh diagram for the bending of the phenyl group in the equatorial plane

2.3.3 Alkyl Derivatives

Despite the broad scope of imido group 5 metal chemistry only a handful of alkyl-containing (imido)niobocene complexes have previously been reported.[24,25,30] We have expanded this field by the preparation of the following new

Table 2. Values for the overlap populations of the N−C and Nb−N bonds and charges (N, Nb) as a function of the bending angle Nb−N−C(Ph) in the equatorial plane

R = *i*Pr, R' = Ph, R" = $SiMe_3$ (**24**). (8)

In the ^{1}H NMR spectra of the ethyl complexes **16** and **19** (Figure 6) the ethyl group displays an A_3BC pattern with typical values of J_{AB} = 7.0, J_{AC} = 7.5, J_{BC} = 14.0 Hz, similar to those reported previously in two ethyl complexes of niobium.[61,62] This observation indicates the inequivalency of the methylene protons due to either H-bonding interactions C−H···N between the alkyl and imido groups, which restrict rotation about the Nb−C bond or the presence of an unusually weak agostic interaction between an α-hydrogen atom of the ethyl group and the metal centre. The latter explication is favoured because in complexes that do not contain electronegative ligands, e.g. [$NbCp_2$-(Et)(RC≡CR)], the same phenomena of possible agostic interactions is observed in the NMR spectra.[62]

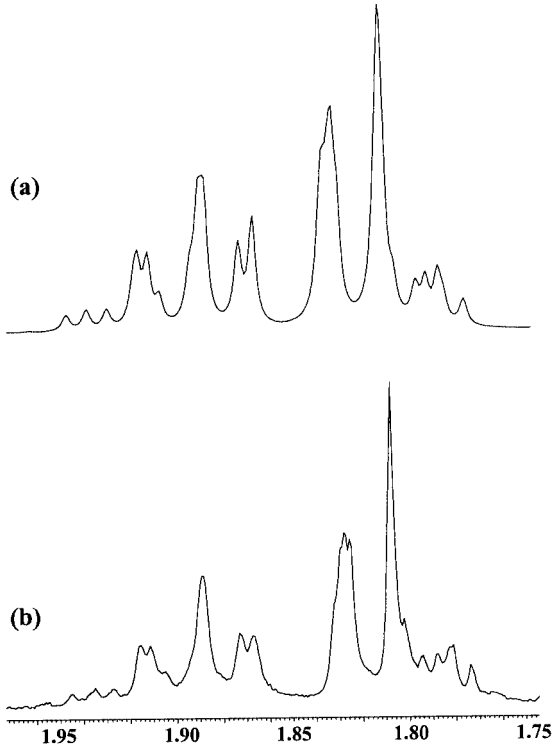

Figure 6. ^{1}H NMR spectra of [Nb(=NC_6H_4Me-4)Cp_2Et] (**19**) in the ethyl region: (a) simulated; (b) experimental

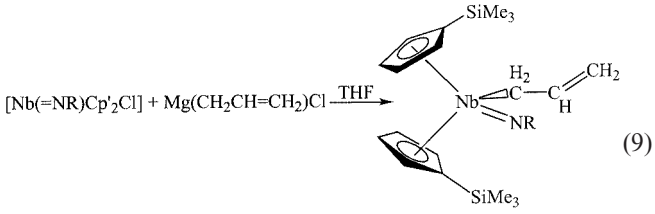
2.3.4 Allyl Derivatives

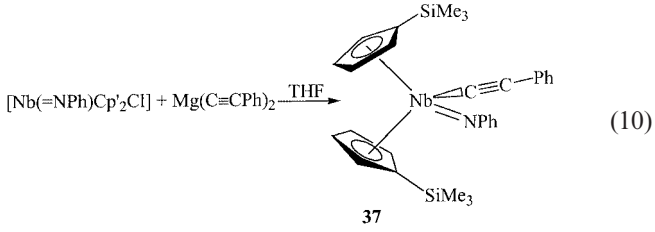
In a similar manner the η^1-allyl(imido)niobocene complexes, [Nb(=NC_6H_4Me-4)$Cp_2(\eta^1$-CH_2CHCH_2)] (**25**)[39] and [Nb(=NR)$Cp'_2(\eta^1$-CH_2CHCH_2)] [R = *t*Bu (**26**), C_6H_4Me-4 (**27**), C_6H_4OMe-4 (**28**)][31] have been synthesized [Equation (9)]. The ^{1}H NMR spectra for the η^1-allyl complexes were similar to that recorded for **7**. Couplings constants are given in Table 1.



(9)

R = *t*Bu (**26**), C_6H_4Me-4 (**27**), C_6H_4OMe-4 (**28**)

Recently, we reported the preparation of first alkynyl-containing niobocene complexes[63] and by a natural extension of this work the alkynyl(imido)niobium complexes [Nb(=N*t*Bu)(η^5-C_5H_5)$_2$(C≡CR)] [R = Me (**29**), $SiMe_3$ (**30**), *t*Bu (**31**), CH_2Ph (**32**)], [Nb(=NC_6H_4Me-4)(η^5-C_5H_5)$_2$(C≡CR)] [R = $SiMe_3$ (**33**), *t*Bu (**34**)], [Nb(=N*t*Bu)(η^5-$C_5H_4SiMe_3$)$_2$(C≡CR)] [R = $SiMe_3$ (**35**), *t*Bu (**36**)], [Nb(=NPh)(η^5-$C_5H_4SiMe_3$)$_2$(C≡CR)] (R = Ph (**37**), *t*Bu (**38**)], [Nb(=NC_6H_4Me-4)(η^5-$C_5H_4SiMe_3$)$_2$(C≡CR)] [R = $SiMe_3$ (**39**), *t*Bu (**40**)], [Nb(=NC_6H_4OMe-4)(η^5-$C_5H_4SiMe_3$)$_2$(C≡CR)] [R = $SiMe_3$ (**41**), *t*Bu (**42**)], were synthesized.[55] The general synthetic method involved the reaction of dialkynylmagnesium reagents and the corresponding (imido)niobocene halide derivative. An example is given in Equation (10).



(10)

37

The molecular structure of **37**, determined by single-crystal X-ray diffraction studies is depicted in Figure 7. Complex **37** presents a typical bent-metallocene structure with two additional ligands. Both cyclopentadienyl rings are η^5-bonded to the metal atom with a Cent−Nb−Cent angle of 128.2°. The alkynyl ligand is σ-bonded to the metal atom as indicated by the C(1)−C(2) distance of 1.20(1) Å which is typical for a C−C triple bond and the Nb−C(1)−C(2) angle of 177.9(6)° whose linear nature confirms that the C(1) and C(2) atoms are sp-hybridized. The Nb−N bond length of 1.804(5) Å, is at the upper limit for those observed for (imido)niobium complexes (1.73−1.80 Å) (see Table 4) and is indicative of an Nb−N triple bond. As in complexes **9** and **13**, the formal electron count is 20.

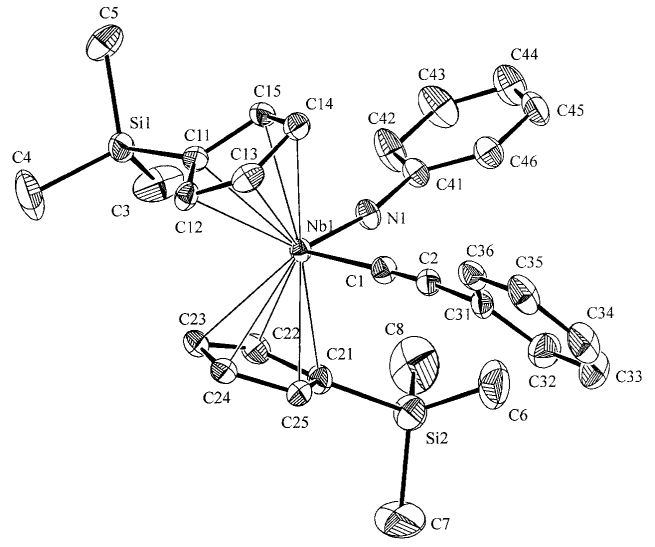


Figure 7. Molecular structure of [Nb(=NPh)(η^5-$C_5H_4SiMe_3$)$_2$-(C≡CPh)] (**37**)

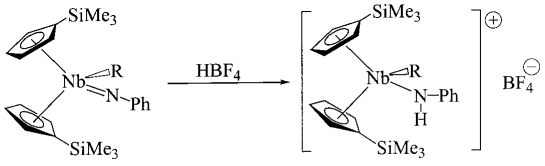
2.3.5 Reactivity

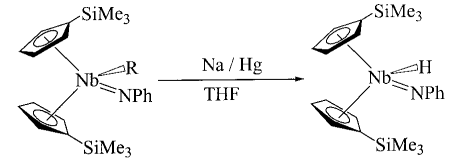
The cationic niobium species, [Nb(NHPh)Cp′$_2$R]$^+$ (R = Cl (**43**), Me (**44**), Et (**45**), *i*Pr (**46**)], were obtained by the reaction of the neutral (imido)niobocene complexes **9** and **22−24** with HBF_4.[53] Protonation took place at the nitrogen atom to give the corresponding amido derivative [Equation (11)].



(11)

R = Cl (**43**), Me (**44**), Et (**45**), *i*Pr (**46**)

The hydride complex [Nb(=NPh)Cp′$_2$H] (**47**)[53] was prepared by initially reducing the (imido)niobocene(v) complexes **9** and **22−24** and their subsequent oxidation by hydrogen abstraction from the solvent to give the corresponding niobium(v) hydride derivative [Equation (12)].

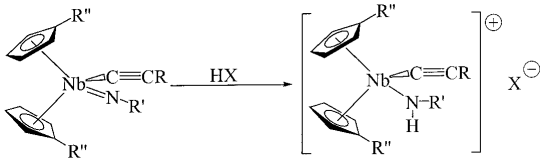


(12)

R = Cl, Me, Et, *i*Pr

47

The reactivity of the alkynyl(imido) complexes **30** and **37** with the protic reagents CF_3COOH and HBF_4 was studied.[55] Protonation of these complexes may occur at the alkynyl and/or the imido moiety as observed previously in niobocene complexes containing only one of these ligands.[53,63] In the reactions of **30** and **37** with CF_3COOH and HBF_4, respectively, the protonated compounds were isolated [Equation (13)]. It was found that in these alkynyl-(imido) complexes protonation takes place preferentially at the nitrogen atom of the imido group leading to the formation of the cationic amide species [Nb(NH*t*Bu)(η^5-C_5H_5)$_2$(C≡CSiMe$_3$)]$^+$ (**48**) and [Nb(NHPh)(η^5-$C_5H_4SiMe_3$)$_2$(C≡CPh)]$^+$ (**49**).[55]

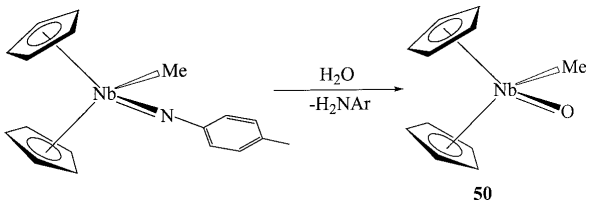


(13)

R = $SiMe_3$, R' = *t*Bu, R" = H, X = CF_3COO (**48**);
R = Ph, R' = Ph, R" = $SiMe_3$, X = BF_4 (**49**).

The normally greater Brønsted basicity of the imido ligand relative to the alkynyl ligand may explain the selective nature of the protonation reaction of these alkynyl(imido)niobocene complexes.

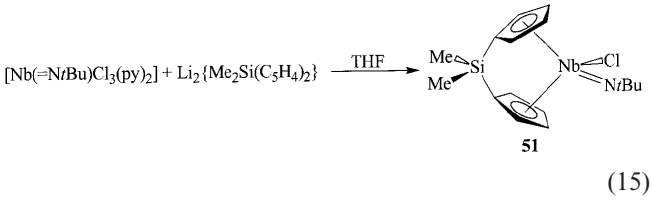
It was found that when [Nb(=NC$_6$H$_4$Me-4)Cp$_2$Me] (**18**) was treated with H_2O, the reaction took place at the Nb−N and not the Nb−C bond of the alkyl group. The alkyl(oxo) complex [Nb(=O)Cp$_2$Me] (**50**) was isolated by recrystallization from a hexane solution.[39] The amine $H_2NC_6H_4$Me-4 was identified by ^{1}H NMR spectroscopy to be the by-product of this reaction [Equation (14)].



50 (14)

2.4 *ansa*-(Imido)niobocene Complexes

In 1996 we reported the first *ansa*-niobocene complexes in which both cyclopentadienyl rings are bound only in an η^5-mode to the niobium atom[64] and following from this work we prepared the *ansa*-(imido)niobocene complex [Nb(=N*t*Bu){Me$_2$Si(η^5-C$_5$H$_4$)$_2$}Cl] (**51**) [Equation (15)].[58] The ^{1}H NMR spectrum reveals the presence of a system similar to that obtained for its non-*ansa* analogues. The C_s symmetry of the molecule is such that there is only one plane of symmetry and the two methyl groups of $SiMe_2$ become inequivalent, as do the cyclopentadienyl protons, thus giving two singlets for the former and four multiplets for the latter. The molecular structure of **51**, determined by single-crystal X-ray diffraction studies, is depicted in Figure 8. The following *ansa*-(imido)-niobocene complexes have also been reported by other authors: [Nb(=NR){Me$_2$C(η^5-C$_5$H$_4$)$_2$}Cl] (R = *t*Bu, SiMe$_3$),[59] [Nb(=NC$_6$H$_3$*i*Pr$_2$-2,6){Me$_2$C(η^5-C$_5$H$_4$)$_2$}Cl].[60]



51 (15)

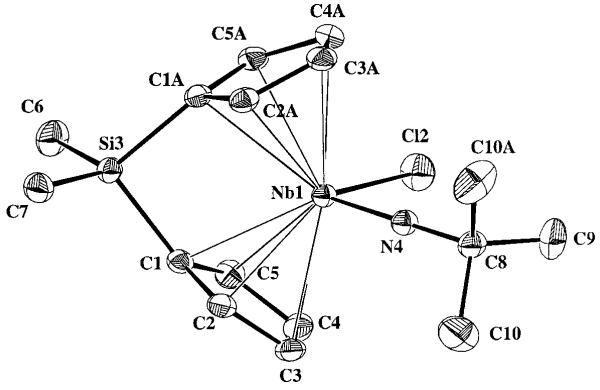


Figure 8. Molecular structure of [Nb(=N*t*Bu){Me$_2$Si(η^5-C$_5$H$_4$)$_2$}Cl] (**51**)

2.4.1 Alkyl, Allyl and Alkynyl Derivatives

The alkyl derivatives [Nb(=N*t*Bu){Me$_2$Si(η^5-C$_5$H$_4$)$_2$}R] [R = Me (**52**), Et (**53**), CH_2Ph (**54**)] were synthesized from **51** and the corresponding Grignard reagent.[58] The allyl and alkynyl products [Nb(=N*t*Bu){Me$_2$Si(η^5-C$_5$H$_4$)$_2$}(η^1-CH$_2$CHCH$_2$)] (**55**)[58] and [Nb(=N*t*Bu){Me$_2$Si(η^5-C$_5$H$_4$)$_2$}(C≡CR)] [R = SiMe$_3$ (**56**), *t*Bu (**57**)][55] were prepared in a similar manner. The ^{1}H NMR spectrum of the ethyl complex **53** showed the same characteristics as those observed for **16** and **19**. The η^1-allyl complex **55** was identical in nature to those already discussed.

2.4.2 Substituted ansa-(Imido)niobocene Complexes

We prepared the first niobocene complex containing a substituted *ansa* ligand [Nb(=N*t*Bu){Me$_2$Si(η^5-C$_5$H$_3$SiMe$_3$)$_2$}Cl] (**56**) [Equation (16)].[58] The synthesis of substituted *ansa*-ligand complexes of niobium can lead to a variety of isomers (Figure 9) depending on the configuration of the cyclopentadienyl rings. These include two *meso*-(*R*,*S*) forms **I** and **II** and the enantiomers *rac*-(*R*,*R*) (**III**) and *rac*-(*S*,*S*) (**IV**). For this complex ^{1}H NMR spectroscopy will show clearly the existence of the *meso* and *rac* isomers. Complex **56** was isolated uniquely as the *meso* isomer as was revealed by ^{1}H NMR spectroscopy. The *meso* isomer contains a plane of symmetry (C_s), which makes the cyclopentadienyl rings of the *ansa* ligand equivalent, and hence only three signals for the ring protons are observed in its ^{1}H NMR spectrum, which in addition gave the expected signals for the *t*Bu and the SiMe$_3$ groups and two for SiMe$_2$. The cyclopentadienyl rings of the *ansa* ligand, however, will be inequivalent in the *rac* complex due to the lack of symmetry (C_1). In the case of **56**, the *rac* isomer is probably disfavoured due to steric effects and for this same reason in the *meso* complex the SiMe$_3$ groups should be pointing away from the bulky imido group.

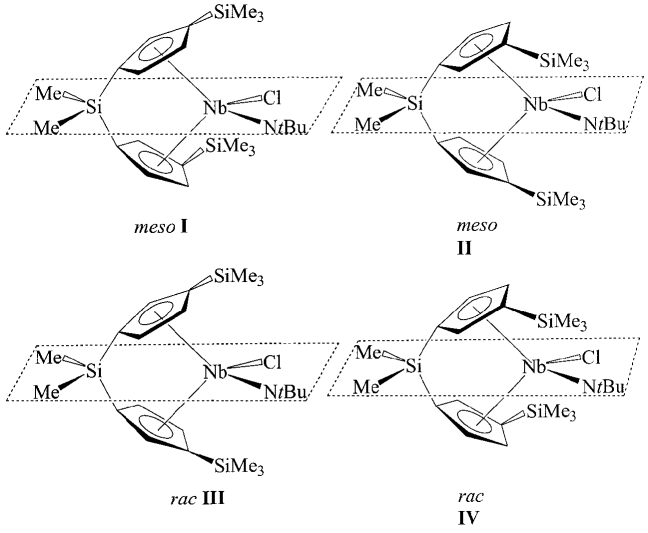

Figure 9. Possible isomers for [Nb(=N*t*Bu){Me$_2$Si(η^5-C$_5$H$_3$SiMe$_3$)$_2$}Cl] (**56**)

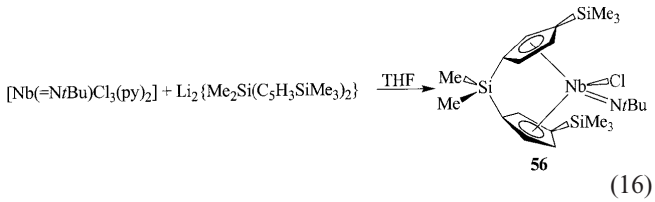
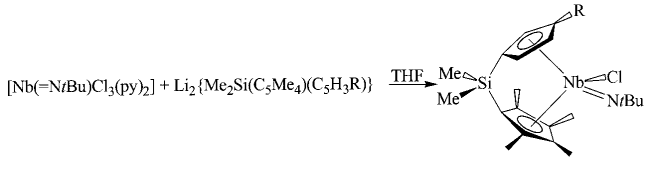


56

(16)

2.4.3 Asymmetric ansa-(Imido)niobocene Complexes

We have prepared the first (imido)niobocene complexes incorporating asymmetric *ansa* ligands. The complexes [Nb(=N*t*Bu){$Me_2Si(\eta^5$-$C_5Me_4)(\eta^5$-$C_5H_3R)$}Cl] [R = H (**57**), Me (**58**), *i*Pr (**59**), $SiMe_3$ (**60**)] were synthesized by the reaction of [Nb(=N*t*Bu)$Cl_3(py)_2$] with Li_2{$Me_2Si(\eta^5$-$C_5Me_4)(\eta^5$-$C_5H_3R)$} [Equation (17)].[57]



R = H (**57**); Me (**58**); *i*Pr (**59**); $SiMe_3$ (**60**)

(17)

2.4.4 Structural Characterization

The ^{1}H NMR spectrum of **57** shows the lack of symmetry in this chiral complex, with the four methyl groups attached to the cyclopentadienyl ring being inequivalent as are the methyl groups of the $SiMe_2$ bridge and the four protons of the unsubstituted cyclopentadienyl moiety.

In the case of complexes **58**−**60** the monosubstitution of one of the cyclopentadienyl rings of the *ansa* ligands gives rise to the possibility of two different isomers (**I**) and (**II**) (Figure 10) depending on the configuration of the cyclopentadienyl rings in which the substituent R can be orientated towards or away from the imido group. The niobium atom is chiral and thus in both cases **I** and **II** should exist as pairs of enantiomers.

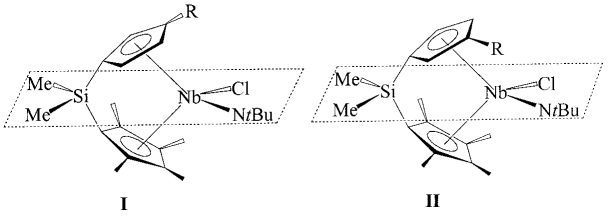


Figure 10. Possible isomers for complexes [Nb(=N*t*Bu){$Me_2Si(\eta^5$-$C_5Me_4)(\eta^5$-$C_5H_3R)$}Cl] [R = Me (**58**), *i*Pr (**59**), $SiMe_3$ (**60**)]

The ^{1}H spectra of **58**−**60** are similar to that observed in **57** and in addition show the existence exclusively of only one of the possible isomers. It is assumed that this corresponds to isomer **I**, i.e., that the substituent R is pointing away from the bulky imido group. The isomer **II** is probably heavily disfavoured due to steric effects.

The molecular structures of **58** and **59** were established by X-ray crystal structure studies; they are shown in Figures 11 and 12, respectively.[57]

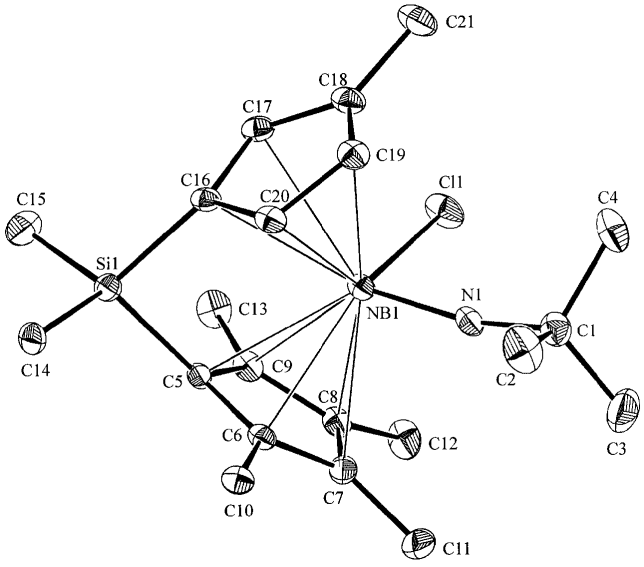

Figure 11. Molecular structure of [Nb(=N*t*Bu){$Me_2Si(\eta^5$-$C_5Me_4)(\eta^5$-$C_5H_3Me)$}Cl] (**58**)

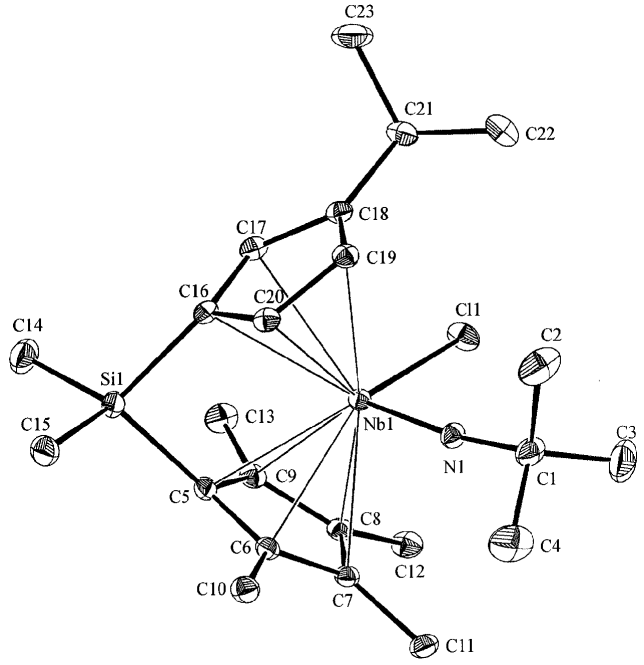

Figure 12. Molecular structure of [Nb(=N*t*Bu){$Me_2Si(\eta^5$-$C_5Me_4)(\eta^5$-C_5H_3*i*Pr)}Cl] (**59**)

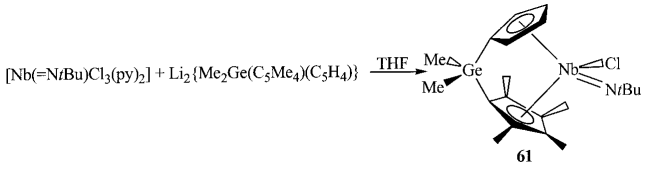
The niobium atoms in both **58** and **59** show a geometry that is typical for pseudo-tetrahedral (imido)niobocene(v) derivatives. The $Me_2Si(C_5Me_4)(C_5H_3R)$ *ansa* ligand chelates the niobium centre, and both cyclopentadienyl rings are bound to the metal atom in an η^5-mode adopting the typical bent-metallocene conformation. The environment of the niobium atom is completed by a chlorine atom and the imido group bonded through the nitrogen atom to the niobium atom. The structure also reveals that the alkyl group in the monosubstituted C_5 ring is oriented away from the

imido group. The Cent−Nb−Cent angles (122.7 and 122.3° in **58**; 122.1° in **59**) are similar to those reported for other *ansa*-niobocene complexes containing the $SiMe_2$-bridged *ansa* ligand (see Table 2). The formal electron count for **58** and **59** is 20.

2.4.5 Asymmetric Complexes with Germanium-Bridged ansa Ligands

The reaction of $Li_2\{Me_2Ge(C_5Me_4)(C_5H_4)\}$ with $[Nb(=NtBu)Cl_3(py)_2]$ gave the niobium derivative $[Nb(=NtBu)\{Me_2Ge(\eta^5\text{-}C_5Me_4)(\eta^5\text{-}C_5H_4)\}Cl]$ (**61**) [Equation (18)].[65] This is the first example of a niobocene complex incorporating a germanium-bridged *ansa* ligand.

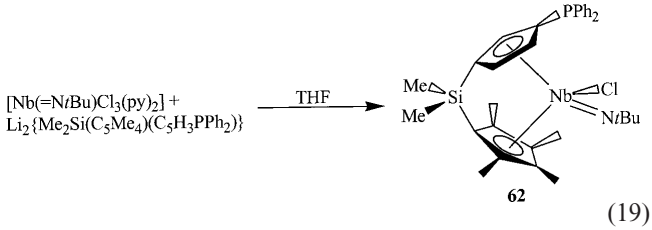


(18)

2.5 (Imido)niobocene Complexes with Phosphane-Substituted Cyclopentadienyl Ligands

The use of phosphane-substituted cyclopentadienyl ligands in the chemistry of group 5 elements has been restricted to one reference concerning the tantalum complex $[Ta(\eta\text{-}C_5Me_5)(\eta\text{-}C_5H_4PPh_2)Cl_2]$ and its reactivity.[66] To the best of our knowledge there have been no reports of this type of compounds in the chemistry of niobium.

By the reaction of the lithium derivative $Li_2\{Me_2Si(C_5Me_4)(C_5H_3PPh_2)\}$ with $[Nb(=NtBu)Cl_3(py)_2]$ we have prepared the *ansa*-phosphane(imido)niobocene complex $[Nb(=NtBu)\{Me_2Si(\eta^5\text{-}C_5Me_4)(\eta^5\text{-}C_5H_3PPh_2)\}Cl]$ (**62**) [Equation (19)].[67] The complex $[Nb(=NtBu)(\eta^5\text{-}C_5H_4PPh_2)_2Cl]$ (**63**), was prepared in a similar way by reaction of 2 equiv. of $Li(C_5H_4PPh_2)$ with $[Nb(=NtBu)Cl_3(py)_2]$.[67]

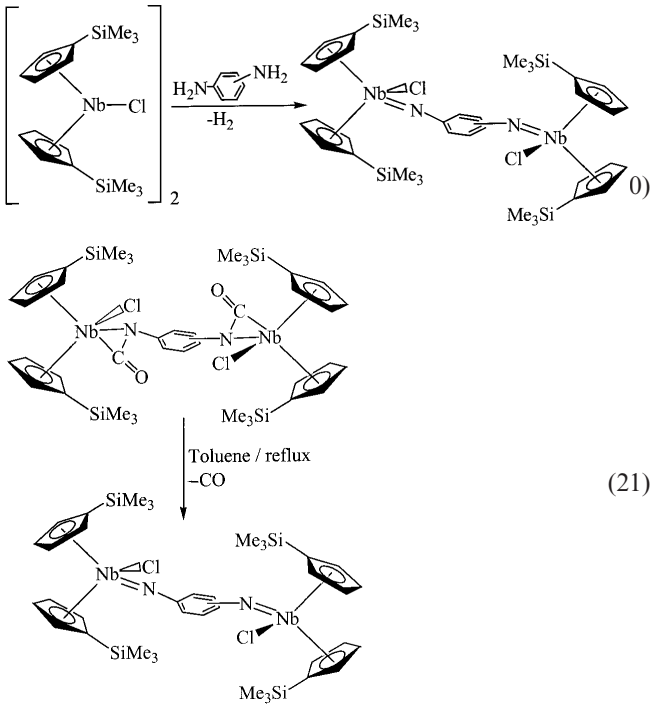


(19)

2.6 Dinuclear (Imido)niobocene Complexes

2.6.1 Synthesis

The [bis(imido)]diniobocene complexes were prepared in a similar manner to their mononuclear analogues. Thus, the complexes $[\{NbCp'_2Cl\}_2(\mu\text{-}1,3\text{-}N_2C_6H_4)]$ (**64**) and $[\{NbCp'_2Cl\}_2(\mu\text{-}1,4\text{-}N_2C_6H_4)]$ (**65**) were prepared by two distinct synthetic routes; firstly by oxidative addition of the bis(amine) and subsequent loss of H_2 [Equation (20)], alternatively by thermal treatment of $[\{NbCp'_2Cl\}_2(OCNC_6H_4NCO)]$ and elimination of CO [Equation (21)].[53]



2.6.2 Characterization

Complexes **64** and **65** were characterized by ^1H NMR spectroscopy which revealed spectra similar to those obtained for other (imido)niobocene complexes. The molecular structure of **64**, determined by single-crystal X-ray diffraction studies, is illustrated in Figure 13.[53]

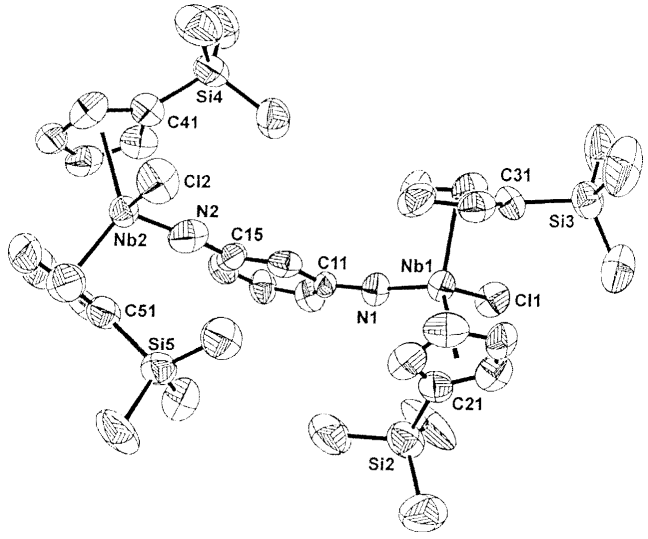


Figure 13. Molecular structure of $[\{NbCp'_2Cl\}_2(\mu\text{-}1,3\text{-}N_2C_6H_4)]$ (**64**)

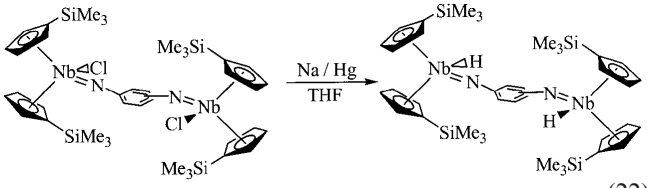
The complex shows two bent niobocene units linked to a phenylenebis(imido) ligand and is to date the only known example of this type reported in the chemistry of metallocene compounds. The formal electron count is 20 at both niobium centres and the structural parameters are similar to those previously discussed for other niobium complexes (see Table 4).[53]

2.6.3 Alkyl Derivatives

The alkyl derivatives [{NbCp′$_2$R}$_2$(μ-1,3-$N_2C_6H_4$)] [R = Me (**66**), Et (**67**), *i*Pr (**68**)] and [{NbCp′$_2$R}$_2$(μ-1,4-$N_2C_6H_4$)] [R = Me (**69**), Et (**70**), *i*Pr (**71**)] were prepared by the reaction of the chloro precursor with the corresponding Grignard reagent.[53]

2.6.4 Hydride Derivatives

The hydride derivatives [{NbCp′$_2$H}$_2$(μ-1,3-$N_2C_6H_4$)] (**72**) and [{NbCp′$_2$H}$_2$(μ-1,4-$N_2C_6H_4$)] (**73**) were prepared according to Equation (22).[53]



(22)

Conclusion

This review gives an insight into our work in the field of (imido)niobium complexes containing at least one cyclopentadienyl ligand. Amongst the compounds described are the first examples of: (a) symmetrically and asymmetrically substituted *ansa*-(imido)niobocene complexes, (b) germanium-bridged *ansa* ligands, (c) (imido)niobocene and *ansa*-(mido)niobocene complexes incorporating phosphane-substituted ligands. (d) [bis(imido)]diniobocene complexes.

The molecular structures for many of the niobocene complexes have been determined and show the linear or near linear nature of the imido group. This indicates that the imido group is acting as a four-electron donor. Thus, the formal electron count is 20 with surplus electrons probably being located in ligand-based orbitals. In addition we have observed in these compounds a lengthening of the niobium−cyclopentadienyl distance compared with their 18-electron analogues.

In symmetrically and asymmetrically substituted *ansa*-(imido)niobocene complexes we have observed that steric conditions are the governing factor in the final orientation of the ligands in the complexes.

Alkyl, allyl and alkynyl derivatives have been readily synthesized by reaction of the initial (imido)niobium chloride precursor with the corresponding magnesium reagent. It was found that protonation and hydrolysis take place preferentially at the imido group and not at the Nb−C σ-bond.

Selective Insertion of Dioxygen into an (η^2-C_{60})−Ir Bond: Synthesis and Structure of the First Metallacyclic Complex with a σ-Coordinated Fullerene Molecule

Alexander V. Usatov,*[a] Ekaterina V. Martynova,[a] Fedor M. Dolgushin,[a] Alexander S. Peregudov,[a] Mikhail Yu. Antipin,[a] and Yurii N. Novikov[a]

Keywords: Fullerenes / Carboranes / Iridium / Oxygen / Insertion

Oxidation of the carboranyliridium fullerene complex [(η^2-C_{60})Ir(*o*-$HCB_{10}H_9CCH_2PPh_2$-*B*,*P*)(*t*BuNC)$_2$] (**I**) in $CHCl_3$ solution by O_2 occurs by a selective insertion of the dioxygen molecule into the longest Ir–C bond (in the *trans*-position relative to the B-σ-carboranyl fragment) to give a new metal complex [σ-C_{60}OO-Ir(*o*-$HCB_{10}H_9CCH_2PPh_2$-*B*,*P*)(*t*BuNC)$_2$] (**II**). Complex **II** was isolated and characterized analytically and by UV, IR, ^{1}H and ^{31}P NMR spectroscopy. An X-ray diffraction study of **II** showed that this complex contains a cyclic iridaperoxide fragment in which the fullerene cage is σ-coordinated to the iridium atom.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2003)

Despite considerable advances in the synthesis of metal complexes of fullerenes and their derivatives, the reactivity of these interesting compounds has been studied rather scarcely.[1] The most interesting results obtained in this field are: (i) the discovery of an interaction between polymeric compounds [$C_{60}M_n$] (M = Pd, Pt) and various phosphanes and phosphites resulting in the known monomeric complexes [(η^2-C_{60})ML_2],[2,3] and (ii) insertion of two isocyanide molecules into the Pt−C(fullerene) bonds in the complex [(η^2-C_{60})Pt(CNR)$_2$] giving rise to a new five-membered metallacyclic complex [C_{60}(C=NR)$_2$Pt(CNR)$_2$].[4]

Recently,[5] we have reported the synthesis and structure of the iridium complex [(η^2-C_{60})Ir(*o*-$HCB_{10}H_9CCH_2PPh_2$-*B*,*P*)(*t*BuNC)$_2$] (**I**) containing both an η^2-coordinated C_{60} fullerene and a chelating carboranylphosphane fragment in the coordination sphere of the metal atom. A salient feature of this complex is a distorted η^2-coordination of the fullerene ligand, which is manifested in an appreciable lengthening of one Ir−C bond relative to the other one due to the strong *trans*-effect of the B-σ-carboranyl group. Having established this fact, we started to investigate the possibility of the selective insertion of various reagents into the most reactive elongated bond.

In studies of the oxidation of complex **I** in various solutions we found that bubbling dioxygen through a solution of **I** in $CHCl_3$ at room temperature led to a gradual disappearance of the absorption band at 460 nm in the UV/Vis spectrum of the reaction mixture (this band is characteristic of (η^2-C_{60})-type metal derivatives[5−7]). The reason for this is the formation of a new complex **II** that was isolated and characterized both analytically and spectroscopically.

The IR spectrum of complex **II** exhibits a strong stretching vibration band of *trans*-arranged isocyanide ligands at 2191 cm^{-1} similar to the IR spectrum of **I**. A rather large frequency shift of this band towards the high-frequency region [cf. ν(NC) = 2168 cm^{-1} for complex **I**][5] points to a considerably higher electron-deficient character of the iridium atom in **II**. The $^{31}P\{^1H\}$ NMR spectrum of **II** exhibits a singlet at δ_P = 20.9 ppm, which is shifted appreciably to high field (δ_P = 37.8 ppm for **I**).[5] The ^{1}H NMR spectral pattern of **II** is similar to that of **I**, exhibiting two singlets for the protons of the *tert*-butyl groups of the isocyanide ligands and an ABX pattern for the protons of methylene group of the five-membered ring. This points to a retention of the molecular chirality of the carborane polyhedron. However, these spectral characteristics are insufficient to draw an unambiguous conclusion about the mutual arrangement of the components in the complex **II** and, correspondingly, to determine the addition position of the dioxygen molecule [this can be either the Ir−C bond or one (or several) of the C=C bonds of the fullerene cage]. To establish the structure of this compound, we grew a single crystal of **II** from $CHCl_3$ solution and performed an X-ray diffraction study. The molecular structure of this complex is shown in Figure 1 while selected geometric parameters are listed in Table 1. Our X-ray diffraction study showed that complex **II** is a five-membered iridaperoxide derivative [σ-C_{60}OO-Ir(*o*-$HCB_{10}H_9CCH_2PPh_2$-*B*,*P*)(*t*BuNC)$_2$] with a σ bond between the Ir atom and fullerene cage. This complex is formed as a result of selective insertion of dioxygen

molecule into the longest Ir−C bond of the metallacyclopropane fragment of complex **I** according to Scheme 1.

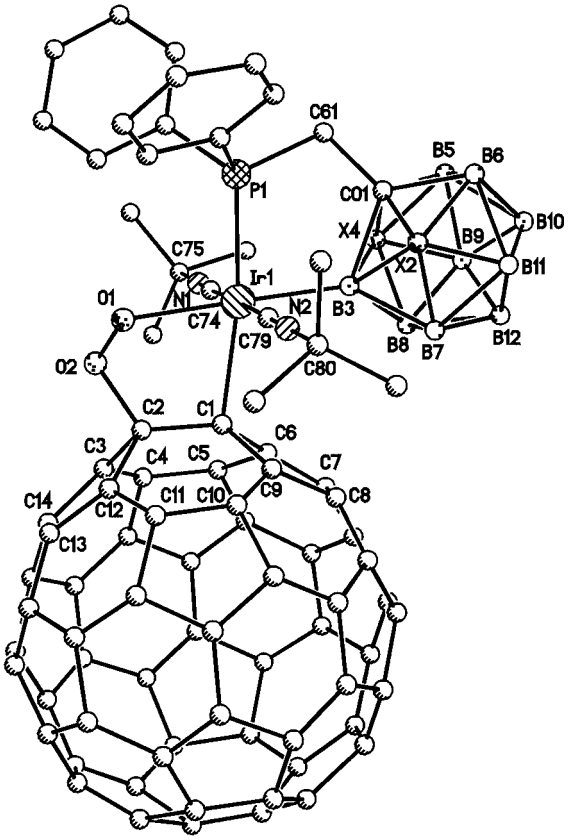

Figure 1. Molecular structure of **II**

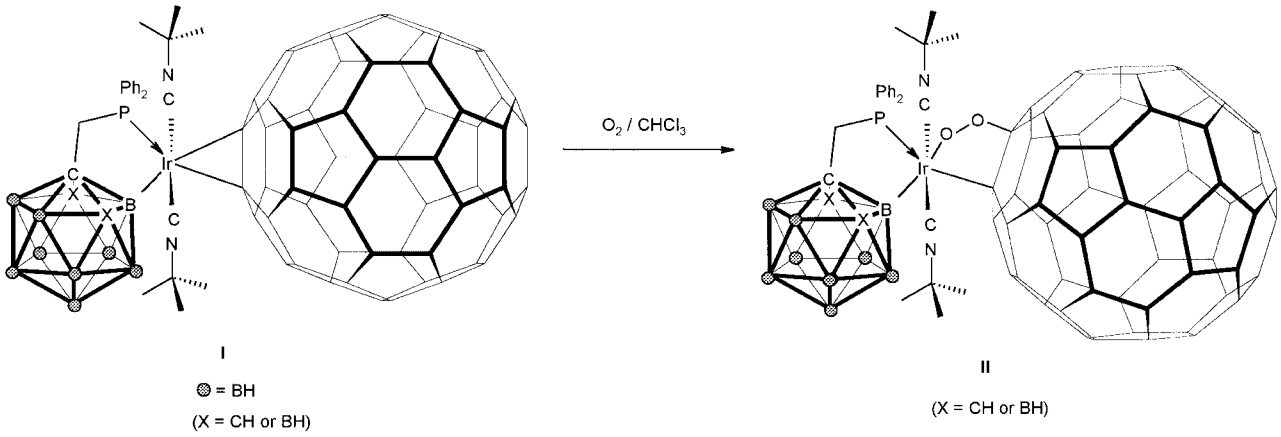
No significant changes were found in the geometry of the carboranylphosphane ligand of **II** relative to the initial compound **I** (this was also confirmed by the spectroscopic data). This ligand is coordinated to the iridium atom by the Ir(1)−B(3) σ-bond with the boron atom in position 3(6) and the Ir(1)−P(1) coordination bond involved in the five-membered metallacycle Ir(1)P(1)C(61)C(01)B(3). The both bond lengths in **I** and **II** are essentially identical. However, the metallacycle conformations in both compounds are appreciably different. In **I**, this cycle has a flattened envelope conformation with the P(1) atom deviating by 0.43 Å from the plane of other four atoms of the cycle. In **II**, the metallacycle adopts a flattened twist-conformation characterized by slight deviations of the P(1) and C(61) atoms in opposite directions from the plane passing through the Ir(1), B(3), and C(01) atoms; the Ir(1)−P(1)−C(61)−C(01) torsion angle is 13.8°. This points to a high lability of this metallacycle in the related complexes. The carbon and boron atoms in the 2- and 4-positions of the carborane polyhedron in both **I** and **II** are disordered with equal weights (labeled X2 and X4, see Figure 1). This is due to the fact that the crystal structure is comprised of both enantiomers differing in the mutual arrangement of these boron and carbon atoms with respect to the plane passing through the C(01), B(3), B(10), and B(12) atoms as a consequence of the molecular chirality of the substituted carborane polyhedron.

Table 1. Selected geometrical parameters for **II**

Bond lengths (Å)			
Ir(1)−P(1)	2.281(2)	C(01)−B(3)	1.826(9)
Ir(1)−B(3)	2.101(8)	O(1)−O(2)	1.417(8)
Ir(1)−O(1)	2.154(5)	O(2)−C(2)	1.48(2)
Ir(1)−C(1)	2.238(6)	O(2)−C(2′)	1.41(2)
Ir(1)−C(74)	1.982(6)	C(1)−C(2)	1.46(2)
Ir(1)−C(79)	1.982(6)	C(1)−C(2′)	1.67(2)
P(1)−C(61)	1.853(7)	N(1)−C(74)	1.135(7)
C(01)−C(61)	1.508(9)	N(1)−C(75)	1.480(8)
C(01)−X(4)	1.631(10)	N(2)−C(79)	1.146(7)
C(01)−X(2)	1.657(9)	N(2)−C(80)	1.466(7)
Bond angles (°)			
B(3)−Ir(1)−O(1)	177.0(2)	C(01)−B(3)−Ir(1)	116.8(4)
C(1)−Ir(1)−P(1)	171.74(17)	C(01)−C(61)−P(1)	112.4(4)
B(3)−Ir(1)−C(1)	103.3(2)	O(2)−O(1)−Ir(1)	103.8(4)
O(1)−Ir(1)−C(1)	76.4(2)	O(1)−O(2)−C(2)	94.2(9)
B(3)−Ir(1)−P(1)	84.90(18)	O(1)−O(2)−C(2′)	109.3(7)
O(1)−Ir(1)−P(1)	95.49(17)	C(74)−N(1)−C(75)	176.7(7)
C(74)−Ir(1)−C(79)	178.1(2)	C(79)−N(2)−C(80)	176.7(7)
C(61)−P(1)−Ir(1)	110.9(2)	N(1)−C(74)−Ir(1)	177.7(6)
C(61)−C(01)−B(3)	113.5(5)	N(2)−C(79)−Ir(1)	179.3(6)

A salient feature of complex **II** is the η^1-coordination of the fullerene ligand to the iridium atom through the Ir(1)−C(1) σ-bond. To the best of our knowledge, no structurally characterized mononuclear complexes with this type of fullerene coordination to the transition metal atom have been reported so far.[1] Although Balch et al.[8a] have suggested the formation of a σ-bond between the fullerene cage and a post transition metal atom (Ag), taking compound $C_{60}[Ag(NO_3)]_5$ as an example, a strong structural disorder (including orientation disordering of the fullerene fragment and a disordering of the silver atoms over several positions) does not allow us to use their results for a reliable description of the geometrical features of this type of fullerene coordination to metal atoms. Among polynuclear complexes, a series of triosmium cluster derivatives with μ_3-η^1:η^1:η^2-C_{60} [8b] and μ_3-η^1:η^2:η^1-C_{60} [8c,8d] ligands have been recently obtained and structurally characterized by Park and coworkers. In these complexes, one of the Os atoms has a π-type coordination with a 6/6 bond of a hexagon ring in the C_{60} moiety, whereas two other Os atoms are σ-bonded to this ring with an average Os−C(C_{60}) distance of 2.24 Å.

The Ir(1)−C(1) σ-bond length in **II** is 2.238(6) Å. This value somewhat exceeds the Ir−C(fullerene) bond lengths typical for a conventional η^2-coordination {cf. 2.228(4) and 2.162(4) Å in **I**[5] and 2.19 Å in [(η^2-C_{60})Ir(CO)Cl(PPh_3)$_2$][1]}. A feature of the crystal structure of complex **II** is the unusual disordering of the fullerene cage due to the type of coordination to the metal atom. The Ir(1)−C(1) σ-bond defines a rigid axis about which the fullerene cage is rotated by about 10°. In this case, only two



Scheme 1

out of sixty fullerene carbon atoms are ordered, namely the C(1) atom and the C(60) atom occupying the diametrically opposite position. The remaining fifty eight carbon atoms are disordered over two equally populated positions. Figure 2 shows a fragment of the complex **II** to illustrate this disordering of the fullerene ligand.

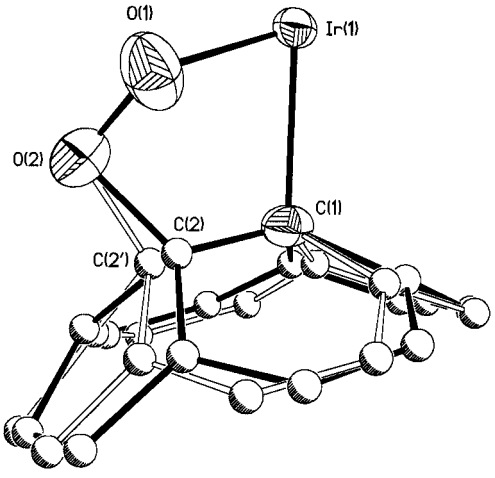


Figure 2. Disordered fragment of molecule **II**

The iridium atom in **II** is also bound to the fullerene cage through a peroxide bridge, which is part of the five-membered cycle Ir(1)−O(1)−O(2)−C(2)−C(1). The crystal structure (Figure 1) unambiguously shows that the dioxygen molecule has inserted into the longer Ir−C(fullerene) bond of the initial complex **I** [this bond is in a pseudo-*trans*-position relative to the Ir(1)−B(3) σ-bond]. As a result, the iridium atom in **II** is close to an octahedral coordination. Specifically, the O(1) atom is in a *trans*-position with respect to the B(3) atom while the C(1) atom is in a *trans*-position with respect to the phosphane ligand [the O(1)−Ir(1)−B(3) and C(1)−Ir(1)−P(1) angles are 177.0(2) and 171.7(2)°, respectively]. The M−O−O−R fragment is not uncommon in transition metal chemistry; however, five-membered metallacycles containing a peroxy group similar to that found in **II** are rarely observed, even though the formation of such compounds has been postulated for olefin oxidation catalyzed by metal complexes. The closest analog of this metallacyclic peroxide fragment is found in the platinum complex $[(PPh_3)_2Pt(O\text{-}O\text{-}C(Me)_2\text{-}C(CN)_2]$ (**III**).[9] Only three structurally characterized iridium complexes containing an Ir−O−O−R fragment are known, where R = $C(sp^3)$[10,11] or a second Ir atom.[12] All these compounds are characterized by a very wide range of their Ir−O and O−O bond lengths (1.99−2.11 and 1.43−1.59 Å, respectively). In complex **II**, the Ir(1)−O(1) and O(1)−O(2) distances are 2.154(5) and 1.417(8) Å, respectively. The dioxairidacycle has an envelope conformation and the angle of folding along the Ir(1)···O(2) line is nearly 60° [the Ir(1)−O(1)−O(2)−C(2) and Ir(1)−O(1)−O(2)−C(2′) torsion angles are 67.1 and 65.8°, respectively]. The corresponding cycle in the platinum complex **III** also has a nonplanar structure with a Pt−O−O−C torsion angle of 53.5°. Disordering of the C(2) atom in the fullerene cage causes a disorder of the oxygen atoms in the peroxy group, increasing the thermal parameters of the O(1) and O(2) atoms (see Figure 2). However, we failed to resolve this disorder due to the spatial proximity of these positions.

A disorder of the fullerene cage and, correspondingly, a low accuracy of its geometric parameters in **II** precludes a detailed consideration of changes in the structure caused by σ-coordination to the iridium atom and peroxy group. In particular, substantially different C(1)−C(2) and C(1)−C(2′) distances [1.46(2) and 1.67(2) Å, respectively; av. 1.56 Å] were obtained for two equivalent positions, C(2) and C(2′), of the C atom bound to the oxygen atom of peroxy group. Nevertheless, both disordered C_{60} cages display different distortions in the vicinity of the key atoms C(1) and C(2) [or C(2′)]. These distortions can be revealed

by comparing the distances from the center of the C_{60} moiety to the carbon atoms along different directions.[13] In particular, in both disordered fullerene cages the distance to the C(1) atom bonded to Ir atom is, on average, 3.83 Å, whereas the distances to the C(2) [or C(2′)] atom bonded to the peroxy group are longer (av. 3.90 Å). The distances to other carbon atoms of the fullerene cage lie between 3.47 and 3.60 Å. Thus, bonding to an O-atom of the peroxy group leads to a greater distortion of the fullerene ligand than that caused by the σ-bond with the Ir atom. Much smaller distortions of the fullerene ligand were found for a conventional η^2-coordination to the iridium atom in **I**, where the average Ir−C distance to the key carbon atoms is 3.73 Å.

In the crystal, there are $3^2/_3$ solvate chloroform molecules per molecule of **II**. The crystal packing (Figure 3) is characterized by shortened Cl···Cl contacts between the solvate chloroform molecules (the shortest distances are 3.31 and 3.43 Å) and by shortened Cl···C distances involving the C(19), C(20), and C(55) atoms of the fullerene ligand (3.13, 3.25 and 3.22 Å, respectively). For comparison, the shortest van der Waals intermolecular contacts are 3.65 Å for Cl···Cl and 3.45 Å for Cl···C.[14] One solvate chloroform molecule forms a weak C−H···O hydrogen bond with the O(1) atom of the peroxy group of **II** [the O(1)···C(1S) distance is 3.02(2) Å and the O(1)···H(1S)−C(1S) angle is 159°].

Thus, we have established that selective insertion reactions can occur involving only one M−C(fullerene) bond in complexes of the (η^2-C_{60})-M type to give the corresponding metallacyclic derivatives with a σ-coordinated fullerene ligand. Oxidation of [(η^2-C_{60})Ir(*o*-$HCB_{10}H_9CCH_2PPh_2$-*B*,*P*)(*t*BuNC)$_2$] by dioxygen resulting in the complex [σ-C_{60}OO-Ir(*o*-$HCB_{10}H_9CCH_2PPh_2$-*B*,*P*)(*t*BuNC)$_2$] is a good example of such a process. To the best of our knowledge, this is not only the first stable mononuclear exohedral fullerene complex in which the fullerene cage is σ-coordinated to the transition metal atom, but also the first structurally characterized complex with a peroxoiridacycle.

Experimental Section

General: IR spectra were obtained on a Specord M80 spectrometer. ^{1}H NMR spectra (400.3 MHz) and ^{31}P{^{1}H} NMR spectra (160.02 MHz) were recorded on a Bruker AMX-400 spectrometer and are quoted relative to residual signals of the solvent (internal standard) and 85% H_3PO_4 (external standard), respectively.

Synthesis of Complex [σ-C_{60}OO-Ir(*o*-$HCB_{10}H_9CCH_2PPh_2$-*B*,*P*)(*t*BuNC)$_2$] (II): Dioxygen was slowly bubbled through a stirred solution of complex **I** (0.0562 g, 0.04 mmol) in dry chloroform (15 mL) at room temperature until disappearance of the absorption band at 460 nm in the UV spectrum of the reaction mixture (ca. 60 h). Chloroform was then removed under reduced pressure and the residue was extracted with THF. The extract was filtered, concentrated to approx. 1.5 mL, and hexane was added. The resulting precipitate was filtered off, washed with hexane, and dried in vacuo

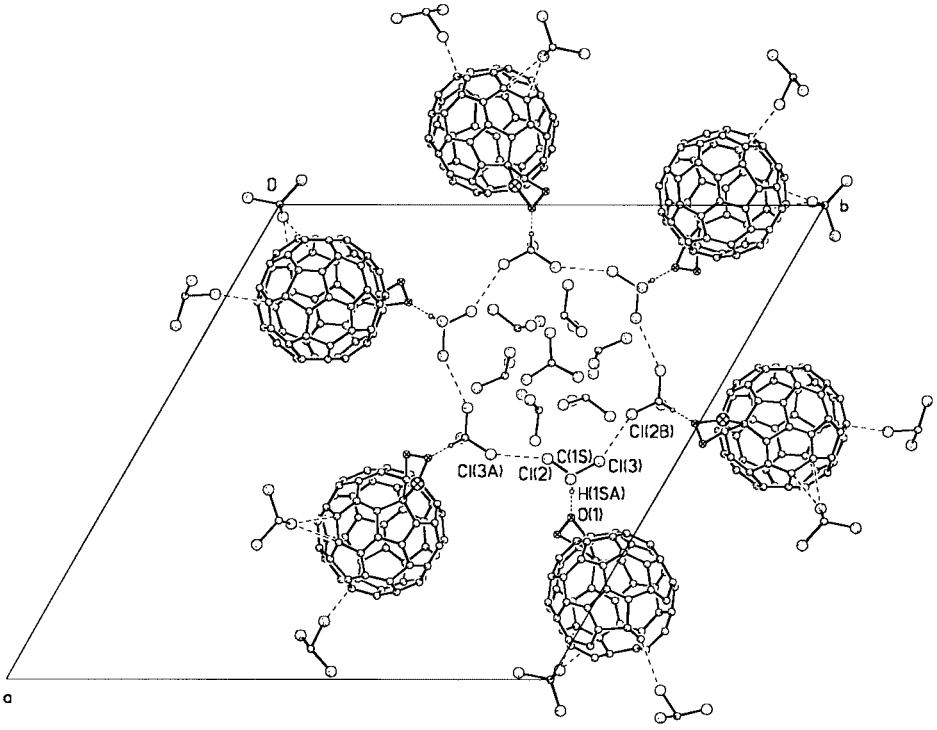

Figure 3. Fragment of crystal packing of solvate **II**·$3^2/_3CHCl_3$ viewed along the *c* direction with intermolecular contacts Cl···Cl, Cl···C and C−H···O (one of two possible orientations of fullerene moiety is shown); the ligand environment of the Ir atoms, apart from the fullerene and oxygen atoms of the peroxide bridge, has been omitted for clarity

to give the complex **II**·$6H_20$ (24.4 mg, 39%) as a dark-green powder. $C_{85}H_{40}B_{10}N_2O_2PIr·6H_20$ (1560.6): calcd. C 65.42, H 3.36; found C 65.53, H 3.73. UV/Vis ($CHCl_3$): λ = 329 nm, 404 (sh), 707. IR (Nujol): $\tilde{\nu}$ = 3568 cm^{-1} (OH), 2581 (BH), 2191 (NC). ^1H NMR ([D_8]THF): δ = 1.30 (s, 9 H, *t*Bu), 1.45 (s, 9 H, *t*Bu), 2.45 (s, 12 H, H_2O), 3.21 (dd, $^2J_{H,P}$ = 6.8, $^2J_{H,H}$ = 16.9 Hz, 1 H, CH_2), 3.50 (s, 1 H, CH^{carb}), 4.19 (dd, $^2J_{H,P}$ = 10.7, $^2J_{H,H}$ = 16.9 Hz, 1 H, CH_2), 7.48 (m, 6 H, Ph), 8.15 (m, 4 H, Ph) ppm. $^{31}P\{^1H\}$ NMR ([D_8]THF): δ = 20.9 ppm.

X-ray Structure Determination of II: Single crystals of **II**·$3^2/_3CHCl_3$ were grown from a chloroform solution of **II**·$6H_20$ at room temperature. The crystals are rhombohedral, space group $R\bar{3}$, a = 29.901(1), c = 42.955(2) Å, V = 33258(1) $Å^3$, Z = 18, $d_{calcd.}$ = 1.699 g/cm^3, and μ(Mo-K_α) = 22.83 cm^{-1}. The intensities of 19332 independent reflections (R_{int} = 0.0635) were measured on a Bruker SMART 1000 CCD diffractometer (graphite monochromated Mo-K_α radiation, λ = 0.71073 Å, ω and scan technique with a 0.3° step in ω and 10 s per frame exposure, θ ≤ 29.5°) at 100.0(2) K. Reflection intensities were integrated using the SAINT software[15] and corrected for absorption semi-empirically (SADABS program)[16] based on multiple measurements of identical reflections and equivalents. The structure was solved by direct methods and refined by full-matrix least-squares against F^2. The uncoordinated carbon atom in the carborane polyhedron is disordered over two equally populated positions labeled X(2) and X(4). The carbon atoms of the C_{60} fullerene ligand [except for the C(1) and C(60) atoms] are disordered over two equally populated positions. The methyl groups of the *tert*-butyl isocyanide ligands are rotationally disordered over two positions with a 3:1 occupancy ratio. In the crystal structure, there are three solvate chloroform molecules in general positions (one of them is disordered) and three solvate chloroform molecules in special positions (one of them occupies a position on the 3 axis and the two others occupy the $\bar{3}$ axes). All disordered atoms in the crystal structure of complex **II** were refined with isotropic thermal parameters. All H atoms of the carborane polyhedron were located from the electron density difference synthesis, while the remaining H atoms were placed geometrically and included in the refinement using a riding model. The refinement converged to wR_2 = 0.1911 and GOF = 1.013 for all independent reflections]R_1 = 0.0649 was calculated against F for a total of 12640 observed reflections with $I > 2\sigma(I)$]; the number of refined parameters was 1013. All calculations were performed using the SHELXTL-97 program[17] on an IBM PC/AT computer.

Macrocyclic Melamine-Based Ligand Complexes as Building Blocks for the Metal-Directed Synthesis of Heterometallic Di- and Trinuclear Compounds

Peter Comba,*[a] Yaroslaw D. Lampeka,*[b] Lutz Lötzbeyer,[a] and Alexander I. Prikhod'ko[b]

Keywords: Template reactions / Nickel / Copper / Macrocycles / N ligands

Heterodi- and heterotrimetallic Ni^{II}/Cu^{II}, Ni^{II}_2/Cu^{II} and Ni^{II}/Cu^{II}_2 complexes of bis- and tris-macrocyclic ligands, linked by a 1,3,5-triazine spacer group, are obtained as products of copper(II)- or nickel(II)-assisted condensations of the open-chain tetraamine complexes $[M^2(2,3,2\text{-tet})]^{2+}$ [2,3,2-tet= bis-*N*,*N*′-(2-aminoethyl)propane-1,3-diamine, $M^2 = Ni^{II}$ or Cu^{II}] with formaldehyde and the monomacrocyclic ligand complexes $[M^1(L^1)]^{2+}$, where L^1 is a cyclam-type macrocycle with a pendent melamine group ($M^1 = Cu^{II}$ or Ni^{II}). The spectroscopic (UV/Vis and EPR) and electrochemical properties of the oligonuclear heterometallic compounds in comparison with those of the homometallic analogues indicate small, but significant, intramolecular metal-metal interactions.

Introduction

A number of metalloproteins have oligonuclear active sites,[1] cooperative effects in dinuclear enzyme mimics have been studied extensively,[2−4] and examples of very active catalysts with more than one metal center involved may indicate that there is some potential in oligonuclear metal catalysts. Generally, the two (or more) metal ions have different functions in enzymatic catalytic processes and, therefore, the two sites in model compounds and active molecular catalysts should be structurally and/or electronically different.[5] The synthesis of ligands with two different coordination sites is not easy,[5,6] and coordination of two different metal ions to symmetrical ligands leads to problems with the separation of the product mixtures, especially with labile metal ions. The sequential synthesis of oligonuclear complexes is therefore an appealing concept,[7] and for oligomacrocylic ligand complexes, consecutive metal-ion-directed processes should be an efficient preparative technique.

There are a few mixed $Ni^{II}Cu^{II}$ complexes of bis-tetraazamacrocyclic ligands[8−10] but no corresponding trinuclear complexes have been described so far. The nickel(II)- and copper(II)-directed reactions of $[M^2(2,3,2\text{-tet})]^{2+}$ [2,3,2-tet = bis *N*,*N*′-(2-aminoethyl)propane-1,3-diamine, $M^2 = Ni^{II}$ or Cu^{II}] with formaldehyde and melamine (melamine = 2,4,6-triamino-1,3,5-triazine) lead to mixtures of homometallic mono-, bis- and tris-macrocyclic ligand complexes.[11−14] The fact that products of different nuclearity are formed in the one-pot reactions suggests that the melamine amino groups of the mono- and bis-macrocyclic ligand complexes can serve as locking fragments in the formation of the second and third macrocyclic subunit. Here we report the use of the recovered mono-macrocyclic ligand complexes as starting materials for the di- and trinuclear mixed-metal complexes (see Scheme 1).

Results and Discussion

The nickel(II)- or copper(II)-assisted reaction of the open-chain tetraamine 2,3,2-tet with the melamine-substituted macrocyclic ligand compounds $[M^1(L^1)]^{2+}$ results in the formation of the desired di- and trinuclear heterometallic species $[M^1M^2(L^2)]^{4+}$, $[M^1_2M^2(L^3)]^{6+}$ and $[M^1M^2_2(L^3)]^{6+}$ ($M^1 = Cu^{II}$, $M^2 = Ni^{II}$; see Scheme 1). Similar to the analogous reactions leading to the corresponding homo-oligonuclear complexes[13,14] the yields of the one-pot template reactions are low (5−10%) and higher for the copper(II)- than for the nickel(II)-directed reactions. The yields are solvent dependent and the highest were obtained in ethanol/acetonitrile mixtures. As a side-product the modified bis-macrocyclic ligand complex $[NiCu(L^{2a})]^{4+}$, in which the melamine NH_2 protons of L^2 are substituted by CH_2OH groups, is formed in appreciable yield. This complex was fully characterized by MS and elemental analysis (see Exp. Sect.).

The mass spectra of the three new hetero-oligonuclear complexes are clear evidence for the successful syntheses. Peaks for the molecular ions, with expected intensity distributions, were observed in all cases (see Figure 1 for an example). As expected, due to the inertness of the oligo-macrocyclic ligand complexes, no peaks of homo-oligonuclear species were observed; i.e., there are no transmetallation reactions. Characteristic peaks in the IR spectra of the complexes {1630 cm^{-1} (δ_{NH2}) and 1560 cm^{-1} (ν_{CN}) for $[NiCu(L^2)]^{4+}$ and 1550 cm^{-1} (ν_{CN}) for $[NiCu_2(L^3)]^{6+}$ and $[Ni_2Cu(L^3)]^{6+}$} are in good agreement with those of the corresponding homo-oligonuclear compounds.[13,14] The electronic spectra of the homo- and heteronuclear complexes are similar (Table 1). The absorption in the UV region is due to the superposition of the MLCT transition {ν_{max} = 39500 cm^{-1} (ε = 8500 $M^{-1}\cdot cm^{-1}$) and 45500 cm^{-1} (ε = 12000) for $[Cu(cyclam)]^{2+}$ and $[Ni(cyclam)]^{2+}$, respectively, cyclam = 1,4,8,11-tetraazacylotetradecane}[13,14] and a melamine-based π-π transition [ν_{max} = 49100 cm^{-1} (ε = 52000)].[13,14] The intensity of the MLCT bands are approximately proportional to the number of copper(II) and nickel(II) sites in the oligonuclear complexes.

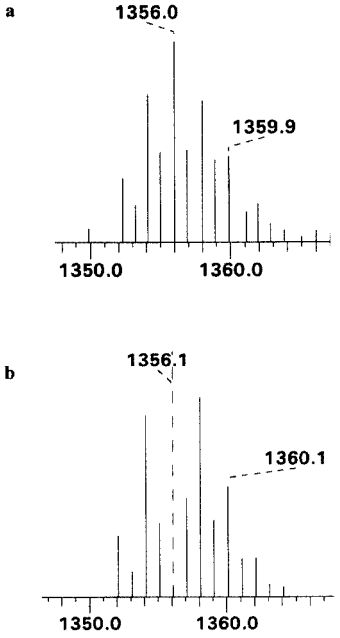

Figure 1. Experimental (a) and calculated (b) distribution of peak intensities for $\{[Ni_2Cu(L^3)](ClO_4)_5\}^+$ in the FAB mass spectrum of the trinuclear mixed-metal complex

The intensities of the d-d electronic transitions are also very similar to the sum of the spectra of the corresponding mononuclear nickel(II) and copper(II) sites (see Table 1). Nickel(II) complexes of melamine-based ligands exist in aqueous solution as equilibrium mixtures of diamagnetic four-coordinate $[NiN_4]$ and paramagnetic six-coordinate $[NiN_4(OH_2)_2]$ species.[14] Because of the larger intensity of the copper(II) d-d transitions those due to nickel(II) appear only as ill-resolved shoulders at the high energy tail of the copper(II) band. This is more pronounced at higher temperatures and in the noncoordinating solvent nitromethane,

where the amount of the diamagnetic form of nickel(II) is dominant (see Table 1).

EPR spectra of the complexes are indicative of the number of copper(II) sites in the oligomacrocyclic ligand complexes. For $[NiCu(L^2)]^{4+}$ and $[Ni_2Cu(L^3)]^{6+}$ the spectra are, as expected, almost identical (Figure 2), and similar to that of $[Cu(L^1)]^{2+}$.[11,13] The spectrum of $[NiCu_2(L^3)]^{6+}$ is similar to that of $[Cu_2(L^2)]^{4+}$ and typical for a dipole-dipole coupled bis(spin 1/2) system. The rather broad features of the two dicopper(II) compounds (spectra d and e) do not allow us to exclude small amounts of $CuNi_2$ or Cu_3 impurities in the samples. However, the spectra are compatible with pure Cu_2 and $NiCu_2$ samples and transmetallation is unexpected for this type of cyclam-based copper(II) and nickel(II) complexes under the conditions employed, and proven by the mass spectroscopic data and elemental analyses. A detailed interpretation of the EPR spectra with the aim of analyzing the solution structural properties, based on MM-EPR,[15] is in process and will be published elsewhere.[16]

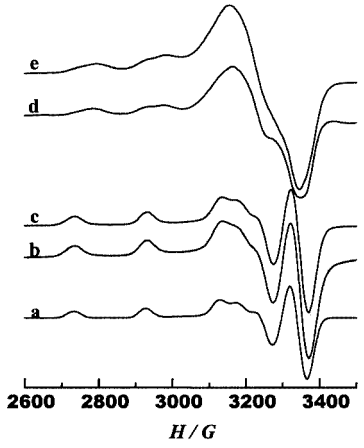

Figure 2. EPR spectra of frozen solutions [DMF/H_2O, (2:1), approx. 10^{-3} M] of: (a) $[Cu(L^1)]^{2+}$, (b) $[NiCu(L^2)]^{4+}$, (c) $[Ni_2Cu(L^3)]^{6+}$, (d) $[Cu_2(L^2)]^{4+}$ and (e) $[NiCu_2(L^3)]^{6+}$

The redox potentials of the $Ni^{III/II}$ couple in aqueous solution (0.1 M $NaNO_3$ or 3.3×10^{-2} M Na_2SO_4) were determined by cyclic voltammetry (Table 1). Due to the more positive $E_{1/2}$ values for the $Cu^{III/II}$ transformation[13] these processes were not observed in the potential range studied (0.2−1.0 V). The CV of $[Ni_2(L^2)]^{4+}$ and $[NiCu(L^2)]^{4+}$ in 0.1 M $NaNO_3$ reveal one quasi-reversible $Ni^{III/II}$ transition each, but the current of the mixed-metal species is approximately half that of the homo-dinuclear complex at the same concentration. Under the same conditions the current observed for $[NiCu_2(L^3)]^{6+}$ is smaller than for $[NiCu(L^2)]^{4+}$; this is believed to be due to a smaller diffusion coefficient of the tris(macrocyclic) ligand cationic complex. A similar effect is observed for $[Ni_2(L^2)]^{4+}$ and $[Ni_2Cu(L^3)]^{6+}$. The potentials of the $Ni^{III/II}$ couple for all hetero-oligonuclear complexes are close to that of the corresponding mononuclear compound. This indicates a negligible electrostatic influence of the copper(II) centers on the redox transformation of the nickel ions.

Due to the stabilization of nickel(III) by coordination of sulfate, the $E_{1/2}$ values in sulfate media are less anodic. As expected, $[NiCu(L^2)]^{4+}$ as well as $[NiCu_2(L^3)]^{6+}$ reveal one electrochemical process with potentials similar to the less anodic peaks observed for $[Ni_2(L^2)]^{4+}$ (Figure 3). $[Ni_2(L^2)]^{4+}$ also undergoes a second redox transformation at higher potential. This was interpreted as being due to hydrogen bonding between a water molecule coordinated to one nickel center and sulfate axially coordinated to the adjacent metal ion.[14] It was therefore unexpected that both nickel centers of $[Ni_2Cu(L^3)]^{6+}$ are electrochemically identical in sulfate media. It appears that the formation of the proposed hydrogen-bonded arrangement is less favorable when water is coordinated to copper(II); a possible reason is the differences in M−O (OH_2) bonds {approx. 2.15 and 2.5 Å for tetragonal nickel(II) and copper(II) tetramines[14]}.

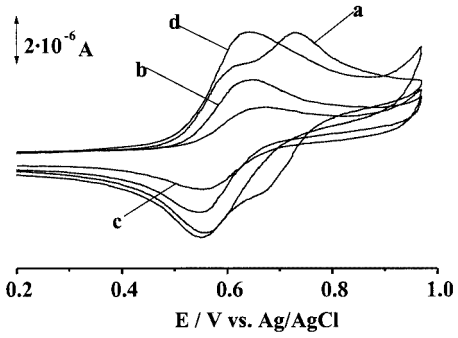

Figure 3. Cyclic voltammograms of 2.5×10^{-3} M solutions of the macrocyclic ligand complexes in 3.33×10^{-2} M Na_2SO_4: (a) $[Ni_2(L^2)]^{4+}$; (b) $[NiCu(L^2)]^{4+}$; (c) $[NiCu_2(L^3)]^{6+}$; (d) $[Ni_2Cu(L^3)]^{6+}$

Conclusion

Based on the available electrochemical and UV/Vis spectroscopic data there is only a weak interaction between the copper(II) and nickel(II) centers. This is supported by the EPR spectra of the systems with two copper centers, which are typical for dipole-dipole coupled dicopper(II) compounds. The electrochemical data indicate that the cooperativity in the binding of sulfate observed for the homometallic dinickel(II) system[14] disappears in the mixed-metal systems. This suggests that axial coordination to the mixed-metal systems is significantly different to that of the homometallic compounds, and this will lead to important differences in the rich host-guest chemistry[13] of the trinuclear systems.

Experimental Section

Physical Methods: Infrared spectra (KBr pellets) were recorded on a Specord 75 IR (Carl Zeiss) spectrometer. Electronic absorption spectra were measured on a Specord M40 (Carl Zeiss) spectrophotometer. EPR spectra were obtained with a Bruker ESP300E spectrometer (9.4635 GHz) as approx. 1×10^{-3} mol·L^{-1} frozen (liquid nitrogen temperature) solutions in DMF/water (2:1). Fast atom bombardment mass-spectra (FAB^+ mode) were obtained

with a MAT8400 mass spectrometer, using *p*-nitrobenzyl alcohol (Nibelol) as the matrix. Cyclic voltammograms were generated using a PI-50−1.1 potentiostat, equipped with a PR-8 function generator (Izmeritel, Gomel) and an N-307 X-Y recorder (ZIP, Krasnodar). A standard three-electrode scheme was used, consisting of a glassy carbon working, a Ag/AgCl reference and a Pt wire auxiliary electrode. All solutions for electrochemistry were purged with nitrogen before measurement. Analytical data were obtained from the microanalytical laboratory of the chemical institutes of the University of Heidelberg.

Materials: AR grade chemicals and solvents were used as supplied for all reactions. Open-chain amine metal complexes $[M(2,3,2\text{-tet})](ClO_4)_2$ [M = Ni or Cu; 2,3,2-tet= bis-*N*,*N*′-(2-aminoethyl)-propane-1,3-diamine] and macrocyclic ligand mononuclear $\{[Ni(L^1)](ClO_4)_2{\cdot}H_2O$ and $[Cu(L^1H)](ClO_4)_3{\cdot}H_2O\}$ and homodinuclear $\{[Ni_2(L^2)](ClO_4)_4{\cdot}2H_2O$ and $[Cu_2(L^2)](ClO_4)_4{\cdot}2.5H_2O\}$ complexes were prepared as described previously.[13,14]

Syntheses: ***Caution! Perchlorate salts of metal complexes are potentially explosive. Although we did not experience any problems, such complexes should be handled very carefully.***

In a typical procedure 4.0 mmol of $[Ni(L^1)](ClO_4)_2{\cdot}H_2O$ {or $[Cu(L^1H)](ClO_4)_3{\cdot}H_2O\}$ and 9.1 mmol of $[Cu(2,3,2\text{-tet})](ClO_4)_2$ {or $[Ni(2,3,2\text{-tet})](ClO_4)_2\}$ were dissolved in a mixture of acetonitrile (25 mL), ethanol (35 mL) and triethylamine (3 mL), and the resulting solution was brought to reflux. A solution of 37% aqueous formaldehyde (23.0 mmol) in ethanol (15 mL) was added dropwise during one hour. The reaction mixture was refluxed for an additional 48 h, then cooled to ambient temperature and filtered. The solution was diluted to 2 L and absorbed onto a Sephadex C-25 (Na^+ form) ion exchange column, which was first washed with water (0.5 L). The first band eluted with 0.25 M $NaClO_4$ contained unchanged starting materials and was discarded.

Two bands eluted from the column with 0.4 M $NaClO_4$. The first band was collected, the solvents evaporated under low pressure to a small volume and left to dry at ambient temperature. The solid red-yellow residue was treated with 30 mL of acetonitrile to extract the macrocyclic complex. This was precipitated from the purple acetonitrile solution by slow diffusion of diethyl ether, and the solid was carefully triturated in 10 mL of 1 M aqueous $NaClO_4$. The precipitate, **$[NiCu(L^{2a})](ClO_4)_4\ 3H_2O$**, was collected by filtration, washed with ethanol and dried in air. Yield 0.22 g, 5%. $C_{23}H_{55}Cl_4CuN_{14}NiO_{21}$ (1127.8): calcd. C 24.49, H 4.92, N 17.39; found C 24.28, H 4.84, N 17.62. MS: *m*/*z* = 972 ($[CuNi(L^{2a}\text{-}2H)](ClO_4)_3^+$), 944 ($[CuNi(L^{2a}\text{-}CH_2OH)](ClO_4)_3^+$), 914 ($[CuNi(L^{2a}\text{-}2CH_2OH)](ClO_4)_3^+$).

$[NiCu(L^2)](ClO_4)_4{\cdot}3H_2O$ eluted as the second band with 0.4 M $NaClO_4$. The eluate was evaporated to 40 mL under reduced pressure and cooled in a refrigerator. The red-orange precipitate was filtered, washed with ethanol and dried in air. Yield 0.47 g, 11%. The product was purified by reprecipitation from an aqueous solution by addition of $NaClO_4$. IR (KBr): $\tilde{\nu}$ = 3210m cm^{-1} [ν(NH), macrocycle], 1630m [δ(NH_2), melamine], 1560s [ν(CN), melamine], ca. 1100vs, 626m [ν(ClO_4)]. $C_{12}H_{52}Cl_4CuN_{14}NiO_{19}$ (960.7): calcd. C 23.60, H 4.90, N 18.35; found C 23.79, H 4.95, N 18.12. MS: *m*/*z* = 914 ($[CuNi(L^2)](ClO_4)_3^+$).

The tris-macrocyclic ligand complexes were eluted as the third band with 0.8 M $NaNO_3$. The eluate was reduced to a volume of 40 mL. After cooling, the precipitate of $NaNO_3$ was removed by filtration. After addition of 2 g of $NaClO_4$ the solution was left at room temperature for a few days to allow crystals to form. The product was filtered, washed with ice-cold water and ethanol and dried in air.

$[NiCu_2(L^3)](ClO_4)_3(NO_3)_3{\cdot}3H_2O$. Yield 0.36 g, 7%. IR (KBr): $\tilde{\nu}$ = 3190m cm^{-1} [ν(NH), macrocycle], 1550s [ν(CN), melamine], 1370s [ν(NO_3)], ca. 1100vs, 626m [ν(ClO_4)]. $C_{30}H_{72}Cl_3Cu_2N_{21}NiO_{24}$ (1403.2): calcd. C 25.68; H 5.17; N 20.96; found C 25.77; H 5.36; N 21.32. MS: *m*/*z* = 1248 ($[NiCu_2(L^3)](ClO_4)_2(NO_3)_3^+$).

$[NiCu_2(L^3)](ClO_4)_6{\cdot}4H_2O$: This product was obtained by addition of $NaClO_4$ to an aqueous solution of $[NiCu_2(L^3)](ClO_4)_3(NO_3)_3{\cdot}3H_2O$. Yield: nearly quantitative. IR (KBr): $\tilde{\nu}$ = 3226 cm^{-1} [ν(NH), macrocycle], 1550s [ν(CN), melamine], ca. 1100vs, 626m [ν(ClO_4)]. $C_{30}H_{74}Cl_6Cu_2N_{18}NiO_{28}$ (1533.5): calcd. C 23.50, H 4.86, N 16.44; found C 23.62, H 5.02, N 16.42.

$[Ni_2Cu(L^3)](ClO_4)_6{\cdot}5H_2O$: Yield 0.21 g, 3%. IR (KBr): $\tilde{\nu}$ = 3200m cm^{-1} [ν(NH), macrocycle], 1550s [ν(CN), melamine], ca. 1100vs, 626m [ν(ClO_4)]. $C_{30}H_{76}Cl_6CuN_{18}Ni_2O_{29}$:calcd. C 22.00, H 4.48, N 17.11; found C 22.06, H 4.65, N 16.78. MS: *m*/*z* = 1356 ($[CuNi_2(L^3)](ClO_4)_5^+$).

Self-Assembly of a One-Dimensional Silver Complex Containing Two Kinds of Helical Chains

Daofeng Sun,[a] Rong Cao,*[a] Yanqiong Sun,[a] Wenhua Bi,[a] Xing Li,[a] Maochun Hong,[a] and Yingjun Zhao[a]

Keywords: Self-assembly / S ligands / N ligands / Silver / Helical structures

Self-assembly of the potassium sulfonate salt K_2pesp [H_2pesp = piperazine-1,4-bis(2-ethanesulfonic acid] with piperazine (PIP) and a silver(I) salt in solution allows the preparation of a novel one-dimensional helical polymer $[Ag(PIP)]_n{\cdot}[Ag(pesd)]_n{\cdot}2nH_2O$ (**1**), which is made up of two independent silver-containing helical chains, namely $[Ag(PIP)]_n$ and $[Ag(pesd)]_n$. There is no direct bonding interaction between the two chains, and the hydrogen bonds between the chains give **1** a two-dimensional layer supramolecular architecture.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2003)

Inorganic supramolecular chemistry, in particular the construction of specific structural networks, is a particularly active field of chemistry.[1] In the past few decades, helical structures have received much attention from chemists due to their fundamental role in biology, and their potential applications in asymmetric catalysis and nonlinear optical materials.[2,3] Although the most effective method to construct helical polymers is to carefully design helical ligands,[4] the use of oligopyridines and other optically active ligands has resulted in a large number of helical structures, such as di- and oligonuclear, infinite single or double helical chains.[5] However, no helical structures constructed from sulfonic ligands have been reported, probably due to the weak coordinating ability of sulfonate ligands.[6,7] Recently, we began to study the reactions of the flexible sulfonate ligand[8] piperazine-1,4-bis(2-ethanesulfonic acid) (H_2pesp) with silver salts, with the aim of obtaining information on the coordination ability of sulfonic ligands, which have previously been regarded as poorly coordinating anions,[7] and for constructing novel coordination architectures. In this paper, we describe a novel silver polymer containing two independent silver helical chains $[Ag(PIP)]_n{\cdot}[Ag(pesp)]_n{\cdot}2nH_2O$ (**1**).

Complex **1** was obtained as colorless crystals by the self-assembly reaction of dipotassium salt of piperazine-1,4-bis(2-ethanesulfonic acid) (K_2pesp), piperazine hexahydrate (PIP) and $AgNO_3$ in H_2O/MeOH at room temperature. X-ray diffraction analysis shows **1** to be a one-dimensional polymer containing two independent silver-containing helical chains, namely $[Ag(pesp)]_n$ and $[Ag(PIP)]_n$. The crystal structure consists of two independent subunits, $[Ag(pesp)]^-$ and $[Ag(PIP)]^+$. In $[Ag(pesp)]^-$, the central silver is coordinated by two oxygen atoms and two nitrogen atoms from different ligands in a distorted tetrahedral geometry similar to that found in $[Ag_2(\mu_2\text{-}OH_2)(pesp)]_n$,[8] with an average Ag−O bond length of 2.433(10) Å and an average Ag−N bond length of 2.334(9) Å. Due to the presence of a flexible ethyl group, one oxygen atom of the sulfonate group and one nitrogen atom of the piperazine unit of $pesp^{2-}$ chelate the silver ion and the whole ligand acts as a μ_2-bridge. The coordination mode of the $pesp^{2-}$ ligand in **1** is quite different from that found in $[Ag_2(\mu_2\text{-}OH_2)(pesp)]_n$,[8] in which $pesp^{2-}$ is almost linear and acts as a μ_6-bridge to link six silver ions. This result illustrates that the flexible $pesp^{2-}$ ligand can adopt diverse coordination modes according to the different geometric requirements of the metal ions.[9] Thus, each $pesp^{2-}$ ligand links two silver ions and to form a one-dimensional anionic 2_1 helical chain, as shown in Figure 1. To the best of our knowledge, this is the first example of a silver(I) helical structure constructed by sulfonate ligands. The charge balance comes from another one-dimensional cationic helical chain, $[Ag(PIP)]_n$. In this $[Ag(PIP)]^+$ unit, the silver ion is coordinated by two nitrogen atoms from two PIP ligands in a linear geometry with the average Ag−N distance being 2.200(10) Å, shorter than that in the $[Ag(pesp)]^-$ unit. Each PIP links two silver ions to form a one-dimensional cationic helical chain (Figure 2). The piperazine rings in both $pesp^{2-}$ and PIP ligands adopt the most stable "chair" configuration as found in other Ag-PIP complexes.[10]

Considering that the most volatile component of the structure should be the piperazine units, thermogravimetric analyses (TGA) were performed to determine the thermal

The $[Ag(pesp)]_n^{n-}$ anion helical chain in **1**: a) along the helical axis; b) space filling representation; selected bond lengths (Å) and angles (°): Ag(1)−N(1) 2.308(9), Ag(1)−N(2) 2.359(9), Ag(1)−O(4) 2.388(8), Ag(1)−O(1) 2.477(10); N(1)−Ag(1)−N(2) 143.1(3), N(1)−Ag(1)−O(4) 119.2(3), N(2)−Ag(1)−O(4) 88.5(3), N(1)−Ag(1)−O(1) 91.1(3), N(2)−Ag(1)−O(1), 113.2(3), O(4)−Ag(1)−O(1), 92.2(3)

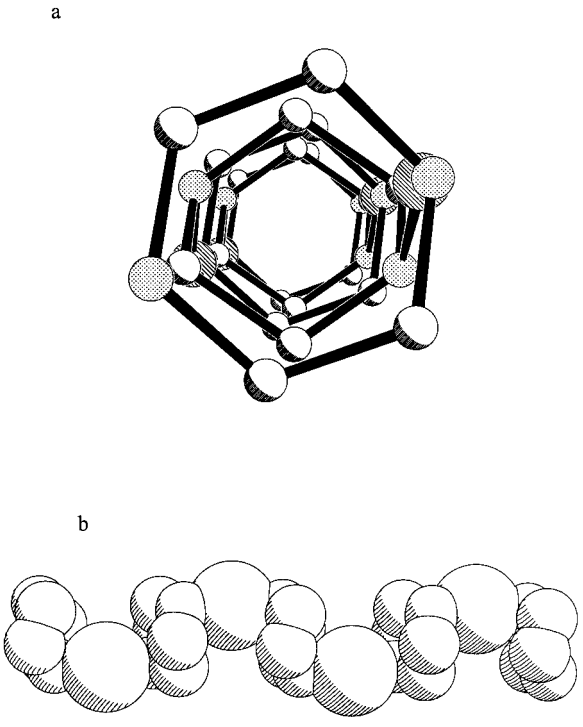

Figure 2. The $[Ag(PIP)]_n^{n+}$ cation helical chain in **1**: a) along the helical axis; b) space filling representation; selected bond lengths (Å) and angles (°): Ag(2)−N(3) 2.197(10), Ag(2)−N(4) 2.203(10); N(3)−Ag(2)−N(4) 153.9(4)

stability of complex **1**. After a total weight loss of 5.50% is achieved at 250 °C, which corresponds to the loss of two uncoordinated water molecules per formula unit, complex **1** starts to decompose gradually and the decomposition ends above 700 °C.

The most intriguing feature of **1** is the independence of the cationic and anionic helical chains. Although some polymeric complexes containing two kinds of helical chains have been reported, the chains are usually not independent and are connected by coordination bonds.[11,12] In **1**, there is no direct bonding interaction between the two chains, only hydrogen bonding interactions between some nitrogen atoms of the PIP ligands and the oxygen atoms of $pesp^{2-}$ are observed — the shortest N−O distance is 2.876(9) Å — and a two-dimensional wave-like layer structure is formed by such weak interactions (Figure 3). Aside from the hydrogen bonds between the chains, there are also weak Ag−O interactions between the layers: the sulfonate oxygen atom [O(3)] coordinates weakly to the silver ion [Ag(2)] of another layer with an Ag−O distance of 2.793 Å. This weak interaction makes the inter-layer distance much shorter (6.667 Å; Figure 4); the free water molecules are found between the layers.

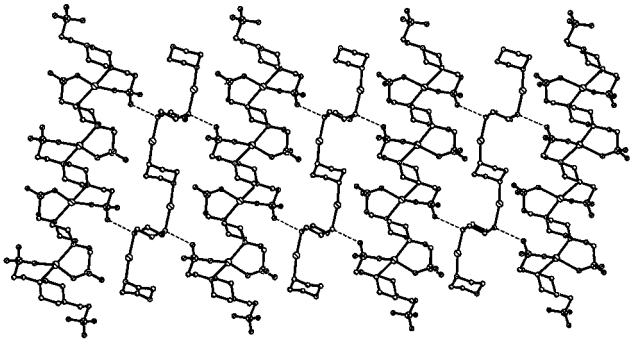

Figure 3. The 2D layer structure of **1** constructed by hydrogen bond between chains

As is well known, the self-assembly reaction is strongly influenced by many factors such as the pH value, the solvent and the metal:ligand ratio. We therefore changed the reaction conditions in order to attempt the preparation of different structures. However, when we adjusted the pH value to 7 or 8 by addition of $HClO_4$, we obtained the polymer $[Ag_2(\mu_2\text{-}OH_2)(pesp)]_n$,[8] which presumably arises from partial protonation of the piperazine moiety this pH value and subsequent loss of its coordination ability. When we attempted the reaction in different solvents and metal:ligand ratios, only an unknown precipitate was obtained, which indicates that the pH value, the solvent and the metal:ligand ratio do indeed influence the formation of **1**. Further study of this reaction is underway and will be reported shortly.

Experimental Section

Synthesis of 1: K_2pesp (0.045 g, 0.125 mmol) and PIP (0.021 g, 0.25 mmol) were dissolved in 10 mL of water. Then, a solution of $AgNO_3$ (0.043 g, 0.25 mmol) in MeOH (5 mL) was carefully layered on it. After standing in the dark for about two weeks, colorless prism-like crystals were obtained. Yield: 35%. $C_{12}H_{30}Ag_2N_4O_8S_2$ (638.2): calcd. C 22.58, H 4.74, N 8.78; found C 22.60, H 4.65, N 8.80. IR (KBr): $\tilde{\nu}$ = 3450(vs), 3261(m), 2827(m), 1655(m), 1552(m), 1460(m), 1358(m), 1315(s), 1250(s), 1200(vs), 1215(vs), 1167(vs), 1039(vs), 866(s), 588(vs) cm^{-1}.

X-ray Crystallography: $C_8H_{18}Ag_2N_2O_7S_2$, (**1**), M_r = 638.26, triclinic, $P\bar{1}$, a = 6.7657(8), b = 10.5093(13), c = 14.8207(18) Å, α = 101.281(2)°, β = 97.091(2)°, γ = 90.516(2)°, V = 1024.9(2) $Å^3$, Z = 2, D_c = 2.068 g/cm^3, μ(Mo-K_α) = 2.162 mm^{-1}, T = 293(2) K, R [$I < 2\sigma(I)$] = 0.0738, wR = 0.1636 for 3604 independent reflections with $F \geq 2.0\sigma(F_o)$.

[a] $R_1 = \|F_0| - |F_c\|/|F_0|$. [b] $wR_2 = [w(F_0^2 - F_c^2)^2/w(F_0^2)^2]^{1/2}$.

The intensity data were collected on a Smart CCD diffractometer with graphite-monochromated Mo-K_α (λ = 0.71073 Å) radiation at room temperature with the ω-2θ scan mode. An empirical absorption correction was applied to the data using the SADABS program. The structures were solved by direct methods. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were generated in idealized positions. All calculations were performed using the SHELXTL program. Crystallographic data for the complex **1** are given in Table 1.

CCDC-188274 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Vanadium-Bromoperoxidase-Mimicking Systems: Direct Evidence of a Hypobromite-Like Vanadium Intermediate

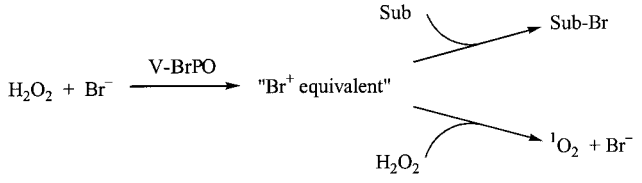
Olga Bortolini,*[a] Mauro Carraro,[b] Valeria Conte,*[c] and Stefano Moro[d]

Keywords: Ab initio calculations / Enzyme models / Mass spectrometry / Peroxo ligands / Vanadium

Here we report a direct observation, by electrospray ionization mass spectrometry, of the intermediate $[VO(OH_2)(OH)(OBr)]^+$, which may be involved in the catalytic cycle of the V-HalPO enzymes. Ab initio calculations also support the stability of such a species.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2003)

Vanadium-dependent bromoperoxidases (V-BrPOs) catalyze the oxidation of bromide ion by hydrogen peroxide.[1−3] Kinetic studies on V-BrPOs indicate a mechanism where V^V ion binds H_2O_2 to produce a peroxo complex that reacts with the Br^- ion to generate an oxidized "bromine equivalent" species, able either to halogenate organic substrates or to react again with H_2O_2 to form singlet oxygen[1−3] (Scheme 1).



Scheme 1. General reactivity for vanadium haloperoxidases

The nature of the intermediate (e.g. HOBr, Br_2, Br_3^-, V_{enz}-OBr, enz-Br), however, is still a matter of some controversy.[1−4] With the aim of shedding light on this point several functional models of V-BrPOs have been reported.[1−4] These, however, fail to reproduce the chemistry of V-BrPOs for different reasons. A two-phase system has also been proposed as a mimicking prototype of the enzymatic activity on the basis of similar reactivity found during peroxidative bromination[5] (Scheme 2).

In this latter case, kinetic data and a product distribution analysis supported the occurrence of a V-containing hypobromite-like intermediate as the "bromine equivalent", although without direct evidence. This proposal was further justified by ab initio calculations which showed that the suggested intermediate lies at a relative minimum of potential energy in comparison with the reactants $[OV(O_2)^+]$/HBr and the couple $[O_2V(H_2O)^+]$/HOBr.[6]

An analysis of the system behaviour[5,6] as a function of the aqueous phase pH and H_2O_2 concentration was performed with styrene as the organic substrate. With this substrate, in our two-phase system, formation of two products has been observed: the corresponding bromohydrin and the dibromide. These crucial results are reported in Table 1.

Variation of the above mentioned parameters produces the selective formation of the mono- or the diperoxovanadium derivative in the aqueous phase, as indicated by ^{51}V NMR analysis of the aqueous phase of the reaction mixture.[4] In particular, at pH 1.1 ($HClO_4$) equal concentrations of NH_4VO_3 and H_2O_2 give rise to more than 95% of the monoperoxo derivative (reaction 1 in Table 1). Upon decreasing the $[NH_4VO_3]/[H_2O_2]$ ratio to 0.5, in otherwise identical conditions, mono- and diperoxovanadium complexes are formed in roughly a 1:1 ratio (reaction 2). By increasing the pH (≥3) the almost exclusive formation of the diperoxo derivative is obtained; in such conditions the efficiency of the reaction strongly decreases (reactions 3−5).[4]

Interestingly, the two reactions (1 and 2) carried out at the same pH (1.1) afforded an almost identical amounts of products. This fact indicates that the dimeric triperoxovanadium derivative, invoked as the active species in the oxybro-

mination reaction, is not involved,[1] and probably that the only peroxo derivative implicated in the formation of the "bromine equivalent" species is the monoperoxo complex. Thus, either the reactivity of the diperoxo complex is markedly lower (reactions 4 and 5), or it acts as a reservoir of the active species.

It has been shown recently that electrospray ionization mass spectrometry (ESI-MS) in association with heteronuclear NMR spectroscopy and ab initio calculations is a powerful combination for the elucidation of solution structures of highly reactive intermediates.[7–9] Therefore, this approach has been applied to the $V/H_2O_2/H^+/Br^-$ system in order to obtain direct experimental information on the occurrence of the postulated "bromine equivalent" species.

The ESI-MS positive-ion mode full scan of solutions containing millimolar vanadate and H_2O_2 at a pH of about 1 ($HClO_4$) in 1:1 water/alcohol (MeOH or EtOH) mixtures shows the occurrence of different species identified as the monoperoxo derivatives $[OV(O_2)(H_2O)]^+$ (at m/z = 117), $[OV(O_2)(H_2O)_2]^+$ (at m/z = 135) and $[OV(O_2)(H_2O)(ROH)]^+$ (at m/z = 149 or 163), depending on the alcohol used, and the dimeric peroxo complexes $[\{OV(O_2)\}_2O(H_2O)_2(ROH)(H)_2]^{2+}$ (at m/z = 142 or 149) and $[\{OV(O_2)\}_2O(H_2O)(ROH)(H)]^+$ (at m/z = 265 or 279). Other significant peaks corresponding to the monomeric and dimeric non-peroxidic species are equally observed as well, in agreement with previously reported data.[7] The addition of a fivefold excess of Br^- to the infused H_2O/MeOH solution gives rise to the formation of a new vanadium species containing a single bromine atom, as demonstrated by the related isotopic cluster. The new complexes, although transferred in the gas-phase in low relative abundance (≤15%), were clearly detected as doublets at m/z = 179 ^{79}Br (181, ^{81}Br), 193 (195) and 197 (199) and tentatively identified as shown in Table 2.

The substitution of methanol with ethanol in the infusion solvent composition produces no significant changes in the full-scan mass spectrum, with the exception that the ionic species at m/z = 193 (195) is replaced by the homologous ethoxy-containing ion at m/z = 207 (209). Further support for the identification of the species was obtained by collision-induced decomposition (MS^2) spectra and the relevant results are collected in Table 2. For low energies (up to 0.5 V), the only peaks observed are those related to ion-molecule reactions of the selected species P with solvent molecules. At higher energies (1.5 V), decomposition takes place with loss of HBr, accompanied by addition of water molecule(s). Formation of dinuclear doubly charged species, i.e. m/z = 147 (149) $[V_2Br_2O_2H_2]^{2+}$ and $[V_2Br_2O_2C_2H_6]^{2+}$ 161 (163), formally deriving from expulsion of O_2, is also observed.[10]

Of special interest is the formal loss of water found in the MS^2 spectra of the -OCH_3 [m/z = 193 (195)] and -OCH_2CH_3 [m/z = 207 (209)] containing derivatives. This process, which corresponds to an internal oxidative decomposition, formally produces ions where a direct coordination of a carbonyl moiety to the metal may be invoked.[4] This gas-phase chemistry has also been observed with other vanadium picolinate[11] and ruthenium[12] derivatives. Synthesis of stable alkyl-V^V complexes has also been reported.[13]

The involvement of fragmentations occurring on vanadium-bound ligands other than OBr confirms that bromide ion is not bound to the complex merely as an ionic couple, but through covalent bonds probably originating from the activation of the peroxidic O–O bridge.[14]

The analysis of the $V/H_2O_2/H^+$ system, upon addition of an excess of Br^-, was completed by extending the ESI-MS inspection to solutions containing a twofold excess of H_2O_2 with respect to vanadate, at a pH of about 2. According to previous studies,[7] the diperoxo complex is the dominant species. These solutions, analyzed both in positive- and negative-ion mode, did not reveal the activation of diperoxovanadium species by bromine ions, in agreement with the reactivity reported above (Table 1).

Further support for the rational formation of the vanadium-containing "bromine equivalent" species was ob-

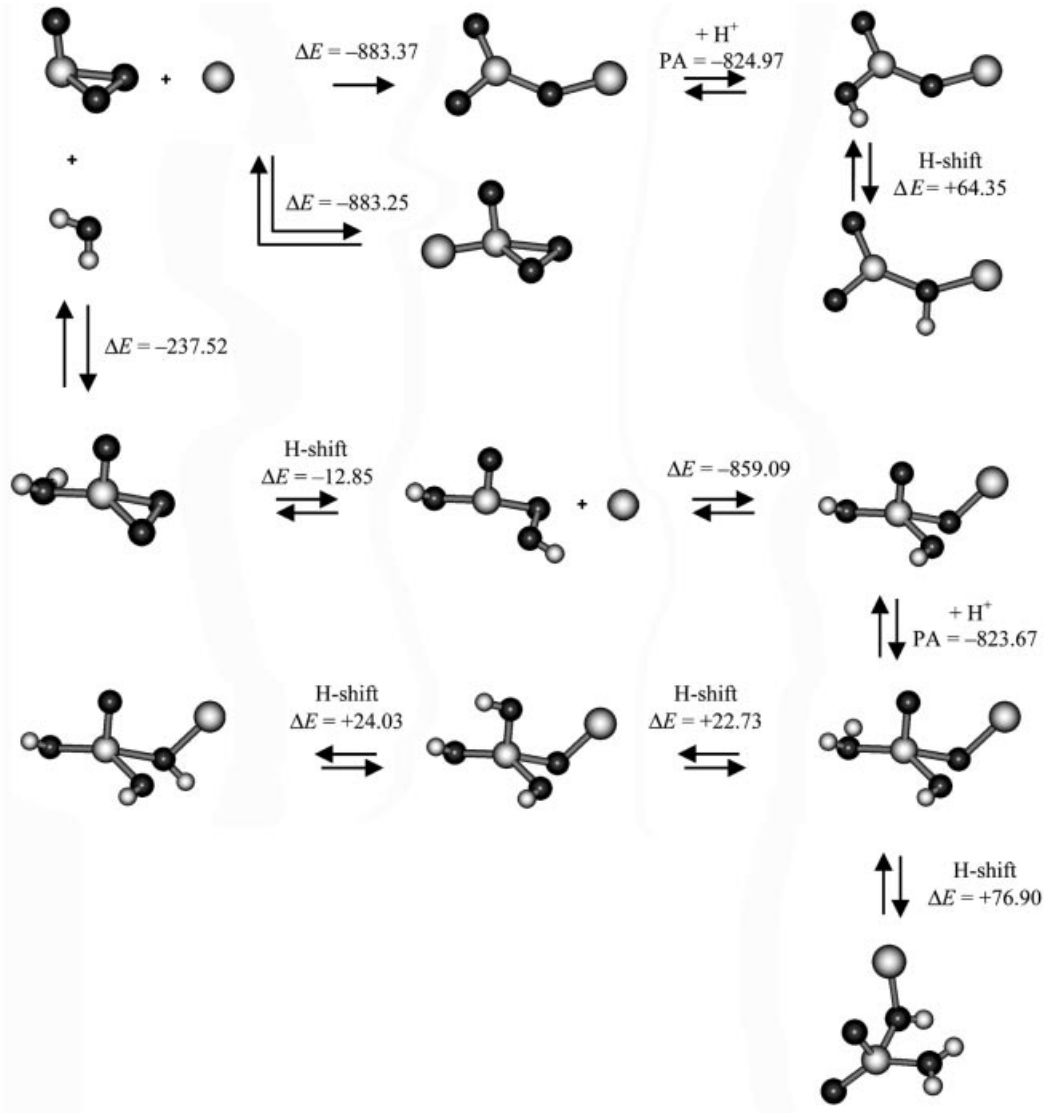
tained by performing ab initio calculations on the various species that can be obtained by reaction of the monoperoxo vanadium compound and bromine, both in the presence or in the absence of a molecule of solvent in the coordination sphere of the metal. Scheme 3 collects the results obtained by effecting geometry optimization of all the structures with density functional theory (DFT) calculations carried out with Becke's hybrid three-parameter functional with Lee−Yang−Parr nonlocal correlation (B3LYP).[15,16] Calculations were conducted with the (99,302) numerical integration grid[16] and full accuracy at all stages in order to achieve SCF convergence. The 6-311G+(d,f) basis set implemented in the Gaussian 98 suite of programs was used.[16] After the geometry optimisation step, the energy values weren evaluated through single point calculations (performed using the SCF=tight option in Gaussian 98) at the B3LYP/6-311G++(3df,3dp) level of theory.[16]

The most interesting feature of the results collected in Scheme 3 is the relative stability of the conjugated acids of the species $[OV(OH)_2(OBr)]$. Such a derivative presents three distinct protonation sites: a) the oxygen atom of the V=O group, b) the -OH oxygen atom, and c) the oxygen atom of the -OBr group. The corresponding protonated species are indicated in Scheme 3. Indeed, the structure with the proton located at the -OBr residue is the one located energetically uphill with respect to the other possible species protonated at the oxygen atom of the hydroxy moiety (ca. 47 kJ mol^{-1}), at the oxo moiety (ca. 24 kJ mol^{-1}) or at both hydroxy and oxo moieties (ca. 77 kJ mol^{-1}). This intermediate, $[OV(OH)_2(OHBr)]^+$, would be the species that releases HOBr — one of the postulated brominating species — in solution. Interestingly, the most stable protonated isomer corresponds to the $[OV(OH_2)(OH)(OBr)]^+$ structure. Following this result this species may be directly involved in the Br^+ transfer process. Furthermore, it should be noted that the thermodynamically feasible coordination of bromide ion to the cationic naked monoperoxo species, a process which does not involve oxidation of the halide, if it occurs in solution during the catalytic process, is probably not located along the reaction coordinate. According to this assumption, we decided to omit from our theoretical study all the possible species with the bromine moiety directly coordinated to the vanadium atom, such as $[OVBr(O_2)(OH_2)]$ and the related protonated derivatives. All these species can



Scheme 3. Ab initio calculations on the formation of the V-OBr intermediates; energy values are reported in kJ mol^{-1}; PA = proton affinity

be considered as real ionic couples, especially in the gas phase, where the electrostatic compensation between the negatively charged bromine ion and the positively charged peroxo-vanadium complexes might be the chemical explanation for their relatively high thermodynamic stabilities.

In conclusion we have reported a direct observation of the intermediate $[OV(OH_2)(OH)(OBr)]^+$ by ESI-MS spectrometry. Ab initio calculations also support the stability of such a species confirming that the choice of an appropriate model and its analysis with suitable techniques allows the collection of significant data for a better understanding of the mechanism of action of the V-HalPO enzymes.

Experimental Section

The ESI-MS measurements (positive-ion mode) were obtained using an LCQ instrument (Thermoquest, San Jose, CA). The peroxovanadium solutions were prepared by dissolving $n Bu_4NVO_3$ (5×10^{-4} mol·L^{-1}) in MeOH/H_2O (or EtOH for the experiments conducted in this solvent) pH 1 $HClO_4$, in the presence of an equimolar amount of H_2O_2. In the experiments conducted in the presence of Br^-, a fivefold excess of KBr was used. Solution flow rate 8 μL·min^{-1}, capillary temperature 180 °C, spray voltage 2.5 kV, capillary voltage 5 V, tube lenses offset 15 V, nebulizing gas N_2 (40 units flow rate). The parameters related to octapoles and detector were achieved by the automatic set-up procedure. Collision-induced decompositions of selected ions were obtained by applying a supplementary r.f. voltage (tickle voltage) to the end-cap electrodes of the ion trap (resonance activation). For experimental details on the two-phase reactions reported in Table 1 see refs.[5,6]

Unprecedented Change of the Jahn−Teller Axis in a Centrosymmetric Cu^{II} Complex Induced by Lattice Water Molecules − Crystal and Molecular Structures of Bis[bis(3,5-dimethylpyrazol-1-yl)acetato]copper(II) and Its Dihydrate

Bojan Kozlevčar,[a] Patrick Gamez,[a] René de Gelder,[b] Willem L. Driessen,*[a] and Jan Reedijk[a]

Keywords: Copper / N ligands / Jahn−Teller distortion / EPR spectroscopy

Two copper coordination compounds with the tridentate (NON) ligand bis(3,5-dimethylpyrazol-1-yl)acetic acid (Hbdmpza) are reported. The central coordination sphere in both compounds is fulfilled by two ligands in $[CuL_2]$. The ligands are centrosymmetrically oriented around the copper ion, thus forming a *trans*-CuN_4O_2 elongated octahedral chromophore. The atoms in both compounds are not positioned at the same places in the Jahn–Teller-distorted octahedral environment. For compound $[CuL_2]$ (**1**) two nitrogen atoms are located on the longer axis [Cu–N: 2.438(2) Å], while the other two nitrogen atoms [Cu–N: 2.006(2) Å] and the two oxygen atoms [Cu–O: 1.983(2) Å] form the basal plane of the octahedron. The coordination sphere for $[CuL_2]\cdot 2H_2O$ (**2**) is composed of four nitrogen atoms [Cu–N: 2.013(3), 2.038(2) Å] that form the basal plane, while the two oxygen atoms are at a longer distance [Cu–O: 2.293(2) Å]. The water molecules in **2** are hydrogen bonded to the non-coordinated carboxylate oxygen atoms, forming bridges between two neighbouring monomeric units and leading to an infinite chain. Significant differences are observed for both compounds by spectroscopic investigations (EPR, IR, ligand field).

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2003)

Introduction

Many *trans*-CuN_4O_2 chromophores are reported in the literature with strong nitrogen donor ligands and weaker oxygen donor ligands. For most of them, the Jahn−Teller axis, i.e. the axis with the longest Cu−L bonds, coincides with the O−Cu−O bond in the elongated distorted octahedron.[1,2] A search of the Cambridge Structural Database revealed that in only 9 of the 277 CuN_4O_2 chromophores does the Jahn−Teller axis coincide with one of the N−Cu−N bonds, and there is only one example of a compressed octahedron (four longer and two shorter bonds).[3] No pair of compounds with the same coordinated ligands — one with the O−Cu−O unit as the Jahn−Teller axis and the other with the N−Cu−N as the Jahn−Teller axis — have been reported.[1,2] The absence of isomers is probably due to steric effects of the ligands, which favour only one of the arrangement types in the coordination sphere. With a special ligand shape, different configurations around the central copper ion may be expected. Bearing this in mind, a vicinal tridentate ligand that produces a nitrogen-oxygen-nitrogen (NON) donor set may be of special interest. In this paper, the comparison of two structures of the ligand bis(3,5-dimethylpyrazol-1-yl)acetic acid with copper(II) is presented.

Results and Discussion

Two copper(II) compounds were synthesised with the deprotonated tridentate ligand bis(3,5-dimethylpyrazol-1-yl)-acetic acid (Hbdmpza) in the $[CuL_2]$ coordination sphere. In both cases bdmpza coordinates through two pyrazole nitrogen atoms and one deprotonated carboxylate oxygen atom (NON donor set). Similar coordination complexes are known for other *d*-block metals and bdmpza.[4−7] The ligands are centrosymmetrically arranged around the copper ion, thus forming *trans*-CuN_4O_2 chromophores. Both new copper compounds show an elongated distorted octahedral geometry, however the coordinated atoms do not play the same role. The coordination environment of **1** (Figure 1) is particularly interesting, with the basal plane composed of two nitrogen atoms [Cu−N: 2.006(2) Å] and two oxygen atoms [Cu−O: 1.983(2) Å], and the remaining two coordinated nitrogen atoms forming the Jahn−Teller axis [Cu−N: 2.438(2) Å].

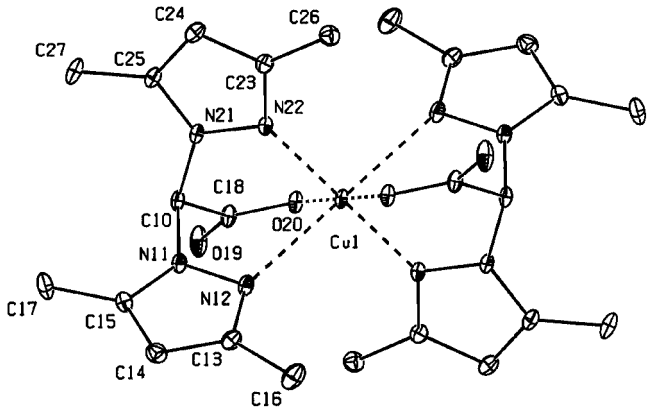

Figure 1. The centrosymmetric structure of **1** with two tridentate scorpionate ligands around the central copper; thermal ellipsoids are drawn at the 10% probability level; all hydrogen atoms have been omitted for clarity.

The more common isomer with the Jahn−Teller axis along the O−Cu−O bonds has also been obtained, but from aqueous solution. In this compound $[CuL_2]\cdot 2H_2O$ (**2**; Figure 2, the basal octahedron plane is composed of four nitrogen atoms [Cu−N: 2.013(3), 2.038(2) Å], while the oxygen atoms are located at a longer distance [Cu−O: 2.293(2) Å]. Such a conformation has also been found in Fe^{II} and Zn^{II} $[ML_2]$ analogues.[5] Each water molecule in **2** forms two hydrogen bonds to the noncoordinated carboxylate oxygen atoms [O···H−O:; 2.813(4), 2.868(4) Å], thereby connecting two neighbouring monomeric units and leading to linear chains of octahedra as shown in Figure 2.

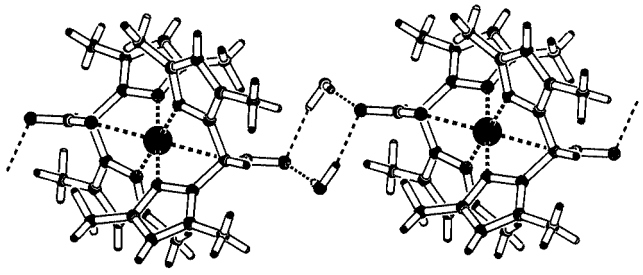

Figure 2. The intermolecular hydrogen-bonding contacts between the coordination octahedra in the structure of the hydrated compound **2**

In the anhydrous compound **1**, a significantly longer C−O distance [1.262(3) Å] is observed for the coordinated carboxylate oxygen atom than for the non-coordinated one [1.214(3) Å]. For the hydrated compound **2**, almost the same C−O distances are observed [1.245(4) and 1.241(4) Å]. These similar C−O bonds for the carboxylate group of **2** are probably due to the binding of both oxygen atoms to a Lewis acid, i.e. to the copper and to a water molecule, while only one carboxylate oxygen is coordinated in **1**.

The solid-state EPR spectrum of compound **1** measured at room temperature shows an isotropic copper(II) signal

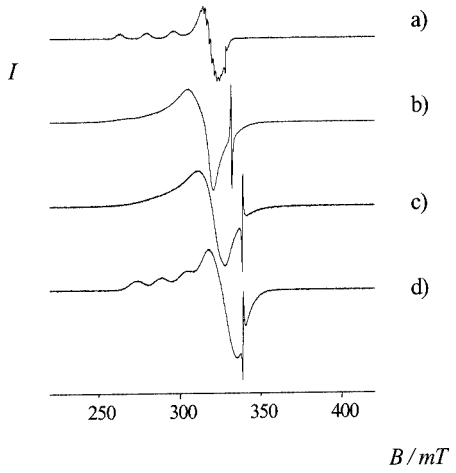

Figure 3. EPR spectra of compounds **1** and **2**, measured under different conditions: a) **1** as a frozen methanol solution at 77 K; b) **1** as a solid at 77 K; c) **1** as a solid at room temp.; d) **2** as a solid at room temp.; the sharp signal closest to 350 mT in all spectra is due to the reference

(Figure 3c). No resolution of $g_{\|}$, $g_{\perp}$ or $A_{\|}$ is observed, which is indicative of exchange narrowing due to the close distance and dipolar coupling between the Cu ions in the lattice. At 77 K, the spectrum reveals an additional low-intensity $g_{\|}$ signal at 260 mT and a small change in the shape of the $g_{\perp}$ signal (Figure 3b). A significantly different feature is observed for the room-temperature solid-state EPR spectrum of **2**. Beside the $g_{\perp}$ signal, a $g_{\|}$ signal with three distinctive $A_{\|}$ signals is present at lower field (Figure 3d). The value of $A_{\|}$ amounts to 15.0 mT, which is typical for a tetragonal Cu centre. The coupling of the *d* electron spin and the nuclear spin results in a hyperfine splitting, and agrees with the anisotropic nature of the coordination sphere that is characteristic of an elongated octahedral geometry. The EPR spectra of frozen methanolic solutions of **1** and **2** are identical (Figure 3a). This is as expected as the water molecules dissociate upon dissolution of **2** in methanol. Solvation of the monomeric complex disrupts the hydrogen-bond network of **2** as the water molecules are probably replaced by methanol molecules. Additional superhyperfine splitting was observed in the frozen solution due to interaction with ^{14}N nuclei from the ligand. Relevant parameters for the solution spectra, which were satisfactorily simulated,[8] are $g_{\|} = 2.289$, $g_{\perp} = 2.061$, $A_{Cu} = 160$ Gs, and $A_N = 15.5$ Gs.

In the region above 3000 cm^{-1} in the vibrational spectra, characteristic bands for H-bonded water O−H stretching vibrations are present only for the hydrated compound **2** (See Figure 4).

The rest of the IR spectra is almost identical for both compounds due to the presence of the same constituents. Exceptions may be found in the regions where the carboxylate group stretching vibrations are expected. Differences are observed at 1650 cm^{-1} for the asymmetric vibration ν_{as}(OOC) and at 1350 cm^{-1} for the symmetric vibration ν_s(OOC): the spectrum of the anhydrous compound **1** shows only one band in both areas, while two bands are observed in the spectrum of the solvated compound **2**. In-

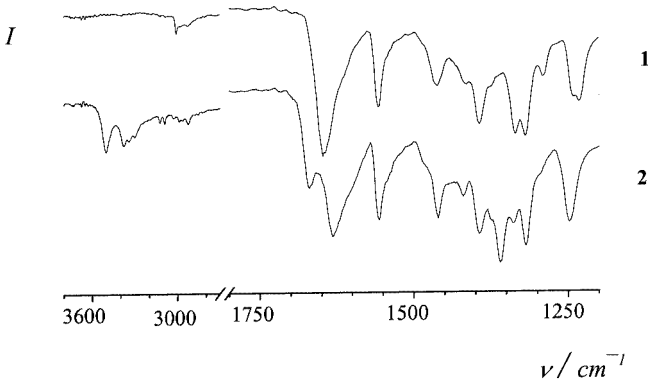

Figure 4. Comparison of two regions in the vibrational spectra of the investigated compounds

terestingly, the stronger ν_{as}(OOC) band of **2** is shifted towards lower energy and the stronger ν_s(OOC) band to higher energy relative to the corresponding bands in the spectrum of **1**. Therefore Δ [= ν_{as}(OOC) − ν_s(OOC)] [9] for **2** is smaller than for **1**. This is related to the typically monodentate carboxylate group in **1** and the pseudo-didentate group in **2**. In the carboxylate group of **1**, more single bond character for the coordinated oxygen atom is present, and more double bond character with the non-coordinated oxygen atom (O=C−O−Cu). The hydrogen bond in **2** attracts the non-coordinated oxygen atom, weakening the double bond (H−O−H···O=C−O−Cu). This is in agreement with the bigger Δ values for monodentate than for didentate carboxylate groups.[9] The IR spectrum of dry **2** is identical to the spectrum of **1**, which is stable under reduced pressure or in diethyl ether.

In the visible part of the electronic spectra, a broad d−d band is observed for compounds **1** and **2**. The peak in the spectrum of **1** is found at 13900 cm^{-1}, while in the spectrum of **2** it appears at 15300 cm^{-1}. The difference is in agreement with a weaker tetragonal chromophore CuN_2O_2 in **1** compared to CuN_4 in **2**.

The pair of compounds **1** and **2** clearly represent an unprecedented change of the Jahn−Teller axis induced by water molecules. The two copper complexes prepared show significantly different results in the vibrational, EPR and electronic spectra. The stabilization of **2** by a hydrogen-bonding network modifies the coordination of the ligand around the copper, although steric hindrance would favour the other alternative (complex **1**). The water molecules apparently direct the Cu−O bonds to be in the Jahn−Teller axis of the copper-centred octahedron.

Experimental Section

General Remarks: All reagents and solvents were purchased from commercial sources and used as received. The ligand bis(3,5-dimethylpyrazol-1-yl)acetic acid was prepared from dibromoacetic acid and 3,5-dimethylpyrazole in a basic solution as described in the literature.[5] C,H,N analyses were carried out by the Microanalysis Department of Leiden University. Infrared spectra were recorded on a Perkin−Elmer Paragon 1000 spectrophotometer, equipped with a Golden Gate Diamond ATR as a sample support. X-band EPR spectra were recorded on a JEOL ESR spectrometer, equipped with an Esprit 330 data system, at room temperature and at 77 K, with dpph as an internal reference (g = 2.0036). The ligand field spectra of the solid compounds were recorded in the 300−2000 nm range on a Perkin−Elmer Lambda 900 UV/Vis/NIR spectrometer in the diffuse reflectance mode with MgO as reference.

[CuL_2] (1): A solution of the ligand (25 mg, 0.10 mmol) in acetonitrile (10 mL) was added to copper(II) acetate hydrate (10 mg, 0.025 mmol). Pale-blue crystals started to precipitate from the transparent solution at room temperature in a few hours. They were filtered off the next day and washed with diethyl ether. $C_{24}H_{30}CuN_8O_4$ (558.1): calcd. C 51.7, H 5.42, N 20.1; found C 51.3, H 5.22, N 20.0. IR (solid): $\tilde{\nu}$ = 1645 cm^{-1} (C−O), 1558 (C−N). UV/Vis-NIR (solid): λ_{max} = 13900 cm^{-1}. EPR (solid, room temp.): g = 2.118.

[CuL_2]·$2H_2O$ (2): The ligand (50 mg, 0.20 mmol), dissolved in acidified water (10 mL), was added to copper(II) acetate hydrate (40 mg, 0.10 mmol). Blue crystals started to precipitate from the transparent solution at room temperature after a few hours. They were filtered off next day and dried for 5 minutes on a filter paper. $C_{24}H_{34}CuN_8O_6$ (594.1): calcd. C 48.5, H 5.77, N 18.9; found C 48.5, H 5.46, N 18.9. IR (solid): $\tilde{\nu}$ = 3504 cm^{-1} (O−H), 3381 (O−H), 1669 (C−O), 1634 (C−O), 1558 (C−N). UV/Vis-NIR (solid): λ_{max} = 15300 cm^{-1}. EPR (solid, room temp.): $g_{\|}$ = 2.288, $g_{\perp}$ = 2.077, $A_{\|}$ = 0.129.

X-ray Crystallography: X-ray data were collected on an Enraf−Nonius CAD4 diffractometer equipped with graphite-monochromated Mo-K_α radiation (0.71073 Å). Crystal data are collected in Table 1. The structure was solved with automated Patterson techniques using DIRDIF/PATTY [10] and refined on F us-

Syntheses and Molecular Structures of Metallasiloxanes Containing Zn_3O_4 and $Zn_6Si_6O_{10}$ Cores

Klaus Merz,[a] Huai-Ming Hu,[a] Stefan Rell,[a] and Matthias Driess*[a]

Keywords: Clusters / Oxides / Siloxides / Zinc

The trinuclear zinc siloxane $[(MeZn)_2Zn(OSiPh_3)_4]$ (**1**) and the first novel siloxane-bridged hexanuclear dimer $[\{Me(THF)Zn\}_2OZn(OSiR_2)(R^1)]_2$ (R = Ph, $R^1 = OSiR_2OSiR_2O$) (**2**) are accessible by Brønsted acid/base reaction of triorganosilanols with the zinc base $ZnMe_2$. Both compounds were characterised by NMR spectroscopy and a single-crystal X-ray structure analysis. The X-ray structures of the reported complexes are discussed.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2003)

Introduction

In recent years, a large variety of molecular metallasiloxanes (M-O-Si) have been synthesised through metallation of organosilanols.[1] These compounds have received considerable attention as versatile precursors for metal silicates[2] and doped metal oxides[3] or as molecular models for heterogeneous silica- and zeolite-supported catalytic systems.[4,5] We discovered recently that the thermolysis of molecular M-O-Si compounds with almost identical M−O and Si−O binding energies facilitates ambident decomposition pathways, affording elemental metal and/or metal oxide particles. The composition of the products can also be easily influenced by the nature of the substituents at the M and Si atoms and the reaction conditions. Thus, solid-to-solid and solid-to-vapour decomposition (CVD) of the tetranuclear zinc siloxane $[XZnOSiR_3]_4$ (X = Me, Et, I) or its polymeric analogue $[(Me_3SiO)_2Zn]_n$ affords nanocrystalline ZnO and/or Zn particles.[6]

Results and Discussion

In order to learn more about the influence of the degree of aggregation of the zinc siloxane precursors and the nature of their organic shell on the size and morphology of the produced Zn and/or ZnO particles, we have been interested in the synthesis of differently preorganised zinc siloxane aggregates. In this contribution, we describe the synthesis and characterisation of the sterically congested trinuclear zinc siloxane $[(MeZn)_2Zn(OSiR_3)_4]$ (**1**) which can be easily expanded to its hexanuclear dimer $[\{Me(THF)Zn\}_2OZn(OSiR_2)(OSiR_2OSiR_2O)]$ (**2**). The latter represents a novel type of metallasiloxane and is the first zinc polysiloxane. In accordance with recent studies, different zinc siloxane aggregates are accessible by Brønsted acid/base reaction of triorganosilanols R_3SiOH (R = Me, Et, *i*Pr) with the zinc bases ZnR_2 (R = Me, Et). Depending on the steric demand of the substituents this reaction furnishes dimeric, trimeric and tetrameric ZnO aggregates.[7,8]

Thus, the reaction of the sterically congested triphenylsilanol Ph_3SiOH with $ZnMe_2$ leads to the Zn_3O_4 aggregate **1** in 75% yield (Scheme 1). The crystal structure of **1** (Figure 1) consists of asymmetric units with a nonlinear array of three zinc atoms [Zn···Zn···Zn = 159.27(3)°] that are bridged by four triphenylsiloxy groups The spirocyclic zinc atom Zn(2) has a distorted tetrahedral geometry, whereas the two terminal zinc atoms (Zn1 and Zn3) are only trigonal-planar coordinated. The observed Zn_3O_4 core of the aggregate is in good agreement with that of the previously reported derivatives $[(MeZn)_2Zn(OSi{\it i}Pr_3)_4]$[7] and $[Me_3SiCH_2ZnOR]_2Zn]$ [R = (2,6-iPr$_2$-C$_6$H$_4$)].[9] Remarkably, the Zn−O distances for the four-coordinate Zn(2) atom [average 1.949(3) Å] are shorter than those for the three-coordinate ones [average 1.981(3) Å] due to the greater partial positive charge at Zn(2). The inconspicuous Zn−C distances average 1.919(6) Å. While the dihedral angle between the two Zn_2O_2 planes of 86.9(1)° is close to the expected value of 90°, the endocyclic O(1)−Zn(2)−O(2) and O(3)−Zn(2)−O(4) angles are, at 84.1(1) and 86.0(1)° respectively, considerably distorted from the ideal tetrahedral value (109.5°). This large distortion is due to the strained four-membered Zn_2O_2 rings which, in turn, result in a corresponding expansion of the exocyclic O−Zn(2)−O angles [average 121.1(1)°]. To our surprise, the preference for the trinuclear structural motif of the Zn atoms in **1** is still preserved if the sterically congested Ph_3SiO groups are fully replaced by the less demanding Ph_2SiO_2 moieties.

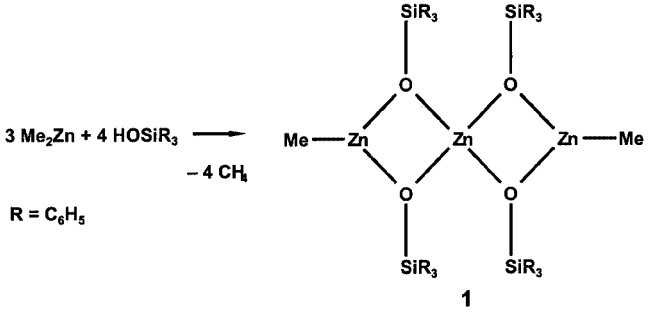

Scheme 1

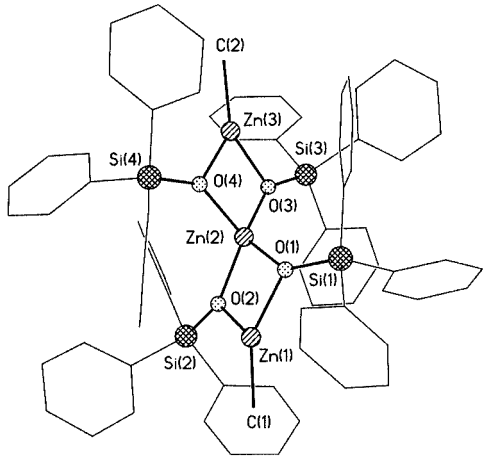

Figure 1. Molecular structure of **1**; hydrogen atoms omitted for clarity; selected distances (Å) and angles (°): Zn(2)−O(2) 1.940(3), Zn(2)−O(4) 1.949(3), Zn(2)−O(1) 1.952(3), Zn(2)−O(3) 1.957(3), Zn(1)−C(1) 1.918(5), Zn(1)−O(1) 1.954(3), Zn(1)−O(2) 2.000(3), Zn(3)−C(2) 1.919(6), Zn(3)−O(4) 1.962(3), Zn(3)−O(3) 2.011(3); O(2)−Zn(2)−O(1) 84.1(1), O(4)−Zn(2)−O(3) 86.1(1), Zn(3)−Zn(2)−Zn(1) 159.27(3), Zn(2)−O(1)−Zn(1) 96.6(1), O(4)−Zn(3)−O(3) 84.2(1), O(3)−Zn(2)−O(1) 124.4 (1), O(4)−Zn(2)−O(2) 119.6 (1), Zn(2)−O(2)−Zn(1) 95.5(1), Zn(2)−O(4)−Zn(3) 95.3(1), Zn(2)−O(3)−Zn(3) 93.5(1)

Thus, the reaction of $Ph_2Si(OH)_2$ with $ZnMe_2$ in THF leads to the hexanuclear $Zn_6Si_6O_{10}$ aggregate **2** in 52% yield (Scheme 2). Although the mechanism is still unknown, it seems likely that the initial steps involve the formation of a Zn_3O_4 core with terminal $OSi(Ph_2)OH$ functions.

Compound **2** crystallises in the monoclinic space group $P2_1/n$ with one half of the molecule in the asymmetric unit. The crystal structure of **2** (Figure 2) reveals a novel type of zinc siloxane in which two spirobicyclic Zn_3O_4 cores are linked together by two R_2Si-fragments.

Additionally, one periphery of each Zn_3O_4 core is bridged by an $Ph_2SiOSiPh_2$ moiety. The Zn atoms are tetrahedral and each of the Zn(2) and Zn(3) atoms bears one

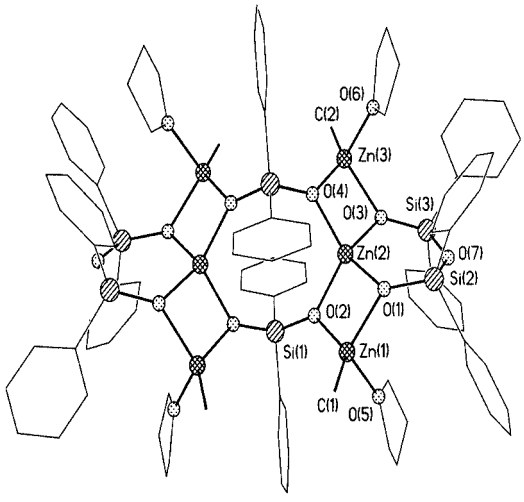

Figure 2. Molecular structure of **2**; hydrogen atoms omitted for clarity; selected distances (Å) and angles (°): Zn(2)−O(2) 1.943(2), Zn(2)−O(4) 1.947(2), Zn(2)−O(1) 1.973(2), Zn(2)−O(3) 1.983(2), Zn(1)−O(2) 2.022(2), Zn(1)−O(1) 2.026(2), Zn(3)−C(2) 1.962(3), Zn(3)−O(4) 2.003(2), Zn(3)−O(3) 2.046(2); O(2)−Zn(2)−O(1) 87.49(6), O(4)−Zn(2)−O(3) 88.08(6), Zn(3)−Zn(2)−Zn(1) 175.94(1), O(2)−Zn(1)−O(1) 83.99(6)

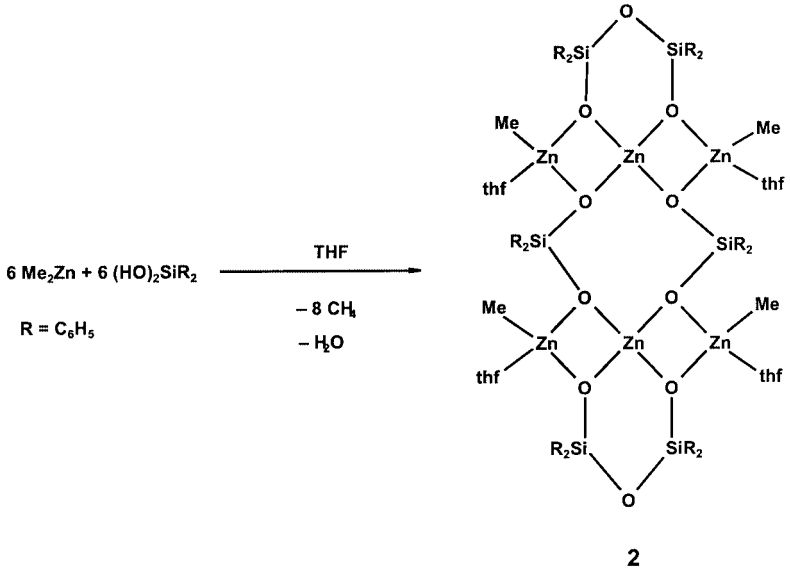

Scheme 2

methyl and one THF ligand. The observed Zn_3O_4 core is practically identical to that in **1**. However, the three Zn atoms of the cores now adopt an almost linear arrangement [Zn···Zn···Zn = 175.94 (1)°]. The Zn−C distances [average 1.954 (5) Å] are longer than those in **1** due to the higher coordination number at the Zn atoms. Another striking structural feature of **2** is that the dihedral angle between the $Zn(2)O_2Zn(3)$ and $Zn(2)O_2(Zn1)$ planes is about 20° smaller than that in **1** [86.9(1)°]. However, the O−Zn−O and Zn−O−Zn angles are almost identical with these values in **1**. Similar to the situation in **1**, the Zn−O distances for the spiro-Zn(2) atom [average 1.962(2) Å] are conspicuously smaller than the corresponding values for Zn(1)−O and Zn(3)−O [average 2.069(2) Å].

Experimental Section

General Remarks: All manipulations were carried out under anaerobic conditions under dry argon using standard Schlenk techniques. Solvents were refluxed over an appropriate drying agent, and distilled and degassed prior to use. NMR spectra were recorded on a Bruker Avance250 spectrometer at ambient temperature operating at 250.1 MHz (^{1}H) or 63 MHz (^{13}C). Chemical shifts are reported relative to TMS at δ = 0.00 ppm (^{1}H).

Preparation of $[(MeZn)_2Zn(OSiPh_3)_4]$ (1): At −78 °C, a solution of $ZnMe_2$ (1.91 g, 20 mmol, 2 M solution in toluene) in toluene (ca. 50 mL) was slowly added to a solution of Ph_3SiOH (7.37 g, 26.7 mmol) in toluene (10 mL), resulting in the immediate evolution of methane. The solution was then allowed to warm to room temperature and all volatiles were removed in vacuo (10^{-3} Torr). Recrystallisation from toluene/hexane gave pure **1** as colourless crystals. Yield: 7.17 g (5.40 mmol, 81%); m.p. 221−223 °C (decomp.). ^{1}H NMR (C_6D_6): δ = − 0.61 (s, 6 H, ZnMe), 7.12−7.83 [m, 60 H, $(C_6H_5)_3Si$] ppm. ^{13}C NMR (C_6D_6): δ = −14.9 (s, 2 C, ZnMe), 137.3−123.6 [m, 64 C, $(C_6H_5)_3Si$] ppm. $C_{74}H_{66}O_4Si_4Zn_3{\cdot}C_7H_8$ (1419.9): calcd. C 65.50, H 5.02; found C 65.30, H 5.00.

Preparation of $[\{Me(THF)Zn\}_2OZn(OSiR_2)(OSiR_2OSiR_2O)]$ (2; R = Ph): Compound **2** was prepared in a similar manner as **1**, starting from $ZnMe_2$ (1.91 g, 20 mmol, 2 M solution in toluene) in toluene (ca. 50 mL) and a solution of $Ph_2Si(OH)_2$ (4.32 g, 20 mmol) in tetrahydrofuran (10 mL). Recrystallisation of the residue from tetrahydrofuran (10 mL) afforded colourless plates. Yield: 3.45 g (1.73 mmol, 52%) of a mixture of stereoisomers. ^{1}H NMR (C_6D_6): δ = −0.53 to −1.11 (12 H, ZnMe), 7.02−8.08 [60 H, $(C_6H_5)_2Si$] ppm. ^{13}C NMR (C_6D_6): δ = −13.7 to −15.3 (m, 4 C, ZnMe), 138.1−124.2 [m, 64 C, $(C_6H_5)_3Si$] ppm. $C_{92}H_{104}O_{14}Si_6Zn_6$ (1994.51): calcd. C 55.40, H 26.00; found C 55.2, H 25.95.

X-ray Crystallographic Study

1: $C_{74}H_{66}O_4Si_4Zn_3{\cdot}C_7H_8$, M = 1419.9, triclinic, space group $P\bar{1}$, a = 13.202(7), b = 13.402(8), c = 21.69(1) Å, α = 97.175(12)°, β = 93.142(11)°, γ = 99.876(12)°, V = 3741(4) Å^3, Z = 2, $2\theta_{max}$ = 59.1°, 24158 measured reflections, 829 parameters, μ = 1.065 mm^{-1}, $R1$ = 0.0685 for 6268 observed reflections [$I > 2\sigma(I)$], $wR2$ = 0.1134 for all reflections.

2: $C_{92}H_{104}O_{14}Si_6Zn_6$, M = 1994.51, monoclinic, space group $P2_1/n$, a = 18.561(4), b = 13.162(3), c = 20.993(4) Å, V = 4690(1) Å^3, Z = 2, $2\theta_{max}$ = 50.28°, 23990 measured reflections, 532 parameters, μ = 1.646 mm^{-1}, $R1$ = 0.0305 for 6728 observed reflections [$I > 2\sigma(I)$], $wR2$ = 0.0770 for all reflections.

The intensity data were collected on a Bruker-axs-SMART 1000 diffractometer (Mo-K_α radiation, λ = 0.71707 Å, T = 203 K). Both structures were solved by direct methods and refined by full-matrix least-squares using SHELXTL-97.[10] The contribution of the disordered solvent in **1** to the structure factors was taken into account by back-Fourier transformation using PLATON/SQUEEZE.[11] All non-hydrogen atoms were refined using anisotropic thermal parameters; hydrogen atoms were included by use of a riding model and fixed isotropic thermal parameters.

CCDC-186433 (**1**) and -186434 (**2**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; fax: (internat.) +44−1223/336−033; E-mail: deposit@ccdc.cam.ac.uk].

The Unexpected Formation of a Novel Fluorinated Triene

Igor Shevchenko,*[a] Vasyl Andrushko,[a] Enno Lork,[b] and Gerd-Volker Röschenthaler*[b]

Keywords: Phosphanes / Bis(trifluoromethyl)acrylonitrile / Alkenes / Ylides / Carbenes

Bis[bis(dialkylamino)phosphanyl]methane (**1**) and 4,4,4-trifluoro-3-(trifluoromethyl)-2-butenenitrile (**2**) unexpectedly gave triene **3**. According to the X-ray structure analysis compound **3** exists in the solid state exclusively as one isomer.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2003)

Among known compounds containing three conjugated C=C double bonds, there are only two fluorine substituted examples: perfluoro-1,3,5-hexatriene[1–5] and 1,6-dichlorohexafluoro-1,3,5-hexatriene.[6] Here we wish to report on an unusual reaction of bis[bis(dimethylamino)phosphanyl]-methane (**1**) with 4,4,4-trifluoro-3-(trifluoromethyl)-2-butenenitrile (**2**) which, unexpectedly, gave the triene **3**. The second product of this reaction was identified as the fluorine-substituted ylide **4** (Scheme 1).

It is interesting to note that one of the trifluoromethyl groups of the starting acrylonitrile **2** loses two fluorine atoms and adds one of the diethylamino groups which was initially connected to a trivalent phosphorus atom of **1**. The mechanism of this reaction includes the intermediate formation of the ylide **5**, which was detected in the ^{31}P NMR spectrum of the reaction mixture as two characteristic doublets at δ = 73.78 and 67.18 ppm ($^2J_{P,P}$ = 102.4 Hz). These signals decrease slowly in intensity during the course of the reaction and the two doublets of the final product **4** appear. Intermediate **5** can react further with **2** to give the unstable betaine **6**, which decomposes into compound **7** and HF. The hydrogen fluoride thus formed cleaves the P–N bond of the trivalent phosphorus atom of **5** immediately to give **4** and diethylamine. This amine then adds across the C=C double bond of **7**, yielding the intermediate compound **8**, which splits off hydrogen fluoride and gives the unsymmetrical double ylide **9**. These considerations are supported by the fact that the reaction mixture contains a certain amount of diethylammonium fluoride.

The most probable route of formation of the symmetric molecule **3** is the dimerization of carbene **10**. This carbene can be formed during the disintegration of **9** into **5**; the cleavage of the ylidic bond in compound **9** is probably reversible. Of course, some aspects of the detailed mechanism shown in Scheme 1 may differ slightly; for example, some of the proposed steps may be concerted. However, the general concept of an exchange between a fluorine atom and a diethylamino group probably does not differ considerably from the proposed scheme, as a similar process has been observed recently.[7]

The triene **3** was isolated as a slightly yellow crystalline product. The structure of a single crystal was determined by X-ray analysis (Figure 1).

The three double bonds are not conjugated as they are not coplanar. The diethylamino and trifluoromethyl groups at the terminal double bonds, and the central double bond, have a *trans*-configuration. It is interesting to note that no

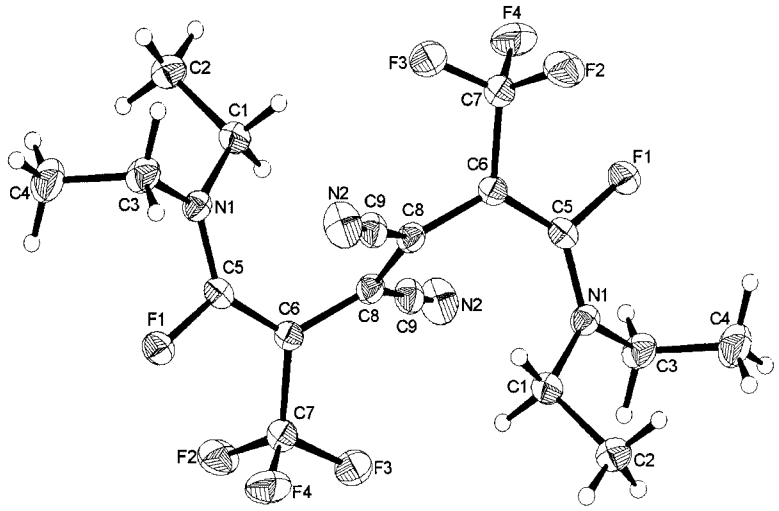

Figure 1. Selected bond lengths [Å] and angles [°]: N(1)−C(5) 1.3296(19), C(5)−F(1) 1.3523(17), C(5)−C(6) 1.361(2), C(6)−C(7) 1.496(2), C(6)−C(8) 1.470(2), C(8)−C(8) 1.365(3); N(1)−C(5)−F(1) 111.85(12), N(1)−C(5)−C(6) 132.27(14), F(1)−C(5)−C(6) 115.88(12), C(8)−C(6)−C(7) 119.23(13), C(9)−C(8)−C(6) 117.98(12), C(8)−C(8)−C(9) 117.35(17)

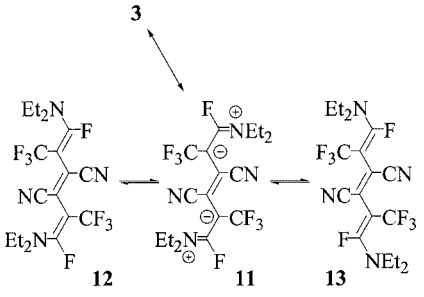
other possible steric isomers have been found in the crystalline form. An explanation for this phenomenon can be found in the NMR spectra, where a fast interconversion between the isomers in solution at room temperature can be seen. The ^{19}F NMR spectrum displays a doublet for the CF_3 groups ($\delta = -56.6$ ppm, $^4J_{F,F} = 18$ Hz) and a broad unresolved signal for the CF fluorine atoms ($\delta = -66.2$ ppm). At +60 °C the rate of interconversion substantially exceeds the NMR detection limit and the broad signal transforms into a quadruplet with the same coupling constant. An analysis of the low temperature spectra leads to several conclusions. Interconversion between the isomers proceeds rather easily as the other isomers begin to appear at −25 °C. At −60 °C the spectrum shows three isomers in the proportion 1:1:3 indicating that one of the isomers is more stable than the other two. The appearance of only three isomers indicates that the rotation occurs only at terminal double bonds, whereas the central C=C bond retains its *trans*-configuration (otherwise the number of isomers would be larger[4]). The relatively easy rotation around the terminal double bonds is probably accounted for by the π-electron donating ability of the diethylamino groups and the electron-accepting ability of the trifluoromethyl groups, leading to the conjugation of the free electron-pairs of the nitrogen atoms with the adjacent double bonds and formation of the betainic structure **11** (Scheme 2).

Although the lengths of all the C=C double bonds are equal, the influence of **11** should be rather large. The C(5)−N(1) bond is substantially shorter than the other two bonds to nitrogen (132.96 vs. 148.56 pm) and the diethylamino groups have an almost ideal flat conformation. Thus, rotation can occur via the resonance structure **11** to give the two other possible isomers **12** and **13**.



Scheme 2

Experimental Section

General Remarks: All operations were performed under nitrogen in a dry box. The solvents were dried by the usual procedures. NMR: Spectrometer Bruker AC-200 (^1H at 200.1 MHz, ^{13}C at 50.3 MHz, ^{31}P at 81.3 MHz); reference substances were $SiMe_4$ (TMS) ext. (^1H, ^{13}C), and 85% H_3PO_4 ext. (^{31}P). MS: Spectrometer Finnigan MAT 8430; E.I. at 70 eV. Materials: Compound **1** was obtained from methylenebis(dichlorophosphane) and diethyl(trimethylsilyl)amine in petroleum ether at 0 °C (yield 70%; b.p. 108−110 °C, 0.07 Torr). Compound **2** was obtained by adding gaseous hexafluoroacetone to (triphenylphosphoranylidene)acetonitrile without solvent at 20 °C (yield 90%; b.p. 88−90 °C) .

Compound 3: Compound **2** (140 mg, 0.74 mmol) was added to **1** (120 mg, 0.33 mmol) without solvent at 20 °C. After completion of the slightly exothermic reaction the mixture was heated to 50 °C for 15 min. Dichloromethane (2 mL) was then added followed by addition of diethyl ether (0.5 mL) and the mixture left at −15 °C for 2−3 days. The crystals of **3** that formed were isolated, washed

with diethyl ether (2 × 2 mL) and dried in vacuo (0.05 mm). Yield 36 mg (49%), m.p. 78−80 °C. ^{1}H NMR ($CDCl_3$): δ = 1.26 (t, $^3J_{H,H}$ = 7.0 Hz, 12 H, CH_2CH_3), 3.32 (dq, $^3J_{H,H}$ = 7.0, $^3J_{F,H}$ = 3.2 Hz, 8 H, CH_2CH_3) ppm. ^{19}F NMR ($CDCl_3$): δ = −56.6 (d, $^4J_{F,F}$ = 18 Hz, 6 F), −66.2 (broad, 2 F) ppm. MS (EI): $M_{calcd.}$ = 444.37; $M_{exp.}$ = 444. $C_{18}H_{20}F_8N_4$ (444.4): calcd. C 48.65, H 4.54, N 12.61; found C 48.64, H 4.51, N 12.56.

Compound 4: The solvent was evaporated from the mother liquor remaining after crystallisation of **3** and the resulting oil was extracted with hexane (4 × 10 mL). The extracts were combined and concentrated to a volume of 5 mL. In order to dissolve the precipitated oil the mixture was heated to boiling point, cooled to room temperature and left to stand for 30 min and then cooled to −15 °C for 3−4 days. The crystals formed were separated from the mother liquor and dried in vacuo (0.05 mm). Yield 82 mg (49%). M.p. 90−91 °C. ^{1}H NMR ($CDCl_3$): δ = 1.14 (t, $^3J_{H,H}$ = 7.03 Hz, 6 H, NCH_2CH_3), 1.16 (t, $^3J_{H,H}$ = 7.03 Hz, 12 H, NCH_2CH_3), 2.3−2.7 (m, 2 H, P-CH_2-P), 2.9−3.4 [m, 12 H, NCH_2CH_3, 1 H, $CH(CF_3)_2$] ppm. ^{13}C NMR ($CDCl_3$): δ = 12.68 (dm, $J_{P,C}$ = 238.9 Hz, 1 C, P*C*CN), 13.48 (m, 4 C, NCH_2CH_3), 15.13 (m, 2 C, NCH_2CH_3), 34.26 (ddd, $^1J_{P,C}$ = 19.5, $^1J_{P,C}$ = 87.8, $^2J_{F,C}$ = 48.8 Hz, P*C*P), 39.36 (m, 4 C, NCH_2CH_3), 42.89 (d, $^3J_{F,C}$ = 18.5 Hz, 2 C, NCH_2CH_3), 47.44 [m, 1 C, $CH(CF_3)_2$], 124.16 [q, $^1J_{F,C}$ = 281.8 Hz, 2 (CF_3)], 124.90 (d, $^2J_{P,C}$ = 12.6 Hz, CN) ppm. ^{19}F NMR ($CDCl_3$): δ = −67.04 (dd, $^3J_{H,F}$ = 7.8, $^3J_{P,F}$ = 3.6 Hz, 6 F) ppm. ^{31}P NMR ($CDCl_3$): δ = 62.23 (dd, $^2J_{P,P}$ = 68.2, $^3J_{P,F}$ = 17.1 Hz,), 155.05 (dd, $^2J_{P,P}$ = 68.2, $^1J_{F,P}$ = 958.1 Hz) ppm. $C_{18}H_{33}F_7N_4P_2$ (500.42): calcd. C 43.20, H 6.64, N 11.20; found C 44.39, H 6.98, N 12.20.

X-ray Crystallographic Study: Empirical formula $C_{18}H_{20}F_8N_4$; formula weight 444.38; monoclinic; crystal dimensions 0.70 × 0.50 × 0.50 mm; space group $P2_1/n$; a = 1002.40(10), b = 897.50(10), c = 1165.1(2) nm, β = 108.620(10)°, V = 0.9933(2) nm^3, Z = 2; $D_{calcd.}$ = 1.486 mg/mm^3; F_{000} = 456; $2\theta_{max}$ = 27.50°; reflections collected 3031; independent reflections 2269 [R(int) = 0.0209]; completeness to theta (27.50°) = 99.2%; refinement method: full-matrix least-squares on F^2; data/restraints/parameters: 2269/0/141; goodness-of-fit on F^2 = 1.041; final R indices [$I > 2\sigma(I)$] $R1$ = 0.0385, $wR2$ = 0.0930; R indices (all data) $R1$ = 0.0576, $wR2$ = 0.1031; extinction coefficient 0.019(3). CCDC-174595 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Molecular Tectonics: Design of 1-D Coordination Networks Based on Pyrene-Bearing Pyrazolyl Units

Abdelaziz Jouaiti,[a] Mir Wais Hosseini,*[a] and Nathalie Kyritsakas[b]

Keywords: N ligands / Coordination networks / Silver / Palladium

The synthesis of a new ligand based on a pyrene backbone bearing four pyrazolyl units is reported. Whereas this compound forms a discrete exo-binuclear complex with palladium, in the presence of silver a 1-D coordination network is obtained and structurally characterised in the solid state by X-ray diffraction method.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2003)

Introduction

Coordination networks i.e. periodic molecular assemblies formed by the self-assembly of organic and metallic tectons (active molecular building blocks) has attracted increasing interest over the last decade.[1] The formation of coordination networks results from the interconnection of metallic centres by organic ligands through coordination bonds. Both the metal centre and the organic ligand must permit the iteration of the coordination process in order to behave as tectons.[2] In other words, the organic tecton must posses at least two coordination sites or poles[3] divergently oriented. The dimensionality of the network depends on the number of translations of the coordination pattern in different directions of space. Thus, a 1-D coordination network is generated by a single translation of the coordination pattern. For the design of coordination networks, one must take into account the interplay between the organic (number of coordination sites, topology) and metallic (number of coordination and geometry) tectons. For 1-D coordination networks, the majority of cases reported deal with bis-monodentate tectons.[4] However, a few examples of bis-bidentate[5,6] bis-tridentate[7−9] and a combination of mono- and tridentate[3] tectons have been also published.

Here we report the formation of the 1-D coordination network **7** formed between the pyrene-based tecton **4**, bearing four pyrazolyl units, and the silver cation, and the synthesis of two discrete binuclear palladium complexes **5** and **6**.

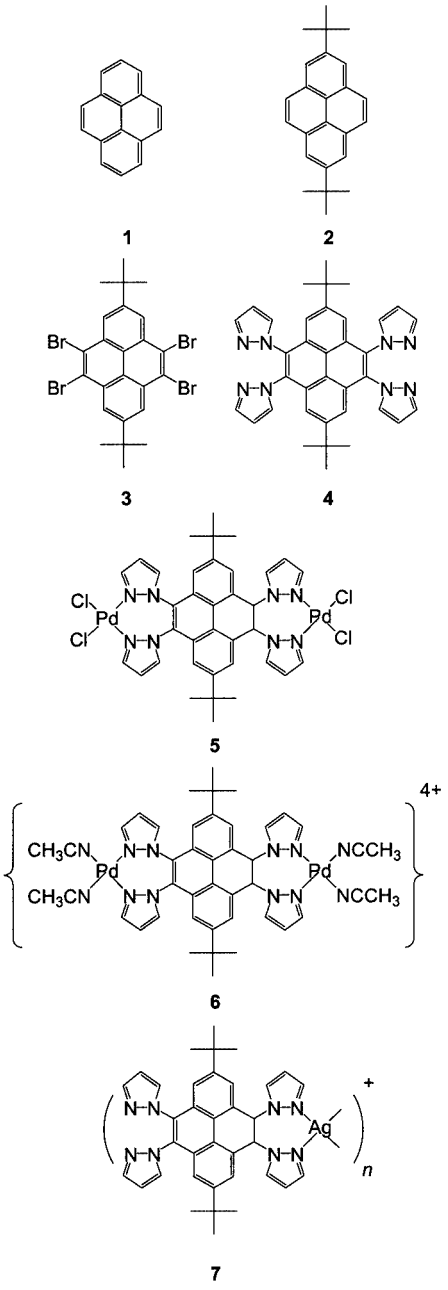
Results and Discussion

As stated above, examples of coordination networks containing bis-chelate tectons are rather rare. In a continuation of our efforts towards the design of new types of coordination networks,[10] we thought that the pyrene-based tecton **4** bearing four pyrazolyl units may be of interest for the formation of 1-D coordination networks in the presence of connecting transition metals. The synthesis and binding ability of pyrazole-based ligands have been reported.[11] The design of the tecton **4** was based on the use of pyrene as the backbone because the latter permits the introduction of four monodentate units in positions 4, 5, 9 and 10 in a symmetrical fashion. The pyrazolyl group was the obvious candidate as the monodentate unit. Indeed, when four such units are connected through their nitrogen atoms to the pyrene backbone at positions 4, 5, 9 and 10, due to their localisation, each set of two pyrazolyl units on each side of the backbone will behave as a chelate, thus affording a bis-chelate tecton. Pyrene has previously been used as a backbone to anchor bipyridine,[12,13] terpyridine[13] and quinoline[14] units. Due to its planarity, pyrene **1** is poorly soluble in common solvents, and so we thought that the introduction of bulky and nonplanar *tert*-butyl substituents at positions 2 and 7, remote from the binding zones of the ligand, should overcome this insolubility problem.

For the synthesis of compound **4**, pyrene **1** was the starting material. The introduction of the *tert*-butyl groups at positions 2 and 7, leading to compound **2**, was achieved following reported procedures.[15] The bromination of **2** by Br_2 in the presence of $FeCl_3$ in CCl_4, leading to the tetrabromo compound **3**, was also achieved following reported procedures.[16] Finally, the desired compound **4** (Scheme 1) was obtained in 24% yield upon treatment of the tetrabromo compound **3** with sodium pyrazolate in DMF.



Scheme 1

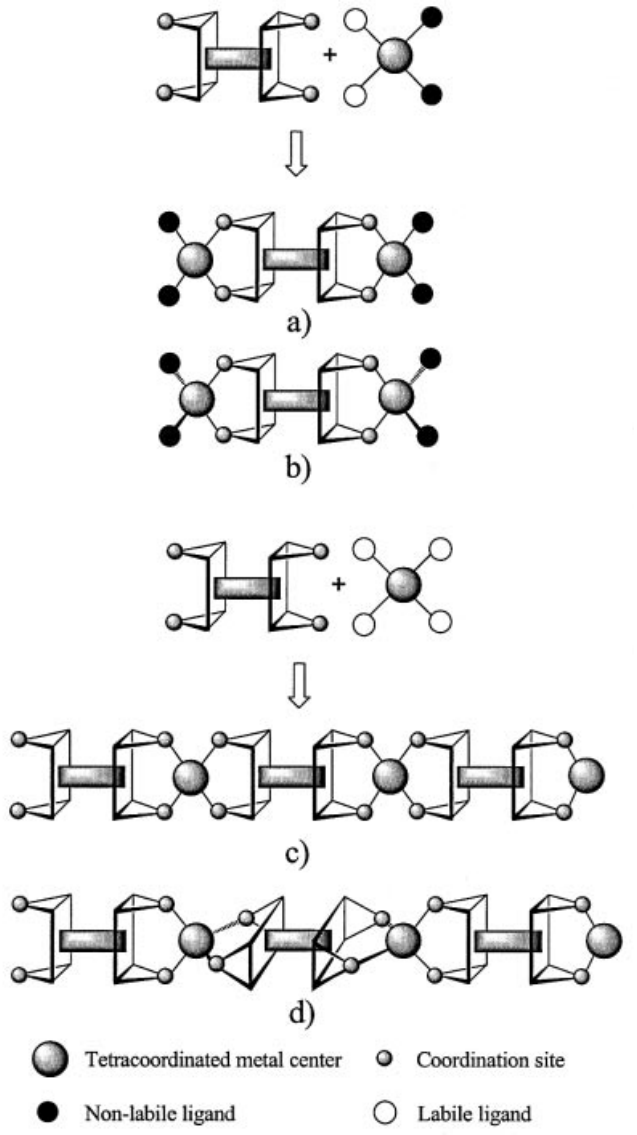


Figure 1. Schematic representation of the formation of discrete exo-binuclear complexes formed between an exo-bis-chelate ligand and deprotected metal centres adopting a square planar (a) or tetrahedral (b) coordination geometry, or infinite 1-D coordination networks in the presence of metal centres adopting a square planar (c) or tetrahedral (d) coordination geometry

Among many coordination possibilities that the bis-chelate tecton **4** may offer, one may envisage the formation of discrete exo-binuclear complexes upon binding of metal centres possessing only two available coordination sites and adopting either a square planar (Figure 1a) or a tetrahedral (Figure 1b) coordination geometry.

The quantitative formation of the exo-binuclear palladium complex **5** was demonstrated by treating the ligand **4** with $[PdCl_2(CH_3CN)_2]$ in a mixture of CH_2Cl_2 and CH_3CN at room temperature. Complex **5** is rather insoluble in common solvents. However, suitable yellow-orange single-crystals could be obtained from a DMSO/MeOH mixture. The structure of **5** was investigated in the solid state by X-ray diffraction, which revealed the following features (Figure 2). The crystal (triclinic, space group $P\bar{1}$) is composed of discrete binuclear complexes **5**, two DMSO and one water solvent molecules. Although the H_2O molecule is H-bonded to the O atom of DMSO (d_{O-O} = 2.74 Å), no specific interactions between the solvent molecules and complex **5** could be identified. For the pyrene moiety, possessing a centre of symmetry, the aromatic core, as expected, is planar. Both *tert*-butyl groups are disordered over two positions. The py-

razolyl units [average N−N distance of ca 1.35 Å and $d_{N-C(Py)}$ = 1.43 Å] are tilted with respect to the plane of pyrene (NNCC dihedral angles of −69° and 73.9°). The two sets of two pyrazolyl units forming two chelates are located above and below the main plane of the ligand. Consequently, the two square-planar Pd centres are also located above and below the main plane of the pyrene backbone. The coordination sphere around each Pd^{II} is composed of two N atoms belonging to two adjacent pyrazolyl units in *cis* configuration (average d_{Pd-N} of 2.03 Å, NPdN angle of ca 88°) and two Cl^- anions (d_{Pd-Cl} = 2.28 Å, ClPdCl angle of ca 92°).

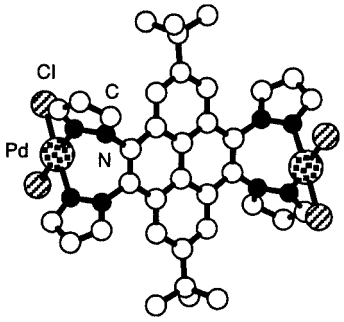

Figure 2. Crystal structures of the exo-binuclear palladium complex formed with pyrazolyl-based ligand **4**; solvent molecules (DMSO, H_2O) and H atoms are omitted for clarity; for bond lengths and angles see text

When dealing with 1-D coordination networks based on bidentate tectons, many structural frameworks may be envisaged.[17] In particular, in the presence of the tecton **4**, 1-D networks may be generated by using tetracoordinate metal centres adopting either a square planar (Figure 1c) or tetrahedral (Figure 1d) coordination geometry.

Since the Cl^- anions bound to Pd^{II} are not sufficiently labile for generating a network in the presence of free tecton **4** (neutral ligand), the binuclear complex **6**, for which the Cl^- anions are substituted by acetonitrile molecules and the positive charge on the complex is compensated by tetrafluoroborate anions, was prepared in quantitative yield upon treatment of **4** with $[Pd(CH_3CN)_4][BF_4]_2$ in a mixture of CH_2Cl_2 and CH_3CN at room temperature. The much more soluble complex **6** was characterised by NMR spectroscopy. Considering the discrete complex **6** as a metalla tecton, the formation of a 1-D network of the square-planar type shown in Figure 1c was attempted in the presence of the free ligand **4**. Unfortunately, crystallisation under different conditions (variation of the solvent and co-solvent, temperature) afforded only an amorphous and insoluble powder which could not be structurally characterised.

The formation of 1-D networks **7** of the tetrahedral type presented schematically in Figure 1d was investigated using the Ag^+ cation, which may adopt a tetrahedral coordination geometry. In a crystallisation tube, upon slow diffusion of a solution of $Ag(PF)_6$ (10 mg, excess) in EtOH (3 mL) into a solution of compound **4** (5 mg) in $CHCl_3$ (2 mL), colourless crystals of network **7** were obtained at room temp. in the dark over a period of a week and studied by X-ray diffraction of a single crystal (Figure 3). The crystal (triclinic system, space group $P\bar{1}$) is composed of **4**, the Ag^+ cation, a PF_6^- anion and $CHCl_3$ solvent molecules. Although the $CHCl_3$ molecule is rather weakly H-bonded to the PF_6^- anion (d_{H-F} = 2.35 Å), no specific interactions between the cationic part of the crystal and the solvent or anion could be observed.

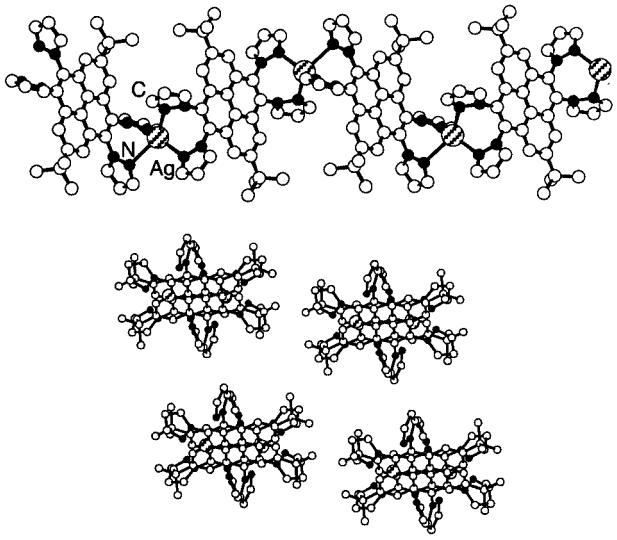

Figure 3. A portion of the crystal structures of the stair-type, 1-D coordination network formed by the self-assembly of **4** and Ag^+ cation (top) and the parallel packing of the 1-D networks (bottom); anions (PF_6^-), solvent molecules ($CHCl_3$) and H atoms are omitted for clarity; for bond lengths and angles see text.

The cationic portion of the crystal is an infinite coordination network formed upon interconnection of the organic tectons **4** by silver cations (Figure 3 top). As in the case of the square-planar discrete binuclear Pd complex mentioned above, the pyrazolyl units are tilted with respect to the plane of pyrene (NNCC dihedral angles of −82.3° and 85.0°) and located on the opposite faces of the centrosymmetric ligand **4**, thus offering two chelates, one on each face of the ligand. The coordination sphere around the silver cation is composed of four N atoms (d_{Ag-N} varying between 2.24 Å and 2.50 Å) belonging to two sets of two pyrazolyl units of consecutive ligands. The coordination geometry around the silver cation is a severely distorted tetrahedron (NAgN angle varying between 84.7° and 139.7°). The stair-type 1D network **7** may be described as the translation into a single direction of space of the coordination node composed of a tetracoordinate silver cation and two sets of two pyrazolyl units belonging to two consecutive ligands **4**. The cationic 1-D networks are packed parallel to each other (Figure 3 bottom) and the empty spaces are occupied by chloroform molecules.

In summary, the synthesis of the new ligand **4** based on a pyrene backbone bearing four pyrazolyl units was achieved. Whereas the compound **4** was shown to bind two PdX_2 moieties (X = Cl^- or CH_3CN) to form the exo-binuclear

palladium complexes **5** and **6**, respectively, in the presence of $AgPF_6$, the formation of a 1-D coordination network **7** based on the interconnection of the organic tecton **4** by silver cation adopting a tetrahedral coordination geometry was demonstrated in the solid state by X-ray diffraction on single-crystal. The preparation of either other discrete complexes or coordination networks using the ligand **4** and other transition metals is currently under investigation.

Experimental Section

Synthesis of 4: NaH (50% in oil, 0.69 g, 14.3 mmol) was added in small portions to a solution of pyrazole (1 g, 14.7 mmol) in dry DMF (45 mL) under argon and the mixture stirred at room temperature for 35 min. A solution of the tetrabromo compound **3** (1.0 g, 1.58 mmol), prepared according to published procedures,[16] was added to this mixture in one portion. The mixture turned blue instantaneously. Upon heating the mixture at 130 °C for 40 h., a dark red solution was obtained. The solvents were evaporated to dryness and the residue was taken up in water (50 mL). The brownish solid was filtered, washed with water (50 mL) and finally dried under vacuum. The pure compound **4** (0.22 g) was obtained in 24% yield after column chromatography (SiO_2, CH_2Cl_2, 0−1% MeOH). m.p. > 300 °C, ^{1}H NMR ($CDCl_3$, 200 MHz, 25 °C): δ = 1.33 (s, 18 H, CH_3), 6.37 (t, 2 Hz, 4 H, $H_{pyrazolyl}$), 7.48 (d, 2 Hz, 4 H, $H_{pyrazolyl}$), 7.86 (d, 2 Hz, 4 H, $H_{pyrazolyl}$), 7.98 (s, 4 H, H_{pyrene}) ppm. ^{13}C NMR ($CDCl_3$, 75 MHz, 25 °C): δ = 31.4, 106.7, 122.0, 127.7, 133.0, 133.1, 141.3, 151.1 ppm. $C_{36}H_{34}N_8$: (578.72): calcd. C 74.72, H 5.92, N 19.36; found C 74.33, H 5.88, N 19.12.

Synthesis of 5: A solution of $[PdCl_2(CH_3CN)_2]$ (18 mg, 0.069 mmol) in CH_3CN (4 mL) was added to a solution of **4** (20 mg, 0.035 mmol) in CH_2Cl_2 (3 mL) under argon and the mixture stirred overnight at room temperature. The solvents were evaporated to dryness and the residue was taken up in CH_2Cl_2 (5 mL) and filtered. The solid was further washed with diethyl ether (10 mL). The pure complex **5** obtained in quantitative yield (32 mg) was insoluble in all common solvents. ^{1}H NMR (DMSO, 200 MHz, 25 °C): δ = 1.29 (s, 18 H, CH_3), 6.51 (broad, 4 H, $H_{pyrazolyl}$), 6.99 (broad, 4 H, $H_{pyrazolyl}$), 8.27 (s, 4 H, H_{pyrene}), 8.86 (broad, 4 H, $H_{pyrazolyl}$) ppm. $C_{36}H_{34}Cl_4N_8Pd_2{\cdot}CH_3CN$ (974.4): calcd. C 46.84, H 3.83, N 12.94; found C 46.70, H 3.60, N 12.72.

Synthesis of 6: A solution of $[Pd(CH_3CN)_4][BF_4]_2$ (50 mg, 0.11 mmol) in a 1:1 mixture of CH_3CN and CH_2Cl_2 (10 mL) was added to a solution of **4** (30 mg, 0.05 mmol) in CH_2Cl_2 (5 mL) under argon and the mixture stirred overnight at room temperature. The solvents were evaporated to dryness affording the desired complex in quantitative yield. ^{1}H NMR (CD_3CN, 200 MHz, 25 °C): δ = 1.45 (s, 18 H, CH_3), 2.17 (s, 12 H, CH_3CN), 7.06 (t, J = 1.6 Hz, 4 H, $H_{pyrazolyl}$), 8.03 (s, 4 H, H_{pyrene}), 8.42 (d, J = 1.5 Hz, 4 H, $H_{pyrazolyl}$), 8.55 (d, J = 1.5 Hz, 4 H, $H_{pyrazolyl}$) ppm.

Crystallisation Conditions

Complex 5: In a crystallising tube, MeOH was slowly diffused into a solution of **5** in DMSO at room temperature affording, after several days, yellowish-orange crystals.

Network 7: In a crystallising tube, a solution of $AgPF_6$ (excess, 10 mg) in EtOH was slowly diffused into a solution of **5** (5 mg) in $CHCl_3$ at room temperature and in the dark. After a week, colourless crystals were obtained.

Crystal Structure Characterisation: X-ray diffraction data collection was carried out on a Kappa CCD diffractometer equipped with an Oxford Cryosystem liquid N_2 device, using graphite-monochromated Mo-K_α radiation. For all structures, diffraction data were corrected for absorption and analysed using OpenMolen package.[18] All non-H atoms were refined anisotropically.

Crystallographic Data for 5 (Yellow Crystals, 294 K): $C_{36}H_{34}Cl_4N_8Pd_2{\cdot}2DMSO{\cdot}H_2O$, M = 1107.62, triclinic, a = 13.1079(3), b = 13.6607(4), c = 15.1388(4) Å, α = 92.145(5), β = 99.638(5), γ = 115.715(5), U = 2389.3(4) Å^3, space group $P\bar{1}$, Z = 2, $D_{calcd.}$ = 1.54 g cm^{-3}; μ = 1.108 mm^{-1}, 5800 data with $I > 3\sigma(I)$, R = 0.054, Rw = 0.087.

For 7 (Colourless Crystals, 173 K): $C_{36}H_{34}AgN_8{\cdot}PF_6{\cdot}4CHCl_3$, M = 1309.07, triclinic, a = 11.4299(4), b = 15.5450(5), c = 17.8274(6) Å, α = 103.614(5), β = 101.712(5), γ = 110.022(5), U = 2749.5(6) Å^3, space group $P\bar{1}$, Z = 2, $D_{calcd.}$ = 1.58 g cm^{-3}; μ = 1.037 mm^{-1}, 6900 data with $I > 3\sigma(I)$, R = 0.085, Rw = 0.096.

CCDC-193060 (**5**) and 193061 (**7**) contain the supplementary crystallographic data for this paper. Unique Magnetic Behavior in a One-Dimensional Coordination Polymer [Co(tmpyim)$_2$(tp)]

Licun Li,*[a] Zhiliang Liu,[a] Scott S. Turner,[b] Daizheng Liao,[a] Zonghui Jiang,*[a] and Shiping Yan[a]

Keywords: Magnetic properties / Crystal structure / Radicals / Terephthalate

A one dimensional cobalt(II)–radical complex [Co(tmpyim)$_2$(tp)] [tmpyim = 4,4,5,5-tetramethyl-2-(3′-pyridyl)-imidazoline-1-oxyl 3-oxide and tp = terephthalate dianion] has been synthesized and characterized by X-ray crystallography. The crystal structure consists of infinite chains of Co(tmpyim)$_2$ units cross-linked by terephthalate ligands. The magnetic behavior of the complex is unique and is discussed in connection with the crystal structure.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2003)

In the field of molecular-based magnetic materials, it is fundamentally important to understand the interactions between organic or inorganic spin-carriers and the structure-function relationships of the magnetic systems.[1−2] The so-called "crystal engineering" approach has been used extensively to control material structure and dimensionality in which extended inorganic structures with organic bridges are synthesized to give coordination polymers or networks.[3−4]

Metal complexes based on pyridyl-substituted nitronyl nitroxides have attracted considerable attention in recent years due to the ability of these radicals to coordinate metal ions and act as magnetic couplers, giving rise to new functional materials with a variety of structural topologies.[5−12] The terephthalate ligand is a versatile ligand with good binding ability, as exemplified by the formation of polymeric structures.[13−15] In this paper we report the crystal structure and magnetic properties of a one-dimensional Co^{II}−radical complex with a terephthalate bridge, [Co(tmpyim)$_2$(tp)] (**1**) [tmpyim = 4,4,5,5-tetramethyl-2-(3′-pyridyl)imidazoline-1-oxyl 3-oxide and tp = terephthalate dianion).

The structure of **1** (Figure 1) shows that each terephthalate dianion binds to two Co^{II} ions in a bis-bidentate mode, leading to a 1-D chain structure. Two tmpyim radical ligands coordinate to the Co^{II} ion through the nitrogen atoms of their pyridyl rings. The Co^{II} ion has a distorted octahedral coordination environment, which is centrosymmetric. Four carboxylato oxygen atoms from two tp ligands form the equatorial plane. The Co−O bond lengths in the basal plane are 2.117(2) and 2.122(2) Å for Co(1)−O(3) and Co(1)−O(4), respectively. The axial positions, occupied by nitrogen atoms from the tmpyim ligands, have a Co−N bond length of 2.144(3) Å. The dihedral angle between the pyridyl ring and the nitroxide group [O(1)−N(1)−C(3)−N(2)−O(2)] is 31.6°. The shortest contact between nitroxide groups is 3.860 Å. However, it should be noted that the closest contact is observed between the oxygen atom [O(1)] of the nitroxide group and the carbon atom [C′(5)] belonging to the adjacent chain [O(1)−C′(5) = 3.156 Å; Figure 2]. The intrachain Co^{II}−Co^{II} distance is 10.633 Å and the shortest interchain Co^{II}−Co^{II} separation is 7.119 Å, which corresponds to the unit cell length (*b*).

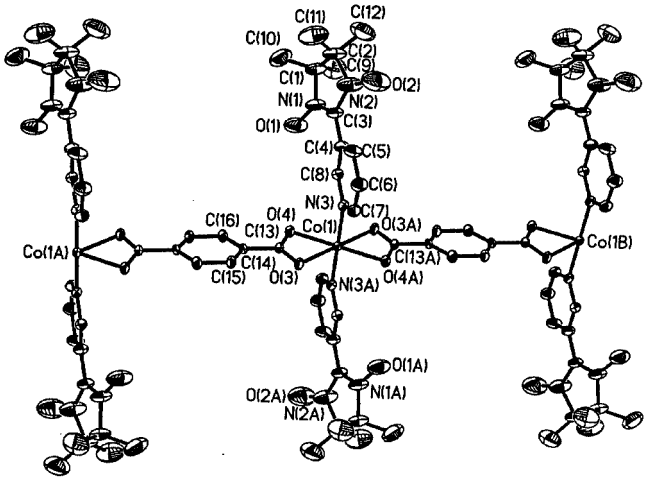

Figure 1. View of the molecular structure of [Co(tmpyim)$_2$(tp)] with atom labeling and 30% thermal ellipsoids

The magnetic susceptibility of complex **1** was measured in the temperature range 2−300 K, with an applied field of

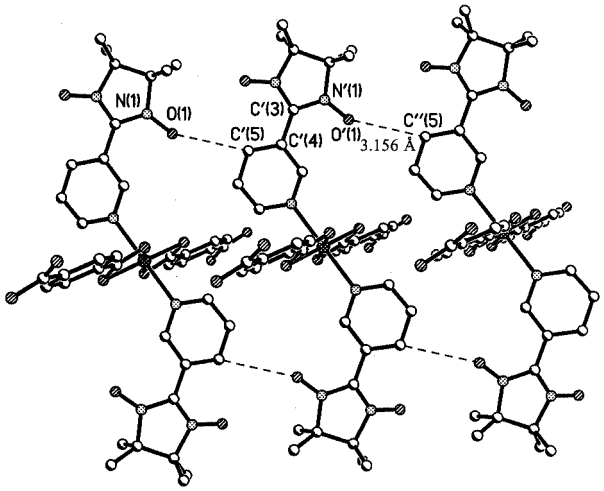

Figure 2. The closest contact in $[Co(tmpyim)_2(tp)]$ showing exchange coupling through NO···C interactions

1000 G. The plot of effective magnetic moment μ_{eff} versus T is shown in Figure 3.

At room temperature, μ_{eff} is equal to 6.13 μ_B, which is much higher than that expected for noninteracting S_{Co} = 3/2 and S_{rad} =1/2 spins, indicating that an important orbital contribution is involved. The plot of μ_{eff} versus T reveals four domains: (i) from 300 K to 55.1 K, μ_{eff} increases continuously from 6.13 μ_B to a value of 6.46 μ_B; (ii) between 55.1 K and 25 K μ_{eff} decreases gradually with decreasing temperature; (iii) from 25 K to 2 K, μ_{eff} increases rapidly to reach a maximum of 6.84 μ_B at 3 K; (iv) below 2 K, μ_{eff} decreases again on cooling. This magnetic behavior is unique. In complex **1**, there are four kinds of magnetic interactions, namely: (i) Co^{II} interacting with the coordinated tmpyim radical, (ii) a $Co^{II}-Co^{II}$ interaction *via* the terephthalate bridge, (iii) a magnetic coupling between neighboring tmpyim radicals through the NO···C pathway (3.156 Å), and (iv) a through-space interaction between neighboring NO groups of tmpyim radicals (3.860 Å). The magnetic interaction between the cobalt(II) ions should be very weakly antiferromagnetic and can be neglected since the tp bridge is long.[16] The extent of magnetic coupling of the two adjacent NO groups depends on their separation and the relative orientation of the π* orbitals.[17] In complex **1**, the shortest O−O separation between the nitroxide groups is rather large (3.860 Å) and the planes of the π systems of the nitroxide radicals form an angle of 26.8° with the plane defined by the two adjacent NO groups. These geometrical parameters are not disposed favorably for strong overlap and lead to weakly antiferromagnetic interactions.[17−19] The last kind of magnetic coupling is also weak and should be dominant only at low temperatures. Therefore the magnetic behavior of the complex between 300 K and 55.1 K must correspond to that of Co^{II} interacting with the coordinated tmpyim radical, which implies that the magnetic interaction between cobalt(II) and tmpyim radical is ferromagnetic. The decrease of μ_{eff} between 55.1 K an 25 K is attributed to the spin-orbit coupling of the cobalt(II) ion. Regarding the interaction between radicals, the crystal structure shows that the closest contact involves the oxygen atom [O(1)] of the uncoordinated NO group, which carries a large, positive spin density, and the carbon atom [C′(5)] of the adjacent tmpyim radical, which carries a small, negative spin density [O(1)···C′(5) = 3.156 Å]. These two atoms carrying opposite signs of the spin density alternate, leading to ↑N(1)−O(1)↑···↓C′(5)−↑C′(4)−↓C′(3)−↑N′(1)−↑O′(1)···↓C″(5), which matches McConnell's criteria.[20] Thus, the exchange coupling between neighboring tmpyim radicals through an NO···C pathway should be ferromagnetic and so results in the increase in μ_{eff} between 25 K and 2 K. The μ_{eff} value decreases below 2 K due to the weak antiferromagnetic interaction between neighboring NO groups of the tmpyim

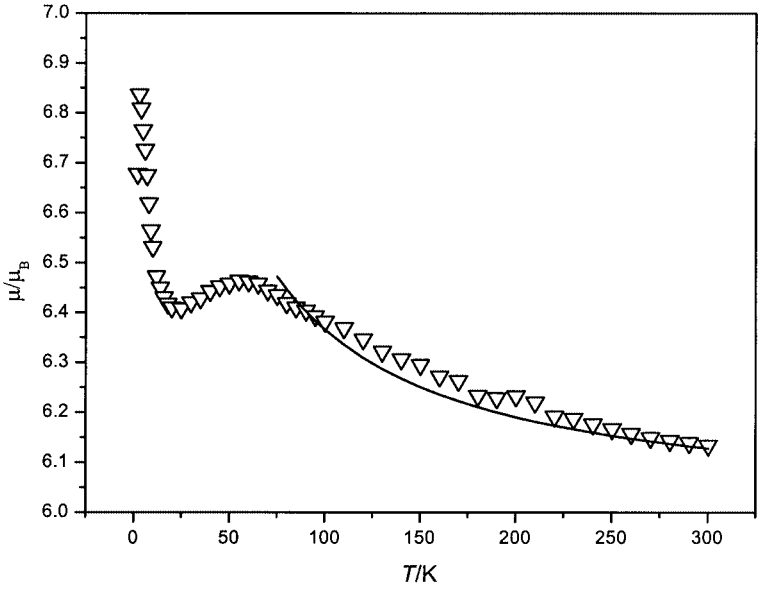

Figure 3. A plot of μ_{eff} (▽) versus T for $[Co(tmpyim)_2(tp)]$

radicals, spin-orbital coupling and zero-field splitting. It would be very difficult to incorporate all of these into a model to fit the magnetic data at the lower temperature. However, according to Sinn,[21] the higher temperature magnetic data above 70 K may be approximately interpreted by the isotropic spin Hamiltonian. For the $Co(tmpyim)_2$ unit, the spin Hamiltonian can be expressed as

$$\hat{H} = -2J\sum(\hat{S}_{Co}\hat{S}_R + \hat{S}_{Co}\hat{S}_R)$$

where J represents the magnetic interaction between the Co^{II} ion and the coordinated tmpyim radical. The expression of the magnetic susceptibility is given below:

$$\chi_M = \frac{N\beta^2}{4kT}\frac{35g_1^2 + 10g_2^2\exp(-5x) + g_3^2\exp(-8x) + 10g_4^2\exp(-3x)}{3 + 2\exp(-5x) + \exp(-8x) + 2\exp(-3x)}$$

with $x = J/kT$, $g_1 = (3g_{Co} + 2g_R)/5$, $g_2 = (11g_{Co} + 4g_R)/15$, $g_3 = (5g_{Co} - 2g_R)/3$ and $g_4 = g_{Co}$.

The best fit (line in Figure 3) for the magnetic data (70−300 K) leads to $g_{Co} = 2.86$, $g_{rad} = 2.00$, $J = 7.62$ cm^{-1}, $R = 7.67 \times 10^{-5}$ (the residual value R is defined as $[(\chi_M)_{obsd} - (\chi_M)_{calcd.}]^2/[(\chi_M)_{obsd.}]^2$). The fitting results show that the exchange coupling between the Co^{II} ion and the tmpyim radical is weakly ferromagnetic. In complex **1**, the magnetic orbital of the tmpyim radical is a π* orbital and the spin density can delocalized on the pyridyl ring by spin polarization. The cobalt ion has two magnetic orbitals with σ symmetry ($d_{x^2-y^2}$, d_{z^2}),which are orthogonal to the magnetic orbital of the nitroxide, leading to a ferromagnetic interaction, and one magnetic orbital with π symmetry (either of d_{xy}, d_{xz}, d_{yz}) that will able to overlap with the magnetic orbital of the nitroxide, leading to antiferromagnetic coupling. The magnetic coupling constant J can be expressed as $J = 1/3(J_{x^2-y^2,\pi^*} + J_{z^2,\pi^*} + J_{xy,\pi^*})$.[22] The first two terms are ferromagnetic and are capable of overcoming the third antiferromagnetic term, leading to a ferromagnetic interaction being observed between the cobalt(II) ion and the tmpyim ligand. Since the nitroxide moiety has a large dihedral angle of 31.6° to the plane of the tmpyim pyridyl ring, which reduces the possibility of delocalizing the spin density of the NO group, the exchange coupling between the cobalt(II) ion and tmpyim is weak. The obtained g_{Co} value is considered to be acceptable in view of the corresponding value of other high-spin octahedral Co^{II} complexes.[23,24]

Experimental Section

General: Elemental analysis was carried out on a Perkin−Elmer elemental analyzer model 240. Infrared spectra were recorded on a Shimadzu IR spectrophotometer model 408, as KBr pellets. Variable temperature magnetic susceptibilities on polycrystalline samples in a gelatin capsule were measured on a Quantum Design MPMS-7 SQUID magnetometer.

Preparation of 1: An aqueous solution (10 mL) of dipotassium terephthalate (0.121 g, 0.5 mmol) was added to a solution of $[Co(ClO_4)_2]\cdot 6H_2O$ (0.183 g, 0.5 mmol) and tmpyim (0.234 g, 1 mmol) in H_2O (10 mL). The reaction mixture was then stirred for 1 h. Dark blue single crystals suitable for X-ray analysis were obtained by slow evaporation at room temperature after three weeks. $C_{32}H_{36}CoN_6O_8$ (691.60): calcd. C 55.57, H 5.25, N 12.15; found C 55.46, H 5.51, N 12.50. Important IR absorptions (KBr): $\tilde{\nu}$ = 1550 (s) cm^{-1}, 1400 (s) cm^{-1}, 1370 (br) cm^{-1}.

X-ray Crystallographic Analysis of 1: A dark blue crystal (0.30 × 0.25 × 0.20 mm) was selected and mounted on a glass fiber. All measurements were made on a Bruker Smart 1000 diffractometer equipped with graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å). A total of 6654 reflections including 2897 independent reflections (R_{int} = 0.0559) were collected in the 2.13 < θ < 25.03° range at room temperature. A summary of the crystallographic data is given in Table 1. The absorption correction was performed empirically.[25] The structure was solved by direct methods using the SHELXS-97 program[26] and refined with SHELXL 97[27] by full-matrix least-squares methods on F^2. All non-hydrogen atoms were refined anisotropically, while the hydrogen atoms were located geometrically and refined isotropically.

CCDC-192270 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Symmetric Tetraalkynyldisilanes

Carsten Ackerhans,[a] Herbert W. Roesky,*[a] Denis Vidovic,[a] and Jörg Magull[a]

Dedicated to Professor M. F. Hawthorne on the occasion of his 75th birthday

Keywords: Alkynes / Bulky ligands / Silanes / Silicon

The reaction of the tetrachlorodisilane $R_2Si_2Cl_4$ (**1**) [R = $CH(SiMe_3)_2$] with the lithium salt R*C≡CLi of the parent alkyne results in the replacement of the chlorine atoms with alkynyl groups to yield the product $R_2Si_2(C{\equiv}CR^*)_4$ [R* = Ph (**2**), *t*Bu (**3**), $SiMe_3$ (**4**), *n*-C_3H_7 (**5**)]. Compounds **2** and **3** were characterized by X-ray structural analysis.

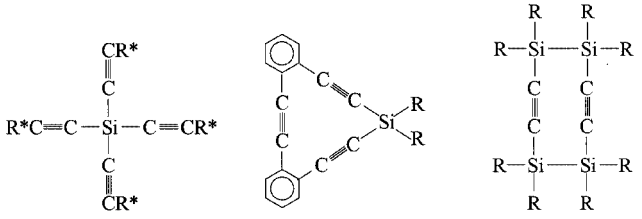
Introduction

In recent years many alkynylsilicon compounds have been synthesised[1] where the number of alkynyl groups attached to the central silicon atom varies from one to four (Scheme 1: **A**). Some of these products have been isolated.[2,3] Moreover, in a few compounds the alkynyl group acts as a linker between silicon and carbon atoms or two silicon atoms, respectively, forming chains[4,5] or heterocycles.[6,11] In Scheme 1 two examples of heterocycles containing alkynyl groups are shown. In compound **B** silicon and carbon atoms and in **C** two silicon atoms are linked together. However, to the best of our knowledge, a disilane carrying four alkynyl groups has not been reported previously.



Scheme 1

Recently we have reported the reaction of the tetraaminodisilane $R_2Si_2(NH_2)_4$ [R = $CH(SiMe_3)_2$] with HBr and HI, with elimination of ammonia and formation of the halodisilanes $R_2Si_2X_4$ (X = Br, I).[12] A similar reaction using alkynes did not succeed as their acidity is lower than both HBr and HI. As an alternative approach we used the lithium salts R*C≡CLi [R* = Ph (**2**), *t*Bu (**3**), $SiMe_3$ (**4**), *n*-C_3H_7 (**5**); Scheme 2] as a starting material for the reaction with the tetrachlorodisilane $R_2Si_2Cl_4$ (**1**) [R = $CH(SiMe_3)_2$] with elimination of LiCl.

Results and Discussion

Synthesis and Spectra

Lithiation of R*C≡CH was accomplished with a solution of butyllithium in hexane at −78 °C. The tetrachlorodisilane was then added at the same temperature. The reaction mixture was slowly warmed to room temperature, the LiCl separated by filtration and finally the solvent removed under vacuum to yield compounds **2**−**5**. The products **2**−**4** were obtained as colourless solids whereas **5** was isolated as a colourless oil. Single crystals of **2** and **3** suitable for X-ray crystallographic measurements were isolated from hexane solutions.

E-mail: hroesky@gwdg.de

In the mass spectra compounds **2**−**5** were identified by their molecular ion peaks [M^+] at m/z = 778 (**2**), 698 (**3**), 762 (**4**), and 642 (**5**); in the IR spectra the absorptions for the C≡C vibrations are in the range between 2100 and 2200 cm^{-1}.

The ^1H NMR spectra of **2**−**5** show resonances for the protons of the methyl groups of the bis(trimethylsilyl)methyl ligands in the range δ = 0.49 to 0.59 ppm, whereas the resonances of the corresponding CH groups are in the range between δ = 0.21 and 0.53 ppm. Additionally, the resonances of the substituents of the alkynyl groups are found in each spectrum. For compound **2** the aromatic protons are found as two multiplets, one at δ = 6.87 to 6.91 ppm (*m*-, *p*-Ph) and the other at δ = 7.47 to 7.52 ppm (*o*-Ph). The protons of the *t*Bu groups of **3** appear as a singlet at δ = 1.17 ppm and the trimethylsilyl protons resonate in the spectrum of **4** at δ = 0.13 ppm. The spectrum of **5** exhibits three multiplets for the aliphatic protons [δ = 0.83 (CH_2-CH_3), 1.38 (CH_2-CH_3), and 1.99 ppm (C≡C-CH_2)].

In the ^{13}C NMR spectra of **2**−**5** the resonances of the CH_3 groups of the ligands are in the range between δ = 3.3 and 3.5 ppm and those for the CH groups between δ = −0.3 and 0.4 ppm. The triple-bonded carbon atoms of the inner atoms with respect to the silicon atom exhibit resonances between δ = 110.6 and 120.2 ppm, while for the outer atoms they are observed between δ = 80.9 and 110.9 ppm. The resonances of the acetylenic substituents are found in the expected range.

The trimethylsilyl groups resonate in the ^{29}Si NMR spectra between δ = 0.8 and 1.2 ppm and the silicon atoms of the central disilane unit resonate between δ = −54.2 and −56.5 ppm.

X-ray Structural Analysis

The single-crystal structural analysis of compounds **2** (Figure 1) and **3** (Figure 2) shows that the central disilane unit is connected to four alkynyl groups in an anticlinic conformation. The coordination sphere of the silicon atoms is completed in each case by a bis(trimethylsilyl)methyl group.

The disilane **2** crystallises in the orthorhombic space group $Pna2_1$ and **3** in the monoclinic space group $C2/c$. The unit cell of **3** contains eight molecules of the disilane and an additional two molecules of cyclohexane and two more of *n*-hexane.

The Si−Si bond length in both compounds is essentially identical [2.378(1) Å (**2**) and 2.373(1) Å (**3**)] and is only slightly shorter than that in the chloro compound **1** [2.380(2) Å].[12]

The bond length between the central silicon atoms and the acetylenic carbon atoms averages to 1.833 Å for **2** and 1.832 Å for **3** and is similar to the corresponding bond length in $Si(C_2SiMe_3)_4$ (1.825 Å).[2] The C−Si−C angle at the silicon atom averages to 106.73° (**2**) and 107.75° (**3**). Selected bond lengths and angles for **2** and **3** are listed in Table 1.

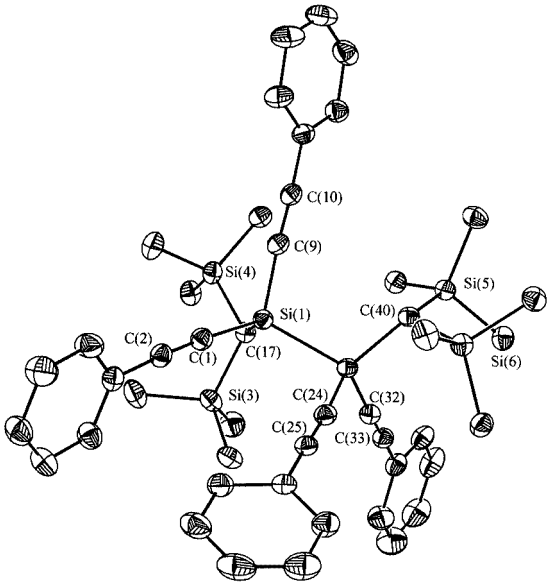

Figure 1. Molecular structure of **2** in the crystal (50% probability thermal ellipsoids)

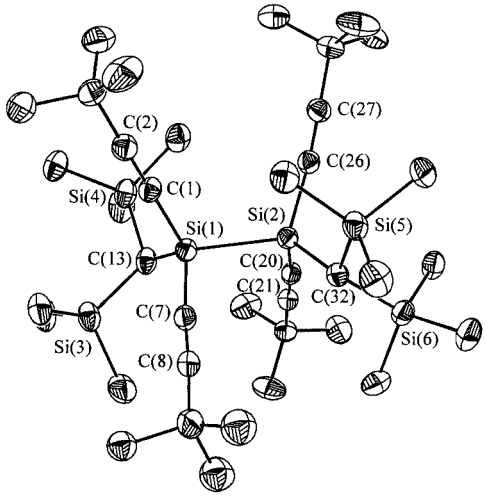

Figure 2. Molecular structure of **3** in the crystal (50% probability thermal ellipsoids)

C(1)−Si(1)−C(17/13)	110.41(12)	109.18(13)

Conclusion

This work shows that alkynes are slim enough to allow fourfold substitution on a disilane sterically hindered by

two bis(trimethylsilyl)methyl groups. The easiest way to synthesise this class of compounds is using the lithium salt of the corresponding alkyne and the tetrachlorodisilane. The products are useful precursors for heterocyclic and polymeric silicon-containing materials after manipulation of the alkyne groups.

Experimental Section

General Remarks: All reactions were performed under dry nitrogen using standard Schlenk and syringe techniques. The solvents were dried according to literature methods[13] and freshly distilled and saturated with nitrogen prior to use. Melting points were measured on a Büchi B-540 melting point apparatus. IR spectra were recorded using a BIO-RAD Digilab FTS 7 spectrophotometer. Mass spectra (MS) were obtained on a Finnigan MAT 95 or a Finnigan MAT 8200 spectrometer using the EI technique. NMR spectra were recorded on a Bruker AC 250 or a Bruker Avance 500 spectrometer; chemical shifts are quoted relative to external $SiMe_4$. Elemental analyses were performed by the Analytical Laboratory of the Institute of Inorganic Chemistry at the University of Göttingen.

General Procedure: A solution of butyllithium (40 mmol) in *n*-hexane (25 mL, 1.6 M) was added dropwise to a solution of the alkyne (40 mmol) in hexane (100 mL) at −78 °C. Subsequently **1** (5.2 g, 10 mmol) dissolved in *n*-hexane (50 mL) was added over a period of 30 min and the mixture was allowed to warm to room temperature overnight. The precipitate was removed from the solution by filtration and the volume of solvent was reduced to 20 mL under vacuum. Products **2**−**4** were obtained as colourless solids and **5** was obtained as a colourless oil after complete removal of the solvent.

1,2-Bis[bis(trimethylsilyl)methyl]tetra(phenylethynyl)disilane (2): Yield: 6.1 g (7.8 mmol, 78%). M.p. 110 °C. ^{1}H NMR (C_6D_6): δ = 0.53 [s, 2 H, C*H*($SiMe_3$)$_2$], 0.59 [s, 36 H, Si(C*H*$_3$)$_3$], 6.87−6.91 (m, 12 H, *o*-, *p*-Ph-*H*), 7.47−7.52 (m, 8 H, *m*-Ph-*H*) ppm. ^{13}C NMR (C_6D_6): δ = 0.4 [*C*H($SiMe_3$)$_2$], 3.4 [Si(*C*H$_3$)$_3$], 92.5 (Si-C≡*C*-Ph), 110.6 (Si-*C*≡C), 123.6, 128.5, 128.9, 132.0 (arom.-*C*) ppm. ^{29}Si NMR (C_6D_6): δ = −54.2 (*Si*-C≡C-Ph), 1.4 (*Si*Me_3) ppm. X-ray Crystallographic Study of 2 and 3

The crystals were mounted on glass fibre in rapidly cooled mineral oil. Diffraction data (see also Table 2) were collected on a Stoe IPDS II diffractometer at 133(2) K, with graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å), using the ω-scan technique. The structures were solved by direct methods using SHELXS-97[15] and refined against F^2 on all data by full-matrix least-squares with SHELXL-97.[16] All non-hydrogen atoms were refined anisotropically. All hydrogen atoms were included in the model at geometrically calculated positions and refined using a riding model. CCDC-191736 (**2**) and CCDC-191737 (**3**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Chelation versus Cyclometalation in a Cationic Dppn−Rh^{I} Complex − A Unique Rearrangement of Norbornadiene via C−H Activation of the Pyridazine Ring

Reto Dorta,[a] Leonid Konstantinovski,[a] Linda J. W. Shimon,[b] Yehoshoa Ben-David,[a] and David Milstein*[a]

Keywords: Rhodium complexes / Mono- and dinuclear complexes / C−H activation / Rearrangement of norbornadiene / ^{1}H-^{15}N GHMBC NMR / X-ray structure

The tetradentate ligand 3,6-bis(2-pyridyl)pyridazine (dppn) was treated with cationic Rh^{I} precursors. The mononuclear complexes [Rh(dppn)(NBD)]BF_4 (**1**) and [Rh(dppn)(COD)]BF_4 (**5**) were obtained in quantitative yield when treating dppn with [Rh(NBD)$_2$]BF_4 or [Rh(COD)$_2$]BF_4 respectively. Treatment of **1** with a second equivalent of the metal precursor [Rh(NBD)(CH$_3$CN)$_2$]BF_4 led to the dinuclear complex [Rh$_2$(dppn-H)(NBD)(η^1-C$_7$H$_9$)(CH$_3$CN)$_2$](BF_4)$_2$ (**2**) [dppn-H = μ-C$_4$HN$_2$(C$_5$H$_4$N)$_2$-3,6], a mixed Rh^{I}–Rh^{III} complex. This complex arises from C–H activation of the pyridazine ring, followed by a unique rearrangement of the NBD ligand. Compound **2** was also obtained directly by treating dppn with 2 equiv. of [Rh(NBD)(CH$_3$CN)$_2$]BF_4. The complex [Rh$_2$(dppn-H)(NBD)(η^1-C$_7$H$_9$)(CH$_3$OH)$_2$(CH$_3$CN)](BF_4)$_2$ (**4**) was obtained by dissolving **2** in methanol. Full characterization of compounds **1**, **4** and **5** included an investigation by ^{1}H-^{15}N GHMBC NMR spectroscopy and single-crystal X-ray structures of **1** and **4**.

Introduction

Late transition metal systems with chelating nitrogen ligands are the subject of intense recent research due to their catalytic potential in processes such as the polymerization of olefins,[1] the selective C−H bond activation,[2] and the catalysis by monolayers.[3] The ease of C−H activation, when such ligands are employed, might depend on their inherently electron-rich nature. In particular, it has been shown that *ortho*-metalation of aromatic *N*-donor ligands by d^8-M^{I} complexes is strongly dependent on the basic properties of the metal precursor.[4] In addition, dinucleating ligands that can form homo- or heterodinuclear transition metal complexes with well-defined geometries are of considerable interest, considering the rapidly evolving area of dimetallic catalysts,[5] and supramolecular chemistry.[6] We thus decided to investigate the coordination chemistry of the tetradentate ligand 3,6-bis(2-pyridyl)pyridazine (dppn) towards cationic Rh^{I} precursors, especially in view of the fact that surprisingly little is known about its coordination behaviour and its reactivity with d^8-M^{I} metal precursors.[7]

In this paper we report the unexpected reactivity of this ligand towards cationic diene−Rh^{I} precursors (diene = norbornadiene and cyclooctadiene) giving rise to mono- and dinuclear complexes. Surprisingly, the dinuclear complex consists of an Rh^{I}−Rh^{III} complex arising from C−H activation of the pyridazine ligand, followed by a unique rearrangement of the norbornadiene ligand, rather than the expected *N*,*N*-coordinated bis(Rh^{I}) complexes. Full characterization of the resulting compounds included an investigation by ^{1}H-^{15}N GHMBC NMR spectroscopy and the single-crystal X-ray structures of two of them.

Results and Discussion

The ligand 3,6-bis(2-pyridyl)pyridazine (dppn) was synthesized in two steps in 45% overall yield. Lithiation of 2-bromopyridine with BuLi and subsequent reaction of the lithiated adduct with trimethyltin chloride yielded (2-pyridyl)trimethyltin in quantitative yield.[8] The second step consisted of a double Stille-type coupling between the organotin compound and 3,6-dichloropyridazine which was performed using Pd^0 or Pd^{II} catalyst precursors. The highest yield (45%) was obtained with 1 mol % of $PdCl(PPh_3)_2(CH_2Ph)$ as the catalyst.[9]

Upon addition of 1 equiv. of dppn to a stirred CH_2Cl_2 solution of [Rh(NBD)$_2$]BF_4 or [Rh(NBD)(CH$_3$CN)$_2$]BF_4, precipitation of a dark red solid took place within 30 min.

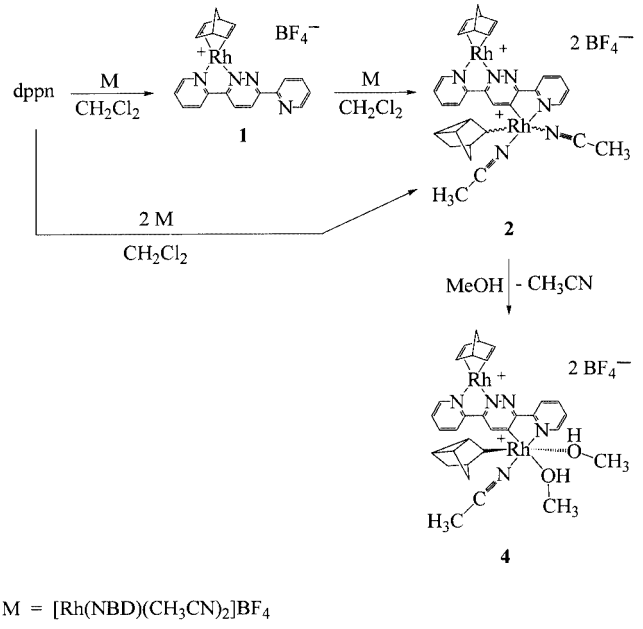
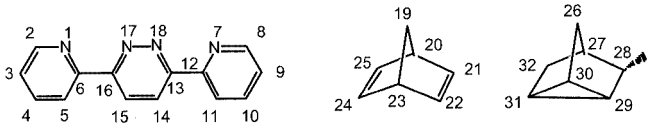
This compound was characterized as [Rh(dppn)(NBD)]BF_4 (**1**) (Scheme 1) using various NMR techniques. As expected, the ligand dppn gave rise to ten distinct signals in the ^{1}H NMR spectrum. Except for the routine NMR methods used for such organometallic compounds, we also performed a ^{1}H-^{15}N GHMBC experiment, a technique used for the characterization of bioorganic molecules,[10] but which has very rarely been applied to transition metal complexes.[11] The resulting spectrum clearly showed the four signals of the nitrogen atoms of dppn (Figure 1). The correlation provided their ^2J and ^3J couplings to the neighboring hydrogen atoms. Very clear shifts in the nitrogen spectrum were seen for N(1), N(17) and N(18) (for atom numbering see Scheme 2) and are given in Table 1. The noncoordinated pyridine moiety [N(7)] showed essentially the same shift as seen in the free ligand.[12] Furthermore, the two nitrogen atoms coordinated to the rhodium metal gave rise to coupling constants of $J_{N\text{-}Rh}$ = 20−30 Hz.



Scheme 1. Synthetic route to complexes **1**, **2** and **4**



Scheme 2. Numbering scheme used for the characterization of the compounds

Crystals of **1** suitable for an X-ray crystallographic analysis were grown by diffusion of diethyl ether into a concentrated solution of **1** in methanol and confirmed the structure. The crystal consists of discrete [Rh(dppn)(NBD)]$^+$ cations, BF_4^- counterions and methanol solvent molecules. An ORTEP view of the cationic complex with the atomic numbering scheme, together with selected bond lengths and angles, is shown in Figure 2. The Rh atom is in a square-

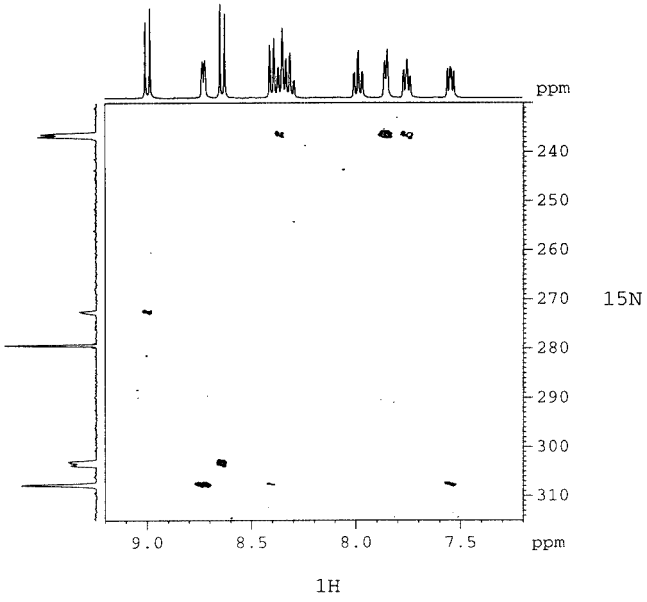


Figure 1. ^{1}H-^{15}N GHMBC NMR in CD_3NO_2 of complex **1**

planar arrangement with the two *cis*-nitrogen atoms of the dppn molecule acting as a bidentate chelating ligand through two neighboring pyridyl and pyridazinyl nitrogen atoms. As in complex **4** (see below), the N−Rh distance of the pyridazinyl is slightly shorter than the corresponding pyridyl N−Rh distance and concomitantly the Rh−olefin bond *trans* to it somewhat longer. The noncoordinating N atoms are mutually *trans* to each other with respect to the C(9)−C(10) (for atom numbering see Figure 2) axis, as previously observed in other crystallographically characterized mononuclear complexes of dppn.[7,13]

Treatment of **1** with a second equivalent of [Rh(NBD)-$(CH_3CN)_2$]BF_4 in CH_2Cl_2 led to the slow formation of a pink precipitate. The product was tentatively identified as the complex [Rh_2(dppn-H)(NBD)(η^1-C_7H_9)$(CH_3CN)_2$]-$(BF_4)_2$ (**2**) (Scheme 1) [dppn-H = μ-$C_4HN_2(C_5H_4N)_2$-3,6]. Characterization of **2** by NMR spectroscopy was hampered by its low solubility in noncoordinating, polar solvents. Despite this, the ^{1}H NMR spectrum in CD_2Cl_2 clearly showed that the dppn ligand was orthometalated on the pyridazine ring giving rise to only nine proton signals. Furthermore, two resonances at δ = 2.34 and 2.64 ppm were attributed to the two acetonitrile molecules bound to the Rh^{III} metal center.[14] The formulation of **2** was also supported by elemental analysis. When **2** was dissolved in the weakly coordinating solvent methanol, dissociation of one of the acetonitrile ligands (peak at δ = 2.34 ppm) was observed, leading most probably to a highly labile 14e-Rh^{III} complex. Slow addition of diethyl ether to a concentrated solution of **2** in methanol gave **4** as a deep red solid. Characterization of **4** by ^{1}H NMR in [D_4]methanol showed that indeed, both of the methanol molecules are highly labile and exchange rapidly with the deuterated solvent. The structure of the compound was elucidated by using various NMR techniques to assign all the protons and carbon atoms. Especially for complex **4**, the ^{1}H-^{15}N GHMBC

NMR experiment proved to be extremely informative (Table 1). As expected, the signal of one of the nitrogen atoms [N(18)] of the pyridazyl unit is not seen due to the lack of ^{2}J and ^{3}J coupling with any hydrogen atoms. In **4**, both pyridyl moieties are bound to the metal atom and show significant shifts of the signals of the nitrogen atoms [N(1) and N(7)] compared to those of the free ligand dppn. In addition, both nitrogen atoms [N(1) and N(7)] gave rise to coupling constants with the corresponding rhodium centers ($J_{N\text{-}Rh}$ = 24.7 and 42.4 Hz, respectively) as well as the coordinated pyridazyl nitrogen atom ($J_{N\text{-}Rh}$ = 40.2 Hz).[15] To unambiguously ascertain the exact structure of **4**, crystals suitable for X-ray crystallography were grown by slow diffusion of diethyl ether into a concentrated methanol/CH_2Cl_2 solution containing **4**. The ORTEP representation along with selected bond lengths and angles is shown in Figure 3. In complex **4**, the deprotonated ligand acts as a quadridentate ligand chelating the two metal atoms on opposite sides, one through one pyridyl and one pyridazinyl nitrogen atom, the other through one pyridyl nitrogen and one pyridazinyl carbon atom. The two metal centers differ in their geometry and their oxidation state, one being a square-planar Rh^{I} and the other an octahedral Rh^{III}. The part of the ligand with the square-planar metal atom shows nearly identical bond lengths and angles as seen in complex **1**. The octahedral metal atom is surrounded by the chelating C,N fragment of dppn, the 3-nortricyclyl unit, one acetonitrile and two methanol molecules. To the best of our knowledge, there are only two previous structural reports of methanol bonded to Rh^{III}, one involving a Cp^*Rh^{III} complex,[16] and the other one being $[RhCl_2(MeOH)(PCP)]$ [PCP = C_6H_3-2,6-$(CH_2PCy_2)_2$].[17] Interestingly, the two methanol molecules are *trans* to the two carbon fragments, whereas the acetonitrile molecule lies *trans* to the pyridine unit. The two methanol ligands show markedly different bond lengths to the metal atom: Rh(2)−O(2) is 2.202(3) Å, and Rh(2)−O(1) is 2.298(3) Å. This indicates that the latter is the additional sixth ligand with respect to the pentacoordinate complex **2**, whereas the methanol molecule *trans* to the pyridazyl moiety is the methanol ligand displacing the acetonitrile ligand of **2**. The lability of both methanol ligands is also reflected when comparing their metal−O bond lengths to the ones found in $[Cp^*Rh\{\eta^1(N7)\text{-}9\text{-}MH\}(CH_3OH)_2](OTf)_2\cdot CH_3OH$ (9-MH = 9-methylhypoxanthine).[16] In addition, the X-ray structure reveals that hydrogen bonding occurs between one of the coordinated methanol molecules and one of the fluorine atoms of tetrafluoroborate ($F_3BF\cdots HOCH_3$ 1.973 Å). Chelation on the

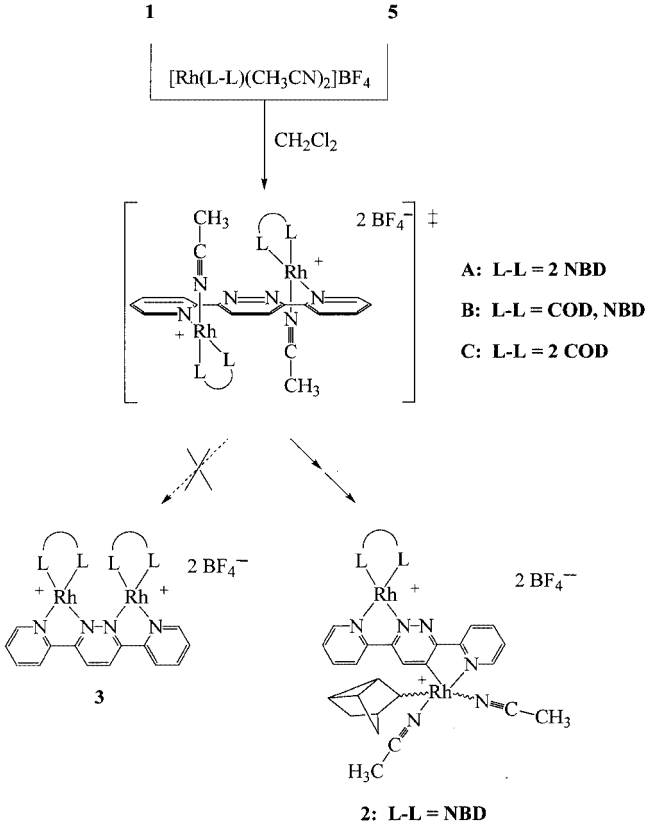
opposite side of the ligand gives rise to a relatively large separation between the two metal atoms (Rh···Rh 6.737 Å).

We thus clearly see that compounds **2** and **4** are the product of oxidative addition of the C−H bond on the pyridazine ring resulting in the formation of dinuclear Rh^{I}−Rh^{III} species. The C−H activation step is most probably followed by Rh−H addition to the double bond of the norbornadiene moiety and subsequent rearrangement of the norbonenyl molecule.[18] To the best of our knowledge, the rearrangement on a metal center of norbornadiene resulting in the formation of a 3-nortricyclyl ligand unit is unprecedented, although such rearrangements are thought to be involved in catalytic reactions such as the di- and trimerization of norbornadiene,[19] and catalytic amination reactions.[20] Complex **2** was also prepared directly by treating the ligand dppn with 2 equiv. of [Rh(NBD)$(CH_3CN)_2$]BF_4 in a CH_2Cl_2 solution (Scheme 1). To obtain a more detailed picture of this reaction, we monitored the transformation on a small scale in an NMR tube using deuterated dichloromethane. Although complex **1** is not very soluble in dichloromethane, the addition of 1 equiv. of [Rh(NBD)-$(CH_3CN)_2$]BF_4 to **1** gave a deep red solution. Recording the ^{1}H NMR spectrum after 10 min showed the formation of compound **A** (Scheme 3).[21] The formulation of this intermediate is supported by several characteristic peaks in the ^{1}H NMR spectrum. Firstly, the aromatic region shows 5 signals for the 10 hydrogen atoms of the ligand dppn indicating the presence of a symmetrical species. One of these signals (corresponding to 2 hydrogen atoms) is shifted downfield and is attributed to the α-hydrogen atoms on the two pyridyl moieties that are bound to the metal center. Furthermore, the signals of the NBD also indicate that both rhodium atoms are in an electronically equivalent situation. A peak at δ = 2.20 ppm for the methyl groups of the two acetonitrile ligands shows coordination of these molecules to the metal center {for [Rh(NBD)$(CH_3CN)_2$]BF_4 at δ = 2.30 ppm, the chemical shift of free CH_3CN is δ = 2.05 ppm}. After 30 min, the peaks of the product **2** can already be seen (ca. 10% by integration) and after 2 h, product **2** started to precipitate. During the transformation of **A** to **2**, the unknown dinuclear complex **3**, as shown in Scheme 3, was not observed. The X-ray structure of **1** shows that a complex such as **3** is not obtained most likely because of steric crowding of the two vicinal norbornadiene ligands. Furthermore, no hydride or norbornenyl were detected, indicating that the C−H activation step (or an earlier step) is probably rate-determining in the overall process.



Scheme 3. Reaction pathway of the mononuclear complexes **1** and **5** with a second equivalent of [Rh(diene)$(CH_3CN)_2$]BF_4

As expected, C−H activation did not take place when complex **1** in dichloromethane was treated with the relatively electron-poor complex $[Rh(NBD)_2]BF_4$. The reaction did also not take place in coordinating solvents such as acetonitrile, pyridine, acetone or methanol. Such coordinating solvents stabilize complexes of the type $[Rh(NBD)(solvent)_2]BF_4$ and retard binding to the pyridine moiety of dppn to give **A**. The unique rearrangement of NBD to the final 3-nortricyclyl unit seems to be a prerequisite in this reaction. To test this, we synthesized the analogous mononuclear cyclooctadiene complex $[Rh(dppn)(COD)]BF_4$ (**5**), which was fully characterized including by ^1H-^{15}N GHMBC NMR (Table 1). When **5** was treated with 1 equiv. of $[Rh(COD)(CH_3CN)_2]BF_4$ in deuterated dichloromethane, products arising from C−H activation were not observed, showing that if indeed C−H activation takes place, it is reversible and the resulting labile hydride does not insert into the double bond of the diene. Instead, the dinuclear complex **C**, analogous to **A**, was formed in this case (Scheme 3). On the other hand, when complex **5** was added to 1 equiv. of $[Rh(NBD)(CH_3CN)_2]BF_4$, we observed intermediate **B** before disappearance of the NBD signals and concomitant formation of the characteristic signals for 3-nortricyclyl were seen.[22] Interestingly, reaction of 2-phenylpyridine with 1 equiv. of $[Rh(NBD)(CH_3CN)_2]PF_6$ did not give any activation of the phenyl ring of this ligand. The unique reactivity of **1** might thus arise from the hindered rotation of the pyridazine ring as shown in structure **A** and the subsequently easier approach of the metal center towards the C−H bond.[23]

Summary

We have reported the reactivity of cationic diene−Rh^I complexes with the linear tetradentate ligand dppn. Clean formation of the mononuclear complexes **1** and **5** was observed when the corresponding precursors were treated with an equimolar amount of the ligand and the X-ray study of one of them (**1**) showed the expected chelation through two neighboring nitrogen atoms of dppn. Surprisingly, further reaction of **1** or **5** with $[Rh(NBD)(CH_3CN)_2]BF_4$ gave rise to C−H activation of the pyridazine ring of the ligand and a unique rearrangement of the norbornadiene yielding a 3-nortricyclyl ligand unit. Complete characterization includes the X-ray crystallographic study of complex **4**. Complexes **1**, **4** and **5** were also characterized by ^1H-^{15}N GHMBC NMR spectroscopy, a technique which proved extremely useful for the characterization of these complexes. Several control experiments showed that this reactivity is not only crucially dependent on the basicity of the metal precursor used, but that the presence of at least one metal precursor with coordinated NBD is a prerequisite. Furthermore, it seems to be unique to the ligand used, possibly by the influence of the *N*,*N*-coordinated metal center on the C−H activation process by the second metal center. Further work is underway to extend the chemistry of these dppn−Rh systems and to explore their catalytic potential.

Experimental Section

General Procedures: All experiments were carried out under purified nitrogen in a Vacuum Atmospheres glove box equipped with an MO 40−2 inert gas purifier. All solvents were reagent-grade or better. All nondeuterated solvents were refluxed in the presence of sodium benzophenone ketyl and distilled under argon. Deuterated solvents were used as received. All the solvents were degassed with argon and kept in the glove box over molecular sieves. Commercially available reagents were used as received. The complexes $[Rh(NBD)_2]BF_4$, $[Rh(NBD)(CH_3CN)_2]BF_4$, $[Rh(COD)_2]BF_4$ and $[Rh(COD)(CH_3CN)_2]BF_4$ [24] were prepared according to literature procedures. ^1H and ^{13}C (DEPT) 1D NMR spectra were recorded with a Bruker DPX-250 spectrometer. A Bruker DRX-400 spectrometer operating at 400.13 MHz (^1H), 100.61 MHz (^{13}C) or 40.54 MHz (^{15}N) was used for 2D spectra. The spectrometer was equipped with a 5-mm Bruker inverse multinuclear resonance probe with a single-axis (*z*) gradient coil. Measurements were carried out at a probe temperature of 25 °C using concentrations of ca. 20 mg/ml. 2D ^1H-^{13}C correlation spectra were acquired with 1 K points in F_2, 128−256 complex increments in F_1 and 4−8 scans per increment for GHMQC; 1 K−2 K points in F_2, 128−256 increments in F_1 and 8−16 scans for GHMBC experiments. 2D ^1H-^{15}N correlation spectra were measured using the Bruker standard microprogram GHMBC. The GHMBC spectra were collected with 2 K × 256 (512) data points and 96−120 scans for each increment using the spectral widths in F_1 and F_2 of ca. 8−9 ppm for proton and 100−300 ppm for nitrogen-15. The long-range delay was optimized for 50−60 ms. Apodization was done with a sine bell in both dimensions. All ^{15}N spectra were referenced to liquid ammonia. Abbreviations used in the description of NMR spectroscopic data are as follows: br., broad; s, singlet; d, doublet; t, triplet; m, multiplet. The atom numbering in Scheme 2 has been used for the characterization of the compounds. Elemental analyses were performed by H. Kolbe, Mikroanalytisches Laboratorium, 45470 Mülheim, Germany.

Synthesis of dppn: (a) Preparation of 2-$(CH_3)_3Sn(C_5H_4N)$: To a solution of BuLi (50.000 mmol) in diethyl ether (50.0 mL) at −78 °C was added dropwise a solution of 2-bromopyridine (7.90 g, 50.000 mmol) in diethyl ether (25.0 mL). The resulting solution was stirred at −78 °C for 2 h. $SnCl(CH_3)_3$ (9.95 g, 50.000 mmol), dissolved in THF (10.0 mL), was added dropwise and the resulting deep-red solution was warmed to room temperature overnight during which time a heavy precipitate formed. The precipitate was filtered off and the solution was concentrated in vacuo and distilled under reduced pressure (135 °C, ca. 10 Torr). Yield: 12.10 g, 100%. **(b) Preparation of dppn:** 2,6-dichloropyridazine (2.60 g, 17.450 mmol), $Sn(C_5H_4N)(CH_3)_3$ (10.60 g, 44.000 mmol) and $PdCl(Ph_3P)_2(CH_2Ph)$ (0.50 g, 0.661 mmol) were placed in a Schlenk tube containing xylenes (300.0 mL) and refluxed under argon for 24 h. The resulting brown solution was treated at 0 °C with a saturated solution of KF (210.0 mL) and diethyl ether (300.0 mL) was added. The slurry was stirred for 40 min and poured into H_2O (750.0 mL). The product was extracted with diethyl ether, dried ($MgSO_4$), filtered and concentrated in vacuo. Chromatography on deactivated silica (eluent: hexane/diethyl ether, 1:1) gave dppn as a golden-colored, crystalline material. Yield: 1.84 g, 45%. ^1H NMR ($CDCl_3$): δ = 7.41 (ddd, ^3J = 7.6, ^3J = 4.8, ^4J = 1.2 Hz, 2 H, 3,9-H), 7.91 (ddd, ^3J = 7.7, ^4J = 1.8 Hz, 2 H, 4,10-H), 8.70 (d, 2 H, 14,15-H), 8.76 (m, 4 H, 2,5,8,10-H) ppm. ^{13}C NMR ($CDCl_3$): δ = 121.92 (2 C, C-3,9), 125.53 (2 C, C-14,15), 125.77 (2 C, C-5,11), 138.10 (2 C, C-4,10), 150.52 (2 C, C-2,8), 154.29 (2 C, C-13,16), 159.03 (2 C, C-6,12) ppm. ^{15}N ($CDCl_3$): δ = 306.89 (s,

^{2}J with 2,8-H, ^{3}J with 3,5,9,11-H, 2 N, N-1,7), 387.98 (s, ^{3}J with 14,15-H, 2 N, N-17,18) ppm. MS (EI): m/z = 235 [M^{+}].

Preparation of [Rh(dppn)(NBD)]BF$_4$ (1): A solution of dppn (100.0 mg, 0.427 mmol) in CH_2Cl_2 (3.0 mL) was added to a solution of [Rh(NBD)$_2$]BF$_4$ (159.0 mg, 0.427 mmol) in CH_2Cl_2 (3.0 mL). Stirring the resulting red solution at room temperature led to the precipitation of a deep red solid. The suspension was stirred for another 3 h, the solid filtered, washed with diethyl ether (2 times 5.0 mL) and dried in vacuo. Yield: 220.0 mg, 100%. Crystals suitable for an X-ray analysis were grown by slow concentration of a concentrated solution of **1** in methanol. ^{1}H NMR (CD_3NO_2): δ = 1.61 (br. s, 2 H, 19-H), 4.19 (br. s, 2 H, 20,23-H), 4.77 (br. s, 4 H, 21,22,24,25-H), 7.55 (ddd, ^{3}J = 7.5 Hz and 4.8, ^{4}J = 0.9 Hz, 1 H, 9-H), 7.76 (ddd, ^{3}J = 7.4 Hz and 5.3, ^{4}J = 1.3 Hz, 1 H, 3-H), 7.87 (d, ^{3}J = 5.1 Hz, 1 H, 5-H), 8.00 (ddd, ^{3}J = 7.8, ^{4}J = 1.7 Hz, 1 H, 10-H), 8.32 (ddd, ^{3}J = 7.8, ^{4}J = 1.4 Hz, 1 H, 4-H), 8.36 (d, ^{3}J = 7.7 Hz, 1 H, 2-H), 8.40 (d, ^{3}J = 8.0 Hz, 1 H, 11-H), 8.64 (d, ^{3}J = 9.0 Hz, 1 H, 15-H), 8.73 (d, ^{3}J = 4.6 Hz, 1 H, 8-H), 9.00 (d, ^{3}J = 9.0 Hz, 1 H, 14-H) ppm. ^{13}C NMR (CD_3OD): δ = 52.16 (d, $^{3}J_{Rh,C}$ = 2.5 Hz), 63.55 (d, $^{2}J_{Rh,C}$ = 6.1 Hz), 66.50 (d, $^{1}J_{Rh,C}$ = 9.8 Hz), 121.84, 123.69, 126.20, 127.84, 128.27, 128.45, 137.82, 141.25, 150.05, 150.26, 151.16, 153.59, 159.92 ppm. ^{15}N NMR (CD_3NO_2): δ = 242.45 (d, ^{2}J with 2-H, ^{3}J with 3-H and 5-H, $^{1}J_{N,Rh}$ = 19.3 Hz, 1 N, N-1), 271.03 (d, ^{3}J with 14-H, $^{2}J_{N,Rh}$ = 10.6 Hz, 1 N, N-18), 309.21 (s, ^{3}J with 9-H and 11-H, 1 N, N-7, ^{2}J with 8-H), 312.04 (d, ^{3}J with 15-H, $^{1}J_{N,Rh}$ = 20.2 Hz, 1 N, N-17) ppm. $C_{21}H_{18}BF_4N_4Rh$ (516.13): calcd. C 48.87, H 3.52, N 10.86; found C 48.81, H 3.54, N 10.80.

In situ Characterization of A: A solution of [Rh(NBD)(CH$_3$CN)$_2$]BF$_4$ (12.5 mg, 0.034 mmol) in CD_2Cl_2 (0.5 mL) was added to a suspension of [Rh(dppn)(NBD)]BF$_4$ (17.6 mg, 0.034 mmol) in CD_2Cl_2 (0.5 mL). The resulting red solution was transferred to an NMR tube and the spectrum was measured after 10 min. ^{1}H NMR (CD_2Cl_2): δ = 1.43 (s, 4 H), 2.20 (br. s, 6 H), 3.99 (br. s, 4 H), 4.45 (br. s, 8 H), 7.68 (dt, 2 H), 8.18 (dd, 2 H), 8.30 (d, 2 H), 8.36 (d, 2 H), 9.18 (s, 2 H) ppm.

In situ Characterization of C: A solution of [Rh(COD)(CH$_3$CN)$_2$]BF$_4$ (15.0 mg, 0.039 mmol) in CD_2Cl_2 (0.5 mL) was added to a suspension of [Rh(dppn)(COD)]BF$_4$ (21.0 mg, 0.039 mmol) in CD_2Cl_2 (0.5 mL). The resulting deep red solution was transferred to an NMR tube and the spectrum was measured. ^{1}H NMR (CD_2Cl_2): δ = 2.07 (d, br, 4 H), 2.28 (s, 6 H), 2.49 (br. s, 4 H), 4.58 (br. s, 8 H), 7.73 (dt, 2 H), 8.17 (dd, 2 H), 8.37 (d, 2 H), 8.48 (br, 2 H), 9.18 (s, 2 H) ppm.

Preparation of [Rh$_2$(dppn-H)(NBD)(η^1-C$_7$H$_9$)(CH$_3$CN)$_2$](BF$_4$)$_2$ (2): A solution of [Rh(NBD)(CH$_3$CN)$_2$]BF$_4$ (37.4 mg, 0.103 mmol) in CH_2Cl_2 (3.0 mL) was added to a suspension of [Rh(dppn)(NBD)]BF$_4$ (53.0 mg, 0.103 mmol) in CH_2Cl_2 (3.0 mL). The resulting red solution was stirred overnight during which time a slow precipitation of a pink solid occurred. The solid was recovered, washed with diethyl ether and dried in vacuo. Yield: 67.0 mg, 74%. ^{1}H NMR (CD_2Cl_2): δ = 0.8−1.5 (several m, 7 H), 1.54 (s, 2 H), 1.71 (br. s, 1 H), 2.34 (s, 3 H), 2.51 (br. s, 1 H), 2.64 (s, 3 H), 4.09 (br. s, 2 H), 4.56 (br. s, 4 H), 7.52−7.68 (m, 3 H), 8.04 (dt, not well defined, 1 H), 8.15 (m, 1 H), 8.28 (dt, J = 7.7 Hz, 1 H and 1.5 Hz), 8.72 (m, 2 H), 8.89 (br. s, 1 H) ppm. $C_{32}H_{32}B_2F_8N_6Rh_2$ (880.10): calcd. C 43.67, H 3.67, N 9.55; found C 44.29, H 3.76, N 9.36.

