X-ray Crystallographic Study of [Pt(DMeDPQ)(bipy)](PF$_6$)$_2$·0.5{(C$_{20}$H$_{16}$N$_4$)(CH$_4$O)}: Suitable crystals of the title complex were obtained by slow solvent evaporation from a methanol solution of **1**. Diffraction data were collected with a Siemens P4 automatic four-circle diffractometer. A summary of the crystallographic data and the structure refinement is reported in Table 4. No crystal deterioration was evidenced by monitoring of three standard reflection measurements. The reflection intensities were evaluated by a learnt-profile procedure[23] among 2θ shells and then corrected for Lorentz-polarisation effects. Absorption correction was applied by fitting a pseudo-ellipsoid to the azimuthal scan data (0−360° range by a 10° step) of 15 high reflections.[24] Data collection and reduction were performed with the SHELXTL[25] package. The diffraction data did not allow us to determine uniquely the crystal packing symmetry and the structure modellisation was carried out in all the three possible monoclinic space groups *C*2, *Cm* and *C*2/*m*. The refinement in the two acentric space groups was seriously hampered by several very strong parameter correlations (> 0.9) while the centrosymmetric one shows incompatibility between the crystallographic point symmetries and the compound moieties in special positions. The structure was solved in *C*2/*m* by a combination of standard direct methods[26] and Fourier synthesis, and refined by minimizing the function $\Sigma w(F_o^2 - F_c^2)^2$ with the full-matrix least-squares technique based on all independent *F*, with SHELXL-97.[27] All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were included in the model refinement with the "riding model" method with the X−H bond geometry and isotropic displacement parameter depending on the parent atom X. The co-crystallised methanol and uncoordinated quinoxaline molecules were placed in crystallographic special positions having a higher symmetry than these molecules. This generates a significant symmetry disorder. Further, one hexafluorophosphate anion shows the usual rotational disorder evidenced by the overlap of two symmetric orientations related by the intersecting mirror plane. All attempts to represent the biggest ellipsoids as adjacent atomic partial occupancies were unsuccessful. The final geometrical calculations and drawings were carried out with the PARST program[28] and the XPW utility of the Siemens package, respectively. CCDC-237593 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: + 44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

A Triiron Complex Containing the Carboxylate-Free $\{Fe_3(\mu_3\text{-}O)\}^{7+}$ Core and Distorted Pentagonal-Bipyramidal Metal Centres

Subramanya Gupta Sreerama[a] and Samudranil Pal*[a]

Keywords: Trinuclear iron(III) complex / Crystal structure / Magnetic properties / Redox properties

The reaction of $Fe(ClO_4)_3\cdot 6H_2O$, 1,2-bis(biacetylmonoximeimino)ethane (H_2bamen) and triethylamine (1:1:2 mol ratio) in methanol affords a trinuclear complex with the formula $[Fe_3(\mu_3\text{-}O)(\mu_3\text{-bamen})_3]ClO_4\cdot 2H_2O$. The structure of the complex cation in this species shows a symmetric planar central $\{Fe_3(\mu_3\text{-}O)\}^{7+}$ unit coordinated to three N_4O_2 donor bridging (via oximate groups) ligands ($bamen^{2-}$). The N_4O_3 coordination sphere around each metal centre is very close to pentagonal-bipyramidal. Four N atoms of one $bamen^{2-}$ and the oxo group satisfy five coordination sites and form a pentagonal plane around the metal ion. The axial sites are occupied by two oximato O atoms from the other two $bamen^{2-}$ ligands. Thus, in addition to the μ_3-oxo group, two oximate groups provide two additional bridges between each pair of metal centres. In the crystal lattice, the water molecules exist as hydrogen-bonded dimers and these water dimers together with the perchlorate ions form a hydrogen-bond-supported helix. The complex cations form a chain via C–H···O interactions involving a methyl group and a metal-coordinated oximato O atom. The helix of $\{(H_2O)_2ClO_4^-\}$ units and the chain of $[Fe_3O(bamen)_3]^+$ cations are connected by O–H···O interactions which involve a water molecule and a second oximato O atom. In its cyclic voltammogram, the complex displays metal-centred oxidation as well as reduction responses. Variable-temperature magnetic susceptibility measurements revealed the presence of an antiferromagnetic interaction [J = –41.0(2) cm^{-1}] between the Fe^{III} centres in this complex.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

Trinuclear μ_3-oxo-bridged transition metal ion complexes have been of considerable interest for their molecular structures, magnetic properties and intramolecular electron transfer features in the mixed-valence variety. Such complexes are also useful precursors for the synthesis of higher nuclearity metal clusters. A number of complexes containing the $\{M_3(\mu_3\text{-}O)\}$ unit have been reported.[1–11] Essentially in all of them, the triangular metal ion core with the central oxo bridge is stabilised by six carboxylate groups (RCO_2^-) and three monodentate ligands (L). In these complexes of general formula $[M_3(\mu_3\text{-}O)(\mu_2\text{-}O_2CR)_6L_3]^{0/+}$, each metal ion is in a distorted octahedral coordination sphere. The O atoms of the bridging carboxylate groups constitute an O_4 square plane and the μ_3-O and the monodentate ligand L occupy the remaining two *trans* sites. The central $\{M_3(\mu_3\text{-}O)\}$ core is usually planar and has close to threefold symmetry. Complexes of $\{M_3(\mu_3\text{-}O)\}$ without carboxylate ligands are very rare although a few mixed-ligand complexes of this type are known.[12,13] However, in these complexes the $\{M_3(\mu_3\text{-}O)\}$ unit is asymmetric and pyramidal. Recently, we reported a carboxylate-free trinuclear complex containing the planar and symmetric $\{Mn_3(\mu_3\text{-}O)\}^{7+}$ core with a Schiff base (H_2bamen, two H represent the dissociable oxime protons) derived from 1 equiv. of ethylenediamine and 2 equiv. of biacetylmonoxime.[14] The metal ions in $[Mn_3(\mu_3\text{-}O)(\mu_3\text{-bamen})_3]^+$ are in a distorted pentagonal-bipyramidal N_4O_3 coordination sphere. A ferromagnetic interaction is operative between the metal ions in this complex. In contrast, the known μ_3-oxo-bridged trimanganese(III) complexes with carboxylate groups of formula $[Mn_3(\mu_3\text{-}O)(\mu_2\text{-}O_2CR)_6(py)_3]^+$ are antiferromagnetic.[3] Because of this variation, and also to examine whether the stabilisation of the $\{Mn_3(\mu_3\text{-}O)\}^{7+}$ unit by three $bamen^{2-}$ ligands is unique or can be extended to Fe^{III}, we attempted to synthesise the triiron(III) analogue of $[Mn_3(\mu_3\text{-}O)(\mu_3\text{-bamen})_3]^+$ and compare its structure and properties with the known $[Fe_3(\mu_3\text{-}O)(\mu_2\text{-}O_2CR)_6L_3]^+$ complexes. Indeed we were able to isolate the trinuclear μ_3-oxo-bridged Fe^{III} complex using H_2bamen. In the following account, we describe the synthesis, X-ray structure and physical properties of $[Fe_3(\mu_3\text{-}O)(\mu_3\text{-bamen})_3]ClO_4\cdot 2H_2O$.

Results and Discussion

Synthesis and Characterisation of $[Fe_3O(bamen)_3]ClO_4\cdot 2H_2O$

The complex was synthesised in good yield by allowing $Fe(ClO_4)_3\cdot 6H_2O$, H_2bamen and triethylamine to react in a

molar ratio in methanol under aerobic conditions. It precipitates as a brown solid from the reaction mixture. The elemental analysis data are satisfactory for the assigned molecular formula. In CH_3CN solution, the molar conductivity value of the complex (152 Ω^{-1} cm^2 M^{-1}) is consistent with 1:1 electrolytic behaviour.[15]

The infrared spectrum of the complex does not display any peak near 3000 cm^{-1}. The oxime OH groups of the ligands are therefore deprotonated. A broad peak centred at 3500 cm^{-1} is most likely due to the lattice water molecules. The presence of perchlorate is indicated by the bands at 1090 and 621 cm^{-1}. Two strong bands can be observed at 1641 and 1533 cm^{-1}. Comparable bands observed for complexes with dioxime ligands have been attributed to the coupled C···N and C···C stretching modes.[16] There is a 1:1 correlation between the infrared spectrum of this complex and that of $[Mn_3O(bamen)_3]ClO_4{\cdot}2H_2O$.[14] This observation, together with the elemental analysis and molar conductivity data, suggests that the present complex is most likely the Fe^{III} analogue of $[Mn_3O(bamen)_3]ClO_4{\cdot}2H_2O$.

The electronic spectrum of the complex in CH_3CN solution shows a weak absorption at 720 nm followed by three strong absorptions in the range of 383−248 nm. Weak absorptions observed for $[Fe_3O(O_2CR)_6(H_2O)_3]^+$ in the range of 980−625 nm have been assigned to d-d transitions and the large extinction coefficients which are unusual for spin-forbidden transitions can be attributed to the spin-exchange between the metal ions.[1] The higher energy intense absorptions are most likely due to ligand-to-metal and intraligand charge transfer transitions.[16]

Structure of $[Fe_3O(bamen)_3]^+$

An X-ray crystallographic study revealed that $[Fe_3O(bamen)_3]ClO_4{\cdot}2H_2O$ is isomorphous with the corresponding Mn^{III} analogue $[Mn_3O(bamen)_3]ClO_4{\cdot}2H_2O$.[13] Both species crystallise in the same space group with very similar unit cell dimensions. The structure of $[Fe_3O(bamen)_3]^+$ is illustrated in Figure 1. The cation contains three bridging N_4O_2 donor bamen^{2-} ligands, one μ_3-oxo group and three metal centres. The presence of one ClO_4^- anion per complex cation indicates that the oxidation state of each metal centre is +3. The C−N and N−O bond lengths in the oximate [−(CH$_3$)C=N−O$^-$] fragments are in the ranges 1.277(4)−1.288(4) Å and 1.337(4)−1.353(4) Å, respectively. These bond lengths are similar to the corresponding ones reported for deprotonated oxime functionalities.[14,17] All other intraligand bond parameters are unexceptional. The metal ions are heptacoordinated and each bamen^{2-} is coordinated to all three Fe atoms. Four N atoms coordinate one metal centre forming three five-membered chelate rings and the two oximato O atoms coordinate to the other two metal centres. As a result, each pair of iron centres is bridged by two oximate groups (=N−O$^-$) in a reciprocal fashion with respect to the N and O atom coordination. The seventh coordination site is satisfied by the μ_3-oxo atom. Thus, each metal ion has an N_4O_3 coordination sphere. The Fe−N_{imine} bond lengths [2.233(3)−2.250(3) Å] are significantly shorter than the Fe−$N_{oximate}$ bond lengths [2.302(3)−2.340(3) Å] (Table 1). This difference is possibly due to the bridging nature of the oximate groups and the rigidity of the N_4 fragment of the ligands.[14,18] The central $\{Fe_3(\mu_3\text{-}O)\}^{7+}$ core is essentially planar. The solid angle at the μ_3-O centre is 359.95° and its displacement from the Fe_3 plane is 0.024(2) Å. The Fe−μ_3-O bond lengths [1.898(2)−1.911(2) Å] and the Fe···Fe distances [3.2992(9)−3.3013(7) Å] are similar to the corresponding values reported for complexes containing the $\{Fe_3(\mu_3\text{-}O)\}^{7+}$ core.[6,9,11] The N_4O_3 coordination geometry around each Fe atom can be best described as pentagonal-bipyramidal. The four N atoms and the μ_3-O atom constitute the pentagonal plane and the two oximato O

atoms occupy the two axial sites. The mean deviations from the pentagonal $N_4(\mu_3\text{-}O)$ plane are in the range 0.21−0.22 Å. The $O_{oximate}$−Fe−N/O7 angles fall in the range 80.69(10)−98.73(11)° and the $O_{oximate}$−Fe−$O_{oximate}$ angles are within 177.17(10)−177.74(10)°.

Hydrogen Bonding and Crystal Packing

In the crystal lattice of $[Fe_3O(bamen)_3]ClO_4{\cdot}2H_2O$, the water molecules and the perchlorate ions exist in a helical fashion through hydrogen bonding interactions (Figure 2). Two water molecules form a linear dimer [O···O distance, 2.890(8) Å; O−H···O angle, 149.8°]. The hydrogen bond acceptor molecule in this water dimer is again hydrogen-bonded to one perchlorate oxygen atom [O···O distance, 3.119(8) Å; O−H···O angle, 142.8°]. The donor water molecule of the dimer in the $\{(H_2O)_2ClO_4^-\}$ unit is hydrogen-bonded with a perchlorate oxygen atom (O···O distance, 3.026(8) Å; O−H···O angle, 160.3°) of a symmetry-related $\{(H_2O)_2ClO_4^-\}$ unit. These three hydrogen bonding interactions lead to the helical arrangement of the water molecules and the perchlorate ions (Figure 2). Interestingly, the cations also exist in a chain-like arrangement via inter-cation C−H···O interactions [C···O distance, 3.346(5) Å; C−H···O angle, 147.4°] involving a methyl group (C17) and an oximato O atom (O6).[19−21] Another metal-coordinated oximato O atom (O1) and the O atom of the acceptor molecule in the water dimer present in the $\{(H_2O)_2ClO_4^-\}$ unit are within hydrogen bond lengths [O···O distance, 3.201(7) Å; O−H···O angle, 128.1°]. This is also reflected in the rather long Fe3−O1 bond [1.997(2) Å] compared with the other Fe−$O_{oximate}$ bonds [1.979(2)−1.989(2) Å]. Thus, the chain of cations and the helix of $\{(H_2O)_2ClO_4^-\}$ units are bridged by O−H···O interactions (Figure 3). There are no other inter-chain or inter-helix noncovalent interactions. The same packing arrangement of the water molecules, the perchlorates and the complex cations can be observed in the crystal lattice of $[Mn_3O(bamen)_3]ClO_4{\cdot}2H_2O$.[14]

Redox Properties

The electron transfer behaviour of $[Fe_3O(bamen)_3]ClO_4{\cdot}2H_2O$ in CH_3CN has been studied using cyclic voltammetry. The complex displays a reversible oxidation response at $E_{1/2}$ = 1.05 V (ΔE_p = 80 mV) and another reversible reduction response at $E_{1/2}$ = −1.05 V (ΔE_p = 60 mV) (Figure 4). The peak currents observed for these two responses are similar to the peak currents of known one-electron processes under identical conditions.[18,22] The depro-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

tonated ligand ($bamen^{2-}$) does not display any response in the potential range +2.1 to −2.1 V. Thus, the oxidation response can be assigned to the $Fe^{III}{}_2Fe^{IV}/Fe^{III}{}_3$ couple and the reduction response to the $Fe^{III}{}_3/Fe^{III}{}_2Fe^{II}$ couple. On the anodic side of the SCE, in addition to the reversible oxidation response, two more irreversible oxidation responses (E_{pa} = 1.41 and 1.75 V) can be observed. However, the peak current of the lower potential response is 1/3rd and that of the higher potential response is almost double the peak current of the reversible oxidation response. The corresponding Mn^{III} analogue displays two reversible and one irreversible metal-centred oxidations.[14] Thus, the irreversible oxidations observed for the present complex may perhaps involve the metal centres. However, the irreversible nature clearly indicates that the corresponding oxidised species are unstable in the cyclic voltammetric time scale. Similarly, on the cathodic side of the SCE, an irreversible reduction at −1.66 V having a peak current similar to that of the reversible reduction response was observed. This response may be due to the $Fe^{III}{}_2Fe^{II} \rightarrow Fe^{III}Fe^{II}{}_2$ process as the ligand is redox inactive at this potential. It is interesting to note that there are no reports of metal-centred oxidations displayed by $[M_3O(O_2CR)_6L_3]^+$ species containing first row metal ions. Normally for these species, metal-centred reductions are observed and very few of them display more than one reversible redox step.[9]

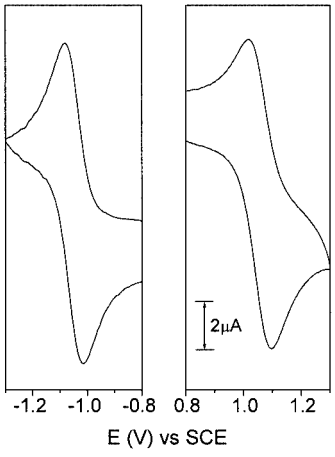

Figure 4. Cyclic voltammograms (scan rate 50 mV s^{-1}) of $[Fe_3O(bamen)_3]ClO_4{\cdot}2H_2O$ in acetonitrile (0.1 M TBAP) at a platinum electrode (298 K)

Magnetic Properties

A powdered sample of $[Fe_3O(bamen)_3]ClO_4{\cdot}2H_2O$ was used for the measurements of the magnetic susceptibilities at a fixed magnetic field of 5 kG in the temperature range 18−300 K. The effective magnetic moment of the complex at 300 K is 5.00 μ_B. The moment gradually decreases with the lowering of the temperature and reaches a value of 1.71 μ_B at 18 K. The nature of the curve obtained by plotting the moment against temperature (Figure 5) clearly indicates the antiferromagnetic character of the complex and the value of the moment at the lowest temperature is consistent with an S = 1/2 ground state. The data were fitted using an expression for χ_M vs. T obtained from the isotropic spin exchange Hamiltonian $H = -2J(S_1S_2 + S_2S_3 + S_3S_1)$ for a triangular triiron(III) complex in which all the metal ions are equivalent and have the same spin state $S_1 = S_2 = S_3 = 5/2$.[23] The best least-squares fit[24] was obtained with $J = -41.0(2)$ cm^{-1} and $g = 1.984(4)$ ($R = 1.50 \times 10^{-4}$). Complexes of formula $[Fe_3(\mu_3\text{-}O)(\mu_2\text{-}O_2CR)_6L_3]^+$ are known to be antiferromagnetic and the J values reported for such species span the range −15 to −33 cm^{-1}.[1,3−5,11] It has also been noted that the antiferromagnetic interaction decreases as the metal ion is changed from Fe^{III} to Mn^{III} in the acetate complexes of $\{M_3(\mu_3\text{-}O)\}^{7+}$. In this type of species, the metal ions are in a distorted octahedral coordination sphere. The unpaired electrons present in the σ-interacting e_g orbitals are involved in the antiferromagnetic exchange process. Thus, the decrease in the $-J$ value has been attributed to the decrease in the number of unpaired electrons in the e_g orbitals as one goes from high-spin Fe^{III} ($t_{2g}{}^3e_g{}^2$) to high-spin Mn^{III} ($t_{2g}{}^3e_g{}^1$).[3] Interestingly, the antiferromagnetic interaction in $[Fe_3O(bamen)_3]^+$ is noticeably higher than that in the $[Fe_3O(O_2CR)_6L_3]^+$ complexes and a ferromagnetic interaction [J = 22.3(1) cm^{-1}][14] is operative in $[Mn_3O(bamen)_3]^+$ rather than a weaker antiferromagnetic interaction as observed in $[Mn_3O(O_2CR)_6L_3]^+$. It is very likely that the change in the coordination geometry around the metal ions from octahedral in $[M_3O(O_2CR)_6L_3]^+$ to pentagonal-bipyramidal in $[M_3O(bamen)_3]^+$ is primarily responsible for the differences in the magnetic properties of these two types of complex containing the same $\{M_3(\mu_3\text{-}O)\}^{7+}$ core. It may be noted that in the pentagonal-bipyramidal coordination sphere the highest energy d_{z^2} orbital in the high-spin Fe^{III} species will have an unpaired electron but that in the high-spin Mn^{III} species will be empty. Thus, the alteration in the nature of the spin-coupling from ferromagnetic in $[Mn_3O(bamen)_3]^+$ to antiferromagnetic in $[Fe_3O(bamen)_3]^+$ is perhaps dictated by the absence or presence of an electron in the d_{z^2} orbital of the metal ion.

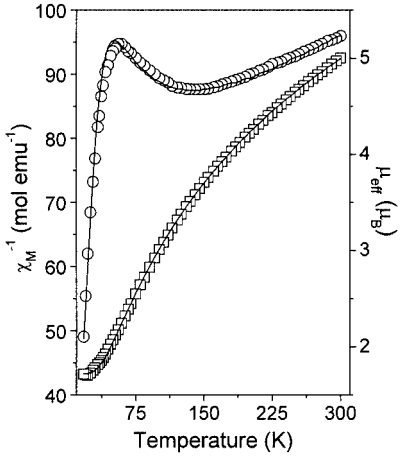

Figure 5. Temperature dependence of the inverse molar magnetic susceptibilities (open circles) and effective magnetic moments (open squares) of $[Fe_3O(bamen)_3]ClO_4{\cdot}2H_2O$; the continuous lines were generated from the best least-squares fit parameters given in the text

Conclusion

Before we reported the cationic complex $[Mn_3O(bamen)_3]^+$ [14], examples of carboxylate-free complexes containing the symmetric $\{M^{III}{}_3(\mu_3\text{-}O)\}$ unit were nonexistent. Now, we have been able to isolate the Fe^{III} analogue of the above complex. As in the Mn^{III} species, the metal ions in $[Fe_3O(bamen)_3]^+$ are in a pentagonal-bipyramidal N_4O_3 coordination sphere assembled by the bridging hexadentate N_4O_2 donor $bamen^{2-}$ and the μ_3-oxo group. Thus, like carboxylates, three $bamen^{2-}$ ligands are fairly efficient at stabilising the planar triangular ensemble of Mn^{III} and Fe^{III} ions with the central oxo bridge. A comparison of the redox and magnetic properties of $[M_3O(O_2CR)_6L_3]^+$ in which the metal ions are octahedral, with that of $[M_3O(bamen)_3]^+$ (M = Mn^{III} and Fe^{III}], reveals some interesting differences. Both $[M_3O(bamen)_3]^+$ species exhibit several metal-centred redox steps uncommon for $[M_3O(O_2CR)_6L_3]^+$ complexes. The $[M_3O(O_2CR)_6L_3]^+$ species are antiferromagnetic. However, the antiferromagnetic exchange is weaker in the Mn^{III} complexes than in the Fe^{III} complexes. On the other hand, $[Mn_3O(bamen)_3]^+$ is ferromagnetic whereas the Fe^{III} analogue is antiferromagnetic. The extent of antiferromagnetic coupling in $[Fe_3O(bamen)_3]^+$ is noticeably larger than in the carboxylate complexes of $\{Fe_3(\mu_3\text{-}O)\}^{7+}$.

Experimental Section

Materials: The Schiff base H_2bamen was prepared according to a reported procedure.[25] All other chemicals and solvents were of commercially available analytical grade and were used as received.

Physical Measurements: Microanalytical (C, H, N) data were obtained with a Perkin−Elmer Model 240C elemental analyser. A Shimadzu 3101-PC UV/Vis/NIR spectrophotometer was used to record the electronic spectrum. The infrared spectrum was collected in a KBr pellet with a Jasco-5300 FT-IR spectrophotometer. The variable-temperature (18−300 K) magnetic susceptibility measurements were performed using the Faraday technique with a set-up consisting of a George Associates Lewis coil force magnetometer, a CAHN microbalance and an Air Products closed-cycle helium cryostat. $Hg[Co(NCS)_4]$ was used as the standard. Diamagnetic corrections (-468×10^{-6} emu mol^{-1} for $[Fe_3O(bamen)_3]ClO_4{\cdot}2H_2O$) calculated from Pascal's constants[26] were used to obtain the molar paramagnetic susceptibilities. The solution electrical conductivity was measured with a Digisun DI-909 conductivity meter. A CH-Instruments model 620A electrochemical analyser was used for cyclic voltammetric experiments with an acetonitrile solution of the complex containing tetrabutylammonium perchlorate (TBAP) as the supporting electrolyte. The three electrode measurements were carried out at 298 K under nitrogen with a platinum working electrode, a platinum wire auxiliary electrode and a saturated calomel reference electrode (SCE). The potentials reported in this work are uncorrected for junction contributions.

Synthesis of $[Fe_3O(bamen)_3]ClO_4{\cdot}2H_2O$: A methanol solution (20 mL) of $Fe(ClO_4)_3{\cdot}6H_2O$ (1.022 g, 2.21 mmol) was added to a suspension of H_2bamen (500 mg, 2.21 mmol) in methanol (20 mL). The colour of the reaction mixture immediately became brown. To this brown solution was added triethylamine (435 mg, 4.3 mmol, 0.6 mL) and the reaction mixture was stirred in air at room temperature (298 K) for 8 h. The brown solid which precipitated was collected by filtration, washed with ice-cold methanol and finally dried in air. Recrystallisation was performed by dissolving the complex in a methanol/xylene mixture (2:1). Yield, 460 mg (63%). $C_{30}H_{52}ClFe_3N_{12}O_{13}$ (991.84): calcd. C 36.33, H 5.28; N 16.95; found C 36.12, H 5.48, N 17.13. Selected IR bands [cm^{-1}]: $\tilde{\nu}$ = 3500 br, 1641 s, 1533 s, 1431 m, 1379 m, 1323 m, 1188 m, 1090 vs, 692 s, 621 m, 592 m, 505 s, 411 s. Electronic spectroscopic data in CH_3CN: $\lambda_{max.}$ [nm] (ε [$M^{-1}\,cm^{-1}$]) = 720 (115), 383 (11 900), 277sh (37 900), 248 (47 800). Molar conductivity (CH_3CN): Λ_M [$\Omega^{-1}\,cm^2\,M^{-1}$] = 152.

X-ray Crystallography: Single crystals were grown by slow concentration of a methanol/xylene (2:1) solution of the complex. A crystal of dimensions 0.48 × 0.40 × 0.24 mm was used for data collection with an Enraf−Nonius Mach-3 diffractometer using graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å) by the ω-scan method at 298 K. Unit cell parameters were determined by a least-squares fit of 25 reflections having θ values in the range 9−11°. Intensities of three check reflections were measured every 1.5 h during the data collection to monitor the crystal stability and no decay was observed. The ψ-scans[27] of 6 reflections having θ and χ values within 1−21° and 80−86°, respectively, were used for an empirical absorption correction. The structure was solved by direct methods in the $P\bar{1}$ space group and refined on F^2 by full-matrix least-squares procedures. The asymmetric unit contains a molecule of $[Fe_3O(bamen)_3]ClO_4$ and two water molecules. All non-H atoms were refined using anisotropic thermal parameters. The H atoms of the water molecules were located in a difference map and refined with geometric restraints with $U_{iso}(H) = 1.5U_{eq}(O)$. The remainder of the H atoms were included in the structure factor calculation in idealised positions using the riding model but they were not refined. The programs of the WinGX package[28] were used for data reduction and the absorption correction. The structure solution and refinement were performed with the SHELX-97 programs.[29] The ORTEX6a[30] and the PLATON[31] packages were used for molecular graphics. Selected crystal and refinement data are summarised in Table 2. Crystallographic data have been deposited with the

COVER PICTURE

The cover picture shows the stable and well-defined metallocene bis(trimethylsilyl)acetylene complexes $Cp_2M(L)(\eta^2\text{-}Me_3SiC_2SiMe_3)$ (M = Ti, without L; M = Zr, L = THF, pyridine), of the pentamethylcyclopentadienyl complexes $Cp^*_2M(\eta^2\text{-}Me_3SiC_2SiMe_3)$ (M = Ti, Zr) and the ethylene-bis(tetrahydroindenyl) complexes *rac*-(ebthi)$M(\eta^2\text{-}Me_3Si\text{-}C_2SiMe_3)$ (M = Ti, Zr). These form an essential basis for recent applications in chemistry. By using different Cp ligands (Cp, Cp*, ebthi), additional ligands (THF, pyridine), and metals (Ti, Zr), a fine-tuning of several stoichiometric and catalytic reactions was feasible. The latter complexes offer a number of compelling advantages over the widely used other similar metallocene reagents. As a metaphor, this piece of basic research stands "*solid as a rock in heavy seas*" (in the photo the Baltic Sea nearby Rostock-Warnemünde), alluding to the fact that fundamental preparative organometallic chemistry provides a solid foundation for attractive applications. Details of this chemistry are described in the Microreview by U. Rosenthal et al. on p. 4739 ff.

Bis(trimethylsilyl)acetylene Complexes of Titanocenes and Zirconocenes: Their Recent Chemistry and Reactions with Lewis Acids

Uwe Rosenthal,*[a] Vladimir V. Burlakov,[b] Perdita Arndt,[a] Wolfgang Baumann,[a] Anke Spannenberg,[a] and Vladimir B. Shur[b]

Dedicated to Prof. Dr. Dirk Walther on the occasion of his 65th birthday[‡]

Keywords: Lewis acids / Metallocenes / Polymerization / Titanium / Zirconium

The chemistry of the metallocene bis(trimethylsilyl)acetylene complexes [$Cp_2M(L)(\eta^2$-$Me_3SiC_2SiMe_3)$] [M = Ti, without L (**1**); M = Zr, L = THF (**2a**); M = Zr, L = pyridine (**2b**)], the pentamethylcyclopentadienyl complexes [$Cp^*_2M(\eta^2$-$Me_3SiC_2SiMe_3)$] [M = Ti (**3**), Zr (**4**)], and the ethylenebis(tetrahydroindenyl) (ebthi) complexes *rac*-[(ebthi)$M(\eta^2$-$Me_3SiC_2SiMe_3)$] [M = Ti (**5**), Zr (**6**)] has been described in several reviews. A fine-tuning of the reactions is possible by varying the Cp ligands (Cp, Cp*, ebthi), additional the co-ligands (THF, pyridine), and/or metals (Ti, Zr), and it has been pointed out that these complexes offer a number of compelling advantages over other, similar, widely used metallocene reagents. In this microreview recent (2000–2004) examples of the chemistry of complexes **1**–**6** are summarized, and some special interactions with Lewis acids are described. In these reactions the metallocene cores "Cp'_2Ti" and "Cp'_2Zr" (Cp′ = substituted Cp ligands) are mostly formed after dissociation of the alkyne. As examples of this, a new selective zirconocene coupling route to large, functionalized macrocycles has been established from **2b** and polyynes, complex **1** catalyses the first anti-Markovnikov hydroamination of terminal alkynes, complexes **1** and **3** selectively form polynuclear titanium complexes by C–C coupling of N-containing heterocycles, and complexes **1**, **2b**, **3**, and **6** promote selective C–H and C–F bond-cleavage reactions of fluorinated N-containing heterocycles. Beside this recent chemistry, this microreview also focuses on the reactions of the above-mentioned complexes with the Lewis acids diisobutylaluminum hydride and tris(pentafluorophenyl)borane. For example, complexes **1**, **2b**, and **6** react with iBu$_2$AlH to give heterodimetallic complexes containing tetracoordinate planar carbon atoms. The titanium complex **1** reacts with $B(C_6F_5)_3$ with elimination of the alkyne and gaseous hydrogen to give an electrophilic substitution of the Cp or Cp* ligand in which zwitterionic Ti^{III} complexes are formed. The zirconium complexes **4** and **6** do not liberate hydrogen in the reaction with $B(C_6F_5)_3$, although, after C–H activation of one methyl group of the Cp* or Cp part of the ebthi ligand and a B–C bond formation, zwitterionic complexes containing alkylidene groups with agostic interactions with the metal center are obtained. Complex **5** reacts with $B(C_6F_5)_3$ with Si–C bond cleavage of the alkyne and formation of an alkynylboranate $[Me_3SiC{\equiv}CB(C_6F_5)_3]^-$, which is complexed by the "*rac*-(ebthi)Ti" fragment to give a zwitterionic complex. Some of the formed heterodinuclear complexes and the zwitterionic complexes are active catalysts in the ring-opening polymerization of lactones, cyclic carbonates, and epoxides, as well as the polymerization of ethylene.

Introduction

Coordinatively and electronically unsaturated complex fragments are often required to realize stoichiometric and catalytic reactions of organometallic compounds. These core complexes coordinate to the substrates, activate them, and push them in the direction of the desired products. This is nicely illustrated in manifold reactions of the complex fragments titanocene "Cp_2Ti" and zirconocene "Cp_2Zr" as unstable 14-electron compounds with a d^2 configuration (M^{II}). The possible interactions between occupied and unoccupied orbitals explain why these "Cp_2M" metallocenes react with a variety of unsaturated compounds to form metallacycles, having with a high potential to undergo diverse conversions with further substrates. An important question in this context is what ligand can be used that sufficiently stabilizes the metallocene fragment but is re-

leased under mild conditions to generate the unstable and very reactive metallocene core.

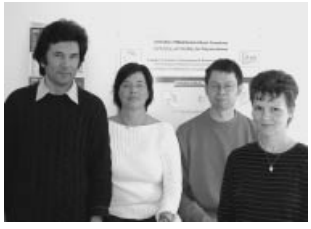
Many systems are known to generate titanocene "Cp_2Ti" or zirconocene "Cp_2Zr" very well. Selected examples are mixtures of $[Cp_2ZrCl_2]$ with *n*BuLi, which form $[Cp_2Zr(\pi$-n-butene$)]$ via $[Cp_2Zr(\sigma$-$nBu)_2]$, and the reaction of $[Cp_2ZrCl_2]$ with EtMgCl, which forms $[Cp_2Zr(\pi$-ethylene$)]$ via $[Cp_2Zr(\sigma$-$Et)_2]$. In some cases these complexes are stabilized by additional ligands, such as those found in the complexes $[Cp_2Zr(PR_3)(\pi$-*n*-butene$)]$ or $[Cp_2Ti(PMe_3)(\pi$-ethylene$)]$. Other complexes like $[Cp_2Ti(PMe_3)_2]$ and $[Cp_2Zr(\pi$-1,3-butadiene$)]$ can also be used. This chemistry has been summarized in a number of excellent reviews and various informative contributions in textbooks.[1−15]

The applicability and the success of these systems often depends on their preparative accessibility, on the selectivity of the conversions, and on the inertness of the stabilizing ligands. From this point of view, all of the above -mentioned systems have certain disadvantages. Nevertheless, they have been frequently and successfully used for organic synthesis over the few last years.

We have described the stable and well-defined metallocene bis(trimethylsilyl)acetylene complexes $[Cp_2M(L)(\eta^2$-$Me_3SiC_2SiMe_3)]$ [M = Ti, without L (**1**); M = Zr, L = THF (**2a**); M = Zr, L = pyridine (**2b**)], the pentamethylcyclopentadienyl complexes $[Cp^*_2M(\eta^2$-$Me_3SiC_2SiMe_3)]$ [M = Ti (**3**), Zr (**4**)], and the ethylenebis(tetrahydroindenyl) complexes *rac*-$[(ebthi)M(\eta^2$-$Me_3SiC_2SiMe_3)]$ [M = Ti (**5**), Zr (**6**)] as novel reagents for this type of chemistry (Scheme 1). All these complexes are synthesized under anaerobic conditions by the reaction of the corresponding dichlorides $[Cp'_2MCl_2]$ (Cp′ = substituted Cp; M = Ti, Zr) with magnesium in THF at room temperature in the presence of bis(trimethylsilyl)acetylene.[16−25]

The chemistry of these complexes, and particularly their bonding situation, their spectroscopic properties, their reactivity and mechanistic behavior etc., has been described in several reviews.[16−25] Variation of the Cp ligands (Cp, Cp*, ebthi), additional the co-ligands (THF, pyridine) and/or the metals (Ti, Zr) enables a fine-tuning of their reactivity. It has been pointed out that these complexes offer a number of compelling advantages over other widely used

Uwe Rosenthal, born in 1950 in the Altmark, Germany, studied chemistry (1968−1972), received his Ph.D. under the supervision of E. Kurras (1976), and completed his habilitation (1991) at the University of Rostock. He pursued postdoctoral work at the A. N. Nesmeyanov Institute of Organoelement Compounds of the Russian Academy of Sciences in Moscow with M. E. Vol'pin and V. B. Shur (1988) and became a visiting research scientist at the Max Planck Institute of Kohlenforschung in Mülheim/Ruhr with G. Wilke and K. Pörschke (1990−1991). He headed the Max Planck Research group "Complex Catalysis" (1992−1996) and became Professor of Inorganic Chemistry at the University of Rostock (1993). Today he is Vice Director of the Leibniz Institute of Organic Catalysis at the University of Rostock, a member of the Advisory Editorial Board of Organometallics and member of the reviewing board for "The Chemistry of Inorganic Molecules" of the Deutsche Forschungsgemeinschaft. His scientific interests are concentrated in organometallic chemistry (Cr, Ni, Ti, Zr, B, Al, Si) and complex catalysis (C−C single bond coupling and cleavage reactions and activation of small molecules, alkynes, diynes, and organosilicon compounds).

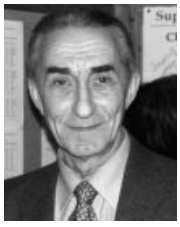


Vladimir V. Burlakov (left) was born in Moscow in 1955. He graduated from the M.V. Lomonosov Moscow Institute of Fine Chemical Technology in 1982. Since 1982, he has been working at the A. N. Nesmeyanov Institute of Organoelement Compounds of the Russian Academy of Sciences (Moscow). In 1995, he received his Ph.D. degree with M. E. Vol'pin and V. B. Shur. Since 1992, he has often been a visiting research scientist in Rostock, hosted by the Rosenthal group. His scientific interests are focused on the transformation of unsaturated hydrocarbons and small molecules mediated by metal complexes of Group IV.

Perdita Arndt (center left), born in 1953 in Stralsund, Germany, studied chemistry (1972−1976) and obtained her Diploma (1976) with U. Kibbel at the University of Rostock. From 1976−1991 she worked as research assistant in the Division of Complex Catalysis in Rostock, Institute of Organic Chemistry, Academy of Sciences with a six-month break working in the group of S. Pasynkiewicz at the Technical University of Warsaw (1978). In 1981 she graduated under supervision of E. Kurras at the University of Rostock (organochromium chemistry) and entered the Max Plank Research group "Complex Catalysis" at the University of Rostock (1992−1996) followed by scientific work at the Institute of Organic Catalysis Research (1997−2002) and the Leibniz Institute for Organic Catalysis at the University of Rostock (from 2003).

Wolfgang Baumann (center right), born in 1962 in Zweibrücken (Palatinate), studied chemistry at the University of Kaiserslautern (1982−1988), obtained his Diploma there in 1988, and did his doctoral work in the group of C. G. Kreiter (preparative organometallic chemistry: photochemistry of carbonyl-cyclopentadienyliron compounds). After graduation in 1990 he became "scientific coordinator" at the "Graduiertenkolleg" Chemical Reactivity and Molecular Order at the University of Siegen (1990−1991) and did postdoctoral work (organolithium chemistry, solid-state NMR) in the group of H. Günther (1991−1993). He has since worked in the Max Planck Research Group "Complex Catalysis" at the University of Rostock (1993−1996), the Institute of Organic Catalysis Research (1997−2002), and the Leibniz Institute of Organic Catalysis at the University of Rostock (from 2003).

Anke Spannenberg (right), born in 1967 in Rostock, Germany, studied chemistry and mathematics at the College of Education in Güstrow (1985−1990), graduated (Dr. rer. nat.) in 1994 under the supervision of H.-J. Holdt at the University of Rostock, and became a member of the Max Planck Research group "Complex Catalysis" at the University of Rostock (1995−1996). As a research scientist she has been working at the Institute of Organic Catalysis Research (1997−2002) and since 2003 at the Leibniz Institute for Organic Catalysis at the University of Rostock. Her scientific interests focus on X-ray crystal structure analysis.



Vladimir B. Shur was born in Moscow in 1936. He graduated from the Moscow Institute of Chemical Technology in 1959. From 1959 to 1962, he worked in industry. Since 1962 he has been working at the A. N. Nesmeyanov Institute of Organoelement Compounds of the Russian Academy of Sciences (Moscow). In 1972, he received his Ph.D. degree with M. E. Vol'pin. From 1964 to 1989, he was head of the research group on nitrogen fixation in the Laboratory of Complex Organometallic Catalysts, headed by M. E. Vol'pin. In 1989, he received his degree of Doctor of Chemical Sciences. In the same year, he became head of the Laboratory of Metal Complex Activation of Small Molecules. Since 1991, he is Professor of Chemistry. His scientific interests focus on molecular nitrogen fixation, C−H bond activation, acetylene complexes of the Group IV metals, and coordination and catalytic chemistry of anticrowns.

MICROREVIEWS: This feature introduces the readers to the author's research through a concise overview of the selected topic. Reference to important work from others in the field is included.

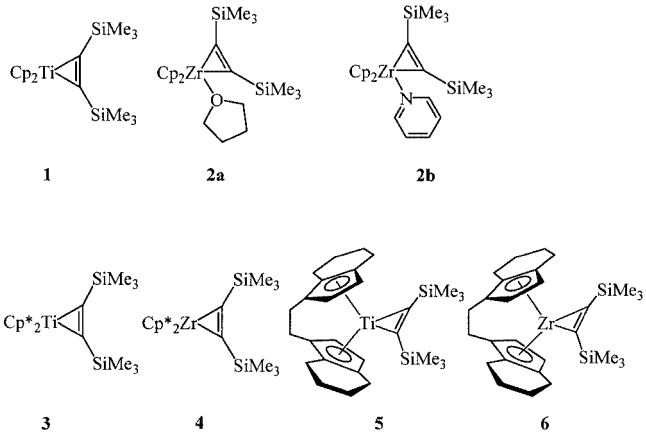


Scheme 1

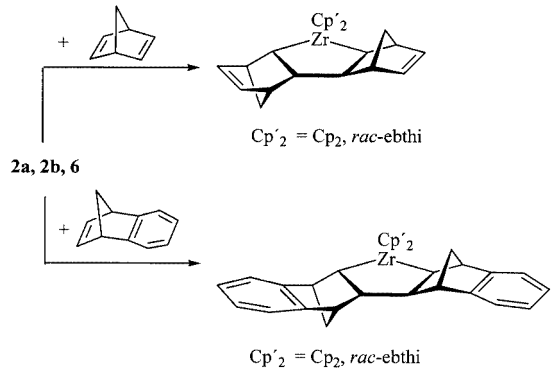
systems that significantly expand the scope of metallocene-based coupling reactions.[18]

In this microreview recent (2000−2004) examples of the chemistry of complexes **1**−**6** are summarized, and some special interactions with Lewis acids are described.

New Reactions

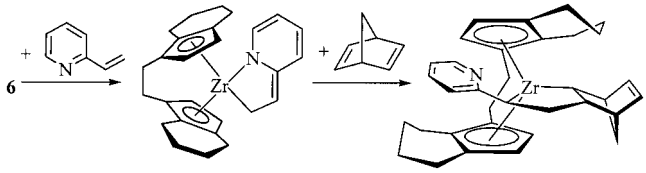
Two different reaction pathways for complexes **1**−**6** — coupling and elimination of the bis(trimethylsilyl)acetylene — represent the two most commonly found types of reactions of these complexes, with the latter one being the most attractive because of the generation of metallocenes.[18] The formation of stable substituted titanocenes by elimination of bis(trimethylsilyl)acetylene from the corresponding alkyne complexes has been documented in some excellent papers by Mach and coworkers.[26,27]

The reaction of **2a**, **2b**, or **6** with norbornadiene or benzonorbornadiene proceeds with elimination of the alkyne (and THF or pyridine) to give zirconacyclopentanes bearing additional functional groups (Scheme 2).[28] Note that in almost all reaction schemes the elimination of co-ligands and/or bis(trimethylsilyl)acetylene is omitted for simplicity.



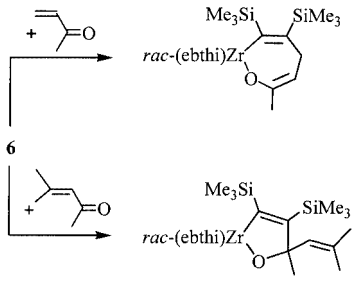
Scheme 2

Another substituted zirconacyclopentane has been isolated from the reaction of **6** with 2-vinylpyridine and norbornadiene. This complex is formed, via a 2-vinylpyridine complex intermediate,[29] by elimination of the bis(trimethylsilyl)acetylene and coupling of the coordinated pyridine and norbornadiene fragments (Scheme 3).[28]



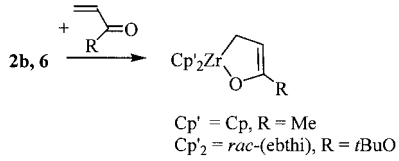
Scheme 3

Polar functionalized olefins also react with complexes **2b** and **6**, although in a different manner, to give either coupling products with the alkyne or substitution of the alkyne.[30] Complex **6** forms a novel 1,4-conjugated insertion product with methyl vinyl ketone, whereas mesityl oxide forms a zirconadihydrofuran by insertion of the carbonyl group (Scheme 4).



Scheme 4

In contrast, **2b** and methyl vinyl ketone, or **6** and *tert*-butyl acrylate, eliminate the alkyne to yield a different zirconadihydrofuran (Scheme 5).

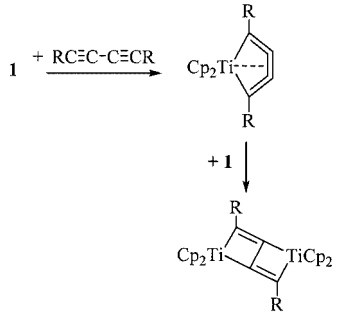


Scheme 5

It is well known that the five-membered titanacyclocumulenes (1-titanacyclopenta-2,3,4-trienes), which can be considered formally as mononuclear "*cis*-diyne" complexes, are formed in the reactions of **1** with 1,3-butadiynes.[17] These compounds react, in the case of titanium, with further complex **1** to yield the dinuclear "*trans*-diyne" complexes with "zigzag butadiyne ligands" — μ-η(1,3),η(2,4)-

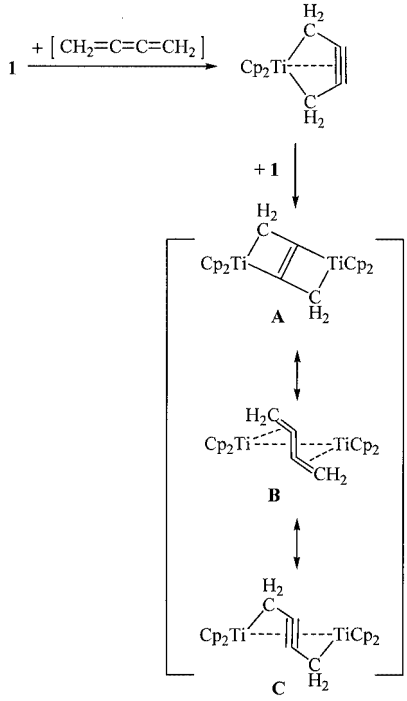
 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

trans,trans-tetradehydrobutadiene moieties — between the two titanocene cores (Scheme 6).



Scheme 6

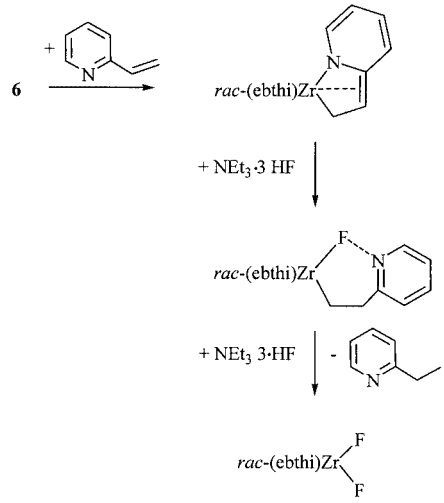
The novel reaction of 2 equiv. of **1** with 1,4-dichloro-2-butyne gives, probably by the formation of 1,2,3-butatriene, $[Cp_2TiCl_2]$, and $Me_3SiC_2SiMe_3$, 1-titanacyclopent-3-yne, formally a "*cis*-triene" complex, which reacts with additional **1** to give a "*trans*-triene" complex with bridging "zigzag butatriene ligands" between the two titanium centers (Scheme 7).[23,31] Its structure is best described as a 2,5-dititanabicyclo[2.2.0]hex-1(4)-ene (**A**) rather than the resonance structures B — a μ-*trans*-butatriene-bridged π-complex — or C — a butynediyl-bridged σ-propargylic complex (Scheme 7).



Scheme 7

Suzuki and coworkers have reported the complexation of 1,2,3-butatrienes with zirconocene with formation of the corresponding 1-zirconacyclopent-3-ynes.[32,33] Jemmis,[34] Lin,[35] and Jiao,[36] and their coworkers, have compared these rather exotic compounds by detailed calculations.

The zirconocene monofluoride *rac*-[(ebthi)Zr(F)-$(CH_2CH_2$-2-py)] and difluoride *rac*-[(ebthi)ZrF_2] have been obtained, via the 2-vinylpyridine complex *rac*-[(ebthi)Zr(2-vipy)], by reaction with triethylamine tris(hydrofluoride) (Scheme 8).[37]



Scheme 8

This novel method for the synthesis of zirconocene difluorides and alkyl monofluorides via the 2-vinylpyridine complexes $[Cp'_2Zr(L)$(2-vipy)] has also been reported for other compounds of the type $[Cp'_2Zr(L)(\eta^2\text{-}Me_3SiC_2SiMe_3)]$ with different ligand Cp'_2 systems, such as $(thi)_2$ [bis(η^5-tetrahydroindenyl)], $Me_2Si(\eta^5\text{-}C_5H_4)_2$ [dimethylsilylbis(η^5-cyclopentadienyl)], and ebthi.

In the last few years several research groups have taken advantage of the above-mentioned complexes for stoichiometric and catalytic reactions. Tilley and coworkers have reported that the complex $[Cp_2Zr(pyridine)(\eta^2\text{-}Me_3SiC_2\text{-}SiMe_3)]$ (**2b**) is best suited for a new selective zirconocene-coupling reaction of polyynes to give large, functionalized macrocycles in which zirconacyclopentadienes are bridged by different groups.[38–40] Protolysis of these products gives the corresponding substituted butadienes. A large number of dimeric and trimeric bridged metallacycles have been synthesized by this method (Scheme 9) including, most recently, several substrates with fluoro substituents.[41]

Beller et al. have described the first anti-Markovnikov hydroamination of terminal alkynes with the complex $[Cp_2Ti(\eta^2\text{-}Me_3SiC_2SiMe_3)]$ (**1**) as a precatalyst (Scheme 10).[42]

This complex was subsequently compared to the corresponding substituted complexes $[Cp'_2Ti(\eta^2\text{-}Me_3SiC_2\text{-}SiMe_3)]$ [Cp′ = Cp* (**3**) and C_5H_4Et], which need a higher reaction temperature.[43] Detailed theoretical calculations by Jiao have revealed that the experimentally observed regioselectivity is determined by the relative stability of the postulated intermediate π-complexes "$[CpTi(NH_2)$-$(=NH)(\eta^2\text{-}HC{\equiv}CH)]$", in which the electrostatic substitution favors the Markovnikov product for aniline and the sterically repulsive destabilization disfavors the Markovnikov

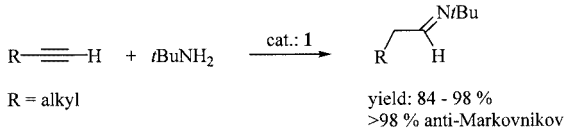
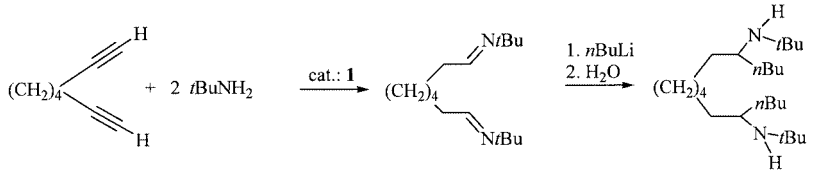


Scheme 10

product for *tert*-butylamine. The one-pot synthesis of several branched secondary aliphatic amines by the hydroamination of terminal alkynes with aliphatic primary amines in the presence of **3** gave the aldimines, in situ, which react with organolithium compounds to give the α-branched amines in high yields (Scheme 11).[44]

Odom and coworkers have compared the activity of complex **1** with a series of other titanium complexes as precata-



Scheme 11

lysts for intermolecular alkyne hydroamination; they found that it has a lower activity than the commercially available $Ti(NMe_2)_4$.[45]

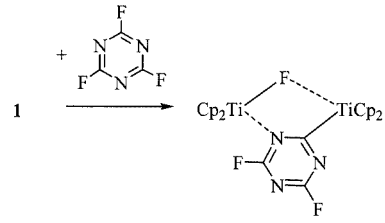
Beckhaus and coworkers have published very recently a series of excellent examples of molecular self-organization. The selective formation of polynuclear titanium complexes was realized in the reactions of **1** and **3** with different N-heterocyclic compounds[46,47] by directed reduction of six-membered nitrogen heterocycles and molecular self-organization (Scheme 12).

In these reactions, after dissociation of the bis(trimethylsilyl)acetylene from complexes **1** and **3**, the formed titanocene "Cp_2Ti" and permethyltitanocene "Cp^*_2Ti" moieties react in the same manner with triazine — by C−C bond coupling — to give dinuclear chelate complexes. However, different products were formed with pyrazine: a tetranuclear, pyrazine-bridged complex from **1**, and a trinuclear chelate complex, in a spontaneous threefold C−C coupling reaction, from **3**. Complex **1** gives an octanuclear complex with pyrimidine, whereas the reaction of **1** with triazine leads, by C−C coupling, to a dimeric chelate ligand.[46]

As discussed before for Tilley's reaction with [Cp_2Zr(pyridine)(η^2-$Me_3SiC_2SiMe_3$)] (**2b**),[38−41] the good solubility of the starting materials **1** and **3** allows a smooth separation of the in-most-cases sparingly soluble products. The bis(trimethylsilyl)acetylene formed from these reactions is soluble and volatile, and is thus easy to remove.

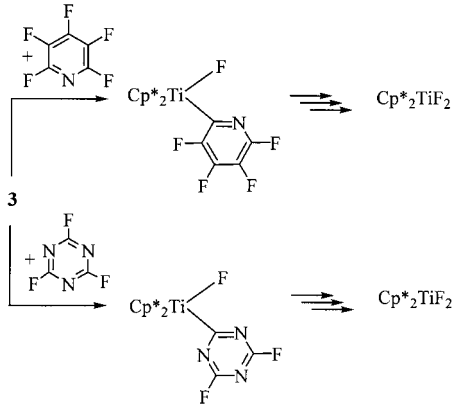
The crucial step of C−H activation has also been described by Beckhaus and coworkers for some reactions of complexes **1** and **3** with pyridine, fluorinated pyridines, and other N-containing heterocyclic compounds (Scheme 13).[47] Complex **1** and pyridine, for example, give a hydride-bridged dinuclear titanium fulvalene derivative after C−H activation, whereas monofluoropyridine reacts with **1**, by C−F activation, to give a fluoride-bridged dinuclear titanium complex. It is remarkable that no product resulting from a C−H activation was found in this case. Pentafluoropyridine reacts with **1** to give a similar perfluorinated product.

A fluoride-bridged dinuclear titanium complex is formed in the reaction with 2,4,6-trifluoro-1,3,5-triazine by C−F activation (Scheme 14).



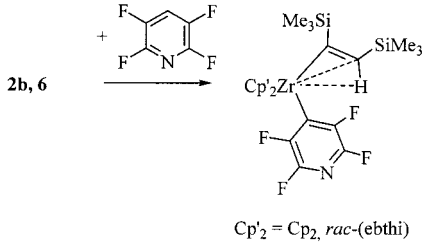
Scheme 14

The reaction of complex **3** with pentafluoropyridine or cyanuric fluoride forms, after C−F activation, mononuclear fluorotitanium(IV) complexes as intermediates, as proved by ^1H and ^{19}F NMR measurements, which go on to react with an excess of the substrates to give the difluoride [$Cp^*_2TiF_2$] (Scheme 15).



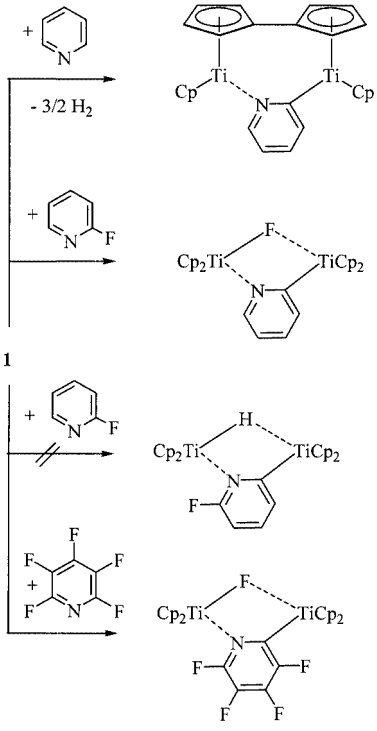
Scheme 15

The corresponding zirconocene complexes **2b** and **6** behave completely differently in such reactions.[48] Tetrafluoropyridine reacts with **2b** or **6** by C−H activation to give 4-substituted pyridyl complexes that contain alkylidene groups with agostic interactions to the metal center (Scheme 16).



Cp'$_2$ = Cp$_2$, *rac*-(ebthi)

Scheme 16



Scheme 13

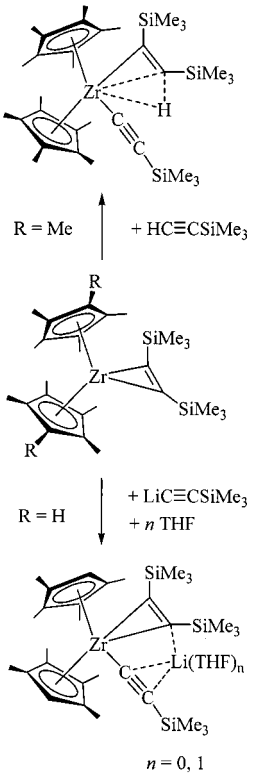
This result is opposite to the above-mentioned titanium case in which C−F activation was preferred over C−H activation and the 2-position reacted. The reason for this could be a bimolecular reaction with precoordination of the N-atom of the pyridine and an attack of a second zirconocene in the 4-position. Such a coordination of the pyridine is impossible for complex **1**.

Mach and coworkers have recently described some reactions of substituted zirconocene complexes of bis(trimethylsilyl)acetylene with terminal acetylenes and lithium acetylides.[49] For example, complex **4** reacts with $HC{\equiv}CSiMe_3$ to give the agostic alkenyl-alkynyl complex $[Cp^*_2Zr\{\eta^3\text{-}[C(SiMe_3){=}CHSiMe_3]\}(\eta^1\text{-}C{\equiv}CSiMe_3)]$, as described before for the permethyltitanocene complex **3**. The corresponding complex $[(\eta^5\text{-}C_5HMe_4)_2Zr(\eta^2\text{-}Me_3SiC_2SiMe_3)]$ yielded the diamagnetic zirconate complex $Li[\{(\eta^5\text{-}C_5HMe_4)_2Zr\}\{\eta^1\text{-}(C{\equiv}CSiMe_3)\}\{\eta^2\text{-}(Me_3SiC{\equiv}CSiMe_3)\}]$ with $LiC{\equiv}CSiMe_3$ (Scheme 17).



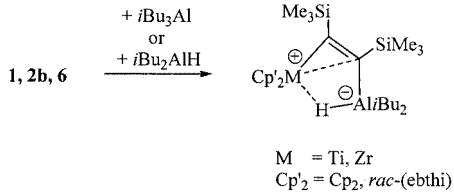
Scheme 17

New Reactions with Lewis Acids

One of the most remarkable discoveries during the past few decades was that the activity of metallocene-based Ziegler−Natta polymerization catalysts is based on cationic $[Cp'_2MR]^+$ complexes containing a metal atom in the +4 oxidation state. Such cationic moieties can easily be prepared by interaction of metallocene complexes $[Cp'_2MX_2]$ (Cp′ = substituted or unsubstituted η^5-cyclopentadienyl, X = Me, CH_2Ph, H etc.) with strong Lewis acids (LA) such as $B(C_6F_5)_3$, Ph_3C^+ etc. After abstraction of X, the metallocenium ion-pair complexes with noncoordinating anions to give $[Cp'_2MX]^+[(\mu\text{-}X)\text{-}LA]^-$ complexes.

As well as the above-mentioned $[Cp'_2MX_2]$ complexes, the titana- and zirconacyclopropenes **1**−**6** also possess two M−C σ-bonds and their reactions with Lewis acids such as $B(C_6F_5)_3$, Al*i*Bu$_3$, and HAl*i*Bu$_2$ have been investigated in detail. The reaction of alkynyl- and alkenylmetallocene complexes with organoaluminum or -boron compounds has been intensively investigated by Erker[50] and Binger;[51] it leads to dimetallic systems of the type $[Cp_2M^1](\mu\text{-}\eta^1{:}\eta^2\text{-}RCCR)(\mu\text{-}X)[M^2R^2_2]$ (M^1 = Zr, Hf, X = Cl, H, M^2 = Al, Ga; M^1 = Ti, X = H, M^2 = B) containing a planar-tetracoordinate carbon atom bridging between a group-4 transition metal and a main group element.

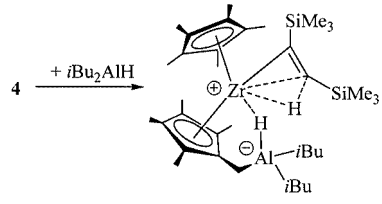
The reactions of the alkynyltitanocene and -zirconocene complexes **1**, **2b**, and **6** with Al*i*Bu$_3$ lead to similar heterodimetallic complexes, along with formation of isobutene and HAl*i*Bu$_2$.[52] These complexes are better prepared, however, by the direct reaction of the alkyne complexes with HAl*i*Bu$_2$ (Scheme 18).



Scheme 18

The X-ray crystal structure analyses of the complexes show planar, bicyclic, five-membered-ring systems containing the metal atom, the hydridic hydrogen, Al, C_β, and C_α. Some of these complexes are very active catalysts for the ring-opening polymerization of ε-caprolactone.[52]

Interestingly, the reaction of **4** with HAl*i*Bu$_2$ gave no such complexes. Instead, an electrophilic substitution of a hydrogen atom from one of the methyl groups of the Cp* ring by the HAl*i*Bu$_2$ moiety occurred.[53] No hydrogen or alkyne were liberated, and a product with an agostic σ-alkenyl group at the zirconium center and a μ-H atom between Al and Zr was isolated (Scheme 19).

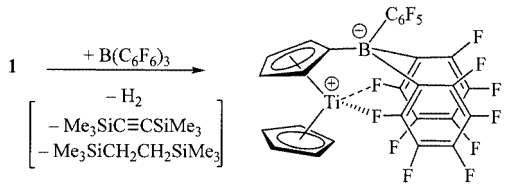


Scheme 19

In the reaction of **1** with $B(C_6F_5)_3$ in toluene at room temperature the titanium(III) complex of $[TiCp\{\eta^5\text{-}C_5H_4B(C_6F_5)_3\}]$, a novel type of zwitterionic complex containing the $B(C_6F_5)_3$ group in the Cp ligand and no σ-bonded organic substituents at the titanium atom, was

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

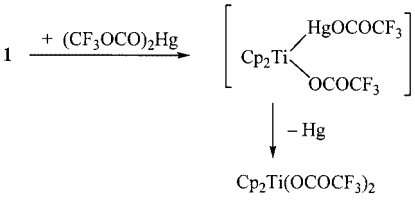
formed. Hydrogen, alkyne, and 1,2-bis(trimethylsilyl)ethane are liberated by the electrophilic substitution of a hydrogen atom of one of the η^5-C_5H_5 rings by a $B(C_6F_5)_3$ group (Scheme 20).[54,55]



Scheme 20

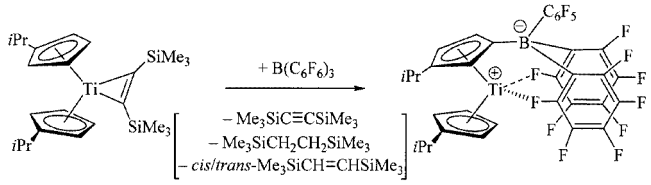
The reaction of $[Cp_2Ti(PhC_2SiMe_3)]$ with $B(C_6F_5)_3$ under the same conditions gives an identical product, but with a strongly diminished rate of reaction. The complex $[Cp_2Ti(PhC_2Ph)]$ does not react with $B(C_6F_5)_3$ at all under the same conditions, not even after one month. Thus, the replacement of the Me_3Si groups of the acetylene ligand by Ph substituents sharply decreases the reactivity of the corresponding acetylene complexes $[Cp_2Ti(R^1C_2R^2)]$ toward $B(C_6F_5)_3$.[56]

An attempt to electrophilically mercuriate the Cp rings in **1** by reaction with $Hg(OCOCF_3)_2$ was undertaken to obtain the complex $[TiCp(OCOCF_3)\{\eta^5$-$C_5H_4Hg(OCOCF_3)\}]$. It appeared, however, that the process proceeds in another way, and $[Cp_2Ti(OCOCF_3)_2]$ was isolated after the liberation of metallic mercury and alkyne (Scheme 21).[57]



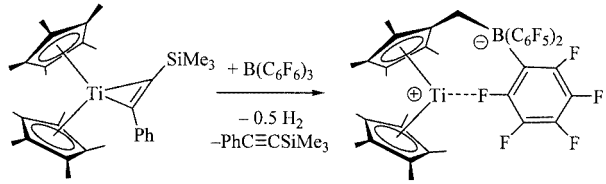
Scheme 21

The reaction of $[(\eta^5$-$iPrC_5H_4)_2Ti(\eta^2$-$Me_3SiC_2SiMe_3)]$ with $B(C_6F_5)_3$ in toluene at room temperature also produces the zwitterionic titanium(III) complex $[Ti(\eta^5$-$iPrC_5H_4)\{\eta^5$-1,3-$iPrC_5H_3B(C_6F_5)_3\}]$ in which the 3-H atom of one of the C_5 rings has been substituted by a $B(C_6F_5)_3$ group (Scheme 22).[56] This complex is analogous in its structure to the titanium(III) zwitterion $[TiCp\{\eta^5$-$C_5H_4B(C_6F_5)_3\}]$ formed from the reaction of $B(C_6F_5)_3$ with **1** (Scheme 20). In this reaction, 1,2-bis(trimethylsilyl)ethene was also detected in addition to the silylated alkyne and 1,2-bis(trimethylsilyl)ethane. A characteristic feature of both zwitterionic complexes is the presence of coordinative bonds between the *ortho*-fluorine atoms of two C_6F_5 substituents and the positively charged titanium center.



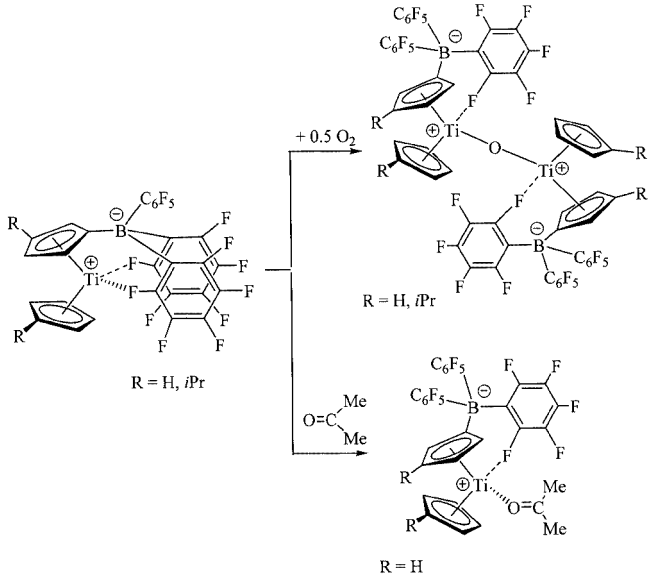
Scheme 22

An electrophilic substitution of a hydrogen atom of one of the methyl groups of the Cp* ring by a $B(C_6F_5)_3$ moiety was also found in the reaction of $B(C_6F_5)_3$ with $[Cp^*_2Ti(\eta^2$-$PhC_2SiMe_3)]$ — the zwitterionic Ti^{III} complex $[TiCp^*\{\eta^5$-$C_5Me_4CH_2B(C_6F_5)_3\}]$ was isolated (Scheme 23).[58]



Scheme 23

The oxidation of $[TiCp\{\eta^5$-$C_5H_4B(C_6F_5)_3\}]$ and $[Ti(\eta^5$-$iPrC_5H_4)\{\eta^5$-1,3-$iPrC_5H_3B(C_6F_5)_3\}]$ by atmospheric oxygen affords the isostructural zwitterionic titanoxanes $[Cp\{\eta^5$-$C_5H_4B(C_6F_5)_3\}Ti]_2(\mu$-O) and $[(\eta^5$-$iPrC_5H_4)\{\eta^5$-1,3-$iPrC_5H_3B(C_6F_5)_3\}Ti]_2(\mu$-O), respectively, which contain two zwitterionic units in the molecule (Scheme 24).[56] In each of these units only one *ortho*-fluorine atom of a $B(C_6F_5)_3$ group is involved in coordination to the titanium atom.



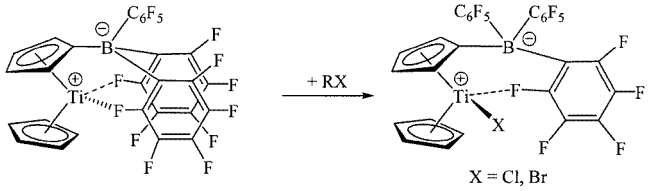
Scheme 24

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

These complexes are active catalysts for the cationic ring-opening polymerization of ε-caprolactone, THF, and propylene oxide, whereas γ-butyrolactone and 1-methyl-2-pyrrolidone are not polymerized under the same conditions.[59]

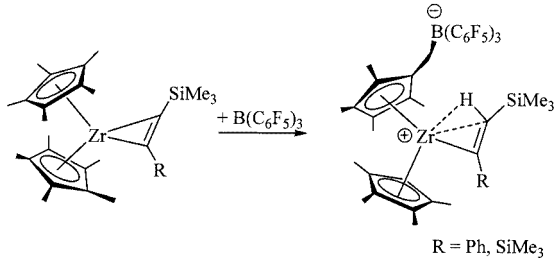
[TiCp{η^5-$C_5H_4B(C_6F_5)_3$}] also reacts readily with acetone to give the zwitterionic adduct [(Me_2CO)TiCp{η^5-$C_5H_4B(C_6F_5)_3$}], where the acetone is bonded to the Ti^{III} center through the oxygen atom and only one *ortho*-fluorine atom of the $B(C_6F_5)_3$ group is coordinated to the metal (Scheme 24).[56]

The monohalide complexes [TiXCp{η^5-$C_5H_4B(C_6F_5)_3$}] (X = Cl, Br) are produced by the reaction of [TiCp{η^5-$C_5H_4B(C_6F_5)_3$}] with alkyl halides (Scheme 25). A characteristic feature of the resulting complex is the coordination between one *ortho*-fluorine atom of one C_6F_5 group and the titanium center. As found for the zwitterionic titanoxanes, the chloride complex catalyses the cationic ring-opening polymerization of THF.[60,61]



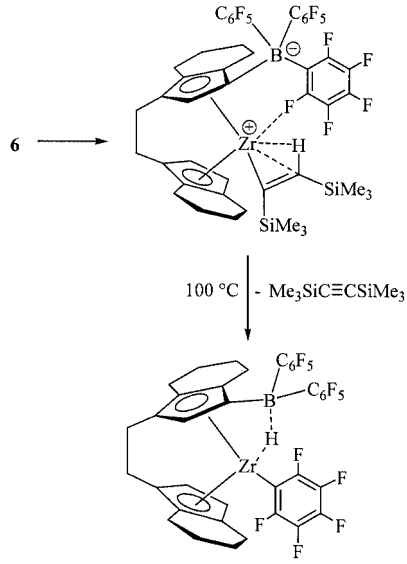
Scheme 25

The reactions of the corresponding zirconium complexes with $B(C_6F_5)_3$ differ from the reaction mode presented above. No hydrogen or alkyne are liberated in the reaction of [$Cp^*_2Zr(\eta^2$-$RC_2SiMe_3)$] (R = Ph, Me_3Si) with $B(C_6F_5)_3$ and the zwitterionic Zr^{IV} derivative [ZrCp*{η^5-$C_5Me_4CH_2B(C_6F_5)_3$}{C(R)=CH($SiMe_3$)}], which contains a σ-alkenyl group at the zirconium center, is produced (Scheme 26).[58]



Scheme 26

The reactions of the *rac*-ebthi complexes **5** and **6** with $B(C_6F_5)_3$ also proceed totally differently for Ti and Zr.[62] For **6** an electrophilic substitution of one H atom of the Cp ring in the 3-position occurs to give a zwitterionic alkenyl complex without liberation of hydrogen or alkyne (Scheme 27).

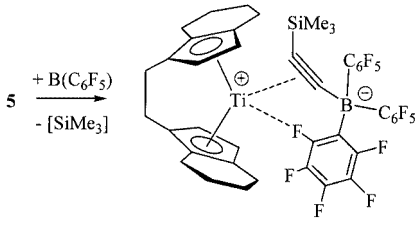


Scheme 27

When this complex is heated to 100 °C in solution the alkyne is eliminated and one B−C bond is cleaved, with a subsequent transfer of one C_6F_5 group from boron to zirconium, to give a complex with one μ-H atom between B and Zr (Scheme 27).

Both complexes are important for the understanding of deactivation processes in the polymerization of olefins and demonstrate the importance of the proper addition sequence when adding reagents in order to achieve catalytic activity. If **6** is first treated with ethene, the zirconacyclopentane formed is subsequently activated by $B(C_6F_5)_3$ to give a catalyst that is active for the polymerization of ethylene. However, if the borane is added to **6** first, neither the obtained complex nor the thermolysis product (Scheme 27) react with ethylene. Interestingly, the analogous complexes [ZrCp*{η^5-$C_5Me_4CH_2B(C_6F_5)_3$}{C(R)=CH($SiMe_3$)}] (R = Ph, $SiMe_3$; Scheme 26) are active in ethylene polymerization, presumably because they have no C−F interactions due to steric reasons.

In the reaction of **5** with $B(C_6F_5)_3$ neither an electrophilic substitution of an H atom nor an elimination of the alkyne was observed. Instead, after substitution of one of the $SiMe_3$ groups in the coordinated bis(trimethylsilyl)acetylene by $B(C_6F_5)_3$, the first zwitterionic titanium(III) η^2-(trimethylsilyl)alkynylboranate complex *rac*-[{(ebthi)Ti}$^+$-{[η^2-$Me_3SiC_2B(C_6F_5)_3$]}−] was obtained (Scheme 28).

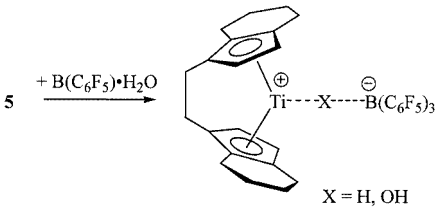


Scheme 28

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

In this complex the $[Me_3SiC_2B(C_6F_5)_3]^-$ ligand is unsymmetrically and weakly bonded to the Ti center by its C≡C bond as well as by one of the *ortho*-F atoms of the $B(C_6F_5)_3$ group. Complexes of alkynylboranates have not been isolated or characterized before, although they have frequently been postulated as reactive intermediates, for example in the $B(C_6F_5)_3$-catalyzed C−C coupling of alkynyl groups by bis(alkynyl)zirconocene(IV) complexes[63] and in the reaction of alkynylstannanes with boranes.[64]

Reaction of **5** with the Brönsted acid $B(C_6F_5)_3{\cdot}H_2O$ gives a mixture of the blue complexes [*rac*-(ebthi)Ti]$^+$-$[HOB(C_6F_5)_3]^-$ and [*rac*-(ebthi)Ti]$^+[HB(C_6F_5)_3]^-$ (Scheme 29).[65]



Scheme 29

These complexes form a series of compounds of the type [*rac*-(ebthi)Ti]$^+[XB(C_6F_5)_3]^-$ with X = $Me_3SiC{\equiv}C$, OH, and H.

Conclusion

The reactions presented here show once again that the metallocene bis(trimethylsilyl)acetylene complexes $[Cp_2M(L)(\eta^2\text{-}Me_3SiC_2SiMe_3)]$ [M = Ti, without L (**1**); M = Zr, L = THF (**2a**); M = Zr, L = pyridine (**2b**)], the pentamethylcyclopentadienyl complexes $[Cp^*_2M(\eta^2\text{-}Me_3SiC_2SiMe_3)]$ [M = Ti (**3**), Zr (**4**)], and the complexes *rac*-[(ebthi)M(η^2-$Me_3SiC_2SiMe_3$)] [ebthi = ethylenebis(tetrahydroindenyl); M = Ti (**5**), Zr (**6**)] offer a number of compelling advantages over other, widely used metallocene reagents as they are readily prepared directly from the dichlorides $[Cp'_2MCl_2]$, are stable at room temperature for a long time under argon atmosphere, and allow a control over the stoichiometry of reactions at elevated temperatures. The side-products of the reactions — bis(trimethylsilyl)acetylene, THF, and pyridine — are soluble and volatile and thus easy to remove. These complexes allow reactions in a broad variety of solvents, in particular nonpolar solvents such as pentane.

Acknowledgments

This work was supported by the Deutsche Forschungsgemeinschaft (SPP 1118, Project No. Ro 1269/6), the Fonds der Chemischen Industrie, the Land Mecklenburg-Vorpommern, and the Russian Foundation for Basic Research (Project No. 02-03-32589). Funding and facilities provided by the Leibniz-Institut für Organische Katalyse an der Universität Rostock are gratefully acknowledged. The work reported in this contribution would not have been possible without the excellent efforts by various former Ph.D. students and scientists and a lot of other colleagues whose names appear in the list of references, as well as our technical staff, in particular Petra Bartels and Regina Jesse. We thank Dr. Barbara Heller and Professor Rüdiger Beckhaus for many useful suggestions and discussions.

Vinylic Deprotonation in the Coordination Sphere of Platinum(II): Regioselective Formation of Alkenyl Complexes

Giuseppe Lorusso,[a] Giovanni Boccaletti,[a] Nicola G. Di Masi,[a] Francesco P. Fanizzi,[b,c] Luciana Maresca,*[a] and Giovanni Natile[a]

Keywords: Platinum / Alkenes / Brönsted acidity / Deprotonation reaction / (*E*)/(*Z*) isomerization

Reaction of [PtCl(η^2-CH_2=CHAr)(tmeda)](ClO_4) (**1**) [Ar = C_6H_5 (**1a**), 4-$CH_3OC_6H_4$ (**1b**), 3-$NO_2C_6H_4$ (**1c**); tmeda = *N*,*N*,*N*′,*N*′-tetramethylethylenediamine) with triethylamine, or even with inorganic carbonate, leads to the abstraction of a vinylic proton and formation of the (alkenyl)platinum species [PtCl{(*E*)-CH=CHAr}(tmeda)] (**2**) in high yield. The initially formed (*E*) isomer, in solution of chlorinated solvents, partly isomerizes into the (*Z*) form [equilibrium ratio (*E*)/(*Z*) ≈ 4:1]; the isomerization reaction is rather slow and is catalyzed by visible light. The nature of the phenyl substituent (electron donor OMe or electron-withdrawing NO_2 group) does not appear to affect the rate of deprotonation. The nature and stereochemistry of the formed (alkenyl)platinum species has been elucidated through 1D and 2D ^1H and ^{13}C NMR spectroscopy.

Introduction

In a recent paper we described the allylic deprotonation of the alkene in cationic [PtCl(η^2-alkene)(tmeda)]$^+$ complexes (tmeda = *N*,*N*,*N*′,*N*′-tetramethylethylenediamine). The reaction requires the use of a noncoordinating base (NEt_3) and, under suitable conditions, it can lead to the removal of two allylic protons and formation of a dimeric species with an η^1,η^3-allyl bridging ligand.[1] We have extended the investigation to styrene analogues of the previous compounds, [PtCl(η^2-styrene)(tmeda)](ClO_4), for which only vinylic protons can be removed. The Brönsted acidity of vinylic protons has already been reported for styrenes coordinated to a metal center and in a cationic substrate.[2−6] There is, however, only one report concerning platinum complexes, which involves dicationic species that are known to be rather reactive towards deprotonation.[7]

Results and Discussion

[PtCl(η^2-CH_2=CHPh)(tmeda)](ClO_4) (**1a**) is readily deprotonated by a base in chlorinated solvents. The reaction is fast and quantitative in the presence of a moderate excess of triethylamine (3 h, 25 °C, **1a**/NEt_3 = 1:2.5), but slower in the presence of anhydrous sodium carbonate in heterogeneous conditions (ca. 80% yield at 25 °C after 3 d). Moreover, it is completely regioselective and leads to the exclusive formation of the (*E*) isomer [PtCl{(*E*)-CH=CHPh}(tmeda)] [(*E*)-**2a**] (Scheme 1).

The stereochemistry of **2a** was unequivocally determined on the basis of NMR spectroscopic data. The signals of the vinylic protons appear at δ = 6.46 and 7.31 ppm with $^3J_{H,H}$ = 16.3 Hz which is typical for protons that are mutually *trans* with respect to a carbon−carbon double bond.[8] ^{13}C and $^1H/^{13}C$ INVERSE HETCOR spectra set the signals of the vinylic carbon atoms at δ = 121.3 and 135.8 ppm with $J_{Pt,C}$ = 1009 Hz for the former and < 60 Hz for the latter (Figure 1 and Table 1). The more shielded and strongly Pt-coupled carbon atom is the one directly bound to the metal center. It is worth noting that this carbon atom carries the less shielded proton (δ = 7.31 ppm).

Complex (*E*)-**2a** in chloroform solution partially isomerizes to the (*Z*) form. The transformation is photocatalyzed since at ambient temperature (ca. 25 °C) the equilibrium is attained in the dark after ca. 100 d and if the sample is exposed to visible light after ca. 35 h. At equilibrium the (*E*)/(*Z*) ratio is ca. 4:1. In the (*Z*) isomer the two vinylic protons have $^3J_{H,H}$ = 10.7 Hz consistent with their mutual *cis* position.[9] All other proton resonances change slightly on going from the (*E*) to the (*Z*) form, with the only exception being the phenyl *ortho*-proton signals which are shifted by more than 1 ppm at lower field [δ = 7.27 and 8.50 ppm for the (*E*) and (*Z*) isomer, respectively]. In the (*Z*) isomer the phenyl ring is *cis* to the platinum atom with respect to

the olefin double bond, the *ortho* protons are close to and deshielded by the metal center.[10]

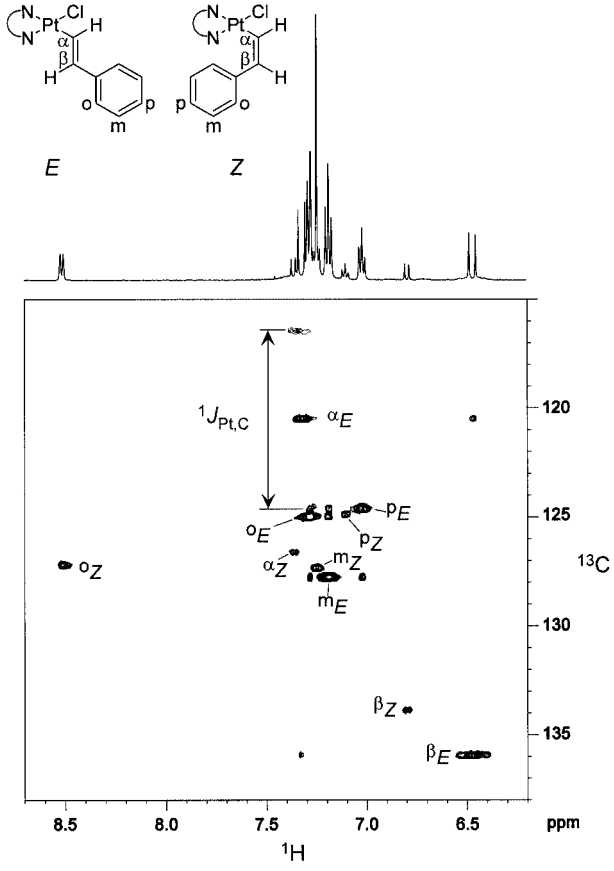

Figure 1. Aromatic portion of the $^1H/^{13}C$ HETCOR spectrum (500 MHz, $CDCl_3$, 25 °C) for an equilibrated solution of (*E*)- and (*Z*)-**2a**; some two-bond carbon-to-hydrogen correlation peaks are also visible

An interesting aspect of the present reaction is its complete stereoselectivity leading to the exclusive formation of the (*E*) isomer. The (*E*) isomer is also thermodynamically preferred because of smaller intramolecular steric interactions. However, the kinetic preference for the (*E*) isomer is greater than the thermodynamic preference for the same isomer, therefore, starting from the pure (*E*) isomer (kinetically determined composition), a significant amount of the (*Z*) form (ca. 20%) is also found at equilibrium.

The behavior of [PtCl(η^2-4-MeO-styrene)(tmeda)](ClO_4) (**1b**) in which the phenyl ring carries an electron-donor substituent, and that of [PtCl(η^2-3-NO_2-styrene)(tmeda)](ClO_4) (**1c**) carrying an electron-withdrawing substituent, is practically the same as that of **1a**. Therefore, the presence of substituents of different types on the styrene phenyl ring does not appear to significantly affect the rate of deprotonation.

Treatment of the alkenyl complexes with mineral acids ($HClO_4$, 0.02 M in water) reverses the reaction, reforming the parent η^2-alkene complexes.

In a thorough work by Gladysz on C−H bond activation of coordinated olefins in cationic complexes of rhenium(II) promoted by K(*t*BuO), the attention was focused on the two different deprotonation pathways involving either allylic or vinylic protons.[3d] It was shown that both types of deprotonation can take place depending upon the experimental conditions. Vinylic deprotonation was preferred in THF or DMSO, while allylic deprotonation was preferred in *t*BuOH. A greater thermodynamic stability of the alkenyl species (sp^2 carbon atom bound to the metal atom), as compared to the η^1-allyl complex (sp^3 carbon atom bound to the metal atom), was given as a rationale for the observed preference in THF and DMSO. On the contrary, the formation of large hydrogen-bonded aggregates of solvent molecules, around the tBuO$^-$ anion, was proposed to be responsible for the enhanced selectivity for less hindered allylic protons in *tert*-butyl alcohol. The relevance of steric

Table 1. ^1H NMR spectroscopic data (300 MHz, $CDCl_3$, 25 °C) for [PtCl(η^1-$C_\alpha H{=}C_\beta HAr$)(tmeda)] complexes **2**; coupling constants in Hz are reported in parentheses ($^3J_{H,H}$), brackets [$J_{Pt,H}$] and braces {$J_{Pt,C}$}; *ortho*, *meta*, and *para* protons of the aryl substituents are indicated by *o*, *m* and *p*, respectively

factors was also supported by the observation that vinylic deprotonation in *t*BuOH increased as the number of substituents on the allylic carbon increased.

In our investigations (ref.[1] and present work), we always use a very bulky base (NEt_3) since the use of less bulky nucleophiles such as OH^-, OMe^- or even $NHEt_2$ leads to stable addition products {[PtCl{η^1-$CH_2CHR(X)$}(tmeda)]; R = H, alkyl or aryl; X = OH, OMe or $NHEt_2$} which have no tendency, whatsoever, to lose HX and form allyl- or alkenylplatinum species.[11] Also triethylamine can add to the coordinated olefin, leading to the formation of an alkylplatinum derivative, but only in the case of unsubstituted ethylene.[11] Having used a bulky base it is obvious that, in the presence of allylic protons (more exposed to the solvent than vinylic protons), these are preferentially removed leading to formation of allylplatinum species. Only in the absence of allylic protons (such as in the case of styrene), will vinylic deprotonation take place. Moreover, it is very likely that both allylic and vinylic deprotonations take place through a direct attack of the base (NEt_3) on the leaving proton. The understanding of the reaction on the basis of a simple Brönsted acid-base model is also supported by the observation that mineral acids can protonate the alkenyl species leading back to the π-olefin complex.

The kinetic preference for the (*E*) isomer is also worthy of further discussion. The alkene complex [PtCl(η^2-CH_2=CHAr)(tmeda)]$^+$ is present in solution in two enantiomeric forms having opposite configurations at the =CHAr stereocenter (Scheme 1). The proton abstraction by an achiral base (such as NEt_3) will occur at a similar rate for the two enantiomers and the (*E*) or (*Z*) configuration of the formed alkenyl complex will depend exclusively upon the *trans* or *cis* position of the abstracted proton with respect to the Ar substituent. The kinetic preference for the (*E*) isomer indicates that the proton is removed exclusively in the position *trans* to Ar, which is more exposed to the solvent and more susceptible to undergo attack by a bulky nucleophile. In this context it could be worth mentioning that acidity data for the free styrene indicate that the most acidic protons are not those on the unsubstituted atom, but on the carbon atom bearing the phenyl substituent.[13,14]

The formation of an alkenyl complex by deprotonation of a coordinated alkene is unprecedented in platinum chemistry except for a recent report on dicationic platinum species of formula [Pt(PNP)(alkene)]$^{2+}$ [PNP = 2,6-bis(diphenylphosphanylmethyl)pyridine]. In methanol the styrene derivative exhibited a spontaneous deprotonation leading to formation of the alkenyl complex [Pt(PNP)(HC=CHPh)]$^+$ which precipitated from solution.[7] The authors did not specifically discuss the (*E*) or (*Z*) configuration of the obtained alkenyl complex; however, their NMR spectroscopic data are in full agreement with those found in our case for the (*E*) isomer. Moreover, since the (*E*) isomer is usually preferred, also on a thermodynamic basis, it is not clear if the obtained isomer was also the one preferred on a kinetic basis. Our alkene complexes, being monocationic, have a smaller propensity to undergo deprotonation than the dicationic complex mentioned above and require the use of a base. Moreover, in the case of the dicationic alkene complex, the formed alkenyl species, being insoluble in methanol, precipitated from the solution and this could have favored its formation.

Conclusion

This study, besides providing a quick and clean route to the synthesis of (*E*)-alkenyl complexes, has also given valuable information on the possible reaction mechanism. Abstraction of the proton *trans* to the phenyl substituent leads to the exclusive formation of the (*E*) isomer. The (*E*) isomer is also thermodynamically favored but not to the extent of precluding the formation of a small amount of (*Z*) isomer (ca. 20%) at equilibrium. The equilibration reaction is rather slow (at room temperature in the dark it requires some weeks) and can be accelerated by visible light. There appears to be a direct correlation between overall charge of the complexes and deprotonation propensity of the coordinated alkene.

Experimental Section

General Methods: The reagents and solvents employed are commercially available and were used as received without further purification. The complex [PtCl(η^2-propene)(tmeda)](ClO_4) was prepared as already reported.[11] All complexes described in this work gave satisfactory elemental analysis. ^1H and ^{13}C NMR spectra were recorded with DRX500 Avance and DPX300 Avance Bruker instruments equipped with probes for inverse detection and with *z* gradient for gradient-accelerated spectroscopy. ^1H and ^{13}C NMR spectra were referenced to TMS; the residual proton signal of the solvent was used as internal standard. Standard Bruker automation programs and pulse sequences were used for $^1H/^{13}C$ inversely detected gradient-sensitivity enhanced heterocorrelated 2D NMR for normal coupling (INVIEAGSSI). ^1H 2D NOESY experiments were performed at room temperature by collecting a 512 × 1024 matrix with 64 scans per t_1, and a mixing time of 1200 ms. Each block of data was preceded by eight dummy scans. The data were processed in the phase-sensitive mode.

Preparation of Alkene Complexes: [PtCl(η^2-CH_2=CHC_6H_4X)(tmeda)](ClO_4) [X = H, (**1a**), 4-OCH_3 (**1b**), 3-NO_2 (**1c**)]. Complexes **1a**−**c** were prepared by propene exchange in the cationic complex [PtCl(η^2-propene)(tmeda)](ClO_4).[11] In a typical experiment [PtCl(η^2-propene)(tmeda)](ClO_4) (250 mg, 0.51 mmol) was suspended in 4 mL of dichloromethane and treated with a 10-fold excess of the incoming olefin (**a** = styrene, **b** = 4-MeO-styrene, **c** = 3-NO_2-styrene). After 24 h of stirring at room temperature, the solid was recovered on a sintered glass filter, washed with diethyl ether and dried. The yield was always above 90%.

Preparation of Alkenyl Complexes: [PtCl(η^1-CH=CHC_6H_4X)(tmeda)] {X = H [(*E*)-**2a**], 4-OCH_3 [(*E*)-**2b**], 3-NO_2 [(*E*)-**2c**]}, by deprotonation with NEt_3. In a typical experiment the styrene complex **1** (0.4 mmol) was suspended in dichloromethane (8 mL) and triethylamine was added whilst stirring at room temperature (2.5-fold the stoichiometric amount). The mixture was left stirring for several hours, while dissolution of the solid was observed. The resulting solution was concentrated under vacuum; the viscous resi-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

due was triturated with diethyl ether and dried. The obtained solid was then washed with water (to remove the alkylammonium salt) and dried again under vacuum leaving a pale yellow compound which was identified as the alkenyl complex **2**. The isolated yield, based on platinum, was ca. 85% for (*E*)-**2a** and (*E*)-**2b** and ca. 50% for (*E*)-**2c**, which required purification of the crude reaction product (Sefadex; eluent chloroform/acetone, 98:2, v/v). All manipulations were carried out by shielding the reaction vessel from light. The alkenyl complexes (*E*)-**2** were also prepared by deprotonation of the corresponding alkene complexes with Na_2CO_3. In a typical experiment **1** (0.25 mmol) was suspended in chloroform (5−6 mL), where it is sparingly soluble, treated with powdered Na_2CO_3 (0.50 mmol), and the mixture stirred for 70 h at 25 °C. After filtration, the mother liquor was concentrated under vacuum and the viscous residue was triturated with diethyl ether and dried. The obtained solid was the alkenyl species **2**, the yield (always based on platinum) was 80% for (*E*)-**2a** and 85% for (*E*)-**2b**.

The Reverse Reaction: The alkenyl species (*E*)-**2** (0.10 mmol) was treated with an aqueous solution (6 mL) containing $HClO_4$ (0.02 M). After 48 h of stirring, the solid was recovered by filtration of the mother liquor, washed with very small amounts of cold water, and dried in a dessicator. It always corresponded to the parent π-alkene complex.

(*E*)/(*Z*) Isomerization of the Alkenyl Ligand: NMR tubes containing $CDCl_3$ solutions (0.7 mL of a 6 mM solution) of the (*E*)-alkenyl species, were exposed to a neon lamp (75 W) and the ^1H NMR spectrum scanned every 4−6 h. The intensity ratio of two well-separated signals, one belonging to the (*E*) and the other to the (*Z*) isomer [the high-field vinylic signal of the (*E*) isomer and the *ortho*-phenyl signals of the (*Z*) form], was plotted against time. A constant ratio was reached at about 35 h for all compounds.

[8] The coupling constants with the ^{195}Pt nucleus are $J_{Pt,H}$ = 50 and 48 Hz for the more and the less shielded proton, respectively.

[9] In the (*Z*) isomer the vinyl hydrogen signals appear at δ = 6.79 and 7.35 ppm, and the vinyl carbon signals at δ = 126.8 and 134.0 ppm; also in this case the more shielded carbon atom is bound to the less shielded proton.

[10] Large downfield shifts are typical for signals of protons at a pseudoaxial position above the platinum center in a square-planar complex: A. Albinati, P. J. Pregosin, F. Wombacher, *Inorg. Chem.* **1990**, *29*, 1812; Y. Liu, C. Pacifico, G. Natile, E. Sletten, *Angew. Chem. Int. Ed.* **2001**, *40*, 1226. It has been proposed that a C−H bond, close to the apical position of the Pt atom, may undergo 3-center-4-electron interaction with a filled orbital of the Pt atom. This interaction, unlike the 3-center-2-electron agostic interactions, would cause a downfield shift in the ^1H NMR spectrum: W. Yao, O. Eisenstein, R. H. Crabtree, *Inorg. Chim. Acta* **1997**, *254*, 105; L. Bremmer, J. M. Charnock, P. L. Goggin, R. J. Goodfellow, A. G. Orpen. T. F. Koetzle, *J. Chem. Soc., Dalton Trans.* **1991**, 1789.

Keywords: Composite materials / Cyclic hexaselenium / Cyclic hexatellurium / Solid solvent silver iodide / Selenium / Tellurium

The new deeply colored solids $(AgI)_2Te_6$ and $(AgI)_2Se_6$ are obtained under hydrothermal conditions in hydroiodic acid. They contain molecules of cyclic hexatellurium and hexaselenium (Te_6, Se_6, respectively, both chair conformations) stabilized in a matrix of AgI. Whereas Se_6 molecules are well known as isolated species in rhombohedral selenium, Te_6 molecules are not known to exist in any modification of that element. They can be stabilized only in an appropriate "solid solvent" like AgI. To date, the new compound $(AgI)_2Te_6$ is the second example only of a composite material containing cyclic Te_6 molecules [the first example is $Re_6Te_{10}Cl_6(Te_6)$].

Introduction

The stabilization of unusual molecules of group 15 and 16 elements in composite materials based on a matrix of solid CuI has been generally known for about 30 years.[1] In particular, those molecules that do not exist as free molecules in one of the known element modifications of the respective group 15 or 16 element have attracted great attention in the past (for example see ref.[2]). Among others, the scientific interest in the field of those materials is focused on the chemical bonding nature in "nonexistent" molecules of, for example, phosphorus[3] as potential candidates for a suitable stabilizing matrix. The possibility of isolating the molecules from the solid composite by either dissolving the CuI matrix in a suitable liquid or vice versa is another area of interest.[4] The only known example in which AgI serves as a "solid solvent" instead of CuI is AgITe[5] with a Te_∞ screw.

