by means of Equation (1),[8] in which Φ and τ are the emission quantum yield (0.073) and lifetime (1.9 ns) of the donor **ZnU**, respectively, d_{DA} is the donor−acceptor center-to-center distance, n is the refractive index of toluene and J^F is the overlap integral. κ^2, the orientation factor, takes into account the relative orientation of the transition dipole moments of the donor and the acceptor and in a pair of reactants freely diffusing in solution the value is statistical, i.e. 2/3, since they can randomly approach. In the present case, the statistical value 2/3 can be considered a good approximation because of the length and flexibility of the bond connecting the two components.

$$k_{en}^F = \frac{8.8\times10^{-25}\kappa^2\Phi}{n^4\tau d_{DA}^6}J^F \qquad (1)$$

The Förster overlap integral, J^F, is calculated from the overlap between the luminescence spectrum of the donor **ZnU**, $F(\bar{\nu})$ (cm^{-1} units) and the absorption spectrum $\varepsilon(\bar{\nu})$ of the acceptor **FBS** (cm^{-1} units), according to Equation (2).[8]

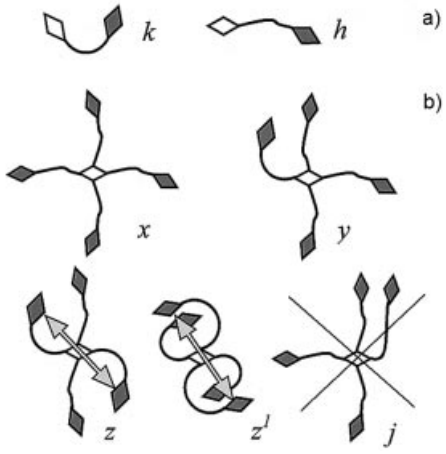
$$J^F = \frac{\int F(\bar{\upsilon})\varepsilon(\bar{\upsilon})/\bar{\upsilon}^4 d\bar{\upsilon}}{\int F(\bar{\upsilon})d\bar{\upsilon}} \qquad (2)$$

From the experimental emission and absorption spectra, an overlap integral J^F of $5.55 \times 10^{-14}\ cm^3\ M^{-1}$ was calculated, and from Equation (1) a critical transfer distance R_c of 28 Å was calculated. This is the distance at which the energy transfer rate equals the intrinsic deactivation rate of the donor and, given the sixth power dependence [see Equation (1)], for distances slightly larger, no energy transfer can occur because the intrinsic deactivation prevails. From Equation (1), the distance d_{DA}, at which the transfer occurs with the experimental rate of $3.6 \times 10^9\ s^{-1}$, can be calculated as being ca. 20 Å.

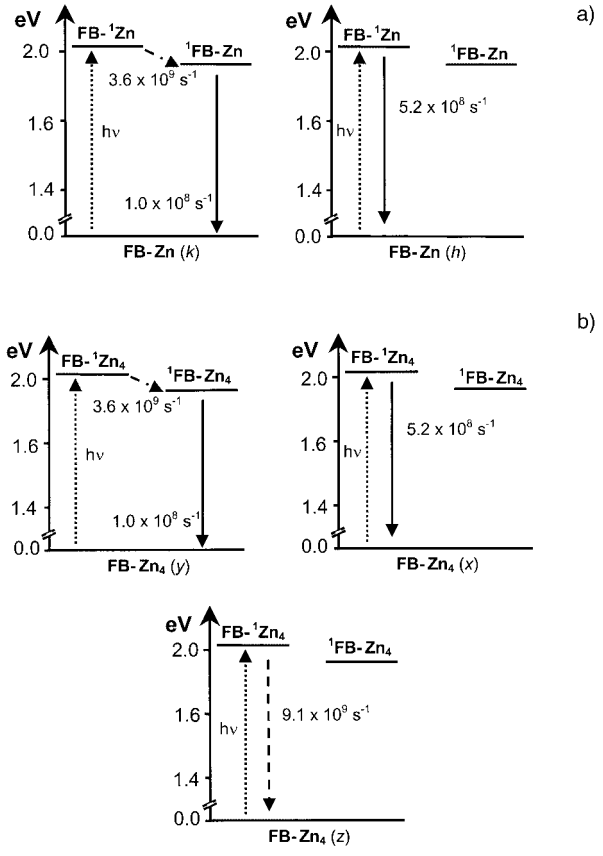
The presence of two different lifetimes in the decay of luminescence of the zinc donor component can be assigned to the presence of two different conformations of the dyad.

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

In order to elucidate this point, a series of calculations based on the semiempirical AM1 hamiltonian[10] were carried out to describe a minimum conformation for this compound in vacuo. It was found that the most stable conformation corresponds to a bent structure, with a torsion angle of 67° defined by the C2′−C1′−N1−C6 atoms, and a heat of formation of 1174 kcal/mol. The C1′ and C2′ atoms are in the ribose unit and the N1 and C6 (C6 is the carbon atom involved in the double bond) are in the uracil nucleic base. In this conformation, the distance between the two chromophores Zn and FB is 23 Å, i.e. a distance in reasonable agreement with that calculated from the experimental energy transfer rate according to the Förster theory (ca. 20 Å, see above). However, we note that the molecule is quite free to rotate about the saturated bridges and that small variations of the torsion angle mentioned above lead to negligible variations in the overall energy of the compound. For example, a small increase in the twisting angle mentioned above, from 67° to 97°, leads to distances d−d greater than 28 Å, but the corresponding destabilization of the molecule is only 0.5 kcal/mol. It is quite possible that interaction of this molecule with a suitable solvent stabilizes an energy minimum corresponding to a donor−acceptor distance of at least 30 Å. Such a distance implies a reduced and, possibly, a no more competitive rate constant for the energy transfer process. The greatest distance achieved by rotation around the above twisting angle is ca. 32 Å.



Scheme 2. Cartoon representation of the different conformations for **FB-Zn** (a) and **FB-Zn$_4$** (b); white diamonds represent the free-base porphyrin energy acceptor and gray diamonds the Zn porphyrin energy donor; the arrows indicate exciton interactions



Scheme 3. Energy level scheme and photoinduced processes which can occur in the different conformations of **FB-Zn** (a) and **FB-Zn$_4$** (b); dotted lines represent light absorption, dashed lines represent non-radiative transitions, solid lines are radiative processes and dash-dot lines, energy transfer

On this basis, we interpret the results of the photoinduced processes in the dyad **FB-Zn** as follows. The dyad is composed of two populations of conformers which equilibrate on a long time scale compared to the photoinduced processes and therefore behave as independent species. Although the theoretical results in the gas phase indicate a folded structure as a shallow minimum conformer, the solution experimental results indicate that a more displaced conformation has been stabilized by solvent interactions and accounts for 70% of the population. A schematic illustration of the two conformers, whose structures are compatible with both the experimental findings and the theoretical results, is shown in Scheme 2 (a). Both conformers are in a bent configuration. However, in isomer *k* (Scheme 2, a) the two porphyrins are nearly overlapping, with a distance of the order of 20−23 Å between the donor−acceptor couple, which is sufficient to promote a dipole−dipole type energy transfer process. In the second open conformation, *h*, the planes containing the porphyrins are displaced and the center-to-center distance is increased to a value of ca. 32 Å, which does not allow Förster energy transfer to take place effectively.

Scheme 3 (a) shows schematic energy level diagrams illustrating the photoinduced processes occurring in both conformations of **FB-Zn**.

The Pentad

Unlike that found for the dyad, the absorption spectrum of the pentad **FB-Zn$_4$**, does not result from the simple superposition of the spectra of the component units. Figure 5 shows the absorption spectrum of the pentad compared with the sum of its components. Large effects on the Soret band, namely broadening, decrease in epsilon and a minor red shift are observed and, in addition, a rather important change in epsilon, a red shift and a change in spec-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

tral shape in the Q band region are also observed. Whenever porphyrins are connected to other species, some change in the Soret band region, which corresponds to the S_0-S_2 transition, is generally encountered. However, the effect on the Q band region, which corresponds to the S_0-S_1 transition, is rather unusual. This observation can be taken as indication of a rather important coupling between components. Since the type and length of the linker is not expected to couple the components substantially, a through-space interaction can be invoked to explain this observation. This must occur in a conformation where the components are in close contact and which can only be possible in **FB-Zn$_4$** and not in **FB-Zn**, since no such interaction was apparent in the latter.

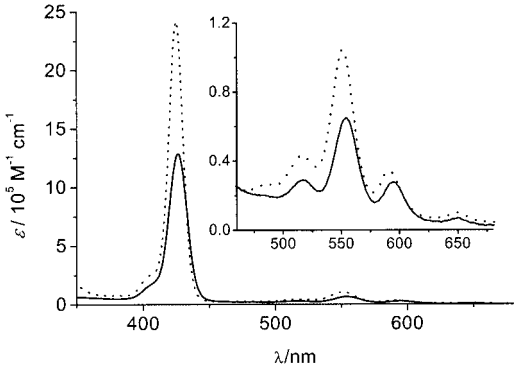


Figure 5. Molar absorption coefficient of **FB-Zn$_4$** in toluene solution (solid line); the sum of the molar absorption coefficients of the components, one **FBS** and four **ZnU** units, is also reported (dotted line)

Selective excitation of the free-base component at 650 nm results in a decrease of the emission quantum yield of this component compared to its model, from 0.18 to 0.13 (Table 1). This confirms the perturbation of the radiative and non-radiative parameters of the units when they are incorporated into the pentameric array. Under these strong coupling conditions, a quantitative consideration of the emission quantum yields of the individual components of the pentad as performed in Figure 2 for the dyad, is rather unreliable. In fact, that type of determination relies strongly on the fact that the properties of the components are not substantially modified when incorporated into the arrays. It is evident from both the ground state absorption spectrum (Figure 5) and from the free-base porphyrin emission yield (Table 1), which appears decreased in the pentad, that this is not the case. A qualitative experiment comparing the overall emission quantum yield of optically matched solutions of the dyad and the pentad is presented in Figure 6. This shows that the emission in the higher order array is strongly diminished for both the zinc porphyrin and the free-baseporphyrin. This cannot be attributed to an increased efficiency of the intramolecular energy transfer process, but rather to an overall increase in the non-radiative decay involving both components of the pentad, i.e. the free-base porphyrin and the Zn porphyrin.

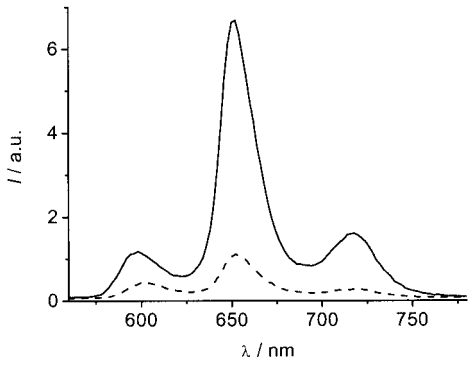

Figure 6. Emission detected from optically matched (A = 0.18) toluene solutions of **FB-Zn** (solid line) and **FB-Zn$_4$** (dashed line) after excitation at 550 nm

Upon excitation at 532 nm, the time-resolved luminescence of the pentad **FB-Zn$_4$** is reduced with respect to that of an optically matched **FB-Zn** dyad. The initial intensity at 600 nm is ca. 25% that of the dyad. A satisfactory fit of the decay at 600 nm, illustrated in Figure 7, was obtained using three exponentials of 110 ps (50%), 240 ps (15%) and 1.9 ns (35%). In this case, the band at 720 nm typical of the free-base porphyrin emission, is extremely low because of the numerical predominance of the zinc porphyrin chromophore, and no rise in the luminescence signal could be detected.

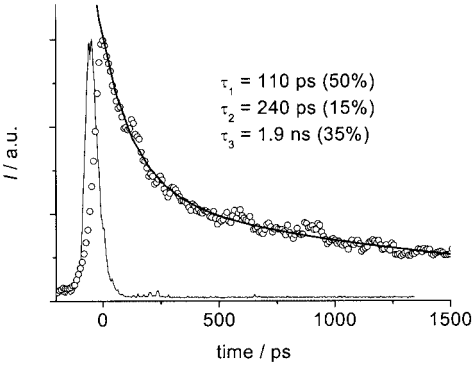

Figure 7. Time-resolved luminescence of **FB-Zn$_4$** in toluene solution after excitation at 532 nm; decay at 600 nm (O) and tri-exponential fitting with lifetimes of 110 ps, 240 ps and 1.9 ns. The exciting flash profile is also shown

The two longest lifetimes, 1.9 ns and 240 ps, are similar to those found in the dyad **FB-Zn**, and can be similarly assigned to unquenched conformations (1.9 ns), where the donor and acceptor are at the extremities of an extended linker and to quenched conformations (240 ps) with the donor and the acceptor at the extremities of a bent linker. The shortest (110 ps) and most important component in the luminescence decay, which accounts for ca. 50% of the intensity, is new and may be assigned to a different type of conformer which is only possible in the pentad. Multi-exponential decay of the zinc porphyrin luminescence is

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

typical of flexible zinc porphyrin-based star compounds with a central free base porphyrin energy acceptor and has been frequently reported in the literature.[4k−4l]

In spite of the fact that the overall yield of the luminescence of the pentad is extremely low, sensitization of the free-base by the zinc component still occurs, as illustrated by the excitation spectrum registered at 720 nm, which is a wavelength normally indicative of free-base porphyrin emission (Figure 8). In this excitation spectrum, there is a clear contribution to the free-base emission from the zinc porphyrin donor band at 550 nm. Its extent is partial as in the dyad **FB-Zn**, and may be assigned to the fact that some conformations in **Fb-Zn$_4$** do not contribute to energy transfer. In spite of the fact that we could observe some sensitization of the free-base emission by the zinc porphyrin component (see Figure 8), the overall emission of the free-base porphyrin does not appear to increase in the pentad but rather to decrease, as shown in Figure 6. At the same time, we determined a quenching of the zinc porphyrin luminescence without detecting a corresponding sensitization in the free-base acceptor. A similar behavior was reported by Sanders et al. for a pentaporphyrin composed of a free base tetrapyridylporphyrin core coordinated via four axial bonds to a cyclic tetra-Zn porphyrin.[4s] The authors assigned the quenching of the luminescence of both components to an undefined photoinduced electron transfer process. In the present case, no photoinduced electron transfer can occur spontaneously since, according to their redox potentials,[6] the energy of the highest excited state (2.05 eV, Table 1) is insufficient to promote an electron transfer between the components. Therefore, in order to explain this observation, we have to assume that a remarkable loss of emission from the zinc porphyrin component, as well as from the free-base porphyrin unit, must take place through some non-radiative path.

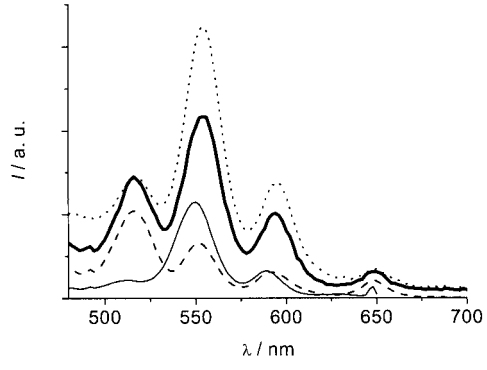

Figure 8. Excitation spectrum registered at λ_{em} = 720 nm (thick line) and absorption spectrum (dotted line) of **FB-Zn$_4$** in toluene solution; for comparative, purposes the excitation spectra of the models **ZnU** at λ_{em} = 646 nm (thin solid line) and **FBS** at λ_{em} = 720 nm (dashed line) are shown; the spectra are arbitrarily scaled

Some strong interacting conformer could account for the observed phenomena, namely non-additivity of absorption and a dramatic decrease in emission quantum yield of the pentad compared to the dyad as well as a new fast component (110 ps) in the quenching of the luminescence. This conformation must be precluded in the dyad, where the above effects were not observed. For the pentad, a series of different conformations can be envisaged, some of which are shown in Scheme 2 (b.) Conformation *x* (fully extended) and conformation *y* (partially bent) resemble the respective conformations of the dyad and should behave similarly. However, the conformations resulting from the concomitant bending of two (or more) Zn porphyrins over the free base component, denoted as *z* or *z'*, are unique to the pentad. Other types of conformations unique to the pentad, denoted as *j*, with the Zn porphyrins in a parallel arrangement, can be neglected. In fact, it seems unlikely that this type of conformation could affect the radiative parameters of the free-base component which is not involved in the interaction. Therefore, type *z* conformers are most likely responsible for the strong interaction observed in the pentad and this is supported by the data presented in the following sections.

A simplified interpretation of the data can be attempted as follows. The pentad is assumed to take (at least) three different types of conformations denoted as *x*, *y* and *z*. Conformations *x* and *y* behave "regularly" i.e. similarly to the corresponding bent or extended conformations in the dyad, as confirmed by the similar lifetimes detected in the luminescence quenching of the Zn porphyrin donor. The *z* type conformations may be responsible for the different behavior of the pentad array compared to the dyad. The short luminescence lifetime of the zinc porphyrin component (110 ps) is assigned to this type of conformation which, unlike the 240 ps component assigned to an energy transfer process in conformation *y*, has to be regarded as a fast, non-radiative decay of the excited state. In this type of conformation, an electronic, exciton type interaction also involving the free-base component, can occur. This induces a strong perturbation of the individual parameters of the components resulting in a greatly increased non-radiative decay. Since it accounts for about half of the excited state population, as calculated from the luminescence of the components, its behavior dominates the observed phenomena.

The ensemble Zn−FB−Zn in *z*, or Zn−Zn−FB−Zn−Zn in *z'*, typical of the pentad, is therefore deemed responsible for the new properties, caused by the strong electronic coupling between the components. Deactivation of the excited ensemble Zn−FB−Zn (or Zn−Zn−FB−Zn−Zn) proceeds rapidly, by non-radiative pathways, without producing any sensitization localized at the free-base. The free-base itself, when selectively excited, displays a decreased emission quantum yield in the pentad. This indicates that, irrespective of the excited component, the Zn−FB−Zn ensemble seems to follow non-radiative decay paths.

Further evidence supporting the importance of a conformation where the free-base porphyrin is somehow shielded from the exterior is given by the electrochemistry[6] and the triplet excited state lifetime data reported below.

A nanosecond flash photolysis experiment on the pentad **FB-Zn$_4$** in air free solution allows detection of the porphyrin triplet states of the zinc porphyrin donor and of the free-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

base porphyrin acceptor. The lifetime of the triplet state localized on the zinc porphyrin, FB-$^3Zn_4$, decays with a lifetime of 0.5 μs and sensitizes the lower energy triplet localized on the free-base porphyrin ^{3}FB-Zn_4, which has a lifetime of 500 μs, much higher than that measured in the model **FBS** and in the dyad **FB-Zn** which are, under the same conditions, 200 μs and 160 μs, respectively (Figure 9). This indicates that the reactive FB-$^3Zn_4$ excited state of the pentad is better shielded from trace impurities and oxygen contained in the solvent than in the models and the dyad, and supports the assignment of a rather compact structure which protects the central free-base porphyrin, as in the *z* conformations.

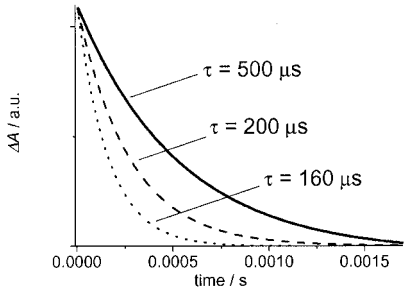

Figure 9. Normalized decay for absorption of the free-base triplet excited state in the model, ^{3}FBS (dashed line), in the dyad, ^{3}FB-Zn (dotted line), and in the pentad, ^{3}FB-Zn_4 (full line)

A similar indication comes from electrochemistry, which was reported previously.[6] The central free-base porphyrin behaves as an encapsulated electroactive molecule in pentaporphyrin **FB-Zn_4**, which is masked from electron transfer by the experimental conditions employed. The electrochemical studies make it clear that, in a flexible molecule such as pentaporphyrin **FB-Zn_4**, a substantial reduction of the electron transfer rate to the porphyrin core may be reasonably expected, i.e. the restricted accessibility to this core is probably assignable to conformational effects rather than to steric factors alone.

Scheme 3 shows the type of photoinduced processes which can occur in the arrays for extended (*x*), singly bent (*y*) or multiply bent (*z*) conformations.

Circular Dichroism Spectroscopy

In order to obtain further insight into the type and strength of interactions postulated in the different conformational cases, circular dichroism experiments were performed. The models **FBS** and **ZnU** display no optical activity when excited at the absorption bands of the porphyrin, while both **FB-Zn** and **FB-Zn_4** are optically active. Data from CD experiments for the dyad and the pentad in the Soret band region are shown in the upper panel of Figure 10 while the lower panel shows the electronic absorption bands for comparative purposes.

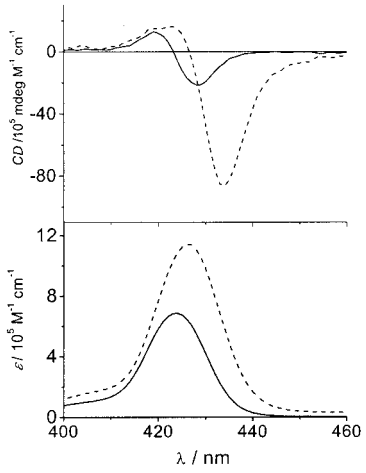

Figure 10. CD (upper panel) and UV (lower panel) spectra of **FB-Zn** (solid line) and **FB-Zn_4** (dashed line) in toluene solutions

The zero value of the CD signal at the wavelength of the maximum UV/Vis absorption band, together with the lack of signal for the separate units composing the pentad, indicates exciton coupling as the origin for the observed CD spectrum. In the simple case of the dyad, the CD spectrum arising from the exciton coupling between Zn and FB was calculated and the results obtained for the Soret band region are displayed in Figure 11. The molecular geometry used in the calculations was that obtained from the AM1 optimization, corresponding to the conformation *k* in Scheme 2 (a). The protocol described by Tinoco [11] for exciton coupling in the case of strongly allowed transitions was implemented by using energies and transition dipole moments calculated with the ZINDO/S program.[10]

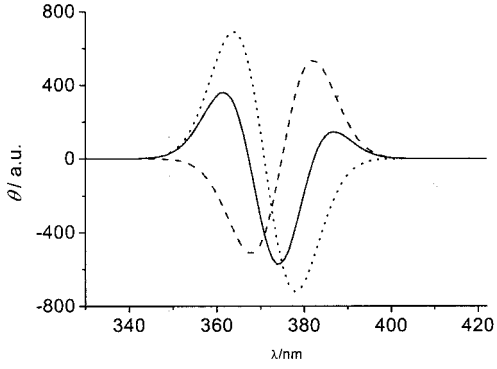

Figure 11. Calculated CD spectrum for the dyad **FB-Zn**; the solid line results from the sum of the exciton splitting of the parallel (dotted line) and perpendicular (dashed line) components of the Soret band

The calculations show that the crossed interactions between the two Soret states of **ZnU** and **FBS** give rise to two exciton bands of opposite sign (represented by the dotted and dashed curves in Figure 11), with a resulting component (solid line) presenting a dissymmetric pattern, the

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

negative part being larger and at longer wavelength than the positive one. The other, smaller component calculated on the low energy side was not detected experimentally, and is derived from a direct inclusion of the two transition dipole components typical of the Soret band. In fact, usually just the parallel component of the band is included in the calculation, as the perpendicular one is partially deleted by the librational modes, as recently shown for similar compounds.[12] While the calculated energy appears, as usual, shifted to the blue when using the ZINDO/S program, the pattern and intensity of the signals appear consistent with experiment and, since the calculated CD spectrum appears very sensitive to the geometry adopted, these results corroborate the conformational hypotheses presented above.

Complexation

Zinc porphyrins are known to axially bind pyridine or pyridyl residues with association constants of the order of 10^4 M^{-1}. These constants have been found to increase dramatically up to ca. 10^8 M^{-1} when multiple bonds contribute to the complex formation (cooperative effect).

We have undertaken these experiments with both monodentate and bidentate pyridyl complexing agents in order to obtain information about the geometry of and the interactions between the zinc porphyrin chromophores. We have derived the association constants using different methods and additionally, we have monitored the effect of full complexation on several spectroscopic properties (i.e. luminescence and CD spectroscopy) with the aim of further understanding these systems.

Association of a pyridyl residue to Zn porphyrin induces a red shift, both on the Soret and Q absorption bands, and on the emission spectrum of the zinc porphyrins. A typical example is shown in Figure 12 for complexation of **ZnU** by pyridine (PYR). The spectral change, which is proportional to the concentration of complex, can be treated according to the equation below, which has been adapted and developed previously.[4j,13]

$$Obs = Obs_0 + \frac{\Delta Obs}{2S_0}\left\{K_d + X + S_0 - \left[(K_d + X + S_0)^2 - 4XS_0\right]^{1/2}\right\} \quad (3)$$

In this equation, the association constant K_{ass} is $1/K_d$, *Obs* is any observed signal intensity (i.e. absorbance or emission intensity), S_0 is the concentration of **ZnU**, or **FB-Zn** or **FB-Zn$_4$** (constant), X is the concentration of the complexing agent (variable), ΔObs is the maximum variation of the observed signal intensity under examination. The fitting of the absorbance data points of the maximum of the Soret band absorbance of the complexed form, at 431 nm, and the fitting of the emission intensity at $\lambda = 610$ nm are given in the insets of Figure 12.

Binding of the bidentate 1,4-diazabicyclo[2.2.2.]octane, DABCO, to Zn porphyrins to form a 1:2 complex has been reported to induce a shift in the UV-absorbance of the 1:1 complex by ca. 6 nm, caused by exciton coupling between the parallel porphyrin units.[14] Therefore, titration of the pentad with DABCO could give an indication of a simultaneous complexation of two porphyrins.[15] As illustrated in Figure 13, the complexation behavior of **FB-Zn$_4$** by DABCO is similar to that of **ZnU** by PYR. A single isosbestic point can be observed, indicating that only the uncomplexed and the 1:1 complex are present without any intermediate 2:1 (Zn porphyrin/DABCO) complex formation. This is indicative of the fact that in **FB-Zn$_4$** there are no couples of Zn porphyrins available for a cooperative binding. Further support for this observation comes from the comparison of the association constants derived by absorp-

[a] Determined by spectrophotometric titration. The absorbance signal at $\lambda = 431 \pm 1$ was fitted to the equation given in the text. [b] Determined by spectrofluorimetric titrations upon excitation at the isosbestic of the absorption bands of uncomplexed and complexed forms, $\lambda = 428 \pm 1$. The emission signal at $\lambda = 610$ nm was fitted to the equation given in the text.

tion and emission methods. Table 2 shows these association constants determined for **ZnU**, **FB-Zn** and **FB-Zn$_4$** with PYR, DABCO and 4,4′ bipyridine (BIPY), respectively. The association constants of bidentate DABCO and BIPY with the dyad and pentad do not appear to differ substantially from the model **ZnU**. This indicates that the multiple binding sites of the pentad, compared to the model **ZnU** and the dyad **FB-Zn** are not detected by the bidentate complexing agent and confirms that the Zn porphyrin units in the pentad are not available for a cooperative binding, either because they are engaged in some different type of interaction, or because they cannot approach each other at an appropriate distance to complex at both ends of the bidentate units.

As a further experiment to help in the interpretation of the data, we observed the kind of changes in the emission and CD spectra brought about by complexation of the dyad and pentad with mono or bidentate bases. Figure 14 shows examples of the changes in the emission spectra occurring upon complexation of BIPY (concentration of complex > 95%) with the model **ZnU**, the dyad **FB-Zn** and the pentad **FB-Zn$_4$**. The results obtained using PYR and DABCO in place of BIPY (not reported) are essentially the same. In the axially bound model **ZnU**, maxima at 609 nm and 662 nm, compared to 598 nm and 646 nm in unbound **ZnU**, appear and an increased intensity of the first band (ratio 1.36) and a decrease in the intensity of the second band (ratio 0.7) with respect to unbound **ZnU** can be seen. Comparison of the emission spectra in Figure 14 confirms that the changes in the emission spectra of the dyad and the pentad can be ascribed only to the different luminescent properties of the axially coordinated zinc porphyrin. No other effect due to changes in the emission properties of the zinc porphyrin in the arrays can be detected.

An experiment similar to the one described for the emission experiment, was also carried out for the CD spectra. CD spectra of the dyad **FB-Zn** (middle panel) and the pentad **FB-Zn$_4$** (bottom panel) before and after complexation with BIPY (complex concentration > 95%), respectively, are shown in Figure 15. The spectrum for **ZnU**, where no signal was detected since it is not optically active, is given in the top panel for purposes of comparison. In **FB-Zn**, the CD signal was slightly shifted, similarly to the shift occurring in the absorption spectrum of the complexed **FB-Zn** as expected for an exciton coupling interaction. This indicates

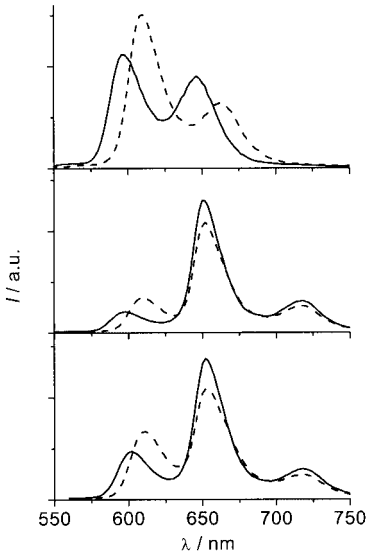

Figure 14. Emission spectra of **ZnU** (top panel), **FB-Zn** (middle panel) and **FB-Zn$_4$** (lower panel) in toluene solutions before (solid line) and after (dashed line) addition of BIPY (concentration of the complex > 95%)

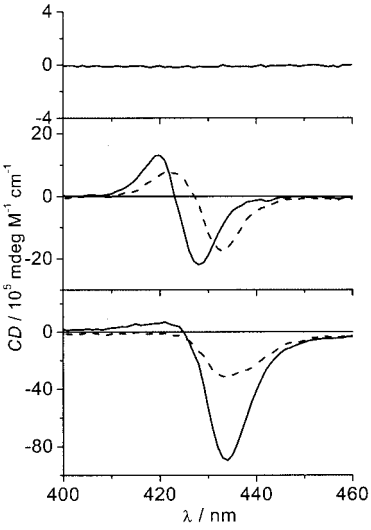

Figure 15. CD spectra of **FB-Zn** (middle panel) and **FB-Zn$_4$** (lower panel) in toluene solutions before (solid line) and after (dashed line) addition of BIPY (concentration of the complex > 95%); the top panel shows the signal obtained for the model **ZnU** for comparative purposes

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

that the presence of BIPY does not alter the type of interaction in conformer *k*, which is responsible for the CD signal, as discussed in the previous section. Conversely, in the pentad **FB-Zn$_4$** axial binding to the zinc porphyrin unit by BIPY has a stronger effect on the signal. There was no shift, but a sizeable decrease of the CD band intensity was observed. The results obtained using DABCO or PYR are essentially the same.

An attempted interpretation of the results presented above follows. An increase in the luminescence would be expected if the postulated non-radiative decay responsible for the decrease in the luminescence yield of the pentad and for the rapid quenching assigned to non-radiative decay (110 ps) of the zinc porphyrin luminescence, is caused by a direct interaction between two zinc porphyrins. In that case, complexation by a bidentate BIPY should disrupt such an aggregate and re-establish the luminescence. The absence of this effect on the luminescence upon BIPY binding confirms that configuration *j* in Scheme 2 cannot be responsible for the detected decrease in luminescence yield.

If the CD spectra are considered, the behavior of **FB-Zn** is quite regular − upon complexation there is no disruption of the interaction responsible for exciton coupling, just a slight shift, which is in agreement with the change in the absorption spectrum of the complex form. This probably indicates that complexation of the Zn porphyrin in conformation *k*, occurs on the Zn porphyrin face remote from the free-base unit. In the case of the pentad, the situation is less straightforward. The complexing bases are unable to suppress the optical activity but modify it substantially. Whether this is indicative of the disruption of some exciton coupling in the pentad or just of a change in the parameters (distance, angles) caused by BIPY complexation, with a consequent cancellation of exciton contributions, is difficult to say. As a consequence, the existence of a conformer with more than two zinc porphyrins in a bent conformation over the central free-base, as in z^1, can not be excluded. In fact, in the latter case, complexation of the more internal Zn porphyrin would require some displacement or decoupling of the external Zn-porphyrin.

Conclusions

In conclusion, we have shown that the photoinduced processes in an **FB-Zn** dyad, covalently joined by a flexible nucleosidic linker, can be rationalized on the basis of the existence of two different conformers accounting, respectively, for ca. 30% and ca. 70% of the population. The major conformer is an extended one in which the distance between chromophores does not allow energy transfer to occur, while the minor conformer is a bent one where the shorter distance between chromophores allows energy transfer by a Förster mechanism with a rate of 3.6×10^9 s^{-1}. This latter bent isomer is assigned to the detected CD spectrum, which is deriving from the excitonic coupling of the electric transition dipole moments of the Soret band.

The corresponding pentad **FB-Zn$_4$** exhibits extremely complex behavior, which can only be explained by the existence of three different conformers. The two first identified conformers, which account for ca. 35% and 15% , respectively, correspond to one approximately extended conformation with a distance between chromophores which inhibits energy transfer, and one bent conformation with a distance that allows energy transfer toward the free-base porphyrin core to occur. These first two conformers are similar to those observed for the dyad **FB-Zn**. However, the most striking feature in this pentaporphyrin **FB-Zn$_4$** is the observed overall decrease in the luminescence quantum yield. This is attributed to the presence of a third conformer, which is only possible in the pentamer and accounts for ca. 50% of the population. In this conformer, a very fast, non-radiative decay of the excited state of the zinc porphyrin units (rate of ca. 10^{10} s^{-1}) is also associated with a decrease in the radiative rate constant of the central free-base porphyrin. On the basis of this evidence, a strongly interacting geometry, where Zn porphyrins are folded over the central free-base porphyrin, is assigned to this conformer. CD spectroscopy data, complexation experiments with mono and bidentate bases, electrochemistry results and reactivity of the excited states with external quenchers, all provide further support to the postulated model.

Experimental Section

Synthesis of the Dyad (FB-Zn): *p*-Tolualdehyde (49 mg, 0.41 mmol, 3 equiv.), the aldehyde **ZnU** (210 mg, 0.14 mmol, 1 equiv.) and pyrrole (36 mg, 37 μL, 0.55 mmol, 4 equiv.) were dissolved in chloroform, which had been dried with molecular sieves. $BF_3{\cdot}OEt_2$ (56 μL of a 3.2 M solution in chloroform) was then added. The solution turned red immediately. The reaction mixture was stirred at room temperature under argon for one and a half hours. *p*-Chloranil (100 mg, 0.41 mmol, 3 equiv.) was then added to oxidize the porphyrinogen formed during condensation and the mixture was refluxed for one and a half hours. The acidic solution was finally neutralized by addition of NEt_3 (25 μL) and the solvent was evaporated. The product was purified by column chromatography over silica gel (Φ = 3 cm, *h* = 23 cm, eluent: EtOAc/hexane, 50:50 to 60:40). The desired dyad **FB-Zn** was finally isolated in 10% yield (28 mg, 0.013 mmol).

FB-Zn: Purple glassy product. ^{1}H NMR ($CDCl_3$, 300 MHz): δ = 8.99 (s, 4 H, H_β), 8.96 (d, ^3J = 5.1 Hz, 2 H, H_β), 8.94 (d, ^3J = 5.1 Hz, 2 H, H_β), 8.87 (d, ^3J = 5.0 Hz, 2 H, H_β), 8.84 (d, ^3J = 4.6 Hz, 4 H, H_β), 8.81 (d, ^3J = 4.8 Hz, 2 H, H_β), 8.27 (d, ^3J = 8.3 Hz, 2 H, H_B), 8.10 (d, ^3J = 7.9 Hz, 2 H, H_o), 8.09 (d, ^4J = 1.7 Hz, 2 H, $H_{o''}$), 8.08 (d, 2 H, $H_{B'}$, hidden), 8.06 (d, ^4J = 1.7 Hz, 4 H, $H_{o'}$), 8.02 (d, 4 H, $H_{o'''}$, ^3J = 8.0 Hz), 7.99 (d, ^3J = 8.0 Hz, 2 H, H_A), 7.78 (t, ^4J = 1.6 Hz, 1 H, $H_{p''}$), 7.75 (t, ^4J = 1.7 Hz, 2 H, $H_{p'}$), 7.55 (d, ^3J = 7.9 Hz, 2 H, $H_{A'}$), 7.40 (d, ^3J = 6.1 Hz, 4 H, $H_{m'''}$), 7.28 (d, ^3J = 7.8 Hz, 2 H, H_m), 6.07 (d, ^3J = 4.6 Hz, 1 H, 1′-H), 5.50 (t, ^3J = 5.3 Hz, 1 H, 2′-H), 5.46 (t, ^3J = 5.1 Hz, 1 H, 3′-H), 4.51 (m, ^3J = 3.3 Hz, 2 H, 5′-H), 4.43 (t, ^3J = 3.6 Hz, 1 H, 4′-H), 4.37 (t, ^3J = 5.7 Hz, 2 H, $CH_2\gamma$), 2.99 (t, ^3J = 6.7 Hz, 2 H, $CH_2\alpha$,), 2.70 (s, 3 H, 7′-CH_3), 2.52 (s, 6 H, 7-CH_3), 2.41 (m, ^3J = 4.1 and 7.0 Hz, 2 H, $CH_2\beta$), 2.16 (s, 6 H, CH_3 2′,3′-OAc), 1.53 (s, 36 H, *t*Bu), 1.48 (s, 18 H, *t*Bu), −2.79 (s, 2 H, NH) ppm. MS (FAB$^+$): *m*/*z* = 2104.5 [M]$^+$, calcd. 2104.9.

Spectroscopic and Photophysical Determinations: Toluene (spectroscopic grade, C. Erba) was used as received. Titration experiments for the determination of association constants were performed using a constant concentration of porphyrins and variable concentrations of PYR, DABCO and BIPY. Absorption spectra were recorded with a Perkin−Elmer Lambda 9 spectrophotometer. Emission spectra were measured using a Spex Fluorolog II spectrofluorimeter equipped with a Hamamatsu R928 photomultiplier and are uncorrected unless stated otherwise. Relative luminescence intensities were evaluated from the area (on an energy scale) of the luminescence spectra corrected for the photomultiplier response. Luminescence quantum yields φ for the components were obtained with reference to a standard zinc(II) porphyrin [Zn(II){5,10,15,20-tetrakis(4-*tert*-butylphenyl)porphyrin}] in toluene with φ = 0.08.[4h] Circular dichroism spectra were obtained with a Jasco J-710 dichrograph. Experiments at 77 K were done using quartz capillary tubes immersed in liquid nitrogen contained in a home-made quartz dewar.

Fluorescence lifetimes in the nanosecond range were determined using an IBH Time Correlated Single Photon Counting apparatus with excitation at 337 nm. Luminescence lifetimes shorter than one nanosecond were determined by an apparatus based on a Nd:YAG laser (Continuum PY62−10) with a 35 ps pulse duration, at 532 nm, 1 mJ/pulse and a Streak Camera. The luminescence signals from 1000 laser shots were averaged and the time profile was measured from the streak image in a wavelength range of ca. 20 nm about the selected wavelength. The fitting of the luminescence decays were performed by standard iterative non linear programs taking into consideration the instrumental response. Further details on the equipment can be found elsewhere.[16]

Transient absorbance in the nanosecond range made use of a laser flash photolysis apparatus based on a Nd:YAG laser (JK Lasers) delivering 532 nm pulses of 18 ns. Absorbance of the solutions at the exciting wavelength was ca 0.2 and an energy of 5 mJ/pulse was used for the determination of the spectra. In order to prevent undesired second-order T−T annihilation reactions, an energy of ca. 0.5 mJ/pulse was used for the triplet lifetime determination. Experiments were conducted in home-made, 10 mm optical path cuvettes, bubbled with argon for 5 min and sealed.

Computation of the integral overlap and of the rate for the energy transfer processes according to the Förster mechanism were performed with the use of Matlab 5.2.[17] Estimated errors are 10% on lifetimes, 20% on quantum yields and 30% on association constants. Working temperature, if not otherwise specified, was 295 ± 2 K.

The Hyperchem package [10] was used for both the conformational calculations (AM1 Hamiltonian) and the excited states properties calculations (ZNDO/S) of the free-base porphyrin and zinc porphyrin units necessary to perform the exciton coupling calculations.

Controlled Access to Mixed-Metal Pyridazine-Linked Cryptates

Tanya K. Ronson,[a] Jane Nelson,[b,c] Geoffrey B. Jameson,[d] John C. Jeffery,[e] and Sally Brooker*[a]

Keywords: Cryptates / Cyclic voltammetry / Heterometallic complexes / N ligands / Structure elucidation

The pyridazine-linked cryptand L [formed by the 3+2 condensation of 3,6-diformylpyridazine with tris(2-aminoethyl)amine (tren)] has been used to generate a series of heterodinuclear cryptates by a one-pot two-step method. The cryptates $[Mn^{II}Cu^{I}L](ClO_4)_2(BF_4)$, $[Fe^{II}Cu^{I}L](BF_4)_3{\cdot}CH_3CN$ and $[Ni^{II}Cu^{I}L](BF_4)_3{\cdot}H_2O$ have been structurally characterized, with elemental analyses and mass spectroscopic data providing further evidence of their heterodinuclear nature. The synthesis, structures and characterisation of the corresponding mononuclear cryptates $[M^{II}L](X)_2$ (M = Mn, Fe, Ni, X = BF_4^- or ClO_4^-) are also reported, along with the synthesis and characterisation of the homodinuclear dizinc(II) and disodium(I) cryptates, $[Zn_2L](ClO_4)_4$ and $[Na_2L](CF_3SO_3)_2$. Electrochemical studies on the heterodinuclear cryptates in CH_3CN indicate that the presence of the divalent cation influences the electrochemical potential and reversibility of the $Cu^{I} \rightarrow Cu^{II}$ oxidation with the redox potential of the Cu^{I}/Cu^{II} couple being inversely correlated with the distance between the two metal ions in the solid state as determined by X-ray crystallography. The previously synthesised $[Co^{II}Cu^{I}L](BF_4)_3$ is an exception to this trend, probably due to oxidation of the Co^{II} ion prior to that of the Cu^{I} ion.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

There are now a large number of cryptates reported and these have recently been reviewed.[1] However, very few mixed-metal cryptates have been prepared. Such heterodinuclear complexes are of interest as models for metalloenzyme active sites[2] and to study the mutual influences of the two metal centres on the electronic, magnetic and electrochemical properties of these systems.[3] Heterodinuclear cryptates synthesised to date include several structurally characterised transition metal-lanthanide cryptates of iminophenolate cryptands[4] and a $Fe^{II}Co^{II}$ cryptate of another iminophenolate cryptand,[5] although in this case the structural data are ambiguous.[6] An imidazolate-bridged $Zn^{II}Cu^{II}$ cryptate of an octa-amino cryptand has also been reported and is of interest as a model compound for the CuZn family of superoxide dismutases.[7]

Recently, we developed a system where we were able to isolate the mixed-valent complex $[Cu^{II}Cu^{I}L](BF_4)_3$ and the heterodinuclear complex $[Co^{II}Cu^{I}L](BF_4)_3$ [L is the cryptand formed by the 2+3 condensation of 3,6-diformylpyridazine with tris(2-aminoethyl)amine (tren), Figure 1].[8] In addition, we prepared the mononuclear cryptates $[Cu^{II}L](BF_4)_2$ and $[Co^{II}L](BF_4)_2$ of the same symmetrical cryptand.[9,10] This is possible because the binding of a single stereochemically demanding cation alters the conformation of the host in such a way as to prevent the formation of a homodinuclear complex. The resulting unsymmetrical mononuclear cryptates still have up to eight donor atoms available for coordination and so are able to bind a second non-stereochemically demanding cation such as copper(I)

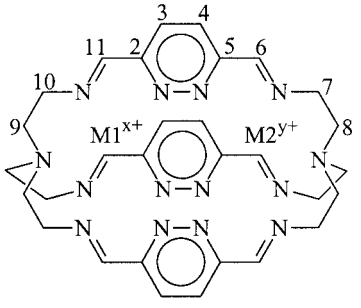

Figure 1. Schematic representation of the complex cations of the pyridazine containing cryptand L which have been prepared in this study, numbered as used in the NMR spectroscopic data assignments; note: M2^{y+} is (a) the same as M1^{x+} in the homodimetallic complexes, (b) absent in the monometallic complexes, (c) the Cu^{I} ion in the heterobimetallic complexes

using four of these donor atoms, resulting in heterodinuclear complexes. Mixed metal complexes of symmetrical ligands are very unusual for acyclic systems and there are only a few examples for macrocyclic ligands.[4,5,7,11]

In this paper we report on the synthesis and characterisation of the heterodinuclear cryptates $[Mn^{II}Cu^{I}L](ClO_4)_2(BF_4)$, $[Fe^{II}Cu^{I}L](BF_4)_3{\cdot}CH_3CN$ and $[Ni^{II}Cu^{I}L](BF_4)_3{\cdot}H_2O$. We have completed a systematic study of the effect of the divalent cation on the copper(I) ion across the series $[M^{II}Cu^{I}L](X)_3$ (M = Mn, Fe, Co, Ni, Cu; X = BF_4^- or ClO_4^-), focussing on the electrochemical properties of these systems. In this context, it is useful to have a complex of a non-redox active cation; hence we have prepared $[Zn_2L](ClO_4)_4$. For completeness, the mononuclear cryptates $[Mn^{II}L](ClO_4)_2$, $[Fe^{II}L](BF_4)_2$ and $[Ni^{II}L](X)_2$ (X = BF_4^-, ClO_4^-) are also reported.

Results and Discussion

Synthesis and Characterisation of Mononuclear and Homodinuclear Cryptates

As we had previously observed that L readily forms the mononuclear cryptates $[Co^{II}L](BF_4)_2$ and $[Cu^{II}L](BF_4)_2$,[9,10] attempts were made to synthesise other mononuclear cryptates of first-row transition metals. The cryptates $[Mn^{II}L](ClO_4)_2$ and $[Ni^{II}L](X)_2$ (X = BF_4^-, ClO_4^-) were readily obtained in good purity and yield from the addition of one equivalent of the appropriate metal salt to L. The synthesis of $[Fe^{II}L](BF_4)_2$ proceeded in a lower yield and was sensitive to air and traces of solvent water.

Infrared spectra of the mononuclear cryptates confirmed that the L cryptand remains intact {imine at 1652 cm^{-1} for $[Mn^{II}L](ClO_4)_2$, 1638 cm^{-1} for $[Fe^{II}L](BF_4)_2$ and 1647 cm^{-1} for $[Ni^{II}L]^{2+}$} and confirms the presence of the expected anions {1116 and 1088 cm^{-1} for $[Mn^{II}L](ClO_4)_2$, 1052 and 1032 cm^{-1} for $[Fe^{II}L](BF_4)_2$, 1050 cm^{-1} for $[Ni^{II}L](BF_4)_2$ and 1083 cm^{-1} for $[Ni^{II}L](ClO_4)_2$}. In each case, the microanalyses support the proposed formula. The electrospray mass spectra show peaks for the successive loss of the two counterions. The molar conductivity values of 280 $mol^{-1}\,cm^2\,\Omega^{-1}$ for $[Mn^{II}L](ClO_4)_2$, 286 $mol^{-1}\,cm^2\,\Omega^{-1}$ for $[Fe^{II}L](BF_4)_2$ and 301 $mol^{-1}\,cm^2\,\Omega^{-1}$ for $[Ni^{II}L](BF_4)_2$ in acetonitrile indicate that all three cryptates behave as 2:1 electrolytes in solution.

The UV/Vis spectrum of yellow $[Mn^{II}L](ClO_4)_2$ in acetonitrile shows strong ligand-centred π-π* transitions at 208 nm (ε = 62100 $M^{-1}\,cm^{-1}$) and 250 nm (ε = 35100 $M^{-1}\,cm^{-1}$), with a lower intensity shoulder tailing off to longer wavelengths. The UV/Vis spectrum of $[Fe^{II}L](BF_4)_2$ in acetonitrile shows a band of at least four overlapping metal-to-ligand charge-transfer transitions with distinct peaks at 428 nm (ε = 4800 $M^{-1}\,cm^{-1}$) and 588 nm (ε = 8030 $M^{-1}\,cm^{-1}$) and shoulders at 370 nm and 540 nm. There are also transitions at 213 nm (ε = 64700 $M^{-1}\,cm^{-1}$) and a shoulder at about 250 nm which are probably due to ligand-centred π-π* transitions. The UV/Vis spectrum of $[Ni^{II}L](BF_4)_2$ in acetonitrile shows a band of overlapping weak d-d transitions (ε ≈ 30 $M^{-1}\,cm^{-1}$) with maxima at 825 and 908 nm. This is consistent with the presence of octahedral nickel(II). A second band at 211 nm (ε = 68700 $M^{-1}\,cm^{-1}$) with a shoulder at about 250 nm is assigned to ligand-centred π-π* transitions.

The ^1H NMR spectrum of $[Fe^{II}L](BF_4)_2$ at 243 K (Figure 2) is consistent with the existence of an unsymmetrical cryptate with the low spin iron(II) ion being located in one tren-derived cap site of the cryptand. The three strands are identical as expected. Each methylene group is differentiated into an axial triplet and equatorial doublet signal as a result of the accidental similarity of the geminal $^2J_{ax/eq}$ and vicinal $^3J_{ax/ax'}$ coupling constants of ca. 11−13 Hz (cf. 11−12 Hz for L).[9] Two-dimensional correlation NMR spectroscopic techniques were used to identify the signals for each end of the cryptand. The two ends of the cryptand were tentatively assigned by comparison with the $[ZnL](ClO_4)_2$ and $[Fe^{II}Cu^{I}L]^{3+}$ spectra and on the basis that the signals for the protons at end of the cryptand containing iron(II) are expected to be more deshielded due to the lower electron density in this half of the cryptand. It is worth noting that if this latter point is incorrect (and there are some inconsistencies in the carbon NMR spectrum), then the 'end' assignments would need to be reversed. At higher temperatures the ^1H NMR spectrum of $[Fe^{II}L](BF_4)_2$ shows significant changes, with the signals for the end of the cryptand which is believed to contain the iron(II) ion shifting, broadening or disappearing altogether as the

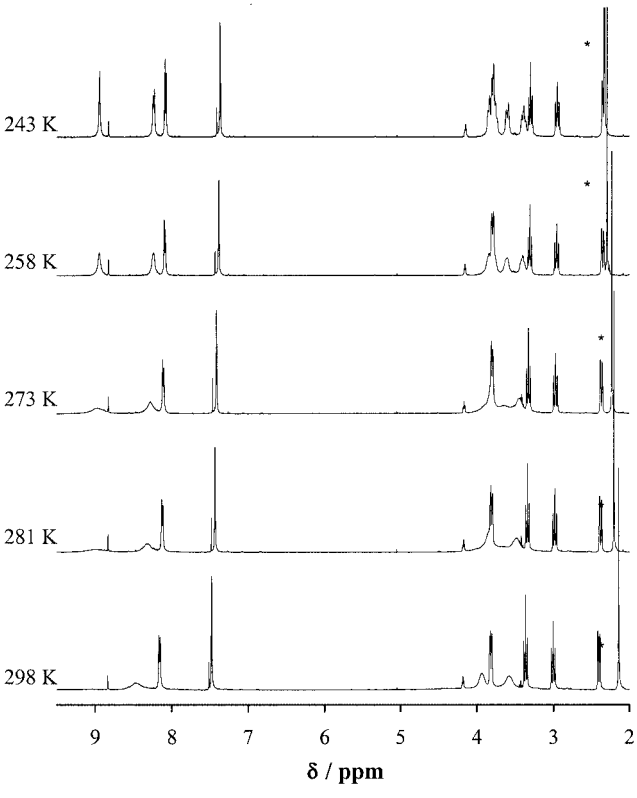

Figure 2. Variable temperature ^1H NMR spectra of $[Fe^{II}L](BF_4)_2$ in CD_3CN; the strong signal to the right hand side of the asterisk * is H_2O; note that the spectra at 273 K and 281 K were recorded on a different sample to the other spectra

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

temperature is raised to 298 K (Figure 2). The signals for the other half of the cryptand remain sharp at all temperatures examined. This type of behaviour is characteristic of paramagnetic compounds, suggesting the existence of an equilibrium involving at least a small amount of high spin Fe^{II}. The broadening and shifting become more severe as the temperature is increased, in accordance with Curie-law behaviour. Another possibility that this temperature-dependent behaviour is simply due to fluxionality in the uncoordinated 'end' is believed to be unlikely on the basis that (a) the ^1H NMR spectrum of $[ZnL](ClO_4)_2$ is sharp at room temperature, (b) it would require the 'end' assignments to be reversed, and (c) whilst at first glance the H^{9a}/H^{9b} and H^{10a}/H^{10b} pairs of alkyl signals each appear to coalesce into two broad signals, for H^9 and H^{10}, respectively, at higher temperatures (δ = 3.94 and 3.59 ppm at 298 K), the position of these signals is not exactly at the averaged position (e.g. see relative positions of $H^{10a+10b}/H^{10}$ vs. H^{7b} as a function of temperature) and more seriously the integration is not correct as each broad signal integrates as equivalent to only one proton (not two). Finally, the H^{11} and H^3 signals shift as well as broaden.

The previous synthesis of $[Cu^I_2L](BF_4)_2$ and $[Ag^I_2L](ClO_4)_2$[9,10] suggested that it should be possible to synthesise homodinuclear cryptates of other non-stereochemically demanding metal ions.

The addition of two equivalents of zinc perchlorate to L in acetonitrile resulted in the dinuclear cryptate $[Zn_2L](ClO_4)_4$. The IR spectrum of $[Zn_2L](ClO_4)_4$ confirms that the cryptand is intact with an imine band at 1653 cm^{-1}. The bands for the ClO_4^- counterions, centred around 1121 cm^{-1} and 629 cm^{-1}, are both clearly split into three peaks indicating that there may be some interaction with the $[Zn_2L]^{4+}$ cation which lowers the symmetry of the ClO_4^- ion. The electrospray mass spectrum of $[Zn_2L](ClO_4)_4$ only shows peaks for the mononuclear species $[ZnL]^{2+}$ and $[ZnL](ClO_4)^+$. The elemental analysis, however, fits the dinuclear formulation. The UV/Vis spectrum of yellow $[Zn_2L](ClO_4)_4$ in acetonitrile shows transitions at 206 nm (ε = 51900 $M^{-1}\,cm^{-1}$) and 251 nm (ε = 30400 $M^{-1}\,cm^{-1}$) with lower intensity shoulders tailing to longer wavelengths.

The conductivity measurement of 359 $mol^{-1}\,cm^2\,\Omega^{-1}$ in acetonitrile is consistent with the complex being a 3:1 electrolyte (3:1, 340−420 $mol^{-1}\,cm^2\,\Omega^{-1}$)[12] instead of a 4:1 electrolyte as expected. The lower than expected conductivity value may well be a consequence of the reduced mobility often observed for large polycations,[12] although the 3:1 electrolyte cryptates described here have conductivity values within the expected ranges. Another, less likely, explanation is that it might be due to the symmetrical (see NMR spectrum later) coordination of one of the ClO_4^- counterions to the two zinc ions in solution. This would be consistent with the split ClO_4^- bands observed in the solid-state infrared spectrum (KBr disc), however, it would require a very different binding arrangement to those observed for all of the complexes of L studied to date, and such a bridging arrangement of the anion would also be unique for an imine, as opposed to amine, cryptand.[1] An X-ray structure determination would be required to test the latter hypothesis; however, the crystals of $[Zn_2L](ClO_4)_4$ obtained from acetonitrile were not of X-ray quality. Attempts to synthesise the BF_4^- analogue of $[Zn_2L](ClO_4)_4$ were unsuccessful, suggesting that the presence of ClO_4^- is necessary to form the dinuclear complex.

An attempted synthesis of $[Zn_2L](ClO_4)_4$ in methanol and a recrystallisation of $[Zn_2L](ClO_4)_4$ from dimethylformamide (DMF) both resulted in the mononuclear cryptate $[ZnL](ClO_4)_2$ in a slightly impure form. The NMR spectra of this mononuclear zinc complex in CD_3CN are sharp, in direct contrast to the broad and temperature-dependent ^1H NMR spectra obtained for $[Fe^{II}L](BF_4)_2$, and are consistent with an unsymmetrical cryptate in which the zinc(II) ion is located in one tren-derived cap site of the cryptand (see Exp. Sect. and Supporting Information). As expected, the ^1H NMR spectrum of the dinuclear zinc complex, $[Zn_2L](ClO_4)_4$, in CD_3CN is simple due to its high symmetry, with just one resonance for the imine protons and one for the aromatic protons, together with the expected two sets of axial and equatorial resonances for the tren-derived caps. This shows that in acetonitrile solution the dinuclear cryptate is stable with respect to the mononuclear analogue. Thus, the use of acetonitrile as the solvent also appears to be crucial for the stability of the dinuclear complex $[Zn_2L](ClO_4)_4$.