Preparation of [Rh$_2$(dppn-H)(NBD)(η^1-C$_7$H$_9$)(CH$_3$OH)$_2$(CH$_3$CN)](BF$_4$)$_2$ (4): Complex **2** (80.0 mg, 0.091 mmol) was dissolved in methanol (3.0 mL) and stirred at room temperature for 1 h. Addition of diethyl ether to the resulting red solution led to the precipitation of a red solid that was filtered, washed with additional diethyl ether and dried in vacuo. Yield: 76.0 mg, 93%. Crystals suitable for X-ray crystallography were obtained by slow diffusion of diethyl ether into a concentrated methanol/CH_2Cl_2 solution and subsequent slow concentration. ^{1}H NMR (CD_3OD): δ = 0.82 (dd, ^{3}J = 11.5 Hz, 2 H, 26-H), 0.86 (br. s, 1 H, 27-H), 1.02 (d, J = ca. 9 Hz, 1 H, 32-H), 1.10 (br. s, 1 H, 30-H), 1.04 (s, 1 H, 29-H), 1.16 (d, J ca. 9 Hz, 1 H, 32-H), 1.32 (br. s, 1 H, 31-H), 1.60 (s, 2 H, 19-H), 2.58 (br. s, 1 H, 28-H), 2.75 (s, 3 H, CH_3CN), 4.14 (br. s, 2 H, 20,23-H), 4.69 (t, ^{3}J = 2.0 Hz, 4 H, 21,22,24,25-H), 7.73 (ddd, ^{3}J = 7.7 Hz and 5.3, ^{4}J = 1.1 Hz, 1 H, 3-H), 7.76 (ddd, ^{3}J = 6.0, ^{4}J = 1.2 Hz, 1 H, 9-H), 7.92 (d, ^{3}J = 5.2 Hz, 1 H, 2-H), 8.24 (ddd, ^{3}J = 7.8, ^{4}J = 1.4 Hz, 1 H, 10-H), 8.31 (ddd, ^{3}J = 7.6 Hz,^{4}J = 1.6 Hz, 1 H, 4-H), 8.32 (d, ^{3}J = 7.4 Hz, 1 H, 8-H), 8.71 (d, 5, ^{3}J = 8.2 Hz, 1 H), 8.73 (d, ^{3}J = 8.0 Hz, 1 H, 11-H), 8.82 (s, 1 H, 15-H) ppm. ^{13}C NMR (CD_3OD): δ = 3.41 (CH_3CN), 13.45 (C-27), 13.86 (C-29), 19.18 (C-30), 33.26 (C-26), 34.27 (C-32), 37.10 (C-31), 45.29 (d, C-28), 53.31 (d, J = 2.3 Hz, 2 C, C-20,23), 64.78 (d, J = 5.8 Hz, C-19), 67.24 (t, J = 9.0 Hz, 4 C, C-21,22,24,25), 123.41 (C-8), 125.29 (C-5), 125.62 (br, CH_3CN), 128.62 (C-9), 129.22 (C-3), 135.28 (C-15), 141.53 (C-9), 142.55 (C-4), 151.37 (2 C, C-2,11), 155.08 (C-6), 156.51 (C-13), 160.56 (C-12), 169.44 (C-16) ppm. ^{15}N NMR (CD_3OD): δ = 174.10 (^{3}J with CH_3CN, $^{1}J_{N,Rh}$ = 45.9 Hz, 1 N, CH_3CN), 234.51 (d, ^{2}J with 8-H, ^{3}J with 9-H and 11-H, $^{1}J_{N,Rh}$ = 42.4 Hz, 1 N, N-7), 238.32 (d, ^{2}J with 2-H, ^{3}J with 3-H and 5-H, $^{1}J_{N,Rh}$ = 24.7 Hz, 1 N, N-1), 283.20 (d, ^{3}J with 15-H, $^{1}J_{N,Rh}$ = 40.2 Hz, 1 N, N-17) ppm. $C_{32}H_{37}B_2F_8N_5O_2Rh_2$ (903.13): calcd. C 42.56, H 4.13, N 7.75; found C 42.85, H 4.15, N 7.98.

Preparation of [Rh(dppn)(COD)]BF$_4$ (5): A solution of dppn (79.1 mg, 0.338 mmol) in CH_2Cl_2 (3.0 mL) was added to a solution of [Rh(COD)$_2$]BF$_4$ (137.1 mg, 0.338 mmol) in CH_2Cl_2 (3.0 mL). The resulting solution was stirred at room temperature for 24 h. Some of the compound readily precipitated from the solution. Addition of diethyl ether led to complete precipitation of a green compound that was washed with diethyl ether and dried in vacuo. Yield: 174.0 mg, 97%. ^{1}H NMR (CD_3NO_2): δ = 2.29 (m, 4 H, CH_2 of COD), 2.63 (m, 4 H, CH_2 of COD), 4.92 (s, 4 H, 4 olefins COD), 7.54 (ddd, ^{3}J = 7.6, 4.8, ^{4}J = 1.2 Hz, 1 H, 9-H), 7.80 (ddd, ^{3}J = 7.4, 5.4, ^{4}J = 1.4 Hz, 1 H, 3-H), 7.97 (ddd, ^{3}J = 7.8, ^{4}J = 1.7 Hz, 1 H, 10-H), 8.05 (d, 5, ^{3}J = 5.3 Hz, 1 H), 8.31 (ddd, ^{3}J = 7.8, ^{4}J = 1.5 Hz, 1 H, 4-H), 8.38 (m, 2 H, 2,11-H), 8.64 (d, ^{3}J = 9.1 Hz, 1 H, 15-H), 8.75 (dd, ^{3}J = 4.8 Hz, 1 H, 8-H), 9.09 (d, ^{3}J = 9.1 Hz, 1 H, 14-H) ppm. ^{15}N NMR (CD_3NO_2): δ = 235.13 (d, ^{2}J with 2-H, ^{3}J with 3-H and 5-H, $^{1}J_{N,Rh}$ = 26.0 Hz, 1 N, N-1), 271.05 (s, ^{3}J with 14-H, 1 N, N-18), 300.24 (d, $^{1}J_{N,Rh}$ = 20.5 Hz, ^{3}J with 15-H, 1 N, N-17), 307.71 (s, ^{3}J with 9-H and 11-H, ^{2}J with 8-H, 1 N, N-7) ppm. $C_{22}H_{22}BF_4N_4Rh$ (532.17): calcd. C 49.65, H 4.17, N 10.53; found C 49.60, H 4.14, N 10.39.

X-ray Crystal Structure Determination of 1 and 4: Single crystals of **1** and **4** were mounted on a nylon loop and flash-frozen in a nitrogen stream at 120 K. Data were collected with a Nonius Kappa CCD diffractometer mounted on an FR590 generator equipped with a sealed tube with Mo-K_α radiation (λ = 0.71073 Å) and a graphite monochromator. The structures were solved using direct method with SHELXS-97 and refined by full-matrix least-squares technique with SHELXL-97 based on F^2.[25] CCDC-183245 (**1**), and -183246 (**4**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Center, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Complex 1: $C_{21}H_{18}N_4Rh{\cdot}BF_4{\cdot}CH_3OH$, dark orange, plates, 0.10 × 0.10 × 0.05 mm, triclinic, $P\bar{1}$ (no. 2), a = 7.887(2), b = 11.904(2), c = 12.564(3) Å, α = 110.10(3), β = 99.17(3), γ = 98.63(3)° from 20° of data, V = 1066.6(4) Å^3, Z = 2, M_w = 548.16, $D_{calcd.}$ = 1.707 Mg/m^3, μ = 0.859 mm^{-1}. The final cycle of refinement based on F^2 gave an agreement factor R = 0.0336 for data with $I > 2\sigma(I)$ and R = 0.0437 for all data (5490 reflections) with a goodness-of-fit of 1.017. Idealized hydrogen atoms were placed and refined in riding mode.

Complex 4: $C_{32}H_{37}N_5Rh_2{\cdot}(BF_4)_2{\cdot}CH_2Cl_2$, red, 0.2 × 0.2 × 0.2 mm, triclinic, $P\bar{1}$, a = 12.114(2), b = 12.400(2), c = 15.136(3) Å, α = 67.58(3), β = 83.86(3), γ = 69.04(3)° from 20° of data, V = 1961.6(6) Å^3, Z = 2, M_w = 988.03, $D_{calcd.}$ = 1.673 Mg/m^3, μ = 1.053 mm^{-1}. The final cycle of refinement based on F^2 gave an agreement factor R = 0.0497 for data with $I > 2\sigma(I)$ and R = 0.0537 for all data (8833 reflections) with a goodness-of-fit of 1.055. Idealized hydrogen atoms were placed and refined in riding mode.

[12] The unexpectedly large shift for signal of the noncoordinated N(18) nitrogen atom in complexes **1** and **5** (compared to that of the free ligand) might be due to the influence of the coordinated Rh−N(17) moiety adjacent to it.

[13] [13a] A. M. Manotti Lanfredi, A. Tiripicchio, M. Ghedini, G. De Munno, *Acta Crystallogr., Sect. B* **1982**, *38*, 1165−1168. [13b] M. Ghedini, M. Longeri, F. Neve, *Inorg. Chim. Acta* **1987**, *132*, 223−228. [13c] R. Dorta, L. J. W. Shimon, D. Milstein, unpublished results.

[14] Such pentacoordinated Rh^{III} complexes are fairly common; for recent examples from this laboratory, see: R. Goikhman, D. Milstein, *Angew. Chem. Int. Ed.* **2001**, *40*, 1119−1122.

[15] In general, the Rh−N coupling constants in complexes **1, 4** and **5** seem to follow a trend with smaller coupling constants for Rh^{I} than for Rh^{III} [except for Rh−N(17) in **4**]. Studies on other rhodium complexes are needed in order to confirm this observation.

[21] Attempts to isolate intermediates **A**, **B** and **C** gave mixtures containing some starting and/or final product.

[22] Unfortunately, the resulting complex could not be isolated as a clean compound.

[23] Alternatively, C−H activation of the electron-rich pyridazyl ring might be easier than C−H activation of a phenyl ring.

Dedicated to Professor Dr. Rüdiger Mews on the occasion of his 60th birthday

Keywords: Antiaromaticity / Fluorinated 1,3λ⁴δ²,2,4-benzodithiadiazines / Electrophilic cyclisation / Molecular structure / NICS / Nucleophilic cyclisation

The series of title compounds has been prepared through both electrophilic ($C_6H_nF_{5-n}$–N=S=N–$SiMe_3$ + SCl_2) and nucleophilic (C_6HF_4–S–N=S=N–$SiMe_3$ + CsF) intramolecular *ortho*-cyclisation reactions, and the former route seems to be the more effective. High regioselectivity of the ring-closing procedures is observed in both cases. The compounds were characterised by X-ray crystallography and multinuclear (^{1}H, ^{13}C, ^{15}N and ^{19}F) NMR spectroscopy. In accordance with GIAO calculations, ^{15}N{^{1}H} experiments and the effects observed on complete substitution of hydrogen by fluorine, the high-field signal in the ^{15}N NMR spectra can be assigned to N-4 and the low-field signal to N-2. In the crystal, 5,6,7-trifluoro- (**5**) and 5,6,8-trifluoro-1,3λ⁴δ²,2,4-benzodithiadiazine (**6**) are planar, whereas the 6,8-difluoro derivative **3** is bent along the S1···N4 line by 8.3°. According to NICS calculations the heterocycle moiety in this compound class is antiaromatic while the carbocycle is aromatic. The fluorine substituents increase the aromaticity – and in some cases (especially when a fluorine atom is present in the 8-position) the antiaromaticity – of the corresponding rings. The *ortho*-fluoro-containing starting material $C_6H_nF_{5-n}$–N=S=N–$SiMe_3$ (n = 2: **10**) cyclises to the fluorinated 2,1,3-benzothiadiazole **27** upon treatment with CsF instead of SCl_2. For starting compound 6-HC_6F_4–S–N=S=N–$SiMe_3$ (**14**) the planar (*Z*,*E*) configuration features a short intramolecular H···N contact, as evidenced by X-ray diffraction. Both the reaction pathways mentioned are also discussed.

1. Introduction

Hyperelectronic (π- and σ-excessive) 1,3λ⁴δ²,2,4-benzodithiadiazines[1−4] **1** (Scheme 1) reveal a nontrivial combination of definite features of antiaromaticity[5] with moderate thermal stability. In particular, the compounds in series **1** possess a cyclic 12π-electron system with a notably low IE_1 [6−8] in planar or nearly planar molecular conformations observed both in the gas phase[9] and in the crystal,[1−4] low-lying π*-excited states[1−4,10] localised predominantly on the heterocycle,[11] and enhanced magnetic shielding of the ^{1}H, ^{13}C and ^{19}F (for the monofluoro derivatives) nuclei attached to C-5 and C-8 − i.e., those closest to the heterocycle − with respect to those attached to C-6 and C-7,[1,3,4] this probably being due to paratropic ring currents.[5] At the same time, the compounds in series **1** are thermally stable up to ca. 100 °C. At higher temperatures and in dilute hydrocarbon solutions, compounds **1** quantitatively yield persistent 1,2,3-benzodithiazolyl radicals (Scheme 1),[10,12] which are also the products of photolysis reactions of **1**.[10,13] The key intermediates are singlet 1,2,3-benzodithiazol-2-ylnitrenes (Scheme 1), identified under matrix isolation conditions.[13] The other aspects of the heteroatom reactivity of **1** have been studied only to a limited extent. Since both the π-excess and the antiaromaticity are destabilising factors, one might believe that the heteroatom reactivity of **1** should be high; consequently, many new reactions should be found in which this reactivity takes on many different forms. Additionally, several new structures should no doubt be observed among the reaction products of **1**. Currently, however, the only fact that is known is that the compounds in series **1** are able to iminate some S^{II} [4]

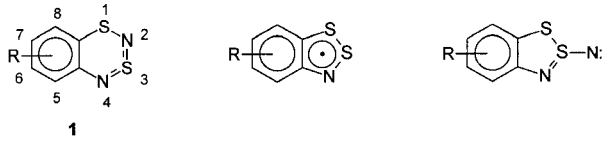
and P^{III} [14] derivatives oxidatively, another reaction most probably mediated by the nitrenes mentioned above. Reversible cycloaddition to norbornadiene[1] as well as reduction and hydrolysis to 2-aminobenzenethiols (isolated in the form of their corresponding disulfides)[3] have also been described.



1

In this work, compounds **1**: R = H (**2**), 6,8-F_2 (**3**), 6,7-F_2 (**4**), 5,6,7-F_3 (**5**), 5,6,8-F_3 (**6**), 5,6,7,8-F_4 (**7**)

Scheme 1

The fluorinated compounds in series **1** are all unknown except for the 5-, 6- and 7-fluoro derivatives[3,4] and the 5,6,7,8-tetrafluoro derivative.[2] Nevertheless, they are interesting not only from a general point of view, but also in the context of further investigation of the peculiarities of the molecular and electronic structures of these compounds. For instance, it was found by gas electron diffraction (GED) that a free molecule of the parent 1,3$\lambda^4\delta^2$,2,4-benzodithiadiazine **2** is bent significantly, while a free molecule of its tetrafluoro derivative **7** is planar.[9] The bent geometry of the former was attributed to pseudo-Jahn−Teller distortion to minimize the antiaromaticity,[4,9] whereas the planar geometry of the latter was thought to be due to a conflict between the pseudo-Jahn−Teller effect and the perfluoro (or π-fluoro) effect, caused by the presence of a fluorine atom in the 8-position, resolved in favour of the latter.[9] To verify this conclusion it is necessary to perform GED on 6,8-difluoro- (**3**) and 5,6,7-trifluoro-1,3$\lambda^4\delta^2$,2,4-benzodithiadiazine (**5**), the free molecules of which would be expected to be planar and bent, respectively, and these experiments are currently underway.

This work deals with the preparation and X-ray structural characterisation of a number of new fluorinated derivatives of 1,3$\lambda^4\delta^2$,2,4-benzodithiadiazine **2**, as well as with the quantitative estimation of the (anti)aromaticity of the compounds in series **1** for both the fluorocarbon and the hydrocarbon series, by application of the Nucleus-Independent Chemical Shift (NICS) concept.[15] On the basis of the theoretical calculations, a more detailed structural study was also performed for all fifteen possible fluoro-substituted 1,3$\lambda^4\delta^2$,2,4-benzodithiadiazines.

2. Results and Discussion

The monofluorinated compounds of series **1** had previously been synthesised by 1:1 condensation of the corresponding Ar−N=S=N−$SiMe_3$ with SCl_2, followed by the electrophilic *ortho*-cyclisation of the [Ar−N=S=N−S−Cl] intermediates.[3,4] The tetrafluoro derivative **7** was obtained by the nucleophilic ring-closure of the intermediate $[Ph_F-S-N=S=N]^-$ anion generated from Ph_F−S−N=S=N−$SiMe_3$ and CsF.[2] Both approaches were applied in this work.

2.1. Electrophilic Cyclisation

The Ar−N=S=N−$SiMe_3$ starting materials **8**−**10** (Scheme 2) for the electrophilic ring-closure procedure were synthesised by a general method[3,4,16,17] from the corresponding Ar−N=S=O compounds and $LiN(SiMe_3)_2$. Earlier, the less common $Me_3SnN(SiMe_3)_2$ was used to transform the polyfluorinated Ar−N=S=O into Ar−N=S=N−$SiMe_3$.[18,19] Further treatment of **8**−**10** with SCl_2 afforded the desired compounds **3**−**5** (Scheme 2). From these experiments it appears that the introduction of up to three fluorine atoms into the carbocycle does not deactivate Ar−N=S=N−$SiMe_3$ toward the electrophilic cyclisation needed to obtain **1**. It should be noted that only 75% of the stoichiometric amount of SCl_2 was used in these preparations, so as to suppress any further reaction of **3**−**5** with SCl_2, it having previously been found that the compounds in series **1** readily react with SCl_2 to yield 1,2,3-benzodithiazolium chlorides (Herz salts).[4]

8, **11**: R = 3,5-F_2; **9**, **12**: R = 3,4-F_2; **10**, **13**: R = 2,3,4-F_3

Scheme 2

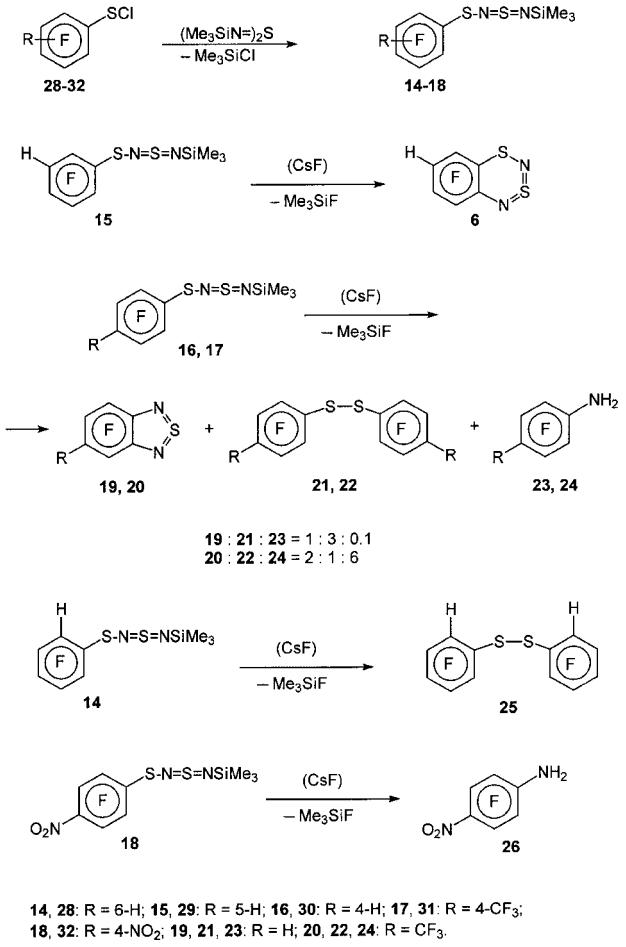
The cyclisation proved to be effectively regioselective in the case of **9**, which possesses two non-equivalent positions at which the ring-closure may occur (cf. refs.[3,4]). Only **4** (Scheme 2) was isolated from the reaction mixture, and the second possible isomer was not detected. It had previously been shown[3] that the regioselectivity in these types of cyclisation reactions is consistent with the thermodynamics of the corresponding intermediate σ complexes as well as with factors of kinetic control for an orbital-controlled electrophile-nucleophile reaction. At the same time, the ratio of the isomers observed in the reaction mixture is obviously affected by the difference in their rates of reaction with SCl_2.[4] The structures of **3** and **5** were confirmed by X-ray crystallography (see below).

As reaction by-products, the corresponding sulfur diimides $(Ar-N=)_2S$ were identified in all cases. One can explain their formation in terms of dimerisation of [Ar−N=

S=N−S−Cl] intermediates through [2π + 2π] cycloaddition reactions, followed by decomposition of the nonsymmetric dimers to $(Ar-N=)_2S$ and the well-known $[S_3N_2Cl]Cl$.[20] Dilution of the reaction solutions reduces the yields of the $(Ar-N=)_2S$ by-products.

2.2. Nucleophilic Cyclisation

The $Ar_F-S-N=S=N-SiMe_3$ starting materials **14**−**18** (Scheme 3) for the nucleophilic cyclisation reactions were obtained through the known 1:1 condensation of the corresponding Ar_FSCl compounds with $(Me_3SiN=)_2S$.[2,3,19] The structure of **14** was confirmed by X-ray crystallography (Figure 1). The planar (*Z*,*E*) configuration features a short intramolecular H···N contact or hydrogen bond (cf. hydrocarbon analogues[21]).



Scheme 3

The compounds **14**−**18** were treated with CsF in boiling acetonitrile (cf. ref.[2]) in an attempt to close the ring and obtain the target heterocycles; this was successful only in the case of **15** (Scheme 3). The cyclisation of **15** to **6** again proved to be highly regioselective, since the second possible isomer was not observed. It had previously been shown,[19] for the closely related nucleophilic cyclisation reactions affording polyfluorinated naphtho[1,2-*c*][1,2,5]thiadiazoles,

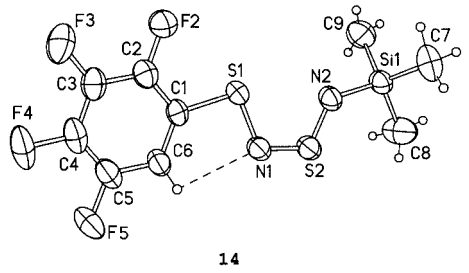


Figure 1. Molecular structure of **14**; selected bond lengths [Å] and bond angles [°]: C1−S1 1.762(3), S1−N1 1.662(3), N1−S2 1.552(3), S2−N2 1.494(3), N2−Si1 1.748(3), N1−H 2.504; C1−S1−N1 98.55(15), S1−N1−S2 116.19(15), N1−S2−N2 113.58(15), S2−N2−Si1 129.17(19)

that the preferred direction of the ring-closure is consistent with essentially the same factors as described above for the electrophilic cyclisation reactions. The structure of **6** was confirmed by X-ray crystallography (see below).

In the cases of **16** and **17**, only polyfluorinated 2,1,3-benzothiadiazoles **19** and **20** (i.e., the smaller-sized heterocycles) could be detected in the reaction mixtures, along with the corresponding Ar_FSSAr_F and Ar_FNH_2 derivatives (in different ratios). In the case of **14** (a potential precursor of **5**: see Scheme 2), however, only the disulfide **25** (Scheme 3) was identified by ^{19}F NMR in the crude reaction product, and was subsequently isolated; in the case of **18** only amine **26** (Scheme 3) was obtained in high yield.

Similar thiadiazoles, disulfides and/or amines had previously been obtained from unsuccessful attempts to prepare fluorinated naphthalene- and pyridine-fused 1,3λ⁴δ²,2,4-dithiadiazines from the corresponding $Ar_F-S-N=S=N-SiMe_3$ derivatives upon treatment with CsF[3,19] (cf. also the formation of the corresponding disulfide, rather than the target compound **2**, from $2\text{-}O_2NC_6H_4-S-N=S=N-SiMe_3$ on treatment with CsF[2]). The results were attributed then to both low nucleophilicity and thermal stability of the $[Ar_F-S-N=S=N]^-$ anions and explained in terms of: (1) *ipso*-cyclisation followed by ring-opening reactions to form $[Ar_F-N=S=N-S]^-$ anions, (2) elimination of sulfur and *ortho*-cyclisation of $[Ar_F-N=S=N]^-$ anions to form thiadiazoles, or (3) decomposition to Ar_FNH_2. The decomposition of $[Ar_F-S-N=S=N]^-$ anions before cyclisation yields Ar_FSSAr_F.[3,19]

The same explanation is obviously valid for this work. The difference between the successful $Ar_F-S-N=S=N-SiMe_3$-based syntheses of the title compounds (Ar_F = C_6F_5,[2] 5-HC_6F_4) and their failed counterparts (Ar_F = 6-HC_6F_4, 4-HC_6F_4) is in accordance with the known relative propensities of fluorine atoms in different positions of partially fluorinated aromatic compounds to nucleophilic substitution.[22] In the case of **14** one can also consider that the intramolecular H···N interaction (see Figure 1) stabilises the $[Ar_F-S-N^--S\equiv N]$ thiazylamide form of the intermediate anion (cf. refs.[17,23,24]) more than the $[Ar_F-S-N=S=N]^-$ sulfur diimide one, the former obviously being unable to cyclise in either *ortho* or *ipso* fashion. Taking into

account the high yield of cyclisation of the [4-$F_3CC_6F_4NSN]^-$ anion to the corresponding thiadiazole under the same conditions,[25] one can also explain the predominant formation of amine **24** from compound **17** (Scheme 3) by the direct decomposition of the [4-$F_3CC_6F_4NSNS]^-$ anion to the radical anion [4-$F_3CC_6F_4N]^{\cdot -}$, followed by reaction with the solvent to give the final product **24**. This explanation is also applicable to the formation of **26** from **18** (Scheme 3).

Thus, the synthetic usefulness of the nucleophilic approach to fluorinated 1,3$\lambda^4\delta^2$,2,4-benzodithiadiazines is limited. On the other hand, this type of cyclisation reaction is a convenient method for the synthesis of fluorinated 2,1,3-benzothiadiazoles.[16,19,25] For example, compound **10** (the precursor of **5** under electrophilic cyclisation conditions; Scheme 2) afforded fluorinated thiadiazole **27** in good yield upon treatment with CsF (Scheme 4).

2.3. X-ray Molecular Structures and Comparison with Calculated Gas-Phase Data

According to X-ray crystallography[1–4] and gas electron diffraction[9] data, as well as post-HF and DFT calculations,[4,9,11] the compounds in series **1** are structurally nonrigid because they possess a low-energy vibrational mode that allows the molecule to be deformed easily upon going from the gas phase to the solid. For example, a molecule of **2** is significantly bent along the S1···N4 line in the gas phase[9] and perfectly planar in the crystal.[1] In contrast, a molecule of **7** is flat in the gas phase[9] and folded in the solid state.[2] (For an in-depth discussion of the structures of **2** and **7** in the two phases, including an analysis of the experimental gas-phase geometries, see ref.[9]; the results of GED measurements on **3** and **5** will be published elsewhere.) The 6-fluoro derivative of **2** is nearly planar in the crystal.[3] This structural dichotomy is also observed for compounds **3**, **5** and **6** in the crystal (Figure 2 and Table 1). According to X-ray diffraction data, molecules **5** and **6** are planar, whilst a molecule of **3** is bent along the S1···N4 line by 8.3°; this is the largest deviation from planarity so far found in the solid state for fluoro-containing compounds of series **1**.[2,3] For compound **4** the crystals obtained were not suitable for X-ray diffraction.

The bond lengths and bond angles of **3**, **5** and **6** (Table 1) are typical.[1–4,9] As in the parent compound **2** and the tetrafluoro derivative **7**, four of the π-electrons in the heterocycle are localised to some extent in two of the N–S bonds, giving rise to one long and two short bonds. We also note that the bond lengths in the N=S=N moiety of **5** are practically identical, as also found for **2**,[1] whereas for **3** and **6** they are slightly different, as found for **7**.[2]

Thus, in the crystal, compound **2** and its 5-F_3C, 6-F, 7-Br, 7-H_3CO, 5,6,7-F_3 (**5**) and 5,6,8-F_3 (**6**) derivatives are planar, whereas the 5-H_3CO, 5-Br, 6-H_3C, 8-Br, 6,8-F_2 (**3**) and 5,6,7,8-F_4 (**7**) derivatives are bent along the S1···N4 line by up to 10.8° (for the 5-H_3CO derivative) (see refs.[1–4] and this work). Of the two crystallographically independent molecules of the 6-Br derivative, one is perfectly planar whereas the other is bent by 3.1°, which directly indicates the importance of packing effects.[4]

Table 1 also compares the solid-state geometries with those obtained in the gas phase by calculation, for those derivatives for which crystal structures exist. The choice of the method/basis set combination was based on previous calculations on **2** and **7**, which showed that B3LYP/6-311+G* performs quite well for these systems, unlike MP2, which incorrectly reproduces the conformation of the heterocycle.[9] (Cartesian coordinates and energies for **2** and its fifteen fluorinated derivatives can be found in the Supporting Information; symmetries and relative energies can be found in Table 3). The calculations rigorously maintain the equal bond lengths in the N=S=N fragment for all sixteen compounds; the largest difference is 0.005 Å. However, the localisation of the π-electrons in the heterocycle is adequately reproduced. The variation in the N=S bond lengths for the various derivatives is negligible: for N2–S3 this is limited to 0.005 Å, and for S3–N4 to 0.006 Å. The values in Table 1 illustrate this. For the S–N single bond,

[a] Bond lengths in Å and bond angles in °. [a] For atomic numbering see Scheme 1 and Figure 2.

S1−N2, the variation is larger, amounting to 0.021 Å, and seems to depend on the presence of the fluorine atom in the 8-position and thus on the conformation of the heterocycle. If the atom is present and the compound has C_s symmetry, the S1−N2 bond is shorter, as is again illustrated in Table 1. The typical C−C double/single-bond alternation, as observed in the calculations on **2** and **7**,[9] is found for all other compounds in the series and thus seems to be independent of the number and position of the fluorine atoms.

A closer look at the various C−F bond lengths displays some interesting patterns. The C−F distance for a particular position (i.e., C5, C6, C7 or C8) is shorter when that fluorine atom has another fluorine atom *ortho* to it than when it does not, which corresponds to the known shortening of the C−F bond in r_0 structures observed by microwave spectroscopy on going from fluorobenzene to 1,2-difluorobenzene.[26] The difference in the bond lengths between these two situations depends on the position of the fluorine atom: for F5 and F8 the difference is limited to 0.009 Å on average and for F6 and F7 it is 0.012 Å on average. In any of the derivatives of **2**, the C8−F8 distance is always the largest, C7−F7 and C6−F6 are intermediate and the C5−F5 bond length is the shortest. The four torsion angles that define the conformation of the heterocycle (see ref.[9] for further details) do not vary significantly with the number and the position of the fluorine atoms. The largest differences for each angle range from 1.0° for C5−C4a−C8a−S1 through 1.9° (N4−C4a−C8a−S1) and 2.4° (S3−N2−S1−C8a) to 3.8° for C4a−C8a−S1−N2.

2.4. Spectral Properties

The experimental assignment of the ^{1}H and ^{13}C NMR spectra of compound **2**, the parent compound in the **1** series, is based on double resonance, COLOC and off-resonance techniques. For the fluorinated derivatives, mono-resonance and off-resonance techniques as well as analyses of ^{1}H-^{1}H, ^{1}H-^{19}F, ^{13}C-^{19}F and ^{19}F-^{19}F spin-spin coupling constants were used to obtain full assignments. These are given in Table 2.

In the ^{15}N{^{1}H} NMR spectrum of **2**, the signal at δ = 263.1 ppm is a doublet on selective decoupling with 8-H, but a singlet on selective decoupling with 5-H. From this, it is possible to assign the signal at δ = 263.1 ppm to N-4 and the signal at δ = 269.2 ppm to N-2. This is also in agreement with an empirical analysis of the ^{15}N NMR spectroscopic data for various 5-, 6-, 7- and 8-R substituted derivatives of **2**.[3] Comparison of ^{15}N and ^{15}N{^{1}H} NMR spectra (see footnotes to Table 2; the latter feature the lack of the N^4-H^5 spin-spin coupling, cf. ref.[3]) unambiguously identifies the high-field resonance of the 6-F derivative of **2** as well as of compounds **3** and **4** as N-4 and the low-field resonance as N-2. For the previously studied compounds of series **1**, the δ^{15}N values lie in a narrow range of ca. 280−250 ppm (except for **7**[2]), with a weak dependence on the nature of the carbocyclic substituent. In the case of polyfluorinated derivatives **5**, **6** (Table 2) and **7**,[2] one nitrogen resonance is shifted to higher field (up to δ = 233 ppm for **7**[2]). It is known for related heterocycles that replacement of the four hydrogen atoms by fluorines increases the ^{15}N shielding in 2,1,3-benzothiadiazole but does not affect the δ^{15}N of 1,3λ⁴δ²,5,2,4-benzotrithiadiazepine.[27,28] Consequently, and in agreement with the discussion above, it is feasible that the high-field signal in the ^{15}N NMR spectra of **5**−**7** belongs to N-4 and the low-field signal to N-2. In agreement with the experiment, the GIAO calculations systematically predict that the N-2 nucleus of the studied compounds should be definitely deshielded relative to the N-4 nucleus for all but the 5-fluoro derivative, since the calculations for this last compound fail to predict the coincidence of both signals. For the 7-fluoro derivative the experimental assignment is difficult, but from the excellent qualitative agreement between theory and experiment for the other derivatives, one can be confident in again assigning the high-field signal to N-4 and low-field signal to N-2. Quantitative prediction of the δ^{15}N values, on the other hand, is prob-

[a] The doublet at δ = 275.7 ppm is not changed on going to the $^{15}N\{^1H\}$ spectrum; thus, the corresponding spin-spin coupling constant (ca. 2.2 Hz) is not $^3J(N^4\text{-}H^5)$ (cf. ref.[3]) and the signal does not belong to N-4. [b] Uncertain experimental assignments. [c] The doublet of doublets of doublets at δ = 250.1 ppm becomes a doublet of doublets on going to the $^{15}N\{^1H\}$ spectrum while the triplet at δ = 265.4 ppm is not affected. [d] The quadruplet at δ = 258.8 ppm becomes a triplet on going to the $^{15}N\{^1H\}$ spectrum while the signal at δ = 265.0 ppm is not affected.

lematic: DFT performs better than HF but the rms deviation for all the compounds under consideration in Table 2 is still δ = 103.9 ppm for HF and 60.0 ppm for DFT.

A similar observation can be made for the δ^{19}F values. Here, the rms differences are 8.6 and 3.6 ppm respectively. The spread in the specific values of the different compounds is larger for this nucleus, but HF seems to do better when the number of fluorine atoms increases. Both methods do, however, qualitatively reproduce the spectrum of all compounds, except for **6**, in which 5-F and 6-F have been switched. The assignments of the ^{19}F NMR spectrum of **7**, previously uncertain,[2] can now be confidently made, on the basis of the superior DFT shifts.

For the ^{1}H NMR spectrum, the difference in performance of the two methods is a considerably smaller: the rms values are now 0.56 ppm for HF and 0.49 ppm for DFT, with HF performing better than DFT for compounds with a larger number of fluorine atoms. The only false prediction found for this nucleus, by both methods, is for the 6-fluoro derivative, in which 5-H and 8-H have been switched, but since both the calculated and the experimental differences in chemical shifts are very small, solvent effects can be used to account for this discrepancy.

For the δ^{13}C values, the rms differences for both methods are comparable: 2.6 ppm for HF and 2.7 ppm for DFT, but, in contrast to what was found for hydrogen, the performance of HF deteriorates relative to that of DFT when the number of fluorine atoms increases. The rather surprising fact that DFT falters slightly in the case of the carbon chemical shifts, when it had been clearly superior for the other nuclei, may be explained in terms of basic density functional theory. This indicates that the usual theorems do not hold in the presence of an external magnetic field and the functional has to depend both on the electron density ρ and the current density *j*, induced by the magnetic field.[29] The functionals used here, including B3LYP, do not, and this may explain why DFT would be less reliable for compounds or specific fragments of compounds in which the effect of the current density *J* is logically larger, such as the aromatic ring in these 1,3λ⁴δ²,2,4-benzodithiadiazines. Only for the parent compound **2** and its 6-fluoro and 7-fluoro derivatives are the ^{13}C chemical shifts reproduced perfectly by both methods. For both **4** and **6** the two methods agree on the chemical shifts and the previously uncertain experimental assignments can be confidently made. For the 5-fluoro derivative of **2**, DFT switches C-4a and C-7 and incorrectly reproduces the shifts of C-6, C-8 and C-8a − the small difference calculated for C-8 and C-6 might explain this, even though the HF calculation displays the same small difference yet makes a correct prediction. In the case of compound **5**, DFT switches C-5 and C-6 but the small calculated difference may again be the cause. For **7** the assignments of C-5 and C-8 can now be made unambiguously, from the results of both methods, but those of C-6 and C-7 remain doubtful. Compound **3** fares the worst where HF is concerned, since only C-4a is correctly predicted and the rest is switched; even though DFT performs better, the correct assignment of C-6 and C-8 remains a problem.

Despite the small problems that remain, the two methods used here perform generally well on a qualitative and sometimes even on a quantitative level. More sophisticated computational methods were not evaluated since computational time and efficiency become an important factor in those cases, and an evaluation of that type is beyond the scope of this study.

The most interesting feature of the NMR spectra of previously studied compounds of series **1**[1,3,4] is the enhanced shielding of the ^{1}H, ^{13}C and ^{19}F nuclei (for the *mono*fluoro derivatives) attached to C-5 and C-8 − i.e., those closest to the heterocycle − as compared to those attached to C-6 and C-7, probably due to paratropic ring currents. However, this is not the case for **3**−**6** (Table 2) and **7**.[2] The GIAO calculations at HF and B3LYP levels of theory (Table 2) reproduce these shielding patterns. However, the results of these calculations cannot be interpreted in chemical terms. One can only think that for **3**−**7** the mutual influence of the fluorine atoms dominates all other effects on δ^{19}F.

The long-wavelength absorption maxima in the UV/Vis spectra of compounds **3**−**6** (Table 5) and **7**[2] are found in the 620−635 nm range (i.e., essentially the same as for the non-fluorinated analogues),[1,3,4] with only a weak dependence upon the number and positions of the fluorine substituents. These results are in agreement with the conclusion,[11] based on resonance Raman data, that the low-energy electronic transition in the UV/Vis spectra, responsible for the blue colour of solutions of the compounds in series **1**, is localised mainly on the sulfur−nitrogen chain.

2.5. Antiaromaticity

The aromaticity or antiaromaticity of π-systems is characterised by a combination of energetic, geometric and magnetic criteria. Application of these criteria usually yields different, and very frequently contradictory, results.[5] In these situations the Nucleus-Independent Chemical Shift (NICS) concept[15] appears to be a useful criterion for the quantification of (anti)aromaticity. For all 15 possible (poly)fluorinated compounds, and also the parent, the NICS values both of the carbocycle and of the heterocycle were calculated at the HF level of theory, together with a selected number at the DFT/B3LYP level, and studied as a function of the number and the position of fluorine atoms.

The heterocyclic ring of the parent compound **2** has a positive NICS value and is antiaromatic, whilst the carbocyclic ring has a negative value and is aromatic (Table 3). In comparison, at the same level of theory, but with the B3LYP/6-31G* geometry, the NICS values for benzene, naphthalene and D_{4h}-cyclooctatetraene are δ = −9.7, −9.9 and 30.1 ppm[15] (for a minireview on the antiaromaticity of planar cyclooctatetraene, see ref.[30]). For 1,3λ⁴δ²,5,2,4-trithiadiazepine (10π-electron sulfur−nitrogen heterocycle) this value is δ = −9.3 ppm.[31] The NICS values (Table 3) also show that fluorination increases the aromaticity of the carbocyclic moieties of the compounds in series **1**. These effects have been discussed previously with respect to fluor-

Table 3. Calculated NICS values (ppm) for all possible fluoro-substituted 1,3λ^{4}δ^2,2,4-benzodithiadiazines and the parent compound **2** in their minimum energy conformations [B3LYP/6-311+G* geometries and energies, except for C_1-**7** for which the MP2/6-31G* geometry was used (see ref.[9] for details)]; values at HF/6-31+G* and B3LYP/6-31+G* levels and relative energies ΔE [kJ·mol^{-1}] are given for each isomer

Compound	ΔE	Conformation	HF/6-31+G*		B3LYP/6-31+G*

inated pyridines and pyridones and were explained in terms of the increased π-electron density in the ring system due to the positive mesomeric effect from the fluorine substituents.[32] The antiaromaticity of the heterocyclic moieties of the compounds in series **1** also depends on the number of fluorine substituents, but in a more complicated way. In some cases fluorine substituents increase the antiaromaticity (Table 3), whereas in some other cases (cf. **2**, **4** and **5**) fluorination does not affect the NICS value for the heterocycle.

The positions of the fluorine substituents seem to be of importance, especially the presence of a fluorine atom in the 8-position (cf. **2** and its 8-F, 5,8-F_2 and 6,7,8-F_3 derivatives **3**, **6** and **7** in Table 3): the very position responsible for the flattering of the heterocyclic ring on going from **2** to **7**.[9] It is clear from the results of the HF calculations in Table 3 that the presence of the fluorine atom in the 8-position and the resulting increase in symmetry to C_s reduces the aromaticity of the carbocycle and increases the antiaromaticity of the heterocycle, roughly by about 1 and 5 ppm, respectively. This effect can also be seen in the DFT calculations, but the shifts in NICS values are larger there. There is no relation between NICS values and energetic stabilisation.

The NICS values of the carbocycle at the DFT level seem unexpectedly low, at least in comparison with the data of other compounds described above, while those at the HF level "fit" better. However, from the discussion of the performance of both levels of theory in the prediction of NMR shifts it is difficult to assess which of the two methods generates the more "reasonable" values. On the other hand, if the value for **2** at the DFT level is taken at face value, one might be inclined to assume the compound's carbocycle is non-aromatic (NICS close to zero), which is clearly incorrect. Apart from the difference in scale, this is the only item that distinguishes the two methods.

Table 3 also lists data for two transition states (TS): the planar conformation of **2** and the nonplanar one of **7**. Even though the differences between TSs and ground states are not extreme, the values for the TSs − especially those for the heterocycle − are clearly located outside the set of the values for the ground states; this may be seen as an additional criterion for the assignment of the electronic states of a given conformer.

From the NICS values (Table 3 and ref.[15]), one can conclude that the antiaromaticity of the heterocycle moiety in compound **2** is about 1/3 of the antiaromaticity of D_{4h} cyclooctatetraene. According to recent estimations of resonance energy, however, the destabilization of D_{4h} cyclooctatetraene due to the cyclic interaction of the π bonds (i.e., the antiaromaticity) is negligible.[30] Taking these findings into account, along with the fact that only the heterocyclic moieties of the compounds in series **1** are antiaromatic, whereas the carbocyclic moieties are aromatic (and the C4a−C8a) bond belongs to both moieties at the same time), as well as other available data on these compounds' molecular and electronic structures[1−4,6−9,11] and thermal stabilities,[10,12] one can speculate that, in terms of the aromaticity/antiaromaticity concept,[5] 1,3λ^{4}δ^2,2,4-benzodithiadiazines could reasonably be classified on the whole as conjugated non-aromatic substances.

3. Conclusions

Novel fluorinated derivatives of 1,3λ^{4}δ^2,2,4-benzodithiadiazines (series **1**) have been prepared and characterised structurally. They are interesting not only from structural

and theoretical points of view, the latter including an extension of the aromaticity/antiaromaticity concept to non-traditional compounds, but also for applications in synthesis. As noted above, hydrolysis of the compounds in series **1** produces 2,2′-diaminodiphenyl disulfides.[3] The latter are well-known starting materials in the preparation of 1,5-benzothiadiazepines with anti-anginal and anti-hypertensive activities.[33] In this context one can believe that these fluorinated derivatives (from this work and refs.[2−4]) have some prospects in the synthesis of currently unknown fluorinated 1,5-benzothiadiazepines with potentially useful pharmacological properties.

Experimental Section

General: The ^{1}H, ^{13}C and ^{15}N NMR spectra were measured in $CDCl_3$ (unless otherwise indicated) with a Bruker DRX 500 spectrometer at frequencies of 500.13, 125.76 and 50.68 MHz, respectively, with TMS and NH_3 (liq.) as standards; the ^{19}F NMR spectra were recorded with a Bruker AC 200 machine at a frequency of 188.28 MHz with C_6F_6 as the standard. The high-resolution mass spectra (EI, 70 eV) were collected with a Finnigan MAT MS-8200 instrument, and the UV/Vis spectra were recorded with Specord M40 and HP 8453 spectrophotometers. The GC-MS measurements of solutions in CH_2Cl_2 were performed with a Hewlett−Packard G1800A GCD apparatus.

The X-ray structure determinations (Table 4) were carried out with a Bruker P4 diffractometer with the use of Mo-K_α radiation with a graphite monochromator, at −30 °C for **5** and **6**, and at 20 °C for **3** and **14**. The structures were solved by direct methods by use of the SHELXS-97 program and refined by the least-squares method in the full-matrix anisotropic (isotropic for H atoms) approximation by use of the SHELXL-93 and SHELXL-97 programs. The structure of **6** was refined as a merohedric twin (the law of twinning is 100, 0−10, 00−1). Hydrogen atoms were located on difference Fourier maps for **5** and **14**, or geometrically for **3** and **6**. Atomic coordinates, thermal parameters, bond lengths and bond angles; CCDC-178645 (**3**), -178646 (**5**), -178647 (**6**), and -178648 (**14**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Theoretical calculations were performed with Gaussian98,[34] by application of standard gradient techniques at the DFT/B3LYP level of theory using the 6-31G* and the 6-311+G* basis sets on all atoms; all basis sets were used as implemented in the program. Initially, the geometries of all compounds were optimised at the B3LYP/6-31G* level in C_s symmetry and force field calculations were used to ascertain whether the resulting structures were energy minima. When necessary, the symmetry was reduced in the subsequent B3LYP/6-311+G* calculation. Chemical shielding factors were calculated at all atomic positions and at both ring centres (non-weighted mean of the heavy-atom coordinates) for the NICS values, both at the HF/6-31+G* and B3LYP/6-31+G* levels, at the B3LYP/6-311+G* geometry, by use of the GIAO method implemented in Gaussian 98. Chemical shifts for the carbon and hydrogen atoms were obtained by subtracting the chemical shielding values of these atoms from those calculated for tetramethylsilane (TMS), which are δ = 200.7499 and 32.6074 ppm, respectively, at the HF/6-31+G* level, and δ = 191.6496 and 32.1776 ppm, respectively, at the B3LYP/6-31+G* level, based on a B3LYP/6-311+G* geometry. Chemical shifts for the fluorine atoms were obtained by subtracting the chemical shielding values of these atoms from that calculated for hexafluorobenzene (C_6F_6), which is δ = 388.5052 ppm at the HF/6-31+G* level and 347.9219 ppm at the B3LYP/6-31+G* level, based on a B3LYP/6-311+G* geometry. Chemical shifts for the nitrogen atoms were obtained by subtracting the chemical shielding values of these atoms from that calculated for ammonia (NH_3), which is 266.1027 ppm at the HF/6-

31+G* level and 263.9129 ppm at the B3LYP/6-31+G* level, based on a B3LYP/6-311+G* geometry.

The Ar_FSCl compounds **28** (Ar_F = 6-HC_6F_4)[35] and **30** (Ar_F = 4-HC_6F_4)[36] were prepared by known methods. The syntheses described below were carried out under argon (except for **29**, **31** and **32**) in absolute solvents with stirring. The reagents were added dropwise, and the solvents were distilled off at reduced pressure. CsF was calcinated and SCl_2 was distilled directly before use. Tables 5 and 6 list the physical and analytical data for the compounds synthesised.

6,8-Difluoro- (3), 6,7-Difluoro- (4) and 5,6,7-Trifluoro-1,3λ⁴δ²,2,4-benzodithiadiazine (5): Solutions of the corresponding Ar−N=S=N−$SiMe_3$ compounds (**8**−**10**, 0.010 mol) and SCl_2 (0.77 g, 7.50 mmol) in CH_2Cl_2 (30 mL) were mixed by adding them to 300 mL (600 mL in the preparation of **5**) of CH_2Cl_2 at 40 °C over a period of 1 h. After an additional hour, the reaction mixture was cooled to 20 °C and filtered, the solvent was distilled off, and the residue was sublimed under vacuum and recrystallised from hexane (to purify **5** at least three sublimation-recrystallisation cycles were necessary). Compounds **3**−**5** were obtained as black crystals.

5,6,8-Trifluoro-1,3λ⁴δ²,2,4-benzodithiadiazine (6): A solution of compound **15** (1.57 g, 0.005 mol) in MeCN (20 mL) was added over 1 h to a refluxing suspension of CsF (0.76 g, 0.005 mol) in MeCN (80 mL). After an additional 1/2 h, the reaction mixture was cooled to 20 °C and filtered, the solvent was distilled off, and the residue was sublimed under vacuum and recrystallised from hexane. Compound **6** was obtained as black crystals.

1-Fluoroaryl-3-trimethylsilyl-1,3-diaza-2-thiaallenes 8−10: A solution of the corresponding ArNSO compound **11**−**13** (0.060 mol) in hexane (25 mL) was added at −30 °C to a suspension of LiN($SiMe_3$)$_2$ (10.00 g, 0.060 mol) in hexane (50 mL). The temperature was allowed to rise to 20 °C over 2 h, and Me_3SiCl (6.60 g, 0.060 mol) in hexane (10 mL) was added. The precipitate was filtered off, the solvent was distilled off, and the residue was distilled under vacuum. Compounds **8**−**10** were obtained as orange oils.

1-Polyfluoroaryl-4-trimethylsilyl-2,4-diaza-1,3-dithia-2,3-butadienes 14−18: A solution of the corresponding Ar_FSCl compound **29**−**33** (0.025 mol) in CH_2Cl_2 (10 mL) was added at 20 °C (this temperature was −30 °C in the syntheses of **17** and **18**, followed by slow warming to 20 °C) over a period of 1 h to a solution of $Me_3SiN=)_2S$[19] (5.15 g, 0.025 mol) in CH_2Cl_2 (25 mL). After an additional 16 h, the solvent was distilled off, the residue was distilled under vacuum (for **15** and **16**) or recrystallised from hexane (for **14**, **17** and **18**), followed (for **18**) by vacuum sublimation. Compounds **15** and **16** were obtained as red oils, and compounds **14**, **17** and **18** as transparent yellow crystals.

Transformations of Compounds 14 and 16−18 by Treatment with CsF: A solution of the corresponding compound **14** or **16**−**18** (0.050 mol) in MeCN (20 mL) was added over a period of 1 h to a refluxing suspension of CsF (0.76 g, 0.005 mol) in MeCN (80 mL). After an additional 1/2 h, the reaction mixture was cooled to 20 °C and filtered, and the solvent was distilled off. The residue was worked up as follows:

Starting Compound 14: The residue was chromatographed on a silica column with hexane as the eluent. 2,2′,3,3′,4,4′,5,5′-Octafluoro-

Found (calcd.) % Cl: **29**: 16.22 (16.40); **31**: 12.25 (12.48); **32**: 13.70 (13.58).

diphenyl disulfide (**25**,[37] identified by high-resolution MS and ^1H and ^{19}F NMR) was obtained as yellow oil in a 10% yield.

Starting Compound 16: The residue was distilled under vacuum, yielding, according to GC-MS and ^{19}F NMR, 0.10 g of a 1:3:0.1 mixture of 4,5,7-trifluoro-2,1,3-benzothiadiazole (**19**)[25] 2,2′,3,3′,5,5′,6,6′-octafluorodiphenyl disulfide (**21**)[38] and 2,3,5,6-tetrafluoroaniline (**23**).[39]

Starting Compound 17: The residue was distilled under vacuum, yielding, according to GC-MS and ^{19}F NMR, 0.35 g of a 2:1:6 mixture of 4,6,7-trifluoro-5-trifluoromethyl-2,1,3-benzothiadiazole (**20**),[25] 4,4′-bis(trifluoromethyl)-2,2′,3,3′,5,5′,6,6′-octafluorodiphenyl disulfide (**22**),[40] and 2,3,5,6-tetrafluoro-4-(trifluoromethyl)-aniline (**24**).[41]

Starting Compound 18: The residue was sublimed under vacuum and recrystallised from hexane/$CHCl_3$. 2,3,5,6-Tetrafluoro-4-nitroaniline (**26**,[42] identified by comparison of its m.p. and ^1H and ^{19}F NMR spectra with those of an authentic[42] sample) was obtained as yellow crystals in 74% yield.

4,5-Difluoro-2,1,3-benzothiadiazole (27): A solution of compound **10** (1.32 g, 0.005 mol) in MeCN (20 mL) was added over 1 h to a refluxing suspension of CsF (0.76 g, 0.005 mol) in MeCN (80 mL). After an additional hour, the reaction mixture was cooled to 20 °C and filtered, the solvent was distilled off, and the residue was chromatographed on a silica column (with $CHCl_3$ as the eluent) and sublimed under vacuum followed by recrystallisation from hexane. Compound **27** was obtained as colourless crystals.

Polyfluorinated *N*-Sulfinylarylamines 11−13: The Ar−N=S=O compounds were prepared by Michaelis reaction from the corresponding $ArNH_2$ (Aldrich) and $SOCl_2$ in benzene. After the usual workup, compound **11** was obtained as yellow crystals (from hexane), and compounds **12** and **13** as yellow oils.

2,3,4,6-Tetrafluoro- (29), 2,3,5,6-Tetrafluoro-4-trifluoromethyl- (31) and 2,3,5,6-Tetrafluoro-4-nitrophenylsulfenyl Chloride (32): An excess of dry Cl_2 was slowly passed through a solution of the corresponding Ar_FSH [Ar_F = 5-HC_6F_4 (**33**), 4-$F_3CC_6F_4$,[41,43] 4-$O_2NC_6F_4$ [44]] in CCl_4 (40 mL) at ambient temperature. The solvent was distilled off and the residue was distilled (for **29** and **31**) or sublimed (for **32**) under vacuum. Compounds **29** and **31** were obtained as red oils, and compound **32** as yellow crystals.

2,3,4,6-Tetrafluorobenzenethiol (33): A solution of BuLi (4.78 g, 0.075 mol) in hexane (50 mL) was added at −80 °C to a solution of 1,2,3,5-tetrafluorobenzene (11.32 g, 0.075 mol) in Et_2O (70 mL). After 1 h, finely powdered sulfur (2.40 g, 0.075 mol) was added to the reaction solution at the same temperature. The temperature was allowed to rise to 20 °C, and the reaction mixture was quenched with 1:2 diluted HCl (25 mL). The organic layer was separated, washed with H_2O (20 mL) and dried with $CaCl_2$. The solvent was distilled off and the residue was distilled under vacuum. Compound **33** was obtained as a colourless liquid.

Fluorinated 1,3-Diaryl-1,3-diaza-2-thiaallenes (34−36): The $(Ar-N=)_2S$ compounds [Ar = 3,5-$F_2C_6H_3$ (**34**), 3,4-$F_2C_6H_3$ (**35**), 2,3,4-$F_3C_6H_2$ (**36**)] were obtained as by-products in the preparations of compounds **3**−**5**, respectively, and were isolated as orange-yellow crystals by fractional sublimation followed by recrystallisation from hexane.

Acknowledgments

The Novosibirsk authors are grateful to Mrs. Nina F. Yakusheva for her assistance in the preparations, and to the Russian Foundation for Basic Research for financial support of their work (grants 99-03-33115 and 01-03-06190) including instrumental facilities at the Collective Analytical Center of the Siberian Division of the Russian Academy of Sciences (grant 00-03-40135), and for access to the Cambridge Structural Database (grant 99-07-90133) and to the STN International databases via the STN Center at their Institute (grant 00-03-32721). A.Yu. M. is also grateful to the Siberian Division of the Russian Academy of Sciences for the N. N. Vo-

rozhtsov Award for young scientists. F. B. and C. V. A. gratefully acknowledge support by the University of Antwerp under grant GOA-BOF-UA No. 23.

The Ambivalent Bonding of the 3(5)-Isopropylpyrazolyl Moiety in Homo- and Heteroscorpionate Hydrobis(3-R_1-5-R_2-pyrazolyl)(*y*-isopropylpyrazolyl)-boratocobalt(II) Complexes (y = 3 or 5)[‡]

Keywords: Cobalt / Borates / N ligands / NMR spectroscopy

The synthesis of hydrotris(pyrazol-1-yl)borate ligands (Tp^x) by condensation of sodium borohydride with 3(5)-isopropylpyrazole and either 5(3)-methyl-3(5)-phenylpyrazole or 3,5-diphenylpyrazole gave the novel heteroscorpionate ligands hydrobis(5-methyl-3-phenylpyrazolyl)(5-isopropylpyrazolyl)-borate and hydrobis(3,5-diphenylpyrazolyl)(5-isopropylpyrazolyl)borate, respectively. These were converted into $CoTp^x(NCS)$ complexes as well as $CoTp^x_2$ in the case of the former ligand. In an attempted synthesis of heteroscorpionates bearing two y-isopropylpyrazolyl moieties (y = 3 or 5) formation of the homoscorpionate hydrotris(3-isopropylpyrazolyl)borate along with the above-mentioned heteroscorpionates was noticed; no formation of the desired heteroscorpionates could be detected. The bis[hydrobis(5-methyl-3-phenylpyrazolyl)(5-isopropylpyrazolyl)borato]cobalt(II) and tetrahydrofuranothiocyanatobis[hydrobis(5-methyl-3-phenylpyrazolyl)(5-isopropylpyrazolyl)borato]cobalt(II) tetrahydrofuran solvate complexes were studied by X-ray crystallography. Two Tp^x ligands provide six nitrogen donors from pyrazol-1-yl residues to form a Tp^x_2Co complex in which two 5-isopropylpyrazolyl rings are placed in a plane of symmetry, whereas the same Tp^x ligand is bound in an η^3 fashion in the pentacoordinate $[CoTp^x(NCS)(THF)]\cdot THF$ complex, in which a nitrogen atom from thiocyanate and an oxygen atom from THF complete the coordination sphere of the central metal ion. These compounds as well as the complexes thiocyanatohydrobis(3,5-diphenylpyrazolyl)(5-isopropylpyrazolyl)boratocobalt(II) and thiocyanatohydrotris(3-isopropylpyrazolyl)boratocobalt(II) were characterized by ^1H NMR and IR spectroscopy.

Introduction

Tris(pyrazolyl)borate anions (Tp^x) provide three *cis*-arranged nitrogen donors that are able to coordinate to transition metal ions, leaving the remaining coordination sites of the central metal ion to perform extraneous chemistry with more weakly bound ligands.[1] The stereochemistry of these reactions can be influenced by the symmetry of the Tp^x moiety, including the induction of asymmetry in catalytic reactions. One of the approaches used successfully for the latter is based on the preparation of Tp^x ligands containing chiral substituents attached to the periphery of Tp^x.[2−4] Another approach for the formation of chiral Tp^x ligands is the synthesis of heteroscorpionates composed of three different pyrazolyl residues.[5] Here we describe the synthesis of heteroscorpionates composed of two different pyrazoles, which were separated from the post-synthetic mixture as their cobalt(II) complexes.

Results and Discussion

Spontaneously formed heteroscorpionate tris(pyrazolyl)borate ligands can be obtained during the condensation of the borohydride anion with 3(5)-R-pyrazoles or 3(5)-R_1-5(3)-R_2-pyrazoles. The first spontaneous heteroscorpionate ligand was synthesized by Trofimenko, who isolated the bis-ligand complex $[Co\{HB(3\text{-}i\text{Prpz})_2(5\text{-}i\text{Prpz})\}_2]$.[6] At that time it was not clear if the heteroscorpionate was formed during the synthesis of $NaTp^x$ or exclusively during the conversion of the homoscorpionate $[HB(3\text{-}i\text{Prpz})_3]^-$ (Tp^{iPr}) into the heteroscorpionate upon heating of the $[Co(Tp^{iPr})_2]$ complex. In the latter case the driving force of the borotropic shift of the 3-isopropyl- into the 5-isopropylpyrazolyl moiety could be the release of steric clashes between six 3-isopropyl substituents around the metal ion. Later it was demonstrated that heteroscorpionate ligands are also formed during the condensation of pyrazoles with borohydrides.[7,8] This ambivalency of 3- versus 5- substitution of 3(5)-R_1-5(3)-R_2-pyrazoles can be used to construct mixed-pyrazole or even chiral Tp^x ligands.

We have used 3(5)-isopropylpyrazole for the synthesis of heteroscorpionate Tp^x ligands in order to study the bonding ambivalency of 3(5)-isopropylpyrazole in synthetic, mixed-pyrazole heteroscorpionates. The 5(3)-methyl-3(5)-phenyl-

[‡] Complexes of Heteroscorpionate Trispyrazolylborate Anionic Ligands, VII. Part VI: Ref. [9]

[b] Faculty of Chemistry, University of Wrocław, 14 Joliot-Curie Str., 50-383 Wrocław, Poland

pyrazole or 3,5-diphenylpyrazole provided the additional pyrazolyl moieties to construct heteroscorpionates.

Structures of 1 and 2 in the Solid State

The heteroscorpionate obtained from condensation of $NaBH_4$ with 3-*i*PrpzH and 5-Me-3-PhpzH was found to be $[HB(5\text{-Me-3-Phpz})_2(5\text{-}i\text{Prpz})]^-$. Two cobalt(II) complexes of this anion were synthesized and studied by X-ray crystallography: the bis-ligand homoleptic complex $[Co\{HB(3\text{-Ph,5-Mepz})_2(5\text{-}i\text{Prpz})\}_2]$ (**1**) and the mono-ligand complex $[Co\{HB(3\text{-Ph,5-Mepz})_2(5\text{-}i\text{Prpz})\}(NCS)(THF)]\cdot THF$ (**2**). The molecular structures of the complexes are shown in Figure 1 and 2, respectively. The cobalt-centered bite angles (β) of the ligand in complexes **1** and **2** are 168.9° and 163.3°, respectively, while the corresponding boron-centered bite angles (α) are 88.5° and 85.2°, respectively (the bite angles were calculated as previously, i.e. disregarding hydrogen atoms).[5] The molecule of **1** is centrosymmetric. The boron-cobalt distance is 3.17 Å in **1**, while that in **2** is 3.12 Å. Thus the Tp^x ligand in **1** is bound less tightly to the cobalt center than in **2**. Accordingly, the average Co−N distance in **1** is 2.17 Å, while that in **2** is 2.09 Å (see captions to Figure 1 and 2). Such a structural difference could be anticipated due to substantial crowding around the metal ion in hexacoordinate $CoTp^x_2$ complexes. Nevertheless, this is only the second case of structurally characterized mono- and bis-ligand pentacoordinate $[CoTp^x(NCS)(THF)]$ and hexacoordinate $CoTp^x_2$ complexes constructed with the same Tp^x ligand. The first example was demonstrated for the heteroscorpionate ligand $[HB(5\text{-Me-3-Phpz})_2(3\text{-Me-5-Phpz})]^-$, for which a similar relationship was found: β = 154.6° and 149.2°, α = 85.7° and 81.9°; average Co−N bond length = 2.26 Å and 2.23 Å; Co−B distance = 3.15 Å and 3.09 Å, for $CoTp^x_2$ and $[CoTp^x(NCS)(THF)]$ complexes, respectively.[8,9]

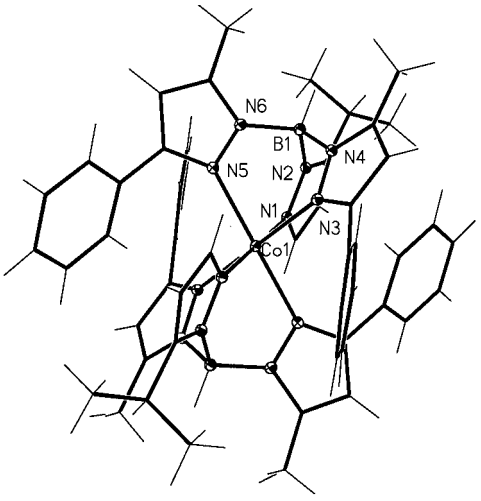

Figure 1. View of **1**; selected bond lengths [Å] and angles [°]: Co(1)−N(1) 2.0469(12), Co(1)−N(3) 2.2341(12), Co(1)−N(5) 2.2194(13); N(1)−Co(1)−N(5) 89.43(5), N(1)−Co(1)−N(3) 90.66(5), N(5)−Co(1)−N(3) 79.55(5)

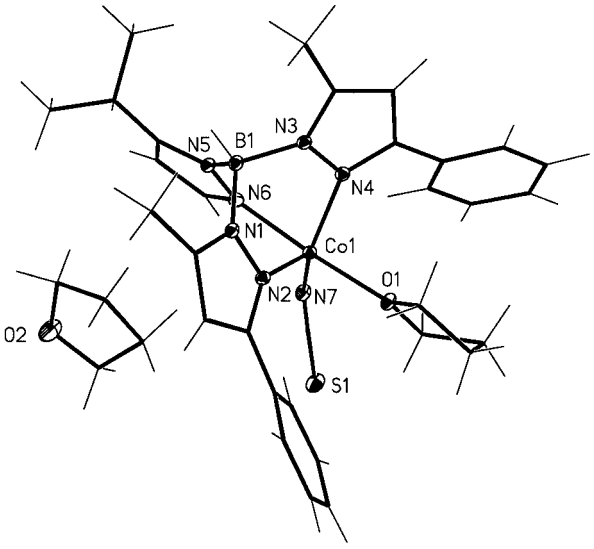

Figure 2. View of **2**; selected bond lengths [Å] and angles [°]: Co(1)−N(2) 2.0830(19), Co(1)−N(4) 2.0540(19), Co(1)−N(6) 2.1351(19), Co(1)−N(7) 1.999(2), Co(1)−O(1) 2.1193(16); N(2)−Co(1)−N(4) 93.03(7), N(2)−Co(1)−N(6) 88.05(7), N(4)−Co(1)−N(6) 84.25(7), N(7)−Co(1)−N(2) 124.92(8), N(7)−Co(1)−N(4) 141.39(8), N(7)−Co(1)−N(6) 89.73(7), N(7)−Co(1)−O(1) 88.46(7), N(2)−Co(1)−O(1) 96.76(7), N(4)−Co(1)−O(1) 94.32(7), N(6)−Co(1)−O(1) 175.06(7)

The β and α bite angles of Tp^x in **1** are much lower than those found in $[HB(3\text{-}i\text{Prpz})_2(5\text{-}i\text{Prpz})]_2Co$, which are 191.5° and 103.0°, respectively.[6] However, the Tp^x ligand in the latter is bound more tightly than that in **1**; the cobalt-boron distance is 3.15 Å. The ^1H NMR spectra of **1** and **2** are consistent with the crystal structures (see below).

A detailed analysis of the molecular structure of **2** shows some unexpected features. The 5-isopropylpyrazolyl moiety is bound more weakly than two 5-methyl-3-phenylpyrazolyl residues (see caption of Figure 2) whereas one might have expected the opposite effect due to the lack of a bulky 3-substituent and the presence of a large 5-isopropyl substituent which should result in a shortening of the Co−N(5-*i*Prpz) bond. This may be due to the specific arrangement of the remaining monodentate ligands: the coordinated THF molecule is placed within the pocket formed by the two 5-phenyl substituents, while the N-coordinated thiocyanate is very close to, and placed almost co-planar with, the 5-isopropylpyrazolyl ring. This close proximity induces a considerable weakening of the Co−N(5-*i*Prpz) bond. There are two additional intermolecular contacts (2.95 Å and 2.94 Å) between the thiocyanato sulfur atom and the *m*-H(3-Ph) and 4-H(5-Me-3-Phpz) atoms of two different molecules.

^1H NMR Spectra

The ^1H NMR spectroscopy of high-spin cobalt(II) complexes is a convenient method for the structural elucidation of $CoXTp^x$ and $CoTp^x_2$ complexes in solution[5−12] as the chemical shifts are dominated by the dipolar contribu-

tion.[12] The resonances of the 3-*i*Pr hydrogens are shifted considerably upfield, whereas those of the 5-*i*Pr hydrogens are shifted in opposite directions. The ^{1}H NMR spectrum of a side-product obtained in the synthesis of Tp^x from 3(5)-*i*PrpzH and 3,5-diPhprH, i.e. [Co(Tp^{iPr})(NCS)(CD_3OD)] (**4**, Figure 3A) indicated that heteroscorpionate [HB(3-*i*Prpz)$_2$(5-*i*Prpz)]$^-$. From this one can conclude that the driving force for the borotropic shift converting homo- to heteroscorpionates is the steric hindrance in [CoTp*i*Pr$_2$].[6] On the other hand, the ^{1}H NMR spectrum of the heteroscorpionate [Co{HB(5-*i*Prpz)(3,5-diPhpz)$_2$}(NCS)(CD_3OD)] (**3**, Figure 3B) clearly indicates the presence of a 5-*i*Pr substituent in the [CoTp^x(NCS)] complex on the basis of the methyl(*i*Pr) resonance at δ = 16.3 ppm. The presence of a 5-*i*Pr-pyrazolyl moiety in the mono-ligand complex **3** suggests that steric repulsion between the two 3-*i*Pr-pyrazolyl residues in the $CoTp^x_2$ complex is not necessary for the borotropic shift. This is strongly supported by the fact that 5-*i*Pr-pyrazolyl is present also in the synthetic heteroscorpionate Tp^x ligand both in the mono-ligand complex **2** (Figure 3C) and the bis-ligand complex **1** (Figure 3D). The symmetry of the ^{1}H NMR spectrum of **1** suggests that the Tp^x ligands are arranged in an antiperiplanar (*trans*) conformation similarly to those in [Co{HB(3-*i*Prpz)$_2$(5-*i*Prpz)}$_2$].[6] The Tp^x ligands in **1** are more sterically demanding and the boron-attached hydrogen atoms are about 0.02 Å more distant than those in [Co{HB(3-*i*Prpz)$_2$(5-*i*Prpz)}$_2$] (see above). Therefore, the 5-*i*Pr-pyrazolyl moiety is bound more weakly in **1** than in [Co{HB(3-*i*Prpz)$_2$(5-*i*Prpz)}$_2$]; the B-*H* and 3-H resonances are observed at δ = 75.2 and −29.4 ppm, respectively, while they are found at about δ = 93 and −63 ppm in the latter complex. However, the steric hindrance of [HB(3-Ph,5-Mepz)$_2$(5-*i*Prpz)]$^-$ ligand is still small enough to form the $CoTp^x_2$ complex **1**. The synthesized heteroscorpionate is a typical case of a Tp^x ligand with intermediate steric hindrance, which, depending on the synthetic procedure, forms both the stable mono-ligand complex **2** and its bis-ligand counterpart **1**. A slight structural modification by introducing a 5-phenyl- instead of a 5-methyl-substituent, resulting in formation of the heteroscorpionate [HB(5-*i*Prpz)(3,5-diPhpz)$_2$]$^-$ produces a more demanding ligand, which in the same synthetic procedure gives only the mono-ligand complex **3**.

We also varied the stoichiometry of 3(5)-*i*PrpzH and 3,5-diPhpzH in favor of the former to obtain another heteroscorpionate, [HB(*y*-*i*Prpz)$_2$(3,5-diPhpz)]$^-$ (where y = 3 or 5). However, we found that a higher percentage of homoscorpionate was obtained, without detectable amounts of the desired heteroscorpionate.

Because we were aiming for the latter, another modified pyrazole, namely 5(3)-isopropyl-3(5)-phenylpyrazole was subsequently successfully used to construct the heteroscorpionate [HB(3-Ph,5-*i*Prpz)$_2$(3,5-diMepz)]$^-$ anion which was thermally converted when isolated as its cobalt complex [CoTp^x(NCS)] into [Co{HB(5-*i*Pr-3-Phpz)(3-*i*Pr-5-Phpz)-(3,5-diMepz)}(NCS)] (**5**) in about 50% yield.[13]

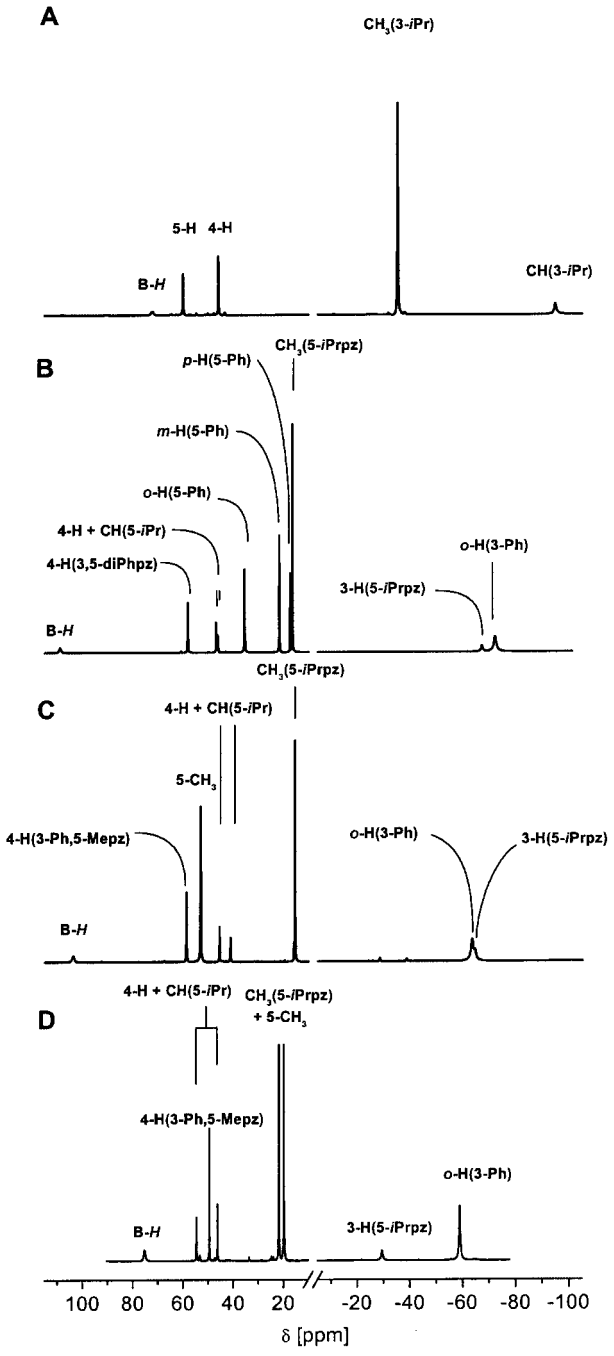

Figure 3. ^{1}H NMR spectra of: [Co(Tp^{iPr})(NCS)(CD_3OD)] (**A**); [Co{HB(5-*i*Prpz)(3,5-diPhpz)$_2$}(NCS)(CD_3OD)] (**B**); [Co{HB(5-Me-3-Phpz)$_2$(5-*i*Prpz)}(NCS)(CD_3OD)] (**C**) in [D_4]methanol; and [Co{HB(3-Ph,5-Mepz)$_2$(5-*i*Prpz)}$_2$] in [D]chloroform (**D**)

Experimental Section

Methods and Instruments: Elemental analyses were performed with Perkin−Elmer 2400 CHN analyzer. The ^{1}H NMR spectra were obtained with a Bruker AMX300 spectrometer operating in the quadrature mode at 300 MHz. The residual peaks of deuterated solvents were used as internal standards. The FT IR spectra were recorded in KBr pellets on a Perkin−Elmer 1725X instrument.

Syntheses: 5(3)-Methyl-3(5)-phenylpyrazole (5-Me-3-PhpzH), 3(5)-isopropylpyrazole (3-*i*PrpzH) and 3,5-diphenylpyrazole (3,5-diPhpzH) were synthesized by known methods.[5,6] [CoTp^x(NCS)] complexes were synthesized in the presence of an excess of metal ion and thiocyanate anion, followed by extraction of the product into dichloromethane, as previously reported.[5]

Bis[hydrobis(5-methyl-3-phenylpyrazolyl)(5-isopropylpyrazolyl)-borato]cobalt(II) ([Co{HB(3-Ph,5-Mepz)$_2$(5-*i*Prpz)}$_2$], 1), and Tetrahydrofuranothiocyanatohydrobis(5-methyl-3-phenylpyrazolyl)(5-isopropylpyrazolyl)boratocobalt(II) Tetrahydrofuran Solvate ([Co{HB-(3-Ph,5-Mepz)$_2$(5-*i*Prpz)}(NCS)(THF)]·THF, 2): $NaBH_4$ (0.57 g, 15.04 mmol) was heated with 5-Me-3-PhpzH (4.15 g, 26.2 mmol) and 3-*i*PrpzH (2.06 g, 18.75 mmol) in heptadecane (30 cm^3) with vigorous stirring in a 250-cm^3 three-necked round-bottomed flask attached to a wet-test meter and condenser. The device was flushed with nitrogen before heating was started. The temperature was gradually increased up to the boiling point of heptadecane (302 °C). Heating was continued until 1010 cm^3 of hydrogen had been collected. Heptane (60 cm^3) was added to the solution after cooling to about 100 °C and the mixture was left overnight at room temperature. The deposited precipitate was filtered off, washed with petroleum ether and vacuum dried (0.89 g, 1.94 mmol, ca. 13% yield). The crude product was converted into [CoTp^x(NCS)] complexes by standard methods. These complexes were then dissolved in THF. Dissolution was accompanied by the formation of a yellowish-white precipitate, which was filtered off, washed with small amount of THF and crystallized from dichloromethane. Yellowish-orange crystals of **1** were collected after re-concentration of the solution (256 mg, 0.275 mmol, 14.2% yield). One of the crystals was examined crystallographically (Table 1). The THF filtrate was layered with heptane. From this fraction reddish-violet crystals of **2** were collected (104 mg, 0.15 mmol, ca. 7.7% yield). One of the crystals was used for an X-ray crystallographic measurement (Table 1).

Thiocyanatohydrobis(3,5-diphenylpyrazolyl)(5-isopropylpyrazolyl)-boratocobalt(II) ([Co{HB(3,5-diPhpz)$_2$(5-*i*Prpz)}(NCS)(CH$_3$OH)], 3) and Thiocyanatohydrotris(3-isopropylpyrazolyl)boratocobalt(II) ([Co(Tp^{iPr})(NCS)], 4): $NaBH_4$ (0.46 g, 12.1 mmol) was heated with 3-*i*PrpzH (2.54 g, 23.05 mmol) and 3,5-diPhpzH (2.93 g, 13.3 mmol) in octadecane (40 cm^3) with vigorous stirring in a 250-cm^3 three-necked round-bottomed flask attached to a wet-test meter and condenser. The temperature was gradually increased up to the boiling point of octadecane (315 °C). Heating was continued until 930 cm^3 of hydrogen had been collected and then for a further hour. A white precipitate formed after cooling the mixture to about 100 °C. Heptane (80 cm^3) was then added to the suspension, which was then stirred for 2 hours at room temperature. The crude product was filtered off, washed with petroleum ether and dried to give 1.66 g of a mixture of NaTp^x salts.

NaTp^x (210 mg) was converted into a mixture of [CoTp^x(NCS)] complexes and this mixture was dissolved in methanol (5 cm^3). The insoluble blue material, identified as [Co(Tp$^{Ph}{}_2$)(NCS)],[7] was separated by passing the solution through a short bed of celite. The filtrate contained 44% [Co(Tp^{iPr})(NCS)] and 56% [Co{HB(3,5-diPhpz)$_2$(5-*i*Prpz)}(NCS)] which were identified by their ^{1}H NMR spectra. The filtrate was left to crystallize by slow evaporation of methanol. In the first instance pink, plate-shaped crystals of [Co{HB(3,5-diPhpz)$_2$(5-*i*Prpz}(NCS)(CH$_3$OH)]·CH$_3$OH were separated and collected (yield 65 mg, 0.092 mmol), and finally pink, cube-shaped crystals of [Co(Tp^{iPr})(NCS)] were collected, which turned blue upon drying at high vacuum (48 mg, 0.105 mmol).

Two New Zeolite-Like Supramolecular Copper Complexes

Daofeng Sun,[a] Rong Cao,*[a] Yanqiong Sun,[a] Xing Li,[a] Wenhua Bi,[a] Maochun Hong,[a] and Yingjun Zhao[a]

Keywords: Copper / Supramolecular chemistry / Hydrogen bonds / Zeolite analogues / Amines

Assembly of sodium 5-sulfoisophthalate (NaH_2SIPA) with copper(II) nitrate in the presence of an amine results in the formation of two new types of supramolecular copper complexes $[\{Cu(H_2O)_2(HSIPA)\}\cdot 2H_2O\cdot(PIP)_{1/2}]_n$ (**1**) and $[\{Cu(H_2O)_3(HSIPA)\}\cdot 6H_2O\cdot(hmt)_{1/2}]_n$ (**2**). Both complexes have 1D zigzag chain structures formed by the interconnection of four- or five-coordinate copper ions by carboxylate ligands. The 3D supramolecular architectures are dependent on the guest amine.

Introduction

Crystal engineering of supramolecular architectures or metal-organic coordination polymers is a maturing field and has attracted much attention in the past decades.[1−4] With the recent development of self-assembly supramolecular chemistry, it is possible to rationally design and synthesize supramolecular architectures or metal-organic coordination polymers based on covalent or supramolecular contacts (such as hydrogen bond, π-π interactions etc.).[5−7] However, the assembly of porous materials from organic ligands and metal-ion building blocks to generate new supramolecular architectures is still a challenge.[8−10] Based on the different interactions between building blocks, two principle methods can be achieved to construct open supramolecular architectures: one is based upon covalent bonds and the other on supramolecular contacts.[11] The use of covalent bonds to engage metal ions and organic ligands, such as polycarboxylic acids or 4,4′-bipy, has resulted in a large number of porous frameworks with various dimensionalities and topologies.[12−15] In contrast, the use of supramolecular contacts to construct porous supramolecular frameworks is much less common, although a few examples have been reported.[16−20]

Currently, one of the problems when constructing porous networks is the presence of an interpenetrated network if the void is more than 50% of the crystal by volume.[21] The use of guest molecules as templates — as in zeolite-like metal phosphates — can reduce the interpenetration, and this has been well documented.[4,21,22] Furthermore, the porous architectures can be tailored by changing the structure of the guest molecules.[23] In this paper, we report two new zeolite-like supramolecular copper(II) complexes, $[\{Cu(H_2O)_2(HSIPA)\}\cdot 2H_2O\cdot(PIP)_{1/2}]_n$ (**1**) and $[\{Cu(H_2O)_3(HSIPA)\}\cdot 6H_2O\cdot(hmt)_{1/2}]_n$ (**2**) (H_3SIPA = 5-sulfoisophthalic acid, PIP = piperazine, hmt = hexamethylenetetramine), constructed by a combination of coordination and hydrogen bonds. These two complexes possess quite different architectures based on the guest amine molecules.

Results and Discussion

Complexes **1** and **2** were prepared in the presence of an amine in solution at room temperature. X-ray diffraction shows that both **1** and **2** possess one-dimensional zigzag chain structures and the hydrogen-bond interactions between chains make them three-dimensional channel-like frameworks in which the guest amine molecules reside.

Complex **1** possesses a one-dimensional zigzag chain structure. As shown in Figure 1, the central copper ion is coordinated by two oxygen atoms from two different $HSIPA^{2-}$ ligands and two coordinated water molecules — with the average $Cu-O_{SIPA}$ distance being 1.951(5) and $Cu-O_w$ being 1.965(7) Å — in a square -planar geometry, whereas the protonated sulfonate group does not participate in the coordination. Thus, every copper ion is linked by two $HSIPA^{2-}$ ligands to form a one-dimensional zigzag chain. The organic amine molecules (PIP) are found on the same side of the chain. Three kinds of strong hydrogen bonds are found between the chains: a) hydrogen bonds between uncoordinated carboxylate oxygen atoms and coordinated water molecules (O···O distances: 2.626 and 2.756 Å); b) hydrogen bonds between sulfonate oxygen atoms and the coordinated water molecules (O···O distances: 2.660 Å); and c) hydrogen bonds between uncoordinated carboxylate or sulfonate oxygen atoms and the guest amine or water molecules. The hydrogen-bond interactions between chains

make the complex a three-dimensional open supramolecular architecture with channels along the *a* axis (Figure 2). These channels possess approximate dimensions of 11.016 × 9.894 Å and are occupied by amine and free water molecules that form hydrogen bonds with the oxygen atoms of the sulfonate group and with coordinated water molecules (O···O distance: 2.636−2.819 Å; O···N distance: 2.819 Å).

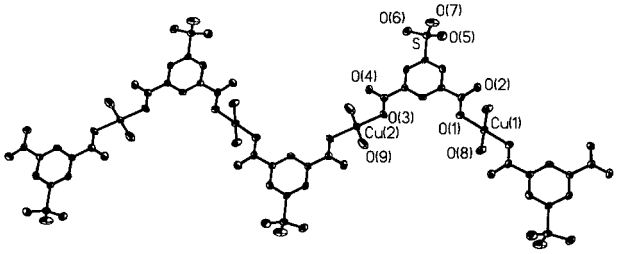

Figure 1. The one-dimensional zigzag chain structure of **1**, showing the coordination environment of the central metal ion

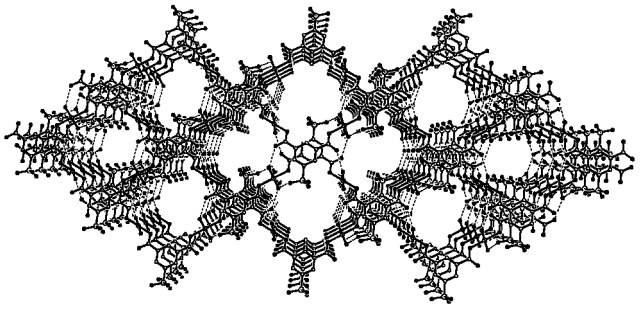

Figure 2. The 3D channel-like supramolecular architecture of **1** along the *a* axis; guest amine and water molecules are omitted for clarity

Complex **2** also has a one-dimensional zigzag chain, different from **1**, where the central copper ion is coordinated by two oxygen atoms from two different $HSIPA^{2-}$ ligands and three coordinated water molecules — with the average $Cu-O_{SIPA}$ distance being 1.960 Å, $Cu-O_w$ being 2.068 Å — in a pyramidal geometry (Figure 3). Two carboxylate oxygen atoms and two coordinated water molecules form the equatorial plane, and another coordinated water molecule occupies the axial position. As in $[Zn(ta)(phen)(H_2O)]_n$ and other similar complexes,[24,25] an axial elongation of the M−O bonds is observed [$Cu-O_w$ distance: 2.241(7) Å which is much longer than others]. Similar to **1**, every copper ion is linked by two $HSIPA^{2-}$ ligands to form a one-dimensional zigzag chain and the amine molecules (hmt) are found on the same side of the chain. Three kinds of hydrogen bonds are observed in **2**: a) hydrogen bonds between uncoordinated carboxylate oxygen atoms and coordinated water molecules (O···O distances: 2.634−2.729 Å); b) hydrogen bonds between sulfonate oxygen atoms and the free water molecules (O···O distances: 2.746−2.954 Å); and c) hydrogen bonds between sulfonate oxygen atoms or coordinated water molecules and the guest amine molecules. The chain is linked by hydrogen bonds of type *a* to generate a two-dimensional porous layer structure (Figure 4), which is further linked by hydrogen bonds of type *b* in an $O_{SIPA}\cdots O_w\cdots O_{SIPA}$ fashion to form a 3D open supramolecular framework with channels along the *c* axis (Figure 5). These channels, with approximate dimensions of 16.445 × 6.474 Å, are occupied by amine (hmt) and free water molecules that form hydrogen bonds with the oxygen atoms of the sulfonate group and with coordinated water molecules (O···O distance: 2.644−2.788 Å; O···N distance: 2.711−2.879 Å).

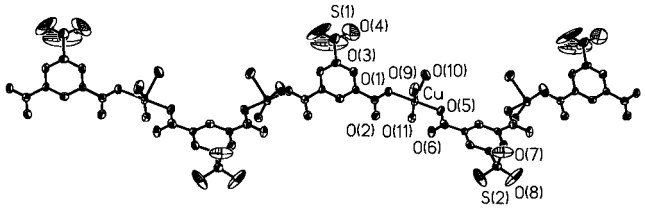

Figure 3. The one-dimensional zigzag chain structure of **2**, showing the coordination environment of the central metal ion

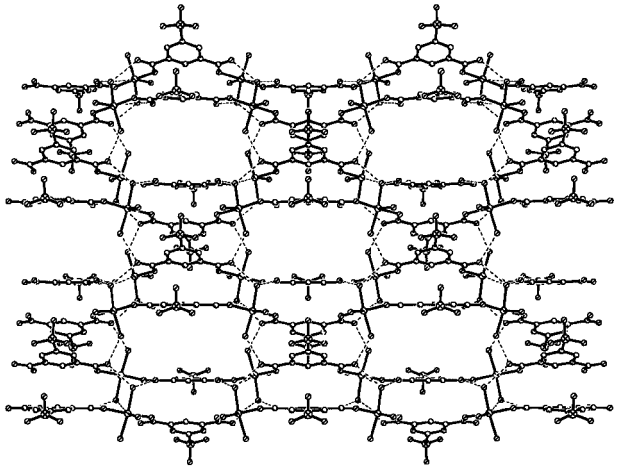

Figure 4. The 2D porous supramolecular architecture of **2** along the *c* axis

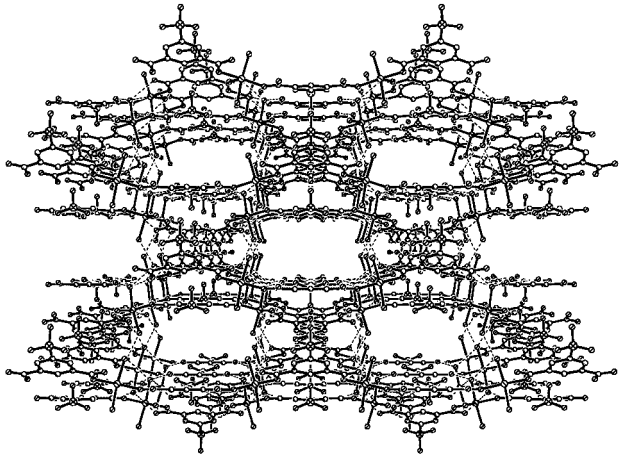

Figure 5. The 3D channel-like supramolecular architecture of **2** along the *c* axis; guest amine and water molecules are omitted for clarity

Thermogravimetric analysis (TGA) determined the thermal stability of complexes **1** and **2**. For **1**, the weight loss of 4.41% from 25 to 93 °C is equivalent to the loss of one uncoordinated water molecule (calcd. 3.71%). A total weight loss of 12.02% is achieved at 280 °C, which corresponds to the loss of another uncoordinated water molecule and 0.5 guest amine molecules per formula unit (calcd. 12.55%). However, the loss of the coordinated water molecules in **1** is not observed before 300 °C where the decomposition starts; decomposition ends above 800°C. For **2**, there is three-step weight loss in the range from 25 to 800 °C. The first weight loss of 21.20% from 25 to 145 °C corresponds to the loss of the six free water molecules per formula unit (calcd. 20.38%); the second weight loss of 12.80% from 145 to 300 °C corresponds to the loss of 0.5 guest amine molecules per formula unit (calcd. 13.21%) and the third weight loss of 10.25% from 300 to 325 °C corresponds to the loss of the coordinated water molecules (calcd. 10.19%); after 325 °C, complex **2** starts to decompose and the decomposition ends above 800 °C. This result may indicate that the guest molecules are difficult to remove from the host molecules due to the existence of strong hydrogen bonds between the host and guest molecules.

Although both **1** and **2** have three-dimensional supramolecular architectures, they are quite different due to the influence of the amine molecules. In **1**, the central copper ion is four-coordinate in a square planar geometry, and the uncoordinated carboxylate oxygen atoms, which act as hydrogen-bond acceptors, point toward different sides of the chain (Figure 6a), which makes the angle of the zigzag chain almost 90°. The chains are superimposed above each other in a staggered arrangement through hydrogen bonds between the uncoordinated carboxylate oxygen atoms and coordinated water molecules (Figure 7a). In **2**, the copper ion is five-coordinate in a pyramidal geometry, and the uncoordinated carboxylate oxygen atoms, which act as hydrogen-bond acceptors, point toward the same side of the chain (Figure 6b), which makes the angle of the zigzag chain about 120°. The superposition of the chains in **2** is quite different from that in **1**: first, two chains are linked by hydrogen bonds in staggered arrangement to form a double chain, which is further linked to generate a 2D porous layer. Secondly, the hydrogen bonds between the oxygen atoms of the sulfonate group and free water molecules in an $O_{SIPA}\cdots O_w\cdots O_{SIPA}$ fashion give rise to the final 3D open framework (Figure 7b). We propose that the structural differences between **1** and **2** arise from the influence of the guest amine molecules: the difference in the backbone of the guest molecules results in a difference of the coordination modes of the central metal ions, which further influences the arrangement of the hydrogen-bond acceptor, and leads to the difference in the final 3D supramolecular architectures. This result indicates that the host structures assembled are greatly affected by the guests,[23] and therefore changing the guest molecule, even only slightly, should lead to different structural supramolecular complexes constructed from covalent or supramolecular contacts, or a combination of the two.

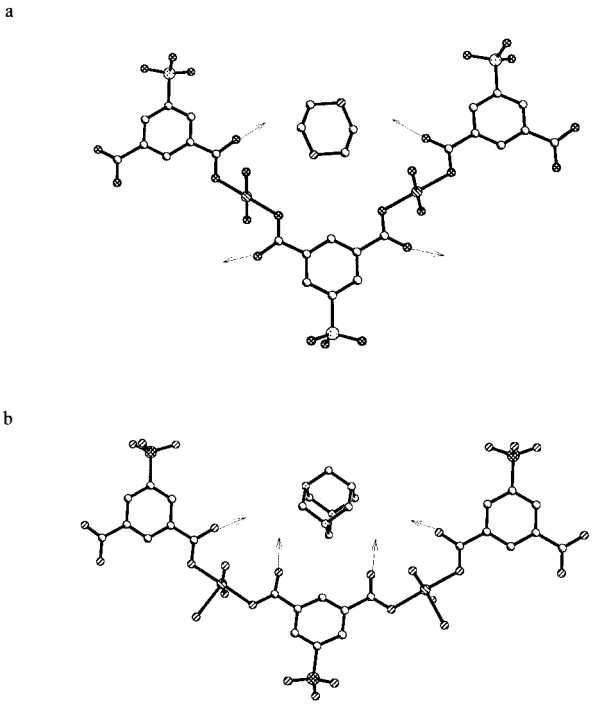

Figure 6. The different arrangement of the uncoordinated carboxylate oxygen atoms for **1** (a) and **2** (b)

Conclusion

In conclusion, two new zeolite-like supramolecular copper complexes have been prepared in the presence of amines at room temperature. Although both complexes possess one-dimension zigzag chain structures, the different guest amines result in different three-dimensional supramolecular architectures. Although guest-dependent supramolecular structures are known, their construction is still a challenge to chemists and will be an active field in the future.

Experimental Section

General Remarks: All chemicals were used as purchased without purification. Thermogravimetric experiments were performed using a TGA/SDTA851 instrument (heating rate of 10 °C/min, argon stream). IR spectra were recorded on a Magna 750 FT-IR spectrophotometer as KBr pallets. Elementary analyses were carried out in the elementary analysis group of this institute.

Synthesis of $[\{Cu(H_2O)_2(HSIPA)\}\cdot 2H_2O\cdot(PIP)_{1/2}]_n$ (1): NaH_2SIPA (0.034 g, 0.125 mmol) was dissolved in 15 mL water and $Cu(NO_3)_2\cdot 5H_2O$ (0.06 g, 0.25 mmol) was added with stirring at 60 °C. After stirring for 15 min, a solution of PIP (0.02 g, 0.25 mmol) in ethanol (5 mL) was added, and 15 min later a blue precipitate had formed. After filtration, the light-blue solution was allowed to stand in air at room temperature until blue prism-like crystals were obtained. Yield: 40%. $C_{10}H_{16}CuNO_{11}S$ (485.38): calcd. C 28.51, H 3.83, N 3.33; found C 28.60, H 3.75, N 3.40. IR (KBr): $\tilde{\nu}$ = 3211

cm^{-1} (vs), 3035 (vs), 2829 (s), 1605 (vs), 1556 (vs), 1444 (s), 1362 (vs), 1174 (s), 1043 (vs), 771 (s), 733 (m), 623 (s).

Synthesis of $[\{Cu(H_2O)_3(HSIPA)\}\cdot 6H_2O\cdot(hmt)_{1/2}]_n$ (2): The procedure was the same as that for **1** except that PIP was replaced by hmt. Yield: 50%. $C_{11}H_{26}CuN_2O_{15.5}S$ (529.94): calcd. C 24.95, H 4.95, N 5.29; found C 24.70, H 5.10, N 5.50. IR (KBr): $\tilde{\nu}$ = 3440 cm^{-1} (vs), 3120 (vs), 1637 (vs), 1574 (s), 1441 (vs), 1358 (vs), 1259 (s), 1178 (vs), 1109 (s), 1047 (vs), 1024 (s), 976 (m), 775 (s), 725 (vs), 633 (s).

X-ray Crystallographic Study: $C_{10}H_{16}CuNO_{11}S$ (**1**), M_r = 485.38, triclinic, $P\bar{1}$, a = 7.5666(4), b = 10.4595(3), c = 10.5323(5) Å, α = 75.387(2), β = 76.875(2), γ = 87.483(2)°, V = 785.44(6) $Å^3$, Z = 2, D_c = 2.052 $g\cdot cm^{-3}$, μ(Mo-K_α) = 2.901 mm^{-1}, T = 293(2) K, R [$I < 2\sigma(I)$] = 0.0753, wR = 0.1807 for 2749 independent reflections with $F \geq 2.0\ \sigma(F_o)$.
$C_{11}H_{26}CuN_2O_{15.50}S$ (**2**), M_r = 529.94, monoclinic, $C2/m$, a = 15.3759(3), b = 18.8359(6), c = 14.1292(2) Å, β = 90.324(2)°, V = 4092.02(16) $Å^3$, Z = 8, D_c = 1.720 $g\cdot cm^{-3}$, μ(Mo-K_α) = 1.251 mm^{-1}, T = 293(2) K, R [$I < 2\sigma(I)$] = 0.0864, wR = 0.1939 for 3711 independent reflections with $F \geq 2.0\ \sigma(F_o)$.

The intensity data were collected on a Smart CCD diffractometer with graphite-monochromated Mo-K_α (λ = 0.71073 Å) radiation at room temperature in the ω-2θ scan mode. An empirical absorption correction was applied to the data using the SADABS program. The structures were solved by direct methods. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were generated in idealized positions. All calculations were performed using the SHELXTL program. Selected bond lengths and angles for the two complexes are given in Table 1.
CCDC-189986 (**1**) and -189987 (**2**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44−1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Tripodal Phosphane Ligands with Novel Linker Units and Their Rhodium Complexes as Building Blocks for Dendrimer Catalysts

Ralf A. Findeis[a] and Lutz H. Gade*[a]

Dedicated to Professor Gottfried Huttner on the occasion of his 65th birthday

Keywords: Phosphane ligands / Hydrogenation / Catalysis / Dendrimers / Rhodium

An efficient strategy for the backbone functionalization of a tripodal phosphane ligand which allows its attachment to solid supports and polymers has been developed. Using pentaerythrol (**1**) as the starting material, the functionalized phosphane tripod $HOCH_2CH_2OCH_2C(CH_2PPh_2)_3$ (**9**) was obtained in good yield in a four-step synthesis. Reaction of **9** with $[Mo(CO)_3(MeCN)_3]$ and $[Rh(COD)_2][A]$ gave the complexes $[\{HOCH_2CH_2OCH_2C(CH_2PPh_2)_3\}Mo(CO)_3]$ (**10**) and $[\{HOCH_2CH_2OCH_2C(CH_2PPh_2)_3\}Rh(COD)][A]$ (A = BF_4: **11a**, PF_6: **11b**), respectively, two of which were characterised by X-ray diffraction. The carbosilane dendrimer $Si\{(CH_2)_3SiMe_2Cl\}_4$ "G[0]-[Cl]$_4$" (**12**) and its first generation analogue $Si[(CH_2)_3SiMe\{(CH_2)_3SiMe_2Cl\}_2]_4$ "G[1]-[Cl]$_8$" (**15**) were reacted with, respectively, four and eight molar equivalents of the lithium alkoxy derivative of **9** giving the two functionalized dendrimers G[0]-$[OCH_2CH_2Otriphos]_4$ (**13**) and G[1]-$[OCH_2CH_2Otriphos]_8$ (**16**). These were metallated with four and eight molar equivalents of $[Rh(COD)_2][BF_4]$ in CH_2Cl_2, selectively yielding the metallated dendrimers G[0]-$[OCH_2CH_2OtriphosRh(COD)BF_4]_4$ (**14**) and G[1]-$[OCH_2CH_2OtriphosRh(COD)BF_4]_8$ (**17**). Comparative catalytic hydrogenation of styrene and 1-hexene using $[Rh(triphos)(COD)][BF_4]$ (**11a)** and the metallodendrimers **14** and **17** showed that the fixation to the low generation dendrimers did not alter the catalytic hydrogenation properties of the catalysts.

Introduction

The immobilization of molecular catalysts may lead to catalytic phases which combine the virtues of homogeneous catalysis (high activity and selectivity, directed catalyst design) with those of heterogeneous catalysts (e.g. facile catalyst separation and recycling).[1] However, leaching of the metal is a major practical problem, regardless of the method of catalyst fixation and the nature of the support material.[2] This may be suppressed to various degrees by using polydentate ligands which form thermally and kinetically stable complexes with the catalyst metal. Polydentate phosphanes have been widely employed in this context and tripodal systems, such as the "triphos" ligand $MeC(CH_2PPh_2)_3$, are good examples of this capacity.[3] Their use as ligands in heterogenized metal catalysts requires the functionalization of their backbone structure, preferentially in the apical position. Modified triphos ligands have been employed for the physisorption of Ru and Rh complexes on oxidic supports[4] and the covalent fixation of such catalyst precursors to polystyrene.[5] Immobilized triphos-based catalysts have been studied in catalytic hydrogenation and hydroformylation as well as the isomerization of allylic alcohols.[6] Additionally, backbone-functionalized triphos complexes have been employed in two-phase catalysis.[7]

Since the first reports of the dendrimer fixation of molecular catalysts,[8] a variety of ligands and catalytically active complexes has been immobilized on the inside and outside of dendritic polymers.[9] Due to the importance of phosphanes in homogeneous catalysis, the immobilization of both chiral and achiral phosphane ligands has been studied in a range of such systems.[10] However, there is as yet no report of the fixation of triphos derivatives to dendrimers. To this end, efficient preparative methods for the synthesis of functionalized triphos ligands were required. Important contributions to this field have been reported by Bianchini and Huttner and their co-workers in recent years.[3–7,11–16]

Previously published syntheses of such derivatives partially suffer from the nontolerance of certain functional groups (e.g. C-C multiple bonds)[11] or the fact that the phosphanyl groups are introduced at a very early stage of the reaction sequence, making subsequent work up more difficult.[12–16] Moreover, if expensive (chiral) phosphanyl functions are to be introduced in an early reaction step of the synthetic pathway[17] the loss of phosphane during the overall sequence may be considerable. A strategy in which the phosphane is introduced in the final step of the ligand-linker synthesis, was therefore an important objective of our work. In this paper

we report the efficient synthesis of triphos derivatives containing an ether-alcohol function in the apical position of the ligand backbone, their fixation to zeroth- and first-generation carbosilane dendrimers and their metallation to give cationic rhodium complexes. These were then employed in a comparative study as hydrogenation catalysts.

Results and Discussion

Synthesis of the Tripodal Phosphane $HOCH_2CH_2OCH_2C(CH_2PPh_2)_3$ (9)

We chose pentaerythol (**1**) as the starting material for the synthesis of an apically functionalized *triphos* ligand. This tetraalcohol is a cheap basic chemical which possesses a functionalized neopentane structure and thus appears to be well suited for the synthetic objective. There are several reports in the literature, namely from Huttner and coworkers, of the use of this starting material in *triphos* chemistry; however, these workers decided to functionalize the apical position after introduction of the phosphane groups.[13−16] As stated above, this sequence will reduce the overall yields based upon the phosphane starting material. Since the diphenylphosphanyl groups referred to in this work are model systems for more complex tridentate P-donor ligands, this point was of particular importance to us.

The four hydroxyl functions in **1** are chemically equivalent, and in order to attach a linker group to only one of these it had to be differentiated with respect to the others. This is readily achieved by reaction of **1** with triethyl orthoacetate in toluene to give the known methyl trioxabicyclooctane derivative **2** (Scheme 1).[18] The unchanged "apical" OH-function was then coupled with benzyl-protected 2-chloroethanol[19] as a linker unit to give $BzOCH_2CH_2OCH_2C(CH_2O)_3CCH_3$ (**3**), which, in turn, was hydrolysed yielding the triol $BzOCH_2CH_2OCH_2C(CH_2OH)_3$ (**4**). After functional group interconversion with $SOCl_2$ in dry pyridine, giving the trichloride **5**, and hydrogenolytic deprotection, compound **6** was reacted with Ph_2PH under strongly basic reaction conditions to yield the target phosphane $HOCH_2CH_2OCH_2C(CH_2PPh_2)_3$ (**9**) in good yield.

The differentiation of the OH groups by orthoester protection requires the multistep sequence in the synthesis of **9** as discussed above. This leads to moderate overall yields of the triphos derivative in spite of the relatively high yields in each individual reaction step. It was therefore desirable to devise a shorter route to compound **9**. This was possible via the 3-chloro-2,2-bis(chloromethyl)propan-1-ol (**7**), which is directly accessible from pentaerythrol (Scheme 1).[20] Reaction of **7** with THP-protected 2-bromoethanol gave $THPOCH_2CH_2OCH_2C(CH_2Cl)_3$ (**8**), which was converted into compound **6** by hydrolytic deprotection. This strategy provided a facile access to large quantities of the key intermediate **6**.

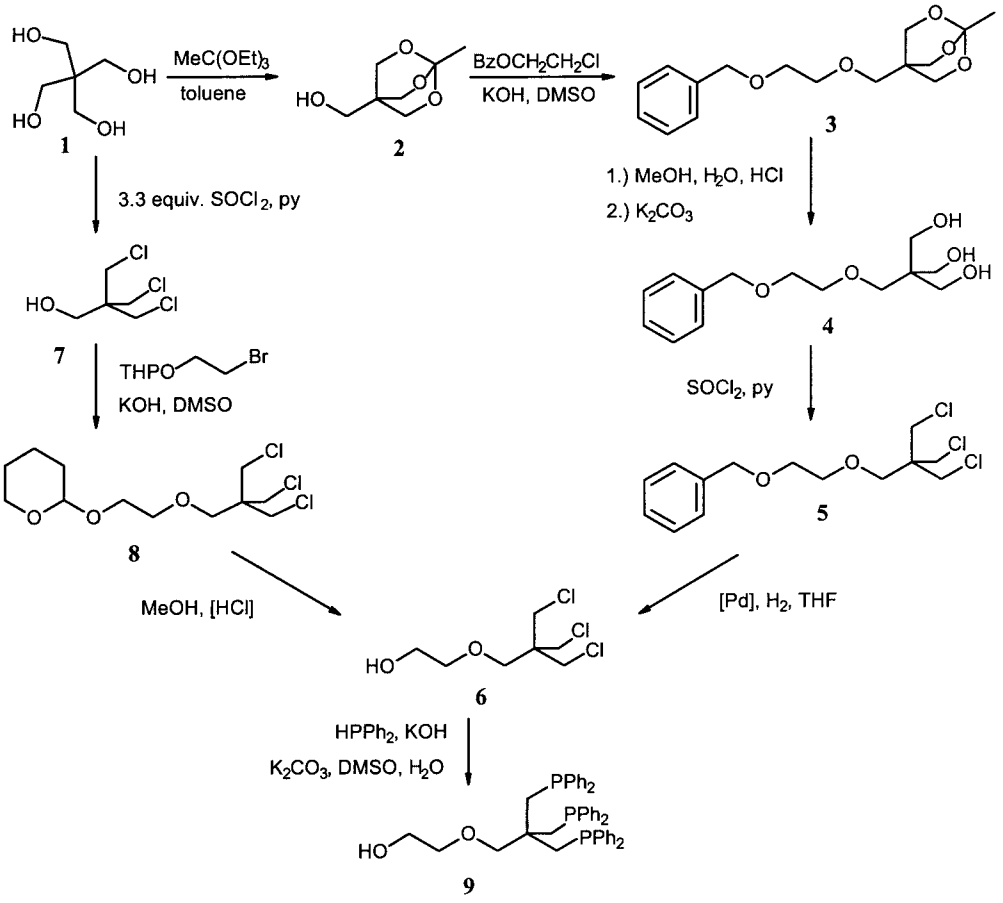
Synthesis and Structural Characterization of the Tripod-Metal Complexes $[\{HOCH_2CH_2OCH_2C(CH_2PPh_2)_3\}Mo(CO)_3]$ (10) and $[\{HOCH_2CH_2OCH_2C(CH_2PPh_2)_3\}Rh(COD)][A]$ ($A^- = BF_4^-$: 11a; $A^- = PF_6^-$: 11b).

In order to assess the structural details and the ligand properties of the triphosphane $HOCH_2CH_2OCH_2C(CH_2PPh_2)_3$ (**9**), it was reacted with one molar equivalent of $[Mo(CO)_3(MeCN)_3]$ to yield the yellow, air stable triphosphane-molybdenum complex $[\{HOCH_2CH_2OCH_2C(CH_2PPh_2)_3\}Mo(CO)_3]$ (**10**; Scheme 2). The ^{31}P NMR resonance of the coordinated phosphane ligand is observed at $\delta = 15.6$ ppm (**9**: $\delta = -25.8$ ppm) and the ν(CO) bands appear in the IR spectrum at 1929 and 1834 cm^{-1}. The molecular ion peak at $m/z = 866$ in the mass spectrum confirms the formulation of the complex.

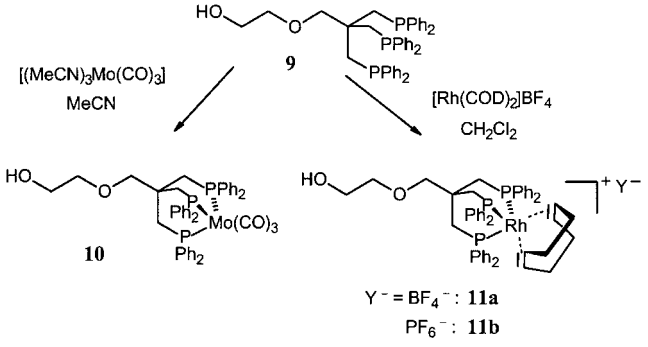
Single crystals of complex **10**, which were suitable for an X-ray diffraction study, were obtained by slow diffusion of diethyl ether into a CH_2Cl_2 solution of the compound. The molecular structure of **10** is displayed in Figure 1a along with its principal bond lengths and angles. The phosphane ligand adopts the expected facial coordination mode in a molybdenum complex having a slightly distorted octahedral coordination geometry. The Mo−P distances of 2.5242(9) to 2.5302(8) Å and the M−CO bond lengths of 1.965(3) to 1.968(3) Å are within the expected range. Both the P−Mo−P and the C−Mo−C angles, which lie in the ranges of 81.11(3) to 84.67(3)° and 84.4(1) to 86.8(1)°, respectively, are below 90° defining a slightly elongated trigonal antiprismatic first coordination sphere (Figure 1b).

In view of the principal objective of this work, the synthesis of cationic triphos-rhodium hydrogenation catalysts attached to dendritic supports, the ligand-linker unit **9** was reacted with $[Rh(COD)_2]BF_4$ to give the Rh^I complex $[\{HOCH_2CH_2OCH_2C(CH_2PPh_2)_3\}Rh(COD)][BF_4]$ (**11a**; Scheme 2) which was characterised by elemental analysis and ^1H, ^{13}C and ^{31}P NMR spectroscopy. The most characteristic spectroscopic feature is the doublet at $\delta = 4.3$ ppm in the ^{31}P NMR spectrum ($^1J_{Rh,P} = 106.8$ Hz) indicating the equivalence of all three phosphorus nuclei on the NMR time scale at 293 K. The observation of an essentially unchanged single phosphorus resonance even at −80 °C is consistent with a rapid dynamic exchange, probably according to a turnstile mechanism, as was previously observed for $[Rh(triphos)(COD)]PF_6$ and $[Ir(triphos)(COD)]PF_6$.[21] We were unable to obtain single crystals of compound **11a** which were suitable for X-ray diffraction. This was achieved, however, after anion exchange with $NH_4[PF_6]$ giving the yellow crystalline complex $[\{HOCH_2CH_2OCH_2C(CH_2PPh_2)_3\}Rh(COD)][PF_6]$ (**11b**; Scheme 2). A single crystal X-ray structure analysis of complex **11b** established its molecular structure, which is displayed in Figure 2a, while the inner coordination environment of the rhodium atom is highlighted in Figure 2b.

The coordination geometry of the complex displayed in Figure 2b is a distorted trigonal bipyramid, the apical position being occupied by the phosphorus atom P(1) and the centroid of the olefinic double bond C(5)−C(6). Whereas



Scheme 1. The two synthetic strategies for the preparation of the ligand-linker **9**



Scheme 2. Synthesis of the tripod-metal complexes **10** and **11a/b**

the Rh−P bond length to the apical phosphane unit [Rh−P(1) 2.303(2) Å] is significantly shorter than for those of the two equatorial phosphanes [Rh−P(2) 2.405(2), Rh−P(3) 2.406(2) Å], the Rh−C distances to the apical olefin carbon atoms [Rh−C(5) 2.264(6), Rh−C(6) 2.327(6) Å] are significantly greater than for the equatorial π-olefin ligands [Rh−C(1) 2.180(6), Rh−C(2) 2.155(6) Å]. The P(1)−Rh−centroid{C(5)/C(6)} angle of 170.13(4) deviates slightly from the ideal of 180°, while the P(1)−Rh−P(2/3) and P(1)−Rh−centroid{C(1)/C(2)} angles are close to 90°. As observed in the crystal structure of the molybdenum complex **10**, the oxygen atoms in the $HOCH_2CH_2O$- spacer in **11b** adopt a gauche conformation.

The packing of the molecules of **11b** in the unit cell is displayed in Figure 2c. For the sake of clarity, the phenyl groups of the diphenylphosphane units, and the lattice solvent molecules (CH_2Cl_2), have been omitted. The molecules are arranged in such a way that the apical alcohol units of the tripod ligands face each other forming intermolecular hydrogen bonds while the PF_6 anions are arranged along channels in the crystal near to the positively charged rhodium complex units.

Fixation of [{$HOCH_2CH_2OCH_2C(CH_2PPh_2)_3$}-Rh(COD)][$BF_4$] (11a) to Zeroth and First Generation Carbosilane Dendrimers

In order to asses the suitability of the apically derivatized *triphos* ligand **9** for the fixation of rhodium hydrogenation catalysts to carbosilane dendrimers, the known zeroth generation dendrimer $Si\{(CH_2)_3SiMe_2Cl\}_4$, "G[0]-$[Cl]_4$" (**12**) and its first generation analogue $Si[(CH_2)_3SiMe\{(CH_2)_3SiMe_2Cl\}_2]_4$, "G[1]-$[Cl]_8$" (**15**) [22] were reacted with, respectively, four and eight molar equivalents of the lithium alkoxy derivative of **9**. After work up the two func-

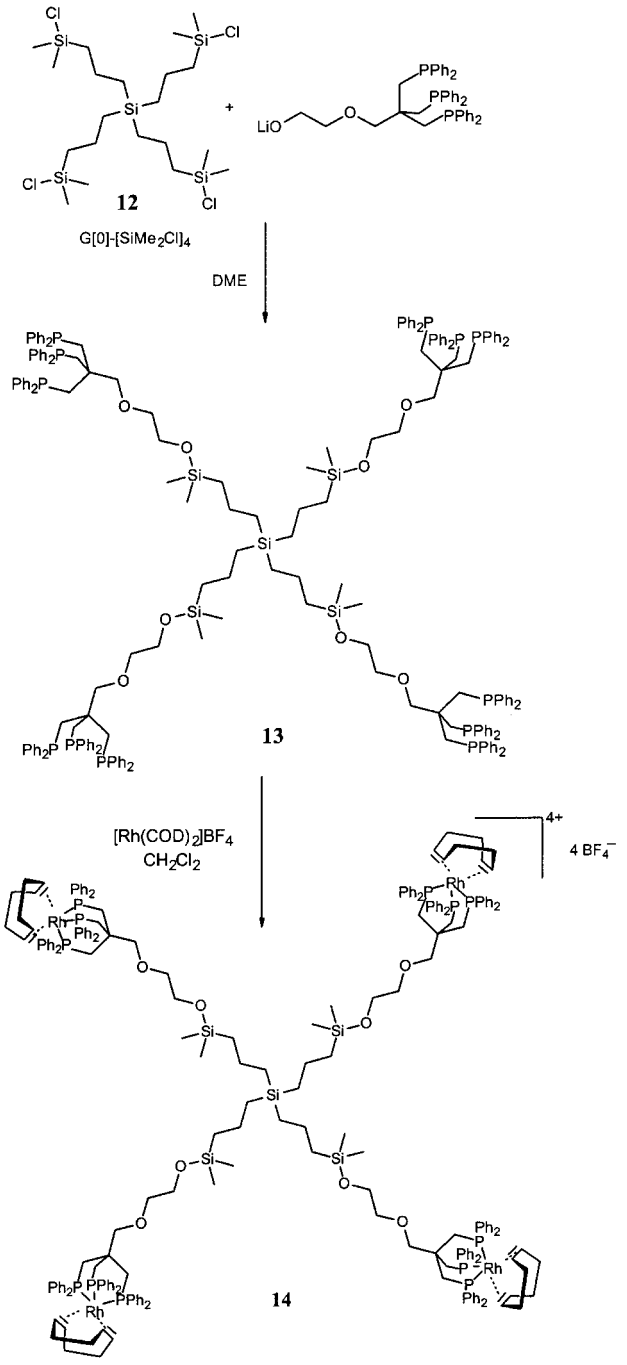


Scheme 3. Fixation of **9** to the end groups of the zeroth generation dendrimer G[0]-[$SiMe_2Cl$]$_4$ (**12**) to give G[0]-[OCH_2CH_2Otriphos]$_4$ (**13**) and subsequent metallation yielding G[0]-[OCH_2CH_2OtriphosRh(COD)BF_4]$_4$ (**14**)

by electrospray mass spectrometry, which confirmed the uniformity of the products. The molecular ion peaks were observed at m/z = 1002.2 for compound **14**, corresponding to the $[(M - 4BF_4)/4]^+$ ion, and at m/z = 1041.3 for the octametallated dendrimer **17**, corresponding to the $[(M - 8BF_4)/8]^+$ ion.

Comparison of the Catalytic Behavior of the Rhodium Complexes [Rh(triphos)(COD)][BF_4], 11a, 14 and 16 (cat1−4) in the Hydrogenation of Styrene and 1-Hexene

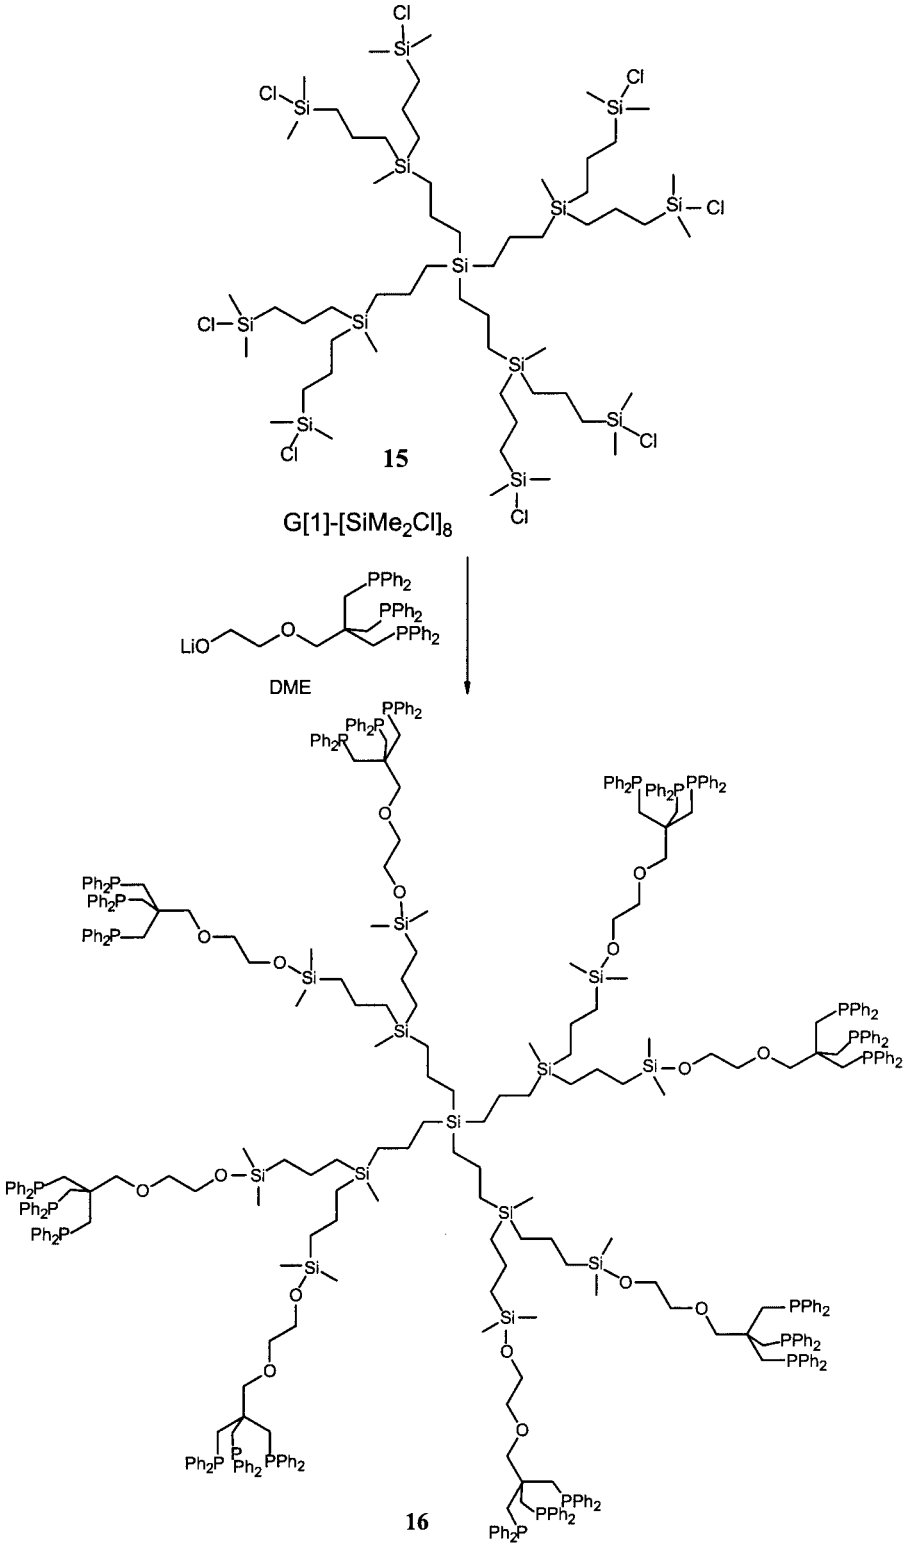
As outlined in the introduction, the hydrogenation of olefins was to be investigated in a comparative study of the catalytic properties of the mononuclear *triphos*-rhodium complexes [Rh(triphos)(COD)][BF_4] (**cat1**) and **11a** (**cat2**) as well as their dendrimer-linked derivatives **14** (**cat3**) and **16** (**cat4**). Mononuclear triphos-rhodium catalysts have been studied previously and were found to be active hydrogenation catalysts for simple nonfunctionalized alkenes.[17,21a,23,24] All catalytic tests were carried out at 1 bar of H_2 pressure and 20 ± 1 °C with an equivalent amount of catalyst (1 mol %), i.e. a constant number of catalytic sites in the system.

As simple substrates for catalytic hydrogenations styrene and 1-hexene are frequently chosen, the latter in order to assess the competition between hydrogenation and alkene isomerization within the coordination sphere of the catalyst.[25] After an initial induction period, during which the COD ligand is reduced, the hydrogenation of the styrene occurs at a constant rate until an almost quantitative conversion of the substrate. The catalytic activities of the catalysts **cat1** − **cat4** did not vary significantly and were found to be at TOF = 10 h^{-1} under the standard conditions cited above.

As has been shown by van Leeuwen and co-workers, carbosilane metallodendrimer catalysts of the first and second generation may possess the required molecular dimensions to allow recycling by membrane filtration.[11] If performed in batch reactors, this requires catalysts which retain their original activity after separation and reintroduction to a catalytic conversion. The dendrimer catalysts **cat3** and **cat4** were found to be isolable (removal of the solvent and reaction product under vacuum) after a complete conversion and re-usable for a subsequent cycle without significant decrease in activity during the first three cycles of catalyst isolation and reintroduction to a new batch of substrates.

In order to test the activity of the new dendritic catalysts towards a second standard substrate employed in hydrogenation tests, the hydrogenation at 1 bar H_2 pressure was carried out using 1-hexene. A competing reaction in this transformation is the isomerization of the alkene to a mixture of (*E*)- and (*Z*)-2-hexene. The typical course of this reaction, as followed by GC-MS, is again represented for **cat4** in Figure 4.

After an induction period, during which the catalytically active species is generated, the conversion of 1-hexene sets in, giving hexane, (*Z*)-2-hexene and (*E*)-2-hexene with a turnover frequency of 30 h^{-1} based on the 1-hexene consumed. After the complete consumption of 1-hexene, the hydrogenation of (*Z*)-2-hexene leads to the further production of hexane, albeit at a lower rate. The curve representing the generation of hexane levels off when the concentration of the *Z*-isomer has dropped to about 30% of its maximum value. As observed for practically all cationic rhodium hydrogenation catalysts, the conversion of the *E*-isomer is

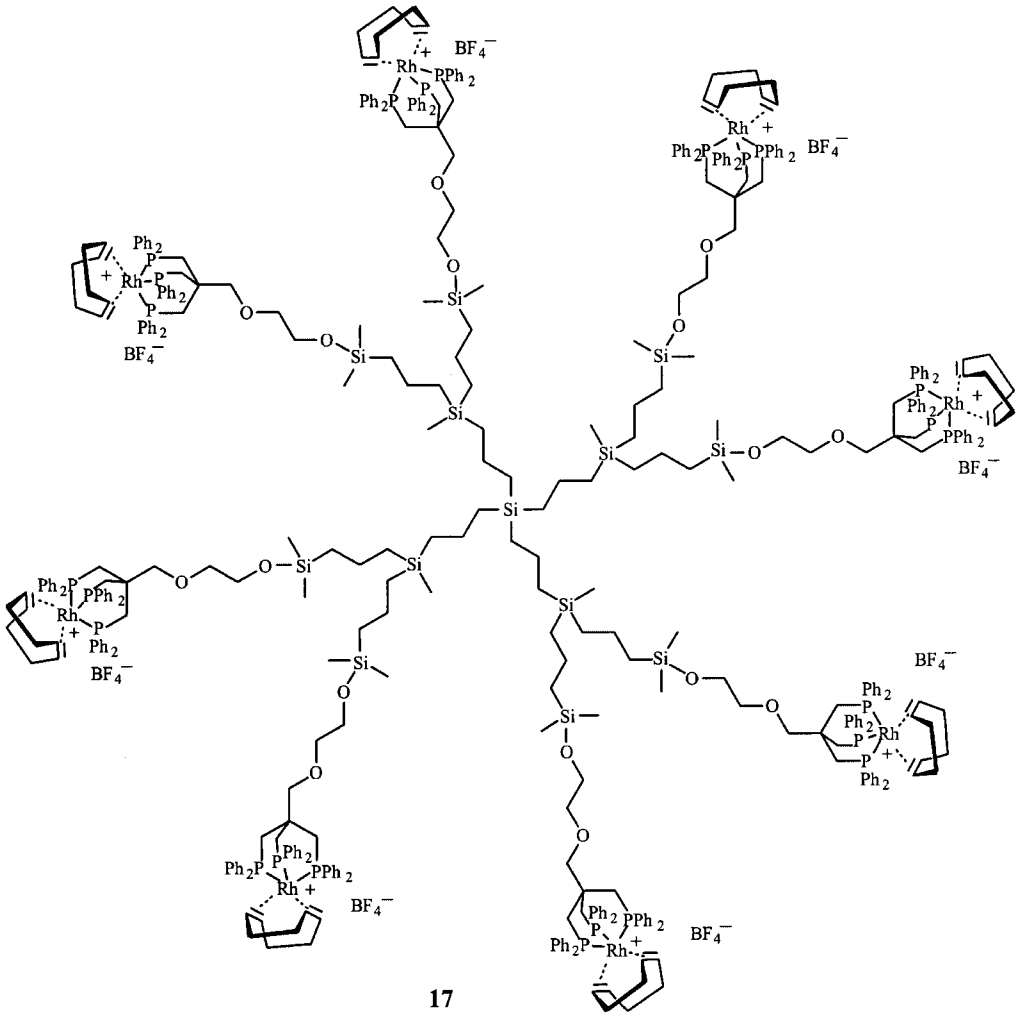


Scheme 4. Fixation of **9** to the end groups of the first generation dendrimer G[1]-[$SiMe_2Cl$]$_8$ (**15**) to give G[1]-[OCH_2CH_2Otriphos]$_8$ (**16**)

much slower and essentially insignificant on the chosen time scale.[25] Comparison of **cat1** − **cat4** showed an overall identical catalytic behaviour.

Conclusions

In this paper we have presented an efficient strategy for the backbone functionalization of the *triphos* ligand which



17

Figure 3. First generation rhododendrimer G[1]-[OCH_2CH_2OtriphosRh(COD)BF_4]$_8$ (**17**)

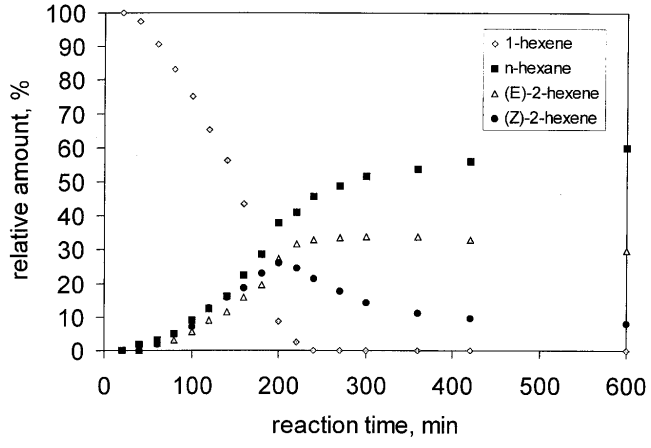


Figure 4. A typical conversion diagram for the hydrogenation of 1-hexene, represented here for the rhododendrimer **16** (**cat4**)

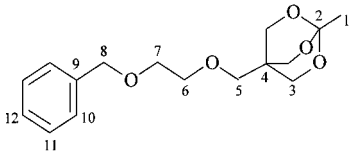
allows its attachment to solid supports and polymers. We have also been able to completely characterise two carbosilane dendrimer derivatives and found them to be sufficiently robust to allow for several recycling steps. Fixation to the low-generation dendrimers did not alter the catalytic hydrogenation properties of the triphos-rhodium catalyst. This constitutes the basis for the extension of this work to higher dendrimer generations which is currently under way.

Experimental Section

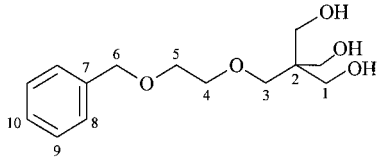
All manipulations were performed under nitrogen (desiccant P_4O_{10}, Granusic®, J. T. Baker) on a high vacuum line using standard Schlenk techniques, or in a glovebox. All reaction flasks were heated prior to use by means of three evacuation-refill cycles. Solvents and solutions were transferred by needle-septa techniques. Solvents were dried according to standard methods and saturated with nitrogen. The deuterated solvents used for the NMR spectroscopic measurements were degassed by three successive "freeze-pump-thaw" cycles and stored over 4 Å molecular sieves. Solids were separated from suspensions by filtration through dried Celite or by centrifugation. The ^1H, ^{13}C, ^{19}F, ^{29}Si and ^{31}P NMR spectra were recorded on Bruker AC 200, Bruker Avance 250 and Bruker AMX 400 FT NMR spectrometers. ^1H and ^{13}C data are listed in parts per million [ppm] relative to tetramethylsilane and were refer-

enced using the residual protonated solvent peak (^{1}H) or the carbon resonance (^{13}C). ^{29}Si, ^{19}F and ^{31}P NMR spectroscopic data are listed in ppm relative to, respectively, tetramethylsilane, $FCCl_3$ and 85% H_3PO_4 as external standards. Infrared spectra were recorded on a Nicolet Magna IRTM 750 spectrometer. Elemental analyses were carried out by the microanalytical service at the chemistry department at Strasbourg. 4-(Hydroxymethyl)-1-methyl-2,6,7-trioxabicyclo[2.2.2]octane (**2**),[18] benzyl 2-chloroethyl ether,[19] diphenylphosphane,[26] 3-chloro-(2,2-chloromethyl)-propan-1-ol (**7**),[20] 2-(2-Bromoethoxy)tetrahydropyran,[27] $[(MeCN)_3Mo(CO)_3]$,[28] $[Rh(COD)_2]BF_4$,[29] G[0]-$[Cl]_4$ (**12**),[30] G[1]-$[Cl]_8$ (**15**) [31] and $[CH_3C(CH_2PPh_2)_3Rh(COD)]BF_4$ [21] were prepared according to published procedures. All other chemicals used as starting materials were obtained commercially and used without further purification.

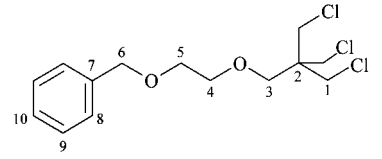
Preparation of $BzOCH_2CH_2OCH_2C(CH_2O)_3CCH_3$ (3): 4-(Hydroxymethyl)-1-methyl-2,6,7-trioxabicyclo[2.2.2]octane (**2**; 14.3 g, 89.0 mmol) was added to a stirred suspension of finely powdered KOH (11.2 g, 200 mmol) and benzyl 2-chloroethyl ether (30.9 g, 181 mmol) in 150 mL of DMSO. The reaction mixture was stirred at 60 °C for 2 h and then cooled to room temperature. Water (500 mL) was then added and the solution thus obtained was extracted with three portions of Et_2O (200 mL). The combined organic extracts were washed with 100 mL of a saturated aqueous solution of NaCl, then with 100 mL of water and subsequently dried over Na_2SO_4. After removal of the solvent by distillation, the yellow oily residue was purified by column chromatography to yield $BzOCH_2CH_2OCH_2C(CH_2O)_3CCH_3$ (**3**) as a colourless, viscous liquid. Yield: 20.5 g (70.2 mmol, 79%). R_f (Al_2O_3 60 neutral, EtOAc/*n*-hexane = 2:8): 0.49. ^{1}H NMR (300.17 MHz, $CDCl_3$, 295 K): δ = 1.42 (s, 3 H, H-1), 3.23 (s, 2 H, H-5), 3.54−3.60 (m, 4 H, H-6,7), 4.00 (s, 6 H, H-3), 4.54 (s, 2 H, H-8), 7.25−7.35 (m, 5 H, H-10,11,12) ppm. $^{13}C\{^1H\}$ NMR (75.48 MHz, $CDCl_3$, 295 K): δ = 23.2 (CH_3, C-1), 34.6 (C, C-4), 69.0 (CH_2, C-3), 69.1(CH_2, C-6/7), 69.3 (CH_2, C-6/7), 70.9 (CH_2, C-8), 72.8 (CH_2, C-5), 108.1 (C, C-2), 127.2 (CH, C-12), 127.3 (CH, C-11), 128.1 (CH, C-10), 137.9 (C, C-9) ppm. IR (film): $\tilde{\nu}$ = 3007 (w), 2876 (m), 1485 (m), 1453 (m), 1401 (s) 1354 (m), 1296 (m), 1209 (m), 1165 (m), 1127 (s), 1055 (s), 989 (m), 930 (m), 864 (s), 739 (m), 698 (m), 617 (m) cm^{-1}. $C_{16}H_{22}O_5$ (294.35) calcd. C 65.29. H 7.53: found C 65.41. H 7.62.



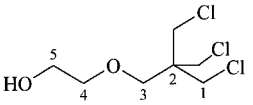
Preparation of $BzOCH_2CH_2OCH_2C(CH_2OH)_3$ (4): A solution of (18.2 g, 61.8 mmol) of $BzOCH_2CH_2OCH_2C(CH_2O)_3CCH_3$ (**3**) in 40 mL of methanol and 50 mL of 2 N HCl was stirred at room temperature for 6 h. Solid Na_2CO_3 (7.51 g, 71.3 mmol) was carefully added to the reaction mixture in small portions and the solution was subsequently stirred for another 18 h at ambient temperature. The solvents were removed by distillation, the residue was extracted with methanol and the solution was evaporated to dryness to yield pure $BzOCH_2CH_2OCH_2C(CH_2OH)_3$ (**4**) as a soft amorphous solid. Yield: 14.4 g (53.1 mmol, 86%). ^{1}H NMR (300.17 MHz, $CDCl_3$, 295 K): δ = 3.53 (s, 2 H, H-3), 3.60 (br. s, 4 H, H-4,5), 3.65 (s, 6 H, H-1), 4.54 (s, 2 H, H-6), 7.25−7.35 (m, 5 H, H-8,9,10) ppm. $^{13}C\{^1H\}$ NMR (75.48 MHz, $CDCl_3$, 295 K): δ = 45.0 (C, C-2), 64.5 (CH_2, C-4/5), 69.0 (CH_2, C-4/5), 70.8 (CH_2, C-6), 72.8 (CH_2, C-3), 73.2 (CH_2, C-1) 127.7 (CH, C-10), 127.8 (CH, C-9), 128.4 (CH, C-8), 137.6 (C, C-7) ppm. IR (film): $\tilde{\nu}$ = 3413 (vs), 2931 (s), 2878 (s), 1448 (s), 1410 (s), 1094 (s), 1040 (s), 837 (m), 746 (m), 699 (s) cm^{-1}. $C_{14}H_{22}O_5$ (270.33) calcd. C 62.20, H 8.20: found C 61.88. H 8.03.



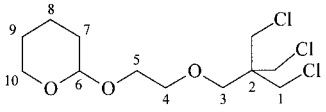
Preparation of $BzOCH_2CH_2OCH_2C(CH_2Cl)_3$ (5): $SOCl_2$ (20.5 g, 172 mmol) was added dropwise to a stirred mixture of $BzOCH_2CH_2OCH_2C(CH_2OH)_3$ (**4**; 14.1 g, 52.2 mmol) and dry pyridine (13.6 g, 172 mmol) at 0 °C. After complete addition, the reaction mixture was stirred for 30 min at 0 °C, then for 30 min at room temperature, and finally at 110−120 °C for 2.5 h. After cooling to 0 °C 150 mL of iced water was added and the aqueous phase thus obtained was twice extracted with 50 mL of CH_2Cl_2. The combined organic layers were treated with 100 mL of dilute HCl and with 2 × 100 mL of water and were then dried over Na_2SO_4. The solvent was removed by distillation at normal pressure, and the residue was purified by column chromatography to give $BzOCH_2CH_2OCH_2C(CH_2Cl)_3$ (**5**) as a colourless liquid. Yield: 9.52 g (29.2 mmol, 56%). R_f (Kieselgel, EtOAc/*n*-hexane = 1:9) = 0.34. ^{1}H NMR (300.17 MHz, $CDCl_3$, 295 K): δ = 3.53 (s, 2 H, H-3), 3.59−3.67 (m, 4 H, H-4,5), 3.64 (s, 6 H, H-1), 4.54 (s, 2 H, H-6), 7.25−7.34 (m, 5 H, H-8,9,10) ppm. $^{13}C\{^1H\}$ NMR (75.48 MHz, $CDCl_3$, 295 K): δ = 44.3 (CH_2, C-1), 46.3 (C, C-2), 68.6 (CH_2, C-4/5), 69.3 (CH_2, C-4/5), 71.0 (CH_2, C-6), 73.2 (CH_2, C-3), 127.6 (CH, C-10), 127.7 (CH, C-9), 128.4 (CH, C-8), 138.2 (C, C-7) ppm. IR (film): $\tilde{\nu}$ = 3029 (w), 2920 (m), 1495 (w), 1453 (m), 1434 (m), 1354 (m), 1307 (m), 1267 (m), 1104 (s), 871 (m), 798 (m), 741 (m), 698 (s), 616 (w) cm^{-1}. $C_{14}H_{19}Cl_3O_2$ (325.66): calcd. C 51.63. H 5.88: found C 51.89. H 5.74.



Preparation of $HOCH_2CH_2OCH_2C(CH_2Cl)_3$ (6) by Deprotection of $BzOCH_2CH_2OCH_2C(CH_2Cl)_3$ (5): A mixture of $BzOCH_2CH_2OCH_2C(CH_2Cl)_3$ (**5**; (8.32 mg 25.5 mmol) and 310 mg of Pd/C was stirred in THF at room temp under 1 bar of H_2 for 12 h. The reaction mixture was then filtered through celite, the solvent removed by distillation at normal pressure and the oily residue purified by fractional distillation at reduced pressure giving compound $HOCH_2CH_2OCH_2C(CH_2Cl)_3$ (**6**) as a colourless liquid. Yield: 4.88 g (20.7 mmol, 81%). B.p.: 97−99 °C/0.64 Torr. ^{1}H NMR (400.1 MHz, $CDCl_3$, 295 K): δ = 3.48 (s, 2 H, H-3), 3.54 (t, $^3J_{H,H}$ = 4.3 Hz, 2 H, H-4/5), 3.59 (s, 6 H, H-1), 3.68 (t, $^3J_{H,H}$ = 4.3 Hz, 2 H, H-4/5) ppm. $^{13}C\{^1H\}$ NMR (100.6 MHz, $CDCl_3$, 295 K): δ = 44.5 (CH_2, C-1), 46.5 (C, C-2), 62.0 (CH_2, C-5), 68.8 (CH_2, C-4), 73.0 (CH_2, C-3) ppm. IR (film): $\tilde{\nu}$ = 3373 (br), 2962 (s), 2877 (s), 1476 (m), 1434 (s), 1360 (m), 1308 (m), 1126 (s), 1062 (s), 871 (s), 806 (m), 759 (m), 742 (m), 701 (m) cm^{-1}. $C_7H_{13}Cl_3O_2$ (235.54): calcd. C 35.69, H 5.56; found C 35.23, H 5.50.

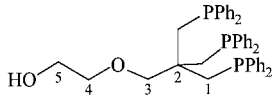


Preparation of $THPOCH_2CH_2OCH_2C(CH_2Cl)_3$ (8): Finely powdered KOH (9.45 g, 168 mmol) was added at room temperature to a vigorously stirred solution of 3-chloro-2,2-bis(chloromethyl)propan-1-ol (**7**; 8.02 g, 41.9 mmol) and (2-bromoethoxy)tetrahydropyran (26.2 g, 125 mmol) in 40 mL of DMSO. There was a strong evolution of heat during the addition and the temperature was controlled by occasional cooling with an ice bath. After complete addition of the solid KOH the reaction mixture was stirred at 60 °C for another 2 h and then cooled to room temperature. Water (180 mL) was added, and the aqueous phase was extracted with 3 × 50 mL of CH_2Cl_2. The combined organic extracts were washed with 3 × 50 mL H_2O and then dried over Na_2SO_4. After removal of the solvent by distillation the residue was subjected to fractional distillation under reduced pressure to give $THPOCH_2CH_2OCH_2C(CH_2Cl)_3$ (**10**) as a colourless liquid. Yield: 9.78 g (30.6 mmol, 73%). B.p.: 115 °C/0.19 Torr. ^1H NMR (400.1 MHz, $CDCl_3$, 295 K): δ = 1.43−1.57 (m, 6 H, H-7,8,9), 3.44 (s, 2 H, H-3), 3.46−3.62 (m, 4 H, H-4,5), 3.59 (s, 6 H, H-1), 3.77−3.85 (m, 2 H, H-10), 4.69 (t, $^3J_{H,H}$ = 3.3 Hz, 1 H, H-6) ppm. $^{13}C\{^1H\}$ NMR (100.6 MHz, $CDCl_3$, 295 K): δ = 19.5 (CH_2, C-7/8/9), 25.6 (CH_2, C-7/8/9), 30.8 (CH_2, C-7/8/9), 44.5 (CH_2, C-1), 46.5 (C, C-2), 62.3 (CH_2, C-5), 66.7 (CH_2, C-10), 68.8 (CH_2, C-4), 70.8 (CH_2, C-3), 99.1 (CH, C-6) ppm. IR (film): $\tilde{\nu}$ =2942 (s), 2871 (m), 1440 (m), 1352 (m), 1260 (m), 1201 (m), 1128 (s), 1076 (s), 1036 (s), 1020 (m), 986 (m), 871 (m), 814 (w), 742 (w), 702 (w) cm^{-1}. $C_{15}H_{27}Cl_3O_3$ (319.66): calcd. C 45.09, H 6.62; found C 45.39, H 6.38.

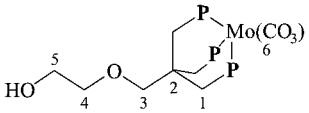


Preparation of $HOCH_2CH_2OCH_2C(CH_2Cl)_3$ (6) by Deprotection of $THPOCH_2CH_2OCH_2C(CH_2Cl)_3$ (8): Solid *p*-toluenesulfonic acid (220 mg) was added to a solution of $THPOCH_2CH_2OCH_2C(CH_2Cl)_3$ (**10**; 11.2 g, 35.1 mmol) in 50 mL of methanol. The reaction mixture was stirred at room temperature for 15 h, neutralised with solid K_2CO_3 and the solvent removed by distillation. The remaining residue was subjected to a fractional distillation as described above to give **6**. Yield: 7.78 g (32.9 mmol, 93%).

Preparation of $HOCH_2CH_2OCH_2C(CH_2PPh_2)_3$ (9): A solution of $HPPh_2$ (7.80 g, 41.9 mmol) in 10 mL of DMSO was added to a vigorously stirred suspension of K_2CO_3 (32.1 g, 233 mmol) in 45 mL of DMSO and this was followed by the addition of KOH (3.95 g, 70.4 mmol) in 3.0 mL of degassed water. The deep-red suspension thus obtained was stirred for 30 min at room temperature and then a solution of of $HOCH_2CH_2OCH_2C(CH_2Cl)_3$ (**6**; 3.14 g, 13.3 mmol) in 15 mL of DMSO was added with a syringe. The reaction mixture was stirred at 90 °C for 2 h and then at 110 °C for another hour. After cooling, 250 mL of water was added, the aqueous phase separated and the volatile organic components removed in vacuo. The residue was extracted with 2 × 20 mL of toluene, the solution treated with 2 × 10 mL of degassed water and then dried over Na_2SO_4. After removal of the solvent the residue was extracted with methanol and the target compound $HOCH_2CH_2OCH_2C(CH_2PPh_2)_3$ (**9**) was obtained as a colourless solid directly from the extract. Yield: 6.64 g (9.71 mmol, 73%). M.p.: 138 °C. ^1H NMR (400.14 MHz, $CDCl_3$, 295 K): δ = 2.38 (d, $^1J_{P,H}$ = 2.9 Hz, 6 H, H-1), 2.81 (t, $^3J_{H,H}$ = 4.4 Hz, 2 H, H-4/5), 3.24 (s, 2 H, H-3), 3.27 (t, $^3J_{H,H}$ = 4.4 Hz, 2 H, H-4/5), 7.16−7.25 (m, 30 H, aromat. H) ppm. $^{13}C\{^1H\}$ NMR (100.63 MHz, $CDCl_3$, 295 K): δ = 37.5−37.9 (m, CH_2, C-1), 41.7 (q, C, $^2J_{PC}$ = 11.4 Hz, C-2), 60.0 (s, CH_2, C-5), 70.5 (s, CH_2, C-4), 76.5 (q, CH_2, $^3J_{PC}$ = 7.6 Hz, C-3), 127.2−127.5 (m, CH, aromat. C), 131.8−132.1 (m, CH, aromat. C), 138.3 (m, C, aromat. C) ppm. $^{31}P\{^1H\}$ NMR (161.9 MHz, $CDCl_3$, 295 K): δ = −25.8 (s) ppm. IR (CH_2Cl_2): $\tilde{\nu}$ = 3395 (br), 3072 (m), 2864 (m), 1585 (w), 1481 (m), 1434 (s), 1405 (m), 1307 (w), 1259 (m), 1120 (s), 1061 (s), 1026 (m), 999 (m), 869 (m), 831 (m), 693 (m) cm^{-1}. $C_{43}H_{43}O_2P_3$ (684.73): calcd. C 75.43, H 6.33; found C 75.26, H 6.42.

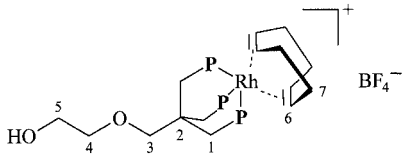


Preparation of $[\{HOCH_2CH_2OCH_2C(CH_2PPh_2)_3\}Mo(CO)_3]$ (10): A solution of $[(MeCN)_3Mo(CO)_3]$ (368 mg, 1.21 mmol) in 5 mL of acetonitrile was slowly added to a stirred suspension of $HOCH_2CH_2OCH_2C(CH_2PPh_2)_3$ (**9**; 831 mg, 1.21 mmol) in 10 mL of acetonitrile. The reaction mixture was stirred at ambient temperature for 16 h and the product was then precipitated by addition of Et_2O. The light brown solid was isolated by filtration, washed with Et_2O and dried under vacuum. Complex $[\{HOCH_2CH_2OCH_2C(CH_2PPh_2)_3\}Mo(CO)_3]$ (**10**) was obtained as an ochre microcrystalline solid after recrystallisation from acetonitrile/Et_2O. Yield: 963 mg (1.11 mmol, 92%). M.p.: 293 °C (dec.). ^1H NMR (300.17 MHz, CD_2Cl_2, 295 K): δ = 2.36 (m, 6 H, H-1), 3.43 (s, 2 H, H-3), 3.69 (t, $^3J_{H,H}$ = 5.6 Hz, 2 H, H-4/5), 3.81 (t, $^3J_{H,H}$ = 5.6 Hz, 2 H, H-4/5), 7.08−7.39 (m, 30 H, aromat. H) ppm. $^{13}C\{^1H\}$ NMR (75.48 MHz, CD_2Cl_2, 295 K): δ = 31.2 (m, CH_2, C-1), 41.7 (q, C, $^2J_{PC}$ = 7.1 Hz, C-2), 62.4 (s, CH_2, C-5), 73.3 (s, CH_2, C-4), 84.4 (q, CH_2, $^3J_{PC}$ = 9.8 Hz, C-3), 128.4−129.3 (m, aromat. C), 132.0−132.2 (m, aromat. C), 138.8−139.2 (m, aromat. C), 221.3 (m, CO, C-6) ppm. $^{31}P\{^1H\}$ NMR (161.9 MHz, CD_2Cl_2, 295 K): δ = 15.6 (s) ppm. IR (KBr): $\tilde{\nu}$ = 3444 (br), 3057 (w), 2901 (w), 1929 (vs), 1834 (vs), 1481 (m), 1433 (s), 1118 (m), 1082 (m), 999 (w), 831 (m), 737 (m), 697 (s), 623 (m) cm^{-1}. MS (FAB): *m/z* = 866.0 $[M + H]^+$. $C_{46}H_{43}MoO_5P_3$ (864.71): calcd. C 63.90, H 5.01; found C 63.72, H 4.88.



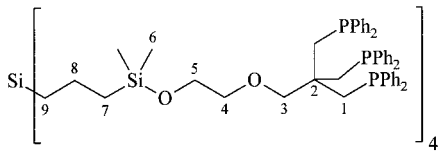
Preparation of $[\{HOCH_2CH_2OCH_2C(CH_2PPh_2)_3\}Rh(COD)]BF_4$ (11a) and of $[\{HOCH_2CH_2OCH_2C(CH_2PPh_2)_3\}Rh(COD)]PF_6$ (11b): A solution of $HOCH_2CH_2OCH_2C(CH_2PPh_2)_3$ (**9**; 766.9 mg, 1.12 mmol) in 15 mL of CH_2Cl_2 was slowly added to a stirred solution of $[Rh(COD)_2]BF_4$ (454.8 mg, 1.12 mmol) in 15 mL of CH_2Cl_2. The reaction mixture was stirred at room temperature for 14 h, accompanied by a change of colour from red-brown to orange and the product was then precipitated by addition of pentane. The yellow, microcrystalline solid obtained after washing with *n*-pentane and drying in vacuo was the pure complex $[\{HOCH_2CH_2OCH_2C(CH_2PPh_2)_3Rh(COD)\}]BF_4$ (**11a**).

11a: Yield: 1.03 g (1.05 mmol, 94%). M.p.: 165 °C (dec.). ^{1}H NMR (300.17 MHz, CD_2Cl_2, 295 K): δ = 2.41−2.46 (m, 4 H, H-7$_{exo}$), 2.60 (s, 6 H, H-1), 2.76−2.82 (m, 4 H, H-7$_{endo}$), 3.65 (s, 2 H, H-3), 3.75 (t, $^3J_{H,H}$ = 5.2 Hz, 2 H, H-4/5), 3.84 (t, $^3J_{H,H}$ = 5.2 Hz, 2 H, H-4/5), 4.08 (s, 4 H, H-6), 7.10−7.39 (m, 30 H, aromat. H) ppm. ^{13}C{^{1}H} NMR (75.48 MHz, CD_2Cl_2, 295 K): δ = 30.8 (m, CH_2, C-1), 33.6 (s, CH_2, C-6), 41.0 (m, C, C-2), 62.3 (s, CH_2, C-5), 73.6 (s, CH_2, C-4), 83.3 (q, CH_2, $^3J_{PC}$ = 11.0 Hz C-3), 84.8 (m, CH, C-7), 128−135 (m, aromat. C) ppm. ^{31}P{^{1}H} NMR (121.5 MHz, CD_2Cl_2, 295 K): δ = 4.3 (d, $^1J_{RhP}$ = 106.8 Hz) ppm. IR (film): $\tilde{\nu}$ = 3418 (br), 3051 (w), 2933 (w), 2870 (w), 1483 (m), 1433 (s), 1083 (vs), 1054 (s), 830 (m), 744 (m), 696 (s) cm^{-1}. $C_{51}H_{55}BF_4O_2P_3Rh$ (982.63): calcd. C 62.34, H 5.64; found C 62.11, H 5.75.

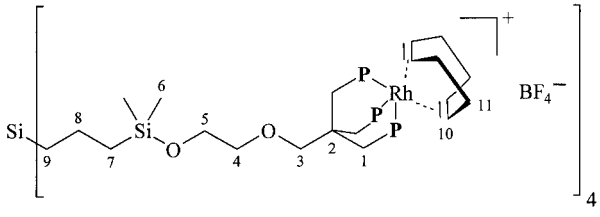


Complex **11b** was obtained by addition of NH_4PF_6 (163 mg, 3.46 mmol) in 5 mL of methanol to a solution of [{$HOCH_2CH_2OCH_2C(CH_2PPh_2)_3$}Rh(COD)]$BF_4$ (**11a**; 170 mg, 0.173 mmol) in 5 mL of methanol. The reaction mixture was stirred at room temperature for 15 h, the precipitate separated by filtration, washed with 2 × 3 mL of methanol and 2 × 5 mL of *n*-pentane and then dried in vacuo. The complex [{$HOCH_2CH_2OCH_2C(CH_2PPh_2)_3$}Rh(COD)]$PF_6$ (**11b**) was isolated as a yellow microcrystalline solid. Yield: 160.3 mg (0.153 mmol, 89%). M.p.: 185 °C (dec.). ^{1}H NMR (300.17 MHz, CD_2Cl_2, 295 K): δ = 2.43−2.49 (m, 4 H, H-7$_{exo}$), 2.63 (s, 6 H, H-1), 2.78−2.85 (m, 4 H, H-7$_{endo}$), 3.67 (s, 2 H, H-3), 3.78 (t, $^3J_{H,H}$ = 5.2 Hz, 2 H, H-4/5), 3.85 (t, $^3J_{H,H}$ = 5.2 Hz, 2 H, H-4/5), 4.11 (s, 4 H, H-6), 7.11−7.42 (m, 30 H, aromat. H) ppm. ^{13}C{^{1}H} NMR (75.48 MHz, CD_2Cl_2, 295 K): δ = 31.2 (m, CH_2, C-1), 33.2 (CH_2, C-6), 41.1 (m, C, C-2), 62.5 (CH_2, C-5), 73.7 (CH_2, C-4), 83.5 (q, CH_2, $^3J_{PC}$ = 10.9 Hz C-3), 85.0 (m, CH, C-7), 128−135 (m, aromat. C) ppm. ^{19}F{^{1}H} NMR (376.47 MHz, CD_2Cl_2, 295 K): δ = −73.8 (d, $^1J_{P,F}$ = 715 Hz) ppm. ^{31}P{^{1}H} NMR (121.51 MHz, CD_2Cl_2, 295 K): δ = −143.2 (sept), 5.5 (d, $^1J_{Rh,P}$ = 104.4 Hz) ppm. IR (film): $\tilde{\nu}$ = 3419 (br), 2929 (w), 2862 (w), 2815 (w), 1482 (m), 1434 (s), 1122 (m), 1085 (m), 844 (s), 745 (m), 697 (m) cm^{-1}. $C_{51}H_{55}F_6O_2P_4Rh$ (1040.79): calcd. C 58.86, H 5.33; found C 59.10, H 5.21.

Preparation of G[0]-[OCH_2CH_2Otriphos]$_4$ (13): A 1.6 M solution of *n*BuLi in hexanes (1.40 mL, 2.23 mmol) was added to a stirred solution of $HOCH_2CH_2OCH_2C(CH_2PPh_2)_3$ (**9**; 1.53 mg, 2.23 mmol) in 15 mL of DME at −78 °C. The reaction mixture was warmed to ambient temperature and then stirred for another 30 min. After re-cooling to −78 °C a solution of G[0]-[Cl]$_4$ (**12**; 318.9 mg, 559 μmol) in 10 mL of DME was added dropwise and the reaction mixture was then stirred at ambient temperature for 36 h. After removal of the volatiles, the residue was extracted with toluene and the extract filtered through Celite. Compound G[0]-[OCH_2CH_2Otriphos]$_4$ (**13**) was obtained as a soft amorphous solid after removal of the solvent and drying under vacuum. Yield: 1.66 g (525 μmol, 94%). ^{1}H NMR (300.17 MHz, $CDCl_3$, 295 K): δ = 0.04 (s, 24 H, H-6), 0.50−0.61 (m, 16 H, H-7, 9), 1.22−1.35 (m, 8 H, H-8), 2.55 (s, 24 H, H-1), 2.76 (t, $^3J_{H,H}$ = 4.3 Hz, 8 H, H-4/5), 3.15 (s, 8 H, H-3), 3.21 (t, $^3J_{H,H}$ = 4.3 Hz, 8 H, H-4/5), 7.21−7.36 (m, 120 H, aromat. H) ppm. ^{13}C{^{1}H} NMR (75.48 MHz, $CDCl_3$, 295 K): δ = −0.1 (s, CH_3, C-6), 19.3 (s, CH_2, C-7/8/9), 20.0 (s, CH_2, C-7/8/9), 27.3 (s, CH_2, C-7/8/9), 40.4 (m, CH_2, C-1), 44.9 (q, CH_2, $^2J_{PC}$ = 12.4 Hz, C-2), 63.2 (s, CH_2, C-4/5), 73.5 (s, CH_2, C-4/5), 79.5 (q, CH_2, $^3J_{PC}$ = 17.0 Hz, C-3), 129.8−135.2 (m, aromat. C) ppm. ^{29}Si{^{1}H} NMR (79.49 MHz, CD_2Cl_2, 295 K): δ = 0.4 (s, *Si*), 18.7 (s, *Si*−O) ppm. ^{31}P{^{1}H} NMR (121.51 MHz, CD_2Cl_2, 295 K): δ = −26.9 (s) ppm. MS (FAB): *m*/*z* = 3164.3 [M + H]$^+$. $C_{192}H_{216}O_8P_{12}Si_5$ (3163.93): calcd. C 72.89, H 6.88; found C 72.41, H 6.76.

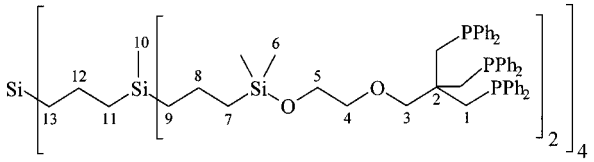


Preparation of G[0]-[OCH_2CH_2OtriphosRh(COD)BF_4]$_4$ (14): A solution of G[0]-[OCH_2CH_2Otriphos]$_4$ (**13**; 305 mg, 96.3 μmol) in 15 mL of CH_2Cl_2 was slowly added with a cannula to a stirred solution of [Rh(COD)$_2$]BF_4 (385 mg, 949 μmol) in 10 mL of CH_2Cl_2. The reaction mixture was stirred at room temperature for 24 h and the product was then precipitated by addition of *n*-pentane. The precipitate was separated by filtration, washed with 3 × 10 mL of *n*-pentane and then dried in vacuo. The reaction product G[0]-[OCH_2CH_2OtriphosRh(COD)BF_4]$_4$ (**14**) was obtained as a yellow solid. Yield: 369 mg (84.7 μmol, 88%). M.p.: 161 °C (dec.). ^{1}H NMR (300.17 MHz, CD_2Cl_2, 295 K): δ = 0.01 (s, 24 H, H-6), 0.49−0.55 (m, 8 H, H-9), 0.60−0.66 (m, 8 H, H-8), 0.86−0.91 (m, 8 H, H-7), 2.43 (br. s, 16 H, H-11$_{exo}$), 2.58 (s, 24 H, H-1), 2.77 (br. s, 16 H, H-11$_{endo}$), 3.61 (s, 8 H, H-3), 3.69 (t, $^3J_{H,H}$ = 4.9 Hz, 8 H, H-4/5), 3.82 (t, $^3J_{H,H}$ = 4.9 Hz, 8 H, H-4/5), 4.09 (br. s, 16 H, H-10), 7.09−7.37 (m, 120 H, aromat. H) ppm. ^{13}C{^{1}H} NMR (75.48 MHz, CD_2Cl_2, 295 K): δ = −2.0 (s, CH_3, C-6), 17.3 (s, CH_2, C-7/8/9), 17.9 (s, CH_2, C-7/8/9), 21.1 (s, CH_2, C-7/8/9), 30.8 (m, CH_2, C-1), 33.2 (s, CH_2, C-10), 40.6 (m, C, C-2), 61.9 (s, CH_2, C-5), 73.1 (s, CH_2, C-4), 83.0 (q, $^3J_{P,C}$ = 10.2 Hz, CH_2, C-3), 84.5 (m, CH, C-10), 128.2−135.5 (m, aromat. C) ppm. ^{29}Si{^{1}H} NMR (79.49 MHz, CD_2Cl_2, 295 K): δ = 0.2 (s, *Si*), 17.8 (s, *Si*−O) ppm. ^{31}P{^{1}H} NMR (121.51 MHz, CD_2Cl_2, 295 K): δ = 4.5 (d, $^1J_{Rh,P}$ = 104.3 Hz) ppm. IR (KBr): $\tilde{\nu}$ = 2913 (m), 2870 (m), 1432 (m), 1250 (w), 1084 (s), 1047 (m), 833 (m), 737 (m), 696 (s) cm^{-1}. MS (ESI): *m*/*z* = 1002.2 [(M − 4BF_4)/4]$^+$. $C_{224}H_{264}B_4F_{16}O_8P_{12}Rh_4Si_5$ (4355.50): calcd. C 61.77, H 6.11; found C 61.32, H 6.02.

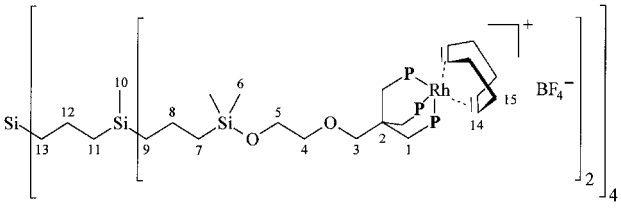


Preparation of G[1]-[OCH_2CH_2Otriphos]$_8$ (16): A 1.6 M solution of *n*BuLi in *n*-hexane (1.77 mL, 2.83 mmol) was added to a solution of $HOCH_2CH_2OCH_2C(CH_2PPh_2)_3$ (**9**; 1.94 g, 2.83 mmol) in 10 mL of DME at −78 °C. The reaction mixture was warmed to room temperature and then subsequently stirred for 30 min. After re-cooling to −78 °C, a solution of G[1]-[Cl]$_8$ (**15**; 514.0 mg, 353 μmol) in 15 mL of DME was added with the aid of a syringe and the reaction mixture was then stirred for 36 h at ambient temperature. After removal of the volatiles, the residue was extracted with toluene and the extract filtered through Celite. After removing the solvent in vacuo, the reaction product G[1]-[OCH_2CH_2Otriphos]$_8$ (**16**) was obtained as an analytically pure soft solid. Yield: 2.13 g (321 μmol, 91%). ^{1}H NMR (300.17 MHz, $CDCl_3$, 295 K): δ = 0.16 (s, 48 H, H-6), 0.20 (s, 12 H, H-10), 0.67−0.77 (m, 48 H, H-7, 9,

11, 13), 1.41−1.51 (m, 24 H, H-8, 12), 2.71 (s, 48 H, H-1), 2.92 (t, $^3J_{H,H}$ = 5.4 Hz, 16 H, H-4/5), 3.29 (s, 16 H, H-3), 3.37 92 (t, $^3J_{H,H}$ = 5.4 Hz, 16 H, H-4/5), 7.33−7.51 (m, 240 H, aromat. H) ppm. $^{13}C\{^1H\}$ NMR (75.48 MHz, $CDCl_3$, 295 K): δ = −1.9 (s, CH_3, C-10), −1.5 (s, CH_3, C-6), 17.7 (s, CH_2, C-7/8/9), 17.8 (s, CH_2, C-11/12/13), 20.8 (s, CH_2, C-7/8/9), 21.8 (s, CH_2, C-7/8/9), 22.3 (s, CH_2, C-11/12/13), 22.9 (s, CH_2, C-11/12/13), 38.1 (m, CH_2, C-1), 42.8 (q, $^2J_{P,C}$ = 12.5 Hz, C, C-2), 61.3 (s, CH_2, C-4/5), 71.5 (s, CH_2, C-4/5), 77.4 (q, $^3J_{P,C}$ = 12.5 Hz, CH_2, C-2), 128.1−140.0 (m, aromat. C) ppm. $^{29}Si\{^1H\}$ NMR (79.49 MHz, CD_2Cl_2, 295 K): δ =0.5 (s, *Si*), 0.9 (s, *Si*Me), 17.6 (s, *Si*Me_2O) ppm. $^{31}P\{^1H\}$ NMR (121.51 MHz, $CDCl_3$, 295 K): δ = −27.3 (s) ppm. MS (MALDI-TOF): *m*/*z* = 6642.9 $[M]^+$. $C_{400}H_{468}O_{16}P_{24}Si_{13}$ (6640.59): calcd. C 72.35, H 7.10; found C 71.83, H 6.93.



Preparation of G[1]-[OCH_2CH_2OtriphosRh(COD)BF_4]$_8$ (17): A solution of G[1]-[OCH_2CH_2Otriphos]$_8$ (**16**; 717.2 mg, 108 μmol) in 15 mL of CH_2Cl_2 was added to a stirred solution of $[Rh(COD)_2]BF_4$ (351 mg, 864 μmol) in 10 mL of CH_2Cl_2. The reaction mixture was stirred at ambient temperature for 24 h and the product subsequently precipitated by addition of pentane. After centrifugation, the precipitate was washed with 3 × 10 mL of *n*-pentane and then dried in vacuo. The metallodendrimer G[1]-[OCH_2CH_2OtriphosRh(COD)BF_4]$_8$ (**17**) was obtained as a yellow powder. Yield: 945 mg (97.2 μmol, 90%). M.p.: 156C (dec.). ^1H NMR (400.2 MHz, CD_2Cl_2, 295 K): δ = 0.09 (s, 12 H, H-10), 0.20 (s, 48 H, H-6), 0.51−0.67 (m, 48 H, H-7,9,11,13), 1.28−1.38 (m, 24 H, H-8,12), 2.45 (m, 32 H, H-15), 2.60 (s, 48 H, H-1), 2.78 (m, 32 H, H-15), 3.62 (s, 16 H, H-3), 3.70 (m, $^3J_{H,H}$ = 6.1 Hz, 32 H, H-14), 7.08−7.50 (m, 120 H, aromat. H) ppm. $^{13}C\{^1H\}$ NMR (75.48 MHz, CD_2Cl_2, 295 K): δ = δ = −1.6 (s, CH_3, C-6), 17.9 (s, CH_2, C-7/8/9), 18.2 (s, CH_2, C-11/12/13), 18.6 (s, CH_2, C-7/8/9), 18.6 (s, CH_2, C-11/12/13), 20.9 (s, CH_2, C-7/8/9), 23.2 (s, CH_2, C-11/12/13), 31.2 (m, CH_2, C-1), 33.5 (s, CH_2, C-15), 41.1 (m, C, C-2), 62.3 (s, CH_2, C-5), 73.7 (s, CH_2, C-4), 83.4 (q, $^3J_{P,C}$ = 10.2 Hz, CH_2, C-3), 84.9 (m, CH, C-14), 128.2−135.3 (m, aromat. C) ppm. $^{29}Si\{^1H\}$ NMR (79.49 MHz, CD_2Cl_2, 295 K): δ = 0.5 (s, *Si*Me), 17.6 (s, *Si*Me_2O) ppm. $^{31}P\{^1H\}$ NMR (121.51 MHz, CD_2Cl_2, 295 K): δ = 4.4 (d, $^1J_{Rh,P}$ = 106.8 Hz) ppm. IR (KBr): $\tilde{\nu}$ = 2912 (m), 2870 (m), 1482 (m), 1433 (s), 1250 (m), 1084 (s), 1051 (s), 833 (m), 743 (m), 695 (s), cm^{-1}. MS (ESI): *m*/*z* = 1041.3 $[(M - 8\ BF_4)/8]^+$. $C_{464}H_{564}B_8F_{32}O_{16}P_{24}Rh_8Si_{13}$ (9023.73) calcd. C 61.76, H 6.30; found C 61.21, H 6.09.



Catalyst Testing: The catalyst tests were carried out in THF at 1 bar H_2 pressure using 1 mol % of rhodium. The course of the catalytic hydrogenation was monitored by GC/MS spectrometry performed with a Shimadzu GC-17A/GCMS-QP5050A. Column: SGE BPX5, 5% phenyl, polysilyphenylene-siloxane, nonpolar, 30 m, 0.22 mm, carrier gas He. The products were analysed by comparison of the recorded mass spectra and retention times with those of authentic samples. The measured relative ratio of the products was calibrated by comparative measurements with known substance ratios using pure substances.

X-ray Diffraction Study of Compounds 10 and 11b: Suitable crystals of the complexes **10** and **11b** were obtained by layering concentrated solutions of the compounds in dichloromethane with hexanes and allowing slow diffusion at room temperature. The crystal data were collected on a Nonius Kappa CCD diffractometer at −100 °C and transferred to a DEC Alpha workstation; for all subsequent calculations the Nonius OpenMoleN package was used.[32] The structures were solved by direct methods with absorption corrections being part of the scaling procedure of the data reductions. After refinement of the heavy atoms, difference Fourier maps revealed the maxima of residual electron density close to the positions expected for the hydrogen atoms; they were introduced as fixed contributors in the structure factor calculations with fixed coordinates (C−H: 0.95 Å) and isotropic temperature factors [B(H) = 1.3 B_{eqv}(C) Å^2] but not refined. Full least-square refinements on F^2. A final difference map revealed no significant maxima of electron density. The scattering factor coefficients and the anomalous dispersion coefficients were taken from ref.[33] Crystal data and experimental details for the crystals of **10** and **11b** are given in Table 1.

Table 1. X-ray experimental data of compounds **10** and **11b**

	10	**11b**
Formula	$C_{46}H_{43}MoO_5P_3$	$C_{52}H_{57}Cl_2F_6O_2P_4Rh$

The Structure of Some Amine Solvates of Magnesium Bis(tetrahydroborate) and DFT Calculations on Solvates of Lithium Tetrahydroborate[‡]

Mathias Bremer,[a] Heinrich Nöth,*[a] and Marcus Warchhold[a]

Dedicated to Professor Gottfried Huttner on the occasion of his 65th birthday

Keywords: Amine ligands / Borates / Density functional calculations / Lithium / Magnesium

Eight solvates of magnesium bis(tetrahydroborate) have been prepared and characterised by NMR and IR spectroscopy, and five of them also by X-ray crystallography. Compounds $Mg(BH_4)_2 \cdot 3NH_2tBu$ and $Mg(BH_4)_2 \cdot 3pip$ each have a distorted trigonal-bipyramidal structure (with the BH_4 group viewed as a simple ligand) while the putative $Mg(BH_4)_2 \cdot 6py$ proved to be $[Mg(BH_4)_2 \cdot 4py]$ with a pseudooctahedral structure, two py molecules being present as solvent of crystallization. Similarly, $Mg(BH_4)_2 \cdot 8DMSO$ contains the cation $[Mg(DMSO)_6]^{2+}$ in the crystal, and $Mg(BH_4)_2 \cdot 6NH_2Bzl$ has an ionic lattice made up of $Mg(NH_2Bzl)_6^{2+}$ and BH_4^- ions. The BH_4 groups in the molecular compounds are bonded to the Mg centre through double hydrogen bonds. In order to study the bonding in alkali and alkali earth metal tetrahydroborates, DFT calculations were performed for $LiBH_4$ and its ammonia and dimethyl ether solvates. The minimum-energy structure for a $LiBH_4$ molecule has C_{3v} symmetry; this is not changed when one ammonia molecule is added and is also the result for $LiBH_4 \cdot 3NH_3$. Addition of the first NH_3 or Me_2O molecule contributes more to the stabilisation than a second or a third molecule.

Introduction

The BH_4 anion is a versatile ligand. In mononuclear complexes, one, two or three of its hydrogen atoms may bond to the metal centre. In di-, tri-, and tetranuclear complexes, and also in polymeric compounds, two, three, or even all four hydrogen atoms of the BH_4 ion may be involved in coordination to the metal centres.[1,2] While the structures of the diethyl ether and amine solvates of the alkali metal tetrahydroborates, particularly those of lithium, are fairly well known, there is little structural information on solvates of magnesium bis(tetrahydroborate). So far, only two compounds − $Mg(BH_4)_2 \cdot 3thf$[3,4] and $Mg(BH_4)_2 \cdot$diglyme − have been structurally investigated.[5] Both are mononuclear, with $Mg(\mu\text{-}H_2BH_2)_2$ units to which the diethyl ether ligands are coordinated. Although many other solvates of magnesium bis(tetrahydroborate) have been reported,[6−10] no structural information as to the bonding of the BH_4 group is known. In pursuit of our interest in studying the structures of tetrahydroborates of main group metals systematically we have prepared a number of new solvates of $Mg(BH_4)_2$ and determined their crystal structures. Moreover, we also performed DFT calculations on mononuclear $LiBH_4 \cdot n OMe_2$ and $LiBH_4 \cdot n NH_3$ in the expectation that they might offer insights into the hydrogen bonding of the BH_4 group and the stability of the solvates.

Preparation and Spectra

Magnesium bis(tetrahydroborate) is regarded as a salt-like compound, due to its comparatively high melting point (180 °C)[11] and very low solubility in non-polar solvents. It was first prepared by Wiberg and Bauer,[12] from Et_2Mg and diborane in diethyl ether solution, while it was later shown by Ashby and Becker that dimeric $EtMgBH_4 \cdot OEt_2$ is a better starting material.[13] It reacts with diborane in diethyl ether solution to give a solid 2:3 diethyl ether adduct of magnesium tetrahydroborate. Under similar conditions we obtained $Mg(BH_4)_2 \cdot 2OEt_2$ as a viscous oil, which reacts rapidly with moisture [see Equation (1)].

$$EtMg(BH_4) + B_2H_6 \rightarrow Mg(BH_4)_2 + \text{“}EtBH_2\text{''} \quad (1)$$

It is clear that the formation of $Mg(BH_4)_2$ as in Equation (1) requires several steps. ^{11}B NMR spectroscopy gives an insight into the course of the reaction. Figure 1 shows spectra taken at different ratios of $EtMgBH_4/B_2H_6$ in diethyl ether solution. Trace 1 shows the (undecoupled) ^{11}B quintuplet signal of the starting material at $\delta = -43.1$ ppm.

[‡] Metal Tetrahydroborates and Tetrahydroborato Metallates, 28. Part 27: Ref.[1]

[a] Department of Chemistry, University of Munich, Butenandstr. 5−13, 81377 Munich, Germany

Trace 2 shows in addition a quadruplet and a triplet at δ = −27 and −18 ppm; these are typical for $EtBH_3^-$ and $Et_2BH_2^-$. More diborane (trace 3) gives rise to the formation of more $Et_2BH_2^-$ besides BEt_3 (signal at δ = 86 ppm). Trace 5 reveals that the addition of even more diborane transforms the ethylhydridoborates completely into BH_4^- and ethyldiboranes. Moreover, BEt_3 reacts with diborane to give the ethyldiboranes and the former compound vanishes completely, as shown in trace 6. The 1:1 signal ratio of the broad signal at δ = 42.9 ppm and the triplet of triplets at δ = 4.8 ppm are indicative of the preferred formation of asymmetrically substituted diethyldiborane $Et_2BH_2BH_2$. After removal of all volatiles, only the quintuplet signal of magnesium tetrahydroborate could be noted. The most striking feature of this process is that the anion Et_3BH^- is not observed. We assume that this species reacts very rapidly with "BH_3" to give BEt_3 and BH_4^-. In a similar reaction, Et_2BH is formed by hydride abstraction from $Et_2BH_2^-$ by diborane. Et_2BH then picks up BH_3 to give asymmetrical diethyldiborane. The characterising NMR spectroscopic data are listed in the legend of Figure 1.

It is known from previous work[6−10] that $Mg(BH_4)_2$ readily forms solvates with diethyl ethers and amines. Adducts with ammonia[8,9] and with methylamines[10] are readily available, as is the complex with isopropylamine,[10] but all these adducts deteriorate quickly at ambient temperature. We were, however, able to obtain the last of these compounds as single crystals, but these became rapidly turbid during their isolation at low temperature (ca. −30 °C). In contrast, $Mg(BH_4)_2{\cdot}3H_2NCMe_3$ (**1**) was isolable and stable at −30 °C. All the new compounds, as well as a previously described pyridine adduct,[10] were obtained either by dissolving $Mg(BH_4)_2$ in the amine as solvent or by replacement of THF from $Mg(BH_4)_2{\cdot}3$thf with a new ligand L′, and crystallisation of the complexes by addition of cyclohexane to the resulting solutions. Reactions proceeded as shown in Equation (2). The compounds listed in Table 1 were obtained. The yields were not optimised, only the material that crystallised or precipitated being isolated.

$$Mg(BH_4)_2{\cdot}n\mathrm{L} + n\,\mathrm{L}' \rightarrow Mg(BH_4)_2{\cdot}n\mathrm{L}' + n\,\mathrm{L} \quad (2)$$

^{11}B NMR spectra were recorded either in the corresponding amine as solvent or in DMSO. The shielding of the boron nuclei and the coupling constants observed are practically independent of the coordinated ligand (diethyl ethers, amines). The small but significant low-field shift of the ^{11}B NMR signal relative to $NaBH_4$ [$\delta^{11}B$ = −41; $^1J(BH)$ = 82 Hz] suggests that there is a weak interaction between the tetrahydroborate anion and the Mg cation, but on the other hand, the fairly similar shielding also suggests that $Mg(BH_4)_2$ is present in amine solution as a salt [Mg(amine)$_n$]$(BH_4)_2$, and hence that the solution state is different to the structure in the solid state except in the case of compound **4**. As with most tetrahydroborates, neither the ^{11}B chemical shift nor the coupling constant give a reliable in-

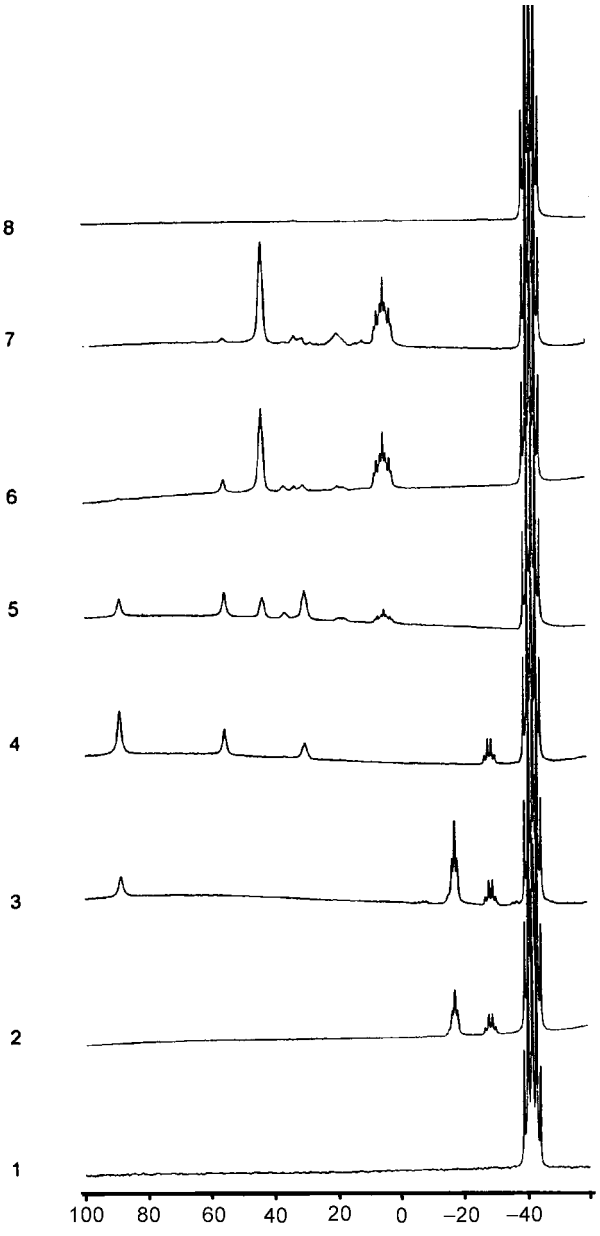

Figure 1. ^{11}B NMR spectra of a solution of $EtMgBH_4$ to which diborane dissolved in diethyl ether was added incrementally; assignment of chemical shifts (in $\delta^{11}B$) are as follows: BH_4^- −43.1, H_3BEt^- −30.3, $H_2BEt_2^-$ −18.1, $H_2BH_2BEt_2$ 4.8, H_2BEt 29.8, $H_2BH_2BEt_2$ 42.9, $HBEt_2$ 54.9, BEt_3 87.3

dication as to the bonding of the BH_4 group to Mg^{2+}. The quintuplet structure of the signal shows four chemically equivalent hydrogen atoms: this may be due to a free anion or to rapid exchange between bridging and terminal hydrogen atoms.[14]

Thanks to its higher time resolution, IR spectroscopy may be more informative as far as the interaction of the cation with the BH_4 anion is concerned. Depending on the type of hydrogen bond the local symmetry of the BH_4 anion changes from C_{3v} to C_{2v} and then to C_{3v} for the single bridge $Mg(H-BH_3)$ to the double bridge $Mg(H_2BH_2)$ and then to the triple bridge $Mg(H_3BH)$. The expected spectra are different for the three types of bonding. For double hydride bridges, four active IR bands, due to two $\nu_{as}BH_2$ vibrations and two $\nu_{sym}BH_2$ vibrations, would be expected, while for C_{3v} symmetry three bands, due to ν_{as} and ν_{sym} for the H_3B group and one stretching frequency for the single B−H bond, should be observable.

The presence of four bands in the IR spectrum of $Mg(BH_4)_2 \cdot 2OEt_2$ thus points to double hydride bridges, and this suggests hexacoordination at the Mg centre (two oxygen and four hydrogen atoms, see Table 2).

In contrast, the crown diethyl ether complex exhibits only three bands, which are found in the same region as for $NaBH_4$,[15] and this is indicative of an ionic structure. The same feature is found for the DMSO compound **6**, but this is not compatible with its $\delta^{11}B$ value (−33.8). The structure in DMSO solution may therefore be different from that in the solid state. One can imagine an equilibrium in solution of a type as shown in Equation (3).

$$Mg(DMSO)_6^{2+} + 2\,BH_4^- \rightleftarrows Mg(DMSO)_5BH_4^+ + BH_4^- + DMSO \quad (3)$$

The diethylenetriamine complex **7** shows an IR spectrum typical of free BH_4 anions in the BH stretching range. This compound should therefore have the constitution $[Mg(dta)_2](BH_4)_2$, with hexacoordinated Mg ions. In contrast, complex **8** − which contains only one molecule of the amine − has five BH bands in the stretching region. This indicates that it most probably has the structure $[Mg(pmdta)H_2BH_2]BH_4$.

Crystal Structures

In order to investigate the type of hydride bridging between the BH_4 anion and the Mg ion in the solid state, single crystals of **1**−**4** and also of **6** were studied by X-ray crystallography. The tBuNH$_2$ solvate **1** crystallises in the monoclinic space group $P2_1/n$ with $Z = 8$ (i.e., there are two independent molecules in the asymmetric unit). The molecular parameters of the two molecules are fairly similar, and so only one of them is depicted in Figure 2. Both BH_4 groups in the molecule are bonded to the magnesium ion through two hydrogen atoms. A distorted trigonal-bipyramidal arrangement of two boron and three nitrogen atoms around the magnesium centre is observed, with two nitrogen atoms in the apical positions. The apical Mg−N distances are longer [2.243(2), 2.277(2) Å] than the equatorial Mg−N bond [2.212(2) Å]. The atoms Mg1, B1, B2, and N2 lie almost in a perfect plane. Interestingly, the B−Mg−B angle is quite open, at 137.87(8)°. The Mg···B distances in **1** are on average 0.097 Å longer than in $Mg(BH_4)_2 \cdot 3thf$.[3,4] Although all hydrogen positions around the boron atoms were found in the difference Fourier map and refined well, the B−H distances nevertheless have to be regarded as approximate distances.

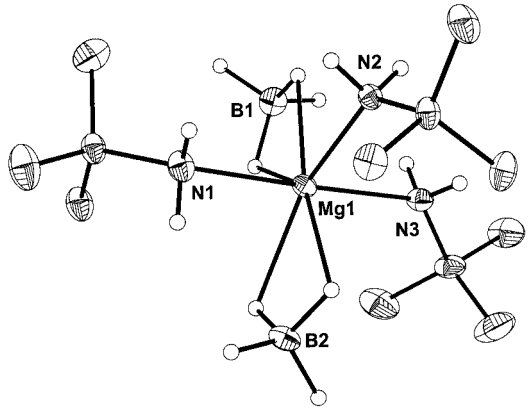

Figure 2. The molecular structure of compound **1**; thermal ellipsoids are represented on a 25% probability scale; selected atom distances (in Å) and bond angles (in °): Mg1−N1 2.243(2), Mg1−N2 2.212(2), Mg1−N3 2.227(2), Mg···B1 2.549(2), Mg1···B2 2.521(2), Mg−H_{br} 2.08 (aver.), B−H_{br} 1.15(1) (aver.), B−H_{term} 1.12(1) (aver.); B1−Mg1−B2 137.8(8), N1−Mg1−N2 89.48(6), N1−Mg1−N3 177.55(7), N2−Mg−N3 90.44(7)

In principle, the same molecular structure as for **1** was found for **2** (see Figure 3). However, this molecule crystallises in the triclinic system with the centrosymmetric space group $P\bar{1}$, $Z = 2$. In contrast to **1**, one of the two apical N atoms has a short Mg−N bond [2.233(4) Å] while the second [2.249(4) Å] is longer, practically as long the

equatorial Mg−N distance [2.244(4) Å]. Moreover, the two Mg···B distances are quite different, although their average value corresponds to the Mg···B distance found for **1**.

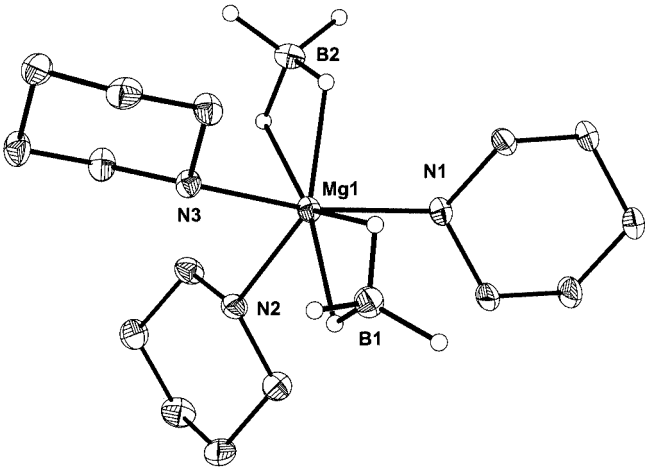

Figure 3. The molecular structure of compound **2**; thermal ellipsoids are represented on a 25% probability scale; selected atom distances (in Å) and bond angles (in °): Mg1−N1 2.233(4), Mg1−N2 2.244(4), Mg1−N3 2.249(4), Mg1···B1 2.536(6), Mg1···B2 2.520(6), Mg−H 1.99(5) (aver.), B−H_{br} 1.12(5) (aver.), B−H_{term} 1.15(5) (aver.); B1−Mg1−B2 143.6(2), N1−Mg1−N2 102.2(2), N1−Mg1−M3 165.0(2), N2−Mg1−N3 92.7(2)

The composition of the pyridine complex of $Mg(BH_4)_2$ suggested an ionic structure $[Mg(py)_6](BH_4)_2$. This is not the case, however, as shown by the X-ray structure analysis of the orthorhombic crystals, space group *Ccca* (see Figure 4). The asymmetric unit contains molecular $Mg(BH_4)_2$·4py, and in addition there are two pyridine molecules. The $Mg(BH_4)_2$·4py molecule possesses D_2 point group symmetry. All its pyridine molecules are arranged in a plane around the Mg centre, while the boron atoms stand perpendicularly on the MgN_4 plane. Thus, the geometry for the MgB_2N_4 unit is a distorted octahedron with the Mg atom in its centre. In agreement with the higher coordination number, the Mg···B distances are longer than those in **1** and **2**, but these lengths are considerably greater than would be expected. As a consequence, the Mg−H bond lengths are also long, and one should note, although with caution, that the bridging hydrogen B−H bond lengths are shorter than those of the terminal B−H bonds. On the other hand, the Mg−N bond lengths [varying from 2.197(2) to 2.224(3) Å] are longer than in **1** or **2**. One might argue that the difference in Mg−N bond length could be smaller because of the sp^2-type N atoms of the pyridine molecules.

In contrast to the molecular compounds, the benzylamine adduct **4** proved to be ionic. The crystals are monoclinic, space group $P2_1/c$, $Z = 4$. Figure 5 shows the cation, together with a BH_4 anion and two further boron atoms. The sites of these two boron atoms are occupied with SOFs of 0.5 on inversion centres. Although the highest residual electron densities are found around these boron atoms, assignment to boron-bonded hydrogen atoms was not possible. It should be noted that a set of tetrahedrally oriented H atoms would, by symmetry, be transformed into eight H positions about these boron atoms, and SOFs of 0.5 would be expected for these hydrogen atoms. It follows that it would be unlikely that these could be well located, because of the expected very low electron density for these hydrogen atoms.

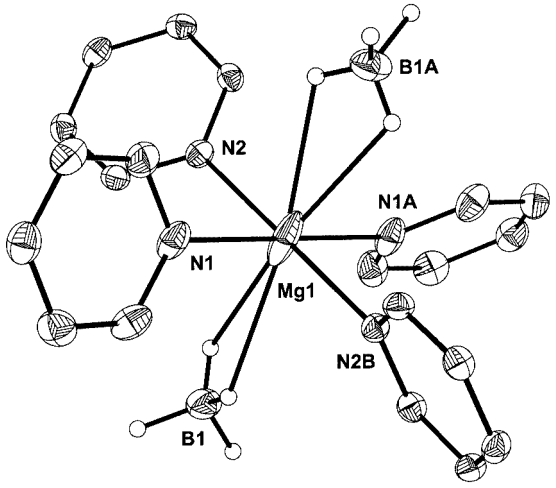

Figure 4. The molecular structure of compound **3**; thermal ellipsoids are represented on a 25% probability scale; selected atom distances (in Å) and bond angles (in °): Mg1−N1 2.224(3), Mg1−N2 2.197(2), Mg1···B1 2.988(4), Mg1−H_{br} 2.40(4) (aver.), B−H_{br} 0.98(5), B−H_{term} 1.13(3); B1−Mg1−B1A 180, B1−Mg1−N1 90, N1−Mg1−N1A 180

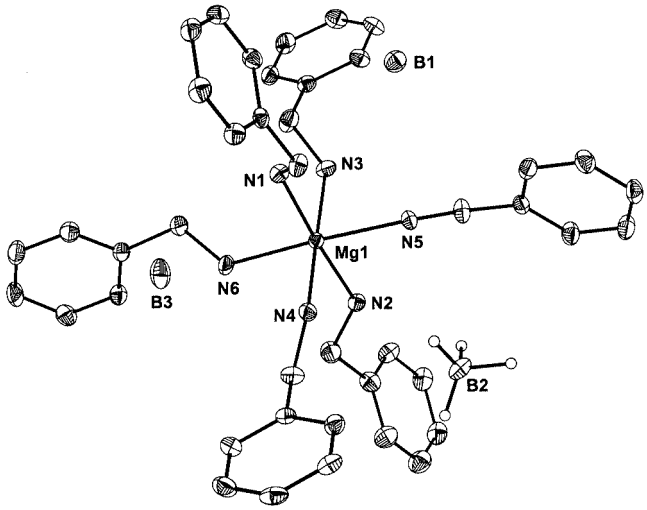

Figure 5. The molecular structure of compound **4**; thermal ellipsoids are represented on a 25% probability scale; selected atom distances (in Å) and bond angles (in °): Mg1−N1 2.252(2), Mg1−N2 2.247(2), Mg1−N3 2.263(2), Mg1−N4 2.258(2), Mg1−N5 2.258(2), Mg1−N6 2.233(2); N1−Mg1−N2 176.50(9), N1−Mg1−N3 89.92(8), N1−Mg1−N4 87.88(8), N1−Mg1−N5 89.62(8), N1−Mg1−N6 91.23(9), N3−Mg1−N4 176.89(6), N5−Mg1−N6 176.95(5)

The Mg ion occupies a slightly distorted octahedral environment. One of the six Mg−N bonds is significantly shorter [2.233(2) Å] than the other five [2.247−2.263(2) Å]. The N−Mg−N bond angles of adjacent N atoms range from 87.88(8) to 91.23(9)°, while those of opposite N atoms are practically identical [176.89(9) to 176.95(9)°].

Figure 6 shows the structure of compound **6**. The asymmetric unit of the cell is $[Mg(DMSO)_6]_{1/2}\cdot(BH_4)\cdot DMSO$. A symmetry operation through an inversion centre generates the cation $Mg(DMSO)_6^{2+}$ and an additional BH_4, besides a DMSO molecule. The Mg−O distances range from 2.056 through 2.072 to 2.093(2) Å, and the O−Mg1−O bond angles are consequently 180° for opposite oxygen atoms and very close to 90° for adjacent oxygen atoms. The S−O bond lengths of the coordinated DMSO molecules are slightly longer [1.516 to 1.521(2) Å] than those in the free DMSO molecule [1.501(3) Å], while the S−C bonds are slightly shorter for coordinated DMSO [aver. 1.769(5) Å] than for non-coordinated DMSO (1.779 Å). On the other hand the O−S−C bond angles in the coordinated DMSO molecules are slightly smaller than those in free DMSO.

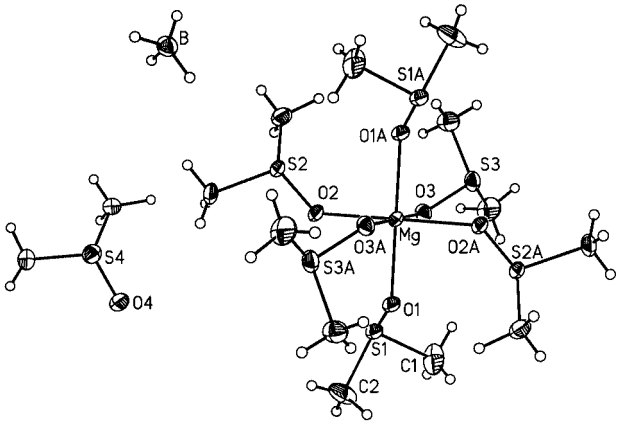

Figure 6. The molecular structure of compound **6**; thermal ellipsoids are represented on a 25% probability scale; selected atom distances (in Å) and bond angles (in °): Mg1−O1 2.056(2), Mg1−O2 2.093(2), Mg1−O3 2.072(2), B1−H1 1.10(4), B1−H2 0.75(4), B1−H3 1.02(4), B1−H4 1.15(4), S1−O1 1.520(2), S1−C1 1.769(5), S1−C2 1.769(5), S2−O2 1.521(2), S3−O3 1.516(2), S4−O4 1.501(3), S4−C7 1.781(5), S4−C8 1.777(5); O1−Mg1−O1A 180; O1−Mg1−O2 89.86(9), O1−Mg1−O2A 90.14(9), O1−Mg1−O3 90−20(9), O1−Mg1−O3A 89.80(9), H−B−H 92−122(3), S1−O1−Mg1 124.8(1), O1−S1−C1 104.9(2), O1−S1−C2 103.7(2), C1−S1−C2 97.4(2), S2−O2−Mg1 118.6(1), O2−S2−C3 105.2(2), O2−S2−C4 105.1(2), C3−S2−C4 98.4(3), S3−O3−Mg1 122.7(1), O3−S3−C5 105.9(2), O3−S3−C6 104.1(2), O4−S4−C7 107.1(2), O4−S4−C8 106.2(2), C7−S4−C8 96.7(2)

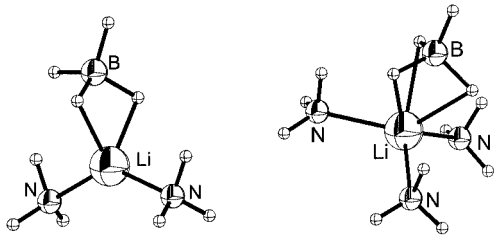
DFT Calculations

As far as magnesium tetrahydroborates are concerned, the structures determined so far show that only $\mu_2{}^1$ bonding (double hydride bridge to a single central atom) of the tetrahydroborate ion is present irrespective of the solvate ligand. In contrast, $LiBH_4$ forms a large variety of solvates with different types of bonded BH_4 groups ranging from molecular units with $\mu_2{}^1$-$\mu_3{}^1$-bonded BH_4 anions to dimers with two $2\mu_1{}^1$-$\mu_1{}^2$ BH_4 groups (two single and one H atom bridging two Li ions) to polymeric structures in which all H atoms of the BH_4 anion are involved.[1,16] Such a situation is also observed in the linear polymeric structure of $Ba(BH_4)\cdot 2thf$.[17] It was therefore of interest to obtain some insight into what should be expected when the $LiBH_4$ molecule is solvated, as these results may also be important for other alkali metal and alkaline earth metal tetrahydroborate compounds. For this reason we conducted DFT calculations on free $LiBH_4$ molecules and some of their ammonia and dimethyl ether solvates. These calculations were performed by use of the Gaussian 98 program package.[18] All calculations were conducted at the B3LYP level of theory[18,19] with the triple ξ basis set 6-311++G(d,p).[20] A frequency analysis after geometry optimisation showed no imaginary frequencies, and so the geometry represents a minimum on the energy hypersurface.

As the BH_4 anion approaches the Li cation, one would expect that the bond of the bridging hydrogen atoms should become longer than the terminal B−H bonds. This difference should increase as the BH_4 group becomes more polarized by the Li cation. Since it is difficult to determine the B−H distances reliably by X-ray diffractometry it is advisable to inspect the stretching frequencies of the B−H bonds (Scheme 1). Tables 3, 4, and 5 summarise the point group symmetries, the calculated wavenumbers of the B−H stretching vibrations and the calculated B−H bond lengths. Calculations with H_2O as a ligand could not be performed successfully as there is always a hydride−proton interaction giving rise to a very strong distortion. We therefore used dimethyl ether as the model for Li−O interactions. It should be noted that a distorted μ_2 coordination was found for $LiBH_4\cdot 2NH_3$; it is not included in the data of Table 5.



Scheme 1. Calculated geometries for $LiBH_4$ |1582NH_3 and $LiBH_4$ |1583NH_3 (see Table 3)

First, it follows that, on using a larger basis set for the $LiBH_4$ molecules of point group symmetry C_{3v}, significant differences result for $\nu_{sym}BH_{br}$ but particularly for νBH_{term}. Addition of NH_3 to $LiBH_4$ strengthens the bridging B−H bonds and weakens the terminal B−H bond, while addition of three ammonia molecules produces a remarkable weakening of the BH_{term} bond and a strengthening of the bridging B−H bonds. The same trend holds for the dimethyl ether adducts.

On the other hand, the calculated B−H distances, and in particular the Li···B atom distances, increase with increasing coordination number at the cation. Table 3 shows a comparison of calculated and observed Li···B, Li···N, and Li−H distances. The calculated and observed data (but not the trend) are compatible.

Moreover, the trend in bonding should be reflected by the calculated electronic energies (Table 4). The data given are corrected by unscaled zero point energies and are relative to $LiBH_4$ with C_{3v} point group symmetry and triple hydride bridging. Data for the solvated $LiBH_4$ molecule are

also scaled for $Li(H_3BH)$ and free solvent molecules with $E = 0$ kJ/mol.

There is an energy difference of 90 kJ/mol between singly and doubly bridged $LiBH_4$, while the energy difference between the latter and the triply bridged molecule is only 19 kJ/mol. Dimerization of $LiBH_4$ affords a stabilization by 68 kJ/mol, and successive addition of ammonia produces a large stabilization for the addition of the first molecule, and less for each other step as one adds two or three molecules. $LiBH_4{\cdot}3NH_3$ is the most stable monomeric arrangement. Calculations also show that $(LiBH_4{\cdot}NH_3)_2$ is 7 kJ/mol more stable than $LiBH_4{\cdot}3NH_3$. A similar trend holds for the dimethyl ether adducts of $LiBH_4$. These adducts are more stable than the solvates with ammonia molecules.

Discussion

At present, only two types of magnesium bis(tetrahydroborates) are known: molecular mononuclear solvates and ionic mononuclear complexes. The structure of solvent-free $Mg(BH_4)_2$ is still unknown, but in view of the effective radii of Br^- and BH_4^-, which are very similar, one might expect that $Mg(BH_4)_2$ should have the same structure as $MgBr_2$. Thus, $MgBr_2$ forms THF solvates such as $MgBr_2{\cdot}3THF$.[21,22] While a multitude of different bonding situations has been found for $LiBH_4$, ranging from solvated mononuclear to polymeric species,[1,16] only one type of bonding has so far been detected for $Mg(BH_4)_2$: $Mg(\mu_2^1\text{-}H_2BH_2)$, irrespective of the number of additional ligands associated with Mg^{2+}. For instance, $Mg(BH_4)_2{\cdot}3THF$, **1** and **2** can be regarded as deriving from a trigonal-bipyramidal geometry[3,4] if we involve the boron atoms in bonding and neglect the bridging hydrogen atoms. If we consider only the nearest neighbours to magnesium, then the coordination number is 7 (four H and three N or O atoms). Compound **3** can be viewed as distorted octahedral, the Mg ion coordinated to four N and two B atoms, or as octacoordinated (four H and four N atoms).

The second type is ionic, with the general composition $[MgL_6](BH_4)_2$ (compounds **4**, **6** and most probably also **7**). These compounds are formed if the donor numbers of the solvent molecules are high.[23] The order of increasing donor strength found for $Mg(BH_4)_2$ is: ether < THF < $NH_2tBu \approx$ pip < py < NH_2Bzl < DMSO. In comparison with complexes of the other alkali earth metals, the order $Ba^{2+} < Sr^{2+} < Ca^{2+} < Mg^{2+}$ demonstrated by Irvin and Williams[24,25] is compatible with the solvates of these alkali earth metal tetrahydroborates.

It is astonishing that no di- or trinuclear solvates of magnesium bis(tetrahydroborate) are yet known; one might expect that solvates of the type $L_2(BH_4)Mg(BH_4)_2Mg(BH_4)L_2$ should be stable by analogy to $MgBr_2{\cdot}2THF$, which forms a polymer in the solid state with hexacoordinated Mg^{2+}.[22] Thus, there is no reason why solvates of magnesium bis(tetrahydroborate) should not have as rich a structural chemistry as the solvates of $LiBH_4$.

Experimental Section

General: All experiments were performed under anhydrous conditions by use of Schlenk techniques and dinitrogen as a protecting gas. The amines used were distilled before use. $Mg(BH_4)_2$ was prepared from $EtMgBH_4$ [13,26] and diborane in diethyl ether. NMR: Jeol XL400, $BF_3{\cdot}OEt_2$ as external standard. IR: Nicolet 520 FT-IR or Perkin−Elmer 325 (samples in Nujol): X-ray: Siemens P4 diffractometer equipped with an LT2 low-temperature device and a CCD area detector for compounds **1**−**4**. Data for compound **6** were collected with a scintillation counter in the ω/2θ mode. Mo-K_α radiation, graphite monochromator.

Magnesium Bis(tetrahydridoborate) Bis(diethyl ether) (9): A solution of iodine (25.4 g, 100 mmol) in diglyme (50 mL) was slowly added to a stirred solution of $NaBH_4$ (7.5 g, 200 mmol) in diglyme (30 ml). The diborane generated was carried by a stream of N_2 into a solution of $EtMgBH_4$ (25 mmol) in diethyl ether (100 mL). After this solution had been stirred for 2 h, all volatile components were removed in vacuo (1 Torr). The diethyl ether adduct of $Mg(BH_4)_2$ was a solid that liquefied on standing at ambient temperature. The coordinated diethyl ether could be removed (monitoring by weight loss) by keeping the compound in high vacuum (0.001 Torr) for 12 h. Yield of **9**: 4.75 g (93.8%). $\delta^{11}B$ (ether) = −43.0 [^1J(BH) = 82.4 Hz] ppm. δ^1H (C_6D_6) = 0.21 [q, ^1J(HB) = 82 Hz], 0.90 (t, CH_3), 3.61 (q, CH_2) ppm. $\delta^{13}C$ (C_6D_6) = 65.7 (CH_2), 13.7 (CH_3) ppm. $C_8H_{28}B_2MgO_2$ (202.25): calcd. H^- 3.98, B 10.69, Mg 12.02; found H^- 3.71, B 10.55, Mg 12.03.

Magnesium Bis(tetrahydroborate) Tris(*tert*-butylamine) (1): $Mg(BH_4)_2$ (134 mg, 2.78 mmol) was dissolved in *tert*-butylamine (15 mL). Methylcyclohexane (5 mL) was added with stirring. This addition caused the precipitation of a small amount of a solid, which was discarded. The filtrate was kept at 8 °C for a week. Colourless prisms separated and were isolated by filtration. The crystals deteriorated rapidly when a stream of dinitrogen was passed over them. Therefore, some of these crystals were removed from the supernatant liquid and placed in perfluoroether oil for X-ray diffraction. The composition is the result of the structure determined by X-ray crystallography. Yield: 280 mg (37%). M.p. 134−136 °C (dec., sealed capillary). $\delta^{11}B$ = −38.5 [^1J(BH) = 82 Hz] ppm. IR: $\tilde{\nu}$ = 2422 (sh), 2369 (st), 2325 (st), 228 (st) cm^{-1}.

Magnesium Bis(tetrahydroborate) Tris(piperidine) (2): $Mg(BH_4)_2$ (178 mg, 3.29 mmol) was dissolved in piperidine (10 mL), and cyclohexane (5 mL) was added to the stirred solution. Insoluble material was removed from the turbid solution. The filtrate was stored at 8 °C. Colourless prisms of composition $Mg(BH_4)_2{\cdot}3pip$ (as determined by X-ray crystallography) were isolated. Yield: 298 mg (29%). M.p. 50−53 °C (dec.). $\delta^{11}B$ (piperidine) = −40.3 [^1J(BH) = 82 Hz] ppm.

Magnesium Bis(tetrahydroborate) Hexakis(pyridine) (3): $Mg(BH_4)_2$ (94 mg, 1.7 mmol) and 1,3,5-trimethyl-1,3,5-triazine (0.25 mL, 1.78 mmol) were dissolved in pyridine (10 mL). Cyclohexane (2 mL) was added with stirring. A colourless solid precipitated and was removed by filtration. Storage at 8 °C gave crystals of composition $Mg(BH_4){\cdot}6py$. Yield: 130 mg (14%). M.p. 57 − 59 °C (dec.). Attempts to obtain compound **3** from $Mg(BH_2)_4$ and pyridine in the absence of the triazine gave no crystals but only oily products. $\delta^{11}B$ = −37.6 [^1J(BH) = 82 Hz] ppm.

Magnesium Bis(tetrahydroborate) Hexakis(benzylamine) (4): Cyclohexane (5 mL) was added to a solution of $Mg(BH_4)_2$ (196 mg, 3.62 mmol) in benzylamine (25 mL). The solid that formed was removed by filtration and the filtrate was cooled to −35 °C. After 3 weeks, colourless prisms had formed and were isolated. Yield: 1.33 g (53%). M.p. 59−60 °C (dec.). $\delta^{11}B$ (benzylamine) = −37.8 [^1J(BH) = 83 Hz)] ppm. IR: $\tilde{\nu}$ = 2327 (sh), 2316 (st), 2252 (st), 2182 (st) cm^{-1}. $C_{42}H_{62}B_2MgN_6$ (696.5): calcd. C 72.38, H 8.97, N 12.06; found C 71.10, H 8.55, N 12.00.

Magnesium Bis(tetrahydroborate) Bis(15-crown-5) (5): $Mg(BH_4)_2{\cdot}3THF$[3] (3.78 g, 14.0 mmol) was dissolved in THF (40 mL), and 15-crown-5 (5.6 mL, 28 mmol) was added dropwise to the stirred solution. This resulted in the formation of a precipitate, which was isolated by centrifugation and then dried in vacuo. No single crystal could be obtained. Yield: 6.64 g (96.1%). M.p. 311−313 °C. $C_{20}H_{48}B_2MgO_{10}$ (494.52): calcd. C 48.58, H 9.78, H^- 1.63, B 4.37; found C 48.92, H 9.91, H^- 1.59, B 4.31.

Magnesium Bis(tetrahydroborate) Octakis(dimethyl sulfoxide) (6): $tBuSMg(BH_4){\cdot}OEt_2$[26] (1.24 g, 5.7 mmol) was dissolved in a min-

imum amount of DMSO. Ether was allowed to diffuse into this solution over 3 d. Colourless, clear crystals formed during this period and proved to be **6**. The compound hydrolyses only very slowly in air. Yield: 0.88 g (22%). M.p. 118−121 °C. δ^1H ([D$_6$]DMSO) = −0.33 [q, ^1J(HB) = 79.1 Hz] ppm. $C_{16}H_{56}B_2MgO_8S_8$ (679.07): calcd. C 28.30, H 8.31, H$^-$ 1.18, B 3.18, Mg 3.58; found C 27.80, H 8.35, H$^-$ 1.22, B 3.24, Mg 3.48.

Magnesium Bis(tetrahydroborate) Bis(diethylenetriamine) (7): Diethylenetriamine (5 mL, 49 mmol) was added dropwise to a stirred THF solution (50 mL) of $Mg(BH_4)_2$·3THF (3.38 g, 12.5 mmol). This resulted in the immediate precipitation of a colourless solid. After the mixture had been stirred for an additional hour, the solid was isolated by centrifugation. The product did not dissolve in diethyl ether but did so readily in DMSO. Ether was allowed to diffuse into this solution over several days. Clear crystals of **7** separated. These can be kept in air for several minutes without noticeable hydrolysis. Yield: 3.12 g (96.3% before crystallisation). M.p. 298−301 °C. δ^1H ([D$_6$]DMSO) = −0.33 [q, ^1J(HB) = 81.5 Hz], [sept, ^1J(H^{10}B) = 27.3], 3.40 (m, 4 H), 3.31 (m, 4 H) ppm. δ^{13}C (DMSO) = 52.3, 41.4 ppm. $C_8H_{34}B_2MgN_6$ (260.32): calcd. C 36.91, H 13.16, H$^-$ 3.09, B 8.38, Mg 9.34, N 32.27; found C 37.97, H 12.73, H$^-$ 2.98, B 8.31, Mg 9.29, N 31.99.

Magnesium Bis(tetrahydroborate) *N*,*N*,*N*′,*N*′,*N*′′-Pentamethyldiethylenetriamine (8): Pentamethyldiethylenetriamine (5 ml, 38 mmol) was added with stirring to a solution of $Mg(BH_4)_2$·3THF (2.87 g, 10.6 mmol) in THF (50 mL). The solution was kept at −18 °C for 24 h. Over this time clear needles separated; these hydrolysed rapidly on contact with air or water. Yield: 1.52 g (63.1%). δ^1H ([D$_6$]DMSO) = −0.32 [q, ^1J(H^{11}B) = 81.9 Hz, sept, ^1J(H^{10}B) = 28.0 Hz], 2.51 (s, 3 H, MeN), 2.62 (t, 4 H, Me_2NCH_2), 2.71 (t, 4 H, $MeNCH_2$), 3.73 (s, 12 H, NMe_2) ppm. δ^{13}C = 42.9 (MeN), 45.8 (NMe_2), 56.0 (Me_2NC), 57.9 ($MeNC$) ppm. $C_9H_{31}B_2MgN_3$ (227.29): calcd. C 47.56, H 13.75, H$^-$ 3.54, B 9.51, N 18.49, Mg 10.69; found C 46.39, H 12.96, H$^-$ 3.47, B 9.43, N 16.57, Mg 10.58.

X-ray Structure Determinations: Crystals were covered with perfluoropolyether oil and selected under dinitrogen gas. They were placed on a glass fibre, mounted on a goniometer head and cooled to −80 °C by means of a Siemens LT2 low-temperature device. After cell determination, the data were collected in the hemisphere mode (implemented in the program SMART[27]) on 1284 frames. Data reduction was performed with the program SAINT,[28] and the structure was solved and refined with the SHELX programmes.[29] Parameters for non-hydrogen atoms were anisotropically refined, and the hydrogen atoms bonded to the boron atoms were placed in the found positions while the CH hydrogen atoms were placed in calculated positions. Isotropic thermal parameters for the boron-bonded hydrogen atoms were freely refined but fixed in the final cycles of the refinement. A summary of relevant data is given in Table 6. Additional crystallographic data for the structures were deposited with the Cambridge Crystallographic Data Centre as supplementary publications numbers CCDC-186646 (**1**), -186647 (**2**), -186648 (**3**), -186649 (**4**) and -186650 (**6**). These can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336033; E-mail: deposit@ccdc.cam.as.uk].

Acknowledgments

We thank the Fonds der Chemischen Industrie and particularly Chemetall GmbH for support of this work. We also acknowledge the help by Mr. Peter Mayer for many measurements, and Mrs. E. Kiesewetter for recording IR spectra.

Preparation of the First Complexes of Bidentate Sulfimides; the X-ray Crystal Structures of $[PdBr_2\{1,4\text{-}(PhS\{NH\})_2C_6H_4\}]_2$, $[PdCl_2\{1,2\text{-}(PhS\{NH\})(PhS)C_6H_4\}]$ and *trans*-$[PdCl_2\{1,2\text{-}(PhS\{NH\})(PhS)C_6H_4\}PPh_3]$

Keywords: S ligands / N ligands / Palladium / Bridging ligands

Reaction of $[PPh_4]_2[Pd_2X_6]$ (where X = Cl, Br or I) with 1,4-$(PhS\{NH\})_2C_6H_4$ (**1**) in dichloromethane results in the formation of $[Pd\{1,4\text{-}(PhS\{NH\})_2C_6H_4\}X_2]_2$ (**2**). X-ray crystallography (performed using a synchrotron source) confirms that in the case where X = Br (**2a**) both the bis-sulfimides act as bridging ligands through N–Pd bonds producing an 18-membered ring system linking the four sulfur atoms into an almost perfect square. Changing the reaction solvent to methanol/dichloromethane results in the formation of a polymeric material. Reaction of $[PdCl_2(PhCN)_2]$ with 1,2-$(PhS\{NH\})(PhS)C_6H_4$ (**3**) results in the formation of $[PdCl_2\{1,2\text{-}(PhS\{NH\})(PhS)C_6H_4\}]$ (**4**) in which **3** acts as a bidentate ligand, bound by N–Pd and S–Pd bonds to form a unique MSCCSN metallacycle. The Pd–S bond is broken upon reaction with one equivalent of PPh_3, generating *trans*-$[PdCl_2\{1,2\text{-}(PhS\{NH\})(PhS)C_6H_4\}PPh_3]$ (**5**); further reaction with PPh_3 results in complete removal of **3** from the system and formation of *trans*-$[PdCl_2(PPh_3)_2]$.

Introduction

Recent work within our group has demonstrated that the mononuclear sulfimide Ph_2SNH is an excellent ligand insofar as it readily forms N-bound complexes with a range of transition metal centres.[1] In addition, its importance as a ligand is enhanced by the fact that it is capable of stabilising unusual coordination geometries[2] and that significant hydrogen-bonding effects can be observed between the ligand and counterions.[3] In order to build upon these results, we have recently reported the preparation of a range of new sulfimide systems based upon polysulfide starting materials.[4] These include the bis-sulfimide 1,4-$(PhS\{NH\})_2C_6H_4$ (**1**) and the mixed sulfide/sulfimide 1,2-$(PhS\{NH\})(PhS)C_6H_4$ (**3**), both of which prove to have an interesting structure in their own right thanks to the appearance of hydrogen-bonding arrays generated by interactions between the sulfimide units and waters of crystallisation. They both also have clear potential as new ligands. Ligand **1** has the obvious potential to act as a bidentate bridge between two metal centres. Examples of such ligands are, of course, well-known and they can often act as the lynchpin for much important chemistry. By way of example, Godfrey et al. recently demonstrated the ability of 1,3-bis(diphenylphosphinoyl)propane to bridge manganese centres in binuclear complexes.[5] In this particular case the ligand is crucial to the product's ability to reversibly take up SO_2. Such properties highlight the need to investigate new ligand systems of this type, and here we demonstrate for the first time that **1** can act in this way and in doing so highlight the potential of an entirely new class of bidentate ligand. In the case of **3** the presence of both nitrogen and sulfur atoms capable of binding to metal centres provides the potential for the system to act as a bidentate chelating ligand. The use of ligands containing coordination sites of different binding strengths continues to be of importance (for example with the use of hemilabile ligands within catalytically important systems)[6] and here we show that **3** can indeed act as a bidentate ligand.

Results and Discussion

We have recently demonstrated that reaction of 1,4-$(PhS)_2C_6H_4$ with MSH (*O*-mesitylsulfonylhydroxylamine) results in the formation of a salt of the protonated bis-sulf-

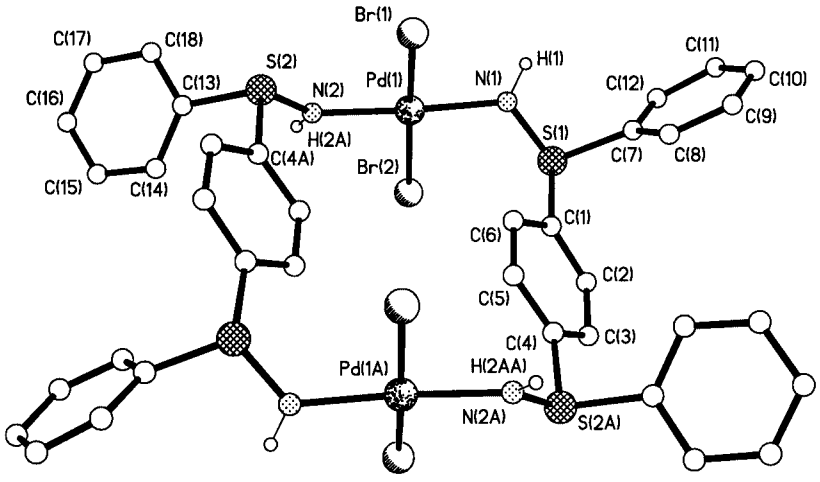

Figure 1. The X-ray crystal structure of one of the two unique molecules in the unit cell of **2a**; selected bond lengths (Å) and angles (°): Pd(1)−N(1) 2.020(5), Pd(1)−N(2) 2.025(5), Pd(1)−Br(1) 2.4411(9), Pd(1)−Br(2) 2.4227(9), N(1)−S(1) 1.622(5), N(2)−S(2) 1.618(5); Pd(1)−N(2)−S(2) 122.4(3), Pd(1)−N(1)−S(1) 122.2(3), Br(2)−Pd(1)−Br(1) 170.91(3), N(1)−Pd(1)−N(2) 174.7(2)

imide $[1,4\text{-}(PhS\{NH_2\})_2C_6H_4]^{2+}$ from which the free bis-sulfimide **1** may be generated by treatment with the base DBU. Compound **1** is an air-stable, colourless material which may be crystallised in hydrated or water-free forms, both of which have structures containing extended hydrogen-bonding arrays. In the light of the high affinity of the related monosulfimide Ph_2SNH for metal centres one might expect **1** to readily react with transition metal complexes and we have now found this to indeed be the case.

Reaction of a stirred suspension of **1** with $[PPh_4]_2[Pd_2Br_6]$ in CH_2Cl_2 results in the formation of an insoluble orange/red product **2a**. The IR spectrum of **2a** clearly indicates the presence of **1** as a ligand. We have previously shown that in complexes of Ph_2SNH the two key features which vary in the IR spectra are the SN and NH stretches, and in this case they are shifted from 928 and 3111 cm^{-1} respectively in the free ligand to 880 and 3260 cm^{-1} upon coordination. In addition, microanalysis confirms the formulation "$[PdBr_2\{1,4\text{-}(PhS\{NH\})_2C_6H_4\}]_n$", although, of course, it provides no information as to the value of *n*. Standard crystallisation techniques cannot be used upon **2a** as, once formed, it appears to be totally insoluble in a range of solvents. Small microcrystals of the product can, however, be obtained by changing the reaction conditions. If CH_2Cl_2 is added to a solid mixture of the two reagents without stirring, then a slow reaction occurs and **2a** forms as crystals large enough to be investigated by X-ray crystallography using a synchrotron source.

X-ray crystallography performed in this manner reveals that the structure of **2a** consists of two $PdBr_2$ units linked by two bis-sulfimide ligands, resulting in an overall binuclear 18-membered ring arrangement (Figure 1).

The resulting relative dispositions of the Pd−Br, P−N, S−N and bridging phenyl units are best illustrated by the side on view shown in Figure 2 (this illustrates the structure of one of the two independent molecules in the unit cell − see X-ray text below). The Pd−Br bonds are almost perpendicular to the Pd_2N_4 plane [N(2)−Pd(1)−Br(2) = 85.7°] while the S−N bonds of each of the ligands also project on either side of this plane (in what has been referred to as a "sofa-bed" arrangement).[7] The linking phenyl units of each ligand are parallel to each other and inclined at an angle of 52.8° to the Pd_2N_4 plane. Perhaps the most intriguing thing about the structure is that the positions of the sulfur atoms are such that they define an almost perfect square, with S(2)−S(1) = 6.325 Å, S(2)−S(1A) = 6.326 Å and S(1)−S(2)−S(1A) = 91.5°. As Figure 2 shows, the fact that the bridging phenyls are offset relative to each other precludes any π-π interactions. Unlike many of the complexes of Ph_2SNH we have previously investigated there appear to be no significant interactions between the N−H groups of the ligands and halide ligands of adjacent molecules.

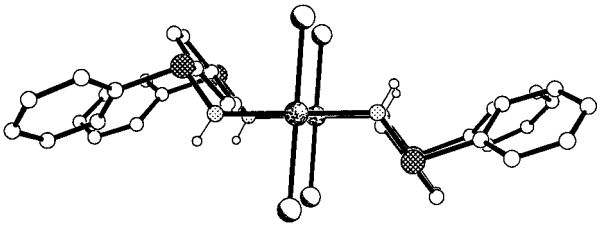

Figure 2. The X-ray crystal structure of **2a** viewed side-on, illustrating the relative disposition of the sulfimide groups and the bridging phenyls

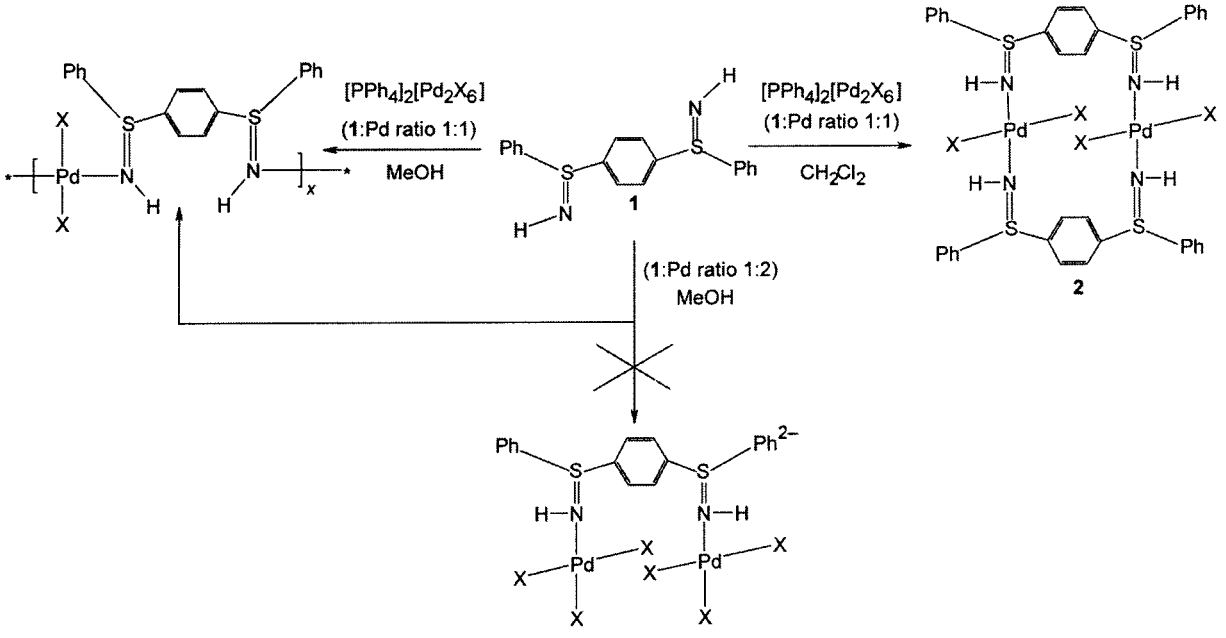
Complex **2a** appears to be the only isolable material from this reaction. The initial yield equates to 67% based upon palladium and more of the same material is obtained when the reaction filtrate is treated with Et_2O. The latter proced-

ure generates **2a** as an orange solid which does not then redissolve back into the CH_2Cl_2. From this observation we can conclude that a small amount of another, soluble, complex of **1** is present in the initial filtrate; however, all attempts to isolate this result in formation of **2a** and so it is difficult to speculate as to its nature. The reaction of $[PPh_4]_2[Pd_2I_6]$ with **1** appears to proceed in an identical manner to that of its bromo counterpart (Scheme 1). Again, the product is an insoluble orange/red material whose IR spectrum is extremely similar to that of **2a**. Taken together with microanalysis this allows us to formulate it as $[PdI_2\{1,4\text{-}(PhS\{NH\})_2C_6H_4\}]_2$ (**2b**) with confidence. Although we have yet to produce crystals suitable for X-ray crystallographic confirmation, we have every reason to believe that **2b** has the same kind of binuclear structure as **2a**. Likewise $[PdCl_2\{1,4\text{-}(PhS\{NH\})_2C_6H_4\}]_2$ (**2c**) forms in the analogous reaction with $[PPh_4]_2[Pd_2Cl_6]$; in this case microanalysis results indicate that the dichloromethane solvate forms. The IR spectrum of this material is, however, very similar to that of **2a** and **2b** and in this case Pd−Cl stretches at 346 and 304 cm^{-1} consistent with the *trans*-halides are observed.

The reaction time needed for the formation of compounds **2** is long (typically three days), a fact dictated by the insolubility of **1** in CH_2Cl_2. Although this would appear inefficient, in fact it is key to the formation of the binuclear product; changing the solvent system has a dramatic effect upon the course of the reaction (Scheme 1). Compound **1** is actually soluble in methanol and so addition of a solution of the ligand in this solvent to a solution of $[PPh_4]_2[Pd_2Br_6]$ in CH_2Cl_2 results in an immediate reaction. Again, an insoluble product is generated (with just $[PPh_4]Br$ left in solution, as shown by IR spectroscopy) but in this case rather than the bright orange red colour of **2a** the product is a pale brown colour. IR spectroscopy reveals the presence of bands due to **1** but the key stretches, ν[N−H] and ν[N−S], are both stronger and broader than those in **2a** and are shifted to 3220 and 897 cm^{-1}, respectively. Microanalysis supports the formulation $[PdBr_2\{1,4\text{-}(PhS\{NH\})_2C_6H_4\}]$ but unlike **2a** (which shows the peaks which may be predicted from the aforementioned single crystal data) the X-ray powder pattern of this product shows no discernible peaks. This leads us to believe that this product is an amorphous polymeric material rather than the binuclear structure of **2a**. Interestingly, it forms even when only one equivalent of **1** is used in the reaction. In this case the expected $[PPh_4]_2[(PdBr_3)_2\{1,4\text{-}(PhS\{NH\})_2C_6H_4\}]$ (in which the bis-sulfimide would link two $[PdBr_3]^-$ units) does not form. Rather, the polymeric material is generated, while the reaction filtrate contains just $[PPh_4]Br$ and unchanged $[PPh_4]_2[Pd_2Br_6]$ (as shown by IR spectroscopy). Given that it is reasonable to assume this reaction proceeds via a transient intermediate of the form $[PdBr_3\mathbf{1}]^-$ in which one of the nitrogen atoms of the ligand is bound to palladium, it would appear that the halide *trans* to N in this case is activated towards displacement by another nitrogen. Similar results are observed for reactions involving $[Pd_2Cl_2]^{2-}$ and $[Pd_2I_2]^{2-}$, generating insoluble polymeric products which are very pale brown and dark brown, respectively. The IR spectra of both products are analogous to that of the bromide product with broad ν[N−H] (3211 and 3217 cm^{-1} for chloride and iodide, respectively) and very broad ν[N−S] peaks (centred on 897 cm^{-1} in both cases).

It would appear, therefore, that only when the reaction of **1** with $[Pd_2X_6]^{2-}$ is slowed down by the use of CH_2Cl_2 as solvent is a molecular product seen; the use of methanol



Scheme 1

encourages the fast formation of a polymeric material. It should be noted, though, that in some solvents the reaction does not proceed at all. For example, if the reactions are attempted in MeCN then after three days of stirring the mixture simply consists of a suspension of unchanged **1** in the solution of the palladium starting material. As for the structure of the polymeric complexes we can only speculate that they possess a linear polymeric arrangement made up of alternating PdX_2**1** units. Of course other structural motifs could be envisaged and it may even be that the material contains a mixture of different oligomers (although we can be sure that none of the binuclear complex is present thanks to the IR and powder X-ray results); only single crystal X-ray crystallography would provide an unequivocal answer and we have yet to obtain crystalline samples. Once formed the material is totally insoluble in all solvents and techniques used to obtain single crystals of **2a** are not amenable in this case due to the fast reaction time.

Reaction of $[PdCl_2(PhCN)_2]$ with 1,2-(PhS{NH})-(PhS)C_6H_4 (**3**; molar ratio 1:1) in CH_2Cl_2 results in the formation of an orange solution from which a mass of dark orange/red crystals appears upon standing overnight. X-ray crystallography reveals that this product is $[PdCl_2\{1,2-(PhS\{NH\})(PhS)C_6H_4\}]$ (**4**) in which **3** acts as a bidentate ligand bound to the palladium through the sulfimide nitrogen and the thioether sulfur (Figure 3) (Scheme 2).