In the course of a sequence of hydrothermal syntheses under strongly acidic conditions (concentrated hydroiodic acid) aiming to form new argyrodites (argyrodite: Ag_8GeS_6) with improved silver ionic conduction by systematic substitution of S with Se/Te and/or halides,[6] we repeatedly obtained deeply colored by-products of initially unknown chemical character. Analytical scanning electron microscopy, in combination with X-ray investigations, revealed the unexpected formation of the two new compounds $(AgI)_2Te_6$ (= $AgITe_3$) and $(AgI)_2Se_6$ (= $AgISe_3$) with cyclic Te_6 and Se_6 molecules (chair conformation) that are embedded in a matrix of AgI. Although we have not been able to produce the title compounds without any contaminants, we decided to publish our preliminary results. The reason for this is that it was explicitly stated in ref.[7] that $(AgI)_2Ch_6$ (Ch: Se, Te) should not exist. Furthermore, to the best of our knowledge, $(AgI)_2Te_6$ is only the second literature example of cyclic Te_6, which, in contrast to Se_6, is *not* known to exist in one of the elemental modifications of tellurium.

Results and Discussion

Both title compounds crystallize isotypically to $CuBrSe_3$[8] but *not* to $CuISe_3$,[9] although the latter was claimed to be more likely in a former paper.[10] The difference between $CuBrSe_3$ and $CuISe_3$ is related to the stacking and coordination of the cyclic Se_6 molecules only, but not to the molecular structure of Se_6.

To date, $(AgI)_2Te_6$ and $(AgI)_2Se_6$ can only be obtained as components of hydrothermal reaction products containing at least two phases. Because of the characteristic color and morphology of the crystalline samples, it is possible to separate them mechanically under the light microscope. Typically single crystals of the tellurium compound show a significantly better quality for structure determinations than those of the selenium compound. The latter crystals are unfortunately characterized by extended intergrowth. On the other hand, an excellent X-ray powder diagram can only be obtained for the selenium compound (Figure 1). It is for

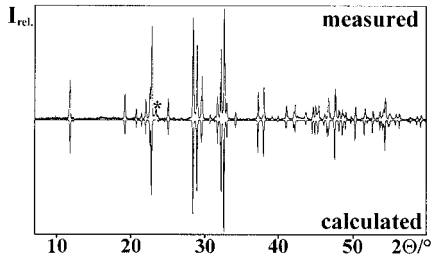

Figure 1. X-ray powder diagram for $(AgI)_2Se_6$ (Cu-$K_{\alpha 1}$, Siemens D5000) relative to a calculated pattern based on single crystal data (*: α-Se)

this reason that we restrict the subsequent structure discussion involving structural details of $(AgI)_2Se_6$ (e.g. bond lengths) to reasonably rounded values. Table 1 contains a summary of all relevant X-ray data for $(AgI)_2Te_6$ and $(AgI)_2Se_6$, whereas in Table 2 and 3 the atomic coordinates and relevant interatomic distances are given.

The structure projection of $(AgI)_2Te_6$ (Figure 2), which is representative for $(AgI)_2Se_6$ also, clearly shows the composite character of this material with respect to the Te_6/Se_6 units embedded in a matrix of AgI. The silver and iodine atoms form zigzag chains along [001] that are separated by Te_6 units. In addition to the two iodine atoms, each silver atom is coordinated by two tellurium/selenium atoms from different Te_6/Se_6 units that are stacked along [010], such that each Ag has a total coordination number of four. Only four of the six Te/Se atoms of each Te_6/Se_6 unit coordinate

directly to a silver atom. This feature is consistent with the corresponding coordination for the cyclic Se_6 units in $(CuBr)_2Se_6$ and $(CuI)_2Se_6$, and indicates a bonding interaction between Ag and Te/Se (see below).

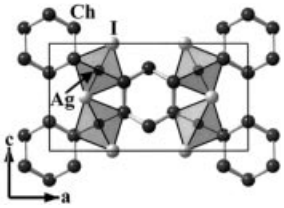

Figure 2. Crystal structure of $(AgI)_2Ch_6$ (Ch: Se, Te) projected along [010]; the coordination of Ag ($2 \times$ Ch, $2 \times$ I) is emphasized by a shaded polyhedral representation; the distance between neighboring Ch_6 molecules along [010] corresponds to the lattice constant *b*

In further compounds with cyclic Se_6 molecules, for example $(PdCl_2)Se_6$ and $Rb_3AsSe_4(Se_6)_2$ (see ref.[11,12] and papers cited therein), *differences* in the coordination of the Se_6 units with respect to the matrix are found relative to the title compounds [e.g. in $(PdCl_2)Se_6$ only *two* of the six Se atoms are coordinated to Pd].

However, in the cluster compound $Re_6Te_{16}Cl_6$ [13] [= $Re_6Te_{10}Cl_6(Te_6)$], the analogous Te_6 molecules are *similar* to those in $(AgI)_2Te_6$ as *four* of the six Te atoms are coordinated directly to surrounding Re_6 clusters. The comparison with $(AgI)_2Te_6/Se_6$ has to be restricted to the cyclic Te_6 molecules only, because $Re_6Te_{16}Cl_6$ is a unique cluster compound with a completely different structural chemistry.

A closer inspection of the bond lengths (Table 3 and Figure 3) shows that the average Te−Te distance for Te_6 in $(AgI)_2Te_6$ ($d_{av(Te-Te)}$ = 273.9 pm) is slightly shorter than for the infinite helices in α-Te[14] (d_{Te-Te} = 283.4 pm) and for Te_6 in $Re_6Te_{10}Cl_6(Te_6)$ (d_{av} = 281 pm). Interestingly, the $d_{av(Se-Se)}$ value of 237 pm for Se_6 in $(AgI)_2Se_6$ is closer to, for example, Se_6 in $(CuBr)_2Se_6$ ($d_{av(Se-Se)}$ = 237 pm), Se_6 in $(PdCl_2)Se_6$ ($d_{av(Se-Se)}$ = 236 pm) and Se_6 in rhombohedral selenium[15] (d_{av} = 235.6 pm]. For a more detailed discussion of the geometry see ref.[6]

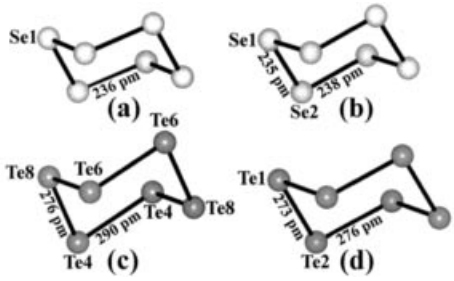

Figure 3. Cyclic Ch_6 molecules (chair conformation) in rhombohedral selenium (a), $(AgI)_2Se_6$ (b), $Re_6Te_{10}Cl_6(Te_6)$ (c), and $(AgI)_2(Te_6)$ (d)

In addition, the bond length d_{Ag-I} = 288 pm in $(AgI)_2Te_6$ [280 pm in $(AgI)_2Se_6$] compares well with d_{Ag-I} = 281.7 pm in β-AgI.[16]

The bond lengths $d_{Ag-Te/Se}$ are somewhat puzzling because the values d_{Ag-Te} = 279.6 pm and d_{Ag-Se} = 269 pm are in the range expected for covalent interactions $d_{Ag-Te/Se}$ (sum of atomic radii for Ag^0 and Te^0/ Se^0: 288/261 pm) in a variety of compounds (for an overview concerning the range of experimental d_{Ag-Te} see ref.[17]). This finding does not seem to be consistent with the conventional formulation $Ag^{1+}I^{1-}(Te_6)^{\pm 0}$ and $Ag^{1+}I^{1-}(Se_6)^{\pm 0}$, and suggests a van der Waals interaction between Ag and Te (Se) rather than a covalent one, and thus emphasizes the special bonding character in composite materials such as the title compounds. A similar ambiguity was found and discussed in the context of those materials that contain copper halides as a stabilizing matrix instead of silver iodide.[2]

Calculations of densities of states, crystal orbital Hamilton populations (COHP) and ELF representations (ELF: electron localization function,[18] Figure 4) based on the TB-LMTO-ASA formalism[6,19] clearly show significant differences between the Te (Se) atoms that are coordinated directly to Ag (Te2, Se2) and those that are not (Te1, Se1). From Figure 4 it is evident that, in contrast to Te1 (Se1), *one lone pair* of each Te2 (Se2) is involved in a bonding interaction with neighboring Ag atoms, resulting in a charge transfer from Te2 (Se2) to Ag. Further, it is interesting to note that the COHP values for the electronic states that are dominated by the cyclic Te_6 (Se_6) indicate that these electronic states are exclusively bonding below the Fermi energy (E_F) with an unusual steep transition to antibonding states immediately above E_F. This finding might be one of the keys to a deeper understanding of why Te_6 is stabilized in appropriate matrices like AgI only and is not known as a free molecule in an elemental Te modification. Raman and IR spectroscopic measurements, together with more detailed calculations of the electronic structure, are currently under progress.

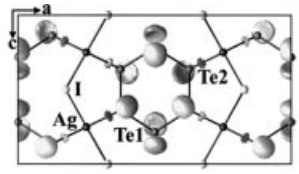

Figure 4. Projection of the crystal structure of $(AgI)_2Te_6$ with a superimposed ELF pattern (0.9-localization domain); the polarizing interaction between Ag^+ and *one* lone pair at each of the four Te2 is indicated by a significant reduction in the effective volume of the interacting lone pair relative to those of the noninteracting lone pairs

Experimental Section

$AgISe_3$ was repeatedly obtained as major component of a hydrothermal reaction product. A stoichiometric mixture of the roughly homogenized elements [silver powder (Degussa), selenium metal grey (Fluka AG- 99.995%, typical weight sum: 0.5 g)] was placed in a quartz tube ($l \approx 8$ cm, $\varnothing = 8$ mm, $V \approx 4$ cm^3), together with about 0.5 mL of concentrated HI (Merck- 57%). Subsequently, the glass tube was sealed and transferred to a steel autoclave (Berghof BAR 845, internal volume: approximately 240 cm^3). The pressure

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

balance inside the autoclave was achieved with water as counter pressure medium. The autoclave was then heated up to 220 °C and kept at this temperature for 5 days. Finally, the temperature was lowered at a rate of 2 °C/h down to room temperature. Red transparent hexagonal crystals of $(AgI)_2Se_6$, characterized by strong intergrowth were separated mechanically from the other products under the light microscope. $(AgI)_2Se_6$ is not significantly air sensitive. Crystals of the grey-metallic-black $(AgI)_2Te_6$ were obtained by a similar procedure [tellurium powder (Johnson Matthey GmbH, 99.5%)] with traces of GeO_2 as "mineralizer". The chemical composition of the selected crystals was checked by EDX analyses prior to X-ray structure determination. Further details of the crystal-structure investigation of $(AgI)_2Se_6$ and $(AgI)_2Te_6$ may be obtained from the Fachinformationzentrum Karlsruhe, 76344 Eggenstein-Leopoldshafen (Germany), on quoting the depository number CSD-414116 and -414117.

Synthesis of (Indenylidene)phosphoranes − A Novel Class of Ligand Precursors for Main-Group and Transition Metal Organometallics[‡]

Konstantin A. Rufanov,*[a] Burkhard Ziemer,[a] Markus Hummert,[b] and Stefan Schutte[b]

Dedicated to Professor Manfred Meisel on the occasion of his 65th birthday

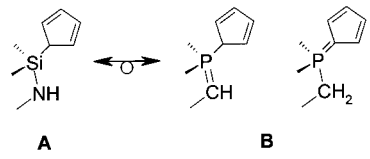
Keywords: Bridging ligands / Constrained geometry catalysts / Cyclopentadienyl ligands / Isoelectronic analogues / Isolobal relationship / Phosphoranes / Phosphorus ylides / Indenyl / Sodium

$IndPPh_2$ (**1**) reacts with RCH_2Br to form the phosphonium salts $[RCH_2P(Ph)_2Ind]^+Br^-$ (**2**: R = Ph; **3**: R = C_6F_5) in high yields. Oxidation of **1** with H_2O_2 in THF proceeds smoothly to give the phosphane oxide $IndP(O)Ph_2$ (**4**). Dehydrobromination of **2** and **3** with NaH in THF yields the corresponding indenylidenephosphoranes $C_9H_6{=}P(Ph)_2CH_2R$ (**5**: R = Ph; **6**: R = C_6F_5). Further deprotonation of **6** with excess NaH results in formation of sodium 1-{[(pentafluorophenyl)methylidene]-diphenylphosphoranyl}indenide (**7**), isolated as a solvate with three THF molecules. A detailed NMR study of new ligand precursors and X-ray structure studies of **5** and **7** have been accomplished. A short F→Na coordination contact in the molecular structure of **7** has been detected.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

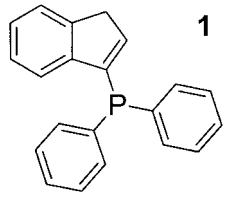
Introduction

Linked (cyclopentadienylsilyl)amine systems **A** (Scheme 1) became one of the best established and developed classes of specially designed ligand precursors[1−5] for bridged cyclopentadienyl−amido early transition metal complexes, the so-called "constrained geometry catalysts".[6] Depending on the nature of the ligand framework, these complexes give high molecular weight PE with long-chain branching. Furthermore, because of their more open coordination spheres (relative to *ansa*-metallocenes), they have the pronounced ability to incorporate higher olefins.[7−12] Isoelectronic analogues of systems **A** are the linked cyclopentadienylphosphoranylidene systems (**B**, left). These compounds do exist in the thermodynamically more stable form of the cyclopentadienylidenephosphoranes (**B**, right). Some examples of similar compounds are known from the literature;[13] however, neither a general synthetic route towards these ligand precursors for organometallic chemistry nor their organometallic derivatives have been explored.



Scheme 1

In this paper we describe a synthetic approach towards and a detailed NMR study of type **B** ligand precursors on the basis of stable Ph_2PInd (**1**), as well as the first alkali metal derivative of one such new ligand, along with their crystal structures.



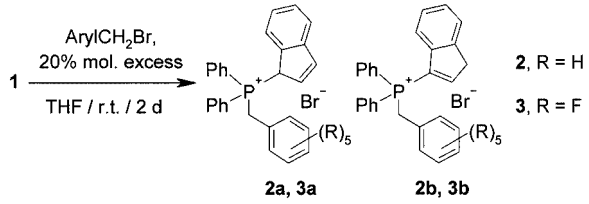
Results and Discussion

As the simple (cyclopentadienyl)phosphanes are eager to dimerise by Diels−Alder reaction, **1** was chosen for our preliminary studies. Of the two isomers of this compound, earlier described by Anderson and co-workers,[14] the thermodynamically most stable is the vinylic isomer. It was synthesised in 89% yield by a slightly modified procedure starting from IndLi and Ph_2PCl in toluene.[15] Quaternisation of **1** with bulky $tBuCH_2Br$ or Me_3SiCH_2Br was un-

[‡] Organophosphorus(V) Ligands for Coordination and Organometallic Chemistry, I

[a] Institut für Chemie, Humboldt-Universität zu Berlin, Brook-Taylor-Strasse 2, 12489 Berlin, Germany
[b] Institut für Chemie, Technische Universität Berlin, Strasse des 17. Juni 135, 10623 Berlin, Germany

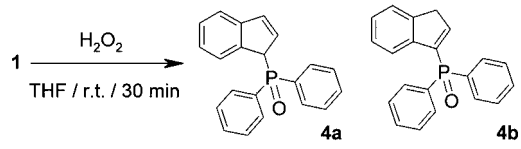
successful,[16] we therefore decided to use the more electrophilic $C_6H_5CH_2Br$ and $C_6F_5CH_2Br$. In both cases, using 20% molar excess of benzyl bromides, complete quaternisation was achieved in THF at room temperature after 2 d (Scheme 2). Corresponding phosphonium salts **2** and **3** are only slightly soluble in THF and were isolated as white powders in practically quantitative yields.[17]



Scheme 2

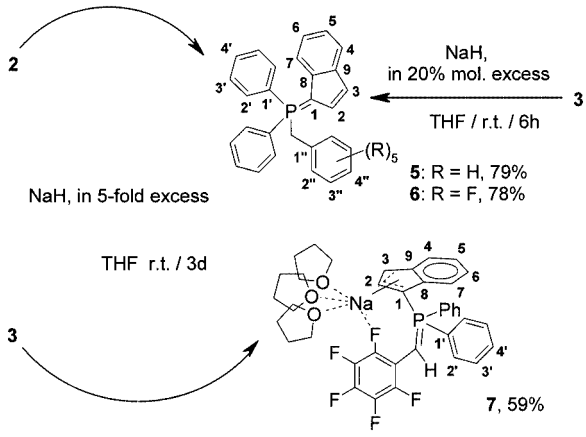
According to ^{31}P NMR spectroscopic data, **2** and **3** exist as mixtures of allylic (**2a**: δ = 32.8 ppm; **3a**: δ = 15.6 ppm) and vinylic (**2b**: δ = 31 ppm; **3b**: δ = 13 ppm) isomers depending on the position of the double bond in the indenyl ring. The ratio of isomers differs from one sample to another in an irregular way, which precludes accurate assignment of arylic and vinylic signals in ^1H and ^{13}C NMR spectra that have been measured in [D$_6$]DMSO. ^1H NMR benzylic signals are located between δ = 5.0 and 5.5 ppm and ^{13}C signals at δ = 30.0 ppm for **2** and δ = 19.0 ppm for **3**. Allylic signals of isomers **a** are located at $\delta \approx 6.3$ ppm ($^2J_{PH}$ = 21 Hz) and 44 ppm ($^1J_{P,C}$ = 42 Hz), while those of isomers **b** are shifted downfield to δ = 4 ppm and 42 ppm in the ^1H and ^{13}C NMR spectra, respectively.

Interestingly, a similar situation arises when phosphane oxide **4** is synthesised by oxidation of **1** with H_2O_2 in THF (Scheme 3).[18] Compound **4**, obtained quantitatively, exists as a 1:4 isomeric mixture of corresponding allylic and vinylic phosphane oxides **4a** and **4b**, respectively.[19]



Scheme 3

The reaction of the phosphonium salt **2** with a five-fold molar excess of NaH in THF was rather slow, took 3 d, and resulted in a dark green solution (Scheme 4). Upon concentration of the solution to one quarter of its initial volume, the desired indenylidenephosphorane **5** precipitated at −78 °C after 1 d as a yellow-green, light-sensitive microcrystalline powder.[20] Crystallisation from CH_2Cl_2 gave block crystals. The X-ray structure of **5** was determined and showed nearly ideal tetrahedral coordination of the central phosphorus atom with C−P−C angles between 104° and 116°. The C−P bond lengths are also not very different: 1.828(4) Å for $PhCH_2$−P, 1.797(4) Å for C_{Ph}−P and 1.727(4) Å for C_{Ind}=P.[21,22] The molecular structure of **5** with thermal ellipsoids of 50% probability as well as selected bond lengths and angles are shown in Figure 1.



Scheme 4

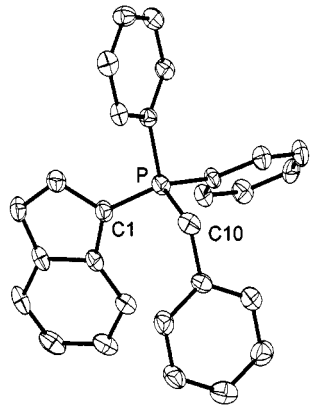


Figure 1. Molecular structure of **5** showing the atom numbering scheme with 50% probability thermal ellipsoids; all hydrogen atoms are omitted for clarity; selected bond lengths [Å] and angles [°]: C(1)−P(1) 1.733(4), C(1)−C(2) 1.420(5), C(10)−P(1) 1.832(4), C(1)−P(1)−C(10) 116.4(2); C(1)−P(1)−C(Ph) 108.9(2), C(Ph)−P(1)−C(Ph′) 108.3(2)

Under the same reaction conditions, phosphonium salt **3** was converted directly into the Na salt **7**. Obviously, CH acidity of the benzylic CH_2 group is much higher in the case of the pentafluorobenzyl derivative, and further deprotonation with NaH (applied in fivefold excess) proceeds quicker and results in the formation of sodium 1-{[(pentafluorophenyl)methylidene]diphenylphosphoranyl}-indenide (**7**).[23] The synthesis of **6** was achieved in another experiment using only 20% molar excess of NaH and a shorter reaction time: after 6 h in THF, it was obtained in 78% yield as a yellow powder.[24] Both indenylidenephosphoranes **5** and **6** are rather stable and can be handled in air without special care for several minutes. They are more soluble in ethereal and aromatic solvents than in aliphatic ones. Gold-yellow Na salt **7** crystallises with three THF molecules (coordinated by sodium) in the asymmetric unit.[25,26] While their O atoms occupy fixed positions

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

around the sodium atom, all carbon atoms are disordered. The structure refinement of the latter had to be split on two sides in each case. For this reason only the C atoms of the major components could be refined anisotropically. The ratios between major and minor components vary from 64:36, 66:34 to 83:17, respectively. The sodium atom shows predominantly η^3-coordination with the allylic part of the indenyl fragment, with the shortest distance to the C2 atom (2.67 Å). Similar delocalisation of the carbanionic charge was found by Schmidbaur and co-workers in the crystal structure of the solvent-free potassium salt of dimethylphosphonium bis(benzylide) K[$Me_2P(CHPh)_2$]. The lattice did not contain discrete complex molecules, but was rather a coordination polymer; the metal atoms interacted preferentially with ylidic carbanions and the *ortho* and *para* positions of the benzylide rings.[27] In the molecular structure of **7**, a short F→Na coordination contact was found. The intramolecular distance between the sodium cation and one of the *ortho*-F atoms of the C_6F_5 group is only 2.67 Å, i.e. more than 1 Å shorter than the sum of the van der Waals radii of these elements (3.74 Å).[28] The molecular structure of **7** with thermal ellipsoids of 50% probability as well as selected bond lengths and angles are shown in Figure 2.

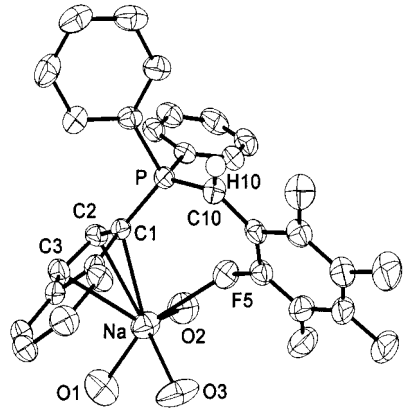

Figure 2. Molecular structure of **7** showing the atom numbering scheme with 50% probability thermal ellipsoids; all hydrogen atoms except for H(10) of the bridging moiety are omitted; only oxygen atoms of coordinated THF molecules are shown for clarity; selected bond lengths [Å] and angles [°]: P−C(10) 1.714(2), P−C(1) 1.747(1), P−C(Ph) 1.827(2), P−C(Ph′) 1.828(2), C(1)−C(2) 1.431(2), C(2)−C(3) 1.383(2), Na−C(1) 2.874(2), Na−C(2) 2.679(2), Na−C(3) 2.741(2), Na−O(1) 2.373(2), Na−O(2) 2.322(2), Na−O(3) 2.271(2), Na−F(5) 2.669(1), F(5)−C(C_6F_5) 1.374(2), F(3)−C(C_6F_5) 1.354(2); C(10)−P−C(1) 118.77(8), C(10)−P−C(Ph) 103.51(8), C(1)−P−C(Ph′) 109.02(8), C(1)−P−C(Ph) 106.37(7), C(Ph)−P−C(Ph′) 103.61(8), P−C(1)−Na 125.21(8), O(3)−Na−O(2) 116.93(6), O(3)−Na−O(1) 87.75(6), O(2)−Na−O(1) 88.00(6), O(3)−Na−F(5) 81.70(5), O(2)−Na−F(5) 78.87(5), O(1)−Na−F(5) 157.07(5), C(C_6F_5)−F(5)−Na 140.0(1)

Because of the importance of **5**, **6** and **7** for further syntheses of organometallic derivatives, a detailed NMR study of these compounds has been performed using $^1H/^{13}C$ COSY, APT and DEPT methods and heteronuclear NMR spectroscopy. The complete set of data obtained is given in Table 1. It is interesting to note that in the ^{13}C NMR spectrum of **7** signals for C1 appear considerably shifted downfield, and the signals for C1′ and P*C*H are shifted upfield, relative to those in the spectrum of **6**. In the ^{19}F NMR spectrum the signals of *ortho*- and *para*-F substituents in **7** also appear at a much lower field than in **6**, while those of *meta*-F substituents are almost unaffected. Also, no difference between the *ortho*-F atoms can be detected, which indicates free rotation of the C_6F_5 substituent of **7** when it is in solution.

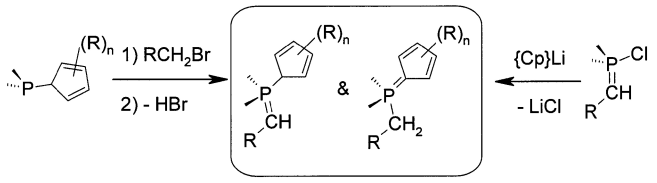
Conclusion

Series of phosphoranes **B** with different R substituents can be synthesised easily using the developed synthetic scheme or, alternatively, from chlorophosphonium ylides with sterically encumbered {Cp}-type anions. A combination of these two methods allows a wide range of the type **B** ligand precursors to be synthesised (Scheme 5).[29]



Scheme 5

In this preliminary work we have formed the basis for the further development and revival of organometallic chemistry in the so-called "post-metallocene" epoch. Systematic study of thus developed linked cyclopentadienylphosphoranylidene ligands for the syntheses of alkali, rare-earth and transition metal complexes is the subject of our current efforts.

Acknowledgments

K. R. thanks Dr. Heinz-Jürgen Kroth for multinuclear NMR experiments, Profs. Herbert Schumann (Berlin Technical University) and Igor Fedushkin (Razuvaev-Institute of Chemistry, Nizhnij Novgorod, Russian Federation) for fruitful discussions and the Graduate College Programme 352 of the DFG for a postdoctoral fellowship.

[15] **General Remarks:** All synthetic procedures were performed under purified argon using standard Schlenk techniques. Solvents were distilled from an appropriate drying agent and degassed prior to use. The ^{1}H, ^{13}C, ^{19}F and ^{31}P NMR spectra were obtained with Bruker ARX-200, -300 or -400 spectrometers. Mass spectra were measured with a Varian CH-7a MAT device using electron impact with an excitation energy of 70 eV. Indene, Ph_2PCl, $C_6H_5CH_2Br$, $C_6F_5CH_2Br$, *n*BuLi and NaH were used as supplied (Merck, Aldrich). **Starting Phosphane, Ph_2PInd (1):** Indene (29 g, 250 mmol) was dissolved in pentane (900 mL). While the solution was stirred vigorously and cooled with an ice bath, *n*BuLi (110 mL 2.5 M solution in hexanes, 275 mmol) was added over a period of 2−3 h.. The mixture was stirred overnight. The white precipitate of IndLi was filtered off, washed with pentane (3 × 100 mL) and dried in vacuo for several hours. The thus obtained IndLi (12.2 g, 100 mmol) was suspended in toluene (400 mL), and under continuous stirring a solution of Ph_2PCl (22 g, 100 mmol) in toluene (100 mL) was added over a period of 4−5 h. The reaction mixture was stirred overnight, LiCl was filtered off, toluene was removed in vacuo, the crude product washed with hexane (4 × 50 mL) and dried in vacuo, to afford **1** in 89% yield and 95% purity as a light grey powder. ^{1}H NMR (200 MHz, C_6D_6, 25 °C): δ = 7.52−6.98 (m, 14 H, H_{Aryl}), 6.12 (dd, 1 H, vinylic H), 3.07 (t, 2 H, allylic H) ppm. ^{31}P NMR (200 MHz, C_6D_6, 25 °C): δ = −21 ppm.
[16] No reaction was observed after stirring of **1** with 50% molar excess of RCH_2Br (R = *t*Bu or TMS) at room temperature in THF for 30 h.
[17] **Phosphonium Salts $[C_6H_5CH_2P(Ph)_2Ind]^+Br^-$ (2) and $[C_6F_5CH_2P(Ph)_2Ind]^+Br^-$ (3)**: $C_6H_5CH_2Br$ (8.5 g, 50 mmol) or $C_6F_5CH_2Br$ (13 g, 50 mmol) was added at once to a solution of **1** (12 g, 40 mmol) in THF (300 mL). The reactions were very slow and only after 3 d complete, resulting in a white precipitate of **2** or **3**, which was filtered off, washed with THF and pentane, and dried in vacuo. Yields in both cases > 95%. **2**: M.p. 253−255 °C. EIMS: *m*/*z* (%) = 391.0 (100) $[M]^+$. **3**: M.p. 228−230 °C. EIMS: *m*/*z* (%) = 481.0 (100) $[M]^+$.
[18] **Phosphane Oxide $IndP(O)Ph_2$ (4)**: A 34% aqueous solution of H_2O_2 (2 mL, 20 mmol) was slowly added with a syringe to a stirred solution of **1** (3.0 g, 10 mmol) in THF (50 mL). After 30 min, the solution was quickly dried with Na_2SO_4, and THF was removed in vacuo, yielding an off-white microcrystalline powder of **4**. Yield: 3.15 g (100%). M.p. 137−138 °C. EIMS: *m*/*z* (%) = 316.1 (32) $[M]^+$, 201.0 (100) $[M^+ - Ind]$. $C_{21}H_{17}OP$ (316.34): calcd. C 79.73, H 5.42; found C 80.07, H 5.66.
[19] NMR measured in CD_2Cl_2: ^{1}H: **4a:** δ = 7.8−6.9 (m, aryl, Ph), 6.83, 6.38 (AB system, $^{3}J_{AB}$ = 3 Hz, vinylic protons), 4.72 (d, $^{2}J_{PH}$ = 25 Hz, allylic H); **4b:** δ = 7.8−6.9 (m, aryl, Ph), 6.71 (dt, vinylic H), 3.5 (br. s, 2 allylic H) ppm. ^{31}P: **4a:** δ = 32.3 ppm; **4b:** δ = 23.2 ppm.
[20] **Indenylidenephosphorane $C_9H_6{=}P(Ph)_2CH_2C_6H_5$ (5):** NaH (2.4 g, 100 mmol) was added under argon to a stirred suspension of **2** (9.42 g, 20 mmol) in THF (100 mL). Slowly the solution began to darken. The reaction was complete after 48 h, resulting in a dark green solution and white precipitate, which was filtered off. The filtrate was concentrated to one quarter of its initial volume (ca. 20−25 mL). The desired ylide **5** precipitated from the solution at −78 °C after 1 d as a yellow-green, light-sensitive microcrystalline powder. Yield: 6.16 g (79%). M.p. 224−226 °C. EIMS: *m*/*z* (%) = 390.1 (73) $[M]^+$, 299.0 (18) $[M^+ - C_7H_8]$, 276.1 (22) $[M^+ - Ind]$, 185.1 (100) $[Ph_2P]^+$. $C_{28}H_{23}P$ (390.47): calcd. C 86.13, H 5.94; found C 86.19, H 5.70.
[21] **X-ray Crystallographic Study:** Crystallisation of **5** was achieved from CH_2Cl_2. A suitable light-yellow, nearly colourless crystal with linear dimensions of 0.35 × 0.20 × 0.18 mm was mounted on the end of a glass fibre and investigated with a Siemens SMART CCD at 173(2) K, using graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å). Data were collected with an area detector by use of ω scans. The structure was solved by direct methods and expanded by difference Fourier syntheses using the SHELX-97 software package; the intensities were corrected for Lorentz, polarisation and absorption effects using SADABS ($T_{min.}$ = 0.9601, $T_{max.}$ = 0.9777). Experimental and Theoretical Studies of Homoleptic Tellurium Cyanides $Te(CN)_x$: Crystal Structure of $Te(CN)_2$

Thomas M. Klapötke,*[a] Burkhard Krumm,[a] Juan Carlos Gálvez-Ruiz,[a][‡] Heinrich Nöth,[a][‡] and Ingo Schwab[a]

Dedicated to Professor H. Schmidbaur on the occasion of his 70th birthday

Keywords: Cyanides / Structure elucidation / Tellurium / Ab initio calculations

The labile tellurium cyanide species $Te(CN)_2$ and $Te(CN)_4$ have been prepared by treatment of tellurium(IV) tetrahalides with cyanide. Both are thermosensitive solids and, in addition, the tetracyanide was found to be pyrophoric. The crystal structure of $Te(CN)_2$ has been determined. The structures of $Te(CN)_2$, $Te(CN)_4$, and $Te(CN)_6$ have been calculated at various levels of theory.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

A search for low-valent tellurium pseudohalides leads to few reports on the existence of dicyanotellane, $Te(CN)_2$ (**1**). This almost "forgotten" molecule was first prepared in 1908 by the reaction of $TeBr_4$ with excess AgCN,[1] and since then it has had a scanty publication history.[2−4] Somewhat surprising is the fact that **1** had been investigated by IR spectroscopy,[3] and used for an attempted synthesis only once, respectively.[4] The stable dicyanides of the lighter homologues of **1**, $S(CN)_2$ and $Se(CN)_2$, have been characterized in more detail,[5,6] while the $O(CN)_2$ molecule probably only exists as an intermediate and has been studied by theoretical methods.[7] The Te^{II} dihalides $TeHal_2$ (Hal = Cl, Br, I) are not stable towards disproportionation in the condensed phase,[8] but have been investigated in the gas phase;[9,10] the difluoride TeF_2 does not seem to exist at all. To the best of our knowledge, structurally characterized binary covalent main-group cyanides—apart from HCN, $(CN)_2$, and the halogen derivatives HalCN—are limited to $P(CN)_3$, $As(CN)_3$, $S(CN)_2$, and $Se(CN)_2$, whose reports date back to the 1960s.[11,12] This let us believe that the elucidation of the structural and spectroscopic properties of $Te(CN)_2$ (**1**) might be worthwhile.

Results and Discussion

Similar to the original procedure, $Te(CN)_2$ (**1**) can be obtained in analytically pure form from the reaction of $TeBr_4$ or TeI_4 with excess AgCN by separation of its colorless solutions in Et_2O under meticulously anhydrous conditions [Equation (1)].

$$TeHal_4 + 3\,AgCN \xrightarrow[-\,3\,AgHal]{60\,^\circ C\,/\,C_6H_6} Te(CN)_2\,(\mathbf{1}) + HalCN \qquad (1)$$

Hal = Br, I

After evaporation of the solvents, careful sublimation of the faintly brownish residue in vacuo ($<10^{-4}$ mbar/<80 °C) yielded an almost colorless solid, which is very sensitive towards hydrolysis; above 100 °C slow decomposition to elemental tellurium and cyanogen occurs.

The vibrational spectra (IR/Raman) of solid **1** exhibit the symmetric and antisymmetric C≡N stretching vibrations at 2176/2177 (A_1) and 2168/2170 (B_1), and bands at 410/409 (A_1 Te−C stretch), 398/395 (B_2 Te−C stretch), 296/− (B_1 TeCN deformation), 277/279 (A_2 TeCN deformation), and 147/136 cm^{-1} (A_1 CTeC deformation). The significant differences in frequencies and intensities (see Figure 1) obtained from the calculated values for the gas phase may result from intermolecular interactions in solid **1** (vide infra). Even if appropriate scaling factors for the calculated vibrational frequencies of **1** were available for all methods, this would give only partial improvement of the computed spectra because of a non-linear systematic difference in the Te−C and C≡N stretching vibrations. In the mass spec-

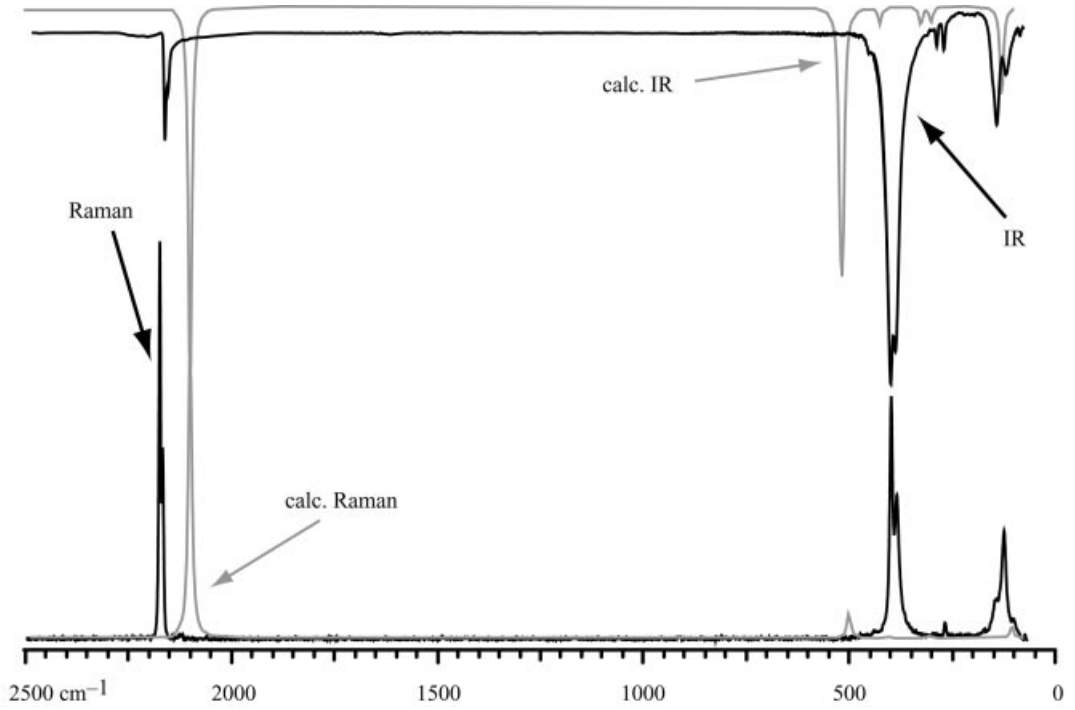

Figure 1. Experimental and calculated vibrational spectra of **1**, unscaled frequencies obtained at the MP2(FC)/MDF28-cc-pVQZ level

trum (EI), the parent ion is detected at m/z = 182, along with the fragments $[TeCN]^+$ at m/z = 156 and Te_2^+ at m/z = 256. The ^{125}Te NMR spectrum shows a single resonance at δ = 567 ppm in [D$_8$]THF (δ = 585 ppm in Et$_2$O). In the ^{13}C NMR spectrum in [D$_8$]THF, a resonance at δ = 86.2 ppm with a coupling $^1J_{C-Te}$ of 330.2 Hz is found. The broad ^{14}N NMR resonance at δ = −70 ppm ($\Delta\nu_{1/2}$ = 1300 Hz) is overlapped by the sharp resonance for dinitrogen at δ = −71.5 ppm. A minor second resonance at δ = −123 ppm ($\Delta\nu_{1/2}$ = 170 Hz) is assigned to cyanogen.

From saturated solutions of **1** in diethyl ether to which small amounts of *n*-heptane were added, off-white needles were formed under strictly anhydrous conditions at −25 °C after an extended period (18 months). In contrast, slow sublimation produced only amorphous solids. A single crystal suitable for X-ray diffraction was obtained only after several attempts because **1** in solution mostly decomposed faster than it crystallized. X-ray diffraction revealed a molecular structure with space group $R\bar{3}c$. Whereas the calculated gas phase structures of **1** at all theoretical levels applied

have the expected C_{2v} symmetry with a C−Te−C angle of about 95° (see Table 1), comparable to $TeCl_2$ in the gas phase with 97.0(6)°,[10] the crystal structure of **1** reveals two almost identical Te−C bond lengths [2.090(5) and 2.091(6) Å], but two slightly different C−N bond lengths [1.131(7) and 1.149(7) Å], with a C−Te−C angle of 85.4(2)° (see Figure 2). The Te−C distance in **1** is in the same range as found for diaryl-substituted tellanes Ar_2Te,[13] but with a more acute C−Te−C angle than the latter. Available structural data for $S(CN)_2$ and $Se(CN)_2$, as far as their poor quality allows conclusions, suggest a different structure in the solid state with C−S and Se−C angles of 96 and 99°, respectively.[5,12] This unusual small angle in **1** is most likely caused by the near square-planar coordination around Te^{II}

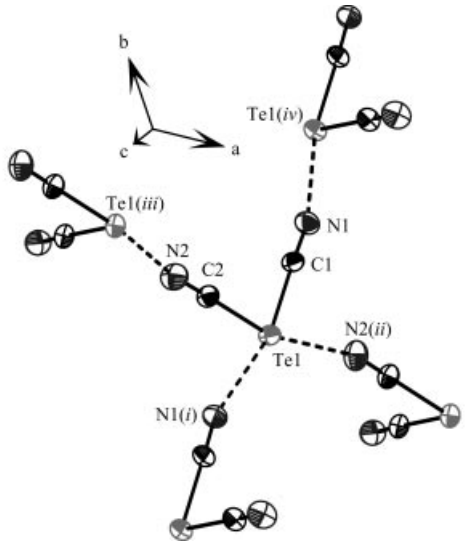

Figure 2. ORTEP plot of the molecular structure of **1** with thermal ellipsoids drawn at 50% probability; selected bond lengths [Å], distances [Å] and angles [°]: Te1−C1 2.090(5), Te1−C2 2.091(6), N1−C1 1.131(7), N2−C2 1.149(7); C1−Te1−C2 85.4(2), N1−C1−Te1 178.3(5), N2−C2−Te1 179.2(5); Te1···N1(*i*) 2.758(5), Te1···N2(*ii*) 2.745(5); C1−Te1···N1(*i*) 163.3(5), C1−Te1···N2(*ii*) 77.8(5), C2−Te1···N1(*i*) 78.0(5), C2−Te1···N2(*ii*) 163.2(5), N1(*i*)···Te1···N2(*ii*) 118.8(1); *i* = −1/3 + *x*, −1/6 + *x* − *y*, −1/6 + *z*; *ii* = 4/3 − *x* + *y*, −1/3 + *y*, −1/6 + *z*; *iii* = 1/3 + *x*, −1/3 + *x* − *y*, 1/6 + *z*; *iv* = 2/3 − *x* + *y*, 1/3 + *y*, −1/6 + *z*

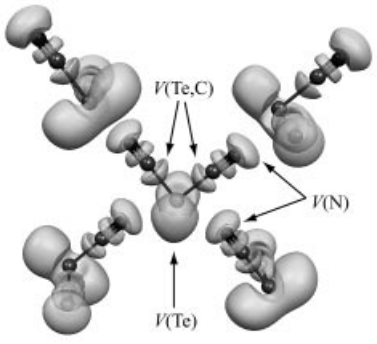

Figure 3. Ball-and-stick model with superimposed ELF isosurface of five $Te(CN)_2$ (**1**) molecules in the arrangement found by X-ray structure analysis (representing the full first coordination sphere for the central molecule, equivalent to Figure 2), single point calculation at the B3LYP/MWB46-VDZ level of theory; η = 0.78, grid increment 0.2 Å

created by the two covalent cyano groups attached to tellurium and two additional strong Te···N secondary interactions [2.745(5) and 2.758(5) Å] with two cyano-N atoms of two neighboring $Te(CN)_2$ molecules (see Figure 2), which are "pushed away" by the two lone pairs of Te^{II}. This can be conveniently visualized by the use of ELF analysis,[14] by using the experimental geometry of a part of the unit cell (see Figure 3). This coordination to adjacent molecules builds up a three-dimensional network, which connects all molecules of **1** contained in the unit cell. Furthermore, this network, when looked upon along the *c* axis, features small tubes of about 8 Å in diameter containing small residual electron densities, which have been assigned to disordered carbon atoms of a solvate, diethyl ether or *n*-heptane that was used during the crystallization process (see Figure 4).

The only report of a reaction of **1** is the attempted reaction with cyanide in MeCN solution, which did not furnish the tricyanotellurate(II) anion, $[Te(CN)_3]^-$.[4] Our experiments to halogenate **1** gave no clear results; reaction with XeF_2 in MeCN or EtCN led to colorless solutions, which were stable at −20°C for several hours. However, at higher temperatures, decomposition/dismutation reactions occurred, and sublimation of the dark residues thereof resulted in the isolation of starting material **1**.

The reaction of TeF_4 with Me_3SiCN, in a manner similar to the synthesis of $Te(N_3)_4$,[15] yields tellurium(IV) cyanide, $Te(CN)_4$ (**2**), one of the elusive neutral main-group tetracyanide species; a highly pyrophoric and thermally unstable solid. Compound **2** is obtained in CH_2Cl_2 or THF suspension at −20 °C [Equation (2)].

$$TeF_4 + 4\ Me_3SiCN \xrightarrow[-\ 4\ Me_3SiF]{-20\ °C\ /\ CH_2Cl_2} Te(CN)_4\ (\mathbf{2}) \qquad (2)$$

Above this temperature, rapid decomposition was observed that yielded a brownish oil, which was shown to contain **1** by ^{125}Te NMR spectroscopy. Reductive decomposition with extrusion of R−R species is also reported for some other R_4Te compounds.[16] After removal of all volatile materials from a suspension of **2** in CH_2Cl_2 at −20 °C, the remaining colorless powder was filled into a small Schlenk tube under argon for further investigations, upon which in two separate attempts a severe explosion destroyed parts of the glassware, presumably owing to thermal decomposition. The characterization of **2** is limited to Raman spectroscopy, since all other methods failed due to the enormous pyrophoric character, thermal sensitivity and insolubility. The fact that four equivalents of Me_3SiCN were consumed strongly suggests full substitution of all four fluorine atoms of TeF_4 to give the tetracyanide **2**. In the experimental Raman spectrum, four different C≡N stretching vibrations were detected, which complies with the basic considerations for two different cyano groups, axial and equatorial. The insolubility in all common solvents prevented crystallization and characterization by NMR spectroscopy.

In order to obtain a derivative of **2**, we probed the possible existence of pentacyanotellurate(IV) $[Te(CN)_5]^-$; re-

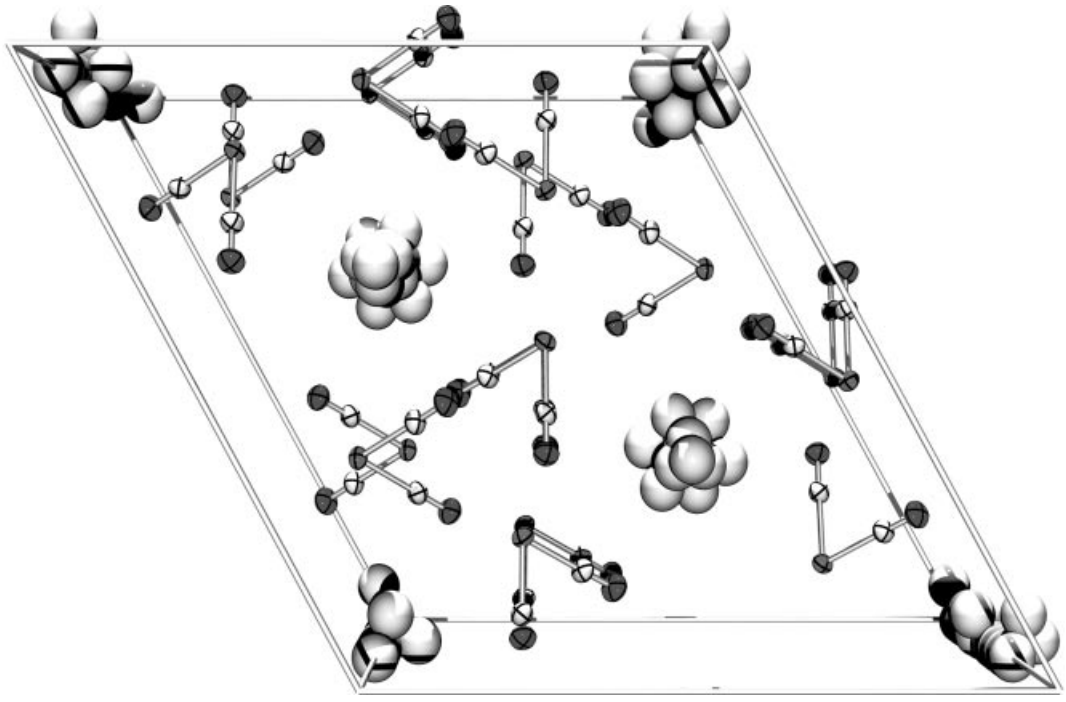

Figure 4. Unit cell of crystalline **1**, atoms within $0.5 \leq z \leq -1$ omitted, view along the *c*-axis (001), the residual electron densities assigned to carbon atoms [C11−C15, site occupation factor (SOF) = 0.207] of disordered solvate molecules are depicted as gray spheres within the free tubular spaces, thereof C11, C12, and C13 on a threefold axis

cently, we were able to characterize the stable azido analogue $[Te(N_3)_5]^-$.[15] Similar anions of the type $[aryl_5Te]^-$ can be trapped and have been proven to exist at low temperatures by ^{125}Te NMR spectroscopy.[17] Unfortunately, the reaction of $[Me_4N][TeF_5]$ with Me_3SiCN causes instantaneous decomposition to elemental tellurium, cyanide ion and cyanogen.

Since $Te(CN)_4$ (**2**) and $Te(N_3)_4$ [15,18] both seem to be highly sensitive compounds, and as examined for the hypothetical hexaazide,[18,19] we also investigated the possible existence of $Te(CN)_6$ with theoretical methods. The electronic structures of the $Te(CN)_2$ (**1**, C_{2v}), $Te(CN)_4$ (**2**, C_{2v}, see Figure 5), and $Te(CN)_6$ (O_h) molecules were calculated by using different ab initio and density functional methods (Table 1). All geometries have been fully optimized within C_1-symmetry and then recalculated in the obtained higher symmetry [**1** and **2**: C_{2v}; $Te(CN)_6$: O_h] at the level chosen, which led to minimum structures without imaginary frequencies. In addition, geometry optimization at the relativistic Dirac−Hartree−Fock level was performed for **1**, by using an energy-minimized relativistic Gaussian basis set for tellurium with either 4-component Dirac−Coulomb or Levy−Leblond Hamiltonians. The reductive decomposition of the $Te(CN)_x$ molecules yields energetic differences for the products $Te(CN)_{x-2}$ and one molecule of cyanogen of 75.78 kJ mol^{-1} ($x = 2$), −357.81 kJ mol^{-1} ($x = 4$), and −343.32 kJ mol^{-1} ($x = 6$) at the MP2(FC)/MDF28-cc-pVDZ level, respectively (corrected for the atomization energy of tellurium: 196.7 kJ mol^{-1}), thereby adding strong evidence for the instability of **2** and, even more for the hypothetical $Te(CN)_6$, relative to **1**.

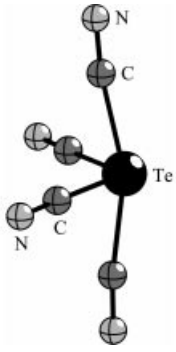

Figure 5. Calculated molecular structure of **2** (C_{2v}) at the MP2(FC)/MDF28-cc-pVTZ level of theory; selected bond lengths [Å] and angles [°]: Te−C_{eq} 2.042, C_{eq}−N_{eq} 1.177, Te−C_{ax} 2.180, C_{ax}−N_{ax} 1.179; C_{eq}−Te−C_{eq} 105.60, C_{ax}−Te−C_{ax} 158.50, Te−C_{eq}−N_{eq} 177.73, Te−C_{ax}−N_{ax} 172.21

Our present study involved the preparation and characterization of homoleptic tellurium cyanide species $Te(CN)_2$ (**1**) and $Te(CN)_4$ (**2**), as well as the calculation of their structures and that of hypothetical $Te(CN)_6$. A first comprehensive investigation of a chalcogen cyanide $Te(CN)_2$ (**1**), including an exact determination of its crystal structure is now at hand.

Experimental Section

General: All manipulations of air- and moisture-sensitive materials were performed under purified argon using flame-dried glass vessels and Schlenk techniques. Tellurium dioxide, silver cyanide and trimethylsilyl cyanide (Aldrich) were dried or distilled prior to use. Tellurium(IV) tetrahalides were prepared according to the literature.[8c,15] Ethers and hydrocarbons were dried with sodium/benzophenone and freshly distilled, CH_2Cl_2 was dried with CaH_2 and stored over molecular sieves (4 Å). Infrared spectra were recorded with a Bruker IFS 66/vS (as KBr and PE pellets), Raman spectra with a Perkin−Elmer 2000 NIR FT spectrometer fitted with an Nd-YAG laser (1064 nm). NMR spectra were recorded with a JEOL Eclipse 400 instrument, and chemical shifts are reported with respect to Me_4Si (^{13}C), $MeNO_2$ (^{14}N) and Me_2Te (^{125}Te). Mass spectra were recorded with a JEOL MStation JMS 700 spectrometer, tellurium-containing fragments refer to ^{130}Te. Elemental analysis: Analytical service (LMU).

$Te(CN)_2$ (1): In a flame-dried Schlenk tube connected with a D3 glass frit, $TeBr_4$ (3.5 mmol, 1.5 g), AgCN (37.3 mmol, 5.0 g) and benzene (10 mL) were stirred at 60 °C for 3 d. After the supernatant solution was decanted, the remaining residue was extracted with boiling diethyl ether (3 × 15 mL), and the ethereal extracts were filtered through the glass frit. Evaporation of all volatile material at 10^{-3} mbar and ambient temperature left a colorless solid, which was carefully sublimed at $<10^{-4}$ mbar and <80 °C; **1** has an off-white color (yield 68 %). M.p. 80−82 °C. IR: $\tilde{\nu}$ = 2176 (vs, νCN), 2168 (s, νCN), 462 (sh), 410 (vs, νTeC), 398 (vs, νTeC), 296 (w, δTeCN), 277 (w, δTeCN), 147 (m, δCTeC) cm^{-1}. Raman (200 mW, 25 °C): $\tilde{\nu}$ = 2177 (100, νCN), 2170 (50, νCN), 409 (69, νTeC), 395 (40, νTeC), 279 (5, δTeCN), 136 (30, δCTeC) cm^{-1}. ^{13}C NMR (100.6 MHz, [D$_8$]THF, 25 °C): δ = 86.2 ($^1J_{C-Te}$ = 330.2 Hz) ppm. ^{14}N NMR (28.9 MHz, [D$_8$]THF, 25 °C): δ ($\Delta\nu_{1/2}$) = −70 (1300 Hz) ppm. ^{125}Te NMR (126.1 MHz, [D$_8$]THF, 25 °C): δ = 567 ppm. EI MS m/z (%) = 256 (20) [Te_2^+], 182 (90) [M^+], 156 (68) [$TeCN^+$], 130 (100) [Te^+]. C_2N_2Te (179.63): C 13.4, N 15.6; found C 13.6, N 15.4.

$Te(CN)_4$ (2): In a flame-dried Schlenk tube, TeF_4 (1.0 mmol, 0.20 g) was suspended in dry CH_2Cl_2 (5 mL) at −20 °C. After addition of Me_3SiCN (4.4 mmol, 0.44 g) in one portion, the mixture was stirred at −20 °C for 7 h, then all volatile materials were evaporated in vacuo at this temperature. ***CAUTION:*** The remaining colorless powder tends to suddenly decompose when either exposed to temperatures above −20 °C or upon contact with air. Raman (200 mW, −20 °C): $\tilde{\nu}$ = 2204 (25, νCN), 2191 (45, νCN), 2149 (40, νCN), 2129 (15, νCN), 640 (65), 474 (35), 426 (br, 55), 381 (br, 55), 220 (75), 155 (50) cm^{-1}.

Crystal Data for 1: C_2N_2Te (179.63), colorless needle, 0.08 × 0.1 × 0.6 mm, hexagonal, space group $R\bar{3}c$, a = 16.288(1), b = 16.288(1), c = 21.267(1) Å, α = 90°, β = 90°, γ = 120°, V = 4886.3(4) Å^3, Z = 36, $\rho_{calcd.}$ = 2.198 g cm^{-3}, μ = 5.321 mm^{-1}, $F(000)$ = 2808, Siemens P4 diffractometer with CCD Area Detector, Mo-K_α, λ = 0.71073 Å, T = 193 K, 2θ range = 4.80−58.32°, $-10 \le h \le 19$, $-21 \le k \le 13$, $-28 \le l \le 28$, reflections collected: 7815, independent reflections: 1478 (R_{int} = 0.0414), observed reflections: 943 [$I > 4\sigma(I)$], SADABS absorption correction, structure solution: SHELXS-97, heavy-atom method, data/parameters ratio: 24.6:1 [16.8:1 for $I > 4\sigma(I)$], final R indices [$I > 4\sigma(I)$]: $R1$ = 0.0370, $wR2$ = 0.1079, $R1$ = 0.0511, $wR2$ = 0.1159 (all data), GOF on F^2 = 1.084, largest difference peak/hole: 1.319/−1.841 e Å^{-3}. Residual peaks (five with 1.15−2.4 e Å^{-3}) were considered to be carbon atoms (disordered diethyl ether or *n*-heptane) and refined isotropically (U_{eq} = 0.15) with the same SOF (0.207) for all atoms. CCDC-244701 (**1**) contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) + 44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Computational Details: Gaussian03 program package on Itanium2 (64 bit),[20] DFT and MP2(FC) methods, employing the MWB46 large-core and the MDF28 small-core pseudopotentials with the corresponding cc-pVnZ-PP basis sets for tellurium,[21] and the cc-pVnZ basis sets for carbon and nitrogen atoms;[22] (very) tight geometry optimizations for **1** and **2**, and $Te(CN)_6$ until max. force = 2/15 × 10^{-6} a.u., root-mean-square force = 1/10 × 10^{-6} a.u., max. displacement = 6/60 × 10^{-6} a.u., root-mean-square displacement = 4/40 × 10^{-6} a.u. Fully relativistic direct 4-component Dirac−Hartree−Fock and MP2 calculations have been performed with the DIRAC program package[23] on Pentium4 by using the Dirac−Coulomb-Hamiltonian, a relativistic dual family basis set for tellurium (20s18p11d+1s1p1d) applying strict kinetic balance,[24] and cc-pVDZ basis sets for carbon and nitrogen atoms. ELF values have been calculated with the ToPMoD package and visualized with Molekel 4.2.[25]

A Novel Dinuclear Fe^{II} Spin-Crossover Complex Based on a 2,2-Bipyrimidine Bridge Ligand: $[Fe(CH_3bipy)(NCS)_2]_2bpym$

Ana B. Gaspar,[a] Vadim Ksenofontov,[a] Víctor Martinez,[c] M. Carmen Muñoz,[b] José A. Real,*[c] and Philipp Gütlich*[a]

Keywords: Spin crossover / Iron(II) bpym-bridged dinuclear compounds / Pressure-induced spin transition / Mössbauer spectroscopy

The dinuclear iron(II) complex $\{[Fe(CH_3bipy)(NCS)_2]_2bpym\}$ has been synthesised and its crystal structure determined at 293 K. The magnetic properties display intramolecular antiferromagnetic coupling at 1 bar ($J = -4.2$ cm^{-1}), and the onset of a pressure-induced spin conversion is observed at 11 kbar. Magnetic field Mössbauer measurements have been carried out at 4.2 K, and indicate that the HS species correspond to [HS-HS] pairs.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

Spin crossover (SCO) materials present magnetic and optical bistability due to a high-spin (HS) to low-spin (LS) cooperative spin transition driven by an external perturbation such as a change in temperature and/or pressure or irradiation with light.[1] Many publications stress the potential for applications of such compounds in information storage, as sensors, or as molecular switches.[2] The characteristics of this class of bistable compounds, for example, transition temperatures, hysteresis, thermochromism, photochromism as well as thermodynamic and kinetic properties, depend on the interplay between the ligand-field strength at the transition-metal ion and the interactions between the metal complex, the counterions, and solvate molecules as governed by crystal packing. In comparison with monomers, a little is known on cooperativity in small clusters or extended coordination polymers of Fe^{II}. Understanding the cooperativity between clusters and the synergy, if any, between intracluster magnetic exchange coupling and the SCO phenomenon has been the subject of investigation,[3] and continues to present other fundamental challenges.

Dinuclear iron(II) complexes of the type $\{[Fe(L)(NCX)_2]_2bpym\}$ (L: 2,2′-bipyrimidine, 2,2′-bithiazoline, 2,2′-dipyridylamine, X: S, Se) and $\{[Fe(phdia)(NCS)_2]_2(phdia)\}$ (phdia: 4,7-phenanthroline-5,6-diamine) provide a first step in the research line aimed at combining magnetic exchange and SCO phenomena in a molecule or polymeric network.[4] Extensive research has led to the conclusion that the plateau of the spin-transition curve, a special feature of this class of compounds, is constituted mainly of [HS−LS] pairs. This result confirmed that the spin conversion in these dinuclear entities proceeds through [HS-HS] ⇄ [HS−LS] ⇄ [LS−LS] pairs. The appearance of [HS−LS] species should be interpreted in terms of a synergy between intramolecular and intermolecular cooperative interactions (short- and long range) that energetically stabilises the mixed pairs, gives rise to the plateau region of a two-step transition curve and determines its width. Further, a form of synergy between spin-crossover and magnetic-coupling phenomena has been observed under the application of hydrostatic pressure or by light irradiation. Presently, the question is posed as to whether all dinuclear compounds will exhibit this two-step behaviour and/or synergy between electronic properties. In this respect, a very gradual SCO behaviour without a plateau has been observed in the $\{[Fe(dpa)(NCS)_2]_2bpym\}$ derivative,[5] the lack of such a plateau being ascribed to interdimer interactions. Murray[6] and Kaizaki[7] and their groups have reported new dinuclear iron(II) SCO systems based on pyrazolate bridges in which the conversion takes place through [HS−HS] ⇄ [LS−LS] pairs.

Here we report on the synthesis and characterisation by means of X-ray, magnetic and Mössbauer spectroscopic studies of a novel dinuclear SCO system $\{[Fe(CH_3bipy)(NCS)_2]_2bpym\}$ (**1**), where CH_3bipy = 6-methyl-2,2′-bipyridine.

The crystal structure determination on **1** was performed at 293 K. The structure of **1** consists of centrosymmetric

discrete dinuclear molecules, in which two iron(II) ions are bridged by a bpym ligand in a bis-bidentate fashion. A perspective view of the molecule with the labeling of the atoms is shown in Figure 1. The Fe···Fe intramolecular distance is 6.052(5) Å. Each iron atom is bound to six nitrogen atoms that belong to two NCS^- groups in a *cis*-position, one CH_3bipy ligand, which occupies the terminal positions in the iron surrounding, and one bridging bpym ligand. The Fe−N bond lengths involving NCS^- [2.060(16) and 2.148(10) Å] are much shorter than those involving the CH_3bipy and bpym ligands [from 2.144(8) to 2.222(9) Å,] (Table 1). The [FeN_6] chromophore is rather distorted with Fe−N bond lengths characteristic for an iron(II) ion in the HS state. Whereas the N−C−S groups are quasi-linear, the Fe−*N*−C(S) linkages are significantly bent [Fe−N3−C5 = 156.3(11)° and Fe−N4−C6 = 159.2(11)°]. There is no π−π stacking between dimers. The shortest intermolecular Fe···Fe separation is 8.250(4) Å ($i = x, 1 - y, z$).

Table 1. Selected bond lengths [Å] and angles [°] for **1**

Fe−N(1)	2.292(13)	N(1)−Fe−N(2)	69.6(4)
Fe−N(2)	2.272(9)	N(1)−Fe−N(3)	85.2(5)
Fe−N(3)	2.148(10)	N(3)−Fe−N(6)	164.9(4)
Fe−N(4)	2.060(16)	N(6)−Fe−N(5)	75.6(4)
Fe−N(5)	2.144(8)	N(5)−Fe−N(4)	105.3(5)
Fe−N(6)	2.222(9)	N(4)−Fe−N(2)	93.8(5)

The $\chi_M T$ vs. T curve for **1** at ambient pressure shows that the iron(II) centres of the dinuclear entities are antiferromagnetically coupled with a typical value for the magnetic coupling constant[3,4] $J = -4.2$ cm^{-1} and $g = 2.21$ [$\hat{H} = -J\hat{S}_a\hat{S}_b + g\beta(\hat{S}_a + \hat{S}_b)H$ (Figure 2)]. The maximum of the χ_M vs. T curve is centred at $T_c = 15$ K. Up to applied pressures of about 7 kbar, the magnetic properties of **1** remain practically unaltered. Further increase in the pressure up to 11 kbar induces a very incomplete spin transition around 100 K that involves 10% of the metal ions, the rest are antiferromagnetically coupled. Zero-field Mössbauer measurements of compound **1** have been carried out at 4.2 K (see a in Figure 3). At this temperature, the spectra consist of one doublet corresponding to the $S = 2$ high-spin state characterised by a quadrupole splitting of ΔE_Q(HS) = 2.91(3) mm s^{-1} and an isomer shift of δ(HS) = 0.87(1) mm s^{-1} (relative to α-Fe). The application of an external magnetic field of 50 kOe at 4.2 K causes only a broadening of the paramagnetic doublet lines of the HS species, which indicates that the HS species of **1** correspond to the [HS−HS] pairs[4] (see b in Figure 3). The effective magnetic field at the iron nuclei may be estimated by using the expression $H_{eff} \approx H_{ext} - [220 - 600(g - 2)] <S>$ (1). The effective field felt by the iron nuclei, H_{eff}, estimated from the spectrum was 14 kOe. To explain this value, one must consider the electronic levels of a dinuclear unit in the presence of antiferromagnetic coupling.[3−4] Admixture of upper levels of higher multiplicity with $S \geq 1$ to the singlet ground state $S = 0$ of the antiferromagnetically coupled pair caused by temperature and magnetic field splitting leads to a non-zero expectation value of $<S>$.

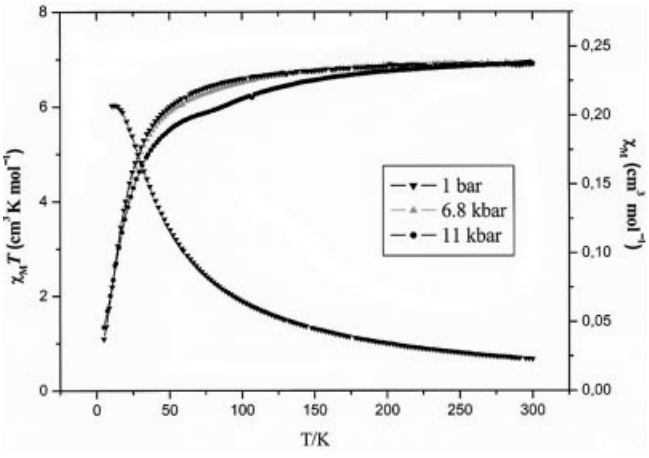

Figure 2. $\chi_M T$ and χ_M vs. T curves for {[Fe(CH_3bipy)$(NCS)_2]_2$-bpym} (**1**) at different pressures, 1 bar, 6.8 kbar, 11 kbar

The significantly higher pressures required to trigger the spin transition in **1** than the analogous dinuclear system {[Fe(bpym)$(NCS)_2]_2$bpym}[3,4] is not surprising despite the fact that the molecular structures of both compounds are similar. At ambient pressure, the complex {[Fe(bpym)-$(NCS)_2]_2$bpym} is paramagnetic in the temperature region 4−300 K and shows the intramolecular antiferromagnetic interaction. At $p = 9$ kbar, {[Fe(bpym)$(NCS)_2]_2$bpym} undergoes spin transition at $T_{1/2} \approx 150$ K involving 50% of iron atoms and ultimately causing the disappearance of antiferromagnetic coupling. The average Fe−N bond lengths are 2.188 Å and 2.180 Å for **1** and {[Fe(bpym)$(NCS)_2]_2$bpym}, respectively. Hence, the strength of the ligand field is expected to be weaker for **1** than for {[Fe(bpym)$(NCS)_2]_2$bpym}, which should be the

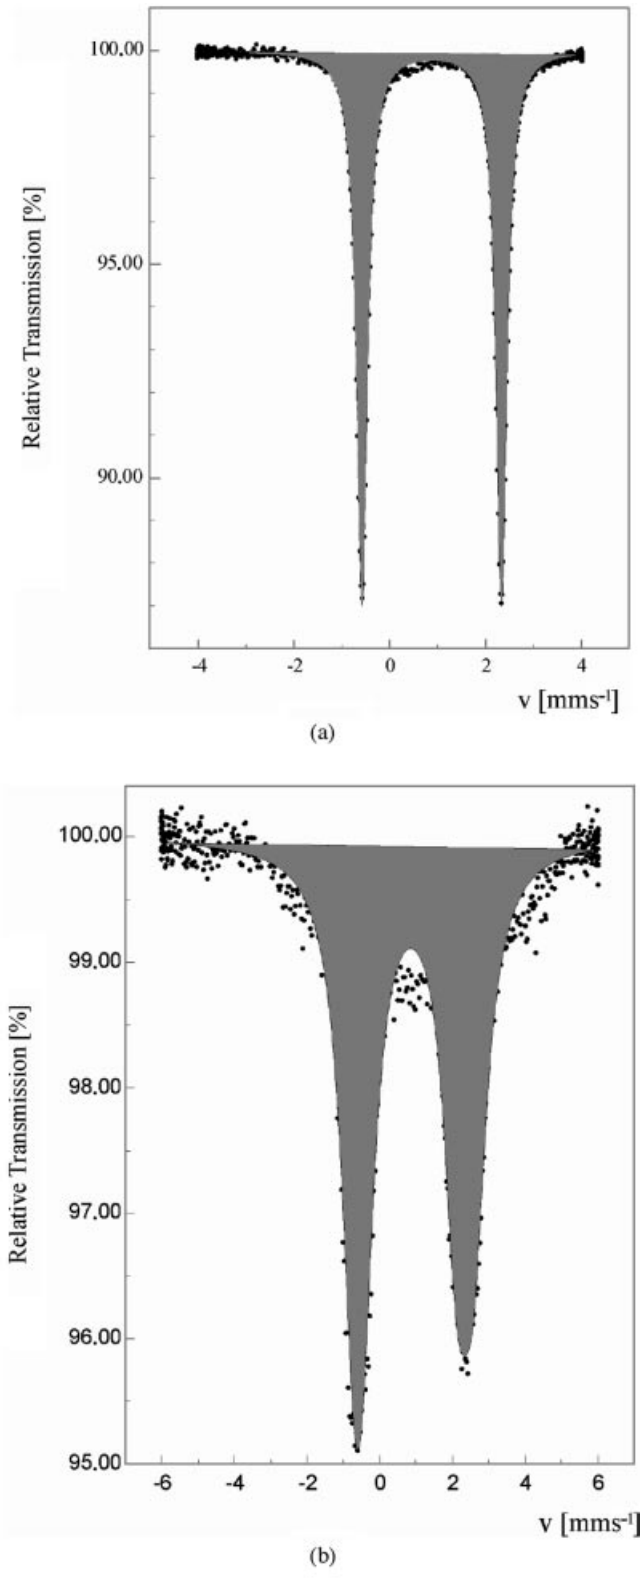

Figure 3. (a) Mössbauer spectra of {[Fe(CH_3bipy)($NCS)_2$]$_2$bpym} (**1**) at 4.2 K; (b) at 4.2 K and $H = 50$ kOe

reason for the difference in sensitivity to pressure-induced spin conversion.

Further dinuclear iron(II) examples of the present and related types are being sought.

Experimental Section

General Remarks: All reactions were carried out under Ar using standard Schlenk techniques. The ligand 6-methyl-2,2′-bipyridine (CH_3bipy) was synthesised according to a procedure described previously.[1] 2,2′-Bipyrimidine (Lancaster), $FeSO_4 \cdot 7H_2O$ (Panreac), and KNCS (Aldrich) were used as received.

{[Fe(CH_3bipy)($NCS)_2$]$_2$bpym} (1): To a solution of $FeSO_4 \cdot 7H_2O$ (0.25 mmol) in methanol (15 mL) was added a methanol solution (15 mL) of KNCS (0.5 mmol). The solution was stirred for 15 min, and the resulting precipitate (K_2SO_4) was filtered. The colourless solution containing Fe/NCS^- (1:2) was mixed with a solution of CH_3bipy (0.5 mmol) in methanol (25 mL), and the colour of the solution changed to orange. To this solution was added dropwise bpym (0.25 mmol) dissolved in methanol (15 mL). The final dark red solution was filtered and allowed to evaporate for a week, giving cubic black crystals of {[Fe(CH_3bipy)($NCS)_2$]$_2$bpym} (**1**) suitable for X-ray studies. Yield: 70%. $C_{34}H_{26}Fe_2N_{12}S_4$ (842.6): calcd. C 48.47, H 3.11, N 19.95; found C 48.16, H 3.15, N 19.18.

X-ray Crystallographic Study: Diffraction data for {[Fe(CH_3bipy)($NCS)_2$]$_2$bpym} was collected at room temperature with an Enraf−Nonius CAD-4 diffractometer by using graphite-monochromated Mo-K_α radiation with the ω-2θ scan method. The unit cell parameters were determined from least-squares refinement on the setting angles from 25 centered reflections in the range $12° < \theta < 20°$. No significant fluctuations were observed in the intensities of three standard reflections monitored periodically throughout data collections. The structure of {[Fe(CH_3bipy)($NCS)_2$]$_2$bpym} was solved by standard Patterson methods and refined by the full-matrix least-squares method on F^2. The computations were performed using SHELXS-86 and SHELXL-93.[8] All non-hydrogen atoms were refined anisotropically. Details are listed in Table 2. CCDC-239827 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) + 44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Magnetic Susceptibility Measurements under Hydrostatic Pressure: The variable-temperature magnetic susceptibility measurements were performed on small single crystals by using a Quantum Design MPMS2 SQUID susceptometer equipped with a 5.5 T magnet and operating at 1 T and 1.8−375 K, the PAR 151 Foner-type magnetometer, equipped with a cryostat operating in the temperature range 2−300 K. The hydrostatic pressure cell made of hardened beryllium bronze with silicon oil as the pressure-transmitting medium operates in the pressure range 1 bar $< p <$ 13 kbar Cylindrically shaped powder sample holders with dimensions of 1 mm in diameter and 5−7 mm in length were used. The pressure was measured by using the pressure dependence of the superconducting transition temperature a of built-in pressure sensor made of high purity tin.[9] Experimental data were corrected for diamagnetism using Pascal's constants.

Mössbauer Spectroscopy: ^{57}Fe Mössbauer spectra were recorded with a constant-acceleration conventional spectrometer and helium bath cryostat. A superconducting magnet was applied to create a magnetic field directed parallel to the wave vector of the γ-quanta. The sample and the Mössbauer source ^{57}Co/Rh were immersed in liquid helium. About 40 mg of microcrystalline powder were placed in a 16 mm diameter absorber holder made of polished transparent acryl. The Recoil 1.03a Mössbauer Analysis Software was used to fit the experimental spectra.

Spin Glass Behaviour in a 1D Mixed Molybdenum-Vanadium Heteropolyoxometalate-Bridged Coordination Polymer

Cai-Ming Liu,*[a] Jian-Lin Luo,[b] De-Qing Zhang,*[a] Nan-Lin Wang,[b] Zhao-Jia Chen,[b] and Dao-Ben Zhu*[a]

Keywords: Nickel / Hydrothermal synthesis / Polyoxometalate / Crystal structure / Magnetic properties

A 1D trimetallic coordination polymer containing mixed molybdenum-vanadium heteropolyoxometalate bridges, {[Ni(phen)$_2$(H$_2$O)]$_2$[Ni(phen)$_2$][V$^{IV}_8$Mo$^{VI}_6$Mo$^{V}_2$O$_{40}$(PO$_4$)]}{[Ni(phen)$_2$(H$_2$O)]$_2$[V$^{IV}_8$Mo$^{VI}_6$Mo$^{V}_2$O$_{40}$(PO$_4$)$_2$]}·5H$_2$O·2EtOH (**1**) (phen = 1,10-phenanthroline, EtOH = ethanol), has been synthesised hydrothermally. An X-ray crystallographic study revealed that **1** is composed of 1D zigzag chains of {[Ni(phen)$_2$(H$_2$O)]$_2$[Ni(phen)$_2$][V$^{IV}_8$Mo$^{VI}_6$Mo$^{V}_2$O$_{40}$(PO$_4$)]}$_n^{n+}$ cations, {[Ni(phen)$_2$(H$_2$O)]$_2$ [V$^{IV}_8$Mo$^{VI}_6$Mo$^{V}_2$O$_{40}$(PO$_4$)$_2$]}$^-$ anions and solvent molecules. Both the cation and the anion in **1** are mixed molybdenum-vanadium heteropolyoxometalates with covalently linked nickel complex fragments. Magnetic investigations of **1** indicate spin glass behaviour and several magnetic transitions occur at low temperatures (below 20 K). (© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

Heteropolyoxometalates with specific topological structural characteristics have a large range of potential applications in catalysis, nanotechnology, material science, medicine, biochemistry, magnetochemistry and other important areas.[1] One powerful strategy for the preparation of new heteropolyoxometalates with large clusters or high-dimensional extended solid frameworks has involved the hybrid reaction of a metal oxide and a traditional polymolybdate under hydrothermal conditions.[1a,2] On the other hand, use of the bridging capabilities of transitional metal complex fragments has recently been exploited to build more and more high-dimensional organic-inorganic hybrid oxide materials.[3−5] Therefore, connecting heteropolyoxometalate ions with transition metal complex fragments via covalent bonds forming heteropolyoxometalate coordination polymers is considerably appealing.[5] To date, many mixed molybdenum-vanadium polyoxometalate coordination polymers have been reported which include 1D chain-like complexes such as [Ni(en)$_2$]$_2$[Ni(en)$_2$Mo$^{VI}_6$V$^{VI}_{10}$O$_{40}$(V^{IV}O$_4$)]·4H$_2$O,[5f] 2D layer complexes such as [Co(en)$_2$][Co(bpy)$_2$]$_2$[PMo$^{VI}_5$Mo$^{V}_3$V$^{IV}_8$O$_{44}$]·4.5H$_2$O (en = ethylenediamine, bpy = 2,2′-bipyridine),[5a] [en]$_{0.5}$[Cu(en)$_2$]$_2$[Cu(en)$_2$Mo^{VI}Mo$^{V}_2$V$^{VI}_8$O$_{40}$(Mo^{IV}O$_4$)]·0.5H$_2$O[5f] and [Cu(en)$_2$(H$_2$O)]{PMo$^{VI}_8$V$^{IV}_6$O$_{42}$[Cu(en)$_2$][Cu$_{0.5}$(en)]$_3$}·5.5H$_2$O (en = ethylenediamine)[5e] and the 3D framework complex H$_3${V^{V}Mo$^{VI}_8$V$^{IV}_6$O$_{42}$[Cu(en)$_2$]$_4$}[MoO$_4$]$_2$·14H$_2$O (en = ethylenediamine).[5e] However, to the best of our knowledge, no heteropolyoxometalate coordination polymer exhibiting spin glass behaviour has been found although spin glass has become one of fundamental and general forms of magnetism[6] and many crystalline molecular materials have been reported to exhibit this important phenomenon.[7] In this paper, we report the hydrothermal synthesis, crystal structure and magnetic properties of a 1D coordination polymer with mixed molybdenum-vanadium heteropolyoxometalate bridges, namely {[Ni(phen)$_2$(H$_2$O)]$_2$[Ni(phen)$_2$][V$^{IV}_8$Mo$^{VI}_6$Mo$^{V}_2$O$_{40}$(PO$_4$)]}{[Ni(phen)$_2$(H$_2$O)]$_2$[V$^{IV}_8$Mo$^{VI}_6$Mo$^{V}_2$O$_{40}$(PO$_4$)$_2$]}·5H$_2$O·2EtOH (**1**) (phen = 1,10-phenanthroline, EtOH = ethanol). Both the cation and the anion are heteropolyoxometalates with covalently linked transitional metal complex fragments. Interestingly, this complex exhibits spin glass behaviour and several magnetic transitions at low temperature.

Results and Discussion

A single-crystal X-ray structure analysis revealed that complex **1** consists of 1D zigzag cationic {[Ni(phen)$_2$(H$_2$O)]$_2$[Ni(phen)$_2$][V$^{IV}_8$Mo$^{VI}_6$Mo$^{V}_2$O$_{40}$(PO$_4$)]}$_n^{n+}$ chains and {[Ni(phen)$_2$(H$_2$O)]$_2$[V$^{IV}_8$Mo$^{VI}_6$Mo$^{V}_2$O$_{40}$(PO$_4$)$_2$]}$^-$ anions as well as solvent water molecules and solvent ethanol molecules (Figure 1 and 2). There are mixed molybdenum-vanadium polyoxoanion clusters [V$^{IV}_8$Mo$^{VI}_6$Mo$^{V}_2$O$_{40}$(PO$_4$)]$^{5-}$ in both the anion and the cation. This heteropolyanion shows a tetra-capping Keggin structural

feature and is very similar to that in $[Ni(tea)_2]_3[PMo^{VI}_5Mo^{V}_3V^{IV}_8O_{44}]\cdot tea\cdot H_2O$ (tea = triethylenediamine),[2] $\{Co(tea)_2\}_2Na[PMo^{VI}_6Mo^{V}_2V^{IV}_8O_{44}]\cdot 8H_2O$,[2] $[Co(en)_2][Co(bpy)_2]_2[PMo^{VI}_5Mo^{V}_3V^{IV}_8O_{44}]\cdot 4.5H_2O$,[5a] $\{Mo^{VI}_6Mo^{V}_2V^{IV}_8O_{40}(PO_4)[Co(phen)_2(H_2O)]_2\}\text{-}[Co_2(phen)_2(OH)_2(H_2O)_4]_{1/2}$ [5b] and $\{Mo^{VI}_5Mo^{V}_3V^{IV}_8O_{40}(PO_4)[Co(phen)(en)(H_2O)]_2\}[Co(phen)_3]\cdot 1.5H_2O$ (en = ethylenediamine).[5b] The $[V^{IV}_8Mo^{VI}_6Mo^{V}_2O_{40}(PO_4)]^{5-}$ unit is constructed from eight VO_5 square pyramids by sharing square edges thus forming a central belt and two Mo_4 rings are bonded above and below this V_8 belt. A disordered PO_4^{3-} anion is located in the centre as a guest.

Two terminal nickel(II) complex fragments $[Ni(phen)_2(H_2O)]^{2+}$ link to two terminal V-O groups of the heteropolyoxoanion cluster $[V^{IV}_8Mo^{VI}_6Mo^{V}_2O_{40}(PO_4)]^{5-}$ from the opposite sides to generate the anion $\{[Ni(phen)_2(H_2O)]_2[V^{IV}_8Mo^{VI}_6Mo^{V}_2O_{40}(PO_4)_2]\}^{-}$ which is quite similar to the trimetallic nanocluster anion $\{Mo^{VI}_6Mo^{V}_2V^{IV}_8O_{40}(PO_4)[Co(phen)_2(H_2O)]_2\}^{-}$ in $\{Mo^{VI}_6Mo^{V}_2V^{IV}_8O_{40}(PO_4)[Co(phen)_2(H_2O)]_2\}[Co_2(phen)_2(OH)_2(H_2O)_4]_{1/2}$.[5b]

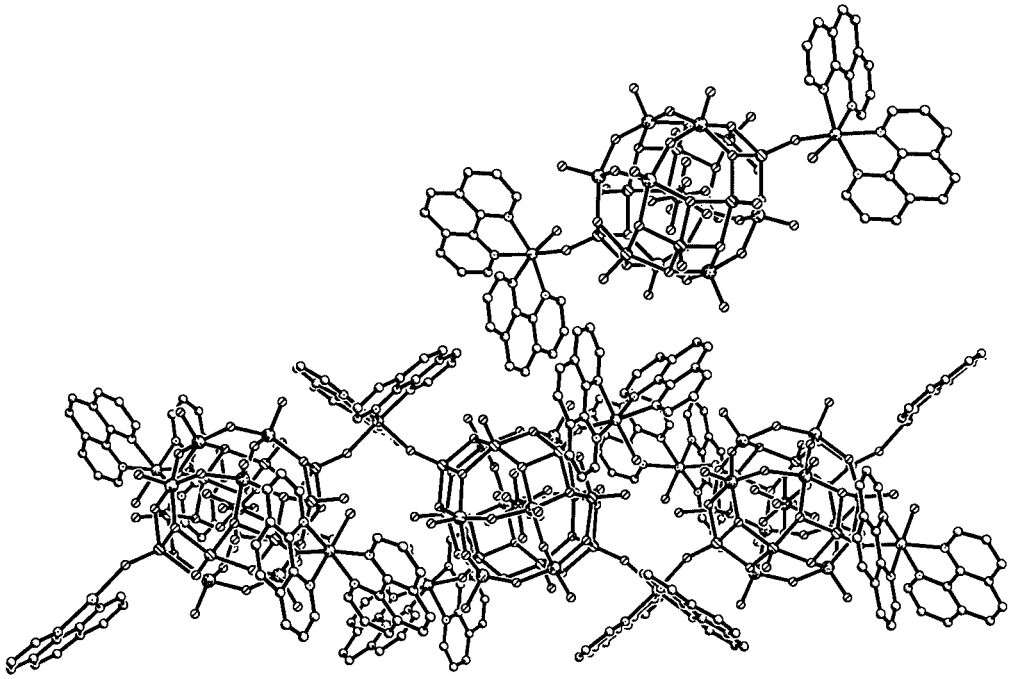

Figure 2. Molecular structure of complex **1** showing the zigzag cation chain (below) and an isolated anion (above); all solvent water molecules and ethanol molecules as well as H atoms are omitted for clarity

The Ni···Ni separation distance of 15.131Å is a little longer than the corresponding Co···Co separation distance of 14.843Å in $\{Mo^{VI}_6Mo^{V}_2V^{IV}_8O_{40}(PO_4)[Co(phen)_2(H_2O)]_2\}$-$[Co_2(phen)_2(OH)_2(H_2O)_4]_{1/2}$.[5b] The cation $\{Ni(phen)_2$-$(H_2O)\}_2[Ni(phen)_2][V^{IV}_8Mo^{VI}_6Mo^{V}_2O_{40}(PO_4)]\}^+$ also contains $\{[Ni(phen)_2(H_2O)]_2[V^{IV}_8Mo^{VI}_6Mo^{V}_2O_{40}(PO_4)_2]\}^-$ components but they are further connected to each other through *cis*-nickel complex fragments, $[Ni(phen)_2]^{2+}$, acting as bridges. Both $[Ni(phen)_2(H_2O)]^{2+}$ and $[Ni(phen)_2]^{2+}$ fragments connect the terminal V−O groups in the cation $\{Ni(phen)_2(H_2O)\}_2[Ni(phen)_2][V^{IV}_8Mo^{VI}_6Mo^{V}_2O_{40}(PO_4)]\}^+$. The Ni···Ni separation distance between two opposite $[Ni(phen)_2(H_2O)]^{2+}$ fragments (15.272 Å) is a little longer than that between two opposite $[Ni(phen)_2]^{2+}$ fragments (15.077 Å). These zigzag cationic chains are arranged parallel to the *c*-axis to form a layer along the *bc* plane with an interchain distance of about 15.7Å, whereas the isolated anions are located between cation layers to form the anion layer. It is noteworthy that although polyoxometalates with covalently linked transitional metal complex fragments have been extensively observed in many organic-inorganic hybrid oxide materials,[1e,3][5b][5c,8] cases of polyoxometalates with covalently linked transitional metal complex fragments acting as both the cations and the anions are quite rare. Complex **1** is the first coordination polymer of this type. The other reported complex with heteropolyoxocations and heteropolyoxoanions coexisting is $[PMo^{VI}_6Mo^{V}_2V^{IV}_8O_{44}$-$\{Co(2,2'\text{-bipy})_2(H_2O)\}_4][PMo^{VI}_4Mo^{V}_4V^{IV}_8O_{44}\{Co(2,2'$-$bipy)_2(H2O)\}_2]\cdot 4H_2O$ (2,2′-bipy = 2,2′-bipyridine, phen = 1,10-phenanthroline)[5d] which is a zero-dimensional polyoxometalate.

As shown in Table 1, the Mo−O and V−O bond lengths are $Mo-O_t$ 1.654(6)−1.676(6)Å, $Mo-O_b$ 1.854(7)−2.004(7) Å, $V-O_t$ 1.600(6)−1.640(6) Å and $V-O_b$ 1.915(6)−2.019(7) Å for the anion $\{[Ni(phen)_2(H_2O)]_2$-$[V^{IV}_8Mo^{VI}_6Mo^{V}_2O_{40}(PO_4)_2]\}^-$ and $Mo-O_t$ 1.658(6)−1.672(6) Å, $Mo-O_b$ 1.859(7)−1.994(6) Å, $V-O_t$ 1.591(6)−1.643(5) Å and $V-O_b$ 1.923(6)−2.007(6) Å for the cation $\{Ni(phen)_2(H_2O)\}_2[Ni(phen)_2][V^{IV}_8Mo^{VI}_6Mo^{V}_2$-$O_{40}(PO_4)]\}^+$. The assignments of the oxidation states for the Mo atoms and the V atoms are consistent with the electric charge and can be confirmed by bond valence sum calculations[9] which give values of 5.840 for Mo1, 5.851 for Mo2, 5.673 for Mo3, 5.815 for Mo4, 4.040 for V1, 3.910 for V2, 4.098 for V3, 3.909 for V4 (the cation part), and 5.871 for Mo5, 5.723 for Mo6, 5.804 for Mo7, 5.780 for Mo8, 3.875 for V5, 4.063 for V6, 3.906 for V7 and 4.065 for V8 (the anion part), respectively. The average values calculated for the oxidation state of V are 3.988 for the cation $\{Ni(phen)_2(H_2O)\}_2[Ni(phen)_2][V^{IV}_8Mo^{VI}_6Mo^{V}_2O_{40}(PO_4)]\}^+$ and 3.977 for the anion $\{[Ni(phen)_2(H_2O)]_2[V^{IV}_8$-$Mo^{VI}_6Mo^{V}_2O_{40}(PO_4)_2]\}^-$ (expected value for V^{IV}_8 is 4.000). Both the average values calculated for the oxidation state of Mo in the cation $\{Ni(phen)_2(H_2O)\}_2[Ni(phen)_2][V^{IV}_8$-$Mo^{VI}_6Mo^{V}_2O_{40}(PO_4)]\}^+$ and in the anion $\{[Ni(phen)_2(H_2O)]_2[V^{IV}_8Mo^{VI}_6Mo^{V}_2O_{40}(PO_4)_2]\}^-$ are 5.795 (expected value for $Mo^{VI}_6Mo^{V}_2$ is 5.750) and the calculated result is in good agreement with the formula of **1**.

The 2−300 K magnetic susceptibility, χ, of a polycrystalline sample of **1** could be fitted to the Curie−Weiss law above 70 K with C = 9.77 $cm^{-3}\cdot mol^{-1}\cdot K$ and θ = −36.49 K, indicating antiferromagnetic interactions of

[a] Symmetry transformations used to generate equivalent atoms: $-x, y, -z + 3/2$.

nearest-neighbour spin units. As shown in Figure 3, χT has a value of 8.90 emu·K·mol^{-1} at room temperature which is smaller than that expected for the total value of 16 uncoupled $S = 1/2$ spins of the V^{4+} atoms, 4 uncoupled $S = 1/2$ spins from the Mo^{5+} atoms and 5 uncoupled $S = 1$ spins from the Ni^{2+} atoms (≈ 13.83 emu·K·mol^{-1} assuming $g = 2.0$ for V^{4+} and Mo^{5+} and $g = 2.25$ for Ni^{2+}). This is due to spin pairing[5,10] which is favoured by electron delocalisation in the cluster $[V^{IV}{}_8Mo^{VI}{}_6Mo^{V}{}_2O_{40}(PO_4)]^{5-}$. The value of χT decreases upon cooling but a sharp increase in $\chi T(T)$ occurs near 50 K and a maximum of 27.02 emu K·mol^{-1} is reached at 16 K. Below 16 K, $\chi T(T)$ decreases abruptly down to 2 K because of saturation effects and/or increasing antiferromagnetic interactions.

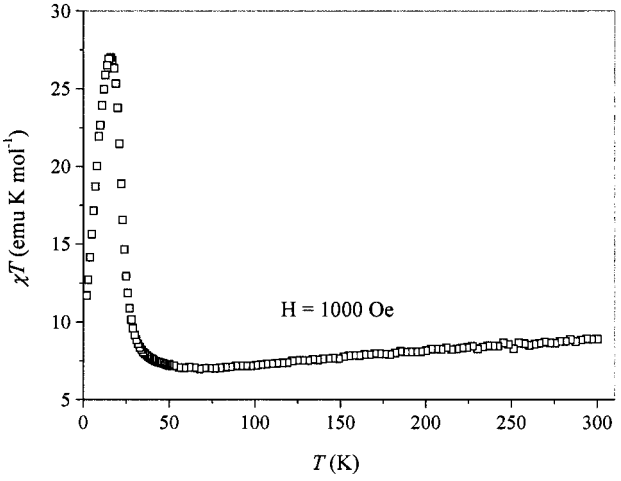

Figure 3. χT vs. T plot of **1** at 1000 Oe

The ac susceptibility measurements indicated that both real χ' and imaginary χ'' components of the susceptibility show rather complicated behaviour (Figure 4). Firstly, there are two peaks in the $\chi'(T)$ and $\chi''(T)$ curves: both the cusped one and the rounded one are frequency dependent while the latter is more sensitive to frequency, suggesting unusual spin glass behaviour. Secondly, below 8 K, $\chi'(T)$ increases gradually, possibly indicating the existence of another phase transition. This peculiar ac susceptibility behaviour may occur for a *ferroglass* system (also called a re-

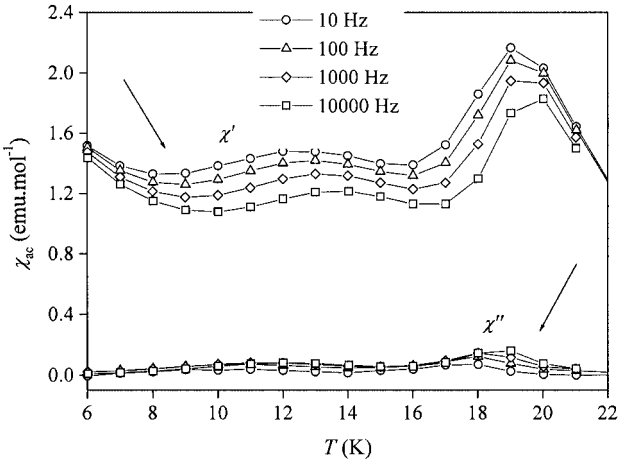

Figure 4. Real(χ') and imaginary(χ'') parts of the *ac* susceptibility at a bias DC field of 10 Oe for **1**

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

entrant spin glass system) because it generally undergoes multiple magnetic phase transitions.[11] Therefore, the cusped peak could be assigned to a spin glass transition while the rounded one probably corresponds to a ferroglass transition.[11b] The spin-freezing temperature T_f (= 19 K) may be defined approximately by the sharp cusp in χ' at 10 Hz and the spin-freezing at a lower temperature T_{fg} may be estimated by the rounded peak in χ' at 10 Hz (T_{fg} = 12 K). The spin-glass state was also confirmed by the divergence of the zero-field-cooled (ZFC) and field-cooled (FC) $\chi(T)$ data of **1** below 20 K, indicating the occurrence of irreversibility of magnetisation. Furthermore, hysteresis can be observed with coercive fields (*Hc*) of 191 Oe at 20 K (Figure 5), 386 Oe at 12.5 K and 660 Oe at 5 K, respectively. However, the field dependent magnetisation of **1** measured at 5 K shows that at the highest field measured (50 kOe), a low magnetisation value of 7.4 $N\beta$ is achieved and saturation does not occur, this being consistent with weak ferromagnetism owing to spin glass.

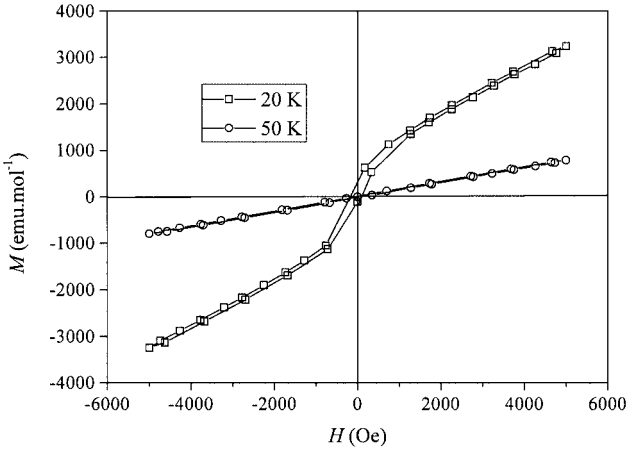

Figure 5. Hysteresis loops at 20 K and 50 K

In summary, the successful synthesis of $Ni_5[V^{IV}{}_8Mo^{VI}{}_6Mo^{V}{}_2O_{40}(PO_4)]_2(phen)_{10}(H_2O)_9(EtOH)_2$ **1** indicates that a new type of organic-inorganic hybrid oxide material in which polyoxometalate clusters act as both the cation and the anion can be prepared hydrothermally. The anion in **1** is a trimetallic nanocluster $\{Mo^{VI}{}_6Mo^{V}{}_2V^{IV}{}_8O_{40}(PO_4)[Ni(phen)_2(H_2O)]_2\}^-$ and the cation $\{Ni(phen)_2(H_2O)\}_2[Ni(phen)_2][V^{IV}{}_8Mo^{VI}{}_6Mo^{V}{}_2O_{40}(PO_4)]\}^+$ also contains trimetallic units $\{Mo^{VI}{}_6Mo^{V}{}_2V^{IV}{}_8O_{40}(PO_4)[Ni(phen)_2(H_2O)]_2\}^-$ which are further connected to each other through *cis*-nickel complex fragments, $Ni(phen)_2{}^{2+}$, to form a zigzag chain. Both the cation and the anion in **1** are high-spin systems which would generate randomness either in the positions of the spins or the signs of the neighbouring couplings in a field and spin glass behaviour is then expected.