Further attempts to synthesise homodinuclear cryptates were carried out with the non-stereochemically demanding cations manganese(II) and sodium ions and resulted in $Mn^{II}_2LCl_4\cdot H_2O$ and $[Na_2L](CF_3SO_3)_2$, respectively, in the analytically pure form. Interestingly the conductivity value for $Mn^{II}_2LCl_4\cdot H_2O$ (224 $mol^{-1}\,cm^2\,\Omega^{-1}$ in methanol) is closest to that for a 2:1 electrolyte (ref. 2:1: 160−220 $mol^{-1}\,cm^2\,\Omega^{-1}$, 3:1: 290−350 $mol^{-1}\,cm^2\,\Omega^{-1}$)[12] rather than a 4:1 electrolyte initially expected. This suggests that either two of the chloride anions are coordinated to the manganese(II) ions in the dimanganese cryptate, either in a monodentate or bridging fashion, or that a monomanganese cryptate with a $[MnCl_4]^{2-}$ counterion has formed. The latter of these possibilities is not supported by negative ion mass spectrometry as this shows no evidence for the presence of $[MnCl_4]^{2-}$. Attempts to grow single crystals of $Mn^{II}_2LCl_4\cdot H_2O$ and $[Na_2L](CF_3SO_3)_2$, suitable for X-ray diffraction, were unsuccessful.

The addition of two equivalents of manganese(II) perchlorate to L resulted only in the mononuclear cryptate $[Mn^{II}L](ClO_4)_2$ (described above). Thus, although it appears to be possible to synthesise dinuclear cryptates of L with non-stereochemically demanding divalent cations, the choice of counterion and/or solvent appears to be crucial.

Synthesis and Characterisation of Heterodinuclear Cryptates

The previous synthesis of $[Co^{II}Cu^{I}L](BF_4)_3$ and $[Cu^{II}Cu^{I}L](BF_4)_3$[8] suggested that it should be possible to synthesise other heterodinuclear cryptates of L by the addition of a non-stereochemically demanding cation to the

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

mononuclear cryptates $[M^{II}L](X)_2$ (M = Mn, Fe, Ni; X = BF_4^- or ClO_4^-). The heterodinuclear cryptates $[Mn^{II}Cu^{I}L](ClO_4)_2(BF_4)$, $[Fe^{II}Cu^{I}L](BF_4)_3{\cdot}CH_3CN$ and $[Ni^{II}Cu^{I}L](BF_4)_3{\cdot}H_2O$ were synthesised by the addition of one equivalent of an appropriate salt of the divalent cation followed by the addition of $Cu^{I}(CH_3CN)_4BF_4$. This one-pot approach is analogous to that used to synthesise the heterodinuclear cryptate $[Co^{II}Cu^{I}L](BF_4)_3$, except that acetonitrile was used as the solvent instead of methanol. The synthesis of $[Mn^{II}Cu^{I}L](ClO_4)_2(BF_4)$ required the addition of 1.1 equivalents of $Cu^{I}(CH_3CN)_4BF_4$ to avoid the formation of a yellow by-product proposed to be $[Mn^{II}L](ClO_4)_2$. The cryptates $[Mn^{II}Cu^{I}L](ClO_4)_2(BF_4)$ and $[Ni^{II}Cu^{I}L](BF_4)_3{\cdot}H_2O$ were isolated in good yield and purity by diethyl ether diffusion into the acetonitrile reaction mixtures. When this approach was used to isolate $[Fe^{II}Cu^{I}L](BF_4)_3{\cdot}CH_3CN$ a green crystalline by-product, apparently $[Cu^{II}L](BF_4)_2$, resulted. The production of this by-product was avoided by precipitating the product from the reaction mixture and recrystallising the crude product from acetonitrile by diethyl ether diffusion. The success of this strategy suggests that once formed there is no significant dissociation of the heterodinuclear cryptate in this case. The elemental analyses of all three complexes were consistent with their proposed formulae, with the metal analyses providing additional evidence of the presence of the two different metal ions.

Imine bands (and the absence of amine or carbonyl absorptions) in the infrared spectra of these heterodinuclear cryptates confirms that the L cryptand remains intact {1652 cm^{-1} for $[Mn^{II}Cu^{I}L](ClO_4)_2(BF_4)$, 1635 cm^{-1} for $[Fe^{II}Cu^{I}L](BF_4)_3{\cdot}CH_3CN$ and 1636 cm^{-1} for $[Ni^{II}Cu^{I}L](BF_4)_3{\cdot}H_2O$}. The infrared spectra of $[Fe^{II}Cu^{I}L](BF_4)_3{\cdot}CH_3CN$ and $[Ni^{II}Cu^{I}L](BF_4)_3{\cdot}H_2O$ show bands for the tetrafluoroborate counterions at 1083 cm^{-1}. The infrared spectrum of $[Mn^{II}Cu^{I}L](ClO_4)_2(BF_4)$ confirms the presence of both counterions with bands at 1117 cm^{-1} for ClO_4^- and 1083 cm^{-1} for BF_4^-.

The mass spectra of the three heterodinuclear cryptates confirm the presence of both metal ions with peaks observed for the mixed-metal clusters [MCuL] (M = Mn, Fe, Ni) in all cases. There is no evidence in any of the mass spectra for homodinuclear species of the type $[M_2L]$ or $[Cu_2L]$.

The conductivity values of 407 $mol^{-1}\,cm^2\,\Omega^{-1}$ for $[Mn^{II}Cu^{I}L](ClO_4)_2(BF_4)$, 393 $mol^{-1}cm^2\Omega^{-1}$ for $[Fe^{II}Cu^{I}L](BF_4)_3{\cdot}CH_3CN$ and 403 $mol^{-1}\,cm^2\,\Omega^{-1}$ for $[Ni^{II}Cu^{I}L](BF_4)_3{\cdot}H_2O$ indicate that all three cryptates behave as 3:1 electrolytes in acetonitrile solution.

The UV/Vis spectrum of $[Mn^{II}Cu^{I}L](ClO_4)_2(BF_4)$ has a band at 250 nm (ε = 33000 $M^{-1}\,cm^{-1}$) which is assigned to ligand-centred π-π^* transitions and is similar to that observed in the mononuclear cryptates and the free ligand L. This band has a broad shoulder at about 280 nm. No band corresponding to charge transfer transitions of the copper(I) ion can be clearly distinguished. The UV/Vis spectrum of $[Fe^{II}Cu^{I}L](BF_4)_3{\cdot}CH_3CN$ shows a group of at least four overlapping transitions with distinct peaks at 443 nm (ε = 10700 $M^{-1}\,cm^{-1}$) and 557 nm (ε = 10500 $M^{-1}\,cm^{-1}$) and shoulders at 390 nm and 540 nm. These transitions, which obscure any possible Cu^{I} MLCT band, are similar to those seen for $[Fe^{II}L](BF_4)_2$. There is also a strong π-π^* transition at 211 nm (ε = 75000 $M^{-1}\,cm^{-1}$) with a very broad shoulder extending out to 300 nm. The UV/Vis spectrum of $[Ni^{II}Cu^{I}L](BF_4)_3{\cdot}H_2O$ shows a band of weak d-d transitions ($\varepsilon \approx 20\ M^{-1}\,cm^{-1}$) with a peak at 806 nm. This is similar to the UV/Vis spectrum of $[Ni^{II}L](BF_4)_2$ and is consistent with the presence of octahedral nickel(II). There is also an additional band at 413 nm (ε = 2510 $M^{-1}\,cm^{-1}$) which is assigned to charge-transfer transitions of the copper(I) ion and is similar to that observed in $[Cu^{I}_2L](BF_4)_2$ (390 nm, ε = 3960 $M^{-1}\,cm^{-1}$).[10] Finally, a shoulder, due to ligand-centred π-π^* transitions, is observed at 250 nm.

The magnetic moments of 5.9 BM for $[Mn^{II}Cu^{I}L](ClO_4)_2(BF_4)$ and 3.1 BM for $[Ni^{II}Cu^{I}L](BF_4)_3{\cdot}H_2O$ are consistent with the presence of the spin-free paramagnetic divalent cation and the d^{10} copper(I) ion. The complex $[Fe^{II}Cu^{I}L](BF_4)_3{\cdot}CH_3CN$ was determined to be diamagnetic, which is consistent with the presence of low spin iron(II) and copper(I). The ^1H NMR spectrum of $[Fe^{II}Cu^{I}L](BF_4)_3{\cdot}CH_3CN$ (Figure 3) at 298 K shows sharp peaks, further confirming the diamagnetic nature of this complex. The spectrum is similar to that of $[ZnL](ClO_4)_2$ in that it is sharp and lacks end-to-end symmetry, and broadly similar to that of $[Fe^{II}L](BF_4)_2$, except that there is no broadening at room temperature and $^3J_{eq/eq}$ (ca. 4 Hz) coupling is observed. These observations, together with the absence of dissociation in solution noted earlier, indicate a regular octahedral site for the Fe^{II} ion in the $[Fe^{II}Cu^{I}L](BF_4)_3{\cdot}CH_3CN$ cryptate.

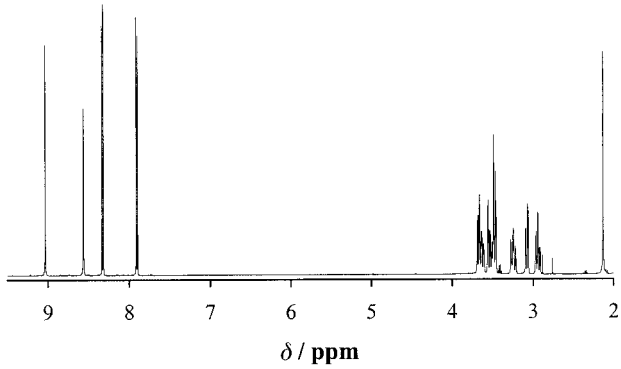

Figure 3. ^1H NMR spectrum of $[Fe^{II}Cu^{I}L](BF_4)_3{\cdot}CH_3CN$ at 298 K in CD_3CN

Crystal Structures of Mononuclear Cryptates

Single crystals of the mononuclear cryptates $[Mn^{II}L](ClO_4)_2$, $[Fe^{II}L](BF_4)_2$ and $[Ni^{II}L](ClO_4)_2$ were obtained by diethyl ether diffusion into dimethylformamide, acetonitrile and acetonitrile solutions of the cryptates, respectively, and the crystal structures were determined by X-ray diffraction techniques.

The d^5 manganese(II) ion in each of the two independent $[Mn^{II}L]^{2+}$ cryptates in the asymmetric unit is seven coordi-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

nate as a consequence of binding to three imine nitrogen atoms, three pyridazine nitrogen atoms and the bridgehead nitrogen atom (Figure 4, Table 1). However, the interaction with the bridgehead nitrogen atom is comparatively weak [av. $Mn-N_{imine}$ = 2.209 Å, av. $Mn-N_{pyridazine}$ = 2.384 Å, av. $Mn-N_{bridgehead}$ = 2.524 Å]. The $N_{bridgehead}\cdots N_{bridgehead}$ distance [N(4)···N(5) = 10.236(5) Å, N(54)···N(55) = 10.311(5) Å] is short in comparison with the free cryptand [10.443(7) Å].[9]

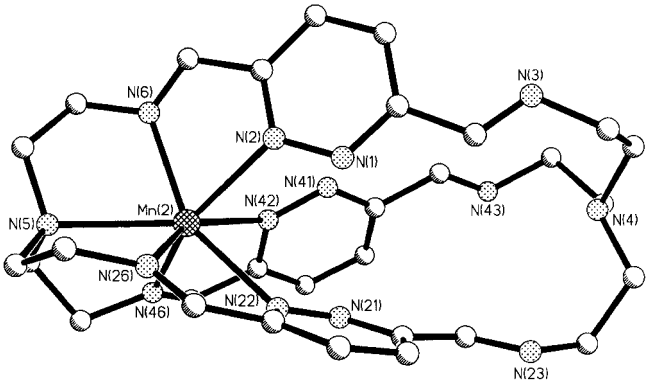

Figure 4. Perspective view of one of the two unique $[Mn^{II}L]^{2+}$ cations of $[Mn^{II}L](ClO_4)_2$; hydrogen atoms have been omitted for clarity

The structure of $[Ni^{II}L](ClO_4)_2$ is very similar to that of $[Co^{II}L]^{2+}$.[9] The nickel(II) ion in each of the two independent cryptates in the asymmetric unit is six coordinate as a consequence of binding to three imine nitrogen atoms and three pyridazine nitrogen atoms (Figure 5, Table 1). The twist angle (φ) of the nickel(II) ion [46.4° for Ni(2) and 47.0° for Ni(52)] indicates a distorted octahedral geometry (φ = 60° for octahedral and 0° for trigonal prismatic).[1] This is very similar to the twist angle of 46.9° seen for the cobalt(II) ion in $[Co^{II}L]^{2+}$.[9] The coordination of the nickel ion does not change the $N_{bridgehead}\cdots N_{bridgehead}$ distance of the cryptand by much [N(4)···N(5) = 10.519(9) Å, N(54)···N(55) = 10.421(9) Å; L 10.443(7) Å].

The structure of $[Fe^{II}L](BF_4)_2$ is similar to that of the above mononuclear cryptates, however, as the X-ray analysis is of poor quality, it is not discussed further (see Supporting Information).

The structures of $[M^{II}L]^{2+}$ (M = Mn, Fe, Co, Ni, Cu) indicate that L is able to accommodate a single, relatively stereochemically demanding, cation in geometries ranging from five to seven coordinate, although six coordination is the most common. In all of these mononuclear cryptates, all three of the strands of the organic host have all *trans* conformations. These strands would therefore have to change their conformations to all *cis* before a second metal cation could bind.

Crystal Structures of Heterodinuclear Cryptates

Single crystals of the heterodinuclear cryptates $[Mn^{II}Cu^{I}L](ClO_4)_2(BF_4)$, $[Fe^{II}Cu^{I}L](BF_4)_3{\cdot}2.5CH_3CN$ and $[Ni^{II}Cu^{I}L](BF_4)_3$ were obtained by the slow diffusion of diethyl ether vapour into acetonitrile solutions of the cryptates. A summary of key crystallographic information is given in Figures 6, 7, 8 and Tables 1−2. The structures of $[Mn^{II}Cu^{I}L]^{3+}$ and $[Ni^{II}Cu^{I}L]^{3+}$ are end-for-end disordered, as was the case in the previously determined structure of $[Co^{II}Cu^{I}L]^{3+}$ with the three strands of the cryptand also disordered in order to accommodate the differing coordination geometries of the two different metal cations.[8] Unless otherwise stated, only the major occupancy forms of each cryptate will be discussed. The structure of $[Fe^{II}Cu^{I}L]^{3+}$ is the first structure of a heterodinuclear cryptate of L that is not end-for-end disordered.

The structures of $[Mn^{II}Cu^{I}L]^{3+}$, $[Ni^{II}Cu^{I}L]^{3+}$ and $[Fe^{II}Cu^{I}L]^{3+}$ are similar to each other. In all cases, the divalent cation is six-coordinate and binds to three pyridazine and three imine nitrogen atoms. This is also observed in the previously reported heterodinuclear cryptate $[Co^{II}Cu^{I}L]^{3+}$ and the mixed-valent cryptate $[Cu^{II}Cu^{I}L]^{3+}$.[8]

Of all the $[M^{II}Cu^{I}L]^{3+}$ cryptates (M = Mn, Co, Fe, Ni, Cu), the geometry of the iron(II) ion in $[Fe^{II}Cu^{I}L]^{3+}$ is closest to a regular octahedron indicating that iron(II) is the most stereochemically demanding cation. Here the twist angle (φ) of the iron(II) ion within the N_6 donor set is 50.4°. In contrast, the twist angle of the manganese(II) ion in $[Mn^{II}Cu^{I}L]^{3+}$ [35.9° for Mn(2)] indicates that the geometry is intermediate between octahedral and trigonal prismatic. This is significantly different from the more octahedral geometries observed for the six-coordinate cryptates $[Co^{II}L]^{2+}$, $[Ni^{II}L]^{2+}$ and $[M^{II}Cu^{I}L]^{3+}$ (M = Fe, Co, Ni, Cu), where the twist angles range from 45.4−50.4° (Table 2). However, this is consistent with manganese(II) being less stereochemically demanding than the other divalent cations as a result of its d^5 configuration. The greater deviation from regular octahedral geometry for manganese(II) in $[Mn^{II}Cu^{I}L]^{3+}$ is also reflected in the wider range of *cis* N−M−N angles (71.5−105.4° for Mn(2) compared with 80.7−97.0° for Fe(2) in $[Fe^{II}Cu^{I}L]^{3+}$) (Table 2).

The non-stereochemically demanding copper(I) ion in $[Mn^{II}Cu^{I}L]^{3+}$, $[Ni^{II}Cu^{I}L]^{3+}$ and $[Fe^{II}Cu^{I}L]^{3+}$ has a distorted trigonal-pyramidal geometry and is coordinated by three imine nitrogen atoms and the bridgehead nitrogen atom. However, the interactions with the imine nitrogen atoms are stronger than those with the bridgehead nitrogen atoms [av. $Cu(1)-N_{imine}$ = 2.00 Å, $Cu(1)-N_{bridgehead}$ = 2.33 Å] (Table 2). The copper(I) ion is displaced from the mean plane of the three imine nitrogen donors towards the centre of the cavity by 0.24−0.31 Å (Table 2), that is, away from the bridgehead nitrogen atom. This is also seen in the structure of the dicopper(I) cryptate $[Cu^{I}_2L](BF_4)_2$, where the two copper(I) ions are displaced from their $(N_{imine})_3$ mean planes, away from the bridgehead nitrogen atoms, by 0.238 and 0.234 Å, respectively,[10] and in the structures of other tren-derived Schiff-base cryptates.[13] Thus, although the copper(I) ions are within bonding distance of the bridgehead nitrogen atom, this interaction is primarily due to their enforced proximity. The distances between Cu(1) and the pyridazine nitrogen atoms {for example, in $[Fe^{II}Cu^{I}L]^{3+}$, shortest $Cu-N_{pyridazine}$ distance is 3.007 Å,

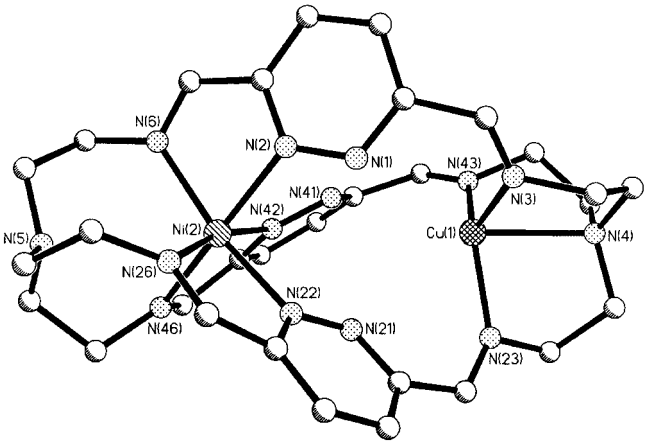

Figure 8. Perspective view of the major occupancy form of one of the two unique $[Ni^{II}Cu^{I}L]^{3+}$ cations of $[Ni^{II}Cu^{I}L](BF_4)_3{\cdot}H_2O$; hydrogen atoms have been omitted for clarity

for Cu(1)−N(41)} preclude further strong bonding interactions. In all cases, the geometry of the copper ion is consistent with the proposed +1 oxidation state.

In the series of heterodinuclear cryptates, the $M^{II}\cdots Cu^{I}$ interatomic distance follows the order Mn > Co > Cu > Ni > Fe (Table 2), decreasing with the decreasing ionic radius of the divalent cation.[14] This order is also weakly correlated to the trigonal prismatic twist angle φ, with Mn having the smallest (36°) and Fe the largest (50°) twist angle. The trend in $N_{bridgehead}\cdots N_{bridgehead}$ distances is less clear, although $[Fe^{II}Cu^{I}L]^{3+}$, which has the shortest $M^{II}\cdots Cu^{I}$ interatomic distance of 4.723(6) Å, also has the shortest $N_{bridgehead}\cdots N_{bridgehead}$ distance of 10.059(6) Å (Table 2). Conversely, the manganese cryptate $[Mn^{II}Cu^{I}L]^{3+}$ has the longest $M^{II}\cdots Cu^{I}$ interatomic distance of 5.231(10) Å and the longest $N_{bridgehead}\cdots N_{bridgehead}$ distance of 10.455(10) Å.

The structures of $[Mn^{II}Cu^{I}L]^{3+}$and $[Ni^{II}Cu^{I}L]^{3+}$ show both differences and similarities to the structures of the corresponding mononuclear cryptates $[Mn^{II}L]^{2+}$ and $[Ni^{II}L]^{2+}$. In both heterodinuclear cases, the L cryptand has adopted a conformation with mutually *cis* imino C=N functions in each strand in order to bind the copper(I) ions. This is in contrast to the mutually *trans* conformations seen in the corresponding mononuclear cryptates. For $[Mn^{II}Cu^{I}L]^{3+}$, the binding of copper(I) has also altered the coordination geometry of the manganese(II) ion, reducing its coordination number from seven to six as a result of a lengthening of the $Mn-N_{bridgehead}$ distance from 2.524(3) Å in $[Mn^{II}L]^{2+}$ to 2.931(6) Å in $[Mn^{II}Cu^{I}L]^{3+}$. Coordination of the copper(I) ion has also increased the overall length of the cryptand. The $N_{bridgehead}\cdots N_{bridgehead}$ distance is 10.455(10) Å for Mn(1) in $[Mn^{II}Cu^{I}L]^{3+}$ and 10.236(5) Å for $[Mn^{II}L]^{2+}$. The distorted octahedral geometry of the nickel(II) ion in $[Ni^{II}Cu^{I}L]^{3+}$ is similar to that seen in the mononuclear nickel(II) cryptate $[Ni^{II}L]^{2+}$. The twist angles of nickel(II) [47.2° for Ni(2) and 47.3° for Ni(3)] are very similar to that seen in $[Ni^{II}L]^{2+}$. The N···N bridgehead distances [10.309(6) and 10.413(6) Å for the two unique cations] are slightly shorter than those of $[Ni^{II}L]^{2+}$ [10.519(9) and 10.421(9) Å for the two unique cations].

The cryptate $[Fe^{II}Cu^{I}L]^{3+}$ is of some interest as a structural model for the oxygen binding site of cytochrome c oxidase. This dinuclear site consists of a heme a_3 iron and a copper ion (Cu_B) with an interatomic distance of 4.5−5.2 Å depending on the source of the enzyme.[15] The cation $[Fe^{II}Cu^{I}L]^{3+}$ has a similar Fe···Cu interatomic distance to cytochrome c oxidase with the same oxidation states present as in the fully reduced form of the enzyme. However, the iron(II) ion in $[Fe^{II}Cu^{I}L]^{3+}$ has more donor atoms than the

[a] $E_{1/2}$ and $\triangle E$ in V. I = irreversible, hence value quoted is E_{pa}; QR = quasi-reversible; all other processes are reversible. Potentials for reversible processes are quoted from the cyclic voltammogram and potentials for quasi-reversible processes are quoted from the square wave voltammogram or the cyclic voltammogram. For quasi-reversible processes $\triangle E$ is only quoted where E_{pa} and E_{pc} are well defined. All potentials are vs. 0.01 mol L^{-1} $AgNO_3$/Ag. [b] Process overlaps with neighbouring process hence this is an estimated $E_{1/2}$ only. [c] As previously reported in reference.[9] [d] As previously reported in reference.[10] [e] When scanning out to −0.7 V an additional irreversible oxidation process is observed at +0.39 V which is associated with the reduction processes. [f] E_{pc} quoted (not $E_{1/2}$) since E_{pa} is poorly defined.

heme a_3 iron of cytochrome c oxidase and therefore seems less likely to bind exogenous ligands like oxygen, although the Cu^{I} ions will readily accept additional donor(s) on oxidation.

Electrochemical Studies on Mononuclear Cryptates

Unless otherwise stated, in this paper all potentials are quoted vs. 0.01 mol L^{-1} $AgNO_3$/Ag and all controlled potential experiments were carried out until the current reached 1% of the initial value.

The series of mononuclear cryptates show irreversible oxidation waves starting from about +1 V (Table 3) that are probably ligand-centred. In the case of iron(II) and cobalt(II), quasi-reversible oxidation waves at +0.78 and +0.29 V[9], respectively, which are likely to be attributable to metal-centred processes, are observed. For the copper(II) complex a reversible metal-centred reduction is observed at −0.38 V.[10]

The cyclic voltammogram of $[Mn^{II}L](ClO_4)_2$ (Figure 9, Table 3) reveals an irreversible oxidation process at +1.03 V. A coulometry experiment at +1.20 V resulted in no colour change and the transfer of 1.00 electron equivalents, indicating that this is a one-electron oxidation. Significant changes in the cyclic voltammogram of the complex after this oxidation indicated that this process is chemically irreversible. Further investigation would be required to determine whether the process at +1.03 V is metal- or ligand-centred. The absence of oxidation processes below +1.03 V indicates that the manganese(II) oxidation state is stabilised by the soft nitrogen donors and, more importantly, the seven coordinate geometry provided by L, as expected on the basis of the research of McKee and co-workers.[16] On scanning to negative potentials, three almost reversible, probably ligand-centred, processes are seen (Table 3). These are similar to the processes seen for $[Zn_2L](ClO_4)_4$ (see later), but are more spread out and occur at more negative potentials. Coulometry at −1.39 V resulted in the transfer of 1.80 electron equivalents and precipitation of the product. As all three reduction processes have similar peak heights and peak separations, it is likely that they are all two-electron processes. This provides further evidence that L is able to undergo two-electron reductions. However, it should be noted that the close proximity of these potentials diminishes confidence in the coulometric result.

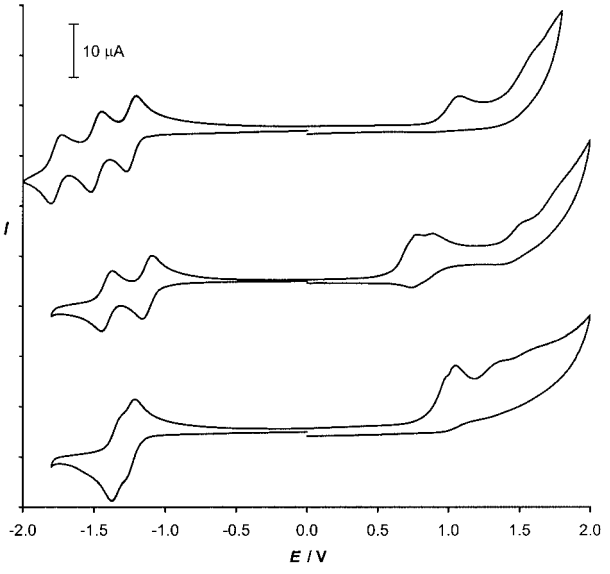

Figure 9. Full range cyclic voltammograms of the mononuclear cryptates $[Mn^{II}L](ClO_4)_2$ (top), $[Fe^{II}L](BF_4)_2$ (middle) and $[Ni^{II}L](BF_4)_2$ (bottom) in acetonitrile (200 mV s^{-1} vs. 0.01 mol L^{-1} $AgNO_3$/Ag); each scan starts at 0 V and initially scans to negative potentials

The cyclic voltammogram of the monoiron cryptate $[Fe^{II}L](BF_4)_2$ shows two almost reversible reductions (Figure 9, Table 3). A further quasi-reversible process is observed at −1.87 V (see Supporting Information). These processes are similar to the reduction processes observed for

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

$[Mn^{II}L](ClO_4)_2$, but start at slightly less negative potentials and are more spread out. Coulometry at −1.26 V resulted in the transfer of 1.89 electrons suggesting that they are two-electron processes. This reduction resulted in decomposition of the complex as indicated by the cyclic voltammograms recorded after the coulometry experiment. On scanning to positive potentials two closely overlapping quasi-reversible oxidation processes are observed. As noted earlier, at least one of these processes is likely to be due to Fe^{II} to Fe^{III} oxidation.

The cyclic voltammogram of the nickel cryptate $[Ni^{II}L](BF_4)_2$ shows two closely overlapping reversible reduction processes (Figure 9, Table 3). Coulometry at −1.50 V resulted in the transfer of 1.97 electron equivalents and some precipitation. This suggests that both processes correspond to one-electron transfers, assuming that precipitation occurred after the second process rather than after the first. On scanning to more negative potentials a further quasi-reversible reduction process occurs. On scanning to positive potentials two overlapping irreversible oxidation processes are seen (Table 3). Although we are unable, in the absence of ESR experiments, to decide unambiguously whether any processes in these cyclic voltammograms are metal-centred, the fact that no oxidation processes of any sort occur below +0.99 V in this case demonstrates the stability of the nickel(II) oxidation state in the cryptand.[17]

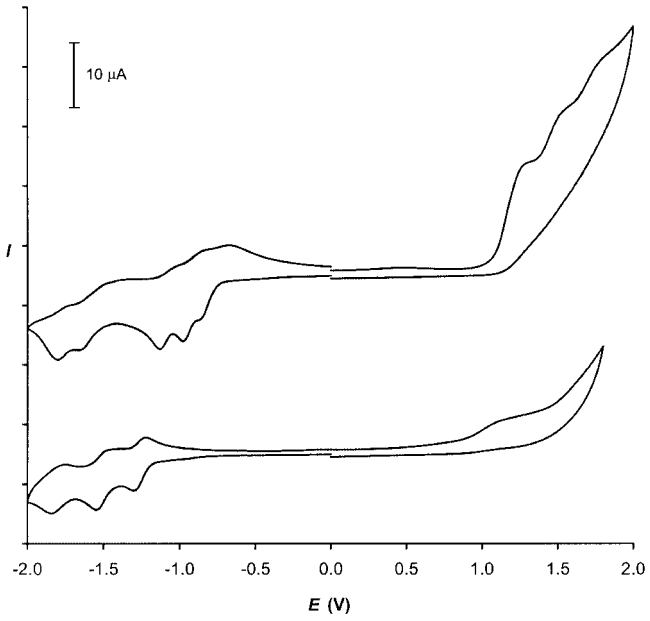

Figure 10. Full range cyclic voltammograms of $[Zn_2L](ClO_4)_4$ in acetonitrile before (top, two separate scans both starting from 0 V but one initially scanning to negative potentials and the other to positive potentials) and after (bottom, a single scan starting from 0 V and initially scanning to negative potentials) coulometry at −1.30 V (200 mV s^{-1} vs. 0.01 mol L^{-1} $AgNO_3$/Ag)

Electrochemical Studies on the Homodinuclear Zinc Cryptate

The electrochemistry of $[Zn_2L](ClO_4)_4$ was investigated in order to study the electrochemical processes of the L cryptand since the coordinated zinc ions are not expected to undergo reduction or oxidation in the potential range accessible in acetonitrile. The cyclic voltammogram of $[Zn_2L](ClO_4)_4$ shows three high-current irreversible oxidation processes as well as several reduction processes (Figure 10, Table 3). The oxidation processes had previously been observed in other cryptates of L,[10] and are also seen for some of the cryptates of L described here (Table 3), and are assigned to ligand oxidations. The first three overlapping reduction processes of $[Zn_2L](ClO_4)_4$ (Figure 11, Table 3) are almost reversible as indicated from a variable scan rate study. These processes are tentatively assigned to reduction of the three strands of the L cryptand. On scanning to more negative potentials two further quasi-reversible reduction processes are seen, which may correspond to further ligand reduction.

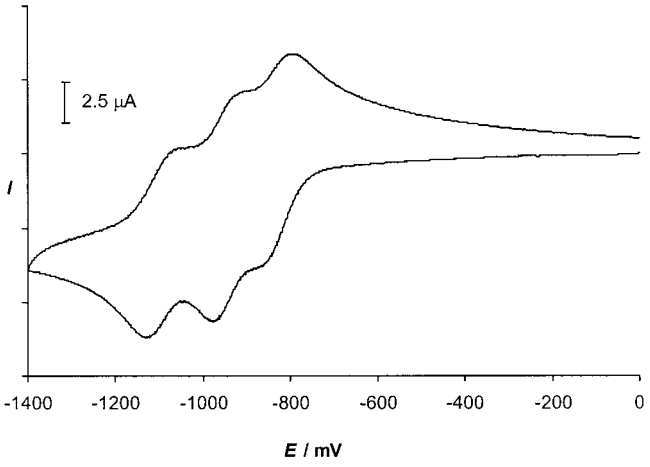

Figure 11. Cyclic voltammogram of $[Zn_2L](ClO_4)_4$ in acetonitrile showing the first three reversible reduction processes (200 mV s^{-1} vs. 0.01 mol L^{-1} $AgNO_3$/Ag). The scan starts at 0 V

The peak separations for the first two reduction processes in particular are smaller than expected for a one-electron process but larger than expected for a fully reversible two-electron process in our electrochemical cell. The closely overlapping nature of these processes made them difficult to study separately by coulometry. Coulometry at −1.30 V resulted in the transfer of just 2.00 electron equivalents, with coulometry at −1.05 V giving a similar result. During this two-electron reduction the pale yellow solution initially became an intense purple colour and then gradually became orange-yellow as the final two-electron reduction product formed. These colour changes could be accounted for by chemical reaction of an unstable radical product. Cyclic voltammograms measured after the two-electron reduction was complete demonstrate that the cryptate has indeed been altered: the behaviour at positive potentials has been affected (Figure 10), and whilst there are still three reduction processes at negative potentials, these are now at significantly more negative potentials and are more spread out (Figure 10 and 11). The processes, which now occur at $E_{1/2}$ = −1.26 V (ΔE = 0.07 V), −1.50 V (ΔE = 0.09 V) and −1.80 V (ΔE = 0.09 V), appear to be less reversible. These results indicate that the reduction of $[Zn_2L](ClO_4)_4$ is

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

chemically irreversible and that the product of this reduction is harder to reduce than the original complex.

Electrochemical Studies on Heterodinuclear Cryptates

The electrochemical properties of the series of heterodinuclear cryptates $[M^{II}Cu^{I}L](X)_3$ (M = Mn, Fe, Co, Ni; X = BF_4^- or ClO_4^-) were investigated to study the effect of the divalent cation on the electrochemistry of the copper(I) ion and vice versa. In all cases, following the addition of the Cu^{I} ion, a reversible or quasi-reversible wave corresponding to the $Cu^{I} \rightleftarrows Cu^{II}$ couple is observed in the voltammograms. This wave is usually in the potential range which is inactive in the monometallic precursor complexes (exceptions include the $[Co^{II}Cu^{I}L]^{3+}$ and $[Cu^{II}Cu^{I}L]^{3+}$ complexes). In addition, a copper deposition and stripping peak is observed following the application of potentials below about −1 V for all except the $[Fe^{II}Cu^{I}L]^{3+}$ complex.

The cyclic voltammogram of the heterodinuclear cryptate $[Mn^{II}Cu^{I}L](ClO_4)_2(BF_4)$ (Figure 12, Table 3) shares several features with that of $[Mn^{II}L](ClO_4)_2$, as well as additional features due to the presence of copper(I). The reduction region contains two almost reversible processes at $E_{1/2}$ = −1.25 V (ΔE = 0.08 V) and −1.46 V (ΔE = 0.09 V). These processes are similar to the first two reduction processes for $[Mn^{II}L](ClO_4)_2$ and are probably ligand-centred. On scanning to more negative potentials there are two further overlapping quasi-reversible processes with $E_{1/2}$ approximately equal to −1.77 and −1.89 V which are probably also ligand-centred. There is also an irreversible reduction process at −0.86 V. This process is associated with a stripping wave at −0.54 V (resulting from deposition of copper on the electrode), which is present when scanning to potentials below about −0.8 V, and is assigned to the $Cu^{I} \rightarrow Cu^{0}$ process.

There is an irreversible oxidation process at +1.07 V. This is similar to the process seen at +1.03 V for $[Mn^{II}L](ClO_4)_2$ and may be metal or ligand-centred. There is also an additional quasi-reversible oxidation process at $E_{1/2}$ = +0.25 V (ΔE = 0.10 V) and an irreversible oxidation process at about +0.81 V. Coulometry at +0.50 V resulted in the transfer of 1.06 electron equivalents leading to the assignment of the process at $E_{1/2}$ = +0.25 V to $Cu^{I} \rightleftarrows Cu^{II}$. The colour change from orange-brown to green during this oxidation is consistent with this assignment. The cyclic voltammogram of the bulk oxidation product was unchanged from that of the original $[Mn^{II}Cu^{I}L]^{3+}$ cyclic voltammogram, apart from some reduction in the peak size of the processes at +0.25 V and +1.07 V which may indicate partial decomposition of the complex.

The cyclic voltammogram of $[Fe^{II}Cu^{I}L](BF_4)_3{\cdot}CH_3CN$ shows three reversible reduction processes (Figure 12, Table 3). These are similar to the ligand-centred processes seen for $[Fe^{II}L](BF_4)_2$ although they occur at less negative potentials and are closer together. Coulometry at −1.15 V resulted in the transfer of 2.05 electron equivalents (I_f, 2.5% of I_i) and some precipitation. This suggests that the process at −1.07 V is a two-electron reduction. There is also an almost reversible oxidation process at $E_{1/2}$ = +0.49 V (ΔE = 0.10 V). Coulometry at +0.60 V resulted in the transfer of 1.40 electron equivalents (I_f, 2% of I_i). Although it is not possible to conclude whether this is a one- or two-electron process from coulometry, comparison with the cyclic voltammograms of $[M^{II}Cu^{I}L]^{3+}$ (M = Mn, Ni, Cu) indicates that this is probably a one-electron oxidation corresponding to $Cu^{I} \rightleftarrows Cu^{II}$. The cyclic voltammogram was largely unchanged after this oxidation, although all processes appeared less reversible and a small copper stripping wave was present at −0.56 V. This indicates that the complex was at least partially intact after oxidation. On scanning to more positive potentials two further irreversible oxidation processes are seen; one of these is likely to be due to oxidation of Fe^{II}.

The cyclic voltammogram of the heterodinuclear cryptate $[Ni^{II}Cu^{I}L](BF_4)_3{\cdot}H_2O$ is complex showing at least four closely spaced processes in the reduction region, with $E_{1/2}$

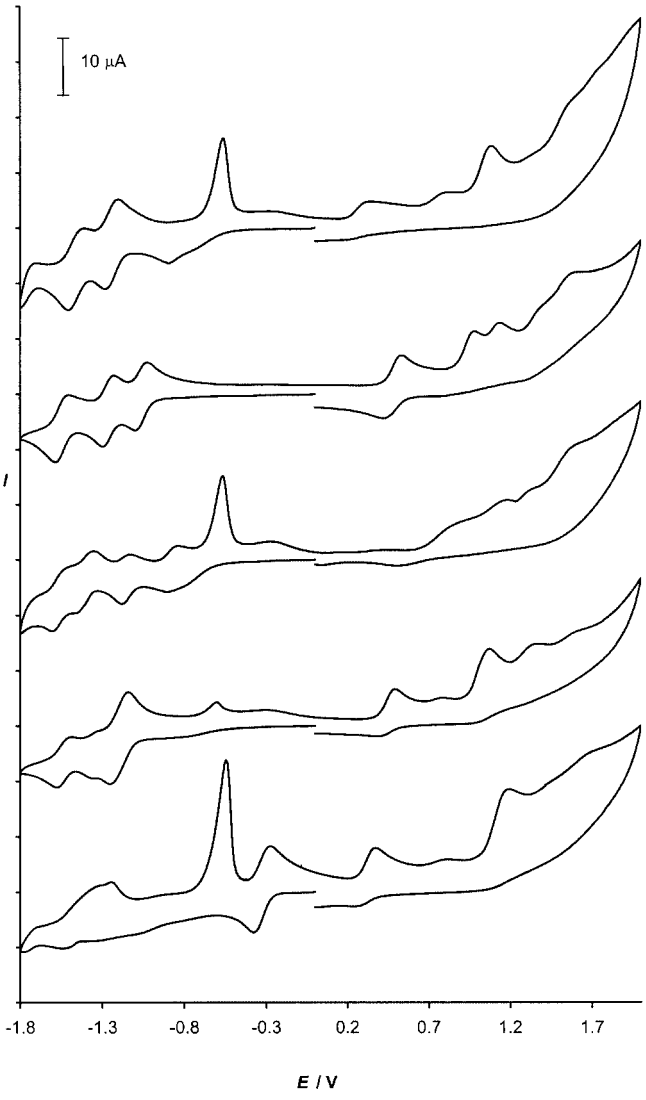

Figure 12. Full range cyclic voltammograms of the heterodinuclear cryptates in acetonitrile. From top to bottom: $[Mn^{II}Cu^{I}L](ClO_4)_2(BF_4)$, $[Fe^{II}Cu^{I}L](BF_4)_3{\cdot}CH_3CN$, $[Co^{II}Cu^{I}L](BF_4)_3$, $[Ni^{II}Cu^{I}L](BF_4)_3{\cdot}H_2O$ and $[Cu^{II}Cu^{I}L](BF_4)_3$ (200 mV s^{-1} vs. 0.01 mol L^{-1} $AgNO_3$/Ag); each scan starts at 0 V and initially scans to negative potentials

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

approximately equal to −1.19, −1.36, −1.53 and −1.89 V (Figure 12 and Supporting Information, Table 3). The overlapping nature of the processes meant that coulometry experiments could not be carried out. A small stripping wave occurs at −0.59 V when scanning to potentials below −1.00 V, which is due to the formation of copper on the electrode.

On scanning to positive potentials a reversible oxidation process is seen at $E_{1/2}$ = +0.46 V. Coulometry at +0.70 V resulted in the transfer of 1.01 electron equivalents indicating that this is a one-electron process. This process is therefore assigned to $Cu^{I} \rightleftarrows Cu^{II}$. Furthermore, the colour changed during this oxidation from orange-brown to green, consistent with this assignment. The cyclic voltammogram of the oxidation product was unchanged immediately after the oxidation, indicating that the $[Ni^{II}Cu^{II}L]^{4+}$ product is stable under argon in dry acetonitrile. The cyclic voltammogram of $[Ni^{II}Cu^{I}L](BF_4)_3{\cdot}H_2O$ also shows an irreversible oxidation process at +1.07 V, which may correspond to the oxidation of nickel(II) to nickel(III)[17] or a ligand-centred process.

As shown in Figure 12, the cyclic voltammogram of $[Co^{II}Cu^{I}L](BF_4)_3$ is complex with many processes (Table 3). The reduction region shows a series of quasi-reversible processes, as well as a stripping wave at −0.54 V. These processes are probably a mixture of metal- and ligand-centred reductions.

The oxidation region shows several quasi-reversible and irreversible processes. Applying a potential of 0.00 V failed to generate current flow confirming that oxidation occurs at positive potentials vs. $AgNO_3$/Ag(s). On scanning to positive potentials, there are two quasi-reversible processes with poorly resolved oxidation peaks on the forward scan and reduction peaks at +0.58 and +0.08 V on the return scan. Coulometry at +1.00 V resulted in the transfer of 2.00 electron equivalents and caused the colour of the complex to change from orange to dark brown. Subsequent coulometry at +0.25 V resulted in the transfer of 0.95 electron equivalents. These results suggest that the two quasi-reversible processes are both one-electron oxidations. As the Co^{II} to Co^{III} oxidation in the mononuclear cryptate $[Co^{II}L](BF_4)_2$ occurs at the relatively low potential of $E_{1/2}$ = +0.29 V,[9] it is possible that the cobalt(II) (rather than Cu^{I}) centre is oxidised first, followed by conformational changes deriving from the appreciably smaller radius of the Co^{III} cation.

The electrochemical properties of the heterodinuclear cryptates $[M^{II}Cu^{I}L](X)_3$ (M = Mn, Fe, Co, Ni, Cu, X = BF_4^- or ClO_4^-) indicate that the divalent cation influences the potential and reversibility of the $Cu^{I} \rightleftarrows Cu^{II}$ process (Table 3, Figure 13). For the cryptates $[M^{II}Cu^{I}L]^{3+}$ (M = Mn, Fe, Ni, Cu) the $E_{1/2}$ for the $Cu^{I} \rightleftarrows Cu^{II}$ process in CH_3CN is inversely correlated with the solid-state $M^{II}\cdots Cu^{I}$ distance and follows the order: Fe (+0.49 V; 4.72 Å) > Ni (+0.46 V; 4.86 Å) > Cu (+0.33 V; 4.96 Å) > Mn (+0.25 V; 5.23 Å). Therefore the influence of the divalent cation on the electrochemistry of the copper(I) ion is predominantly electrostatic, with the copper(I) ion becoming harder to oxidise with closer proximity to the positively charged divalent cation. The copper(I) ion appears to be most stable towards reduction and towards any subsequent dissociation in $[Fe^{II}Cu^{I}L](BF_4)_3{\cdot}CH_3CN$ since no stripping wave is observed, even on scanning to −1.80 V.

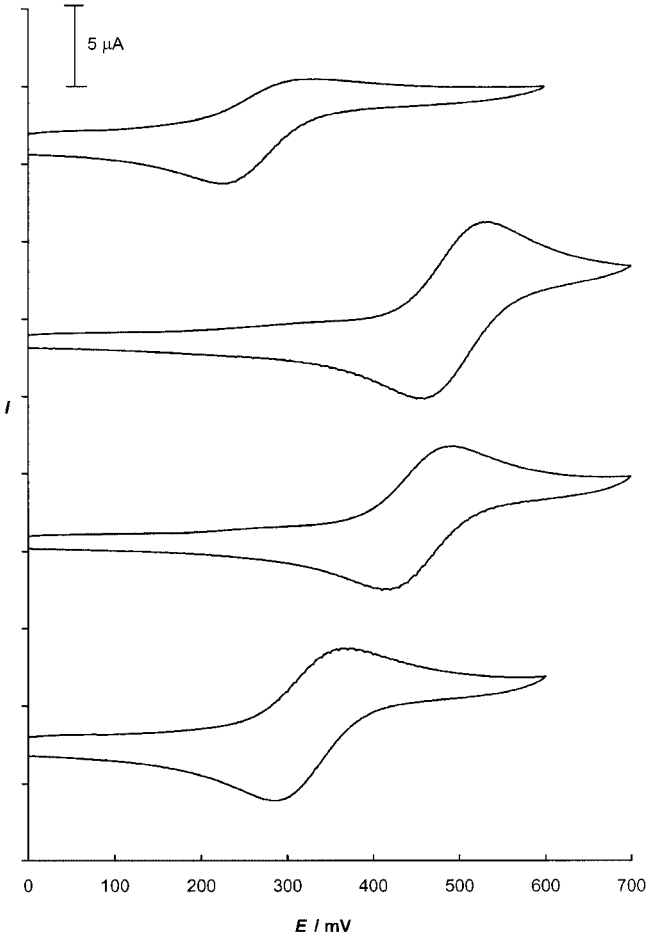

Figure 13. Cyclic voltammograms of heterodinuclear cryptates in acetonitrile showing the $Cu^{I} \rightleftarrows Cu^{II}$ process; from top to bottom: $[Mn^{II}Cu^{I}L](ClO_4)_2(BF_4)$, $[Fe^{II}Cu^{I}L](BF_4)_3{\cdot}CH_3CN$, $[Ni^{II}Cu^{I}L](BF_4)_3{\cdot}H_2O$ and $[Cu^{II}Cu^{I}L](BF_4)_3$ (200 mV s^{-1} vs. 0.01 mol L^{-1} $AgNO_3$/Ag); each scan starts at 0 V

Neither of the candidates for the $Cu^{I} \rightleftarrows Cu^{II}$ process for $[Co^{II}Cu^{I}L](BF_4)_3$, E_{pc} = +0.08 and +0.58 V ($M^{II}\cdots Cu^{I}$ 5.08 Å), fits into the above trend. This cryptate also shows the least reversible oxidation in this series of heterodinuclear cryptates. The anomalous behaviour of $[Co^{II}Cu^{I}L](BF_4)_3$ could be accounted for by the oxidation of the cobalt(II) ion (i.e. Co^{II} to Co^{III} at E_{pc} = +0.08 V) before the copper(I) ion (i.e. Cu^{I} to Cu^{II} at E_{pc} = +0.58 V). Oxidation of cobalt(II) to cobalt(III) may affect the M···Cu distance and would nevertheless enhance the positive charge (from +2 to +3) near the copper(I) ion, thus increasing its oxidation potential as observed.

It would be of interest to monitor the reciprocal effect of the copper(I) ion on the electrochemistry of the divalent cation in $[M^{II}Cu^{I}L](X)_3$ (M = Mn, Fe, Co, Ni, X = BF_4^- or ClO_4^-). However, this is ruled out due to the difficulty

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

of differentiating such metal-centred processes from ligand-centred processes with the facilities available to us.

Conclusion

The symmetrical cryptand L readily forms mononuclear cryptates with first-row transition-metal ions with geometries ranging from five to seven coordinate. Addition of copper(I) to these unsymmetrical monometallic cryptates results in the controlled formation of the heterodinuclear cryptates $[M^{II}Cu^{I}L](X)_3$ (M = Mn, Fe, Co, Ni, X = BF_4^- or ClO_4^-). This is the first series of this kind to be reported.

The syntheses of $[Zn_2L](ClO_4)_4$ and $Mn_2LCl_4{\cdot}H_2O$ demonstrate that L can also form homodinuclear complexes with relatively non-stereochemically demanding divalent cations. However, the choice of counterion and/or solvent appears to be crucial for the formation of the dinuclear complexes, and there is evidence of interaction of the counterions with the divalent zinc or manganese ions. Electrochemical studies on $[Zn_2L](ClO_4)_4$ revealed that the L cryptand is able to undergo a series of reductions and oxidations, which were also observed in several other cryptates of L.

The series of heterodinuclear cryptates has been structurally characterised. In all cases, the divalent cation has a distorted octahedral geometry and the copper(I) ion has a distorted trigonal pyramidal geometry. The $M^{II}\cdots Cu^{I}$ distance in these cryptates decreases with decreasing ionic radius of the divalent cation.

Cyclic voltammetric studies on this series of heterodinuclear cryptates show that the $E_{1/2}$ of the Cu^{I}/Cu^{II} couple follows the order Fe > Ni > Cu > Mn and is inversely correlated to the $M^{II}\cdots Cu^{I}$ distance. The previously synthesised $[Co^{II}Cu^{I}L](BF_4)_3$ does not follow this trend, probably because the cobalt ion is in the +3 state at the time when Cu^{I} is oxidised.

Experimental Section

General: 3,6-Diformylpyridazine,[18] L[9] and $Cu^{I}(MeCN)_4X$ (X = BF_4^-)[19] were synthesised as described previously. For the electrochemical studies HPLC grade MeCN was distilled from CaH_2 immediately before use. Chloroform was extracted with the equivalent volume of water, four times, and dried over Na_2SO_4, before use. All other solvents and reagents were used as received. Physical measurements were carried out as described previously,[18,20] except for the following: the electrochemistry was carried out with 1 mmol L^{-1} dry acetonitrile solutions and 0.1 mol L^{-1} tetraethylammonium perchlorate or tetrabutylammonium hexafluorophosphate as the supporting electrolyte, on an EG&G Princeton Applied Research 273A potentiostat using a 0.01 mol L^{-1} $AgNO_3$/Ag reference electrode. As a further reference check, ferrocene was added at the conclusion of each experiment: the Fc/Fc^+ couple consistently occurred at $E_{1/2}$ = +0.07 ± 0.01 V with ΔE = 0.07 V. Magnetic measurements were carried using a Johnson−Matthey magnetic susceptibility balance MSB-MKI. All magnetic data were corrected for diamagnetic contributions using Pascal's constants.

Caution: *Whilst no problems were encountered in the course of this work perchlorate mixtures are potentially explosive and should therefore be handled with appropriate care.*

Preparation of $[Mn^{II}L](ClO_4)_2$: L (0.060 g, 0.1 mmol) was suspended in methanol (20 mL) and stirred. To this was added a methanol solution (10 mL) of $Mn(ClO_4)_2{\cdot}6H_2O$ (0.037 g, 0.1 mmol) which caused the cream suspension to turn bright yellow. After stirring overnight, the suspension was filtered yielding $[Mn^{II}L](ClO_4)_2$ as a yellow powder (0.066 g, 77%). Single crystals suitable for X-ray diffraction were obtained by recrystallisation of the product from DMF by vapour diffusion of diethyl ether. IR (KBr, inter alia): $\tilde{\nu}$ = 3415 (b, s), 1652 (m), 1144 (s), 1116 (s), 1088 (s), 625 cm^{-1} (m). UV/Vis (MeCN): λ_{max} (ε) = 208 (62100), 250 nm (35100 L $mol^{-1}cm^{-1}$), 290 (sh). MS (ESI): *m/z* (%) = 746 (34) $[MnC_{30}H_{36}N_{14}(ClO_4)^+]$, 324 (100) $[MnC_{30}H_{36}N_{14}^{2+}]$. μ = 6.3 BM (293 K); Λ_m(MeCN) = 280 $mol^{-1}\,cm^2\,\Omega^{-1}$ (2:1 = 220−300 $mol^{-1}\,cm^2\,\Omega^{-1}$).[12] $C_{30}H_{36}MnN_{14}(ClO_4)_2$ (846.6): calcd. C 42.56, H 4.29, N 23.16; found C 42.44, H 4.47, N 22.97.

Preparation of $[Fe^{II}L](BF_4)_2$: L (0.045 g, 0.08 mmol) was suspended in degassed acetonitrile (30 mL) and stirred under a nitrogen atmosphere. To this was added an acetonitrile solution (5 mL) of $Fe(BF_4)_2{\cdot}6H_2O$ (0.026 g, 0.08 mmol), which caused the suspension to clarify and become deep purple. After stirring under a nitrogen atmosphere for 4 h the volume of the solution was reduced to about 15 mL in vacuo. Diethyl ether diffusion into the resulting solution gave $[Fe^{II}L](BF_4)_2$ as a purple crystalline solid (0.032 g, 52%). ^1H NMR (500 MHz, solvent CD_3CN, reference CH_3CN, 243 K): δ = 8.94 (s, 1 H, H^{11}), 8.24 (d, 1 H, H^3), 8.08 (d, 1 H, H^4), 7.37 (s, 1 H, H^6), 3.71−3.88 (m, 3 H, H^{7b}, H^{10a}, H^{10b}), 3.61 (br, d, 1 H, H^{9b}), 3.39 (br, t, 1 H, H^{9a}), 3.30 (t, 1 H, H^{7a}), 2.95 (t, 1 H, H^{8a}), 2.36 (m, 1 H, H^{8b}); at 298 K: 8.49 (s, br), 8.16 (d), 7.48 (s), 3.94 (s, br), 3.82 (dt), 3.59 (s, br), 3.37 (t), 3.00 (t), 2.40 (dd). IR (KBr, inter alia): $\tilde{\nu}$ = 3414 (b, s), 1638 (m), 1617 (m), 1534 (w), 1437 (m), 1053 (s), 1032 (s), 521 cm^{-1} (w). UV/Vis (MeCN): λ_{max} (ε) = 213 (64700), 250 (sh), 370 (sh), 428 (4800), 540 (sh), 588 nm (8030 L $mol^{-1}\,cm^{-1}$). MS (ESI): *m/z* (%) = 735 (26) $[FeC_{30}H_{36}N_{14}(BF_4)^+]$, 648 (25) $[FeC_{30}H_{36}N_{14}^+]$, 615 (100) $[NaC_{30}H_{36}N_{14}^+]$, 324 (69) $[FeC_{30}H_{36}N_{14}^{2+}]$. Λ_m(MeCN) = 286 $mol^{-1}\,cm^2\,\Omega^{-1}$ (2:1 = 220−300 $mol^{-1}\,cm^2\,\Omega^{-1}$).[12] $C_{30}H_{36}FeN_{14}(BF_4)_2$ (822.2): calcd. C 43.83, H 4.41, N 23.85; found C 43.78, H 4.54, N 23.86.

Preparation of $[Ni^{II}L](BF_4)_2$: L (0.062 g, 0.1 mmol) was suspended in acetonitrile (40 mL) and stirred. To this was added an acetonitrile solution (10 mL) of $Ni(BF_4)_2{\cdot}6H_2O$ (0.036 g, 0.1 mmol), which caused the suspension to clarify and become pale greenish yellow. After stirring overnight, the volume was reduced to about 10 mL in vacuo. Diffusion of diethyl ether into the resulting solution gave brown crystals of $[Ni^{II}L](BF_4)_2$ (0.069 g, 80%). IR (KBr, inter alia): $\tilde{\nu}$ = 3419 (b, s), 1647 (m), 1440 (m), 1050 (s), 521 cm^{-1} (w). UV/Vis (MeCN): λ_{max} (ε) = 211 (68700), 250 (sh), 825 (30), 908 nm (30 L $mol^{-1}\,cm^{-1}$). MS (ESI): *m/z* (%) = 737 (52) $[NiC_{30}H_{36}N_{14}(BF_4)^+]$, 325 (100) $[NiC_{30}H_{36}N_{14}^{2+}]$. μ = 3.1 BM (293 K); Λ_m(MeCN) = 301 $mol^{-1}\,cm^2\,\Omega^{-1}$ (2:1 = 220−300 $mol^{-1}\,cm^2\,\Omega^{-1}$).[12] $C_{30}H_{36}N_{14}Ni(BF_4)_2$ (825.0): calcd. C 43.67, H 4.40, N 23.77; found C 43.86, H 4.42, N 23.57.

Preparation of $[Ni^{II}L](ClO_4)_2$: L (0.029 g, 0.05 mmol) was suspended in acetonitrile (10 mL) and stirred. To this was added an acetonitrile solution (8 mL) of $Ni(ClO_4)_2{\cdot}6H_2O$ (0.018 g, 0.05 mmol), which caused the suspension to clarify and become pale greenish yellow. After stirring overnight, the volume was reduced to about 5 mL in vacuo. Diffusion of diethyl ether into the

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

resulting solution gave brown crystals of $[Ni^{II}L](ClO_4)_2$ (0.034 g, 81%). IR (KBr, inter alia): $\tilde{\nu}$ = 3414 (b, m), 2916 (m), 2849 (m), 1647 (m), 1442 (m), 1329 (m), 1083 (b, s), 622 cm^{-1} (s). $C_{30}H_{36}N_{14}Ni(ClO_4)_2$ (850.3): calcd. C 42.38, H 4.27, N 23.06; found C 42.55, H 4.18, N 23.19.