The resulting metallacycle, which shows significant deviation from planarity (thus, for example, the two sulfurs ap-

Figure 3. pear 0.2821 Å (S1) and 0.2162 Å (S2) above the mean plane of the six atoms in the metallacycle), constitutes a rare example of an XNSCCS ring. A search of the Cambridge Structural Database[8] reveals only eight examples within which such an arrangement is observed. As Figure 4 shows, the only examples (**a** and **b**) in which atom X is a metal contain a tridentate ligand.[9] The rest consist of the two examples shown wherein X is a nitrogen atom (**c** and **d**) together with four examples in which this atom is carbon (including the one shown, **e**).[10a−10f]

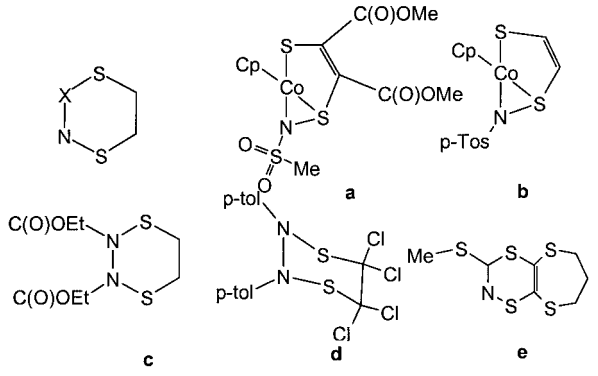

Figure 4. Previous examples of species exhibiting the XSCCSN cyclic unit observed in **4**

Perhaps the most intriguing feature of the structure of **4** is the fact that the molecules arrange themselves into dimers (Figure 5). These units are held together by hydrogen bonding between the N−H groups and chlorides of opposite molecules. The contact between molecules is close, with a Pd−Pd distance of 3.512 Å. Interestingly, this value is almost exactly the same as the closest Pd−Pd interactions in $[Pd(S_2N_2H)(PMe_2Ph)_2][BF_4]$ which also has Pd attached to a sulfur and to an N−H unit on an S−N bond.[11] In that case a 1-D structure was formed by an infinite array of the cations; in the case of **4** this cannot take place as the orientation of the non-bridging phenyl groups — both to one side of the plane of each metallacycle — precludes the close approach of further molecules.

That the thioether group of **3** should coordinate to a metal centre is of no great surprise given that the coordination chemistry of such units is extensive. In general, however, such ligands are relatively weakly bound and, indeed, can often act as easily substituted leaving groups. Of the two coordination sites in **4** one would thus expect the Pd−S bond to be broken by an incoming ligand and this can be demonstrated by the reaction of **4** with triphenylphosphane. Slow addition of the solid phosphane to a stirred solution of **4** in CH_2Cl_2 results in lightening of the colour of the solution; removal of the solvent in vacuo followed by trituration with petroleum ether results in a yellow solid **5** (Scheme 2) The ^{31}P NMR spectrum of this solid ($CDCl_3$) consists of a singlet at $\delta = 27.7$ ppm while the IR spectrum confirms the presence of bands typically associated with both sulfimide units (911 cm^{-1}) and with phosphanes (1096 cm^{-1}). Slow diffusion of diethyl ether into a CH_2Cl_2 solution of the product results in the formation of orange crystals for which X-ray crystallography reveals the structure shown in Figure 6. As Figure 6 shows, **5** consists of a palladium centre coordinated to a PPh_3 ligand and to **3** (acting in this case as a monodentate N-bound ligand) bound in a *trans* fashion. Two *trans*-chloride ligands make up the rest of the coordination sphere.

The course of the reaction of **4** with PPh_3 thus involves two steps: substitution of the Pd−S bond by the phosphane, followed by isomerisation to the observed *trans* arrangement. Presumably the latter effect is brought about by the significant steric interactions that would be present between the six phenyl groups in the initially formed *cis*

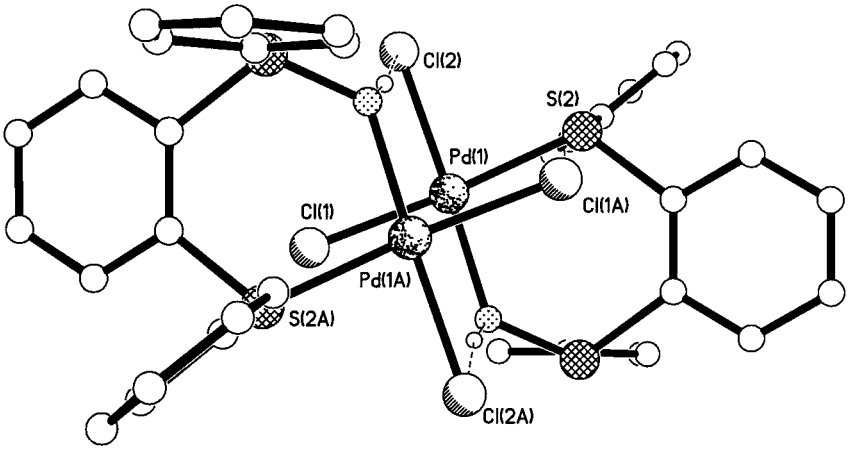

Figure 5. The formation of dimers within the overall structure of **4**; intra-dimer distances (Å) and angles (°): Pd(1)−Pd(1A) 3.512, S(2)−Cl(1A) 3.428, N(1)−Cl(2A) 3.469(2), N(1)−H(1)−Cl(2A) 165(3)

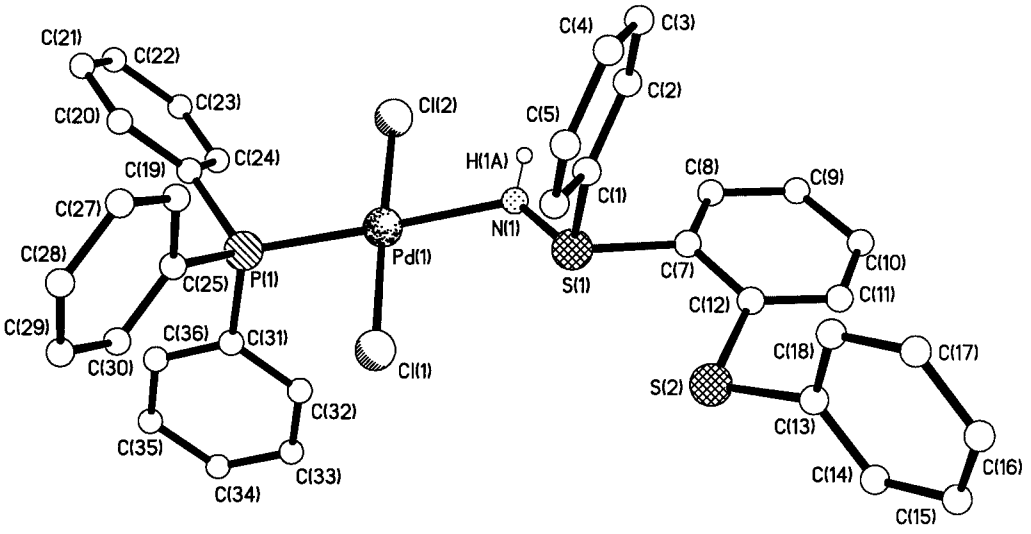

Figure 6. The X-ray crystal structure of **5**; selected bond lengths (Å) and angles (°): Pd(1)−N(1) 2.094(6), N(1)−S(1) 1.603(6), S(1)−C(7) 1.823(7), C(7)−C(12) 1.382(9), C(12)−S(2) 1.798(8), S(2)−C(13) 1.773(7), Pd(1)−Cl(1) 2.2873(18), Pd(1)−Cl(2) 2.3010(17), Pd(1)−P(1) 2.2331(14); Pd(1)−N(1)−S(1) 121.6(3), N(1)−S(1)−C(7) 106.0(3), S(1)−C(7)−C(12)115.9(6), C(12)−S(2)−C(13) 102.8(3), Cl(1)−Pd(1)−N(1) 94.79(18), Cl(2)−Pd(1)−N(1) 84.47(18)

intermediate. The ^{31}P chemical shift of the phosphane group is consistent with it being *trans* to an N−H unit.

Addition of the phosphane to **4** has to be very slow in order to obtain pure **5**. If this is not carefully observed then variable amounts of a yellow, far less soluble product are obtained. Microanalysis indicates that this product is $[PdCl_2(PPh_3)_2]$ and in such cases it appears in the ^{31}P NMR spectrum of the product as a peak at $\delta = 23.4$ ppm. The ability of PPh_3 to break the Pd−N bond as well as the Pd−S bond of the starting material can be confirmed by addition of one molar equivalent of the phosphane to **5**. This results in the immediate precipitation of the sparingly soluble $[PdCl_2(PPh_3)_2]$.

Conclusion

The isolation and full characterisation of **2a** (together with **2b** and **2c**) constitutes the first successful use of a bis-sulfimide system as a ligand. It is, therefore, the first example of the use of an entirely new class of bidentate ligand and this observation strongly suggests that many more examples of complexes of **1** should be isolable (although the observed polymer formation upon using methanol as solvent does highlight a problem which may need to be resolved in other systems). Such results also indicate that the coordination chemistry of other examples of bis-sulfimides should be extensive. Although (as shown in previous work) the *ortho*-isomer 1,2-$(PhS\{NH\})_2C_6H_4$ cannot be formed in the same manner as **1**, the mixed sulfimide/sulfide 1,2-$(PhS\{NH\})(PhS)C_6H_4$ (**3**) is known and the isolation of complex **4** confirms its potential as a chelating ligand. The isolation of **5** also confirms that the Pd−S bond within this molecule is significantly weaker than the Pd−N bond.

Experimental Section

Compounds **1** and **3** were prepared by the reaction of MSH with appropriate thioether starting materials.[4] Salts of the type $[PPh_4]_2[Pd_2X_6]$ were prepared from $PdCl_2$ (X = Cl or Br) as reported previously[12] or, in the case of X = I, by addition of a hot solution of NaI (20 mmol) and PdI_2 (2.2 mmol) in EtOH (100 mL) to a hot solution of $[PPh_4]I$ (2.2 mmol) in the same solvent (100 mL) followed by filtration. $[PdCl_2(PhCN)_2]$ was prepared by the dissolution of $PdCl_2$ into hot benzonitrile followed by precipitation with 60:80 petroleum ether. Microanalysis was performed by the Loughborough Departmental service. ^{31}P NMR spectra were recorded on a Jeol FX90Q spectrometer operating at 36.21 MHz. IR spectra were run on a Perkin Elmer PE2000 spectrometer.

$[PdBr_2\{1,4\text{-}(PhS\{NH\})_2C_6H_4\}]_2$ (2a): A solution of $[PPh_4]_2[Pd_2Br_6]$ (0.102 g, 0.074 mmol) in CH_2Cl_2 (20 mL) was treated with **1** (0.05 g, 0.15 mmol) added in one portion with stirring. The resulting mixture was then stirred for three days during which time a red/orange precipitate formed. The latter was filtered from the solution, washed with CH_2Cl_2 (50 mL), Et_2O (20 mL) and then dried in vacuo yielding 60 mg of red/orange solid. A further 10 mg was obtained when the filtrate was treated with Et_2O. Total yield 70 mg, 79%. $C_{36}H_{32}Br_4N_4S_4Pd_2$ (1181.3): calcd. C 36.8, H 2.7, N 4.8; found C 36.3, H 2.6, N 4.4. IR (KBr): $\tilde{\nu} = 3260$ cm^{-1} (ν N−H), 880 (ν N−S).

Microcrystalline material of sufficient size for use in synchrotron X-ray crystallography was generated by a variation on the above procedure wherein the starting materials were mixed (in the same amounts as above) as solids and then the CH_2Cl_2 added without

stirring. After one week the solution was decanted from the resulting crystalline mass which was then washed with CH_2Cl_2. The IR spectrum of the material prepared this way was identical to that prepared above.

[PdI$_2${1,4-(PhS{NH})$_2$C$_6$H$_4$}]$_2$ (2b): This was prepared as a red/orange solid by reaction of $[PPh_4]_2[Pd_2I_6]$ (0.202 g, 0.122 mmol) with **1** (0.079 g, 0.244 mmol) in exactly the same way as for **3**. Yield 105 mg, 63%. $C_{36}H_{32}I_4N_4Pd_2S_4$ (1369.3): calcd. C 31.6, H 2.4, N 4.1; found C 31.9, H 2.4, N 4.1. IR (KBr): $\tilde{\nu}$ = 3260 cm^{-1} (ν N−H), 880 (ν N−S).

[PdCl$_2${1,4-(PhS{NH})$_2$C$_6$H$_4$}]$_2$·CH$_2$Cl$_2$ (2c): This was prepared as a red/orange solid by reaction of $[PPh_4]_2[Pd_2Cl_6]$ (0.082 g, 0.077 mmol) with **1** (0.050 g, 0.154 mmol) in exactly the same way as for **3**. Yield 45 mg, 61%. $C_{37}H_{34}Cl_6N_4Pd_2S_4$ (1088.5): calcd. C 40.8, H 3.1, N 5.1; found C 40.3, H 3.1, N 4.8. IR (KBr): $\tilde{\nu}$ = 3260 cm^{-1} (ν N−H), 898 (ν N−S).

[PdCl$_2${1,2-(PhS{NH})(PhS)C$_6$H$_4$}] (4): A solution of $[PdCl_2(PhCN)_2]$ (0.176 g, 0.460 mmol) in dichloromethane (10 mL) was treated with a solution of 1,2-(PhS{NH})(PhS)C_6H_4 (0.142 g, 0.460 mmol) in an equal volume of the same solvent added dropwise with stirring. After addition of the ligand a precipitate was present which then redissolved after a minute of stirring. The solution was then left to stand for 48 hours and the resulting orange/red or brown crystals were collected. Yield: 0.165 g (86%). $C_{18}H_{15}Cl_2NPdS_2$ (486.7): calcd. C 44.4, H 3.1, N 2.9; found C 44.4, H 3.0, N 2.8. IR (KBr): $\tilde{\nu}$ = 3215, 3053, 944 cm^{-1}.

***trans*-[PdCl$_2${1,2-(PhS{NH})(PhS)C$_6$H$_4$}PPh$_3$] (5):** A solution of **4** (0.039 g, 0.08 mmol) in dichloromethane (10 mL) was treated with solid PPh_3 (21 mg, 0.08 mmol) added slowly in small portions with vigorous stirring. After complete addition of the PPh_3 the clear solution was reduced in volume and petroleum ether 40:60 (50 mL) was added. The resulting solid was then recrystallised from dichloromethane/Et_2O giving orange crystals. Yield: 0.036 g (61%). $C_{36}H_{30}Cl_2NPPdS_2$ (749.0): calcd. C 57.2, H 3.9, N 1.7; found C 57.7, H 4.0, N 1.9. ^{31}P NMR ($CDCl_3$): δ = 27.7 ppm. IR (KBr): $\tilde{\nu}$ = 3294, 3048, 1096, 911 cm^{-1}.

X-ray Crystallographic Study: Data (Table 1) for **2a** were collected at 150 K on a Bruker AXS SMART 1 K CCD area-detector diffractometer using synchrotron radiation (λ = 0.6879 Å) at Daresbury SRS Station 9.8.[13,14] Absorption correction was applied semi-empirically from equivalent and repeated data. The structure was solved by direct methods and refined by full-matrix least-squares on F^2. The asymmetric unit comprises two half molecules on centres of symmetry. Some disorder is present within one of the molecules with alternative positions for the sulfimide SNH unit with 90.4:9.6 (4)% refined occupancies. Hydrogen atoms were placed in geometrical positions and allowed to ride on their attached atom with U_{iso}(H) set to be 1.2 times U_{eq} of the carrier atom.

Data for **4** and **5** were collected at 150 K with a Bruker AXS SMART 1000 CCD diffractometer using Mo-K_α radiation (λ = 0.71073 Å). Both structures were solved by Patterson synthesis and refined by full-matrix least-squares methods on F^2. NH hydrogens were located from the difference map and their coordinates were freely refined. All other hydrogens were placed in geometrical positions using a riding model as described above. Some disorder is present in **5** with alternative positions for the sulfur and nitrogen atoms with refined occupancies of 84.0:16.0 (5)%.

The programs used were Bruker SMART,[15a] SAINT,[15a] SHELXTL[15b] and local programs.

Coordination Modes of 9-Methyladenine in *cis*-Platinum(II) Complexes with Dimethyl(phenyl)phosphanes as Ancillary Ligands − Synthesis and Characterization of *cis*-$[PtL_2(9\text{-MeAd})_2](NO_3)_2$, *cis*-$[PtL_2\{9\text{-MeAd}(-H)\}]_3(NO_3)_3$, and *cis*-$[L_2Pt\{9\text{-MeAd}(-H)\}PtL_2](NO_3)_3$

Bruno Longato,*[a] Lucia Pasquato,[b] Adele Mucci,*[c] and Luisa Schenetti*[c]

Keywords: Coordination modes / N ligands / NMR spectroscopy / P ligands / Platinum

Treatment of 9-methyladenine (9-MeAd) with *cis*-$[PtL_2(NO_3)_2]$ (**1**) (L = PMe_2Ph) in a 2:1 molar ratio generated the bis(adduct) *cis*-$[PtL_2(9\text{-MeAd})_2](NO_3)_2$ (**2**), which was isolated and fully characterized by multinuclear (^1H, ^{31}P, ^{13}C, ^{195}Pt and ^{15}N) NMR analysis, which showed that the two nucleobases are selectively coordinated through the N1 atom. Small amounts of a mono(adduct) *cis*-$[PtL_2(S)(9\text{-MeAd})]^{2+}$ (**3**) (S = solvent) and of a diplatinated species *cis*-$[L_2Pt(S)\{9\text{-MeAd}(-H)\}PtL_2]^{3+}$ (**4**) are formed in DMSO solution when 9-MeAd is present in smaller quantities than **1**. Complex **3** is platinated at N1, with a solvent molecule representing the fourth ligand around the metal center. Complex **4** contains an adenine molecule deprotonated and platinated at N1,N6,N7, with two *cis*-L_2Pt units bonded to nitrogen atom N1 and to nitrogen atoms N6 and N7, respectively. With increasing relative concentration of the nucleobase, both complexes **3** and **4** progressively convert into the bis(adduct) **2**, the only species detectable in solution when the Ad/Pt molar ratio is 2:1. The trinuclear compound *cis*-$[L_2Pt\{9\text{-MeAd}(-H)\}]_3(NO_3)_3$ (**5**) (L = PMe_2Ph), containing an NH_2-deprotonated nucleobase bridging the metal centers through the N1 and N6 atoms, is quantitatively formed when the dinuclear hydroxo complex *cis*-$[Pt(\mu\text{-OH})L_2]_2(NO_3)_2$ (**6**) reacts with 9-MeAd in CH_3CN solution. The isolated complex was fully characterized by multinuclear NMR spectroscopy and mass spectrometry. It appears to be stable in solution in CH_3CN and chlorinated solvents, whereas in DMSO it partially converts into a new species, probably the dinuclear analog *cis*-$[PtL_2\{9\text{-MeAd}(-H)\}]_2(NO_3)_2$, in which the adenine maintains its coordination mode. At equilibrium the trinuclear/dinuclear species molar ratio is 20:1. Through the addition of a stoichiometric amount of nitrate **1** to a DMSO solution of **5** we were able to generate the diplatinated compound **4** in high yield. Complex **4** displays a new coordination mode for the adeninate ion, with N1 bonded to one platinum atom whereas N6 and N7 are chelated to a second one.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2003)

Introduction

Among the model nucleobases, 9-substituted adenine exhibits the most versatile coordination properties.[1] As a neutral molecule it generally binds a metal atom at the N7 position, less frequently at the N1 atom, and only rarely through both these donor atoms (Scheme 1).[2,3]

Deprotonation of the exocyclic NH_2 group affords an additional site for metal coordination, and adducts of the adeninate ligand in which N1 and N6 bridge two metal atoms have been characterized.[4] More recently, chelation of a metal atom with the involvement of the adeninate N1 and N6 atoms, followed by conversion into the more stable N6/N7 isomer, has also been described.[5]

As part of a study dealing with the role of the ancillary ligands in the reactivity of platinum complexes toward model nucleobases, we have found that coordination of the neutral 9-methyladenine (9-MeAd) at the metal center of the water-soluble *cis*-$[Pt(NO_3)_2(PMe_3)_2]$ complex occurs selectively at the N1 atom, as indicated by a comprehensive multinuclear NMR analysis of the isolated bis(adduct) *cis*-$[Pt(PMe_3)_2(9\text{-MeAd})_2]^{2+}$.[6] We have also shown that the dinuclear hydroxo complex *cis*-$[Pt(\mu\text{-OH})(PMe_3)_2]_2^{2+}$ is able to deprotonate the NH_2 group of the adenine, as shown in Equation (1).

$$cis\text{-}[Pt(\mu\text{-OH})L_2]_2^{2+} + 2\,(9\text{-MeAd}) \rightarrow cis\text{-}[PtL_2\{9\text{-MeAd}(-H)\}]_2^{2+} + 2\,H_2O \quad (1)$$

The resulting cation, *cis*-$[Pt(PMe_3)_2\{9\text{-MeAd}(-H)\}]_2^{2+}$, contains adeninate ions bridging two *cis*-L_2Pt^{2+} units through the N1 and N6 atoms, a coordination mode previously established for the 9-ethyladenine (9-EtAd) analog

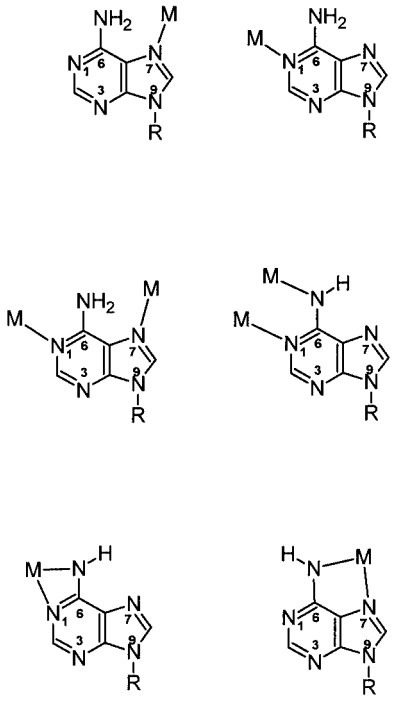
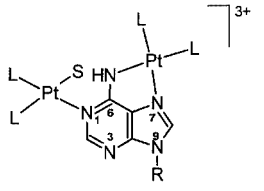


Scheme 1. Coordination modes of neutral and deprotonated 9-substituted adenines

cis-$[Pt(PMe_3)_2\{9\text{-EtAd}(-H)\}]_2(NO_3)_2$ by X-ray diffraction.[7]

In this paper we present the synthesis and characterization of three new (adenine)platinum(II) complexes with dimethyl(phenyl)phosphanes (L= PMe_2Ph) as ancillary ligands. The addition of a stoichiometric amount of nucleobase to *cis*-$[PtL_2(NO_3)_2]$ (**1**) in DMSO solution quantitatively forms the complex *cis*-$[PtL_2(9\text{-MeAd})_2](NO_3)_2$ (**2**). Similarly to the trimethylphosphane analog,[6] the bis(adduct) **2** contains the neutral 9-MeAd ligands coordinated at the N1 site. In order to investigate the possible involvement of the N7 site, we also examined mixtures of 9-MeAd and nitrate **1**, by ^{31}P NMR spectroscopy, at Ad/Pt molar ratios lower than 2. Under these conditions we noticed, concomitantly with the formation of the mono(adduct) *cis*-$[PtL_2(S)(9\text{-MeAd})]^{2+}$ (**3**, S = solvent), the presence of significant amounts of the diplatinated complex *cis*-$[L_2Pt(S)\{9\text{-MeAd}(-H)\}PtL_2]^{3+}$ (**4**), containing a deprotonated adenine molecule binding two *cis*-L_2Pt^{2+} units through the N1 and the N6/N7 atoms, as shown in Scheme 2.



Scheme 2. Proposed structure for complex **4**; S represents a solvent molecule

The deprotonation of the nucleobase induced by simultaneous platination at the N1 and the N7 sites is a reversible process, since the bis(adduct) **2** is the only product obtained when the Ad/Pt ratio is adjusted to 2. Together with the details of the spectroscopic characterization of this diplatinated species **4**, we report here on the synthesis of *cis*-$[PtL_2\{9\text{-MeAd}(-H)\}]_3(NO_3)_3$ (**5**), a cyclic trinuclear complex formed by condensation of the dinuclear hydroxo complex *cis*-$[Pt(\mu\text{-OH})L_2]_2(NO_3)_2$ (**6**) with adenine. The trinuclear complex **5**, in which the NH_2-deprotonated adenines bridge the metal centers through the N1 and N6 atoms, converts easily, although not quantitatively, into the diplatinated species **4** upon treatment with the nitrate **1** in DMSO solution. A detailed multinuclear (^1H, ^{13}C, ^{31}P, ^{195}Pt and ^{15}N at natural abundance) NMR study of the reaction mixture allowed the complete characterization of the complex **4**, in which the adenine exhibits an unprecedented coordination mode.

Results and Discussion

Treatment of 9-Methyladenine with *cis*-$[PtL_2(NO_3)_2$ (1) − Characterization of *cis*-$[PtL_2(9\text{-MeAd})_2](NO_3)_2$ (2) and *cis*-$[PtL_2(S)(9\text{-MeAd})](NO_3)_2$ (3)

In spite of the low solubility of *cis*-PtL_2Cl_2 (L = PMe_2Ph) in water, substitution of the chloride ligands occurs easily when a suspension of the compound is treated with $AgNO_3$. The resulting dinitrato complex **1** dissolves in coordinating solvents such as DMSO, CH_3CN, H_2O and DMF to form the ionic complexes *cis*-$[PtL_2S_2]^{2+}$ (S represents a solvent molecule). As would be expected,[8] solutions of **1** in water are acidic as a result of an acid/base equilibrium [Equation (2)] and the dinuclear hydroxo complex **6** is obtained in good yield when the solutions are neutralized with a strong base.[8,9]

$$2\ cis\text{-}[PtL_2(H_2O)_2]^{2+} \rightleftarrows cis\text{-}[Pt(\mu\text{-OH})L_2]_2^{2+} + 2\ H_3O^+ \quad (2)$$

Both the nitrato complex **1** and the hydroxo complex **6** appear to be very reactive towards the model nucleobase 9-MeAd. Thus, addition of 2 equiv. of 9-MeAd to a DMSO solution of **1** causes the dissolution of the nucleobase within a few minutes, with the quantitative formation of the bis(adduct) **2**. This complex was isolated and fully characterized by multinuclear NMR spectroscopy and the pertinent data are reported in Tables 1−4.

All the NMR spectra display two sets of resonances, attributed to two species (in a 48:52 ratio) containing two N1-coordinated adenine units. The correct assignment of the coordination sites requires the use of suitable two-dimensional inverse detection NMR techniques, as underlined in a previous report.[6] The first step is the contextual assignment of all protons and carbon atoms of the adenine moiety through ^1H,^{13}C correlation experiments. In particular, 2-H and 8-H are distinguishable by their $^1J_{H,C}$ coupling constants [^1J(2-H,C2) = 200 Hz; ^1J(8-H,C8) = 212 Hz] and their cross-peaks with C6 (detected through 2-H and NH_2) and C5 (detected through 8-H and NH_2) which are the

most deshielded and shielded adenine carbon atoms, respectively (Table 2). The second step is represented by $^1H,^{15}N$ inverse detection experiments, which show that only the 2-H protons correlate with platinated nitrogen atoms (recognisable by the presence of a $^2J_{N,P}$ coupling constant of about 50 Hz), enabling the presence of an isomeric mixture of N1- and N7-coordinated bases to be definitely ruled out. The presence of two species must be due to the hindered rotation of the nucleobases around the platinum−nitrogen bond, resulting in a *head-to-head* and *head-to-tail* arrangement of the adenines. This finding is in agreement with results previously reported for the complex with L = PMe_3,[6] showing that it is the phenyl group in the ancillary ligand − and not the adenine coordination site − that influences the conformer ratio. It should be noted that each conformer displays a couple of diastereotopic methyl signals readily attributable to the corresponding phosphorus atom through $^1H,^{31}P$ correlation experiments. The methyl proton signals allow the ^{195}Pt resonances to be detected in inverse detection mode. The same ^{31}P and ^{195}Pt signals are detectable, even though more weakly, through the 2-H protons, confirming the platination of atom N1.

The coordination of the adenine is a reversible process. In fact, addition of nitrate **1** to a solution of bis(adduct) **2** causes the immediate appearance of an AB multiplet at δ = −12.07 and −20.14 ppm in the ^{31}P NMR spectrum (Table 3), in addition to the resonances of **2**. It is reasonable to attribute the AB multiplet to the mono(adduct) **3**, in which the fourth ligand should be a solvent molecule, as suggested by the large difference between the $^1J_{P,Pt}$ values for the two ^{31}P resonances. The multinuclear NMR characterization of this species (Table 1−4) supports the hypothesis of the formation of a mono(adduct). In fact, almost all the adenine signals are very similar to those of the bis(adduct) **2**, and only 8-H, NMe and N1, which in this case is also the only platinated nitrogen atom, are slightly deshielded with respect to **2**. The highest chemical shift difference is that observed above for one phosphorus resonance, found at δ = −12.07 ppm, relative to δ ≈ −19.7 ppm in the bis(adduct) **2** and attributable with confidence to the substitution of an adenine moiety by a solvent molecule to form the mono(adduct) **3**. The presence of a cross-peak between the adenine 2-H and the deshielded P at δ = −12.07 ppm in the inverse detection correlation experiment indicates that this signal is due to the phosphane group *trans* to N1, and hence *cis* to the entering solvent molecule.

In addition to the mono- and bis(adducts), solutions of 9-MeAd and nitrate **1** contain a third species (complex **4**), readily detectable when the Ad/Pt molar ratio is about 1:3. This minor component (ca. 8%) features two AB multiplets, with the same relative intensities, in the ^{31}P NMR spectrum (Figure 1).

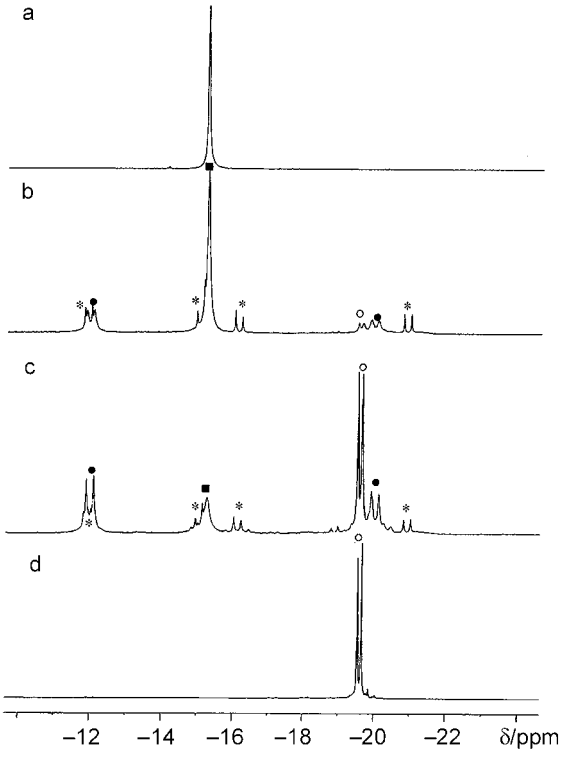

Figure 1. ^{31}P NMR spectra (central part, at 121.5 MHz in $[D_6]$DMSO) of: a) approximately 0.1 M solution of nitrate **1**; b) after addition of nucleobase (molar ratio Ad/Pt = 1:2.85); c) molar ratio Ad/Pt = 1:1; d) molar ratio Ad/Pt = 2:1; ■ denotes nitrate **1**, ○ denotes bis(adduct) **2**, • denotes mono(adduct) **3**, * denotes complex **4**

The resonances labelled by stars in Figure 1 (part b and c) disappear when the Ad/Pt molar ratio is increased to 2, leaving the singlets of the bis adduct **2** at δ = −19.61 and −19.73 ppm as the only detectable signals (Figure 1, part d). The characterization of the adenine complex **4** is discussed later.

Treatment of 9-Methyladenine with *cis*-[Pt(μ-OH)L_2]$_2$(NO_3)$_2$ (6) − Characterization of the Trinuclear Complex *cis*-[PtL_2{9-MeAd(−H)}]$_3$(NO_3)$_3$ (5)

We have shown that the dinuclear hydroxo complex *cis*-[Pt(μ-OH)L_2]$_2^{2+}$ (L = PMe_3) reacts with 9-MeAd (or 9-EtAd) in water as shown in Equation (1), to give the dinuclear complex *cis*-[PtL_2{9-MeAd(−H)}]$_2^{2+}$ containing the NH_2-deprotonated nucleobase, bridging two metal centers through atoms N1 and N6.[6,7] Under the same conditions, the dinuclear hydroxo complex **6** gives a very complex mixture of products, as indicated by the plethora of resonances in the ^{31}P NMR spectrum of the resulting solution, whereas in aprotic solvents a much simpler pattern is obtained. Thus, a suspension of **6** and 9-MeAd (molar ratio 1:2) in [D_6]DMSO becomes clear in ca. 30 min and the ^{31}P NMR spectrum of the resulting solution shows the presence of two AB systems at δ = −18.94/−16.15 and −21.69/−20.95 ppm, the relative intensities of which (20:1) have not changed significantly after several days, indicating that an equilibrium has already been reached. Moreover, in CD_3CN only one AB system is obtained, at δ = −20.03/−17.58 ppm, with well-resolved ^{195}Pt satellites. This spectrum also remains unchanged after several days. The elemental analysis of the product formed in acetonitrile is consistent with the formulation [PtL_2{9-MeAd(−H)}]$_n$(NO_3)$_n$, whereas the ESI-MS spectrum shows the highest *m*/*z* value at 1982, with the expected isotopic distribution, due to the cation {[PtL_2{9-MeAd(−H)}]$_3$(NO_3)$_2$}$^+$, strongly supporting the trinuclear nature of **5**. The stability of isolated **5** is confirmed by the presence of a single set of resonances in the ^{1}H and ^{31}P NMR spectra in $CDCl_3$ or CD_3CN solutions. In contrast, partial conversion into a new species occurs after a few hours at room temperature in [D_6]DMSO, since the ^{31}P NMR spectrum exhibits the same pattern as found when the condensation reaction [Equation (1)] was performed in this solvent. The NMR spectroscopic data obtained through multinuclear experiments are collected in Tables 1−4. ^{1}H,^{15}N NMR correlation spectra (Figure 2) clearly show that platination involves atoms N1 and N6.

The nitrogen signals at δ = −199.2 ppm (detected through the 2-H proton at δ = 8.12 ppm) and δ = −270.8 ppm (detected through the NH proton at δ = 7.17 ppm) are clearly attributable to atoms N1 and N6, respectively. These two resonances in fact display the typical *f*1 modulation due to $^2J_{N,P}$ couplings, in addition to the *f*2 modulation due to $J_{H,N}$ coupling constants. The ^{15}N chemical shift changes of the platinated nitrogen atoms, a shielding of δ = 58 ppm for N1 and a deshielding of δ = 26 ppm for N6, are similar to those found for the dinuclear analog *cis*-[$Pt(PMe_3)_2${9-MeAd(−H)}]$_2$(NO_3)$_2$.[7] In the current case, however, the ^{31}P NMR spectrum obtained for **5** at a low field (36.23 MHz) does not exhibit the long-range platinum-phosphorus couplings found in structurally authentic-

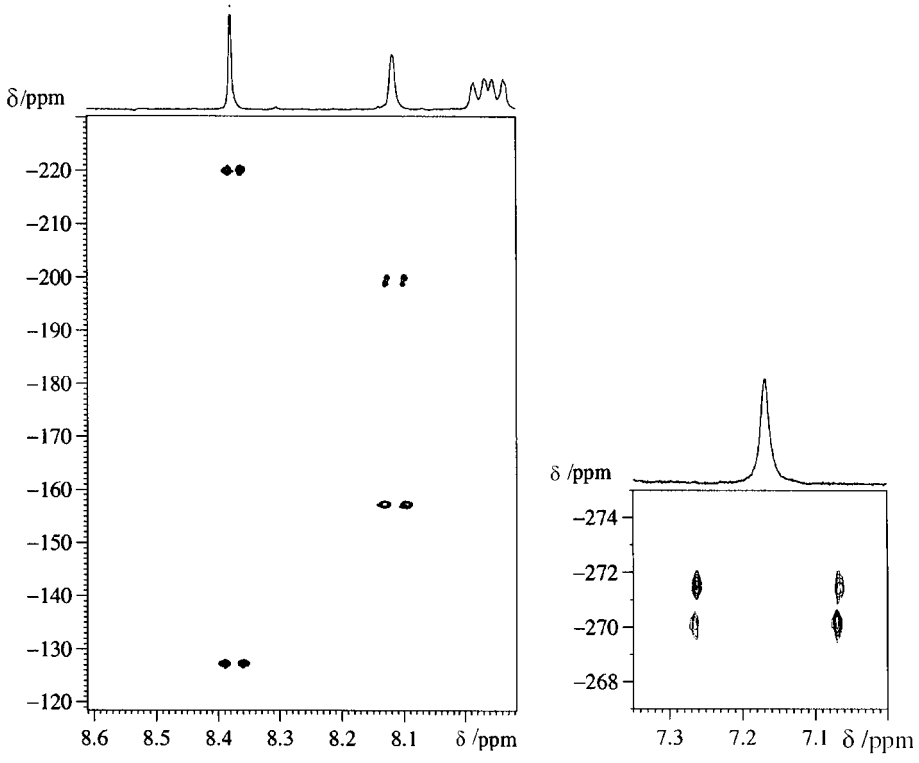

Figure 2. ^{1}H,^{15}N inverse detected spectra of complex **5**; left: HMBC experiment (aromatic region, evolution time 50 ms); right: HMQC experiment (NH region, evolution time 5.6 ms)

ated dinuclear species,[7] in agreement with the higher nuclearity of the complex **5** evidenced by mass spectrometry. The minor component found in the [D_6]DMSO solution of **5** is tentatively attributable to the dinuclear cation *cis*-[PtL_2{9-MeAd(−H)}]$_2^{2+}$ in equilibrium with the predominant trinuclear one. The ^{31}P NMR parameters of the dinuclear species (δ = −21.69/−20.95 ppm) indicate more shielded and less differentiated ^{31}P nuclei than in the trinuclear analog. These spectroscopic features have also been observed with other di- and trinuclear cyclic oligomers containing bridging nucleobases.[10]

Spectroscopic Characterization of the Diplatinated Complex *cis*-[L_2Pt(S){9-MeAd(−H)}PtL_2](NO_3)$_3$ (4)

Solutions of nitrate **1** and 9-MeAd at low Ad/Pt molar ratios contain, in addition to the mono- and bis(adducts), a third species, labelled above as complex **4**, characterized by two AB systems in the ^{31}P NMR spectrum (Figure 1, part b). Its characterization was accomplished by the same multinuclear approach as used for the bis and mono(adducts) on a sample containing Ad/Pt in a 1:3.4 ratio and the results are reported in Tables 1−4. The inverse detection ^{1}H,^{13}C, ^{1}H,^{31}P and ^{1}H,^{195}Pt correlation experiments clearly show that this species contains a single adeninate unit coordinated to two different metal centers, as shown in Scheme 2. The three signals at δ = 8.46, 8.44 and 6.5 ppm (with the same relative intensities) are readily attributable to the 2-H, 8-H and NH protons and belong to the same deprotonated adenine molecule, as inferred from the ^{1}H,^{13}C heteronuclear multiple bond correlation spectrum (Figure 3).

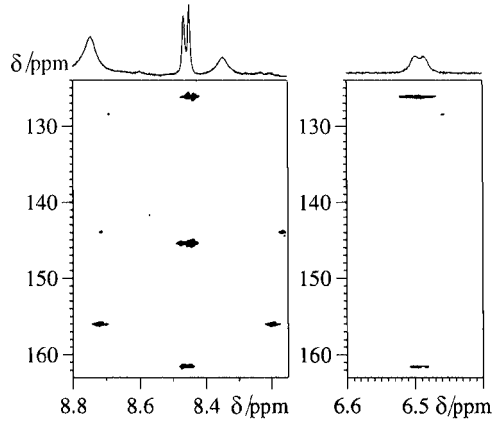

Figure 3. ^{1}H,^{13}C inverse detected spectrum of complex **4** acquired, with a 42 ms evolution delay, on the sample containing Ad/Pt in a 1:3.4 ratio; the spectrum displays, besides the long-range correlations, residual one-bond correlations at δ = 156.1 and 144.0 ppm

In fact, we observe that the 2-H and 8-H protons both detect C4 at δ = 145.5 ppm, the 8-H and NH protons C5 at δ = 126.2 ppm, and the 2-H and NH protons C6 at δ = 161.6 ppm. Furthermore, in the ^{1}H,^{31}P spectrum (Figure 4), 2-H correlates with ^{31}P at δ = −11.98 ppm, 8-H with ^{31}P at δ = −15.12 ppm, and NH with ^{31}P at δ = −16.19 ppm. This is a behavior typical of protons close to or bonded to platinated nitrogen atoms, suggesting three-site (N1, N6 and N7) platination of the deprotonated nucleobase.

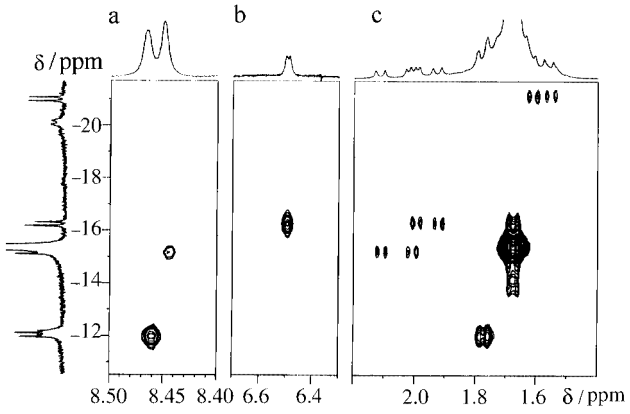

Figure 4. ^{1}H,^{31}P inverse detected spectrum of complex **4** acquired, with a 42 ms evolution delay, on a sample containing Ad/Pt in a 1:3.4 ratio: a) aromatic region, b) NH region, c) aliphatic region; the highest correlation in the aliphatic region is due to unchanged nitrate **1** (methylphosphane signals are found at δ = 1.67 ppm in the ^{1}H NMR spectrum, whereas the ^{31}P NMR signal is at δ = −15.3 ppm)

In addition, the ^{1}H,^{195}Pt spectrum confirms that NH metalation occurs with a ^{195}Pt signal that resonates at δ = −4378 ppm, even though the cross peaks are of low intensity under these conditions. The same experiment performed at low field (200 MHz) allows a second correlation to be detected between 2-H and a ^{195}Pt at δ = −4272 ppm. The low concentration of the diplatinated species did not allow us to detect these two signals in the directly acquired ^{195}Pt spectrum and all ^{15}N signals in the ^{1}H,^{15}N inverse detection mode.

The presence of a deprotonated adenine moiety in this intriguing species prompted us to investigate the involvement of the N7 sites of the trinuclear complex **5** in the platination process when the nitrate **1** is added. The ^{31}P NMR spectrum of a [D_6]DMSO solution of **5** and **1** in 1:3 molar ratio, measured immediately after the mixing of the reactants, is reported in Figure 5.

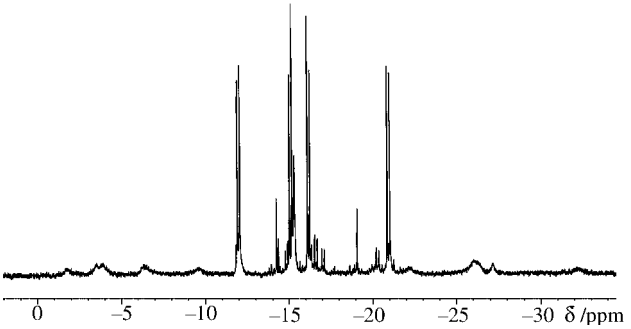

Figure 5. ^{31}P NMR spectrum of a [D_6]DMSO solution of **5** and **1** in 1:3 molar ratio

Figure 5 shows that we were able to obtain a solution containing a major product (80%) displaying the spectroscopic characteristics already found for the diplatinated spe-

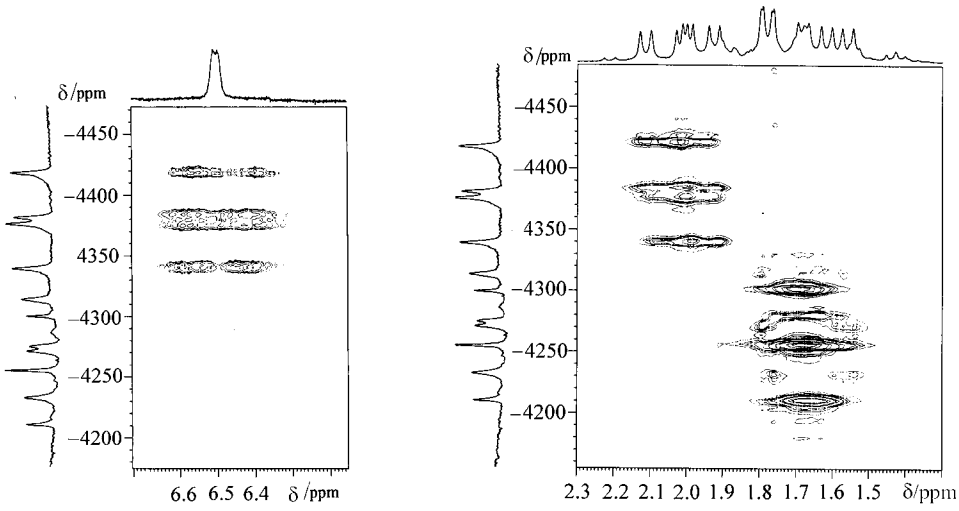

Figure 6. $^{1}H,^{195}Pt$ inverse detected spectra of complex **4** obtained from **5** and **1** in 1:3 molar ratio; left: HMBC experiment (NH region, evolution time 6.2 ms); right: HMBC experiment (aliphatic region, evolution time 12.5 ms); a high correlation in the aliphatic region due to unchanged nitrate **1** ($\delta^{195}Pt = -4254$ ppm) is also present

cies **4**, the unchanged nitrate **1** and other minor species. The directly acquired ^{195}Pt spectrum (displayed as *f*1 trace in Figure 6) reveals the presence of two well-resolved double doublets at the expected chemical shifts, together with the triplet due to the unchanged nitrate **1**. The $^{1}H,^{195}Pt$ spectrum (Figure 6) shows the correlations already found for the diplatinated complex **4** in the sample with Ad/Pt in a 1:3.4 ratio. Furthermore, the signals of the methyl groups bonded to the phosphorus nuclei at $\delta = -15.12$ and -16.19 ppm (see Figure 4) detect ^{195}Pt at $\delta = -4378$ ppm, whereas the signals of the methyl groups bonded to the phosphorus nuclei at $\delta = -11.98$ and -20.96 ppm detect ^{195}Pt at $\delta = -4272$ ppm. Overall, the H,Pt and H,P correlations strongly suggest that nitrogen atoms N6 and N7 chelate or bridge a platinum atom at $\delta = -4378$ ppm, whereas N1 of the same adeninate unit is bonded to a platinum atom at $\delta = -4272$ ppm.

The high concentration of the diplatinated complex **4** allowed us to determine all $^{1}H,^{15}N$ correlations and $^{2}J_{N,P}$ couplings (Figure 7 and Table 4) and to confirm the three-site platination of adenine.

It is evident from Figure 7 that NH and the two aromatic adenine protons detect platinated nitrogen atoms: NH detects N6 at $\delta = -243.6$ ppm, whereas 2-H and 8-H detect N1 at $\delta = -190.0$ ppm and N7 at $\delta = -187.5$ ppm, respectively. These three signals, in addition to a *f*2 modulation due to $J_{H,N}$ couplings, display the *f*1 modulation due to $^{2}J_{N,P}$ typical of metalation, definitely establishing that the adenine unit has three platinated sites. The N1 and N7 coordination shifts ($\delta \approx -50$ ppm) are very similar to those previously observed for platinated N1 sites, while a more marked shift ($\delta = -53$ ppm) is observed for N6 in the diplatinated complex **4** with respect to N6 in the trinuclear complex **5** ($\delta = -26$ ppm). It is also worth mentioning that the NH proton of **4** shows (in ^{1}H NMR spectra recorded at low field or in coupled $^{1}H,^{195}Pt$ correlation spectra) a

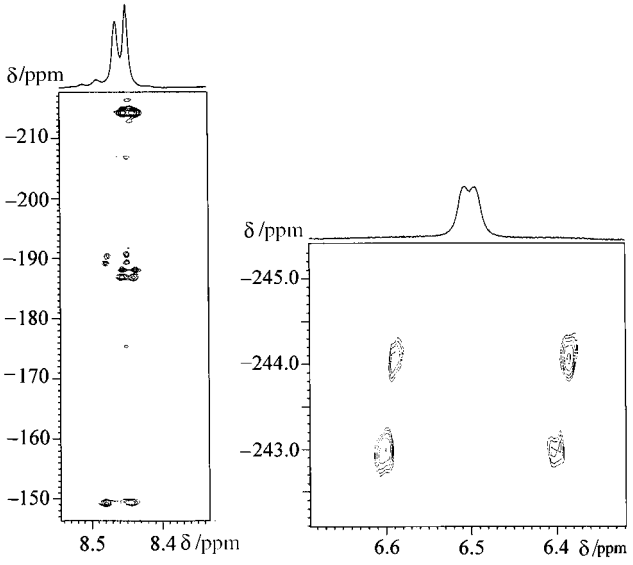

Figure 7. $^{1}H,^{15}N$ inverse detected spectra of complex **4** obtained from **5** and **1** in 1:3 molar ratio; left: HMBC experiment (aromatic region, evolution time 50 ms); right: HMQC experiment (NH region, evolution time 5.6 ms)

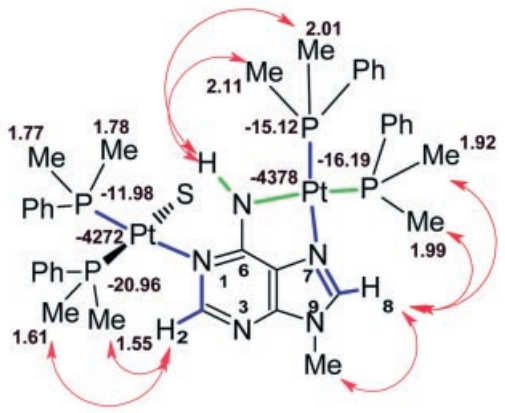
$^{2}J_{H,Pt}$ value of 89 Hz, while the corresponding coupling is unresolved in the trinuclear complex **5**. Both these observations suggest probable chelation in the case of **4**.

To gain further insight into the structure of this interesting complex, a nuclear Overhauser effect[11] study was undertaken, in order to find protons spatially close together. The results validate all the attributions previously derived on the bases of heteronuclear correlations and are graphically summarized in Scheme 3.

Both NOESY (nuclear Overhauser enhancement spectroscopy) and ROESY (rotating-frame Overhauser enhancement spectroscopy) experiments[10] were performed, but the



Scheme 3. The most significant NOE correlations (red arrows) and heteronuclear H,P correlations (blue and green paths) for complex **4**

best results were achieved through the second type of experiment. In the NOESY spectra, indeed, not all the cross peaks were detected and those present were of both signs. This means that the correlation time of complex **4** is $\omega_0\tau_c \approx 1.1$ (at 400 MHz), as is the case for molecules of molecular weight around 1200 Da at this field value,[10] confirming that the diplatinated species **4** has the nuclearity depicted in Scheme 2. The same experiment carried out on the trinuclear complex **5** shows, in fact, only negative cross-peaks, as to be expected for species of higher molecular weight. The nuclear Overhauser study confirms that, in this class of platinum complexes, the higher long-range coupling constants are those between a phosphorus atom and the nuclei of the ligand in a *trans* relationship to it (see Scheme 3). In the case of **4**, for instance, 2-H − which correlates with ^{31}P at δ = −11.98 ppm − is spatially closer to the methyl groups (δ = 1.55 and 1.61 ppm) bonded to ^{31}P at δ = −20.96 ppm, the NH proton that correlates with ^{31}P at δ = −16.19 ppm is spatially closer to the methyl groups (δ = 2.01 and 2.11 ppm) bonded to ^{31}P at δ = −15.12 ppm, and 8-H − which correlates with ^{31}P at δ = −15.12 ppm − is spatially closer to the methyl groups (δ = 1.92 and 1.99 ppm) bonded to ^{31}P at δ = −16.19 ppm. In addition, a weak Overhauser effect is detected between the NH proton and the methyl groups at δ = 1.55 and 1.61 ppm, but is higher than that with the methyl groups at δ = 1.77 and 1.78 ppm. This strongly suggests a distortion of the coordination plane of the platinum atom bonded to N1 (δ = −4272 ppm) with respect to the adenine plane, in agreement with previous findings.[3] Additional evidence is provided by the significant deshielding experienced by the methyl groups of the two phosphane ligands bonded to the chelated ^{195}Pt atom at δ = −4378 ppm, consistent with their proximity to the aromatic plane. The chemical shifts of the phosphane ligands bonded to ^{195}Pt at δ = −4272 ppm are very similar to those found for the mono(adduct) **3** and indicate the presence of a solvent molecule in the fourth coordination platinum site. Finally, we observe that the N6/N7 complexation could hardly be deduced from trends in ^{13}C or ^{1}H chemical shifts. More significant are the changes observed in the ^{15}N chemical shifts upon coordination and the value of the coupling constant (89 Hz) between the NH proton and the chelated ^{195}Pt at δ = −4378 ppm.

The formation of the diplatinated complex **4** under the two different sets of conditions described deserves further comment. Concomitant platination at the N1 and N7 sites of neutral adenines is known when the donor atoms in ancillary ligands are nitrogen or chlorine atoms.[3,12] As observed above, N1 is the preferred metalation site of neutral adenine when phosphanes are used as ancillary ligands, but N6/N7 platination also occurs in the presence of a large excess of platinum. The formation of complex **4** could be explained in terms of the initial formation of an N1- and N7-diplatinated intermediate in which the pK_a of NH_2 is lowered by the phosphane ligands, with the consequent formation of an adeninate ion that eventually chelates one platinum atom through N6 and N7. This hypothesis requires the presence of a base in the reaction medium, a role that can be played by the solvent and/or by residual water molecules. The participation of water molecules in the deprotonation is indicated by the observed changes to the signal of a trace of water in [D_6]DMSO solution. This signal is shifted significantly downfield when platinum is in large excess, and progressively moves upfield to its normal δ value (δ = 3.3 ppm) when the Ad/Pt ratio is enhanced. Nevertheless, a direct contribute of the solvent as a base cannot be ruled out.

The disruption of the original N1/N6-bridged trinuclear complex **5** is required when it is treated with the nitrate **1** to form **4**; metalation at N7 probably occurs, forming highly charged, sterically crowded and unstable species that rearrange to less charged and crowded complexes. This process could, in the simplest case, produce two isomeric diplatinated and chelated N1/N6 or N6/N7 complexes. The latter of these is the more stable form found in DMSO solution, in agreement with the higher stability of five-membered rings with respect to four-membered rings, as already reported for mononuclear molybdenum adeninate complexes.[5]

Conclusion

We have reported here on the different coordination modes of 9-MeAd in platinum complexes with phosphanes as ancillary ligands. The results can be summarized as follows:

i) 9-MeAd in its neutral form binds selectively at the N1 site to the metal center of the *cis*-L_2Pt^{2+} units. The role of the different substituents on the phosphane ligands (L = PMe_3, PMe_2Ph) is merely to change slightly the relative stability of the conformers in the bis (adduct) **2**.

ii) The deprotonation of the nucleobase at the NH_2 amino group, promoted by the hydroxo ligand present in the reacting platinum complex **6**, results in the formation of cyclic adducts *cis*-$[PtL_2\{9\text{-MeAd}(-H)\}]_n^{n+}$, in which the

adeninate ions selectively bind the metal atom at the N1 and N6 positions. The relative stability of the oligomers is dependent on the ancillary ligands and on the solvent. The dinuclear complex ($_n$ = 2) is the more stable species when L is PMe_3, whereas the trinuclear **5** appears to be the more stable form with the more sterically demanding PMe_2Ph ligand.

iii) The involvement of the N7 adenine atom in the platination process occurs concomitantly with the N6 chelation, which in turn requires NH_2 deprotonation. The three-site platination of the same adenine unit observed in complex **4** represents an unprecedented coordination mode of 9-MeAd in platinum(II) complexes.

Experimental Section

Materials and Methods: The nucleobase 9-MeAd[13] and the platinum complexes *cis*-[$PtCl_2(PMe_2Ph)_2$][14] were synthesized as previously reported. ^{1}H, ^{13}C, ^{31}P, ^{195}Pt and ^{15}N NMR spectra were obtained in [D_6]DMSO solutions at 300 K in 5-mm sample tubes with Bruker 400AMX WB (operating at 400.13, 100.61, 161.98, 85.88 and 40.56 MHz, respectively) or Bruker AVANCE 300 MHz (operating at 121.5 MHz for ^{31}P) spectrometers, unless otherwise stated. The ^{1}H and ^{13}C chemical shifts were referenced by assigning ^{1}H impurity in the solvent at δ = 2.49 ppm and the ^{13}C multiplet at δ = 39.5 ppm, respectively. The external references were H_3PO_4 (85% w/w in D_2O) for ^{31}P, Na_2PtCl_4 in D_2O (adjusted to δ = −1628 ppm from Na_2PtCl_6) for ^{195}Pt and CH_3NO_2 (in $CDCl_3$ at 50% w/w) for ^{15}N. Inverse detected spectra were obtained through heteronuclear multiple-quantum or multiple-bond correlation (HMQC or HMBC) experiments,[15,16] using parameters similar to those previously reported.[6] The conditions for NOESY and ROESY phase-sensitive spectra[11] by time-proportional phase incrementation (TPPI) were: mixing time 200 ms, spectral width 8.7 ppm with 4096 complex points in *f*2; 512 *t*1 values and 128 scans for *t*1 value. A squared sine function (SSB 2) in *f*2 and in *f*1 was applied prior to Fourier transformation. For the ROESY experiment the spin-lock field was 4000 Hz.

Synthesis of *cis*-[$Pt(NO_3)_2(PMe_2Ph)_2$] (1): A solution of $AgNO_3$ (1.26 g, 7.44 mmol) in H_2O (15 mL) was added to a water (100 mL) suspension of *cis*-[$PtCl_2(PMe_2Ph)_2$] (2.02 g, 3.72 mmol). The AgCl precipitate was eliminated by filtration and the filtrate was concentrated under vacuum to provide **1** as a white solid (1.43 g, 65%). ^{1}H NMR (400.13 MHz, [D_6]DMSO): δ = 1.67 (d, $^2J_{H,P}$ = 11.9 Hz, 6 H, PMe_2), 7.48 (m, 2 H, *m*-H), 7.56 (m, 1 H, *p*-H), 7.70 (m, 2 H, *o*-H) ppm. ^{13}C NMR (100.61 MHz, [D_6]DMSO): δ = 11.8 (m, $^1J_{C,P}$ = 45 Hz, PMe), 128.9 (d, $^1J_{C,P}$ = 67.2 Hz, C1), 128.9 (t, $^2J_{C,P}$ = 5.7 Hz, C_{ortho}), 131.4 (t, $^3J_{C,P}$ = 5.5 Hz, C_{meta}), 138.0 (s, C_{para}). ^{195}Pt NMR (85.88 MHz, [D_6]DMSO): δ = −4254 (t, $^1J_{Pt,P}$ = 3840 Hz) ppm. ^{31}P NMR (161.98 MHz, [D_6]DMSO): δ = −15.32 (s, $^1J_{P,Pt}$ = 3842 Hz) ppm. ^{31}P NMR (121 MHz, CD_3CN): δ = −18.3 (br. s, $^1J_{P,Pt}$ approximately 3800 Hz), in D_2O: δ = −17.2 (s, $^1J_{P,Pt}$ 3824 Hz). $C_{16}H_{22}N_2O_6P_2Pt$ (595.4): calcd. C 32.28, H 3.72, N 4.70; found C 32.22, H 3.65, N 4.72.

Synthesis of *cis*-[$Pt(PMe_2Ph)_2$(9-MeAd)$_2$]$(NO_3)_2$ (2): A suspension of *cis*-[$Pt(NO_3)_2(PMe_2Ph)_2$] (250 mg, 0.41 mmol) and 9-MeAd (125 mg, 0.84 mmol) in water (50 mL) was stirred at room temperature for approximately 1 h. The resulting solution was concentrated under vacuum and the residue was dissolved in MeOH (20 mL). The solution was filtered to eliminate traces of platinum, and addition of Et_2O afforded a white, microcrystalline precipitate, which was further purified from MeOH/Et_2O, filtered and dried under vacuum. The yield of pure product was 222 mg (61%). $C_{28}H_{36}N_{12}O_6P_2Pt$ (893.7): calcd. C 37.63, H 4.06, N 18.80; found C 37.53, H 4.15, N 18.68. ^{1}H NMR (400.13 MHz, [D_6]DMSO): major conformer: δ = 1.73 (d, $^2J_{H,P}$ = 11.2 Hz, 3 H, PMe), 1.80 (d, $^2J_{H,P}$ = 11.2 Hz, 3 H, PMe), 3.64 (s, 3 H, NMe), 7.3−7.7 (m, 5 H, Ph), 8.20 (s, 1 H, 8-H), 8.73 (s, 1 H, 2-H); minor conformer: δ = 1.64 (d, $^2J_{H,P}$ = 11.2 Hz, 3 H, PMe), 1.86 (d, $^2J_{H,P}$ = 11.2 Hz, 3 H, PMe), 3.66 (s, 3 H, NMe), 7.3−7.7 (m, 5 H, Ph), 8.22 (s, 1 H, 8-H), 8.84 (s, 1 H, 2-H) ppm. ^{31}P NMR (161.98 MHz, [D_6]DMSO): major conformer: δ = −19.73 (s, $^1J_{P,Pt}$ = 3231 Hz); minor conformer: δ = −19.61 (s, $^1J_{P,Pt}$ = 3225 Hz) ppm. ^{31}P NMR (36.23 MHz, D_2O): δ = −22.14 (s, $^1J_{P,Pt}$ = 3140 Hz) and −22.45 (s, $^1J_{P,Pt}$ = 3142 Hz) ppm.

Preparation of *cis*-[{$Pt(\mu$-OH)$(PMe_2Ph)_2$}$_2$]$(NO_3)_2$ (6): A solution of $AgNO_3$ (0.98 g, 5.78 mmol) in H_2O (12 mL) was added to a suspension of *cis*-[$PtCl_2(PMe_2Ph)_2$] (1.57 g, 2.89 mmol) in water (67 mL). The immediately formed precipitate of AgCl was filtered and the resulting solution was neutralized with a solution (31.0 mL) of NaOH (0.092 M). After the mixture had been stirred at room temperature for 0.5 h, the white precipitate that separated was recovered by filtration, washed twice with H_2O (10 mL), recrystallized from EtOH/Et_2O and dried under vacuum to give **6** (0.72 g, 45%). ^{1}H NMR (300 MHz, [D_6]DMSO): δ = 1.54 (d, $^2J_{P,H}$ = 11.7 Hz, 6 H, PMe), 4.09 (s broad, 1 H, OH), 7.74−7.49 (m, 5 H, Ph) ppm. ^{31}P NMR (161.98 MHz, [D_6]DMSO): δ = −14.50 (s, $^1J_{P,Pt}$ = 3456 Hz) ppm. $C_{32}H_{46}N_2O_8P_4Pt_2$ (1100.8): calcd. C 34.98, H 4.03, N 2.54; found C 35.02, H 3.98, N 2.61.

Synthesis of *cis*-[$Pt(PMe_2Ph)_2${9-MeAd(−H)}$]_3(NO_3)_3$ (5): A suspension of *cis*-[$Pt(\mu$-OH$)_2(PMe_2Ph)_2$]$(NO_3)_2$ (210 mg, 0.19 mmol) and 9-MeAd (57 mg, 0.38 mmol) in CH_3CN (3 mL) was stirred at room temperature for approximately 1 h. Addition of Et_2O to the resulting solution afforded a white, microcrystalline precipitate, which was filtered off, washed with Et_2O and dried under vacuum to give **5** (184 mg, 71%). ^{1}H NMR (300 MHz, $CDCl_3$): δ = 8.31 (s, 1 H, 8-H), 8.15 (s, 1 H, 2-H), 7.85−7.37 (m, 10 H, Ph), 7.22 (s, 1 H, NH), 3.71 (s, 3 H, NMe), 1.89 (d, $^2J_{H,P}$ = 11.5 Hz, 3 H, PMe), 1.71 (d, $^2J_{H,P}$ = 11.6 Hz, 3 H, PMe), 1.13 (d, $^2J_{H,P}$ = 10.0 Hz, 3 H, PMe), 1.11 (d, $^2J_{H,P}$ = 10.3 Hz, 3 H, PMe) ppm. ^{31}P NMR (161.98 MHz, $CDCl_3$): δ = −21.88 (d, $^2J_{P,P}$ = 23.9, $^1J_{P,Pt}$ = 3842 Hz), −18.06 (d, $^2J_{P,P}$ = 23.9, $^1J_{P,Pt}$ = 3163 Hz) ppm. ^{1}H NMR (300 MHz, CD_3CN): δ = 8.175 (s, 1 H, 8-H), 8.06 (s, 1 H, 2-H), 7.85−7.37 (m, 10 H, Ph), 7.24 (s, 1 H, NH), 3.71 (s, 3 H, NMe), 1.82 (d, $^2J_{H,P}$ = 11.5 Hz, 3 H, PMe), 1.73 (d, $^2J_{H,P}$ = 11.6 Hz, 3 H, PMe), 1.09 (d, $^2J_{H,P}$ = 10.0 Hz, 3 H, PMe), 1.078 (d, $^2J_{H,P}$ = 10.3 Hz, 3 H, PMe) ppm. ^{31}P NMR (161.98 MHz, CD_3CN): δ = −20.69 (d, $^2J_{P,P}$ = 24.3, $^1J_{P,Pt}$ = 3340 Hz), −18.06 (d, $^2J_{P,P}$ = 24.3, $^1J_{P,Pt}$ = 3190 Hz) ppm. ^{1}H NMR (300 MHz, [D_6]DMSO): δ = 1.08/1.14 (d, $^2J_{H,P}$ = 10.7 Hz, 18 H, PMe), 1.78/1.84 (d, $^2J_{H,P}$ = 11.7 Hz, 18 H, PMe), 3.58 (s, 9 H, NMe), 7.17 (d, $J_{H,P}$ = 6.5 Hz, NH), 7.3−7.6 (m, 18 H, $H_{meta,para}$), 7.84 (m, 6 H, H_{ortho}), 7.96 (m, 6 H, H_{ortho}), 8.12 (s, 3 H, 2-H), 8.38 (s, 3 H, 8-H) ppm. ^{31}P NMR (161.98 MHz, [D_6]DMSO): δ = −16.15 (d, $^2J_{P,P}$ = 24.4, $^1J_{P,Pt}$ = 3170 Hz), −18.94 (d, $^2J_{P,P}$ = 24.4, $^1J_{P,Pt}$ = 3320 Hz). $C_{66}H_{84}N_{18}O_9P_6Pt_3$ (2044.6): calcd. C 38.77, H 4.14, N 12.33; found C 38.85, H 4.24, N 11.88.

Acknowledgments

We would like to thank Dr. Roberta Seraglia of the Istituto di Scienze e Tecnologie Molecolari − C.N.R. (Padova) for the mass spec-

trum. Thanks are due to the Centro Interdipartimentale Grandi Strumenti of Modena University for the use of the Bruker AMX 400 WB spectrometer. This work was financially supported by the Ministero dell'Universita' e della Ricerca Scientifica e Tecnologica (PRIN 2001).

Supramolecular Organisation of Polymeric Coordination Chains into a Three-Dimensional Network with Nanosized Channels that Clathrate Large Organic Molecules

Xian-Ming Zhang,[a,b] Ming-Liang Tong,[a] Meng-Lian Gong,[a] and Xiao-Ming Chen*[a]

Keywords: Coordination polymers / Microporous materials / Inclusion compounds / Supramolecular chemistry

Hydrothermal treatment of a mixture of $[Zn(MeCO_2)_2]\cdot H_2O$, terephthalic acid, and 2,2′-bipyridine resulted in a coordination polymer [Zn(bpy)(tp)](bpy) (**1**; bpy = 2,2′-bipyridine, H_2tp = terephthalic acid) which crystallizes in the monoclinic space group $C2/c$, $M_r = 541.85$, $a = 15.388(11)$, $b = 21.963(11)$, $c = 7.670(8)$ Å, $\beta = 112.82(2)°$, $V = 2387(3)$ Å^3, $Z = 4$, $D_c = 1.506$ g·cm^{-3}. An X-ray single-crystal structural analysis reveals that **1** is a three-dimensional network with nanosized channels constructed from one-dimensional coordination chains via C–H···O hydrogen bonds and aromatic intercalations. TGA and XRPD showed that the porous network of **1** is very stable while the guest 2,2′-bipyridine molecules in the channels are removable. Compound **1** shows a strong ligand-centred emission at room temperature in the solid state.

Introduction

Microporous inorganic materials including zeolites, aluminium phosphates, and transition metal phosphates are particularly important for their applications as molecular sieves, desiccants, ion exchangers, and catalysts,[1−7] and thus they have been studied in detail in the past decades. Several years ago, microporous compounds were extended to pure organic and metal-organic frameworks, or coordination polymers.[8−20] Compared with inorganic compounds, organic and coordination polymers built from molecular building blocks hold great promise for their ease of processability, flexibility, structural diversity, and geometrical control, such as the size, shape, and symmetry.[12] However, most pure organic and coordination polymers do not possess a porous structure because of the interpenetration of two or more independent networks and the collapse of the network in the absence of guest molecules.[21] Thus, the designed construction of extended porous organic or metal-organic frameworks from molecular building blocks is one of the most challenging issues in current synthetic chemistry.

Recent progress in the design and synthesis of porous metal-organic frameworks has been recently made by Yaghi, Williams, Kitagawa, and their co-workers, in particular, using the concept of secondary building units (SBUs) for understanding and predicting the topologies of structures.[12] The terephthalate (tp) anion is one of the best ligands for the design and construction of inorganic-organic hybrid porous frameworks owing to its thermal stability and symmetry. Hong and co-workers[22] recently attempted to construct a porous coordination polymer with mixed tp and 1,10-phenanthroline (phen) ligands via aromatic π-π stacking interactions, but, due to the ill-suited orientation of the phen and tp groups, and the existence of coordinated water molecules, the networks obtained were not porous. From entropic and kinetic points of view, it is advantageous to arrange the building blocks in a more orderly fashion and remove the coordinated water molecules by reaction at higher temperatures and for longer times.[8] We report here a new porous compound [Zn(bpy)(tp)](bpy) (**1**) generated by a high temperature hydrothermal reaction, which is constructed from infinite zigzag coordination polymeric chains via C−H···O hydrogen bonds and aromatic π-π stacking interactions.

Results and Discussion

Synthesis and Characterization

While well established for the syntheses of zeolites, the hydrothermal method has more recently been adapted to the preparation of complexes. There are a variety of hydrothermal parameters such as reaction time, temperature, pH value, and molar ratio of reactants, and small changes in one or more of the parameters may have a profound influence on the final reaction outcome. Compared with typical hydrothermal conditions for the synthesis of coordination

polymers (120−180 °C and 2−7 days), compound **1** was synthesized at a higher reaction temperature (200 °C) during an exceptionally long reaction time (25 days).

Description of Crystal Structure

X-ray crystallography reveals that **1** consists of one-dimensional zigzag $[Zn(bpy)(tp)]_n$ chains and free bpy groups. There are 0.5 zinc atoms, and 0.5 tp, 0.5 coordinated bpy and 0.5 free bpy ligands in each asymmetric unit. The zinc atom in **1** has a highly distorted octahedral coordination environment with four oxygen atoms [Zn(1)−O(1) 2.380(4), Zn(1)−O(2) 2.057(4) Å, O(1)−Zn(1)−O(2) 59.3(2)°] from two tp groups and two nitrogen atoms [Zn(1)−N(1) 2.132(4) Å and N(1)−Zn(1)−N(1a) 77.2(2)°] from a chelating bpy ligand, as shown in Figure 1. Each tp group acts in a bis-bidentate mode and bridges two zinc atoms, resulting in $[Zn(bpy)(tp)]_n$ chains with additional bpy ligands found alternately on both sides. The Zn···Zn···Zn angle formed by three adjacent zinc atoms is 128°. Both carboxylate ends function in an asymmetric chelate mode, as evidenced by the Zn(1)−O(1) and Zn(1)−O(2) bond lengths.

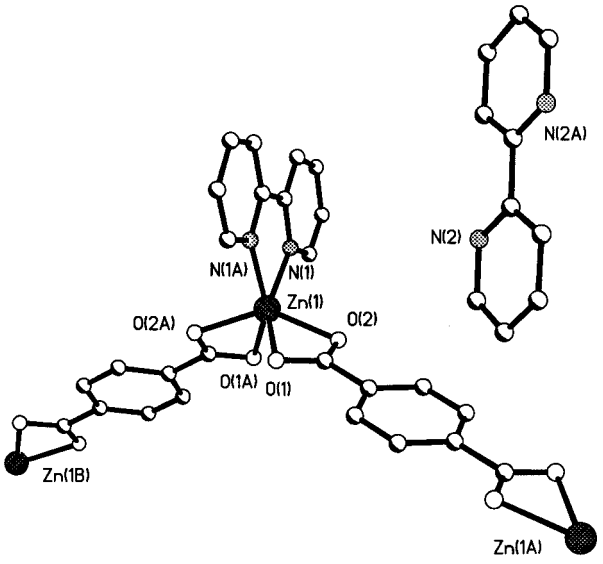

Figure 1. Perspective view of the coordination environment of the zinc atom and the guest bpy molecule in **1**

Two strong bands at 1563 (s) and 1395 (s) cm^{-1} in the IR spectrum are due to the antisymmetric and symmetric stretching vibrations of the carboxylate group, respectively. The difference (Δ = 168 cm^{-1}) between $\nu_{asym}(CO_2)$ and $\nu_{sym}(CO_2)$ is similar to that of an ionic carboxylate, which may be attributed to existence of the C−H···O hydrogen bond associated with the carboxylate oxygen atoms (see below), hence the carboxylate end behaves like a bridging carboxylate-*O*,*O*′ group in the IR spectrum of **1**.

It should be noted that there are persistent one-dimensional C−H···O hydrogen bond interactions between adjacent $[Zn(bpy)(tp)]_n$ chains. Recent studies[23] have revealed that the C···O distance (*D*) in C−H···O hydrogen bond is in the range of 3.0−4.0 Å. The C−H···O angle θ in the range of 110−180° is acceptable, although a linear C−H···O bond (150° < θ < 180°) is structurally more important. In **1** the C(3)···O(1) distance of 3.489 Å and C(3)−H(3a)···O(1) angle of 157.3° indicate a strong C−H···O hydrogen bond. Two complementary C−H···O hydrogen bonds form a double-linked C−H···O hydrogen bond interaction which further extends the $[Zn(bpy)(tp)]_n$ chains into undulating $[Zn(bpy)(tp)]_n$ layers, as shown in Figure 2a. Within the layer, the separation between two adjacent bpy ligands is ca. 7.0 Å. Hydrogen bond interactions are usually important in the synthesis of supramolecular architectures,[24] and in **1** they undoubtedly play an important role in the stabilization of the layer structure and the control of the orientation of the tp ligands. Besides the C−H···O hydrogen bond, the pyridyl C(8) [with H(8a)] atom also forms a hydrogen bond with the carboxy O(2) atom from an adjacent layer, in which the C(8)···O(2) distance and C(8)−H(8a)···O(2) angle are 3.254 Å and 129.3°, respectively (Figure 2b).

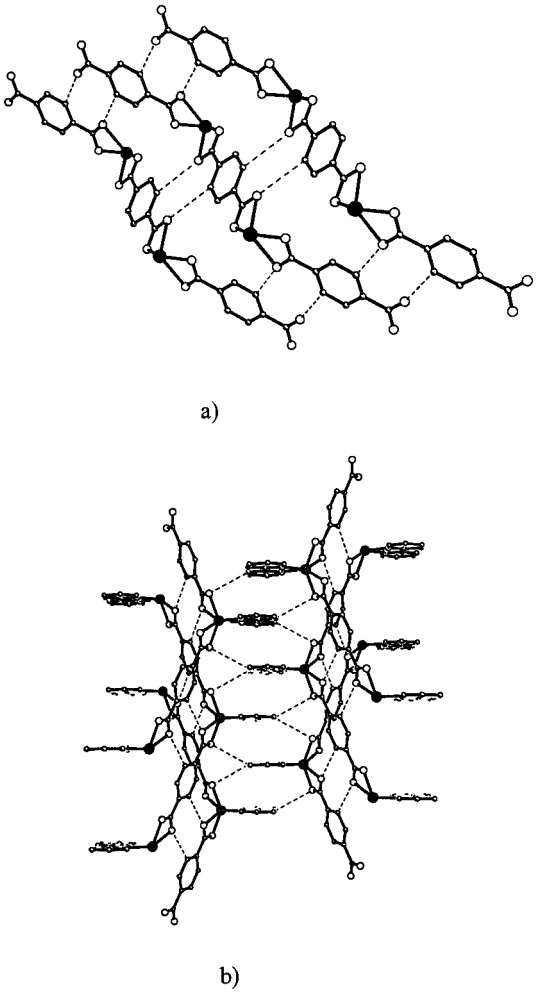

Figure 2. Perspective views of the two-dimensional layers constructed by the zigzag chains and C−H···O hydrogen bonds: (a) top-view of a single layer; (b) side-view of two layers exhibiting the intercalation of the lateral bpy ligands

Aromatic π-π stacking interactions are also apparent in **1**, as shown in Figure 2b. Aromatic π-π stacking interactions can be depicted by centroid-centroid distance, plane-to-plane distance, and displacement angle.[25] The displacement angle means the angle formed between the ring-centroid vector and the ring normal to one of the pyridine planes. In **1**, the centroid-centroid distance (3.85 Å) between two coordinated pyridine fragments, plane-to-plane distance (3.46 Å) and displacement angle (26°) indicate strong π-π stacking interactions between adjacent bpy ligands. All lateral bpy ligands from adjacent undulating $[Zn(bpy)(tp)]_n$ layers are parallel-displaced and intercalated in a zipper-like mode similar to some previously documented examples,[26] which, in combination with the C(8)−H(8a)···O(2) hydrogen bond, further extends the undulating layers into a three-dimensional supramolecular network featuring one-dimensional nanosized saddle-like channels running along the *c* axis (Figure 3). The guest bpy molecules reside in the channels and exhibit an intermolecular parallel-displaced stacking geometry (plane-to-plane distance 3.5 Å) between themselves. Although the three-dimensional structure of **1** is somewhat similar to that of $[Cu(4,7\text{-phen})(H_2O)_3](ClO_4)_2\cdot(4,7\text{-phen})_2$,[27] it is, in fact, constructed in a significantly different fashion. The three-dimensional architecture of this copper compound is formed by the parallel stacking of adjacent S-shaped "triple chains"; in contrast, that of **1** is formed by the zipper-like intercalation of the lateral bpy ligands.

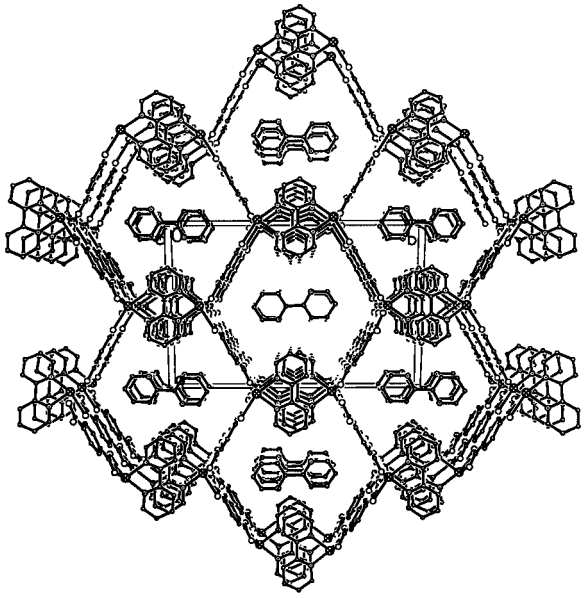

Figure 3. Perspective view of the three-dimensional network along the *c* axis

It is worthwhile to note that the free dimensions (13 × 7 Å) of these channels produced after calcination of **1** occupy as much as 40.7% of the crystal volume,[28,29] a figure similar to those of $[Cu_3(TMA)_2(H_2O)_3]$[8] and $[Zn_2(BTC)(NO_3)](H_2O)(EtOH)_5$ [30] (41% and 43.6%, respectively) and those (47% to 50%) of the most open zeolites, such as the faujasite, paulingite, and zeolite A families.[2] In the formation of the channels in **1**, the C−H···O hydrogen bonds play a critical role because they make the tp ligands arranged in an orderly fashion, which minimizes the volume occupied by the network skeleton by controlling the orientation of the tp building blocks, leaving the large one-dimensional channels that are occupied by the guest bpy molecules.

In order to study the microporosity chemistry of **1**, thermogravimetric analysis (TGA) was performed in air and at 1 atm. pressure at a heating rate of 10 °C·min^{-1} on a polycrystalline sample of this material, which showed the following clear and well-separated weight loss steps. As shown in Figure 4, a total weight loss of 29.0% occurred over the temperature range 190−310 °C, corresponding to the removal of one free bpy molecule per formula unit (calcd. 28.8%), followed by a two-step total weight loss of 56.3% between 340 and 640 °C consistent with the removal of coordinated bpy and tp ligands. The remaining weight of 14.7% corresponds to the percentage (15.0%) of the Zn and O components, indicating that the final product is ZnO. It should be noted that no weight loss was observed in the temperature range 310−340 °C. Therefore the TGA curve of **1** indicates that: 1) the free bpy molecules are removed from the channels in the temperature range 190−310 °C, whereas the coordinated bpy and tp ligands do not decompose over this temperature range; 2) in air and under 1 atm. pressure, a phase formulated as [Zn(bpy)(tp)] is stable in the temperature range 310−340 °C, which is unusually high for a one-dimensional coordination polymer.

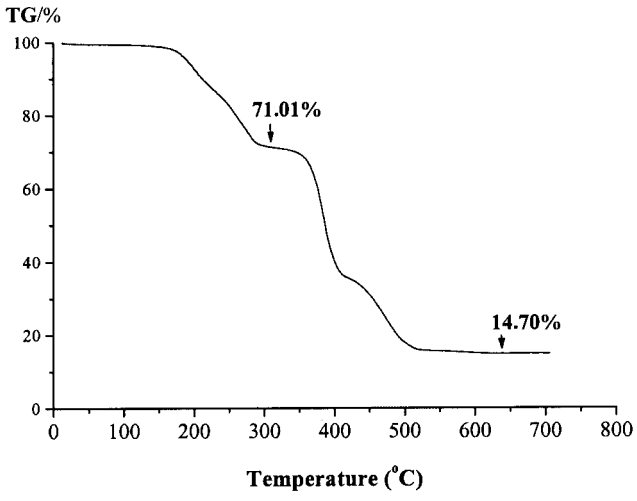

Figure 4. Thermogravimetric analysis curve of **1**

The above conclusions have also been supported by calcination of **1**. Elemental microanalysis (C 56.05, H 3.14, N 7.26) of **1** after calcination (designated as **1′**) in air at 220 °C and 10^{-2} Torr for 10 hours shows that the free bpy molecules are removed in the course of calcination. The X-ray powder diffraction patterns (Figure 5) of **1** and **1′** are similar while the positions, intensities and widths of some

peaks show minor differences, thus indicating that the porous network of **1** is retained after the calcination and removal of guests.

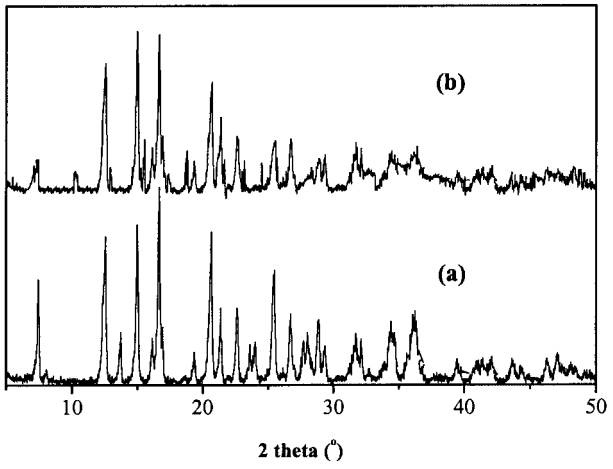

Figure 5. The XRPD patterns for: (a) as-synthesized **1** with bpy in the channels, and (b) the calcinated material

Photoluminescence

In the solid state, **1** shows an intense and broad emission band ranging from 400 to 600 nm upon photoexcitation (λ_{ex} = 260 nm; Figure 6). The maxima of the emission bands are located at 468 and 540 nm. According to the literature,[31,32] the emission at 468 nm can be assigned to the $^1\pi,\pi^*$ state of the bpy ligands and the small shoulder at 540 nm to the $^1\pi,\pi^*$ state of free bpy molecules. The blue shift of the emission at 468 nm compared to that of free bpy ligand is possibly due to the fact that the bpy ligands are not allowed to relax along the inter-ring torsional mode upon photoexcitation.

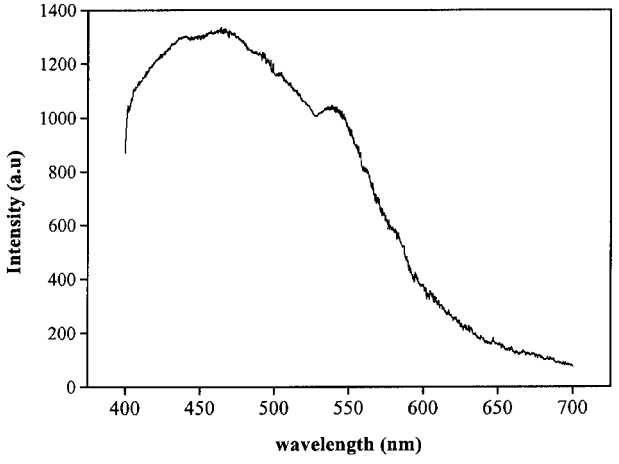

Figure 6. Photoluminescent spectrum of **1** excited at 260 nm

Experimental Section

General Remarks: Elemental analyses were performed on a Perkin−Elmer 240 elemental analyzer. The FT-IR spectra were recorded from KBr pellets between 400 and 4000 cm^{-1} on a Nicolet 5DX spectrometer. Thermal gravimetric analyses (TGA) were performed under a static air atmosphere using a Perkin−Elmer 7 thermogravimetric analyzer with a heating rate of 10 °C·min^{-1}. The XRPD patterns were recorded a Rigaku D/Max 3III diffractometer with a scanning rate of 4 deg·min^{-1}. Photoluminescence of **1** was performed at room temperature on a Hitachi F-4500 spectrometer.

Preparation of 1: A mixture of $Zn(MeCO_2)_2{\cdot}H_2O$ (0.112 g), H_2tp (0.083 g), NaOH (0.040 g), bpy (0.079 g), and water (10 mL) in a 1:1:2:1:1100 molar ratio was stirred for 20 min in air, then sealed in a 23 mL Teflon-lined stainless steel container, which was heated to 200 °C for 25 days. After cooling to room temperature at a rate of 5 °C per hour, pale-yellow large block crystals (ca. 3.2 × 2.3 × 1.5 mm) of **1** were recovered in 60% yield based on bpy. $C_{28}H_{20}N_4O_4Zn$ (541.85): calcd. C 60.06, H 3.72, N 10.34; found C 59.87, H 3.81, N 10.26. IR (KBr): $\tilde{\nu}$ = 3436 cm^{-1} m, 3069 w, 1563 s, 1443 m, 1395 s, 1294 m, 1174 w, 1018 w, 903 m, 842 s, 760 s, 546 m.

Preparation of the Porous Framework 1′: Compound **1** was calcinated in a vacuum oven at 220 °C under a pressure of ca. 10^{-2} Torr for 10 h. $C_{18}H_{12}N_2O_4Zn$ (385.69): calcd. C 56.05, H 3.14, N 7.26; found C 55.94, H 3.07, N 7.21.

X-ray Crystallographic Study: Diffraction intensities were collected at 293 K on a Siemens R3 diffractometer (Mo-K_α, λ = 0.71073 Å). Lorentz-polarization and absorption corrections were applied. The structures were solved by direct methods (SHELXS-97)[33] and refined by full-matrix least-squares techniques (SHELXL-97). Analytical expressions of neutral-atom scattering factors were employed, and anomalous dispersion corrections were incorporated. In all cases, all non-hydrogen atoms were refined anisotropically and hydrogen atoms of organic ligands were geometrically placed. The crystallographic data are listed in Table 1 and selected interatomic distances and angles are given in Table 2.

Synthesis, Structural Study, and In Vitro Trypanocidal and Antitumour Activities of Tetrakis(3-methoxypropyl)tin and (3-Methoxypropyl)tin Chlorides

Tomáš Lébl,*[a] Aleš Smička,[a][†] Jiří Brus,[b] and Clemens Bruhn[c]

Dedicated to Professor Jaroslav Holeček on the occasion of his 70th birthday

Keywords: Chelates / Drug research / O ligands / Structure elucidation / Tin

A set of four water-soluble (3-methoxypropyl)stannanes of general formula $(CH_3OCH_2CH_2CH_2)_xSnCl_{4-x}$, where x = 4 (**1**), x = 3 (**2**), x = 2 (**3**), and x = 1 (**4**), was prepared. For **3** and **4**, which were isolated in the crystalline state, it was shown by X-ray diffraction that the tin atom is coordinated in distorted octahedral and trigonal-bipyramidal geometries, respectively (i.e., the oxygen atoms of the 3-methoxypropyl groups were coordinated to the central tin atom in both cases, forming chelates). For all compounds, structures in $CDCl_3$ and [D_6]DMSO solutions were proposed on the basis of their ^{13}C and ^{119}Sn NMR spectra. In $CDCl_3$ solution, the degree of donor-acceptor bonding between the central tin atom and oxygen atom of the 3-methoxypropyl substituent was evaluated on the basis of ^{17}O NMR chemical shifts and $^{3,6}J(^1H,^{119}Sn)$ long-range coupling constants. Compounds **2** and **3** exhibited promising in vitro antitumour and trypanocidal activities.

(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2003)

Introduction

Organotin compounds have shown a wide spectrum of biological merits. Their antitumour properties in vitro against a wide panel of tumour cell lines of human origin are fairly well known,[1] and it has also been proposed that anticancer reagents could also be used against trypanosomal diseases (human sleeping sickness and domesticated live stock diseases).[2] Recently, it was found that several organotin thiolates exhibit high in vitro levels of activity in comparison with the arsenic derivatives used for chemotherapy.[3] However, the antitumour and trypanocidal efficiencies of organotin derivatives seem to be limited by their low water solubility.[4] Particular attention has therefore recently been paid to the synthesis of organotin compounds with higher water solubilities.[5]

In 1997, Susperregui et al. reported the synthesis and structures of water-soluble [3-(2-methoxy)ethoxy]propyltin chlorides.[6] Interesting in vitro and vivo trypanocidal activity was later described for bis[3-(2-methoxy)ethoxy]-propyltin dichloride and the corresponding oxide.[7] Those papers suggest that the replacement of alkyl by alkoxyalkyl substituents could constitute a route to water-soluble organotin derivatives. In order to check whether the replacement of a 1-butyltin moiety, as conventionally used in organotin drug research, by a 3-methoxypropyltin one would deliver water-soluble and biologically active derivatives, (3-methoxypropyl)stannanes of general formula $(CH_3OCH_2CH_2CH_2)_xSnCl_{4-x}$ (x = 1−4) have been synthesized and structurally characterized, both in the solid state and in solution, and their in vitro antitumour and trypanocidal activities were tested.

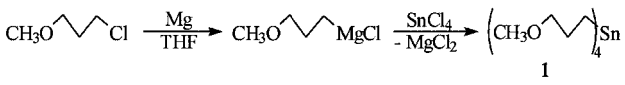
Results and Discussion

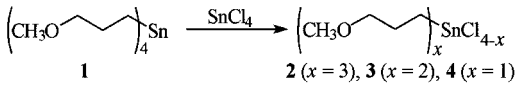
Synthesis

Tetrakis(3-methoxypropyl)tin (**1**) was synthesised as shown in Scheme 1, by treatment of tin tetrachloride with excess (3-methoxypropyl)magnesium chloride (previously prepared from 3-methoxypropyl chloride and magnesium chips in THF). Tetraorganostannane **1** was isolated by vacuum distillation as a colourless liquid in a yield of 92% with respect to $SnCl_4$.



Scheme 1

(3-Methoxypropyl)tin chlorides **2**−**4** were synthesised by means of a Kocheshkov redistribution reaction (Scheme 2),[8] by treatment of tetraorganostannane **1** with the appropriate amount of tin tetrachloride (3:1, 1:1, and 1:3 for **2**, **3**, and **4**, respectively). Although Kocheshkov reactions usually display low selectivity, the (3-methoxypropyl)tin chlorides **2**−**4** could be isolated by vacuum distillation in yields of about 95%. Such a high selectivity might be explained by suppression of 3-methoxypropyl group cleavage by intramolecular O→Sn coordination (see below) and consequently lower reactivities in the products **2**, **3**, and **4**.



Scheme 2

Solid-State Structures

Only the (3-methoxypropyl)tin chlorides **3** and **4** were isolated in a crystalline state, and their structures were determined by X-ray diffraction (Figure 1 and Figure 2). Selected bond lengths and angles are listed in Table 1 and Table 2, respectively.

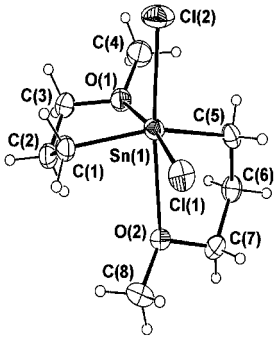


Figure 1. Solid-state structure of bis(3-methoxypropyl)tin dichloride (**3**)

Both complexes consist of discrete molecules. For compound **3**, the environment around the central tin atom has a deformed octahedral geometry (skew) with both oxygen atoms coordinated to the tin atom in a *cis* configuration [O−Sn−O 89.4(1)°]. Two chlorine atoms are also mutually *cis* [Cl−Sn−Cl 97.26(7)°], while two C−Sn bonds are at an angle of 148.5(2)°. The shape of the coordination polyhedron is thus similar to that of the analogous bis[3-(2-methoxy)-ethoxy]propyltin dichloride.[6] The tin atom in **4**, on the other hand, is coordinated as a distorted trigonal-bipyramid with the carbon atom and the two chlorine atoms in the equatorial plane [C−Sn−Cl(1) = 129.3(9), C−Sn−Cl(3) = 120.5(9), Cl(1)−Sn−Cl(3) = 102.31(5)°] and the oxygen atom and the third chlorine atom in axial positions [O−Sn−Cl(2) = 175.7(1)°]. The whole equatorial plane is tilted towards the oxygen atom [C−Sn−Cl(2) = 102.9(6), Cl(1)−Sn−Cl(2) = 95.80(5), Cl(3)−Sn−Cl(2) = 98.17(6)°]. The crystal-state structure of **4** differs from that of the analogous [3-(2-methoxy)ethoxy]propyltin trichloride in that the oxygen atom of one water molecule is used in order to reach an octahedral coordination.[6]

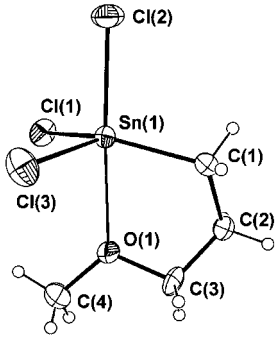

Figure 2. Solid-state structure of (3-methoxypropyl)tin trichloride (**4**)

Table 1. Selected bond lengths [Å] and angles [°] for **3**

Sn(1)−O(1)	2.559(4)	Sn(1)−Cl(2)	2.419(2)
Sn(1)−O(2)	2.556(4)	Sn(1)−C(1)	2.136(6)
Sn(1)−Cl(1)	2.432(2)	Sn(1)−C(5)	2.138(6)
C(1)−Sn(1)−C(5)	148.5(2)	C(1)−Sn(1)−Cl(1)	100.3(2)
O(1)−Sn(1)−O(2)	89.4 (1)	C(1)−Sn(1)−Cl(2)	102.5(2)
Cl(1)−Sn(1)−Cl(2)	97.26(7)	C(5)−Sn(1)−Cl(1)	99.7(2)
Cl(1)−Sn(1)−O(1)	84.9(1)	C(5)−Sn(1)−Cl(2)	98.9(2)
Cl(2)−Sn(1)−O(2)	173.4(1)	C(1)−Sn(1)−O(2)	83.2(2)

Table 2. Selected bond lengths [Å] and angles [°] for **4** (values are given for one split layer)

Sn(1)−Cl(1)	2.332(1)	Sn(1)−O(1)	2.394(3)
Sn(1)−Cl(2)	2.390(1)	Sn(1)−C(1)	2.09(3)
Sn(1)−Cl(3)	2.327(1)		
O(1)−Sn(1)−Cl(2)	175.7(1)	Cl(1)−Sn(1)−Cl(2)	95.80(5)
C(1)−Sn(1)−Cl(1)	129.3(9)	Cl(1)−Sn(1)−Cl(3)	102.31(5)
C(1)−Sn(1)−Cl(2)	102.9(6)	Cl(3)−Sn(1)−Cl(2)	98.17(6)
C(1)−Sn(1)−Cl(3)	120.6(9)		

The Sn−O bond length in the distorted trigonal-bipyramidal geometry of **4** [2.394(40) Å] is slightly shorter than the Sn−O bond lengths found in the distorted octahedral geometry of **3** [2.559(4) and 2.556(4) Å]. This is in agreement with increasing Lewis acidity of the central tin atom. The Sn−O bonds are in both cases shorter than those in the analogous [3-(2-methoxy)ethoxy]propyltin chlorides [2.442(2), 2.65(1), and 2.67(1) Å, respectively].[6] However, the oxygen atom of the water molecule in [3-(2-methoxy)-ethoxy]propyltin trichloride has a significantly stronger bond [Sn−O 2.292(5) Å] than oxygen atoms of chelating alkoxypropyl groups.[6]

The Sn−C [2.09(3)−2.145(4) Å] and Sn−Cl [2.3274(12)−2.4328(12) Å] bond lengths in compounds **3** and **4** are similar to those found in the analogous [3-(2-methoxy)ethoxy]propyltin chlorides [2.127−2.15(2) and 2.351−2.426(6) Å, respectively].[6] In the trigonal-bipyramidal geometry of **4**, the apical chlorine atom has a slightly weaker bond to the central tin atom [Sn−Cl(2) = 2.3904(12) Å] than the equatorial ones [Sn−Cl(1) = 2.3317(14), Sn−Cl(3) = 2.3274(12) Å], due to the *trans* effect of the coordinated oxygen atom of the 3-methoxypropyl group.

The sixfold- and fivefold-coordinated tin atoms observed for (3-methoxypropyl)tin chlorides **3** and **4** in the crystalline state are in accordance with ^{119}Sn solid-state NMR chemical shifts of δ = −133 and −157 ppm, respectively. Moreover, the ^{119}Sn CP/MAS spectrum of **3** showed a 1:2:4:1:4:4 splitting pattern due to the interaction of ^{119}Sn nuclei with two equivalent $^{35/37}$Cl spins (Figure 3).[9]

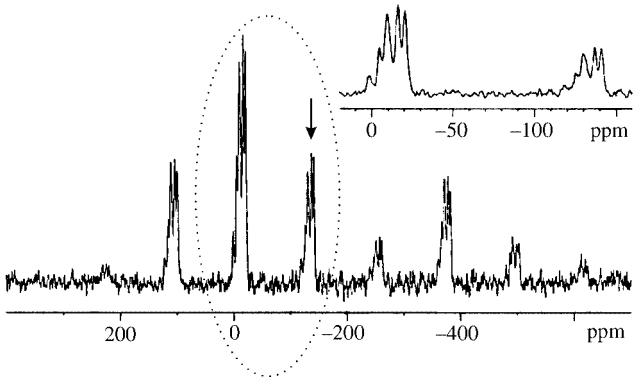

Figure 3. ^{119}Sn CP/MAS NMR spectrum of bis(3-methoxypropyl)-tin dichloride (**3**); the vertical arrow indicates the centre band

Structures in Solution

Methoxypropylstannanes **1**−**4** were characterised in $CDCl_3$ solution by ^{1}H NMR spectroscopy (see Exp. Sect.). In order to evaluate these solution structures both in non-coordinating and in coordinating solvents, their ^{13}C, ^{17}O, and ^{119}Sn NMR spectra were measured in $CDCl_3$ and [D_6]DMSO. All relevant NMR parameters are summarised in Table 3. The values of the $J(^1H,^{119}Sn)$ coupling constants obtained from gradient-assisted 1D ^{1}H,^{119}Sn HMQC and 2D ^{1}H,^{119}Sn J-HMBC spectra are given in Table 4.[10] The numbering scheme used for the hydrogen and carbon atoms is given in Scheme 3.

The ^{119}Sn chemical shift values of the (3-methoxypropyl)-stannanes **1**−**4** in $CDCl_3$ solution are shifted upfield [$\Delta\delta(^{119}Sn)$ = 1.3, 103.8, 234.9, and 132.4 ppm, respectively] with respect to analogous 1-butyltin compounds.[11] The ^{119}Sn chemical shifts were found not to be concentration-dependent, and so only intramolecular side-arm donation can be assumed. In the case of tetra-organotin compound **1**, the value of $\Delta\delta(^{119}Sn)$ is negligible. Accordingly, O→Sn interaction, if present, must be very weak. The tin atom is coordinated as a slightly distorted tetrahedron, as is evident from $^1J(^{13}C,^{119}Sn)$ = 324.5 Hz (average angle C−Sn−C 107°).[12] For triorganotin compound **2**, the significant upfield shift [$\Delta\delta(^{119}Sn)$ = 103.8 ppm] indicates a pentacoordinated tin atom. The value of $^1J(^{13}C,^{119}Sn)$ = 434.6 Hz (average angle C−Sn−C 118°) shows that coordination polyhedron of **2** has a *trans*-trigonal-bipyramidal shape.[12] Consequently, one oxygen atom has to be coordinated to the central tin atom while the other two are not. However, only one set of signals for the 3-methoxypropyl groups was observed in the ^{1}H and ^{13}C NMR spectra at room temperature and in [D_8]toluene at 180 K. This indicates the existence of an exchange that is fast on the NMR timescale even at 180 K. In the case of (3-methoxypropyl)tin chlorides **3** and **4**, the moderate differences between the ^{119}Sn chemical shifts in $CDCl_3$ solution and in the solid state (δ = 24 and 18 ppm, respectively) show that the distorted octahedral (Figure 2) and trigonal-bipyramidal (Figure 3) structures determined by X-ray diffraction are retained upon dissolution in $CDCl_3$.[9] The agreement of the C−Sn−C angles as calculated from the coupling constant $^1J(^{13}C,^{119}Sn)$ = 731.6 Hz (148°) and as determined by X-ray diffraction [148.5(2)°] confirms the suitability of the equation used for calculation.[12]

The values of $\delta(^{17}O)$ are shifted downfield as the Lewis acidity of the central tin atom increases (Table 3). Since the oxygen atom in the 3-methoxypropyl substituent is regarded as a pure σ-donor, this denotes an increasing degree of donor-acceptor bonding between the central tin atom and the oxygen atom in the organic substituent.[13] The values of the $^{3,6}J(^1H,^{119}Sn)$ long-range coupling constants between the ^{119}Sn nucleus and the CH_3O protons also increase with the same trend (Table 4). On the assumption that the contributions of the scalar coupling pathways through the CH_3O→Sn coordinative bond [$^3J(^1H,^{119}Sn)$] and through the covalent bonds of 3-methoxypropyl chain [$^6J(^1H,^{119}Sn)$] have the same signs, their sum and the increasing strength of CH_3O→Sn coordinative bonding could be responsible for this increasing trend.

For (3-methoxypropyl)tin chlorides **2**−**4** in deuteriochloroform solutions, the values of $^2J(^{119}Sn,^{13}C)$ are higher and the values of $^3J(^{13}C,^{119}Sn)$ lower than the corresponding values for analogous 1-butyltin chlorides. In the case of **3**, $^2J(^{13}C,^{119}Sn)$ was even higher than $^3J(^{13}C,^{119}Sn)$ (i.e., opposite to the trend usually observed for 1-butylstannes (Table 3).[11] It is likely that this represents the sum of two scalar coupling pathways contributions − through the co-

Table 3. ^{13}C, ^{17}O, and ^{119}Sn NMR spectral parameters for (3-methoxypropyl)stannanes **1**−**4** in non-coordinating solvent ($CDCl_3$) and in coordinating solvent ([D_6]DMSO) at 300 K

Compound	Solvent	δ(^{13}C) [ppm] (J(^{13}C,^{119}Sn) [Hz])				δ(^{119}Sn)	δ(^{17}O)
		C1	C2	C3	C4	[ppm]	[ppm]
1	$CDCl_3$	4.9 (324.5)	26.7 (18.6)	76.0 (59.3)	58.4 (−)	−4.3	−17.0
	[D_6]DMSO	5.2 (325.3)	26.2 (19.3)	75.2 (52.3)	57.7 (−)	−1.2	−
2	$CDCl_3$	14.7 (434.6)	25.6 (26.5)	74.7 (55.7)	58.5 (−)	49.0	−15.8

3	$CDCl_3$	26.6 (731.6)	24.5 (42.7)	72.4 (34.0)	58.6 (−)	−108.6	−13.0
	[D_6]DMSO	30.8 (840.4)	24.7 (44.7)	73.0 (95.1)	58.2 (−)	−170.5	−
4	$CDCl_3$	26.0 (845.2)	23.8 (67.0)	70.2 (79.3)	58.5 (−)	−138.5	−3.0
	[D_6]DMSO	[a]	25.6 (62.5)	73.8 (229.6)	57.8 (−)	−445.6	−

[a] Not obtained, probably due to the existence of a dynamic equilibrium (Scheme 4).

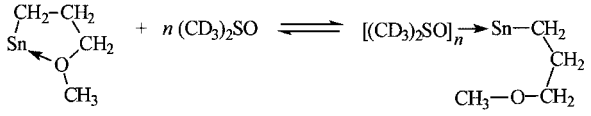
Table 4. J(^1H,^{119}Sn) coupling constants for (3-methoxypropyl)stannanes **1**−**4** in $CDCl_3$

Compound	J(^1H,^{119}Sn) [Hz]			
	H1[a]	H2[a]	H3[b]	H4[b]
1	51.2	47.8	[c]	0.52
2'	60.8	86.2	1.31	[d]
3	95.9	195.8	7.73	1.86
4	104.9	254.2	5.07	2.24

[a] Obtained from the ^1H,^{119}Sn HMQC spectra. [b] Obtained by 2D ^1H,^{119}Sn J-HMBC. [c] Not obtained due to an overlap. [d] Not obtained, probably due to the existence of a fast dynamic equilibrium as discussed in the text.

Scheme 3

valent bonds of the 3-methoxypropyl chain and through the coordinative O→Sn bond − of opposite signs in this case. In [D_6]DMSO solution, the values of δ(^{119}Sn) and the coupling constants J(^{13}C,^{119}Sn) of compounds **1**−**4** and their 1-butyltin analogues are not very different.[11] It therefore seems highly probable that the oxastannacycles are cleaved because of an equilibrium in which the donor oxygen atoms of the 3-methoxypropyl substituents are replaced by the stronger Lewis base [D_6]DMSO (Scheme 4). Unfortunately, this dynamic equilibrium disables the measurement of ^1H,^{119}Sn J-HMBC and the determination of long-range J(^1H,^{119}Sn) coupling constants.



Scheme 4

Trypanocidal and Antitumour Activities

All four (3-methoxypropyl)stannanes **1**−**4** have moderate water solubility (0.6, 3.0, 4.0, and 6.6 g/L H_2O at 25 °C, respectively). For compounds **1**, **2**, and **3**, trypanocidal activity tests afforded MEC values of 24000, 3300, and 3700 nM, respectively. Compound **4** showed no trypanocidal activity. The trypanocidal activity of compounds **2** and **3** is slightly higher than that of bis[3-(2-methoxy)ethoxy]propyltin dichloride and oxide (5900 and 6800 nM, respectively) but is significantly lower than those of the arsenic derivatives Arsobal and Cymelarsan (5 and 0.6 nM, respectively).[7] Compounds **1** and **4** exhibited no antitumour activity (ID_{50} > 62500). For compounds **2** and **3** the ID_{50} values were in the ranges of 1259−2443 and 9200−31512 ng/mL, respectively, and hence markedly below the standard of the clinically used drugs cisplatin (ID_{50} = 169−3269 ng/ml), doxorubicine (ID_{50} = 8−199 ng/mL) and taxol (ID_{50} < 3 ng/mL).

The very low activity and the complete absence of activity observed for compounds **1** and **4** are in accord with the usually low biological activities of tetra- and monoorganotin compounds.[14] The antitumour and trypanocidal activity of (3-methoxypropyl)tin chlorides **2** and **3** are rather poor, but still promising. It can be concluded that the replacement of a 1-butyl substituent by a 3-methoxypropyl moiety can considerably increase the water solubility of organotin derivatives, whereas antitumour and trypanocidal activity is preserved. The substitution of chlorine atoms by moieties that might improve targeting of the parasite and/or tumours could also improve the activity.

Experimental Section

Preparative Techniques and Starting Materials: All reactions were carried out under argon by standard Schlenk techniques.[15] THF was distilled from sodium benzophenone ketyl. Methanol was dried by distillation from CH_3ONa. Tin tetrachloride was distilled prior to use. All other starting compounds were used without further purification.

Preparation of 3-Methoxypropyl Chloride: A solution of CH_3ONa in methanol (5 M, 64 mL, 0.32 mol) was added dropwise over 3 h, with vigorous stirring, to 1-bromo-3-chloropropane (50.0 g, 0.32

mol). The reaction mixture was stirred overnight at room temperature and then heated under reflux as long as the solution remained basic. Afterwards, water (150 mL) was added and the obtained solution was extracted with diethyl ether (3 × 100 mL). The organic layers were combined and dried with Na_2SO_4. The diethyl ether was removed by distillation. Rectification of the residue afforded 3-methoxypropyl chloride (16.2 g, yield 47%) as a colourless liquid, boiling at 110−112 °C. ^{1}H NMR ($CDCl_3$): δ = 2.09 (m, 2 H), 3.42 (s, 3 H), 3.58 (t, $^3J_{H,H}$ = 5.9 Hz, 2 H), 3.70 (t, $^3J_{H,H}$ = 6.5 Hz, 2 H) ppm. ^{13}C NMR ($CDCl_3$): δ = 32.61, 41.82, 58.68, 69.01 ppm.

Preparation of Tetrakis(3-methoxypropyl)tin (1): A solution of 3-methoxypropyl chloride (10.0 g, 0.92 mol) in THF (15 mL) was added to Mg chips (2.2 g, 0.92 mol, activated by I_2). About 10% of the solution was added at once and the reaction was initiated by addition of 2 drops of 1,2-dibromethane. The remaining solution was then added dropwise in such a manner as to maintain the reaction mixture at reflux. The reaction mixture was then heated under reflux for 30 min. After the mixture had then been cooled to −50 °C, neat $SnCl_4$ (5.2 g, 20 mmol) was added dropwise with vigorous stirring. The reaction mixture was left to warm to room temperature and then heated under reflux for 5 h. Water (10 mL) was added and the resulting precipitate was filtered off and washed with benzene. The THF and benzene solutions were combined and dried with Na_2SO_4, and the solvents were removed by rotary evaporation. The residue was distilled at 3−4 Pa, and **1** (7.6 g, yield 92%) was obtained as a colourless liquid, boiling at 120−126 °C. ^{1}H NMR ($CDCl_3$): δ = 0.73 (m, 8 H), 1.69 (m, 8 H), 3.29 (t, $^3J_{H,H}$ = 6.6 Hz, 8 H), 3.31 (s, 12 H) ppm. $C_{16}H_{36}O_4Sn$ (411.14): calcd. C 46.74, H 8.83, Sn 28.87; found C 46.66, H 8.79, Sn 28.43.

Preparation of (3-Methoxypropyl)tin Chlorides 2−4: A mixture of **1** (1.50 g, 1.23 mmol) and $SnCl_4$ [0.32 g, 1.23 mmol for $(CH_3OCH_2CH_2CH_2)_3SnCl$ (**2**); 0.95 g, 3.65 mmol for $(CH_3OCH_2CH_2CH_2)_2SnCl_2$ (**3**); 2.90 g, 11.13 mmol for $CH_3OCH_2CH_2CH_2SnCl_3$ (**4**)] was heated at 200 °C for 3 h. The resulting (3-methoxypropyl)tin chlorides **2**−**4** were purified by vacuum distillation.

Compound 2: 1.73 g, yield 95%, colourless liquid, b.p. 114−116 °C/1−2 Pa. ^{1}H NMR ($CDCl_3$): δ = 1.20 (t, $^3J_{H,H}$ = 7.7 Hz, 8 H), 1.91 (m, 8 H), 3.34 (s, 12 H), 3.39 (t, $^3J_{H,H}$ = 6.1 Hz, 8 H) ppm. $C_{12}H_{27}ClO_3Sn$ (373.48): calcd. C 38.59, H 7.29, Cl 9.49, Sn 31.78; found C 38.65, H 7.31, Cl 9.73, Sn 31.26.

Compound 3: 2.36 g, yield 96%, colourless crystals, b.p. 128−132 °C/7 Pa, m.p. 80−83 °C. ^{1}H NMR ($CDCl_3$): δ = 1.67 (m, 8 H), 2.05 (m, 8 H), 3.44 (s, 12 H), 3.54 (t, $^3J_{H,H}$ = 5.5 Hz, 8 H) ppm. $C_8H_{18}Cl_2O_2Sn$ (335.82): calcd. C 28.61, H 5.40, Cl 21.11, Sn 35.34; found C 28.65, H 5.34, Cl 20.95, Sn 35.67.

Compound 4: 4.22 g, yield 96%, colourless crystals, b.p. 95−100 °C/1 Pa, m.p. 69−71 °C. ^{1}H NMR ($CDCl_3$): δ = 2.11 (m, 8 H), 2.21 (m, 8 H), 3.53 (s, 12 H), 3.61 (t, $^3J_{H,H}$ = 5.5 Hz, 8 H) ppm.

$C_4H_9Cl_3OSn$ (298.16): calcd. C 16.11, H 3.04, Cl 35.67, Sn 39.81; found C 16.16, H 3.10, Cl 36.20, Sn 39.56.

X-ray Diffraction Measurements: Diffraction experiments were carried out with Mo-K_α radiation using a Stoe IPDS diffractometer at 203(2) K (**3**) and 220(1) K (**4**). The structures were successfully solved by direct methods (SHELXS-86).[16] Further refinements were carried out against F^2 (SHELXL-97).[17] All non-H atoms were refined with anisotropic displacement parameters, hydrogen atoms were placed in calculated positions and refined according to the riding model. Crystal data and details of data collection and refinement are given in Table 1, Table 2, and Table 5. CCDC-178265 (**3**) and -178264 (**4**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Microanalyses: Microanalyses (C, H, Sn, Cl) were carried out with a Fison EA 1108 instrument in the Microanalytical Laboratory at the University of Pardubice.

NMR Measurements: ^{1}H, ^{13}C, ^{17}O, and ^{119}Sn NMR spectra were recorded in a 5-mm tuneable probe with a Bruker AMX 360 (^{1}H: 360.14 MHz; ^{13}C: 90.57 MHz; ^{17}O: 48.82 MHz; ^{119}Sn: 134.28 MHz) and a Bruker AVANCE 500 spectrometer (^{1}H: 500.13 MHz; ^{13}C: 125.77 MHz; ^{119}Sn: 186.48 MHz). ^{1}H and ^{13}C chemical shifts are given in ppm with respect to Me_4Si, and ^{119}Sn chemical shifts with respect to Me_4Sn. The gradient-assisted 1D ^{1}H,^{119}Sn HMQC and 2D ^{1}H,^{119}Sn J-HMBC spectra were recorded as explained elsewhere,[10] with the Bruker AVANCE 500 spectrometer. ^{119}Sn CP/MAS NMR spectra were recorded with a Bruker DSX 200 spectrometer equipped with a double-bearing CP/MAS probe at room temperature. The ^{119}Sn chemical shifts were calibrated indirectly with reference to tetracyclohexyltin (δ = −97.35 ppm) and were allocated approximately to the centre of gravity of the signals.

Trypanocidal and Antitumour Screening: The trypanocidal activity tests were carried out in vitro on cultures of *Trypanosoma equiperdum*.[18] The MEC values indicated for these activities correspond to the minimal efficient concentration that would allow complete depletion of trypanosome population within 24 h. In vitro antitumour screening against seven tumoural cell lines of human origin (A, 498 − a renal cancer, EVSA-T − a breast cancer, H 226 − a non-small cell lung cancer, IGROV − an ovarian cancer, M19 − a melanoma, MCF-7 − a breast cancer, WiDr − a colon carcinoma) were performed in accordance with procedures already described elsewhere.[19]

Acknowledgments

The financial support from the Ministry of Education, Youth and Sports of the Czech Republic (Project LN 00 A028) and the Grant Agency of the Czech Republic (grant 203/00920) is gratefully acknowledged. We are grateful to Prof. T. Baltz and Prof. C. Giroud for performing the trypanocidal screening and to Prof. M. Gielen for arranging antitumour screening. T. L. and A. S. thank Prof. Jaroslav Holeček for fruitful discussions about chemistry and life, and all that helped us to finish this paper.

Synthesis, Crystal Structure, and Photophysical and Magnetic Properties of Dimeric and Polymeric Lanthanide Complexes with Benzoic Acid and Its Derivatives

Alex Wai-Hing Lam,[a] Wing-Tak Wong,*[a,b] Song Gao,[b] Gehui Wen,[c] and Xi-Xiang Zhang[c]

Keywords: Carboxylate ligands / Lanthanides / Luminescence / Magnetic properties

A new family of lanthanide carboxylate complexes with benzoic acid and its derivatives was synthesised and characterised. The structures of the complexes were established by X-ray crystallography, which revealed that various chelating modes of the carboxylate ligands are present on the metal ion, resulting in the formation of dimeric and polymeric skeletons. The photophysical properties of the Eu and Tb complexes were studied: the complexes exhibited sensitised luminescence in the visible spectral region, but the luminescence intensities and lifetimes were very sensitive to quenching by the OH groups of methanol molecules. The solid-state magnetic properties of the Gd and Tb complexes demonstrated the presence of weak antiferromagnetic exchange interactions at very low temperatures, caused by interaction between the neighbouring ions along the chain.

Introduction

The design of molecular systems that combine binding abilities and photosensitising properties for the construction of efficient photoluminescent lanthanide complexes continues to be an active area of research. Several classes of ligand have been utilised for the preparation of such complexes; they include cryptands,[1] podands,[2] calixarenes,[3] macrocyclic ligands,[4] β-diketones,[5] carboxylic acid derivatives,[6] terphenyl ligands,[7] and proteins.[8] Most of the complexes investigated emit red or green light (Eu^{3+} and Tb^{3+} luminescence, respectively), but there are also complexes of different Ln^{3+} ions that luminesce in other spectral regions. Efficient luminescent materials may have several applications: as luminescent probes in biomedical assays,[9] as luminescent sensors for chemical species (H^+, O_2, halide ions, OH^-),[4c] and as electroluminescent devices,[10] for example. Besides the quantum yield of the luminescent lanthanide materials, other aspects such as light output, solubility, volatility, and photo-, thermo- and thermodynamic stabilities may be critical to many applications, and must also be controlled.

Variation of the coordination geometries of the central metal atom, and also of the carboxylate ions in the lanthanide carboxylate complexes, are interesting themes of structural chemistry.[11] Over the past twenty years, many structural studies of lanthanide carboxylates have been reported, and diverse coordination types recognised. A large number of lanthanide carboxylate complexes have been found to be dimeric or polymeric.[11a] A one-dimensional system is believed to impose the greatest restriction on metal−metal interaction, and energy migration that depends on such interaction between nearest neighbours in the lattice will thus be dominant in the chain direction. Research studies on polynuclear lanthanide complexes may therefore provide information concerning exchange and magnetic interaction mechanisms. Numerous aromatic carboxylic acids of europium and terbium are chelated in binary or ternary fashion and exhibit high stability and strong luminescence. Tb^{3+} luminescence is enhanced by more than 10^4-fold by dipicolinic acid, and Eu^{3+} luminescence is similarly enhanced by diketonates. The common feature for strong sensitisation is the direct coordination of a conjugated π-electron system to the metal ions. Photoluminescence properties notwithstanding, several studies have demonstrated that luminescent lanthanide complexes have potential for application as emitters in electroluminescent (EL) devices.[12] Kido et al.[13] reported organic electroluminescent devices based on trivalent terbium or europium complexes with β-diketones.

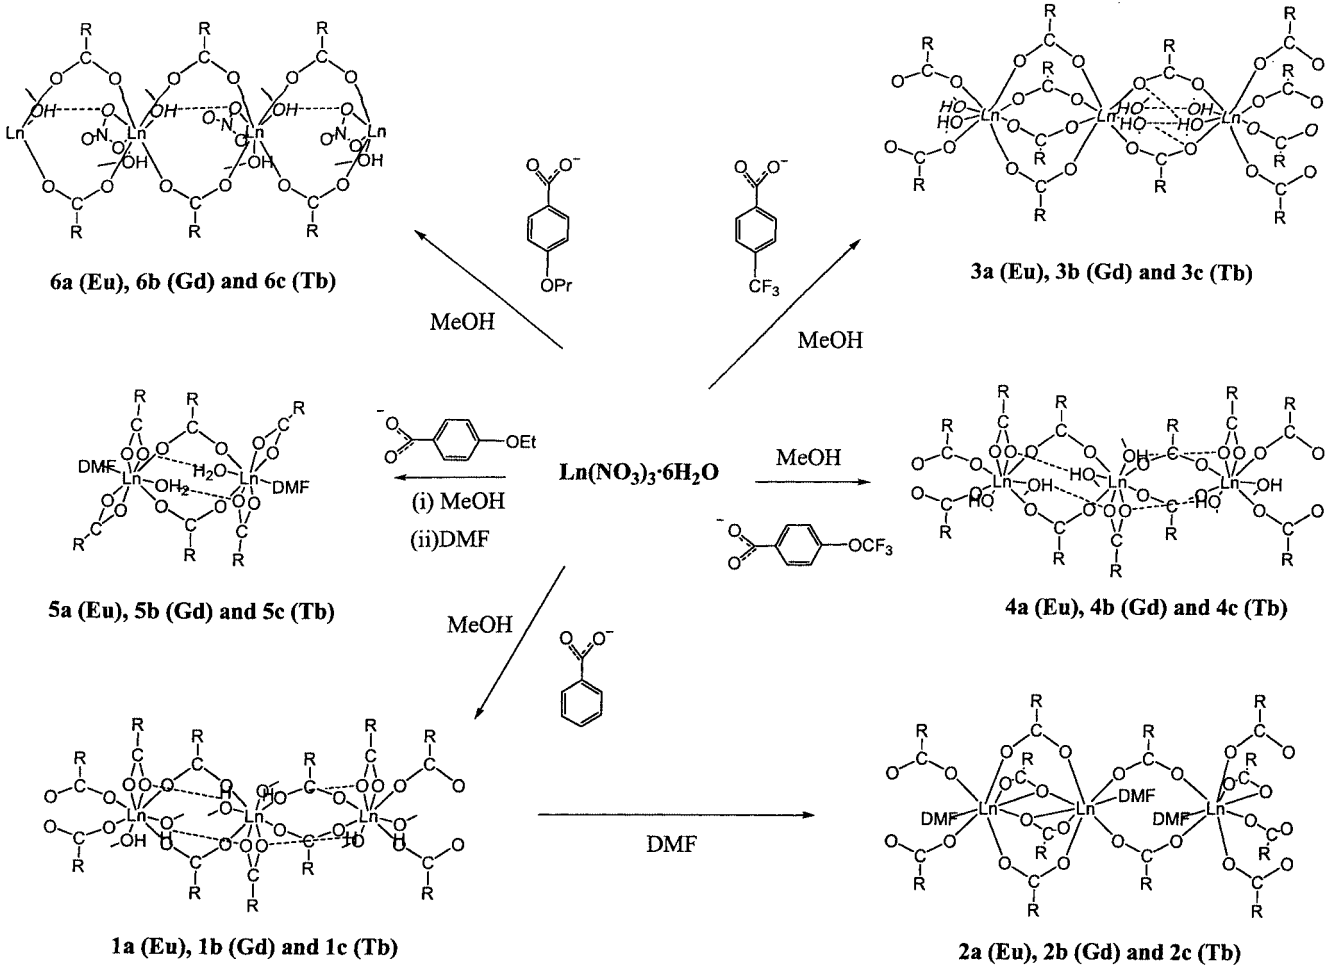
However, these complexes were limited by their poor photostabilities. As complexes with unlimited polymeric chain structures, lanthanide carboxylates have not only good luminescent properties, but also good ultraviolet absorption properties. Some representative examples of lanthanide carboxylate complexes that can be fabricated as EL devices are $[Tb(AHB)_3]$ (AHBA = 2-amino-4-hexadecylbenzoic acid),[14] $[Tb(MeOBB)_3]$ and $[Eu(MeOBB)_3]$ [MeOBB = 2-(4-methoxybenzoyl)benzoic acid].[15]

In view of the potential applications of lanthanide carboxylates and the fascinating properties of carboxylate ligands, a new series of lanthanide carboxylate complexes (Eu, Gd, and Tb) with benzoic acid and its derivatives were synthesised: $[Ln_2(Bz)_6(MeOH)_4]_n$ (**1a**−**c**), $[Ln(Bz)_3(DMF)]_n$ (**2a**−**c**) (HBz = benzoic acid), $[Ln(cf_3)_3(MeOH)_2]_n$ (**3a**−**c**) (Hcf_3 = 4-trifluoromethylbenzoic acid), $[Ln(ocf_3)_3(MeOH)_2]_n$ (**4a**−**c**) ($Hocf_3$ = 4-trifluoromethoxybenzoic acid), $[Ln(oet)_3(DMF)(H_2O)]_2$ (**5a**−**c**) (Hoet = 4-ethoxybenzoic acid), and $[Ln(opr)_2(NO_3)(MeOH)_2]_n$ (**6a**−**c**) (Hopr = 4-*n*-propoxybenzoic acid). Their structures demonstrate the rich coordination chemistry of lanthanide carboxylate complexes, and the structures of Eu, Gd and Tb complexes with the same ligand are isomorphous. The luminescent and magnetic properties of these lanthanide complexes have also been studied and are discussed.

Results and Discussion

Syntheses and Crystal Structures of Lanthanide Complexes

Treatment of hydrated lanthanide (Eu, Gd, and Tb) nitrates with NaOH and the corresponding benzoic acid ligands in MeOH (1:3:3 ratio) afforded precipitates of the complexes (Scheme 1). The complexation of the lanthanide complexes was confirmed by IR spectroscopy, the absence of ν(COOH) absorption bands of the ligands at about 1700 cm^{-1} in all spectra indicating the coordination of ligands to the metal. All the IR spectra show the presence of absorption bands characteristic of the carboxylate groups. The bands at about 1600−1500 cm^{-1} correspond to the asymmetric vibrations of COO^- groups, while those at about 1450−1350 cm^{-1} are attributable to their symmetric vibrations. Several $\nu(COO^-)_{as}$ bands suggest that different coordination modes of carboxylate groups are present in the complexes, as is confirmed by structural analyses. Complexes with coordinated MeOH molecules exhibited a broad



Scheme 1

ν(O−H) band at about 3500 cm^{-1}, and those complexes containing the fluorinated benzoate ligands showed the corresponding ν(C−F) stretching range from 1300 to 1100 cm^{-1}. The presence of absorption bands at about 1660 cm^{-1} is attributable to the ν(C=O) of the DMF molecule, which confirms the successful replacement of MeOH by DMF molecules in complexes **2a**−**c** and **5a**−**c**. According to the ESI-MS studies of the complexes, a series of characteristic peaks were observed, the most intense peaks corresponding to the formulation of anionic fragments being $[LnL_4]^-$ and $[Ln_2L_7]^-$, where L is the respective benzoate ligand. This observation revealed that dimeric or oligomeric complexes would retain their dimeric/oligomeric natures in solution. The thermal decomposition behaviour of the complexes was investigated by a TGA study, although no attempt was made to identify the intermediate products formed during this thermolysis. The first step in the thermogram corresponds to the distinct loss of coordinated solvent molecules [MeOH (ca. 30−120 °C) or DMF (ca. 100−160 °C)], in line with their X-ray crystallographic results. The total weight losses are compatible with the formulas, and the masses of the final products correspond to the complete combustion of the complexes to their corresponding oxides (Eu_2O_3, Gd_2O_3, Tb_2O_3, or Tb_4O_7) at 900 °C.

Single crystals of complexes **1a**−**c**, **2a**−**c**, **3a**, **3c**, **4a**−**c**, **5b**, **5c**, and **6c** were obtained by slow evaporation of their corresponding solvents for a period of time, and their structures were established by X-ray crystallography. Structures of complexes (Eu, Gd, and Tb) with a particular ligand are isostructural, so a detailed structural description of the complexes is exemplified by one of them.

The polymeric structure of complex **1a** is displayed in Figure 1, and selected bond lengths and bond angles are given in Table 1. This analysis revealed that there are two independent and distinct Eu^{3+} ions, bridged through four ligand carboxylate groups to form an infinite chain along the *a* axis. Each Eu^{3+} ion is coordinated by two O atoms from a bidentate chelating carboxylate group, four from four different ligands in a bridging mode, and two O atoms from two methanol molecules. Along the chain, the metal−metal distances and angle are: Eu(1)···Eu(2) = 4.90 Å, Eu(1)···Eu(2*) = 4.93 Å and Eu(2*)−Eu(1)−Eu(2) = 165.7°. The coordination geometry around the Eu(1) atom can be described as a distorted square antiprism, in which the top square face is defined by O(2), O(4), O(5), and O(14), and the bottom one is formed by O(6), O(7), O(9), and O(13). The dihedral angle between the square faces is 9.16°. Meanwhile, the geometry of the Eu(1) atom can also be described as a distorted bicapped trigonal prism, in which the top plane is defined by O(2), O(5), and O(7), and the bottom plane is completed by O(4), O(9), and O(14). The O(6) and O(13) atoms cap two quadrilateral faces of the trigonal prism. The dihedral angle between the planes is 10.35°. This observation of coordination polyhedra also applies for the Eu(2) atom, which can be described as a distorted square antiprism or a bicapped trigonal prism. The dihedral angles between the square and the trigonal planes are 8.55 and 12.17°, respectively. The Eu−O bond lengths range from 2.309(6) to 2.535(6) Å for both Eu^{3+} ions. The Eu−O(CO) carboxylate bond lengths of the bidentate chelating species [2.468(6)−2.527(6) Å] are longer than those of the bridging one [2.309(6)−2.367(6) Å], due to the formation of an unstable four-membered ring.[16] The Eu−O(MeOH) distances range from 2.496(6) to 2.537(6) Å. Intra-chain hydrogen bonding is observed between the methanol H atoms and the carboxylate O atoms [O(13)···O(11) = 2.72 Å, O(14)···O(12*) = 2.83 Å, O(15)···O(5*) = 2.76 Å, O(16)···O(6) = 2.82 Å]. Although the methanol H atoms could not be located, an analysis of the spatial relationships of the proximal potential donors and acceptors indicated an unambiguous pattern for the hydrogen bonding interactions. This type of coordination mode of ligands has been observed in the complex $\{[Eu(\alpha\text{-}C_5H_3O_3)_3(H_2O)_2]\cdot NO_3(4,4'\text{-Hbpy})\}_n$.[17]

A perspective view of the polymeric structure of complex **2a** is shown in Figure 2 and selected bond lengths and bond angles are summarised in Table 2. The structure demonstrates that each Eu^{3+} ion is connected to two neighbouring ones by six ligands through the carboxylate groups, to form an endless polymer. The carboxylate groups of the six molecules of benzoate are bidentate bridging and tridentate chelating-bridging. Four of the six carboxylate groups simultaneously bridge two Eu^{3+} ions, while the other two carboxylate groups chelate one Eu^{3+} ion and at the same time bridge two Eu^{3+} ions. Each Eu^{3+} ion is further coordinated to one DMF molecule to form eight-coordinate metal ions. The intra-chain Eu···Eu distances within the structure are Eu(1)···Eu(1*) = 3.93 Å and Eu(1)···Eu(1′) = 5.34 Å. The angle Eu(1′)−Eu(1)−Eu(1*) is 169.5°, and we can regard this as a linear chain along the *c* axis. The alternating metal−metal distances along the chain can be explained by the chelating-bridging carboxylate groups linking the Eu^{3+} ions, which result in shorter Eu···Eu distances than seen in other polymeric lanthanide carboxylates.[18] In addition, the larger steric effect of DMF relative to MeOH may cause the lengthening of the Eu···Eu distances; a similar observation has been noted in the Eu^{3+} complex with *N*-methylglycine.[19] The Eu−O(CO) bond lengths of bidentate bridging carboxylate groups [2.306(3)−2.403(3) Å] are smaller than those of the tridentate chelating-bridging moieties [2.333(3)−2.580(3) Å].

A crystal of complex **3a** suitable for X-ray analysis was sealed in a capillary and the molecular structure was established by X-ray crystallography. As illustrated in Figure 3, the Eu^{3+} ion in complex **3a** is coordinated by eight oxygen atoms, six of which [O(1), O(2), O(3), O(4*), O(5), and O(6)] are from six different carboxylate groups, while the other two [O(7) and O(8)] are from two coordinated methanol molecules. The Eu(1) atom is connected to two neighbouring Eu atoms [Eu(1′), Eu(1*)] alternatively by two bridging carboxylate groups and by four bridging carboxylate groups, to form an infinite one-dimensional chain along the *a* axis. Thus, along the chain, the Eu···Eu distances in the complex are alternatively long [Eu(1)···Eu(1′) = 5.42 Å] and short [Eu(1)···Eu(1*) = 4.19 Å]. With the alternating Eu···Eu distances and the chain

angle [Eu(1′)−Eu(1)−Eu(1*) = 158.4°], the carboxylate linked one-dimensional array can be best described as a linear chain. Intra-chain hydrogen bonding is observed between the doubly bridged Eu(1)···Eu(1′) unit, arising from a coordinated methanol H atom and carboxylate O atoms [O(8)−H(20)···O(1*) = 2.22 Å and O(8)−H(20)···O(7*) = 2.20 Å, respectively]. The single coordination mode may be accounted for by the presence of a bulky CF_3 group. This matches well with the results reported by Tahir et al.[20] for a cerium 3,5-dinitrobenzoate dihydrate complex $[Ce_2(C_7H_3N_2O_6)_6(H_2O)_4]_n$. The outer sphere in each repeating unit of $[Eu(cf_3)_3(MeOH)_2]$ contains one solvated methanol molecule. Two CF_3 groups of the ligands are disordered in the monomeric unit. Like those in complexes **1a**−**c**, the coor-

dination polyhedron of complex **3a** can best be described as either a distorted square antiprism or a bicapped trigonal prism, with the dihedral angles between the corresponding planes being 3.78 and 7.10°, respectively. For the square antiprism geometry, the top square plane is defined by O(1), O(2), O(7), and O(8), and the bottom plane is completed by O(3), O(4*), O(5), and O(6). For the distorted bicapped trigonal geometry the top plane is formed by O(1), O(3), and O(5), and the bottom plane is composed of O(2), O(4*), and O(6), while the O(7) and O(8) atoms cap two quadrilateral faces of the trigonal prism. The Eu−O(CO) distances [2.360(5)−2.446(4) Å] and the Eu−O(MeOH) distances [2.521(5)−2.600(5) Å] are similar to those in complex **1a**. Table 3 summarises selected bond lengths and bond angles in complexes **3a** and **3c**.

The coordination geometry of the carboxylate ligands in complexes **4a−c** is similar to that in the lanthanide benzoate complexes **1a−c**. A perspective drawing of complex **4a** is illustrated in Figure 4, and selected bond lengths and bond angles are shown in Table 4. Each Eu^{3+} ion is connected to two neighbouring ones through four bridging carboxylate groups to form an infinite one-dimensional chain along the *a* axis. The coordination sphere is completed by a bidentate chelating carboxylate group and two

methanol molecules. An intra-chain hydrogen bond between the coordinated methanol H atoms and chelating carboxylate O atoms is observed [O(10)−H(14)···O(5*) = 1.82 Å] and [O(11)−H(13)···O(4*) = 2.47 Å]. Along the infinite chain, the Eu···Eu distances in complex **4a** are alternatively long [Eu(1)···Eu(1′) = 5.03 Å] and short [Eu(1)···Eu(1*) = 4.86 Å]. With the alternating Eu···Eu distances and the chain angle [Eu(1′)−Eu(1)−Eu(1*) = 159.3°], the carboxylate-linked one-dimensional array can best be described as a linear chain. The difference between the alternating metal−metal distances is smaller than in complex **2a**, because the bridging unit in **4a** is made up of the same number of ligands and coordinating modes. However, this coordination geometry should not cause such a difference in the metal−metal distances along the chain. This can be explained by studying the molecular structure, in which the orientations of the carboxylate ligands align in the same direction in the alternating monomeric unit. Increased steric hindrance in that unit would result in a slightly longer metal−metal distance. Similarly to that in complex **3a**, the coordination geometry about the Eu(1) atom may be described either as a distorted square antiprism or as a bicapped trigonal prism. The square planes formed around the Eu(1) atom by O(1*)−O(2)−O(4)−O(11) and O(5)−O(7)−O(8)−O(10) adopt a distorted square antiprism geometry, with the dihedral angle between these planes being 11.74°. Meanwhile, the geometry of the distorted bicapped trigonal prism is made up of the top plane [O(1*)−O(4)−O(8)] and the bottom plane [O(2)−O(7)−O(11)], while the quadrilateral faces of the trigonal prism are capped by atoms O(5) and O(10). The dihedral angle between the planes is 16.46°. The

Eu−O(CO) bond lengths of the chelating and bridging carboxylate groups are 2.513(5)−2.532(7) Å and 2.296(6)−2.369(6) Å, respectively, while the Eu−O(MeOH) distances are 2.486(6) and 2.541(6) Å. These Eu−O bond lengths fall in the usual range of other known lanthanide carboxylates.[18a,18b]

The molecular structure of complex **5b** was established by X-ray crystallography, and the polymeric structure of the complex is depicted in Figure 5. Selected bond lengths are given in Table 5. The structure consists of an asymmetric dimer in which Gd^{3+} ions, in non-equivalent positions, are connected by two ligands through the carboxylate groups. These two carboxylate groups are bidentate bridging, and bind to two Gd^{3+} ions simultaneously. Each Gd^{3+} ion is further coordinated to two bidentate chelating carboxylate groups, one water molecule and one dimethylformamide (DMF) to form eight-coordinate metal ions. Furthermore, intramolecular hydrogen bonding interaction links the two Gd^{3+} ions through the coordinated water H atom and carboxylate O atom of the ligands [O(21)−H(72)···O(13) = 2.35 Å and O(22)−H(70)···O(2) = 1.75 Å]. The Gd···Gd distance is 4.46 Å, longer than that in the Gd^{3+} complex $[Gd(C_3H_5O_2)_3(H_2O)_2]_2{\cdot}4H_2O{\cdot}2(CH_4N_2S)$[21] because of the larger steric effect from the ethoxybenzoate ligand. The coordination polyhedron of the Gd(1) atom can be described either as a distorted bicapped trigonal prism or as a square antiprism. In the bicapped trigonal prism description, the top plane is formed by O(2), O(4), and O(7), and the bottom plane is completed by O(10), O(19), and O(21), while the quadrilateral faces of the trigonal prism [O(2)−O(4)−O(10)−O(19) and O(4)−O(7)−O(19)−O(21)] are capped by O(1) and O(5), respectively. The dihedral angle between the trigonal faces is 5.50°. Besides this description, it can also be treated as a distorted square antiprism. One square face is defined by O(1), O(4), O(5), and O(19), whereas the other face is completed by O(2), O(7), O(10), and O(21). The dihedral angle between the square faces is 7.60° and the Gd(1)−O bond lengths range from 2.333(5) to 2.541(5) Å. The Gd(1)−O distances for the chelating carboxylate groups [2.414(5)−2.541(5) Å] are significantly longer than those of the bridging carboxylate groups [2.333(5)−2.359(6) Å], since lengthening of the chelating carboxylate group is caused by the formation of an unstable four-membered chelate ring with the Gd^{3+} ion. In addition,

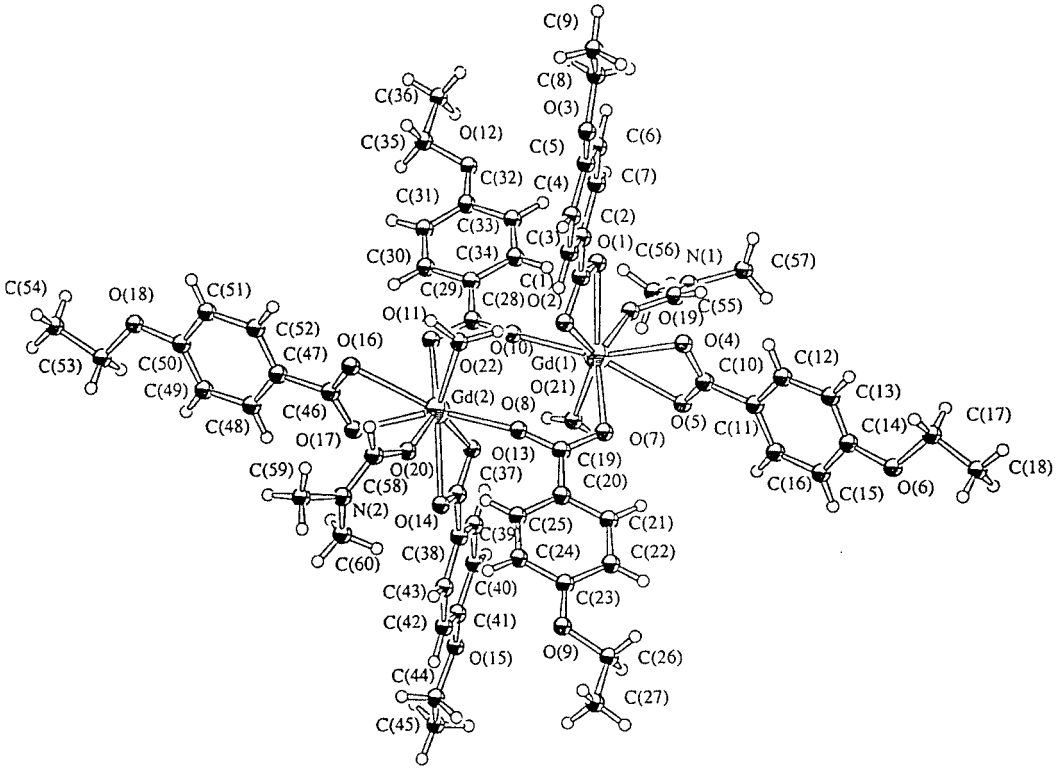

Figure 5. Molecular structure of $[Gd(oet)_3(DMF)(H_2O)]_2$ (**5b**) with the atomic numbering scheme for non-hydrogen atoms

the description of the coordination sphere around the Gd(2) atom is similar to that of Gd(1). The distorted bicapped trigonal prism consists of the top plane [O(11)−O(13)−O(17)] and the bottom plane [O(8)−O(20)−O(22)], with a dihedral angle of 5.74° between them. For the distorted square antiprism, the defining planes are made up by O(8)−O(11)−O(13)−O(22) and O(14)−O(16)−O(17)−O(20), with a dihedral angle of 6.25°. The Gd(2)−O distances [2.326(5)−2.532(5) Å] are close to the value of the Gd(1)−O distances, and the Gd(2)−O distances of chelating carboxylate [2.418(5)−2.532(5) Å] are longer than those of the bridging carboxylate [2.326(5)−2.365(6) Å], which are consistent with the Gd(1) values.

The molecular structure of complex **6c** is shown in Figure 6, and selected bond lengths and bond angles are tabulated in Table 6. The Tb^{3+} ion is connected to two neighbouring metal ions through four bidentate bridging carboxylate ligands to form an infinite chain along the *c* axis, and it is coordinated by eight oxygen atoms: four from carboxylate ligands, two from a nitrate ion and two from the methanol molecules. Along the chain, the Tb···Tb distance is 5.35 Å and the Tb(1*)−Tb(1)−Tb(1*) angle is 173.6°, and the structure of the complex can thus be de-

			6c		
Tb(1)···Tb(1*)	5.35	Tb(1)−O(7)	2.521(4)	N(1)−O(8)	1.256(7)
Tb(1)−O(1)	2.273(4)	Tb(1)−O(8)	2.564(4)	N(1)−O(9)	1.234(7)
Tb(1)−O(2)	2.282(4)	Tb(1)−O(10)	2.413(4)	O(11)−H(30)···O(7*)	2.19
Tb(1)−O(4)	2.288(4)	Tb(1)−O(11)	2.474(4)		
Tb(1)−O(5)	2.277(4)	N(1)−O(7)	1.255(6)	Tb(1*)−Tb(1)−Tb(1*)	173.6

scribed as a linear chain skeleton. Intra-chain hydrogen bonding was observed between the coordinated methanol H atom and the O atom of the coordinated nitrate [O(11)−H(30)···O(7*) = 2.19 Å]. The coordination polyhedron around the Tb^{3+} ion can be described both as a distorted square antiprism and as a bicapped trigonal prism. It is hard to distinguish the polyhedron from these two typical coordination geometries, so both are illustrated here. For the distorted square antiprism geometry, the top square plane can be defined by O(1), O(2), O(8), and O(10), whereas the bottom plane is completed by O(4), O(5), O(7), and O(11). The dihedral angle between these two planes is 12.33°. For the distorted bicapped trigonal prism, on the other hand, the top plane is defined by O(1), O(4), and O(11), and the bottom plane is formed by O(2), O(5), and O(7), while O(8) and O(10) cap the quadrilateral faces of the trigonal prisms O(1)−O(2)−O(4)−O(7) and O(1)−O(2)−O(5)−O(11), respectively. The dihedral angle between the trigonal planes is 5.93°. The Tb−O(CO), Tb−O(NO_2), and Tb−O(MeOH) distances are 2.273(4)−2.288(4) Å, 2.521(4)−2.564(4) Å, and 2.413(4)−2.474(4) Å, respectively. The significant differences between the N−O bond lengths [1.234(7), 1.255(6), and 1.258(7) Å] indicate that the nitrate ion is bonded to the metal ion in a bidentate mode, as is evident from the IR spectra. Only two ligands are coordinated to the metal ion instead of the three in the previously described lanthanide carboxylates, and this is believed to be caused by steric hindrance by the propoxy groups, which prevents another ligand from coordinating to the metal to result in a longer metal−metal distance. An interesting feature of this complex is the propoxy groups on the benzoate ligands "bobbing up and down" along the chain.

Photophysical Properties

All complexes are soluble in hot MeOH or DMF solution, the improved solubility of the complexes being due to the *para*-substituted alkoxy and fluorinated groups. Consequently, the photophysical investigations were mainly carried out in MeOH solution, and solid-state luminescence was also studied.

Both the solid-state and the solution-state excitation spectra of the europium and terbium complexes match the corresponding electronic absorption profiles of the respective ligands throughout the UV spectral region, showing that ligand-to-metal energy transfer occurs. In addition, the absence of observable *f-f* absorption transitions in the excitation spectra reveals that the sensitisation process is favoured by indirect excitation. Excitation of the ligand-centred (LC) absorption bands results in the well-known narrow emission bands of the Eu^{3+} and Tb^{3+} ions, and their emission spectra are essentially identical in the solid state and in the solution state. Europium complex **1a** emits red light upon LC excitation, originating from the $^5D_0 \rightarrow {}^7F_n$ (n = 0, 1, 2, 3, 4) transitions, with the strongest emission due to the $^5D_0 \rightarrow {}^7F_2$ transition at 618 nm (Figure 7). The terbium complex **1c**, on the other hand, exhibits bright green luminescence in which the peaks in the emission spectrum correspond to the $^5D_4 \rightarrow {}^7F_n$ (n = 6, 5, 4, 3) transitions, with the strongest emission corresponding to the $^5D_4 \rightarrow {}^7F_5$ transition at 545 nm (Figure 8). Both of their time-resolved luminescence spectra show monoexponential decay, with luminescence lifetimes of 0.43 and 1.30 ms, respectively. A summary of the luminescent properties of the complexes is given in Table 7. The solid-state luminescent properties of both Eu and Tb benzoate complexes are similar to those reported by Wang[22] and Ronda,[23] in which the benzoate complexes have different structures. Degassed samples exhibit nearly identical luminescence observations and lifetime values, suggesting that oxygen quenching of the excited state can be neglected in this case. Although we have not been able to evaluate the efficiency of the energy transfer involved in these complexes quantitatively, there is an almost negligible emission intensity from the benzoate ligand, suggesting that the energy transfer process from ligand to metal is fairly efficient. This phenomenon is similar to those seen in other lanthanide benzoate complexes.[22−24]

Table 7. Luminescence lifetime of the europium and terbium carboxylate complexes measured in MeOH (τ_{MeOH}) and MeOD (τ_{MeOD}), as well as the number of coordinated solvent molecules (q) as determined by Horrocks' equation

Complex	τ_{MeOH} [ms]	τ_{MeOD} [ms]	q
1a	0.48	2.17	3.4±0.5
1c	1.30	1.59	1.2±0.5
3a	0.39	1.98	4.3±0.5
3c	0.98	1.21	1.6±0.5
4a	0.40	2.12	4.2±0.5
4c	0.90	1.12	1.8±0.5
6a	0.45	1.90	3.6±0.5
6c	1.03	1.36	2.0±0.5

The known sensitivity of Eu^{3+} and Tb^{3+} luminescence towards quenching by hydroxy groups in the solvent provides an experimental tool with which to estimate the degree of shielding by the ligands. An empirical relationship has been established by Horrocks and Sudnich,[25] estimating the number of coordinated methanol molecules (q) as $q = A(\tau_{MeOH}^{-1} - \tau_{MeOD}^{-1})$, where A is 2.1 for the Eu^{3+} and 8.4 for the Tb^{3+} complexes, and τ^{-1} is the reciprocal luminescence lifetime, measured separately in MeOH and in [D_4]methanol.

The luminescence lifetime of the complexes increases significantly in deuterated MeOH, indicating the quenching effect of the excited state of Ln^{3+} ions by the O−H oscillators of the coordinated methanol. The solvation parameter q determined is 3.4±0.5 and 1.2±0.5 for **1a** and **1c**, respectively (the error of ±0.5 is generally assumed to be reasonable for this calculation).[25b] This is consistent with three and one coordinated methanol molecule(s) in the first coordination sphere for the Eu^{3+} and Tb^{3+} ions. Additional contribution of solvent-based quenching from the second-sphere interaction may be considered. Parker et al.[26] have shown that significant lifetime differences can also be observed even when no solvent molecules are directly coordinated to the lanthanide ion. This is attributable to the contribution of second-sphere interaction and/or hydrogen bonding of solvent molecules to the ligand, giving rise to apparent q values of anywhere between 0 and 1.

Georges et al.[6a] reported the luminescent properties of terbium chelated with benzoic acid derivatives in aqueous solution, and suggested that, if the benzoic acid derivatives have similar triplet-state energy levels, sensitisation of the terbium luminescence is mainly determined by the ability of the acid to bind to the lanthanide ion. An electron-donating substituent group will increase the negative charge shift of the carboxylic carbon atom and hence also the stability constant of the complex. They also showed that the triplet-state energy levels of benzoic acid derivatives with *para*- and *ortho*-substituted OH and NH_2 groups are in the range of 23500−25500 cm^{-1}, which is above the emission level of $^5D_0$ for Eu^{3+} and $^5D_4$ for Tb^{3+} ions. This therefore supports the observation of stronger sensitisation of the terbium complexes than of the europium complexes, because of the smaller overlap between the ligand triplet and europium ion excited states. The above ligands' triplet state values can be used as a reference for our benzoate ligands and support the luminescent behaviour of the lanthanide complexes in our systems, in which stronger terbium emissions were observed.

The luminescence properties of lanthanide benzoate DMF complexes **2a** and **2c** display characteristic narrow-line emission bands, similar to those observed in complexes **1a** and **1c**, upon excitation of the LC absorption band at 277 nm in DMF and in the solid state. The reason for preparing these complexes with coordinated DMF molecules was to enhance the luminescence intensity and lifetime by eliminating the O−H oscillators that quenched the excited state of lanthanide ions from the coordinated methanol. Unfortunately, complexes **2a** and **2c** exhibit relatively weak luminescence upon LC excitation. This can be accounted for by the instability of the complexes in solution, arising from the possible association/dissociation process, since DMF is a strong O-donor solvent that may compete with the benzoate ligand to coordinate to the Ln^{3+} ions. The smaller antenna effect therefore results in lower sensitisation from the ligand to the metal ions, and thus lowers the luminescence intensity. Similar observation are made for complexes **5a** and **5c**.

Complexes **3a**, **3c**, **4a**, **4c**, **6a**, and **6c** show luminescent behaviour similar to that of complexes **1a** and **1b** in the solid state and in the solution state. Comparison of the lanthanide complexes with different benzoate ligands suggests that, according to their luminescent properties, electron-donating substituted groups such as ethoxy and propoxy increased the stability of the complexes, resulting in longer lifetimes and stronger intensities than seen for the benzoate lanthanides, while relatively shorter lifetimes were observed for electron-withdrawing groups such as trifluoromethyl and trifluoromethoxy. Concentrations of the complexes below 10^{-5} M result in changes of the excitation spectra as time passes, indicating that partial decomplexation occurs, which is understandable in view of the relatively weak coordination of bidentate carboxylate ligands. No attempts at quantum yield measurements were therefore made.

Magnetic Properties

The short metal−metal distance within the molecules demonstrated significant potential interest in terms of the study of the magnetic exchange interactions between those ions. We have previously reported the magnetic properties of the tetranuclear μ_4-oxo complexes, which exhibit antiferromagnetic coupling at low temperature.[27] From the evidence of the X-ray analyses of the complexes, they all have metal−metal distances (3.90−5.35 Å) believed to correspond to some magnetic interaction between the ions along the chain. Solid-state magnetic measurements were therefore carried out for the gadolinium and terbium complexes. Table 8 summarises the magnetic properties of these complexes.

The temperature dependence of the magnetic properties of the dimeric complexes **5b** and **5c** were investigated at 100

Table 8. Magnetic data of the gadolinium and terbium carboxylate complexes

[a] Fitted by Equation (2). [b] Fitted by Equation (1).

Oe and 10 kOe field, respectively, over a temperature range of 2−300 K. Plots of χ_M^{-1} vs. T for these complexes obey the Curie−Weiss law, giving C = 15.48 and 21.28 $cm^3 \cdot K \cdot mol^{-1}$ and θ = −1.34 and −10.50 K for **5b** and **5c**, respectively. The $\chi_M T$ value (15.86 $cm^3 \cdot K \cdot mol^{-1}$) of complex **5b** remain almost constant − and close to the expected value of two non-interacting free Gd^{3+} ions − from 300 to 25 K.[28] A dramatic drop in value below 25 K to 10.74 $cm^3 \cdot K \cdot mol^{-1}$ at 2 K was observed (Figure 9). This feature is indicative of weak antiferromagnetic coupling between the Gd^{3+} ions in the molecule. We can analyse the data quantitatively by using the equation deduced from the isotropic spin Hamiltonian, $H = -JS_{Gd1}S_{Gd2}$, with the quantum numbers $S_{Gd1} = S_{Gd2} = 7/2$. Equation (1) is for the magnetic susceptibility of dimeric system[29] with $x = J/kT$ and N = Avogadro's number, β = Bohr magneton, k = Boltzmann constant.

$$\chi_M = \left(\frac{2N\beta^2 g^2}{kT}\right)\left(\frac{e^x + 5e^{3x} + 14e^{6x} + 30e^{10x} + 55e^{15x} + 91e^{21x} + 140e^{28x}}{1 + 3e^x + 5e^{3x} + 7e^{6x} + 9e^{10x} + 11e^{15x} + 13e^{21x} + 15e^{28x}}\right) \quad (1)$$

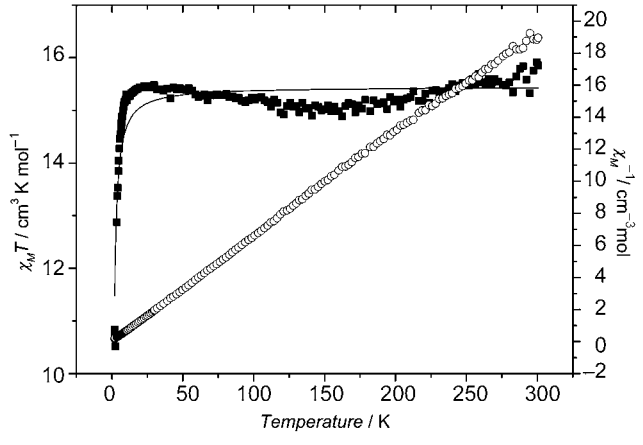

Figure 9. Temperature dependence of $\chi_M T$ (filled squares) and χ_M^{-1} (open circles) of $[Gd(oet)_3(DMF)(H_2O)]_2$ (**5b**) with diamagnetic correction; the solid line represents the best calculated curve

The magnetic interaction parameter J can be evaluated by fitting the data for the dimer system with Equation (1). The J value is −0.068 cm^{-1} whereas g is 1.98. A good agreement between the experimental and calculated values is reflected by the small R value [$R = \Sigma(\chi_M T_{calcd.} - \chi_M T_{obsd.})^2/\Sigma(\chi_M T_{obsd.})^2$] of $4.8 \cdot 10^{-4}$. Meanwhile, the $\chi_M T$ value of complex **5c** decreases gradually from room temperature (20.77 $cm^3 \cdot K \cdot mol^{-1}$) to 2 K (11.57 $cm^3 \cdot K \cdot mol^{-1}$). This room-temperature value is smaller than the expected values for two free non-interacting Tb^{3+} ions, which is primarily a consequence of the ligand field effect that the lowest J multiplet of the Russell−Saunders ground term was perturbed. The dramatic drop in $\chi_M T$ is mainly due to the splitting of the ligand field of the Tb^{3+} ions because of strong spin-orbit coupling, and partly contributed to the possible antiferromagnetic coupling between the Tb^{3+} ions in the dimer unit at a lower temperature.

A relatively longer metal−metal distance than seen in complexes **5b** and **5c** is associated with complex **6c** (5.35 Å). We believed such a large separation might give rise to some magnetic exchange behaviour, and so the solid-state magnetic properties of complexes **6b** and **6c** were studied over the 2−300 K temperature range, at 100 Oe applied field; χ_M is the molar magnetic susceptibility per monomer unit of the polymeric chain. For complex **6b**, the $\chi_M T$ value at room temperature is 7.23 $cm^3 \cdot K \cdot mol^{-1}$, close to the expected value for one isolated Gd^{3+} ion ($^8S_{7/2}$). However, the whole profile of the $\chi_M T$ vs. T plot is indicative of weak antiferromagnetic coupling, resulting in a nonmagnetic ground state for the Gd^{3+} ions. The abrupt drop of $\chi_M T$ at below 60 K, to the minimum value of 6.58 $cm^3 \cdot K \cdot mol^{-1}$, together with the negative θ value of −0.58 K, suggests the presence of weak antiferromagnetic coupling between the metal ions. As complex **6b** consists of an infinite chain with equal spacing, it can be quantitatively analysed by use of the equation deduced from the isotropic spin Hamiltonian, $H = -JS_{Gd1}S_{Gd2}$, with the quantum numbers $S_{Gd1} = S_{Gd2} = 7/2$. The analytical expression of Equation (2) for

the magnetic susceptibility of an infinite chain of classical spins was derived by Fisher[30] with

$$u = \coth\left[\frac{2JS(S+1)}{kT}\right] - \left[\frac{kT}{2JS(S+1)}\right]$$

and the other symbols as defined in Equation (1).

$$\chi_M = \frac{Ng^2\beta^2 S(S+1)}{3kT}\frac{1+u}{1-u} \quad (2)$$

A quantitative analysis of the data, based on Equation (2), shows a good fit of $\chi_M T$ with $J = -0.019$ cm^{-1}, $g = 1.92$ and $R = 1.17 \cdot 10^{-5}$. The magnetic behaviour of complex **6c** is similar to that of the Gd complex, indicating the possible presence of antiferromagnetic interaction between the Tb^{3+} ions. The data fit well with the Curie−Weiss law, with $C = 10.70$ cm^3 K·mol^{-1} and $\theta = -2.30$ K. The $\chi_M T$ value exhibits a continuous decrease upon cooling, from 10.5 cm^3·K·mol^{-1} at room temperature to 10.58 cm^3·K·mol^{-1} at ca. 130 K, and then drop very rapidly to 8.94 cm^3·K·mol^{-1} at 2 K. The continuous decrease in $\chi_M T$ as the temperature is lowered is probably primarily a result of the ligand field effect stemming from the strong spin-orbit coupling of the Tb^{3+} ions together with possible contribution from weak intra- and intermolecular antiferromagnetic coupling between the Tb^{3+} ions. The other complexes **1b**, **1c**, **2b**, **2c**, **3c**, **4b** and **4c**, but not **3b**, exhibit weak antiferromagnetic coupling between the lanthanide ions at low temperature, with behaviour similar to that of other homoleptic lanthanide complexes.[29,31]

Conclusion

A new series of lanthanide carboxylate complexes with benzoate-type ligands were successfully synthesised and demonstrated a rich coordination chemistry in the solid state. All benzoate ligands can sensitise lanthanide luminescence, especially for the terbium ion, but coordinated methanol molecules cause the quenching of lanthanide excited states. Although the use of *para*-substituted benzoate ligands improved the solubilities of the complexes, it gives rise to steric hindrance between the ligands, so that they have relatively shorter luminescence lifetimes than the complexes with benzoate ligands. Weak antiferromagnetic interactions between the neighbouring ions along the chain were observed at low temperature in studies of magnetic properties.

Experimental Section

General: All chemicals were purchased from commercial sources and were used as received without any further purification. The solid-state infrared spectra were recorded with a Bio-Rad FTS-7 FT-IR spectrometer on KBr pellets. Elemental analyses were performed by Butterworth Laboratories, UK. Thermal gravimetric analysis (TGA) was conducted with a Perkin−Elmer TGA 7 thermogravimetric analyser under nitrogen, over the 30−900 °C temperature range and with a heating rate of 20 °C/min. Electronic absorption spectra were recorded with a Hewlett Packard 8453 UV/Vis spectrophotometer at room temperature. Luminescence spectra were recorded with a Perkin−Elmer LS-50B luminescence spectrometer equipped with a Hamamatse R928 photomultiplier tube, with excitation and emission slit widths of 2.5−15 nm depending on the intensity of the emission. Solid samples were ground into fine powders prior to the luminescence measurements. Both aerated and deoxygenated solution luminescence spectra were measured at room temperature in the $1 \cdot 10^{-4}$ to $2 \cdot 10^{-5}$ M concentration range. For deoxygenated samples, the solutions were subjected to at least three freeze-pump-thaw cycles. Corrections were made for all excitation and emission spectra. Luminescence lifetimes, τ, were measured with the instrument in time-resolved mode, and are averages of at least three independent measurements made by monitoring the decay at a wavelength corresponding to the maximum intensity in the emission spectrum (618 nm for Eu and 545 nm for Tb), after pulsed excitation. The resulting first-order decay curve gave linear plots of ln(*Int*) vs. *t* from which the lifetime was calculated by $\tau = -1/\text{slope}$. Temperature-dependent magnetic susceptibilities of solid samples were recorded on a Quantum Design SQUID magnetometer (MPMS-5S) and a Oxford MagLab2000 magnetometer in the 2−300 K temperature range with applied fields of 100 Oe and 10000 Oe, respectively. The diamagnetic correction was estimated by use of Pascal's constants. Quantitative analyses of the magnetic susceptibility data for the complexes were performed by use of the Nonlin fitting program (Version 3.0).

Syntheses of the Lanthanide Complexes: Since the syntheses of the lanthanide complexes used similar procedures, the synthesis of complex **1a** is described as a general method. The respective ligands 4-(trifluoromethyl)benzoic acid, 4-(trifluoromethoxy)benzoic acid, 4-ethoxybenzoic acid, and 4-*n*-propoxybenzoic acid were used instead of benzoic acid for the preparation of complexes **2a**−**c**, **3a**−**c**, **4a**−**c**, **5a**−**c**, and **6a**−**c**.

General Method: Benzoic acid (82 mg, 0.672 mmol) and NaOH (26.9 mg, 0.672 mmol) in methanol (5 mL) were stirred at room temperature for 30 min. $Eu(NO_3)_3 \cdot 6H_2O$ (100 mg, 0.224 mmol) in methanol (2 mL) was added to the reaction mixture, and a white precipitate appeared after 1 d. The reaction mixture was further stirred for 12 h, and the precipitate was filtered and washed with methanol. **1a:** Yield: 202 mg, 78 %. IR (KBr disc): $\tilde{\nu}$ = 3527 br, 3450 br, 3072 m, 3060 m, 3029 w, 1593 s, 1539 vs, 1520 vs, 1428 vs, 714 s, 551 w cm^{-1}. ESI-MS (negative mode): *m*/*z* = 1152, 637. $C_{46}H_{46}Eu_2O_{16}$ (1158.78): calcd. C 47.68, H 4.00; found C 47.6, H 4.0. **1b:** Yield: 195 mg, 75 %. IR (KBr disc): $\tilde{\nu}$ = 3530 br, 3445 br, 3071 m, 3055 m, 3027 w, 1593 s, 1543 vs, 1522 vs, 1429 vs, 715 s, 553 w cm^{-1}. ESI-MS (negative mode): *m*/*z* = 1162, 642. $C_{46}H_{46}Gd_2O_{16}$ (1169.36): calcd. C 47.25, H 3.97; found C 47.3, H 4.0. **1c:** Yield: 210 mg, 81 %. IR (KBr disc): $\tilde{\nu}$ = 3528 br, 3449 br, 3072 m, 3058 m, 3030 w, 1594 s, 1541 vs, 1521 vs, 1430 vs, 714 s, 554 w cm^{-1}. ESI-MS (negative mode): *m*/*z* = 1166, 644. $C_{46}H_{46}O_{16}Tb_2$ (1172.71): calcd. C 47.11, H 3.95; found C 47.3, H 3.9. The product was dissolved in hot methanol for crystallisation and colourless single crystals of **1a**−**c** were obtained on slow evaporation of the solvent over a few days.

Complexes **2a**−**c** were prepared by dissolving complexes **1a**−**c**, respectively, in a minimum amount of hot dimethylformamide, colourless single crystals of **2a**−**c** being obtained after 2 d. **2a:** Yield: 80 mg, 61 %. IR (KBr disc): $\tilde{\nu}$ = 3065 m, 1661 s, 1603 s, 1558 s, 1527 s, 1446 m, 1422 s, 1399 s, 1374 m, 1107 w, 857 m, 723 s cm^{-1}. $C_{24}H_{22}EuNO_7$ (588.40): calcd. C 48.99, H 3.77, N 2.38; found C

49.0, H 3.7, N 2.4. **2b:** Yield: 76 mg, 58 %. IR (KBr disc): $\tilde{\nu}$ = 3060 m, 1658 s, 1603 s, 1559 s, 1530 s 1450 m, 1422 s, 1402 s, 1376 m, 1107 w, 855 m, 724 s cm^{-1}. $C_{24}H_{22}GdNO_7$ (593.69): calcd. C 48.55, H 3.74, N 2.36; found C 48.6, H 3.8, N 2.4. **2c:** Yield: 85 mg, 65 %. IR (KBr disc): $\tilde{\nu}$ = 3061 m, 1657 s, 1605 s, 1558 s, 1527 s 1448 m, 1423 s, 1400 s, 1375 m, 1107 w, 856 m, 723 s cm^{-1}. $C_{24}H_{22}NO_7Tb$ (595.37): calcd. C 48.42, H 3.72, N 2.35; found C 48.4, H 3.7, N 2.3.

The synthesis of complexes **3a**−**c** was similar to that described in the General Method. **3a:** Yield: 97 mg, 55 %. IR (KBr disc): $\tilde{\nu}$ = 3503 br, 3389 br, 3183 w, 3067 w, 1595 s, 1543 s, 1527 s, 1431 s, 1329 s, 1163 m, 1118 s, 1066 s, 1020 m, 868 m, 789 s, 709 m, 490 m cm^{-1}. ESI-MS (negative mode): *m*/*z* = 1628, 908. $C_{26}H_{20}EuF_9O_8$ (783.38): calcd. C 39.86, H 2.57; found C 39.8, H 2.6. **3b:** Yield: 86 mg, 49 %. IR (KBr disc): $\tilde{\nu}$ = 3505 br, 3389 br, 3175 w, 3072 w, 1599 s, 1547 s, 1531 s, 1437 s, 1335 s, 1165 m, 1118 s, 1068 s, 1018 m, 868 m, 789 s, 711 m, 490 m cm^{-1}. ESI-MS (negative mode): *m*/*z* = 1638, 914. $C_{26}H_{20}F_9Gd_8O$ (788.67): calcd. C 39.60, H 2.56; found C 39.6, H 2.5. **3c:** Yield: 105 mg, 60 %. IR (KBr disc): $\tilde{\nu}$ = 3503 br, 3393 br, 3185 w, 3073 w, 1597 s, 1551 s, 1531 s, 1435 s, 1333 s, 1165 m, 1118 s, 1068 s, 1018 m, 870 m, 791 s, 711 m, 490 m cm^{-1}. ESI-MS (negative mode): *m*/*z* = 1642, 915. $C_{26}H_{20}F_9O_8Tb$ (790.34): calcd. C 39.51, H 2.55; found C 39.6, H 2.6. Colourless block-shaped single crystals of **3a** and **3c** were obtained from the filtrate on slow evaporation of the solvent for 3 d.

The synthesis of complexes **4a**−**c** was similar to that described in the General Method. **4a:** Yield: 110 mg, 59 %. IR (KBr disc): $\tilde{\nu}$ = 3447 br, 1601 s, 1559 s, 1541 s, 1437 s, 1319 s, 1288 s, 1206 s, 1167 s, 783 m cm^{-1}. ESI-MS (negative mode): *m*/*z* = 1740, 972. $C_{26}H_{20}EuF_9O_{11}$ (831.38): calcd. C 37.56, H 2.42; found C 37.5, H 2.5. **4b:** Yield: 117 mg, 63 %. IR (KBr disc): $\tilde{\nu}$ = 3437 br, 1605 s, 1560 s, 1545 s, 1437 s, 1313 s, 1286 s, 1209 s, 1169 s, 783 m cm^{-1}. ESI-MS (negative mode): *m*/*z* = 1750, 978. $C_{26}H_{20}F_9GdO_{11}$ (836.67): calcd. C 37.32, H 2.41; found C 37.3, H 2.4. **4c:** Yield: 119 mg, 65 %. IR (KBr disc): $\tilde{\nu}$ = 3420 br, 1605 s, 1557 s, 1541 s, 1433 s, 1311 s, 1279 s, 1211 s, 1167 s, 783 m cm^{-1}. ESI-MS (negative mode): *m*/*z* = 1754, 979. $C_{26}H_{20}F_9O_{11}Tb$ (838.35): calcd. C 37.25, H 2.40; found C 37.3, H 2.4. Colourless rod-shaped single crystals of **4a**−**c** were obtained from the filtrate on slow evaporation of solvent for a week.

The synthesis of complexes **5a**−**c** was similar to that described in the General Method. **5a:** Yield: 182 mg, 55%. IR (KBr disc): $\tilde{\nu}$ = 3003 w, 2978 m, 2935 m, 2887 m, 1660 s, 1609 s, 1589 s, 1558 s, 1522 s, 1437 m, 1421 s, 1389 m, 1255 s, 784 w cm^{-1}. ESI-MS (−ve): *m*/*z* = 1460, 813. $C_{60}H_{72}Eu_2N_2O_{22}$ (1477.14): calcd. C 48.79, H 4.91, N 1.90; found C 48.8, H 5.0, N 1.9. **5b:** Yield: 172 mg, 52%. IR (KBr disc): $\tilde{\nu}$ = 3005 w, 2979 m, 2934 m, 2890 m, 1659 s, 1610 s, 1588 s, 1557 s, 1524 s, 1440 m, 1420 s, 1388 m, 1253 s, 783 w cm^{-1}. ESI-MS (negative mode): *m*/*z* = 1471, 818. $C_{60}H_{72}Gd_2N_2O_{22}$ (1487.73): calcd. C 48.44, H 4.88, N 1.88; found C 48.5, H 5.0, N 1.9. **5c:** Yield: 187 mg, 57%. IR (KBr disc): $\tilde{\nu}$ = 3003 w, 2978 m, 2934 m, 2888 m, 1659 s, 1607 s, 1589 s, 1558 s, 1524 s, 1439 m, 1419 s, 1389 m, 1255 s, 783 w cm^{-1}. ESI-MS (negative mode): *m*/*z* = 1474, 820. $C_{60}H_{72}N_2O_{22}Tb_2$ (1491.08): calcd. C 48.33, H 4.87, N 1.88; found C 48.4, H 4.9, N 1.9. Recrystallisation of the products from hot DMF afforded colourless rod-shaped single crystals of **5b** and **5c** after a few weeks.

The synthesis of complexes **6a**−**c** was similar to that described in the General Method. **6a:** Yield: 103 mg, 72 %. IR (KBr disc): $\tilde{\nu}$ = 3405 br, 3079 w, 2966 m, 2938 m, 2878 m, 1607 s, 1522 m, 1507 s, 1421 s, 1388 s, 1312 m, 1257 s, 1171 m, 786 w cm^{-1}. ESI-MS (negative mode): *m*/*z* = 1558, 869. $C_{22}H_{30}EuNO_{11}$ (636.44): calcd. C 41.52, H 4.75, N 2.20; found C 41.6, H 4.8, N 2.3. **6b:** Yield: 115 mg, 81%. IR (KBr disc): $\tilde{\nu}$ = 3406 br, 3079 w, 2965 m, 2938 m, 2878 m, 1607 s, 1522 m, 1508 s, 1421 s, 1389 s, 1311 m, 1257 s, 1173 m, 787 w cm^{-1}. ESI-MS (negative mode): *m*/*z* = 1569, 874. $C_{22}H_{30}GdNO_{11}$ (641.72): calcd. C 41.18, H 4.71, N 2.18; found C 41.2, H 4.8, N 2.2. **6c:** Yield: 128 mg, 90%. IR (KBr disc): $\tilde{\nu}$ = 3416 br, 3082 w, 2967 m, 2938 m, 2876 m, 1609 s, 1524 m, 1506 s, 1419 s, 1385 s, 1314 m, 1257 s, 1171 m, 787 w cm^{-1}. ESI-MS (negative mode): *m*/*z* = 1572, 875. $C_{22}H_{30}NO_{11}Tb$ (642.40): calcd. C 41.07, H 4.70, N 2.18; found C 41.1, H 4.7, N 2.2. A mixture of 4-*n*-propoxybenzoic acid, NaOH and $Tb(NO_3)_3{\cdot}6H_2O$ was left standing at room temperature, and colourless rod-shaped single crystals of **6c** were obtained on slow evaporation of the solvent for a few days.

Crystallography: Single crystals suitable for X-ray crystallographic analyses were mounted on sealed glass capillaries by use of epoxy resin. Diffraction data were collected at ambient temperature with a Rigaku AFC7R diffractometer, a Marresearch Image Plate Scanner or a Bruker AXS SMART-CCD 1000 diffractometer by use of graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å) with ω-2θ and ω scan techniques. A summary of crystallographic data and structure refinements is listed in the Supporting Infornmation. All data sets were collected for Lorentz and polarisation effects and the absorption corrections based on ψ-scan methods[32] or inter-image scaling were also applied. All structures were solved by a combination of Patterson methods (DIRDIF92, PATTY)[33] or direct methods (SIR92[34] or SHELXS-86[35]) and difference Fourier techniques. The solutions were refined on *F* by full-matrix, least-squares analysis, with all metal and non-hydrogen atoms refined anisotropically for structures **2a**−**b**, **3c**, **4a**−**c**, and **6c**, while structures **1a**−**c**, **2c**, **3a**, **5b**, and **5c** were refined anisotropically for all metal and heavy atoms. All hydrogen atoms were included in the structure factor calculations but were not refined. All calculations were performed with a Silicon-Graphics workstation with the aid of the program package TeXsan.[36] CCDC-195568 to -195581 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Supporting Information: A summary of crystallographic data, including the data collection and structure solution parameters for complexes **1a**−**c**, **2a**−**c**, **3a**, **3c**, **4a**−**c**, **5b**−**c** and **6c** is shown in Table S1. Magnetic data of complexes **5c**, **6b** and **6c** are illustrated in Figures S1−3, respectively (see also footnote on the first page of this article).

Triorganotin Fluoride Structures: A Ligand Close-Packing Model with Predominantly Ionic Sn−F Bonds

Jens Beckmann,[a] Dagmar Horn,[a] Klaus Jurkschat,*[a] Fred Rosche,[a] Markus Schürmann,[a] Uwe Zachwieja,[a] Dainis Dakternieks,*[b] Andrew Duthie,[b] and Allan E. K. Lim[b]

Keywords: Ab initio calculations / Chain structures / Hypervalent compounds / Tin / Fluorides / X-ray diffraction

The synthesis and complete characterization by multinuclear NMR, infrared, and Mössbauer spectroscopy, by single crystal X-ray analysis, as well as by electrospray mass spectrometry of the new soluble triorganotin fluoride Me_2PhSnF (**1**) is reported. The crystal structure of **1** reveals a *rod-like* polymeric structure in the solid state. Solutions of **1** in apolar solvents, such as toluene, contain mixtures of interconvertible oligomers. Ab initio MO calculations on model compounds H_3SnF, $[H_3SnFSnH_3]^+$, and $[FH_3SnFSnH_3F]^-$ indicate that the Sn–F bonds are substantially ionic in character, and suggest open-chain species, rather than cyclic species. In donor solvents, such as pyridine, **1** forms complexes with the solvent, such as Me_2PhSnF·pyridine. The solid-state structure of $(Me_3SiCH_2)_3SnF$ (**2**) is reformulated as monomeric with a weak intermolecular Sn···F interaction that gives rise to a [4+1] coordination. The relative short Sn–Sn separation enables the fluorine atoms to oscillate (flip-flop) between two neighboring $(Me_3SiCH_2)_3Sn$– groups, which is expressed in the X-ray experiment by a dynamic disorder. Ab initio MO calculations on a model compound, $[H_3SnFSnH_3]^+$, suggest only a small energy barrier for the flip-flop motion.

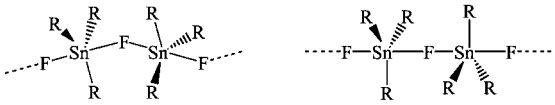
Introduction

Organometallic fluorides have received considerable attention owing to their structural diversity, which is associated with the ambivalent nature of fluorine. Fluorine is both monovalent and an excellent donor.[1] As it is also the most electronegative element, fluorine typically forms very polar or ionic bonds with most main-group elements[2] and transition metals.[3]

Triorganotin fluorides, R_3SnF, have been known for many decades,[4,5] and the nature of the Sn−F bonds remains controversial. Owing to its high melting point and virtual insolubility in organic solvents, Okawara et al. originally proposed an ionic structure for Me_3SnF.[6] However, on the basis of an early X-ray structure and IR and Raman spectroscopy, the structure of Me_3SnF was reformulated as a polymeric arrangement consisting of planar trimethyltin groups bridged by fluorine atoms.[7] Despite the fact that disorder precluded a satisfactory refinement of the X-ray structure of Me_3SnF, the comparatively short Sn−F bond lengths (2.15, 2.45 Å) and the slightly bent Sn−F−Sn bond angle (141°) were interpreted in terms of a predominantly covalent Sn−F bond character.[8−10] A similar arrangement was observed in the X-ray structure of nBu_3SnF; however, disorder again prevented the complete refinement of this structure.[11] Due to their bent Sn−F−Sn linkages, Me_3SnF and nBu_3SnF were both classified as *zigzag* polymers (**I**).[12] In contrast, the structures of the polymeric triorganotin fluorides Ph_3SnF[13] and $(PhCH_2)_3SnF$[14] consist of symmetric Sn−F−Sn bridges with equal Sn−F bond lengths (2.15 Å and 2.16 Å), whereas $cHex_3SnF$[15] contains unsymmetric bridges (2.05/2.30 Å). The latter compounds reveal (almost) linear Sn−F−Sn linkages and hence, are classified as *rod-like* polymers (**II**).[12]



I **II**

The X-ray structure of $(Me_3SiCH_2)_3SnF$ deserves a special comment.[16] The authors suggested a *rod-like* polymer with symmetric Sn−F−Sn bridges. The two equally long Sn−F bonds (2.57 Å) were interpreted in terms of a highly ionic bond character.[15]

Monomeric structures have been reported for triorganotin fluorides containing more sterically demanding substitu-

ents, such as $[(Me_2PhSi)_3C]Me_2SnF$, $[(Me_3Si)_3C]Ph_2SnF$,[17] and $(2,4,6\text{-}Me_3C_6H_2)_3SnF$.[18] The latter compound was used to establish a standard "covalent" Sn−F bond length (1.96 Å).[18] Monomeric triorganotin fluorides were also obtained using the intramolecular coordination of the so-called *built-in* ligands.[19−23] Similarly, triorganotin fluorides react with additional fluoride ions to form monomeric triorganodifluorostannates, $R_3SnF_2^-$.[24−27]

Besides X-ray diffraction studies, ^{119}Sn Mössbauer spectroscopy,[12,28−41] ^{119}Sn MAS NMR spectroscopy,[42−47] IR spectroscopy,[6,10,36,48−52] and Raman spectroscopy[36,39,52] have been applied to distinguish between polymeric and monomeric triorganotin fluorides. Consequently, iBu$_3$SnF,[44] $(PhCH_2CH_2CH_2)_3SnF$,[53] and $(F_3C)_3SnF$[54] were assigned as polymeric structures, whereas $(PhMe_2CCH_2)_3SnF$,[53,55] $[(Me_3Si)_3C]Me_2SnF$,[17] $[(Me_3Si)(Me_2FSi)_2C]Me_2SnF$,[56] and $[(Me_3Si)_2(Me_2FSi)C]Me_2SnF$[57] have been identified as monomers. Furthermore, in the presumed polymeric triorganotin fluorides, R_3SnF (R = Me, Et, *n*Pr, *n*Bu, *n*Pen, *n*Hex, *n*Oct, *n*Dec), the effect of the lengths of the alkyl chain on the melting point, solubility, and the degree of crystallinity were studied, however, without the support of spectroscopy.[58]

Recently, Gillespie et al. used results from ab initio calculations to reinterpret the nature of bonds containing fluorine.[59] They concluded that a large majority of element−fluorine bonds, including Si−F bonds, possess substantial ionic character, and molecules such as SiF_4 are therefore more appropriately described using a ligand close-packing model with predominately ionic Si−F bonds.[60,61] A search of the literature revealed only two publications that included ab initio studies of molecules containing tin−fluorine bonds,[62,63] although neither of these studies focused directly on the nature of the Sn−F bonds.

The unusually high solubility of the new triorganotin fluoride $PhMe_2SnF$ enabled a comprehensive study of a polymeric triorganotin fluoride in solution. We now report on the results of this study, as well as on the reinvestigation of the structure of $(Me_3SiCH_2)_3SnF$.[16] The ab initio electronic structure calculations of the model compounds H_3SnF, $[H_3SnFSnH_3]^+$, and $[FH_3SnFSnH_3F]^-$ are also reported.

Results and Discussion

Dimethylphenyltin fluoride Me_2PhSnF (**1**) and tris(trimethylsilylmethyl)tin fluoride $(Me_3SiCH_2)_3SnF$ (**2**) were prepared in good yields from Me_2PhSnI and $(Me_3SiCH_2)_3SnCl$ (**2a**) by halide exchange reactions with KF and NH_4F, respectively, in a two-layer solvent system (water/diethyl ether) [Equation (1)].

$$R_2R'SnX \xrightarrow[-\ NH_4Cl\ or\ -\ KCl]{KF\ (ex)\ or\ NH_4F\ (ex)/H_2O/ether} R_2R'SnF \quad (1)$$

X = Cl, I

1, R = Me, R' = Ph

2, R = R' = CH_2SiMe_3

For putative polymeric triorganotin fluorides, **1** and **2** reveal very low melting points, 124−126 °C and 123−127 °C, respectively. In comparison, Me_3SnF and Ph_3SnF melt at temperatures exceeding 250 °C or decompose without melting.[4,5] This observation prompted us to investigate the structures of **1** and **2** in greater detail.

Characterization of 1 and 2 in the Solid State

The ^{119}Sn MAS NMR spectrum of Me_2PhSnF (**1**) exhibits a triplet centered at $\delta = -49.3$ ppm with a $^1J(^{119}Sn\text{-}^{19}F)$ coupling of 1235 Hz, thus unambiguously revealing a polymeric arrangement with symmetric Sn−F−Sn bridges on the NMR time scale. The ^{119}Sn MAS NMR parameters of **1** agree well with those reported for the polymeric parent compounds Me_3SnF [triplet at $\delta = 24.3$ ppm, $^1J(^{119}Sn\text{-}^{19}F) = 1300$ Hz] and Ph_3SnF [triplet at $\delta = -211.9$ ppm, $^1J(^{119}Sn\text{-}^{19}F) = 1530$ Hz].[44] The integration over all spinning sidebands of the three independent manifolds confirms the 1:2:1 ratio required for a triplet. The large sideband manifolds were also utilized to perform a tensor analysis according to the method of Herzfeld and Berger.[64,65] The isotropic chemical shielding (δ_{iso}), anisotropy (ζ), asymmetry (η) and chemical shift tensor components (σ_{11}, σ_{22}, σ_{33}) are presented in Table 1, alongside the same parameters for the related compounds Me_3SnF, Ph_3SnF, and $[Ph_3SnF_2]^-$.[27,44,45] Comparison of the data reveals that the average anisotropy for **1** is substantially larger ($|\zeta_{avg}| = 312$ ppm) than for Me_3SnF ($|\zeta_{avg}| = 221$ ppm), Ph_3SnF ($|\zeta_{avg}| = 250$ ppm) and $[Ph_3SnF_2]^-$ ($|\zeta_{avg}| = 219$ ppm), which clearly indicates that this parameter not only depends on the coordination number, but also on the local symmetry around the tin atoms. The lower symmetry in **1** as compared with Me_3SnF and Ph_3SnF is also reflected in the asymmetry, which is in the range between 0.80 and 1.00 for the three manifolds. For the parent compounds, which possess threefold symmetry axes, group theory requires the asymmetry to be 0.00,[66] which is indeed what was observed.[44,45]

In sharp contrast, the ^{119}Sn MAS NMR spectrum of $(Me_3SiCH_2)_3SnF$ (**2**) shows a doublet centered at 165.8 with a $^1J(^{119}Sn\text{-}^{19}F)$ coupling of 2167 Hz, indicating a monomer with tetracoordinated tin atoms. The ^{119}Sn MAS NMR parameters of **2** are similar to those of monomeric $(2,4,6\text{-}Me_3C_6H_2)_3SnF$ [two doublets due to crystallographically independent tin atoms at $\delta = -70.6$ ppm, $^1J(^{119}Sn\text{-}^{19}F) = 2300$ Hz; and $\delta = -82.2$ ppm, $^1J(^{119}Sn\text{-}^{19}F) = 2256$ Hz].[45] The integration over the two spinning sideband manifolds confirms that both sites of the doublet are of equal intensity. The reasonably small sideband manifolds of **2** were used to perform a tensor analysis as described above; the parameters obtained along with those for $(2,4,6\text{-}Me_3C_6H_2)_3SnF$ are presented in Table 1.[44] It is interesting to note that, for compound **2**, the asymmetry η is 0.00, which strongly indicates the presence of a threefold symmetry axis for the geometry around the tin atom;[66] this result is indeed confirmed by the single-crystal X-ray structure analysis (see below). The average anisotropy of **2** ($|\zeta_{avg}| = 95$ ppm) lies between those of the (symmetrically substituted) pentacoordi-

[a] Mes = 2,4,6-$Me_3C_6H_2$.

nated compounds (Me_3SnF, Ph_3SnF, $[Ph_3SnF_2]^-$) and monomeric $(2,4,6\text{-}Me_3C_6H_2)_3SnF$ ($|\zeta_{avg}|$ = 63 ppm). Given that the symmetry of **2** is higher than that in $(2,4,6\text{-}Me_3C_6H_2)_3SnF$,[18] this observation may indicate a weak intermolecular Sn···F interaction ([4+1] coordination). Since this additional interaction is indeed confirmed by the single-crystal X-ray structure analysis (see below), it seems that the anisotropy ζ is more sensitive than the $^1J(^{119}Sn\text{-}^{19}F)$ coupling towards weak interactions. However, more systematic work is needed to prove this hypothesis.

The ^{119}Sn Mössbauer spectrum of **1** is also in good agreement with a polymeric structure.[37] The quadrupole splitting and the isomeric shift, 3.87 and 1.30 mm·s^{-1}, respectively, are indicative of pentacoordinated tin atoms. Notably, the quadrupole splitting and the isomeric shift for Me_3SnF and Ph_3SnF were reported to be 3.80 and 1.36 mm·s^{-1}, and 3.62 and 1.32 mm·s^{-1}, respectively.[36] In contrast, the Mössbauer spectrum of **2** is consistent with a monomeric structure containing tetracoordinated tin atoms; the quadrupole splitting and the isomeric shift are 2.97 and 1.29 mm·s^{-1}, respectively.[37]

In the pioneering work of Kriegsmann et al., the IR spectra of the triorganotin fluorides, R_3SnF (R = Me, Et, *n*Pr, *n*Bu), were compared, both in the solid state (polymeric) and in the gas phase (monomeric). They concluded that the asymmetric Sn−F stretching vibration for polymeric triorganotin fluoride compounds lies between 340 and 360 cm^{-1}, whereas for monomeric compounds the Sn−F stretching vibrations are between 530 and 590 cm^{-1}.[36,48,50] The IR spectrum (KBr pellet) of **1** shows a broad absorption at 340 cm^{-1}, consistent with a polymeric structure. In contrast, the IR spectrum (KBr pellet) of **2** shows no band between 300 and 400 cm^{-1}, but a band, which appears at 471 cm^{-1}, is tentatively assigned to an Sn−F stretching vibration. The position of this band lies between those of monomeric and polymeric triorganotin fluoride compounds. This supports the interpretation of the single-crystal X-ray diffraction analysis which shows that compound **2** exhibits a structure between the polymeric and monomeric forms, with a [4+1]-coordinated tin atom (see below).[36,48,50]

Single-Crystal X-ray Analyses of 1, 2, and 2a

The X-ray structure of Me_2PhSnF (**1**) is illustrated in Figure 1; selected bond parameters are collected in the caption of the figure, and details of the structure solution are listed in Table 3. Compound **1** features a slightly distorted *rod-like* polymeric arrangement with almost symmetric Sn−F bond lengths. All tin atoms in **1** are crystallographically related and adopt slightly distorted trigonal-bipyramidal geometries [geometrical goodness $\Delta\Sigma(\theta)$ = 88.4°], with the axial and equatorial positions occupied by two fluorine and three carbon atoms, respectively.[67,68] The slight distortion is best reflected in the C(1)−Sn(1)−C(11) and F(1)−Sn(1)−F(1a) bond angles, which are 116.5(1) and 179.44(7)°, respectively. The Sn−F bond lengths of **1** are 2.162(1) and 2.179(1) Å, and are only 0.016 and 0.033 Å longer than those of Ph_3SnF.[13] The tin atom is displaced by 0.030(2) Å from the plane defined by C(1), C(2), C(11), in the direction of F(1). In the crystal lattice, Me_2PhSnF (**1**) forms stapled layers of parallel but isolated polymer chains (Figure 2). The shortest distance between these polymer chains is 3.656(4) Å, between C(14) and C(16c) (c = 0.5 + x, y, −0.5 − z) of neighboring phenyl groups.

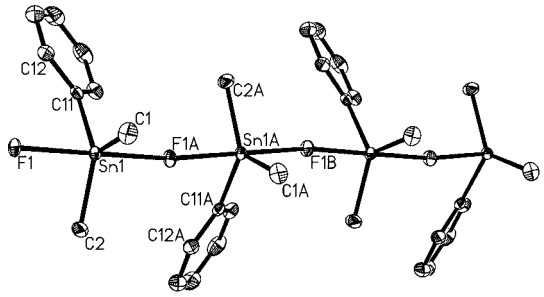

Figure 1. General view (SHELXTL) of a part of the polymeric chain of **1** showing 30% probability displacement ellipsoids and the atom numbering (SHELXTL-PLUS); selected bond lengths [Å] and angles [°]: Sn(1)−C(1) 2.112(3), Sn(1)−C(2) 2.115(3), Sn(1)−C(11) 2.123(3), Sn(1)−F(1) 2.162(1), Sn(1)−F(1a) 2.179(1), C(1)−Sn(1)−C(2) 121.7(1), C(1)−Sn(1)−C(11) 116.5(1), C(2)−Sn(1)−C(11) 121.7(1), C(1)−Sn(1)−F(1) 91.78(9), C(2)−Sn(1)−F(1) 89.99(8), C(11)−Sn(1)−F(1) 90.72(7), C(1)−Sn(1)−F(1a) 88.63(8), C(2)−Sn(1)−F(1a) 90.12(8), C(11)−Sn(1)−F(1a) 88.76(7), F(1)−Sn(1)−F(1a) 179.44(7), Sn(1)−F(1)−Sn(1b) 172.57(7) (symmetry transformation used to generate equivalent atoms: a = $-x$ + 1/2, y + 1/2, z; b = x, y − 1, z)

Despite having a very low melting point, Me_2PhSnF (**1**) is a polymer in the solid state. Apparently, this observation may simply be explained by the well-known correlation between the symmetry and the melting point of a molecule. It

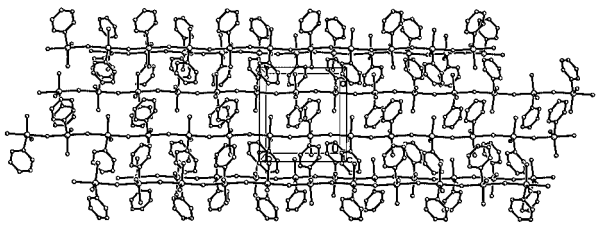

Figure 2. Perspective view (SHELXTL) of stapled layers of parallel polymer chains running through the crystal lattice of **1**

has been suggested that highly symmetrical molecules can absorb appreciable amounts of energy, before vibrations induce disruption from the crystal lattice.[69] In fact, all other structurally investigated polymeric triorganotin fluoride complexes bear three identical organic substituents and hence, possess a higher degree of symmetry than **1**.

The X-ray structure of $(Me_3SiCH_2)_3SnF$ (**2**) is illustrated in Figure 3; selected bond parameters are collected in the caption of the figure, and details of the structure solution are listed in Table 3. As previously reported by Zakharov et al.,[16] the structure of **2** is characterized by an infinite chain of tin atoms, with an Sn−Sn separation of 5.151(1) Å. However, the Sn−F distances are not equal [2.565(8) Å],[16] but show two pairs of different values [2.027(6)/3.125(6) Å and 2.377(6)/2.774(6) Å] as result of the dynamic disorder of the tin and fluorine atoms, respectively. The tin atoms exhibit strongly distorted trigonal-bipyramidal configurations [geometrical goodness $\Delta\Sigma(\theta)$ = 47.1° (Sn1), 54.0° (Sn1′)],[67,68] and represent positions halfway along the tetrahedron−trigonal bipyramid pathway. The distortion from the ideal trigonal bipyramid is reflected in the C−Sn(1)−C and C−Sn(1′)−C angles of 116.5(2) and 117.4(2)°, respectively. The origin for the deviation of these angles from tetrahedral is not mostly due to the steric hindrance of the organic substituents, as observed for Mes_3SnF (mean C−Sn−C 116.8°),[18] nor due to substituent electronegativity (Bent's rule),[70] but is rather the result of the intermolecular Sn(1)···F(1A) and Sn(1′)···F(1A) distances of 2.774(6) and 3.125(6) Å, respectively, being shorter than the sum of the van der Waals radii of tin and fluorine (3.63 Å).[70] This view is supported by the solid-state structure of $(Me_3SiCH_2)_3SnI$,[71] which shows C−Sn−C angles (111.7−115.2°) that are closer to those in a tetrahedral geometry.[72] Most interestingly, it appears that the intermolecular Sn···F interactions are not unambiguously reflected by the ^{119}Sn MAS NMR spectrum of **2**, which reveals a doublet and not a doublet of doublets (see above). The latter observation further strongly supports a dynamic rather than a statistical disorder in the structure of **2**. Given the sensitivity of ^{119}Sn MAS NMR spectroscopy, statistically disordered tin sites would give rise to the observation of two independent doublets. It is also worth mentioning that the molecular structure of $(Me_3SiCH_2)_3SnCl$ (**2a**) exhibits an analogous disorder, as shown in Figure 4; selected bond parameters are collected in the caption of the figure and details of the structure solution are listed in Table 2. The Sn−Sn separation in the infinite chain of tin atoms is 5.564(2) Å, and the pairs of Sn−Cl distances are 2.508(9)/3.056(9) and 2.498(10)/3.066(10) Å.[72] The geometrical goodness $\Delta\Sigma(\theta)$ of the respective tin atoms is 54.45° (Sn1) and 70.02° (Sn1′).[67,68]

Characterization of 1 and 2 in Solution

$PhMe_2SnF$ (**1**) and $(Me_3SiCH_2)_3SnF$ (**2**) are highly soluble in common organic solvents, such as chloroform, tolu-

ene, or methanol, which is in contrast to most polymeric triorganotin fluorides.[4,5]

The osmometric molecular weight determination of **1** (in toluene) reveals a strong, but steady concentration and temperature dependence, as illustrated in Figure 5. The highest molecular mass observed was 12000 g·mol^{-1}, corresponding to a degree of association exceeding 50 molecular units. In contrast, the molecular weight determination of **2** (in CH_2Cl_2) showed only the presence of monomers.5

Being consistent with the afore-mentioned ^{119}Sn MAS NMR spectrum, the ^{119}Sn NMR spectrum of **1** in [D$_8$]toluene displays a broad triplet at $\delta = -53.0$ ppm [$\nu_{1/2} = 250$, $^1J(^{119}\text{Sn-}^{19}\text{F}) = 1334$ Hz], the shape of which is somewhat distorted and similar to that reported for nBu$_3$SnF.[46] The ^{19}F NMR spectrum of **1** in [D$_8$]toluene shows a signal at $\delta = -139.0$ ppm ($\nu_{1/2} = 150$ Hz) with an unresolved $^1J(^{19}\text{F-}^{119/117}\text{Sn})$ coupling of 1260 Hz. Bearing in mind the natural abundance of the isotopes ^{119}Sn and ^{117}Sn, the magnitude of the integral ratio between the main signal and the tin satellites confirms the Sn−F−Sn connectivity. The presence of only one signal in both the ^{119}Sn and ^{19}F NMR spectrum suggests the fast exchange, on the ^{119}Sn and ^{19}F NMR time scales, of rapidly interconverting oligomers with varying degrees of association. We speculate that the $^1J(^{119}\text{Sn-}^{19}\text{F})$ coupling is maintained because the majority of F−Sn−F

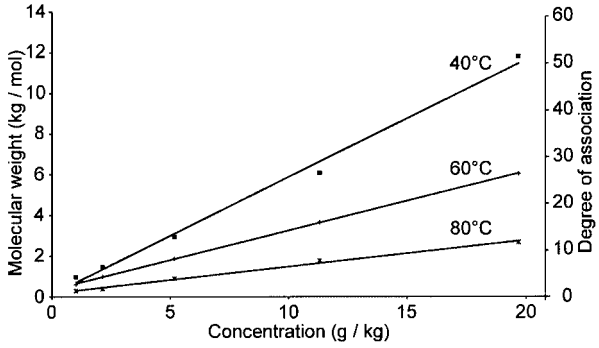

Figure 5. Osmometric molecular mass determination of **1** in toluene at 40, 60, and 80 °C (concentrations: 1.0, 2.1, 5.1, 11.3, 19.7 g·kg^{-1})

fragments present in these oligomers possess lifetimes that are comparatively long on the ^{119}Sn and ^{19}F NMR time scales.[46] Attempts to slow down the exchange process at −80 °C indeed show that the ^{119}Sn and ^{19}F spectra in [D$_8$]toluene become more complex. However, the broadness of the signals precluded the recognition of distinctive NMR multiplets or signals. All attempts to identify monomers at 80 °C or very low concentration (10 mg·mL^{-1} for ^{119}Sn; 0.25 mg·mL^{-1} for ^{19}F) failed. The IR spectrum of a saturated solution of **1** in CH_2Cl_2 shows a very strong asymmetric stretching Sn−F vibration at 339 cm^{-1}, which is almost identical to the corresponding band in the solid state and indicates bridging fluorine atoms.

At high molecular weights, a remarkable viscosity was noticed for solutions of **1** in toluene, which increases with higher concentrations and lower temperatures. Similar ob-

servations have already been reported for solutions of nBu$_3$SnF in different solvents, for which the effect was studied in greater detail.[73−75] Additives, such as pyridine or aniline, reduce the viscosity to that of the pure solvent.[73] No attempts were made to determine the viscosity of **1** in different solvents. Instead, a solution of **1** in [D$_5$]pyridine was investigated by ^{119}Sn NMR spectroscopy, which shows a broad signal centered at $\delta = -84.0$ ppm ($\nu_{1/2}$ = 800 Hz) at room temperature, and a doublet centered at $\delta = -91.5$ ppm ($\nu_{1/2}$ = 350 Hz) with a $^1J(^{119}\text{Sn-}^{19}\text{F})$ coupling of 1905 Hz at −25 °C. The ^{19}F NMR spectrum of the same solution at room temperature and at −25 °C shows a signal centered at $\delta = -168.6$ ppm [$^1J(^{19}\text{F-}^{119}\text{Sn}) = 1840$ Hz], and at $\delta = -164.4$ ppm [$^1J(^{19}\text{F-}^{119}\text{Sn}) = 2100$ Hz], respectively. The observation of a doublet in the ^{119}Sn NMR spectrum, and the intensity ratio of the satellites to the main signal in the ^{19}F NMR spectrum suggest the formation a monomeric complex, PhMe$_2$SnF·pyridine. An analogous complex, namely Ph$_3$SnF·pyridine, has already been mentioned in the literature.[24]

The ^{119}Sn NMR spectrum ($CDCl_3$) of **2** shows a doublet centered at $\delta = 193.0$ ppm with a $^1J(^{119}\text{Sn-}^{19}\text{F})$ coupling of 2340 Hz, which agrees reasonably well with the ^{119}Sn MAS NMR parameters (see above), although the difference in the chemical shift in solution and in the solid state (δ = 31.0 ppm) is much bigger than that in compound **1** (δ = 4.8 ppm). One possible explanation is that in solution the tetrahedral configuration of the tin atom in **2** is much less distorted than in the solid state, i.e. compound **2** is entirely monomeric. The ^{19}F NMR spectrum of **2** reveals a signal at $\delta = -207.2$ ppm, with a well-resolved $^1J(^{19}\text{F-}^{119}\text{Sn})$ coupling of 2370 Hz. The integration of the main signal with respect to the tin satellites confirms the monomeric structure.

Electrospray Mass Spectrometry

In order to identify the association of organotin ions with the parent compounds by autoionization, ESI MS spectra of PhMe$_2$SnF (**1**) and (Me$_3$SiCH$_2$)$_3$SnF (**2**) were recorded in acetonitrile. The following mass clusters showing the expected isotopic patterns were observed: **1**, negative mode: $Me_2PhSnF_2^-$ (265.0), $(Me_2PhSn)_2F_3^-$ (509.0), $(Me_2PhSn)_3F_4^-$ (753.0), positive mode: Me_2PhSn^+ (227.0), $(Me_2PhSn)_2F^+$ (471.0), $(Me_2PhSn)_3F_2^+$ (715.0), $(Me_2PhSn)_4F_3^+$ (961.0); **2**, negative mode: $(Me_3SiCH_2)_3SnF_2^-$ (419.1), positive mode: $(Me_3SiCH_2)_3Sn^+$ (381.1), $[(Me_3SiCH_2)_3Sn]_2F^+$ (779.2).

The ready formation of charged species suggests a highly ionic character of the Sn−F bonds in **1** and **2**. The degree of association is generally higher for species related to **1** than for those related to **2**, which correlates well with the observed Lewis acidities of the parent compounds. For some of the organotin anions detected under electrospray conditions, analogs were already identified in previous studies by ^{119}Sn NMR and ^{19}F NMR spectroscopy, e.g. $R_3SnF_2^-$ and $(R_3SnF)_2F^-$ (R = Me, nBu, Ph).[25,76,77] The observation of the uncoordinated (solvent-free) triorganotin cations, Me_2PhSn^+ (227.0) and $(Me_3SiCH_2)_3Sn^+$ (381.1), is also worth mentioning as the stabilities of such species were questioned for a long time.[78,79] Recently, the crystal structure of an isolated nBu$_3$Sn$^+$ cation (counter anion $CB_{11}Me_{12}^-$) undeniably proved the stabilities of these species.[80]

Conductivity measurements of **2** in acetonitrile, at $c = 10^{-3}$ mol·L^{-1}, reveal no change in conductivity compared with that of the pure solvent (1.7 μS). The result is consistent with extensive ion-pairing.

Ab Initio Computational Study of Model Compounds Containing Sn−F Bonds

The three model compounds H$_3$SnF (**3**), [H$_3$SnFSnH$_3$]$^+$ (**4**), and [FH$_3$SnFSnH$_3$F]$^-$ (**5**) were selected as subjects for the computational investigation. H$_3$SnF (**3**) is the simplest example of a monomeric tetravalent tin compound containing a tin−fluorine bond, whereas [H$_3$SnFSnH$_3$]$^+$ (**4**) and [FH$_3$SnFSnH$_3$F]$^-$ (**5**) represent two possible ways of defining a subsection of a polymeric tin fluoride chain. It is expected that the actual properties of the Sn−F−Sn linkages in a polymeric chain would be intermediate between those of the two extremes modeled herein. Furthermore, **4** and **5** resemble the corresponding ditin ions that have been detected in the ESI MS analyses of **1** and **2**.

The B3LYP/TZ-optimized structures of the model compounds, alongside selected geometric parameters are depicted in Figure 6. The calculated Sn−F bond length of H$_3$SnF (**3**) of 1.946 Å appears to agree with the Sn−F bond length of 1.961(4) Å observed in the monomeric triorganotin fluoride (2,4,6-Me$_3$C$_6$H$_2$)$_3$SnF.[18] For [H$_3$SnFSnH$_3$]$^+$ (**4**) and [FH$_3$SnFSnH$_3$F]$^-$ (**5**), staggered and eclipsed conformations were located on the potential energy surfaces; however, the differences in calculated bond lengths and angles between rotamers are negligible in both cases. Therefore, only the staggered conformations will be discussed here. As expected, the Sn−F distances increase when the coordination numbers of both tin and fluorine are increased: the Sn−F distance in **4** is 2.124 Å, and the distance from Sn to the bridging F atom in **5** increases further to 2.255 Å when the coordination number of tin is raised from four to five. This result is consistent with the experimentally obtained Sn−F bond lengths in polymeric organotin fluorides. For instance, the mean Sn−F bond lengths in **1**, Ph$_3$SnF, and cHex$_3$SnF are 2.171(2), 2.145(1), and 2.177(1) Å, respectively. The distance between the tin and the nonbridging fluorine atoms in **5** (2.041 Å) is also somewhat larger than the Sn−F distance in H$_3$SnF (**3**). The equilibrium Sn−F−Sn angles for all four fluorine-bridged ditin systems are calculated to be 180°. The SnH$_3$ moieties in **4** and **5** are effectively able to undergo free internal rotation, the calculated energy difference between the staggered and eclipsed conformations is only 0.02 kcal·mol^{-1} and 0.05 kcal·mol^{-1} for **4** and **5**, respectively. Both conformers of **4** and the staggered conformer of **5** are calculated to be minima on the B3LYP/TZ potential energy surface, whereas the eclipsed conformer of **5** is a first-order saddle point possessing one imaginary frequency (30i cm^{-1}) associated with rotation of the SnH$_3$ moieties towards the staggered con-

formation. The fact that the eclipsed conformer of **4** is calculated to be a minimum instead of a transition state analogous to the eclipsed conformer of **5**, could be an artifact due to the extreme flatness of the potential energy surface around the calculated stationary points, as illustrated by the very small difference in energy between the staggered and eclipsed conformations in **4**.

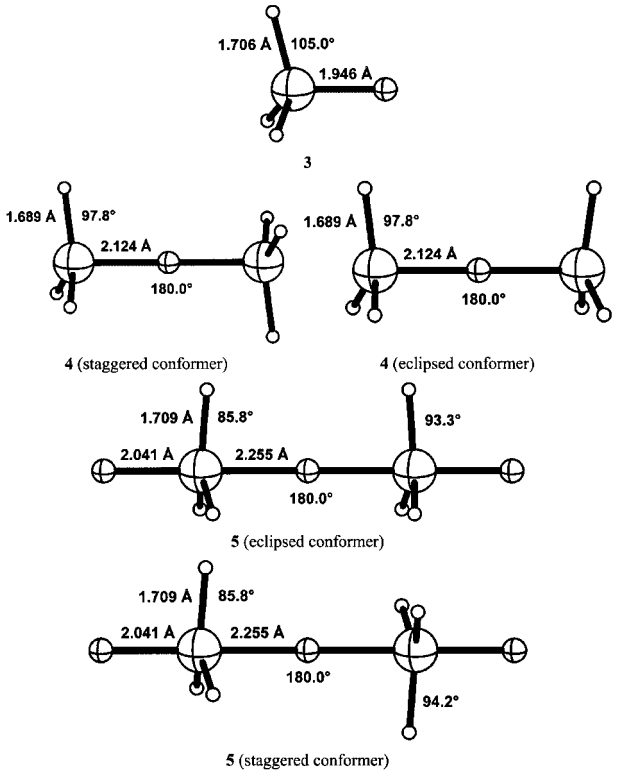

Figure 6. B3LYP/TZ-optimized structures and selected geometrical parameters of the model compounds **3**, and both eclipsed and staggered conformers of **4** and **5**

The Sn−F−Sn bending potential curves for both conformers of **4** and **5** are plotted in Figure 7. For both cases, it was found that the staggered conformation is slightly lower in energy than the eclipsed conformation at all Sn−F−Sn angles studied. The energy difference between the two conformers is smallest at the equilibrium Sn−F−Sn angle of 180°, and increases slightly as the Sn−F−Sn angle is reduced. This is consistent with the observation of staggered conformations in crystal structures of polymeric triorganotin fluorides, e.g. **1**, Ph_3SnF[13] and *c*Hex_3SnF.[15] However, the small energy differences calculated herein imply that the experimentally observed preference for polymeric triorganotin fluorides to adopt staggered conformations could be due to crystal-packing or steric effects, rather than electronic factors. All four curves are indicative of a very flat bending potential surface around the equilibrium Sn−F−Sn angle of 180°. Both curves corresponding to **4** lie below room temp. (= 0.6 kcal·mol^{-1}) between 160 and 180°, whereas the curves corresponding to **5** lie below room temp. between 140 and 180°. According to the criteria set forth by Gillespie et al., the linear Sn−F−Sn equilibrium angle and the high flexibility of the Sn−F−Sn linkages are indicative of highly ionic Sn−F bonds.[59] Thus, the observation of *zigzag* polymeric structures (bent Sn−F−Sn linkages) for Me_3SnF[8−10] and nBu_3SnF,[11] may be attributed to a combination of this flexibility and crystal packing effects, rather than being an indication of covalent bond character.[8−10] Despite the high flexibility of the Sn−F−Sn linkages, the preference of the F−Sn−F angles to be close to 180° (Bent's rule) precludes the formation of small or medium-sized rings in solution, e.g. similar to *cyclo*-$(R_2AlF)_3$.[81] The average internal angle of a *n*-membered ring is required by three-dimensional geometry to be less than (for puckered rings) or equal to (for flat rings) $[(n-2)/n] \times 180°$.[82] Constraining the F−Sn−F angles to be linear, would therefore necessitate large values of *n* before the Sn−F−Sn linkages are able to adopt favorable angles (> 150°).

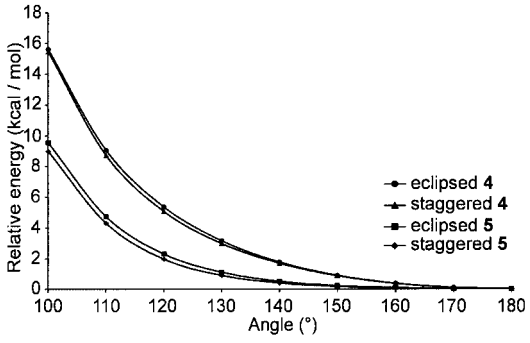

Figure 7. Energy profiles for the Sn−F−Sn bending deformations of both eclipsed and staggered conformers of **4** and **5**

Natural Population Analysis (NPA)[83] atomic charges calculated for **3** and the staggered conformers of **4** and **5** clearly show a significant localization of negative charge on the fluorine atoms in the model compounds, hence providing further evidence of the high ionic character of the Sn−F bond (Table 2). The bonds between tin and the bridging fluorine atoms are apparently slightly more ionic than the bonds between tin and non-bridging fluorine atoms.

In order to investigate the possibility that an oscillating (flip-flop) motion of the fluorine atoms between two neighboring tin atoms could be the reason for the disorder observed in the X-ray structure solution of **2**, a potential energy surface scan of the staggered conformer of **4** was performed, where the Sn−Sn separation is fixed at various values and the fluorine atom is moved from one tin atom to another. The calculated energy profiles are plotted in Figure 8. At a small Sn−Sn separation of 4.25 Å, which is extremely close to the equilibrium distance of 4.248 Å calculated for **4**, and a reasonable approximation to the measured Sn−Sn separations in the X-ray structures of all polymeric triorganotin fluorides, e.g. Ph_3SnF (4.29 Å),[13] $(PhCH_2)_3SnF$ (4.33 Å),[14] and **1** (4.33 Å), the curve re-

sembles a parabola with a minimum at the halfway point, where both Sn−F distances are 2.125 Å. However, when the Sn−Sn separation is increased, the curves become double-minimum potentials, which possess two minima approximately 2 Å away from the two tin atoms and a local maximum at the halfway point between the two tin atoms. This situation resembles that found in monomeric triorganotin fluorides, e.g. (2,4,6-$Me_3C_6H_2)_3SnF$ (Sn−Sn separation 6.42 Å, mean Sn−F distance 1.96 Å).[18] Most interestingly, the energy barrier between the two minima is found to increase substantially with increasing Sn−Sn separation. Thus, for very large Sn−Sn separations, as observed in (2,4,6-$Me_3C_6H_2)_3SnF$, the fluorine atoms are trapped in their respective potential wells. However, for reasonably small Sn−Sn separations, as observed in **2** (5.15 Å), the energy barrier is low enough to be exceeded and the fluorine atoms may oscillate (flip-flop) between the two potential wells. In the X-ray experiment of **2**, this motion is evidenced by a dynamic disorder (see above). It was further noticed that disorder prevented the complete refinement of the X-ray structure of Me_3SnF.[8−10] From the indisputable Sn−Sn separation (4.6 Å) it can be surmised that the disorder in Me_3SnF might also be due to dynamic factors rather than on statistical grounds.[84] In contrast, the Sn−Sn separation in the unsymmetric polymer *c*Hex_3SnF (4.35 Å)[15] is only marginally greater than in symmetric polymers, such as Ph_3SnF,[13] $(PhCH_2)_3SnF$,[14] and **1**. In view of the calculated energy profiles and the two unsymmetric Sn−F bonds (2.05/2.30 Å), the structure of *c*Hex_3SnF should also reveal a dynamic disorder reflected on the low energy barrier found for small Sn−Sn separations. In fact, the disorder of almost all carbon atoms in the structure of *c*Hex_3SnF strongly supports this assumption.[15]

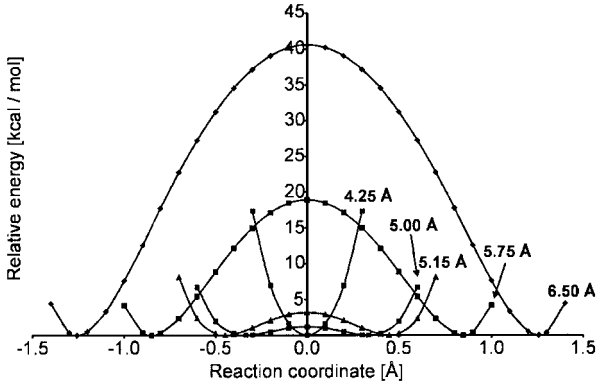

Figure 8. Energy profiles for the motion of the fluorine atoms from one tin atom to another in the staggered conformer of **4**, at Sn−Sn separations of 4.25, 5.0, 5.15, 5.75, and 6.5 Å; the zero of the reaction coordinate is set to the halfway point between the two tin atoms, where both Sn−F bond lengths are equal; calculated equilibrium Sn−F distances are 2.125, 2.165, 2.112, 2.026, and 1.992 Å, respectively

Experimental Section

General: ($Me_3SiCH_2)_3SnCl$ [$\delta(^{119}Sn)$ = 172.6 ppm] was prepared according to literature procedures.[85] Solution ^1H, ^{13}C, ^{19}F, ^{29}Si, and ^{119}Sn NMR spectra were obtained using a Bruker DRX 400 spectrometer. Chemical shifts (δ) are given in ppm and are referenced against $SiMe_4$, $SnMe_4$, and $CFCl_3$. ^{119}Sn MAS NMR spectra were recorded with a Bruker MSL 400 spectrometer using cross-polarization and high-power proton decoupling. An 8-μs 90° pulse, 5 ms of contact time and a recycle delay of 10 s were used. Chemical shifts (δ_{iso}) are quoted relative to $SnMe_4$, using solid *c*Hex_4Sn (δ_{iso} = −97.35 ppm) as a secondary reference. Typically, 12−15 K transitions were recorded for a signal-to-noise ratio suitable for tensor analyses. At least two experiments at independent spinning frequencies ranging from 4−12 kHz were recorded to determine the isotropic chemical shifts. The tensor analyses were performed according to the method developed by Herzfeld and Berger;[64][65] WINFIT software (Bruker) was used to analyze the spectra.[86] The principle components of the shielding tensors are reported using Haeberlen's notation as the isotropic chemical shift ($\delta_{iso} = -\sigma_{iso}$), the anisotropy ($\zeta = \sigma_{33} - \sigma_{iso}$) and the asymmetry ($\eta = |\sigma_{22} - \sigma_{11}|/|\sigma_{33} - \sigma_{iso}|$), σ_{11}, σ_{22}, σ_{33} are the three components of the shielding tensor expressed in its principal axis system with the following convention: $|\sigma_{33} - \sigma_{iso}| \geq |\sigma_{11} - \sigma_{iso}| \geq |\sigma_{22} - \sigma_{iso}|$.[87] With this convention, ζ is a signed value expressed in ppm and η is a dimensionless parameter, the value of which varies between 0 and 1. The Mössbauer spectra were recorded in constant-acceleration mode with a homemade instrument, designed and built by the Institut voor Kernen Stralingsfysica (IKS), Leuven, Belgium. The isomer shifts refer to a source of $Ca^{119m}SnO_3$ from Amersham, U.K., with the samples being maintained at 90(2) K. The data were treated with a least-squares iterative program that deconvoluted the spectrum into a sum of Lorentzians. FT infrared spectra were recorded using a Bruker IFS28 spectrometer. Electrospray mass spectra were obtained with a Platform II single quadrupole mass spectrometer (Micromass, Altrincham, U.K.) using an acetonitrile mobile phase. Acetonitrile solutions (0.1 mM) of the compounds were injected directly into the spectrometer via a Rheodyne injector equipped with a 50-μL loop. A Harvard 22 syringe pump delivered the solutions to the vaporization nozzle of the electrospray ion source at a flow rate of 10 $\mu L \cdot min^{-1}$. Nitrogen was used as both a drying gas and for nebulization with flow rates of approx. 200 $mL \cdot min^{-1}$ and 20 $mL \cdot min^{-1}$, respectively. Pressure in the mass analyzer region was usually about $4 \cdot 10^{-5}$ mbar. Typically 10 signal-averaged spectra were collected. Microanalyses were performed using an instrument from Carlo Erba Strumentazione (Model 1106). Molecular weight determinations were performed with a Gonotec Osmomat 070 osmometer.

Dimethylphenyltin Fluoride, Me_2PhSnF (1): A solution of PhMgBr (80 mL, 50.0 mmol) in THF, which was prepared from C_6H_5Br (7.85 g) and magnesium turnings (1.22 g), was added dropwise at 0 °C to a solution of Me_2SnCl_2 (5.00 g, 22.8 mmol) in THF (80 mL). The reaction mixture was heated at reflux for 1.5 h and the THF was distilled off. Diethyl ether (150 mL) was added to the residue and the resulting suspension was stirred for 15 min. This suspension was hydrolyzed with an aqueous HCl solution (50 mL, 4%), while cooling with ice. The organic layer was separated and the aqueous layer extracted three times with diethyl ether (30 mL). The combined organic phases were dried with Na_2SO_4. Filtration of the sodium sulfate and evaporation of the diethyl ether in vacuo gave Me_2Ph_2Sn (10.15 g, 33.5 mmol) as a yellow oil [$\delta^{119}Sn(CH_2Cl_2/D_2O$ capillary) = −60.1 ppm] of sufficient purity. Iodine (5.71 g, 45 mmol) was added in small portions to an ice-cooled magnetic-

ally stirred solution of Me_2Ph_2Sn (10.15 g, 22.5 mmol) in CH_2Cl_2 (100 mL). The reaction mixture was stirred at 0 °C for 2.5 h followed by the removal of dichloromethane and benzene in vacuo, giving a yellow oil, Me_2PhSnI (17.69 g) consisting of Me_2PhSnI [$\delta^{119}Sn(CH_2Cl_2/D_2O$ capillary) = −15.3 ppm]. A solution of KF (1.88 g, 32.4 mmol) in water (30 mL) was added to a solution of Me_2PhSnI (2.86 g, 8.1 mmol) in diethyl ether (30 mL). The reaction mixture was stirred for 24 h and was then left for a few hours without stirring giving rise to the formation of colorless crystals of Me_2PhSnF at the phase boundary (1.36 g, 6.7 mmol, 83% yield), m.p. 124−126 °C. ^1H NMR ($CDCl_3$): δ = 7.38 [complex pattern, $^2J(^1H\text{-}^{117/119}Sn)$ = 30 Hz, 2 H, *o*-H], 7.27 (complex pattern, 3 H, *m*-, *p*-H), 0.34 [s, $^2J(^1H\text{-}C\text{-}^{119/117}Sn)$ = 71 Hz, 6 H, *Me*] ppm. $^{13}C\{^1H\}$ NMR ($CDCl_3$, c = 0.228 mol·L^{-1}): δ = 144.6 [$^1J(^{13}C\text{-}^{117/119}Sn)$ = 707/741 Hz, C_i], 135.3 [$^2J(^{13}C\text{-}^{117/119}Sn)$ = 49 Hz, C_o], 128.6 (C_p), 127.9 [$^3J(^{13}C\text{-}^{117/119}Sn)$ = 65 Hz, C_m], −0.05 [$^1J(^{13}C\text{-}^{117/119}Sn)$ = 544/568 Hz, CH_3] ppm. ^{19}F NMR ($CDCl_3$): δ = −137.4 [$^1J(^{19}F\text{-}^{119/117}Sn)$ = 1255 Hz] ppm; ([D$_8$]toluene): δ = −139.0 [$^1J(^{19}F\text{-}^{119/117}Sn)$ = 1260 Hz] ppm. $^{119}Sn\{^1H\}$ NMR ($CDCl_3$): δ = −52.3 [$^1J(^{119}Sn\text{-}^{19}F)$ = 1340 Hz]; ([D$_8$]toluene): δ = −53.0 ppm [$^1J(^{119}Sn\text{-}^{19}F)$ = 1334 Hz] ppm. $^{13}C\{^1H\}$ MAS NMR: δ = −0.3, 1.6 (CH_3), 144.8, 136.6, 134.4, 128.5 (phenyl carbon atoms) ppm. $^{119}Sn\{^1H\}$ MAS NMR: δ = −49.5 [$^1J(^{119}Sn\text{-}^{19}F)$ = 1235 Hz] ppm. IR (KBr): $\tilde{\nu}$ = 3066 w, 2995 w, 2912 wbr, 1431 s, 1197 s, 1082 s, 998 w, 778 vs, 727 vs, 699 vs, 561 s, 531 s, 340 vs cm^{-1}. $C_8H_{11}FSn$ (244.91): calcd. C 39.2, H 4.5; found C 39.3, H 4.5.

Tris(trimethylsilylmethyl)tin Fluoride, $(Me_3SiCH_2)_3SnF$ (2): A saturated aqueous solution of NH_4F (30 mL) was added to a solution of $(Me_3SiCH_2)_3SnCl$ (0.80 g, 1.9 mmol) in diethyl ether (50 mL). The reaction mixture was stirred for 24 h and the organic layer was separated. The aqueous layer was extracted twice with diethyl ether (20 mL) and the combined organic phases were dried with Na_2SO_4. After filtration from the latter, the diethyl ether was distilled leaving a colorless residue which was recrystallized from dichloromethane giving $(Me_3SiCH_2)_3SnF$ (0.71 g, 1.8 mmol, 92% yield) of m.p. 123−127 °C. ^1H NMR ($CDCl_3$): δ = 0.11 (s, 27 H, CH_3), 0.23 [d, $^3J(^1H\text{-}^{19}F)$ = 4.2, $^2J(^1H\text{-}^{117/119}Sn)$ = 72.5/75.3 Hz, CH_2] ppm. $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 6.1 [$^1J(^{13}C\text{-}^{119}Sn)$ = 286, $^2J(^{13}C\text{-}^{19}F)$ = 10 Hz; Sn*C*H$_2$Si], 1.5 (Si*Me*$_3$) ppm. ^{19}F NMR ($CDCl_3$): δ = −207.2 [$^1J(^{19}F\text{-}^{119}Sn)$ = 2369 Hz] ppm. $^{29}Si\{^1H\}$ NMR ($CDCl_3$): δ = 2.0 [$^2J(^{29}Si\text{-}^{119/117}Sn)$ = 29 Hz] ppm. $^{119}Sn\{^1H\}$ NMR ($CDCl_3$): δ = 196.4 [$^1J(^{119}Sn\text{-}^{19}F)$ = 2340, $^1J(^{119}Sn\text{-}^{13}C)$ = 282, $^2J(^{119}Sn\text{-}^{29}Si)$ = 30 Hz] ppm. $^{13}C\{^1H\}$ MAS NMR: δ = 3.7 (CH_3), 8.0 (broad, CH_2) ppm. $^{119}Sn\{^1H\}$ MAS NMR: δ = 165.8 [$^1J(^{119}Sn\text{-}^{19}F)$ = 2167 Hz] ppm. IR (KBr): $\tilde{\nu}$ = 2954 s, 2897 s, 1450 w, 1407 w, 1353 w, 1307 w, 1248 vs, 1023 vs, 833 vsbr, 752 s, 719 s, 689 s, 616 w, 596 s, 577 w, 529 s, 471 sbr, 283 w cm^{-1}. $C_{12}H_{33}FSi_3Sn$ (399.38): calcd. C 36.1, H 8.3; found C 36.2, H 8.1. Molecular weight (5.04 mg·g^{-1} CH_2Cl_2, T = 30 °C): 464 g·mol^{-1}.

X-ray Crystallographic Study: Intensity data for the colorless crystals were collected with a Nonius KappaCCD diffractometer with graphite-monochromated Mo-K_α radiation. The data collections covered almost the whole sphere of reciprocal space with 2 sets at different κ angles and 185 frames (**1**) and 360 frames via ω rotation (Δ/ω = 1°) (**2**, **2a**) at two times 5 s (**2a**), 10 s (**1**), and 30 s (**2**) per frame (Table 3). The crystal-to-detector distance was 3.0 cm (**2**, **2a**) and 3.4 cm (**1**). Crystal decay was monitored by repeating the initial frames at the end of the data collection. There was no indication for any decay when analyzing the duplicate reflections. The structure was solved by direct methods using SHELXS-97[88] and successive difference Fourier syntheses. Refinement was performed with full-matrix least-squares methods using SHELXL-97.[89] The

Table 3. Crystal data and structure refinement for **1**, **2**, and **2a**

	1	**2**	**2a**
Empirical formula	$C_8H_{11}FSn$	$C_{12}H_{33}FSi_3Sn$	$C_{12}H_{33}ClSi_3Sn$
Formula mass [g/mol]	244.86	399.34	415.79
Crystal system	orthorhombic	hexagonal	hexagonal
Crystal size [mm]	0.30 × 0.06 × 0.06	0.15 × 0.13 × 0.12	0.25 × 0.23 × 0.23
Space group	*Pbca*	*P*6(3)	*P*6(3)
a [Å]	9.3997(3)	10.6877(3)	10.6330(4)
b [Å]	8.6639(2)	10.6877(3)	10.6330(4)
c [Å]	22.3783(7)	10.3022(2)	11.1281(3)
V [Å^3]	1822.45(9)	1019.13(5)	1089.59(6)
Z	8	2	2
$\rho_{calcd.}$ [Mg/m^3]	1.785	1.301	1.267
T [K]	173(1)	291(1)	291(1)
μ [mm^{-1}]	2.748	1.423	1.446
F(000)	944	412	428
θ range [°]	3.68 to 27.48	2.96 to 24.98	3.83 to 25.02
Index ranges	$-12 \le h \le 12$ $-10 \le k \le 10$ $-29 \le l \le 29$	$-12 \le h \le 12$ $-10 \le k \le 10$ $-10 \le l \le 10$	$-12 \le h \le 12$ $-10 \le k \le 10$ $-11 \le l \le 11$
No. of reflections collected	10202	11175	12312
Completeness to θ_{max}	95.4%	93.8%	94.3%
No. of independent reflections/R_{int}	1998	1128	1226
No. of reflections observed with [$I > 2\sigma(I)$]	1246	820	833
No. of refined parameters	93	58	59
GooF (F^2)	1.014	0.912	0.940
$R1(F)$ [$I > 2\sigma(I)$]	0.0223	0.0228	0.0276
$wR2(F2)$ (all data)	0.0504	0.0538	0.0746
$(\Delta/\sigma)_{max}$	< 0.001	< 0.001	< 0.001
Largest difference peak/hole [e/Å^3]	0.793/−0.693	0.394/−0.182	0.376/−0.226

H atoms were placed in geometrically calculated positions using a riding model with U_{iso} constrained at 1.2 (for aryl groups) and 1.5 (for methyl groups) times U_{eq} of the carrier C atom. TWIN refinements were applied for **2** and **2a**, because a racemic twinning was present with a Flack parameter of 0.47(12) (**2**) and 0.52(13) (**2a**).[90] The TWIN refinement improved the *R* values of *R*1 [(0.0002) (**2**), (0.0003) (**2a**)] and of *wR*2 [(0.0004) (**2**), (0.0005) (**2a**)]. Atomic scattering factors for neutral atoms and real and imaginary dispersion terms were taken from International Tables for X-ray Crystallography.[91] The figures were created by SHELXTL.[92] CCDC-179688 (**1**), -179689 (**2**), and -179690 (**2a**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Anionic Cyclopentadienyl C_{60} Complexes of Molybdenum and Tungsten; The Strange Case of Iron

David M. Thompson,[a] Marni Jones,[a] and Michael C. Baird*[a]

Keywords: Fullerenes / Molybdenum / Tungsten / Iron

Thermal and photochemical reactions of the carbonylate salts A[(η^5-C_5H_5)Fe$(CO)_2$], A[(η^5-C_5H_5)Mo$(CO)_3$] and A[(η^5-C_5H_5)W$(CO)_3$] (A = Na, PPN) in THF with C_{60} result in all cases in electron transfer to give $[C_{60}]^-$ and the transient 17-electron, metal-centered radicals CpFe$(CO)_2$, CpMo$(CO)_3$ and CpW$(CO)_3$, respectively. Subsequent self-coupling of the three metal-centred radicals then results in the formation of the metal-metal bonded dimers [CpFe$(CO)_2]_2$, [CpMo$(CO)_3]_2$ and [CpW$(CO)_3]_2$. In contrast, while the mixture of Na[C_{60}] and [CpFe$(CO)_2]_2$ does not react further under photochemical conditions, photolysis of mixtures of Na[C_{60}] and both [CpMo$(CO)_3]_2$ and [CpW$(CO)_3]_2$ ultimately results in complete homolysis of the dimers and regeneration of the corresponding metal-centered radicals, which then combine with the $[C_{60}]^-$ remaining in solution to form the η^2-C_{60} complexes A[CpMo$(CO)_2$(η^2-C_{60}] and A[CpW$(CO)_2$(η^2-C_{60}].