Experimental Section

Materials and Methods: All reagents were obtained from commercial sources and used without further purification. The elemental analyses were performed with a Heraeus Chn-Rapid elemental analyser. The inductively coupled plasma (ICP) analysis was conducted with a Perkin−Elmer Optima 3300DV spectrometer. The infrared spectra were recorded with a Pekin-Elmer 2000 spectrophotometer with pressed KBr pellets. X-ray photoelectron spectroscopy data were obtained with an ESCALab220i-XL electron spectrometer from VG Scientific using 300-W Al-K_α radiation. The base pressure was around 3×10^{-9} mbar. The binding energies were referenced to the C 1s line at 284.6 eV from adventitious carbon. The magnetic susceptibility measurements for **1** were carried out on a polycrystalline sample (202.84 mg) using a MagLab System 2000 magnetometer in a field up to 5 T. Diamagnetic corrections were estimated from Pascal's constants.[12]

Synthesis of 1: A mixture of NH_4VO_3 (3 mmol), $H_3[P(Mo_3O_{10})_4]\cdot xH_2O$ (0.5 mmol), $Ni(NO_3)_2$ (1 mmol), 1,10-phenanthroline (1 mmol), *N*,*N*′-diethylethylenediamine (3 mmol), ethanol (0.2 mL) and H_2O (18 mL) was stirred for 20 min and then transferred into a 30 mL Teflon-lined steel autoclave. The mixture was heated at 170 °C for 6 days and black block crystals of **1** were separated from the blue supernatant solution in ca. 40% yield (463 mg) based on V. $C_{124}H_{110}Mo_{16}N_{20}Ni_5O_{99}P_2V_{16}$ (6169.89): calcd. C 24.14, H 4.54, N 1.80, Mo 24.9, Ni 4.8, V 13.2; found C 24.06, H 4.60, N 1.75, Mo 24.8, Ni 4.7, V 13.2. IR (KBr): $\tilde{\nu}$ = 1055(w) [$\nu_{(P-O)}$], 951(vs) [$\nu_{(M=O)}$], 792(s) cm^{-1} [$\nu_{(M-O-M)}$] (M = V or Mo). XPS: calcd. C 1s 284.75, O 1s 530.10, P 2p 132.90, Ni $2p_3$ 855.90, V $2p_3$ 516.10, Mo 3d 231.80 eV.

X-ray Crystal Structure Determination: A black single crystal of **1** with dimensions 0.37 × 0.27 × 0.17 mm was selected and mounted on a Rigaku RAXIS RAPID IP imaging plate system with Mo-K_α radiation (λ = 0.71073Å) at 300(2) K in the range $1.38° < \theta < 27.48°$. An empirical absorption correction from Ψ scans was applied. A total of 28115 reflections were collected ($-64 \le h \le 64$, $-20 \le k \le 20$, $-33 \le l \le 33$) of which 18729 were unique (R_{int} = 0.0441) and 15227 with $I > 2\sigma(I)$. The structure was solved by the Patterson method and refined using full-matrix least-squares techniques based on F^2 using the SHELXL 97 program. All nonhydrogen atoms were refined anisotropically and all hydrogen atoms but those in water molecules were placed as riding atoms.

Crystal Data For 1: $C_{124}H_{110}Mo_{16}N_{20}Ni_5O_{99}P_2V_{16}$, monoclinic, space group *C*l*2c*, *Mr* = 6169.89, *a* = 49.658(10), *b* = 15.675(3), *c* = 25.916(5) Å, β = 115.39(3)°, *V* = 18225(6) Å^3, *Z* = 4, $D_{calcd.}$ = 2.242 g·cm^{-3}, *T* = 293(2) K, μ = 2.457 mm^{-1}, R_1 = 0.0694, wR_2 = 0.1855 for 15227 observed reflections [$I > 2\sigma(I)$], GOF = 1.087.

CCDC-213185 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

One-Pot Synthesis of Pyridyltellurium Derivatives from a Reaction with Isopropylmagnesium Chloride and X-ray Crystal Structures of Various Pyridyl Ditellurides

Kuldip K. Bhasin,*[a] Veena Arora,[a] Thomas M. Klapötke,[b] and Margaret-Jane Crawford[b]

Dedicated to the memory of Prof. R. C. Paul (1919−2002)

Keywords: Grignard reaction / Pyridyl telluride / Tellurium / Transmetallation

A one-pot synthesis of various symmetrical and unsymmetrical 2-pyridyl-, 2-bromo-5-pyridyl-, and 2,5-dibromo-3-pyridyltellurium compounds has been carried out, at room temperature, by selective single bromine-magnesium exchange of 2-bromo-, 2,5-dibromo- and 2,3,5-tribromopyridine, respectively, with isopropylmagnesium chloride. This exchange reaction gives the corresponding pyridylmagnesium chlorides, which, upon insertion of elemental tellurium (activated), give the pyridyltelluromagnesium chlorides, and, subsequently, the corresponding dipyridyl ditellurides upon aerial oxidation. The pyridyltelluromagnesium chlorides give unsymmetrical pyridyltellurium derivatives in good yield upon treatment with alkyl halides. The X-ray crystal structures of bis(2-pyridyl) ditelluride, bis(2,5-dibromo-6-methyl-3-pyridyl) ditelluride and bis(2,5-dibromo-3-pyridyl) ditelluride are discussed.

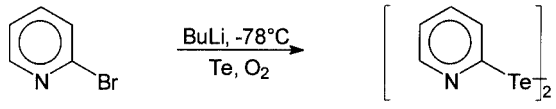
Introduction

Organic synthesis using tellurium-based methodologies has recently become increasingly important.[1,2] Compared to alkyl- and aryltellurium compounds,[3,4] the use of pyridyltellurium derivatives in organic synthesis has been relatively less studied. This may primarily be due to the lack of a convenient and efficient synthesis of these compounds. Most recently developed methods for the syntheses of dipyridyl ditellurides involve either deprotonation of BF_3-complexed pyridine[5] or bromine-lithium exchange[6] of 2-bromopyridine with BuLi at −78 °C followed by tellurium insertion and subsequent aerial oxidation. The low temperature invariably required in these preparations restricts its utility in large-scale preparations (Scheme 1).



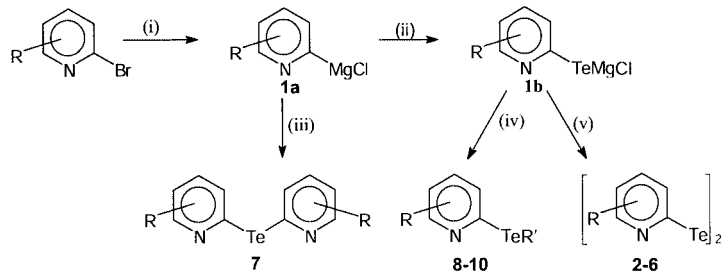
Scheme 1. Preparation of dipyridyl ditellurides at low temperature

[a] Department of Chemistry and Centre of Advanced Studies in Chemistry, Panjab University, Chandigarh-160014, India
[b] Department of Chemistry, University of Munich, Butenandtstrasse 5−13 (D), 81377 Munich, Germany

Owing to the instability of the lithiated pyridine the reaction has to be carried out at low temperature in order to avoid its decomposition. The corresponding pyridylmagnesium halides are comparatively stable even at higher temperatures (>25 °C). However, pyridylmagnesium halides are extremely difficult to generate directly from the corresponding halides and magnesium.[7−10] Meunier et al.[11] have reported a magnesium-halogen exchange reaction that generates pyridylmagnesium halides, although the successful quenching of pyridylmagnesium halides with electrophiles was achieved only recently.[12−14] In continuation of our ongoing project on the chemistry of pyridyltellurium compounds,[15−18] we decided to examine the reactivity of pyridylmagnesium halides for the synthesis of pyridyltellurium derivatives. Colonna et al. have also reported the synthesis of dipyridyl ditelluride in very low yield by employing magnesium-halogen exchange of 2-bromopyridine with ethylmagnesium bromide, although the results were later found to be non-reproducible.[19]

Result and Discussion

We found that elemental tellurium adds smoothly to 2-pyridylmagnesium chloride (**1a**), generated in situ by the bromine-magnesium exchange reaction between 2-bromopyridine and *i*PrMgCl in THF, at room temperature, to afford a species chemically equivalent to 2-pyridyltelluromag-



R = H, CH_3 and R' = CH_3, allyl, i-C_3H_7

Scheme 2. Reagents and conditions: (i) *i*PrMgCl (1.2 equiv.), THF, room temp.; (ii) Te, 15 min; (iii) R-Py_2Te_2; (iv) R′X (X = Br, I), (v) H_2O, O_2

nesium chloride (**1b**). Its aerial oxidation gave dipyridyl ditelluride in moderate to excellent yields. Reaction of **1b** with a number of electrophiles gives unsymmetrical 2-alkyltelluropyridines in good yields (Scheme 2).

This protocol was extended to the selective synthesis of various symmetrical 3,3′-dipyridyl and 5,5′-dipyridyl ditellurides. We found that when *i*PrMgCl reacts with 2,5-dibromopyridine, a single bromine-magnesium exchange takes place at C-5 of the pyridine ring, which is attributed to the fact that electrophilic attack at C-5 is more favorable than atC-2. The bromine-magnesium exchange with 2,3,5-tribromopyridine occurs at C-3 due to the *ortho* activating effect of the bromine present at C-2. Further bromine-magnesium exchange was not possible even after the addition of a twofold excess of *i*PrMgCl, as shown in Scheme 3. The present methodology was also successfully extended to a variety of methyl-substituted 2-bromopyridines. The scope and efficiencies are summarized in the Exp. Sect.

As a part of our ongoing study, we also compared the efficiency of the reaction by employing different Grignard reagents, such as ethylmagnesium bromide, *n*-propylmagnesium bromide, isopropylmagnesium chloride and butylmagnesium chloride. The results are given for the formation of bis(2-pyridyl) ditelluride in Table 1. These results show that a more sterically hindered Grignard reagent gives a better yield. This may be attributed to the fact that a more hindered Grignard reagent imparts stability to the pyridylmagnesium halide, thereby increasing the yield.

Table 1. Influence of the different Grignard reagents on the efficiency of the reaction

Grignard reagent	Compound	Solvent	Yield (%)
EtMgBr	Bis(2-pyridyl) ditelluride	THF	5
*i*PrMgCl	Bis(2-pyridyl) ditelluride	THF	80
*n*BuMgCl	Bis(2-pyridyl) ditelluride	THF	70
*n*PrMgBr	Bis(2-pyridyl) ditelluride	THF	27

It is important to note that the use of an equimolar amount of bromopyridine and *i*PrMgCl resulted in a poor yield; however, a slight excess of *i*PrMgCl increased the yield considerably. We must emphasise that the conditions throughout the reaction have to be extremely dry as even traces of moisture can hinder the insertion of tellurium into the species **1a**.

Among the various applications of organotellurium compounds, transmetallation with organolithium or organocuprate reagents[20] is considered to be synthetically important. As a representative example, the transmetallation reaction of isopropyltelluropyridine with *i*PrMgCl was also carried out for C−C bond formation. Subsequent quenching with benzaldehyde in THF at room temperature gave phenyl(2-pyridyl)methanol in 65% yield, indicating a clean tellurium-magnesium exchange as shown in Scheme 4. This exchange is operationally simple and represents a consider-

able improvement over the reported method[21] in terms of the reaction conditions, ease and efficiency of the reaction on a molar scale.

Table 2. Chemical-shift values (δ) of various symmetrical pyridyltellurium derivatives[a]

Compound	^{1}H (CH_3)	^{13}C (CH_3)	^{125}Te
Py_2Te_2	–	–	439
$(3\text{-}CH_3Py)_2Te_2$	2.449	24.679	473
$(4\text{-}CH_3Py)_2Te_2$	2.224	20.741	422
$(5\text{-}CH_3Py)_2Te_2$	2.286	17.807	436
$(3\text{-}CH_3\text{-}5\text{-}Br\text{-}Py)_2Te_2$	2.432	24.484	485
$(5\text{-}Br\text{-}Py)_2Te_2$	–	–	440
$(2,5\text{-}Br_2\text{-}Py)_2Te_2$	–	–	414
$(6\text{-}CH_3\text{-}2,5\text{-}Br_2\text{-}Py)_2Te_2$	2.609	23.881	407

[a] ^{125}Te chemical shift values could not be determined for unsymmetrical pyridyltellurium derivatives due their instability, particularly in solution.

^{125}Te NMR chemical shifts are listed in Table 2 and are found to be sensitive to the nature of the substituents present on the pyridine ring. The chemical shift for $(Br_2PyTe)_2$ is found at the most shielded position (δ = 407 ppm) and that for $(3\text{-}CH_3\text{-}5\text{-}BrPyTe)_2$ is found at the most deshielded position (δ = 485 ppm). For compounds **3** and **4**, in which a methyl group is substituted on the pyridine ring at the *meta* and *para* positions to the tellurium atom, respectively, the observed signals at δ = 422 and 436 ppm, respectively, indicate that the ^{125}Te resonance is influenced by polar effects due to shielding by an electron-donating group[22] i.e. the methyl group. Interestingly, when the methyl group is present *ortho* to tellurium on the ring, deshielding of the ^{125}Te resonance is observed (signals at δ = 473 and 485 ppm for compounds **2** and **7**, respectively). Conformational constraints and through-space interactions between the methyl group and tellurium are suggested as possible reasons for this observation. It is also noted that the ^{125}Te resonances for **8** and **9** are at δ = 407 and 414 ppm, respectively, which is attributed to intramolecular through-space interactions between the bromine and tellurium atoms. These interactions, being intramolecular, are also likely to be found in solution ppm. ^{125}Te NMR spectra of alkylpyridyltellurium compounds could not be recorded, as these compounds are exceedingly unstable in solution.

Solid-State Structures

Molecular Geometry and Crystal Structure of Bis(2-pyridyl) Ditelluride (1)

A single crystal of **1** was obtained by slow evaporation of a solution of **1** in diethyl ether and hexane. The molecular structure of **1** with the atom numbering scheme is given in Figure 1. Selected bond angles and bond lengths are given in Table 3. The molecule crystallizes in the triclinic $P\bar{1}$ space group with unit-cell dimensions a = 6.2870(4) Å, b = 8.4928(7) Å, c = 11.7370(12) Å and α = 109.101°, β = 99.717°, γ = 89.829(6)°. The molecular geometry of the pyridine rings is as expected in terms of bond angles and bond lengths. The two pyridine rings have an average C–C bond length of 1.37 Å and C–C–C bond angle of 119° (slightly distorted). The Te–Te bond length is significantly shorter (2.6759 Å) than the single covalent Te–Te bond length (2.74 Å) on the Pauling scale.[23] The Te(1)–C(1) [2.136(7) Å] and Te(2)–C(6) [2.144(6) Å] distances are also slightly longer than the some of the Pauling single-bond covalent radii for Te–C(sp^2) single bonds (2.11 Å), but are similar to the values found in bis(2-naphthyl) ditelluride[24] [2.135(6), 2.127(5) Å]. The C–E–E–C torsion angles are similar: 87.1° for E = S,[25] 84.3(2)° for E = Se[26] and 86.3(2)° for E = Te.

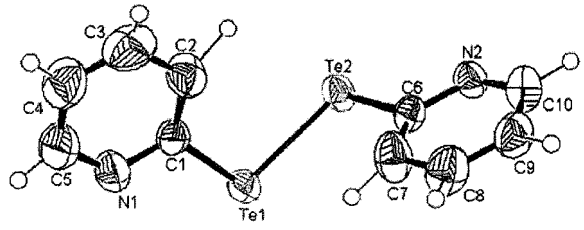

Figure 1. Perspective view of bis(2-pyridyl) ditelluride

Molecular Geometry and Crystal Structure of Bis(2,5-dibromo-3-pyridyl) Ditelluride (8)

Needle-shaped copper-colored crystals of compound **8** were obtained by slow evaporation of a solution in dichloromethane and hexane. The molecular structure of **8** with atom numbering scheme is given in Figure 2 (a). Selected bond angles and bond lengths are given in Table 4. The molecule crystallizes in the monoclinic space group $C2/c$ with cell dimensions a = 12.5073(15) Å, b = 9.4521(11) Å, c = 14.1713(13) Å and α = 90.00°, β = 111.707°, γ = 90.00°. The Te(1)–Te(2) bond length of this ditelluride [2.6830(15) Å] is significantly shorter than the sum of the Pauling single-bond covalent radii but is quite similar to the value found for compound **1**. The Te(1)–C(1) [2.127(13) Å] distance is also quite similar to the single C–Te bond in compound **1**. The Te(1)–N(1) distance (3.421 Å) is much higher than the sum of the covalent radii but is within the van der Waal distance of 3.61 Å[27] and therefore can be

considered as a weak interaction. The Te(1)−Br(1) distance (3.82 Å) is shorter than the sum of the van der Waal radii (4.06 Å). The Br(1)···Br(1) contacts (3.61 Å) are shorter than the Br(1)···Br(2) and Br(2)···Br(2) short contacts (3.948 Å and 3.960 Å, respectively). These observations clearly indicate that the molecules are bridged together by intermolecular secondary interactions. The crystal packing depicting these secondary interactions is shown in Figure 2 (b) and the distances are given in Table 5.

Table 5. Secondary interactions in bis(2,5-dibromo-3-pyridyl) ditelluride

Atoms	Interatomic distances	Symmetry transformations

structure of **9** with atom numbering scheme is given in Figure 3a. Selected bond angles and bond lengths are given in Table 6. The molecule crystallizes in the monoclinic space group *C*2/*c* with cell dimensions a = 13.7342(15) Å, b = 12.1460(6) Å, c = 11.8950(10) Å and α = 90.00°, β = 116.663(8)°, γ = 90.66(8)°. The Te(1)−Te(2) bond length of this ditelluride [2.6847(11) Å] is only slightly longer than in molecule **8**, and the C(1)−Te(1) distance [2.130(8) Å] is also slightly longer than in **8**. The Te(1)−Br(1) distance [3.868 Å] is shorter than the sum of the van der Waal radii (4.06 Å) and therefore can be considered as a weak interaction. The various secondary interactions observed in the molecule are shown in Figure 3b and listed in Table 7.

Table 7. Secondary interactions in bis(2,5-dibromo-6-methyl-3-pyridyl) ditelluride

Atoms	Interatomic distances	Symmetry transformations
Te1···Br1	3.868	$x, -y, 0.5 + z$
Br1···Br2	3.937	$0.5 + x, 0.5 + y, z$
Br1···Br2	4.039	$x, -y, z - 0.5$

Conclusion

We have presented a mild and efficient protocol for hitherto difficult to synthesize pyridyltellurium compounds in moderate to excellent yields using readily available reagents, at room temperature, and studied their application in transmetallation reactions.

Experimental Section

All experiments were carried out under a dry, oxygen-free nitrogen atmosphere. All the reagents and solvents were purified and dried by standard techniques and deoxygenated by bubbling oxygen-free dry nitrogen gas through them prior to use. Infrared spectra were recorded between KBr pellets on a Perkin-Elmer Model 1430 ratio recording spectrometer. ^{1}H and ^{13}C NMR spectra were recorded in $CDCl_3$ using TMS as an internal standard — ^{125}Te NMR spectra are referenced to dimethyl telluride — on a Jeol 300 MHz spectrometer. The mass spectra were obtained on a VG 705 11 250J Mass spectrometer. Carbon, hydrogen and nitrogen were estimated microanalytically on a Perkin- Elmer 2400 CHN elemental analyzer. Bromopyridines were prepared from the corresponding 2-aminopyridines by literature methods.[28,29]

General Method for the Preparation of Symmetrical Dipyridyl Ditellurides: Bromopyridine (20 mmol) was added dropwise to a vigorously stirred mixture of isopropylmagnesium chloride (22 mmol) in THF. After stirring for 2 h at room temperature the mixture was cooled in an ice bath and elemental tellurium (20 mmol) was added. After all the tellurium had dissolved, the stirring was stopped and the reaction was diluted with acidified water. The mixture was then extracted with diethyl ether (4 × 100 mL) and the organic layer was dried over anhydrous sodium sulfate. The solvent was removed on a rotary evaporator and the residue was purified by silica gel column chromatography with hexane/ethyl acetate (5:1) as eluent.

Bis(2-pyridyl) Ditelluride{[(C_5H_4N)Te]$_2$} (1): Yield: 2.8 g (70%). M.p. 48−50 °C. ^{1}H NMR (300 MHz, $CDCl_3$, 25 °C): δ = 6.98 (dt, $^4J_{H,H}$ = 2.0, $^3J_{H,H}$ = 8.0 Hz, 2 H, *m* to N), 7.35 (dt, $^4J_{H,H}$ = 2.0, $^3J_{H,H}$ = 8.0 Hz, 2 H, *p* to N), 7.94 (d, $^3J_{H,H}$ = 8.0 Hz, 2 H, *o* to Te), 8.42 (d, $^3J_{H,H}$ = 8.0 Hz, 2 H, *o* to N) ppm. ^{13}C NMR: δ = 121.57, 131.15, 135.3, 137.0, 149.9 ppm. ^{125}Te NMR: δ = 439 ppm. General Method for the Preparation of Unsymmetrical Pyridyl Tellurides and Dipyridyl Monotellurides: A solution of bromopyridine (20 mmol) in THF (20 mL) was treated with *i*PrMgCl (22 mmol) at room temperature. After two hours of stirring elemental tellurium (20 mmol) was added in parts. When all the tellurium had dissolved, the mixture was cooled in an ice bath and an equivalent amount of alkyl halide/bromopyridine was added. The reaction was monitored by TLC. When the spot corresponding to ditelluride had disappeared, the reaction mixture was washed with distilled water and extracted with dichloromethane. The product was purified by column chromatography using 1% ethyl acetate in hexane as eluent.

Bis(4-methyl-2-pyridyl) Telluride [(4-MeC$_5$H$_3$N)$_2$Te] (10): Viscous liquid. Yield: 40%. ^1H NMR (300 MHz, $CDCl_3$, 25 °C): δ = 2.27 (s, 6 H, CH_3), 6.92 (d, $^3J_{H,H}$ = 4.8 Hz, 2 H, *m* to N), 7.56 (s, 2 H, *o* to Te), 8.35 (d, $^3J_{H,H}$ = 4.8 Hz, 2 H, *o* to N) ppm. ^{13}C NMR: δ = 20.85, 124.05, 132.06, 135.70, 148.17, 150.23 ppm. ^{125}Te NMR: δ = 378 ppm. EI-MS: *m*/*z* (%) = 314 (51.1) [M − Te]$^+$, 183 (43.5) [M − Te$_2$]$^+$, 92 (100) [CH_3Py]$^+$. Crystal Structure Determination and Refinement: A crystal of **1**, **8** or **9** were mounted on an Enraf−Nonius CAD-4 diffractometer in Lindeman glass capillaries at 293(2) K. Final cell dimensions and reflection intensities were measured with graphite-monochromated Mo-K_α radiation in the ω-2θ scan mode. Anisotropic thermal parameters were used for heavier atoms Te and Br only. Carbon atoms were refined isotropically and hydrogen atoms were placed in calculated positions riding their respective bonded atoms. All other relevant information about the data collection and the refinement id presented in Table 8. The crystal structure was solved by direct methods and refined on F^2 using SHELX-97.[30]

Manganese(II) Complexes Coordinated by a New Derivative of Bipyridine: 9′-[4,5-Bis(methylthio)-1,3-dithiol-2-ylidene]-4′,5′-diazafluorene

Qin-Yu Zhu ,[a] Jie Dai,*[a−c] Ding-Xian Jia,[a] Li-Hui Cao,[a] and Hai-Hong Lin[a]

Keywords: Diazafluorene / Manganese(II) complex / Crystal structure / Catalysis

Manganese(II) complexes with the ligand 9′-[4,5-bis(methylthio)-1,3-dithiol-2-ylidene]-4′,5′-diazafluorene (L) have been synthesized, and the single-crystal structures of complexes $[Mn(L)_2(H_2O)_2](ClO_4)_2·(L)_2·2C_2H_5OH·2CH_3CN$ (**1**), $[Mn(L)_2Cl_2]·1.5CH_2Cl_2$ (**2**) and $[Mn(L)_2(NO_3)_2]$ (**3**) have been characterized. Complex **1** is *trans*-coordinated with N···H–O and S···S contacts, while the other two complexes are *cis*-coordinated with short π···π stacking. Solvent-free powder samples were also obtained and these complexes showed catalytic activity in the decomposition of H_2O_2 in the presence of added imidazole; the perchlorate compound was the most effective.

Introduction

Recent decades have seen considerable interest in the design and synthesis of manganese complexes because of their potential use as magnetic materials[1] and catalysts, such as for the disproportionation of hydrogen peroxide.[2] The role of manganese ions in biological systems has been increasingly recognized,[3] e.g. in manganese superoxide dismutase (MnSOD).[4] 1,10-Phenanthroline, bipyridine and their derivatives are well-known excellent N ligands used in manganese model compounds for biological simulations.[5] Consequently, we became interested in ligands of 9′-(4,5-disubstituted-1,3-dithiol-2-ylidene)-4′,5′-diazafluorenes (L),[6] which include a bipyridine moiety and have a similar structure to 1,10-phenanthroline. These ligands also have a conjugated dithiole moiety that influences the relative energy levels of orbitals compared with those of 1,10-phenanthroline and bipyridine. In this paper, we present the synthesis, crystal structures and catalytic properties of a series of Mn^{II} complexes with this type of ligands, $[Mn(L)_2(H_2O)_2](ClO_4)_2$, $[Mn(L)_2Cl_2]$ and $[Mn(L)_2(NO_3)_2]$. Manganese complexes with such ligands are expected to be a new molecular system.

Results and Discussion

Structural Descriptions

$[Mn(L)_2(H_2O)_2](ClO_4)_2·2L·2C_2H_5OH·2CH_3CN$ (1)

In the crystal structure of compound **1** (see a in Figure 1) the manganese atom is symmetrically chelated by four nitrogen atoms from two ligands L, forming a quasi-planar structure that includes the manganese(II) ion with a mean deviation of 0.1119 Å. Perpendicular to the plane are two coordinated water molecules at *trans*-axial positions. Mn(1)−N(1) and Mn(1)−N(2) distances are 2.321 and 2.283 Å, respectively, and in the perpendicular position the Mn(1)−O(1) distance is 2.171 Å, forming an axial-pressed octahedral geometry. Table 1 lists selected bond lengths, angles and interaction distances for **1**−**3** (shorter than the sum of van der Waals radii).

Compound **1** crystallizes in the triclinic space group with co-crystallized free ligand and solvents. Complex molecules form one layer and two free ligands form another layer (see b in Figure 1). These parallel layers are alternately arranged and are linked with N···H−O hydrogen bonds (2.700 Å) and an S···S contact (3.526 Å). These blocks are further linked to a 1D column structure along the *a* axis by hydrogen bonds between coordinated water molecules and the solvent molecules. There are also short S···S interactions (3.311 Å) between the columns.

$[Mn(L^1)_2Cl_2]·1.5CH_2Cl_2$ (2)

Figure 2 (a) shows the X-ray crystal structure of the compound **2**. The complex crystallizes in a monoclinic system with eight complex molecules and 12 dichloromethane molecules in a unit cell. In the crystal structure of **2**, the Mn

		N(3)−Mn(1)−N(4)	76.50	N(3)−Mn(1)−N(4)	77.69
S(3)···S(8)^{i}	3.526(5)	C(17)···C(7)^{iii}	3.37(1)	C(27)···C(23)^{iv}	3.390(5)
S(7)···S(7)^{ii}	3.311(5)	C(18)···C(6)^{iii}	3.28(1)	C(2)···C(11)^{v}	3.371(7)
O(1)···N(3)	2.70(1)	C(20)···C(8)^{iii}	3.38(1)		
		C(21)···C(8)^{iii}	3.354(9)		

atom also exhibits a six-coordinate environment that consists of the four nitrogen atoms from the two ligands and two *cis* chloride ions, but the geometry is distorted far from formal octahedral. The mean deviation from the plane of the two ligands is 0.0720 and 0.1478 Å, respectively. The dihedral angle between the least-squares planes of the two ligands is 92.671°.

Mn(1)−Cl(1), 2.458 Å, and Mn(1)−Cl(2), 2.425 Å, bond lengths are similar to those of $[Mn(phen)_2Cl_2]$,[5c] a (dichloro)Mn^{II} complex showing a coordination environment resembling that of **2**. The bonds of Mn(1)−N(3) (2.431 Å) and Mn(1)−N(2) (2.420 Å) *trans* to Cl(1) and Cl(2), are longer than those of Mn(1)−N(1) (2.304 Å) and Mn(1)−N(4) (2.298 Å). This suggests that the axes Cl(1)−Mn(1)−N(3) and Cl(2)−Mn(1)−N(2) are elongated and the octahedral geometry is distorted. There is short π···π stacking between the conjugated ligands (in the range of about 3.3−3.5 Å, Table 1). These interactions and the coordination bonds result in 1D zigzag chains along the *b* axis (Figure 2, b).

$[Mn(L^1)_2(NO_3)_2]$ (3)

Figure 3 (a) shows the X-ray crystal structure of **3**. The complex crystallizes as a monoclinic system with two complex molecules in a unit cell. In the crystal structure of **3**, the coordination environment around the manganese(II) center is a distorted octahedral coordination geometry, like that of **2**. The Mn^{II} ion is coordinated by four nitrogen atoms from two chelating ligands and the two *cis*-oxygen atoms from two nitrate anions. The mean deviation from the plane of the two ligands is 0.0563 and 0.0590 Å, respec-

tively, which are better than those of **2**. The dihedral angle between least-squares planes of the two ligands is 95.09°. The crystal is also stabilized by interligand π···π stacking, but the crystal packing is quite different from that of **2**. Ligand planes from two different symmetrical molecules are arranged alternately with C···C distances of 3.37 or 3.38 Å, forming 1D ligand columns along the *a* axis (Figure 3, b). In Figure 3 (b), A and B represent ligands orientated in

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

different directions and those molecules interact further with others in the same manner as described above (1D ligand columns). By the metal coordination linkage these π···π-assembled ligand columns form a 2D structure parallel with the (001) plane.

Synthesis and Properties

Table 2 gives selected IR vibration bands of the powder samples and their assignments. The shift of the ν(C=N) band is not very notable for the coordination of Mn^{II}, whereas the ν(C=C) band at 1488 cm^{-1} for the free ligand L is clearly shifted to lower energy for complexes, due to the metal coordination. In contrast to the C=C bands, the S−C−S vibrations at about 857 cm^{-1} are enhanced. The ClO_4^- and NO_3^- vibrations of the complexes **1′** and **3** at around 1130 and 1442 cm^{-1} confirm the presence of these counterions.

Table 2. Characteristic IR bands of the ligand and its complexes [cm^{-1}]; **1′** and **2′** are solvent-free compounds corresponding to **1** and **2**

Compound	ν(C=N)	ν(C=C)	ν(S−C−S)	Anion
L	1540 vs	1488 vs	857 m	
1′	1538 vs	1478 vs	868 m	1130 vs
2′	1536 vs	1473 vs	867 m	
3	1539 vs	1479 s	868 m	1442 s

Although single crystals suitable for X-ray diffraction were obtained and the structures of **1**−**3** have been successfully determined, the composition of the powder samples of **1′** and **2′** differ from those of the crystals. Crystals of **1** and **2** contain solvent molecules that are easily lost from the powder samples in vacuo. Interestingly, free ligand is not contained in **1′**, unlike crystals of **1**. Both the results of elemental analysis and IR measurement suggest this conclusion. IR spectra of the three powder complexes are essentially the same, except for the band of the anions and no peak splits (for free L) were found for **1′**. Unlike the synthesis of powder **1′**, **1** was obtained by adding some ethanol solvent to the reaction filtrate, which decreased the solubility of the ligand and therefore free L co-crystallized with the molecules of complex and solvents. Owing to the space filling of those free L molecules, **1** has a different structure (C_i) to those of **2** and **3** (C_2) (see Figure 1−3).

To further understand the structure of **1′**, ESR spectra of **1′** and **3** were recorded (Figure 4). A *trans* structure would show an axial field character in the ESR spectra with *g* values of 2 and 6 for monomeric Mn^{II} complexes,[7] but the ESR patterns of **1′** and **3** do not satisfy an axially symmetric electron environment. A higher rhombic distortion from octahedral geometry can be deduced for the complexes owing to the *cis* instead of *trans* structure. Examples of Mn^{II} complexes have been discussed in detail.[8] The results are in accord with the structure determination of **3**. Since the signal characters of **1′** and **3** are similar, the most promising structure of **1′** is a *cis*-coordination geometry, as in the crystal structures of **2** and **3**.

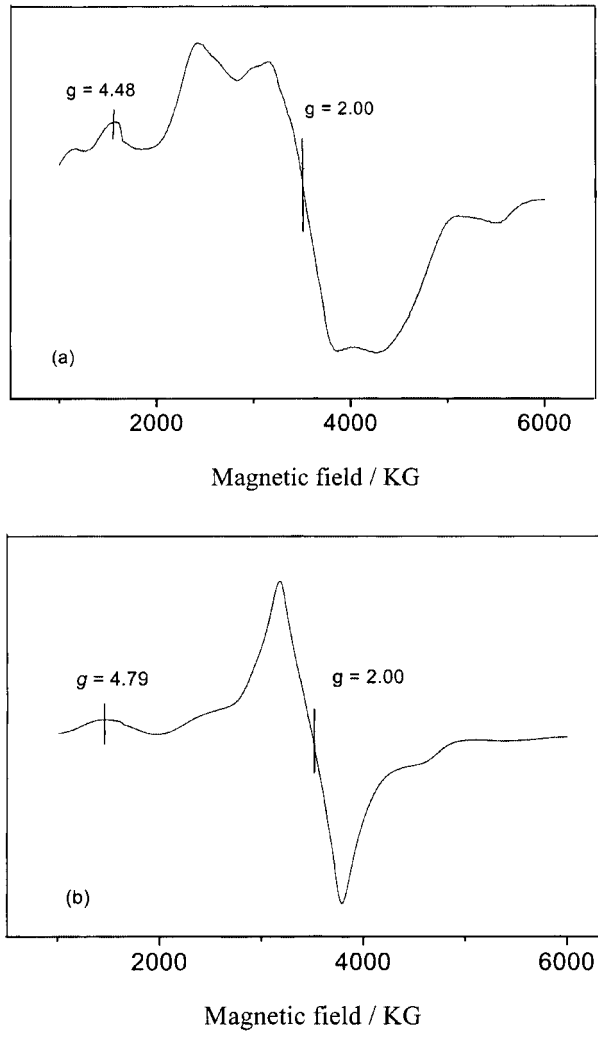

Figure 4. ESR spectra of **1′** (a) and **3** (b) powder samples measured at room temperature

Several manganese(II) complexes have been studied for catalytic activity in decomposing H_2O_2. Since our new ligands are derivatives of bipy and phen (ligands that are widely used in such catalytic systems), it seemed worthwhile to study the catalytic activity of the new Mn^{II} compounds. Unfortunately, unlike Mn^{II} complexes of bipy and phen, compounds **1**−**3** are all insoluble in water; therefore, it is impossible to discuss the influences of the conjugated electron-donor moiety of dithiole on activity by direct comparison with those of bipy or phen complexes. However, catalytic activities of **1**−**3** were determined in a heterogeneous reaction system (Figure 5). All the complexes showed activity for the catalytic decomposition of H_2O_2 in the presence of added imidazole. Among them $[Mn(L)_2(H_2O)_2](ClO_4)_2$ (**1′**) is the most effective. Experiments were repeated several times to ensure consistency of the results. The higher

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

activity of **1′** is attributed to the coordinated water molecules, which are exchangeable in the catalytic system.

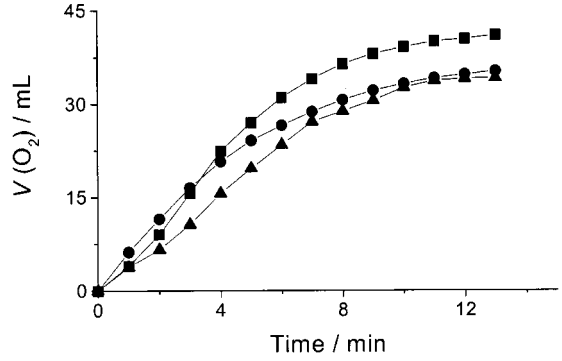

Figure 5. Activity in the catalytic decomposition of H_2O_2 in the presence of imidazole: **1′** (squares), **2′** (triangles) and **3** (circles)

Experimental Section

General Remarks: The ligand L, 9′-[4,5-bis(methylthio)-1,3-dithiol-2-ylidene]-4′,5′-diazafluorene, was prepared according to ref.[9] Acetonitrile was dried and distilled by a standard method before use. Elemental analyses of C, H and N were performed using an EA1110 elemental analyzer. IR spectra were recorded as KBr discs with a Nicolet Magma 550 FT-IR spectrometer. ESR spectra were recorded with a Jeol-FE1XG spectrometer at room temperature.

Synthesis of Complexes

$[Mn(L)_2(H_2O)_2](ClO_4)_2$ (1′): A dichloromethane solution (20 mL) of the ligand L (0.1 mmol, 36 mg) was slowly added dropwise to an acetonitrile solution (4 mL) of $Mn(ClO_4)_2{\cdot}6H_2O$ (0.05 mmol, 18.1 mg). The resultant orange precipitate, formed after the mixture was stirred at room temperature for 30 min, filtered off, washed with acetonitrile and dichloromethane and, finally, dried in vacuo over silica gel (yield: 48 mg, 65%). $C_{32}H_{28}Cl_2MnN_4O_{10}S_8$ (1010.9): calcd. C 38.02, H 2.79, N 5.54; found C 37.96, H 2.87 N 5.69.

$[Mn(L)_2Cl_2]$ (2′): To an ethanol solution (10 mL) of $MnCl_2{\cdot}4H_2O$ (0.05 mmol, 10.0 mg) was slowly added dropwise a dichloromethane solution (20 mL) of the ligand L (0.1 mmol, 36 mg). Then, all the procedures were similar to that of **1** (yield: 49 mg, 67%). $C_{32}H_{24}Cl_2MnN_4S_8$ (846.9): calcd. C 45.39, H 2.84, N 6.62; found C 45.27, H 2.78, N 6.56.

$[Mn(L)_2(NO_3)_2]$ (3): A dichloromethane solution (20 mL) of the ligand L (0.1 mmol, 36 mg) was slowly added dropwise to an ethanol solution (5 mL) of $Mn(NO_3)_2$ ca. 0.1 mmol, 20 μL, 50% w/w aqueous solution). Subsequent procedures were similar to that of **1** (yield: 45 mg, 65%). $C_{32}H_{24}MnN_6O_6S_8$ (900.0): calcd. C 42.71, H 2.67, N 9.34; found C 37.12, H 2.38, N 5.49.

$[Mn(L)_2(H_2O)_2](ClO_4)_2{\cdot}(L)_2{\cdot}2C_2H_5OH{\cdot}2CH_3CN$ (1): Crystals of complex **1** was prepared by slowly adding dropwise a dichloromethane solution (10 mL) of the ligand L (0.02 mmol, 7.2 mg) to an acetonitrile solution (3 mL) of $Mn(ClO_4)_2{\cdot}6H_2O$ (0.01 mmol, 3.62 mg). The resultant mixture was stirred at room temperature for 30 min and then filtered. Ethanol was then gently layered on the filtrate, which was sealed in bottles and left undisturbed at room temperature for several days. The so-obtained orange, single crystals were suitable for X-ray diffraction.

$[Mn(L)_2Cl_2]{\cdot}1.5CH_2Cl_2$ (2) or $Mn(L)_2(NO_3)_2]$ (3): Crystals of **2** or **3** were prepared in dilute solutions by similar procedures to that above. Filtrates were sealed in bottles and left undisturbed at room temperature for several days to afford orange single crystals suitable for X-ray diffraction.

Hydrogen Peroxide Disproportionation Studies: Aqueous H_2O_2 (2 wt.%, 5 mL) was added to a solid mixture consisting of the complex (2.3×10^{-3} mmol) and imidazole (5 mg). This combination was

then stirred and thermostatted at 25 °C. Evolved O_2 was measured volumetrically.

X-ray Crystallographic Study: X-ray crystallographic data for complexes **1**−**3** were obtained using a Rigaku Mercury CCD area detector with graphite-monochromated Mo-K_α (λ = 0.71070 Å) radiation, at 193 K. Table 3 lists selected crystallographic data for three complexes and details of data collection. An empirical absorption correction was applied and data were corrected for Lorentz and polarization effects. All structures were solved by direct methods[10] and expanded using Fourier techniques.[11] Non-hydrogen atoms were refined anisotropically. Hydrogen atoms were refined using the riding model. The final cycle of full-matrix least-squares refinement on F^2 was based on observed reflections and variable parameters and converged to unweighted and weighted agreement factors. Calculations were performed using the CrystalStructure software package. CCDC-236214 to -236216 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: + 44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Synthesis and Characterization of Lithium Complexes of 2-(Diphenylphosphanylamino)pyridine and *N*,2-Bis(diphenylphosphanyl)benzeneamine

Kochappilly O. Xavier,[a] Elena Smolensky,[a] Moshe Kapon,[a] Stephen M. Aucott,[b] J. Derek Woollins,[b] and Moris S. Eisen*[a]

Keywords: Lithium complexes / (Diphenylphosphanylamino)pyridine / *N*,2-Bis(diphenylphosphanyl)benzeneamine / Hard-soft interactions / *N*,*N*-chelation / *N*,*P*-chelation / X-ray diffraction

Lithium complexes of 2-(diphenylphosphinoamino)pyridine and *N*,2-bis(diphenylphosphanyl)benzeneamine have been synthesized from the corresponding neutral compounds. In the former complex, the metal ion is coordinated to both nitrogen atoms, forming a constrained four-membered ring, whereas the latter complex forms a five-membered ring as the metal ion coordinates preferentially to the phosphorus atom. Coordination of the metal ion in both complexes is dictated primarily by soft–hard interactions and, subsequently, by the constrained geometry of the ring formed. Both lithium complexes and the corresponding neutral compounds have been characterized by single-crystal X-ray diffraction.

Introduction

Alkali metal salts play an important role in advanced organic and organometallic transformations.[1] The most extensively used salts contain lithium because this metal cation has the highest charge density of all alkali-metal cations, and inorganic and organic lithium compounds are reasonably soluble in organic solvents.[2] Over 95% of natural products syntheses employ at least one lithium-containing species.[3] *N*-Lithiated species, a very important family in organic chemistry, are the favorite bases in forming ketone enolates,[4] generating low steady-state concentrations of some relatively unstable carbanions,[5] and in preparing heterocyclic thiazenes that incorporate an RC(=N−)N< moiety using lithium amidinates.[6] They are also the main synthons used to introduce an amido group to either early or late transition metal complexes.[7] Since the bonding in these lithium complexes is ionic, the solid-state structures are highly dependent on the steric and electronic properties of the substituents at the anionic center. In addition, the presence of coordinative solvents reduces the high tendency of organolithium compounds to self-assemble into higher aggregates.[3,8]

In the last decade lithium complexes containing *N*,*N*- and *P*,*N*-ligations have attracted much attention. Representative examples of these ligations (Scheme 1) are amidinate,[9] β-diketiminate,[10] pyridylamine,[11] diaminobenzene,[12] phosphanamide,[13] phosphane *Janus Head*,[14] phospha-amidinate,[15] and amidophosphane.[16]

Recently, we have shown that lithium benzamidinates can form dimeric and trimeric species, depending on the solvent,[17] and that the coordination of TMEDA (tetramethylethylenediamine) to lithium benzamidinates guarantees the formation of mononuclear species.[18] These lithium complexes are useful reagents for the bidentate chelation of main group, early- and late-transition metal centers that produce, in some cases, homogeneous complexes as catalysts for the stereoregular polymerization of α-olefins.[18,19]

In the lithium benzamidinate/TMEDA complex the metal ion is coordinated symmetrically by both nitrogen atoms of the benzamidinate moiety, forming an η^2-ligation and, with the two nitrogen atoms of TMEDA, a tetrahedral environment (Figure 1).

With pyridylamine and amidophosphane ligations η^2-coordination to the metal ion is normally observed since both heteroatoms (P or N) are located *ortho* to the lithiated position of the aromatic ring (aminobenzene or pyridine), forming a "single side arm coordination". In such coordination there is still space for donor solvent coordination and, commonly, the dimer four-membered ring is the favorite aggregation state.[20]

A basic conceptual question regards the coordination of the alkali metal ion in non-symmetrical systems where, as well as a hard atom (N), the competitive chelation of additional soft and/or hard atoms is also possible. Two systems were selected for this study. The first asymmetric ligation contains the N−C−N−P backbone in which the cen-

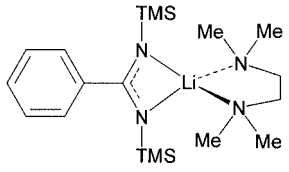

Figure 1. Lithium benzamidinate complex with TMEDA ligation

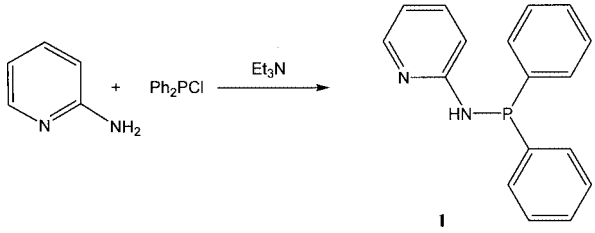
tral nitrogen atom belongs to a pyridine ring, whereas the second asymmetric system includes a P−C−C−N−P backbone in which the C−C moiety is part of an aromatic ring.

Regarding the former system, only one known structure contains an N−C−N−P moiety in which the nitrogen atoms are attached to a lithium ion and the phosphorus atom is part of a P−N−P−N cyclobutane moiety.[21] Interestingly, 13 structures are known in which an *ortho*-amidopyridinium moiety is anchored to a lithium center, although without the presence of soft (phosphane) atoms.[22,11] Regarding the latter system, structures of late transition metal complexes anchoring the ligand to the metal ion by one or two phosphane P atoms are known but no crystal structure has been reported for alkali or early transition metals of this unsymmetrical ligation.[23] We present here the solid-state characterization of lithium complexes for both N−C−N−P and P−C−C−N−P backbones. To compare the effect of the alkali center, crystallographic parameters of the neutral systems are also described.

Results and Discussion

2-(Diphenylphosphanylamino)pyridine (**1**) was prepared according to a published procedure[23b] and recrystallized before use [Equation (1)]. X-ray diffraction (Figure 2, Table 1) shows that **1** is a dimeric polymorph that crystallizes in a different space group to the structure known in the literature[23b] although with almost identical bond lengths and angles.



(1)

Lithium complex **2** was prepared quantitatively from the reaction of the neutral compound **1** with butyllithium (1:1)

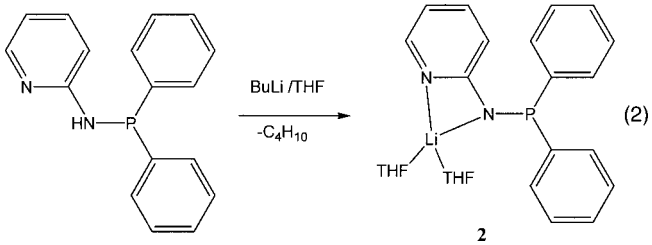
in a tetrahydrofuran solution [Equation (2)]. Complex **2** is bright yellow and is highly soluble in organic solutions. By cooling to −78 °C a crystallized product was obtained and subsequently characterized by low-temperature X-ray diffraction (Figure 3, Table 1) and spectroscopic methods.



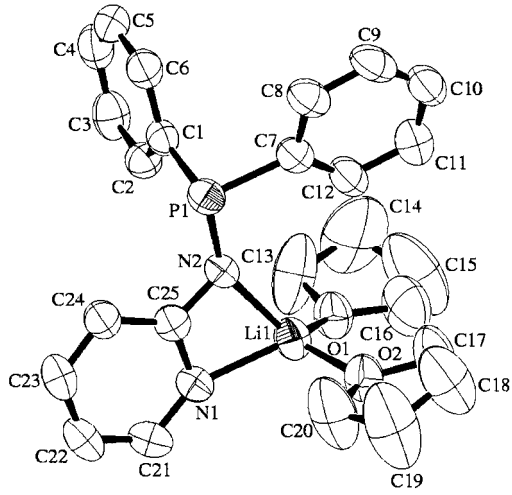


Figure 3. Molecular structure of complex **2**; thermal ellipsoids given at 50% probability

X-ray analysis shows that the complex has a structure containing one symmetrical diazaallyl moiety as the core unit [Li(1)−N(1)−C(25)−N(2)] bonded in addition to two equidistant molecules of tetrahydrofuran, forming a tetracoordinated lithium atom.

Comparison of the neutral and the lithiated complex indicates the electronic effects introduced by the lithium atom. In the neutral compound the aromatic carbon atom exhibits a shorter distance to the pyridine nitrogen atom [N(2)−C(1) = 1.341(4) Å] than to the aminophosphane nitrogen atom [N(1)−C(1) = 1.391(4) Å]. In the lithiated complex the distances become almost equivalent [N(1)−C(25) = 1.364(4) Å and N(2)−C(25) = 1.355(4) Å] and are very close to the geometrical average in the neutral compound. The N(1)−C(25) and C(25)−C(24) bonds [1.418(4) Å] are longer than those in the neutral compound, for which N(2)−C(1) and C(1)−C(5) = 1.384(5) Å, respec-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

tively. The charge has little effect on the N−P bond length as N(2)−P(1) = 1.676(3) Å and N(1)−P(1) = 1.695(3) Å for **2** and **1**, respectively.

The Li−N(Py) bond length in complex **2** [2.043(6) Å] lies in the middle of the range (1.96−2.19 Å) indicated by other well-defined lithium complexes bearing a pyridine ring (Table 2).

Table 2. Li−N(Py) bond lengths in representative complexes

Complex	Li−N(Py) [Å]	Ref.

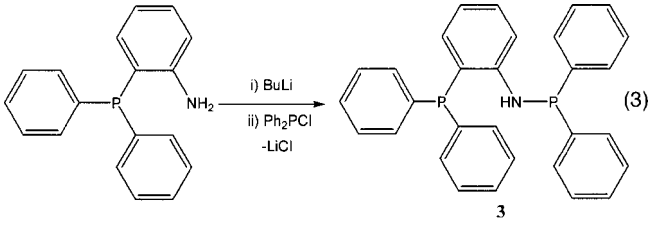
[a] A-PySiMe$_3$ = 6-methyl-2-(trimethylsilylamino)pyridine. [b] bpg = *N*,*N*-bis(2-pyridylmethyl)glycine.

The organic compound *N*,2-bis(diphenylphosphanyl)benzenamine (**3**) was prepared from deprotonated 2-(diphenylphosphanyl)benzeneamine with butyllithium and concomitant addition of chlorodiphenylphosphane [Equation (3)].[14] Pale yellow single crystals of **3** suitable for X-ray diffraction (Figure 4, Table 1) were obtained by recrystallization from toluene at −40 °C.



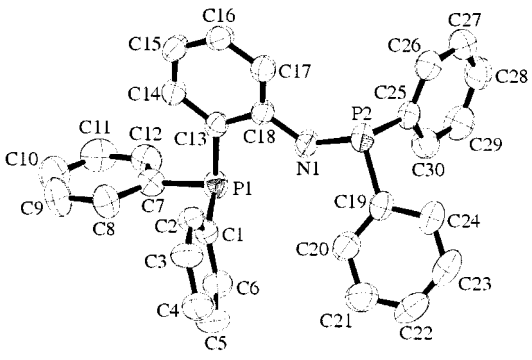


Figure 4. Molecular structure of compound **3**; thermal ellipsoids given at 50% probability

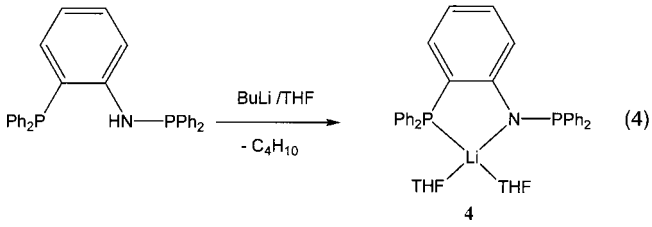
The corresponding lithium *N*,2-bis(diphenylphosphanyl)-benzenamine (**4**) was prepared by deprotonation of *N*,2-bis(diphenylphosphanyl)benzenamine (**3**) with butyllithium [Equation (4)]. The reaction proceeds in THF in good yield (85%), producing a yellow product that can be easily recrystallized from THF at −20 °C.



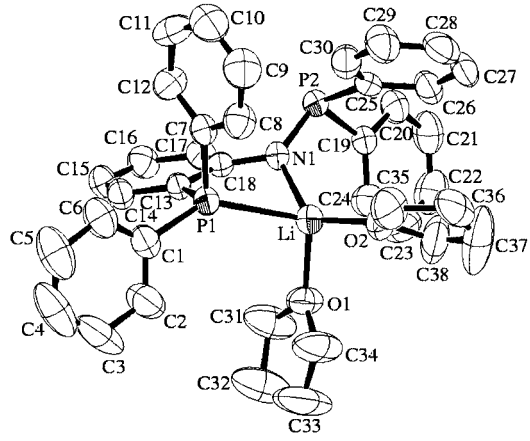


Figure 5. Molecular structure of complex **4**; thermal ellipsoids given at 50% probability

The X-ray structure of complex **4** (Figure 5, Table 1) shows a core unit of a five-membered ring, P(1)−C(13)−C(18)−N(1)−Li, with the lithium atom tilted down from the plane formed by the four additional atoms. The lithium atom is coordinated by the nitrogen atom and *ortho*-phosphorus atom in addition to two molecules of THF, forming a highly distorted tetrahedron. Whereas the average Li−O bond length in lithiated complexes is normally around 1.92−1.94 Å, in complex **4** one bond is rather short and the second is rather long [O(2)−Li = 1.901(4) Å and O(1)−Li = 1.963(4) Å]. This increase is a result of the rejection of the lone pair of electrons of one oxygen atom and one of the phosphorus atoms [O(1)−P(1) = 3.61 Å]. Interestingly, no interaction is exhibited between the lithium atom and the phosphorus atom attached to the nitrogen atom. Seemingly, this interaction induces a higher energy and is observed only when no other donating atoms are present in sterically less demanding positions.[28] Comparison of the neutral and lithiated complexes shows that the increase in charge at the nitrogen atom causes almost no change in aromatic C−C bond lengths, although the bonds connecting the substituents to the aromatic ring do lengthen, i.e. C(13)−C(18) = 1.421(4) Å, N(1)−C(18) =

Table 3. Comparison of bond angles and lengths in four- and five-membered ring *N*,*N*- and *N*,*P*-ligated lithium complexes

	Complex	Bond angles [°] Bond lengths [Å]	Ref.
Four-membered ring complexes:			
	$[Li\{P(Ph)C(Ph)NSiMe_2tBu\}(THF)]_2$	N–Li–P = 68.0(3) Li–N = 1.991(10) Li–P = 2.641(9)	[15]
	$[Ph_2PC\{NiPr\}_2Li(TMEDA)]$	N–Li–P = 66.54(16) Li–N = 1.927(5) Li–P = 2.625(5)	[29]
	[Li(FIso)(THF)$_2$][a]	N(1)–Li–N(2) = 68.2(1) Li–N(1) = 2.036(4) Li–N(2) = 2.041(4)	[9a]
	$[PhC(NSiMe_3)_2Li(TMEDA)]$	N(1)–Li–N(2) = 69.19(19) Li–N(1) = 2.019(6) Li–N(2) = 2.033(6)	[19]
	$\{[Li(A\text{-}PySiMe_3)](thf)\}_2$[b]	N(1)–Li–N(2) = 67.4(2) Li–N(1) = 2.042(7) Li–N(2) = 2.097(7)	[11b]
	$[Li(PyNPPh_2)_2(thf)_2]$ (**2**)	N(1)–Li–N(2) = 68.1(2) Li–N(1) = 2.043(6) Li–N(2) = 2.012(7)	this work
Five-membered ring coplexes:			
	$[Ph_2PC_6H_4\{2\text{-}N(2,6\text{-}Me_2Ph)\}Li(thf)_2]$	N–Li–P = 76.63(17) Li–N = 1.990(5) Li–P = 2.620(5)	[16a]
	$[Ph_2PC_6H_4\{2\text{-}N(C_6H_4PPh_2)\}Li(thf)_2]$	N–Li–P = 73.09(15), 73.35(15) Li–N = 2.039(5) Li–P = 2.779(5), 2.824(5)	[16b]
	$[PPh_2PC_6H_4(2\text{-}NPPh_2)Li(thf)_2]$ (**4**)	N–Li–P = 76.31(11) Li–N = 1.985(5) Li–P = 2.618(3)	this work

[a] Fiso = *N*,*N*-bis(2,6-diisopropylphenyl)formamidine. [b] A-PySiMe$_3$ = 6-methyl-2-(trimethylsilylamino)pyridine.

1.386(3) Å, P(1)−C(13) = 1.817(3) Å, and C(14)−C(19) = 1.411(3) Å, N(1)−C(18) = 1.402(3) Å, P(1)−C(13) = 1.830(3) Å, for **4** and **3**, respectively. Notably, the distance between the *ortho* substituents decreases only slightly upon the attachment of the lithium atom: N(1)−P(1) = 2.99 and 2.80 Å in **3** and **4**, respectively.

Comparison of the Li−N bond lengths in complexes **2** and **4** is of interest. In complex **2** the average bond length of 2.02 Å is a result of resonance among the aminopyridine ring whereas in complex **4** a shorter bond length [1.985(6) Å] is observed. This difference in bonding also occurs in other lithium benzamidinate complexes.[9]

The rings formed by the metal atom and the *N*,*P*- and *N*,*N*-ancillary ligations are also of interest. When four-membered rings are formed, the N−Li−P or N−Li−N bond angle is within 66.5−69.2°, while for five-membered rings this angle is between 73.0 and 76.6° (Table 3). The N−Li−N angle in the four-membered ring in complex **2** is similar to that found in benzamidinate complexes, whereas the N−Li−P angle in the five-membered ring in complex **4** exhibits an angle close to the highest observed value (76.31°).

Conclusions

Two lithium complexes and their corresponding parent neutral ligands have been characterized by single-crystal X-ray diffraction. In the phosphanylpyridine complex **2** the metal ion is coordinated to the hard nitrogen ligands, forming a constrained four-membered metallacycle, regardless of possible coordination with the soft phosphorus atom to form a less constrained five-membered ring. In the diphosphane complex **4** the metal ion forms a five-membered ring that connects soft and hard moieties. Coordination to the second phosphorus moiety is sterically hindered.

Experimental Section

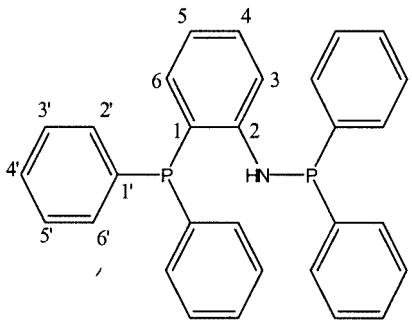
General Remarks: All manipulations of air-sensitive materials were carried out with the vigorous exclusion of oxygen and moisture in

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

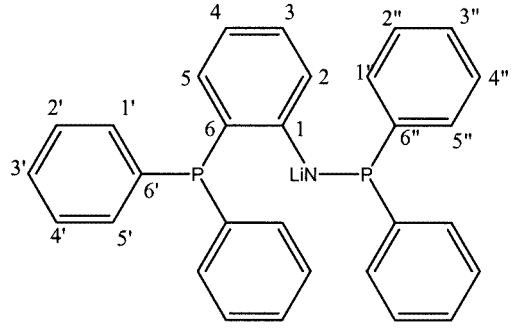
flame dried Schlenk-type glassware connected to a dual-manifold Schlenk line, or interfaced to a high-vacuum (10^{-6} Torr) line, or in a nitrogen-filled Vacuum Atmospheres glove box with a medium-capacity recirculator (1−2 ppm O_2). Argon and nitrogen were purified by passage through an MnO oxygen-removal column and a Davison molecular sieves (4-Å) column. THF and [D_8]THF solvents were distilled under argon from sodium/benzophenone. Hydrocarbon solvents (C_6D_6, toluene) were distilled under nitrogen from Na/K alloy. All solvents for vacuum-line manipulations were stored in vacuo over Na/K alloy in resealable bulbs. The neutral ligands Ph_2PNPy (**1**) (Py = pyridine) and *ortho*-$Ph_2PNHC_6H_4PPh_2$ (**3**) were prepared according to literature methods.[23] NMR spectra were recorded with Bruker Avance 300 and 500 spectrometers. Chemical shifts for ^1H and ^{13}C NMR are referenced to internal solvent resonance and are reported relative to tetramethylsilane. Experiments were conducted in Schlenk vessel sealed tubes (J. Young stopcock) after vacuum transfer of the solvent in a high-vacuum line.

Synthesis of Li(Ph_2PNPy)$(THF)_2$ (2): *n*BuLi (0.24 g, 3.78 mmol as a 1.6 M solution in hexane) was added dropwise at −78 °C under nitrogen to a stirred solution of the ligand Ph_2PNHPy (1.05 g, 3.78 mmol) in THF (20 mL). After stirring at −78 °C for 30 min, the resultant solution was allowed to warm to room temperature and stirred for a further 12 h. After the resulting solution was concentrated to 3 mL and cooled slowly to −78 °C, yellow crystals precipitated; 1.45 g (95%). $C_{25}H_{30}LiN_2O_2P$ (428.4 g): calcd. C 70.09, H 7.06, N 6.54; found C 69.69, H 7.40, N 6.27. ^1H NMR (C_4D_8O, 300 MHz): δ = 1.73 (m, 4 H, CH_2CH$_2$O), 3.57 (m, 4 H, CH$_2$O), 6.05 (dd, ^3J = 5.1 Hz; ^3J = 6.3 Hz, 1 H, NCHC*H*CHCHC), 6.56 (d, ^3J = 8.1 Hz, 1 H, NCHCHCHC*H*C), 7.12 (dd, ^3J = 6.3, ^3J = 8.1 Hz, 1 H, NCHCHC*H*CHC), 7.15 (m, 6 H, 2 × C_6H_5 *m*- and *p*-H), 7.32 (m, 4 H, 2 × C_6H_5 *o*-H), 7.63 (d, ^3J = 5.1 Hz, 1 H, NC*H*CHCHCHC) ppm. ^{13}C NMR (C_4D_8O, 150 MHz): δ = 22.5, 64.1, 105.3, 107.2 (d, $^1J_{c\text{-}p}$ = 30.0 Hz), 124.5, 124.9, 125.0, 128.5, 128.7, 133.9 (d, $^3J_{c\text{-}p}$ = 7.5 Hz), 144.4 ppm. ^{31}P NMR (C_6D_6): δ = 32.14 ppm.

Synthesis of $Ph_2PNHC_6H_4PPh_2$ (3): $Ph_2PNHC_6H_4PPh_2$ was synthesized according to a reported method.[12] This procedure involves the deprotonation of 2-(diphenylphosphanyl)benzeneamine with BuLi, followed by reaction with PPh_2Cl to obtain the product.[12] Single crystals for X-ray diffraction were obtained by recrystallization from toluene at −40 °C. ^1H NMR (C_6D_6, 300 MHz): δ = 5.88 (m, 1 H, C_6H_4 3-H), 6.68 (m, 1 H, C_6H_4 5-H), 6.96 (m, 1 H, C_6H_4 6-H), 7.03−7.19 (m, 14 H, C_6H_5 2′-,6′′-H and non-marked rings), 7.30−7.41 (m, 6 H, C_6H_5 3′-,5′-H), 7.72 (m, 1 H, C_6H_4 4-H) ppm. ^{13}C NMR (C_6D_6, 150 MHz): δ = 115.5, 116.0, 120.4, 127.8, 128.3, 128.8, 129.0, 129.1, 129.29, 129.35, 131.5, 131.9, 134.3, 134.6, 135.1, 135.2, 150.5 ppm. ^{31}P NMR (C_6D_6): δ = 21.01 (P_A), 28.01 (P_X) ppm.



Synthesis of Li($Ph_2PNC_6H_4PPh_2$)$(THF)_2$ (4): *n*BuLi (0.347 g, 5.42 mmol, 1.6 M solution in hexane) was added dropwise at −78 °C under nitrogen to a stirred solution of the ligand $Ph_2PNHC_6H_4PPh_2$ (2.50 g, 5.42 mmol) in THF (50 mL). After stirring at −78 °C for 30 min, the obtained solution was allowed to warm to room temperature and stirred for a further 12 h. The resulting solution was then concentrated to dryness to obtain 2.15 g (85%) of yellow product. Single crystals for X-ray diffraction were obtained by recrystallization of the solid from THF at −20 °C. $C_{38}H_{40}LiNP_2O_2$ (611.2 g): calcd. C 74.61, H 6.60, N 2.29; found C 72.71, H 6.61, N 2.59. ^1H NMR (C_4D_8O, 300 MHz): δ = 1.76 (m, 4 H, CH_2CH_2O), 3.62 (m, 4 H, CH_2O), 6.09 (m, 1 H, C_6H_4 3-H), 6.37 (m, 1 H, C_6H_4 5-H), 6.78 (m, 1 H, C_6H_4 6-H), 6.91−7.02 (m, 6 H, C_6H_5 1′-,3′-,5′-H), 7.18−7.22 (m, 6 H, C_6H_5 1′′-,3′′-,5′′-H), 7.23−7.28 (m, 8 H, C_6H_4 2′-,2′′-,4′-,4′′-H), 7.34 (m, 1 H, C_6H_4 4-H) ppm. ^{13}C NMR (C_4D_8O, 150 MHz): δ = 26.5, 68.6, 114.5 (d, $^1J_{c\text{-}p}$ = 30.0 Hz), 119.6, 120.2, 120.3, 128.1, 129.1, 129.2, 130.0, 130.08, 130.16, 131.9, 131.9, 133.2, 133.6, 134.8, 134.8, 135.7, 136.0, 140.1, 149.6 (d, $^2J_{c\text{-}p}$ = 20.0 Hz) ppm. ^{31}P NMR: (C_6D_6): δ = 12.99 (P_A), 42.46 (P_X) ppm.



X-ray Crystallographic Study: X-ray crystallographic experiments were carried out with a Nonius Kappa CCD diffractometer with graphite-monochromatized Mo-K_α radiation (λ = 0.71073 Å). Crystals were placed in a Parothone N oil in a glove box. Single crystals were mounted on the diffractometer under a stream of cold N_2 at 230 K. Data were collected using ω and φ scans to cover the Ewald sphere. Accurate cell parameters were obtained with refined collections of intensities and were corrected in the usual way. Structures were solved by direct methods and completed using successive Fourier difference maps. Refinements were performed anisotropically with respect to the non-hydrogen atoms. Hydrogen atoms were placed at calculated positions and refined using the riding model until convergence was reached. Data collection and reduction, cell refinements were carried out with the Nonius software package.[30] Structure solution and refinement were carried out by the SHELXS-97[31] and SHELXL-97[32] software packages, respectively. The ORTEP program incorporated in the TEXRAY Structure Analysis Package was used for molecular graphics.[33] Details are listed in Table 4. CCDC-250098 to -250101 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: + 44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Thallium−Arene Contacts in a Rare Yttrium Tris(pyrazolyl)hydroborate "ate" Complex

Fábio A. Kunrath,[a] Osvaldo L. Casagrande Jr.,*[b] Loic Toupet,[c] and Jean-François Carpentier*[d]

Keywords: Arene ligands / N ligands / Noncovalent interactions / Thallium / Yttrium

A salt elimination reaction between $[YCl_3(THF)_{3.5}]$ and 1 or 2 equiv. of $Tl(Tp^{Ms*})$ [Tp^{Ms*} = HB(3-mesitylpyrazolyl)$_2$(5-mesitylpyrazolyl)$^-$] leads in both cases to single metathesis, giving a mixture of the mono-Tp^{Ms*} complex $[YCl_3(Tp^{Ms*})Tl]$ (**1**) and another complex, $[YCl_2(Tp^{Ms**})]$ (**2**) [Tp^{Ms**} = HB(3-mesitylpyrazolyl)(5-mesitylpyrazolyl)$_2^-$], that results from the transfer of a second mesityl group to the 5-position of the pyrazolyl ring. The solid-state structure of **1** shows a unique "ate" dimeric structure with the Tl^+ cations coordinated by two μ^2- and two μ^3-bridging Cl atoms as well as two η^3-mesityl ligands.

Introduction

Tris(pyrazolyl)hydroborate (Tp) ligands, first introduced by Trofimenko,[1] are an attractive class of sterically demanding ancillaries for a wide variety of ionic metal centers.[2] Of particular interest is the case of group 3 metals,[3] due to their predominant ionic character. Indeed, one of the most attractive features of the Tp ligands is their steric tunability. This is a crucial advantage in lanthanide chemistry, which is recognized to be largely affected by steric factors.[4] Half-sandwich trivalent lanthanide Tp halide complexes are commonly prepared by salt metathesis (elimination) routes from the corresponding $LnX_3(L)_n$ (L = donor solvent) and $M(Tp^R)$ salts, leading to the desired neutral $[Ln(Tp^R)X_2]$ or $[Ln(Tp^R)_2X]$ complexes.[3] This procedure is sometimes plagued by the formation of ionic "ate" complexes, a feature very often observed in lanthanide chemistry with alkali metal salts.[4] A few examples of such lanthanide Tp "ate" complexes have indeed been reported, for example $[Na(THF)_3][YbCl_3(Tp^{Me2})]$ and $[H_2pz^{Me2}][YbCl_3(Tp^{Me2})]$.[5] The use of thallium salts has so far been considered to prevent this undesired formation, as TlCl usually precipitates irreversibly from solution. In this contribution, we report the first example of a lanthanide "ate" complex containing a thallium atom, which shows unusual thallium−arene contacts with the aromatic rings of a Tp ligand bearing mesityl substituents in the solid state. Migration of a mesityl group during coordination of the Tp^{Ms*} ligand to the yttrium atom is also described.

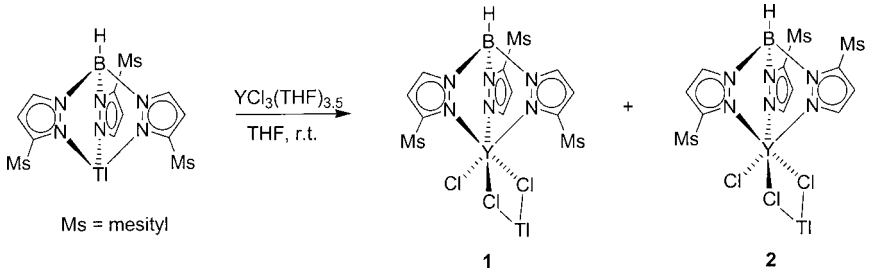
Results and Discussion

We are interested in the coordination of the Tp^{Ms*} ligand [Tp^{Ms*} = HB(3-mesitylpyrazolyl)$_2$(5-mesitylpyrazolyl)$^-$] to group 3 metal centers because of its particular steric properties that confer very high polymerization activity towards ethylene to some related catalyst species.[6] Salt-elimination reactions of $[YCl_3(THF)_{3.5}]$ with 1 or 2 equiv. of $Tl(Tp^{Ms*})$ in THF under different conditions (20−60 °C, 1−7 d) led only to mono-Tp complexes. This observation likely reflects the high steric hindrance of the Tp^{Ms*} ligand to the small yttrium atom. These reactions are, however, not as selective as with the ubiquitous Tp^{Me2} ligand. In fact, besides significant amounts of free 3-mesitylpyrazole (Hpz^{Ms}; ca. 10−20% based on initial Tp^{Ms*}) arising from the decomposition of the Tp^{Ms*} ligand,[5] mixtures of two Tp complexes were invariably produced [Equation (1)]. The most abundant complex formed (NMR yield in the range 20−50% based on Y, depending on the reaction conditions) is the mono-Tp^{Ms*} complex $[YCl_3(Tp^{Ms*})Tl]$ (**1**), which is readily separated from the mixtures by recrystallization due to its poor solubility in toluene, consistent with its ionic "ate"



(1)

nature. Complex **1** is, to the best of our knowledge, the first structurally characterized example of a group 3 metal complex incorporating a thallium cation, irrespective of the nature of the other ancillary ligands. The identity of **1** was unambiguously established by a single-crystal X-ray diffraction study, elemental analysis, and NMR spectroscopy. Key ^{1}H NMR resonances for **1** in [D$_8$]THF include a set for one 5-mesitylpyrazolyl ring and a set for the two 3-mesitylpyrazolyl rings. The 3-H signal of the 5-mesitylpyrazolyl ring appears at lower field (δ = 8.08 ppm) than the 5-H signals of the 3-mesitylpyrazolyl rings (δ = 7.65 ppm), as observed previously in [Tp^{Ms*}ZrCl$_3$].[6c] The second complex present in the mixture (**2**; ca. 15−30% based on Y) shows an inversion (2:1 vs. 1:2 in **1**) of the relative intensities of the 5-mesityl- and 3-mesitylpyrazolyl sets. This pattern is consistent with the formation "[YCl$_2$(Tp^{Ms**})]" (**2**) [Tp^{Ms**} = HB(3-mesitylpyrazolyl)(5-mesitylpyrazolyl)$_2^-$].[7−9] This Tp^{Ms*}/Tp^{Ms**} rearrangement indicates that the B−N bonds in these yttrium systems are labile, as also observed recently in the preparation of [NiCl(Tp^{Ms**})][6f] and the hydrolysis product [{(Tp^{Ms**})ZrCl$_2$}$_2$(μ-O)].[6c] Crystal data and refinement details for **1** are summarized in the Exp. Sect., and selected bond lengths and angles are listed in Table 1. Two independent molecules were found in the asymmetric unit of **1**, but both are quite similar, so that only the distances and the angles for one of them are listed in Table 1. As depicted in Figure 1, complex **1** is dimeric in the solid state with a structure that can be described as two pseudo-octahedral [Y(Tp^{Ms*})Cl$_3$]$^-$ anions that are bound to two Tl$^+$ cations by three bridging Cl atoms. The Cl(1) and Cl(3) atoms are doubly bridging between Y(1) and Tl(2)/Tl(2)* and the Cl(2) atom is triply bridging between Tl(2), Tl(2)* and Y(1). The Tl···Tl separation of 4.870 Å is non-bonding considering the sum of the van der Waals

radii (4.00 Å).[10] Each thallium cation is coordinated to four Cl atoms with similar distances [average Tl−Cl = 3.1283(15) Å]. Interestingly, in addition to the chloro ligands, there are six Tl···C contacts from two mesityl groups at less than 3.60 Å [C(6)*−C(8)*: 3.280−3.542 Å; C(18)−C(20): 3.374−3.565 Å]; this value is slightly lower than the sum of the van der Waals radii of Tl[10] and an aromatic ring (3.73 Å).[11] These contacts are in the upper limit of the range (3.10−3.50 Å) for Tl−C bonds in complexes with discrete arenes η^6-bonded to Tl^+.[12] Although others have considered 3.74 Å as an upper bonding limit,[13] the remaining six Tl···C(mesityl) contacts in **1** (3.635−3.859 Å and 3.696−3.850 Å for the two rings) are significantly longer and we prefer to view them as essentially non-interacting. Overall, the geometry around the thallium atoms can thus be described as distorted octahedral by considering the centroid of the η^3-mesityl ligands as a monodentate ligand [Cl(2)−Tl(2)−Ct(01)* = 157.14°; Cl(2)*−Tl(2)−Ct(02)* = 159.27°; Cl(3)−Tl(2)−Ct(01)* = 160.33°]. The average thallium−centroid distance is 3.268 Å.

The yttrium center features a distorted octahedral geometry as evidenced by the *cis*-L−Y−L angles [78.31(15)−95.29(5)°]. As expected, the N−Y−N angles involving the pyrazolyl-ring donor atoms are all smaller than 90°, allowing the face formed by three chloride ligands to open considerably. The average Y−N and Y−Cl distances of 2.439(4) and 2.579(15) Å, respectively, are comparable to those found in other yttrium−Tp^{Me2} complexes, such as [$Y(Tp^{Me2})Cl_2$(phen)][14] [2.448(6) and 2.600(2) Å, respectively]. The modest torsion-angle values in **1** [B(1)−N(1)−N(2)−Y(1) = −3.0(6)°; B(1)−N(3)−N(4)−Y(1) = 0.3(7)°; B(1)−N(5)−N(6)−Y(1) = −5.7(6)°] are diagnostic of relatively low steric congestion around the yttrium center due to the coordination of just one Tp^{Ms*} ligand to the metal center.

Conclusion

In conclusion, we have described an unusual dimeric "ate" species that features Tl^+ cations coordinated by μ^2,μ^3-bridging Cl atoms as well as two η^3-mesityl ligands. The present Tl···C contacts can be viewed as supramolecular interactions which fill the large gap in the Tl coordination sphere,[15] but they may also be the origin of the formation of this unique Y−Tl "ate" complex. Decomposition and isomerization processes, generating a free pyrazole group and an isomerized Tp^{Ms**} ligand coordinated to a lanthanide metal center, have also been seen. These new elements further show the complexity of lanthanide−Tp chemistry when using salt-elimination routes.

Experimental Section

Salt Elimination Reaction between Tl(Tp^{Ms*}) and [$YCl_3(THF)_{3.5}$]. Synthesis of [$YCl_3(Tp^{Ms*})Tl$] (1) and "[$Y(Tp^{Ms**})Cl_2$]" (2): All manipulations were performed under purified argon using standard high-vacuum Schlenk techniques or in a glovebox. Solvents were distilled from Na/benzophenone (THF) and Na/K alloy (toluene) under argon and degassed thoroughly prior to use. In a typical procedure, [$YCl_3(THF)_{3.5}$] (0.380 g, 0.85 mmol) and THF (40 mL) were introduced into a Schlenk flask and the suspension was stirred at 70 °C for 3 h. The clear solution was cooled slowly to room temperature and a solution of Tl(Tp^{Ms*})[17] (0.650 g, 0.85 mmol) in THF (30 mL) was added dropwise with a cannula over 15 min. A grayish solid precipitated immediately. The mixture was stirred for 2 h, and then it was filtered and volatiles were removed from the filtrate under vacuum. The ^{1}H NMR spectrum ([D_8]THF, 300 MHz, 20 °C) of the residue showed the absence of initial reagents and the presence of free 3-mesitylpyrazole [δ = 7.57 (s, 1 H, 5-H pz), 6.85 (s, 2 H, *m*-C_6H_2 Ms), 6.06 (s, 1 H, 4-H pz), 2.32 (s, 3 H, 4-Me Ms), 2.01 (s, 6 H, 2-,6-Me Ms) ppm], [$YCl_3(Tp^{Ms*})Tl$] (**1**) [δ = 8.08 (s, 1 H, 3-H pz), 7.69 (s, 2 H, 5-H pz), 6.97 (s, 2 H, C_6H_2 Ms), 6.82 (s, 4 H, C_6H_2 Ms), 6.10 (s, 1 H, 4-H pz), 6.00 (s, 2 H, 4-H pz), 2.36 (s, 3 H, Me Ms), 2.26 (s, 6 H, 2 Me Ms), 2.05 (s, 9 H, 3 Me Ms), 1.87 (s, 6 H, 2 Me Ms), 1.72 (s, 6 H, 2 Me Ms) ppm] and another species assigned to "[$YCl_2(Tp^{Ms**})$]" (**2**) [key resonances: δ = 8.17 (d, $J_{H,H}$ = 2.0 Hz, 2 H, 3-H pz), 7.42 (d, $J_{H,H}$ = 2.1 Hz, 1 H, 5-H pz), 6.81 (s, 2 H, C_6H_2 Ms), 6.71 (s, 4 H, C_6H_2 Ms), 5.96 (d, $J_{H,H}$ = 2.1 Hz, 2 H, 4-H pz), 5.90 (d, $J_{H,H}$ = 2.1 Hz, 1 H, 4-H pz) ppm] in a ratio of 5:2:1. The residue was extracted with toluene (2 × 40 mL) and filtered. The clear solution was left at room temperature for 48 h, during which time a colorless crystalline material precipitated. This was filtered off, washed with toluene (2 × 15 mL) and dried under vacuum to afford **1** as a white crystalline solid (0.310 g, 33%), from which X-ray quality crystals were collected. $C_{36}H_{40}BCl_3N_6TlY$ (967.22): calcd. C 44.71, H 4.17, N 8.69; found C 44.26, H 4.35, N 9.12.

Crystallographic Data for 1·2THF: $C_{88}H_{112}B_2Cl_6N_{12}O_4Tl_2Y_2$, M = 2222.78, triclinic, T = 120 K, space group $P\bar{1}$, a = 14.8421(2), b = 17.1968(3), c = 19.1037(3) Å, α = 83.200(1), β = 78.279(1), γ = 78.986(1)°, V = 4670.3(1) Å^3, Z = 2, D_c = 1.581 g·cm^{-3}, μ(Mo-K_α) = 4.896 mm^{-1}; 21392 reflections collected, 15501 unique, full-matrix least squares on F^2 refinement, R_1 = 0.0486 [$I > 2\sigma(I)$], wR_2 = 0.1060 [$I > 2\sigma(I)$] (0.1224 for all data). An orange crystal of dimensions 0.45 × 0.38 × 0.30 mm was coated with oil, mounted on a fiber and X-ray diffraction data were collected using a Nonius KappaCCD diffractometer with graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å) employing CCD scans to cover the reciprocal space up to 27.50° with 99.7% completeness. Integration of raw data yielded a total of 60449 reflections, merged into 15501 unique reflections with R_{int} = 0.0823 after applying Lorentz, polarization and absorption correction. The structure was solved by Patterson methods using SHELXS-97.[16] Atomic positions and displacement parameters, at the anisotropic level for all non-hydrogen atoms, were refined using full-matrix least-squares procedures based on F^2 using SHELXL-97.[16] Refinement of 1016 parameters using all reflections converged at R_1 = 0.0486, wR_2 = 0.1060. The locations of the largest peaks in the final difference Fourier map calculation as well as the magnitude of the residual electron densities (highest residual electron density peak of 1.2 Å^3) were of no chemical significance. The cell of **1** was found to contain four molecules of crystallization (THF). CCDC-237703 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge, CB2 1EZ, UK; Fax: + 44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

[7] Complex **2** could not be isolated in pure form (samples were still contaminated by **1**) and no elemental analysis could be run to establish if it is a neutral or an "ate" complex.

[8] Similar salt-elimination reactions using 2 equiv. of the symmetrically bonded Tl(Tp^{Ms}) [instead of Tl(Tp^{Ms*})] in THF under different conditions led systematically to mixtures of products, of which the NMR spectra in [D_8]THF indicated the presence of the isomerization complexes **1** (> 30%) and **2** (> 10%) and other unidentified products. Attempts to isolate products from these mixtures were unsuccessful.

[9] Tp^{Ms} and Tp^{Ms*} complexes of Yb^{II} have been prepared, and isomerization of Tp^{Ms} to Tp^{Ms*} has been observed to take place during the salt-metathesis process: I. Lopes, R. Dias, A. Domingos, N. Marques, *J. Alloys Compd.* **2002**, *344*, 60−64.

Synthesis and Structural Characterization of Three-Coordinate Mn^{II}, Fe^{II}, and Zn^{II} Complexes Containing a Bulky Diamide Ligand $[DippN(CH_2)_3NDipp]^{2-}$ (Dipp = 2,6-*i*$Pr_2C_6H_3$)

Keywords: Iron / Manganese / N ligands / Zinc

The reaction of $DippNH(CH_2)_3NHDipp$ (**1**) (Dipp = 2,6-*i*$Pr_2C_6H_3$) with 2 equiv. of MeLi in diethyl ether resulted in the formation of the monomeric dilithium salt $[(Dipp)N(CH_2)_3N(Dipp)][Li(OEt_2)]_2$ (**2**) in high yield. Further reactions of **2** with $MnCl_2$, $FeCl_2$, and $ZnCl_2$, respectively, afforded the complexes $[M_2\{N(Dipp)(CH_2)_3N(Dipp)\}_2]$ [M = Mn (**3**), Fe (**4**), Zn (**5**)] with three-coordinate metal centers. Complexes **2**–**5** were characterized by X-ray structural analysis. The complexes contain a nonplanar MNMN central core. The diamide ligand in complexes **3**–**5** displays a boat conformation and is both chelating and bridging, so that one of the nitrogen atoms is three-coordinate and the other four-coordinate. Complexes **3**–**5** are the first examples with diamide ligands in such a bonding mode. The magnetic investigations of compounds **3** and **4** reveal an antiferromagnetic exchange between the metal atoms.

Introduction

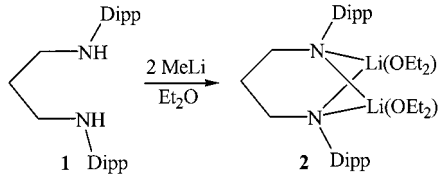
Transition metal complexes with three-coordinate metal centers are rare, since it is difficult to reach the preferred stable configurations with 16 or 18 valence electrons around the metal center using only three donor ligands.[1] Metal amide complexes are of wide interest as they show a broad range of structures and reaction types.[2] Transition metal amides, for instance, are the first examples with unusually low coordinate metal centers due to the strong M−N bonds and flexible steric properties of the amine ligands.[2b] In addition, transition metal amides are a useful hydrocarbon-soluble source of M^{n+} cations and have proved to be good starting materials to prepare other species.[3] However, reports of saturated hydrocarbon-bridged bidentate diamide ligands are rare.[2b] Considering the recent success in the synthesis of complexes of main-group elements, transition metals and lanthanides of unusual properties with the Dippnacnac ligand $[HC(CMeNDipp)_2]^-$ (Dipp = 2,6-*i*$Pr_2C_6H_3$),[4] we were interested in investigating the behavior of the bulky chelating diamide ligand $[DippN(CH_2)_3NDipp]^{2-}$, which has similar steric properties to Dippnacnac and is expected to result in interesting new organometallic chemistry.

The bulky chelating diamide ligand $[DippN(CH_2)_3NDipp]^{2-}$ was previously used by McConville and co-workers as a non-cyclopentadienyl ligand to prepare group 4 complexes that can catalyze olefin polymerization under "living" conditions.[5] Cloke and Roesky et al. have reported lanthanide complexes bearing this ligand.[6] Recently, we obtained the aluminum hydride $[DippN(CH_2)_3NDipp]AlH(NMe_3)$ and its derivatives $\{[DippNH(CH_2)_3NDipp]Al\}_2(\mu\text{-}E)_2$ (E = S, Se and Te) by hydrogen transfer from chalcogen to nitrogen.[7] Herein we describe the synthesis and structural analysis of the dilithium salt $[N(Dipp)(CH_2)_3N(Dipp)][Li(OEt_2)]_2$ (**2**) and the resulting complexes with three-coordinate Mn^{II}, Fe^{II}, and Zn^{II} of composition $[M_2\{N(Dipp)(CH_2)_3N(Dipp)\}_2]$ [M = Mn (**3**), Fe (**4**), Zn (**5**)].

Results and Discussion

Synthesis of Compounds 2−5

The lithiation of $DippNH(CH_2)_3NHDipp$ (**1**) with 2 equiv. of MeLi in diethyl ether proceeds smoothly to afford $[(Dipp)N(CH_2)_3N(Dipp)][Li(OEt_2)]_2$ (**2**) as colorless crystals in high yield (Scheme 1). The existence of the coordi-



Scheme 1

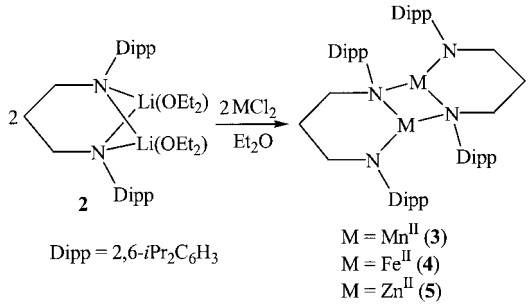
nated diethyl ether molecules was confirmed by ^{1}H NMR spectroscopy, elemental analysis, and an X-ray solid-state structural analysis. The dilithium salt **2** is soluble in diethyl ether and stable under an inert gas and is a useful reagent for metathesis reactions with metal halides.

The reaction of **2** with 1 equiv. of anhydrous $MnCl_2$, $FeCl_2$, or $ZnCl_2$, respectively, in diethyl ether at low temperature smoothly provided the corresponding dimeric compounds $[M_2\{N(Dipp)(CH_2)_3N(Dipp)\}_2]$ [M = Mn (**3**), Fe (**4**), Zn (**5**)] in good yield (Scheme 2). The same products were obtained even when 2 equiv. of MCl_2 were employed. Complexes **3**−**5** are soluble in CH_2Cl_2 and THF and have a moderate solubility in diethyl ether and toluene.



Scheme 2

Complexes **2**−**5** were characterized by EI-MS, ^{1}H NMR and IR spectroscopy and X-ray solid-state structural analysis. The molecular ion peaks of **3**−**5** in the EI mass spectra were all observed. However, the most intense peaks of these complexes show different fragments: **3**: *m*/*z* = 705 [M − CH_2NDipp]$^+$; **4**: *m*/*z* = 504 [M − N(Dipp)$(CH_2)_3$N-(Dipp)]$^+$; **5**: *m*/*z* = 456 [1/2 M]$^+$. In the the monomeric compounds {such as [N(Dipp)$(CH_2)_3$N(Dipp)]AlX·NMe_3 (X = H, F)}[7] the four isopropyl methine groups (C*H*Me_2) are not equivalent and give two resonances in the ^{1}H NMR spectra, whereas compound **5** gives four isopropyl methine resonances, which is consistent with restricted rotation about the N−C_{ipso} bond. The doublets in the range of δ = 0.16−1.36 ppm correspond to the protons of methyl groups (CH*Me*$_2$).

X-ray Solid-State Structural Analyses

The X-ray solid-state structural analyses for complexes **2**−**5** were undertaken. Crystallographic data for these complexes are given in the Exp. Sect. and selected bond lengths and angles in Tables 1 and 2.

The X-ray structural analysis of **2** (Figure 1) reveals a monomer with two three-coordinate lithium atoms. Each of the lithium atoms is bonded to two nitrogen atoms of the chelating ligand and one oxygen atom of the coordinated ether ligand. It is better to describe the coordination sphere of the Li atoms as trigonal-planar rather than trigonal-pyramidal. Two C_3N_2Li six-membered rings are formed, one of which displays a boat conformation while the other is in a chair conformation. The interplanar angle between the two central LiN_2 planes is 43.8°. The Li−N distances are in the normal range (1.94−2.15 Å).[2b] In addition, there are some very close contacts between Li(1), Li(2) and various carbon and hydrogen atoms from the chelating ligand [Li(1)−H(26a): 2.29(4) Å; Li(2)−C(2): 2.36(2) Å; Li(2)−H(2a): 2.02(4) Å]. Similar contacts have been observed in [Li(Dipp)NCH_2CH_2N(Dipp)Li]$_2$.[2b]

The X-ray solid-state structural analysis reveals that complexes **3**−**5** are isostructural and dimeric. The dimers are formed through two bridging nitrogen atoms. Compound $[Mn_2\{N(Dipp)(CH_2)_3N(Dipp)\}_2]$ (**3**; Figure 2) crystallizes in the triclinic space group $P\bar{1}$, while compounds $[Fe_2\{N(Dipp)(CH_2)_3N(Dipp)\}_2]$ (**4**; Figure 3) and $[Zn_2\{N(Dipp)(CH_2)_3N(Dipp)\}_2]$ (**5**; Figure 4) crystallize in the monoclinic space group *C*2/*c*. The central core of these compounds contains a nonplanar MNMN four-membered ring, which is in a butterfly configuration, with dihedral angles of 28.6° in **3**, 30.9° in **4**, and 35.0° in **5**. This arrangement is caused by the strain of the bulky aryl groups. Each metal atom is surrounded by three nitrogen atoms and always lies out of the plane formed by these nitrogen atoms (0.33 Å in **3**, 0.26 Å in **4**, and 0.26 Å in **5**), so that all the metal atoms are in a trigonal-pyramidal geometry. The two ligands chelate two metal atoms to fuse two six-membered MN_2C_3 rings, which display a boat conformation with the two metal atoms at the stern and the corresponding opposite carbon atoms at the bow. The metal atoms are about 0.20 Å (av. 0.17 Å in **3**, 0.22 Å in **4**, and 0.18 Å in **5**) out of the plane formed by the two carbon and two nitrogen atoms. The opposite carbon atoms are about 0.70 Å (av. 0.72 Å in **3**, 0.71 Å in **4**, and 0.73 Å in **5**) out of the plane.

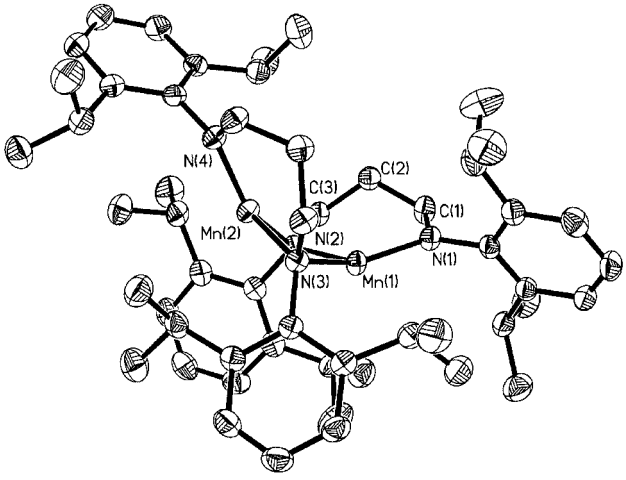

Figure 2. ORTEP drawing for **3** (50% probability ellipsoids)

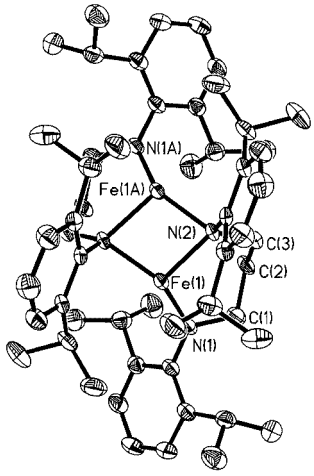

Figure 3. ORTEP drawing for **4** (50% probability ellipsoids)

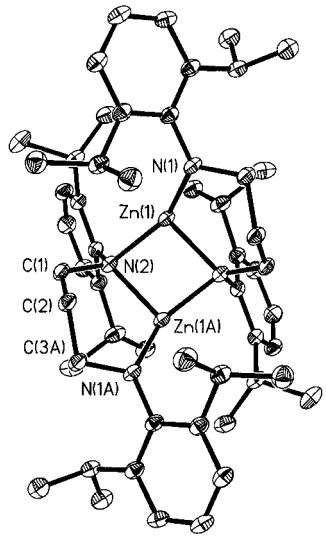

Figure 4. ORTEP drawing for **5** (50% probability ellipsoids)

The ligand in complexes **3**−**5** is both chelating and bridging, so that one of the nitrogen atoms is three-coordinate and the other four-coordinate. To the best of our knowledge, complexes **3**−**5** are the first examples with the diamide ligands in such a bonding mode. The terminal M−N distances in these complexes (Mn−N: 1.93 Å; Fe−N: 1.88 Å; Zn−N: 1.85 Å) are significantly shorter than those of the corresponding bridging ones (Mn−N: 2.10 Å; Fe−N: 2.05 Å; Zn−N: 2.04 Å). The M−N distances decrease in the order Mn−N > Fe−N > Zn−N, while the N−M−N angles increase in the order N−Mn−N < N−Fe−N < N−Zn−N, which is consistent with the relative sizes of the cations: $Mn^{2+} > Fe^{2+} > Zn^{2+}$.[8] The terminal and bridging M−N distances in **3** and **4** are about 0.06 Å shorter than the corresponding distances in the dimeric silylamides $Mn_2[N(SiMe_3)_2]_4$ [9] and $Fe_2[N(SiMe_3)_2]_4$.[10] The terminal M−N bond lengths in complexes **3** and **4** are even shorter than those found in amides with two coordinate metal centers $[Mn\{N(SiMePh_2)_2\}_2]$ (Mn−N 1.99 Å) and $[Fe\{N(SiMe_2Ph)_2\}_2]$ (Fe−N 1.92 Å).[11] This possibly results from the strong N→Si interaction in the silylamide.[10]

The M−M distances and the M−N−M angles in complexes **3** and **4** are 2.69 Å and 79.2°, and 2.56 Å and 77.0°, respectively, which indicates that there is some contact between the metal centers. The M−M distances are significantly shorter than those in the commonly planar MNMN four-membered rings.[9,10]

Magnetic Susceptibility Measurements

The temperature dependence of the molar magnetic susceptibility, χ_m and $\chi_m T$, for compounds **3** and **4** are displayed in Figures 5 and 6, respectively. The plots of $\chi_m T(T) - T$ for the two compounds indicate a magnetic behavior with an antiferromagnetic exchange interaction between the nearest neighboring spins. The value of $\chi_m T$ at 300 K is estimated to 6.82 emu·K·mol^{-1} for **3** and 5.16 emu·K·mol^{-1} for **4**. These values are lower than those of

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

the spin-only value ($S = 5/2$ for Mn^{II} dimer and $S = 2$ for Fe^{II} dimer). This reveals that there is an antiferromagnetic exchange interaction between the two metal atoms in both compounds.