Preparation of $[Zn_2L](ClO_4)_4$: L (0.120 g, 0.2 mmol) was suspended in acetonitrile (50 mL) and stirred. To this was added an acetonitrile solution (5 mL) of $Zn(ClO_4)_2{\cdot}6H_2O$ (0.151 g, 0.4 mmol), which caused the cream suspension to clarify and become bright yellow. After stirring overnight, the volume was reduced to about 20 mL in vacuo. Diffusion of diethyl ether into the resulting solution gave $[Zn_2L](ClO_4)_4$ as a yellow crystalline solid (0.181 g, 80%). ^1H NMR (500 MHz, solvent CD_3CN, reference CH_3CN, 298 K): δ = 8.96 (s, 1 H, H^6), 8.34 (s, 1 H, H^3), 3.97 (br, t, 1 H, H^{7a}), 3.77 (dd, 1 H, H^{7b}), 3.24 (dd, 1 H, H^{8b}), 3.08 (td, 1 H, H^{8a}). ^{13}C NMR (126 MHz, solvent CD_3CN, reference CH_3CN, 298 K): δ = 166.1 (C^6), 153.7 (C^2), 135.1 (C^3), 58.8 (C^7), 54.0 (C^8). IR (KBr, inter alia): $\tilde{\nu}$ = 3417 (s, b), 1653 (m), 1437 (w), 1326 (w), 1147 (s), 1121 (s), 1077 (s), 637 (m), 629 (m), 624 cm^{-1} (m). UV/Vis (MeCN): λ_{max} (ε) = 206 (51900), 251 (30400 L mol^{-1} cm^{-1}), 290 (sh), 350 (sh) nm. MS (ESI): *m/z* (%) = 757 (73) $[ZnC_{30}H_{36}N_{14}(ClO_4)^+]$, 328 (100) $[ZnC_{30}H_{36}N_{14}{}^{2+}]$. Preparation of $[Na_2L](CF_3SO_3)_2$: L (0.040 g, 0.07 mmol) was suspended in acetonitrile (20 mL) and stirred. To this was added an acetonitrile solution (10 mL) of $Na(CF_3SO_3)$ (0.024 g, 0.14 mmol), which caused the suspension to clarify slightly. After stirring overnight, the mixture was filtered to remove unreacted L. Diffusion of diethyl ether into the resulting solution gave the product as a white crystalline solid (0.021 g, 33% yield). ^1H NMR (500 MHz, solvent CD_3CN, reference CH_3CN, 298 K): δ = 8.56 (s, 1 H, H^6), 7.96 (s, 1 H, H^3), 3.86 (t, 2 H, H^7), 2.95 (t, 2 H, H^8). ^{13}C NMR (126 MHz, solvent CD_3CN, reference CH_3CN, 298 K): δ = 160.2 (C^6), 156.2 (C^2), 131.7 (C^3), 58.7 (C^7), 54.7 (C^8). IR (KBr, inter alia): $\tilde{\nu}$ = 3414 (m, b), 2850 (m), 2806 (m), 1654 (m), 1266 (s), 1223 (m), 1146 (s), 1033 (s), 639 (s), 516 cm^{-1} (m). UV/Vis (MeCN): λ_{max} (ε) = 247 nm (50400 L mol^{-1} cm^{-1}). MS (ESI): *m/z* (%) = 615 (100) $[NaC_{30}H_{36}N_{14}{}^+]$. $C_{30}H_{36}N_{14}Na_2(CF_3SO_3)_2$ (936.8): calcd. C 41.03, H 3.87, N 20.93; found C 41.07, H 3.95, N 21.09.

Preparation of $[M^{II}Cu^{I}L](X)_3$ (M = Mn, Fe, Ni, X = BF_4^- or ClO_4^-): L (0.06 g, 0.1 mmol) was suspended in acetonitrile (40 mL) and stirred under a nitrogen atmosphere. To this was added an acetonitrile solution (10 mL) of an appropriate salt of the divalent cation (0.1 mmol), which caused the suspension to clarify. After stirring for 30 min, solid $Cu^I(CH_3CN)_4BF_4$ (0.03 g, 0.1 mmol) was added to the solution causing it to change colour. After stirring overnight, the volume was reduced to about 20 mL in vacuo. Diffusion of diethyl ether into the resulting solution gave the products as crystalline solids.

$[Mn^{II}Cu^{I}L](ClO_4)_2(BF_4)$: Prepared as above, except that $Cu^I(CH_3CN)_4BF_4$ (0.035 g, 0.11 mmol) was added. Reddish brown crystals (0.088 g, 88% yield). IR (KBr, inter alia): $\tilde{\nu}$ = 3482 (b, s), 1652 (m), 1575 (w), 1440 (w), 1325 (w), 1143 (s), 1117 (s), 1083 (s), 1032 (m), 628 cm^{-1} (m). UV/Vis (MeCN): λ_{max} (ε) = 250 nm (33000 L mol^{-1} cm^{-1}), 280 (sh). MS (FAB): *m/z* (%) = 910 (17) $[MnCuC_{30}H_{36}N_{14}(ClO_4)_2]$, 809 (100) $[MnCuC_{30}H_{36}N_{14}(ClO_4)]$, 797 (26) $[MnCuC_{30}H_{36}N_{14}(BF_4)]$, 710 (48) $[MnCuC_{30}H_{36}N_{14}]$, 655 (77) $[CuC_{30}H_{36}N_{14}]$. μ = 5.9 BM (293 K); Λ_m(MeCN) = 407 $mol^{-1}cm^2\Omega^{-1}$ (3:1 = 340−420 mol^{-1} cm^2 Ω^{-1}).[12] $C_{30}H_{36}CuMnN_{14}(ClO_4)_2(BF_4)$ (996.9): calcd. $[Fe^{II}Cu^{I}L](BF_4)_3{\cdot}CH_3CN$: Prepared as above, except that the crude product was precipitated out by the addition of diethyl ether (approximately 50 mL) and then recrystallised from acetonitrile to give purple crystals (0.076 g, 75% yield). ^1H NMR (500 MHz, solvent CD_3CN, reference CH_3CN, 298 K): δ = 9.03 (s, 1 H, H^{11}), 8.56 (d, 1 H, H^6), 8.33 (d, 1 H, H^3), 7.90 (d, 1 H, H^4), 3.67 (dd, 1 H, H^{10b}), 3.62 (ddd, 1 H, H^{7a}), 3.54 (dd, 1 H, H^{7b}), 3.45−3.52 (m, 2 H, H^{10a}, H^{9b}), 3.25 (m, 1 H, H^{9a}), 3.08 (dd, 1 H, H^{8b}), 2.91 (td, 1 H, H^{8a}). ^{13}C NMR (126 MHz, solvent CD_3CN, reference CH_3CN, 298 K): δ = 170.8 (C^{11}), 161.6 (C^2), 158.9 (C^6), 157.5 (C^5), 131.6 (C^3), 128.1 (C^4), 61.1 (C^7), 60.6 (C^1), 54.6 (C^9), 52.3 (C^8). IR (KBr, inter alia): $\tilde{\nu}$ = 3424 (br), 1635 (m), 1532 (m), 1312 (m), 1123 (s), 1083 (s), 1034 (s), 533 (w), 521 cm^{-1} (w). UV/Vis (MeCN): λ_{max} (ε) = 211 (75000), 390 (sh), 441 (10700), 540 (sh), 580 nm (10500 L mol^{-1} cm^{-1}). MS (FAB): *m/z* (%) = 711 (100) $[FeCuC_{30}H_{36}N_{14}]$, 648 (86) $[FeC_{30}H_{36}N_{14}]$. μ = 0.0 BM (293 K); Λ_m(MeCN) = 393 mol^{-1} cm^2 Ω^{-1} (3:1 = 340−420 mol^{-1} cm^2 Ω^{-1}).[12] $C_{30}H_{36}CuFeN_{14}(BF_4)_3.CH_3CN$ (1013.6): calcd. C 37.92, H 3.88, N 20.73, Fe 5.51, Cu 6.27; found C 37.97, H 3.95, N 20.57, Fe 5.28, Cu 6.74.

$[Ni^{II}Cu^{I}L](BF_4)_3{\cdot}2H_2O$: Reddish brown crystals (0.076 g, 75% yield). IR (KBr, inter alia): $\tilde{\nu}$ = 3419 (b), 1636 (m), 1083 (s), 1035 (s), 533 (w), 521 cm^{-1} (w). UV/Vis (MeCN): λ_{max} (ε) = 250 (sh), 413 (2560), 806 nm (20 L mol^{-1} cm^{-1}). MS (ESI): *m/z* (%) = 737 (7) $[NiC_{30}H_{36}N_{14}BF_4{}^+]$, 400 (2) $[NiCuC_{30}H_{36}N_{14}BF_4{}^{2+}]$, 325 (100) $[NiC_{30}H_{36}N_{14}{}^{2+}]$, 238 (33) $[NiCuC_{30}H_{36}N_{14}{}^{3+}]$. μ = 3.1 BM (293 K); Λ_m(MeCN) = 410 mol^{-1} cm^2 Ω^{-1} (1:3 = 340−420 mol^{-1} cm^2 Ω^{-1}).[12] $C_{30}H_{36}CuNiN_{14}(BF_4)_3{\cdot}2H_2O$ (1011.4): calcd. C 35.63, H 3.99, N 19.39, Ni 5.80, Cu 6.28; found C 36.00, H 3.67, N 19.16, Ni 5.62, Cu 6.25.

X-ray Crystallography: Data were collected on Bruker SMART diffractometers (Universities of Canterbury, Auckland and Bristol), using graphite-monochromated Mo-K_α radiation (λ = 0.71013 Å). The data were corrected for Lorentz and polarisation effects and semi-empirical absorption corrections were applied. The structures were solved by direct methods (SHELXS-97)[21] and refined against all F^2 data. (SHELXL-97).[22] Hydrogen atoms were inserted at cal-

[a] Due to the use of SQUEEZE[23] these values refer only to the disordered cation.

culated positions (except where noted) and rode on the atoms to which they are attached (including isotropic thermal parameters which were equal to 1.2 times the equivalent isotropic displacement parameter for the attached non-hydrogen atom) and all non-hydrogen atoms were made anisotropic. CCDC 224698−224703 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) + 44-1223-336-033; E-mail: deposit@ccdc.cam.uk].

$[Mn^{II}Cu^{I}L_I](ClO_4)_2(BF_4)$: Notwithstanding several 0k0 reflections for which $I/\sigma(I) > 5$, we have solved this structure in $P2_1/n$. In space group Pn the pairs of cations are very clearly related by a centre of symmetry. The appearance of significant intensity for the 0k0 reflections is attributed to partial ordering of the anion species: in space group $P2_1/n$, each of the three anion sites is a composite of BF_4^- and ClO_4^- and in space group Pn ordering of the anions was not discernible. In view of the highly disordered anion sites, which together indicated an approximately 2:1 ratio ClO_4^-:BF_4^-, the structure was subjected to the SQUEEZE procedure of the PLATON suite.[23] A void volume of 968 Å^3 per cell containing 562 electrons was calculated. The electron count is very close to that calculated (568 electrons) for 8ClO_4^- and 4BF_4^- per cell. In contrast to poor convergence behaviour for refinements with disordered anion species, refinements on the SQUEEZEd structure converged quickly.

$[Fe^{II}Cu^{I}L_I](BF_4)_3{\cdot}2.5CH_3CN$: One of the BF_4^- anions was disordered over two sites with a common fluorine atom. One of the two acetonitrile molecules was disordered across a centre of inversion.

$[Ni^{II}Cu^{I}L_I](BF_4)_3$: The two complete cryptates in the asymmetric unit were both "end-for-end" disordered: in the first cryptate Cu(1) and Ni(2) are 0.76 occupancy [Cu(2) and Ni(1) minor occupancy] and in the second cryptate Cu(4) and Ni(3) are 0.65 occupancy [Cu(3) and Ni(4) minor occupancy]. Consequently the pyridazine rings of all strands are also disordered and this has been modelled. The SQUEEZE option of PLATON[23] was used to account better for the disordered anions and solvent molecules. This was found to be a reasonable approach as a total of 740 electrons in the void volume per cell was calculated, slightly greater than that of the best model, which comprised twelve BF_4^-, eight CH_3CN and four H_2O species for a total of 720 electrons per cell.

For crystal data see Table 4.

Supporting Information (see also footnote on the first page of this article): A table of the UV/Vis spectroscopic data, the ^{1}H NMR spectrum of $[ZnL](ClO_4)_2$, a summary of the X-ray structural parameters for $[Fe^{II}L](BF_4)_2$, and additional cyclic voltammograms of the cryptates described in this paper are provided.

Structural Properties of Bis(hexacarbonyldicobalt) Complexes with Heteroatoms Next to the Former Triple Bonds − A Contribution to the Mechanism of the Pauson−Khand Reaction

Daniel B. Werz,[a] J. Hilko Schulte,[a] Bernhard J. Rausch,[a] Rolf Gleiter,*[a] and Frank Rominger[a]

Keywords: Alkynes / Chalcogens / Cobalt / Pauson−Khand reaction

The bis(hexacarbonyldicobalt) complexes of cyclic diynes with sila-, thia- and selena-substituted acetylene units have been isolated. The structural features of these complexes have been elucidated by means of X-ray diffraction analyses on single crystals. In three cases (**24′**, **25′** and **29′**) the X-ray investigations show bis(pentacarbonyldicobalt) complexes instead of bis(hexacarbonyldicobalt) ones. Their empty coordination sites are each occupied by divalent chalcogen moieties from the opposite side of the molecule affording distorted C_2Co_2 cores. These results corroborate the possibility of intramolecular activation in Pauson–Khand reactions of chalcogen-containing substrates.

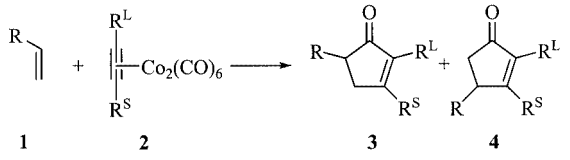
Introduction

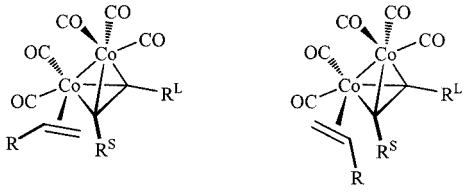
The reaction of hexacarbonyldicobalt complexes of alkynes with olefins to yield cyclopentenones, first described by Pauson et al.,[1,2] has emerged as a frequently used procedure in chemistry.[3−6] Although this reaction has been known for more than 30 years, the mechanistic elucidation is still in progress. Some points which have been looked at more closely are the structural details of hexacarbonyldicobalt complexes[7,8] of various alkynes, and substituent[9] and solvent effects.[10] The energetics of reasonable intermediates along the possible pathway have also been calculated by computational chemistry.[11] One of the major questions in this field of chemistry is (besides the formation of stereoisomers)[12] the understanding of the formation of regioisomers and their control. The reaction of unsymmetrical alkynes with terminal olefins yields regioisomeric mixtures of cyclopentenones as shown in Scheme 1.



1 2 3 4

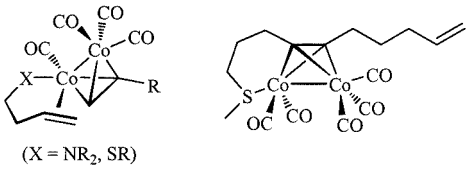
Scheme 1

Usually, the larger substituent (R^L) at the alkyne adopts the α-position to the CO group, whereas the substituent (R) at the olefin gives rise to the 1:1 mixture shown. To rationalize these results, an equilibrium between **5** and **6** was assumed before the insertion step.[3−6]



5 6

This assumption was further corroborated by a study in which heteroatoms were tethered to the olefin by a carbon chain. This led to the postulation that an intermediate such as **7** was involved,[13a] which would lead to a preference for **3**. Experiments with externally added sulfides confirmed this view.[13b]



(X = NR_2, SR)

7 8

With respect to the role of heteroatom participation it is also of interest that the amine oxide promoted Pauson−Khand reaction is accelerated in the presence of heteroatoms such as sulfur, nitrogen and even oxygen in

[a] Organisch-Chemisches Institut der Universität Heidelberg, Im Neuenheimer Feld 270, 69120 Heidelberg, Germany
E-mail: rolf.gleiter@urz.uni-heidelberg.de

the homopropargylic position.[14] During these studies even intermediates such as **8** could be detected.[14]

Our interest in the effect of heteroatoms in the Pauson–Khand reaction, especially sulfur, arose when we studied the twofold Pauson–Khand reaction of cyclic diynes **9** and **10** with ethylene (Scheme 2).[9a,10c] We found a strong increase in the yield when **10** was used. Here the sulfur atom takes the homopropargylic position. To learn more about the effects of chalcogen atoms, even in other positions, we have synthesized a series of bis(hexacarbonyldicobalt) complexes of cyclic diynes with heteroatoms next to the $[C_2Co_2(CO)_6]$ core. In this paper we report on the syntheses and the structural investigations of these species. These studies allowed us to isolate three species in which a CO ligand is replaced by an intramolecular thio(seleno) ether ligand and to characterize them crystallographically.

Results and Discussion

We used the recently synthesized cyclic sila-, thia- and selenadiynes as starting materials. They were treated with octacarbonyldicobalt in dichloromethane to afford the corresponding complexes after crystallization or column chromatography. The resulting products, which could be obtained in 33–85% yield, are red to black solids, and several of them are sensitive to light. All new bis(hexacarbonyldicobalt) complexes and the isolated yields obtained for the syntheses of **13**–**30** are given in Table 1.

Most of the bis(hexacarbonyldicobalt) complexes show three characteristic absorptions in the IR spectrum in the range between 2000 and 2100 cm^{-1}. Group-theory considerations reveal that a $C_2Co_2(CO)_6$ core with a local C_{2v} symmetry should show five different IR-active vibrations in this range. The smaller number can be explained easily by the relatively low resolution of the spectrometer.

To study the structural data of these complexes, efforts were made to obtain single crystals suitable for X-ray crystallography. This was possible except for **17** and **18**. The crystallisation was performed either by solvent evaporation at room temperature or by crystallizing the complexes from the crude reaction mixture at −78 °C.

All the complexes are dominated by the bulky $C_2Co_2(CO)_6$ units (Figures 1 and 2). The tethers between

these moieties often tend to adopt a zig-zag arrangement. However, the longer the tethers become, the more gauche conformations can be observed. Such conformations minimize the empty space between the coordinated triple bonds, as shown in Figure 2.

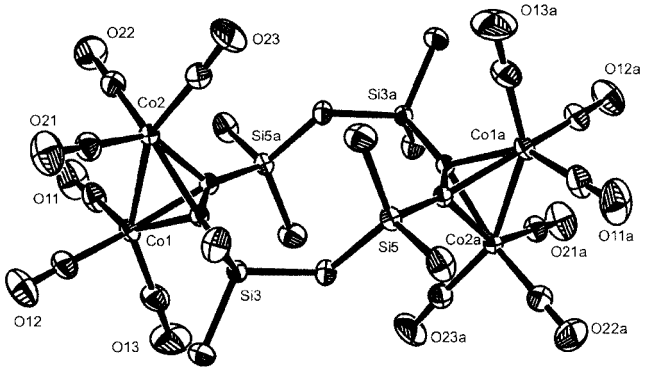

Figure 1. ORTEP plot (50% ellipsoid probability) of the molecular structure of **14**

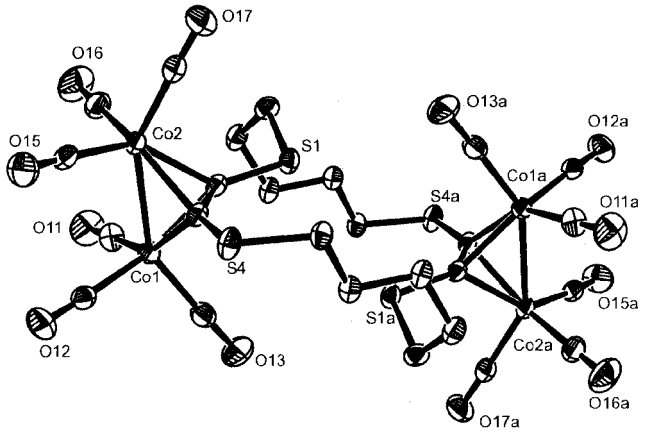

Figure 2. ORTEP plot (50% ellipsoid probability) of the molecular structure of **27**

Typical structural features of the heterosubstituted pseudo-tetrahedral Co_2C_2 cores are the planarity of the Co-coordinated fragments (the former triple bond and the adjacent heteroatoms or methylene groups lie in one plane), the elongation of the former triple bond due to its coordination (132−135 pm) and the bent geometry of the coordinated alkyne moieties (134−150°). The metal−carbonyl bond lengths vary between 177 and 185 pm. The longer distances are found *trans* to the acetylenic group, whereas the shorter ones are found in the *cis* position. These differences can be rationalized in terms of metal−ligand d → π* back-donation.[11a] The six CO ligands do not participate equally in the redistribution of electron density from the coordinated triple bond. As a result, different bond lengths are observed. Further structural data (except for **15**, which shows strong disorder) are given in Table 2; for the definition of the parameters see Figure 3.

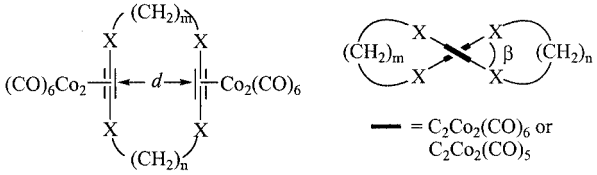

Figure 3. Definition of the transannular distance *d* and the torsion angle *β* in heterosubstituted cyclic bis(hexacarbonyldicobalt) and bis(pentacarbonyldicobalt) complexes

It is interesting to note that the bond lengths of the coordinated triple bonds in the chalcogen-substituted diyne complexes are somewhat larger than the values found in CH_2-substituted diyne complexes.[8l] This observation shows that the assumption of stronger bonding between the electron-rich triple bond of chalcogen-substituted acetylenes and the electron-poor $Co_2(CO)_6$ moiety is reasonable. Furthermore, a comparison of the Co−CC distances of the sila-substituted complexes **13** and **14** with the distances found in the chalcogen-substituted complexes reveals much

longer distances for the slightly electron-poor sila-substituted alkyne, indicating a weaker coordination..

Crystallization experiments with **24**, **25** and **29** afforded crystals in which the molecules have lost two CO ligands (**24′**, **25′** and **29′**). The empty coordination sites are occupied by chalcogen donors placed at the opposite side of the molecule. A top and side view of structure **25′** is shown in Figure 4. Due to the C_1 symmetry of **24′**, and **29′**, and their low solubility in the usual solvents, it was not possible to get reliable NMR spectroscopic data for these compounds. The IR data show no significant differences to the corresponding bis(hexacarbonyldicobalt) complexes. Therefore, only the X-ray data of **24′**, **25′** and **29′** are discussed.

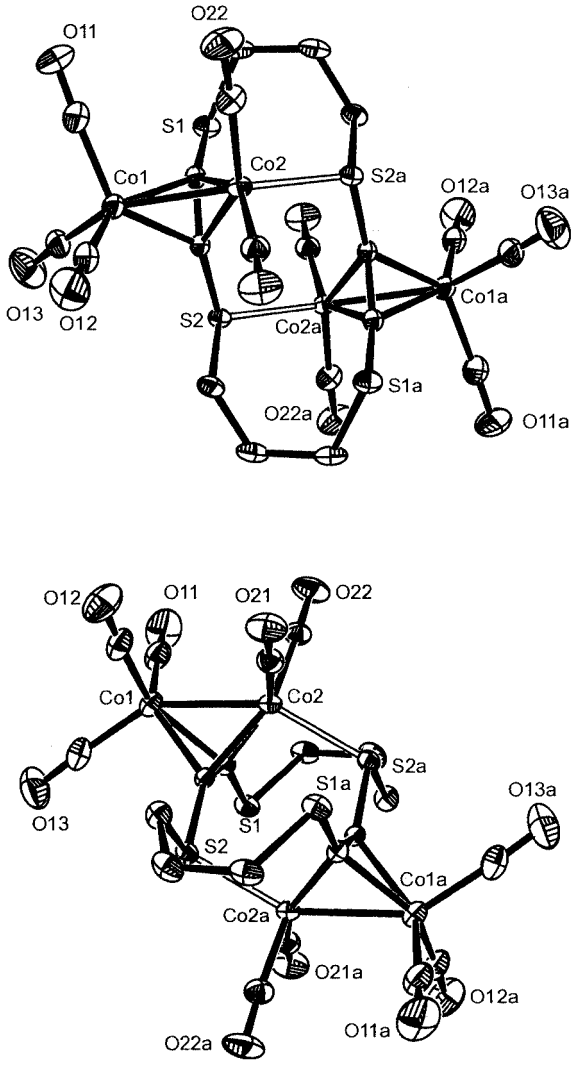

Figure 4. ORTEP plots (50% ellipsoid probability) of the bis(pentacarbonyldicobalt) complexe **25′** (top view and side view)

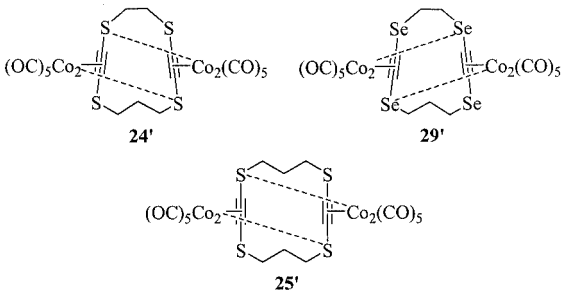

In Table 3 we present their most important structural features. From **24′** we obtained two different modifications (α and β). As Table 3 demonstrates, the C_2Co_2 core is much more distorted due to the chalcogen ligand — the Co−CC distances vary between 191 and 199 pm. The smaller $X-C{\equiv}C_{coord.}$ angles might be caused by the formation of a chelate complex. In Figure 5 the averaged structural parameters of a dithia-substituted $C_2Co_2(CO)_6$ core (type **A**) are compared with a dithia-substituted $C_2Co_2(CO)_5$ core with a further (pseudoaxial) sulfur ligand (type **B**). The averaged parameters are based on data of the four systems of type **A** and five systems of type **B**. Whereas the Co−CC distance in type **A** shows a value of 196 pm, the coordinating sulfur ligand strongly disfavors the former C_{2v} symmetry. As a result the Co−CC bond lengths vary between 192 and 198 pm. The changed electron density is also responsible for the different lengths of the OC−Co bonds indicating a significant change in metal−ligand d → π* backbonding. To the best of our knowledge, there is only one crystallographically characterized example in the literature showing a pentacarbonyldicobalt complex coordinated by a divalent sulfur atom in an intramolecular manner.[15] Selenium as a coordinating moiety and a doubly bridged bis(pentacarbonyldicobalt) complex were, until now, unknown.

Figure 5. Comparison of the bond lengths (with standard deviation) in dithia-substituted hexacarbonyldicobalt complexes (type **A**) and pentacarbonyldicobalt complexes (type **B**); the averaged values refer to data of four systems of type **A** and five systems of type **B**

Conclusions

Our in-depth study of the structural features of sila-, thia- and selena-substituted bis(hexacarbonyldicobalt) complexes has revealed that the molecular solid-state structures of these complexes are the result of an interplay between the bulky $C_2Co_2(CO)_6$ moieties and the conformational needs of the tethers. In many cases the tethers adopt conformations that minimize the empty space between the bulky units. Our search to find evidence for cobalt−chalcogen interactions proved to be successful. Cobalt−heteroatom interactions, especially cobalt−sulfur interactions, are thought to play an important role in Pauson−Khand reactions. Two tetrathia- as well as one tetraselenacyclodiyne afforded bis(pentacarbonyldicobalt) complexes with coordinating divalent chalcogen atoms occupying the sixth coordination site of the C_2Co_2 core.

Experimental Section

General Methods: Moisture- and oxygen-sensitive reactions were conducted in oven-dried glassware under argon using dried solvents. Melting points are uncorrected. Due to the black color of several compounds some of the melting points (**23**−**25** and **28**) were determined by differential scanning calorimetry (DSC). Materials used for column chromatography: Neutral alumina (Merck), Celite (Fluka). ^{1}H NMR and ^{13}C NMR: Bruker Avance 300 (^{1}H at 300 MHz and ^{13}C at 75.47 MHz), Bruker Avance 500 (^{1}H at 500 MHz and ^{13}C at 125.77 MHz) using the residual solvent as internal standard. IR: Bruker Vector 22 FT-IR. UV/Vis: Hewlett Packard 8452 A spectrometer. MS (FAB+, EI+): High resolution: Jeol JMS-700. FD mass spectra refer to data from a Jeol JMS-700 instrument and were measured from dichloromethane solutions (c = 3−5 mg·mL^{-1}) of the corresponding complexes. For FD mass spectra no high resolution is possible. Elemental analyses were carried out by the Mikroanalytisches Laboratorium der Universität Heidelberg. The starting materials were prepared according to literature methods.[16−19]

General Procedure for the Preparation of the Bis(hexacarbonyldicobalt) Complexes from Cyclic Diynes: The cyclic diyne was dissolved in 30−50 mL of dichloromethane and the octacarbonyldicobalt was added in one portion. The reaction flask was wrapped with aluminium foil to exclude daylight. The resulting dark mixture was stirred at room temperature in the dark for 1−2 h. The crude mixture was filtered and stored at −78 °C overnight. In many cases crystals of the pure product could be obtained. In other cases, the crude product was absorbed on Celite and purified by column chromatography on neutral alumina (grade III), eluting with mixtures of light petroleum/diethyl ether.

(μ:μ-5,5,6,6-Tetramethyl-5,6-disila-1-thiacyclonona-3,7-diyne)bis(hexacarbonyldicobalt) (13): Starting materials: 5,5,6,6-tetramethyl-5,6-disila-1-thiacyclonona-3,7-diyne (250 mg, 1.10 mmol) and octacarbonyldicobalt (840 mg, 2.40 mmol). Yield: 727 mg (83%). Red solid, m.p. 104 °C (dec). ^{1}H NMR (500 MHz, C_6D_6): δ = 0.43 (br., 12 H, CH_3), 3.87 (br., 4 H, CH_2) ppm. ^{13}C NMR (125 MHz, C_6D_6): δ = 1.4 (CH_3), 40.1 (CH_2), 78.9 (C), 110.4 (C), 200.9 (CO) ppm. IR (KBr): $\tilde{\nu}$ = 2964, 2085, 2052, 2023, 1577, 1405 cm^{-1}. HRMS (FAB+): calcd. ($C_{22}H_{17}Co_4O_{12}SSi_2$) 796.7307; found 796.7300.

(μ:μ-1,1,3,3,6,6,8,8-Octamethyl-1,3,6,8-tetrasilacyclodeca-4,9-diyne)bis(hexacarbonyldicobalt) (14): Starting materials: 1,1,3,3,6,6,8,8-octamethyl-1,3,6,8-tetrasilacyclodeca-4,9-diyne (50 mg, 0.16 mmol) and octacarbonyldicobalt (220 mg, 0.65 mmol). Yield: 120 mg (85%). Dark red solid, m.p. 124 °C (dec). ^{1}H NMR (300 MHz, $CDCl_3$): δ = 0.38 (br., 28 H, CH_3/CH_2) ppm. ^{13}C NMR (75 MHz, $CDCl_3$): δ = 3.7 (CH_3), 5.8 (CH_2), 93.9 (C), 200.7 (CO) ppm. IR (KBr): $\tilde{\nu}$ = 2957, 2083, 2045, 2017, 1629, 1534, 1408 cm^{-1}. MS (FD+): m/z = 860 [M$^+$]. $C_{26}H_{28}Co_4O_{12}Si_4$ (880.6): calcd. C 35.46, H 3.21; found C 35.58, H 3.50.

(μ:μ-1,4-Dithiacyclotrideca-5,12-diyne)bis(hexacarbonyldicobalt) (15): Starting materials: 1,4-dithiacyclotrideca-5,12-diyne (210 mg, 1.00 mmol) and octacarbonyldicobalt (752 mg, 2.20 mmol). Yield: 590 mg (75%). Red solid, m.p. > 200 °C (dec). ^{1}H NMR (300 MHz, $CDCl_3$): δ = 1.72 (m, 4 H, CH_2), 3.10 (m, 10 H, CH_2) ppm. ^{13}C NMR (75 MHz, $CDCl_3$): δ = 27.1 (CH_2), 30.2 (CH_2), 33.9 (CH_2), 36.1 (CH_2), 91.6 (C), 100.4 (C), 199.0 (CO) ppm. IR (KBr): $\tilde{\nu}$ = 2936, 2089, 2050, 2023, 1625, 1432 cm^{-1}. UV/Vis (CH_2Cl_2): λ_{max} (log ε) = 266 nm (4.55), 292 (4.41), 314 (4.29), 360 (3.68), 374 (3.61), 408 (3.41). MS (FD+): m/z = 782 [M$^+$]. $C_{23}H_{14}Co_4O_{12}S_2$ (782.2): calcd. C 35.32, H 1.80, S 8.20; found C 35.20, H 1.95, S 8.08.

(μ:μ-1,5-Dithiacyclotetradeca-6,13-diyne)bis(hexacarbonyldicobalt) (16): Starting materials: 1,5-dithiacyclotetradeca-6,13-diyne (224 mg, 1.00 mmol) and octacarbonyldicobalt (752 mg, 2.20 mmol). Yield: 610 mg (77%). Red solid, m.p. 125 °C. ^{1}H NMR (300 MHz, $CDCl_3$): δ = 1.70 (m, 8 H, CH_2), 1.92 (m, 4 H, CH_2), 3.21 (m, 4 H, CH_2) ppm. ^{13}C NMR (75 MHz, $CDCl_3$): δ = 27.8 (CH_2), 32.0 (CH_2), 35.6 (CH_2), 35.8 (CH_2), 36.9 (CH_2), 94.2 (C), 102.3 (C), 199.2 (CO) ppm. IR (KBr): $\tilde{\nu}$ = 2936, 2088, 2050, 2022, 1625, 1432 cm^{-1}. UV/Vis (CH_2Cl_2): λ_{max} (log ε) = 286 nm (4.35), 318 (4.10), 352 (4.69). MS (FD+): m/z = 796 [M$^+$]. $C_{24}H_{16}Co_4O_{12}S_2 \cdot 0.5CH_2Cl_2$ (838.7): calcd. C 35.84, H 2.09; found C 35.68, H 2.14.

(μ:μ-1,6-Dithiacyclopentadeca-7,14-diyne)bis(hexacarbonyldicobalt) (17): Starting materials: 1,6-dithiacyclopentadeca-7,14-diyne

(μ:μ-1,4,11,14-Tetrathiacycloeicosa-2,12-diyne)bis(hexacarbonyldicobalt) (28): Starting materials: 1,4,11,14-tetrathiacycloeicosa-2,12-diyne (307 mg, 0.89 mmol) and octacarbonyldicobalt (610 mg, 1.78 mmol). Yield: 421 mg (52%). Black solid, m.p. 138 °C (dec). ^{1}H NMR (300 MHz, $CDCl_3$): δ = 1.55 (br., 8 H, CH_2), 1.86 (br., 8 H, CH_2), 2.95 (br., 8 H, CH_2) ppm. ^{13}C NMR (75 MHz, $CDCl_3$): δ = 28.1 (CH_2), 29.2 (CH_2), 37.6 (CH_2), 99.3 (C), 198.7 (CO) ppm. IR (KBr): $\tilde{\nu}$ = 2931, 2857, 2087, 2049, 2026, 1637, 1458, 870 cm^{-1}. UV/Vis (CH_2Cl_2): λ_{max} (log ε) = 280 nm (4.29), 318 (4.15), 472 (3.38), 556 (3.02). MS (FD+): m/z = 916 [M$^+$]. $C_{28}H_{24}Co_4O_{12}S_4$ (916.5): calcd. C 36.70, H 2.64, S 14.00; found C 36.51, H 2.94, S 13.99.

(μ:μ-1,4,7,10-Tetraselenacyclotrideca-2,8-diyne)bis(pentacarbonyldicobalt) (29′): Starting materials: 1,4,7,10-tetraselenacyclotrideca-2,8-diyne (102 mg, 0.24 mmol) and octacarbonyldicobalt (160 mg, 0.48 mmol). Yield: 143 mg (63%). Black solid, m.p. 144 °C (dec). ^{13}C NMR (75 MHz, $CDCl_3$): δ = 24.2 (CH_2), 27.3 (CH_2), 28.7 (CH_2), 31.2 (CH_2), 32.9 (CH_2), 208.1 (CO) ppm. IR (KBr): $\tilde{\nu}$ = 2924, 2056, 2016, 1621, 1404, 803 cm^{-1}. UV/Vis (CH_2Cl_2): λ_{max} [nm] (log ε): 304 (4.25), 348 (4.09), 448 (3.75), 490 (3.58). MS (FD+): m/z = 950 [M$^+$].

(μ:μ-1,4,9,12-Tetraselenacyclohexadeca-2,10-diyne)bis(hexacarbonyldicobalt) (30): Starting materials: 1,4,9,12-tetraselenacyclohexadeca-2,10-diyne (150 mg, 0.32 mmol) and octacarbonyldicobalt (219 mg, 0.64 mmol). Yield: 110 mg (33%). Black solid, m.p. 147 °C (dec). ^{1}H NMR (300 MHz, CD_2Cl_2): δ = 2.05 (br., 8 H, CH_2), 3.02 (br., 8 H, CH_2) ppm. ^{13}C NMR (75 MHz, CD_2Cl_2): δ = 31.0 (CH_2), 32.4 (CH_2), 105.1 (C), 206.7 (CO) ppm. IR (KBr): $\tilde{\nu}$ = 2929, 2090, 2053, 2037, 2011, 1637, 1413, 1200 cm^{-1}. UV/Vis (CH_2Cl_2): λ_{max} (log ε): 250 nm (4.25), 276 (3.91), 306 (4.04), 482 (3.44). MS (FD+): m/z = 1047 [M$^+$]. $C_{24}H_{16}Co_4O_{12}Se_4$ (1047.9): calcd. C 27.51, H 1.54; found C 26.95, H 1.68.

X-ray Diffraction Analyses: The reflections were collected with Bruker Smart CCD and Bruker APEX diffractometers (Mo-K_α radiation, graphite monochromator). Intensities were corrected for Lorentz and polarization effects. Numerical (face indexing for **23**) or empirical absorption corrections were applied using SADABS.[20] The structures were solved by direct methods. The structural parameters of the non-hydrogen atoms were refined anisotropically (except the carbon atoms of **22**) according to a full-matrix least-squares technique (F^2). The hydrogen atoms were calculated according to stereochemical aspects. In **15** we found disorder between the sulfur atoms and the methylene units by a C_2 axis. In **24′α**, **24′β** (two different modifications of **24′**) and **29′** we found disorder between the ethane and the propane chain by an inversion center. In **16**, **26**, **28** and **30** we found some disorder in the alkane chains, and the minor positions were refined as isotropic only. Structure solution and refinement were carried out with SHELXTL software package.[20] ORTEP drawings were obtained using the ORTEP-3 for Windows program by Farrugia.[21] Tables 4, 5 and 6 contain the crystallographic data and details of the data collection and the refinement procedure. CCDC-223985 to -224001 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) + 44-1223/336-033; E-mail: data.request@ccdc.cam.ac.uk].

Acknowledgments

We are grateful to the Deutsche Forschungsgemeinschaft (SFB 623), the Fonds der Chemischen Industrie and the BASF Aktienge-

sellschaft, Ludwigshafen, for financial support. D. B. W. and J. H. S. thank Michela Doria, Mathias Basler, Markus Seitz and Fanny Caroline Liu for preparative assistance. D. B. W. is grateful to the Studienstiftung des deutschen Volkes for a graduate fellowship. We thank Prof. W. Siebert for helpful discussions.

Ruthenium-Mediated C−C Coupling Reactions of Alkynes − The Key Role of Ruthenacyclopentatriene Complexes

Roland Schmid[a] and Karl Kirchner*[a]

Keywords: Ruthenium / Cyclopentadienyl Ligands / Acetylenes / Oxidative coupling / Carbenes / Vinylidene ligands

This review describes the highlights of the reactions of the substitutionally labile neutral pseudo 14VE complexes RuCp′(COD)Cl (Cp′ = Cp, Cp*; COD = 1,5-cyclooctadiene) and the cationic complexes $[CpRu(CH_3CN)_2L]^+$ and $[Ru(\eta^5\text{-}C_5H_4CH_2CH_2\text{-}\kappa^1P\text{-}PPh_2)]^+$ with alkynes. The ligand L is a co-ligand, whose nature turns out to be critical to the outcome of the reaction, and varies from halides to tertiary phosphanes, tertiary stibines, CO, and acetonitrile. Along these lines vast and diversified varieties of rearrangements within and between molecules ligated to the transition-metal center has been discovered. A crucial role in all reactions reported is the intermediacy of electrophilic ruthenacyclopentatriene complexes, an entity featuring a biscarbene functionality.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

1. Introduction

Of the diverse elemental combinations, carbon−carbon bond-forming reactions have attracted great interest for their many applications in industrial and synthetic processes. This type of conversion is catalyzed mainly by transition-metal compounds. The basis of the catalytic action is the remarkable ability of transition-metal containing fragments to coordinate organic molecules. Besides the fascinating world of the structural chemistry of these complexes thus generated, a crucial consequence is the essential modification of the chemical behavior through ligation. In fact, some of the most powerful and selective methods for preparing organic molecules involve organometallic catalysis. Specifically of interest to our group are C−C and C−heteroatom bond-forming reactions involving alkynes, such as the cyclotrimerization of alkynes or the cyclocotrimerization of two alkynes with unsaturated organic compounds containing C=X bonds (X = C, O, S, N etc.) for obtaining carbocycle and heterocycle structures as exemplarily shown in Scheme 1.

The development of cyclization methods is a continuing challenge because of the ubiquitous occurrence of cyclic structures, especially among bioactive targets. For instance, the vast majority of pharmaceuticals in use today contain either one or two 5- or 6-membered rings. Among the wide range of transition-metal compounds that were found to actively catalyze cyclizations we have focused particularly on the ruthenium chemistry. Lying at the heart of the periodic table, ruthenium combines the valuable properties of both early- and late-transition-metal relatives. Thus, the

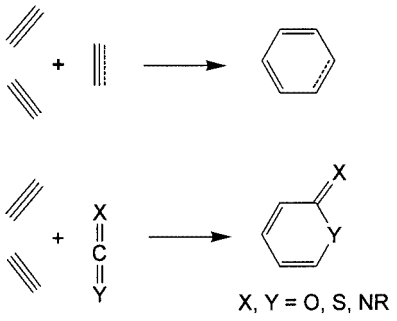
Roland Schmid (1945−2004) was a full professor of chemistry at the Vienna University of Technology, Vienna, and Head of the Organometallic Chemistry Division. He studied chemistry at the Vienna University of Technology, where he obtained his Ph.D. in 1971 with Prof. Viktor Gutmann. Since 1999 he was full Professor at the Institute of Applied Synthetic chemistry at the Vienna University of Technology. He has authored and co-authored over 140 research and review papers and the book "Non-formal Kinetics − in Search for Chemical Reaction Pathways". His research and teaching interests focused on general and inorganic chemistry, inorganic reaction mechanisms, solution chemistry, and chemistry for mechanical engineering.

Karl Kirchner (born in 1960 in Wiener Neustadt, Austria) obtained his Ph.D in 1987 at the Vienna University of Technology under the supervision of Prof. Roland Schmid. After a two-year postdoctoral stay at Washington State University with Prof. John P. Hunt and an additional postdoctoral year with Nobellaureate Prof. Henry Taube at Stanford University, he joined the research group of Prof. Roland Schmid. He became an associate Professor in 1994 at the Vienna University of Technology. He has authored and co-authored more than 110 research and review papers His research interests are in the fields of coordination chemistry, organometallic chemistry, and homogeneous catalysis.

MICROREVIEWS: This feature introduces the readers to the authors′ research through a concise overview of the selected topic. Reference to important work from others in the field is included.

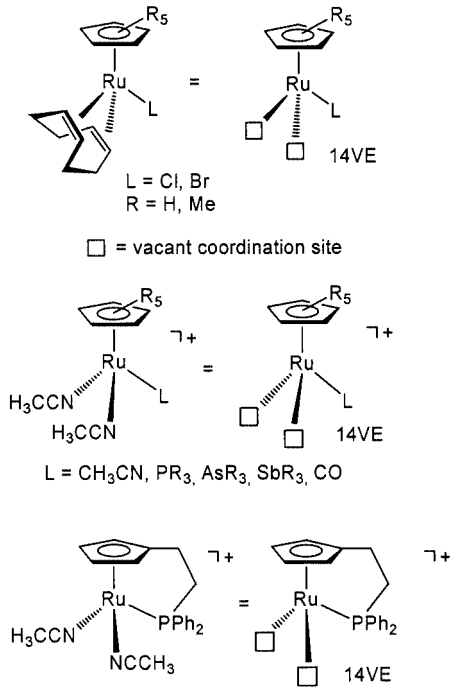


Scheme 1

high reactivity of elements to its left, and the less oxophilic and Lewis acidic nature of those to its right, results in a special array of desirable properties.[1] Accordingly, ruthenium is characterized by a high capacity of multiple metal bonding on the one hand and functional group tolerance on the other. For instance, even the formation of cyclic organosulfur compounds is mediated by appropriate ruthenium complexes,[2,3] while many other transition-metal centers are deactivated because of strong coordination to sulfur compounds.

The elucidation of the mechanistic aspects of homogeneous catalysis has been an ambitious scientific goal from the beginning of the interest in organometal catalysis. Unfortunately, kinetic studies in this field of research are scarce. One of the reasons is the fact that often the rates of the successive steps are too fast to be observed separately, and the diverse reaction intermediates are not stable enough to be characterized. Fortunately, due to the enormous progress in computational chemistry in the last several years, theoretical methods are playing an increasingly important role in identifying possible elementary reactions. These may be substitution, oxidative addition, reductive elimination, migratory insertion, hydrogen exchange, β-hydrogen transfer, σ-bond metathesis, and nucleophilic addition reactions.[4] Ultimately, one would like to understand these fundamental transformations to be able to monitor and tune changes in reactivity toward an obvious synthetic purpose. Thus it has become very useful for us to combine, whenever possible, experimental work with theoretical studies based on density functional theory (DFT) calculations.

In what follows we cover important results of our recent research in the context of work from others in the field. Specifically, we will describe the highlights of the reactions of the substitutionally labile neutral pseudo 14VE complexes RuCp′(COD)L (Cp′ = Cp, Cp*; COD = 1,5-cyclooctadiene; L = Cl, Br) and the cationic complexes $[CpRu(CH_3CN)_2L]^+$ and $[Ru(\eta^5\text{-}C_5H_4CH_2CH_2\text{-}\kappa^1P\text{-}PPh_2)(CH_3CN)_2]^+$ with various triple and double bonds. The ligand L is a co-ligand, whose nature turns out to be critical to the outcome of the reaction, and varies from halides to tertiary phosphanes, tertiary arsanes, tertiary stibines, CO, and acetonitrile (Scheme 2). Along these lines there are many diverse rearrangements within and between molecules ligated to the transition-metal center.



Scheme 2

2. The Cyclotrimerization of Alkynes Mediated by the Cp′RuCl Fragment

The thermal cyclotrimerization of acetylene to benzene is an intriguing process. Based on experimental heats of formation of benzene and acetylene, this trimerization is extremely exothermic ($\Delta H° = -143$ kcal/mol).[5] On the other hand, and contrary to the Hammond postulate, the activation energy is prohibitively high and is calculated to lie in the 60−80 kcal/mol region.[6] Such high barriers arise from the fact that some bonding orbitals of the reactants have to become antibonding orbitals in the product and vice versa. Therefore substantial distortions of the acetylenes have to occur so as to switch electron density from bonding regions in the reactants to bonding regions in the product.[6a] Another contribution to the high barrier stems from closed-shell repulsions between the filled π-orbitals (HOMO−HOMO interactions),[6b] despite some aromatic stabilization of the transition state.[7]

Noteworthy, the activation energy is diminished appreciably through the coordination of the alkynes to the transition-metal centers. Actually, since the pioneering work done in 1948 by Reppe,[8] who found that low-valent nickel complexes catalyze alkyne cyclooligomerization, the transition-metal mediated [2+2+2] cycloaddition of alkynes has developed as a very efficient method for synthesizing functionalized arene systems.[9] Subsequently, a wide array of transition-metal containing fragments were found to actively catalyze the reaction. Of these, derivatives of cobalt and ruthenium proved particularly efficient, while tolerating the presence of varied functionality of the alkyne. For the

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

former, the $CpCoL_2$ (L = CO, PR_3, olefin) catalyst family was studied in great detail.[10,11] In recent years, the ruthenium complexes Cp′Ru(COD)L and Ru(η^5-C_9H_7)(COD)Cl were found to promote the cyclotrimerization of 1,6-diynes, as well as the cyclocotrimerization of 1,6-diynes with terminal alkynes,[12] olefins,[13] allylic ethers,[14] dicyanides,[15] nitriles,[16] tricarbonyl compounds,[17] isocyanates,[2] isothiocyanates, and CS_2.[3]

One problem that should be noted is that the reactions rarely proceed with high chemo- and regioselectivity. That is, when the method is to be applied to the preparation of substituted aromatic compounds from three different, unsymmetrical acetylenes, 38 homo- and cross-coupling products may possibly be produced.[18] Thus, the assembly of such acetylenes to form strictly one single aromatic compound is a formidable challenge. For this goal, a knowledge of the detailed mechanism of the catalytic cycles might be very helpful. The issues to be addressed are among others: which intermediate controls the selectivity of the overall cyclotrimerization process or what determines the size of the rings to be formed. Actually, in the development of cyclization methods, facilitating formation of unusual ring sizes represents a significant objective.[19]

There are three recent theoretical examinations of the mechanism of acetylene cyclotrimerization. One is based on $CpCo(L)_2$ complexes,[20] and the other two on the Cp′RuCl fragment.[21,22] The proposal derived from DFT/B3LYP calculations performed by our group is shown in Scheme 3 and reveals a few uncommon intermediates (see also Figure 1, Figure 2, and Figure 3). In the first step, the starting precatalyst Cp′Ru(COD)Cl undergoes two ligand-substitution reactions resulting in the formation of the bis-acetylene complex **A**. Subsequent oxidative coupling of the two acetylene ligands generates the metallapentatriene complex **B**. In the next step, **B** is readily able to coordinate a third acetylene to give the acetylene-coordinated ruthenacycle **C**. No less than three successive intermediates could be found for subsequent arene formation. The first, an unusual ruthenabicyclo[3.2.0]heptatriene **D** rearranges to a very unsymmetrical metallaheptatetraene **E**. Ultimately, an η^2-coordinated benzene ring appears in species **F** through a reductive elimination step. Completion of the cycle is achieved by an exothermic displacement of the arene by two acetylene molecules thereby regenerating **A**.

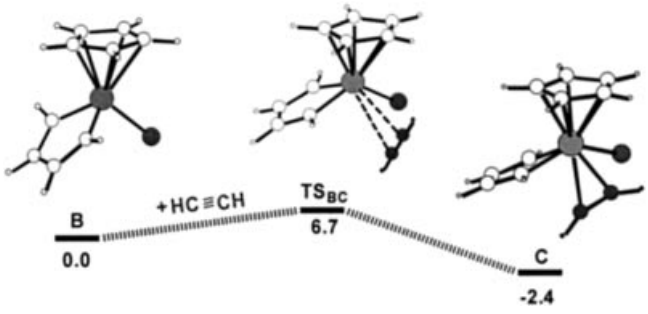


Figure 1. Energy profile for the cyclotrimerization of acetylene (energies in kcal mol^{-1}, relative to the bisacetylene complex **A**)

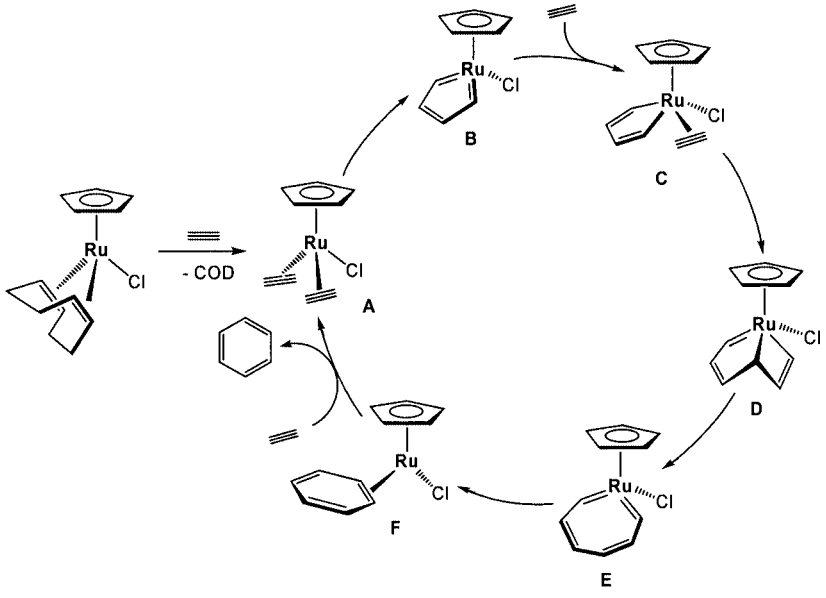
Some remarks about the key intermediates follows.

B: It is now safe to assume that all cyclization processes are initiated by a metallacycle as the first key intermediate. However, the bonding modes in **B** can vary with the metal fragment. While in the similar CpCo system the respective intermediate is better formulated as a metallacyclopentadiene (type **I**), in the RuCp′Cl case, **B** is clearly a metallacylopentatriene complex (type **II**) featuring a bis-carbene functionality. In recent years several ruthanacyclopentatriene complexes (and metallacylopentatriene complexes in general) have been isolated and unequivocally characterized by NMR spectroscopy and X-ray crystallography.[23] Two bi-



Scheme 3

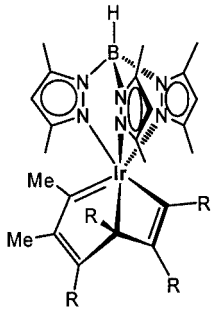
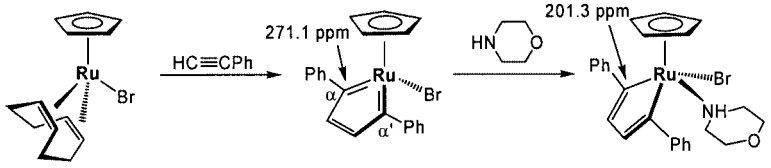
I II

cyclic analogues also have been isolated and characterized by X-ray crystallography.[24] In fact RuCp′(COD)L (L = Cl, Br) reacts with aryl acetylenes to give stable ruthenacyclopentatriene complexes (Scheme 4) that exhibit characteristic ^{13}C NMR resonances in the range of about 270−240 ppm. The oxidative coupling takes place regioselectively in a head-to-head fashion with the substituents ending up in the α and α′ position. It should be noted that ruthenacylopentatrienes serve as key intermediates in several catalytic reactions involving alkynes, for example, the double cyclopropanation of 1,6-diynes with strained cyclic olefins,[13a] the reaction of two alkyne molecules with carboxylic acids,[25] the cycloisomerization of alkynes and propargylic alcohols,[26] or the hydrative diyne cyclization.[27] The reactivity of **B** is guided by the possibility of an attack by another alkyne (or a nucleophile in general). It has been demonstrated that these species behave as masked, coordinatively unsaturated complexes and react readily with donor ligands such as tertiary phosphanes, phosphites, or amines to give "normal" metallacyclopentadiene complexes (Scheme 4).[23a,28] This is not a simple nucleophilic addition at the metal center but involves severe changes in the bonding mode. Addition of substrates to **B** becomes increasingly difficult in the case of a bulky co-ligand (see below), as well as bulky substituents in the 1- and 4-positions.

D: It may be noted that, very recently, such a structure could indeed be isolated for the first time, viz. a stable iridabicyclo[3.2.0]hepta-1,3,6-triene, which is reversibly transformed into an iridacycloheptatriene.[29] The crucial inter-





Scheme 4

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

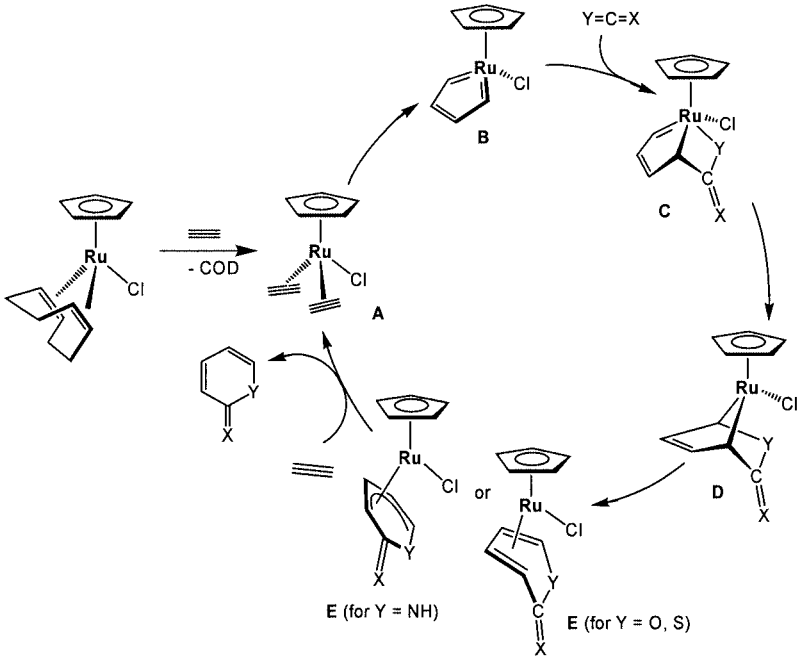
mediate **D** is shown in Figure 2 in order to emphasize the steric constraints between the hydrogen atom of the metallacycle (i.e. from the first two acetylene molecules) and that of the Cp ring. It is easy to see that this intermediate controls the selectivity of the overall cyclotrimerization process. Acetylene molecules carrying two bulky substituents will therefore experience considerable repulsion at this stage. In fact, cyclotrimerization is found to work well only when parent 1,6-diynes or unsymmetrical 1,6-diynes react with terminal alkynes.