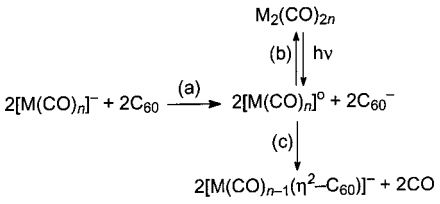
Introduction

Molecular transition metal-fullerene compounds generally fall into two main classes, endohedral compounds in which the metal atom is confined within a fullerene molecule,[1] and η^2-transition metal complexes in which the fullerene behaves essentially as a weakly conjugated, electron-deficient alkene ligand η^2-bonded to the metal via a [6-6] ring junction.[2] Most known examples of η^2-complexes are neutral compounds in which the fullerene has either added to a neutral precursor, thus increasing the coordination number about the metal, or has displaced a ligand such as CO or a phosphane.[2] We have recently described a third synthetic methodology, an approach which results in the formation of unusually stable anionic η^2-fullerene complexes.[3]

It is well-known that C_{60} contains a low lying, triply degenerate LUMO and is therefore readily reduced,[4] and we have found that the carbonylate anions $[M(CO)_n]^-$ (M = Co, n = 4; M = Mn, Re, n = 5) are sufficiently reducing in THF solution that they convert C_{60} to the radical anion $[C_{60}]^-$ as in step (a) of Scheme 1.[3] When reduction is carried out in refluxing THF with A[$M(CO)_5$] (A = Na, PPN; M = Mn, Re), the rates at which the 17-electron intermediates $M(CO)_5$ couple [step (b) of Scheme 1] and undergo CO substitution [step (c) of Scheme 1] are similar and comparable amounts of $M_2(CO)_{10}$ and the stable complexes A[$Mn(CO)_4$(η^2-C_{60})] are formed.[3b−3d] However, under photolytic conditions, the 18-electron dimers $M_2(CO)_{10}$ undergo dissociation back to the radicals [reverse of step (b)] which then react with the $[C_{60}]^-$ remaining in solution to give higher yields of the η^2-C_{60} products.[3b−3d] In contrast, with A[$Co(CO)_4$] (A = Na, PPN), no $Co_2(CO)_8$ is formed in either the thermal or the photochemical reactions, possibly because the rate of dimerization of the $Co(CO)_4$ radical is slow relative to the rate of CO substitution by $[C_{60}]^-$.[3d] Interestingly, the η^2-fullerene complex $[Co(CO)_3(\eta^2\text{-}C_{60})]^-$ is thermally rather labile, and the sodium salt Na[$Co(CO)_3$(η^2-C_{60})] decomposes in refluxing THF to give the unusual mixed-metal fulleride compound $NaCoC_{60}$·3THF.[3a,3d]



Scheme 1

In view of the rich variety of chemistry observed with these three carbonylate anions, we have extended our studies to anionic cyclopentadienyl analogues of iron, molybdenum and tungsten, A[(η^5-C_5H_5)$M(CO)_n$] (A = Na, PPN; M = Fe, n = 2; M = Mo, W, n = 3); these are found to exhibit analogous but different patterns of reactivity.

Results and Discussion

As an extension of our earlier research on reactions of the carbonylate anions $[Co(CO)_4]^-$ $[Mn(CO)_5]^-$ and $[Re(CO)_5]^-$ with C_{60},[3] we have now investigated the analogous reactions of C_{60} with the anionic complexes

[a] Department of Chemistry, Queen's University, Kingston, Ontario, K7L 3N6, Canada

$[CpFe(CO)_2]^-$, $[CpMo(CO)_3]^-$ and $[CpMo(CO)_3]^-$. These anions are all highly reducing,[7] and we anticipated chemistry rather similar to that outlined in Scheme 1, that is single-electron transfer processes followed by dimerization of the resulting metal-centered radicals and/or combination of the metal-centered radicals with the $[C_{60}]^-$ radical anion. Sodium salts were utilized in all cases because of their ease of preparation, while PPN salts were also utilized in the case of molybdenum and tungsten in unsuccessful attempts to obtain suitable crystals of the new η^2-C_{60} complexes for crystallographic purposes, as we had done previously with the manganese system.[3b]

Reactions of A[CpFe(CO)$_2$] (A = Na$^+$, PPN$^+$) with C$_{60}$

The thermal reactions of $A[CpFe(CO)_2]$ ($A = Na^+$, PPN^+) proceeded extremely rapidly. The first IR spectrum run following the addition of C_{60} to a THF solution of either salt (recorded within 1−2 min) revealed only the ν_{CO} bands of $[CpFe(CO)_2]_2$ with intensities similar to those of the starting $CpFe(CO)_2^-$, while ES-MS revealed a strong peak at 720 Da/e and with an isotope distribution consistent with $[C_{60}]^-$. Consistent with the presence of $[C_{60}]^-$ in solution, a near IR spectrum of a THF solution exhibited a peak at 1078 nm.[4] Refluxing these solutions over several hours resulted in no further changes to any of the spectra, and we were able to selectively precipitate $A[C_{60}]$ from the THF solutions by adding a small amount of pentane.

The reactions appear to involve extremely facile initial electron transfer from $[CpFe(CO)_2]^-$ to C_{60} and subsequent dimerization of the $CpFe(CO)_2$ radicals [Equation (1) and (2)].

$$[CpFe(CO)_2]^- + C_{60} \rightarrow CpFe(CO)_2 + [C_{60}]^- \quad (1)$$

$$CpFe(CO)_2 \rightarrow 0.5[CpFe(CO)_2]_2 \quad (2)$$

It was initially thought that $[CpFe(CO)(C_{60})]^-$ was perhaps not being formed because the rate of $CpFe(CO)_2$ radical dimerization is very nearly diffusion controlled[8] and, possibly, much higher than the rate of CO substitution by $[C_{60}]^-$. However, since photolysis of $[CpFe(CO)_2]_2$ is known to result in metal-metal bond homolysis, it was anticipated that continued photolysis would provide a source of $CpFe(CO)_2$ radicals which would be able to react with $[C_{60}]^-$ at least to some extent.[8]

To our surprise, however, the photochemical reactions of $A[CpFe(CO)_2]$ ($A = Na^+$, PPN^+) with C_{60} proceeded in an analogous fashion to the thermal reactions, the only product detected in IR spectra being, again, the dimer $[CpFe(CO)_2]_2$ in high yield. Subsequent photolyses run for up to 96 h revealed no changes to the IR spectra. Tandem ES-MS measurements revealed the strong peak of C_{60}^- at 720 Da/e.

It seems possible that the Cp ring provides steric hindrance and prevents coordination of fulleride to the relatively small iron. While other complexes have been reported containing both metal-fullerene and metal-Cp bonds,[2] there are no examples of the smaller first row transition metals showing both ligands coordinated. Thus the steric argument seems reasonable.

Reactions of A[CpM(CO)$_3$] (M = Mo, W; A = Na$^+$, PPN$^+$) with C$_{60}$

Thermal reactions of $A[CpMo(CO)_3]$ ($A = Na^+$, PPN^+) with C_{60} in refluxing THF resulted in a gradual loss (over 3 h) of the ν_{CO} bands of $[CpMo(CO)_3]^-$ and the appearance of the ν_{CO} bands of $[CpMo(CO)_3]_2$.

The intensities of the product peaks were in both cases similar to those of the starting carbonylate anion before reaction. The presence of $[C_{60}]^-$ in the solutions was confirmed by observation of a peak at 720 Da/e in the ES mass spectrum and a peak at 1074 nm in the near NIR spectrum.[4] As with the iron system, continued refluxing of the solutions resulted in no further changes to any of the spectra, and thus the reactions were as in Equation (3) and (4).

$$[CpMo(CO)_3]^- + C_{60} \rightarrow CpMo(CO)_3 + [C_{60}]^- \quad (3)$$

$$CpMo(CO)_3 \rightarrow 0.5[CpMo(CO)_3]_2 \quad (4)$$

In contrast, photolysis of THF solutions of $A[CpM(CO)_3]$ (A = Na, PPN) in the presence of C_{60} yielded much more interesting results. In the case of $A[CpMo(CO)_3]$, the ν_{CO} bands of $[CpMo(CO)_3]^-$ were replaced over the course of about 3 h by two sets of ν_{CO} bands, those at 1911, 1956 and 2012 cm^{-1} attributable to $[CpMo(CO)_3]_2$, and two new ν_{CO} bands at 1818 and 1900 cm^{-1}. After 48 h, the latter pair of peaks dominated the IR spectrum.

ESMS monitoring of these reactions at times when the ν_{CO} bands of $[CpMo(CO)_3]_2$ and the new pair at 1900 and 1818 cm^{-1} were present in the IR spectrum revealed peaks at 720 and 939 Da/e with isotope distributions consistent with attributions to $[C_{60}]^-$ and $[CpMo(CO)_2(C_{60})]^-$, respectively. As the reaction continued and the intensities of the ν_{CO} band of $[CpMo(CO)_3]_2$ decreased, the intensity of the peak at 720 Da/e in the ESMS also decreased. When only the ν_{CO} bands at 1818 and 1900 cm^{-1} were present, photolysis was discontinued and the reaction mixtures were worked up as above to give $A[CpMo(CO)_2(C_{60})]$. The latter complexes are soluble in THF, and IR spectra of their THF solutions revealed the two ν_{CO} bands at 1800 and 1900 cm^{-1}. Furthermore, ESMS revealed a single peak at 939 Da/e, consistent with the isotope distribution anticipated for $[CpMo(CO)_2(C_{60})]^-$ (Figure 1).

On this basis, the course of the photochemical process clearly involves electron transfer and molybdenum-centered radical coupling, as in Equation (3) and (4), but the latter is reversed photochemically[9] and gives rise to coupling of molybdenum-centered and fulleride radicals, as in Equation (5) [M = Mo].

$$CpM(CO)_3 + [C_{60}]^- \rightarrow [CpM(CO)_2(C_{60})]^- + CO \quad (5)$$

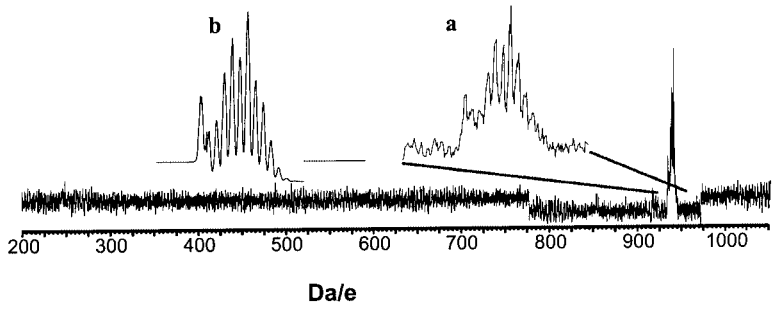


Figure 1. Negative-ion mode ES mass spectrum of PPN[CpMo(CO)$_2$(C_{60})]: (a) observed; (b) calculated

Interestingly, it was also observed that increasing the cone voltage from 10 mV to 30−50 mV resulted in loss of intensity from the peak at 939 Da/e and gain in intensity of a peak at 909 Da/e, a new peak with a position and isotope distribution consistent with [CpMo(CO)(C_{60})]$^-$. As has been established previously,[5c] successive decarbonylation of transition metal carbonylates with increasing cone voltage is a general phenomenon and this result was anticipated. Further increasing the cone voltage above 50 mV resulted in the observation of a peak at 720 Da/e with an isotope distribution consistent with [C_{60}]$^-$. No anionic daughter ions of the type [CpMo(CO)$_x$]$^-$ (x = 1−2) were observed.

A ^{1}H NMR spectrum of the complex was recorded in [D_8]THF, and exhibited a singlet at δ = 5.65 ppm attributable to the Cp ring protons. A ^{13}C NMR spectrum of PPN[CpMo(CO)$_2$(C_{60})] was also recorded in [D_8]THF, and the chemical shifts of the resonances are listed in Table 1, where the approximate relative intensities of the sp^2-hybridized carbon resonances are also given. As with the ^{13}C NMR spectra of other transition metal fullerene complexes,[2b] rigorous assignments of the sp^2-carbon resonances are not possible, although the numbers and intensities of the peaks between δ = 135 and 180 ppm can be used to determine the symmetry of the anion. Resonances in this region at δ = 134.7, 133.6, 130.5 and 128.4 ppm are attributed to the phenyl ring carbons on the PPN$^+$ cation on the basis of comparison with the spectrum of the chloride salt. Of the remaining 18 resonances, one (δ = 125.99 ppm) is readily attributed to the Cp ring carbons, and 17 to fullerene cage carbons. A fullerene bound to a metal by a [6-6] ring junction in an olefinic coordination mode (C_{2v} symmetry) should exhibit 17 ^{13}C resonances, one for the two coordinated (sp^3-hybridized) carbons and 16 attributable to the sp^2-carbons,[2b] and thus the ^{13}C NMR spectroscopic data are consistent with a structure of C_{2v} symmetry.

The near-IR spectra of solutions of A[CpMo(CO)$_2$(η^2-C_{60})] revealed no absorptions in the range 800−1400 nm, results consistent with observations made previously for A[Mn(CO)$_4$(η^2-C_{60})].[3d] Despite many attempts to obtain X-ray quality crystals, none of the crystals obtained proved to be amenable to solution by X-ray crystallography. Confirmation of the correct elemental composition was provided, however, by high resolution ESMS experiments on PPN[CpMo(CO)$_2$(C_{60})]; a peak at 938.9491 Da/e was observed, differing by 14.7 mDa (15.7 ppm) from the theoretical mass of 938.9344 Da/e.

Table 1. ^{13}C NMR spectroscopic data for PPN[CpMo(CO)$_2$(η^2-C_{60})]

Chemical shift of peak (δ)	Relative intensity[a]	Assignment
93.36		sp^3-C_{60}
125.99		Cp
128.40		PPN$^+$
130.53		PPN$^+$
133.39		PPN$^+$
134.74		PPN$^+$
136.60	1.60	sp^2-C_{60}
142.01	2.00	sp^2-C_{60}
142.64	1.96	sp^2-C_{60}
143.37	3.44	sp^2-C_{60}
144.20	2.29	sp^2-C_{60}
145.77	1.26	sp^2-C_{60}
145.90	2.29	sp^2-C_{60}
146.19	1.86	sp^2-C_{60}
146.39	2.16	sp^2-C_{60}
146.43	2.18	sp^2-C_{60}
146.50	1.00	sp^2-C_{60}
147.41	2.36	sp^2-C_{60}
148.08	0.97	sp^2-C_{60}
151.48	1.98	sp^2-C_{60}
156.89	0.77	sp^2-C_{60}
179.32	1.61	sp^2-C_{60}

[a] The relative intensities were calculated arbitrarily as ratios of the intensity of the peak at δ = 146.50 ppm. The intensities calculated in this way are approximate at best and are probably only valid for carbons in the general environment (sp^2 carbons)

The thermal and photochemical reactions of A[CpW(CO)$_3$] (A = Na$^+$, PPN$^+$) with C_{60} in THF parallel those of molybdenum. Reactions in refluxing THF were monitored by IR spectroscopy and ESMS, and the sole products were [CpW(CO)$_3$]$_2$ (in high yield) and A[C_{60}]. These products presumably arise as postulated in Equation (3) and (4) for molybdenum, and involve initial electron transfer from [CpW(CO)$_3$]$^-$ to C_{60} to give the CpW(CO)$_3$ radical and the [C_{60}]$^-$ radical anion followed by dimerization of CpW(CO)$_3$

In contrast, the photochemical reactions of A[CpW(CO)$_3$] (A = Na$^+$, PPN$^+$) with C_{60} in THF resulted in the slow but clean formation of A[CpW(CO)$_2$(C_{60})] (A = Na$^+$, PPN$^+$), via the same intermediates — the CpW(CO)$_3$

radical and the $[C_{60}]^-$ radical anion — observed in the thermal reactions. The photochemical reactions were monitored by IR spectroscopy and ESMS, and the ν_{CO} bands of $A[CpW(CO)_3]$ were found to be replaced initially by the ν_{CO} bands of $[CpW(CO)_3]_2$, and then by the ν_{CO} bands of $[CpW(CO)_2(C_{60})]^-$ (1809, 1894 cm^{-1}) over several hours. Tandem ESMS measurements revealed peaks at 720 Da/e and 1025 Da/e with intensities linked to the intensities of the carbonyl absorptions of $[CpW(CO)_3]_2$ and those at 1809 and 1894 cm^{-1}, respectively.

When only the ν_{CO} bands at 1809 and 1894 cm^{-1} were evident in the IR spectrum (96 h for the Na^+ salt, 48 h for the PPN^+ salt), photolysis was discontinued and the black product was precipitated from the solution by the addition of pentane and identified by IR spectroscopy and ESMS. The latter exhibits a peak at 1025 Da/e with an isotope pattern consistent with $[CpW(CO)_2(C_{60})]^-$ (Figure 2). Increasing the cone voltage from 10 to 30−50 V resulted in the appearance of a peak at 997 Da/e^- with an isotope distribution consistent with $[CpW(CO)(C_{60})]^-$. Further increasing the cone voltage beyond 50 V resulted in the observation of the peak of $[C_{60}]^-$ at 720 Da/e.

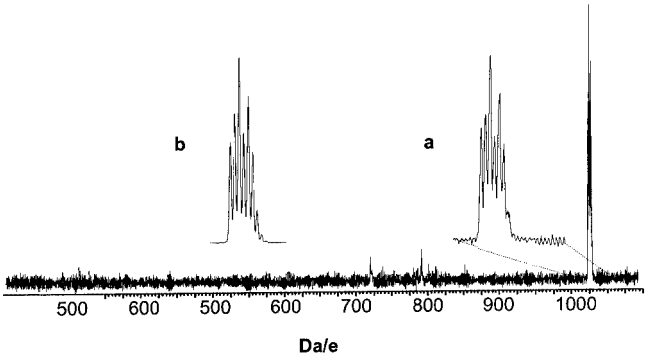

Figure 2. Negative-ion mode ES mass spectrum of $PPN[CpW(CO)_2(C_{60})]$: (a) observed; (b) calculated

Although we could again obtain crystals by layering THF solutions with pentane, the X-ray diffraction pattern generated by the crystals gave insufficient data for a structure solution. However, a ^1H NMR spectrum was obtained (δ_{Cp} = 5.56 in $[D_8]$THF), and confirmation of the elemental composition for $PPN[CpW(CO)_2(C_{60})]$ was provided by high resolution ESMS experiments in which a peak at 1024.9689 Da/e was observed, differing by 11.0 mDa (10.8 ppm) from the theoretical mass of 1024.9799 Da/e.

Thus the photochemical reactions of $PPN[CpW(CO)_3]$ and $PPN[CpW(CO)_3]$ with C_{60} both proceed as in Equations 3−5 and result in the formation of the complexes $PPN[CpM(CO)(C_{60})]$ (M = Mo, W) via a mechanism similar to those found for the manganese and cobalt complexes reported previously.[3b−3d] Given that no $[CpM(CO)_2(C_{60})]^-$ is observed in the thermal reactions, it seems that the rate of metal-centered radical dimerization is considerably higher than the rate of $[C_{60}]^-$ substitution. However, photolysis provides a constant supply of $CpM(CO)_3$ radicals through dimer homolysis, and the apparently irreversible nature of $[C_{60}]^-$ substitution for CO leads to an accumulation of $[CpM(CO)_2(C_{60})]^-$. By further analogy with $PPN[Mn(CO)(C_{60})]$, for which η^2-coordination of the fullerene has been established crystallographically,[3b] we presume that the molybdenum and tungsten complexes should also be formulated as η^2-complexes with the C_{60} coordinated via a [6-6] ring junction, as in Figure 3.

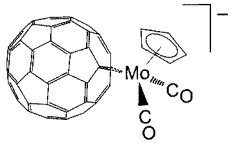

Figure 3. Proposed Structure of the $[CpMo(CO)_2(C_{60})]^-$ anion

Conclusions

Thermal and photochemical reactions of the carbonylate salts $A[(\eta^5\text{-}C_5H_5)M(CO)_n]$ (A = Na, PPN; M = Fe, n = 2; M = Mo, W, n = 3) with C_{60} result in all cases in electron transfer to give $[C_{60}]^-$ and the transient 17-electron, metal-centered radicals $CpFe(CO)_2$ or $CpM(CO)_3$. Subsequent self-coupling of $CpFe(CO)_2$ and $CpM(CO)_3$ then gives the metal-metal bonded dimers $[CpFe(CO)_2]_2$ and $[CpM(CO)_3]_2$. Interestingly, while the mixture of $Na[C_{60}]$ and $[CpFe(CO)_2]_2$ does not react further under photochemical conditions, photolysis of the mixtures of $Na[C_{60}]$ and $[CpM(CO)_3]_2$ ultimately results also in complete homolysis of the dimers and regeneration of the metal-centered radicals, which then combine with the $[C_{60}]^-$ remaining in solution to form the η^2-C_{60} complexes $A[CpM(CO)_2(\eta^2\text{-}C_{60})]$.

Experimental Section

All reactions were carried out using standard Schlenk line techniques or under Vacuum Atmospheres or MBraun glove boxes. Argon and nitrogen were purified by passing over a column of BASF catalyst heated to 140 °C and subsequently over a second column containing 5 Å molecular sieves. Solvents were purified by distillation over a drying agent under a blanket of nitrogen or argon. In most cases Na wire was used as the drying agent, the exceptions being dichloromethane and acetonitrile for which CaH_2 and P_2O_5 were used, respectively.

Infrared (IR) spectra were recorded on a Bruker IFS 25 FTIR spectrometer, and negative ion mode electrospray mass spectrometry (henceforth ESMS)[5] experiments on a VG Quattro spectrometer with nitrogen as the nebulizing gas. Typical concentrations of the species being studied were 1−5 mM, and the capillary voltage, cone voltage, lens parameters, ionization energy and ramp, position of the source, flow rate of the sample and time of acquisition were all varied in order to optimize the intensity of the peak being studied. Low cone voltages <30 V were normally used to observe parent ions in solution, and higher cone voltages (up to 150 V) to observe fragmentation products. High resolution ESMS experiments were carried out on a Micromass Q-TOF-2 quadrupole time-of-flight mass spectrometer. Mass-to-charge ratios reported below refer in all cases to the strongest peak in what are always complex distributions of isotopomers.

^{1}H NMR spectra were recorded on a Bruker AC-200 spectrometer and were referenced internally to the known residual ^{1}H signal in the deuterated solvent relative to TMS. ^{13}C NMR spectra were recorded on a Bruker AM-500 spectrometer, and were internally referenced relative to the solvent resonances. Near-IR spectra in the region 800−1300 nm were run on a Cary 17 UV/Vis spectrophotometer, and UV/Vis spectra in the region 190 nm−820 nm on a HP 8452A Diode Array Spectrophotometer.

Unless explicitly stated otherwise, all chemicals were obtained from Aldrich, Fisher or Strem and were used as received. C_{60} was obtained from MER Corporation. The compounds Na[(η^5-C_5H_5)Fe(CO)$_2$],[6a] Na[(η^5-C_5H_5)Mo(CO)$_3$][6a] and Na[(η^5-C_5H_5)W(CO)$_3$][6a] were prepared as in the literature.

PPN[(η^5-C_5H_5)Fe(CO)$_2$]: This compound was prepared utilizing a modification of a reported procedure.[6b] A solution of [(η^5-C_5H_5)Fe(CO)$_2$]$_2$ (2.0 g) in 30 mL of THF was stirred over 80 g of 1% sodium amalgam for 30 min. The resulting red supernatant was then cannulated into a 250 mL flask and a solution containing an excess of [PPN]Cl in dry CH_3CN was added. The solution was stirred vigorously for 30 min, by which time a white precipitate of NaCl was evident. The solution was separated from the solid by filtration through Celite and the solvent was removed under reduced pressure to give PPN[(η^5-C_5H_5)Fe(CO)$_2$] as a deep red solid.[6b]

PPN[(η^5-C_5H_5)M(CO)$_3$] (M = Mo, W): These compounds were prepared from the corresponding sodium salts as described for the iron analogue except that dichloromethane was used as a solvent for the [PPN]Cl; yellow products were obtained. The products were characterized by ^{1}H NMR and IR spectroscopy. For PPN[(η^5-C_5H_5)Mo(CO)$_3$], ν_{CO} = 1782, 1895 cm^{-1} (CH_2Cl_2).[6a] For PPN[(η^5-C_5H_5)W(CO)$_3$], ν_{CO} = 1775, 1892 cm^{-1} (CH_2Cl_2).[6a]

Thermal Reactions of A[CpFe(CO)$_2$] (A = Na, PPN) with C_{60}: C_{60} (100 mg, 0.14 mmol) was added to a solution of Na[CpFe(CO)$_2$] (0.40 g, 0.14 mmol) in 10 mL of THF. The solution immediately turned a deep red color, and an IR spectrum recorded within 2 min revealed only the ν_{CO} bands of [CpFe(CO)$_2$]$_2$ at 1782 and 1992 cm^{-1}. The reaction was refluxed for 3 h, but no further changes occurred in the carbonyl region. The solution was filtered through Celite, 25 mL of hexanes was added to the filtrate and a black solid precipitated from the red solution. The black solid was filtered and characterized as NaC_{60} on the basis of an absorption at 1078 nm in the NIR[4] and a peak at 720 Da/e in the ES mass spectrum (both THF solutions). Removal of the solvent from the red solution under reduced pressure yielded [CpFe(CO)$_2$]$_2$, identified by IR spectroscopy (1782 and 1992 cm^{-1} in THF). Very similar observations were made with PPN[CpFe(CO)$_2$].

Thermal Reactions of A[CpMo(CO)$_3$] (A = Na, PPN) with C_{60}: A solution of Na[CpMo(CO)$_3$] (37 mg, 0.14 mmol) in 10 mL of THF was treated with C_{60} (100 mg, 0.14 mmol) and the mixture was refluxed. The color of the solution quickly turned deep red and the ν_{CO} bands of [CpMo(CO)$_3$]$^-$ were gradually replaced by those of [CpMo(CO)$_3$]$_2$ (1911, 1956, and 2012 cm^{-1}) over 3 h. ESMS monitoring revealed the presence of a peak at 720 Da/e. After 4 h of refluxing, no further changes to the carbonyl region of the IR spectrum were evident and the solution was filtered. The filtrate was treated with 25 mL of pentane to give a black precipitate of NaC_{60}, identified as above by ESMS and near IR spectroscopy (characteristic peak at 1078 nm[4]). [CpMo(CO)$_3$]$_2$ was recovered by removing solvent from the filtrate under reduced pressure (ν_{CO} 1911, 1956, 2012 cm^{-1}). The compounds PPN[CpMo(CO)$_3$] and A[CpW(CO)$_3$] (A = Na, PPN) reacted similarly.

Photochemical Reactions of A[CpFe(CO)$_2$] (A = Na, PPN) with C_{60}: C_{60} (100 mg, 0.14 mmol) was added to a solution of Na[CpFe(CO)$_2$] (0.40 g, 0.14 mmol) in 10 mL of THF. The solution immediately turned deep red, and an IR spectrum recorded immediately revealed only the ν_{CO} bands of [CpFe(CO)$_2$]$_2$ at 1782 and 1992 cm^{-1}. A Hanovia lamp, placed inside a water-cooled quartz tube, was situated 10−12 cm away from the reaction vessel and the stirred reaction mixture was photolyzed for 96 h. During this time no further changes in the IR occurred while ESMS revealed only a peak at 720 Da/e. Workup procedures were as described above for the thermal reactions, and again yielded only NaC_{60} and [CpFe(CO)$_2$]$_2$. Similar results were obtained with PPN[CpFe(CO)$_2$].

Photochemical Reactions of A[CpMo(CO)$_3$] (A = Na, PPN) with C_{60}. Syntheses of A[CpMo(CO)$_3$(η^2-C_{60})]: A solution of Na[CpMo(CO)$_3$] (37 mg, 0.14 mmol) in 10 mL THF was treated with C_{60} (100 mg, 0.14 mmol) and the mixture was photolyzed as above. The solution quickly turned deep red, and the ν_{CO} bands of Na[CpMo(CO)$_3$] decreased over 3 h as ν_{CO} bands at 1818, 1900, 1911, 1956, and 2012 cm^{-1} appeared and gained in intensity. On further photolysis, the solution turned brown as the ν_{CO} bands at 1818 and 1900 cm^{-1} continued to gain intensity while those at 1911, 1956, and 2012 cm^{-1}, attributable to [CpMo(CO)$_3$]$_2$, decreased. ESMS monitoring of the solution revealed peaks at 720 and 937 Da/e which increased in intensity over the first 3 hours, but the latter thereafter gained intensity at the expense of the former. Increasing the cone voltage in any ESMS experiment resulted in a loss of intensity from the peak at 937 Da/e$^-$, an increase in the intensity of the peak at 720 Da/e and the appearance of a new peak 909 Da/e. The reaction was halted after 96 h, the solution was then filtered through Celite and pentane was added to the now green filtrate to precipitate Na[CpMo(CO)$_2$(η^2-C_{60})]. This was washed with pentane and dried under reduced pressure; yield 77 mg (58%). The compound was characterized by IR spectroscopy (ν_{CO} 1818, 1900 cm^{-1} in THF) and ESMS (937 Da/e, THF).

The synthesis of PPN[CpMo(CO)$_3$(η^2-C_{60})] proceeded similarly and was carried out several times; it was typically finished within 36 h to give amber-green solutions of the product in 70−90% isolated yield (140−180 mg). PPN[CpMo(CO)$_2$(η^2-C_{60})] was characterized by ESMS (939 Da/e) as well as IR (ν_{CO} 1818, 1900 cm^{-1}), ^{1}H NMR (δ_{Cp} = 5.65 in [D$_8$]THF) and ^{13}C NMR spectroscopy (Table 1; in [D$_8$]THF). The near IR spectrum (THF) exhibited no absorptions between 800 and 1400 nm, but the UV/Vis spectrum (THF) exhibited absorptions at 336, 400−600 (broad band) and 583 nm. While crystals of this compound were obtained by layering THF solutions with hexanes, they did not give useful elemental analyses and were not of sufficient quality for X-ray crystallographic analysis. However the anion was characterized unambiguously by high resolution ESMS; 938.9491 Da/e; calc. 938.9344; difference 15.7 ppm.

Photochemical Reactions of A[CpW(CO)$_3$] (A = Na, PPN) with C_{60}. Syntheses of A[CpW(CO)$_3$(η^2-C_{60})]: These reactions were carried out as described for the molybdenum analogues and proceeded similarly. Combining Na[CpW(CO)$_3$] with C_{60} resulted in the formation of a red solution, loss of intensities of the ν_{CO} bands of Na[CpW(CO)$_3$] (1744, 1793 and 1895 cm^{-1}) over 3 h and appearance of ν_{CO} bands at 1809, 1894, 1904, 1953, and 2010 cm^{-1}. On further photolysis, the ν_{CO} bands at 1809 and 1894 cm^{-1}, attributed to [CpW(CO)$_2$(η^2-C_{60})]$^-$, continued to gain intensity while the ν_{CO} bands (of [CpW(CO)$_3$]$_2$) at 1904, 1953, and 2010 cm^{-1} grew weaker. ESMS monitoring of the reaction revealed peaks at 720 Da/e and 1025 Da/e which increased in intensity over the first

3 h, at which point that at 720 Da/e began to lose intensity in favor of the peak at 1025 Da/e, attributed to $[CpW(CO)_2(\eta^2\text{-}C_{60})]^-$. The reaction was stopped after 96 h, and the solution was then filtered through Celite and worked up as above to give 67 mg of $Na[CpW(CO)_2(\eta^2\text{-}C_{60})]$ (46% yield).

A similar procedure was used to synthesize $PPN[CpW(CO)_2(\eta^2\text{-}C_{60})]$ from $PPN[CpW(CO)_3]$ in yields ranging from 141−198 mg (65−91%). The product was characterized using IR (ν_{CO} 1809, 1894 cm^{-1}), ^1H NMR (δ = 5.56 ppm in $[D_8]$THF) and near IR (no absorptions in the region 800−1400 nm) spectroscopy and ESMS (1025 Da/e). Although crystals were obtained by layering THF solutions with hexanes, they did not give useful elemental analyses and were not of sufficient quality for X-ray crystallographic analysis. Therefore the anion was characterized unambiguously as such by high resolution ESMS: 1024.9689 Da/e; calcd. 1024.9799; difference 10.8 ppm.

Acknowledgments

We thank the Natural Sciences and Engineering Research Council for a Research Grant to MCB and a Graduate Fellowship to DMT, and ALCAN for a Graduate Fellowship to DMT. We also thank Prof. J. A. Stone, Mr. T. Hunter and Dr. I. Galetich for assistance with the mass spectrometry measurements.

A New Highly Active Diphosphane-Palladium(II) Complex as a Catalyst Precursor for the Heck Reaction

Elucidation of the Solution Structures of Transition Metal Complex Ion Pairs by NOE NMR Experiments

Alceo Macchioni[a]

Keywords: Ion pairs / NMR spectroscopy / Transition metals

Our results from structural investigations of transition metal complex ion pairs in solution by homonuclear and heteronuclear 1D- and 2D-NOE NMR spectroscopy are reviewed. Both model (**A**) and catalytically active (**B**) complexes have been taken into account; their general formulas are: *trans*-$[ML_2(N,X)(Y)(Z)]^+A^-$ (**A**) {M = Fe^{II}, Ru^{II} and Os^{II}, L = PMe_3, Y = CO, Z = COMe, A^- = BPh_3R^-, $CF_3SO_3^-$, BF_4^-, PF_6^- and $B[3,5\text{-}(CF_3)_2C_6H_3]_4^-$; M = Ir^{III}, L = PR_3, Y = Z = H and A^- = BPh_4^-, $CF_3SO_3^-$, BF_4^-, PF_6^-} and $[M'(N,X)(R,olefin)]^+A^-$ (**B**) {M′ = Pt, R = Me, olefin = ethene, propene and CH_2=CHCOOMe, A^- = BF_4^-; M′ = Pd, (R,olefin) = η^1,η^2-5-methoxycyclooctenyl, A^- = BPh_4^-, $CF_3SO_3^-$, BF_4^-, PF_6^-, SbF_6^- and $B[3,5\text{-}(CF_3)_2C_6H_3]_4^-$}, where N,X = bis(pyrazolyl)methane, bipyridine, α-diimines, α-diamines or α-oxo imines. The detection of dipolar interionic interactions in ^{1}H-NOESY and ^{19}F,^{1}H-HOESY NMR spectra allowed relative anion-cation orientations to be determined, these being well defined in most cases, with one orientation predominating in solution. We often found that the anion approaches the complexes from the side of the N,X-ligands, due to an accumulation of positive charge at the junction of the moieties containing the N- and X-donor atoms. In square-planar complexes **B**, the apparently favoured apical positions were often protected either by electronic factors [N,X = bis(2-pyridyl)amine or bis(pyrazolyl)methane] or by a combination of electronic and steric factors (N,X = α-diimines). For M′ complexes, bearing Ar–N=C(Me)–C(Me)=N–Ar ligands, the position of the counter-anion is finely modulated by the steric hindrance of the *ortho*-aryl substituents. The accessibility of the metal centre, which is directly associated with the catalytic performances of the complexes, was determined by using the counter-anion as a probe. Finally, average interionic distances were estimated for model complexes **A**, bearing unsymmetrical BPh_3R^- counter-anions, based on the quantification of interionic NOEs.

(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2003)

1 Introduction

Several stoichiometric and catalytic reactions mediated by cationic transition metal complexes are strongly affected by the phenomenon of ion-pairing. In most cases the counter-anion effect is carried out through competition with the substrate for coordination to the metal ion; consequently, in terms of reaction rate and yield, better results are obtained when less strongly coordinating anions are used.[1] As an example, Evans et al.[2] showed in 1995 that the degree and rate of conversion of the Diels−Alder reaction between methacrolein and cyclopentadiene, catalysed by dicationic Cu^{II} compounds bearing bis(oxazoline) ligands, was significantly affected by the nature of the counter-anion, and that higher performances were obtained with use

Alceo Macchioni was born in Città della Pieve, Italy, in 1963. He obtained his "Laurea" in Chemistry from the University of Perugia in 1988. He received his Ph.D. degree in Chemistry in 1992 from the same university under the supervision of Giuseppe Cardaci. After a postdoctoral stay (November 1992 until February 1995) with Paul S. Pregosin and Luigi M. Venanzi, Zürich, Switzerland, he returned to Italy as a Researcher at the University of Perugia. In April 2001 he obtained the "Idoneità" to be Associate Professor in General and Inorganic Chemistry. He has recently received the "Raffaello Nasini" prize from the Inorganic Division of the Italian Chemical Society. His main research interests are the synthesis and characterization of ruthenium and palladium complexes and their application in homogeneous catalysis, with particular attention to the role of noncovalent interactions in their structure and reactivity in solution.

MICROREVIEWS: This feature introduces the readers to the authors' research through a concise overview of the selected topic. Reference to important work from others in the field is included.

of the least strongly coordinating anion (SbF_6^-) of those tested. Kündig et al. found a similar counter-anion influence[3] in the same reaction with catalysis by monocationic Ru^{II} compounds.

Consequently, new types of anions have been engineered in order to diminish their coordinating power. The strategy of introducing large and highly fluorinated moieties, or electron-withdrawing substituents in general, into the counter-anions has often been used to achieve this goal.[4,5]

In some cases the anion plays a direct role in the stoichiometric and catalytic processes.[6−8] RajanBabu et al.,[9] for instance, showed the synergistic effect of hemilabile coordination and the counter-anion effect in hydrovinylation catalysed by cationic Ni^{II} compounds. Faita et al.[10] found that the enantioselectivity of a reaction could be inverted by use of a suitable counter-anion, while Marks and Chen[11] suggested that ion-pairing affects the stereochemistry of propylene chain formation during single-site olefin polymerization. Finally, Arndtsen et al.[12] showed that the use of chiral counter-anions[13] may provide a novel method for inducing enantioselectivity.

It seems clear from the examples reported above that the ion-pairing phenomenon has an established relevance in transition metal chemistry. Until seven years ago, however, there had been no detailed investigations into the structures of transition metal complex ion pairs in solution; that is, the environment in which they "work". Very little was known about the relative anion-cation orientation and, consequently, of the possibility of having one or more favoured points of anchorage for the two ionic moieties. A few structural studies in solution, concerning organolithium[14,15] and organoammonium[16] ion pairs, appeared in the literature after the mid 1980s. They were based on Nuclear Overhauser Effect (NOE) NMR spectroscopy; that is, on the detection of inter-ionic dipolar interactions[17] between the atoms of the cations (lithium or hydrogen) and those of the anions (hydrogen or fluorine).

Our laboratory decided to investigate transition metal complex ion pairs by application of 1D- and 2D-NOE NMR spectroscopy (both homonuclear and heteronuclear). We began by developing appropriate methodologies on "model" systems. We then considered transition metal complexes with structures or reactivities that were affected by the nature of the counter-anion, in the hope of obtaining a better understanding of the role of anion-cation interactions and, possibly, of correlating them with the reactivity of the complexes. During the course of our studies we realized that the detection of anion-cation interactions can afford precious information about the electron density distribution around the metal ion. In particular, the accessibility of the metal centre in square-planar complexes for a generic nucleophile can be accurately determined by assuming that the anion is a good probe.

The main results of our studies to date are reviewed here. After an examination of some basic aspects of NOE theory essential for facilitating the reading of this paper, the results of qualitative NOE NMR investigations and the consequent interionic structures are reported for compounds grouped according to the geometry of the metal centre. When the analysed complexes are active catalysts, the connections between the interionic interactions and the catalytic performances are outlined. The last paragraph illustrates the results of quantitative NOE measurements, which have allowed average interionic distances to be estimated.

2 NOE and Suitable Systems for Investigation

In an ideal two-spin (I = 1/2) system, the NOE, defined as the fractional change in the intensity of one nucleus (I) on perturbation of the nucleus (S), dipolar coupled to it, is related to the cross-relaxation rate constant (σ_{IS}) and the dipolar longitudinal relaxation rate constant (ρ_{IS}) according to Equation (1),[18] where I^0 is the equilibrium intensity of I, and γ_S and γ_I are the giromagnetic ratios;[19] σ_{IS} can be related to the molecular tumbling rate by Equation (2), where μ_0 is the permeability constant in a vacuum, $\hbar$ is Planck's constant divided by 2π, τ_c is the rotational correlation time, and ω_I and ω_S are the resonance frequencies of the I and S nuclei, respectively.

$$NOE = f_I\{S\} = \frac{(I - I^0)}{I^0} = \frac{\gamma_S}{\gamma_I}\frac{\sigma_{IS}}{\rho_{IS}} \quad (1)$$

$$\sigma_{IS} = \frac{1}{10}\left[\left(\frac{\mu_0}{4\pi}\right)\hbar\gamma_I\gamma_S r_{IS}^{-3}\right]^2 \tau_c\left[\frac{6}{1+(\omega_I+\omega_S)^2\tau_c^2} - \frac{1}{1+(\omega_I-\omega_S)^2\tau_c^2}\right] \quad (2)$$

When small molecules in nonviscous solvents are considered (as in all our cases) the *extreme narrowing limit* approximation is reached. In such a situation $\omega_{I(or\ S)}\tau_c << 1$ and, consequently, σ_{IS} simply depends on τ_c and r_{IS} according to Equation (3).

$$\sigma_{IS} \propto \tau_c r_{IS}^{-6} \quad (3)$$

Because σ_{IS} is related to the internuclear distance (r_{IS}), the NOE is often *qualitatively* used to obtain information about the proximity of the I and S nuclei.

By considering Equation (4) (where I_z is the macroscopic longitudinal magnetization due to I, and τ_m is the mixing time[20]), σ_{IS} can be *quantitatively* derived (a) by limiting attention to the linear build-up of the I enhancement for short mixing times ($\tau_m \rightarrow 0$), or (b) by measuring the complete kinetics of NOE build-up and fitting the experimental data with the theoretical Equations derived from integration of Equation (4), in which the proportionality constant between $dI_z/d\tau_m$ and σ_{IS} depends on the type of NOE NMR experiment.[21]

$$\left.\frac{dI_z}{d\tau_m}\right|_{\tau_m=0} \propto \sigma_{IS} \quad (4)$$

By comparison of σ_{IS} with that relative to two nuclei (A and B) of known internuclear distance (r_{AB} = calibration or reference distance), an estimation of r_{IS} can be obtained by Equation (5), if it is assumed that the proportionality constant between σ and r^{-6} is the same for the two couples of nuclei (IS and AB); this condition is satisfied when the rotational correlation times (τ_c), the other variable on which σ depends, of the I-S and A-B vectors are the same.

$$\frac{\sigma_{IS}}{\sigma_{AB}} = \left(\frac{r_{IS}}{r_{AB}}\right)^{-6} \quad (5)$$

The essential features of NOE illustrated above should be sufficient for understanding of which systems can be successfully investigated and what precautions must be taken. Some obvious requirements for the systems are: (1) the presence of NMR-active nuclei with high receptivity (H or F) in both ionic moieties, and (2) the presence of magnetically nonequivalent nuclei, spatially dispersed around the ionic moieties, that will make it possible to discriminate different anion-cation orientations. Protons or fluorine atoms are frequently present in cationic moieties bearing the transition metal ion and in its usual counter-anions, and condition (1) is respected. Requirement (2) is often satisfied by the transition metal cation but rarely by its counter-anion.

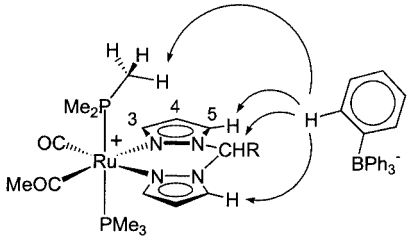
NOEs strongly decrease with increasing r_{IS}. As a consequence, NOEs can be observed only if the internuclear distances are shorter than ca. 5 Å, thereby introducing the apparent limitation that only intimate ion pairs can be structurally investigated. However, this is only an apparent limitation, because, if we are interested in studying systems in which ion-pairing affects the reactivity, an acceptable percentage of intimate ion pairs have to be present. A real limitation, however, is that when a quantitative analysis is carried out, the correlation times of the reference and distances of interest must be the same. In fact, the reference distance must refer to a pair of nuclei belonging to the cation or the anion (intramolecular distance), while the distances that we want to estimate are between the nuclei of the cation and those of the anion (interionic distances). Their correlation times are not necessarily the same and have to be determined in order to verify that the interionic distances are reasonably accurate. These last are inevitably average distances, because of the presence of several motions in ionic compounds: (1) overall rotation of ion pairs and/or ions constituting them, (2) ion pair dissociation and formation, and (3) internal motions (Me group rotations around single bonds and chair-boat inversion of the six-member cycles etc.). Although these motions could affect both τ_c and r_{IS}, it has been found[22] that the distances calculated from the observed σ by assuming rigid isotropic motion are not often in error by more than about 10%.

3 Qualitative NMR Investigations

The results illustrated in this section derive from NOESY and HOESY NMR studies carried out in deuterated solvents with low dielectric constants ([D_2]dichloromethane: ε = 8.93 at 298 K; [D]chloroform: ε = 4.81 at 293 K) for 10^{-2}–10^{-1} M solutions. Under such conditions, compounds are mainly present in solution as intimate ion pairs.[23] The interionic NOEs observed in the spectra were classified as strong, medium and weak. Consequently, the relative anion-cation orientation is qualitatively, or perhaps better semiquantitatively, deduced by means of simple triangulations. Most of the complexes considered in this paper were synthesized in our laboratory. Nevertheless, the synthetic procedures are not illustrated here, but can be found in the quoted references.

3.1 Octahedral Iron(II), Ruthenium(II), Osmium(II) and Iridium(III) Complex Ion Pairs

The interionic structure of *trans*-[Ru(COMe)-{(pz_2)CHR}(CO)(PMe_3)$_2$]BPh_4 (R = H or pz; pz = pyrazol-1-yl ring) in [D_2]dichloromethane was investigated first.[24,25] The interionic contacts, between the *ortho*-protons of the anion and the 5- and CHR protons (medium) of the cation and the phosphane protons (weak) observed in the ^{1}H-NOESY NMR spectra, and the absence of interactions with the COMe protons, allowed us to conclude that the anion is specifically located close to the bis(pyrazolyl) ligand (Scheme 1).



Scheme 1

The same relative anion-cation orientation was found (a) by ^{19}F,^{1}H-HOESY NMR studies with fluorinated counterions (BF_4^-, PF_6^- and $CF_3SO_3^-$) (Figure 1), (b) for isoelectronic and isostructural iron(II) and osmium(II)[26] complexes, and (c) for similar ruthenium(II) complexes containing neutral N,O-ligands.[27] An explanation of the observed specific localization of the anion with respect to the cation was found with the help of quantum mechanical and mechanical docking calculations.[28] There is, in fact, an accumulation of positive charge at the −CHR carbon atom, while the negative charge is concentrated on the oxygen atom of the COMe group. The ion pair with the counteranion on the side of the pyrazolyl rings is consequently dictated by a gain in the electrostatic interaction energy. When BPh_4^- is taken into account, the observed relative anion-cation position is further stabilized by the favourable lipophilic interactions between the phenyl groups of the anion and the pyrazolyl rings. Very interesting studies carried out by Schneider and co-workers on organic ion pairs in water[29,30] show that π-stacking interactions give the ion pairs additional stabilization of about 2 kJ/mol for every

phenyl moiety. In our complexes, we found that two phenyl groups of BPh_4^- are oriented in such a way that they are almost parallel to the two pyrazolyl rings, as illustrated in Scheme 2 for *cis*-[Ru(COMe){$(pz_2)CH_2$}$(CO)_2(PMe_3)$]-BPh_4.[28]

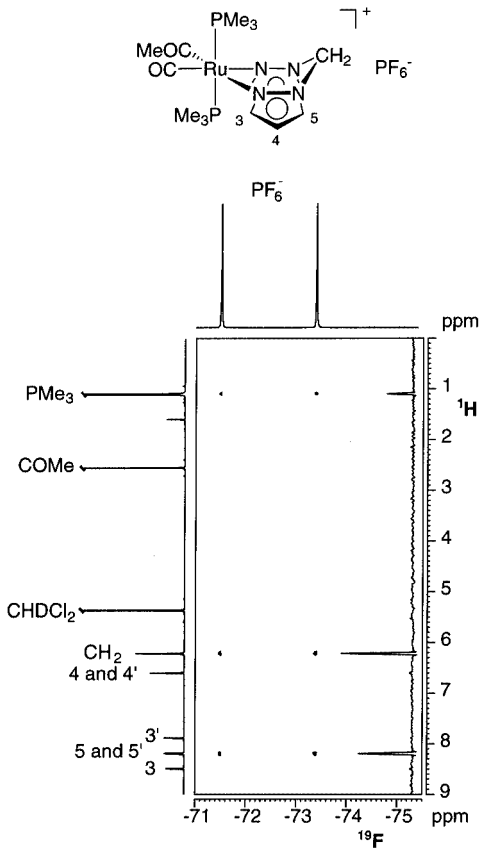


Figure 1. ^{19}F, ^1H-HOESY NMR spectrum of the *trans*-[Ru(COMe){$(pz_2)CH_2$}$(CO)(PMe_3)_2$]PF_6 complex, showing the heteronuclear interionic contacts of PF_6^- with CH_2, H5/H5′ and PMe_3 protons; the F1 trace (indirect dimension) relative to one component of the fluorine doublet is reported on the right (376.65 MHz, 298 K, [D_2]dichloromethane, τ_m = 0.8 s); reproduced from ref.[37] with the permission of the American Chemical Society

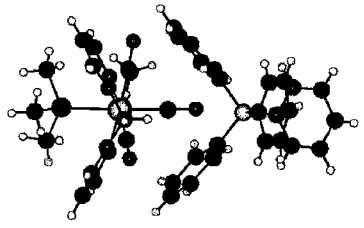

Scheme 2. Reproduced from ref.[28] with the permission of the American Chemical Society

According to Schneider this should give rise to a consequent energy gain of about 4 kJ/mol, which could compensate for the reduction of favourable Coulomb interaction due to an increase in the average anion-cation distance on going from BF_4^- or PF_6^- to BPh_4^-. Studies in more polar solvents (acetone, methanol and nitromethane) indicated that the same interionic structure is maintained but the anion-cation dipolar interactions are more difficult to detect because the increased solvent polarity decreases the percentage of intimate ion pairs. The effect of increasing the polarity of the solvent is also mimed by the reduction of the coordinating property of the counter-anion when, for instance, the poorly coordinating B[3,5-$(CF_3)_2(C_6H_3)$]$_4^-$ counter-ion is used. Very weak interionic contacts were observed for *trans*-[Ru(COMe){$(pz_2)CH_2$}$(CO)(PMe_3)_2$]B[3,5-$(CF_3)_2C_6H_3]_4$ complex in [D_2]dichloromethane, while interionic interactions of acceptable intensity between the fluorine atoms of the counter-anion and the "usual" protons of the cation in [D]chloroform were visible in the ^{19}F,^1H-HOESY NMR spectra.

Interestingly, results from NOE and Pulsed-Field Gradient Spin-Echo (PGSE)[31−34] NMR experiments in [D]chloroform for analogous complexes bearing the more coordinating BPh_4^- anion indicated that the same anion-cation orientation is present, but that aggregates higher than ion pairs form at elevated concentrations in solution.[35]

With the aim of obtaining even more detailed information about anion-cation orientation in solution, *trans*-[Ru(COMe){$(pz_2)CH_2$}$(CO)(PMe_3)_2$]BPh_3R (R = Me, *n*Bu and *n*Hex) compounds, with unsymmetrical counter-anions, were synthesized and investigated.[36,37] The results obtained corresponded to our expectations: the counter-anion is located in the same position, but it orients the aliphatic chain far from the cationic organometallic moiety. By assuming this orientation, the anion maximizes the favourable lipophilic interactions allowing two π-stackings with the energetic gain mentioned above.

The possibility that the high specificity in the anion-cation interactions could be confined to the presence of N-aromatic ligands was excluded by synthesis and investigation of analogous ruthenium(II) compounds bearing α-diimines or substituted ethylenediamines.[38] A section of the ^1H-NOESY NMR spectra, relating to the simplest compound taken into account, is reported in Figure 2, and shows interionic interactions between the anion and the protons of the ethylenediamine, the intensity decreasing on moving from NH_2^d to NH_2^a. In the absence of conjugation, the anion is not only still located close to the N,N-ligand, but it even prefers the N-arm *trans* to the COMe group, where the electron density is less, due to the high *trans* influence of COMe. The introduction of steric hindrance in the N,N-ligand (by use of $NRHCH_2CH_2NR'H$ ligands) affords a fine modulation of the anion position that shifts toward less crowded "places". For example, when R = R′ = $CH_2C_6H_5$ (bz), two stereoisomers are present, depending on the orientation of the bz groups with respect to the phosphanes. In the stereoisomer with the two bz groups oriented toward the same phosphane, the anion stays close to the N,N-ligand but preferentially interacts with the protons of the other phosphane group.

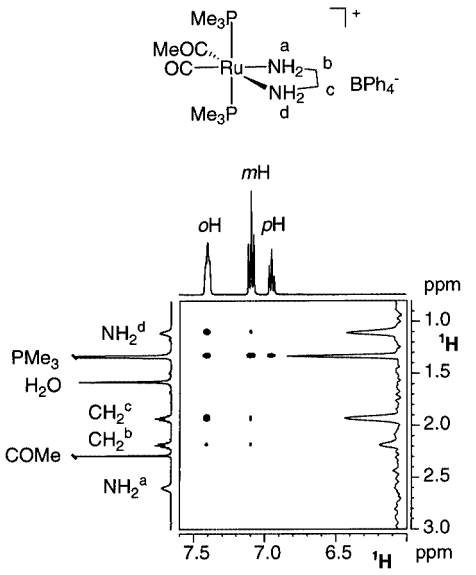

Figure 2. A section of the ^{1}H-NOESY NMR spectrum of the illustrated complex, showing the gradual decrease of the interionic contact intensity on passing from positions d to a; the 1D trace relative to the *ortho*-proton column is reported on the right (400.13 MHz, 298 K, [D_2]dichloromethane, τ_m = 0.8 s)

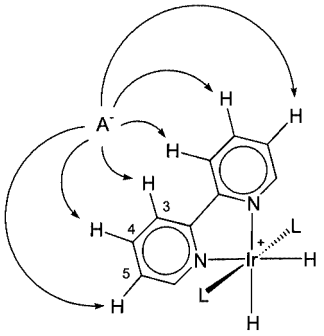
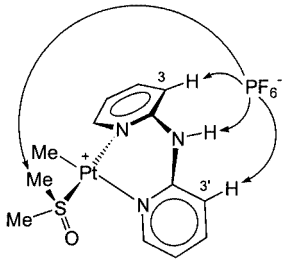
Inspection of *cis,trans*-[Ir(bipy)H_2($PRPh_2$)$_2$]A complex ion pairs (A^- = PF_6^-, BF_4^-, $CF_3SO_3^-$ and BPh_4^-; R = Me and Ph) afforded other hints about the tendency of the anion to stay close to N,N-ligands.[39] In such complexes, the anion would have the apparently favourable possibility to bind near the MH_2 group, which would give the closest M−anion distance and allow hydrogen bonding.[40] Instead, the anion is specifically located near to the bipy ligand interacting with the 3- (strong), 4- (medium), 5- (weak) and phosphane protons (Scheme 3); the interaction specificity falls off with increasing anion size. Calculations identify the predominant location of the positive charge at the bipyridyl ring carbon atoms that take part in the interring C−C bond. The electrostatic potential calculated for the cation confirms the location of the preferred binding site. Pregosin et al.[41] recently reported specific anion-cation interactions in similar dihydridoiridium(II) complexes.



Scheme 3

3.2 Square-Planar Platinum(II) and Palladium(II) Complex Ion Pairs

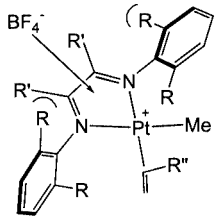
In the case of ionic square-planar complexes, the determination of the relative anion-cation position might appear to be trivial because of the apparently favoured option for the anion to approach the organometallic moiety from the apical positions. In our studies we soon realized that the apical positions are usually protected both by electronic and by steric properties of the coordinated ligands. The first square-planar complex that we investigated[42] was [PtMe(dpa)(Me_2SO)]PF_6 [where dpa = bis(2-pyridyl)amine], and we found that the anion is located in the periphery of the N,N-ligand, close to the amine NH-proton. The ^{19}F,^{1}H-HOESY NMR spectra showed only selective interionic interactions between the fluorine nuclei and the bridging NH (strong), 3- and 3′- (strong) and DMSO (very weak) protons (Scheme 4).



Scheme 4

The most reasonable explanation of this observation is the formation of NH···FPF_5^- hydrogen bonds, providing electronic protection of the metal centre.

Access to the metal centre can also be denied by a synergistic effect between electrostatic attraction and the introduction of suitable steric hindrance in the apical positions. This was made evident in an investigation of the interionic structures of [PtMe(η^2-olefin)(α-diimines)]BF_4 complexes[43] {where α-diimines = [2,6-$(R)_2$-C_6H_3]N=C(R′)-C(R′)=N[2,6-$(R)_2$-C_6H_3], R = H, Me, Et and *i*Pr, R′ = H and Me, olefin = CH_2=CHR′′ with R′′ = H, Me and COOMe}. In these complex ion pairs, the anion is located on the side of the diimine ligands, but accessibility of the metal centre for it is finely modulated by the steric hindrance of the R and R′′ groups (Scheme 5) which protect the apical positions.[44]



Scheme 5

When R′′ = Me and R ≥ Et, the anion is completely trapped between the R and R′ substituents and does not interact with any olefin or Me protons. For R′′ = Me and R = H and Me, weak interionic NOEs between fluorine nuclei of the anion and olefin and Me protons are visible in the $^{19}F,^{1}H$-HOESY NMR spectra (Figure 3). Interestingly, in agreement with our findings for these platinum(II) complexes and our calculations on octahedral complexes, Tilset et al. showed[45] by DFT calculations that the association of solvent molecules such as H_2O or TFE (trifluoroethanol) to the cationic square-planar σ-complex [(α-diimine)PtMe(CH_4)]$^+$ occurs at the C−C diimine bond where the positive charge accumulates.

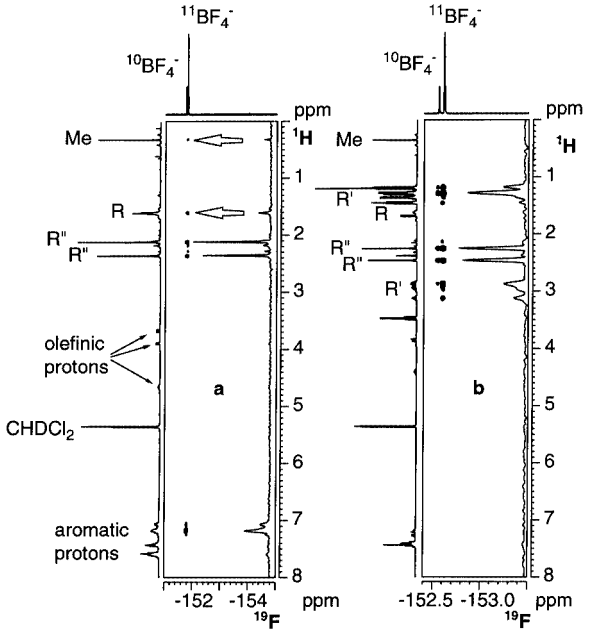


Figure 3. The two ^{19}F, ^{1}H-HOESY NMR spectra (376.65 MHz, 298 K, [D_2]dichloromethane, τ_m = 0.8 s) show the disappearance of interionic interactions between BF_4^- and Me−Pt and R′′ (indicated with arrows) on going from R = H (a) to R = *i*Pr (b); the F1 trace (indirect dimension) relative to one component of the fluorine doublet is reported on the right of every spectrum

The complexes illustrated in Scheme 5 were studied because they are analogous to nickel(II) and palladium(II) compounds that have been established to be the catalytic resting state of olefin polymerization[46,47] and for which R substituents have been found to affect their catalytic activity.[48,49] Bulky substituents block the axial coordination sites and consequently slow the chain-transfer rate relative to propagation, resulting in the formation of polymers with higher molecular weights. Our results confirm the protection of the axial coordination sites exerted by R groups but they also allow the steric hindrance necessary to afford complete protection to be directly evaluated, if it is assumed that BF_4^- is a good nucleophilic probe.

In the absence of specific F···H interactions and/or steric protection, the two axial positions are preferred and equally populated by the counter-anion. As an example, in [Pd(η^1,η^2-C_8H_{12}OMe)(bipy)]A complexes {where bipy = 2,2′-bipyridine and A$^-$ = BPh_4^-, $CF_3SO_3^-$, BF_4^-, PF_6^-, SbF_6^- and B[3,5-$(CF_3)_2C_6H_3]_4^-$} the anion occupies the axial positions even if it slightly prefers to locate close to the bipy ligand and, in particular, close to the N-arm *trans* to the Pd−C σ-bond (Figure 4).[50] This anion-cation relative orientation is always observed independently of the nature of the counter-anions; instead the intensity of the interionic NOEs decreases with decreasing coordinating tendency of the anion: $CF_3SO_3^-$ > BF_4^- > PF_6^- > B[3,5-$(CF_3)_2C_6H_3]_4^-$.

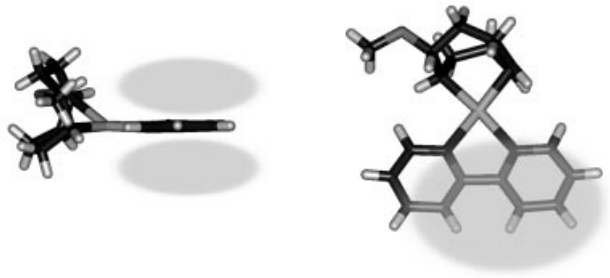

Figure 4. Two views of the solution interionic structure of [Pd(η^1,η^2-C_8H_{12}OMe)(bipy)]A complexes, in which the gray clouds represent the action space of the A$^-$ counter-anion; the two positions above and below the coordination plane are equally populated, and the anion is shifted on the side of bipy ligand with a slight preference for the ring *trans* to the Pd−C σ-bond

It is known that complexes [Pd(η^1,η^2-C_8H_{12}OMe)(bipy)]A are good catalysts for alternating CO/styrene co-polymerization carried out under mild conditions[51] and that the A$^-$ counter-anion strongly affects the catalytic performances.[50] Higher catalytic efficiency is obtained by use of less strongly coordinating anions: that is, those showing weaker interionic interactions. The persistence of the same anion-cation orientation on changing the anion features (size and electron density distribution) and the correlation between the catalytic performances of the complexes with the noncoordinating power of the anion, clearly indicate that the anion competes with the substrates for coordination to the metal ion. Interestingly, the interionic solid-state structure is different from that observed in solution. In fact, due to the stack between two cation moieties, in the solid state the counter-anions are located sideways surrounding the coordination plane (Figure 5).

The substitution of bipy with the nonplanar $(pz_2)CH_2$ ligand results in a very specific localization of the counter-anion (PF_6^-), far from the apical positions and close to the CH_2 moiety of the N,N-ligand.[52] Because of the small axial steric hindrance introduced by the $(pz_2)CH_2$ ligand, the reason for such an unexpected specificity has to be sought in the formation of $^-F_5P-F\cdots H_2C(pz_2)$ weak interactions. As a confirmation, analogous five-coordinated palladium complexes [Pd(η^1,η^2-C_8H_{12}OMe)(pz_3)CH)]PF_6 showed a remarkable specificity of interaction between the counter-ion and the (pz_3)CH and 5′/5′′′-protons (Figure 6) in solution; in the solid state, H-bonding between the highly polarized (pz_3)CH proton and fluorine lone pairs (3.16−3.20 Å) gives rise to a sort of anion-cation recognition.[52]

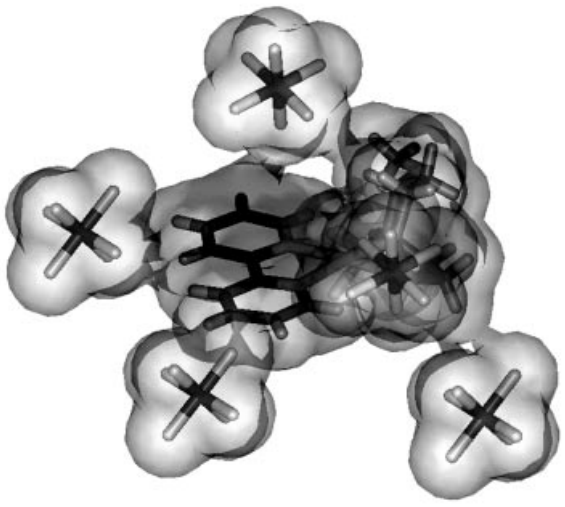

Figure 5. Solid-state structure of [Pd(η^1,η^2-C_8H_{12}OMe)(bipy)]PF_6, showing one cationic moiety surrounded by five counter-anions lying in the periphery of the coordination plane leaving the apical positions free; the van der Waals surface is also shown

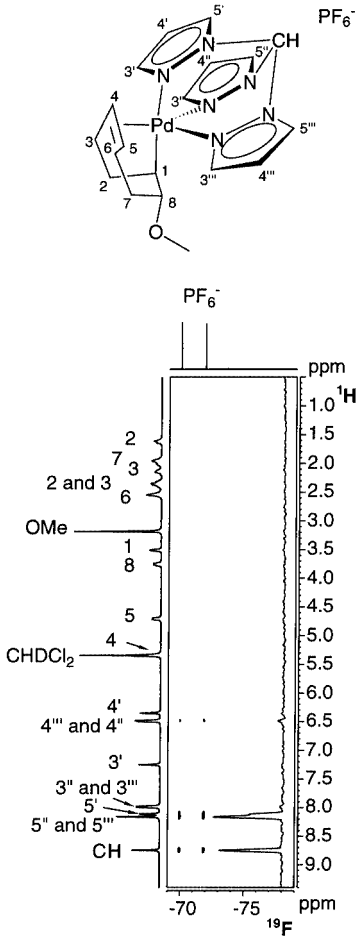

Figure 6. ^{19}F, ^1H-HOESY NMR spectrum (376.65 MHz, 188 K, [D_2]dichloromethane, τ_m = 0.8 s) of [Pd(η^1,η^2-C_8H_{12}OMe)-{(pz_3)CH}]PF_6 recorded showing the remarkable specificity of interaction between PF_6^- and the 5′-5′′′ and 4′-4′′′ (very weak) protons of the cation; the 1D-trace relative to the PF_6^- column is reported on the right; reproduced from ref.[52] with the permission of the American Chemical Society

The introduction of more hindered substituents, such as α-diimines {[2,6-$(R)_2$-C_6H_3]N=C(R′)-C(R′)=N[2,6-$(R)_2$-C_6H_3] where R = H, Me, Et and *i*Pr, R′$_2$ = Me_2 and An}, the steric contribution of which in the axial positions is easily tuned, afforded results similar to those found for the platinum complexes discussed above.[53] Two new pieces of information were produced: a) for R′$_2$ = Me_2, complete steric protection of the metal centre already occurs with R = Me, and b) for R′$_2$ = An (9-Anthryl) and R′ = *i*Pr, nonspecific interionic structure was observed. The first point indicates that the steric hindrance in the axial positions was additive over all the ligands coordinated to the metal ion. Consequently, when there is a methoxycyclooctenyl moiety as well as the α-diimine ligand, it is sufficient that R = Me to protect the metal centre completely. As a confirmation, in the case of platinum complexes shown in Scheme 5, complete protection occurs for R′′ = Me and R = Et but not for R′′ = H and R = Et. Point b) allows even more interesting deductions. In fact, the substitution of the two R′ methyl groups with the An moiety[54] has the effect of dispersing the positive charge on the side of the N,N-ligand or of making it difficult to approach. Consequently, the anion no longer has its "anchorage" point and it interacts with several protons, including those belonging to the methoxycyclooctenyl moiety. One implication is that steric protection alone does not guarantee a specific interionic structure, but that, if for electronic reasons, the latter is present, modulation of the introduced steric hindrance finely determines the relative anion-cation position. This point may have interesting connections with the catalytic performances of [PdMe(η^2-olefin)(α-diimines)]A complexes toward olefin polymerization. From the literature, it is known that the molecular weights of the obtained polymers increase in the following order: R′ = Me > An > H.[47] It seems reasonable that, when R′ = H, the reduced steric protection deriving from the less restricted rotation around the N−C(*ipso*) bond favours the chain-transfer process, with polymers of lower molecular weight consequently being obtained. The reason why higher polymers are obtained with R′ = Me relative to R′ = An, however, is not obvious. Our results indicate that, in complexes in which R groups are the same, there is a greater dispersion of the positive charge for R′ = An than for R′ = Me. It could be that, in the latter case, the association of olefin is slowed by its favourable interaction with the C−C diimine carbon atoms, affording a sort of added electronic protection of the axial coordination sites and reducing the chain-transfer process rate.

All [Pd(η^1,η^2-C_8H_{12}OMe)(N,N)]A complexes are active catalysts for the CO/*p*-methylstyrene alternating copolymerization, and the counter-anion effect has been discussed above. As far as the N,N-ligand effect is concerned, in contrast to olefin polymerization, increased steric hindrance on the apical positions decreases the catalytic performance. For example, when N,N = [2,6-$(R)_2$-C_6H_3]N=C(Me)−C(Me)=N[2,6-$(R)_2$-C_6H_3] for R = H, the compound is a reasonably

good catalyst for the CO/styrene copolymerization reaction. In contrast, the complex with R = *i*Pr is completely inactive in the copolymerization, but catalyses the formation of the homopolymer (polystyrene). This is probably due to the need for initial CO coordination at the fifth coordination site[55] in the copolymerization reaction; this is difficult to approach when sterically protected by the substituents in the N,N-ligands. The information derived from investigation of the interionic structure could also be useful for probing accessibility of the metal centre in this case.

Another example of reduced anion-cation interaction specificity was observed during the investigation of $[Pt(Me)(PPh_3)(dmphen)]PF_6$ complexes (where dmphen = 2,9-dimethyl-1,10-phenanthroline).[56] In such tetrahedral distorted square-planar complexes, the anion is located on the side of the phenanthroline but has sufficient mobility to interact with all the protons, with the exception of those of the Me group bonded directly to the platinum centre. The explanation can be found in (a) the difficulty that the anion has in approaching the carbon atoms of the pyridyl ring junctions, where it is reasonable to assume that the positive charge accumulates, and (b) the inclination (42.6°) of the coordination plane with respect to that containing the phenanthroline ligand.

Finally, we have recently synthesized $[Pd(\eta^1,\eta^2\text{-}C_8H_{12}O\text{-}Me)(N,O)]BF_4$ compounds {where N,O = $[2,6\text{-}(i\text{Pr})_2\text{-}C_6H_3]N{=}C(Ph){-}C(Ph){=}O$, $[2,6\text{-}(i\text{Pr})_2\text{-}C_6H_3]N{=}C(Me){-}C(Ph){=}O$} in which only the N-arm affords steric protection of the axial positions.[57] The counter-anion can choose between the least crowded side, close to the O-arm, or the electronically favoured position close to the $-N{=}C(R)$ bond. The interionic contacts observed in $^{19}F,^1H$-HOESY NMR spectra suggest that the two anion-cation orientations are simultaneously present in solution with almost equal probability.

4 Quantitative NMR Investigations

After we had found preferred anion-cation orientations in most of the investigated transition metal complex ion pairs in solution, we then attempted to quantify the NOEs for estimation of average interionic distances. The first systems to be investigated were chosen on the basis of (a) their stabilities, because quantitative NOE measurements are rather time-consuming, especially if the complete kinetics of NOE build-up has to be recorded, and (b) the existence of a well-defined anion-cation "anchorage" point, in that the deduced interionic distances, already averaged by fast internal motions and ion dissociation and re-association, would be difficult to interpret if more than one anion-cation orientation were present in solution. Considering these two points, we decided to start our investigations with *trans*-$[Ru(COMe)\{(pz_2)CH_2\}(CO)(PMe_3)_2]BPh_3R$ (R = Me and Ph) complexes,[37] the semiquantitative interionic structures of which were already known. As anticipated in Section 2, the interionic NOEs can be related to σ_{IS} and consequently to the interionic distances by fitting the experimental NOE data of the complete kinetics of the NOE build-up or the initial linear trends for short mixing times. A reference distance is needed in both cases, and it inevitably refers to two nuclei belonging to the same ionic moiety. The possibility of applying Equation (5) to estimate the average interionic distances is subordinated to inspection of the correlation time of the reference distance (intramolecular) and those of interest (interionic). The *o*-H/*m*-H distance in BPh_3R^- was chosen as the reference distance, because its value in the solid state (2.47 Å) was known from neutron diffraction investigations relating to a cationic platinum(II) dinuclear single hydrido-bridged complex.[58] The complete kinetics of NOE build-up was measured by selective inversion of several target resonances by use of the *selno* (*se*lective *no*esy)[59,60] and *selnogp* (*se*lective *no*esy with field *g*radient *p*ulses)[61,62] NMR pulse sequences. An example is reported in Figure 7, in which the kinetics of NOE build-up for H4, CH_2 and *o*-H upon irradiation of H5 are reported (R = Ph). The determined structure and selected internuclear distances for the complex with the BPh_3Me^- counter-anion are illustrated in Scheme 6.

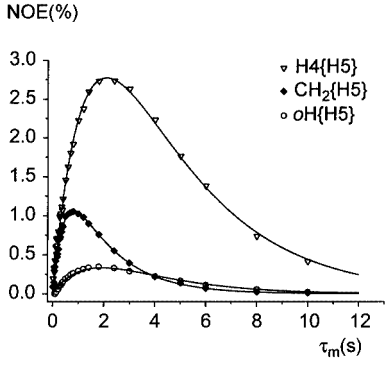

Figure 7. Experimental data relating to % NOE as a function of τ for the irradiation of H5 protons for the complex *trans*-$[Ru(COMe)\{(pz_2)CH_2\}(CO)(PMe_3)_2]BPh_4$ (400.13 MHz, 302 K, $[D_2]$dichloromethane, Gaussian-shaped pulse); reproduced from ref.[37] with the permission of the American Chemical Society

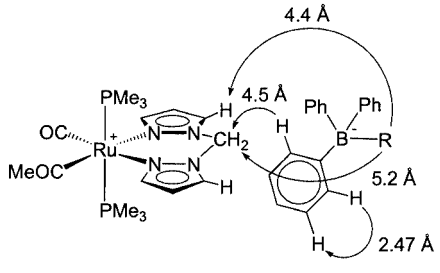

Scheme 6

An interesting point is the difference between <r>(CH_2-*o*H) (= 4.5 Å) and <r>(CH_2−BMe) (= 5.2 Å). In fact,

$\Delta<r> = 0.7$ Å and this agrees perfectly with a situation in which the anion orients the Me group far away from the metal centre.

The distances involving the protons of the counter-anion, which can undergo dynamic motion (demonstrated by the equivalence of the four phenyl groups) and those of CH_2 and H5 protons (involved in the chair-boat inversion of the six-membered Ru−N−N−CH_2−N−N ring) were increased by 10% in order to correct, at least partially, for overestimation of the short distances.

In order to check the accuracy of the determined average interionic distances, rotational correlation times were estimated by two independent NMR methodologies: ^{13}C relaxation measurements[63−65] and the dependence of ^1H-^1H cross-relaxation on the temperature. The latter methodology is based on nonlinear fitting of the experimental σ_{IS} values against T (see Figure 8), in which the dependence of the rotational correlation time on temperature is introduced by means of Equation (6), where E_R is the activation energy for rotational reorientation, τ_0 is a constant, and k is the Boltzmann constant.[66,67]

$$\tau_c = \tau_0 \cdot e^{\frac{E_R}{kT}} \quad (6)$$

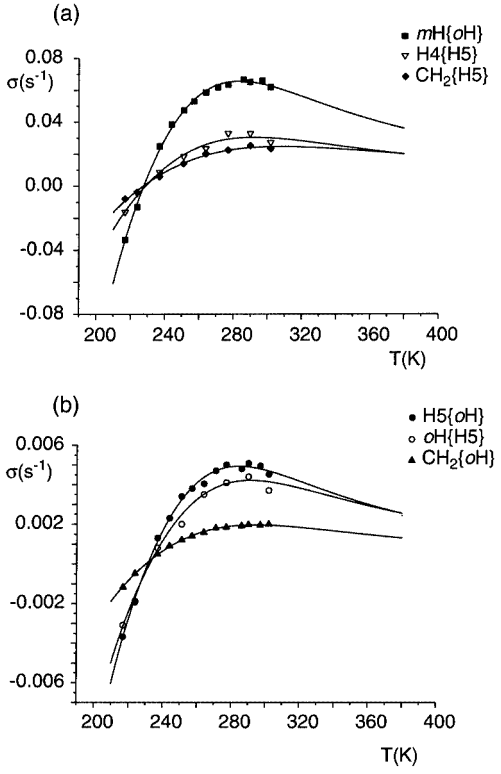

Figure 8. Intramolecular (a) and interionic (b) experimental values of σ_{IS} as a function of temperature and best nonlinear least-squares fits for the complex *trans*-[Ru(COMe){$(pz_2)CH_2$}-$(CO)(PMe_3)_2$]BPh_4; it can be seen that the temperature values of the σ zero cross and maximum points are the same for both intermolecular and interionic couples of nuclei, indicating the same correlation times (400.13 MHz, 298 K, [D_2]dichloromethane); reproduced from ref.[37] with the permission of the American Chemical Society

With both methodologies, it was found that intramolecular and interionic couples of nuclei have rotational correlation times that are the same within experimental error (ca. 100 ps)[37] and are about 3.8 times higher than those relating to pairs of nuclei belonging to *trans*-[Ru(COMe){$(pz_2)BH_2$}(CO)$(PMe_3)_2$]. The latter compound[68] is isosteric with, and has almost the same mass as, the cationic fragment of the investigated ruthenium(II) ion pairs. Consequently, it was concluded that the overall ion pair rotation contributes mainly to the dipolar relaxation processes and that the determined interionic average distances were accurate. The error on r_{IS} was estimated to be ± 0.2 Å in view both of the goodness of the fittings and of the presence of the exchange processes mentioned above.

The usefulness of the average interionic distances can be seen by considering the complexes containing unsymmetrical BPh_3R^- counter-anions. While the tendency of the anion to orient the R aliphatic chain far away from the metal centre is clearly illustrated when R = *n*Bu and *n*-Hex, by the absence of interionic NOEs in the ^1H-NOESY NMR spectra of the terminal Me, when R = Me, this is not true because, while also orienting the methyl group far away from the metal centre, it remains close enough to interact with CH_2 and H5 cationic protons. Only the $\Delta<r>$ value mentioned above allows us to conclude that B−Me is oriented like the other B−R moieties.

5 Conclusion

The structures of transition metal complex ion pairs in solution can be determined by the use of NOE NMR spectroscopy, which provides valuable information about the interplay between interionic weak interactions and the reactivity of complexes. ^1H-NOESY and ^{19}F,^1H-HOESY investigations of several Fe^{II}, Ru^{II}, Os^{II}, Pd^{II}, Pt^{II} and Ir^{III} complex ion pairs have shown that in most cases there is a predominant relative anion-cation orientation, determined mainly by a gain in electrostatic interaction energy. This in turn is derived from positioning the anion close to the cationic moiety where the positive charge accumulates; we have very often found this to be far away from the metal centre. In complexes bearing N,N-ligands, the positive charge is concentrated in the bridging units of the two moieties containing the N-donor. Steric effects are important in the modulation of the fine anion-cation orientation, and two different cases have been observed, depending on whether or not the "steric protection" acted on the point at which the positive charge was located. In the first case, a general loss of specificity was observed; in the second case a remarkably well-defined interionic structure was observed. Quantitative NOE measurements were carried out on systems belonging to this second case and the average interionic distances were estimated. Despite the precautions that must be taken and the careful checks that must be made, the possibility of determining average interionic distances offers a unique tool for detailed structural investigation of ion pairs in solution.

[19] A term ρ_I* has to be added to ρ_{IS} when relaxation of other dipole-dipole systems occurs. ρ_I* accounts for intermolecular dipole-dipole interaction with paramagnetic species, quadrupolar relaxation, chemical shift anisotropy (CSA) relaxation, scalar relaxation and spin rotation relaxation. The effect of the term ρ_I* is to reduce the NOE enhancement.
[20] In this paper both the evolution periods of 1D transient experiments and the mixing times of the NOESY or HOESY experiments are indicated with τ_m. τ_m represents the time during which the NOE develops after (a) the selective inversion of a single resonance in 1D experiments or (b) frequency labelling of all resonances in 2D experiments.

Keywords: Phosphane ligands / Arene ligands / Atropisomerism / Rhodium / NMR spectroscopy / Asymmetric catalysis

(*R*)-methylbinapium, a Hayashi-type phosphonium-MOP ligand, reacts with $[Rh(cod)_2][BF_4]$ in ethanol to afford the chiral mixed bis(monophosphane)rhodium(I) complex $[Rh(\eta^5$-H-MOP)$(MePh_2P)][BF_4]$. The constitutional and geometrical features of this complex have been determined by exhaustive ^1H, ^{11}B, ^{13}C, ^{31}P and ^{103}Rh 1-D, 2-D and NOE NMR spectroscopy and optical rotation measurements. The chelating η^5-(γ-phosphanyldiene) ligand character of H-MOP in this complex is an extension to Rh^I of similar coordination modes studied by Pregosin in the coordination sphere of Ru^{II}. The process of its formation relies on an enantiospecific reductive cleavage of a P^+–C bond, which is also reminiscent of Pregosin's P–C bond cleavages in the ruthenium series. The complex is a catalytic precursor for the hydrogenation of (Z)-α-acetamidocinnamic acid.

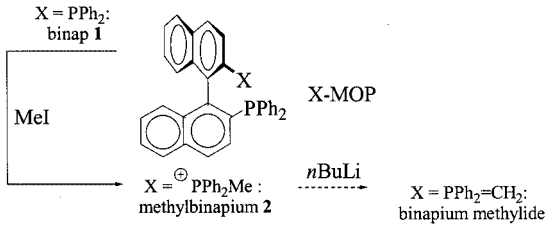
Introduction

According to the recent literature, the dogma stating that only chelating chiral *di*phosphane ligands can lead to high *ee*'s in reductive asymmetric catalysis has exceptions provided that the alternative *mono*phosphane ligands contain a resolved atropisomeric biaryl axis.[1] Monophosphite, monophosphonites and phosphoramidites of binaphthol are thus efficient ligands for the rhodium-catalyzed asymmetric hydrogenation of acrylic acid derivatives,[1,2] while Hayashi's X-MOP ligands (Scheme 1) are efficient ligands for the palladium-catalyzed reduction of allylic alcohols,[3] palladium-catalyzed hydrosilylation of olefins,[4] or rhodium-catalyzed arylation of imines.[5] The intriguing stereochemical efficiency of the X-MOP ligands is similar to that of the homoleptic binap ligand **1** (formally PPh_2-MOP).[6] This is assumed to mainly result from steric/electronic effects, but it might also be enhanced by the transient coordination of one or more C=C bonds of the naphthyl groups. Indeed, Pregosin's work definitely shows that binap and biphep can act as two-, four-, six-, or eight-electron donors in ruthenium(II) complexes.[7,8] On the other hand, binap- and MeO-biphep-ruthenium complexes have been reported to undergo selective hydrolytic P−C bond cleavage leading to complexes containing both a monophosphane H-MOP ligand and a diphenylphosphinoyl ligand.[9,10] In a few cases, the H-MOP ligand displays an η^4-coordination of one naphthyl substituent.[7,9]



Scheme 1. X-MOP ligands

Our initial goal was to look for chiral phosphoniophosphane ligands capable of providing hybrid chelation by primary P→$[Rh]^{\delta-}$ dative and secondary electrostatic $P^+\cdots[Rh]^{\delta-}$ interactions.[11] The results with "methyldiopium" as a ligand prototype suggested that the electrostatic interaction might be too loose due to the flexibility of the diopium skeleton.[12] The 1,1-binaphthyl core of **2**, a P^+-MOP ligand previously termed as "methylbinapium" (Scheme 1),[13] was therefore devised as a more rigid skeleton. The coordination chemistry of binapium **2** is, however, quite versatile.[12,13] While the methylbinapium skeleton is known to enter the coordination sphere of rhodium(I) as its ylide form (Scheme 1, X = PPh_2=CH_2),[14] the outcome of our attempts to introduce methylbinapium **2** (X = $^+PPh_2CH_3$) directly into the coordination sphere of rhodium(I) is here disclosed.

Results and Discussion

Reactivity of Methylbinapium 2 with [Rh(cod)$_2$][BF$_4$]

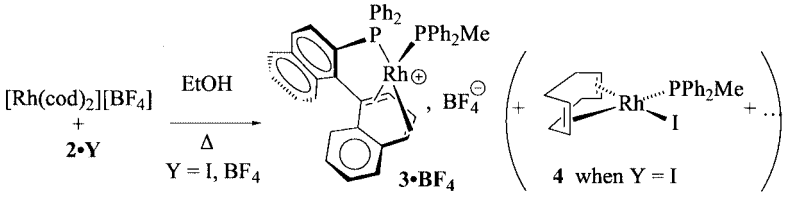
"(*R*)-methylbinapium" **2** was prepared by a one-step symmetry breaking of the parent C_2-symmetric diphosphane **1** with MeI.[13] The steric hindrance exerted by the phosphonium terminus towards the P^{III} terminus was illustrated by both the X-ray-crystal structure of binapium iodide **2·I**, and by its lack of reactivity toward electrophiles [e.g. MeI or Fe(CO)$_4$(NMe$_3$)].[13] It is therefore not surprising that **2·I** did not react with either [RhCl(cod)]$_2$ or [Rh(cod)$_2$][BF$_4$] under conventional conditions. Under harsher conditions, however, namely in boiling ethanol for two days, [Rh(cod)$_2$][BF$_4$] did react with a single equivalent of binapium iodide **2·I**. The expected product [RhI(cod)-(**2**)][BF$_4$] was not observed, but column chromatography allowed the separation of two complexes. An apolar complex was eluted first and assigned to structure **4** on the basis of its ^{1}H, ^{13}C and ^{31}P NMR spectroscopic data. The major polar complex was then eluted. Its ^{1}H and ^{31}P NMR spectra indicate the absence of both a cyclooctadiene ligand and any phosphonium group, and display two coupled nonequivalent P atoms at a rhodium center. The structure of this complex was later assigned as the H-MOP complex **3·BF$_4$** (Scheme 2, see below). Surprisingly, in the presence of two equivalents of **2·I**, the conversion of [Rh(cod)$_2$][BF$_4$] was much slower. This was ascribed to a harmful effect of the excess iodide ions competing with the hindered P^{III} center of **2**. Indeed, reaction of [Rh(cod)$_2$][BF$_4$] with the tetrafluoroborate salt **2·BF$_4$** proceeded more rapidly and more selectively: after refluxing for 20 h in ethanol, complex **3·BF$_4$** was the sole rhodium complex observed by ^{31}P NMR analysis of the crude material.

Structure Determination of Complex 3.

The major signal in the ES-MS spectrum at m/z = 741.2 is consistent with the parent cationic fragment [(MePh$_2$P)(H-MOP)Rh]$^+$. The complete multinuclear NMR assignment and the corresponding structure were determined in $CDCl_3$ solution. The ionic nature of the complex could be first refined as a [RhPP′]$^+$[BF$_4$]$^-$ form from the ^{11}B and ^{103}Rh NMR signals at δ = −0.59 ppm and −391 ppm (dd, $^1J_{PRh}$ = 199.6, $^1J_{P'Rh}$ = 206.0 Hz), respectively. The shielded ^{103}Rh signal is typical for a rhodium(I) complex in this environment.[15] The HMQC ^{1}H-^{31}P spectrum (Figure 1) displays a strong coupling of the ^{31}P/^{103}Rh ABX pattern [δ = 18.31 ppm (dd) and 57.39 ppm (dd), $^1J_{PRh}$ = 200, $^1J_{PRh}$ = 206, $^2J_{PP}$ = 39 Hz] with five inequivalent aromatic protons, and three equivalent shielded protons of a methylphosphane unit at δ = 1.50 ppm (d, $^2J_{PH}$ = 9 Hz). This observation supports a [Rh(PAr$_3$)(PAr$_2$Me)]$^+$ complexation pattern.

A weaker coupling of the ^{31}P nuclei also occurs with an intriguing ^{1}H nucleus at δ = 5.44 ppm. According to the ^{1}H-^{1}H COSY spectrum, this proton shows a $^3J_{H,H}$ coupling of 6.2 Hz with a proton whose signal appears at δ = 7.57 ppm, itself similarly coupled with a third proton (δ = 7.07 ppm). These latter three protons, referred to as H4, H3, and H2 (see Scheme 3), are also weakly coupled with ^{31}P nuclei ($J_{PH} \leq 1$ Hz). They were assigned to the protons of the η^4-diene-Rh moiety of a chelating H-MOP ligand. The η^4-coordination was confirmed by the high field resonance (δ = 97.3−105.5 ppm) of the corresponding carbon atoms C2, C3, C4 and C1, as well as by their $^1J_{RhC}$ values (c.a. 5 Hz). By contrast, the resonance at lower field of the adjacent C5 and C10 carbons (δ = 119.7 and 122.4 ppm) and the absence of coupling to the ^{103}Rh nucleus rule out the possibility of an η^6-coordination mode previously encountered in other cationic phosphane-rhodium complexes.[16] In the ruthenium series, due to the absence of $^1J_{RuC}$ information, it is more difficult to draw the line between η^4- and η^6-coordination. Nevertheless, in the related complex [Ru(η^5-H-MOP)(PPhEt$_2$)(PPh$_2$OH)]$^{2+}$[OTf]$_2$, which was assigned an η^4-diolefin structure, the effect of the proximate Ru atom on the uncoordinated C5 and C10 atoms was reported to result in chemical shifts of δ = 116.2 and 116.4 ppm, respectively. These are of the same order of magnitude as those of C5 and C10 in the rhodium complex **3**.[7] It is also worth noting that the η^4-coordination mode in **3** is consistent with a classical 16-electron count in the coordination sphere of phosphanylrhodium(I) complexes.

Although we were unable to isolate a crystal suitable for an X-ray diffraction analysis, the structure of the complex is probably very static, as indicated by VTP NMR analysis at 313 and 223 K: apart from a slight broadening, no significant shift nor decoalescence of the ^{1}H and ^{31}P signals was observed. ^{1}H-^{1}H NOE experiments allowed us to confirm the above topological assignment and to gain insights into the geometrical relationships between protons (Scheme 3). In particular, they show that in the preferred conformation, the methyl group is oriented towards the PPh$_2$ terminus of the naphthylphosphane ligand, while both phenyl rings of the methyldiphenylphosphane ligand are oriented towards the diene moiety. Although direct information on the conformation of the η^4-naphthyl group is not available, the absence of an NOE between the latter phenyl ring protons



Scheme 2. Reaction of methylbinapium **2** with [Rh(cod)$_2$][BF$_4$]

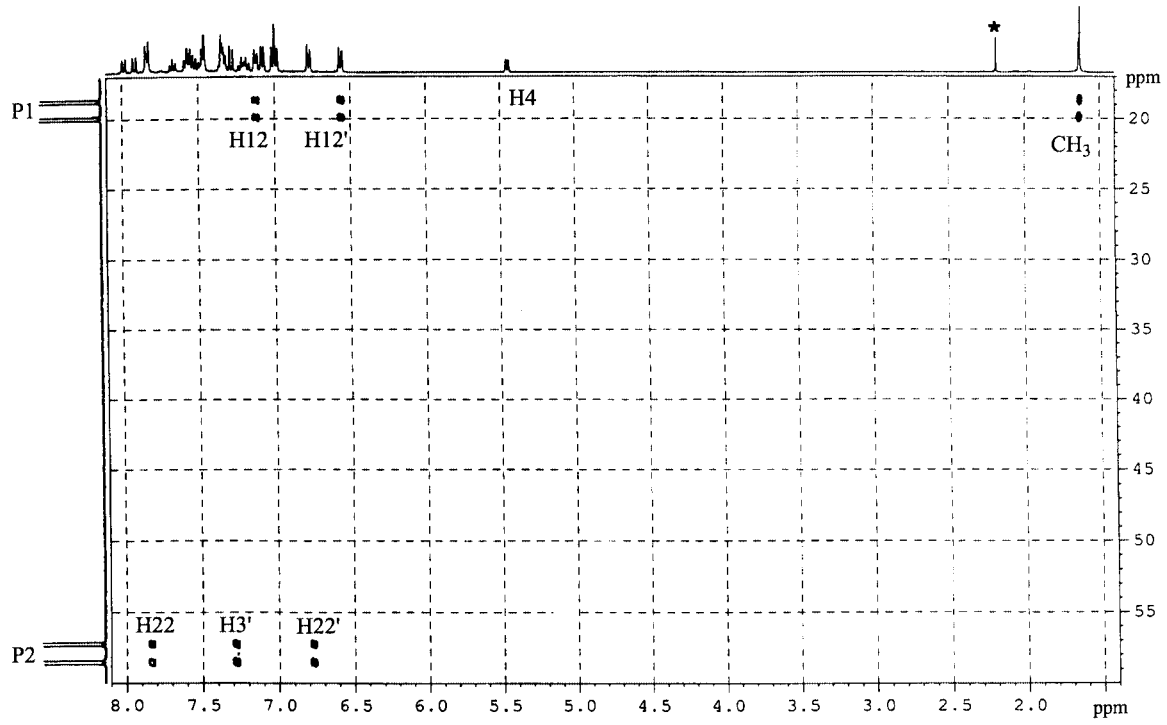


Figure 1. 400−162 MHz HMQC ^{1}H-^{31}P NMR spectrum of **3·BF$_4$** in $CDCl_3$ solution at 298 K; a weaker correlation of H4 with P1 and P2 is also seen at a lower threshold of the 2D plot (atom numbering in Scheme 3); *: residual acetone peak

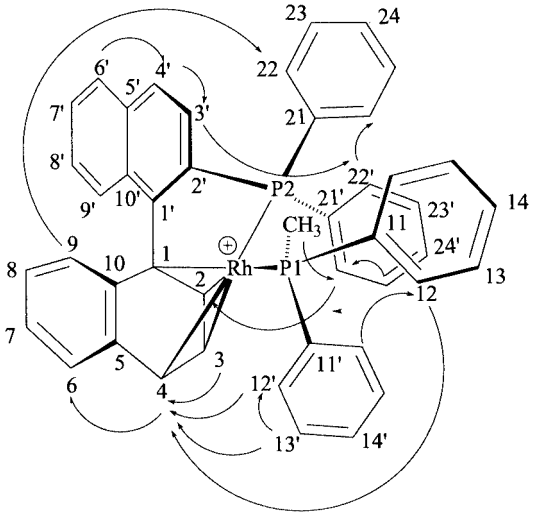


Scheme 3. 3D structural assignment based on ^{1}H-^{1}H NOE experiments

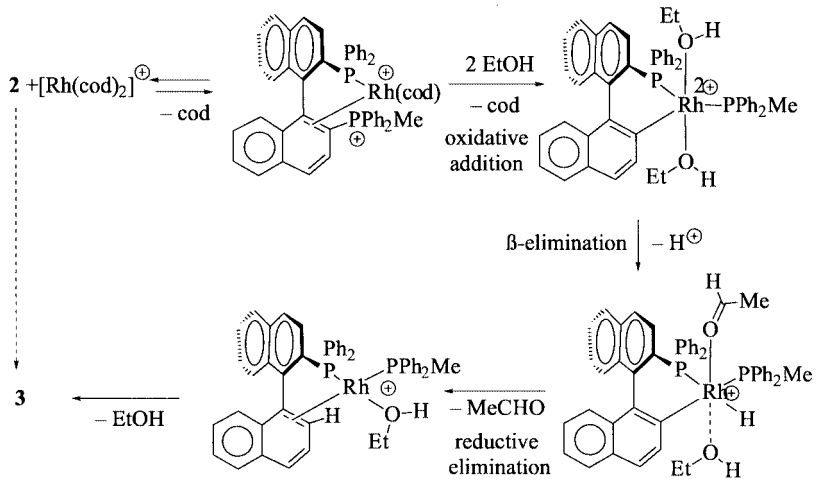
and the H6−H9 protons would be consistent with a folding along the C1···C4 axis. Such a folding (ca. 35°) was indeed reported to occur in the related complex [(η^4-naphthalene)RhCp].[17] Finally, NOE data also support a classical face-to-edge conformation of the phenyl substituents in both the $RhPPh_2$ units.

The optical rotation of complex **3·BF$_4$** is high: $[\alpha]_D^{25} = +175$ ($c = 0.1$, CH_2Cl_2). For comparison, the optical rotation of the enantiomerically pure complex [{(*R*)-binap}(cod)Rh][ClO_4] is $[\alpha]_D^{20} = +180$ ($c = 0.05$, CH_2Cl_2),[6] and that of free (*S*)-H-MOP prepared by Hayashi is $[\alpha]_D^{25} = +102$ ($c = 2.03$, $CHCl_3$).[18] The chiral information brought by the (*R*)-binapium reactant is therefore qualitatively preserved: the complex is enantiospecifically obtained as an enriched scalemic mixture.

In summary, the complex thus contains both an η^5-(σ-P, π-arene) (*S*)-H-MOP ligand and an independent η^1,σ-P methyldiphenylphosphane ligand. It provides a generalization to rhodium(I) of similar well-documented complexation patterns in ruthenium(II) complexes.[7−9] It is, however, worth noting that other chelating ω-phosphanylalkene ligands associated with an independent monophosphorus(III) ligand at a rhodium(I) center are known.[19]

Reaction Mechanism via Reductive P$^+$−C Bond Cleavage

The formation of complex **3** formally results from a complexation-reduction process. The reducing agent here is the ethanol solvent, which is also commonly used to convert rhodium(III) salts to rhodium(I) complexes.[24] A plausible mechanism involving elementary processes at Rh^I and Rh^{III} centers is depicted in Scheme 4. Starting from (*R*)-binapium, the final stereoselective reductive elimination would finally lead to an (*S*)-H-MOP ligand.[18] The overall P$^+$−C bond cleavage process is reducing in nature, and is therefore basically complementary to the related "acid-induced" and "solvent-induced" P−C bond cleavage processes identified by Pregosin in the coordination sphere of ruthenium complexes.[7] A related reductive P−C bond cleavage was also invoked in the coordination sphere of a rhodium complex converting PPh_3 to PPh_2(*n*-Pr) under hydrogen in the pres-

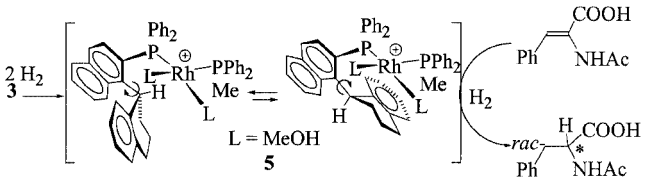


Scheme 4. Plausible mechanism for the formation of complex **3**

ence of propylene at 130 °C.[20] It is also worth noting that Hayashi recently reported a selective P^V-C bond cleavage by *n*BuLi in neutral $P(O)Ph_2$-MOP derivatives.[21]

Catalytic Hydrogenation with Complex 3

The chiral structure of complex **3** combines the essential features of classical $[P_2Rh(diene)]^+$ catalytic precursors for asymmetric hydrogenation of prochiral acrylic acid derivatives,[22] albeit in another connectivity pattern, $[P(Pdiene)Rh]^+$. These features prompted us to test complex **3** in a 1% catalytic ratio for the hydrogenation of (*Z*)-α-acetamidocinnamic acid, a reference substrate. Under 1 bar of hydrogen in methanol, the conversion into *N*-acetylphenylalanine reached only 6% after 40 h. Under 20 bar of hydrogen, however, the conversion reached 95%, although no significant enantioselectivity was obtained. According to the generally accepted mechanism for rhodium-catalyzed hydrogenation,[22] the η^4-diene moiety should be hydrogenated in situ to a putative (but likely) tetralinyl-substituted naphthylphosphane complex **5**. In this complex, the (*S*) configuration of the chiral carbon center should result from the initial (*S*)-configuration of the chirality axis of H-MOP (Scheme 5). The fate of the 1,1′-tetralinylnaphthtylphosphane ligand has been investigated by MM2 calculations. The latter suggest that, in contrast to H-MOP, this ligand no longer contains a frozen atropisomeric axis.[23] Both "atropisomers" are essentially isoenergetic,[23b] and the rotation barrier could be estimated at approx. 45 kcal·mol^{-1}.[23c] In qualitative accordance with the experimental observations, the same method applied to the parent H-MOP ligand affords a much higher barrier of about 130 kcal·mol^{-1}.[3,4] The 1,1′-tetralinylnaphthtylphosphane ligand can therefore be qualified as "weakly" chiral. The negligible *ee* is therefore consistent with all reports on the enantioselectivity control by monophosphane ligands bearing a remote chiral center on their backbone.[22]



Scheme 5. Catalytic hydrogenation of (*Z*)-α-acetamidocinnamic acid with complex **3** as precursor

Conclusion

The novelty of the above results comes from two points: (i) the η^5-(σ-P,π-arene) hetero-chelating behaviour of an atropisomeric biarylphosphane at a rhodium(I) center; (ii) a selective reductive P^+-C bond cleavage leading to a mixed bis(monophosphane)rhodium(I) complex. This peculiar organometallic chemistry and the preliminary catalytic results pave the way to more general studies of this type of complexes in other Rh-catalyzed processes, such as C–C bond forming reactions.[3,4,5]

Experimental Section

Reactions were carried out under a nitrogen atmosphere using Schlenk tube and vacuum line techniques. Ethanol was distilled over drierite. Dichloromethane was distilled over P_2O_5. (−)-(*R*)-Binap and methyl iodide were purchased from Fluka. Ammonium tetrafluoroborate was purchased from Aldrich. $[Rh(cod)_2][BF_4]$ was prepared from $[RhCl(cod)]_2$, itself prepared from cyclooctadiene and $RhCl_3{\cdot}3H_2O$ (Johnson–Mattey) according a modified described procedure (no carbonate was added).[24] NMR spectra were recorded in $CDCl_3$ solution, on Bruker AC 200 and AMX 400 spectrometers. Positive chemical shifts at low field are expressed in ppm relative to internal TMS for ^1H and ^{13}C, and external 85% H_3PO_4 in D_2O for ^{31}P. ^{103}Rh chemical shifts are given to high fre-

quency of Ξ(^{103}Rh) = 3.16 MHz. Optical rotations were measured in a 1-dm cell with a Perkin−Elmer 241 polarimeter.

Methylbinapium 2: (*R*)-Methylbinapium iodide **2·I** (m.p. 307−310 °C) was prepared in 97% yield from (*R*)-binap **1** according to described procedures.[13,14] The tetrafluoroborate salt **2·BF$_4$** was obtained quantitatively by metathesis of **2·I** and [NH$_4$][BF$_4$].

Complex 3·BF4: (*R*)-Binapium tetrafluoroborate **2·BF$_4$** (0.115 g, 0.16 mmol) and [Rh(cod)$_2$][BF$_4$] (0.065 g, 0.16 mmol) were mixed in ethanol (15 mL). The suspension was heated, and the resulting deep orange solution was refluxed for 20 h. The solvent was then evaporated under reduced pressure. ^{31}P NMR analysis of the crude material indicated the presence of complex **3·BF$_4$** along with traces of binapium oxide [^{31}P NMR (81 MHz, CDCl$_3$): δ = 26.52 (s, 1 P, MePh$_2$*P*$^+$), 31.67 (s, 1 P, Ph$_2$*P*=O)]. Further purification was achieved by chromatography over silica gel eluting with CH$_2$Cl$_2$/acetone mixtures of increasing polarity (from 100:0 to 80:20). The most colored fractions were collected and the solvents evaporated, leading to an orange solid (0.060 g, 45%) which was used for full spectroscopic analysis and optical rotation measurement. TLC (SiO$_2$, CH$_2$Cl$_2$/acetone 80:20) R_f = 0.60. (+)ES-MS: *m*/*z* = 741.2 with consistent isotopic pattern. $[\alpha]_D^{25}$ = +175, $[\alpha]_{578}^{25}$ = +202. $[\alpha]_{546}^{25}$ = +278 (c = 0.1, CH$_2$Cl$_2$). ^{11}B (128.4 MHz, CDCl$_3$): δ = −0.59 (q, $^1J_{FB}$ = 1.0 Hz, *B*F$_4$). Other NMR assignments were achieved with the help of ^{1}H{^{31}P}, ^{31}P{^{1}H}, ^{13}C{^{1}H}, ^{13}C{^{1}H, ^{31}P}, ^{1}H-^{31}P{^{1}H} HMQC, ^{31}P-^{103}Rh ^{1}J-HMQC, ^{1}H-^{13}C{^{31}P}, ^{1}H-^{1}H{^{31}P} GS-HMQC, ^{1}H-^{1}H GS-COSY45, ^{1}H{^{31}P} dpfgse TOCSY, and ^{1}H-^{1}H{^{31}P} dpfgse (t_m = 600 ms) NOE experiments.

Hydrogenation Procedure: Complex **3·BF$_4$** (0.005 g, 0.006 mmol) and (*Z*)-α-acetamidocinnamic acid (0.123 g, 0.6 mmol) were placed in a glass vessel in a steel autoclave under 1 bar of nitrogen atmosphere. Methanol was then syringed in, and the autoclave was pressurized to 21 bar with hydrogen gas. After stirring at 25 °C for 40 h, the autoclave was opened and the solvent evaporated to dryness to give an orange solid. ^{1}H NMR analysis of the crude material in [D$_6$]DMSO indicated an exclusive 95% conversion of the staring material to *N*-acetylphenylalanine. The catalyst residue was removed by treatment with a 5 N aqueous NaOH solution and washing with Et$_2$O. After acidification with HCl, the aqueous layer was extracted with Et$_2$O. The organic layer was dried over MgSO$_4$ and the solvents evaporated giving a white powder (0.87 g) consisting in 95% *N*-acetylphenylalanine and 5% unchanged olefin according to ^{1}H NMR spectroscopy. $[\alpha]_D^{25}$ = +0.007 (*c* = 1, EtOH).

Rhodium Clusters Substituted by Cycloheptatrienyl Ligands: Synthesis and Solid-State Structure of $[Rh_{11}(CO)_{14}(\mu_3\text{-}\eta^2\text{:}\eta^3\text{:}\eta^2\text{-}C_7H_7)_3]$

Roberto Della Pergola,*[a] Emanuela Comensoli,[b] Luigi Garlaschelli,[b] Mario Manassero,*[c] Mirella Sansoni,[c] and Donatella Strumolo[b]

Keywords: Rhodium / Carbocycles / Cluster compounds / Carbonyl ligands

The cluster $[Rh_{11}(CO)_{14}(C_7H_7)_3]$ (**1**) was obtained from the reaction of $[Rh_6(CO)_{16}]$ and an excess of cycloheptatriene in refluxing toluene. Initially, the substituted cluster $[Rh_6(CO)_{13}(C_7H_8)]$ (**2**) could be identified spectroscopically, which is transformed into **1** after prolonged refluxing. In the solid state, the eleven rhodium atoms define a trioctahedral metal cage, condensed through a common edge. The three planar, equivalent C_7 rings sit on the top of triangular faces. The spectroscopic characterisation of the product is hampered by its low solubility.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2003)

Ligands derived from cycloheptatriene are widely employed in organometallic chemistry; mononuclear[1] and cluster compounds[2] containing such a ring are well documented in the literature. When supported by a cluster, the C_7 rings can bind one, two or three metal atoms. Relevant examples of these different bonding modes are: (i) $[Ru_6C(CO)_{11}(C_7H_9)(C_7H_7)]$[3] and $[Co_4(CO)_6(C_7H_9)(C_7H_7)]$,[4] where η^5-C_7H_9 and μ_3-η^7-C_7H_7 binding modes are displayed in the same molecule, (ii) $[Ru_4(CO)_7(C_7H_7)_2]$, which contains edge-bridging μ_2-η^3:η^4 units,[5] and (iii) $[Ru_6C(CO)_{14}(C_7H_8)]$, where a facial μ_3-η^2:η^2:η^2 binding mode is present.[3] Upon coordination to several metal atoms, the reactivity of the ring is modified, and the hapticity of the ligand can be changed either by a ring contraction,[3] by reductive coupling,[6] or by a ligand-to-ligand hydrogen transfer.[3,4]

We have recently isolated $[Ir_6(CO)_{13}(C_7H_8)]$, and described its peculiar reactivity toward reducing agents, which is assisted by a reversible modification of the bonding mode of the cyclic ligand.[7]

The substitution of rhodium clusters with carbocyclic ligands is relatively unexplored: reactions of $Rh_4(CO)_{12}$ and $Rh_6(CO)_{16}$ with polyenes have been described,[8] but only $[Rh_6(CO)_{14}(\eta^4\text{-}C_6H_8)]$,[9] $[Rh_4(CO)_8(\mu_3\text{-}C_8H_8)]$ and $[Rh_4(CO)_6(\mu_3\text{-}C_8H_6R_2)(\eta^4\text{-}C_8H_6R_2)]$[10] have been structurally characterised. For these reasons we have re-examined the substitution of $[Rh_6(CO)_{16}]$ with cycloheptatriene. We found a behaviour different from that already reported,[8] and from that of $Ir_6(CO)_{16}$,[7] which allowed us to isolate a new rhodium cluster that is highly substituted by the C_7 ring.

Results

The carbonyl substitution of $Rh_6(CO)_{16}$ with cycloheptatriene proceeds in boiling toluene. After about six hours most of the starting material has been converted into a new, soluble cluster. The infrared spectrum of the toluene solution allows the unequivocal identification of this primary product as $[Rh_6(CO)_{13}(C_7H_8)]$ (**2**), since its carbonyl stretching bands (2093s, 2064vs, 2035s, 2006m, 1794m cm^{-1}) are almost superimposable with those of the corresponding iridium analogue $[Ir_6(CO)_{13}(C_7H_8)]$.[7] All attempts to grow crystals, isolate in the solid state, purify, or convert **2** into an anionic derivative failed, owing to its high solubility and moderate stability. Currently, we are trying to identify the decomposition products, to reconstruct the steps of the subsequent cluster build-up. At this early stage of the reaction, a brown microcrystalline precipitate is also present, which can be easily confused with unreacted $Rh_6(CO)_{16}$.[8] However, $[Ir_6(CO)_{13}(C_7H_8)]$ is poorly soluble in toluene and it crystallizes directly on cooling the reaction mixture.[7] Therefore we measured the crystallographic parameters of the dark solid residue, and found a com-

pletely unexpected unit cell. Thus, the course of the reaction was investigated more deeply. The solution was subjected to a few additional cycles of heating and cooling: after 10 additional hours the solution was colourless, and **2** had been completely converted into a material that is very insoluble in THF, CH_2Cl_2, MeCN and hydrocarbon solvents. Several of the well-shaped crystals were big enough for a X-ray analysis, and a structural characterisation of the new cluster $[Rh_{11}(CO)_{14}(C_7H_7)_3]$ (**1**) was performed. The powder residue could only be partially characterised. The elemental analysis established a Rh/C_7 ring ratio of 2, and its infrared spectrum, as a nujol mull, showed bands at 1977m, 1954s, 1804m cm^{-1}. It was found, by XRPD, to be poorly crystalline. These data suggest that this material, which is the main product of the reaction, is composed of highly substituted clusters whose formulation can be related neither to **1** nor to **2**.

The solid state structure of **1**, together with the numbering scheme, is shown in Figure 1. Figure 2 shows, with two different orientations, the connectivity of the CO's and the C_7H_7 rings to the metallic framework, which can be described as three octahedra, mutually fused through a face and all sharing a common edge [Rh(1)−Rh(1′)]. Owing to the crystallographic symmetry, only three metal atoms, three independent carbonyl groups and four carbon atoms of the C_7H_7 ring occupy the asymmetric unit. The molecule contains terminal [CO(1)], edge-bridging [CO(2)] and face-bridging [CO(3)] CO ligands, 15 sites in total, which are all indicated in the figures. However, we strongly believe that **1** contains only 14 CO molecules, and that the six equivalent

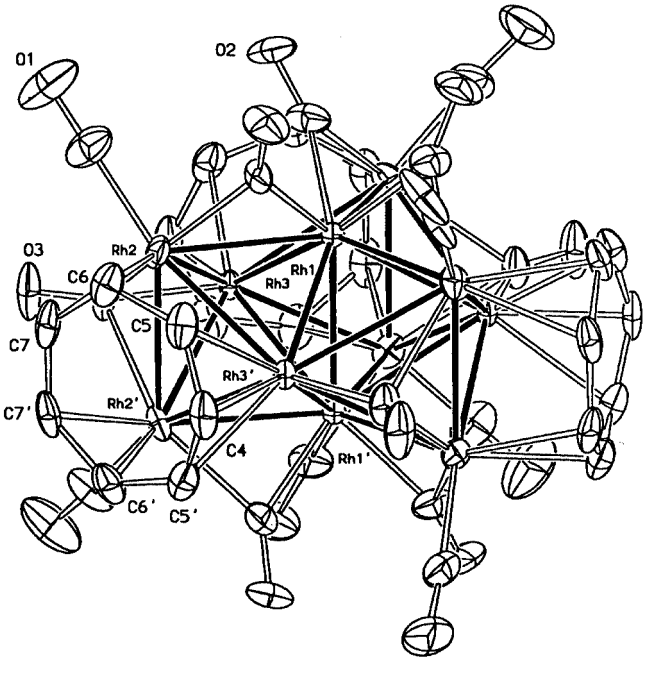

Figure 1. The solid state structure of $[Rh_{11}(CO)_{14}(C_7H_7)_3]$; relevant bond lengths (Å): Rh(1)−Rh(1′) 2.821(1), Rh(1)−Rh(2) 2.684(1), Rh(1)−Rh(3) 2.720(1), Rh(2)−Rh(2′) 2.733(1), Rh(2)−Rh(3) 2.885(1), Rh(2)−Rh(3′) 2.855(1), Rh(3)−C(4) 2.142(4), Rh(3)−C(5) 2.323(4), Rh(2)−C(6) 2.159(4), Rh(2)−C(7) 2.209(5); average C−C(ring) 1.416

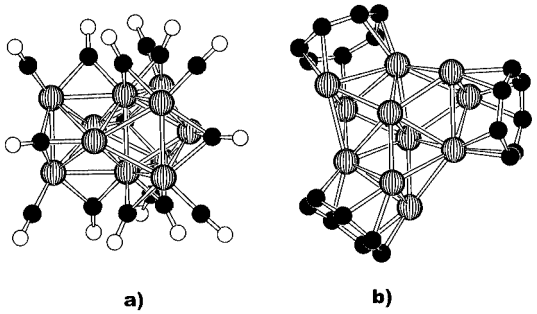

Figure 2. The disposition of the carbonyls (a) and the C_7H_7 (b) around the metallic framework of $[Rh_{11}(CO)_{14}(C_7H_7)_3]$

CO(2) sites are randomly occupied by five ligands. As a matter of fact the occupancy factor of CO(2) is lower than unity, and close to the expected value of 5/6 (0.83). Under this assumption, **1** possesses 148 valence electrons, a number which has been observed in Rh,[11] Pt−Rh[12] or Ir[13] clusters with the same framework. The three independent metal atoms are very different for the number of Rh−Rh, Rh−CO and $Rh-C_{ring}$ connectivities; however, local electron counts[13] at the three sites differ by less than one electron, and the small discrepancies cannot be rationalized in terms of bond-length variations, even if the asymmetry of the face bridging CO(3) [2.335(3) Å for Rh(2)−CO(3) and 1.977(7) for Rh(3)−CO(3)] is consistent with the unbalanced distribution of electrons. For example, Rh(1) has a (formal) excess of one electron, but the longest bonds within the cluster are the Rh(2)−Rh(3) interactions. It is likely that the lengths of the Rh−Rh bonds reflect the steric and electronic requirements of the carbocycle. In keeping with this, the bond lengths of the organic unit are spread over a wide range: 2.142(4)−2.323(4) for $Rh-C_{ring}$ and 1.378(6)−1.447(7) Å for C−C bonds.

The almost planar cycloheptatrienyl rings are bound to triangular faces in the μ_3-η^2:η^3:η^2 fashion and are coordinated through one allylic system to Rh(3) and through two C=C double bonds to Rh(2). A slightly different arrangement for the same ligand has frequently been observed: in the μ_3-η^2:η^3:η^3 bonding mode one carbon atom, shared by two allylic moieties, is connected to two metal atoms with comparable distances.[4,7] In **1** the two external atoms of the allylic systems are very far from the nonbonded rhodium atom [Rh(2)−C(5) is about 2.9 Å] and the cluster can be classified as a genuine example of μ_3-η^2:η^3:η^2 hapticity. In any case, the neutral ligand must be considered as a seven-electron donor. Alternatively, the molecule can be described as being derived from the homoleptic $[Rh_{11}(CO)_{23}]^{3-}$,[11] by formal substitution of nine CO's with three tropylium cations ($[C_7H_7]^+$ is a six-electron donor).

Unfortunately, the analytical and spectroscopic characterisation of **1** is hampered by its low solubility, which is not unexpected for a neutral, high-nuclearity cluster. Even if the compound were available in larger amounts, it is unlikely that the number of CO ligands could be confirmed by microanalysis, since the differences would be below the experimental errors. To confirm the presence of **1** among

the products of the reaction, the determination of the cell parameters is more straightforward than infrared spectroscopy as five crystals, selected from among the bigger ones with difficulty, were not sufficient to record an infrared spectrum of reasonable quality.

Despite the lack of spectroscopic data on $[Rh_{11}(CO)_{14}(C_7H_7)_3]$, this compound is important since it sheds a new light on the reactivity of rhodium clusters[8,10] with cyclic unsaturated hydrocarbons: the carbonyl substitution can be accompanied by unpredictable cluster reconstruction, leading to highly substituted, high-nuclearity clusters. The reproducible preparation and the symmetrical structure of **1** are strong evidences of its high stability. Among the group 9 metal clusters it may be compared to $[Ir_7(CO)_{12}(C_8H_{12})(C_8H_{11})(C_8H_{10})]$, which shows stages of cyclooctadiene dehydrogenation.[14]

Experimental Section

In a typical preparation, $[Rh_6(CO_{16}]$ (0.30 g, 0.28 mmol) and cycloheptatriene (0.3 mL, 3 mmol) were suspended in 10 mL of toluene. The mixture was refluxed for five days, without stirring, switching the heating on and off at the beginning and at the end of the day's work. The residue, insoluble in most common solvents, was collected by filtration, and washed with toluene. $[Rh_2(CO)_4(C_7H_7)]_n$: calcd. for C 32.3, H 1.7; found C 31.7, H 1.9.

Well-shaped, prismatic crystals of **1** were selected under the lens of a microscope and used for characterisation.

Crystal data and other experimental details are summarized in Table 1. The diffraction experiment was carried out on a Bruker SMART CCD area-detector diffractometer at 223 K using Mo-K_α radiation (λ = 0.71073 Å) with a graphite monochromator in the incident beam. Intensity data were processed with the software SAINT,[15a] and an empirical absorption correction was applied (SADABS).[15b] The calculations were performed using the Personal Structure Determination Package[16] and the physical constants tabulated therein. Scattering factors and anomalous dispersion corrections were taken from ref.[17] The structure was solved by direct methods (SHELXS 86)[18] and refined by full-matrix least-squares using all reflections and minimizing the function $\Sigma w(F_o^2 - kF_c^2)^2$ (refinement on F^2). Anisotropic thermal factors were refined for all the non-hydrogen atoms. Hydrogen atoms were placed in their ideal positions and not refined. In the final difference Fourier map the maximum residual electron density was 1.40(49) e·Å^{-3} at 0.66 Å from Rh(2).

Gold(I) Macrocycles and [2]Catenanes Containing Sulfone-Functionalised Diacetylide Ligands

Fabian Mohr,[a] Michael C. Jennings,[a] and Richard J. Puddephatt*[a]

Keywords: Self assembly / Catenanes / Macrocycles / Gold / Aurophilicity

The reaction of the polymeric digold(I) diacetylide $[(AuCCCH_2OC_6H_4)_2SO_2]_n$ with diphosphane ligands PP leads to the formation of either macrocyclic ring complexes $[(AuCCCH_2OC_6H_4)_2SO_2(\mu\text{-PP})]$ or [2]catenanes $[(AuCCCH_2OC_6H_4)_2SO_2(\mu\text{-PP})]_2$ by a self-assembly process. With the diphosphane ligands $Ph_2PCCPPh_2$, $[Fe(C_5H_4PPh_2)_2]$ and $Ph_2P(CH_2)_nPPh_2$ (n = 4, 5 and 6), macrocyclic ring complexes result, but with the diphosphane ligand $Ph_2P(CH_2)_3PPh_2$, the [2]catenane selectively crystallises from an isomeric mixture of products.

Introduction

The promise of useful applications of nanoscale devices has stimulated intense research into the synthesis and properties of mechanically interlocked molecules such as catenanes and rotaxanes.[1−5] Synthetic strategies based on ideas such as π-π interactions, metal ion templation, hydrophobic forces and hydrogen bonding have been developed to assemble such supramolecular structures.[6,7] The vast majority of catenanes and rotaxanes prepared to date are based either on organic or inorganic molecules, and the first organometallic [2]catenane was reported only in 1993.[8]

Gold(I) has proven to be a versatile building-block for constructing organometallic network polymers, rings and catenanes because of the low steric effects associated with its tendency for linear coordination and the potential to form Au···Au aurophilic attractions that can enhance association between gold(I) centers.[9,10] These aurophilic attractions (bond energies of ca. 7−11 kcal mol^{-1}) result in gold−gold distances ranging from 2.75 to 3.40 Å.[11] Gold(I) is a labile metal center and so easy rearrangements can occur to give thermodynamic control of the self-assembly processes. Recently, the first detailed studies of organometallic [2]catenanes containing gold(I) centres and diacetylide bridging ligands have been reported.[12−15] This work has shown that both the "hinge group" (X) in the diacetylide ligand and the "spacer group" between the phosphorus atoms (Y) (Figure 1) determine whether [2]catenanes or macrocyclic complexes are formed. Short and sterically demanding spacer groups Y such as $(CH_2)_2$, HC=CH, C≡C and $[Fe(C_5H_4)_2]$ form macrocycles, whilst longer spacer groups such as $(CH_2)_4$ and $(CH_2)_5$ may form [2]catenanes, depending on the nature of the hinge group. The case where the spacer group is $(CH_2)_3$ represents the borderline between macrocycle and [2]catenane formation: mixtures of both structural forms are usually observed. The hinge group effect depends at least in part on the orientation of the aryl groups (the twist angles of the two aryl groups with respect to the plane of the hinge atom, Figure 2), with the combinations of angles approximating to 90, 45 or 45, 45 (found with X = CH_2, CMe_2 or CHAr) favouring [2]catenane formation, while the combination 90, 0 (found with X = O or S) is particularly unfavourable to [2]catenane formation and so leads to formation of the simple macrocycles only. The unfavourable combination of angles 90, 0 found with X = S arises from π-bonding between the sulfur atom and adjacent aryl groups. This p_π-p_π bonding should not be present on oxidation of S to SO_2, and so catenation might then be possible. In order to study this potential method of triggering catenation, the selectivity of formation of [2]catenanes or macrocyclic rings with gold(I) bound to the sulfone-functionalized diacetylide and diphosphane ligands has been studied, and the results are presented below.

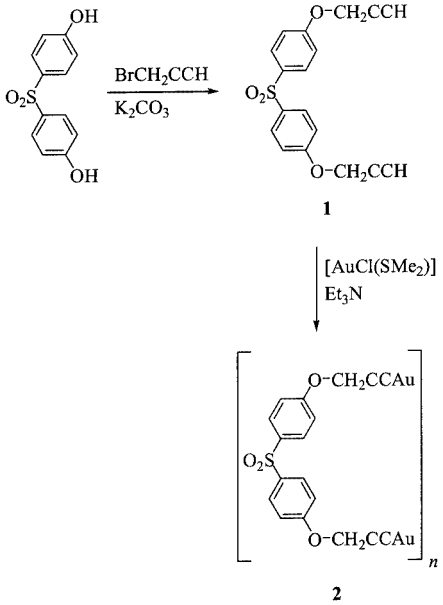
Results and Discussion

Ligand and Gold(I) Oligomer Synthesis

Reaction of bis(4-hydroxyphenyl) sulfone with propargyl bromide under basic conditions gives the bis(alkyne) compound **1** (Scheme 1) in high yield. This was easily converted into the oligomeric digold(I) diacetylide complex **2** by reaction with [AuCl(SMe$_2$)] in the presence of triethylamine (Scheme 1). Complex **2** was isolated in high yield as a yellow powder, which was insoluble in common organic solvents. Like other gold(I) acetylides, it is presumed to have a polymeric structure in which each acetylide group is σ-bonded (η^1) to one gold atom and π-bonded (η^2) to another.[16] This is supported by the IR spectrum of **2**, which exhibits a weak band at 1996 cm^{-1}, considerably lower (133 cm^{-1}) than the corresponding band in the precursor **1** as would be expected if the alkynyl groups act as π donors.

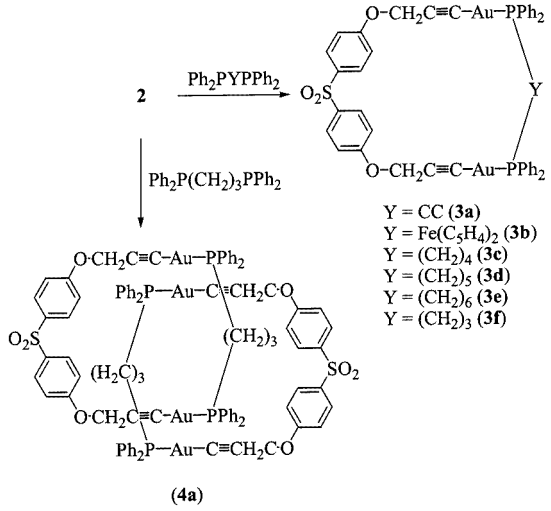


Scheme 1

Reactions with Diphosphane Ligands

Macrocyclic Ring Complexes

Reactions of complex **2** with a variety of diphosphane ligands gave colourless or pale-yellow, air-stable solids in good yields (Scheme 2). The new complexes were characterized by ^{1}H and ^{31}P NMR spectroscopy, MALDI-TOF mass spectrometry, elemental analyses and, in a number of cases, by X-ray crystallography. The ^{31}P NMR spectra of the complexes show one singlet, with chemical shifts ranging from δ = 18.59 (**3a**) to 37.57 ppm (**3e**). The ^{1}H NMR spectra show, in addition to the spacer group and OCH_2 resonances, two pairs of doublets at δ ≈ 7.8 and 7.1 ppm, corresponding to the protons on the *p*-disubstituted SC_6H_4O rings. The simple ^{1}H NMR spectra as well as the presence of only one singlet in the ^{31}P NMR spectra show that these molecules have a high degree of symmetry and exist as single isomers in solution. The spectroscopic data are consistent with macrocyclic ring structures for the complexes containing the diphosphane ligands $Ph_2PCCPPh_2$ (**3a**), [Fe($C_5H_4PPh_2$)$_2$] (**3b**) and $Ph_2P(CH_2)_nPPh_2$ [*n* = 4 (**3c**), 5 (**3d**) and 6 (**3e**)]. The MALDI-TOF mass spectra show molecular ion peaks in each case, with no peak corresponding to the potential [2]catenane but this is not definitive evidence since the mechanical bond of a [2]catenane may be easily broken. The proposed macrocyclic structures of complexes **3a**, **3b** and **3d** have been confirmed crystallographically. Figures 3, 4, and 5 show the molecular structures, while selected bond lengths and angles are listed in Tables 1, 2, and 3.



Scheme 2

The complexes consist of 23- (**3a**), 24- (**3b**) and 26-membered (**3d**) rings in which one diphosphane and one diacetylide ligand bridge two gold(I) centers. The angles C−Au−P are close to linearity in each case, as expected for gold(I). The molecular structures of the macrocyclic complexes are similar, but the three complexes pack very differently in the crystal space. Complex **3a** forms a polymeric

structure (Figure 6), resulting from aurophilic attractions [Au(1)···Au(2A) 3.1819(3) Å] between adjacent rings. Related polymers, formed by aurophilic attractions, are known with phosphane−gold(I) units in combination with halides, thiolates or acetylides.[9,11,17] In addition, the macrocycles in **3a** adopt an *anti* arrangement to minimise steric interactions. Macrocycle **3b** forms discrete dimeric units consisting of two rings connected by close gold−gold contacts [Au(2)···Au(2A) 3.1488(7) Å] (Figure 7), again the rings adopt an *anti* arrangement. In contrast, complex **3d** forms neither dimeric units nor a polymer: discrete macrocycles fill the crystal space.

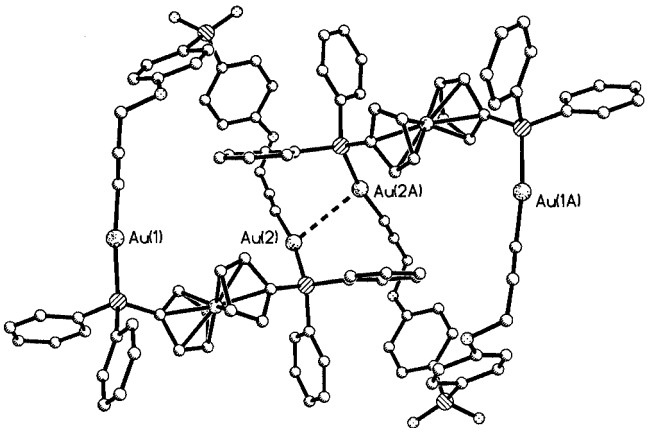

Figure 7. Packing of complex **3d** to form dimeric units

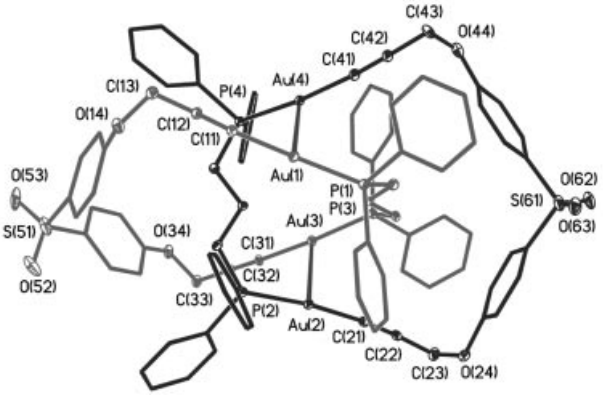

Figure 8. Molecular structure of complex **4a**; ellipsoids show 25% probability levels, C_6H_4 and phenyl rings are shown as lines and hydrogen atoms have been omitted for clarity

A [2]Catenane and Its Equilibrium with a Macrocycle

Reaction of complex **2** with $Ph_2P(CH_2)_3PPh_2$ gives a colourless, air-stable solid (Scheme 2). The ^{31}P NMR spectrum of this product contained two major singlet resonances, and the ^1H NMR spectrum contained two major pairs of doublets for the C_6H_4 protons. There was also a third minor set of resonances. This indicates that the compound exists as a mixture of three isomers, as discussed previously for the complex $[Me_2C(C_6H_4OCH_2CC)_2Au_2(Ph_2PCH_2CH_2CH_2PPh_2)]$.[15] The two major isomers are assigned as the macrocyclic ring **3f** and the [2]catenane **4a** (Scheme 2). The [2]catenane is characterized by lower chemical shifts for the C_6H_4 protons (**4a**: δ = 6.16 and 7.30 ppm; **3f**: δ = 7.07 and 7.78 ppm) and for the phosphorus atoms (**4a**: δ = 31.47 ppm; **3f**: δ = 35.32 ppm). The proton shielding arises as a result of the rigid structure of the [2]catenane with close edge-to-face contact between the C_6H_4 groups and phenyl groups of the interlocked molecule, and is characteristic of the [2]catenane structure with $Ph_2P(CH_2)_3PPh_2$ ligands.[15] Curiously, single crystals of the pure [2]catenane **4a** were insoluble in common organic solvents. The MALDI-TOF mass spectrum of the crystals of **4a** does not show a molecular ion peak for the [2]catenane, but only a molecular ion peak for the simple macrocycle **3f**. Presumably the mechanical link is broken under the conditions used.

The structure of the [2]catenane **4a** is shown in Figure 8 and selected bond lengths and angles are listed in Table 4. The two macrocyclic rings are interlocked across the diphosphane ligand backbones. There are two close gold−gold contacts [Au(1)···Au(4) 3.2392(7) Å and Au(2)···Au(3) 3.3164(6) Å] and these aurophilic attractions no doubt favour the [2]catenane formation. In addition, there are several close phenyl−C_6H_4 and phenyl−phenyl interactions (Figure 8), and the sum of these secondary bonding energies is clearly enough to overcome the negative entropy associated with [2]catenane formation.

Conclusion

It is shown that the reaction of the sulfone-functionalised polymeric dialkynyldigold(I) complex **2** (Scheme 1) with diphosphane ligands can lead to the self-assembly of macrocyclic rings or of a [2]catenane, depending on the nature of the spacer group in the diphosphane ligand. Short or bulky spacer groups form macrocyclic rings, because the ring cavity is too small to allow interlocking to form the [2]catenane. A [2]catenane is formed, in equilibrium with the macrocyclic complex, with the intermediate-length $(CH_2)_3$ spacer group. A macrocycle is formed with the longer $(CH_2)_5$ spacer group and, probably, also with the $(CH_2)_4$ spacer group. The aim of this work was to study the influence of the sulfone unit as a "hinge group" X (Figure 1), in supporting [2]catenane formation. Compared to the hinge groups studied previously, it is clear that the SO_2 group is better than X = S or O, but not so good as X = CH_2, CMe_2, C_6H_{10} (cyclohexylidene) or $CH(C_6H_4Br)$ for promoting formation of [2]catenanes. Thus, when X = S or O, no [2]catenane is detected in any case, whereas the carbon-based hinge groups give catenanes when the diphosphane is $Ph_2P(CH_2)_nPPh_2$, with n = 3−5.[12−15] Some key structural parameters are listed in Table 5. The hinge angles are not greatly distorted from the ideal tetrahedral angles and are slightly more open than for the sulfide hinge group (Table 5). The aryl groups in all complexes studied are twisted out of the plane defined by the C−S−C group with angles between the 90, 90° and 90, 45° combinations that are favourable for [2]catenane formation and very different from the case with X = S (Table 5). It is therefore not obvious why [2]catenane formation is less favoured when X = SO_2 than when X = CH_2 or CMe_2 (Table 5). The differ-

[a] Two values because of structural disorder. [b] Two values for two independent rings.

ences could be caused by subtle differences in hinge angles, or by electronic effects of the hinge groups on the strengths of phenyl−aryl attractions. Nevertheless, the comparison of the hinge groups S and SO_2 does show how the orientation of the aryl groups can be controlled and the effect could in principle be used to trigger catenation on oxidation of S to SO_2. Our attempts to demonstrate the effect directly have been unsuccessful since the Au−C bonds are not stable to strongly oxidising conditions.

Experimental Section

General Remarks: NMR spectra were recorded using Varian Mercury 400 and Inova 600 MHz spectrometers. ^1H and ^{13}C NMR chemical shifts are reported relative to tetramethylsilane, while ^{31}P NMR chemical shifts are reported relative to 85% H_3PO_4 as an external standard. IR spectra were recorded using a Perkin−Elmer 2000 FT-IR as Nujol mulls on NaCl plates. MALDI-TOF spectra were recorded using a Micromass MALDI-LR instrument in positive ion mode. The samples were dissolved in CH_2Cl_2 and spotted onto a dried layer of matrix [1 μL of α-cyano-4-hydroxycinnamic acid (10 mg/mL in CAN/EtOH, 50:50)]. The samples were analysed in reflection mode and mass spectra were externally calibrated using a tryptic digest of alcohol dehydrogenase. The complex [AuCl(SMe$_2$)] was prepared by a literature procedure.[18] All other chemicals and solvents were from commercial sources and used as received. All reactions involving gold complexes were carried out in reactions vessels shielded from light. Elemental analyses were carried out by Guelph Chemical Laboratories, Guelph, Canada.

Diacetylide Ligand 1: $BrCH_2C{\equiv}CH$ (2.4 g, 17.58 mmol) and K_2CO_3 (1.6 g, 11.58 mmol) were added to a solution of $O_2S(4\text{-}C_6H_4OH)_2$ (2.0 g, 7.99 mmol) in acetone (50 mL). The mixture was heated under reflux for about 24 h. The cooled solution was filtered to give a pale yellow filtrate. The solvent was removed under reduced pressure and the resultant off-white solid dried under vacuum. Yield: 2.3 g, 88%. IR (nujol): $\tilde{\nu}$ = 2080 (br, w) 2129 cm^{-1} (s) (C≡C). ^1H NMR (400 MHz, [D$_6$]acetone, 25 °C): δ = 7.91 (d, J = 9.4 Hz, 4 H, C_6H_4), 7.16 (d, J = 8.6 Hz, 4 H, C_6H_4), 4.89 (d, J = 2.4 Hz, 2 H, OCH_2), 3.14 (t, J = 2.4 Hz, 2 H, C≡H) ppm. ^{13}C NMR (100 MHz, [D$_6$]acetone, 25 °C): δ = 161.2, 135.2, 129.6, 115.6 (all C_6H_4), 78.2 (C≡CH), 77.2 (C≡*C*H), 56.2 (OCH_2) ppm. MS: *m*/*z* (%) = 326 (72) $[M]^+$. $C_{18}H_{14}O_4S$ (326.4): calcd. C 66.24, H .32; found C 65.79, H 4.57.

Digold(I) Diacetylide 2: [AuCl(SMe$_2$)] (0.452 g, 1.53 mmol) was dissolved in THF (50 mL)/MeOH (30 mL). A solution of **1** (0.250 g, 0.77 mmol) and Et_3N (0.4 mL, 2.87 mmol) in THF (20 mL)/MeOH (10 mL) was added to this. The resulting mixture was stirred for 3 h to produce a yellow precipitate. The solid was then collected by filtration, washed with THF, MeOH, Et_2O and pentane, and dried. Yield: 0.499 g, 91%. The product was insoluble in common organic solvents. IR (nujol): $\tilde{\nu}$ = 1996 cm^{-1} (w) (C≡C). $C_{18}H_{12}Au_2O_4S$ (718.3): calcd. C 30.10, H 1.68; found C 30.56, H 1.92.

Macrocycle 3a: A mixture of **2** (0.100 g, 0.139 mmol) and $Ph_2PCCPPh_2$ (0.044 g, 0.112 mmol) in CH_2Cl_2 (10 mL) was stirred for 3 h at room temperature. The mixture was filtered through Celite and the filtrate concentrated under vacuum (ca. 2−3 mL). Addition of Et_2O precipitated an off-white solid. The powder was collected by filtration, washed with Et_2O and pentane, and dried. Yield 0.078 g, 51%. ^{31}P NMR (162 MHz, $CDCl_3$, 25 °C): δ = 18.59 ppm. ^1H NMR (400 MHz, $CDCl_3$, 25 °C): δ = 7.86 (d, J = 7.9 Hz, 4 H, C_6H_4), 7.62−7.69 (m, 8 H, Ph), 7.52−7.58 (m, 4 H, Ph), 7.43−7.49 (m, 8 H, Ph), 7.13 (d, J = 9.3 Hz, 4 H, C_6H_4), 4.91 (s, 4 H, OCH_2) ppm. MALDI-TOF MS: *m*/*z* (%) = 1113 (19) $[MH]^+$. $C_{44}H_{32}Au_2O_4PS{\cdot}1/2Et_2O$ (1149.7): calcd. C 48.05, H 3.24; found C 48.86, H 2.92. Crystals suitable for X-ray diffraction were grown by slow diffusion of hexane into a concentrated CH_2Cl_2 solution.

Macrocycle 3b: This was prepared by the procedure described for **3a** from **2** (0.075 g, 0.104 mmol) and [Fe($C_5H_4PPh_2$)$_2$] (0.046 g, 0.083 mmol). The product was isolated as a pale-yellow solid. Yield 0.097 g, 74%. ^{31}P NMR (162 MHz, $CDCl_3$, 25 °C): δ = 36.79 ppm. ^1H NMR (400 MHz, $CDCl_3$, 25 °C): δ = 7.87 (d, J = 8.6 Hz, 4 H, C_6H_4), 7.36−7.51 (m, 20 H, Ph), 7.16 (d, J = 9.3 Hz, 4 H, C_6H_4), 4.94 (s, 4 H, OCH_2), 4.33 (s, 4 H, C_5H_4), 4.27 (s, 4 H, C_5H_4) ppm. MALDI-TOF MS: *m*/*z* (%) = 1273 (100) $[MH]^+$. $C_{52}H_{40}Au_2FeO_4P_2S{\cdot}0.2CH_2Cl_2$ (1289.7): calcd. C 48.50, H 3.15; found C 48.54, H 3.18. Crystals suitable for X-ray diffraction were grown by slow diffusion of Et_2O into a concentrated nitrobenzene solution.

Macrocycle 3c: This was prepared by the procedure described for **3a** from **2** (0.100 g, 0.139 mmol) and $Ph_2P(CH_2)_4PPh_2$ (0.113 g, 0.083 mmol). The product was isolated as a colourless solid. Yield 0.110 g, 71%. ^{31}P NMR (162 MHz, $CDCl_3$, 25 °C): δ = 38.27 ppm. ^1H NMR (400 MHz, $CDCl_3$, 25 °C): δ = 7.85 (d, J = 8.6 Hz, 4 H, C_6H_4), 7.60−7.38 (m, 20 H, Ph), 7.15 (d, J = 8.6 Hz, 4 H, C_6H_4), 4.90 (s, 4 H, OCH_2), 2.27 (m, 4 H, CH_2), 1.65 (m, 4 H, CH_2) ppm. MALDI-TOF MS: *m*/*z* (%) = 1144 (100) $[MH]^+$. $C_{46}H_{40}Au_2O_4P_2S$ (1144.8): calcd. C 48.26, H 3.52; found C 48.16, H 3.75.

Macrocycle 3d This was prepared by the procedure described for **3a** from **2** (0.100 g, 0.139 mmol) and $Ph_2P(CH_2)_5PPh_2$ (0.052 g, 0.118 mmol). The product was isolated as a cream-coloured solid. Yield 0.126 g, 80%. ^{31}P NMR (162 MHz, $CDCl_3$, 25 °C): δ = 37.06 ppm. ^1H NMR (400 MHz, $CDCl_3$, 25 °C): δ = 7.87 (d, J = 8.6 Hz, 4 H, C_6H_4), 7.54−7.62 (m, 8 H, Ph), 7.39−7.51 (m, 12 H, Ph), 7.16 (d, J = 8.6 Hz, 4 H, C_6H_4), 4.95 (s, 4 H, OCH_2), 2.29 (m, 4 H,

CH_2), 1.50 (m, 6 H, CH_2) ppm. MALDI-TOF MS: *m/z* (%) = 1159 (100) $[MH]^+$. $C_{47}H_{42}Au_2O_4P_2S{\cdot}1/2CH_2Cl_2$ (1201.2): calcd. C 47.49, H 3.61; found C 47.62, H 3.70. Crystals suitable for X-ray diffraction were grown by slow diffusion of hexane into a concentrated CH_2Cl_2 solution.

Macrocycle 3e: This was prepared by the procedure described for **3a** from **2** (0.075 g, 0.104 mmol) and $Ph_2P(CH_2)_6PPh_2$ (0.038 g, 0.084 mmol). The product was isolated as a colourless solid. Yield 0.073 g, 61%. ^{31}P NMR (162 MHz, $CDCl_3$, 25 °C): δ = 37.57 ppm. ^1H NMR (400 MHz, $CDCl_3$, 25 °C): δ = 7.83 (d, *J* = 8.6 Hz, 4 H, C_6H_4), 7.37−7.65 (m, 20 H, Ph), 7.09 (d, *J* = 9.3 Hz, 4 H, C_6H_4), 4.84 (s, 4 H, OCH_2), 2.31, 1.51, 1.36 (m, 4 H, CH_2) ppm. MALDI-TOF MS: *m/z* (%) = 1173 (100) $[MH]^+$. $C_{48}H_{44}Au_2O_4P_2S{\cdot}CH_2Cl_2{\cdot}Et_2O$ (2502.7): calcd. C 48.47, H 3.95; found C 48.58, H 3.79.

Macrocycle 3f and [2]Catenane 4a: This was prepared as an equilibrium mixture by the procedure described for **3a** from **2** (0.075 g, 0.104 mmol) and $Ph_2P(CH_2)_3PPh_2$ (0.035 g, 0.085 mmol). The product was isolated as a colourless solid. Yield 0.093 g, 80%. **3f**: ^{31}P NMR (162 MHz, $CDCl_3$, 25 °C): δ = 35.32 ppm. ^1H NMR (600 MHz, $CDCl_3$, 25 °C): δ = 7.78 (d, *J* = 9 Hz, 4 H, C_6H_4), 7.36−7.51 (m, 20 H, Ph), 7.07 (d, *J* = 9 Hz, 4 H, C_6H_4), 4.95 (s, 4 H, OCH_2), 2.42 (m, 8 H, CH_2), 1.78 (m, 4 H, CH_2). **4a**: ^{31}P NMR (162 MHz, $CDCl_3$, 25 °C): δ = 31.47 ppm. ^1H NMR (600 MHz, $CDCl_3$, 25 °C): δ = 7.30 (d, *J* = 9 Hz, 4 H, C_6H_4), 7.36−7.51 (m, 20 H, Ph), 6.16 (d, *J* = 9 Hz, 4 H, C_6H_4), 4.94 (s, 4 H, OCH_2), 2.73 (m, 8 H, CH_2), 1.82 (m, 4 H, CH_2) ppm. MALDI-TOF MS: *m/z* (%) = 1131 (100) $[M/2 + H]^+$. $C_{90}H_{76}Au_4O_8P_4S_2$ (2261.5): calcd. C 47.80, H 3.39; found C 47.47, H 3.62. Crystals of **4a** suitable for X-ray diffraction were grown by slow diffusion of hexane into a concentrated CH_2Cl_2 solution.

X-ray Crystallographic Study: Data for **3a**, **3b**, **3d** and **4a** were collected at −73 °C by using a Nonius Kappa CCD diffractometer operating with Mo-K_α radiation (graphite monochromator, λ = 0.7107 Å) using COLLECT software.[19] The unit cell parameters were calculated and refined from the full data set. Crystal cell refinement and data reduction was carried out using DENZO and absorption correction was carried out using SCALEPACK.[20] The structures were solved by direct methods[21] (**3a**, **3b** and **4a**) or Patterson methods[22] (**3d**) and were refined using Fourier techniques.[23] Hydrogen atoms were included at geometrically determined positions riding on their respective carbon atoms. The atomic scattering factors were taken from standard sources.[24,25] All calculations were performed using the SHELXTL 5.1 program package.[26] Table 6 summarises the crystallographic and refinement details for all complexes. CCDC-185297 (**3a**), -185298 (**3b**), -185299 (**3d**) and -185300 (**4a**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

3a: A colourless needle of $[(\mu\text{-}Ph_2PCCPPh_2)Au_2(\mu\text{-}CCCH_2\text{-}OC_6H_4S(O)_2C_6H_4OCH_2CC)]{\cdot}3CH_2Cl_2$ was mounted on a glass fibre. All of the non-hydrogen atoms were refined with anisotropic thermal parameters. One of the three occluded solvent molecules showed some occupational disorder. All three solvent molecules were refined with the bond lengths fixed (C−Cl = 1.65 Å and Cl···Cl = 2.74 Å). Solvent molecule one (C41) and two (C51) were refined anisotropically. The third solvent molecule (C61) was refined isotropically as a 70:30 disorder. The hydrogen atoms were included for all solvent molecules.

3b: A yellow-orange diamond plate of [μ-[Fe($C_5H_4PPh_2$)$_2$]Au$_2$(μ-$CCH_2OC_6H_4S(O)_2C_6H_4OCH_2CC$)]·1/2$PhNO_2$·$Et_2O$ was mounted on a glass fibre. The SO_2 bridging ligand was disordered. It was modeled as a mixture of two isotropic moieties (60:40). All of the remaining non-hydrogen atoms were refined with anisotropic thermal parameters. The nitrobenzene was modeled at a half occupancy and the ether at full occupancy. Both solvent molecules were kept isotropic.

3d: A colourless plate of [(μ-$Ph_2P(CH_2)_5PPh_2$)Au$_2$(μ-$CCCH_2OC_6H_4S(O)_2C_6H_4OCH_2CC$)]·2.75$CH_2Cl_2$ was mounted on a glass fibre. All of the non-hydrogen atoms were refined with anisotropic thermal parameters. The solvent molecules showed some disorder. One solvent molecule (C41) was refined anisotropically. The second solvent molecule (C51) was refined at 75% occupancy with the bond lengths fixed as above. The third solvent molecule (C61) was refined isotropically as a 70:30 disorder, with fixed bond lengths. The hydrogen atoms were included for all solvent molecules.

4a: A colourless crystal of [(μ-$Ph_2P(CH_2)_3PPh_2$)Au$_2$(μ-$CCCH_2OC_6H_4S(O)_2C_6H_4OCH_2CC$)]$_2$·2$CH_2Cl_2$ was mounted on a glass fibre. All of the non-hydrogen atoms were refined with anisotropic thermal parameters. The two solvent molecules were refined anisotropically, with hydrogen atoms included and with bond lengths fixed as above.

Synthesis and Characterization of a Carbene·SO_2 Adduct − New Insights into the Structure and Bonding of Thiourea *S,S*-Dioxides[‡][‡‡]

Michael K. Denk,*[a] Ken Hatano,[b] and Alan J. Lough[c]

Keywords: Carbenes / Sulfenes / Density functional calculations / Thermochemistry / Sulfur ylides

The title compound 1,3-di-*tert*-butylimidazol-2-ylidene·SO_2 (**2**) was obtained from the respective stable carbene **1** and SO_2 in quantitative yield and investigated by single crystal X-ray crystallography and NMR spectroscopy. Quantum chemical calculations show that thiourea-*S,S*-dioxides like **2** are Lewis acid-base adducts of the respective diamino carbenes with SO_2 (CS bond energies < 20 kcal·mol^{-1}). They possess long CS bonds and a pyramidal sulfur atom and are thus structurally distinct from sulfur ylides or sulfenes.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2003)

Introduction

Despite the frequent assumption of their involvement as reactive intermediates, sulfenes ($R_2C{=}SO_2$)[1] have remained elusive and are thus clearly distinct from the growing list of isolable compounds featuring carbon-sulfur double[1,2] and even triple bonds.[2]

Sulfenes can be generated in situ by the 1,2-elimination of HCl from sulfonyl chlorides (R_2CH-SO_2Cl) or by fluorodesilylation of 2-silylsulfochlorides.[1h] The reaction of carbenes with SO_2 can result in the formation of sulfenes but has found little synthetic use. While the formation of sulfene, $CH_2{=}SO_2$, from methylene and SO_2 was deduced from the formation of secondary products only,[3] diphenylsulfene has been isolated in a frozen matrix and characterized by its IR and Raman spectra at 100 K.[4]

Thiourea *S,S*-dioxide (**2**),[5−7] a stable, commercially available compound has been known since 1910[5] and is readily obtained by oxidation of thiourea (**1**) with peracids. It could be described as a donor-stabilized sulfene but the X-ray structure of **2** shows a long C-S bond (185 pm) and a pyramidal sulfur atom.[8] The C-S double bond of a sulfene would imply a short C-S bond and a planar or close to planar C-SO_2 fragment.

Using X-ray data[8c] and EHMO calculations,[8d] Chen and Wang[8d] have concluded that the C-S bond in **2** is essentially a single bond. Despite this attempt to clarify the bonding situation, **2** is still usually written with a C-S double bond.

In 1994, Skrypnik and Lyashchuk reported the isolation of the diamino ketene **4′**[9a,9c] and the stable sulfene **5′** (Scheme 1).[9b,9c] The existence of **4′** has since been refuted through high level ab initio calculations[10] which demonstrated that **4′** would only have the marginal stability of a van-der-Waals complex.[10] Two notes questioning the existence of **5′**[10b,10c] have appeared in the literature, but, in the absence of additional experimental or computational data, the issue remains unresolved. X-ray data reported for **5′**[9b] are limited to selected bond lengths and bond angles and have not been deposited in the Cambridge database.

Our interest in the subject was triggered by our previous investigations of stable diamino carbenes,[11] diamino silylenes[12] and related species and, in particular, by the question whether thiourea *S,S*-dioxides like **2** or **5′** could act as synthons for diamino carbenes. We now present experimental evidence (NMR spectroscopy, X-ray crystallographic data) and quantum chemical calculations which indicate that thiourea *S,S*-dioxides (including **5′**) are not sulfenes or sulfur ylides but Lewis acid-base adducts of diamino carbenes.

Results and Discussion

Reaction of the stable carbene **3** or **3′** with SO_2 did not give any indication of the formation of **5** (previously unknown) or **5′** (ref.[9b]).

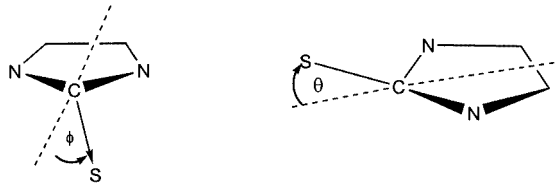

Figure 2. horizontal (φ) and vertical (θ) tilt angles used in the description of **7**

Much to our surprise, reaction of the closely related but electronically less stabilized[12] carbene **6**[11a] with SO_2 led to the clean formation of **7**, which was characterized by single crystal X-ray crystallography (Figure 1),[14−17] multinuclear NMR spectroscopy, and computational methods.[18−22]

Compound **7** is poorly soluble in hydrocarbons such as hexane and toluene but dissolves well in THF and dichloromethane. These solutions are unreactive towards oxygen, pyridine and CsF but are sensitive to moisture.[13] Attempts to sublime **7** ($T \leq 110$ °C, 0.05 Torr) resulted in decomposition. The compound is undissociated in benzene solution (^{1}H NMR spectroscopy) and is unaffected by prolonged storage under vacuum. Samples heated to 100 °C for 24 h show no signs of decomposition (^{1}H NMR, IR spectroscopy) but decomposition occurs upon melting (123 °C).

The C-S bond length of 203.0(2) pm in **7** exceeds the sum of the covalent single-bond-radii of sulfur and carbon (187 pm).[23] The pyramidal SO_2 fragment is off-center from its idealized position (C-S bond axis bisecting the N−C−N angle) by $\varphi = 6.3°$ and is also tilted away from the N−C−N plane by $\theta = 10.8°$ (Figure 2).

The C-S bond length in **7** is also significantly longer than that reported for **2**, which may be related to the fact that **2**, unlike **7**, shows hydrogen bonding in the solid state (NH···OS 186 pm).[8] Hydrogen bonding can enhance the Lewis acidity of the SO_2 fragment by reducing its electron density. Despite the difference of the C-S bond lengths in **2** and **7**, the C-S bond energies (see below) are very similar so that fundamental differences in the bonding situation for **2** and **7** must be ruled out.

Preservation of the solid-state structure of **7** in solution would give rise to an AA′BB′ spin system for the ring protons. However, between −100 °C and 25 °C the VT ^{1}H NMR spectrum of **7** shows only two singlets, one for the ethylene protons (4 H) and the one for the two *tert*-butyl groups (18 H).

A rapid equilibrium between the conformers **7a**/**7b** (Figure 3) can occur through rotation of the SO_2 group or inversion of the sulfur atom and can explain the observed be-

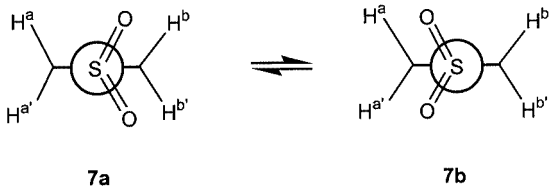

Figure 3. Dynamic behavior of **7**

havior of **7**. The high configurational stability of the pseudo-tetrahedral sulfur geometry (e.g. in sulfoxides) seems incompatible with the observed dynamic behavior and the rotational mechanism is more likely.[27]

The ^1H and ^{13}C NMR shifts of **7** resemble that of the stable carbene **6**. Coordination of **6** to SO_2 leads to a moderate shielding of the carbene carbon atom [$\delta^{13}C$ = +238 (**6**), +231 ppm (**7**)], a trend that is analogous to the shielding effect caused by protonation of **6** ($\delta^{13}C$, [**6H**]$^+$**SCN**$^-$, $CDCl_3$, N_2CH +152.4 ppm).[11e]

The structural and spectroscopic data characterize **7** as a Lewis acid-base adduct of the carbene **6** and are inconsistent with those presented for **5′** which has been described as a stable sulfene (short C-S bond, planar N_2CSO_2 framework).[9b] This discrepancy and the doubts raised about the existence of **5′** elsewhere,[10b,10c] have prompted us to study the bonding situation through high level quantum chemical methods.[18–22]

Computational Structures of Sulfene *S,S*-Dioxides

A method for the calculation of accurate structures of **7** was established by comparison of computational structures with the experimental structures. Computational structures[19] were obtained with Gaussian 98[18] at the HF and DFT[20,21] levels. The respective methyl-substituted compounds **5Me** and **7Me** were chosen as model compounds for **5** and **7**.

Structures obtained with density functional methods are usually more accurate than Hartree−Fock structures but the effect can be obscured by internal error compensation and can become apparent only for larger than usual basis sets. The MPW1PW91/6-31G(d)[20] structure of SO_2 (Table 1) is very similar to the HF/6-31G(d) structure, but the higher accuracy of the MPW1PW91 approach becomes obvious for more extended basis sets.

The superior accuracy of MPW1PW91 structures[20] has been established through calculations on large test sets of organic and inorganic compounds[20a] and is also obvious for the structures calculated in this study. While the C-S bond length of **7Me** calculated at the MPW1PW91/6-31G(2d) level (202.02 pm) is in excellent agreement with the experimental value[24] [**7**: 203.0(2) pm], the B3LYP/6-31G(2d) value of 234.27 pm deviates significantly.

At the MPW1PW91/6-31G(2d) level, the structures of **5Me** (Table 2) and **7Me** (Table 3) are very similar. In particular, they display a *pyramidal* geometry at the sulfur atom and *long* C-S bonds (**5Me**: 199 pm, **7Me**: 202 pm). The computational structure of **5Me** is thus in qualitative disagreement with the structure published for **5′**. The possibility of a second minimum with a planar CSO_2 geometry and a short C-S bond was considered as a possible source for the discrepancy and studied by starting the optimization pro-

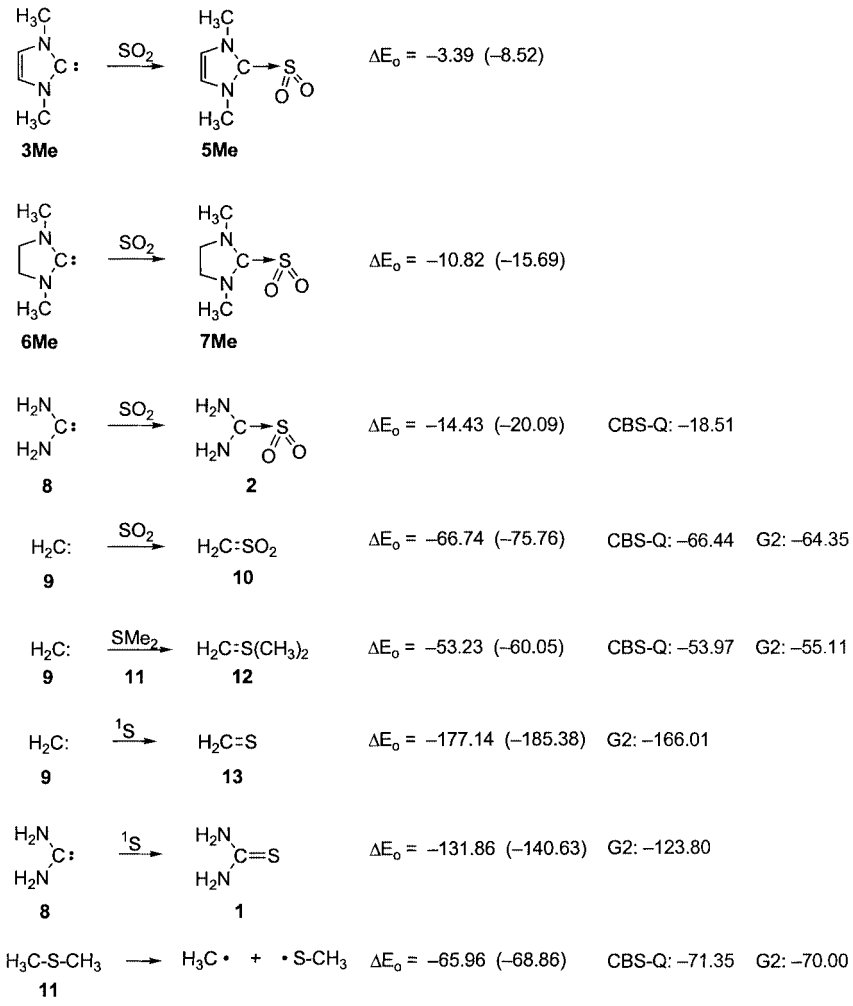

Scheme 2. CS bond energies of selected sulfur compounds; B3LYP/6-311G(3df,p)//MPW1PW91/6-31G(2d) and, in parentheses), MPW1PW91/6-311G(3df,p)//MPW1PW91/6-31G(2d); zero-point energies of the DFT calculations are at the MPW1PW91/6-31G(2d) level and were added without scaling

cess of **5Me** with a sulfene structure analogous to **5′**. The sulfene geometry reported for **5′** (Table 2) is unstable at all levels investigated (HF, MPW1PW91, or B3LYP methods with 6-31G(d) or 6-31G(2d) basis sets) and reverts to structures with long C-S bonds and pyramidally coordinated sulfur atoms.

The computational instability of the sulfene structure and the fact that we were unable to obtain **5′** or to observe the spectroscopic data (^{1}H NMR, ^{13}C NMR) published for it suggest that the compound may indeed be nonexistent.[10b]

Computational charge densities (Table 4) of **5Me** and **7Me** show a net transfer of charge density from the carbenes **3Me** and **6Me** to SO_2 and are consistent with the description of SO_2 acting as a Lewis acid. The net transfer of charge density occurring in the formation of **5Me** and **7Me** is very similar. The electron-deficient sulfur atom in SO_2 (+1.64) accepts only a small additional charge (0.04) from the carbene in both cases: most of the transferred electron density ultimately resides on the more electronegative oxygen atoms. The carbene carbon atoms show a loss of 0.09 charge units, with some of the electron depletion relayed to the nitrogen atoms (0.06 in **7Me** and 0.09 in **5Me**)

To further study the possible existence of **5′**, C-S bond-dissociation energies were obtained from DFT, CBS-Q, and G2 calculations.

Thermochemistry of the C-S bond

The C-S bond energies of **2**, **5Me**, **7Me**, sulfene ($H_2C=SO_2$, **10**), *S*,*S*-dimethylsulfoniumylide [$H_2C=S(CH_3)_2$, **12**], thioformaldehyde ($H_2C=S$, **13**), and dimethyl sulfide [$(CH_3)_2S$, **11**] were calculated from the reaction energies ΔE_o of the respective bond formation reactions (Scheme 2 and Table 6). The established accuracy of the G2 and CBS-Q method assures an absolute error of less than 2 kcal·mol^{-1} which is significantly better than the maximum absolute error of about 10 kcal·mol^{-1} obtained with current DFT methods.[22,26]

The computationally derived C-S bond energies fall into four distinct groups which are readily identified with dative bonds (**2**, **5**, **7**), single bonds (**11**), double bonds (**1**, **13**) and

[a] Single point energies of MPW1PW91/6-31G(2d) structures with zero-point energies (first column) added without scaling.

bond orders which are intermediate between single and double bonds (sulfur ylides **10**, **12**).

The C-S bond dissociation energy of sulfene (**10**; CBS-Q: 66.44 kcal·mol^{-1}) is significantly lower than that of thioformaldehyde (**13**; G2: 166.01 kcal·mol^{-1}) and only slightly higher than that of the sulfur ylide **12** (G2: 55.11 kcal·mol^{-1}). This allows the conclusion that the C-S bond in **10**, despite its short distance and the planar coordination of the sulfur atom, is also ylidic in nature. The C-S bond dissociation energies of **2**, **5** and **7** (3.39−20.09 kcal·mol^{-1}) are of a magnitude commonly observed for Lewis acid-base adducts and rule out a description of these compounds as sulfur ylides.

While the accuracy of the CBS-Q and G2 approach leaves little room for interpretation, the modifying influence of steric hindrance remains to be discussed.

The free rotation of the SO_2 group in **7**[27] is evidence against the presence of a strong steric interaction between the *tert*-butyl groups and the SO_2 fragment. The presence of steric effects would also manifest itself in a specific elongation of the C-S bond lengths. However, the computational C-S bond length obtained for the methyl-substituted **7Me** is virtually identical to that observed for the *tert*-butyl-substituted compound **7**.

A sterically induced transformation of a dative C-S bond (**5Me**) into a double bond (as the one claimed for **5′**) can be ruled out because steric hindrance can only lead to a decrease of the C-S bond energy. The marginal C-S bond energy of **5Me** correlates well with the fact that the formation of **5** and **5′** could not be observed in this study.

Conclusion

Based on thermochemical data, thiourea *S*,*S*-dioxides must be described as Lewis acid-base complexes of diaminocarbenes with SO_2. This description of the bonding situation is consistent with their reactivity as reducing agent[4] and formamidine synthons.[4] The synthesis of the carbene complex, thiourea *S*,*S*-dioxide (**2**), by de Berry Barnett in 1910,[5] thus precedes the synthesis of the first transition metal carbene complex reported by Fischer and Maasböl[25] by more than 50 years.

Experimental Section

All operations were performed under argon (99.995%) with usual Schlenk techniques. The stable carbenes **3**[11b−11d] and **6**[11a] were obtained by published procedures.

Synthesis and Characterization of 1,3-Di-*tert*-butylimidazolidin-2-ylidene·SO_2 (7): A slow stream of SO_2 was passed over a magnetically stirred solution of **6**[11a] (5.20 g, 28.2 mmol) in 150 mL of dry THF at 25 °C. The colorless solution became slightly turbid and a crystalline, colorless precipitate formed after a few minutes. Filtration through a medium porosity Schlenk frit gave 6.94 g of **7** (quantitative yield). m.p. 123 °C (dec.). ^{1}H NMR (C_6D_6): δ = 1.25 (s, 18 H, *t*Bu), 2.78 (s, 4 H, CH_2). ^{13}C(C_6D_6): 29.7 [C(CH_3)$_3$], 44.6 (CH_2), 55.2 [C(CH_3)$_3$], 231.0 ppm (N_2C) ppm. [19] The structures are optimized with tight optimization and verified as local minima through frequency calculations. The calculations were performed without symmetry restrictions. Without this precaution, structures with virtual frequencies corresponding to methyl rotations or SO_2 rocking vibrations can be obtained. Zero point energies were obtained at the MPw1PW91/6-31G(2d)//MPw1PW91/6-31G(2d) level and were included without scaling. The energies were converted using the factor 1 Hartree = 627.5905 kcal·mol^{-1}.

[24] Irrespective of the employed basis set [6-31G(d), 6-31G(2d)], the B3LYP structures of **7Me** give unrealistic CS bond lengths (>230 pm vs. exp. 203 pm). Equally unsatisfactory CS distances are obtained for other commonly used density functionals (SVWN5, B3PW91, G96LYP, BH&HLYP, B1LYP). For the test case of SO_2, The quality of the MPW1PW91 structures increases smoothly with the total number of primitive gaussians (6-31G(d) < 6-311G(d) < 6-31G(2d) < 6-311G(2d) < 6-31G(3d) < 6-311G(3d) while the quality of the HF structures is inconsistent. For example, the HF/6-31(2d) structure of SO_2 is *less accurate* than the HF/6-31(d) structure. The inclusion of diffuse functions, which are typically added to improve the structures of electron-rich systems, in particular anions, did not lead to improved structures of SO_2.

[25] E. O. Fischer, A. Maasböl, *Angew. Chem. Int. Ed. Engl.* **1964**, *3*, 580.

[26] L. A. Curtiss, K. Raghavachari, G. W. Trucks, J. A. Pople, *J. Chem. Phys.* **1991**, *94*, 7221−7230.

[27] PM3 calculations show low rotational barriers for **7Me** (3.65 kcal·mol^{-1}) and **7** (5.75 kcal·mol^{-1}).

[28] Estimated errors for the computational structures of **7Me/5Me** can be inferred from a comparison of the MPW1PW91/6-31G(d) structure of SO_2 with the experimental structure. This leads to estimated errors of 0.84 pm (0.59%) for the SO bond lengths and 0.23 deg (0.19%) for the O−S−O angles. For the remainder of the geometrical parameters, the errors obtained for the G2 test set of molecules (ref.[20]) may be assumed.

Dynamic Properties of Methyl(trimethylphosphane)nickel Complexes Containing (2-Diphenylphosphanyl)phenylamido Ligands

Hans-Friedrich Klein,*[a] Robert Beck,[a] and Olaf Hetche[a]

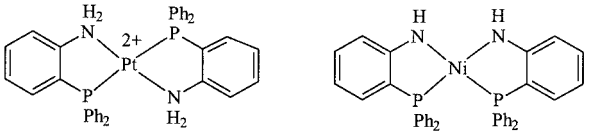
Keywords: Solution dynamics / Nickel / Coordination numbers 4 and 5 / Structure elucidation

P,N-chelates of nickel NiCl[2-(Ph_2P)C_6H_4NR](PMe_3) (**1**: R = H; **2**: R = $SiMe_3$) have been obtained from $NiCl_2(PMe_3)_2$ and 2-(Ph_2P)C_6H_4NRLi. Reaction with MeLi affords methylnickel compounds NiMe[2-(Ph_2P)C_6H_4NR](PMe_3) (**3**: R = H; **4**: R = Me; **5**: R = $SiMe_3$). By the same route NiMe[2-(R^1R^2P)C_6H_4NR](PMe_3) (**6**: R^1 = R^2 = $CHMe_2$) was synthesized. Solutions in THF contain *cis* and *trans* isomers of square-planar complexes, and dynamic NMR spectroscopy shows dissociation of trimethylphosphane to be more rapid in the *trans* isomers. In a crystal of **5** the molecular structure is *cis*-**5**. Out of these complexes only **3** and **4** add trimethylphosphane to form pentacoordinate compounds NiMe[2-(Ph_2P)C_6H_4NR](PMe_3)$_2$ (**7**, **8**) in the crystal as shown by the molecular structure of **7** while in THF equilibria **7** ⇄ *cis*-**1** and **8** ⇄ *cis*-**2** are observed by NMR spectroscopy. The same solution properties are found with NiMe[2-(R^1R^2P)C_6H_4NR](PMe_3)$_2$ (**9**: R^1 = CMe_3, R^2 = Ph).

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2003)

Introduction

A well-known strategy to avoid a bridging coordination mode in transition metal amides is the use of chelating ligands. As a convenient anchoring group the 2-(diphenylphosphanyl) group induces P,N-chelating systems to form five-membered metallacyles. Usually these are derived from 2-(diphenylphosphanyl)aniline which is isoelectronic with P,O-chelating 2-(diphenylphosphanyl)phenol and because of its potential in homogeneous catalysis of olefin reactions merits further investigation. 2-(Diphenylphosphanyl)aniline has been shown by Cooper et al.[1] to form mononuclear bis(chelate) compounds of platinum and nickel acting either as a neutral or as an anionic 4-electron donor (Scheme 1).



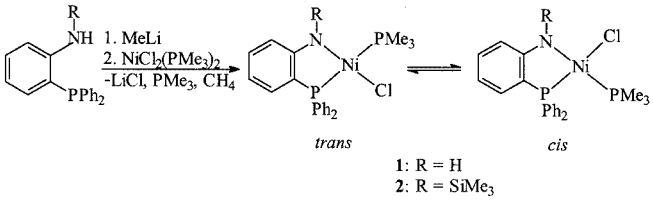
trans-bis(amino)platinum(II) *cis*-bis(amido)nickel(II)

Scheme 1. Square-planar bis(P,N-chelates)

2-(Diphenylphosphanyl)-*N*-methylanilido compounds of rhodium(I) and iridium(I) have been investigated by Dahlenburg et al.,[2] while 2-(diphenylphosphanyl)-*N*,*N*-dimethylaniline in penta- and tetracoordinate complexes of nickel(II) with added Et_2AlCl turns out to be a catalyst in the oligomerization of propene as described by Corain et al.[3]. As a model of a growing alkylmetal chain we have synthesized some methylnickel complexes containing P,N-chelating and trimethylphosphane ligands and report here on molecular structures and dynamic properties in solution.

Results and Discussion

N-Lithiated 2-(diphenylphosphanyl)anilines react with *trans*-$NiCl_2(PMe_3)_2$ [Equation (1)] to afford the chloronickel complexes **1** and **2** as green solids which are sparingly soluble in pentane or ether.



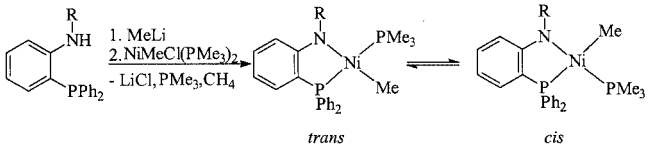
(1)

The ^{31}P NMR spectrum obtained from a THF solution of **1** or **2** at 233 K shows four doublet resonances. The pair containing the large P,P coupling is assigned to *trans*-**1** (62%) and *trans*-**2** (66%), while the pair showing the small P,P coupling is due to *cis*-**1** (38%) and *cis*-**2** (34%), respectively. Similar mixtures of isomers have been observed with related cationic palladium complexes.[4]

Added trimethylphosphane accelerates the exchange of ligands but does not alter the green color of these solutions

[a] Eduard-Zintl-Institut für Anorganische and Physikalische Chemie der Technischen Universität Darmstadt, Petersenstrasse 18, 64285 Darmstadt, Germany

and thereby indicates the absence of a pentacoordinate compound. Addition of a second mol-equiv. of LiMe or use of *trans*-NiMeCl(PMe_3)$_2$ as a reactant [Equation (2)] furnishes the corresponding methylnickel compounds.

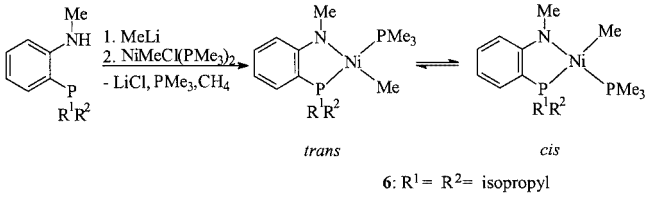


3: R = H
4: R = Me
5: R = $SiMe_3$

(2)

The reaction mixture displays a deep red color, while removal of THF solvent together with 1 mol-equiv. of trimethylphosphane during workup causes a change to orange-yellow, finally yielding orange solids **3**−**5**. The microcrystalline compounds are highly hygroscopic and under argon decompose above 122 °C, 105 °C, and 83 °C, respectively.

Using 2-(diisopropylphosphanyl)-*N*-methylaniline in a similar synthesis [Equation (3)] affords red crystals of **6** that decompose above 104 °C. NMR spectra of THF solutions of **3**−**6** again each display a double set of the expected resonances which are assigned to *cis* and *trans* isomers. In particular, $NiCH_3$ protons opposite to the chelating ^{31}P donor resonate between δ = −0.82 and −0.77 ppm with unresolved *trans* coupling ($_{cis}{}^3J_{P,H}$ = 4.5−6.1 Hz) while for those opposite to the amide donor at δ = −0.04(3) ppm a doublet of doublets pattern is observed ($^3J_{P,H}$ = 3.8−4.1 Hz). In toluene solution the *trans* isomers are observed as the dominant species (> 95%).



6: R^1 = R^2 = isopropyl

(3)

The ^{31}P NMR spectra in THF show a large coordination chemical shift of the chelate-P nucleus by 52 ppm to low field and a resonance for the coordinated trimethylphosphane ligand at δ ≈ −2 ppm. Surprisingly, the *cis* and *trans* isomers show different behavior at variable temperatures. Only the *cis* isomers continue to display a doublet of doublets ($^2J_{P,P}$ ≈ 30 Hz) between 298 and 213 K (Figure 1) while the large *trans* coupling ($^2J_{P,P}$ ≈ 300 Hz) is attained in the low-temperature limit. Upon warming, both doublet resonances of *trans*-**3**−**6** collapse to singlets caused by incipient dissociation of trimethylphosphane. Therefore, the slightly shifted broad singlet at δ = −5 ppm (298 K) must be regarded as an average of rapidly exchanging free and coordinated trimethylphosphane which also involves the pentacoordinate species (see below).

Single crystals of **5** obtained from pentane when subject to an X-ray diffraction experiment were shown to consist of *cis*-**5** (Figure 2). The unit cell contains two molecules that differ mainly in the rotational position of a phenyl substituent. The nickel atom is located in a square-planar arrangement of ligand functions. Bond lengths C−Ni and N−Ni are as usual[5] but opposite N,P and C,P donor atoms deviate from linearity by 10 and 20°, respectively. The chelate bond Ni−P1 is by 8 pm longer than Ni−P2 due to the

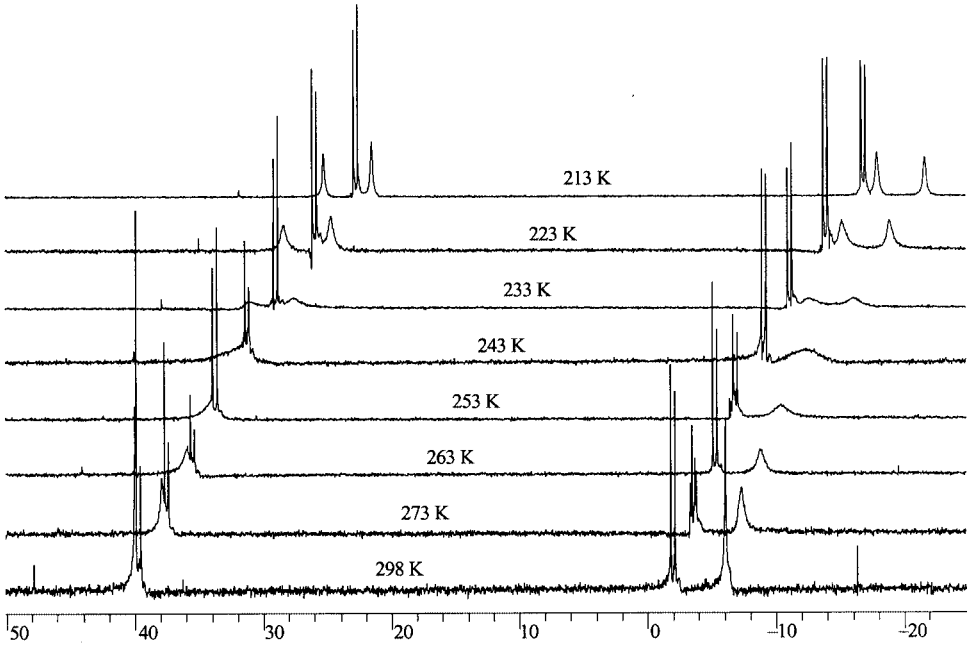


Figure 1. ^{31}P NMR spectra of **3** (THF, 213−298K)

larger *trans* influence of the NiMe group relative to the amide donor. The Me_3Si group is clearly oriented above the plane of the metallacycle.

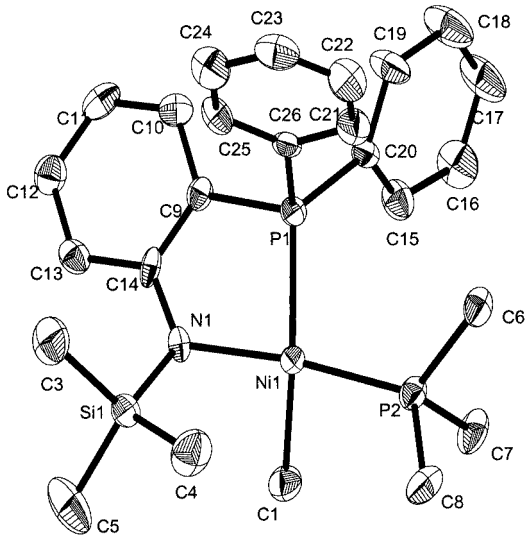

Figure 2. Molecular structure of *cis*-**5** (ORTEP plot with hydrogen atoms omitted); selected bond lengths [Å] and angles [°]: Ni−C1 1.971(11), Ni−N 1.956(8), Ni−P1 2.219(3), Ni−P2 2.124(3), P1−C9 1.814(10), C9−C14 1.387(15), C14−N 1.367(14), N−Si 1.731(8); N−Ni−P2 170.0(3), N−Ni−P1 84.0(3), C1−Ni−P1 160.8(4), N−Ni−C1 91.6(4), P1−Ni−P2 102.26(11), C1−Ni−P2 84.9(4), C9−P1−Ni 96.3(3), C14−N−Ni 117.6(6), Si−N−Ni 115.8(5), C14−N−Si 123.6(6)

Added trimethylphosphane makes **3** and **4** better soluble in pentane and causes a deep red color. Upon cooling, dark red crystals of **7** and **8** are isolated that show an even better thermal stability than their parent complexes reminding one of the pair $NiMe_2(PMe_3)_2$ and $NiMe_2(PMe_3)_3$.[6] Only **6** does not change color under these conditions and is recovered unchanged. Analytical and spectroscopic data are consistent with pentacoordinate compounds **7** and **8**. In solution dissociation of the ligands is excessive, and in ^{31}P NMR experiments a low-temperature limit of ligand motions was only attained with **7** revealing the coordination geometry. A doublet at $\delta = -16$ ppm (2 P) for trimethylphosphane and a triplet at $\delta = 23$ ppm for the PPh_2 group with $^2J_{P,P} = 192$ Hz are consistent with all three phosphorus donor atoms in equatorial sites leaving methyl and amide groups in axial positions of a trigonal bipyramid.

The molecular structure (Figure 3) confirms the configuration of **7** as derived from spectroscopic data. The nickel atom is centered in a trigonal bipyramid with axial C and N and three equatorial P donor atoms. Bond lengths are not notably different from those in *cis*-**5**, and the chelate bite angle [P1−Ni−N 85.60(13)°] is only slightly larger than in *cis*-**5** [P1−Ni−N 84.0(3)°]. A difference is recognized in a trigonal-planar arrangement of bonds to N in **7** (sum of angles 359.7°) as compared with a more pyramidal geometry in *cis*-**5** (sum of angles 357.0°). Interestingly, the sum of internal angles in the metallacycle of **7** (539.7°) is closer to the value of a regular pentagon (540°) than in *cis*-**5** (530.0°) suggesting a better fit of the former and a slight thermodynamic advantage for the pentacoordinate complex molecule.

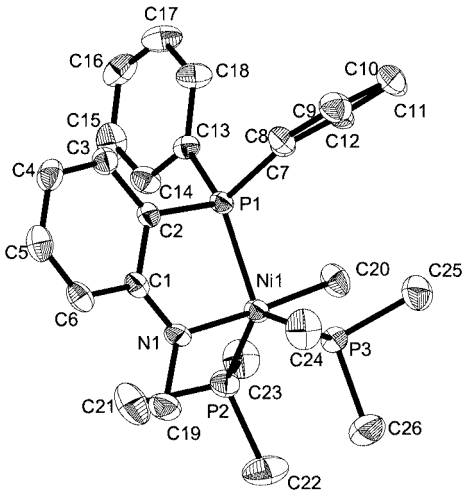

Figure 3. Molecular structure of **7** (ORTEP plot with hydrogen atoms omitted); selected bond lengths [Å] and angles [°]: Ni−C20 1.996(6), Ni−N 1.974(4), Ni−P1 2.202(2), Ni−P2 2.224(2), Ni−P3 2.253(2), N−C1 1.452(6), N−C19 1.452(6), C1−C2 1.423(7); N−Ni−C20 176.7(3), P1−Ni−P2 125.90(6), P1−Ni−P3 110.71(6), P2−Ni−P3 123.36(7), P1−Ni−N 85.60(13), P1−Ni−C20 91.1(2), Ni−N−C1 120.9(3), C1−N−C19 116.5(4), Ni−N−C19 122.3(3)

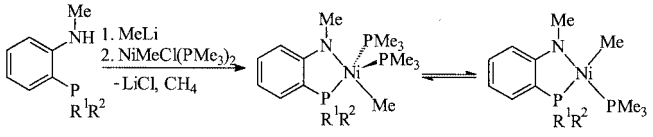
A prochiral P-donor function was introduced using 2-[*tert*-butyl(phenyl)phosphanyl]-*N*-methylaniline as a prechelate reactant [Equation (4)]. The red crystals of pentacoordinate **9** are highly soluble in pentane and under argon decompose above 115 °C.



7: $R^1 = R^2 = H$
8: $R^1 = R^2 = Me$
9: $R^1 = Ph$, $R^2 = CMe_3$ (4)

One bulky alkyl substituent in the 2-(phosphanyl) group does not interfere with the reversible uptake of trimethylphosphane. With **9** we have not been able to isolate a 16-VE species in an analytically pure state.

A close structural relationship between **8** and [2-(diphenylphosphanyl)phenolato-*O*,*P*]methylbis(trimethylphosphane)nickel[7] is found in agreement with expectation for isoelectronic molecules (Table 1).

Ligand mobility in P,N-chelates of nickel appears to be generally higher than in P,O-chelates, but only the first dissociation step (Scheme 2) could be demonstrated by experiment.

While removal of the second trimethylphosphane ligand was achieved with P,O-chelating ligands by formation of μ_2-

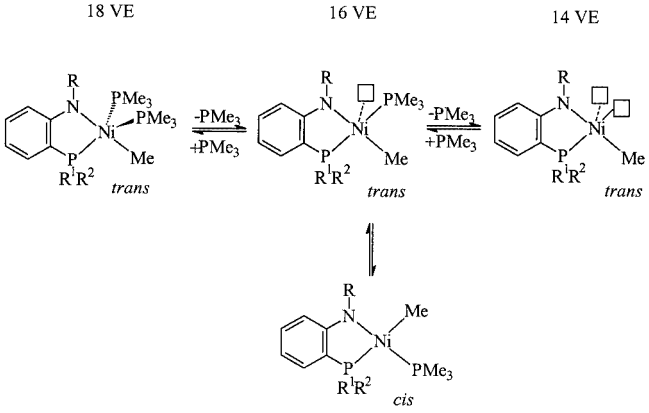

Scheme 2. Dynamic coordination in methylnickel P,N-chelates

O-bridged dinuclear complexes,[8] our attempts to remove the last trimethylphosphane ligand from the metal atom by favoring a bridging coordination mode of the amide function met with thermal decomposition (in boiling toluene). However, this result does not exclude a 14-electron species as an intermediate providing still another vacant coordination site for substrate binding.

Therefore, the tetracoordinate complexes **3**−**5** as prime candidates were examined with respect to catalytic activity in ethene oligomerization under otherwise same conditions as with the isoelectronic and highly active P,O-chelates.[7] A toluene solution (80 mL) containing 0.1 mmol of complex was kept in a steel autoclave under 50 bar of ethene at 80 °C. No drop of pressure was observed within 12 h which corresponds with no activity.

Conclusion

Methyl(trimethylphosphane)nickel complexes of P,N-chelating 2-(phosphanyl)anilines can be smoothly synthesized from convenient starting compounds as thermally stable materials. Solution dynamics of ligand motions and solvent-dependent equilibria of square-planar *cis* and *trans* isomers are novel and characteristic properties when compared with isoelectronic P,O-chelates. Rapid addition and dissociation of trimethylphosphane exclusively involve equatorial positions of a trigonal bipyramid with axial methyl and N-donor groups. Replacing an oxygen by a nitrogen donor atom in five-membered metallacycles of nickel brings about gross electronic changes whereby catalytic activity in oligomerization of ethene is completely lost. A coarse tuning by electronic effects of substituents attached to the metallacycle would be necessary to recover such activity.

Experimental Section

General Procedures and Materials: All air-sensitive and volatile materials were handled using standard vacuum techniques and were kept under argon. Microanalyses: Kolbe Microanalytical Laboratory, Mülheim/Ruhr, FRG. Melting points/decomposition temperatures: Sealed capillaries, uncorrected values. Chemicals (Merck/Schuchardt) were used as purchased. Literature methods were applied in the preparation of $NiCl_2(PMe_3)_2$, $NiMeCl(PMe_3)_2$,[6] 2-(diphenylphosphanyl)aniline,[9] 2-(diphenylphosphanyl)-*N*-methylaniline, 2-(diisopopylphosphanyl)aniline[10] and 2-[*tert*-butyl(phenyl)phosphanyl]-*N*-methylaniline.[11] IR: Nujol mulls between KBr discs, Bruker spectrophotometer type FRA

106. ^{1}H and ^{13}C NMR spectra (300 MHz and 75 MHz, respectively) were recorded with a Bruker ARX-300 spectrometer, ^{31}P NMR spectra (81 MHz) with a Bruker AM-200 instrument. ^{13}C and ^{31}P resonances were obtained with broad-band proton decoupling.

2-(Diphenylphosphanyl)-*N*-(trimethylsilyl)aniline: 2-(Diphenylphosphanyl)aniline (1.20 g, 4.32 mmol) in diethyl ether (80 mL) was combined with 1.6 M BuLi solution in hexane (2.7 mL, 4.32 mmol) and kept at 20 °C for 30 min. Chlorotrimethylsilane (470 mg, 4.32 mmol) was added, and after 16 h, LiCl was filtered off and the solution concentrated to a volume of 40 mL. Cooling to 4 °C afforded white crystals. Yield 1.10 g (73%); m.p. 76−77 °C. ^{1}H NMR (300 MHz, [D$_8$]THF): δ = 0.01 (s, 9 H, SiCH$_3$), 4.30 (d, $^4J_{P,H}$ = 9.3 Hz, 1 H, NH), 6.45 (dt, ^3J = 7.6, ^4J = 0.7 Hz, 1 H, CH), 6.65 (m, 2 H, CH), 7.01 (dt, ^3J = 6.5, ^4J = 1.5 Hz, 2 H, CH), 7.13−7.20 (m, 10 H, CH) ppm. ^{13}C NMR (75 MHz, [D$_8$]THF): δ = −1.89 (s, CH$_3$), 114.7 (s, CH), 116.9 (d, $^4J_{P,C}$ = 2.2 Hz, CH), 120.9 (d, $^3J_{P,C}$ = 5.6 Hz, C), 127.4 (s, CH), 127.6 (d, $^2J_{P,C}$ = 7.8 Hz, CH), 129.1 (s, CH), 132.5 (d, $^1J_{P,C}$ =18.7 Hz, CH), 133.7 (d, $^3J_{P,C}$ = 5.5 Hz, C), 135.1 (d, $^2J_{P,C}$ = 7.7 Hz, C), 150.1 (d, $^1J_{P,C}$ = 19.5 Hz, CH) ppm. ^{31}P NMR (81 MHz, [D$_8$]THF): δ = −10 (s) ppm. $C_{21}H_{24}NPSi$ (349.5): calcd. C 72.17, H 6.92, N 4.01; found C 72.45, H 6.63, N 3.95.

2-[*tert*-Butyl(phenyl)phosphanyl]-*N*-methylaniline: This prechelate ligand was obtained in a procedure given for 2-(diphenylphosphanyl)-*N*-methylaniline[10] starting from *N*-methylaniline and chloro(*tert*-butyl)phenylphosphane. Yield 52%, yellow oil; b.p. 189−190 °C/7 mbar. IR (Nujol, 4000−400 cm^{-1}): ṽ = 3349 vs (νN−H), 3052 m, 2926 m (νH−C=), 2810 (νNC−H), 1587 s, 1569 s (νC=C), 1518 s, 1454 s, 1435 s, 1419 m, 1312 m (δ_{as}PCH), 1289 m (δ_sPCH), 1165 m, 1089 w, 1046 w, 1029 vw, 999 vw, 912 vw, 746 vs, 729 w, 698 vs (γC−H), 515 m, 496 m, 482 m. ^{31}P NMR (81 MHz, CD_2Cl_2, 296 K): δ = −16 (s) ppm.

Chloro[2-(diphenylphosphanyl)anilido-*N*,*P*](trimethylphosphane)-nickel (1): 2-(Diphenylphosphanyl)aniline (750 mg, 2.70 mmol) in 50 mL of THF was combined at −70 °C with 1.6 M MeLi in diethyl ether (1.7 mL, 2.70 mmol), and this solution was added dropwise at −70 °C to $NiCl_2(PMe_3)_2$ (762 mg, 2.70 mmol) in 50 mL of THF causing the red color to turn green. The mixture was warmed to 20 °C and concentrated to dryness in vacuo. The solid residue was extracted with three 80-mL portions of diethyl ether through a glass-sinter disc (G3) and the green solution cooled to 4 °C to afford green crystals. Yield 710 mg (59%); m.p. 95−96 °C (dec.). IR (Nujol): ṽ = 3377 cm^{-1} (N−H). ^{1}H NMR (200 MHz, [D$_8$]THF, 233 K): *cis*-**1** (63%): δ = 1.07 (d, $^2J_{P,H}$ = 10.1, 9 H, PCH$_3$), 3.65 (s, 1 H, NH), 5.91 (m, 1 H, CH), 6.22 (m, 1 H, CH), 6.67 (m, 1 H, CH), 7.15 (m, 1 H, CH), 7.45−7.55 (m, 6 H, CH), 7.82−7.86 (m, 4 H, CH); *trans*-**1** (37%): δ = 1.33 (d, $^2J_{P,H}$ = 10.0 Hz, 9 H, PCH$_3$), 4.59 (s, 1 H, NH), 6.10 (m, 1 H, CH), 6.37 (m, 1 H, CH), 6.67 (m, 1 H, CH), 7.01 (m, 1 H, CH), 7.15 (m, 1 H, CH), 7.31 (m, 1 H, CH), 7.55−7.59 (m, 6 H, CH), 7.98−8.07 (m, 4 H, CH) ppm. ^{31}P NMR (81 MHz, [D$_8$]THF, 233 K): *cis*-**1** (63%): δ = −9 (d, $^2J_{P,P}$ = 89 Hz, 1 P, PCH$_3$), 52 (d, $^2J_{P,P}$ = 89 Hz, 1 P, PC_6H_5); *trans*-**1** (37%): δ = −9 (d, $^2J_{P,P}$ = 347 Hz, 1 P, PCH$_3$), 31 (d, $^2J_{P,P}$ = 347 Hz, 1 P, PC_6H_5) ppm. $C_{21}H_{24}ClNNiP_2$ (445.0): calcd. C 56.49, H 5.42, N 3.14; found C 56.68, H 5.50, N 3.05.

Chloro[2-(diphenylphosphanyl)-*N*-(trimethylsilyl)anilido-*N*,*P*](trimethylphosphane)nickel (2): 2-(Diphenylphosphanyl)-*N*-(trimethylsilyl)aniline (840 mg, 2.40 mmol) in 50 mL of THF was combined at −70 °C with 1.6 M MeLi in diethyl ether (1.5 mL, 2.40 mmol), and this solution was added as above to $NiCl_2(PMe_3)_2$ (677 mg, 2.40 mmol) in 50 mL of THF causing the red color to turn green. The mixture was warmed to 20 °C, stirred for 3 h, and concentrated to dryness in vacuo. The residue was extracted with three 80-mL portions of diethyl ether and the green solution cooled to 4 °C to afford green rectangular crystals. Yield 745 mg (60%); m.p. 108−109 °C (dec.). ^{1}H NMR (200 MHz, [D$_8$]THF, 233 K): *cis*-**2** (66%): δ = 0.02 (s, 9 H, SiCH$_3$), 1.06 (d, $^2J_{P,H}$ = 9.2 Hz, 9 H, PCH$_3$), 5.93 (m, 1 H, CH), 6.23 (m, 1 H, CH), 6.71 (m, 2 H, CH), 6.83 (m, 2 H, CH), 7.41−7.49 (m, 6 H, CH), 7.76−7.85 (m, 4 H, CH); *trans*-**2** (34%): δ = 0.06 (s, 9 H, SiCH$_3$), 1.39 (d, $^2J_{P,H}$ = 11.1 Hz, 9 H, PCH$_3$), 6.15 (m, 1 H, CH), 6.40 (m 1 H, CH), 7.05 (m, 2 H, CH), 7.49−7.58 (m, 6 H, CH), 8.00−8.02 (m, 4 H, CH) ppm. ^{31}P NMR (81 MHz, [D$_8$]THF, 233 K): *cis*-**2** (66%): δ = −8 (d, $^2J_{P,P}$ = 88 Hz, 1 P, PCH$_3$), 52 (d, $^2J_{P,P}$ = 88 Hz, 1 P, PC_6H_5); *trans*-**2** (34%): δ = −9 (d, $^2J_{P,P}$ = 348 Hz, 1 P, PCH$_3$), 32 (d, $^2J_{P,P}$ = 348 Hz, 1 P, PC_6H_5) ppm. $C_{24}H_{32}ClNNiP_2Si$ (517.1): calcd. C 55.57, H 6.22, N 2.70, P 11.94; found C 55.18, H 5.78, N 2.66, P 11.95.

[2-(Diphenylphosphanyl)anilido-*N*,*P*](methyl)(trimethylphosphane)-nickel (3): 2-(Diphenylphosphanyl)aniline (910 mg, 3.28 mmol) in 70 mL of diethyl ether was combined at −70 °C with 1.6 M MeLi in diethyl ether (2.1 mL, 3.28 mmol), and this solution was added dropwise at −70 °C to $NiMeCl(PMe_3)_2$ (860 mg, 3.28 mmol) in 50 mL of diethyl ether. The mixture was warmed to 20 °C and concentrated to dryness in vacuo. The resulting orange solid was extracted with three 70-mL portions of fresh diethyl ether and the solution concentrated at 20 °C to afford orange crystals of **3** (358 mg). From the mother liquor at −27 °C a light yellow solid (632 mg) was obtained which consisted of **3** only (NMR). Combined yields 990 mg (71%); m.p. 105−106 °C (dec.). IR (Nujol): ṽ = 3348 cm^{-1} (N−H). ^{1}H NMR (300 MHz, [D$_8$]THF): *cis*-**3** (60%): δ = −0.07 (dd, $_{trans}{}^3J_{P,H}$ = 4.1, $_{cis}{}^3J_{P,H}$ = 8.8 Hz, 3 H, NiCH$_3$), 1.29 (d, $^2J_{P,H}$ = 3.6 Hz, 9 H, PCH$_3$), 3.44 (s, 1 H, NH), 5.85 (m, 1 H, CH), 6.64−6.67 (m, 1 H, CH), 6.85 (t, ^3J = 6.9 Hz, 1 H, CH), 7.31 (m, 1 H, CH), 7.33−7.36 (m, 6 H, CH), 7.62−7.67 (m, 4 H, CH); *trans*-**3** (40%): δ = −0.82 (d, $^3J_{P,H}$ = 6.1 Hz, 3 H, NiCH$_3$), 1.09 (d, $^2J_{P,H}$ = 8.6 Hz, 9 H, PCH$_3$), 3.06 (s, 1 H, NH), 5.88 (dd, ^3J= 7.0, ^4J= 1.4 Hz, 1 H, CH), 5.91 (dd, ^3J = 8.2, $^4J_{P,H}$ = 5.0 Hz, 1 H, CH), 6.64−6.67 (m, 2 H, CH), 7.36−7.41 (m, 6 H, CH), 7.70−7.77 (m, 4 H, CH) ppm. ^{13}C NMR (75.4 MHz, [D$_8$]THF, 296 K): *cis*-**3** (60%): δ = 4.2 (dd, $^2J_{P,C}$ = 33.8, $^2J_{P,C}$ = 62.6 Hz, NiCH$_3$), 12.6 (d, $^1J_{P,C}$ = 21.9 Hz, PCH$_3$), 108.8 (d, $^3J_{P,C}$ = 6.2 Hz, C-2), 115.9 (d, $^2J_{P,C}$ = 9.5 Hz, *m*-C), 128.9 (d, $^2J_{P,C}$ = 9.3 Hz, *p*-C), 130.2 (s, C-5), 134.1 (d, $^2J_{P,C}$ = 11.4 Hz, *o*-C), 134.3 (s, C-3), 134.7 (s, *i*-C), 134.9 s, C-6), 171.4 (d, $^2J_{P,C}$ = 31.0 Hz, NC-1); *trans*-**3** (40%): δ = −16.8 (d, $^2J_{P,C}$ = 24.1 Hz, NiCH$_3$), 16.3 (d, $^1J_{P,C}$ = 28.9 Hz, PCH$_3$), 110.4 (d, $^3J_{P,C}$ = 5.6 Hz, C-2), 114.8 (d, $^3J_{P,C}$ = 3.0 Hz, C-5), 128.9 (d, $^2J_{P,C}$ = 8.6 Hz, *m*-C), 130.4 (s, *p*-C), 132.6 (d, $^2J_{P,C}$ = 10.2 Hz, *o*-C), 133.2 (s, C-3), 134.7 (s, C-4), 134.9 (s, *i*-C), 135.2 (s, C-6), 169.9 (d, $^2J_{P,C}$ = 32.7 Hz, NC-1) ppm. ^{31}P NMR (81 MHz, [D$_8$]THF): *cis*-**1** (60%, 193 K): δ = −2 (d, $^2J_{P,P}$ = 27 Hz, 1 P, PCH$_3$), 40 (d, $^2J_{P,P}$ = 27 Hz, 1 P, PC_6H_5); *trans*-**3** (40%, 193 K): δ = −2 (d, $^2J_{P,P}$ = 303 Hz, 1 P, PCH$_3$), 40 (d, $^2J_{P,P}$ = 303 Hz, 1 P, PC_6H_5); *cis*-**1** (60%, 296 K): δ = −2 (d, $^2J_{P,P}$ = 25 Hz, 1 P, PCH$_3$), 40 (d, $^2J_{P,P}$ = 25 Hz, 1 P, PC_6H_5); *trans*-**3** (40%, 296 K): δ = −5 (s, 1 P, PCH$_3$), 37 (s, 1 P, PC_6H_5) ppm. $C_{22}H_{27}NNiP_2$ (425.1): calcd. [2-(Diisopropylphosphanyl)-*N*-methylanilido-*N*,*P*](methyl)(trimethylphosphane)nickel (6): 2-(Diphenylphosphanyl)-*N*-methylaniline (780 mg, 3.49 mmol) in 50 mL of diethyl ether was combined at −70 °C with 1.6 M MeLi in diethyl ether (2.3 mL, 3.50 mmol), and to the yellow fluorescent solution was added solid $NiMeCl(PMe_3)_2$ (912 mg, 3.49 mmol). The mixture was warmed to 20 °C and concentrated to dryness in vacuo. The resulting orange solid was extracted with two 50-mL portions of pentane, and the combined solutions after repeatedly concentrating and cooling to −27 °C afforded red crystals of **6** (751 mg). Yield 58%; m.p. 104−105 °C (dec.). ^{1}H NMR (300 MHz, [D$_8$]THF, 296 K): *trans*-**6** (78%): δ = −0.65 (d, $^3J_{P,H}$ = 9.1 Hz, 3 H, $NiCH_3$), 1.00 (d, $^2J_{P,H}$ = 3.6 Hz, 18 H, PCH_3), 2.67 (s, 3 H, NCH_3), 5.82 (m, 1 H, CH), 5.89 (d, ^3J = 7.2 Hz, 1 H, CH), 6.57−6.63 (m, 2 H, CH), 7.22−7.27 (m, 6 H, CH), 7.46− 7.48 (m, 4 H, CH); *cis*-**6** (22%): δ = −0.07 (dd, $_{trans}{}^3J_{P,H}$ = 3.7, $_{cis}{}^3J_{P,H}$ = 6.5 Hz, 3 H, $NiCH_3$), 1.00 (br. s, 9 H, PCH_3), 2.48 (s, 3 H, NCH_3). ^{1}H NMR (300 MHz, [D$_8$]toluene): *trans*-**6** (> 98%): δ = 0.33 (dd, $^3J_{P,H}$ = 4.1 and 8.2 Hz, 3 H, $NiCH_3$), 1.00 (d, $^2J_{P,H}$ = 6.2 Hz, 9 H, PCH_3), 1.24 (br. d, $^3J_{P,H}$ = 7.1 Hz, 6 H, $PCHCH_3$), 1.28 (br. d, $^3J_{P,H}$ = 7.1 Hz, 6 H, $PCHCH_3$), 2.34 (m, 2 H, PCH), 2.98 (s, 3 H, NCH_3), 6.40 (t, ^3J = 7.1 Hz, 1 H, CH), 6.49 (dd, ^3J = 8.4, ^4J = 2.2 Hz, 1 H, CH), 7.12 (t, ^3J = 7.4 Hz, 1 H, CH), 7.31 (dt, ^3J = 7.1, $^4J_{P,H}$ = 1.4 Hz, 1 H, CH) ppm. ^{13}C NMR (75.4 MHz, [D$_8$]THF, 296 K): *trans*-**6**: δ = −14.3 (d, $^2J_{P,C}$ = 16.8 Hz, $NiCH_3$), 16.7 (d, $^1J_{P,C}$ = 7.6 Hz, PCH_3), 44.4 (s, N*C*H$_3$), 108.5 (s, C-2), 110.4 (d, $^2J_{P,C}$ = 12.5 Hz, 5-C), 128.9 (d, $^2J_{P,C}$ = 8.6 Hz, *m*-C), 129.4−131.9 (m, *p*-C/C-3), 133.3 (d, $^2J_{P,C}$ = 11.5 Hz, *o*-C), 134.4 (d, $^2J_{P,C}$ = 12.4 Hz, C-4), 135.3 (s, *i*-C), 139.8 (s, C-6) ppm. ^{31}P NMR (81 MHz, [D$_8$]THF, 193 K): *trans*-**6** (78%): δ = −11 (d, $^2J_{P,P}$ = 326 Hz, 1 P, PCH_3), 45 (d, $^2J_{P,P}$ = 297 Hz, 1 P, $PCHCH_3$); *cis*-**1** (22%): δ = −1 (d, $^2J_{P,P}$ = 25 Hz, 1 P, PCH_3), 45 (d, $^2J_{P,P}$ = 25 Hz, 1 P, $PCHCH_3$) ppm. ^{31}P NMR (81 MHz, [D$_8$]toluene): *trans*-**6** (> 98%): δ = −18 (d, $^2J_{P,P}$ = 327 Hz, 1 P, PCH_3), 40 (d, $^2J_{P,P}$ = 327 Hz, 1 P, $PCHCH_3$) ppm. $C_{17}H_{33}NNiP_2$ (371.1): calcd. C 54.87, H 8.94, N 3.76, P 16.65; found C 54.88, H 8.83, N 3.71, P 16.70.

[2-(Diphenylphosphanyl)anilido-*N*,*P*](methyl)bis(trimethylphosphane)nickel (7): 2-(Diphenylphosphanyl)aniline (810 mg, 2.92 mmol) in 50 mL of diethyl ether was combined at −70 °C with 1.6 M MeLi in diethyl ether (1.8 mL, 2.92 mmol), and this solution was added dropwise at −70 °C to $NiMeCl(PMe_3)_2$ (763 mg, 2.92 mmol) in 50 mL of diethyl ether. Workup proceeded as with **3**, and crystallization from 70 mL of pentane, containing excess PMe_3 (1.23 g, 16.1 mmol), afforded dark red crystals that were dried in vacuo at −5 °C for 10 min. Yield 790 mg of **7** (54%); m.p. 110−111 °C (dec.). IR (Nujol): $\tilde{\nu}$ = 3361 cm^{-1} (N−H). ^{1}H NMR (300 MHz, [D$_8$]THF, 296 K): *trans*-**7** (66%): δ = −0.75 (d, $^3J_{P,H}$ = 8.6 Hz, 3 H, $NiCH_3$), 1.00 (d, $^2J_{P,H}$ = 3.6 Hz, 18 H, PCH_3), 2.78 (NH 3,44s, 1 H, NH), 5.86 (m, 1 H, CH), 6.19 (dd, ^3J = 6.2, ^4J = 1.6 Hz, 1 H, CH), 6.66 (m, 1 H, CH), 6.85 (m, 1 H, CH), 7.30−7.38 (m, 6 H, CH), 7.64−7.74 (m, 4 H, CH); *cis*-**7** (34%): δ = −0.06 (m, 3 H, $NiCH_3$), 1.00 (d, $^2J_{P,H}$ = 3.6 Hz, 9 H, PCH_3), 3.44 (s, 1 H, NH), 5.88 (m, 1 H, CH), 6.20 (m, 1 H, CH) ppm. ^{13}C NMR (75.4 MHz, [D$_8$]THF, 296 K): *trans*-**7**: δ = −14.1 (m, $NiCH_3$), 16.7 (d, $^1J_{P,C}$ = 7.2 Hz, PCH_3), 45.1 (s, NCH_3), 108.5−135.4 (s, 10 C) ppm. ^{31}P NMR (81 MHz, [D$_8$]THF, 233 K): *trans*-**7** (66%): δ = −26 (br. s, 2 P, PCH_3), 27 (br. s, 1 P, PC_6H_5); *cis*-**7** (34%): δ = −1 (d, $^2J_{P,P}$ = 26 Hz, 1 P, PCH_3), 39 (d, $^2J_{P,P}$ = 26 Hz, 1 P, PC_6H_5) ppm. $C_{25}H_{35}NNiP_3$ (501.1): calcd. C 59.79, H 7.23, N 2.79, P 18.50; found C 58.80, H 7.39, N 2.74, P 18.33.

[2-(Diphenylphosphanyl)-*N*-methylanilido-*N*,*P*](methyl)bis(trimethylphosphane)nickel (8). Method a: 2-(Diphenylphosphanyl)-*N*-methylaniline (845 mg, 2.90 mmol) in 70 mL of THF was combined at −70 °C with $NiMe_2(PMe_3)_3$ (920 mg, 2.90 mmol) in 80 mL of diethyl ether. Warming to 20 °C caused evolution of gas and a dark red color. After 3 h, the volatiles were removed in vacuo and the residue was extracted with 70 mL of pentane, containing excess PMe_3 (610 mg, 8.0 mmol). Cooling to −27 °C afforded dark

red crystals of **8**: Yield 478 mg (32%). **Method b:** 2-(Diphenylphosphanyl)-*N*-methylaniline (770 mg, 2.64 mmol) in 70 mL of diethyl ether was combined at −70 °C with 1.6 M MeLi in diethyl ether (1.7 mL, 2.64 mmol), and to the yellow fluorescent solution was added $NiMeCl(PMe_3)_2$ (690 mg, 2.64 mmol) in 50 mL of diethyl ether. The deep red mixture was warmed to 20 °C and after 3 h concentrated to dryness in vacuo. The resulting solid was worked up as above affording crystals of **8**. Yield 912 mg (67%); m.p. 117−119 °C (dec.). ^{1}H NMR (300 MHz, [D$_8$]THF, 296 K): *trans*-**8** (79%): δ = −0.74 (d, $^3J_{P,H}$ = 10.1 Hz, 3 H, $NiCH_3$), 1.02 (d, $^2J_{P,H}$ = 4.8 Hz, 18 H, PCH_3), 1.24 (d, $^2J_{P,H}$ = 12.6 Hz, 9 H, PCH_3), 2.66 (s, 3 H, NCH_3), 5.95 (t, ^3J = 7.2 Hz, 1 H, CH), 6.12 (dd, $^4J_{P,H}$ = 5.0, ^3J = 8.5 Hz, 1 H, CH), 6.86 (dt, ^3J = 8.1, ^4J = 1.5 Hz, 1 H, CH), 7.22 (dt, ^3J = 7.4, ^4J = 1.5 Hz, 1 H, CH), 7.21−7.29 (m, 3 H, CH), 7.59−7.67 (m, 2 H, CH); *cis*-**8** (21%): δ = −0.07 (dd, $^3J_{P,H}$ = 4.2, $^3J_{P,H}$ = 8.2 Hz, 3 H, $NiCH_3$), 1.12 (d, $^2J_{P,H}$ = 4.8 Hz, 9 H, PCH_3), 1.47 (d, $^2J_{P,H}$ = 13.2 Hz, 9 H, PCH_3), 2.59 (s, 3 H, NCH_3), 5.83 (t, ^3J = 7.1 Hz, 1 H, CH), 6.17 (dd, $^4J_{P,H}$ = 5.2, ^3J = 8.2 Hz, 1 H, CH), 6.41 (dt, ^3J = 8.8, ^4J = 1.5 Hz, 1 H, CH), 6.86 (dt, ^3J = 8.1, ^4J = 1.5 Hz, 1 H, CH), 7.31−7.33 (m, 3 H, CH), 7.70−7.80 (m, 2 H, CH) ppm. ^{13}C NMR (75.4 MHz, [D$_8$]THF, 296 K): *trans*-**8**: δ = −14.4 (d, $^2J_{P,C}$ = 14.5 Hz, $NiCH_3$), 16.3 (d, $^2J_{P,C}$ = 6.9 Hz, PCH_3), 29.1 (d, $^1J_{P,C}$ = 5.8 Hz, CCH_3), 36.3 d $^2J_{P,C}$ = 11.9 Hz, CCH_3), 44.6 (s, NCH_3), 107.5 (s, C-2), 110.1 (s, C-5), 110.7 (d, $^2J_{P,C}$ = 10.8 Hz, *o*-C), 127.9 (s, C-3), 128.5 (d, $^3J_{P,C}$ = 6.8 Hz, *p*-C), 131.8 (s, C-4), 132.8 (d, $^3J_{P,C}$ = 8.4 Hz, *m*-C), 133.9 (s, *i*-C), 134.8 (s, C-6), 170.5 (m, NC-1) ppm. ^{31}P NMR (81 MHz, [D$_8$]THF, 233 K): *trans*-**8** (79%): δ = −16 (d, $^2J_{P,P}$ = 181 Hz, 2 P, PCH_3), 31 (t, $^2J_{P,P}$ = 181 Hz, 1 P, PC_6H_5); *cis*-**8** (21%): δ = −1 (d, $^2J_{P,P}$ = 29 Hz, 1 P, PCH_3), 57 (d, $^2J_{P,P}$ = 29 Hz, 1 P, PC_6H_5) ppm. $C_{26}H_{38}NNiP_3$ (515.2): calcd. C 60.49, H 7.42, N 2.71, P 18.00; found C 60.71, H 7.30, N 2.75, P 18.10.

{2-[*tert*-Butyl(phenyl)phosphanyl]-*N*-methylanilido-*N*,*P*}(methyl)bis-(trimethylphosphane)nickel (9): 2-[*tert*-Butyl(phenyl)phosphanyl]-*N*-methylaniline (680 mg, 2.50 mmol) in 80 mL of diethyl ether was treated at − 50 °C whilst stirring with 1.6 M MeLi in diethyl ether (1.6 mL, 2.50 mmol). After warming to 20 °C, the mixture was stirred until evolution of gas had ceased. At − 50 °C this reagent was combined with $NiClMe(PMe_3)_2$ (655 mg, 2.50 mmol) in 50 mL of diethyl ether. The mixture was stirred at 20 °C for 3 h and concentrated to dryness in vacuo. The resulting orange solid was extracted with two 50-mL portions of pentane and the solution concentrated at 20 °C to afford short red rods of **9**. Yield 583 mg (47%), m.p. 115−117 °C (dec.). ^{1}H NMR (300 MHz, [D$_8$]THF, 296 K): *trans*-**9** (79%): δ = −0.74 (d, $^3J_{P,H}$ = 10.1 Hz, 3 H, $NiCH_3$), 1.02 (d, $^2J_{P,H}$ = 4.8 Hz, 18 H, PCH_3), 1.24 (d, $^2J_{P,H}$ = 12.6 Hz, 9 H, PCH_3), 2.66 (s, 3 H, NCH_3), 5.95 (t, ^3J = 7.2 Hz, 1 H, CH), 6.12 (dd, $^4J_{P,H}$ = 5.0, ^3J = 8.5 Hz, 1 H, CH), 6.86 (dt, ^3J = 8.1, ^4J = 1.5 Hz, 1 H, CH), 7.22 (dt, ^3J = 7.4, ^4J = 1.5 Hz, 1 H, CH), 7.21−7.29 (m, 3 H, CH), 7.59−7.67 (m, 2 H, CH); *cis*-**9** (21%): δ = −0.07 (dd, $_{trans}{}^3J_{P,H}$ = 4.2 Hz, $_{cis}{}^3J_{P,H}$ = 8.2 Hz, 3 H, $NiCH_3$), 1.12 (d, $^2J_{P,H}$ = 4.8 Hz, 9 H, PCH_3), 1.47 (d, $^2J_{P,H}$ = 13.2 Hz, 9 H, PCH_3), 2.59 (s, 3 H, NCH_3), 5.83 (t, ^3J = 7.1 Hz, 1 H, CH), 6.17 (dd, $^4J_{P,H}$ = 5.2, ^3J = 8.2 Hz, 1 H, CH), 6.41 (dt, ^3J = 8.8, ^4J = 1.5 Hz, 1 H, CH), 6.86 (dt, ^3J = 8.1, ^4J = 1.5 Hz, 1 H, CH), 7.31−7.33 (m, 3 H, CH), 7.70−7.80 (m, 2 H, CH) ppm. ^{13}C NMR (75.4 MHz, [D$_8$]THF, 296 K): *trans*-**9**: δ = −14.4 (d, $^2J_{P,C}$ = 14.5 Hz, $NiCH_3$), 16.3 (d, $^2J_{P,C}$ = 6.9 Hz, PCH_3), 29.1 (d, $^1J_{P,C}$ = 5.8 Hz, CCH_3), 36.3 (d, $^2J_{P,C}$ = 11.9 Hz, CCH_3), 44.6 (s, NCH_3), 107.5 (s, C-2), 110.1 (s, C-5), 110.7 (d, $^2J_{P,C}$ = 10.8 Hz, *o*-C), 127.9 (s, C-3), 128.5 (d, $^3J_{P,C}$ = 6.8 Hz, *p*-C), 131.8 (s, C-4), 132.8 (d, $^3J_{P,C}$ = 8.4 Hz, *m*-C), 133.9 (s, *i*-C), 134.8 (s, C-6), 170.5 (m, NC-1) ppm. ^{31}P NMR (81 MHz, [D$_8$]THF, 233 K): *trans*-**9** (79%): δ = −16 (d, $^2J_{P,P}$ = 181 Hz, 2 P, PCH_3), 31 (t, $^2J_{P,P}$ = 181 Hz, 1 P, PC_6H_5); *cis*-**9** (21%): δ = −1 (d, $^2J_{P,P}$ = 29 Hz, 1 P, PCH_3), 57 (d, $^2J_{P,P}$ = 29 Hz, 1 P, PC_6H_5) ppm. $C_{24}H_{42}NNiP_3$ (495.2): calcd. C 58.09, H 8.53, N 2.82, P 18.73; found C 58.06, H 8.40, N 2.73, P 18.70.

Crystal Structure Analyses: Crystal data are presented in Table 2. Data collection: Complex *cis*-**5**: A crystal was sealed under argon in a glass capillary and mounted on a Stoe Stadi-4 diffractometer. Reflections were collected (ω-scans) using graphite-monochromated Mo-K_α radiation; absorption corrections based on ψ-scans were applied. The structure was solved by direct and conventional Fourier methods. All non-hydrogen atoms were treated anisotropically, hydrogen atoms were treated with a riding model in idealized positions. The final *wR*2 value is high due to poor crystal quality, but there is no doubt about the space group. Complex **7**: Crystal mounting, data collection, structure solution, and refinement as for *cis*-**5**. Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre. Copies of the data [CCDC-186327 (*cis*-**5**) and -186328 (**7**)] can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033, E-mail: deposit@ccdc.cam.ac.uk].

Fluxional and Rigid (Trimethylphosphane)cobalt Complexes Containing Chelating (2-Diphenylphosphanyl)anilido Ligands

Hans-Friedrich Klein,*[a] Robert Beck,[a] Ulrich Flörke,[b] and Hans-Jürgen Haupt[b]

Keywords: Chelates / Cobalt / P ligands / Structure elucidation

2-(Diphenylphosphanyl)anilines (P^NHR) eliminate methane upon reaction with $[CoMe(PMe_3)_4]$ forming the complexes $[Co(\eta^2\text{-}P\text{^}NR)(PMe_3)_3]$ (**1**: R = H; **2**: R = Me) and $[Co(\eta^2\text{-}P\text{^}NR)(PMe_3)_2]$ (**3**: R = Me). Reaction with HCl gives $[CoCl(\eta^1\text{-}P\text{^}NHR)(PMe_3)_2]$ (**4**: R = H; **5**: R = Me) and reaction with CO or olefin gives $[Co(\eta^2\text{-}P\text{^}NR)(CO)(PMe_3)_2]$ (**6**: R = H; **7**: R = Me) and $[Co(\eta^2\text{-}P\text{^}NR)(olefin)(PMe_3)_2]$ (**8**: R = H, olefin = C_2H_4; **9**: R = Me, olefin = C_2H_4; **10**: R = Me, olefin = C_3H_6), respectively. No catalytic transformation of the olefins was observed. Oxidation by iodomethane yields a cobalt(II) compound $[CoI(\eta^2\text{-}P\text{^}NR)(PMe_3)_2]$ (**11**: R = Me). By treating 2-(diphenylphosphanyl)aniline with $[CoMe_2(PMe_3)_3]$ a methylcobalt(II) complex $[CoMe(\eta^2\text{-}P\text{^}NR)(PMe_3)_2]$ (**12**: R = H) is obtained, while an excess of the aniline produces $[Co(\eta^2\text{-}P\text{^}NR)_2]$ (**13**: R = H; **14**: R = Me) or $[Co(\eta^2\text{-}P\text{^}NR)_2(PMe_3)]$ (**15**: R = H; **16**: R = Me). The methylcobalt(III) complexes *mer-trans*-$[CoIMe_2(\eta^2\text{-}P\text{^}NR)(PMe_3)_2]$ were obtained from LiP^NR and $[CoClMe_2(PMe_3)_3]$. Dynamic ^{31}P NMR spectra and the structures of complexes **3**, **6**, **12**, and **13** are discussed.

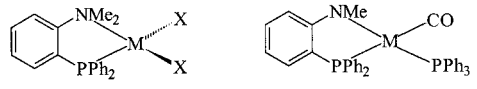
Introduction

Molecular derivatives of 2-(diphenylphosphanyl)aniline are well known as P,N-chelating ligands for the late transition metals,[1] and palladium(II), in particular, has been extensively investigated regarding certain aspects of homogeneous catalysis. Examples of first-row transition metals in early studies by Venanzi et al.[2] are molecular dihalides of cobalt and nickel (high-spin) which have a tetrahedral coordination geometry.

Formulae A



M = Co, Ni; X = Cl, Br, I M = Rh, Ir

Vaska-type square-planar complexes of rhodium(I) and iridium(I) containing 2-(diphenylphosphanyl)-*N*-methylanilido ligands have been investigated by Dahlenburg et al.,[3] and examples of a μ^2-bridging coordination mode of the 2-(diphenylphosphanyl)anilido ligand have been found in triangular clusters of ruthenium[4] and osmium.[5]

Here we describe the synthesis and structural properties of some novel mononuclear complexes of cobalt(I) and their transformation by oxidative addition reactions including an unexpected cyclometallation reaction.

Results and Discussion

2-(Diphenylphosphanyl)anilines react with $[CoMe(PMe_3)_4]$ [Equation (1)] with the elimination of methane to afford the pentacoordinate cobalt(I) complexes **1** and **2** as brown solids that are freely soluble in pentane or diethyl ether.

[b] Anorganische und Analytische Chemie der Universität Paderborn, Warburger Straße, 33098 Paderborn, Germany

Complex **1** forms dark brown crystals, while **2** is obtained as a solid wax, in moderate yield, from pentane containing excess trimethylphosphane. When dissociation of ligands is favoured, by applying fresh solvent or warming solid **2** in vacuo, a gradual transformation to the tetracoordinate complex **3** is achieved which eventually forms small red brown rods that are highly air-sensitive but thermally stable up to 135 °C. The observed magnetic susceptibility ($\mu_{eff}/\mu_B = 2.97$) is typical for tetrahedral complexes of cobalt(I).

Complexes **1** and **2** show a characteristic pattern of ^{31}P NMR signals: a doublet of triplets at $\delta = 52$ ppm for the chelating P nucleus, which experiences a coordination chemical shift of $\delta = 70$ ppm, a doublet of doublets at $\delta = -7$ ppm for two isochronic P nuclei and a doublet of triplets at $\delta = 28$ ppm for a third trimethylphosphane P nucleus (Figure 1).

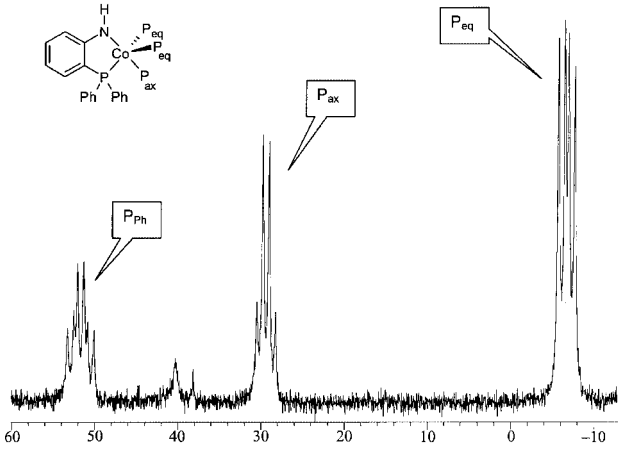

Figure 1. ^{31}P NMR spectrum of **1** (81 MHz, [D$_8$]THF, 233 K)

The values of the coupling constants ($J = 99$ and 61 Hz) fall in the range expected for the angles P−Co−P (90−110°) and suggest a trigonal-bipyramidal coordination geometry with two trimethylphosphane groups in equatorial positions.

In the molecular structure of **3** (Figure 2) a tetrahedral coordination geometry is confirmed by the angles P−Co−P (108−109°). The chelate bite angle P1−Co−N [86.34(8)°] is slightly larger than that found in a related pentacoordinate nickel(II) complex,[6] and the sum of the internal angles in the metallacycle (539.9°) equals that of a regular pentagon; N coordination to the cobalt(I) ion (16 valence electrons) [Co−N 1.926(2) Å] is found to be a normal distance,[7] and remarkably, the sum of the angles at the nitrogen atom (359.9°) indicates planarity as is the case in the nickel complex (18 valence electrons).

Reactions

Ethereal HCl protonates the N donor and one of the trimethylphosphane groups, thereby opening the chelate ring in **1** or **2** while retaining the Ph_2P donor group and generating the tetracoordinate complexes **4** and **5** [Equation (2)]. The process can be reversed by treating the compound with methyllithium. In a most convenient synthesis $CoCl(PMe_3)_3$ is treated with the appropriate 2-(diphenylphosphanyl)aniline [Equation (3)].

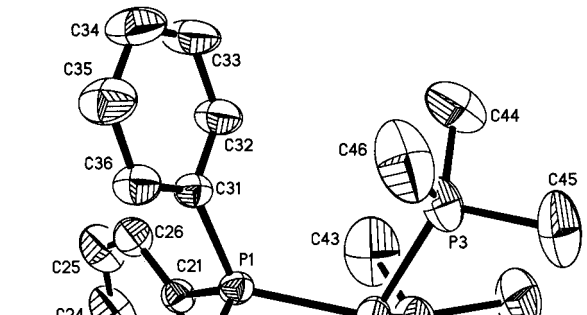

Figure 2. Molecular structure of **3** (ORTEP plot with hydrogen atoms omitted); selected bond lengths [Å] and angles [°]: Co−N1 1.926(2), Co−P1 2.2374(9), Co−P2 2.2243(10), Co−P3 2.2473(12), P1−C11 1.815(3), C11−C16 1.426(4), C16−N1 1.363(4); N1−Co−P1 86.34(8), N1−Co−P2 128.00(9), N1−Co−P3 118.97(9), C1−N1−Co 121.3(2), C16−N1−Co 122.24(18), C1−N1−C16 116.4(3), P1−Co−P2 108.58(4), P1−Co−P3 107.87(4), P2−Co−P3 103.64(4), Co−P1−C11 98.72(9), P1−C11−C16 114.4(2)

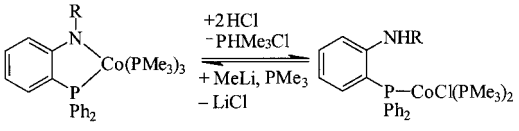
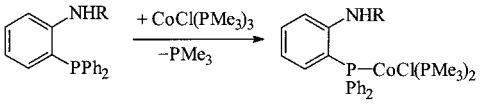


1, 2 **4**: R = H, **5**: R = Me (2)

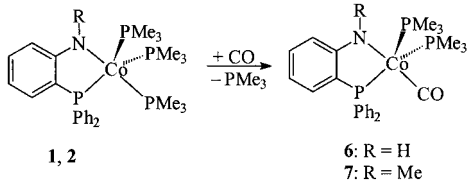


4: R = H, **5**: R = Me (3)

Complexes **4** and **5** form green solids that are insoluble in pentane, highly soluble in THF, and are best recrystallised from diethyl ether. IR spectra in the ν(NH) region show the expected number of bands at 3404 and 3318 cm^{-1} (**4**) that are close to those of 2-(diphenylphosphanyl)aniline.

A band occurring at 3332 cm^{-1} (**5**) is shifted by 30 cm^{-1} with respect to 2-(diphenylphosphanyl)-*N*-methylaniline indicating an intramolecular hydrogen bond N−H···Cl in **5**.

The values of the magnetic susceptibilities (**4**: μ_{eff}/μ_B = 3.29; **5**: μ_{eff}/μ_B = 3.25) are consistent for tetrahedral high-spin complexes.[8] Under 1 bar of CO **1** and **2** smoothly form monocarbonyl complexes [Equation (4)].



1, 2 **6**: R = H, **7**: R = Me (4)

From pentane, red crystals of **6** and **7** are obtained that are thermally stable up to 150 °C. IR spectra contain single ν(CO) bands of terminal carbonyl ligands (**6**: 1887 cm^{-1}; **7**: 1906 cm^{-1}) indicating that only one of the possible two isomers is present. The ^{31}P NMR doublet and triplet resonances at characteristic shifts, along with the larger coupling (J = 97 Hz) indicate that the carbonyl ligand resides in an axial position. This configuration is also adopted in the

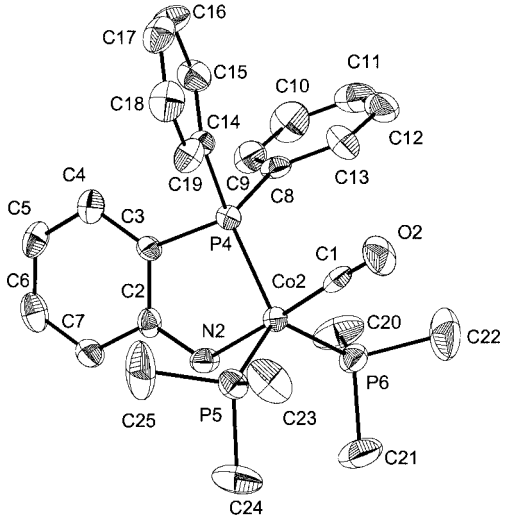


Figure 3. Molecular structure of **6** (ORTEP plot with hydrogen atoms omitted); selected bond lengths [Å] and angles [°]: Co−C1 1.754(14), C1−O2 1.157(15), Co−P4 2.210(3), Co−P5 2.184(3), Co−P6 2.194(3), Co−N2 1.907(9), N2−C2 1.360(14), C2−C3 1.411(15), P4−C3 1.80(1); N2−Co−C1 176.9(5), N2−Co−P4 84.3(3), N2−Co−P5 86.1(3), N2−Co−P6 88.2(3), Co−N2−C2 122.6(8), N2−C2−C3 118.8(9), C2−C3−P4 111.6(8), C3−P4−Co 100.6(4)

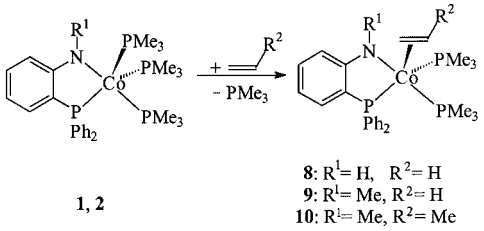
crystal, as shown by the molecular structure of **6** (Figure 3).