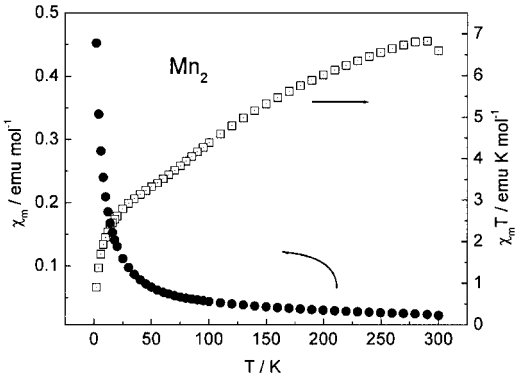

Figure 5. Plots of $\chi_m(T) - T$ and $\chi_m T(T) - T$ for compound **3**

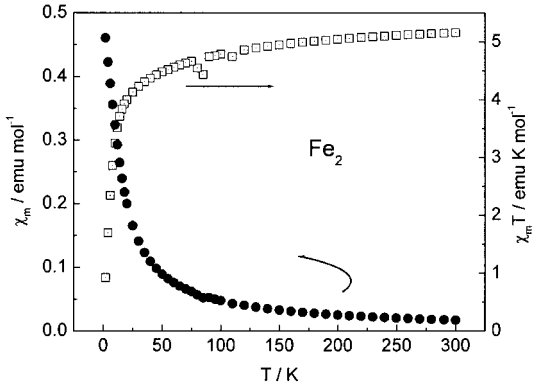

Figure 6. Plots of $\chi_m(T) - T$ and $\chi_m T(T) - T$ for compound **4**

In summary, we have successfully synthesized and characterized novel dimeric Mn^{II}, Fe^{II}, and Zn^{II} complexes, which contain three-coordinate metal centers by using the bulky diamide ligand $DippNH(CH_2)_3NHDipp$. In complexes **3**−**5** the ligand is both chelating and bridging, so that one of the nitrogen atoms is three-coordinate and the other four-coordinate. Complexes **3**−**5** are the first examples with diamide ligands in such a bonding mode.

Experimental Section

General: All reactions were performed using standard Schlenk and dry-box techniques. Solvents were appropriately dried and distilled under dinitrogen prior to use. ^1H and ^7Li NMR spectra were recorded with Bruker AM-250, AM-300 and AM-500 instruments. The chemical shifts are reported in ppm with reference to external standards: $SiMe_4$ for ^1H and $LiCl/D_2O$ for ^7Li. The magnetic susceptibility measurements were carried out with a Quantum-Design-MPMS-5S SQUID magnetometer in the range from 300 K to 2 K. The powdered samples were placed in a gel bucket and fixed in a nonmagnetic sample holder. Elemental analyses were performed by the Analytisches Labor des Instituts für Anorganische Chemie der Universität Göttingen. Mass spectra were recorded with a Finnigan Mat 8230. IR spectra were measured with a Bio-Rad Digilab FTS-7 spectrometer as Nujol mulls between KBr plates. [DippNH$(CH_2)_3$NH(Dipp)] (**1**) was prepared according to a literature method.[5c]

[N(Dipp)$(CH_2)_3$N(Dipp)][Li(OEt_2)]$_2$ (2): MeLi (5.5 mL, 1.6 M in diethyl ether, 8.8 mmol) was added at −78 °C to a diethyl ether (35 mL) solution of **1** (1.58 g, 4 mmol). The mixture was warmed to room temperature and stirred for an additional 14 h. The precipitate was removed by filtration. The filtrate was concentrated to about 10 mL and kept at −26 °C for 24 h to give colorless crystals. The crystals were collected by filtration and the mother liquor was concentrated to about 4 mL and kept at −26 °C for 24 h to give colorless crystals. Total yield: 2.04 g (92%). M.p. 110 °C (dec). ^1H NMR (250 MHz, C_6D_6): $\delta = 0.95$ (t, 12 H, $J = 7.1$ Hz, MeCH$_2$O), 1.23 (d, 12 H, $J = 6.8$ Hz, Me_2CH), 1.34 (d, 12 H, Me_2CH), 1.79 (br., 2 H, NCH$_2CH_2$), 3.00−3.25 (m, 4 H, $J = 7.2$ Hz, NCH_2CH$_2$), 3.12 (t, 8 H, $J = 7.0$ Hz, MeCH$_2$O), 3.38 (sept, 4 H, $J = 6.9$ Hz, CHMe$_2$), 6.91−7.22 (m, C_6H_3, 6 H) ppm. ^7Li NMR (300 MHz, C_6D_6): $\delta = 1.90$ ppm. $C_{35}H_{60}Li_2N_2O_2$ (554.75): calcd. C 75.78, H 10.90, N 5.05; found C 75.92, H 11.02, N 4.85.

[Mn$_2${N(Dipp)$(CH_2)_3$N(Dipp)}$_2$] (3): A solution of **2** (1.1 g, 2 mmol) in diethyl ether (10 mL) was added to a suspension of $MnCl_2$ (0.25 g, 2 mmol) in diethyl ether (30 mL) at −78 °C. The mixture was warmed to room temperature and stirred for additional 14 h. The precipitate was removed by filtration and extracted with dichloromethane (10 mL). A yellow-green solid was obtained by removing the solvent in vacuo. The mother liquor was concentrated to about 10 mL and yellow-green crystals were obtained at room temperature after 5 d. Total yield: 0.64 g (72%). M.p. 220 °C (dec). EI-MS: *m/z* (%) = 894 (49) $[M]^+$, 705 (100) $[M - CH_2NDipp]^+$, 447 (68) $[1/2\ M]^+$. $C_{54}H_{80}Mn_2N_4$ (895.10): calcd. C 72.39, H 8.94, N 6.26; found C 72.15, H 8.94, N 6.17. IR (KBr, nujol mull): $\tilde{\nu}$ = 1426 (w), 1308 (w), 1260 (w), 1243 (w), 1169 (w), 1092 (w), 1073 (w), 1041(w), 1019 (w), 857 (w), 800 (w), 786 (w), 722 (w) cm^{-1}.

[Fe$_2${N(Dipp)$(CH_2)_3$N(Dipp)}$_2$] (4): A solution of **2** (1.1 g, 2 mmol) in diethyl ether (10 mL) was added to a suspension of $FeCl_2$ (0.25 g, 2 mmol) in diethyl ether (30 mL) at −78 °C. The mixture was warmed to room temperature and stirred for additional 14 h. The precipitate was removed by filtration. The dark-blue filtrate was concentrated to about 10 mL and crystals of **4** were obtained at room temperature after 5 d. Yield: 0.67 g (75%). M.p. 228 °C (dec). EI-MS: *m/z* (%) = 896 (68) $[M]^+$, 504 (100) $[M - N(Dipp)(CH_2)_3N(Dipp)]^+$, 448 (13) $[1/2\ M]^+$. $C_{54}H_{80}Fe_2N_4$ (896.92): calcd. C 72.25, H 8.92, N 6.24; found C 72.08, H 8.63, N 6.13. IR (KBr, nujol mull): $\tilde{\nu}$ = 1403 (w), 1308 (w), 1262 (w), 1201 (w), 1155 (w), 1094 (m), 1030 (m), 973 (w), 933 (w), 918 (w), 890 (w), 801 (m), 750 (w), 722 (m), 658 (w), 597 (w), 564 (w), 540 (w), 465 (w) cm^{-1}.

[Zn$_2${N(Dipp)$(CH_2)_3$N(Dipp)}$_2$] (5): The procedure is the same like that described for **3**. Yield: 0.72 g (79%). M.p. 223 °C (dec). EI-MS: *m/z* (%) = 916 (7) $[M]^+$, 456 (100) $[1/2\ M]^+$. ^1H NMR (500 MHz, $CDCl_3$): $\delta = 0.16$ (d, 6 H, $J = 6.8$ Hz, Me_2CH), 0.43 (d, 6 H, Me_2CH), 0.99 (d, 6 H, Me_2CH), 1.21−1.28 (m, 24 H, Me_2CH), 1.36 (d, 6 H, Me_2CH), 2.20−2.34 (m, 4 H, $J = 9.7$ Hz, NCH$_2CH_2$), 2.71(t, 2 H, $J = 7.1$ Hz, NCH_2CH$_2$), 2.81 (m, 2 H, $J = 6.9$ Hz, CHMe$_2$), 3.02 (t, 2 H, NCH_2CH$_2$), 3.12 (m, 4 H, NCH_2CH$_2$), 3.27 (m, 2 H, CHMe$_2$), 3.72 (m, 2 H, NCH_2CH$_2$), 3.97 (t, 2 H, NCH_2CH$_2$), 4.04 (m, 2 H, CHMe$_2$), 3.72 (m, 2 H, CHMe$_2$), 6.78−7.45 (m, 12 H, C_6H_3) ppm. $C_{54}H_{80}N_4Zn_2$ (915.96): calcd. C 70.75, H 8.73, N 6.11; found C 70.34, H 8.68, N 5.85. IR

X-ray Crystallography: Crystallographic data for **2**−**4** (Table 3) were collected with a Stoe−Siemens−Huber four-circle diffractometer coupled to a Siemens CCD area-detector with graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å) and for **5** with a Bruker three-circle diffractometer equipped with a SMART 6000 CCD area-detector using Cu-K_α radiation (λ = 1.54178 Å). All structures were solved by direct methods (SHELXS-97)[12] and refined against F^2 using SHELXL-97.[13] All non-hydrogen atoms were refined anisotropically. The central carbon atom C(2) in **2** is disordered over two positions C(2) and C(2′), which were isotropically refined with site-occupation factors of 0.34 and 0.66, respectively. CCDC-233452 (**2**), -233453 (**3**), -233454 (**4**), and -233455 (**5**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: + 44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Mono- and Dinuclear Rhenium Polyhydride Complexes Bearing the Chelating Ligand 1,2-Bis(dicyclohexylphosphanyloxy)ethane

Sandra Bolaño,[a] Jorge Bravo,*[a] and Soledad García-Fontán*[a]

Dedicated to the memory of Dr. Juan Carlos del Amo[‡]

Keywords: Rhenium / Hydrido ligands / P ligands / Fluxionality

Variable-temperature NMR spectroscopic studies of new rhenium polyhydride compounds of the type $[ReH_7(dcype)]$ (**1**), $[Re_2H_8(dcype)_2]$ (**3**) and $[ReH_5(dcype)L]$ (**5a–f**) [dcype = $Cy_2PO(CH_2)_2OPCy_2$; L = $PPh_n(OR)_{3-n}$, n = 0–2, R = Me, Et] show them to be highly fluxional classical hydride complexes. In the case of the ethoxy compounds **5b**, **5d** and **5f**, three hydride interchange processes were observed in the temperature range 283–173 K and their activation parameters were determined by NMR line-shape analysis. A mechanism is proposed for each. Protonation of **1** and **5** with $HBF_4{\cdot}OMe_2$ gave the nonclassical hydrides $[ReH_8(dcype)]BF_4$ (**2**) and $[ReH_6(dcype)L]BF_4$ (**6**) which are relatively stable. Compound **2** decomposes at 273 K in solution releasing H_2,whereas compound **6** can be stored at room temperature for more than 24 h without decomposition. Protonation of **3** with $HBF_4{\cdot}OMe_2$ gave the classical dinuclear hydride $[Re_2H_9(dcype)_2]BF_4$.

Introduction

Transition metal polyhydride complexes are notable for exhibiting H−H distances that range from 1.6 Å or more in the case of "classical" hydrides to 0.8−1.0 Å in "nonclassical" hydrides,[1] with intermediate distances having been observed in "elongated dihydrogen" or "stretched dihydride" complexes[2] such as $[ReH_7\{P(p\text{-tolyl})_3\}_2]$, in which there is an H−H distance of 1.35 Å.[3] The exact length of the H−H bond in such elongated η^2-H_2 ligands appears to depend heavily on the nature of the non-hydrogen ligand {e.g. the phosphane ligand in the $[ReH_7\{P(C_6H_4\text{-}p\text{-}X)_3\}_2]$ family to which the above compound belongs and in other $[ReH_7(PR_3)_2]$ compounds[4]} which can also have a marked influence on the stability of the complex[5] and on properties such as the susceptibility to protonation of the hydride ion in $[ReH_2(CO)(NO)(PR_3)_2]$.[6] Structures with elongated dihydrogen have been regarded as the result of a process of oxidative addition of dihydrogen that has been arrested at an intermediate stage but theoretical calculations have suggested, alternatively, that two of their hydrogen atoms move freely in a large region of the coordination sphere of the metal atom.[7]

Transition metal polyhydrides are also notable for their fluxionality. Because of their intermediate electronegativity, the nondirectionality of the 1s orbital and the absence of steric hindrance, the hydrogen ligands readily switch positions. The nature of these exchange processes and their thermodynamics can be explored by means of variable-temperature NMR spectroscopy.

Complexes of rhenium polyhydrides have proved useful in organometallic chemistry for the activation of C−H bonds by various routes.[8] They can also undergo a variety of thermal, photochemical or oxidative substitution reactions in which H_2 is replaced by a two-electron donor.[9] Although many rhenium polyhydride complexes of phosphanes are known, less attention has been given to complexes of phosphites $[P(OR)_3]$, phosphonites $[PR_1(OR)_2]$ and phosphinites $[PR_2(OR)_1]$. These ligands are all weaker σ-donors and stronger π-acceptors than phosphanes[10] and can therefore be expected to have different influences on the above-mentioned ligand-sensitive properties of the complex. Further control over these properties might come from the use of chelating ligands which afford two or more conformers, if it can be proved possible to favour one or another of these different forms.[11]

In previous work we synthesised, characterised and investigated the protonation of rhenium polyhydride complexes of the chelating ligand 1,2-bis(diphenylphosphanyloxy)-

ethane.[12] Here we describe the ligand dependence of the properties of an analogous series in which the ligand is 1,2-bis(dicyclohexylphosphanyloxy)ethane (dcype), with or without a monodentate phosphorus ligand (a methyl or ethyl phosphite, phosphonite or phosphinite).

Results and Discussion

Synthesis and Properties of $[ReH_7(dcype)]$ (1) and $[ReH_8(dcype)]BF_4$ (2)

Treatment of the complex $[ReOCl_2(OMe)(dcype)]$ (prepared as previously reported[13]) with a 30-fold excess of $NaBH_4$ in absolute ethanol produced the violet complex **1** which is stable in air at room temperature in both the solid state and solution. Its IR spectrum shows two medium bands at 1933 and 1956 cm^{-1} which are attributable to ν(Re−H) vibrations.[14]

$[ReH_7\{Cy_2PO(CH_2)_2OPCy_2\}]$ **1** $[ReH_8\{Cy_2PO(CH_2)_2OPCy_2\}](BF_4)$ **2**

$[Re_2H_8\{Cy_2PO(CH_2)_2OPCy_2\}_2]$ **3** $[Re_2H_9\{Cy_2PO(CH_2)_2OPCy_2\}_2](BF_4)$ **4**

$[ReH_5\{Cy_2PO(CH_2)_2OPCy_2\}\{PPh_n(OR)_{3-n}\}]$ **5**

R = Me		R = Et	
$n = 0$	**5a**	$n = 0$	**5b**
$n = 1$	**5c**	$n = 1$	**5d**
$n = 2$	**5e**	$n = 2$	**5f**

$[ReH_6\{Cy_2PO(CH_2)_2OPCy_2\}\{PPh_n(OR)_{3-n}\}](BF_4)$ **6**

R = Me		R = Et	
$n = 0$	**6a**	$n = 0$	**6b**
$n = 1$	**6c**	$n = 1$	**6d**
$n = 2$	**6e**	$n = 2$	**6f**

At room temperature, the ^1H NMR spectrum of **1** in C_6D_6 shows the hydride resonance as a seven-proton triplet at $\delta = -6.55$ ppm ($J_{PH} = 17$ Hz), while the $^{31}P\{^1H\}$ NMR spectrum displays a singlet at $\delta = 157.0$ ppm which becomes an octuplet when an off-resonance experiment is performed [$J_{PH(residual)} = 15$ Hz]. These results confirm the number of hydride ions coordinated to the rhenium atom and show the magnetic equivalence of the two phosphorus atoms in the bidentate ligand. When the NMR experiments were performed at 183 K in CD_2Cl_2, both the ^1H and the ^{31}P signals broadened slightly which can be seen as reflecting a step towards resolution of a very fast fluxional process which renders the hydrido ligands equivalent. The value of T_1(min) at 400 MHz as measured by the standard inversion-recovery method is 88 ms at 217 K, confirming the classical nature of this complex.[1c]

Treatment of a solution of compound **1** in CD_2Cl_2 with 2 equiv. of $HBF_4{\cdot}OMe_2$ in an NMR tube at 183 K yielded the nonclassical polyhydride complex $[ReH_8(dcype)]BF_4$ (**2**).[15] At that temperature its $^{31}P\{^1H\}$ NMR spectrum shows a single very broad signal at $\delta = 144.7$ ppm, while a broad signal at $\delta = -5.38$ ppm in its ^1H NMR spectrum corresponds to the hydrido ligands. This cationic complex is therefore, like compound **1**, stereochemically nonrigid on the NMR time scale. The value of T_1(min) of this signal at 400 MHz is 13 ms at 226 K (Figure 1), denoting the presence of at least one dihydrogen ligand.

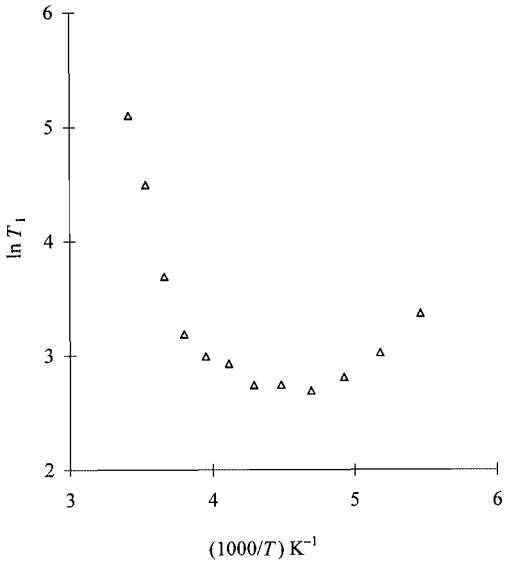

Figure 1. Plot of ln T_1 (CD_2Cl_2, 400 MHz) versus 1000/T for **2**

Between 183 and 273 K, the ^1H NMR spectrum of **2** shows just a slight sharpening of its signals, but between 273 and 293 K the hydride signal becomes a broad quintuplet integrating to nine protons ($J_{PH} = 8$ Hz) and a new singlet appears at $\delta = 4.6$ ppm which is attributable to H_2 (Figure 2).

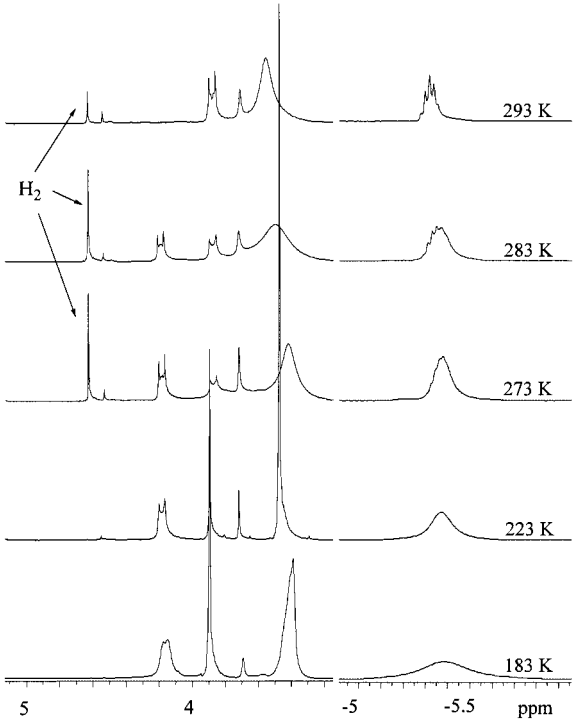

Figure 2. Selected regions of the ^1H NMR spectra obtained at various temperatures following protonation of $[ReH_7(dcype)]$ **(1)** with $HBF_4{\cdot}OMe_2$ in CD_2Cl_2

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

In the $^{31}P\{^1H\}$ NMR spectrum, the broad signal at δ = 144.7 ppm sharpens when the temperature is raised and between 273 and 293 K is progressively replaced by a new singlet at δ = 151.3 ppm (Figure 3). This signal remains unaltered when the sample is maintained at 293 K for 24 h.

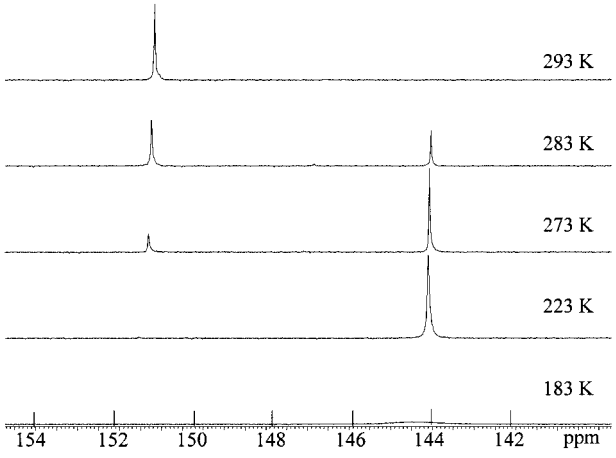

Figure 3. $^{31}P\{^1H\}$ NMR spectra obtained at various temperatures following protonation of [ReH_7(dcype)] **(1)** with an excess of $HBF_4{\cdot}OMe_2$ in CD_2Cl_2

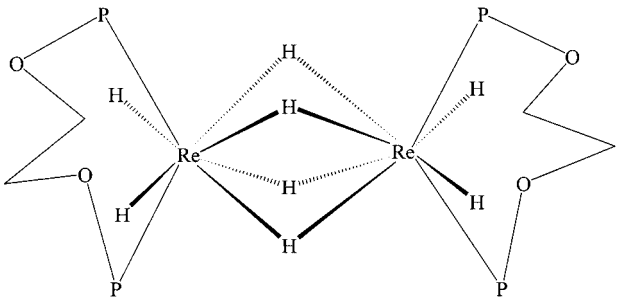
The spectroscopic features observed at room temperature coincide with those of [Re_2H_9(dcype)$_2$]BF_4 (**4**) (see next subsection). It seems likely that at temperatures above 273 K the dinuclear compound [Re_2H_8(dcype)$_2$] (**3**) is formed from the nonclassical compound **2** with release of H_2 and immediately reacts with the excess $HBF_4{\cdot}OMe_2$ which is present in solution, thus yielding compound **4**.

Synthesis and Properties of [Re_2H_8(dcype)$_2$] (3) and [Re_2H_9(dcype)$_2$]BF_4 (4)

Heating of a solution of the heptahydride **1** to reflux in toluene for 24 h[14] resulted in the precipitation of a yellow solid with analytical and spectroscopic data in accordance with the formulation [Re_2H_8(dcype)$_2$] (**3**). The $^{31}P\{^1H\}$ NMR spectrum of a solution of **3** in CD_2Cl_2 exhibits a single singlet at δ = 162.4 ppm showing the magnetic equivalence of the four P nuclei, while the ^1H NMR spectrum shows an eight-proton quintuplet at δ = −7.37 ppm ($^2J_{PH}$ = 9 Hz). The postulated structure of this compound (Scheme 1) has four bridging and four terminal H atoms as has been described for similar systems.[10a,16]



Scheme 1

Unfortunately, the poor solubility of compound **3** in dichloromethane prevented variable-temperature (VT) NMR spectroscopy. However, treatment of a suspension of **3** in CD_2Cl_2 in an NMR tube at 174 K with an excess of $HBF_4{\cdot}OMe_2$ resulted in the disappearance of the precipitate and the appearance of new NMR signals [$^{31}P\{^1H\}$ NMR: δ = 151.9 ppm (s); ^1H NMR: δ = −5.61 ppm (br. s)] corresponding to a protonated compound, **4**, which was amenable to a VT NMR study. Raising of the temperature from 174 to 293 K converted the broad singlet in the hydride region into a quintuplet (J_{PH} = 8 Hz) which remained unaltered for several days. There was no evidence of evolution of H_2 gas. The T_1(min) value for the hydride signal at 400 MHz was 94 ms at 239 K showing the classical nature of this compound. These findings suggest the formulation (μ-H_3) [Re_2H_9(dcype)$_2$]BF_4 indicating protonation of a hydride bridge as proposed for a similar system.[10a]

Syntheses and Properties of [ReH_5(dcype)L] (5a−f) and [ReH_6(dcype)L]BF_4 (6a−f) (L = $PPh_n(OR)_{3-n}$, n = 0−2, R = Me, Et)

Treatment of compound **1** with the monodentate ligands L = $PPh_n(OR)_{3-n}$ (n = 0−2, R = Me, Et) yielded the pentahydrides [ReH_5(dcype)L] as solids which are stable in air. Their IR spectra exhibit 3−4 bands between 1895 and 2000 cm^{-1} which correspond to Re−H stretching vibrations. Room-temperature ^1H NMR spectra of CD_2Cl_2 solutions of these compounds display, at high field (δ = −7 to −8 ppm), a double triplet which integrates to five protons. $^{31}P\{^1H\}$ NMR spectra show a doublet and a triplet in a 2:1 intensity ratio which are attributable to the dcype and L ligands, respectively, and form an AX_2 system. These spectroscopic features reflect fluxional processes which make the hydride nuclei equivalent. When the ^1H NMR spectra were recorded with decoupling of the ^{31}P nuclei, the hydride signals became singlets, showing the absence of coupling among the hydrido ligands. As the number of OR groups in the monodentate ligand L increased, the hydride signal shifted upfield in response to the increased electron-withdrawing character of L.

As representative examples of the VT NMR spectra of compounds **5**, Figures 4 and 5 (a) show the $^{31}P\{^1H\}$ spectrum and the hydride region of the $^1H\{^{31}P\}$ spectrum of [ReH_5(dcype){$P(OEt)_3$}] (**5b**). As was mentioned above, at 298 K this compound like other transition metal polyhydrides[17] shows marked fluxionality. As the temperature is lowered from 298 K to 198 K, the triplet observed at δ = 145 ppm in the $^{31}P\{^1H\}$ NMR spectrum becomes a double doublet in which the outer peaks are less intense than the inner ones, indicating that the coupling constants between the P nucleus of the monodentate ligand and the two dcype P nuclei have different signs.[18] At the same time, the doublet at δ = 157.5 ppm first becomes a single broad hump (at 228 K) and then a broad singlet and a broad doublet which narrows progressively, showing the transition from an AX_2 to an AMX system. Lowering of the temperature below 198 K broadens all these signals which probably reflects the initial stages of the freezing of the interconversion equilib-

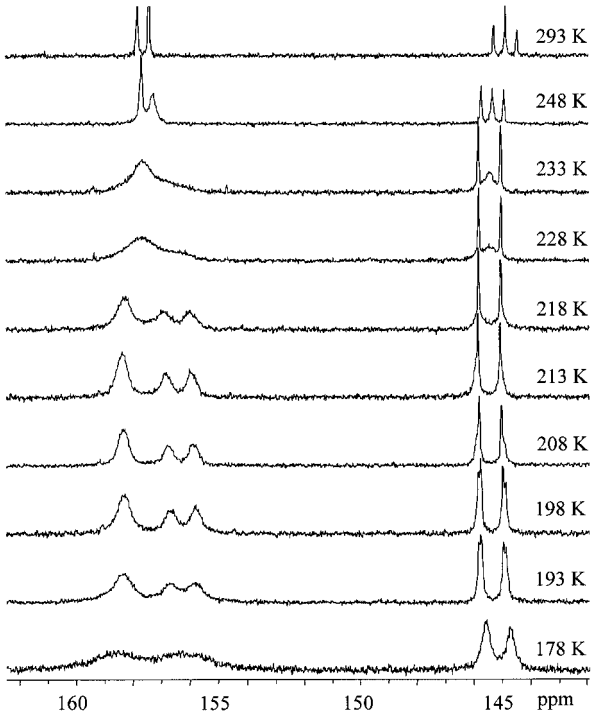

Figure 4. $^{31}P\{^{1}H\}$ NMR spectra of compound **5b** at various temperatures

rium between the conformers of the chelate ring of the bidentate ligand.

Their VT $^{1}H\{^{31}P\}$ NMR spectra [Figure 5, a) shows that of **5b**] show compounds **5** to be more rigid than the analogous complexes of 1,2-bis(diphenylphosphanyloxy)-ethane,[12] since in most cases there is a separate signal for each hydrido ligand at the lowest temperature attainable. This afforded an opportunity to investigate the interchange processes in which the hydrido ligands are involved. From 198 to 173 K the five signals become slightly broader (for example, the signal of **5b** at $\delta = -8.40$ ppm broadens from $W_{1/2} = 16$ Hz to $W_{1/2} = 38$ Hz) which is in keeping with the behaviour of the ^{31}P NMR signals and is likewise attributable to the initial stages of the freezing of the chelate ring conformer interconversion. As the temperature is progressively increased above 198 K, three signals ($\delta = -6.50$, -8.09 and -10.19 ppm in the spectrum of **5b**) coalesce to form a signal so broad that at 218 K it disappears into the baseline. Meanwhile, at 213 K the two remaining signals (located at $\delta = -8.40$ and -6.80 ppm in the case of **5b**) also begin to coalesce, suggesting the existence of a second interchange process involving the other two hydrido ligands. Finally, a third process which makes all five protons equivalent, appears at 233 K and results in the room-temperature spectrum showing a single signal which for **5b** is located at $\delta = -8.00$ ppm.

Plausible mechanisms for the above processes are indicated in Scheme 2. Cyclic interchange of three hydride ions defining one of the triangular faces of a distorted dodecahedral coordination polyhedron, as proposed by Crabtree et al.[19] for $[ReH_5(PPh_3)_2(py)]$, may account for the lowest-temperature process. The second process, which was not observed in the case of Crabtree's complex, may be the interchange of the other two protons. Finally, the equivalence of all five protons at high temperature may be due to the pseudorotation illustrated in Scheme 2 (b).

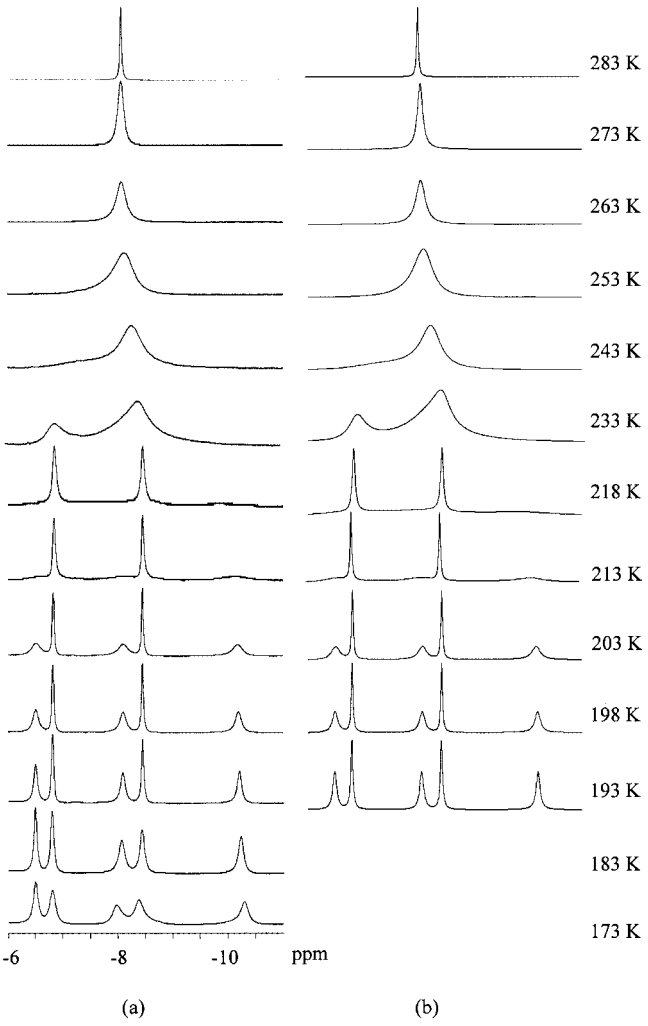

Figure 5. The observed (a) and simulated (b) hydride region of the $^{1}H\{^{31}P\}$ NMR spectra of compound **5b** at various temperatures

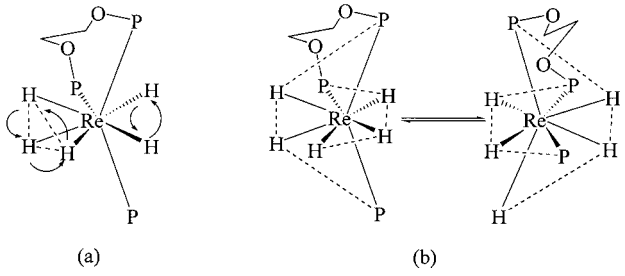

Scheme 2

Line-shape analysis performed using g NMR software[20] [Figure 5, b) shows the hydride region of the simulated VT ^{1}H NMR spectrum of **5b**] allowed us to calculate the thermodynamic parameters of the above interchange processes from the Eyring plots shown in Figure 6. Table 1 lists the results for the series of ethoxy compounds **5b**, **5d** and

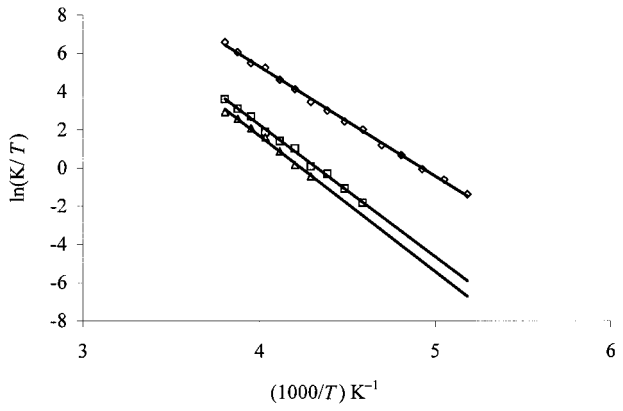

Figure 6. Eyring plots for the low- (open diamonds), medium- (open squares) and high-temperature (open triangles) interchange processes

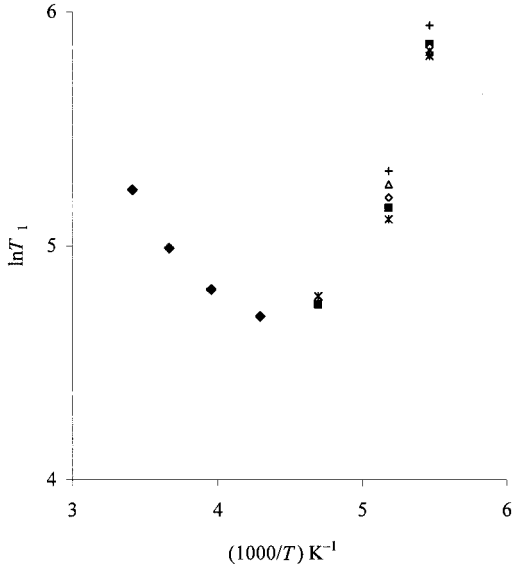

Figure 7. Plots of $\ln T_1$ values vs. temperature for the hydride signals of compound **5b** in CD_2Cl_2, at 400 MHz; solid diamonds indicate the signal at $\delta = -8.15$ ppm (fast-exchange motion), solid squares the signal at $\delta = -6.82$ ppm; * the signal at $\delta = -8.45$ ppm, triangles the signal at $\delta = -6.51$ ppm, open diamonds the signal at $\delta = -8.09$ ppm; + the signal at $\delta = -10.19$ ppm

5f. The activation energy of each process shows a clear trend, falling as the donor capacity of L increases.

Figure 7 shows plots of $\ln T_1$ against the temperature for the hydride signals of **5b** in CD_2Cl_2 at 400 MHz. At about the lowest coalescence temperature, all five signals have similar T_1 values of about 110 ms, values which increase as the temperature is lowered further. Similar behaviour is exhibited by the rest of compounds **5**, with the minimum T_1 values listed in Table 2. These compounds can, accordingly, all be regarded as classical in nature.

Table 2. T_1(min.) data at 400 MHz for compounds **5a**−**f** and **6a**−**f**

Compound	T [K]	T_1 [ms]
$[ReH_5(dcype)\{P(OMe)_3\}]$ (**5a**)	227	114

$[ReH_4(\eta^2\text{-}H_2)(dcype)\{PPh_2(OEt)\}]^+$ (**6f**)	226	32

Protonation of compounds **5a**−**f** with $HBF_4{\cdot}O_2Me$ at 183 K in CD_2Cl_2 yielded the cationic complexes $[ReH_6(dcype)L]^+$ (**6a**−**f**) which in view of their T_1(min.) values (24−42 ms at 400 MHz) (Table 2) must each contain at least one dihydrogen ligand.[21] As a result of their marked fluxionality, their ^1H NMR spectra show single broad hydride resonances between $\delta = -5$ ppm and −6 ppm (Table 3) at 183 K. As the temperature is raised to 293 K, these signals become broad quadruplets (**6a**−**d**) or double triplets (**6e**,**f**). These compounds are fairly stable, showing the first sign of decomposition [loss of H_2(g)] only when kept at room temperature for more than 24 h. As reported for the related compound $[ReH_6\{Ph_2PO(CH_2)_2OPPh_2\}]BF_4$,[12] their thermal stability increases with the electron-withdrawing character of the monodentate phosphorus ligand L. When they were treated with Et_3N, the starting pentahydrides **5a**−**f** were obtained. At 183 K the $^{31}P\{^1H\}$ NMR spectra of the compounds show two broad signals which resolve into a typical AX_2 system when the temperature is raised (see Table 3).

Conclusions

The new rhenium polyhydride compounds $[ReH_7(dcype)]$ (**1**), $[Re_2H_8(dcype)_2]$ (**3**) and $[ReH_5(dcype)L]$ (**5a**−**f**) [dcype =

[a] In CD_2Cl_2 at 400 MHz. [b] Cyclohexyl and phenyl proton resonances are omitted. [c] Temperature 174 K. [d] Temperature 233 K.

$Cy_2PO(CH_2)_2OPCy_2$; L = $PPh_n(OR)_{3-n}$, n = 0−2, R = Me, Et] are all highly fluxional classical hydride complexes but the combination of both the chelating ligand dcype and the monodentate ligand L in compounds **5** results in pentahydrides that are rigid enough to allow investigation of the various hydride interchange processes and calculation of the corresponding energy barriers. In contrast to other rhenium pentahydride systems, for which two interchange processes have been proposed (cyclic permutation of three hydride ions and a pseudorotation),[19] compounds **5** show signs of three processes, the third being the interchange of two hydride ions. Protonation of pentahydrides **5** with $HBF_4{\cdot}OMe_2$ provided the relatively stable dihydrogen complexes $[ReH_6(dcype)L]BF_4$ (**6**) which can be stored at room temperature for more than 24 h without decomposition.

Experimental Section

General Methods: All operations were carried out under argon using standard Schlenk techniques. Solvents were purified by distillation from the appropriate drying agents and degassed before use.[22] All other reagents and chemicals were reagent grade and, unless otherwise stated, were used as received from commercial suppliers. The ligand $Cy_2PO(CH_2)_2OPCy_2$ (dcype) and the complex $[ReOCl_2(OMe)(dcype)]$ were prepared as described in the literature.[13] Deuterated solvents for NMR measurements (Merck and Aldrich) were dried with molecular sieves (4 Å). Combustion C,H analyses were performed with a Fisons EA-1108 apparatus. NMR spectra were recorded with a Bruker AMX 400 spectrometer. Chemical shifts are reported in ppm relative to tetramethylsilane and were calibrated against the residual solvent resonance for ^{1}H. Peak positions in ^{31}P{^{1}H} spectra were measured relative to external H_3PO_4 (85%) with downfield shifts considered positive. Variable-temperature spin-lattice relaxation times T_1 were determined in deuterated dichloromethane by the inversion-recovery method using a standard 180°−τ−90° pulse sequence and 16 different values of τ at each temperature. Infrared spectra (IR) of samples in KBr pellets were recorded with a Bruker Vector IFS28 FT spectrometer.

$[ReH_7(dcype)]$ (1): An excess of $NaBH_4$ (0.30 g, 7.91 mmol) in ethanol (20 mL) was added to a suspension of $[ReOCl_2(OMe)(dcype)]$ (0.20 g, 0.26 mmol) in ethanol (10 mL). After 6 h of vigorous stirring, the solvent was removed under vacuum and the product was extracted with benzene (30 mL). This solution was concentrated in vacuo and the oil obtained was treated with ethanol (5 mL) giving a tan solid which was filtered, washed with ethanol and dried under vacuum (0.127 g, 75% yield). $C_{26}H_{55}O_2P_2Re$ (648.32): calcd. C 48.12, H 8.5; found C 47.70, H 8.6. IR (KBr pellets): $\tilde{\nu}_{(Re-H)}$ = 1933 (m), 1956 (m) cm^{-1}. ^{1}H NMR (C_6D_6, 400 MHz): δ = −6.55 (t, $J_{P,H}$ = 17 Hz, 7 H, Re*H*), 1.10−2.20 (m, 44 H, Cy), 3.8 [m, 4 H, −$(CH_2)_2$−] ppm. ^{31}P{^{1}H} NMR (C_6D_6, 161 MHz): δ = 157.0 (s) ppm.

$[Re_2H_8(dcype)_2]$ (3): When compound **1** (0.10 g, 0.10 mmol) was dissolved in toluene (10 mL) and heated to reflux for 24 h, a yellow solid was obtained. This solid was filtered and dried under vacuum (0.08 g, 80% yield). $C_{52}H_{104}O_4P_4Re_2$ (1289.70): calcd. C 48.43, H 8.13; found C 48.01, H 7.98. IR (KBr pellets): $\tilde{\nu}_{(Re-H)}$ = 2012 (w), 2028 (w) cm^{-1}. ^{1}H NMR (CD_2Cl_2, 400 MHz): δ = −7.37 (quint, $J_{P,H}$ = 9 Hz, 8 H, Re*H*), 0.70−1.94 (m, 88 H, Cy), 3.77 [m, 8 H, −$(CH_2)_2$−] ppm. ^{31}P{^{1}H} NMR (CD_2Cl_2, 161 MHz): δ = 162.4 (s) ppm.

The Role of Secondary Interactions in Group 11 Metal Complexes Containing the Ferrocene Ligand $FcCH_2NHpyMe$ in Supramolecular Structures

Eva M. Barranco,[a] Olga Crespo,[a] M. Concepción Gimeno,*[a] Peter G. Jones,[b] and Antonio Laguna[a]

Keywords: Ferrocenyl derivatives / Group 11 compounds / Supramolecular chemistry / Aurophilic attractions / N ligands

The ferrocene ligand 6-[(ferrocenylmethyl)amino]-2-picoline, $FcCH_2NHpyMe$ [Fc = $(\eta^5\text{-}C_5H_5)Fe(\eta^5\text{-}C_5H_4)$], has been prepared by treatment of $FcCH_2NMe_2$ with 6-amino-2-picoline, NH_2pyMe. The coordination chemistry with group 11 metals has been studied and several complexes with coordination of the metal atom to the pyridine nitrogen atom, such as $[M(PPh_3)(FcCH_2NHpyMe)]OTf$, $[Au(C_6F_5)(FcCH_2NHpyMe)]$ and $[AuR_3(FcCH_2NHpyMe)]$ (M = Au, Ag; R_3 = $(C_6F_5)_3$, $(C_6F_5)_2Cl$; OTf = trifluoromethanesulfonate), have been obtained. The complex $[Cu(FcCH_2NHpyMe)_2]PF_6$ has also been synthesised with a probable coordination of the copper centre to the pyridine and amine nitrogen atoms. Deprotonation of the NH group allows the synthesis of dinuclear complexes of the type $[M_2(PPh_3)_2(FcCH_2NpyMe)]X$ or $[Au_2(C_6F_5)(PPh_3)(FcCH_2NpyMe)]$ with a mixed pyridine–amide ligand. Some of the complexes have been characterised by X-ray diffraction and show the presence of intramolecular aurophilic interactions in the dinuclear complex and intermolecular interactions leading to chains in the mononuclear complex. Other types of secondary bonds are present in these structures, such as hydrogen bonding and weak η^2 interactions between the gold centre and the cyclopentadienyl ring.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

Gold complexes with nitrogen ligands, especially with amine ligands, have not been extensively studied until recently perhaps because of their limited stability.[1] This can be rationalised in terms of incompatibility between the soft metal centre and the hard nitrogen donor. Additional stabilisation of these compounds may be provided by aurophilic interactions or by formation of N−H···X hydrogen bonds. In this manner, several complexes of stoichiometry [AuClL] have been recently reported.[2] Stabilisation of these complexes with a phosphane ligand is also possible and several examples of the type $[AuL(PR_3)]^+$ are known.[3] However, complexes in which there are more than one type of nitrogen donor atoms in the same ligand are not frequent. As far as we are aware there is only one gold(I) derivative, namely $[(AuPPh_3)_4NQuin]BF_4$ (NQuin = 8-quinolinaminato),[4] with a pyridine−imido ligand as well as some gold(III) compounds with amine−amide ligands.[5] Here we report the synthesis of several gold, silver and copper complexes containing the ligand $FcCH_2NHpyMe$ which has two types of nitrogen donor atoms belonging to the amine and the pyridine groups. In our work with ferrocene derivatives[6] we have observed that the ferrocenyl group confers a great deal of stability on these types of ligands. Consequently, in this case, it is possible to coordinate the pyridine nitrogen atom to the metal fragments and also to substitute the proton in the NH group with the isolobal fragments $AgPPh_3^+$ or $AuPPh_3^+$, leading to the formation of the mixed gold or silver complexes with the pyridine−amide ligands. The crystal structure determinations provide experimental evidence for the importance of secondary bonds in the molecular architectures. Here, aurophilic interactions and hydrogen bonding are present in some of the complexes as illustrated by X-ray diffraction.

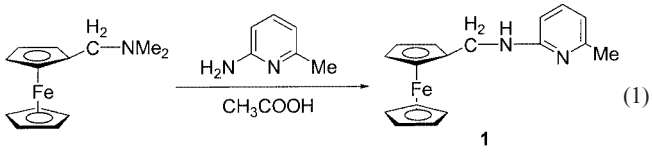
Results and Discussion

Synthesis of the Complexes

The reaction of $FcCH_2NMe_2$ with 6-amino-2-picoline (NH_2pyMe) in acetic acid gives the ferrocene ligand $FcCH_2NHpyMe$ (**1**) [Equation (1)]. A closely related ferrocene derivative, FcCONHpyMe, has previously been reported and the effect of protonation on the spectroscopic and redox properties was studied.[7] Compound **1** has been characterised by NMR spectroscopy and its ^1H NMR spectrum shows the three resonances for the three types of pyridine protons as two doublets and a doublet of doublets

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim DOI: 10.1002/ejic.200400479

with the NH signal at $\delta = 4.73$ ppm, the signal of the methylene protons at $\delta = 4.12$ ppm and the cyclopentadienyl proton signals at $\delta = 4.10$, 4.19 and 4.22 ppm in a ratio of 2:5:2, respectively. The positive liquid secondary-ion mass spectrum (LSIMS) exhibits the molecular peak at m/z = 306 as the most intense.



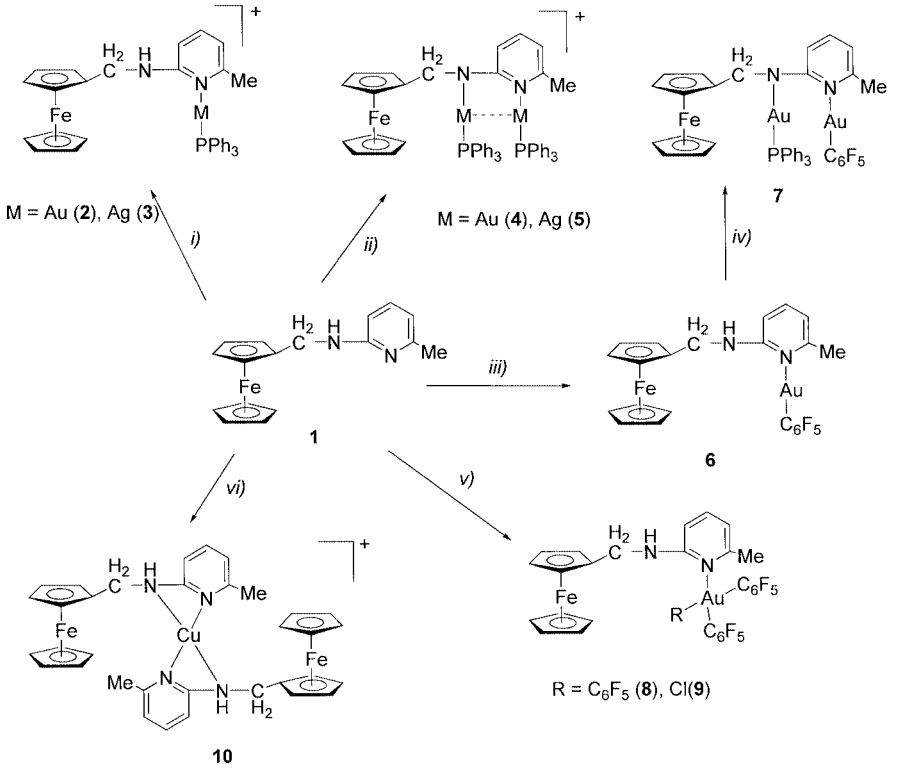
(1)

1

The reactivity of ligand **1** towards several gold, silver and copper compounds has been studied. Thus, treatment of **1** with [M(OTf)PPh_3] in a 1:1 molar ratio affords complexes of stoichiometry [M(PPh_3)($FcCH_2NHpyMe$)]OTf [M = Au (**2**), Ag (**3**)] (see Scheme 1).

Complexes **2**−**3** are air- and moisture-stable yellow solids. Their IR spectra show bands for the trifluoromethanesulfonate group at $\tilde{\nu} \approx 1265$ [vs, br., $\nu_{as}(SO_3)$], 1223 [s, $\nu_s(CF_3)$], 1150 [s, $\nu_{as}(CF_3)$] and 1023 [s, $\nu_s(SO_3)$] cm^{-1}. The ^1H NMR spectra for both complexes show broad signals at $\delta \approx 4.3$ ppm where the resonances for the ferrocenyl, methylene and NH protons are overlapping. The signals of only two of the pyridine protons can be observed because that of the other is also overlapping with those of the phenyl protons. In the $^{31}P(^1H)$ NMR spectra one sharp (in **2**) or broad (in **3**) resonance appears. At −55 °C the broad singlet from **3** splits into two doublets because of the coupling with the $^{109,107}Ag$ nuclei. The positive liquid secondary-ion mass spectra (LSIMS+) exhibit the molecular peaks at m/z (%) = 917 (5) [**2**] or 825 (12) [**3**] or the cationic peaks [M − OTf] at m/z (%) = 765 (95) [**2**] or 676 (30) [**3**].

The reaction of ligand **1** with the oxonium compound $[O(AuPPh_3)_3]ClO_4$ proceeds with the deprotonation of the NH group and coordination of two $AuPPh_3^+$ fragments to the amine nitrogen atom and to the pyridine group, giving the complex $[Au_2(PPh_3)_2(FcCH_2NpyMe)]ClO_4$ (**4**). This derivative, with triflate as counter anion, is also accessible by treatment of complex **2** with [Au(acac)(PPh_3)]. The analogous silver derivative $[Ag_2(PPh_3)_2(FcCH_2NpyMe)]OTf$ (**5**) can be obtained by treatment of **3** with [Ag(OTf)(PPh_3)] in the presence of triethylamine. The IR spectra show absorptions from the perchlorate anion at $\tilde{\nu} = 1096$ (vs, br.) and 623 (m) cm^{-1} for **4** and for **5** the typical absorptions for the trifluoromethanesulfonate anion can be observed. In the ^1H NMR spectra the resonances for the ferrocenyl protons appear as two singlets for the methyl and unsubstituted Cp groups, three multiplets for the α and β protons of the substituted Cp group and for the methylene protons. The resonance of the NH group disappears. For the pyridine protons, only two resonances can be observed because the third overlaps with the signals from the phenyl protons. The $^{31}P(^1H)$ NMR spectrum of complex **4** shows two resonances for the two inequivalent phosphorus atoms. For compound **5** the spectrum at room temperature consists of two



Scheme 1. i) [M(OTf)(PPh_3)], ii) $[O(AuPPh_3)_3]ClO_4$ or 2 [Ag(OTf)(PPh_3)] + NEt_3, iii) [Au(C_6F_5)(tht)], iv) [Au(acac)(PPh_3)], v) [Au(C_6F_5)$_3$(OEt_2)] or 1/2 $[Au(C_6F_5)_2Cl]_2$, vi) 1/2 $[Cu(NCMe)_4]PF_6$

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

broad signals that split at −55 °C into four doublets as a consequence of the coupling of two inequivalent phosphorus atoms with the two silver nuclei. In the LSIMS+ mass spectra the cationic molecular peaks appear at *m/z* (%) = 1223 (20) [**4**] and 1044 (40) [**5**].

Treatment of **1** with an equimolar amount of $[Au(C_6F_5)(tht)]$ (tht = tetrahydrothiophene) affords the compound $[Au(C_6F_5)(FcCH_2NHpyMe)]$ (**6**). Complex **6** is an air- and moisture-stable yellow solid which is a nonconductor in acetone solution. The IR spectrum shows bands arising from the pentafluorophenyl group at $\tilde{\nu}$ = 1500 (vs), 954 (s) and 793 (m) cm^{-1}. In the ^1H NMR spectrum of **6** the typical resonances for the ferrocenyl, methyl and methylene (as a doublet) protons are apparent. The three pyridine protons appear as two doublets and a doublet of doublets and the resonance for the NH proton has shifted downfield to δ = 6.73 ppm. The ^{19}F NMR spectrum shows the three resonances for a pentafluorophenyl group as two multiplets for the *ortho*- and *meta*-fluorine atoms and a triplet for the *para*-fluorine atom. The LSIMS+ mass spectrum shows the molecular peak at *m/z* (%) = 670 (85) and a peak arising from loss of the pentafluorophenyl group at *m/z* (%) = 503 (7) can also be observed. The reaction of complex **6** with 1 equiv. of $[Au(acac)(PPh_3)]$ leads to deprotonation of the amine group and coordination of the nitrogen atom to the $AuPPh_3^+$ fragment. The compound $[Au_2(C_6F_5)(PPh_3)(FcCH_2NpyMe)]$ (**7**) is an air- and moisture-stable yellow solid which is a nonconductor in acetone solution. The ^1H NMR spectrum shows the resonances for the ferrocenyl unit, a singlet for the unsubstituted cyclopentadienyl Cp ligand and a broad multiplet for the substituted cyclopentadienyl Cp unit. The methylene and the methyl protons appear as a multiplet and a singlet, respectively, and the resonances for the phenyl and pyridine groups are overlapping. The signal for the NH proton disappears. The ^{31}P NMR spectrum shows one singlet for the phosphorus atom and the ^{19}F NMR spectrum has a typical pattern for the pentafluorophenyl group. In the LSIMS+ spectrum the molecular peak at *m/z* (%) = 1128 (5) and the $[M + AuPPh_3]^+$ fragment at *m/z* (%) = 1587 (10) may be observed.

Ligand **1** also reacts with gold(III) complexes of the type $[Au(C_6F_5)_3(OEt_2)]$ or $[Au(C_6F_5)_2Cl]_2$ to afford the compounds $[Au(C_6F_5)_3(FcCH_2NHpyMe)]$ (**8**) or $[Au(C_6F_5)_2Cl(FcCH_2NHpyMe)]$ (**9**), respectively. Complexes **8** and **9** are air- and moisture-stable yellow solids which are nonconductors in acetone solution. Their IR spectra show typical bands for the pentafluorophenyl fragments bonded to gold(III) at $\tilde{\nu} \approx$ 1507 (s), 972 (s), 800 (s) and 795 (m) cm^{-1}. The ^{19}F NMR spectrum of **8** shows the typical pattern of an $Au(C_6F_5)_3$ group in which the *trans*-pentafluorophenyl groups are equivalent. Six resonances in a 2:1 ratio are observed corresponding to the *ortho*-, *meta*- and *para*-fluorines of the inequivalent C_6F_5 moieties. For compound **9**, two inequivalent pentafluorophenyl units may be observed corresponding to a *cis* configuration. The ^1H NMR spectrum is in agreement with the formula. In the LSIMS+ spectra the molecular peaks appear at *m/z* (%) = 1004 (5) and 872 (100), respectively.

A copper derivative $[Cu\{(FcCH_2NHpyMe)\}_2]PF_6$ (**10**) has been obtained by treatment of **1** with $[Cu(NCMe)_4]PF_6$ in a molar ratio of 2:1. Because of the tendency of Cu^I to adopt higher coordination numbers than gold, we propose a tetrahedral derivative with the copper atom bonded to both pyridine and amine nitrogen atoms. In the ^1H NMR spectrum both ferrocene units are equivalent and the protons appear as a broad resonance. A singlet for the methyl protons and a multiplet for the methylene protons also appear. The pyridine units show two multiplets for the two different types of protons.

Crystal Structure Determinations

The crystal structure of the cyclohexane solvate of $[Au_2(PPh_3)_2(FcCH_2NpyMe)]ClO_4$ (**4**) has been determined by a single-crystal X-ray diffraction study (Figure 1). A selection of bond lengths and angles are shown in Table 1. The gold atoms have a distorted linear geometry with angles N(1)−Au(1)−P(1) of 172.8(2)° and N(2)−Au(2)−P(2) of 170.26(14)°. This distortion may be a consequence of a short intramolecular gold(I)−gold(I) interaction of 2.9732(5) Å. The Au−N distances are 2.091(5) Å to the pyridine nitrogen atom and 2.052(5) Å to the amine nitrogen atom which are among the longest found in

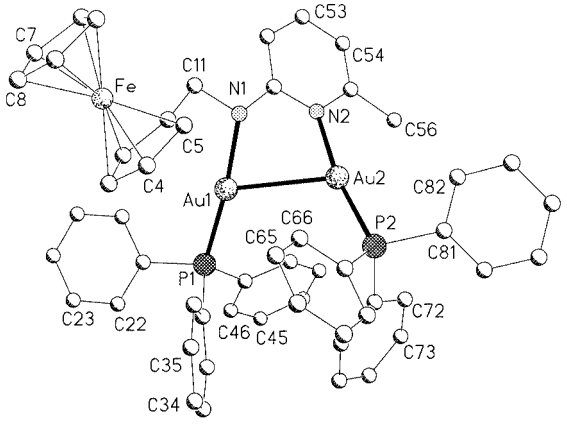


Figure 1. Structure of the cation of complex **4** showing the atom labelling scheme; radii are arbitrary, H atoms are omitted for clarity

Table 1. Selected bond lengths [Å] and angles [°] for **4**

Au(1)−N(1)	2.054(5)	Au(2)−P(2)	2.2341(18)

complexes with the unit $N_{pyridinic}-Au-PPh_3$. The latter generally range from 1.986(3)[8] to 2.108[9] Å. The longer Au−P bond in **4** is opposite to the shorter Au−N bond. The values are similar to those observed in other complexes with the N−Au−P unit.[8,9] The two P−Au−N units are skewed with respect to each other as shown by the torsion angle P(1)−Au(1)−Au(2)−P(2) of −45.8(1)°. The cyclopentadienyl rings display an essentially eclipsed geometry [torsion angle C(1)−Cp−Cp−C(6) 0.3°]. The gold atom Au(1) is located close to and with short contacts to the C(1)−C(2) bond of the cyclopentadienyl group [distances to C(1) and C(2): 3.150 and 3.357 Å] indicating a weak η^2 interaction with the Cp ring in a similar manner as has already been observed in other gold and silver complexes with ferrocene derivatives.[10,11] In the lattice there are several O···H interactions involving the oxygen atoms of the perchlorate anion and the protons of the phenyl and cyclopentadienyl moieties. These contacts are around 2.6 Å and are mostly of such a linearity as to be considered hydrogen bonds.

The structure of complex **6** has been confirmed by X-ray diffraction and is shown in Figure 2. Selected bond lengths and angles are shown in Table 2. The gold centre has a linear geometry with an angle C−Au−N of 177.65(13)°. The Au−N distance is 2.073(4) Å. Few examples of compounds with the $N_{pyridinic}-Au-C_6F_5$ moiety have been characterised by X-ray analysis and this value is shorter than the Au−N bond length of 2.124(15) Å in [Au(C_6F_5)(3-Fcpy)] (3-Fcpy = 3-ferrocenylpyridine).[12] It is similar, however, to that in [Au(C_6F_5)(3-Mepy)] (2.066 Å)[2a] or the Au−N(sp^2) value of 2.069(5) Å found in [Au(C_6F_5)($N_2C_2Ph_4$)].[13] The Au−C distance is 1.988(5) Å and resembles the values found in the complexes cited above. The cyclopentadienyl ring deviates slightly from an eclipsed geometry [torsion angle C(31)−Cp−Cp−C(41) 7.7°]. The NH group does not participate in hydrogen bonding but has a short intramolecular contact of 2.55 Å to the gold atom (N−H···Au 117°). The molecules are associated through intermolecular aurophilic interactions of 3.429 Å giving a chain of gold atoms parallel to the short axis (Figure 3). The chain structure is reinforced by offset ring stacking, with a perpendicular distance of ca. 3.33 Å and a centroid−plane distance of 3.48 Å. The molecules are further linked to form a 3D structure through C−H···F hydrogen bonds.

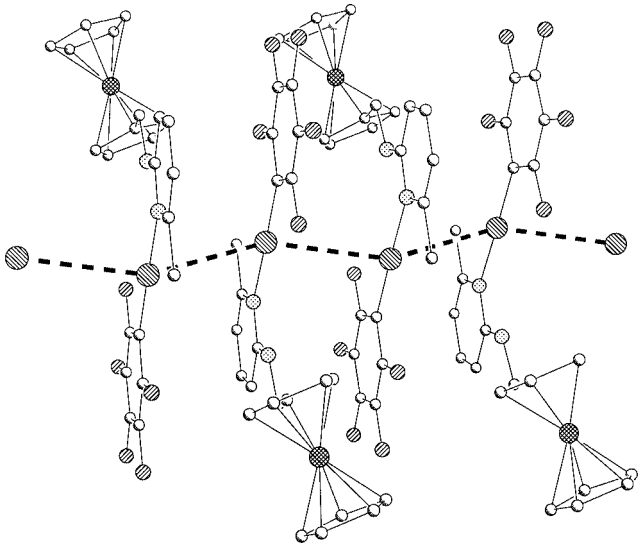

Figure 3. Association of molecules in complex **6** through aurophilic interactions; H atoms (expect NH) are omitted for clarity

The structures of complexes **8** and **9** have also been established by X-ray diffraction studies and the molecules are shown in Figures 4 and 5, respectively. Selected bond lengths and angles are collected in Tables 3 and 4. In both complexes the gold(III) centres are in a square-planar geometry with the mean deviations from the ideal angles being 3.6° (**8**) and 3.8° (**9**). In **8** the Au−C bond lengths are 2.026(6), 2.064(5) and 2.071(5) Å, the shortest is to the pentafluorophenyl group *trans* to the pyridine ligand. In **9** the distances are 2.012(2) and 2.028(3) Å which are similar to the shortest distance in compound **8**. This shows the higher *trans* influence of the pentafluorophenyl group compared with amine or chloro ligands. The Au−N distances are 2.104(4) and 2.101(2) Å and are very similar because

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

both have a pentafluorophenyl group *trans* to them. Few examples with the units N−Au(C_6F_5)$_3$ or N−Au−*trans*-(C_6F_5)$_2$Cl have been structurally characterised but the values are similar to those reported, as for example in [{Au(C_6F_5)$_3$}$_2${Fc(Spy)$_2$}].[6f] The cyclopentadienyl rings in these complexes are eclipsed with torsion angles C(1)−Cp−Cp−C(6) of 0.9° in **8** and 8.8° in **9**. Both complexes show intramolecular N−H···Au hydrogen contacts of 2.62(8) and 2.67(9) Å, respectively, but these are better considered as the weaker parts of three-centred interactions involving F5 or Cl, respectively, as the main hydrogen bond acceptor. Additional C−H···F (and C−H···Cl for **9**) hydrogen bonds between various molecules create a 3D extended structure in **8** or the disposition of the molecules into planes in **9** (Figure 6). Table 5 lists the hydrogen bonds found in these complexes.

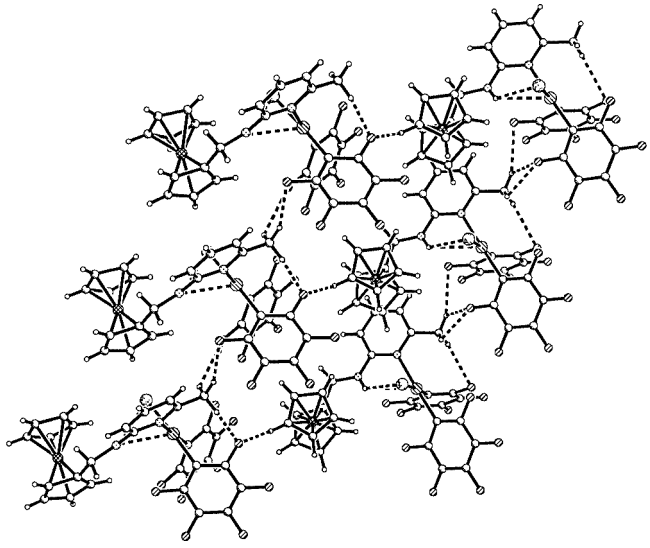

Figure 6. Supramolecular structure through hydrogen bonding in complex **9**

Conclusions

The ligand $FcCH_2NHpyMe$ can form several complexes with copper, silver or gold with different geometries and coordination modes. Coordination through the pyridine nitrogen atom is ususally preferred by the three metals but bonding to the amine nitrogen atom can be achieved using deprotonating agents causing substitution of the proton for the isolobal $AgPPh_3^+$ or $AuPPh_3^+$ fragments. In the structures of these derivatives it is worth mentioning the presence of intra- and intermolecular gold−gold interactions. In some cases the aurophilic interactions provide a supramolecular chain-like structure. The presence of other secondary interactions is also noteworthy, for example the weak η^2 interaction between the gold centre and the cyclopendienyl ring and the intra- and intermolecular hydrogen bonds.

Experimental Section

Instrumentation: Infrared spectra were recorded in the range 4000−200 cm^{-1} with a Perkin−Elmer 883 spectrometer using Nujol mulls between polyethylene sheets. Conductivities were measured in ca. 5×10^{-4} mol·dm^{-3} solutions with a Philips 9509 conductimeter. C, H, N and S analyses were carried out with a Perkin−Elmer 2400 microanalyser. Mass spectra were recorded with a VG Autospec instrument with the liquid secondary-ion mass spectroscopy (LSIMS) technique using nitrobenzyl alcohol as a matrix. NMR spectra were recorded with a Varian Unity 300 spectrometer or a Bruker ARX 300 spectrometer in $CDCl_3$. Chemical shifts are given relative to $SiMe_4$ (^1H, external), $CFCl_3$ (^{19}F, external) or 85% H_3PO_4 (^{31}P, external).

Starting Materials: The starting materials [Au(acac)(PPh_3)],[14] [$O(AuPPh_3)_3$]ClO_4,[15] [Au(C_6F_5)(tht)],[16] [Au(C_6F_5)$_3$(OEt_2)],[17] [Au(C_6F_5)$_2$Cl]$_2$ [18] and [Ag(OTf)(PPh_3)][19] were prepared according to published procedures. All other reagents were commercially available.

Synthesis of $FcCH_2NHpyMe$ (1): To a solution of 6-amino-2-picoline (0.756 g, 7 mmol) in acetic acid (30 mL) was added $FcCH_2NMe_2$ (1.7 g, 14 mmol) and the mixture was heated at 80 °C for 3 h. The solution was then cooled and an aqueous solution of $NaHCO_3$ was added in order to raise the pH to 7. The organic phase was extracted with CH_2Cl_2 (3 × 1 mL) and dried with $MgSO_4$. The solution was then concentrated to ca. 2 mL and chromatographed on alumina with diethyl ether/hexane (4:1) as eluent. Evaporation of the solvent to ca. 5 mL and addition of hexane gave the ligand **1** as an orange solid. Yield 40%, 856.9 mg. Λ_M = 0.4 Ω^{-1}·cm^2·mol^{-1}. $C_{17}H_{18}FeN_2$ (306.2): calcd. C 66.69, H 5.92, N 9.15; found C 66.57, H 5.90, N 9.10. ^1H NMR: δ = 2.39 (s, 3 H, Me), 4.10 (m, 2 H, C_5H_4), 4.12 (m, 2 H, CH_2), 4.19 (s, 5 H, C_5H_5), 4.22 (m, 2 H, C_5H_4), 4.73 (br. m, 1 H, NH), 6.23 [d, *J*(H,H) = 8.3 Hz, 1 H, py], 6.46 [d, *J*(H,H) = 7.7 Hz, 1 H, py], 7.35 [dd, *J*(H,H) = 8.3, 7.7 Hz, 1 H, py] ppm.

Synthesis of [M(PPh_3)($FcCH_2NHpyMe$)]OTf, M = Au (2), Ag (3): To a solution of **1** (0.031 g, 0.1 mmol) in dichloromethane (20 mL) was added [Au(OTf)(PPh_3)] (0.061 g, 0.1 mmol) or [Ag(OTf)(PPh_3)] (0.052 g, 0.1 mmol) and the mixture was stirred for 30 min. Evaporation of the solvent to ca. 5 mL and addition of hexane (10 mL) gave complexes **2** or **3** as orange solids.

Complex 2: Yield 72%, 65.8 mg. Λ_M = 120 Ω^{-1}·cm^2·mol^{-1}. $C_{36}H_{33}AuF_3FeN_2O_3PS$ (914.27): calcd. C 47.30, H 3.63, N 3.06, S 3.50; found C 46.86, H 3.29, N 2.90, S 3.64. ^1H NMR: δ = 2.58 (s, 3 H, Me), 4.3 (br. m, 10 H, C_5H_4, C_5H_5, NH, CH_2), 6.46 [d, *J*(H,H) = 6.6 Hz, 1 H, py], 6.63 [d, py, *J*(H,H) = 7.4, 1 H], 7.2−7.8 (m, 16 H, Ph, py) ppm. $^{31}P(^1H)$ NMR: δ = 30.6 (s, 1 P, PPh_3) ppm.

Complex 3: Yield 85%, 70.31 mg. Λ_M = 110 Ω^{-1}·cm^2·mol^{-1}. $C_{36}H_{33}AgF_3FeN_2O_3PS$ (827.171): calcd. C 52.38, H 4.03, N 3.41, S 3.88; found C 52.24, H 4.22, N 3.33, S 3.87. ^1H NMR: δ = 2.44 (s, 3 H, Me), 4−5 (br. m, 10 H, C_5H_4, C_5H_5, CH_2), 6.47 (m, 1 H, py), 6.52 (m, 1 H, py), 6.76 (s, 1 H, NH), 7.2−7.8 (m, 16 H, py, Ph) ppm. $^{31}P(^1H)$ NMR (−55 °C): δ = 11.3 [2 d, *J*(^{107}AgP) = 475.1, *J*(^{109}AgP) = 547.4 Hz, 1 P, PPh_3] ppm.

Synthesis of [M_2(PPh_3)$_2$($FcCH_2NpyMe$)]X, M = Au, X = ClO_4 (4), M = Ag, X = OTf (5)

Complex 4: To a solution of **1** (0.031 g, 0.1 mmol) in dichloromethane (20 mL) was added [$O(AuPPh_3)_3$]ClO_4 (0.149 g, 0.1 mmol) and the mixture was stirred for 2 h. Evaporation of the solvent to ca. 5 mL and addition of diethyl ether (10 mL) gave complex **4** as a yellow solid. Yield 95%, 124.33 mg. Λ_M = 110 Ω^{-1}·cm^2·mol^{-1}. $C_{52}H_{45}Au_2ClFeN_2O_4P_2$ (1308.806): calcd. C 48.11, H 3.58, N 2.12; found C 47.98, H 3.39, N 1.99. ^1H NMR: δ = 2.56 (s, 3 H, Me), 4.04 (m, 2 H, C_5H_4), 4.16 (s, 5 H, C_5H_5), 4.18 (m, 2 H, CH_2), 4.23 (m, 2 H, C_5H_4), 6.44 [d, *J*(H,H) = 7.0 Hz, 2 H, py], 6.68 [d, *J*(H,H) = 8.4 Hz, 2 H, py], 7.1−7.8 (m, 31 H, py, Ph) ppm. $^{31}P(^1H)$ NMR: δ = 30.5 (s, 1 P, PPh_3), 24.3 (s, 1 P, PPh_3) ppm.

The triflate salt $[Au_2(PPh_3)_2(FcCH_2NpyMe)]OTf$ is also accessible by treatment of complex **2**, $[Au(PPh_3)(FcCH_2NHpyMe)]OTf$, with $[Au(acac)(PPh_3)]$ in dichloromethane. Yield, 89%.

Complex 5: To a solution of **1** (0.031 g, 0.1 mmol) in dichloromethane (20 mL) was added $[Ag(OTf)(PPh_3)]$ (0.104 g, 0.2 mmol) and NEt_3 (0.021 mL, 0.15 mmol) and the mixture was stirred for 1 h. Evaporation of the solvent to ca. 5 mL and addition of hexane (10 mL) gave complex **5** as a red solid. Yield 70%, 82.61 mg. Λ_M = 100 $\Omega^{-1}\cdot cm^2\cdot mol^{-1}$. $C_{53}H_{45}Ag_2F_3FeN_2O_3P_2S$ (1180.226): calcd. C 54.30, H 3.96, N 1.17, S 2.68; found C 54.13, H 4.05, N 1.31, S 2.34. ^1H NMR: δ = 2.50 (s, 3 H, Me), 4.04 (m, 2 H, C_5H_4), 4.10 (m, 2 H, CH_2), 4.14 (s, 5 H, C_5H_5), 4.23 (m, 2 H, C_5H_4), 6.49 (m, 1 H, py), 6.56 (m, 1 H, py), 7.1−7.8 (m, 31 H, py, Ph) ppm. $^{31}P(^1H)$ NMR (−55 °C): δ = 10.4 [2 d, $J(^{107}AgP)$ = 402.9, $J(^{109}AgP)$ = 465.9 Hz, 1 P, PPh_3], 11.2 [2 d, $J(^{107}AgP)$ = 430.1, $J(^{109}AgP)$ = 492.5 Hz, 1 P, PPh_3] ppm.

Synthesis of $[Au(C_6F_5)(FcCH_2NHpyMe)]$ (6): To a solution of **1** (0.031 g, 0.1 mmol) in dichloromethane (20 mL) was added $[Au(C_6F_5)(tht)]$ (0.045 g, 0.1 mmol) and the mixture was stirred for 30 min. Evaporation of the solvent to ca. 5 mL and addition of hexane (10 mL) gave complex **6** as a yellow solid. Yield 76%, 49.86 mg. Λ_M = 4 $\Omega^{-1}\cdot cm^2\cdot mol^{-1}$. $C_{22}H_{16}AuF_5FeN_2$ (656.056): calcd. C 41.22, H 2.71, N 4.18; found C 41.09, H 2.50, N 3.99. ^1H NMR: δ = 2.80 (s, 3 H, Me), 4.07 [d, J(H,H) = 5.1 Hz, 2 H, CH_2], 4.20 (s, 5 H, C_5H_5), 4.20 (m, 2 H, C_5H_4), 4.27 (m, 2 H, C_5H_4), 6.55 [d, J(H,H) = 7.2 Hz, 1 H, py], 6.64 [d, J(H,H) = 8.7 Hz, 1 H, py], 6.73 (m, 1 H, NH), 7.58 [dd, J(H,H) = 8.7, 7.2 Hz, 1 H, py] ppm. ^{19}F NMR: δ = −117.3 (m, 2 F, *m*-F), 160.5 [t, J(F,F) = 20.6 Hz, 1 F, *p*-F], −164.1 (m, 2 F, *o*-F) ppm.

Synthesis of $[Au_2(C_6F_5)(PPh_3)(FcCH_2NpyMe)]$ (7): To a solution of complex **6** (0.067 g, 0.1 mmol) in dichloromethane (20 mL) was added $[Au(acac)(PPh_3)]$ (0.056 g, 0.1 mmol) and the mixture was stirred for 2 h. Evaporation of the solvent to ca. 5 mL and addition of diethyl ether (10 mL) gave complex **7** as a yellow solid. Yield 66%, 72.74 mg. Λ_M = 8 $\Omega^{-1}\cdot cm^2\cdot mol^{-1}$. $C_{39}H_{30}Au_2F_5FeN_2P$ (1102.21): calcd. C 43.64, H 2.86, N 2.48; found C 43.42, H 2.80, N 2.33. ^1H NMR: δ = 2.67 (s, 3 H, Me), 3.80 (m, 2 H, CH_2), 4.12 (s, 5 H, C_5H_5), 4.31 (m, 4 H, C_5H_4), 6.26 [d, J(H,H) = 6.0 Hz, 1 H, py], 6.53 [d, J(H,H) = 8.7 Hz, 1 H, py], 7.1−7.8 (m, py, Ph) ppm. ^{19}F NMR: δ = −116.0 (m, 2 F, *m*-F), 163.3 [t, 1 F, *p*-F, J(F,F) = 20.6 Hz], −164.5 (m, 2 F, *o*-F) ppm. $^{31}P(^1H)$ NMR: δ = 30.7 (s, 1 P, PPh_3) ppm.

Synthesis of $[Au(C_6F_5)_2X(FcCH_2NHpyMe)]$, X = C_6F_5 (8), Cl (9): To a solution of **1** (0.031 g, 0.1 mmol) in dichloromethane (20 mL) was added $[Au(C_6F_5)_3(OEt_2)]$ (0.077 g, 0.1 mmol) or $[Au(C_6F_5)_2Cl]_2$ (0.056 g, 0.05 mmol) and the mixture was stirred for 1 h. Evaporation of the solvent to ca. 5 mL and addition of hexane (10 mL) gave complexes **8** or **9** as yellow solids.

Complex 8: Yield 75%, 75.25 mg, Λ_M = 4 $\Omega^{-1}\cdot cm^2\cdot mol^{-1}$. $C_{35}H_{18}AuF_{15}FeN_2$ (1004.35): calcd. C 41.86, H 1.81, N 2.79; found C 41.79, H 1.56, N 2.34. ^1H NMR: δ = 2.71 (s, 3 H, Me), 4.11 (m, 2 H, CH_2), 4.20 (m, 9 H, C_5H_5, C_5H_4, NH), 5.89 (m, 1 H, py), 6.57 (m, 2 H, py), 7.53 (m, 1 H, py) ppm. ^{19}F NMR: δ = −121.6

(m, 4 F, *m*-F), −123.0 (m, 2 F, *m*-F), −156.2 [t, *J*(F F) = 19.5 Hz, 2 F, *p*-F], −156.7 (t, *J*(F,F) = 19.6 Hz, 1 F, *p*-F], −160.8 (m, 4 F, *o*-F), −161.4 (m, 2 F, *o*-F) ppm.

Complex 9: Yield 74%, 64.39 mg, Λ_M = 18 $\Omega^{-1}\cdot cm^2\cdot mol^{-1}$. $C_{29}H_{18}AuClF_{10}FeN_2$ (872.61): calcd. C 39.91, H 2.08, N 3.22; found C 39.89, H 1.65, N 2.93. ^{1}H NMR: δ = 2.85 (s, 3 H, Me), 4.12 (m, 2 H, CH_2), 4.20 (m, 9 H, C_5H_5, C_5H_4), 4.41 (m, 1 H, NH), 6.04 (m, 1 H, py), 6.60 [2 d, *J*(H,H) = 7.3, 8.5 Hz, 2 H, py], 7.58 [dd, *J*(H,H) = 7.3, 8.5 Hz, 1 H, py] ppm. ^{19}F NMR: δ = −122.0 (m, 2 F, *m*-F), −123.0 (m, 2 F, *m*-F), −154.7 [t, *J*(F,F) = 19.6 Hz, 1 F, *p*-F], −156.0 [t, *J*(F,F) = 19.6 Hz, 1 F, *p*-F], −160.0 (m, 2 F, *o*-F), −161.2 (m, 2 F, *o*-F) ppm.

Synthesis of $[Cu(FcCH_2NHpyMe)_2]PF_6$ (10): To a solution of **1** (0.031 g, 0.1 mmol) in dichloromethane (20 mL) was added $[Cu(NCMe)_4]PF_6$ (0.037 g, 0.1 mmol) and the mixture was stirred for 2 h. Evaporation of the solvent to ca. 5 mL and addition of hexane (10 mL) gave complex **10** as a yellow solid. Yield 72%, 54.83 mg. Λ_M = 134 $\Omega^{-1}\cdot cm^2\cdot mol^{-1}$. $C_{32}H_{32}CuF_6Fe_2N_4$ (761.592): calcd. C 49.75, H 4.42, N 6.82; found C 49.55, H 4.40, N 6.83. ^{1}H NMR: δ = 2.53 (s, 6 H, Me), 4.0 (m, 4 H, CH_2), 4.35 (m, 18 H, C_5H_5, C_5H_4), 5.60 (m, 2 H, NH), 6.58 (m, 3 H, py), 7.57 (m, 1 H) ppm.

X-ray Crystallography: Data were recorded with a Stoe-STADI-4 (**6**), Siemens P4 (**4**, **8**) or Bruker SMART 1000 CCD (**9**) diffractometer. Data collection type: ω/θ-scans (**6**), ω-scans (**4**, **8**) or ω- and φ-scans (**9**). The structures were refined on F^2 using the program SHELXL-97.[20] All non-hydrogen atoms were refined anisotropically. Aminic hydrogen atoms were identified from difference syntheses but were refined freely only for **6**. Other hydrogen atoms were included either as rigid methyl groups (not well resolved for **4** and **8**) or using a riding model. Refinement special details: The structure of **4** contains one well-resolved cyclohexane solvate molecule. Additionally, two peaks of ca. 2 e/Å^3 near the cyclohexane may represent an alternative disordered solvent site. The structure of **8** contains one poorly resolved pentane solvate molecule which was refined isotropically. The molecular weights and related parameters correspond to the idealised compositions including solvent. Further crystallographic data are collected in Table 6. CCDC-229959 to -229962 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ; Fax: (internat.) + 44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

A Kinetic Study on the Reactions of Azolato-Bridged Dinuclear Platinum(II) Complexes with Guanosine 5′-Monophosphate

Seiji Komeda,[a,b] Hirotoshi Yamane,[b] Masahiko Chikuma,[b] and Jan Reedijk*[a]

Keywords: Azoles / Platinum complexes / Cisplatin / Antitumor agents

By using ^{1}H NMR spectroscopy the reactions of [{*cis*-Pt(NH_3)$_2$}$_2$(μ-OH)(μ-pz)](NO_3)$_2$ (**1**), [{*cis*-Pt(NH_3)$_2$}$_2$(μ-OH)(μ-1,2,3-ta-*N1,N2*)](NO_3)$_2$ (**2**) and [{*cis*-Pt(*R,R*-dach)}$_2$(μ-OH)(μ-pz)](NO_3)$_2$ (**3**) with guanosine 5′-monophosphate (GMP) were monitored spectroscopically in 0.1 M phosphate D_2O solutions at three different pD values (5.4, 6.9, 8.4). From the investigations some kinetic information was obtained. The reaction rate for all these complexes become higher when the pD decreases. In addition, for the reactions performed in unbuffered solutions (pD 8.2), the reactivity of all the complexes for GMP was found to increase dramatically. The 1:2 reaction products were characterized by ^{1}H, ^{195}Pt, and ^{31}P NMR spectroscopy. Reactions of **2** with GMP include an unusual ligand-binding isomerization, resulting from the Pt atom migration along the 1,2,3-triazolato ring.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

The antitumor activity of the square-planar platinum(II) complex, *cis*-diamminedichloroplatinum(II) (cisplatin), was discovered by Rosenberg[1,2] in the mid 1960's. Cisplatin was subsequently approved for clinical use in 1979 and is now one of the most well-established and most sold successful antitumor drugs. Not exceptionally for an antitumor drug, its chemotherapy involves some serious side effects[3−6] and it also may result in acquired drug resistance.[7,8] It has been generally accepted that the local DNA kink resulting from the formation of the 1,2-intrastrand crosslink at d(GpG) site is connected with cisplatin's antitumor activity.[9,10] Therefore, a successful approach to circumvent the cross-resistance is likely to be the design of a Pt^{II} complex which would react with DNA in a different way from that of cisplatin.[11,12]

Earlier reports by some of us have shown that the azolato-bridged dinuclear platinum(II) complexes, [{*cis*-Pt(NH_3)$_2$}$_2$(μ-OH)(μ-pz)](NO_3)$_2$ (pz = pyrazolate) (**1**) and [{*cis*-Pt(NH_3)$_2$}$_2$(μ-OH)(μ-1,2,3-ta-*N1,N2*)](NO_3)$_2$ (1,2,3-ta = 1,2,3-triazolate) (**2**), exhibit remarkably high in vitro cytotoxicity on several human tumor cell lines[13] and largely circumvent the cross-resistance to cisplatin.[14,15] These complexes were aimed to provide a 1,2-intrastrand GG crosslink with a minimal kink of DNA. This type of DNA adducts would sufficiently induce the desired cytotoxic effect[16] and may expect a different biological consequence compared to cisplatin (Figure 1).

On the other hand, replacing the terminal ammine ligands with primary and secondary amines, such as ethylenediamine, diaminocyclohexane, and isopropylamines, this series of azolato-bridged dinuclear Pt^{II} complexes exhibits a decrease in cytotoxicity.[13,17] This tendency agrees with the general structure-activity relationship in mononuclear cisplatin derivatives. Full interpretation of this relationship requires a proper way to investigate their DNA binding (coordination) rate, and to compare them with the reported cytotoxic profiles.[13] In this paper we report a kinetic study on the reactions of these three azolato-bridged dinuclear Pt^{II} complexes with guanosine 5′-monophosphate (GMP), the most simple DNA fragment, in solution at different pH.

Results and Discussion

Reactions of compounds **1**, **2**, and [{*cis*-Pt(*R,R*-dach)}$_2$(μ-OH)(μ-pz)](NO_3)$_2$ (**3**) with GMP (stoichiometric (2 equiv.) or excess (4 equiv.) per Pt complex) were monitored by ^{1}H NMR in D_2O solution with/without 0.1 M phosphate buffer. These azolato-bridged dinuclear platinum(II) complexes react with 2 equiv. of GMP to yield the final products, **I**-(GMP)$_2$, **II**-(GMP)$_2$, and **III**-(GMP)$_2$ (see Schemes 1 and 2). Upon incubating these compounds with GMP, the ^{1}H NMR signals corresponding to azolates of **1**−**3** and an H8 signal of the free GMP decreases in intensity with time (see Figures 2−4). The supposed intermediates could hardly be traced for all the reactions, not even in

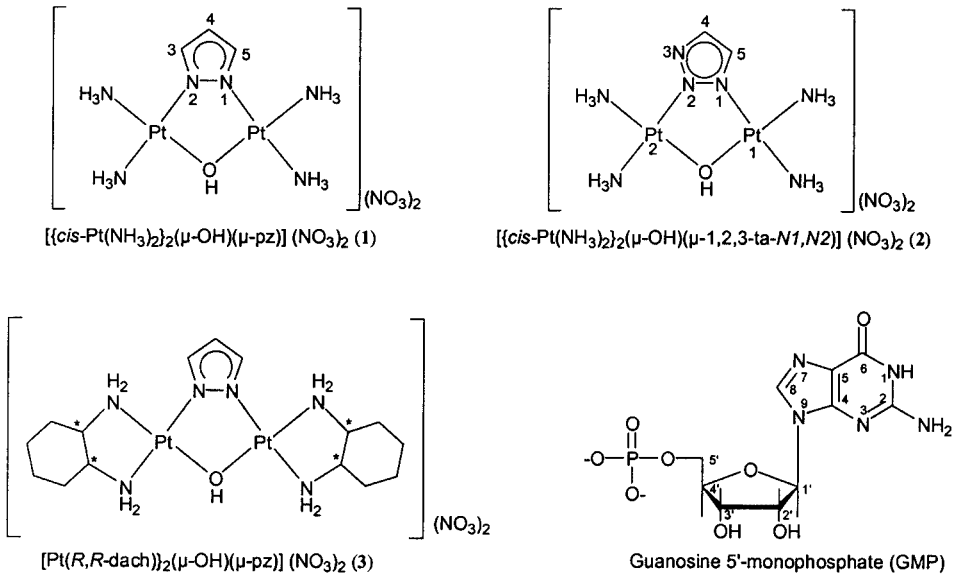

Figure 1. Schematic representation of [{*cis*-Pt(NH_3)$_2$}$_2$(μ-OH)(μ-pz)](NO_3)$_2$ (**1**), [{*cis*-Pt(NH_3)$_2$}$_2$(μ-OH)(μ-1,2,3-ta-*N1*,*N2*)](NO_3)$_2$ (**2**), [Pt(*R*,*R*-dach)}$_2$(μ-OH)(μ-pz)] (NO_3)$_2$ (**3**), and guanosine 5′-monophosphate (GMP)

the reactions with stoichiometric (2 equiv.) GMP at 310 K. Therefore, the rate-determining step is obviously the reaction in which an N7 of the first GMP displaces the leaving hydroxo groups. Hence, the first substitution reaction of these complexes with GMP appears to proceed by an associative process which is followed by the second substitution reaction, in which the hydroxyl or water ligand undergoes relatively rapid substitution by the second nucleotide.

Characterization of the Reaction Products

The ^{1}H, ^{31}P, and ^{195}Pt NMR spectroscopic data for the reaction products, [{*cis*-Pt(NH_3)$_2$(GMP-*N7*)}$_2$(μ-pz)]$^-$(**I**-(GMP)$_2$], [{*cis*-Pt(NH_3)$_2$(GMP-*N7*)}$_2$(μ-1,2,3-ta-*N1*,*N3*)]$^-$ [**II**-(GMP)$_2$], and [{*cis*-Pt(*R*,*R*-dach)(GMP-*N7*)}$_2$(μ-pz)]$^-$ [**III**-(GMP)$_2$] measured in 0.1 M phosphate D_2O (pD 7.0) solution at 298 K are summarized in Table 1.

^{1}H NMR

As mentioned above, **1** reacts with GMP in a bifunctional way to provide **I**-(GMP)$_2$ (Scheme 1). The signal of the H8 proton appears at slightly lower field as a completely broadened signal at 310 K, indicating a hindered rotation about the Pt−N7 bonds.[14,15] The signal becomes sharper to some extent upon increase of the temperature.[14] Referred to the H8 signal of free GMP, cisplatin-platinated GMP shows a 0.44 ppm downfield shift[18] owing to the inductive effect by platinum coordination (Figure 2). On the other hand, the H8 of **I**-(GMP)$_2$ appears at only 0.09 ppm lower field (323 K), indicating a ring-currency effect caused by well-stacked intramolecular guanine bases and by close proximity to the pyrazolate ring, which will compensate for the inductive effect.[14,15] The smaller $J_{1'-2'}$ (3.873 Hz) indicates the increase in N-type population of the sugar puckering.[19,20] Significant upfield shifts are observed for the H1′, H4′, and H5′ protons, but no significant changes are seen for H2′ and H3′. This phenomenon could have the same origin as for the H8 proton, but no proof is available as yet.