E: This intermediate is most interesting as it reveals a notable asymmetry of the Cp-bonding or, in other words, ring slippage. The Cp ring can be considered as having a hapticity between η^3 and η^5, as is also found in other systems.[30] The asymmetry of **E** removes the symmetry-forbidden character from the final step.

F: This final complex is surprising when considering the 18e rule, because the benzene ring is η^2-bonded rather than η^4 as in the corresponding isoelectronic CpCo system. This becomes possible because of significant contraction of all of the five Ru−C(Cp) bonds. In this respect, the particular role played by the other co-ligand (in our case chloride) is worth emphasizing. If it were labile, the arene would be η^6-coordinated. The resulting stable and inert sandwich complexes would deactivate the catalyst and thus quench the catalytic cycle. This is exemplified when the complexes $[RuCp(CH_3CN)_3]^+$ or $[FeCp^*(CH_3CN)_3]^+$ are used as mediators for alkyne coupling reactions.[31,32]

3. The Cyclocotrimerization of Alkynes with Unsaturated Organic Molecules Mediated by the Cp′RuCl Fragment − Chemoselective Formation of Pyridine-2-one and Thiopyran-2-imine from Isocyanates and Thioisocyanates

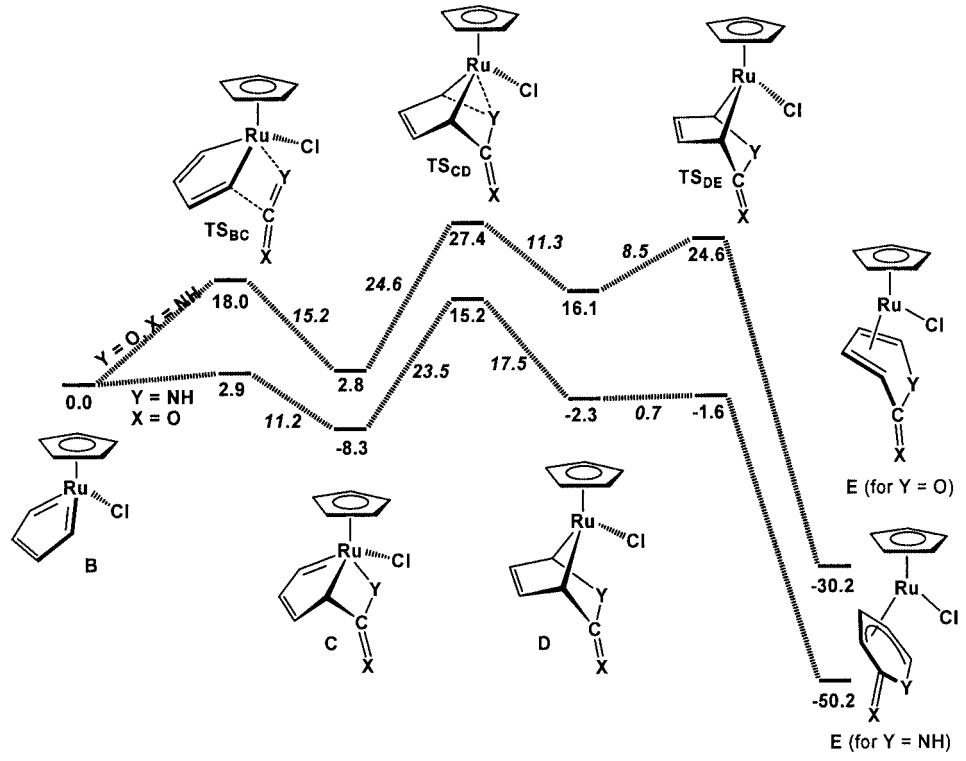
As mentioned above, the cyclocotrimerization of two alkynes with unsaturated organic compounds containing C=X bonds (X = O, S, N etc.) is a synthetically useful and atom economic process for obtaining a variety of six-membered heterocyclic systems. Here we focus exemplarily on the particularly intriguing case of coupling of diynes with ambidentate molecules RN=C=X (X = O, S). Clearly, there are two different kinds of ring closures possible, which lead to either pyridine-2-ones and pyridine-2-thiones, or to pyran-2-imines and thiopyran-2-imines according to Scheme 1. Experimentally it was found that in the case of X = O, pyridine-2-ones, that is the nitrogen-heterocycle, are exclusively formed, whereas in the case of X = S, the chemoselectivity is reversed to give thiopyran-2-imines, that is the sulfur-heterocycle. Gratifyingly, the different chemoselectivities were reproduced well by the theoretical studies using DFT/B3LYP calculations performed in our laboratory.[33] The course of the reactions is characterized by two intermediates that are not so trivial in addition to the metallacyclopentatriene **B**, viz. the bicyclic carbene **C**, and the coordinatively unsaturated metallaheteronorbonene **D**, according to Scheme 5.



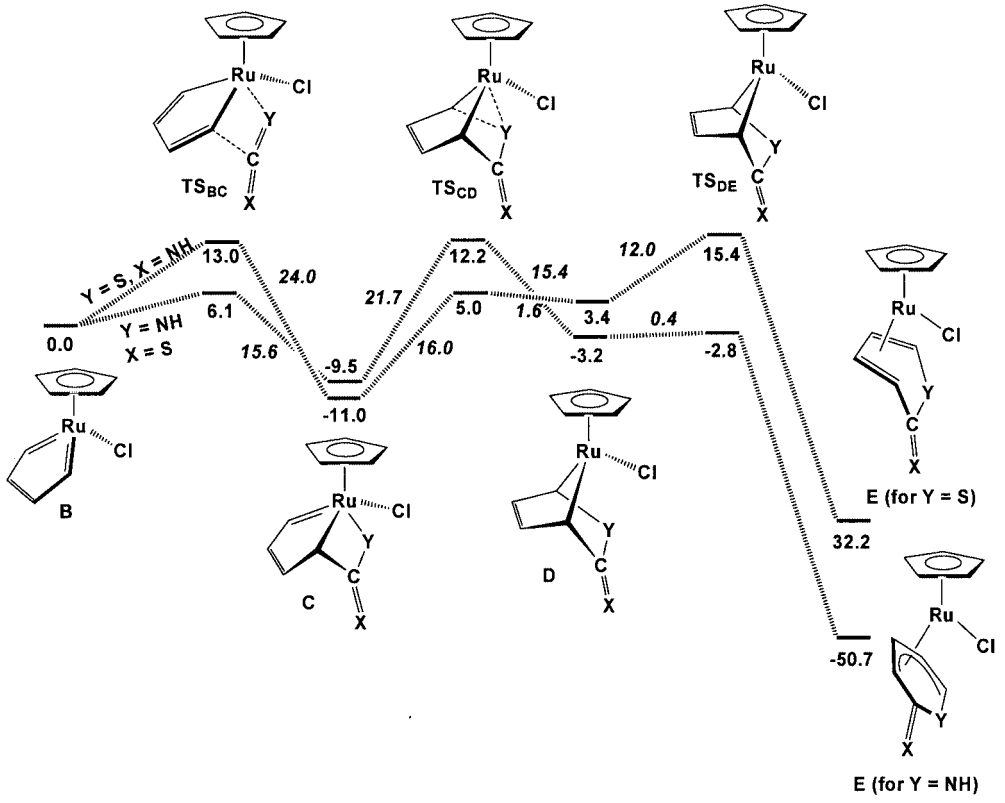
Scheme 5

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

According to the proposed mechanism, the key reaction step is addition of a double bond to the metallacyclopentatriene to give a bicyclic carbene intermediate. This double-bond-addition is initiated by η^1 attack at the ruthenium center, and it is only the attacking atom that is finally incorporated in the cycle. Thus, the chemoselectivity arises from



Scheme 6



Scheme 7

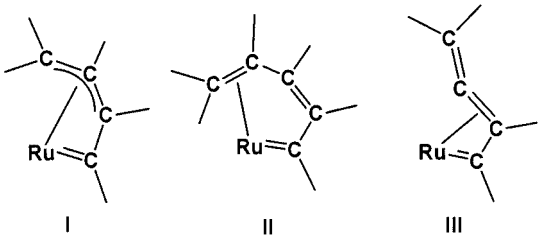
 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

the fact that, for HNCO, N attack is preferred over O, but for HNCS, S attack is preferred over N. The energy profile for the two alternatives, viz. the orientation of N, O, and S towards the ruthenium center, is shown in Scheme 6 and Scheme 7.

4. Dramatic Changes seen upon Replacement of Cl in Cp′RuCl with ER_3 (P, Sb) and CO

At first glance, the 14-electron fragment $[RuCp(PR_3)]^+$ would seem a promising candidate for mediating cyclization reactions, since it is possible to vary the properties of the phosphane ligand through the substituents. In this way, the regioselectivity of the coupling process might be controlled. However, although this species is catalytically active in the isomerization of allyl alcohols[34] and is a catalyst for the transfer hydrogenation of acetophenone and cyclohexanone as well as the isomerization of allyl ethers,[35] the cyclotrimerization of alkynes is not initiated. Instead, a number of unusual and interesting products are obtained, depending on the structure of the alkyne and the substituent of the phosphane ligand.

In most reactions of the $[RuCp(PR_3)]^+$ fragment with alkynes the key intermediate is a cationic metallacyclopentatriene − in contrast to a metallacyclopentadiene − featuring two highly electrophilic carbene carbon atoms. In two cases, namely the reactions of $[RuCp(PCy_3)(CH_3CN)_2]^+$ and $[RuCp(SbPh_3)(CH_3CN)_2]^+$ with 2,8-decadiyne, such intermediates have been unequivocally identified by means of $^{13}C\{^1H\}$ NMR spectroscopy. The characteristic resonances in their $^{13}C\{^1H\}$ NMR spectra at $\delta = 325.6$ and 330.0 ppm, respectively, can be associated with the carbene ring carbon atoms. It is also very important to note that the initial oxidative coupling step with terminal alkynes takes place selectively in a head-to-tail rather than in head-to-head fashion as observed for the RuCp′Cl fragment. Thus, the substituents in the cationic metallacyclopentatriene intermediate are exclusively in the α- and β′-position (see Scheme 9). The electrophilicity of the two carbene carbon atoms gives rise to a wide array of inter-ligand transformations, preventing the attack of a third alkyne molecule. Among other structures, ruthenium allyl carbene (**I**), butadienyl carbene (**II**), and allenyl carbene complexes (**III**) are formed (Scheme 8).[36,37]



Scheme 8

4.1. Formation of Ruthenium Allyl Carbenes − Migration of a PR_3 Ligand

As shown in Scheme 9 (and in Scheme 10), the phosphane coligand migrates from Ru to C generating an allyl carbene. In the case of terminal alkynes, C−C coupling is highly selective in a head-to-tail fashion, with the result that the substituents are at the carbene carbon atom and the internal carbon atom of the allylic moiety, whereas with the diynes, the two internal sp carbon atoms are involved. In the allyl carbene systems formed in both cases, all four carbon atoms of the C_{1-4} chain are bonded to the RuCp fragment. This reaction proceeds very fast even if bulky phosphanes such as PCy_3 are used and substituents at the α-, α′-carbon atoms of the metallacycle are present. A structural view of $[CpRu(=CH\text{-}(\eta^3\text{-}CC(CH_2)_3CHPCy_3)]PF_6$ showing the migration of the bulky PCy_3 ligand is depicted in Figure 4.

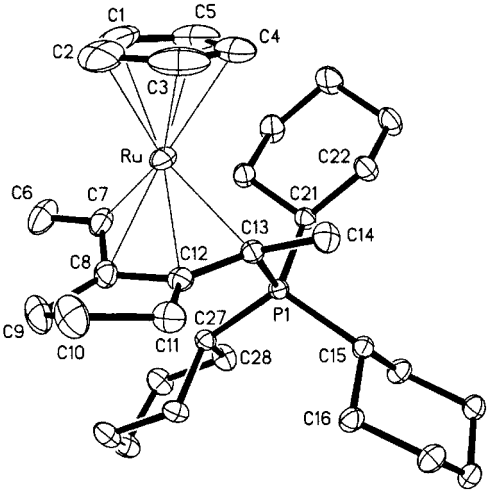


Figure 4. Structural view of $[CpRu(=CH\text{-}(\eta^3\text{-}CC(CH_2)_3CHPCy_3)]\text{-}PF_6$ (PF_6^- omitted for clarity)

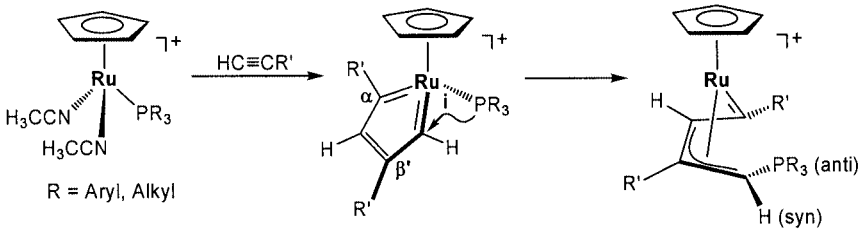

Scheme 9

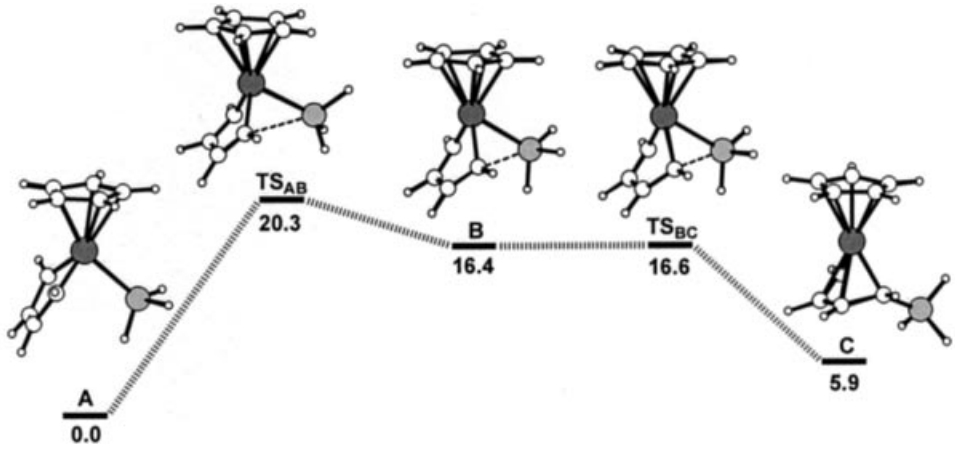

Figure 5. Energy profile of the B3LYP potential energy surfaces for the conversion of the ruthenacyclopentatriene complex **A** into the allyl carbene **C**

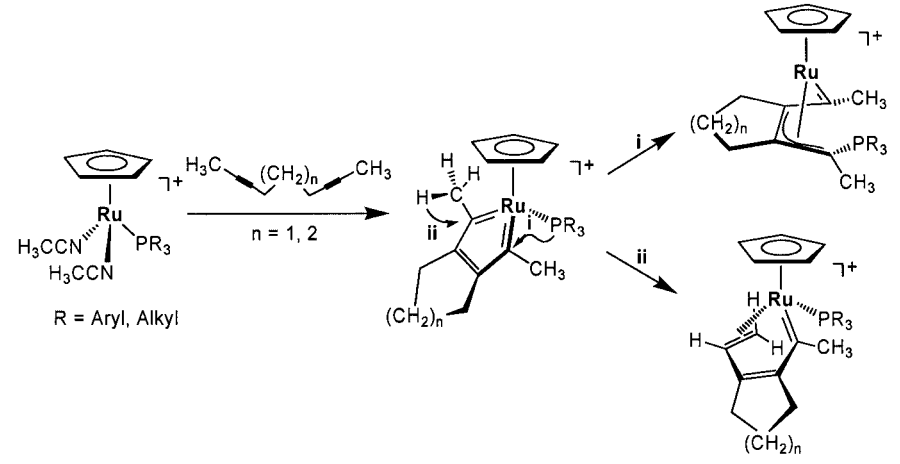
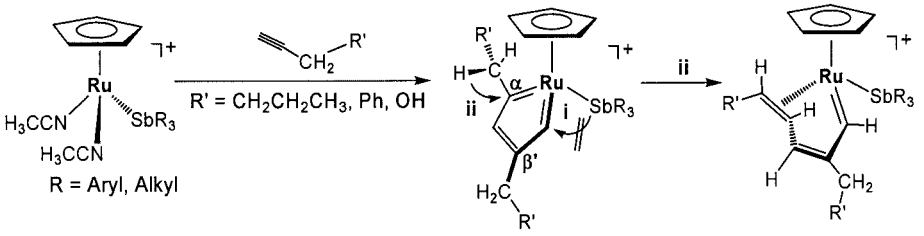
In the absence of kinetic data DFT/B3LYP calculations have been performed to shed light on the mechanism of this unusual phosphane migration process; the results are shown in Figure 5. The conversion of the metallacyclopentatriene **A** into the final allylcarbene complex **C** proceeds with relatively small activation barriers; the rate-limiting step is the initial distortion to produce the intermediate **B**. The metallacycle bends and approaches the C atoms in the β-position to the metal. Conversely, at the other side of the molecule, the Ru−C$_\alpha$ bond stretches and this carbon atom starts to form a new C$_\alpha$−P bond. This feature is already obvious in the transition state **TS$_{AB}$**, and the activation energy is 20.3 kcal mol^{-1}. **TS$_{AB}$** is much closer in energy to **B** than to **A**. The final transformation involves complete Ru−P bond breaking and formation of the C$_\alpha$−P bond, with simultaneous formation of the allylcarbene, and the adjustments of the carbon chain, which involve formation of the Ru−C$_\beta$ bonds.

4.2. Formation of Ruthenium Butadienyl Carbenes − Carbene to Olefin Interconversion through a 1,2-Hydrogen Shift

If the alkyne has an α-alkyl substituent, in some cases, a competitive intramolecular 1,2-hydrogen migration results in the formation of a butadienyl carbene (Scheme 10). A structural view of [CpRu(=C(CH$_3$)C(CH$_2$)$_4$C-η^2-CH=



Scheme 10



Scheme 11

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

$CH_2)(PPh_3)]PF_6$ is given in Figure 6. When pathway (i) is preferred over (ii), the phosphane ligand is more nucleophilic. In this respect, the mechanistic change-over from (i) to (ii) is noted when phosphane is replaced by other group 15 ligands AsR_3 and SbR_3 (Scheme 11). Thus, arsane and stibine ligands have no tendency to migrate.[37] Under certain circumstances both allyl carbene and butadienyl carbene complexes can undergo further transformations as follows.

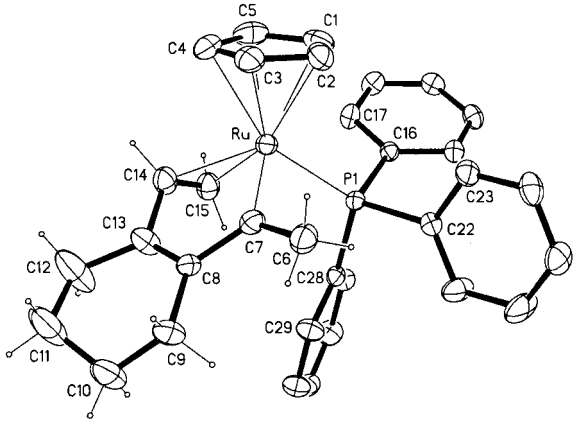


Figure 6. Structural view of $[CpRu(=C(CH_3)C(CH_2)_4C\text{-}\eta^2\text{-}CH=CH_2)(PPh_3)]PF_6$ (PF_6^- omitted for clarity)

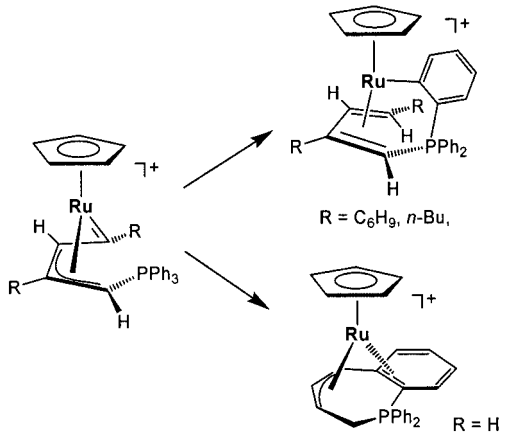
4.3. Ruthenium Allyl Carbenes as Masked Coordinatively Unsaturated Complexes − Intramolecular C−H Bond Activation

Ruthenium η^3-allyl carbene complexes act as pseudo-16e species and are capable of activating C−H bonds of aryl and alkyl groups of the phosphane.[38] This occurs if the phosphanes are sufficiently bulky such as PPh_3 or PCy_3, whereas no such reaction is observed with PMe_3. Pertinent reactions are given in Scheme 12 to 14. The initially formed allyl carbene complexes are not stable and, in some cases, transform slowly at room temperature into novel η^4-butadiene complexes featuring an orthometallated arene ligand derived from PPh_3.

A somewhat different reaction takes place when the parent acetylene is used: the allyl carbene intermediate eventually rearranges into $[RuCp(\eta^3\text{-}CHCHCH-CH_2PPh_2\text{-}\eta^2\text{-}C_6H_4)]^+$, as shown in Scheme 12. The structure and bonding features of this complex are rather unusual. Firstly, an *ortho* C−H bond of the PPh_3 substituent is activated that results in C−C bond formation between the carbene carbon atom of the allyl carbene moiety and the *ortho* arene carbon atom. In the course of this process the *ortho* hydrogen atom is transferred to the terminal carbon of the allyl carbene unit; this involves carbon $sp^2 \rightarrow sp^3$ rehybridization. Furthermore, besides coordination to an η^3-allyl moiety, the metal center is η^2-coordinated to a double bond of a phenyl ring adjacent to the P-donor of the PPh_3 substituent. This bonding mode is very rare, and thus only a few examples



Scheme 12

have been reported recently.[39] Molecular structures of $[RuCp(\eta^4\text{-}CH(C_6H_9)CHC(C_6H_9)CH-PPh_2(\eta^1\text{-}C_6H_4))]PF_6$ and $[RuCp(\eta^3\text{-}CHCHCH-CH_2PPh_2\text{-}\eta^2\text{-}C_6H_4)]PF_6$ are shown in Figure 7 and Figure 8.

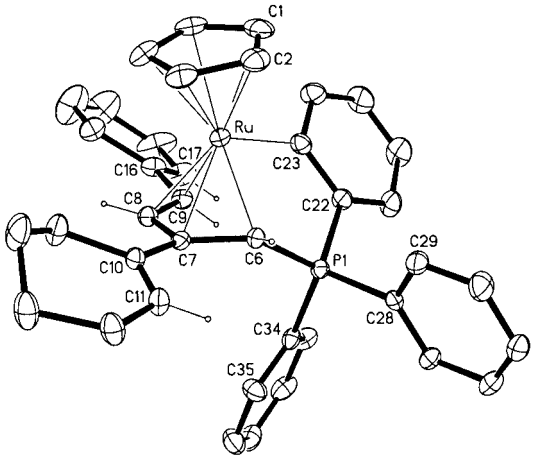


Figure 7. Structural view of $[RuCp(\eta^4\text{-}CH(C_6H_9)CHC(C_6H_9)CH-PPh_2(\eta^1\text{-}C_6H_4))]PF_6$ (PF_6^- omitted for clarity)

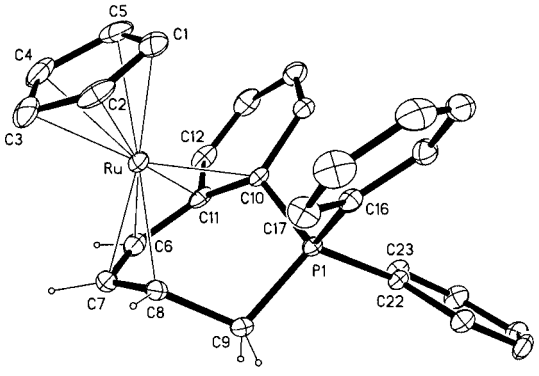

Figure 8. Structural view of $[RuCp(\eta^3\text{-}CHCHCH\text{-}CH_2PPh_2\text{-}\eta^2\text{-}C_6H_4)]PF_6$ (PF_6^- omitted for clarity)

Another example of facile intramolecular C−H bond activation initiated by allyl carbenes is shown in Scheme 13. Here one cyclohexyl substituent of the phosphane ligand is

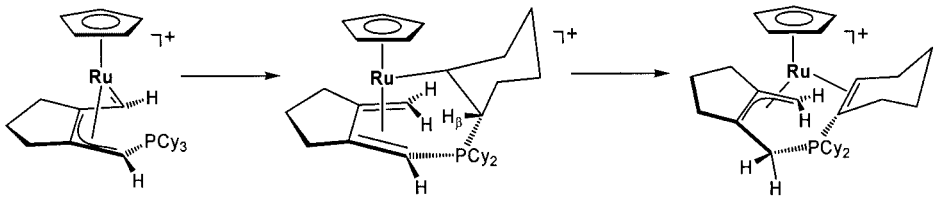

Scheme 13

converted into an η^2-coordinated cyclohexenyl ligand (Figure 9). The reaction does not stop after the oxidative addition step but β-elimination also takes place The overall transformation involves the transfer of two hydrogen atoms from a cyclohexyl ring of PCy_3 to the C4 chain of the allyl carbene moiety. Notably, related reactions have been reported recently, which in some cases require the addition of olefin as an external hydrogen acceptor.[40]

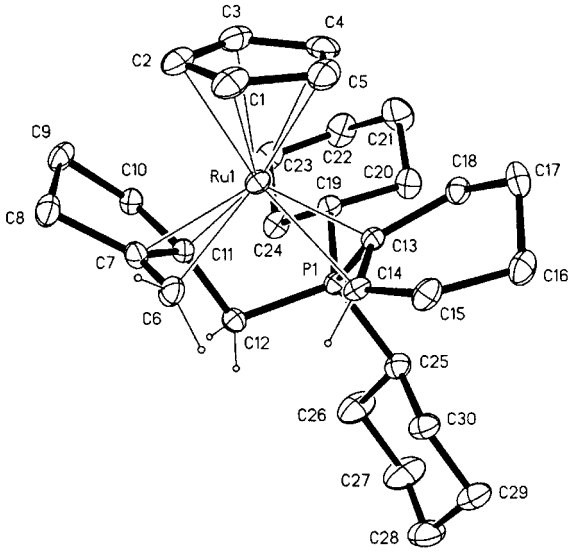

Figure 9. Molecular view of $[CpRu(\eta^3\text{-}CH_2C(CH_2)_3CCH_2PCy_2(\eta^2\text{-}C_6H_9)]PF_6$ (PF_6^- omitted for clarity)

In analogous fashion to RuCp complexes, reactions of acetylenes with the Cp* analogue $[RuCp^*(PEt_3)(CH_3CN)_2]^+$ have been performed. Scheme 14 summarizes the reactions of $[RuCp^*(PEt_3)(CH_3CN)_2]^+$ with the alkynes HC≡CR (R = COOMe, *n*Bu) and 1,6-heptadiyne. The η^3-allyl carbene complexes were obtained in high isolated yields. However, in contrast to the RuCp analog η^3-allyl carbene complexes, these compounds are unstable in solution and react slowly at room temperature to afford $[Ru(\eta^6\text{-}C_5Me_4CH_2)(\eta^4\text{-}CH(R)=CH-C(R)=CHPEt_3)]PF_6$ and $[Ru(\eta^6\text{-}C_5Me_4CH_2)(\eta^4\text{-}CH_2=C(CH_2)_3C=CH-PEt_3)]PF_6$, respectively. In both, one of the ring methyl C−H bonds

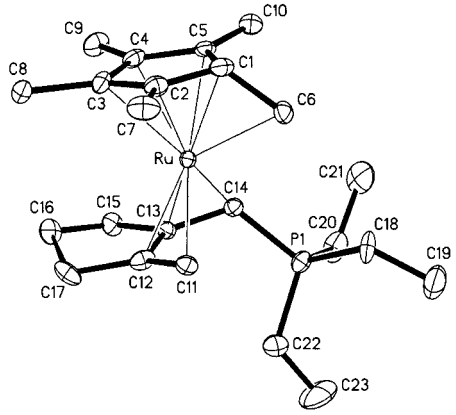

Figure 10. Structural view of $[Ru(\eta^6\text{-}C_5Me_4CH_2)(\eta^4\text{-}CH_2=C(CH_2)_3C=CHPEt_3)]PF_6$ (PF_6^- omitted for clarity)

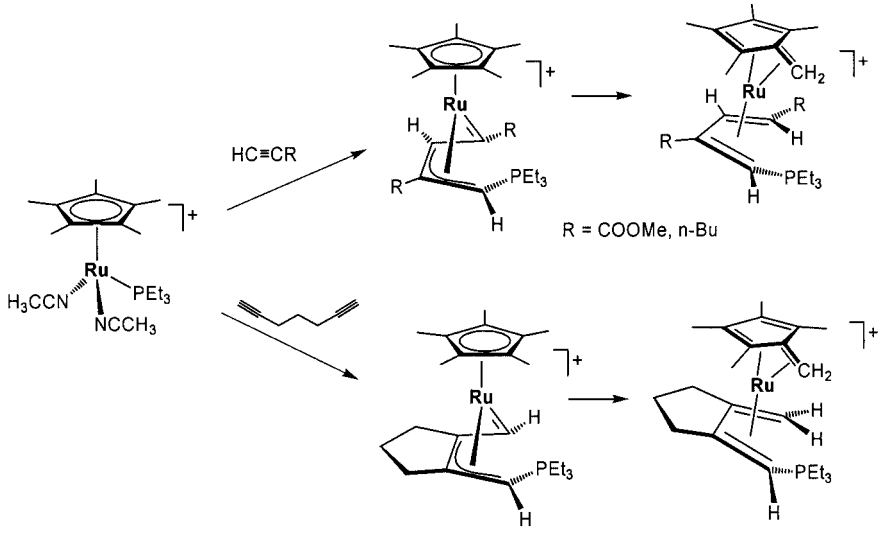


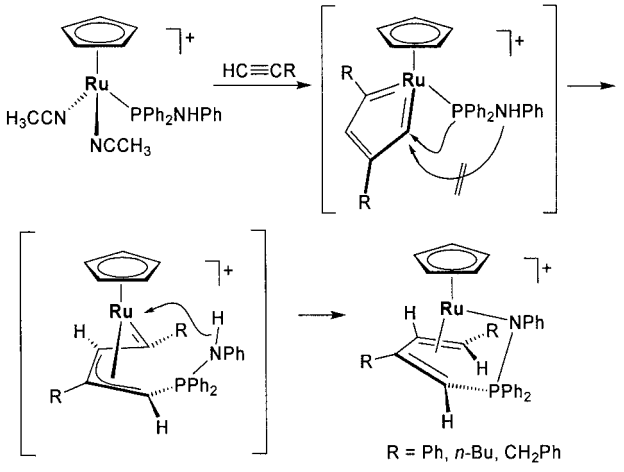
Scheme 14

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

of the Cp* ligand has been cleaved (Scheme 14). In these transformations, the hydrogen atom is transferred to the carbene carbon atom at the inside face of the molecule to form an η^4-diene unit. Based on the NMR spectroscopic data, the newly formed η^6-$C_5Me_4CH_2$ ligand may be envisioned as a tetramethylfulvene rather than a tetramethylcyclopentadienyl-σ-alkyl ligand. The X-ray data are also consistent with a tetramethylfulvene rather than an η^1:η^5-$CH_2C_5Me_4$ (σ:η^5-$CH_2C_5Me_4$) description. A structural view of $[Ru(\eta^6\text{-}C_5Me_4CH_2)(\eta^4\text{-}CH_2{=}C(CH_2)_3\text{-}C{=}CHPEt_3)]PF_6$ is depicted in Figure 10. Related methyl C−H activation processes of transition-metal coordinated C_5Me_5 and C_6Me_6 ligands have been reported previously.[41,42]

4.4. Formation of Ruthenium Butadiene Amido Complexes

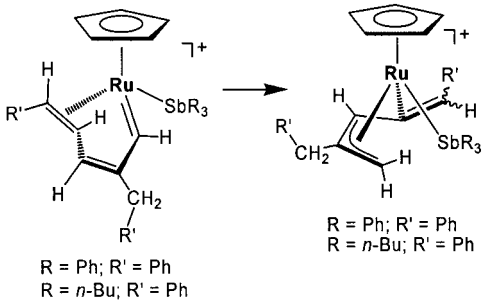
The above reactions of $[RuCp(PR_3)(CH_3CN)_2]PF_6$ with alkynes all involve phosphane migration and subsequent C−H bond activation at either the phosphane substituent or the Cp* ligand. In this respect it is interesting to switch over to the phosphanyl-amine ligand PPh_2NHPh from PR_3 in order to see whether migration appears at the P or the N site, and whether there will be N−H or C−H bond activation. Accordingly, the reaction of $[RuCp(PPh_2NHPh)(CH_3CN)_2]PF_6$ with HC=CR (R = Ph, *n*Bu, CH_2Ph), 1,6-heptadiyne, and 1,7-octadiyne results in the formation of the η^4-butadiene amido complexes $[RuCp(\eta^4\text{-}C_4H_3(R)_2\text{-}PPh_2\text{-}\kappa^1\text{-}(N)\text{-}NPh)]PF_6$, $[RuCp(\eta^4\text{-}C_4H_3(CH_2)_3\text{-}PPh_2\text{-}\kappa^1\text{-}(N)\text{-}NPh)]PF_6$, and $[RuCp(\eta^4\text{-}C_4H_3(CH_2)_4\text{-}PPh_2\text{-}\kappa^1\text{-}(N)\text{-}NPh)]PF_6$ in good yields (Scheme 15).[43] Thus, migration of the κ^1(P)-coordinated PPh_2NHPh ligand occurs through P rather than N in an analogous manner to that in the η^3-allyl carbene complexes already described. In contrast, however, instead of activation of a C−H bond involving the phenyl substituents of the PPh_2NHPh ligand, facile N−H activation of the NHPh-moiety occurs. In this way, RuCp η^4-butadiene amido complexes are afforded. This is noteworthy in view of the comparatively strained four-membered Ru-*N*−P−C ring system formed, in contrast to a five-membered Ru−C−C−P−C ring system in case of C−H bond activation.



Scheme 15

4.5. Reactivity of Ruthenium Butadienyl Carbenes

In special cases, butadienyl carbene complexes undergo further rearrangement such as in the reaction of $[RuCp(SbR_3)(CH_3CN)_2]^+$ with $HC{\equiv}CCH_2Ph$,[37] to give an η^3-allyl-vinyl complex (Scheme 16). When $HC{\equiv}CCH_2OH$ is the alkyne, an η^3-allyl-acyl complex is obtained as illustrated in Scheme 17.



Scheme 16

The alkynes utilized above contain an α-alkyl substituent that is capable of facile 1,2-hydrogen shift. With alkynes lacking α-C−H bonds, namely $HC{\equiv}CC_6H_9$ and the propargylic alcohols $HC{\equiv}CC_6H_{10}OH$ and $HC{\equiv}CCMe_2OH$, η^3-butadienylvinyl complexes are formed as presented in Scheme 18.

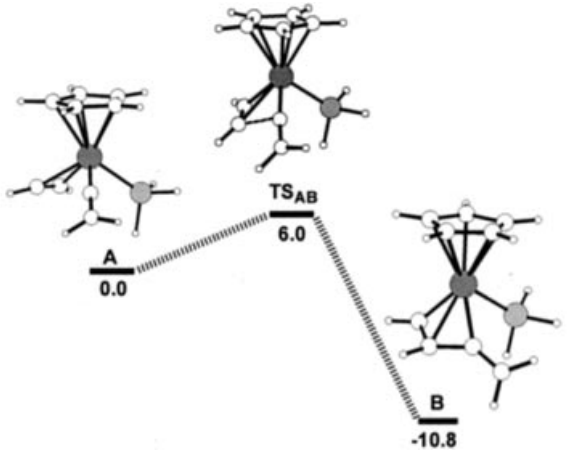

Figure 12. Energy profile of the B3LYP potential energy surface for the conversion of the vinylidene-acetylene complex **A** into the allenyl carbene **B**

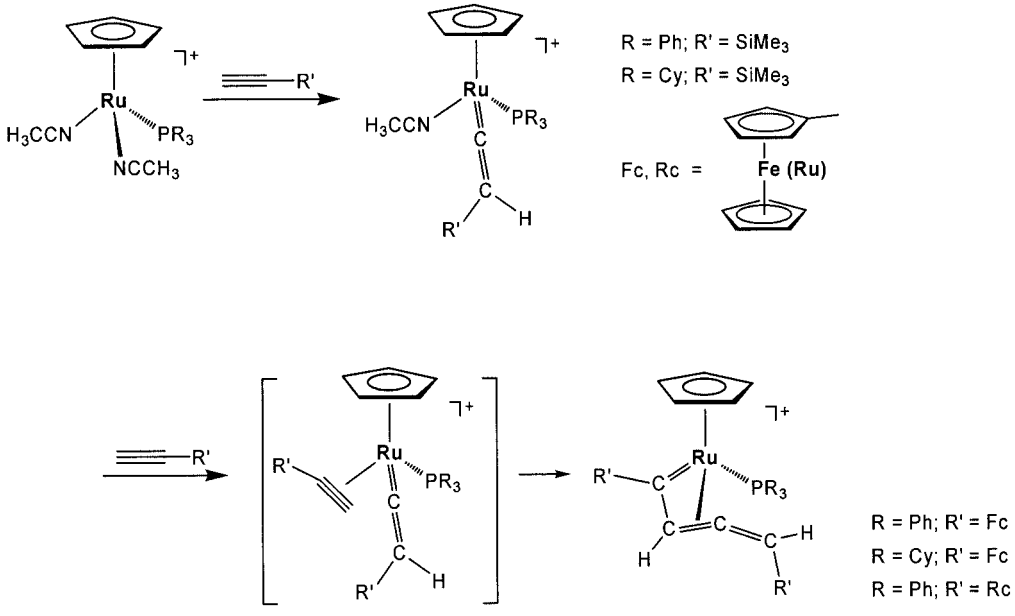
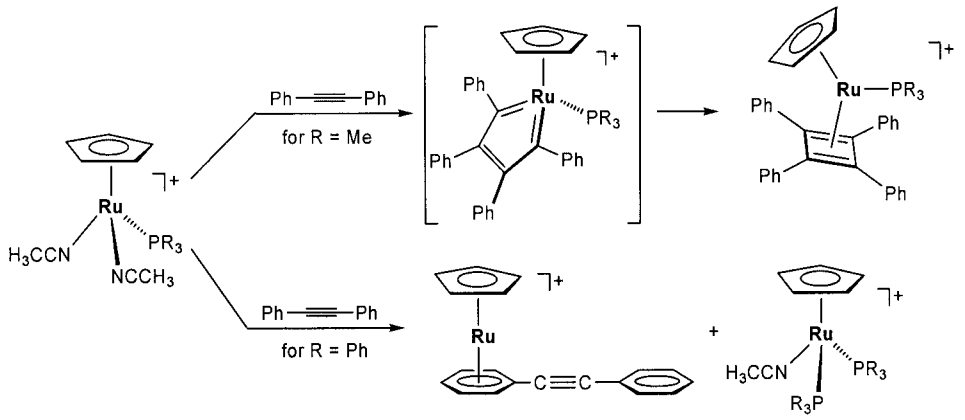
4.6. Formation of Ruthenium Allenyl Carbenes

The formation of allenyl carbene complexes has also been observed in the reaction of $[RuCp(PR_3)(CH_3CN)_2]^+$ with a very atypical alkyne, viz. ferrocenyl and ruthenocenyl acetylene (see Scheme 19 and Figure 11).[36] This new type of C−C bond formation is affected by the strong electronic coupling between the ferrocenyl moiety and the conjugated



Scheme 19

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim



Scheme 20

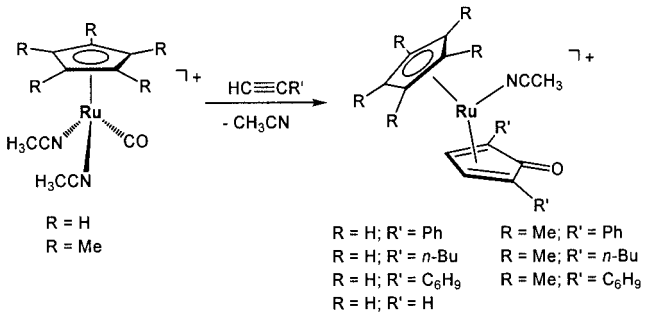
allenyl carbene unit, which facilitates transient vinylidene formation with subsequent alkyne insertion into the Ru=C double bond. The strong electronic coupling is also apparent from the X-ray structures of the products. The alkyne-vinylidene coupling reaction is extremely facile requiring merely 6 kcal/mol according to recent DFT/B3LYP calculations performed with the model complexes $[RuCp(PH_3)(\eta^2\text{-}HC{\equiv}CH)(=CCH_2)]^+$ (Figure 12).

4.7. Formation of Ruthenium Cyclobutadiene Complexes

Under particular instances the metallacyclopentatriene can transform into an η^4-cyclobutadiene complex. This outcome has been observed in the reaction of $[RuCp(PMe_3)(CH_3CN)_2]^+$ with PhC≡CPh as shown in Scheme 20. Theoretical calculations reveal that this transformation is actually symmetry forbidden that involves HOMO/LUMO crossing. Thus, the kinetic barrier becomes prohibitively high, albeit the reaction appears to be energetically favorable. Any cyclobutadiene complexes known hitherto are derived from acetylenes with bulky substituents, such as phenyl or trimethylsilyl.[44,23b] There is obviously a subtle balance of factors that influence the availability of the cyclobutadiene pathway. In fact, in the above example, on switching from $[RuCp(PMe_3)(CH_3CN)_2]^+$ to $[RuCp(PPh_3)(CH_3CN)_2]^+$, a completely different reaction outcome is observed: sandwich complexes are formed. In a forthcoming paper we will investigate the detailed mechanism of the cyclobutadiene pathway, of which to date very little is known.

4.8. Formation of Ruthenium Cyclopentadienone Complexes

Similarly to tertiary phosphanes, in the present type of conversions, carbon monoxide is also not a spectator ligand, but instead functions as an active ligand. Thus the mono-carbonyl complex $[RuCp'(CO)(CH_3CN)_2]^+$ reacts with terminal and internal alkynes to afford ruthenium cyclopentadienone complexes (Scheme 21 and Scheme 22).[45]



Scheme 21

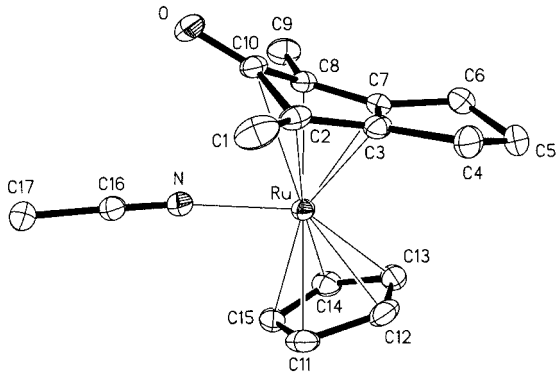


Figure 13. Molecular structure of $[RuCp(\eta^4\text{-}OC_5Me_2C_3H_6)(CH_3CN)]PF_6$ (PF_6^- omitted for clarity)

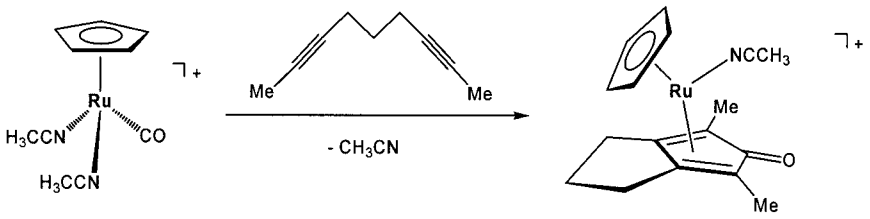

Scheme 22

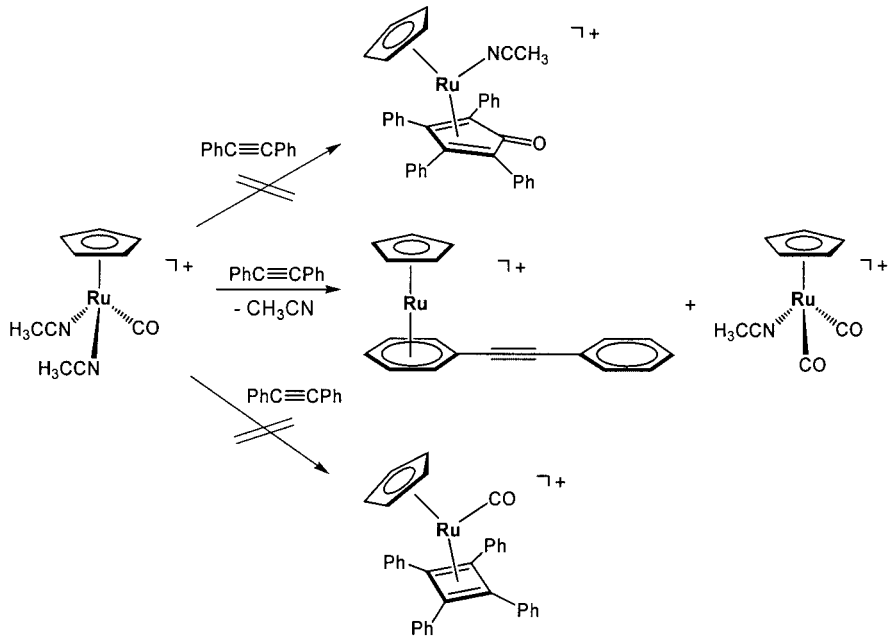

Scheme 23

A structural view of $[RuCp(\eta^4\text{-}OC_5Me_2C_3H_6)(CH_3CN)]PF_6$ is depicted in Figure 13.

These reactions are highly selective, yielding, in the case of terminal alkynes, only one regioisomer with the substituents exclusively in the α,α′-positions of the cyclopentadienone moiety. Further, in this case the substituent on the alkyne is of critical importance to the outcome of the reaction. Specifically, the reaction with PhC≡CPh does not yield the cyclopentadienone complex, but rather the sandwich complex $[RuCp(\eta^6\text{-}C_6H_5PhC{\equiv}CPh]^+$ and a biscarbonyl complex $[RuCp(CO)_2(CH_3CN)]^+$ in a 1:1 ratio (Scheme 23). Other reactions are also known in which

cyclopentadienone complexes are formed from carbonyls and acetylenes. The first reported cyclopentadienone complex, $Fe(\eta^4\text{-}C_5H_4O)(CO)_3$, was obtained by treating $Fe(CO)_5$ with an excess of HC≡CH.[46] Other examples are complexes of the types $M(\eta^4\text{-}C_5H_4O)(CO)_3$ (M = Fe, Ru),[47] $MCp(\eta^4\text{-}C_5H_4O)$ (M = Co, Rh),[48] and $V(\eta^4\text{-}C_5H_4O)(CO)(PMe_3)$.[23f]

4.9. Formation of Arenes and Arene Complexes − Cyclotrimerization of Alkynes

In contrast to the above systems, if $[RuCp(L)(CH_3CN)_3]^+$ is used when L = CH_3CN, the catalytic cyclotrimerization of alkynes is promoted as shown in Table 1, although, this does not occur in a selective manner, and 1,2,4- as well as 1,3,5-trisubstituted arenes are formed in most cases.[31] However, in the course of the catalytic process, several pathways that form stable and inert sandwich complexes of the type $[RuCp(\eta^6\text{-arene})]^+$ become readily available. In this way the catalytically active intermediates are consumed and the catalytic cycle is gradually quenched. Therefore, albeit active in various other C−C bond coupling reactions, involving even alkynes, $[RuCp(CH_3CN)_3]^+$ is an unsuitable catalyst for the cyclotrimerization of alkynes. The formation of arene complexes may be prevented under photochemical conditions since the arene ligands in $[RuCp(\eta^6\text{-arene})]^+$ are known to be photo-labile.[49]

5. What Happens if the Phosphane Ligand is Tethered?

What is the reason for the extraordinary difference in behavior between the two fragments RuCpCl and $[RuCp(PR_3)]^+$? There are at least two reasons for this: the first is the charge on the complex: clearly, a cationic complex will be more electrophilic than a neutral complex; the other is the greater steric requirements of the tertiary phosphane ligand than the chloride ligand. To elucidate this point further, we tethered the phosphane ligand onto the Cp ring via a two-carbon linker under, otherwise, the same

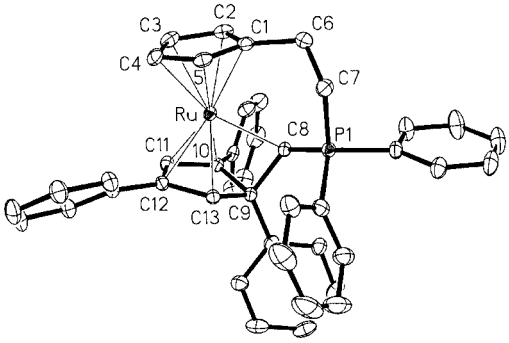

Figure 14. Structural view of $[Ru(\eta^5\text{-}C_5H_4CH_2CH_2PPh_2\text{-}\kappa^1C\text{-}CH\text{-}\eta^4\text{-}C_5Ph_3H_2)]PF_6$ (PF_6^- omitted for clarity)

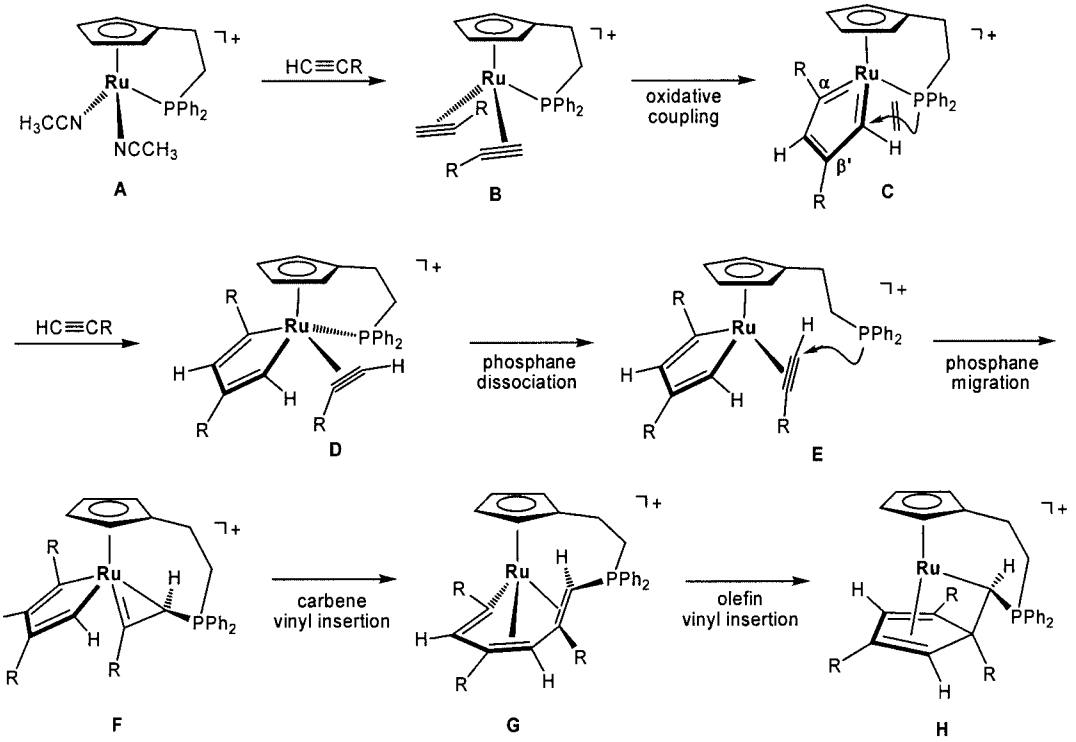

Scheme 24

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

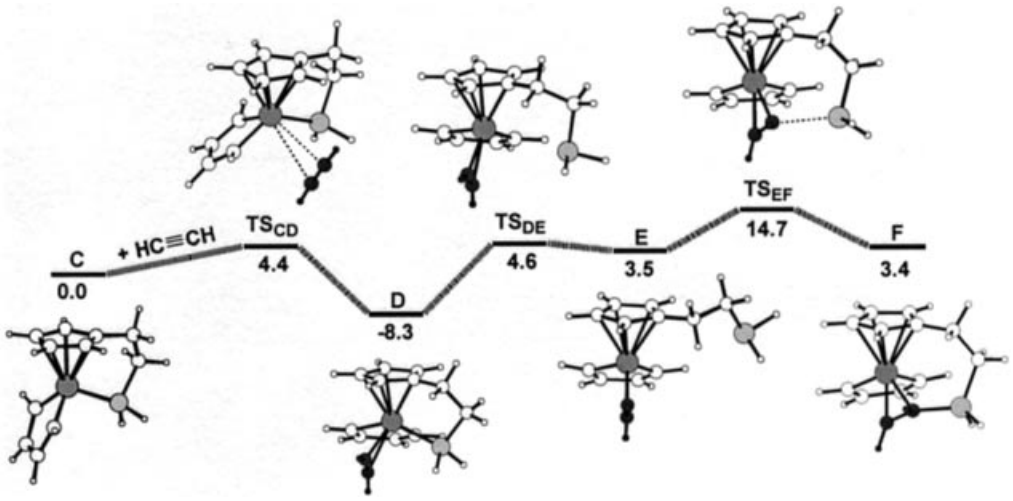

Figure 15. Energy profile of the B3LYP potential energy surfaces for the conversion of the ruthenacyclopentatriene complex **C** into the 1-metallacyclopropene **F**

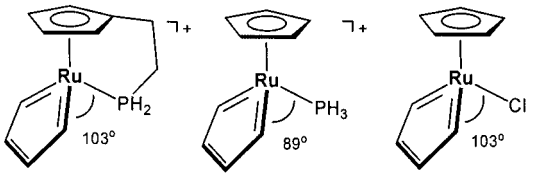
reaction conditions.[50] In fact, the arrested phosphorus moiety diverts the previously direct nucleophilic attack of the coordinated trialkylphosphane to the α-carbon atom of the metallacyclopentatriene. Instead, a third alkyne molecule is added, which finally leads to an unusual C−C coupling process that involves three alkynes and the tethered phosphane, to give the cycloaddition product **H** as shown in Scheme 24. A structural view of [Ru(η^5-$C_5H_4CH_2CH_2PPh_2$-κ^1C−CH-η^4-$C_5Ph_3H_2$)]PF_6 is given in Figure 14.

According to DFT/B3LYP calculations (Figure 15 and Figure 16), this intriguing [2+2+1] alkyne cyclotrimerization proceeds through Ru−P bond dissociation, phosphane attack at the coordinated acetylene to yield the 1-metallacyclopropene **F**, carbene vinyl insertion, and olefin vinyl insertion processes. Thus, in the present case, tethering can be considered to delay phosphane migration. The tethering of the phosphane ligand opens the interligand space between the metallacycle plane and the Ru−P vector and is depicted in Scheme 25. It is interesting to note that the corresponding angle of 103° in the tethered complex parallels that in RuCpCl, which mediates the cyclotrimerization of alkynes (vide supra).



Scheme 25

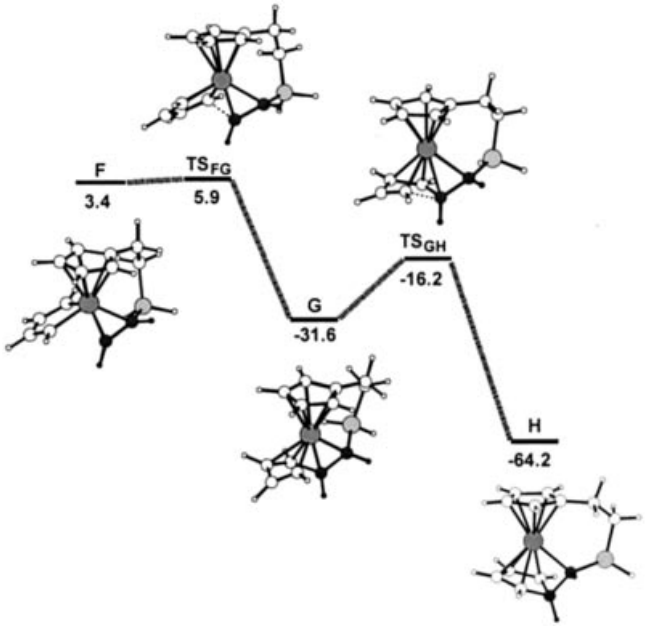


Figure 16. Energy profile of the B3LYP potential energy surfaces for the conversion of the 1-metallacyclopropene **F** into the final cyclotrimerization product **H**

Complex **C** is easily able to accommodate a third alkyne to afford the metallacyclopentadiene acetylene complex **D**. In the crowded complex **D**, the Ru−P bond is labilized, giving a free phosphane arm in **E** through an endothermic reaction,. The effect of ring strain introduced by a two-carbon tether has been demonstrated recently by Casey et al.[51] The subsequent reaction steps are quite straightforward: Nucleophilic attack of the pendant phosphane ligand at the coordinated acetylene results in the formation of the novel metallacyclopentadiene 1-metallacyclopropene complex **F**. The activation energy for this intramolecular process is 11.2 kcal/mol. It should be noted that related coupling reactions between a coordinated alkyne and a coordinated phosphane to yield 1-metallacyclopropenes and vinyl complexes have been reported in the literature.[52,53] Further, intermolecular nucleophilic additions of phosphanes and phosphites to alkyne ligands are feasible.[54] Complex **F** is prone to C−C coupling between the carbene carbon atom of the 1-metallacyclopropene moiety and the α-carbon

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

atom of the metallacyclopentadiene unit bearing no substituent, to give **G**. This reaction requires an activation energy of only 2.5 kcal/mol and is energetically very favorable releasing 35.0 kcal/mol. The final and rate-determining step is the insertion of the vinyl moiety into the η^2-olefin unit to give **H**, thus completing the [2+2+1] cyclotrimerization.