The carbonyl and amide ligands occupy axial positions with tighter bonding [Co−N = 1.907(9) Å] than that in **3** which arises from a push-pull stabilisation of ligands in *trans* positions [C−Co−N 176.9(5)°]. The chelate bite angle P4−Co−N [84.3(3)°] is only 2° larger than it is in **3**, and the sum of the internal angles in the metallacycle is 537.9°. There is a close structural correspondence between **6** and a related carbonylbis(trimethylphosphane)cobalt(I)(*P*,*O*-chelate) complex[9] as can be expected of isoelectronic O and NH donors.

Brown solutions of **1** or **2** in pentane under 1 bar of ethene or propene turn red and upon cooling afford red crystals of monoolefin complexes **8**−**10** [Equation (5)], in the case of **6** and **7** together with crystals of **3**. No reaction is observed in neat cyclopentene.



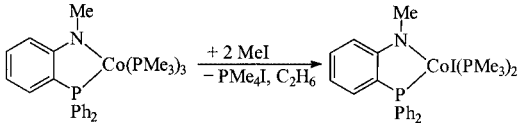
1, 2 **8**: R^1 = H, R^2 = H; **9**: R^1 = Me, R^2 = H; **10**: R^1 = Me, R^2 = Me (5)

Careful drying under a gas blanket of olefin and manual selection of crystals gives analytically pure samples of **8**−**10**. All three compounds are solids with low melting points that are sensitive towards heat and oxygen, already releasing olefin at 20 °C in vacuo. As no structural proof has been obtained by X-ray diffraction on single crystals, ^{31}P NMR spectroscopy was used to support pentacoordination in compounds **8**−**10**. At 193 K ligand mobility is slow enough to reveal the ground-state geometry through a doublet of doublets pattern of three ^{31}P NMR signals (Table 1).

Table 1. ^{31}P NMR spectroscopic data (81 MHz, [D_8]THF, 193 K) for (olefin)cobalt compounds **8**−**10** [δ in ppm, J in Hz]

	δ(P_{Ph})		δ(P_{ax})		δ(P_{eq})	
	$^2J(P_{Ph}P_{eq})$	$^2J(P_{Ph}P_{ax})$	$^2J(P_{ax}P_{Ph})$	$^2J(P_{ax}P_{eq})$	$^2J(P_{eq}P_{Ph})$	$^2J(P_{eq}P_{ax})$
8	61 (dd)		23 (dd)		3 (dd)	
	34	30	30	52	34	52
9	61 (dd)		23 (dd)		3 (dd)	
	36	32	32	56	36	56
10	61 (dd)		22 (dd)		3 (dd)	
	38	30	30	52	38	52

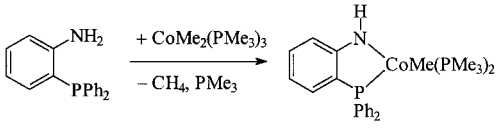
^{31}P nuclei of axial and equatorial trimethylphosphane groups are coupled with an equatorial chelating ^{31}P nucleus leaving an equatorial position for the olefin ligand. Reaction of **2** with iodomethane [Equation (6)] − oxidative substitution of a trimethylphosphane group and quaternisation − takes an unexpected course.



2 **11** (6)

Black crystals of an iodocobalt(II) complex **11** are obtained from diethyl ether. Elemental analysis shows that the cobalt atom has lost the initial methylmetal function and is coordinated to five ligands. Accordingly, the magnetic susceptibility (μ_{eff}/μ_B = 2.09) is as expected for a pentacoordin-

ate cobalt (d^7) compound.[10] A corresponding methylcobalt(II) complex **12** is obtained by reaction of 2-(diphenylphosphanyl)aniline with $CoMe_2(PMe_3)_3$ [Equation (7)].



12 (7)

The black crystals of **12** are freely soluble in pentane and are thermally even more stable than **11**. The magnetic susceptibility (μ_{eff}/μ_B = 1.65) is at the lower end of that expected for a trigonal-bipyramidal configuration of the Co atom (d^7, 17 valence electrons).[10] While no solution structure of **12** could be derived from spectroscopic data, the molecular structure was revealed by X-ray diffraction (Figure 4).

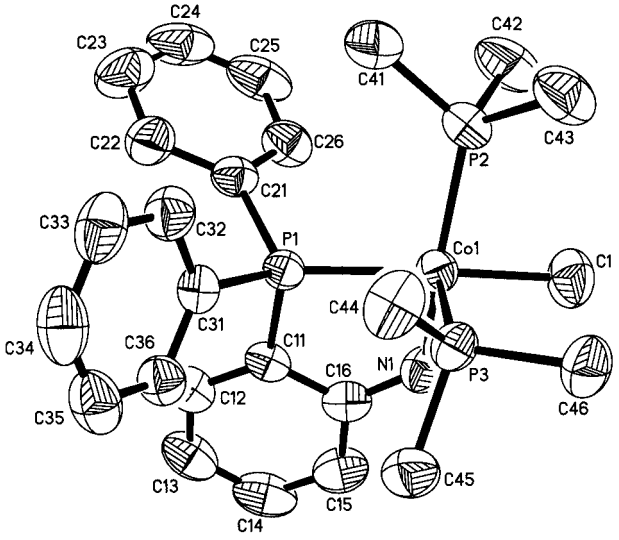


Figure 4. Molecular structure of **12** (ORTEP plot with hydrogen atoms omitted); selected bond lengths [Å] and angles [°]: Co–C1 2.019(3), Co–N1 1.929(2), Co–P1 2.2472(8), Co–P2 2.1858(9), Co–P3 2.2833(8), N1–C16 1.351(3), C16–C11 1.407(4), C11–P1 1.808(3); P1–Co–C1 162.43(10), N1–Co–P2 154.60(7), N1–Co–P3 102.47(7), N1–Co–P1 82.64(7), Co–N1–C16 125.32(18), N1–C16–C11 118.5(2), C16–C11–P1 111.83(19), C11–P1–Co 101.65(9)

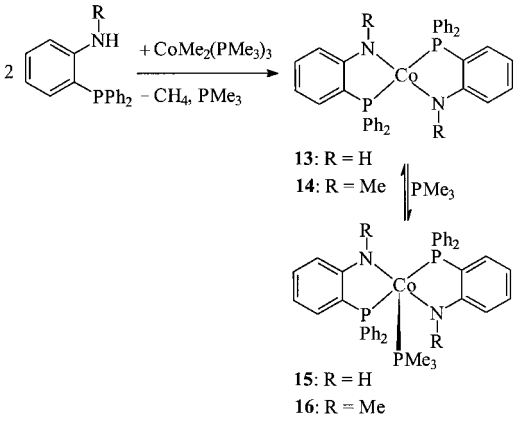
The cobalt centre of **12** is located above an almost square plane (P1,P2,C1,N1) with an apical trimethylphosphane group (P3) attached to it at the longest Co–P distance. The void *trans* to P3 is large enough for, although not occupied by, a hydride ligand. This is seen from the IR spectrum where the ν(CoH) region is empty along with the d^7 valence state of the Co atom. The methyl ligand (C1) is arranged in the opposite position to the chelating P donor (P1) which is different from an otherwise related pentacoordinate methylnickel(II) complex (18 electrons), where it is *trans* to the amide donor.[6] The chelate bite angle is close to that in **3**, and the sum of the internal angles (539.9°) indicates a relaxed metallacycle. Reactivity of the methylmetal function is sufficient to afford bis(P,N)chelate compounds of cobalt(II) [Equation (8)].

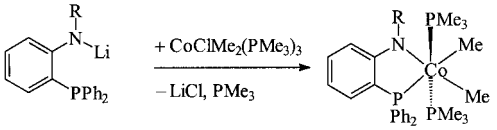


(8)

The molecular complexes **13** and **14** (15 metal valence electrons) are stable up to 250 and 200 °C, respectively. Only when additional trimethylphosphane is supplied in excess, does it coordinate to afford the pentacoordinate species **15** and **16**. Magnetic susceptibilities (**13**: μ_{eff}/μ_B = 2.05; **14**: μ_{eff}/μ_B = 2.33; **15**: μ_{eff}/μ_B = 2.10; **16**: μ_{eff}/μ_B = 2.04) fall in the range expected for tetracoordinate (low-spin)[9,11] and pentacoordinate[9,10] cobalt(II) compounds but give no further clue to the configuration of the complexes.

In the molecular structure of **13** (Figure 5) a *trans* square-planar arrangement of ligands is revealed around a cobalt atom sitting in a centre of inversion. The chelate bite angle is normal [P–Co–N 83.6(2)°] and so are the bond lengths [Co–N 1.858(6), Co–P 2.212(6) Å]. The structure of **13** is the first for this type of bis(*P*,*N*)chelate cobalt complex, with the *trans* configuration differing from that of isoelectronic *cis*-bis(*P*,*O*)chelate cobalt compounds.[9]

In an attempted synthesis of methylcobalt(III) complexes containing chelating 2-(diphenylphosphanyl)anilido ligands no reaction of $CoMe_3(PMe_3)_3$ with 2-(diphenylphosphanyl)aniline or 2-(diphenylphosphanyl)-*N*-methylaniline was observed. An alternative route [Equation (9)] afforded the dimethylcobalt(III) compounds **17** and **18**.



17: R = H
18: R = Me (9)

Highly soluble short orange rods of **17** and **18** are crystallised from pentane and melt at 85 and 89 °C, respectively. Under conditions of low ligand mobility (193 K) the ^{31}P NMR signals recorded as a triplet (1 P) and doublet (2 P) indicate a meridional arrangement of P donor functions in

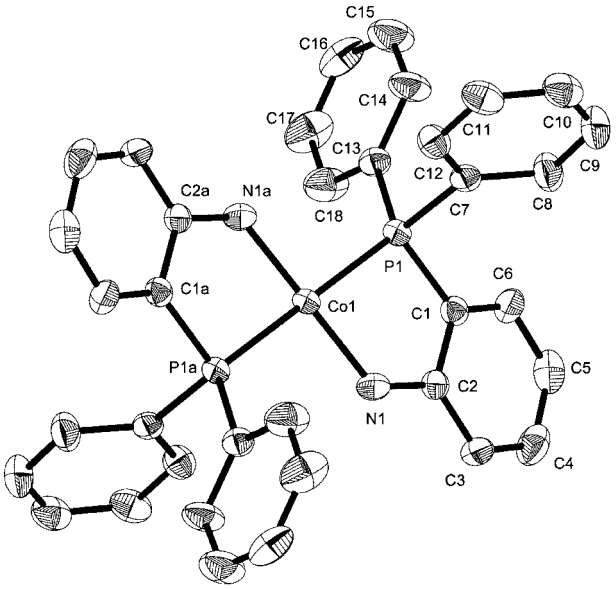


Figure 5. Molecular structure of **13** (ORTEP plot with hydrogen atoms omitted); selected bond lengths [Å] and angles [°]: Co−N1 1.858(6), Co−P1 2.212(2), P1−C1 1.798(8), C1−C2 1.398(10), C2−N1 1.389(9); C2−N1−Co 124.6(5), N1−C2−C1 117.0(7), C2−C1−P1 111.5(6), C1−P1−Co 100.8(3)

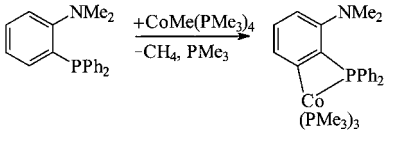
octahedral complexes of a low-spin Co (d^6) ion. Complex **15** tends to lose one of the methyl groups since after repeated recrystallisations black crystals of **12** were obtained.

Reactions involving methylcobalt compounds thus far have been directed towards a prechelate NH function and proceed with the elimination of methane. Surprisingly, [CoMe(PMe_3)$_4$] was found to react smoothly at −70 °C with 2-(diphenylphosphanyl)-*N*,*N*-dimethylaniline. Evolution of gas was observed while heating to 20 °C, and eventually dark red crystals of **19** were obtained and found to arise from a cyclometallation reaction [Equation (10)].



(10)

19

The ^{31}P NMR spectrum at 233 K clearly shows the characteristic shifts and coupling pattern of an *ortho*-metallated tris(trimethylphosphane)cobalt complex.[12] As no further signals are detected, the absence of possible isomers of **19** is confirmed. This unusual result is supported by the ^{13}C NMR spectroscopic data. Only ten resonances of aromatic carbon nuclei were detected whereas eighteen are expected to arise from altogether five available *ortho*-CH groups.

Consequently, a thorough search for isomers of **19** was undertaken. In view of an 80% yield the synthesis was repeated on a larger scale (see Exp. Sect.) to afford 85% of the product, and 270 mg of solid residue could be scrutinised by IR and ^{13}C NMR spectroscopy. Again only the signals of **19** were detected besides some trimethylphosphane oxide and the well-known marks of silicon grease, which amounts to an estimated regioselectivity of better than 99%.

Complexes of rhodium and iridium, containing 2-(diphenylphosphanyl)-*N*,*N*-dimethylaniline as a bidentate ligand, have been described,[13] and no *ortho*-metallation was reported. Clearly, this spontaneous transformation with cobalt and its unexpected absolute selectivity merit further investigation.

Experimental Section

General Procedures and Materials: All air-sensitive and volatile materials were handled using standard vacuum techniques and were kept under argon. Microanalyses: Kolbe Microanalytical Laboratory, Mülheim/Ruhr, FRG. Melting points/decomposition temperatures: Sealed capillaries, uncorrected values. Chemicals (Merck/Schuchardt) were used as purchased. Literature methods were applied in the preparation of [CoCl(PMe_3)$_3$],[14] [CoMe(PMe_3)$_4$],[15] [CoMe$_2$(PMe_3)$_3$],[10] [CoClMe$_2$(PMe_3)$_3$],[16] 2-(diphenylphosphanyl)aniline,[17] 2-(diphenylphosphanyl)-*N*-methylaniline,[18] and 2-(diphenylphosphanyl)-*N*,*N*-dimethylaniline.[19] IR: Nujol mulls between KBr discs, Bruker spectrophotometer type FRA 106. ^{1}H and ^{13}C NMR spectra (300 MHz and 75 MHz, respectively) were recorded with a Bruker ARX-300 spectrometer, ^{31}P NMR spectra (81 MHz) with a Bruker AM-200 instrument. ^{13}C and ^{31}P NMR resonances were obtained with broad-band proton decoupling. MS: Varian Mat-311 (FD). Magnetic susceptibility data were obtained by the Faraday method, Cahn D 200 torsion balance and Bruker BMN-200/60 magnet system at 1.5 Tesla.

[2-(Diphenylphosphanyl)anilido-*N*,*P*]tris(trimethylphosphane)cobalt (1). Method a: 2-(Diphenylphosphanyl)aniline (1202 mg, 3.70 mmol) in diethyl ether (40 mL) was combined with [CoMe(PMe_3)$_4$] (1400 mg, 3.70 mmol) in diethyl ether (40 mL) at −70 °C causing the evolution of gas and giving a brown heterogeneous mixture. This was heated to 20 °C and stirred for 1 h. The dark solid of **1** was isolated by decanting and washing with cold pentane and dried in vacuo. From the liquor, at 4 °C, another 260 mg of black crystals of **1** were obtained. Combined yield 1710 mg (82%). **Method b:** Chloro[2-(diphenylphosphanyl)anilido-*N*,*P*]bis(trimethylphosphane)cobalt (**4**) (980 mg, 1.87 mmol) and trimethylphosphane (1500 mg, 19.7 mmol) in THF (40 mL) were combined at −70 °C with MeLi (1.6 M) in diethyl ether (1.2 mL, 1.80 mmol) causing the dark green colour to turn red brown. The mixture was heated to 20 °C and stirred for 30 min. The volatiles were removed in vacuo and the residue was extracted with three portions of diethyl ether (80 mL). Fractional crystallisation at 4 °C afforded black crystals of **1**. Yield 664 mg (63%); m.p. 118−119 °C (dec.). IR (Nujol): $\tilde{\nu}$ = 3331 cm^{-1} (N−H). ^{1}H NMR (300 MHz, [D$_8$]THF, 233 K): δ = 0.88 (br. s, 9 H, PCH_3), 1.28 (br. s, 18 H, PCH_3), 2.95 (s, 1 H, NH), 5.69 (t, ^3J = 6.8 Hz, 1 H, CH), 6.23 (t, ^3J = 4.9 Hz, 1 H, CH), 6.38 (t, ^3J = 7.1 Hz, 1 H, CH), 7.06 (t, ^3J = 7.4 Hz, 1 H, CH), 7.19−7.25 (m, 6 H, CH), 7.62−7.66 (m, 4 H, CH) ppm. ^{31}P NMR (81 MHz, [D$_8$]THF, 233 K): δ = −7 (dd, $^2J_{P,P}$ = 99 and 61 Hz, 2 P, PCH_3), 28 (dt, $^2J_{P,P}$ = 61 and 60 Hz, 1 P, PC_6H_5), 52 (dt, $^2J_{P,P}$ = 99 and 61 Hz, 1 P, PCH_3) ppm. $C_{27}H_{42}CoNP_4$ (563.5): calcd. C 57.55, H 7.51, N 2.49, P 21.99; found C 58.29, H 7.53, N 2.48, P 21.60.

[2-(Diphenylphosphanyl)-*N*-methylanilido-*N*,*P*]tris(trimethylphosphane)cobalt (2). Method a: 2-(Diphenylphosphanyl)-*N*-

methylaniline (750 mg, 1.95 mmol) in THF (50 mL) was combined with $CoMe(PMe_3)_4$ (740 mg, 1.95 mmol) in THF (50 mL) at 20 °C. The mixture was stirred for 16 h and the solvents were evaporated to dryness in vacuo. The residue was extracted with two portions of pentane (50 mL) and the red brown solution cooled to −27 °C to afford a black solid which was isolated by decanting and drying in vacuo to give a waxy solid of **2**. Yield 395 mg (35%). **Method b:** Chloro[2-(diphenylphosphanyl)-*N*-methylaniline]bis(trimethylphosphane)cobalt (**5**) (580 mg, 1.08 mmol) and trimethylphosphane (1100 mg, 14.4 mmol) in THF (70 mL) were combined at −70 °C with MeLi (1.6 M) in diethyl ether (0.67 mL, 1.08 mmol) causing the dark green colour to turn red brown. The mixture was warmed to 20 °C and stirred for 30 min. The volatiles were removed in vacuo and the residue was extracted with three 50 mL portions of pentane. Crystallisation at 4 °C afforded black crystals of **2**. Yield 395 mg (29%); m.p. 130−135 °C (dec.). ^{1}H NMR (300 MHz, [D$_8$]THF, 233 K): δ = 0.90 (br. s, 9 H, PCH_3), 1.25 (br. s, 18 H, PCH_3), 2.66 (s, 3 H, NCH_3), 5.80−7.78 (m, 14 H, CH) ppm. ^{31}P NMR (81 MHz, [D$_8$]THF, 233 K): δ = −8 (dd, $^2J_{P,P}$ = 103 and 59 Hz, 2 P, PCH_3), 29 (dt, $^2J_{P,P}$ = 60 and 59 Hz, 1 P, PC_6H_5), 52 (dt, $^2J_{P,P}$ = 103 and 59 Hz, 1 P, PCH_3) ppm. MS (70 eV): *m/z* (%) = 577 (20) [M$^+$], 501 (30) [M$^+$ − PMe_3].

[2-(Diphenylphosphanyl)-*N*-methylanilido-*N*,*P*]bis(trimethylphosphane)cobalt (3): 2-(Diphenylphosphanyl)aniline (685 mg, 2.35 mmol) in THF (50 mL) was combined with [$CoMe(PMe_3)_4$] (890 mg, 2.35 mmol) in THF (50 mL), at −70 °C, and after heating to 20 °C, the mixture was stirred for 16 h. The volatiles were removed in vacuo and the residue was extracted with two portions of pentane (50 mL). Crystallisation at 4 °C afforded red brown rods of **3**. Yield 763 mg (69%); m.p. 135−136 °C (dec.). Magnetic moment (299 K): μ_{eff} = 2.97 μ_B. $C_{25}H_{35}CoNP_3$ (501.4): calcd. C 59.89, H 7.04, N 2.79, P 18.53; found C 59.78, H 7.00, N 2.83, P 18.75.

Chloro[2-(diphenylphosphanyl)aniline]bis(trimethylphosphane)cobalt (4): 2-(Diphenylphosphanyl)aniline (584 mg, 2.10 mmol) in THF (50 mL) was combined with $CoCl(PMe_3)_3$ (680 mg, 2.10 mmol) in THF (50 mL) and within 10 min a dark green solution formed. After 1 h, the volatiles were removed in vacuo and the residue was extracted with three portions of diethyl ether (80 mL). Crystallisation at 4 °C afforded dark green prisms of **4**. Yield 716 mg (65%); m.p. 126−127 °C (dec.). Magnetic moment (299 K): μ_{eff} = 3.25 μ_B. IR (Nujol): $\tilde{\nu}$ = 3404, 3211 cm^{-1} (N−H). $C_{24}H_{34}ClCoNP_3$ (523.8): calcd. C 55.03, H 6.54, N 2.67, P 17.74; found C 55.09, H 6.40, N 2.66, P 17.89.

Chloro[2-(diphenylphosphanyl)-*N*-methylaniline]bis(trimethylphosphane)cobalt (5): 2-(Diphenylphosphanyl)-*N*-methylaniline (803 mg, 2.75 mmol) in THF (50 mL) and [$CoCl(PMe_3)_3$] (890 mg, 2.75 mmol) in THF (50 mL) formed a dark green solution. After 1 h, the volatiles were removed in vacuo and the residue was extracted as above. Crystallisation at 4 °C afforded dark green platelets of **5**. Yield 1130 mg (77%); m.p. 130−131 °C (dec.). Magnetic moment (299 K): μ_{eff} = 3.29 μ_B. IR (Nujol): $\tilde{\nu}$ = 3332 cm^{-1} (N−H). $C_{25}H_{36}ClCoNP_3$ (537.9): calcd. C 55.83, H 6.75, N 2.60, P 17.28; found C 55.78, H 6.52, N 2.58, P 17.33.

Carbonyl[2-(diphenylphosphanyl)anilido-*N*,*P*]bis(trimethylphosphane)cobalt (6): A sample of **1** (710 mg, 1.26 mmol) in THF (70 mL) was stirred under 1 bar of CO for 30 min and afforded a red solution. The volatiles were removed in vacuo and the residue was extracted with two portions of pentane (70 mL). At 4 °C short orange red rods of **6** were obtained. Yield 487 mg (75%); m.p. 153−157 °C (dec.). IR (Nujol): $\tilde{\nu}$ = 3375 cm^{-1} (N−H), 1887 cm^{-1} (CO). ^{1}H NMR (300 MHz, [D$_8$]THF, 296 K): δ = 1.15 (s, 18 H, PCH_3), 1.35 (br. s, 1 H, NH), 5.93 (dd, ^3J = 7.2, ^4J = 1.1 Hz, 1 H, CH), 6.34 (dd, ^3J = 5.1, $^4J_{P,H}$ = 3.1 Hz, 1 H, CH), 6.60 (dd, ^3J = 6.7, ^4J = 1.4 Hz, 1 H, CH), 7.06 (dt, ^3J = 7.8, ^4J = 1.4 Hz, 1 H, CH), 7.25−7.31 (m, 6 H, CH), 7.52−7.61 (m, 4 H, CH) ppm. ^{13}C NMR (75.4 MHz, [D$_8$]THF, 296 K): δ = 18.6 (s, PCH_3), 109.7 (d, $^3J_{P,C}$ = 4.5 Hz, CH), 116.7 (d, $^1J_{P,C}$ = 13.2 Hz, CH), 128.5 (d, $^2J_{P,C}$ = 9.4 Hz, CH), 130.3 (s, CH), 132.7 (d, $^2J_{P,C}$ = 12.5 Hz, CH), 133.8 (s, CH), 135.0, 142.0 (s, C) ppm. ^{31}P NMR (81 MHz, [D$_8$]THF, 233 K): δ = 5 (d, $^2J_{P,P}$ = 97 Hz, 2 P, PCH_3), 63 (t, $^2J_{P,P}$ = 97 Hz, 1 P, PC_6H_5) ppm. $C_{25}H_{33}CoNOP_3$ (515.4): calcd. C 58.26, H 6.45, N 2.72, P 18.03; found C 58.03, H 6.64, N 2.66, P 18.11.

Carbonyl[2-(diphenylphosphanyl)-*N*-methylanilido-*N*,*P*]bis(trimethylphosphane)cobalt (7): A sample of **2** (590 mg, 1.02 mmol) in THF (70 mL) was stirred under 1 bar of CO for 30 min to afford a light red solution. The volatiles were removed in vacuo and the residue was extracted with two portions of pentane (70 mL). At 4 °C short dark red rods of **7** were obtained. Yield 492 mg (91%); m.p. 165−170 °C (dec.). IR (Nujol): $\tilde{\nu}$ = 1906 cm^{-1} (CO). ^{1}H NMR (300 MHz, [D$_8$]THF, 296 K): δ = 1.17 (s, 18 H, PCH_3), 2.74 (s, 3 H, NCH_3), 5.72 (dd, ^3J = 7.4, ^4J = 1.3 Hz, 1 H, CH), 6.22 (dd, ^3J = 6.2, $^4J_{P,H}$ = 2.8 Hz, 1 H, CH), 6.60 (dd, ^3J = 6.2, ^4J = 1.4 Hz, 1 H, CH), 7.15 (dd, ^3J = 7.4, ^4J = 1.4 Hz, 1 H, CH), 7.31−7.36 (m, 6 H, CH), 7.45−7.52 (m, 4 H, CH) ppm. ^{13}C NMR (75.4 MHz, [D$_8$]THF, 296 K): δ = 18.1 (s, PCH_3), 39.4 (s, NCH_3), 109.2 (s, CH), 112.5 (d, $^4J_{P,C}$ = 4.9 Hz, CH), 117.2 (d, $^1J_{P,C}$ = 14.9 Hz, CH), 127.4 (d, $^2J_{P,C}$ = 12.3 Hz, CH), 130.3 (s, CH), 133.4 (d, $^2J_{P,C}$ = 12.5 Hz, CH), 133.7, 135.0 (s, C), 169.1 (d, $^2J_{P,C}$ = 30.5 Hz, NC) ppm. ^{31}P NMR (81 MHz, [D$_8$]THF, 233 K): δ = 6 (d, $^2J_{P,P}$ = 97 Hz, 2 P, PCH_3), 65 (t, $^2J_{P,P}$ = 97 Hz, 1 P, PC_6H_5) ppm. $C_{26}H_{35}CoNOP_3$ (529.4): calcd. C 58.99, H 6.66, N 2.65, P 17.55; found C 58.98, H 6.73, N 2.55, P 17.48.

[2-(Diphenylphosphanyl)anilido-*N*,*P*](ethene)bis(trimethylphosphane)cobalt (8): A sample of **1** (580 mg, 1.02 mmol), suspended in pentane (70 mL), was stirred under 1 bar of C_2H_4 for 30 min to afford a red solution which was filtered and cooled to −27 °C. Short red rods of **8** were dried in a stream of ethene at 20 °C. Yield 281 mg (53%); m.p. 45−50 °C (dec.). IR (Nujol): $\tilde{\nu}$ = 3342 cm^{-1} (N−H). ^{1}H NMR (300 MHz, [D$_8$]THF, 296 K): δ = 1.17 (d, $^2J_{P,H}$ = 7.3 Hz, 9 H, PCH_3), 1.32 (d, $^2J_{P,H}$ = 4.5 Hz, 9 H, PCH_3), 1.74 (m, 2 H, C=CH_2), 2.85 (m, 2 H, C=CH_2), 4.21 (br. s, 1 H, NH), 5.85 (m, 1 H, CH), 5.94 (m, 1 H, CH), 6.71 (m, 2 H, CH), 7.35−7.39 (m, 6 H, CH), 7.75−7.78 (m, 4 H, CH) ppm. ^{13}C NMR (75.4 MHz, [D$_8$]THF, 296 K): δ = 17.8 (d, $^1J_{P,C}$ = 19.4 Hz, PCH_3), 20.4 (d, $^1J_{P,C}$ = 16.3 Hz, PCH_3), 44.1 (m, CH_2), 108.1, 111.5, 123.2 (s, CH), 127.3 (m, C), 128.8, 130.7, 133.2 (s, CH), 134.4 (d, $^2J_{P,C}$ = 25.3 Hz, C), 141.7 (s, CH) ppm. ^{31}P NMR (81 MHz, [D$_8$]THF, 193 K): δ = 3 (dd, $^2J_{P,P}$ = 34 and 52 Hz, 1 P, PCH_3), 24 (dd, $^2J_{P,P}$ = 30 and 52 Hz, 1 P, PCH_3), 61 (dd, $^2J_{P,P}$ = 34 and 30 Hz, 1 P, PC_6H_5) ppm. $C_{26}H_{37}CoNP_3$ (515.4): calcd. C 60.59, H 7.24, N 2.72, P 18.03; found C 60.54, H 7.43, N 2.74, P 17.92.

[2-(Diphenylphosphanyl)-*N*-methylanilido-*N*,*P*](ethene)bis(trimethylphosphane)cobalt (9): A sample of **2** (720 mg, 1.24 mmol) in pentane (70 mL) was stirred under 1 bar of C_2H_4 for 30 min to afford a red solution which was filtered and cooled to 4 °C. Short red rods of **9** were dried in a stream of ethene at 20 °C. Yield 410 mg (62%); m.p. 45−50 °C (dec.). ^{1}H NMR (300 MHz, [D$_8$]THF, 296 K): δ = 0.72 (d, $^2J_{P,H}$ = 7.2 Hz, 9 H, PCH_3), 1.30 (d, $^2J_{P,H}$ = 3.9 Hz, 9 H, PCH_3), 1.73 (m, 2 H, C=CH_2), 2.16 (s, 3 H, NCH_3), 2.81 (m, 2 H, C=CH_2), 5.80 (m, 2 H, CH), 6.66−6.68 (m, 2 H, CH), 7.31−7.33 (m, 6 H, CH), 7.67−7.75 (m, 4 H, CH) ppm. ^{13}C NMR (75.4 MHz, [D$_8$]THF, 296 K): δ = 17.8 (d, $^1J_{P,C}$ = 22.6 Hz, PCH_3), 20.4 (d, $^1J_{P,C}$ = 14.6 Hz, PCH_3), 38.2 (s, NCH_3), 45.3 (d,

$^2J_{P,C}$ = 18.3 Hz, CH_2), 45.9 (m, CH_2), 108.4, 111.0, 123.3 (s, CH), 128.4 (d, $^1J_{P,C}$ = 19.1 Hz, C), 128.8, 130.7, 133.2 (s, CH), 133.8 (d, $^2J_{P,C}$ = 24.3 Hz, C), 141.7 (s, CH), 166.0 (s, NC) ppm. ^{31}P NMR (81 MHz, [D$_8$]THF, 193 K): δ = 3 (dd, $^2J_{P,P}$ = 36 and 56 Hz, 1 P, PCH_3), 23 (dd, $^2J_{P,P}$ = 32 and 56 Hz, 1 P, PCH_3), 61 (dd, $^2J_{P,P}$ = 36 and 32 Hz, 1 P, PC_6H_5) ppm. $C_{27}H_{39}CoNP_3$ (529.2): calcd. C 61.25, H 7.42, N 2.65, P 17.55; found C 61.18, H 7.52, N 2.51, P 17.62.

[2-(Diphenylphosphanyl)-*N*-methylanilido-*N*,*P*](propene)bis(trimethylphosphane)cobalt (10): A sample of **2** (830 mg, 1.43 mmol) in pentane (70 mL) was stirred under 1 bar of C_3H_6 for 30 min to afford a red solution which was filtered and cooled to −27 °C. Red triangular platelets of **10** together with those of **2** were dried in a stream of propene at 20 °C and separated mechanically. Yield 179 mg (23%); m.p. 85−87 °C (dec.). ^{1}H NMR (300 MHz, [D$_8$]THF, 296 K): δ = 0.74 (d, $^2J_{P,H}$ = 8.0 Hz, 9 H, PCH_3), 1.30 (d, $^2J_{P,H}$ = 6.1 Hz, 9 H, PCH_3), 1.36 (m, 3 H, CCH_3), 2.42 (s, 3 H, NCH_3), 2.79 (m, 1 H, C=CH), 2.81 (m, 2 H, C=CH_2), 6.55 (m, 1 H, CH), 6.61 (m, 1 H, CH), 6.55 (m, 2 H, CH), 7.21−7.35 (m, 6 H, CH), 7.65−7.80 (m, 4 H, CH) ppm. ^{31}P NMR (81 MHz, [D$_8$]THF, 193 K): δ = 3 (dd, $^2J_{P,P}$ = 38 and 52 Hz, 1 P, PCH_3), 22 (dd, $^2J_{P,P}$ = 30 and 52 Hz, 1 P, PCH_3), 61 (dd, $^2J_{P,P}$ = 38 and 30 Hz, 1 P, PC_6H_5) ppm. $C_{28}H_{41}CoNP_3$ (543.2): calcd. C 61.88, H 7.60, N 2.58, P 17.10; found C 61.08, H 7.65, N 2.56, P 17.41.

[2-(Diphenylphosphanyl)-*N*-methylanilido-*N*,*P*](iodo)bis(trimethylphosphane)cobalt(diethyl ether) (11): A sample of **2** (780 mg, 1.35 mmol) in THF (50 mL) was combined with iodomethane (441 mg, 3.10 mmol), at −70 °C, and the solution heated to 20 °C to form a heterogeneous mixture. After 3 h, an off-white solid of tetramethylphosphonium iodide (IR) was removed by filtration and the dark brown solution concentrated to dryness in vacuo. Extraction with three portions of diethyl ether (80 mL) and crystallisation at 4 °C afforded black cubic crystals of **11**. Yield 426 mg (45%); m.p. 85−86 °C (dec.). Magnetic moment (299 K): μ_{eff} = 2.09 μ_B. $C_{29}H_{45}CoINOP_3$ (702.4): calcd. C 49.59, H 6.46, N 1.99, P 13.23; found C 50.20, H 6.12, N 2.10, P 14.03.

[2-(Diphenylphosphanyl)anilido-*N*,*P*](methyl)bis(trimethylphosphane)cobalt (12): 2-(Diphenylphosphanyl)aniline (615 mg, 2.11 mmol) in diethyl ether (50 mL) and $CoMe_2(PMe_3)_3$ (670 mg, 2.11 mmol) in diethyl ether (50 mL) were combined at −70 °C and heated to 20 °C. After 16 h, the volatiles were removed in vacuo, and the solid residue was extracted with two portions of pentane (50 mL). Crystallisation at 4 °C afforded black crystals of **12**. Yield 752 mg (71%); m.p. 117−119 °C (dec.). IR (Nujol): $\tilde{\nu}$ = 3341 cm^{-1} (N−H). Magnetic moment (299 K): μ_{eff} = 1.65 μ_B. MS (70 eV): *m*/*z* (%) = 502 (14) [M$^+$], 350 (30) [M$^+$ − 2 PMe_3]. $C_{25}H_{36}CoNP_3$ (502.4): calcd. C 59.77, H 7.22, N 2.79, P 18.49; found C 59.78, H 7.12, N 2.78, P 18.31.

Bis[2-(diphenylphosphanyl)anilido-*N*,*P*]cobalt (13). Method a: 2-(Diphenylphosphanyl)aniline (1060 mg, 3.84 mmol) in diethyl ether (50 mL) and $CoMe_2(PMe_3)_3$ (610 mg, 1.92 mmol) in diethyl ether (50 mL) were combined at −70 °C and heated to 20 °C. After 16 h, the volatiles were removed in vacuo, the solid residue was washed with cold pentane (5 mL) and extracted with two portions of diethyl ether (50 mL). Crystallisation at 4 °C afforded dark red crystals of **13**. Yield 458 mg (39%). **Method b:** 2-(Diphenylphosphanyl)-aniline (2050 mg, 7.39 mmol) in THF (30 mL) and $CoCl_2$ (480 mg, 3.69 mmol) in THF (50 mL) were combined at −70 °C and MeLi (1.6 M) in diethyl ether (4.6 mL, 7.39 mmol) was added causing the colour to turn dark red. The mixture was warmed to 20 °C and the volatiles were removed in vacuo. The residue was extracted with two portions of diethyl ether (50 mL) and kept at 4 °C to afford crystals of **13**. Yield 1150 mg (51%); decomp. > 250 °C. IR (Nujol): $\tilde{\nu}$ = 3337 cm^{-1} (N−H). Magnetic moment (299 K): μ_{eff} = 2.05 μ_B. $C_{36}H_{30}CoN_2P_2$ (611.5): calcd. C 70.71, H 4.95, N 4.58, P 10.13; found C 71.09, H 5.33, N 4.39, P 10.46.

Bis[2-(diphenylphosphanyl)-*N*-methylanilido-*N*,*P*]cobalt (14). Method a: 2-(Diphenylphosphanyl)-*N*-methylaniline (1040 mg, 3.59 mmol) in diethyl ether (40 mL) and $CoMe_2(PMe_3)_3$ (570 mg, 1.79 mmol) in diethyl ether (70 mL) were combined at −70 °C and heated to 20 °C. After 5 h, the volatiles were removed in vacuo, the solid residue was extracted with two portions of diethyl ether (70 mL). Crystallisation at 4 °C afforded dark red crystals of **14**.Yield 551 mg (48%). **Method b:** 2-(Diphenylphosphanyl)aniline (1130 mg, 3.86 mmol) in THF (30 mL) and $CoCl_2$ (250 mg, 1.93 mmol) in THF (70 mL) were combined at −70 °C and MeLi (1.6 M) in diethyl ether (2.42 mL, 3.86 mmol) was added causing the colour to turn dark red. The mixture was heated to 20 °C and the volatiles were removed in vacuo. The residue was extracted with two portions of diethyl ether (50 mL) and kept at 4 °C to afford crystals of **14**. Yield 390 mg (32%); decomp. > 202 °C. Magnetic moment (299 K): μ_{eff} = 2.33 μ_B. $C_{38}H_{34}CoN_2P_2$ (639.6): calcd. C 71.36, H 5.36, N 4.38, P 9.69; found C 70.78, H 5.46, N 4.39, P 9.88.

Bis[2-(diphenylphosphanyl)anilido-*N*,*P*](trimethylphosphane)cobalt (15): A sample of **13** (660 mg, 1.07 mmol) was recrystallised from diethyl ether (40 mL) containing excess trimethylphosphane (280 mg, 3.67 mmol) at 4 °C to afford bunches of red brown crystals. Yield 248 mg **15** (47%); m.p. 148−150 °C (dec.). IR (Nujol): $\tilde{\nu}$ = 3337 cm^{-1} (N−H). Magnetic moment (299 K): μ_{eff} = 2.10 μ_B. $C_{39}H_{39}CoN_2P_3$ (687.6): calcd. C 68.12, H 5.72, N 4.07, P 13.51; found C 68.10, H 5.85, N 4.02, P 13.61.

Bis[2-(diphenylphosphanyl)-*N*-methylanilido-*N*,*P*](trimethylphosphane)cobalt (16): A sample of **14** (450 mg, 0.70 mmol) was recrystallised from diethyl ether (50 mL) containing excess trimethylphosphane (730 mg, 9.59 mmol) at −27 °C to afford bunches of short red brown rods of **16**. Yield 206 mg (41%); m.p. 165−167 °C (dec.). Magnetic moment (299 K): μ_{eff} = 2.04 μ_B. $C_{41}H_{43}CoN_2P_3$ (715.7): calcd. C 68.81, H 6.06, N 3.91, P 12.98; found C 68.79, H 5.45, N 4.06, P 13.25.

***mer-trans*-Dimethyl[2-(diphenylphosphanyl)anilido-*N*,*P*]bis(trimethylphosphane)cobalt (17):** 2-(Diphenylphosphanyl)aniline (850 mg, 3.06 mmol) in diethyl ether (70 mL) were treated with MeLi (1.6 M) in diethyl ether (1.9 mL, 3.06 mmol). At −70 °C, $CoClMe_2(PMe_3)_3$ (1080 mg, 3.06 mmol) in diethyl ether (50 mL) was added to the mixture which was heated to 20 °C and stirred for 16 h. The volatiles were removed in vacuo, and the solid residue was extracted with two portions of pentane (70 mL). Crystallisation at −27 °C afforded short orange rods of **17**. Yield 1030 mg (65%); m.p. 85−87 °C (dec.). IR (Nujol): $\tilde{\nu}$ = 3338 cm^{-1} (N−H). ^{1}H NMR (200 MHz, [D$_8$]THF, 233 K): δ = −0.65 (q, $^3J_{P,H}$ = 6.6 Hz, 3 H, $CoCH_3$), 0.50 (t, $^3J_{P,H}$ = 9.9 Hz, 3 H, $CoCH_3$), 0.67 (br. s, 18 H, PCH_3), 1.47 (br. s, 1 H, NH), 6.02 (t, ^3J = 6.9 Hz, 1 H, CH), 6.37 (t, ^3J = 5.9 Hz, 1 H, CH), 6.67 (t, ^3J = 7.5 Hz, 1 H, CH), 7.19−7.26 (m, 6 H, CH), 7.49 (m, 1 H, CH). 7.78−7.82 (m, 4 H, CH) ppm. ^{31}P NMR (81 MHz, [D$_8$]THF, 193 K): δ = 12 (br. s, 2 P, PCH_3), 41 (br. s, 1 P, PC_6H_5) ppm. $C_{26}H_{39}CoNP_3$ (517.5): calcd. C 60.35, H 7.60, N 2.71, P 17.96; found C 60.09, H 7.60, N 2.65, P 17.99.

***mer-trans*-[2-(Diphenylphosphanyl)-*N*-methylanilido-*N*,*P*]dimethylbis(trimethylphosphane)cobalt (18):** 2-(Diphenylphosphanyl)-*N*-methylaniline (345 mg, 1.18 mmol) in diethyl ether (70 mL) was

treated with MeLi (1.6 M) in diethyl ether (0.74 mL, 1.18 mmol). At −70 °C, $CoClMe_2(PMe_3)_3$ (417 mg, 1.18 mmol) in diethyl ether (50 mL) was added to the mixture which was heated to 20 °C and stirred for 16 h. The volatiles were removed in vacuo, and the solid residue was extracted with two portions of pentane (70 mL). Crystallisation at −27 °C afforded short orange rods of **18**. Yield 630 mg (59%); m.p. 89−91 °C (dec.). ^{1}H NMR (300 MHz, [D$_8$]THF, 233 K): δ = −0.60 (q, $^3J_{P,H}$ = 6.7 Hz, 3 H, $CoCH_3$), 0.53 (t, $^3J_{P,H}$ = 9.2 Hz, 3 H, $CoCH_3$), 0.64 (br. s, 18 H, PCH_3), 2.48 (s, 3 H, NCH_3), 6.20 (t, ^3J = 6.8 Hz, 1 H, CH), 6.35 (t, ^3J = 7.0 Hz, 1 H, CH), 6.67 (t, ^3J = 7.9 Hz, 1 H, CH), 6.96−7.01 (m, 6 H, CH), 7.55 (t, ^3J = 6.8 Hz, 1 H, CH), 7.69−7.75 (m, 4 H, CH) ppm. ^{31}P NMR (81 MHz, [D$_8$]THF, 193 K): δ = 15 [d(br), $^2J_{P,P}$ = 35 Hz, 2 P, PCH_3), 40 (t, $^2J_{P,P}$ = 35 Hz, 1 P, PC_6H_5) ppm. $C_{27}H_{41}CoNP_3$ (531.5): calcd. C 61.02, H 7.78, N 2.64, P 17.48; found C 61.08, H 7.43, N 2.64, P 17.43.

[3-(Dimethylamino)-2-(diphenylphosphanyl)phenyl-*C*^{1},*P*]tris(trimethylphosphane)cobalt (19): 2-(Diphenylphosphanyl)-*N*,*N*-dimethylaniline (1100 mg, 3.60 mmol) in diethyl ether (50 mL) was combined at −70 °C with $CoMe(PMe_3)_4$ (1360 mg, 3.60 mmol) in diethyl ether (80 mL), with the evolution of a gas. The mixture was heated to 20 °C and turned red brown. The volatiles were removed in vacuo, the residue was extracted with two portions of pentane (80 mL), and from the red solution dark red crystals of **19** were obtained. Yield 1550 mg (85%); m.p. 112−113 °C (dec.). ^{1}H NMR (300 MHz, [D$_8$]THF, 296 K): δ = 1.02 (d, $^2J_{P,H}$ = 5.6 Hz, 9 H, PCH_3), 1.23 (br. s, 18 H, PCH_3), 2.13 (s, 6 H, NCH_3), 5.90 (m, 1 H, CH), 6.19−6.28 (m, 2 H, CH), 7.22−7.24 (m, 6 H, CH), 7.75−7.79 (m, 4 H, CH) ppm. ^{13}C NMR (75.4 MHz, [D$_8$]THF, 296 K): δ = 22.2−22.7 (m, PCH_3), 23.3 (m, PCH_3), 43.3 (s, NCH_3), 109.3 (s, CH), 125.9 (d, $^3J_{P,C}$ = 3.1 Hz, CH), 126.0 (s, CH), 126.3 (d, $^3J_{P,C}$ = 5.6 Hz, CH), 126.9 (s, CH), 133.2 (d, $^3J_{P,C}$ = 7.6 Hz, CH), 133.3 (d, $^3J_{P,C}$ = 7.6 Hz, CH), 139.1 (d, $^1J_{P,C}$ = 9.6 Hz, C), 171.3 (m, CoC) ppm. ^{31}P NMR (81 MHz, [D$_8$]THF, 233 K): δ = −24 (dt, $^2J_{P,P}$ = 89 and 68 Hz, 1 P, PC_6H_5), −4 (dt, $^2J_{P,P}$ = 89 and 47 Hz, 2 P, PCH_3), 22 (dt, $^2J_{P,P}$ = 68 and 47 Hz, 1 P, PCH_3) ppm. $C_{29}H_{46}CoNP_4$ (591.5): calcd. C 58.89, H 7.84, N 2.37, P 20.95; found C 58.92, H 7.82, N 2.27, P 20.83.

Crystal Structure Analyses: Crystal data are presented in Tables 2 and 3. Data collection: Complex **3**: A crystal was sealed under argon in a glass capillary and mounted on a Bruker AXS P4 diffractometer. Reflections were measured (ω-scans) using graphite-monochromated Mo-K_α radiation; Lp correction and absorption correction based on ψ-scans were applied. The structure was solved by direct and conventional Fourier methods. All non-hydrogen atoms were treated anisotropically, hydrogen atoms were treated with a riding model in idealised positions. Complex **6**: A crystal was sealed under argon in a glass capillary and mounted on a Stoe Stadi-4 diffractometer. Intensities were collected (ω-scans) using graphite-monochromated Mo-K_α radiation. No absorption correction was applied. The structure was solved as for **3**. Complex **12**: Crystal mounting, data collection, structure solution and refinement as for **3**. Complex **13**: A crystal was sealed under argon in a glass capillary and mounted on a Stoe Stadi-4 diffractometer. Reflections were collected (ω-scans) using graphite-monochromated Mo-K_α radiation. Absorption corrections based on ψ-scans were applied. The structure was solved as for **3**. Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre. Copies of the data (CCDC-184429 for **3**, -186376 for **6**, -184430 for **12**, -186377 for **13**) can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Use of Molecular Scaffolding for the Stabilization of an Intramolecular Dative P^{III}-P^{V} System

Petr Kilian,[a] Douglas Philp,[a] Alexandra M. Z. Slawin,[a] and J. Derek Woollins*[a]

Keywords: Phosphorus heterocycles / Strained molecules / Neighbouring-group effects / Phosphorus−phosphorus bond

The reaction of $NapP_2S_4$ (**1**; Nap = naphthalene-1,8-diyl) with chlorine gas gave [$Nap(PCl_2)(PCl_4)$] (**2**), displaying a rare σ^4P-σ^6P bonding interaction. An X-ray structure analysis confirmed the PCl_5-like, P–P bond containing phosphonium-phosphoride structure of **2** in the crystal, which was also found in solution at low temperature. At ambient and higher temperatures, dynamic behaviour on the NMR time-scale was observed, which was assigned to interchange of the ionic phosphonium-phosphoride form **2** and the molecular bis(phosphorane) $Nap(PCl_3)_2$ form **3**, rather than to the ionic phosphonium salt-phosphorane form [$Nap(PCl_3)(PCl_2)$][Cl] **4**. Electronic structure calculations were performed at the B3LYP/6–31G(d,p) level of theory on structures **2** and **3**; structure **3** was located as a local minimum on the potential energy surface, 15 kcal·mol^{-1} higher in energy than structure **2**. The crystal structure and calculated P–P distances are 2.34 and 2.31 Å for **2** and **3**, respectively. An activation energy of 19.7 kcal·mol^{-1} was found for the transition state structure by coordinate driving calculations; the line-shape analysis of variable temperature $^{31}P\{^1H\}$ NMR spectra gave an activation energy of 14.4 kcal·mol^{-1}.

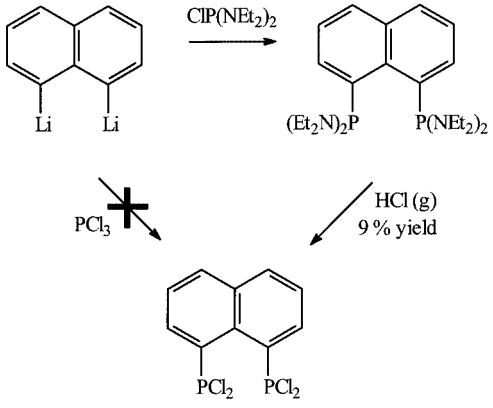
Introduction

Sterically overcrowded and therefore structurally distorted molecules or molecular ions have attracted the attention of chemists for many years. Bay region substituted polycyclic aromatic hydrocarbons, such as 1,8-disubstituted naphthalenes, are one of the most intensively studied systems in this field. The rigidity of the naphthalene backbone combined with the close proximity of functional groups in these species offer an ideal scaffolding for unusual chemistry as well as interesting bonding and geometry.

In the case of 1,8-diphospha-substituted naphthalenes, $NapP_2S_4$ (**1**, Nap = naphthalene-1,8-diyl) has been widely used as a synthon,[1−3] however there is an obvious lack of further suitably versatile, easily accessible starting materials, such as $Nap(PCl_2)_2$ or $Nap(PH_2)_2$. Halophosphoranes and halophosphanes are especially valuable synthons in organophosphorus chemistry. The preparation of the most desirable derivative $Nap(PCl_2)_2$ has been published recently.[4] As the direct method of preparation from lithiated naphthalene ($NapLi_2$) and PCl_3 was not successful (Scheme 1), protection was employed. Thus the reaction of $NapLi_2$ and protected chlorophosphane, followed by deprotection (Scheme 1) gave the desired $Nap(PCl_2)_2$. Formation of stable intermediates in the deprotection step, though, resulted in a low overall yield, which seems to restrain broader synthetic use of this method. In the search for further methods for the preparation of halogenated 1,8-diphosphanaphthalene synthons, we have obtained a new derivative $Nap(PCl_4)(PCl_2)$ **2**, which is not only a promising synthon, but also contains a very rare $\sigma^4P-\sigma^6P$ bond as well as showing interesting fluxionality on the NMR timescale.



Scheme 1. Route to $Nap(PCl_2)_2$ via $NapLi_2$

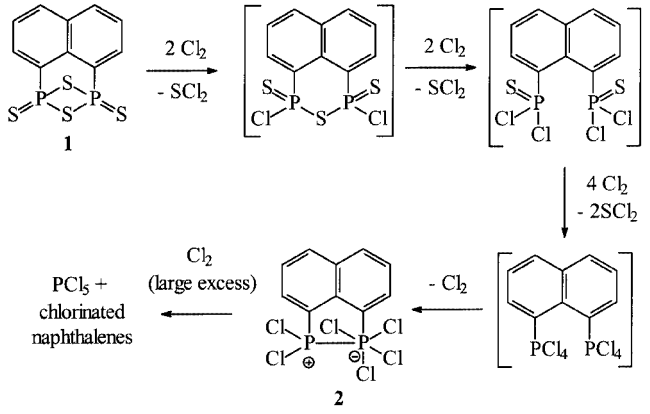
Results and Discussion

Synthesis

The reaction of $NapP_2S_4$ **1** with a slight excess of chlorine gas proceeded with complete desulfuration, yielding the yellow solid $Nap(PCl_4)(PCl_2)$ **2** (Scheme 2). A plausible mechanism for the chlorination involves consequential meta-

[a] School of Chemistry, University of St. Andrews, St. Andrews, Fife, KY16 9ST, United Kingdom
E-mail: jdw3@st-andrews.ac.uk

thesis of a) bridging and b) terminal sulfur atoms, leading to the bis(phosphorane) $Nap(PCl_4)_2$. The next step — a spontaneous elimination of Cl_2 from $Nap(PCl_4)_2$ with formation of **2** — is obviously a consequence of the excessive steric strain connected with such an overcrowded molecular geometry: $Nap(PCl_4)_2$ would contain two five-coordinate P atoms kept in close proximity by the rigid organic backbone causing extensive shielding of the coordination sphere of each P atom. Instead of back formation of $Nap(PCl_4)_2$, a simultaneous P−P and P−C bond cleavage leading to PCl_5 and chlorinated naphthalenes on prolonged chlorination was observed by ^{31}P and ^{1}H NMR spectroscopy.



Scheme 2. Reaction of $NapP_2S_4$ (**1**) with chlorine gas.; undetected intermediates are in square brackets

The purification of the crude product **2** was performed by subliming off the major by-product (PCl_5) and further volatiles, followed by twofold recrystallisation from hot THF, resulting in a moderate yield 20% of pure **2.** The oxidation state of the phosphorus atoms in **2** is +4, thus the formation of **2** represents a formal reduction of P^V to P^{IV}.

X-ray Investigations

A single crystal X-ray structure determination (Figure 1, Table 1) proved the phosphonium-phosphoride structure of **2** in the crystal. Compound **2** possesses approximate C_S symmetry, with the carbon atoms of the naphthalene backbone, the two P atoms as well as Cl(4) and Cl(6) forming a nearly ideal plane (mean deviation of 0.02 Å) with atoms Cl(6) and P(1) lying only 0.05 Å above and below this plane; the dihedral angle P(1)−C(1)···C(9)−P(2) is 2°. The P−P interaction in **2** is clearly attractive, the P−P bond length (2.34 Å) is slightly shorter than the peri-separation [C(1)···C(9) distance] of 2.51 Å in the organic backbone. It is only very recently that the first examples of P−P bonding interaction (σ^3P-σ^4P^+ type) in 1,8-P,P-naphthalenes were described.[5] The vast majority of nonbridged 1,8-P,P-naphthalenes show significantly longer P···P distances, twisting of the naphthalene ring and distortions of the *ipso*-C geometries as a result of repulsive P···P interactions. For example, no evidence of a P···P attractive interaction (e.g. dative bond) was found in the phosphonium salts **A** (Figure 2, P···P distances: 3.19 and 3.26 Å), where the P environments are similar to those in **2**.[6] Compound **2** thus represents only the second type of attractive P−P interaction in 1,8-P,P-naphthalenes proved by means of a single crystal X-ray structure determination.

P(9)−Cl(3)	2.164(2)	2.162	2.216
P(9)−Cl(4)	2.178(2)	2.160	−
P(1)−Cl(4)	−	−	2.277
P(9)−Cl(5)	2.149(2)	2.158	2.216
P(9)−Cl(6)	2.088(2)	2.082	2.077
C(1)−C(10)	1.422(6)	1.430	1.429
C(9)−C(10)	1.425(6)	1.431	1.430
C(1)−P(1)−P(9)	99.7(2)	99.0	85.9
C(9)−P(9)−P(1)	86.1(1)	84.8	98.9
C(10)−C(1)−P(1)	111.6(3)	112.8	119.9
C(10)−C(9)−P(9)	118.4(3)	120.4	112.5
C(1)−C(10)−C(9)	124.0(4)	123.1	122.8

The P−P distance of 2.34 Å in **2** lies near to the upper limit of the range for P−P single bonds (2.20−2.35 Å) and is the longest observed for σ^4P-σ^6P bonds reported to date [range 2.165−2.2962(6) Å].[7,8] The rather long P−P bond length may be accounted for by: i) a released, but still significant, strain in the structure of **2** (indicated by angular distortions of both P environments), ii) a mismatch between the optimal P−P bond length and the peri separation on

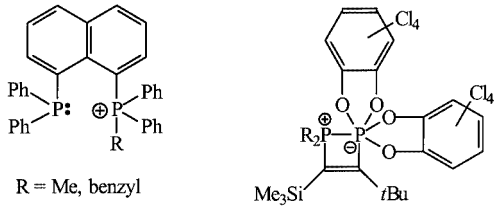

Figure 2. Structural formula of phosphonium salts **A** and $\sigma^4P\rightarrow\sigma^6P$ ylide **B**.; non-coordinating counteranions were present in salts **A**

the naphthalene skeleton, and iii) the lower basicity of the organo-PCl_2 group compared, for example, to the trialkylphosphanyl group. The P(1) environment is distorted tetrahedral [C(1)−P(1)−P(9) angle 99.7(2)°], whilst the P(9) environment is distorted octahedral [C(9)−P(9)−Cl(6) angle 99.1(2)°]. As expected, the P−Cl bond lengths of the four-coordinate P(1) atom are shorter than these of the six-coordinate P(9) atom [1.978(2)−1.988(2) vs. 2.088(2)−2.178(2) Å]. It should be noted that **2** represents a rare examples of an organochlorophosphorane having a solid-state structure similar to that of solid $[PCl_4][PCl_6]$.[9]

From the few examples of the donor type $\sigma^4P\rightarrow\sigma^6P$ linkage known,[7,8,10−13] it can be concluded that a strong donor-acceptor interaction is required for its stabilisation. This interaction is facilitated by both the high Lewis acidity and the basicity of the σ^6P and σ^4P atoms, respectively, which are dictated by the electron-withdrawing or -donating nature of the substituents. As the organo-PCl_2 group in **2** cannot be regarded as a strong donor, the release of the steric strain by formation of a P−P bond and the coherent transformation of the naphthalene ring into a planar geometry is probably the important factor contributing to the stabilization of the unusual $\sigma^4P\rightarrow\sigma^6P$ bond in **2**. Indeed, a similar "scaffolding" mechanism was found to play an important role in the stabilisation of unusual P−P interactions (including $\sigma^4P\rightarrow\sigma^6P$) in the unsaturated four-membered ring skeleton **B** (Figure 2).[11]

NMR Investigations and Study of the Equilibrium Processes

The $^{31}P\{^1H\}$ NMR spectrum of **2** at 303 K ([D8]THF, 109.4 MHz) indicated a dynamic behaviour on the NMR timescale. The spectrum consists of two broad doublets (AX system, δ_P = 82.9 and −225.9 ppm; $^1J_{P,P}$ = 118.5 Hz). At low temperature (213 K) the two doublets sharpen (δ_P = 82.9 and −227.9 ppm; $^1J_{P,P}$ = 88.3 Hz). Such a spectrum results from an ionic phosphonium-phosphoride structure; the chemical shifts are similar to those of PCl_4^+ (δ_P = 86 ppm) and PCl_6^-(δ_P = −290 ppm) as well as to those observed in the solid state ^{31}P MAS spectrum of ionic $[P(CH_2Cl)Cl_3][P(CH_2Cl)Cl_5]$ (δ_P = 111 and −206 ppm).[9] The relatively small magnitude of the $^1J_{P,P}$ coupling observed in **2** is not without precedent, a similar magnitude of 122 Hz was observed in a diphosphete[8] containing a σ^4P-σ^6P bond with a slightly shorter P−P bond length of 2.30 Å. Both the linewidth and $^1J_{P,P}$ increase substantially with temperature, only subtle δ_P changes were observed (Figure 3). At temperatures higher than 303 K the linewidth is so high that a determination of $^1J_{P,P}$ is impossible; at 333 K ([D8]THF) approximate coalescence temperature was reached, as virtually no ^{31}P resonances were observed.

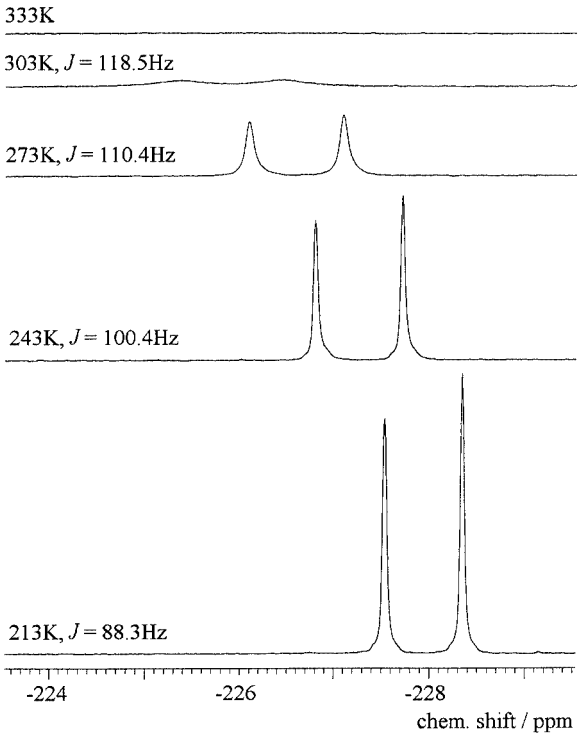

Figure 3. Variable temperature $^{31}P\{^1H\}$ NMR spectra (109.4 MHz) of a saturated solution of **2** in [D8]THF; high-field half spectrum region is shown, 1024 scans for each temperature; the same line shapes were observed in the low-field half spectrum region

Considerable theoretical and stereochemical interest is attached to phosphorus pentahalides and their organo-substituted relatives because of the variety of structures they adopt. There are three possible structures available for the R_2PCl_3 organochlorophosphoranes, these being ionic $[R_2PCl_2][R_2PCl_4]$ (like PCl_5), molecular pseudo-trigonal bipyramidal R_2PCl_3 (like PF_5) and ionic phosphonium salt $[R_2PCl_2][Cl]$ (like PBr_5). The relevant bisfunctional equivalents to these structures are depicted in Figure 4, compound **2** representing an intramolecular equivalent of the PCl_5-like structure. This structure (**2**) has been found both in the solid state and in solution at low temperatures. In order to explain the NMR fluxionality observed at ambient and higher temperatures described above, the interchange between **2** and **3** or **4** may thus be considered (Figure 4).

The interchange between **2** and **4** would involve the presence of Cl^- in the solution. Measurement of the ^{35}Cl NMR spectra of a solution of **2** ([D8]toluene, 49.0 MHz, 298 K, 45000 scans) showed no evidence for the presence of Cl^- ions, and thus mitigated against the presence of **4** under these conditions.

Further uncertainty about the presence of **4** in the system arises from the unexpected features found in the ^{31}P NMR spectra of an equilibrium mixture with respect to those of

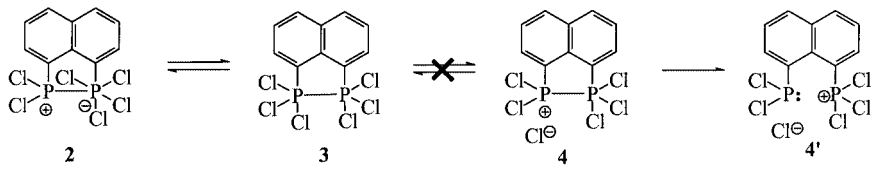

Figure 4. Possible equilibrium structures in solution at ambient and higher temperatures; **2**: ionic phosphonium phosphoride; **3**: molecular bis(pseudo-trigonal bipyramidal); **4**: ionic phosphonium salt-phosphorane; **4′**: ionic phosphanyl-phosphonium salt

the isostructural phosphonium salts **A** (Figure 2). The NMR and X-ray data of **A** (Figure 2) were discussed recently[6] and we assume that some parallels between phosphonium salts **A** and **4** can be drawn. The X-ray data show that there is no P→P$^+$ bonding interaction in **A**. The NMR spectroscopic data of **A** are consistent with this (although dynamic behaviour was observed due to hindered rotation), the magnitudes of $J_{P,P}$ (27−32 Hz) observed were too small for a conventional P−P bond. Although there are differences in the electronegativities of the substituents in **4** and **A**, we expect repulsive P−P interaction in **4**, the more precise description of bonding thus being **4′** (Figure 4). The measurement of a VT $^{31}P\{^1H\}$ NMR spectrum of a solution of **2** showed an increase of the magnitude of $J_{P,P}$ with increasing temperature (Figure 3). The preservation of $^1J_{P,P}$ at higher temperatures indicates that the P−P bond is retained throughout. This behaviour is obviously inconsistent with the P···P nonbonding interaction in **4′**, providing further support that **3** is involved.

In order to gain further insight into the equilibrium processes depicted in Figure 4, we performed electronic structure calculations on structures **2** and **3** at the B3LYP/6−31G(d,p) level of theory. The calculated structures are shown in Figure 5. The geometry around the two P centres in **2** is reproduced well by the calculations (Table 1). Structure **3** was located as a local minimum on the potential energy surface 15 kcal·mol^{-1} higher in energy than structure **2**. A shorter P−P bond length (2.31 Å) was found in **3**. Although both σ^5P environments in **3** are approximately trigonal bipyramidal, and the phosphorus atoms lie in the plane of the naphthalene ring, they are not related by any symmetry element in the molecule. In the trigonal bipyramidal geometry of P(1) the C(1) and Cl(4) atoms are axial, whereas in the trigonal bipyramidal geometry of P(9), Cl(3) and Cl(5) occupy the axial positions.

This result again demonstrates the stabilisation of an unusual bonding geometry in peri-substituted naphthalenes. Up to now, only two X-ray structures of compounds containing a σ^5P-σ^5P bond have been reported, in which the P−P bond was axial[14] and equatorial.[15,16]

In order to further assess the fluxional behaviour of **2**, we performed coordinate driving calculations in which one chlorine atom from the octahedral P centre was transferred in a concerted manner to the tetrahedral P centre, thus converting **2** into **3**. The calculations indicated that these interconversions are plausible and a transition state structure (Figure 6) is obtained for the axial chlorine [Cl(4)] transfer

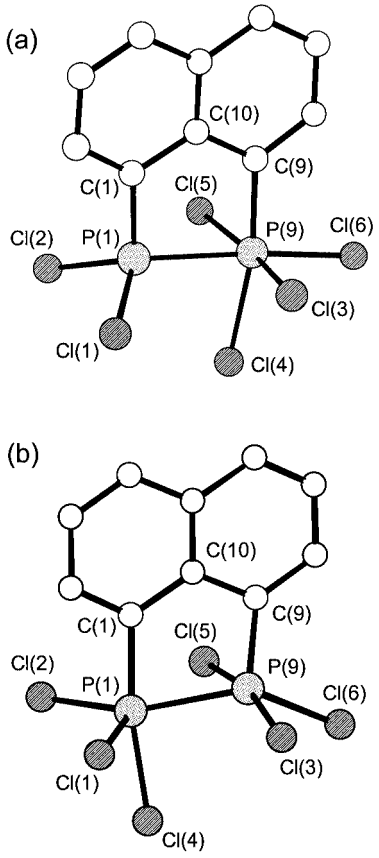

Figure 5. Calculated [B3LYP/6−31G(d,p)] structures of: (a) compound **2**, and (b): compound **3** (H atoms omitted for clarity); for selected bond lengths and angles see Table 1

pathway. The calculated activation energy is 19.7 kcal·mol^{-1} for the conversion of **2** to **3**.

The approximate activation energy of 14.4 kcal·mol^{-1} was found by line shape analysis of the variable temperature $^{31}P\{^1H\}$ NMR spectra, using the expression $k = \pi(\Delta\nu)$, where $\Delta\nu$ is the difference (Hz) between the line width at a temperature T, where exchange of sites is taking place (273 K), and the line width in the absence of exchange (183 K). The Eyring equation was subsequently employed to calculate the $\Delta G^{\ddagger}$ value at T. The values obtained independently from NMR spectroscopic data and coordinate driving calculations show good agreement; the relatively high barrier probably reflects the significant shortening of the P−P distance in the transition state.

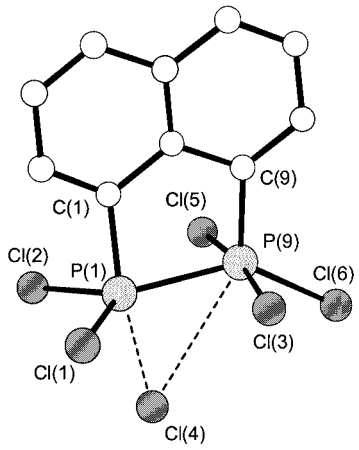

Figure 6. Calculated [B3LYP/6−31G(d,p)] transition state structure for the conversion of **2** to **3** (H atoms omitted for clarity); selected bond lengths [Å] and angles [°] P(1)−P(9) 2.256, Cl(4)−P(1) 2.460, Cl(4)−P(9) 2.970, P(1)−Cl(4)−P(9) 67.0

By analogy with $P(CH_2Cl)Cl_4$, which has δ_P = −39.0 ppm for the pseudo-trigonal bipyramidal structure (in solution),[9] we anticipate a similar chemical shift in **3**. Not surprisingly, given the inequality in the populations of **2** and **3** suggested by our calculations, separated signals were not observed in the 121.4 MHz ^{31}P NMR spectrum at any temperature studied (193−373 K). However, changes were observed in linewidth, $^1J_{P,P}$ and δ_P, which is consistent with a dominant population (namely **2**) being in exchange on the NMR timescale with a second minor population (namely **3**) at higher temperatures. The observed increase of $^1J_{P,P}$ with increasing temperature probably reflects an increasing population of **3** (where a shorter P−P bond is found) with increasing temperature. Note that in **3**, the two phosphorus centres are not necessarily magnetically equivalent. The degree of inequivalence depends on the rate of ligand exchange (a process similar to pseudorotation), which is necessarily a concerted process in the sterically overcrowded environment. The presence of an ionic-molecular equilibrium would suggest substantial solvent-dependence of $^1J_{P,P}$. The magnitude of $^1J_{P,P}$ at 273 K, determined from the 121.4 MHz ^{31}P NMR spectra, is 131 Hz in [D_8]toluene solution and 100 Hz in [D_2]dichloromethane solution. Thus, the less-polar solvent (toluene) shifts the equilibrium to the molecular form **3**.

Conclusion

$NapP_2S_4$ (**1**) was used previously as a source of the $NapP_2$ moiety in many reactions with nucleophiles, though generally P−S−P bridge or P=S moieties were retained in their products. In this paper we have shown that **1** can be completely desulfurated in the reaction with chlorine gas, giving $NapP_2Cl_6$ (**2**). In analogy to PCl_5 or $PhPCl_4$, **2** is expected to allow access to new main-group derivatives of 1,8-P,P-naphthalene with interesting bonding and chemistry. NMR spectroscopic data and calculations suggest that the dynamic process observed in solutions of **2** might be explained by interchange between the ionic phosphonium-phosphoride form **2** and the molecular bis(phosphorane) form **3**; an intramolecular equivalent to the dynamic equilibrium of ionic $[PCl_4][PCl_6]$ and molecular PCl_5 forms.

Experimental Section

General Remarks: All manipulations were performed using standard Schlenk techniques with carefully dried and deoxygenated solvents under an oxygen-free argon atmosphere. Compound **1** was prepared as described previously.[17] NMR: Varian Unity Plus 500, Bruker AM 300 and Jeol GSX 270; Ra: Perkin−Elmer System 2000. MS: VG Autospec.

$NapP_2Cl_6$ (2): Chlorine gas was bubbled through an externally cooled (0 °C), vigorously stirred suspension of **1** (14.3 g, 45.2 mmol) in dichloromethane (90 cm^3). The reaction was completed after ca. 10 min, during which time the solid dissolved completely, and a new yellow solid (**2**) precipitated. The product was collected by filtration, washed with dichloromethane (30 cm^3) and dried in vacuo. PCl_5 and further volatile by-products were sublimed off at 120−130 °C in vacuo (≈ 13 Pa). The remaining solid was of sufficient purity for further synthetic use, although its ^{31}P NMR spectrum (in THF, −30 °C, external lock) showed the presence of small amounts of partially oxidized/hydrolysed by-products. These impurities can be removed by twofold recrystallisation from hot THF. Yield after twofold recrystallisation 3.60 g (20%) of **2** in the form of yellow, extremely moisture sensitive crystals. Compound **2** is barely soluble in cold dichloromethane and toluene, but more soluble in THF. The crystals used for X-ray work were obtained from hot toluene. M.p. 208−211 °C with gas evolution. ^1H NMR (500 MHz, CD_2Cl_2, 258 K, TMS): δ = 7.75 [m, 1 H, H(3)], 7.95 [t, $^3J_{H,H}$ = $^3J_{H,P}$ = 7.7 Hz, 1 H, H(8)], 8.02 [t, $^3J_{H,H} \approx {}^4J_{H,H} \approx$ 6.0 Hz, 1 H, H(4)], 8.42−8.50 [m (overlapped), 2 H, H(6) and H(7)], 8.76 [dd, $^3J_{H,P}$ = 33.1, $^3J_{H,H}$ = 7.6 Hz, 1 H, H(2)] ppm. $^{13}C\{^1H\}$(125.7 MHz, [D_8]THF, 258 K, TMS), only signals of tertiary carbons could be assigned as the solubility of **2** at low temperatures was very low: δ = 124.9 [t (virtual), $^2J_{C,P} \approx$ 14.1 Hz, C(2)], 129.9−129.5 [m (overlapped), C(8) and C(3)], 131.8 [s, C(4)], 135.6 [s, C(7)], 140.7 [s; C(6)] ppm. $^{31}P\{^1H\}$ (121.4 MHz, CD_2Cl_2, external reference 85% H_3PO_4, for numbering of atoms see Figure 1): at 298 K 2× broad d (AX system), δ_P −225.4 [P(9)] and 83.2 [P(1)], $^1J_{P,P}$ = 105.7 Hz; at 223 K 2×d (AX system), δ_P −227.9 [P(9)] and 82.2 [P(1)], $^1J_{P,P}$ = 83.8 Hz. Raman (sealed capillary): $\tilde{\nu}$ = 3068 (s, Ar-H), 1556 (s), 1365 (s), 435 and 420 (m, P-Cl), 322 cm^{-1} (vs). MS (EI+, 70 eV, sampled neat): *m/z* = 365 [M − Cl], 330 [M − 2Cl], 293 [M − 3Cl, base peak].

Computational Methodology: All calculations were performed on a dual processor Silicon Graphics Octane^2 Workstation. Initial guess structures were constructed using Maestro (Version 3.0.r38) and computations were carried out using Jaguar (Version 4.1.r53).[18] The identity of ground and transition states was verified by vibrational frequency analysis and the calculated transition state possessed one imaginary vibration which corresponded to the reaction coordinate.

X-ray Crystallographic Study: Crystal data for **2**: $C_{10}H_6Cl_6P_2$, mol. wt. 400.8, yellow plates, 0.1 × 0.1 × 0.1 mm, monoclinic, space group $P2_1/n$, Z = 4, a = 8.1613(9), b = 18.053(2), c = 10.0490(9) Å, β = 97.197(3)°, V = 1468.9(3) $Å^3$, $\rho_{calcd.}$ 1.363 $Mg{\cdot}m^{-3}$, $2\theta_{max}$ = 46.46°, graphite monochromated Mo-K_α radiation (λ = 0.71073

Å), μ(Mo-K_α) = 1.363 mm^{-1}, T = 293 K. Data were measured on a Bruker SMART CCD, and Lorentzian polarisation and absorption (SADABS, max./min. transmission 1.0000/0.7767) corrections were performed. Of 6227 measured data, 2085 were unique and 1706 observed [$I > 2\sigma(I)$]. The structure was solved by direct methods. The non-hydrogen atoms were refined anisotropically, the hydrogen atoms were idealised and refined isotropically using a riding model. Structural refinements were performed with the full-matrix least-squares method on F^2 using the program SHELXTL (Version 5.10, Bruker AXS, 1997) to give R_1 = 0.0438 and wR_2 = 0.1114, with a residual electron density of 0.82 eÅ^{-3}.

CCDC-182100 contains the supplementary crystallographic data for **2**. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44−1223/336−033; E-mail: deposit@ccdc.cam.ac.uk].

Synthesis, Crystal Structure, and Photoluminescent Properties of a Tetracarbonyl(naphthyridylcarbamoyl)rhenium(I) Complex and a Highly Emissive Tetracarbonyl(naphthyridylamido)rhenium(I) Complex

Jing-Lin Zuo,[a] Wen-Fu Fu,[b] Chi-Ming Che,*[a,b] and Kung-Kai Cheung[b]

Keywords: Carbonyl ligands / N ligands / Photoluminescence / Rhenium / Structure elucidation

The reactions of $Re(CO)_5X$ (X = Cl, Br) with 7-amino-2,4-dimethyl-1,8-naphthyridine (H_2L^1) and 7-[2-(6-chloropyridyl)-amino]-2,4-dimethyl-1,8-naphthyridine (HL^2) in the presence of *t*BuOK afforded the η^1-naphthyridylcarbamoyl complex $[Re(CO)_4(HL^1CO)]$ (**1**) and the naphthyridylamido complex $[Re(CO)_4(L^2)]$ (**2**), respectively. The structures of HL^2, **1**·$CHCl_3$, **1**·HL^3·$2CH_2Cl_2$ [HL^3 = (7-chloronaphthyridyl)(5,7-dimethylnaphthyridyl)amine], and **2** have been determined by X-ray crystallography. Complex **1** displays a weak emission at 453 nm in an EtOH/MeOH (1:4, v/v) glassy solution at 77 K; complex **2** exhibits an intense (quantum yield: 0.22 in CH_2Cl_2) and long-lived emission (46 μs in CH_2Cl_2), with a solvent-sensitive λ_{max}, in degassed solutions at room temperature.

Introduction

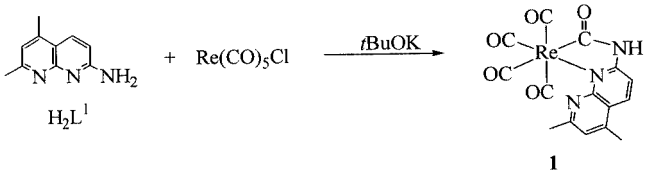
Carbonylrhenium(I) complexes have been the subject of extensive photochemical and photophysical studies over the past several decades. These complexes display interesting photochemical,[1] and rich photoluminescent and electroluminescent properties.[2−4] Recent studies have also demonstrated their applications as luminescent probes for chemosensing.[5] In the course of our studies on the photoluminescent properties of carbonylrhenium(I) complexes, we have paid attention to the species containing tetracarbonylrhenium(I) units. This class of carbonylrhenium(I) complexes, such as the $[Re(CO)_4(bpm)]^+$ cation (bpm = 2,2′-bipyrimidine) and some neutral *ortho*-metalated species, exhibits substantially long emission life-times and high emission quantum yields compared with the extensively studied tricarbonylrhenium(I) species $Re(CO)_3(L-L)X$ (L−L = a bidentate *N*,*N*′-chelating ligand such as 1,10-phenanthroline and 2,2′-bipyridine; X = a monodentate anionic ligand such as Cl^- or Br^-).[6]

In the present paper, we report on the synthesis and the photophysical properties of the tetracarbonyl(η^1-naphthyridylcarbamoyl)rhenium(I) complex $[Re(CO)_4(HL^1CO)]$ (**1**, H_2L^1 = 7-amino-2,4-dimethyl-1,8-naphthyridine), and the naphthyridylamido complex $[Re(CO)_4L^2]$ {**2**, HL^2 = 7-[2-(6-chloropyridyl)amino]-2,4-dimethyl-1,8-naphthyridine}, both of which have been characterized by X-ray crystallography. The η^1-carbamoyl complex **1** was prepared from the reaction between $Re(CO)_5Cl$ and H_2L^1, probably by an interesting intramolecular migratory insertion of CO into the Re^I−amide bond. The amido complex **2** exhibits an intense, long-lived emission in degassed solutions at room temperature.

Results and Discussion

Synthesis and Spectral Features

Treatment of $Re(CO)_5Cl$ with naphthyridylamine H_2L^1 in dichloromethane in the presence of *t*BuOK afforded complex **1** in a 40% yield (Scheme 1). The η^1-carbamoyl group in this complex probably results from the migratory insertion of CO into the rhenium(I)−amide bond. We propose that the reaction might first generate the amine intermediate **I** (Scheme 2), followed by the deprotonation of the coordinated amine ligand in **I** by *t*BuOK to give the arylamide intermediate **II**.[7] This then readily undergoes an intramolecular migratory insertion of CO into the Re−amide bond, giving complex **1**. The synergistic action of the naph-



H_2L^1 **1**

Scheme 1. Synthesis of the η^1-naphthyridylcarbamoyl complex **1**

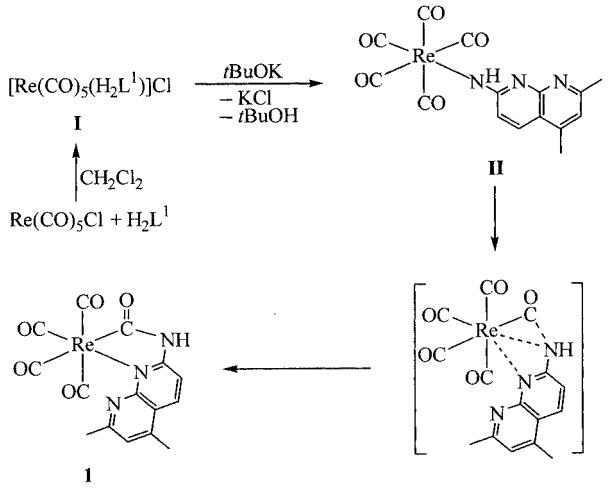
[b] Department of Chemistry, The University of Hong Kong, Pokfulam Road, Hong Kong

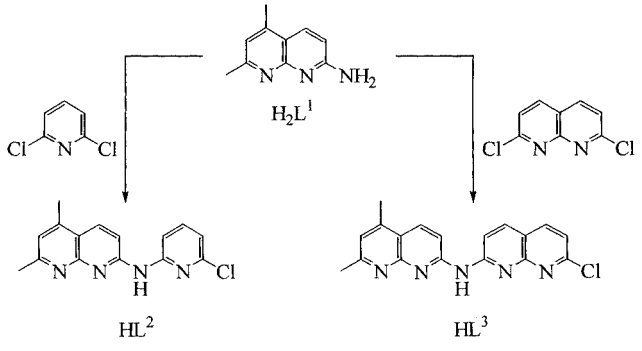


Scheme 2. Proposed mechanism for the formation of complex **1** by migratory insertion of CO into a Re−amido bond

thyridyl group should facilitate such CO insertion processes.

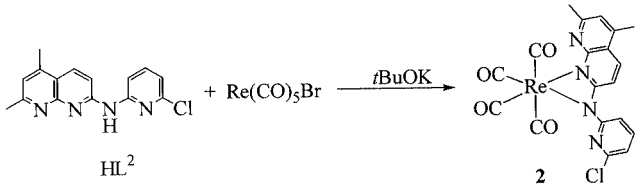
Migratory insertion of CO into a low-valent metal−nitrogen bond is not unprecedented,[8a,9] but is less common than the migratory insertion of CO into an M−R or M−H bond (which has been widely encountered in organometallic chemistry).[10] The mechanism we propose here (Scheme 2) is similar to that of the *ortho*-metalation of the (arylamido)iridium(I) complex *trans*-$Ir(PPh_3)_2(CO)(NHAr)$,[8] and to the formation of the (η^1-carbamoyl)dicarbonylrhenium complex $[(CO)_2RReC(=O)N(CH_3)CH_2CH_2(\eta^5\text{-}C_5H_4)]$ by insertion of CO into an Re−N bond.[9a]

We speculate that replacement of the H atom of the NH group in **II** by a bulky group may prevent or retard the foregoing CO insertion reaction. To test this possibility, we converted H_2L^1 into two new naphthyridylamine ligands HL^2 and (7-chloronaphthyridyl)(5,7-dimethylnaphthyridyl)-amine (HL^3), according to the reactions shown in Scheme 3. Indeed, reaction of $Re(CO)_5Br$ with HL^2 under conditions similar to those for the reaction between $Re(CO)_5Cl$ and H_2L^1 did not give an η^1-carbamoyl complex. Instead, the reaction afforded the amido complex **2** in an 80% isolated yield (Scheme 4).



Scheme 3. Synthesis of HL^2 and HL^3

The reaction of HL^3 with $Re(CO)_5Br$ was also examined, but no identifiable rhenium complexes were obtained in this case. Ligand HL^3 was found to be less reactive than H_2L^1 and HL^2. For example, treatment of $Re(CO)_5Br$ with a 1:1 mixture of HL^3 and H_2L^1 in dichloromethane produced a mixture of **1** and free HL^3, and gave crystals of $\mathbf{1}\cdot HL^3\cdot 2CH_2Cl_2$ on recrystallization from dichloromethane/hexane.



Scheme 4. Synthesis of the naphthyridylamido complex **2**

All the new compounds in this work display parent ion peaks in their mass spectra. The IR spectra of complexes **1** and **2** show CO stretches at frequencies ranging from 1928 to 2103 cm^{-1}; this ν(CO) frequency range is similar to that of the cyclometalated tetracarbonylrhenium(I) complex $[Re(CO)_4\{\mu_2\text{-}C(NHR)(NHC_6H_4)\}]$ (1916−2081 cm^{-1}),[11] but different from the typical ν(CO) frequency range of tricarbonylrhenium(I) complexes (ca. 1700−2000 cm^{-1}).[12] The ν(CO) band at 2087 cm^{-1} for **1**, and at 2103 cm^{-1} for **2**, could be assigned to the *trans*-$Re(CO)_2$ subunits of the $Re(CO)_4$ moieties in the two complexes, since the strong *trans* influence of CO would weaken the Re−CO π-back bonding and thus increase the ν(CO) frequency. However, we cannot exclude the possibility of mixing between the stretching vibrations of the *trans*- and *cis*-$Re(CO)_2$ subunits.

Crystal Structures

Table 6 shows the crystal and refinement data for HL^2, $\mathbf{1}\cdot CHCl_3$, $\mathbf{1}\cdot HL^3\cdot 2CH_2Cl_2$, and **2**. The ORTEP drawings or unit cell diagrams for these crystals are depicted in Figures 1−5. Selected bond lengths and angles are compiled in Tables 1−4.

The free ligand HL^2 is basically planar (Figure 1) and adopts a configuration that is similar to the *anti-syn* configuration of the dimer of 2,2′-dipyridylamine.[13] The N(2)−C(6) and N(2)−C(8) distances are 1.378(6) and 1.400(6) Å, respectively (see Table 1). These are longer than the corresponding C−N distances in pyridine or naphthyridine.

Complex **1** exhibits a distorted octahedral rhenium(I) center and has a strained five-membered metallacycle involving the Re(1), N(1), C(6), N(2), and C(1) atoms (Figure 2) and the Re1, N2, C6, N1, and C5 atoms (Figure 3). The C−Re−N angle in the metallacycle is 76.2(3)° for $\mathbf{1}\cdot CHCl_3$ (Table 2), and 75.8(2)° for $\mathbf{1}\cdot HL^3\cdot 2CH_2Cl_2$ (Table 3). The average Re−CO bond length for the terminal CO groups *trans* to the HL^1CO ligand (1.952 Å) is shorter than the average Re−CO bond length of the *trans*-$Re(CO)_2$ subunit (1.994 Å). The Re−C(carbamoyl) bond lengths of 2.146(7) Å in $\mathbf{1}\cdot CHCl_3$, and of 2.158(7) Å in $\mathbf{1}\cdot HL^3\cdot 2CH_2Cl_2$, are similar to that in $[(CO)_2BrReC(=O)N(CH_3)CH_2CH_2(\eta^5\text{-}C_5H_4)]$ (2.19 Å).[9a] There are hydrogen bonds between complex **1** and the free ligand HL^3 in $\mathbf{1}\cdot HL^3\cdot 2CH_2Cl_2$

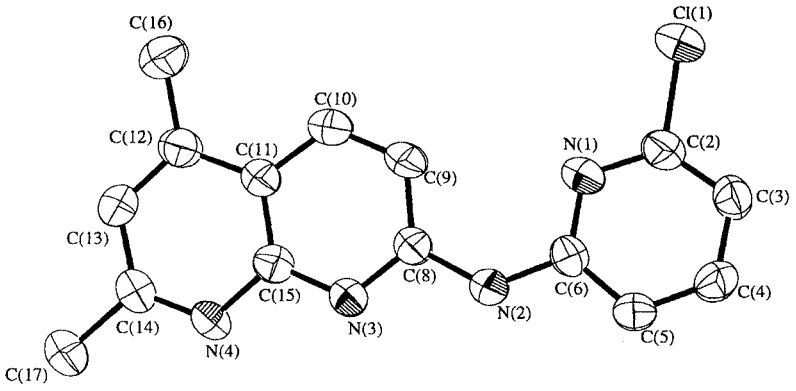


Figure 1. Molecular structure and atomic numbering scheme of HL^2 (probability level of thermal ellipsoids: 50%); hydrogen atoms are not shown

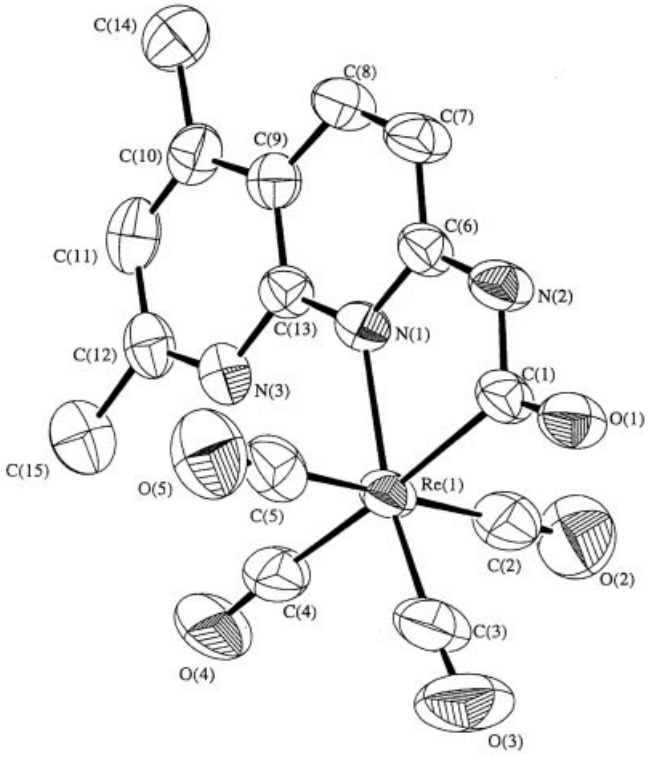

Figure 2. Molecular structure and atomic numbering scheme of **1**·$CHCl_3$ (probability level of thermal ellipsoids: 50%); the hydrogen atoms and the solvent molecules are not shown

[N(1)−H(1)···N(7)* 3.17 Å, O(5)*···H(2)−N(6) 2.86 Å], as shown in Figure 4. Accordingly, the HL^3 ligand in this crystal can be considered as an organic guest incorporated into the host complex **1** (incorporation of an organic guest into organometallic complexes may be potentially useful for nonlinear optical, conducting and ferromagnetic materials[14]).

Complex **2**, which also exhibits a distorted octahedral rhenium(I) center, features a highly strained four-membered metallacycle consisting of the Re(1), N(1), C(10), and N(2) atoms with an N(1)−Re−N(2) angle of 59.5° (Figure 5). The average Re−CO distance for the CO groups *trans* to the naphthyridylamide ligand (1.932 Å) is shorter, while the average Re−CO bond length of the *trans*-$Re(CO)_2$ subunit (2.04 Å) is longer than the corresponding average Re−CO distances in **1**·$CHCl_3$ and **1**·HL^3·$2CH_2Cl_2$. The Re−N(amide) and Re−N(naphthyridine) distances are 2.206(5) and 2.152(5) Å, respectively, which are similar to the average Re−N(bpm) distance of 2.16 Å in [$Re(CO)_4$(bpm)][BF_4].[6] The conformation of the naphthyridylamido ligand L^2 in **2** is similar to that in the free amine HL^2. However, the N(1)−C(5) [1.358(8) Å] and N(1)−C(10) [1.351(8) Å] bonds of the ligand L^2 in **2** are shorter than the corresponding N−C bonds [1.378(6) and 1.400(6) Å, respectively] in the free ligand HL^2.

Electronic Absorption Spectra

Table 5 shows the UV/Vis spectroscopic data of complexes **1** and **2**, together with those of the free ligand HL^2. The absorptions of **1** and **2** at $\lambda < 330$ nm are similar to those of the (carbonyl)(diimine)Re^I complexes;[6,15] we assign these bands mainly to $\pi\rightarrow\pi^*$ transitions. In dichloromethane solution, complex **2** exhibits a broad lower energy absorption band at λ_{max} = 415 nm ($\varepsilon = 1.7\cdot10^4$ $mol^{-1}\cdot dm^3\cdot cm^{-1}$) and a shoulder at 432 nm ($\varepsilon = 1.5\cdot10^4$ $mol^{-1}\cdot dm^3\cdot cm^{-1}$), both of which are absent in the spectra of HL^2 in the same solvent. The 415-nm absorption is solvent-sensitive and is blue-shifted to 410 nm in acetonitrile (see Table 5). We assign this absorption to the $d\pi(Re)\rightarrow\pi^*$ (heterocyclic ligand) transition.[16] Note that on going from **2** to **1** the lowest-energy absorption band shifts to considerably higher energies (from 432 to 358 nm). This may be attributed to the different electronic properties of the coordinated naphthyridylamido and -carbamoyl groups. For example, the partial delocalization of electron density from the metal center to the carbamoyl moiety in complex **1** would raise the energy of the MLCT transition, whereas in complex **2**, the Re($d\pi$) orbitals would be destabilized due to coordination of the electron-rich naphthyridylamido group to Re^I, leading to a reduction in MLCT transition energy.

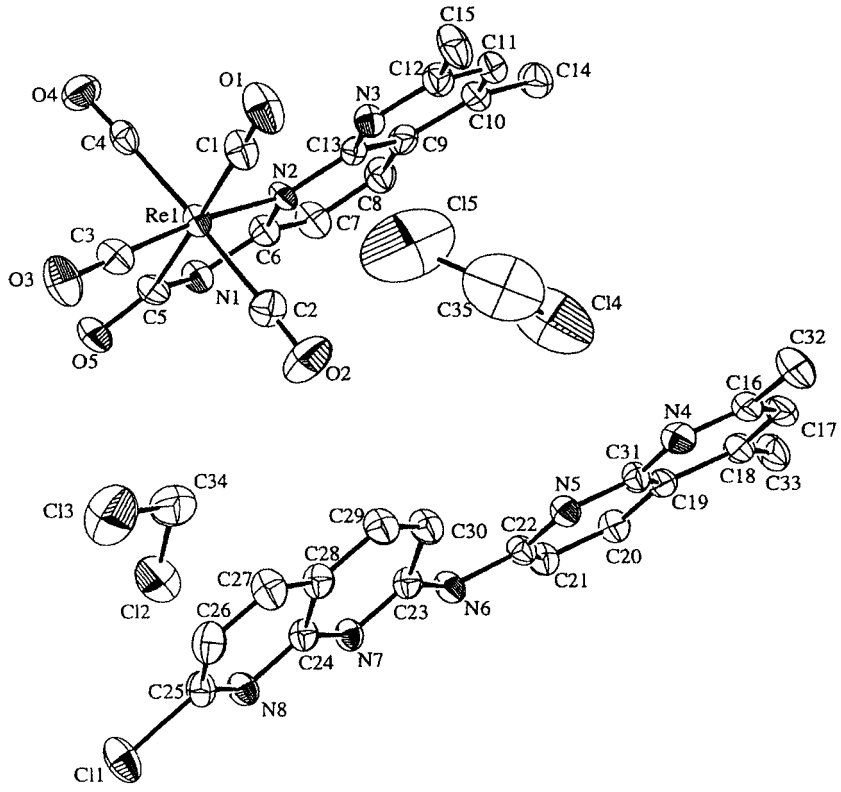

Figure 3. Molecular structure and atomic numbering scheme of **1**·HL^3·$2CH_2Cl_2$ (probability level of thermal ellipsoids: 50%); hydrogen atoms are not shown

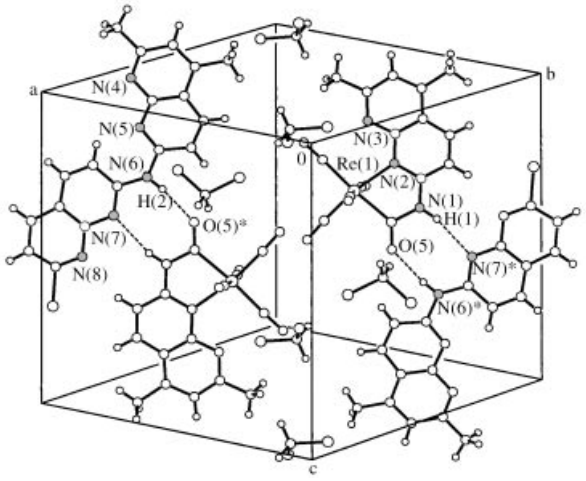

Figure 4. Unit cell diagram for **1**·HL^3·$2CH_2Cl_2$

Photoluminescent Properties

Complex **1** displays a weak emission at λ_{max} = 453 nm in an EtOH/MeOH (1:4, v/v) glassy solution at 77 K. However, no emission was detected when this complex was dissolved in dichloromethane or acetonitrile at room temperature.

On excitation at 400−430 nm, complex **2** exhibits an intense structured emission in an EtOH/MeOH (1:4, v/v) glassy solution at 77 K (λ_{max} = 499 and 533 nm), with a vibrational shift of 1280 cm^{-1} (Figure 6). The emission of **2** in dichloromethane at 77 K is intense and structured (λ_{max} = 512 and 550 nm). On the basis of previous work,[15,17] we tentatively assign the structured 77 K emission to be $^3(\pi\pi^*)$ in nature.

Complex **2** emits strongly in fluid solutions as well. A broad emission analogous to the ^{3}MLCT emission of $[Re(CO)_4(bpm)]^+$ or $[Re^I(CO)_3(L-L)X]$ (L−L = aromatic diimines)[17] was observed at λ_{max} = 520 nm in dichloromethane, 535 nm in acetonitrile, 522 nm in toluene, 505 nm in benzene, and 515 nm in tetrahydrofuran at room temperature (Table 5). We suggest that this solvent-dependent broad emission has an admixture of ^{3}IL and ^{3}MLCT characters (the ^{3}MLCT emissions from (carbonyl)Re^I complexes of aromatic diimines are also solvent-dependent).

Note that the free ligand HL^2 gives a broad emission at λ_{max} = 400 nm in acetonitrile at room temperature. This emission has a substantially higher energy than that of complex **2**, and is assigned to be a $^1(\pi\pi^*)$ emission in nature. As expected, the intraligand fluorescence of HL^2 has a short life-time ($\leq 10^{-3}$ μs, Table 5).

It is interesting to note the very long emission life-times (25−46 μs in degassed solutions, 142 and 150 μs in EtOH/MeOH and CH_2Cl_2 glassy solutions at 77 K) and high emission quantum yields (up to 0.22) for complex **2** (Table 5), which are in contrast to those reported for $[Re(CO)_4(L-L)]^+$ (life-time < 10 μs and quantum yield < 0.05).[15] The long emission life-time is characteristic of an organic triplet emission and reflects substantial ^{3}IL character in the excited state.

Experimental Section

General: 7-Amino-2,4-dimethyl-1,8-naphthyridine (H_2L^1) and 2,7-dichloro-1,8-naphthyridine were prepared by literature methods.[18] All reactions were performed under nitrogen using standard Schlenk techniques. ^1H and $^{13}C\{^1H\}$ NMR spectra were recorded with a Bruker DPX 300 or DRX 500 FT NMR spectrometer. Chemical shifts were referenced to tetramethylsilane. Fast atom bombardment (FAB) mass spectra were obtained with a Finnigan Mat 95 mass spectrometer using a 3-nitrobenzyl alcohol matrix. UV/Vis absorption spectra were measured with a Perkin−Elmer Lambda 19 UV/Vis spectrophotometer. Elemental analyses were performed by Butterworth Laboratory. Steady-state emission measurements were performed with a SPEX Fluorolog-2 spectrophotometer. The emission spectra were corrected for monochromator and photomultiplier efficiency and for xenon lamp stability. Quantum yields of the complexes were determined relative to quinine sulfate in 1.0 N sulfuric acid at 298 K ($\Phi = 0.54$). Emission lifetime measurements were performed with a Quanta Ray DCR-3 Nd-YAG laser (pulse output 355 nm, 8 ns). The fluorescent lifetimes were obtained by a picosecond laser spectrophotometer equipped with a C4334 streakscope connected to the C4792-01

streak trigger. The decay signal was recorded with a R928 PMT (Hamamatsu), which was connected to a Tektronix 2430 digital oscilloscope. Solutions for the photophysical experiments were degassed by at least four freeze-pump-thaw cycles.

Syntheses

7-[2-(6-Chloropyridyl)amino]-2,4-dimethyl-1,8-naphthyridine (HL^2): A suspension of H_2L^1 (1.73 g, 0.01 mol), 2,6-dichloropyridine (1.48 g, 0.01 mol), and powdered KOH (0.7 g, 0.012 mol) in toluene (300 mL) was refluxed for 24 h. On removal of the solvent, the residue was washed with water and diluted aqueous HCl, followed by chromatography on a silica gel (70−230 mesh) column using petroleum ether (boiling range 40−60 °C) and ethyl acetate (4:1, v/v) as the eluent. The pale yellow fraction was collected and the solvents were evaporated to give a pale yellow product. Yield: 1.19 g (42%). ^{1}H NMR ($CDCl_3$, 300 MHz): δ = 2.6−2.7 (s, 6 H, CH_3), 7.0−8.5 (m, 6 H, aryl H), 7.6 (s, 1 H, NH) ppm. FAB-MS: *m/z* = 285 $[M]^+$. IR (KBr): $\tilde{\nu}$ = 3233, 1587, 1505, 1458, 1344, 983, 784, 713, 554 cm^{-1}.

[a] 1:4 (v/v).

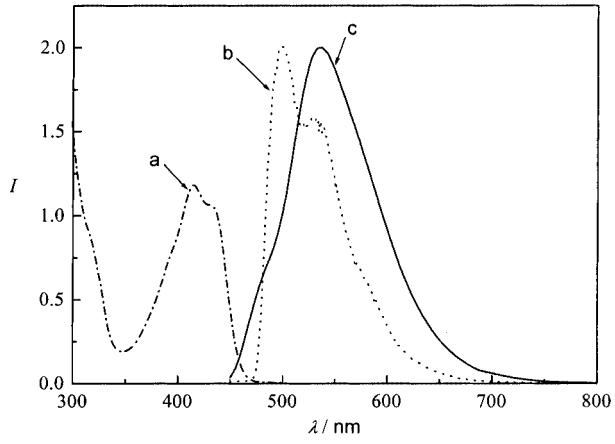

Figure 6. Electronic absorption spectrum (a) and emission spectra (b, c) of **2**; the absorption spectrum was measured in CH_3CN at 298 K, whereas the emission spectra were measured in EtOH/MeOH (1:4, v/v) glassy solutions at 77 K (b) and in degassed acetonitrile at 298 K (c); I = intensity (arbitrary units)

(7-Chloronaphthyridyl)(5,7-dimethylnaphthyridyl)amine (HL^3): This ligand was prepared according to the same procedure as that for HL^2, except that 2,7-dichloro-1,8-naphthyridine was used instead of 2,6-dichloropyridine and the eluent for the chromatography was methanol/dichloromethane (5:95, v/v). Yield: 1.18 g (35%). ^1H NMR ($CDCl_3$, 300 MHz): δ = 2.6−2.7(s, 6 H, CH_3), 6.7−8.1(m, 7 H, aryl H), 8.3 (s, 1 H, NH) ppm. FAB-MS: m/z = 336 $[M]^+$. IR (KBr): $\tilde{\nu}$ = 3223, 3046, 1674, 1593, 1486, 1313, 1147, 850, 789, 595, 462 cm^{-1}. UV/Vis (CH_2Cl_2): λ_{max} (ε): 253 ($2.1\cdot10^4$), 329 ($1.1\cdot10^4$), 359 ($1.8\cdot10^4$), 375 ($2.6\cdot10^4$), 419 ($5.9\cdot10^3$), 443 nm ($6.8\cdot10^3$).

$[Re(CO)_4(HL^1CO)]$ (1): A mixture of H_2L^1 (173 mg, 1 mmol), $Re(CO)_5Cl$ (362 mg, 1 mmol), and *t*BuOK (112 mg, 1 mmol) in CH_2Cl_2 (20 mL) was refluxed overnight. After filtration and concentration, a yellow solid was obtained. The solid was washed with toluene and recrystallized from chloroform/pentane. Yield: 203 g (40%). $C_{15}H_{10}N_3O_5Re\cdot0.5H_2O$ (507.47): calcd. C 35.5, H 2.2, N 8.3; found C 35.4, H 2.3, N 8.7. ^1H NMR ($CDCl_3$, 300 MHz): δ = 2.67 (s, 3 H, CH_3), 2.75 (s, 3 H, CH_3), 7.15 (s, 1 H, aryl H), 7.30 (d, $^3J_{H,H}$ = 9.3 Hz, 1 H, aryl H), 8.23 (d, $^3J_{H,H}$ = 8.4 Hz, 1 H, aryl H), 10.37 (s, 1 H, NH) ppm. $^{13}C\{^1H\}$ NMR ($CDCl_3$, 500 MHz): δ = 18.1 (CH_3), 23.7 (CH_3), [109.7, 116.1, 122.7, 136.2, 146.2, 153.7, 161.2] (aryl C), 163.5 (carbamoyl C), [187.1, 190.1, 191.8] (terminal CO) ppm. FAB-MS: m/z = 498 $[M]^+$. IR (KBr): $\tilde{\nu}$ = 3310 (w), 2087 (s), 2008 (s), 1928 (s), 1653 (m), 1614 (s), 1593 (s), 1538 (s), 1044 (s), 862 (s), 701 (s), 615 (s), 580 (s) cm^{-1}.

$[Re(CO)_4L^2]$ (2): A mixture of HL^2 (284 mg, 1 mmol) and *t*BuOK (112 mg, 1 mmol) in CH_2Cl_2 (20 mL) was heated under reflux for 30 min, followed by the addition of $Re(CO)_5Br$ (406 mg, 1 mmol). The mixture was then stirred for 6 h. After filtration and concentration, a yellow solid was obtained, which was chromatographed on a silica gel column using dichloromethane as the eluent. Recrystallization from dichloromethane/hexane afforded complex **2** as yellow prismatic crystals. Yield: 466 mg (80%). $C_{19}H_{12}ClN_4O_4Re$ (581.98): calcd. C 39.2, H 2.1, N 9.6; found C 39.5, H 2.2, N 9.4. ^1H NMR ($CDCl_3$, 300 MHz): δ = 2.58 (s, 3 H, CH_3), 2.65 (s, 3 H, CH_3), 6.62−8.29 (m, 6 H, aryl H) ppm. $^{13}C\{^1H\}$ NMR ($CDCl_3$, 500 MHz): δ = 17.8 (CH_3), 25.2 (CH_3), [113.4, 114.8, 115.0, 120.6, 135.7, 140.1, 145.4, 148.4, 152.5, 159.6, 162.1, 177.7] (aryl C), [185.6, 189.2, 189.3, 191.0] (terminal CO) ppm. FAB-MS: m/z = 581 $[M]^+$. IR (KBr): $\tilde{\nu}$ = 2925 (w), 2103 (m), 2009 (s), 1981 (s), 1946 (s), 1931 (s), 1682 (m), 1579 (m), 1455 (s), 1336 (m), 1152 (m), 776 (m), 626 (w), 585 (m) cm^{-1}.

X-ray Crystallography: The data of HL^2, **1**·HL^3·$2CH_2Cl_2$, and **2** were collected with a Mar diffractometer equipped with a 300-mm image plate detector, whereas those of **1**·$CHCl_3$ were collected with a Rigaku AFC7R diffractometer, using graphite-monochromatized Mo-K_α radiation (λ = 0.71073 Å for **1**·$CHCl_3$ and **2**, and 0.71069 Å for the others; data see Table 6). The structures were solved by direct methods (SIR92:[19] HL^2 and **1**·HL^3·$2CH_2Cl_2$) or by Patterson methods (PATTY:[20] **1**·$CHCl_3$ and **2**), expanded by Fourier methods, and refined by full-matrix least squares using the software package TeXsan[21] with a Silicon Graphics Indy computer. Note that the chlorine atoms of the $CHCl_3$ solvent molecule in **1**·$CHCl_3$ were disordered, with Cl(1), Cl(1′), Cl(2), Cl(2′), Cl(3), and Cl(3′) each having an occupation number of 0.5. In the least-squares refinements, all the non-H atoms, except C(16) and the disordered Cl atoms in **1**·$CHCl_3$, were refined anisotropically. The H atoms bonded to the N(2) atom in HL^2 and to the N(1) and N(6) atoms in **1**·HL^3·$2CH_2Cl_2$ found in the difference Fourier synthesis were refined. All the other H atoms placed at calculated positions with thermal parameters equal to 1.3 times that of the attached C atoms were not refined. CCDC-176086 (HL^2), -176087 (**1**·$CHCl_3$), -176088 (**1**·HL^3·$2CH_2Cl_2$), and -176089 (**2**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Synthesis, Spectra and Crystal Structure of Two Copper(I) Complexes of Acetonethiosemicarbazone

Sanchai Lhuachan,[a] Sutatip Siripaisarnpipat,*[b] and Narongsak Chaichit[c]

Keywords: Copper / Electrochemistry / Schiff bases / IR spectroscopy

The reaction of copper(I) chloride with acetonethiosemicarbazone (tscac) in a copper to tscac molar ratio of 1:2 forms the cationic complex $[Cu(tscac)_2]Cl$ (**1**). When the ratio of the copper to tscac was reduced to 1:1, a dimeric complex $[Cu_2Cl_2(tscac)_2]_2$ (**2**) was obtained. In complex **2**, two $CuCl_2$ species act as bridging groups between two $Cu(tscac)_2$ moieties forming an eight-membered ring, whereas in complex **1**, there is no $CuCl_2$ moiety in the structure. In both complexes the copper(I) center is coordinated in a distorted tetrahedral geometry to two tscac groups through the sulfur and the imine nitrogen atom. In dimeric complex **2**, the sulfur atom in each tscac ligand coordinates weakly to copper(I) in the $CuCl_2$ moiety giving the distorted tetrahedral geometry. For the free ligand, the $\nu_{c=s}$ vibration at 789 cm^{-1} appears at lower energy than in complexes **1** and **2** (754 and 744 cm^{-1} respectively) indicating coordination at the sulfur atom. The complexes synthesized by either electrochemical or chemical methods are identical.

Introduction

Thiosemicarbazone and its derivatives are chelating ligands with sulfur and nitrogen donor atoms forming a five-membered chelate ring. In a few cases they behave as monodentate ligands and bond through the sulfur atom only.[1] These ligands show antitubercular activity and activity against influenza and have been suggested as possible pesticides and fungicides. These activities are due to their ability to chelate trace metals. It has been reported that copper ions enhance the antitubercular activity of thiosemicarbazone,[2] leading to an increased interest in the chemistry of transition metal chelates of thiosemicarbazone and its derivatives. The preparation and crystal structures of copper(II) complexes of thiosemicarbazide, thiosemicarbazone and their derivatives have been reported.[3–8] The copper(I) complexes of some *N*- and *S*-substituted thiosemicarbazones are polymeric, the metal ion being bonded through the nitrogen and sulfur of the thiosemicarbazone moiety.[1] We report here a comparison of the crystal structures of two copper(I) complexes of acetonethiosemicarbazone, i.e. $[Cu(tscac)_2]Cl$ (**1**) and $[Cu_2Cl_2(tscac)_2]_2$ (**2**) which were prepared by both chemical and electrochemical methods. Their spectroscopic data are also reported.

Results and Discussion

Electrolysis of elemental copper in an ammonium chloride solution containing the ligand for half an hour at 4.5 V and 40 mA was found to be optimum for the formation of complex **1** with the highest yield (98%). A total of 72 coulombs of electricity was passed leading to the dissolution of 0.054 g of copper. The electrochemical efficiency (E_f), which is defined as mol of metal dissolved per Faraday of electricity, was found to be 1.14. This means the anodic reaction involves a one-electron transfer. For the preparation of complex **2**, the optimum conditions for the electrolysis were one hour at 3.5 V and 40 mA. The 144 coulombs of electricity applied led to the dissolution of 0.108 g of copper. The electrochemical efficiency (E_f) was found to be 0.96. This means the anodic reaction also involves a one-electron transfer.[9] X-ray analyses for these complexes showed that the complexes prepared by both chemical and electrochemical methods have the same molecular and crystal structures. Consequently, only the crystal structures of com-

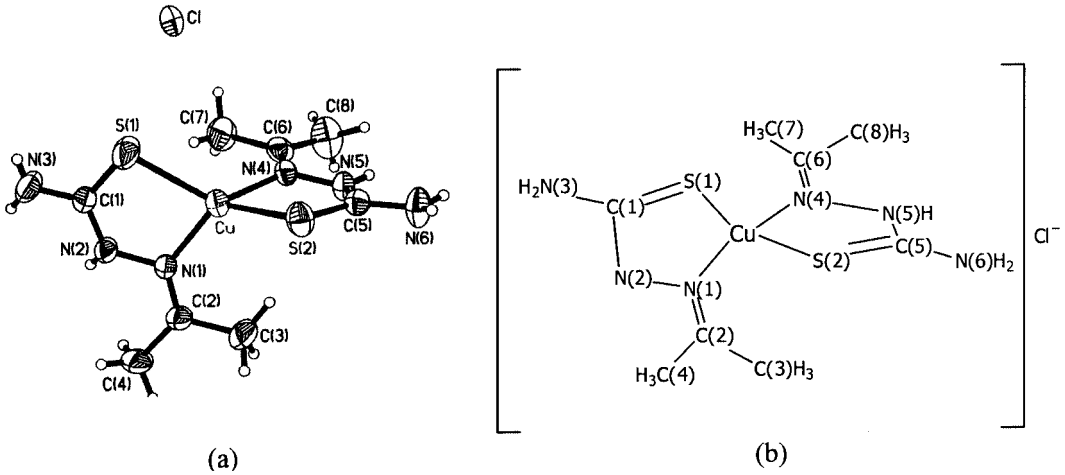

Figure 1. (a) Perspective view of complex **1** with thermal ellipsoids at the 50% probability level; (b) structural formula

plexes **1** and **2** prepared by chemical methods are discussed below.

Complex **1** consists of a distorted tetrahedral $[Cu(tscac)_2]^+$ cation and a chloride counteranion (Figure 1). The copper tetrahedron consists of two sulfurs and two nitrogens of two acetonethiosemicarbazone ligands forming two five-membered chelate rings. All the atoms of the five-membered rings are essentially coplanar and the planes of those rings are almost perpendicular. The average Cu−S distance is similar to the Cu−S distance in $[Cu(tsc)Cl_2]$.[3]

Complex **2** crystallizes as a neutral tetranuclear copper(I) complex with general formula $[Cu_2Cl_2(tscac)_2]_2$. Two $Cu(tscac)_2$ moieties are bridged by two $CuCl_2$ groups forming an eight-membered ring. In each $Cu(tscac)_2$ moiety, a copper center [Cu(1)] is coordinated in a distorted tetrahedral geometry by two sulfur atoms [S(1) and S(2)] and two nitrogen atoms [N(1) and N(4)] of two tscac ligands, forming two five-membered rings as in complex **1**. The coordination around the other copper center [Cu(2)] in the bridging $CuCl_2$ is also tetrahedral. Each $CuCl_2$ acts as a bridging group between two $Cu(tscac)_2$ moieties through the S(1) and S(2) atoms and gives rise to the tetranuclear copper(II) complex shown in Figure 2. The imino protons of the two tscac ligands are non-equivalent and give rise to NMR signals at $\delta = 10.31$ and 11.41 ppm. The center of each molecule is a crystallographic center of symmetry which is surrounded by four copper and four sulfur atoms forming an eight-membered ring. The two Cu−Cl distances are significantly different by 0.08 Å and longer than those for $[Cu^{II}(tsc)Cl_2]$.[3] The elongation of the Cu−Cl bond in this complex may be a result of the spatial arrangement of a hydrogen bonding interaction between the amino group and the chloride ion. The closest hydrogen bond length is 3.159 Å between N(3) and Cl(1). This interaction causes the non-equivalence of the amino protons. The torsion angles Cl(1)−Cu(2)−S(1)−C(1), Cl(2)−Cu(2)−S(1)−C(1) and Cu(2)−S(1)−C(1)−N(3) are 22.19(15)°, 140.89(14)° and −22.3(4)°, respectively, showing that the Cl(1) and N(3) atoms are in a suitable position for the formation of an intramolecular hydrogen bond. The Cu(1)−S bond length is 0.01 Å shorter than the Cu(2)−S bond length, indicating the weaker nature of the Cu(2)−S bond. As Cu(1) is part of two five-membered rings the length of the Cu(1)−S bond must be squeezed. The molecule forms weak intermolecular hydrogen bonds as indicated in Figure 3. The formation of two five-membered rings around Cu(1) causes the deviation of the angles around Cu(1) from tetrahedral angles, and this deviation is greater than that around Cu(2). The angle between the planes of the two five-membered rings is almost perpendicular (approx. 80°). All the atoms of the five-

membered rings are essentially coplanar. The principle distances and angles are presented in Table 1.

A comparison between the vibrational bands of tscac in $[Cu(tscac)_2]Cl$ and $[Cu_2Cl_2(tscac)_2]_2$ leads to the following observations:

(1) The absorption bands at 2800−3300 cm^{-1} are assigned to NH_2 and N−H stretching modes.[8] A broad peak at 3554 cm^{-1} in the spectrum of $[Cu_2Cl_2(tscac)_2]_2$ indicates the existence of weak hydrogen bonding (N−H···Cl) as seen in the crystal structure.

(2) The $\nu_{C=N}$ band at 1594 cm^{-1} in the free ligand is shifted to lower frequency in the complexes {1546 cm^{-1} in $[Cu(tscac)_2]Cl$ and 1555 cm^{-1} in $[Cu_2Cl_2(tscac)_2]_2$}. This shift supports the coordination of copper to the imine nitrogen.[8] The bands between 1400−1500 cm^{-1} in the spectra of the free ligands and the complexes can be assigned to the ν_{C-N} band.

(3) The absorptions at 789, 754 and 744 cm^{-1} can be assigned to the C=S stretching in the free ligand, $[Cu(tscac)_2]Cl$ and $[Cu_2Cl_2(tscac)_2]_2$ respectively. These shifts to lower energy in the complexes indicate a weaker C=S bond upon coordination with copper. A comparison of the vibrational frequencies in the tscac ligand and the complexes is shown in Table 2.

Table 2. Comparison of some vibration frequencies and bond lengths in tscac and the complexes

Compound	C=S		C=N	
	$\tilde{\nu}$ (cm^{-1})	Distance (Å)	$\tilde{\nu}$ (cm^{-1})	Distance (Å)
tscac	789 s	1.690[2]	1594 s	1.292[2]
$[Cu(tscac)_2]Cl$	752 s	1.6900(19)	1546 s	1.289(2)
		1.6988(17)		1.285(2)
$[Cu_2Cl_2(tscac)_2]_2$	744 s	1.708(4)	1555 s	1.290(5)
		1.713(4)		1.280(5)

Both complexes are ESR silent and display no d-d electronic spectra, consistent with the presence of Cu^I species.

The reactions at the anode were established by the weight loss of the copper sheet, which was weighed before and after the reaction. The electrochemical efficiency of 0.96 and 1.14 found for both complexes indicates that the anode material loses one electron per atom. The colorless gas observed at the cathode is formed as a result of the reduction of hydrogen ion either from the ligand or the acid. Mabrouk and co-workers[9] have suggested that in the electrochemical synthesis of metal complexes with thiosemicarbazide the ligand loses a proton and becomes negatively charged. If the reactions in this study occurred as described above, the number of tscac protons in the complexes should not be equal to the number of protons in the free ligand. The ^1H NMR spectra, however, show an equal number of protons in the free ligand and the complexes. In addition, the preparative results show that hydrochloric acid must be

added to the reaction mixture otherwise the electrolysis will not occur. Therefore the hydrogen gas must be formed from the protons in the hydrochloric acid not in the ligand.

Conclusion

It can be concluded from the electrolysis data (see Exp. Sect.) that the electrolysis of copper in the presence of acetonethiosemicarbazone occurs as follows [Equation (1) and (2)]:

$$\text{Cu} + 2\,\text{Tscac} + \text{Cl}^-_{(aq)} \xrightarrow{\text{for 1 : 2 adduct } ([\text{Cu(tscac)}_2]\text{Cl})} \text{complex } \mathbf{1} + e^- \quad (1)$$

$$\text{and for 1 : 1 adduct } ([\text{Cu}_2(\text{tscac})_2\text{Cl}_2]_2)\quad 4\,\text{Cu} + 4\,\text{Tscac} + 4\,\text{Cl}^- \longrightarrow \text{complex } \mathbf{2} + 4\,e^- \quad (2)$$

Alternatively the complexes may be prepared by chemical synthesis as outlined below

Experimental Section

Materials and Instruments: All chemicals are commercially available (BDH Co., Carlo Erba, Merck Co., Fluka, May & Baker Co. Ltd., Mallinckvodt Co.) and used without further purification. The infrared spectra were measured as KBr discs on a Perkin−Elmer Model SYSTEM 2000 spectrophotometer. ^{1}H NMR spectra were recorded on a JEOL Model JNM-A500 FT NMR 500 MHz spectrometer with deuterated dimethyl sulfoxide (DMSO) as solvent and internal standard. X-ray analyses were carried out using a Siemens Smart CCD diffractometer.

The electrochemical cell consists of a platinum cathode and the sacrificial copper anode immersed in an ammonium chloride solution containing acetonethiosemicarbazone. The complexes were prepared using the method described by Mabrouk and coworkers[9] with slight modification. After each electrolysis the electrochemical efficiency(E_f) was determined. The electrochemical efficiency is defined as mol of metal dissolved per Faraday of electricity. The amount of electricity used for each experiment in this study is equal to 72 coulomb or 7.5×10^{-4} Faradays. Theoretically, this amount of electricity dissolves Cu^+ 7.5×10^{-4} mol or Cu^{2+} 3.75×10^{-4} mol. Therefore, the E_f for Cu^+ and Cu^{2+} must be close to 1 and 0.5 mol·F^{-1}. This means that after electrolysis the E_f for one-electron transfer must be close to 1 and for two-electron transfer to 0.5. The variation of voltage, current and time was performed in order to determine the optimum electrolysis conditions. The electrochemical conditions described below are the optimum conditions for each complex.

Acetonethiosemicarbazone (tscac): The ligand was prepared using the method described by Sunner[10] with a slight modification. Thiosemicarbazide (2 mmol) was added to acetone (50 mL) and the mixture was heated and stirred until a white precipitate had formed. The compound was collected (yield 98%) and recrystallized from a mixture of water and acetone. ^{1}H NMR (500 MHz, [D$_6$]DMSO, 25 °C): δ = 1.89 (s, 3 H, CH$_3$), 1.90 δ (s, 3 H, CH$_3$), 7.49 (br, 1 H, NH$_2$), 7.95 (br, 1 H, NH$_2$) and 9.87 (br, 1 H, NH) ppm.

Complex 1 by Chemical Synthesis: In this synthesis the mol ratio of Cu:tscac is 1:2. A 6 M solution of NH_3 was added to a solution of CuCl (1.5 mmol in 6 M HCl) until the pH of the solution was 4−5. After adding thiosemicarbazone (3.0 mmol in 50 mL acetone) dropwise with stirring at room temperature, the reaction mixture formed two layers. Concentrated ammonium chloride solution was then added to the two layers until a single layer formed. The reaction mixture became pale yellow and was then filtered. Upon slow evaporation for 12−24 hours at room temperature, yellow octahedral crystals were formed. The product was collected, washed with water and acetone and dried in an oven at 60−70 °C. Yield: 40% (0.109 g). The infrared spectrum shows the presence of the tscac ligand in the yellow product. ^{1}H NMR (500 MHz, [D$_6$]DMSO, 25 °C): δ = 2.00 (m, 12 H, CH$_3$), 7.63 and 8.86 (br, 4 H, NH$_2$), 10.92 (s, 2 H, NH).

Complex 2 by Chemical Synthesis: This complex was prepared in a similar procedure to that described above, but using a mol ratio of Cu:tscac of 1:1. After slow evaporation of the solvent from the pale yellow solution for 1−2 days at room temperature, colorless needles were formed. The product was filtered, washed with water and acetone, and dried in an oven at 60−70 °C. Yield: 38% (0.132 g). The infrared spectrum shows the presence of tscac in the product. This complex turns green when exposed to air for several weeks. ^{1}H NMR (500 MHz, [D$_6$]DMSO, 25 °C): δ = 2.00 (m, 12 H, CH$_3$), 7.98 and 8.47 (s, 4 H, NH$_2$), 10.31 and 11.41 (s, 2 H, NH).

Complex 1 by Electrochemical Synthesis: The electrochemical oxidation of a copper anode in an acidic solution containing acetone (50 mL), 6 M HCl (0.5 mL), acetonethiosemicarbazone (1.5 mmol) and ammonium chloride (0.5 g) for half hour at 4.5 V and 40 mA led to the dissolution of 47.4 mg of copper as the Cu^I ion. The reaction mixture became pale yellow and was then filtered to remove insoluble impurities. The solvent was then slowly evaporated from the filtrate at room temperature. After 6 hours, yellow crystals formed. These were then filtered off, washed with water and acetone successively and dried in an oven at 60−70 °C. Yield: 98% (0.266 g). The infrared spectrum shows the presence of tscac in the yellow crystals. The electrochemical efficiency of this reaction was evaluated (see above).

Complex 2 by Electrochemical Synthesis: The electrochemical oxidation of a copper anode in an acidic solution containing acetone (50 mL), 6 M HCl (0.5 mL), acetonethiosemicarbazone (1.5 mmol) and ammonium chloride (0.5 g) for one hour at 3.5 V and 40 mA led to the dissolution of 94.8 mg of copper as the Cu^I ion. The reaction mixture was pale yellow solution and then was filtered to remove the impure particles. The reaction mixture became pale yellow and was then filtered to remove insoluble impurities. The solvent was then slowly evaporated from the filtrate at room temperature. After 8 hours, pale yellow crystals had formed. These were then filtered off, washed with water and acetone successively and dried in an oven at 60−70 °C). Yield: 69% (0.273 g). The infrared spectrum shows the presence of coordination between Cu and tscac. The electrochemical efficiency of this reaction was evaluated (see above). This complex did not give a suitable crystal for the collection of X-ray diffraction data.

X-ray Crystallographic Study: The diffraction data for all complexes with appropriate size crystals were collected at 298(2) K on a 1 K Bruker Smart CCD area detector diffractometer using ω rotation scans with a scan width of 0.3° and graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å). For data collection and data integration, the SMART and SAINT programs were used[11] and empirical absorption correction was performed with the pro-

gram SADABS.[12] The structures were solved by direct methods using the SHELXTL program system[13] for all complexes and were refined by full-matrix least-squares first with isotropic and then with anisotropic thermal parameters for all non-hydrogen atoms. For all complexes the hydrogen atoms were located from a Fourier difference map and refined. Crystal parameters and refinement results for all complexes showed that the complexes prepared by both methods resulted in the same crystal structure. Crystal data and refinement results of complexes **1** and **2** prepared by chemical method are listed in Table 3.

Thermodynamic and Kinetic Data for the Base-On/Base-Off Equilibration of Alkylcobalamins

Mohamed S. A. Hamza,[a,b] Xiang Zou,[c] Kenneth L. Brown,[c] and Rudi van Eldik*[a]

Keywords: Alkylcobalamins / Metal−carbon bond / Kinetics / High-pressure chemistry / Catalysis

The base-on/base-off equilibration of a series of alkylcobalamins (XCbl) was studied as a function of the electronic properties of X. A square scheme was developed to incorporate all species that participate in this equilibration. The equilibrium between five- and six-coordinate species was studied for several alkylcobalamins (protonated base-off) and alkylcobinamides as a function of pressure by using UV/Vis spectroscopy. In addition, the kinetics of the acid-induced base-on/base-off equilibration of β-$NCCH_2$Cbl, β-CF_3Cbl and CNCbl were studied; the data obtained reveal evidence for an acid-catalysed reaction path. The results of this study and the observed correlations are discussed in reference to those reported in the past, and enable the formulation of an overall equilibration scheme.

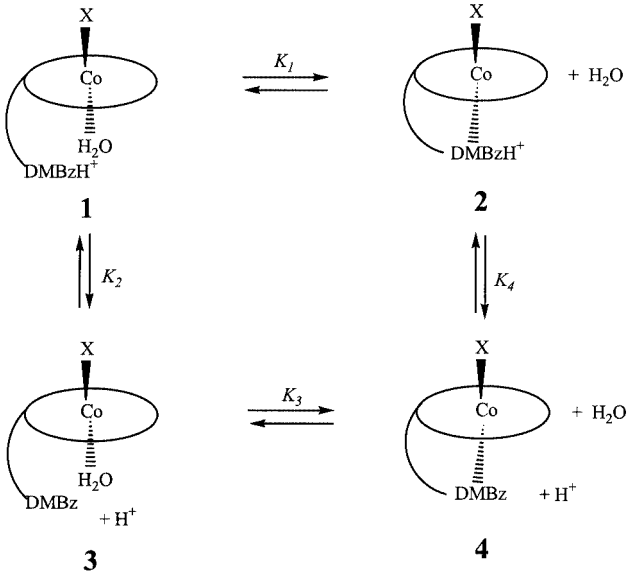
Introduction

In general there is a need to investigate ligand substitution reactions *trans* to the axial alkyl ligand in coenzyme B_{12} and other β-alkylcobalamins, for comparison with the work performed on substitution reactions *trans* to a non-alkyl ligand. Methylcobalamin (CH_3Cbl) and coenzyme B_{12} (AdoCbl) undergo substitution of their axial benzimidazole ligand by a protein histidine residue during complexation to the CH_3Cbl-dependent methionine synthase,[1] the class I[2] AdoCbl-dependent mutases, methylmalonyl coenzyme A mutase, and glutamate mutase,[3] and the class III AdoCbl-dependent D-lysine-5,6-aminomutase.[4]

One of the most characteristic chemical properties of cobalamins is the base-on/base-off equilibrium in which the axially coordinated dimethylbenzimidazole (DMBz) nucleotide is displaced by H_2O and protonated. This reaction is accompanied by a large change in the electronic spectrum upon conversion of the (red) base-on to the (yellow) base-off form. The base-on/base-off equilibrium can best be described by the reactions outlined in Scheme 1.



Scheme 1

In this square scheme, **1** represents the protonated base-off cobalamin species, by far the major contributor at low pH, **2** the protonated base-on species, which must be a minor contributor at all pH values, **3** the deprotonated base-off species, which can be a significant contributor at neutral pH for some X, and **4** the deprotonated base-on species, the major species at neutral pH. The introduction of **2** is new and is based on the kinetic data for the base-on/base-off equilibration presented in this report. Coordination (ring closure) of the protonated base-off cobalamin species

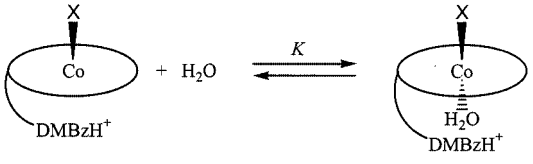
1 is expected to be unfavorable with respect to chelation of the deprotonated base-off species **3**, such that $K_1 << K_3$.

Although it is known that the base-on form (**4**) is a six-coordinate species, one of the remaining questions is whether the base-off forms (**1** and **3**) are six-coordinate aqua complexes or five-coordinate species without a water molecule occupying the sixth coordination site, or whether they exist in equilibrium between the five- and six-coordinate forms. Physicochemical measurements including electronic absorption, IR and NMR spectra of corrinoid Co^{III} complexes have suggested that the presence of an alkyl group as a strong donor ligand increases the fraction of the five-coordinate species.[5−8] The temperature dependence of the UV/Vis spectra of alkyl cobinamides (RCbi's, derivatives in which the axial nucleotide is chemically removed) suggests that the ratio of six-coordinate to five-coordinate species increases on decreasing the temperature.[5] Increasing temperature also favours the five-coordinate form when diethyl phosphite is the upper axial ligand, and in this case it was also shown qualitatively that increasing pressure favours the six-coordinate form.[9] No structural data on the five-coordinate forms have yet been reported and more direct evidence for the reversible coordination of water is clearly desirable.

Wirt and Chance[10] provided evidence for a five-coordinate/six-coordinate equilibrium in base-off CH_3Cbl and AdoCbl from the temperature dependence of the 1s-3d pre-edge transition in the X-ray absorption edge spectra of these complexes. In addition to the spectroscopic evidence, thermodynamic parameters for this equilibrium provide evidence that the base-off RCbl's exist as an equilibrium mixture of six-coordinate aqua and five-coordinate species, and that this equilibrium is sensitive to the nature of the organic ligand.[11]

Recently, the equilibrium between the five- and six-coordinate base-off forms of both methylcobalamin and vinylcobinamide was studied as a function of pressure, and it was found that this equilibrium is shifted towards the formation of the six-coordinate species upon increasing pressure.[12] This has led us to investigate the equilibrium between the five- and six-coordinate species [shown by way of example for the protonated base-off species **1** in Equation (1)] for many of the available alkylcobalamins (protonated base-off) and cobinamides, in order to investigate the influence of the group X on this equilibrium and to understand the mechanistic implications of its occurrence.



5 **1** (1)

In addition, a systematic study of the kinetics of the base-on/base-off equilibration for β-$NCCH_2$Cbl, β-CF_3Cbl and CNCbl was undertaken, and the data obtained reveal evidence for the acid-catalysed reaction path shown in Scheme 1. The reported results enable us to draw a consistent mechanistic picture for such ligand displacement reactions.

Results

According to Scheme 1, the base-on/base-off reaction must be viewed as the sum of two consecutive equilibria, either deprotonation of **1** followed by coordination (ring closure) of **3**, involving dissociation of a coordinated water molecule, or coordination (ring closure) of **1** followed by deprotonation of the base-on species **2**. It follows from the square scheme that $K_2K_3 = K_1K_4$. Values of $pK_{base\text{-}off}$ [Equation (2), where $K_{base\text{-}off}$ represents the apparent acid dissociation constant of a mixture of species **1** and **2**] have been reported for a large number of cobalamins, and range from about 4.0 (*n*-heptylCbl) to −2.4 in the case of H_2OCbl.[13,14] The pK_a of the detached axial nucleoside α-ribazole ($pK_a = 5.56$),[15] or the virtually identical value for the appropriate microscopic pK_a of the detached axial nucleotide, α-ribazole-3′-phosphate ($pK_a = 5.54$),[16] can be used for the value of pK_2.

$$K_{base\text{-}off} = \frac{K_2(1+K_3)}{(1+K_1)} \quad (2)$$

Based on the definition of $K_{base\text{-}off}$ [Equation (2)], it can be shown (see Supporting Information; see also footnote on the first page of this article) that f_{off}, the fraction of base-off species, is given by Equation (3).

$$f_{off} = \frac{([H^+]+K_2)}{([H^+]+K_{base\text{-}off})(1+K_1)} \quad (3)$$

Equations (2) and (3) simplify to Equations (4) and (5) on the basis that it is reasonable to expect K_1 to be very small, so that $1 + K_1 \approx 1$.

$$K_{base\text{-}off} = K_2(1+K_3) \quad (4)$$

$$f_{off} = \frac{([H^+]+K_2)}{([H^+]+K_{base\text{-}off})} \quad (5)$$

Equation (5) indicates that the fraction of base-off cobalamin depends on the pH, such that an increase in $[H^+]$ will increase the concentration of **1**, and therefore the fraction of base-off species in solution. However, under neutral experimental conditions (pH ≥ 7) or under conditions in which typical cyanation reactions were studied (pH = 11), Equation (5) simplifies to Equation (6). Equations (5) and (6) allow the calculation of the fraction of base-off form from $K_{base\text{-}off}$, K_2 and $[H^+]$ under all experimental

conditions, where Equation (6) is identical to that used before for pH ≥ 7.[13]

$$f_{off} = \frac{K_2}{K_{base\text{-}off}} \quad (6)$$

Effect of Pressure on the UV/Vis Spectra of XCbl and XCbi

There is good evidence that Cbi's (and protonated, base-off Cbl's) with strong donor ligands (e.g. vinyl, methyl, sulfite, dialkyl phosphites) exist as temperature-dependent mixtures of five- and six-coordinate aqua forms based on UV/Vis and EXAFS data.[5,10,17] Increasing temperature favours the five-coordinate form, and with diethyl phosphite as the β-axial ligand, it has also been shown qualitatively that increasing pressure favours the six-coordinate form.[9]

Organocobalamins (XCbl) with different X (Ado, Et, Me, $BrCH_2$, CF_3CH_2, $NCCH_2$, CF_3, CN) are believed to exist in aqueous solution in a base-on form (**4**) and two base-off forms (**1** and **3**), which can both be either five- or six-coordinate, as shown for **1** in Equation (1). UV/Vis spectra of cobalamins such as AdoCbl and ethylcobalamin in their protonated, base-off forms, exhibit reversible changes on heating the solution, changing the solvent or drying the solid (when a thin film was used to record the reflectance spectrum).[5,18] The spectrum of protonated base-off cobalamin at high temperature is similar to the spectra of cobinamides, suggesting that temperature affects the spectra of base-off cobalamin and the analogous cobinamides in the same way. The UV/Vis spectra of methylcobinamide, isopropylcobinamide and sulfitocobinamide at low temperature (−180 °C in ethanol or a mixture of ethanol, methanol and propan-2-ol) were assigned to the six-coordinate complexes. However, the spectra of these complexes at 20 °C were assigned to the five-coordinate complexes.[5] In the case of ethylcobalamin, the calculated[13] fraction of base-off cobalamin [ca. 4.7% from Table 1 for the two base-off forms **1** and **5** in Equation (1)] at equilibrium is in reasonable agreement with the values of 13 and ca. 15%, from NMR measurements and optical spectra, respectively.[5,18] The ratio of the species in Equation (1) is probably similar for ethylcobinamide, so that ethylcobalamin exists as a mixture of 85% **4**, 0% **3** and 15% **5**.[19] For AdoCbl, calculations suggest ca. 1.3% **3** and **5** in aqueous solution at room temperature, whereas the spectrum indicates the presence of ca. 90% **4** and ca. 10% **3** and **5**; by analogy with ethylcobalamin, one may assume 0% **3** and 10% **5**. We conclude that the base-off forms of AdoCbl and ethylcobalamin are mainly five-coordinate species at room temperature.

In addition to the spectroscopic evidence for the existence of a five-coordinate/six-coordinate equilibrium for corrinoid alkyl(aqua)cobalt complexes, and the sensitivity of this equilibrium to the inductive effect of the alkyl ligand, there are thermodynamic results that suggest the same equilibrium occurs in the base-off alkylcobalamins.[11] It was found that this equilibrium is displaced toward the six-coordinate aqua species as the organic ligand becomes more electron-withdrawing, where there is an increasing compensation for the entropy loss from the entropy gain of H_2O dissociation, and the entropy change no longer varies with the alkyl ligand. However, for some compounds with the highest value of $-\Delta S$ (and the lowest $-\Delta G$), the loss of entropy upon coordination of the pendent axial nucleotide is largely uncompensated for by the entropic effect of the loss of an axial water ligand, i.e. these compounds are largely five-coordinate.[11] The UV/Vis spectrum of protonated base-off AdoCbl (3×10^{-5} M in 1 M $HClO_4$), exhibits a band at ca. 450 nm as shown in Figure 1. Increasing the pressure to 150 MPa resulted in a small increase in absorbance at the maximum with no isosbestic points being observed. Similar UV/Vis spectra were observed in the case of *n*PrCbl. On the basis that such five-coordinate species exhibit a band at ca. 440−460 nm, compared to a band at ca. 500−522 nm for six-coordinate cobalamins or cobinamides,[8,18] the observed spectral changes suggest that the protonated base-off forms of these complexes mainly exist as five-coordinate species in solution irrespective of pressure. The fractions of the six-coordinate species are apparently very small, i.e., no shift in the equilibrium towards six-coordinate species can be induced by pressure.

[a] See Equation (2) in the text. [b] See Equation (4) and Scheme 1 in the text. [c] Fraction base-off = $K_2/K_{base\text{-}off}$. [d] Ref.[21] [e] At 25 °C, ref.[21] [f] Refs.[11,13] [g] Refs.[34,35]

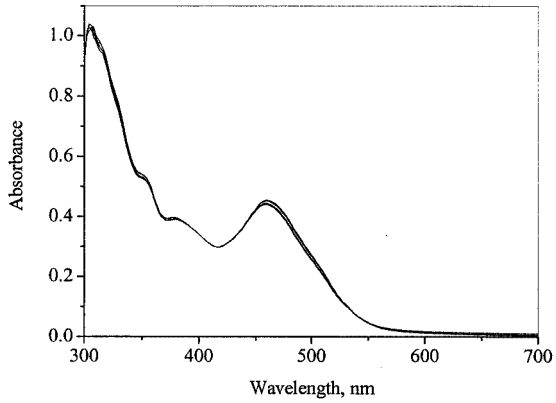

Figure 1. UV/Vis spectra of β-AdoCbl (base-off) (0.5 M $HClO_4$) recorded as a function of pressure (5, 50, 100 and 150 MPa)

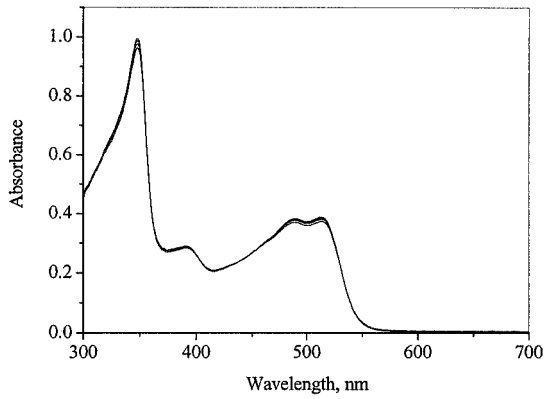

Figure 2. UV/Vis spectra of β-CF_3Cbl (base-off) (0.5 M $HClO_4$) recorded as a function of pressure (5, 50, 100 and 150 MPa).

The UV/Vis spectra of β-CF_3Cbi, β-CF_3Cbl (protonated base-off), H_2O(CN)Cbi (exists as a mixture of α- and β-isomers), and $(H_2O)_2$Cbi exhibit bands at 500−520 and 520−540 nm. Increasing the pressure to 150 MPa again resulted in a very small increase in absorbance with no isosbestic points observed [as shown in Figure 2 for β-CF_3Cbl (base-off)], suggesting that these complexes mainly exist as six-coordinate species irrespective of pressure. Thus, the fraction of the five-coordinate species in these compounds is very small. Interestingly, β-CF_3CH_2Cbl (protonated base-off), β-$NCCH_2$Cbl (protonated base-off) and the cobinamides of these complexes exhibit the main band at 454 and 478 nm, respectively.[20] The absorbance at these maxima increases slightly and is accompanied by a slight shift in the band position on increasing pressure. More importantly, however, a significant increase in absorbance at ca. 480−540 nm was observed upon increasing the pressure step-wise from 5 to 150 MPa. These changes in the UV/Vis spectra are accompanied by isosbestic points at 304, 365, 450 and 595 nm as shown in Figure 3 for β-$NCCH_2$Cbl (protonated base-off), suggesting that an equilibrium between the five- and six-coordinate species occurs [see also Supporting Information, Figure S-1 for the UV/Vis spectra of β-CF_3CH_2Cbl (protonated base-off) as a function of pressure]. Similar changes to those obtained upon increasing the pressure were obtained upon decreasing the temperature. This equilibration involves the coordination of a water molecule to the five-coordinate species to form the six-coordinate aqua complex, and indicates that these complexes exist as a mixture of five- and six-coordinate species in solution.

We recently studied this equilibrium for both MeCbl (protonated base-off) and vinylcobinamide,[12] and found that increasing pressure displaces the observed equilibrium [Equation (1)] from the five-coordinate towards the six-coordinate form for both complexes. A significant increase in the absorbance at ca. 490 nm was observed, accompanied by good isosbestic points. Values of the equilibrium constant {K = [six-coordinate]/[five-coordinate] as defined in Equation (1)} as a function of pressure were calculated

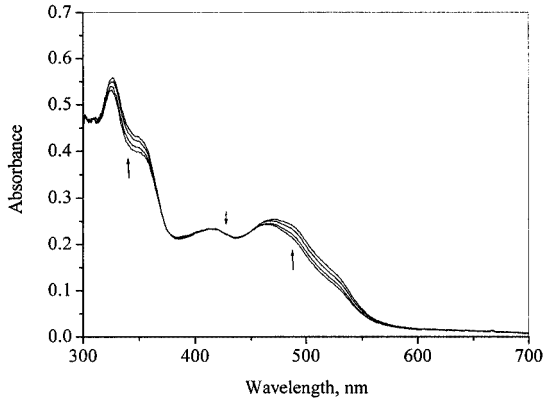

Figure 3. UV/Vis spectra of β-$NCCH_2$Cbl (base-off) (0.5 M $HClO_4$) recorded as a function of pressure (5, 50, 100, and 150 MPa, accompanied by an increase in absorbance around 480−540 nm)

from the increase in absorbance at 490 nm using the relative optical density for the fully formed six-coordinate and five-coordinate species derived from the temperature-dependence studies.[5] The reaction volume, ΔV, was found to be -12.4 ± 1.0 and -12.5 ± 1.2 cm^3 mol^{-1} for the conversion of the five- to the six-coordinate species in vinylcobinamide and MeCbl (base-off), respectively.[12] Their identical values underline the close parallel between Cbi's and protonated Cbl's, and their agreement with the theoretical value of -13.1 cm^3 mol^{-1} expected for the coordination of a water molecule to a five-coordinate species confirm that conversion of the five- to the six-coordinate form involves the coordination of one water molecule to the five-coordinate form.[12]

Based on the UV/Vis spectra recorded under pressure, we conclude that the protonated base-off species of the first two compounds (AdoCbl and *n*PrCbl) of the series of alkylcobalamins (see Table 1 for a list of these XCbl's) investigated during the course of this work are mainly five-coordinate species irrespective of pressure. For some of the XCbl's (X = Me, CF_3CH_2, $NCCH_2$ and vinyl) we suggest that the protonated base-off forms exist in solution as an equilibrium between five- and six-coordinate species. However, for

the last three complexes in the XCbl series (X = CF_3, CN and H_2O), the base-off forms of these compounds are mainly six-coordinate aqua species irrespective of pressure. It seems clear that the X group in the upper, β-axial position has a significant influence on this equilibrium, and by increasing the electron-withdrawing ability of the alkyl group the equilibrium is shifted towards the six-coordinate complexes.

Kinetics of the Base-On/Base-Off Equilibration

β-CF_3Cbl, β-$NCCH_2$Cbl and CNCbl were selected for this study, since the p$K_{base\text{-}off}$ values of these complexes are 1.81, 1.44 and 0.1, respectively.[15,21,22] These p$K_{base\text{-}off}$ values are in the range which allow a titration with acid to be carried out in order to dechelate the DMBz in the α-position. At the same time, the DMBz dissociation rate of these compounds can be monitored with stopped-flow techniques, since, from the electron-inductive effect of these X, the rate of DMBz dissociation is expected to be much slower for these complexes than for those with strongly donating X. The DMBz dissociation rates of other XCbl's such as MeCbl and CF_3CH_2Cbl are much too fast to be monitored by the stopped-flow technique.[23,24]

The kinetic results for the stopped-flow "pH-jump" reaction of 3×10^{-5} M β-$NCCH_2$Cbl (pH = 5, unbuffered solution) with different concentrations of $HClO_4$ (0.01−0.3 M) at I = 1 M ($NaClO_4$) and 5 °C are shown in Figure 4. The values of $k_{obsd.}$ first decrease with increasing acid concentration in the lower concentration range (0.005−0.05 M), and then increase linearly with increasing acid concentration at higher concentrations (0.05−0.3 M). A combination of these concentration dependencies results in the curved dependence observed in Figure 4. The first part of the plot at low acid concentration is incomplete since the reaction becomes too fast to be monitored by stopped-flow and the change in absorbance at 530 or 478 nm becomes too small. The second part of the plot is expected to level off (base-off, k_{-3}), but shows a significant increase in $k_{obsd.}$ with increasing acid concentration. This linear increase in $k_{obsd.}$ is ascribed to an acid-catalysed dechelation reaction, the slope of which represents the rate constant for the acid-catalysed reaction (k^H) and the intercept of which represents the rate constant for the spontaneous dechelation of DMBz (k_{-3}). We conclude that dechelation of DMBz to give β-$NCCH_2$Cbl (base-off) is catalysed by acid. Reenstra and Jencks previously reported that the reaction between CNCbl and HCN is also catalysed by acid, but no kinetic data were given.[25] In terms of the overall base-on/base-off equilibration presented in Scheme 1, the rate law for the acidification reaction of β-$NCCH_2$Cbl is given in Equation (7), in which k_{-3} and k_3 represent the rate constants for the spontaneous dechelation of **4** and chelation of **3**, respectively, $K_2/(K_2 + [H^+])$ represents the fraction of the base-off species in the form of **3** that can undergo chelation, and k^H represents the acid-catalysed reaction path, i.e. the product of the protonation constant for **4** and the dechelation rate constant k_{-1} of **2**, such that $k^H = k_{-1}/K_4$.

$$k_{obs} = k_{-3} + \frac{k_3 K_2}{K_2 + [H^+]} + k^H [H^+] \quad (7)$$

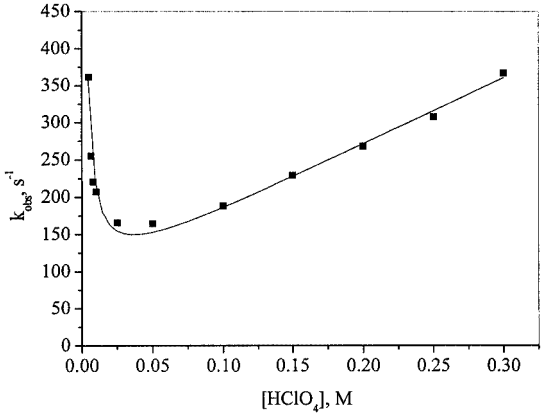

Figure 4. $k_{obsd.}$ versus [$HClO_4$] for the reaction between β-$NCCH_2$Cbl and $HClO_4$ at 5 °C and I = 1 M ($NaClO_4$); the solid line is a fit to Equation (7) in the text.

A non-linear least-squares fit of the data shown in Figure 4 to the rate law in Equation (7), with pK_2 = pK_{Bz} = 5.56,[15] results in $k_3 = (4.4 \pm 0.3) \times 10^5$ s^{-1}, $k_{-3} = 83 \pm 13$ s^{-1} and $k^H = 913 \pm 71$ M^{-1} s^{-1}. It follows that K_3 (= k_3/k_{-3}) equals 5300, which is in very good agreement with the value of 5620 previously reported from thermodynamic considerations.[13] Also, the value of k_{-3} is in good agreement with the acid-independent limiting rate constant obtained when the nucleophile concentration dependence was studied for the reaction of β-$NCCH_2$Cbl and CN^-.[26]

Similar results to those obtained for β-$NCCH_2$Cbl, were obtained for the reaction of β-CF_3Cbl with $HClO_4$. The data for the reaction of 3×10^{-5} M β-CF_3Cbl with $HClO_4$ (0.01−1 M) are shown in Figure 5. The data again show a decrease in $k_{obsd.}$, followed by an increase in $k_{obsd.}$ at higher acid concentrations. The non-linear least-squares fit of the data to the rate-law in Equation (7) resulted in $k_3 = (7.80 \pm 0.07) \times 10^4$ s^{-1}, $k_{-3} = 7.7 \pm 0.2$ s^{-1} and $k^H = 31.8 \pm 0.4$ M^{-1} s^{-1}. It follows that $K_3 = 1.01 \times 10^4$, which is in good agreement with the reported value of 1.3×10^4.[13] Also k_{-3} is in good agreement with the acid-independent limiting rate constant (8.2 s^{-1}) previously determined from the concentration dependence of the reaction of CN^- with β-CF_3Cbl.[27]

Similar results to those obtained for the acidification of β-$NCCH_2$Cbl and β-CF_3Cbl, were obtained for the reaction of CNCbl with $HClO_4$. The data for the reaction of 3×10^{-5} M CNCbl with $HClO_4$ (0.01−1.0 M) at 25 °C again show a decrease in $k_{obsd.}$ followed by a slight increase in $k_{obsd.}$ at higher acid concentrations (see Figure S-2 in the Supporting Information). The increase in $k_{obsd.}$ in this case was not as prominent as in the previous two cases because the value of p$K_{base\text{-}off}$ in this case is only 0.1,[22] which means that more acidic conditions are required to give signific-

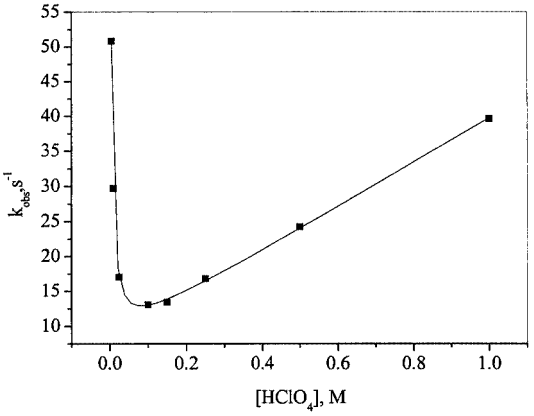

Figure 5. $k_{obsd.}$ versus [$HClO_4$] for the reaction between β-CF_3Cbl and $HClO_4$ at 10 °C and I = 1 M ($NaClO_4$); the solid line is a fit to Equation (7) in the text

ant proportions of the protonated base-off cobalamin. The non-linear least-squares fit of the data resulted in k_3 = (9.2 ± 0.6) × 10^3 s^{-1}, k_{-3} = 0.19 ± 0.04 s^{-1} and k^H = 0.28 ± 0.06 M^{-1} s^{-1}, from which it follows that K_3 = 4.85 × 10^4, which is significantly smaller than the value determined previously (2.9 × 10^5).[13] The value of k_{-3} is also higher than the limiting rate constant (0.042 s^{-1}) determined from the concentration dependence of the reaction of CN^- with CNCbl.[25,26] These differences are in part caused by the lower value of $pK_{base-off}$ and the consequently much higher concentration of $HClO_4$ required to obtain the base-off form.

By way of comparison, the values of k_{-3} for the spontaneous ring opening of β-$NCCH_2$Cbl, β-CF_3Cbl, and CNCbl to give the corresponding unprotonated base-off cobalamins were found to be 83, 7.7 and 0.19 s^{-1}, respectively. The rate constant k_3 for ring closure of the unprotonated base-off forms of these cobalamins was found to be 4.4 × 10^5, 7.8 × 10^4 and 9.2 × 10^3 s^{-1}, respectively, and the acid catalysed rate constant k^H for the ring opening of the unprotonated base-on forms was found to be 913, 31.8 and 0.28 M^{-1} s^{-1}, respectively. These rate constants all follow the same trend for the three complexes, which can be ascribed to the influence of the axial group (X) in the upper, β-position (see further discussion related to Table 1). Thus, our systematic study of the acid dependence of the base-on/base-off reactions has revealed rate constants for the individual reaction steps that present a consistent picture of the overall mechanism and are in agreement with the earlier reported overall equilibrium data for this process, which plays a crucial role in the ligand substitution reactions at the DMBz site of the complexes.

Discussion

It seems clear that the alkyl group (X) in the *trans* position, which controls the equilibrium between the base-on and base-off cobalamin species shown in Scheme 1, as well as the ratio between the five- and six-coordinate species shown in Equation (1), must play a crucial role in controlling the ligand displacement mechanism of these complexes.

The complex-formation constants for the substitution of the α-axial water molecule in a series of alkyl cobinamides by nitrogenous ligands decrease and approach zero as the *trans* ligand is varied in the order H_2O > cyanide > CF_3 > $NCCH_2$ > CH_2CF_3 > methyl > Ado > ethyl.[5,18,28] This weakening of the bond between cobalt and all other ligands (X) only makes sense if the bond to H_2O is also being weakened in the same way in the above *trans* effect order. One would therefore expect that the Co−OH_2 bond could be weakened to such an extent that a five-coordinate complex could be formed. In the case of Co^{II} complexes, [$CoL_5(H_2O)$] where L = CN^-, MeNC and PhNC, water can readily be removed to produce a five-coordinate complex when L = PhNC, or a dimer with a metal−metal bond when L = CN^- or MeNC, and the formation constant is indeed very low.[29]

The stretching frequency ν_{CN} (for cyanide *trans* to X), when X = H_2O, was found to be 2133 cm^{-1}. However, this value was found to be 2082 cm^{-1}, when X = Et, which is close to the stretching frequency for free CN^- (2079 cm^{-1}),[18,29c] i.e., the coordinated cyanide ion becomes more ionic in character. It is clear from this argument that the positive charge on Co decreases from X = H_2O to X = Et. It was also found that the Co−N and Co−C bond lengths in RCbl's increase in the order H_2O < CN < CF_3 < $NCCH_2$ < CF_2H < CF_3CH_2 < CH_3 < Ado.[30−32] This suggests that AdoCbl is a labile complex for ligand substitution reactions. Furthermore, in the case of AdoCbl steric effects may also play an important role in controlling its substitution behaviour.[33]

Table 1 shows that there is a significant increase in $E_{1/2}$ from −1.54 V (X = Et) to −0.07 V (X = H_2O), which reflects the effect of the X group on $E_{1/2}$.[34,35] These data suggest that there is a relationship between the electrochemical behavior and electron density on the Co centre in XCbl's. However, electrochemical studies on XCbl [X = CH_3, CH_3CH_2, $CH_2CH_2CH_3$, $CH_2CH(CH_3)_2$ and $CH_2C(CH_3)_3$], suggest that the bulkiness of X may have a significant influence on the $E_{1/2}$ values.[35] The decrease in $E_{1/2}$ may reflect changes in the Co−X distance which modulates the energy of the lowest σ-type MO (LUMO) of these complexes. The energy of the σ-LUMO (the orbital in which the electron added to RCo must enter) increases when the Co−X distance decreases.[35]

Kräutler et al.[36,37] have compared the crystal structure of AdoCbl with that of cob(II)alamin, which is the intermediate that arises from homolytic cleavage of the β-axial bond. It was found that the two structures are indeed very similar, indicating that it is not just a distortion of the corrin moiety that leads to the homolysis products, but rather strong stabilisation of the radicals by the environment. The structure of cob(II)alamin showed that the cobalt ion is shifted 0.12 Å out of the plane of the corrin nitrogen atoms towards the DMBz ligand. More recently, Jensen et al.[38] ascribed the difference between MeCbl and AdoCbl to the

different electronic nature of the two Co−C bonds. According to B3LYP DFT calculations, the HOMO energy is higher in AdoCbl than in MeCbl, favoring homolytic cleavage. This is due to the 5′-deoxyadenosyl group, which interacts with the corrin ring and induces more electron density on the cobalt centre.

As mentioned previously, most of the known cobalt corrinoid complexes are six-coordinate species, except when one of the axial ligands is a polarizable group such as SO_3^{2-} or an organic ligand, where there is a possibility of a five-coordinate complex.[5] The ratio of the base-on form (six-coordinate species) to the base-off forms (five- and six-coordinate aqua species) is related to the value of K_3 for the formation of the base-on species from the base-off species. Thus, when the $pK_{base\text{-}off}$ value of the protonated base-off complex is high and close to the value for free DMBz (viz. 5.54),[15,16] the fraction of five-coordinate species in this equilibrium will be significant. It was found that the change in the spectrum on drying or heating cobalamin (a qualitative measure of the ease with which DMBz is displaced) does depend on the nature of the axial ligand in the order expected from the $pK_{base\text{-}off}$ values: CN ($pK_{base\text{-}off}$ = 0.1) ≈ ethynyl (0.7) < CF_3 (1.44) < vinyl (2.4) < methyl (2.89) < Ado (3.67) < ethyl (4.14).[14,39]

The values of K_3, the fraction of base-off species, the values of $pK_{base\text{-}off}$ and the thermodynamic parameters associated with the base-off/base-on equilibrium of XCbl are summarized in Table 1. This table shows the effect of the alkyl group (X) located in the *trans* position and the *trans* effect order for the different XCbl complexes. The value of K_3 varies from 20 in the case of CH_3CH_2Cbl to 4.9×10^7 in the case of H_2OCbl. Consequently, the fraction of the base-off form of XCbl decreases significantly from 0.047 in the case of CH_3CH_2Cbl to 2×10^{-8} for H_2OCbl.

The differences between the ^{31}P NMR chemical shifts for the base-on and base-off forms of XCbl, $\Delta\delta(^{31}P)$, are also included in Table 1. These values show a regular variation with the apparent free energy of coordination of the pendant axial DMBz ligand.[21] These effects are interpreted in terms of variations in the axial Co−N bond length leading to progressive changes in the base-on phosphodiester conformation throughout the series of cobalamins. Interestingly, $\delta(^{31}P)$ for base-on Cbl's is linearly related to the axial Co−N bond length (slope = −2.26 ± 0.08 ppm/Å),[32] but $\delta(^{31}P)$ for the base-off Cbl's is the same for all XCbl. When the axial ligand is bound moderately weakly in a base-on cobalamin such as MeCbl (K_3 = 467) or CF_3CH_2Cbl (K_3 = 923), the RO−P−OR bond angle is nearly identical for the base-on and base-off species and hence a negligible value of $\Delta\delta(^{31}P)$ results. However, for those cobalamins such as AdoCbl (K_3 = 76.6) or EtCbl (K_3 = 20) in which the axial base is bound more weakly, the axial Co−N bond becomes longer (2.24 Å in AdoCbl), the RO−P−OR bond angle decreases and the ^{31}P resonance is shifted upfield, producing a negative $\Delta\delta(^{31}P)$. However, in the case of CNCbl, where the axial ligand is bound significantly more tightly (K_3 = 2.9×10^5), the Co−N bond length is short (1.97 Å), the RO−P−OR bond angle increases, and the ^{31}P resonance is shifted downfield and produces a positive $\Delta\delta(^{31}P)$.[21]

Table 1 also shows that the enthalpy of formation of the base-on species, ΔH_3, (the average value is −33 ± 6 kJ·mol^{-1})[11,13] is independent of the nature of the upper axial group (X), despite the variation in K_3. Thus, all the variation in K_3 and $pK_{base\text{-}off}$ must be due to variation in the entropy change, ΔS_3, upon coordination of the axial nucleotide; ΔS_3 varies from −100 ± 12 (X = Et) to −20 ± 5 (X = CF_3) and −21 ± 5 J K^{-1} mol^{-1} (X = CN). This suggests that for the compounds with the strongest electron-donating group (X = Et and Pr) and the most negative ΔS_3 values, the entropy loss associated with the restriction of the pendant axial nucleotide during formation of the base-on species is largely uncompensated by any gain in entropy due to loss of an axial water ligand. This in turn suggests that the base-off species of these complexes are largely pentacoordinated under these conditions. The equilibrium in Equation (1) is displaced towards the formation of the six-coordinate species by increasing electron-withdrawing X groups; thus, for X = CF_3 and CN, the loss of entropy associated with the axial DMBz coordination is compensated for by an increase in entropy due to axial water loss.[11] These results are in agreement with our findings for the equilibrium between five- and six-coordinate species obtained from the UV/Vis spectra recorded under pressure.

We conclude from the above discussion, and based on the trends observed in Table 1, that the base-off forms of some XCbl's such as AdoCbl and ethylcobalamin are mainly five-coordinate. However, in the case of CF_3Cbl, CNCbl and H_2OCbl, the percentage of the base-off forms is very small and they mainly exist as six-coordinate species. The structure of the base-off forms of the other cobalamins (X = Me, CH_2Br, CH_2CF_3, vinyl, etc.) are intermediate and exist as an equilibrium mixture of the five- and six-coordinate species. A decrease in the labilisation effect of X on going from adenosyl to CH_2CF_3 and CF_3 causes a drastic decrease in the fraction of the base-off species and also in the fraction of the five-coordinate species. These effects can play a significant role in the ligand substitution behaviour of the investigated complexes.

Our systematic study of the acid dependence of the base-on/base-off reactions has revealed rate constants for the individual reaction steps that present a consistent picture for the overall mechanism and are in agreement with the earlier reported overall equilibrium data for this process. In addition, the reported kinetic data reveal evidence for an acid-catalysed pathway for the dechelation of DMBz.

Experimental Section

Materials: All the chemicals used were p.A. grade and used as received without further purification. $HClO_4$ and $NaClO_4$ were purchased from Merck. Ultrapure water was used in the kinetic and thermodynamic measurements. The preparations and measurements were carried out in diffuse light since all the alkylcobalamins are known to be very light-sensitive.[18,40] Cyanocobalamin and Ad-

oCbl were supplied by Sigma and H_2Ocbl acetate by Roussel. The other alkylCbl's were prepared as described in the literature[20,41] by treating Co^{II} cobalamin with suitable alkylating agents. In a typical reductive alkylation, H_2OCbl (10 mg, ca. 0.01 mmol) in 5.0 mL of 10% acetic acid or 5% NH_4Cl was purged with argon for 1 h, zinc wool (0.01 mol), freshly activated with 1.0 M HCl, was added, and the reduction was allowed to proceed for 30 min. Alkyl halide (ca. 1 mmol; R = *n*Pr, CF_3CH_2, CF_3 and $NCCH_2$ for the preparation of *n*PrCbl, CF_3CH_2Cbl, CF_3Cbl and $NCCH_2$Cbl, respectively) was introduced, and the reaction was allowed to proceed for 30 min. Alkylcobinamides were prepared by treating (cobinamide)Co^{II}, generated by zinc reduction of Factor B[42,43] [a mixture of the two diastereomers of (aqua)(cyano)cobinamide], with the appropriate alkyl halides. The reaction mixtures were desalted by chromatography on Amberlite XAD-2[15] and the β-isomers were separated by HPLC.[20,44,45]

Instrumentation and Measurements: The pH of the solutions was measured using a Mettler Delta 350 pH meter with a combined glass electrode, calibrated with standard buffer solutions at pH = 4.0, 7.0 and 10.0. UV/Vis spectra were recorded with Shimadzu UV-2101 and Cary 1 spectrophotometers. UV/Vis spectra under high pressure were recorded with the Shimadzu spectrophotometer utilizing a home-made high-pressure unit.[46] Analytical HPLC was performed on a 4.6 × 250 mm Beckman C_8 ultrasphere column while semipreparative HPLC was performed on a 10 × 250 mm Beckman C_8 ultrasphere column, using 50 mM aqueous ammonium phosphate buffer (pH = 3.0) and acetonitrile as described previously.[20,44,45] Kinetic measurements were carried out with an Applied Photophysics SX 18MV stopped-flow instrument coupled to an online data acquisition system. At least eight kinetic runs were recorded under all conditions, and the reported rate constants represent the mean values. All kinetic measurements (pH jump experiments) were carried out under pseudo-first-order conditions, i.e. the acid concentration was in at least tenfold excess over the cobalamin concentration. The UV/Vis spectrophotometers and stopped-flow instruments were thermostatted to the desired temperature ±0.1 °C.

Facile Metal-Mediated Synthesis of Macrocyclic Diselenoethers

Jeremy S. L. Yeo,[a] Jagadese J. Vittal,[a] and T. S. Andy Hor*[a]

Keywords: Platinum / Selenium / Alkylation / Metallacycles / Synthesis design

Nucleophilic attack of $[Pt_2(\mu\text{-}Se)_2(PPh_3)_4]$ on dihaloalkanes gives stable diselenolato complexes, which release macrocyclic diselenoethers upon treatment with dihaloalkanes. The overhead-bridged diplatinum intermediates have been isolated and structurally characterized by single-crystal X-ray crystallography.
(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2003)

Introduction

Organoselenium compounds are particularly valuable in electronic,[1] magnetic,[2] catalytic[3] as well as numerous chemotherapeutic[4] and biomedical[5] applications. However, the synthesis of many of these reagents is often tedious and cumbersome.[6] For example, the multi-step preparation of 1,2-bis[(3-chloro-1-propyl)selenio]benzene requires purification by column chromatography and gives a low yield of 31%.[6a] We are therefore interested in the use of organometallic selenido complexes as a source of new organoselenium compounds or an alternative convenient means to prepare known substrates. The complex $[Pt_2(\mu\text{-}Se)_2(PPh_3)_4]$[7] (**1**) is particularly attractive because it can be prepared easily in good yields, is stable with a good shelf-life, and, most importantly, has two nucleophilic selenide centres where functionalization and transformation can take place. We hereby demonstrate a number of possibilities to activate selenide using common organic halides. In doing so, we prepared a range of new organoselenide ligands[8] that could have a significant bearing towards our ultimate goal in metal-assisted syntheses of new organoselenium materials.

Results and Discussion

Treatment of **1** in MeOH with an almost twofold excess of 1,4-dibromobutane at room temperature resulted in a solution which gave a yellow precipitate upon reaction with NH_4PF_6. Positive-mode ESMS analysis (CH_2Cl_2/MeOH) suggested alkylation at both selenide centres to give a dicationic selenolato complex $[Pt_2(\mu,\eta\text{-}Se_2C_4H_8)(PPh_3)_4]^{2+}$ (**2**; m/z = 825). A single-crystal X-ray structural determination of its acetone solvate revealed a hinged $\{Pt_2Se_2\}$ core [θ Pt(1)-Se(1)···Se(1A)−Pt(1A) 140.2°] with a C_4 overhead bridge across the two selenide atoms, thus giving a C_2 symmetry at the molecular centre (Figure 1). The inner C_2 moiety is disordered with an occupancy of 0.7 for C(2) and 0.3 for C(2A). Its ^{31}P NMR spectrum at room temp. suggests that all phosphanes are equivalent (δ = 19.1 ppm).

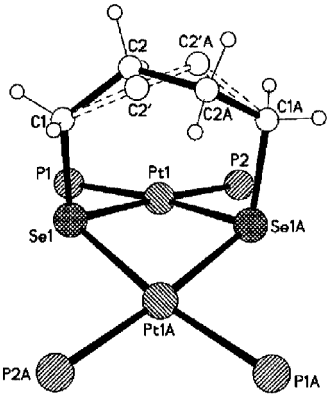

Figure 1. The cation of the molecular structure of $[Pt_2(\mu,\eta\text{-}Se_2C_4H_8)(PPh_3)_4][PF_6]_{1.5}[Cl]_{0.5}$ **2·2(CH$_3$)$_2$CO** with the phenyl rings omitted for clarity; selected bond lengths [A] and angles [°]: Pt(1)−P(1) 2.31(5), Pt(1)−P(2) 2.29(5), Pt(1)-Se(1) 2.48(2), Pt(1)−Se(1A) 2.46(2), Se(1)−C(1) 2.0(3), C(1)−C(2) 1.5(4), C(2)−C(2A) 1.540(19), C(1A)−C(2A) 1.4(3), Pt(1)−Se(1)−Pt(1A) 93.8(7), Se(1)−Pt(1)−Se(1A) 81.8(8), P(1)−Pt(1)−P(2) 99(2), P(1)−Pt(1)−Se(1) 87.1(15), P(2)−Pt(1)−Se(1) 174.0(15), P(1)−Pt(1)−Se(1A) 168.8(15), C(2)−C(1)−Se(1) 116(10), C(1)−C(2)−C(2A) 116(10)

Repeating the preparation with a 100-fold excess of 1,4-dibromobutane (DBB) gave an orange oil which was characterized by ESMS to contain 1,6-diselenacyclodecane **P1** {[**P1** + MeCN + H]$^+$: m/z = 312; [**P1** + MeCN + Na]$^+$: m/z = 335} (Figure 2). Extraction with C_6H_6 followed by careful evaporation of the solvents in vacuo afforded pure **P1** as a white powder (71%); its composition was verified by ^1H and ^{13}C NMR spectroscopy.[9] Fujihara et al. reported the synthesis[9] of **P1** in low yields (3%) by the

[a] Department of Chemistry, National University of Singapore, 3 Science Drive 3, Singapore 117543, Singapore

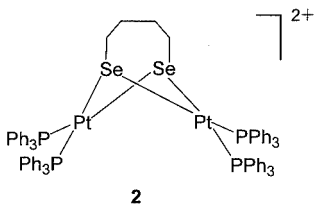
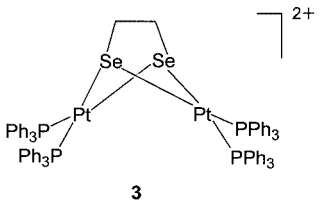
method given in Equation (1). **P1** can also be obtained by reacting **2** with a large excess of 1,4-dibromobutane.



2



3

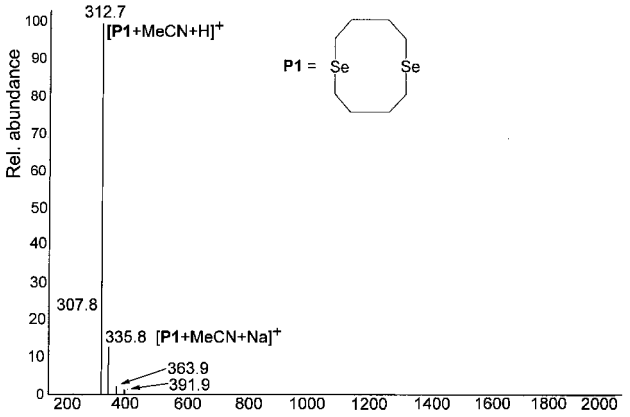


Figure 2. Positive-ion ESMS spectrum of 1,6-diselenacyclodecane (**P1**) in MeCN/H_2O (50:50) solution

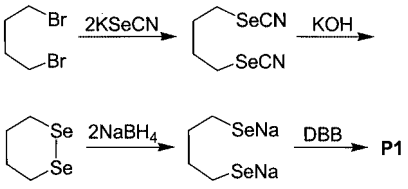

(1)

Reaction of **1** with 1,2-dichloroethane gave another stable selenolato-bridged compound $[Pt_2(\mu,\eta\text{-}Se_2C_2H_4)(PPh_3)_4]^{2+}$ (**3**; Figure 3). The shorter alkyl chain does not appear to affect the stability of the $\{Pt_2Se_2\}$ core or the bridging or chelating ability of the diselenolate ligand. We are currently studying the synthesis of other $[Pt_2(\mu,\eta\text{-}Se_2R)_2(PPh_3)_4]^{2+}$ (R = $CH_2C{=}CCH_2$ and $CH_2C_6H_4CH_2$) and their synthetic utility.

The formation and/or isolation of these organoselenium products illustrates the potential use of a selenide complex such as **1** as a stoichiometric reagent for the synthesis of selenium-containing macrocycles. A likely formation pathway is illustrated in Scheme 1.

A key to this function is the nucleophilic nature of the μ_2-selenide. The stability of similar chalcogenolato complexes has been reported elsewhere.[10] The second alkylation would considerably weaken the metal-ligand bonds which facilitate the liberation of the organoselenium moiety. Re-entry of the chloride to the coordination sphere regenerates $[PtCl_2(PPh_3)_2]$, which is the precursor of **1**, and turns this from a stoichiometric to a potentially catalytic synthesis. The value of this cycle lies in its simplicity in terms of principle and experimental procedures, the use of simple reagents and ambient conditions, and the ease of isolation through extraction. The major advantages are the ability to choose a wide range of alkyl and aryl halides and the flexibility of the $\{Pt_2Se_2\}$ core in accommodating different organic residues as its overhead bridge. These collectively determine the molecular skeleton of the desirable products and make this a potentially powerful entry to selenium macrocycles.

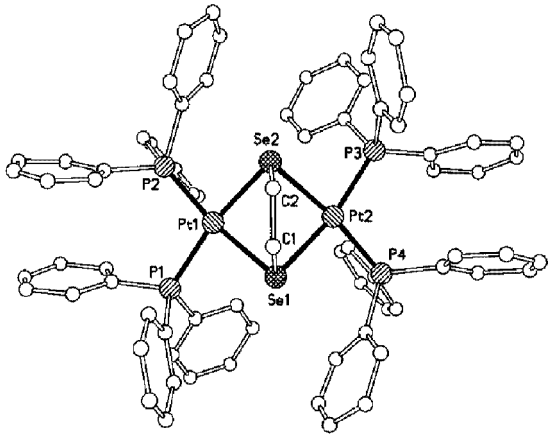

Figure 3. The cation of the molecular structure of $[Pt_2(\mu,\eta\text{-}Se_2C_2H_4)(PPh_3)_4][PF_6]_2$, **3·0.33$CH_2Cl_2$·0.17MeCN·2.83$H_2O$**; selected bond lengths [Å] and angles [°]: Pt(1)−P(1) 2.300(15), Pt(1)−P(2) 2.293(14), Pt(1)−Se(1) 2.478(6), Pt(1)−Se(2) 2.476(6), Se(1)−C(1) 2.00(6), Se(2)−C(2) 1.98(5), C(1)−C(2) 1.50(7), Pt(1)−Se(1)−Pt(2) 86.34(18), Se(1)−Pt(1)−Se(2) 77.78(19), P(1)−Pt(1)−P(2) 97.6(5), P(2)−Pt(1)−Se(1) 172.2(4), P(1)−Pt(1)−Se(2) 167.4(4), C(1)−C(2)−Se(2) 112(4)

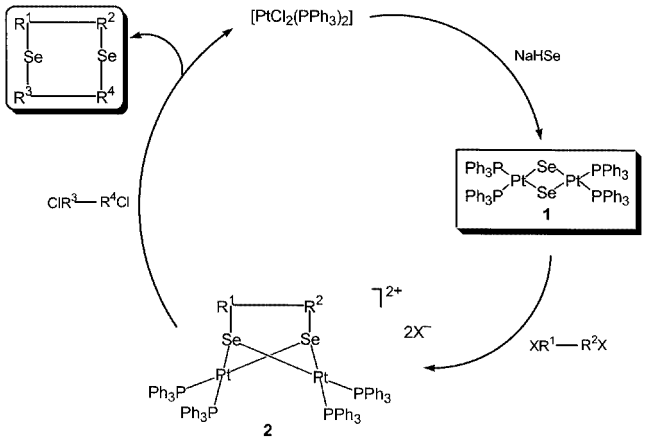

Scheme 1. A stoichiometric pathway with a catalytic-like cycle showing the roles played by **1** and a general representation of **2** and **3** in the preparation of organoselenium compounds

Conclusion

The high nucleophilicity of bridging selenide towards various organic halides makes **1** a potentially rich source of organoselenium substrates. This could lead to many new materials since **1** is reactive to many forms of organic halides. The question is the delicate control of the disintegration of the dinuclear core, stabilization of the mononuclear complex, and its subsequent breakdown to liberate the organoselenium residue. Our next target is to understand the subtle balance of these sequential, yet competing, processes. Such understanding is a prerequisite for us to harness a complex disintegration process whereby we can develop synthetically viable methods for laboratory-scale preparation of materials that are otherwise difficult to obtain.

Experimental Section

General Procedures and Chemicals: All substrates used for analysis were commercially available from Aldrich. We followed a modified preparation of $[Pt_2(\mu\text{-}Se)_2(PPh_3)_4]$ (**1**).[11] All reactions were performed under a positive pressure of purified Ar unless otherwise stated. Solvents were distilled and degassed before use.

Instrumental: Samples for ESMS analysis were prepared in 1 mL MeCN solutions of the analytes. Electrospray mass spectra were obtained with a Finnigan/MAT TSQ 7000 mass spectrometer with the MeCN/H_2O (50:50) mobile phase driven at 0.03 mL min^{-1} using a Thermo Separation products SpectraSystem TSP4000 LC pump. Samples were injected through a Rheodyne valve fitted with a 5 μL sample loop. The source temperature was 200 °C. The capillary potential tip was 4500 V, with nitrogen used both as a drying and a nebulizing gas. Peaks were assigned from the *m*/*z* values and from the isotope distribution patterns that were simulated using the ISOTOPE program.[12] The *m*/*z* values given are for the most intense peak in the envelope in each case. ^1H NMR and ^{13}C NMR spectra were recorded at 25 °C on a Bruker ACF 300 spectrometer (at, 300 and 75.47 MHz respectively) with Me_4Si as internal standard. The ^{31}P NMR spectra were recorded at 121.39 MHz with 85% H_3PO_4 as external reference. Elemental analyses were performed by the microanalytical laboratory of the Department of Chemistry at the National University of Singapore.

$[Pt_2(\mu\text{-}Se_2C_4H_8)(PPh_3)_4][PF_6]_{1.5}[Cl]_{0.5}$ (2): Excess 1,4-dibromobutane (11.1 mg, 20.0 μL, 0.0512 mmol) was added to a brown suspension of **1** (44.1 mg, 0.0276 mmol) in methanol (20 mL). The resultant yellow solution was stirred for 3 h, after which excess NH_4PF_6 (10.0 mg, 0.0614 mol) was added to give a yellow suspension. After stirring for 1 h, deionized water (50 mL) was added to induce precipitation. The suspension was filtered, the solid washed successively with 100 mL portions of deionized water and diethyl ether, and dried under vacuum yielding a yellow powder of **2**. The solid was dissolved in dichloromethane/acetone and this solution layered with hexane. Pale yellow crystals suitable for X-ray analysis were obtained. Yield: 24.2 mg (46%). $C_{76}H_{68}Cl_{0.5}F_9P_{5.5}Pt_2Se_2$ (1888.6): calcd. C 48.3, H 3.6, P 9.0; found C 47.6, H 3.6, P 8.2. ^1H NMR ($CDCl_3$): δ = 1.18−1.26 (m, 8 H, $4CH_2$), 6.92−7.74 (m, 60 H, 12 C_6H_5) ppm. $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 19.1 (t, $^1J_{P,Pt}$ = 2964 Hz) ppm.

$[Pt_2(\mu\text{-}SeC_2H_4)_2(PPh_3)_4][PF_6]_2$ (3): By using a similar procedure as for **2**, excess 1,2-dichloroethane (8.1 mg, 10.2 μL, 0.0821 mmol) and **1** (50.7 mg, 0.0317 mmol) gave an orange powder of **3**. The solid was dissolved in dichloromethane/acetonitrile and this solution layered with hexane. Orange crystals suitable for X-ray analysis were obtained. Yield: 26.4 mg (43%). $C_{74}H_{64}F_{12}P_6Pt_2Se_2$ (1915.3): calcd. C 46.4, H 3.4, P 9.7; found C 46.0, H 3.3, P 9.0. ^1H NMR ($CDCl_3$): δ = 1.18 (s, 4 H, $2CH_2$), 6.98−7.77 (m, 60 H, 12 C_6H_5) ppm. $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 12.9 (t, $^1J_{P,Pt}$ = 3117 Hz) ppm.

X-ray Crystal Structure Determinations

$2\cdot 2(CH_3)_2CO$: $C_{82}H_{80}Cl_{0.5}F_9O_2P_{5.5}Pt_2Se_2$: M = 2004.62, crystal dimensions: 0.32 × 0.30 × 0.08 mm^3. Monoclinic, space group *I*2/*m*, a = 17.6277(16), b = 24.464(2), c = 20.905(3) Å, β = 91.887(2)°, V = 9010.2(18) $Å^3$, Z = 4, $d_{calcd.}$ = 1.478 $g\cdot cm^{-3}$, μ(Mo-K_α) = 4.081 mm^{-1}. 25888 Reflections measured, 8126 unique (R_{int} = 0.0812), final $R1$ and $wR2$ values 0.0639 and 0.1775 for 4807 independent reflections [$I \geq 2\sigma(I)$] and 424 parameters.

$3\cdot 0.33CH_2Cl_2\cdot 0.17MeCN\cdot 2.83H_2O$:
$C_{74.67}H_{70.83}Cl_{0.67}F_{12}N_{0.17}O_{2.83}P_6Pt_2Se_2$: M = 2001.37, crystal dimensions: 0.20 × 0.10 × 0.08 mm^3. Monoclinic, space group $P2_1/c$, a = 32.6363(19), b = 18.0886(10), c = 43.093(3) Å, β = 100.262(2)°, V = 25033(3) $Å^3$, Z = 12, $d_{calcd.}$ = 1.593 $g\cdot cm^{-3}$, μ(Mo-K_α) = 4.427 mm^{-1}. 145023 Reflections measured, 44105 unique (R_{int} = 0.1330), final $R1$ and $wR2$ values 0.0678 and 0.1710 for 16422 independent reflections [$I \geq 2\sigma(I)$] and 942 parameters.

The data collection was performed on a Bruker AXS APEX diffractometer, equipped with a CCD area-detector using Mo-K_α radiation (λ = 0.71073 Å) at −50 °C. The SMART[13] software package was used for collecting frames of data, indexing reflections, and the determination of lattice parameters, SAINT[13] for integration of intensity of reflections and scaling, SADABS[14] for empirical absorption correction, and SHELXTL[15] for space group and structure determination, refinements, graphics, and structure reporting. Hydrogen atoms were not located. The structures were refined by full-matrix least-squares on F^2 with anisotropic thermal parameters for non-hydrogen atoms, unless otherwise indicated [$R_1 = \Sigma||F_0| - |F_c||/\Sigma|F_0|$, and $wR_2 = \{\Sigma[w(F_0^2 - F_c^2)^2]/\Sigma[w(F_0^2)^2]\}^{1/2}$ (where $w^{-1} = \sigma^2(F_0^2) + (aP)^2 + (bP)$].

For **$2\cdot 2(CH_3)_2CO$**, the original cell data in *C*2/*m* were transformed to the equivalent nonstandard space group *I*2/*m*. The cation has a crystallographic twofold symmetry and the C(2) carbon was found to be disordered. Two positions for this methylene carbon atom were resolved with occupancies of 0.7 and 0.3. Only isotropic thermal parameters were refined for these carbon atoms. The carbon atoms C(1F) to C(6F) of a phenyl ring were treated as a regular hexagon and only isotropic thermal parameters were refined. During the metathesis reaction with NH_4PF_6 half a molecule of chloride ions were retained in the compound which was found to be severely disordered. They were found in seven places in the asymmetric unit and each chloride was found on the mirror plane. In total two acetone molecules were disordered over three locations on the twofold crystallographic axis. All the hydrogen atoms were added in the calculated positions for the purpose of structure factor calculations only. In the final least-squares refinement based on F^2, the model converged at $R1$ = 0.0639 and $wR2$ = 0.1775 for 4807 reflections with $I \geq 2\sigma(I)$ and 424 variables. Despite the disorder of the methylene group and the chloride anions, the structural connectivity is proved beyond any doubt in the cation. We were unable to solve the structure in *C*2. In any case, between centrosymmetric and noncentrosymmetric space groups, the centrosymmetric description is recommended by Marsh.[16]

For **3·0.33CH_2Cl_2·0.17MeCN·2.83H_2O** all the carbon atoms of the phenyl rings were treated as regular hexagons and only isotropic thermal parameters were refined. Common isotropic thermal parameters were refined for the F atoms of each PF_6^- anion and soft constraints were imposed to maintain the octahedral geometry around the phosphorus atom. All the hydrogen atoms were added in their calculated positions for the purpose of structure factor calculations only. From the Fourier-difference routines a molecule of CH_2Cl_2 and half a molecule of MeCN were located. Hard geometrical constraints were imposed for these molecules in the least-squares refinement. Of the twelve sites of the asymmetric unit containing 8.5 H_2O molecules, seven were assigned to disordered O atoms with occupancies of 0.5. In the final least-squares refinement based on F^2, the model converged at $R1 = 0.0678$ and $wR2 = 0.1710$ for 16422 reflections with $I \geq 2\sigma(I)$ and 942 variables. Despite the weak data, the structural connectivity is proved beyond any doubt in the cation.

CCDC-175722 and CCDC-175723 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Halogen Atoms as Reactive Centers for the Introduction of Functional Side Chains into (Arene)ruthenium(0) Complexes[‡]

Gregor Bodes,[a] Frank W. Heinemann,[a] Günter Jobi,[a] Jens Klodwig,[a] Stefan Neumann,[a] and Ulrich Zenneck*[a]

Dedicated to Professor Horst Kisch on the occasion of his 60th birthday

Keywords: Arene complexes / Electrophilic substitution / Lithiation / Ruthenium

Substitution of the naphthalene ligand of [(COD)(η⁶-naphthalene)Ru] (**2**) (COD = 1,5-cyclooctadiene) by suitable haloarenes (halogen = F, Cl, Br, I) affords several new mono- and dihaloarene(cyclooctadiene)ruthenium complexes. Depending on the number and position of the halogen and organyl substituents, the haloarenes form achiral or planar-chiral π-ligands; [(η⁶-bromoarene)(COD)Ru] complexes are prone to rapid bromine/lithium exchange with *n*BuLi at low temperatures, while the chloro and fluoro derivatives undergo *ortho*-metalation under the same conditions. The lithiated species react readily with chiral or achiral electrophiles such as chlorodiorganophosphanes, carbonyl chlorides, aldehydes, lactones, ketones, and epoxides to yield substituted [(η⁶-arene)(COD)Ru] complexes with donor functions in their side chains, inaccessible by other routes. Enantiopure complexes are obtained when achiral lithioarene complexes are combined with chiral electrophiles, but pairs of diastereomers are formed if the lithioarene ligand is a planar-chiral species. Dinuclear ruthenium complexes [1,1-bis{(COD)(η⁶-phenyl)Ru}-1,4-butanediol] (**28**) and [1,1-bis{(COD)(η⁶-4-fluorophenyl)Ru}-1,4-butanediol] (**30**) with two (η⁶-aryl)-(COD)Ru units linked by a common 1,4-butanediol side chain are formed through the reactions between the appropriate lithioarene complexes and γ-butyrolactone.

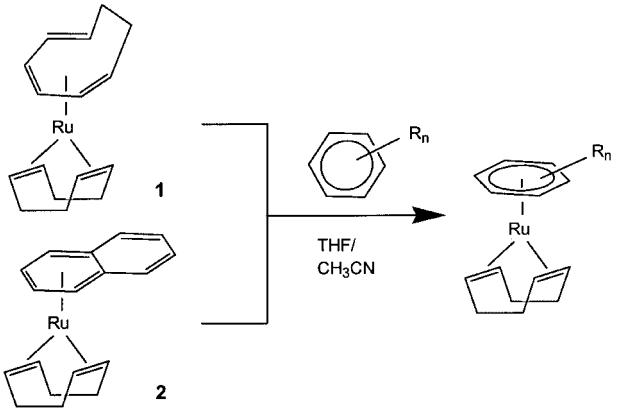
Introduction

(Arene)ruthenium(0) complexes are useful catalysts for hydrogenation,[2,3] isomerization,[4] and dimerization[5,6] reactions of alkenes. Their (arene)ruthenium(II) counterparts catalyze enantioselective hydrogen transfer to ketones[7,8] and imines[9] in the presence of enantiomerically pure chiral β-amino alcohols[7] or 1,2-diamines,[8,9] affording high yields and high *ee*s at the same time. Thanks to the particular stability of the arene−metal bond,[10] (arene)ruthenium complexes may be converted from Ru^0 into Ru^{II} without the loss of the arene ligand, simply by addition of hydrochloric acid.[2] Only the co-ligands that complete the coordination sphere are exchanged in parallel with the redox process. Of course, it would be very promising to perform the catalytic reactions of (arene)ruthenium complexes in both redox states with enantiopure species whose chirality was connected with the arene ligand. The preparation of [(η⁶-arene)-(COD)Ru] complexes is well known since the work of Bennett, Vitulli, and Pertici,[3,11,12] who introduced [(COD)(η⁶-1,3,5-cyclooctatriene)Ru] (**1**) and [(COD)(η⁶-naphthalene)Ru] (**2**) as suitable starting materials (Scheme 1).



Scheme 1. Synthesis of [(η⁶-arene)(COD)Ru] complexes by ligand exchange

However, bulky, polar, or highly substituted arenes cannot be introduced in this way. An alternative route to such complexes utilizes bromine/lithium exchange between [(η⁶-bromoarene)(COD)Ru] complexes and *n*-butyllithium at

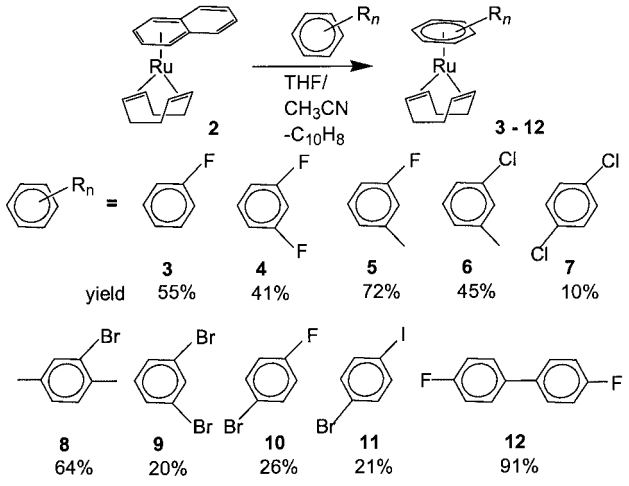
low temperatures.[13] The lithiated species can be treated with alkyl chloroformates to form ester-substituted [(η^6-arene)(COD)Ru] compounds. Through the introduction of chiral alkyl chloroformates [alkyl = (−)-menthyl], this directly affords enantiopure asymmetric complexes. To develop the high potential of this approach, we investigated the preparation and reactivity of (mono- and dihaloarene)ruthenium(0) complexes systematically. These allow the introduction of many electrophiles of choice. Examples are provided for chlorodiorganophosphanes, carbonyl chlorides, aldehydes, lactones, ketones, and epoxides. Novel (arene)ruthenium(0) complexes with donor functions such as PR_2 and OH in the side chain are of interest, as these functions should offer the potential to control the reactivity of the different types of (arene)ruthenium catalysts.



Scheme 2. Preparation of [(COD)(η^6-haloarene)Ru] complexes

Results and Discussion

Preparation of [(COD)(η^6-haloarene)Ru] Complexes

Mono- or dihaloarenes (fluorobenzene, 1,3-difluorobenzene, 3-fluorotoluene, 3-chlorotoluene, 1,4-dichlorobenzene, 2-bromo-1,4-xylene, 1,3-dibromobenzene, 1-bromo-4-fluorobenzene, 1-bromo-4-iodobenzene, and 4,4′-difluoro-1,1′-biphenyl) replace the naphthalene ligand of [(COD)(η^6-naphthalene)Ru] (**2**) in the presence of acetonitrile at room temperature in moderate to excellent yield (Scheme 2). The reaction fails with the triply substituted arenes 3,5-dibromotoluene, 1,2,3- and 1,3,5-tribromobenzene, and 1,2,3-trichlorobenzene.

Two different tendencies are exemplified by the experimental results. If one halogen atom of an incoming arene ligand is accompanied by one or two organyl substituents, the yield increases, but it is reduced with a second halogen atom. So far, no trihalobenzenes have been coordinated successfully. The only dihalobenzene that gives yields of more than 50% is 1,4-dibromobenzene;[13] in all other cases it is between 10 and 21%. As the minimum yield is obtained with 1,4-dichlorobenzene, there must be more than one reason for the diminishing effect, but electronegativity is most probably one of them. The electron-donating effects of the alkyl substituents favor π-complexation directly. As a consequence, even multiply alkyl-substituted arenes can be introduced. Not only 1,2,4-trimethylbenzene, but also 1,2,3,4-tetramethylbenzene, are prone to this type of reaction.[3] Two of the (dihalobenzene)ruthenium complexes have been characterized by X-ray diffraction: [(η^6-1-bromo-4-fluorobenzene)(COD)Ru] (**10**) and [(η^6-1-bromo-4-iodobenzene)(COD)Ru] (**11**) (Figure 1). Thanks to the pronounced chemical differences between their halogen atoms, **10** and **11** are both suitable for stepwise substitution reactions.

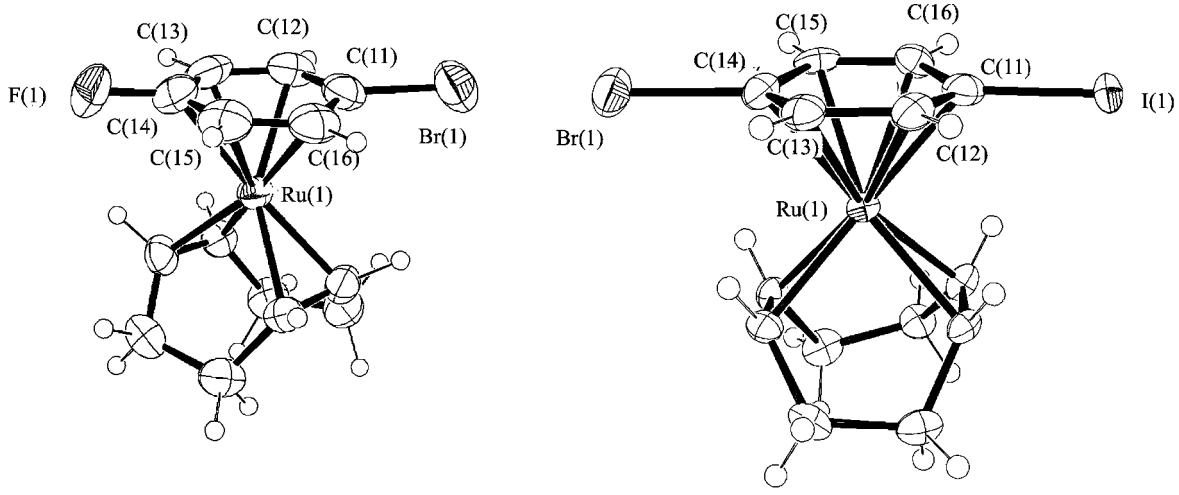


Figure 1. Molecular structures of **10** (left) and **11** (right) in the solid state; selected bond lengths [pm] for **10**: Ru(1)−C(11) 225.4(6), Ru(1)−C(12) 219.6(7), Ru(1)−C(13) 226.4(7), Ru(1)−C(14) 224.2(7), Ru(1)−C(15) 220.4(7), Ru(1)−C(16) 224.6(7); selected bond lengths [pm] for **11**: Ru(1)−C(11) 217.1(9), Ru(1)−C(12) 226.8(9), Ru(1)−C(13) 226.5(9), Ru(1)−C(14) 219.4(9), Ru(1)−C(15) 227.8(9), Ru(1)−C(16) 226.4(9)

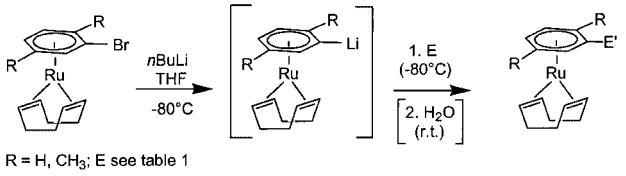
The coordinated arene ring is boat-like and distorted in both cases, as two *para*-positioned ring carbon atoms are situated significantly closer to the central metal atom than the other four. In the case of **10** the average value is 220 pm for Ru(1)−C(12) and Ru(1)−C(15), but 225 pm for the other Ru−C_{ring} distances. The corresponding values for **11** are 218 pm for Ru(1)−C(11)/(14) versus 226 pm. This deviation from planarity is a known effect in [(η⁶-arene)(COD)Ru] complexes.[13,14] Its observation, undisturbed in the case of [(COD)(η⁶-1,4-dihalobenzene)Ru] complexes, provides evidence for the interligand influence of COD and arene ligands even in the case of electronegative 1,4-disubstitution of the arene.

Electrophilic Substitution of [(η⁶-bromoarene)(COD)Ru] Complexes

Metalation and subsequent reactions of organometallic compounds are standard derivatization methods.[15] The electrophilic substitution of [(η⁶-bromoarene)(COD)Ru] complexes is initiated by a rapid bromine/lithium exchange at low temperatures. Examples are given for [(η⁶-2-bromo-1,4-xylene)(COD)Ru] (**8**), [(η⁶-1-bromo-4-fluorobenzene)(COD)Ru] (**10**), [(η⁶-bromobenzene)(COD)Ru] (**13**), [(η⁶-2-bromotoluene)(COD)Ru] (**14**),[13] and *n*-butyllithium as the metalation agent. In all cases, the bromine/lithium exchange is accomplished within a few minutes in THF as the solvent at −80 °C, and the electrophiles are added at the same temperature immediately after its completion. In the case of OH-group formation, the reaction sequence finishes with a hydrolysis. We tested this type of reaction with chlorodiorganophosphanes, carbonyl chlorides, ketones, epoxides, aldehydes, and lactones as electrophiles. (Scheme 3, Table 1)

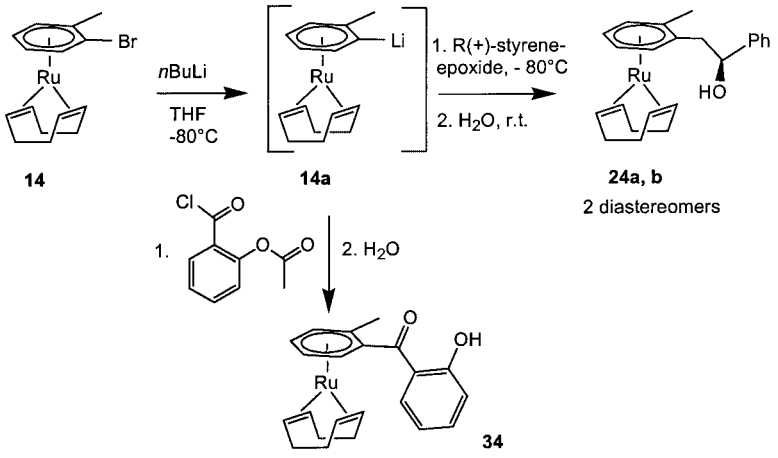


Scheme 3. Electrophilic substitution reaction of [(η⁶-bromoarene)(COD)Ru] complexes

The reaction sequence proceeds very well, and so the introduction of side chains with phosphanyl, ester, oxo, and hydroxy groups, including phenolic hydroxy functions, is a favorable preparative route. The mononuclear and dinuclear complexes **15**−**34** are accessible in this way. We had previously attempted the direct preparation of some related complexes by ligand exchange as an alternative and straightforward approach and had failed in several interesting cases. Acidic hydrogen atoms, phosphanyl groups, and bulky substituents on incoming arene ligands block the arene ligand exchange reaction of ruthenium(0).[1] Neither the NMR spectra, nor other experimental observations point to direct interactions between the donor centers of the side chains and the ruthenium atoms in **15**−**34**. As [(η⁶-arene)(COD)Ru] complexes are closed-shell 18-valence electron species, there is no driving force for such an effect. The potential interaction will come into play when an electron-deficient situation is created for the ruthenium atom by oxidation or COD ligand displacement, through a catalytic application of the complexes.[16]

Table 1. Products of electrophilic substitution of [(η⁶-bromoarene)(COD)Ru] complexes

Starting material	Electrophile E	Product	Yield (%)
13	$ClP(iPr)_2$	[(COD)(diisopropyl-η⁶-phenylphosphane)Ru] (**15**)	83
14	$ClP(iPr)_2$	[(COD)(diisopropyl-η⁶-2-tolylphosphane)Ru] (**16**)	86
13	$ClP(tBu)_2$	[(COD)(di-*tert*-butyl-η⁶-phenylphosphane)Ru] (**17**)	78
14	$ClPPh_2$	[(COD)(diphenyl-η⁶-2-tolylphosphane)Ru] (**18**)	73
14	acetyl chloride	[(COD)(η⁶-2-methylacetophenone)Ru] (**19**)	90
13	pivalyl chloride	[(COD)(*tert*-butyl η⁶-phenyl ketone)Ru] (**20**)	94
14	pivalyl chloride	[(COD)(*tert*-butyl η⁶-2-tolyl ketone)Ru] (**21**)	91
13	ClCOPh*t*Bu	[(COD)(4-*tert*-butylphenyl η⁶-phenyl ketone)Ru] (**22**)	67
13	(1*S*)-(−)-camphanic chloride	(−)-[(COD)(camphanoyl η⁶-phenyl ketone)Ru] (**23**)	43
14	(*R*)-(+)-styrene epoxide	[(COD){1-phenyl-2-(η⁶-2-tolyl)ethanol}Ru] (**24a**, **24b**)	31
13	acetone	[(COD){dimethyl(η⁶-phenyl)methanol}Ru] (**25**)	65
13	cyclohexanone	[(COD)(η⁶-phenylcyclohexanol)Ru] (**26**)	69
13	γ-butyrolactone	[(COD)(3-hydroxypropyl η⁶-phenyl ketone)Ru] (**27**) [1,1-bis-{(COD)(η⁶-phenyl)Ru}-1,4-butanediol] (**28**)	21 45
10	γ-butyrolactone	[(COD)(η⁶-4-fluorophenyl 3-hydroxypropyl ketone)Ru] (**29**) [1,1-bis-{(COD)(η⁶-4-fluorophenyl)Ru}-1,4-butanediol] (**30**)	40 16
14	γ-butyrolactone	[(COD)(3-hydroxypropyl η⁶-2-tolyl ketone)Ru] (**31**)	44
13	1,2-*O* isopropylidene-3-*O*-methyl-α-D-xylopento-dialdofuranose-(1,4)	[(COD){(6-methoxy-2,2-dimethyltetrahydrofuro[2,3-*d*]-[1,3]dioxol-5-yl)(η⁶-phenyl)methanol}Ru] (**32a**, **32b**)	48
8	(−)-menthyl chloroformate	[(COD)(menthyl η⁶-1,4-xylene-2-carboxylate)Ru] (**33a**, **33b**)	42
14	*o*-acetylsalicoyl chloride	[(COD)(*o*-hydroxyphenyl η⁶-2-tolyl ketone)Ru] (**34**)	60



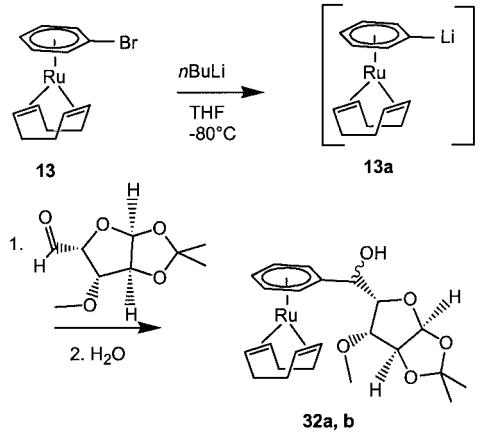
Scheme 4. Electrophilic substitution reactions of [(η^6-2-bromotoluene)(COD)Ru] (**14**)

[(η^6-bromobenzene)(COD)Ru] (**13**) is an achiral starting material and the same is true for its lithium exchange product [(η^6-lithiobenzene)(COD)Ru] (**13a**). Treatment with optically pure (1*S*)-(−)-camphanoyl chloride therefore directly affords enantiopure (−)-[(COD)(camphanoyl η^6-phenyl ketone)Ru] (**23**). The electrophilic substitution reaction does not affect the stereogenic centers of the incoming electrophile. Because of the planar chirality of their arene ligands, **8** and **14** consist of racemic mixtures of asymmetric compounds, and so a subsequent reaction with enantiopure electrophiles produces pairs of diastereomers. An example is the combination of **14** with (*R*)-(+)-styrene epoxide. The two C_1-symmetric diastereomers **24a** and **24b** are formed in this way (Scheme 4).

Diastereomers **32a** and **32b** are also obtained by treatment of achiral **13** with 2-*O* isopropylidene-3-*O*-methyl-α-D-xylopentodialdofuranose-(1,4), as the transformation of its aldehyde function into a secondary benzyl alcohol by addition to the (arene)ruthenium fragment is not diastereoselective (Scheme 5).

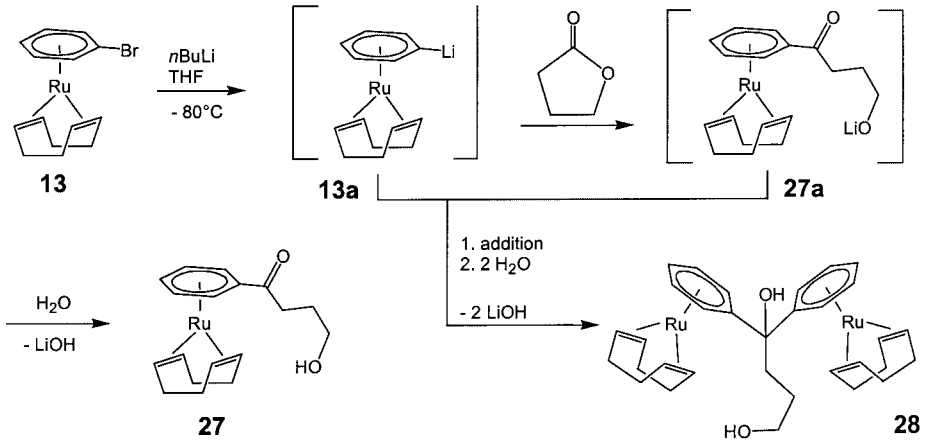
To our surprise, electrophilic substitution of **14** with *o*-acetylsalicoyl chloride causes a spontaneous cleavage of the ester group, which was replaced by a phenolic OH group in the end product. Lithiated **14a** thus yields [(3-hydroxyphenyl η^6-2-tolyl ketone)(COD)Ru] (**34**) as the only isolable product. (Scheme 4) Complex **34** was our target product from the beginning, as it contains an OH group at a suitable distance from the metal atom, but the experimental finding represents a nice shortcut in the right direction. As in the case of the (bromoarene)ruthenium complexes, the handling of the novel compounds **15** to **34** causes no problems. All are stable in the solid state, show no sign of hydrolysis, and are only slightly air-sensitive in solution.

Another surprising result occurred when the bromine/lithium exchange product **13a** of bromobenzene complex **13** was treated with γ-butyrolactone. Not only was the designed ring-opening/addition product [(COD)(3-hydroxypropyl η^6-phenyl ketone)Ru] (**27**) formed (in moderate yield), but dinuclear [1,1-bis{(COD)(η^6-phenyl)Ru}-1,4-butanediol] (**28**) was isolated as the main product. The results obtained from the combination of the 1-bromo-4-fluorobenzene complex **10** and γ-butyrolactone are very similar, except that the yield of mononuclear product [(COD)(η^6-4-fluorophenyl 3-hydroxypropyl ketone)Ru] (**29**) exceeds that of dinuclear [1,1-bis{(COD)(η^6-4-fluorophenyl)Ru}-1,4-butanediol] (**30**).



Scheme 5. Preparation of diastereomeric furanose-substituted complexes **32a** and **32b**

The first addition intermediate **27a**, most probably due to a high ketone reactivity,[1] couples with its lithiobenzene precursor complex **13a** to form a 1,4-butanediolate interme-



Scheme 6. Formation of dinuclear (arene)ruthenium complex **28**

diate. Both branches of the reaction sequence are terminated by hydrolysis, the lithium ions being replaced by hydrogen atoms. (Scheme 6)

This route represents a new and effective pathway to benzyl carbon atom linked (bisarene)diruthenium complexes. A special property is the bifunctionalization of the common 1,4-butanediol side chain. Both dinuclear complexes **28** and **30** have been characterized by X-ray diffraction: their molecular structures are depicted in Figure 2.

The X-ray results are in full accordance with the analytical and spectroscopic findings on the complexes, which confirm their dinuclear nature, the introduction of only one side chain per $\{(\eta^6\text{-aryl})(\text{COD})\text{Ru}\}_2$ unit, and the absence of ketone functions. The molecular structures of **28** and **30** in the solid state represent different rotamers. This applies to the relative orientation of the $(\eta^6\text{-aryl})(\text{COD})\text{Ru}$ complex units as well as for the 1,4-butanediol chains. In the case of **28** the two (COD)Ru fragments are located opposite to the C116−C117−C214 bond angle of the bridging benzyl carbon atom C117. Its reduction to 106.3° is a consequence of that arrangement. In contrast to that, the (COD)Ru(2) fragment of **30** interacts directly with the arene ligand of Ru(1) and the corresponding C116−C117−C216 benzyl carbon bond angle of **30** is increased significantly. The

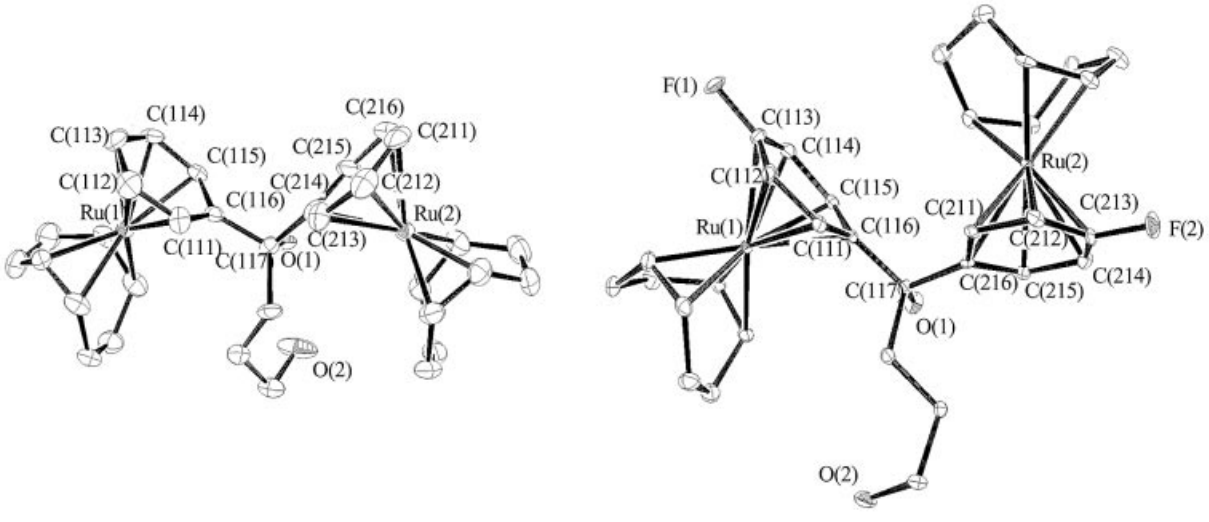


Figure 2. Molecular structures of [1,1-bis{(COD)(η^6-phenyl)Ru}-1,4-butanediol] (**28**, left) and [1,1-bis{(COD)(η^6-4-fluorophenyl)Ru}-1,4-butanediol] (**30**, right) in the solid state; hydrogen atoms have been omitted for clarity; selected bond lengths [ppm] of **28**: Ru(1)−C(111) 227.6(7), Ru(1)−C(112) 220.0(8), Ru(1)−C(113) 225.9(7), Ru(1)−C(114) 225.3(7), Ru(1)−C(115) 222.0(6), Ru(1)−C(116) 231.1(6); bond angle [°]: C(116)−C(117)−C(214) = 106.3(5); selected bond lengths [ppm] of **30**: Ru(1)−C(111) 223.7(3), Ru(1)−C(112) 219.3(3), Ru(1)−C(113) 225.9(2), Ru(1)−C(114) 228.0(3), Ru(1)−C(115) 220.7(3), Ru(1)−C(116) 229.4(2); bond angle [°]: C(116)−C(117)−C(216) = 112.19(19)

$Ru-C_{aryl}$ bond lengths of both species cover a range from 220 to 231 pm. As in the case of the dihaloarene complexes, the arene ligands are slightly boat-like distorted.

The molecular packing of the dinuclear complexes in the solid state is dominated by the formation of infinite zigzag chains of the 1,4-butanediol substituents by intermolecular O−H−O bridges. (Figure 3).

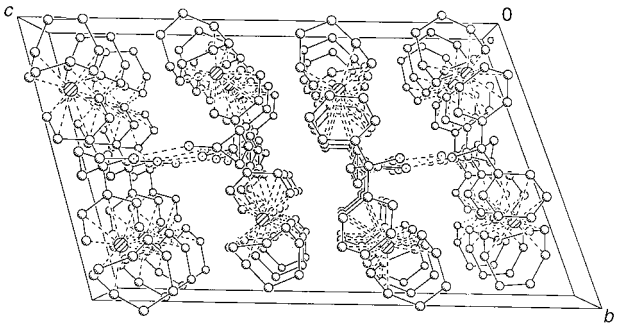

Figure 3. Molecular packing of **28** in the solid state; O−H−O bridges are indicated by the dotted lines between the stacks

Interestingly, a single *o*-methyl group is a steric protector sufficiently powerful to disfavor the formation of dinuclear 1,4-butanediol complexes in the γ-butyrolactone reactions almost completely. 2-Bromotoluene complex **14** therefore forms [(COD)(3-hydroxypropyl η^6-2-tolyl ketone)Ru] (**31**) as the isolable main product. A dinuclear analogue to **28** and **30** can only be detected by mass spectrometry, as a small side product.

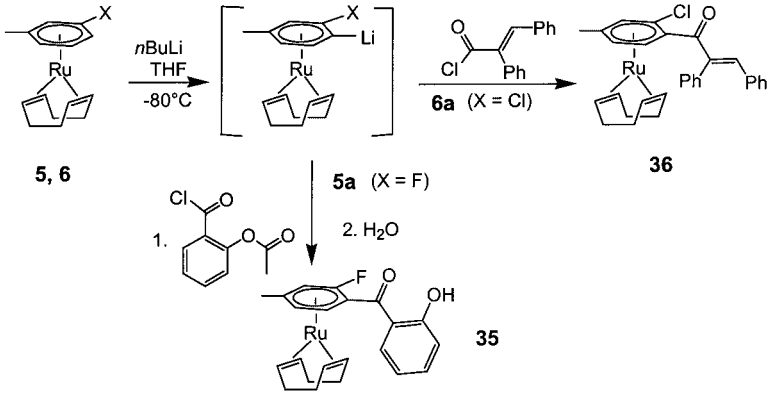
Electrophilic Substitution through *ortho*-Metalation of (Chloro- and fluoroarene)ruthenium Complexes

(Chloro- and fluoroarene)metal complexes follow a different reaction pathway when they are attacked by organolithium agents. The main route is no longer halogen/lithium exchange, but *ortho*-metalation is observed instead.[17] This type of reactivity was tested by treatment of *n*BuLi with [(COD)(η^6-3-fluorotoluene)Ru] (**5**) and [(η^6-3-chlorotoluene)(COD)Ru] (**6**). *o*-Acetylsalicoyl chloride was treated with metalated fluoro derivative **5a**, and α-phenylcinnamoyl chloride with the corresponding chloro complex **6a**. (Scheme 7)

As in the case of the bromine/lithium exchange products, the *ortho*-metalation intermediates **5a** and **6a** allow effective introduction of electrophiles. The metalation takes place selectively at the less sterically hindered *o*-position with respect to the halogen substituent. As the chlorine and fluorine atoms remain in the complexes they might be usable a second time for subsequent modification of complexes **35** and **36**. In analogy to phenol complex **34**, the ester function of *o*-acetylsalicoyl chloride is again split spontaneously in the reaction and the target phenolic side chain OH group is formed directly.

Conclusions

[(COD)(η^6-haloarene)Ru] complexes are easily accessible by arene ligand substitution of [(COD)(η^6-naphthalene)Ru] (**2**) by suitable mono- and dihaloarenes. The reaction works with F, Cl, Br, and I as arene ring substituents, and the incoming haloarene may have one or two halogen atoms and a maximum number of three substituents. Depending on the number and position of the halogen atom(s) and organyl substituent(s), the haloarenes form achiral or planar-chiral π-ligands. [(COD)(η^6-haloarene)Ru] complexes are valuable starting materials for the introduction of arene ligand side chains with functional groups that would otherwise block the π-complexation of arene ligands to Ru^0 or Ru^{II}. The bromine atom of [(η^6-bromoarene)(COD)Ru] complexes is rapidly exchanged for a lithium atom when they are treated with *n*BuLi at low temperatures, but the chloro and fluoro derivatives undergo *ortho*-metalation under the same conditions. The re-



Scheme 7. Electrophilic substitution reaction by *ortho*-metalation

sulting lithiobenzene species react effectively with a great variety of chiral or achiral electrophiles to yield substituted [(η^6-arene)(COD)Ru] complexes with donor functions such as OH or PR_2 groups in the side chains. Enantiopure complexes are obtained when achiral lithioarene complexes are combined with chiral electrophiles, but pairs of diastereomers are formed if the lithioarene ligand is a planar chiral species. Because of the high reactivity of the primary products, the combination of sterically unhindered lithiobenzene complexes and γ-butyrolactone results in the formation of dinuclear [1,1-bis{(η^6-aryl)(COD)Ru}-1,4-butanediol] complexes, each with two [(η^6-aryl)(COD)Ru] units linked by a common 1,4-butanediol side chain.

The new reaction sequences allow a completely new means of ligand design for (arene)ruthenium catalysts of interest, the selectivity and reactivity of which may now be controlled by highly variable side chains with σ-ligand properties of choice. This point is currently under investigation. In a subsequent paper we will report on the oxidation of some of the (η^6-arene)Ru^0 complexes with the donor side chains reported here to form corresponding (η^6-arene)Ru^{II} species, the tethering of the donor function to the metal atom, and first insights into their potential as hydrogen-transfer catalysts.[16]

Experimental Section

General: All reactions were carried out under dry, oxygen-free nitrogen. Solvents were purified by conventional methods, distilled, and stored under nitrogen. NMR spectra were recorded at close to room temperature with Jeol JNM-PMX 60, FT-JNM-EX 270, and FT-JNM-GX 270 spectrometers, with dimethylpolysiloxane and the solvent signals as internal standards. Mass spectra were recorded with a Varian MAT 212 spectrometer. Microanalyses were performed at the analytical department of the institute, on Carlo Erba Elemental Analyzers Mod. 1106 and Mod. 1108, for crystalline products only. Column chromatography (15 × 1 cm) was accomplished on neutral degassed alumina (Merck), deactivated with 5% degassed water. The starting materials [(COD)(η^6-naphthalene)Ru] (**2**),[12] [(η^6-bromobenzene)(COD)Ru] (**13**),[13] and [(η^6-2-bromotoluene)(COD)Ru] (**14**)[13] were prepared as reported in the literature.

Preparation of [(COD)(η^6-haloarene)Ru] Complexes (General Procedure): [(COD)(η^6-naphthalene)Ru] (**2**) and an excess of the haloarene were dissolved in THF and acetonitrile. After the mixture had been stirred at room temperature (room temp.) for 3 d, all volatile components were removed in vacuo at 45 °C. Filtering of the obtained oils through alumina/5%H_2O and recrystallization (if possible) yielded the products.

Bromine/Lithium Exchange and Electrophilic Substitution Reactions of [(η^6-Bromoarene) (COD)Ru] Complexes (General Procedure): The bromoarene complex was dissolved in THF and cooled to −80 °C, and a solution of *n*-butyllithium in hexane was added by syringe. The reaction mixture was stirred for 10 min and a solution of the electrophile in THF was added at the same temperature. The mixture was then allowed to warm slowly to room temp. over 2 h. In the case of Li alkoxide intermediates, a small portion of degassed water was added by syringe to produce the OH groups. The mixture was stirred for a few minutes and the solvents were removed in vacuo. The residue was extracted with *n*-hexane and toluene and the combined liquids were filtered through Al_2O_3/5%H_2O. If necessary, the product was purified by column chromatography on Al_2O_3/5%H_2O with *n*-hexane as the mobile phase.

***o*-Lithiation and Electrophilic Substitution Reactions of (η^6-Chloro- and η^6-fluoroarene)ruthenium Complexes (General Procedure):** The chloro- or fluoroarene complex was dissolved in THF and cooled to −80 °C, and a solution of *n*-butyllithium in hexane was added by syringe. After 5 min, a solution of the electrophile in THF was added at the same temperature, and the mixture was allowed to come to room temp. over 2 h. All volatile components were removed in vacuo. The residue was extracted with *n*-hexane and toluene and the product was purified by column chromatography on Al_2O_3/5%H_2O with *n*-hexane as the mobile phase.

[(COD)(η^6-fluorobenzene)Ru] (3): Reaction mixture: [(COD)(η^6-naphthalene)Ru] (**2**) (1300 mg, 3.84 mmol), fluorobenzene (10 mL, 106.6 mmol) in 20 mL of THF and 1 mL of acetonitrile. Yield 650 mg (2.12 mmol, 55%) of **3**. MS (FD+): *m*/*z* = 306 [M^+]. ^{1}H NMR (269.7 MHz, C_6D_6): δ = 5.14 (dd,$^3J\{H_oH_m\}$ = 5.5, $^3J\{H_oF\}$ = 2.7 Hz, 2 H, H_o); 4.74 (td, $^3J\{HH\}$ = 5, $^4J\{H_mF\}$ = 2.7 Hz, 2 H, H_m); 4.20 (td, $^3J\{H_pH_m\}$ = 5, $^3J\{H_pF\}$ = 3.8 Hz, 1 H, H_p); 3.60 (m, 4 H, olefin. COD); 2.39 (m, 8 H, aliphat. COD) ppm. $^{13}C\{^1H\}$ NMR (100.4 MHz, C_6D_6): δ = 138.0 (d, $^1J\{CF\}$ = −271 Hz, *ipso*-C); 86.1 (s, C_p); 81.1 (d, $^4J\{CF\}$ = 6 Hz, C_m); 80.6 (d, $^3J\{CF\}$ = 22.4 Hz, C_o); 61.6 (C olefin. COD); 33.0 (C aliphat. COD) ppm. $C_{14}H_{17}FRu$ (305.2): calcd. C 55.1, H 5.6; found C 54.6, H 6.3.

[(COD)(η^6-1,3-difluorobenzene)Ru] (4): Reaction mixture: **2** (1300 mg, 3.84 mmol), 1,3-difluorobenzene (10 mL, 101.4 mmol) in 20 mL of THF and 1 mL of acetonitrile. Yield 510 mg (1.57 mmol, 41%) of **4**. ^{1}H NMR (399.65 MHz, C_6D_6): δ = 5.61 (s, 1 H, aromat. H); 4.76 (m, 1 H, aromat. H); 4.48 (m, 2 H, aromat. H); 3.57 (m, 4 H, olefin. COD); 2.24 (m, 8 H, aliphat. COD) ppm. $C_{14}H_{16}F_2Ru$ (233.2): calcd. C 52.01, H 4.99; found C 52.19, H 5.35.

[(COD (η^6-3-fluorotoluene))Ru] (5): Reaction mixture: **2** (1300 mg, 3.84 mmol), 3-fluorotoluene (10 mL, 90.5 mmol) in 30 mL of THF and 1 mL of acetonitrile. Yield 930 mg (2.76 mmol, 72%) of **5**. MS (FD+): *m*/*z* = 320 [M^+]. ^{1}H NMR (399.65 MHz, C_6D_6): δ = 5.12 (s, 1 H, H^1); 5.00 (d, $^3J\{H^2H^3\}$ = 5 Hz, 1 H, H^2); 4.96 (td, $^3J\{H^{2/4}H^3\}$ = 5, $^4J\{H^3F\}$ = 3 Hz, 1 H, H^3); 4.00 (dd, $^3J\{H^4H^3\}$ = 5, $^3J\{H^4F\}$ = 4.5 Hz, 1 H, H^4); 3.38 (m, 4 H, olefin. COD); 2.28 (m, 8 H, aliphat. Crystal Structure Determinations: Suitable crystals of **10**, **11**, **28**, and **30** were taken directly from the mother liquor. Data were collected with a Siemens P4 diffractometer for **10**, **11**, and **28** and with a Nonius KappaCCD for **30**, with use of Mo-K_α radiation (λ = 0.71073 Å) and a graphite monochromator. The crystal structures were solved by direct methods and refined by use of the SHELXTL 5.03[18] programs for **10** and **28**, and SHELXTL NT 5.10[19] for **11** and **30**. Non-hydrogen atoms were refined anisotropically. Hydrogen atoms are either geometrically positioned (**10** and **28**) or their positions were derived from a difference Fourier map and refined with a fixed common isotropic displacement parameter (**11** and **30**). Other experimental details are given in Tables 2 and 3. Crystallographic data for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Center as supplementary publication nos. CCDC-186921 (**10**), -186922 (**11**), -186923 (**28**), and -186924 (**30**). Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB21EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.ca.ac.uk].

Synthesis, Structure and Reactivity of Ruthenium(II) Carbonyl Complexes Containing Bis(pyrazol-1-yl)methane and Bis(*N*-methylimidazol-2-yl)methane

Barbara A. Messerle,*[a] Vicki-Anne Tolhurst,[a] and Peter Turner[b]

Keywords: N ligands / Ruthenium / Structure elucidation / Reactivity

A series of ruthenium(II) complexes with the pyrazolylalkane ligands bis(pyrazol-1-yl)methane (BPM) (**I**) and bis(3,5-dimethylpyrazol-1-yl)methane (dmBPM) (**II**), and the imidazolylalkane ligand bis(*N*-methylimidazol-2-yl)methane (BIM) (**III**) have been synthesised and characterised. The complexes $[Ru(N\text{-}N)(CO)_2X_2]$ [N-N = BPM, X = Cl (**1a**), Br (**1b**); N-N = dmBPM, X = Cl (**2**); N-N = BIM, X = Cl (**3**)] were prepared from the stoichiometric reaction of $[Ru(CO)_2X_2]_n$ and the bidentate N-donor ligand in refluxing methanol. The crystal structure of **2** showed the complex to have octahedral geometry about the ruthenium centre, with the carbonyl and chloride ligands being coordinated *cis* and *trans*, respectively. The complex $[Ru(BPM)_2(CO)(Cl)][BPh_4]$ (**4**) was prepared from the reaction of $RuCl_3$ and BPM in refluxing DMF, or from the decarbonylation of $[Ru(BPM)(CO)_2Cl_2]$ (**1a**) in the presence of BPM and $NaBPh_4$. The NMR spectra of **4** were fully assigned from 2D NMR experiments. The NOESY showed a *cis* coordination of the chloride and carbonyl ligands, and this was confirmed by single crystal X-ray diffraction studies.