The reaction of GMP with **2** (Scheme 2), results in a sharp peak assigned to the H8 of the platinated GMP (observed at $\delta = 0.46$ ppm lower field than that of a free GMP, Figure 3), which is comparable to that of cisplatin-platinated GMP. This implies less stacked guanine ligands and allowance of a relatively free rotation about the Pt−N7

Table 1. The ^{1}H, ^{31}P, and ^{195}Pt NMR spectroscopic data of 1:2 complexes, **I**-(GMP)$_2$, **II**-(GMP)$_2$, and **III**-(GMP)$_2$ measured in 0.1 M phosphate D_2O (pD 7) solution at 298 K

Compound	δ(^{1}H), ppm H8	H1′ ($J_{1'-2'}$, Hz)	azolates	δ(^{31}P), ppm	δ(^{195}Pt), ppm

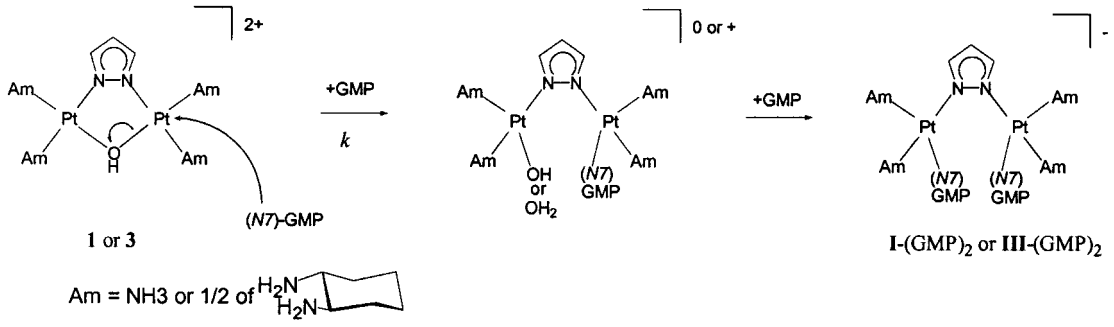

Scheme 1. Two-step reaction of compound **1** (and **3**) with 5′GMP

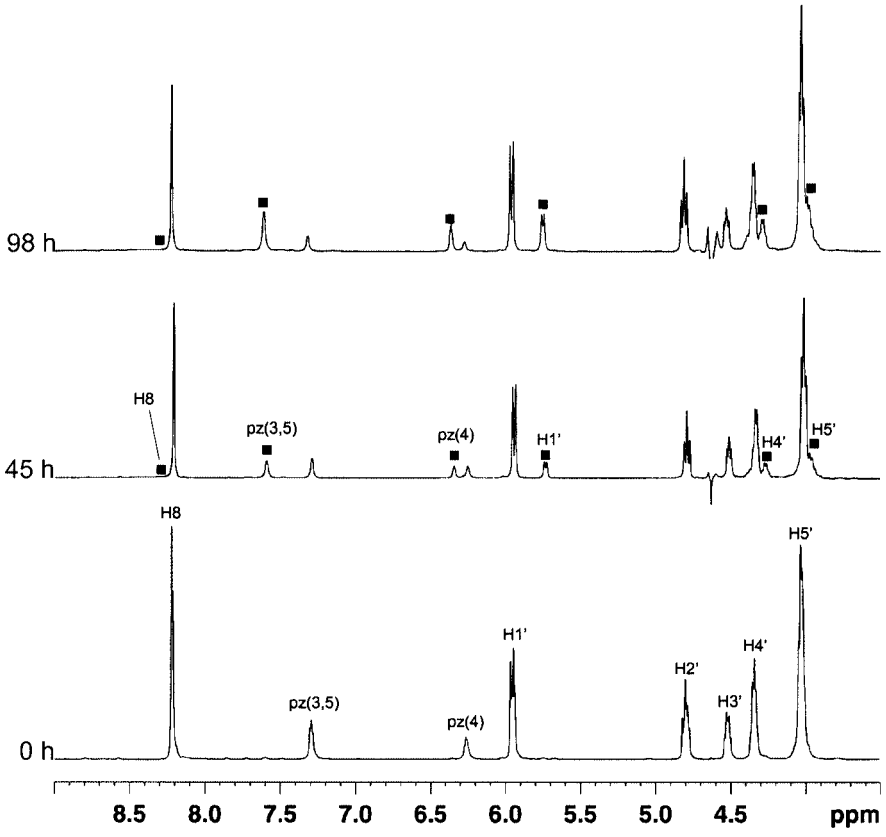

Figure 2. ^{1}H NMR spectra on the reaction of **1** with excess (4 equiv.) of GMP in unbuffered D_2O solution (pD 8.2) measured at 310 K as a function of time. The symbol (filled black squares) shows the newly appeared H8 and sugar ring proton signals (H1′, H4′ and H5′) of GMP ligands, and pz protons in a 1:2 complex, $[\{cis\text{-}Pt(NH_3)_2(GMP\text{-}N7)\}_2(\mu\text{-}pz)]^-$ (**I**-$(GMP)_2$]

bonds.[14] An interesting aspect that should be emphasized, is that the signals of ta(4) and (5) in the bridging 1,2,3-triazolate have shifted to higher field and now appear as a single peak (i.e. a highly symmetric species must be present). This phenomenon clearly indicates that the present reaction includes the same isomerization as we reported earlier for the reaction of **2** with 9EtG.[14] Thus, after the first substitution by N7 of GMP, the Pt atom initially coordinating to N2 of the 1,2,3-triazolate ring migrates from N2 to N3, to provide the symmetric 1:2 complex, **II**-$(GMP)_2$. This migration of the platinum(II) is to be seen as a novel isomerization reaction, since substitution reactions of square-planar metal complexes usually proceed via penta-coordination transition states. It seems obvious that N3 is not able to coordinate at the axial Pt position as long as N2 is coordinating to Pt2. Unlike the products of the pyrazolato-bridged complexes, no significant upfield shifts on the sugar ring proton signals are observed. The $J_{1'\text{-}2'}$ is found to be 5.637 Hz, indicating a sugar puckering with a similar N/S population as that of free GMP.[19,20]

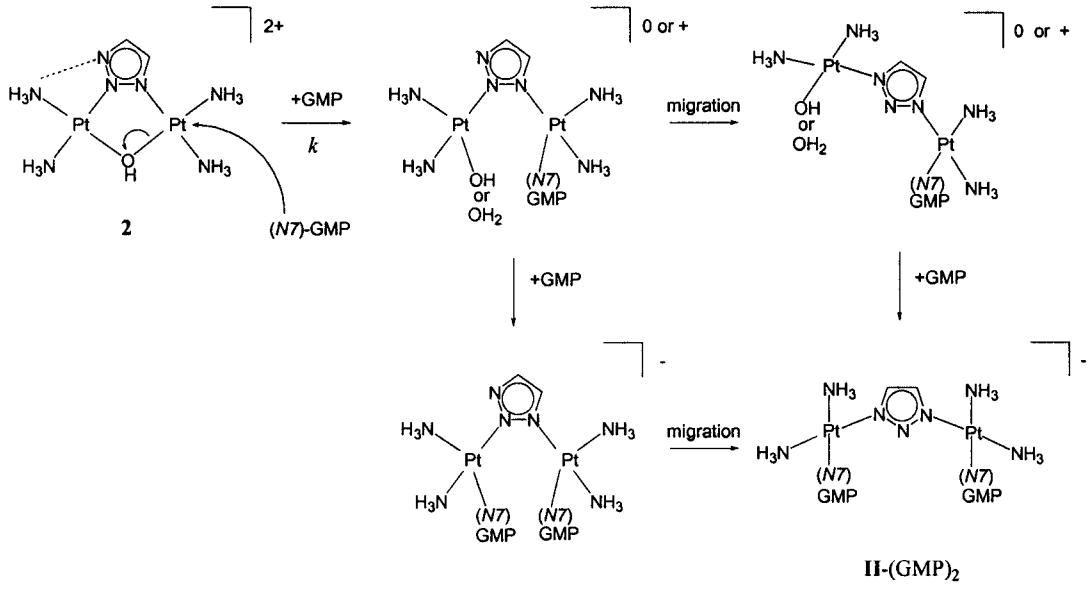

Scheme 2. Reaction steps of compound **2** with 5′GMP

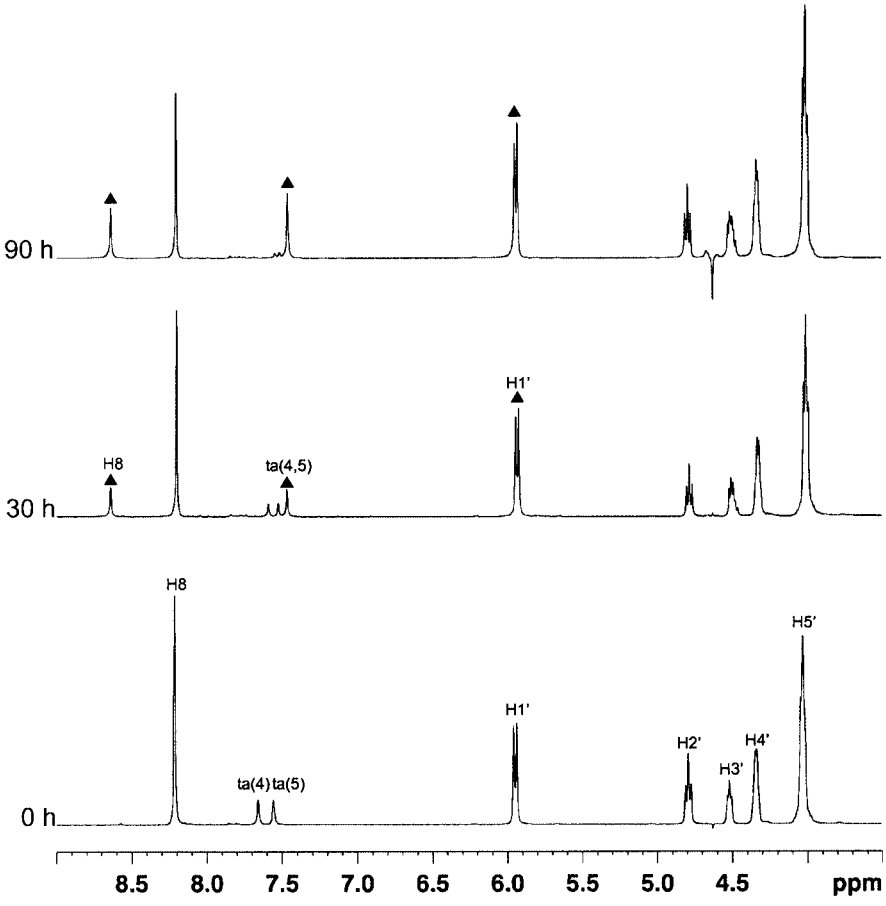

Figure 3. ^1H NMR spectra on the reaction of **2** with excess (4 equiv.) of GMP in unbuffered D_2O solution (pD 8.2) measured at 310 K as a function of time. The symbol (filled black triangles) shows the newly appeared H8 and sugar ring proton signals (H1′) of GMP ligands, and azolate protons in a 1:2 complex, $[\{cis\text{-}Pt(NH_3)_2(GMP\text{-}N7)\}_2(\mu\text{-}1,2,3\text{-}ta\text{-}N1,N3)]^-$ [**II**-$(GMP)_2$]

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

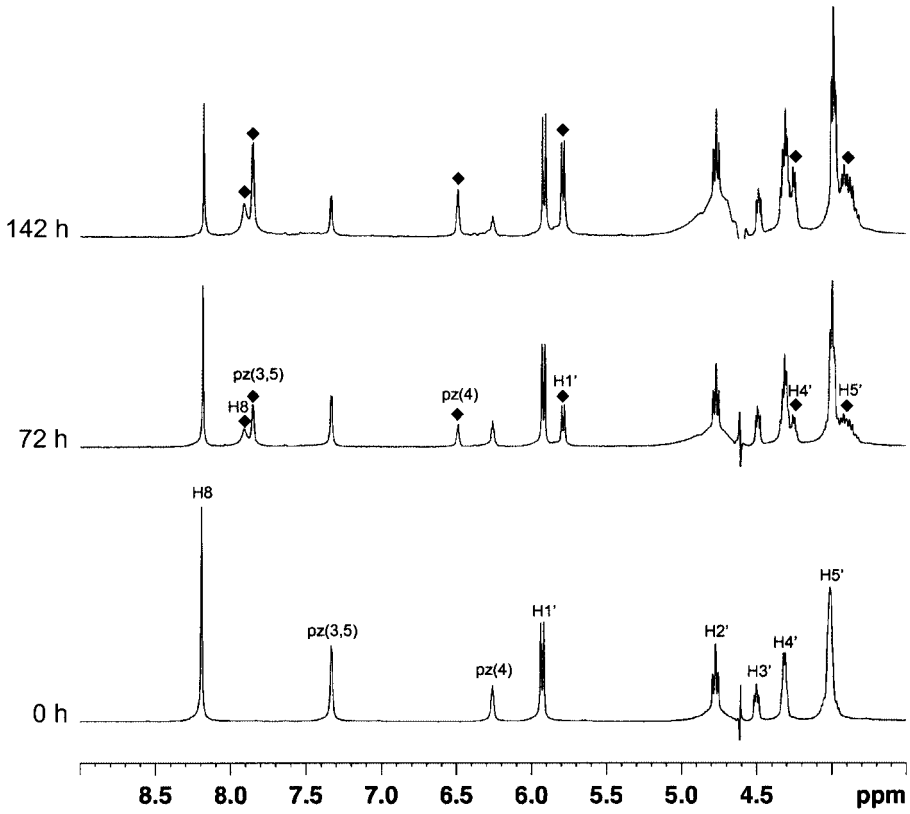

Figure 4. ^{1}H NMR spectra on the reaction of **3** with excess (4 equiv.) of GMP in unbuffered D_2O solution (pD 8.2) measured at 310 K as a function of time. The symbol (filled black diamonds) shows the newly appeared H8 and sugar ring proton signals (H1′, H4′ and H5′) of GMP ligands, and azolate protons in a 1:2 complex, [{Pt(*R*,*R*-dach)$_2$(GMP-*N7*)}$_2$(μ-pz)]$^-$ (**III**-(GMP)$_2$]

The ^{1}H NMR profiles of **III**-(GMP)$_2$ are similar to those of **I**-(GMP)$_2$ (Figure 4). A broad H8 signal is observed at higher field compared to free GMP. This upfield shift also agrees with well-stacked guanine ligands. The H1′ ($J_{1'-2'}$ = 4.959 Hz), H4′ and H5′ protons show significant upfield shifts, just as found for **I**-(GMP)$_2$.

^{195}Pt NMR

The ^{195}Pt NMR chemical shifts for the **I**-(GMP)$_2$, **II**-(GMP)$_2$, and **III**-(GMP)$_2$ are all found in the region expected for a [PtN$_4$] coordination sphere, further confirming the platinum coordination to N7 of GMP. The spectrum found for compound **2** is split into two signals,[13] owing to the two slightly different [PtN$_3$O] environments. On the other hand, the single peak observed for **II**-(GMP)$_2$, is supportive for the isomerization reaction, just as expected from the ^{1}H NMR study.

^{31}P NMR

Given that the 1:2 complexes have strong intramolecular hydrogen bonding between the ammine ligands and phosphate group, higher field shifts of their ^{31}P NMR signals, compared to free GMP (pD = 7.0), could be expected. The signals of the phosphate groups for **I**-(GMP)$_2$ and **II**-(GMP)$_2$ are observed at δ = 0.09−0.12 ppm lower field, and that for **III**-(GMP)$_2$ appeared at only 0.09 ppm higher field. These deviations from free GMP are not considered to be significant.

pH-Titration Experiments

The pH titration curves for GMP, **II**-(GMP)$_2$ and **III**-(GMP)$_2$ are depicted in Figure 5. As is clear from the plots, the N7 (*de*)protonation effects of the GMP ligands of **II**-(GMP)$_2$ and **III**-(GMP)$_2$ are absent, confirming the plati-

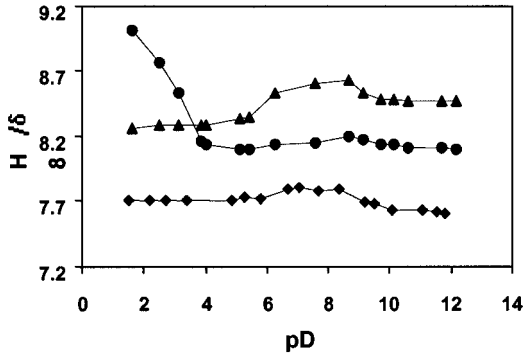

Figure 5. Plots of chemical shift (δ) of H8 resonance vs. pD for free GMP (filled black circles), **II**-(GMP)$_2$ (filled black triangles) and **III**-(GMP)$_2$ (filled black diamonds). pH titrations were performed in unbuffered D_2O solution at 298 K with adjusting pD with 0.1 M DNO_3 and 0.1 M NaOD

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

num coordination at the N7 site for these complexes. A pH-titration graph of H8 of **I**-$(GMP)_2$ is uninformative, due to the complete broadening at room temp. as stated above.

Kinetic Aspects

The reactions of **1**−**3** with GMP were monitored by ^1H NMR spectroscopy at 310 K. The reactions with stoichiometric quantities (2 equiv.) of GMP do fit to second-order plots (Figure 6). The reaction rates as determined for the reaction of the complexes are presented in Table 2.

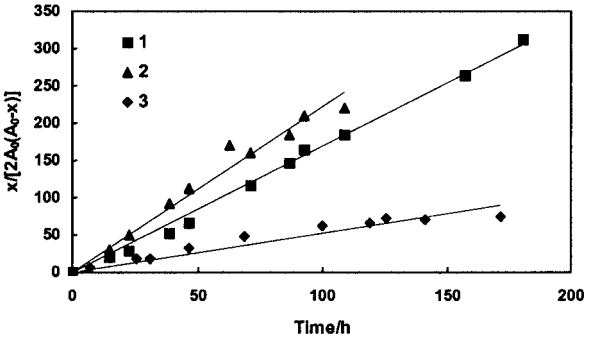

Figure 6. Second-order plots of the reactions of **1** (filled black squares), **2** (filled black triangles) and **3** (filled black diamonds) with 2 equiv. of GMP in unbuffered D_2O solution (pD 8.2) at 310 K. Values for k were calculated from the slope of the lines, as given in Equation (1)

Table 2. Obtained second-order rate constants (k in $M^{-1}s^{-1}$) of the platinum complexes for the reactions of **1**−**3** with 2 equiv. of GMP at 310 K in D_2O with or without 0.1 M phosphate

	Reaction rates k [$M^{-1}s^{-1}$]		
pD/compound	**1**	**2**	**3**
5.4[a] (2 equiv.)	$2.36\cdot10^{-4}$	$3.34\cdot10^{-4}$	$1.53\cdot10^{-4}$
6.9[a] (2 equiv.)	$1.39\cdot10^{-4}$	$2.64\cdot10^{-4}$	$1.11\cdot10^{-4}$
8.4[a] (2 equiv.)	$1.25\cdot10^{-4}$	$2.36\cdot10^{-4}$	$6.94\cdot10^{-5}$
8.2[b] (2 equiv.)	$4.67\cdot10^{-4}$	$6.15\cdot10^{-4}$	$1.46\cdot10^{-4}$

[a] Reactions were performed in 0.1 M phosphate D_2O solution. [b] Reactions were performed in unbuffered D_2O solution.

Compound **2** is found to react faster with GMP than **1**. Even though the amino groups in dach ligands of **3** should have similar *trans* effects on the leaving OH group as the ammine ligands,[21] the dach-containing complex reacts with GMP at a significantly slower rate compared to **1**. The kinetic rate of ligand-exchange reactions with associative mechanism are known to be negatively influenced by steric hindrance of the substrates, and more than those with dissociative reactions. Therefore, the observed kinetic difference could be ascribed to the steric effects of the bulky cyclohexane rings. Another contribution might be the reduced potential of dach to form hydrogen bonds compared to ammonia, since the first contact of these cationic azolato-bridged compounds is supposed to be non-covalent interactions, such as ionic and hydrogen bonds. Comparison of all the kinetic data shows that the reaction rates for all the complexes are faster when the pD decreases (see Figure 7). The pK_b value for the bridging OH group of this series of azolato-bridged dinuclear Pt complexes is very low [e.g. pK_b = 0.4 for complex **1** (unpublished observations)], and no direct contribution to the kinetics can be expected within the pD range applied for this study. However, an increase in H^+ concentration could catalytically act on the hydroxo bridge to promote the first substitution reaction.

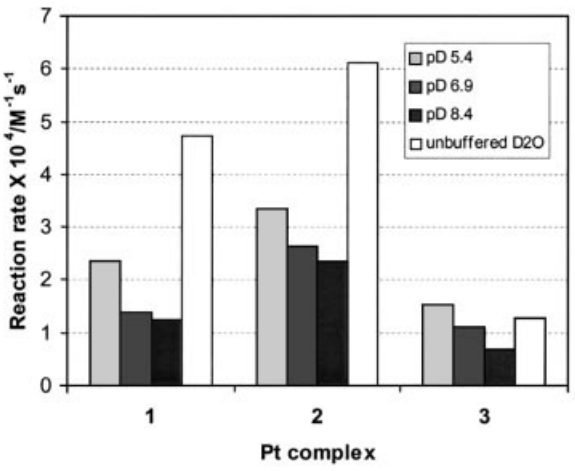

Figure 7. Column graph showing the second-order rate constants for the reaction of **1**−**3** with 2 equiv. of GMP in 0.1 M phosphate D_2O solutions with different pD (5.4, 6.9, and 8.4) and unbuffered D_2O solution (pD 8.2)

Interestingly, in unbuffered D_2O solutions, the reactivity of all complexes for GMP dramatically increases. This may be indicative for the affinity of the OH bridge and/or amine ligands of the platinum complexes for phosphate, i.e. the phosphate in the buffer competitively binds to the platinum complexes electrostatically and competes with the phosphate groups of GMP. This tendency is more pronounced in the reactions of **1** and **2**, thereby clearly demonstrating the importance of the non-covalent (dipolar) interaction with the phosphate group of the GMP as an initial step of the reaction. For confirmation, we undertook a similar kinetic study in other salts, or buffer solutions, such as MES buffer, using HPLC (data not shown). No such a large decrease in the kinetic rate compared to an unbuffered solution was found, and therefore, a high non-covalent (dipolar) affinity of these complexes can be expected also for the phosphate backbone of DNA. This interaction might be important for the processes, such as major-groove or minor-groove binding. Cisplatin, as a neutral molecule, is known to be activated and positively charged by hydrolysis (a first-order reaction with $t_{1/2}$ = 2 h[23]), and the activated species appears to coordinate to nucleic acids, promptly. Therefore, for these azolato-bridged dinuclear platinum(II) non-covalent accumulation on DNA must be more probable.

Conclusion

Interactions between transition-metal complexes and DNA have been investigated, since DNA has been believed and accepted to be one of the critical targets of cisplatin. The azolato-bridged dinuclear Pt^{II} complexes react with GMP at a relatively slow rate, and show a clear tendency to faster reactions with GMP, when the solution pH decreases. This series of Pt^{II} complexes was aimed to generate a 1,2-intrastrand crosslinks with a minimum kink of DNA. According to our recent report using the hairpin-stabilized double-stranded DNA, d(TATGGCATT$_4$ATGCCATA),[16] **1** indeed yields only the 1,2-intrastrand GG crosslink on a hairpin-stabilized double-stranded DNA, while **2** serves not only as the intrastrand crosslinker, but also generates interstrand GC crosslinks as a minor product. This behaviour appears to, depend on the different configuration about the triazolate ring, such as *N1*,*N2*- and *N1*,*N3*-coordination of the two Pt^{II} atoms. It is as yet too early to conclude that only such coordination interactions would trigger the cytotoxic effects. Accordingly, also ionic (non-coordination) interactions with DNA should also be taken into consideration[24] for the following reasons:

i) The reactions with small DNA fragments proceed at much slower rate compared with cisplatin.

ii) The complexes possess a 2+ charge.

iii) The complexes appear to have a significant affinity with the phosphate group.

Therefore, dipolar or ionic interactions, in addition to coordination, may indeed have a significant influence on the cytotoxicity of such compounds.

Experimental Section

Materials: Guanosine 5′-monophosphate (GMP) was obtained from Sigma. The azolato-bridged dinuclear platinum complexes, [*cis*-{Pt(NH$_3$)$_2$}$_2$(μ-OH)(μ-pz)](NO$_3$)$_2$ (**1**), [*cis*-{Pt(NH$_3$)$_2$}$_2$(μ-OH)(μ-1,2,3-ta-*N1*,*N2*)](NO$_3$)$_2$ (**2**) were prepared as reported before.[12,13]

Preparation of [{Pt(*R*,*R*-dach)}$_2$(μ-OH)(μ-pz)](NO$_3$)$_2$ (3): 50 mL of a water solution containing 0.224 g of Hpz (3.24 mmol) and 0.62 g of [{Pt(*R*,*R*-dach)}(μ-OH)]$_2$(NO$_3$)$_2$ (0.81 mmol) was stirred and heated at 60 °C in the dark. After 3 h incubation, the solution was filtered and the solvents evaporated to dryness, and the resulting white material was washed with 200 mL of ice-cold EtOH and diethyl ether. Recrystallization was carried out from water. Yield: 0.39 g (57%). $C_{15}H_{32}N_8O_7Pt_2{\cdot}H_2O$: calcd. C 21.33, H 4.06, N 13.27; found C 21.44, H 3.86, N 13.23%. ^{1}H NMR (D$_2$O, ppm): δ = (pz resonance) 7.39 (2 H, d), 6.30 (1 H, t), (cyclohexane resonance) 2.40 (4 H, b), 2.07 (4 H, b), 1.59 (4 H, b), 1.32 (4 H, b), 1.17 (4 H, b). ^{195}Pt NMR (D$_2$O, ppm): δ = −2272 (reference: Na$_2$PtCl$_6$).

NMR Measurements: All the NMR spectra were recorded on a Bruker DPX300 spectrometer at 300 MHz. For the monitoring of the GMP reactions, kinetic samples were measured at 310 K. Regarding the characterization for the resulting products, ^{1}H, ^{31}P, and ^{195}Pt NMR spectra were measured at 298 K in a 50 mM phosphate buffer solution (pD = 7.0) and referred to TSP and Na$_2$PtCl$_6$, and H$_3$PO$_4$ (85% in D$_2$O), respectively. For a pH titration study, the pD was adjusted with 0.1 and 1 M solutions of NaOD and DNO$_3$, and the ^{1}H NMR spectra were measured at 298 K.

Reactions in the NMR Tube: The reactions of complexes **1**−**3** with GMP were performed in the NMR tube at 310 K and followed by ^{1}H NMR spectroscopy as a function of time. The reactions of the platinum complexes (4 mM) with stoichiometric (2 equiv., 8 mM) and excess amount (4 equiv., 16 mM) of GMP were carried out in unbuffered D$_2$O solutions (pD of the reaction solution at $T = 0$ is 8.2) and 0.1 M phosphate buffered D$_2$O solutions (pD 5.4, 6.9, and 8.4). The reactions performed in pD 5.4 solutions increased the pD value by approximately 0.2 units after 1 week, and the pD values did not change for those performed in unbuffered D$_2$O solutions during the reaction.

Kinetic Analysis: To determine the time-dependent concentration of the reactants (**1**−**3**) and final product (**I**-(GMP)$_2$, **II**-(GMP)$_2$, and **III**-(GMP)$_2$], the relative integration values for the azolate protons [pz(3,5), ta(4,5), and pz(4) for **1**, **2**, and **3**, respectively) were applied. The kinetic data obtained from the stoichiometric reactions fit to the second-order kinetics [Equation (1); correlation coefficients are 0.963−0.998], Therefore, for the determination of the second-order rate constants (k), the following equation was applied:

$$x/[2A_0(A_0 - x)] = kt \quad (1)$$

where A_0 is the initial concentration of the reactant (**1**−**3**) and x is the concentration of the final product (1:2 complex) at time t. The k values obtained correspond to the first steps of the series of the reactions.

pH Titration Experiments: After each reaction of **2** and **3** with 2 equiv. of GMP in unbuffered D$_2$O solution was completed, the pD of the samples was adjusted by 0.1 M DNO$_3$ and NaOD and measured at 298 K using a PHM 80 pH meter (Radiometer) before and after each ^{1}H NMR measurement.

Synthesis, X-ray Crystal Structure and Magnetic Properties of Oxalato-Bridged Copper(II) Complexes with 2,3-Bis(2-pyridyl)pyrazine, 2,3-Bis(2-pyridyl)quinoxaline and 2,2′-Bipyrazine as Peripheral Ligands

Keywords: Copper / Magnetic properties / N ligands / Oxalate

Five oxalate-containing copper(II) complexes of formula $[Cu(dpq)(H_2O)(ox)]\cdot 5H_2O$ (**1**), $[Cu(dpp)(H_2O)(ox)]\cdot H_2O$ (**2**), $[Cu(bpz)(ox)]_n$ (**3**), $[Cu_2(dpp)_2(H_2O)_2(NO_3)_2(ox)]\cdot 4H_2O$ (**4**) and $[Cu_2Cl_2(bpz)_2(H_2O)_2(ox)][Cu(bpz)(H_2O)_2(ox)]\cdot 2H_2O$ (**5**) [dpq = 2,3-bis(2-pyridyl)quinoxaline; dpp = 2,3-bis(2-pyridyl)-pyrazine; bpz = 2,2′-bipyrazine; ox = oxalate] were prepared and their structures were determined by X-ray diffraction on single crystals. Complexes **1** and **2** are discrete mononuclear complexes with oxalate and dpq (**1**)/dpp (**2**) acting as bidentate ligands. Complex **3** is a neutral oxalato-bridged (2,2′-bipyrazine)copper(II) chain where the oxalate adopts a bidentate/monodentate coordination mode, whereas **4** is an oxalato-bridged copper(II) dinuclear complex with ox and dpp acting as bis-bidentate and bidentate ligands, respectively. The structure of **5** contains neutral $[Cu(bpz)(H_2O)_2(ox)]$ (mononuclear) and $[Cu_2(bpz)_2(H_2O)_2Cl_2(ox)]$ (dinuclear) units where the bpz acts as a bidentate ligand and the oxalate group adopts the bidentate (mononuclear) and bis-bidentate (dinuclear) coordination modes. The copper atoms have distorted square pyramidal (**1** and **2**) and elongated octahedral (**3**–**5**) geometries: two nitrogen atoms from heterocyclic N-donors and two oxalate-oxygen atoms occupy the equatorial positions (**1**–**5**) and a water molecule (**1** and **2**), two oxalate-oxygen atoms (**3**), a water molecule and a nitrate-oxygen (**4**), and either two water molecules (**5**), mononuclear) or a chlorine atom and a water molecule (**5**, dinuclear) fill the axial ones. Magnetic susceptibility measurements for **3**–**5** in the temperature range 1.9–290 K reveal the occurrence of weak (J = –1.4 cm^{-1}, **3**) and strong (–312 and –345 cm^{-1} for **4** and **5**, respectively; $\hat{H} = -J\cdot\hat{S}_A\cdot\hat{S}_B$) antiferromagnetic interactions between the copper(II) atoms in agreement with the out-of-plane (**3**) and in-plane (**4** and **5**) exchange pathways involved.

Introduction

An impressive amount of work has been devoted to magneto-structural studies of oxalato-bridged copper(II) complexes.[1−5] The four main reasons accounting for this continuous interest are: (i) the remarkable efficiency of the oxalate ligand (the dianion of oxalic acid H_2ox) to mediate strong magnetic interactions between copper(II) ions when adopting the bis-bidentate bridging mode (singlet-triplet energy gap up to -386 cm^{-1} between a pair of copper(II) ions separated by more then 5.4 Å);[1,5] (ii) the copper(II) ion is the simplest case of magnetic exchange given that it corresponds to a doublet spin state without orbital contribution; (iii) the great plasticity of the coordination sphere of the copper(II) ion (four-, five- and six-coordinate geometries are commonly observed), which allows variations of the orientation and symmetry of the molecular orbital describing its unpaired electron (magnetic orbital) simply by changing the nature of the blocking N-donor ligand used;[1a,1c,1e] (iv) X-ray quality crystals which are commonly air- and moisture-stable can be obtained from aqueous solutions containing oxalate, copper(II) and organic ligands by slow evaporation of the solvent at room temperature.

The major synthetic problem chemists had to overcome when investigating the formation of discrete oxalate-containing copper(II) complexes is the formation of the insoluble, oxalato-bridged copper(II) chain $Cu(C_2O_4)\cdot$

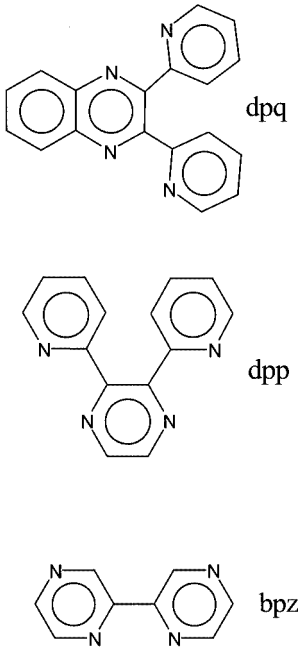
$1/3H_2O$.[3b,6] The formation of this chain is precluded in the presence of polydentate nitrogen-donor ligands (L) allowing the formation of mixed-ligand species [CuL(ox)], which, in turn, can be used as ligands in designing higher nuclearity species. Two representative examples of this versatility are $[Cu(tmen)(ox)\cdot 4H_2O]$ and $[Cu(terpy)(H_2O)(ox)]\cdot 4H_2O$ (tmen = *N*,*N*,*N*′,*N*′-tetramethylethylenediamine; terpy = 2,2′:6′,2′′-terpyridine).[1c,1e,7] The reaction of the former neutral mononuclear complex with the preformed species $[Cu(tmen)]^{2+}$ and $[Cu(dien)]^{2+}$ (dien = diethylenetriamine) in aqueous solution provides a direct route towards the centrosymmetric and asymmetric oxalato-bridged copper(II) complexes of formula $[Cu_2(tmen)_2(H_2O)_2(ox)](ClO_4)_2\cdot 1.25H_2O$ and $[Cu(dien)(ox)Cu(H_2O)_2(tmen)](ClO_4)_2$.[1c,1e] As for the terpy-containing precursor, its reaction with the partially blocked species $[Cu(terpy)]^{2+}$ and $[VO(ox)]\cdot 4H_2O$[8] affords the oxalato-bridged homo- and heterometallic compounds $[Cu_2(terpy)_2(H_2O)_2(ox)][Cu_2(terpy)_2(ox)](ClO_4)_4\cdot 2H_2O$ and $[Cu(terpy)(ox)VO(ox)(H_2O)]\cdot H_2O$.[7,9]

Following our previous magneto-structural works where the nitrogen heterocycles 2,2′-bipyridine (bipy),[1d,1i,1m,3g,10] 1,10-phenanthroline (phen),[1f,11] 2,2′-dipyridylamine (dpa)[1p] and 2,2′-bipyrimidine (bpym)[4a] were used as blocking ligands in the copper(II)-oxalate system, we tried to extend these studies to less-common nitrogen donors such as 2,3-bis(2-pyridyl)quinoxaline (dpq), 2,3-bis(2-pyridyl)pyrazine (dpp) and 2,2′-bipyrazine (bpz; Scheme 1). Our first attempts afforded the copper(II) complexes of formula $[Cu(dpq)(H_2O)(ox)]\cdot 5H_2O$ (**1**), $[Cu(dpp)(H_2O)(ox)]\cdot H_2O$ (**2**), $[Cu(bpz)(ox)]_n$ (**3**), $[Cu_2(dpp)_2(H_2O)_2((NO_3)_2(ox)]\cdot 4H_2O$ (**4**) and $[Cu_2(bpz)_2(H_2O)_2Cl_2(ox)][Cu(bpz)(H_2O)_2(ox)]\cdot 2H_2O$ (**5**). Their preparation, structural characterization and magnetic investigation are presented here.



Scheme 1

Results and Discussion

Short Description of the Synthesis

Compound **2** was synthesized by treating a suspension of copper(II) oxalate (insoluble) and the N-donor ligand (dpp). Preparations of complexes **1**, **3**, **4** and **5** were in each case accomplished by treating a common, soluble copper(II) salt with the chosen N-donor ligand, and subsequently adding a solution containing oxalate. The reaction medium was H_2O/EtOH in the cases of **1**, **2** and **4**, H_2O in the case of **3** and **5**. For **1**, **2** and **4** the stoichiometric amounts of reactants used are reflected in the stoichiometry of the products; for **3** and **5** (L = bpz) deficiency and excess, respectively, of oxalate are present in the reaction mixture as compared to the products formed, the Cu^{II}/bpz/ox reactants ratios being 2:2:1 and 1.5:1.5:1, respectively.

Description of the Structures

$[Cu(dpq)(H_2O)(ox)]\cdot 5H_2O$ (1)

The structure of compound **1** is composed of discrete, neutral $[Cu(ox)(H_2O)(dpq)]$ molecules (Figure 1) and water of hydration. The copper atom has a distorted square-pyramidal environment (tetragonality parameter $\tau = 0.17$),[12] binding equatorially to two oxalate oxygen atoms [1.9344(15) and 1.9677(14) Å for Cu−O] and two dpq nitrogen atoms [1.9718(17) and 2.1244(16) Å for Cu−N(pyridyl) and Cu−N(pyrazine), respectively]; a water molecule coordinates in the apical position [2.1867(15) Å for $Cu-O_w$]. The equatorial plane of copper is tetrahedrally distorted (maximum atomic deviation 0.092 Å), with the metal atom displaced by 0.234 Å from the best mean plane toward the apical ligand. The dihedral angle between the equatorial plane and the best plane through the oxalate group is 7.6°. The quinoxaline group makes dihedral angles of 12.9 and 58.2° with the coordinated and uncoordinated pyridyl rings, respectively.

[a] Symmetry transformations used to generate equivalent atoms: (b) $1-x, 1-y, -z$; (c) $1+x, y, z$; (d) $1+x, y, z-1$; (e) $1-x, -y, -1-z$; (f) $-x, 1-y, 1-z$; (g) $x, y-1, z$; (h) $-x, -y, -z$.

oxalate region of one molecule and the pyrazine ring of the other, the distances from individual pyrazine atoms to the oxalate plane ranging from 3.22 to 3.50 Å. This arrangement gives rise to the shortest metal···metal distance in the crystal [4.4193(5) Å for Cu···Cu(1a); (a) = $-x, 1-y, -z$], and also effectively screens the sixth coordination position of the copper atom, the Cu···N(2a) distance being 3.58 Å. There is additionally a slight π-π overlap between the benzo parts of the quinoxaline ligands of centrosymmetrically related molecules, the distances from the quinoxaline plane to three overlapping atoms ranging from 3.43 to 3.48 Å. The molecules are laced together through an extensive network of hydrogen bonds where oxalate, uncoordinated nitrogen and all water molecules are involved (see Table 1). The supramolecular arrangement features parallel sheets of molecules (Figure S1 in the Supporting Information).

The oxalate and dpq groups both coordinate in a monobidentate fashion, and thus have sites available for further metal binding. The bond lengths in the oxalate group are as typically found for this ligand in the didentate coordination mode, the C−O bonds of the coordinated oxygens [1.289(2) and 1.281(2) Å] being significantly longer than those of the uncoordinated ones [1.238(2) and 1.225(2) Å]. dpq is known to act as a chelate ligand either by forming a five-membered ring involving one pyridyl and one pyrazine nitrogen, or by forming a seven-membered ring involving the two pyridyl nitrogen atoms.[13,14] To the best of our knowledge, only two copper(II) complexes with unsubstituted dpq have been structurally characterized previously.[14] In one of these a seven-membered chelate ring was found[14a] and in the second ($[CuBr(dpq)]HSO_4\cdot$dpq) both chelate modes are present.[14b] In addition, the structures of two copper(II) complexes with methyl- or methoxy-substituted dpq (substitution at benzo carbon atoms) have been reported, and in both cases seven-membered chelate rings occur.[13h,15] Compound **1** is therefore the second example of a dpq-containing copper(II) complex with a five-membered chelate ring. It is noteworthy that the Cu−N(2)(pyrazine) bond length of 2.1244(16) Å is rather long for a copper−nitrogen bond in the equatorial plane of a square pyramid, and it is much longer than the Cu−N(1)(pyridyl) bond [1.9718(17) Å]. A similar feature was observed in $[CuBr(dpq)]HSO_4\cdot$dpq [2.101(8) vs. 2.016(8) Å].[14b] A certain difference in pyrazine and pyridyl Cu−N bond lengths is to be expected due to the weaker σ-donor strength of the pyrazine group.[13e] However, it is likely that steric effects also play a role in lengthening the Cu−N(pyrazine) bond in cases where the quinoxaline moiety is close to coplanar with the equatorial plane. In compound **1** this is indicated by the fact that the O(1)−Cu−N(2) angle of 101.63(6)° is much wider than the O(2)−Cu−N(1) angle of 90.88(6)°, possibly to make more room for the benzo part of the dpq ligand. A further indication of the steric effect is found when making a comparison with related dpp-containing copper(II) complexes where no benzo group is present. Studies of these compounds have shown that, although weak, axial bonds are often formed to the pyrazine nitrogen, presumably due to the weaker σ-donor strength mentioned above; the Cu−N(pyrazine) bond is comparable to, or only slightly longer than, the Cu−N(pyridyl) bond in cases where dpp chelates in two equatorial positions to a copper atom with square planar or square pyramidal geometry.[16] Analogous features have also been observed in

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

the copper(II) complexes of the more rigid pap ligand (pap = pyrazino[2,3-*f*][4,7]phenanthroline).[16b,17]

[Cu(dpp)(H_2O)(ox)]·H_2O (2)

The structure of compound **2** consists of neutral, mononuclear [Cu(dpp)(H_2O)(ox)] units (Figure 2) and water of hydration. The copper coordination sphere is square pyramidal with bidentate oxalate and dpp binding in the equatorial plane [1.941(2) and 1.953(2) Å for Cu−O and 1.988(2) and 1.989(2) Å for Cu−N] and a water molecule in the apical position [2.250(2) Å for Cu−O_w]. The mean equatorial plane of copper has a very slight tetrahedral distortion (maximum deviation 0.024 Å), and copper is displaced by 0.169 Å from this plane in the direction toward the apical oxygen atom. The oxalate group is essentially coplanar with the equatorial plane (dihedral angle 0.9°). The pyrazine ring makes a dihedral angle of 12.2° with the coordinated pyridyl ring, and a dihedral angle of 66.6° with the free pyridyl ring.

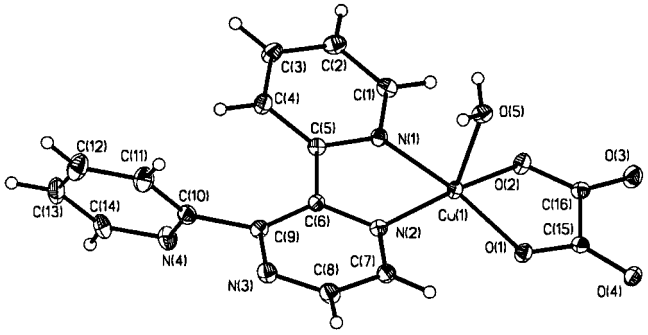

Figure 2. The complex unit [Cu(dpp)(H_2O)(ox)] in compound **2** showing the atomic numbering scheme; thermal ellipsoids are plotted at the 30% probability level

In the crystal there is a slight π-π overlap between the oxalate group of the reference molecule and the coordinated pyridyl ring of a molecule displaced by the unit-cell translation along the *a* axis, with distances from the oxalate plane to the overlapping atoms being 3.30−3.42 Å. This arrangement also screens the sixth coordinating position of copper. There is also a slight π-π overlap between the uncoordinated and coordinated pyrazine of two molecules related by a screw-axis translation (3.46−3.62 Å). The complex molecules are connected by hydrogen bonds into a three-dimensional network: the coordinated water links neighbouring molecules to oxalate groups through hydrogen bonds, and the crystal water connects to pyridyl nitrogen atoms through hydrogen bonds (see Table 2 and Figure S2). The shortest intermolecular metal···metal distance is 5.911(1) Å [Cu(1)···Cu(1a); (a) = $-x$, $y - 0.5$, $2 - z$] and occurs between molecules connected by a hydrogen bond between coordinated water and oxalate oxygen.

The oxalate shows the typical features of bidentate bonding, with two long [1.281(4), 1.297(3) Å] and two short [1.218(3), 1.235(3) Å] C−O bonds. dpp bond lengths and angles compare well with previous findings.[16] The rotation of the uncoordinated pyridyl ring is also of a similar magnitude to that observed in other complexes with bidentate dpp.[16b,16e] In compound **2** the bonds from pyrazine and pyridyl nitrogen atoms to copper are comparable in length [1.982(2) and 1.988(2) Å, respectively], as has been observed earlier for equatorially coordinated, bidentate dpp,[16] but in contrast to the observation in **1** where the pyrazine ring is part of the quinoxaline moiety.

[Cu(bpz)(ox)]$_n$ (3)

The structural building blocks in **3** are the neutral [Cu(bpz)(ox)] units. Both ox and bpz are bidentate ligands and they surround the copper atom in a close to square-planar geometry [1.9252(14) and 1.9258(15) Å for Cu−O and 1.9837(17) and 1.9869(16) Å for Cu−N]. Copper also has, however, two weak axial connections to semicoordinated oxalate oxygen atoms of centrosymmetrically related mol-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

ecules [2.6170(18) and 2.7518(17) Å for Cu(1)−O(3a) and Cu(1)−O(1b); (a) = $-x$, $-y$, $-z$ and (b) = $1-x$, $-y$, $-z$] resulting in a 4+2 coordination sphere for copper, and formation of a chain with double out-of-plane oxalato bridges (Figure 3). The equatorial plane of copper has a moderate tetrahedral distortion (maximum atomic deviation 0.101 Å), the copper atom being displaced by only 0.004 Å from this plane toward O(3b). The dihedral angles between the equatorial plane and the oxalate and bpz planes are 12.8° and 5.3°, respectively.

[a] Symmetry operations used to generate equivalent atoms: (a) $1-x$, $-y$, $-z$; (b) $-x$, $-y$, $-z$; (c) $1+x$, $1+y$, $1+z$; (d) $1+x$, $1+y$, z; (e) x, y, $1+z$.

The overlap between parallel oxalate groups across the Cu(1)···O(3b)/Cu(1b)···O(3) bridge is associated with π-π stacking, with an interplanar spacing of 2.88 Å. The other pair of axial bonds [Cu(1)···O(1a)/Cu(1a)···O(1)] leads to overlap between oxalate and bpz groups, the distance from the oxalate plane to the overlapping bpz atoms ranging from 2.90 to 3.37 Å. The shortest intermetallic distance in the crystal, 3.5279(6) Å, is found between copper atoms linked by the latter type of oxalate bridge [Cu(1)···Cu(1a)]. The intermetallic distance across the Cu(1)−O(3b)/Cu(1b)−O(3) bridge is 4.8952(9) Å. The chains in the crystal are linked through C−H···O interactions, forming parallel layers (Figure 4, Figure S3 and Table 3).

To the best of our knowledge the only copper(II) bpz complex previously characterized by X-ray crystallography is $[Cu(bpz)(H_2O)(C_5O_5)]$ (C_5O_5 is the dianion of croconic acid).[18] In this compound an axially bound water molecule precludes a chain formation analogous to that found in **3**;

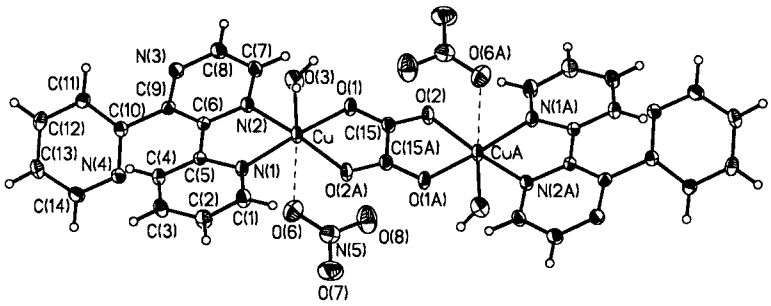

Figure 5. The complex unit $[Cu_2(dpp)_2(H_2O)_2((NO_3)_2(ox)]\cdot 4H_2O$ (**4**), showing the atomic numbering scheme; thermal ellipsoids are plotted at the 30% probability level; symmetry operations: (a) $1 - x$, $1 - y$, $1 - z$

instead the complex units are connected pairwise through weak Cu···O(croconate) interactions. The two pyrazine rings in **3** are practically coplanar (dihedral angle 3.3°), as was the case in the croconato compound. The bond lengths and angles involving bpz are similar in the two bpz-containing copper(II) compounds. Structures of a number of bpz complexes with Ag^{I},[19] Fe^{II},[20] Co^{II},[21] Ru^{II} and Ru^{I},[22] Pd^{II} and Pt^{II} [23] have been reported. In several of these polynuclear complexes the simultaneous occurrence of the chelating and monodentate binding modes for this ligand[19,23] imposes a twist between the two pyrazine ligands.

$[Cu_2(dpp)_2(H_2O)_2(NO_3)_2(ox)]\cdot 4H_2O$ (4)

The structure of **4** is built of centrosymmetric oxalato-bridged dinuclear $[Cu_2(dpp)_2(H_2O)_2(NO_3)_2(ox)]$ units (Figure 5) and water of hydration. The copper coordination may be described as elongated octahedral of the 4+1+1′ type, where two oxalate oxygen atoms and two dpp nitrogen atoms occupy the equatorial positions [1.982(2) and 1.990(2) Å for Cu−O and 1.960(2) and 1.981(2) Å for Cu−N]; a water molecule coordinates in one axial position [2.238(2) Å for $Cu-O_w$] and a semicoordinated nitrate oxygen atom completes the coordination sphere [2.750(3) Å for Cu−O]. The equatorial plane of copper is essentially planar [maximum atomic deviation 0.013 Å] and the copper atom is displaced by 0.160 Å toward the axial water molecule. The bis-bidentate bridging oxalate group is planar and makes a dihedral angle of 7.3° with the mean copper equatorial plane. The dihedral angles between the pyrazine ring and the coordinated and uncoordinated pyridyl rings are 13.0° and 39.4°, respectively. The plane of the nitrate makes dihedral angles of 15.3° and 19.4° with the oxalate group and the equatorial plane, respectively, the average distances between the individual nitrate atoms and the oxalate and equatorial planes being 3.01 and 2.96 Å, respectively. The intramolecular copper···copper distance across the oxalate bridge is 5.171(1) Å.

The packing of the dinuclear units in the crystal results in partial π-π overlap between the pyrazine ring and pyridyl rings of two neighbouring molecules, the distances from the pyrazine plane to the overlapping pyridyl atoms being in the range 3.29−3.63 Å (Figure S4). The molecules are connected by hydrogen bonds involving water, oxalate and nitrate (Table 4 and Figure S4). The shortest intermolecular metal···metal distance occurs between atoms displaced by a unit translation along the *b*-axis (7.2598 Å). The corresponding molecules are connected by hydrogen bonds between coordinated water and nitrate.

The oxalate shows the typical features of bis-bidentate bonding, with the four Cu−O bonds being of the same length [1.254(3)/1.248(3) Å], intermediate between the bond lengths found in bidentate oxalate. The dpp bond lengths and angles compare well with those of compound **2** and with previous findings.[16] The Cu−N(pyrazine) bond [1.981(2) Å] is slightly longer than the Cu−N(pyridyl) bond [1.960(2) Å], but they are still similar, in contrast to the observation in **1** where the pyrazine ring is part of the quinoxaline moiety and steric effects probably tend to lengthen the bond to pyrazine.

$[Cu_2(bpz)_2(H_2O)_2Cl_2(ox)][Cu(bpz)(H_2O)_2(ox)]\cdot 2H_2O$ (5)

Two types of neutral complex units have cocrystallized in this compound: dinuclear $[Cu_2(bpz)_2(H_2O)_2Cl_2(ox)]$ and mononuclear $[Cu(bpz)(H_2O)_2(ox)]$ (Figure 6). The oxalate bridges the metal atoms in the bis-bidentate mode in the dinuclear unit whereas it acts as a bidentate ligand in the mononuclear one. A corresponding situation with coexistence of two analogous complex units in the same crystal was observed by some of us several years ago in copper(II) complexes of formula $[Cu_2(bipy)_2(H_2O)_2(ox)]X_n\cdot[Cu(bipy)(ox)]$ [X = NO_3^-, BF_4^-, ClO_4^- (n = 2) and SO_4^{2-} (n = 1)] where the bidentate bipy ligand was used instead of bpz.[1d,1i,10b] Each copper atom in the dinuclear unit of **5** has an elongated octahedral coordination sphere (4+1+1′ coordination) with two oxalate oxygen atoms [1.956(6) to 1.987(6) Å for Cu−O] and two bpz nitrogen atoms [1.988(7) to 2.009(7) Å for Cu−N] in the equatorial plane and a water molecule [2.509(7) and 2.514(7) Å for $Cu-O_w$] and a chlorine atom [2.629(3) and 2.649(3) Å for Cu−Cl] in the axial positions. The equatorial plane of each copper atom has a small tetrahedral distortion (maximum atomic deviations from the mean plane of 0.053 and 0.047 Å, respectively), and the copper atoms are displaced by 0.103 and 0.089 Å from this plane toward the axial chlorine atom. The dihedral angle between the bridging oxalate and either of the equatorial planes is 4.9°. The copper···copper distance across the bridging oxalate in the dinuclear unit is 5.1345(16) Å. The copper coordination geometry in the

[a] Symmetry transformations used to generate equivalent atoms: (a) $1-x, 1-y, 1-z$; (b) $x, y-1, z$; (c) $1-x, 2-y, 1-z$; (d) $1+x, y, z$. [b] Bifurcated hydrogen bond.

mononuclear unit is also elongated octahedral. The equatorial bonds between copper and oxalate oxygen atoms are somewhat shorter [1.928(6) and 1.937(6) Å] than those found in the dinuclear compound, while the Cu−N bonds are of similar lengths [1.992(7) and 2.013(7) Å]. Both of the axial ligands are water molecules [2.506(7) and 2.541(7) Å for $Cu-O_w$]. The copper equatorial plane is close to planar (maximum atomic deviation 0.015 Å). It is essentially coplanar with oxalate (dihedral angle 1.4°) and makes an angle of 8.7° with the bpz best plane.

The standard deviations in the bond lengths and angles of compound **5** are somewhat higher than in **1**−**4**, but the typical feature of two long C−O oxalate bonds (for oxygen coordinated to copper) and two shorter bonds involving non-coordinated oxygen is clearly seen in the mononuclear unit, while in the dinuclear unit all the C−O bonds are equal within the limits of errors. In the dinuclear unit the two pyrazine rings within each bpz moiety are practically coplanar (dihedral angles 2.8 and 3.1°), as was found in **3** and the $[Cu(bpz)(H_2O)(C_5O_5)]$ complexes.[18] In the mononuclear unit of **5** the bpz ligand is slightly more twisted, the dihedral angle between the two pyrazine rings being 12.1°.

In the crystal the molecules are linked through hydrogen bonds (see Table 5) and partial π-π overlap, resulting in an arrangement of wave-type layers (Figure S5). The most pronounced π-π interaction appears to be between the bpz and oxalate groups of neighbouring mononuclear units, the average distance from oxalate atoms to bpz plane being 3.22 Å.

IR Spectroscopy

The IR spectra of **1**−**5** have in common the occurrence of a strong and broad absorption centred at about 3420 cm^{-1} which is due to the OH stretching of both coordinated and crystallization water molecules participating in hydrogen bonds.[24] The C−H stretching vibrations of dpp in **2** and **4** (triplet between 3200 and 3060 cm^{-1}) and bpz in **3** and **5** (quadruplet between 3100 and 2925 cm^{-1}) are also observed in the high-frequency region. In the case of complex **1**, the C−H stretching vibrations of dpq are obscured by the strong and broad OH absorption of the water molecules. The characteristic bands of bidentate (**1**, **2** and **5**) and bridging (**3**−**5**) oxalate are also observed in the IR spectra of this series:[1i,1o,1p,18,25,26] ν_{as}(CO) vibration at 1708, 1650 and 1680 cm^{-1} (**1**), 1705, 1685 and 1660 cm^{-1} (**2**), 1712, 1680 and 1650 cm^{-1} (**3**), 1640 cm^{-1} (**4**) and 1710 sh, 1665 and 1640 cm^{-1} (**5**); ν_s(CO) stretching at 1411, 1357 and 1268 cm^{-1} (**1**), 1395, 1295 and 1255 cm^{-1} (**2**), 1406 and 1245 cm^{-1} (**3**), 1360 and 1310 cm^{-1} (**4**) and 1410, 1345, 1310 and 1275 cm^{-1} (**5**); δ(OCO) vibration at 790 (**1**), 792 (**2**), 789 (**3**), 790 (**4**) and 794 cm^{-1} (**5**). Finally, the bands observed at 1380, 1320 and 1080 cm^{-1} in the IR spectrum of **4** suggest the occurrence of monodentate coordination of the nitrate ion.[27]

Magnetic Properties

Compounds **3**−**5** were magnetically characterised by following the thermal variation of the magnetic susceptibility (χ_M). The magnetic properties of compounds **1** and **2** were not investigated because they are mononuclear.

The temperature dependence of the $\chi_M T$ product for **3** is shown in Figure 7. At room temperature, $\chi_M T$ is equal to 0.41 $cm^3\cdot mol^{-1}\cdot K$, a value which is as expected for a magnetically isolated spin doublet. Upon cooling, $\chi_M T$ smoothly decreases to reach a value of about 0.26 $cm^3\cdot mol^{-1}\cdot K$ at 1.9 K. The shape of this plot is indicative of a weak antiferromagnetic interaction. In agreement with

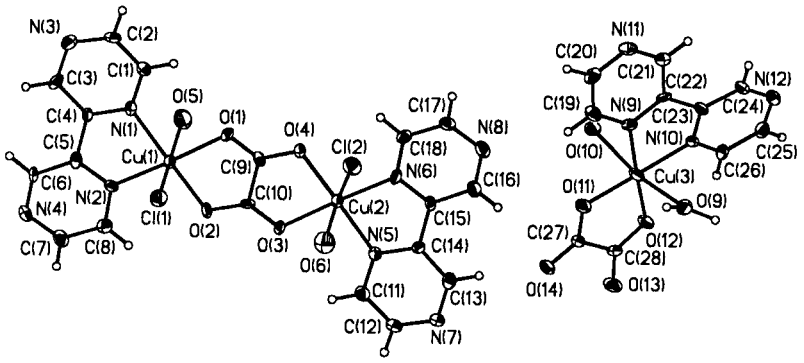

Figure 6. The dinuclear and mononuclear building blocks in $[Cu_2(bpz)_2(H_2O)_2Cl_2(ox)][Cu(bpz)(H_2O)_2(ox)]\cdot 2H_2O$ (**5**) showing the atom numbering scheme; thermal ellipsoids are plotted at the 30% probability level

the alternating chain structure of **3**, we analysed its magnetic data by the alternating-chain spin-exchange model through the Hamiltonian $\hat{H} = -J\Sigma(\hat{S}_{2i} \cdot \hat{S}_{2i-1} + \alpha\hat{S}_{2i} \cdot \hat{S}_{2i+1})$ where J and αJ are the alternating exchange-coupling parameters. The best-fit parameters are: $J = -1.44$ cm^{-1}, $\alpha J = -0.69$ cm^{-1}, $g = 2.10$ and $R = 1.4 \times 10^{-6}$; R is the agreement factor defined as $\Sigma_i[(\chi_M T)_{obs}(i) - (\chi_M T)_{calc}(i)]^2/\Sigma_i[(\chi_M T)_{obs}(i)]^2$. The calculated curve reproduces the experimental data very well. The weak intrachain magnetic interactions in **3** are as expected taking into account the out-of-plane exchange coupling involved. In fact, the unpaired electron on each copper(II) ion in this compound is defined by a $d_{x^2-y^2}$-type magnetic orbital (the x and y axes corresponding roughly to the copper−nitrogen bonds) that is mainly centred on the metal atom. The interchain exchange pathway involves axially coordinated oxalate oxygen atoms [2.75 and 2.62 Å for Cu(1)−O(1a) and Cu(1)−O(3b), respectively] whose spin density must be very weak. Consequently, simple symmetry considerations show that the overlap between the planar magnetic orbitals through the out-of-plane exchange pathway has to be very small and a weak magnetic interaction (either antiferro- or ferromagnetic depending on structural parameters such as the angle at the atom of the bridge and value of the axial bond) is expected,[29] as observed. Looking at the different intrachain out-of-plane exchange pathways occurring in **3**, [Cu(1)O(1)O(1a)Cu(1a) and Cu(1)O(2)-C(10)O(3)O(3b)C(10b)O(2b)Cu(1b)], most likely the strongest antiferromagnetic interaction ($J = -1.44$ cm^{-1}) corresponds to the shorter pathway (double oxalate−oxygen bridge) whereas the weakest one ($\alpha J = -0.69$ cm^{-1}) is ascribed to the longer pathway. Concerning the significance of these coupling values, it should be noted that: (i) weak antiferromagnetic interactions between copper(II) ions through double oxalate−oxygen bridge were observed in the complexes $H_2Im[Cu(ox)_2]$ (Him = imidazole, $J = -1.09$ cm^{-1})[2e] and $Na_2[Cu(ox)_2]\cdot 2H_2O$ ($J = -1.2$ cm^{-1}),[2b] and (ii) either weak antiferro- or ferromagnetic interactions were reported for the copper(II) complexes $M_2[Cu(ox)_2]\cdot 2H_2O$ [M = K$^+$ ($J = -0.7$ cm^{-1}) and NH_4^+ ($J = -0.6$ cm^{-1})],[2a] $[Cu(pyim)(H_2O)(ox)]\cdot 2H_2O$ [pyim = 2-(2-pyridyl)imidazole, $J = +0.04$ cm^{-1}][18] and $[Cu(H_2bim)(H_2O)(ox)]\cdot H_2O$ [H_2bim = 2,2′-biimidazole, $J = -0.08$][18] where the longer out-of-plane exchange pathway occurs.

The temperature dependence of χ_M for **4** [χ_M is the magnetic susceptibility per two copper(II) ions] is shown in Figure 8. The thermal dependence of the $\chi_M T$ product is shown in the inset of this figure. At room temperature, $\chi_M T$ is equal to 0.45 cm^3·mol^{-1}·K, a value which is well below that expected for two magnetically isolated spin doublets [0.75 cm^3·mol^{-1}·K for $g = 2.0$]. This value strongly decreases when cooling and it vanishes at low temperatures. The susceptibility plot exhibits a maximum at 260 K. These features are characteristic of a strong antiferromagnetic interaction between the two copper(II) ions in **4**. The experimental data closely follow Equation (1)

$$\chi_M = (2N\beta^2g^2/kT)[3 + \exp(-J/kT)]^{-1} + \text{tip} \quad (1)$$

which is the Bleaney−Bowers expression for a coupled dinuclear copper(II) complex, the Hamiltonian being $\hat{H} = -J\hat{S}_A \cdot \hat{S}_B$. N, g and β have their usual meanings and the tip is the temperature-independent paramagnetism for two copper(II) ions (120 cm^3·mol^{-1}). The best-fit parameters are: $J = -312$ cm^{-1}, $g = 2.09$ and $R = 1.9 \times 10^{-5}$ (R is the agreement factor defined as $\Sigma_i[(\chi_M)_{obs}(i) - (\chi_M)_{calc}(i)]^2/\Sigma_i[(\chi_M)_{obs}(i)]^2$). The strong intramolecular antiferromagnetic interaction in **4** is as expected keeping in mind the effective σ in-plane overlap between the two $d_{x^2-y^2}$ magnetic orbitals on each copper(II) ion [the x and y axes being roughly defined by the Cu(1)−N(1) and Cu(1)−N(2) bonds].[1c,1i,1e,5] This remarkable efficiency of the oxalato bridge to mediate strong antiferromagnetic interactions in dinuclear copper(II) complexes through the σ in-plane exchange pathway is well-known and it is illustrated by the magneto-structural data listed in Table 6. The small structural distortions in this series account for the differences observed in the magnetic coupling values.

The thermal dependence of the $\chi_M T$ product [per two copper(II) ions] for **5** is shown in Figure 9. $\chi_M T$ decreases upon cooling, tends to a quasi plateau at temperatures below 80 K and further decreases at very low temperatures. Keeping in mind that the structure of compound **5** contains both an oxalato-bridged copper(II) dinuclear unit and a

mononuclear one, this plot is interpreted as follows: the strong decrease of $\chi_M T$ in the high temperature range is due to a strong antiferromagnetic interaction within the dinuclear entity whereas the quasi plateau corresponds to the Curie law behaviour expected for the mononuclear copper(II) unit; the decrease of $\chi_M T$ in the very low temperature range is attributed to intermolecular magnetic interactions between the mononuclear copper(II) entities. Consequently, the magnetic data of **5** were analysed with Equation (2)

$$\chi_M = (2N\beta^2 g_d^2/kT)[3 + \exp(-J/kT)]^{-1} + [N\beta^2 g_m^2/k(T - \theta)] + \text{tip} \quad (2)$$

which is the sum of the Bleaney−Bowers equations for a coupled dinuclear copper(II) species, the Curie law for a mononuclear copper(II) unit (with a θ term accounting for the magnetic interaction between the mononuclear entities) and the temperature-independent paramagnetism [180 $cm^3 \cdot mol^{-1}$ for three copper(II) ions]. J is the magnetic coupling through the oxalate bridge in the dinuclear complex, and g_d and g_m are the mean g factors for the di- and mononuclear complexes, respectively. A least-squares fit of the experimental data of **5** with Equation (2) leads to the following set of parameters:

$J = -345\ cm^{-1}$, $g_d = 2.05$, $g_m = 2.10$, $\theta = -0.3$ K and $R = 4.8 \times 10^{-5}$ (R is the agreement factor defined as $\Sigma_i[(\chi_M T)_{obs}(i) - (\chi_M T)_{calc}(i)]^2/\Sigma_i[(\chi_M T)_{obs}(i)]^2$). The calculated curve reproduces very well the experimental data in the whole temperature range. The magnetic coupling in **5** compares well with that in complex **4** in agreement with the same σ in-plane exchange pathway that is involved in them. The slightly longer copper···copper separation across the bridging oxalate in **4** versus **5**, together with the somewhat larger dihedral angle between the oxalate and the mean equatorial plane in **4**, weaken somewhat the antiferromagnetic coupling in **4** as compared to that of **5** (see end of Table 6). The intermolecular interactions between the mononuclear units in the crystal of **5** (Figure S5 and Table 5) provide the exchange pathway for the weak antiferromagnetic coupling ($\theta = -0.3$ K) observed in the very low temperature range.

Finally, complex **5** provides an additional example of coexistence in the same crystal of the magnetic orbital [represented by the mononuclear copper(II) unit] and its combination through the oxalato bridge (dinuclear unit). Four examples of oxalate-containing copper(II) complexes with this special feature have previously been described, the blocking ligand being the parent bipy molecule.[1d,1i,10b]

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

Conclusions

The use of oxalate with the blocking ligands dpq, dpp and bpz has led to the preparation of five new copper(II) complexes with terminal (**1**, **2** and **5**) and bridging (**3**−**5**) oxalate. Strong (**4** and **5**) and weak (**3**) antiferromagnetic interactions between the copper(II) ions across bridging oxalato are observed, in agreement with the σ in-plane (**4** and **5**) and out-of-plane (**3**) exchange pathways involved. This study illustrates once more the importance of a detailed structural knowledge when interpreting magnetic properties.

Experimental Section

Materials: Copper(II) nitrate trihydrate, copper(II) chloride dihydrate, copper(II) triflate and potassium oxalate monohydrate were purchased from commercial sources and used as received. Cu(ox)·1/3H_2O and the ligands dpp, dpq and bpz were prepared as reported in the literature.[6,30−32] Elemental analyses (C,H,N) were carried out by the Microanalytical Service of the Universidad Autónoma de Madrid.

Compound 1: dpq (0.106 g, 0.5 mmol) was added to 100 mL of an H_2O/EtOH (80:20, v/v) mixture containing $Cu(NO_3)_2·3H_2O$ (0.17 g, 0.5 mmol) and the resulting brown solution was gently refluxed for fifteen minutes. Then, $K_2ox·H_2O$ (0.092 g, 0.5 mmol) was added whilst stirring and the solution turned olive green in a few minutes. Dark green parallelepipeds of **1** suitable for X-ray diffraction were obtained by slow evaporation of the solvent at room temperature. Yield 75%. $C_{20}H_{24}CuN_4O_{10}$ (543.97): calcd. C 44.18, H 4.41, N 10.30; found C 43.96, H 4.35, N 10.21.

Compound 2: Cu(ox)·1/3H_2O (g, 0.5 mmol) and dpp (g, 0.5 mmol) were suspended in 50 mL of an H_2O/EtOH (50:50 v/v) mixture and refluxed during half an hour under continuous stirring. The resulting blue solution was filtered and allowed to evaporate at room temperature. Single crystals of **2** were obtained as deep-blue parallelepipeds after a few days. Yield 85%. $C_{16}H_{14}CuN_4O_6$ (421.85): calcd. C 45.57, H 3.32, N 13.28; found C 45.36, H 3.25, N 13.19.

Compound 3: Solid bpz (0.030 g, 0.20 mmol) was added with stirring to an aqueous solution (20 mL) containing $Cu(CF_3SO_3)_2$ (0.072 g, 0.20 mmol). Then, $K_2ox·H_2O$ (0.018 g, 0.10 mmol) dissolved in a minimum amount of water (5 mL) was slowly added. X-ray quality crystals of **3** were grown as blue polyhedra from the resulting solution on standing at room temperature. Yield 70% (on the basis of oxalate). $C_{10}H_6CuN_4O_4$ (309.73): calcd. C 38.79, H 1.94, N 18.09; found C 38.50, H 1.88, N 17.96.

Compound 4: $Cu(NO_3)_2·3H_2O$ (0.032 g, 0.26 mmol) was dissolved in 5 mL of EtOH/H_2O (1:1 mixture) and added to a solution of dpp (0.060 g, 0.26 mmol) in 15 mL of EtOH/H_2O. $K_2ox·H_2O$ (0.023 g, 0.13 mmol) (3:4 mixture) was then added to the resulting solution whilst stirring. After evaporation of the solvents at room temperature, green prisms of **4** suitable for X-ray diffraction appeared. Yield 70%. $C_{30}H_{32}Cu_2N_{10}O_{16}$ (915.74): calcd. C 39.35, H 3.52, N 15.30; found C 39.21, H 3.37, N 15.20.

Compound 5: Solid bpz (0.030 g, 0.20 mmol) was added with stirring to an aqueous solution (20 mL) containing $CuCl_2·2H_2O$ (0.034 g, 0.20 mmol). Then, $K_2ox·H_2O$ (0.018 g,0.10 mmol) dissolved in a minimum amount of water (5 mL) was slowly added with continuous stirring. X-ray quality crystals of **5** were grown as green polyhedra from the resulting solution on standing at room temperature. Yield 60% (on the basis of oxalate). $C_{28}H_{30}Cl_2Cu_3N_{12}O_{14}$ (1020.2): calcd. C 32.98, H 2.94, N 16.47; found C 32.79, H 2.83, N 16.38.

Physical Measurements: IR spectra of **1**−**5** (4000−400 cm^{-1}) were recorded on a Bruker IF S55 spectrophotometer with samples prepared as KBr pellets. Variable-temperature (2−290 K) magnetic susceptibility measurements on polycrystalline samples of **3**−**5** were carried out with a Quantum Design SQUID susceptometer using an applied magnetic field of 1000 G over the whole temperature range. The complex $(NH_4)_2Mn(SO_4)_2·6H_2O$ was used as a susceptibility standard. Diamagnetic corrections for the constituent atoms were estimated from Pascal's constants[33] as -132×10^{-6} (**3**), -433×10^{-6} (**4**) and -604×10^{-6} $cm^3·mol^{-1}$ (**5**). Corrections for the sample holder were also applied.

Crystal Structure Determination: Diffraction data for **1**, **2**, **3** and **5** were collected with a Bruker-AXS SMART 2 K CCD area detector diffractometer at 173 K (**1**, **2**) and 293 K (**3**, **5**). In the case of **4**, data were collected at 293 K with an Enraf-Nonius CAD-4 diffractometer. Crystal parameters and refinement results are listed in Table 7. Empirical absorption corrections were carried out using SADABS for compounds **1**, **2**, **3** and **5**,[34a] while a semiempirical correction based on psi-scans of six reflections was used for **4**.[34b] The structures were solved by direct methods and refined by full-matrix least-squares based on F^2, including all reflections. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms bound to carbon were included at idealized positions, whereas those of water molecules were located in Fourier difference maps (the hydrogen atoms of only one of the water molecules were detectable in the difference map of compound **5**). All hydrogen atoms included in the structure factor calculation were refined according to the riding model. The two triclinic compounds (**1** and **3**) were both found to belong to the centrosymmetric space group. In the case of compound **3**, the structure was initially solved in the non-centrosymmetric space group $P1$, but conversion to $P\bar{1}$ was later done, as solution and refinement showed this to be the correct choice. For the two monoclinic compounds where the space groups were not determined uniquely by the systematic absences (**2** and **5**), the structure solutions and refinements confirmed the non-centrosymmetric choice ($P2_1$). Refinement of racemic twinning was performed for compound **5** yielding 0.38:0.62 as the fractional contributions of the twin components.

Data collection and data reduction for **1**, **2**, **3** and **5** were done with the SMART and SAINT programs,[35a,35b] whereas for **4** the CAD-Express and XCAD programs[35c,34b] were used. All other calculations were performed with SHELXS-86, SHELXL-93, SHELXS-97, SHELXL/PC and XP.[36]

CCDC-240026 to -240030 for **1**−**5**, respectively, contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: + 44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Supporting Information (see also footnote on the first page of this article): Figures of the crystal packing (Figures S1−S5) for complexes **1**−**5**.

Acknowledgments

The work described here was supported by the Spanish Ministry of Science and Technology (Project BQU2001-2928). Thanks are due to the University of Bergen and the NFR (Research Council of Norway) for grants allowing the purchase of X-ray equipment. One of us (J. C.) acknowledges the Mexican Government for a predoctoral fellowship through the PROMEP Program.

The Anderson-Type Anion $(TeMo_6O_{24})^{6-}$ – A Multidentate Ligand for Trivalent Rare Earth Cations

Daniel Drewes,[a] Eva Melanie Limanski,[a] and Bernt Krebs*[a]

Dedicated to Professor Philipp Gütlich on the occasion of his 70th birthday

Keywords: Polyoxometalates / Molybdenum / Lanthanides / Tellurium / Self-assembly

The syntheses and structural characterizations of four novel lanthanide polyoxomolybdates containing the Anderson-type anion $(TeMo_6O_{24})^{6-}$ are presented. Depending on the size of the trivalent rare earth cations, in the solid-state structures of $\{[La(H_2O)_6]_2(TeMo_6O_{24})\}_n \cdot 6nH_2O$ (**1**), $\{[Ce(H_2O)_7]_2(TeMo_6O_{24})\}_n \cdot 7nH_2O$ (**2**), $\{[Pr(H_2O)_7]_2(TeMo_6O_{24})\}_n \cdot 8nH_2O$ (**3**) and $\{[Nd(H_2O)_7]_2(TeMo_6O_{24})\}_n \cdot 8nH_2O$ (**4**) two different arrangements of the building unit are present. The $(TeMo_6O_{24})^{6-}$ anion acts as a hexadentate ligand for La^{III} and as a tetradentate ligand for Ce^{III}, Pr^{III} and Nd^{III}, leading to two different infinite one-dimensional chains. The crystal structures of the new compounds are compared with known lanthanide polyoxomolybdates containing the $(TeMo_6O_{24})^{6-}$ anion and the influence of the Ln^{III} ionic radii is discussed.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

Polyoxotungstates and -molybdates[1,2] have been investigated extensively over the last years. Owing to their unusual properties such as high charges and ionic masses etc., they attract current attention in view of their potential in medicine, material science, and catalysis.[3–6] The fascination of polyoxometalate chemistry arises from the remarkable size and challenging geometry of several mixed-valence nanostructured polyoxomolybdates synthesized by the group of A. Müller.[7–10] However, complex and largely unknown self-assembly reaction mechanisms are responsible for the formation of polyoxometalates and make it difficult to develop a straightforward reaction route for their syntheses.

Lanthanide containing polyoxoanions differ fundamentally from transition metal substituted anions and exhibit unique structures because of the lanthanides' preferred coordination numbers eight and nine. In order to establish a consistent picture of lanthanide containing polyoxomolybdates, we started synthesizing and characterizing novel exponents in this class of compounds. In 2004, we were able to report the crystal structures of $[(CH_3)_4N]_x(NH_4)_{14-x}[Ln_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4] \cdot nH_2O$ (Ln = La^{III}, Ce^{III}, Pr^{III}, Sm^{III}, Gd^{III}).[11] We affirmed that the well-known $[Eu_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]^{14-}$ anion reported by Yamase et al.[12] can be formed by a wide range of lanthanides.

In the case of the $(LnW_{10}O_{36})^{9-}$ anions (Ln = Pr^{III}, Nd^{III}, Sm^{III}, Gd^{III}, Tb^{III}, Dy^{III}), the effect of lanthanide contraction on these anions was discussed by Ozeki and Yamase.[13] Sécheresse et al. showed that the linkage of the monovacant lacunary $(SiW_{11}O_{39})^{8-}$ anions by lanthanide cations is dependent on the nature of the rare earth cation.[14] This example shows the necessity to investigate the dependency of the arrangement of different polyoxo building units on the size of the Ln^{III} atoms.

Recently, we have reported the syntheses and crystal structures of six novel lanthanide polyoxomolybdates containing the Anderson-type anion $(TeMo_6O_{24})^{6-}$. The polyoxometalates $K_{6n}(TeMo_6O_{24})_n\{[Ln(H_2O)_7]_2(TeMo_6O_{24})\}_n \cdot 16nH_2O$ (Ln = Eu^{III}, Gd^{III}) and $K_{3n}\{Ln(H_2O)_5(TeMo_6O_{24})\}_n \cdot 6nH_2O$ (Ln = Tb^{III}, Dy^{III}, Ho^{III}, Er^{III}) exhibit lanthanide cations and $(TeMo_6O_{24})^{6-}$ anions at a ratio of 1:1. Depending on the size of the rare earth cations, two different arrangements of the building units could be found.[15] This paper describes the syntheses and structures of four novel lanthanide polyoxomolybdates with a $(TeMo_6O_{24})^{6-}$:Ln^{III} ratio of 1:2 (Ln = La, Ce, Pr, Nd). While the cerium, praseodymium and neodymium compound show a linkage of the $(TeMo_6O_{24})^{6-}$ building units which can also be found in the europium and gadolinium compounds mentioned above, the lanthanum compound shows a novel type of combination.

Results and Discussion

The four novel compounds $\{[La(H_2O)_6]_2(TeMo_6O_{24})\}_n \cdot 6nH_2O$ (**1**), $\{[Ce(H_2O)_7]_2(TeMo_6O_{24})\}_n \cdot 7nH_2O$ (**2**),

E-mail: krebs@uni-muenster.de

$\{[Pr(H_2O)_7]_2(TeMo_6O_{24})\}_n \cdot 8nH_2O$ (**3**) and $\{[Nd(H_2O)_7]_2(TeMo_6O_{24})\}_n \cdot 8nH_2O$ (**4**) were synthesized in a two-step reaction. At first, the $(TeMo_6O_{24})^{6-}$ anion was formed by potassium molybdate and telluric acid at pH 5.5. Afterwards, the trivalent rare earth cations were added as chloride or nitrate. Single crystals of **1**−**4** formed after a few days.

All compounds crystallize in the triclinic crystal system, space group $P\bar{1}$. The asymmetric unit contains half a formula unit. The tellurium atom Te(1) is situated at an inversion center in all cases. It is located at the center of a nearly regular hexagon which is formed by the six molybdenum atoms of the $(TeMo_6O_{24})^{6-}$ anion. Consequently, all Te···Mo distances are almost identical in **1**−**4**. The molybdenum and tellurium atoms are nearly planar since the Te(1) atom is situated at a distance of less than 0.06 Å from the [Mo(1), Mo(2), Mo(3)] plane in all compounds. The Te^{VI} atom is surrounded octahedrally by six oxygen atoms. The Te−O bond lengths and O−Te−O bond angles summarized in Table 1 show only little distortion of the TeO_6 octahedra. The corresponding bond lengths and angles differ only slightly in all four compounds.

The corresponding molybdenum−oxygen bond lengths of the $(TeMo_6O_{24})^{6-}$ anions show great similarities in **1**−**4**. The Mo−O distances can be divided into three groups: terminal oxygen atoms, molybdenum-bridging oxygen atoms with middle oxygen−molybdenum bond lengths and oxygen atoms bound to one tellurium and two molybdenum atoms with long oxygen−molybdenum bond lengths. As expected, the terminal oxygen atoms show the shortest molybdenum−oxygen bond lengths [between 1.69(1) and 1.73(1) Å]. The long Mo−O bond lengths are located *trans* to the short Mo−O bonds and show M−O distances between 2.22(1) Å and 2.32(1) Å. The intermediate Mo−O bonds show Mo-O distances between 1.89(1) Å and 1.96(1) Å. As usual for polyoxomolybdates, the O−Mo−O bond angles differ significantly from the ideal 90° and 180° bond angles and confirm the distortion of the MoO_6 octahedra. The Mo−O bond lengths and O−Mo−O bond angles are summarized in Table 1.

In the lanthanum compound **1**, the $(TeMo_6O_{24})^{6-}$ anion acts as a hexadentate ligand for the lanthanum atoms and is bound to four La^{III} atoms. Each La atom achieves ninefold coordination by six water molecules and three terminal oxygen atoms of two $(TeMo_6O_{24})^{6-}$ anions. These nine oxygen atoms build up a tricapped-trigonal prism. Figure 1 shows a detail of the resulting infinite one-dimensional $\{[La(H_2O)_6]_2(TeMo_6O_{24})\}_n$ chain. The one-dimensional chains are linked by an extensive hydrogen bond network.

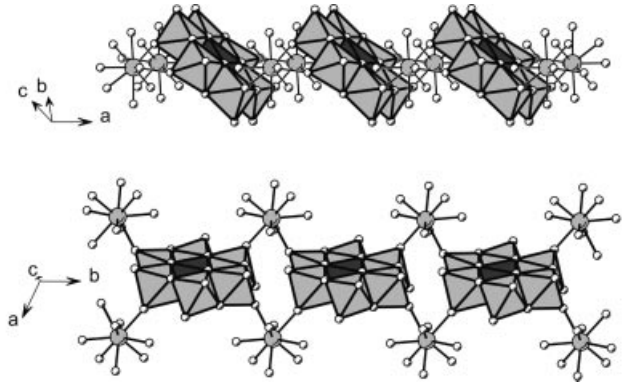

Figure 1. Details of the infinite one-dimensional chains of $\{[La(H_2O)_6]_2(TeMo_6O_{24})\}_n$ in **1** (top) and of $\{[Ln(H_2O)_7]_2(TeMo_6O_{24})\}_n$ (Ln = Ce, Pr, Nd; bottom) in **2**−**4**

In the cerium, praseodymium and neodymium containing compounds **2**−**4**, the Anderson anion acts as a tetradentate ligand coordinating four Ce^{III}, Pr^{III} or Nd^{III} atoms by terminal oxygen atoms. The lanthanide atoms are coordinated by two terminal oxygen atoms of two $(TeMo_6O_{24})^{6-}$ anions and seven water molecules, forming a tricapped-trigonal prism. Figure 1 shows the infinite one-dimensional $\{[Ln(H_2O)_7]_2(TeMo_6O_{24})\}_n$ chain (Ln = Ce, Pr, Nd) in detail. As in **1**, the chains are connected via a hydrogen bond network. This type of chain can also be found in $K_{6n}(TeMo_6O_{24})_n\{[Eu(H_2O)_7]_2(TeMo_6O_{24})\}_n \cdot 16nH_2O$ (**5**) and $K_{6n}(TeMo_6O_{24})_n\{[Gd(H_2O)_7]_2(TeMo_6O_{24})\}_n \cdot 16nH_2O$ (**6**).[15] In contrast to **2**−**4**, the com-

pounds **5** and **6** contain two crystallographically independent $(TeMo_6O_{24})^{6-}$ anions. One of these ions acts as a tetradentate ligand for the lanthanide ions, the second one is surrounded by potassium ions and crystal water and has no bonding to the lanthanide cations.

The crystal structures of **1**−**4** differ not only in the coordination sphere of the lanthanide atoms. Figure 2 and 3 show the different arrangements of the one-dimensional chains for **1** on the one hand and **2**−**4** on the other. In **1**, the $\{[La(H_2O)_6]_2(TeMo_6O_{24})\}_n$ chains run along [100], while the $\{[Ln(H_2O)_7]_2(TeMo_6O_{24})\}_n$ chains in **2**−**4** run along [010]. While the lattice parameters in **2**−**4** are very similar, they differ clearly from those found for **1**. The differences in the crystal structures can also be fixed on the Ln···Ln distances. Within the $\{[Ln(H_2O)_x]_2(TeMo_6O_{24})\}_n$ chains (x = 6, 7), the shortest La···La distance [7.82(1) Å] in **1** differs clearly from the shortest Ln···Ln distances in **2**−**4** [8.70(1) Å for **2**, 8.65(1) Å for **3**, 8.62(1) Å for **4**, respectively]. In contrast to that, the shortest Ln···Ln distances between two different chains are shorter in **2**−**4** [6.25(1) Å for **2**, 6.18(1) Å for **3**, 6.16(1) Å for **4**, respectively] than in **1** [6.77(1) Å].

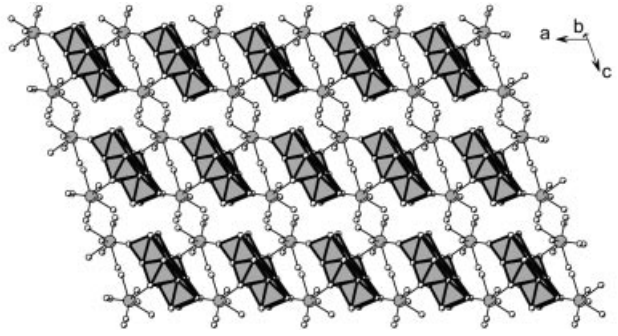

Figure 2. View of the crystal structure of $\{[La(H_2O)_6]_2(TeMo_6O_{24})\}_n \cdot 6nH_2O$ (**1**). The $\{[La(H_2O)_6]_2(TeMo_6O_{24})\}_n$ chains run along [100]. The hydrate water molecules are omitted partially for clarity

We have reported recently that for terbium(III), dysprosium(III), holmium(III) and erbium(III) a further linkage

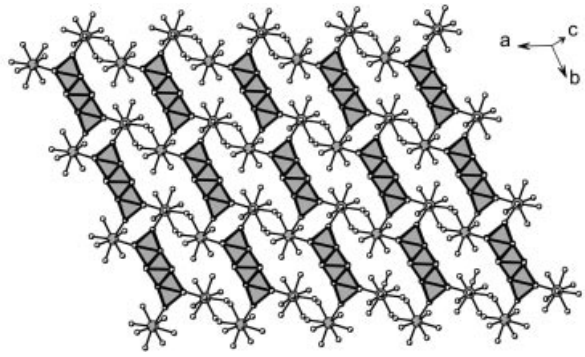

Figure 3. View of the crystal structure of $\{[Pr(H_2O)_7]_2(TeMo_6O_{24})\}_n \cdot 8nH_2O$ (**3**). The $\{[Pr(H_2O)_7]_2(TeMo_6O_{24})\}_n$ chains run along [010]. The hydrate water molecules are omitted partially for clarity

of the Anderson-type anions can be found.[15] In $K_{3n}\{Tb(H_2O)_5(TeMo_6O_{24})\}_n \cdot 6nH_2O$ (**7**), $K_{3n}\{Dy(H_2O)_5(TeMo_6O_{24})\}_n \cdot 6nH_2O$ (**8**), $K_{3n}\{Ho(H_2O)_5(TeMo_6O_{24})\}_n \cdot 6nH_2O$ (**9**) and $K_{3n}\{Er(H_2O)_5(TeMo_6O_{24})\}_n \cdot 6nH_2O$ (**10**), the $(TeMo_6O_{24})^{6-}$ anion acts as a tridentate ligand for the lanthanide atoms. As a result of the lanthanide contraction, the coordination number of these smaller rare earth cations is only eight. Within the $\{Ln(H_2O)_5(TeMo_6O_{24})\}_n^{3n-}$ chains, the Ln^{III} atoms are coordinated by five water molecules, two terminal oxygen atoms of two Anderson anions and one molybdenum-bridging oxygen atom. These eight oxygen atoms form a square-antiprismatic prism.

The oxidation states of the lanthanide cations were checked by the bond valence method.[16] New bond-valence parameters for Ln−O bonds have been reported recently.[17] Table 2 summarizes the calculated bond valences for the lanthanide atoms of the new compounds **1**−**4** and the compounds **5**−**10** reported previously. The calculated valences vary only slightly and affirm that the lanthanide atoms are trivalent in all compounds, although the yellow color of the cerium containing compound **2** could lead to the assumption that Ce^{III} was oxidized to Ce^{IV}. The average Ln−O bond lengths show not only the influence of the lanthanide contraction but also point to the additional decrease of the

Table 2. Comparison of Ln−O bond lengths and calculated bond valences of **1**−**10**

Ln−O bond lengths which is caused by the change of the coordination number from 9 to 8.

Conclusions

The decrease of radii of the trivalent rare earth cations leads to three different one-dimensional chains in **1**, **2**−**6** and **7**−**10**. As a result, the solid-state structures show varieties which are not only limited to slight changes of Ln−O bond lengths, but also cause diverse coordination spheres, lattice parameters and distances between the one-dimensional chains. The influence of the size of the Ln^{III} atoms can be watched closely in the $(TeMo_6O_{24})^{6-}/Ln^{III}$ system because the $(TeMo_6O_{24})^{6-}$ anions exhibit numerous potential bonding partners for the lanthanide cations and therefore enable different arrangements of the building units with different coordination spheres of the lanthanide atoms. In the crystal structures reported, the $(TeMo_6O_{24})^{6-}$ anion can act as a tridentate, tetradentate and hexadentate ligand, respectively. Linking these discrete entities to build up solid-state materials is of great interest beyond the structural point of view, but also for possible applications in different fields of chemistry. It still remains a challenge to investigate the dependency of the crystal structures on the lanthanide radii to establish a consistent picture of lanthanide containing polyoxomolybdates.

Experimental Section

Instrumentation and Analytical Procedures: IR spectra were measured with a Perkin−Elmer 683 spectrometer as KBr pellets. The atomic ratios of the heavy elements were determined by energy dispersive X-ray fluorescence analysis (EDX). Diffraction experiments were performed with a STOE IPDS imaging plate system (for **2**) and a BRUKER SMART APEX diffractometer with CCD detector (for **1**, **3** and **4**), both using graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å). Structures were solved by Patterson Synthesis with the SHELXS-97[18] and refined with the SHELXL-97 program.[19] No hydrogen atoms were included during the refinement. All atoms were refined anisotropically by full-matrix least-squares calculations based on F^2. The programs SADABS[20] (for **1**, **3** and **4**) and DECAY[21] (for **2**) were applied for the absorption correction. As usual for polyoxometalates, the crystal structures of **2**−**4** show disorder in the crystal water part of the structure.

Syntheses of Heteropolymolybdates: All starting materials and chemicals were used without further purification.

Preparation of $\{[La(H_2O)_6]_2(TeMo_6O_{24})\}_n \cdot 6nH_2O$ (1): K_2MoO_4 (1 g, 4.2 mmol) was dissolved in 30 mL of water, to which telluric acid (0.160 g, 0.7 mmol), dissolved in 10 mL of water, was added. The pH was adjusted to 5.5 by adding 4 M hydrochloric acid. The colorless solution was heated to 80 °C and stirred for 30 min. $La(NO_3)_3 \cdot 6H_2O$ (0.303 g, 0.7 mmol) was dissolved in 4 mL of water and added slowly to the hot solution while stirring. After 15 minutes, the solution was filtered. Colorless single crystals suitable for X-ray diffraction were obtained from the solution after two days. $La_2TeMo_6O_{42}H_{36}$ (1689.34). Yield: 340 mg (57%, based on La). IR (KBr disc, cm^{-1}): $\tilde{\nu}$ = 3434 vs (br), 3245 s (br), 1638 s, 1454 w, 1385 w, 1120 w, 941 s, 914 s, 893 s, 869 m, 679 s, 614 s, 446 s. EDX: found (calcd.) for $La_2TeMo_6O_{42}H_{36}$: La:Te:Mo = 1.95:0.97:6.00 (2.00:1.00:6.00).

Preparation of $\{[Ce(H_2O)_7]_2(TeMo_6O_{24})\}_n \cdot 7nH_2O$ (2): This compound was prepared similarly to **1**, with $CeCl_3 \cdot 7H_2O$ (0.261 g, 0.7 mmol) instead of $La(NO_3)_3 \cdot 6H_2O$. Yellow single crystals were obtained from the solution after two days. $Ce_2TeMo_6O_{45}H_{42}$ (1745.81). Yield: 349 mg (57%, based on Ce). IR (KBr disc, cm^{-1}): $\tilde{\nu}$ = 3444 vs (br), 3164 s, 1636 s, 1384 w, 942 s, 918 s, 890 s, 665 s, 614 m, 494 s, 449 s. EDX: found (calcd.) for $Ce_2TeMo_6O_{45}H_{42}$: Ce:Te:Mo = 1.88:0.93:6.00 (2.00:1.00:6.00).

Preparation of $\{[Pr(H_2O)_7]_2(TeMo_6O_{24})\}_n \cdot 8nH_2O$ (3): This compound was prepared similarly to **1**, with $Pr(NO_3)_3 \cdot 6H_2O$ (0.305 g, 0.7 mmol) instead of $La(NO_3)_3 \cdot 6H_2O$. Green single crystals suitable for X-ray diffraction were obtained from the solution after two days. $Pr_2TeMo_6O_{46}H_{44}$ (1765.41). Yield: 362 mg (58%, based on Pr). IR (KBr disc, cm^{-1}): $\tilde{\nu}$ = 3437 vs (br), 3167 s, 1634 s, 1385 s, 940 s, 914 s, 872 s, 668 s, 614 s, 492 m, 449 m. EDX: found (calcd.) for $Pr_2TeMo_6O_{46}H_{44}$: Pr:Te:Mo = 2.10:0.93:6.00 (2.00:1.00:6.00).

Preparation of $\{[Nd(H_2O)_7]_2(TeMo_6O_{24})\}_n \cdot 8nH_2O$ (4): This compound was prepared similarly to **1**, with $NdCl_3 \cdot 6H_2O$ (0.251 g, 0.7 mmol) instead of $La(NO_3)_3 \cdot 6H_2O$. After one day light pink single crystals suitable for X-ray diffraction were obtained from the solution. $Nd_2TeMo_6O_{46}H_{44}$ (1772.02). Yield: 297 mg (48%, based on Nd). IR (KBr disc, cm^{-1}): $\tilde{\nu}$ = 3386 vs (br), 1634 s, 1384 w, 942 s, 914 s, 870 m, 673 s, 614 s, 490 m, 448 s. EDX: found (calcd.) for $Nd_2TeMo_6O_{46}H_{44}$: Nd:Te:Mo = 1.88:1.03:6.00 (2.00:1.00:6.00).

Mechanistic Investigation of the Oxidation of Glyoxylic and Pyruvic Acids by Tris(biguanide)manganese(IV) in Weakly Acidic Aqueous Media

Basab Bijayi Dhar,[a] Ritam Mukherjee,[a] Subrata Mukhopadhyay,*[a] and Rupendranath Banerjee*[a]

Keywords: Kinetics / Mechanism / Redox reaction / Manganese(IV) / Glyoxylic acid / Pyruvic acid

In this study the kinetics of two electron transactions between the reducing substrates glyoxylic and pyruvic acids and the oxidising complex cation, tris(biguanide)manganese(IV) in aqueous acidic media have been examined. Under the experimental conditions (pH = 1.50–3.78) only the fully protonated form of the oxidant reacts with the anions of the substrates whereas the parent acids, viz. glyoxylic and pyruvic acids, were found to be unreactive. The second-order rate constants for the oxidations of glyoxylate and pyruvate by the title Mn^{IV} species are $(2.24 \pm 0.10) \times 10^{-1}$ and $(5.40 \pm 0.30) \times 10^{-2}$ $M^{-1}s^{-1}$, respectively, at 25.0 °C and at I = 1.0 M ($NaNO_3$ or $NaClO_4$). A rate-liming one-electron change between the redox partners seems justified.

Introduction

Tris(biguanide)manganese(IV) {Figure 1; $[Mn(LH_2)_3]^{4+}$ (LH_2 = biguanide, $C_2N_5H_7$)} is a rare example of a water-soluble mononuclear Mn^{IV} complex stable over a wide range of acidity levels (10^{-6} to 2 M).[1] In aqueous solutions the title Mn^{IV} complex behaves as a mild dibasic acid (pK_{a1} = 5.30 ± 0.20, pK_{a2} = 7.60 ± 0.30) and the deprotonations are believed to originate from the protons bound to the ligand sp^2 nitrogen atoms.[2] Though quite a few di-, tri- and tetranuclear Mn^{IV} complexes can be stabilised in aqueous solution[3] and have interesting solution chemistry,[4] the aqueous solution chemistry of mononuclear Mn^{IV} remained unexplored until recently when we reported[2] the oxidation of Fe^{2+} by Mn^{IV}. Parallel to our report, Gould et al.[5] observed that the oxidation of Fe^{2+} by this Mn^{IV} species is noticeably accelerated by chloride ions in what the authors viewed as the accelerating effect of the polarisable anion on the redox reaction between two positively charged metal centres.

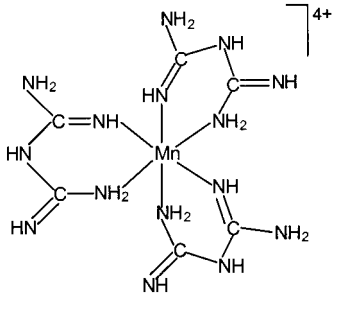

Figure 1. Structure of $[Mn(LH_2)_3]^{4+}$ drawn on the basis of its crystal structure

The present investigation deals with the kinetic and mechanistic aspects of the oxidation of two small carboxylic acids of biological relevance, viz. glyoxylic and pyruvic acid. Detailed kinetic studies of their oxidations are of importance because Mn^{III} species are involved in metabolic processes such as glycine catabolism[6a] and plant physiology,[6b] whereas the reducing substrate pyruvic acid is involved in a major metabolic sequence (TCA cycle) in living systems.[6c] Complete oxidation of these carboxylic acids with α-carbonyl groups ultimately leads to CO_2 with generation of energy in the metabolic processes. We also note that examples of oxidations of these substrates by higher valent oxidising species are only scarce in the literature.[7]

Results and Discussion

Equilibrium Studies and Preliminary Observations

Using a Metrohm 736 GP Titrino auto-titrator yielded pK_a values for glyoxylic and pyruvic acid from the pH-titration curves of 3.20 ± 0.10 and 2.50 ± 0.10, respectively, at 25.0 °C and at I = 1.0 M ($NaNO_3$ or $NaClO_4$). These values are in agreement with those previously reported.[7h,7i] Most of the kinetic runs were performed at 433 nm, i.e. the observed visible absorption maximum of the Mn^{IV} complex. At this wavelength, all other reaction components ex-

cept Mn^{IV} are transparent. No additional buffer was used in the kinetic experiments since the pH drift was well within 0.05 units during the reaction. We observed no Mn^{2+} catalysis (studied up to 0.10 M) in the title reaction.

Stoichiometry and Reaction Products

Results of the stoichiometry experiments yielded $\Delta[Mn^{IV}]/\Delta[\text{Reductant}] = 0.98 \pm 0.10$ for glyoxylic oxidation and 1.07 ± 0.05 for pyruvic acid oxidation. The presence of the oxidation product formic acid in the oxidation of glyoxylic acid was tested for by the addition of chromotropic acid which gave a violet colour.[8] Acetic acid was detected in the pyruvate oxidation by the addition of lanthanum nitrate and iodine which produced a deep blue precipitate.[8] We verified that the reaction products, Mn^{2+} or the released biguanide did not interfere with these qualitative experiments. The generation of gaseous CO_2 in both the reactions was confirmed by GC analysis as described earlier.[9] The overall redox processes for glyoxylic acid and pyruvic acid are thus described by Equation (1) and (2), respectively.

$$Mn^{IV} + CHOCOOH + H_2O \rightarrow Mn^{2+} + HCO_2H + CO_2 + 2\,H^+ \quad (1)$$

$$Mn^{IV} + CH_3COCOOH + H_2O \rightarrow Mn^{2+} + CH_3CO_2H + CO_2 + 2\,H^+ \quad (2)$$

The small amounts of evolved gas in these reactions did not interfere with the kinetic measurements. Iodometric determination of copper in the cupric biguanide which precipitated[10] from the solution indicated release of more than 90% biguanide.