6. Outlook

It is highly fascinating to witness the vast and diversified varieties of rearrangements within and between molecules ligated to the ruthenium(II) center. Tertiary phosphanes and carbon monoxide, which ordinarily are spectator ligands, function here as active ligands and give rise to a wide array of scenarios that compete with the process of trimerization. This may be compared with the behavior of other metal centers so as to arrive at a deeper understanding of the individuality of the various transition metals. Unfortunately, experimental results are often difficult to compare directly because of the variable reactions conditions applied. The better choice may involve the use of reliable theoretical studies which, however, are still in their infancy and hence scarce.

The reactions surveyed here may be compared with the theoretical study of acetylene trimerization with $CpCoL_2$ (L = CO, PR_3, olefin). At least two fundamental differences are obvious: (i) for $CpCoL_2$, the coligands L serve as leaving ligands only, that give way to the incoming acetylenes; (ii) there is a larger variety of intermediates for the ruthenium system. This may partly be related to the atomic radii; the smaller radius of Co (1.09 vs. 1.21 Å for Ru)[55] may control interligand interactions (through-space coupling)[56] in a different way. In this respect, it might be relevant to undertake investigations of the rhodium analog CpRh.

We can be convinced that in the future an ever-increasing number of theoretical treatments will follow, which ultimately will help us understand chemical periodicity from first principles.

A Structural Study of Bisphosphonate Metal Complexes − Three New Polymeric Structures of the Calcium Complex of Clodronic Acid

Mervi Kontturi,*[a] Sirpa Peräniemi,[b] Jouko J. Vepsäläinen,[b] and Markku Ahlgrén[a]

Keywords: Bisphosphonate / Clodronate / Calcium / Layered compounds / X-ray diffraction

Three novel calcium complexes of clodronic acid were prepared and their structures determined by single-crystal X-ray diffractometry. Previously, a monomeric structure, $[Ca\{Cl_2C(PO_3H)_2\}(H_2O)_5]$ (**1**), has been determined, but the new structures are polymeric: $[\{Ca_2[Cl_2C(PO_3)_2](H_2O)_6\}\cdot 4.5H_2O]_n$ (**2**), $[\{Ca_2Na_{0.5}[Cl_2C(PO_3)_2](H_2O)_8\}Cl_{0.5}\cdot 4H_2O]_n$ (**3**) and $[\{Ca_5[Cl_2C(PO_3)_2]_2(H_2O)_{15}\}(NO_3)_2\cdot 1.5H_2O]_n$ (**4**); and they provide new, important information about the binding abilities of clodronic acid. Compounds **2**–**4** crystallise in the triclinic crystal system, the space group being $P\bar{1}$ with $Z = 2$. Compound **2** consists of Ca atoms and Cl_2MBP ligands connected to one-dimensional chains. The chains are held together by hydrogen bonds formed by aqua ligands and lattice water molecules. The structure of **3** consists of similar calcium clodronate chains forming two-dimensional layers through additional, six-coordinate Na atoms. Compound **4** consists of two-dimensional calcium clodronate layers, the calcium atoms are connected by Cl_2MBP– and aqua ligands. The nitrate groups and lattice water molecules lie between the layers and hold them together. The layered compounds **3** and **4** reveal substantial porosity.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

Bisphosphonates, BP, are an interesting class of compounds due to their pharmaceutical applications,[1−4] and also due to their potential chemical applications in ion exchange, sorption, catalysis, and so forth.[5−8] Typically, bisphosphonates are used to inhibit the mineralization of soft tissues and as a therapy for bone-formation and resorption disorders.[1−4] It has been proposed that one stage of the mechanism of action of the non-nitrous methylenebisphosphonates (MBP) is that they are rapidly adsorbed onto the hydroxyapatite surface of bone by forming a layered structure.[4,9−11] Recently, new insights have been reported concerning the molecular mechanism of action of MBPs.[12]

The use of BPs in ion exchange, sorption and catalysis is based on their ability to form porous materials when complexing with metal atoms and their effectiveness is related to the degree of porosity. The structures of these materials consist of chains, layers or pillared layers; dimensionality depends on the number of donor atoms of the ligands, but also on the size of the organic group between the phosphonate groups and on the degree of protonation of the phosphonate group.[5−8]

Clodronate, disodium dichloromethylenebisphosphonate tetrahydrate, is one of the best-documented MBP derivatives that is used effectively in medical applications.[13] However, there are no studies on how clodronate can form a layered structure on the hydroxyapatite surface of bone. Clodronate has six possible O-donor atoms, and therefore we can presume that it also forms polymeric structures to be utilized in chemical applications. The previously reported crystal structure of calcium clodronate, $[Ca\{Cl_2C(PO_3H)_2\}(H_2O)_5]$ (**1**), revealed that Cl_2MBP itself acted only as a bidentate chelating ligand with Ca, forming a monomeric complex.[14] However, we have reported structures of alkaline earth metal complexes of a symmetrical diethyl ester derivative of clodronic acid in which one O atom of each of the two phosphonate groups is masked by an ethyl group, and the results showed that this ligand provides 3−5 donor O atoms, producing dimeric and polymeric structures.[15] In the present study, three new polymeric structures of the calcium complex of clodronic acid, $[\{Ca_2[Cl_2C(PO_3)_2](H_2O)_6\}\cdot 4.5H_2O]_n$ (**2**), $[\{Ca_2Na_{0.5}[Cl_2C(PO_3)_2](H_2O)_8\}Cl_{0.5}\cdot 4H_2O]_n$ (**3**) and $[\{Ca_5[Cl_2C(PO_3)_2]_2(H_2O)_{15}\}(NO_3)_2\cdot 1.5H_2O]_n$ (**4**), are depicted.

Results and Discussion

The previously-published calcium clodronate **1** was prepared from calcium monohydrogenphosphate and the disodium salt of clodronic acid by slow evaporation at 60 °C.[14,16] We prepared this monomeric structure and the new polymeric calcium clodronate compounds from the disodium salt of clodronic acid (clodronate) and calcium nitrate (compounds **1**, **2** and **4**) or from clodronate and calcium

chloride (compound **3**) using a gel method. The gel-crystallisation tests revealed that concentrated solutions of the starting materials always produced calcium complex **1**. On the other hand, the new polymeric compounds were prepared under carefully controlled conditions; the effective factors are the pH of the ligand solution, the metal concentration and the rate of the diffusion and precipitation processes. In the preparation of **1**, clodronate (0.069 mmol) was used in the gel (pH 4.2, 1 mL), and the metal salt was offered as a concentrated $Ca(NO_3)_2 \cdot 4H_2O$ solution (3.34 M, 1 mL), which was placed above the gel and after one week was replaced by an acetone/ethanol (1:1) solution. Compound **4** was prepared under similar conditions, but using only a quarter of the amount of clodronate (0.017 mmol) in pH 5.0 and by placing a pure tetramethoxysilane (TMOS)-gel layer between the original gel and the precipitants. Compound **2** was also prepared from clodronate (0.017 mmol) but in pH 6.2. A pure TMOS-gel layer was placed above the native gel, and the concentration of the Ca solution was 1/75 of the former. No organic precipitant was needed to obtain the crystals of **2**. Compound **3** was prepared using the same amount of clodronate as in **1** and $CaCl_2$ (0.14 mmol), both of which were in the gel (pH 3.2, 1 mL), and acetone was placed above the gel immediately after gelation.

The calcium clodronate compound **1** consists of monomeric units,[14] while calcium compounds **2**−**4** are polymeric. The density increases with the dimensionality: it is lowest for **1** (1.86 g/cm^3) and highest for **4** (2.04 g/cm^3). Compound **2**, $[\{Ca_2[Cl_2C(PO_3)_2](H_2O)_6\} \cdot 4.5H_2O]_n$, consists of infinite chains, the asymmetric unit containing two independent Ca atoms and one Cl_2MBP ligand (see Figure 1, left). Compound **3**, $[\{Ca_2Na_{0.5}[Cl_2C(PO_3)_2](H_2O)_8\}Cl_{0.5} \cdot 4H_2O]_n$ (see Figure 2, left), consists of chains similar to those in **2**, the chains being connected to a two-dimensional layered structure by six-coordinate Na centres. Compound **4**, $[\{Ca_5[Cl_2C(PO_3)_2]_2(H_2O)_{15}\}(NO_3)_2 \cdot 1.5H_2O]_n$, consists of two-dimensional layers of calcium clodronate, the asymmetric unit containing five independent calcium atoms connected to each other by Cl_2MBP− and aqua ligands (see Figure 3, left).

In compounds **1**−**4**, the calcium atoms are hepta-coordinated, the geometry around the metal atom is a distorted, monocapped trigonal prism, and the average Ca−O bond length is 2.41(6) Å. In **2** and **3** there are two crystallographically independent Ca atoms in the asymmetric unit (see Figure 1, right, and Figure 2, right). Four of the O atoms around the two Ca atoms are from the chelating Cl_2MBP ligands, and the coordination sphere is completed by three aqua ligands. The coordinated Cl_2MBP ligands form both four- and six-membered chelate rings with the metal atoms. In **3** one aqua ligand of Ca1 also acts as a bridge between Ca1 and an additional, six-coordinate Na atom [Na−O 2.44(2) Å], which lies in the centre of symmetry. The rest of the coordination sites around Na are occupied by aqua ligands.

In **4** there are five crystallographically independent Ca atoms (see Figure 3, left). The coordination sphere of calcium atoms 1, 2, 4 and 5 consists of four oxygen atoms from two chelating ligands, forming both four- and six-membered chelate rings. The coordination spheres of the Ca atoms are completed with three aqua ligands. The coor-

Figure 1.  © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

dination sphere of calcium atom 3 consists of only two phosphonate oxygen atoms originating from two different Cl_2MBP ligands and the rest of the sites are occupied by five aqua ligands.

In the monomeric compound **1**, one of the oxygen atoms of both phosphonate groups of Cl_2MBP is coordinated to the Ca atom, the second oxygen atom being unbound and the third protonated.[14] In the case of the polymeric compounds **2**−**4**, there are neither unbound nor protonated oxygen atoms: the Cl_2MBP ligands are coordinated to the ambient calcium atoms through all six oxygen atoms, acting as chelating and bridging ligands. In **2** and **3** all Cl_2MBP ligands form two six-membered and two four-membered chelate rings simultaneously and are coordinated to four metal atoms. In **4** one ligand acts similarly to these, while the other one is connected to six Ca atoms. The bond lengths and angles of the Cl_2MBP ligand in compounds **2**−**4** are all typical.

Some porosity was found in all compounds. In **2** the chains are connected to each other by intermolecular hydrogen bonds, forming layers parallel to the (010) plane. The chlorine atoms and aqua ligands point towards the interlayer section, and the space is filled with lattice water molecules (Figure 1, right). Between the infinite chains there are intermolecular hydrogen bonds involving the aqua ligands and phosphonate O atoms [O···O distances 2.603(12)−3.051(8) Å and angles 118−179°]. In **3** the layers are parallel to the (−111) plane. The structure reveals substantial porosity in the packing diagram, as seen in Figure 2, right. Along the *a* axis, the layers are packed one on top of the other, forming pillars where two Na and four Ca atoms in a 24-membered ring define a cavity on the plane. The aqua ligands of each metal atom point into the cavity, and the Cl3 ions sit in the middle of the opening surrounded by lattice water molecules. There are also smaller pores between the layers. Intramolecular hydrogen bonds are formed between the aqua ligands, and the intermolecular hydrogen bonds involve both water molecules and chlorine Cl3 atoms [O···O/Cl distances 2.718(2)−3.339(4) Å and angles 119−170°] holding the layers together. In compound **4**, the layers are parallel to the (011) plane, and tunnels are formed between the layers along the *a* axis. The tunnels are filled with nitrate molecules and lattice water molecules (see Figure 3, right). Both inter- and intramolecular hydrogen bonds are found, the O···O distances being 2.457(12)−3.084(4) Å and the angles 117−177°. The intermolecular hydrogen bonds hold the adjacent calcium clodronate layers together, and involve water molecules and the O atoms of nitrate.

Conclusion

The previously-published structure and the present ones clearly differ: in compound **1**, the Cl_2MBP ligand provides only two donor O atoms, being chelated to one Ca atom;[14] while in the new polymeric compounds **2**−**4**, all Cl_2MBP ligands provide six donor O atoms, forming two six-membered and two four-membered chelate rings and acting as mono- and polyatomic bridges between the Ca atoms. As a result, the Cl_2MBP ligands in **2**−**4** are tightly bound to several Ca atoms through all O atoms, resulting in one-dimensional chains or two-dimensional layers, connected to a three-dimensional open network through hydrogen bonds. In compound **3**, the porosity is marked. These new findings concerning the coordination abilities of clodronic acid may explain its activity in forming a layered structure on the hydroxyapatite surface of bone and also provide new information about the ability of clodronic acid to form porous materials that can be used in chemical applications.

Experimental Section

General Remarks: All reagents used for the synthesis and characterisation of compounds **2**−**4** were of analytical reagent grade. The synthesis and characterisation of clodronic acid and its disodium salt $Na_2[CCl_2(PO_3H_2)]\cdot 4H_2O$ have been reported earlier.[14] The metal complexes were crystallised using gel methods **A** (**3**) and **C** (**1**, **2**, and **4**). In method **A**, a carefully weighed amount of $Na_2[CCl_2(PO_3H)_2]\cdot 4H_2O$ and metal salt were dissolved in water (2 × 0.45 mL) and warmed to 40 °C in a water bath. The solutions were then mixed together, and the TMOS (0.1 mL) was added. The two-phase system was shaken until homogeneous, and the emulsion was left to form a gel. Crystallisation was induced by adding an organic precipitant (1 mL) above the gel. In method **C**, $Na_2[CCl_2(PO_3H)_2]\cdot 4H_2O$ was dissolved in water (0.9 mL); and if necessary, the pH was adjusted with NaOH (0.02−1.0 M). TMOS (0.1 mL) was added; and the two-phase system was shaken until homogeneous. The emulsion was left to form a gel. In the preparation of **2** and **4**, after gelation a pure TMOS-gel layer (0.5 mL, 20 % v/v) was added above the native gel. The metal salt was dissolved in water (1.0 mL), added above the gel, and after 1−2 weeks replaced with organic precipitant (1.0 mL).

$[Ca\{Cl_2C(PO_3H)_2\}(H_2O)_5]$ (1): Preparation of **1** by slow evaporation at 60 °C has been described previously.[14,16] In this investigation, **1** was prepared with method **C** by placing clodronate (0.069 mmol, pH 4.5) in TMOS-gel and adding a water solution of $Ca(NO_3)_2\cdot 4H_2O$ (3.34 M, pH 4.2) above the gel. After one week the metal salt solution was replaced with a 1:1 acetone/ethanol solution. In a few weeks the crystals formed in the shape of cubes. The measured cell dimensions and results of elemental analysis agree with the earlier results.[14]

$[\{Ca_2[Cl_2C(PO_3)_2](H_2O)_6\}\cdot 4.5H_2O]_n$ (2): In the preparation of **2** with method **C**, clodronate (0.017 mmol) was dissolved in water and the pH was adjusted to 6.2. A water solution of $Ca(NO_3)_2\cdot 4H_2O$ (0.043 M, pH 4.5) was added above a pure TMOS-gel layer. Two days later the colourless, plank-like crystals were formed above the gel. $CH_{21}Ca_2Cl_2O_{16.5}P_2$ (510.18): calcd. C 2.35, H 4.15; Ca, 15.7; found C 2.11, H 3.90; Ca, 15.6.

$[\{Ca_2Na_{0.5}[Cl_2C(PO_3)_2](H_2O)_8\}Cl_{0.5}\cdot 2H_2O]_n$ (3): In the preparation of **3** with method **A**, both clodronate (0.069 mmol) and calcium chloride (0.14 mmol) were dissolved in water (pH 3.2) and TMOS was added. After gelation, acetone was placed above the gel, and in six months thin crystals were formed above the gel. $CH_{20}Ca_2Cl_{2.5}Na_{0.5}O_{16}P_2$ (530.39): calcd. C 2.26, H 3.80; found C 2.04, H 4.12.

$[\{Ca_5[Cl_2C(PO_3)_2]_2(H_2O)_{15}\}(NO_3)_2\cdot 1.5H_2O]_n$ (4): In the preparation of **4** with method **C**, clodronate (0.017 mmol) was dissolved

X-ray Crystallographic Study: Single-crystal x-ray diffraction studies were performed on a Nonius Kappa CCD diffractometer using Mo-K_α radiation (λ = 0.71073 Å). Denzo and Scalepack[17] programs were used for cell refinements and data reduction. The structures were solved by direct methods with SHELXS 97.[18] Structural refinements were carried out with SHELXL 97.[19] The hydrogen atoms were placed in calculated positions and not refined. In **2** two water molecules, O33 and O34 are disordered over two positions with population parameters 50/50 and water molecule O35 is disordered around a centre of symmetry. The hydrogen atoms of the disordered water molecules were omitted in the calculations. In **3** the Cl3 atom is disordered around a centre of symmetry. Crystallographic data of compounds **2**–**4** are summarised in Table 1.

CCDC-233048 (compound **2**), -233049 (compound **3**), -233050 (compound **4**) contain the supplementary crystallographic data for this paper. Synthesis and Crystal Structure of $Cs_2(CN_3H_6)_3[(C_2H_5)_2NH_2][W_7O_{22}(O_2)_2]\cdot 3H_2O$

Hiroyuki Suzuki,[a] Masato Hashimoto,*[a] and Seichi Okeya[a]

Keywords: Polyoxometallates / Peroxoisopolytungstates / Clathrates / Crystal structures

A novel diperoxoheptatungstate was crystallised as a Cs^+–$CN_3H_6^+$–$(C_2H_5)_2NH_2^+$ salt and characterised by a single-crystal X-ray diffraction method. The anion has a Lindqvist heptametallate structure. The metal atoms are located in a bent 2-3-2 arrangement with the central W_3 section (W3, W4 and W5) as the hinge. The peroxo groups coordinate the tungsten atoms at both ends of the W_3 section (W3 and W5). In the crystal polyanions, caesium and guanidinium cations, and water of crystallisation form tunnel-like cavities, and the diethylammonium cations are accommodated in the cavities, suggesting a clathrate-like feature for the compound.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

Polyoxometallates are aggregates of oxo anions involving transition metals of groups 5 and 6. By substituting oxo groups in a polyoxometallate with peroxo groups, a peroxopolyoxometallate is formed. The peroxopolyoxometallates are known to be effective oxidising agents. Several peroxopolyoxometallates have thus been examined as oxidation catalysts, and epoxidation of alkene and hydroxylation of benzene are mentioned as examples of catalytic reactions.[1−3]

Peroxopolyoxometallates constructed from only oxoanions of addenda atoms such as V, Mo and W are called peroxoisopolyoxometallates, and from both addenda and hetero atoms such as P, S and As are called peroxoheteropolyoxometallates. The catalytic properties of the peroxopolyoxometallates depend on their components; generally, peroxoheteropolyoxometallates are more active than peroxoisopolyoxometallates, and tungstates are more active than molybdates.[4,5] Other than functioning as catalysts, the peroxopolyoxometallates have application in photoresist materials and as precursors of oxides.[6]

While extensive research in the application of peroxopolyoxometallates has been done, the basic chemistry of peroxopolyoxometallates has not been well-investigated. Especially, the chemistry of peroxoisopolytungstates is not well-known and only four anionic structures, $[W(O_2)_4]^{2-}$,[7] $[W_2O_3(O_2)_2(H_2O)_2]^{2-}$,[8] $[W_4O_6(O_2)(OH)_2(H_2O)_2]^{2-}$ [9] and $[W_4O_{12}(O_2)_2]^{4-}$ [10] have been reported so far, probably due to the instability of the system and compounds formed, and the slow formation of the anions. On the other hand, a spectroscopic work has been reported and a number of structurally unknown species have been detected.[11,12]

The authors have therefore been working with isolating peroxoisopolytungstates as single crystals to elucidate synthetic conditions and structures of the complexes. In the course of the investigation on peroxoisopolytungstates formed in aqueous medium, a novel diperoxoheptatungstate anion was isolated as a ceasium/diethylammonium/guanidinium salt. The preparation and structure of this compound is described here.

Results and Discussion

An ORTEP[13] diagram of all non-H atoms in the asymmetric unit is shown in Figure 1 with atom numbering. The anion has a Lindqvist heptametallate structure. The metal atoms are located in a bent 2-3-2 arrangement in which the central W_3 section (W3, W4 and W5) acts as a hinge. The dihedral angle between least-squares planes defined by W1−W2−W5−W4−W3 and W3−W4−W5−W6−W7 is 84.67(1)°. The peroxo groups coordinate the tungsten atoms at both ends of the W_3 section (W3 and W5), protruding from opposite sides of the W_2 units. The two W atoms are thus heptacoordinated with a pentagonal bipyramidal geometry. The other W atoms are hexacoordinate. Selected bond lengths are listed in Table 1. The ranges of the bond lengths of W−O (terminal) and W−O (bridge) are 1.713(4)−1.751(4) Å and 1.758(4)−2.324(4) Å, respectively.

Although O10 and O12 are asymmetrically bridging, the short bond lengths W4−O10 [1.784(4) Å] and W4−O12 [1.758(4) Å] indicate that these O atoms behave like the terminal oxygen atoms of W4. The long W−O bond lengths *trans* to W4−O10 and W4−O12, W4−O13 [2.222(4) Å]

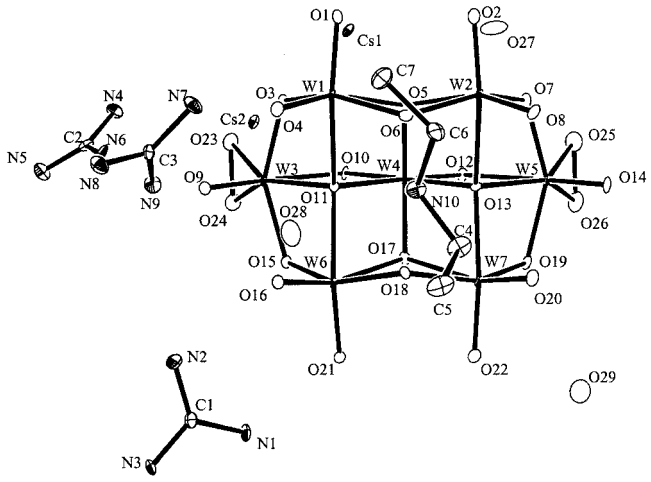

Figure 1. An ORTEP view of $Cs_2(CN_3H_6)_3[(C_2H_5)_2NH_2][W_7O_{22}(O_2)_2]\cdot 3H_2O$, displacement ellipsoids are drawn at the 50% probability level; selected bond lengths (Å) and angles (°): W(1)−O(1) 1.742(4), W(1)−O(4) 1.742(4), W(2)−O(2) 1.747(5), W(2)−O(8) 1.732(4), W(3)−O(9) 1.723(4), W(5)−O(14) 1.713(4), W(6)−O(16) 1.745(4), W(6)−O(21) 1.751(4), W(7)−O(20) 1.744(5), W(7)−O(22) 1.744(5), W(1)−O(3) 1.947(4), W(1)−O(6) 1.938(4), W(1)−O(5) 2.283(4), W(1)−O(11) 2.208(4), W(2)−O(5) 2.285(4), W(2)−O(6) 1.953(4), W(2)−O(7) 1.947(4), W(2)−O(13) 2.207(4), W(3)−O(3) 1.973(4), W(3)−O(10) 2.3237(4), W(3)−O(11) 2.081(4), W(3)−O(15) 1.984(4), W(4)−O(5) 1.883(4), W(4)−O(10) 1.784(4), W(4)−O(11) 2.252(4), W(4)−O(12) 1.758(4), W(4)−O(13) 2.222(4), W(4)−O(17) 1.898(4), W(5)−O(7) 1.964(4), W(5)−O(12) 2.367(4), W(5)−O(13) 2.110(4), W(5)−O(19) 1.993(4), W(6)−O(11) 2.204(4), W(6)−O(15) 1.950(4), W(6)−O(17) 2.227(4), W(6)−O(18) 1.935(4), W(7)−O(13) 2.174(4), W(7)−O(17) 2.280(4), W(7)−O(18) 1.930(4), W(7)−O(19) 1.951(4), W(3)−O(23) 1.955(5), W(3)−O(24) 1.943(5), W(5)−O(25) 1.948(5), W(5)−O(26) 1.942(5), O(23)−O(24) 1.479(7), O(23)−O(24) 1.468(7), O(23)−W(3)−O(24) 44.3(2), O(25)−W(5)−O(26) 44.6(2)

and W4−O11[2.252(4) Å], are the result of the *trans* influence of O10 and O12. The same phenomenon has been observed in peroxoheptamolybdates.[14−16]

In the vicinity of the peroxo groups (O23−O24 and O25−O26), the W−O bond lengths are in the range of 1.942(5)−1.955(5) Å, and the O23−O24 and O25−O26 bond lengths are 1.479(7) Å and 1.467(7) Å, respectively. The angles O23−W3−O24 and O25−W5−O26 of the peroxo group are 44.6(2)° and 44.3(2)°, respectively. These values are normal for compounds of this type.

The existence of such a polyanion has been predicted by an ^{17}O NMR study.[11,12] However, this is the first example of the isolation and structural analysis of this type of anion. On the other hand, the corresponding molybdates have already been isolated and structurally analysed.[14] Structures of heptatungstates without peroxo groups have also been reported.[17,18] The bond lengths in peroxoheptamolybdate, heptatungstate and the present peroxoheptatungstate are compared in Table 1;[17−21] no significant differences are observed, and any discrepancies may be partly due to the accuracy of the measurements. The slightly shorter bond lengths in the present compound are a result of the low temperature at the time of the measurement.

Packing diagrams are shown in Figures 2 and 3. Three H_2O molecules, three $CN_3H_6^+$ and two Cs^+ ions, and one $(C_2H_5)_2NH_2^+$ ion surround the anion. The polyanions, cations and water of crystallisation are linked by hydrogen bonds and electrostatic interactions (Table 2) to stabilise the whole crystal structure. Generally, the peroxoheptatungstate was considered to be difficult to isolate in the solid state and it has not been achieved before, although the existence of the anion in aqueous solution has been determined by spectroscopic methods.[11,12] The reason for the isolation of the peroxoheptatungstate as single crystals this time may have depended on the stabilisation of the whole crystal structure by the coexistence of not a single but several kinds of cations in the composition. As can be seen in Figure 3, the polyanions, the caesium and guanidinium cations, and the water of crystallisation form tunnel-like cavities, and the diethylammonium cations are accommodated in these cavities. The ammonium cation is held in the structure by hydrogen bonds with the polyanion and water of crystallisation in the walls of the tunnels. The bond lengths are listed in Table 2. The compound thus has a

Experimental Section

Preparation of $Cs_2(CN_3H_6)_3[(C_2H_5)_2NH_2][W_7O_{22}(O_2)_2]\cdot 3H_2O$: Tungsten powder (1.83 g) was slowly dissolved in 30% hydrogen peroxide (25 mL), and the mixture was diluted to 100 mL with H_2O. Care must be taken here because of a vigorous reaction. The pH of the solution was adjusted to ca. 4.0 with aqueous LiOH (2.7 M). CsCl, $(CN_3H_5)\cdot HCl$, $(C_2H_5NH)\cdot HCl$ (molar ratio W/cation = 1:0.5 for each) were then added to the resulting solution. Colourless plate-shaped crystals appeared at room temperature in about 40 days.

Crystallographic Data for $Cs_2(CN_3H_6)_3[(C_2H_5)_2NH_2][W_7O_{22}(O_2)_2]\cdot 3H_2O$: M_r = 2276.77, monoclinic, $P2_1/c$, a = 13.4459(3), b = 11.3009(2), c = 25.0294(2) Å, β = 90.4760(10)°, V = 3803.11(11) Å^3, Z = 4, D_x = 3.977 g/cm^3, T = 100(2) K, μ (Mo-K_α) = 23.08 mm^{-1}, R_1 [$F_o > 4.0\sigma(F_o)$] = 0.0270, wR_2 (all data) = 0.0627, goodness of fit = 0.998, R(int.) = 0.0643, reflections measured 63317, unique reflection 11647, parameter 497.

Intensity data of $Cs_2(CN_3H_6)_3[(C_2H_5)_2NH_2][W_7O_{22}(O_2)_2]\cdot 3H_2O$ was collected on SMART CCD SYSTEM. Data reduction and absorption correction based on psi-scans were applied with TEXSAN.[22] All calculations were performed with SHELX97.[23] Cs and W atoms were located by a direct method and all other atoms by successive Fourier syntheses. All non-H atoms were refined anisotropically by full-matrix least-squares based on F^2.

CCDC-227357 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Center, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Cobalt-Mediated Cyclooligomerization Reactions of Borylacetylenes

Avijit Goswami,[a] Claus-Jürgen Maier,[a] Hans Pritzkow,[a] and Walter Siebert*[a]

Dedicated to Professor Helmut Werner on the occasion of his 70th birthday

Keywords: Boranes / Catalysts / (Cyclobutadiene)cobalt complexes / Mono(boryl)acetylenes / Triborylbenzenes

Reaction of bis(diethylamino)acetylene (**1**) with lithium and chlorobis(dimethylamino)borane yields 1-[bis(dimethylamino)boryl]-2-(diethylamino)acetylene (**2**). Treatment of 1-aryl-2-(trimethylstannyl)acetylenes **3** with chlorobis(diisopropylamino)borane results in the quantitative formation of 1-aryl-2-[bis(diisopropylamino)boryl]acetylene compounds **4**. The 1-aryl-2-borylacetylene derivatives **5**, **6**, and **7** are obtained by the reaction of **3** with the appropriate haloborane, or by reacting **4** with two equivalents of HCl and one equivalent of catechol, dithiocatechol and 2-hydroxythiophenol. The catalytic cyclotrimerizations of **5a–d** with $[CpCo(CO)_2]$ or $[Co_2(CO)_8]$ lead to isomeric mixtures of the triborylbenzene derivatives **8a–d** and **8a′–d′**, whereas **6a–d** and **7a–b** undergo cyclotrimerization only with catalytic amount of $[Co_2(CO)_8]$, to give isomeric mixtures of the triborylbenzene derivatives **12a–d/12a′–d′** and **13a–b/13a′–b′**, respectively. The reaction of **2** with a stoichiometric amount of (η^5-cyclopentadienyl)bis(ethene)cobalt leads to (η^5-cyclopentadienyl)(η^4-cyclobutadiene)cobalt complexes **9**. The analogous complexes **10** and **11** are obtained by the reactions of **6** and **7** with a stoichiometric amount of (η^5-cyclopentadienyl)dicarbonylcobalt. Treatment of $Co_2(CO)_8$ with **5a**, **6a**, and **7a** yields the dicobaltatetrahedranes **14a**, **15a** and **16a**. Compound **15a** reacts with two equivalents of diphenylacetylene and 1-(1,3,2-benzodioxaborolyl)-2-phenylacetylene (**5a**), to furnish (1,3,2-benzodithiaborolyl)pentaphenylbenzene (**17**) and bis(1,3,2-benzodioxaborolyl)(1,3,2-benzodithiaborolyl)-triphenylbenzene (**18**), respectively. The new compounds have been characterized by NMR spectroscopy and mass spectrometry, as well as by X-ray structural analyses for **4a**, **5a**, **6a**, and **10a**.

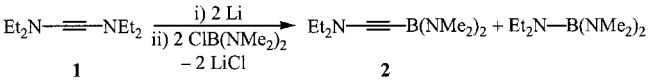
Introduction

Over the past decades, the cyclooligomerization reactions of alkynes with transition metal complexes have received considerable attention.[1] $[CpCo(CO)_2]$[2] is a convenient and efficient reagent for the syntheses of CpCo−cyclobutadiene complexes,[3] cyclopentadienones,[4] and benzene derivatives,[5] whereas $[Co_2(CO)_8]$ is used in Pauson−Khand[6] and [2+2+2] cyclotrimerization reactions.

Recently, we reported the Co-catalyzed [2+2+2] cyclotrimerization of mono-[7] and bis(catecholboryl)acetylenes.[8] With both types of acetylenes, only benzene derivatives were obtained — no CpCo-cyclobutadiene complexes were observed — even when using stoichiometric amounts of $[CpCo(CO)_2]$ and the corresponding acetylene.

To study the influence of the substituents with respect to the formation of CpCo−cyclobutadiene and/or benzene derivatives, we have synthesized new mono(boryl)acetylene derivatives with terminal boryl and amino or aryl substituents. Compound **2**, which has both amino and boryl substituents (Scheme 1), can react similarly to the push−pull acetylene $Me_2N-C\equiv C-COOMe$,[9] and undergoes dimerization.



Scheme 1

The influence of the substituents at the boryl group is of particular interest, as amino groups at the boron center may reduce its Lewis acidity. A large part of this work concentrates on the reactivity of arylalkynyl boranes **5**, **6**, and **7**, in which two oxygen atoms (in **5**), two sulfur atoms (in **6**) and one oxygen and one sulfur atom (in **7**) are bound to the boron atom. It is expected that the heteroatoms have different electronic and steric effects on the reactivity of the acetylenes **5**−**7**. In this paper, we report the syntheses, structures and reactivities of the monoborylacetylene derivatives **2** and **4**−**7**.

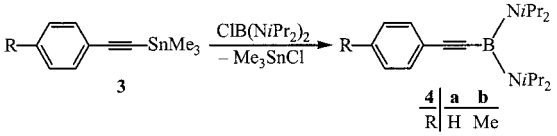
Results and Discussion

Synthesis and Properties of Mono(boryl)acetylene Derivatives 2, 4, 5, 6 and 7

Bis(diethylamino)acetylene (**1**) is obtained by treating 2-fluoro-1,1-dichloroethene or trichloroethene with *N*,*N*-disubstituted lithium amides and secondary amines.[10] In **1**, the N−C≡C bond is cleaved by lithium in THF to give two lithium compounds (Et_2NLi and $Et_2N-C{\equiv}CLi$), which react with various electrophiles. The mixture was treated with chlorobis(dimethylamino)borane to give $Et_2N-B(NMe_2)_2$ (70%) and 1-amino-2-borylacetylene (**2**) (43%), which were separated by fractional distillation (Scheme 1). Their compositions were determined by mass spectrometric and NMR spectroscopic data.

The reactions of chlorobis(diisopropylamino)borane with 1-trimethylstannyl-2-arylacetylenes **3** led to light-yellow compounds **4** in quantitative yields (Scheme 2). Compounds **4**[11] were characterized by ^1H, ^{13}C, and ^{11}B NMR spectroscopy, as well as by mass spectrometry.



Scheme 2

In the ^{11}B NMR spectrum, the signal at δ = 26 ppm of **4a** indicates a trigonal-planar boryl group, which we confirmed by X-ray structural analysis. In the linear B−C≡C−C moiety (Figure 1) the C≡C bond is slightly widened relative to other R−C≡C−R compounds (1.18 Å).[12]

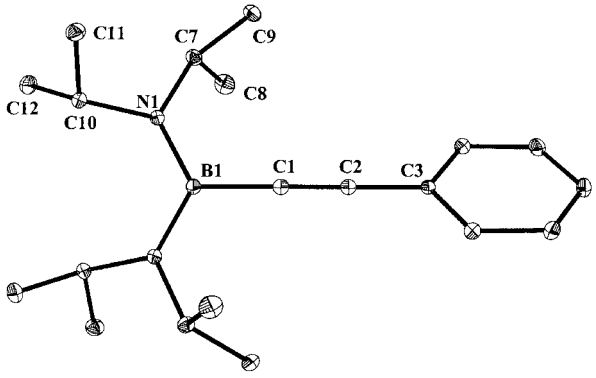


Figure 1. Molecular structure of **4a** in the solid state; hydrogen atoms are omitted for clarity; selected bond lengths [Å] and bond angles [°]: C1−C2 1.210(14), C2−C3 1.434(14), N1−B1 1.434(8), B1−C1 1.559(15), C1−C2−C3 180.0, C2−C1−B1 180.0

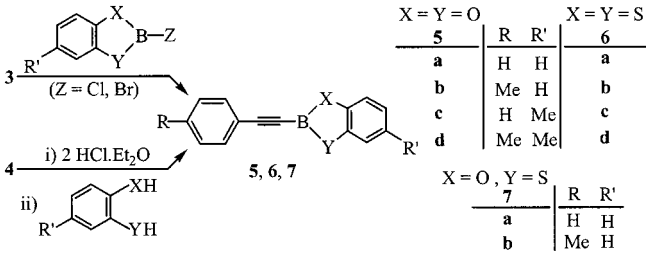
The syntheses of compounds **5**, **6**, and **7** were achieved by two reaction procedures. A solution of 1-aryl-2-(trimethylstannyl)acetylene (**3**) in toluene was reacted with the corresponding haloborane to give **5**−**7**. When compound **4** was treated with two equivalents of HCl and one equivalent of catechol or dithiocatechol or 2-hydroxythiophenol in THF, the corresponding alkynes **5**, **6**, and **7** were obtained as crystalline solids (Scheme 3). These compounds are soluble in benzene and toluene, but are less soluble in hexane and pentane. The ^1H NMR spectra of **5**−**7** show the expected multiplicities of the aromatic protons in the region δ = 6.9−7.9 ppm. In the ^{13}C NMR spectra, the signals for the boron-bound carbon atoms were not observed; the signals for the β carbon atoms (δ = 84−109 ppm) are shifted to lower fields relative to the alkylacetylenes (δ = 70−80 ppm),[13] which may indicate an interaction of the empty orbital at the boron atom with the π system of the triple bond.



Scheme 3

The structures of **5a** and **6a** were determined by performing single-crystal X-ray analyses (Figures 2 and 3). Each compound has a linear B−C≡C−C moiety (**5a**: exactly; **6a**: approximately) and the C≡C bond lengths are slightly longer than those of normal alkyne compounds. The B−C bonds are rather short. This finding is in agreement with structural data for oxygen-substituted bis(catecholboryl)acetylenes.[14]

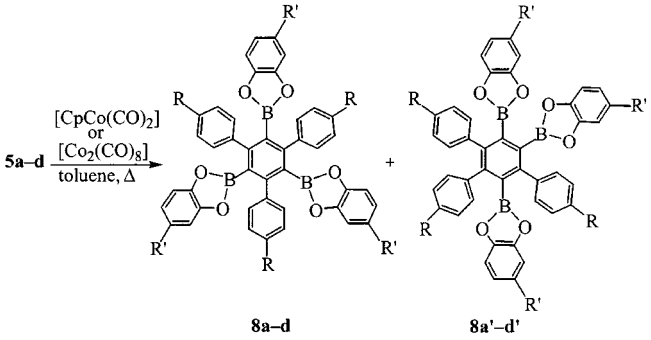
Trimerization of 5 to Triboryl-triarylbenzene Derivatives 8

Only a few triborylbenzene derivatives are known,[15] of which some have been prepared in low yields by Grignard reactions. Recently, we obtained triborylbenzene derivatives[7] by cyclotrimerization of monoborylacetylenes in the presence of catalytic amount of dicarbonyl(η^5-cyclopentadienyl)cobalt. Analogously, in refluxing toluene, the monoborylalkyne derivatives **5a**−**d** formed isomeric mixtures of the 1,3,5- and 1,2,4-triborylbenzene derivatives **8a**−**d** and **8a′**−**d′** in the presence of a catalytic amount of $[CpCo(CO)_2]$ or $[Co_2(CO)_8]$ (Scheme 4). The isomers could not be separated.



Scheme 4

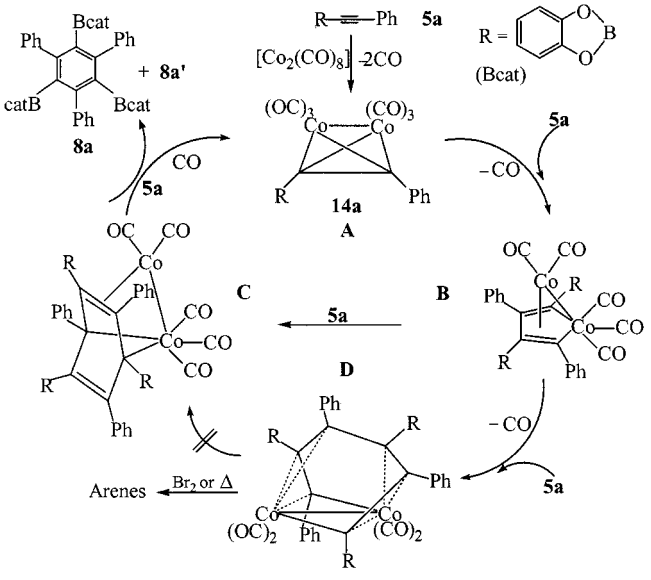
The air-stable solids **8a**−**d** and **8a′**−**8d′** are light-yellow in color and are not soluble in most organic solvents; **8a**/**8a′** dissolve partially in chloroform, whereas **8b**−**d** and **8b′**−**d′** are slightly soluble in dichloromethane and toluene. Compounds **8a**−**d** and **8a′**−**d′** were characterized by ^{1}H, ^{13}C, and ^{11}B NMR spectroscopy, elemental analysis, and mass spectrometry. The ^{11}B NMR spectra exhibit broad signals at δ = 24 ppm for **8a**/**8a′**, δ = 22 ppm for **8b**/**8b′** and **8d**/**8d′**, and δ = 23 ppm for **8c**/**8c′**. In the ^{1}H NMR spectrum of **8a**/**8a′**, several peaks appear in the region δ = 7.2−7.6 ppm that are due to aromatic protons of the catechol and phenyl substituents. In the ^{13}C NMR spectrum, three signals at δ = 112.7, 123.2, and 147.8 ppm are observed for the carbon atoms of the catechol groups. The signal at δ = 139.9 ppm is assigned to the *ipso*-carbon atoms of the central ring of the isomer **8a** and three signals at δ = 134.6, 137.3, and 142.5 ppm to the *ipso*-carbon atoms of the central ring of the isomer **8a′**. The ^{13}C NMR spectroscopic signals of the carbon atoms of the phenyl substituents appear at δ = 121.2, 128.5, 130.0, and 132.8 ppm. Similarly, the ^{1}H NMR spectra of **8b**−**d** and **8b′**−**d′** show the expected multiplets (in the region δ = 6.9−7.6 ppm for the aromatic protons) and singlets near δ = 2.3−2.4 ppm (methyl groups). The ^{13}C NMR spectra reveal chemical shifts of the *ipso*-carbon atoms of the central ring of the isomers **8b**−**d** near δ = 140−141 ppm and the *ipso* carbon atoms of the isomers **8b′**−**d′** in the region δ = 136−148 ppm.

Thermal reactions of **5a**−**d** with a stoichiometric amount of $[CpCo(CO)_2]$ did not provide any (cyclobutadiene)cobalt complex: only the cyclotrimerization products were found. Likewise, photochemical activation of $[CpCo(CO)_2]$ and **5a**−**d** did not yield (cyclobutadiene)cobalt complexes: only the starting materials were recovered.

Catalytic Cycles with $[CpCo(CO)_2]$ and $[Co_2(CO)_8]$

The postulated mechanism of $[CpCo(CO)_2]$-catalyzed cyclotrimerization[5a,16] of acetylene is suggested for **5a**. Under thermal conditions, two alkyne ligands displace the CO groups to form a bis(alkyne)cobalt complex, followed by reductive coupling of the alkyne units to give a coordinatively unsaturated cobaltacyclopentadiene complex. Coordination of a third molecule of **5a** could then lead to an 18-VE complex, which undergoes alkyne insertion to form the corresponding cobaltacycloheptatriene compound. Subsequent reductive elimination of the CpCo complex fragment leads to the formation of the triborylbenzene derivatives **8a**/**8a′**. Recently, Vollhardt et al.[17] reported the synthesis of a (η^2-alkyne)cobaltacyclopentadiene complex, which indirectly proves the proposed catalytic cycle, although no direct evidence for the intermediacy of the postulated cobaltacycloheptatriene was obtained. According to ab initio and density functional theory (DFT) investigations of the mechanism,[16] a cobaltacycloheptatriene is in fact very unlikely to form.

Analogously, the catalytic oligomerization of **5a** with octacarbonyldicobalt led to the triborylbenzene derivatives **8a**/**8a′** in 71% yield. One of our aims is to isolate intermediates to shed more light on the catalytic cycle proposed in Scheme 5, which is a short version of the Knox−Pauson−Spicer mechanism.[18] In the first step, elimination of two CO ligands leads to the unsaturated species $[Co_2(CO)_6]$, which reacts with **5a** to give the boryl-substituted dicobaltatetrahedrane complex **14a** (**A**). Subsequent elimination of CO and insertion of one molecule of **5a** should yield the intermediate **B**, of which many examples are known.[19] However, under our conditions, **B** was not detected. A Diels−Alder-type reaction of **B** with **5a** may



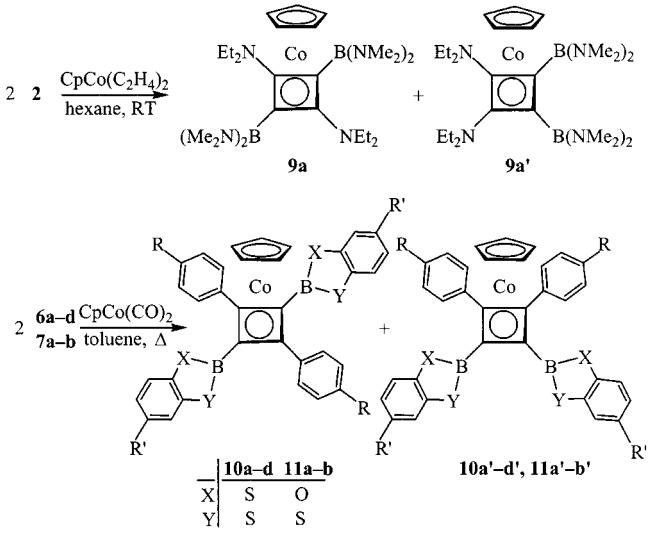
Scheme 5

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

lead to **C**, which eliminate **8a/8a′** and the pentacarbonyldicobalt fragment reacts with CO and **5a** to give **14a**. We did not observe the postulated intermediates **C** and the "flyover" dicobaltacyclooctadiene complex **D**; several examples have been reported of the latter species.[18,20] It has been demonstrated that drastic conditions[21] or chemical promoters[18] transform **D** into arenes and, therefore, **D** is not on the main path of the catalytic reaction to arenes.[18]

Synthesis of CpCo−Diborylcyclobutadiene Complexes 9, 10 and 11

In 1965, Pettit et al.[22] reported the first generation of the tricarbonyl(η^4-cyclobutadiene)iron complex. Among the various synthetic methods, the reactions of alkynes with transition metal carbonyl complexes in particular have been studied extensively during the last three decades.[23] In an analogous manner, compound **2** was treated with (η^5-cyclopentadienyl)bis(ethene)cobalt in hexane and compounds **6** and **7** with dicarbonyl(η^5-cyclopentadienyl)cobalt in refluxing toluene to give the corresponding (η^4-cyclobutadiene)(η^5-cyclopentadienyl)cobalt complexes **9**, **10**, and **11** in good yields (Scheme 6). Purification of compounds **9a/9a′** by column chromatography on aluminum oxide led to decomposition. Because of a paramagnetic impurity in the crude product, compounds **9a/9a′** could not be characterized by NMR spectroscopy. EI-MS data confirm the identity of **9a/9a′** through the appearance of the molecular ion peaks with the expected isotopic patterns. Compounds **10** and **11** are partially soluble in toluene and chloroform; in methanol, a fast reaction, leading to the formation of $B(OMe)_3$, takes place.



Scheme 6

Purification of **10** and **11** can be accomplished by washing repeatedly with hexane. Complexes **10** and **11** were characterized by ^1H, ^{13}C, and ^{11}B NMR spectroscopy, elemental analysis, and mass spectrometry. The ^{11}B NMR spectra show broad signals at $\delta = 58$ ppm for **10a/10d**, and $\delta = 57$ ppm for **10b/10c**. The ^1H NMR spectra of **10** exhibit multiplets in the region $\delta = 7.0-7.9$ ppm that are due to the aromatic protons, in addition to the Cp resonances ($\delta = 4.6-4.9$ ppm). Four quaternary carbon atoms of diboryl-substituted (η^4-cyclobutadiene)cobalt complexes **10** were detected in the ^{13}C NMR spectrum in the region $\delta = 79-89$ ppm. From the NMR spectra, it is not possible to make a distinction between the *trans* (**10a−d**) and *cis* isomers (**10a′−d′**) of the cyclobutadiene complexes. For steric reason, the *trans* isomers **10a−d** seem to be more favored, which is confirmed by the solid state structure of **10a**. However, several complexes are known that have *cis*-bis(trimethylsilyl)cyclobutadiene ligands.[1c,24] The problem was resolved unequivocally by analyzing the major peaks in terms of the degradation of the cyclobutadiene ring in the mass spectra. In general, three different acetylenes are released from the molecular ion of the *cis* isomer, but only a single acetylene is released from the *trans* isomer.[25] Here, in all cases, three kinds of acetylenes were released from the molecular ion. Therefore, mass spectra gave evidence for both the *cis* isomer and the *trans* isomers, but the *cis* isomer could not be identified by NMR spectroscopic measurements.

The structure of **10a** was characterized by performing a single-crystal X-ray diffraction analysis. Two independent molecules were found; the structure of one is shown in Figure 4. The solid state structure of **10a** reveals that both phenyl groups, as well as one of dithiacatecholboryl groups, do not lie in the plane of the cyclobutadiene ring. From the internal bond angles of the cyclobutadiene ring of **10a**, it is found that there is a little deviation from the exact square-planar shape because the internal bond angles for both the carbon atoms attached to the boron atom are smaller than those attached to the phenyl groups.

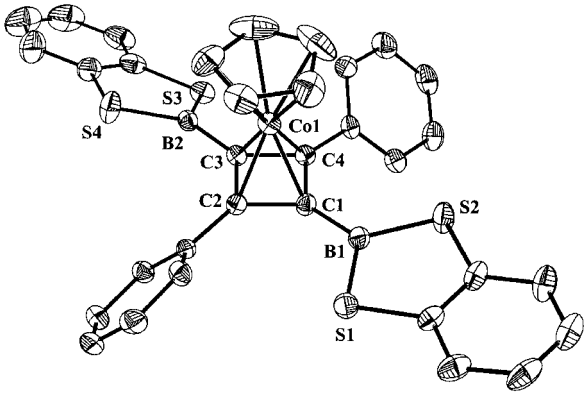


Figure 4. Molecular structure of **10a** in the solid state; hydrogen atoms are omitted for clarity; selected bond lengths [Å] and bond angles [°]: C1−C2 1.460 (5), C2−C3 1.465(5), C3−C4 1.476(5), C4−C1 1.462(5), C1−B1 1.528(6), C3−B2 1.527(6), C2−C1−C4 89.2(3), C1−C2−C3 91.4(3), C2−C3−C4 88.5(3), C1−C4−C3 90.9(3)

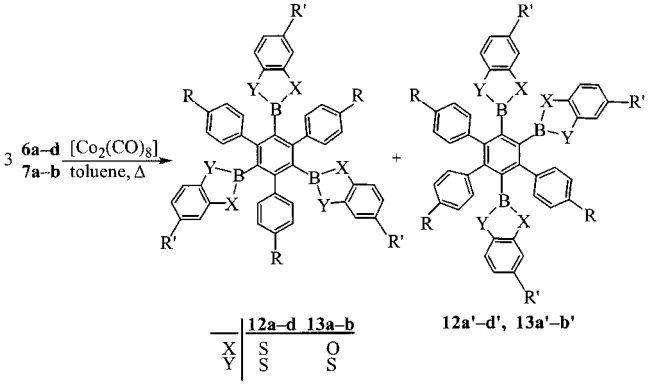
Similarly, ^{11}B NMR spectra show broad signals at $\delta = 45$ ppm for **11a/11a′** and $\delta = 46$ ppm for **11b/11b′**. The ^1H NMR spectra exhibit multiplets in the region $\delta =$

7.1−7.9 ppm that are due to aromatic protons. In the ^{13}C NMR spectra of **11a/11a′** and **11b/11b′**, the signals in the region δ = 84−86 ppm are assigned to the *ipso*-carbon atoms of the central C_4 ring and to the signals of the Cp carbon atoms (δ = 83−87 ppm). The EI mass spectra of **11a**−**b** and **11a′**−**b′** show ion fragmentations similar to those mentioned above, with the expected isotopic patterns. It is important to mention that no benzene derivatives were observed in the reactions of $[CpCo(CO)_2]$ with the alkynes **6** and **7** (Scheme 6).

$[Co_2(CO)_8]$-Catalyzed Cyclotrimerization of 6 and 7 to Triborylbenzenes 12 and 13

Arnett et al.[26] prepared the sterically encumbered hexaisopropylbenzene by $[Co_2(CO)_8]$-catalyzed trimerization of bis(isopropyl)acetylene. Analogously, in refluxing toluene, the mono(boryl)acetylene derivatives **6** and **7** formed the triborylbenzene derivatives **12** and **13** in the presence of a catalytic amount of $[Co_2(CO)_8]$ (Scheme 7). The isomeric mixture (1,3,5- and 1,2,4-substituted) could not be separated. Purifications of **12** and **13** were achieved by washing repeatedly with hexane, toluene and CH_2Cl_2.



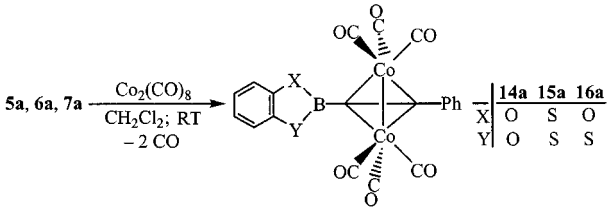
Scheme 7

The compounds **12** and **13** are air-stable solids and are not soluble in most common organic solvents; slight solubility in chloroform enables NMR spectra to be measured. All compounds were characterized by ^1H, ^{13}C, and ^{11}B NMR spectroscopy, elemental analysis, and mass spectrometry. The ^{11}B NMR spectra show broad signals at δ = 62 ppm for **12a/12a′** and δ = 60 ppm for **12b/12b′**, **12c/12c′**, and **12d/12d′**. In the ^1H NMR spectra, multiplets (δ = 6.9−7.9 ppm) are observed for the aromatic protons of **12a**−**d** and **12a′**−**d′**. In the ^{13}C NMR spectra, the signals in the region δ = 126−128 ppm are assigned to the *ipso*-carbon atoms of the central ring of the isomers **12a**−**c** and those in the region δ = 128−141 ppm to the *ipso* carbon atoms of the isomers **12a′**−**c′**. The quaternary carbon atoms of **12d/12d′** were not observed.

The ^{11}B NMR spectra of **13a/13a′** exhibit broad signals at δ = 53 ppm and of **13b/13b′** at δ = 52 ppm. The ^1H NMR spectra show multiplets in the aromatic region for the aryl protons of **13a/b** and **13a′/b′**. The ^{13}C NMR spectra reveal the signals of the *ipso*-carbon atoms of the central ring of **13a** at δ = 132.8 ppm and at δ = 132.7 ppm for **13b**.

Synthesis and Properties of Dicobaltatetrahedranes 14a, 15a, and 16a

(Alkyne)hexacarbonyldicobalt complexes are obtained by treating alkynes with $Co_2(CO)_8$.[27] Analogously, the mono(boryl)acetylene derivatives **5a**, **6a**, and **7a** reacted with $Co_2(CO)_8$ in CH_2Cl_2; elimination of two CO units resulted in the corresponding complexes **14a**, **15a** and **16a** (Scheme 8). These compounds were isolated by column chromatography as brown-red oils,[28] which we characterized by ^1H, ^{13}C, and ^{11}B NMR spectroscopy, IR spectroscopy, and mass spectrometry.

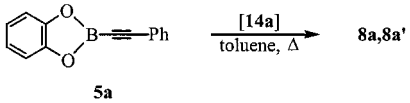


Scheme 8

The ^{11}B NMR spectrum of **14a** shows a broad signal at δ = 33 ppm. The ^1H NMR spectrum exhibits the signals of the aromatic protons in the region δ = 7.2−7.7 ppm. In the ^{13}C NMR spectrum, the arene carbon atoms give rise to signals at δ = 112.6, 123.2, and 147.8 ppm for the catechol unit and at δ = 121.2, 128.5, 130.0, and 130.2 ppm for the phenyl group. The signal of the carbon atom bound to the boron atom are not observed, while the carbon atom attached directly to the phenyl group appears at δ = 104.3 ppm. The carbonyl ligands exhibit a signal in the ^{13}C NMR spectrum at δ = 200.2 ppm.