Introduction

Organometallic ruthenium complexes are efficient catalysts for a variety of processes,[1] such as the coupling of pyridine, carbon monoxide and hexenes,[2] the coupling of aromatic carbon-hydrogen bonds with olefins,[3] and the intramolecular cyclisation of hydroxyenynes to form furan derivatives.[4,5] Catalytically active ruthenium complexes containing N-donor ligands are becoming more significant, leading to the development of new ruthenium complexes with N-donor ligands and suitable co-ligands for optimum catalytic activity. The preparation of a number of ruthenium carbonyl systems containing 2,2′-dipyridyl and its derivatives has been reported,[6−8] and in some cases these complexes are efficient catalysts for processes such as the reduction[9] and hydrogenation[10] of CO_2 and, in particular, the water-gas shift reaction, in both homogeneous[11−14] and heterogeneous environments.[15−17]

The sp^2-N donor poly(pyrazol-1-yl)methane and poly(imidazol-2-yl)methane ligands, such as bis(pyrazol-1-yl)methane (**I**) (BPM),[18] bis(3,5-dimethylpyrazol-1-yl)methane (**II**),[18] tris(pyrazol-1-yl)methane (**III**) (TPM),[18] bis(*N*-methylimidazol-2-yl)methane (**IV**) (BIM),[19] and tris(*N*-methylimidazol-2-yl)methanol (**V**; TIM) are neutral ligands closely related to the poly(pyrazolyl)borate ligands.[20] The basicity of the sp^2-N donor atoms of the five-membered heterocycles of BPM and BIM are considerably different to that of N-atoms of other ligands containing heterocycles, such as 2,2′-bipyridyl (BIPY), which has a significant effect on the relative degree of electron donation to the metal by the ligand.[21] A number of complexes containing poly(pyrazol-1-yl)methane ligands have been synthesised for metals in groups 5, 6, 9 and 10.[22] Only a limited number of poly(pyrazol-1-yl)methane complexes of metals of group 8 have been reported;[23,24] these include $[Ru(TPM)(OH_2)_3](p\text{-}CH_3C_6H_4SO_3)_2\cdot 1.5H_2O$[25] and [Ru(TPM)(COD)Cl]Cl (COD = 1,5-cyclooctadiene).[26] Group 8 metal complexes containing poly(imidazol-2-yl)methane ligands have also been reported and include $[Ru(BIM)(CO)(PPh_3)H]Cl$,[27] $[M(TIM)(CO)(PPh_3)H]Cl$ (M = Ru, Os)[28] and $[Fe(TIM)_2][FeCl_4]$.[29] We have recently reported a series of ruthenium(II) complexes with the pyrazolylalkane ligands TPM and BPM, $[RuCl(PPh_3)_2(TPM)]X$ (X = Cl, BF_4), $[Ru(CO)H(PPh_3)(BPM)_2]Cl$ and $[Ru(PPh_3)(BPM)(\mu\text{-}Cl)_3Ru(PPh_3)(BPM)]Cl$.[30]

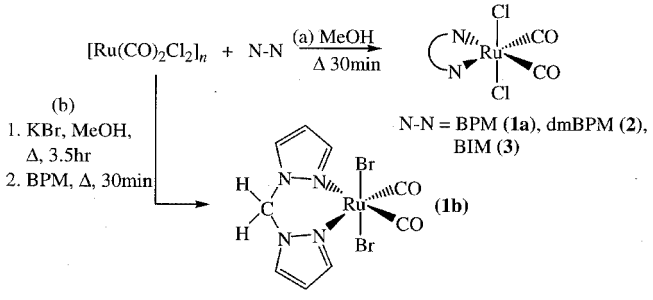
Herein we report the preparation of a series of neutral and charged ruthenium carbonyl complexes containing the N-donor ligands BPM, dmBPM, and BIM. These complexes are of interest for their possible application in hydrogenation catalysis. The complexes $[Ru(N\text{-}N)(CO)_2X_2]$ [N-N = BPM, X = Cl (**1a**), Br (**1b**); N-N = dmBPM, X = Cl (**2**); N-N = BIM, X = Cl (**3**)] were prepared from the stoichiometric reaction of $[Ru(CO)_2X_2]_n$ and the bidentate ligand in refluxing methanol. The ionic complex $[Ru(BPM)_2(CO)Cl][BPh_4]$ (**4**) was prepared from the reaction of $RuCl_3$ and BPM in refluxing DMF, and from the decarbonylation of $[Ru(BPM)(CO)_2Cl_2]$, followed by the addition of BPM and $NaBPh_4$.

Results And Discussion

Synthesis of $[Ru(N\text{-}N)(CO)_2X_2]$ Complexes

Preparations of the complexes $[Ru(N\text{-}N)(CO)_2X_2]$ are outlined in Scheme 1. Treatment of $[Ru(CO)_2Cl_2]_n$ with the bidentate nitrogen ligands in refluxing methanol results in the isolation of $[Ru(N\text{-}N)(CO)_2Cl_2]$ [N-N = bis(pyrazol-1-yl)methane (BPM) (**1a**), bis(3,5-dimethylpyrazol-1-yl)methane (dmBPM) (**2**), bis(N-methylimidazol-2-yl)methane



Scheme 1. Preparation of neutral organoruthenium complexes **1(a,b)**, **2** and **3**

(BIM) (**3**)] in good yields as yellow solids (Scheme 1a). The preparation of $[Ru(BPM)(CO)_2Br_2]$ (**1b**) involved an initial halide exchange reaction between $[Ru(CO)_2Cl_2]_n$ and KBr, followed by the addition of BPM (Scheme 1b). This complex was isolated in fair yield as an orange solid. Attempts to prepare the complex $[Ru(BPM)(CO)_2I_2]$ from the reaction of $[Ru(CO)_2Cl_2]_n$ with NaI resulted in an orange solid. Unfortunately, residual NaI remained and a pure complex could not be obtained. CI mass spectra of the chloride complexes exhibit peaks corresponding to M^+ ions for all complexes, confirming the complexes to be monomeric. Subsequent loss of CO ligands are observed followed by peaks corresponding to the [M − 2CO − Cl] and [M − 2CO − 2Cl] ions. FAB mass spectra of the bromide complex show similar results, exhibiting peaks corresponding to the M^+ ions with subsequent loss of CO ligands.

The ^1H NMR spectra of **1(a, b)**, **2** and **3** exhibit resonances typical of symmetrical complexes containing such ligands. The protons of the two nitrogen-containing rings of each ligand are equivalent, with only one set of resonances observed for the aromatic protons of the pyrazolyl or imidazolyl rings. Broad singlets are observed for the methylene protons of the BPM and dmBPM ligands of **1(a, b)**, due to the fluxionality of the puckered six-membered ring containing the central Ru atom. At room temperature, the resonance due to the methylene protons of the dmBPM ligand of **2** is not observed, however, on reducing the temperature to −28 °C two resonances due to the two inequivalent protons of the methylene group of dmBPM are observed, where the six-membered ring is in a nonexchanging boat conformation. A similar ligand geometry was observed in the complex $[Ru(BPM)_2(PPh_3)Cl]Cl$.[30] The assignments are consistent with the *cis*-(CO), *trans*-(halide) structure of the complexes. The $^{13}C\{^1H\}$ NMR spectra for each of the complexes **1(a, b)** and **2** are also consistent with the ^{13}C nuclei of the two aromatic rings of the ligands being equivalent.

The IR spectra of these complexes in the ν(C≡O) region show two C≡O stretches at typical wavenumbers for terminal carbonyl ligands, indicating that the complexes have octahedral ruthenium centres with C_{2v} symmetry, and that the coordination sphere about the ruthenium centre is *cis*(CO)-*trans*(halide). The ν(C≡O) frequencies and $^{13}C\{^1H\}$ NMR carbonyl resonances are listed in Table 1. A shift in ν(C≡O) frequencies towards lower wavenumbers is observed in the order BPM > dmBPM > BIM, which is associated with a downfield shift for the ^{13}C CO resonance. The additional four electron-donating methyl groups on the dmBPM ligand give the ligand a better electron-donating ability than BPM. The trend also shows that the imidazolyl ligand is a better electron donor than pyrazolyl ligands. A marginal shift in ν(C≡O) frequencies to lower wavenumber

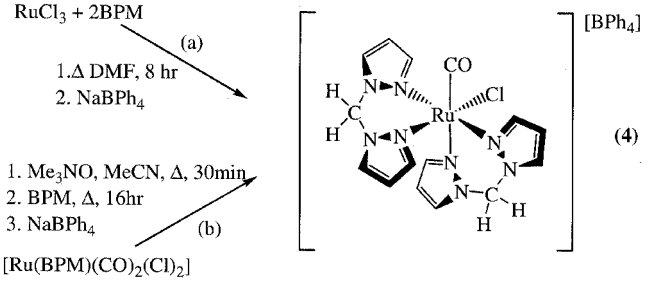
$[Ru(bipy)(CO)_2I_2]$	2056, 2000	198.5

is also observed for the complexes $[Ru(BPM)(CO)_2X_2]$ (Cl > Br). This trend has been observed on a number of occasions for dipyridylruthenium complexes.[6,31,32]

Synthesis of $[Ru(BPM)_2(CO)Cl][BPh_4]$

The complex $[Ru(BPM)_2(CO)Cl][BPh_4]$ (**4**) was prepared by two methods (Scheme 2). Firstly, $RuCl_3{\cdot}xH_2O$ was allowed to react with two equivalents of BPM in refluxing DMF for 8 hours (Scheme 2a). After cooling, the solvent volume was reduced by distillation and $NaBPh_4$ was added. Et_2O was then added to the reaction to afford an off-white precipitate. This was recrystallised from acetone and diethyl ether to afford $[Ru(BPM)_2(CO)Cl][BPh_4]$ (**4**). This method is analogous to the preparation of $[Ru(BIPY)_2(CO)Cl][ClO_4]$.[33] Complex **4** was also prepared by the monodecarbonylation of $[Ru(BPM)(CO)_2Cl_2]$ **(1a)**. Complex **1a** was reacted with excess Me_3NO in refluxing MeCN after which one equivalent of BPM was added and the reaction refluxed for a further 16 hours. The addition of $NaBPh_4$ after this time resulted in the formation of compound **4** (Scheme 2b). This method proved to be the more efficient, with 37% yield obtained. The positive electrospray mass spectrum of the cation of **4** gave a M^+ ion mass of 460.9, consistent with the cation formula. Loss of CO is observed (432.9 $[M - CO]^+$) followed by loss of chlorine (396.9 $[M - CO - Cl]^+$). The infrared spectrum of $[Ru(BPM)_2(CO)Cl][BPh_4]$ exhibits a ν(CO) frequency of 1970 cm^{-1}. This is similar to the CO(str) frequency of $[Ru(BIPY)_2(CO)Cl][ClO_4]$,[33] again showing that the two ligands have similar electron-donating properties to the ruthenium centre.



Scheme 2. Preparation of $[Ru(BPM)_2(CO)Cl][BPh_4]$ (**4**)

Attempts to prepare the halogen-free compounds $[Ru(BPM)_2(CO)_2][BPh_4]_2$ and $[Ru(BIM)_2(CO)_2][BPh_4]_2$ by dechlorination with trifluoromethanesulfonic acid or silver triflate, followed by the addition of BPM and $NaBPh_4$, were unsuccessful. These methods have been reported for the preparation of $[Ru(BIPY)_2(CO)_2]^{2+}$. No product could be isolated from the reaction of $[Ru(BPM)(CO)_2Cl_2]$ or $[Ru(BIM)(CO)_2Cl_2]$ and silver triflate, while the reaction of $[Ru(BIM)(CO)_2Cl_2]$ with trifluoromethanesulfonic acid followed by the addition of $NaBPh_4$ resulted in the quantitative protonation of the BIM ligand affording an ionic compound (Figure 1). Important crystal data are given in Table 2 with important bond lengths and bond angles listed in Table 3. Figure 2 shows the dimeric nature of the cation through H-bonding.

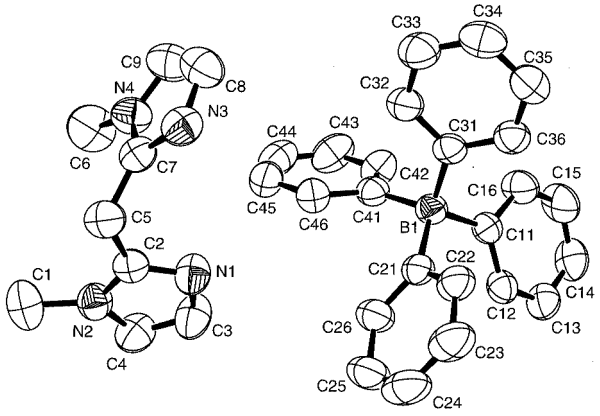


Figure 1. Molecular projection of the asymmetric unit of [HBIM][BPh_4], showing atom labelling scheme; thermal ellipsoids are drawn at the 50% probability level; H-atoms removed for clarity

NMR Spectroscopic Studies of $[Ru(BPM)_2(CO)(Cl)][BPh_4]$

The ^1H and $^{13}C\{^1H\}$ NMR spectra were completely assigned for $[Ru(BPM)_2(CO)Cl][BPh_4]$ (**4**) (at 250 K). At room temperature, rapid conformational exchange is observed, so that the resonances of the protons of the two BPM ligands are completely equivalent. At 250 K, the resonances of the protons of the four pyrazole rings of the ligands are found to be inequivalent, indicating that the two BPM ligands are mutually *cis*, and that the chloride and carbonyl ligands are mutually *cis*. It was not possible to distinguish the positions of the carbonyl and the chloride ligands. The NOESY spectrum shows the chelating ligands to be puckered and the six-membered chelate ring to have a boat conformation with only one methylene proton interacting with the closest protons of the pyrazole rings. A similar geometry is observed in the complex $[Ru(BPM)_2(PPh_3)Cl]Cl$, where the complete coordination sphere of the ruthenium centre could be determined because of strong NOESY interactions between the protons of the pyrazole rings and the triphenylphosphane ligand.[30] The atom labelling used for the assignment of NMR spectra of **4** is shown in Figure 3.

Structures of $[Ru(dmBPM)(CO)_2Cl_2]$ (2) and $[Ru(BPM)_2(CO)Cl][BPh_4]$ (4)

Important crystal data are listed in Table 2 with important bond lengths and bond angles of $[Ru(dmBPM)(CO)_2Cl_2]$ (**2**) and $[Ru(BPM)_2(CO)Cl][BPh_4]$ (**4**) listed in Table 4 and 5, respectively. Both compounds are noncentrosymmetric and crystallise in the $P\bar{1}$ (#2) space group. The ruthenium centres in both complexes have a distorted octahedral geometry, with the bis(pyrazol-1-yl)methane ligands chelating the ruthenium centres to form six-membered chelate rings with boat conformations. The structure of $[Ru(dmBPM)(CO)_2Cl_2]$ (Figure 4) shows the carbonyl and chloride ligands to have *cis* and *trans* arrangements, respectively. The structures of both *cis*(CO), *cis*(Cl)-

[Ru(BIPY)$(CO)_2Cl_2$] and *cis*(CO), *trans*(Cl)-[Ru(BIPY)-$(CO)_2Cl_2$] have been reported previously.[34] The structure of the [Ru$(BPM)_2$(CO)Cl]$^+$ cation (Figure 5) shows the carbonyl and chloride ligands to have *cis* coordination with respect to each other, as was observed for the complex in solution at low temperatures using NMR spectroscopy.

The Ru−N distances for **2** [2.165(2) and 2.167(2) Å] are significantly longer than those seen in the analogous bipyridine complexes *cis*(CO), *cis*(Cl)-[Ru(BIPY)$(CO)_2Cl_2$] and *cis*(CO), *trans*(Cl)-[Ru(BIPY)$(CO)_2Cl_2$] [2.117(8) and 2.090(8), 2.112(12) and 2.102(9) Å, respectively],[34] where the longer Ru−N bond length corresponds to the bond *trans* to the carbonyl ligand in the *cis*(CO), *cis*(Cl)-[Ru(BIPY)$(CO)_2Cl_2$] structure. The Ru−N bond lengths of **2** are also considerably longer than those in the cation of **4** [2.076(4)−2.140(4) Å] and can be attributed to the increased steric interaction caused by the methyl substituents present on the pyrazolyl rings. The Ru−Cl bond lengths [2.3941(7), 2.4155(7) Å] are similar, as would be expected for a *cis*(CO), *trans*(Cl) geometry. Both distances are similar to those of *cis*(CO), *trans*(Cl)-[Ru(BIPY)$(CO)_2Cl_2$] [2.391(5), 2.390(5) Å (Ru−Cl); 1.85(17), 1.817(8) Å (Ru−C)].[34] The distortion in the octahedral geometry about the ruthenium centre is evident by the slight deviation from ideal bond angles about the ruthenium centre. The

bite angle of the dmBPM ligand [86.38(8)°] is similar to that in *trans*-$[Ru(BPM)(CO)(PMe_3)_2(COMe)]^+$ [84.3(5)°][35] and $[Ru_2(PPh_3)_2(BPM)_2(\mu\text{-}Cl)_3]Cl$ [88.4(3)°].[30]

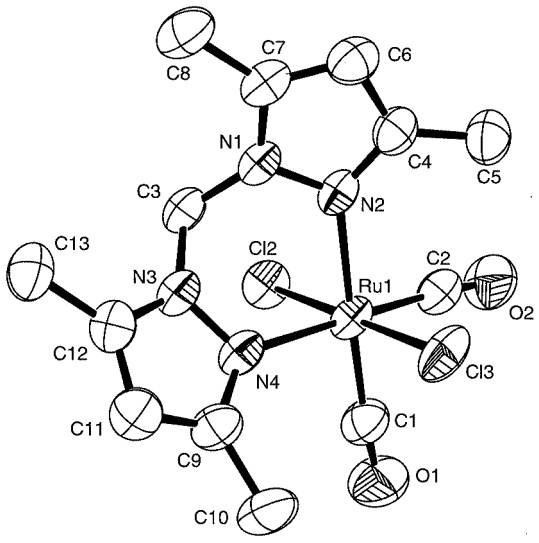

Figure 4. Molecular projection of $[Ru(dmBPM)(CO)_2Cl_2]$ (**2**) showing atom labelling scheme; thermal ellipsoids are drawn at the 50% probability level; H-atoms removed for clarity

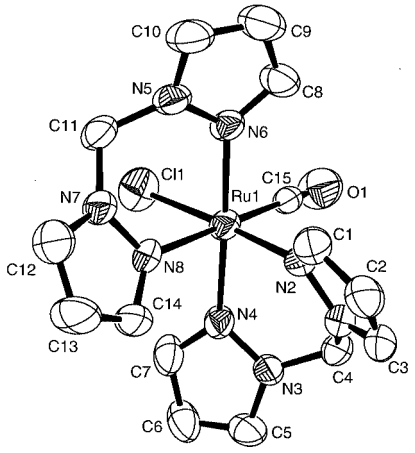

Figure 5. Molecular projection of $[Ru(BPM)_2(CO)Cl][BPh_4]$ (**4**) showing atom labelling scheme; thermal ellipsoids are drawn at the 50% probability level; H-atoms removed for clarity

The structure of the cation of **4** shows the CO and Cl ligands to have *cis* coordination with respect to each other. The Ru−N bond lengths are shorter than those of the neutral complex **2** because of the absence of the methyl moieties on the pyrazolyl rings of the ligands, but are similar to those of $[Ru(BIPY)_2(CO)Cl]^+$ [mean value 2.10(2) Å].[33] Similar to $[Ru(BIPY)_2(CO)Cl]^+$, three Ru−N bond lengths of **4** are similar, ranging from 2.071(4) to 2.095(4) Å, with one longer bond [2.140(4) Å], corresponding to the Ru−N bond *trans* to the carbonyl ligand; this is in accordance with the increased *trans* influence, CO > N_{ligand} > Cl. The Ru−Cl and Ru−C bond lengths in **4** of 2.3986(16) and 1.930(5) Å, respectively, are also similar to those reported for $[Ru(BIPY)_2(CO)Cl]^+$.[33] The slightly distorted octahedral geometry about the ruthenium centre in **4** is not unlike related structures, with the bite angle of the ligands being 88.66(15) and 87.01(14)°, similar to those in the compounds described above.

Reactivity of $[Ru(N\text{-}N)(CO)_2Cl_2]$ Compounds

The catalytic activity of the $[Ru(N\text{-}N)(CO)_2Cl_2]$ compounds was investigated. The analogous dipyridylruthenium compounds are active in the water-gas shift reaction as well as a number of other catalytic processes. The processes we investigated included hydrogenation, hydrosilylation, intramolecular cyclisation of unsaturated carboxylic acids to form lactones, and intermolecular coupling reactions. All reactions were conducted at 60 °C over several days. All coupling reactions were unsuccessful, as were the hydrogenation reactions. The activity of the complexes toward H_2 was monitored using *para*-hydrogen NMR experiments (4 atm H_2). No activation of H_2 by the ruthenium compounds was observed, at various temperatures or under photolytic conditions.

Conclusions

A series of organoruthenium compounds containing the bidentate ligands bis(*N*-methylimidazol-1-yl)methane and bis(pyrazol-1-yl)methane ligands have been prepared that are free of phosphane coligands. Structural elucidation of $[Ru(dmBPM)(CO)_2Cl_2]$ (**2**) shows it to be a mononuclear compound with *cis*(CO), *trans*(Cl) coordination in a distorted octahedral geometry. All other prepared analogous compounds are assigned with the same coordination environment based on spectral similarities. The ionic compound $[Ru(BPM)_2(CO)Cl][BPh_4]$ (**4**) was prepared by two routes. Structural elucidation of $[Ru(BPM)_2(CO)Cl][BPh_4]$ (**4**) shows it to have a *cis* arrangement of the two bis(pyrazol-1-yl)methane ligands. This was also confirmed by NOESY and COSY NMR spectroscopy and is similar to the previously reported $[Ru(BPM)_2(PPh_3)Cl]Cl$.[14] We were unable to prepare the halide-free compound $[Ru(BPM)_2(CO)_2][BPh_4]$. The activation of small molecules by the ruthenium compounds was investigated, with the ruthenium compounds described herein having quite different reactivity to that of $[Ru(BIPY)(CO)_2Cl_2]$.

Experimental Section

All reactions were performed under nitrogen gas using standard Schlenk techniques. Ruthenium(III) trichloride hydrate was obtained from Johnson−Matthey, and used without purification. The ruthenium complex $[Ru(CO)_2Cl_2]_n$ [36] and the ligands bis(pyrazol-1-yl)methane (BPM),[18] bis(3,5-dimethylpyrazol-1-yl)methane (dmBPM)[18] and bis(*N*-methylimidazol-1-yl)methane (BIM)[19] were prepared according to literature procedures. All solvents were degassed prior to use. DMF was freshly distilled under reduced pressure from $MgSO_4$ prior to use.

The positive electrospray mass spectra of the complexes were recorded on a Finnigan/MAT TSQ7000 LCMS mass spectrometer. CI mass spectra were recorded on a Finnigan PolarisQ GCMS/MS ion trap mass spectrometer and LSIMS mass spectra were recorded on a Kratos Analytical Concept ISQ mass spectrometer using an mnba matrix. Infrared spectra (cm^{-1}) were recorded using an ATI Mattson *Genesis Series* FTIR Spectrometer. ^1H and $^{13}C\{^1H\}$ NMR spectra were recorded on Bruker DPX300, DPX400, DPX500 or Varian Gemini 200 spectrometers at 300 K unless otherwise stated. Chemical shifts are internally referenced to residual solvent.

$[Ru(BPM)(CO)_2Cl_2]$ (1a): $[Ru(CO)_2Cl_2]_n$ (99 mg, 0.43 mmol) and BPM (70 mg, 0.44 mmol) were refluxed in MeOH (40 mL) for 30 mins. The yellow solution was cooled to room temperature and the volume reduced in vacuo (to about 5 mL) to afford a pale yellow precipitate. The solid was collected and washed with Et_2O (yield 90 mg, 55%). Recrystallisation by vapour diffusion of $MeNO_2$ and Et_2O at −30 °C afforded pale yellow block crystals. ^1H NMR (200 MHz, [D$_6$]acetone): δ = 6.63 (t, $^3J_{H\text{-}H}$ = 2.50 Hz, 2 H, pz-H), 7.26 (br. s, 2 H, CH_2), 8.16 (d, $^3J_{H\text{-}H}$ = 2.30 Hz, 4 H, pz-H), 8.24 (d, $^3J_{H\text{-}H}$ = 2.20 Hz, 4 H, pz-H) ppm. $^{13}C\{^1H\}$ NMR (100 MHz, [D$_6$]acetone): δ = 63.4 (CH_2), 108.5 (C4), 135.3 (C5), 147.2 (C3), 196.4 (CO) ppm. CI-MS: *m*/*z* = 376 [M^+; $^{101}Ru(^{12}C_7N_4H_9)(^{12}CO)_2{}^{35}Cl_2$], 348 [M − CO; $^{101}Ru(^{12}C_7N_4H_9)(^{12}CO)^{35}Cl_2$], 320 [$M^+$ − 2CO; $^{101}Ru(^{12}C_7N_4H_9)^{35}Cl_2$], 285 [$M^+$ − 2CO-Cl; $^{101}Ru(^{12}C_7N_4H_9)^{35}Cl$], 250 [$M^+$ − 2CO − 2Cl; $^{101}Ru(^{12}C_7N_4H_9)$] 148 (L). $C_9H_8Cl_2N_4O_2Ru$ (376.18) calcd. C 28.74, H 2.14, N 14.90; found C 28.95, H 2.04, N 14.89.

$[Ru(dmBPM)(CO)_2Cl_2]$ (2): Procedure as above using dmBPM (yield 54 mg, 30%). Recrystallisation by vapour diffusion of $MeNO_2$ and Et_2O at −30 °C afforded pale yellow block crystals. ^1H NMR (500 MHz, [D$_8$]THF, −28 °C): δ = 2.48 (s, 6 H, pz-CH_3), 2.63 (s, 6 H, pz-CH_3), 6.15 (s, 2 H, pz-H), 6.20 (d, $^2J_{H\text{-}H}$ = 15.09 Hz, 1 H, CH_2), 7.53 (d, $^2J_{H\text{-}H}$ = 15.09 Hz, 1 H, CH_2) ppm. ^1H NMR (500 MHz, [D$_8$]THF, 27 °C): δ = 2.46 (s, 6 H, pz-CH_3), 2.63 (s, 6 H, pz-CH_3), 6.09 (s, 2 H, pz-H) ppm. $^{13}C\{^1H\}$ NMR (75 MHz, [D$_8$]THF, 27 °C): δ = 10.8, 15.5, 56.3, 108.8, 142.7, 155.3, 197.1 (C≡O) ppm. CI MS: *m*/*z* = 431 [M^+; $^{101}Ru(^{12}C_{11}N_4H_{16})(^{12}CO)_2{}^{35}Cl_2$], 403 [$M^+$ − CO; $^{101}Ru(^{12}C_{11}N_4H_{16})(^{12}CO)^{35}Cl_2$], 375 [$M^+$ − 2CO; $^{101}Ru(^{12}C_{11}N_4H_{16})^{35}Cl_2$], 340 [$M^+$ − 2CO − Cl; $^{101}Ru(^{12}C_{11}N_4H_{16})^{35}Cl$], 305 [$M^+$ − 2CO − 2Cl; $^{101}Ru(^{12}C_{11}N_4H_{16})$], 204 [L; $^{12}C_{11}N_4H_{16}$]. $C_{13}H_{16}Cl_2N_4O_2Ru$ (432.27): calcd. C 36.11, H 3.73, N 12.97; found C 36.04, H 3.76, N 12.86.

$[Ru(BIM)(CO)_2Cl_2]$ (3): Procedure as above using BIM (yield 197 mg, 55%). Recrystallisation from $MeNO_2$ at −30 °C afforded pale yellow block crystals. ^1H NMR (300 MHz, CD_3NO_2, 27 °C): δ = 6.16 (s, 6 H, CH_3), 6.77 (s, 2 H, CH_2), 8.65 (d, $^3J_{H\text{-}H}$ = 1.11 Hz, 2 H, mim-H), 8.81 (d, $^3J_{H\text{-}H}$ = 1.50 Hz, 2 H, mim-H) ppm. $^{13}C\{^1H\}$ NMR (75 MHz, CD_3NO_2, 27 °C): δ = 23.9, 34.6, 123.8, 130.7, 144.1, 198.4 ppm. CI-MS: *m*/*z* = 375 [M^+ − CO;

$^{101}Ru(^{12}C_9N_4H_{12})(CO)^{35}Cl_2]$, 347 [$M^+$ − 2CO; $^{101}Ru(^{12}C_9N_4H_{12})^{35}Cl_2]$, 312 [$M^+$ − 2CO − Cl; $^{101}Ru(^{12}C_9N_4H_{12})^{35}Cl]$, 176 [$M^+$ − 2CO − 2Cl − Ru; $^{12}C_9N_4H_{12}$]. $C_{11}H_{12}Cl_2N_4O_2Ru$ (404.22): calcd. C 32.69, H 2.99, N 13.86; found C 32.76, H 2.90, N 13.80.

[Ru(BPM)(CO)$_2$Br$_2$] (1b): $[Ru(CO)_2Cl_2]_n$ (202 mg, 0.87 mmol) and KBr (1.0 g, 8.40 mmol) were refluxed in degassed MeOH (40 mL) for 3.5 hours. BPM (147 mg, 0.99 mmol) was then added to the orange solution and the reaction was refluxed for a further 30 mins. The orange solution was cooled to room temperature affording a colourless precipitate which was collected by filtration. The solvent of the filtrate was removed in vacuo and the resulting orange solid was isolated and washed with MeOH (184 mg, 50%). ^{1}H NMR (200 MHz, [D$_6$]acetone, 27 °C): δ = 6.64 (t, $^3J_{H\text{-}H}$ = 2.58 Hz, 2 H, pz-H), 7.29 (br. s, 2 H, CH_2), 8.20 (d, $^3J_{H\text{-}H}$ = 2.34 Hz, 4 H, pz-H), 8.25 (d, $^3J_{H\text{-}H}$ = 2.06 Hz, 4 H, pz-H) ppm. $^{13}C\{^1H\}$ NMR (50 MHz, [D$_6$]acetone, 27 °C): δ = 64.19 (CH_2), 108.83 (C4), 135.76 (C5),148.45 (C3), 197.72 (CO) ppm. LSIMS: *m*/*z* = 466 [M^+; $^{101}Ru(^{12}C_7N_4H_9)(^{12}CO)_2{}^{80}Br_2]$, 438 [$M^+$ − CO; $^{101}Ru(^{12}C_7N_4H_9)(^{12}CO)^{80}Br_2]$, 410 [$M^+$ − 2CO) [$^{101}Ru(^{12}C_7N_4H_9)^{80}Br_2$ 410], 386 [M^+ − Br; $^{101}Ru(^{12}C_7N_4H_9)(^{12}CO)_2{}^{80}Br_2]$, 358 [$M^+$ − CO − Br; $^{101}Ru(^{12}C_7N_4H_9)(^{12}CO)^{80}Br]$. $C_9H_8Br_2N_4O_2Ru$ (465.06): calcd. C 23.24, H 1.73, N 12.05; found C 23.44, H 1.78, N 12.01.

[Ru(BPM)$_2$(CO)Cl][BPh$_4$] (4): Method 1. $RuCl_3{\cdot}3H_2O$ (100 mg, 0.48 mmol) and BPM (123 mg, 0.83 mmol) were refluxed in DMF for 8 hours. The reaction mixture was cooled, $NaBH_4$ (2.62 mg, 0.77 mmol) was added and the reaction stirred for 1 hour. The solution was then cooled and the volume of solvent reduced to about 5 mL. Et_2O was then added to the solution resulting in an off-white precipitate which was collected and washed with Et_2O. The off-white compound was recrystallised from acetone and Et_2O (89 mg, 15%). NMR assignments refer to the numbering given in Figure 3. ^{1}H NMR (500 MHz, [D$_6$]acetone, −23 °C): δ = 5.92 (d, $^3J_{H\text{-}H}$ = 2.36 Hz, H*r*), 6.25 (d, $^3J_{H\text{-}H}$ = 2.13 Hz, H*h*), 6.29 (d, $^3J_{H\text{-}H}$ = 2.52, $^3J_{H\text{-}H}$ = 2.60 Hz, H*q*), 6.40 (t, $^3J_{H\text{-}H}$ = 2.36 Hz, H*g*), 6.63 (d, $^3J_{H\text{-}H}$ = 14.66 Hz, H*n*), 6.70 (t, $^3J_{H\text{-}H}$ = 2.60 Hz, H*l*), 6.71 (t, $^3J_{H\text{-}H}$ = 2.44 Hz, H*b*), 6.77 (t, BPh_4), 6.92 (t, BPh_4), 7.11 (d, $^3J_{H\text{-}H}$ = 13.79 Hz, H*d*), 7.24 (d, $^3J_{H\text{-}H}$ = 14.98 Hz, H*o*), 7.32 (t, BPh_4), 7.63 (d, $^3J_{H\text{-}H}$ = 13.87 Hz, H*e*), 8.09 (d, $^3J_{H\text{-}H}$ = 2.21 Hz, H*a*), 8.14 (d, $^3J_{H\text{-}H}$ = 2.13 Hz, H*k*), 8.23 (d, $^3J_{H\text{-}H}$ = 3.00 Hz, H*p*), 8.29 (t, $^3J_{H\text{-}H}$ = 2.68, $^3J_{H\text{-}H}$ = 3.00 Hz, H*f*), 8.38 (d, $^3J_{H\text{-}H}$ = 2.68 Hz, H*m*), 8.41 (d, $^3J_{H\text{-}H}$ = 2.84 Hz, H*c*) ppm. ^{13}C NMR (125 MHz, [D$_6$]acetone, −23 °C): δ = 64.1 (C*d,e*), 64.7 (C*o,n*), 109.1 (C*g*), 109.3 (C*l*), 109.6 (C*q*), 110.0 (C*b*), 122.9 (BPh_4), 126.6 (BPh_4), 135.8 (C*f*), 136.8 (C*p*), 137.4 (BPh_4), 137.4 (C*m*), 137.7 (C*c*), 144.0 (C*h*), 145.7 (C*r*), 147.2 (C*k*), 149.5 (C*a*) ppm. C 60.04, H 4.65, N 14.37; found C 60.16, H 4.99, N 14.07.

Method 2. A mixture of $[Ru(BPM)(CO)_2Cl_2]$ (103 mg, 0.452 mmol) and Me_3NO (90 mg, 2.00 mmol) in MeCN was refluxed for 30 mins. BPM (150 mg, 1.01 mmol) was then added to the reaction mixture which was then refluxed for a further 16 hours. The yellow solution was allowed to cool slightly, after which $NaBPh_4$ (459 mg, 1.34 mmol) was added. A pale yellow precipitate was formed on cooling, which was collected and washed with Et_2O (132 mg, 37%). Suitable crystals for X-ray diffraction were grown from $MeNO_2/Et_2O$.

Catalysis Reactions

Coupling of HC≡CPh and HSiEt$_3$: *Typical reaction*. Phenylacetylene (25 mg, 0.25 mmol), triethylsilane (29 mg, 0.25 mmol), [Ru(BIM)(CO)$_2$Cl$_2$] (5.3 mg, 14.1 μmol) and [D$_3$]$MeNO_2$ were sealed in an NMR tube. The mixture was heated to 60 °C and the reaction was monitored using NMR spectroscopy. After one week, no coupling product was observed.

Coupling of Acetophenone and 1-Pentene: *Typical reaction*. Acetophenone (35 mg, 0.29 mmol), 1-pentene (17 mg, 0.25 mmol), [Ru(dmBPM)(CO)$_2$Cl$_2$] (5.7 mg, 12.9 μmol) and [D$_8$]THF were sealed in an NMR tube. The mixture was heated to 60 °C and the reaction was monitored using NMR spectroscopy. After one week, no coupling product was observed.

Cyclisation of *cis*-3-Methyl-2-pentene-4-yn-1-ol to 2,3-Dimethylfuran: *Typical reaction*. *cis*-3-Methyl-2-pentene-4-yn-1-ol (63 mg, 0.66 mmol), [Ru(BIM)(CO)$_2$Cl$_2$] (2.8 mg, 6.9 μmol) and [D$_8$]THF were sealed in an NMR tube. The mixture was heated to 60 °C and the reaction was monitored using NMR spectroscopy. After one week, no cyclisation product was observed.

Cyclisation of 4-Pentynoic acid to γ-Methylene-γ-butyrolactone: *Typical reaction*. 4-Pentynoic acid (58 mg, 0.59 mmol), [Ru(BIM)(CO)$_2$Cl$_2$] (2.4 mg, 5.9 μmol) and [D$_8$]THF were sealed in an NMR tube. The mixture was heated to 60 °C and the reaction was monitored using NMR spectroscopy. After one week, no cyclisation product was observed.

Parahydrogen Experiments: Hydrogen enriched in the *para* spin state was prepared by cooling H_2 to 77 K over a paramagnetic catalyst. An atmosphere of H_2 equivalent to ca. 3 atm. pressure at 298 K was introduced into the resealable NMR tube on a high vacuum line already containing the sample and deuterated solvent. The samples were thawed immediately prior to use and introduced into the NMR spectrometer at the pre-set temperature.

X-ray diffraction studies

Data collection used a Bruker SMART 1000 CCD diffractometer equipped with an Oxford System Cryostream low-temperature attachment, with graphite monochromated Mo-K_α radiation (λ_{max} = 0.71073 Å), *T* = 173 K ([Ru(dmBPM)(CO)$_2$Cl$_2$]) or 293 K ([HBIM][BPh$_4$] and [Ru(BPM)$_2$(CO)Cl][BPh$_4$]). Data integration and reduction were performed with SAINT and XPREP.[37] A Gaussian absorption correction was applied to the data of [Ru(BPM)$_2$(CO)Cl][BPh$_4$] and [HBIM][BPh$_4$].[37,38] A semi-empirical correction was determined with SADABS[39] for [Ru(dmBPM)(CO)$_2$Cl$_2$]. Molecular projections of all structures were generated with Ortep-3.[40] All structures were solved by direct methods using SHELXS-97[41] and structure refinement was done using SHELXL-97.[42] All non-hydrogen sites for the three structures were treated anisotropically. All hydrogen atoms were calculated and refined isotropically. H(20) in [HBIM][BPh$_4$] was modelled with isotropic displacement parameters.

CCDC-184163 (**2**), -184164 (**4**) and -184165 ([HBIM][BPh$_4$]) contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; fax: (internat.) +44−1223/336−033; E-mail: deposit@ccdc.cam.ac.uk].

Evolution of Defects in the Bulk Structure of MoO_3 During the Catalytic Oxidation of Propene

Thorsten Ressler,*[a] Julia Wienold,[a] Rolf E. Jentoft,[a] and Frank Girgsdies[a]

Keywords: Molybdenum / EXAFS spectroscopy / X-ray diffraction / Heterogeneous catalysis / Oxidation

The evolution of characteristic defects in the bulk structure of MoO_3 under propene oxidation conditions was investigated by in situ X-ray absorption spectroscopy and X-ray diffraction. Under the reaction conditions employed (273 K to 773 K, and propene to oxygen ratios from 1:1 to 1:5), orthorhombic MoO_3 remains the only crystalline phase detected by XRD. The starting temperature for the reaction of propene and oxygen in the presence of MoO_3 coincides with the temperature at which reduction of MoO_3 begins in He, H_2 and propene ($\approx$ 620 K). At temperatures below 720 K, and independent of the atmosphere used, partial reduction of MoO_3 is observed resulting in the formation of "$Mo_{18}O_{52}$" type defects in the layer structure of α-MoO_3. At temperatures above 720 K, and under oxygen or in an oxidizing atmosphere, the "$Mo_{18}O_{52}$" type defects are reoxidized to MoO_3. Evidently, the catalytically active molybdenum oxide phase develops under partial oxidation conditions at temperatures below 720 K, and does not possess the undisturbed ideal layer structure of orthorhombic α-MoO_3. The results presented clearly show the necessity and the potential for bulk structural investigations of heterogeneous catalysts under the reaction conditions used. The bulk structure, and particularly the type and number of defects in the material ("real" structure) considerably affect the catalytic properties. Hence, in order to rationally design a most active heterogeneous catalyst, both the structure and reactions of the surface, and the structure, defects, and reactions of the bulk need to be known in detail, and carefully considered.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2003)

Introduction

Molybdenum trioxide, MoO_3, is an active catalyst for the oxidation of propene in the presence of gaseous dioxygen at temperatures above about 600 K. Moreover, MoO_3 constitutes a suitable three-dimensional model system for the more complex molybdenum based mixed oxide catalysts that are employed industrially for various partial oxidation reactions. Hence, the structural features and the catalytic properties of MoO_3 have been investigated in detail over the last five decades in order to reveal structure-activity relationships and to aid the rational design of improved catalyst materials.[1−4] Accordingly, the various steps of the molecular mechanism of the oxidation of propene in the presence of MoO_3 have been suggested to include adsorption of propene on the surface of the catalyst, abstraction of hydrogen, and the formation of an allylic species.[5,6] Subsequently, oxygen from the lattice of MoO_3 is incorporated in the allylic species, forming the partial oxidation product acrolein, or the total oxidation product carbon dioxide. The bulk of the metal oxide is then reoxidized by oxygen from the gas phase ("redox mechanism" or "Mars−van Krevelen mechanism").[7−9]

Although it is assumed that the lattice oxygen of MoO_3 participates in the oxidation of propene, little is known about defects in the regular layer structure of MoO_3 that may form under the reaction conditions, or about the structural properties and the role of these defects in the partial oxidation reactions proceeding on the surface of the MoO_3 catalyst. The question remains, how close is the "real" bulk structure of MoO_3 under the reaction conditions to the "ideal" structure of orthorhombic α-MoO_3?

Under propene oxidation reaction conditions, MoO_3 exhibits a slightly reduced average valence, which, according to the conventional redox mechanism, has to be attributed to different rates for the reduction and the re-oxidation of the molybdenum trioxide.[1] Since molybdenum is known to form a number of well-defined suboxides with average valences between 6.0 (MoO_3) and 4.0 (MoO_2) (i.e. $Mo_{18}O_{52}$, $Mo_{17}O_{47}$, Mo_9O_{26}, Mo_8O_{23}, Mo_5O_{14}, Mo_4O_{11}), it has been speculated that one of these suboxides constitutes the active phase in a molybdenum oxide partial oxidation catalyst. Thus, stoichiometric reduction and oxidation of various molybdenum oxides have been studied extensively in the past, with various attempts to correlate the observations made with the catalytic behavior of the materials investigated.[1] Those studies have proven extremely valu-

able to elucidate the evolution of the phase composition and the bulk structure during reduction and oxidation of the molybdenum oxides, and to determine the solid-state kinetics of these reactions. Recently, we were able to show that only $Mo_{18}O_{52}$ is a possible intermediate of the reduction of MoO_3 in propene and the oxidation of MoO_2 in oxygen,[10] while none of the well-defined suboxides were detected during reduction of MoO_3 in hydrogen at temperatures below about 700 K.[11] However, the evolution of the bulk structure of MoO_3 under catalytic reaction conditions and the formation of defects have largely been neglected in the past.

Investigations of the relationships between the structure and the reactivity of a heterogeneous catalyst need to be performed in situ (i.e. under "real" reaction conditions), with simultaneous monitoring of the catalyst structure and the gas phase composition.[12] Naturally, "post mortem" investigations of catalysts at room temperature, in air or in an inert atmosphere, cannot provide unambiguous correlations between the structure and the reactivity of the solid. Only few bulk structural techniques can readily be employed to study an active heterogeneous catalyst under "real" reaction conditions at elevated temperatures ($\geq$ 473 K) and pressures ($\geq$ 1 bar). Due to the low absorbance of hard X-rays (photon energy $\geq$ 5 keV) by gases or window materials, conventional experimental set-ups for X-ray diffraction (XRD) and X-ray absorption spectroscopy (XAS) can easily be combined with suitable environmental cells for catalytic studies. In addition to steady-state investigations, both techniques permit experiments with a suitable time-resolution (approx. 1 min) to monitor the structural evolution of the bulk phases, which can be used to elucidate the solid-state kinetics of the reactions involved.[10,13,14]

XAS and XRD are complementary techniques because together they provide information on the quantitative phase composition of amorphous and crystalline phases, the short-range and long-range order structure of the phases present, the electronic structure, and the crystallite size, microstrain, and morphology. As this data is of paramount importance to reveal structure-reactivity relationships in heterogeneous catalysis, XAS and XRD have been extensively employed under these reaction conditions.[15] However, the evolution of defects in the regular bulk structure of heterogeneous catalysts, and the relationships between the "real" structure of a solid catalyst and its reactivity has received little attention. In the future, new insight into the importance of defects in the "real" structure of solid heterogeneous catalysts, for the catalytic properties of the material can be expected from time-resolved in situ bulk structural investigations.

In this work in situ XAS and XRD combined with mass spectrometry are employed to elucidate the phase compositions, and the long-range and short-range structural evolution of MoO_3 during the temperature-programmed reaction of propene and oxygen. The formation of characteristic defects in the bulk structure of MoO_3 under reaction conditions is described as a function of the reaction temperature and the reducing potential of the gas phase.

Results

In Situ XRD − Evolution of the Long-Range Structure

Figure 1 shows the evolution of XRD patterns measured during the temperature-programmed treatment of MoO_3 in helium in the temperature range 573−773 K, with a heating rate of 0.1 K/min. The onset temperature for the reduction of MoO_3 to form MoO_2 is at about 620 K. At temperatures between 620 K and 720 K only MoO_2 and MoO_3 are detected, whereas at temperatures above 720 K Mo_4O_{11} is formed from a parallel reaction of MoO_3 and MoO_2.[11]

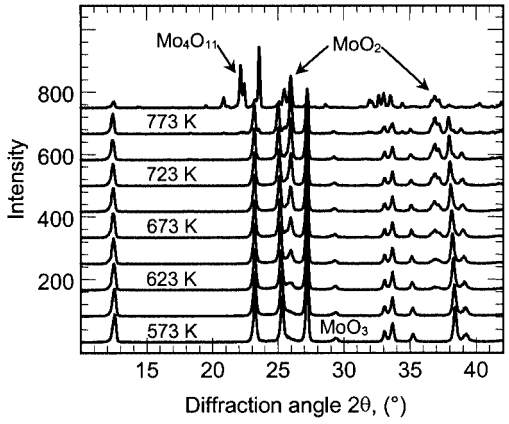

Figure 1. Evolution of XRD patterns during thermal treatment of MoO_3 in helium (573−773 K, about 0.1 K/min). The crystalline phases detected (MoO_3, MoO_2, Mo_4O_{11}) are indicated

During the temperature-programmed treatment of MoO_3 in oxygen (20% in He) in the temperature range 473−773 K with a heating rate of 0.1 K/min, MoO_3 remains the only crystalline phase detected by XRD. The evolution of ratios of integrated intensities of selected *hkl* reflections and the crystallite sizes calculated for these reflections during thermal treatment of MoO_3 in oxygen are shown in Figure 2, part (a) and (b), respectively. While the ratios shown remain nearly constant up to about 620 K, the ratios 110/101 and 020/101 increase substantially between about 620 K and about 700 K, and almost return to their original room temperature value at about 720 K. The ratio 020/110 does not change significantly in the temperature range studied. The apparent crystallite sizes calculated for the 101 and 110 reflections exhibit an increase above 673 K, while the crystallite size calculated for the 002 reflection shows a decrease between 573 K and 673 K. On cooling to room temperature, the crystallite sizes calculated for the *hkl* reflections shown are similar to those determined prior to the temperature treatment. A Williamson−Hall analysis,[16] using selected *hkl* reflections in a 2θ range from 6.0 to 55.0, only shows minor strain in the original MoO_3 materials. A certain anisotropy in the direction of the strain in the MoO_3 lattice can be deduced from the considerable scatter of the individual points in the Williamson−Hall plot obtained. However, the lack of suitable higher-order reflections did not permit a direction-dependent strain analysis. During treatment in oxygen, a slight increase in the strain occurred

at about 620 K, followed by a decrease at about 720 K (inset in Figure 2). This behavior coincides with the deviations observed in the ratios of integrated intensities [Figure 2 (a)].

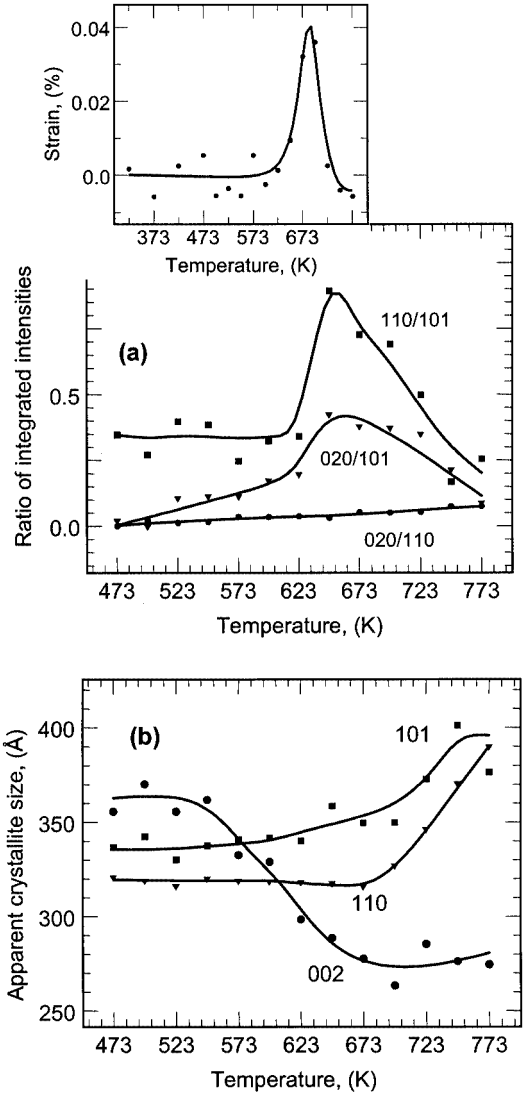

Figure 2. Evolution of ratio of integrated intensities (a) [for MoO_3 at 300 K, initial values are $A(110/101) = 4.6$, $A(020/101) = 1.9$, and $A(020/110) = 0.4$; ratios are arbitrarily displaced on y axis] and particle size (b) of selected *hkl* reflections of MoO_3 during thermal treatment of MoO_3 in oxygen (20% O_2 in He, 473−773 K, about 0.1 K/min). The inset in (a) shows the evolution of strain in the MoO_3 structure obtained from a Williamson−Hall analysis

During the temperature-programmed reaction (TPR) of propene (10 vol-%) and oxygen (10 vol-%) in the presence of MoO_3 from 473 K to 773 K, with a heating rate of 0.1 K/min, MoO_3 remains the only crystalline phase detected by XRD. The evolution of ratios of integrated intensities of selected *hkl* reflections and apparent crystallite sizes calculated for these reflections are shown in Figure 3, part (a) and part (b), respectively. Similar to the treatment in oxygen, the ratio 020/101 increases at temperatures above about 620 K, while the ratio 020/110 remains unaffected. On the other hand, the ratio 020/101 does not decrease above 720 K, but remains at a higher value. The ratio 110/101 continuously decreases between 473 K and 773 K. The apparent crystallite sizes calculated for the 110 and 002 reflections are similar to those observed during the treatment in oxygen [Figure 2, part (b)]. A Williamson−Hall analysis, using selected *hkl* reflections in the 2θ range from 6.0 to 55.0 of the diffraction patterns measured during the TPR of propene and oxygen, shows a considerable increase in the strain at temperatures above 620 K [inset in Figure 3, (a)]. This behavior coincides with the deviations observed in the ratios of integrated intensities [Figure 3, (a)].

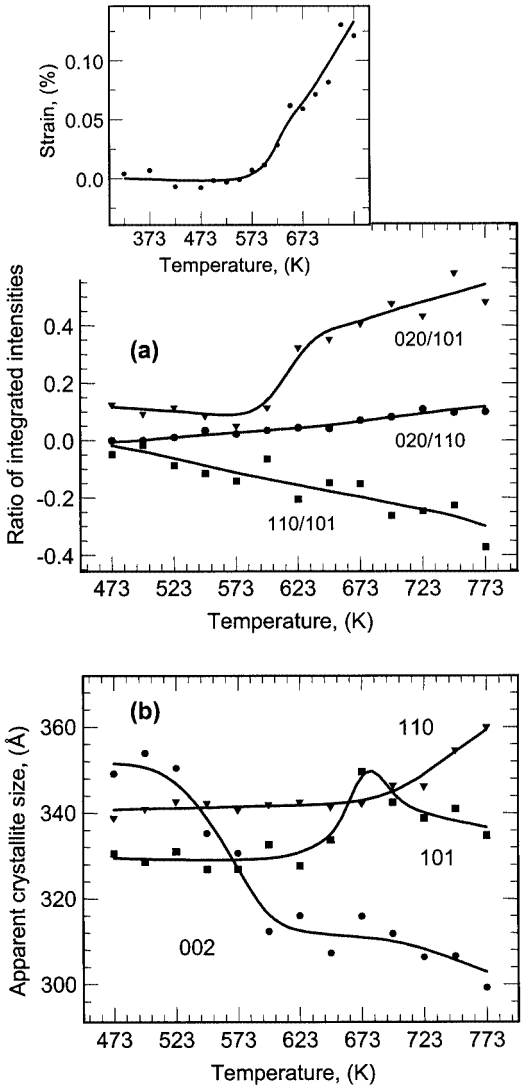

Figure 3. Evolution of ratio of integrated intensities (a) (for clarity, ratios are arbitrarily displaced on *y* axis) and particle size (b) of selected *hkl* reflections of MoO_3 during the temperature-programmed reaction of propene and oxygen (10% O_2 and 10% propene in He, 473−773 K, about 0.1 K/min). The inset in (a) shows the evolution of strain in the MoO_3 structure obtained from a Williamson−Hall analysis

In Situ XAFS − Evolution of Average Valence and Short-Range Structure

The development of the Mo-*K* edge position seen in the time-resolved XAFS spectra measured during the treatment

of MoO_3 in oxygen, and during the TPR of propene (10 vol-%) and oxygen (ratios 1:1, 1:3, and 1:5) in the presence of MoO_3 (473−773 K, 10 K/min), is depicted in Figure 4. The large number of spectra measured in the energy-dispersive mode permits reliable interpretation of small changes (< 0.1 eV) in the Mo-*K* edge position. The shift of the Mo-*K* edge position towards smaller photon energy at a temperature of about 620 K indicates the reduction of molybdenum. According to the calibration curve shown in ref.10,[10] a Mo-*K* edge shift of 0.2 eV corresponds to a difference in average valence of about 0.033. The degree of reduction under the reaction conditions for temperatures between 620 K and 720 K is related to the reducing potential of the gas phase (1:1 > 1:3 > 1:5). For the treatment of MoO_3 at temperatures above 720 K in oxygen, and in propene and oxygen with a ratio of 1:5, a shift of the Mo-*K* edge position towards higher photon energies indicates a re-oxidation of the partially reduced MoO_3. Conversely, for the reaction of propene and oxygen (ratios 1:1 and 1:3) in the presence of MoO_3, no shift of the Mo-*K* edge to higher photon energies is observed and the molybdenum oxide phase remains partially reduced at temperatures up to 773 K.

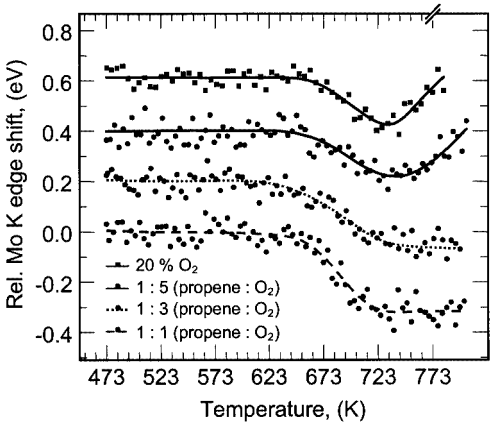

Figure 4. Evolution of Mo-*K* edge position (relative to the edge position of MoO_3, and displaced for clarity) during thermal treatment of MoO_3 in oxygen (20% in He) and during the temperature-programmed reaction of propene and oxygen in the presence of MoO_3 (10% O_2 and 10% propene in He) (473−773 K, 10 K/min, held at 773). The three different ratios of oxygen and propene employed are indicated

A principal component analysis of the XAFS spectra measured during the TPR did not afford conclusive results on the identity of the molybdenum oxide phases present. However, in addition to the temperature effect on the near-edge spectra, at least two primary components appear to be necessary to reconstruct the experimental spectra. Furthermore, the evolution of the mixing coefficients of the least important primary component shows a behavior similar to the Mo-*K* edge-shift data depicted in Figure 4.

The evolution of Mo-*K* near-edge spectra measured in the conventional XAFS mode during the TPR of propene (10%) and oxygen (10%) (300−773 K, 5 K/min) in the presence of MoO_3, together with the corresponding evolution of the average molybdenum valence, is depicted in Figure 5, part (a). Besides temperature broadening, no significant changes to the shape of the XAFS spectrum of MoO_3 occur under the reaction conditions. However, a detailed analysis of the Mo-*K* edge position again reveals a slight reduction of the molybdenum oxide at temperatures above about 620 K. Using a previously reported calibration to transform the edge-shift into average valence,[10] results in an average valence of about 5.94 for the molybdenum oxide under the reaction conditions, at temperatures above 673 K. If the type of defects formed under the TPR conditions were consistent with an "$Mo_{18}O_{52}$" type shear structure, an average valence of 5.94 would correspond to a phase composition of 75% MoO_3 and 25% $Mo_{18}O_{52}$. The evolution of the gas phase composition during the TPR of oxygen and propene in the presence of MoO_3 in a ratio of 1:1 is depicted in Figure 5, part (b). The onset temperature for the reaction is about about 620 K, producing both the partial oxidation product, acrolein and the total oxidation product, carbon dioxide. The onset temperature for the oxidation of propene was the same for all ratios of propene to oxygen measured (ratios 1:1 > 1:3 > 1:5).

Since the mass spectrometer used for the XRD and XAS experiments was not calibrated, only qualitative catalysis data can be provided. However, at 713 K, the conversion of propene in the presence of MoO_3 has been reported to be 7%, with an acrolein yield of 2%,[5] and it is assumed that the catalytic behavior of the material used here is similar. A comparison of the ratio of the ion currents of CO_2 and acrolein measured during the TPR indicates a minimum selectivity towards acrolein at about 673 K (Figure 6). This minimum selectivity is most pronounced for a ratio of propene and oxygen of 1:1.

The evolution of the Fourier-transformed Mo-*K* edge $\chi(k)$ of MoO_3 during the TPR of propene and oxygen (ratio 1:1) is depicted in Figure 7. A continuous decrease in amplitude of the higher Mo−Mo backscattering shells can be seen. As reported previously, $Mo_{18}O_{52}$ constitutes a suitable reference phase for the type of structural defects observed during reduction of MoO_3 in propene.[10] A schematic representation of the structures of orthorhombic α-MoO_3 (*Pbnm*, a = 3.936 Å, b = 13.855 Å, c = 3.696 Å)[17] and $Mo_{18}O_{52}$ ($P\bar{1}$, a = 8.145 Å, b = 11.890 Å, c = 21.230 Å, α = 102.7 °, β = 67.8 °, γ = 110.0 °)[18] is depicted in Figure 8.

The $Mo_{18}O_{52}$ structure is derived from the MoO_3 structure by crystallographic-shear operations. Hence, both contain a van der Waals gap between the individual layers, in contrast to other molybdenum oxides possessing crystallographic-shear structures such as Mo_8O_{23} and Mo_9O_{26}.[19] A comparison of the radial distribution functions of MoO_3 and $Mo_{18}O_{52}$ for a 1 nm cluster is shown in Figure 9.

The magnitude of the Fourier-transformed (FT) XAFS $\chi(k)$ of $Mo_{18}O_{52}$ will be considerably smaller than that of MoO_3 as a result of the large number of slightly different distances in the structure of $Mo_{18}O_{52}$.

In order to simulate the influence of adding certain amounts of $Mo_{18}O_{52}$ to MoO_3 on the FT[$\chi(k)$] of the re-

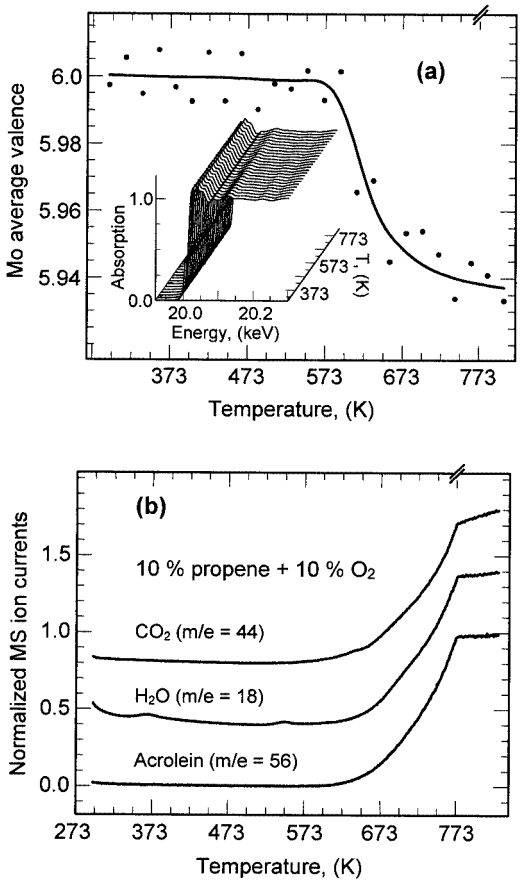

Figure 5. (a) Evolution of Mo-*K* edge position (relative to the edge position of MoO_3, and displaced for clarity) during the temperature-programmed reaction of propene and oxygen in the presence of MoO_3 (10% O_2 and 10% propene in He) (300−773 K, 5 K/min, held at 773) (inset shows evolution of XANES spectra during the TPR). (b) Evolution of the corresponding gas phase composition [CO_2 (*m/e* = 44), H_2O (*m/e* = 18), acrolein (*m/e* = 56)] during the temperature-programmed reaction of propene and oxygen

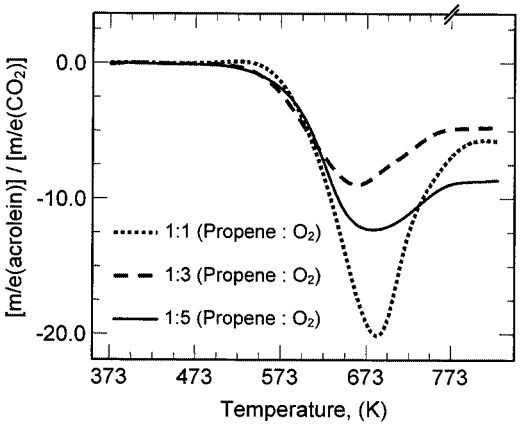

Figure 6. Ratio of the ion currents of CO_2 (*m/e* = 44) and acrolein (*m/e* = 56) measured the during temperature-programmed reaction of propene (10%) and oxygen (10% [dotted], 30% [solid], 50% [dashed]) in the presence of MoO_3 (values are displaced on the *y* axis)

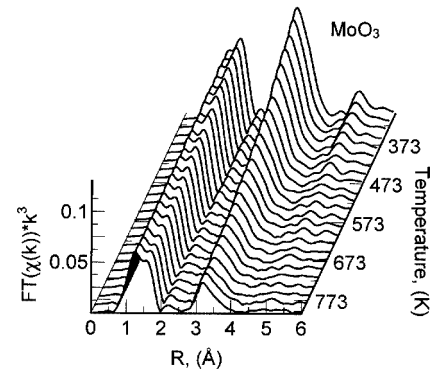

Figure 7. Evolution of Fourier-transformed $\chi(k)$ of MoO_3 during the temperature programmed reaction of propene and oxygen (10% O_2 and 10% propene in He) (300−773 K, 5 K/min, held at 773) (note inverse temperature scale) (Figure 5)

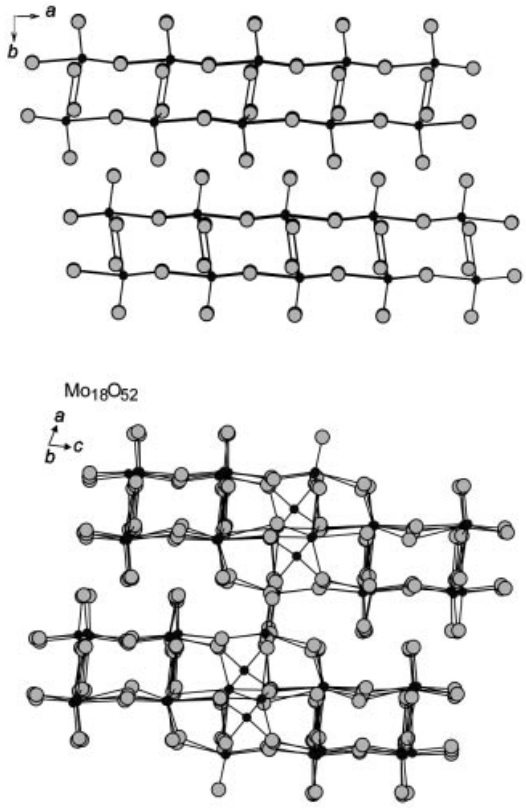

Figure 8. Schematic representations of the layer structures of MoO_3 (projection parallel to 001) and $Mo_{18}O_{52}$ (arbitrary projection for comparison with MoO_3)

sulting mixture, numerical mixtures of the experimental $\chi(k)$ of MoO_3 and $Mo_{18}O_{52}$ were calculated. The evolution of the Fourier-transformed $\chi(k)$ of these mixtures of MoO_3 and $Mo_{18}O_{52}$ is shown in Figure 10. Evidently, adding $Mo_{18}O_{52}$ to MoO_3 results in a decrease in the amplitude of all backscattering shells, in particular of the higher Mo−Mo shells. However, even for concentrations of $Mo_{18}O_{52}$ as large as 40%, the resulting FT[$\chi(k)$] strongly resembles that of MoO_3.

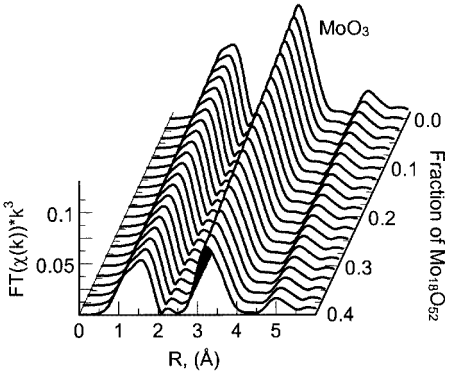

Figure 10. Evolution of Fourier-transformed $\chi(k)$ of calculated mixtures of experimental $\chi(k)$ of MoO_3 and $Mo_{18}O_{52}$, with increasing concentration of $Mo_{18}O_{52}$ (100% to 60% MoO_3)

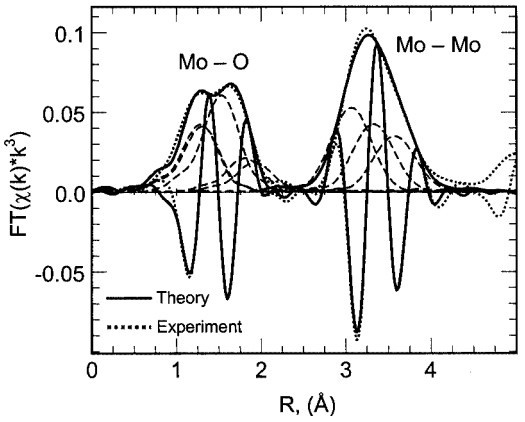

Figure 11. XAFS refinement of a theoretical Mo-K edge $\chi(k)$ (solid) to an experimental Fourier-transformed $\chi(k)$ of MoO_3 (dotted) (Table 1). The main Mo−O and Mo−Mo single-scattering paths are indicated (dashed)

The large number of different distances in the structures of MoO_3 and $Mo_{18}O_{52}$ prevents a conventional XAFS refinement of each individual distance and coordination number. Therefore, using theoretical XAFS phases and amplitudes calculated for the structure of orthorhombic α-MoO_3, structural parameters of the most prominent single-scattering and multiple-scattering paths (Table 1) in MoO_3 were refined to the calculated and measured $\chi(k)$, according to the XAFS analysis procedure described above. Thus, a detailed XAFS analysis of the set of $\chi(k)$ values of the numerical mixtures of MoO_3 and $Mo_{18}O_{52}$ (Figure 10), and the experimental spectra measured during the TPR of propene and oxygen (1:1) in the presence of MoO_3 (Figure 7) was performed to quantify the effect of the contribution of $Mo_{18}O_{52}$ on the structural parameters obtained for the MoO_3 phase. The very good agreement between refinement and experimental data that can be achieved using this fitting procedure is evident from the results of the refinement shown in Figure 11 and Table 1. For the numerical mixtures of MoO_3 and $Mo_{18}O_{52}$, the XAFS refinement procedure described above failed for concentrations of $Mo_{18}O_{52}$ larger than 27%.

The evolution of the Debye temperatures of molybdenum and oxygen backscatterers in the MoO_3 structure as a function of the concentration of $Mo_{18}O_{52}$ in the numerical mixtures and as a function of temperature during the TPR of propene and oxygen are depicted in Figure 12 (a) and Figure 12 (b), respectively. For the numerical mixtures, the Debye temperature of oxygen continuously increases for concentrations of $Mo_{18}O_{52}$ larger than 5%. The Debye temperature of molybdenum decreases linearly over the concentration range studied. For the TPR experiment, both Debye temperatures decrease almost linearly in the temperature range from 300 K to about 620 K. Above about 620 K, the Debye temperature of oxygen greatly increases, whereas the Debye temperature of molybdenum continues to decrease. For the series of XAFS spectra measured during the treatment of MoO_3 in oxygen, the increase of the Debye temperature of oxygen starting at about 620 K is followed by a decrease at temperatures above about 720 K.

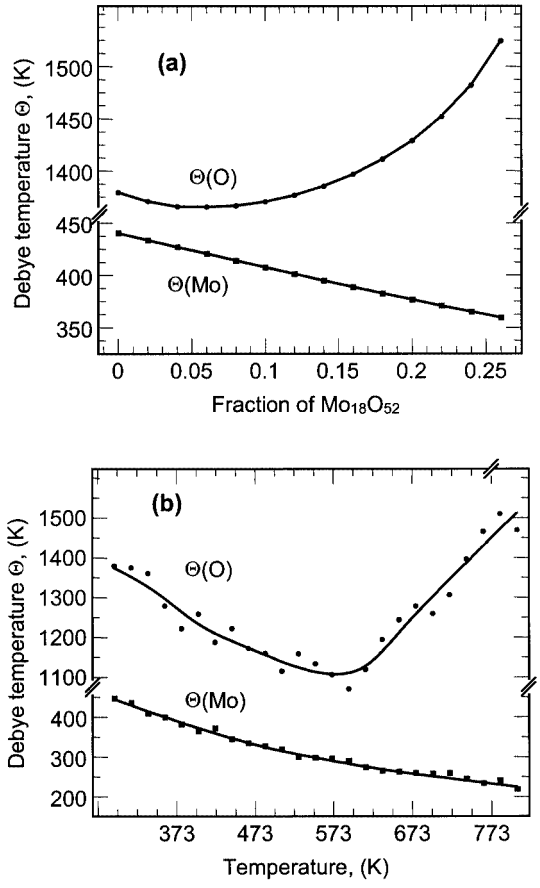

Figure 12. Evolution of Debye temperatures of molybdenum and oxygen backscatterers in the structure of MoO_3 obtained from XAFS refinement, (a) as a function of the concentration of $Mo_{18}O_{52}$ in the mixtures of MoO_3 and $Mo_{18}O_{52}$ in Figure 10 and (b) during the temperature-programmed reaction of propene and oxygen in the presence of MoO_3 (Figure 7) (10% O_2 and 10% propene in He) (300−773 K, 5 K/min, held at 773)

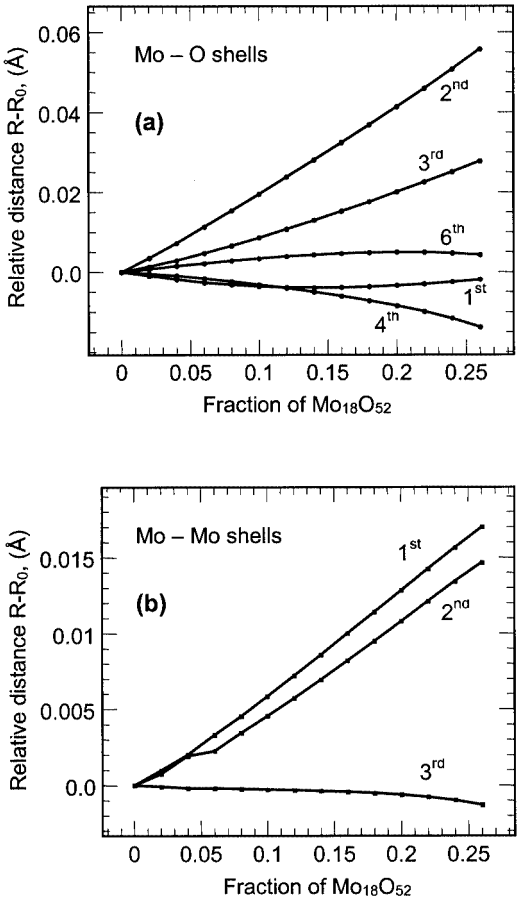

Figure 13. Evolution of relative Mo−O (a) (R_0 1st = 1.683 Å, 2nd = 1.710 Å, 3rd = 1.938 Å, 4th = 2.227 Å, 6th = 2.349 Å) and Mo−Mo (b) (R_0 1st = 3.421 Å, 2nd = 3.693 Å, 3rd = 3.946 Å) distances in the structure of MoO_3 obtained from XAFS refinement to the mixtures of MoO_3 and $Mo_{18}O_{52}$ in Figure 10

The evolution of the Mo−O and Mo−Mo distances in the first neighboring shells of the structure of MoO_3 as a function of the concentration of $Mo_{18}O_{52}$ in the numerical mixtures is displayed in Figure 13 (a and b), respectively. Figure 14 (a and b) show the evolution of Mo−O and Mo−Mo distances during the TPR of propene and oxygen. For the numerical mixtures, a pattern of increasing and decreasing distances are seen in the Mo−O and Mo−Mo distances. For the TPR experiment, there is a minor increase in the Mo−O distances in the temperature range from 300 K to about 620 K, corresponding to the anisotropic thermal expansion of MoO_3. At temperatures above about 620 K, several Mo−O distances show a strong deviation from their behavior at lower temperatures, resulting in a pattern of increasing and decreasing Mo−O distances very similar to that observed for the numerical mixtures. At temperatures above about 620 K, the Mo−Mo distances show a distinct deviation from their behavior at temperatures between 300 K and 620 K.

In order to validate the analysis procedure chosen, the suitability of other suboxides (i.e. Mo_4O_{11}, Mo_5O_{14}, and Mo_8O_{23}) to explain the deviations observed in the XAFS fit parameters was tested accordingly. Addition of more than 10% of Mo_4O_{11} and Mo_8O_{23} resulted in a considerable distortion of the FT[$\chi(k)$] and, hence, the failure of the XAFS fitting procedure used. For tetragonal Mo_5O_{14}, the radial distribution function also consists of a number of slightly different Mo−O and Mo−Mo distances. However, the XAFS parameters obtained from an analysis of numerical mixtures of the experimental $\chi(k)$ of MoO_3 and Mo_5O_{14} did not exhibit the characteristic increase in the Debye temperature of oxygen, or the characteristic pattern of increasing and decreasing Mo−O distances at temperatures above about 620 K. Hence, of the suboxides tested, only the shear-structure $Mo_{18}O_{52}$ constitutes a suitable reference for the type of defects observed in MoO_3 under reaction conditions.

Discussion

Changes in the bulk structure of an alkene oxidation catalyst under reaction conditions can occur when the lat-

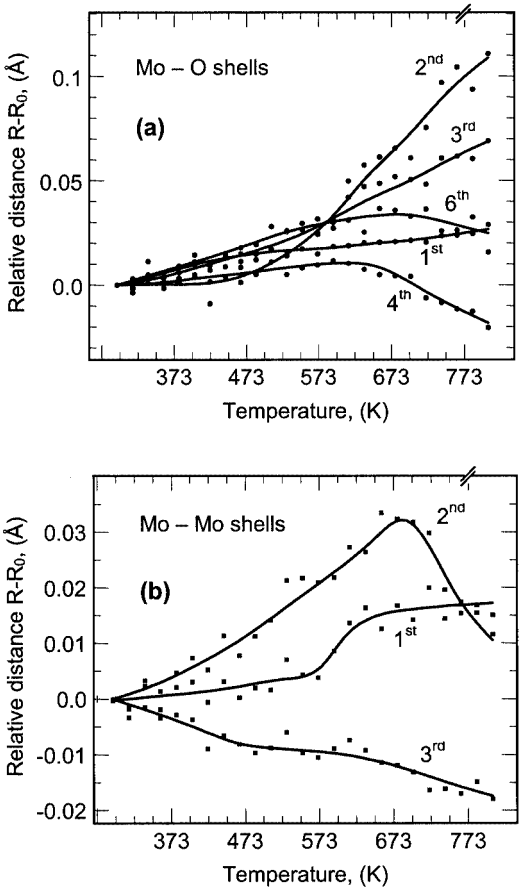

Figure 14. Evolution of relative Mo−O (a) and Mo−Mo (b) distances in the structure of MoO_3 during the temperature-programmed reaction of propene and oxygen in the presence of MoO_3 (Figure 7) (10% O_2 and 10% propene in He) (300−773 K, 5 K/min, held at 773)

tice oxygen of the catalyst participates in the oxidation of the alkene (''redox'' mechanism), and if the corresponding reduction and re-oxidation of the catalyst bulk proceed at different rates. In this work we investigated the evolution of the bulk structure of MoO_3, in combination with the catalytic activity under the reaction conditions of propene oxidation by oxygen. In order to reveal structure-reactivity relationships for MoO_3, this study focused on two characteristic features. First, the onset temperature of the oxidation of propene was correlated to changes in the molybdenum average valence and the bulk structure of MoO_3. Second, the nature of the structural defects induced in the layer structure of MoO_3 under reaction conditions was elucidated.

Onset of Reduction of MoO_3 in He, H_2, Propene, and Propene and Oxygen

From the data presented here and in previous reports it becomes evident, that the onset temperature for the reduction of MoO_3 in He (Figure 1), H_2,[13] propene,[10] and propene and oxygen (Figure 4) is approximately the same (≈ 620 K), and independent of the composition of the gas phase. Only in hydrogen, where the incorporation of hydrogen into the MoO_3 lattice facilitates the formation of MoO_2 product nuclei, is the onset temperature slightly shifted towards lower temperatures (≈ 600 K).[20] Apparently, the onset temperature for the reduction of MoO_3 coincides with the attainment of oxygen vacancies in the MoO_3 lattice with sufficient mobility. Only when the molybdenum-oxygen bonds in the MoO_3 lattice are weakened, and the oxygen in the lattice is sufficiently mobile and can participate in oxidation reactions proceeding at the surface of the catalyst, can stoichiometric reduction of MoO_3 with hydrogen or propene take place. Moreover, the onset of the reduction of MoO_3 coincides with the onset of propene oxidation on this material. This holds for both reduction of MoO_3 in propene and for the reaction of propene and oxygen in the presence of MoO_3. Again, it seems that both partial and total oxidation of propene on MoO_3 require a certain mobility of the lattice oxygen of MoO_3 and the formation of partially reduced defects, in order to proceed. Abstraction of a proton from propene to form an allylic species is a necessary prerequisite for the oxidation of propene to proceed on MoO_3 and determines the rate of conversion of propene. However, catalytic activity of MoO_3 is observed only after the Mo−O bonds in the lattice have become sufficiently weak to permit defect formation and activation of oxygen from the gas phase.

Evolution of the Average Valence of MoO_3 under the Reaction Conditions

The degree of reduction and, hence, the degree of defects in MoO_3 under partial oxidation conditions, can be estimated from the average valence of the molybdenum oxide (Figure 5), obtained from comparing the Mo-*K* edge position to that of suitable references. At a temperature of about 620 K, slight reduction of the molybdenum oxide occurs (Figure 4), independent of the composition of the gas phase. This is in agreement with the proposition that in this temperature range the oxygen ions in the lattice are mobile enough to be exchanged with oxygen in the gas phase (in oxygen), or to participate in the oxidation of propene (propene and oxygen), resulting in partially reduced MoO_3. In the temperature range from about 620 K to about 720 K, this partially reduced MoO_3 is not completely reoxidized by the oxygen in the gas phase. This may be because of the different rates of reduction (release of oxygen from the bulk) and re-oxidation of the bulk, or because, within this temperature range, the shear-structure defects formed do not readily back-transform into oxygen vacancies that could diffuse through the bulk to the surface and be filled with oxygen from the gas phase.

At reaction temperatures above about 720 K, re-oxidation of the partially reduced MoO_3 occurs during the treatment of MoO_3 in oxygen, and in propene and oxygen (ratio of 1:5) (Figure 4). Conversely, during the reaction of propene and oxygen (ratio of 1:1 and 1:3), re-oxidation of molybdenum is not detected at reaction temperatures above about 720 K. Apparently, at these ratios, the reducing potential of the gas phase with respect to the MoO_3 bulk is still too high to allow reoxidation of the molybdenum oxide.

Evidently, the ability of the atmosphere to reduce or oxidize the bulk material depends not only on the presence of oxygen in the gas phase, but also on the ratio of the reductant (propene) and the oxidant (oxygen). With an increasing concentration of oxygen, the reducing potential of the gas phase decreases until the partially reduced molybdenum oxide is reoxidized at temperatures above about 720 K.

Bulk Structural Evolution of MoO_3 under the Reaction Conditions

During the treatment of MoO_3 in oxygen or during the TPR in propene and oxygen, MoO_3 remains the only crystalline phase detected. In the temperature-programmed experiments, the evolution of the lattice parameters of MoO_3 is dominated by the anisotropic thermal expansion of MoO_3.[10] Therefore, the analysis described focused on integrated intensities and apparent crystallite sizes calculated for selected *hkl* reflections. The non-uniform behavior of the ratios of integrated intensities and apparent crystallite sizes (i.e. integral breadth) at temperatures above about 620 K (Figure 2 and Figure 3) indicates the formation of characteristic defects in the parent layer structure of MoO_3 without resulting in a long-range ordered separate phase under these reaction conditions. On the basis of our previous results on the reduction of MoO_3 in propene,[10] we suggest that the structure of molybdenum trioxide under propene oxidation reaction conditions corresponds to a defect-rich MoO_3 containing "$Mo_{18}O_{52}$" type defects. The close relationship between the structures of MoO_3 and $Mo_{18}O_{52}$ (Figure 8) facilitates the formation of "$Mo_{18}O_{52}$" type defects under these reaction conditions. Conversely, formation of other partially reduced molybdenum oxides that also contain shear-structures or tetrahedrally coordinated Mo, would require massive restructuring. Hence, they are less probable intermediates or structures formed at temperatures below 700 K. Therefore, the deviations observed in the ratios of integrated intensities (*h0l* > *hk0*, *hkl*) and apparent crystallite sizes, and the increase of strain in the MoO_3 lattice at temperatures above about 620 K, are caused by the formation of shear-structural defects (e.g. Wadsley defects) in the layer structure of MoO_3 under the reaction conditions (Figure 2 and Figure 3). In future work, these characteristic deviations may serve as starting points for a detailed investigation of the structural relationships between MoO_3 and $Mo_{18}O_{52}$, and of the effects of a transition between the two structures on the XRD patterns measured under reaction conditions.

The number of "$Mo_{18}O_{52}$" type defects formed cannot readily be estimated from the effect on the Fourier transform of the Mo-*K* edge XAFS measured under reaction conditions. A comparison of the radial distribution functions of MoO_3 and $Mo_{18}O_{52}$ for a 1 nm cluster (Figure 9) indicates that because of the large number of slightly different distances in the structure of $Mo_{18}O_{52}$, the magnitude of the Fourier transform of $Mo_{18}O_{52}$ is considerably smaller than that of MoO_3. Hence, even major fractions of $Mo_{18}O_{52}$ in MoO_3 may hardly be noticed from changes in the MoO_3 Fourier transform (Figure 10). Thus, the Mo-*K* XAFS spectra of MoO_3 under the reaction conditions correspond largely to that of pure defect-free MoO_3 (Figure 7) at elevated temperatures. The considerable number of defects in the MoO_3 structure (≈ 25% as estimated from the average Mo valence) is only accessible from their second order influence on the structural parameters, as obtained from an XAFS refinement of a MoO_3 model structure to the spectra of MoO_3 under reaction conditions (Figure 11).

Simulating the effect of the presence of "$Mo_{18}O_{52}$" in MoO_3 by calculating XAFS functions that correspond to mixtures of these two oxides, resulted in characteristic deviations in the XAFS fit parameters obtained for MoO_3 [i.e. increase in the Debye temperatures, and increase and decrease in the Mo−O distances in the 1st coordination shell, Figure 12, part (a) and Figure 13]. For the experimental spectra measured under the reaction conditions, at temperatures below about 620 K, the evolution of the XAFS fit parameters is dominated by the regular effect of the increasing reaction temperature [i.e. decreasing Debye temperatures and slightly increasing Mo−O distances, Figure 12, part (b) and Figure 14]. However, at temperatures above about 620 K, the oxygen Debye temperatures increase drastically, while the Mo−O distances in the 1st coordination shell exhibit a characteristic pattern of increasing and decreasing distances. The deviations observed in the XAFS fit parameters obtained for MoO_3 under reaction conditions at temperatures above about 620 K are similar to those obtained for the analysis of the mixtures of MoO_3 and $Mo_{18}O_{52}$. Therefore, the XAFS analysis of the Mo-*K* edge spectra measured under the reaction conditions corroborates the formation of "$Mo_{18}O_{52}$" type defects in the layer structure of MoO_3 during oxidation of propene at temperatures below 720 K.

Regarding the evolution of the bulk structure of MoO_3 in a reducing atmosphere of propene and oxygen (ratio of 1:1) at temperatures above 720 K, two possibilities with respect to the formation of oxygen vacancies can be envisioned. First, the "$Mo_{18}O_{52}$" type defects in the structure vanish at the expense of an increasing number of free oxygen vacancies in the MoO_3 structure. This would result in an average valence below 6.0 and an overall structure of the material close to that of MoO_3. Second, the "$Mo_{18}O_{52}$" type defects persist even at higher temperatures, resulting in an average valence below 6.0 and a disturbed bulk structure of MoO_3. The experimental data shown corroborate the second possibility (Figure 5, Figure 12, and Figure 13). Apparently, this very dynamic system under these reaction conditions is not governed by the energy necessary to break up the "$Mo_{18}O_{52}$" type defects and to form vacancies that can be filled with gas phase oxygen. Instead, the density of vacancies in the MoO_3 layer structure, resulting from the ratio of the rate of reduction of the MoO_3 lattice by propene and the rate of re-oxidation by gas phase oxygen, energetically favors the shear-structure defects, rather than the free oxygen vacancies.[21,22] Only at an increased oxygen partial pressure and temperatures above about 720 K, is the rate of re-oxidation of the MoO_3 lattice sufficient to allow the release of oxygen vacancies from the shear-structure de-

fects and, subsequently, filling of the oxygen vacancies by gas phase oxygen.

A schematic model for the behavior of MoO_3 under propene oxidation conditions is depicted in Figure 15.

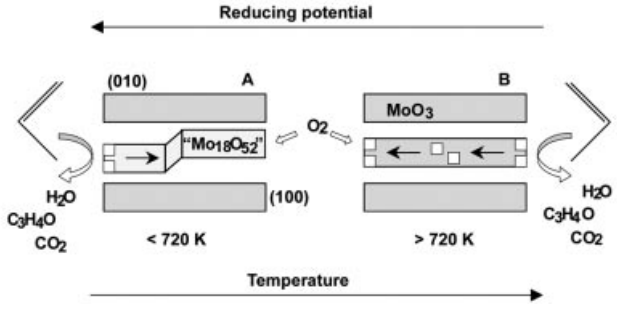

Figure 15. Schematic representation of the structure of MoO_3 under the reaction conditions (propene and oxygen), as a function of temperature and reducing potential of the gas phase. A) Below 720 K, **or** in a reducing gas phase. B) Above 720 K, **and** in an oxidizing gas phase. "$Mo_{18}O_{52}$" refers to crystallographic-shear type defects in the MoO_3 structure (squares indicate oxygen vacancies)

Oxygen vacancies are generated mostly at the side facets of the MoO_3 layer structure and can diffuse easily along the [100] or the [001] direction into the bulk.[23–26] Evidently, both reaction temperature and the reducing potential of the gas phase influence the bulk structure of the molybdenum oxide material under reaction conditions. By varying the reducing potential in the gas phase, the degree of reduction of the MoO_3 bulk can be adjusted. If the gas phase becomes oxidizing with respect to the bulk, at temperatures above about 720 K re-oxidation of the "$Mo_{18}O_{52}$" type defects in the MoO_3 layer structure takes place (B in Figure 15). Conversely, under a reducing atmosphere with respect to the MoO_3 bulk, "$Mo_{18}O_{52}$" type defects persist in the MoO_3 structure and the material is not completely reoxidized at elevated temperatures (A in Figure 15).

Evidently, under propene oxidation reaction conditions, the structure of the molybdenum oxide catalyst is not identical to that of the initial MoO_3. Rather, given the oxidation and reduction kinetics of molybdenum oxides at temperatures below about 720 K, the material corresponds to partially reduced metastable MoO_3 with a considerable number of "$Mo_{18}O_{52}$" type defects in the parent layer structure. From Figure 6 it can be seen that the catalytically most active and selective molybdenum oxide phase for propene oxidation to form acrolein develops under the reaction conditions. Possibly, a certain number of "$Mo_{18}O_{52}$" type defects have to be present in the bulk structure of MoO_3 to result in an improved selectivity in the partial oxidation of propene in the presence of MoO_3. The minor total oxidation activity at temperatures below about 600 K (Figure 6), which is not accompanied by a change in the average valence of the molybdenum oxide, may be assigned to adsorbed oxygen species.[27] However, a detailed analysis of the effect of oxygen partial pressure and temperature on the reactivity and selectivity of MoO_3 is not the subject of this report and shall be pursued in future studies. Furthermore, molybdenum trioxide obtained by various preparation routes will be investigated to elucidate the dependence of the defect type and the catalytic properties on the preparation conditions. In order to obtain more active and selective molybdenum oxide phases (e.g. Mo_5O_{14}), ternary oxides such as mixed molybdenum vanadium oxides are needed. It has to be clarified if these oxides need to be prepared, or if they can be obtained as binary molybdenum oxides by careful tailoring of the preparation conditions.

Many of the attempts to reveal the catalytic properties of MoO_3 described in the literature are restricted to "post-mortem" investigations, or studies on stoichiometric reactions involving molybdenum oxides and, for instance, oxidation by oxygen, or reduction by hydrogen or propene. Those investigations are valuable to elucidate the structural evolution of the material under noncatalytic conditions. Our previous investigations on the reduction and re-oxidation of MoO_3 allowed us to interpret the structural changes described here. However, only investigating the catalyst under reaction conditions (in situ) employing the modern in situ techniques available will eventually result in a complete description of the evolution of the bulk structure of the catalytically relevant material.

Naturally, an investigation of the evolution of the bulk structure of MoO_3 under reaction conditions cannot provide information on the individual steps of the partial oxidation of propene proceeding on the surface of the molybdenum oxide material used. However, while studying these surface reaction steps on defined model systems such as thin films or molecular molybdenum oxides, one needs to be aware of the importance of the bulk structure for the catalytic properties of a "real" heterogeneous catalyst. Attempting to access the reactivity of individual molybdenum oxide polyhedra, in order to model partial oxidation reactions proceeding on the surface of a bulk molybdenum oxide catalyst, requires taking into account the paramount role of the underlying bulk structure of the catalyst. By neglecting either the bulk or the surface, all the properties essential for the material to function as a heterogeneous catalyst cannot be comprehended and, hence, any attempts to design an improved catalyst based on this incomplete picture will fail. Eventually, a rational design of a most active heterogeneous catalyst will only be possible if both the structure and reactions of the surface, and the structure and reactions of the bulk are adequately understood and considered.

Conclusion

In this work we presented investigations on the evolution of characteristic defects in the bulk structure of MoO_3 under propene oxidation conditions using in situ X-ray absorption spectroscopy and X-ray diffraction. Under the reaction conditions employed (273 K to 773 K, and propene to oxygen ratios from 1:1 to 1:5), MoO_3 remains the only crystalline phase detected by XRD. The onset temperature for the temperature-programmed reaction of propene and oxygen in the presence of MoO_3 coincides with the onset

of the reduction of MoO_3 in He, H_2, or propene ($\approx$ 620 K). Thus, the weakening of Mo−O bonds in MoO_3, the sufficient mobility of oxygen ions, and the formation of defects are essential for the reduction of MoO_3 and for its function as a heterogeneous catalyst.

Various in situ experiments indicate that the structural evolution of MoO_3 during the TPR, reduction, and treatment in He is surprisingly similar. At temperatures below about 720 K, and independent of the atmosphere used, partial reduction of MoO_3 is observed, resulting in the formation of "$Mo_{18}O_{52}$" type defects in the bulk structure. At temperatures above about 720 K, and in oxygen or in an oxidizing atmosphere (sufficiently low propene to oxygen ratio), the "$Mo_{18}O_{52}$" type defects are reoxidized to MoO_3. Evidently, the catalytically active molybdenum oxide phase under partial oxidation conditions at temperatures below 720 K does not correspond to the original MoO_3 possessing the undisturbed ideal layer structure of orthorhombic α-MoO_3. Instead, at these temperatures, the catalytically active phase, which is partially reduced and possesses a large number of "$Mo_{18}O_{52}$" type defects (crystallographic-shear structures) in the layer structure of MoO_3, develops under reaction conditions.

The results presented clearly show the necessity and the great potential for bulk structural investigations of heterogeneous catalysts under reaction conditions. Evidently, the bulk structure and particularly the type and number of defects in the material ("real" structure) considerably affect the catalytic properties. Hence, in order to rationally design a most active heterogeneous catalyst, both the structure and reactions of the surface, and the structure, defects, and reactions of the bulk need to be known in detail, and carefully considered.

Experimental Section

MoO_3 Preparation and Characterization

Molybdenum trioxide (MoO_3) was prepared by thermal decomposition of ammonium heptamolybdate (AHM), $(NH_4)_6Mo_7O_{24}{\cdot}4H_2O$[28] (Aldrich Co.), under a stream of synthetic air (room temp. − 773 K with 2 K/min, held for 2 h at 773 K). The phase purity of the compound obtained was verified by XRD. The molybdenum trioxide used in this study is identical to that used in ref. 10 and 11.[10,11]

X-ray Diffraction

In situ XRD experiments were performed on a STOE STADI P powder diffractometer equipped with a secondary monochromator (Cu-K_α radiation) and a scintillation counter operated in the stepping mode. The in situ cell consisted of a Bühler HDK S1 high temperature diffraction chamber. The gas phase composition at the cell outlet was analyzed on line with a Pfeiffer Prisma 200 quadropole mass spectrometer in the multiple ion detection mode. In situ XRD measurements were conducted under atmospheric pressure with flowing reactants ($\approx$ 100 mL/min). Details on the XRD setup used can be found elsewhere.[11] Crystallite sizes were calculated from the integral breadth of selected *hkl* reflections using the Scherrer formula.[29]

In situ X-ray Absorption Spectroscopy

For in situ XAS experiments, MoO_3 was mixed with boron nitride (ratio 1:4) and 37 mg of the mixture was pressed with a force of 1 ton into a 5 mm diameter self-supporting pellet. The absorption jump, $\Delta\mu x$, at the Mo-*K* edge was about 1.5. In situ XAS experiments were performed in transmission in a flow-reactor[30] at atmospheric pressure with flowing reactants ($\approx$ 30 mL/min). The gas phase composition at the cell outlet was continuously monitored using a mass spectrometer in the multiple ion detection mode (QMS200 from Pfeiffer). Further details about the experimental XAS set-up used can be found in ref.[11].

In situ transmission XAS experiments were performed at the Mo-*K* edge (19.999 keV) at beamline X1 at the Hamburg Synchrotron Radiation Laboratory, HASYLAB, using a Si(311) double crystal monochromator (measuring time about 4.5 min/scan). The storage ring operated at 4.4 GeV with injection currents of 150 mA. Time-resolved in situ XAS experiments were carried out at the Mo-*K* edge utilizing an energy-dispersive spectrometer (European Synchrotron Radiation Facility, ESRF, ID24[31]) equipped with a curved Si(111) polychromator in the transmission mode[32] (measuring time about 3 s/scan). The storage ring operated at 6.0 GeV with injection currents of 90 mA in the 16-bunch mode.

XAFS Data Analysis

X-ray absorption fine structure (XAFS) analysis was performed using the software package WinXAS v2.2,[33] following recommended procedures from the literature.[34] Background subtraction and normalization were carried out by fitting linear polynomials to the pre-edge and the post-edge region of an absorption spectrum. The Mo-*K* edge absorption threshold was determined from the first root in the first derivative of the near-edge region (XANES). Principal component analysis (PCA)[35] was used to identify the number and type of Mo oxide phases[10] present during the thermal treatment of MoO_3 under various atmospheres.

The X-ray absorption fine structure (EXAFS) $\chi(k)$ was extracted by using cubic splines to obtain a smooth atomic background, $\mu_0(k)$. The radial distribution function $FT[\chi(k)]$ was calculated by Fourier transformation of the k^3-weighted experimental $\chi(k)$ function, multiplied by a Bessel window, into the R space. EXAFS data analysis was performed using theoretical backscattering phases and amplitudes calculated with the ab initio multiple-scattering code FEFF7.[36] Single scattering and multiple scattering paths in the MoO_3 model structure were calculated up to 5.0 Å, with a lower limit of 2.0% in amplitude with respect to the strongest backscattering path. EXAFS refinements were performed in the *R* space to the magnitude and the imaginary part of a Fourier-transformed k^3-weighted experimental $\chi(k)$, by using the standard EXAFS formula (k range from 3.1 to 15.4 $Å^{-1}$, *R* range 0.9 to 4.1 Å).[37] Structural parameters that were determined by a least-squares EXAFS fit to the experimental spectra are (i) one E_0 shift for oxygen and molybdenum backscatterers, (ii) two Debye temperatures for oxygen and molybdenum backscatterers, (iii) distances of the single-scattering paths with an amplitude larger than 10% were allowed to vary, distances of multiple-scattering paths were correlated to the corresponding single-scattering paths, (iv) one third cumulant for all scattering paths. Coordination numbers (CN) were kept constant in the refinement.

Acknowledgments

The synchrotron radiation facilities HASYLAB, Hamburg, Germany, and ESRF, Grenoble, France, are acknowledged for provid-

ing beamtime for this work. TR thanks the Deutsche Forschungsgemeinschaft, DFG, for financial support (Habilitations-Stipendium). T. Neisius and O. Timpe are acknowledged for participating in the XAS experiments. The authors are grateful to Prof. R. Schlögl for many fruitful discussions and continuous support.

[(η⁶-Cyclooctatetraene){η⁵-(+)-neomenthylcyclopentadienyl}ruthenium(II)] Hexafluorophosphate: Synthesis and Characterization of a Chiral Mixed Sandwich Complex

Xiaofeng Zhang,[a][‡] Marc H. Prosenc,[a] Timo Meyer-Friedrichsen,[a][‡‡] and Jürgen Heck*[a]

Dedicated to Prof. Dr. Rüdiger Mews on the occasion of his 60th birthday

Keywords: Chirality / Cyclopentadienyl ligands / Sandwich complexes / Ruthenium

Three different {η⁵-(+)-neomenthylcyclopentadienyl}ruthenium complexes have been synthesized from (–)-menthol: [(η⁶-benzene){η⁵-(+)-neomenthylcyclopentadienyl}ruthenium(II)] hexafluorophosphate (**1**), [tris(acetonitrile){η⁵-(+)-neomenthylcyclopentadienyl}ruthenium(II)] hexafluorophosphate (**2**) and [(η⁶-cyclooctatetraene){η⁵-(+)-neomenthylcyclopentadienyl}ruthenium(II)] hexafluorophosphate (**3**). X-ray structural determination (space group $P2_12_12_1$) and NMR spectroscopic studies of **3** show it exists as a single stereoisomer in both the solid and solution phase, with $[\alpha]_D^{20} = +92.5$. The chiral modification of the Cp ligand induces anisochrony for all of the magnetically active nuclei of the unsubstituted COT ligand.

(© Wiley-VCH Verlag GmbH & Co KGaA, 69451 Weinheim, Germany, 2003)

Introduction

Iterative nucleophilic and electrophilic addition to a coordinated cyclooctatetraene (COT) in $[(\eta^6\text{-COT})(\eta^5\text{-Cp})M]^+$ (Cp = cyclopentadienyl; M = Fe, Ru) has been shown to be a powerful tool for the formation of stereo- and regioselectively substituted cycloocta-1,3-dienes.[1,2] Since the first nucleophilic addition creates a stereogenic carbon atom in the *cyclo*-C_8 ligand (Figure 1), we attempted to synthesize a starting COT complex containing a chiral modified Cp ligand, which would be expected to influence the stereochemical selectivity of the initial nucleophilic addition. We chose the (+)-neomenthyl substituent as a chiral auxiliary on the cyclopentadienyl ring [(+)-NMCp];[3] this has widely been used in the synthesis of Cp complexes active in enantioselective transformations.[4]

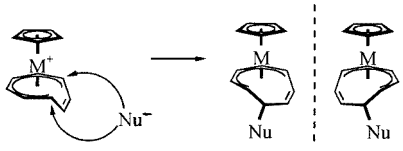

Figure 1. Nucleophilic attack on the two enantiotopic sites in $[(\eta^6\text{-COT})(\eta^5\text{-Cp})M]^+$ (M = Fe, Ru)

Results and Discussion

Synthesis

(+)-Neomenthylcyclopentadiene [(+)-NMCpH] was prepared according to a known procedure[3] and subsequently transformed into the thallium salt by addition of TlOEt (Scheme 1).

The thallium salt [(+)-NMCp]Tl reacts with $[(\eta^6\text{-}C_6H_6)RuCl_2]_2$ [5] in acetonitrile, yielding $[(\eta^6\text{-}C_6H_6)\{\eta^5\text{-}(+)\text{-NMCp}\}Ru]X$ [X = Cl, Scheme 1, b; X = PF_6 (**1**), Scheme 1, c]. Irradiation of complex **1** in acetonitrile with a high-pressure mercury lamp gives the {η⁵-(+)-NMCp}Ru half-sandwich complex **2**. Addition of COT to a solution of **2** in acetonitrile affords product **3** as a light yellow powder in very good yields. Crystals of **3** are air-stable and soluble in dichloromethane but almost insoluble in diethyl ether.

X-ray Structure Analysis

Crystals of **3** suitable for X-ray structural analysis were grown by slow diffusion of diethyl ether into a CH_2Cl_2 solution of **3** at room temperature. Data collection parameters and selected bond lengths and angles are listed in Table 1 and Table 2, respectively. Complex **3** crystallizes in the chiral orthorhombic space group $P2_12_12_1$. The cation (Fig-

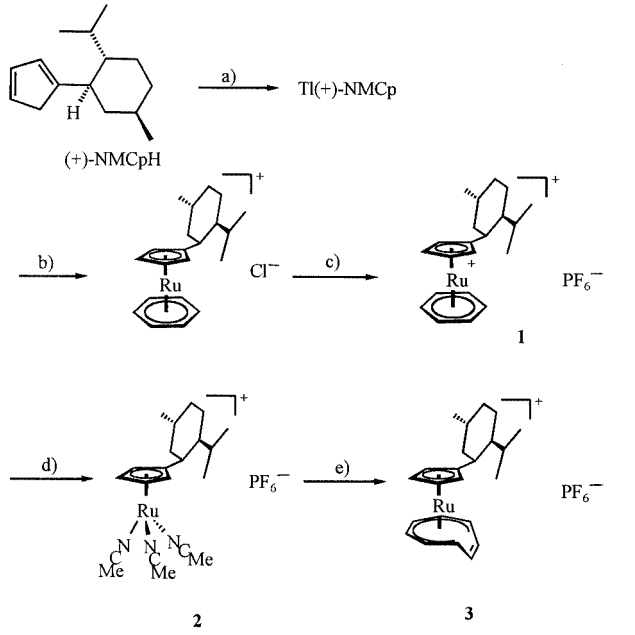

Scheme 1. Synthesis of [(η⁶-cyclooctatetraene){η⁵-(+)-neomenthylcyclopentadienyl}ruthenium(II)] hexafluorophosphate (**3**): a) TlOEt, THF, room temperature; b) MeCN, $[(\eta^6\text{-}C_6H_6)RuCl_2]_2$, room temperature; c) MeOH, NH_4PF_6; d) MeCN, hν; e) COT, MeCN

ure 2) adopts a typical sandwich-like structure with the Cp ligand and the η⁶-coordinated part of the COT ligand almost parallel. The uncoordinated double bond of the COT ligand, C7−C8, protrudes from the plane of the metal-bound carbon atoms *exo* with respect to the metal center. The dihedral angle between the "best" planes of the coordinated carbon atoms C1−C2−C5−C6 and of the carbon atoms C1−C6−C7−C8 is 120°, very similar to the corresponding structural feature in $[(\eta^6\text{-COT})(\eta^5\text{-Cp})Fe]^+$.[6] The COT ring exhibits slight rotational disorder by a torsion around the axis connecting the Ru atom and the six coordinated carbon atoms. This results in large anisotropic temperature factors for the atoms in the COT ring and a very short C7−C8 bond length of 128.9(3) pm (typical C=C double bond length of 134 pm).

Attempts to resolve this disorder did not improve the model; the *R*1 value rises about 0.5% and standard deviations increase as well. Most notably, the C7−C8 bond lengths in the disordered model were not chemically sensible; a nondisordered model was thus used and refined anisotropically. The Ru−C(COT) bond lengths of 214.1−222.6 pm are in the typical range of cationic $(\eta^6\text{-}cyclo\text{-}C_8)Ru$ complexes.[1b] The distances between the Ru center and the carbon atoms of the Cp ligand of 218.1(2)−222.98(19) pm correspond to Ru−C(Cp) bond lengths of other cationic CpRu complexes[7] except for the bond to C9 [226.14(16) pm], the atom which bears the (+)-neomenthyl substituent. This slight elongation of the Ru−C9 bond may be due to packing effects within the crystal.

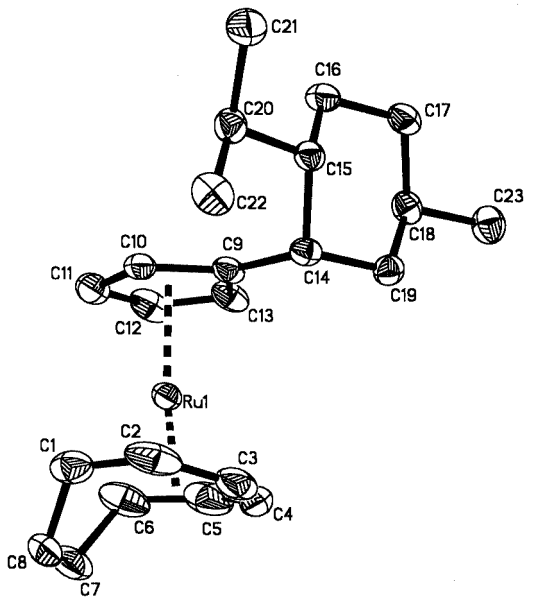

Figure 2. Molecular structure of [(η^6-cyclooctatetraene){η^5-(+)-neomenthylcyclopentadienyl}ruthenium(II)] hexafluorophosphate (**3**); thermal ellipsoids are drawn at the 50% probability level and the hydrogen atoms and the PF_6^- counterion are omitted for clarity

The most important result of this structural analysis is the unambiguous identification of the presence of only one stereoisomer, the (+)-neomenthyl derivative; this is also confirmed by ^1H and ^{13}C NMR spectra of **3** (vide infra). The (+)-neomenthyl substituent adopts a conformation which places it at the most remote position with respect to the sandwich moiety.

NMR Spectroscopy

Complex **3** displays ^1H and ^{13}C NMR signals due to the (+)-neomenthyl substituent (^1H: δ = 0.7−2.9 ppm; ^{13}C: δ = 20−50 ppm), and the Cp and COT ligands (^1H: δ = 5.0−6.3 ppm; ^{13}C: δ = 82−138 ppm). The ^1H and ^{13}C chemical shifts of the metal-bound hydrocarbon units clearly testify to the cationic nature of **3**,[1b] and the number of signals confirms the formation of a single stereoisomer. Due to the chiral (+)-neomenthyl substituent all of the Cp protons are inequivalent and give rise to four multiplets in the range δ = 5.3−5.6 ppm, consistent with the chemical shifts observed in other monocationic CpRu sandwich complexes.[1,8]

Remarkably, the chiral (+)-neomenthyl substituent also induces anisochrony in all of the nuclei of the COT ligand. In Figure 3, both experimental (bottom) and calculated (top) ^1H NMR spectra of the COT region display signals due to eight chemically inequivalent hydrogen atoms. Even the uncoordinated C=C double bond, which is most distant from the chiral neomenthyl group, displays two different resonance signals in the ^1H and ^{13}C NMR spectra (δ = 5.0840 and 5.0934 ppm for 7-H and 8-H, δ =134.99 and 135.07 ppm for C-7 and C-8). The largest shift difference of the resonance signals of nuclei which are equivalent in the COT ligand of a corresponding complex without a chiral induction, for example [(η^5-Cp)Ru(η^6-COT)]$^+$, is found for 1-H and 6-H (δ = 5.6937 and 5.7903 ppm), and C-3 and C-4 (δ = 104.1 and 103.2 ppm).

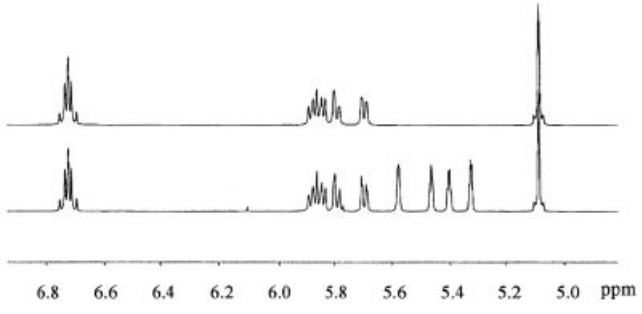

Figure 3. Experimental (bottom) and calculated (top) ^1H NMR spectra of [(η^6-cyclooctatetraene){η^5-(+)-neomenthylcyclopentadienyl}ruthenium(II)] hexafluorophosphate (**3**); signals due to theCp ligand are omitted from the calculated spectrum for simplicity [parameters used for the calculation: δ = 5.0840, 5.0934 (7-H, 8-H), 5.6937, 5.7903 (1-H, 6-H), 5.8419, 5.8717 (2-H, 5-H), 6.7085, 6.7294 ppm (3-H, 4-H); $^3J_{1\text{-}2}$ = 8.474, $^3J_{1\text{-}8}$ = 2.644, $^3J_{2\text{-}3}$ = 6.940, $^3J_{3\text{-}4}$ = 8.963, $^3J_{4\text{-}5}$ = 6.968, $^3J_{5\text{-}6}$ = 8.764, $^3J_{6\text{-}7}$ = 2.514, $^3J_{7\text{-}8}$ = 6.558 Hz; significant changes in the calculated spectra are observed on changing the shifts by 0.001 ppm and the coupling constants by 0.001 Hz]

Optical Activity

A specific optical rotation of $[\alpha]_D^{20}$= +92.5 was determined for **3**. The optical activity of complex **3** is consistent with a Cotton effect observed in CD spectra of **3**, which is negative for the electronic absorption at higher energy (λ = 267 nm: [θ] = −6760 °·L·mol^{-1}·cm^{-1}) and positive at lower energy (λ = 325 nm: [θ] = +3500 °·L·mol^{-1}·cm^{-1}). Since the molar extinction coefficient of these absorption bands is very low [ε (267 nm) = 1726 L·mol^{-1}·cm^{-1}; ε (325 nm) = 673 L·mol^{-1}·cm^{-1}], we assign these Cotton effects to d-d transitions.

Conclusions

The introduction of the chiral (+)-neomenthyl substituent on the cyclopentadienyl ligand allows the synthesis of the [(η^6-cyclooctatetraene){η^5-(+)-neomenthylcyclopentadienyl}ruthenium(II)] cation, which is the first structurally characterized chiral cyclooctatetraene complex. The chiral Cp ligand even induces inequivalence at all positions of the COT ligand as demonstrated by NMR experiments. This inequivalence suggests that chiral induction in nucleophilic additions to the COT ligand may be possible, and this is currently under investigation.

Experimental Section

General: All reactions were carried out under nitrogen. Solvents were saturated with nitrogen and freshly distilled from an appropriate drying agent. NMR: Bruker WM 500, AM 360 and Varian

Gemini 200. IR (KBr disks): FT-IR 1720 X (Perkin−Elmer). UV/Vis (MeCN solution): Perkin−Elmer, Model 554. CD (MeCN solution): Jasco, Model J 500-C. Elemental analysis: Heraeus-CHN-O-Rapid (Zentrale Elementanalytik, Fachbereich Chemie, Universität Hamburg). (+)-Neomenthylcyclopentadiene[3] and $[(\eta^6\text{-}C_6H_6)RuCl_2]_2$ [5] were synthesized according to literature procedures. $RuCl_3{\cdot}xH_2O$ was a gift from Degussa AG. Cyclohexadiene and TlOEt were purchased from Aldrich and Merck, respectively.

[(+)-Neomenthylcyclopentadienyl]thallium: A solution of TlOEt (4.0 mL, 56.1 mmol) in THF (10 mL) was added to a solution of (+)-NMCpH (11.27 g, 55.1 mmol) in THF (120 mL) at room temperature. After stirring for 17 h, about 100 mL of the solvent was evaporated in vacuo. The resulting off-white precipitate was collected on a filter and washed with small amounts of toluene. The solid material was dried in vacuo. Yield: 6.98 g (31.1%) of [(+)-NMCp]Tl. The product is air-sensitive and was used without further purification.

[(η^6-Benzene){η^5-(+)-neomenthylcyclopentadienyl}ruthenium(II)] Hexafluorophosphate (1): Solid [(+)-NMCp]Tl (5.9 g, 14.47 mmol) was added to a suspension of $[(\eta^6\text{-}C_6H_6)RuCl_2]_2$ (3.14 g, 6.28 mmol) in acetonitrile (300 mL). After stirring at room temperature for 20 h, the reaction mixture was filtered through Celite and the filter was washed four times with 10 mL of acetonitrile. The acetonitrile solution was concentrated to dryness, and the residue was dissolved in absolute methanol (40 mL). Solid NH_4PF_6 (2.21 g, 13.56 mmol) was added to the methanol solution, whereupon the product precipitated. After 3.5 h of stirring, the reaction mixture was filtered, and the solid material was washed three times with methanol and once with diethyl ether. The light yellow solid material was dried in vacuo yielding 4.30 g (64.9%) of **1**. IR: $\tilde{\nu}$ = 3094 (m), 2943 (s), 2871 (m), 2845 (m), 1443 (s), 1410 (m), 1391 (m), 1382 (w), 1367 (w), 840 (broad vs), 558 (vs), 443 (m), 423 (m) cm^{-1}. ^1H NMR (360 MHz, CD_3CN): δ = 0.727 (d, ^3J = 6.5 Hz, 3 H, Me), 0.882 (d, ^3J = 6.4 Hz, 3 H, Me), 0.930 (d, ^3J = 6.3 Hz, 3 H, Me), 0.84−1.17 [m, 3 H, (+)-neomenthyl], 1.22 [m, 1 H, (+)-neomenthyl], 1.60−1.82 [m, 4 H, (+)-neomenthyl], 2.80 [m, 1 H, (+)-neomenthyl], 5.21 (m, 1 H, Cp), 5.25 (m, 1 H, Cp), 5.32 (m, 1 H, Cp), 5.44 (m, 1 H, Cp), 6.10 (s, 6 H, C_6H_6) ppm. ^{13}C NMR (50 MHz, CD_3CN): δ = 20.76, 22.05, 23.02, 24.87, 28.42, 30.26, 35.78, 36.26, 44.25, 48.46 [(+)-neomenthyl], 79.05 (Cp), 80.46 (Cp), 82.37 (Cp), 83.48 (Cp), 87.13 (C_6H_6), 118.25 (C_qCp) ppm. $C_{21}H_{29}F_6PRu$ (527.50): calcd. C 47.82, H 5.54; found C 48.18, H 5.74.

[Tris(acetonitrile){η^5-(+)-neomenthylcyclopentadienyl}-ruthenium(II)] Hexafluorophosphate by Photolysis of 1: A solution of **1** (3.62 g, 6.86 mmol) in acetonitrile (300 mL) was irradiated with a high-pressure Hg lamp for 26 h. The solution was then concentrated to dryness and the residue identified as $[(MeCN)_3(\eta^5\text{-}NMCp)Ru]PF_6$ (**2**) by means of ^1H NMR spectroscopy. This was used for the reaction with COT (vide infra) without further purification. ^1H NMR (200 MHz, CD_2Cl_2): δ = 0.84 (d, ^3J = 6.2 Hz, Me), 0.95 (d, ^3J = 6.2 Hz, Me), 0.97 (d, ^3J = 6.2 Hz, Me), 0.9−1.7 [m, 9 H, (+)-neomenthyl], 2.44 (s, 9 H, MeCN), 2.7 [m, 1 H, (+)-neomenthyl], 4.13 (m, 1 H, Cp), 4.21 (m, 1 H, Cp), 4.30 (m, 1 H, Cp), 4.51 (m, 1 H, Cp) ppm.

[(η^6-Cyclooctatetraene){η^5-(+)-neomenthylcyclopentadienyl}-ruthenium(II)] Hexafluorophosphate (3): COT (3.1 mL, 27.6 mmol) was added to a solution of **2** (3.9 g, 6.8 mmol) in acetonitrile (180 mL). The solution was stirred overnight at room temperature and then concentrated to dryness. The residue was suspended in a mixture of diethyl ether (10 mL) and CH_2Cl_2 (4 mL). The light yellow solid material was filtered and dried in vacuo. Yield: 3.5 g (93%) of **3** as a light yellow powder. IR (KBr): $\tilde{\nu}$ = 3130 (m), 2974 (s), 2952 (s), 2924 (s), 2868 (s), 2853 (s), 2844 (m), 1690 (m), 1460 (s), 1447 (m), 1401 (m), 1386 (s), 1370 (m), 1332 (m), 1148 (m), 831 (vs), 798 (s), 742 (m), 640 (w), 558 (vs), 519 (w), 427 (m), 421 (m) cm^{-1}. ^1H NMR (500 MHz, CD_3CN): δ = 0.709 (d, ^3J = 6.4 Hz, 3 H, Me), 0.874 (d, ^3J = 6.1 Hz, 3 H, Me), 0.929 (d, ^3J = 6.1, 3 H, Me), 0.9−1.5 [m, 3 H, (+)-neomenthyl], 1.28 [m, 1 H, (+)-neomenthyl], 1.44 [m, 1 H, (+)-neomenthyl], 1.65 [m, 2 H, (+)-neomenthyl], 1.82 [m, 1 H, (+)-neomenthyl], 1.97 [m, 1 H, (+)-neomenthyl], 2.87 [m, 1 H, (+)-neomenthyl], 5.084 (m, 1 H, 7-H or 8-H), 5.093 (m, 1 H, 8-H or 7-H), 5.33 (m, 1 H, Cp), 5.40 (m, 1 H, Cp), 5.46 (m, 1 H, Cp), 5.57 (m, 1 H, Cp), 5.694 (dm, 1 H, 1H or 6-H), 5.790 (dm, 1 H, 6-H or 1-H), 5.842 (m, 1 H, 2-H or 5-H), 5.872 (m, 1 H, 5H or 2H), 6.709 (m, 1 H, 3-H or 4-H), 6.729 (m, 1 H, 4-H or 5-H) ppm (the chemical shifts for the COT protons were taken from the calculated spectra, see Figure 3). ^{13}C NMR (50 MHz, CD_3CN): δ = 20.6, 22.0, 22.9, 24.8, 28.7, 30.2, 35.7, 36.3, 43.8, 48.5, [(+)-neomenthyl], 83.0, 84.3, 84.9, 86.9 (Cp), 88.7, 88.9, 94.1, 94.5, 103.2, 104.1 (COT), 114.3 (C_qCp), 134.99, 135.07 (COT) ppm. $[\alpha]_D^{20}$ = +92.5 (*c* = 0.6, CH_2Cl_2). CD (MeCN): λ_{max} (ε, [θ]) = 267 (1726, −6760), 325 (673, +3500) nm ($L{\cdot}mol^{-1}{\cdot}cm^{-1}$, $°{\cdot}L{\cdot}mol^{-1}{\cdot}cm^{-1}$). $C_{23}H_{31}F_6PRu$ (553.52): calcd. C 49.91, H 5.64; found C 49.14, H 5.71.

X-ray Structural Analysis of 3: Suitable crystals were obtained by slow diffusion of diethyl ether into a CH_2Cl_2 solution of **3**. Determination of cell parameters and collection of reflection intensities were carried out using a Bruker−Apex three-circle diffractometer with a CCD detector at −120 °C. An absorption correction was applied using the SADABS Program (see Table 1). The structure was solved by direct methods using SHELXS-97[9] and refined using SHELXL-97.[10] All non-hydrogen atoms were refined anisotropically and the hydrogen atoms were included in calculated positions using a riding model approach. For more details see Table 1. CCDC-188541 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Acknowledgments

This work was supported by the Deutsche Forschungsgemeinschaft (DFG) HE 1309/2 and by the Fonds der Chemischen Industrie. We thank the BASF for the donation of cyclooctatetraene and the Degussa AG for the donation of $RuCl_3$. M. H. P. thanks the DFG for a fellowship PR 654-1/1.

Synthesis and Characterization of Lanthanide(III) Bis(guanidinate) Derivatives and the Catalytic Activity of Methyllanthanide Bis(guanidinate) Complexes for the Polymerization of ε-Caprolactone and Methyl Methacrylate

Yunjie Luo,[a] Yingming Yao,[a] Qi Shen,*[a] Kaibei Yu,[b] and Linhong Weng[c]

Keywords: Lanthanides / N ligands / Structure elucidation / Polymerization / ε-Caprolactone / Methyl methacrylate

The synthesis and structure of new lanthanide complexes with the guanidinate ligand $[(Me_3Si)_2NC(NiPr)_2^-]$ are described. Reaction of a THF slurry of $LnCl_3$ with a hexane solution of $[(SiMe_3)_2NC(NiPr)_2]Li$ (**1**) in a 1:2 molar ratio afforded the new soluble organolanthanide complexes $[(SiMe_3)_2NC(NiPr)_2]Ln(\mu\text{-}Cl)_2Li(THF)_2$ [Ln = Yb (**2**), Nd (**3**)]. Alkylation of **2** and **3** with 2 equiv. of MeLi in hexane gave $[(SiMe_3)_2NC(NiPr)_2]Ln(\mu\text{-}Me)_2Li(TMEDA)$ [Ln = Yb (**4**), Nd (**5**)] in good yield as crystalline solids. The molecular structures of **2** and **5** were determined by single-crystal X-ray analysis. The lanthanide ions in these complexes display a distorted pseudo-octahedral coordination geometry. Complexes **4** and **5** exhibited extremely high activity for the ring-opening polymerization of ε-caprolactone to give high molecular weight polymers. Complex **5** also showed good catalytic activity for the syndiotactic polymerization of methyl methacrylate.

Introduction

Guanidinate anions, $[(RN)_2C(NR_2')]^-$, are isoelectronic alternatives to cyclopentadienyl ligands and their electronic properties and steric bulk can be modified by variation of the substituents on the nitrogen atoms. As a result, guanidinates have attracted increasing attention as ancillary ligands in the coordination and organometallic chemistry of main group and transition metals,[1] and some of these complexes have been reported to exhibit interesting reactivity. For example, neutral and cationic Zr^{IV} bis(guanidinate) complexes are catalysts for the polymerization of α-olefins,[2] and mono- and dianionic guanidinate complexes of Ta^{IV} and (hydrocarbyl)Zr^{IV} bis(guanidinate) complexes react with Me_3SiCl, ArNC,[3] and 2,6-dimethylphenyl isocyanide,[4] respectively. However, the application of guanidinate ligands in organolanthanide chemistry has been quite limited; to date, only three papers concerning the synthesis and characterization of lanthanide guanidinate complexes have been published,[5–7] with one of these discussing the catalytic activity of $La[CyNC\{N(SiMe_3)_2\}NCy](OC_6H_3tBu_2\text{-}2,6)_2$ complexes for the ring-opening polymerization of D,L-lactide.[7]

We have recently become interested in understanding the chemistry of organolanthanide complexes with nitrogen-based polydentate ligands.[8] As an extension of our studies in this area, we have prepared the lanthanide guanidinate complexes $[(SiMe_3)_2NC(NiPr)_2]Ln(\mu\text{-}Cl)_2Li(THF)_2$ [Ln = Yb (**2**), Nd (**3**)] and $[(SiMe_3)_2NC(NiPr)_2]Ln(\mu\text{-}Me)_2Li(TMEDA)$ [Ln = Yb (**4**), Nd (**5**)]. Complexes **4** and **5** are highly active for the ring-opening polymerization of ε-caprolactone, and **5** is also able to catalyze the polymerization of methyl methacrylate.

Results and Discussion

Synthesis and Characterization of the Chloro and Methyl Complexes 2, 3 and 4, 5

The reaction of *N*,*N*′-diisopropylcarbodiimide with 1 equiv. of $LiN(SiMe_3)_2$ in hexane gives a quantitative yield of $[(SiMe_3)_2NC(NiPr)_2]Li$ (**1**); thus, in most cases a freshly prepared solution of the lithium guanidinate was used directly in the following metathesis reactions. Treatment of a hexane solution of **1** with a THF slurry of $LnCl_3$ in a 2:1 molar ratio at room temperature afforded after workup the chlorolanthanide guanidinate complexes $[(SiMe_3)_2NC(NiPr)_2]_2Ln(\mu\text{-}Cl)_2Li(THF)_2$ [Ln = Yb (**2**), Nd (**3**)] in 76 and 82% yield, respectively.

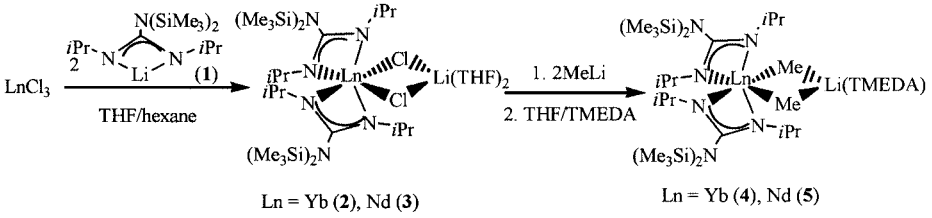

Scheme 1

Elemental analyses show both **2** and **3** to be lanthanide monochloride bis(guanidinates), complexed with LiCl·2THF. An X-ray determination of the structure of **2** reveals it to be an "ate" complex possessing two chloro bridges to an Li cation as shown in Scheme 1 and Figure 1.

Complexes **2** and **3** are useful precursors for further transformation. They react with 2 equiv. of MeLi in hexane to produce the μ-methyl "ate" derivatives **4** and **5** in 72 and 76% yield, respectively (Scheme 1). Use of 1 equiv. of MeLi gave the same methyl complexes, albeit in quite low yield.

All the complexes synthesized are air- and moisture-sensitive and have good solubility in toluene, diethyl ether and tetrahydrofuran (THF).

The N=C=N stretch of the parent carbodiimide (2117 cm^{-1}) is absent in the IR spectra of these complexes while a C=N stretch at approximately 1640 cm^{-1} is observed. These data suggest that the π-electrons within the double bonds of the N−C−N linkage are delocalized in all the complexes.[9]

Crystals of **2** suitable for X-ray diffraction were grown from THF, while **5** crystallized from a solution of a mixture of THF and TMEDA.

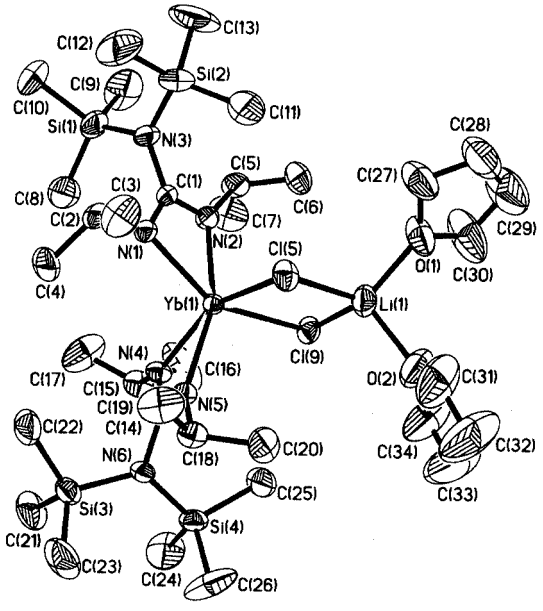

Figure 1. ORTEP diagram of $[(SiMe_3)_2NC(NiPr)_2]_2Yb(\mu\text{-}Cl)_2Li(THF)_2$ (**2**) showing non-hydrogen atom numbering scheme

An ORTEP diagram of **2** is shown in Figure 1. Crystal and structural refinement data are listed in Table 1, and selected bond lengths and angles are given in Table 2. As shown in Figure 1, **2** is a dinuclear lanthanide−lithium complex with two chloro bridges. The $[(SiMe_3)_2NC(NiPr)_2]_2Yb$ moiety is bonded through two chloro bridges to a lithium cation, which in turn is bonded to two oxygen atoms of two THF molecules. The Yb ion displays a distorted octahedral geometry defined by the four nitrogen atoms of the two chelating bidentate guanidinate ligands and the two chloride ligands, while the Li ion adopts a distorted tetrahedral geometry. The nearly identical C−N distances within the chelating guanidinate ligands (see Table 2) suggest that the π-electrons within the NCN fragments are delocalized. The guanidinate ligands bind to Yb through two nitrogen atoms to yield a planar four-membered ring with bite angles of 57.09(13)° and 57.18(12)°. The Yb−N bond lengths vary from 2.295(3) to 2.332(3) Å, similar to the values reported for $[(SiMe_3)_2NC(NCy)_2]_2[N(SiMe_2)]Yb$[5] and $\{[(SiMe_3)_2NC(NiPr)_2]_2Y(\mu\text{-}Cl)\}_2$.[6] The Yb−Cl bond lengths are 2.6076(14) and 2.6306(13) Å, respectively, which are similar to those in $Li[YbCl_2(C_5H_4SiCH_3Ph_2)_2](Et_2O)_2$.[10] The C(1)−Yb−C(14) angle is 131.09(12)°, similar to that found in $[(SiMe_3)_2NC(NCy)_2]_2YbN(SiMe)_2$ (130.5°),[5] but greater than the corresponding angle in $\{[(SiMe_3)_2NC(NiPr)_2]_2Y(\mu\text{-}Cl)\}_2$ [123.09(15)°].[6] The Cl(1)−Yb−Cl(2) angle [84.42(4)°] is also greater than that in $\{[(SiMe_3)_2NC(NiPr)_2]_2Y(\mu\text{-}Cl)\}_2$ [76.30(4)°],[6] and smaller than that in $Li[YbCl_2(C_5H_4SiCH_3Ph_2)_2](Et_2O)_2$ [87.14(3)°].[10]

The orientation of the $N(SiMe_3)_2$ groups relative to the NCNYb plane is approximately perpendicular and is similar to the analogous Sm,[5] Yb,[5] and Y[6] complexes. This disposition prevents π-overlapping between these two moieties; however, it increases the steric bulk above and below the planar guanidinate ligand.

An ORTEP diagram of **5** is presented in Figure 2. Details concerning the data collection are listed in Table 1 and selected bond lengths and angles are given in Table 3.

The crystal structure of **5** is similar to that of **2**, even though **5** is only monomeric in the solid state. The geometry of the Nd ion is best described as a distorted pseudo-octahedron defined by the four nitrogen atoms of the two chelating bidentate guanidinate ligands and the two μ-methyl groups. The Li ion adopts a distorted tetrahedral geometry with two μ-Me groups and two N atoms of a TMEDA molecule coordinated to it.

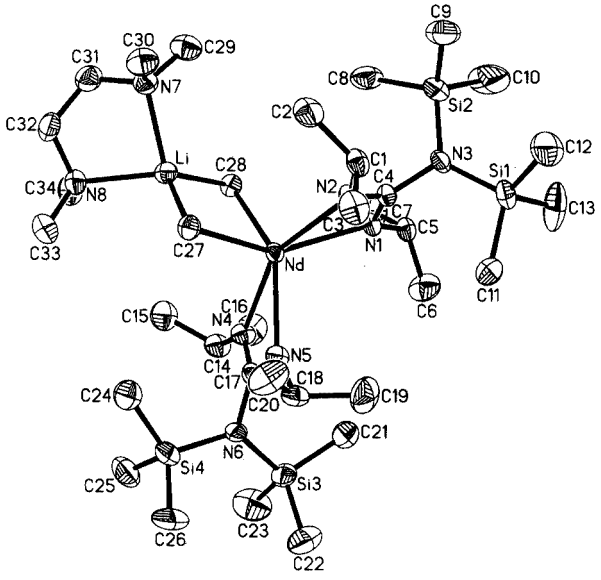

Figure 2. ORTEP diagram of $[(SiMe_3)_2NC(NiPr)_2]_2Nd(\mu\text{-}Me)_2Li(TMEDA)$ (**5**) showing the atom-numbering scheme; hydrogen atoms have been omitted for clarity

The Nd−N bond lengths within each NdN_2C moiety differ by approximately 0.05 Å. The Nd−C_{methyl} bond lengths are 2.590(8) and 2.595(8) Å, which are identical to those in $[(tBuCp)_2Nd(\mu\text{-}Me)]_2$ [2.594(15) Å][11] and similar to those in $[(SiMe_3)_2NC(NiPr)_2]_2Y(\mu\text{-}Me)_2Li(TMEDA)$ [2.505(4) and 2.508(4) Å].[6] The bite angles of the two ligands are 53.5(2) and 54.0(2)°, which are close to that found in $[(SiMe_3)_2NC(NiPr)_2]_2Y(\mu\text{-}Me)_2Li(TMEDA)$ [55.36(10)°].[6] The Me−Nd−Me angle of 89.3(2)° is similar to the angle in $[(tBuCp)_2Nd(\mu\text{-}Me)]_2$ [88.4(7)°].[11]

Polymerization of ε-Caprolactone and Methyl Methacrylate by Complexes 4 and 5

Both **4** and **5** were found to catalyze the polymerization of ε-caprolactone and methyl methacrylate in toluene solution. The preliminary results are listed in Tables 4 and 5, respectively.

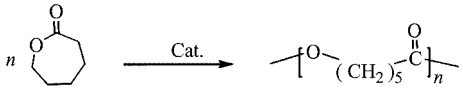
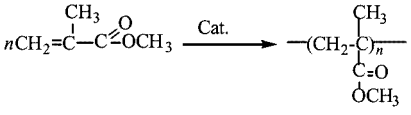
[a] General polymerization conditions: catalyst concentration 0.5 mol % monomer, solvent toluene, solvent/monomer 2 (v/v), polymerization time 3 h. [b] Yield: weight of polymer obtained/weight of monomer used. [c] Measured by GPC calibrated with standard polystyrene samples.

Both complexes showed high activity for the ring-opening polymerization of ε-caprolactone (Scheme 2). The identity of the central metal atom has a large effect on the catalytic activity. For example, using **5** as a catalyst gives yields as high as 100% in 15 min over $[M]/[I]$ mol ratios of 500:1 to 1000:1 at 20 °C, while under the same conditions **4** gave yields of only 61.2−27.2%. The order of reactivity Nd > Yb is in agreement with that found for metallocene-based organolanthanide catalysts.[12] The polymerization systems give high molecular weight polymers ($M_n > 10^4$). The molecular mass distributions are broader than those obtained with the homoleptic (phosphoraniminato)lanthanide complexes,[13] especially when long reaction times are used (Entries 4, 6 and 7); this may be due to a transesterification reaction.



Scheme 2

Complex **5** also exhibits good catalytic activity for the polymerization of methyl methacrylate (Scheme 3). Triad microstructural analysis of the polymers was carried out using ^1H NMR spectra in $CDCl_3$. The catalytic activity increased with increasing polymerization temperature. For example, only a 10% yield was obtained at −78 °C, while at 40 °C, a yield of 82% could be realized. Moreover, the present polymerization system gives the syndio-rich polymers, and the syndiotacticity decreases with increasing polymerization temperature.



Scheme 3

Conclusions

In summary, we have successfully synthesized a series of new soluble lanthanide bis(guanidinate) complexes free of cyclopentadienyl ligands, and characterized some of their structural features by X-ray crystallography. Moreover, we have found that the "ate" methyllanthanide bis(guanidinate) complexes show highly catalytic activity for the ring-opening polymerization of ε-caprolactone, and good catalytic activity for the polymerization of methyl methacrylate to give syndiotactic polymers. A systematic study of the catalytic activity of methyllanthanide guanidinate complexes in the polymerization of other monomers is ongoing in our laboratory.

Experimental Section

General Procedures: All manipulations were performed under pure argon with rigorous exclusion of air and moisture using standard Schlenk techniques. Solvents were distilled from Na/benzophenone ketyl prior to use. Deuterated benzene was dried with sodium and vacuum-transferred. Anhydrous $LnCl_3$ [14] and $LiN(SiMe_3)_2$ [15] were prepared according to literature procedures. *N*,*N*′-Diisopropylcarbodiimide was purchased from Aldrich and purified by distillation. ε-Caprolactone was purchased from Acros, dried by stirring with CaH_2 for 48 h, then distilled under reduced pressure. Methyl methacrylate was dried by stirring with CaH_2 for 48 h, then distilled under reduced pressure. Melting points were determined in argon-filled capillary tubes and are uncorrected. Lanthanide metal analyses were carried out by complexometric titration. The content of lithium was determined with a Hitachi 180−80 polarized Zeeman atomic absorption spectrophotometer. Carbon, hydrogen, and nitrogen analyses were performed by direct combustion with a Carlo−Erba EA-1110 instrument. The IR spectra were recorded with a Nicolet Magna-IR 550 spectrometer. ^1H and ^{13}C NMR spectra were obtained using a Unity Inova-400 spectrometer. Molecular weight and molecular weight distributions were determined against polystyrene standards by gel permeation chromatography (GPC) at 30 °C with a Waters 1515 apparatus with three HR columns (HR-1, HR-2 and HR-4) using THF as the eluent.

Synthesis of [(SiMe$_3$)$_2$NC(N*i*Pr)$_2$]Li (1): $LiN(SiMe_3)_2$ (1.67 g, 10.00 mmol) in hexane (30 mL) was added dropwise to a hexane solution (50 mL) of *N*,*N*′-diisopropylcarbodiimide (1.6 mL, 10.00 mmol) at room temperature. The resulting reaction mixture was stirred for 30 min and gave a clear pale-yellow solution. After removal of the reaction solvent, crude **1** was isolated as a white powder (2.88 g, 9.81 mmol, 98.3%). $C_{13}H_{32}LiN_3Si_2$ (293.60): calcd. C 53.19, H 11.01, N 14.32; found C 52.79, H 11.24, N 13.82. ^1H NMR ([D$_6$]benzene): δ = 3.78 (m, 2 H, C*H*Me$_2$), 1.17 [d, 12 H, CH(C*H*$_3$)$_2$], 0.35 [s, 18 H, Si(C*H*$_3$)$_3$] ppm. ^{13}C NMR ([D$_6$]benzene): δ = 164.36 (*C*N$_3$), 46.17 (*C*HMe$_2$), 28.19 [(*C*H$_3$)$_2$CH], 3.03 [CN[Si(*C*H$_3$)$_3$]$_2$) ppm. IR (KBr pellets): $\tilde{\nu}$ = 3449 (s), 2963 (m), 1636 (s), 1450 (m), 1389 (m), 1327 (m), 1258 (m), 1173 (m), 1049 (m), 957 (m), 841 (s), 686 (m) cm^{-1}.

Synthesis of [(SiMe$_3$)$_2$NC(N*i*Pr)$_2$]$_2$Yb(μ-Cl)$_2$Li(THF)$_2$ (2): A hexane solution (50 mL) of in situ generated [(SiMe$_3$)$_2$NC(N*i*Pr)$_2$]Li (**1**) (3.90 g, 13.30 mmol) was added to a slurry of $YbCl_3$ (1.85 g, 6.62 mmol) in THF (30 mL). The reaction mixture was stirred for 24 h at room temperature and the solvents were stripped off in vacuo. The residual yellow powder was extracted with diethyl ether and LiCl was centrifuged off. The yellow supernatant was then concentrated and cooled to −15 °C overnight to give bright-yellow crystals. Yield: 4.87 g (5.03 mmol, 76%). M.p.165−168 °C. $C_{34}H_{80}Cl_2LiN_6O_2Si_4Yb$ (968.28): calcd. C 42.17, H 8.34, Li 0.72, N 8.68, Yb 17.87; found C 41.63, H 8.26, Li 0.81, N 8.41, Yb 18.52. ^1H NMR ([D$_6$]benzene): δ = 4.15, 3.84 (m, 4 H, C*H*Me$_2$), 3.64 (m, 8 H, THF-α-C*H*$_2$), 1.47 (m, 8 H, THF-β-C*H*$_2$), 1.33, 1.09 [d, 24 H, CH(C*H*$_3$)$_2$], 0.23 [s, 36 H, Si(C*H*)$_3$] ppm. IR (KBr pellets): $\tilde{\nu}$ = 3283 (m), 3182 (m), 2966 (m), 1635 (s), 1466 (m), 1388 (m), 1321 (m), 1253 (s), 1172 (m), 1057 (s), 952 (m), 841 (s), 756 (m), 686 (m) cm^{-1}.

Synthesis of [(SiMe$_3$)$_2$NC(N*i*Pr)$_2$]$_2$Nd(μ-Cl)$_2$Li(THF)$_2$ (3): As for the synthesis of **2**, using **1** (11.38 mmol), $NdCl_3$ (1.40 g, 5.59 mmol), and THF (60 mL). Recrystallization from toluene yielded blue purple needles of **3** (4.31 g, 4.58 mmol, 82%). M.p. 176−178 °C. $C_{34}H_{80}Cl_2LiN_6NdO_2Si_4$ (939.48): calcd. C 43.46, H 8.60, Li 0.74, N 8.95, Nd 15.35; found C 42.76, H 8.78, Li 0.71, N 8.34, Nd 15.72. ^1H NMR ([D$_6$]benzene): δ = 4.15, 3.85 (m, 4 H, C*H*Me$_2$), 3.61 (m, 8 H, THF-α-C*H*$_2$), 1.45 (m, 8 H, THF-β-C*H*$_2$), 1.33, 1.09 [d, 24 H, CH(C*H*$_3$)$_2$], 0.23 [s, 36 H, Si(C*H*)$_3$] ppm. IR (KBr pellets): $\tilde{\nu}$ = 3296 (m), 2971 (m), 1636 (s), 1466 (m), 1373 (m), 1327 (m), 1258 (s), 1172 (m), 1057 (s), 941 (s), 833 (s), 756 (m), 686 (m) cm^{-1}.

Synthesis of [(SiMe$_3$)$_2$NC(N*i*Pr)$_2$]$_2$Yb(μ-Me)$_2$Li(TMEDA) (4): A Schlenk bottle was charged with **2** (8.23 g, 8.5 mmol) and hexane (100 mL). The solution was cooled to −78 °C, and MeLi (11.4 mL, 16.99 mmol) was added by syringe. The reaction mixture was kept at −78 °C for 1 h, then slowly warmed to room temperature and stirred overnight. After removal of volatiles under vacuum, the yellow residue was extracted with toluene, and LiCl was removed by centrifugation. The supernatant was removed in vacuo, and THF (20 mL) containing TMEDA (1 mL) was added. Cooling to −15 °C overnight gave **3** as bright yellow cubic crystals. Yield 6.1 g (6.12 mmol, 72%). M.p. 100−102 °C. $C_{34.25}H_{90.50}LiN_8Si_4Yb$ (931.01): calcd. C 44.18, H 9.82, Li 0.75, N 12.04, Yb 18.59; found C 43.81, H 9.54, Li 0.71, N 11.98, Yb 18.32. ^1H NMR ([D$_6$]benzene): δ = 2.15 (m, 4 H, C*H*Me$_2$), 1.25 [m, 24 H, CH(C*H*$_3$)$_2$], 0.33 [s, 36 H, Si(C*H*)$_3$], −6.11 (s, 12 H, TMEDA-C*H*$_3$), −7.74 (br, 4 H, TMEDA-C*H*$_2$), −9.81 (s, 4.5 H, C$_6$*H*$_{12}$), −15.45 (br, 6 H, μ-C*H*$_3$) ppm. IR (KBr pellets): $\tilde{\nu}$ = 3449 (m), 2963 (s), 1636 (s), 1466 (m), 1381 (m), 1327 (m), 1258 (s), 1180 (m), 1049 (m), 957 (s), 918 (m), 841 (s), 756 (m), 686 (m) cm^{-1}.

Synthesis of [(SiMe$_3$)$_2$NC(N*i*Pr)$_2$]$_2$Nd(μ-Me)$_2$Li(TMEDA) (5): As for the synthesis of **4**, using **3** (5.60 mmol), MeLi (7.6 mL, 11.32 mmol), and hexane (60 mL). Recrystallization from THF containing TMEDA gave blue-purple cubic crystals. Yield 3.84 g (4.26 mmol, 76%). M.p. 118−120 °C. $C_{34.25}H_{90.50}LiN_8NdSi_4$ (902.21): calcd. C 48.26, H 10.13, N 12.42, Nd 15.99. Li 0.77; found C 47.86, H 9.90, N 11.83, Nd 15.86, Li 0.75. ^1H NMR ([D$_6$]benzene, ppm): δ = 3.51 (m, 4 H, C*H*Me$_2$), 2.83 [m, 24 H, CH(C*H*$_3$)$_2$], 2.16 [s, 36 H, Si(C*H*)$_3$], 1.24 (s, 12 H, TMEDA-C*H*$_3$), 0.51 (br, 4 H, TMEDA-C*H*$_2$), 0.19 (s, 4.5 H, C$_6$*H*$_{12}$), −2.21 (br, 6 H, μ-C*H*$_3$) ppm. IR (KBr pellets): $\tilde{\nu}$ = 3442 (m), 2963 (s), 1636 (s), 1466 (m), 1373 (m), 1327 (m), 1258 (s), 1180 (m), 1049 (s), 957 (s), 918 (m), 841 (s), 756 (m), 686 (m) cm^{-1}.

A Typical Procedure for Polymerization Reactions: The procedures for the polymerization of ε-caprolactone and methyl methacrylate are similar (Table 5), and a typical polymerization procedure is given below (Entry 1, Table 5). A 50-mL Schlenk flask, equipped with a magnetic stirring bar, was charged with a 2.7 mM solution of initiator in toluene. To this solution was added 1 mL of ε-caprolactone using a syringe. The contents of the flask were then stirred vigorously at 20 °C for 15 min , during which time the mixture became very viscous, thus disrupting the stirring. The reaction mixture was quenched by the addition of 1 M HCl solution and was then poured into ethanol to precipitate the polymer, which was dried under vacuum and weighed.

X-ray Structural Determination of 2 and 5: Single crystals were sealed in a thin-walled glass capillary filled with argon for X-ray structural analysis. Diffraction data for **2** were collected with a Bruker SMART CCD area detector using and ω scans. Data for **5** were collected with a Siemens P4 four-circle diffractometer. The structures were solved by direct methods and refined by full-matrix least-squares procedures based on $|F|^2$. All non-hydrogen atoms were refined with anisotropic displacement coefficients. Hydrogen atoms were treated as idealized contributions. The structures of both **2** and **5** were solved and refined using SHELXS-97 and SHELXL-97 programs, respectively. CCDC-192647 (**2**) and

-192648 (**5**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

The Effect of Phenyl Substituents on the Activity of Some Zirconocene Photoinitiators[‡]

Eleonora Polo,*[a] Andrea Barbieri,[a] and Orazio Traverso[b]

Keywords: Homogeneous catalysis / Metallocenes / Photolysis / Polymerisation / Zirconium

In this paper we report the synthesis of several unbridged zirconocenes, **1a**–**c**, **2** and **5**, each bearing a phenyl substituent in the 2-position of the cyclopentadienyl ring. We also report their photochemical behaviour and we compare the results with those obtained with the corresponding unsubstituted metallocenes **3a**–**c** and **4**. Study of their electronic spectra and EPR/spin trapping experiments showed photogeneration of ligand- and zirconium-centred radicals, thus making these complexes suitable as photoinitiators for radical polymerisation processes. The substitution of the hydrogen atom in the 2-position with a phenyl group had positive effects both on the absorption coefficients, improving the light absorption efficiency, and on the reaction yields of *tert*-butyl acrylate polymerisation. These results can be explained in terms of the combined effects of greater persistence of the radical in solution and/or increased efficiency of the radical in initiating the polymerisation process.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2003)

Introduction

A growing area of interest in photochemistry is the design of new photoinitiators for use in pigmented coatings, photoresists, adhesives, and holography;[2−4] of these, initiators with absorption peaks at wavelengths longer than 300 nm are of particular interest since they can be used with the visible light produced by continuous wave lasers.[5]

Since the absorption of a photon generates an electronically excited state that does not occur thermally or occurs only at very high temperatures, photoinitiated reactions and thermally activated processes can induce different reaction pathways. Light can be used as a clean, tuneable and versatile "reagent", thus allowing selective activation of a photoinitiator, also in the presence of organic solvents and chemical contaminants. Another advantage offered by photoinitiation is that the light can be spatially directed and turned on or off simply.

The desirability of expanding the application of photoinitiated chemistry has recently resulted in the discovery of several classes of inorganic and organometallic photoinitiators.[6−9] Among these, metallocenes have attracted increasing interest due to the "tuneability" of their structures and because they leave few toxic residues and photobleach with high efficiency, thus leaving clear or colourless coatings after exposure to argon lasers.

In the context of our research into metallocenes suitable as photoinitiators in radical polymerisation processes, we have recently[1] explored the possible use of several known and new zirconocenes. In the light of the encouraging results obtained, we then investigated possible improvements to their activity as photoinitiators through the introduction of particular substituents in the cyclopentadienyl moiety to modify the electronic distribution.

In this paper we report the photochemical behaviour of several unbridged zirconocenes, each bearing a phenyl substituent in the 2-position of the cyclopentadienyl ring. This substitution should help in stabilising the radical of the polymerisation initiator and enhance the polymerisation efficiency, due to the potential delocalisation of the spare electron offered by the phenyl ring, thus prolonging its life in solution. The introduction of this substituent should increase the absorption coefficients, thus improving the light absorption efficiency.

Several zirconium complexes were synthesised and studied: bis[η^5-(2-phenyl-4,5,6,7-tetrahydro-1*h*-indenyl)]zirconium dichloride [**1a**, $(C6Ph)_2ZrCl_2$], bis[η^5-(2-phenyl-4,5,6,7,8-hexahydroazulenyl)]zirconium dichloride [**1b**, $(C7Ph)_2ZrCl_2$], bis[η^5-(2-phenyl-4,5,6,7,8,9-hexahydro-1*H*-cyclopenta[8]annulenyl)]zirconium dichloride [**1c**, $(C8Ph)_2ZrCl_2$] and bis[η^5-(2-phenylindenyl)]zirconium dichloride [**2**, $(IndPh)_2ZrCl_2$]. The results were compared with those obtained with the corresponding unsubstituted

[‡] Zirconocenes as Photoinitiators for Free Radical Polymerisation of Acrylates, 2. Part 1: Ref.[1]

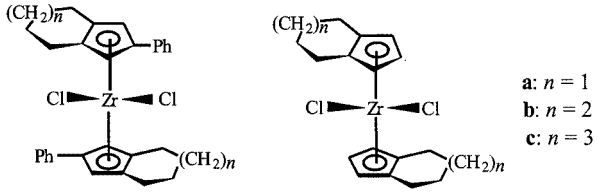
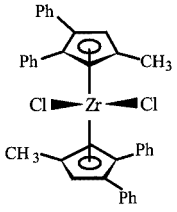
metallocenes: bis[η^5-(4,5,6,7-tetrahydro-1*H*-indenyl)]zirconium dichloride [**3a**, $(C6)_2ZrCl_2$], bis[η^5-(4,5,6,7,8-hexahydroazulenyl)]zirconium dichloride [**3b**, $(C7)_2ZrCl_2$], bis[η^5-(4,5,6,7,8,9-hexahydro-1*H*-cyclopenta[8]annulenyl)]-zirconium dichloride [**3c**, $(C8)_2ZrCl_2$], and bis(η^5-indenyl)-zirconium dichloride (**4**, Ind_2ZrCl_2).



1a–c **3a–c**

Another similar complex, bis(4-methyl-1,2-diphenylcyclopentadienyl)zirconium dichloride [**5**, $(CpMePh_2)_2ZrCl_2$], was also synthesised and tested. It should combine the above advantages with a shorter and cheaper synthetic procedure.

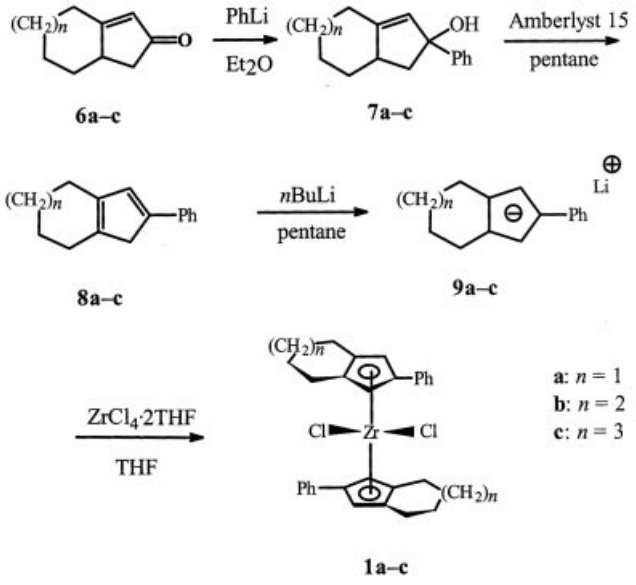


5

Results and Discussion

Ligand and Complex Synthesis

The synthetic approach is outlined in Scheme 1. The starting enones **6a–c** were obtained by a synthetic procedure previously designed in our laboratories.[10]

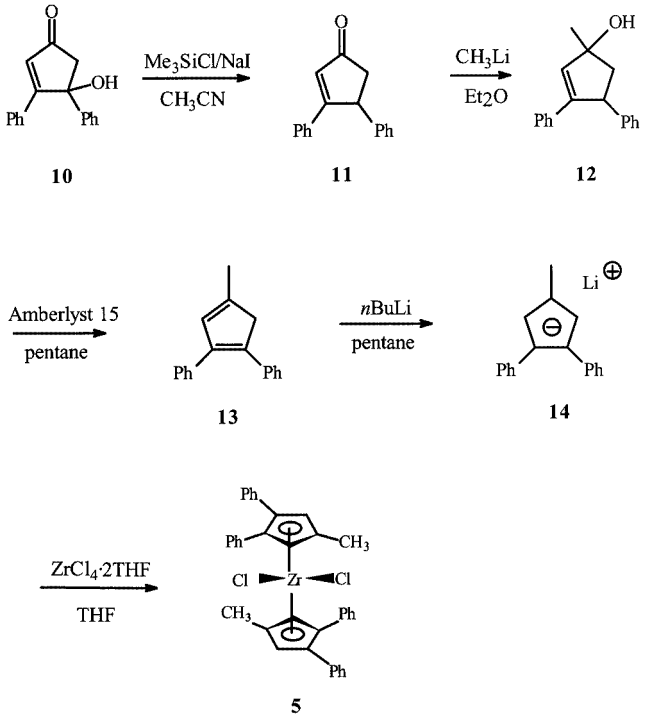


Scheme 1

2-Phenyl-substituted ligands can easily be obtained in three steps from the enones **6a–c**. Treatment of **6a–c** with phenyllithium gave the allyl alcohols **7a–c**, which were dehydrated under very mild conditions by treatment at room temp. with Amberlyst 15, a strongly acidic ion-exchange resin. Since the resulting dienes **8a–c** polymerise quite easily, it is crucial to use low temperatures and short workup times for the dehydration step in order to improve the reaction yields. The use of an ion-exchange resin gave better yields than the usual acid workup, since the reagent can be easily and rapidly removed from the reaction medium by simple filtration. Furthermore, in the case of these phenyl-substituted ligands, filtration through Florisil afforded only one of the three possible isomeric dienes, thus making the hydrogen abstraction easier, since only the isomer bearing an allylic $-CH_2-$ group can easily be dehydrogenated.[11]

Treatment of the dienes with a slight excess of *n*-butyllithium gave the corresponding lithium salts **9a–c**, with overall yields over the three preceding steps ranging from 60 to 70%. Treatment of the lithium salts **9a–c** with $ZrCl_4$·2THF in THF in a 2.3:1 molar ratio resulted in the formation of the corresponding metallocenes **1a–c**, in yields ranging from 68 to 72%.

The synthesis of the complex **5** was performed according to Scheme 2, starting from 4-hydroxy-3,4-diphenylcyclopent-2-en-1-one.



Scheme 2

The synthesis of the ligand **14**[12,13] and of the corresponding metallocenes have already been described by others,[14,15] but we have found that the reaction yields were hardly reproducible. Our modified procedure proved more reliable and gave higher yields both of the intermediates and of the metallocene **5**.

The starting compound was converted into the enone **11** by treatment with the reagent Me_3SiCl/NaI in acetonitrile (a synthetic equivalent of Me_3SiI)[16,17] under very mild conditions. Treatment with methyllithium, followed by dehydration with Amberlyst 15, gave the diene **13** as the sole isomer, if Florisil treatment was used. Treatment with *n*-butyllithium and metallation with $ZrCl_4 \cdot 2THF$ gave the metallocene **5**.

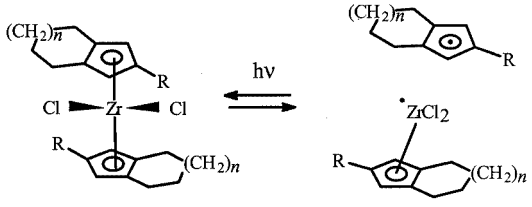
Photochemistry

UV/Vis spectra of the complexes **1a**−**c**, **2** and **5** were recorded in benzene and compared with those obtained previously[1] for the complexes **3a**−**c** and **4**. While we did not observe significant variations in the position of the λ maxima (just a slight shift towards shorter wavelengths), we did see that the substituents in the cyclopentadienyl ring increased the extinction coefficients by more than one order of magnitude (Table 1), a feature particularly interesting for the efficiency of the process.

Table 1. Spectroscopic properties of the complexes in benzene

Complex		λ_{max} [nm]	ε_{max} [$mol^{-1} \cdot L \cdot cm^{-1}$]
1a	$(C6Ph)_2ZrCl_2$	320	23500
1b	$(C7Ph)_2ZrCl_2$	300	18000
1c	$(C8Ph)_2ZrCl_2$	300	14000
2	$(IndPh)_2ZrCl_2$	300	60500
		310	60500
		330	41000
3a	$(C6)_2ZrCl_2$	310	1600
		350	1100
3b	$(C7)_2ZrCl_2$	310	2380
		345	1540
3c	$(C8)_2ZrCl_2$	305	2920
		345	1720
4	$(Ind)_2ZrCl_2$	310	1475
		380	720
5	$(CpMePh_2)_2ZrCl_2$	290	12000

These zirconium(IV) complexes possess d^0 configuration, so any dominant effect of Ligand-Field (LF) and/or Metal-to-Ligand Charge Transfer (MLCT) transitions can reasonably be excluded. Since the free ligand shows absorption bands at lower energies ($\lambda \geq 330$ nm), the observed shift supports the hypothesis of a prevalent Ligand-to-Metal Charge Transfer (LMCT) character for the electronic transition, consistent with the formation of ligand- and metal-centred radicals (Scheme 3). The photochemistry of the complexes strongly supports the LMCT assignment.[18,19]



Scheme 3

Selective photolysis was carried out on the complexes in benzene at the wavelengths corresponding to their LMCT transitions, in order to test their photoreactivity in solution and whether they might be possible candidates for free radical photopolymerisation. The nature of the complexes has a significant influence on their photoreactivity in solution; in particular, the introduction of the phenyl substituent seems to accelerate the initial decomposition of the complexes, but only to a certain extent. In the cases of complexes **1a**−**c**, **4** and **5**, we observed percentages of degradation (estimated by UV/Vis spectroscopy) varying from 10 to 40% with respect to the initial values after only 10 min (Figure 1). After that time, though, a sort of plateau was reached, and this persisted for the rest of the irradiation time, as if a photostationary equilibrium had been established. The photodecomposition was reversible; after 24 h of storage in the dark, the initial spectral pattern and absorbance values were almost completely recovered. In contrast, only 15% of the unsubstituted complexes **3a**−**c** was degraded even after 1 h of irradiation.

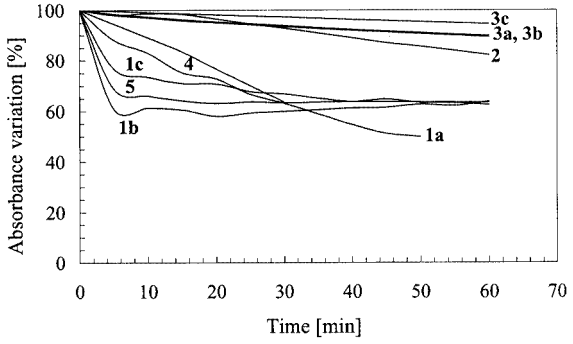


Figure 1. Percentage variation of the absorption band maxima of complexes in benzene as a function of the irradiation time

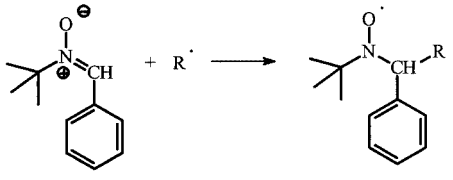
A particular case is represented by complex **2**, which shows a similar photostability to the complexes **3a**−**c**, despite its phenyl substituent. This effect can be attributed to the extra stabilisation given by the indenyl aromatic system.

EPR Spin Trapping Investigation

To establish the nature of the species produced upon irradiation, EPR/spin trapping experiments were carried out by direct irradiation of benzene solutions of the zirconocenes inside the spectrometer cavity. The spin trap *N-tert*-butyl-α-phenylnitrone (PBN) was used to identify the nature of the radical species (Scheme 4).[20,21]



Scheme 4

Besides the signals already recorded with the reference complexes **3a**−**c** and **4**, the spectra of the phenyl-substituted complexes **1a**−**c**, **2** and **5** showed the presence of a

second radical species, consistent with the presence of a cyclopentadienyl radical.[22] Since the hyperfine coupling constant (*hfcc*) values are common to all the phenyl-substituted complexes, including the metallocene **5**, which does not possess a second ring, they can reasonably be assigned to a radical delocalised on the phenyl ring.

Table 2. *hfcc* values of the radical spin adducts with PBN in benzene

Complex		Species I			Species II		
		a_N [G]	a_H [G]	[%]	a_N [G]	a_H [G]	[%]

Polymerisation Activity

The polymerisation of acrylates has great industrial significance and has been the subject of intensive experimental investigations and practical applications. On the basis of the photochemical findings, polymerisation tests were performed on *tert*-butyl acrylate (*t*BA), the least reactive monomer in the acrylates series. For this reason, the commercial product does not contain stabilisers as the other acrylates do, and its chemical sluggishness makes it a good terminating agent for the polymerisation of the other acrylate monomers. A positive result obtained in *t*BA polymerisation can be considered evidence of a high efficiency of a metallorganic complex as a radical initiator and can rule out the possibility that the polymer obtained may have come from direct photochemical activation of the monomer.

The polymerisation tests were carried out in benzene and the tacticity of the polymer formed was estimated by deconvolution of the methine peaks of poly(*t*BA) at $\delta \approx 42$ ppm in the $^{13}C\{^1H\}$ NMR spectra.

The final result of the polymerisation might be due to the combined effects of two factors: i) the photoreactivity of the complex in solution, and ii) the efficiency of the radical in promoting the polymerisation process.

The polymer yields obtained with the complexes **1a**,**b**, **2** and **5** were at least twice as high as those obtained with the corresponding unsubstituted metallocenes **3a**–**c** and **4**. This improvement in the polymerisation outcome can be explained by better persistence of the radical initiating species in solution. The extra stabilisation provided by the phenyl ring can slow down recombination and fragmentation processes, thus guaranteeing higher concentrations of radical initiators in solution. Particularly interesting is the bis(2-phenylindenyl)zirconium dichloride (**2**), which offers the highest percentage in conversion combined with the best photostability in solution. Complex **5** also deserves more studies, since it combines good monomer conversion with a shorter synthetic preparation.

Another interesting feature is that the polymerisation yields are linear with the irradiation time. This result could be a possible sign of a living radical process.[23] Further studies in order to ascertain the nature of this process unambiguously are currently in progress.

As was to be expected, the stereochemical outcome of the reaction was quite independent of the complex used and the data were quite similar to those reported with the unsubstituted complexes, with a content of syndiotactic triads [rr] ranging from 30 to 35% and of isotactic triads [mm] around 6%. This result is consistent with the radical nature of the process.

Table 3. *tert*-Butyl acrylate polymerisation data

Complex		20% (v/v) *t*BA in C_6H_6 [a]			
		Yield [%][b]	Stereochemistry [%][c]		
			[rr]	[mr]	[mm]

[a] Polymerisation conditions: a 20% (v/v) monomer solution in benzene in a 4-mL cuvette was irradiated ($\lambda > 320$ nm) for 1 h in the presence of 7 mg of the metallocene. [b] Degree of polymerisation: (weight of polymer obtained/weight of starting monomer) × 100. [c] Percentage composition of syndiotactic [rr], atactic [mr], and isotactic [mm] triads in the polymer, calculated from deconvolution of the ^{13}C NMR peaks at $\delta = 41-43$ ppm.

Conclusion

On the basis of their photochemical behaviour in solution, known and new phenyl-substituted metallocene complexes **1a**–**c**, **2** and **5** have been used here for the first time as photoinitiators for radical polymerisation processes.

An interesting feature is the high extinction coefficients of these new complexes, which improve the light absorption efficiency of the irradiation process, and the possibility to shift their λ maxima towards lower energies by a judicious choice of phenyl substituents without the necessity to modify the entire synthetic procedure.

The radical species involved in the photoinduced cleavage of the metal–ligand bond have been identified and *t*BA polymerisation has been studied in detail and the results compared with those obtained with the complexes **3a**–**c** and **4**, already described in the first paper of this series.[1]

The substitution of the hydrogen atom in position 2 of the cyclopentadienyl ring with a phenyl group increased the polymerisation yields significantly, due to the combined effects of a longer persistence of the radical in solution and/

or increased efficiency of the radical in initiating the polymerisation process.

Experimental Section

General Remarks: All manipulations of air- and/or moisture-sensitive materials were carried out under an inert gas by use of a dual vacuum/argon line and standard Schlenk techniques. All solvents were thoroughly dehydrated and deoxygenated under argon before use. They were dried and purified by heating at reflux under argon in the presence of a suitable drying agent (pentane, petroleum ether, diethyl ether, benzene, toluene and THF: Na/benzophenone ketyl or potassium; CH_2Cl_2: CaH_2) followed by distillation and storage under argon in Young's ampoules. CH_3CN was dried with 4 Å molecular sieves. Solvents and solutions were transferred under positive argon pressure through stainless steel cannulas (diameter 0.5−2.0 mm) and mixtures were filtered in a similar way with modified cannulas that could be fitted with glass fibre filter disks (Whatman GFC). Unless otherwise specified, all reagents were purchased from commercial suppliers (Aldrich and Fluka) and used without further purification. Reaction courses and product mixtures were routinely monitored by thin layer chromatography (TLC) on pre-coated silica gel F_{254} plates. Preparative flash chromatography was carried out with 60 Å silica gel (230−400 mesh ASTM). Anhydrous magnesium sulfate was used for drying. Elemental analyses were performed with a Carlo Erba 1106 Elemental Analysis apparatus.

NMR Spectra: ^1H (200.13 MHz) and ^{13}C (50.32 MHz) NMR spectra were recorded at room temperature with a Bruker AC 200 spectrometer. Spectra were referenced internally to the residual protio solvent resonance relative to tetramethylsilane (δ = 0 ppm). Deuterated solvents were dried and distilled under argon in the presence of a suitable drying agent ($CDCl_3$: CaH_2; C_6D_6: K) and stored under argon in Young's ampoules.

EPR Studies: The spin trap PBN was purchased from Sigma−Aldrich Chem. Co. and used without further purification. The EPR/spin trapping experiments were performed with a Bruker EMX spectrometer, operating in the X-band (microwave frequency = 9.74 GHz, microwave power = 20 mW, magnetic field modulation frequency = 100 kHz, magnetic field modulation amplitude = 1 G). Sample solutions were freeze-pump-thaw-degassed and then irradiated with a 350-W medium-pressure Hg lamp directly in the EPR spectrometer cavity (Bruker ER-4104OR, TE102). Hyperfine coupling constants (*hfcc*s) were calculated by best-fit simulation of experimental spectra with NIEHS WinSim software.[24]

Photochemical Experiments: Irradiation was performed with an Oriel 500-W high-pressure Hg lamp equipped with cut-off filters for wavelength selection and a water filter to prevent thermal processes. UV/Vis spectra were recorded with a Perkin−Elmer Lambda 40 double-beam spectrophotometer.

Polymerisation Tests: *tert*-Butyl acrylate was dehydrated with CaH_2 and vacuum-distilled immediately before sample preparation. In a typical experiment, a 20% (v/v) monomer solution in benzene in a 4-mL cuvette was irradiated at λ > 320 nm for 1 h in the presence of 7 mg of the metallocene. All polymerisations were carried out at 20 °C. The reaction was quenched by addition of a small amount of aqueous hydrochloric acid, and the polymer was precipitated by pouring CH_3OH/HCl (10:1) into the reaction mixture. The polymer was collected by filtration and dried overnight under high vacuum.

Preparation of the Complexes: The enones **6a**−**c**,[11] 4-hydroxy-3,4-diphenylcyclopent-2-en-1-one (**10**),[13] the metallocenes Ind_2ZrCl_2 (**3**)[25] and (2-phenylindenyl)$_2ZrCl_2$ (**4**)[26] were prepared as described in the literature.

Allylic Alcohols 7. General Procedure: Enone **6** (8.80 mmol) in anhydrous diethyl ether (20 mL) was cooled to 0 °C under nitrogen. Phenyllithium (6.5 mL, 10.4 mmol, 1.6 M in cyclohexane/ether) was slowly added, and the yellow solution became brown. The cooling bath was removed and the mixture was stirred at room temp. until TLC (eluent: diethyl ether/petroleum ether, 1:1) showed only traces of the starting material (about 2 h). The reaction mixture was then cooled to 0 °C, the excess of alkylating agent was decomposed by careful addition of iced water, and the separated organic phase was washed several times with diethyl ether. The collected organic fractions were dried and the solvent was evaporated under reduced pressure. The crude alcohol **7** was obtained in quantitative yield as a mixture of two diastereoisomers.

2-phenyl-2,4,5,6,7,7a-hexahydro-1*H*-inden-2-ol (7a). Major Isomer: ^1H NMR ($CDCl_3$): δ = 1.20−1.50 (m, 3 H), 1.60 (s, 1 H, exchanged on D_2O addition, O*H*), 1.70−2.20 (m, 6 H), 2.40−2.65 (m, 2 H, CH_2Cp), 5.40 (m, 1 H, =C*H*Cp), 7.10−7.60 (m, 5 H, Ar*H*) ppm. **Minor Isomer:** ^1H NMR ($CDCl_3$): δ = 1.20−1.50 (m, 3 H), 1.60 (s, 1 H, exchanged on D_2O addition, O*H*), 1.70−2.20 (m, 6 H), 2.40−2.65 (m, 2 H, CH_2Cp), 5.50 (m, 1 H, =C*H*Cp), 7.10−7.60 (m, 5 H, Ar*H*) ppm.

2-phenyl-1,2,4,5,6,7,8,8a-octahydroazulen-2-ol (7b). Major Isomer: ^1H NMR ($CDCl_3$): δ = 1.35−1.95 (m, 11 H), 2.35−2.60 (m, 2 H), 2.65−2.81 (m, 1 H), 5.48 (m, 1 H, =C*H*Cp), 7.15−7.60 (m, 5 H, Ar*H*) ppm. **Minor Isomer:** ^1H NMR ($CDCl_3$): δ = 1.35−1.95 (m, 11 H), 2.35−2.60 (m, 2 H), 2.65−2.81 (m, 1 H), 5.58 (m, 1 H, =C*H*Cp), 7.15−7.60 (m, 5 H, Ar*H*) ppm.

2-phenyl-2,4,5,6,7,8,9,9a-octahydro-1*H*-cyclopenta[8]annulen-2-ol (7c). Major Isomer: ^1H NMR ($CDCl_3$): δ = 1.38−2.40 (m, 13 H), 2.40−2.60 (m, 2 H), 2.62−2.70 (m, 1 H), 5.52 (m, 1 H, =C*H*Cp), 7.10−7.65 (m, 5 H, Ar*H*) ppm. **Minor Isomer:** ^1H NMR ($CDCl_3$): δ = 1.38−2.40 (m, 13 H), 2.40−2.60 (m, 2 H), 2.62−2.70 (m, 1 H), 5.60 (m, 1 H, =C*H*Cp), 7.10−7.65 (m, 5 H, Ar*H*) ppm.

Dienes 8. General Procedure: Crude alcohol **7** (max, 8.80 mmol), partially dissolved in pentane (30 mL), was stirred at room temp. with Amberlyst 15 (1.27 g). After 1 h, the reaction was complete (TLC: diethyl ether/petroleum ether, 2:1). Magnesium sulfate was added and, after a further 5 min of stirring, the suspension was filtered through a short column (*h* = 6 cm; i.d. = 3 cm) of Florisil (100−200 mesh) and the solvents were evaporated under reduced pressure, keeping the temperature below 30 °C. A yellow solid was obtained.

2-phenyl-4,5,6,7-tetrahydro-1*H*-indene (8a): ^1H NMR ($CDCl_3$): δ = 1.60−1.80 (m, 4 H, CCH$_2$CH_2), 2.20−2.45 (m, 4 H, CCH_2CH$_2$), 3.25 (d, *J* = 1.17 Hz, 2 H, CH_2Cp), 6.70 (d, *J* = 1.17 Hz, 1 H, =C*H*Cp), 7.10−7.70 (m, 5 H, Ar*H*) ppm.

2-phenyl-4,5,6,7,8-hexahydroazulene (8b): ^1H NMR ($CDCl_3$): δ = 1.55−1.82 (m, 6 H, CCH$_2$CH_2), 2.40−2.52 (m, 4 H, CCH_2CH$_2$), 3.25 (d, *J* = 1.08 Hz, 2 H, CH_2Cp), 6.70 (d, *J* = 1.08 Hz, 1 H, =C*H*Cp), 7.15−7.20 (m, 1 H, Ar*H*), 7.20−7.35 (m, 2 H, Ar*H*), 7.35−7.50 (m, 2 H, Ar*H*) ppm.

2-phenyl-4,5,6,7,8,9-hexahydro-1*H*-cyclopenta[8]annulene (8c): ^1H NMR ($CDCl_3$): δ = 1.40−1.60 (m, 4 H, CCH$_2$CH_2), 1.60−1.80 (m, 4 H, CCH$_2$CH_2), 2.45−2.60 (m, 4 H, CCH_2CH$_2$), 3.25 (s, 2 H, CH_2Cp), 6.72 (s, 1 H, =C*H*Cp), 7.10−7.65 (m, 5 H, Ar*H*) ppm.

Lithium Salts 9. General Procedure: Diene **8** (max, 8.80 mmol) was placed in a Schlenk flask, degassed, dissolved in anhydrous petroleum ether (30 mL) and cooled to 0 °C. *n*-Butyllithium (5 mL, 2.5 M solution in hexanes, 12.5 mmol) was added dropwise, and the solution was stirred at 0 °C for 30 min, then allowed to reach room temp. and stirred overnight. Lithium salt **8** separated from the solution as powdery solid, which was filtered through a cannula and washed twice with petroleum ether. The residual solvent was pumped off, leaving the lithium salt **9** as yellow pyrophoric powder.

2-Phenyl-4,5,6,7-tetrahydro-1*H*-indenyllithium (9a): 1.07 g. Yield over three steps: 60%; average yield per step 84%.

2-Phenyl-4,5,6,7,8-hexahydroazulenyllithium (9b): 1.24 g. Yield over three steps: 65%; average yield per step 87%.

2-Phenyl-4,5,6,7,8,9-hexahydro-1*H*-cyclopenta[8]annulenyllithium (9c): 1.44 g. Yield over three steps: 71%; average yield per step 89%.

Metallocene Dichlorides 1. General Procedure: $ZrCl_4 \cdot 2THF$ (4.5 mmol) in THF (20 mL) was added dropwise to solutions of the lithium salts **9** (9.6 mmol) in anhydrous THF (20 mL). The reaction mixtures were stirred overnight. The solvent was then removed under vacuum, and the residues were extracted with toluene, filtered, concentrated and layered with pentane. Fine, deep yellow solids precipitated and were isolated by filtration, washing with pentane and concentration under high vacuum.

Bis[η^5-(2-phenyl-4,5,6,7-tetrahydro-1*H*-indenyl)]zirconium Dichloride (1a): 1.80 g. Yield 68%. $C_{30}H_{30}Cl_2Zr$ (552.69): calcd. C 65.2, H 5.5, Cl 12.8; found C 65.8, H 5.7, Cl 12.4. ^{1}H NMR ($CDCl_3$): δ = 1.2−1.5 (m, 4 H, CCH_2CH_2), 1.6−1.9 (m, 4 H, CCH_2CH_2), 2.1−2.4 (m, 8 H, CCH_2CH_2), 6.1 (s, 4 H, CHCp), 7.0−7.4 (m, 10 H, ArH) ppm. ^{13}C NMR ($CDCl_3$): δ = 22.0 (CCH_2CH_2), 23.8 (CCH_2CH_2), 113.7 (CH Cp), 123.9 (C=CH Cp), 125.2 (*m*CH Ar), 127.3 (*p*CH Ar), 129.0 (*o*CH Ar), 130.8 (CH_2C=CCp), 133.3 (CC= Ar) ppm.

Bis[η^5-(2-phenyl-4,5,6,7,8-hexahydroazulenyl)]zirconium Dichloride (1b): 2.17 g. Yield 78%. $C_{32}H_{34}Cl_2Zr$ (580.74): calcd. C 66.2, H 5.9, Cl 12.2; found C 65.8, H 6.2, Cl 12.0. ^{1}H NMR ($CDCl_3$): δ = 1.6−2.1 (m, 12 H, CCH_2CH_2), 2.2−2.7 (m, 8 H, CCH_2CH_2), 6.3 (s, 4 H, CH Cp), 7.1−7.6 (m, 10 H, ArH) ppm. ^{13}C NMR ($CDCl_3$): δ = 28.6 (CH_2), 30.0 (CH_2), 32.0 (CH_2), 116.4 (CH Cp), 124.4 (C= CH Cp), 125.3 (*m*CH Ar), 127.2 (*p*CH Ar), 129.0 (*o*CH Ar), 133.3 (CC=Ar), 134.6 (CH_2C=C Cp) ppm.

Bis[η^5-(2-phenyl-4,5,6,7,8,9-hexahydro-1*H*-cyclopenta[8]annulenyl)]-zirconium Dichloride (1c): 2.10 g. Yield 72%. $C_{34}H_{38}Cl_2Zr$ (608.80): calcd. C 67.1, H 6.3, Cl 11.7; found C 66.8, H 6.8, Cl 11.3. ^{1}H NMR ($CDCl_3$): δ = 1.0−1.5 (m, 12 H, CCH_2CH_2), 1.6−1.9 (m, 4 H, CCH_2CH_2), 2.0−2.3 (m, 4 H, CCH_2CH_2), 2.3−2.6 (m, 4 H, CCH_2CH_2), 5.6 (s, 4 H, CH Cp), 7.0−7.5 (m, 10 H, ArH) ppm. ^{13}C NMR ($CDCl_3$): δ = 25.9 (CH_2), 26.4 (CH_2), 31.1 (CH_2), 32.3 (CH_2), 107.6 (CH Cp), 124.3 (*m*CH Ar), 124.7 (C=CH Cp), 126.0 (*p*CH Ar), 127.5 (CH_2C=C Cp), 128.6 (*o*CH Ar), 134.9 (CC= Ar) ppm.

3,4-Diphenylcyclopent-2-en-1-one (11): The alcohol **10** (0.5 g, 2 mmol), dissolved in dry benzene (10 mL), and Me_3SiCl (12 mmol, a slightly exothermic reaction occurs) were added to a suspension of NaI (12 mmol) in anhydrous CH_3CN (0.6 mL, 12 mmol). The mixture was stirred at room temp. in the dark until TLC (eluent: diethyl ether/petroleum ether, 1:5:1), showed only traces of the starting alcohol (about 1 h). The reaction mixture was then cooled to 0 °C, quenched with water and extracted several times with diethyl ether. The collected organic fractions were washed with aqueous sodium thiosulfate, water and brine and dried. The solvent was evaporated under reduced pressure to give a deep yellow solid, which was purified by flash chromatography (eluent: diethyl ether/petroleum ether, 1:1.5) to give the enone **11** (0.44 g, 1.86 mmol). (Yield 93%). M.p. 108−110 °C. ^{1}H NMR ($CDCl_3$): δ = 2.46 (dd, *J* = 2.0, 18.8 Hz, 1 H, *cis*-PhCHCH_2), 3.14 (dd, *J* = 7.3, 18.8 Hz, 1 H, *trans*-PhCHCH_2), 4.65 (dt, *J* = 7.3, 1.7 Hz, 1 H, PhC*H*CH$_2$), 6.77 (d, *J* = 1.5 Hz, 1 H, COC*H*), 7.11−7.42 (m, 8 H, Ar*H*), 7.47−7.61 (m, 2 H, Ar*H*) ppm. ^{13}C NMR ($CDCl_3$): δ = 46.68, 46.75, 126.96, 127.06, 127.90, 128.70, 129.06, 129.11, 130.79, 133.18, 141.22, 142.41, 175.12, 208.12 ppm.

1-Methyl-3,4-diphenylcyclopent-2-en-1-ol (12): Methyllithium (2.15 mmol, 1.5 M in diethyl ether) was added dropwise to a solution of enone **11** (0.44 g, 1.86 mmol) in anhydrous THF (20 mL), cooled to 0 °C. The yellow solution turned orange. The mixture was stirred for 30 min at 0 °C and for 30 min at room temperature (TLC: diethyl ether/petroleum ether, 1.5:1). The reaction mixture was then again cooled to 0 °C, the excess of alkylating agent was decomposed by careful addition of iced water, and the separated organic phase was washed several times with diethyl ether. The collected organic fractions were dried and the solvent was evaporated under reduced pressure. The crude alcohol **12** was obtained in quantitative yield as a mixture of two diastereoisomers. **Major Isomer:** ^{1}H NMR ($CDCl_3$): δ = 1.59 (s, 3 H, CH_3), 1.68 (s, 1 H, O*H*), 1.96−2.12 (m, 1 H, *cis*-PhCHCH_2), 2.63−2.82 (m, 1 H, *trans*-PhCHCH_2), 4.27−4.42 (m, 1 H, PhC*H*CH$_2$), 6.34 (d, *J* = 1.5 Hz, 1 H, COC*H*), 7.18−7.41 (m, 10 H, Ar*H*) ppm. **Minor Isomer:** ^{1}H NMR ($CDCl_3$): δ = 1.50 (s, 3 H, CH_3), 1.72 (s, 1 H, O*H*), 1.96−2.12 (m, 1 H, *cis*-PhCHCH_2), 2.63−2.82 (m, 1 H, *trans*-PhCHCH_2), 4.27−4.42 (m, 1 H, PhC*H*CH$_2$), 6.78 (d, *J* = 1.5 Hz, 1 H, COC*H*), 7.08−7.41 (m, 10 H, Ar*H*) ppm.

4-Methyl-1,2-diphenylcyclopentadiene (13): The crude alcohol **12** (max. 1.56 mmol) in diethyl ether (30 mL) was stirred at room temp. with Amberlyst 15 (1.27 g). After 1 h, the reaction was complete (TLC: diethyl ether/petroleum ether, 2:1). Magnesium sulfate was added and, after a further 5 min of stirring, the suspension was filtered and the solvents were evaporated under reduced pressure. The residue was dissolved in petroleum ether and filtered through a short column (*h* = 6 cm; i.d. = 3 cm) of Florisil (100−200 mesh) and the solvents were evaporated under reduced pressure, keeping the temperature below 30 °C. A yellow solid (0.30 g, 1.31 mmol) was obtained (yield over two steps: 80%; average yield per step: 89%). ^{1}H NMR ($CDCl_3$): δ = 2.19 (d, *J* = 1.5 Hz, 3 H, CH_3), 3.49 (d, *J* = 1.1 Hz, 2 H, CH_2Ph), 6.37 (d, *J* = 1.3 Hz, 1 H, C=C*H*), 7.11−7.46 (m, 10 H, Ar*H*) ppm. ^{13}C NMR ($CDCl_3$): δ = 16.2, 48.8, 126.0, 126.9, 127.7, 128.2, 128.35, 132.1, 137.6, 137.5, 136.6, 141.4, 144.0 ppm.

4-Methyl-1,2-diphenylcyclopentadienyllithium (14): The diene **13** (0.30 g, 1.31 mmol) was placed in a Schlenk flask, degassed, dissolved in anhydrous petroleum ether (30 mL) and cooled to −20 °C. *n*-Butyllithium (2.20 mmol, 2.5 M solution in hexanes) was added dropwise, and the solution was stirred at −20 °C for 2 h and then allowed slowly to reach room temp. and stirred overnight. The lithium salt **14** separated from the solution as a powdery solid, which was filtered through a cannula and washed twice with petroleum ether. The residual solvent was pumped off, leaving the lithium salt **14** (0.30 g, 1.24 mmol) as a pale yellow pyrophoric powder (yield 95%).

Bis(1,2-diphenyl-4-methylcyclopentadienyl)zirconium Dichloride (5): The lithium salt **14** (0.30 g, 1.24 mmol) was dissolved in anhydrous THF (20 mL), and a solution of $ZrCl_4 \cdot 2THF$ (4.5 mmol) in THF

(20 mL) was added dropwise. The reaction mixture was stirred overnight. The solvent was then removed under vacuum, and the residue was extracted with toluene, filtered, concentrated and layered with pentane. A powdery, deep yellow solid (0.62 g, 0.99 mmol) precipitated and was isolated by filtration and washing with pentane (yield 80%). $C_{36}H_{30}Cl_2Zr$ (624.35): calcd. C, 69.2, H 4.8; Cl, 11.4; found C 69.1, H 4.9; Cl, 11.3. ^{1}H NMR ($CDCl_3$): δ = 1.73 (s, 6 H, C*H*$_3$), 6.38 (s, 4 H, Cp*H*), 7.11−7.49 (m, 20 H, Ar*H*) ppm. ^{13}C NMR ($CDCl_3$): δ = 15.2, 118.9, 127.4, 128.0, 128.8, 129.4, 133.2 ppm.

Photochromic Properties of a Spirooxazine and a Spiropyran in Alcoholic Solutions of Zirconium and Aluminium Alkoxides: Influence of the Ethyl Acetoacetate Chelating Agent on the Optical Properties

Aurélie Lafuma,[a] Sandrine Chodorowski-Kimmes,[b] Francis X. Quinn,[b] and Clément Sanchez*[a]

Keywords: Alkoxides / Sol-gel processes / Spiro compounds / Photochromism / Aluminium / Zirconium

The photochromism of two spiro compounds, a spiropyran and a spirooxazine, dissolved in alcoholic solutions of metal alkoxides $M(OR)_n$ (M = Zr, Al) has been studied. In the case of the aluminium alkoxide $Al(OsBu)_3$, special photochromic behaviour is observed characteristic of complexation between the coloured form of the dyes and the aluminium. This chemical interaction induces a considerable shift in the absorption spectra and a significant retardation rate in the dark. Addition of ethyl acetoacetate, a bidentate chelate of aluminium, leads to the disappearance of this particular photochromic behaviour.

(© Wiley-VCH Verlag GmbH & Co KGaA, 69451 Weinheim, Germany, 2003)

Introduction

Photochromism involving changes in the visible absorption spectrum has drawn much attention over the last decades because of the variety of practical applications of photochromic systems.[1] In particular, the synthesis of solid photochromic materials using the sol-gel process has been studied extensively.[2−18] Little is known, however, about the dye−matrix interaction. The photochromic properties of spiro compounds are well known. Spiropyrans have been widely studied in the past[1,19−21] and, more recently, spirooxazines have been investigated.[1,22,23] Interest in these compounds is in part explained by their high durability with respect to photoexcitation.

The photochromism of these molecules is due to photocleavage of the spiro bond under UV irradiation, creating an open merocyanine structure (photomerocyanine) which absorbs in the visible region. The reverse reaction proceeds thermally or under irradiation with visible light. Two spiro compounds (Figure 1) have been used in this study: a spiropyran denoted **SP** (1′,3′,3′-trimethyl-6-nitrospiro[2*H*-1-benzopyran-2,2′-indoline]) and a spirooxazine denoted **SO** (1,3,3-trimethylspiro[indoline-2,3′-3′*H*-naphtho[2,1-*b*][1,4]-oxazine]). The photochromism of these two dyes in different solvents is well documented,[24,25] and is very sensitive to the chemical environment of the molecule. In particular, the photochromic band of merocyanine in the visible region is known to be solvatochromic. This absorption band shifts as a function of the polarity of the solvent and the colour changes. **SP** presents a negative solvatochromism characteristic of a prevalent zwitterionic coloured form, whereas **SO** presents a positive solvatochromism characteristic of a prevalent quinonic coloured form. In this paper, we report the photochromic properties (absorption properties and kinetics of thermal bleaching of the coloured form) of **SO** and **SP** in several alcoholic solutions of metal alkoxides $M(OR)_n$ (M = Zr, Al).

Usually such alkoxides are used for the synthesis of sol-gel materials in which **SO** and **SP** can be doped. The physicochemical properties of these materials depend on the chemical nature of the alkoxide(s) and especially on their possible complexation by a chelating agent. Since in solid media photochromism is directly linked to the local envir-

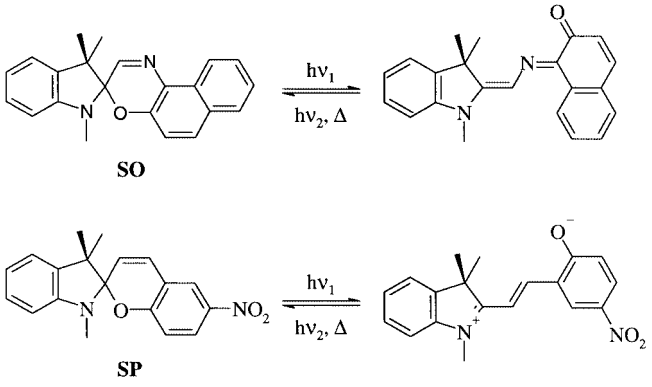

Figure 1. Molecular structures of **SO** and **SP** photochromic dyes

onment of the organic doped dye, it is important to determine the possible chemical interaction likely to occur with corresponding molecular precursor(s). Thus, we have studied the photochromic behaviour of **SO** and **SP** in these alkoxides modified or not by a chelating agent. This study will help us in future work on solid media using **SO** and **SP** as local probes of their environment and for understanding their photochromic behaviour in terms of physicochemical dye−matrix interactions.

In the case of the aluminium alkoxide Al(O*s*Bu)$_3$ we observed a significant modification of the photochromic behaviour of **SO** and **SP**, which can be attributed to a complexation of the photomerocyanine by aluminium. Addition of the aluminium chelating agent ethyl acetoacetate (EtacH) to the alkoxide Al(O*s*Bu)$_3$ leads to the superposition of both the complexed and the normal photochromisms for **SP** as well as the sudden disappearance of the complexed photochromism for **SO**.

Results

Characterisation of Metal Alkoxides

Metal alkoxides M(OR)$_n$ in alcoholic solutions can exist as a variety of oligomeric species,[26,27] especially if the charge on the metal ion is less than its usual coordination number. The principal oligomeric structures proposed in the literature[28−34] for the three commercial alkoxides used in this study Zr(O*n*Pr)$_4$, Al(O*s*Bu)$_3$ and [Al(O*s*Bu)$_2$(Etac)] are shown in Figure 2. For Zr(O*n*Pr)$_4$ the oligomeric structures contain solvent molecules.

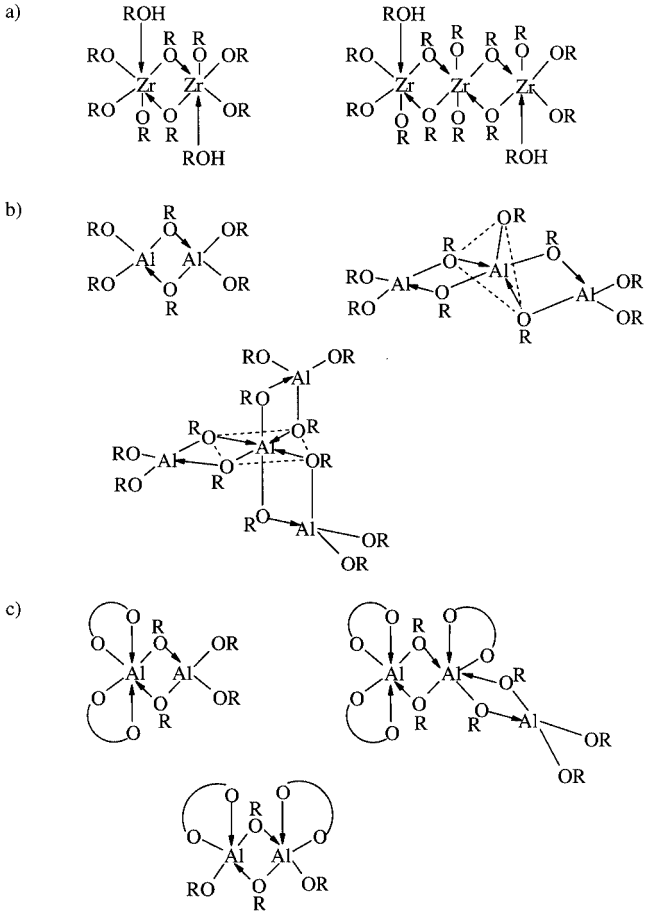

Figure 2. Prevalent oligomeric structures proposed for the metal alkoxides: (a) Zr(O*n*Pr)$_4$; (b) Al(O*s*Bu)$_3$; (c) [Al(O*s*Bu)$_2$(Etac)]

To follow the influence of EtacH on [Al(O*s*Bu)$_2$(Etac)] we synthesised intermediate alkoxides denoted [Al(O*s*Bu)$_{3-x}$(Etac)$_x$], by mixing Al(O*s*Bu)$_3$ with ethyl acetoacetate in molar ratios x = EtacH/Al with x = 0.2, 0.3, 0.4, 0.5, 0.6, 0.8 and 1. The reaction was exothermic.

The complexation between the bidentate chelate EtacH and aluminium was monitored by FTIR spectroscopy (Figure 3). The characteristic bands for EtacH are between 1745−1720 cm^{-1} and 1650−1630 cm^{-1} due to the stretching vibrations ν_{C-O} of the ketonic and enolic forms, respectively. In pure EtacH the ketonic isomer predominates[35] (Figure 4). There is no band due to the ketonic form of the Etac groups in the spectrum of Al(O*s*Bu)$_{3-x}$(Etac)$_x$ or Al(O*s*Bu)$_2$(Etac). Only the bands characteristic of the enolic form appear between 1630−1610 cm^{-1} and 1525 cm^{-1} (ν_{C-O} and ν_{C-C}, respectively). This suggests that Equation (1) occurs.

$$Al(OsBu)_3 + x\ EtacH \rightarrow Al(OsBu)_{3-x}(Etac)_x + x\ sBuOH \quad (1)$$

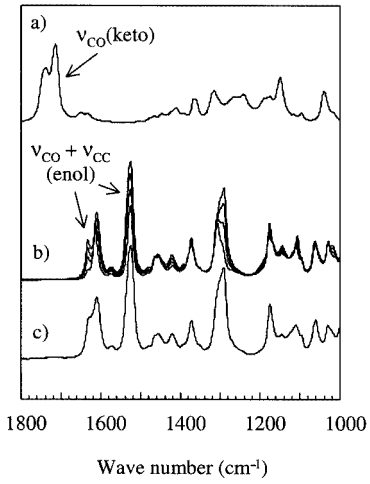

Figure 3. Infrared spectra of a) EtacH, b) Al(O*s*Bu)$_{3-x}$(Etac)$_x$, c) [Al(O*s*Bu)$_2$(Etac)]

We used ^{13}C NMR spectroscopy to look for free EtacH in the alkoxides Al(O*s*Bu)$_{3-x}$(Etac)$_x$. The spectra of Al(O*s*-Bu)$_{2.7}$(Etac)$_{0.3}$ and Al(O*s*Bu)$_2$(Etac)$_1$ (Figure 5) display two broad bands at $\delta \approx$ 175.6 and 188.7 ppm. These two bands are characteristic of carbon atoms C-4 and C-2 of the Etac ligand chelated to the aluminium atom, and they confirm that the Etac groups are bonded to the aluminium centres in an enolic form (Figure 4). In comparison, the peaks indicating free EtacH are at δ = 173.5 and 176.7 ppm for the enolic form and at δ = 167.9 and 200.9 ppm for the diketonic form. Thus, the prevalent ketonic isomer of free Et-

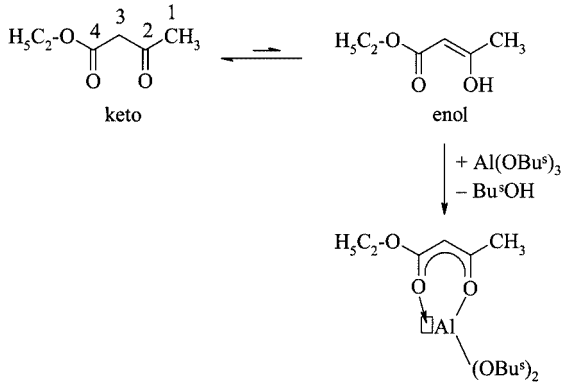

Figure 4. Keto-enol equilibrium of ethyl acetoacetate (EtacH), and schematic representation of the complexation of Al(O*s*Bu)$_3$ with the enol form of EtacH

acH is not present in the alkoxide Al(O*s*Bu)$_{3-x}$(Etac)$_x$: ^{13}C NMR spectroscopy suggests that the reaction in Equation (1) is quantitative in agreement with the reported behaviour of the reactions between metal alkoxides and chelating agents.[26]

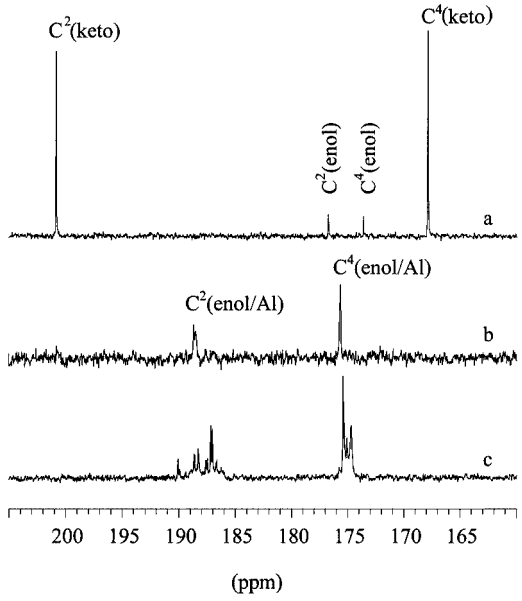

Figure 5. ^{13}C NMR spectra of (a) EtacH, (b) Al(O*s*Bu)$_{2.7}$(Etac)$_{0.3}$, (c) Al(O*s*Bu)$_2$(Etac)$_1$

^{27}Al NMR spectroscopy is very sensitive to the coordination number of aluminium.[33,34,36] The experimental and simulated ^{27}Al NMR spectra of the alkoxides Al(O*s*Bu)$_3$, Al(O*s*Bu)$_2$(Etac) (commercial) and Al(O*s*Bu)$_2$(Etac)$_1$ (prepared by mixing Al(O*s*Bu)$_3$ and EtacH at a molar ratio Etac/Al = 1) are presented in Figure 6. In Al(O*s*Bu)$_3$, the aluminium centres are mainly in tetracoordinate and pentacoordinate sites. The spectrum of Al(O*s*Bu)$_2$(Etac) is clearly different, however, with an observed increase in the coordination number of the aluminium atoms, with evidence for pentacoordinate and hexacoordinate sites. The spectra of Al(O*s*Bu)$_2$(Etac) and Al(O*s*Bu)$_2$(Etac)$_1$ are quite similar and indicate mainly hexacoordinate sites. The ^{27}Al NMR spectra of the alkoxides Al(O*s*Bu)$_{3-x}$(Etac)$_x$ (Figure 7) and their simulations (Table 1) reveal the direct influence of the bidentate ligand on the increase in aluminium's coordination number leading to a decrease of the Lewis acidity of the aluminium atom as *x* increases.

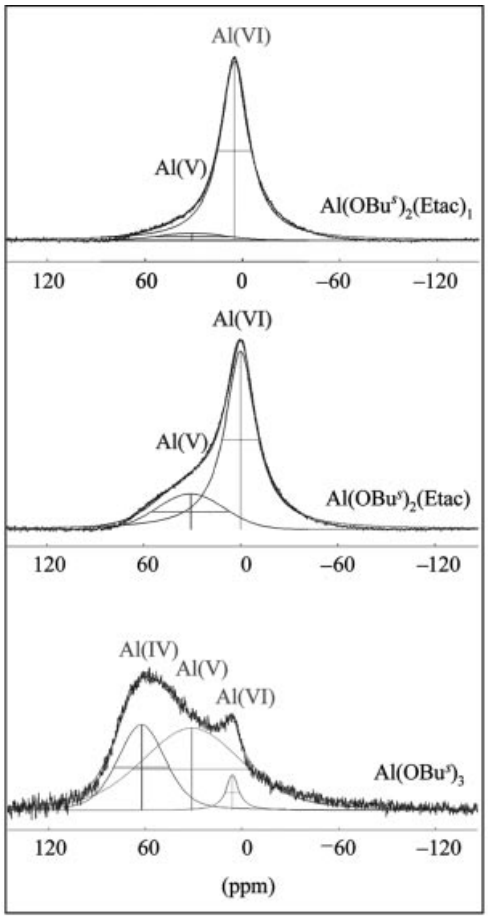

Figure 6. ^{27}Al NMR spectra of Al(O*s*Bu)$_3$, Al(O*s*Bu)$_2$(Etac)$_1$ and Al(O*s*Bu)$_2$(Etac) and their simulations

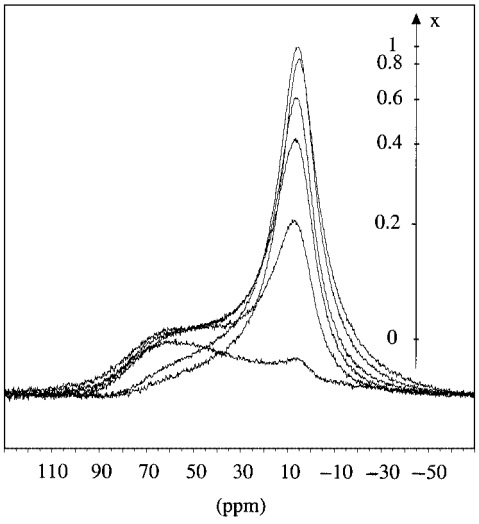

Figure 7. ^{27}Al NMR spectra of Al(O*s*Bu)$_3$ and Al(O*s*Bu)$_{3-x}$(Etac)$_x$ ($0.2 \leq x \leq 1$)

Table 1. Percentage of tetracoordinate, pentacoordinate and hexacoordinate aluminium in the alkoxides $Al(OsBu)_3$ 75%, $Al(OsBu)_{3-x}(Etac)_x$ and $Al(OsBu)_2(Etac)$

Alkoxide	Al^{IV} (%)	Al^{V} (%)	Al^{VI} (%)
$Al(OsBu)_3$ 75%	32	63	5
$Al(OsBu)_{2.8}(Etac)_{0.2}$	28	29	43
$Al(OsBu)_{2.6}(Etac)_{0.4}$	10	39	51
$Al(OsBu)_{2.4}(Etac)_{0.6}$	4	42	54
$Al(OsBu)_{2.2}(Etac)_{0.8}$	1	16	83
$Al(OsBu)_2(Etac)_1$	0	6	94
$Al(OsBu)_2(Etac)$	0	23	77

The oligomeric structures of the alkoxides $Al(OsBu)_{3-x}(Etac)_x$ can therefore be considered as intermediates between the oligomers of $Al(OsBu)_3$ and $Al(OsBu)_2(Etac)$ (see b and c in Figure 2).

Absorption Spectra

The absorption properties of the coloured forms of **SO** and **SP** in alcoholic solutions of zirconium and aluminium alkoxides were compared with those obtained in the corresponding solvent of the alkoxide (PrOH or *s*BuOH) or in the chelating agent EtacH (Table 2). Several metal alkoxides noted as $M(OR)_n$ x% (M = Zr, Al) were used at different percentage x by weight in the corresponding alcohol ROH.

Table 2. Absorption maxima [nm] of **SO** and **SP** in metal alkoxides $M(OR)_n$ [$M(OR)_n$ at a concentration c in ROH]

		SO $\lambda_{B,max}$ [nm]	SP $\lambda_{B,max}$ [nm]	
Solvent:				
PrOH		611	541	
*s*BuOH		611	551	
EtacH		600	567	
	c[M(OR)n] [mol·L^{-1}]	$\lambda_{B,max}$ [nm]	$\lambda_{B1,max}$ [nm]	$\lambda_{B2,max}$ [nm]
Alkoxide:				
$Zr(OnPr)_4$ 70%	2.1	610	496	–
$Zr(OnPr)_4$ 7%	0.17	611	530	–
$Al(OsBu)_3$ 75%	2.8	595	464	–
$Al(OsBu)_3$ 10%	0.33	593	457	–
$Al(OsBu)_{2.8}(Etac)_{0.2}$	2.5	594	463	–
$Al(OsBu)_{2.7}(Etac)_{0.3}$	2.5	605	462	550
$Al(OsBu)_{2.6}(Etac)_{0.4}$	2.5	–	461	555
$Al(OsBu)_{2.4}(Etac)_{0.6}$	2.3	–	466	555
$Al(OsBu)_{2.2}(Etac)_{0.8}$	2.2	–	469	555
$Al(OsBu)_2(Etac)_1$	2.1	609	469	555
$Al(OsBu)_2(Etac)$	2.2	610	460	557

The absorption spectrum of **SO** in the alkoxide $Zr(OnPr)_4$ in PrOH at 70% by weight is similar to that obtained in PrOH. For **SP**, the maximum absorption wavelength measured in $Zr(OnPr)_4$ shows a hypsochromic shift of 45 nm relative to **SP** in PrOH, which suggests a weak stabilizing interaction between the coloured form of **SP** and zirconium (see a in Figure 8). This shift is reduced to 11 nm with a dilution of $Zr(OnPr)_4$ in PrOH at 7% by weight.

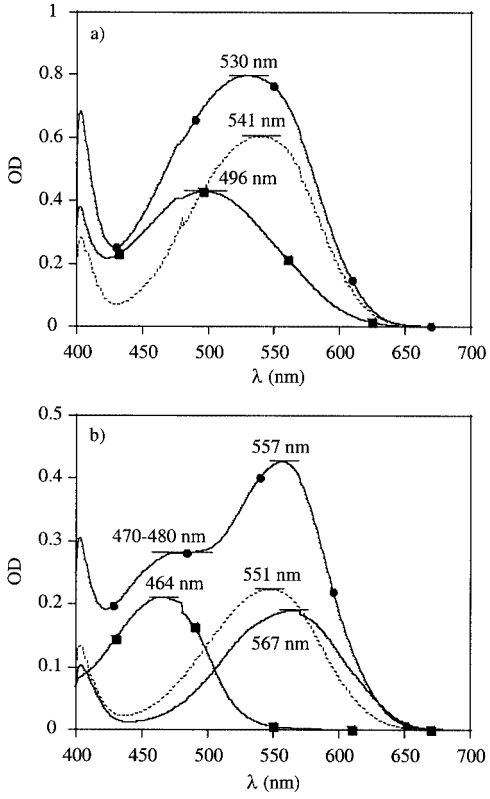

Figure 8. Visible absorption spectra of **SP** under UV irradiation in: (a) $Zr(OnPr)_4$ 70% (squares), $Zr(OnPr)_4$ 7% (dots) and PrOH (···); (b) $Al(OsBu)_3$ 75% (squares), $Al(OsBu)_2(Etac)$ (dots), *s*BuOH (···) and EtacH (—)

A drastic change in the absorption spectra of the coloured form of these dyes is observed in $Al(OsBu)_3$. The absorptions of the photomerocyanine isomers that exist before irradiation are shifted hypsochromically by 20 and 90 nm for **SO** and **SP**, respectively, relative to the values observed in *s*BuOH. This reveals a strong interaction between the photomerocyanine of the dyes and the aluminium alkoxide. This specific photochromic behaviour does not disappear with dilution of $Al(OsBu)_3$ in *s*BuOH by up to 10% by weight.

In the alkoxide $Al(OsBu)_2(Etac)$, **SO** exhibits classic photochromism whereas **SP** presents an absorption spectrum with two bands: one at 460 nm characteristic of a complexed photomerocyanine and the other at 555 nm close to the value obtained in EtacH (Figure 8, part b) revealing the direct influence of Etac on the photochromic behaviour. The absorption spectra of **SP** in the alkoxides $Al(OsBu)_{3-x}(Etac)_x$ before and during UV irradiation (Figure 9) confirm the direct link between the molar ratio x and the behaviour of the complexed dyes. Two distinct situ-

ations are observed: (a) only when x is less than 0.3 do **SO** and **SP** show photochromism whose characteristic features correspond to a complexed dye, and (b) when x is greater than or equal to 0.3 **SO** displays its usual photochromic response whereas **SP** shows a superposition of free and complexed photochromic dyes. This suggests competition between the chelation of aluminium by the ligand EtacH and its chemical interaction with the photomerocyanine of the dye.

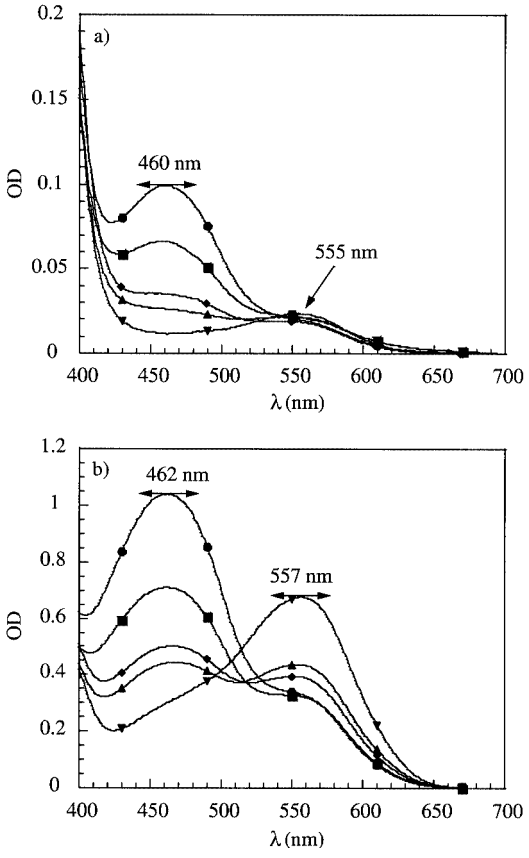

Figure 9. Visible absorption spectra of **SP** in $Al(OsBu)_{2.7}(Etac)_{0.3}$ (dots), $Al(OsBu)_{2.6}(Etac)_{0.4}$ (squares), $Al(OsBu)_{2.4}(Etac)_{0.6}$ (diamonds), $Al(OsBu)_{2.2}(Etac)_{0.8}$ (tringles, up), $Al(OsBu)_2(Etac)_1$ (triangles, down): (a) of initial coloured state and (b) under UV irradiation

Kinetics of Thermal Bleaching

The kinetics of thermal bleaching of photomerocyanines were investigated in solutions of aluminium alkoxides (Table 3) The kinetic fading rate constants k_Δ at the absorption maximum of **SO** and **SP** were obtained using a mono-exponential simulation of the thermal fading versus time. When the dye exhibited superposition between a free and a complexed photochromism two kinetics of thermal bleaching $k_\Delta(\lambda_1)$ and $k_\Delta(\lambda_2)$ at each maximum of absorption λ_1 and λ_2 were observed. This suggests that no exchange between the two coloured photomerocyanines occurs during fading. To control the effect of viscosity on the fading rate we also report the relative viscosity of several aluminium alkoxides (Table 3).

Table 3. Relative viscosity η of aluminium alkoxides and thermal fading k_Δ of **SO** and **SP** in these media

	SO k_Δ [s^{-1}]	**SP** k_Δ [s^{-1}]		
Solvent:				
*s*BuOH	0.5	$2.6\ 10^{-3}$		
EtacH	1.1	$1.5\ 10^{-2}$		
	η [cP]	k_Δ [s^{-1}]	$k_\Delta(460)$ [s^{-1}]	$k_\Delta(555)$ [s^{-1}]
Alkoxide:				
$Al(OsBu)_3$ 75%	28	$2.6\ 10^{-2}$		–
$Al(OsBu)_3$ 10%	–	$5.6\ 10^{-2}$	$2.8\ 10^{-4}$	–
$Al(OsBu)_{2.8}(Etac)_{0.2}$	25	$5.4\ 10^{-2}$	$1.2\ 10^{-4}$	–
$Al(OsBu)_{2.7}(Etac)_{0.3}$	–	0.4	$3.6\ 10^{-4}$	$6\ 10^{-4}$
$Al(OsBu)_{2.6}(Etac)_{0.4}$	23	–	$7.3\ 10^{-4}$	$5.2\ 10^{-4}$
$Al(OsBu)_{2.4}(Etac)_{0.6}$	21	–	$1.1\ 10^{-3}$	10^{-3}
$Al(OsBu)_{2.2}(Etac)_{0.8}$	17	–	$1.4\ 10^{-3}$	$1.5\ 10^{-3}$
$Al(OsBu)_2(Etac)_1$	16	0.8	$2.7\ 10^{-3}$	$2.2\ 10^{-3}$
$Al(OsBu)_2(Etac)$	33	0.81	$8.8\ 10^{-4}$	$1.2\ 10^{-3}$

For **SO** when x is less than 0.3 the kinetics of thermal bleaching of the complexed coloured isomer are especially slow, indicating chemical stabilisation of the photomerocyanine by aluminium. For x greater than or equal to 0.3 the chemical interaction between **SO** and aluminium disappears but we still observe an increase in the fading rate with x. This might be due to the increase of the hydrophobic nature of the medium combined with the addition of Etac, for which the thermal fading k_Δ is especially fast: $k_\Delta(\text{EtacH}) \leq k_\Delta[Al(OsBu)_{3-x}(Etac)_x] \leq k_\Delta(s\text{BuOH})$ for $x \geq 0.3$.

For **SP** when x is less than 0.3 the kinetics of thermal bleaching of the complexed isomer are slower than for the free isomer. This reveals a strong chemical stabilisation of the coloured photomerocyanine by aluminium. For x greater than 0.3 the thermal fading $k_\Delta(465)$ and $k_\Delta(555)$ are quite similar and become faster as x increases (Figure 10). These two values probably correspond to an average value $<k_\Delta>$ resulting from a fast chemical exchange of the metal/ligand type[37–39] between aluminium and the photomerocyanine of **SP**. The increase of this average value $<k_\Delta>$ with x could result from the decrease of the medium's viscosity and from the percentage of the complexed population of **SP**.

Discussion

The observed changes in the photochromic properties of **SO** and **SP** obtained in $Al(OsBu)_3$ are characteristic of strong chemical interactions between the coloured forms of these dyes and the aluminium. For **SO** in $Al(OsBu)_3$ we observed a hypsochromic shift of 15 nm for the complexed photomerocyanine. This is surprising given that **SO** is known to show a positive solvatochromism associated with its prevalent quinonic structure. This shift could be ex-

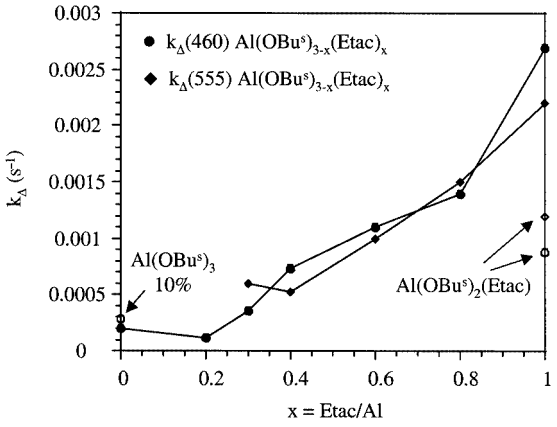

Figure 10. Evolution of the thermal fading of the free, k_Δ(555), and the complexed, k_Δ(460), photomerocyanines of **SP** with the molar ratio x = Etac/Al of the aluminium alkoxides

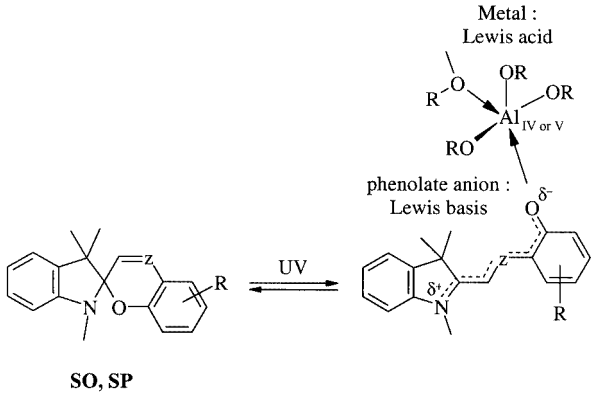

Figure 11. Schematic representation of the chemical interaction between the aluminium alkoxide and the photomerocyanine of **SO** and **SP** (Z = C or N); the depicted Al site is a representation of a trivalent aluminium cation with unsaturated coordination (tetra- or pentacoordinated)

plained by the stabilisation of the zwitterionic photomerocyanine of **SO** complexed with aluminium. The thermal fading of **SO** in 10% Al(O*s*Bu)$_3$ of low viscosity is, surprisingly, ten times slower than the fading rate usually observed in butanol. This confirms the chemical stabilisation of the coloured form of **SO**. A similar, but more noticeable, result was observed for **SP**, with a hypsochromic shift of 90 nm and a fading rate ten times slower in 10% Al(O*s*Bu)$_3$ than in butanol.

Addition of the chelating agent EtacH decreases the Lewis acidity of the aluminium atoms (its coordination increases), and this leads to the appearance of the free photochromic behaviour of the two dyes for x greater than or equal to 0.3. This result proves that the coloured form of the dye is sensitive to the low coordinate aluminium sites. Thus, we suggest that a monodentate Lewis acid/base interaction between the phenolate anion of the zwitterionic form of the photomerocyanine and the electronic lacuna of the tetracoordinate or pentacoordinate aluminium might be responsible for the changes in the photochromic properties (Figure 11). This interaction is monodentate since the photochromism of the **SP** complex still exists in the alkoxides Al(O*s*Bu)$_2$(Etac)$_1$ and Al(O*s*Bu)$_2$(Etac) without tetracoordinate aluminium according to the ^{27}Al NMR simulations. This would explain the sudden and progressive disappearance of the photochromism of the complexed forms of **SO** and **SP** for x greater than or equal to 0.3 in Al(O*s*Bu)$_{3-x}$(Etac)$_x$, since the complexation of the tetracoordinate or pentacoordinate aluminium by the chelating agent EtacH is in competition with the complexation of the coloured form of **SO** and **SP**.

In Zr(O*n*Pr)$_4$, **SP** displays a weak stabilizing interaction with zirconium (small hypsochromic shift of 45 nm) whereas the photochromism of **SO** is similar to that in PrOH. The affinity of zirconium for alcohols has been discussed in the literature.[40,41] In particular it is well known that zirconium alkoxide solvates are quite stable. Indeed, the XRD structure of [Zr(O*i*Pr)$_4$,HO*i*Pr]$_2$ has been reported [42] but such affinity for alcohol ligands should be less effective for aluminium alkoxides. Besides, Al(O*s*Bu)$_3$ is known to be a much stronger Lewis acid than Zr(O*n*Pr)$_4$. This could explain both why the chemical complexation of the coloured forms of the dyes occurs more easily in Al(O*s*Bu)$_3$ in *s*BuOH than in Zr(O*n*Pr)$_4$ in PrOH, and the greater sensitivity of Zr(O*n*Pr)$_4$ upon dilution in PrOH compared with Al(O*s*Bu)$_3$ in *s*BuOH.

Conclusion

We have studied the photochromic properties of **SO** and **SP** in alcoholic solutions of zirconium and aluminium alkoxides. The photochromism of **SP** in Zr(O*n*Pr)$_4$ reveals a weak stabilizing interaction with zirconium, whereas the photochromism of **SO** is not affected by this medium. In Al(O*s*Bu)$_3$ both **SO** and **SP** show specific photochromism characteristic of a strong chemical interaction between the coloured form of the dyes and the aluminium (hypsochromic shift of the absorption maxima and decrease of the thermal fading). This complexed photochromism can be attributed to an acid/base Lewis interaction between the phenolate anion of the zwitterionic photomerocyanine and the electronic lacuna of the tetracoordinate or pentacoordinate aluminium centre. Addition of the chelating agent EtacH to Al(O*s*Bu)$_3$ leads to the disappearance of the complexed photochromism from the molar ratio Etac/Al = 0.3. Thus, the Etac/Al ratio controls the photochromic behaviour of **SO** and **SP** in the alkoxides Al(O*s*Bu)$_{3-x}$(Etac)$_x$ and the colour obtained under UV irradiation.

Finally this study provides useful data for a good understanding of the photochromism observed in solid materials obtained by the sol-gel process of these alkoxides.

Experimental Section

Synthesis: Zr(O*n*Pr)$_4$ (70% in PrOH by weight), PrOH and *s*BuOH were purchased from Fluka. Al(O*s*Bu)$_3$ (75% in *s*BuOH by weight)

and Al(O*s*Bu)$_2$(Etac) (Etac = $C_6H_9O_3$) (95% in *s*BuOH by weight) were purchased from Gelest. Ethyl acetoacetate (EtacH), and the **SO** and **SP** dyes were purchased from Aldrich. Zr(O*n*Pr)$_4$ was used at 70% and 7% by weight in PrOH, Al(O*s*Bu)$_3$ was used at 75% and 10% by weight in *s*BuOH, Al(O*s*Bu)$_2$(Etac) was used at 70% by weight in *s*BuOH. Al(O*s*Bu)$_{3-x}$(Etac)$_x$ alkoxides were synthesised by mixing Al(O*s*Bu)$_3$ with ethyl acetoacetate at a molar ratio x = EtacH/Al with x = 0.2, 0.3, 0.4, 0.5, 0.6, 0.8 and 1. Solutions of **SO** and **SP** with these different metal alkoxides were prepared at a constant concentration of 5 10^{-3} mol·L^{-1}.

FTIR Spectroscopy: FTIR spectra were recorded with a 550 Magna Nicolet spectrometer using the ATR technique and a ZnSe crystal.

NMR Spectroscopy: ^{13}C NMR spectra were recorded in C_6D_6 with a Bruker AC 300 spectrometer in 5-mm tubes. Chemical shifts are given with respect to tetramethylsilane (TMS). ^{27}Al NMR spectra were recorded with a Bruker MSL 400 (104.26 MHz) spectrometer at room temperature. The reference (δ = 0 ppm) was an acidic aqueous solution of aluminium nitrate. The sample was held in an 8-mm tube which was in turn placed in a 10-mm tube with C_6D_6 in the annulus as the lock solvent; 144 transients were accumulated for each sample with pulse widths of 10 μs and recycle delays of 10 s. A blank spectrum (including the probe signal) was recorded under the same experimental conditions and subtracted from each spectrum.

Viscosity Measurements: Relative viscosities were measured with a Carri-med CHR apparatus using a cylindrical geometry. Measurements were obtained under a constant pressure of 10 Pa, the equipment could not detect viscosity under 10^{-2} kg·m^{-1}·s^{-1}.

Optical Experiments: A schematic representation of the basic set-up is given in Figure 12. UV light was filtered from a 400-W Xe lamp and used to activate the photocolouration of the photochromic samples. The light beam was then turned off to follow the dark fading for 10 min. The absorption spectra before and during UV irradiation, and kinetics of dark fading were recorded with a Uvikon 940 spectrophotometer in 1-mm thick quartz cells at room temperature. The kinetics of bleaching were studied by monitoring the fading of the absorbance at each wavelength of absorption maxima of the visible spectrum. The thermal bleachings were fitted ($R^2 > 0.95$) by using a mono-exponential equation: $A = B \exp(-k_\Delta t) + C$ (with C being the initial optical density before UV irradiation).

Alkylzinc Complexes with Achiral and Chiral Monoanionic *N,N,O* Heteroscorpionate Ligands

Ina Hegelmann,[a] Alexander Beck,[a] Christian Eichhorn,[b] Bernhard Weibert,[a] and Nicolai Burzlaff*[a]

Keywords: Scorpionate ligands / Zinc / Bioinorganic chemistry / Tripodal ligands / N ligands

The synthesis of the new chiral ligand (3,5-di-*tert*-butylpyrazol-1-yl)(3′,5′-dimethylpyrazol-1-yl)acetic acid (bpaH^{tBu2,Me2}) (**4**) has been achieved. Two different synthetic routes to its precursor 3,5-di-*tert*-butyl-1-[(3,5-dimethyl-1*H*-pyrazol-1-yl)methyl]-1*H*-pyrazole (bpm^{tBu2,Me2}) (**3**) are reported. Deprotonation at the methylene group, followed by reaction with carbon dioxide, yielded a racemic mixture of **4**. The chemical behaviour of bis(3,5-di-*tert*-butylpyrazol-1-yl)acetic acid (bd*t*bpzaH) (**2**) and the new chiral *N,N,O* scorpionate ligand **4** involving their coordination to zinc ions was studied. [Zn(bpa^{tBu2,Me2})Cl] (**5**) was formed from a mixture of $ZnCl_2$, **4** and base. Reaction of bis(3,5-di-*tert*-butylpyrazol-1-yl)acetic acid (bd*t*bpzaH) (**2**) with $Zn(CH_3)_2$ or $Zn(CH_2CH_3)_2$ gave the alkylzinc complexes [Zn(bd*t*bpza)(CH_3)] (**6**) and [Zn(bd*t*bpza)(CH_2CH_3)] (**7**). [Zn(bpa^{tBu2,Me2})(CH_3)] (**8**) was obtained from a synthesis analogous to that of **6** with **4**. The further reactions of **6** and **8** with acetic acid resulted in the acetato complexes [Zn(OAc)(bd*t*bpza)] (**9**) and [Zn(OAc)(bpa^{tBu2,Me2})] (**10**). The chiral methyl complex **8** may serve as a precursor for structural model complexes of the active sites of zinc enzymes, such as thermolysin or carboxypeptidase A. [Zn(bpa^{tBu2,Me2})$_2$] (**11**) was formed from a side reaction. Crystal structures of **4**, **5**, **8** and **11** were obtained; **5** crystallised as the dimer [Zn(bpa^{tBu2,Me2})Cl]$_2$; **11** presents an unusual zinc binding geometry.

Introduction

Zinc complexes with *N,N,O* ligands can serve as models for the active site of zinc-containing enzymes that bind the metal ion with two histidine groups and one aspartate or glutamate group. Examples are carboxypeptidase A, thermolysin (Figure 1) and other proteases.[1–5]

There are only a few examples of *N,N,O* tripod ligands that mimic this motif. Carrano et al. used the scorpionate ligand (3-*tert*-butyl-2-hydroxy-5-methylphenyl)bis(3,5-dimethylpyrazol-1-yl)methane to generate model complexes of zinc-containing enzymes.[6] However, instead of a carboxylate *O*-donor, this ligand contained a phenolate *O*-donor. By insertion of formaldehyde or carbon dioxide into a B–H bond of zinc bis(pyrazol-1-yl)hydroborate complexes, Parkin et al. also formed *N,N,O* model complexes.[7] Recently, we reported on the synthesis of structural models for this class of enzymes by using bis(3,5-di-*tert*-butylpyrazol-1-yl)acetic acid.[8]

Since enzymes are chiral compounds there has been a major effort in bioinorganic chemistry to supply chiral models for the active sites of metalloenzymes. Alsfasser et al.[9] and Vahrenkamp et al.[10] achieved this by including amino acids in the ligand systems. Modification of hydrotris(pyrazol-1-yl)borate (Tp) ligands by chiral pyrazoles de-

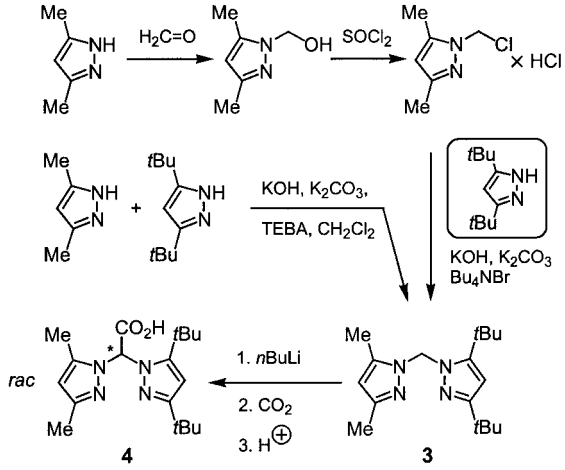
rived from the chiral pool is another way to form chiral *N*,*N*,*N* tripod ligands. This was the method used by Tolman et al.[11]

In recent years some of these zinc model complexes have been tested as catalysts for CO_2 activation.[12] Major progress has been made by using Zn^{II}-based catalysts for the copolymerisation of carbon dioxide and epoxides with the focus being on the tacticity of the polycarbonates.[13,14]

Results and Discussion

Based on the ligand synthesis of bdmpza published by Otero et al.,[15] we recently developed a simple synthesis for the sterically hindered bd*t*bpzaH (**2**) suitable for use in forming the model complexes [Zn(bd*t*bpza)Cl].[8] This route was also applied in the synthesis of a racemic mixture of a new chiral *N*,*N*,*O* scorpionate ligand. The unsymmetrical 3,5-di-*tert*-butyl-1-[(3,5-dimethyl-1*H*-pyrazol-1-yl)methyl]-1*H*-pyrazole (bpm^{tBu2,Me2}) (**3**) served as the starting material.[16] It was obtained by a phase-transfer-catalysed reaction of 1-chloromethyl-3,5-dimethylpyrazole hydrochloride with 3,5-di-*tert*-butylpyrazole under basic conditions (Scheme 1). However, the one-step phase-transfer-catalysed reaction of 3,5-dimethylpyrazole with 3,5-di-*tert*-butylpyrazole, dichloromethane and base was more convenient (Scheme 1).



Scheme 1

After separation by column chromatography on silica, **3** was isolated in a yield of up to 17% from the reaction mixture of the three possible products. Since the other two products bis(3,5-dimethylpyrazol-1-yl)methane and especially bis(3,5-di-*tert*-butylpyrazol-1-yl)methane (**1**) can also be isolated in pure form and used for further syntheses, the second synthetic route is currently preferred. Two sets of signals are detected for the two different pyrazolyl rings in the ^1H and ^{13}C NMR spectra. Two medium-intensive IR bands at 1559 and 1541 cm^{-1} are also found for these two pyrazolyl rings.

Deprotonation of a methylene group in **3** followed by reaction with carbon dioxide and acidic workup yielded a racemic mixture of (3,5-di-*tert*-butylpyrazol-1-yl)(3′,5′-dimethylpyrazol-1-yl)acetic acid (bpaH^{tBu2,Me2}) (**4**) (Scheme 1). As in **3** two sets of signals are found in the IR, ^1H and ^{13}C NMR spectra. A strong IR band at 1758 cm^{-1} and a ^1H NMR signal at $\delta = 11.09$ ppm are an indication of the carboxylate group. Crystals of **4** suitable for X-ray structure determination were obtained by crystallisation from acetone (Figure 2). Bond lengths and bond angles in **4** (Table 1) are in good agreement with those reported earlier for bd*t*bpzaH (**2**).[8]

The proton of the carboxylate group was located. It forms an intermolecular hydrogen bond to a pyrazole nitrogen atom of another molecule [*d*(H10−N11) = 1.576(3) Å].

Reaction of **4** with base and water-free $ZnCl_2$ yielded [Zn(bpa^{tBu2,Me2})Cl] (**5**) [Equation (1)]. Suitable crystals of **5** were obtained from dichloromethane. Complex **5** crystallised as a cross-linked dimer [Zn(bpa^{tBu2,Me2})Cl]$_2$ (Figure 3). Selected bond lengths and bond angles of **5** are summarised in Table 2.