Kinetics

No immediate spectroscopic change was observed on mixing either glyoxylic or pyruvic acid with the Mn^{IV} complex over the entire range of experimental pH values examined (1.50−3.78). The whole reaction course follows first-order kinetics and the $\log(A_t - A_\infty)$ versus time plots were found to be linear to more than three half-lives. In all the kinetic runs, A_∞ values were less than 0.01. The first-order rate constants, k_o, as described by Equation (3), were obtained from least-squares slopes of these plots and are presented in Table 1. Moreover, a tenfold variation in the initial $[Mn^{IV}]$ value (0.02−0.20 mM) resulted in no change in the k_o values within experimental uncertainty (± 5%).

$$-d[Mn^{IV}]/dt = k_o[Mn^{IV}] \quad (3)$$

Table 1. Some representative first-order rate constants for oxidation of glyoxylic and pyruvic acid by $[Mn(LH_2)_3]^{4+}$ at $T = 25.0$ °C, $I = 1.0$ M ($NaNO_3$), $\lambda = 433$ nm [concentration of complex used 0.10 mM; the k_o values calculated using Equation (7a) are given in parentheses]

pH	RCOCOOH [M]	$10^4 k_o$ (R = H) [s^{-1}]	$10^4 k_o$ (R = CH_3) [s^{-1}]
1.46	0.02	0.8 (0.79)	0.8 (0.79)
1.70		1.4 (1.37)	1.4 (1.30)

3.50		30 (30.3)	9.6 (9.66)
3.78		35 (35.4)	10 (10.2)
2.37	0.01	2.8 (2.88)	2.1 (2.11)
	0.03	8.7 (8.64)	6.3 (6.34)
	0.05	15 (14.4)	11 (10.6)

[a] $10^4\,k_o$ (R = H) [s^{-1}] values are 8.3 and 11 at $I = 0.5$ and 0.2 M ($NaNO_3$), respectively. [b] $10^4\,k_o$ (R = CH_3) [s^{-1}] values are 6.5 and 8.2 at $I = 0.5$ and 0.2 M ($NaNO_3$), respectively. [c] $10^4\,k_o$ [s^{-1}] values are 16 and 8.8 for glyoxylic and pyruvic acid, respectively, at $I = 1.0$ M ($LiClO_4$). [d] Reactions carried out in the presence of externally added 1.00 m M biguanide. [e] $10^4\,k_o$ [s^{-1}] values are 23 and 9.0 for glyoxylic and pyruvic acid, respectively, at $I = 1.0$ M (NaCl).

For both the reducing agents, the k_o values were found to increase significantly with the pH of the reaction medium (Table 1). The title Mn^{IV} complex is a weak acid ($pK_{a1} = 5.30$) and thus its deprotonation may be disregarded, whereas the concentration of both the neutral and anionic forms of the reducing agents are substantial under the pH interval studied (1.46−3.78).

The observed rate constants depend remarkably on the ionic strength of the reaction medium maintained by $NaNO_3$ or $NaClO_4$ (Table 1). A considerable increase in the reaction rate over the entire pH range for both the reductants with a decrease in ionic strength indicates a reaction between oppositely charged ions. The rate constants were also found to increase substantially when $LiClO_4$ was used instead of Na^+ salts for maintaining the ionic strength of the reaction mixture. As the redox partners of the title reactions are oppositely charged, conventional metal ion catalysis can be ruled out.[11] We also verified that the reactions are not accelerated by addition of chloride. A possible reason for the rate enhancement in the presence of Li^+ may be explained by the very high approximate hydration number of Li^+ (25.3), as estimated by transference data,[12] compared with that of Na^+ (16.6). This results in a major lowering of the effective concentration of solvent water which in turn increases the activity of the redox partners.[7h]

Reactions studied in the presence of 6% (v/v) acrylonitrile showed slow polymerisation after consumption of ca. 40−50% of the initial Mn^{IV} amount. The $\log(A_t - A_\infty)$ versus time plots under these conditions showed a definite up-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

ward curvature after ca. 50% completion of the reaction, probably due to heterogeneity in the reaction media. Polymerisation of acrylonitrile is more prominent in the case of glyoxylic acid than in that of pyruvic acid.

Scheme 1 provides a reasonable explanation for the kinetic observations considering the acid dissociation constants of the complex in aqueous solution (K_{a1} and K_{a2} are 5.01×10^{-6} and 2.50×10^{-8} M, respectively) and K_a values (i.e. the measured acid dissociation constants of glyoxylic and pyruvic acid under experimental condition, 6.31×10^{-4} M for glyoxylic and 3.16×10^{-3} M for pyruvic acid).

$$RCOCOOH \overset{K_a}{\rightleftharpoons} RCOCOO^- + H^+ \quad (4)$$

$$[Mn(LH_2)_3]^{4+} + RCOCOOH \xrightarrow{k_1} Products \quad (5)$$

$$[Mn(LH_2)_3]^{4+} + RCOCOO^- \xrightarrow{k_2} Products \quad (6)$$

(R = H for glyoxylic and CH_3 for pyruvic acid)

Scheme 1

Scheme 1 leads to the rate law of Equation (7), where $T_R = [RCOCOOH] + [RCOCOO^-]$.

$$k_o(K_a + [H^+])/T_R = k_1[H^+] + k_2K_a \quad (7)$$

The left-hand-side values of Equation (7) were found to be nearly a constant within allowable uncertainty in the entire pH range studied, both for glyoxylic [$(1.40 \pm 0.02) \times 10^{-4}$ s^{-1}] and pyruvic acid [$(1.60 \pm 0.06) \times 10^{-4}$ s^{-1}]. We thus found no contribution from k_1 for both the reducing agents to the overall rates. Equation (7) can thus be simplified to Equation (8).

$$T_R/k_o = 1/k_2 + [H^+]/(k_2K_a) \quad (8)$$

Plots of T_R/k_o versus $[H^+]$ yielded straight lines (Figure 2) with intercepts yielding k_2 values of $(2.24 \pm 0.10) \times 10^{-1}$ and $(5.40 \pm 0.30) \times 10^{-2}$ M^{-1}s^{-1} for glyoxylic and pyruvic acid, respectively. From the slopes, using such k_2 values, K_a values could be determined. These kinetically evaluated K_a values agree well (within 10%) with the literature values supporting the proposed reaction scheme.

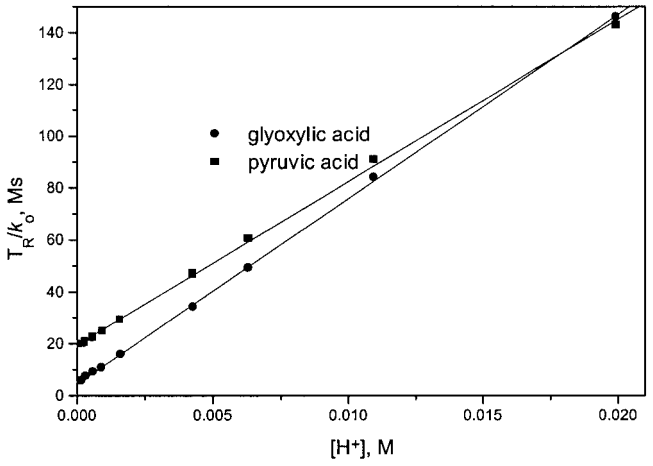

Figure 2. Plot of T_R/k_o versus $[H^+]$; [complex] = 0.10 mM, T_R = 0.02 M, I = 1.0 M ($NaNO_3$), T = 25.0 °C

Mechanism

The reducing anions glyoxylate and pyruvate have been found to be the only reactive species and this result supports the well-accepted concept that deprotonated reductants are more effective than their conjugate acids in reducing higher valent metal centres.[2,7h,9,13] However, we were astonished at the extent of this behaviour since we recently observed that both glyoxylic and pyruvic acids are reactive in reducing ethylenebis(biguanide)silver(III).[7h,7j] (One of the referees of this article commented that these reducing agents have inherent equilibria between the gem-diol and carbonyl forms in aqueous solution. Literature reports also support this.[7c] The reactivity of glyoxylate and pyruvate anions as found in this investigation is thus the combined reactivities of their gem-diol and carbonyl forms.)

The reduction of Mn^{IV} to Mn^{II} and the oxidation of the reductants chosen in this study are both net two-electron transactions. Nevertheless, it is extremely unlikely that the Mn^{IV} reduction proceeds in a single step. Moreover, polymerisation experiments also lend support to single-electron steps which generate polymerisation initiating radicals. Generation of these substrate radicals by one-electron oxidation has been well established by EPR spectroscopy.[14]

Pyruvate oxidation by the Mn^{IV} complex was found to be slower than glyoxylate oxidation. The increase in reaction rate may originate from the weaker C−C bond energy in glyoxylic acid compared with that in pyruvic acid due to the presence of an electron-donating methyl group in pyruvic acid which increases the electron density at the carbonyl carbon atom. The weakening of the C−C bond in glyoxylic acid may be a driving force for a faster initial electron transfer leading to a quicker overall oxidation of glyoxylic acid.[7g] A similar explanation was also offered for the oxidation of these reducing agents by Cr^{VI} [7g] and ethylenebis(biguanide)silver(III).[7h,7j] Moreover, the presence of a strongly reducing aldehyde function in glyoxylic acid may also be another explanation, at least in part, for obtaining a higher rate.

The Mn^{IV} centre in the title complex is coordinatively saturated and thus replacement of the strong field chelating biguanide ligand by the substrate anions seems to be unlikely. The estimated maximum value for the pre-equilibrium formation of a 1:1 adduct between Mn^{IV} and $RCOCOO^-$ (R = H for glyoxylate and CH_3 for pyruvate) lies between 1 and 10 and this does not confirm a strong inner-sphere attachment. However, we note that among the three s^2 metal-ion centres studied for the reduction of Mn^{IV}, only the reaction of In^I with $[Mn(LH_2)_3]^{4+}$ is subject to kinetic saturation for which an association constant of 6×10^3 M^{-1} for the formation of this adduct (believed to be due to strong hydrogen bonding) was estimated by Gould et al.[5] The estimated low value for the formation of adducts in the present study may be due to electrostriction[15] or a

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

process aided by hydrogen bonding[16] involving the reductants and the NH or NH_2 fragments of the ligand biguanide moiety of the title complex. The presence of a strong chelating ligand can be expected to stabilise Mn^{IV} to a great extent and render the complex a mild oxidant. Cyclic voltammetric studies of an aqueous solution (deoxygenated by purging with nitrogen) of the Mn^{IV} complex (0.10 mM) in the presence of 0.1 M Et_4NClO_4 as a supporting electrolyte revealed a single irreversible wave corresponding to Mn^{IV}/Mn^{III} reduction at ca. 0.4 V versus Ag/AgCl (ΔE_p = 400 ± 50 mV depending on scan rate, 50−300 mV s^{-1}). A direct outer-sphere oxidation by this weakly oxidising Mn^{IV} may thus be eliminated. We observed that more than 90% of the biguanide ligand is released at the end of the reaction (tested using an ammoniacal $CuSO_4$ solution)[10] and the high protonation constants of biguanide[17] encourages the overall reactions to completion.

Experimental Section

Materials: The complex salt $[Mn(C_2N_5H_7)_3]_2SO_4(NO_3)_6{\cdot}3H_2O$ was prepared by a known procedure. The crystals obtained were sufficiently pure as indicated by satisfactory C, H, N analyses: $C_{12}H_{48}Mn_2N_{36}O_{25}S$ (1238): calcd. C 11.63, H 3.88, N 40.71; found C 11.3, H 3.9, N 39.9. Biguanide sulfate $[C_2N_5H_7{\cdot}H_2SO_4]$ was prepared by a known method reported previously.[10b] An aqueous solution of glyoxylic acid was prepared by dissolving solid glyoxylic acid monohydrate (98%, Lancaster) in water and this was standardised either with standard alkali using Weslow's indicator or by spectrophotometry[18] at 520 nm (ε = 17990 $M^{-1}cm^{-1}$ as estimated by us, in agreement with the literature value of 17870 $M^{-1}cm^{-1}$)[18] after converting glyoxylic acid to 1,5-diphenylformazancarboxylic acid. Both results agree well with each other (within 4%). We found that an aqueous solution of ca. 0.5 M glyoxylic acid is stable for at least one weak when kept at low temperature (ca. 5−10 °C) and in the dark. Pyruvic acid (98%, Sigma) was used and standardised using spectrophotometry[19] at 515 nm (ε = 1400 $M^{-1}{\cdot}cm^{-1}$). An aqueous solution of $NaNO_3$ or $NaClO_4$ (G. R., E. Merck) was standardised by passing through a Dowex 50 W X-8 strong cation exchange resin in the H^+ from and titrating the liberated acid with standard NaOH to a phenolphthalein end point. All other chemicals were of reagent grade. Most of the kinetic measurements were carried out at I = 1.0 M ($NaNO_3$ or $NaClO_4$ resulted in almost the same k_o values). All solutions were prepared in water which had been deionised and doubly distilled.

Equilibrium Measurements: The acid dissociation constants, K_a, of both the glyoxylic[7h] and pyruvic acids were determined by titrating several aliquots of different strengths with carbonate-free deoxygenated NaOH solution at 1.0 M $NaNO_3$ using a Titrino Autotitrator (Metrohm, 736 GP) at (25.0 ± 0.1) °C.

Physical Measurements and Kinetics: All absorbance versus time data were recorded with a Shimadzu (1601 PC) spectrophotometer using 1.00-cm quartz cells. The kinetics were monitored in situ in the "kinetic mode" of the instrument at 433 nm which is one of the absorption peaks of the Mn^{IV} complex. An electrically controlled thermostat (25 ± 0.1) °C cell housing (CPS-240) was employed. For faster reactions, the reductant solution (adjusted to the desired pH) was injected directly into the spectrophotometer cell containing other components of the reaction mixture kept at the same pH. The desired concentrations of the complex and the reducing agent were achieved after mixing. The solution pH values were adjusted with HNO_3 or NaOH. Solution pH values ranged from 1.52 to 3.78 and were measured with an Ag/AgCl combined glass electrode attached to a Metrohm 736 GP Titrino autotitrator. The electrode calibration was carried out as reported previously.[20] Production of CO_2 as the gaseous reaction product was qualitatively confirmed by GC analysis. The gaseous product formed during the reaction was analysed by gas chromatography using a Chemito (India) GCHT 8610 instrument equipped with TCD (a Porapak Q and molecular sieves 13X column). A splitless mode of injection of 500 μL of the sample was used. The oven, injector, and detector temperatures were kept at 50, 100 and 150 °C, respectively. The carrier hydrogen gas flow was adjusted to 30 mL·min^{-1}. Cyclic voltammetric studies were performed with an Electrochemical Analyser (Model 600A, CH Instruments, USA) using a three-component electrode system consisting of Pt wire working and auxiliary electrodes and an Ag/AgCl reference electrode.

Stoichiometry and Reaction Products: The stoichiometries were evaluated by estimating unchanged glyoxylic or pyruvic acid spectrophotometrically. Reaction mixtures containing an excess of 4−6 equiv. of glyoxylic or pyruvic acid relative to the title complex were allowed to react under nitrogen until the solutions turned colourless. To estimate the unspent glyoxylic acid[18] freshly prepared phenylhydrazine hydrochloride (1%) solution was added (3.0 mL) into the reaction mixture. The resultant solution was incubated at ca. 110 °C for 10 min and then cooled to room temperature (ca. 25 °C) followed by successive addition of 2.5-mL aliquots of concentrated HCl and 1% $K_3Fe(CN)_6$. The reaction mixtures were allowed to stand for ca. 5 min for the quantitative formation of a pink formazan derivative of glyoxylic acid which was analysed at 520 nm (ε = 17990 $M^{-1}cm^{-1}$).[18] To estimate unchanged pyruvic acid[19] freshly prepared 2,4-dinitrophenylhydrazine solution in MeOH (1 mL, 1%) and 0.1 M HCl (1 mL) were added to the reaction mixture along with K-phosphate (K_2HPO_4) buffer (0.1 M) of pH = 7.5. The resultant solution was incubated at ca. 80 °C for 10 min and then cooled in an ice box for 10 min. A 50% KOH solution (5 mL) was then added to the solution which was again incubated at room temperature for 10 min. The red colour of the 2,4-dinitrophenylhydrazone pyruvate derivative was then analysed at 515 nm (1400 $M^{-1}{\cdot}cm^{-1}$).[19] The biguanide ligand in the product solution was isolated as $[Cu(LH_2)_2]SO_4$ by the addition of Cu^{II} sulfate. The amount of Cu^{II} thus consumed was determined iodometrically after decomposing the copper complex.[10]

Diastereomeric Halfsandwich Rhenium Complexes Containing Hemilabile Phosphane Ligands[‡]

Stefan Dilsky[a] and Wolfdieter A. Schenk*[a]

Dedicated to Professor Johann Weis on the occasion of his 60th birthday

Keywords: Rhenium / Chiral complexes / Chiral P ligands / Hemilabile P ligands / Sandwich complexes

The syntheses and some typical reactions of diastereomeric rhenium complexes $[CpRe(NO)(CO)\{P(Ph)(R)(R')\}]BF_4$ (R = Me, Ph; R′ = 2-C_6H_4OMe, $CH_2C_4H_3S$, $CH_2C_4H_7O$) (**3a**–**e**) are described. Reduction of the carbonyl ligand with $NaBH_4$ in THF gave the corresponding methyl complexes $[CpRe(NO)\{P(Ph)(R)(R')\}(CH_3)]$ (**4a**–**e**). Acid treatment of the methyl complexes leads to liberation of methane and coordination of the additional donor site of the potentially bidentate phosphane ligand. Of the chelate complexes **5a**–**e**, those with R′ = 2-C_6H_4OMe (**5a**, **d**) decomposed in solution at room temperature. In donor solvents, the chelate ring opens giving the stable solvated complexes $[CpRe(NO)\{P(Ph)(R)(R')\}](solvent)]BF_4$ (solvent = CH_3CN, THF) (**6b**–**e**, **7d**). The new compounds are thus suitable starting materials for the syntheses of diastereomeric rhenium complexes $[CpRe(NO)\{P(Ph)(R)(R')\}(L)]BF_4$.

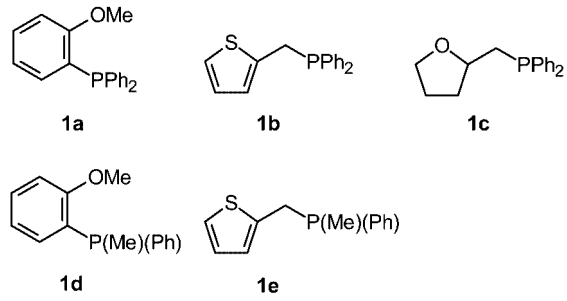
Introduction

Since the first successful enantiomer separation of the pseudotetrahedral *at-metal* chiral complex $[CpMn(CO)(NO)(PPh_3)]PF_6$ by Brunner,[1] a large variety of different *at-metal* chiral, kinetically stable or labile complexes has been synthesised. Some of them have been of synthetic interest, e.g. (R_{Fe})-$[CpFe(CO)(PPh_3)\{C(O)Me\}]$ which has been used, inter alia, in the total synthesis of Captopril.[2,3] Other complexes of this type were investigated as potential catalysts[2] and the chiral Lewis acidic rhenium complex $[CpRe(NO)(PPh_3)]^+$ has been studied in great detail by Gladysz et al.[4,5] We have recently extended this work to thiolate and thioaldehyde complexes of $[CpRe(NO)(PPh_3)]^+$ and its congeners $[CpRe(NO)\{P(OPh)_3\}]^+$ and $[CpRe(NO)\{P(iPr)_3\}]^+$.[6–9] By introducing a second stereogenic centre at the phosphane ligand, higher selectivities in reactions at coordinated ligands might be achieved. Moreover, by introducing a second donor atom into the phosphane, a hemilabile[10,11] ligand can be created which should serve to stabilise reactive intermediates.

Results

Phosphane Synthesis

The hemilabile ligands which are central to this study are shown in Scheme 1.



Scheme 1

The prototypic **1a** is commercially available, whereas **1b** was obtained by a slight modification of a known[12] synthesis as follows. Cleavage of PPh_3 with lithium in THF and alkylation of the resultant lithium diphenylphosphide with 2-(chloromethyl)thiophene gave **1b** in 87% yield. *C*-chiral racemic **1c** has been obtained previously via a similar approach.[13] Cleavage of bis(2-anisyl)phenylphosphane with sodium in liquid ammonia followed by alkylation with methyl iodide gave the *P*-chiral racemic ether phosphane ligand **1d**[14] in 63% yield. Deprotonation of methylphenylphosphane with butyllithium in THF followed by alky-

lation with 2-(chloromethyl)thiophene gave *P*-chiral **1e** (73%).

The phosphanes **1a**, **1b** and **1d** are colourless solids which are readily soluble in most organic solvents. They can be recrystallised from alcohols or saturated hydrocarbons and may be handled in air for short periods of time. Compound **1c** had been reported as a waxy solid, whereas the phosphane **1e** is a colourless, air-sensitive oil with an unpleasant odour. The ^{31}P NMR signals are shifted to high field as the number of alkyl substituents increases. The methylene group of **1e** can be observed as an ABX system with $^{2}J_{H,H} = 14.4$ Hz and $^{2}J_{P,H} = 3.6$ Hz.

Crystal and Molecular Structure of 1b·BH_3

Compound **1b** was converted into its borane adduct by treatment with BH_3·SMe_2 in THF. Recrystallisation from ethanol/hexane gave crystals suitable for a single-crystal X-ray structure determination (Figure 1).

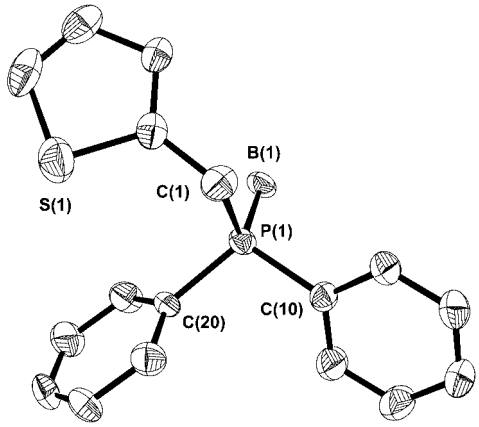

Figure 1. Molecular structure of $PPh_2(CH_2C_4H_3S)$·BH_3 (**1b**·BH_3), hydrogen atoms omitted for clarity. Space group $Pna2_1$; selected distances [pm] and angles (°) (standard deviations in parentheses): P(1)−B(1) 190.4(4), P(1)−C(1) 182.9(3), P(1)−C(10) 181.2(3), P(1)−C(20) 180.6(3); C(1)−P(1)−B(1) 111.98(19), C(10)−P(1)−B(1) 110.52(17), C(20)−P(1)−B(1) 117.02(17), C(1)−P(1)−C(10) 105.82(16), C(1)−P(1)−C(20) 104.13(17), C(10)−P(1)−C(20) 106.58(15)

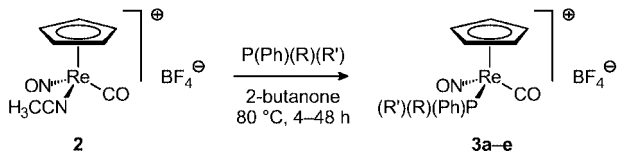
As expected, the BH_3 group is bound to phosphorus rather than to the sulfur atom of the thiophene moiety. The P−B and P−C bond lengths are in agreement with those of similar borane adducts.[15,16] The angles at the tetrahedral phosphorus atom are slightly distorted reflecting the low electronegativity of the BH_3 substituent.

Carbonyl Complexes

The chiral racemic rhenium complex $[CpRe(CO)(NO)(NCCH_3)]BF_4$ (**2**) was the common starting material for the following syntheses and is readily accessible from $[Re_2(CO)_{10}]$ in three steps.[4] The acetonitrile ligand is known to be easily replaceable by phosphanes[7,17,18] and this methodology was also successful with the phosphanes **1a**−**e** [Equation (1)].



(1)

R \ R'	2-C_6H_4OMe	$CH_2C_4H_3S$	$CH_2C_4H_7O$
Ph	**3a** (85%)	**3b** (83%)	**3c** (95%)
Me	**3d** (62%)	**3e** (76%)	

Compounds **3d** and **3e** were obtained as 1:1 mixtures of diastereoisomers, i.e. Re−P bond formation proceeds without diastereoselectivity. All new complexes $[CpRe(CO)(NO)(PR_3)]BF_4$ (**3a**−**e**) are yellow to yellow-brown air-stable solids (e.g. **3d** melts in air without decomposition). While **3c** is soluble in THF, **3b** and **3d** are insoluble in THF and **3e** is insoluble even in acetone. Due to the stereogenic metal centre, the PCH_2-protons in **3b** can be observed as an ABX system with $^{2}J_{H,H} = 15$ Hz and $^{2}J_{P,H} = 10$ Hz. Diastereomeric **3e** exhibits two such sets of signals. The ^{31}P NMR signals are shifted 25 to 30 ppm downfield compared with the free ligand. The CO and NO stretching frequencies appear in the ranges expected for cationic complexes of this kind.

Crystal and Molecular Structures of 3a, 3b and 3d−AlF_4

Three of the new complexes were investigated by X-ray diffraction. Figure 2−4 show views of the cations.

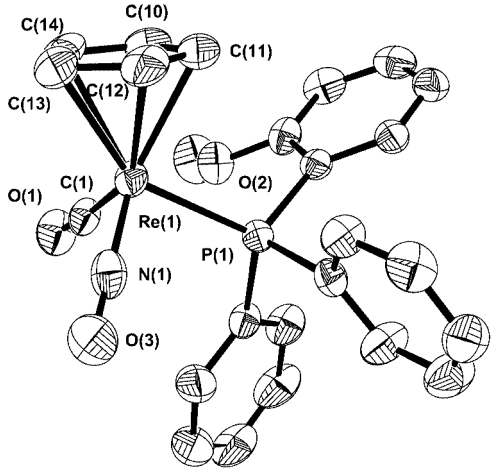


Figure 2. Structure of the cation of $[CpRe(CO)(NO)\{PPh_2(2\text{-}C_6H_4OMe)\}]BF_4$ (**3a**), hydrogen atoms omitted for clarity. Space group $P2_1/c$; selected distances [pm] and angles (°) (standard deviations in parentheses): Re(1)−C(10) 228.2(7), Re(1)−C(11) 229.7(6), Re(1)−C(12) 231.8(6), Re(1)−C(13) 229.9(6), Re(1)−C(14) 229.9(7), Re(1)−C(1) 191.6(6), Re(1)−N(1) 180.1(6), Re(1)−P(1) 239.26(14); Re(1)−C(1)−O(1) 175.1(6), Re(1)−N(1)−O(3) 178.8(5), N(1)−Re(1)−C(1) 97.2(3), P(1)−Re(1)−N(1) 91.37(17), P(1)−Re(1)−C(1) 88.32(18)

Due to the similar sizes of the CO and NO ligands these two groups are usually disordered.[19] Since the extent of this disorder is variable, the apparent Re−C and Re−N bond lengths can vary from their normal values as in **3a** to

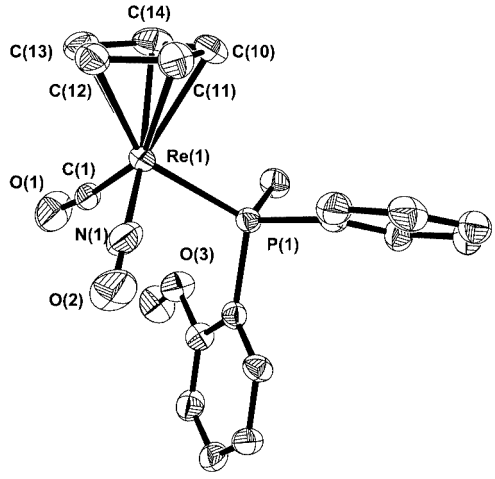

Figure 4. Structure of the cation of [CpRe(CO)(NO){P(Ph)(Me)(2-C_6H_4OMe)}]AlF_4 (**3d-AlF$_4$**), hydrogen atoms omitted for clarity. Space group $P2_1/n$; selected distances [pm] and angles (°) (standard deviations in parentheses): Re(1)−C(10) 231.7(7), Re(1)−C(11) 229.3(7), Re(1)−C(12) 227.7(7), Re(1)−C(13) 229.4(7), Re(1)−C(14) 227.5(7), Re(1)−C(1) 186.2(6), Re(1)−N(1) 183.3(7), Re(1)−P(1) 239.65(17); Re(1)−C(1)−O(1) 173.1(7), Re(1)−N(1)−O(2)−176.3(8), N(1)−Re(1)−C(1) 95.8(3), P(1)−Re(1)−N(1) 89.6(2), P(1)−Re(1)−C(1) 91.1(2)

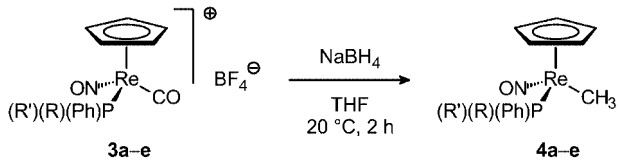
almost equal values as in **3d**. The topological similarity of the CO and NO ligands also thwarted any attempts to separate the diastereoisomers of **3c**−**e** by crystallisation. Moreover, the disorder makes it impossible to determine the relative configuration of the cation of **3d**−**AlF$_4$**.

Neither the NO ligands are bent nor are the cyclopentadienyl ligands slipped in any of the three structures. The rhenium atoms are octahedrally surrounded with the cyclopentadienyl ligand serving as a six-electron donor. In **3a** and **3d**−**AlF$_4$**, the N(1)−Re(1)−C(1) angles are significantly larger [97.2(3)° and 95.8(3)°, respectively] than in **3b** [92.4(2)°]. As the structure of the prototypic $[CpRe(CO)(NO)(PPh_3)]^+$ reveals the same widened N(1)−Re(1)−C(1) angle [95.5(5)°],[20] we have to conclude that the angle in **3b** is abnormally small. This is surprising since the phosphorus ligands of this study all have similar steric and electronic properties.

The surprising appearance of AlF_4^- as a counterion in the structure of **3d**−**AlF$_4$** was traced back to an impurity in the $[NO]BF_4$ which was used in the synthesis of [CpRe-(CO)(NO)($NCCH_3$)]BF_4 (**2**).

Methyl Complexes

The hydride reduction of a Re−CO group has already been described by Gladysz,[4,17] Casey,[21] Graham[22] and our group.[7] The new methyl complexes **4a**−**e** were obtained in the same way in good yields as orange or orange-red solids [Equation (2)].



(2)

R \ R'	2-C_6H_4OMe	$CH_2C_4H_3S$	$CH_2C_4H_7O$
Ph	**4a** (87%)	**4b** (75%)	**4c** (82%)
Me	**4d** (82%)	**4e** (81%)	

Complexes **4a**−**e** are readily soluble in common organic solvents except aliphatic hydrocarbons. This again makes a separation of the diastereomeric complexes **4c**−**e** difficult. Nevertheless, a diastereomeric excess of 35% was achieved during the workup of **4e**. This helped in the assignment of the spectroscopic data of the two diastereoisomers. Characteristic spectroscopic features for all methyl complexes are the low frequency of the NO stretching vibration and the high-field shift of the Re−CH_3 resonance in ^{13}C NMR spectroscopy. Furthermore, the phosphorus resonances are shifted downfield compared with those of the cationic starting materials.

Crystal and Molecular Structure of 4d

Crystals of the *unlike* isomer (R_{Re},S_P/S_{Re},R_P)-**4d** suitable for X-ray diffraction were grown at −30 °C by layering a toluene solution of the diastereomeric mixture with petroleum ether. A comparison of this structure with those of similar alkyl complexes (e.g. [CpRe(NO){P(*i*Pr)$_3$}(CH_3)][7]

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

and [CpRe(NO)(PPh_3)(CH_2Ph)][23]) did not reveal any significant differences (Figure 5).

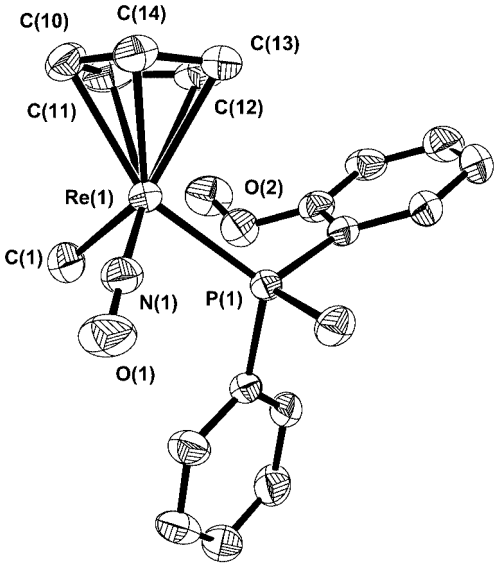


Figure 5. Molecular structure of (R_{Re},S_P/S_{Re},R_P) [CpRe(NO){P(Ph)(Me)(2-C_6H_4OMe)}(CH_3)] (**4d**), hydrogen atoms omitted for clarity. Space group *P*1; selected distances [pm] and angles (°) (standard deviations in parentheses): Re(1)−C(10) 228.4(4), Re(1)−C(11) 234.0(4), Re(1)−C(12) 233.6(4), Re(1)−C(13) 225.7(4), Re(1)−C(14) 222.8(4), Re(1)−C(1) 214.1(4), Re(1)−N(1) 175.6(3), Re(1)−P(1) 234.30(9); Re(1)−N(1)−O(1) 177.9(3), N(1)−Re(1)−C(1) 95.55(18), P(1)−Re(1)−N(1) 88.89(11), P(1)−Re(1)−C(1) 90.24(12)

The P(1)−Re(1) bond in **4d** is 3 pm shorter than in [CpRe(NO){P(*i*Pr)$_3$}(CH_3)] and even 2 pm shorter than in [CpRe(NO)(PPh_3)(CH_2Ph)], reflecting the smaller size of the phosphane ligand. Moreover, the C(1)−Re(1) distance is remarkably shorter [214.1(4) pm] than in [CpRe(NO){P(*i*Pr)$_3$}(CH_3)] [218.2(5)].[7] The cyclopentadienyl ligand is slightly slipped such that the two carbon atoms which are approximately *trans* to the strongly π-accepting NO ligand have moved about 8 pm away from the rhenium atom. As in [CpRe(NO){P(*i*Pr)$_3$}(CH_3)] and [CpRe(NO)(PPh_3)(CH_2Ph)], the N(1)−Re(1)−C(1) angle is widened [95.55(18)°], although the NO and CH_3 ligands are the smallest substituents.

Chelate Ring Closure

It is known that methylrhenium complexes liberate methane when treated with acids.[5,24,25] In the absence of donors, the solvent dichloromethane stabilises the resultant 16 valence electron complex. The CH_2Cl_2 complex thus obtained served as a starting material for a variety of compounds,[5] although it tends to undergo side reactions[6,26] and to decompose above −20 °C.[24,26] The phosphane ligands in this study offer donor functionalities (e.g. oxygen or sulfur), which should serve to stabilise the complex by intramolecular coordination. When the methyl complexes were treated with HBF_4 in dichloromethane, three complexes with chelate structures could be isolated, namely **5b**, **5c** and **5e** [Equation (3)].

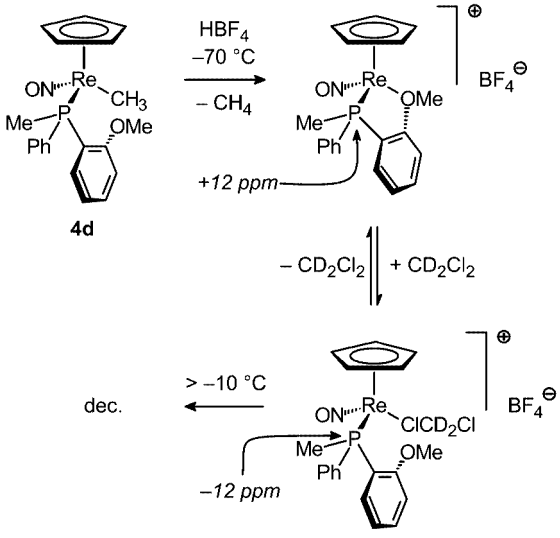
Attempts to obtain ring-closed products from the anisyl-substituted phosphane complexes **4a** and **4d** were only partially successful (see below). Two different samples of **4e** with 0 and 34% *de*, respectively, were employed in this reaction in order to gain some insight into the stereochemistry of the demethylation step. In both cases the *de* was retained in the product **5e**.

Although no crystals suitable for X-ray diffraction could be grown, the ring closure can be unambiguously inferred from ^{31}P NMR spectroscopic data. It is known that in chelate complexes the phosphorus chemical shift depends on the ring size. For five-membered rings, an additional 20−30 ppm downfield shift is typical.[27,28] The ^{31}P NMR spectra of **5b**, **5c** and **5e** exhibit this feature, an example is shown in Figure 6. The NO stretching frequency was found in the typical range for cationic ether[29] or thioether[6,30,31] complexes of the general formula $[CpRe(NO)(PR_3)(L)]^+$. All other spectroscopic data are also in agreement with a cationic structure.

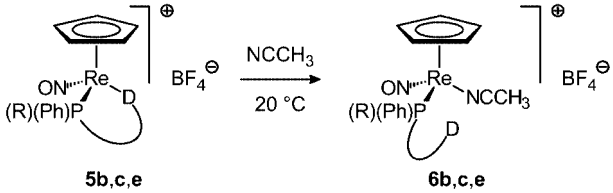
The reaction of **4d** with HBF_4 was investigated by low-temperature NMR spectroscopy. The phosphorus spectrum at −50 °C shows, aside from the expected downfield signals of two diastereomeric ring-closed complexes, a second pair of signals belonging to a cationic, ring-opened complex. Raising the temperature to 20 °C led to a decrease of the downfield signals and an increase of the upfield signals. Continued measurements at 20 °C revealed a slow decrease of both signal sets and, after 24 h, none of the signals could be observed any more. This can be interpreted in terms of a low stability of the ring-closed complex. At temperatures around −30 °C, there seems to be an equilibrium between ring-closed and ring-opened species, were the dichloromethane solvent acts as a ligand. The dichloromethane complex slowly decomposes at temperatures above −20 °C and is removed from the equilibrium which eventually leads to complete decomposition (Scheme 2). Nevertheless, this process is slowed down by the hemilabile ligand, compared with the rapid decomposition of $[CpRe(NO)(PPh_3)(ClCH_2Cl)]BF_4$.[24]



Scheme 2

Stabilitiy of the Ring-Closed Complexes and Preparation of Solvated Complexes

In the acid-promoted ring closure reactions of **5c** and **5e**, no diastereoselectivity was observed thus so far ruling out the possibility of a kinetic diastereoisomeric enrichment. If the diastereomeric complexes differ in energy, a thermodynamic enrichment might be possible. To check this, complexes **5b**, **5c** and **5e** were dissolved in polar solvents (e.g. THF, acetone or acetonitrile at 20 °C or reflux) and the mixtures analysed by ^{31}P NMR spectroscopy. While the acetone solutions did not show any enrichment or decomposition even after being heated to reflux for 24 h, a small diastereomeric enrichment was observed for **5e** in THF. Due to the different solubility of the diastereomers, only a suspension of **5e** in THF could be obtained with one diastereomer preferentially dissolved. The extraction of **5e** with THF led to a *de* of 60%, allowing the assignment of the spectroscopic data to the respective isomers. Upon dissolving the complexes in acetonitrile, new upfield signals in the ^{31}P NMR spectra appeared immediately. After 4 h, only the upfield signals remained. NMR and IR spectroscopic analyses suggested a ring-opening with the acetonitrile occupying the vacated coordination site as shown for **6b**, **6c** and **6e** [Equation (4)].



(4)

R \ D	$CH_2C_4H_3S$	$CH_2C_4H_7O$
Ph	**6b** (90%)	**6c** (82%)
Me	**6e** (93%)	

Crystal and Molecular Structure of 6e

The compositions of the acetonitrile complexes were corroborated by X-ray crystallography. Suitable crystals of the *unlike* diastereomer (R_{Re},S_P/S_{Re},R_P)-$[CpRe(NO)\{P(Ph)(Me)(CH_2C_4H_3S)\}(NCCH_3)]BF_4$ (**6e**) were obtained at 20 °C by layering a THF solution of the diastereomeric mixture with hexane. Figure 7 shows a view of the cation.

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

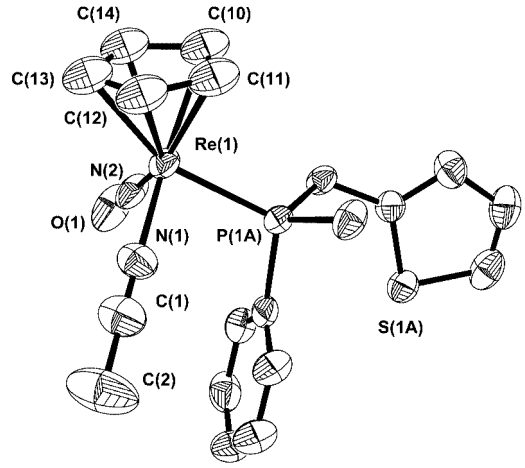


Figure 7. Structure of the cation of (R_{Re},S_P/S_{Re},R_P)-[CpRe(NO){P(Ph)(Me)($CH_2C_4H_3S$)}($NCCH_3$)]BF_4 (**6e**), hydrogen atoms omitted for clarity. Space group $P2_1/c$; selected distances [pm] and angles (°) (standard deviations in parentheses): Re(1)−C(10) 222.3(8), Re(1)−C(11) 228.3(8), Re(1)−C(12) 231.9(8), Re(1)−C(13) 226.9(7), Re(1)−C(14) 221.6(8), Re(1)−N(1) 205.5(6), Re(1)−N(2) 176.0(6), Re(1)−P(1A) 236.3(2); Re(1)−N(2)−O(1) 178.9(5), Re(1)−N(1)−C(1) 176.9(6), N(1)−C(1)−C(2) 178.6(8), N(1)−Re(1)−N(2) 96.9(2), P(1A)−Re(1)−N(1) 85.03(17), P(1A)−Re(1)−N(2) 92.86(18)

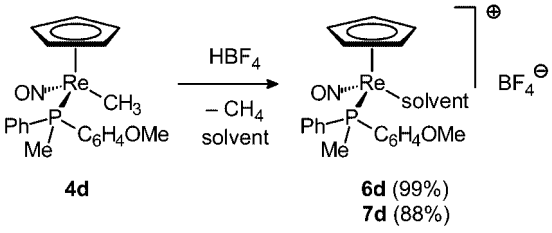
The cyclopentadienyl moiety is again slightly slipped such that the two carbon atoms *trans* to the NO ligand have moved away from the rhenium atom. The nitrosyl and nitrile ligands are perfectly linear and the N(1)−Re(1)−N(2) angle is in the typical range. This is somewhat in contrast to the structure of (S_{Re},S_C)-[CpRe(NO)(PPh_3){NCCH-(Ph)CH_2CH_3}]PF_6 where a significantly bent nitrile ligand and a widened N(1)−Re(1)−N(2) angle were observed.[32]

The refinement of the structure of **6e** indicated some disorder which revealed the presence, in the crystal, of ca. 10% of the *like* isomer. This is related to the predominating *unlike* isomer through a reflection of the phosphane ligand at a mirror plane which bisects the N(1)−Re(1)−N(2) angle and passes through the centre of the cyclopentadienyl ring, the rhenium atom and two carbon atoms of the thiophene ring (Figure 8).

Treatment of the methyl complex **4d** with HBF_4 either in a mixture of dichloromethane and acetonitrile or in pure THF gave the cationic solvated complexes **6d** and **7d** without any decomposition. Complex **7d** could be isolated with a *de* of 30% [Equation (5)].



(5)

solvent = CH_3CN (**6d**), THF (**7d**)

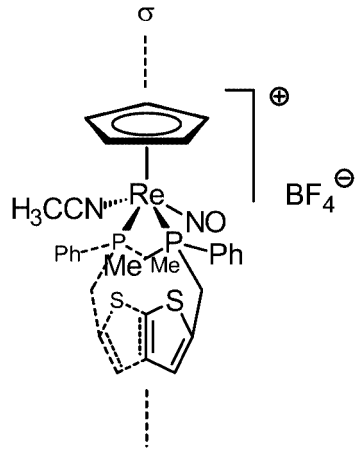


Figure 8. Disorder in the structure of *unlike*-**6e**; the phosphane ligand is reflected along an imaginary mirror plane which contains the Cp centre, the rhenium atom and two carbon atoms of the thiophene moiety giving rise to the *like* diastereoisomer

Crystal and Molecular Structure of 7d

The structure of the *like* isomer of the THF complex **7d** was determined by X-ray diffraction. Figure 9 shows the cation.

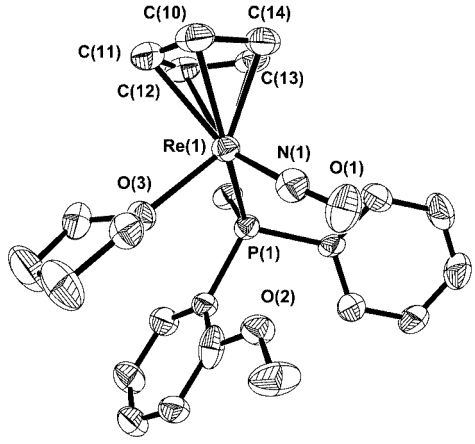

Figure 9. Structure of the cation of (S_{Re},S_P/R_{Re},R_P)-[CpRe(NO){P(Ph)(Me)(2-C_6H_4OMe)}(THF)]BF_4 (**7d**), hydrogen atoms omitted for clarity. Space group $P2_1/c$; selected distances [pm] and angles (°) (standard deviations in parentheses): Re(1)−C(10) 228.9(8), Re(1)−C(11) 235.0(8), Re(1)−C(12) 230.6(8), Re(1)−C(13) 220.8(7), Re(1)−C(14) 217.7(8), Re(1)−N(1) 174.9(7), Re(1)−O(3) 214.6(5), Re(1)−P(1) 238.64(18); Re(1)−N(1)−O(1) 176.0(7), N(1)−Re(1)−O(3) 96.9(3), P(1)−Re(1)−N(1) 90.8(2), P(1)−Re(1)−O(3) 87.60(14)

As for the methyl complex **4d** and the acetonitrile complex **6e** the cyclopentadienyl ligand is slipped, the difference between the longest and the shortest Re−C distances being 17 pm. Once again, the angle between the smallest ligands THF and NO is widened [96.9(3)°]. Since this widening has been observed for all N−Re−X angles in all structures discussed herein, the origin of this distortion must be electronic in nature.

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

All acetonitrile complexes were isolated in high yields as yellow or brown solids. Except for [CpRe(NO){P(Ph)(Me)($CH_2C_4H_7O$)}($NCCH_3$)]BF_4 (**6c**), the compounds are stable in acetone and even in dichloromethane solution, whereas **6c** decomposes rapidly in both solvents.

The formation of the THF complex **7d** deserves some comment. It implies that the superior donor ability of THF compared with the aryl methoxy group overrides the entropy effect of the five-membered chelate ring.

Discussion

It was the goal of this work to prepare diastereomeric rhenium complexes which contain stereogenic centres both at the metal and the phosphane ligand. Furthermore, the phosphanes bear a donor function (e.g. oxygen or sulfur) to allow intramolecular stabilisation of reactive intermediates. Five such hemilabile phosphanes were investigated. Adapting published methods, the phosphanes could be coordinated successfully to the rhenium complexes.

The phosphanes **1a** and **1d** which contain an *ortho*-anisyl group as a potential donor did not give stable chelate complexes. Although low temperature NMR experiments revealed that at −50 °C the intramolecularly stabilised complex [CpRe(NO){P(Ph)(Me)(2-C_6H_4OMe)}]BF_4 (**5d**) is formed, the ring opens at temperatures above −30 °C giving rise to another cationic complex, probably the dichloromethane adduct which itself decomposes at temperatures above −10 °C. The oxygen of the anisyl group is even less efficient as a donor than THF. On the other hand, ring closure was observed with the phosphanes **1b**, **1c** and **1e**. In these cases, neither THF nor acetone are strong enough donors to break the Re−O or Re−S bonds, while acetonitrile opens the rings irreversibly. As yet, no complete separation of the diastereoisomers could be achieved either during the formation of the ring-closed complexes or by fractional crystallisation (except for **4e**, **5e** and **7d**). On the other hand, once a sample enriched in one diastereomer is employed, then the degree of enrichment is carried over to the next step. This is in line with earlier observations that substitution reactions at half-sandwich complexes of rhenium proceed with retention of configuration.[33,34]

Conclusions

Diastereomeric rhenium complexes containing a stereogenic metal centre and a chiral phosphane ligand are readily accessible. Furthermore, if the phosphanes contain a second donor atom, e.g. oxygen or sulfur, chelate ring closure can occur. The stability of the chelate ring can be tuned by an appropriate choice of donor function. Further modifications of the system are necessary to give access to diastereomerically pure complexes.

Experimental Section

All experiments were carried out in Schlenk tubes under nitrogen using suitably purified solvents. IR: Bruker IFS 25. ^{1}H NMR: Bruker AMX 400, Jeol JNM-LA 300, δ values relative to TMS. ^{13}C NMR: Bruker AMX 400, Jeol JNM-LA 300, δ values relative to TMS, assignments were routinely checked by DEPT procedures. In some cases the ^{13}C NMR signals of quaternary carbon atoms were too weak to be detected. The ^{1}H and ^{13}C NMR signals of the phenyl groups attached to phosphorus are very similar for all compounds and have therefore been omitted from the lists of spectroscopic data. ^{31}P NMR: Bruker AMX 400, Jeol JNM-LA 300, δ values relative to 85% H_3PO_4. Elemental analyses: Analytical Laboratory of the Institut für Anorganische Chemie. BF_4^- salts occasionally give low carbon values due to trace formation of fluorocarbon compounds which escape detection. GC-MS: Fisons Instruments Trio-1000. The following starting materials were obtained as described in the literature: 2-(chloromethyl)thiophene,[35] $PPh_2(CH_2C_4H_7O)$ (**1c**),[13] $PPh(2\text{-}C_6H_4OMe)_2$,[36] PPh(Me)(H)[37] and [CpRe(CO)(NO)($NCCH_3$)]BF_4 (**2**).[4] All other reagents were used as purchased.

$PPh_2(CH_2C_4H_3S)$ (1b): This compound has been obtained previously via Li reduction of Ph_2PCl.[12] However, no yields or physical data were given. We found the following synthesis to be more convenient. A solution of $LiPPh_2$, prepared from PPh_3 (8.00 g, 30.5 mmol) and excess lithium in THF (50 mL), was treated with NH_4Cl (1.45 g, 27.1 mmol) to quench LiPh. Freshly distilled 2-(chloromethyl)thiophene (5.00 g, 37.7 mmol) was added dropwise to the red solution at 20 °C. After stirring for 1 h at 20 °C, water (15 mL) was added. The organic layer was separated, the aqueous phase extracted four times with diethyl ether (50 mL) and the combined organic phases dried with $MgSO_4$. The solvent was removed under vacuum and the colourless residue purified by recrystallisation from methanol or by column chromatography over silica (20 cm, petroleum ether/diethyl ether, 1:2). Yield 7.50 g (87%), white solid, m.p. 50 °C. ^{1}H NMR (400 MHz, $CDCl_3$, 20 °C): δ = 3.53 (s, br, 2 H, PCH_2), 6.60 (m, 1 H, thiophene *H*), 6.74 (m, 1 H, thiophene *H*), 6.96 (m, 1 H, thiophene *H*) ppm. ^{13}C NMR (100 MHz, $CDCl_3$, 20 °C): δ = 30.0 (d, $^1J_{P,C}$ = 15 Hz, P*C*H_2), 123.7 (d, $^4J_{P,C}$ = 3 Hz, thiophene *C*H), 125.7 (d, $^3J_{P,C}$ = 7 Hz, thiophene *C*H), 126.8 (d, $^4J_{P,C}$ = 1 Hz, thiophene *C*H), 139.8 (d, $^2J_{P,C}$ = 11 Hz, PCH_2*C*) ppm. ^{31}P NMR (162 MHz, $CDCl_3$, 20 °C): δ = −10.7 (s) ppm. $C_{17}H_{15}PS$ (282.35): calcd. C 72.32, H 5.35, S 11.36; found C 72.10, H 5.54, S 10.87.

P(Me)(Ph)(2-C_6H_4OMe) (1d): The preparation of **1d** starting from $PPh(2\text{-}C_6H_4OMe)_2$ was briefly mentioned in the literature, but no details were given.[14] To a solution of sodium (4.00 g, 174 mmol) in liquid ammonia (400 mL) was added $PPh(2\text{-}C_6H_4OMe)_2$ (28.0 g, 86.9 mmol) and the mixture kept at −78 °C for 6 h. NH_4Cl (4.50 g, 84.1 mmol) was then added followed by the dropwise addition of MeI (6.00 mL, 13.7 g, 96.5 mmol). The ammonia was evaporated overnight, the remaining pasty solid was washed twice with water (50 mL) and distilled (kugelrohr, oven temperature 180 °C). The colourless distillate solidified upon cooling to 20 °C. Yield 12.5 g (63%) (ref.[14] 56%), white solid, m.p. 46 °C (ref.[38] 46−47 °C). The NMR spectroscopic data were consistent with those given in ref.[38].

P(Ph)(Me)($CH_2C_4H_3S$) (1e): P(Ph)(Me)(H) (2.52 g, 20.3 mmol) was dissolved in THF (10 mL) and deprotonated with BuLi (8.5 mL 2.5 M, 21.3 mmol) at −78 °C. The orange solution thus obtained was slowly added to a cooled (−78 °C) solution of freshly distilled 2-(chloromethyl)thiophene (2.69 g, 20.3 mmol) in THF (10 mL). The mixture was warmed to 20 °C overnight, water (3 mL) was added, the organic layer was separated and the aqueous layer extracted three times with diethyl ether (20 mL). The combined extracts were dried with $MgSO_4$, the solvent removed and the residue distilled under vacuum. Yield 3.26 g (73%), colourless

[CpRe(CO)(NO){PPh$_2$(CH$_2$C$_4$H$_7$O)}]BF$_4$ (3c): A solution of acetonitrile complex **2** (1.00 g, 2.29 mmol) and phosphane **1c** (0.88 g, 3.26 mmol) in 2-butanone (20 mL) was heated to reflux for 48 h. Acetone (20 mL) was added, the mixture filtered through silica gel and the silica layer washed twice with acetone (10 mL). The combined filtrate was evaporated to dryness and the residue washed with diethyl ether. Yield 1.45 g (95%), yellow crystalline solid, m.p. 156 °C (dec.). Both diastereomers: ^{1}H NMR (400 MHz, CD_2Cl_2, 20 °C): δ = 1.60−2.11 (m, 8 H, CH_2CH_2), 2.92−3.19 (m, 4 H, PCH_2), 3.53−3.85 (m, 6 H, CH_2OCH), 5.77 (d, $^3J_{P,H}$ = 0.4 Hz, 5 H, C_5H_5), 5.78 (d, $^3J_{P,H}$ = 0.4 Hz, 5 H, C_5H_5) ppm. ^{13}C NMR (100 MHz, CD_2Cl_2, 20 °C): δ = 25.1 (s, *C*H$_2$), 25.2 (s, *C*H$_2$), 33.5 (d, $^3J_{P,C}$ = 12 Hz, *C*H$_2$), 33.6 (d, $^3J_{P,C}$ = 12 Hz, *C*H$_2$), 37.9 (d, $^1J_{P,C}$ = 37 Hz, P*C*H$_2$), 38.3 (d, $^1J_{P,C}$ = 37 Hz, P*C*H$_2$), 68.3 (s, O*C*H$_2$), 68.4 (s, O*C*H$_2$), 74.2 (d, $^2J_{P,C}$ = 3 Hz, O*C*H), 74.5 (d, $^2J_{P,C}$ = 3 Hz, O*C*H), 94.3 (s, *C*$_5$H$_5$), 195.4 (d, $^2J_{P,C}$ = 8 Hz, *C*O), 195.5 (d, $^2J_{P,C}$ = 8 Hz, *C*O) ppm. ^{31}P NMR (162 MHz, CD_2Cl_2, 20 °C): δ = 2.6 (s) ppm. IR (CH_2Cl_2): $\tilde{\nu}$ = 2019 (CO), 1763 (NO) cm^{-1}. $C_{23}H_{24}BF_4NO_3PRe$ (666.43): calcd. C 41.45, H 3.63, N 2.10; found C 41.34, H 3.88, N 1.90.

[CpRe(CO)(NO){P(Ph)(Me)(2-C$_6$H$_4$OMe)}]BF$_4$ (3d): A solution of acetonitrile complex **2** (1.00 g, 2.29 mmol) and phosphane **1d** (1.00 g, 4.34 mmol) in 2-butanone (20 mL) was heated to reflux for 30 h. Acetone (20 mL) was added, the mixture filtered through silica gel and the silica layer washed twice with acetone (10 mL). The solvent was removed under vacuum and the oily residue dissolved in THF (10 mL). Upon stirring, a yellow solid separated which was collected by filtration and washed repeatedly with THF until the washings remained almost colourless. Yield 0.88 g (62%), bright yellow crystalline solid, m.p. 134 °C. Both diastereomers: ^{1}H NMR (400 MHz, CD_2Cl_2, 20 °C): δ = 2.46 (d, $^2J_{P,H}$ = 10.4 Hz, 3 H, PCH_3), 2.52 (d, $^2J_{P,H}$ = 10.4 Hz, 3 H, PCH_3), 3.73 (s, 3 H, OCH_3), 3.79 (s, 3 H, OCH_3), 5.82 (s, 10 H, C_5H_5) ppm. ^{13}C NMR (100 MHz, CD_2Cl_2, 20 °C): δ = 20.3 (d, $^1J_{P,C}$ = 42 Hz, P*C*H$_3$), 20.4 (d, $^1J_{P,C}$ = 42 Hz, P*C*H$_3$), 56.0 (s, O*C*H$_3$), 56.2 (s, O*C*H$_3$), 94.2 (s, *C*$_5$H$_5$), 94.2 (s, *C*$_5$H$_5$), 195.2 (d, $^2J_{P,C}$ = 9 Hz, *C*O), 195.8 (d, $^2J_{P,C}$ = 9 Hz, *C*O) ppm. ^{31}P NMR (162 MHz, CD_2Cl_2, 20 °C): δ = −15.0 (s), −13.0 (s) ppm. IR (CH_2Cl_2): $\tilde{\nu}$ = 2021 (CO), 1763 (NO) cm^{-1}. $C_{20}H_{20}BF_4NO_3PRe$ (626.37): calcd. C 38.35, H 3.22, N 2.24; found C 38.60, H 3.35, N 2.22.

[CpRe(CO)(NO){P(Ph)(Me)(CH$_2$C$_4$H$_3$S)}]BF$_4$ (3e): A solution of acetonitrile complex **2** (600 mg, 1.37 mmol) and phosphane **1e** (400 mg, 1.82 mmol) in 2-butanone (15 mL) was heated to reflux for 4 h. Upon cooling, a yellow precipitate formed. Diethyl ether (15 mL) was added and the solid was collected by filtration and washed with THF. Yield 640 mg (76%), yellow crystalline solid, m.p. 233 °C. Both diastereomers: ^{1}H NMR (400 MHz, CD_3CN, 20 °C): δ = 2.19 (d, $^2J_{P,H}$ = 10.4 Hz, 3 H, PCH_3), 2.19 (d, $^2J_{P,H}$ = 10.4 Hz, 3 H, PCH_3), 4.04, 4.13 (ABX system, $^2J_{H,H}$ = 15.7, $^2J_{P,H}$ = 9.3 Hz, 2 H, PCH_2), 4.07, 4.11 (ABX system, $^2J_{H,H}$ = 15.4, $^2J_{P,H}$ = 10.0 Hz, 2 H, PCH_2), 5.88 (d, $^3J_{P,H}$ = 0.6 Hz, 5 H, C_5H_5), 5.90 (d, $^3J_{P,H}$ = 0.6 Hz, 5 H, C_5H_5), 6.80 (m, 2 H, thiophene *H*), 6.93 (m, 2 H, thiophene *H*), 7.27 (m, 2 H, thiophene *H*) ppm. ^{13}C NMR (100 MHz, CD_3CN, 20 °C): δ = 16.1 (d, $^1J_{P,C}$ = 40 Hz, P*C*H$_3$), 16.2 (d, $^1J_{P,C}$ = 40 Hz, P*C*H$_3$), 35.2 (d, $^1J_{P,C}$ = 34 Hz, P*C*H$_2$), 35.4 (d, $^1J_{P,C}$ = 34 Hz, P*C*H$_2$), 94.7 (d, $^2J_{P,C}$ = 1 Hz. *C*$_5$H$_5$), 94.8 (d, $^2J_{P,C}$ = 1 Hz. *C*$_5$H$_5$), 127.1 (d, 4$J_{P,C}$ = 4 Hz, thiophene *C*H), 127.1 (d, 4$J_{P,C}$ = 4 Hz, thiophene *C*H), 128.3 (d, 4$J_{P,C}$ = 4 Hz, thiophene *C*H), 128.3 (d, 4$J_{P,C}$ = 4 Hz, thiophene *C*H), 129.7 (d, 3$J_{P,C}$ = 7 Hz, thiophene *C*H), 129.8 (d, 3$J_{P,C}$ = 7 Hz, thiophene *C*H), 134.1 (d, $^2J_{P,C}$ = 10 Hz, PCH$_2$*C*), 134.2 (d, $^2J_{P,C}$ = 10 Hz, PCH$_2$*C*), 195.9 (d, $^2J_{P,C}$ = 7 Hz, *C*O), 195.9 (d, $^2J_{P,C}$ = 7 Hz, *C*O) ppm. ^{31}P NMR (162 MHz, CD_3CN, 20 °C): δ = −6.4 (s), −5.5 (s) ppm. IR (Nujol): $\tilde{\nu}$ = 2016 (CO), 1763 (NO) cm^{-1}. $C_{18}H_{18}BF_4NO_2PReS$ (616.40): calcd. C 35.07, H 2.94, N 2.27, S 5.20; found C 34.83, H 2.92, N 2.30, S 5.09.

[CpRe(NO){PPh$_2$(2-C$_6$H$_4$OMe)}(CH$_3$)] (4a): To a suspension of carbonyl complex **3a** (300 mg, 0.44 mmol) in THF (15 mL) was added $NaBH_4$ (50 mg, 1.32 mmol). The colour of the mixture changed from brown to red and a gas was evolved. After 2 h, the solution was evaporated to dryness, the residue dissolved in benzene (15 mL), filtered through silica gel and the silica washed with benzene. The clear, orange filtrate was evaporated to 1 mL and the product precipitated upon addition of petroleum ether and storing overnight at −30 °C. Yield 220 mg (87%), orange crystalline solid, m.p. 55 °C (dec.). ^{1}H NMR (400 MHz, C_6D_6, 20 °C): δ = 1.45 (d, $^3J_{P,H}$ = 6.4 Hz, 3 H, ReCH_3), 3.05 (s, 3 H, OCH_3), 4.61 (s, 5 H, C_5H_5) ppm. ^{13}C NMR (100 MHz, C_6D_6, 20 °C): δ = −35.7 (d, $^2J_{P,C}$ = 7 Hz, Re*C*H$_3$), 55.0 (s, O*C*H$_3$), 89.6 (d, $^2J_{P,C}$ = 2 Hz, *C*$_5$H$_5$)

[D_6]acetone, 20 °C): δ = −5.8 (s) ppm. Both diastereomers: IR (CH_2Cl_2): $\tilde{\nu}$ = 1701 (NO) cm^{-1}. $C_{23}H_{28}BF_4NO_3PRe$ (670.47): calcd. C 41.20, H 4.21, N 2.09; found C 40.49, H 4.18, N 2.00.

X-ray Structure Determinations: Single crystals of **1b**·BH_3, **3a**, **3b**, **3d**−**AlF_4**, **4d**, **6e** and **7d**·CH_2Cl_2 were bonded to a glass fibre with frozen hydrocarbon oil in each case. A Bruker Smart Apex CCD instrument was used for data collection (graphite monochromator, Mo-K_α radiation, λ = 0.71073 Å). The structures were solved using Patterson methods and refined with full-matrix least-squares against F^2 (SHELXS-97).[39] Hydrogen atoms were included in their calculated positions and refined using a riding model. The details of the measurements are summarised in Table 1. Further data may be obtained from the Cambridge Crystallographic Data Centre. CCDC-242558 (for **1b**·BH_3), -242219 (for **3a**), -242220 (for **3b**), -242221 (for **3d**−**AlF_4**), -242222 (for **4d**), -242223 (for **6e**) and -242224 (for **7d**·CH_2Cl_2) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Hydrogen-Bonded Network and Layered Supramolecular Structures Assembled from ClO_4^- Counterions with Unprecedented Monomeric $[AgL_2]^+$ and Chain Polymeric $[AgL_2]_n^{n+}$ Complex Cations (L = Thioamide or Thiourea-Like Ligands)

Keywords: X-ray diffraction / Silver / Supramolecular chemistry / S ligands / Bridging ligands

The complexes $[Ag(etu)_2]ClO_4$ (**1**) and $[\{Ag(py2tH)_2\}(ClO_4)(H_2O)_{0.5}]_n$ (**2**) have been obtained from the reactions of $AgClO_4$ with the corresponding thioamide ligands (etu = imidazolidine-2-thione; py2tH = pyridine-2-thione). Complex **1**, consisting of centrosymmetric monomeric $[Ag(etu)_2]^+$ cations and ClO_4^- counterions, constitutes the first bis[thio(mono- or di)amide] complex (M = Cu, Ag) known thus far to possess a linear MS_2 mononuclear core. Component ions behave in the crystal structure as complementary partners, with all four N–H groups of each $[Ag(etu)_2]^+$ cation and all four oxygen atoms of each ClO_4^- anion involved in N–H···O–Cl hydrogen bonding associations. This leads to the assembly of a three-dimensional supramolecular network. Complex **2**, whose previously reported structure has been redetermined with higher precision, contains *catena*-$[Ag(py2tH)_2]_n^{n+}$ polymeric cations consisting of linear chains of linked $Ag_2(\mu\text{-}S)_2$ rings, with distorted tetrahedral AgS_4 centres. Supramolecular association through N–H···O–Cl, N–H···O(water) and Cl–O···H–O–H···O–Cl hydrogen bonding, where all N–H groups and H_2O molecules and only one or two oxygen atoms of each ClO_4^- anion are involved, leads to the formation of a two-dimensional layered supramolecular structure. A correlation of some stereochemical parameters and a simple qualitative sulfur-bridge bonding model has been developed for **2** and other related thioamide complexes containing $M_2(\mu\text{-}S)_2$ rings or M–S–M′ single bridges. For these structural units, suitable ranges of tilt and twist dihedral angles have been estimated and assigned to different bonding types.

Introduction

Considerable attention is currently directed to the study of metal−thioamide coordination chemistry with both heterocyclic and thiourea-like ligands. This interest is mainly encouraged by the flexible coordination capability of the thioamide group which, as a neutral ligand, may be involved, as shown in Scheme 1, in equilibrium with its imino−thiol and amino−thione tautomers. The latter form, with sulfur as donor atom, is dominant for metal coordination, while a "zwitterionic" immonium−thiolate resonance form contributes to the delocalisation of the π-electron density and to some electron enrichment at the thione sulfur atom, which may be seen as formally close to a thiolate sulfur atom. On the other hand, thioamide ligands are easily deprotonated to give their thionate anionic form. In this case, and because of the accumulation of the actual anionic

charge mainly at the sulfur atom, its coordination potential is not only closer to that of a thiolate group, but also further enhanced by the donor capacity of the nitrogen atom via the S-to-N backbone.

Extensive reviews and publications, mainly from Raper, focus on the study of the donor behaviour of heterocyclic thioamides and related ligands towards transition and non-transition metal ions,[1−5] silver being the least referenced within the Group 11 metals. One of the points of interest arises from the Cu^{II}-thione redox chemistry as a way of modelling the electronic and structural properties of Cu−cysteine environments in "blue" copper proteins.[2] Additional attention is directed to the employment of thioamide ligands, with the aim of reducing the toxicity associated with coinage metal thiolate complexes and their heteroleptic phosphane derivatives (M^{I} = Au, Ag), which are used as both effective antiarthritic and antitumour (Au),[6] and potential antimicrobial (Ag)[7] drugs. Current research on inorganic-organic hybrid materials containing S,N-donor ligands has led to the characterization of silver thioamide coordination polymers,[8−10] which show interesting infinite chain (1D), layered (2D), and network (3D) structures containing these ligands in a variety of coordination modes.

A bibliographic and database search covering homoleptic complexes of neutral thioamide ligands with monovalent Group 11 metals of known structure, with general formula $[M_x(L)_y]^{x+}$, has revealed an extensive and varied family of compounds, which possess many different stoichiometries ranging from M/L = 1:1 to 1:4 ratios. Although we restrict our attention here to homoleptic complexes, unexpected variations are found when comparing observed structures, and this even occurs, in some cases, for compounds of almost the same chemical formula. No 1:1 cationic complex has so far been crystallographically characterised.[11]

The adamantane-like tetrahedral cage $M_4(\mu\text{-}S)_6$, which is the most frequently encountered structural unit in polynuclear thiolates,[12,13] is also present in cationic thioamide complexes. This tetrahedral cage is known to exist, with no terminal ligands and thus with trigonal coordination of all four metal atoms, in $[Cu_4L_6]^{4+}$ species [L = tu (thiourea),[14,15] thpym2tH$_2$ (tetrahydropyrimidine-2-thione),[16] and with the accommodation of some terminal ligands and both tetrahedral and trigonal metal sites in complexes $[Cu_4(tu)_7](SO_4)_2$,[17] $[Cu_4(tu)_9](NO_3)_4$,[18] and $[\{Cu_4(tu)_6(tu)_{3/2}\}(SO_4)_2]_n$.[19] To the best of our knowledge, none of the reported $[Cu_4L_{10}]^{4+}$ complexes of thioamide ligands contains such a tetrahedral cage with all four metal centres tetrahedrally coordinated.

An alternative structure to the tetrahedral $M_4(\mu\text{-}S)_6$ cage has been found in the complex $[Cu_4(mpym2tH)_6](BF_4)_4$ (mpym2tH = 1-methylpyrimidine-2-thione).[20] It consists of an $M_4(\mu\text{-}S)_4$ eight-membered ring with a rhomboidal planar array of metal atoms. In this case, two S-terminal, two μ_2-S bridging and two μ_3-S,N bridging ligands give rise to CuS_3 and CuS_2N trigonal-planar environments. A silver complex of the same stoichiometry, $[\{Ag_4(py2tH)_6\}(NO_3)_4]_n$ (py2tH = pyridine-2-thione), shows a third structural pattern consisting of a double chain polymeric framework, where silver atoms are linked in a tetrahedral fashion by two μ_2-S and two remarkable μ_4-S bridging ligands.[21]

The structural diversity already noted for some $[M_4L_6]^{4+}$ cations also extends to $[M_4L_9]^{4+}$ species. As cited above, a *tetrahedro*-$[M_4(\mu\text{-}SR)_6]$ cage is present in $[Cu_4(tu)_9]^{4+}$,[18] whereas a *quadro*-$[M_4(\mu\text{-}SR)_4]$ ring containing a planar M_4 arrangement has been established in the complex $[Cu_4(etu)_9](NO_3)_4\cdot 6H_2O$ [etu = imidazolidine-2-thione (ethylenethiourea)],[1,22] where four μ_2-S bridging, four S-terminal and one central μ_4-S bridging ligand account for the tetrahedral geometry of each metal atom. A third structure for this stoichiometry has been encountered in the infinite polymer $[\{Cu_4(tu)_9\}(NO_3)_4]_n$,[23] consisting of chains of linked *quadro*-$[M_4(\mu\text{-}SR)_6(SR)_2(SR)_{2/2}]$ rings, with a planar arrangement of the four metal atoms and tetrahedral MS_4 environments.

The reported structures of the cationic complexes with the general formula $[ML_2]_n^{n+}$ include monomeric (the only cationic thioamide complexes known for Au^{I}) and cyclic tetrameric discrete species, and infinite chain polymers (we return later to some details of these structures).

Two discrete and two polymeric structures have been described for cationic thioamide complexes of stoichiometry M/L = 2:5, none of which contains a *tetrahedro*-$[M_4(\mu\text{-}SR)_6]$ cage. Two trigonal-planar CuS_3 units share a unique μ_2-S bridging ligand in the dinuclear complex $[Cu_2(mimtH_2)_5]SO_4$ (mimtH$_2$ = 1-methylimidazoline-2-thione).[24] A planar core of four tetrahedrally coordinated metal atoms, which is encompassed by four S-terminal and six μ_2-S bridging ligands, *quadro*-$[(MSR)_4(\mu\text{-}SR)_6]$, constitutes the structural unit adopted by the discrete tetranuclear compound $[Cu_4(bzimtH_2)_{10}](ClO_4)_4$ (bzimtH$_2$ = benzimidazoline-2-thione).[25] Making allowances for the different thioamide ligands and counter-anions present in this complex and in the previously cited $[\{Cu_4(tu)_9\}(NO_3)_4]_n$,[23] detachment of one of the terminal ligands from the discrete structure gives rise to the repeat unit *quadro*-$[M_4(\mu\text{-}SR)_6(SR)_3]$ that generates the polymeric framework of the latter.

While the structure of the infinite polymer $[\{Cu_2(tu)_5\}SO_4]_n$ is formed by cationic chains of alternating trigonal-planar MS_3 and tetrahedral MS_4 sites,[26] that of the polymeric compound $[\{Cu_4(tu)_{10}\}(SiF_6)_2]_n$[27] is somewhat more complicated. It consists of infinite chains of alternating $[(MSR)_3(\mu\text{-}SR)_3]$ six-membered rings and μ_2-S bridging ligands, which are in turn cross-linked via $[\{M(SR)_2\}_2(\mu\text{-}SR)_2]$ four-membered rings to give a three-dimensional polymer with all the metals in tetrahedral MS_4 sites.

Cationic thioamide complexes of stoichiometry corresponding to the general formula $[ML_3]_n^{n+}$ are the most numerous for Cu and Ag, with crystallographically demonstrated nuclearities *n* of 1, 2, and (in only one case) 4. While monomers, as in $[Ag(mimtH_2)_3](NO_3)$, show a trigonal planar MS_3 coordination,[28−31] dimeric cations, as in $[Ag_2(dmtu)_6](ClO_4)_2$ (dmtu = *N*,*N*′-dimethylthiourea), contain $[\{M(SR)_2\}_2(\mu\text{-}SR)_2]$ four-membered rings with tetrahedral MS_4 sites.[32−36] These latter sites are also present in

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

the complex $[Cu_4(tu)_{12}](SO_4)_2$,[37] which contains a *quadro*-$[\{Cu(SR)_2\}_4(\mu\text{-}SR)_4]$ cationic eight-membered ring. Finally, the structural pattern richest in thioamide ligands possesses a stoichiometry M/L = 1:4 and corresponds, as in $[Ag(mpy2tH)_4]BF_4$ (mpy2tH = 1-methylpyridine-2-thione), to monomeric complexes with an MS_4 (M = Cu, Ag) tetrahedral coordination environment.[38−40]

As evidenced by the stoichiometry-structure relationships outlined above, an extensive range of stereochemical arrangements is available for $[M_xL_n]^{x+}$ thioamide complexes. These, however, are significantly less explored for silver than for the other two coinage metals.

With the aim of obtaining further structural data, particularly for cationic thio(mono- or di)amide complexes, as well as examining their relationship to previous structures, we have carried out the synthesis and crystal structure determination of the compounds $[Ag(etu)_2]ClO_4$ (**1**) and $[\{Ag(py2tH)_2\}(ClO_4)(H_2O)_{0.5}]_n$ (**2**). Complex **1**, containing mononuclear $[M(thioamide)_2]^+$ cations with a linear MS_2 coordination, represents the first reported Ag complex displaying this structural pattern. Although not yet encountered for Cu, this pattern corresponds to the only structural type established thus far for related Au complexes. The structure of complex **2** was previously reported with a misprinted space group and only a brief discussion;[21] the redetermination reported here, from low-temperature data, is of considerably greater precision (standard uncertainties reduced by a factor of 3 or more) and permits more detailed analysis.

Results and Discussion

Spectroscopic Properties

In agreement with the increasing participation of the immonium-thiolate resonance form (Scheme 1) to the electronic structure of a thioamide complex on S-coordination, the IR bands possessing significant contribution from ν(CS) or ν_{as}(N−C−N) vibrations (at 510, 1500 cm^{-1} in etu as free ligand) shift to lower[41] and higher[42] frequencies (495, 1522 cm^{-1}), respectively, in the spectrum of complex **1**; ν(SH), which appears as a weak band near 2500 cm^{-1} in free py2tH, is absent in the IR spectrum of complex **2**. This fact, together with the positive shift of the ring breathing mode[43] of py2tH itself (984 cm^{-1}) to 995 cm^{-1} in the same complex, is also in accordance with S-coordination. As expected from the role of the perchlorate as counter-anion, no significant splitting of its IR-active bands, associated with $\nu(T_2)$ (centred at 1090 cm^{-1}) and $\delta(T_2)$ (626 cm^{-1}) vibrational modes, is observed in the spectra of the two complexes.

S-coordination causes small downfield shifts relative to the free ligand in the ^1H NMR spectra, the largest [$\Delta\delta$ = 1.0 (**1**), 0.7 (**2**) ppm] occurring for the N−H protons.[44] The chemical shifts of these [8.90 (**1**), 14.10 (**2**) ppm], as well as their positive coordination shifts, reflect, as in the IR spectra, the relevant contribution of the immonium-thiolate resonance form in both complexes. ^{13}C NMR spectra are more sensitive to S-donation, the carbon atom of the thione group being the most affected, with high-field coordination shifts[45,46] of δ = −5.2 and −10.2 ppm, respectively, for complexes **1** and **2**.

Structures of the Complexes

Homoleptic complexes of general formula $[ML_2]X$, where M = Cu^I or Ag^I, X^- is an uncoordinated anion, and L is a neutral thio(mono- or di)amide ligand, are not very numerous. To the best of our knowledge, seven complexes have so far been crystallographically characterised. Six of them are $[M(dmtu)_2]X$ (M = Cu, X = NO_3^-;[47] M = Ag, X = ClO_4^- [36]), $[Cu(quinoline\text{-}2\text{-}thione)_2]X$ (X = ClO_4^-, $PO_2F_2^-$),[48] and $[Ag(py2tH)_2]X$ (X = BF_4^-, ClO_4^-),[21] all consisting of linear-chain $[M(\mu\text{-}S)_2]_\infty$ polymeric cations formed by distorted MS_4 tetrahedra, which are linked by sharing opposite edges. The structures of the last two compounds have appeared recently, ostensibly as anhydrous and isomorphous in space group *P*1, though the corresponding entries (with refcodes MOGNAF and MOGNEB) in the Cambridge Structural Database (CSD, version 5.24, November 2002)[49] actually show them to be hydrates and in space group $P\bar{1}$. As only a brief description of the cationic chains was given by the previous authors, with no information on other aspects of the structures, and as our results for the perchlorate are more precise, from low-temperature data, further details of the crystal structure will be given here for complex **2**. The remaining previously reported compound of M/L = 1:2 stoichiometry, $[Ag(1\text{-}azacycloheptane\text{-}2\text{-}thionato)_2]_4(NO_3)_4$, has a totally different structure consisting of discrete $[(AgSR)_4(\mu\text{-}SR)_4]$ cationic rings with trigonal AgS_3 sites.[50]

By contrast, corresponding complexes with Au^I are more numerous and all of those known have mononuclear structures with strictly or essentially linear AuS_2 coordination. Reported $[AuL_2]X$ complexes include those with L = etu, X = $[AuI_2]^-$ [51] or Cl^-;[52] L = tu, X = Br^- [53] or ClO_4^-;[54] L = py2tH, X = ClO_4^-;[55] L = dmtu or detu, X = ClO_4^-.[56] The $[Au(etu)_2]^+$ cation in $[Au(etu)_2]Cl\cdot H_2O$ is somewhat more distorted, with an S−Au−S angle of 167.1°, owing to the *cis* configuration of the heterocyclic rings of the two ligands. This is favoured by the formation of hydrogen bonds that involve the O atom of water and two N−H groups belonging to different ligands.[52]

Despite the fact that $Ag(tu)_2Cl$ is not genuinely homoleptic, its polymeric structure may be referred to here for comparison.[57] It contains both nearly trigonal-planar AgS_3 and flattened tetrahedral $AgS_3\cdots Cl$ environments. The corresponding complex $Cu(tu)_2Cl$[58] adopts a similar structure.

Complex 1

This consists of ClO_4^- anions and mononuclear $[Ag(etu)_2]^+$ cations. The cation (Figure 1) lies on a crystallographic inversion centre, and thus the coordination of Ag is strictly linear (Table 1). The anion lies on a two-fold rotation axis and is disordered over two orientations. Interac-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

tions among the ions appear to be of normal electrostatic and van der Waals character, together with hydrogen bonding as described below, with no significant influence on metal coordination. This is supported by the fact that the shortest Ag···Ag separation, 3.513 Å, is more than twice the van der Waals radius (3.44 Å), and the closest inter-cation Ag···S contact, 3.275 Å, is markedly greater than the sum of the corresponding covalent radii (2.55 Å) and only slightly less than the sum of the van der Waals radii (3.50 Å).[59] This is the first homoleptic silver complex of thio-(mono- or di)amide ligands with a silver/sulfur stoichiometry of 1:2 for which a monomeric cation has been crystallographically established. The closest previous approach to this is in the structure of [Ag(*N*-(diethylaminothiocarbonyl)benzamidine-*S*)$_2$]NO_3, where a secondary Ag···S interaction between two adjacent molecules (3.034 Å) induces a significant bending at the primary S−Ag−S centre (159.4°).[60]

Table 1. Selected bond lengths [Å] and angles [°] for **1**

Ag(1)−S(1)	2.4058(8)	Ag(1)−S(1A)	2.4058(8)
S(1)−Ag(1)−S(1A)[a]	180	Ag(1)−S(1)−C(1)	105.80(10)

[a] Symmetry operation for equivalent atoms: A: 1 − *x*, 1 − *y*, 1 − *z* (inversion centre).

The etu ligand is approximately planar and forms a twist dihedral angle (see later for a definition and discussion of twist and tilt dihedral angles with respect to the coordination of bridging ligands) of 11.4° with the central C−S−Ag−S−C segment, so that the whole cation does not deviate greatly from planarity. This near-planarity, together with the 105.8° bond angle at S(1), suggests that coordination of the ligand to Ag^I is essentially through a sulfur lone pair in an in-plane sp^2 hybrid orbital. The cations are arranged in planes corresponding to the (202) lattice planes of the crystal structure, as shown in Figure 2, with the anions lying between these planes. The main deviation of the ligand from planarity is a small distortion towards an envelope conformation, with C(3) as the flap; this can also be seen in Figure 2.

A three-dimensional framework of N−H···O−Cl hydrogen bonding, involving both the amine N−H groups of each ligand and all four perchlorate oxygen atoms, reinforces the ionic interactions and gives rise to a supramolecular assembly of complex cations and ClO_4^- anions, shown in Figure 3 (where only one disorder component of each anion is included). Despite the two-fold disorder of

plexes of thiourea and thioamide ligands recorded in the CSD.

Complex 2

The complex $[\{Ag(py2tH)_2\}(ClO_4)\cdot 0.5(H_2O)]_n$ contains polymeric $[Ag(py2tH)_2]_n^{n+}$ cations, discrete ClO_4^- anions, and uncoordinated water molecules. All three chemically distinct components are linked together by a network of hydrogen bonds, in addition to the ionic interactions involving the polymeric cations and the anions.

All the py2tH ligands employ only sulfur atoms for coordination to Ag^I, each ligand bridging a pair of metal atoms in distorted AgS_4 tetrahedral environments, to give linear polymeric chains of linked $Ag_2(\mu\text{-}S)_2$ rings, which run parallel to the crystallographic *b* axis. Figure 4 shows the three crystallographically independent Ag_2S_2 rings, and Figure 5 the resultant chain polymer. The two outer rings in Figure 4 are crystallographically centrosymmetric, and hence are strictly planar, with the ligands in *anti* configurations. The central ring, by contrast, is not planar but folded, with its ligands in the *syn-exo* configuration; the two AgS_2 planes define a dihedral (hinge) angle of 152° about the S···S diagonal. Planar *anti* and folded *syn* Ag_2S_2 rings thus alternate along the chain. Ag−S bond lengths span the range

2.5491(7)−2.7770(7) Å (Table 3), the sum of the corresponding covalent radii being about 2.55 Å.[59] The nonplanar ring contains the least and the most symmetrical bridges, with the difference in Ag−S bond lengths being approximately 0.23 Å for S(1) and only 0.02 Å for S(2), while it is 0.12 Å for S(3) and 0.04 Å for S(4). Other structural parameters characteristic of these Ag_2S_2 rings are the Ag···Ag distances ranging from 2.769 to 2.969 Å (less than twice the covalent radius, 3.06 Å[59]) and the markedly acute Ag−S−Ag angles, between 63.5 and 69.3°.

Distortion of the two crystallographically independent AgS_4 centres from a regular tetrahedron is clearly reflected in the S−Ag−S angles [Table 2; a range of 30.7° for Ag(1) and 15.5° for Ag(2)], and in the dihedral angles formed by the two AgS_2 half-ring planes at each Ag atom [74.5° for Ag(1) and 86.9° for Ag(2); these would be 90° for a regular tetrahedron]. These figures show that the tetrahedral coordination is substantially less regular for Ag(1). The surrounding sheaths of pyridine rings prevent secondary covalent interactions between Ag and S atoms of different chains. However, the N−H amine groups of these rings, together with the ClO_4^- anions and the uncoordinated water molecules, provide a hydrogen-bonding pathway linking neighbouring cationic chains, causing these to assemble into a two-dimensional sheet supramolecular structure, as shown in Figure 6, where parts of two chains are included, together with the anions and water molecules lying between them. Contacts between hydrogen-bonded sheets involve only ligand C−H groups and perchlorate oxygen atoms, which do not take part in the interactions within the sheets.

Details of the hydrogen bonds are given in Table 2. Each water molecule (there is one for every two Ag^I centres and two anions) acts as a donor in two hydrogen bonds to perchlorate oxygen atoms, and as an acceptor of two hydrogen bonds from amine groups. Thus, two of the four crystallographically independent amine groups form hydrogen bonds to water molecules, while the other two form hydrogen bonds to perchlorate anions. There are two crystallographically distinct anions; for one of them, two oxygen atoms act as hydrogen-bond acceptors (O13 from water, O14 from amine), while the other has just one oxygen atom (O22) accepting two hydrogen bonds, one from water and

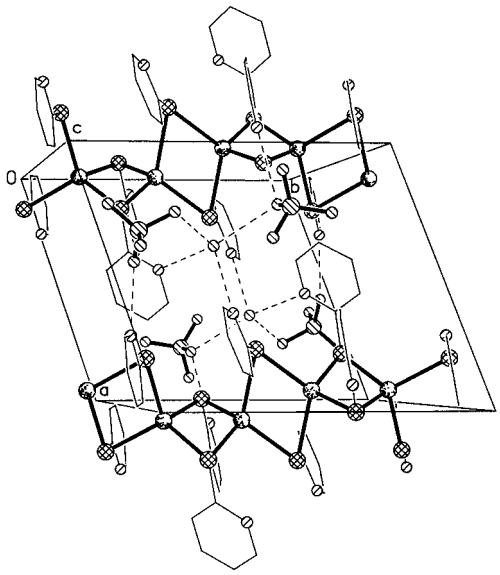

Figure 6. The crystal structure of complex **2**, showing hydrogen bonding interactions as dashed lines; H atoms are omitted for clarity

the other from an amine group. There is no disorder in the structure, and the hydrogen bonds are somewhat stronger (shorter and more linear) than those in the structure of complex **1** discussed above.

Stereochemistry and Sulfur-Bridge Bonding

The bonding of the ligands to Ag^I in the polymeric complex **2** is clearly not as simple as the single lone-pair donation from the sulfur sp^2 orbital to the metal atom for the terminal ligands in **1**. Examination of some details of the varied orientation of the bridging ligands may be informative in order to rationalise the stereochemistry and metal−ligand bonding for the Ag_2S_2 rings of the polymeric cation in **2**, in terms of electron donation by a combination of suitable molecular orbitals of the ligands. These include one or both of the two non-bonding sulfur sp^2 in-plane hybrid orbitals and the thioamide pπ-molecular orbital of the heterocycle; this orbital is perpendicular to the others and is concentrated in the C−S portion of the ligand molecule, with a major contribution of the sulfur atom.[61] These bridging ligand molecular orbitals (HOMOs), each accommodating one electron pair, are able to interact with two

vacant tetrahedral sp^3 or other hybrid orbitals, one for each silver atom of the Ag−S−Ag bridge. Considerations of this kind, aimed at proposing an M−S bonding model from an analysis of the stereochemistry, have previously been performed for dinuclear[1,32] and some polymeric[22,23,27,55,56] sulfur-bridged complexes of thioamide or thiourea ligands. All these earlier examples, however, contain both bridging and terminal ligands, which is not the case here.

Two structural parameters may be used to describe the orientation of each of the four independent planar bridging ligands in the complex cation of **2**. These are: (a) the "tilt" angle of each ligand S−C bond with respect to its Ag−S−Ag′ planar unit, and (b) the pair of "twist" dihedral angles of each ligand plane relative to its respective Ag−S−C and Ag′−S−C planes (Figure 7). Values of these parameters have been calculated for **2** and for related complexes (in this case from the corresponding crystallographic data in the CSD), and they are listed in Table 4.

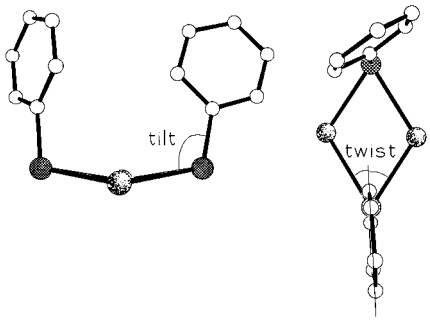

Figure 7. Two views of an M_2S_2 ring with bridging ligands, illustrating the tilt and twist angles characterising the stereochemistry of the ligand arrangement

As defined above, a "tilt" angle close to 0° would imply that the ligand plane and the Ag_2S moiety tend to be coplanar, so that the two S−Ag bonds are formed primarily from the two sulfur sp^2 orbitals with their two electron pairs. This corresponds to an Ag−S−Ag three-centre, four-electron bonding system (type **A**), with ideal "twist" angles of 0° and 180° and an Ag−S−Ag bond angle of 120°; here the line defined by the two N atoms (in thiourea ligands) or its corresponding N···C vector (in thiomonoamides) would be essentially parallel to the Ag···Ag line. Some examples of this arrangement[57,58,63] are included in Table 4, which also shows that all four ligands in complex **2** have tilt angles between 79 and 85° and pairs of "twist" angles markedly different from 0 or 180°. Thus, each of these ligands is almost normal to the Ag_2S unit to which it is attached, making the simultaneous involvement of both sulfur sp^2 orbitals and electron pairs in the formation of Ag−S−Ag bridges unlikely.

On the other hand, a "twist" angle close to 0° would indicate that one of the two silver atoms of a given Ag−S−Ag′ bridge lies nearly in the ligand plane, allowing conventional electron donation from one sulfur sp^2 orbital to an orbital of the Ag atom. In order to complete the bonding scheme for the Ag−S−Ag′ bridge, taking into account that the planar bridging ligands are approximately normal to the Ag−S−Ag′ fragment (Table 4), optimal overlap of an orbital on the Ag′ atom would be obtained by using the thioamide (C=S) pπ-MO, which is perpendicular to the sp^2 orbital. In this case, the Ag−S−Ag′ three-centre, four-electron bridge bonding system (type **B**) would be related to a pair of ideal "twist" angles of 0° and 90° for the atoms Ag and Ag′, respectively (difference, $\Delta_{tw} = 90°$), provided the corresponding "tilt" angle is close to 90°. While this optimal bonding model presumes an ideal value of about 90° for the Ag−S−Ag′ bond angle, this is actually significantly lower in most M_2S_2 rings formed with thioamide ligands (in the range 67−80°, with a few reaching 90°; below 70° in our case).[1,64]

The results in Table 4 show that, for complex **2**, only ligands 2 and 4 [i.e. those containing S(2) and S(4)] approach the above ideal conditions, as can be seen by comparison of Figures 4 and 7. Whereas one of the two twist angles of these ligands closely matches the value of 90° [S(2)] or 0° [S(4)], the second twist in each of the two pairs departs by about 20° from the ideal value. However, the differences between the two twist angles within the pairs, $\Delta_{tw} = 67.3°$ [S(2)] and 71.7° [S(4)], are very close to the respective values of the Ag−S−Ag′ bond angles (66.6, 69.3°), both being far from 90° in contrast to the bonding model initially assumed. These features suggest that maximal overlap of either one sulfur sp^2 or (C=S) pπ-MO orbital on the bridging thioamide ligand is not accomplished in the Ag(1)−S(2)−Ag(2) unit nor in the ring containing ligand 4, so that the proposed bonding mode needs some modification to allow for the actual value of Δ_{tw}. This parameter corresponds, in fact, to the dihedral angle defined by the Ag−S−C and Ag′−S−C planes about the common S−C line, and is always slightly larger than the corresponding Ag−S−Ag′ in-plane angle. Exact coincidence of these two angles would only be attained if the S−C internuclear vector were normal to the Ag−S−Ag′ plane, the difference between the two values increasing as the inclination of the S−C vector decreases.

In order to identify a better correlation of a given pair of twist angles (α_1, α_2 with $\alpha_2 > \alpha_1$ and $\Delta_{tw} = \alpha_2 - \alpha_1$) with the bonding mode **B**, we consider angles within the limits $-45 \le \alpha_1 \le 45$ and $45 \le \alpha_2 \le 135°$. These, with associated tilt angles close to 90°, would correspond to the full set of possible orientations of the bridging thioamide ligands, given by (α_1, $\alpha_1 + \Delta_{tw}$), to which both sulfur sp^2 and (C=S) pπ-MO orbitals would contribute. Among all these geometries, optimal overlap with one of the two Ag orbitals would be achieved through the sp^2 orbital in the (0, Δ_{tw}) ideal case ($\alpha_1 = 0$), but through the (C=S) pπ orbital for the (90 − Δ_{tw}, 90) ideal pair ($\alpha_2 = 90°$). Conversely, poor overlap would be expected for orientations close to those defined by the extreme values of the given ranges, (−45, 45) and (45, 135). A combination of the steric requirements of the bridging ligands, hydrogen-bonding effects and crystal packing requirements affects to some extent the ideal geometry based on electronic factors alone, and gives rise to the large variations observed in the structural parameters α_i and Δ_{tw} (see Table 4). This bonding model **B**, which allows

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

us to rationalise the stereochemistry of the ligands 2 and 4 in complex **2**, has been proposed to be involved in most of the $M_2(\mu\text{-}S)_2$ (M = Ag, Cu) rings in reported thio(mono- or di)amide complexes.[1,57]

Although all four ligands in complex **2** show tilt angles close to 90°, ligands 1 and 3 behave differently from the case of ligands 2 and 4 considered above, in that their respective twist angles have opposite signs and very close absolute values (Table 4). As can be seen in Figures 4 and 7, this means that the planes corresponding to ligands 1 and 3 are not only almost normal to their respective Ag−S−Ag′ units, but virtual bisectors of these. With this geometry, the only orbital that a thioamide ligand can contribute to bridge bonding is one sulfur non-bonding sp^2 orbital with its electron pair. In either of these ligands, this orbital with two orbitals of a pair of Ag atoms would lead to delocalised three-centre, two-electron, electron-deficient bonding systems (type **C**) at the S(1) and S(3) bridges, as was previously proposed for the Cu_2S_2 rings present in the $[Cu_4(tu)_9]_n(NO_3)_{4n}$ polymer.[23] This assessment is supported by the short metal−metal distances and accompanying sharp bridge angles [Ag(1)···Ag(1A) 2.769 Å, Ag(1)−S(3)−Ag(1A) 63.46°; and Ag(1)···Ag(2) 2.858 Å, Ag(1)−S(1)−Ag(2) 64.74°], while corresponding values for bridges at S(2) and S(4), assumed to be three-centre, four-electron conventional bonding systems, are larger [Ag(1)···Ag(2) 2.858 Å, Ag(1)−S(2)−Ag(2) 66.64°; and Ag(2)···Ag(2B) 2.969 Å, Ag(2)−S(4)−Ag(2B) 69.34°]. Therefore, a pair of twist angles (−α, α), where $\Delta_{tw} = 2\alpha$, would correspond to the above ideal orientation in which a thioamide plane is exactly bisecting the M−S−M′ angle, the bridge bonding being probably related to an electron-deficient system to which sulfur supplies only two electrons from one of its two sp^2 orbitals. However, other geometry-determining factors such as crystal packing, hydrogen bonding or steric demands of the ligands, can cause the thioamide plane to deviate somewhat from the bisector of the M−S−M′ plane while preserving the close perpendicularity between these planes. This results in general orientations for this bonding mode, which are more accurately denoted by pairs of different twist angles ($-\alpha_1$, α_2), with suitable α_i values in the approximate range $25° < |\alpha_i| < 45°$ and where $\Delta_{tw} = \alpha_2 + |\alpha_1| < 80°$. This latter condition ensures a relatively sharp bridge angle and concomitant short metal−metal distance, both characteristic features of this bonding mode **C**.