Similarly, in their ^{11}B NMR spectra, the signals of the complexes **15a** and **16a** appear at δ = 59 and 47 ppm, respectively. The ^1H NMR spectra show multiplets in the regions δ = 7.1−7.8 ppm for **15a** and δ = 7.1−7.5 ppm for **16a**. The characteristic carbonyl ligands in the ^{13}C NMR spectra appear at δ = 199.5 ppm for **15a** and δ = 200.6 ppm for **16a**.

Complex **14a** can also act as a catalyst for the cyclotrimerization of **5a**. When a catalytic amount of **14a** and 1-(catecholboryl)-2-phenylacetylene (**5a**) were heated in toluene, the triborylbenzene derivatives **8a/8a′** were obtained in good yield (Scheme 9).



Scheme 9

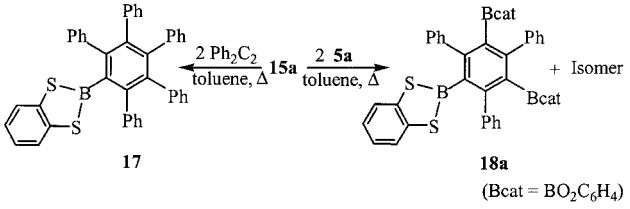
(1,3,2-Benzodithiaborolyl)pentaphenylbenzene and Bis(1,3,2-benzodioxaborolyl)(1,3,2-benzodithiaborolyl)triphenylbenzene (17 and 18)

Recently, we have shown the use of C_2Co_2 clusters for the preparation of different substituted arenes.[8] Analogously, we have heated diphenylacetylene and a stoichiometric amount of **15a** in toluene, which resulted in the formation of (1,3,2-benzodithiaborolyl)pentaphenylbenzene (**17**) in good yield (Scheme 10). Compound **17** is not soluble in common organic solvents and, therefore, NMR spectroscopic measurements were not possible. Compound **17** was characterized by mass spectrometry, which confirms the identity of **17** through the appearance of the molecular ion peak at $m/z = 608$.



Scheme 10

Similarly, compound **15a** was treated with two equivalents of 1-(catecholboryl)-2-phenylacetylene (**5a**) in toluene under reflux, which led to the formation of an isomeric mixture **18** in moderate yield. Because of the complete insolubility of compound **18**, NMR spectroscopic measurements were not possible. Compound **18** was characterized by EI mass spectrometry, which indicated the molecular ion peak of **18** at $m/z = 692$.

Conclusions

We have studied the reactions of boryl-substituted acetylenes with catalytic and stoichiometric amounts of $[CpCo(C_2H_4)_2]$, $[CpCo(CO)_2]$, and $[Co_2(CO)_8]$. [2+2+2] Cyclotrimerization products **8** are obtained from the reactions of (catecholboryl)acetylenes **5** with a catalytic amount of $[CpCo(CO)_2]$ or $[Co_2(CO)_8]$. (η^4-Cyclobutadiene)cobalt complexes are not formed from (thermal and photochemical) reactions of **5** with stoichiometric amount of $[CpCo(CO)_2]$. Treatment of nitrogen- and sulfur-bound borylacetylenes **2**, **6**, and **7** with a stoichiometric amount of $[CpCo(C_2H_4)_2]$ or $[CpCo(CO)_2]$ opened a long-sought route to the new class of boryl-substituted (η^4-cyclobutadiene)cobalt complexes. Possibly because of steric reasons, the nitrogen-substituted borylacetylene **2** does not undergo catalytic cyclotrimerization with $[CpCo(C_2H_4)_2]$ or $[CpCo(CO)_2]$. On the other hand, triborylbenzene derivatives **12** and **13** are obtained from the reactions of **6** and **7**, respectively, with a catalytic amount of $[Co_2(CO)_8]$. Surprisingly, we found that changing the heteroatom(s) bound to the boron atom causes a remarkable difference in the reactivities of **6** and **7** when compared to that of **5**. Most likely, this behavior of **6** and **7** arises from interactions of the sulfur atom(s) with the cobalt center, which might prevent the formation of coordinatively unsaturated cobaltacyclopentadiene complexes (the postulated precursor en route to cyclotrimerization products). Instead of cyclotrimerization products, (η^4-cyclobutadiene)cobalt complexes **10** and **11** are obtained. Reactions of **5a**, **6a**, and **7a** with a stoichiometric amount of $[Co_2(CO)_8]$ lead to the Co_2C_2 clusters **14a**, **15a**, and **16a**, respectively.

Experimental Section

General: All reactions were performed under nitrogen using standard Schlenk techniques. Solvents were dried with the appropriate drying agents and distilled under nitrogen. Glassware was dried with a heat gun under high vacuum. ^1H, ^{13}C, and ^{11}B NMR spectroscopy: Bruker AC 200 spectrometer; ^1H and ^{13}C spectra were referenced to $(CH_3)_4Si$ and ^{11}B spectra to $F_3B{\cdot}OEt_2$. IR spectra were recorded on a Bruker IFS 28 FT spectrometer. Mass spectra were obtained on Finnigan MAT 8230 plus spectrometers using the EI technique. Elemental analyses were carried out at the Microanalytical Laboratory, University of Heidelberg. Melting points (uncorrected) were obtained on a Büchi apparatus, using capillaries that were filled under nitrogen and sealed. Bis(diethylamino)acetylene[10] (**1**), $(i\mathrm{Pr}_2\mathrm{N})_2\mathrm{BCl}$,[29] 1-aryl-2-(trimethylstannyl)acetylenes[30] **3**, and chlorocatecholborane[31] were prepared according to literature procedures. Bromo(dithiocatechol)borane and bromo(1,3,2-benzothiaoxaborol), which have not been reported previously in the literature, were prepared by the reactions of dithiocatechol and 2-hydroxythiophenol with excess BBr_3. Catechol, 4-methylcatechol, dithiocatechol, 4-methyldithiocatechol, and 2-hydroxymercaptanol were purchased from Aldrich.

1-[Bis(dimethylamino)boryl]-2-(diethylamino)acetylene (2): Bis(diethylamino)acetylene (**1**, 1.18 g, 7.0 mmol) was added slowly at room temperature to a stirred suspension of lithium powder (0.34 g, 49.7 mmol) in diethyl ether (20 mL). The reaction mixture was heated under reflux for 3 h. After cooling, the mixture was stirred at ambient temperature for 40 h. The ether was evaporated by vacuum, THF (20 mL) was added, and the THF solution was heated for 1 h. The solid that formed was separated by filtration and washed with a small amount of THF. After drying under high vacuum, a green solid (a mixture of Et_2NC_2Li and $LiNEt_2$) was obtained. Chlorobis(dimethylamino)borane (1.26 g, 9.4 mmol) was added within 10 min at −60 °C to a solution of lithium compounds (0.85 g, 4.7 mmol) in THF (10 mL). The reaction mixture was stirred for 16 h. After filtration, the solvent was evaporated under high vacuum. Compound **2** and $Et_2B(NMe)_2$ were obtained by fractional distillation. Yield 0.39 g (43%), colorless liquid, b.p. 50 °C/0.2 Torr. ^1H NMR (200.1 MHz, $CDCl_3$): δ = 1.18 (t, $^3J_{H,H}$ = 7.2 Hz, 6 H, CH_2CH_3), 2.68 (s, 12H, NCH_3), 2.90 (q, $^3J_{H,H}$ = 7.2 Hz, 4 H, CH_2CH_3) ppm. ^{13}C NMR (50.3 MHz, $CDCl_3$): δ = 12.90 (CH_2CH_3), 40.60 (NCH_3), 48.20 (CH_2CH_3) ppm. ^{11}B NMR (64.2 MHz, $CDCl_3$): δ = 26 ppm. MS (70 eV, EI): m/z (%) = 195 (100) [M^+], 180 (31) [$M^+ - CH_3$], 123 (93) [$M^+ - NEt_2$].

1-[Bis(diisopropylamino)boryl]-2-phenylacetylene (4a) and 1-[Bis(diisopropylamino)boryl]-2-tolylacetylene (4b): Chlorobis(diisopropylamino)borane (2.59 g, 10.5 mmol) in toluene (10 mL) was added slowly at −78 °C to a stirred solution of 1-trimethylstannyl-2-arylacetylene (**3a**: 2.80 g; **3b**: 2.94 g; 10.5 mmol) in toluene (40 mL). The reaction mixture was stirred overnight to reach room temperature, the solvent was evaporated under high vacuum, and the residue was distilled.

4a: Yield 3.1 g (94%), pale-yellow liquid, b.p. 102 °C/0.01 Torr. ^{1}H NMR (200.1 MHz, $CDCl_3$): δ = 1.38 [d, $^3J_{H,H}$ = 6.9 Hz, 24 H, $CH(CH_3)_2$], 3.55 [sept., $^3J_{H,H}$ = 6.9 Hz, 4 H, $CH(CH_3)_2$], 7.4−7.5 (m, C_6H_5, 5H) ppm. ^{13}C NMR (50.3 MHz, $CDCl_3$): δ = 24.23 [$CH(CH_3)_2$], 46.71 [$CH(CH_3)_2$], 104.6 (C_{sp}−C_i), 125.1, 127.8, 128.3, 130.9 (C_6H_5) ppm; C_{sp}−B not found. ^{11}B NMR (64.2 MHz, $CDCl_3$): δ = 26 ppm. MS (70 eV, EI): *m*/*z* (%) = 312 (13) [M^+], 297 (100) [$M^+ - CH_3$], 269 (87) [$M^+ - i$Pr], 212 (31) [$M^+ - N(i\text{Pr})_2$]. MS (70 eV, HR-EI): *m*/*z* (%) = 312.2759 (8) [M^+; $^{12}C_{20}{}^1H_{33}{}^{11}B^{14}N_2$: 312.2736]; Δmmu = 2.3.

4b: Yield: 3.0 g (87%), yellow liquid, b.p. 112 °C/0.02 Torr. ^{1}H NMR (200.1 MHz, $CDCl_3$): δ = 1.35 [d, $^3J_{H,H}$ = 7.0 Hz, 24H, $CH(CH_3)_2$], 2.32 (s, CH_3, 3 H), 3.53 [sept., $^3J_{H,H}$ = 6.9 Hz, 4H, $CH(CH_3)_2$], 7.3−7.6 (m, 4H, C_6H_5) ppm. ^{13}C NMR (50.3 MHz, $CDCl_3$): δ = 21.32 (CH_3), 24.25 [$CH(CH_3)_2$], 46.81 [$CH(CH_3)_2$], 104.5 (C_{sp}−C_i), 125.3, 127.5, 128.7, 131.2 (C_6H_4) ppm; C_{sp}−B not found. ^{11}B NMR (64.2 MHz, $CDCl_3$): δ = 26 ppm. MS (70 eV, EI): *m*/*z* (%) = 326 (100) [M^+]. MS (70 eV, HR-EI): *m*/*z* (%) = 326.2899 (100) [M^+; $^{12}C_{21}{}^1H_{35}{}^{11}B^{14}N_2$: 326.2893]; Δmmu = 0.6.

Two General Procedures for 1-Aryl-2-borylacetylenes 5, 6, and 7. Procedure A: The appropriate 1-aryl-2-(trimethylstannyl)acetylene **3** was dissolved in toluene (50 mL) and then the corresponding haloborane in toluene (10 mL) was added slowly at −20 °C. The reaction mixture was stirred overnight at ambient temperature. After evaporation of the solvent under high vacuum, a crystalline solid was obtained.

Procedure B: The appropriate 1-aryl-2-[bis(diisopropylamino)-boryl]acetylene **4** was dissolved in THF (50 mL) and then 2 equiv. of HCl·Et_2O (2 M) was added slowly at −78 °C. Stirring was continued for 45 min and NH_2iPr_2Cl formed as a white solid. The corresponding aromatic diol in THF (15 mL) was then added dropwise and the reaction mixture was stirred overnight at room temperature. After filtration of the solid, the solution was reduced to near dryness, and a crystalline product was obtained.

1-(Catecholboryl)-2-phenylacetylene (5a): Starting materials: **3a** (4.8 g, 18 mmol), $H_4C_6O_2BCl$ (2.78 g, 18 mmol). Yield 2.8 g (71%), orange-red solid, m.p. 76 °C. ^{1}H NMR (200.1 MHz, $CDCl_3$): δ = 7.2−7.7 (m, 9 H, H_{aryl}) ppm. ^{13}C NMR (50.3 MHz, $CDCl_3$): δ = 105.1 (C_{sp}−C_i), 112.7, 123.3, 147.9 (catechol), 121.2, 128.6, 130.1, 132.8 (C_6H_5) ppm; C_{sp}−B not observed. ^{11}B NMR (64.2 MHz, $CDCl_3$): δ = 25 ppm. MS (70 eV, EI): *m*/*z* (%) = 220 (100) [M^+]. MS (70 eV, HR-EI): *m*/*z* (%) = 220.0715 (100) [M^+; $^{12}C_{14}{}^1H_9{}^{11}B^{16}O_2$: 220.0695]; Δmmu = 2.0.

1-(Catecholboryl)-2-tolylacetylene (5b): Starting materials: **3b** (2.4 g, 8.6 mmol), $H_4C_6O_2BCl$ (1.32 g, 8.6 mmol). Yield 1.4 g (69%), yellow solid, m.p. 72 °C (dec.). ^{1}H NMR (200.1 MHz, $CDCl_3$): δ = 2.35 (s, 3 H, CH_3), 7.0−7.5 (m, 8 H, H_{aryl}) ppm. ^{13}C NMR (50.3 MHz, $CDCl_3$): δ = 21.67 (CH_3), 103.4 (C_{sp}−C_i), 112.6, 123.1, and 147.8 (catechol), 115.5, 121.3, 129.2, 132.7 (tolyl) ppm; C_{sp}−B not observed. ^{11}B NMR (64.2 MHz, $CDCl_3$): δ = 25 ppm. MS (70 eV, EI): *m*/*z* (%) = 234 (100) [M^+]. MS (70 eV, HR-EI): *m*/*z* (%) = 234.0833 (100) [M^+; $^{12}C_{15}{}^1H_{11}{}^{11}B^{16}O_2$: 234.0852]; Δmmu = 1.9.

1-(4-Methylcatecholboryl)-2-phenylacetylene (5c): Starting materials: **3a** (4.1 g, 15.4 mmol), $CH_3C_6H_3O_2BCl$ (2.59 g, 15.4 mmol). Yield 2.4 g (66%), yellow solid, m.p. 75 °C. ^{1}H NMR (200.1 MHz, $CDCl_3$): δ = 2.39 (s, CH_3, 3 H), 6.9−7.6 (m, 8 H, H_{aryl}) ppm. ^{13}C NMR (50.3 MHz, $CDCl_3$): δ = 21.38 (CH_3), 93.37 (C_{sp}−C_i), 111.9, 113.2, 123.6, 130.0, 145.7, 147.8 (catechol), 121.2, 128.8, 132.7, 133.2 (C_6H_5) ppm; C_{sp}−B not observed. ^{11}B NMR (64.2 MHz, $CDCl_3$): δ = 24 ppm. MS (70 eV, EI): *m*/*z* (%) = 234 (100) [M^+]. MS (70 eV, HR-EI): *m*/*z* (%) = 234.0834 (100) [M^+; $^{12}C_{15}{}^1H_{11}{}^{11}B^{16}O_2$: 234.0852]; Δmmu = 1.8.

1-(4-Methylcatecholboryl)-2-tolylacetylene (5d): Starting materials: **4b** (4.44 g, 13.6 mmol), HCl·OEt_2 (13.6 mL, 27.2 mmol), 4-methylcatechol (1.68 g, 13.6 mmol). Yield 2.1 g (62%), brown solid, m.p. 73 °C (dec.). ^{1}H NMR (200.1 MHz, $CDCl_3$): δ = 2.35 (s, 3 H, CH_3), 2.37 (s, 3 H, CH_3), 6.9−7.5 (m, 7 H, H_{aryl}) ppm. ^{13}C NMR (50.3 MHz, $CDCl_3$): δ = 21.40 and 21.65 (CH_3), 83.81 (C_{sp}−C_i), 111.9, 113.1, 123.1, 138.9, 145.4, 147.5 (catechol), 119.0, 129.2, 132.0, 132.8 (tolyl) ppm; C_{sp}−B not observed. ^{11}B NMR (64.2 MHz, $CDCl_3$): δ = 23 ppm. MS (70 eV, EI): *m*/*z* (%) = 248 (100) [M^+]. MS (70 eV, HR-EI): *m*/*z* (%) = 248.1008 (100) [M^+; $^{12}C_{16}{}^1H_{13}{}^{11}B^{16}O_2$: 248.1015]; Δmmu = 0.7.

1-(Dithiocatecholboryl)-2-phenylacetylene (6a): Starting materials: **3a** (4.1 g, 15.4 mmol), $H_4C_6S_2BBr$ (3.55 g, 15.4 mmol). Yield 2.8 g (72%), brown-red solid, m.p. 82 °C. ^{1}H NMR (200.1 MHz, $CDCl_3$): δ = 7.4−7.8 (m, 9 H, H_{aryl}) ppm. ^{13}C NMR (50.3 MHz, $CDCl_3$): δ = 84.01 (C_{sp}−C_i), 125.7, 126.5, 140.9 (dithiocatechol), 128.4, 129.7, 131.1, 132.2 (C_6H_5) ppm; C_{sp}−B not observed. ^{11}B NMR (64.2 MHz, $CDCl_3$): δ = 47 ppm. CI-MS: *m*/*z* (%) = 252.1 [M^+] (70)

1-(Dithiocatecholboryl)-2-tolylacetylene (6b): Starting materials: **3b** (1.7 g, 6.09 mmol), $H_4C_6S_2BBr$ (1.4 g, 6.09 mmol). Yield 1.2 g (74%), light-yellow solid, m.p. 86 °C. ^{1}H NMR (200.1 MHz, $CDCl_3$): δ = 2.38 (s, 3 H, CH_3), 7.15−7.50 (m, 8 H, H_{aryl}) ppm. ^{13}C NMR (50.3 MHz, $CDCl_3$): δ = 21.07 (CH_3), 92.43 (C_{sp}−C_i), 122.2, 126.0, 140.9 (dithiocatechol), 126.8, 127.1, 128.4, 132.2 (tolyl) ppm; C_{sp}−B not observed. ^{11}B NMR (64.2 MHz, $CDCl_3$): δ = 48 ppm. MS (70 eV, EI): *m*/*z* (%) = 266 (100) [M^+]. MS (70 eV, HR-EI): *m*/*z* (%) = 266.0401 (100) [M^+; $^{12}C_{15}{}^1H_{11}{}^{11}B^{32}S_2$: 266.0395]; Δmmu = 0.6.

1-(4-Methyldithiocatecholboryl)-2-phenylacetylene (6c): Starting materials: **4a** (3.5 g, 11.2 mmol), HCl·OEt_2 (11.2 mL, 22.4 mmol), 4-methyldithiocatechol (1.75 g, 11.2 mmol). Yield 2.3 g (77%), yellow solid, m.p. 88 °C. ^{1}H NMR (200.1 MHz, $CDCl_3$): δ = 2.42 (s, 3 H, CH_3), 7.13, 7.41, 7.64 (m, 8 H, H_{aryl}) ppm. ^{13}C NMR (50.3 MHz, $CDCl_3$): δ = 21.07 (CH_3), 93.37 (C_{sp}−C_i), 126.1, 126.8, 127.1, 135.9, 137.6, 140.9 (dithiocatechol), 122.2, 128.4, 129.7, 132.2 (C_6H_5) ppm; C_{sp}−B not observed. ^{11}B NMR (64.2 MHz, $CDCl_3$): δ = 47 ppm. MS (70 eV, EI): *m*/*z* (%) = 266 (100) [M^+]. MS (70 eV, HR-EI): *m*/*z* (%) = 266.0399 (100) [M^+; $^{12}C_{15}{}^1H_{11}{}^{11}B^{32}S_2$: 266.0395]; Δmmu = 0.4.

1-(4-Methyldithiocatecholboryl)-2-tolylacetylene (6d): Starting materials: **3b** (3.05 g, 10.9 mmol), $CH_3C_6H_3S_2BBr$ (2.66 g, 10.9 mmol). (tricarbonylcobalta)tetrahedrane (15a), and 3-(1,3,2-Benzothiaoxaborolyl)-4-phenyl-1,2-bis(tricarbonylcobalta)tetrahedrane (16a): A solution of an alkyne (**5a:** 1.29 g; **6a:** 1.48 g; **7a:** 1.39 g; 5.9 mmol) in CH_2Cl_2 (10 mL) was added at −20 °C to a solution of $Co_2(CO)_8$ (2.03 g, 5.9 mmol) in CH_2Cl_2 (20 mL). The mixture was stirred for 48 h at room temperature and the solvent was evaporated to near dryness. The residue was separated by column chromatography (Florisil®; hexane) to give two fractions. Using hexane as the eluent, $[Co_2(CO)_8]$ was obtained first. The second fraction (hexane/toluene, 1:4) contained the corresponding dicobalt complex.

14a: Yield 1.51 g (50%), red oil. ^{1}H NMR (200.1 MHz, $CDCl_3$): δ = 7.2−7.7 (m, 9 H, H_{aryl}) ppm. ^{13}C NMR (50.3 MHz, $CDCl_3$): δ = 104.3 (C_{ipso}), 112.7, 123.2, 147.8 (catechol), 121.2, 128.5, 130.0, 132.8 (C_6H_5), 200.1 (CO) ppm; CB was not observed. ^{11}B NMR (64.2 MHz, $CDCl_3$): δ = 33 ppm. Novel Bonding Modes between Tetrathiafulvalenes (TTFs) and Transition Metal Centers: π-Bonding and Covalent $TTFSiMe_2-ML_n$ Coordination to Platinum

Mathuresh N. Jayaswal,[a] Harmel N. Peindy,[a] Fabrice Guyon,*[a] Michael Knorr,*[a] Narcis Avarvari,[b] and Marc Fourmigué[b]

Keywords: Platinum / Tetrathiafulvalene / pi interactions / Si ligands / X-ray diffraction

Two novel strategies for coordinating TTF to transition metal centers have been developed. The reaction of tetrathiafulvalene (TTF) or 3,4-dimethyltetrathiafulvalene (*o*-Me_2TTF) with [Pt(η^2-C_2H_4)(PPh_3)$_2$] leads to the π complexes [Pt(η^2-TTF)(PPh_3)$_2$] (**1**) and [Pt(η^2-*o*-Me_2TTF)(PPh_3)$_2$] (**2**), respectively. An X-ray crystallographic study performed on **2** confirmed, that TTFs act as a π acidic ligand. NMR studies revealed the existence, in solution, of an equilibrium between free and complexed TTF. Dilithiation of *o*-Me_2TTF and subsequent silylation with $ClSiMe_2H$ afforded 3,4-dimethyl-3′,4′-(dimethylsilyl)tetrathiafulvalene (**3**), which has been structurally characterized. **3** reacts by oxidative addition across [Pt(η^2-C_2H_4)(PPh_3)$_2$] to give [Pt{η^2-*o*-($SiMe_2$)$_2$-$TTFMe_2$}(PPh_3)$_2$] (**4**), in which the TTF ligand is covalently ligated to platinum via $SiMe_2$ bridges. The redox properties of **3** and **4** have been investigated by cyclic voltammetry. Strong cathodic shifts of the two redox processes were observed for **4**, implying the TTF core.

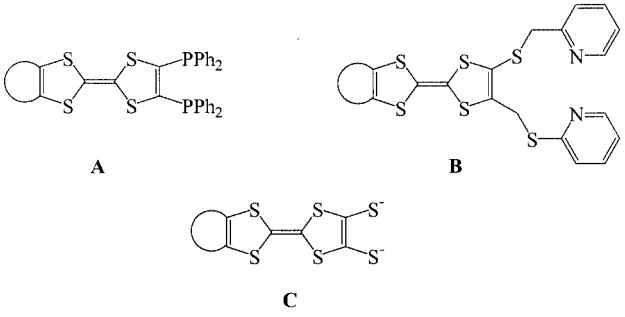
Introduction

From the research devoted to novel functionalized tetrathiafulvalenes (TTFs) has emerged, in the past few years, the synthesis of derivatives incorporating substituents allowing the coordination to transition metal fragments.[1] Such molecules are particularly interesting in molecular materials science for the elaboration of hybrid organic/inorganic multifunctional materials.[2] Two main strategies have been used for the synthesis of transition metal complexes incorporating the TTF unit: (i) the functionalization of TTFs with phosphane (**A**) or pyridine ligands (**B**) taking advantage of the donor coordinating properties of these substituents,[3] and (ii) the coordination of metal fragments to the tetrathiolate or dithiolate tetrathiafulvalene ($TTFS_4^{4-}$ and $TTFS_2^{2-}$ (**C**), respectively) via covalent metal-ligand bonds (Scheme 1).[4]



Scheme 1. Schematic drawings of TTF derivatives used as ligands

Organometallic chemistry, however, offers additional alternative routes to link a metal center to an organic substrate, such as oxidative addition and π-coordination. Starting with a $Pt^0(PPh_3)_2$ fragment, we present herein two novel synthetic approaches for the development of organometallic complexes incorporating the TTF unit. Firstly, since there are no reports of studies devoted to the synthesis of transition metal complexes incorporating a π-ligated TTF unit, it was tempting to evaluate the ability of TTF to act as a π-acidic ligand. Our second strategy is based on the functionalization of TTFs with SiR_2-H moieties followed by the oxidative addition of the Si−H bond to the low valent platinum center. In this paper we describe the synthesis and characterization of the complexes [Pt(η^2-TTF)(PPh_3)$_2$], [Pt(η^2-*o*-Me_2TTF)(PPh_3)$_2$], and [Pt{*o*-($SiMe_2$)$_2$$TTFMe_2$}-($PPh_3$)$_2$], which, to the best of our knowledge, represent the first examples of two novel bonding modes between TTF derivatives and transition metal centers i.e. π bonding and covalent bonding via an SiR_2 bridge.

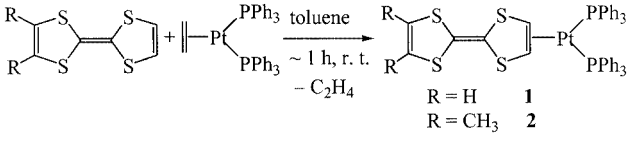
Results and Discussion

Synthesis and Characterization of $[Pt(\eta^2\text{-TTF})(PPh_3)_2]$ (1) and $[Pt(\eta^2\text{-}o\text{-}Me_2TTF)(PPh_3)_2]$ (2)

The displacement of the ethylene ligand in $[Pt(\eta^2\text{-}C_2H_4)(PPh_3)_2]$ by other olefins such as styrene, propenoates, cycloalkenes, tetracyanoethylene, allenes, and other olefinic compounds represents a convenient method of preparing Pt^0 complexes of the type $[Pt(olefin)PPh_3)_2]$, since volatile ethylene can be easily removed. The olefinic structure of TTF led us to investigate its reactivity towards the reactive starting material $[Pt(\eta^2\text{-}C_2H_4)(PPh_3)_2]$. After stirring a solution of $[Pt(\eta^2\text{-}C_2H_4)(PPh_3)_2]$ in toluene with a slight excess of TTF for 1 hour, concentration and addition of heptane afforded bright yellow $[Pt(\eta^2\text{-TTF})(PPh_3)_2]$ (**1**) (Scheme 2). The coordination of TTF via the H−C=C−H bond can be inferred unambiguously from the NMR spectra. Thus, in the proton NMR spectrum, two olefinic hydrogen atoms give rise to a broadened triplet at δ = 3.96 with a $^3J_{P,H}$ coupling of 2.5 Hz, and an additional $^3J_{Pt,H}$ coupling of 60.2 Hz. For comparison, the ethylene protons of $[Pt(\eta^2\text{-}C_2H_4)(PPh_3)_2]$ resonate at a much higher field (δ = 2.14 ppm), Furthermore, two singlets can be seen at δ = 6.35 and 6.32 ppm in an approximate ratio of 1:1. These resonances can be interpreted by the existence, in solution, of an equilibrium between free and complexed TTF. This is corroborated by the $^{31}P\{^1H\}$ NMR spectrum which displays two singlets at δ 27.8 and 16.1 in an approximate ratio of 3:1, flanked by platinum satellites ($^1J_{P,Pt}$ = 3444 and 4083 Hz, respectively). The more intense system centered at 27.8 ppm can be attributed to the $(PPh_3)_2Pt$ fragment complexed by the TTF. Note that the $^{31}P\{^1H\}$ NMR spectrum of the starting material $[Pt(\eta^2\text{-}C_2H_4)(PPh_3)_2]$ consists of a singlet at δ 35.8 with a $^1J_{P,Pt}$ coupling of 3741 Hz. The second system centered at δ = 16.1 ppm can be tentatively assigned to the platinum fragment $[Pt(PPh_3)_2]$, resulting from the decomplexation of TTF, which may be stabilized by weak interactions with the sulfur atoms. The reversible coordination/decoordination of an olefin has already been reported in the case of the complexes $[Pt(\eta^2\text{-}C_2H_4)(PCy_3)_2]$ and $[Pt(\eta^2\text{-norbornene})(PPh_3)_2]$.[5]



Scheme 2

In order to probe whether, in the case of an asymmetric TTF derivative such as 3,4-dimethyltetrathiafulvalene (*o*-Me_2TTF), coordination to platinum occurs via the double bound substituted with two hydrogens or, alternatively, via the double bond substituted by the two methyl groups, we also treated $[Pt(\eta^2\text{-}C_2H_4)(PPh_3)_2]$ with the 3,4-dimethyltetrathiafulvalene. During the reaction, pure yellow $[Pt(\eta^2\text{-}o\text{-}Me_2TTF)(PPh_3)_2]$ (**2**) precipitated (Scheme 2). The NMR spectra indicate the exclusive coordination of the substituted TTF via the H−C=C−H moiety. Thus, as observed for **1**, the proton NMR spectrum exhibits the signals for the olefinic H atoms centered at δ = 3.95 ($^3J_{P,H}$ = 2.4 Hz and $^3J_{Pt,H}$ = 61 Hz). The resonance of the Me groups appears as a singlet at δ = 2.00. The additional singlets observed at δ 6.30 and 1.96 stemming from 3,4-dimethyltetrathiafulvalene indicate, that as in the case of **1**, an equilibrium occurs in solution between free and complexed 3,4-dimethyltetrathiafulvalene (ratio 1:3.3). Cooling the solution resulted in the progressive increasing of the ratio of complexed to uncomplexed TTF. The $^{31}P\{^1H\}$ NMR spectrum is very similar to that of **1** mentioned above, and requires no special comments.

Molecular Structure of 2

Complex **2** crystallizes, with one solvent molecule (toluene), in the triclinic space group $P\bar{1}$. The molecular structure of the Pt^0 complex is characterized by a trigonal planar ligand arrangement with the alkene in the plane of the triangle (Figure 1). The Pt−P distances [2.293(2) and 2.294(2) Å] lie in the typical range observed in other [Pt(olef-

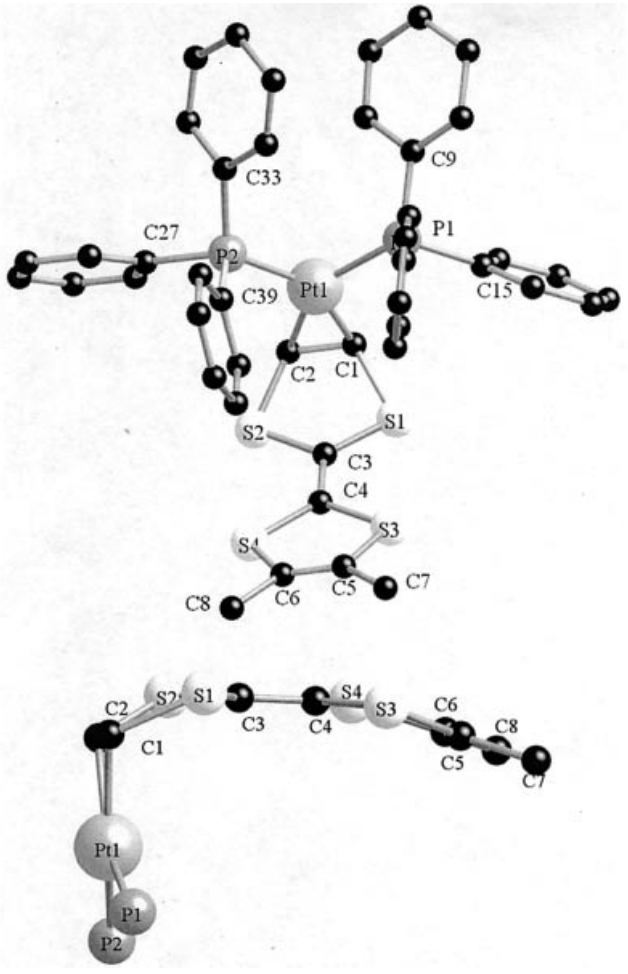


Figure 1. Top: molecular structure of **2** with labelling scheme; bottom: view of the Pt-TTFMe_2 core showing the boat conformation of the TTFs; hydrogen atoms are omitted for clarity

Table 1. Comparison of selected geometric parameters between **2** and $[Pt(PPh_3)_2(CH_2{=}CH_2)]$[7]

Complex	P−Pt−P	Pt−P	C−Pt−C	C(1)−C(2)	Pt−C
2	103.55(8)	2.293(2) 2.294(2)		1.360(11)	2.059 2.007
$Pt(PPh_3)_2(CH_2{=}CH_2)$	111.6(1)	2.265(2) 2.270(2)	39.7(4)	1.43(1)	2.11(1) 2.12(1)

in)$(PPh_3)_2$] complexes.[6] The P−Pt−P angle [103.55(8)°] is more acute than in the ethylene complex (Table 1). The Pt−C bonds are significantly shorter in **2** in comparison with the starting material $[Pt(CH_2{=}CH_2)(PPh_3)_2]$. The TTF part is strongly folded along the S···S axis of each fulvalene, with values of 31.02(54)° for S(1)···S(2) and 16.52(21)° for S(3)···S(4), while the central core [S(1−4), C(3) and C(4)] is nearly planar (Figure 1, bottom). Thus, the boat conformation is much more pronounced in **2** compared with the geometry of the free *o*-Me_2TTF, for which angles of 0.6° and 1.88° have been reported.[8] These deformations have already been observed with several metal-coordinated TTF derivatives (see for example ref.[3c]) but not with such magnitude. The increasing of the out-of-plane bend leads to significant changes for the other structural parameters. Table 2 provides a comparison of selected bond lengths and angles between **2**, and uncoordinated *o*-Me_2TTF. As can be seen, the external C−S bonds become longer upon coordination. This may be due to a reduction of conjugation within the fulvalene rings, which also leads to a shortening of the C(5)−C(6) bond length [1.305(11) vs. 1.338(4) Å]. Conversely, due to the interaction with the platinum, there is a significant lengthening of the C(1)−C(2) bond as observed in almost all cases of coordinated olefins.[9] In contrast to the symmetrical structure of *o*-Me_2TTF, C(1) and C(2) are not equivalent in **2**: (i) the Pt−C bond lengths are quite different (Table 1), and (ii) the value observed for the S(1)−C(1)−C(2) angle [112.3(6)°] suggests that the C(1) atom approaches a tetrahedral hybridization, whereas the C(1)−C(2)−S(2) angle remains nearly unchanged upon complexation, indicating an sp^2 hybridization for C(2) [119.9(6)°].

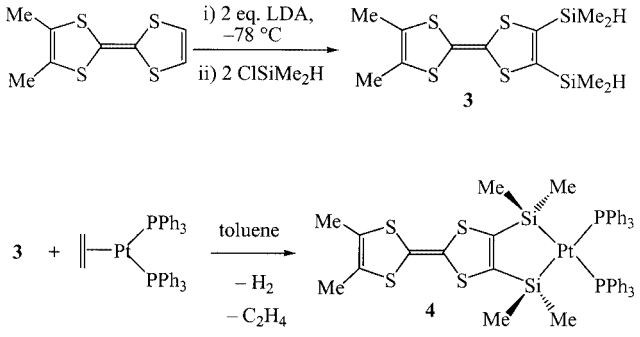
Synthesis and Characterization of a Bis(silylated) Platinum-TTF Complex

One common strategy for the synthesis of substituted TTFs takes advantage of the acidity of the TTF hydrogen atoms.[10] Indeed, treatment with *n* equivalents of strong bases such as LDA at low temperature affords TTF−Li_n, which can be treated with a variety of electrophiles. Using this procedure, 3,4-dimethyltetrathiafulvalene was dilithiated with 2 equivalents of LDA, then silylated with chlorodimethylsilane to give 3,4-dimethyl-3′,4′-(dimethylsilyl)-tetrathiafulvalene (**3**) (Scheme 3).



Scheme 3

Compound **3** was isolated in 72% yield as orange air-stable solid, soluble in aliphatic hydrocarbons. Recrystallization from a concentrated hexane solution afforded single-crystals suitable for an X-ray diffraction study. The geometry of **3** is shown in Figure 2, structural parameters are given in Table 2. The framework of 3,4-dimethyltetrathiafulvalene is only slightly influenced by the substitution with the dimethylsilyl functions. The geometry around the Si atoms is essentially tetrahedral, with C−Si−C angle values varying between 108.49(17) and 111.5(2)°. The C(1)−Si(1) and C(2)−Si(2) bond lengths [1.886(2) and 1.873(3) Å] are quite similar to that in $(TTF)_2SiMe_2$ [1.868(5) Å].[11]

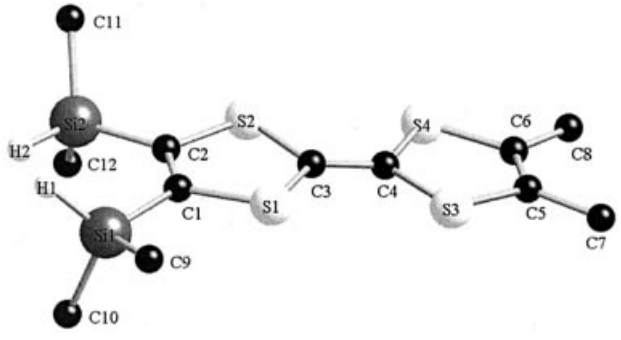


Figure 2. Molecular structure of **3**

By taking advantage of the reactivity of the Si−H bond towards low valent transition metal centers, compound **3** seemed to be a promising precursor to covalently link a platinum fragment to the TTF unit.[12] Thus, **3** reacts by oxidative addition with one equivalent of [Pt(η^2-C_2H_4)$(PPh_3)_2$] in toluene to afford the platinum bis(silyl) complex [Pt{*o*-$(Me_2Si)_2TTFMe_2$}$(PPh_3)_2$] (**4**) (Scheme 3). The chelating coordination of the two $SiMe_2$ groups on each Pt center was confirmed by the ^1H NMR spectrum [singlet, δ = −0.13 ppm, ^3J(Pt−H) = 22.1 Hz], and the $^{31}P\{^1H\}$ NMR spectrum [δ = 30.0 ppm, ^1J(Pt−P) = 1716 Hz].

Cyclic voltammetric data for *o*-Me_2TTF, **3**, and **4** are given in Table 3. In each case, two reversible or quasi reversible single-electron oxidation waves were observed corresponding to the oxidation of the TTF core (Figure 3). Substitution of the olefinic hydrogens in *o*-Me_2TTF by the Si-Me_2H group induces a slight cathodic shift for the first oxidation wave due to the inductive effect of the methyl group, whereas $E_2^{1/2}$ remains unchanged. More interesting is the fact that the bis(silyl) complex **4** shows a strong cathodic shift (nearly 0.2 V) for the two redox processes. This observation is contrary to the tendency reported in the case of TTFs functionalized with phosphane or pyridine. The latter always display shifts towards more anodic potentials upon coordination.[3e,3j] This implies a strong interaction between the TTF core and the metallic fragment. Note also that the second oxidation wave in **4** appears not totally reversible at standard scan rates (50−250 mV·s^{-1}), since an additional reduction peak was observed at $E_{pc} \approx 0$ V. This peak disappeared when the scan rate was faster (= 1 V·s^{-1}) or when the potential was reversed just before the second oxidation wave (Figure 3). Nevertheless the potential, and the reversibility of the first electron transfer offer the possibility of synthesizing open shell species from this organometallic complex.

Table 3. Voltammetric data (*E* in V vs. Ag/0.1 M $AgClO_4$)

Compound	$E_1^{1/2}$	$E_2^{1/2}$

Conclusion

In summary, the bonding modes between tetrathiafulvalenes and transition metal centers described in this paper highlight the possible development of novel classes of TTF derivatives using strategies from organometallic chemistry. For example, insertion of unsaturated organic substrates such as alkynes into the platinum-silicon bond may be an original tool for introducing functionalization to the TTF core.[13] On the other hand, the reactivity of the Si−H bond is not restricted to platinum, and generalization to other metal centers may provide a family of transition metal−silicon complexes in which the redox properties of the TTF may be fine-tuned by the metallic fragment. Both approaches, as well as potential applications in materials science, are currently being pursued in our laboratories.

Experimental Section

General Comments: All reactions were performed under dry nitrogen using standard Schlenk techniques. Solvents were dried by standard methods, freshly distilled, and saturated with nitrogen prior to use. TTF,[14] *o*-Me_2TTF,[15] and [Pt(PPh_3)$_2$(C_2H_4)][16] were prepared according to published procedures. The ^{1}H, ^{31}P{^{1}H}, and ^{195}Pt NMR spectra were recorded at 300.13, 81.01, and 42.95 MHz, respectively, on a Bruker Avance 300 instrument. ^{195}Pt chemical shifts were externally referenced to aqueous K_2PtCl_4 with downfield chemical shifts reported as positive. Elemental analyses were performed at the Université de Bourgogne with an EA 1108 Fisons instrument.

Electrochemical Measurements: Voltammetric analyses were carried out, at ambient temperature, in a standard three-electrode cell with a Radiometer PGP 201 potentiostat. The electrolyte consisted of a 0.2 M *n*Bu_4NPF_6 solution in CH_2Cl_2. The working electrode was a platinum disk electrode, and the auxiliary electrode was a platinum wire. The reference electrode was a silver/silver ion electrode, Ag/Ag^+ (0.1 M $AgClO_4$ in acetonitrile) separated from the solution by a sintered glass disk. After each measurement the reference was checked against the ferrocene-ferrocenium couple (+ 0.16V relative to this reference electrode).

Synthesis of [Pt(η^2-TTF)(PPh_3)$_2$] (1): To a solution of [Pt(η^2-C_2H_4)(PPh_3)$_2$] (375 mg, 0.5 mmol) in toluene (8 mL) was added TTF (110 mg, 0.54 mmol). The solution was stirred at room temperature for 1 h. Hexane was then added and the resultant solution cooled to 4 °C. The solid, which formed, was collected by filtration, washed with hexane and dried to provide **1** as an orange solid. (393 mg, 85% yield).^{1}H NMR ($CDCl_3$): δ = 3.96 (t br., 2 H, H-TTF, $^3J_{H,P}$ = 2.5, $^2J_{H,Pt}$ = 60.2 Hz), 6.32 (s, 2 H, H-TTF) 7.14−7.24 (m, 30 H, Ph). ^{31}P{^{1}H} NMR: δ = 27.85 (s, $^1J_{Pt,P}$ = 3444 Hz) ppm. $C_{42}H_{34}P_2PtS_4$ (924.00): calcd. C 54.60, H 3.71; found C 55.01, H, 3.60.

Synthesis of [Pt(η^2-*o*-Me_2TTF)(PPh_3)$_2$] (2): To a solution of [Pt(η^2-C_2H_4)(PPh_3)$_2$] (337 mg, 0.45 mmol) in toluene (8 mL) was added *o*-Me_2TTF (116 mg, 0.5 mmol). The solution was stirred at room temperature for 0.5 h. The orange complex precipitated gradually from solution. After cooling at 4 °C the supernatant liquid was decanted, and the residue washed with hexane. (381 mg, 89% yield).^{1}H NMR ($CDCl_3$): δ = 2. 00 (s, 6 H, CH_3), 3.95 (t br., 2 H, H-TTF, $^3J_{H,P}$ = 2.4, $^2J_{H,Pt}$ = 61.0 Hz), 7.16−7.24 (m, 30 H, Ph) ppm. ^{31}P{^{1}H} NMR: δ = 27.8 (s, $^1J_{Pt,P}$ = 3450 Hz) ppm. ^{195}Pt{^{1}H} NMR: δ = −3206 (t, $^1J_{Pt,P}$ = 3450 Hz) ppm. $C_{44}H_{38}P_2PtS_4$ (952.05): calcd. C 55.51, H 4.02; found C 55.86, H, 4.17.

Synthesis of 3,4-Dimethyl-3′,4′-(dimethylsilyl)tetrathiafulvalene (3): A solution of *o*-Me_2TTF (0.23 g, 1 mmol) in THF (20 mL) was treated at −78 °C with LDA (2.5 mmol). The yellow precipitate was stirred at −78 °C for 4 h, and then treated with chlorodimethylsilane (2.6 mmol). The reaction temperature was allowed to rise slowly overnight to room temperature. The solvent was then removed under reduced pressure, and the residue was extracted with diethyl ether. After evaporation of the diethyl ether, the resultant solid was recrystallized from hexane to give **3** as orange crystals (250 mg, 72% yield). ^{1}H NMR ($CDCl_3$): δ = 0.34 (d, 12 H, $SiMe_2$, $^3J_{H,H}$ = 3.8 Hz), 1.94 (s, 6 H, Me-TTF), 4.49 (h, 2 H, Si−H) ppm. IR (KBr): $\tilde{\nu}$ = 2163 (Si−H) cm^{-1}. $C_{12}H_{20}S_4Si_2$ (348.70): calcd. C 41.33, H 5.78; found C 41.45, H 5.75.

Synthesis of [Pt{*o*-(Me_2Si)$_2$TTFMe_2}(PPh_3)$_2$] (4): To a solution of 3,4-dimethyl-3′,4′-(dimethylsilyl)tetrathiafulvalene (**3**) (105 mg, 0.3 mmol) in toluene (7 mL) was added [Pt(η^2-C_2H_4)(PPh_3)$_2$] (210 mg, 0.28 mmol) in toluene (7 mL). The resultant orange solution was stirred at room temperature for 2 h. The yellow complex precipitated gradually from solution. The supernatant liquid was decanted and the residue was washed with hexane (224 mg, 75% yield). ^{1}H NMR ($CDCl_3$): δ = −0.13 (s, 12 H, $SiMe_2$, $^2J_{Pt,H}$ = 22.1 Hz), 1.91 (s, 6 H, Me-TTF), 7.16−7.30 (m, 30 H, Ph) ppm. ^{31}P{^{1}H} NMR: δ = 30.0 (s, $^1J_{Pt,P}$ = 1716 Hz) ppm. $C_{48}H_{48}P_2PtS_4Si_2$ (1066.35) calcd. C 54.07, H 4.54; found C 54.40, H 4.65.

Crystallographic Data Collection and Structure Determinations of 2 and 3: Suitable crystals of **2** and **3** for X-ray diffraction were obtained by crystallization from toluene and hexane, respectively. A single-crystal of each compound was mounted in a glass capillary using Araldite glue. Data were collected with a Stoe-IPDS diffractometer, with graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å). Details are given in Table 4. A numerical absorption correction was applied (FACEIT, Stoe). The structures were solved by direct methods, and refined by full-matrix least-squares on F^2 with anisotropic thermal parameters for all non-H atoms. H atoms were included in calculated positions, and constrained to ride on the parent C atoms. All calculations were performed with the SHELTX package.[17] CCDC-226740 for [$Pt(PPh_3)_2$(*o*-Me_2TTF)] and -226741 for [*o*-Me_2TTF($SiMe_2H)_2$] contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Center, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) +44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Synthesis and Characterization of Potassium Complexes Containing Terminal η^2-Pyrazolato Ligands

Wenjun Zheng,[a] Mary Jane Heeg,[a] and Charles H. Winter*[a]

Keywords: Hydrogen bonds / N ligands / Potassium / Pyrazolato ligands

The potassium complexes [K(η^2-3,5-R_2pz)(η^6-18-crown-6)] (R = Ph, *t*Bu; pz = pyrazolato) were prepared by treatment of 3,5-diphenylpyrazole or 3,5-di-*tert*-butylpyrazole with potassium hydride in the presence of 18-crown-6. These complexes contain η^6-18-crown-6 and terminal η^2-pyrazolato ligands, and constitute the first examples of group 1 metal complexes with this pyrazolato ligand coordination mode. In contrast to [K(η^2-3,5-Ph_2pz)(η^6-18-crown-6)] and [K(η^2-3,5-*t*Bu_2pz)(η^6-18-crown-6)], the aqua complex [K(η^2-3,5-Me_2pz)(H_2O)(η^6-18-crown-6)] was obtained when 3,5-dimethylpyrazole was treated with potassium hydride and 18-crown-6 in the presence of a small amount of water. [K(η^2-3,5-Me_2pz)(H_2O)(η^6-18-crown-6)] contains an η^2-pyrazolato ligand that is bent towards being co-facial with the best plane of the 18-crown-6 ligand, to allow hydrogen bonding between the pyrazolato ligand nitrogen atoms and the coordinated aqua ligand. The hydrogen bonding thus confers a novel terminal π-facial η^2-bonding mode to the pyrazolato ligand. All compounds were characterized by elemental analysis, NMR spectroscopy, and mass spectrometry.

Introduction

The coordination chemistry of metal complexes with pyrazolato (pz) ligands is currently a topic of considerable interest.[1−6] While many bridging coordination modes have been documented, pyrazolato ligands bonded to single metal centers (terminal coordination) are less common and are restricted to η^1,[1] η^2,[1e,2−4] and η^5.[5] The terminal η^1- and η^2-coordination modes reported to date involve donation of the in-plane nitrogen atom lone pairs to the metal centers, whereas only the rare η^5-bonding mode entails bonding with the out-of-plane π-orbitals of the aromatic pyrazolato ring.[5] Although many main group element pyrazolato complexes have been structurally characterized,[1,2,6] group 1 complexes are limited to a few examples with bridging pyrazolato ligands[7,8] and a small number containing tris(pyrazolyl)borate and related ligands.[9] Structurally characterized potassium pyrazolato complexes are restricted to [(μ-η^2:η^1:η^1-3,5-Ph_2pz)K(THF)]$_6$,[8a] an erbium complex [K{Er(η^2-3,5-*t*Bu_2pz)$_4$}$_n$] with the potassium ion trapped in a bridged η^3-coordination mode,[8b] and a complex in which potassium is bonded to a structurally complex manganese-containing pyrazolato ligand through an η^5-interaction.[5b] No examples of terminal η^2-pyrazolato ligand coordination to a group 1 metal have been reported, most likely due to the propensity of these ligands to bridge between the large group 1 metal ions.

We have recently reported examples of the slipped η^2-coordination mode of triazolato and tetrazolato ligands to the [K(18-crown-6)]$^+$ fragment.[10] In these complexes, there was significant asymmetry in the potassium−nitrogen bond lengths (Δ_{K-N} = 0.35−0.60 Å), and there were no obvious steric interactions that would cause such slipped pyrazolato ligand coordination modes. These results prompted us to investigate the coordination chemistry of analogous potassium pyrazolato complexes. Herein we report the synthesis, structure, and properties of several pyrazolato complexes of the [K(η^6-18-crown-6)]$^+$ fragment. The new complexes contain terminal η^2-pyrazolato ligands, and represent the first structurally characterized group 1 pyrazolato complexes with this coordination mode.

Results and Discussion

The synthetic chemistry is shown in Scheme 1. Treatment of equimolar quantities of potassium hydride, 3,5-diphenylpyrazole or 3,5-di-*tert*-butylpyrazole, and 18-crown-6 in tetrahydrofuran afforded colorless solids after filtration and removal of the solvent. However, the crude products could not be purified by recrystallization in common organic solvents or by other methods. Infrared spectra of the crude products show strong, broad stretches centered at approximately 3400 cm^{-1}, which suggest the presence of water in the products. Since commercial 18-crown-6 could form a hydrate, the solutions were further treated with excess potassium metal in refluxing tetrahydrofuran to eliminate any water that might be associated with the 18-crown-6. Follow-

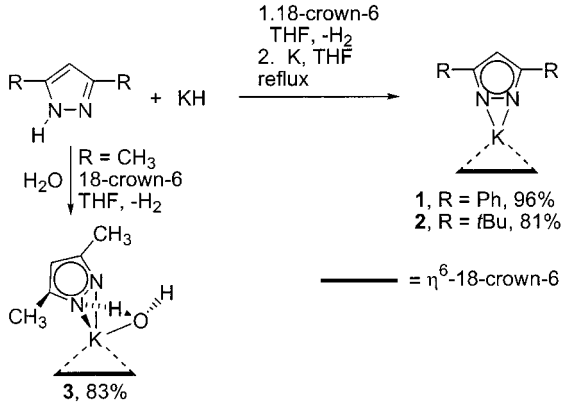
ing this treatment, the products were purified in several different ways. Filtration of the hot reaction solution and then allowing this solution to cool slowly to room temperature led to the direct crystallization of [K(η^2-3,5-Ph_2pz)(η^6-18-crown-6)] (**1**, 96%). The infrared spectrum of **1** does not show any absorption band near 3400 cm^{-1}, suggesting a water-free formulation. The complex [K(η^2-3,5-*t*Bu_2pz)(η^6-18-crown-6)] (**2**) did not crystallize from tetrahydrofuran on cooling after filtration. Removal of the tetrahydrofuran under reduced pressure afforded crude **2** as a colorless solid. Recrystallization from toluene at −20 °C afforded analytically pure **2** in a 81% yield as colorless crystals. There are no absorption bands at around 3400 cm^{-1} in the infrared spectrum of **2**. Due to the presence of the lipophilic *tert*-butyl groups, **2** is soluble in common organic solvents. By contrast, **1** is only soluble in polar solvents such as methanol and hot tetrahydrofuran. Attempts were made to prepare a 3,5-dimethylpyrazolato complex that was analogous to **1** and **2**. Treatment of equimolar quantities of potassium hydride, 3,5-dimethylpyrazole, and 18-crown-6 in tetrahydrofuran, followed by hot filtration of the reaction solution, led to colorless single crystals of [K(η^2-3,5-Me_2pz)(H_2O)(η^6-18-crown-6)] (**3**, 83%) on cooling of the tetrahydrofuran solution, without the need for further treatment with potassium metal. A crystal structure as described below reveals the presence of coordinated water. All attempts to prepare the water-free 3,5-dimethylpyrazolato analogue of **3** have thus far failed, and only **3** has been isolated. Apparently, **3** is highly crystalline and precipitates as soon as it forms. Further treatment of **3** with excess potassium metal as for **1** and **2** afforded a product that was only slightly soluble in tetrahydrofuran. This product gave complex ^1H NMR spectra and was not pursued further. Complexes **1**−**3** are thermally stable at room temperature and are unaffected by exposure to relatively dry ambient air for a few minutes. However, the complexes are hygroscopic and lose crystallinity upon extended exposure to ambient atmosphere. For this reason, **1**−**3** were handled under dry argon in this study.



Scheme 1

^1H and $^{13}C\{^1H\}$ NMR spectra, infrared spectra, and element analysis data are consistent with the formulations of **1**−**3**. In addition, the X-ray crystal structures of **1** and **3** were determined and are described below. The ^1H NMR spectra of **1**−**3** show resonance signals for the pyrazolato ligand, as well as resonances at about δ = 3.6 ppm for the protons of the 18-crown-6 ligand. A broad resonance at δ = 5.4 ppm in the ^1H NMR spectrum of **3** in [D_4]methanol is assigned to the protons of the aqua ligand. It is not clear if the water molecule is still coordinated to the potassium ion in **3**, or if it has been displaced by the methanol solvent. The infrared spectrum of **3** displays a broad absorption at 3400 cm^{-1}, which is assigned to the stretches associated with the aqua ligand. This band did not disappear completely even after **3** was heated at 100 °C for 15 h, suggesting strong bonding between the potassium ion and oxygen atom of the aqua ligand. The mass spectra of **1**−**3** show a parent ion at *m*/*z* = 303, which is consistent with the [K(18-crown-6)]$^+$ moiety.

Complexes **1** and **3** were structurally characterized by X-ray crystallography, the crystal data are given in Table 1. Perspective views of **1** and **3** are shown in Figure 1 and Figure 2, respectively, and an extended diagram that emphasizes the hydrogen bonding of **3** is given in Figure 3. We were unable to solve the X-ray crystal structure of **2** due to disorder in the crystals, but its solid-state structure is presumably very similar to that of **1**.

Complex **1** contains the η^2-3,5-diphenylpyrazolato and η^6-18-crown-6 ligands, and there are no significant intermolecular contacts (Figure 1). The potassium−nitrogen bond lengths [2.722(3), 2.766(4) Å] are similar and are consistent with idealized η^2-bonding. These bond lengths are within the range of those found in [(μ-η^2:η^1:η^1-3,5-Ph_2pz)K(THF)]$_6$ (K−N 2.716−2.869 Å).[8a] The potassium−oxygen bond lengths range between 2.78−2.95 Å, and are similar to other structurally characterized complexes containing [K(η^6-18-crown-6)]$^+$ fragments.[11] The angle formed between the plane of the pyrazolato C_3N_2 core and the best plane of the six oxygen atoms of the 18-crown-6 ligand is 85.01(10)°. Such an arrangement is consistent with donation of the in-plane lone pairs of the nitrogen atoms to the potassium ion, and is very similar to the η^2-coordination mode that has been documented in many main group element complexes.[1e,2] The potassium ion is located 0.710(2) Å above the best plane of the 18-crown-6 ligand oxygen atoms, towards the side with the pyrazolato ligand. This arrangement certainly facilitates bonding to the pyrazolato ligand. Selected bond lengths and angles for **1** are presented in Table 2.