Zn(1)−O(1A)	1.942(2)	O(1A)−Zn(1)−N(21)	103.95(9)
Zn(1)−Cl(1)	2.233(2)	N(11)−Zn(1)−Cl(1)	109.77(8)
		N(21)−Zn(1)−Cl(1)	115.91(6)
		O(1A)−Zn(1)−Cl(1)	117.42(9)

The coordination sphere around the zinc atom is almost tetrahedral, although the angle N(11)−Zn−N(21) [95.17(10)°] is smaller than the ideal tetrahedral one would be. Nevertheless, this tetrahedron is less flattened compared to that previously observed in the structure of the monomer [Zn(bd*t*bpza)Cl].[8] The coordination of the carboxylate group to the zinc atom is less of an *anti*- and more of a *syn*-type compared with the structure of [Zn(bd*t*bpza)Cl].[8] The better donor properties of this *syn*-type coordination may explain the high $\nu_{as}(CO_2^-)$ absorption around 1696 cm^{-1} (KBr pellet). This $\nu_{as}(CO_2^-)$ absorption is rather broad in solution and is found at 1687 cm^{-1}. An IR signal at 1468 cm^{-1} is assigned to $\nu_s(CO_2^-)$. The proposal of a *syn*-type coordination is also supported by a significantly shorter Zn−O(1) distance [1.942(2) Å] and a longer Zn−Cl distance [2.233(2) Å] compared to those in [Zn(bd*t*bpza)Cl] [1.990(2) and 2.170(2) Å].[8] Again, two sets of signals are observed in the NMR spectra due to the two different pyrazolyl groups. Not all of the quaternary signals are detected in the ^{13}C NMR spectrum that might be caused by a monomer/dimer equilibrium.

In the presence of Lewis base type ligands such as pyridine (py) an equimolar amount of acetic acid selectively cleaves one of the Zn−C bonds of dimethylzinc to form methane and the dimer $[Zn(OAc)(CH_3)(py)]_2$.[17] We have observed, that with sterically demanding bis(pyrazol-1-yl)-acetic acids, monomeric four-coordinated alkyl[bis(pyrazol-1-yl)acetato]zinc complexes are obtained in a similar way. Thus, reaction of bis(3,5-di-*tert*-butylpyrazol-1-yl)acetic acid (**2**) with dialkylzinc ZnR_2 (R = CH_3, CH_2CH_3) generates alkylzinc complexes [Zn(bd*t*bpza)(CH_3)] (**6**) and [Zn(bd*t*bpza)(CH_2CH_3)] (**7**) [Equation (2)] with the elimination of alkane.

R^1	*t*Bu	*t*Bu	Me
R^2	*t*Bu	*t*Bu	*t*Bu

Earlier studies by H. Vahrenkamp et al.[18] and G. Parkin et al.[19] have already shown that four-coordinated alkyl[hydrotris(pyrazol-1-yl)borato]zinc complexes can be obtained by metathesis of ZnR_2 with potassium or thallium salts of sterically demanding hydrotris(pyrazol-1-yl)borate ligands. Since bis(pyrazol-1-yl)acetic acid, and not an alkali carboxylate ligand salt, was used for this synthesis, the workup procedure was simple and **6** and **7** were obtained in high yield and purity; [Zn(bd*t*bpza)(CH_3)] (**6**) is characterised by resonances attributed to the Zn−Me group at δ = −0.35 ppm (^1H NMR) and δ = −10.1 ppm (^{13}C NMR). For the Zn−Et group of [Zn(bd*t*bpza)(CH_2CH_3)] (**7**) signals are found in the ^1H NMR spectrum at δ = 0.52 ppm (q, $^3J_{H,H}$ = 8.0 Hz, CH_2) and δ = 1.29 ppm (t, $^3J_{H,H}$ = 8.0 Hz, CH_3) and in the ^{13}C NMR spectrum at δ = 3.3 ppm (CH_2) and δ = 11.9 ppm (CH_3). The remaining resonances of **6** and **7** can be assigned to the bis(3,5-di-*tert*-butylpyrazol-1-yl)acetato ligand. The analogous reaction of (3,5-di-*tert*-butylpyrazol-1-yl)(3′,5′-dimethylpyrazol-1-yl)acetic acid ($bpaH^{tBu2,Me2}$) (**4**) with dimethylzinc gave the chiral methylzinc complex $[Zn(bpa^{tBu2,Me2})(CH_3)]$ (**8**) [Equation (2)]. The resonances attributed to the Zn−Me group are observed at δ = −0.42 ppm (^1H NMR) and δ = −14.1 ppm (^{13}C NMR). In the infrared spectrum the $\nu_{as}(CO_2^-)$ absorption is assigned to a band at 1669 cm^{-1} and $\nu_s(CO_2^-)$ is assigned to a band at 1466 cm^{-1}. Two sets of NMR and IR signals are found for the two different pyrazolyl groups of the (3,5-di-*tert*-butylpyrazol-1-yl)(3′,5′-dimethylpyrazol-1-yl)acetato ligand. Complex **8** was obtained as a racemic mixture of a chiral complex. Crystals of **8** suitable for X-ray structure determination were obtained from a racemic solution of **8** in CH_2Cl_2. The structure of complex **8** represents one of the rare examples of monomeric four-coordinated alkylzinc complexes and is the first with a carboxylate *O*-donor ligand. Monomers of both enantiomers crystallised in the cell as a result of the centrosymmetric space group (Figure 4). Selected bond lengths and bond angles of **8** are summarised in Table 3.

The Zn−CH_3 bond length in complex **8** [1.962(8) Å] is similar to that in $[Zn(CH_3)Tp^{Me2}]$ [1.981(8) Å].[19] The most striking features of the molecular structure of **8** are

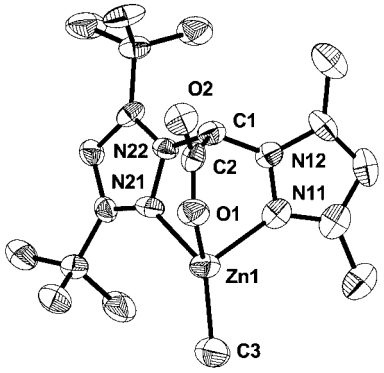

Figure 4. Molecular structure of [Zn(bpa^{tBu2,Me2})(CH$_3$)] (**8**); thermal ellipsoids are drawn at the 50% probability level

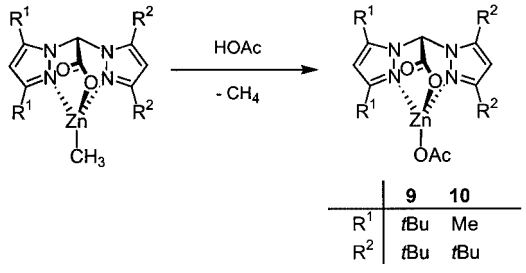
Table 3. Selected bond lengths and angles of complex **8**

Distance [Å]	**8**	Angle [°]	**8**
Zn(1)−N(11)	2.085(7)	N(11)−Zn(1)−N(21)	88.3(3)
Zn(1)−N(21)	2.104(6)	O(1)−Zn(1)−N(11)	88.5(2)
Zn(1)−O(1)	2.054(6)	O(1)−Zn(1)−N(21)	87.0(2)
Zn(1)−C(3)	1.962(8)	C(3)−Zn(1)−N(11)	119.8(3)
		C(3)−Zn(1)−N(21)	133.1(3)
		C(3)−Zn(1)−O(1)	126.8(3)

the two different angles C(3)−Zn−N(11) [119.8(3)°] and C(3)−Zn−N(21) [133.1(3)°]. Obviously, the methyl group C(3) is avoiding the bulky *tert*-butyl group. This implies a possible stereoselective induction for future alkyl-transfer reactions.

The reactivity of **6** and **8** towards acetic acid has been examined to provide acetato complexes as useful precursors to enzyme models. A slight excess of acetic acid cleaves the Zn−CH$_3$ bond with the elimination of methane and yields [Zn(OAc)(bd*t*bpza)] (**9**) and [Zn(OAc)(bpa^{tBu2,Me2})] (**10**) [Equation (3)].



(3)

Therefore, **6** and **8** exhibit a reactivity similar to that of [Zn(CH$_3$)(Tp^{Ph})] and [Zn(CH$_3$)(Tp^{tBu})].[18,19] Signals at δ = 2.12 ppm in the ^{1}H NMR and δ = 21.1 ppm in the ^{13}C NMR spectra of **9** are assigned to the methyl group of the acetato ligand. The carboxylate signal of the acetato ligand was found at δ = 178.2 ppm in the ^{13}C NMR spectrum. Most of the NMR signals of **9** are broad compared to those of the recently published [Zn(bd*t*bpza)Cl] complex. These broad resonances may indicate an η^1/η^2 equilibrium of the acetato ligand. Two additional IR signals at 1633 cm^{-1} and 1602 cm^{-1} are therefore assigned to $\nu_{as}(CO_2^-)$ of η^1- and η^2-bound acetato ligands. The IR signals at 1681 cm^{-1} and 1467 cm^{-1} are assigned to $\nu_{as}(CO_2^-)$ and $\nu_s(CO_2^-)$ of the bd*t*bpza ligand. This is proof of the monomeric structure of **9**, since the monomer [Zn(bd*t*bpza)Cl] shows a similar $\nu_{as}(CO_2^-)$ signal at 1681 cm^{-1}.[8] The value of $\Delta\nu_{as\text{-}s}$ indicates the binding mode of the carboxylate ligand. Values of $\Delta\nu_{as\text{-}s} \geq 200$ cm^{-1} are typical for a unidentate binding mode of acetates which is in good agreement with the $\Delta\nu_{as\text{-}s}$ values of the bis(pyrazol-1-yl)acetato ligands in the complexes **5**−**9**.[20]

The NMR spectra of the complex [Zn(OAc)(bpa^{tBu2,Me2})] (**10**) formed in benzene are similar to those of **9** although two sets of signals for the two different pyrazolyl groups are visible. Three ^{1}H NMR signals at δ = 2.10 ppm, δ = 2.36 ppm and δ = 2.49 ppm are ascribed to two methyl groups of the bpa^{tBu2,Me2} ligand and one of the acetato ligand. A resonance at δ = 22.1 ppm in the ^{13}C NMR spectrum is assigned to the methyl group of the acetato ligand. The carboxylate signal of the acetato ligand was found at δ = 181.2 ppm in the ^{13}C NMR spectrum of **10**. Most of the NMR signals of **10** are broader than those of **9**. Quaternary carbon atoms are difficult to detect in the ^{13}C NMR spectrum due to the signals being broad. A ^{1}H NMR spectrum at −70 °C shows two sets of signals, again indicating an η^1/η^2 equilibrium of the acetato ligand. These slight differences compared with **9** might be explained by the fact that complex **10** is sterically less hindered. In addition to two acetato $\nu_{as}(CO_2^-)$ absorptions at 1624 cm^{-1} and 1601 cm^{-1}, weak IR signals are visible at 1442 cm^{-1} and 1427 cm^{-1} which might be assigned to $\nu_s(CO_2^-)$. The resulting $\Delta\nu_{as\text{-}s}$ values of 159 cm^{-1} and 197 cm^{-1} also verify an η^1/η^2 equilibrium.

[Zn(OAc)(bd*t*bpza)] (**9**) and [Zn(OAc)(bpa^{tBu2,Me2})] (**10**) may also be prepared by reaction of bd*t*bpzaH (**2**) or (bpaH^{tBu2,Me2}) (**4**) with Zn(OAc)$_2$ or from the reaction of

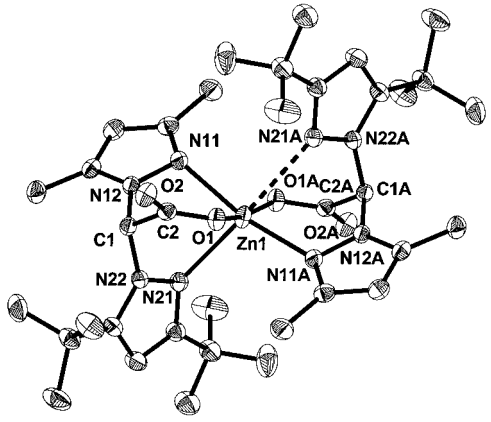


Figure 5. Molecular structure of [Zn(bpa^{tBu2,Me2})$_2$] (**11**); thermal ellipsoids are drawn at the 50% probability level; only one of the zinc positions is shown

the chloro complexes [Zn(bd*t*bpza)Cl] or [Zn(bpa^{tBu2,Me2})Cl] (**5**) with silver acetate. Due to a more complicated workup in these routes along with the formation of by-products we prefer the alkylzinc route.

During the synthesis of **10** in an acetonitrile solution a sandwich complex [Zn(bpa^{tBu2,Me2})$_2$] (**11**) was formed as a by-product. The facile formation of the related six-coordinated complexes [Zn(Tp^R)$_2$] in the reactions of [Zn(Tp^R)X] (X = OH, CH_3, Cl) has already been reported by H. Vahrenkamp et al.,[18] G. Parkin et al.[19] and Kläui et al.[21] with either octahedral[19] or tetrahedral[21] structures of the complexes [Zn(Tp^R)$_2$]. This redistribution seems to be favoured by polar solvents and sterically less demanding ligands, since the synthesis of [Zn(OAc)(bd*t*bpza)] (**9**) is less problematic. Crystals of compound **11** suitable for X-ray analysis were obtained from a solution in $CHCl_3$ (Figure 5). Bond lengths and bond angles of **11** are summarised in Table 4.

Table 4. Selected bond lengths and angles of complex **11**

Distance [Å]	**11**	Angle [°]	**11**
Zn(1)−N(11)	2.156(3)	N(11)−Zn(1)−N(21)	83.99(9)
Zn(1)−N(21)	2.3456(17)	O(1)−Zn(1)−N(11)	86.66(10)
Zn(1)−N(21A)	2.7319(18)	O(1)−Zn(1)−N(21)	89.62(8)
Zn(1)−O(1)	2.006(3)		
Zn(1)−Zn(1A)	0.405(2)		

A structural model with the zinc atom in the centre of the symmetry resembled that of [Zn(bdmpza)$_2$], which we reported recently.[8] The main differences were the extraordinary long bonds of the Zn atom to each of the nitrogen atoms of the two 3,5-di-*tert*-butylpyrazol-1-yl rings. This distance Zn−N(21) [2.5369(14) Å] was in between that of [Zn(bdmpza)$_2$] [2.180(3) Å] and the sum of the van der Waals radii [N 1.55 Å; Zn 1.40 Å]. Until now examples of octahedral zinc complexes with a longer Zn−N distance were rare, and in most cases were caused by a disorder.[22] In addition to the long bond the thermal ellipsoid of the zinc atom is rather elongated towards the two 3,5-di-*tert*-butylpyrazol-1-yl rings. Therefore, the zinc atom in **11** is disordered with two equally occupied positions slightly off the centre of symmetry; **11** exhibits a distorted square-pyramidal coordination with the 3,5-di-*tert*-butylpyrazol-1-yl group slightly bent away from the Zn−N(21) axis and the other 3,5-di-*tert*-butylpyrazol-1-yl group has a weak interaction with the zinc ion from the base direction of the pyramid.

Conclusions

A synthetic route to a racemic mixture of the new chiral scorpionate ligand (3,5-di-*tert*-butylpyrazol-1-yl)(3′,5′-dimethylpyrazol-1-yl)acetic acid (**4**) was found via 3,5-di-*tert*-butyl-1-[(3,5-dimethyl-1*H*-pyrazol-1-yl)methyl]-1*H*-pyrazole (**3**). It is sterically less hindered than the recently published bis(3,5-di-*tert*-butylpyrazol-1-yl)acetic acid (**2**), but its coordination properties are similar to those of **2**. The reaction of **2** or **4** with dialkylzinc yields the new alkylzinc complexes [Zn(bd*t*bpza)(CH_3)] (**6**), [Zn(bd*t*bpza)(CH_2-CH_3)] (**7**) and [Zn(bpa^{tBu2,Me2})(CH_3)] (**8**). Complex **8** is an example of rare monomeric alkylzinc complexes and is the first one with a carboxylate *O*-donor ligand. Acetato complexes [Zn(OAc)(bd*t*bpza)] (**9**) and [Zn(OAc)(bpa^{tBu2,Me2})] (**10**), that serve as models for the active sites of the zinc-containing enzymes carboxypeptidase A or thermolysin, were obtained by reaction of **6** and **8** with acetic acid. Future work has to define a synthetic way to obtain enantiomerically pure bis(pyrazol-1-yl)acetic acids and has to prove whether the configuration of these is stable. This might be useful for structural model complexes of metalloenzymes as well as for organometallic complexes with bis(pyrazol-1-yl)acetate ligands. The first examples of manganese, rhenium and ruthenium complexes with non-chiral bis(pyrazol-1-yl)acetate ligands have already been published.[23]

Experimental Section

General: All experiments were carried out in Schlenk tubes using suitable purified solvents. Microcrystalline precipitates were separated by centrifugation with a Hettich Rotina 46 R Schlenk tube centrifuge. IR: Biorad FTS 60, CaF_2 cuvets (0.5 mm). ^1H and ^{13}C NMR: Bruker WM 250, Bruker AC 250, JEOL GX 400, δ values relative to TMS; in some cases the ^{13}C NMR signals of quaternary carbon atoms were too weak to be detected. EI-MS and FAB MS: modified Finnigan MAT 312. Elemental analyses: Analytical Laboratory of the Fachbereich Chemie, Universität Konstanz. A modified Siemens P4 diffractometer was used for X-ray structure determinations. 3,5-Dimethylpyrazole, 2,2,6,6-tetramethyl-3,5-heptanedione, Zn(CH_3)$_2$ solution, Zn(CH_2CH_3)$_2$ solution and $ZnCl_2$ were used as purchased. 1-Chloromethyl-3,5-dimethylpyrazole hydrochloride was synthesised according to the literature.[24] 3,5-Di-*tert*-butylpyrazole was obtained by a standard literature method from 2,2,6,6-tetramethyl-3,5-heptanedione and hydrazine hydrate.[25] The synthesis of bis(3,5-di-*tert*-butylpyrazol-1-yl)acetic acid (bd*t*bpzaH) (**2**) via bis(3,5-di-*tert*-butylpyrazol-1-yl)methane (**1**) was reported recently.[8]

Ligand Syntheses

Synthesis of 3,5-Di-*tert*-butyl-1-[(3,5-dimethyl-1*H*-pyrazol-1-yl)methyl]-1*H*-pyrazole (bpm^{tBu2,Me2}) (3): 3,5-Dimethylpyrazole (6.93 g, 72.1 mmol), 3,5-di-*tert*-butylpyrazole (13.0 g, 72.1 mmol), KOH (8.42 g, 150 mmol), K_2CO_3 (20.7 g, 150 mmol) and benzyltriethylammonium chloride (2.00 g) were dissolved in dichloromethane (300 mL) and heated under reflux for 12 h. Salts were removed by filtration and the filtrate was concentrated in vacuo to dryness. The white residue was dissolved in water and extracted with pentane (4 × 200 mL). The organic layer was dried (Na_2SO_4) and the solvent removed in vacuo yielding a crude mixture of bis(3,5-dimethylpyrazol-1-yl)methane (bdmpzm), bis(3,5-di-*tert*-butylpyrazol-1-yl)methane (bd*t*bpzm) (**1**) and 3,5-di-*tert*-butyl-1-[(3,5-dimethyl-1*H*-pyrazol-1-yl)methyl]-1*H*-pyrazole (bpm^{tBu2,Me2}) (**3**). Column chromatography with pentane on silica (20 cm) yielded a fraction of bd*t*bpzm (**1**) and with pentane/ethyl acetate (14:1) a pure fraction of bpm^{tBu2,Me2} (**3**). The solutions were dried (Na_2SO_4) and solvents were evaporated; bd*t*bpzm (yield 8.52 g, 63%) was used as described earlier to synthesise bd*t*bpza (**3**).[8] The white residue of

bpm^{tBu2,Me2} (**3**) was recrystallised from acetone to give **3** as colourless crystals, which were dried in vacuo. R_f (pentane/ethyl acetate, 14:1, v/v, silica 60 plate, ammonium vanadate stain) = 0.78 [bd*t*bpzm (**1**)], 0.30 [bpm^{tBu2,Me2} (**3**)]; yield (**3**) 3.52 g (17%); m.p. 75 °C. ^{1}H NMR ($CDCl_3$, 250 MHz): δ = 1.25 (s, 9 H, CH_3), 1.37 (s, 9 H, CH_3), 2.18 (s, 3 H, CH_3), 2.32 (s, 3 H, CH_3), 5.78 (s, 1 H, H_{pz}), 5.86 (s, 1 H, H_{pz}), 6.27 (s, 2 H, CH_2) ppm. ^{13}C NMR ($CDCl_3$, 62.5 MHz): δ = 11.4 (CH_3), 13.4 (CH_3), 30.3 (CH_3), 30.4 (CH_3), 31.6 (C-*t*Bu), 31.9 (C-*t*Bu), 63.1 (CH_2), 101.0 (C_{pz}), 106.5 (C_{pz}), 141.2 (C_{pz}), 147.6 (C_{pz}), 152.6 (C_{pz}), 160.1 (C_{pz}) ppm. EI MS (70 eV): *m*/*z* (%) = 288 (26) [M^+], 193 (30) [$M^+ - C_5H_7N_2$], 108 (100) [$M^+ - C_{11}H_{19}N_2$]. IR (THF): $\tilde{\nu}$ = 1559 (C=N), 1541 (C=N) cm^{-1}. $C_{17}H_{28}N_4$ (288.44): calcd. C 70.79, H 9.78, N 19.42; found C 70.99, H 9.88, N 19.17. Reaction of 1-chloromethyl-3,5-dimethylpyrazole hydrochloride with 1 equiv. of 3,5-di-*tert*-butylpyrazole, traces of benzyltriethylammonium chloride and excess of KOH and K_2CO_3 in THF yielded an identical sample of **3**.

Synthesis of (3,5-Di-*tert*-butylpyrazol-1-yl)(3′,5′-dimethylpyrazol-1-yl)acetic Acid (bpaH^{rBu2,Me2}) (4): A solution of 3,5-di-*tert*-butyl-1-[(3,5-dimethyl-1*H*-pyrazol-1-yl)methyl]-1*H*-pyrazole (bpm^{tBu2,Me2}) (**3**) (6.50 g, 22.5 mmol) in THF (100 mL) was treated with *n*BuLi (ca. 1.6 M solution in hexane, 15.0 mL, 24.0 mmol) at −70 °C. The solution was heated to −45 °C over a period of 2 h and finally flushed with a flow of carbon dioxide. At ambient temperature, the solvent was removed in vacuo and the white residue dissolved in water (100 mL). The aqueous solution was acidified with concentrated HCl to a pH value of 1 and extracted with diethyl ether (4 × 200 mL). The combined organic layers were dried (Na_2SO_4) and concentrated in vacuo to give a white residue. The residue was washed with pentane (2 × 200 mL) to remove unchanged bpm^{tBu2,Me2} (**3**) and dried in vacuo to yield (3,5-di-*tert*-butylpyrazol-1-yl)(3′,5′-dimethylpyrazol-1-yl)acetic acid (bpaH^{tBu2,Me2}) (**4**) as a colourless powder. Yield 4.00 g (53%); m.p. 172 °C (dec.). ^{1}H NMR ($CDCl_3$, 250 MHz): δ = 1.25 (s, 9 H, CH_3), 1.28 (s, 9 H, CH_3), 2.11 (s, 3 H, CH_3), 2.19 (s, 3 H, CH_3), 5.82 (s, 1 H, H_{pz}), 5.98 (s, 1 H, H_{pz}), 7.14 (s, 1 H, CH), 11.09 (br. s, 1 H, CO_2H) ppm. ^{13}C NMR ($CDCl_3$, 62.5 MHz): δ = 11.5 (CH_3), 13.1 (CH_3), 30.1 (CH_3), 30.3 (CH_3), 31.6 (C-*t*Bu), 32.1 (C-*t*Bu), 72.6 (CH), 102.0 (C_{pz}), 108.1 (C_{pz}), 141.3 (C_{pz}), 148.6 (C_{pz}), 154.7 (C_{pz}), 160.3 (C_{pz}), 166.1 (CO_2H) ppm. EI MS (70 eV, 160 °C): *m*/*z* (%) = 332 (7) [M^+], 288 (20) [$M^+ - CO_2$], 193 (100) [$M^+ - C_5H_7N_2 - CO_2$], 109 (58) [$M^+ - C_{11}H_{19}N_2 - CO_2$], 57 (20) [$C_4H_9$]. IR (THF): $\tilde{\nu}$ = 1758 (CO_2H), 1560 (C=N), 1546 (C=N) cm^{-1}. $C_{18}H_{28}N_4O_2$ (332.45): calcd. C 65.03, H 8.49, N 16.85; found C 64.79, H 8.76, N 16.31.

Synthesis of Model Compounds

Synthesis of [Zn(bpa^{rBu2,Me2})Cl]$_2$ (5): $ZnCl_2$ (200 mg, 1.47 mmol) was added to a solution of (3,5-di-*tert*-butylpyrazol-1-yl)(3,5-dimethylpyrazol-1-yl)acetic acid (bpaH^{tBu2,Me2}) (**4**) (400 mg, 1.20 mmol) in acetonitrile (30 mL), and the solution was stirred vigorously at ambient temperature. After 5 min, potassium *tert*-butoxide (135 mg, 1.20 mmol) was added. Within 1 min, a white precipitate formed. After 2 h, the solvent was removed in vacuo. The residue was dissolved in dichloromethane (15 mL) and salts were separated by centrifugation or filtration through Celite. Dichloromethane was removed in vacuo, the residue washed with diethyl ether (2 × 10 mL) and dried in vacuo to afford [Zn(bpa^{tBu2,Me2})Cl]$_2$ (**5**) as a white crystal powder. An air-exposed solution in dichloromethane at room temperature yielded, within 1 d, prism-like colourless crystals suitable for X-ray structure determination. Yield 390 mg (75%); m.p. 259 °C. ^{1}H NMR ($CDCl_3$, 250 MHz): δ = 1.37 (s, 9 H, CH_3), 1.48 (s, 9 H, CH_3), 2.47 (s, 3 H, CH_3), 2.50 (s, 3 H, CH_3), 6.00 (s, 1 H, H_{pz}), 6.09 (s, 1 H, H_{pz}), 6.82 (s, 1 H, CH) ppm. ^{13}C NMR ($CDCl_3$, 62.5 MHz): δ = 11.5 (CH_3), 13.6 (CH_3), 30.1 (CH_3), 30.4 (CH_3), 31.6 (C-*t*Bu), 32.5 (C-*t*Bu), 70.0 (CH), 103.1 (C_{pz}), 107.8 (C_{pz}), four C_{pz} signals not detected, 164.6 (CO_2^-) ppm. EI MS (70 eV, 270 °C): *m*/*z* (%) = 430 (2) [M^+], 386 (48) [$M^+ - CO_2$], 329 (100) [$M^+ - CO_2 - C_4H_9$], 290 (22) [$M^+ - C_5H_8N_2 - CO_2$], 108 (39) [$C_6H_8N_2$]. IR (CH_2Cl_2): $\tilde{\nu}$ = 1687 br (*as*-CO_2^-), 1561 (C=N), 1548 (C=N), 1468 (*s*-CO_2^-) cm^{-1}. IR (KBr): $\tilde{\nu}$ = 1696 (*as*-CO_2^-), 1558 (C=N), 1547 (C=N), 1467 (*s*-CO_2^-) cm^{-1}. $C_{18}H_{27}ClN_4O_2Zn$ (432.27): calcd. C 50.01, H 6.30, N 12.96; found C 49.86, H 6.51, N 12.68.

Method A. General Procedure for Bis(pyrazol-1-yl)acetato(alkyl)-zinc Complexes: A solution of a sterically demanding bis(pyrazol-1-yl)acetic acid in diethyl ether was added to a slight excess of dialkylzinc in diethyl ether. Gas evolution was observed. The solution was stirred at ambient temperature for 1 h. After this time, gas evolution had ceased and the solvent was evaporated. The white residue was dissolved in CH_2Cl_2 or benzene and filtered through Celite. The solvent was again removed in vacuo to yield the product as a white residue.

Synthesis of [Zn(bd*t*bpza)(CH$_3$)] (6): Reaction of bis(3,5-di-*tert*-butylpyrazol-1-yl)acetic acid (bd*t*bpzaH) (**2**) (500 mg, 1.20 mmol) in diethyl ether (10 mL) with $Zn(CH_3)_2$ (0.620 mL of a 2 M solution in toluene, 1.24 mmol) in diethyl ether (10 mL) according to Method A and subsequent workup with CH_2Cl_2 (20 mL) yielded product **6** as a white residue. Yield 550 mg (92%); m.p. 229 °C (dec.). ^{1}H NMR ($CDCl_3$, 250 MHz): δ = −0.35 (s, 3 H, CH_3), 1.36 (s, 18 H, CH_3), 1.53 (s, 18 H, CH_3), 6.08 (s, 2 H, H_{pz}), 7.32 (s, 1 H, CH) ppm. ^{13}C NMR ($CDCl_3$, 62.5 MHz): δ = −10.1 (CH_3-Zn), 30.2 (CH_3), 31.2 (CH_3), 32.0 (C-*t*Bu), 32.3 (C-*t*Bu), 72.1 (CH), 103.1 (C_{pz}), 155.1 (C_{pz}), 163.1 (C_{pz}), 166.3 (CO_2^-) ppm. EI MS (70 eV, 180 °C): *m*/*z* (%) = 481 (18) [$M^+ - CH_3$], 452 (8) [$M^+ - CO_2$], 435 (100) [$M^+ - C_4H_9$], 393 (83) [$M^+ - CO_2 - C_4H_9$], 371 (71) [$M^+ - Zn - CH_3 - CO_2$], 321 (12) [$M^+ - Zn - CH_3 - CO_2 - 2\ C_4H_9$], 57 (62) [$C_4H_9$]. IR ($CH_2Cl_2$): $\tilde{\nu}$ = 1673 (*as*-CO_2^-), 1543 (C=N), 1465 (*s*-CO_2^-) cm^{-1}. $C_{25}H_{42}N_4O_2Zn$ (496.01): calcd. C 60.54, H 8.53, N 11.30; found C 60.50, H 8.72, N 11.30.

Synthesis of [Zn(bd*t*bpza)(CH$_2$CH$_3$)] (7): Reaction of bis(3,5-di-*tert*-butylpyrazol-1-yl)acetic acid (bd*t*bpzaH) (**2**) (500 mg, 1.20 mmol) in diethyl ether (20 mL) with $Zn(CH_2CH_3)_2$ (1.30 mL of a 1 M solution in hexane, 1.30 mmol) in diethyl ether (10 mL) according to Method A and subsequent workup with CH_2Cl_2 (20 mL) yielded product **7** as a white residue. Yield 502 mg (82%); m.p. 168−170 °C. ^{1}H NMR ($CDCl_3$, 250 MHz): δ = 0.52 (q, $^3J_{H,H}$ = 8.0 Hz, 2 H, CH_2), 1.29 (t, $^3J_{H,H}$ = 8.0 Hz, 3 H, CH_3), 1.35 (s, 18 H, CH_3), 1.52 (s, 18 H, CH_3), 6.06 (s, 2 H, H_{pz}), 7.30 (s, 1 H, CH) ppm. ^{13}C NMR ($CDCl_3$, 62.5 MHz): δ = 3.3 (CH_2), 11.9 (CH_3), 30.2 (CH_3), 31.2 (CH_3), 32.0 (C-*t*Bu), 32.3 (C-*t*Bu), 72.1 (CH), 103.1 (C_{pz}), 155.1 (C_{pz}), 163.0 (C_{pz}), 166.6 (CO_2^-) ppm. EI MS (70 eV, 240 °C): *m*/*z* (%) = 479 (40) [$M^+ - CH_2CH_3$], 435 (96) [$M^+ - CH_2CH_3 - CO_2$], 407 (56) [$M^+ - CO_2 - C_4H_9$], 371 (100) [$M^+ - CH_2CH_3 - CO_2 - Zn$], 321 (14) [$M^+ - CH_2CH_3 - CO_2 - Zn - 2\ C_4H_9$], 193 (53) [$C_{12}H_{21}N_2$], 57 (43) [$C_4H_9$]. IR ($CH_2Cl_2$): $\tilde{\nu}$ = 1671 (*as*-CO_2^-), 1544 (C=N), 1465 (*s*-CO_2^-) cm^{-1}. $C_{26}H_{44}N_4O_2Zn$ (510.04): calcd. C 61.23, H 8.70, N 10.98; found C 60.75, H 8.82, N 10.43.

Synthesis of [Zn(bpa^{rBu2,Me2})(CH$_3$)] (8): Reaction of (3,5-di-*tert*-butylpyrazol-1-yl)(3,5-dimethylpyrazol-1-yl)acetic acid (bpaH^{tBu2,Me2}) (**4**) (0.970 g, 2.92 mmol) in diethyl ether (20 mL) with $Zn(CH_3)_2$ (1.65 mL of a 2 M solution in toluene, 3.30 mmol) in diethyl ether (20 mL) according to Method A and subsequent workup with

CH_2Cl_2 (20 mL) yielded product **8** as a white residue. Yield 1.12 g (93%); m.p. 187 °C. ^{1}H NMR ($CDCl_3$, 250 MHz): δ = −0.42 (s, 3 H, CH_3), 1.38 (s, 9 H, CH_3), 1.52 (s, 9 H, CH_3), 2.30 (s, 3 H, CH_3), 2.50 (s, 3 H, CH_3), 5.99 (s, 1 H, H_{pz}), 6.01 (s, 1 H, H_{pz}), 6.89 (s, 1 H, CH) ppm. ^{13}C NMR ($CDCl_3$, 62.5 MHz): δ = −14.1 (CH_3-Zn), 11.5 (CH_3), 12.9 (CH_3), 30.3 (CH_3), 30.5 (CH_3), 31.5 (C-*t*Bu), 32.1 (C-*t*Bu), 70.2 (CH), 102.1 (C_{pz}), 107.3 (C_{pz}), 141.6 (C_{pz}), 150.7 (C_{pz}), 154.1 (C_{pz}), 162.7 (C_{pz}), 165.4 (CO_2^-) ppm. FAB MS (NBOH matrix): *m*/*z* (%) = 809 (21) [$M_2H^+ - CH_3$], 763 (10) [$M_2H^+ - CH_3 - CO_2$], 411 (100) [MH^+], 395 (9) [$M^+ - CH_3$], 365 (31) [$M^+ - CO_2H$], 351 (78) [$M^+ - CH_3 - CO_2$], 287 (86) [$M^+ - CH_3 - CO_2 - Zn$]. IR (CH_2Cl_2): $\tilde{\nu}$ = 1669 (*as*-CO_2^-), 1559 (C=N), 1539 (C=N), 1466 (*s*-CO_2^-) cm^{-1}. $C_{19}H_{30}N_4O_2Zn$ (411.85): calcd. C 55.41, H 7.34, N 13.60; found C 55.02, H 7.21, N 13.62.

Method B. General Procedure for Acetato[bis(pyrazol-1-yl)acetato]-zinc Complexes: An excess of acetic acid was added to a solution of a methyl[bis(pyrazol-1-yl)acetato]zinc complex in benzene. Gas evolution was observed. The solution was stirred at ambient temperature for 30 min. After this time, gas evolution had ceased, the solution was filtered through Celite and the volume of the solution was reduced in vacuo to 1 mL. The product was precipitated with hexane and dried in vacuo to yield the product as a white solid.

Synthesis of [Zn(OAc)(bd*t*bpza)] (9): Reaction of [Zn(bd*t*bpza)-(CH_3)] (**6**) (480 mg, 0.968 mmol) in benzene (10 mL) with acetic acid (100%, 70.0 μL, 1.22 mmol) according to Method B afforded [ZnOAc(bd*t*bpza)] (**9**) as a white crystalline powder. A similar result in yield and purity was obtained from an acetonitrile solution. Yield 400 mg (77%); m.p. 109−111 °C. ^{1}H NMR ($CDCl_3$, 250 MHz): δ = 1.37 (s, 18 H, CH_3), 1.53 (s, 18 H, CH_3), 2.12 (s, 3 H, CH_3−Ac), 6.12 (s, 2 H, H_{pz}), 7.36 (s, 1 H, CH) ppm. ^{1}H NMR (C_6D_6, 250 MHz): δ = 1.21 (s, 18 H, CH_3), 1.43 (s, 18 H, CH_3), 1.93 (s, 3 H, CH_3−Ac), 6.01 (s, 2 H, H_{pz}), 7.55 (s, 1 H, CH) ppm. ^{13}C NMR ($CDCl_3$, 62.5 MHz): δ = 21.1 (CH_3-Ac), 29.9 (CH_3), 31.0 (CH_3), 32.0 (C-*t*Bu), 32.3 (C-*t*Bu), 72.6 (CH), 103.4 (C_{pz}), 155.7 (C_{pz}), 163.2 (C_{pz}), 166.0 (CO_2^-), 178.2 (CO_2^-) ppm. ^{13}C NMR (C_6D_6, 62.5 MHz): δ = 21.9 (CH_3-Ac), 30.5 (CH_3), 30.8 (CH_3), 32.2 (C-*t*Bu), 32.4 (C-*t*Bu), 75.0 (CH), 103.0 (C_{pz}), 154.7 (C_{pz}), 161.8 (C_{pz}), 168.5 (CO_2^-), 179.8 (CO_2^-) ppm. EI MS (70 eV, 200 °C): *m*/*z* (%) = 494 (55) [$M^+ - CO_2$], 479 (43) [$M^+ - CO_2CH_3$], 437 (85) [$M^+ - CO_2 - C_4H_9$], 371 (61) [$M^+ - CO_2CH_3 - CO_2 - Zn$], 193 (100) [$C_{12}H_{21}N_2$], 179 (66) [$C_{11}H_{19}N_2$]. IR ($CH_2Cl_2$): $\tilde{\nu}$ = 1681 (*as*-CO_2^-), 1633 (*as*-CO_2^-), 1602 (*as*-CO_2^-), 1546 (C=N), 1467 (*s*-CO_2^-) cm^{-1}. $C_{26}H_{42}N_4O_4Zn$ (540.02): calcd. C 57.83, H 7.84, N 10.37; found C 58.00, H 8.20, N 10.98.

Synthesis of [Zn(OAc)(bpa^{rBu2,Me2})] (10): Reaction of [Zn-(bpa^{tBu2,Me2})(CH_3)] (**8**) (400 mg, 0.971 mmol) in benzene (5 mL) with acetic acid (100%, 57.0 μL, 1.00 mmol) according to Method B but without filtration through Celite afforded [Zn(OAc)(bpa^{tBu2,Me2})] (**10**) as a white crystalline powder. Yield 401 mg (91%); m.p.

Synthesis of [Zn(OAc)(bpa^{rBu2,Me2})] (10) in Acetonitrile: Reaction of [Zn(bpa^{tBu2,Me2})(CH_3)] (**8**) (310 mg, 0.753 mmol) in acetonitrile (5 mL) with acetic acid (100%, 80.0 μL, 1.40 mmol) according to Method B afforded [Zn(OAc)(bpa^{tBu2,Me2})] (**10**) as a white crystalline powder. The spectroscopic data are identical to those of **10** that was obtained in benzene solution. Yield (**10**) 162 mg (47%).

[Zn(bpa^{rBu2,Me2})$_2$] (11): During the synthesis of **10** in acetonitrile a white precipitate formed in the solution that was filtered off. This white residue was dissolved in CH_2Cl_2, filtered through Celite and dried in vacuo to yield [Zn(bpa^{tBu2,Me2})$_2$] (**11**) as a white crystalline powder. Additional purification can be achieved by extraction with CH_2Cl_2 from a water suspension. Crystals suitable for X-ray structure determination were obtained from a solution in $CHCl_3$. Yield 80.0 mg (29%); m.p. 207 °C (dec.). ^{1}H NMR ($CDCl_3$, 400 MHz): δ = 1.08 (s, 9 H, CH_3), 1.53 (s, 9 H, CH_3), 1.92 (s, 3 H, CH_3) 2.42 (s, 3 H, CH_3), 5.86 (s, 1 H, H_{pz}), 5.96 (s, 1 H, H_{pz}), 6.90 (s, 1 H, CH) ppm. ^{13}C NMR ($CDCl_3$, 62.5 MHz): δ = 11.8 (CH_3), 13.1 (CH_3), 30.1 (CH_3), 30.8 (CH_3), 31.6 (C-*t*Bu), 32.3 (C-*t*Bu), 70.5 (CH), 102.6 (C_{pz}), 107.6 (C_{pz}), 140.8 (C_{pz}), 150.8 (C_{pz}), 153.0 (C_{pz}), 163.0 (C_{pz}), 166.4 (CO_2^-) ppm. EI MS (70 eV, 250 °C): *m*/*z* (%) = 684 (0.5) [$M^+ - CO_2$], 353 (2) [$C_{17}H_{28}N_4$ + Zn], 288 (5.5) [$C_{17}H_{28}N_4$], 192 (26) [$C_{12}H_{20}N_2$], 177 (100) [$C_{11}H_{17}N_2$]. IR (CH_2Cl_2): $\tilde{\nu}$ = 1664 (*as*-CO_2^-), 1562 (C=N), 1540 (C=N), 1466 (*s*-CO_2^-) cm^{-1}. $C_{36}H_{54}N_8O_4Zn \cdot 2\,CHCl_3$ (967.01): calcd. C 47.39, H 5.87, N 11.64; found C 47.08, H 6.02, N 11.41.

X-ray Structure Determinations: Single crystals of **4**, **5** and **8** were sealed in glass capillaries at room temperature. A modified Siemens P4 diffractometer was used for data collection (Wyckhoff technique, graphite monochromator, Mo-K_α radiation, λ = 0.71073 Å, scan rate 4−30°min^{-1} in ω). The data set of **11** was collected with a Bruker Smart Apex. The structures were solved using direct methods {Siemens SHELXS-93[26]} and refined with full-matrix least squares against F^2 {Siemens SHELXL-97[26]}. A weighting scheme was applied in the last steps of the refinement with $w = 1/[\sigma^2(F_o^2) + (aP)^2 + bP]$ and $P = [2F_c^2 + \max(F_o^2,0)]/3$. Hydrogen atoms were included in their calculated positions and refined in a riding model. Compound **4** crystallised with one third of an acetone molecule in a special position. The carboxylic proton of **4** was found. In the case of **5** the asymmetric unit is filled by half of a dimer of the molecule. In the asymmetric unit of structure **5** one and a half molecules of dichloromethane were found and refined. The half molecule was found in a special position. One molecule of dichloromethane co-crystallised with **8**. In the case of complex **11** one molecule of $CHCl_3$ crystallised with half of the molecule. All details and parameters of the measurements are summarised in Table 5. The structure pictures were prepared with the program Diamond 2.1c.[27] CCDC-184127 [Zn(bpa^{tBu2,Me2})Cl]$_2$ (**5**), -184128 [Zn(bpa^{tBu2,Me2})(CH_3)] (**8**) and -184129 [Zn(bpa^{tBu2,Me2})$_2$] (**11**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Acknowledgments

Generous financial support by the Fonds der Chemischen Industrie (Liebig-Stipendium to N. B.) and the European Commission (Copernicus 2 Program, Contract no. ICA2-CT-2000−10002) is gratefully acknowledged. Special thanks to Prof. Dr. H. Fischer for support and discussion and also to Prof. Dr. W. A. Schenk for giving us access to a Bruker Smart Apex in Würzburg. We are indebted to Mr. Hägele and Mr. Galetskiy for recording mass spectra.

New Dinuclear Palladium Phosphane Complexes Stabilised by 8-Thiotheophylline

Antonio Romerosa,*[a] Carlos López-Magaña,[a] Mustapha Saoud,[a] and Sonia Mañas[a]

Keywords: Palladium / Nucleobases / Bioinorganic chemistry / P ligands

The new purine derivatives SS-bis-8-(thio)-theophylline (8-$BTTH_2$) and 8-phenylthiotheophylline (8-PhTTH), have been synthesised and characterised by elemental analysis, mass spectrometry and standard spectroscopic measurements. Reaction of 8-$BTTH_2$ with *cis*-$[PdCl_2(PPh_3)_2]$ leads to the formation of the binuclear palladium complex $[Pd(PPh_3)(\mu\text{-}Cl)(8\text{-}TT)]_2$ (8-TTH_2 = 8-thiotheophylline) in which PPh_3-induced cleavage of the S–S bridge takes place. This complex reacts with pyridine to give a different dimeric palladium complex, $[Pd(\mu\text{-}S,N\text{-}8\text{-}TT)(PPh_3)Py]_2$, in which each of the two 8-thio-(theophylline) anions binds two metals through the N7 and S atoms. The process leading to the palladium complex has also been elucidated.

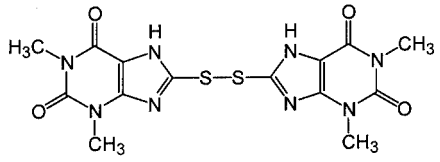
Introduction

The interaction between metal ions and purine bases has been an important area of research in recent years. This is mainly a consequence of the biological relevance of purines, which are one of the principal constituents of nucleic acid derivatives.[1,2] Purines possess a variety of potential donor groups in their molecular skeleton and consequently behave as effective ligands towards a wide range of metal ions. Coordination to a metal ion often alters the main chemical properties of the purine molecules.[3,4] As a consequence, some metal complexes are active drugs for medical purposes.[5] The most well-known and best studied metal-based drugs are the anticancer compounds of platinum.[6]

A deep knowledge of the action mechanism of the drugs is indispensable in designing improved drugs with increased potency and reduced side effects. Ligand exchange plays an important role in determining the biological activity, as very few metal-based drugs reach the biological target without being modified. Most of them interact with different macromolecules, such as S-donor compounds, and/or water. Therefore, understanding how a drug is transformed upon interacting with biological ligands has become of paramount importance. Usually, the biomolecules that interact with and alter the metal-based drug, provoking a specialised therapeutic effect, are structurally complicated. As a consequence, it is useful to mimic their reactivity towards the metal centre through simplified model molecules. Aiming at obtaining a new simple model for addressing the interaction of purines with transition metal ions, we have synthesised the new ligand *S*,*S*-bis(8-thiotheophylline) (**1**,8-$BTTH_2$) (Scheme 1) in which two purines are linked by a disulfide group bonded through the C8 atom. This ligand can indeed interact with a metal ion through either the imidazolic N7 atom or the exocyclic O atoms, but the possibility of the sulfur atoms of the disulfide group coordinating to the metal also exists. Accomplishing the latter S-coordination is also important to mimic the coordination abilities of disulfide groups in biomolecules.



8-$BTTH_2$ (**1**)

Scheme 1

The evaluation of the chemical properties of the interaction of **1** with *cis*-$[PdCl_2(PPh_3)_2]$ shows that it is of interest as a biological model. Palladium is a biologically active metal, somewhat similar to platinum, although more reactive, and widely used to promote homogeneous catalytic processes and highly efficient organic syntheses.[7] In the case at hand, the presence of two PPh_3 ancillary ligands, not only makes the palladium complexes soluble in common organic solvents but also provides an NMR-active label, the P-nucleus of the phosphane, which allows us to study its reaction with **1** by $^{31}P\{^1H\}$ NMR spectroscopy.

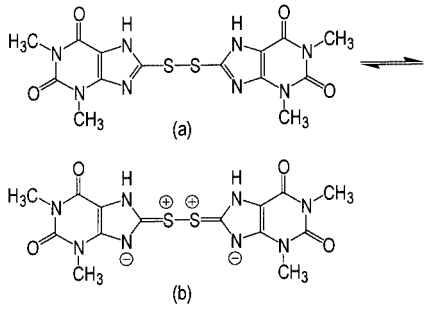
Results and Discussion

Synthesis and Characterisation of *S*,*S*-bis(8-thitheophylline) (1)

The oxidation of the 8-thiotheophillinate potassium salt by the smooth oxidant I_2, which was prepared in situ by reaction of 8-thiotheophylline (8-TTH_2) with KOH, affords the new purine derivative *S*,*S*-bis(8-thiotheophylline) in which two theophylline molecules are held together, through their C8 atoms, by a disulfide bridge.

The IR spectrum of **1** shows a simplification and an intensity reduction of the absorption bands between 2500 and 3700 cm^{-1} compared to that of the parent 8-TTH_2 molecule, which is in agreement with the formation of the disulfide bridge. Key points of the ^1H NMR spectroscopic analysis are the absence of the 8-TTH_2 N−H resonances[8] (δ = 12.95 and 13.36 ppm) and the observation of a unique broad signal at δ = 4.67 ppm that can only be assigned to the imidazolic N−H resonance. The chemical shift of the N7−H proton in **1** appears in the range expected for aliphatic amines, in agreement with their basic character. This fact is better understood by assuming the existence of a partial negative charge on the purine imidazolic ring (Scheme 2). The charge separation may simply be accomplished by moving a lone pair from each of the two S atoms to each of the C8 purine imidazolic carbon atoms. In the resonance structure (b), the S atoms bear a positive charge and, therefore, are well suited to be attacked by nucleophiles. The low acidity of the N7 proton indeed suggests a large contribution of the structure (b) and points to the tendency of this new purine derivative to react with electron rich species through the disulfide group.



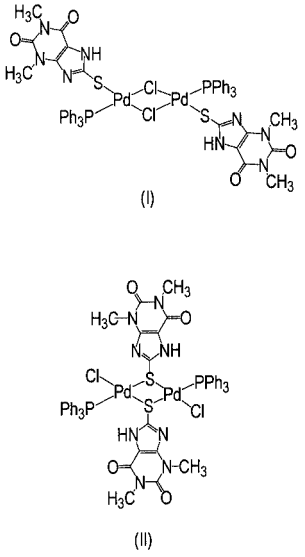
Scheme 2

The $^{13}C\{^1H\}$ NMR spectrum provides the conclusive evidence that confirms the proposed structure for **1**. Particularly, and in keeping with the presence of a substituted S atom, the C-8 resonance appears much closer (δ = 148 ppm) to that in 8-methylthiotheophylline (δ = 153.0 ppm)[12] than in 8-TTH_2 (δ = 163.8 ppm).[13]

Characterisation and Mechanistic Studies of the Formation of the Palladium Complexes 6 and 7

Different synthetic strategies may be used to prepare **6**: (i) the reaction of **1** with *cis*-$[PdCl_2(PPh_3)_2]$ and KOH in refluxing EtOH, (ii) the reaction of **1** with KOH and $Na_2[PdCl_4]$ and PPh_3 in EtOH/H_2O, and (iii) the reaction of **2**, (**3** or **4**) with *cis*-$[PdCl_2(PPh_3)_2]$ (or $Na_2[PdCl_4]$ and PPh_3) in EtOH under reflux. It is also important to point out that **6** was obtained from the above reactions with high yields irrespective of the molar ratio used. However, a higher yield was obtained from method (ii) using a 1:2:2:4 molar ratio between **1**, KOH, Pd^{2+}, and PPh_3.

Unfortunately, **6** was not soluble enough in the non-coordinating solvent to obtain its ^1H, $^{31}P\{^1H\}$ and $^{13}C\{^1H\}$ NMR spectra.[9] We could conclude that the palladium complex **6** contains a PPh_3 group, a chloride ligand and an 8-TTH^- ligand, the latter coordinated through the S donor atom [ν(N7-H) = 3059−2790 cm^{-1}] on the basis of the synthetic procedures, the elemental analysis and IR spectrum. In order to complete the square-planar geometry around the palladium atom, one can hypothesise that a dimeric structure exists in which the bridging tethering ligand is either the chloride (I) or the sulfur atom of the purine group (II) (Scheme 3). Both structures are realistic and have several precedents in the relevant literature.[10−13]



Scheme 3

Although a definitive comparison between the two proposed structures was not possible on the basis of the data collected, an important element in distinguishing between them comes from the observation that dimeric palladium(II) complexes with halide bridges are readily cleaved by unidentate ligands such as pyridine or PPh_3, while the corresponding palladium(II) thiolato bridges are not.[14−16] Since **6** readily reacts with pyridine to give **7**, we may reasonably assume that structure (I) is much more probable than (II).

In order to understand better the metal-purine interaction in the present palladium complexes, we have decided to study the mechanism responsible for the surprising formation of complex **7**, carrying out a variety of experiments that are discussed below. The first aim of our study was to elucidate the process responsible for the S−S bond

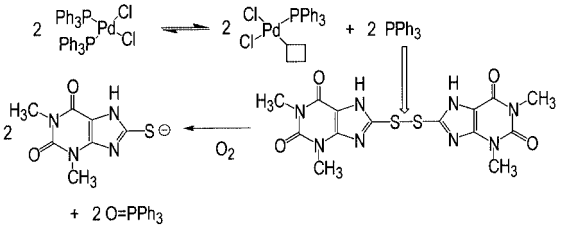
breakage, a result which is quite surprising. The rupture of the S−S bond during the reaction leading to **6** and **7** needs a reducing agent that provides the necessary electrons to accomplish the reduction. Therefore, it is conceivable that the disulfide bond of **1** breaks during the synthetic process leading to **6** and, therefore, it is plausible that one or more compounds implicated in the reaction should take the role of the reducing agent.

Of the several experiments carried out in order to understand the nature of the compounds responsible for the in situ reduction of the disulfide it is worth mentioning the stability tests of **1** in different solvents and pH, and the reactivity tests of 8-TTH_2, **1**, **2**, **3**, and **4** with *cis*-$[PdCl_2(PPh_3)_2]$ (or $[PdCl_4]^{2-}$ and PPh_3) carried out using different stoichiometries and pH conditions. From a perusal of these experiments we may conclude that: a) EtOH and MeOH, in both basic (KOH, pyridine) or acidic (HCl) conditions, do not reduce **1** even after prolonged reflux (up to two days); b) compound **6** was obtained irrespective of the molar proportion of the reagents; c) there are many pathways to access **6** in refluxing EtOH; d) to obtain **6** from 8-TTH_2 a basic medium (KOH or NaOH) is mandatory.

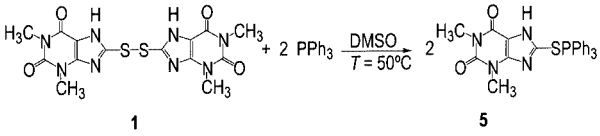
Monitoring the reaction between **1** and *cis*-$[PdCl_2(PPh_3)_2]$ by $^{31}P\{^1H\}$ and ^1H NMR spectroscopy provided additional pieces of information to clarify the reduction step of the S−S bond. This study was carried out as follows: ligand **1** and *cis*-$[PdCl_2(PPh_3)_2]$ (1:2 molar ratio) were placed into an NMR tube and CD_3OD was added from a syringe at 20 °C. At this temperature a $^{31}P\{^1H\}$ NMR spectrum was immediately acquired, showing only the *cis*-$[PdCl_2(PPh_3)_2]$ resonance. A reaction only took place after heating the solution to 50 °C. After 6 hours of heating at this temperature, the *cis*-$[PdCl_2(PPh_3)_2]$ resonance was no longer observed while the $^{31}P\{^1H\}$ resonance of $O{=}PPh_3$ appeared (δ = 29.58 ppm, confirmed also by GC-MS analysis) and a red orange precipitate was formed. This precipitate was filtered out from the solution, washed with ethanol and dried. On the basis of IR data the red solid was assigned as **6**.

An interpretation of the above results suggests that the reducing agent responsible for the S−S bond cleavage should be the PPh_3. In effect, the phosphane may be readily produced from *cis*-$[PdCl_2(PPh_3)_2]$ (Scheme 4) through a dissociation equilibrium[17,18] and its capacity to efficiently reduce disulfide groups in proteins and other disulfide derivatives has been documented.[19] In order to confirm whether PPh_3 is the only reducing agent or whether the palladium metal also plays a role in this process, the reactivity of **1** with PPh_3 in MeOH and DMSO as well as of **3** with PPh_3 in MeOH were studied in situ, carrying out bulk experiments.

From these experiments, we may conclude that PPh_3 alone is responsible for the cleavage of the S−S bond in **1** while the metal plays no role in the process. In this regard, it is important to stress that during the in situ reaction between **1** and PPh_3 in CD_3OD, $O{=}PPh_3$ is produced in quantitative yield. On carrying out the same reaction in DMSO (Scheme 5) the phenylthiotheophylline (**5**, 8-PhTTH), a new thiopurine containing an S-PPh_3 group, was formed. Compound **5** was fully characterised (see Exp. Sect.), but for the present discussion it is important to stress that in the $^{13}C\{^1H\}$ NMR spectrum, C8 resonates at δ = 170.3 ppm ([D_6]DMSO), very deshielded with respect to the corresponding signal for the *S*-alkyl-substituted 8-TTH_2 derivatives[11] ($\delta \approx 150$ ppm).



Scheme 4

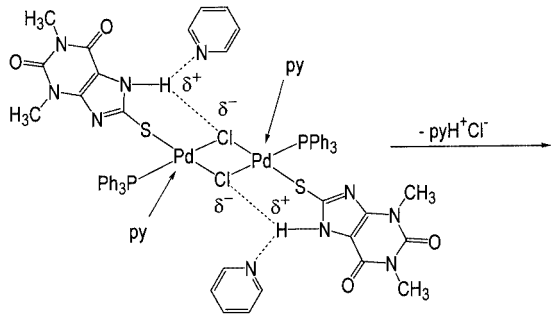


Scheme 5

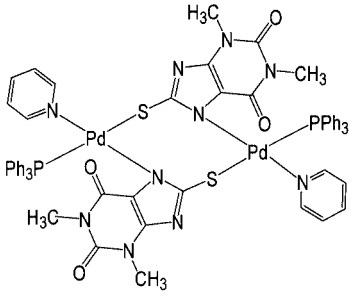
Finally, the orange compound **6** reacts simply with pyridine to give **7** which likely forms via cleavage of the bridging structure followed by nucleophilic substitution of the bridging chloride ligand by pyridine (Scheme 6).[21,22] In this basic medium, deprotonation of the N7 imidazolic nitrogen easily takes place to yield the corresponding anion which may coordinate to the palladium metal. Moreover, and in keeping with this overall mechanism, formation of PPh_3 is not observed by NMR spectroscopic methods when **6** is dissolved in [D_5]pyridine.

Crystal Structure of $[Pd(\mu\text{-S},N\text{-8-TT})(PPh_3)Py]_2{\cdot}9H_2O$ (7)

Orange prismatic crystals of the dimeric palladium complex $[Pd(\mu\text{-S},N\text{-8-TT})(PPh_3)Py]_2{\cdot}9H_2O$ (**7**) suitable for an X-ray study were obtained from a pyridine/acetonitrile solution of complex **6**. Although both IR and $^{31}P\{^1H\}$ NMR ($CDCl_3$) spectra are in good agreement with the solid-state structure of **7**, the ^1H NMR spectrum recorded in $CDCl_3$ does not match up with it. The most significant discrepancy is the appearance of four different singlets in the range typical of the $N{-}CH_3$ groups of the purines (δ = 3.14, 3.22, 3.40 and 3.52 ppm). Such behaviour points to the magnetic inequivalence of the purine $N{-}CH_3$ groups and also indicates that the two purines have different chemical environments. Other important ^1H NMR spectroscopic features are a broad signal at δ = 13.21 ppm, suggesting that the N7 purine atom is protonated, and a resonance at δ = 11.38 ppm that cannot easily be assigned, even though an N7 purine imidazolic proton seems a realistic assignment for this low-field shifted resonance.[1,20] Recording the ^1H NMR spectrum at different temperatures in $CDCl_3$ points



6



7

Scheme 6

towards the existence of a temperature dependent equilibrium for **7**. Notably, while the N−CH_3, pyridine and PPh_3 signals do not vary significantly with the temperature in the -60 to +60 °C range, the two low-field signals at δ = 11.38 and 13.21 ppm are lost at higher temperatures. This fact suggests that complex **7** encompasses an equilibrium between two different species. Recording the ^{1}H NMR spectrum of **7** in [D_5]pyridine further corroborates this finding as the proton spectrum contains only two signals in the purine N−CH_3 region (δ = 3.14 ppm for N1−CH_3; δ = 3.29 ppm for N3−CH_3) while the N7−H signals are no longer evident. By slow evaporation of the [D_5]pyridine solution orange crystals are obtained, which display IR and ^{1}H NMR ($CDCl_3$) spectra identical to those of the original compound **7**.[21]

In order to determine the structure of the palladium compound **7** and to collect important geometrical information on this class of compounds, an X-ray analysis has been carried out on a single crystal. The diffraction study showed that a dinuclear palladium complex and nine water molecules form the asymmetric unit cell. Four water molecules are located in a precise position of the lattice while the remaining five are disordered. An ORTEP drawing of the complex is shown in Figure 1 with the atomic numbering scheme. Details of crystal data and relevant information are summarized in Table 1.

Each metal atom in **7** displays a distorted square-planar coordination with the triphenylphosphane molecule located *cis* to a pyridine N atom and *cis* to the S atom of an 8-

TT^{2-} ligand. A *trans*-located N7 imidazolic atom from a second 8-TT^{2-} ligand completes the coordination polyhedron about each palladium atom. A remarkable feature of the present structure is that each palladium atom is linked by two different molecules of purine, i.e. each purine ligand in the dimeric structure binds two different palladium atoms, the first one using the S-atom and the second one through the imidazolic N7 atom. Thus, an eight-membered ring containing Pd1-S1-C8A-N7A-Pd2-S2-C8B-N7B and featuring a boat geometry is formed (Figure 2). For both metals, the square-planar coordination deviates slightly from planarity (Pd1, rms deviation 0.024; Pd2, rms deviation 0.070), the largest deviation being 4.15(69)° Å (for

Pd1) and 3.87(81)° Å (for Pd2). The dihedral (OR torsion) angle between the palladium planes is 71.00(31)°.

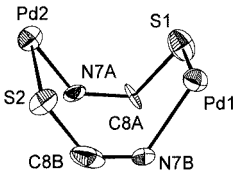

Figure 2

The two purine molecules are practically planar (the torsional angles between the imidazolic and pyrimidinic mean planes are: 3.10(1.34)°, (molecule A); and 4.12(1.24)°, (molecule B) and also non parallel to one another [angle between imidazolic mean plane of A and B purine molecules: 16.12(45)°], while the exocyclic groups do not show any significant deviation from the plane containing the purine ligand.

The bond lengths between palladium and the NNSP donor set are similar for both metal atoms, the largest difference being only 0.0423(399) Å between the N7A−Pd2 and N7B−Pd1 bond length. The analysis of the coordination distances showed the well-known *trans*-effect exerted by the P atoms. In fact, the longer P−Pd separation [P1−Pd1: 2.2655(75) Å] is opposite to the shorter N7 metal distance [N7B−Pd1: 2.0601(190) Å] and vice versa [P2−Pd2: 2.2863(77) Å; N7A−Pd2 2.1024(209) Å]. The distances N(pyridine)−Pd, and S−Pd are similar for both metal centres [N11P−Pd1: 2.0791(92) Å; N1P−Pd2: 2.0791(100) Å]. The two Pd−N(pyridine) distances are longer than the covalent Pd−N bond length (1.98 Å) and are even longer than the Pd−N bond lengths of other Pd−N(pyridine) complexes (1.98−2.04 Å) according to a search in the Cambridge Structural Database,[22] although they are similar to those found in palladium complexes in which pyridine is *trans* to an alkyl C atom.[23] Palladium complexes featuring a coordination sphere containing N, S, P and N atoms are unknown, and therefore no comparative information is available to discuss the *trans*-effect seen in **7** in detail.

A final comment relevant to the Pd1−Pd2 separation [4.1364(70) Å], is that this distance excludes any significant bonding interactions between the two metal centres. The rest of the bond lengths and angles are similar to those found in other N(7)-bonded purine complexes,[6,24] and do not deserve any additional comments.

Conclusions

The mild oxidation of 8-thiotheophylline (8-TTH_2) with I_2 leads to the formation of **1**, a new thiopurine derivative containing two theophylline units bonded through the C8 carbon atoms by a S−S bridge. Reaction of **1** with *cis*-[$PdCl_2(PPh_3)_2$] gives **6** in which two palladium atoms are likely to be bridged by two chlorides and each metal is additionally coordinated to one PPh_3 group and to the deprotonated thiol group of the 8-thiotheophylline ligand. It is conceivable that PPh_3 released from the *cis*-[$PdCl_2(PPh_3)_2$], is responsible for the cleavage of the S−S bond in **1**. Complex **6** reacts with pyridine to give the dimetallic complex **7** which was authenticated by X-ray methods. In the latter complex two palladium atoms are held together by two molecules of 8-TT^{2-} through the N7 and S atom. Each metal completes a square-planar coordination by using one PPh_3 and one pyridine molecule. The bonding pattern of the thiotheophyllinate anion in **7** is without precedent and represents a remarkable and curious coordination mode of purine derivatives. The process leading to **7** has been rationalised and likely proceeds via nucleophilic substitution of the two chloride bridges and subsequent deprotonation of the 8-TTH^- by pyridine.

The experimental results suggest: a) The coordination of the present thiopurine occurs through the S-atom; b) phosphane metal complexes, like the palladium one used in this work as the starting material, may be biologically relevant due to their capacity of easily dissociating the phosphane ligand, which, in turn, may react with disulfide groups of sulfur-containing proteins resulting in the cleavage of the S−S bridges. Although the solubility of the present palladium complexes do not allow any possible application in medicinal chemistry, this kind of study, possibly extended to other nucleobases and/or to different transition metal complexes and phosphanes, is important because it can bring about new metal-nucleobase interactions. Current studies are in progress in our laboratories in order to verify whether the use of palladium and platinum complexes, stabilised by water soluble phosphanes, may lead to the synthesis of metal-purine derivatives of higher solubility in biological conditions.

Experimental Section

All reagents were of analytical grade and were used without further purification. The complexes *cis*-[$PdCl_2(PPh_3)_2$],[6] $Na_2[PdCl_4]$ and the ligand 8-thiotheophylline[25] (8-TTH_2) were prepared as described previously. All reactions were routinely performed under argon by using standard Schlenk-tube techniques. Deuterated solvents for NMR spectroscopic measurements were dried over molecular sieves (4 Å). ^1H, $^{13}C\{^1H\}$ and $^{31}P\{^1H\}$ NMR spectra were recorded on a Bruker AVANCE DPX 300 spectrometer. Peak positions are relative to tetramethylsilane (^1H, $^{13}C\{^1H\}$) and were calibrated with respect to the residual protonated solvent (^1H) or to the solvent resonance ($^{13}C\{^1H\}$). The $^{31}P\{^1H\}$ NMR spectra are given with respect to external 85% H_3PO_4 in D_2O with downfield values taken as positive. Infrared spectra were recorded on KBr discs on a IR-ATI Mattson Infinity Series. Elemental analyses (C, H N, S) were performed on a Fisons Instruments EA 1108 elemental analyser. GC/MS analyses were carried out using a Varian GC/MS Saturn 3 gas chromatograph-ion-trap mass spectrometer, using a stationary phase column DB-5MS (J&W Scientific,Folsom, Ca, USA), 30 m × 0.25 mm I.D. × 0.25 μm film thickness. Melting points were measured on a BÜCHI 530 instrument.

Synthesis of *S,S*-Bis(8-thiotheophylline) [1, 8-$BTTH_2$]: The ligand **1** was prepared by stirring 8-thiotheophylline (8-TTH_2) (1.00 g,

5.0 mmol) with KOH (0.28 g, 4.8 mmols) in EtOH (20 mL) for 30 min. Further addition of I_2 (1.32 g, 5.2 mmol) at room temperature, and reflux for 6 hours gave **1** as a pale yellow powder that was filtered off, washed with H_2O (2 × 2 mL), EtOH (2 × 2 mL) and finally vacuum dried. Yield: 1.37 g, 65%. m.p.: 294−295 °C. $C_{14}H_{14}N_8O_4S_2$ (422.44): calcd. C 39.8, H 3.3, N 26.5, S 14.2; found C 41.2, H 3.4, N 24.6, S 14.0. M.p.: 294−295 °C. IR: ν(N−H) 3115−2660 cm^{-1} (br. w.); ν(C6=O) 1717 (s); ν(C2=O) 1640 (s). ^1H NMR (22 °C, [D_6]DMSO): δ = 3.33 (s, N1-CH_3), 3.56 (s, N3-CH_3), 4.67 (w, N7−H) ppm. $^{13}C\{^1H\}$ NMR (22 °C, [D_6]DMSO): δ = 27.5 (N1-CH_3), 29.8 (N3-CH_3), 112.2 (C5), 146.9 (C4), 148.80 (C8), 151.0 (C6), 154.8 (C2) ppm.

Synthesis of the Potassium Salts of 8-Thiotheophyllinate [2, K_2(8-TT)] and *S,S*-Bis(8-thiotheophyllinate) [3, K_2(8-BTT)]: 8-TTH_2 (for **2**; 5 mmol, 1 g) or 8-$BTTH_2$ (for **3**; 2.5 mmol, 1 g) was introduced, via a dropping funnel, to a solution of KOH (0.27 g. 4.8 mmol) in EtOH (10 mL); a white precipitate immediately separated. The mixture was stirred and refluxed for 2 hours, slowly cooled down to room temperature, the precipitate filtered off, washed with two portions (2 mL) of cold EtOH and, finally, dried under vacuum.
2: Yield: 0.86 g, 60%. $C_7H_6K_2N_4O_2S$ (288.41): calcd. C 29.1, H 2.1, N 19.4, S 11.1; found C 29.1, H 2.3, N 19.2, S 10.9. IR: ν(C6=O) 1672 cm^{-1} (s); ν(C2=O) 1631 (s); ν(C=C) + ν(C=N) 1526, 1518, 1553, 1445. ^1H NMR (22 °C, CD_3OD): δ = 3.25 (s, N1-CH_3), 3.41 (s, N3-CH_3) ppm.
3: Yield: 0.87 g, 70%. $C_{14}H_{12}K_2N_8O_4S_2$ (498.62): calcd. C 33.7, H 2.4, N 22.5, S 12.9; found C 33.5, H 2.5, N 22.2, S 12.5. IR: ν(C6=O) 1687 cm^{-1} (s); ν(C2=O) 1631 (s); ν(C=C) + ν(C=N) 1565, 1525, 1454. ^1H NMR (22 °C, CD_3OD): δ = 3.36 (s, N1-CH_3), 3.51 (s, N3-CH_3) ppm.

Synthesis of the Pyridinium Salt of *S,S*-Bis(8-thiotheophyllinate) [4, $(PyH)_2$(8-BTT)]: Pyridine (5 mL) was added to a vigorously stirred suspension of **1** (0.5 g, 1.18 mmol) in EtOH (15 mL). The yellow solution obtained was stirred for 2 h at room temperature and concentrated to ca. 5 mL. The addition of pentane (10 mL) gave a pale yellow precipitate that was filtered off, washed twice with pentane (5 mL) and dried under vacuum. The crude yellow powder thus obtained contained some pyridine and did not give reproducible elemental analyses. Nevertheless, an analytically pure compound was obtained by recrystallisation from hot EtOH.

An in situ NMR spectroscopy experiment in which **1** (20 mg, 0.0047 mmol) was dissolved in [D_5]pyridine (0.5 mL) showed that **4** was the only product formed. Yield: 0.24 g, 35%. $C_{24}H_{22}N_{10}O_4S_2$ (578.62): calcd. C 49.8, H 3.8, N 24.2, S 11.1; found C 49.4, H 4.2, N 23.8, S 10.7. IR: ν(PyN-H) 3110 cm^{-1} (w.); ν(C6=O) 1718, 1704 (s); ν(C2=O) 1644 (s); ν(C=C)+ν(C=N) 1594, 1547, 1485 (s). ^1H NMR (22 °C, [D_5]pyridine): δ = 3.43 (s, N1-CH_3, 6 H), 3.70 (s, N3-CH_3, 6 H), 8.67−7.72 (m, Py, 20 H) ppm.

Reaction of 1 with PPh_3 in Ethanol: A suspension of **1** (0.5 g, 1.18 mmol), KOH (0.07 g, 1.25 mmol) and PPh_3 (0.62 g, 2.34 mmol) in EtOH (5 mL) was refluxed for 3 hours. The resulting colourless solution was kept at room temperature overnight to leave a pale yellow precipitate, which was filtered off, washed with cold EtOH and vacuum dried. NMR spectroscopy and elemental analysis allowed us to confirm that this compound is **2** (Yield: 0.44 g, 65%). A second crop of **2** was obtained from the mother liquor. Total yield: 0.52 g, 76%.

An in situ NMR spectroscopy experiment (0.5 mL CD_3OD, T = 50 °C) showed that O=PPh_3 and an insoluble white precipitate, which was separated and identified as **2**, were formed during the reaction of **1** (0.017 g, 0.04 mmol) with KOH (0.003 g, 0.05 mmol) and PPh_3 (0.025 g, 0.09 mmol).

Reaction of 1 with PPh_3 in DMSO or Dioxane. Synthesis of 8-Phenylthiotheophylline [(5), 8-PhTTH]: Compound **1** (0.5 g, 1.18 mmol) and PPh_3 (0.65, 2.48 mmol) were added to 5 mL of DMSO (or dioxane). The suspension was stirred at 30 °C for 1 h and then heated to 50 °C for 2 h. The addition of heptane (15 mL) to the hot solution yielded a pale yellow precipitate that was filtered off, washed with pentane (2 × 10 mL) and vacuum dried. The crude compound was recrystallised twice from hot EtOH to give analytically pure yellow microcrystals of **5**.

In situ NMR spectroscopy monitoring of this reaction ([D_6]DMSO, T = 60 °C) confirmed that the only soluble compound formed was **5**. Yield: 0.17 g, 30%. $C_{25}H_{22}N_4O_2PS$ (473.51): calcd. C 63.4, H 4.7, N 11.8, S 6.8; found C 63.2, H 4.5, N 11.6, S 6.5. IR: ν(N−H) 3200−2620 cm^{-1} (br. w.); ν(C6=O) 1690 (s); ν(C2=O) 1642 (s). ^1H NMR (22 °C, [D_6]DMSO): δ = 3.15 (s, N1-CH_3, 3 H), 3.35 (s, N3-CH_3, 3 H), 7.24−7.65 (m, Ph, 5 H), 11.33 (w, N7−H, 1 H) ppm. $^{13}C\{^1H\}$ NMR (22 °C, [D_6]DMSO): δ = 27.7 (N1-CH_3), 29.8 (N3-CH_3), 104.3 (C5), 129.1−133.8 (m, Ph), 149.9 (C4), 151.1 (C2), 151.6 (C6), 170.3 (C8) ppm. $^{31}P\{^1H\}$ NMR (22 °C, [D_6]DMSO): δ = 27.5 ppm.

Synthesis of [Pd(PPh_3)(μ-Cl)(8-TT)]$_2$ (6). Method A: Compound **1** (0.1 g, 0.24 mmol) was added to a solution of KOH (0.028 g, 0.5 mmol) in EtOH (20 mL). After 5 min, *cis*-[$PdCl_2(PPh_3)_2$] (0.350 g, 0.50 mmol) was added to the reaction mixture to yield a red orange suspension. This was left for 30 min at room temperature and then heated to reflux for 2 hours. A red orange precipitate formed, which was filtered off, washed twice with EtOH (5 mL) and air dried. Yield: 0.27 g, 91%.

Method B: A solution of $Na_2[PdCl_4]$ (0.06 g, 0.20 mmol) in 5 mL of water was added at room temperature to a suspension of PPh_3 (0.131 g, 0.5 mmol), 1 (0.05 g, 0.12 mmol) and KOH (0.012 g, 0.2 mmol) in 15 mL of EtOH. The mixture was stirred at room temperature for 1 h and then refluxed for 2 h. The red orange precipitate of 6 was isolated as described above. Yield: 0.1 g, 70%.

Method C: One equivalent of **3** (or **4**) was reacted in refluxing EtOH with two mol equivalents of *cis*-[$PdCl_2(PPh_3)_2$] (or $Na_2[PdCl_4]$ and PPh_3 in a 1:2 molar ratio). After 1 h the precipitate was separated, washed and dried as described previously. Yield: 73%.

Method D: Reaction of one equivalent of **2** with a stoichiometric amount of *cis*-[$PdCl_2(PPh_3)_2$] (or 1 $Na_2[PdCl_4]$ + 2 PPh_3) in refluxing EtOH, gave **6** as a red orange precipitate within 1 h. The compound was separated, washed and dried as described previously. Yield: 73%.

$C_{50}H_{44}Cl_2N_8O_4P_2Pd_2S_2$ (1230.76): calcd. C 48.8, H 3.6, N 9.1, S 5.2; found C 48.5, H 3.8, N 9.2, S 4.9. IR: ν(N7 H) 3059−2790 cm^{-1} (w); ν(C6=O) 1673 (s); ν(C2=O) 1625 (s); ν(C=C) + ν(C=N) 1583, 1535, 1520 (s); δ(Ph−H) 740, 703, 688, 516, 507.

In Situ Reaction of 1 with *cis*-[$PdCl_2(PPh_3)_2$] in CD_3OD: Compound **1** (30 mg, 0.071 mmol), *cis*-[$PdCl_2(PPh_3)_2$] (100 mg, 0.142 mmol) and CD_3OD (0.5 mL) were placed into a 5-mm NMR tube maintained at 20 °C. A $^{31}P\{^1H\}$ NMR spectrum was immediately acquired, showing only the resonance due to the starting metal complex *cis*-[$PdCl_2(PPh_3)_2$]. The temperature was then raised to 50 °C causing the separation of a red orange solid within 6 h. Formation of O=PPh_3 was observed by $^{31}P\{^1H\}$ NMR spectroscopy and GC-MS analysis. The red precipitate was separated,

washed with two portions (0.5 mL) of CH_3OH and vacuum dried. This residue was dissolved in $[D_6]$DMSO (0.5 mL) and $^{31}P\{^1H\}$ NMR spectroscopy confirmed that it was **6**.

Synthesis of $[Pd(PPh_3)Py(\mu\text{-S,N-8-TT})]_2\cdot 9H_2O$ (7): Compound **6** (0.15 g, 0.12 mmol) was introduced into a vessel containing acetonitrile (5 mL). The temperature was kept at 50 °C and pyridine (1 mL) was then added. The red orange solution obtained from this was left to stand at room temperature. Orange prismatic crystals were obtained by slow evaporation of the solvent. Yield: 0.05 g, 30%. $C_{60}H_{52}N_{10}O_4P_2Pd_2S_2\cdot 9H_2O$ (1478.05): calcd. C 48.7, H 4.8, N 9.5, S 4.3; found C 49.0, H 5.1, N 9.2, S 4.1. IR: ν(C6=O) 1673 cm^{-1} (s); ν(C2=O) 1625 (s); ν(C=C) + ν(C=N) 1603, 1521 (s); δ(Ph−H) 762, 696, 534, 514, 491. ^1H NMR (22 °C, $CDCl_3$): δ = 3.14, 3.22 (s, N1-CH_3, 3 H), 3.40, 3.52 (s, N3-CH_3, 3 H), 7.18−7.70 (m, Ph, 5 H), 7.18−8.62 (m, Py, 5 H), 11.40 (s, 1 H), 13.23 (w, 1 H) ppm. $^{31}P\{^1H\}$ NMR (22 °C, $CDCl_3$): δ = 27.35 ppm. ^1H NMR (22 °C, $[D_5]$pyridine): δ = 3.14 (s, N1-CH_3, 6 H), 3.29 (s, N3-CH_3, 6 H), 7.02−7.70 (m, Ph, 5 H), 7.02−7.78 (m, Py, 5 H) ppm. $^{31}P\{^1H\}$ NMR (22 °C, $[D_5]$pyridine): δ = 36.18 ppm.

In Situ Reaction of 6 with $[D_5]$pyridine: Compound **6** (35 mg, 0.028 mmol) was placed into an NMR tube and $[D_5]$pyridine (0.5 mL) was added. Dissolution took place after heating at 50 °C to give a red orange solution. $^{31}P\{^1H\}$ NMR spectroscopic monitoring showed the presence of several compounds with **7** being the most abundant (82%). Formation of $O{=}PPh_3$ or PPh_3 was not observed. Compound **7** was precipitated as an orange microcrystalline solid by addition of acetonitrile (2 mL).The compound was confirmed by IR and NMR spectroscopy. The identification of the secondary compounds that accompany the formation of **7** was not attempted.

X-ray Crystallography: Crystals suitable for the X-ray diffraction study were obtained from a solution of **7** in acetonitrile/pyridine (1:1) by slow evaporation. Data were collected at 293 K on a Stoe-Siemens AED diffractometer, using graphite-monochromatised Mo-K_α radiation (λ = 0.71069 Å). The unit cell parameters were obtained from least-squares refinement of 32 well-centred reflections ($12.5° < \theta < 15.9°$). The data were collected by the ω − 2θ scan mode ($1.55° < 2\theta < 25°$) and were corrected for Lorentz and polarisation effects as well as for absorption effects. Details of crystal data and relevant information are summarised in Table 1. The structure was solved using the Sir97 program.[26] In the final refinement the SHELX-96 program[27] was used and in the graphic representation the ORTEP program.[28] Refinement was done by full-matrix least-squares calculations, initially with isotropic thermal parameters. In the final refinement, all purine non-hydrogen atoms and water oxygen atoms were refined anisotropically, whereas purine hydrogen atoms were placed at their calculated positions and then refined isotropically. All of the phenyl rings were treated as rigid bodies with D_{6h} symmetry and C−C distances fixed at 1.39 Å. No significant peaks were detected in the final least-squares cycles. Selected bond lengths and angles are listed in Table 2.

CCDC-194639 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

$[Cu(hyetrz)_3](CF_3SO_3)_2\cdot H_2O$ [hyetrz = 4-(2′-hydroxyethyl)-1,2,4-triazole] represents the first structurally characterised ferromagnetically coupled Cu^{II} chain compound containing triple N^1,N^2-1,2,4-triazole bridges. *catena*-[μ-Tris{4-(2′-hydroxyethyl)-1,2,4-triazole-N^1,N^2}copper(II)] bis(trifluoromethanesulfonate) hydrate ($C_{14}H_{23}F_6S_2O_{10}CuN_9$) crystallises in the triclinic space group $P\bar{1}$, a = 13.54(3), b = 14.37(3), c = 15.61(4) Å, α = 95.9(1), β = 104.9(1), γ = 106.5(1)°, V = 2763(11) Å^3, Z = 4 (Cu^{II} units). The Cu^{II} ions are linked by triple N^1,N^2-1,2,4-triazole bridges yielding an alternating chain with Cu1–Cu2 = 3.8842(4) Å and Cu2–Cu3 = 3.9354(4) Å. Analysis of the magnetic data according to a high-temperature series expansion gives a J value of +1.45(3) cm^{-1}. The nature and the magnitude of the ferromagnetic exchange have been discussed on the basis of the structural features.

Introduction

Polynuclear coordination compounds containing derivatives of 1,2,4-triazole have been of increasing interest during the last decade. Several studies have dealt with the search for magneto-structural correlations for transition metal(II) compounds containing N^1,N^2-1,2,4-triazole bridges.[1−14] On the other hand, polynuclear (1,2,4-triazole)iron(II) compounds have been found to yield spin transition materials exhibiting cooperative behaviour.[15−17]

Although a wealth of polynuclear transition metal(II) compounds have been structurally and magnetically characterised, an incomplete picture concerning the interplay of the 1,2,4-triazole derivatives and noncoordinated anions still exists when determining the structural features and the associated magnetic behaviour. Dinuclear Cu^{II} compounds could be obtained by using polyfunctional 1,2,4-triazole derivatives with N-donating substituents, forming five-membered chelate rings. The magnetic properties of these could be fine-tuned by playing upon the coordination geometry of the double N^1,N^2-1,2,4-triazole bridges residing in the equatorial plane of the Cu^{II} ions.[1−7] A correlation between the magnitude of the antiferromagnetic (AF) interaction and the ligand bridge geometry could be established for the first time for this class of compounds.[5,10,11] The geometry of the bridging ligand network appears mainly to be determined by the geometric requirements of the Cu^{II} atom and the spatial disposition of the ligands. Therefore, no direct influence of the incorporated noncoordinated anions in determining the crystal packing and its possible effect on the 1,2,4-triazole bridge geometry could be proposed.

Generally, depending upon the experimental conditions, the reaction of 4-R-substituted 1,2,4-triazole ligands with Cu^{II} salts of potentially noncoordinating anions either yield linear chain Cu^{II} compounds[8,18,19] or linear trinuclear Cu^{II} entities.[20−23] The propagation of the AF exchange is indeed drastically decreased in these triply N^1,N^2-1,2,4-triazole-bridged trinuclear[20] and linear-chain Cu^{II} compounds[8] compared with the dinuclear bis(μ-N^1,N^2-1,2,4-triazole) compounds.[1−7,10] Actually, in these dinuclear systems, the propagation of the AF exchange may proceed very efficiently via the $d_{x^2-y^2}$ orbitals on the Cu^{II} ions which interact with the σ-orbitals of the nitrogen atoms of the bridging ligand, which are all situated in the equatorial plane. The introduction of an additional ligand in the Cu···Cu linkage, as in the case of the linear tri- and polynuclear Cu^{II} systems, brings the equatorial planes of the Jahn−Teller-distorted octahedral Cu^{II} ions in positions canted by about 60° towards one another. Consequently, the AF coupling can only proceed efficiently via a single 1,2,4-triazole ligand, and will be very weak, typically of the order of a few wavenumbers.

Indeed, the AF coupling between nearest-neighbour Cu^{II} ions within the linear trinuclear $[Cu_3\{4\text{-(2-pyridyl)-1,2,4-triazole}\}_{10}(H_2O)_2](ClO_4)_6\cdot 7H_2O$ has been found to be

-5.41 cm^{-1},[20] whereas the isotropic exchange constant is only $-1.01(2)$ cm^{-1} for the 3-D network built up from linear trinuclear Cu^{II} cations, $[Cu_3\{1,2\text{-bis}(1,2,4\text{-triazol-4-yl})\text{ethane}\}_5(H_2O)_2]^{6+}$.[23] Furthermore, the linear-chain compound $[Cu(hyetrz)_3](ClO_4)_2\cdot 3H_2O$ [hyetrz = 4-(2′-hydroxyethyl)-1,2,4-triazole] also exhibits a very weak AF coupling of $J = -1.18(2)$ cm^{-1}.[8]

Surprisingly, the magnetic data for the linear trinuclear Cu^{II} compounds $[Cu_3(metrz)_6(H_2O)_4](CF_3SO_3)_6(H_2O)_4$ (metrz = 3-methyl-4-ethyl-1,2,4-triazole)[21] and $[Cu_3(etrz)_9(H_2O)_3](CF_3SO_3)_6$ (etrz = 4-ethyl-1,2,4-triazole),[22] indicate a weak overall ferromagnetic (F) interaction. Unfortunately, the magnetic data could not be satisfactorily interpreted, nor could it be related to the structural features, possibly due to the lack of detailed crystallographic data.

These unprecedented magnetic data might be related to the presence of the trifluoromethanesulfonate anion, which could play an important role in determining the crystal packing of these compounds, thereby indirectly influencing the orientation of the 1,2,4-triazole ligands. In order to check this hypothesis, an extended crystallographic and magnetic study on $[Cu(hyetrz)_3](CF_3SO_3)_2\cdot H_2O$ has been carried out, which would allow an excellent comparison with the perchlorate derivative on which we reported previously.[8]

Results and Discussion

Description of the X-ray Structure of $[Cu(hyetrz)_3](CF_3SO_3)_2\cdot H_2O$

A projection of the cationic linear Cu^{II} chain is depicted in Figure 1, and the relevant bond length and bond angle information is given in Table 1.

The coordination polymer consists of a crystallographically independent unit comprising two Cu^{II} ions, Cu1 and Cu3, in special positions and another Cu^{II} ion in a general position (Cu2), along with six symmetry-independent hyetrz ligands. The linear chain running along the *c* axis (see Figure 2) is generated by the inversion involving the crystallographic centres of symmetry located on Cu1 and Cu3. $[Cu(hyetrz)_3](ClO_4)_2\cdot 3H_2O$[8] crystallises in the monoclinic space group $P2_1/n$, whereas the title compound crystallises in the triclinic space group $P\bar{1}$. However, this does not change the local symmetry around the Cu^{II} ions, since in both compounds the inversion centres are located on the metal ions.

Three hyetrz ligands act as bidentate ligands linking the Cu^{II} ions via the nitrogen atoms N1 and N2. All metal ions are in a distorted (4+2) octahedral environment formed by six N-donating hyetrz ligands. The basal plane is formed by four nitrogen donor atoms with distances between 1.989(3)

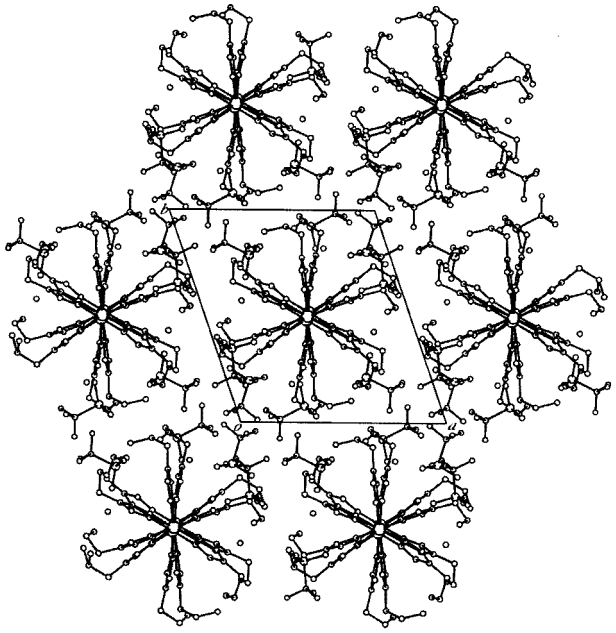

Figure 2. View of the crystal structure of $[Cu(hyetrz)_3](CF_3SO_3)_2\cdot H_2O$ along the *c* axis

and 2.116(3) Å, whereas two hyetrz ligands are coordinated in the axial positions at significantly longer distances [2.328(3)−2.409(3) Å]. This distribution of Cu−N distances is the signature for a static Jahn−Teller distortion, as has comparably been found for $[Cu(hyetrz)_3](ClO_4)_2\cdot 3H_2O$[8] and $[Cu(4\text{-amino-}1,2,4\text{-triazole})_3](ClO_4)_2\cdot 0.5H_2O$.[18] The range of Cu−N distances is, however, slightly larger for $[Cu(hyetrz)_3](CF_3SO_3)_2\cdot H_2O$. All Cu^{II} ions are not significantly displaced from their equatorial coordination plane [δ(Cu2) ≈ 0.02 Å]. The least-squares planes through the equatorial planes of the Cu^{II} octahedra make angles of 55.51(7)° for Cu1 and Cu2, 50.40(6)° for Cu2 and Cu3, which is slightly different from what has been found for $[Cu(hyetrz)_3](ClO_4)_2\cdot 3H_2O$. In that case, the least-squares planes through the equatorial planes of the octahedrally coordinated Cu^{II} ions make angles of 46(1)° for Cu1 and Cu2, 53(3)° for Cu2 and Cu3.[8] The important distortions from O_h symmetry around the Cu^{II} ions imply that the three hyetrz ligands linking neighbouring Cu^{II} ions do not conserve a perfect trigonal symmetry, as has been observed for the perchlorate derivative. The deviation from threefold symmetry is, however, significantly more pronounced for the present compound. All 1,2,4-triazole rings are fairly planar; the deviation from the least-squares plane through the ring atoms is smaller than 0.01(1) Å. The least-squares planes through the hyetrz ligands linking Cu1 and Cu2 are 52.4(1)° for hyetrz-1 and hyetrz-2, 59.3(1)° for hyetrz-2 and hyetrz-3, and 74.1(1)° for hyetrz-1 and hyetrz-3. This very much resembles the bridging mode between Cu1 and Cu2 in the perchlorate derivative with angles between the least-squares planes of 54(2)° for hyetrz-1 and hyetrz-2, 69(2)° for hyetrz-2 and hyetrz-3, and 64.6(4)° for hyetrz-1 and hyetrz-3. It is important to notice that there are significant differences in the bridging mode between Cu2 and Cu3 for both Cu^{II} hyetrz linear-chain compounds. In fact, for $[Cu(hyetrz)_3](CF_3SO_3)_2\cdot H_2O$ the threefold symmetry of the triple hyetrz linkage between Cu2 and Cu3 shows severe distortions, yielding angles of 77.1(1)° between hyetrz-4 and hyetrz-5, 61.4(1)° between hyetrz-5 and hyetrz-6, and 46.3(1)° between hyetrz-6 and hyetrz-4. On the other hand for $[Cu(hyetrz)_3](ClO_4)_2\cdot 3H_2O$,[8] the threefold symmetry of the triple hyetrz linkage between Cu2 and Cu3 shows comparable distortions as does Cu1 and Cu2 with angles of 50(3)° between hyetrz-4 and hyetrz-5, 71(1)° between hyetrz-5 and hyetrz-6, and 66(3)° between hyetrz-6 and hyetrz-4.

These differences in the hyetrz bridging geometry for $[Cu(hyetrz)_3](CF_3SO_3)_2\cdot H_2O$ is also reflected by the Cu−Cu distances, which are significantly different for the two pairs of the Cu^{II} ions, i.e., Cu1−Cu2 = 3.8843(2) Å, whereas Cu2−Cu3 = 3.9352(2) Å. This indeed is in contrast to $[Cu(hyetrz)_3](ClO_4)_2\cdot 3H_2O$, where the analogy between the two linkages leads to quasi equal Cu−Cu separations with Cu1−Cu2 = 3.8530(8) Å and Cu2−Cu3 = 3.8293(2) Å.[8]

Careful inspection of the triple N^1,N^2-1,2,4-triazole geometry between Cu1 and Cu2 reveals similar features as found in $[Cu(hyetrz)_3](ClO_4)_2\cdot 3H_2O$ for both Cu−Cu linkages; hyetrz-1 links Cu1 and Cu2 with a long distance [Cu1−N11 = 2.370(2) Å] and a rather small angle [Cu1−N11−N12 = 123.8(1)°] involving Cu1, whereas the

distance (Cu2−N12 = 1.994(2) Å] and angle [Cu2−N12−N11 = 122.3(1)°] involving Cu2 may be considered as normal. Maintaining these Cu^{II} ions under these geometric dispositions, apparently requires an extremely large Cu1−N11−N12−Cu2 torsion angle of −28.98(9)°. Also, hyetrz-2 shows considerable asymmetry in the bridging mode with respect to the Cu−N bond lengths. As for hyetrz-1, the short distance [Cu1−N21 = 2.018(2) Å] corresponds to a normal Cu1−N21−N22 angle of 120.3(1)°. However, for hyetrz-2 the long Cu2−N22 distance of 2.360(2) Å is now accompanied by a much larger Cu2−N22−N21 angle of 128.2(1)°. In this case, a torsion angle of −16.31(9)° is required. In contrast, hyetrz-3 links Cu1 and Cu2 with approximately identical Cu1−N31 = 2.067(2) Å and Cu2−N32 = 2.066(2) Å distances. However, the N^1,N^2-1,2,4-triazole bridging mode shows a rather high degree of asymmetry with respect to the Cu−N−N bond angles, which are Cu1−N31−N32 = 129.3(1)° and Cu2−N32−N31 = 125.3(1)°. The torsion angle Cu1−N31−N32−Cu2 is only −3.27(9)°.

The difference observed in the two unequal bridging modes is confirmed by the torsion angles for the ligands linking Cu2 and Cu3: −13.5(1), −11.3(1), and −20.3(1)° for hyetrz-4, hyetrz-5, and hyetrz-6, respectively. This is in sharp contrast to $[Cu(hyetrz)_3](ClO_4)_2\cdot 3H_2O$, where the torsion angles for the hyetrz ligands, having short Cu−N distances, are about −11°. The triflate derivative has corresponding ligands with torsion angles of up to −20°.

The large deviation from threefold symmetry for the present linear Cu^{II} chain is also confirmed by the fact that Cu2 is displaced by 0.238(1) Å from the Cu1−Cu3 axis, as well as by the zig-zag character of the linear chain. The latter is illustrated by the angle of 173.003(6)° between the vectors through the pairs of Cu^{II} ions (Cu1,Cu2) and (Cu2,Cu3), which is slightly smaller than the 175.18(2)° found for the perchlorate analogue. Clearly, in order to establish the linkage of Cu^{II} ions in Jahn−Teller-distorted octahedra, by triple μ-N^1,N^2-1,2,4-triazole bridges, the geometrical disposition of the ligands becomes such that important deviations from the ideal threefold axis running through the Cu^{II} ions are required. This may be illustrated by Figure 2 showing a view of the linear-chain structure along the *c* axis.

The third coordination sphere is occupied by the noncoordinated water molecules and triflate anions, which are situated between the linear chains. It is important to notice the orientation of the triflate anions, which appear to direct themselves towards the hydroxyethyl substituents of the hyetrz ligands. The relatively short O···O contacts listed in Table 2 provide evidence for a pronounced hydrogen bonding network between the triflate anions, the hydroxyethyl groups and the lattice water molecules as observed in the trinuclear Fe^{II} spin crossover compound $[Fe_3(hyetrz)_6(H_2O)_6](CF_3SO_3)_6$.[24] Unfortunately, an extended analysis of the hydrogen bonding interactions could not be carried out, since the hydrogen atoms concerned could not be located and because of the positional disorder in the triflate anions. As observed for $[Cu(hyetrz)_3](ClO_4)_2\cdot 3H_2O$, the terminal hydroxy groups of the ligands are highly agitated. The hyetrz-3 oxygen atom is shared between two split locations O38 and O39 with occupancy of 1/2 on each site. There appears to be a short O28···O48 contact of 2.690(5) Å. This would imply the occurrence of a hydrogen bond between hydroxy groups from hyetrz ligands, originating from neighbouring (i.e., intrachain) triple μ-triazole links. Also in the present compound, there is no indication for hydrogen bonding interactions taking place between hydroxyethyl groups of hyetrz ligands originating from different linear Cu^{II} chains (i.e., interchain).

Table 2. Interatomic distances (up to 3 Å) for the hydrogen bonding interactions in $[Cu(hyetrz)_3](CF_3SO_3)_2\cdot H_2O$ (labeled atoms are generated by symmetry operations: a: 1 − *x*, −*y*, −*z*; b: 1 − *x*, 1−*y*, −*z*)

O18···O87a	2.961(5)
O38···O96b	2.821(8)
O58···O106	2.791(4)
O39···O120	2.825(9)
O48···O120	2.883(5)
O58···O110	2.874(5)
O28···O48	2.690(5)
O110···O95	2.857(6)

Even if the substitution of the perchlorate anion by the triflate anion does not change the local Cu^{II} symmetry, the respective position of the cationic chains is affected by the cell difference between the two compounds. An illustration of this change is the triangle drawn normally to the axes of three adjacent chains. In the perchlorate compound it is equilateral with the length of one side being 13.6±0.2 Å, whereas in the triflate compound it is distorted at 13.0, 14.1, and 16.3 Å.

Spectroscopic Properties

The UV/Vis spectrum of $[Cu(hyetrz)_3](CF_3SO_3)_2\cdot H_2O$ shows a broad asymmetric band with a maximum situated at $15.4\cdot 10^3$ cm^{-1}, which is in agreement with the presence of CuN_6 chromophores, as well as with the tetragonal distortion of the Cu^{II} octahedra.[25]

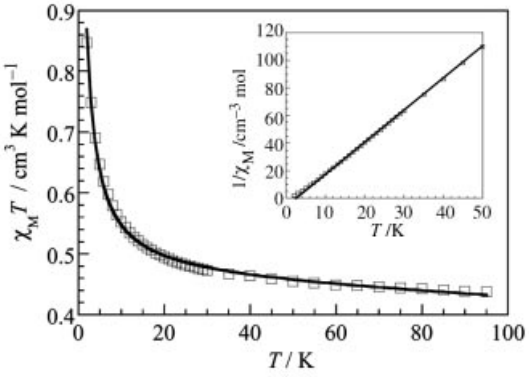

Figure 3. Observed (white squares) and calculated [line; J = +1.45(3) cm^{-1}, g = 2.20(1)] $\chi_M T$ vs. T curves for $[Cu(hyetrz)_3](CF_3SO_3)_2\cdot H_2O$; the $1/\chi_M$ vs. T curve is displayed in the insert

Magnetic Measurements

The magnetic behaviour of $[Cu(hyetrz)_3](CF_3SO_3)_2 \cdot H_2O$ is shown in Figure 3 in the form of a $\chi_M T$ vs. T plot, χ_M being the molar magnetic susceptibility and T the temperature.

At 300 K, the $\chi_M T$ value is 0.409 $cm^3 \cdot mol^{-1} \cdot K$, which is approximately the value expected for a single uncoupled Cu^{II} ion. The value of $\chi_M T$ progressively increases upon cooling, after which the $\chi_M T$ value starts to increase rather abruptly below 40 K reaching a value of 0.847 $cm^3 \cdot mol^{-1} \cdot K$ at 2 K. This behaviour is characteristic for compounds with an overall F interaction between the metal(II) ions. The occurrence of an F interaction is also illustrated by the $1/\chi_M$ vs. T plot displayed in the insert of Figure 3. A qualitative analysis of the magnitude of the F interaction has been made based on the Curie−Weiss law, $1/\chi_M = (T - \theta)/C$, yielding a Curie constant C of 0.41(1) $cm^3 \cdot K \cdot mol^{-1}$ and a Curie−Weiss temperature θ of 3.9(2) K. The magnetic data have been interpreted using the expression for the molar magnetic susceptibility of an $S = 1/2$ linear chain with a high-temperature series expansion proposed by Baker [Equation (1)],[26] in which $x = J/2kT$ and J is the isotropic exchange parameter defined by the phenomenological spin Hamiltonian [Equation (2)].

$$\chi_M = \left(\frac{Ng^2\mu_B{}^2}{4kT}\right) \cdot \left(\frac{1+5.79799x+16.902653x^2+29.376885x^3+29.832959x^4+14.036918x^5}{1+2.79799x+7.008678x^2+8.6538644x^3+4.5743114x^4}\right)^{2/3} \quad (1)$$

$$\mathbf{H} = -J[\Sigma_{i<j}\mathbf{S}_i\mathbf{S}_j] - g\mu_B H \Sigma_i \mathbf{S}_i \quad (2)$$

In Equation (1), N, g, μ_B, k, and T have their usual meanings. The g factor must be considered as an average value of the local Zeeman factors and intercluster exchange interactions were supposed to be negligible. The assumption of negligible magnetic exchange between second neighbour Cu^{II} ions is justified in view of the study of the triply N^1,N^2-1,2,4-triazole-bridged $Fe^{II}-Fe^{II}-Fe^{II}$ [24,27] and $Co^{II}-Co^{III}-Co^{II}$ [28] trinuclear clusters, where the central metal ion is diamagnetic, and no magnetic interactions could be detected between the paramagnetic terminal metal ions. A good fit in the temperature range 2−100 K has been obtained for the parameters $g = 2.20(1)$ and $J = +1.45(3)$ cm^{-1} (see Figure 3).

The magnetisation as a function of the applied magnetic field has been recorded at 2 K (see Figure 4). Upon applying a magnetic field, the magnetisation increases progressively, reaching a value of 1.007 $N\mu_B$ at 50 kOe. The value corresponds to the theoretical value of ca. 1 $N\mu_B$ expected for an $S = 1/2$ ion, as may be calculated from Equation (3).

$$M_{sat} = Ng\mu_B S \quad (3)$$

The X-band powder EPR spectrum recorded for $[Cu(hyetrz)_3](CF_3SO_3)_2 \cdot H_2O$ at 298 K only shows a rather broad (about 2000 Gauss) isotropic signal at $g = 2.09$, which may be the signature for exchange broadening. Furthermore, no indication for Cu···Cu exchange splittings is observed.[25]

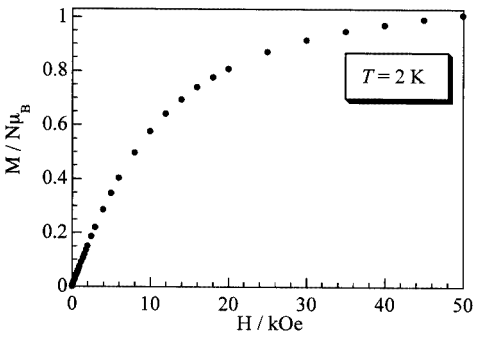

Figure 4. Magnetisation as a function of the applied magnetic field recorded at 2 K for $[Cu(hyetrz)_3](CF_3SO_3)_2 \cdot H_2O$

Concluding Remarks

X-ray structures of polymeric chain compounds containing triple N^1,N^2-1,2,4-triazole bridges have long been hard to establish and only a few examples forming Cu^{II} structures are known.[8,18,19] Structural information on these compounds are of great interest since the fascinating X-ray structure of the corresponding Fe^{II} spin transition materials has not yet been solved.[16] $[Cu(hyetrz)_3](CF_3SO_3)_2 \cdot H_2O$ represents the first example of a linear Cu^{II} chain of this family exhibiting an overall F interaction. This F coupling of $J = +1.45(3)$ cm^{-1} is rather weak, but certainly significant. The isotropic exchange J results from the competition between ferromagnetic and antiferromagnetic contributions [Equation (4)].[29]

$$J = J_{AF} + J_F \quad (4)$$

Generally, it may be expected that for Cu^{II} ions linked by polyatomic bridging ligands such as μ-N^1,N^2-1,2,4-triazoles, the F contribution is very small, and only the AF part significantly contributes to the overall magnetic interaction.[26] This for instance is the case for $[Cu(hyetrz)_3](ClO_4)_2 \cdot 3H_2O$, where a weak AF coupling [$J = -1.18(2)$ cm^{-1}] has been found.[8] The reasons for these differences in magnetic behaviour are likely to originate from significant differences in structural parameters.

Actually, the present complex has a linear-chain structure, which deviates somewhat more from threefold symmetry as compared with $[Cu(hyetrz)_3](ClO_4)_2 \cdot 3H_2O$. This mainly originates from the larger distortions observed in the Cu2−Cu3 linkage, leading to a more pronounced zigzag character of the linear chain, and importantly, to larger Cu−N−N−Cu torsion angles, which reach values of up to −20°. In both chains, the AF contribution of the exchange

only proceeds via one N^1,N^2-1,2,4-triazole bridge out of the three bridging ligands. These are the ligands linking the Cu^{II} ions with short Cu−N distances, i.e., hyetrz-3 and hyetrz-6. In both compounds, these ligands are indeed differently oriented with respect to the Cu^{II} ions, and thus with respect to the magnetic orbital situated on the Cu^{II} ions; these subtle variations in the structural parameters may change the magnetic properties. All of these factors may contribute to a reduction of the magnitude of the J_{AF} component, and for particular values of the structural parameters the J_F component may start to dominate. As a consequence the overall magnetic interaction may switch from AF to F. Apparently, the two linear-chain compounds represent two borderline cases, where either AF or F coupling is taking over. At this stage, it is rather hazardous to draw conclusions concerning the influence of a change in a structural parameter on the magnetic orbital overlap, and thus on the magnitude of the J_{AF} component. For this purpose, theoretical calculations would probably be worthwhile.

It is remarkable that in all the antiferromagnetically coupled triple N^1,N^2-1,2,4-triazole-bridged Cu^{II} compounds, the Cu−N−N−Cu torsion angles, involving the ligands responsible for the exchange coupling, are very low, i.e., 7.9(7)° and 4.9(8)° for $[Cu_3\{1,2\text{-bis}(1,2,4\text{-triazol-4-yl})\text{ethane}\}_5(H_2O)_2]^{6+}$,[23] or close to −11° for $[Cu(hyetrz)_3](ClO_4)_2\cdot 3H_2O$,[8] whereas these are rather large for the present ferromagnetically coupled triflate chain.

An overall weak F coupling has also been found for the linear trinuclear Cu^{II} compounds $[Cu_3(metrz)_6(H_2O)_4](CF_3SO_3)_6(H_2O)_4$,[21] and $[Cu_3(etrz)_9(H_2O)_3](CF_3SO_3)_6$.[22] The magnetic data could not, however, be related to the structural parameters. Only an X-ray crystallographic study of a low quality at 298 K has been reported for $[Cu_3(metrz)_6(H_2O)_4](CF_3SO_3)_6(H_2O)_4$, revealing rather short Cu···Cu separations of 3.719(7) Å, which could be related to the dynamic Jahn−Teller effect involving the central Cu^{II} ion leading to a perfectly symmetric octahedron with six relatively short Cu−N distances of 2.14(5) Å. It may be expected that upon decreasing temperature the dynamic Jahn−Teller distortion freezes into a static Jahn−Teller distortion. Since the F coupling occurs at these low temperatures, the non-detailed room-temperature structure could not provide any information on how the structural features may be related to the magnetic interaction observed for this compound.

An interesting structural feature in the ferromagnetically coupled Cu^{II} systems mentioned above, as well as in $[Cu(hyetrz)_3](CF_3SO_3)_2\cdot H_2O$ is the presence of the noncoordinated trifluoromethanesulfonate anion. It may be thought that this type of bulky anion determines, in some way, the crystal packing and in turn indirectly the geometry of the triple N^1,N^2-1,2,4-triazole bridge network. This may proceed in such a way that accidental orthogonality may occur, i.e., for certain values of the structural parameters the competition of J_{AF} and J_F results in taking over the F component, yielding an overall F interaction in triple 1,2,4-triazole-bridged Cu^{II} compounds.

Derivatives of 1,2,4-triazole are very useful for obtaining diazine-type bridged polynuclear transition metal(II) compounds having relatively short metal−metal distances. All possibilities are provided for fine-tuning the magnetic properties of the corresponding polynuclear Cu^{II} compounds by playing on the nature of the bridging units (number and geometry). Now these possibilities can also be extended towards F interactions for the chain compounds.

Experimental Section

Starting Materials: Commercially available solvents, hydrazine monohydrate, triethyl orthoformate, 2-hydroxyethylamine, and copper(II) trifluoromethanesulfonate were used without further purification.

Synthesis of 4-(2′-hydroxyethyl)-1,2,4-triazole (hyetrz): The ligand hyetrz has been prepared as already described.[8]

Synthesis of $[Cu(hyetrz)_3](CF_3SO_3)_2\cdot H_2O$: $Cu(CF_3SO_3)_2$ (0.21 g, 0.6 mmol), dissolved in water (10 mL), was added to hyetrz (0.2 g, 1.8 mmol), dissolved in water (10 mL). The reaction mixture was filtered. After a couple of weeks, blue prism-shaped single crystals were collected after slow evaporation of the solvent at room temperature. Crystals were washed with water and air-dried. Yield: 175 mg, 40%. IR (KBr): $\nu_{as}(SO_3^-) = 1269\ cm^{-1}$.

Physical Measurements: IR spectra were carried out with a Perkin−Elmer Paragon 1000 FT-IR spectrophotometer. UV/Vis spectra were recorded with a CARY 5E spectrophotometer using the diffuse reflectance technique, with polytetrafluoroethylene as a reference. X-band powder EPR spectra were obtained with a Bruker ER083CS electron spin resonance spectrometer. Magnetic susceptibilities were carried out in the temperature range 300−2 K with a quantum design MPMS-5S SQUID magnetometer. Magnetic data were corrected for diamagnetic contributions, which were estimated from the Pascal constants and were fitted to theoretical expressions by means of a Simplex routine. All parameters (J, g) were varied independently during the fitting procedure. This routine minimises the function $R = (\chi_{obs} - \chi_{calc})^2/[(\chi_{obs})^2]^{1/2}$.

Crystallographic Data Collection and Structure Determination: A blue, hexagonal crystal of approximate dimensions 0.60 × 0.50 × 0.35 mm was analysed at room temperature with an ENRAF-NONIUS CAD4 diffractometer using the monochromated Mo-K_α X-ray radiation ($\lambda = 0.7073$ Å). Accurate unit-cell parameters were obtained by least-squares refinement from 20 centred reflections in the range $15° \le \theta \le 16°$. Crystal data and details of data collection and refinement are given in Table 3. The intensities of three standard reflections, each monitored over 2 h, revealed no significant decay over the course of data collection. A semiempiric correction of absorption, based on ψ scans of three axial reflections, was applied.[31] The structure was solved by direct methods with the program SIR92.[32] Structure refinement based on F^2 was carried out by extended block-diagonal matrix methods, each block constituted by a chemical entity as Cu, hyetrz, CF_3SO_3, H_2O. Locations of hydrogen atoms which can be predicted were generated geometrically (C−H = 1.0 Å) and included in the refinement with an isotropic fixed thermal parameter. All non-hydrogen atoms were refined with anisotropic thermal parameters. The high values of thermal parameters of the oxygen atoms of the triflate and the hydroxy groups suggest disordered positions of these entities. One oxygen atom belonging to a hydroxy group was located on two

different disordered sites with an occupancy factor of 1/2. Final reliability factors converged to $R(F) = 0.038$ and $wR(F^2) = 0.120$. Neutral atom scattering factors and anomalous dispersion corrections were taken from International Tables for Crystallography.[33] A final difference Fourier map showed residual density less than ± 0.24 e·Å^{-3}. Final positional parameters are listed in the supplementary material deposited at the CCDC. Illustrations and calculations were carried out using programs written or modified locally. Crystallographic data have been deposited at the Cambridge Crystallographic Data Centre as supplementary publication no CCDC-185233. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB21EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Synthesis, Structure, and Reactivity of a New Mononuclear Molybdenum(VI) Complex Resembling the Active Center of Molybdenum Oxotransferases

Rupam Dinda,[a] Parbati Sengupta,[a] Saktiprosad Ghosh,*[a] and William S. Sheldrick[b]

Keywords: Molybdenum / Bioinorganic chemistry / Substrate binding / Enzyme models

The design, synthesis, and structure determination of a pentacoordinate square-pyramidal molybdenum(VI) complex MoO_2L (where LH_2 is a diacidic tridentate ONO donor ligand) is reported. The substrate binding capacity of MoO_2L has been demonstrated by the formation and isolation of six-coordinate octahedral complexes $[MoO_2L(B)]$ (where B = imidazole, 1-methylimidazole, pyridine, or γ-picoline) and the structures of $[MoO_2L(Imz)]$ and $[MoO_2L(Py)]$ have been solved by X-ray crystallography. Oxo transfer of MoO_2L to the substrate PPh_3 has been demonstrated by the formation of MoOL and [MoOL(bipy)]. Thus, the complex MoO_2L behaves as a model for the active center of oxotransfer molybdoenzymes and is of interest in bioinorganic chemistry.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2003)

Introduction

It is now established that suitable models for the active centers of oxotransfer molybdoenzymes should be capable of: (1) oxygen atom transfer to or from the substrate,[1] (2) approaching the coordination environment of the oxomolybdenum center of the relevant enzyme(s), and (3) being unresponsive to the formation of (μ-oxo)Mo^V dimers.[2] To meet criterion (3) sterically hindered ligands, like 2,6-bis(2,2-diphenyl-2-mercaptoethenyl)pyridine $[LN(SH)_2]$, have been synthesized. The Mo^{VI} complex (MoO_2LNS_2) was subsequently isolated and structurally characterized by single-crystal X-ray analysis.[3,4] This complex was shown to be a viable structural model of the active sites of several oxotransfer molybdoenzymes and it was proposed that the presence of at least one coordinated sulfur atom as well as a proper steric environment provided by the ligand to prevent Mo^V-O-Mo^V dimer formation are essential features of a model complex.[3] One of our studies on the Mo^{VI} complexes of thiosemicarbazone-type ONS donor ligands showed for the first time that the steric factor is not absolutely essential[5] to prevent the (μ-oxo)Mo^V dimer formation. In this paper we report our recent findings that indicate that even Mo^{VI} complexes of some selected ONO donor ligands may mimic the active sites of some oxotransfer molybdoenzymes.

We report the synthesis, characterization, substrate binding, and oxo transfer reactions of the complex MoO_2L, where H_2L is the ONO donor ligand 2-hydroxyacetophenone hydrazone of 2-aminobenzoylhydrazine. The five-coordinate complex (MoO_2L) is quite interesting with respect to coordination chemistry because pentacoordinated Mo^{VI} complexes, in general, are rare[2,6,7] and those with an ONO donor environment are rarer still. Most pentacoordinate Mo^{VI} complexes with oxygen−sulfur donor ligands are mono(μ-oxo)-bridged dimers, each Mo^{VI} center featuring an S_2O_3 coordination, and are trigonal-bipyramidal.[6] The structures of the pentacoordinate complex MoO_2L (**1**) and its adducts $MoO_2L(Imz)$ (**2**) and $MoO_2L(Py)$ (**4**) are determined by a single-crystal X-ray diffraction technique.

The (oxo)Mo^{IV} complexes MoOL (**6**) and [MoOL(bipy)] (**7**), obtained by oxo transfer of MoO_2L to the substrate PPh_3, are isolated and characterized. MoO_2L (**1**) is found to mimic the active center of oxotransfer molybdoenzymes and hence is of interest in bioinorganic chemistry.

Results and Discussion

In this work, a tridentate diacidic Schiff base (H_2L) is used as ligand. It is prepared by condensing 2-hydroxyacetophenone with anthranilhydrazide in ethanol.[8] The stoichiometric reaction (Scheme 1) of bis(acetylacetonato)-dioxomolybdenum(VI) with H_2L in refluxing ethanol afforded the orange five-coordinate complex MoO_2L (**1**) in excellent yield. The $[MoO_2L(B)]$ complexes **2**−**5** were prepared by reaction of MoO_2L with different heterocyclic bases (B) in ethanol [B = imidazole (**2**), 1-methylimidazole (**3**), pyridine (**4**), or γ-picoline (**5**)].

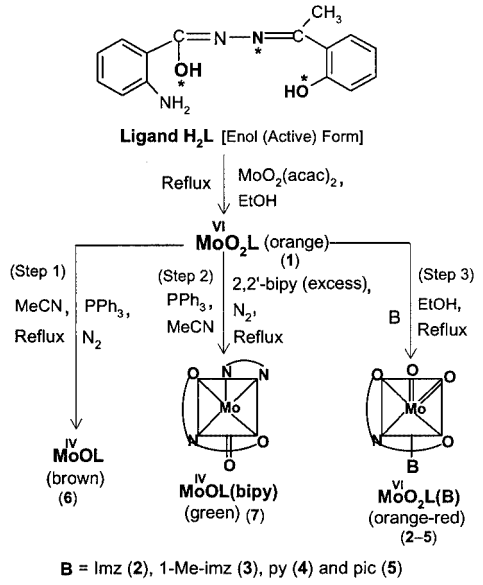

Scheme 1. Reaction diagram for the isolation of dioxomolybdenum(VI) and oxomolybdenum(IV) complexes

All these complexes are diamagnetic, indicating the presence of molybdenum in the +6 oxidation state, and are nonconducting in solution.

Selected spectroscopic data of the complexes are summarized in Table 1. In all of them, the ligand is found to act in its enol form coordinating through the deprotonated phenolate oxygen, enolate oxygen, and the azomethine nitrogen atoms. The IR spectra of the complexes do not exhibit the ligand bands at 3477 cm^{-1} [ν(OH)], 3209 cm^{-1} [ν(NH)], and 1640 cm^{-1} [ν(C=O)].[9,10] Characteristic strong bands at 1600 and 1540 cm^{-1} due to ν(C=N) and ν(C=C/aromatic) stretching modes of the ligand[10,11] are located in the spectra of both the ligand and the complexes. The Mo=O stretching modes occur as a pair of sharp strong peaks in the 930−894 cm^{-1} range.[5,12−14]

Table 1. Characteristics IR bands [cm^{-1}] and electronic spectral data [nm ($dm^3 \cdot mol^{-1} \cdot cm^{-1}$)] for the complexes

	ν(Mo=O)[a]	λ_{max} (ε)[b]
MoO_2L (**1**)	912, 894	420 (10034), 312 (15419)
MoO_2L(Imz) (**2**)	920, 895	428 (8352), 316 (17032)
MoO_2L(1-Me-Imz) (**3**)	923, 889	429 (8492), 318 (16912)
MoO_2L(Py) (**4**)	929, 902	432 (9400), 327 (14272)
MoO_2L(γ-Pic) (**5**)	929, 912	427 (8372), 319 (16703)
MoOL (**6**)	964	691 (265), 426 (1091), 312 (1997)
MoOL(bipy) (**7**)	937	679 (121), 427 (2067), 318 (5345)

[a] In KBr pellet. [b] In DMF.

Electronic spectra of the complexes in DMF display an intense band in the 440−420-nm region associated with a relatively weak band in the 330−310-nm region; these are believed to be of O (phenolate and enolate) → Mo LMCT origin.[5,14−16]

The ^1H NMR ([D_6]DMSO) spectrum of the free ligand exhibits an OH (phenolic) resonance at δ = 13.4 ppm. Signals for CH_3 protons at δ = 2.46 ppm and aromatic protons at 7.64−6.57 ppm are also found.[8] In the complex, the signal for the OH proton disappears, indicating deprotonation of the phenolic OH group in the complex MoO_2L. The NMR spectroscopic data of all the complexes are given in the Exp. Sect.

The relevant electrochemical data for the Mo^{VI} complexes **1**−**5** in DMF vs. SCE are summarized in Table 2. All reductions are irreversible. The cyclic voltammograms of the parent complex **1** show (Figure 1) only one reductive response at −1.22 V. The process may be represented as a metal-centered one-electron transfer involving the Mo^{VI} and the Mo^{V} oxidation states.[17−19] The CV traces of complexes **2**−**5** (Figure 2) exhibit two irreversible reductive responses[5,14−16] within the potential window −0.6 to −1.4 V, which are assigned to Mo^{VI}/Mo^{V} and Mo^{V}/Mo^{IV} processes, respectively. The lack of anodic response, even at a high scan rate, is clearly due to rapid decomposition of the reduced species.[19]

Table 2. Cyclic voltammetric results for dioxomolybdenum(VI) complexes at 298 K

Description of the Crystal Structures

MoO_2L

Crystals of this orange compound consist of discrete molecules of MoO_2L. The structure is presented in Figure 3 and the geometric data are given in Tables 3 and 4. The coordination environment of the Mo^{VI} acceptor center consists of two oxo oxygen atoms, one enolate oxygen, one phenolate oxygen, and an azomethine nitrogen atom. This is a rare example of a five-coordinate Mo^{VI} complex.[2] No structural evidence for the achievement of hexacoordination through Mo=O···Mo bridging is observed. This MoO_2L complex could be isolated from an alcohol (MeOH, EtOH) or acetonitrile medium, from which it is found to crystallize without any solvent molecule. The molecular geometry of MoO_2L is best represented as a distorted square-pyramid with one axial oxo oxygen atom [O(2)], and three O atoms [O(1,3,4)] and the N(1) atom describing the equatorial plane. Distortion of the square plane is evident from the difference in the Mo−O(1), Mo−O(3), Mo−N(1), and Mo−O(4) bond lengths as well as the difference in the bond angles at the Mo atom [72.51(6) to 155.20(8)°]. The length of the Mo=O(1) bond lying *trans* to N(1) is practically equal to Mo=O(2); the position *trans* to O(2) remains unoccupied. The length of the two Mo−O bonds corresponding to the enolate [O(3)] and phenolate [O(4)] oxygen atoms are found to differ by only 0.077 Å. The bite angles of the ligand at Mo, O(4)−Mo−N(1) and O(3)−Mo−N(1), are 72.51(6) and 81.11(7)°, respectively, generating five-membered and six-membered chelate rings at the Mo^{VI} center. The tendency of the *cis* MoO_2 group to compress bond angles is reflected in the mean value of 76.81° for these bite angles. The lengths of the Mo=O, Mo−O and Mo−N bonds are unexceptional.[12,14,20,21] The Mo acceptor center is displaced from the average equatorial plane described by O(1)−O(3)−N(1)−O(4) towards the axial oxo oxygen atom O(2), the distance of O(2) from this plane being 2.0511 Å. Such a displacement of the Mo atom from the equatorial plane towards the apical oxo oxygen atom is also found in the aldehyde oxidoreductase of *Desulfovibrio gigas*.[22,23] This displacement, naturally, makes the Mo^{VI} acceptor center somewhat inaccessible to the donor approaching from the opposite direction. Hence, it is evident that the discrete MoO_2L molecule has a square-pyramidal structure with the sixth position, *trans* to the oxo oxygen atom O(2), vacant. This vacant sixth position is expected to act like the substrate-binding site of a molybdoenzyme. This expectation was fulfilled when MoO_2L yielded a host of six-coordinate adducts of the type MoO_2L(B), where B is a monodentate Lewis base like imidazole, substituted imidazole, pyridine or picoline. The structures of two such adduct molecules [MoO_2L(Imz)] (**2**) and [MoO_2L(Py)] (**4**) were determined by single-crystal X-ray diffraction techniques and one (**4**) is discussed below. As the structures of **2** and **4** are similar, all crystallographic data, as well as the corresponding ORTEP diagram of **2**, are included in the Supporting Information.

[MoO_2L(Py)]

Crystals of [MoO_2L(Py)] (**4**) consist of discrete molecular species and the structure is presented as Figure 4. The molybdenum(VI) center is present in a distorted octahedral donor environment consisting of *cis*-oxo atoms O(1,2), *trans*-phenolate and enolate oxygen atoms O(3,4), which are

cis to O(1,2), an azomethine nitrogen atom N(1) and the tertiary nitrogen atom N(3). The structure of complex **4** can be derived from the structure of the coordinately unsaturated pentacoordinate square-pyramidal complex MoO_2L (**1**) by the addition of pyridine to the vacant axial position *trans* to the oxo atom O(2). The angle between the equatorial plane defined by O(1)−O(3)−N(1)−O(4) and that of the coordinated pyridine ring is 95.7°. The angle O(2)−Mo−N(3) is 170.04°, pointing to considerable distortion of the coordination octahedron around the Mo^{VI} center in compound **4**. A remarkable feature is that the values of the bond lengths and bond angles around the Mo^{VI} center in **1** are essentially the same in **4** (Table 4). Even the length of the metal−oxygen double bond (Mo=O) axial to the coordinated pyridine ligand, which is known to be highly influenced by axial coordination in many (oxo)metal complexes and is thought to be a measure of σ-donor capacity of the coordinated ligand, remains practically unchanged.[12,14,20,21] The length of the relevant bond [N(3)−Mo] is found to be longer than the other type of molybdenum−nitrogen (azomethine) bond N(1)−Mo, and indicates rather weak attachment of the pyridine ligand to the MoO_2^{2+} moiety. This is substantiated by TG and DTA studies of **4**, which reveal rather easy loss of the pyridine ligand on controlled heating.

Reactivity of the Complex 1 (MoO_2L)

Substrate Binding

The reaction (Scheme 1, step 3) can be considered as a substrate-binding reaction of the MoO_2L core when a heterocyclic base (substrate) binds to the distorted square-pyramidal MoO_2L moiety forming a distorted octahedral species. This reaction reminds us of the substrate binding of molybdoenzymes.

Oxo Transfer to Substrate

The tendency of the Mo^{VI} complex MoO_2L to transfer an oxygen atom to substrates has been examined in CH_3CN using PPh_3 as the substrate. The parent complex **1** has a band at 420 nm due to an L(O)→ M(Mo) LMCT transition. When the complex is treated with PPh_3, this band is found to be shifted towards a lower energy region and a new band appears at 691 nm. The oxo-transfer reaction may be represented as $Mo^{VI}O_2L + PPh_3 \rightarrow Mo^{IV}OL + OPPh_3$.

PPh_3O has been isolated and identified by IR and ^{31}P NMR spectroscopic data. This oxo-transfer reaction may be visualized[24] as a simple bimolecular reaction.[5]

Oxomolybdenum(IV) Complexes

The oxomolybdenum(IV) complexes were synthesized by two different methods (Scheme 1, steps 1 and 2) described later. Complexes **6** and **7** have poor solubility in many common organic solvents but are highly soluble in DMF and DMSO, and when the solutions are exposed to air they slowly oxidize to the parent MoO_2L in solution. As four-coordinate (oxo)Mo^{IV} complexes are unlikely, they are probably polymeric species in the solid state.[5] All the complexes are nonelectrolytes in DMF, and measurement of magnetic susceptibility indicated that they are diamagnetic at room temperature.[5,25,26]

Some spectral characteristics of compounds **6** and **7** are listed in Table 1. As already found in the case of its MoO_2^{2+} complexes, the ligand H_2L binds in a dianionic tridentate manner in its Mo^{IV} complexes. The IR spectra of these MoO^{IV} complexes clearly reveal that coordination takes place from the deprotonated phenolic and enolic oxygen atoms and the azomethine nitrogen atom. These complexes exhibit a single strong sharp band in the 964−937-cm^{-1} region,[5] representing the $\nu(Mo{=}O)_t$ mode.

The electronic spectra of the (oxo)Mo^{IV} compounds were recorded in dry DMF solution, and the compounds are found to display (Table 1) several absorption maxima in the 691−320-nm range, including a new band of moderate intensity in the low-energy 691−679-nm region. Absorption in this region is a characteristic feature of the $[MoO]^{2+}$ core.[5,27,28]

The proposed structure of **7**, which can be derived from the structure of its precursor complex **1**, is shown in Scheme 1.

The electron-transfer behavior of the complexes **6** and **7** (Table 5) was examined in CH_3CN using the conditions described in the Exp. Sect. The representative cyclic voltammograms of the complexes are shown in Figure 5. Controlled-potential coulometry indicates that these are one-electron processes. The (oxo)Mo^{IV} complexes undergo one-electron reduction to the corresponding Mo^{III} complexes and are oxidized by a one-electron process to Mo^{V} complexes. Similar observations were noted by Boyd and Spence,[27] as well as our own group.[5]

Table 5. Cyclic Voltammetric Results for Oxomolybdenum (IV) Complexes at 298 K

Complex[a]	Mo^{V}/Mo^{IV}	Mo^{IV}/Mo^{III}			
	E_{pa} [V]	E_{pc} [V]	E_{pa} [V]	ΔE_p [mV]	$E_{1/2}$ [V]
6	+1.02	−1.03	–	–	–
7	+1.10	−0.24	−0.15	90	−0.195

[a] Solvent: CH_3CN; working electrode: platinum; reference electrode: SCE; $E_{1/2} = 0.5\ (E_{pa} + E_{pc})$; $\Delta E_p = E_{pc} - E_{pa}$; E_{pc} and E_{pa} are the cathodic and anodic peak potentials, respectively; scan rate: 100 mVs^{-1}.

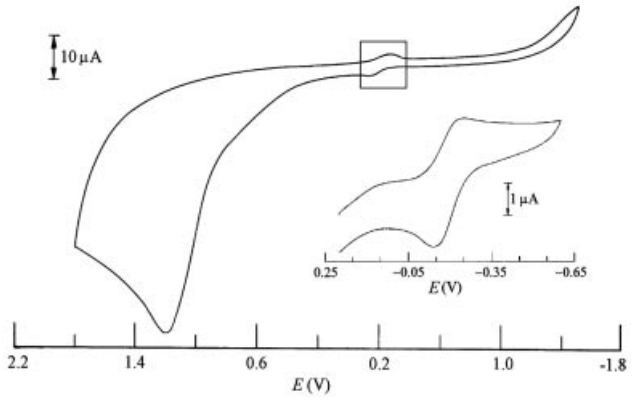

Figure 5. Cyclic voltammograms (scan rate 100 mV/s, solvent CH_3CN, 0.1 M TEAP) of MoOL(bipy) (**7**), cathodic scan (inset)

MoOL (6)

The redox behavior of this complex is found to be irreversible. At a scan rate of 100 mV s^{-1}, there is a reduction peak near −1.03 V corresponding to Mo^{IV} to Mo^{III} reduction and an anodic peak at +1.02 V for the Mo^{IV} to Mo^{V} oxidation.

MoOL(bipy) (7)

The cyclic voltammogram of this complex exhibits an irreversible anodic response (Figure 5) and a quasi-reversible cathodic response (inset, Figure 5). An initial anodic scan at a rate of 100 mV s^{-1} reveals an irreversible oxidation wave near +1.10 V, which is assigned to the one-electron oxidation of the Mo^{IV} complex to the corresponding Mo^{V} species. On the cathodic side, there is a minor reversible peak at $E_{1/2} = -0.195$ V whose current height is less than 1/10 that of the anodic peak. This small peak probably arises due to the generation of a very small amount of an Mo^{V} or Mo^{VI} species from the parent Mo^{IV} complex **7** during the preparation of the solution and performing the CV experiment. As Mo^{V} or Mo^{VI} species are expected to be more easily reduced than the corresponding Mo^{IV} species, this couple is observed at a much less negative potential than the Mo^{IV}/Mo^{III} couple observed in complex **6**. Due to the introduction of a strong donor bipy ligand the Mo^{IV}/Mo^{III} couple for **7** is expected to shift to a more negative potential and was therefore not observed within the potential window scanned in our experiment.

Conclusion

Preparation and characterization of dioxomolybdenum(VI) and oxomolybdenum(IV) complexes involving a diacidic tridentate ONO donor in the form of the 2-hydroxyacetophenone hydrazone of *o*-aminobenzoylhydrazine (LH_2) is reported. The main complex MoO_2L is a structurally characterized pentacoordinate distorted square-pyramidal species with one vacant position (*trans* to one of the M=O oxygen atoms). This vacant position is found to act as a substrate-binding site, and six-coordinate adducts, like $[MoO_2L(Py)]$ and $[MoO_2L(Imz)]$, are easily formed by the attachment of pyridine or imidazole to this position. The molybdenum center of MoO_2L is found to mimic the active site of some oxotransfer molybdoenzymes, as evidenced by the transfer of an oxo oxygen atom to the substrate PPh_3. Careful analysis of the structural data of MoO_2L indicates that the metric values of the structural features of the complex resemble those of the aldehyde oxidoreductase from *Desulfovibrio gigas* in which the Mo^{VI} center is also pentacoordinate and distorted square-pyramidal.[22,23] The magnitude of the deviation of the Mo^{VI} center towards the apical oxygen atom O(2) is also similar to that found in the molybdoenzymes referred to above.[22,23] It is known that the active sites of some oxotransfer molybdoenzymes contain at least one S donor atom around MoO_2^{2+} or MoO^{2+} cores along with N and O donor points. However, in the present case, the donor environment around the MoO_2^{2+}/MoO^{2+} core consists only of N and O donor points. This work suggests that the presence of at least one sulfur donor in the coordination sphere of the oxomolybdenum core may not be absolutely essential for all oxotransfer molybdoenzymes.

Experimental Section

General Remarks: $[MoO_2(acac)_2]$ was prepared as described in the literature.[29] Reagent grade solvents were dried and distilled prior to use. All other chemicals were reagent grade, available commercially, and used as received. Tetraethylammonium perchlorate (TEAP) used for electrochemical work was prepared as reported in the literature.[30] Elemental analyses were performed with a Perkin−Elmer 240 C, H, N analyzer. IR spectra were recorded with a Perkin−Elmer 783 spectrometer. ^1H NMR spectra were recorded with a Bruker AVANCE DPX 300 MHz spectrometer using $SiMe_4$ as an internal standard. Electronic spectra were recorded with a Shimadzu UV/Vis recording spectrophotometer. Magnetic susceptibility was measured with a PAR model 155 vibrating sample magnetometer with $Hg[Co(SCN)_4]$ as calibrant. Electrochemical data were collected using an EG&G PARC electrochemical analysis system (model 250/5/0) and a PC-controlled EG&G/PARC−VERSASTAT2 potentiostat at 298 K under dry nitrogen. Cyclic voltammetry experiments were carried out with a platinum working electrode, a platinum auxiliary electrode, SCE as the reference electrode, and TEAP as the supporting electrolyte. The value

for the ferrocenium/ferrocene couple under the experimental conditions was 0.40 V.

Synthesis of Ligand H_2L: The Schiff base ligand 2-aminobenzoylhydrazone of 2-hydroxyacetophenone was prepared by the same procedure reported in our previous work.[8]

Synthesis of $[MoO_2L]$ (1): A sample of H_2L (0.28 g, 1.04 mmol) was dissolved in 30 mL of ethanol by warming in a water bath, solid $MoO_2(acac)_2$ (0.33 g, 1.01 mmol) was added to the ligand solution and the mixture was refluxed for 3 h and then filtered. Slow concentration of the orange filtrate over 3 d produced dark orange crystals. Yield 0.32 g (81%). $C_{15}H_{13}MoN_3O_4$ (395.04): calcd. C 45.54, H 3.32, N 10.63; found C 45.94, H 3.30, N 10.01. ^{1}H NMR ([D$_6$]DMSO): δ = 7.93−6.57 (m, 8 H, C_6H_4), 2.78 (s, 3 H, CH_3) ppm.

Synthesis of $[MoO_2L(Imz)]$ (2; Imz = Imidazole): Imidazole (0.05 g, 0.75 mmol) was added to a clear orange solution (obtained by refluxing) of **1** (0.22 g, 0.55 mmol) in ethanol (50 mL) and the mixture was allowed to reflux for 3 h. The volume of this dark orange solution was reduced to 20 mL in a rotary evaporator. On standing at room temperature, the solution deposited shiny brown crystals. Yield 0.21 g (80%). $C_{18}H_{17}MoN_5O_4$ (463.08): calcd. C 46.62, H 3.69, N 15.10; found C 46.31, H 3.49, N 15.07. ^{1}H NMR ([D$_6$]DMSO): δ = 7.94−6.57 (m, 8 H, 3 H, C_6H_4, $C_3N_2H_4$), 2.77 (s, 3 H, CH_3), 12.01 (s, NH, $C_3N_2H_4$) ppm.

Synthesis of $[MoO_2L(1\text{-}Me\text{-}Imz)]$ (3; 1-Me-Imz = 1-Methylimidazol): This compound was prepared using the same procedure as for compound **2**. Yield 0.21 g (78%). $C_{19}H_{19}MoN_5O_4$ (477.09): calcd. C 47.76, H 4.01, N 14.66; found C 47.61, H 3.95, N 14.49. ^{1}H NMR ([D$_6$]DMSO): δ = 7.93−6.57 (m, 8 H, 3 H C_6H_4, $C_4N_2H_6$), 2.78 (s, 3 H, CH_3), 3.71 (s, 3 H, $C_4N_2H_6$) ppm.

Synthesis of $[MoO_2L(py)]$ (4; py = Pyridine): Complex **1** (0.22 g, 0.55 mmol) was treated with 2 mL of pyridine and the mixture was heated until a clear deep yellow solution was produced. Dry ethanol (20 mL) was added to this solution, which was then refluxed for 3 h. Slow concentration of the reaction mixture over 5 d produced yellow crystals. Yield 0.19 g (74%). $C_{20}H_{18}MoN_4O_4$ (474.08): calcd. C 50.59, H 3.82, N 11.80; found C 49.94, H 3.85, N 12.09. ^{1}H NMR ([D$_6$]DMSO): δ = 8.58−6.57 (m, 8 H, 5 H, C_6H_4, C_5H_5N), 2.77 (s, 3 H, CH_3) ppm.

Synthesis of $[MoO_2L(\gamma\text{-}pic)]$ (5; γ-pic = Picoline): This compound was prepared using the same procedure as above (compound **4**). Yield 0.19 g (70%). $C_{21}H_{20}MoN_4O_4$ (488.10): calcd. C 51.60, H 4.12, N 11.46; found C 51.84, H 3.90, N 11.51. ^{1}H NMR ([D$_6$]DMSO): δ = 8.42−6.57 (m, 8 H, 4 H, C_6H_4, C_6H_7N), 2.77 (s, 3 H, CH_3), 2.31 (s, 3 H, CH_3, C_6H_7N) ppm.

Synthesis of [MoOL] (6): A solution of PPh_3 (0.393 g, 1.5 mmol) in 5 mL of acetonitrile was added to a refluxing solution of MoO_2L (0.22 g, 0.55 mmol) in 25 mL of degassed acetonitrile. The reddish orange solution turned dark brown and a brown compound separated within 1 h. The brown compound was collected by rapid filtration of the hot mixture, washed well with hot acetonitrile and dried in vacuo; yield 0.15 g (70%). $C_{15}H_{13}MoN_3O_3$ (379.04): calcd. C 47.46, H 3.45, N 11.07; found C 47.34, H 3.12, N 11.23. ^{1}H NMR ([D$_6$]DMSO): δ = 7.94−6.57 (m, 8 H, C_6H_4), 2.78 (s, 3 H, CH_3) ppm.

Synthesis of [MoOL(bipy)] (7; bipy = 2,2′-Bipyridine): A solution of 2,2′-bipyridine (bipy; 0.78 g, 5.0 mmol) and PPh_3 (0.393 g, 1.5 mmol) in 5 mL of degassed acetonitrile was added to a refluxing solution of 0.22 g (0.55 mmol) of MoO_2L in 25 mL of degassed acetonitrile. The orange-red solution turned green after 1 h of refluxing and refluxing was continued for another 4 h. The green product was precipitated by adding excess dichloromethane (50 mL) followed by excess *n*-hexane (50 mL). The precipitate was rapidly filtered and washed well with *n*-hexane and dried in vacuo; yield 0.18 g (60%). $C_{25}H_{21}MoN_5O_3$ (535.10): calcd. C 55.02, H 3.88, N 12.83; found C 54.91, H 3.90, N 12.41. ^{1}H NMR ([D$_6$]DMSO): δ = 8.70−6.59 (m, 8 H, 8 H, C_6H_4, $C_{10}H_8N_2$), 2.77 (s, 3 H, CH_3) ppm.

Crystallography: Crystal data for compounds **1** and **4**, along with other experimental details, are summarized in Tables 3 and 4. Single-crystal data collection was performed at 293(2) K with a Siemens P4 four-circle diffractometer using graphite-monochromatized Mo-K_α radiation (λ = 0.71073 Å). The complex MoO_2L (**1**) crystallizes in the monoclinic space group $P2_1/n$ whereas the complex $MoO_2L(Py)$ (**4**) crystallizes in the monoclinic space group $C2/c$. The intensities were corrected for Lorentz and polarization effects and semi-empirical absorption corrections were performed on the basis of Ψ scans for nine chosen reflections with high χ values. Following structural solution, positional parameters and temperature factors were refined by full-matrix least squares against F_o^2 with SHELX 97.[31] All non-hydrogen atoms were refined anisotropically and a riding model with isotropic temperature factors was employed for hydrogen atoms. The X-ray crystallographic structure and the corresponding data for the complex **2** [MoO_2L-(Imz)] are reported as Supporting Information. CCDC-186348 (**1**), -186349 (**2**) and -186350 (**4**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Center, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Convenient Controllable Synthesis of Inorganic 1D Nanocrystals and 3D High-Ordered Microtubes

Zhenhui Kang,[a] Enbo Wang,*[a,b] Min Jiang,[a] Suoyuan Lian,[a] Yangguang Li,[a] and Changwen Hu[a]

Keywords: Nanotubes / Polyoxometalates / Synthetic methods

Polyoxometalates (POMs) nanorods, hollow particles, microtubes, and 3D-ordered tube systems were prepared using a novel and simple PEG/H_2O liquid system. POM nanorods with various diameters (30–400 nm) and lengths (500 nm to 2 μm) were produced in a well-controlled manner.

Introduction

Many interesting and technologically important phenomena occur in systems that have a spatial dimension similar to that of fundamental physical, chemical, or biological processes.[1] As a bridge between the molecular and the macroscopic world, mesosystems have become one of the most attractive subjects in physics, materials science, chemistry, and biology.[1] Nanosystems with characteristic lengths between 1 and 100 nm exhibit fascinating properties, such as quantized excitation, coulomb blocking, single-electron tunneling (SET), and metal−insulator transitions.[1] One-dimensional (1D) nanomaterials are of great fundamental and practical interest owing to their novel properties, which depend on their particular sizes and shapes.[1] Recently, much attention has been paid to the construction of advanced materials with such nanoscale building blocks.[2] Therefore, the exploration of preparation methods to control the sizes and shapes of nanomaterials is one of the focuses for the development of nanotechniques.[2−4]

A number of methods have been employed for the preparation of 1D nanomaterials, including template-assisted,[5] vapor-liquid-solid-(VLS-)assisted,[6] and electrochemical processes.[7] For most of these strategies, however, complicated process control, high reaction temperature, and long synthesis time are required. Recently, the introduction of microemulsions (or reverse micelles) has provided a relatively simple and powerful method for controlling the size, shape, and surface texture of nanoparticles and nanorods. In such microenvironments, the nanomaterials are encapsulated in the closed shells of surfactant molecules. The size and shape of nanoclusters can be well controlled by the size of the capsules, which can be controlled by changing the ratios of water and oil.[8] From this model of reaction fields, we speculate that if the closed capsules composed of surfactant molecules could be opened in one direction, a linear reaction field could be formed and a 1D nanomaterial could grow in such a microenvironment. Based on this speculation, we chose the nonionized surfactant polyethylene glycol (PEG) mixed with water so as to form a linear reaction field and explore the controllable synthesis of polyoxometalate (POM) nanocrystals and their nano/microstructure material forms.

As one of the typical inorganic metal oxide clusters, POMs have recently received much attention owing to their novel compositions, structures, and applications in the fields of catalysis, pharmacology, electronic, and magnetic materials.[9,12] They can be regarded as extremely versatile inorganic entities for the construction of functionally active solids and are one of the favorite candidates to be transformed into nanometer-sized materials.

It is noteworthy that POMs are nanosized polyoxometalate clusters that form by a self-assembly process in solution and can be isolated as solids. They have unique physicochemical properties such as strong Brønsted acidity, reversible multielectron redox transformations, activation of molecular oxygen and hydrogen peroxide, high proton mobility across their discrete ionic structure, etc.[9] These properties make POMs promising acid, redox, and bifunctional catalysts in homogeneous and heterogeneous systems. POMs are widely used as model systems for fundamental research, providing unique opportunities for mechanistic studies on

the molecular level. They have also become increasingly important for applied catalysis. Several new industrial processes based on POM catalysis have been commercialized.[12k] Current studies of catalysis by POMs and related systems concentrate on the catalyst preparation, characterization and monitoring, mechanistic aspects, application for organic synthesis and fine and specialty chemicals, and alkane activation. Other topics of interest include the design of advanced solid acid catalysts based on POMs incorporated into mesoporous zeolites.[9,12] POM crystalline nanomaterials, especially nano/microtubes and their 3D-ordered systems, will provide an opportunity to explore their unique properties on catalysis in many fields.

Müller et al.[10] have ingeniously synthesized many giant clusters of POMs on the nanometer scale, including novel kinds of large rings and wheel-shaped systems with 176 or even more Mo atoms. Recently, Misono et al. have studied the growth process of polyoxotungstate $(NH_4)_3PW_{12}O_{40}$ crystalline nanoparticles.[11] However, the rational design and controllable preparation of POM-based crystalline nanomaterials are still huge challenges. Because numerous well-characterized POMs are available,[12] it is extremely important to develop new strategies for the preparation of POM nanocrystals and nano/micro systems to explore their novel properties.

In this paper, we report on the 1D POM crystalline nanorods, hollow particles, nano/microtubes and 3D high-ordered tube systems prepared by a convenient and novel controllable synthesis method. Both the size and shape of these POM crystalline nanorods can be controlled by the use of different kinds of PEG and various volumes of water.

Results and Discussion

POMs Crystalline Nanorods

In our experiments, $AgNO_3$ (0.25 g) and $H_4SiW_{12}O_{40}{\cdot}nH_2O$ (1 g) were dissolved in a mixture of two different PEG/H_2O systems, one with w = 2.5:1 and the other with w = 2.5:2.5 (w = [PEG]/[H_2O]). Both of the systems were stirred before to give transparent sticky fluids. After the two systems were mixed, the reaction mixture remained clear. However, a large amount of white flocculent precipitate formed when a fourfold excess of ethanol was added. Element analysis of the white products give a molar ratio of Ag/Si/W = 4:1:12. The FT-IR spectrum exhibits characteristic peaks at 1100, 1011, 970, 919, 882, and 795 cm^{-1}, which are attributed to the ν(Si=Oa), ν(W=Ot), ν(W−Ob−W), and ν(W−Oc−W) absorptions of a Keggin-type structure, respectively. Transmission electron microscopy (TEM) images of samples taken from the PEG-400/H_2O (w = 2.5:1.5) system showed $Ag_4SiW_{12}O_{40}$ nanorods with a regular shape and size (Figure 1, a and c). The electron diffraction (Figure 1, b) and XRD patterns (Figure 1, d) confirm that these $Ag_4SiW_{12}O_{40}$ nanorods are crystalline.

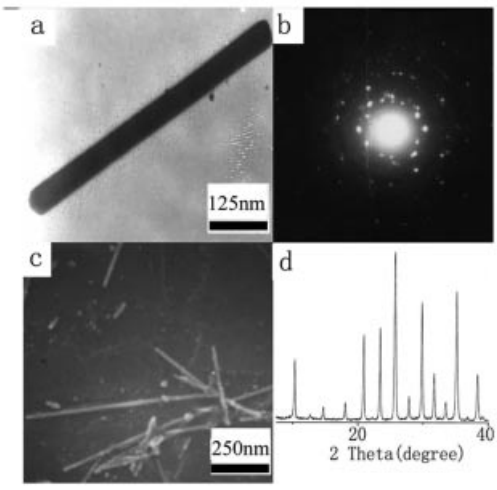

Figure 1. (a) TEM image of $Ag_4SiW_{12}O_{40}$ nanorods taken from the PEG-400/H_2O (w = 2.5:1.5) system; (b) electron diffraction pattern of the nanocrystals of $Ag_4SiW_{12}O_{40}$; (c) SEM image of $Ag_4SiW_{12}O_{40}$ nanorods; (d) XRD patterns of $Ag_4SiW_{12}O_{40}$ nanorods

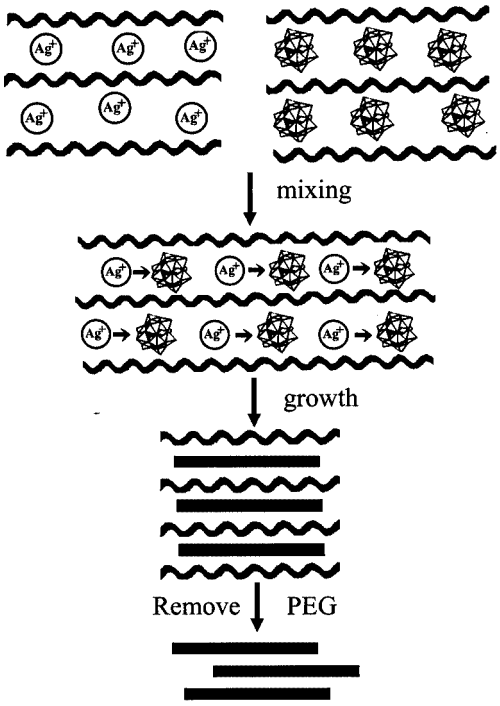
In these experiments, the surfactant PEG molecules act as the most important component introduced into the reaction system. It is known that the nonionized surfactant PEG molecules form chain-like structures due to the assembly in water.[13] Therefore, we can imagine that many 1D liquid reaction fields could be formed when the PEG and a small amount of water are mixed together. The metathetical reactions of $AgNO_3$ and $H_4SiW_{12}O_{40}{\cdot}nH_2O$ and the growth of $Ag_4SiW_{12}O_{40}$ nanoclusters are strictly limited in such divided linear reactions along the directional space. Owing to the inhibition of surfactant PEG, further agglomeration will be stopped and the nanorods are therefore formed and fixed in the linear environments. Scheme 1 illustrates the possible mechanism. The TEM images of POM nanorods shown in Figure 2 proved these assumptions to be correct. Nanorods with various regular sizes and shapes can be prepared in different PEG/H_2O systems.

It is noteworthy that different molecular masses of PEG molecules lead to a variety of lengths of nanorods. Lower molecular weight surfactant of PEG-400 could be selected to prepare shorter POM nanorods with average lengths of 500−800 nm. PEG-600, which has a higher molecular weight, could be used to synthesize longer POM nanorods with average lengths of 1−2 μm. Figure 2, a and b, show the nanorods produced by the PEG-400/H_2O systems. Figure 2, c and d, illustrate the nanorods prepared by the PEG-600/H_2O systems. With increasing molecular mass of PEG, the length of the linear reaction fields is probably greater, and thus the size of nanorods is increased. Therefore, the length of POM nanorods can be controlled by adjustment of the molecular weight of PEG.

We further showed that the content of water in the preparation of 1D POM nanomaterials has a direct influence on the diameter of the nanorods. The relationship between



Scheme 1. Schematic diagram of the proposed formation process of POM nanorods

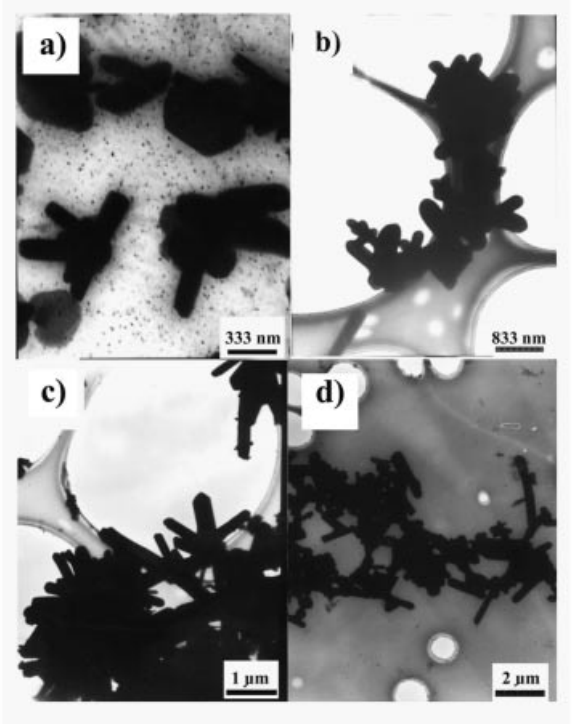


Figure 2. TEM images of $Ag_4SiW_{12}O_{40}$ nanorods with a length of: (a) and (b) 500−800 nm in the PEG-400/H_2O system; (c) and (d) 1−2 μm in the PEG-600/H_2O system

the size of 1D POM nanomaterials and the content of water is shown in Table 1. It is noteworthy that the diameter of the nanorods increases with increasing water content. As noted above, in this liquid system, many linear reaction fields exist, and the nanorods can be formed and fixed there. With the addition of water, the linear reaction field, i.e. the reaction space, will become larger, and thus the nanorods will also have larger diameters. Figure 3 shows nanorods with different diameters prepared in PEG-400/H_2O systems containing different amounts of water. Their diameters vary with the content of water in PEG-400/H_2O systems, namely 30, 70, and 90 nm for (a) PEG-400/H_2O = 2.5:1.0, (b) PEG-400/H_2O = 2.5:1.5, and (c) PEG-400/H_2O = 2.5:2.0, respectively. Similar results are also found in the PEG-600/H_2O (w = 2.5:1.5, 2.5:2.0, 2.5:2.5) systems (as shown in Figure 4), in which nanorods with diameters of (a) 200 nm, (b) 300 nm, and (c) 400 nm are obtained, respectively. Figure 5 shows the SEM images of POM nanorods with different diameters and lengths.

Table 1. Influence of the amount of water in PEG/H_2O systems on the diameters of the POM 1D nanomaterials

Surfactants	$Ag_4SiW_{12}O_{40}$ nanorods/nanowires [nm]	Content of water PEG/H_2O [mL/mL]
PEG-400	30	2.5:1.0
	70	2.5:1.5
	90	2.5:2.0
PEG-600	200	2.5:1.5
	300	2.5:2.0
	400	2.5:2.5

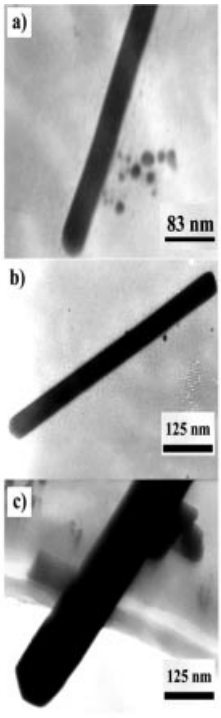

Figure 3. TEM images of nanorods taken from the PEG-400/H_2O systems; the diameters of these nanorods vary with the amount of water, namely 30, 70, and 90 nm for (a) PEG-400/H_2O = 2.5:1.0; (b) PEG-400/H_2O = 2.5:1.5; (c) PEG-400/H_2O = 2.5:2.0 (mL/mL)

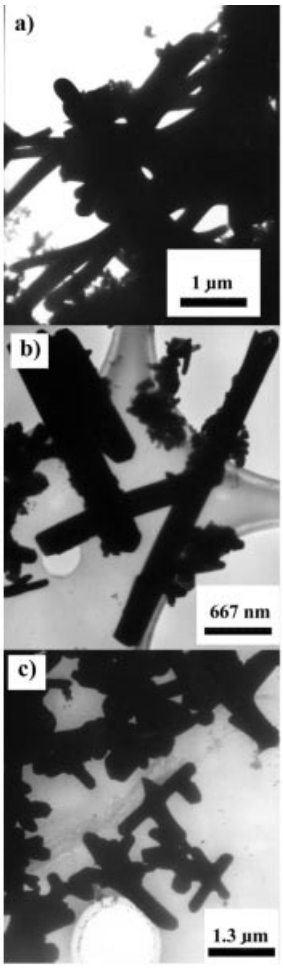

Figure 4. TEM images of nanorods taken from the PEG-600/H_2O systems; the diameters of these nanorods vary with the amount of water, namely 200, 300, and 400 nm for (a) PEG-600/H_2O = 2.5:1.5; (b) PEG-600/H_2O = 2.5:2.0; (c) PEG-600/H_2O = 2.5:2.5 (mL/mL)

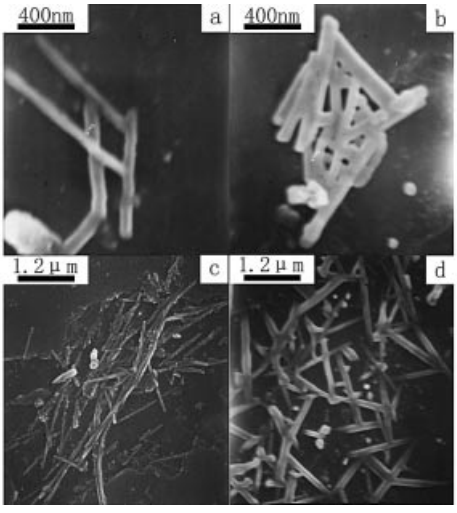

Figure 5. SEM images of POM nanorods with different diameters and lengths

In order to investigate the action of PEG in this liquid system, control experiments without PEG addition were carried out. Figure 6, a−c, show the SEM images of $Ag_4SiW_{12}O_{40}$ particles with a diameter of about 5 μm. Figure 6, d, is the XRD pattern of $Ag_4SiW_{12}O_{40}$ particles. From this figure we can see that the products are huge particles in the ordinary liquid system, hence PEG is a very important factor in controlling the shape and size of products.

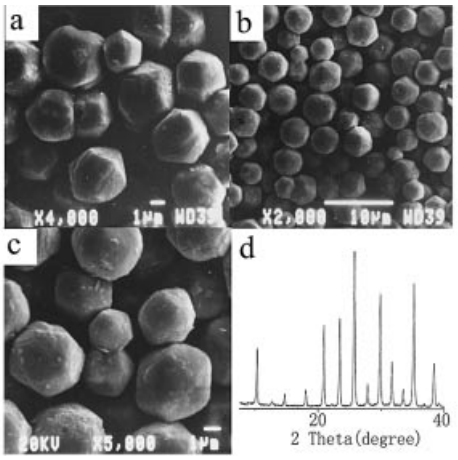

Figure 6. SEM images and XRD pattern of $Ag_4SiW_{12}O_{40}$ particles

In this liquid system, the reaction process was analyzed by conductometry. Figure 7 shows the relationship between the time and the conductivity in the PEG-400/H_2O (w = 2.5:1.5) system. Curve (a) shows the conductivity during the reaction when the solution containing PEG, water, and $AgNO_3$ was added to the other solution containing PEG, water, and $H_4SiW_{12}O_{40}$. Curve (b) shows the conductivity during the reaction when the solution containing PEG, water, and $H_4SiW_{12}O_{40}$ was added to the other solution containing PEG, water, and $AgNO_3$. Because of the coordination action between the Ag^+ and O atom in the PEG, the conductivity of the solution containing PEG, water, and $AgNO_3$ is lower than the solution that contains PEG, water, and $H_4SiW_{12}O_{40}$. When the reaction happens in the linear reaction fields, the formation of $Ag_4SiW_{12}O_{40}$ nanocrystals leads to a decrease of the electrolyte concentration. Thus, the conductivity of the reaction system decreases with the growth of nanocrystals. Curve (b) exhibits a sharp rise at the beginning of the reaction. This is due to the fact that the solution containing PEG, water, and $H_4SiW_{12}O_{40}$ has a higher conductivity than that of the solution that contains PEG, water, and $AgNO_3$.

According to these experimental results, these liquid-phase reactions can be regarded as a method that can be used to control the length and diameter of 1D POM nanomaterials rationally and effectively. During the preparation of 1D POM nanomaterials, the sticky solution, in which the uniform POM nanorods and/or nanowires could be obtained and exist stably without further agglomeration, is one of the important factors.

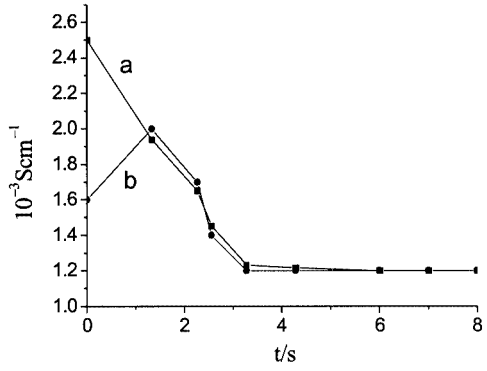

Figure 7. Relationship between the time and the conductivity

POM Hollow Particles

We wanted to produce short POM nanorods by means of the PEG-200/H_2O system, but, hollow particles were obtained instead of the expected short nanorods. This result can be attributed to the following. PEG assembly structures in water are flexible and chain-like. Surfactant PEG with lower molecular weight becomes more flexible and looser aggregates form. For PEG-200, the aggregates in water are different from those that form with higher molecular weight PEGs. The aggregates of PEG 200 in water are so soft that they cannot template the synthesis of POM nanorods. Thus, the soft and crimped aggregates lead to the formation of hollow particles. The diameters of these hollow particles are about 800 nm with homogeneous wall thickness (70 nm). Typical SEM images of hollow POM particles are shown in Figure 8. As noted above, many unique properties make POMs promising acid, redox, and bifunctional catalysts in homogeneous and heterogeneous systems. These hollow POM particles could be useful in a rich variety of applications. For instance, they may be suggested or demonstrated as extremely small containers for microencapsulation − a process that plays an important role in many areas such as catalysis, delivery of drugs, development of artificial cells, and protection of biologically active materials (e.g., enzymes, proteins, or deoxyribonucleic acids, DNAs).[14]

POM Microtubes and a 3D Ordered Microtube System

We can imagine that many 1D liquid reaction fields can be formed when PEG and a small quantity of water are mixed together. The larger the amount of water, the broader the reaction fields become. If the reaction fields are so broad that they can embrace the PEG aggregate then cannular structures may be obtained from PEG/H_2O systems. Figure 9, a, shows the half-tube obtained when PEG-400/H_2O = 2.5:3.5 (mL/mL) was used. Whole microtubes (shown in Figure 9, b−f) with diameters of about 700 nm were obtained using PEG-400/H_2O = 2.5:5 (mL/mL). Here, another important factor is the speed of stirring. High-speed stirring leads to the degradation of POM microtubes. On the contrary, well-grown microtubes were prepared at low stirring speeds (shown in Figure 9, d−f).

During the course of preparing the microtubes, an interesting phenomenon (shown in Figure 10, a) was observed:

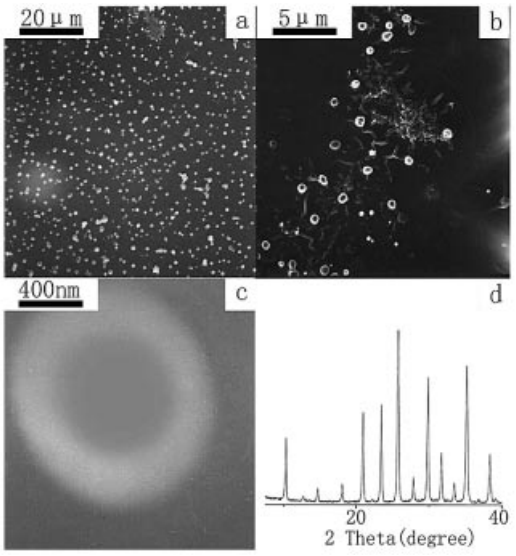

Figure 8. SEM images and XRD pattern of hollow $Ag_4SiW_{12}O_{40}$ particles

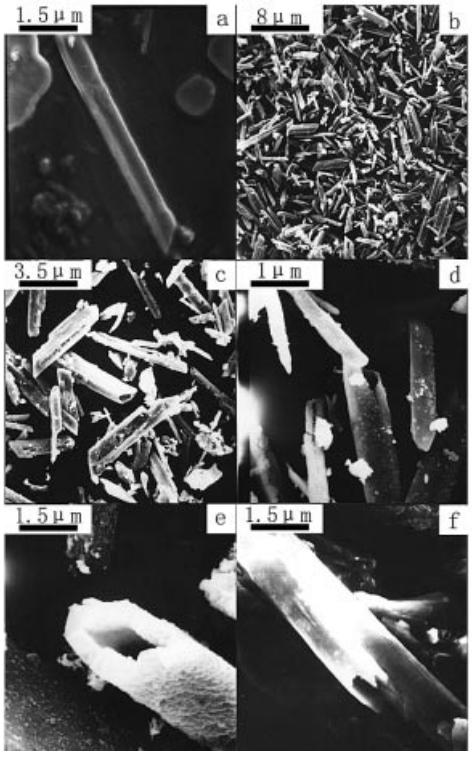

Figure 9. SEM images of $Ag_4SiW_{12}O_{40}$ microtubes

several microtubes fused together. So, we have developed a low-temperature controlled hydrothermal method using PEG/H_2O systems to synthesize 3D highly ordered microtunnel arrays. We mixed an $AgNO_3$/PEG/H_2O system and an $H_4SiW_{12}O_{40}$/PEG/H_2O system and then stirred slowly in order to make the mixture homogeneous. Then, the mixture was sealed in a 25-mL Teflon-lined reactor, with 70% filling, and heated at about 70 °C for 72 h. Figure 10, b and c,

show the SEM images of 3D-ordered microtunnel POM materials with diameters of about 1 μm. These ordered tunnels may be used as a microreactor. They should be useful in various applications, such as catalysis, selective delivery, and template for the synthesis of nanostructure materials.

Conclusion

In conclusion, the novel, and simple liquid PEG/H_2O system was applied in the preparation of POM nanorods, hollow particles, microtubes, and 3D-ordered tube systems. A possible mechanism is that chain-like PEG molecules segment the liquid reaction fields to form many linear microenvironments, in which the interaction of reactants and the growth of nanomaterials are limited in the directional space. From this reaction model, we presume that many other 1D nanomaterials such as metal salts ($BaSO_4$, CdS) and metal oxides (ZnO, CuO, Fe_3O_4) could also be prepared.

Furthermore, 1D POM nanorods, hollow particles, microtubes, and 3D-ordered tube system have been prepared. The regular sizes and shapes are well controlled by the PEG/H_2O systems. Owing to the extensive applications of POMs in catalysis, medicine, and functional materials, the preparation of POM nanostructured materials could provide a new route to explore their excellent properties.

Experimental Section

General: All reagents were purchased from commercial suppliers and used without further purification. The SEM images were obtained with a JEOL JSM-840 operating at 20 kV. The XRD patterns were obtained with a Rigaku D/max 2500V PC diffractometer with Cu-K_α radiation. A JEM-2010 transmission electron microscope was used to examine the morphology of the POMs nanocrystals.

General Preparation of $Ag_4SiW_{12}O_{40}$ Nanorods: $H_4SiW_{12}O_{40}{\cdot}nH_2O$ (1 g) was dissolved in a mixture of PEG-400 (or PEG-600)/H_2O (2.5 mL/1 mL, about 2.5 mL of the mixture) whilst stirring to give a clear and homodisperse system. Another 2.5 mL of PEG-400 (or PEG-600), mixed with 1−2 mL of H_2O and 0.23 g of $AgNO_3$, was stirred until it became clear. The above two solutions were then mixed and stirred for 1 min. Then, a fourfold excess of ethanol was added to form a white precipitate. The white precipitate was centrifuged, washed with ethanol, and dried in air at 50 °C for 1 h. The yield was 90% ($Ag_4SiW_{12}O_{40}$, 1.14 g, based on W). A similar approach was used for the synthesis of POM hollow particles using the PEG-200/H_2O (2.5 mL/1.5 mL) system. A clear and homodisperse system of $AgNO_3$/PEG-200/H_2O (0.5 g/2.5 mL/1.5 mL) and a similar system of $H_4SiW_{12}O_{40}$/PEG-200/H_2O (0.5 g/2.5 mL/1.5 mL) were prepared according to the above procedure. Then, the two systems were mixed and stirred. A fourfold excess of ethanol was added to form a white precipitate. The white precipitate was also centrifuged, washed with ethanol, and dried in air at 50 °C for 1 h. A very similar approach was employed to prepare the $Ag_4SiW_{12}O_{40}$ microtubes. A large amount of water (PEG/H_2O = 1:2) was added to the reaction system, with slow stirring. This mixture was sealed in a 25-mL Teflon-lined reactor, with 70% filling, and heated to about 70 °C for 72 h, to give the 3D-ordered microtube arrays.

[a] mac = methyl acrylate, bac = *n*-butyl acrylate, sty = styrene. – [b] 4-bba = 4-bromobenzaldehyde. – [c] TON = Turnover number (mol product/mol catalyst). – [d] GC yield using 2-methylnaphthalene as internal standard. – [e] TOF = Turnover frequency (mol product/mol catalyst × time). – [f] *trans*-stilbene/*cis*-stilbene = 9. – [g] Dioxane as solvent. – [h] Mesitylene as solvent.

In the first paragraph of the Exp. Sect. on page 2910 it was inadvertently stated that $LiPPh_2$ was prepared from nBuLi and PPh_2Cl. It should correctly say that $LiPPh_2$ was prepared from nBuLi and $HPPh_2$.

COVER PICTURE

The cover picture shows a mixed-valence copper(I,II) coordination polymer $[Cu^{I}_{2}Cu^{II}(4,4'\text{-bpy})_2(pydc)_2]\cdot 4H_2O$ (4,4′-bpy = 4,4′-bipyridine; pydc = pyridine-2,4-dicarboxylate) featuring the "metal-complex ligands" $[Cu^{II}(pydc)_2]^{2-}$ synthesized hydrothermally using $Cu(MeCO_2)_2$, pyridine-2,4-dicarboxylate, 4,4′-bipyridine and NaOH. Single-crystal structure analysis exhibits this compound to be the first porous 3-D framework constructed from five-fold parallel interpenetration of 2-D (6,3) nets (right-hand side). The one-dimensional channels in the 3-D framework (left-hand side) occupying 17.4% of the crystal volume are occupied by guest water molecules. The porous network is stable after removal of the lattice water molecules, which may be attributed to the multiple entanglement of the 2-D nets. Details are discussed in the article by X.-M. Zhang and X.-M. Chen on p. 413ff.

The Chemistry of Borylene Complexes

Holger Braunschweig*[a][‡] and Miriam Colling[b]

Keywords: Boron / Borylene complexes / Transition metals

Over the past seven years, complexes of various transition metals with bridged or terminal borylene ligands BR have for the first time been reported and fully characterised. Being closely related to important organometallic compounds, such as carbene, vinylidene, and carbonyl complexes, they have already attracted considerable interest both from experimental and computational points of view. Those studies have provided some detailed information about the nature of the metal–boron bond and about the nature of metal and borylene moieties required for the formation of stable complexes. Various methods for their preparation have been developed and the first studies on their reactivity have demonstrated an interesting chemistry.

(© Wiley-VCH Verlag GmbH, 69451 Weinheim, Germany, 2003)

1. Introduction

Transition metal complexes with electron-precise, two-centre, two-electron (2c-2e) bonds linking the metal centre to a main group element have now been well established for decades, and for almost any main group element from group 13 to 17. Corresponding complexes with metal−boron bonds, however, became known only much later, indicating the difficulties associated with the synthesis and characterisation of these compounds. Despite very early investigations in this area (vide infra),[1] the first structurally authenticated transition metal complexes of boron date back only to 1990.[2,3] Until then, confirmed knowledge of compounds with direct transition metal−boron bonds was restricted to borides,[4−6] metallaboranes[7−9] and complexes with π-bonded boron-containing ligands such as borole,[10−12] diborolene,[13] borabenzene,[14,15] borazine,[16,17] and diazadiboretidine.[17] The natures of the metal−boron interactions in these classes of compounds are diverse, but none of them is characterised by classical 2c-2e bonds.

Thanks to the vigorous research into transition metal complexes of boron since 1990,[18−21] a variety of different coordination modes for boron-centred ligands have been obtained, allowing for a systematic classification of those compounds (Figure 1). According to the coordination number of boron and the number of metal−boron bonds, one can distinguish between borane (**I**), boryl (**II**), bridged (**III**) and terminal borylene (**IV**) complexes. Borane complexes can be understood as Lewis acid−base adducts of basic metal centres and acidic boranes BR_3, giving rise to fourfold coordination of the boron atom. Boryl complexes, however, show boron in coordination number three, achieved by the linking of a BR_2 group to a metal centre. The borylene ligand BR can adopt two different coordination modes: either bridging between two metal centres − also showing boron in coordination number three − or terminal to one metal centre with formation of a formal

Holger Braunschweig was born in 1961 in Aachen and took up his studies in chemistry at the RWTH Aachen in 1983. He obtained his doctoral degree in 1990 (with Prof. P. Paetzold), spent a year at the University of Sussex, UK (with Prof. M. F. Lappert, FRS), and obtained his venia legendi in 1998 from the RWTH Aachen, after his habilitation with Prof. P. Paetzold. From 2000 he spent two years as a Senior Lecturer and Reader at the Imperial College, London, until being appointed to a chair of Inorganic Chemistry at the University of Würzburg. His research interests are concerned with boron and transition metal chemistry, catalysis, and organometallic polymers.

Miriam Colling was born in 1972 in Geilenkirchen (Germany). After studying chemistry at the RWTH Aachen from 1991 to 1999, she completed her PhD in 2002 (with Dr. H. Braunschweig) on the synthesis, reactivity, and structure of boryl and borylene transition metal complexes.

MICROREVIEWS: This feature introduces the readers to the authors' research through a concise overview of the selected topic. Reference to important work from others in the field is included.

double bond and a decrease in the coordination number to two. Provided that the boron atom in **II**−**IV** is still Lewis acidic, there is the possibility to add a suitable base L, which results in the formation of the corresponding adducts of boryl (**IIa**) and both bridged (**IIIa**) and terminal (**IVa**) borylene complexes. Examples of all types of compounds **I**−**IV** had already been described in earlier literature between 1963 and 1970, but without structural confirmation.[1] The spectroscopic data reported for these compounds are in disagreement with more recent findings and the proposed constitutions of those complexes have to some extent been disproved.

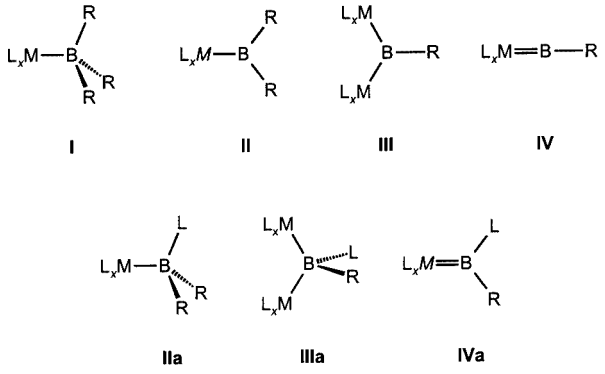

Figure 1. Different types of transition metal complexes of boron

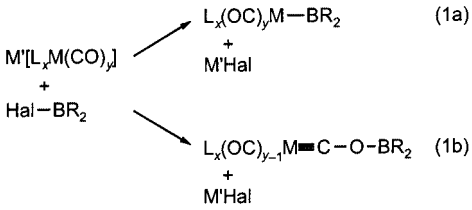
The production of borylene complexes with either bridging or terminal BR ligands is one of the most recent achievements in the field of transition metal complexes of boron, and these compounds are still exceptionally rare in comparison with boryl and other group 13 "elementdiyl" complexes.[22] Thanks to their close relationship to pivotal organometallic compounds such as carbene, vinylidene and especially carbonyl complexes, borylene complexes have already attracted considerable interest.[23−25] This is also reflected by the numerous theoretical studies[26−32] (vide infra), which greatly outnumber the experimental reports. Furthermore, borylene complexes allow for the stabilisation of the hypovalent borylene **:**BR in the coordination sphere of a transition metal centre. In contrast to related subvalent main group element species such as carbenes, silylenes, or alanediyls, no free borylenes are known at ambient temperature and in condensed phase.

2. Terminal Borylene Complexes

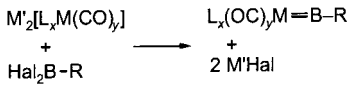
2.1. Synthesis

The salt elimination reaction between mononuclear anionic transition metal carbonyl complexes $M'[L_xM(CO)_y]$ and main group element halides $HalER_z$ is a fundamental reaction in transition metal chemistry, and has had a pivotal role in establishing complexes of the type $[L_x(OC)_yM-ER_z]$ with transition metal−element bonds.[33,34] Over the past decade, salt elimination reactions have also become a very facile method for the synthesis of boryl complexes $[L_x(OC)_yM-BR_2]$ [Equation (1a)]. We have reported, however, that the formation of (boryloxy)-carbyne complexes $[L_x(OC)_{y-1}M{\equiv}C-O-BR_2]$ [Equation (1b)] with nucleophilic attack of the CO oxygen atom represents an alternative reaction pathway to the expected synthesis of boryl complexes in certain cases.[35−37]



(1)

Extension of this synthetic approach to dianionic carbonylates and suitable dihaloboranes [Equation (2)] gave access to the first structurally authenticated terminal borylene complexes $[(OC)_4Fe-B(\eta^5\text{-}C_5Me_5)]$ (**1**)[38] and $[(OC)_5W=B=N(SiMe_3)_2]$ (**2**),[39] reported by Cowley and by us in 1998 (Figure 2). By applying the corresponding precursors $K_2[Fe(CO)_4]$ and $Na_2[Cr(CO)_5]$ we also obtained the related aminoborylene complexes $[(OC)_4Fe=B=N(SiMe_3)_2]$ (**3**)[39] and $[(OC)_5Cr=B=N(SiMe_3)_2]$ (**4**)[39] (Figure 2), the latter of which was subsequently characterised by X-ray structure analysis.[40] The formation of **1**−**4** implies that the boron centre in such terminal borylene complexes requires stabilisation by a sterically demanding and electron-releasing ligand. Evidently, both the $\eta^5\text{-}C_5Me_5$ and the $N(SiMe_3)_2$ ligands provide sufficient steric shielding and π-electron stabilisation. In the case of the former, an alternative point of view may be applied, namely that the electron deficiency of the boron centre is relieved by its incorporation into a non-classical pentacarba-*nido*-hexaborane cage. From our experience with the formation of transition metal−boron bonds by salt elimination reactions, the aminoborane $Br_2B=N(SiMe_3)_2$ appeared to be the most promising borane precursor for the synthesis of terminal aminoborylene complexes because of the increased electrophilicity of the boron centre in relation to (dialkylamino)boranes, and consequent facilitation of the nucleophilic substitution of the halides by transition metals.[41,42]



(2)

Despite significant efforts[43−45] and the vast amount of various borane precursors at hand, all attempts to obtain corresponding $[(OC)_xM=B=NR_2]$ complexes from any other aminoborane $Hal_2B=NR_2$ have so far failed, thus emphasising the particular significance of $Br_2B=N(SiMe_3)_2$ for the production of terminal borylene complexes. The failure to undergo salt elimination reactions with dianionic metal carbonylates according to Equation (2) appears to extend to common alkyl- and aryl(dihalo)boranes Hal_2B-R,[43−45] thus hampering the synthesis of terminal borylene complexes of the type $[(OC)_xM=B-R]$. These compounds are of particular interest, however, since the boron centre is both coordinatively and electronically unsaturated and thus represents a very unusual bonding situation in boron chemistry, known only in a very few methyl-

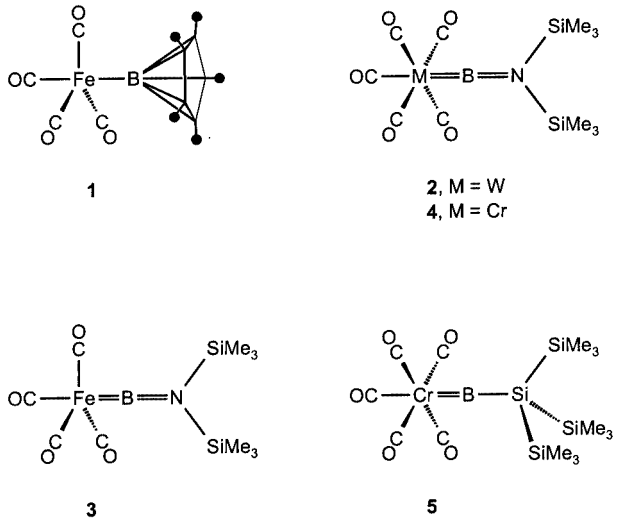


Figure 2. Selected terminal borylene complexes

eneboranes of the $(Me_3Si)_2C{=}B{-}R$ type (R = Me, *t*Bu, 2,3,5,6-tetramethylphenyl, 2,4,6-trimethylphenyl).[46−50] Because of their obvious significance[23] for the understanding of metal−boron bonding, alkyl- and arylborylene complexes $[(OC)_xM{=}B{-}R]$ had already been the subjects of several theoretical studies[28−31] before we succeeded in providing the first experimental evidence for such a compound. The use of the sterically demanding silylborane $Cl_2B{-}Si(SiMe_3)_3$ finally allowed for the synthesis and full characterisation of $[(OC)_5Cr{=}B{-}Si(SiMe_3)_3]$ (**5**) as the first terminal borylene complex with a both coordinatively and electronically unsaturated boron atom[51] (Figure 2). This silylborylene complex proved to be extremely sensitive, in contrast to its rather stable amino analogue $[(OC)_5Cr{=}B{=}N(SiMe_3)_2]$ (**4**), and shows significant decomposition in solution and even in the solid state after several hours at ambient temperature. The enhanced sensitivity of **5** is obviously due to the lack of ligand-to-boron π-interaction, as its steric shielding must be considered equal to or even larger than that in **4**.

As mentioned above, a low-coordinated boron centre displays some potential Lewis acidic character, which in the case of terminal borylene complexes might provide access to corresponding base-stabilised species of the type $[L_xM{=}B(L){-}R]$ (**IVa**, Figure 1). The only example so far was reported in 2000 by Roper, who obtained $[Os(=BNHC_9H_6N)Cl_2(CO)(PPh_3)_2]$[52] (**6**) by treatment of the borylosmium complex $[Cl_2BOsCl(CO)(PPh_3)_2]$ with 8-aminoquinoline as shown in Figure 3.

Subsequent treatment of **6** with $[Bu_4N]I$ yielded the corresponding borylene complex $[Os(=BNHC_9H_6N)Cl(I)(CO)(PPh_3)_2]$ (**7**), in which the chloro ligand *trans* to the boron atom was replaced by iodine, thus providing evidence for the *trans* influence of the borylene ligand.[52]

Obviously, this synthesis of **6** is very specific, but even the salt elimination reaction as in Equation (2) suffers from a certain lack of wider applicability in borylene chemistry. The restriction to a rather narrow range of dihaloboranes has already been discussed, but the same also appears to be

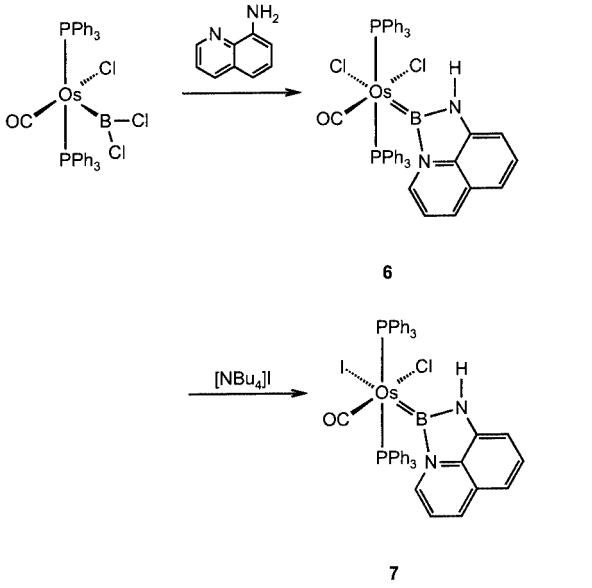

Figure 3. Synthesis of **7**

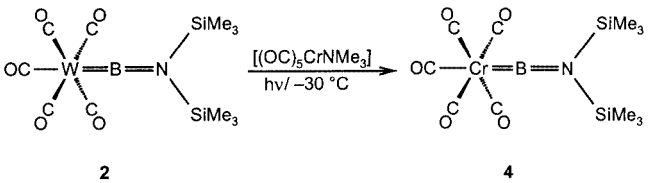
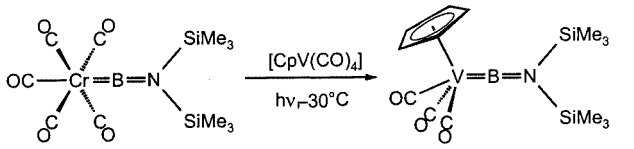
true for the dianionic transition metal precursor. Over the past few years we have employed a wide variety of such dianionic complexes or corresponding synthetic equivalents[53,54] in combination with various dihaloboranes, but without much success.[43−45]

The need for alternative synthetic methods in this chemistry initiated our studies on the potential use of complexes of the type $[(OC)_5M{=}B{=}N(SiMe_3)_2]$ (**2**: M = W; **4**: M = Cr) as a source of the aminoborylene $B{=}N(SiMe_3)_2$. The generation of such hypovalent borylenes B−R − the boron analogues of carbenes CR_2 − usually requires drastic conditions: Timms' classical method involves the reduction of boron trihalides at temperatures above 2000 °C,[55,56] while alternatively, West obtained the silylborylene $B{-}SiPh_3$ photochemically from $RB(SiPh_3)_2$ (R = Me, Mes) in hydrocarbon matrices at −196 °C.[57] The reductive[58,59] or photochemical[60] generation of species B−R in condensed phase might be assumed from the nature of the corresponding trapping products. There is, however, no direct proof for the intermediacy of borylenes − the system $MeBBr_2/2{\cdot}C_8K$ as a source for B−Me in particular has been reported to be questionable.[61] As early as 1973 Timms recognised borylene complexes as a potentially useful source of borylenes in cases in which gaseous species cannot be used.[56] We have recently reported on the first photochemically induced intermetal borylene transfer, as shown in Equation (3), thus proving that terminal borylene complexes may indeed act as a unique source of hypovalent borylenes in condensed phase and close to ambient temperature.[62]



(3)

The formation of **4** as in Equation (3) merely represents an alternative synthesis of an already known compound. However, the generation of $[(\eta^5\text{-}C_5H_5)(OC)_3V{=}B{=}N(SiMe_3)_2]$ (**8**), similarly obtained from **4** and $[(\eta^5\text{-}C_5H_5)V(CO)_4]$ as shown in Equation (4),[63] emphasises the significance of photochemically induced intermetal borylene transfer, since all attempts to obtain the vanadium complex **8** by salt elimination reactions from $Na_2[(\eta^5\text{-}C_5H_5)V(CO)_3]$ and $Hal_2B{=}N(SiMe_3)_2$ failed.[43−45]



4 **8** (4)

2.2. Structure

In solution, the common and most characteristic spectroscopic feature of all terminal borylene complexes with coordinatively unsaturated (i.e., two-coordinate) boron atoms are the ^{11}B NMR resonances, which are significantly deshielded with respect to those of corresponding amino- and silylboryl complexes of the types $[L_xM{-}B(X)NR_2]$[18−21] and $[L_xM{-}B(X)SiR_3]$.[64] The aminoborylene complexes **2**−**4**, and **8** exhibit ^{11}B NMR shifts in the range from δ = 87 to 93 ppm (Table 1), thus resembling those of corresponding bridged borylene complexes with π-donating ligands at the boron atom (vide infra). The silylborylene complex $[(OC)_5Cr{=}B{-}Si(SiMe_3)_3]$ (**5**) is characterised by a strikingly deshielded ^{11}B NMR resonance at δ = 204.3 ppm, and so greatly extends the known dispersion of the ^{11}B nucleus for classical boranes. Similarly low-field-shifted resonances have been reported only for metal clusters containing interstitial boron atoms, such as *cis*- and *trans*-$[Fe_4Rh_2(CO)_{16}B]^-$ (δ = 211 and 205 ppm).[65,66] The observed significant difference between **2** and **5** could be expected for terminal borylene complexes in which the boron centre was not part of a boron−ligand π-system,[23] if one compares the bridged amino- and alkylborylene complexes of the type $[(\mu\text{-}BR)\{(\eta^5\text{-}C_5H_5)Mn(CO)_2\}_2]$ (R = NMe_2: $\delta^{11}B$ = 103 ppm; R = *t*Bu: $\delta^{11}B$ = 170 ppm).[67−69] Because of the higher coordination numbers of the boron centres, $[(OC)_4Fe{-}B(\eta^5\text{-}C_5Me_5)]$ (**1**)[70] and $[Os(=BNHC_9H_6N)Cl(I)(CO)(PPh_3)_2]$ (**7**)[52] display much more shielded ^{11}B NMR resonances − at δ = −35.3 and 51.7 ppm, respectively − with the former being characteristic for apical boron atoms in such *nido*-carboranes.

Crystal structure data are available for the following terminal borylene complexes: $[(OC)_4Fe{-}B(\eta^5\text{-}C_5Me_5)]$ (**1**),[38] $[(OC)_5W{=}B{=}N(SiMe_3)_2]$ (**2**),[39] $[(OC)_5Cr{=}B{=}N(SiMe_3)_2]$

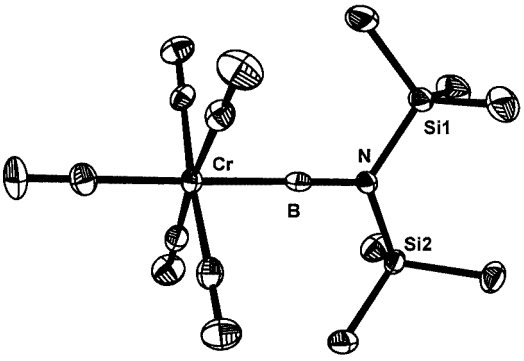
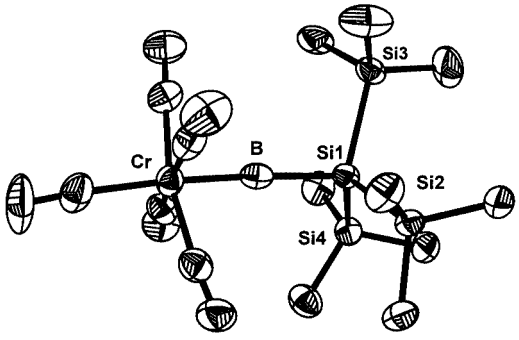
[a] a: From monoboranes; b: from diboranes(4); c: other method; X: no X-ray data available; y: no ^{11}B NMR spectroscopic data available; * geometry from ab initio calculation.

(**4**),[40] $[(OC)_5Cr{=}B{-}Si(SiMe_3)_3]$ (**5**),[51] $[Os(=BNHC_9H_6N)Cl(I)(CO)(PPh_3)_2]$ (**7**),[52] and $[(\eta^5\text{-}C_5H_5)(OC)_3V{=}B{=}N(SiMe_3)_2]$ (**8**)[63] (Table 1). The metal−boron distances in the aminoborylene complexes **2**, **4**, and **8** range from 197.1 to 215.1 pm, which, together with further spectroscopic and structural data, suggests strong boron-to-metal σ-donation and weaker metal-to-boron π-backbonding. For aminoborylene complexes of first row transition metal complexes this situation was predicted on the basis of ab initio calculations.[26] For **1**, which features a six-coordinate borylene ligand in an axial position, an iron−boron distance of 201.0 pm was reported, indicating a corresponding single bond. The base-stabilised borylene complex **7** is characterised by an osmium−boron distance of 205.5 pm, and so is longer than expected for a double bond. Corresponding findings have been made for related base-stabilised silylene complexes.[71−73]

The decisive influence of the boron-bound ligand R on the metal−boron linkage in terminal borylene complexes $[L_xM{=}B{-}R]$ has already to some extent been demonstrated by the mentioned differences in the ^{11}B NMR shifts. In the solid state, this influence becomes even more evident if one compares the results of the X-ray structure analyses of $[(OC)_5Cr{=}B{=}N(SiMe_3)_2]$ (**4**)[40] and $[(OC)_5Cr{=}B{-}Si(SiMe_3)_3]$ (**5**)[51] (Figure 4).



4



5

Figure 4. Structures of **4** and **5** in the crystal

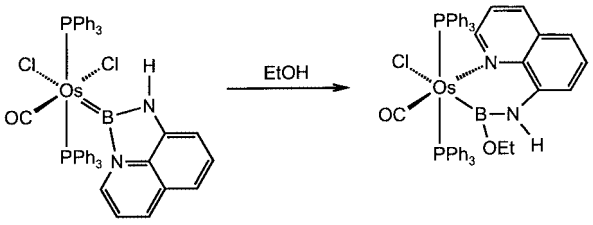
The $Cr(CO)_4$ moieties in both molecules exhibit approximate C_{4v} symmetry, and the central Cr−B−E fragment (E = N, Si) adopts a linear arrangement. The Cr−B distance in **5** was found to be 187.8 pm, and thus 12 pm shorter than in the amino counterpart **4**. Obviously, the electron deficiency of the boron centre in the silylborylene complex demands enhanced Cr−B π-backbonding. Further evidence for increased backbonding in **5** stems from the umbrella effect detected for the equatorial CO ligands and the pronounced *trans* effect the $B{-}Si(SiMe_3)_3$ ligand has on the axial CO ligand.[51] Unlike in the previously mentioned methyleneboranes $(Me_3Si)_2C{=}B{-}R$, there is no spectroscopic, structural, or computational evidence for the presence of nonclassical B−Si−Si three-centre, two-electron bonds (hyperconjugation) − well known to relieve electron deficiency at such coordinatively and electronically unsaturated boron centres − in the case of **5**.[46−50]

The question of the nature of the metal−boron bond in terminal borlyene complexes has been addressed in many theoretical studies in the recent past,[26−32] and the selected examples $[(OC)_5W{=}B{=}N(SiH_3)_2\}]$ (**9**) and $[(OC)_4Fe{-}B(\eta^5\text{-}C_5H_5)]$ (**10**) in particular have been investigated as model compounds for complexes **1** and **2**. It was concluded that borylene ligands BR in general have both good σ-donor and π-acceptor properties, but because of the electrophilicity of the boron centre, terminal borylene complexes should only be stable with sterically protecting and electron-releasing substituents such as $N(SiMe_3)_2$ or $\eta^5\text{-}C_5Me_5$ on the boron atom.[26] The nature of the transition metal−boron bond in $[L_xM{=}B{-}R]$ is obviously strongly influenced by the boron-bonded ligand R. Descriptions based on calculations range from an almost purely RB→TM σ-bonded model (TM = transition metal), for R being a good π-donor, up to a strong TM→BR π-back-donation model when R is a weaker π-donor.[28−30] Recent studies, however, have made the point that the sum of the covalent interactions does not even give a bond order of 1, but the nature of the TM−BR bond is mainly ionic.[29−31]

2.3. Reactivity

In addition to the photochemically induced borylene transfer discussed in Sect. 2.2, knowledge about the reactivity of terminal borylene complexes is restricted to only one recent report by Roper.[52] The base-stabilised borylene complex $[Os(=BNHC_9H_6N)Cl_2(CO)(PPh_3)_2]$ (**6**) undergoes a reaction with ethanol to yield the amino(ethoxy)boryl complex $[Os\{B(OEt)NHC_9H_6N\}Cl(CO)(PPh_3)_2]$ (**11**) as shown in Equation (5), with a 1,2-shift of the quinoline nitrogen atom from the boron to the osmium centre. This alcoholysis of **6** indicated that even the boron atom in base-stabilised borylene complexes displays some electrophilic

character − a fact already predicted by a theoretical study.[26]



6 11 (5)

3. Bridged Borylene Complexes

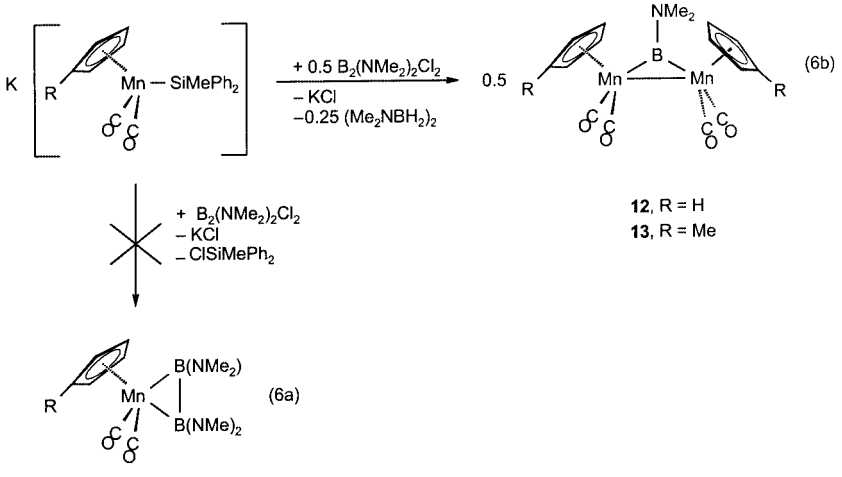
Although bridged borylene complexes [μ-BR(ML_x)$_2$] (**III**) and corresponding base adducts [{μ-BR(L)}(ML_x)$_2$] (**IIIa**) are still rare, they have been known for slightly longer than their terminal counterparts, and their chemistry, briefly summarised in 2000,[24] has developed to a somewhat greater extent. There is now some knowledge about their reactivity, and three different methods for their synthesis have been developed.

3.1. Synthesis

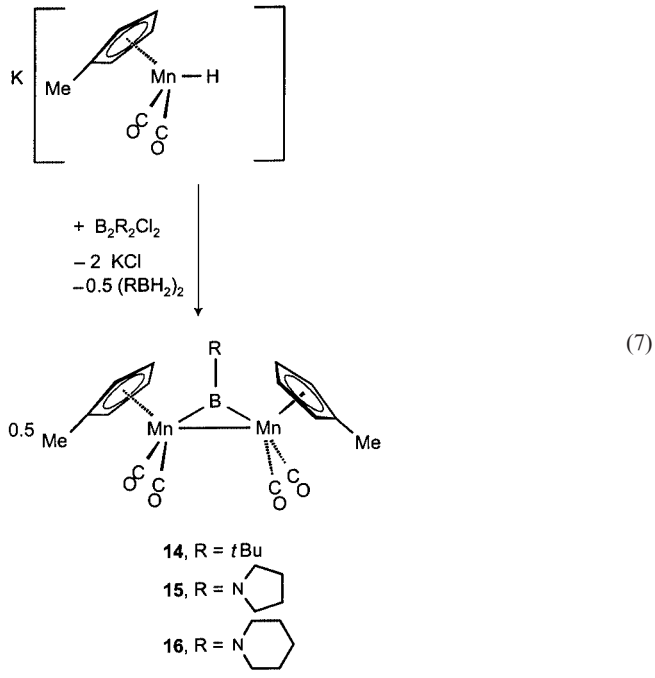
3.1.1. From Diboranes(4)

From 1994 onwards, Hartwig, Marder, Norman, and others have been reporting that certain diboranes(4) of the general formula X_2B-BX_2 (X = OR, F) may undergo oxidative additions to suitable transition metal centres, with cleavage of the boron−boron bond and formation of mono-, bis-, or trisboryl complexes [$L_xM(BX_2)_n$] (n = 1−3).[74−85] Subsequently, we have been able to show that salt elimination reactions between 1,2-dihalodiboranes(4) and anionic transition metal complexes proceed without cleavage of the diborane and hence can provide access to novel complexes of the type [L_xM{B(R)−B(R)X}] (X = Cl, Br, I), featuring η^1-coordinated diborane(4)yl ligands.[35,37][86−89] Our attempts to achieve an η^2- or side-on coordination mode for the diborane(4) moiety as in Equation (6a), by treatment of $ClB(NMe_2)-B(NMe_2)Cl$ with K[η^5-(C_5H_4R)Mn($CO)_2$(Si$MePh_2$)] as a synthetic equivalent for a dianionic transition metal complex,[53] resulted in the unexpected formation [Equation (6b)] of the first borylene complexes [μ-B(NMe_2){η^5-(C_5H_4R)Mn($CO)_2$}$_2$] (**12**: R = H; **13**: R = Me).[90] The dinuclear borylene complexes **12** and **13** are the products of a nonstoichiometric and obviously complex reaction, accompanied by cleavage of the boron−boron bond and the formation of a corresponding diborane(6) derivative ($Me_2N-BH_2)_2$ − the origin of the hydrogen atoms and the fate of the metal-bound silyl group, however, remained unclear.[90] A significant improvement in this synthesis was achieved by employing the related hydride complex K[(η^5-(C_5H_4R)Mn$H(CO)_2$] as a precursor, giving the complexes **12** and **13** in higher yields as products of a stoichiometric reaction, as shown in Equation (7). In this case, a hydrogen transfer from the manganese to the boron centre occurred and resulted in the formation of ($Me_2N-BH_2)_2$. Our further studies have shown that the cleavage of the boron−boron bond in the starting diboranes(4) decisively contributes to the formation of the bridged borylene complexes, since no products with B−Mn bonds were formed from related monoboranes $RBCl_2$.[91] In addition to complexes **12** and **13** we were able to obtain further bridged borylene complexes of the type [μ-BR{η^5-(C_5H_4Me)Mn($CO)_2$}$_2$] {**14**: R = *t*Bu; **15**: R = N(C_4H_8); **16**: N(C_5H_{10})}[88,90,91] by treatment of K[η^5-(C_5H_4Me)MnR-($CO)_2$] (R = H, Si$MePh_2$) with corresponding diboranes(4).

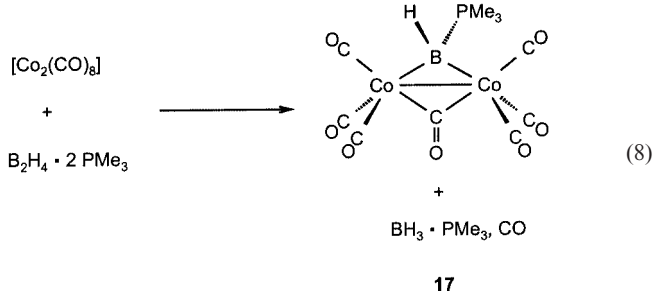
In 1998 Shimoi succeeded in another approach to bridged borylene complexes.[92] By starting from [$Co_2(CO)_8$] and B_2H_4·2PMe_3 it was possible to produce the cobalt borylene complex [μ-BH(PMe_3)(μ-CO){$Co(CO)_3$}$_2$] (**17**) in a cleavage reaction similar to that of a diborane(4). Fragmentation of the 1,2-bis(trimethylphosphane)diborane(4) into BH_3·PMe_3 and BH·PMe_3 and the liberation of one CO group afforded **17** [Equation (8)], which represents the only example of a donor-stabilised bridged borylene complex.



(6)



(7)

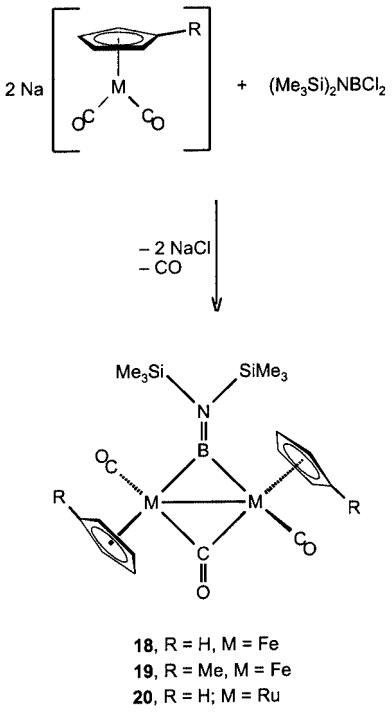


(8)

3.1.2. From Monoboranes

The previously mentioned syntheses of dinuclear borylene complexes are very specific, and are restricted to the two systems discussed. In order to provide a more general route to bridged borylene complexes, we investigated reactions between aminodihaloboranes and anionic transitionmetal compounds in a 1:2 ratio. The bridged borylene complexes $[\mu\text{-}B\{N(SiMe_3)_2\}(\mu\text{-}CO)\{(\eta^5\text{-}C_5H_4R)Fe(CO)\}_2]$ (**18**: R = H; **19**: R = Me)[93] and $[\mu\text{-}B\{N(SiMe_3)_2\}(\mu\text{-}CO)\{(\eta^5\text{-}C_5H_5)Ru(CO)\}_2]$ (**20**)[94] were obtained from $(Me_3Si)_2NBCl_2$ and $Na[(\eta^5\text{-}C_5H_4R)M(CO)_2]$ (M = Fe, R = H, Me; M = Ru, R = H) as shown in Equation (9), with salt elimination and cleavage of one carbonyl ligand.

The formation of the boryleneiron complexes **18** and **19** was observed under all conditions, while the formation of the corresponding ruthenium complex **20** depended on the reaction conditions and stoichiometry employed. Only an excess of $Na[(\eta^5\text{-}C_5H_5)Ru(CO)_2]$ and slow addition of the borane, for example, provided **20** as the sole product. Interestingly, sterically less demanding aminodichloroboranes such as Me_2NBCl_2 reacted in both cases with substitution of only one boron-bonded chloride ion and formation of

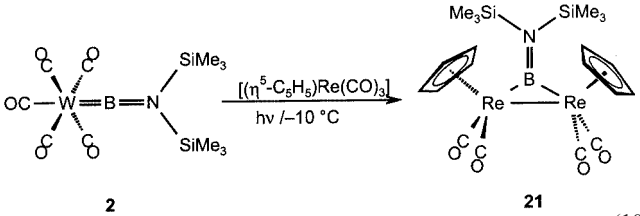


(9)

the corresponding boryl complexes. This result was attributed to the electron-withdrawing effect of the silyl groups, which in the case of $(Me_3Si)_2NBCl_2$ make the boron centre more electrophilic and hence more reactive.[93,94]

3.1.3. By Borylene Transfer

Photochemically induced borylene transfer has already been discussed as a valuable synthetic method for the generation of terminal borylene complexes not accessible through conventional salt elimination reactions. At least in one case, we have recently been able to demonstrate that this method also has similar potential for the synthesis of bridged borylene complexes. While $K[(\eta^5\text{-}C_5H_5)MnR(CO)_2]$ (R = H, $SiMePh_2$) proved to be a versatile precursor for the generation of bridged borylene complexes (vide supra), all of our attempts to extend this to the rhenium analogues by treatment of $K[(\eta^5\text{-}C_5H_5)ReR(CO)_2]$ (R = H, $SiMePh_2$) with mono- or diboranes(4) disappointingly failed.[43–45] Photolysis of $[(OC)_5W{=}B{=}N(SiMe_3)_2]$ (**2**) in the presence of $[(\eta^5\text{-}C_5H_5)Re(CO)_3]$, however, yielded the bridged borylene complex $[\mu\text{-}B\{N(SiMe_3)_2\}\{(\eta^5\text{-}C_5H_5)Re(CO)_2\}$ (**21**) as the only boron-containing species, as in Equation (10).[40]



(10)

3.2. Structure

Because of the formation of two metal−boron bonds, all bridged borylene complexes show characteristically deshielded ^{11}B NMR resonances, ranging from δ = 100 to 120 ppm in the cases of the (amino)borylene complexes **12**, **13**, **15**, **16**, and **18**−**21**, in which B−N π-bonding components are present, (Table 1). For the (*tert*-butyl)borylene complex **14**, which is free of boron−ligand π-interaction, an even more deshielded signal is observed at δ = 170.0 ppm. As in the case of terminal borylene complexes, the base-stabilised complex [μ-BH(PMe$_3$)(μ-CO){Co(CO)$_3$}$_2$] (**17**) is characterised by a significantly shielded ^{11}B NMR resonance at δ = 17.5 ppm, due to the increased coordination number of the boron centre.

X-ray structural data are available for [μ-B(NMe$_2$){(η^5-C$_5$H$_5$)Mn(CO)$_2$}$_2$] (**12**), [μ-BH(PMe$_3$)(μ-CO){Co(CO)$_3$}$_2$] (**17**), [μ-B{N(SiMe$_3$)$_2$}(μ-CO){(η^5-C$_5$H$_4$Me)Fe(CO)}$_2$] (**19**), and two further derivatives of the type [μ-BX{(η^5-C$_5$H$_4$Me)Mn(CO)$_2$}$_2$] (vide infra). The metal and boron atoms in both aminoborylene complexes form isosceles triangles, with metal−metal and metal−boron distances in the range expected for corresponding single bonds (Table 1). The overall molecular structure data resemble those of the isoelectronic vinylidene[95,96] or the corresponding bridged methylene complexes,[97−99] which can be viewed as dimetallacyclopropane derivatives. The tetrahedrally coordinated boron centre in the base-stabilised complex **17** shows the expected increase in the metal−boron distances, which thus range between those in borylcobalt complexes[76,100] and those in cobaltaboranes.[101]

Recently, complex **12** was subject to theoretical investigations, and the theoretically predicted and the experimentally derived structural parameters were found to be in very good agreement (Table 1).[26] From density functional theoretical studies it was found that borylenes BX can be viable ligands in the design of transition metal complexes, which are thermodynamically stable with respect to a homolytic metal−boron bond dissociation. On the one hand, the high thermodynamic stability is traceable to the good σ-donor and π-acceptor properties of BX ligands, owing to the σ- and π-orbital energies. On the other hand, the high polarity and the small HOMO−LUMO gap of the uncoordinated BX ligand suggest low kinetic stability. Increasing the HOMO−LUMO gap by complexation also increases the kinetic stability to a certain extent, but the imbalance between σ-donation and π-acceptance produces a positive charge on BX and promotes nucleophilic attack. In complex **12**, the kinetic stability is enhanced by steric protection of the reactive frontier orbitals of the BNMe$_2$ ligand by complexation at a bridging site and additionally by the bulky methyl substituents. The dinuclear Mn$_2$(η^5-C$_5$H$_5$)$_2$(CO)$_4$ fragment also reduces the build-up of positive charge at BNMe$_2$, since it is an excellent π-donor with just the right frontier orbitals to restore the M−BNMe$_2$ σ-donation and π-back-donation balance.

3.3. Reactivity

In agreement with the previously mentioned computational studies, we found that the (amino)borylene complexes **12** and **13** displayed extremely low reactivity towards nucleophilic substitution at the bridging boron centre. Stability to both air and moisture is the consequence, and these compounds can even be obtained in high yields by aqueous workup.[69] Treatment of **13** with an excess of gaseous HCl, however, provided the (chloro)borylene complex [μ-BCl{(C$_5$H$_4$Me)Mn(CO)$_2$}$_2$] (**22**), which, because of its

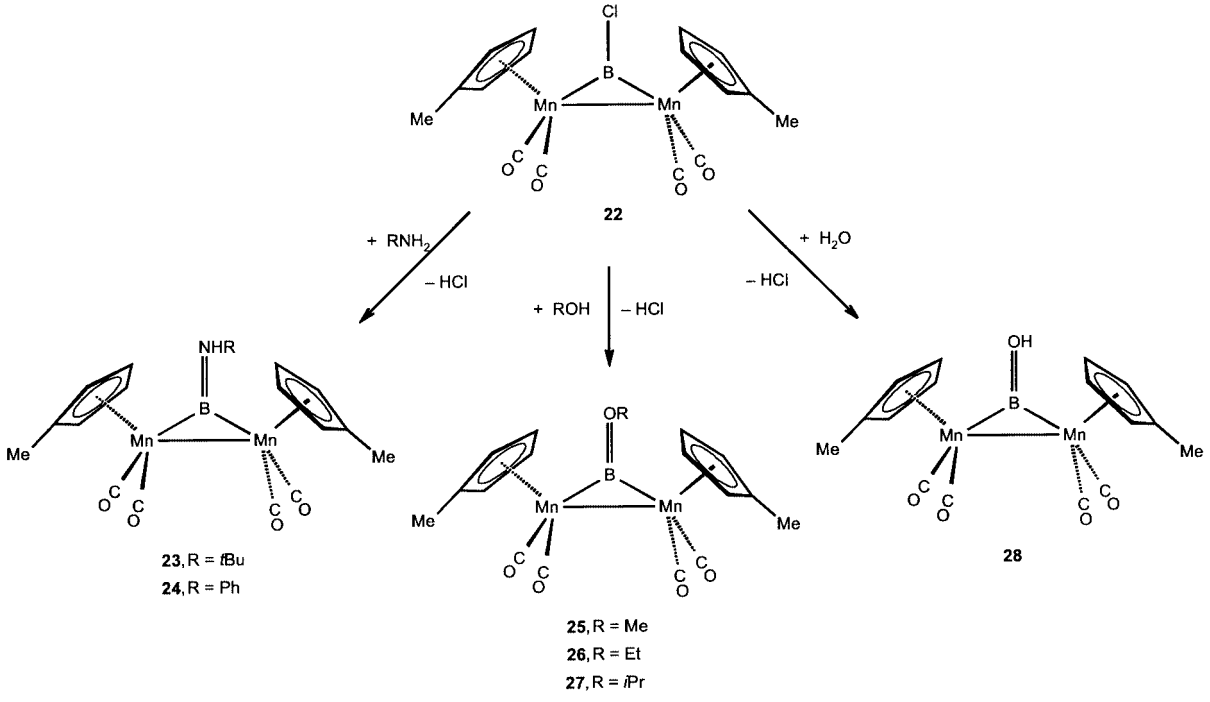


Figure 5. Substitution reactions at the metal-coordinated boryelene ligand

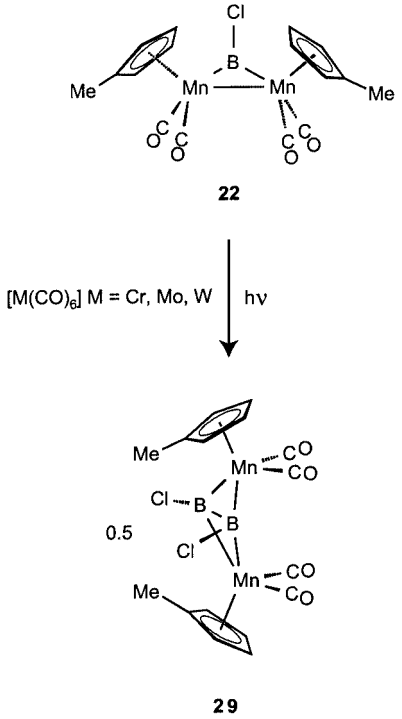
increased reactivity, served as starting material for further substitution reactions at the borylene centre. Treatment with protic reagents such as primary amines, alcohols and water afforded the corresponding substituted borylene complexes [μ-BX{$(C_5H_4Me)Mn(CO)_2$}$_2$] (**23**: X = NH*t*Bu; **24**: X = NHPh; **25**: X = OMe; **26**: X = OEt; **27**: X = O*i*Pr; **28**: X = OH) in high yields (Figure 5).[44,102] Structural data are available for complexes **22**[103] and **26**[44] (Table 1), and match those of the corresponding amino derivative **12**. It should be noted that such reactions at the boron centre with retention of the M−B linkage are very rare for both boryl and borylene complexes, due to the kinetic lability of the metal−boron bond, and have subsequently been observed (by Roper) only in the case of one boryl complex.[104]

Our very recent studies have shown that the photochemistry of bridged borylene complexes differs significantly from that of their terminal counterparts. Irradiation of the bridged (chloro)borylene complex **22** in the presence of $[M(CO)_6]$ (M = Cr, Mo, W) resulted not in the formation of an M=B−Cl species with borylene transfer, but in the novel dimetalla-*nido*-tetraborane [B_2Cl_2{$(\eta^5$-$C_5H_4CH_3)Mn(CO)_2$}$_2$] (**29**) as shown in Equation (11), thus establishing the first synthetic link between electron-precise borylene complexes and electron-deficient metallaboranes.[103]



(11)

Conclusion

Since the first report on a structurally authenticated borylene complex in 1995, the chemistry of these compounds has developed considerably, due to the ambitious experimental and computational effort of several research groups worldwide. As a consequence, there is now a more detailed understanding of the bonding situation in borylene complexes, and some of the reasons why these compounds eluded researchers for such a long time have probably become clearer. Several methods for the preparation of both bridged and terminal species are now at hand, and so future studies can focus now more on the reactivity of theses complexes − the chemistry of terminal borylene complexes especially is as yet virtually unexplored. In view of their close relationship to important organometallics such as carbene or carbonyl complexes, one might even envisage similar applications in stoichiometric or catalytic reactions.

3,6-Di(2-pyridyl)-1,4,2,5-dioxadiazine and a Silver Coordination Polymer with an Unprecedented Metallosupramolecular Topology

Chris Richardson[a] and Peter J. Steel*[a]

Keywords: Silver / Coordination polymers / Bridging ligands / N ligands

The new ligand 3,6-di(2-pyridyl)-1,4,2,5-dioxadiazine (**6**) has been prepared and reacted with silver tetrafluoroborate to form a novel coordination polymer in which adjacent chains are interdigitated and π-stacked.

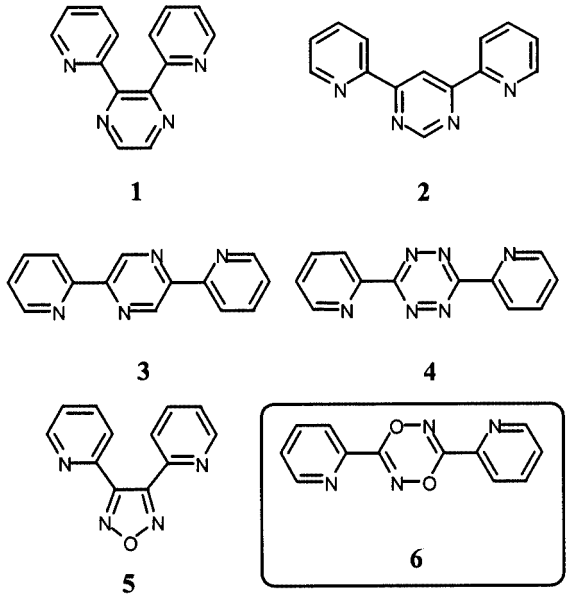
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2003)

Introduction

The use of bridging ligands for the controlled self-assembly of one-, two- or three-dimensional metallosupramolecular species has been the subject of enormous study in recent years.[1] Particularly stable entities can be obtained by employing ligands with chelating binding domains at the metal centres, with 2,2′-bipyridine subunits being the most commonly employed.[2] Similarly well studied are the binuclear ruthenium(II) complexes[3] of *N*,*N*′-chelating bridging ligands, such as 2,3-di(2-pyridyl)pyrazine (**1**),[4,5] 4,6-di(2-pyridyl)pyrimidine (**2**),[6] 2,5-di(2-pyridyl)pyrazine (**3**),[5] and 3,6-di(2-pyridyl)-1,2,4,5-tetrazine (**4**),[5,7] which have been the subject of detailed physicochemical studies of the fundamental nature of metal-metal interactions.

For some time now we have been involved in the synthesis of new heterocyclic ligands that incorporate less-commonly encountered heterocyclic ring systems as donors to metal acceptors. For example, we have reported a number of chelating ligands that contain tetrazole,[8] furoxan,[9] benzotriazole,[10] benzisoxazole,[11] 1,2,5-thiadiazole[12] and 1,2,3-chalcogenadiazole groups.[13] Most recently, we described a study of the binuclear ruthenium(II) complexes of 3,4-di(2-pyridyl)-1,2,5-oxadiazole (**5**),[14] which revealed remarkably strong metal-metal interactions, the magnitude of which was dependent on the specific diastereoisomer. In an attempt to probe the origin of this intriguing result, we have embarked on the synthesis of new ligands that might be used to prepare metal complexes that provide a means to test the mechanism of the observed metal-metal interactions systematically. One such issue is the role of the oxygen atom in ligand **5**.

In this context, we now describe the preparation of the new ligand 3,6-di(2-pyridyl)-1,4,2,5-dioxadiazine (**6**), which is structurally similar to ligands **3** and **4** but differs by being nonaromatic and having two oxygen atoms in the central ring. We then describe a novel coordination polymer obtained from its reaction with silver tetrafluoroborate. Surprisingly, despite the fact that 3,6-diaryl-1,4,2,5-dioxadiazines are readily synthesised,[15] no coordination complexes of any ligands containing this heterocyclic ring system have previously been reported.



Results and Discussion

The new ligand **6** was prepared in three steps from 2-pyridinecarboxaldehyde by conversion into the oxime, chlorination to the known[16] hydroximinoyl chloride and subsequent dehydrochlorination-dimerisation to give **6** in yields that ranged between 55−60%. This reaction proceeds

E-mail: p.steel@chem.canterbury.ac.nz

via a nitrile oxide intermediate.[15] The ligand was initially characterised by melting point, elemental analysis, mass spectrometry and ^{1}H and ^{13}C NMR spectroscopy.[17] However, attempts to prepare bis(2,2′-bipyridine)ruthenium(II) complexes of **6** consistently resulted in the isolation of products containing coordinated picolinate or picolinamide ligands, as determined by FAB mass spectrometric analysis. At this point we became concerned about the integrity of the ligand itself and therefore undertook a single crystal X-ray crystal structure determination of **6**. Interestingly, a search of the Cambridge Crystallographic database located only one structure containing this heterocyclic ring system.[18]

Suitable crystals were readily obtained by slow evaporation of an ethyl acetate solution of the ligand. However, we were disappointed to discover that, although the structure solved and refined well,[19] the central ring was disordered with respect to the positions of the nitrogen and oxygen atoms of the ring, despite the fact that the outer pyridine rings did not show any such disorder (Figure 1). The molecule crystallizes about a crystallographic centre of inversion in the monoclinic space group $P2_1/n$ (see Table 1 for data collection and refinement parameters). The plane of the pyridine ring is inclined to the plane of the central ring at an angle of 21.3(1)° and the molecules pack with the typical herringbone pattern common for aromatic molecules in this space group.[20] Thus, in the crystallization process the molecules pack with the pyridine rings faithfully aligned, but with the central ring equally arranged in the two possible conformations. Notwithstanding this result, the structure of the ligand seemed assured and complexes with other transition metal precursors were sought.

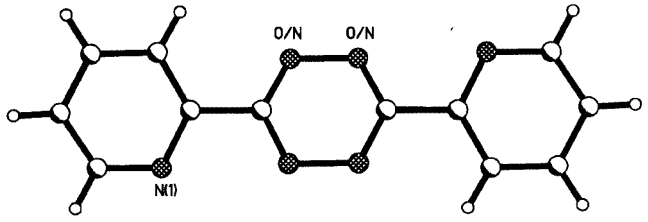

Figure 1. X-ray structure of **6** with a disordered central ring

Since we,[21] and others,[22] have found silver salts to be useful precursors to a variety of interesting metallosupramolecular compounds, including novel coordination polymers,[23] we reacted **6** with silver nitrate in methanol solution to obtain a 1:1 complex $AgL(NO_3)$ (**7**),[24] in excellent yield (96%). All attempts to produce crystals of this product suitable for X-ray structure determination were in vain. Pleasingly, however, reaction of **6** with silver tetrafluoroborate produced the 1:1 M:L complex $AgL(BF_4)$ (**8**),[25] that upon recystallization from acetonitrile underwent reorganisation to a 1:2 complex $AgL_2(BF_4)$, (**9**), which did furnish X-ray quality crystals.

This complex proved to be an intriguing coordination polymer with an unprecedented architecture. Figure 2 shows a perspective view of the contents of the asymmetric unit, along with selected atom labelling and bonding geometry. The asymmetric unit contains one silver atom, two molecules of **6** and a tetrafluoroborate counterion. One of the molecules of **6** acts as a tetradentate ligand, chelating two silver atoms separated by one unit cell translation along the *a* axis [8.011(1) Å]. The other acts as a bidentate ligand coordinating through only two of its four nitrogens, and has its mean plane approximately orthogonal to the first. The silver atom is chelated by three ligands, with bonds to the

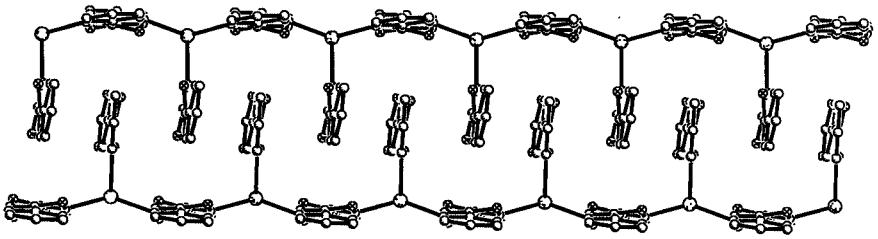

Figure 3. Projection showing the interdigitation of polymer chains

pyridine nitrogens being significantly shorter than those to the dioxadiazine nitrogens, which provide only weak interactions with the metal. These long bonds lead to small bite angles (ca. 65°) at the metal. The resulting hexacoordinate geometry at the metal is trigonal prismatic. Relatively few X-ray crystal structures have been reported that include an AgN_6 coordination environment[26] and these show various coordination geometries consistent with the filled-shell nature of the metal ion.

In both independent molecules of **6** within the complex, the central dioxadiazine ring is far from planar; these exist in boat conformations with the oxygen atoms being displaced from the planes of the carbon and nitrogen atoms by ca. 0.20 Å for the bridging ligand and ca. 0.28 Å for the terminal ligand. In the only other reported crystal structure containing this heterocyclic ring system[18] there are two independent molecules, one of which has the dioxadiazine ring in a chair form and the other in a boat form similar to that found here.

As a consequence of the bridging nature of one of the ligands, the complex extends into a fascinating coordination polymer. As shown in Figure 3, the extended structure consists of two coordination polymer chains which assemble in such a way that the terminal ligands of each chain are interdigitated as a result of π-π stacking interactions. The planes of the individual rings are separated by distances ranging between 3.0 and 3.5 Å and interacting rings have their centroids displaced at distances ranging between 3.38 and 3.81 Å. We believe that this is an unprecedented metallosupramolecular topology, in which the two sides of a ladder-like structure are separated and the rungs are held together by aromatic interactions.

In conclusion, we have shown for the first time that the dioxadiazine ring can be incorporated into chelating and bridging ligands. Studies are in progress to prepare binuclear complexes of this and related ligands with various transition metals.

Direct Synthesis of Enantiopure Tripod Ligands from C_2-Symmetric Precursors

Ina Hegelmann[a] and Nicolai Burzlaff*[a]

Keywords: N ligands / Tripod ligands / Chirality / Prochirality / Ruthenium

A new enantiopure chiral tripod ligand is obtained from C_2-symmetric bis(camphorpyrazol-1-yl)methane by introducing a carboxylate group at the bridging carbon atom. A prochiral centre is formed rather than an additional stereocentre. Therefore, a homochiral tripod ligand is achieved without separation of the stereoisomers.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2003)

Chiral facially coordinating tripod ligands play an important role in stereoselective synthesis.[1] Recently we reported a racemic example of a bis(pyrazol-1-yl)acetato tripod ligand, namely (3,5-di-*tert*-butylpyrazol-1-yl)(3′,5′-dimethylpyrazol-1-yl)acetate (bpa$^{t\mathrm{Bu2,Me2}}$; Figure 1a).[2] Usually, the chirality of these ligands originates from three different donor groups that are bound to a bridging atom with a noncoordinating group, atom or lone pair.

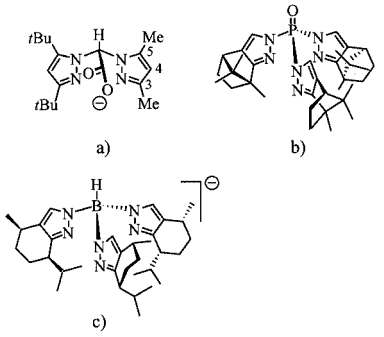

Figure 1. Chiral tripod ligands

For asymmetric induction two problems have to be solved: (a) enantiomeric purity, and (b) a stable configuration of the stereogenic centres. Separation of the enantiomers is often an elaborate, low-yield process and demands a measurement of the enantiomeric purity. If one of the donor groups is chiral and enantiopure, or derived from the chiral pool, the problem is converted into one of separation of the diastereomers. This can be avoided if C_3-symmetric ligands with three identical, chiral donor groups are applied.[3] Chiral pool derived ligands such as [OP(pz$^{\mathrm{cam}}$)$_3$] or [BH(pz$^{\mathrm{menth}}$)$_3$]$^-$ (Figure 1b, c) are often cited as examples.[4] Due to the steric hindrance of the three chiral donor groups, however, the application of these ligands is limited, especially in octahedral complexes. We now report on a general concept to obtain new enantiopure facially binding tripod ligands from C_2-symmetric precursors.

C_2 symmetry is a common feature in chiral bidentate ligands.[5] If two identical enantiopure donor groups Y* are connected by a tetrahedral bridging atom, any additional group Z at this atom will form a prochiral centre rather than an additional stereocentre (Figure 2a).[6] Trihydroxyglutaric acid, either *S*,*S* or *R*,*R*, is a textbook example of this.[6] Inversion of configuration at C3 in (*S*,*S*)-trihydroxyglutaric acid (Figure 2b) yields the identical compound.

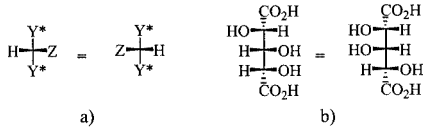

Figure 2. Prochiral centre of (*S*,*S*)-trihydroxyglutaric acid[6]

Therefore, a homochiral tripod ligand can be obtained from a C_2-symmetric precursor without additional separation of enantiomers or diastereomers. As an example of this concept we chose bis(camphorpyrazol-1-yl)methane, an enantiopure but C_2-symmetric bidentate ligand which is obtained in three steps from (+)-camphor (Scheme 1).

As reported by Steel et al., three structural isomers of bis(camphorpyrazol-1-yl)methane (**2a**, **2b** and **2c**) are formed by coupling of camphorpyrazole **1** with CH_2Cl_2 in a two-phase system.[7] Reaction with CH_2Cl_2 as both reactant and solvent reduces the reaction time to 8 hours compared to the 10 days reported previously. Compound **2c** can be separated from the other two structural isomers in two crystallisation steps from pentane and acetone, respectively, to give colourless crystals. A single-crystal X-ray diffraction experiment proved the desired constitution of **2c**.[8] According to Steel et al. isomer **2b** can also be isolated.[7]

By analogy with the synthesis of bis(3,5-dialkylpyrazol-1-yl)acetic acids,[2,9] deprotonation at the bridging carbon

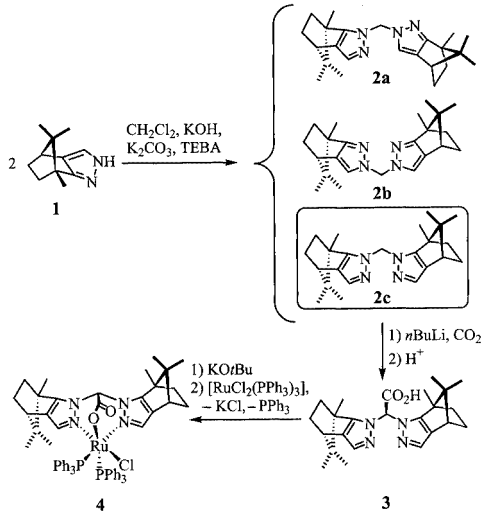

Scheme 1. Synthesis and coordination of bis(camphorpyrazol-1-yl) acetic acid

atom and subsequent reaction with carbon dioxide introduces a carboxylate group at this position. Due to missing substituents at the pyrazolyl carbon C5, **2b** is also deprotonated at C5. A similar deprotonation at C5 has been published recently by Otero et al. for an achiral bis(pyrazol-1-yl)methane.[10] Therefore, only the minor isomer **2c** out of the two C_2-symmetric isomers **2b** and **2c** is suitable for this reaction sequence. Acidic workup yields the enantiopure bis(camphorpyrazol-1-yl)acetic acid bpa^{cam2}H (**3**; Scheme 1).[11] Two sets of signals are found for the camphorpyrazolyl groups in the ^{1}H and ^{13}C NMR spectra. A strong IR band at $\tilde{\nu}$ = 1712 cm^{-1} and a ^{1}H NMR signal at δ = 11.59 ppm confirm the presence of the carboxylate group. Crystals of **3** suitable for X-ray structure determination were obtained from CH_2Cl_2 (Figure 3).[8] The bond lengths and bond angles in **3** are in good agreement with those reported earlier for other achiral bis(3,5-dialkylpyrazol-1-yl)acetic acids.[9,12]

Reaction of the potassium salt of bpa^{cam2}H (**3**) with [$RuCl_2(PPh_3)_3$] yields [Ru(bpa^{cam2})Cl(PPh_3)$_2$] (**4**; Scheme 1). Recently we reported the formation of the ruthenium complexes [Ru(bpza)Cl(PPh_3)$_2$] and [Ru(bdmpza)Cl(PPh_3)$_2$] [bpza = bis(pyrazol-1-yl)acetate; bdmpza = bis(3,5-dimethylpyrazol-1-yl)acetate] in a similar reaction.[13] An asymmetric carboxylate signal ($\tilde{\nu}_{as}$ = 1656 cm^{-1}) in the IR spectrum and the molecular ion peak (MH$^+$ = 1069) in the FAB mass spectrum indicate the coordination of the ligand. As in **3** two sets of signals are observed in the ^{1}H and ^{13}C NMR spectra for the camphorpyrazolyl groups. Two sets of signals in these spectra and two doublets in the ^{31}P NMR spectrum at δ = 39.2 and 42.7 ppm ($^2J_{P,P}$ = 35.6 Hz and 32.4 Hz) are expected for two PPh_3 ligands in a chiral environment. According to the cross coupling observed in the COSY spectrum, two singlets in the ^{1}H NMR spectrum are assigned to the bridging CH group (^{1}H NMR: δ = 6.30 ppm; ^{13}C NMR: δ = 72.9 ppm) and one of the two pyrazole C3 protons (^{1}H NMR: δ = 5.99 ppm; ^{13}C NMR: δ = 138.5 ppm). The second pyrazole C3 proton signal is probably hidden underneath the PPh_3 signals. A rather similar downfield shift of such a C3 proton signal was observed for the asymmetrical isomer of the related ruthenium complex [Ru(bpza)Cl(PPh_3)$_2$], in which one PPh_3 ligand is *trans* to the carboxylate group.[13] Therefore, a geometry with one of the PPh_3 ligands *trans* to the carboxylate group and the other *trans* to the camphorpyrazolyl group is assumed for complex **4**.