Although not present in complex **2**, it is worth mentioning here another ideal orientation in which a thioamide plane, also tending to be orthogonal to its M−S−M′ unit, would not lie in the bisector plane of the latter but perpendicular to it. Here, the N···N line (in thiourea ligands) or its corresponding N···C vector (in thiomonoamides) would be parallel to the M···M′ line. In this geometry, the (C=S) pπ-MO orbital, with the sulfur atom as the major contributor, would extend nearly along the bisector of the M−S−M′ angle, thus allowing the interaction of this ligand-based orbital, accommodating one electron pair, with two empty orbitals of the metal atoms. This would also give rise to a delocalised three-centre, two-electron, electron-deficient bridge bonding system (type **D**). Whereas (−α, α) is a general notation for twist angles that would hold for the two ideal orientations attributable to electron-deficient bridge bonding, the relation $\Delta_{tw} = 180 - 2\alpha$ applies only to the present situation. As reported for $M(tu)_2Cl$ (M = Cu, Ag),[55,56] to the best of our knowledge the only known complexes for which sulfur-bridge bonding has been explained according to model **D**, the overall effect of both stereochemical constraints and electronic factors leads to a deviation of the thiourea plane, and thus of the N···N line, by about 8° from the direction of the M···M′ line, the tilt angle being reasonably close to 90°. For electron-deficient sulfur-bridged bonding with only two electrons supplied by the thioamide (C=S) pπ-MO (type **D**), probable general orientations would be given, though on the basis of only those two complexes, by pairs of twist angles ($-\alpha_1$, α_2), with $\Delta_{tw} = 180 - (\alpha_2 + |\alpha_1|)$ and suitable α_i values both falling within the approximate range $40 \leq |\alpha_i| < 65°$. This should result in a relatively short metal−metal distance.

Assignment of one of the four sulfur-bridge bonding modes here described for thioamide complexes can, therefore, be made quite confidently from the observed stereochemistry, provided the values corresponding to the defined tilt and twist angles lie in the ranges given above. According to these criteria, some selected complexes containing M−S−M′ angular bridges have been included in Table 4, with an indication of the bonding mode thereby deduced. Thus, the four crystallographically independent Ag−S−Ag′ bridges in complex **2**, all with a tilt angle in the range 79.2−85.5° and with different pairs of twist angles for S(2) and S(4) versus S(1) and S(3), are associated with four-electron sp^2 + C=S (mode **B**) and two-electron sp^2 electron-deficient (mode **C**) sulfur-bridging bonding modes, respectively. Although some correlation might be expected between the sulfur-bridge bonding mode (as evidenced by the tilt and twist angles) and Ag−S distances, no simple pattern is found in complex **2**. In particular, mode **C** does not give more symmetrical Ag−S−Ag′ bridges than mode **B**, despite the approximately equal contributions of S orbitals to the two corresponding Ag−S bonds. Clearly, the situation is more complex, with Ag−S distances also depending on the coordination geometry at the soft Ag centre, which is somewhat distorted tetrahedral for Ag(2) and highly distorted for Ag(1), with one S−Ag−S angle as small as 89.62(2)°.

Conclusion

Two silver cationic complexes with perchlorate as the counterion and neutral thio(mono- or di)amide ligands have been prepared and structurally characterised. The centrosymmetric monomeric $[Ag(etu)_2]^+$ complex species in **1** contains a linear MS_2 mononuclear core, unprecedented for bis(thioamide) complexes (M = Cu, Ag). These cations and ClO_4^- counterions assemble as complementary partners involving all available hydrogen bond donor (4 N−H of each

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

cation) and acceptor (4 O of each ClO_4^-) sites in a three-dimensional supramolecular network. Despite having the same stoichiometry, a sulfur-bridged polymeric cation with tetrahedral AgS_4 centres is obtained instead in **2**. There are in this case fewer available hydrogen bond donor (4 N−H + 2 water O−H) than potential acceptor [8 O (ClO_4^-) + 2 O (H_2O)] sites, and so the two crystallographically distinct ClO_4^- counterions act as two connectors (through one or two oxygen atoms, respectively). A two-dimensional layered supramolecular structure assembled through N−H···O−Cl, N−H···O(water) and Cl−O···H−O−H···O−Cl hydrogen bonding results, with no significant connections of this type between sheets. Stereochemical parameters (tilt and twist dihedral angles) for **2** indicate two different sulfur-bridge bonding modes, one conventional four-electron and the other electron-deficient two-electron.

Experimental Section

General Remarks: Reagent-grade solvents were used with no further purification. Ethylenethiourea (Fluka) and pyridine-2-thione (Aldrich) were used as received, while silver(I) perchlorate (Alfa) was recrystallized from acetonitrile. Microanalyses (C, N, H, S) were performed with a Carlo-Erba CHN EA-1108 analyser at the Servei d'Anàlisi Química de la UAB. Infrared spectra (4000−400 cm^{-1}) were recorded from KBr pellets with Perkin-Elmer FT-1710 and FT-2000 spectrometers, and ^1H and ^{13}C NMR spectra from [D_6]DMSO solutions with a Bruker AC-250 spectrometer operating at 250 MHz for ^1H NMR nuclei.

[Ag(etu)$_2$](ClO$_4$) (1): A solution of $AgClO_4$ (0.409 g, 4.0 mmol) in 60 mL of a mixture of methanol/water (2:1, v/v) was added dropwise with stirring to a methanol solution (10 mL) of the ligand (0.414 g, 2.0 mmol). After stirring for 2 h, the volume of the solution was reduced to about 30 mL by passing a slow stream of N_2 through it, and then cooled to 0°C. A precipitate separated, which was filtered, washed with 5 mL of cold ethanol and then with 10 mL of diethyl ether, and dried in vacuo. Colourless crystals of the product, suitable for X-ray diffraction, were isolated by slow concentration of an acetonitrile solution of the complex at room temperature. Total yield 60%. This compound is soluble in methanol, acetonitrile, acetone and DMSO. $C_6H_{12}AgN_4S_2{\cdot}ClO_4$ (438.7): calcd. C 11.64, H 1.95, N 9.05, S 10.36; found C 11.68, H 2.15, N 8.78, S 10.27. IR (KBr): $\tilde{\nu}$ = 3350−3270, 2890, 1522, 1355, 1319, 1280, 1200, 1087, 990, 920, 670, 626, 560, 495 cm^{-1}. ^1H NMR ([D_6]DMSO): δ = 8.90, 3.67 ppm. ^{13}C NMR ([D_6]DMSO): δ = 178.4, 44.9 ppm.

[{Ag(py2tH)$_2$}(ClO$_4$)(H$_2$O)$_{0.5}$]$_n$ (2): A solution of 0.311 g (1.5 mmol) of $AgClO_4$ in 10 mL of ethanol was added dropwise with stirring to an ethanol solution (15 mL) of the ligand (0.334 g, 3.0 mmol). A yellow precipitate formed immediately. After stirring for 1 h, the resulting mixture was kept in an ice bath for 15 min, and then filtered. The yellow solid was washed with 15 mL of diethyl ether and dried in vacuo. Yield 80%. Light yellow crystals of the product were isolated by slow vapour diffusion of diethyl ether into a concentrated acetonitrile solution of the complex at room temperature. This compound is soluble in acetonitrile, acetone and DMSO. $C_{10}H_{10}AgN_2S_2{\cdot}ClO_4{\cdot}0.5H_2O$ (411.6): calcd. C 27.38, H 2.52, N 6.38, S 14.62; found C 27.54, H 2.69, N 6.40, S 14.36. IR (KBr): $\tilde{\nu}$ = 3160, 3100, 3075, 3020, 2908, 1605, 1570, 1500, 1440, 1366, 1257, 1132, 1090, 995, 747, 726, 627, 484, 444 cm^{-1}. ^1H NMR ([D_6]DMSO): δ = 14.10, 8.10, 7.69, 7.19 ppm. ^{13}C NMR ([D_6]DMSO): δ = 167.6, 141.1, 141.0, 131.9, 118.4 ppm.

X-ray Crystallographic Study: Crystals of both complexes were examined with a Bruker AXS SMART CCD diffractometer with graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å), at 173 or 160 K. Almost a whole sphere of data was collected in each case,

using narrow-slice ω scans;[65] semi-empirical absorption corrections were based on repeated and symmetry-equivalent data.[66] The structures were solved by heavy-atom or automatic direct methods, and refined by full-matrix least-squares methods on all unique F^2 values, with anisotropic displacement parameters for all non-H atoms. H atoms bonded to C and N were placed in idealised positions and constrained with a riding model; those of the water molecule in **2** were found in difference maps and were freely refined, with the O−H bond lengths restrained to be similar. Largest features in final difference maps were close to heavy atoms and disordered groups. Details are given in Table 5. CCDC-220964 and -220965 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) + 44-1223-336-033; E-mail: deposit@ccdc. cam. ac. uk].

Construction of Nano-Channels Based on Zinc(II) Pyrazine-2-carboxylate Complexes

Tetsuya Sunahara,[a] Satoru Onaka,*[a] Mitsuhiro Ito,[a] Hiroyuki Imai,[b] Katsuya Inoue,[b] and Tomoji Ozeki[c]

Keywords: Carboxylato ligands / Nanostructures / Self-assembly / Zinc

The reaction of pyrazine-2-carboxylate (pca) and bis(pyridine) derivatives, such as 4,4′-bipyridine (bipy), 1,2-bis(4-pyridyl)ethylene (bpen), 1,2-bis(4-pyridyl)ethane (bpea), 1,3-bis(4-pyridyl)propane (bpp), and 4,4′-azopyridine (azp), with zinc perchlorate gives supramolecules with grid and/or channel structures. The new complexes reported here are *trans*-[Zn(bipy)(pca)(H_2O)]ClO_4·$(EtOH)_{0.5}$·$(H_2O)_{0.5}$ (**1**), [Zn(μ-bpen)(bpen)(pca)(H_2O)]·ClO_4·$2H_2O$ (**2**), [Zn(bpea)(pca)]-ClO_4·$(EtOH)_{0.5}$ (**3**), and [Zn(bpp)(pca)(MeOH)]ClO_4 (**4**). Their structures have been established by single-crystal X-ray diffraction. Some of these complexes contain voids with nanometer dimensions. Small molecules such as H_2O, MeOH, and EtOH contained in these voids can be removed without destruction of the parental suprastructure.

Introduction

The basic concepts for constructing supramolecules by self-assembly techniques have been well developed over the past two decades, especially by Lehn's group.[1−4] The entries to this new field are classified from the structural viewpoint into sphere-like molecules, infinite one-dimensional molecules (molecular wires), multi-dimensional molecules, including interwoven coordination polymers and grid and/or channel-like molecules, and dendrimers; we have used the term "molecular dot" for globular molecules.[5] There has been a plethora of reports on grids and/or channel-like networks composed from metal−ligand components, especially with Mn, Co, Ni, Cu, and Zn as metal ions and 4,4′-bipy, aromatic carboxylates, pyrazine, and pyridylporphyrins as organic linkers.[1−4,6−15] These molecules can also be divided into the following categories with regards to their possible applications to nanotechnologies: chemical sensors, microreactors, molecular devices, optoelectronic devices, drug-delivery systems, thin-film technologies, etc.[16−21] One of our current interests in supramolecules has been directed to the trapping of small environmental gaseous molecules such as CO_2, NO_2, and SO_2 into channel-like structures and their possible conversion into more useful chemicals. Since there have been several reports of the trapping of CO_2 by mononuclear Zn complexes and its subsequent reduction into organic species,[22,23] the design of a microreactor prepared from Zn^{II} supramolecules is especially intriguing for the activation of CO_2 molecules and their conversion into organic derivatives, a process that is the key step in C_1 chemistry. As the first step to achieve this goal, we decided to construct new channel-like and/or cage-like nanostructures containing Zn^{II} and a pyrazine-2-carboxylate linker. The reason for the choice of the pyrazine-2-carboxylate (pca) ligand is its potential multidentate coordination ability, depicted in Scheme 1, where several possible new bridging modes are shown. Such multidentate ex-

amples of pca have not been reported to the best of our knowledge. Here we report on the synthesis of new zinc(II) pyrazine-2-carboxylate complexes with various bis(pyridine) ligands and a structural study of their interlaced supramolecular structures by single-crystal X-ray diffraction.

Results and Discussion

Synthetic Reactions

As described in the Exp. Sect., simply mixing the three components [pcn, the bis(pyridine) ligand, and zinc(II) perchlorate] in EtOH/H_2O at room temperature yielded new cage-type supramolecules. It seems worthy to mention why pcn is employed to build such supramolecules in most reactions instead of simply using pyrazine-2-carboxylic acid (Hpca). At first Hpca was indeed used for such attempts, because several recent reports have shown the versatile nature of pyridine-2-carboxylates and pca was expected to exhibit a similar behavior.[24] However, only limited results were obtained, as described below. Lin et al. have demonstrated that 4-cyanopyridine is susceptible to hydrolysis under hydro(solvo)thermal conditions to yield isonicotinic acid.[24b] With this in mind, zinc perchlorate, 2-cyanopyrazine, and bipy were mixed in EtOH/H_2O in a 1:1:1 molar ratio. After standing at room temperature for several days, pale-yellow crystals of [Zn(pca)(bipy)(H_2O)]ClO_4 (**1**) were obtained. An X-ray diffraction study revealed a grid-like structure in the solid state. A more detailed discussion of this nano-grid can be found below. Thus, we have verified that pcn undergoes hydrolysis under ambient conditions to give pca.

Similar reactions were attempted for various combinations of other ligands; these results are also described below for **2**−**4**. The crux of our synthesis is that the CN group of pcn is oxidized to CO_2^- during the reaction and/or upon exposure to air for several days, thus creating a potentially multidentate linker ligand. The essential contribution of the CO_2^- group in the pca ligand becomes clear when the cage structure of **1** is compared with a similar cage architecture with pyrazine as bridging ligand reported previously by Bourne's group.[25] Their network structures are significantly different from ours: the carboxylate group in pca induces a more sophisticated multidimensional structure which is dependent on the coexistence of bridging ligands, as described in the crystal structure section below. The most common function of pca in **1**−**4** is as a chelating bridging ligand, as depicted in the bottom center of Scheme 1. However, the bridging mode of the O atom of pca in **2** is highly unusual, as described in the following section. Another interesting finding from the present synthesis merits a comment; pcn and/or pca are not incorporated into the final products when pyrazine, 4,4′-bipyridine *N*,*N*′-dioxide (bpyO), and/or azp are used as co-ligands. It is possible that the pcn ligand, which is initially coordinated to the Zn ion by an N atom of the pyrazine skeleton, is affected by the steric and/or electronic influence of the co-ligand and is expelled from the coordination sphere during the hydrolysis of the CN group; the hydrolysis mechanism of the CN group is still unclear. These results strongly suggest that the combination of pca with other potentially bidentate ligands and suitable hydrolysis conditions should allow the synthesis of more sophisticated channel-like structures with multifunctional binding modes of pca different from those in Scheme 1. The next challenge should be to realize other coordination modes such as those of the left and right at the bottom of Scheme 1, where pca functions as a longer grid than those of **1**−**4**.

Molecular and Cage Structures

The minimum units needed to delineate the molecular structure of each product are shown below. Complexes **1**, **4**, and **5** exhibit distorted octahedral skeletons around the Zn ions, whereas **2** has a distorted edge-shared dinuclear octahedral skeleton and **3** exhibits a distorted five-coordinate square-pyramidal one. In **1** (Figure 1a), pca functions as a tridentate bridging ligand as shown in Scheme 1. The sixth coordination site is occupied by the O atom (O1) of a water molecule.

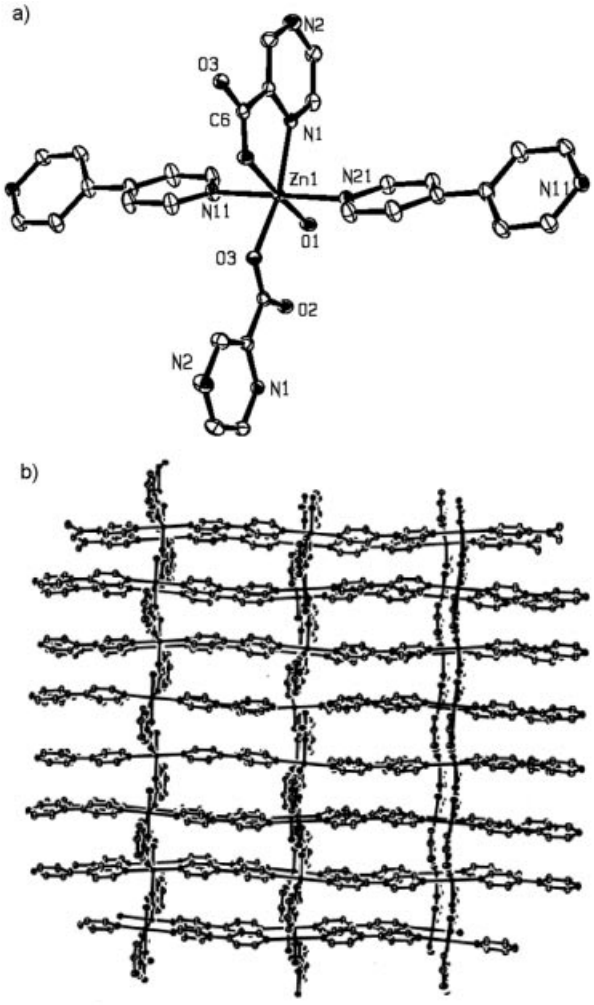

Figure 1. (a) ORTEP drawing of *trans*-[Zn(bipy)(pca)(H_2O)]ClO_4 (**1**); (b) view of the crystal structure of **1** along the *a* axis

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

The coordination mode of pca in **2** is rather complicated. It binds as a chelating ligand to a single Zn ion through N and O atoms, and the same O atom also bridges two Zn ions, as shown in Figure 2a. This type of coordination mode was not expected and is not shown in Scheme 1. The O atom (O3) from a water molecule occupies the sixth coordination site.

The coordination mode of pca in **3** is the same as in **1**, although the fundamental structure of the Zn ion is square-pyramidal (Figure 3a). The function of pca in **4** (Figure 4a) is also the same as in **1**, with a molecule of methanol loosely bound in the sixth coordination site. Although the bridging O atom appears to be free in Figures 1a, 3a, and 4a, which show only the independent part of each molecule, it actually straddles the neighboring Zn ions, thereby forming a multidimensional array by linking the Zn ions.

The two pyrazine rings in **5** (Figure 5a) connect two Zn sites; four water molecules occupy the equatorial *trans* positions, and thus form *trans*-linear infinite chains. The mononuclear Zn complex **6** does not merit special comments.

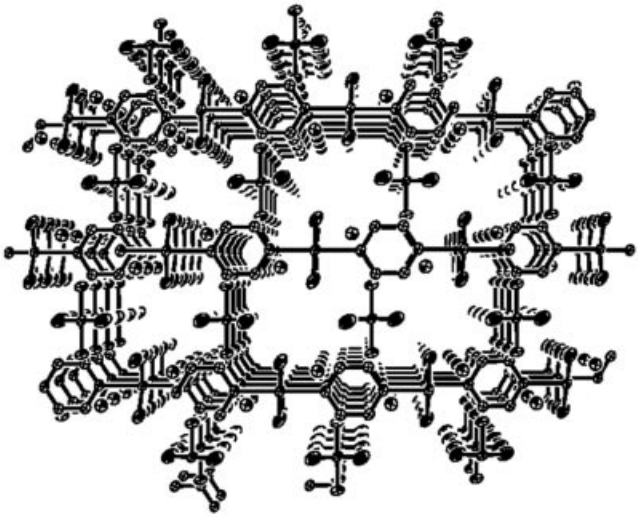

Figure 5. 2D grids built up by hydrogen-bonded networks between 1D chains of **5** and SiF_6^{2-}

The Zn−N and Zn−O bond lengths of pca are 2.082−2.190 and 2.028−2.166 Å, respectively, which are in the normal range for these compounds.[12,13,15,25] One methanol molecule is loosely coordinated to Zn [Zn−O = 2.431(4) Å] in **4**. The Zn−OH_2 distances in **2** and **5** are normal.

The grid architecture of **1** is shown in Figure 1b. It is constructed by pca and bipy linkers with Zn^{II} corners. The approximate size of the cages is 5.9 Å × 11.4 Å; hereafter, the size of the cage is defined by the N·· N distances unless stated otherwise. One H_2O molecule, one EtOH molecule, and a ClO_4 anion are contained in each channel and the ClO_4^- anion tethers solvate molecules through hydrogen bonds.

The function of bpen in **2** is twofold: one bpen ligand connects the neighboring Zn ions directly through two N atoms (two strong interactions) to form a quasi one-dimensional chain, while, at first glance, the other bpen acts as a monodentate ligand through one N atom. However, a

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

closer inspection of the packing diagram reveals that the remaining N atom is connected to the O atom in H_2O, which is coordinated to another Zn ion by a hydrogen bond (weak interactions; Figure 2b). Thus, the fundamental unit of the grid is composed from the dimer $[Zn(bpen)(pca)(H_2O)]_2$. In addition, layers composed from these dimers are connected by other hydrogen bonds among O atoms in ClO_4^- and coordinated H_2O and free H_2O, and thus three-dimensional cages are formed by hydrogen bonds (Figures 2b and c). The ClO_4^- anion is essential for the formation of these three-dimensional architectures. The approximate size of the cages is 3.4 Å × 13.6 Å.

Substituting the $-CH_2-CH_2-$ unit (bpea) in **3** for the $-CH=CH-$ unit (bpen) in **2** causes significant changes in the crystal structure. First, the six-coordination around the Zn ion in **2** is reduced to five in **3**. The basic skeleton around the Zn ion is regarded as a square pyramid. The basal square is constructed from N, O (chelating pca), O (bridging pca), and N (bpea) atoms, and the apex is occupied by the N atom from another bpea ligand (Figure 3a). Next, the main motif (the longer grid) of the supramolecule of **3** contains polymeric, pleated (Z-shaped) chains around the corner zinc ions, which are then interlaced by pca by coordination of O atoms to Zn ions (the shorter grids) yielding a two-dimensional sheet (Figure 3b). The size of the grids is approximately 13.3 Å × 5.7 Å, and the distance between the sheets is 8.96 Å. The ClO_4^- anion and EtOH molecule are situated between the sheets and are not connected to the cages by hydrogen bonds. The incorporated EtOH molecules are depicted in Figure 3c. The cage structure is maintained after the loss of EtOH upon heating, as described below and thus **3′**, which is complex **3** without EtOH, exhibits quite similar lattice constants and the same space group. This phenomenon is important for the construction of a microreactor from these coordination polymers. The thermal behavior is described below.

The polymeric structure of **4** is topologically more complicated (Figure 4b, projected almost along the *c* axis). The skeletal motif looks like an atoll. The other crystal-packing diagram has been shown to emphasize how the organic scaffolds are used to bridge the Zn ions and/or how the motif of the atoll is built up (Figure 4c, projected almost along the *a* axis); the minimum numbers of atoms are employed in this diagram to represent the organic linkers. The side view (Figure 4c) demonstrates clearly that the horizontal layer (which is the vertical column in Figure 4b) is composed of bridging pca ligands thus giving rise to a shorter period. The perpendicular grids in Figure 4b are then constructed by tethering the horizontal layers to different Zn ions by another bpp linker (Figure 4b) and thus these two-dimensional grids are built up to form the three-dimensional framework. One methanol molecule coordinates loosely to each zinc ion to complete the six-coordination (Figure 4d). The whole architecture is best described as an oblate honeycomb; one ClO_4^- anion per Zn ion is positioned in each lacuna. The methanol ligand is easily removed upon heating. The approximate size of the cages is 12.4 Å × 5.3 Å when the methanol is neglected.

Figure 5 shows the almost square grids of **5**, the main component of which is an infinite one-dimensional chain of (pyrazine)Zn units. The chains are "glued" to each other by hydrogen bonds between the F atoms in SiF_6^{2-} and the aromatic protons. Two-dimensional sheets are thus formed in the solid state. The approximate size of the cages is 9.9 Å × 9.3 Å.

We suggested in our previous paper that the length of the linker determines the type and the structure of the polymer formed, and that the dimensionality of the polymer is reduced from two to one if a longer linker is used; these complexes were Mn derivatives containing pyridin-2-ylmethanol and another bridging bis(pyridine) ligand.[26] However, the present exploration suggests that the grid structure becomes highly undulated with the elongation of the distance between two pyridine rings used in this study. For **1**−**4**, pca is an indispensable lattice constituent, although the lattice length made by pca is rather short. An appropriate combination of short and long lattice constituents [pca and bis(pyridine) ligand], together with the multiple coordination modes of pca, will be required to form sophisticated structures containing nano-channels, especially the three-dimensional channels of **4**.

Thermogravimetric Measurements

Our stated aim is the construction of cage-like cavities and/or grid structures which contain enough lacuna to accommodate small gaseous molecules. As was described above, the supramolecules **2**, **3**, and **4** are good candidates for this purpose because their caged structures are maintained after the removal of the solvent molecules. In this section, the process of the loss of H_2O, EtOH, and/or MeOH is explored by the use of thermogravimetric analysis. The samples were exposed to air for 1 h before analyzing them. The results of the thermogravimetric measurements are shown in Figures 6a and b for **2** and **4**, respectively. The TG-DTA plot for **2** (Figure 6a) exhibits two steps of H_2O loss. The first step is assigned to the loss of included H_2O and the latter step to loss of coordinated H_2O. The residual cage is stable up to 280 °C. The TG-DTA plot for **3** (not shown), however, exhibits only a small step corresponding to the loss of ethanol. This indicates that the weakly trapped ethanol molecules are easily lost upon exposure to air during the pre-treatment of the sample; the cage structure is stable up to 300 °C. The TG-DTA plot for **4** (Figure 6b) indicates that the weakly coordinated methanol is easily lost upon heating in the range from 60 to 110 °C. The remaining cage is stable up to 270 °C. These thermogravimetric analyses strongly suggest that the nano-channels in **2**−**4** after the loss of ethanol and/or methanol are good candidates for porous materials to trap small molecules. Therefore, gas-absorption measurements were performed for the residual porous-channel-containing supramolecules **2′**−**4′** {**2′** = $[Zn(\mu\text{-bpen})(bpen)(pca)]ClO_4$; **4′** = $[Zn(pca)(bpp)]ClO_4$} with N_2. However, our preliminary gas-absorption measurements are not indicative of a decent absorption ability, especially at low N_2 pressure. Therefore,

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

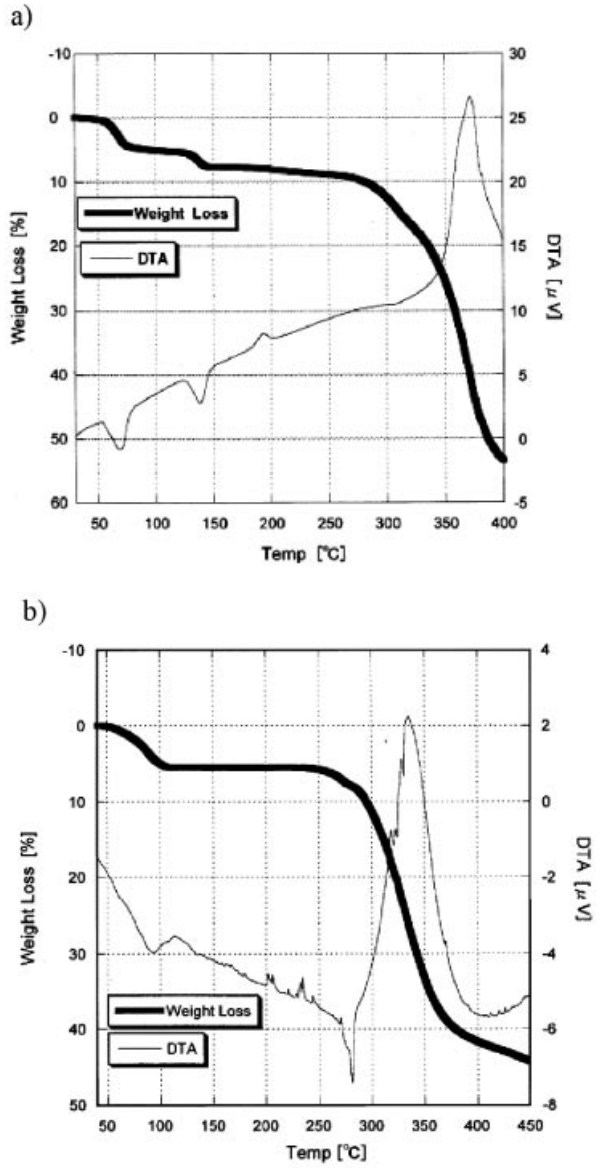

Figure 6. TG-DTA plots for **2** (a) and **4** (b) vs. temperature

our efforts to determine the ability of these porous molecules for this purpose are continuing with other gases.

Conclusion

New caged and/or porous supramolecules have been synthesized from pyrazine-2-carbonitrile, bis(pyridine) ligands, and zinc perchlorate. Hydrolysis of the CN group to CO_2^- during the crystallization process is essential for the success of the synthesis. The channel architectures of the complexes survive after removal of solvent molecules for the three supramolecules chosen as new examples of coordination polymers.

Experimental Section

Materials and General Procedures: Syntheses and manipulations were generally performed in the open air unless otherwise described. Pyrazine-2-carboxylic acid, pyrazine-2-carbonitrile, and pyrazine were purchased from Tokyo Kasei Kogyo Co., Ltd. 4,4′-Bipyridine (bipy) and the other pyridines NC_5H_4-R-C_5NH_4 (R = CH=CH, CH_2-CH_2, $CH_2-CH_2-CH_2$) were purchased from Wako Pure Chemical Ind., Ltd. or Aldrich. The following abbreviations are used for pyrazine derivatives and bis(pyridine) ligands: pcn (pyrazine-2-carbonitrile), Hpca (pyrazine-2-carboxylic acid), bpen [1,2-bis(4-pyridyl)ethylene], bpea [1,2-bis(4-pyridyl)ethane], bpp [1,3-bis(4-pyridyl)propane]. 4,4′-Azopyridine (azp) was synthesized according to a literature method.[27] $Zn(ClO_4)_2·6H_2O$, other ligands, and solvents were also purchased from Wako Pure Chemical Ind., Ltd. or Aldrich. Thermogravimetric measurements were carried out with a Rigaku TAS-300 and TG8101D thermoflex. Gas-absorption measurements were performed with a Yuasa-ionics Autosorb1. ***Caution:*** *Organic perchlorate salts are potentially explosive; all perchlorates salts should be handled with care!*

Synthesis of *trans*-[Zn(bipy)(pca)(H_2O)]ClO_4·$(EtOH)_{0.5}(H_2O)_{0.5}$ (1): A 1:1 mixture of pyrazine-2-carbonitrile (pcn; 105 mg, 1 mmol) and bipyridine (bipy; 155 mg, 1 mmol) was dissolved in 15 mL of EtOH/H_2O (2:1) and the mixture was stirred at room temperature for 2 h. An aqueous solution (5 mL) of $Zn(ClO_4)_2·6H_2O$ (380 mg, 1 mmol) was then added and the mixture stirred for 7 h. The mixture was left standing at room temperature for several days to yield a pale-yellow precipitate. Yield: 240 mg (46%). $C_{17}H_{19}ClN_4O_9Zn$ (524.2): calcd. C 38.89, H 3.47, N 11.34; found C 38.23, H 3.47, N 11.14.

Synthesis of [Zn(μ-bpen)(bpen)(pca)(H_2O)]$ClO_4·2H_2O$ (2): pcn (105 mg, 1 mmol) and bpen (182 mg, 1 mmol) were dissolved in 10 mL of EtOH/H_2O (3:2) and the mixture was stirred at room temperature for 1 h. An aqueous solution (5 mL) of $Zn(ClO_4)_2·6H_2O$ (380 mg, 1 mmol) was then added. The resulting yellow solution immediately became a white suspension upon stirring. After 2 h of stirring, the precipitates were removed by filtration. The filtrate was then left standing at room temperature for several days to yield pale-yellow, plate-like single crystals. X-ray quality single crystals were grown from MeOH/H_2O. Yield: 210 mg (33%). $C_{23}H_{22}ClN_5O_9Zn·2H_2O$ (613.3):calcd. C 44.90, H 3.93, N 11.38; found C 44.70, H 3.90, N 11.35. Upon heating, three H_2O (one coordinated and two free) molecules were lost. Judging from the color and the appearance of the thermally treated compound, the structure of the compound seems unchanged after loss of H_2O, as described in the thermogravimetric section.

Synthesis of [Zn(bpea)(pca)]$ClO_4·(EtOH)_{0.5}$ (3): pcn (105 mg, 1 mmol) and bpea (185 mg, 1 mmol) were dissolved in 15 mL of EtOH/H_2O (2:3) and the mixture was stirred at room temperature for 1 h. An aqueous solution (5 mL) of $Zn(ClO_4)_2·6H_2O$ (380 mg, 1 mmol) was then added. The solution became a white suspension and the mixture was stirred for 10 h. The colorless precipitates were removed by filtration and the filtrate was left standing at room temperature for several days to yield colorless, needle-shaped crystals. The cycle of precipitation and filtration was repeated several times and finally pale-yellow block single crystals were obtained. The yield of combined colorless crystals of **3** was 240 mg (46%) after recrystallization from MeOH/H_2O. $C_{19}H_{21}ClN_4O_7Zn$ (519.6): calcd. C 43.66, H 3.66, N 11.31; found C 43.41, H 3.63, N 11.28. The yellow crystals were determined to be $[Zn(bpea)_2(H_2O)_2](ClO_4)_2(H_2O)_2$ by single-crystal X-ray diffraction.[28] [Zn(bpea)(pca-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

)](ClO4) (**3′**) was obtained upon heating **3**, as demonstrated by a single-crystal X-ray diffraction study. The structural details of **3** and **3′** are described in the text.

Synthesis of [Zn(bpp)(pca)(MeOH)]ClO_4 (4): pcn (60 mg, 0.5 mmol) and bpp (100 mg, 0.5 mmol) were dissolved in 15 mL of EtOH/H_2O (1:2). After stirring of the solution for 1 h, an aqueous solution (5 mL) of $Zn(ClO_4)_2{\cdot}6H_2O$ (190 mg, 0.5 mmol) was added to this mixture with stirring. After stirring at room temperature for 10 h, the solution was left standing at room temperature for several days to give a white, flocculent precipitate. The product was collected on a frit and was recrystallized from MeOH/H_2O to give pale-yellow, pillar-like single crystals of **4**. Yield 190 mg (75%). $C_{19}H_{21}ClN_4O_7Zn$ (518.2): calcd. C 44.03, H 4.08, N 10.81; found C 43.84, H 4.02, N 10.78. Compound **4** was also obtained from the reaction of pca, bpp, and $Zn(ClO_4)_2{\cdot}6H_2O$ in a similar yield.

[Zn(pyz)$(H_2O)_4$]$(SiF_6)(H_2O)$ (5): pcn (210 mg, 2 mmol) and pyrazine (pyz; 170 mg, 2 mmol) were dissolved in 4 mL of EtOH/H_2O (3:1). An EtOH/H_2O (1:1) solution (4 mL) of $Zn(SiF_6){\cdot}xH_2O$ (420 mg, 2 mmol) was then added with stirring. The mixture was left standing at room temperature for several days to give colorless crystals of **5**, whose structure was confirmed by a single-crystal X-ray diffraction study. Yield 270 mg (36%).

[Zn(pca)$_2$$(H_2O)_2$] (6): pca (130 mg, 1 mmol) was dissolved in 10 mL of EtOH/H_2O (1:1) and then 1 mmol of pyrazine (85 mg) was added. An aqueous solution (5 mL) of $Zn(ClO_4)_2{\cdot}6H_2O$ (380 mg, 1 mmol) was added with stirring. After 10 h of stirring, the reaction mixture was left standing at room temperature for several days to yield colorless cubic crystals of **6**, whose structure was confirmed by a single-crystal X-ray diffraction study.[29]

[Zn(bpy-O)$(H_2O)_4$](ClO_4)·(bpy-O)$_2$(7): An ethanol solution (5 mL) of pcn (110 mg, 1 mmol) was mixed with an aqueous solution (10 mL) of bpy-O (185 mg, 1 mmol) with stirring. After 1 h, an EtOH/H_2O solution (2:5; 7 mL) of $Zn(ClO_4)_2{\cdot}6H_2O$ (380 mg, 1 mmol) was added and the mixture stirred for 19 h. The solution was left standing at room temperature to afford colorless plates. A single-crystal X-ray diffraction study showed that the product is [Zn(bpy-O)$(H_2O)_4$](ClO_4)·(bpy-O)$_2$ (**7**).[27] When pca was employed instead of pcn, **6** was isolated. Yield 190 mg (59%).

[Zn(azp)$_2$$(H_2O)_2$]$(ClO_4)$(MeOH) (8), [Zn(azp)$_2$$(H_2O)_4$]$(ClO_4)_2$·(azp)$_{2.5}$ (9) and [Zn$_2$(μ-azp)$_2$(azp)$_4$$(H_2O)_6$]$(ClO_4)_2$ (10): azp (190 mg, 1 mmol) and pcn (110 mg, 1 mmol) were mixed in 6 mL of EtOH/H_2O (1:1) with stirring. An aqueous solution (6 mL) of $Zn(ClO_4)_2{\cdot}6H_2O$ (380 mg, 1 mmol) was then added. After 4 h of stirring, the resulting orange-red precipitate was collected on a frit and recrystallized from MeOH to give red rectangular crystals of **8**; a single-crystal X-ray diffraction study supported the identification.[30] Two kinds of red single crystals (**9** and **10**) were also isolated from the original filtrate. Identification of these crystals was performed by a single-crystal X-ray diffraction study.[30] When pca was employed instead of pcn, **5** was obtained.

X-ray Crystallography: Selected crystals of compounds **1**−**10** were attached on a nylon loop for low-temperature measurements. A Bruker SMART-APEX CCD diffractometer with graphite-monochromated Mo-K_a radiation (λ = 0.71073Å) was used for data collection on these crystals at 100 K. The structures were solved by direct methods using Sir-97 in a WinGx program package and refined with anisotropic thermal parameters by full-matrix least-squares techniques with SHELXS-97 in a WinGx program package.[31] The refinements were made on F^2 data; the final R and wR_2 values are given in Table 1 for **1**−**5**. Crystal data for **6**−**10** are not cited because these are known compounds. Selected bond lengths and angles are given in Table 2. The molecular structures of these compounds are given in the text. CCDC-232435 for (**1**), -232436 (**2**), -232437 (**3**), -232438 (**3′**), -232439 (**4**) and -232440 (**5**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) + 44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Syntheses, Structures, and Luminescent Properties of [Bis(iminoalkyl)pyridine]cadmium(II) Complexes

Rui-Qing Fan,[a] Dong-Sheng Zhu,[a] Ying Mu,*[a] Guang-Hua Li,[b] Yu-Lin Yang,[b] Qing Su,[a] and Shou-Hua Feng[b]

Keywords: Cadmium / Luminescence / N ligands / X-ray diffraction

Four new Cd^{II} complexes of 2,6-bis[1-(phenylimino)ethyl]-pyridine ($\mathbf{L^1}$), 2,6-bis[1-(2,6-diisopropylphenylimino)ethyl]-pyridine ($\mathbf{L^2}$), 2,6-bis[1-(2,6-dimethylphenylimino)ethyl]-pyridine ($\mathbf{L^3}$), 2,6-bis[1-(2-methylphenylimino)ethyl]pyridine ($\mathbf{L^4}$) have been synthesized. These complexes have the formulas $[Cd(\mathbf{L^1})Cl_2]\cdot 1.5CH_3CN$ (**1**), $[Cd(\mathbf{L^2})Cl_2]$ (**2**), $[Cd(\mathbf{L^3})Cl_2]\cdot CH_3CN$ (**3**), and $[Cd(\mathbf{L^4})Cl_2]\cdot CH_3CN$ (**4**). The molecular structures of complexes **1**–**4** were determined by single-crystal X-ray diffraction. Crystallographic studies of **1**–**4** reveal all four complexes to be five-coordinate with geometries that can be best described as distorted trigonal-bipyramidal. All eight compounds ($\mathbf{L^1}$–$\mathbf{L^4}$ and **1**–**4**) are luminescent at room temperature in solution and the solid state. At 298 K in dichloromethane solution, all compounds have fluorescent emissions at about 368–409 nm. The fluorescent emission of these compounds originates from ligand-centered π^*–π transitions. The Cd^{II} centers play a key role in enhancing the fluorescent emission of the ligands.

Introduction

Luminescent coordination compounds with pyridine-type ligands have attracted much attention recently due to their good performance in sensor technologies and electroluminescent devices.[1−7] Several d^{10} metal complexes with pyridine-type ligands have been synthesized and their luminescence behavior studied.[1−3] Among these, luminescent cadmium complexes have been widely investigated as potential luminescent materials.[1b,1d,2a,2b,2d] [Bis(iminoalkyl)pyridine]metal complexes have also been the subject of intense research due to their interesting coordination chemistry and applications in catalysis.[8−17] Many complexes containing one or two bis(iminoalkyl)pyridine ligands with small aryl substituents have been synthesized and characterized.[8−9] Recently, iron and cobalt complexes with bulky aryl-substituted bis(iminoalkyl)pyridine ligands were reported by Brookhart and Gibson et al.[10−12] These complexes exhibit high activity for olefin polymerization. Brookhart et al. have also reported [bis(iminoalkyl)pyridine]ruthenium complexes that can catalyze the epoxidation of olefins.[17] To the best of our knowledge, no investigation has been carried out on the luminescent properties of [bis(iminoalkyl)-pyridine]metal complexes. We explored this possibility and selected four [bis(iminoalkyl)pyridine]cadmium complexes for the present study. Herein we report the syntheses, crystal structures, and luminescent properties of a series of Cd^{II} complexes of ligands $\mathbf{L^1}$−$\mathbf{L^4}$.

Results and Discussion

Synthesis and Characterization

2,6-Bis[1-(phenylimino)ethyl]pyridine ($\mathbf{L^1}$), 2,6-bis[1-(2,6-diisopropylphenylimino)ethyl]pyridine ($\mathbf{L^2}$), 2,6-bis[1-(2,6-dimethylphenylmino)ethyl]pyridine ($\mathbf{L^3}$), and 2,6-bis[1-(2-methylphenylimino)ethyl]pyridine ($\mathbf{L^4}$) were synthesized according to modified published procedures in good yield by condensation of 2,6-diacetylpyridine with the corresponding aniline in refluxing absolute methanol in the presence of a catalytic amount of formic acid (Scheme 1).[8a,10] Cadmium complexes of these ligands were prepared by reaction of $CdCl_2\cdot 2.5H_2O$ with a stoichiometric amount of the corresponding 2,6-bis(iminoalkyl)pyridine ligand in acetonitrile (complexes **1** and **3**) or in dichloromethane (complexes **2** and **4**) at room temperature (Scheme 1). Complexes **1**−**4** were obtained as yellowish crystals in good yield.

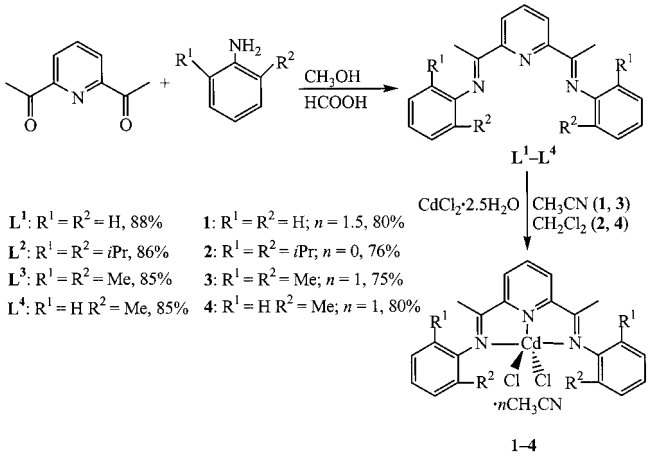

Scheme 1

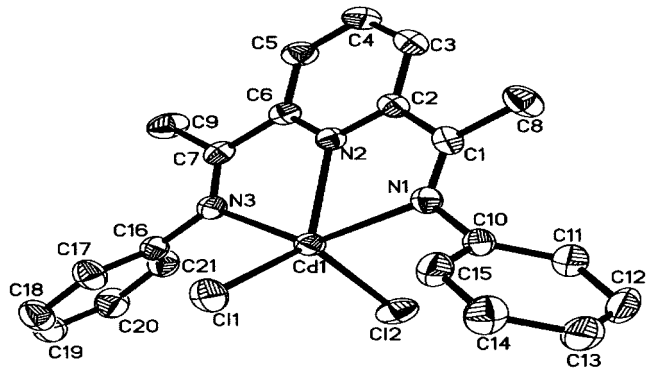

Figure 1. Molecular structure of complex **1** (the other molecule and CH_3CN molecules have been omitted for clarity)

All compounds were characterized by ^1H NMR, UV/Vis, and IR spectroscopy, and elemental analysis. Complexes **1**−**4** were also studied by single-crystal X-ray diffraction.

Structures

Crystals of **1**−**4** suitable for X-ray structural determination were grown from acetonitrile/dichloromethane (2:1) solution (**1**, **3,** and **4**), or from a concentrated dichloromethane solution (**2**). The molecular structures of complexes **1**−**4** are shown below, and selected bond lengths and angles are presented in Table 1.

There are two independent complex molecules and three acetonitrile molecules in the asymmetric unit in the cadmium complex **1** (Figure 1); the two molecules show an approximate C_s symmetry about a plane containing the cadmium atom, two chlorine atoms, and the pyridine nitrogen atom. The dihedral angles between the phenyl rings and the plane formed by three coordinated nitrogen atoms are 75.23(17)° and 82.09(20)° in one of these molecules; these values are larger than those in the other molecule [62.86(17)° and 67.23(14)°, respectively]. The dihedral angles between the two phenyl rings are 83.98(18)° and 74.49(15)°, respectively, in the two molecules. The cadmium atom deviates by 0.077 Å from the coordination plane in one molecule, while in the other the metal atom is displaced by 0.084 Å. For both molecules the central cadmium atom is coordinated to five atoms and the geometry about the cadmium atom is distorted trigonal-bipyramidal, with the equatorial plane defined by the N(2)(pyridine), Cl(1)and Cl(2) atoms and the N(1) and N(3)(imino) atoms in the axial positions. The mean deviation of the cadmium atom from the equatorial plane in one molecule is only 0.019 Å, while in the other the metal atom is displaced by 0.009 Å. In the two molecules, the angles in the equatorial plane range between 113.36(8)° and 128.50(8)°, and the axial Cd−N(imino) bonds subtend an angle of 137.99(11)° [in the other this angle is 137.92(11)°]. The Cd−N(imino) bonds [2.407(3) and 2.419(3) Å] are longer than the Cd−N(pyridine) bonds [2.310(3) Å], as is the case in the other molecule. The imino C=N bonds in **1** have a distinc-

tive double-bond character, with C=N distances in the range 1.271(5)−1.279(5) Å.

Complexes **2** (Figure 2) and **3** (Figure 3) possess structures with approximate C_s symmetry about a plane bisecting the central pyridine ring and containing the cadmium atom and two chlorine atoms, while complex **4** (Figure 4) adopts C_2 symmetry. The central cadmium atom in **2**−**4** is coordinated to five groups and the geometry about

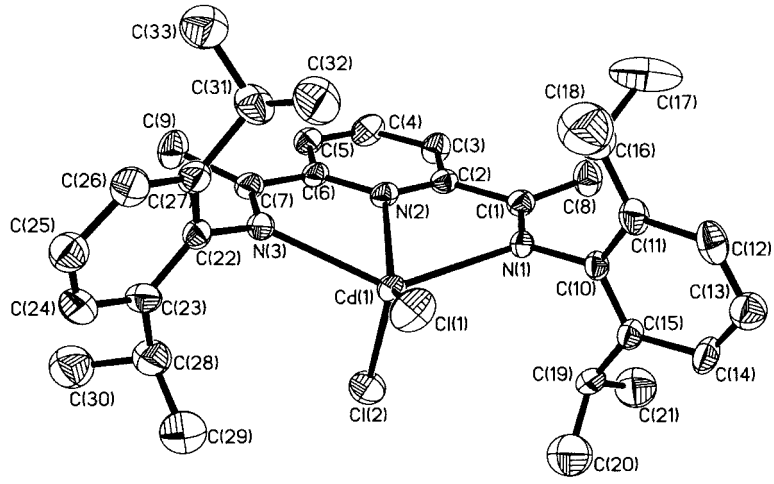

Figure 2. Molecular structure of complex **2**

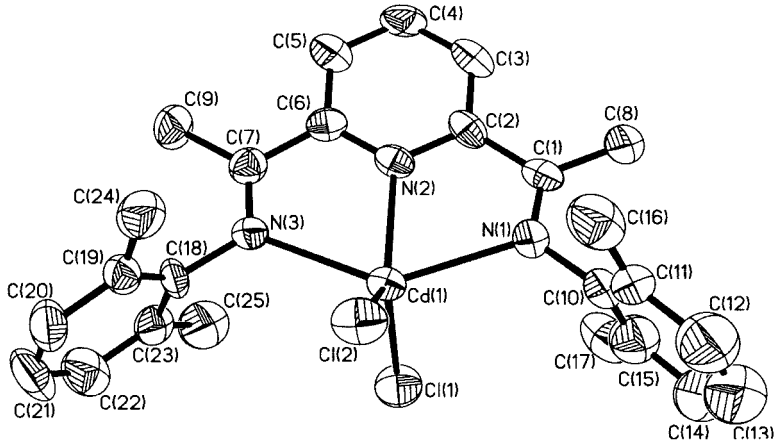

Figure 3. Molecular structure of complex **3** (the CH_3CN molecule has been omitted for clarity)

the cadmium atom is a distorted trigonal bipyramid, with the equatorial plane defined by the N(2)(pyridine), Cl(1) and Cl(2) atoms and the N(1) and N(3)(imino) atoms in the axial positions. Complex **3** contains one independent molecule and one acetonitrile molecule, where as there are two independent molecules and two acetonitrile molecules in the asymmetric unit in the cadmium complex **4**. The mean deviation of the cadmium atoms in **2**−**4** from the equatorial planes is 0.027, 0.020 and 0.002 Å (0.007 Å for the other molecule in **4**), respectively, and the axial Cd−N(imino) bonds subtend angles of 131.99(16)°, 138.40(20)° and 139.20(40)° [137.30(40)° for the other molecule in **4**], respectively. The cadmium atoms in **2**−**4** deviate by 0.652, 0.087 and 0.040 Å (0.037 Å for the other molecule in **4**), respectively, from the coordination plane. The Cd−N(pyridine) bonds in **2**−**4** range from 2.300(6)−2.331(5) Å, while the distances between the cadmium atom and the imino nitrogen atoms in the three complexes are almost the same [2.467(5) and 2.480(5) Å] in **2**, [2.426(6) and 2.431(5) Å] in **3** and [2.359(12) and 2.438(10) Å] in **4** [2.420(10) and 2.420(11) Å for the other molecule in **4**]. The planes of the phenyl rings in **2**−**4** are oriented essentially orthogonal to the coordination plane [ranging between 75.62(46)° and 89.59(52)°]. In each complex the Cd−N(pyridine) bond is significantly shorter than the Cd−N(imino) bonds, with the formal double-bond character of the imino linkages N(1)−C(1) and N(3)−C(7) being retained [C=N distances in range 1.262(16)−1.307(8) Å]. There are no intermolecular packing features of interest in any of the four complexes.

Luminescence Properties

Table 2 presents the absorption and emission data for the new complexes **1**−**4** in dichloromethane solution and in the solid state at room temperature, together with those for ligands $\mathbf{L^1}$−$\mathbf{L^4}$. The four complexes show two main absorption bands, which are similar to ligands $\mathbf{L^1}$−$\mathbf{L^4}$ in the UV region, as shown in Figure 5. The electronic absorption spectra of the complexes show low-energy absorption bands at about 339−350 nm (329−340 nm for ligands $\mathbf{L^1}$−$\mathbf{L^4}$), and higher energy absorption bands at about 301−313 nm (281−291 nm for ligands $\mathbf{L^1}$−$\mathbf{L^4}$), attributed to ligand-centered π−π* transitions. The electronic absorption spectra of the complexes are red-shifted relative to the ligands due to perturbation of the intraligand π−π* transition of the bis(iminoalkyl)pyridine unit by the metal atom. The energy trends of this band for the series **1**−**4** and $\mathbf{L^1}$−$\mathbf{L^4}$ are found to follow the order **3** < **4** < **2** < **1** and $\mathbf{L^3} < \mathbf{L^4} < \mathbf{L^2} < \mathbf{L^1}$, which is in line with the electron-donating ability of the alkyl group (2,6-dimethylphenyl > 2-methylphenyl > 2,6-diisopropylphenyl > phenyl).

[a] Concentration ca. 10^{-5} M.

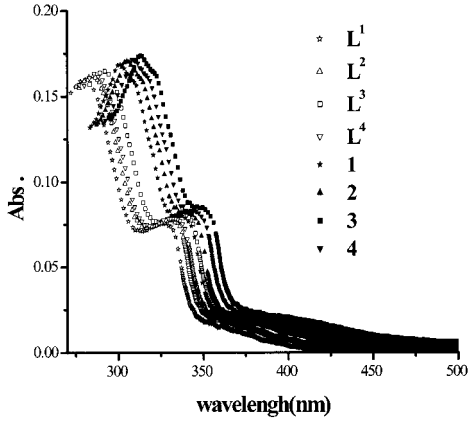

Figure 5. UV/Vis absorption spectra of ligands $\mathbf{L^1}$−$\mathbf{L^4}$ and complexes **1**−**4**

Complexes **1**−**4** have broad fluorescent emission bands in degassed CH_2Cl_2 solution at room temperature, with maxima at 397, 399, 409, and 402 nm for **1**−**4**, respectively (λ_{max} = 368, 375, 381, and 378 nm for $\mathbf{L^1}$−$\mathbf{L^4}$; Figure 6). Similar to the electronic absorption data, the emission energies are found to depend on the bis(iminoalkyl)pyridine ligand. For complexes **1**−**4** and ligands $\mathbf{L^1}$−$\mathbf{L^4}$, emission-energy trends in the order **3** < **4** < **2** < **1** and $\mathbf{L^3} < \mathbf{L^4} < \mathbf{L^2}$

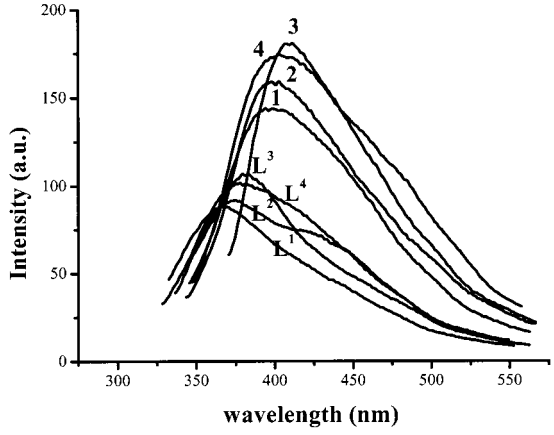

Figure 6. Emission spectra of ligands $\mathbf{L^1}$−$\mathbf{L^4}$ and complexes **1**−**4** in solution at room temperature

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

< $\mathbf{L^1}$ are observed, again in line with the electron-donating ability of the alkyl group. The Cd^{II} centers in complexes **1**−**4** play a key role in enhancing the fluorescent emission of the ligands. The chelation of the ligands to the metal center also contributes to the enhancement of the fluorescent emission by increasing the rigidity of the ligands, thus reducing the loss of energy by thermal vibrational decay. However, in the solid state at room temperature complexes **1**−**4** exhibit a bright, greenish-blue emission band with maxima at 482, 485, 488, and 486 nm, respectively (λ_{max} = 471, 475, 480, and 476 nm for $\mathbf{L^1}$−$\mathbf{L^4}$); these values are red-shifted by about 80 nm (100 nm for $\mathbf{L^1}$−$\mathbf{L^4}$) from the emission in solution. This dramatic red-shift of the emission energy for complexes **1**−**4** and ligands $\mathbf{L^1}$−$\mathbf{L^4}$ from solution to the solid state is probably caused by intermolecular interactions in the solid state that effectively decrease the energy gap.

Conclusion

A series of [bis(iminoalkyl)pyridine]cadmium(II) complexes have been synthesized and characterized. Complexes **1**−**4** and ligands $\mathbf{L^1}$−$\mathbf{L^4}$ have fluorescent emission at 368−409 nm in dichloromethane solution at room temperature. Complexes **1**−**4** and ligand $\mathbf{L^1}$−$\mathbf{L^4}$ have broad fluorescent emission bands in the solid state at room temperature, with λ_{max} = 482, 485, 488, 486 nm for **1**−**4,** and 471, 475, 480, 476 nm for $\mathbf{L^1}$−$\mathbf{L^4}$, respectively. Their luminescent properties show that they are a new class of luminescent metal compounds with potential applications in optoelectronic devices.

Experimental Section

General: All manipulations were carried out under nitrogen using standard Schlenk and cannula techniques or in a conventional nitrogen-filled glove box. Elemental analyses were performed with a Perkin−Elmer 240c elemental analyzer. IR spectra were obtained with a Nicolet Impact 410 FTIR spectrometer using KBr pellets. NMR spectra were recorded with a Varian Mercury 300 MHz spectrometer. UV/Vis spectra were obtained with a Perkin−Elmer Lambda 20 spectrometer. Luminescence spectra were measured with a Perkin−Elmer LS55 Luminescence spectrometer at room temperature. Aniline, 2,6-diisopropylaniline, 2,6-dimethylaniline, and 2-methylaniline were purchased from Aldrich Chemical Co. and used as received. Solvents were refluxed in the presence of an appropriate drying agent, and distilled and degassed prior to use. For methanol, Mg ribbon was used as drying agent, whereas acetonitrile and dichloromethane were dried with calcium hydride. 2,6-Diacetylpyridine was prepared according to a published procedure.[18]

Preparation of 2,6-Bis[1-(phenylimino)ethyl]pyridine ($\mathbf{L^1}$): Aniline (2.8 mL, 31.0 mmol) was added to a solution of 2,6-diacetylpyridine (1.70 g, 10.4 mmol) in absolute methanol (30 mL). After the addition of several drops of formic acid, the reaction mixture was refluxed for 8 h and then allowed to cool down to room temperature. The crude product precipitated as a yellow powder. Pure $\mathbf{L^1}$ was obtained in 88% yield (2.87 g) upon recrystallization from methanol. ^{1}H NMR (300 MHz, $CDCl_3$): δ = 8.36 (d, J = 7.8 Hz, 2 H, Py-H_m), 7.89 (t, J = 7.8 Hz, 1 H, Py-H_p), 7.42−6.85 (m, 10 H, Ar-*H*), 2.42 (s, 6 H, N=C*Me*) ppm. IR (KBr): $\tilde{\nu}$ = 3059 (w), 2919 (w), 2860 (w), 1638 (vs), 1594 (m), 1574 (m), 1482 (s), 1445 (m), 1417 (w), 1361 (s), 1319 (m), 1294 (w), 1255 (w), 1220 (s), 1173 (m), 1150 (w), 1118 (m), 1091 (m), 1076 (m), 1027 (m), 992 (w), 969 (w), 912 (w), 874 (w), 823 (s), 808 (m), 774 (s), 762 (m), 743 (m), 707 (s), 697 (m), 658 (w), 645 (w), 551 (w), 520 (m), 468 (w), 443 (w) cm^{-1}. $C_{21}H_{19}N_3$ (313.4): calcd. C 80.48, H 6.11, N 13.41; found C 80.28, H 6.00, N 13.32.

Preparation of 2,6-Bis[1-(2,6-diisopropylphenylimino)ethyl]pyridine ($\mathbf{L^2}$): 2,6-Diisopropylaniline (8.7 mL, 46.1 mmol) was added to a solution of 2,6-diacetylpyridine (2.5 g, 15.3 mmol) in absolute methanol (50 mL). After the addition of several drops of formic acid, the reaction mixture was refluxed for 24 h and then allowed to cool down to room temperature. The crude product precipitated as yellow powder. Pure $\mathbf{L^2}$ was obtained in 86% yield (6.35 g) upon recrystallization from methanol. ^{1}H NMR (300 MHz, $CDCl_3$): δ = 8.60 (d, J = 7.8 Hz, 2 H, Py-H_m), 7.98 (t, J = 7.8 Hz, 1 H, Py-H_p), 7.21−7.13 (m, 6 H, Ar-*H*), 2.78 (sept, J = 6.8 Hz, 4 H, C*H*Me$_2$), 2.30 (s, 6 H, N=C*Me*), 1.19 (dd, J = 6.8 Hz, 24 H, CH*Me*$_2$) ppm. IR (KBr): $\tilde{\nu}$ = 3068 (w), 2960 (s), 2925 (w), 2870 (w), 1646 (vs), 1588 (w), 1571 (w), 1455 (m), 1438 (m), 1406 (w), 1383 (w), 1368 (s), 1321 (w), 1301 (w), 1255 (w), 1240 (m), 1195 (m), 1121 (m), 1103 (w), 1079 (w), 1059 (w), 1041 (w), 994 (w), 961 (w), 936 (w), 886 (w), 829 (m), 801 (w), 770 (s), 758 (w), 744 (w), 691 (w), 634 (w), 533 (w), 443 (w) cm^{-1}. $C_{33}H_{43}N_3$ (481.7): calcd. C 82.28, H 9.00, N 8.72; found C 82.50, H 8.91, N 8.65.

Preparation of 2,6-Bis[1-(2,6-dimethylphenylimino)ethyl]pyridine ($\mathbf{L^3}$): 2,6-Dimethylaniline (6.4 mL, 51.7 mmol) was added to a solution of 2,6-diacetylpyridine (2.81 g, 17.2 mmol) in absolute methanol (50 mL). After the addition of several drops of formic acid, the reaction mixture was refluxed for 24 h and then allowed to cool down to room temperature. The crude product precipitated as a yellow powder. Pure $\mathbf{L^3}$ was obtained in 85% yield (5.4 g) upon recrystallization from methanol. ^{1}H NMR (300 MHz, $CDCl_3$): δ = 8.56 (d, J = 7.8 Hz, 2 H, Py-H_m), 7.95 (t, J = 7.8 Hz, 1 H, Py-H_p), 7.11−6.95 (m, 6 H, Ar-*H*), 2.27 (s, 6 H, N=C*Me*), 2.07 (s, 12 H, C*Me*) ppm. IR (KBr): $\tilde{\nu}$ = 3068 (w), 3019 (w), 2970 (w), 2944 (w), 2915 (w), 2851 (w), 2727 (w), 1646 (vs), 1594 (m), 1567 (m), 1468 (s), 1437 (m), 1366 (s), 1324 (w), 1297 (m), 1247 (m), 1203 (s), 1160 (w), 1148 (w), 1126 (s), 1093 (s), 1071 (w), 1029 (w), 991 (w), 972 (w), 920 (w), 886 (w), 875 (w), 826 (s), 817 (s), 804 (w), 777 (s), 762 (vs), 744 (w), 692 (m), 623 (m), 576 (w), 541 (w), 530 (w), 493 (w), 422 (w) cm^{-1}. $C_{25}H_{27}N_3$ (369.5): calcd. C 81.26, H 7.37, N 11.37; found C 80.98, H 7.40, N 11.56.

Preparation of 2,6-Bis[1-(2-methylphenylimino)ethyl]pyridine ($\mathbf{L^4}$): 2-Methylaniline (2.2 mL, 20.5 mmol) was added to a solution of 2,6-diacetylpyridine (1.1 g, 6.7 mmol) in absolute methanol (25 mL). After the addition of several drops of formic acid, the reaction mixture was refluxed for 24 h and then allowed to cool down to room temperature. The crude product precipitated as a yellow powder. Pure $\mathbf{L^4}$ was obtained in 85% yield (1.96 g) upon recrystallization from methanol. ^{1}H NMR (300 MHz, $CDCl_3$): δ = 8.42 (d, J = 7.6 Hz, 2 H, Py-H_m), 7.92 (t, J = 7.6 Hz, 1 H, Py-H_p), 7.23−6.69 (m, 8 H, Ar-*H*), 2.34 (s, 6 H, N=C*Me*), 2.14 (s, 6 H, C*Me*) ppm. IR (KBr): $\tilde{\nu}$ = 3068 (w), 3019 (w), 2920 (w), 2856 (w), 1648 (vs), 1601 (m), 1569 (m), 1480(s), 1450 (m), 1363 (s), 1321 (m), 1294 (w), 1255 (w), 1220 (s), 1187 (w), 1155 (w), 1118 (s), 1095 (w), 1073 (m), 1041(m), 964 (w), 933 (w), 880 (w), 851 (w), 817 (s), 780 (s), 740 (s), 727 (s), 651 (w), 642 (w), 567 (w), 533 (w), 446 (m), 405 (w) cm^{-1}. $C_{23}H_{23}N_3$ (341.5): calcd. C 80.90, H 6.79, N 12.31; found C 80.89, H 6.82, N 12.27.

Preparation of {2,6-Bis[1-(phenylimino)ethyl]pyridine}dichlorocadmium(II)·1.5CH$_3$CN (1): A mixture of **L^1** (124 mg, 0.39 mmol) and $CdCl_2·2.5H_2O$ (90 mg, 0.39 mmol) in acetonitrile (30 mL) was stirred under nitrogen at room temperature for 12 h. Evaporation of the solvent gave the crude product as a yellowish powder. Pure **1** was obtained in 80% yield (174 mg) upon recrystallization from acetonitrile/dichloromethane (2:1). ^{1}H NMR (300 MHz, CD_3CN): δ = 8.50 (quint, J = 7.2 Hz, 3 H, Py-*H*), 7.52−7.17 (m, 10 H, Ar-*H*), 2.52 (s, 6 H, N=C*Me*) ppm. ^{13}C NMR (CD_3CN, ^{1}H gated decoupled): δ = 166.30 (N=*C*), 148.41 (Py-C_o), 147.39 (Ar-C_i), 143.44 (Ar-C_o), 129.27 (Ar-C_p), 128.09 (Py-C_p), 126.37 (Py-C_m), 121.66 (Ar-C_m), 17.46 (N=C*Me*) ppm. IR (KBr): $\tilde{\nu}$ = 3089 (w), 3029 (w), 2960 (w), 2915 (w), 2247 (w), 1631 (s), 1591 (s), 1487 (s), br 1450 (m), 1371 (s), 1309 (w), 1284 (w), 1252 (s), 1227 (s), 1185 (w), 1148 (w), 1103 (w), 1071 (w), 1019 (m), 981 (w), 909 (w), 859 (w), 820 (s), 777 (s), 758 (m), 743 (m), 725 (m) 697 (s), 674 (w), 654 (w), 576 (w), 552 (w), 533 (m), 468 (w), 407 (w) cm^{-1}. $C_{21}H_{19}CdCl_2N_3·1.5CH_3CN$ (558.1): calcd. C 51.63, H 4.24, N 11.29; found C 51.60, H 4.31, N 11.25.

Preparation of {2,6-Bis[1-(2,6-diisopropylphenylimino)ethyl]pyridine}dichlorocadmium(II) (2): A mixture of **L^2** (169 mg, 0.35 mmol) and $CdCl_2·2.5H_2O$ (80 mg, 0.35 mmol) in dichloromethane (40 mL) was stirred under nitrogen at room temperature for 12 h. The volume of the reaction mixture was reduced to about 10 mL and the mixture left to stand at 0 °C for several days. Yellowish crystals of **2** formed and were separated from the solution. Yield: 177 mg (76%). ^{1}H NMR (300 MHz, CD_3CN): δ = 8.51 (quint, J = 6.9 Hz, 3 H, Py-*H*), 7.27−7.18 (m, 6 H, Ar-*H*), 2.89 (sept, J = 6.6 Hz, 4 H, C*H*Me$_2$), 2.40 (s, 6 H, N=C*Me*), 1.22 (dd, J = 6.6 Hz, 24 H, CH*Me*$_2$) ppm. IR (KBr): $\tilde{\nu}$ = 3084 (w), 3063 (w), 2965(s), 2925 (m), 2870 (w), 1636 (s), 1584 (s), br 1457 (m), 1371 (s), 1329 (w), 1306 (w), 1249 (s), 1203 (m), 1106 (m), 1054 (w), 1039 (w), 1017 (w), 979 (w), 937 (w), 819 (m), 796 (m), 775 (m), 758 (w), 744 (w), 716 (w), 697 (w), 637 (w), 529 (w), 468 (w), 445 (w), 432 (w) cm^{-1}. $C_{33}H_{43}CdCl_2N_3$ (664.7): calcd. C 59.60, H 6.52, N 6.32; found C 59.99, H 6.85, N 6.68.

Preparation of {2,6-Bis[1-(2,6-dimethylphenylimino)ethyl]pyridine}dichlorocadmium(II)·CH$_3$CN (3): A mixture of **L^3** (137 mg, 0.37 mmol) and $CdCl_2·2.5H_2O$ (85 mg, 0.37 mmol) in acetonitrile (30 mL) was stirred under nitrogen at room temperature for 12 h. Evaporation of the solvent gave the crude product as a yellowish powder. Pure product **3** was obtained in 75% yield (165 mg) upon recrystallization from acetonitrile/dichloromethane (2:1). ^{1}H NMR (300 MHz, CD_3CN): δ = 8.53 (quint, J = 6.3 Hz, 3 H, Py-*H*), 7.25−7.08 (m, 6 H, Ar-*H*), 2.41 (s, 6 H, N=C*Me*), 2.20 (s, 12 H, C*Me*) ppm. IR (KBr): $\tilde{\nu}$ = 3084 (w), 3024 (w), 2969 (w), 2920 (w), 2742 (w), 2247 (w), 1928 (w), 1854 (w), 1633 (s), 1584 (s), 1470 (s), 1443 (s), 1371(s), 1304 (m), 1255 (s), 1215 (s), 1163 (w), 1105 (m), 1093 (m), 1036 (m), 1022 (s), 980 (m), 966 (w), 917 (m), 902 (w), 823 (s), 814 (s), 782 (s), 768 (s), 740 (m), 695 (m), 633 (m), 582 (m), 554 (m), 530 (w), 516 (w), 495 (w), 419 (w) cm^{-1}. $C_{25}H_{27}CdCl_2N_3·CH_3CN$ (593.6): calcd. C 54.61, H 5.09, N 9.43; found C 54.83, H 5.21, N 9.03.

Preparation of {2,6-Bis[1-(2-methylphenylimino)ethyl]pyridine}dichlorocadmium(II)·CH$_3$CN (4): A mixture of **L^4** (131 mg, 0.38 mmol) and $CdCl_2·2.5H_2O$ (86 mg, 0.38 mmol) in dichloromethane (30 mL) was stirred under nitrogen at room temperature

for 12 h. Evaporation of the solvent gave the crude product as yellowish powder. Pure product **4** was obtained in 80% yield (172 mg) upon recrystallization from acetonitrile/dichloromethane (2:1). ^{1}H NMR (300 MHz, CD_3CN): δ = 8.49 (quint, J = 6.6 Hz, 3 H, Py-*H*), 7.33−6.97 (m, 8 H, Ar-*H*), 2.38 (s, 6 H, N=C*Me*). 2.18 (s, 6 H, C*Me*) ppm. IR (KBr): $\tilde{\nu}$ = 3079 (w), 3029 (w), 2975 (w), 2920 (w), 2947 (w), 1638 (s), 1599 (m), 1584 (s), 1487 (s), br 1463 (m), 1368 (s), 1311 (w), 1255 (s), 1230 (s), 1200 (s), 1148 (w), 1113 (m), 1041 (m), 1019 (s), 982 (w), 941 (w), 863 (m), 817 (s), 795 (s), 786 (s), 755 (s), 731 (m), 716 (m), 704 (w), 667 (w), 652 (w), 594 (w), 568 (w), 547 (w), 527 (w), 446 (m), 413 (w) cm^{-1}. $C_{23}H_{23}CdCl_2N_3{\cdot}CH_3CN$ (565.6): calcd. C 53.07, H 4.63, N 9.90; found C 53.43, H 4.91, N 9.65.

X-ray Crystallography of 1−4: The data were collected with a Rigaku R-AXIS RAPID IP or a Siemens SMART 1000 CCD diffractometer equipped with graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å) at 293 ± 2 K. The structure was solved by direct methods and refined by full-matrix least squares based on F^2 using the SHELXTL 5.1 software package.[19] The cadmium and chlorine atoms were located first, and the carbon and nitrogen atoms were found in difference Fourier maps. The hydrogen atoms residing on the carbon atoms were located geometrically. All non-hydrogen atoms were refined anisotropically. Crystallographic data are given in Table 3. CCDC-232412 (**1**), -232417 (**2**), -232418 (**3**) and -232413 (**4**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: + 44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Hydroalumination of Carbon Dioxide, Carbon Disulfide, and Phenyl Isocyanate with an Aluminum Ketiminate Compound

Pei-Cheng Kuo,[a] I-Chun Chen,[a] Jr-Chiuan Chang,[a] Ming-Tsung Lee,[a] Chin-Han Hu,[a] Chen-Hsiung Hung,[a] Hon Man Lee,[a] and Jui-Hsien Huang*[a]

Keywords: Aluminum / Carbon dioxide / Hydrides / Hydroalumination / Insertion / N ligands

The reaction of MeC(O)C(H)=C(Me)NHAr (Ar = 2,6-diisopropylphenyl) (**1**) with excess $LiAlH_4$ in diethyl ether at –78 °C generates [AlH(OCMeCHCMeNAr)$_2$] (**2**) in 76% yield. The aluminum formate compound [Al(OCMeCHCMeNAr)$_2$(OCOH)] (**3**) can be isolated from the reaction of **2** with CO_2 in 93% yield. Compound **3** is thermally stable and remains unchanged when heated under vacuum at 100 °C for 24 h. Similarly, a solution of **2** in dichloromethane reacts with carbon disulfide or phenyl isocyanate at room temperature to yield the insertion products [Al(OCMeCHCMeNAr)$_2$(SCHS)] (**4**) and [Al(OCMeCHCMeNAr)$_2$(OCH=NPh)] (**5**), respectively, in 80% and 92% yield. Reaction of **2** with 1 equiv. of urethane in toluene at refluxing temperature for 1 h yields the aluminum isocyanate compound [Al(OCMeCHCMeNAr)$_2$(NCO)] (**6**). The molecular structures of compounds **2**–**6** have been determined by X-ray crystallography. Density functional calculations show that the isomer of compound **2** with an N–N *trans* arrangement is 3.1 kcal·mol^{-1} lower in energy than the O–O *trans* isomer. Inserting CO_2 into the Al–H bond of compound **2** results in the formation of the formate compound **3**; this reaction is predicted to be exothermic by 29.8 kcal·mol^{-1}.

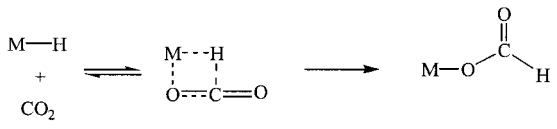
Introduction

Metal−hydride bonds are important in organometallic chemistry because a wide variety of unsaturated small organic molecules can insert into them to yield stable species or intermediates. Among these reactions, the insertion of CO_2 into metal−hydride bonds is particularly interesting. The use of carbon dioxide as a C_1 source is a current research area which is important not only for reducing the dependence on fossil-fuel consumption but also the reduction of greenhouse gases.[1,2] Various methods have been developed for CO_2 activation, and the use of transition-metal compounds as catalysts is common.[3−5] One way to convert CO_2 into functionalized organic molecules is by inserting CO_2 into a transition metal−hydride bond (Scheme 1). Reactions between CO_2 and transition metal hydrides have been reported for many metals, with the main focus on late transition metals.[6−13] The insertion of CO_2 into an aluminum hydride bond has not been reported so far.



Scheme 1

Highly reactive metal−hydrogen bonds also play an important role in catalytic reactions.[14−18] Among these, aluminum hydrides are well known and widely used due to their high reactivity and low cost.[19−27] In this paper we present the synthesis and characterization of aluminum hydride compounds containing substituted ketiminate ligands and their reactions with carbon dioxide, carbon disulfide, and phenyl isocyanate. A related reaction of the aluminum hydride compound with urethane to yield a novel aluminum isocyanate compound is also presented.

Results and Discussion

Reactivity Studies of Ketiminatoaluminum Hydride Compounds

Ketimine **1** [MeC(O)C(H)=C(Me)NHAr; Ar = 2,6-diisopropylphenyl] can be easily synthesized in high yield by an imine condensation reaction between 2,4-pentanedione and 2,6-diisopropylaniline in a 1:1 ratio in methanol.[28] The reaction of compound **1** with an excess of $LiAlH_4$ in diethyl ether at −78 °C, followed by stirring at −10 °C for 2 h, generates [AlH(OCMeCHCMeNAr)$_2$] (**2**) in 76% yield after recrystallization of the crude solids from diethyl ether at −20 °C (Scheme 2). The ^{1}H NMR spectrum of compound **2** in C_6D_6 indicates C_2 symmetry of the molecule, with the two methyl resonances of the ligand backbone appearing at

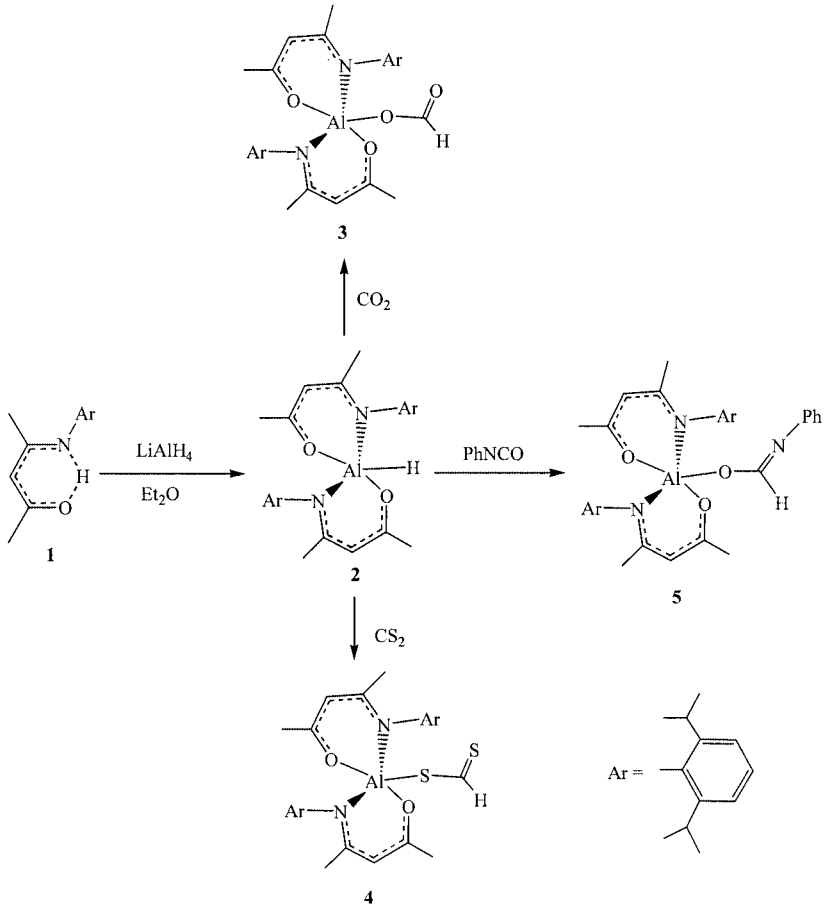


Scheme 2

δ = 1.50 and 1.32 ppm. The N−Ar rotation of compound **2** in solution at ambient temperature is slow due to the high steric hindrance between the isopropyl group and the methyl groups of the ligand backbone. The ^{1}H and ^{13}C NMR spectra of compound **2** confirm this (two sets of isopropyl resonances). The hydride resonance was not observed, presumably due to the interaction of the hydrogen atom with ^{27}Al (I = 5/2).[29] The solid-state IR spectrum shows a ν_{Al-H} band at 1788 cm^{-1}. Moreover, the deuterated compound [AlD(OCMeCHCMeNAr)$_2$] (**2D**), synthesized by treating compound **1** with $LiAlD_4$, exhibits exactly the same ^{1}H NMR spectrum as compound **2**. The ν_{Al-D} band of this compound appears at 1297 cm^{-1} (calculated value 1287 cm^{-1} from the isotope shift). Compound **2** is thermally unstable and decomposes in C_6D_6 at 80 °C, forming unidentified compounds.

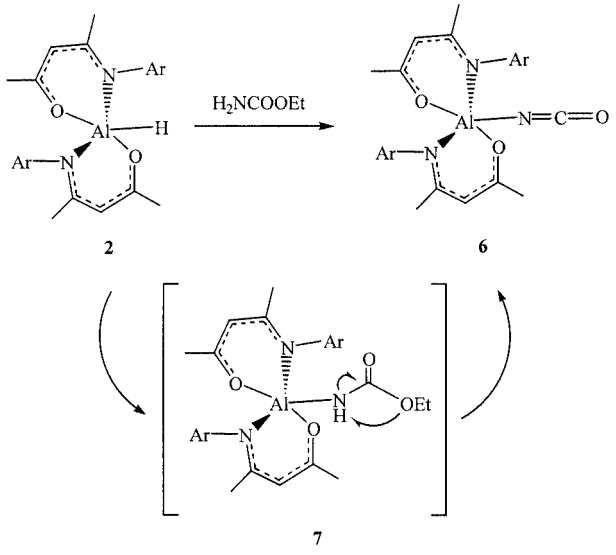
The aluminum hydride compound **2** is reactive toward the C=O, C=S, and C=N functional groups in carbon dioxide, carbon disulfide, and phenyl isocyanate, respectively. The reactions are summarized in Scheme 2. Reaction of compounds **2** or **2D** with CO_2 in dichloromethane solution were completed within minutes after admitting CO_2 gas into the solution. The reactions are exothermic. The aluminum formate compounds [Al(OCMeCHCMeNAr)$_2$(OCOH)] (**3**) and [Al(OCMeCHCMeNAr)$_2$(OCOD)] (**3D**) were isolated in 93% yield from diethyl ether solutions at −20 °C. Compound **3** is thermally stable and remains unchanged even when heated under vacuum at 100 °C for 24 h. The ketiminate backbone of **3** exhibits the same pattern of ^{1}H and ^{13}C NMR resonances as **2**. However, the ^{1}H NMR spectrum of **3** exhibits a singlet at δ = 8.0 ppm for the formate proton, which was not observed for compound **3D**. The ^{13}C{^{1}H} NMR spectrum of compound **3** shows a singlet at δ = 163.8 ppm for the formate carbon atom; this signal is a triplet for compound **3D** with a $^1J_{C,D}$ coupling constant of 31 Hz.

Similarly, reactions of **2** with carbon disulfide and phenyl isocyanate in dichloromethane at room temperature yielded the insertion products [Al(OCMeCHCMeNAr)$_2$(SCHS)] (**4**) and [Al(OCMeCHCMeNAr)$_2$(OCH=NPh)] (**5**) in 80% and 92% yield, respectively. The ^{1}H NMR spectrum of **4** exhibits a downfield singlet at δ = 11.66 ppm for the dithioformate proton, comparable to the values of other metal dithioformate compounds.[30,31] The dithioformate proton resonance was not observed for the corresponding deuterated compound **4D**. In the ^{13}C{^{1}H} NMR spectrum, the carbon resonance of C=S for **4** appears at δ = 240.5 ppm, which is downfield relative to that of the C=O resonance of **3**, but similar to the values of reported metal dithioformate compounds.[30,31] Again, the ^{13}C{^{1}H} NMR spectrum shows that the carbon resonance of C=S for compound **4D** also appears as a triplet at δ = 240.5 ppm with a $^1J_{C,D}$

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

coupling constant of 28 Hz. The ^{1}H NMR spectrum of **5** displays a singlet at δ = 7.74 ppm for the formimidato proton, which was not observed in **5D**. Similarly, the carbon resonance of the C=N fragment appears at δ = 157.8 ppm as a singlet for compound **5**. However, even with very high concentrations of **5D**, no signal was observed for the carbon resonance of the C=N fragment.

An intriguing reaction of **2** occurs with urethane, $H_2NCOOEt$. Reaction of **2** with 1 equiv. of urethane in refluxing toluene for 1 h yielded the aluminum isocyanate compound [Al(OCMeCHCMeNAr)$_2$(NCO)] (**6**) as white crystals in 57% yield (Scheme 3). The ^{1}H and ^{13}C{^{1}H} NMR spectra of **6** show similar patterns for the ketiminate fragments as those of **3** and **4**. The isocyanate functional group exhibits two strong infrared absorptions at 2267 and 2206 cm^{-1}, which are similar to those of other M−NCO compounds in the literature.[32−34] The reaction was also monitored by ^{1}H NMR spectroscopy in a C_6D_6 solution. A possible mechanistic pathway for the formation of **6** is shown in Scheme 3. The first step involves hydrogen elimination to form the aluminum carbamidate intermediate **7**, followed by successive loss of ethanol to form the final aluminum isocyanate compound **6**. Precise control of the reaction time and recrystallization procedure are necessary to avoid further reaction of the by-product, ethanol, with the aluminum ketiminate compounds, which regenerates the ketimine ligands. A related reaction converting an NCO fragment to urethane was reported by Knoth[35] et al. in 1967. A boron compound containing B−NCO, derived from the reaction of B−CO with azide, was converted into B−NHCO$_2$C$_2$H$_5$ in the reactions of 1,12-$B_{12}H_{10}(NCO)_2^{2-}$ and 1,10-$B_{10}Cl_8(NCO)_2^{2-}$ with ethanol/hydrogen chloride, resulting in the formation of the urethanes 1,12-$B_{12}H_{10}(NHCO_2C_2H_5)_2^{2-}$ and 1,10-$B_{10}Cl_8(NHCO_2C_2H_5)_2^{2-}$, respectively.



Scheme 3

Molecular Structures of Ketiminatoaluminum Compounds 2−6

The molecular structures of compounds **2**−**6** are shown in Figures 1−5, and selected bond lengths and angles are listed in Table 1. Compounds **2**−**6** are all five-coordinate trigonal-bipyramidal structures. The two nitrogen atoms of the ketiminate backbone for compound **2** occupy the axial positions while the two oxygen atoms and the hydrido ligand form the equatorial plane. However, the most distinct structural difference between **3**−**6** and **2** is that the two oxygen atoms of the two ketiminate backbones in **3**−**6** occupy the axial positions. A schematic description of the molecular structures of **2**−**6** is shown in Scheme 4. The molecular structures of a series of ketiminatoaluminum halide and alkyl compounds reported in the literature are all shown with an O−O *trans* geometry.[36] A theoretical calculation of the geometry of **2** was therefore performed (vide infra).

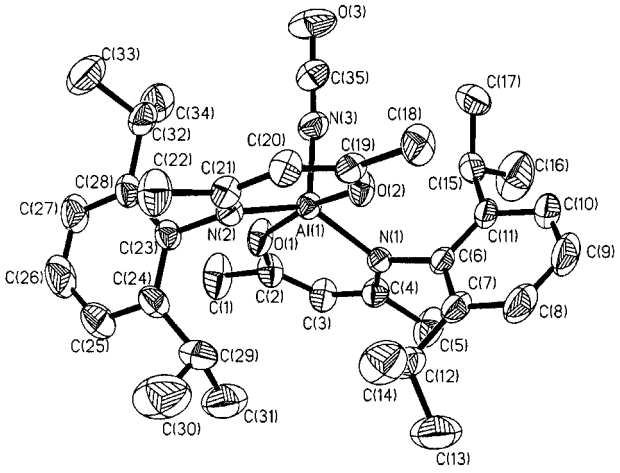

Figure 5. The molecular structure of compound **6**, with ellipsoids drawn at the 50% probability level; all hydrogen atoms have been omitted for clarity

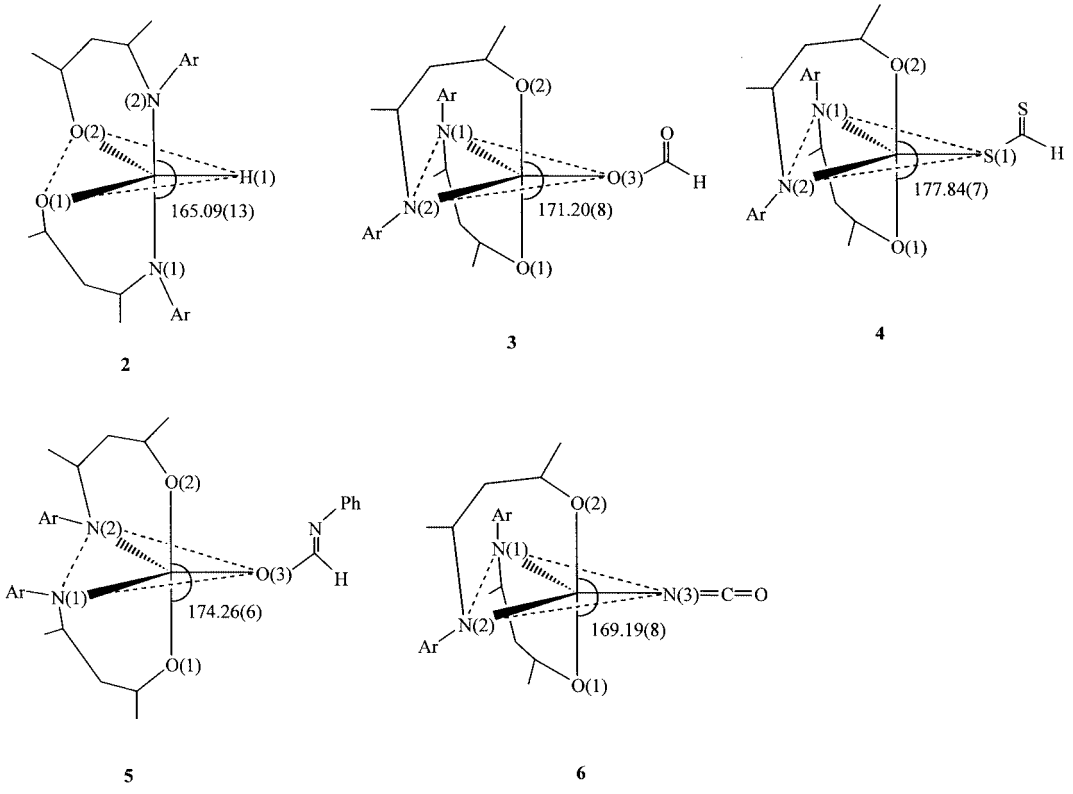
As described above, the molecular structure of **2** is trigonal-bipyramidal with two Al−N(axial) bond lengths of 2.079(3) and 2.064(3) Å. For comparison, the Al−N(equatorial) bonds in compounds **3**−**6**, which range from 1.976(2) to 2.002(1) Å, are generally shorter than the Al−N(axial) bonds. Similarly, the Al−O(equatorial) bonds in compound **2** [1.763(3) and 1.757(3) Å] are shorter than the Al−O(axial) bonds for compounds **3**−**6** [ranging from 1.795(1) to 1.826(1) Å]. A better hybridization of the trigonal-planar sp^2 orbitals of aluminum with the equatorial oxygen or nitrogen atoms forming σ-bonds may be the reason for these shorter distances.

Molecular Structures of Group 13 Metal−NCO Compounds

Compounds containing NCO ligands are very common for late transition metals. However, only a few group 13 metal NCO compounds have been structurally characterized. When searching the Cambridge Crystallographic Database, there are only three M(NCO) (M = group 13) compounds, two B−NCO compounds and one In−NCO compound.[37−39] A comparison of the bond angles and bond lengths of these M(NCO) (M = group 13) compounds is given in Table 2. The NCO angles for all the compounds listed in the table are almost linear [177.8(4)° to 179.5(4)°]. However, the M−NCO angles vary depending on the metals. The In−N−C angle of 147.1(8)° is much smaller than those of compound **6** and the B−N−C compounds; this is probably due to crystal packing effects.[37] The C−N and C−O bond lengths are very similar in all the compounds listed in Table 2 and can be viewed as C≡N triple bonds (normally at 1.16 Å) and C=O double bonds (normally at 1.22 Å), respectively.

Density Functional Theory (DFT) Calculations on the Reaction between CO_2 and 2

The intriguing reactivity of compound **2** toward CO_2 has been carefully calculated. Four structures were considered:

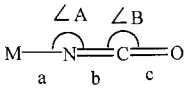


Scheme 4

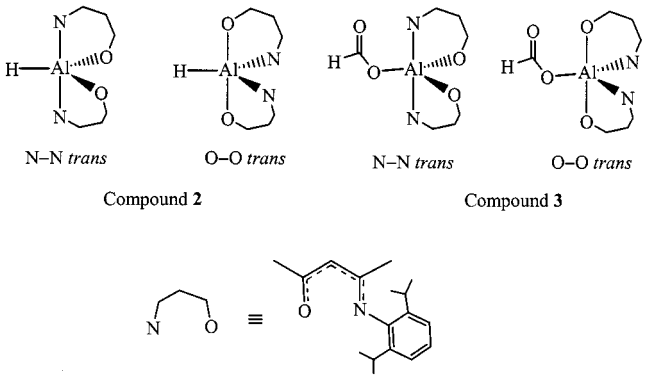
 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

Table 2. Comparisons of bond lengths and angles for M(NCO) (M = group 13) compounds

Compound	Bond angles [°]		Bond lengths [Å]			Ref.
	∠ A	∠ B	a	b	c	
[*closo*-2-$B_{10}H_9NCO]^{2-}$	172.3(3)	177.8(4)	1.498(7)	1.128(7)	1.187(7)	[37]
6	172.4(2)	179.5(4)	1.836(2)	1.151(3)	1.188(3)	this work
$[(Pc)_2In(NCO)_2][PNP]$	147.1(8)	178 (1)	2.155(9)	1.15(1)	1.17(2)	[39]
	164.4(9)	179(1)	2.165(9)	1.17(2)	1.23(2)	[39]



the N−N *trans* and O−O *trans* forms of compound **2**, and the N−N *trans* and O−O *trans* forms of compound **3**, as shown in Scheme 5.



Scheme 5

Density functional theory, which includes Becke's three-parameter nonlocal exchange potential and the nonlocal correlation functional of Lee, Yang, and Parr, was used, along with the 6-31G* basis sets.[40,41] For compound **2**, the isomer with the N−N *trans* arrangement is found to be 3.1 kcal·mol^{-1} lower in energy than the O−O *trans* isomer. This observation is consistent with the solid-state structure of compound **2**, in which the two nitrogen atoms of the ketiminate ligands are found in the axial positions. Inserting CO_2 into the Al−H bond of compound **2** results in the formation of the formate compound **3** in a reaction which was predicted to be exothermic by 29.8 kcal·mol^{-1}. For compound **3**, the N−N *trans* and O−O *trans* isomers are very close in energy, with the former being 0.05 kcal·mol^{-1} more stable. The predicted geometrical parameters at the B3LYP/6-31G* level[42] agree reasonably well with those obtained by X-ray crystallography.

In conclusion, we have synthesized aluminum hydride compounds containing ketiminate ligands. These aluminum hydride compounds show novel reactivity toward CO_2, CS_2, and phenyl isocyanate insertion, which has not been seen before in main-group chemistry. A first example of an aluminum NCO compound, $[Al(OCMeCHCMeNAr)_2(NCO)]$ (**6**), has also been structurally characterized from the reaction of aluminum hydride with urethane. A theoretical calculation proved that the CO_2 insertion product has a lower energy than that of the corresponding aluminum hydride compounds.

Experimental Section

General Procedures: All reactions were performed under dry nitrogen using standard Schlenk techniques or in a glove box. Toluene and diethyl ether were dried by refluxing in the presence of sodium benzophenone ketyl. CH_2Cl_2 was dried with P_2O_5. All solvents were distilled and stored in solvent reservoirs which contained molecular sieves (4 Å) and were purged with nitrogen. ^1H and ^{13}C NMR spectra were recorded with a Bruker AC200 or an Avance 300 M Hz spectrometer. Chemical shifts for ^1H and ^{13}C spectra were recorded in ppm relative to the internal deuterated solvent ($CDCl_3$: ^1H: δ = 7.24 ppm; ^{13}C: δ = 77.0 ppm). Elemental analyses were performed with a Heraeus CHN-OS Rapid Elemental Analyzer at the Instrument Center, NCHU. Ketimine **1** [MeC(O)C(H)=C(Me)NHAr; Ar = 2,6-diisopropylphenyl] was prepared according to a previously reported procedure.[36] $AlCl_3$ (Strem), MeLi, and EtLi (Aldrich) were used as received.