Complex **3** contains the η^2-3,5-dimethylpyrazolato, η^6-18-crown-6 and aqua ligands. The aqua ligand hydrogen atoms are engaged in both intramolecular and intermolecular hydrogen bonding with the pyrazolato ligand. A view of the molecular structure is shown in Figure 2 and a view emphasizing the hydrogen bonding is contained in Figure 3. The potassium−nitrogen bond lengths are 2.955(3) and 3.138(3) Å. These bond lengths are longer than those in **1** due to the higher coordination number at the potassium ion (9 versus 8). In fact, the potassium−nitrogen bond lengths in **3** are even longer than would be expected when the coordination number increases by one, and support the idea that

3 contains a new pyrazolato coordination mode. The longer potassium−nitrogen bond lengths in **3** may also arise as a result of the less basic pyrazolato ligand π-orbitals donating to the potassium ion (i.e. less optimum ionic bonding). The potassium−oxygen bond lengths are 2.848(3) Å for the aqua ligand and 2.84−3.07 Å for the 18-crown-6 ligand. These values are similar to or slightly longer than the related values found in **1** and other [K(η^6-18-crown-6)]$^+$ fragments.[11] The angle formed between the plane of the pyrazolato C_3N_2 core and the best plane of the 18-crown-6 ligand oxygen atoms is 24.40(14)°, which indicates that the planes of the 18-crown-6 ligand oxygen atoms and the pyrazolato ligand are almost coplanar. This situation is very different from that of **1**, where the pyrazolato ligand core plane is nearly perpendicular to the best plane of the 18-crown-6 ligand oxygen atoms. The distance of the nitrogen atoms from the best plane of the 18-crown-6 ligand oxygen atoms is 3.409(3) Å for N(1) and 3.711(3) Å for N(2), indicating that the pyrazolato ligand core plane is twisted slightly relative to that of the 18-crown-6 ligand. The potassium ion is located 0.976(1) Å above the best plane of the 18-crown-6

ligand oxygen atoms. This value is larger than that of **1**, and reflects the larger coordination number in **3** and the differing coordination modes in the two complexes. Selected bond lengths and angles for **3** are given in Table 3.

Inspection of the hydrogen bonding in **3** reveals that one hydrogen atom of the aqua ligand is intramolecularly hydrogen bonded to N(2) of the pyrazolato ligand, with a nitrogen−hydrogen distance of 2.00(5) Å, a N(2)−O(7) distance of 2.813(7) Å, and a N···H−O angle of 154(3)°. The other hydrogen atom of the aqua ligand is intermolecularly hydrogen bonded to N(1) of an adjacent molecule, with a nitrogen−hydrogen distance of 2.01(5) Å, a N(1′)−O(7) distance of 2.883(7) Å, and N···H−O angle of 164(3)°. The intermolecular hydrogen bonding thus leads to dimeric species within the crystal that are connected by 10-membered $H_4N_4O_2$ rings.

The bending of the pyrazolato ligand in **3** towards the plane of the 18-crown-6 ligand and its slight twisting relative to this plane could have several origins. Accommodation of the aqua ligand in **3** requires that the pyrazolato ligand moves on the face of the coordination sphere to facilitate formation of the new potassium−oxygen bond. Such motion would necessarily lead to a reduction of the angle between the planes of the 18-crown-6 and pyrazolato ligands. However, there is a further bending of the pyrazolato ligand toward the 18-crown-6 ligand, as is seen by the 140.7(3)° angle between the KN_2 and C_3N_2 planes. With the observed distortions, the in-plane (and more basic) nitrogen atom lone pairs point more directly toward the aqua ligand hydrogen atoms, which presumably optimizes intramolecular and intermolecular hydrogen bonding. The stronger intramolecular hydrogen bonding to N(2) could infer some less basic character on this atom, which is a possible origin for the longer K−N(2) bond length and the slight twisting of the C_3N_2 plane relative to that of the 18-crown-6 ligand oxygen atoms. The disposition of the pyrazolato ligand in **3** requires that there is at least some donation of electron density to the potassium ion from the out-of-plane π-orbitals on the nitrogen atoms of the pyrazolato ligand. Idealized π-η^2-pyrazolato ligand coordination to a single metal center would have an angle of about 90° between the MN_2 and C_3N_2 planes. Such a coordination mode has not been reported, although this coordination mode has been documented in an ytterbium complex containing a phosphorus−antimony analog of a pyrazolato ligand.[4c] This ytterbium complex has no hydrogen bonding. However, the pyrazolato ligand in **3** represents a distortion that is significantly towards an idealized π-η^2-pyrazolato ligand, and this bonding arrangement is clearly driven by the hydrogen-bond formation with the aqua ligand. The predominately ionic bonding expected for a group 1 salt probably allows for low energy distortions of the ligands about the coordination sphere. The potassium−nitrogen bonding mode in **3** resembles that observed in lanthanide complexes containing μ-η^2:η^2 pyrazolato ligands,[12] since the latter coordination mode also demands donation of some electron density from the out-of-plane π-orbitals on the nitrogen atoms of the pyrazolato ligand.

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

This work documents the first examples of monomeric terminal η^2-pyrazolato ligand coordination to a group 1 metal. The 18-crown-6 ligand saturates the coordination sphere in **1** in such a way that the 3,5-diphenylpyrazolato ligand can just be accommodated by **1**. Optimal ionic bonding then leads to the observed η^2-pyrazolato ligand. In our recent report,[10] the triazolato and tetrazolato complexes [K(*i*Pr$_2$C$_2$N$_3$)(18-crown-6)] and [K(PhCN$_4$)(18-crown-6)] have asymmetric potassium−nitrogen distances (Δ_{K-N} = 0.35−0.60 Å) and there was no evidence for steric interactions that would promote such asymmetric bonding of the heterocyclic ligands. By contrast, **1** contains an essentially idealized η^2-pyrazolato ligand (Δ_{K-N} = 0.044 Å). The nitrogen atom lone pairs in the pyrazolato ligands are definitely more basic than those of the 1,2,4-triazolato and tetrazolato ligands,[13] and the better donor characteristics of the pyrazolato ligands may then facilitate the η^2-coordination mode relative to the more nitrogen-rich heterocyclic ligands. The first examples of terminal η^2-1,2,4-triazolato and tetrazolato ligand coordination have been reported in the past several years.[2d,10,14]

Use of the less sterically demanding 3,5-dimethylpyrazolato ligand leads to the aqua complex **3**, which contains a novel η^2-pyrazolato ligand coordination mode. There is an analogy between **3** and the metal complexes containing slipped cyclopentadienyl ligands.[15−17] In two crystallographically characterized complexes containing terminal η^2-cyclopentadienyl ligands, [Mg(η^5-Cp)(η^2-Cp)(NH$_2$[CH(CH(CH$_3$)$_2$]$_2$)][16a] and [Mg(η^5-Cp)(η^2-Cp)(NH$_2$C(CH$_3$)$_3$](THF)],[16b] the η^2-cyclopentadienyl ligands are stabilized through intramolecular and intermolecular N−H···C hydrogen bonding.[16a] This is similar to the stabilization of the pyrazolato ligand in **3**. The complexes Mg(*t*Bu$_2$pz)$_2$(*t*BupzH)$_2$ [14] and Nd(Me$_2$pz)$_3$(Me$_2$pzH)$_2$(py)[18] contain intramolecular N−H···N hydrogen bonding that appears to enforce η^1-bonding of the pyrazolato ligands.

Experimental Section

General: All reactions were performed under dry argon using standard Schlenk and dry box techniques. Solvents were distilled from various drying agents under argon prior to use. 3,5-Diphenylpyrazole, 3,5-dimethylpyrazole, and 18-crown-6 were purchased from commercial sources. 3,5-Di-*tert*-butylpyrazole was prepared according to literature methods.[19]

^{1}H and ^{13}C{^{1}H} NMR spectra were obtained in dry, degassed [D$_4$]methanol and [D$_8$]tetrahydrofuran, and were referenced to the residual proton or carbon atom resonances of these solvents. Infrared spectra were obtained using Nujol as the medium. Elemental analyses were performed by Midwest Microlab, Indianapolis, IN. Melting points were obtained on a Haake−Buchler HBI digital melting point apparatus and are uncorrected.

[K(η^2-3,5-Ph$_2$pz)(η^6-18-crown-6)] (1): A mixture of 3,5-diphenylpyrazole (2.20 g, 10.0 mmol), potassium hydride (0.42 g, 10.5 mmol), and 18-crown-6 (2.77 g, 10.5 mmol) in tetrahydrofuran (100 mL) was stirred at room temperature for 15 h, after which time hydrogen evolution was complete. This solution was further treated with excess potassium (0.50 g, 13 mmol), and the suspension was refluxed for 0.5 h. The hot solution was filtered through a 2-cm pad of Celite and **1** formed as colorless single crystals as the solution cooled (5.02 g, 96%). M.p.: 173 °C. ^{1}H NMR (CD$_3$OD, 23 °C): δ = 7.35, 7.81 (mult, 10 H, Ph-*H*), 6.94 (s, 1 H, C*H*), 3.53 (s, 24 H, O−CH_2). ^{13}C NMR (CD$_3$OD, 23 °C): δ = 150.73 (s, *C*−Ph), 133.87, 129.77, 128.59, 126.58, (4s, *C*, Phenyl ring), 100.44 (s, *C*H), 71.25 (s, O−*C*H$_2$). MS (EI): *m*/*z*: 303 ([K(18-crown-6)]$^+$, 100%). C$_{27}$H$_{35}$KN$_2$O$_6$ (522.7): calcd. C 62.04, H 6.75, N 5.36; found C 62.18, H 6.82, N, 5.40.

[K(η^2-3,5-*t*Bu$_2$pz)(η^6-18-crown-6)] (2): In a fashion similar to the preparation of **1**, treatment of 3,5-di-*tert*-butylpyrazole (1.80 g, 10.0 mmol) with potassium hydride (0.42 g, 10.5 mmol), 18-crown-6 (2.77 g, 10.5 mmol), and potassium (0.5 g, 13 mmol) in tetrahydrofuran afforded crude **2** as a tetrahydrofuran solution. After removal of the tetrahydrofuran under reduced pressure, the crude material was dissolved in toluene and cooled to −20 °C to afford **2** as colorless crystals (3.92 g, 81%). M.p.: 158 °C. ^{1}H NMR (C$_4$D$_8$O, 23 °C): δ = 5.53 (s, 1 H, C−*H*), 3.62 (s, 24 H, CH_2), 1.25 (s, 18 H, CH_3). ^{13}C NMR (C$_4$D$_8$O, 23 °C): δ = 157.78 (s, *C*−*t*Bu), 92.38 (s, *C*H), 71.02 (s, O−*C*H$_2$), 32.66 (s, *C*−CH$_3$), 25.71 (s, *C*H$_3$). MS (EI): *m*/*z*: 303 ([K(18-crown-6)]$^+$, 100%). C$_{23}$H$_{43}$KN$_2$O$_6$ (482.7): calcd. C 57.23, H 8.98, N 5.80; found C 57.35, H 8.86, N 5.72.

[K(η^2-3,5-Me$_2$pz)(H$_2$O)(η^6-18-crown-6)] (3): Treatment of 3,5-dimethylpyrazole (0.96 g, 10 mmol) with potassium hydride (0.42 g, 10.5 mmol) and 18-crown-6 (2.77 g, 10.5 mmol) in tetrahydrofuran (100 mL) at room temperature for 2 h, followed by reduction in volume to 50 mL under reduced pressure, and after standing for 48 h, afforded **3** as colorless crystals (3.45 g, 83%). M.p.: 145 °C. ^{1}H NMR (CD$_3$OD, 23 °C): δ = 5.80 (s, 1 H, C*H*), 5.4 (br, 2 H, *H*$_2$O), 3.61 (s, 24 H, O−CH_2), 2.19 (s, 6 H, CH_3). ^{13}C NMR (CD$_3$OD, 23 °C): δ = 145.50 (s, *C*−CH$_3$), 104.69 (s, *C*H), 71.35 (s, *C*H$_2$), 11.95 (s, *C*H$_3$). MS (EI): *m*/*z*: 303 ([K(18-crown-6)]$^+$, 100%). IR (Nujol, cm^{-1}): ν_{OH} = 3400 (s). C$_{17}$H$_{33}$KN$_2$O$_7$ (416.6): calcd. C 49.02, H 7.99, N 6.73; found C 48.99, H 7.89, N, 6.64.

X-ray Crystallography: Crystals of **1** (*M* = 522.67) and **3** (*M* = 416.55) were grown as described above and crystallized in the monoclinic crystal system with space group $P2_1/n$. Relevant details and data are summarized in Table 1. The crystals were mounted in thin glass capillaries under an argon atmosphere. Diffraction data were collected on a Bruker P4 four-circle diffractometer coupled to a Bruker CCD area detector at 295(2) K, with graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å). The structures were solved from the Patterson maps using SHELX-97[20] and refined against F^2 on all data by full-matrix least-squares with the same program. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were included in the model at their geometrically calculated positions and held riding or observed on a difference Fourier and refined. CCDC-201685 (**1**) and CCDC-201686 (**3**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB21EZ, UK [Fax: (internat.) + 44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk]. Structure searches were performed using the Cambridge Crystallographic Database, Version 5.24, November 2002.

DFT Calculations on the C−Cl/Si−H Exchange Catalyzed by *P,N*-Chelated Pt^{II} Complexes

Dietmar Sturmayr[a] and Ulrich Schubert*[a]

Keywords: Chlorinated hydrocarbons / Hemilabile ligands / Oxidative addition / Reductive elimination / Silanes

The mechanism of the previously reported C–Cl/Si–H exchange reaction between H_xCCl_{4-x} (x = 0–3) and $HSiMe_2Ph$ catalyzed by [PtMeCl($Ph_2PCH_2CH_2NMe_2$-κ²*P,N*)] [PtMeCl(P∩N)] was investigated by DFT calculations. The energetically less-favored isomer of [PtMeCl(P∩N)], with Cl and P being *cis*, was identified to be the actual catalytic species. The catalytic reaction proceeds by oxidative addition of the silane, de-coordination of the nitrogen atom of the *P,N*-chelating ligand, reductive elimination of the chlorosilane and oxidative addition of the C–Cl bond of H_xCCl_{4-x}. The final step is the reductive elimination of the C–H bond with concomitant re-coordination of the nitrogen atom of the *P,N*-chelating ligand.

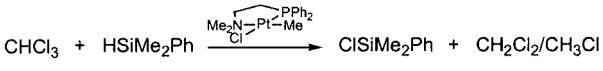
Introduction

We recently reported that the complex [PtMeCl($Ph_2PCH_2CH_2NMe_2$-κ²*P,N*)] [PtMeCl(P∩N)] catalyzes the C−Cl/Si−H exchange reaction between H_xCCl_{4-x} (x = 0−3) and $HSiMe_2Ph$ [Equation (1)].[1] While the chlorinated hydrocarbons are successively dechlorinated, the silane is the chloride sink and $ClSiMe_2Ph$ is formed. The order of reactivity is $CCl_4 > CHCl_3 > CH_2Cl_2 > CH_3Cl$. A related reaction is the [Rh(C_6F_5)(PMe_3)$_3$]-catalyzed hydrodefluorination of C_6F_6 by $HSi(OEt)_3$.[2]



(1)

A remarkable feature of this reaction is that [PtMeCl(P∩N)], where Cl and P are *trans* in the most stable isomer ("*trans*-[PtMeCl(P∩N)]"),[3,4] does not react with either CCl_4 or $HSiMe_2Ph$ alone on a reasonable time scale. The formation of the catalytic species must be the result of an initial reaction of [PtMeCl(P∩N)] with either $HSiMe_2Ph$ or the chlorinated hydrocarbon. We therefore postulated that the energetically less-favored isomer of [PtMeCl(P∩N)] with *cis* Cl and P ("*cis*-[PtMeCl(P∩N)]") might be the actual catalytic species.[1] To shed light on this question and on the further course of the reaction we performed DFT calculations, which are reported in this article.

Getreidemarkt 9/165, 1060 Wien, Austria

Results and Discussion

The theoretical analysis of the catalytic reaction was divided into two parts. In the first part the reaction of both isomers of [PtMeCl(P∩N)] with SiH_4 was analyzed. In the second part the catalytic cycle was studied. SiH_4 and CH_3Cl were used as the reactants to simplify the calculations.

Reaction of [PtMeCl(P∩N)] with SiH_4

When [PtMeCl(P∩N)] is taken as the starting point of the catalytic reaction, the next step must be the reaction with $HSiR_3$. We therefore investigated first the oxidative addition of the silane to the two isomers of [PtMeCl(P∩N)]. Calculations were carried out by method I (see Computational Details) on *P,N*-chelated complexes where the chelate ligand was modeled as $PH_2CH_2CH_2NH_2$.

Reaction of SiH_4 with *trans*-[PtMeCl(P∩N)] (1)

The energy required to form TS_{1-2} from **1** and SiH_4 is 23.6 kcal/mol (Figure 1). A Pt−Si bond of 2.456 Å and a

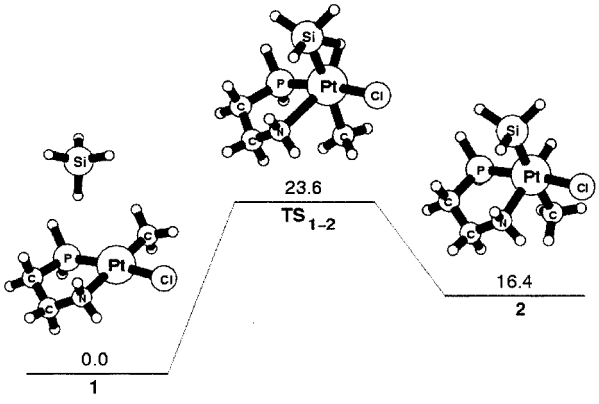

Figure 1. Reaction for the reaction of SiH_4 with **1**; energies in kcal/mol

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim DOI: 10.1002/ejic.200400029

Pt−H bond of 1.582 Å are formed. The Pt−N bond length is increased to 2.686 Å in $\mathbf{TS}_{1-2}$ compared to 2.267 Å in **1**. The eventually formed Pt^{III} complex **2** is 16.4 kcal/mol higher in energy than the reactants **1** and SiH_4. This, and the high activation energy of 23.6 kcal/mol for the initial reaction step, seems to be the reason why no reaction is observed between **1** and $HSiMe_2Ph$.

Reaction of SiH_4 with cis-[PtMeCl(P∩N)] (3)

The activation energy required to form $\mathbf{TS}_{3-4}$ (22.7 kcal/mol; Figure 2) is similar to that for *trans*-[PtMeCl(P∩N)]. The formed Pt−Si bond in $\mathbf{TS}_{3-4}$ (2.736 Å) and the Pt−H bond (1.827 Å) are much longer than the bonds in the corresponding complex $\mathbf{TS}_{1-2}$ in the previous reaction. This means that the interaction of the SiH_4 molecule with the platinum center is weaker. This is also reflected in a shorter Pt−N bond length of 2.248 Å. The reaction of **3** with SiH_4 eventually results in the six-coordinate Pt^{III} complex **4**, releasing 13.1 kcal/mol. Complex **4**, with the silyl ligand *trans* to Cl, is lower in energy than isomer **1** with the silyl ligand *trans* to a methyl ligand.

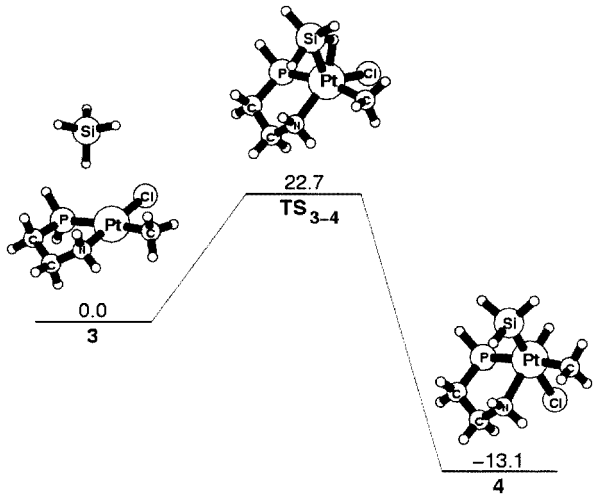

Figure 2. Reaction for the reaction of SiH_4 with **3**; energies in kcal/mol

It appears that the formation of *cis*-[PtMeCl(P∩N)] is necessary for the catalytic reaction to occur. The energy difference between the more stable *trans*-[PtMeCl(P∩N)] (**1**) and *cis*-[PtMeCl(P∩N)] (**3**) is 9.7 kcal/mol, which means that both isomers could be present in the equilibrium. This is in agreement with the fact that hydridosilanes do not react with [PtMeCl(P∩N)], since the activation energy for the reaction of the hydridosilane (22.7 kcal/mol) is quite high. However, when CCl_4 is present, a Cl/H exchange reaction can occur giving the catalytic cycle.

Catalytic Cycle

The mechanism of the Cl/H exchange reaction is examined in this section. The complete cycle was modeled in four steps as described in the following sections. In this part of the work, a much simpler model was used to describe the involved complexes — the *P,N*-chelating ligand was replaced by a PH_3 and an NH_3 ligand, and method II was used.

Oxidative Addition of SiH_4 to [PtMeCl(PH_3)(NH_3)] (5)

The starting point is the catalytic active complex **5** (Figure 3), which is analogous to the previously discussed *cis*-[PtMeCl(P∩N)] (**3**). Complex **5** reacts with SiH_4 to form the transition state $\mathbf{TS}_{5-6}$. The energy required is 24.5 kcal/mol. In $\mathbf{TS}_{5-6}$ a Pt−Si bond of 2.739 Å and a Pt−H bond of 1.822 Å are formed and, as a result, the Si−H bond is stretched to 1.601 Å. The Pt−N bond length is 2.248 Å, therefore the addition of SiH_4 to $\mathbf{TS}_{5-6}$ happens when the *P,N*-ligand is closed. The relaxation of $\mathbf{TS}_{5-6}$ leads to the octahedral Pt^{III} complex [Pt(Me)H(SiH_3)Cl(PH_3)(NH_3)] (**6**). Upon formation of the six-coordinate complex the Pt−Si and Pt−H bonds are shortened to 2.353 and 1.560 Å, respectively, while all other bonds are lengthened. This frees 35.5 kcal/mol, and therefore the energy of **6** is 11.0 kcal/mol lower than that of the starting compounds. Up to this point, the reaction profile is very similar to that discussed before (Figure 3), which shows that the simplification introduced by replacing the chelating $H_2NCH_2CH_2PH_2$ ligand by single NH_3 and PH_3 ligands does not affect the outcome of the calculations very much.

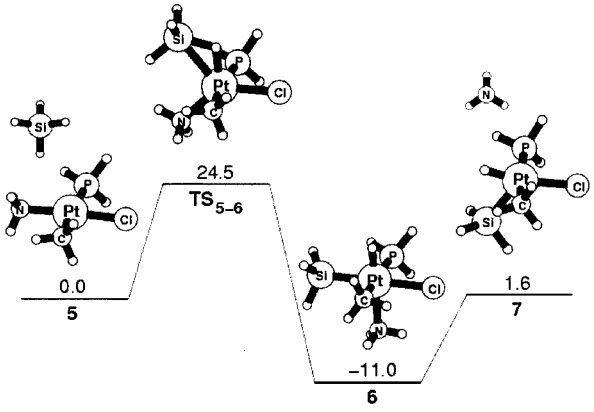

Figure 3. Reaction profile for the oxidative SiH_4 addition to **5**; energies in kcal/mol

The only way for **6** to undergo further reaction is by loss of the NH_3 ligand, which in the real system is the opening of the *P,N*-chelate. The relaxation of **6** after eliminating the NH_3 ligand leads to [Pt(Me)H(SiH_3)Cl(PH_3)] (**7**) which can be described as a distorted trigonal bipyramid. The formation of **7** from **6** is endothermic, and an energy of 12.6 kcal/mol is required for this process.

Reductive H_3SiCl Elimination from 7

The transition state $\mathbf{TS}_{7-8}$ (Figure 4) is formed from **7** by the reorientation of the SiH_3 group towards the chloro ligand, with concomitant increase of the Pt−Si bond length from 2.336 to 2.615 Å and that of the Pt−Cl bond from

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

2.423 to 2.554 Å. The other bond lengths are shortened. The formation of a Si−Cl bond is observed, with a bond length of 2.303 Å in the transition state.

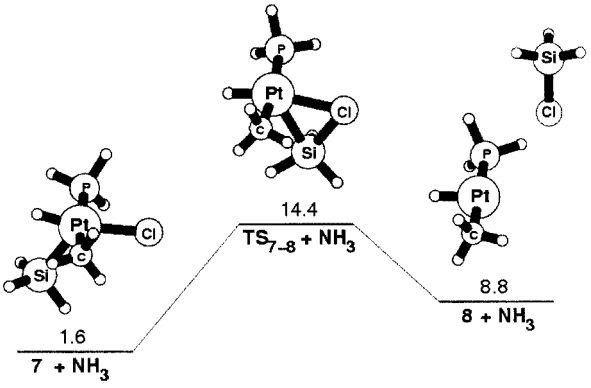

Figure 4. Reaction profile for the reductive H_3SiCl elimination from **7**; energies in kcal/mol

The three-coordinate complex [PtMeH(PH_3)] (**8**) is obtained by elimination of H_3SiCl from $\mathbf{TS}_{7-8}$. An energy of 7.2 kcal/mol is required to eliminate H_3SiCl from **7**. The hydrido ligand in the trigonal-planar complex **8** is *cis* to the phosphorus atom.

Oxidative CH_3Cl Addition to 8

In $\mathbf{TS}_{8-9}$, formed from the oxidative addition of CH_3Cl to **8** (Figure 5), the C−Cl bond is stretched from 1.806 Å in CH_3Cl to 2.284 Å and new Pt−C and Pt−Cl bonds develop (Pt−C: 2.575 Å; Pt−Cl: 2.501 Å). The Pt−P, Pt−C and Pt−H bond lengths are slightly lengthened. The formation of $\mathbf{TS}_{8-9}$ requires 24.9 kcal/mol, which is quite high. On the other hand the relaxation to [Pt(Cl)$Me_2H(PH_3)$] (**9**) frees 36.4 kcal/mol. The five-coordinate complex **9** is a result of the reorientation of the incoming CH_3 group.

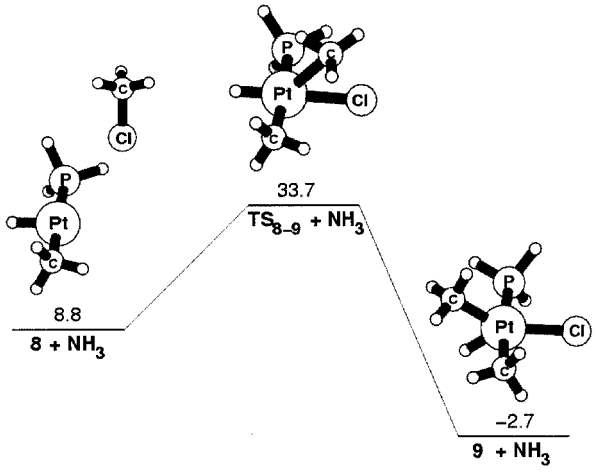

Figure 5. Reaction profile for the oxidative CH_3Cl addition to **8**; energies in kcal/mol

Reductive CH_4 Elimination from 9

The final step, the reductive CH_4 elimination, starts from the five-coordinate complex **9** (Figure 6). Only minor geometric changes are required to form $\mathbf{TS}_{9\text{-}10}$, where the new C−H bond is formed (1.552 Å). The related Pt−H and Pt−C bonds are stretched to 1.585 Å and 2.181 Å respectively. The Cl−Pt−H angle is opened from 139.9° to 153.1° and the Cl−Pt−C angle from 147.6° to 161.2°. An energy of 2.5 kcal/mol is freed by dissociating the CH_4 molecule and, as a result, the three-coordinate complex [PtMeCl(PH_3)] (**10**) is formed.

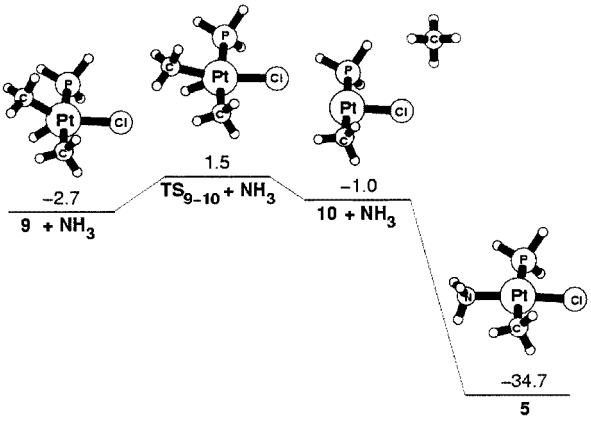

Figure 6. Reaction profile for the reductive CH_4 elimination from **9**; energies in kcal/mol

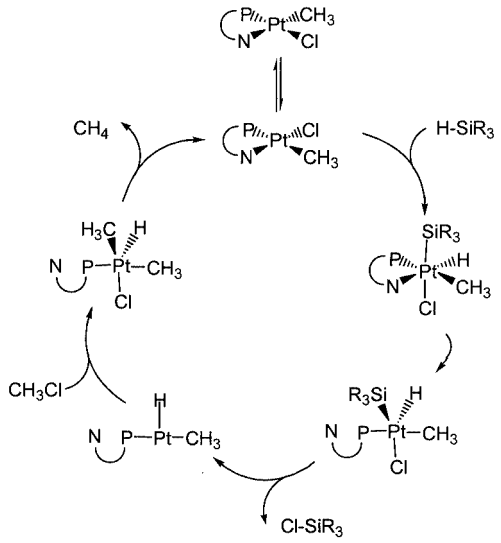
To close the catalytic cycle, the re-coordination of the NH_3 group is needed (representing the closing of the *P,N*-ligand in the real system). This frees 33.7 kcal/mol and results in the re-formation of the four-coordinate complex **5**, which is the starting point of the catalytic cycle.

Conclusions

Since no intermediates were observed in the [PtMeCl(P∩N)]-catalyzed C−Cl/Si−H exchange between H_xCCl_{4-x} and $HSiMe_2Ph$,[1] theoretical calculations were carried out to elucidate the reaction mechanism and the stereochemistry of the intermediates. Based on these calculations, the mechanism shown in Scheme 1 is proposed, which largely corresponds to our initial suggestion.[1]

The formation of *cis*-[PtMeCl(P∩N)] (**3**) is obviously necessary for the catalytic reaction to occur. This isomer is 9.7 kcal/mol less stable than *trans*-[PtMeCl(P∩N)] (**1**), but its reaction with SiH_4 turns out to be energetically more favorable. The oxidative addition of SiH_4 results in an octahedral Pt^{III} complex, therefore it is not necessary for the NH_3 ligand (corresponding to the amino group of the *P,N*-chelating ligand in the real system) to be eliminated for the reaction to occur. De-coordination of the amino group only occurs after the addition of the silane, and all the subsequent steps in the catalytic cycle — elimination of SiH_3Cl, addition of CH_3Cl and elimination of CH_4 — proceed via three- or five-coordinate complexes. The amino group is re-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim



Scheme 1

coordinated in the final step, where the starting complex *cis*-[PtMeCl(P∩N)] (**3**) is regenerated.

The methyl group stays *trans* to phosphorus during the whole reaction. This is obviously a particularly favorable orientation of the ligands, since five-coordinate intermediates with analogous geometries have also been found in the reaction of [$PtMe_2$(P∩N)] and [$Pt(SiH_3)$Me(P∩N)] with chlorinated hydrocarbons and chlorosilanes.[5]

A final point to be made is the importance of the hydrido-methyl intermediate **8**. We have recently postulated such an intermediate, based on spectroscopic evidence, in the reaction of [$PtMe_2$(P∩N)] with $HSiEt_3$ and $HSiMePh_2$. In the first step of this reaction [PtMeH(P∩N)] and Me-SiR_3 are formed; the hydrido-methyl complex may react with a second molecule of silane to give [$Pt(SiR_3)$-Me(P∩N)] and H_2.[6]

Computational Details

The geometry optimizations of the equilibrium geometries and transition structures were performed using the B3LYP version of DFT, which is comprised of Becke's hybrid three-parameter exchange functional and the correlation functional of Lee, Yang and Parr.[7,8] The relativistic effective core potential and basis set of Preuss and co-workers (which is available in the Gaussian 98 software package as the SDD basis set) was used in Methods I and II for platinum.[9] In Method I, the 6-311G++(d) basis set was used for all atoms, except platinum. In Method II, the 6-31G++(d) basis set was used for all atoms, except platinum. Vibrational mode analyses were carried out to confirm that optimized geometries on the potential-energy surfaces correspond to a local minimum without an imaginary frequency mode, or a saddle point with only one imaginary mode. Corrections for zero-point vibrational energies were taken into account in the stationary structures obtained. All the calculations were carried out with the Gaussian 98 package.[10]

Zinc Guanidinate Complexes and Their Application in Ring-Opening Polymerisation Catalysis

Martyn P. Coles*[a] and Peter B. Hitchcock[a]

Keywords: Guanidinate / N ligands / O ligands / Ring-opening polymerisation / Zinc

The insertion reaction between 1 equiv. of carbodiimide, R′N=C=NR′, and the zinc bis(amide) $[Zn\{N(SiMe_3)_2\}_2]$ affords the homoleptic zinc(II) guanidinate compounds $[Zn\{(Me_3Si)_2NC(NR')_2\}_2]$ (**3**, R′ = *i*Pr; **4**, R′ = Cy) in preference to the monosubstituted compounds. Compound **3** also results from the protonation reaction of 1 equiv. of the neutral guanidine $(Me_3Si)_2NC(NiPr)(NHiPr)$ (**2**) with $[Zn\{N(SiMe_3)_2\}_2]$ or $ZnMe_2$. In contrast, the *N*-dimethylguanidine analogue $Me_2NC(NiPr)(NHiPr)$ (**1**) reacts cleanly with 1 equiv. of $ZnMe_2$ to afford the dimeric species $[Zn\{Me_2NC(NiPr)_2\}Me]_2$ (**5**). Attempted protonation of the Zn–C bond in **5** with 2,6-di-*tert*-butylphenol resulted in preferential reaction at the Zn–N bond and formation of the mixed (aryloxo)methyl complex $[Zn(OAr)Me{\cdot}\{Me_2NC(NiPr)(NHiPr)\}]$ (**6**), isolated as the guanidine adduct. Heating of **6**, in an attempt to promote methane elimination, afforded a small amount of the dimetallic complex $[\{Zn(OAr)\}_2(\mu\text{-}\{Me_2NC(NiPr)_2\})(\mu\text{-}NMe_2)]$ (**7**) as a result of the extrusion of NMe_2^- from the guanidine-based ligand. The amine-elimination reaction between $[Zn\{N(SiMe_3)_2\}_2]$ and 1 equiv. of 1,3,4,6,7,8-hexahydro-2*H*-pyrimido[1,2-*a*]pyrimidine (hppH) proceeds smoothly to afford the mixed (guanidinate)(amide) complex $[Zn(hpp)\{N(SiMe_3)_2\}]_2$ (**8**), which forms a dimer in the solid state. Crystal structures of compounds **3**–**8** are reported and a preliminary study of the activity of **8** in the ring-opening polymerisation of lactide is described.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004

Introduction

There has been a great deal of recent interest in the metal-catalysed ring-opening polymerisation (ROP) of cyclic esters, in particular lactide (LA),[1] as benefits over polymers derived from petrochemical sources include the renewable source of feedstock and the biocompatibility of the resultant polyester material.[2] Well-defined metal catalysts have generally allowed a greater control over the selectivity of the polymerisation process to be achieved, and structure-activity correlation studies associated with the ancillary ligands have been the focus of many of the recent developments in this area. As a consequence, many novel metal alkoxide and amide species have been synthesised and shown to be active catalysts for this process, where monomer insertion into the metal−oxygen or metal−nitrogen bond initiates polymerisation, and propagation ideally occurs in a controlled fashion to furnish stereoregular polylactide (PLA).

Anionic, *N*,*N*′-chelating ligands have thus far proved to be one of the most promising classes of supporting group in metal-catalysed lactide polymerisation. In particular, the β-diketiminate anion,[3] in combination with a zinc centre containing a reactive Zn−X bond, has been pursued in this area, exhibiting varying degrees of activity and selectivity dependant on the nature of the X group (Figure 1).[4,5] In general, it has been found that compounds containing a Zn−OR group, especially when R is a small alkyl group such as isopropyl, are significantly more active than those containing the amide group $[N(SiMe_3)_2]^-$, most likely due to a sluggish insertion of the first monomer into the sterically crowded Zn−N linkage. A recent report has also noted that structurally related bis(phosphanyl)methyl complexes of zinc are also active for the ROP of lactide,[6] although in these cases no evidence of "living" behaviour was observed.

A related class of chelating *N*,*N*′-donor ligands that has received attention in this area is the amidinate anion, $[RC(NR')_2]^-$,[7,8] where the metallacycle formed upon complexation to a metal atom differs principally from β-diketiminate compounds in the number of constituent atoms (i.e. 4 vs. 5). A range of different metals have been investigated including Fe,[9] Sn,[10] and the lanthanides[11] where, as for the β-diketiminate complexes, the coordination sphere is usually completed by either alkoxide or amide substituents at which initial reaction with the monomer is considered to take place (Figure 2). A notable exception is the series of homoleptic lanthanide complexes $[Ln\{RC(NCy)_2\}_3]$ (R = Me, Ln = Nd, Gd, Yb; R = Ph, Ln = Nd, Yb),[12] which are reported to be highly active for the ROP of ε-caprolactone, presumably initiating at one of the M−N

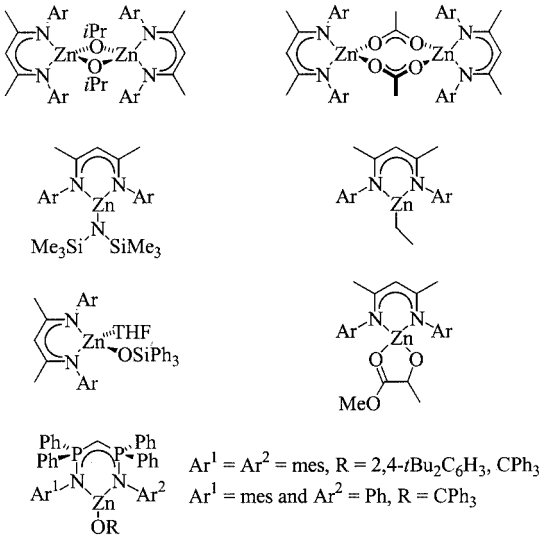

Figure 1. Zinc complexes, supported by β-diketiminate and related ligands, that are active for the ring-opening polymerisation of lactide

metal−amidinate bonds. Extension of this area to include the closely related guanidinate anions, $[R_2NC(NR'_2)]^-$,[13] has focussed mainly on the lanthanides, with catalytic activity observed with examples of both mono-,[14] and bis(ligand)[15] complexes (Figure 3).

Considering the potential for combining an active Zn−X (where X = alkoxide, amide) component with a supporting amidinate or guanidinate ligand set, it came as a surprise to us that no accounts have appeared on the investigation of zinc amidinate and guanidinate complexes as catalysts in this area. Indeed, very few amidine or amidinate complexes of zinc have been reported, with a few notable exceptions being the $[ZnBr_2L_2]$ adduct, where L = neutral *N*,*N*′-di-*p*-tolylformamidine,[16] and the bis(benzamidinate) complex $[Zn\{PhC(NSiMe_3)_2\}_2]$.[17] A report of the reaction between

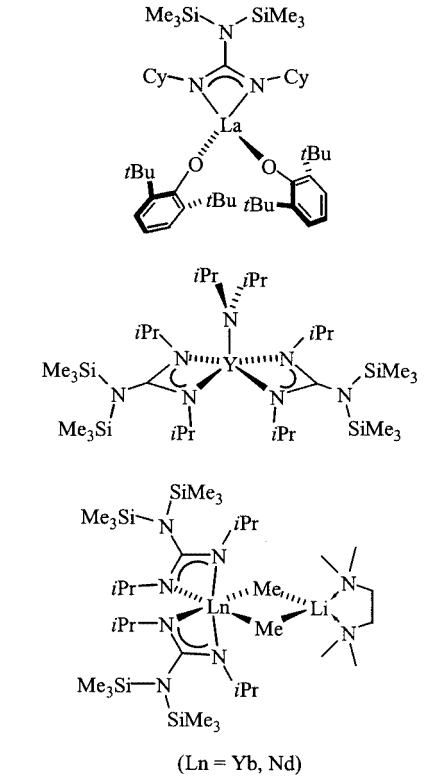

Figure 3. Metal complexes, supported by guanidinate ligands, that are active for ring-opening polymerisation

alkylzinc compounds and amidines to afford Zn(amidinate)$_2$ complexes appeared as unpublished results that, to the best of our knowledge, were never expounded upon.[7]

Recently, the synthesis of tolylformamidinate complexes of zinc was investigated, although the only products forthcoming from the study were cluster species incorporating oxygen.[18] Wheatley and co-workers have investigated mixed Zn/Li species containing *N*,*N*′-diphenylbenzamidin-

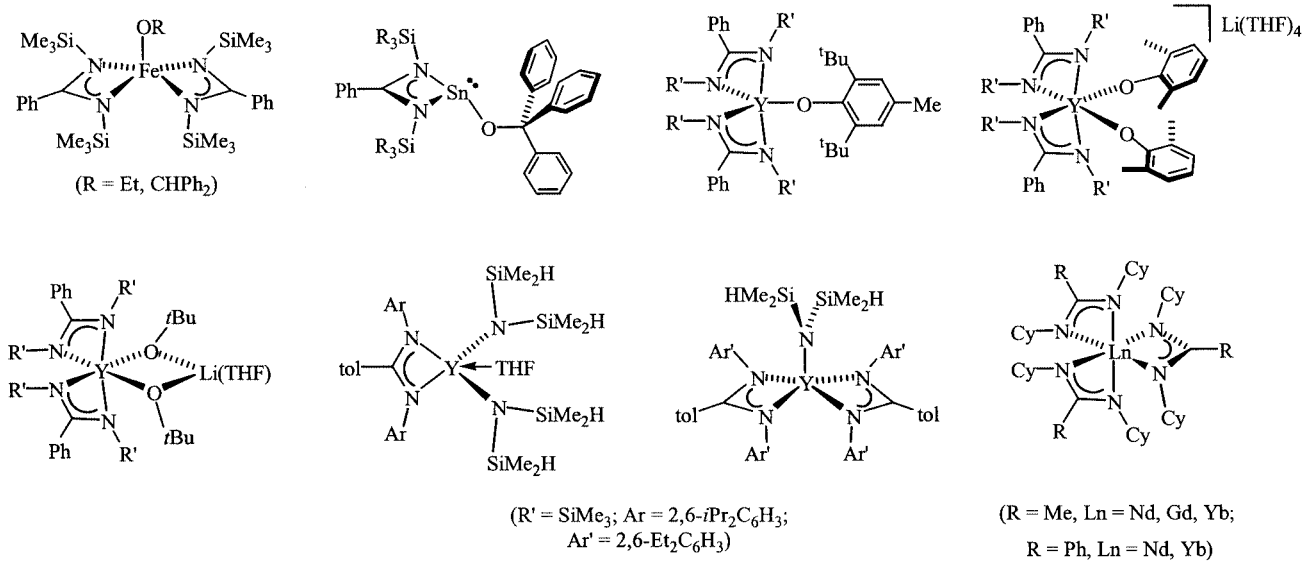

Figure 2. Metal complexes, supported by amidinate ligands, that are active for ring-opening polymerisation

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

ate and reported the reactivity with dry oxygen gas to afford similar oligomeric structures.[19] In contrast, a recent review did not report any zinc complexes containing anionic guanidinate ligands in the literature.[13] During the course of our work, we have developed several areas of research based around amidinate[20] and guanidinate chemistry,[21,22] and wish to report the results from a study into the synthesis and catalytic application of guanidinate-containing zinc complexes.

Results and Discussion

An atom-efficient route that has been employed in the synthesis of metal guanidinate complexes is the insertion of a carbodiimide into an existing metal−amide bond,[14,23] first reported by Lappert and co-workers in 1970.[24] The stoichiometric reaction between R′N=C=NR′ (R′ = *i*Pr, Cy) and [Zn{N(SiMe$_3$)$_2$}$_2$] was therefore investigated as a potential route to mono(guanidinato)zinc−amide complexes (Scheme 1). However, after the appropriate workup, the only product isolated from the reaction for each of the carbodiimides investigated was the homoleptic, bis(guanidinate) complex [Zn{(Me$_3$Si)$_2$NC(NR′)$_2$}$_2$] (**3**, R′ = *i*Pr; **4**, R′ = Cy), resulting from insertion of a molecule of carbodiimide into *both* zinc−amide bonds. Compounds **3** and **4** can be purified by crystallisation from hexane at −30 °C affording colourless crystals in moderate yield. The molecular structures are illustrated in Figures 4 and 5, crystal data are summarised in the Exp. Sect. and selected bond lengths and angles in Table 1.

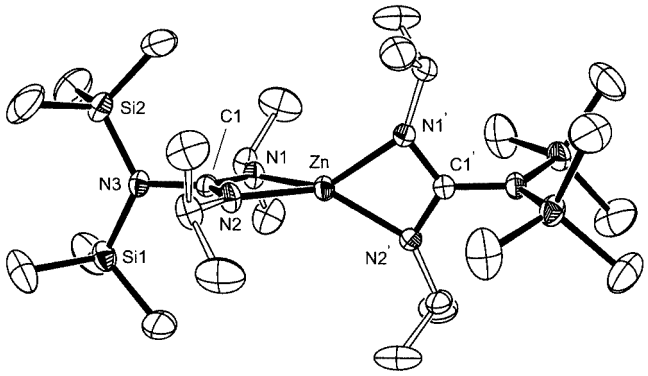

Figure 4. Molecular structure of [Zn{(Me$_3$Si)$_2$NC(N*i*Pr)$_2$}$_2$] (**3**) with thermal ellipsoids drawn at the 30% probability level; hydrogen atoms omitted for clarity

Compounds **3** and **4** are monomeric in the solid state, with the metal coordination sphere consisting of two η^2-guanidinate ligands in a "flattened" tetrahedral geometry. The angles at the metal atom are in the range 66.23(8)−139.32(13)° and 66.03(12)−135.93(12)° for **3** and **4**, respectively, where the lowest value is a consequence of the small bite angle of the ligand. The four-membered metallacycles are essentially planar (largest deviation: **3**, 0.015 Å; **4**, 0 Å) with an angle of 84.06° and 86.95° between the "ZnNCN" least-squares planes for **3** and **4**, respectively. The carbon−nitrogen distances are consistent with delocalisation across the "CN$_2$" fragment of the metallacycle, and the C−N(SiMe$_3$)$_2$ distances [**3**, 1.428(3) Å; **4**, 1.430(5) Å] and large angles between the "CN$_2$" and "NSi$_2$" moieties

[**3**, 87.61°; **4**, 81.46°] are consistent with a single bond with possible N−Si π-interactions.[25]

An alternative approach to the targeted mono(guanidinate) complexes was subsequently investigated, namely the reaction between dimethylzinc and 1 equiv. of the (neutral) guanidine, predicted to proceed by protonolysis of the zinc−carbon linkage. The ligand precursors, $[R_2NC\{NR'\}\{NHR'\}]$, were prepared from the reaction between the lithium diamide $LiNR_2$ (R = $SiMe_3$, Me) and *i*PrN=C=N*i*Pr, followed by quenching of the intermediate lithium salt with a stoichiometric amount of water, to afford $[Me_2NC(N{i}Pr)(NH{i}Pr)]$ (**1**) and $[(Me_3Si)_2NC(N{i}Pr)(NH{i}Pr)]$ (**2**).[26] The compounds were isolated as colourless and yellow liquids, respectively, and were used without further purification. The reaction between **2** and $[Zn\{N(SiMe_3)_2\}_2]$ or $ZnMe_2$ in a 1:1 ratio did not proceed to the mono(ligand) complex, but afforded only the bis(guanidinate) species **3** after the appropriate workup (Scheme 1). In contrast, the reaction of the dimethylamino analogue **1** with $ZnMe_2$ afforded colourless crystals of **5** suitable for an X-ray diffraction study. The molecular structure is illustrated in Figure 6, crystal data are summarised in the Exp. Sect. and selected bond lengths and angles in Table 2.

Compound **5** crystallised as the dimeric compound $[Zn\{Me_2NC(N{i}Pr)_2\}Me]_2$, with a $\mu,\eta^2:\eta^1$-coordination mode of the guanidinate ligand, resulting in an essentially planar Zn_2N_2 ring (largest deviation from least-squares plane: 0.041 Å). Whilst this type of coordination has not previously been observed for monoanionic guanidinate ligands,[27] related tricyclic core structures have been reported

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

for amidinate complexes of lithium,[28−30] magnesium[31] and iron,[32] and we have also observed this structural motif in a recently reported lithium phospha(III)guanidinate complex.[33] In contrast to the majority of these structures which contain crystallographic inversion symmetry, a non-centrosymmetric structure is observed for compound **5**, with a *syn* arrangement of the ligands about the central Zn_2N_2 ring.[29,31] The zinc atoms are present in a distorted tetrahedral geometry [angles in the range 63.50(16)−130.9(2)°], with the "ZnNCN" metallacycle at an angle of 66.19° to the central Zn_2N_2 plane. Examination of the Zn−N bond lengths in **5** suggests a strong association of the monomeric units in the solid state. Indeed, if we consider the dimer as consisting of two [Zn(guanidinate)-Me] fragments, based solely upon metal−nitrogen distances there is an apparent stronger interaction between the ligand of one unit and the metal of another [Zn−N(1) = 2.101(3) Å], than within the chelating guanidinate itself [Zn−N(1′) = 2.201(3) Å]. In all cases the Zn−N distances are significantly longer than in the homoleptic compounds **3** (av. 2.016 Å) and **4** (2.006 Å), despite a reduced angle between the NR_2 plane and the metallacycle in **5** (31.60°) that allows contribution from a zwitterionic resonance to the overall bonding.[25] In agreement with this postulate, the C(2)−N(2) bond length of **5** [1.357(5) Å] is intermediate between the value expected for C−N single and C=N double bonds, and is significantly shorter than the corresponding bonds in **3** [1.428(3) Å] and **4** [1.430(5) Å].

Transformation of the zinc−methyl group to a Zn−O linkage, desirable for applications in ROP, was attempted by reaction with 2,6-di-*tert*-butylphenol (Scheme 1). It was anticipated that the steric bulk of the alkyl substituents positioned about the resultant metal−oxygen bond would disfavour a bridging coordination mode for the aryloxide and promote a low aggregation within the final product. The reaction was performed at room temperature and after the appropriate workup colourless crystals of **6** were obtained. The molecular structure is illustrated in Figure 7, crystal data are summarised in the Exp. Sect. and selected bond lengths and angles in Table 2.

The molecular structure of **6** shows retention of the zinc−methyl group and incorporation of the aryloxide ligand in an overall monomeric, distorted trigonal planar zinc complex (Σ_{angles} at Zn: 359.57°). The coordination sphere of the zinc atom is completed by the *neutral* form of the guanidine ligand, $Me_2NC(NiPr)(NHiPr)$ (**1**), bonding through the N_{imino} atom,[34] such that the "CN_2" component is essentially coplanar with the ZnMeON metallacycle [max. deviation at C(1) 0.15 Å]. This arrangement is likely governed by the formation of an intramolecular hydrogen bond between the amino-NH and the aryloxide-O atoms [H(2a)···O 2.83 Å] which results in a widening of the angle between the N(1) and C(24) atoms at the zinc atom from the ideal trigonal planar angle to 131.30(9)°.

Despite coordinating as a neutral ligand in **6**, the Zn−N bond [1.9952(18) Å] is shorter than those observed in **5** (av. 2.12 Å) where it binds as an anionic ligand, reflecting the reduction in coordination number at the metal centre. This

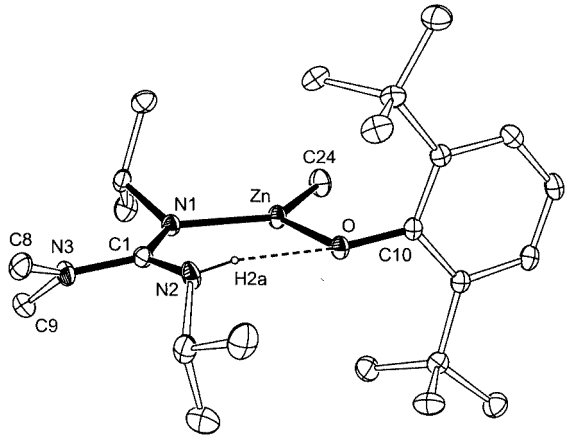

Figure 7. Molecular structure of [Zn(OAr)Me·{Me_2NC-(N*i*Pr)(NH*i*Pr)}] (**6**) with thermal ellipsoids drawn at the 30% probability level; hydrogen atoms, except H(2a), omitted for clarity

shortening may also be enhanced by the intramolecular H-bond noted above. The Zn−O bond [1.9511(15) Å] is relatively long in comparison to related three- and four-coordinate zinc complexes containing this and the similarly substituted 2,4,6-$tBu_3C_6H_2$ aryloxide groups [range: 1.818(1)−1.923(5) Å], and the angle at the oxygen atom [110.96(12)°] is by far the smallest observed [range: 124.04(14)−155.7(10)°].[35] These data suggest that there is a reduced π-donation from the oxygen to the zinc atom in **6** compared with the other examples cited, caused by the localisation of electron density in the hydrogen bond to the amino NH group.

The EI^+ mass spectrum of **6** indicates that, as predicted under these experimental conditions, dissociation of the guanidine occurs resulting in a signal at *m*/*z* (%)= 284 (72) equivalent to the "Zn(OAr)Me" fragment. Slightly more unexpected was the observation of a peak at *m*/*z* (%) = 439 (38) in the same spectrum, corresponding to the monomeric form of the target complex, "Zn{$Me_2NC(NiPr)_2$}(OAr)". This fragment must arise as a result of protonation of the methyl group by the NH functionality, with loss of methane, and prompted us to investigate the thermal stability of **6** in the expectation that, under the correct conditions, reactivity could be promoted at the Zn−C bond. Thus, a mixture of **5** and 1 equiv. of HOAr was heated in toluene, and the resultant solid crystallised from hexane at −30 °C, affording a small number of colourless crystals of **7** that were analysed by NMR spectroscopy and X-ray diffraction. The X-ray diffraction study was performed on representative crystals of **7** to determine the nature of the product; the molecular structure is illustrated in Figures 8 and 9, crystal data are summarised in the Exp. Sect. and selected bond lengths and angles in Table 3.

Compound **7** is a dimetallic zinc complex where the metal atoms are joined by bridging guanidinate and amide groups to generate a six-membered metallacycle. Each zinc atom is also bound by an aryloxide ligand, giving an overall distorted trigonal-planar geometry with the sum of the angles at Zn(1) and Zn(2) equal to 359.54° and 359.37°, respec-

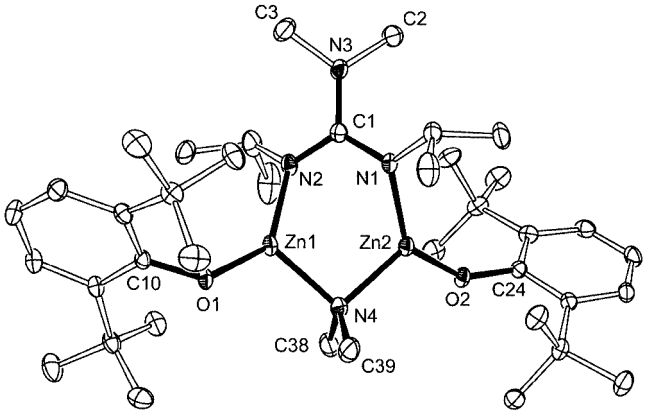

Figure 8. Molecular structure of $[\{Zn(OAr)\}_2(\mu\text{-}\{Me_2NC(NiPr)_2\})(\mu\text{-}NMe_2)]$ (**7**) with thermal ellipsoids drawn at the 20% probability level; hydrogen atoms omitted for clarity

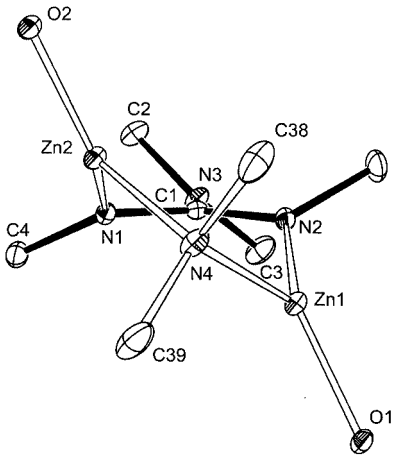

Figure 9. Core of $[\{Zn(OAr)\}_2(\mu\text{-}\{Me_2NC(NiPr)_2\})(\mu\text{-}NMe_2)]$ (**7**) along the approximate N(4)−C(1)−N(3) vector, illustrating the "half-chair" geometry of the metallacycle, and the distribution of the ligand substituents

tively. Overall, the metallacycle adopts a half-chair conformation (Figure 9) with a twist angle of 34.56° between the planes defined by Zn(1)−N(4)−Zn(2) and N(1)−C(1)−N(2). Both the guanidinate and amide bridge symmetrically between the two metal atoms.