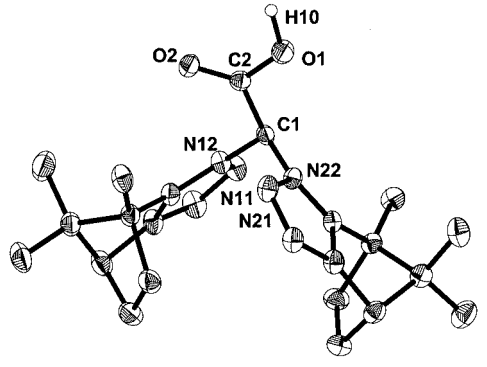

Figure 3. Molecular structure of bpa^{cam2}H (**3**); thermal ellipsoids at 50% probability level; selected bond lengths (Å) and angles (°): C1–C2 1.534(5), C2–O1 1.320(4), C2–O2 1.198(4), C1–N12 1.457(4), C1–N22 1.446(4); O1–C2–O2 126.0(3), C2–C1–N12 111.4(3), C2–C1–N22 112.9(3), N12–C1–N22 111.2(3)[8]

Our results show that new enantiopure facially binding tripod ligands can be obtained from C_2-symmetric precursors. In this concept an additional donor group is introduced at the bridging atom, forming a prochiral centre rather than an additional stereocentre. Therefore, a homochiral ligand is obtained by a simple separation of structural isomers without any separation of enantiomers or diastereomers. Future work to extend this concept will focus on the conversion of other C_2-symmetric ligands into enantiopure tripod ligands.

Experimental Section

bpa^{cam2}H (3): A solution of bpm^{cam2} (**2c**) (288 mg, 0.790 mmol) in THF (20 mL) was treated with *n*BuLi (1.6 M in *n*-hexane, 0.500 mL, 0.800 mmol) at −70 °C. The solution was allowed to warm to −45 °C over a period of 2 h and finally flushed with a flow of CO_2 for 10 min. The solvent was removed in vacuo at ambient temperature and the residue dissolved in water (50 mL). The aqueous solution was acidified with HCl (6 M) to pH 1 and extracted with Et_2O (4 × 50 mL). The combined organic layers were dried (Na_2SO_4) and concentrated in vacuo. Recrystallisation from acetone yielded the acid bpa^{cam2}H (**3**) as a colourless crystalline powder. Yield 247 mg (77%); m.p. 175 °C (dec.). $[\alpha]_D^{23}$ = +55.3 (*c* = 0.01, CH_2Cl_2). ^{1}H NMR (250 MHz, $CDCl_3$): δ = 0.68 (m, 1 H, CH_2), 0.77 (s, 3 H, CH_3), 0.78 (s, 3 H, CH_3), 0.88 (s, 3 H, CH_3), 0.92 (s, 3 H, CH_3), 0.97 (m, 2 H, CH_2), 1.30 (m, 1 H, CH_2), 1.33 (s, 3 H, CH_3), 1.48 (s, 3 H, CH_3), 1.59 (m, 1 H, CH_2), 1.75 (m, 1 H, CH_2), 1.98 (m, 2 H, CH_2), 2.76 (d, $^3J_{H,H}$ = 3.7 Hz, 1 H, CH), 2.82 (d, $^3J_{H,H}$ = 3.7 Hz, 1 H, CH), 6.78 (s, 1 H, H_{pz}), 7.17 (s, 1 H, H_{pz}), 7.37 (s, 1 H, CH), 11.59 (br. s, 1 H, CO_2H) ppm. ^{13}C NMR (62.9 MHz, $CDCl_3$): δ = 11.2, 11.4, 19.3, 19.5, 20.3, 20.4 (6 × CH_3), 27.2, 27.3, 32.1, 33.0 (4 × CH_2), 47.4, 47.5 (2 × CH), 53.2, 53.8, 62.8, 63.1 (4 × C_q), 69.7 (CH), 130.5, 130.6 (2 × C_{pz}), 131.2, 133.0 (2 × CH_{pz}),

154.1, 155.9 (2 × C_{pz}), 165.6 (CO_2H) ppm. FAB MS (NBOH): *m/z* (%) = 409 (10) [MH^+], 189 (100) [$(C_{11}H_{15}N_2)CH_2$]. IR (CH_2Cl_2): $\tilde{\nu}$ = 1712 (CO_2H) cm^{-1}. $C_{24}H_{32}N_4O_2$ (408.54): calcd. C 70.56, H 7.89, N 13.71; found C 70.43, H 7.80, N 13.65.

[Ru(bpa^{cam2})Cl(PPh$_3$)$_2$] (4): A solution of bpa^{cam2}H (585 mg, 1.43 mmol) and KO*t*Bu (137 mg, 1.22 mmol) in THF (40 mL) was stirred at ambient temperature for 1 h. [$RuCl_2(PPh_3)_3$] (1.06 g, 1.11 mmol) was then added and the solvent was removed in vacuo after 1 h. The residue was dissolved in Et_2O (5 mL), precipitated by addition of pentane (50 mL) and filtered off. It was washed with H_2O (2 × 10 mL) and pentane (40 mL) and dried in vacuo to afford [Ru(bpa^{cam2})Cl(PPh_3)$_2$] (**4**) as an amber crystalline powder. Yield 604 mg (51%); m.p. 162 °C (dec.). ^{1}H NMR (600 MHz, $CDCl_3$): δ = 0.46 (m, 3 H, CH_3), 0.54 (m, 1 H, CH_2), 0.67 (s, 3 H, CH_3), 0.80 (s, 3 H, CH_3), 0.85 (s, 3 H, CH_3), 0.88 (m, 1 H, CH_2), 1.03 (m, 2 H, CH_2), 1.44 (s, 3 H, CH_3), 1.47 (s, 3 H, CH_3), 1.71 (m, 1 H, CH_2), 1.78 (m, 2 H, CH_2), 1.86 (m, 1 H, CH_2), 2.43 (d, $^3J_{H,H}$ = 3.4 Hz, 1 H, CH), 2.49 (d, $^3J_{H,H}$ = 3.4 Hz, 1 H, CH), 5.99 (s, 1 H, H_{pz}), 6.30 (s, 1 H, CH), 7.00−7.42 (m, 31 H, H_{pz} and 2 PPh_3) ppm. ^{13}C NMR (150.9 MHz, $CDCl_3$): δ = 11.1, 12.1, 19.1, 19.4, 20.4, 20.5 (6 × CH_3), 26.7, 26.9, 32.7, 34.4 (4 × CH_2), 47.1, 47.2 (2 × CH), 53.2, 54.0, 61.9, 65.0 (4 × C_q), 72.6 (CH), 126.9 (d, $^2J_{C,P}$ = 8.8 Hz, *o*-PPh_3), 127.1 (d, $^2J_{C,P}$ = 8.8 Hz, *o*-PPh_3), 128.5 (s, *p*-PPh_3), 128.6 (s, *p*-PPh_3), 129.3, 129.6 (2 × C_{pz}), 131.9 (CH_{pz}), 134.7 (d, $^3J_{C,P}$ = 9.1 Hz, *m*-PPh_3), 135.0 (d, $^1J_{C,P}$ = 39.2 Hz, *i*-PPh_3), 135.4 (d, $^3J_{C,P}$ = 9.2 Hz, *m*-PPh_3), 136.1 (d, $^1J_{C,P}$ = 38.3 Hz, *i*-PPh_3), 138.6 (CH_{pz}), 155.3, 156.0 (2 × C_{pz}), 166.3 (CO_2^-) ppm. ^{31}P NMR (161.8 MHz, $CDCl_3$): δ = 39.2 (d, $^2J_{P,P}$ = 35.6 Hz), 42.7 (d, $^2J_{P,P}$ = 32.4 Hz). A New Porous 3-D Framework Constructed From Fivefold Parallel Interpenetration of 2-D (6,3) Nets: A Mixed-Valence Copper(I,II) Coordination Polymer $[Cu^{I}_{2}Cu^{II}(4,4'\text{-bpy})_2(pydc)_2]\cdot 4H_2O$

Xian-Ming Zhang[a,b] and Xiao-Ming Chen*[a]

Keywords: Coordination polymers / Microporous materials / Mixed-valent compounds / Copper / N ligands

A mixed-valence copper(I,II) coordination polymer $[Cu^{I}_{2}Cu^{II}(4,4'\text{-bpy})_2(pydc)_2]\cdot 4H_2O$ (4,4′-bpy = 4,4′-bipyridine and pydc = pyridine-2,4-dicarboxylate) featuring the "metal-complex ligands" $[Cu^{II}(pydc)_2]^{2-}$ was designed and synthesized hydrothermally from $Cu(MeCO_2)_2$, pyridine-2,4-dicarboxylate, 4,4′-bipyridine and NaOH. This compound was shown by single-crystal structure analysis to be the first porous 3-D framework constructed from fivefold parallel interpenetration of 2-D (6,3) nets. The one-dimensional channels occupying 17.4% of the crystal volume are occupied by guest water molecules and the porous network is stable after removal of the lattice water molecules, as indicated by TGA and PXRD measurements. The high stability of the 3-D framework may be attributed to the multiple entanglement of the 2-D nets.

Introduction

Within the currently very active research field of coordination polymers, microporous coordination frameworks are functionally related to zeolites, while intertwining networks show intriguing topologies in inorganic chemistry and may enhance the stability of the porous materials.[1−5] Both porous and intertwining frameworks are of fundamental importance in structural design and in the understanding of structure-property correlation. A two-dimensional (2-D) (6,3) net — similar to a brick-wall — is one of the most common topologies in coordination polymers; intertwining of these 2-D (6,3) nets can also ccur in parallel way.[6−8] Surprisingly, most networks consisting of parallel intertwining of (6,3) nets are overall 2-D arrays and only a single 3-D framework constructed from doubly parallel interpenetration of (6,3) nets has been reported to date.[9] Furthermore, the numbers of parallel intertwining (6,3) nets are limited to two, three and six in the known complexes.[6−8,10−13] Recently, we and others have developed routes to mixed-valence copper(I,II)[14−17] and "metal-complex ligand" (or metallo-ligand) complexes[18−20] under hydrothermal or solvothermal conditions. As a sequel, we report here a new porous mixed-valence copper(I,II) coordination polymer $[Cu^{I}_{2}Cu^{II}(4,4'\text{-bpy})_2(pydc)_2]\cdot 4H_2O$ (4,4′-bpy = 4,4′-bipyridine and pydc = pyridine-2,4-dicarboxylate), which contains "metal-complex ligands" and is the first 3-D framework constructed from fivefold parallel intertwining of two-dimensional (6,3) nets.

Results and Discussion

Compound **1** was synthesized under mild hydrothermal conditions (160 °C and 72 hours) and its formation is strongly influenced by the reaction conditions, especially the temperature, reaction time and pH value. The dark brown colour of **1** indicates that it is possibly a mixed-valence copper(I,II) complex. The IR spectrum of complex **1** shows characteristic bands of the dicarboxylate groups at 1634 and 1607 cm^{-1} for the antisymmetric stretching and at 1373 and 1339 for symmetric stretching.[21] The separations (Δ) between $\nu_{asym}(CO_2)$ and $\nu_{sym}(CO_2)$ are 261 and 268 cm^{-1}, respectively. The splitting of $\nu_{asym}(CO_2)$ indicates that the carboxylate groups in **1** function in two different coordination fashions.

An X-ray single-crystal analysis reveals that **1** has a porous three-dimensional framework constructed from fivefold parallel interpenetration of two-dimensional (6,3) nets. Selected bond distances and angles for **1** are listed in Table 1. There are two crystallographically independent copper atoms in **1**, as shown in Figure 1. The Cu(1) atom is trigonally coordinated by two nitrogen atoms from two 4,4′-bpy ligands and one oxygen atom from a pydc ligand. Cu(2), which is located at an inversion center and is coordinated

to two nitrogen and two oxygen atoms from two pydc ligands, shows a slightly distorted square-planar geometry. The Cu(2)−O(3) and Cu(2)−N(1) distances are 1.967(5) and 1.973(6) Å, respectively, and the O(3a)−Cu(2)−N(1) and O(3)−Cu(2)−N(1) bond angles are 95.6(2) and 84.4(2)°, respectively. In fact, there are also two carboxylate oxygen atoms of pydc ligands from adjacent layers weakly bonded to Cu(2), with a Cu−O distance of 2.689(6) Å in the axial direction [Figure 1 (bottom)], and thus the Cu(2) site can be described as having a "4+2" coordination geometry. The Cu^{II} ion with d^9 configuration tends to have a "4+1" or "4+2" coordination geometry because of a strong Jahn−Teller effect, but the Cu^{I} ion with d^{10} configuration tends to have a trigonal or tetrahedral coordination geometry. The coordination symmetry of copper(II) ions in combination with charge balance indicates that Cu(1) is monovalent and Cu(2) is divalent.

Table 1. Selected bond distances [Å] and angles [°] for **1**[a]

Cu(1)−N(2)	1.935(6)	Cu(2)−O(3)	1.967(5)
Cu(1)−N(3a)	1.965(6)	Cu(2)−N(1)	1.973(6)
Cu(1)−O(2)	2.074(6)	Cu(1)···Cu(1a)	11.070
Cu(2)−O(3b)	1.967(5)	Cu(1)···Cu(2)	8.935
Cu(2)−O(1)	2.689(6)		
N(2)−Cu(1)−N(3a)	149.9(3)	O(3)−Cu(2)−N(1)	84.4(2)
N(2)−Cu(1)−O(2)	116.0(2)	O(3b)−Cu(2)−N(1b)	84.4(2)
N(3a)−Cu(1)−O(2)	93.1(2)	O(3)−Cu(2)−N(1b)	95.6(2)
O(3b)−Cu(2)−O(3)	180.0(1)	N(1)−Cu(2)−N(1b)	180.0(1)
O(3b)−Cu(2)−N(1)	95.6(2)		

[a] Symmetry codes: a = $x + 1/2, -y + 1/2, z - 1/2$; b = $-x + 2, -y, -z + 1$.

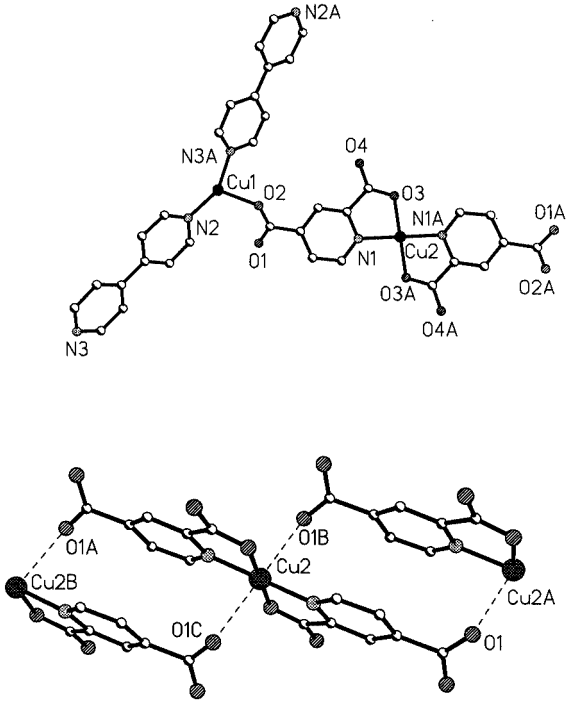

Figure 1. The coordination environments of the copper atoms in **1**

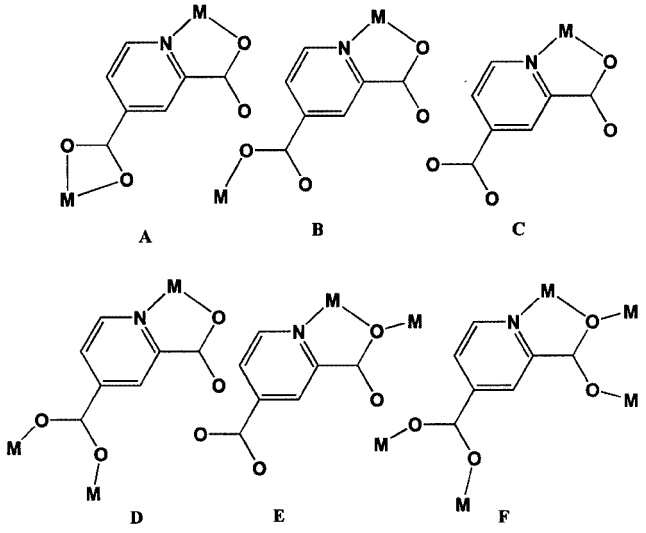
The coordination modes of pydc in its coordination polymers observed up to now are shown in Scheme 1.[18−20] As can be seen, the nitrogen and one of the 2-carboxylate oxygen atoms prefer to chelate one metal atom, and the 4-carboxylate tends to ligate one metal in a bidentate or monodentate mode, to bridge two metal atoms in a carboxylate-*O*,*O*′ mode, or be pendent. The coordination mode of pydc in **1** is shown Scheme 1 (b). In addition, we recently found two other coordination modes in cobalt complexes of pydc, as shown in Scheme 1 (e and f).[22]



Scheme 1. Schematic representation of the observed coordination modes of pydc

In **1**, Cu(2) and two pydc ligands form a $[Cu^{II}(pydc)_2]^{2-}$ "metal-complex ligand', which bridges $[Cu^{I}(4,4'\text{-bpy})]_n^{n+}$ zigzag chains to generate a 2-D wave-like (6,3) brick-wall array [Figure 2 (top)]. The tricoordinate nodes are provided by Cu(1) and the dicoordinate nodes are provided by 4,4′-bpy and the $[Cu^{II}(pydc)_2]^{2-}$ "metal-complex ligand". The shortest Cu(1)···Cu(1) and Cu(1)···Cu(2) distances are ca. 11.07 and 8.94 Å, respectively. Within the layer, there are large brick-like units (size ca. 18 × 16 Å), each of which is formed by four 4,4′-bpy and two $[Cu^{II}(pydc)_2]^{2-}$ "metal-complex ligands". Compared with other known (6,3) networks, the overall structure of **1** is unprecedented, as shown in Figure 2 (bottom). Each single (6,3) network is intertwined with four other networks and the fivefold interpenetration of (6,3) networks results in a 3-D framework. Any two interpenetrating 2-D (6,3) nets in **1** show an interpenetrating mode topologically identical to that of the $[Cu_2^{I}(CN)\{N(CN)_2\}_2]^-$ polyanion.[23,24] Interpenetration in nature is a space-filling effect to produce dense framework but, surprisingly, the fivefold interpenetration of 2-D (6,3) networks in **1** does not occupy all the voids formed by one independent 2-D network [Figure 3 (top)]. A space-filling plot [Figure 3 (bottom)] clearly shows there are one-dimensional channels running along the *a*-axis direction in **1** which are filled by the guest water molecules. Calculations

using PLATON[25] reveal that the free dimensions of these channels in **1** occupy 17.4% of the crystal volume.

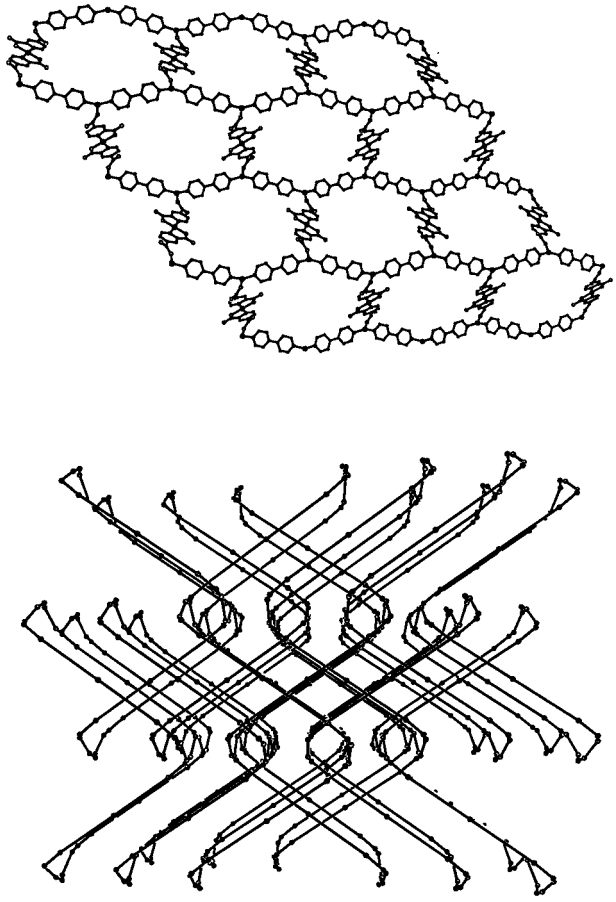


Figure 2. Perspective view of the 2-D (6,3) net in **1** (top) and the fivefold interpenetration of 2-D (6,3) nets (bottom)

Thermogravimetric analysis (Figure 4) in air showed one well-separated weight loss of 9.2% occurring in the temperature range 50−180 °C, corresponding to the removal of water molecules. It should be noted that no weight loss was observed in the temperature range 180−235 °C, indicating the formation of a stable phase formulated as $[Cu^{I}_{2}Cu^{II}(pydc)_2(4,4'\text{-bpy})_2]$ (**1′**). The X-ray powder diffraction patterns (Figure 5) of the as-synthesized **1** and calcinated **1′** are similar, although the intensities and widths of some peaks show some differences, indicating that the porous network of **1** is retained after the calcination and removal of the lattice water molecules.

In summary, a new mixed-valence copper(I,II) coordination polymer $[Cu^{I}_{2}Cu^{II}(4,4'\text{- bpy})_2(pydc)_2]$ has been hydrothermally synthesized, and is the first porous 3-D framework constructed from fivefold parallel interpenetration of 2-D (6,3) nets. The one-dimensional channels are occupied by guest water molecules. The porous network of **1** is stable after removal of the water molecules, which may be due to the multiple entanglement of the 2-D nets.

Experimental Section

General Remarks: Elemental analyses were performed on a Perkin−Elmer 240 elemental analyzer. The FT-IR spectra were recorded from KBr pellets in the range 400−4000 cm^{-1} on a Nicolet 5DX spectrometer. Thermal gravimetric analyses (TGA) were performed under a static air atmosphere with a Perkin−Elmer 7 thermogravimetric analyzer at a heating rate of 10 °C min^{-1}. The

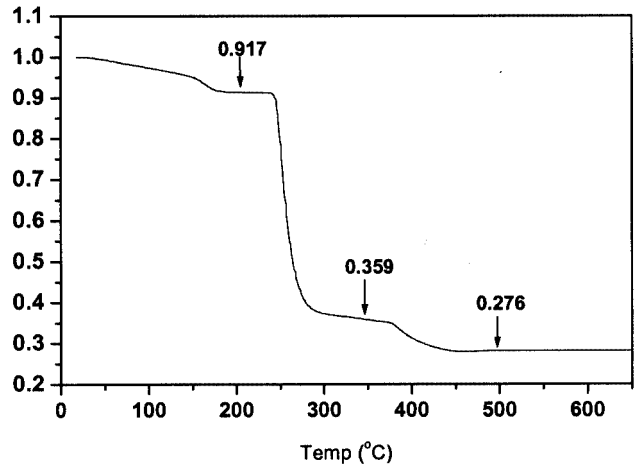

Figure 4. TGA curve of **1** in air

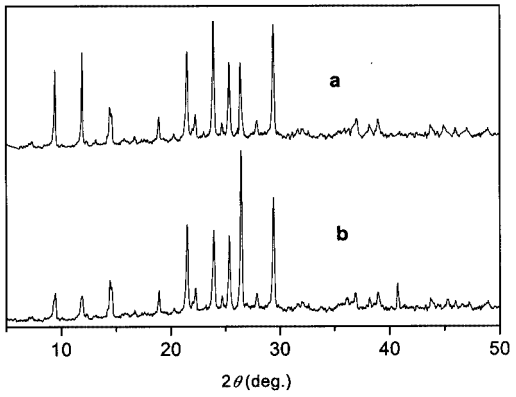

Figure 5. The X-ray powder-diffraction patterns of the as-synthesized **1** (top) and calcinated **1′** (bottom)

XRPD patterns were recorded on a Rigaku D/Max 3III diffractometer with a scanning rate of 4 °min^{-1}.

Preparation: A mixture of $Cu(MeCO_2)_2{\cdot}H_2O$ (0.075 g, 0.5 mmol), H_2pydc (0.042 g, 0.25 mmol), 4,4′-bpy (0.039 g, 0.25 mmol), NaOH (0.02 g, 0.5 mmol) and water (10 mL) in a molar ratio 1.5:1:1:2:2200 was stirred for 20 min in air, then transferred and sealed into a 23 mL Teflon-lined stainless steel container, which was heated to 160 °C for 72 hours. After cooling to room temperature at a rate of 5 °C per hour, dark-brown block crystals of **1** were recovered in 45% yield based on 4,4′-bpy. $C_{34}H_{30}Cu_3N_6O_{12}$ (905.3): calcd. C 45.11, H 3.34, N 9.28; found C 45.06, H 3.37, N 9.22. IR (KBr): $\tilde{\nu}$ = 3444bs, 3096w, 1634s, 1607s, 1552s, 1486m, 1415m, 1373s, 1339s, 1262m, 1091w, 818m, 782w, 732w, 694w cm^{-1}.

X-ray Crystallographic Study: Diffraction data were collected at 293 K on a Siemens R3 diffractometer (Mo-K_α, λ = 0.71073 Å). Lorentz-polarization and absorption corrections were applied. The structure was solved by direct methods (SHELXS-97) and refined by the full-matrix least-squares technique (SHELXL-97).[26] Analytical expressions of neutral-atom scattering factors were employed, and anomalous dispersion corrections were incorporated. In all cases, all non-hydrogen atoms were refined anisotropically and the hydrogen atoms of the organic ligands were placed geometrically. The crystallographic data for **1** are listed in Table 2.

Synthesis, Structure and Reactivity of Sulfur-Rich [Fe(L^1)(L^2)('tpS$_4$')] Complexes with Rigid [Fe('tpS$_4$'] Cores and σ−π Co-Ligands ('tpS$_4$'$^{2-}$ = 1,2-Bis(2-mercaptophenylthio)phenylene(2−); L^1, L^2 = CO, PR_3, NO)[‡]

Dedicated to Professor Gottfried Huttner on the occasion of his 65th birthday

Keywords: Helical structures / Iron / S ligands

Optimisation of synthesis and purification steps has made the new ligand 'tpS$_4$'$^{2-}$ available in preparative amounts. Treatment of $FeCl_2 \cdot 4H_2O$ with 'tpS$_4$'-Li_2 or 'tpS$_4$'-Na_2 yielded [Fe('tpS$_4$')] (**1**), which in the solid state and in the absence of co-ligands probably trimerises to give paramagnetic [Fe('tpS$_4$')]$_3$. The [Fe('tpS$_4$')] fragment displays helical coordination of the 'tpS$_4$'$^{2-}$ ligand and binds σ–π ligands such as CO, NO and phosphanes to give diamagnetic 18-valence-electron complexes of general formula [Fe(L^1)(L^2)('tpS$_4$')]. The *cis*-dicarbonyl complex [Fe(CO)$_2$('tpS$_4$')] (**2**) is labile and readily dissociates CO to give dinuclear [Fe(CO)('tpS$_4$')]$_2$ (**3**). Simultaneous coordination of CO and phosphanes yielded [Fe(CO)(PR_3)('tpS$_4$')] with R = Me (**4**), Et (**5**), Pr (**6**) and Bu (**7**), but it proved impossible to obtain analogous complexes with bulky PPh_3 or PCy_3 ligands. Bis(phosphane) complexes could be obtained only with PMe_3 and the bidentate dppe, which yielded [Fe(PMe_3)$_2$('tpS$_4$')] (**8**) and [Fe(dppe)('tpS$_4$')] (**11**). Alkylphosphanes with longer alkyl substituents, such as P*n*Pr$_3$ and P*n*Bu$_3$, gave the labile derivatives [Fe(PR_3)$_2$('tpS$_4$')] with R = *n*Pr (**9**) and *n*Bu (**10**). Complexes **9** and **10** reversibly dissociate one PR_3 ligand, yielding diamagnetic [Fe(PR_3)('tpS$_4$')] fragments. These findings explain the decisive and hitherto inexplicable influence of PPr_3 and PBu_3 ligands upon the stabilisation of N_2H_2 in the diazene complexes [μ-N_2H_2{Fe(PR_3)('tpS$_4$')}$_2$] with R = Pr, Bu. Treatment of [Fe('tpS$_4$')] (**1**) or [Fe(CO)('tpS$_4$')]$_2$ (**3**) with NO or NO^+ yielded [Fe(NO)$_2$('tpS$_4$')] (**12**). The molecular structures of **3**, **4**, **7** and **8** were determined by X-ray structure analysis. Spectroscopic and structural results indicate that the differences in reactivity between [Fe(L^1)(L^2)('tpS$_4$')] and homologous [Fe(L^1)(L^2)('S$_4$')] complexes can be traced back to subtle electronic and structural effects.

Introduction

The goal of modelling and understanding the activation and turnover of small molecules at the metal/sulfur sites of nitrogenases and hydrogenases accounts for much of the interest in low-molecular-weight iron complexes with sulfur-dominated coordination spheres that are able to bind molecules relevant to enzyme activity.[1,2] In the search for such complexes we have found that iron complexes with the [Fe('S$_4$')] fragment (Scheme 1) are capable in particular of binding CO, NO, N_2H_2, N_2H_4 and NH_3, though not yet N_2.[3] It was also found that the 'S$_4$'$^{2-}$ ligand in the resulting [Fe('S$_4$')] complexes exhibits a pronounced tendency to release the C_2H_4 bridge, yielding 1,2-benzenedithiolate ligands, under photolytic and/or strongly reducing reaction conditions.[4] These findings and the well-known fact that steric constraints exerted by ligands can have a marked influence upon the reactivity of otherwise identical complexes prompted us to synthesise 'tpS$_4$'-H_2 = 1,2-bis(2-mercaptophenylthio)phenylene (Scheme 1).[5]

The 'tpS_4'$^{2-}$ anion is analogous to the 'S_4'$^{2-}$ anion, but has a rigid *o*-phenylene group in place of the flexible C_2H_4 bridge and exclusively aromatic C−S bonds, which are significantly more stable towards C−S cleavage.

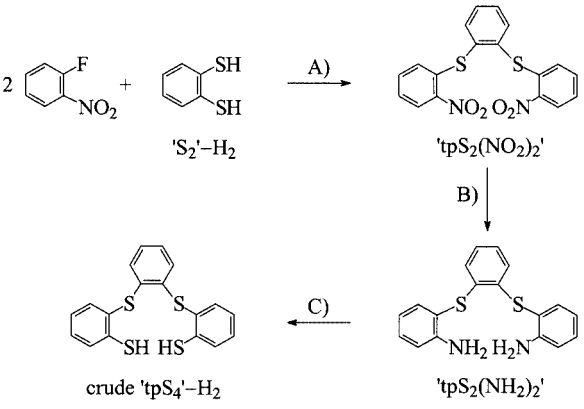
In our recent first paper on [Fe('tpS_4')] complexes we reported the diazene complexes [μ-N_2H_2{Fe(PR_3)('tpS_4')}$_2$] with R = Pr, Bu.[6] A strange and previously inexplicable result was that these complexes were accessible only with PPr_3 and PBu_3, but not with smaller or larger phosphanes such as PMe_3 or PPh_3. Another characteristic feature of these diazene complexes is their tendency to form hydrogen-bridge diastereomers, and [μ-N_2H_2{Fe(PPr_3)('tpS_4')}$_2$] is the first example for which these diastereomers have been characterised by X-ray structure analysis.

In this paper we report an optimised synthesis of 'tpS_4'-H_2 and give an account of the general reactivity of [Fe('tpS_4')] complex fragments with CO and phosphanes, emphasizing the similarities as well as the differences between [Fe('S_4')] and [Fe('tpS_4')] complexes.

Results and Discussion

Optimisation of the Synthesis of 'tpS_4'-H_2

The synthesis of 'tpS_4'-H_2 is a multistep procedure comprising aromatic substitution, reduction, diazotisation and diazonium salt substitution reactions, as shown in Scheme 2.[5]



Scheme 2. Synthesis of crude 'tpS_4'-H_2: (A) + 2 NaOMe, MeOH, 12 h reflux; (B) Zn, NH_4Cl, THF, 3 h reflux; (C) (a) H_2SO_4, $NaNO_2$, H_2O, 0 °C; (b) + KSC(S)OEt, H_2O, 85 °C; (c) + KOH, EtOH, 19 h reflux; (d) + HCl, H_2O

Polyfunctional species are involved in all these steps, and the final crude product was usually heavily contaminated by side-products. Removal of these side-products had previously been achievable only in a very laborious way that included treatment of the crude 'tpS_4'-H_2 with LiOMe to give crude 'tpS_4'-Li_2, and the synthesis of the nickel complex [Ni('tpS_4')]$_2$. Recrystallisation of this nickel complex was the essential purification step. Acidolysis of [Ni('tpS_4')]$_2$ finally yielded pure 'tpS_4'-H_2, which could be converted into pure 'tpS_4'-Li_2 as a storable form. In the end, pure 'tpS_4'-H_2 or 'tpS_4'-Li_2 were obtained only in 100 mg amounts and yields that rarely exceeded 20%.[6]

In optimisation of the reaction conditions we have now found that the steps A and B of Scheme 1 can be scaled up and improved such that the intermediates '$tpS_2(NO_2)_2$' and '$tpS_2(NH_2)_2$' are obtained in nearly quantitative yields. The steps leading to 'tpS_4'-H_2 can also be scaled up, and the resulting crude product is obtained in a form that directly gives white 'tpS_4'-Na_2 in yields of ca. 70% and in gram amounts upon treatment with NaOH. The procedure described here (cf. Exp. Sect.) now makes 'tpS_4'-H_2 readily available in preparative amounts for the synthesis of metal complexes.

Syntheses of [Fe('tpS_4')] Complexes

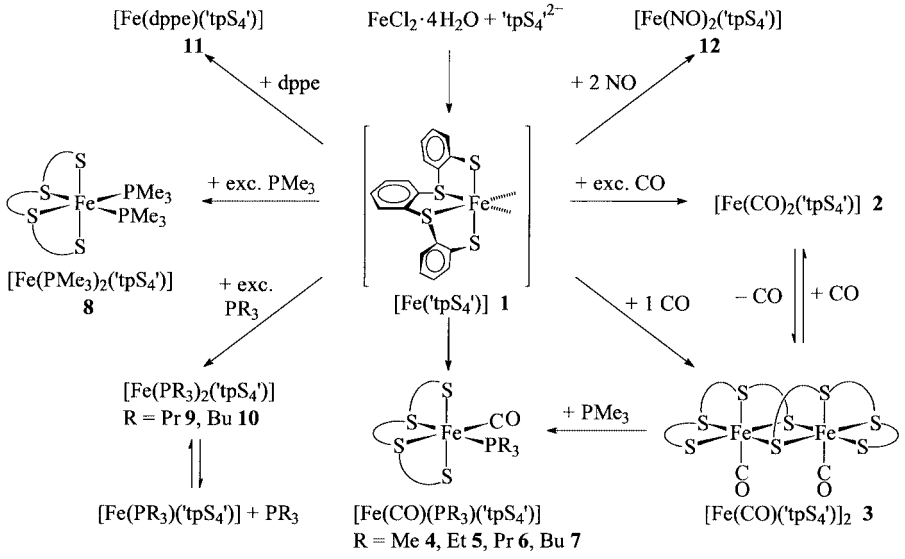
Scheme 3 summarises the syntheses of [Fe('tpS_4'] complexes.

Coordination of anionic 'tpS_4'$^{2-}$ to Fe^{II} centres was readily achieved by treating methanolic solutions of 'tpS_4'-Li_2 (or 'tpS_4'-Na_2) with $FeCl_2{\cdot}4H_2O$. Light brown [Fe('tpS_4')] (**1**) was obtained. This is soluble in coordinating solvents such as THF or MeOH, but also in noncoordinating CH_2Cl_2. In this regard, [Fe('tpS_4')] (**1**) differs remarkably from tetranuclear [Fe('S_4')]$_4$, which is practically insoluble in all common organic solvents.[7] This solubility in THF, MeOH and CH_2Cl_2 made [Fe('tpS_4')] (**1**) the best-suited precursor for [Fe(L^1)(L^2)('tpS_4')] complexes.

The nuclearity of [Fe('tpS_4')] (**1**) remained undetermined. FD mass spectra of **1** showed peaks at *m*/*z* = 412, 824 and 1236, assignable to mono-, di- and trinuclear [Fe('tpS_4')] species. The mass peak at *m*/*z* = 1236 is compatible with the assumption that in the solid state and in the absence of co-ligands, [Fe('tpS_4')] (**1**) trimerises through thiolate bridges in such a way that coordinatively saturated hexacoordinate iron centres result. All X-ray structure determinations of [Fe(L^1)(L^2)('tpS_4')] complexes established a helical coordination of 'tpS_4'$^{2-}$ to the Fe centre (vide infra). Such a coordination can also be assumed for [Fe('tpS_4')] (**1**), the fifth and sixth coordination sites of which may be occupied by solvent molecules in solution. In the solid state, complex **1** is paramagnetic and exhibits μ_{eff} = 3.13 μ_B at room temperature.

Treatment of **1** in THF solution with an excess of CO yielded the *cis*-dicarbonyl complex [Fe$(CO)_2$('tpS_4')] (**2**), as indicated by two ν(CO) bands at 2047 and 2004 cm^{-1} in the IR spectrum. In stark contrast to the analogous [Fe$(CO)_2$('S_4')],[8] which is stable in solution and in the solid state, [Fe$(CO)_2$('tpS_4')] (**2**) is highly labile and could not be isolated in the solid state. Attempts to separate **2** from solution always yielded red-brown powders with IR spectra exhibiting strong ν(CO) bands at 1979 cm^{-1}, indicating that complex **2** had dissociated one CO ligand and that the resulting complex fragments had dimerised to give [Fe(CO)('tpS_4')]$_2$ (**3**).

This indication could be corroborated by independent experiments. Treatment of an MeOH solution of **1** with exactly 1 equiv. of CO directly gave [Fe(CO)('tpS_4')]$_2$ (**3**). Complex **3** is sparingly soluble in all common solvents and



Scheme 3. Synthesis of [Fe('tpS$_4$')] complexes

precipitated from solution. Its dinuclear structure was established by X-ray crystallography.

The dissociation of CO from [Fe(CO)$_2$('tpS$_4$')] (**2**) is reversible. Treatment of an MeOH or THF suspension of **3** with an excess of CO gave a clear solution of [Fe(CO)$_2$('tpS$_4$')] (**2**), from which **3** precipitated again when the atmosphere of CO was replaced by N_2. These observations enabled us to conclude that an equilibrium exists between **2**, **3** and CO. This is driven in the direction of **3** by that compound's low solubility when the partial pressure of CO is decreased.

One more possible reason for the labile bonding of CO in [Fe(CO)$_2$('tpS$_4$')] (**2**) could be the electron density at the iron centre. Comparison of the ν(CO) bands (in KBr) of [Fe(CO)$_2$('tpS$_4$')] and [Fe(CO)$_2$('S$_4$')] (2048/2002 cm^{-1} vs. 2036/1992 cm^{-1}) and [Fe(CO)('tpS$_4$')]$_2$ and [Fe(CO)('S$_4$')]$_2$ (1979 vs. 1965 cm^{-1})[9] shows that the iron centres have a lower electron density in the [Fe('tpS$_4$')] species than in [Fe('S$_4$')], disfavouring the bonding of the π-acceptor CO.

Dinuclear [Fe(CO)('tpS$_4$')]$_2$ (**3**) could also be cleaved by PMe_3 to give mononuclear [Fe(CO)(PMe_3)('tpS$_4$')] (**4**). Complex **4** and the homologous compounds [Fe(CO)(PR$_3$)('tpS$_4$')] with R = Et (**5**), Pr (**6**) and Bu (**7**) were similarly accessible directly from [Fe('tpS$_4$')] (**1**) and equivalent amounts of CO and the corresponding PR_3. The series of complexes **4**–**7** revealed another difference between [Fe('tpS$_4$')] and [Fe('S$_4$')] complexes. While [Fe(CO)(PR$_3$)('S$_4$')] species could be obtained with practically every phosphane, ranging from PMe_3 over PBu_3 up to bulky PPh_3 and PCy_3,[10] [Fe(CO)(PR$_3$)('tpS$_4$')] complexes were accessible only with alkylphosphanes with relatively small cone angles.[11] No evidence could be found for the coordination of PPh_3 or PCy_3 to [Fe(CO)('tpS$_4$')] fragments.

As judged by their NMR spectra, all complexes **4**–**7** are diamagnetic. They each show a characteristic ν(CO) band in the 1959–1955 cm^{-1} range. The influence of the size of the PR_3 moiety for coordination of phosphanes to [Fe('tpS$_4$')] fragments became even more apparent with bis(phosphane) complexes [Fe(PR$_3$)$_2$('tpS$_4$')]. Isolable complexes could be obtained only with PMe_3 and the chelating dppe. Treatment of **1** with an excess of PMe_3 or equivalent amounts of dppe gave [Fe(PMe_3)$_2$('tpS$_4$')] (**8**) and [Fe(dppe)('tpS$_4$')] (**11**), respectively, which could be completely characterised. Treatment of [Fe('tpS$_4$')] (**1**) with PPr_3 or PBu_3, however, yielded very labile [Fe(PR$_3$)$_2$('tpS$_4$')] with R = Pr (**9**) or Bu (**10**), which could be identified only by their molecular ions in their FD mass spectra and by ^{31}P NMR spectroscopy in solution in the presence of excess phosphane. Attempts to isolate **9** or **10** in the solid state resulted in phosphane dissociation and products that gave unsatisfactory elemental analyses. The lability of the bis(phosphane) complexes [Fe(PR$_3$)$_2$('tpS$_4$')] **9** (Pr) and **10** (Bu), which prevents their isolation in the solid state, however, has considerable synthetic value and explains the hitherto unexplained decisive influence of the R substituents for trapping diazene, N_2H_2, from solution and the stabilisation of the diazene complexes [μ-N_2H_2{Fe(PR$_3$)('tpS$_4$')}$_2$] with R = Pr, Bu.

As evidenced by the diamagnetism of complexes **4**–**8** or **11**, binding of σ–π ligands to [Fe('tpS$_4$')] fragments produces a low-spin state in the Fe^{II} centres. The NMR spectra and chemical behaviour of **9** and **10**, on the other hand, indicate that their lability is due to an equilibrium according to Equation (1).

$$[Fe(PR_3)_2('tpS_4')] \rightleftharpoons [Fe(PR_3)('tpS_4')] + PR_3 \quad (1)$$

The resulting five-coordinate [Fe(PR$_3$)('tpS$_4$')] fragment has a vacant coordination site and a low-spin (diamagnetic) Fe^{II} centre, both of which are necessary to enable the coordination and stabilisation of N_2H_2. (In molecular orbital

theory terms, the diamagnetism of [Fe(PR_3)('tpS_4')] means that no electrons occupy antibonding orbitals.)

In concluding experiments, the coordination of NO and NO^+ to [Fe('tpS_4')] fragments was examined. The same complex was formed in all cases, its elemental analysis and spectroscopic data being compatible with the formula [Fe($NO)_2$('tpS_4')] (**12**). In CH_2Cl_2 solution, complex **12** shows two strong ν(NO) bands at 1779 and 1750 cm^{-1}, indicative of a *cis*-Fe($NO)_2$ entity. The strong tendency towards the formation of **12** became evident from the various reactions in which it was formed. For example, complex **12** was produced when [Fe('tpS_4')] (**1**) in CH_2Cl_2 was treated with 2 equiv. of NO gas. The two ν(NO) bands of **12** became visible in the IR spectrum of the solution even after injection of only the first equivalent. Injection of the second equivalent increased the ν(NO) band intensity. Likewise, successive treatment of [Fe(CO)('tpS_4')]$_2$ (**3**) in CH_2Cl_2 with 2 equiv. of NO gas instantaneously gave rise to the formation of [Fe($NO)_2$('tpS_4')] (**12**). No intermediates such as the 19-VE species [Fe(CO)(NO)('tpS_4')] or [Fe(NO)('tpS_4')]$_2$ could be observed by IR spectroscopy. That 19-VE complexes such as [Fe(CO)(NO)('tpS_4')], which may be expected to be labile, may occur can be concluded from the fact that [Fe($CO)_2$('tpS_4')] was formed as the second product in the reaction between [Fe(CO)('tpS_4')]$_2$ (**3**) and NO gas (Figure 1).

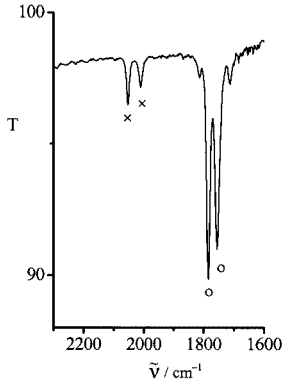


Figure 1. ν(CO)/ν(NO) region of the reaction solution (CH_2Cl_2) when [Fe(CO)('tpS_4')]$_2$ (**3**) is treated with 2 equiv. of NO gas {× = [Fe($CO)_2$('tpS_4')] (**2**), o = [Fe($NO)_2$('tpS_4')] (**12**)}

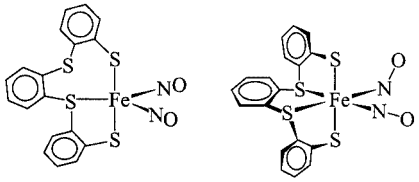
The formation of [Fe($CO)_2$('tpS_4')] can be explained by CO dissociation and transfer reactions between the labile [Fe(CO)(NO)('tpS_4')] and dinuclear **3**. Treatment of **1** or **3** with $NOBF_4$ also yielded [Fe($NO)_2$('tpS_4')]. No other nitrosyl complexes were observed, and the reducing agent necessary for the $NO^+ \rightarrow NO$ conversion was not identified.

The ^1H NMR spectrum of **12** shows only a multiplet for the aromatic protons of the [Fe('tpS_4')] fragment and indicates diamagnetism of **12**, but is inconclusive in any other respect. The insufficient solubility of **12** prevented the recording of ^{13}C NMR spectra. The FD mass spectra showed a minor peak for the molecular ion at m/z = 472 and strong peaks at m/z = 442 as well as at 412, 824 and 1236, assignable to [Fe(NO)('tpS_4')] and [Fe('tpS_4')]$_x$ species with x = 1, 2 and 3. The diamagnetism of **12**, the fact that all [Fe('tpS_4')] complexes with σ−π co-ligands obey the 18-valence-electron rule and the other data are compatible with the alternative structures **I** and **II**.



I **II**

In formula **I**, the two [FeNO] groups are linear and one sulfur donor atom of 'tpS_4'$^{2-}$ is decoordinated. In formula **II**, the 'tpS_4'$^{2-}$ ligand stays tetradentate, but one NO ligand acts as a $1e^-$ donor, the other one as a $3e^-$ donor, and both types of NO possibly isomerise quickly as in, for example, $[Ru(NO)_2Cl(PPh_3)_2]^+$.[12]

In order to examine the stability of [Fe('tpS_4')] fragments towards photolysis, solutions of [Fe(CO)('tpS_4')]$_2$ (**3**), [Fe($PMe_3)_2$('tpS_4')] (**8**) and [Fe(CO)(PMe_3)('tpS_4')] (**4**) were UV-irradiated for prolonged periods of time. The CO ligands of **3** and **4** dissociated, but in no case could decomposition of

X-ray Structure Analyses

The molecular structures of [Fe(CO)('tpS_4')]$_2$·MeOH (**3**·MeOH), [Fe(CO)(PMe_3)('tpS_4')] (**4**), [Fe(CO)(PBu_3)('tpS_4')] (**7**) and [Fe(PMe_3)$_2$('tpS_4')] (**8**) were determined by X-ray crystallography and are shown in Figure 2. Table 1 lists selected distances and angles.

All complexes exhibit six-coordinate Fe centres and helical coordination of the 'tpS_4'$^{2-}$ ligands, resulting in chiral [Fe('tpS_4')] fragments with *trans*-thiolate and *cis*-thioether donors. Figure 1 shows the respective (*R*) enantiomers of **4**, **7** and **8**. In [Fe(CO)('tpS_4')]$_2$ (**3**), two such homochiral (*R*)-[Fe('tpS_4')] fragments are bridged through thiolate donors to give C_2-symmetrical **3**. The structure of **3** is noteworthy because it appears to be favoured in spite of the strikingly different spatial filling of the coordination sphere and the evident resulting steric strain. While the top "half" of **3** is heavily overloaded, the bottom "half" is occupied only by the two CO ligands. The electronic inequivalence of the thiolate donors in C_1-symmetrical [Fe(CO)('tpS_4')] fragments is a potential factor in favour of this type of structure. A precedent has been observed with [Fe(CO)('S_4')][9] and, according to the classification introduced then, the structure shown in Figure 1 (part a) is the αα-*Z*(*RR*) isomer of **3**.

The bond lengths of all four compounds lie in the ranges characteristic for this type of diamagnetic Fe^{II} complexes.[10] For example, terminal Fe−S distances are found in the 224−230 pm range, and Fe−S−Fe bridging distances can be elongated up to 234 pm, indicating the tendency of dinuclear complexes to dissociate into mononuclear species. As also observed for [Fe('S_4')] complexes, no marked *trans* influence of such different donors as S(thiolate), CO or PR_3 upon the respective *trans* bonds can be recognised in any of the [Fe('tpS_4')] complexes. The following structural differences between [Fe(L^1)(L^2)('tpS_4')] and the corresponding [Fe(L^1)(L^2)('S_4')] complexes are to be noted.

In [Fe(L^1)(L^2)('S_4')] complexes, the Fe−S(thioether) and Fe−S(thiolate) distances tend to be equivalent, frequently identical.[3] In [Fe(L^1)(L^2)('tpS_4')] complexes, however, the Fe−S(thioether) distances are usually distinctly shorter than the Fe−S(thiolate) distances. This is certainly not due to a better donor capability of the thioether donors but rather results from the bite angle of the *o*-phenylenebis(thioether) entity, which is smaller than that of the [SC_2H_4S] bridge in the 'S_4'$^{2-}$ ligand. Another major difference is the conformation of the central five-membered chelate ring in [Fe('S_4')] and [Fe('tpS_4')] fragments. Figure 3 shows that this [FeS(2)S(3)] ring adopts a puckered (envelope) conformation in [Fe('S_4')], whereas the chelate ring is virtually planar (coplanar to within 20 pm with the benzene ring) in [Fe('tpS_4')].

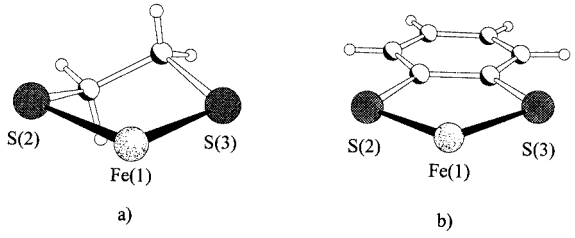

Figure 3. Comparison of the central five-membered [FeS_2C_2] rings in a) [Fe('S_4')] and b) [Fe('tpS_4')] complexes

Thus, the small but significantly different reactivities of [Fe('S_4')] and [Fe('tpS_4')] fragments with regard to the coordination of co-ligands such as CO and phosphanes can be traced back to slightly different electron densities at the Fe centres [cf. the ν(CO) frequencies] as well as to the structural flexibility or rigidity of the central [FeS_2C_2] chelate rings in these complexes.

Conclusion

Optimised synthesis and purification steps have now made 'tpS_4'-H_2 available in the preparative amounts needed

for thorough investigation of its coordination properties. Comparison of the [Fe(L^1)(L^2)('tpS_4')] complexes described in this work with the [Fe(L^1)(L^2)('S_4')] complexes obtained in previous studies shows that [Fe('tpS_4')] and [Fe('S_4')] complex fragments exhibit both close similarities and distinctive differences. While the similarities can be traced back to the identical coordination of Fe^{II} centres by two *trans*-thiolate and two *cis*-thioether donors, the differences result from a slightly lower electron density at the Fe centres and the more rigid core structure of [Fe('tpS_4')] vs. [Fe('S_4')] fragments. These differences are illustrated by, for example, the [Fe(CO)(PR_3)('tpS_4')] and [Fe(CO)(PR_3)('S_4')] complexes. While the [Fe(CO)('tpS_4')] fragment binds only small alkylphosphanes, the [Fe(CO)('S_4')] fragment can also coordinate bulky phosphanes such as PPh_3 and PCy_3. The lability of [Fe(PR_3)$_2$('tpS_4')] with R = Pr (**9**), Bu (**10**), resulting in the reversible dissociation of one PR_3 ligand, explains the decisive influence of PPr_3 and PBu_3 ligands for the stabilisation of N_2H_2 in the diazene complexes [μ-N_2H_2{Fe(PR_3)('tpS_4')}$_2$] with R = Pr, Bu. While PMe_3 gives stable [Fe(PMe_3)$_2$('tpS_4')] (**8**) and PPh_3 or PCy_3 do not coordinate at all to [Fe('tpS_4')] fragments, the medium-sized phosphanes PPr_3 and PBu_3 in solution give rise to five-coordinate [Fe(PR_3)('tpS_4')] species that are diamagnetic and have a vacant site. Diamagnetism and a vacant site are both necessary requirements for the binding and stabilisation of unstable N_2H_2 to [Fe(PR_3)('tpS_4')] fragments. The previously inexplicable stabilisation effect of PPr_3 and PBu_3 in the iron diazene complexes is thus in the end due neither to pronounced electronic nor steric effects, but to a simple dissociation equilibrium between [Fe(PR_3)$_2$('tpS_4')], [Fe(PR_3)('tpS_4')] and PR_3.

Experimental Section

General Methods: Unless noted otherwise, all reactions and operations were carried out at room temperature under nitrogen by use of standard Schlenk techniques. Solvents were dried and distilled before use. As far as possible, reactions were monitored by IR or NMR spectroscopy. Spectra were recorded with the following instruments: IR (KBr disks or CaF_2 cuvettes, solvent bands were compensated): Perkin−Elmer 16 PC FT-IR; NMR: Jeol FT-JNM-GX 270, EX 270 and Lambda LA 400, with the protio solvent signals used as a reference, chemical shifts are quoted on the δ scale (downfield shifts are positive) relative to tetramethylsilane (^{1}H, ^{13}C{^{1}H} NMR) or 85% H_3PO_4 (^{31}P{^{1}H} NMR). Spectra were recorded at 25 °C; MS: JEOL MSTATION 700 spectrometer; elemental analyses: Carlo Erba EA 1106 and 1108 analyser. Magnetic moments were determined with a Johnson−Matthey susceptibility balance. 'tpS_4'-Li_2,[5] PMe_3, PEt_3, P*n*Pr_3 and P*n*Bu_3 [13] were prepared as described in the literature, dppe was purchased from Aldrich.

'$tpS_2(NO_2)_2$': *o*-$C_6H_4(SH)_2$ (15.1 mL, 118.8 mmol) and 2-fluoronitrobenzene (35.1 mL, 332.6 mmol) were added to a solution of NaOMe (13.16 g, 243.6 mmol) in MeOH (400 mL). The solution was heated to reflux for 12 h, in the course of which a bright yellow precipitate formed. After the suspension had cooled to room temperature, the precipitate was separated, washed with MeOH (80 mL), H_2O (120 mL), and again MeOH (30 mL) and dried in vacuo. Yield: 39.64 g (95%). The product was identified by ^{1}H NMR spectroscopy and mass spectrometry.

'$tpS_2(NH_2)_2$': Zinc powder (67.4 g, 1.031 mol) and NH_4Cl (55.2 g, 1.031 mol) were added to a yellow suspension of '$tpS_2(NO_2)_2$' (39.64 g, 103.1 mmol) in THF (600 mL). The resulting grey suspension was heated to reflux for 3 h and filtered while hot. The solid residue was thoroughly extracted with hot THF (400 mL). The filtrate and combined THF washing solutions were concentrated under reduced pressure, yielding a colourless oily residue. This residue was treated with hot EtOH (50 mL) to give a white powder, which was separated, washed with EtOH (50 mL) and dried in vacuo. Additional product precipitated from the combined EtOH filtrates overnight. Yield: 32.79 g (98%). The product was identified by IR and ^{1}H NMR spectroscopy and mass spectrometry.

'tpS_4'-H_2 (Crude Product): Whilst stirring, a white suspension of powdered '$tpS_2(NH_2)_2$' (21.64 g, 66.7 mmol) in H_2O (200 mL) was cooled to 0 °C. In order to keep the suspension at 0 °C, ice (90 g) was added. After addition of a solution of H_2SO_4 (15.9 g, 161.9 mmol) in H_2O (100 mL), an aqueous solution of $NaNO_2$ (9.67 g, 140.1 mmol, 100 mL) was added dropwise. The resulting yellow orange suspension was stirred at 0 °C for another hour and subsequently added dropwise to a hot solution (85 °C) of potassium *O*-ethylxanthogenate (86.5 g, 539.9 mmol) in H_2O (200 mL), yielding a red-brown oil. The reaction mixture was stirred for another 30 min at 85 °C, cooled to room temperature and extracted with CH_2Cl_2 (600 mL). The combined CH_2Cl_2 extracts were dried with Na_2SO_4 and filtered, and the solvents were evaporated to give a dark red oil as residue. EtOH (250 mL) and powdered KOH (42.9 g, 764.6 mmol) were added, and the resulting suspension was heated to reflux for 19 h to give a dark red solution. EtOH was removed in vacuo, the remaining orange-brown residue was dissolved in H_2O (250 mL), and the resulting aqueous solution was extracted with CH_2Cl_2 (300 mL) in a separating funnel. The aqueous solution was separated and acidified with concentrated hydrochloric acid to pH = 0.5, whereupon a red oil separated. The oil/water mixture was extracted several times with CH_2Cl_2 (400 mL), the combined CH_2Cl_2 extracts were dried with Na_2SO_4 and filtered, and the solvents were evaporated to yield an orange-red oily residue, which was dried in vacuo for 12 h. Yield: 18.5 g (77%) of crude product, which contained approximately 62% of 'tpS_4'-H_2 according to the ^{1}H NMR spectrum in CD_2Cl_2.

'tpS_4'-Na_2: A dark red solution of the crude product [12.33 g, containing ca. 62% (21 mmol) of 'tpS_4'-H_2] in THF (50 mL) was combined with an MeOH solution (80 mL) of NaOMe (2.30 g, 42.6 mmol). Volatile components were removed, and the brown-red residue was dried in vacuo for 12 h and subsequently suspended in THF (200 mL). Stirring of the suspension for 1 h resulted in a white solid, which was separated, washed with THF (120 mL) and dried in vacuo for 12 h. Yield: 6.39 g (74%, referred to 'tpS_4'-H_2 contained in the crude product). The product contained traces of THF, which could not be removed by drying in vacuo for 48 h. ^{1}H NMR ([D$_4$]MeOH, 269.72 MHz): δ = 7.52−7.40 (m, 2 H), 7.30−7.18 (m, 2 H), 7.14−7.03 (m, 2 H), 6.82−6.57 (m, 6 H, C_6H_4), 3.70 (m, 4 H), 1.84 (m, 4 H, THF) ppm. ^{13}C{^{1}H} NMR ([D$_4$]MeOH, 100.40 MHz): δ = 149.25, 139.63, 137.98, 134.05, 132.91, 128.42, 126.82, 124.69, 120.90 [C (aryl)], 67.52, 25.16 (THF) ppm. IR (KBr): $\tilde{\nu}$ = 1565 m, 1437 s, 1422 s [ν(C=C)], 739 cm^{-1} vs [δ(C−H)].

[Fe('tpS_4')] (1): $FeCl_2 \cdot 4H_2O$ (68 mg, 0.34 mmol) was added to a light yellow solution of 'tpS_4'-Li_2 (126 mg, 0.34 mmol) in MeOH (30 mL). After stirring for 1 h, the reaction mixture was filtered

and concentrated to dryness. The resulting yellow-brown residue was dried in vacuo overnight and redissolved in CH_2Cl_2 (25 mL) to remove LiCl. The resulting suspension was filtered and the brown-red filtrate was evaporated to dryness. Stirring of the residue with Et_2O (20 mL) yielded brown microcrystals, which were separated, washed with Et_2O (30 mL) and dried in vacuo. Yield: 102 mg (**1**·0.25 CH_2Cl_2) (69%). IR (KBr): $\tilde{\nu}$ = 1566 m [ν(C=C)], 746 cm^{-1} vs [δ(C−H)]. MS (FD, THF, ^{56}Fe): *m*/*z*: 412 [Fe('tpS_4')]$^+$, 824 [Fe('tpS_4')]$_2^+$, 1236 [Fe('tpS_4')]$_3^+$; μ_{eff} (295 K) = 3.13 μ_B. $C_{18.25}H_{12.5}Cl_{0.5}FeS_4$ (**1**·0.25CH_2Cl_2) (433.63): calcd. C 50.55, H 2.91, S 29.58; found C 50.52, H 3.06, S 29.68.

[Fe(CO)('tpS_4')]$_2$ (3): $FeCl_2·4H_2O$ (126 mg, 0.64 mmol) was added to a light yellow solution of 'tpS_4'-Li_2 (236 mg, 0.64 mmol) in MeOH (50 mL). The orange-red reaction mixture was stirred for 1 h and filtered, and CO gas (14.3 mL, 0.64 mmol) was injected into the filtrate by syringe. A brick-red precipitate formed; after 6 h this was separated, washed with MeOH (45 mL) and Et_2O (30 mL), and dried in vacuo. Yield: 234 mg (**3**·MeOH) (81%). IR (KBr): $\tilde{\nu}$ = 1979 cm^{-1} vs [ν(CO)]. MS (FD, THF, ^{56}Fe): *m*/*z*: 412 [Fe('tpS_4')]$^+$, 824 [Fe('tpS_4')]$_2^+$, 1236 [Fe('tpS_4')]$_3^+$. $C_{39}H_{28}Fe_2O_3S_8$ (**3**·MeOH) (912.87): calcd. C 51.32, H 3.09, S 28.10; found C 51.13, H 3.08, S 28.13. Because of the low solubility of **3**, no NMR spectra could be recorded.

[Fe(CO)(PMe_3)('tpS_4')] (4): $FeCl_2·4H_2O$ (59 mg, 0.30 mmol) and PMe_3 (59 μL, 0.30 mmol) were added to a light yellow solution of 'tpS_4'-Li_2 (110 mg, 0.30 mmol) in THF (20 mL) and MeOH (10 mL) to give an olive-green reaction mixture, into which CO gas (16.8 mL, 0.30 mmol) was injected by syringe. A red solution resulted, and this was filtered, reduced in volume to 2 mL and combined with MeOH (20 mL). A light green precipitate formed and was separated, washed with MeOH (20 mL) and Et_2O (20 mL) and dried in vacuo. Yield: 80 mg (**4**·0.5MeOH) (51%). ^{1}H NMR (CD_2Cl_2, 269.72 MHz): δ = 8.25−6.70 (m, 12 H, C_6H_4), 1.44 (br. s, 9 H, CH_3) ppm. ^{13}C{^{1}H} NMR (CD_2Cl_2, 100.40 MHz): δ = 217.25 (d, J_{PC} = 31.1 Hz, *C*O), 157.59, 156.44 (d, J_{PC} = 2.7 Hz), 139.13, 138.97, 137.57, 136.01, 132.23, 132.11, 131.18, 131.04, 130.74, 130.69, 130.33, 129.78, 129.67, 129.40, 122.60, 122.53 [*C* (aryl)], 16.44 (d, J_{PC} = 29.2 Hz, CH_3) ppm. ^{31}P{^{1}H} NMR (CD_2Cl_2, 161.70 MHz): δ = 21.50 (s, PMe_3) ppm. IR (KBr): $\tilde{\nu}$ = 1966, 1957 vs [ν(CO)], 952 cm^{-1} m [δ(PCH)]. IR (THF): $\tilde{\nu}$ = 1959 cm^{-1} vs [ν(CO)]. MS (FD, THF, ^{56}Fe): *m*/*z*: 516 [Fe(CO)(PMe_3)('tpS_4')]$^+$, 412 [Fe('tpS_4')]$^+$, 824 [Fe('tpS_4')]$_2^+$, 1236 [Fe('tpS_4')]$_3^+$. $C_{22.5}H_{23}FeO_{1.5}PS_4$ (**4**·0.5MeOH) (532.51): calcd. C 50.75, H 4.35, S 24.09; found C 50.76, H 4.43, S 23.92.

[Fe(CO)(PEt_3)('tpS_4')] (5): $FeCl_2·4H_2O$ (99 mg, 0.50 mmol) and PEt_3 (158 μL, 0.50 mmol) were added to a light yellow solution of 'tpS_4'-Na_2 (200 mg, 0.50 mmol) in MeOH (10 mL) and THF (20 mL). An olive-green solution resulted, into which CO gas (11.2 mL, 0.50 mmol) was injected by syringe. The reaction mixture was stirred for 2.5 h and filtered, and the dark red filtrate was reduced in volume to 2 mL. Upon addition of MeOH (20 mL), light brown microcrystals formed, and were separated, washed with MeOH (20 mL) and dried in vacuo. Yield: 53 mg (19%). ^{1}H NMR (CD_2Cl_2, 269.72 MHz): δ = 8.07−7.73 (m, 4 H), 7.44−7.25 (m, 4 H), 7.00−6.81 (m, 4 H, C_6H_4), 1.96−1.63 (m, 6 H), 1.28−1.10 [m, 9 H, P(C_2H_5)$_3$] ppm. ^{13}C{^{1}H} NMR (CD_2Cl_2, 67.83 MHz): δ = 217.79 (d, J_{PC} = 30.1 Hz, *C*O), 157.73, 156.83 (d, J_{PC} = 7.3 Hz), 139.11 (d, J_{PC} = 11.9 Hz), 137.11, 136.29, 132.27, 131.97, 131.07, 130.90, 130.66, 130.63, 130.19, 129.74, 129.64, 129.42, 122.48 [*C* (aryl), partly superimposed], 17.83 (d, J_{PC} = 24.9 Hz), 7.99 [d, J_{PC} = 4.7 Hz, P(C_2H_5)$_3$] ppm. ^{31}P{^{1}H} NMR (CD_2Cl_2, 161.70 MHz): δ = 42.56 (s, PEt_3) ppm. IR (KBr): $\tilde{\nu}$ = 1951 cm^{-1} vs [ν(CO)]. IR (THF): $\tilde{\nu}$ = 1955 cm^{-1} vs [ν(CO)]. MS (FD, THF, ^{56}Fe): *m*/*z*: 558 [Fe(CO)(PEt_3)('tpS_4')]$^+$, 412 [Fe('tpS_4')]$^+$, 824 [Fe('tpS_4')]$_2^+$, 1236 [Fe('tpS_4')]$_3^+$. $C_{25}H_{27}FeOPS_4$ (558.57): calcd. C 53.76, H 4.87, S 22.96; found C 53.62, H 5.14, S 22.93.

[Fe(CO)(P*n*Pr_3)('tpS_4')] (6): $FeCl_2·4H_2O$ (157 mg, 0.79 mmol) and P*n*Pr_3 (158 μL, 0.79 mmol) were added to a light yellow solution of 'tpS_4'-Li_2 (292 mg, 0.79 mmol) in THF (25 mL) and MeOH (10 mL). CO gas (17.7 mL, 0.79 mmol) was injected by syringe into the olive-green mixture, which turned into a dark-red solution within 3 h. The solution was filtered, reduced in volume to 5 mL and combined with MeOH (20 mL). Grey microcrystals formed, and were separated, washed with MeOH (30 mL) and Et_2O (20 mL) and dried in vacuo. Yield: 314 mg (**6**·MeOH) (63%). ^{1}H NMR (CD_2Cl_2, 269.72 MHz): δ = 8.08−7.69 (m, 4 H), 7.46−7.23 (m, 4 H), 7.02−6.79 (m, 4 H, C_6H_4), 1.88−1.42 (m, 12 H), 1.01 [t, 9 H, P(C_3H_7)$_3$] ppm. ^{13}C{^{1}H} NMR (CD_2Cl_2, 100.40 MHz): δ = 217.78 (d, J_{PC} = 30.2 Hz, *C*O), 158.01, 156.81 (d, J_{PC} = 7.3 Hz), 139.15, 138.98, 138.84 (d, J_{PC} = 0.9 Hz), 137.02, 136.43, 132.24, 131.98, 131.13, 130.91, 130.64, 130.59, 130.22, 129.70, 129.62, 129.48, 122.49 [*C* (aryl)], 27.98 (d, J_{PC} = 23.8 Hz), 17.52 (d, J_{PC} = 2.0 Hz), 15.99 [d, J_{PC} = 12.9 Hz, P(C_3H_7)$_3$] ppm. ^{31}P{^{1}H} NMR (CD_2Cl_2, 161.70 MHz): δ = 35.88 (s, *Pn*Pr_3) ppm. IR (KBr): $\tilde{\nu}$ = 1957, 1953 cm^{-1} vs [ν(CO)]. IR (THF): $\tilde{\nu}$ = 1955 cm^{-1} vs [ν(CO)]. MS (FD, THF, ^{56}Fe): *m*/*z*: 600 [Fe(CO)(P*n*Pr_3)('tpS_4')]$^+$, 412 [Fe('tpS_4')]$^+$, 824 [Fe('tpS_4')]$_2^+$, 1236 [Fe('tpS_4')]$_3^+$. $C_{29}H_{37}FeO_2PS_4$ (**6**·MeOH) (632.69): calcd. C 55.05, H 5.89, S 20.27; found C 54.56, H 5.78, S 20.57.

[Fe(CO)(P*n*Bu_3)('tpS_4')] (7): $FeCl_2·4H_2O$ (257 mg, 1.29 mmol) and P*n*Bu_3 (257 μL, 1.29 mmol) were added to a light yellow solution of 'tpS_4'-Li_2 (479 mg, 1.29 mmol) in THF (45 mL) and MeOH (20 mL). CO gas (28.9 mL, 1.29 mmol) was injected into the resulting olive-green solution by syringe. The reaction mixture was stirred for 3 h and filtered, and the dark red filtrate was reduced in volume to 5 mL. After addition of MeOH (20 mL), grey-brown microcrystals precipitated and were separated, washed with MeOH (45 mL) and Et_2O (20 mL) and dried in vacuo. Yield: 482 mg (58%). ^{1}H NMR (CD_2Cl_2, 269.72 MHz): δ = 8.08−7.68 (m, 4 H), 7.47−7.20 (m, 4 H), 7.03−6.79 (m, 4 H, C_6H_4), 1.89−1.31 (m, 18 H), 0.94 [t, 9 H, P(C_4H_9)$_3$] ppm. ^{13}C{^{1}H} NMR (CD_2Cl_2, 67.83 MHz): δ = 217.49 (d, J_{PC} = 30.5 Hz, *C*O), 157.78, 156.59 (d, J_{PC} = 7.5 Hz), 138.87, 138.75, 138.56, 136.74, 136.17, 131.93, 131.67, 130.78, 130.58, 130.29, 130.26, 129.89, 129.40, 129.29, 129.13, 122.14 [*C* (aryl)], 25.45 (d, J_{PC} = 3.7 Hz), 25.14 (d, J_{PC} = 23.6 Hz), 24.38 (d, J_{PC} = 12.4 Hz), 13.51 [s, P(C_4H_9)$_3$] ppm. ^{31}P{^{1}H} NMR (CD_2Cl_2, 161.70 MHz): δ = 34.80 (s, *Pn*Bu_3) ppm. IR (KBr): $\tilde{\nu}$ = 1956, 1953 cm^{-1} vs [ν(CO)]. IR (THF): $\tilde{\nu}$ = 1955 cm^{-1} vs [ν(CO)]. MS (FD, THF, ^{56}Fe): *m*/*z* = 642 [Fe(CO)(P*n*Bu_3)('tpS_4')]$^+$, 412 [Fe('tpS_4')]$^+$, 824 [Fe('tpS_4')]$_2^+$, 1236 [Fe('tpS_4')]$_3^+$. $C_{31}H_{39}FeOPS_4$ (642.73): calcd. C 57.93, H 6.12, S 19.96; found C 57.90, H 6.34, S 19.84.

[Fe(PMe_3)$_2$('tpS_4')] (8): $FeCl_2·4H_2O$ (62 mg, 0.31 mmol) and PMe_3 (0.65 mL, 6.21 mmol) were added to a light yellow solution of 'tpS_4'-Li_2 (115 mg, 0.31 mmol) in THF (30 mL) and MeOH (5 mL). The resulting dark green solution was stirred for 17 h, filtered and reduced in volume nearly to dryness. Upon addition of MeOH (20 mL), olive-green microcrystals precipitated, and were separated, washed with MeOH (30 mL) and Et_2O (12 mL) and dried in vacuo. Yield: 108 mg (62%). ^{1}H NMR (CD_2Cl_2, 269.72 MHz): δ = 7.99−7.93 (m, 2 H), 7.86−7.81 (vdd, 2 H), 7.31−7.24 (m, 4 H), 6.88−6.77 (m, 4 H, C_6H_4), 1.38 (vt, 18 H, P(CH_3)$_3$] ppm. ^{13}C{^{1}H} NMR (CD_2Cl_2, 100.40 MHz): δ = 160.17, 140.85, 138.74, 131.22, 130.82, 129.87, 129.65, 128.58, 121.49 [*C*

(aryl)], 18.14 (t, J_{PC} = 12.0 Hz, P(CH_3)$_3$] ppm. $^{31}P\{^1H\}$ NMR (CD_2Cl_2, 161.70 MHz): δ = 22.09 (s, PMe_3) ppm. IR (KBr): $\tilde{\nu}$ = 956, 944 cm^{-1} vs [δ(PCH)]. MS (FD, CH_2Cl_2, ^{56}Fe): *m*/*z*: 564 [Fe(PMe_3)$_2$('tpS$_4$')]$^+$, 412 [Fe('tpS$_4$')]$^+$, 824 [Fe('tpS$_4$')]$_2^+$, 1236 [Fe('tpS$_4$')]$_3^+$. $C_{24}H_{30}FeP_2S_4$ (564.56): calcd. C 51.06, H 5.36, S 22.72; found C 50.51, H 5.64, S 22.96.

[Fe(P*n*Pr$_3$)$_2$('tpS$_4$')] (9): $FeCl_2{\cdot}4H_2O$ (17 mg, 0.08 mmol) and P*n*Pr$_3$ (0.17 mL, 0.8 mmol) were added to a light yellow solution of 'tpS$_4$'-Li$_2$ (31 mg, 0.08 mmol) in THF (6 mL) and MeOH (1 mL). The resulting solution was stirred for 14 h and concentrated to dryness. A dark green residue resulted, and was dried in vacuo for 20 min and dissolved in CD_2Cl_2 (0.7 mL) to which a few drops of P*n*Pr$_3$ had been added, in order to record NMR spectra. $^{31}P\{^1H\}$ NMR (CD_2Cl_2, 161.70 MHz): δ = 29.1 (s, *Pn*Pr$_3$), −33.4 (s, exc. *Pn*Pr$_3$) ppm. MS (FD, CH_2Cl_2, ^{56}Fe): *m*/*z*: 732 [Fe(P*n*Pr$_3$)$_2$('tpS$_4$')]$^+$, 412 [Fe('tpS$_4$')]$^+$, 824 [Fe('tpS$_4$')]$_2^+$, 1236 [Fe('tpS$_4$')]$_3^+$.

[Fe(P*n*Bu$_3$)$_2$('tpS$_4$')] (10): $FeCl_2{\cdot}4H_2O$ (23 mg, 0.12 mmol) and P*n*Bu$_3$ (0.23 mL, 1.2 mmol) were added to a light yellow solution of 'tpS$_4$'-Li$_2$ (43 mg, 0.12 mmol) in THF (10 mL) and MeOH (2 mL). The resulting solution was stirred for 15 h and concentrated to dryness. The resulting dark green residue was dried in vacuo for 15 min and dissolved in CD_2Cl_2 (0.7 mL) to which a few drops of P*n*Bu$_3$ had been added in order to record NMR spectra. $^{31}P\{^1H\}$ NMR (CD_2Cl_2, 161.70 MHz): δ = 30.3 (s, *Pn*Bu$_3$), −30.2 (s, exc. *Pn*Bu$_3$) ppm. MS (FD, CH_2Cl_2, ^{56}Fe): *m*/*z*: 816 [Fe(P*n*Bu$_3$)$_2$('tpS$_4$')]$^+$, 412 [Fe('tpS$_4$')]$^+$, 824 [Fe('tpS$_4$')]$_2^+$, 1236 [Fe('tpS$_4$')]$_3^+$.

[Fe(dppe)('tpS$_4$')] (11): $FeCl_2{\cdot}4H_2O$ (98 mg, 0.49 mmol) and dppe (196 mg, 0.49 mmol) were added to a light yellow solution of 'tpS$_4$'-Li$_2$ (183 mg, 0.49 mmol) in THF (20 mL) and MeOH (8 mL). The resulting dark green solution was stirred for 90 min, filtered, reduced in volume to 5 mL and combined with MeOH (30 mL). A light green precipitate formed, and this was separated, washed with MeOH (30 mL) and Et_2O (10 mL) and dried in vacuo. Yield: 274 mg (**11**·2MeOH) (63%). ^1H NMR (CD_2Cl_2, 269.72 MHz): δ = 8.15−7.97 (m, 6 H), 7.61−7.43 (m, 8 H), 7.34−7.23 (m, 2 H), 7.05 (vt, 4 H), 6.89−6.66 (m, 6 H), 6.59−6.43 (m, 4 H), 6.30 (vdt, 2 H, C_6H_4, C_6H_5), 3.27−2.76 (m, 4 H, $Ph_2PC_2H_4PPh_2$) ppm. $^{13}C\{^1H\}$ NMR (CD_2Cl_2, 100.40 MHz): δ = 157.90 (t, J_{PC} = 4.1 Hz), 140.79 (t, J_{PC} = 6.0 Hz), 138.41, 134.33, 134.15, 134.13, 134.00, 133.97, 133.83, 133.36 (t, J_{PC} = 4.2 Hz), 131.70 (t, J_{PC} = 4.1 Hz), 131.24, 130.42, 130.17, 130.02, 129.70, 128.43 (t, J_{PC} = 3.6 Hz), 127.95, 126.50 (t, J_{PC} = 4.6 Hz), 121.10 (C_6H_4, C_6H_5, partly covered), 26.23 (t, J_{PC} = 21.0 Hz, $Ph_2PC_2H_4PPh_2$) ppm. $^{31}P\{^1H\}$ NMR (CD_2Cl_2, 161.70 MHz): δ = 74.01 (s, $Ph_2PC_2H_4PPh_2$) ppm. IR (KBr): $\tilde{\nu}$ = 735, 695 cm^{-1} vs [δ(PCH)]. MS (FD, CH_2Cl_2, ^{56}Fe): *m*/*z*: 810 [Fe(dppe)('tpS$_4$')]$_3^+$. $C_{46}H_{44}FeO_2P_2S_4$ (**11**·2MeOH) (874.91): calcd. C 63.15, H 5.07, S 14.66; found C 63.39, H 4.87, S 14.65.

[Fe(NO)$_2$('tpS$_4$')] (12): $FeCl_2{\cdot}4H_2O$ (52 mg, 0.25 mmol) was added to a light yellow solution of 'tpS$_4$'-Li$_2$ (93 mg, 0.25 mmol) in CH_2Cl_2 (30 mL) and MeOH (10 mL). The reaction mixture was filtered, and NO gas (11.4 mL, 0.50 mmol) was injected into the dark orange filtrate by syringe. After stirring for 1 h, the solution was reduced in volume to 4 mL. A red-brown solid precipitated, and this was separated, washed with MeOH (20 mL) and Et_2O (20 mL) and dried in vacuo. Yield: 50 mg (**12**·1.5MeOH) (38%). ^1H NMR (CD_2Cl_2, 269.72 MHz): δ = 7.85−6.45 (m, C_6H_4) ppm. MS (FD, CH_2Cl_2, ^{56}Fe): *m*/*z*: 472 [Fe(NO)$_2$('tpS$_4$')]$^+$, 442 [Fe(NO)('tpS$_4$')]$^+$, 412 [Fe('tpS$_4$')]$^+$, 824 [Fe('tpS$_4$')]$_2^+$, 1236

X-ray Structure Analyses of [Fe(CO)('tpS_4')]$_2$·MeOH (3·MeOH), [Fe(CO)(PMe_3)('tpS_4')] (4), [Fe(CO)(PBu_3)('tpS_4')] (7) and [Fe(PMe_3)$_2$('tpS_4')] (8): Dark red single crystals of **3**·MeOH were formed by layering a saturated THF solution of **3** with MeOH. Green platelets of **4** and brown crystals of **7** were grown by layering saturated CH_2Cl_2 solutions of **4** and **7** with MeOH. Black single crystals of **8** were obtained by layering a saturated THF solution of **8** with Et_2O. Suitable single crystals were either embedded in protective perfluoro polyalkyl ether oil or sealed in a glass capillary under N_2. The structures were solved by direct methods, and full-matrix, least-squares refinement was carried out on F^2 values.[14] All non-hydrogen atoms were refined anisotropically. All hydrogen atoms are geometrically positioned. The MeOH solvate molecule in **3**·MeOH is disordered on a crystallographic 4_1 axis, no hydrogen atoms have been taken into account for this molecule. The PBu_3 ligand in **7** is strongly disordered. Selected crystallographic data are summarised in Table 2.[15]

Chloro- and Alkyltitanium Complexes of a New Dianionic Ancillary Ligand: A Linked Amidinate−Amide[‡]

Wouter J. van Meerendonk,[a] Kai Schröder,[a] Edward A. C. Brussee,[a] Auke Meetsma,[a] Bart Hessen,*[a] and Jan H. Teuben[a]

Keywords: N ligands / Tridentate ligands / Titanium / Alkyl complexes

The lithium amidinate $[Me_3SiNC(Ph)N(CH_2)_3N(Me)SiMe_3]$-Li(THF) (**2**), with a pendant methyl(trimethylsilyl)amine functionality, was prepared and found to react with $[TiCl_4(THF)_2]$ to give the titanium amidinate–amide dichloride complex $[\eta^2,\eta^1$-$Me_3SiNC(Ph)N(CH_2)_3NMe]TiCl_2$ (**3**) by elimination of LiCl and Me_3SiCl. The elimination of Me_3SiCl from the cyclopentadienyl derivative $Cp[\eta^2$-$Me_3SiNC(Ph)N(CH_2)_3N(SiMe_3)Me]TiCl_2$ (**5**) to give $Cp[\eta^2,\eta^1$-$Me_3SiNC(Ph)N(CH_2)_3NMe]TiCl$ (**4**) is much less favorable, and was found to be readily reversible. Dialkyltitanium complexes $[\eta^2,\eta^1$-$Me_3SiNC(Ph)N(CH_2)_3NMe]Ti(CH_2R)_2$ [R = Ph (**6**), $SiMe_3$ (**7**)] were prepared, but could not be activated for catalytic ethene polymerization.

Introduction

Amidinate monoanions $[RC(NR')_2]^-$ (R = aryl, alkyl; R′ = aryl, alkyl, $SiMe_3$) form a group of versatile ancillary ligands (binding predominantly in an *N*,*N*′-bidentate fashion) that have been employed extensively in main-group and transition-metal coordination chemistry, organometallic chemistry and catalysis.[1−5] They can also be incorporated as a functionality in polydentate ligand systems. Examples have been reported recently of the synthesis and complexation chemistry of monoanionic tridentate amidinate Lewis base[6−9] and dianionic tetradentate bis(amidinate) ligands.[10−12] One way to prepare amidinate-based polydentate ligands is the reaction of functionalized trimethylsilylamides with nitriles.[6,8,9,12] Here we report the use of this method to prepare the amidinate $[Me_3SiNC(Ph)N(CH_2)_3N(SiMe_3)Me]^-$ with a pendant alkyl(trimethylsilyl)amine functionality. Reaction of the Li salt of this amidinate with titanium chlorides leads to the formation of titanium complexes of the new dianionic amidinate−amide tridentate ligand $[Me_3SiNC(Ph)N(CH_2)_3NMe]^{2-}$ by sequential salt metathesis and Me_3SiCl elimination reactions. The synthesis, structure and reactivity of two of these titanium complexes, $[Me_3SiNC(Ph)N(CH_2)_3NMe]TiCl_2$ and Cp-$[Me_3SiNC(Ph)N(CH_2)_3NMe]TiCl$, are described.

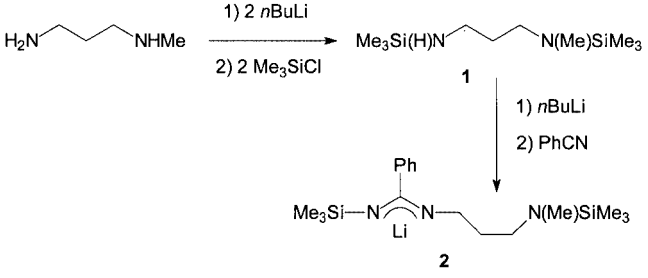
Results and Discussion

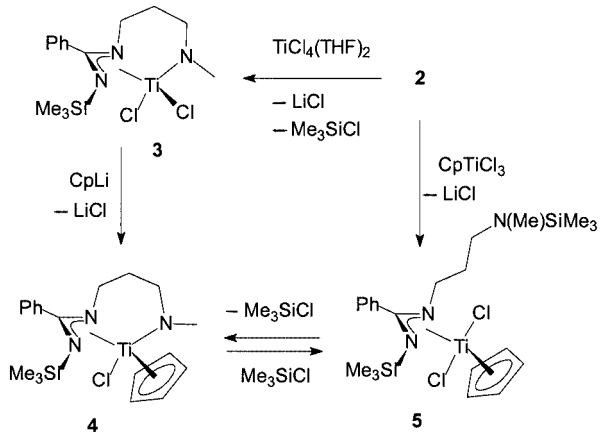
The Li salt of an amidinate with a pendant alkyl(trimethylsilyl)amine group, $[Me_3SiNC(Ph)N(CH_2)_3N(SiMe_3)Me]^-$, was prepared by the deprotonation of the diamine Me_3Si-$N(H)(CH_2)_3N(Me)SiMe_3$ (**1**) with *n*BuLi/hexane in THF, followed by reaction with benzonitrile (Scheme 1). After recrystallization from pentane, the resulting Li amidinate was obtained analytically pure as its THF solvate $[Me_3Si$-$NC(Ph)N(CH_2)_3N(Me)SiMe_3]Li(THF)$ (**2**) in 55% isolated yield. The presence of THF in **2** probably indicates that the pendant methyl(trimethylsilyl)amine functionality is not coordinated to the Li ion, in contrast to the THF-free Li amidinate−amine $[Me_3SiNC(Ph)N(CH_2)_3NMe_2]Li$, which was found to adopt a dimeric structure with a coordinated amine functionality.[9]



Scheme 1

The Li amidinate **2** reacts with $[TiCl_4(THF)_2]$ in THF to give the titanium amidinate−amide complex $[\eta^2,\eta^1$-Me_3Si-$NC(Ph)N(CH_2)_3NMe]TiCl_2$ (**3**) by elimination of LiCl and

Me_3SiCl (Scheme 2). After recrystallization from diethyl ether, complex **3** was obtained as orange-red crystals, analytically pure, in 56% yield.



Scheme 2

A single-crystal X-ray structure determination of **3** (Figure 1) showed that the amidinate moiety of the ligand is *N*,*N*′-dihapto bound to the metal center [Ti−N(1) = 2.077(2) Å and Ti−N(2) = 2.059(2) Å]. The Ti−N distance to the amido nitrogen atom is significantly shorter [Ti−N(3) = 1.863(2) Å] than those to the amidinate nitrogen atoms, probably in response to an amide N(p) π-donation to Ti(d). The amidinate nitrogen atom linked to the alkylamide moiety deviates somewhat from planarity [the sum of the angles around N(2) is 353.8°], but this deviation is not as pronounced as in the vanadium amidinate−amine complex [η^2,η^1-$Me_3SiNC(Ph)N(CH_2)_2NMe_2$]$VCl_2$(THF) in which the sum of the angles around N is 336.4°[6] and where the amidinate−amine tridentate ligand clearly adopts a *fac* coordination geometry. The amide nitrogen atom in **3** is planar [the sum of the angles around N(3) is 360.0°], again indicative of efficient amide-to-metal π-donation. The angles around this atom show significant asymmetry, with the Ti−N−C angle within the six-membered ring [Ti−N(3)−C(13) = 137.0(2)°] being significantly larger than the Ti−N−C(Me) angle [Ti−N(3)−C(14) = 110.2(2)°]. The solution NMR spectra of **3** are consistent with C_s symmetry, indicating that the amidinate−amide acts as a meridional-type ligand, and that the six-membered TiN_2C_3 ring, which adopts a boat-like conformation in the crystal structure, readily inverts.

The rapid formation in high yield of the amidinate−amide complex **3** in the reaction of $TiCl_4(THF)_2$ with the Li amidinate **2** indicates that the Me_3SiCl elimination reaction from [η^2-Me_3Si-$NC(Ph)N(CH_2)_3N(SiMe_3)Me]TiCl_3$, the likely primary product of the salt metathesis reaction, is facile. The reverse reaction − formation of group-4 metal chlorides by reaction of group-4 metal amides with an excess of Me_3SiCl − was reported as a clean, salt-free route to generate group-4 metallocene dichlorides from their corresponding bis(amides).[13−15] Apparently, in our case the chelate effect

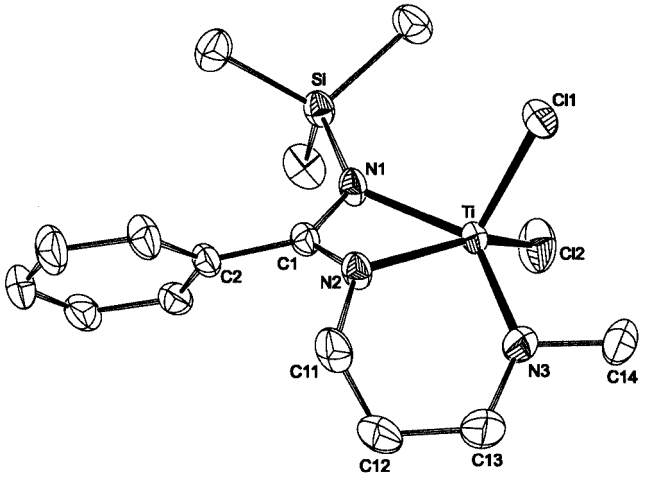


Figure 1. Molecular structure of compound **3**; thermal ellipsoids are drawn at the 50% probability level; Ti−Cl(1) 2.2464(6), Ti−Cl(2) 2.2954(7), Ti−N(1) 2.077(2), Ti−N(2) 2.059(2), Ti−N(3) 1.863(2) Å; Cl(1)−Ti−Cl(2) 107.26(2), N(1)−Ti−N(2) 64.03(6), N(1)−Ti−N(3) 139.40(7), N(2)−Ti−N(3) 84.08(7), N(3)−Ti−Cl(1) 107.72(6), N(3)−Ti−Cl(2) 100.83(6), Ti−N(3)−C(13) 137.0(2), Ti−N(3)−C(14) 110.2(2)°

leads to a thermodynamically favored elimination of Me_3SiCl and formation of the metal−amide bond in **3**.

The reaction of [$CpTiCl_3$] with the Li amidinate **2** in THF, followed by extraction with, and crystallization from, diethyl ether, resulted only in a low isolated yield (13%) of the corresponding amidinate−amide complex Cp[η^2,η^1-$Me_3SiNC(Ph)N(CH_2)_3NMe]TiCl$ (**4**), which was characterized by single-crystal X-ray diffraction (vide infra). Workup of the reaction mixture was made more difficult by the presence of a substantial amount of an orange oil, which appeared to be the major product of the reaction, but which defied crystallization. Investigation of the reaction between [$CpTiCl_3$] and **2** in [D_8]THF at ambient temperature initially showed rapid formation of a primary product, identified as Cp[η^2-$Me_3SiNC(Ph)N(CH_2)_3N(SiMe_3)Me]TiCl_2$ (**5**) from its NMR characteristics (which are identical to those of the orange oil observed in the reaction on preparative scale). This initial reaction is followed by slow release of Me_3SiCl and concomitant formation of the amidinate−amide complex **4** (Scheme 2). Characteristic for the latter are the significant downfield shift of the NMR resonances associated with the NMe group (^{1}H: δ = 3.21 ppm; ^{13}C: δ = 51.0 ppm) relative to those in **5** (^{1}H: δ = 2.29 ppm; ^{13}C: δ = 35.3 ppm). The secondary reaction can be accelerated by increasing the reaction temperature (50−80 °C), but this is then accompanied by the formation of unidentified degradation products. The Me_3SiCl elimination reaction appears to be noticeably faster when the reaction is performed in C_6D_6 rather than in the Lewis basic solvent [D_8]THF, proceeding readily at ambient temperature. The reaction was observed to reach an equilibrium (in C_6D_6 and 25 °C within 30 min), suggesting that the reaction is readily reversible in the mono(cyclopentadienyl)titanium system. Indeed, upon addition of Me_3SiCl to C_6D_6 solutions of the amidinate−amide complex **4** the formation

of **5** could be observed. Examination of C_6D_6 solutions of **4** of known concentration to which 1, 2 or 3 equiv. of Me_3SiCl were added allowed a determination of the equilibrium constant at 25 °C of the equilibrium of **4** + Me_3SiCl with **5** as K = [**5**]/([**4**] + [Me_3SiCl]) = 32(3) L mol^{-1}. Compound **4** was also prepared independently, in 38% isolated yield, by the reaction of the dichloride **3** with CpLi, in which this equilibrium is avoided. This reaction appears to suffer from some reduction of the metal center, as seen from the dark residue left after extraction of the reaction mixture with hexane and the relatively modest isolated yield.

The molecular structure of **4** (Figure 2) shows a fully symmetrically bound η^5-cyclopentadienyl ligand and an η^2,η^1-amidinate−amide ligand in which the TiN_2C_3 ring now adopts a twisted conformation. The amidinate nitrogen atom attached to the alkylamide moiety is significantly less planar [sum of the angles around N(2) is 340.6°] than in **3**. The angles around the (planar) amide nitrogen atom are again highly asymmetric, but in the opposite direction than in **3**: the Ti−N−C angle within the six-membered ring [Ti−N(1)−C(7) = 105.6(2)°] is now significantly smaller than the Ti−N−C(Me) angle [Ti−N(1)−C(6) = 141.6(2)°]. This is probably in response to the twisted conformation of the six-membered ring. It also reduces the steric interaction of the amide methyl group with the cyclopentadienyl ligand, towards which it is pointing. Overall, the metal−ligand distances in **4** are larger than those in **3** [especially the Ti−Cl distance of 2.4038(7) Å, compared to 2.2464(6) and 2.2954(7) Å in **3**] but the metal−amide distances are similar [1.887(2) Å in **4**, 1.863(2) Å in **3**], indicating the importance of the amide-to-metal π-donation.

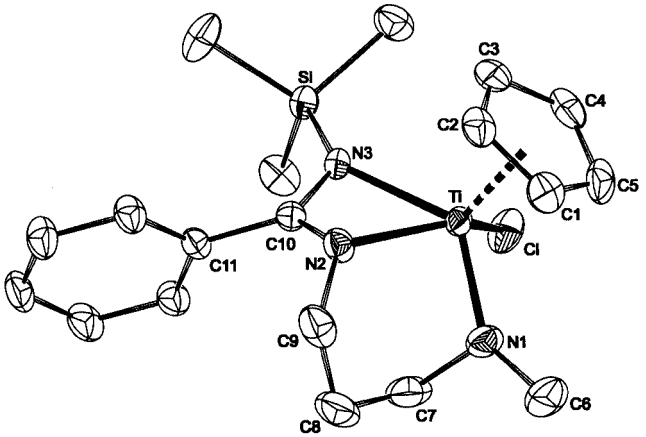

Figure 2. Molecular structure of compound **4**; thermal ellipsoids are drawn at the 50% probability level; Ti−Cl 2,4038(7), Ti−N(1) 1.887(2), Ti−N(2) 2.095(2), Ti−N(3) 2.170(2) Å; N(1)−Ti−N(2) 85.12(7), N(1)−Ti−N(3) 128.61(7), N(2)−Ti−N(3) 61.96(6), N(1)−Ti−Cl 93.96(6), Ti−N(1)−C(6) 141.6(2), Ti−N(1)−C(7) 105.6(2)°

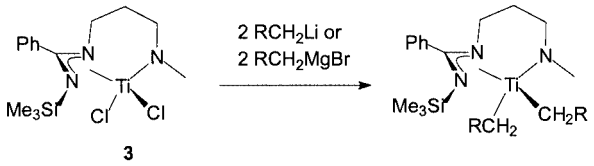
The amidinate−amide dichloride **3** may be converted into the corresponding dialkyltitanium amidinate−amide complexes, which are precursors to cationic monoalkyl species that are interesting as potential olefin polymerization catalysts. Reaction of **3** with 2 equiv. of either $PhCH_2MgBr$ or Me_3SiCH_2Li results in the formation of the dialkyl complexes [η^2,η^1-$Me_3SiNC(Ph)N(CH_2)_3NMe$]-$Ti(CH_2R)_2$ [R = Ph (**6**), $SiMe_3$ (**7**); Scheme 3]. Compound **6** was obtained in 74% yield as yellow crystals by crystallization from pentane, whereas **7** is an extremely soluble oil that only gradually solidifies on standing. The compounds are thermally rather labile, and are best handled and stored below 0 °C. Their solution NMR spectra are consistent with an average C_s symmetry, and each show two doublets for the diastereotopic alkyl methylene protons in the ^{1}H NMR spectrum (**6**: δ = 2.75 and 3.09 ppm, $^2J_{H,H}$ = 9.0 Hz; **7**: δ = 1.56 and 1.86 ppm, $^2J_{H,H}$ = 11.0 Hz).



Scheme 3

The dibenzyl complex **6** was treated with the Lewis acid $B(C_6F_5)_3$ in C_6D_6 and in [D_5]bromobenzene solvents in order to effect the abstraction of a benzyl anion. As the ligand system is sterically not very demanding, the formation of a contact ion pair with an η^6-$PhCH_2B(C_6F_5)_3$ interaction might be anticipated, as was observed recently for titanium in the reaction of [(2,6-diphenylphenoxide)$_2$Ti(CH_2Ph)$_2$] with $B(C_6F_5)_3$.[16,17] However, in both solvents rapid decomposition to a mixture of unidentified products was observed, even when the reaction in [D_5]bromobenzene was performed at −20 °C. Attempts at catalytic ethene polymerization (5 bar of ethene, 150 mL of toluene solvent, 50 °C, 15 μmol of Ti) by treating **6** with $B(C_6F_5)_3$ or **7** with [$PhNMe_2H$][$B(C_6F_5)_4$] in the presence of monomer did not result in ethene uptake, suggesting that the decomposition of the cationic species generated is rapid. It is likely that the present amidinate−amide ligand is either reactive itself and/or provides insufficient steric protection to the highly electron-deficient metal center.

Conclusion

Titanium complexes of the new dianionic η^2,η^1-amidinate−amide ligand can be prepared by sequential salt metathesis and Me_3SiCl elimination reactions that occur upon combining titanium chlorides with a lithium amidinate containing a pendant (trimethylsilyl)amide functionality. The Me_3SiCl elimination reaction forming the titanium−amide bond is thermodynamically favored by its intramolecular nature, but it is reversible, and the equilibrium is dependent on what is probably a combination of electronic and steric factors. The formation of the TiN_2C_3 six-membered ring is clearly less favorable in the more electron-rich and sterically more encumbered [Cp(amidinate)-$TiCl_2$] species **5** than in the (amidinate)$TiCl_3$ intermediate

proposed in the formation of **3**. The dialkyltitanium derivatives [η^2,η^1-$Me_3SiNC(Ph)N(CH_2)_3NMe$]$Ti(CH_2R)_2$ (R = Ph, $SiMe_3$) are readily prepared but are thermally rather labile, and could not be converted into well-defined cationic alkyl compounds that are active in catalytic olefin polymerization. Possibly the present substitution pattern of the ligand ($SiMe_3$ on the amidinate nitrogen atom, Me on the amido nitrogen atom) renders it incapable of stabilizing such highly reactive species, and sterically more demanding substituents may be required for catalytic activity.

Experimental Section

General Remarks: All experiments were carried out under purified dinitrogen using standard Schlenk and glove-box techniques. Solvents were distilled from Na/K alloy (THF, diethyl ether, pentane, hexane) or sodium (toluene) under nitrogen before use. Deuterated solvents were either dried with Na/K alloy and vacuum-transferred before use (C_6D_6, [D_8]THF) or degassed and stored over 4-Å molecular sieves ([D_5]bromobenzene). $[TiCl_4(THF)_2]$[18] and $[CpTiCl_3]$,[19] were prepared according to published procedures. Benzonitrile, *n*BuLi/hexane, Me_3SiCl and $MeNH(CH_3)_3NH_2$ were purchased and used as received. NMR spectra were recorded with Varian Gemini 200, VXR 300 and Unity 500 spectrometers. The ^{1}H NMR spectra were referenced to the resonances of residual protons in the deuterated solvent. Chemical shifts (δ) are given relative to tetramethylsilane (downfield shifts are positive). Elemental analyses were performed at the Microanalytical Department of the University of Groningen. All values are the average of at least two independent determinations.

Synthesis of $Me_3SiN(H)(CH_2)_3N(Me)SiMe_3$ (1): This compound was prepared according to a modification of a published procedure.[20] A 2.5 M solution of *n*BuLi in hexane (160 mL, 0.40 mol) was slowly added to a solution of $MeNH(CH_3)_3NH_2$ (20.9 mL, 0.20 mol) in 50 mL of hexane. After refluxing for 2.5 h, Me_3SiCl (50.5 mL, 0.40 mol) was added dropwise, and the mixture was subsequently refluxed for one more hour. From the resulting deep orange suspension, the volatiles were flash-distilled at 90 °C and 0.05 Torr. Subsequent vacuum distillation of this liquid (14 Torr) yielded the product as a spectroscopically pure colorless liquid at 98−101 °C (29.3 g, 0.126 mol, 63%). ^{1}H NMR (300 MHz, C_6D_6): δ = 0.09 (s, 18 H, $SiMe_3$), 1.46 (m, 2 H, $CH_2CH_2CH_2$), 2.39 (s, 3 H, NCH_3), 2.70 (t, $^3J_{H,H}$ = 7.7 Hz, 2 H, $HNCH_2$), 2.64 (t, $^3J_{H,H}$ = 7.0 Hz, 2 H, $MeNCH_2$) ppm. ^{13}C{^{1}H} NMR (75 MHz, C_6D_6): δ = 0.2 [$Si(CH_3)_3$], 34.0 ($CH_2CH_2CH_2$), 34.1 (NCH_3), 39.8 ($HNCH_2$), 49.0 ($MeNCH_2$) ppm. IR (neat, KBr): $\tilde{\nu}$ = 3420 (br. w), 2969 (s), 2854 (m), 2795 (w), 1453 (w), 1400 (m), 1375 (w), 1330 (w), 1253 (s), 1189 (w), 1144 (m), 1110 (m), 1020 (w), 980 (w), 943 (w), 835 (s), 746 (m), 677 (m) cm^{-1}.

Synthesis of $[Me_3SiNC(Ph)N(CH_2)_3N(Me)SiMe_3]Li(THF)$ (2): A solution of **1** (4.2 mL, 18 mmol) in 50 mL of THF was cooled to −80 °C after which a 2.5 M solution of *n*BuLi in hexane (8 mL, 20 mmol) was added dropwise. The solution was allowed to warm to room temperature and was subsequently stirred for 2 h. The light yellow mixture was cooled to −80 °C and benzonitrile (1.8 mL, 17 mmol) was added, after which the mixture was allowed to warm to room temperature. The volatiles from the orange-yellow mixture were removed in vacuo, and the solid residue was recrystallized twice from pentane. Yield: 4.13 g (9.93 mmol, 55%) of a light yellow solid. ^{1}H NMR (300 MHz, C_6D_6): δ = −0.08 [s, 9 H, $Si(CH_3)_3$], −0.03 [s, 9 H, $Si(CH_3)_3$], 1.28 (m, 4 H, THF β-H), 1.58 (m, 2 H, $CH_2CH_2CH_2$), 2.44 (s, 3 H, NCH_3), 2.47 (t, $^3J_{H,H}$ = 7.0 Hz, 2 H, NCH_2), 2.98 [t, $^3J_{H,H}$ = 7.3 Hz, 2 H, $N(Me)CH_2$], 3.58 (m, 4 H, THF α-H), 7.0−7.2 (m, 5 H, Ph) ppm. ^{13}C{^{1}H} NMR (50 MHz, C_6D_6): δ = −0.9 and 3.6 [$Si(CH_3)_3$], 25.7 (THF β-C), 32.6 ($CH_2CH_2CH_2$), 34.3 (NCH_3), 48.4 and 49.3 (NCH_2), 68.3 (THF α-C), 126.9, 127.8, 128.1 (Ph *C*H), 143.3 (Ph *C*), 177.5 (*N*CN) ppm. $C_{21}H_{40}N_3LiOSi_2$ (413.68): calcd. C 60.97, H 9.75, N 10.16; found C 61.17, H 9.60, N 10.45.

Synthesis of $[Me_3SiNC(Ph)N(CH_2)_3NMe]TiCl_2$ (3): A solution of **2** (2.45 g, 5.93 mmol) and $TiCl_4(THF)_2$ (1.98 g, 5.93 mmol) in 70 mL of THF was stirred overnight at room temperature. The dark red solution was stirred for another 8 h, during which the flask was periodically briefly evacuated. The volatiles were removed in vacuo, and the residue was freed of residual THF by stirring twice with diethyl ether (15 mL), which was subsequently removed in vacuo. The residue was extracted three times with diethyl ether (30 mL) after which the extract was concentrated and cooled to −80 °C, yielding microcrystalline orange-red **3** (1.26 g, 3.31 mmol, 56%). Crystals suitable for X-ray diffraction were obtained by cooling a solution of **3** in diethyl ether to −20 °C. ^{1}H NMR (300 MHz, C_6D_6): δ = 0.24 [s, 9 H, $Si(CH_3)_3$], 1.35 (m, 2 H, $CH_2CH_2CH_2$), 2.60 (m, 2 H, NCH_2), 2.99 (m, 2 H, $MeNCH_2$), 3.74 (s, 3 H, NCH_3), 6.93−6.99 (m, 5 H, Ph) ppm. ^{13}C{^{1}H} NMR (75 MHz, C_6D_6): δ = 0.2 [$Si(CH_3)_3$], 31.8 ($CH_2CH_2CH_2$), 43.0 (NCH_2), 46.6 (NCH_3), 61.8 (NCH_2), 126.8, 127.7, 130.4 (Ph *C*H), 132.7 (Ph *C*) ppm; *N*CN signal not observed. $C_{14}H_{23}Cl_2N_3SiTi$ (380.23): calcd. C 44.22, H 6.10, N 11.05, Ti 12.60; found C 44.36, H 6.03, N 11.12, Ti 12.50.

Synthesis of $Cp[Me_3SiNC(Ph)N(CH_2)_3NMe]TiCl$ (4). Method 1: A solution of **2** (1.07 g, 2.56 mmol) in 40 mL of THF was cooled to −80 °C, after which $CpTiCl_3$ (0.57 g, 2.59 mmol) was added. The solution was allowed to warm to room temperature, during which time the color changed from yellow to orange-red. After stirring for 2 h, the volatiles were removed in vacuo and the residual THF was removed by stirring the mixture in pentane, which was subsequently pumped off. The residue was extracted twice with diethyl ether (20 mL). Concentrating and cooling the extract to −20 °C yielded red crystalline **4** (0.14 g, 0.34 mmol, 13%). Crystals suitable for X-ray diffraction were obtained by cooling a concentrated solution of **4** in diethyl ether from room temperature to 7 °C. **Method 2:** Hexane (15 mL) was condensed onto a mixture of solid **3** (0.11 g, 0.28 mmol) and CpLi (20 mg, 0.28 mmol), frozen in liquid nitrogen. The mixture was allowed to thaw and warm to room temperature. After stirring for one more hour, the suspension was filtered and the volatiles were removed from the filtrate in vacuo. Extraction of the residue with hexane, and concentrating and cooling the extract to −20 °C, yielded microcrystalline **4** (54 mg, 0.13 mmol, 38%). ^{1}H NMR (500 MHz, C_6D_6): δ = 0.17 [s, 9 H, $Si(CH_3)_3$], 1.13, 1.33 (m, 1 H each, $CH_2CH_2CH_2$), 2.43 (ddd, $^2J_{H,H}$ = 12.4, $^3J_{H,H}$ = 8.8, 5.7 Hz, 1 H, $NCHH$), 2.65 (ddd, $^2J_{H,H}$ = 14.8, $^3J_{H,H}$ = 6.2, 4.4 Hz, 1 H, $MeNCHH$), 3.03 (ddd, overlapped, 1 H, $NCHH$), 3.04 (s, 3 H, NCH_3), 3.38 (ddd, $^2J_{H,H}$ = 14.8, $^3J_{H,H}$ = 7.6, 4.3 Hz, 1 H, $NCHH$), 6.24 (s, 5 H, C_5H_5), 6.98−7.03 (m, 5 H, Ph) ppm. ^{13}C{^{1}H} NMR (126 MHz, C_6D_6): δ = 2.6 [$Si(CH_3)_3$], 29.8 ($CH_2CH_2CH_2$), 44.8 ($MeNCH_2$), 49.8 (NCH_3), 58.6 (NCH_2), 114.5 (C_5H_5), 127.0, 128.6, 129.3 (Ph *C*H), 135.0 (Ph *C*), 174.3 (*N*CN) ppm. $C_{19}H_{28}ClN_3SiTi$ (409.89): calcd. C 55.68, H 6.89, N 10.25; found C 55.10, H 6.89, N 9.75.

Reaction of $[CpTiCl_3]$ with 2 in [D_8]THF: Separately prepared solutions of $[CpTiCl_3]$ (17 mg, 0.08 mmol) and **2** (33 mg, 0.08 mmol), each in 0.4 mL of [D_8]THF, were mixed at ambient temperature,

resulting in a rapid color change from light yellow to orange, and the mixture was added into an NMR tube, equipped with a Teflon valve. The ^{1}H and ^{13}C NMR spectra indicated formation of Cp[$Me_3SiNC(Ph)N(CH_2)_3N(Me)SiMe_3$]TiCl (**5**). ^{1}H NMR (300 MHz, [D_8]THF): δ = −0.11, −0.05 [s, 9 H each, Si(CH_3)$_3$], 1.66 (m, 2 H, CH_2), 2.29 (s, 3 H, NCH_3), 2.52 (t, $^3J_{H,H}$ = 6.8 Hz, 2 H, MeNCH_2), 3.03 (m, 2 H, NCH_2), 6.83 (s, 5 H, C_5H_5), 7.33 (m, 2 H, Ph *m*-H), 7.45 (m, 3 H, Ph *o*-H and *p*-H) ppm. ^{13}C(APT) NMR (75 MHz, [D_8] THF): δ = 0.4, 3.3 [Si(CH_3)$_3$], 31.6 (CH_2), 35.3 (NCH_3), 49.8, 52.2 (NCH_2), 122.0 (C_5H_5), 128.7, 130.4, 131.5 (Ph *C*H), 135.2 (Ph *C*), 172.2 (N*C*N) ppm. Upon standing at ambient temperature or 50 °C, gradual formation of **4** and Me_3SiCl was observed. At 50 °C a maximum conversion of 34% was reached (after 24 h, with concomitant formation of some degradation products). ^{1}H NMR (300 MHz, [D_8]THF, characteristic resonances): δ = −0.11 [s, Si(CH_3)$_3$], 3.21 (s, 3 H, NCH_3), 6.30 (s, 5 H, C_5H_5) ppm. ^{13}C(APT) NMR (75 MHz, [D_8]THF): δ = 51.0 (NCH_3), 116.1 (C_5H_5) ppm.

Reaction of 4 with Me_3SiCl: Three NMR tubes were charged each with a solution of **4** in C_6D_6 to which measured amounts of a stock solution of Me_3SiCl in C_6D_6 was added. Initial concentrations of [**4**]/[Me_3SiCl] in the three tubes were: 0.030:0.035, 0.029:0.069 and 0.029:0.100 mol L^{-1}. After 30 min at 25 °C, the relative amounts of **4**, **5** and Me_3SiCl were determined by ^{1}H NMR spectroscopy. Observed ratios after 1 h were the same, indicating that equilibrium had been reached. Values determined for K = [**5**]/([**4**] + [Me_3SiCl]) were 32, 33 and 33(2) L mol^{-1}, respectively, for the three samples. Cp[$Me_3SiNC(Ph)N(CH_2)_3N(Me)SiMe_3$]$TiCl_2$ (**5**): ^{1}H NMR (500 MHz, C_6D_6): δ = −0.04 [s, 9 H, Si(CH_3)$_3$], 0.04 [s, 9 H, Si(CH_3)$_3$], 1.63 (m, 2 H, $CH_2CH_2CH_2$), 2.27 (s, 3 H, NCH_3), 2.49 (t, $^3J_{H,H}$ = 7.3 Hz, 2 H, NCH_2), 3.22 (m, 2 H, NCH_2), 6.55 (s, 5 H, C_5H_5), 6.70−6.95 (m, 5 H, Ph) ppm.

Synthesis of [$Me_3SiNC(Ph)N(CH_2)_3NMe$]$Ti(CH_2Ph)_2$ (6): A solution of **3** (0.316 g, 0.83 mmol) in 30 mL of diethyl ether was cooled to −100 °C and a 1.56 M solution of $PhCH_2MgBr$ in diethyl ether (1.07 mL, 1.66 mmol) was slowly added. The solution was allowed to warm to −15 °C, at which temperature the mixture was stirred for 2 h. During workup the temperature of the mixture was kept at or below −15 °C. The volatiles were removed in vacuo and the mixture was stirred twice with 10 mL of precooled pentane, which was subsequently pumped off. The residue was extracted with pentane, after which the extract was concentrated and cooled to −60 °C. This yielded crystalline **6** (0.302 g, 0.62 mmol, 74%). ^{1}H NMR (300 MHz, C_6D_6): δ = 0.26 [s, 9 H, Si(CH_3)$_3$], 1.07 (m, 2 H, $CH_2CH_2CH_2$), 2.63 (m, 2 H, NCH_2), 2.75, 3.09 (d, $^2J_{H,H}$ = 9.0 Hz, 2 H each, TiCH_2), 3.80 (s, 3 H, NCH_3), 6.9−7.2 (m, 15 H, Ph) ppm. ^{13}C{^{1}H} NMR (75 MHz, C_6D_6): δ = 3.0 [Si(CH_3)$_3$], 31.2 ($CH_2CH_2CH_2$), 40.8 (MeNCH_2), 45.4 (NCH_3), 59.9 (NCH_2), 84.5 (TiCH_2), 122.2, 126.5, 127.2, 128.6, 128.8, 129.3 (Ph *C*H), 134.6 (Ph *C*), 144.4 (CH_2Ph *C*), 177.4 (N*C*N) ppm. $C_{28}H_{37}N_3SiTi$ (491.59): calcd. C 68.41, H 7.59, N 8.55; found C 68.32, H 7.53, N 8.44.

Synthesis of [$Me_3SiNC(Ph)N(CH_2)_3NMe$]$Ti(CH_2SiMe_3)_2$ (7): Pentane (30 mL) was condensed into a vessel containing a solid mixture of **3** (0.31 g, 0.81 mmol) and Me_3SiCH_2Li (0.15 g, 1.63 mmol) that was frozen in liquid nitrogen. The solution was allowed to thaw and warm to −15 °C, at which temperature it was stirred for 2 h. The solution was filtered and the residue was extracted with 30 mL of pentane. From the combined filtrates the volatiles were removed in vacuo to leave **7** as a yellow oil that slowly solidified on standing. Attempts to recrystallize this material from pentane were unsuccessful due to the extreme solubility of the product. The yield of the material (> 95% pure by NMR spectroscopy) was essentially quantitative. ^{1}H NMR (300 MHz, C_6D_6): δ = 0.18 [s, 18 H,

$CH_2Si(CH_3)_3$], 0.22 [s, 9 H, $Si(CH_3)_3$], 1.54 (m, 2 H, $CH_2CH_2CH_2$), 1.56, 1.86 (d, $^2J_{H,H}$ = 11.0 Hz, 2 H each, $TiCH_2$), 2.87 (m, 2 H, $MeNCH_2$), 3.05 (m, 2 H, NCH_2), 3.69 (s, 3 H, NCH_3), 7.1−7.3 (m, 5 H, Ph) ppm. $^{13}C\{^1H\}$ NMR (75 MHz, C_6D_6): δ = 2.6 [$CH_2Si(CH_3)_3$], 2.7 [$NSi(CH_3)_3$], 32.4 ($CH_2CH_2CH_2$), 42.4 ($MeNCH_2$), 45.5 (NCH_3), 60.0 (NCH_2), 78.3 ($TiCH_2$), 126.5, 128.8, 129.6 (Ph *C*H), 134.9 (Ph *C*), 180.5 (N*C*N) ppm.

X-ray Crystallographic Study: Single crystals of **3** and **4** were mounted on a glass fibre in a nitrogen-filled glove-box and transferred to the cold nitrogen stream of an Enraf−Nonius CAD-4F diffractometer (graphite-monochromated Mo-K_α radiation, λ = 0.71073 Å) using inert-gas handling techniques. The structures were solved by Patterson methods and extension of the model was accomplished by direct methods applied to difference structure factors using the program DIRDIF.[21] All hydrogen atoms were located from the difference Fourier map and refined with isotropic displacement parameters. Final refinements on F^2 were carried out by full-matrix least-squares techniques (SHELXL-97[22]). CCDC-183877 (**3**) and -183876 (**4**) contain the supplementary crystallographic data for this paper. Synthesis and Structure of the First Holmium and Erbium Diiodide Complexes of Composition $LLnI_2$ (Ln = Ho, Er)

Grigori B. Nikiforov,[a] Herbert W. Roesky,*[a] Thomas Labahn,[a] Denis Vidovic,[a] and Dante Neculai[a]

Dedicated to Professor M. Mikolajczyk on the occasion of his 65th birthday

Keywords: Lanthanides / Iodides / Coordination chemistry / N ligands

Two new diiodide complexes of stoichiometry $LLnI_2$ [Ln = Ho (**1**), Er (**2**)] with the β-diketiminato ligand 2-{[2-(diethylamino)ethyl]amino}-4-{[2-(diethylamino)ethyl]imino}pent-2-ene have been synthesized by the reaction of the lithium salt of the ligand with the corresponding triiodides. The complexes are thermally stable and soluble in common organic solvents. The X-ray structural and elemental analysis show that $LLnI_2$ is neutral, and as well free of solvent and lithium salt. The complexes adopt a pseudo-octahedral geometry with the two iodine atoms arranged in *trans* position to each other.

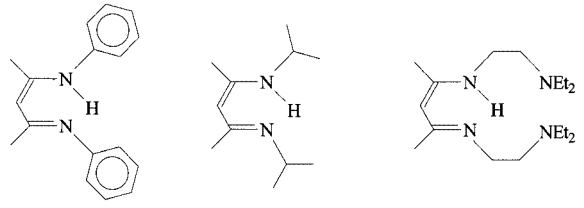
Introduction

Nitrogen-based ligands for preparing lanthanide complexes have been explored increasingly during the last decade.[1−6] Several samarium and gadolinium complexes of stoichiometry $(L1)GdBr_2$, $(L1)_3Ln$,[7] $(L2)_2LnBr$[8] (Ln = Sm, Gd) with different diimine ligands (Scheme 1) have been prepared by Magull et al. Recently, we reported the synthesis of β-diketiminato complexes of praseodymium $(L3)PrX_2$ (X = Cl, Br, BH_4.[9] All these compounds are thermally stable, monomeric in the solid state and soluble in common organic solvents.



L 1 L 2 L 3

Scheme 1. The proton-containing ligands L1, L2, and L3

Iodide complexes of lanthanides are less well known than the corresponding chloride derivatives, presumably due to the lower availability, higher instability, and higher price of the starting material LnI_3.[10,11] Several lanthanide iodide complexes of La^{III},[12] Ce^{III},[13,14] Sm^{III},[15,16,17] Yb^{III},[15,18,19] Lu^{III} [20] have been reported in the literature. The first erbium iodide complex Cp_2ErI was obtained by Maginn et al.[21] in 1963 and characterized by elemental analysis. So far only one iodide complex of erbium $[\{(Me_3Si)_2C_5H_3\}_2ErI](THF)$[20] has been structurally characterized. However, complexes of the lanthanides Tb to Ho are less well known and no reports on holmium iodide complexes can be found in the literature.

Organolanthanide iodide complexes have unique chemical properties due to the more labile Ln−I bond compared to the Ln−Cl ones. This allows metathesis reactions with iodine-containing derivatives. For instance, treatment of the iodide complex with $AgSbF_6$ produces the corresponding fluoride complex;[22] the reaction of $Cp''_2CeI{\cdot}2MeCN$ [Cp'' = 1,3-$C_5H_3(SiMe_3)_2$] with the silver(I) salt $AgBF_4$ in toluene gave the cationic complex in high yield.[12] Similar reactions with the closely related chlorides, however, result in complicated mixtures.[23]

Herein we report the synthesis and characterization of the first monomeric and solvent-free iodide complexes of stoichiometry $LLnI_2$ (Ln = Ho, Er) with the β-diketiminato ligand 2-{[2-(diethylamino)ethyl]amino}-4-{[2-(diethylamino)ethyl]imino}pent-2-ene (L3). The structural characterization of these complexes provides useful data in the rapidly growing field of organolanthanide chemistry. The synthetic methods used to obtain these complexes are also informative with respect to lanthanide halide chemistry. The latter species are important precursor for further reactions.

Results and Discussion

The lanthanide complexes **1** and **2** were prepared in a one-step synthesis from the corresponding THF adducts

[a] Institut für Anorganische Chemie, Universität Göttingen, Tammannstrasse 4, 37077, Göttingen, Germany

E-mail: hroesky@gwdg.de

and stoichiometric amounts of the lithium salt of the ligand in THF followed by recrystallization from toluene (Scheme 2).

$$LnI_3(THF)_x + (L3)Li \xrightarrow[2.\ toluene,\ -LiI]{1.\ THF,\ r.t.} (L3)LnI_2 \quad \begin{matrix} Ln = Ho & \mathbf{1} \\ = Er & \mathbf{2} \end{matrix}$$

$$L3{=}Et_2NCH_2CH_2NC(Me)CHC(Me)NCH_2CH_2NEt_2$$

Scheme 2. Preparation of the compounds **1** and **2**

The yield of the reaction of $LnI_3(THF)_x$ with (L3)Li in THF depends highly on the quality of the triiodide. The LnI_3 compounds can be obtained by a modified procedure[24] from Ln powder and iodine vapour followed by sublimation under vacuum. The high purity LnI_3 received from Aldrich in sealed ampoules under argon is also suitable for the experiment. The precursor LnI_3 can be dissolved by heating the reaction mixture for several hours. Compounds **1** and **2** are soluble in toluene, THF, acetonitrile, and dichloromethane. The ^1H NMR spectra of **1** and **2** in C_6D_6 and CD_2Cl_2, respectively, at room temperature show a set of broad resonances ($\Delta\nu_{1/2}$ ranges from 100 to 1000 Hz) with chemical shifts ranging from $\delta = 60$ to -80 ppm. Lowering of the temperature leads to more distinct resonances; however, the fine structure of the resonances could not be observed due to the paramagnetic nature of holmium and erbium.

The complexes $(L3)LnI_2$ are thermally stable, and their melting points are in the range 192−196 °C. Mass spectrometry and elemental analysis show that compounds **1** and **2** are monomeric, solvent-free and contain no lithium halides. The molecular ions of **1** and **2** in the EI mass spectra are weak. Both compounds exhibit two sets of strong signals in the EI-MS, which correspond to $[(L3)LnI]^+$ and $[M^+ - C_5H_{12}N]$ ions. The theoretical results of an isotope pattern calculation for $[(L3)LnI]^+$ and $[M^+ - C_5H_{12}N]$ are in good agreement with the experimental data. The relative intensities of these signals are nearly the same in both the spectra of **1** and **2** (3.2:1 and 2.9:1 respectively). Thus, in conclusion it is possible to use EI-MS analysis effectively for the characterization of these complexes.

X-ray Structural Analysis of $LLnI_2$

A summary of the crystallographic data and refinement parameters for the structures of **1** and **2** are given in Table 2. Selected bond lengths and angles are listed in Table 1.

Single crystals of **1** and **2** suitable for X-ray diffraction analysis were obtained from a concentrated toluene solution. $(L3)HoI_2$ crystallizes in the triclinic $P\bar{1}$ space group; while $(L3)ErI_2$ crystallizes in the monoclinic $C2/c$ space group and has two symmetrically nonequivalent molecules in the unit cell. The X-ray structural analysis revealed that compounds **1** and **2** are monomeric in the solid state. The X-ray crystal structure of **1** resembles that of **2**, therefore only **1** is shown (Figure 1).

In both compounds the ligand coordinates to the metal center through the four nitrogen atoms. All four nitrogen atoms and the holmium or erbium atom are in the same plane. The iodine atoms in **1** and **2** are almost perpendicularly arranged within the equatorial plane, which is evident from the angles I(2)−Ho−I(1) [153.715(9)°] and

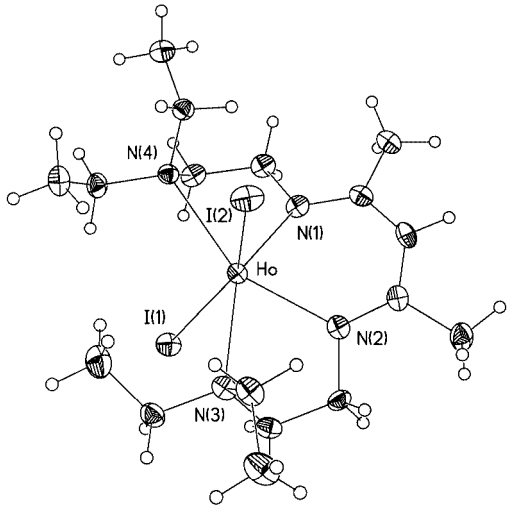

Figure 1. ORTEP drawing (50% thermal probability ellipsoids) of the crystal structure of **1** with atomic numbering scheme

I(1)−Er(1)−I(2) [160.050(16)°] (Table 1). Moreover, each iodine atom is tilted slightly toward the pendant arm. It should be pointed out that the angles between the iodine atoms in **1** and **2** are naturally larger than those between the halogen atoms in $(L3)PrX_2$ (X = Cl, Br) [Cl(2)−Pr−Cl(1) = 136.42(3)°; Br(1)−Pr−Br(2) = 137.080(12)°][9] due to the larger diameter of the praseodymium atom and the smaller ones of chlorine and bromine. For both complexes the metal atoms lie slightly out of the plane of the diimine ligand framework. The coordination number at the holmium and erbium atoms in **1** and **2** is six and the geometry around the metal atom is pseudo-octahedral.

The Ln−N bond lengths of the pendant arm are longer than those of the backbone, as for the distances in the praseodymium complex $(L3)PrX_2$ (X = Cl, Br),[9] due to the coordinative and covalent character involved in different bonding modes. The Er−I bond length is similar to those found in the literature (Er−I: 2.931 Å).[20]

Conclusions

We have reported the synthesis and characterization of two new diiodide complexes of stoichiometry $(L3)LnI_2$. These compounds are easily available when a β-diketiminato-based ligand and holmium or erbium triiodides are used. The X-ray structural and elemental analysis show that $(L3)LnI_2$ is neutral, and free of solvent and lithium salt. The complexes are thermally stable, soluble in common organic solvents and could be used as versatile starting material for studying the chemistry of water- and oxygen-free lanthanide compounds.

Experimental Section

General Remarks: All operations were performed using standard Schlenk line and dry box techniques under purified nitrogen or argon. High-purity water-free holmium and erbium triiodides were

purchased from Aldrich in ampoules sealed under argon. Compound (L3)H [L3 = $Et_2NCH_2CH_2NC(Me)CHC(Me)NCH_2CH_2NEt_2$] was prepared by known literature methods.[9,25,26] The purity of (L3)H was checked by elemental analysis, and ^1H and ^{13}C NMR spectroscopy. Toluene and THF were dried with Na/benzophenone and distilled under nitrogen prior to use; C_6D_6 was dried with Na and degassed; CD_2Cl_2 was dried with CaH_2 and degassed. ^1H NMR spectra were recorded using a Bruker AM 200 spectrometer. Chemical shifts are reported in δ units downfield from Me_4Si with the solvent as the reference signal. Mass spectra were recorded using a Finnigan MAT 8230 instrument, and elemental analysis were carried out at the Analytical Laboratories of the Institute of Inorganic Chemistry at the University of Göttingen. Melting points were determined in sealed capillary tubes under nitrogen and are not corrected.

Synthesis of Complexes 1 and 2. (L3)HoI_2: The methods for the preparation of **1** and **2** are the same, therefore only the method for (L3)HoI_2 is described. Compound (L3)H (0.6 g, 0.64 mL, 2.0 mmol) was added to dry THF (30 mL) in a 50-mL Schlenk flask. The mixture was cooled to −78 °C and a solution of MeLi in Et_2O (1.26 mL, 1.6 M, 2.0 mmol) was added dropwise. The solution was stirred for 1 h at −78 °C, allowed to warm to room temperature, and then stirred at room temp. until methane evolution had ceased. This solution was added dropwise to a suspension of HoI_3 (1.09 g, 2.0 mmol) in THF (30 mL) at room temp. in a 100-mL Schlenk flask. Then the reaction mixture was heated until all the precipitate dissolved. THF was removed under vacuum, and the residue was extracted with 60 mL of toluene. The yellow toluene solution was allowed to stand overnight at room temperature, when a white powder (LiI) separated from a clear yellow solution. The solution was filtered and concentrated to 20 mL. The resulting solution was left undisturbed overnight. Finally, yellow crystals formed, which were separated by filtration, washed with pentane (10 mL), and dried in vacuo. The next portions of crystals was obtained from the toluene solution. Yield of **1** 1.10 g (75%). M.p. 194−196 °C. $C_{17}H_{35}HoI_2N_4$ (714.22): calcd. C 28.58, H 4.90, I 35.59, N 7.85; found C 28.50, H 4.93, I 35.71, N 7.75. EI-MS: *m*/*z* (%) = 714 (1) [M^+], 628 (27) [$M^+ - C_5H_{12}N$], 587 (86) [(L3)HoI^+], 557 (2) [$M^+ - C_{10}H_{24}N$], 536 (3) [$M^+ - C_{12}H_{18}N_2$], 495 (2) [(L3)$HoI^+ - C_5H_{12}N$], 419 (3) [HoI_2^+], 296 (2) [$(L3)^+$], 210 (7) [$(L3)^+ - C_5H_{12}N$], 100 (11) [$C_6H_{14}N$], 86 (100) [$C_5H_{12}N$]. **LErI_2:** Yield of **2** 1.10 g (75%). M.p. 192−194 °C. $C_{17}H_{35}ErI_2N_4$ (716.55): calcd. C 28.49, H 4.89, I 35.48, N 7.82; found C 28.50, H 4.92, I 35.44, N 7.85. EI-MS: *m*/*z* (%) = 715 (1) [M^+], 629 (4.6) [$M^+ - C_5H_{12}N$], 588 (15) [(L3)ErI^+], 558 (2) [$M^+ - C_{10}H_{24}N$], 537 (2) [$M^+ - C_{12}H_{18}N_2$], 499 (2) [(L3)$ErI^+ - C_5H_{12}N$], 296 (5) [$(L3)^+$], 210 (5) [$(L3)^+ - C_5H_{12}N$], 100 (12) [$C_6H_{14}N$], 86 (100) [$C_5H_{12}N$].

X-ray Crystallographic Study: Crystal data and experimental conditions are listed in Table 2. Selected bond lengths and bond angles with standard deviations in parentheses are presented in Table 1. Intensity data for the crystal structures of **1** and **2** were collected with a Stoe image plate IPDS II-system. All structures were solved by direct methods (SHELXS-97) and refined against F^2 using SHELXL-97.[27] The heavy atoms were refined anisotropically. Hydrogen atoms were included using the riding model with U_{iso} tied to U_{iso} of the parent atoms. CCDC-187724 (**1**) and -187725 (**2**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Synthesis and Structure of the First Non-Metallocene Ti^{III} Fluoride Complex $LTiF_2 \cdot 2Me_3SnCl$ Supported by a β-Diketiminato Ligand

Grigori B. Nikiforov,[a] Herbert W. Roesky,*[a] Jörg Magull,[a] Mathias Noltemeyer,[a] Hans-Georg Schmidt,[a] Evgeny G. Ilyin,[b] Yuri B. Kokunov,[b] and Alojz Demsar[a]

Dedicated to Professor F. A. Kuznetsov on the occasion of his 70th birthday

Keywords: Titanium / Fluorides / Coordination chemistry / N ligands

The Ti^{III} dichloride complex $LTiCl_2$ (**1**) and the first non-metallocene Ti^{III} fluoride complex $LTiF_2 \cdot 2Me_3SnCl$ (**2**) supported by the β-diketiminato ligand 2-{[2-(diethylamino)-ethyl]amino}-4-{[2-(diethylamino)ethyl]imino}pent-2-ene have been synthesized. Elemental analysis, mass spectrometry and X-ray structural analysis show that **1** is monomeric, neutral, and free of solvent and lithium salt. The complex adopts a pseudo-octahedral geometry with the two chlorine atoms arranged in *trans* position to each other. Compound **1** is soluble in common organic solvents and thermally surprisingly robust. Complex **2** was prepared using Me_3SnF as a fluorinating agent. X-ray structural analysis revealed that complex **2** consists of the $LTiF_2$ unit and two molecules of Me_3SnCl coordinated through a fluorine bridge to the titanium center. The fluorine atoms in **2** are located in *trans* positions to each other and the geometry around the titanium atom is distorted octahedral. Elemental analysis and mass spectrometry proved that **2** releases the coordinated Me_3SnCl under vacuum or during sublimation.

Introduction

The chemistry of trivalent titanium fluorides has proven to be a promising area of research with far-reaching results. At the moment this area is restricted mainly to cyclopentadienyl-substituted complexes. During the last decade our group has been successful in obtaining and structurally characterizing several Ti^{III} fluoride complexes, namely large clusters[1,2] based on fluorine-bridged organometallic units and the tetranuclear complexes $[\{[C_5H_4(SiMe_3)]_2TiF_2\}_3M]$ (M = Ti,[3] Ga,[3] Al[4]) with the four-membered MF_2Ti rings surrounded by the central metal atom in a propeller like fashion. Furthermore, the dimeric titanium complex $[(C_5H_4Me)_2TiF]_2$[5] has been prepared from the corresponding chlorine derivative.

There is widespread interest in the chemistry of low-valent titanium fluorine species from several perspectives, including synthetic methodology, and structural and theoretical implications. More pertinent to this study, however, is the high catalytic activity displayed by pentamethylcyclopentadienyl-substituted titanium fluorides in combination with methylaluminoxane (MAO) in the polymerization of styrene:[6] β-diketiminato complexes of Ti^{III} with the general formula $LTiCl_2$,[7,8] in the presence of excess methylaluminoxane[7] or $B(C_6F_5)_3$,[8] catalyse the homopolymerization of ethylene and the copolymerization of ethylene with α-olefins. Thus, our interest in the chemistry of titanium fluoride complexes stems from the potential use of Ti^{III} fluoride complexes supported by a new β-diketiminato ligand as a novel olefin polymerisation catalyst.

Mono β-diketiminato Ti^{III} dichlorides are accessible from $TiCl_3$ and the corresponding LiL salt in THF.[8] Access to a fluoride complex of Ti^{III} is possible by the reaction of trimethyltin fluoride with the corresponding chloride complex in non-aqueous solvents.[5]

Herein we report the synthesis and characterization of the new β-diketiminato Ti^{III} dichloride complex $LTiCl_2$ (**1**) [L = $Et_2NCH_2CH_2NC(Me)CHC(Me)NCH_2CH_2NEt_2$] and the first non-metallocene, neutral, solvent-free Ti^{III} fluoride complex $LTiF_2 \cdot 2Me_3SnCl$ (**2**).

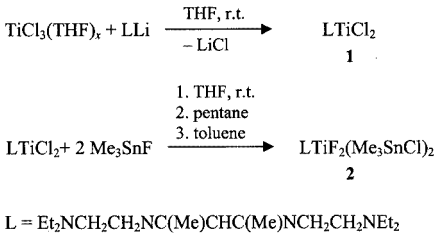
Results and Discussion

The titanium complex **1** was prepared in a one-step synthesis from titanium trichloride and stoichiometric amounts of the lithium salt of the ligand in THF (Scheme 1). The

reaction proceeds at room temperature within 2 h and crystals are easily obtained from the original solution in high yield. Compound **1** is soluble in toluene, THF and dichloromethane, and can be recrystallized from toluene and THF. Complex **1** is thermally stable and can be refluxed in THF without observing any appreciable decomposition. Solid compound **1**, and especially its solution, are air-sensitive, but crystals of **1** are stable in a glove box for one month.



Scheme 1. Synthesis of the complexes **1** and **2**

The melting point of **1** is in the range 144−145 °C. Mass spectrometry and elemental analysis show that compound **1** is monomeric, solvent-free and contains no lithium chloride. Complex **1** exhibits a signal of the molecular ion $[M]^+$ in the EI-MS as well as strong fragments of $[C_5H_{12}N]^+$ and $[C_6H_{14}N]^+$ due to the decomposition of the titanium complex during the EI-MS experiment.

These properties indicate that **1** is a versatile starting material for studying the chemistry of low-valent titanium compounds.

Reaction of **1** with 2 equiv. of Me_3SnF in THF affords a clear solution. After evaporation of the solvent and washing with pentane, the residue was extracted with toluene. Initial addition of toluene caused the precipitate to dissolve, but after several minutes some solid deposited again. This solid is insoluble in toluene and THF and contains titanium, fluorine and non-stoichiometric amounts of the ligand. Complex **2** was purified by crystallization from toluene (Scheme 1). It should be pointed out that crystals of **2** are poorly soluble in toluene and can be obtained from the toluene solution. Complex **2** has good solubility in dichloromethane. Solutions of **2** and the solid are air-sensitive, but crystals of **2** can be kept in the glove box for several months.

The melting point of **2** is in the range 149−151 °C. Elemental analysis shows that complex **2** contains two molecules of Me_3SnCl. The composition was confirmed by EI-MS spectrometry. In the temperature range from room temp. to 120 °C $[Me_3SnCl]^+$ and several other fragments are observed. The elimination of Me_3SnCl ceases at 120 °C and in the temperature range from 155 to 200 °C compound **2** exhibits the molecular ion of $[LTiF_2]^+$.

Complex **2** decomposes and eliminates Me_3SnCl on standing under vacuum over a long period of time at 100−120 °C. The elemental analysis, however, shows that the remaining product does not correspond to the pure fluoride complex $LTiF_2$. Thus, by standing under vacuum it is possible to remove almost all coordinated Me_3SnCl, although the residue is not a pure fluoride complex. Further purification by sublimation at 150−160 °C resulted in a brown powder. The elemental analysis of the sublimate revealed that it is essentially $LTiF_2$. The EI-MS spectrum of this sublimate exhibits the molecular ion $[LTiF_2]^+$ and its corresponding fragments. Unfortunately, all the attempts to recrystallize this product were unsuccessful. Initially, this compound dissolved in toluene, but after several hours an amorphous precipitate deposited from solution.

Complexes **1** and **2** are paramagnetic and exhibit strong broadened proton NMR resonances ($\Delta\nu_{1/2}$ ranged from 50 to 1000 Hz); a fluorine resonance of **2** was not observed. A resonance at $\delta = 0.6$ ppm in the ^1H NMR spectrum of **2** in CD_2Cl_2 can be assigned to Me_3SnCl.

X-ray Structural Analysis of $LTiCl_2$

A summary of the crystallographic data and refinement parameters for the structure of **1** is given in Table 2. Selected bond lengths and angles are listed in Table 1.

Table 1. Selected bond lengths [Å] and angles [°] for compounds **1** and **2**

Complex **1**

		Sn(1)−F(1)−Ti(1)	148.20(1)
		C(13)−Sn(1)−C(12)	114.88(2)
		C(13)−Sn(1)−Cl(1)	96.28(1)
		Cl(1)−Sn(1)−F(1A)	176.60(2)
		C(12)−Sn(1)−F(1A)	84.20(9)

Single crystals of **1** suitable for X-ray diffraction analysis were obtained by recrystallization from THF. $LTiCl_2$ crystallizes in the orthorhombic space group $Pna2_1$. The X-ray structural analysis proves that compound **1** is free of solvent and lithium salt and monomeric in the solid state (Figure 1).

In this complex the ligand coordinates to the metal center through the four nitrogen atoms. All four nitrogen atoms and the titanium atom are in the same plane. The geometry of this complex is similar to those of the praseodymium complexes $LPrX_2$ (X= Cl, Br)[9] containing the same ligand. The chlorine atoms in **1** are almost perpendicular to the equatorial plane, with the Cl(2)−Ti−Cl(1) angle [173.34(2)°] (Table 1) indicating that each chlorine atom is

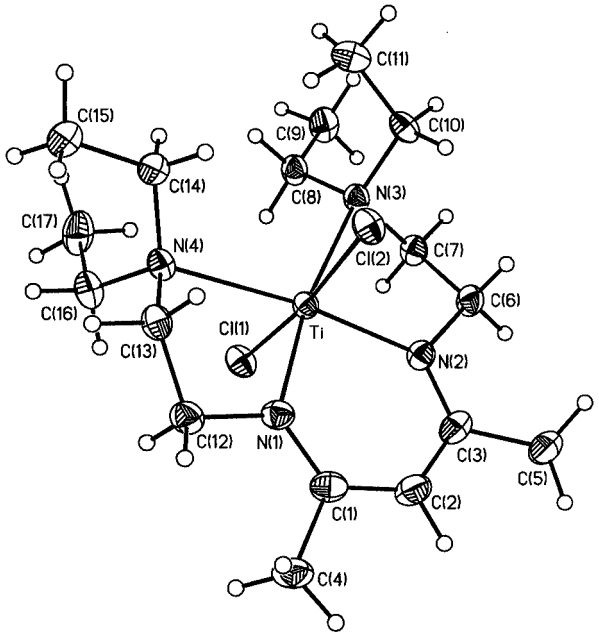

Figure 1. ORTEP drawing (50% thermal probability ellipsoids) of the crystal structure of **1** with atomic numbering scheme

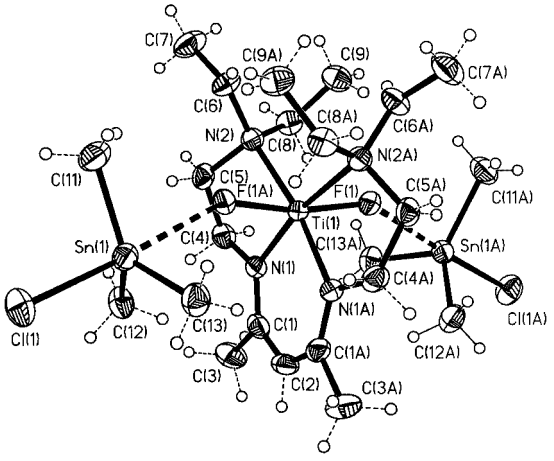

Figure 2. ORTEP drawing (50% thermal probability ellipsoids) of the crystal structure of **2** with atomic numbering scheme

slightly tilted towards the pendant arm. For this complex the titanium atom lies slightly out of the plane of the diimine ligand framework. The coordination number at the titanium atom in **1** is six and the geometry around the metal atom is pseudo-octahedral.

The Ti−N bonds of the pendant arm are longer than those of the backbone, as for the distances in the praseodymium complex $LPrX_2$ (X = Cl, Br),[9] due to the coordinative and covalent character involved in different bonding modes. The Ti−Cl bond length is similar to those found in the literature for β-diketiminato complexes of Ti^{III} (Ti−Cl 2.395 Å[7]).

X-ray Structural Analysis of $LTiF_2 \cdot 2Me_3SnCl$

A summary of the crystallographic data and refinement parameters for the structure of **2** is given in Table 2. Selected bond lengths and angles are listed in Table 1.

Single crystals of **2** suitable for X-ray diffraction analysis were obtained by crystallization from toluene. Complex **2** crystallizes in the monoclinic space group *C*2/*c*. The X-ray structural analysis reveals that compound **2** consists of an $LTiF_2$ unit and two coordinated molecules of Me_3SnCl. Trimethyltin chloride is coordinated through a fluoride bridge to the titanium center (Figure 2). The Sn−F distances [Sn(1)−F(1) 2.559(5) Å] in **2** are considerably longer than those in tin fluoride complexes [Sn−F 2.041(5)[10] Å, 2.126(3)[11] Å for five-coordinate tin] and are similar to those found for $[(acac)_2(\eta^5\text{-}C_5Me_5)Zr(\mu\text{-}F)SnMe_3Cl]$ [Sn−F 2.462(2) Å],[12] where Me_3SnCl is coordinated by a fluorine bridge to the zirconium center. Each Me_3SnCl molecule is tilted slightly towards the pendant arm of the $LTiF_2$ unit [Sn(1)−F−Ti(1) 148.20(1)°] due to repulsion between Me_3SnCl and the ethyl groups of the backbone of the β-diketiminato ligand. The coordination number at the tin atom in **2** is five and the geometry around the tin is pseudo-trigonal-bipyramidal. The fluorine and chlorine atoms in the Me_3SnFCl unit are almost in *trans* positions to each other [F(1)−Ti−Cl(1) 176.60(2)°] (Table 1).

In complex **2** the β-diketiminato ligand coordinates to the titanium center through the four nitrogen atoms. All four nitrogen atoms and the titanium atom lie in the same plane. The fluorine atoms in **2** are almost perpendicular to the equatorial plane [F(1)−Ti−F(1)#1 169.03(1)°] (Table 1) and each fluorine atom is tilted slightly towards the pendant arm. The coordination number at the titanium atom in **2** is six and the geometry around the metal atom is distorted octahedral.

The Ti−N bonds of the pendant arm are longer than those of the backbone, like those in complex **1** and $LPrX_2$ (X = Cl, Br).[9] The Ti−F bond is shorter than that found in the literature for titanium(III) fluoride complexes [Ti−F 1.975(1),[4] 2.094(1),[4] 2.092(2)[5] Å].

Conclusion

We have reported the synthesis and characterization of the Ti^{III} dichloride $LTiCl_2$ and the Ti^{III} fluoride complex $LTiF_2 \cdot 2Me_3SnCl$ supported by the β-diketiminato ligand 2-{[2-(diethylamino)ethyl]amino}-4-{[2-(diethylamino)-ethyl]imino}pent-2-ene. Compound **2** is easily prepared. It has been shown for the first time that Me_3SnF is a good fluorinating reagent for non-metallocene Ti^{III} compounds. Elemental analysis, mass spectrometry and X-ray structural analysis show that **2** is monomeric. Moreover, **2** is thermally unstable and gives off Me_3SnCl under vacuum. The uncoordinated $LTiF_2$ aggregates in toluene solution and therefore we were not able to obtain reliable results in polymerization reactions.

Experimental Section

General Remarks: All operations were performed using standard Schlenk line and dry box techniques under purified nitrogen or argon. Anhydrous titanium trichloride was of commercial reagent quality. The compound LH [L = $Et_2NCH_2CH_2NC(Me)$-$CHC(Me)NCH_2CH_2NEt_2$] was prepared by a known method.[9,13,14] The purity of LH was checked by elemental analysis, and ^1H and ^{13}C NMR spectroscopy. Me_3SnF was prepared by a literature method.[15] The purity of Me_3SnF was checked by elemental analysis and was found to contain less than 1% chlorine. Toluene, pentane and THF were dried with Na/benzophenone and distilled under nitrogen prior to use. C_6D_6 and [D_8]THF were dried with Na and degassed. CD_2Cl_2 was dried with CaH_2 and degassed. ^1H NMR spectra were recorded using a Bruker AM 200 spectrometer. Chemical shifts are reported in δ units downfield from Me_4Si with the solvent as the reference signal. Mass spectra were recorded using a Finnigan MAT 8230 instrument, and elemental analyses were carried out at the Analytical Laboratories of the Institute of Inorganic Chemistry at the University of Göttingen. Melting points were determined in sealed capillary tubes under nitrogen and are not corrected.

Synthesis of Complexes

$LTiCl_2$: LH (1.2 g, 1.28 mL, 4.0 mmol) was added to dry THF (30 mL) in a 50-mL Schlenk flask. The mixture was cooled to −78 °C and a solution of LiMe (2.52 mL; 1.6 M, 4.0 mmol) in Et_2O was added dropwise. The reaction mixture was stirred for 1 h at −78 °C, allowed to warm to room temperature and stirred at room temp. until methane evolution had ceased. This solution was added dropwise to a suspension of $TiCl_3$ (0.62 g, 4.0 mmol) in THF (30 mL) at room temp. in a 100-mL Schlenk flask. Then, the reaction mixture was stirred overnight. The suspension was filtered and concentrated. Finally, the resulting solution was left at −26 °C for 2 d. The red crystals that formed were separated by filtration, washed with pentane (20 mL) and dried in vacuo. Yield of $LTiCl_2$ (1.10 g, 66%). M.p. 144−145 °C. $C_{17}H_{35}Cl_2N_4Ti$ (414.3): calcd. C 49.28, H 8.45, N 13.53; found C 49.20, H 8.39, N 13.45. EI-MS: *m/z* (%) = 414 (6.4) [M^+], 378 (1.2) [LTiCl], 349 (0.6) [LTiCl − C_2H_6], 327 (1.0) [$M^+ - C_5H_{12}N$], 100 (4.0) [$C_6H_{14}N$], 86 (100.0) [$C_5H_{12}N$].

$LTiF_2 \cdot 2Me_3SnCl$: A mixture of $LTiCl_2$ (1.0 g, 2.4 mmol) and Me_3SnF (0.88 g, 4.8 mmol) in a 100-mL Schlenk flask was stirred in THF (40 mL) until all the precipitate dissolved (2 h). Then, the

Sublimation Experiment: Complex **2** (0.265 g, 0.34 mmol) was kept under vacuum at 90−110 °C for 6 h, until evolution of Me_3SnCl ceased. The amount of residue was 0.15 g (calcd. yield of the pure $LTiF_2$ 0.13 g). M.p. 152−156 °C. $C_{17}H_{35}F_2N_4Ti$ (381.5): calcd. C 53.54, H 9.19, N 14.70; found C 49.09, H 8.43, N 13.00. EI-MS: *m/z* (%) = 381 (12) [M^+], 362 (1) [LTiF], 333 (0.5) [$LTiF^+ - C_2H_6$], 309 (0.5) [$M^+ - NC_4H_{10}$], 295 (8) [$M^+ - C_5H_{12}N$], 100 (14) [$C_6H_{14}N$], 86 (100.0) [$C_5H_{12}N$]. This residue was sublimed at 150−160 °C to give 0.09 g of a dark brown powder. M.p. 122−123 °C. $C_{17}H_{35}F_2N_4Ti$ (381.5): calcd. C 53.54, H 9.19, N 14.70; found C 52.88, H 9.18, N 13.96. EI-MS: *m/z* (%) = 397 (1.5), 381 (6) [M^+], 362 (1) [LTiF], 333 (0.5) [$LTiF^+ - C_2H_6$], 309 (0.5) [$M^+ - NC_4H_{10}$], 295 (8) [$M^+ - C_5H_{12}N$], 210 (30) [$L^+ - C_5H_{12}N$], 100 (52) [$C_6H_{14}N$], 86 (100.0) [$C_5H_{12}N$].

X-ray Crystallographic Study: Crystal data and experimental conditions are listed in Table 2. Selected bond lengths and bond angles with standard deviations in parentheses are presented in Table 1. Intensity data for the crystal structure of $LTiCl_2$ were collected with a Stoe image-plate IPDS II-system. Data for the crystal structure of $LTiF_2 \cdot 2Me_3SnCl$ was collected with a Stoe−Siemens four-circle diffractometer. All structures were solved by direct methods (SHELXS-97) and refined against F^2 using SHELXS-97.[16] The heavy atoms were refined anisotropically. Hydrogen atoms were included using the riding model with U_{iso} tied to U_{iso} of the parent atoms. CCDC-189244 (**1**) and -189245 (**2**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Keywords: Aluminum / Hydride ligands / N ligands / S ligands / Cluster compounds

The reaction of $AlH_3{\cdot}NMe_3$ with one equivalent of 2-cyanothiophene in toluene afforded $[HAlNCH_2(C_4H_3S)]_6$ (**2**) in good yield. Treatment of **2** with $SiMe_3Br$ and $SiMe_3Cl$ in toluene under refluxing conditions resulted in the formation of compounds $[BrAlNCH_2(C_4H_3S)]_6$ (**3**) and $[ClAlNCH_2(C_4H_3S)]_6$ (**4**), respectively. In a similar way $[PhC{\equiv}CAlNCH_2(C_4H_3S)]_6$ (**5**) was readily obtained from the reaction between **2** and PhC≡CH. When **2** was treated with PhSH the Al-N cluster core dissociated and a four-membered ring compound $[(PhS)_2AlNHCH_2(C_4H_3S)]_2$ (**6**) was formed. In contrast, a similar hexameric aluminum imide $(HAlNCH_2Ph)_6$ (**1**) retains its Al-N network when treated with PhSH to yield $(PhSAlNCH_2Ph)_6$ (**7**). An exchange of ethyl groups and hydrides occurred when **2** was treated with excess of $ZnEt_2$, forming $[EtAlNCH_2(C_4H_3S)]_6$ **8**. Compounds **2**–**4** and **6**–**8** were characterized by X-ray single-crystal analysis.

Introduction

Recently, we have been actively involved in exploring the reactions of $AlH_3{\cdot}NMe_3$ with compounds containing C-N and C-C multiple bonds.[1] Such reactions lead to the formation of structurally interesting Al-N and Al-C clusters. In particular, a hexameric aluminum imide $(HAlNCH_2Ph)_6$ **1** can be synthesized by the treatment of PhCN with $AlH_3{\cdot}NMe_3$.[1a] We have also demonstrated that the imide **1** is stable toward certain reagents and can be functionalized easily. In our continuing efforts to synthesize functionalized aluminum imides, which can act as potential complexation agents, we have treated 2-cyanothiophene with $AlH_3{\cdot}NMe_3$. Herein we report the synthesis and metathesis reactions of an aluminum imide containing six thiophene groups, $[HAlNCH_2(C_4H_3S)]_6$ (**2**).

Results and Discussion

An interesting feature of the structure of **1** is the orientation of the benzyl groups. Three of them are aligned in one direction while the remaining three are aligned in another direction. This observation has prompted us to synthesize a hexadentate (tridentate on each side of the cluster core), hexameric aluminum imide and we have chosen 2-cyanothiophene for this purpose. Addition of a slight excess of $AlH_3{\cdot}NMe_3$ to one equivalent of 2-cyanothiophene in toluene at −78 °C and refluxing the resultant solution until the evolution of NMe_3 had ceased gave $[HAlNCH_2(C_4H_3S)]_6$ (**2**) in good yield (Scheme 1).

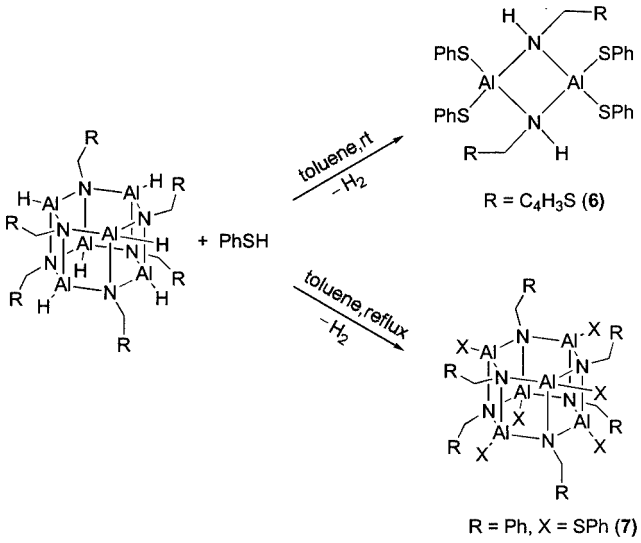
Altering the stoichiometry of the reactants decreased the yield drastically. Six thiophene groups dangling over the Al-N network make **2** hexadentate. A thorough literature search for this type of compounds was done and we found that a hexameric aluminum imide with six NMe_2 groups has been reported.[2] Treatment of **2** with $SiMe_3Br$ or $SiMe_3Cl$ in toluene under refluxing conditions resulted in the formation of compounds $[BrAlNCH_2(C_4H_3S)]_6$ (**3**) and $[ClAlNCH_2(C_4H_3S)]_6$ (**4**), respectively. In a similar way, PhC≡CH reacts with **2** to give $[PhC{\equiv}CAlNCH_2(C_4H_3S)]_6$ (**5**) and evolution of H_2 (Scheme 1). Compounds **3**−**5** were the only isolable products of the respective reactions. In all these cases, all six hydridic hydrogens in **2** are replaced by the corresponding nucleophilic moieties and the Al-N cluster core remains intact. However, when **2** was treated with PhSH the Al-N cluster core dissociated to a four-membered ring $[(PhS)_2AlNHCH_2(C_4H_3S)]_2$ (**6**). In this reaction, migration of a proton from sulfur to nitrogen was observed (Scheme 2).



Scheme 2

There are several four-membered Al-N rings known in the literature.[3] However, none of them carries as many as six sulfur atoms. Hence, compound **6** is the first four-membered aluminum imide carrying six sulfur atoms, of which four are connected directly to the ring aluminum atoms. To compare the stability of **2** with **1** the latter was also treated with PhSH. To our surprise, in contrast to the results of the reaction between **2** and PhSH, the Al-N network of **1** remained intact even under reflux conditions and a hexa-substituted product $(PhSAlNCH_2Ph)_6$ (**7**) was formed. The reaction between $ZnEt_2$ and **2** was also carried out in order to examine the reactivity of the Al−H bonds in **2** toward exchange reactions. Only one such example, in which $AlMe_3$ exchanges methyl groups with the hydrides of $(HAlNiPr)_6$,

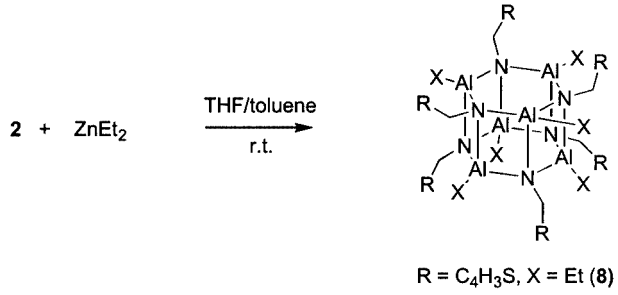
is known in the literature.[4] Compound **2** reacts with an excess of $ZnEt_2$ rapidly at room temperature with replacement of all its hydrides by ethyl groups, giving $[EtAlNCH_2(C_4H_3S)]_6$ (**8**; Scheme 3).[5]



Sdheme 3

Compounds **2**−**4** and **6**−**8** were characterized by single-crystal X-ray structural analysis and the results were compared with IR, mass and elemental analysis data. A strong absorption band at 1860 cm^{-1} in the IR spectrum of **2** can be attributed to ν(Al−H).[6] The absence of this band in the IR spectra of compounds **3**−**6** indicates the lack of an Al−H bond in those compounds. In addition, a sharp band of strong intensity at 2129 cm^{-1} in the IR spectrum of **5** shows the presence of a C≡C moiety in the molecule.[7] Strong evidence for the presence of N−H in compound **6** comes from its IR spectrum, which contains a sharp band at 3248 cm^{-1}. The EI mass spectra of **2**, **3**, **4** and **6** exhibit the molecular ion peaks, whereas a peak related to $[M^+ - C_2H_5]$ is observed in the case of **8**. No molecular ion peak is found in the EI mass spectra of **5** and **7**.

Crystallographic data for the structural analyses of compounds **2**−**4** and **6**−**8** are given in Table 1, and important bond parameters are listed in Table 2. Compound **2** crystallizes in a trigonal space group ($R\bar{3}$) with one sixth of the molecule in the asymmetric unit. An ORTEP plot of **2** is given in Figure 1. The basic central core of the structure is comprised of an Al-N network containing six aluminum atoms and six nitrogen atoms in alternate positions, forming a hexagonal prism. Three of the six thiophenyl methyl groups dangling over one of the hexagonal faces of the polyhedron are oriented in one direction while those on the other hexagonal face are oriented in the opposite direction. The thiophene rings are oriented in such a way that the sulfur atoms are positioned slightly toward the vertical axis of the polyhedron. The bond parameters are similar to the previously studied structures and the Al−N bonds forming the hexagonal faces are significantly shorter than the transverse bonds.[1a,2,8]

Compound **3** crystallizes in the cubic space group $Pa\bar{3}$ with one sixth of the molecule in the asymmetric unit. An ORTEP plot depicting the spatial arrangement of the atoms in compound **3** is shown in Figure 2.

The sulfur atom of the thiophene group is disordered with an occupancy of 0.628(12). ORTEP plots of compounds **4** and **6**−**8** are given in Figures 3−6, respectively.

The bond parameters and the basic structure of the Al-N network in compounds **4** and **8** are similar to those of **2**. However, the orientation of the thiophene groups in compound **8** is quite different from that in the other com-

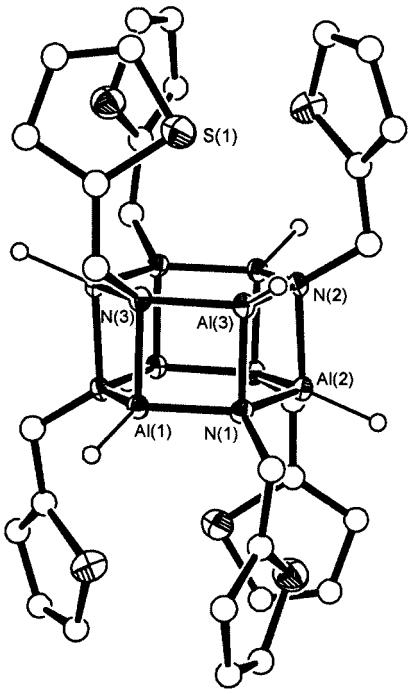

Figure 1. Crystal structure of compound $[HAlNCH_2(C_4H_3S)]_6$ (**2**); all hydrogen atoms, except those on Al, have been omitted for clarity

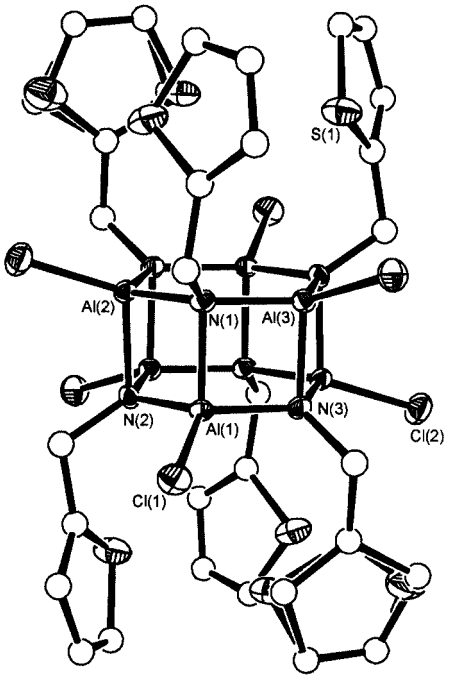

Figure 3. Crystal structure of compound $[ClAlNCH_2(C_4H_3S)]_6$ (**4**); all hydrogen atoms have been omitted for clarity

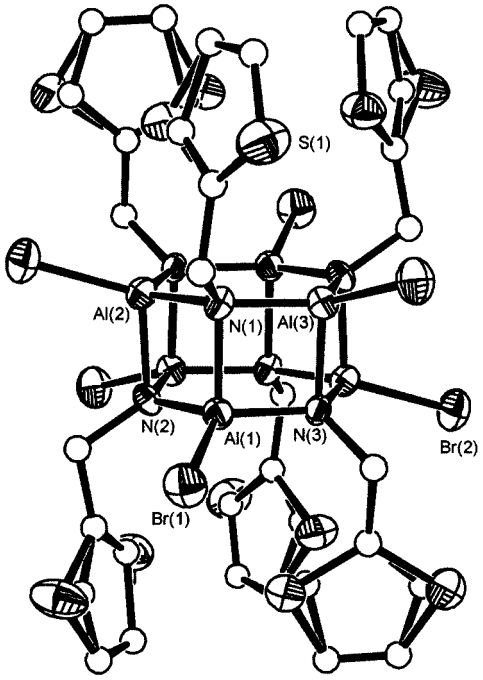

Figure 2. Crystal structure of compound $[BrAlNCH_2(C_4H_3S)]_6$ (**3**); all hydrogen atoms have been omitted for clarity

pounds. The sulfur atoms in **8** are projected away from the vertical axis, whereas they are projected toward the vertical axis in compounds **2**−**4**.

Compound **6** crystallizes in the cubic space group $Pa\bar{3}$ with half of the molecule in the asymmetric unit. Figure 4 shows the molecular structure of **6**. Two thiophenyl methyl groups are mutually *trans* and the phenyl groups on the same side of the plane of the Al-N ring are oriented in the same direction. The average Al−N bond length [1.940(2) Å] is in accordance with those reported in the literature.[3]

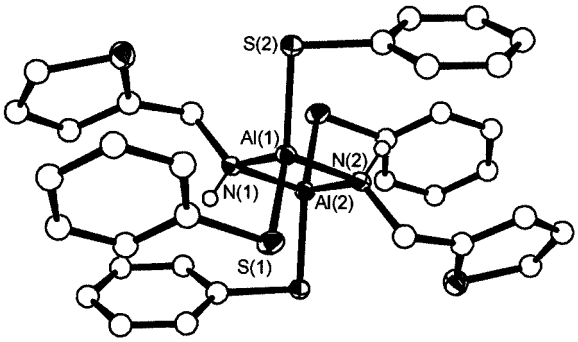

Figure 4. Crystal structure of compound $[(PhS)_2AlNHCH_2(C_4H_3S)]_2$ (**6**); all hydrogen atoms, except those on N, have been omitted for clarity

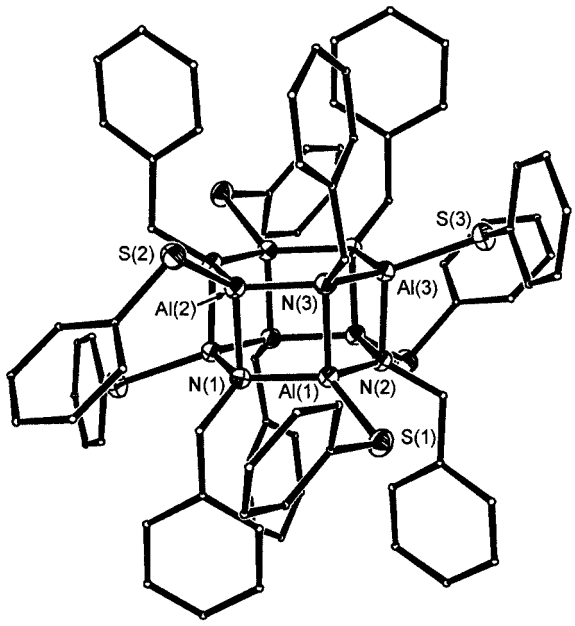
Compound **7** crystallizes in the monoclinic space group *C*2/*c* with half of the molecule in the asymmetric unit (Figure 5). The Al-N polyhedron is completely surrounded by organic moieties on all sides. While the bond parameters are similar to those of **1**, the bond angles between the transverse Al−N bonds and the Al−S bonds in **7** vary significantly from each other, which is not the case with compounds **3**, **4** and **8** (Figure 6; Table 2).



fiture 5. Crystal structure of compound $(PhSAlNCH_2Ph)_6$ (**7**); all hydrogen atoms have been excluded for clarity

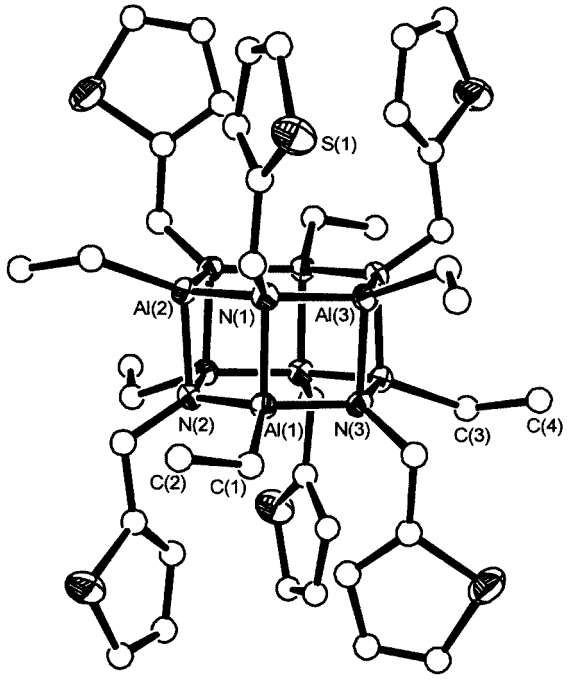


Figure 6. Crystal structure of compound $[EtAlNCH_2(C_4H_3S)]_6$ (**8**); all hydrogen atoms have been excluded for clarity

Conclusion

A hexadentate hexameric aluminum imide $[HAlNCH_2(C_4H_3S)]_6$ **2** has been synthesized and structurally characterized. Its reactivity toward reagents like $SiMe_3Br$, $SiMe_3Cl$, PhC≡CH and PhSH has been examined. We found that the Al−N network in **2** is stable toward $SiMe_3Br$, $SiMe_3Cl$ and PhC≡CH while it dissociates to form a four-membered ring with PhSH. We are currently investigating the ability of **2** and **5** to form complexes with transition metals.

Experimental Section

General Remarks: All experimental manipulations were carried out under an atmosphere of dry nitrogen using standard Schlenk techniques. The samples for spectral measurements were prepared in a dry box. Solvents were purified according to conventional procedures and were freshly distilled prior to use. $AlH_3{\cdot}NMe_3$ [9] and **1**[1a] were prepared as described in the literature. 2-Cyanothiophene, $SiMe_3Br$, $SiMe_3Cl$, PhSH, $ZnEt_2$ and PhC≡CH were procured from Aldrich and used as such. NMR spectra were recorded on a Bruker AM 200 instrument; chemical shifts are reported with reference to TMS. IR spectra were recorded on a Bio-Rad Digilab FTS7 spectrometer. Melting points were obtained on a HWS-SG 3000 apparatus and are uncorrected. CHN analyses were performed at the Analytical Laboratory of the Institute of Inorganic Chemistry at Göttingen, Germany.

Reaction of $AlH_3{\cdot}NMe_3$ with 2-Cyanothiophene. Synthesis of 2: $AlH_3{\cdot}NMe_3$ (30 mL, 0.5 M solution in toluene) was added to a solution of 2-cyanothiophene (1.50 g, 13.74 mmol) in toluene (30 mL) at −78 °C whilst stirring. The reaction mixture was allowed to warm to room temperature and then refluxed until the evolution of NMe_3 ceased. Storing the resultant solution overnight at room temperature afforded colorless crystals of **2**. Yield: 1.23 g (64%). M.p. 238−240 °C. ^1H NMR (200 MHz, $CDCl_3$): δ = 4.31 (s, 12 H, CH_2), 6.74, 6.83, 7.06 (m, 18 H, C_4H_3S) ppm. ^{13}C NMR (125 MHz, $CDCl_3$): δ = 44.07 (CH_2), 124.35, 125.28, 127.23, 146.95 (C_4H_3S) ppm. IR (KBr, nujol mull): $\tilde{\nu}$ = 1860 (s), 1718 (w), 1648 (w), 1596 (w), 1528 (w), 1339 (m), 1269 (m), 1216 (m), 1156 (m), 1075 (w), 1040 (w), 1013 (w), 969 (w), 854 (s), 819 (s), 753 (w), 723 (w), 693 (w), 658 (w), 637 (w), 621 (w), 529 (m), 481 (m), 438 (m), 413 (w) cm^{-1}. EI-MS: *m*/*z* (%) = 834 (20) $[M^+]$, 737 (28) $[M^+ - CH_2C_4H_3S]$, 653 (36) $[M^+ - (CH_2C_4H_3S + C_4H_4S)]$, 113 (100) $[H_2NCH_2C_4H_3S^+]$. $C_{30}H_{36}Al_6N_6S_6$ (834.89): calcd. C 43.16, H 4.35, N 10.07; found C 43.23, H 4.46, N 9.35.

Reaction of 2 with $SiMe_3Br$. Synthesis of 3: $SiMe_3Br$ (1.07 g, 6.99 mmol) was added at room temperature to a suspension of **2** (0.73 g, 0.87 mmol) in toluene (30 mL). The reaction mixture was stirred overnight at room temperature and refluxed for an hour. The solution was filtered and cooled to room temperature to obtain colorless crystals of **3**. Yield: 0.77 g (68%). M.p. 284−287 °C. IR (KBr, nujol mull): $\tilde{\nu}$ = 1887 (m), 1780 (w), 1714 (w), 1647 (w), 1602 (w), 1532 (w), 1433 (m), 1335 (s), 1272 (s), 1226 (m), 1216 (m), 1162 (s), 1135 (w), 1074 (w), 1043 (w), 977 (w), 891 (w), 850 (s), 826 (s), 757 (w), 723 (w), 655 (m), 617 (m), 562 (s), 520 (m), 504 (s), 465 (m), 435 (s) cm^{-1}. EI-MS: *m*/*z* (%) = 1308 (5) $[M^+]$, 179 (100), 113 (16) $[H_2NCH_2C_4H_3S^+]$. $C_{30}H_{30}Al_6Br_6N_6S_6$ (1308.30): calcd. C 27.54, H 2.31, N 6.42; found C 27.15, H 2.85, N 6.19.

Reaction of 2 with $SiMe_3Cl$. Synthesis of 4: The reaction between **2** (0.50 g, 0.60 mmol) and $SiMe_3Cl$ (0.45 g, 4.14 mmol) was carried out in a similar manner to that between **2** and $SiMe_3Br$. Yield: 0.44 g (71%). M.p. 218−223 °C. IR (NaCl, nujol mull): $\tilde{\nu}$ = 1889 (w), 1797 (w), 1724 (w), 1650 (w), 1594 (w), 1531 (w) 1495 (w), 1435 (m), 1341 (s), 1272 (s), 1219 (s), 1158 (s), 1135 (w), 1074 (w), 1042 (w), 972 (w), 896 (w), 855 (s), 824 (s), 753 (w), 728 (w), 685 (w), 653 (w), 622 (m), 593 (m), 564 (w), 540 (w) cm^{-1}. EI-MS:

m/z (%) = 1040 (10) [M^+], 943 (10) [$M^+ - CH_2C_4H_3S$], 97 (100) [$CH_2C_4H_3S^+$]. $C_{30}H_{30}Al_6Cl_6N_6S_6$ (1041.54): calcd. C 34.59, H 2.90, N 8.07; found C 33.57, H 3.47, N 7.64.

Reaction of 2 with PhC≡CH. Synthesis of 5: PhC≡CH (0.42 g, 4.11 mmol) was added at room temperature to a suspension of **2** (0.50 g, 0.60 mmol) in toluene (30 mL). The reaction mixture was stirred for half an hour at room temperature before refluxing it until the evolution of H_2 ceased. The resultant dark brown solution was filtered and kept for crystallisation at room temperature. Yield: 0.55 g (64%). M.p. 270 °C (decomp). ^{1}H NMR (200 MHz, $CDCl_3$): δ = 4.68 (s, 12 H, CH_2), 6.79, 6.95, 7.04 (m, 18 H, C_4H_3S), 7.27 (m, 18 H, *m*- and *p*-C_6H_5), 7.46 (m, 12 H, *o*-C_6H_5) ppm. ^{13}C NMR (125 MHz, $CDCl_3$): δ = 41.28 (CH_2), 67.98 (Al − C), 83.15 (Al − C≡C), 122.14, 128.30, 128.77, 132.14 (C_6H_5), 125.30, 128.23, 129.04, 137.88 (C_4H_3S) ppm. IR (NaCl, nujol mull): $\tilde{\nu}$ = 2129 (s), 2030 (w), 1951 (w), 1880 (w), 1801 (w), 1675 (w), 1653 (w), 1594 (w), 1572 (w), 1540 (w), 1486 (m), 1341 (w), 1276 (w), 1214 (s), 1175 (w), 1156 (m), 1098 (w), 1068 (w), 1044 (w), 1025 (w), 996 (w), 971 (w), 915 (w), 894 (w), 851 (m), 817 (m), 799 (w), 755 (m), 726 (w), 690 (w), 647 (w), 610 (w), 565 (w), 535 (w) cm^{-1}. In the EI-MS spectrum only low molecular weight fragments were found. $C_{78}H_{60}Al_6N_6S_6$ (1434.21): calcd. C 65.26, H 4.21, N 5.85; found C 64.93, H 4.76, N 5.77.

Reaction of 2 with PhSH. Synthesis of 6: PhSH (0.46 g, 4.17 mmol) was added slowly at room temperature to a suspension of **2** (0.50 g, 0.60 mmol) in toluene (30 mL). Evolution of H_2 was observed during the addition. The reaction mixture was stirred overnight and filtered. Colorless crystals of **6** were obtained when the filtrate was stored at room temperature. Yield: 0.63 g (84% based on PhSH). M.p. 143−153 °C. ^{1}H NMR (200 MHz, $CDCl_3$): δ = 2.80 (s, 2 H, NH), 3.90 (s, 4 H, CH_2), 6.42, 6.82 (m, 4 H, C_4H_3S), 7.21 (m, 14 H, C_6H_5S, C_4H_3S), 7.55 (m, 8 H, C_6H_5S) ppm. ^{13}C NMR (125 MHz, $CDCl_3$): δ = 41.38 (CH_2), 123.95, 125.63, 127.17, 137.07 (C_4H_3S), 125.63, 129.07, 129.46, 130.74 (C_6H_5S) ppm. IR (KBr, nujol mull): $\tilde{\nu}$ = 3248 (m), 3231 (w), 3160 (w), 1954 (w), 1882 (w), 1655 (w), 1579 (m), 1473 (m), 1436 (m), 1380 (m), 1326 (w), 1303 (w), 1257 (m), 1205 (m), 1147 (w), 1082 (m), 1066 (w), 1043 (w), 1023 (m), 971 (s), 907 (w), 864 (s), 828 (m), 740 (s), 709 (m), 691 (s), 647 (m), 574 (m), 554 (m), 530 (s), 492 (w), 483 (w), 472 (s) cm^{-1}. EI-MS: *m/z* (%) = 714 (5) [M^+], 605 (68) [M^+ − PhSH], 110 (100) [$PhSH^+$]. $C_{34}H_{32}Al_2N_2S_6$ (714.94): calcd. C 57.12, H 4.51, N 3.92; found C 56.76, H 4.63, N 3.74.

Reaction of 1 with PhSH. Synthesis of 7: PhSH (0.50 g, 4.54 mmol) was added at room temperature to a suspension of **1** (0.52 g, 0.65 mmol) in toluene (30 mL). The reaction mixture was stirred for an hour at room temperature before refluxing it until the evolution of H_2 ceased. The solution was filtered and kept for crystallisation at room temperature. Yield: 0.66 g (70%). ^{1}H NMR (200 MHz, $CDCl_3$): δ = 4.22 (s, 12 H, CH_2), 6.95 (m, 24 H, *o*-$CH_2C_6H_5$ and *o*-SC_6H_5), 7.22 (m, 36 H, *m*-, *p*-$CH_2C_6H_5$ and *m*-, *p*-SC_6H_5) ppm. ^{13}C NMR (125 MHz, $CDCl_3$): δ = 29.70 (CH_2), 126.97 (*p*-$CH_2C_6H_5$), 127.16 (*m*-$CH_2C_6H_5$), 127.56 (*o*-$CH_2C_6H_5$), 137.06 (CH_2-*C*), 128.49 (*p*-SC_6H_5), 128.59 (*m*-SC_6H_5), 129.06 (*o*-SC_6H_5), 130.74 (S-C) ppm. IR (KBr, nujol mull): $\tilde{\nu}$ = 1579 (m), 1496 (m), 1437 (w), 1367 (w), 1300 (w), 1282 (w), 1260 (w), 1198 (w), 1156 (w), 1079 (w), 1066 (w), 1031 (w), 1023 (w), 1003 (w), 974 (w), 810 (w), 735 (s), 693 (w), 667 (w), 547 (s), 524 (m), 480 (s), 459 (w), 439 (w) cm^{-1}. $C_{85}H_{80}Al_6N_6S_6$ (**7**·$C_6H_5CH_3$) (1539.79): calcd. C 66.30, H 5.24, N 5.46; found C 66.67, H 5.35, N 5.16. In the EI-MS spectrum only low molecular weight fragments were found.

Reaction of 2 with $ZnEt_2$. Synthesis of 8: A solution of $ZnEt_2$ (15 mL, 1.1 M solution) in toluene was added dropwise to a solution of **2** (0.85 g, 1.02 mmol) in THF (20 mL). The resultant mixture was stirred overnight at room temperature and then filtered. The filtrate was reduced in volume to 15 mL and stored at 0 °C to obtain colorless crystals of **8**. Yield: 0.81 g (79%). M.p. 262 °C. ^{1}H NMR (200 MHz, $CDCl_3$): δ = 0.20 (m, 12 H, $AlCH_2$), 1.11 (t, 18 H, CH_3), 4.38 (s, 12 H, NCH_2), 6.65, 6.79, 7.09 (m, 18 H, C_4H_3S) ppm. ^{13}C NMR (125 MHz, $CDCl_3$): δ = −1.09 (Al-CH_2), 9.81 (CH_3), 43.45 (NCH_2), 123.63, 124.88, 126.72, 147.37 (C_4H_3S) ppm. IR (NaCl, nujol mull): $\tilde{\nu}$ = 1337 (m), 1269 (m), 1225 (s), 1199 (w), 1157 (w), 1125 (w), 1072 (w), 1006 (s), 990 (s), 973 (s), 927 (s), 848 (s), 823 (s), 767 (s), 717 (s), 696 (s), 636 (s) cm^{-1}. EI-MS: *m/z* (%) = 974 (45) [$M^+ - C_2H_5$], 973 (100) [$M^+ - C_2H_6$]. $C_{42}H_{60}Al_6N_6S_6$ (1003.20): calcd. C 50.28, H 6.03, N 8.38; found C 50.56, H 6.03, N 8.02.

X-ray Structure Determination of 2−4, 6 and 7: A suitable crystal of each compound was mounted on a glass fiber and coated with paraffin oil. Diffraction data for **3** were collected on a Siemens−Stoe AED2 four-circle instrument, and for **2**, **4**, **6**, **7** and **8** the data were collected on a STOE IPDS II diffractometer. All measurements were made with graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å). The structures were solved by direct methods using SHELXS-97[10] and refined against F^2 on all data by full-matrix least-squares with SHELXL-97.[11] All non-hydrogen atoms were refined anisotropically. Neutral-atom scattering factors (including anomalous scattering) were taken from International Tables for X-ray Crystallography.[12] Hydrogen atoms were included at geometrically calculated positions and refined using a riding model.

CCDC-192059 to -192063 and CCDC-192424 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

4-Ethynylpyridine as a Bridging Moiety in Mixed Rh/Re Complexes

Jing-Lin Zuo,[a] Fabrizia Fabrizi de Biani,[b] Ana M. Santos,[a,c] Klaus Köhler,[a] and Fritz E. Kühn*[a]

Keywords: N ligands / Metal-metal interactions / Oligomers / Rhenium / Rhodium

A paramagnetic, dimeric $Rh^{III}Rh^{II}$ complex of the formula $[Rh_2(form)_4(C{\equiv}CC_5H_4N)]$ (**1**) [form = *N*,*N*′-di-*p*-tolylformamidinate; C_5H_4N = pyridyl (py)] has been synthesized and used as starting material to prepare heterotrimetallic complexes of composition $[Rh_2(form)_4(C{\equiv}Cpy)\{Re(CO)_3(bipy)\}][OS(=O)_2CF_3]$ (**2**) and $[Rh_2(form)_4(C{\equiv}Cpy)\{Re(CO)_3(t\text{bu}_2\text{bipy})\}][OS(=O)_2CF_3]$ (**3**). These complexes have been examined by vibrational spectroscopy, EPR spectroscopy, thermogravimetry and cyclic voltammetry. They are heat-stable and can be handled in air without problems. The observed interactions between the Rh_2 and the Re subunits, however, are weak, and a significant charge transfer does not seem to take place. (© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2003)

Introduction

Dimeric rhodium complexes were first reported in the 1960s.[1] Since then a large number of compounds containing RhRh units have been described.[2] However, the number of Rh_2 compounds containing axial Rh−C bonds is rather limited.[3] Metal-metal units, containing axial M−C bonds in general, however, have been shown to be useful building blocks for linear organometallic oligomers and polymers.[3a,4] These oligomers and polymers may display interesting and novel optical and magnetic properties.[5] RN−RhRh as well as RN−RhRh−NR units [R = $C_5H_4NRe(bipy)(CO)_3$, $C_5H_4{-}C_5H_4NRe(Br)(CO)_3$-$NC_5H_4{-}C_5H_4N$, $C_5H_4C{\equiv}CC_5H_4FeC_5H_4C{\equiv}CC_5H_4N$, $C_5H_4C{\equiv}CC_5H_4FeC_5H_5$, etc.], which we used previously as building blocks for organometallic oligomers and polymers, suffer from their weaker nitrogen-rhodium interactions and are more sensitive to temperature, air, moisture and donor solvents.[6] In this work we report on an RhRh moiety with one axial 4-ethynylpyridyl ligand. This axial ligand can act as a useful linker to other transition metal complexes, as exemplified by the formation of [carbonyl(bipyridyl)-rhenium] complexes.

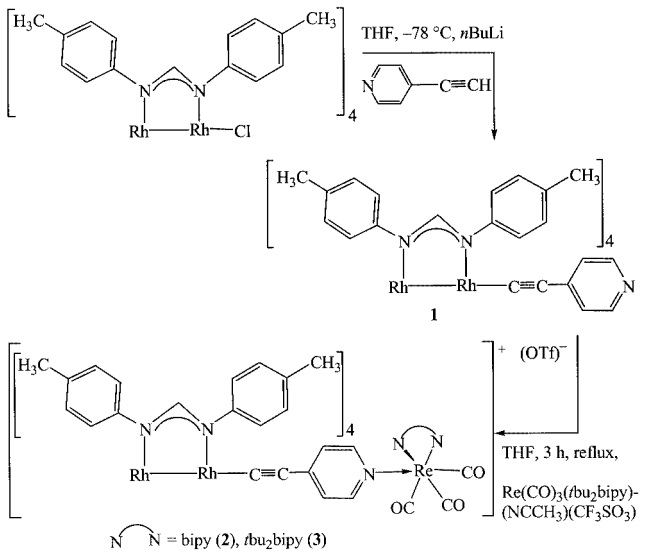
Results and Discussion

Synthesis and Characterization

Our aim was to synthesize compounds with the $[Rh_2(form)_4]$ (form = *N*,*N*′-di-*p*-tolylformamidinate) building block containing the two metal atoms in different oxidation states and only one axial σ-alkynyl moiety as connecting unit. To achieve this, an equimolar amount of *n*BuLi was added dropwise to a solution of 4-ethynylpyridine in dry THF at dry ice temperature. $[Rh_2(form)_4Cl]$ was added, the mixture was allowed to react for 5 h and then slowly brought to room temperature. Stirring was continued for 24 h and then the reaction mixture was exposed to air for another 24 h. The green residue formed was dissolved in CH_2Cl_2 and chromatographed to afford the paramagnetic, neutral $[Rh_2(form)_4(C{\equiv}Cpy)]$ (**1**) as a dark green solid (Scheme 1). Complex **1** displays its asymmetric C≡C vibration at 2120 cm^{-1}. The NC pyridine vibration is observed at 1590 cm^{-1}.

Under FAB-MS conditions the molecular peak $[M]^+$ is observed, as well as $[M - C{\equiv}Cpy]^+$. As in the case of the related Ru derivatives of formula $[Ru_2(form)_4(C{\equiv}Cpy)_2]$,[4d] the axial metal−carbon bond is easy to break under FAB conditions. Under TG conditions the complex starts decomposing at 373 °C by losing its C≡Cpy ligand. A second, distinct decomposition onset is observed at 435 °C when the "form" ligands start to break down. The remaining mass at 650 °C is ca. 45% of the original mass.

A solution of compound **1** and $[Re(CO)_3(L_2)(MeCN)(CF_3SO_3)]$ (L_2 = bipy, $t\text{bu}_2$bipy) in THF was refluxed in the dark for 3 h. The reaction mixture was then cooled to room temperature and the residue was dissolved in CH_2Cl_2 and chromatographed to yield the pale green,



Scheme 1

paramagnetic solids $[Re(CO)_3(bipy)Rh_2(form)_4(C{\equiv}Cpy-4)][OTf]$ (**2**) and $[Re(CO)_3(tbu_2bipy)Rh_2(form)_4(C{\equiv}Cpy-4)][OTf]$ (**3**), respectively (Scheme 1). They display their C≡C vibration at 2108 and 2107 cm^{-1}, respectively, indicating a slightly weakened triple bond in comparison to the precursor complex **1**. The pyridine CN vibrations are observed at 1603 and 1606 cm^{-1}, shifted 13 and 16 cm^{-1}, respectively, in comparison to complex **1**, thus indicating a slight strengthening of the CN bond, possibly due to the increased electron density in the pyridine ring because of its bridging function between the RhRh and the Re units.

In the FAB mass spectrum the $[M]^+$ signals of the cations are observed with low intensities (< 5%) as well as the $[M - Re(CO)_3(L_2)]^+$ and the $[M - C{\equiv}Cpy - Re(CO)_3(L_2)]^+$ signal. The most intense peak in both mass spectra is the $[Re(CO)_3(L_2)]^+$ peak. Under TG conditions the decomposition onset of the complexes **2** and **3** is observed at 365 and 341 °C, respectively, in both cases below the onset of compound **1**, but above the decomposition onset of the Re ligands. This shows that the decomposition of the complexes **2** and **3** starts with the degradation of the Re moiety. Further clearly pronounced decomposition onsets are not observed until the end of the measurement, probably due to a simultaneous decomposition of the different organic ligands above 400 °C. Due to the coordination to the $Rh_2(form)_4(C{\equiv}Cpy)$ building block the Re^I moiety is significantly stabilized {the first decomposition onset of the Re^I precursor, $[Re(CO)_3(tbu_2bipy)(NCCH_3)]$ is observed at 163 °C}. Above a certain temperature level (in the temperature range of 340–370 °C), however, it starts decomposing regardless of the attached molecule. Similar observations have been made for the $[Re(CO)_3(L_2)]$ moiety connected to other dimetallic transition metal complexes by 4-ethynylpyridine units and will be reported elsewhere.

Electrochemical Properties

Cyclic voltammetric measurements of compounds **1**–**3** were performed in a dichloromethane solution containing $[tBu_4N]PF_6$ (0.2 M) as supporting electrolyte. Potentials are quoted vs. an Ag/AgCl reference electrode.

As a main feature, the cyclic voltammetric profile of the parent dinuclear complex **1**, presented in Figure 1, shows a one-electron oxidation ($E^{\circ\prime}$ = +0.55 V) and a one-electron reduction ($E^{\circ\prime}$ = −0.50 V). Both these processes are chemically and electrochemically reversible (peak current ratio at different scan rates is constantly close to 1; ΔE_p departs slightly from the theoretical value of 59 mV). Asymmetric complexes like **1** are commonly described both as an $(Rh_2)^{5+}$ or $Rh^{II}-Rh^{III}$ system.[7a] Nevertheless, it has also been suggested that, while the addition of two axial ligands does not substantially modify the Rh–Rh bonding system, asymmetric complexes such as **1** should present a large polarization toward the formally pentacoordinate rhodium atom.[7b] In spite of this, for reasons which will be discussed shortly, we adopted here the "delocalized" description. The above-mentioned processes are therefore ascribed to formal $(Rh_2)^{5+}/(Rh_2)^{6+}$ electron removal and to $(Rh_2)^{5+}/(Rh_2)^{4+}$ electron addition, respectively. The redox change $(Rh_2)^{6+}/(Rh_2)^{7+}$ is also visible at +1.3 V. This irreversible process results in the decomposition of complex **1** and generates an unknown species which gives rise to a new series of three signals at +1.38, +0.68, −0.36 V (shown in Figure 1).

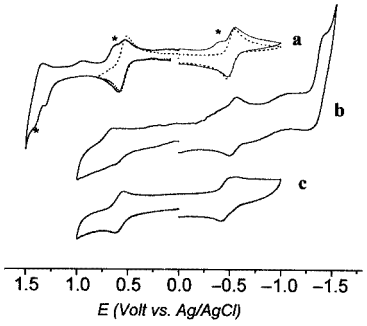


Figure 1. Cyclic voltammograms of a CH_2Cl_2 solution of $[tBu_4N]PF_6$ (0.2 mol dm^{-3}) and the complexes (a) **1**, (b) **2**, (c) **3**; scan rate 0.2 Vs^{-1}

The main features of the cyclic voltammetric profile of the compounds **2** and **3**, also shown in Figure 1, are visible and allow some conclusions to be drawn. The main features of the redox profile of **1** appear in both complexes **2** and **3**. The more anodic irreversible processes are probably masked by the solvent discharge. In the cyclic voltammetric profile of **2** a further reduction process, possessing features of chemical quasi-reversibility, is also visible at $E^{\circ\prime}$ = −1.36 V. We ascribe this redox process to an electron addition to the bipy ligand coordinated to the rhenium atom.[7a] The equivalent redox process, expected for **3**, is not found, as it is probably cathodically shifted because of the presence of the *tert*-butyl substituents and is therefore masked by the solvent discharge. The redox potential values for the visible processes of **2** and **3** remain unaffected with respect to **1**.

The most important change is the anodic shift of 80 mV for the $(Rh_2)^{5+}/(Rh_2)^{6+}$ oxidation process of complex **2** (a minor anodic shift of 30 mV is also visible for complex **3**). This effect is probably due to the electron-withdrawing effect of the Re moiety on the central Rh_2 core. Remarkably, the $(Rh_2)^{5+}/(Rh_2)^{4+}$ reduction process, in which one electron is formally added to the axially ligated formal Rh^{III} ion, is practically unchanged in **1**−**3**. Therefore, it seems that such a substituent effect is mainly transmitted to the axially nonligated formal Rh^{II} ion. In this respect, it is also interesting to compare the redox behavior of complexes **1**−**3** with that of the parent complex $Rh_2(form)_4$, whose electrochemistry has been extensively studied by Piraino et al.[7c] In this complex the redox potential for the $(Rh_2)^{4+}/(Rh_2)^{5+}$ and $(Rh_2)^{5+}/(Rh_2)^{6+}$ changes are +0.25[7d] and +1.06 V,[7d] respectively, compared with −0.50 and +0.55 V for **1**. It is evident that the introduction of the (C≡Cpy) unit as a ligand in the axial position of the Rh−Rh core has a strong effect, inducing a significant cathodic shift on both redox changes. We interpret this behavior as evidence for the strong interaction between the two Rh ions. The formal electrode potentials of the above discussed redox changes are summarized in Table 1.

Table 1. Formal electrode potentials [V] vs. Ag/AgCl for the redox changes exhibited by complexes **1**−**3** in CH_2Cl_2 with $[tBu_4N]PF_6$ (0.2 M) as supporting electrolyte

Complex	$E^{\circ\prime}$ [V], (ΔE [mV])[a], i_p *ratio*[a]						
	$(Rh_2)^{6+}/(Rh_2)^{7+}$	$(Rh_2)^{5+}/(Rh_2)^{6+}$			$(Rh_2)^{5+}/(Rh_2)^{4+}$

EPR Spectra

The EPR spectra of the dirhodium complexes are best described by a spin-Hamiltonian of axial symmetry for one rhodium(II) ion ($4d^7$ "low-spin"). The corresponding EPR parameters are: $g_\perp = 2.110$, $g_\parallel = 1.938$ and $A_\parallel$ (^{103}Rh) = $28{\cdot}10^{-4}$ cm^{-1}, for complex **1**; $g_\perp = 2.105$, $g_\parallel = 1.939$ and $A_\parallel(^{103}Rh) = 29{\cdot}10^{-4}$ cm^{-1} for complex **2** (N−N = bipy, Figure 2); and $g_\perp = 2.103$, $g_\parallel = 1.937$ and $A_\parallel(^{103}Rh) = 27{\cdot}10^{-4}$ cm^{-1} for complex **3** (N−N = $t$bu$_2$bipy). Although not absolutely symmetric, the ^{103}Rh hyperfine structure ($I = 1/2$, natural abundance 100%) was resolved or indicated for $B_o \| z$ in all spectra.

Similar EPR spectra and parameters have been reported for Rh_2 complexes in the literature,[3,7c,8] as, for example, for $[(ap)_4Rh_2(C{\equiv}CH)]$,[3b] $[(ap)_4Rh_2(C{\equiv}C)_2Si(CH_3)_3]$[3a] and $[(ap)_4Rh_2(C{\equiv}C)_2Rh_2(ap)_4]$[3a] (ap = 2-anilinopyridinate). The EPR spectra confirm for all complexes the presence of an $Rh_2^{II,III}$ unit with an electronic configuration of $(\sigma)^2(\pi)^4(\delta)^2(\pi^*)^4(\delta^*)^1$ for the Rh^{II} ion.[3b] The Rh^{III} ion of the $Rh_2^{II,III}$ unit is probably the one bound to the C≡Cpy unit since this ligand is known to be a σ-donor.

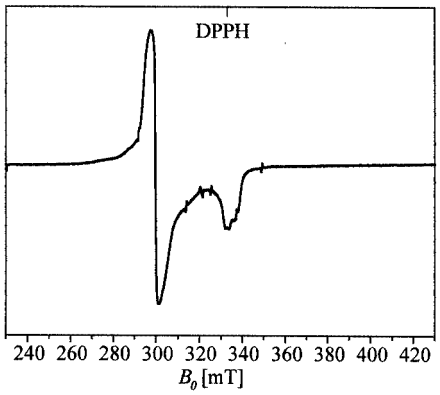

Figure 2. X-band EPR spectrum of complex **2** in a frozen solution of CH_2Cl_2; T_{rec} = 140 K (the spectrum is superimposed by small narrow lines of the standard Mn^{2+} in MgO)

Further conclusions, for example concerning partial spin density distribution to the Rh^{III} ion,[3a] are difficult to draw due to the limited resolution of the parallel features in the EPR spectra. The unequal distribution of the spin density (unpaired electron) over the two rhodium ions is underlined, however, by the observation of an additional hyperfine structure for complex **2** (Figure 2), which could be interpreted as a doublet of doublets [$A_\parallel(^{103}Rh) = 12{\cdot}10^{-4}$ cm^{-1}] observed in the parallel features for this particular EPR experiment.[3a] Regarding the EPR line-widths, the dirhodium unit is (magnetically) independent of the rhenium core connected via a bridging ligand.

Conclusions

Rh-based σ-alkynylpyridine complexes have been synthesized. They are stable to air, moisture and elevated temperatures (TG evidence) and can therefore be handled in air without any problems. However, the interactions along the RhRhC≡CpyRe axis do not allow significant electronic communication between the Rh_2 and the Re unit, as has been shown by CV and EPR experiments. However, the complexes are nevertheless of interest in the context of supramolecular chemistry. Work to replace the N−M bond by a C−M bond in closely related complexes is currently also under way in our laboratory. Furthermore, based on the findings presented here it should be possible to synthesize stable molecular rods based on Rh units ligated with two, instead of one, σ-alkynylpyridine ligands. This approach is also under examination in our laboratory.

Experimental Section

General: Unless stated otherwise, all reactions and manipulations were carried out in dry glassware under nitrogen or argon. Solvents were dried by standard procedures. 4-Ethynylpyridine,[9] $[Rh_2(O_2C{-}CH_3)_4]$,[10a] $[Rh_2(O_2CCF_3)_4]$,[10b] $[Re(N{-}N)(CO)_3(MeCN)]OTf$ (N−N = bipy, $t$bu$_2$bipy; OTf = CF_3SO_3)[11] were prepared according to literature methods. $Rh_2(form)_4Cl$ was prepared according to

the method described for $[Rh_2(ap)_4Cl]$ (ap = 2-anilinopyrinate), using "form" instead of "ap".[12] Elemental analyses were performed in the Mikroanalytisches Laboratorium of the TU München in Garching (Mr. M. Barth). IR (KBr pellets) and Raman spectra (powder samples) were obtained with a Bio-Rad FTS-575C spectrometer at room temperature. Mass spectra were obtained with Finnigan MAT 311 A and MAT 90 spectrometers. Cyclic voltammograms were recorded with a computer-controlled Model 173 Potentiostat/Galvanostat (EG&G Princeton Applied Research). The working electrode was platinum and the reference electrode was silver. Measurements were performed in a dichloromethane solution containing $[tBu_4N]PF_6$ as supporting electrolyte (0.2 M). Potentials are quoted vs. an Ag/AgCl reference electrode. The EPR spectra were recorded with a Jeol JES RE2X at X-band frequency ($\nu \approx 9.05$ GHz, microwave power 2 mW, modulation frequency 100 kHz).

$[Rh_2(form)_4(C{\equiv}Cpy\text{-}4)]$ (1): An equimolar amount of *n*BuLi was added dropwise to a solution of 4-ethynylpyridine (126.0 mg, 1.22 mmol) in 40 mL of dry THF at −78 °C under argon. $[Rh_2(form)_4Cl]$ (190 mg, 0.17 mmol) was added and the mixture was allowed to react at −78 °C for 5 h and then slowly brought to room temperature. Stirring was continued for 24 h and then the reaction mixture was exposed to air for another 24 h. The green residue was dissolved in CH_2Cl_2 and chromatographed on neutral Al_2O_3, eluting with CH_2Cl_2 to afford **1** as a dark green solid. Yield: 100 mg (50%). Dark green crystals were obtained by slow diffusion of Et_2O into a CH_2Cl_2 solution of the complex. $C_{67}H_{64}N_9Rh_2$ (1201.12): calcd. C 67.00, H 5.37, N 10.50; found C 66.55, H 5.70, N 10.36. IR (KBr): $\tilde{\nu}$ = 3019 (w), 2920 (w), 2120 (m, $\nu_{C\equiv C}$), 1590 (m), 1542 (s), 1504 (s), 1332 (m), 1219 (s), 938 (m), 821 (m), 756 (m), 710 (w), 441 (m) cm^{-1}. UV (CH_2Cl_2) = λ_{max} (ε) = 421 (10600), 591 (4200) and 905 (430 $M^{-1}\,cm^{-1}$) nm. FAB-MS (nitrobenzyl alcohol as FAB matrix, ^{103}Rh): *m/z* (%) = 1201 (4) $[M]^+$, 1098 (100) $[Rh_2(form)_4]^+$, 875 (5) $[Rh_2(form)_3]^+$, 652 (9) $[Rh_2(form)_2]^+$, 429 (21) $[Rh_2(form)]^+$.

$[Re(CO)_3(bipy)Rh_2(form)_4(C{\equiv}Cpy\text{-}4)][OTf]$ (2): A solution of compound **1** (60.0 mg, 0.05 mmol) and $[Re(CO)_3(bipy)(MeCN)][CF_3SO_3]$ (31.0 mg, 0.05 mmol) in THF (20 mL) was refluxed in the dark for 3 h. The reaction mixture was then cooled to room temperature and the residue was dissolved in CH_2Cl_2 and chromatographed on neutral Al_2O_3, eluting with CH_2Cl_2/MeOH (100:1) to yield the pale green solid **2** (51.9 mg, 55%). $C_{81}H_{72}N_{11}F_3O_6ReRh_2S$ (1776.62): calcd. C 54.76, H 4.09, N 8.67; found C 55.01, H 3.99, N 8.72. IR (KBr): $\tilde{\nu}$ = 2960 (w), 2923 (w), 2860 (w), 2108 (m), 2023 (s), 1891 (s), 1590 (m), 1543 (s), 1503 (s), 1332 (m), 1260 (m), 1219 (s), 1105 (br), 1020 (m), 812 (s), 765 (m) cm^{-1}. UV (CH_2Cl_2): λ_{max} (ε) = 336 (9120), 590 (2070), 875 (460 $M^{-1}\,cm^{-1}$) nm.

$[Re(CO)_3(tbu_2bipy)Rh_2(form)_4(C{\equiv}Cpy\text{-}4)][OTf]$ (3): A solution of compound **1** (60.0 mg, 0.05 mmol) and $[Re(CO)_3(tBu_2bipy)(MeCN)][CF_3SO_3]$ (36.5 mg, 0.05 mmol) in THF (20 mL) was refluxed in the dark for 3 h. The reaction mixture was then cooled to room temperature and the residue was dissolved in CH_2Cl_2 and chromatographed on neutral Al_2O_3, eluting with CH_2Cl_2/MeOH (200:1) to yield the pale green solid **3** (51.9 mg, 55%). $C_{89}H_{88}N_{11}F_3O_6ReRh_2S$ (1888.83): calcd. C 56.59, H 4.70, N 8.16; found C 56.72, H 4.55, N 8.22. IR (KBr): $\tilde{\nu}$ = 2961 (m), 2922 (m), 2867 (w), 2107 (m), 2027 (s), 1914 (s), 1605 (m), 1546 (s), 1503 (s), 1332 (m), 1261 (s), 1220 (s), 1096 (br), 1030 (m), 814 (s), 637 (w), 442 (w) cm^{-1}. UV (CH_2Cl_2): λ_{max} (ε) = 418 (8930, sh), 574 (1990), 885 (390 $M^{-1}\,cm^{-1}$) nm. FAB-MS (nitrobenzyl alcohol as FAB matrix, ^{103}Rh, ^{187}Re): *m/z* (%) = 1738 (16) $[M]^+$, 1198 (5) $[M - Re(CO)_3(tbu_2bipy)]^+$, 1096 (8) $[M - C{\equiv}Cpy - Re(CO)_3(tbu_2bipy)]^+$, 539 (53) $[Re(CO)_3(tbu_2bipy)]^+$, 429.

Structure and Electronic Properties of [Ni(dsdm){Fe(CO)$_3$}$_2$], an Unusual, Triangular Nickel Diiron Compound

Marie-Cécile Chalbot,[a] Allison M. Mills,[b] Anthony L. Spek,[b] Gary J. Long,[c] and Elisabeth Bouwman*[a]

Keywords: Carbonyl ligands / Cluster compounds / Iron / Nickel

Reaction of the low-spin complex [Ni(dsdm)] with Fe_2CO_9 results in the unique trinuclear cluster [Ni(dsdm){Fe(CO)$_3$}$_2$]. NMR spectroscopy shows that the structure is diamagnetic, and, moreover, that the complex is stable in solution and C_2-symmetric. The X-ray structure reveals short distances between the distorted octahedral nickel(II) ion and the two octahedral iron(0) centers. The observed diamagnetism is explained by the formation of a triangular metal core with three two-electron two-center bonds. The Mössbauer spectra, which are typical of iron(0), are composed of asymmetric quadrupole doublets as a result of the presence of two chemically similar, but crystallographically distinct, iron sites.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2003)

In recent years the discovery of organometallic-like fragments in the active sites of hydrogenase enzymes has given a new impetus to research pertaining to iron carbonyl chemistry. The active site of the enzyme extracted from *D. gigas* has been described as a heterodimetallic nickel-iron cluster in a sulfur-rich environment containing small diatomic CO or CN molecules coordinated to iron,[1] and the structure of the active site in the Fe-only hydrogenase isolated from *D. desulfuricans* comprises a diiron subcluster also containing CO and CN ligands.[2] Although few model compounds that properly match the active-site structure of [NiFe] hydrogenases have been reported, some do show various features of the metal coordination environment.[3−6] In spite of the research both in organometallic chemistry and in bioinorganic chemistry, the number of compounds containing both Ni and Fe bridged by a sulfur donor is rather limited.[7] Of bioinorganic interest among these are the Fe_3Ni cubane clusters and Fe_4S_4 clusters bridged to mononuclear nickel complexes, both cluster types being relevant to the active site in acetyl coenzyme-A synthase,[8,9] as well as a few heterodinuclear complexes relevant to the hydrogenase active site.[10]

In the field of organometallic cluster chemistry a huge number of structures containing the (μ-S)-Fe_2CO_6 fragment have been reported.[11] This Fe_2CO_6 fragment has recently gained renewed attention because of its importance in modeling the active site of Fe-only hydrogenases.[12] Research efforts by organometallic chemists have resulted in several complexes with a cyclopentadienylnickel unit bound to Fe(CO)$_3$ moieties.[13,14]

The mononuclear compound [Ni(dsdm)] {H_2dsdm = [*N*,*N*′-dimethyl-*N*,*N*′-bis(2-sulfanylethyl)ethylenediamine]} is a nickel thiolate complex used in biomimetic studies of [NiFe] hydrogenases.[15] [Ni(dsdm)] contains two *cis* sulfur atoms which are particularly reactive towards dioxygen. Indeed, the oxidation of [Ni(dsdm)] with H_2O_2 or O_2 leads to the fully oxidized [Ni(dsodm)(H_2O)$_2$] complex in which nickel is coordinated to the sulfonato groups.[16,17] Moreover, [Ni(dsdm)] has also been used in attempts to synthesize thiolato-bridged nickel-iron complexes. The reaction of [Ni(dsdm)] with K[HFe(CO)$_4$] leads to [Fe(dsdm)Ni(CO)$_3$]$_2$ and involves the reduction of nickel(II) to nickel(0) followed by the coordination of the dsdm ligand to the iron(II).[18]

We present herein the reaction of [Ni(dsdm)] with Fe_2CO_9, which results in the formation of the novel trinuclear sulfur-bridged nickel-iron complex [Ni(dsdm){Fe(CO)$_3$}$_2$], a diamagnetic compound that contains three metal centers in a compact triangular metal core.

Results and Discussion

A projection of the structure of [Ni(dsdm){Fe(CO)$_3$}$_2$] is shown in Figure 1, and the corresponding bond lengths and angles are listed in Table 1. In this trinuclear compound the Ni(dsdm) moiety coordinates to a diiron hexacarbonyl fragment and the three metals are in a nearly equilateral trian-

gular arrangement with short metal-metal distances. The nickel ion is tetracoordinate to two sulfur and two nitrogen donor atoms of the dsdm ligand, in a distorted tetrahedral geometry. The two sulfur atoms each bridge the nickel ion to one of the iron tricarbonyl moieties. The dihedral angle between the planes of the two five-membered rings formed by Ni with the N,C,C,S atoms of each sulfanylethyl portion of dsdm is 87.91(16)°, indicating a nonplanar [Ni-N_2S_2] environment. The Ni−S distances of 2.1602(11) and 2.1724(11) Å are in the range reported for the trinuclear complex [Ni_3(dsdm)$_2$]Cl_2, a complex that has pseudo-square planar nickel ions, whereas the Ni−N bond lengths of 2.061(3) and 2.077(4) Å are significantly longer.[15] If one includes the two iron centers in the coordination environment of the nickel ion, the geometry of the nickel(II) ion can be regarded as that of a distorted octahedron.

The structure contains two crystallographically distinct iron sites with small variations in the Fe−C distances and Fe−C−O angles. Each iron atom is pentacoordinate in a square-pyramidal geometry with the carbonyl C10 and C13 carbon atoms at the apex. The Fe−S bonds of 2.2553(14)−2.2567(12) Å and the Fe−C and C−O bond lengths of 1.769(4)−1.793(5) Å and 1.145(6)−1.173(5) Å, respectively, are similar to those reported for [EtS-$Fe^I(CO)_3]_2$.[19] The Fe−Fe bond length of 2.6618(9) Å is significantly longer than the 2.523 and 2.537 Å values found in the starting Fe_2CO_9 complex[20] and in the sulfur-bridged diiron complex [EtSFe(CO)$_3$]$_2$,[19] respectively. From structural and spectroscopic information it appears that the two Ni−Fe interactions, at distances of 2.5061(8) and 2.5131(10) Å, must be considered as metal-metal bonds. Including those in the coordination environment of the iron(0) centers, the geometry of the latter can also be regarded as that of a distorted octahedron.

At first sight it appears that a similar arrangement of nickel bridged through sulfur to $Fe_2(CO)_6$ fragments has been reported by Holliday et. al.[21] In the reported struc-

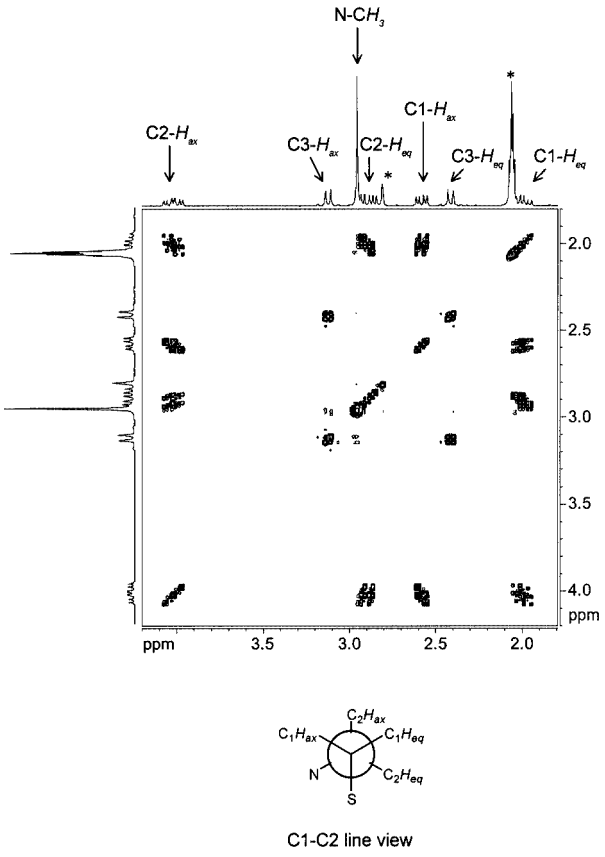

Figure 2. ^{1}H-^{1}H COSY 2D NMR spectrum of [Ni(dsdm){Fe(CO)$_3$}$_2$] at 300 MHz in [D$_6$]acetone; the asterisks denote signals from solvent and impurities

ture the two iron centers are bridged symmetrically by two sulfides, with a sulfur-sulfur distance of 2.83 Å, leading to a structure which, in all aspects, is more similar to the parent [(RS)Fe(CO)$_3$]$_2$ complex[19] if one includes the central NiS_4 unit as a chelating dithiolene group. In [Ni(dsdm){Fe(CO)$_3$}$_2$] the sulfur-sulfur distance in the dithiolate group formed by the tetrahedral Ni(dsdm) unit is too large (4.13 Å) for each sulfur to bind both Fe atoms; thus a $FeSC_3$ chromophore rather than the typical FeS_2C_3 chromophore is observed. The resulting electron deficiency of the iron center in [Ni(dsdm){Fe(CO)$_3$}$_2$] is compensated for by the additional Ni−Fe interactions. The total electron count of the trinuclear cluster is 48, similar to $Fe_3(CO)_{12}$.

[Ni(dsdm){Fe(CO)$_3$}$_2$] is diamagnetic and has been characterized by ^{1}H and ^{13}C NMR spectroscopy in solution. The NMR spectrum exhibits six sharp multiplets and a singlet, which have been assigned to the aliphatic hydrogens by ^{1}H-^{1}H COSY 2-D NMR spectroscopy (Figure 2). The presence of only seven signals indicates that, in solution, the two iron atoms are equivalent. The diamagnetism of the compound arises through the formation of a triangular metal core with three two-electron two-center bonds.

The Mössbauer spectra of [Ni(dsdm){Fe(CO)$_3$}$_2$] obtained at 80 and 297 K are shown in Figure 3. The spectra are composed of asymmetric doublets as a result of the presence of two chemically similar, but crystallographically distinct, iron sites. The spectra have been fitted at a given temperature with two quadrupole doublets both with the same line-width and area.

In Table 2 a comparison of the hyperfine parameters observed for [Ni(dsdm){Fe(CO)$_3$}$_2$] with those of other {Fe(CO)$_3$}$_2$ adducts such as ([Fe(CO)$_3$NH$_2$]$_2$, [Fe(CO)$_3$SMe]$_2$, and [Fe(CO)$_3$SPh]$_2$) is given, revealing the similarity of the chemical bonding found in these adducts.[22−24] In contrast, the hyperfine parameters of [Ni(dsdm){Fe(CO)$_3$}$_2$] are significantly different from those reported for $Fe_2(CO)_9$.[25] In all cases the adduct coordin-

[a] The isomer shifts are given relative to room temperature α-iron foil. [b] These parameters were constrained to be equivalent at a given temperature. [c] This work.

ated to the iron center has reduced the isomer shift relative to that found in $Fe_2(CO)_9$. This reduction corresponds to the expected increase in the *s*-electron density at the iron-57 nucleus. Furthermore, the quadrupole splittings observed for [Ni(dsdm){$Fe(CO)_3$}$_2$] are intermediate between those of the other adducts and $Fe_2(CO)_9$, indicating that the presence of S1 and S2 coordinated to $Fe_2(CO)_6$ in [Ni(dsdm){$Fe(CO)_3$}$_2$] has reduced the electronic asymmetry at the iron site, but to a lesser extent than is found in $Fe_2(CO)_9$.

Conclusion

To supplement the large number of organometallic clusters containing the $Fe_2(CO)_6$ fragment that have been reported, we have described herein the first cluster in which additional Ni−Fe metal-metal bonds are present. The unique nature of [Ni(dsdm){$Fe(CO)_3$}$_2$] is related to the atypical binding of the two thiolate sulfurs to the $Fe_2(CO)_6$ fragment, resulting in short distances between the octahedral, high-spin nickel(II) ion and the two octahedral iron(0) centers. This remarkable structure provides an additional, interesting example of the structural versatility possible for the reaction products formed from the nickel *cis* thiolate complex [Ni(dsdm)]. For comparison, the reaction of the related, but more rigid, [Ni(bme-daco)] complex with Fe_2CO_9 produces a dinuclear nickel-iron tetracarbonyl compound, in which the nickel(II) ion remains low-spin in a square-planar environment.[10]

Experimental Section

General Remarks: [Ni(dsdm)] was synthesized according to standard procedures.[15] The Mössbauer spectra were measured at 80 and 297 K on a constant-acceleration spectrometer, which utilized a room temperature rhodium matrix cobalt-57 source and was calibrated at room temperature with α-iron foil. The spectra were fitted as two symmetric quadrupole doublets and the estimated absolute errors are ± 0.005 mm·s^{-1} for the isomer shifts, ± 0.01 mm·s^{-1} for the quadrupole splittings and line widths, and ± 0.02 (%ε) (mm·s^{-1}) for the absolute spectral areas. UV/Vis-NIR measurements were performed on a Perkin−Elmer Lambda 900 UV/Vis/NIR spectrometer. IR spectra were recorded on a Perkin−Elmer FT-IR Paragon 1000 spectrometer. ^{1}H, ^{13}C, and ^{1}H−^{1}H 2D COSY NMR spectra were recorded on a Bruker 300 DPX MHz spectrometer. Elemental analyses were performed with a Perkin−Elmer series II CHNS/O analyzer 2400.

[Ni(dsdm){$Fe(CO)_3$}$_2$]: The preparation was carried out in dry degassed solvent under an argon atmosphere by using standard Schlenk techniques. Fe_2CO_9 (0.357 g, 1 mmol) was added to a suspension of [Ni(dsdm)] (0.265 g, 1 mmol) in 10 mL of toluene. The reaction mixture was stirred for 48 hours, during which time the toluene solution developed a dark-brown color. The toluene solution was filtered to remove the insoluble material. Crystals suitable for X-ray crystallography were obtained from toluene/hexane two-layer crystallization within one day (yield 0.60 g, 11%). Attempts to optimize the yield were not undertaken. UV/Vis (CH_3CN): λ_{max} (ε) = 1007 (50), 495 (shoulder), 394 (5150) nm. IR (diamond): ν(CO) = 2009, 1956, 1917, 1900, and 1885 cm^{-1}. $C_{14}H_{18}Fe_2N_2NiO_6S_2$: calcd. 30.86, H 3.33, N 5.14, S 11.77, Ni 10.77, Fe 20.50; found C 30.99, H 3.49, N 5.30, S 11.00, Ni 10.70, Fe 19.94. ^{1}H NMR (300 MHz, [D$_6$]acetone): δ = 4.02 (m, 2 H, C2-H_{ax}), 3.13 (d, 2 H, C3-H_{ax}), 2.96 (s, 6 H, N-CH_3), 2.91 (m, 2 H, C2-H_{eq}), 2.58 (dd, 2 H, C1-H_{ax}), 2.42 (d, 2 H, C3-H_{eq}), 1.99 (m, 2 H, C1-H_{eq}) ppm. ^{13}C NMR (300 MHz, $CDCl_3$): δ = 214 (C=O), 60 (*C3*), 54 (*C2*), 51 (CH_3), 38 (*C1*).

X-ray Crystallographic Study: $C_{14}H_{18}Fe_2N_2NiO_6S_2$, M_r = 544.83, dark purple rectangular plates (0.05 × 0.12 × 0.24 mm), monoclinic, $P2_1/c$, a = 9.7562(2), b = 13.9094(4), c = 17.2651(4) Å, β = 121.0760(13)°, V = 2006.68(9) Å^3, Z = 4, ρ_c = 1.803 g·cm^{-3}, μ = 2.595 mm^{-1}; intensity data were collected on a Nonius Kappa CCD diffractometer with rotating anode (Mo-K_α, λ = 0.71073 Å) at 150 K to a maximum resolution of θ_{max} = 27.5°, 20667 measured reflections, 4588 unique reflections, 3081 observed data [$I > 2.0\sigma(I)$], R_{int} = 0.060; convergence was reached at $R1$ [$I > 2.0\sigma(I)$] = 0.0421, $wR2$ = 0.0934, and S = 1.08 for 4588 reflections and 246 parameters, $\Delta\rho_{max/min}$ = 0.49/−0.54 e·Å^{-3}. The structure was solved by direct methods using SHELXS-97[26] and refined on F^2 using SHELXL-97; an empirical absorption correction was applied using DELABS in PLATON[27] (0.589−0.876 transmission); geometrical calculations and molecular graphics preparation were performed with PLATON; all non hydrogen atoms were refined with anisotropic displacement parameters; hydrogen atom were constrained to idealized geometries and allowed to ride on their carrier atoms with an isotropic displacement parameter related to the equivalent displacement parameter of their carrier atoms.
CCDC-184378 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at

Co-Condensation Reactions of Substituted Aromatic Compounds with Lithium Atoms at 77 K

John P. Dunne,[a] Matthias Bockmeyer,[a] and Matthias Tacke*[a]

Keywords: Lithium / C−H bond activation / Co-condensation / Density functional calculations

Lithium atoms were co-condensed with +I-substituted benzene derivatives like trimethyl(phenyl)silane and *tert*-butylbenzene in the presence of THF at 77 K, which resulted in C–H bond activation, to produce the aryllithium compound as well as the coupling of the substituted phenyl radicals. Other +I-substituted benzene derivatives like xylene and mesitylene failed to react with lithium atoms in the presence of THF. Oxygen and nitrogen donor substituted benzene derivatives (anisole, *N*,*N*-dimethylaniline, and *N*,*N*-dimethylbenzylamine) showed activation of the *ortho* C–H bond when co-condensed with lithium atoms in the presence of THF. However, when thioanisole was co-condensed with lithium atoms and THF, a C–S bond cleavage occurred instead. These results were interpreted with the aid of DFT calculations, which show π- and σ-complexes between the lithium clusters and benzene derivatives as reactive intermediates.

Introduction

The activation of carbon−hydrogen bonds has been a major topic of research for the last 30 years.[1−3] Numerous methods have been developed to perform these reactions. Most of these have centred on the oxidative addition of the hydrocarbon moiety to a highly sub-coordinated metal complex as shown in Figure 1,[4,5] however, C−H bond activation is not limited to transition metal chemistry. Another commonly used method is σ-bond metathesis using extremely electrophilic lanthanide centres as outlined below.[6]

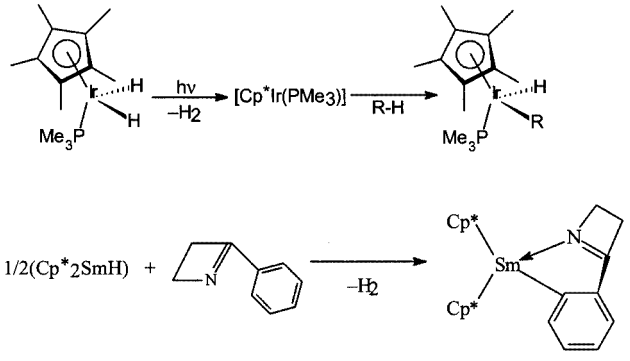

Figure 1. Selected examples of C−H bond activation using metal complexes

To date there has been very little preparative-scale work using metal atoms to perform oxidative addition reactions. Many metals are known to activate methane in a matrix under photochemical conditions,[3,7] but these types of reactions are of no use for preparative scale chemistry. For example, iron atoms when photolysed react with methane to form CH_3FeH at 10 K in an argon matrix.[8]

$$Fe + CH_4 \xrightarrow[Ar,\ 10K]{hv} HFeCH_3$$

Work performed by this group in the 1990s showed that lithium atoms could selectively activate the C−H bond of benzene and toluene in the presence of THF without the need for further photochemical excitation.[9−11] This resulted in the direct synthesis of aryllithium compounds on a synthetic scale.

$$8\ Li(g) + 4\ PhH(g) + 4\ THF(g) \xrightarrow[77K]{cocond.} \left[\text{C}_6\text{H}_5\text{Li(THF)}\right]_4 + 4\ LiH(s)$$

One of the key intermediates in this reaction is an Li_2−benzene π-complex. This complex is capable of undergoing two single electron transfers from the Li_2 cluster to the LUMO of the aromatic ring, resulting in the activation of the aromatic C−H bond.

$$2\ Li(g) + 4\ PhH(g) \xrightarrow[77K]{cocond.} \left[Li{-}Li{\leftarrow}PhH\right] \longrightarrow \left[H\begin{smallmatrix}Li\\ \diagup\ \diagdown\\ Li\end{smallmatrix}Ph\right] \longrightarrow LiH(s) + PhLi(s)$$

The aim of this paper was to (a) expand the number of aromatic substrates for this C−H bond activation, (b) to study how different substituents alter the selectivity of the reaction, and (c) to gain an insight into the electronic limits

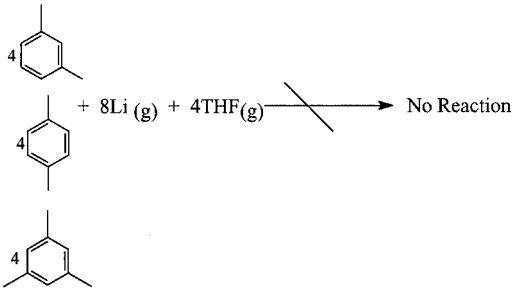
[a] Department of Chemistry, University College Dublin, Belfield, Dublin 4, Ireland
E-mail: matthias.tacke@ucd.ie

of this reaction. For this purpose the following +I-substituted [$C(CH_3)_3$, $SiMe_3$, *p*- and *m*-xylene] benzene derivatives were chosen, as well as a series of donor-substituted (OMe, NMe_2, CH_2NMe_2, SMe) benzene derivatives.

Results

Experimental Study

The +I-substituted benzene derivatives mesitylene and (*meta*- or *para*-)xylene failed to react with lithium atoms at 77 K in the presence of THF as shown in Scheme 1. However, when an $SiMe_3$ substituent was placed on the aromatic ring [as for trimethyl(phenyl)silane] a reaction with lithium atoms was observed at 77 K. The yield for this reaction was 32%, based on the amount of lithium vapourised. A broadened set of signals corresponding to the species 4,4′-bis(trimethylsilyl)biphenyl was observed in the ^{13}C NMR spectrum. However, the ^{7}Li NMR spectrum showed a broad peak at $\delta = -2.99$ ppm, which indicates the presence of an $Li^+(THF)_4$ solvent-separated ion-pair species. These NMR spectroscopic data in conjunction with the dark red/black colour of the solution indicates that the broadened ^{13}C NMR signals are actually of the 4,4′-bis(trimethylsilyl)-biphenyl radical anion. It is formed by the reduction of 4,4′-bis(trimethylsilyl)biphenyl by excess lithium metal, as shown in Scheme 2. When the co-condensation product was redissolved in THF and treated with dimethyl disulfide a full characterisation was achieved (Scheme 2). This showed that the major product is 4,4′-bis(trimethylsilyl)biphenyl (80%) and the minor product trimethyl[4-(methylsulfanyl)-phenyl]silane (20%), identified by NMR spectroscopy and GC MS.[12,13]



Scheme 1. Failed reaction of lithium atoms with +I-substituted benzene derivatives

A similar reaction series is seen when *tert*-butylbenzene was co-condensed with lithium atoms and THF at 77 K as outlined in Scheme 2. The yield for this reaction was lower (1% based on the amount of lithium metal vapourised) than the trimethyl(phenyl)silane co-condensation. When the co-condensation product was treated in situ with Me_2S_2, NMR spectroscopic and GC-MS data identified the major product (70%) as 4,4′-di-*tert*-butylbiphenyl[14] and a minor product (30%) as 1-*tert*-butyl-4-(methylsulfanyl)benzene.[15]

When a donor-substituted aromatic compound was used the observed direction of lithiation changed from *para* to *ortho*. Co-condensation of anisole with lithium atoms and THF at 77 K, led to the observed lithiated compound 2-methoxyphenyllithium, shown by NMR spectroscopy (as shown in Scheme 3). The *ipso*-carbon signal at $\delta = 169.6$ ppm and a singlet at $\delta = 1.56$ ppm in the ^{7}Li NMR spectrum, as well as the integration in the ^{1}H NMR spectrum clearly indicate a tetrameric structure in C_6D_6.[16] The yield of this reaction increased to 30% compared to 12% when toluene was used.[9,10] As in previous co-condensations, a further confirmation of the regiochemistry was gained by the reaction of 2-methoxyphenyllithium with dimethyl disulfide. The observed product of this reaction was 1-methoxy-2-(methylsulfanyl)benzene in a quantitative yield, which was identified from NMR spectroscopic data and GC MS data[17,18] as shown in Scheme 3.