$[AlH(OCMeCHCMeNAr)_2]$ (2): A diethyl ether solution (30 mL) of **1** (10.0 g, 38.6 mmol) was added dropwise whilst stirring at −78 °C to a 100-mL Schlenk flask containing a suspension of $LiAlH_4$ (0.73 g, 19.2 mmol) in diethyl ether (20 mL). The mixture was allowed to warm to −10 °C and then stirred for 2 h. The resulting suspension was filtered through Celite. The filtrate was dried under vacuum to remove volatiles, and the resulting solid was recrystallized from diethyl ether to give 8.0 g of **2** (76% yield). ^1H NMR (C_6D_6): δ = 1.08 (d, 6 H, CHMe_2), 1.12 (d, 6 H, CHMe_2), 1.32 (s, 6 H, C*Me*), 1.34 (d, 6 H, CHMe_2), 1.38 (d, 6 H, CHMe_2), 1.50 (s, 6 H, C*Me*), 3.13 (m, 2 H, C*H*Me_2), 3.40 (m, 2 H, C*H*Me_2), 5.06 (s, 2 H, CMeC*H*CMe), 7.15 (m, 6 H, *Ph*) ppm. ^{13}C NMR (C_6D_6): δ = 23.4 (q, $J_{C,H}$ = 128 Hz, CHMe_2), 24.0 (q, $J_{C,H}$ = 126 Hz, CHMe_2), 24.3 (q, $J_{C,H}$ = 126 Hz, CHMe_2), 24.5 (q, $J_{C,H}$ = 128 Hz, CHMe_2), 24.6 (q, $J_{C,H}$ = 125 Hz,), 25.9 (q, $J_{C,H}$ = 125 Hz,), 28.2 (q, $J_{C,H}$ = 133 Hz,), 28.5 (q, $J_{C,H}$ = 130 Hz,), 100.1 (d, $J_{C,H}$ = 160 Hz,), 123.5 (d, $J_{C,H}$ = 152 Hz,), 123.9 (d, $J_{C,H}$ = 153 Hz,), 125.6 (d, $J_{C,H}$ = 158 Hz,), 129.4 (s), 142.0 (s, Ph C_{ipso}), 145.2 (s, Ph C_{ipso}), 173.0 (s, *C*N), 177.2 (s, *C*O) ppm. IR (KBr): ν_{Al-H} = 1788 cm^{-1}. $C_{34}H_{49}AlN_2O_2$ (544.75): calcd. C 74.96, H 9.07, N 5.14; found C 74.14, H 8.92, N 6.20. **2D** was synthesized following the same procedure except that $LiAlD_4$ was used. The ^1H and ^{13}C

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

NMR spectra of **2D** and **2** are identical. IR (KBr): ν_{Al-D} = 1297 cm^{-1}.

[Al(OCMeCHCMeNAr)$_2$(OCOH)] (3): Carbon dioxide was bubbled through a 30-mL Schlenk flask charged with 15 mL of dichloromethane and **2** (1.0 g, 1.8 mmol) at room temperature for 1 min. The solution was then stirred for 3 min and the volatiles were removed under vacuum to yield a pure white solid (1.0 g) of **3** in 92.6% yield. ^{1}H NMR ($CDCl_3$): δ = 1.05 (d, 6 H, CHMe_2), 1.08 (d, 6 H, CHMe_2), 1.10 (d, 6 H, CHMe_2), 1.16 (d, 6 H, CHMe_2), 1.18 (s, 6 H, C*Me*), 1.65 (s, 6 H, C*Me*), 2.85 (m, 2 H, C*H*Me$_2$), 3.05 (m, 2 H, C*H*Me$_2$), 5.21 (s, 2 H, CMeC*H*CMe), 7.03−7.23 (m, 6 H, *Ph*), 8.23 (s, CO*H*) ppm. ^{13}C NMR ($CDCl_3$): δ = 23.7 (q, $J_{C,H}$ = 127 Hz, C*Me*), 23.9 (q, CHMe_2), 24.3 (q, CHMe_2), 24.8 (br. q, two overlapping peaks, CHMe_2), 25.3 (q, $J_{C,H}$ = 128 Hz, *C*Me), 27.3 (d, $J_{C,H}$ = 126 Hz, *C*HMe$_2$), 28.2 (d, $J_{C,H}$ = 127 Hz, *C*HMe$_2$), 100.1 (d, $J_{C,H}$ = 159 Hz, CMe*C*HCMe), 123.1(d, $J_{C,H}$ = 158 Hz, Ph *C*H), 123.9 (d, $J_{C,H}$ = 158 Hz, Ph *C*H), 125.6 (d, $J_{C,H}$ = 159 Hz, Ph *C*H), 140.6 (s, Ph C_{ipso}), 143.0 (s, Ph C_{ipso}), 145.1 (s, Ph C_{ipso}), 163.8 (d, $J_{C,H}$ = 204 Hz, *C*HO), 177.8 (s, *C*N), 180.6 (s, *C*O) ppm. $C_{35}H_{49}AlN_2O_4$ (588.756): calcd. C 71.40, H 8.39, N 4.76; found C 71.83, H 8.90, N 5.05. The ^{1}H and ^{13}C NMR spectra of **3D** are similar to those of **3** except that the formate proton of **3** (δ = 8.01 ppm) is not present in **3D** and the formate carbon atom (δ = 163.8 ppm) for **3D** appears as a triplet ($^1J_{C,D}$ = 31 Hz).

[Al(OCMeCHCMeNAr)$_2$(SCSH)] (4): An excess of carbon disulfide was added at room temperature to a 30-mL Schlenk flask containing 15 mL of dichloromethane and **2** (1.0 g, 1.8 mmol). The solution was stirred for 1 h and the volatiles were removed under vacuum to yield **4** (0.91 g) as a yellow solid in 80% yield. ^{1}H NMR ($CDCl_3$): δ = 1.03 (d, 6 H, CHMe_2), 1.10 (two overlapping doublets, 12 H, CHMe_2), 1.18 (d, 6 H, CHMe_2), 1.24 (s, 6 H, C*Me*), 1.71 (s, 6 H, C*Me*), 2.89 (m, 2 H, C*H*Me$_2$), 3.07 (m, 2 H, C*H*Me$_2$), 5.20 (s, 2 H, CMeC*H*CMe), 7.06−7.24 (m, 6 H, *Ph*), 11.66 (s, CS*H*) ppm. ^{13}C NMR ($CDCl_3$): δ = 23.6 (q, $J_{C,H}$ = 128 Hz, C*Me*), 23.9 (q, CHMe_2), 24.7 (q, CHMe_2), 25.0 (q, CHMe_2), 25.1 (q, CHMe_2), 25.3 (q, $J_{C,H}$ = 129 Hz, *C*Me), 28.1 (d, *C*HMe$_2$), 28.4 (d, *C*HMe$_2$), 100.4 (d, $J_{C,H}$ = 162 Hz, CMe*C*HCMe), 123.1 (d, $J_{C,H}$ = 159 Hz, Ph *C*H), 124.3 (d, $J_{C,H}$ = 156 Hz, Ph *C*H), 126.1 (d, $J_{C,H}$ = 160 Hz, Ph *C*H), 140.8 (s, Ph C_{ipso}), 143.6 (s, Ph C_{ipso}), 143.7 (s, Ph C_{ipso}), 178.9 (s, *C*N), 180.9 (s, *C*O), 240.5 (d, $J_{C,H}$ = 178 Hz, S*C*SH) ppm. $C_{35}H_{49}AlN_2O_2S_2$ (620.89): calcd. C 67.71, H 7.95, N 4.51; found C 67.36, H 9.05, N 4.49. The ^{1}H and ^{13}C NMR spectra of **4D** are similar to those of **4** except that the resonance of the dithioformate proton of **4** at δ = 11.66 ppm is not observed in **4D** and the resonance of the dithioformate carbon atom (δ = 240.5 ppm) of **4D** appears as a triplet ($^1J_{C,D}$ = 28 Hz).

[Al(OCMeCHCMeNAr)$_2$(OCHNPh)] (5): Phenyl isocyanate (0.40 mL, 3.69 mmol) was added with a syringe at room temperature to a 30-mL Schlenk flask containing 15 mL of dichloromethane and **2** (2.0 g, 3.67 mmol). The solution was stirred for 1 h and volatiles were removed under vacuum to yield a yellow solid. The solid was washed with heptane in several portions to remove unreacted phenyl isocyanate, and was then dried under vacuum to give 2.25 g of **5** (92% yield). ^{1}H NMR ($CDCl_3$): δ = 1.06 (d, 6 H, CHMe_2), 1.10 (d, 6 H, CHMe_2), 1.11 (d, 6 H, CHMe_2), 1.20 (s, 6 H, C*Me*), 1.22 (d, 6 H, CHMe_2), 1.65 (s, 6 H, C*Me*), 2.82 (m, 2 H, C*H*Me$_2$), 3.17 (m, 2 H, C*H*Me$_2$), 5.18 (s, 2 H, CMeC*H*CMe), 6.81−7.25 (m, 6 H, *Ph*), 7.74 (s, CNPh*H*) ppm. ^{13}C NMR ($CDCl_3$): δ = 23.6 (q, $J_{C,H}$ = 127 Hz, C*Me*), 23.8 (q, CHMe_2), 24.3 (q,

CH*Me*$_2$), 24.6 (q, CH*Me*$_2$), 25.0 (q, CH*Me*$_2$), 25.1 (q, $J_{C,H}$ = 127 Hz, C*Me*), 27.3 (d, $J_{C,H}$ = 129 Hz, *C*HMe$_2$), 28.1 (d, $J_{C,H}$ = 127 Hz, *C*HMe$_2$), 100.0 (d, $J_{C,H}$ = 162 Hz, CMe*C*HCMe), 121.5 (d, $J_{C,H}$ = 161 Hz, Ph *C*H), 122.2 (d, $J_{C,H}$ = 161 Hz, Ph *C*H), 122.9 (d, $J_{C,H}$ = 155 Hz, Ph *C*H), 123.8 (d, $J_{C,H}$ = 154 Hz, Ph *C*H), 125.4 (d, $J_{C,H}$ = 159 Hz, Ph *C*H), 128.6 (d, $J_{C,H}$ = 160 Hz, Ph *C*H), 140.6 (s, Ph C_{ipso}), 142.9 (s, Ph C_{ipso}), 145.3 (s, Ph C_{ipso}), 151.2 (s, Ph C_{ipso}), 157.8 (d, $J_{C,H}$ = 180 Hz, *C*NPhH), 177.3 (s, *C*N), 180.2(s, *C*O) ppm. A small amount of phenyl isocyanate was present in the product which resulted in inaccuracy of the elemental analysis. The ^{1}H and ^{13}C NMR spectra of **5D** are similar to those of **5** except that the resonance of the *N*-phenyl formimidato proton of **5** at δ = 7.74 ppm was not observed for **5D**.

[Al(OCMeCHCMeNAr)$_2$(NCO)] (6): A toluene (10 mL) solution of $H_2NCOOEt$ (0.32 g, 3.67 mmol) was added dropwise at room temperature to a 50-mL Schlenk flask containing 20 mL of toluene and **2** (2.0 g, 3.67 mmol). The solution was refluxed for 1 h and the volatiles were removed under vacuum to yield an off-white solid. The solid was washed with a small amount of heptane in several portions to remove free ketiminate ligand. The resulting solid was recrystallized from a toluene solution at −20 °C to yield colorless crystals of **6** (1.23 g) in 57% yield. ^{1}H NMR ($CDCl_3$): δ = 1.05 (2 d, overlapping, 12 H, CH*Me*$_2$), 1.17 (d, 6 H, CH*Me*$_2$), 1.19 (s, 6 H, C*Me*), 1.28 (d, 6 H, CH*Me*$_2$), 1.65 (s, 6 H, C*Me*), 2.75 (m, 2 H, C*H*Me$_2$), 3.14 (m, 2 H, C*H*Me$_2$), 5.17 (s, 2 H, CMe*CH*CMe), 7.03−7.17 (m, 6 H, *Ph*) ppm. ^{13}C NMR ($CDCl_3$): δ = 23.6 (q, $J_{C,H}$ = 127 Hz, C*Me*), 23.7 (q, $J_{C,H}$ = 128 Hz, CH*Me*$_2$), 24.3 (q, $J_{C,H}$ = 127 Hz, CH*Me*$_2$), 24.7 (q, $J_{C,H}$ = 127 Hz, CH*Me*$_2$), 24.8 (q, $J_{C,H}$ = 127 Hz, CH*Me*$_2$), 24.9 (q, $J_{C,H}$ = 128 Hz, C*Me*), 27.9 (d, $J_{C,H}$ = 130 Hz, *C*HMe$_2$), 28.3 (d, $J_{C,H}$ = 130 Hz, *C*HMe$_2$), 100.0 (d, JC,H = Hz, CMe*C*HCMe), 123.0, 123.8, 125.4, 140.0, 142.5, 145.3, 176.7 (s, *C*N), 178.9 (s, *C*O) ppm. $C_{35}H_{48}AlN_3O_3$ (585.35): calcd. C 71.75, H 8.26, N 7.18; found C 71.24, H 7.72, N 7.05.

X-ray Structure Determination of Compounds 2−6: Crystals of compound **2** were obtained from a concentrated diethyl ether solution at −20 °C. Crystals of **4** and **6** were obtained from saturated toluene solutions at −20 °C. Crystals of **3** and **5** were obtained from saturated dichloromethane/diethyl ether solutions at −20 °C. The crystals were sealed in glass capillaries and mounted on a goniostat. All data sets were collected at 150(2) K, except for **6**, which was measured at 298(2) K. Data were collected with a Bruker SMART CCD diffractometer with graphite-monochromated Mo-K_α radiation. Structural determinations were performed using the SHELXTL package of programs. All refinements were carried out by full-matrix least squares using anisotropic displacement parameters for all non-hydrogen atoms. All the hydrogen atoms were placed geometrically and included through the use of a riding model. The crystal data are summarized in Table 3. CCDC-234262 (**2**), -234264 (**3**), -234265 (**4**), -234263 (**5**) and -234261 (**6**) contain the crystallohgraphic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: + 44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Acknowledgments

We thank the National Science Council of Taiwan for financial support and the National Changhua University of Education for supporting the CCD X-ray facility. We would also like to thank Dr. Darin Tiedtke for helpful discussion.

Syntheses, Structures and Magnetic Properties of Novel Oxamido-Bridged Tetranuclear Complexes [Cu_3M] (M = Cu, Mn)

Shi-bin Wang,[a,b] Guang-ming Yang,*[a] Rong-fang Li,[a] Yuan-fang Wang,[a] and Dai-zheng Liao[a]

Keywords: Oxamido bridge / Tetranuclear / Macrocyclic complex / Magnetic property

Three oxamido-bridged tetranuclear complexes with the formulae [(LCu)Cu(LCuSCN)$_2$]·H_2O (**1**), [(LCu)Mn(LCuSCN)$_2$]·1.38CH_3OH (**2**) and {(LCu)Mn[LCuN(CN)$_2$]$_2$}·0.75DMF·0.25H_2O (**3**) (where H_2L = 2,3-dioxo-5,6:15,16-dibenzo-1,4,8,13-tetraazacylotetradeca-7,13-diene) have been prepared and characterised. Their structures were deduced using X-ray crystallography. All three complexes crystallise in the triclinic system, space group $P\bar{1}$. The three copper ions of the complex ligands and the central metal ions (Cu, Mn) remain in the plane and form a scalene triangle. Three copper ions occupy the vertexes and the M(Cu, Mn) ions are located at the centre. Magnetic susceptibility measurements in the 5–300 K temperature range have been carried out for this series of complexes. The experimental data have been fitted according to the Heisenberg Hamiltonian and led to J values equal to –61.80 cm^{-1}, –14.54 cm^{-1} and –12.10 cm^{-1} for complex **1**, **2** and **3**, respectively. Their interaction parameters have been compared with each other. The deviation of the copper ions from the oxamide-bridge plane results in the J value of complex **1** being different from those of other oxamide-bridged copper complexes.

Introduction

A lot of work has been devoted to the study of the exchange interactions in polynuclear systems. One of the challenges in this field is the design of complexes with predictable magnetic properties. To achieve this goal, one of the best strategies for designing and synthesising complexes is the complex-as-ligand approach, i.e. using mononuclear complexes which contain potential donor groups towards another metal ion.[1−5] The attractive feature of this is that the second metal ion will usually be in a different coordination environment from the first, potentially allowing the facile synthesis of homonuclear complexes in which the metals have different geometries and/or oxidation states,[6−11] or heteronuclear complexes.[12−14] At the same time, it was also discovered that the oxamido group is an efficient bridging mediator of magnetic exchange between neighbouring metal ions[15] because (i) the lower electronegativity of nitrogen with respect to oxygen leads to the gap between the oxamide-bridge molecular orbitals and the d metal orbitals being smaller; (ii) the metal-nitrogen and metal-oxygen distances are very close and contribute to maintaining a good overlap between the bridge and the d-metal orbitals.[16] Many complexes including this bridge have been synthesised and their magnetic properties characterised.[17−21] Antiferromagnetic interactions have been observed in these complexes, the magnitudes of which basically depend upon two factors: one is the nature and magnitude of the overlap between the metal d orbitals containing the unpaired electrons and the bridging ligand orbitals. The other is the energy difference between the two magnetic orbitals.

Polymetallic complexes of macrocyclic ligands have been of great interest to supramolecular and coordination chemists because of their special structures. The macrocyclic oxamido, in which an *exo-cis* conformation of the oxygen donors is enforced, allows us to design heterometallic systems and model magnetic systems in a more controlled fashion via the stepwise complication of the macrocyclic *exo* donors.

With these considerations in mind and continuing our work on polynuclear macrocyclic complexes,[19−25] we designed and synthesised a macrocyclic complex ligand LCu (where H_2L = 2,3-dioxo-5,6:15,16-dibenzo-1,4,8,13-tetraazacylotetradeca-7,13-diene) with oxamido bridging. Based on this complex ligand, we described the syntheses, crystal structures and the magnetic properties of three tetranuclear complexes, namely [(LCu)Cu(LCuSCN)$_2$]·H_2O (**1**), [(LCu)Mn(LCuSCN)$_2$]·1.38CH_3OH (**2**) and [(LCu)Mn[LCuN(CN)$_2$]$_2$]·0.75DMF·0.25H_2O (**3**). Although there have been a few papers concerning tetranu-

clear complexes in recent years,[26−32] the structures of the three complexes that we are reporting in this paper are different because the structures of those complexes are square or cubic and little work has been devoted to triangular frameworks in a plane.

Results and Discussion

Description of the Structures

The structure of **1** is shown in Figure 1. It consists of a neutral tetranuclear unit and a large number of disordered waters.

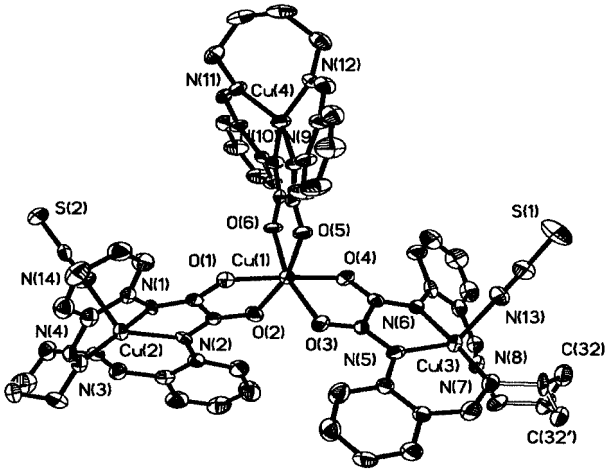

Figure 1. ORTEP plot of **1**; thermal ellipsoids are shown at the 30% probability level

The four copper ions remain in a plane and form a scalene triangle. Cu2, Cu3 and Cu4 occupy the vertexes. Cu1 almost stands on the epicenter since its distances to Cu2, Cu3 and Cu4 are 5.21(2) Å, 5.25 (1) Å and 5.23(2) Å, respectively. The Cu ions deviate from the mean triangular plane by 0.0114(3) Å (Cu1), −0.0040(2) Å (Cu2), −0.0042(2) Å (Cu3) and −0.0032 (1) Å (Cu4). In this molecule, there are three coordination frameworks to every four copper ions. The Cu1 ion is connected to other copper ions via the *exo-cis* oxygen atoms of the oxamido macrocyclic ligands and its coordination polyhedron can be considered as a distorted octahedron. The basal plane of the octahedron consists of O1, O2, O4 and O5 and the apical positions are occupied by O3 and O6. The value that Cu1 deviates from the plane is 0.0463 Å. Cu2 and Cu3 show a (4+1) coordination environment, the four nitrogen atoms of the macrocyclic ligand are situated in the basal position and the coordination is completed by the nitrogen of the SCN^-. The four nitrogen atoms of the macrocyclic ligand deviate significantly from the basal plane [for Cu2, the values are −0.41(2) Å (N1), 0.41 (3) Å (N2), −0.36 (2) Å (N3) and 0.37 (1) Å (N4)]. The coordination environment of Cu2 can be considered as a square pyramid. The Cu−N bond lengths in the plane range from 1.912(1) Å to 1.973 (3) Å for Cu2 and from 1.891(1) Å to 1.995 (3) Å for Cu3. The axial Cu−N bond length is 2.107(1) Å for Cu2 and 2.081 (3) Å for Cu3. These are elongated due to the Jahn−Teller effect of the d^9 electronic configuration. For Cu4, the four-coordinate structure of the complex ligand is maintained. Cu2, Cu3 and Cu4 deviate from the plane of the oxamido bridge ($C_2O_2N_2$) by −0.274(4) Å, 0.166 (1) Å and 0.0457 (1) Å, respectively. Figure 1 indicates that C32 is disordered over two sides.

Complexes **2** and **3** are similar in structure and both consist of a neutral tetranuclear Cu_3Mn unit. Figures 2 and 3 show the common metal part of **2** and **3** with atomic labelling schemes. Within each tetranuclear fragment the Cu1 and Cu2 centres of **2** and the Cu2 and Cu3 centres of **3** are in a (4+1) coordination environment and show square pyramidal structures. The four nitrogen atoms of the macrocyclic ligand form their basal planes and the axial positions are occupied, respectively, by the nitrogen atom from thiocyanate ion for complex **2** and one of the nitrogen atoms of the dicyanamide ion for complex **3**. The Cu3 centre of complex **2** and Cu1 in complex **3** both maintain the four-coordinate structure of the macrocyclic complex ligand. The four copper ions which have pentahedral configurations in these two complexes are displaced from the least-squares basal plane towards the apical ligand by 0.36 (1) Å (Cu1) and 0.47(3) Å (Cu2) for complex **2** and by −0.31(2) Å (Cu2) and 0.39(1) Å (Cu3) for complex **3**. The metal atoms Cu1, Cu2, Cu3 and Mn1 of the two complexes are almost in a plane and form a triangle. The Mn(II) ions in the two complexes are both coordinated to the six oxygen atoms of the oxamido bridges of the three complex ligands. The Mn(II) ions have octahedral geometries and the Mn−O bond lengths range from 2.152(1) Å to 2.179(1) Å for complex **2** and from 2.094 (2) Å to 2.187 (3) Å for complex **3**. The distances from Mn to Cu are 5.514(2) Å (Cu1), 5.547(2) Å (Cu2) and 5.461(2) Å (Cu3) for complex **2** and 5.433 (1) Å (Cu1), 5.441(1) Å (Cu2) and 5.485 (1) Å (Cu3) for complex **3**, respectively. There are many free solvent molecules in both crystal structures. On average, there are 1.38 methanol molecules in the crystalline lattice of complex **2**. However, 0.75 DMF molecules and 0.25 water molecules are distributed in the crystalline lattice of complex **3**.

Selected bond lengths and angles are listed in Tables 1, 2 and 3.

Spectroscopic Characterisation

The $\nu_{(C=O)}$ bands of the oxamido group of the tetranuclear complexes can be observed around 1640cm^{-1} which is lower relative to that of mononuclear CuL (1670cm^{-1}). The IR bands around 1570cm^{-1} can be assigned to the $\nu_{(C=N)}$ mode of the macrocycle. A strong band at ca. 2100cm^{-1} is characteristic of a C−N bond.

The electronic absorption spectra of the three tetranuclear complexes in DMF below 420 nm are dominated by intense bands due to intraligand and charge-transfer transitions in the Cu(II) chromophore. Bands at 670 nm can be attributed to the spin allowed d-d transitions of Cu(II). The coordination environments of manganese in 2 and 3 are distorted octahedral. Thus, according to ligand field theory

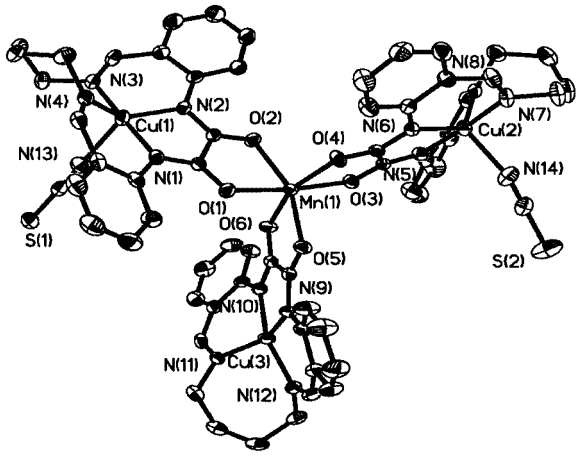

Figure 2. ORTEP plot of **2**; thermal ellipsoids are shown at the 30% probability level

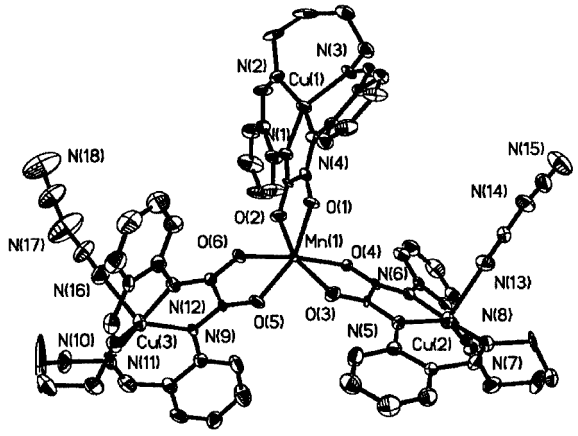

Figure 3. ORTEP plot of **3**; thermal ellipsoids are shown at the 30% probability level

and assuming O_h symmetry, the ground state of manganese is $^6A_{1g}$. Because d-d transitions of manganese [$^6A_{1g} \rightarrow {}^4T_{1g}(G)$. $^4T_{2g}(G)$, $^4A_{1g}$ ···] are spin forbidden, no characteristic bands of manganese were found in the spectra of the complexes.

Magnetic Properties

Variable temperature (5−300 K) magnetic susceptibility data were collected for microcrystalline samples of complexes **1**−**3** in a magnetic field of 10000 G. The χ_M and $\chi_M T$ versus T plot for complex **1** is shown in Figure 4. At 300 K $\chi_M T$ is equal to 1.35cm^{3}mol^{-1}K which is lower than that expected for the four isolated copper ions ($\chi_M T$ = 1.50 cm^{3}mol^{-1}K). This decreases smoothly upon cooling and reaches a minimum at about 70 K with $\chi_M T$ = 1.05cm^{3}mol^{-1}K and increases upon cooling further. At 5 K, $\chi_M T$ is equal to 1.30 cm^{3}mol^{-1}K. The experimental data were fitted using the theoretical expression of the magnetic susceptibility [Equation (1)] which was deduced from the spin Hamiltonian:

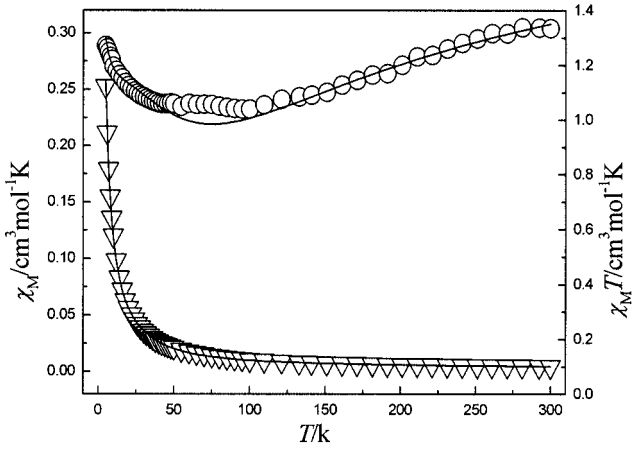

Figure 4. Experimental and calculated variations of the product χ_M and $\chi_M T$ versus T for **1**

$$\chi_M = \frac{2Ng^2\beta^2}{k(T-\theta)}\left[\frac{A}{B}\right] + N\alpha$$

$$A = 5\times\exp(2J/kT) + \exp(-2J/kT) + 2$$
$$B = 5\times\exp(2J/kT) + 3\times\exp(-2J/kT) + 2\times\exp(-2J/kT) + 6 \quad (1)$$

where J is the exchange integral between the Cu(II) ions. (Because Cu2, Cu3 and Cu3 all link to Cu1 through the oxamido bridge and the distances between them are almost similar, we assumed the interaction between them is equal.) $N\alpha$ is the temperature-independent paramagnetic (240×10^{-6} cm^3mol^{-1}) and the other symbols have their usual meanings. The best fitting of the experimental data leads to $J = -61.80 cm^{-1}$, $g = 2.09$, $\theta = 0.8$ and $R = 2.23 \times 10^{-4}$ (R is the agreement factor defined as $\Sigma(\chi_{obs.} - \chi_{calcd.})^2/\Sigma\chi^2_{obs.}$). The results indicate that there is an antiferromagnetic interaction between the copper(II) ions within complex **1**.

According to the Kahn model[33] for the copper complexes, the magnetic exchange pathway is dominated by the interaction between the metal $x^2 - y^2$ orbitals and the oxamido σ orbitals and the antiferromagnetic interaction between the copper(II) ions arises from the nonzero overlap between the magnetic orbitals. The magnitude of the antiferromagnetic interaction is related to the square of the overlap between the magnetic orbitals central to each copper. The antiferromagnetic interaction between the copper(II) ions within complex **1** is weaker than that within other oxamido bridge copper complexes reported previously ($J = 210-80.9$ cm^{-1}).[34−36] This may be attributed to the difference in the ligand environments of the copper ions because the former has less co-planarity between the coordination environments of copper(II) and that of the adjacent copper(II) ions than the latter, resulting in a decrease in overlap between the two magnetic orbitals within the present complex.[37]

Plots of χ_M and $\chi_M T$ versus temperature for complexes **2** and **3** are shown in Figures 5 and 6, respectively. At room temperature, $\chi_M T$ is equal to 5.04 $cm^3mol^{-1}K$ for complex **2** and 5.19 $cm^3mol^{-1}K$ for complex **3**, both of which are lower than 5.50 $cm^3mol^{-1}K$ which would be expected for noninteracting ions [three coppers(II) ions and one manganese(II) ion]. The $\chi_M T$ value decreases steadily upon cool-

$$\chi_M = \frac{N\beta^2}{kT}\left[\frac{A}{B}\right] + N\alpha$$

$$A = 60\times g^2_{4,3/2}\times\exp(18J/kT) + 28\times g^2_{3,3/2}\times\exp(4J/kT) + 10\times g^2_{2,3/2}\times\exp(4J/kT) + 2\times g^2_{1,3/2} + 56\times g^2_{3,1/2}\times\exp(13J/kT) + 20\times g^2_{2,1/2}\times\exp(7J/kT)$$

$$B = 9\times\exp(18J/kT) + 7\times\exp(10J/kT) + \exp(4J/kT) + 3 + 14\times\exp(13J/kT) + 10\times\exp(7J/kT) \quad (2)$$

$$g_{4,3/2} = \frac{3}{8}\times g_{Cu} + \frac{5}{8}\times g_{Mn} \qquad g_{3,3/2} = \frac{7}{24}\times g_{Cu} + \frac{17}{24}\times g_{Mn}$$
$$g_{2,3/2} = \frac{1}{12}\times g_{Cu} + \frac{13}{12}\times g_{Mn} \qquad g_{1,3/2} = \frac{-3}{4}\times g_{Cu} + \frac{7}{4}\times g_{Mn}$$
$$g_{3,1/2} = \frac{1}{6}\times g_{Cu} + \frac{5}{6}\times g_{Mn} \qquad g_{2,1/2} = \frac{-1}{6}\times g_{Cu} + \frac{7}{6}\times g_{Mn}$$

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

ing, showing that an antiferromagnetic interaction between the copper and manganese ions occurs. In the 5−15 K temperature range the $\chi_M T$ plot exhibits a plateau at 1.03 $cm^3mol^{-1}K$ for complex **2** and at 0.96 $cm^3mol^{-1}K$ for complex **3**. The experimental data were fitted using the theoretical expression of the magnetic susceptibility [Equation (2)] which was deduced from spin the Hamiltonian: In Equation (2), the value of $N\alpha$ is 180×10^{-6}.

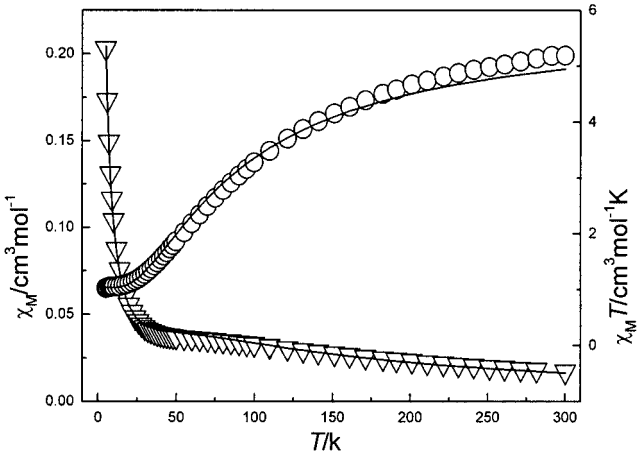

Figure 5. Experimental and calculated variations of the product χ_M and $\chi_M T$ versus T for **2**

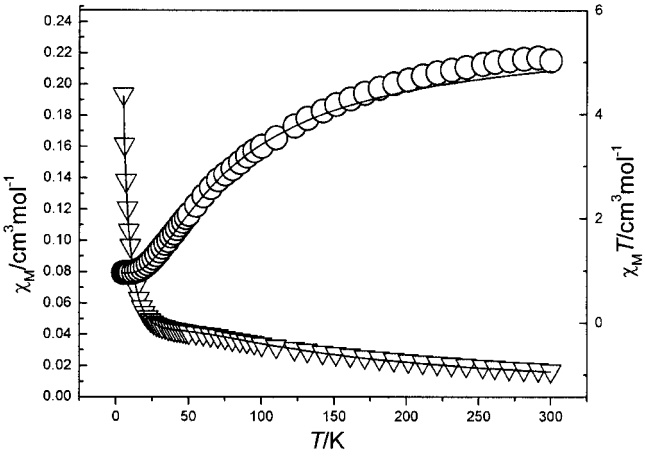

Figure 6. Experimental and calculated variations of the product χ_M and $\chi_M T$ versus T for **3**

The best fit of the data was obtained with the following parameters $J = -14.63\ cm^{-1}$, $g_{Cu} = 2.06$, $g_{Mn} = 1.99$ and $R = 1.05\times10^{-3}$ for complex **2** and $J = -12.22 cm^{-1}$, $g_{Cu} = 2.06$, $g_{Mn} = 1.98$ and $R = 1.20\times10^{-4}$ for complex **3**. The J values of 2 and 3 are in the range of other reported complexes[16,24] with similar structures.

If we compare the J value of complex **1** with those of complexes **2** and **3**, we see that the latter values are lower than the former. The difference may be attributed to the following reasons: (i) the M−O distance is larger for Mn (2.17 Å) than for Cu (2.01Å) or (ii) the energies of the 3d orbitals of Mn(II) are higher than the corresponding ones in Cu(II). The two factors lead to less delocalisation of the d electron towards the oxamido bridge in **2** and **3** than in complex 1, therefore decreasing the antiferromagnetic interaction in **2** and **3**.[38]

Conclusion

By using the macrocyclic oxamido-copper complex as a complex ligand and SCN^{-1} or $N(CN)^{-1}$ as auxiliary ligands, three novel oxamide-bridge tetranuclear complexes have been obtained. In all complexes, the Cu atoms lie at the apexes of a triangle with the M atom located in the plane and at the centre of this triangle. All attempts to crystallise these types of complexes without smaller ions such as SCN^{-1} and $N(CN)^{-1}$ have previously been unsuccessful. It has been confirmed that the smaller ions can make the crystals grow easily in the present systems. Furthermore, we analysed the variable temperature magnetic susceptibilities of the three complexes. The results indicate that there are antiferromagnetic interactions between metal ions in the complexes. We are attempting to replace the metal ion in the centre of the triangle with a diamagnetic ion in order to research further the spin frustration.

Experimental Section

Physical Measurements: Elemental analyses (C, H, N) were performed on a Perkin−Elmer 240 analyser. IR spectra were recorded on a Shimadzu IR spectrometer as KBr pellets. Variable-temperature magnetic susceptibilities from 5−300 K were measured on a Quantum Design MPMS-7 SQUID magnetometer. Diamagnetic corrections were made with Pascal's constants for all the constituent atoms. The electronic absorption spectra were recorded on a JASCO V-5700 spectrometer.

Caution! Perchlorate salts are potentially explosive and should only be handled in small quantities only.

All starting materials were obtained from commercial suppliers and were of AR grade and were used without further purification. The mononuclear precursors were synthesised using the methods reported previously.[12,38]

Preparation of the Complexes: All complexes were prepared using the same method which is described in detail here using $[(LCu)Cu(LCuSCN)_2]\cdot H_2O$ (**1**) as an example. Copper perchlorate (0.2 mmol, 0.0730 g) dissolved in methanol (5 mL) was added to a DMF solution (25 mL) of LCu (0.7 mmol, 0.2860 g). An aqueous solution (5 mL) of KSCN (0.3 mmol, 0.030 g) was then added dropwise to this mixture. After heating to reflux for 2 hours, the resultant green solution was cooled and filtered and the filtrate was allowed to stand for one month until deep green crystals suitable for X-ray analysis separated out. Yield 40%. $C_{62}H_{59}Cu_4N_{14}O_7S_2$ (1430.51): calcd. C 52.12, H 3.92, N 13.73; found C 52.08, H 4.10, N 13.85. IR (KBr): $\tilde{\nu}$ = 2065 (C−N), 1675 (C=O), 1599 (C=O), 1557 cm^{-1}.

$[(LCu)Mn(LCuSCN)_2]\cdot 1.38CH_3OH$ (2): This complex was obtained following the procedure described above for $[Cu_4]$ except that Cu perchlorate was substituted with Mn perchlorate. The solution was left undisturbed and well-formed grey crystals were obtained after about a month. The yield was ca. 54%.

IR (KBr): $\tilde{\nu}$ = 2148 (C−N), 1636 (C=O), 1600 (C=N), 1558 cm^{-1}.

X-ray Data Collections and Structure Determinations

Complex 1: A dark green crystal (0.30 × 0.20 × 0.10 mm) was selected and coated with epoxy resin and mounted on a glass fibre for X-ray data collection. Intensity data were colleted on a BRUKER SMART 1000 diffractometer, using Mo-K_α (λ = 0.71073 Å) radiation. The unit cell constants were determined from a least-squares fit of the setting angles for 25 reflections ($1.67° < \theta < 25.03°$). A total of 10522 unique reflections were observed with $I > 2\sigma(I)$ and were used in the calculations.

The structure was solved by direct methods by using SHELXS-97[39] and refined by least-squares procedures. The hydrogen atoms of the water molecules were not added and the other hydrogen atoms were located geometrically and refined isotropically. The final refinement included 811 variable parameters and converged to $R = 0.0750$, $R_w = 0.1612$.

Complexes 2 and 3: The structure determinations of complexes **2** and **3** were similar to that of complex **1**. The grey prism-like crystals of the two complexes, respectively, were used for X-ray data collection. The unit constants were determined from 25 reflections [$1.66° < \theta < 26.44°$ (**2**), $1.63° < \theta < 25.03°$ (**3**)].

A total of 13938 (**2**) and 11901 (**3**) unique reflections were observed with $I > 2\sigma(I)$ and were used in the calculations. The final refinement included 809 variable parameters for complex **2** and 886 for complex **3** and converged to $R = 0.0596$, $R_w = 0.1155$ (**2**) and $R = 0.1017$, $R_w = 0.2061$ (**3**).

The crystallographic data for **1**, **2** and **3** are listed in Table 4.

CCDC-217659 to -217661 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Incorporation of a (Cyclopentadienyl)molybdenum Oxo Complex in MCM-41 and Its Use as a Catalyst for Olefin Epoxidation

Marta Abrantes,[a] Sandra Gago,[b] Anabela A. Valente,[b] Martyn Pillinger,[b] Isabel S. Gonçalves,*[b] Teresa M. Santos,[b] João Rocha,[b] and Carlos C. Romão*[a]

Keywords: Molybdenum / Sandwich complexes / Mesoporous materials / Supported catalysts / Epoxidation

The tricarbonyl complex [(η^5-C_5H_4-COOMe)$Mo(CO)_3Cl$]-was prepared from the reaction of sodium (methoxycarbonyl)-cyclopentadienide, (C_5H_4-CO_2Me)Na, with (Bu_4N)[Mo-$(CO)_5I$]. Heating the ester with 3-(triethoxysilyl)propylamine gave the amide derivative {[η^5-C_5H_4-CONH-$C_3H_6Si(OEt)_3$]-$Mo(CO)_3Cl$}. The functionalised tricarbonyl complex was immobilised in the ordered mesoporous silica MCM-41 with a loading of 13 wt.-% Mo (1.4 mmol·g^{-1}) by carrying out a grafting reaction in dichloromethane. Powder X-ray diffraction and nitrogen adsorption–desorption analysis indicated that the structural integrity of the support was preserved during the grafting and that the channels remained accessible, despite significant reductions in surface area, pore volume and pore size. The success of the coupling reaction was confirmed by ^{29}Si and ^{13}C (CP) MAS NMR spectroscopy. A supported dioxo complex of the type [(η^5-C_5H_4R)MoO_2Cl] was subsequently prepared by oxidative decarbonylation of the tethered tricarbonyl complex using *tert*-butyl hydroperoxide (TBHP). The oxidised material is an active catalyst for the liquid phase epoxidation of cyclooctene with TBHP as the oxygen source. Similar catalytic results were obtained using the tethered tricarbonyl complex directly as a pre-catalyst since fast oxidative decarbonylation occurs under the reaction conditions used. For both systems, the desired epoxide was the only product and the initial activities were about 13 mol·mol^{-1}_{Mo}·h^{-1}. The solid catalysts were recycled several times. Some activity was lost between the first and second runs but thereafter tended to stabilise.

Introduction

Molybdenum(VI) complexes are versatile catalysts for the oxidation of organic compounds.[1] The most significant reaction in industry is the epoxidation of propylene to propylene oxide by alkyl hydroperoxides, catalysed with high activity and selectivity by soluble Mo^{VI} compounds.[2] In recent years, complexes of the type [$MoO(O_2)_2(L_1)(L_2)$] and [$MoO_2X_2(L_1)(L_2)$] (X = Cl, Br, CH_3) with different combinations of base ligands L_1 and L_2 have been extensively investigated as catalysts for epoxidation reactions, usually employing *tert*-butyl hydroperoxide (TBHP) as the monooxygen source.[3,4] In contrast, cyclopentadienyl oxo complexes of the type [(η^5-C_5R_5)MoO_2Cl], which are isoelectronic with the [$MoO_2X_2(L_1)(L_2)$] complexes, have been less well studied, even though it was reported in 1991 that the pentamethylcyclopentadienyl complex [Cp*MoO_2Cl] is able to catalyse the olefin epoxidation reaction with TBHP.[5] The lack of a convenient synthesis of [(η^5-C_5R_5)MoO_2X] complexes is one reason why their catalytic potential has not been studied in more detail. However, some of us recently reported a simple entry to (η^5-C_5R_5)chlorodioxomolybdenum(VI) complexes (R = H, CH_3, CH_2Ph) based on the oxidative decarbonylation of the readily available [(η^5-C_5R_5)$Mo(CO)_3Cl$] precursors with TBHP.[6] It was found that the dioxomolybdenum(VI) complexes catalyse the epoxidation of cyclooctene, styrene and 1-octene with TBHP as the oxidising agent. Turnover frequencies (TOF) of up to 21000 mol·mol^{-1}_{Mo}·h^{-1} were found and these even surpass that of the well-known CH_3ReO_3/H_2O_2 system. Preliminary results also indicated that the parent tricarbonyl complexes can be applied directly as catalyst precursors in the olefin epoxidation, without isolation of the dioxo complexes prior to use.

Despite the good results obtained for oxomolybdenum(VI) complexes in homogeneous catalysis, increasing attention is being focussed on studying and developing heterogeneous catalysts since these can be easily separated from a reaction mixture and recycled and this is of significant industrial interest.[7] One approach is to link metal complexes to inorganic oxides by way of Lewis base ligands functionalised with alkylalkoxysilanes. For example, Thiel and co-workers prepared covalently anchored complexes of the type [$MoO(O_2)_2$(L−L)] using the mesoporous silica

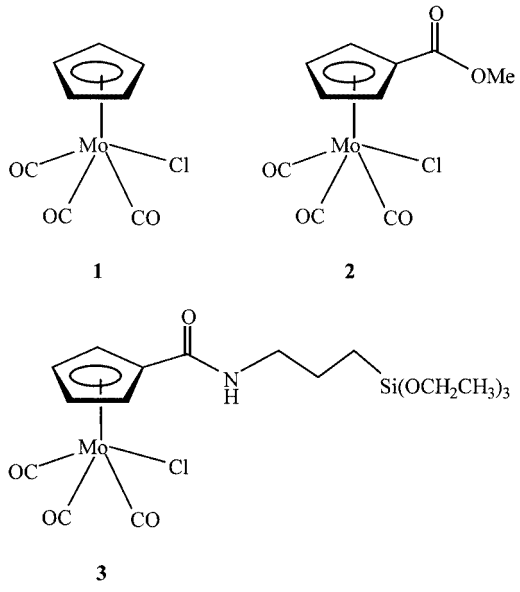
MCM-41 derivatised with a bidentate pyrazolylpyridine ligand.[8] The hybrid system was highly active and truly heterogeneous for the liquid-phase epoxidation of cyclooctene with TBHP as the oxygen source. Molybdenum(VI) complexes of the type $[MoO_2Cl_2(L_1)(L_2)]$ have also been immobilised in MCM-41 derivatised with monodentate nitrile and bidentate bipyridyl ligands.[9] Unfortunately, these catalysts proved to be unstable towards molybdenum leaching which accounted for nearly complete loss of activity in a second reaction cycle. Better results were obtained using 1,4-diazabutadiene ligands covalently linked to the support, although significant catalytic activity was still lost between the first and second runs.[10] In order to obtain more stable catalysts, it would be preferable if the oxomolybdenum fragment was covalently linked to the support, rather than relying on an interaction between the metal centre and a Lewis base ligand. In the present work we set out to prepare an immobilised $[(\eta^5\text{-}C_5R_5)MoO_2Cl]$ complex by oxidative decarbonylation of a monosubstituted $[(\eta^5\text{-}C_5H_4R)Mo(CO)_3Cl]$ precursor covalently anchored to MCM-41. The resultant material has been examined as a catalyst for the epoxidation of olefins using TBHP.

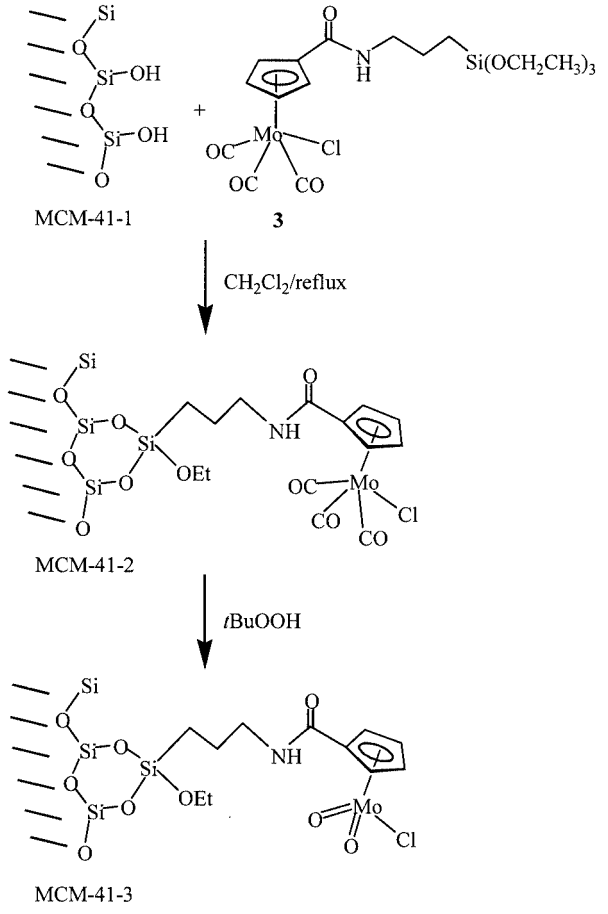
Results and Discussion

Synthesis and Characterisation

The tricarbonyl complex $[(\eta^5\text{-}C_5H_4\text{-}COOMe)Mo(CO)_3Cl]$ (**2**) was prepared from the reaction of sodium (methoxycarbonyl)cylopentadienide, $(C_5H_4\text{-}COOMe)Na$, with $(Bu_4N)[Mo(CO)_5I]$ in THF at reflux. Compound **2** is air sensitive and very insoluble in noncoordinating solvents. As expected, the IR spectrum (KBr) of **2** showed three strong terminal carbonyl absorptions (at 2056, 1990 and 1973 cm^{-1}) and a strong organic carbonyl absorption at 1725 cm^{-1}. For comparison, $[CpMo(CO)_3Cl]$ (**1**) in CCl_4 exhibits three ν_{CO} bands at 2056, 1986 and 1962 cm^{-1}.[11] The ^1H NMR spectrum of **2** contains a pair of pseudo triplets (A_2B_2 pattern) at $\delta = 5.72$ and 6.03 ppm for the cyclopentadienyl protons $H^{3,4}$ and $H^{2,5}$, respectively. A singlet was also observed at $\delta = 3.83$ ppm for the methoxycarbonyl protons ($-OCH_3$). Heating the ester **2** with 3-(triethoxysilyl)propylamine at 120 °C for 3 hours gave the amide derivative $\{[\eta^5\text{-}C_5H_4\text{-}CONH\text{-}C_3H_6Si(OEt)_3]Mo(CO)_3Cl\}$ (**3**) as an oil which was dried under vacuum and used without further purification. A similar method was used by Jia et al. to functionalise a pyrazolylpyridine ligand with (triethoxysilyl)propyl groups.[8] The presence of the amide functional group in **3** was indicated by the IR spectrum which showed the absence of the peak at 1725 cm^{-1} from the starting material and new bands at 3298 (ν_{NH}), 1617 and 1577 cm^{-1} (NHCO). The last two frequencies are similar to those reported for $[(\eta^5\text{-}C_5H_4\text{-}CONH\text{-}R)W(CO)_3CH_3]$ (1641 and 1554 cm^{-1}) and $[(\eta^5\text{-}C_5H_4\text{-}CONH\text{-}R)W(CO)_3I]$ (1642 and 1556 cm^{-1}).[12] Further evidence for the success of the reaction was provided by the ^{13}C spectrum of **3** which contained a weak resonance at $\delta = 163.2$ ppm which was assigned to the carbon atoms of the CONH groups.



Treatment of calcined and dehydrated MCM-41 (MCM-41-1) with a solution of the triethoxysilane compound **3** in dichloromethane at reflux gave the modified material MCM-41-2 containing 13 wt.-% Mo ($1.4\ mmol \cdot g^{-1}$) (Scheme 1). If the surface area is taken as $500\ m^2 \cdot g^{-1}$ (see below), the metal content corresponds to a surface coverage



Scheme 1

of about 1.7 Mo atom per nm^2. This value is similar to experimentally determined values for the concentration of free silanol groups on the surface of pristine MCM-41.[13] Direct evidence for the incorporation of the covalently linked organic system in MCM-41-2 was obtained by recording ^{29}Si MAS NMR spectra (Figure 1). The ^{29}Si MAS NMR spectrum of the parent support MCM-41-1 exhibits two broad resonances at $\delta = -109.9$ and -102.4 ppm, assigned to the species Q^4 and Q^3 of the silica framework, respectively, [$Q^n = Si(OSi)_n(OH)_{4-n}$]. The ^{29}Si CP MAS NMR spectrum shows a marked increase in the relative intensity of the Q^3 peak, confirming that these silicon centres are attached to hydroxy groups. A weak resonance is also present at about -91 ppm corresponding to the Q^2 species. For the grafted material MCM-41-2, both the ^{29}Si MAS and CP MAS NMR spectra clearly show the diminished relative intensity of the Q^2 and Q^3 peaks, indicating the esterification of the isolated silanol groups (single and geminal) by nucleophilic substitution at the silicon atom in the organic ligand. Three additional signals can be observed in the CP MAS spectrum at $\delta = -46.7$, -53.1 and -60.3 ppm, and can be assigned to the T^1, T^2 and T^3 organosilica species, respectively, [$T^m = RSi(OSi)_m(OEt)_{3-m}$]. The presence of residual OEt groups in MCM-41-2 was confirmed by the ^{13}C CP MAS NMR spectrum which contains peaks at $\delta = 23.0$ and 17.6 ppm. Additional peaks were readily assigned to the carbon atoms of the propyl, cyclopentadienyl and CO groups (see Exp. Sect.).

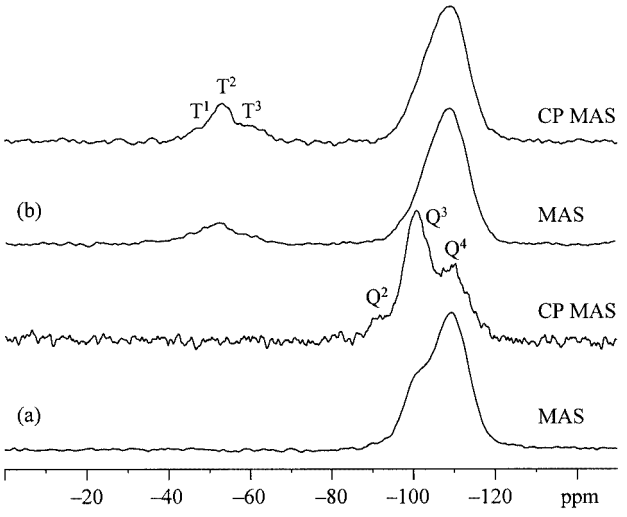

Figure 1. ^{29}Si MAS and CP MAS NMR spectra of (a) MCM-41-1 and (b) MCM-41-Si(OEt)$_n$C$_3$H$_6$NHCOCpMo(CO)$_3$Cl (MCM-41-2)

The powder X-ray diffraction (XRD) pattern of the unmodified MCM-41 sample (MCM-41-1) is typical of a well-ordered mesoporous phase (Figure 2). Several distinct Bragg peaks are present in the range $2\theta = 2-8°$ which can be indexed to different *hkl* reflections for a hexagonal unit cell (using the strongest reflection, d_{100}, $a = 2d_{100}/\sqrt{3} = 41.0$ Å). Upon grafting with **3**, several peaks were still observed indicating retention of the long-range hexagonal symmetry. The significant attenuation of the XRD peak intensities was not interpreted as a loss of crystallinity. Instead, it is likely that there is a reduction in the X-ray scattering contrast between the silica framework and the metal-organic moieties which are located inside the channels of the host.[8b,9b,10a,14] Figure 3 shows the N_2 isotherms of the MCM materials. Unmodified MCM-41 exhibits a reversible type IV adsorption–desorption isotherm, characteristic of a mesoporous solid (pore width between 2 and 50 nm, according to the IUPAC).[15] The values of S_{BET} and V_p are listed in Table 1. A sharp step in the capillary condensation in the primary mesopores can be observed at a relative

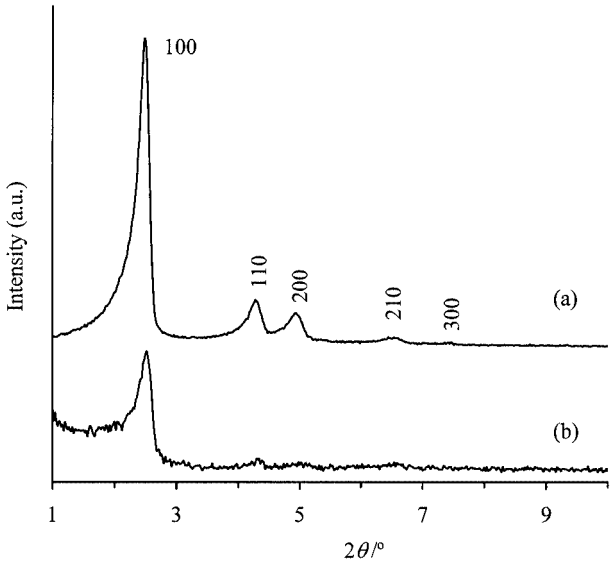

Figure 2. Powder XRD patterns of (a) MCM-41-1 and (b) MCM-41-Si(OEt)$_n$C$_3$H$_6$NHCOCpMo(CO)$_3$Cl (MCM-41-2). The relative intensities for MCM-41-2 have been multiplied by five with respect to those for MCM-41-1

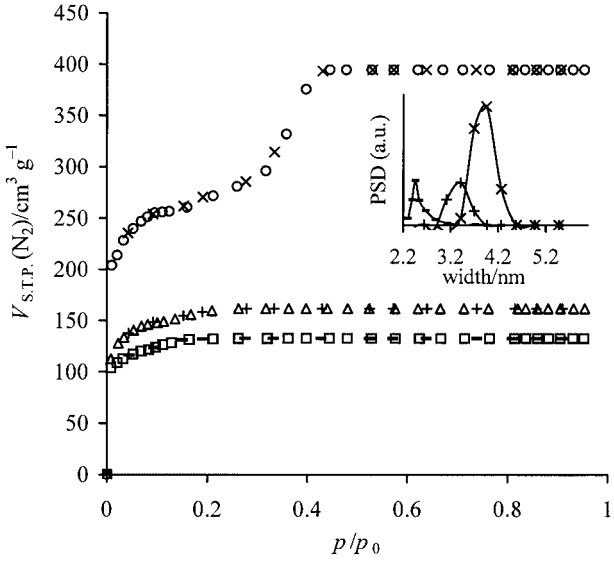

Figure 3. N_2 adsorption (circles: MCM-41-1; squares: MCM-41-2; triangles: MCM-41-3) and desorption (×: MCM-41-1; –: MCM-41-2; +: MCM-41-3) isotherms at 77 K and pore size distribution profiles (inset) of MCM-41-1 (×), MCM-41-2 (–) and MCM-41-3 (+)

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

pressure of ca. 0.3, indicating a narrow pore size distribution. The adsorption isotherm is flat in the high-pressure region ($p/p_0 > 0.6$) which shows that the material has a low external surface area and insignificant secondary mesoporosity. After modification in the preparation of MCM-41-2, S_{BET} and V_p decreased significantly, suggesting that grafting of the bulky complex on the internal silica surface was accomplished (Figure 3, Table 1). This conclusion is also supported by the decrease in the p/p_0 coordinates of the inflection points of the isotherms upon the post-synthesis treatment.[16] The capillary condensation step becomes less pronounced, suggesting that the pore size distribution of the MCM-41 support was partly affected by the modification. The maximum of the PSD curve for MCM-41 determined by the BJH method, d_{BJH}, decreased by 36% after the tethering procedure.

Table 1. Texture parameters of MCM-41 samples from N_2 isotherms at 77 K

Sample	S_{BET} [$m^2 \cdot g^{-1}$]	ΔS_{BET}[a] (%)	V_P [$cm^3 \cdot g^{-1}$]	ΔV_P[b] (%)	d_{BJH} [nm]

Oxidative decarbonylation of the supported metal complex in MCM-41-2 was carried out by treatment of the material with an excess of TBHP (Scheme 1). During the reaction, the material changed colour from brown to pale yellowish-brown. The product, designated as MCM-41-3, was isolated by filtration and the excess TBHP removed by washing with dichloromethane. The presence of an MoO_2 unit in MCM-41-3 was indicated by the IR spectrum which showed two bands for the symmetric (943 cm^{-1}) and asymmetric (911 cm^{-1}) Mo=O stretching vibrations. For comparison, the corresponding stretching frequencies for the complexes (η^5-C_5R_5)chlorodioxomolybdenum(VI) (R = H, CH_3, CH_2Ph) are located at ca. 920/890 cm^{-1} (ν_{sym}/ν_{asym}).[6] In the Raman spectrum of MCM-41-3, bands were observed at 358 and 266 cm^{-1} which can be attributed to symmetric Mo−Cp stretching and MoO_2 wagging modes, respectively (cf. 328 and 261 cm^{-1} for [$CpMoO_2Cl$][6]). The reaction of MCM-41-2 with TBHP was accompanied by some metal leaching, as evidenced by a decrease in the molybdenum content from 13 to 9 wt.-% and a slight increase in the values of S_{BET} and V_p (Figure 3, Table 1).

Catalytic Olefin Epoxidation

The modified materials MCM-41-2 and MCM-41-3 were tested as catalysts or catalyst precursors for the liquid phase epoxidation of cyclooctene with TBHP at 55 °C (Figure 4, Table 2). For comparison, the tricarbonyl complexes **1**−**3** were also tested as homogeneous pre-catalysts for the same reaction. Cyclooctene conversion in the absence of a catalyst or in the presence of the parent MCM-41 sample was negligible after 6 h and the catalytic activity exhibited by the modified mesoporous materials and the tricarbonyl complexes can therefore be attributed to active species containing molybdenum. For all systems, cyclooctene oxide was the only observed reaction product. The kinetic profiles for MCM-41-2 and MCM-41-3 were quite similar (Figure 4). Initially, the reaction is fast but it then slows down somewhat and conversion after 24 hours is far from quantitative (< 63%). Similar kinetic profiles have been reported for complexes belonging to the [$MoO_2X_2(L_1)(L_2)$] family, in which case an auto retardation effect can be observed due to the formation of *tert*-butyl alcohol, a competitive inhibitor for the attack of TBHP at the molybdenum centre.[4e] The initial activity of epoxidation using MCM-41-2, expressed as initial rate per unit weight of solid, is higher than that for MCM-41-3 (Table 2, values in brackets). However, when the initial activities are expressed as initial rate per mol of MCM-41-supported Mo species, the values are practically the same for both samples since MCM-41-2 (13 wt.-% Mo) possesses a higher Mo loading than MCM-41-3 (9 wt.-% Mo). This suggests that the in-situ oxidative decarbonylation of MCM-41-2 by TBHP is fast and probably gives rise to the same type of active metal species present in MCM-41-3 under the catalytic conditions.

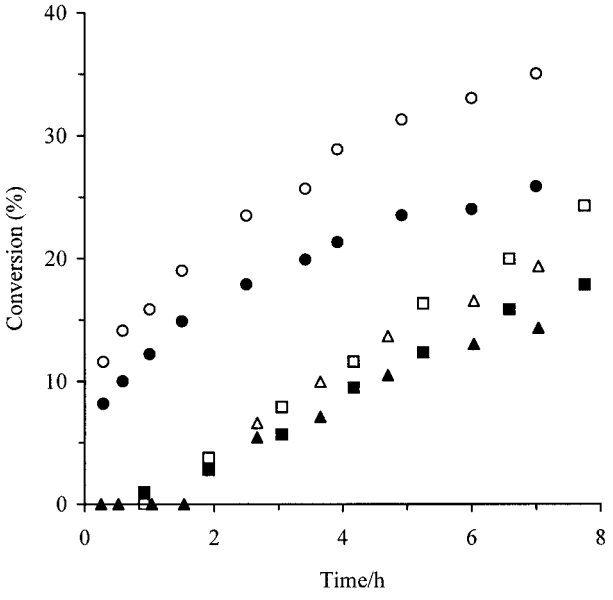

Figure 4. Conversion profiles for the epoxidation of cyclooctene with TBHP at 55 °C using MCM-41-2 (open symbols) or MCM-41-3 (solid symbols): run 1 (circles); run 2 (squares); run 3 (triangles)

The kinetic profile for the homogeneous reaction using the pre-catalyst **3** was similar to that observed using the modified MCM materials (Figure 5). In fact, the initial activities are almost identical (12−13 $mol \cdot mol_{Mo}^{-1} \cdot h^{-1}$). Considerably higher activities were obtained using the tricarbonyl complexes **1** and **2** as precatalysts, particularly in the

[a] Turnover frequency calculated at ca. 18 min. [b] Cyclooctene conversion after 24 h. [c] The values in parentheses are the initial activities expressed per unit weight of catalyst (mmol g_{cat}^{-1}·h^{-1}). [d] An induction period was observed.

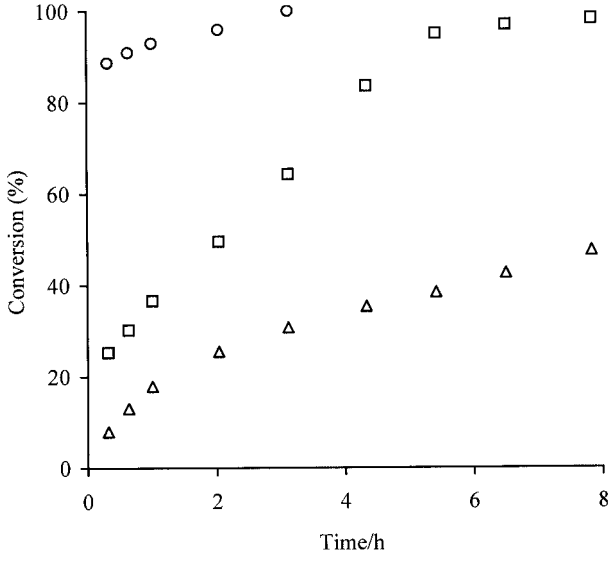

Figure 5. Conversion profiles for the epoxidation of cyclooctene with TBHP at 55 °C using complexes **1** (circles), **2** (squares) and **3** (triangles)

case of the unsubstituted cyclopentadienyl complex (turnover frequency = 140 mol·mol$_{Mo}^{-1}$·h^{-1}). No induction periods were observed using the tricarbonyl complexes **1**−**3** directly, suggesting that the conversion into the corresponding dioxo complexes is quite fast under the applied reaction conditions. Previous studies have shown that the epoxidation of cyclooctene in a homogeneous phase proceeds at practically the same rate in the presence of $CpMo(CO)_3Cl$ or the corresponding $CpMoO_2Cl$ complex and that catalyst/cyclooctene molar ratios as small as 1:10000 give turnover frequencies as high as 21000 mol·mol$_{Mo}^{-1}$·h^{-1} {for [(η^5-C_5Bz_5)MoO_2Cl]}.[6] In the presence of complex **3**, the epoxidation reaction is much slower probably due to the pendant triethoxysilyl groups which may lead to the formation of less reactive dimers/oligomers.

The stabilities of the modified materials MCM-41-2 and MCM-41-3 were studied by recycling the recovered solids twice. Before each reuse, the solid was separated from the reaction solution, thoroughly washed with dichloromethane and dried at room temperature. Some loss of catalytic activity was observed for both samples from the first to the second run but afterwards the activity tended to remain constant (Table 2, Figure 4). After the first run the catalytic results obtained with the two materials were quite similar, suggesting that the materials become much alike after the first run. As mentioned above, the synthesis of MCM-41-3 by treatment of MCM-41-2 with excess TBHP was accompanied by some metal leaching. Hence, one would expect the same to occur when using MCM-41-2 directly under the oxidising catalytic conditions. Indeed, the molybdenum loading after the first run was ca. 83% of the original value which may partly explain the observed catalyst deactivation. In the case of MCM-41-3, no measurable metal leaching occurred during the first run but a significant decrease in activity was nevertheless observed. Both catalyst systems exhibit induction periods of nearly 90 min for the second and third runs, leading to TOFs (calculated for ca. 2.5 h of the third reaction cycle) of 2.5 and 2.0 mol·mol$_{Mo}^{-1}$·h^{-1} for MCM-41-2 and MCM-41-3, respectively. According to studies by Trost and Bergman,[5] the (pentamethyl)cyclopentadienyl analogue [Cp*MoO_2Cl] can react with TBHP to give the peroxo complex [Cp*$MoO(O_2)Cl$] which is inactive as a catalyst for olefin epoxidation.[5] We suspect, therefore, that another reason for the loss of activity between the first and second runs for the systems initially containing MCM-41-2 and MCM-41-3 is because of the formation of supported peroxo complexes. Leaching tests were performed for MCM-41-3 by removing the catalyst from the reaction mixture by hot filtration after 20 minutes. The filtrate was then allowed to react for a further 340 minutes. The conversion of cyclooctene increased by 7%, whereas with the catalyst it increased by 21%. These results suggest that epoxidation in the presence of MCM-41-3 (for the first run) is, to a certain extent, homogeneously catalysed by leached molybdenum species. However, since a sintered glass filter was used it is possible that small catalyst particles were not completely separated by this porous media and that MCM-41-3 is a truly heterogeneous catalyst.[17]

The modified materials MCM-41-2 and MCM-41-3 were tested for the epoxidation of other olefins, namely cyclododecene, *trans*-2-octene and 1-octene. Olefin conversion after 24 hours decreases in the following order for both materials: cyclooctene > cyclododecene > *trans*-2-octene > 1-octene (Figure 6). In the case of *trans*-2-octene the corresponding epoxide is the only product at less than 10% conversion. When the substrate is 1-octene, an unsubstituted and much less reactive olefin, conversion is negligible (< 1%). In the case of cyclododecene, a more bulky substrate, the reaction proceeds to 34−38% conversion after 24 h and the epoxide is the main product, while the corresponding diol is a secondary reaction product obtained in less than 5% yield.

Conclusions

A method has been presented for the immobilisation of a monosubstituted cyclopentadienyltricarbonylchloro molybdenum complex in mesoporous silica. The material can be used as a pre-catalyst for the reaction of *tert*-butyl hydroperoxide and cyclooctene to yield the corresponding epoxide. Upon recycling, some activity is lost between the first and second runs but thereafter it tends to remain constant. According to the leaching test carried out for MCM-41-3, it is possible that epoxidation (in the first run) also occurs in a homogeneous phase. Although the selectivity to the epoxide is very high, the activities are moderate paralleling that observed for the precursor complex (containing the triethoxysilyl group) in a homogeneous phase. We have also noted in this work that the methoxycarbonyl-substituted complex [(η^5-C_5H_4-COOMe)$Mo(CO)_3Cl$] can be used as a pre-catalyst for the olefin epoxidation reaction but the observed activity is much lower than that obtained when the unsubstituted [$CpMo(CO)_3Cl$] is used. These results indicate that a more effectively supported catalyst might be possible by preparing a precursor complex of the type [(η^5-C_5R_5)$Mo(CO)_3X$] where the ligand X terminates in a trialkoxylsilyl group.

Experimental Section

Materials and Methods: All preparations and manipulations were performed using standard Schlenk techniques under oxygen-free and water-free nitrogen. Solvents were dried by standard procedures (THF, *n*-hexane and Et_2O over Na/benzophenone ketyl; CH_2Cl_2 and NCMe over CaH_2), distilled under nitrogen and used immediately (THF) or kept over 4-Å molecular sieves (3-Å for NCMe). Microanalyses for C, H, N were performed at the ITQB (C. Almeida) and Mo was determined by ICP-AES at the Central Laboratory for Analysis, University of Aveiro (E. Soares). Room-temperature powder XRD data were collected with a Philips X'pert diffractometer with a curved graphite monochromator (Cu-K_α radiation) in a Bragg−Brentano para-focusing optics configuration. Samples were step-scanned in 0.02 °2θ steps with a counting time of 2 s per step. The values of the BET specific surface area (S_{BET}, determined in the p/p_0 range 0.03−0.13) and specific total pore volume, V_p, were estimated from N_2 adsorption isotherms measured at 77 K, as described previously.[18] The pore size distributions (PSD) were calculated by the BJH method using the modified Kelvin equation with a correction for the statistical film thickness on the pore walls.[19] The statistical film thickness was calculated using the Harkins-Jura equation in the p/p_0 range 0.1−0.95. IR spectra were measured with a Mattson 7000 FT-IR spectrometer using KBr pellets. Raman spectra were recorded with a Bruker RFS100/S FT instrument (Nd:YAG laser, 1064 nm excitation, InGaAs detector). NMR spectra in solution were recorded with Bruker CXP-300 (^1H) and Bruker AMX-300 (^{13}C) spectrometers. Room temperature ^{29}Si and ^{13}C solid state NMR spectra were recorded at 79.49 and 100.62 MHz, respectively, with a Bruker Avance 400P spectrometer. ^{29}Si MAS NMR spectra were recorded with 40° pulses, spinning rates of 5.0−5.5 kHz and 60 s recycle delays. ^{29}Si CP MAS NMR spectra were recorded with 5.5 μs ^1H 90° pulses, 8 ms contact time, a spinning rate of 5 kHz and 4 s recycle delays. ^{13}C CP MAS NMR spectra were acquired with a 3.5 μs 90° proton pulse and 2 ms contact time with spinning rates of 7−8.5 kHz and 4 s recycle delays. ^{13}C spectra were also recorded in the solid state at 125.76 MHz with a Bruker Avance 500 spectrometer. Chemical shifts are quoted in ppm relative to TMS.

The liquid-phase oxidation of a variety of olefins was carried out at 55 °C under air (atmospheric pressure) in a micro reaction vessel equipped with a magnetic stirrer which was loaded with complex (0.036 mmol) or MCM-catalyst (43.8 mg), olefin (1.8 mmol) and TBHP (2.8 mmol, 5.5 M in decane). Samples were withdrawn periodically and analysed using a gas chromatograph (Varian 3800) equipped with a capillary column (SPB-5, 20 m × 0.25 mm × 0.25 μm) and a flame ionization detector. Undecane was used as an internal standard added after the reaction.

Published procedures were used to prepare the compounds (C_5H_4-COOMe)Na,[20] (Bu_4N)[$Mo(CO)_5I$][21] and [$CpMo(CO)_3Cl$] (**1**).[6] Pure siliceous MCM-41 (MCM-41-1) was synthesised hydrothermally at 100 °C under basic conditions using [($C_{14}H_{29}$)NMe_3]Br as the templating agent and sodium silicate solution as the silica source.[9b] The calcined product (540 °C/6 h) was dehydrated prior to use by heating at 180 °C for 2 h under vacuum.

[(η^5-C_5H_4-COOMe)$Mo(CO)_3Cl$] (2): A solution of (Bu_4N)[$Mo(CO)_5I$] (0.96 g, 1.60 mmol) in THF (20 mL) was mixed with a solution of (C_5H_4-COOMe)Na (0.28 g, 1.9 mmol) in THF (20 mL) and heated to reflux overnight (18 h). The THF was removed from the resultant yellow-brown solution affording an oily residue. Diethyl ether (20 mL), distilled water (20 mL) and acetic acid (0.1 mL) were then added and, after stirring for 20 min, CCl_4 (5 mL) was added and the colour of the emulsion turned red. The mixture was stirred for a further 20 min. The ether phase was then separated and the remaining aqueous phase extracted five times with 20 mL aliquots of diethyl ether. After evaporation of the solvent from the combined ether extracts a red residue was obtained. This was redissolved in acetone (20 mL) and activated charcoal and anhydrous Na_2SO_4 were added. After stirring for 30 min the mixture was filtered. Evaporation of the red filtrate gave an orange solid which was thoroughly washed with water and cold hexane. Yield: 0.22 g, 41%. Selected IR (KBr): $\tilde{\nu}$ = 3114 (m), 2958 (m), 2056 (vs, ν_{CO}), 1990 (vs, ν_{CO}), 1973 (vs, ν_{CO}), 1725 (s, ν_{CO}), 1476 (m), 1434 (m), 1372 (m), 1283 (s), 1194 (m), 1144 (s), 961 (m), 772 (m), 557 (m), 525 (m), 469 (m) cm^{-1}. ^1H NMR (300 MHz, $CDCl_3$, 25 °C, TMS):

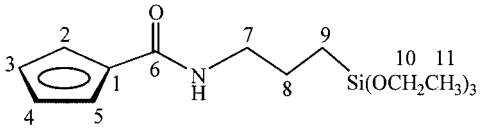
{[η^5-C_5H_4-CONH-$C_3H_6Si(OEt)_3$]Mo(CO)$_3$Cl} (3): One equivalent of 3-triethoxysilylpropylamine was added to [(η^5-C_5H_4-COOMe)-Mo(CO)$_3$Cl] (**2**) (2.27 g, 6.7 mmol) and the mixture stirred at 120 °C for 3 h. After this, low boiling volatiles were removed in vacuo at 50 °C. The resultant brown oil was used without further purification. Selected IR (neat): $\tilde{\nu}$ = 3298 (sh, ν_{NH}), 3108 (w), 2975 (m), 2928 (m), 2886 (m), 2044 (vs, ν_{CO}), 1965 (vs, ν_{CO}), 1926 (vs), 1617 (m, CONH), 1577 (m, CONH), 1470 (m), 1443 (m), 1390 (m), 1280 (m), 1237 (w), 1102 (s), 1077 (s), 958 (s), 786 (vs), 596 (m), 540 (m) cm^{-1}. ^{13}C NMR (75.5 MHz, $CDCl_3$, 25 °C, TMS): δ = 13.8 (C^9), 18.4 (C^{11}), 24.3 (C^8), 46.6 (C^7), 59.4 (C^{10}), 94.9 (C^{1-5}), 95.1, 97.3, 163.2 (C^6), 218 (CO) ppm.



MCM-41-2: A solution of {[η^5-C_5H_4-CONH-$C_3H_6Si(OEt)_3$]Mo-(CO)$_3$Cl} (**3**) (5.0 mmol) in CH_2Cl_2 (10 mL) was added to a suspension of MCM-41-1 (2 g) in toluene (15 mL) and the mixture stirred under reflux for 44 h. The suspension was filtered and the brown powder washed several times with CH_2Cl_2, before drying under vacuum at 40 °C. Selected IR (KBr): $\tilde{\nu}$ = 3419 (br), 3246 (sh, ν_{NH}), 2982 (m), 2939 (sh), 1979 (w, ν_{CO}), 1624 (m, CONH), 1484 (m), 1444 (m), 1393 (m), 1237 (s), 1082 (vs), 954 (br), 797 (s), 564 (br), 454 (vs) cm^{-1}. ^{13}C CP MAS NMR: δ = 8.4 (C^9), 17.6 (C^{11}), 23.0 (C^8), 42.6 (C^7), 58.3 (C^{10}), 86.3 (br., C^{1-5}), 166.7 (C^6) ppm. Elemental analysis found C 16.63, H 3.23, N 1.97, Mo 13.0.

MCM-41-3: MCM-41-2 (0.3 g) was suspended in CH_2Cl_2 (10 mL). Under continuous magnetic stirring, *tert*-butyl hydroperoxide solution (4.1 mmol, 5.0−6.0 M in *n*-decane, 10 equiv.) was added dropwise and the mixture stirred at room temperature for 4 h. The resultant light brown powder was filtered, washed several times with CH_2Cl_2 and dried under vacuum at room temperature. Selected IR (KBr): $\tilde{\nu}$ = 3431 (br), 3262 (sh, ν_{NH}), 2982 (w), 2938 (sh), 1629 (m, CONH), 1508 (w), 1469 (w), 1445 (w), 1384 (w), 1364 (w), 1237 (vs), 1080 (vs), 943 (m, ν_{sym} Mo=O), 911 (m, ν_{asym} Mo=O), 799 (m), 739 (sh), 568 (w), 454 (vs) cm^{-1}. Selected Raman: 2962, 2932, 2895, 1590, 1455, 1321, 1045, 967, 942, 915, 358, 266 cm^{-1}. Elemental analysis found C 11.9, H 2.80, N 1.96, Mo 9.0.

Acknowledgments

The authors are grateful to FCT, POCTI and FEDER for financial support (including Project POCTI//QUI/37990/2001 and a Ph.D. grant to M. A.). S. G. thanks the University of Aveiro for a research grant. Paula Esculcas is acknowledged for assistance with the NMR experiments.

1. General Information

The *European Journal of Inorganic Chemistry* (*EurJIC*) is published twice monthly.

Manuscripts should be submitted online using our online submission service at http://webeos.wiley-vch.de/osm/jsp/osm.jsp. You should prepare a **single file containing all tables, graphics, supporting information (where appropriate) etc.** Acceptable file formats are **Microsoft Word, Rich Text Format, Postscript and PDF**. Avoid the use of page breaks even between the title page and the introduction, and try to fit as many graphics as possible onto a single page if they are not inserted into the correct position in the text. The file should have margins of 2 cm and be 1.5-line spaced.

Authors can follow the progress of their manuscript on their **personal homepage**, which is created automatically upon initial registration. This homepage is the same for the family of Wiley-VCH European journals and can be used to **store all versions of a submitted paper** and to **upload the revised manuscript after acceptance**. Your referee reports for the family of Wiley-VCH European journals are also archived here.

No paper copies of the manuscript are required when using this system.

- The author must inform the editor of all manuscripts submitted, soon to be submitted, or in press at other journals that have a bearing on the manuscript being submitted.
- The correspondence author of a Microreview will receive a complimentary copy of the journal along with a PDF file of his/her paper restricted to 50 printouts; the correspondence author of other articles will receive a PDF file restricted to 25 printouts. Colour figures can be reproduced. Unless essential for the understanding of a paper, authors will be requested to make a contribution towards the costs of colour reproduction. Details will be provided after acceptance of the manuscript.
- We encourage authors to submit pictures for the cover page.

IMPORTANT: Any manuscript already available on personal/group web pages will be considered by the editors as already published and will not be accepted.

2. Types of Contributions

EurJIC publishes articles on synthetic organic chemistry, bioorganic chemistry and physical organic chemistry. All contributions undergo peer review. An author may appeal against the decision on his/her manuscript, in writing. Three types of contributions are accepted for publication:

- **Full Papers** are articles with an Experimental Section that describe a significant contribution to the development of an area of research of importance. There are no restrictions placed on the length of a Full Paper.
- **Short Communications** are brief reports on results of high significance and urgency. Generally, they are no longer than 12−16 double-spaced pages or 3−4 typeset pages. An Experimental Section (as a separate paragraph or as part of the references) is desirable; if it is not included in the paper, the experimental data should be submitted as Supplementary Material for refereeing purposes, and marked as such.
- **A Microreview** introduces the reader to a particular area of an author's research through a concise overview of a selected topic. As a rule, Microreviews are written on invitation, although unsolicited articles are also welcome. It is recommended, however, to contact the editor before submitting an unsolicited Microreview. The content should balance scope with depth; it should be a focused review of 25−30 double-spaced pages or 6−8 typeset pages. Reference to important work from others that is significant to the topic should be included. Microreviews will be refereed but will have no Experimental Section.

A modular version of these Guidelines is available as separate PDF files on the internet at http://www.eurjic.org.

3. Document Templates

Document template files have been created to assist authors in preparing manuscripts for the *European Journal of Inorganic Chemistry*. Use of this easy-to-follow tool facilitates manuscript preparation, reduces revision and shortens publication times.

The files **eurjournw97.dot** for PC, **eurjourn.dot** for Mac (Mac Word 6) or **eurjournoffice2001mac.dot** (Mac Word 2001) can be downloaded from our Guidelines on the World Wide Web (http://www.eurjic.org), where more information on their use may be found.

4. Manuscript Preparation

4.1 General

The whole of the manuscript should be 1.5-line spaced and in a large script (Times New Roman, 12 pt). We recommend that you prepare your text with **Microsoft Word (PC or Macintosh versions)** (see Section 4.2). Use the automatic pagination function incorporated in your word processor to number the pages; do not insert page numbers by hand. Leave a 2-cm margin around the perimeter of each page. **The figures, schemes and graphical abstract in the accepted version should be camera-ready**. Consult a current issue of the journal for an overview of the format. A manuscript should comprise: □ Title Page □ Keywords □ Main Text □ Experimental Section □ Acknowledgments (optional) □ Captions □ Tables □ References □ Schemes and Figures □ Graphical Abstract (without text). □ For Microreviews only: Biographical sketch and a portrait-quality photograph.

4.2 Text

The text should be typed with carriage returns (hard returns) only at the end of a paragraph, title, heading, and similar features. Avoid end-of-line word divisions.

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

Use character formatting for italic and bold characters. Avoid any *special style sheets* to format these features. Write *capital letters* using the keyboard (shift + letter key), **not** the format "Capital letter" in Word.

Use only characters from the Symbol and Normal Text character sets, especially when inserting Greek letters and characters with umlauts, accents, tildes, etc.: α, Å, ã, ä, à.

There are three types of hyphens: normal dashes (-), N-dashes (–), and M-dashes (—) on your keyboard. Use these as illustrated — spacing is important too — in the following examples:

well-known reaction	C–H bond
six-membered ring	Tables 2–4
3-position of the ring	carbon–oxygen bond
signal-to-noise ratio	C–N stretch
Mo-K_α	Diels–Alder reaction
1,2-dicyanobutane	structure–activity relationship
p-tert-butylphenol	
(–)-tartaric acid	
$[M^+ - CH_3]$	carried out at −10°C
80–100 mg	cm^{-1}

Use the symbol × where appropriate, rather than the letter x:
... washed with water (2 × 150 mL) ...
Use the double quotation marks "..." rather than „...“, "..." or «...»

Graphics (including structural formulas, schemes, figures, equations, small graphical items that appear in captions, and tables containing graphical items) must be submitted camera-ready on separate sheets after acceptance of the manuscript (see Section 4.5).

The Field, Object, or Formula-Editor commands on the Insert menu should be avoided, consult the table below to create the depicted graphical symbols.

Instead of these graphical symbols	$P\bar{1}$	L_2^{2+}	$\tilde{\nu}$	$[\alpha]_D^{20}$
please use these text alternatives	*P*1bar	$L_2{}^{2+}$	nu(tilde)	$[\alpha]_D{}^{20}$

Lines or **arcs**, for example to indicate ring compounds, cannot be used within the text. Another method for indicating such compounds must be devised. Please contact the Editorial Office if any help is needed.

4.3 Tables

Use the Insert Table command from the Table menu or use the Insert Table button on the Standard toolbar for creating tables. Exception: Tables *containing* embedded graphical items are treated as graphics and will be scanned. Please do not use hard returns or tabs within the cells of a table; instead use a *soft return* (shift + return).

4.4 References

We strongly recommend the use of the Endnotes feature of Word. If you prefer not to use this function, references should be indicated by numbers in square brackets as superscripts and, if applicable, after punctuation (example: text.[1]). Use the Format Font menu. In the case of Endnotes the square brackets are not needed.

The Author is responsible for correct citations. The *European Journal of Inorganic Chemistry* is a member of Cross Ref. (http://www.crossref.org), a service which links reference citations to the online content that those references cite. This can only function if the citations are accurate. Please ensure that only one reference is cited under each reference number. For example:

[1] A. Einstein, A. N. Other, *Eur. J. Inorg. Chem.* **2003**, 1–15.
[2] P. Pat, A. Pandy, *Chem. Eur. J.* **2003**, *7*, 222–229.

rather than:

[1] A. Einstein, A. N. Other, *Eur. J. Inorg. Chem.* **2003**, 1–15; P. Pat, A. Pandy, *Chem. Eur. J.* **2001**, *7*, 222–229.

References subdivided into parts a, b, etc. are, however, acceptable. For example:

[1] [1a] A. Einstein, A. N. Other, *Eur. J. Inorg. Chem.* **2003**, 1–15.
[1b] P. Pat, A. Pandy, *Chem. Eur. J.* **2001**, *7*, 222–229.

4.5 Graphics

Graphics are schemes, figures, equations, small graphical items that appear in captions, and tables containing graphical items. Graphics differ fundamentally from the text portion of your manuscript in that they must be scanned or electronically processed and will appear in the journal exactly as they are submitted. In the revised version please submit **each graphic in its own file** within a graphic folder. The following formats are preferred: *.chm, *.cdr, *.cdx, *.doc, *.wmf (windows metafile), *.pdf, *.pct, *.tif, *.eps. For good reproduction the resolution should be a minimum of 300 dpi. If you wish to embed graphics in Winword, please send us two files only, one containing the text and one containing all graphics.

Consult the following table for the appropriate size of lettering. Lettering smaller than 3.0 mm will reproduce poorly. Use only one size of lettering per graphic, and please use a font like Times (or Times New Roman) which distinguishes between l (small L) as in HCl (hydrochloric acid) and I (capital i) as in HCI (iodocarbene).

Table 1. Guide for preparing graphics

Letter Size	Font	Maximum Graphic Width[a] 1-Column Format	2-Column Format
	Times New Roman		
3.0 mm	12	13 cm	26 cm
3.5 mm	**14**	**15 cm**[b]	–
4.0 mm	**16**	**17 cm**[b]	–
4.5 mm	18	19 cm	–

[a] Most graphics are in 1-column format. [b] We prefer lettering of 3.5 or 4.0 mm with maximum graphic widths of 15 or 17 cm, respectively.

Note that the graphical abstract must be in one-column format. Typically, one-column graphics constructed with ChemDraw should have the following settings: Print Setup: Orientation Portrait. Caption and Label Settings: Font Times New Roman, Font Style Standard, Size 12. **It is not possible to use colour in the Table of Contents**.

These settings help ensure the correct letter-size-to-graphic-width ratio for best reproduction.
Use abbreviations such as R^1, R^2 (not R_2), R′, R″, Ph, Me, Et, *i*Pr, *t*Bu, Ph, Bzl (benzyl), Bz (benzoyl), Hal, L, M (metal, not Me), X (heteroatom).

Attention **Macintosh** users: Please note that we cannot handle Mac-formatted Zip media.

Please note these details regarding the graphics files:
If the formula schemes of your manuscript are prepared with ChemDraw, please **save them as separate files when you come to submit your revised version**. They can then be collected in a single zip file for upload on your personal homepage.

All other graphics (formulae, schemes and figures not prepared with ChemDraw) should be saved separately as a *.doc file (Word) or in a Word-compatible graphics format [e.g., bitmap (*.bmp), windows metafile (*.wmf), pict (*.pct)].

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

6. Crystallographic Data

Authors must deposit the data of X-ray structure analyses in a crystallographic database before submitting their manuscript, so that referees can access the information electronically. The two databases, the Cambridge Crystallographic Data Centre (CCDC) and the Fachinformationszentrum Karlsruhe (FIZ) have the same procedure for the deposition of data and both will be pleased to provide help. In general, you will receive a depository number from the database two working days after electronic deposition. Send your data to the appropriate address below and quote the standard text, including the depository number, in your manuscript.

- **For all compounds without C-H bonds:**

Fachinformationszentrum Karlsruhe (FIZ)
76344 Eggenstein-Leopoldshafen, Germany
Phone: +49-(0)7247/808-205
Fax: +49-(0)7247/808-666;
E-mail: crysdata@fiz-karlsruhe.de
FTP: ftp.fiz-karlsruhe.de (under path /pub/csd)
WWW: http://www.fiz-karlsruhe.de (under "Products and Services ")

Further details of the crystal-structure investigation(s) may be obtained from the Fachinformationszentrum Karlsruhe, 76344 Eggenstein-Leopoldshafen, Germany, on quoting the depository number(s) CSD-....

- **For all compounds with at least one C-H bond:**

Cambridge Crystallographic Data Centre (CCDC)
12 Union Road, Cambridge CB2 1EZ, UK
Phone: +44-(0)1223/336-408
Fax: +44-(0)1223/336-033
E-mail: deposit@ccdc.cam.ac.uk
WWW: http://www.ccdc.cam.ac.uk

CCDC-****** contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Center, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

NOTE: The International Union of Crystallography has set up a free service to check CIF files. This is based on a rich set of experience with such data: "Checkcif" thoroughly examines crystallographic data in the CIF format for completeness and consistency, and performs geometry and symmetry checks to detect possible errors of analysis, such as high residual electron densities. Authors who submit manuscripts with structural analyses (to be deposited with either FIZ or CCDC) are kindly asked to supply the report generated by the checkcif service.

Finally, before you return your revised manuscript, please update your database entry if necessary.

7. Electronic Supporting Information

A manuscript may include Electronic Supporting Information which will be accessible only on the WWW. Authors must keep a copy to make available to readers who do not have access to the internet. As this material [text, tables, schemes, figures **but not crystallographic (CIF) data** which must be submitted to either the FIZ or the CCDC] undergoes the peer review process, it must be included, clearly marked as "Supporting Information to be published electronically", when the paper is submitted. The following file formats are accepted: MS Winword or ASCII (*.doc, *.txt), MS Excel (*.xls), Encapsulated Postscript (*.eps), Portable Document Format (*.pdf), graphics embedded in MS Winword; if you wish to submit other formats, please consult the Editorial Office. When preparing such material, authors should keep in mind that — once accepted — it will be made available as provided by the author and not edited. Material accepted for electronic publication will be available mostly as PDF files (Adobe Acrobat Reader required) by following the Table of Contents link of EurJIC's WWW home page. A standard text will be added on the first page of the article in the printed version:

- Supporting information for this article is available on the WWW under http://www.eurjoc.org or from the author.

The supporting information file must start with the title of the paper, the authors, and the CASSI abbreviation of the journal to which it was submitted (e.g. *Eur. J. Inorg. Chem.*).

8. Basic Keyword List

An interjournal browsing facility has been developed for the readers of the WILEY-VCH journals *Advanced Synthesis and Catalysis, Angewandte Chemie International Edition, Chemistry − A European Journal, European Journal of Inorganic Chemistry, European Journal of Organic Chemistry, Zeitschrift für Anorganische und Allgemeine Chemie*, and the precursor journals *Chemische Berichte, Liebigs Annalen*, and *Journal für Praktische Chemie*. On the Internet you will be able to jump between thematically related contributions by mouse click.
To be able to offer this option on the WWW we have compiled a common keyword catalogue that is printed here and is also available online (http://www.eurjic.org).

To assist you in finding keywords they are listed according to categories. You may choose keywords from any category. As with all such records, a few guidelines facilitate the catalogue's use, and these are briefly explained below:
1. As many as possible, but at least two, of the maximum of five keywords assigned to an article must come from this list.
2. Named reactions will be incorporated only in exceptional cases. Generally the reaction type is selected instead. For example, Diels-Alder reactions will be found under "Cycloadditions" and Claisen rearrangements under "Rearrangements".
3. Heteroanalogues of compounds are mainly classified under the C variants, for example, (hetero)cumulenes, (hetero)dienes. A few aza and phospha derivatives are exceptions.
4. Compounds with inorganic components that are central to the article are listed under the element, for instance, iron complexes under "Iron". Some group names like "Alkali metals" exist alongside the names of important members of the group like "Lithium". In such cases the group name is used for these members only when comparative studies are described. The members not appearing separately are also categorised under the group name.
5. A keyword in the form "N ligand" is only chosen if a considerable portion of the paper deals with the coordination of any ligand ligating through the atom concerned.
6. Spectroscopic methods are assigned as keywords only if the article is about the method itself, or if the spectroscopic technique has made an important contribution to the problem under investigation.
7. "Structure elucidation" is intended only if the crux of the paper is a structural elucidation or if a combination of several spectroscopic techniques were needed for conclusive solution of the structure.
8. An attempt has been made to avoid synonyms and to select more general concepts rather than specialized terms. Thus the term "Double-decker complexes" is excluded in favour of "Sandwich complexes".

This list will be a "living" catalogue to be flexible enough to absorb the new developments in chemistry. We therefore welcome all suggestions from our authors that might improve its user-friendliness.

Coordination Chemistry: Compound Classes

Cage compounds
Chelates
Clathrates
Cluster compounds
Cuprates
Dendrimers
Heterometallic complexes
Metallacycles
Metallocenes
Nitrogen oxides
Polyoxometalates
Sandwich complexes
Ylides

Coordination Chemistry: Ligand Classes

Alkene ligands
Alkyne ligands
Allyl ligands
Arene ligands
As ligands
Bridging ligands
Carbene ligands
Carbonyl ligands
Carboxylate ligands
Carbyne ligands
Cyclopentadienyl ligands
Diene ligands
Dioxygen ligands
Hydride ligands
Isocyanide ligands
Macrocyclic ligands
N ligands
N,O ligands
N,P ligands
O ligands
Oxo ligands
P ligands
Peroxo ligands
Phosphane ligands
P ligands
S ligands
Si ligands
Tridentate ligands
Tripodal ligands
Vinylidene ligands

Coordination Chemistry: Methodology and Reactions

Carbon dioxide fixation
Chemical vapor deposition
Chiral resolution
Crystal engineering
Ligand design
Matrix isolation
Metathesis
Neighboring-group effects
Nitrogen fixation
O-O activation
Oxidation
Radical reactions
Reduction
Ring-opening polymerization
Solvent effects
Solvolysis
Substituent effects
Template synthesis

Coordination Chemistry: Structure

Agostic interactions
Aurophilicity
Charge transfer
Cooperative effects
Coordination modes
Donor-acceptor systems
Electron deficient compounds
Electronic structure
Electrostatic interactions
Fluxionality
Helical structures
Host-guest systems
Hydrogen bonds
Inclusion compounds
Isolobal relationship
Jahn-Teller distortion
Ligand effects
Metal-metal interactions
Multiple bonds
Noncovalent interactions
Pi interactions
Stacking interactions
Structure elucidation
Through-bond interactions
Through-space interactions

Elements and Element Groups

Actinides
Alkali metals
Alkaline earth metals
Aluminum
Antimony
Argon
Arsenic
Barium
Beryllium
Bismuth
Boron
Bromine
Cadmium
Calcium
Carbon
Cerium
Cesium
Chalcogens
Chlorine
Chromium
Cobalt
Copper
Deuterium
Fluorine
Gallium
Germanium
Gold
Group 13 elements
Group 14 elements
Hafnium
Halogens
Helium
Hydrogen
Indium
Iodine
Iridium
Iron
Krypton
Lanthanides
Lanthanum
Lead
Lithium
Magnesium
Manganese
Mercury
Molybdenum
Neon
Nickel
Niobium
Nitrogen
Noble gases
Osmium
Oxygen
Palladium
Phosphorus
Platinum
Pnicogens
Potassium
Rare earths
Rhenium
Rhodium
Rubidium
Ruthenium
Samarium