Whilst a number of examples of bridging acyclic guanidinates have been reported between Pd, Fe and the s-block metals,[36] by far the most common coordination mode involves chelating to the metal atom,[13] rationalised in terms of the ligand donor orbital pointing towards the "mouth" of the ligand. The C−N distances within the guanidinate ligand (av. 1.35 Å) signify delocalisation of the R_2N lone pair into the core of the ligand, typically observed for this substitution pattern of nitrogen substituents. The average $Zn-N_{amide}$ distance in **7** (1.963 Å) is shorter than that found to the bridging amide group in the homoleptic series $[Zn(NR_2)(\mu\text{-}NR_2)]_2$ (R = Ph,[37] 2.03 Å; R = CH_2Ph,[38] 2.04 Å; R = CH_2iPr,[39] 2.03 Å], a possible consequence of the greater electron-withdrawing ability of the ArO^- ligand. The Zn−O bond lengths (av. 1.843 Å) are within the range

associated with this substituent (vide supra), although the angle at the oxygen atom varies significantly between the two ligands [Zn(1)−O(1)−C(10) 130.0(2)°, Zn(2)−O(2)−C(24) 140.9(2)°] indicating the "soft" character of this angle.

Recently, we[21,22] and others[25,40] have utilised the commercially available bicyclic guanidine 1,3,4,6,7,8-hexahydro-2*H*-pyrimido[1,2-*a*]pyrimidine (hppH) as a ligand precursor in the coordination chemistry of transition-metal and main-group complexes. The major difference of this system in comparison with acyclic guanidinates is that the constraint of the amide substituent and the amidine "CN_2" components of the molecule in the cyclic framework is predicted to enhance electron donation to a metal centre by increasing the contribution to the overall bonding from a zwitterionic resonance form. A potential complication in the application of the anionic ligand $[hpp]^-$ in molecular catalysis that arises from the bicyclic nature of the ligand is the propensity to adopt a bridging coordination mode to different metal centres, extensively exploited by Cotton and others in the support of many dimetallic systems.[30,41] Indeed, we have observed that the stoichiometric reaction between neutral hppH and $ZnMe_2$ affords the fully characterised, trimetallic complex $[Zn_3(hpp)_4Me_2]$ containing both two-coordinate $[\mu\text{-hpp}]^-$ and three-coordinate $[\kappa^{1,2}N\text{-}\kappa^3N'\text{-hpp}]^-$ bonding modes; this will be described fully in a forthcoming publication.[42]

In contrast to the reactions between acyclic guanidines and $[Zn\{N(SiMe_3)_2\}_2]$, the reaction with hppH proceeds smoothly at room temperature to afford the mono(guanidinate) species $[Zn(hpp)\{N(SiMe_3)_2\}]_n$ (**8**) in excellent yield. Low-temperature (−30 °C) crystallisation from a concentrated hexane solution affords colourless crystals suitable

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

for an X-ray diffraction study. The molecular structure is illustrated in Figure 10, crystal data are summarised in the Exp. Sect. and selected bond lengths and angles in Table 3.

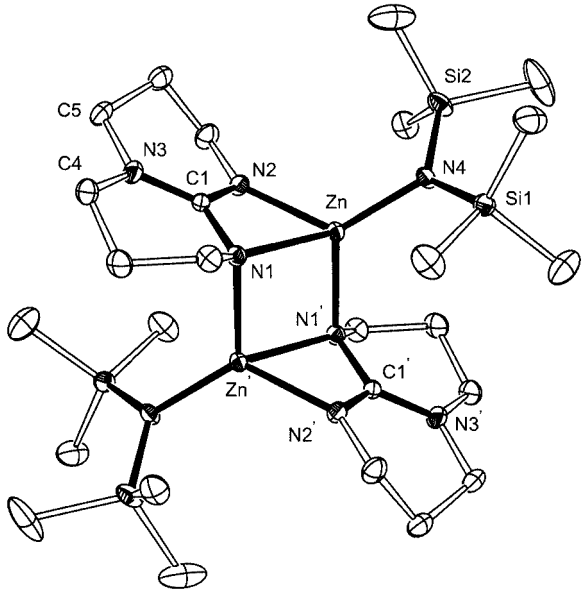

Figure 10. Molecular structure of $[Zn(hpp)\{N(SiMe_3)_2\}]_2$ (**8**) with thermal ellipsoids drawn at the 30% probability level; hydrogen atoms omitted for clarity

Compound **8** crystallised as the dimeric compound $[Zn(hpp)\{N(SiMe_3)_2\}]_2$, with a previously unreported $\mu,\eta^2:\eta^1$-coordination mode for the $[hpp]^-$ anion. Unlike the molecular structure of **5**, complex **8** exists as a centrosymmetric dimer with an *anti* arrangement of ligands about the central Zn_2N_2 metallacycle, a likely consequence of the different steric requirements of the ligands at the zinc centre. The Zn_2N_2 core of the molecule is perfectly planar and forms an angle of 72.9° to the essentially planar ZnN_2C metallacycle (largest deviation from least-squares plane 0.075 Å). The resultant geometry at the zinc centre is therefore best described as distorted tetrahedral with bond angles in the range 64.20(7)° (corresponding to the bite angle of the ligand) to 131.93(8)°.

As in **5**, a strong interaction between the two "monomeric" $[Zn(hpp)\{N(SiMe_3)_2\}]$ units is indicated by the shorter Zn−N(1′) distance [2.0831(19) Å] compared with Zn−N(1) [2.1879(18) Å]. The remaining Zn−N bond of the chelating $[hpp]^-$ anion is shorter [2.0486(19) Å], a probable combination of increased electron donation from $[hpp]^-$ [angle between N(1)−C(1)−N(2) and C(4)−N(3)−C(5) planes 4.57°] and a more electron-deficient zinc atom arising from the presence of the amide vs. the methyl substituent. The $Zn-N_{amide}$ distance [1.9177(18) Å] is slightly longer than the value in related, three-coordinate β-diketiminate[43] and (imine)(oxazoline)[44] zinc amides [1.896(2) and 1.883(3) Å, respectively], which may reflect a weaker bond, more reactive to ROP.

Preliminary NMR investigations of the catalytic activity of **8** towards the ring-opening of D,L-lactide (LA) was performed in CD_2Cl_2 and $[D_8]$toluene. In contrast to many zinc complexes incorporating the relatively bulky $N(SiMe_3)_2$ group, where initiation is reported as being slow,[4] the immediate reaction of **8** to generate a new species (> 98% in ca. 2 min) was observed, as judged by a shift of the $N(Si\mathit{Me}_3)_2$ resonance from δ = −0.02 ppm to δ = 0.05 ppm (CD_2Cl_2). The progress of the reaction was monitored by ^1H NMR spectroscopy, clearly indicating that 45−85 equiv. of LA were polymerised to polylactide (PLA) with more than 95% conversion in less than 2 h. Assuming the rate of initiation is much greater than the rate of propagation, leading to all zinc centres being activated prior to further insertion of monomer, integration of the $N(Si\mathit{Me}_3)_2$ end-group signal versus either the methine or methyl resonances of the growing polymer chain will allow an approximate value of the molecular weight to be calculated. From the ^1H NMR spectra of the polymerisation reactions performed with **8**, this appeared to be a reasonable approximation (vide supra), and a graph of molecular weight vs. conversion was therefore plotted (Figure 11). The straight-line relationships generated for different monomer concentrations and solvents present good evidence that the polymerisation proceeds in a "well-behaved" fashion. In addition, after 18 h at room temperature, a sample of **8** and LA (45 equiv.) that had progressed to more than 98% conversion was able to initiate the polymerisation of a further 50 equiv. of LA in CD_2Cl_2. The fresh monomer was converted into PLA over a period of 2 h, demonstrating the stability of the propagating species over time and providing further indication of the controlled nature of the polymerisation. There was no evidence for a tacticity bias in the ^1H NMR spectrum of the PLA produced by **8**, as indicated by selective decoupling of the methine protons.

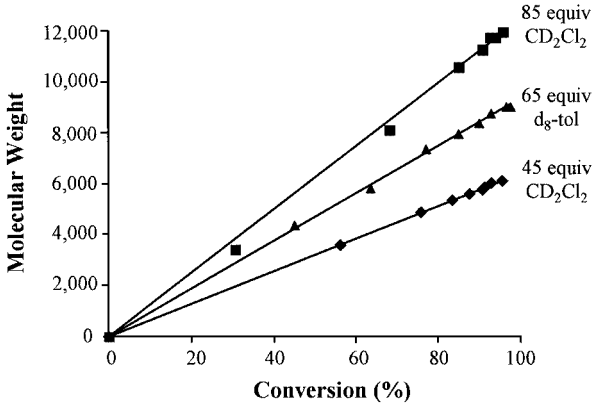

Figure 11. Plot of molecular weight vs. monomer conversion (determined by ^1H NMR spectroscopy) for the polymerisation of LA with **8**

Conclusion

We have demonstrated that the synthesis of mono(guanidinate) complexes of zinc is beleaguered with difficulties,

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

and the nature of the product can be highly dependant on the synthetic protocol employed and substitution pattern of the nitrogen groups contained within the ligand precursor. Initial attempts at formation of the mono(ligand) amide only afforded the homoleptic Zn^{II} guanidinate products **3** and **4** under a variety of conditions. Assuming a stepwise reaction pathway is in operation, proceeding by initial formation of one guanidinate anion at the metal atom, this mono(ligand) product evidently activates the metal−amide bond to further insertion relative to the Zn−N bond of the bis(amide) starting material.

An interesting contrast was noted in the protonation reactivity between $ZnMe_2$ and the neutral diisopropylguanidines $R_2NC(NiPr)(NHiPr)$ (R = $SiMe_3$ and Me), where a similar steric environment at the metal atom is anticipated as the metal-bound nitrogen atoms are substituted by isopropyl groups in each instance. Changing the nitrogen substituents of the NR_2 moiety from trimethylsilyl to methyl, however, arrested multiple protonation of the dialkylzinc and provided a clean and efficient route to the first example of a mono(guanidinate) compound **5** of zinc. It has been previously demonstrated in guanidinate chemistry of aluminium that, despite being remote from the metal centre, the nature of the R substituents can strongly influence the distribution of electron density within the $[R_2NC\{NR'\}_2]^-$ anion and the potential therefore exists to "tune" the reactivity of the metal centre.[25] In general, the larger, more electron-withdrawing silyl substituents will reduce the extent of electron donation through the $N_{amino}-C$ bond by disfavouring delocalisation of the N_{amino} lone-pair into the framework of the ligand. The smaller, electron-donating methyl groups, however, allow the NR_2 and CN_2 components of the ligand to approach coplanarity, thus providing the correct orbital alignment for interaction between the nitrogen lone-pair and the empty p-orbital of the sp^2-carbon atom. The result is the potential for greater electron donation for the anion derived from **1** compared with **2**, which is apparently sufficient to prevent activation of the zinc−methyl bond to further protonation in compound **5**. It is curious to note that in **5**, the usually highly reactive $Zn-CH_3$ bond is even resistant to protonation from a bulky phenol derivative and that the acidic proton preferentially reacts at one of the Zn−N bonds of the guanidinate, affording the mixed methyl(aryloxide) compound **6**.

The molecular structure of **6** confirms retention of the neutral ligand at the zinc centre and reveals an intramolecular hydrogen bond to the aryloxide-O atom. Comparison of the Zn−O bond with other examples of compounds containing the same ligand indicates that the bond in **6** is exceptionally long and angular. This is in agreement with the oxygen lone-pairs participating in the hydrogen bond to the NH group, with the result being consistent with a lower Zn−O bond order than noted in previous examples of zinc complexes incorporating this ligand.

Attempts to promote methane elimination by heating a mixture of **5** and ArOH met with partial success. Loss of the zinc−methyl group was achieved with concomitant conversion of the neutral guanidine ligand to the anionic guanidinate and retention of the aryloxide substituent. However, the guanidinate ligand was found to be unstable under the conditions employed, as indicated by the isolation of a small amount of the dimetallic species $[\{Zn(OAr)\}_2(\mu\text{-}\{Me_2NC(NiPr)_2\})(\mu\text{-}NMe_2)]$ (**7**), formed by amide extrusion from the guanidine or guanidinate ligand. As this product was only isolated in low yield, and as such may represent only a minor component of the product mixture, detailed mechanistic studies into its formation were not carried out. However further work in this area is merited due to the possible implications that such a process has in metal-catalysed guanylation of amines and transamination of guanidines,[45] and C=N metathesis of carbodiimides.[46]

Building on the observation that the introduction of a more electron-donating guanidinate ligand caused multiple protonation at the metal centre to be effectively "shut down" during the synthesis of **5**, we turned our attention to the potentially more strongly electron-donating anion $[hpp]^-$. It has been shown that constraining the NR_2 and CN_2 components in the bicyclic framework of this compound promotes an increased contribution from a zwitterionic resonance form, manifested in shorter Ti−N distances in a series of titanium compounds incorporating the $[hpp]^-$ anion in comparison to acyclic amidinates and guanidinates.[21] Thus, synthesis of $[Zn(hpp)\{N(SiMe_3)_2\}]_2$ (**8**), containing the desired combination of a supporting ancillary guanidinate and reactive zinc−amide bond, was achieved. Compound **8** was found to be active in the small-scale polymerisation of lactide and analysis of the NMR spectroscopic data indicated a well-behaved system.

Overall we have therefore exploited the observation that, in order to prevent the formation of homoleptic Zn^{II} guanidinate compounds, more electron-donating guanidinate anions must be employed. Eventually, the correct combination of ligands was found in **8** and we proved the concept that this compound is an active catalyst for the well-behaved ROP of lactide. The application of **8** in the polymerisation of related monomers and an in-depth study of the structure of the polymeric material will be published in due course.

Experimental Section

General Remarks: All manipulations were carried out under dry nitrogen using standard Schlenk and cannula techniques, or in a conventional nitrogen-filled glovebox operating at < 1 ppm oxygen. Solvents were dried with appropriate drying agents, degassed, and stored over a potassium mirror or activated molecular sieves prior to use. R′N=C=NR′ (R′ = *i*Pr, Cy; Aldrich), $LiNMe_2$ (Fluka), $LiN(SiMe_3)_2$ (Aldrich) and $ZnMe_2$ (ca. 2 M solution in toluene; Fluka) were obtained commercially and used as received, unless stated otherwise. The compound $[Zn\{N(SiMe_3)_2\}_2]$ was synthesised from the reaction between $ZnBr_2$ and 2 equiv. of $LiN(SiMe_3)_2$. The crude product was extracted into hexane and used without further purification. Elemental analyses were performed by S. Boyer at The University of North London. NMR spectra were recorded with a Bruker Avance DPX 300 MHz spectrometer. Coupling constants are quoted in Hertz.

$Me_2NC(NiPr)(NHiPr)$ (1): A slurry of lithium dimethylamide (5.00 g, 98.00 mmol) in Et_2O (100 mL) was cooled to 0 °C and a solution of diisopropylcarbodiimide (12.40 g, 98.00 mmol) in Et_2O (50 mL) was added dropwise with a cannula. The mixture was allowed to warm to room temperature to afford a cloudy yellow solution, that was stirred for a further 14 h under ambient conditions. Degassed water (1.8 mL, 100.00 mmol) was subsequently added dropwise with a syringe causing the formation of a clear yellow solution and a white precipitate. The mixture was filtered through Celite and the volatiles were removed to afford a pale-yellow liquid that was used without further purification. Yield: 11.75 g (70%). ^{1}H NMR ($CDCl_3$, 298 K): δ = 3.37 (sept, $^3J_{H,H}$ = 6.4, 1 H, C*H*Me$_2$), 3.25 (sept, $^3J_{H,H}$ = 6.3, 1 H, C*H*Me$_2$), 2.67 (s, 6 H, N*Me$_2$*), 1.03 (d, $^3J_{H,H}$ = 6.3, 6 H, CH*Me$_2$*), 1.02 (d, $^3J_{H,H}$ = 6.3, 6 H, CH*Me$_2$*) ppm; N*H* signal not observed. ^{13}C NMR ($CDCl_3$, 298 K): δ = 155.8 (*C*N$_3$), 47.3 (*C*HMe$_2$), 45.9 (*C*HMe$_2$), 39.0 (N*Me$_2$*), 25.1 (CH*Me$_2$*), 23.6 (CH*Me$_2$*) ppm.

$(Me_3Si)_2NC(NiPr)(NHiPr)$ (2): Compound **2** was synthesised using a similar procedure to that outlined for the synthesis of **1**, using lithium bis(trimethylsilyl)amide (2.50 g, 14.94 mmol), diisopropylcarbodiimide (1.89 g, 14.94 mmol) and water (0.27 g, 14.94 mmol). The compound was isolated as a colourless liquid and was used without further purification. Yield: 3.21 g (75%). ^{1}H NMR ($CDCl_3$, 298 K): δ = 3.79 (br. sept, $^3J_{H,H}$ = 6.0, 1 H, C*H*Me$_2$), 3.64 (br. sept, $^3J_{H,H}$ = 5.6, 1 H, C*H*Me$_2$), 1.08 (br. d, $^3J_{H,H}$ = 5.9, 6 H, CH*Me$_2$*), 1.04 (br. d, $^3J_{H,H}$ = 5.8, 6 H, CH*Me$_2$*), 1.15 (s, 18 H, Si*Me$_3$*) ppm; N*H* signal not observed. ^{13}C NMR ($CDCl_3$, 298 K): δ = 147.5 (*C*N$_3$), 47.3 (*C*HMe$_2$), 42.0 (*C*HMe$_2$), 24.9 (CH*Me$_2$*), 22.7 (CH*Me$_2$*), 1.6 (Si*Me$_3$*) ppm.

$[Zn\{(Me_3Si)_2NC(NiPr)_2\}_2]$ (3). Method 1: A solution of dimethylzinc (0.9 mL of a 2 M solution in toluene, 1.80 mmol) was further diluted with an additional 20 mL of toluene and cooled to −78 °C. A solution of **2** (0.50 g, 1.74 mmol) in toluene (40 mL) was added dropwise with a cannula and the resultant colourless solution was allowed to warm to room temperature and stirred for 14 h. The mixture was filtered and cooled to −30 °C to afford colourless crystals of $[Zn\{(Me_3Si)_2NC(NiPr)_2\}_2]$. Yield: 0.45 g (48%). $C_{26}H_{64}N_6Si_4Zn$ (638.56): calcd. C 48.91, H 10.10, N 13.16; found C 48.99, H 9.99, N 13.07. ^{1}H NMR (C_6D_6, 298 K): δ = 3.70 (sept, $^3J_{H,H}$ = 6.1, 4 H, C*H*Me$_2$), 1.17 (d, $^3J_{H,H}$ = 6.2, 24 H, CH*Me$_2$*), 0.30 (2, 36 H, Si*Me$_3$*) ppm. ^{13}C NMR (C_6D_6, 298 K): δ = 165.2 (*C*N$_3$), 44.7 (*C*HMe$_2$), 27.0 (CH*Me$_2$*), 2.3 (Si*Me$_3$*) ppm. MS (EI$^+$): *m*/*z* = 636 [M]$^+$, 621 [M − Me]$^+$. **Method 2:** A solution of **2** (0.37 g, 1.29 mmol) in toluene (20 mL) was added dropwise at room temperature to a toluene (25 mL) solution of $[Zn\{N(SiMe_3)_2\}_2]$ (0.50 g, 1.29 mmol) with a cannula. No visible change was observed. The reaction mixture was stirred at room temperature for 18 h, after which time the volatiles were removed to afford a sticky white solid. ^{1}H NMR spectra indicated a 1:1 mixture of **3** (identified from the chemical shift values in comparison with an authentic sample) and unchanged $[Zn\{N(SiMe_3)_2\}_2]$. No further purification was attempted.

$[Zn\{(Me_3Si)_2NC(NCy)_2\}_2]$ (4): A solution of CyN=C=NCy (0.27 g, 1.29 mmol) in toluene (25 mL) was added dropwise to a stirred solution of $[Zn\{N(SiMe_3)_2\}_2]$ (0.50 g, 1.29 mmol) in toluene (25 mL) at room temperature. No visible change was observed, and the resultant colourless solution was stirred at ambient conditions for 16 h. Removal of the volatiles in vacuo afforded crude **2** as a white solid that was crystallised from toluene at −30 °C as analytically pure colourless crystals. Yield: 0.32 g (62%) based on CyN=C=NCy. $C_{38}H_{80}N_6Si_4Zn$ (798.81): calcd. C 57.14, H 10.09, N 10.52; found C 57.05, H 10.09, N 10.56. ^{1}H NMR (C_6D_6, 298 K): δ = 3.37 (m, 4 H, *Cy*), 1.91−1.24 (m, 44 H, *Cy*), 0.33 (s, 36 H, Si*Me$_3$*) ppm.

An analogous reaction procedure using *i*PrN=C=N*i*Pr afforded a colourless crystalline material that analysed for **3**.

$[Zn\{Me_2NC(NiPr)_2\}Me]_2$ (5): A solution of **1** (1.00 g, 5.84 mmol) in toluene (30 mL) was added at room temperature to a solution of dimethylzinc (2.9 mL of a 2 M solution in toluene, 5.80 mmol) that had been further diluted by 50 mL of toluene. Evolution of a gas was observed and the resultant clear yellow solution was stirred under ambient conditions for 12 h. Removal of the volatiles afforded a pale-yellow solid that could be used without further purification. Analytically pure samples were obtained by crystallisation from hexane at −30 °C. Yield 0.98 g (67%). $C_{10}H_{23}N_3Zn$ (501.37): calcd. C 47.91, H 9.25, N 16.76; found C 47.73, H 9.37, N 16.86. ^{1}H NMR (C_6D_6, 298 K): δ = 3.41 (sept, $^3J_{H,H}$ = 6.1, 2 H, C*H*Me$_2$), 2.47 (s, 6 H, N*Me$_2$*), 1.12 (br. d, 12 H, CH*Me$_2$*), −0.12 (s, 3 H, Zn*Me*) ppm. ^{13}C NMR (C_6D_6, 298 K): δ = 166.5 (*C*N$_3$), 47.2 (*C*HMe$_2$), 40.0 (N*Me$_2$*), 25.7 (br., CH*Me$_2$*), −11.2 (Zn*Me*) ppm. MS (EI$^+$): *m*/*z* = 404 $[\{Me_2NC(NiPr)_2\}_2Zn]^+$, 360 $[\{Me_2NC(NiPr)_2\}_2Zn - NMe_2]^+$, 234 $[\{Me_2NC(NiPr)_2\}Zn]^+$.

$[Zn(OAr)Me{\cdot}\{Me_2NC(NiPr)(NHiPr)\}]$ (6): A solution of 2,6-di-*tert*-butylphenol (0.41 g, 2.00 mmol) in toluene (20 mL) was added dropwise at room temperature to a solution of **5** (0.50 g, 2.00 mmol) in toluene (30 mL). The resultant clear, pale-yellow solution was stirred at room temperature for 12 h, after which time the volatile component was removed in vacuo to afford a pale-yellow solid. Crystallisation from hexane afforded **6** as colourless crystals. Despite repeated crystallisations, a persistent, unidentified impurity was observed during the preparation of **6**. As such, accurate analysis was not obtained and the NMR spectroscopic data are reported for the major component, which corresponds to **6**. Yield: 0.43 g (46%) calculated for **6**. $C_{24}H_{45}N_3OZn$ (457.00): calcd. C 63.07, H 9.92, N 9.19; found C 56.74, H 9.39, N 6.73. ^{1}H NMR (C_6D_6, 298 K): δ = 7.46 (d, $^3J_{H,H}$ = 7.8, 2 H, *m*-C_6H_3), 6.92 (t, $^3J_{H,H}$ = 7.7, 1 H, *p*-C_6H_3), 3.29 (sept, $^3J_{H,H}$ = 6.5, 1 H, C*H*Me$_2$), 3.08 (br. sept, 1 H, C*H*Me$_2$), 2.19 (br. s, 6 H, N*Me$_2$*), 1.72 (s, 18 H, C*Me$_3$*), 1.17 (br. d, $^3J_{H,H}$ = 6.4, CH*Me$_2$*), 0.99 (br. d, $^3J_{H,H}$ = 6.0, CH*Me$_2$*), −0.33 (s, 3 H, Zn*Me*) ppm. ^{13}C NMR (C_6D_6, 298 K): δ = 165.7 (*C*N$_3$), 139.0 (*C*), 128.3 (*C*), 125.3 (*C*H), 115.9 (*C*H), 50.1 (br., *C*HMe$_2$), 45.6 (*C*HMe$_2$), 39.8 (N*Me$_2$*), 35.5 (*C*Me$_3$), 32.4 (C*Me$_3$*), 24.9 (CH*Me$_2$*), 22.7 (CH*Me$_2$*), −8.8 (Zn*Me*) ppm. IR (nujol mull, KBr): $\tilde{\nu}$ = 3234 (m), 3140 (m), 1596 (s), 1518 (s), 1404 (s), 1365 (s), 1349 (m), 1318 (m), 1254 (s), 1243 (s), 1198 (w), 1183 (w), 1171 (w), 1136 (w), 1122 (m), 1102 (m), 1064 (w), 1047 (m), 975 (w), 938 (w), 881 (w), 853 (m), 814 (m), 752 (s), 686 (m), 634 (w) cm^{-1}.

$[\{Zn(OAr)\}_2(\mu\text{-}\{Me_2NC(NiPr)_2\})(\mu\text{-}NMe_2)]$ (7): 2,6-Di-*tert*-butylphenol (0.41 g, 2.00 mmol) in toluene (20 mL) was added dropwise at room temperature to a solution of **5** (0.50 g, 2.00 mmol) in toluene (30 mL). The resultant clear, pale-yellow solution was heated at 75 °C for 3 d, after which time a clear colourless solution had formed. The volatiles were removed to afford a waxy solid that was redissolved in hexane. Cooling of this solution to −30 °C afforded a small number of colourless crystals suitable for an X-ray analysis. ^{1}H NMR (C_6D_6, 298 K): δ = 7.36 (d, $^3J_{H,H}$ = 7.7, 4 H, *m*-C_6H_3), 6.86 (t, $^3J_{H,H}$ = 7.7, 2 H, *p*-C_6H_3), 2.98 (sept, $^3J_{H,H}$ = 6.4, 2 H, C*H*Me$_2$), 2.73 (s, 6 H, N*Me$_2$*), 2.16 (s, 6 H, N*Me$_2$*), 1.63 (s, 36 H, C*Me$_3$*), 0.87 (d, $^3J_{H,H}$ = 6.4, 12 H, CH*Me$_2$*) ppm. ^{13}C NMR (C_6D_6, 298 K): δ = 169.8 (*C*N$_3$), 165.6 (*C*), 138.2 (*C*), 125.1 (*C*H), 115.9 (*C*H), 48.6 (*C*HMe$_2$), 44.2 (N*Me$_2$*), 40.2 (N*Me$_2$*), 35.6 (*C*Me$_3$), 31.8 (C*Me$_3$*), 26.1 (CH*Me$_2$*) ppm.

[Zn(hpp){N(SiMe$_3$)$_2$}]$_2$ (8): A solution of hppH (0.18 g, 1.29 mmol) in toluene (20 mL) was added dropwise to a toluene solution (25 mL) of [Zn{N(SiMe$_3$)$_2$}$_2$] (0.50 g, 1.29 mmol) at room temperature. No visible change was observed. The solution was stirred at room temperature for 18 h, after which time the volatile components were removed in vacuo to afford [Zn(hpp)N(SiMe$_3$)$_2$]$_2$ as a white powder. Yield: 0.43 g (90%). Analytically pure samples for applications in polymerisation experiments were obtained by recrystallisation of a sample of **7** from hexane at −30 °C, affording colourless parallelepipedal crystals. $C_{26}H_{60}N_8Si_4Zn_2$ (727.92): calcd. C 42.90, H 8.31, N 15.39; found C 43.05, H 8.20, N 15.27. ^{1}H NMR (C_6D_6, 298 K): δ = 3.22 (m, 8 H, hpp-C*H*$_2$), 2.52 (t, $^3J_{H,H}$ = 6.4, 8 H, hpp-C*H*$_2$), 1.61 (quint, $^3J_{H,H}$ = 5.9, 8 H, hpp-C*H*$_2$), 0.36 (s, 36 H, Si*Me*$_3$) ppm. ^{13}C NMR (C_6D_6, 298 K): δ = 161.6 (*C*N$_3$), 47.9 (hpp-*C*H$_2$), 43.7 (hpp-*C*H$_2$), 23.8 (hpp-*C*H$_2$), 5.6 (Si*Me*$_3$) ppm. MS (EI$^+$): *m*/*z* = 347 [(hpp)Zn{N(SiMe$_3$)$_2$ − Me]$^+$.

X-ray Crystallographic Study: Details of the crystal data, intensity collection and refinement for complexes **3**−**8** are listed in Table 4. Crystals were covered with oil and suitable single crystals were selected under a microscope and mounted on a Kappa CCD diffractometer. The structures were refined with SHELXL-97.[47] Additional features are: [Zn{(Me$_3$Si)$_2$NC(N*i*Pr)$_2$}$_2$] (**3**): The molecule lies on a twofold rotation axis. [Zn{(Me$_3$Si)$_2$NC(NCy)$_2$}$_2$] (**4**): The molecule lies on a site of crystallographic 222 symmetry. [Zn{Me$_2$NC(N*i*Pr)$_2$}Me]$_2$ (**5**): The molecule lies on a twofold rotation axis. [Zn(OAr)Me{Me$_2$NC(N*i*Pr)(NH*i*Pr)}] (**6**): H on N(2) freely refined; all other H atoms riding. [Zn(hpp){N(SiMe$_3$)$_2$}]$_2$ (**8**): The molecule lies on a crystallographic inversion centre. CCDC-199300 (**3**), -199299 (**4**), -228536 (**5**), -228537 (**6**), -228538 (**7**) and -199301 (**8**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: + 44 -1223-336033; E-mail: deposit@ccdc.cam.ac.uk].

Synthesis and Structural Characterization of Monomeric Manganese(II) *N*-Heterocyclic Carbene Complexes [MnX_2(C{N(*i*Pr)C(Me)}$_2$)$_2$] (X = Cl, I, and MeCOO)

Jianfang Chai,[a] Hongping Zhu,[a] Ying Peng,[a] Herbert W. Roesky,*[a] Sanjay Singh,[a] Hans-Georg Schmidt,[a] and Mathias Noltemeyer[a]

Keywords: Carbene ligands / Manganese / Halides / Acetate

Reaction of $MnCl_2(THF)_{1.5}$, MnI_2, or $Mn(MeCOO)_2$ with two equivalents of *N*-heterocyclic carbene [C(Me)N(*i*Pr)]$_2$C (**1**) in THF at room temperature readily afforded the corresponding carbene adducts [MnX_2(C{N(*i*Pr)C(Me)}$_2$)$_2$] [X = Cl (**2**); X = I (**3**); X = MeCOO (**4**)] in good yield. Solid-state structural analysis of complexes **2**–**4** reveals that all complexes are monomeric. In complexes **2** and **3** the central manganese atoms are four coordinate and have a distorted tetrahedral geometry. The manganese atom in compound **4** has a coordination number of six and resides in a highly distorted octahedral geometry. The *N*-heterocyclic carbene ligands in these complexes are coordinated differently to the central metal atoms.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

The first carbenes were isolated in the late 1980s and early 1990s,[1] and since then there has been a revival of interest in carbene ligands,[2] which are formally neutral, two-electron donors. A major portion of the work has focused on *N*-heterocyclic carbenes due to their easy preparation and good thermal stability, which have been used to prepare a variety of main-group, transition metal, and lanthanide complexes.[2a,2c] A significant number of these complexes, especially the late transition metal complexes, have been shown to be effective catalysts in a number of organic reactions, such as hydrosilylation,[3] hydrogenation and hydroformylation of olefins or copolymerization of ethylene and CO.[2,4] In addition, palladium *N*-heterocyclic carbene complexes have been successfully applied in various C−C bond forming syntheses, in particular the Heck, Suzuki, and Kumada reactions.[2,5] Recently, iron(II) halides possessing *N*-heterocyclic carbenes of composition FeX_2L_2 [X = Cl, Br; L = C{N(*i*Pr)C(Me)}$_2$] were found to be remarkably active and efficient catalysts for atom-transfer radical polymerization.[6]

Manganese(II) complexes bearing tertiary phosphane ligands have been extensively studied.[7] It seems that chelating bidentate phosphane ligands are necessary to prepare monomeric manganese dihalide adducts such as dmpe and diphos. The isolation of [$MnX_2(PPh_3)_2$] has been questioned and it is likely that the complexes are [$MnX_2(OPPh_3)_2$] instead.[8] Until now, only one monomeric manganese(II) dihalide with a nonchelating phosphane ligand of composition [$MnI_2(PEt_3)_2$] has been unambiguously characterized.[8] *N*-Heterocyclic carbenes are considered to be analogues of tertiary phosphanes,[9] although they are stronger σ-donor ligands and therefore, in general, form more stable bonds to metals. Compared with tertiary phosphane ligands, *N*-heterocyclic carbene ligands have better thermal stability and oxidation resistance and a mobile steric effect upon changing the substituents at the nitrogen atoms.[2b] However, manganese *N*-heterocyclic carbene complexes are rare and have not attracted much attention to date.[2a] To the best of our knowledge, only a few manganese *N*-heterocyclic carbene complexes are known including [$Mn(MeC_5H_4)(CO)_2$(C{N(Me)CH_2}$_2$)],[10] [$MnBr(CO)_3$-(C{N(Me)CH_2}$_2$)],[10] and [$Mn(CO)_5$C{N(BH_3)C(Me)-C(Me)N(Me)}][11] with a formal oxidation state of +1 at the manganese. Therefore, we became interested in the synthesis and structures of *N*-heterocyclic carbene complexes containing manganese(II). Recently, we reported the first structurally characterized manganese *N*-heterocyclic carbene complex of composition [Mn(NHAr){HC-(CMeNAr)$_2$}(C{N(*i*Pr)C(Me)}$_2$)] (Ar = 2,6-*i*$Pr_2C_6H_3$), which shows that the Mn−C(carbene) bond length (2.27 Å) is in the range of an Mn−C single bond and that Mn→C(carbene) back-bonding is negligible.[12] For a better understanding of manganese *N*-heterocyclic carbene complexes and for comparison of *N*-heterocyclic carbenes with

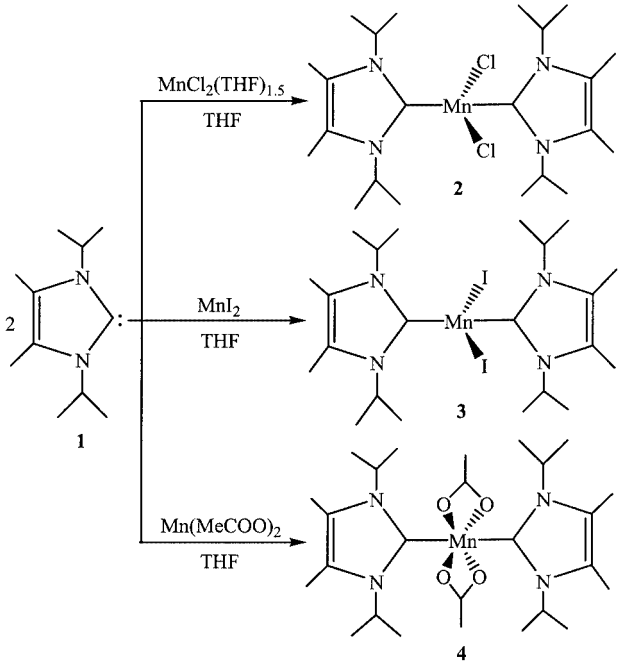
tertiary phosphane ligands, we describe herein the synthesis and structural characterization of several monomeric adducts of manganese(II) halides and acetate with *N*-heterocyclic carbenes $[MnX_2(C\{N(iPr)C(Me)\}_2)_2]$ [X = Cl (**2**); X = I (**3**); X = MeCOO (**4**)].

Results and Discussion

Synthesis of Compounds 2−4

The isolation of free stable *N*-heterocyclic carbenes enables the easy synthesis of a variety of carbene adducts that were previously inaccessible.[13] The reaction of $[MnCl_2(THF)_{1.5}]$, MnI_2, or $Mn(MeCOO)_2$ with two equivalents of $[C(Me)N(iPr)]_2C$ (**1**) in THF at room temperature readily afforded the corresponding carbene adducts in good yield (91% **2**, 77% **3**, and 81% **4**; Scheme 1). Compounds **2** and **4** are colorless solids and compound **3** is a light-orange solid. Compounds **2** and **3** are moderately air sensitive and can even be exposed to air for a short period of time when in the solid state, while compound **4** is much more sensitive to air. Compounds **2**−**4** are poorly soluble in non-polar solvents, although they are readily soluble in solvents such as CH_2Cl_2 and MeCN. Compound **4** has also a good solubility in THF, but **2** and **3** are sparingly soluble in THF. Complexes **2**−**4** have been characterized by mass spectrometry, IR spectroscopy, X-band EPR spectroscopy, microanalysis and single crystal X-ray structural analysis. The EI mass spectra of these compounds are similar: the molecular ion peak is not observed, but free carbene appears as the most intense signal at m/z = 180 (100%), which indicates the cleavage of the Mn−C(carbene) bond in these compounds under the experimental conditions. This is consistent with the results reported in the literature.[14] The IR spectrum of **4** displays two prominent vibrations for the O−C−O part of the acetate group ν_{as} (1599 cm^{-1}) and ν_s (1406 cm^{-1}). The absorption at about 1600 cm^{-1} is broad.



Scheme 1

X-ray Diffraction Analyses for Complexes 2−4

Compounds **2** and **3** are the first structurally characterized manganese halides possessing *N*-heterocyclic carbene ligands. Single crystals of **2** and **3** suitable for X-ray structural analysis were obtained by recrystallization from THF solutions at 4 °C. The molecular structures of **2** and **3** are shown in Figures 1 and 2, respectively; selected bond

N(3)−C(1)−Mn(1)	124.5(3)	N(4)−C(1)−Mn(1)	131.2(3)

lengths and angles are listed in Table 1. The manganese centers are four coordinate and have a distorted tetrahedral geometry in which each manganese is bonded to two halides and two carbene carbons. A crystallographic twofold axis passes through the metal center bisecting the angles X−Mn−X and C−Mn−C. There is a slight difference between the two structures due to the different ionic radius of Cl and I: the X−Mn−X (111.5°) and C−Mn−C (103.0°) angles in **2** are slightly larger than the corresponding ones in **3** (109.0° and 102.4°, respectively). The dihedral angle between the two carbene planes is 84.5° in **2** and 77.0° in **3**. These differences possibly result from the stronger repulsion between iodine and carbene in **3** than that between chlorine and carbene in **2**; this is also reflected in the EPR spectra.

The Mn−C(carbene) bond lengths (av. 2.21 Å) in **2** and **3** are in the expected range of Mn−C single bonds, but significantly shorter than the Mn−P bond lengths found in $[MnI_2(PEt_3)_2]$[8] (av. 2.53 Å) and $[MnI_2(PPhMe_2)]_n$ [15] (av. 2.67 Å). The Mn−I distances (av. 2.72 Å) in **3** are a little longer than those in $[MnI_2(PEt_3)_2]$ (av. 2.67 Å)[8] due to the different *trans* influence. However, the I−Mn−I (109.0°) and C−Mn−C (102.4°) angles in **3** are significantly smaller than the corresponding ones (120.1° and 115.1°, respectively) in $[MnI_2(PEt_3)_2]$.[8]

The N(1)−C(1)−Mn(1) (131.6°) and N(3)−C(6)−Mn(1) (132.3°) angles deviate significantly from their counterparts N(2)−C(1)−Mn(1) (123.9°) and N(4)−C(6)−Mn(1) (122.6°) in **2**, which implies that both the *N*-heterocyclic carbenes undergo *in-plane* bending.[16] However, *out-of-plane* bending is only observed for one *N*-heterocyclic carbene ligand [C(6), N(3), C(7), C(8) and N(4)] and the Mn(1)−C(6) bond lies out of the *N*-heterocyclic carbene plane by 6.4°. The other *N*-heterocyclic carbene and the central manganese atom are coplanar. In **3**, both the *N*-heterocyclic carbene ligands undergo *out-of-plane* bending, as shown by the Mn−C bond angles, which deviate from the corresponding *N*-heterocyclic carbene planes by 4.7° and 4.3°, respectively. These angles are in the normal range.[14]

Compound **4** is the first structurally characterized monomeric manganese complex containing two symmetric chelating acetate groups. Single crystals suitable for X-ray structural analysis were grown from THF solution at −26 °C. The molecular structure is shown in Figure 3; selected bond lengths and bond angles are listed in Table 2. Complex **4** crystallizes in the monoclinic space group *C*2/*c*. The central manganese atom is surrounded by four oxygen atoms from the two chelating carboxy groups and two carbene carbon atoms in a highly distorted octahedral geometry. The complex adopts a symmetric structure. A mirror plane passes through the manganese atom bisecting the two acetate groups and the two carbenes.

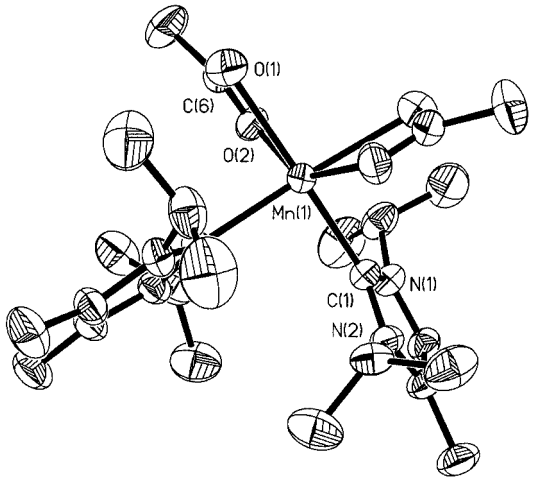

Figure 3. Molecular structure of **4** (50% probability ellipsoids); hydrogen atoms are omitted for clarity

The two acetate groups are symmetrically bonded, in a chelating fashion, to the manganese atom, resulting in the formation of two MnOCO four-membered rings. Both rings are planar and nearly orthogonal, as shown by a dihedral angle of 85.8°. Manganese complexes containing chelating carboxy groups are rare.[17] The Mn−O distances from the O *trans* to the *N*-heterocyclic carbene carbon (2.34 Å) are slightly longer than those (2.23 Å) from the O *cis* to the carbon, probably due to the strong donor property of the *N*-heterocyclic carbene. Accordingly, the shorter Mn−O bond is associated with a longer carboxy C−O bond. The average value (2.29 Å) of the Mn−O distance is significantly longer than that of the bridging carboxyl group in the $[Mn_2(\mu\text{-MeCOO})_x]^{4-x}$ system (1.99−2.13 Å),[18] and is also longer than that (av. 2.07 Å) of the chelating acetate group in $[Mn(MeCOO)(CO)_2(PPh_3)_2]$.[19] The distance from

O(2)−Mn(1)−O(1A)	98.60(8)	N(2)−C(1)−Mn(1)	126.67(18)
N(1)−C(1)−Mn(1)	129.32(18)		

the manganese atom to the central carbon atom of the acetate group (2.61 Å) is in the non-bonding range.[19]

The C−Mn−C angle in **4** is 96.7°, which shows that the two *N*-heterocyclic carbenes are in a *cis* position. The Mn−C distance (2.25 Å) is in the range (2.20−2.27 Å) of the Mn−C(*N*-heterocyclic carbene) distances known and is slightly longer than those in **2** and **3**.

Interestingly, no *in-plane* or *out-of-plane* bending of the *N*-heterocyclic carbenes is found in **4**. The similar N(1)−C(1)−Mn(1) (129.3°) and N(2)−C(1)−Mn(1) (126.7°) angles do not support any *in-plane* bending of the *N*-heterocyclic carbenes.

Solid-State Powder EPR Measurements

Manganese(II) complexes give a great variety of EPR signals related to their structures.[20] The X-band EPR spectra of complexes **2**−**4** were recorded at ambient temperature for powder samples. As expected, a strong resonance in complexes **2** and **3** is observed near $g_{eff} = 4.3$ due to their tetrahedral geometry.[21a] In addition, compound **2** exhibits two shoulders at lower field and several weaker bands at higher field, while the spectrum of **3** is much simpler: another strong resonance ($g_{eff} = 2$) and a very weak one at high field. The spectrum of compound **4** exhibits a very strong band ($g_{eff} = 2$) and a weaker one (near $g_{eff} = 4.3$) and has shoulders at higher and lower field of the main line. The spectrum of **4** is very similar to that of $[Mn(o\text{-phen})_2(NCS)_2]$, which has a very small D value (near zero) and a large λ value (near 1/3) (D and λ are zero-field splitting parameters).[21b] The spectrum is consistent with the symmetric structure of **4** and the *cis* arrangement of the two carbene ligands.

Conclusion

In summary, we have shown that the *N*-heterocyclic carbene ligand $[C(Me)N(i\text{Pr})]_2C$ (**1**) forms stable adducts **2**−**4** with manganese(II) halides and acetate. The X-ray structural analyses show that complexes **2**−**4** are monomeric and the *N*-heterocyclic carbene ligands in these complexes are arranged differently at the central metal atoms. These results indicate that the *N*-heterocyclic carbene ligand is a better ligand to form monomeric adducts than the tertiary phosphane ligand.

Experimental Section

General: All reactions were performed using standard Schlenk and drybox techniques. Solvents were appropriately dried and distilled under dinitrogen prior to use. Elemental analyses were performed by the Analytisches Labor des Instituts für Anorganische Chemie der Universität Göttingen. Mass spectra were obtained on a Finnigan Mat 8230. IR spectra were recorded on a Bio-Rad Digilab FTS-7 spectrometer as Nujol mulls between KBr plates. The EPR spectra were recorded on a Bruker Elexsys E 500 X-band spectrometer. All samples were measured as crystalline powders in an argon atmosphere at room temperature with a modulation frequency of 100 kHz, 3−5 G modulation amplitude, about 9.42 GHz microwave frequency and microwave power in the range between 2 and 10 mW as spectrometer settings. $[C(Me)N(i\text{Pr})]_2C$[22] (**1**) was prepared by the literature protocol.

Preparation of 2: THF (40 mL) was added to a mixture of **1** (0.72 g, 4 mmol) and $[MnCl_2(THF)_{1.5}]$ (0.47 g, 2 mmol) at room temperature. The suspension was stirred for 13 h. The solvent was concentrated to about 3 mL and the colorless precipitate was collected by filtration. Yield: 0.88 g (91%). M.p. 268−270 °C. $C_{22}H_{40}Cl_2MnN_4$ (486.42): calcd. C 54.27, H 8.22, N 11.51; found C 54.32, H 8.23, N 11.52. IR (KBr, Nujol mull): $\tilde{\nu}$ = 1629 cm^{-1} (m), 1552 (w), 1401 (m), 1376 (s), 1360 (s), 1262 (vw), 1218 (m), 1168 (w), 1136 (m), 1107 (w), 1070 (m), 1023 (w), 968 (vw), 931 (vw), 905 (w), 885 (w), 803 (vw), 751 (m), 722 (m), 674 (vw), 544 (m), 412 (w).

Preparation of 3: The procedure is the same as that described for **2**. Yield: 1.03 g (77%). M.p. 273−283 °C. $C_{22}H_{40}I_2MnN_4$ (669.32): calcd. C 39.46, H 5.98, N 8.37; found C 39.54, H 6.00, N 8.34. IR (KBr, Nujol mull): $\tilde{\nu}$ = 1629 cm^{-1} (m), 1552 (w), 1398 (m), 1377 (s), 1364 (s), 1291 (vw), 1262 (vw), 1219 (m), 1191 (vw), 1168 (w), 1136 (m), 1109 (w), 1071 (m), 1023 (w), 968 (vw), 931 (vw), 905 (w), 886 (w), 848 (vw), 803 (vw), 750 (m), 722 (m).

Preparation of 4: THF (40 mL) was added to a mixture of **1** (0.72 g, 4 mmol) and $Mn(MeCOO)_2$ (0.34 g, 2 mmol) at room temperature. A clear solution was obtained immediately and stirred for 6 h. The solution was concentrated to about 5 mL and kept at −26 °C for 3 days to give colorless crystals. Yield: 0.86 g (81%). M.p. 156−158 °C. $C_{26}H_{46}MnN_4O_4$ (532.96): calcd. C 58.54, H 8.63, N 10.51; found C 58.58, H 8.67, N 10.14. IR (KBr, Nujol mull): $\tilde{\nu}$ = 1750 cm^{-1} (vw), 1695 (vw),1628 (s), 1599 (vs), 1573 (s), 1406 (s), 1323 (m), 1260 (m), 1238 (w), 1222 (m), 1195 (w), 1167 (vw), 1138 (m), 1112 (m), 1073 (w), 1048 (vw), 10231 (vw), 917 (w), 908 (w), 888 (vw), 804 (s), 751 (m), 722 (m), 658 (s), 648 (w), 616 (m), 544 (m), 483 (w), 457 (vw), 411 (vw).

X-ray Crystallography: Crystallographic data (see Table 3) for complexes **2**−**4** were collected on a Stoe−Siemens−Huber four-circle diffractometer coupled to a Siemens CCD area detector with graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å). All structures were solved by direct methods (SHELXS-97)[23] and refined against F^2 using SHELXL-97.[24] All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were included at geometrically calculated positions and refined using a riding model.

Dedicated to G.-V. Röschenthaler on the occasion of his 60th birthday

Keywords: Syntheses / Crystal structures / Iridium(I) / Fluoro complexes / Pentafluorosilicates

Cyclooctadienefluorotriphenylphosphaneiridium(I) [IrF(C_8H_{12})(PPh_3)] (**3**) was prepared and its structure determined by single crystal X-ray diffraction analysis. Complex **3** crystallises in the monoclinic space group $P2_1/n$. The lattice parameters are a = 931.9(3) pm, b = 1629.4(7) pm, c = 1592.9(7) pm, $\alpha = \gamma = 90°$, β = 92.85(3)°. Number of molecules per unit cell is 4. The square planar iridium complex **3** exhibits an Ir–F bond length of 201.3(5) pm. **3** was obtained in Teflon tubes, whereas the use of glass vessels led to cyclooctadiene-bis(triphenylphosphane)iridium(I)-pentafluorosilicate(IV) ([Ir(C_8H_{12})(PPh_3)$_2$][SiF_5]) (**4**). The composition of **4** was confirmed by single crystal X-ray diffraction analysis. **4** crystallises in the monoclinic space group $P2_1/c$. The lattice parameters are a = 1157.4(9) pm, b = 1864.4(9) pm, c = 1922.5(17) pm, $\alpha = \gamma = 90°$, β = 96.16(7)°. The number of molecules per unit cell is 4. The square-planar coordinated iridium cation [Ir(C_8H_{12})(PPh_3)$_2$]$^+$ is separated from the trigonal bipyramidal [SiF_5]$^-$ anion by 461.1 pm (shortest Ir···F distance) and thus it is assumed that no interactions occur between the fluorine and iridium atoms.

Introduction

There is ongoing interest in low oxidation state transition metal compounds containing fluorine-metal and carbon-metal bonds as a result of their use in synthesis and catalysis.[1−3] In the presence of π back-bonding ligands fluoro complexes of d^8 metals are stable although they object the predicted hard/soft acid/base (HSAB) rules. This has been shown for the iridium Vaska system $IrF(CO)(PPh_3)_2$, whose derivatives are the only known *organometallic fluorides* in the chemistry of iridium(I).[1,4] Compounds of this type are certainly the most extensively studied and readily prepared systems but structural characterisation has not been accomplished. Thus far, bond length parameters are available only for iridium d^6 centers e.g. Cp*$IrF(Ph)(PMe_3)$,[5] $Ir(Cl)F(NSF_2)(CO)(PPh_3)_2$,[6] [IrF($\eta^2$-NH=$NC_6H_3$-2-$CF_3$)(CO)($PPh_3$)$_2$][$BF_4$],[7] $Ir(FBF_3)Me_2(PMe_2Ph)_3$,[8] and [Ir{C(F)O}F(CO)$_2$(PEt_3)$_2$][BF_4].[9] Iridium(I) complexes with cyclooctadiene or cyclooctene as the stabilising C-based ligands are well-known and widely used as starting materials in organometallic chemistry. However, appropriate fluorides are missing, although some are accessible, as in the case of homologous rhodium(I) olefin complexes.[10−12]

Moreover, complexes of weakly or non-coordinating fluorinated anions such as $[BF_4]^-$, $[PF_6]^-$, $[AsF_6]^-$ and $[SbF_6]^-$ are of special interest in organometallic fluorine chemistry. For instance, the iridium complex [Ir(C_8H_{12})(PCy_3)(py)][PF_6] has been widely used as a catalyst for the reduction of hindered alkenes and [Ir(C_8H_{12})(PPh_3)$_2$][PF_6] has also proven to be useful as a hydrogenation catalyst.[13,14] However, the investigation of pentacoordinate fluorosilicon anions enjoys increasing interest. Large cations are required for the stabilisation of the rather unstable $[SiF_5]^-$ anion ($[SiF_5]^- \rightarrow SiF_4 + F^-$).[15] In recent years a rising number of transition metal complexes containing $[SiF_5]^-$, like in [PtCl(CO)(PEt_3)$_2$][SiF_5],[16] [Ir(H_2)(CO)(PPh_3)$_3$][SiF_5],[17] [Au(PPh_3)$_3$][SiF_5],[18] [Ir(CO)$_2$($PtBu_2Ph$)$_2$][SiF_5],[19] [Ir(H_2)(CO)$_2$($PtBu_2Ph$)$_2$][SiF_5][19] and [Co(NioxH)$_2$(PPh_3)$_2$][SiF_5] ($NioxH_2$ is 1,2-cyclohexanedione dioxime)[20] have been reported.

Herein, we describe the syntheses and characterisations of the novel organoiridium(I) fluoro complex $IrF(C_8H_{12})(PPh_3)$ (**3**) and of the complex salt [Ir(C_8H_{12})(PPh_3)$_2$][SiF_5] (**4**). The crystal structure analysis of **3** lead to the first iridium(I) fluorine bond parameters, whereas that of **4** is probative for the formation of the $[SiF_5]^-$ anion.

Results and Discussion

During our research with the aim of obtaining novel iridium fluorides, the use of most of the usual fluorination ag-

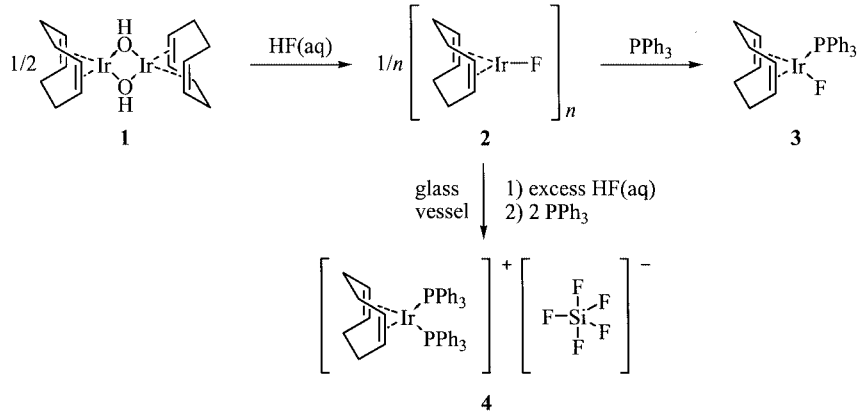

Scheme 1

ents including AgF, Me_3SnF, $(Me_2N)_3S^+(Me_3SiF_2)^-$ (TASF) or XeF_2 failed. The synthesis of $IrF(C_8H_{12})(PPh_3)$ (**3**) was finally successful using aqueous HF as the fluorinating agent, according to the procedure described for the rhodium(I) analogue.[10]

Treatment of a solution of $[Ir(\mu\text{-}OH)(C_8H_{12})]_2$ (**1**)[21] in THF with 73% aqueous HF in a Teflon tube gave compound **2** as a yellow precipitate in virtually quantitative yield (Scheme 1). Due to its insolubility in organic solvents NMR spectroscopic data are not available and, unfortunately, the mass spectrum only shows the fragmentation pattern of the coordinated cyclooctadiene ligand. The formation of an iridium fluoro complex can only be derived from the IR spectrum of compound **2**, which exhibits the $\tilde{\nu}_{IrF}$ stretching mode at 478 cm^{-1} similar to that of $\tilde{\nu}_{IrF}$ = 451 cm^{-1} in $IrF(CO)(PPh_3)_2$.[22] Therefore, a polymeric structure for compound **2** is proposed.

Reaction of triphenylphosphane with a suspension of **2** in THF results in the formation of a reddish solution. After addition of pentane, $IrF(C_8H_{12})(PPh_3)$ (**3**) crystallised as an orange solid. The ^1H NMR spectrum of **3** shows two sets of resonances for the four olefinic protons of the cyclooctadiene ligand. Due to the asymmetric coordination at the iridium(I) centre, one resonance appears at δ = 5.42 ppm (*m*, 2 H), whereas the other one is shifted upfield to δ = 2.59 ppm (*m*, 2 H). These values are similar to those (δ = 5.15 and 2.73 ppm) reported for $IrCl(C_8H_{12})(PPh_3)$.[23] The difference between the two signals is presumably due to the unequal *trans* influence of PPh_3 and F^-. In the ^{19}F NMR spectrum of **3**, a singlet was observed at $\delta = -219.3$ ppm, characteristic of an iridium(I)-bound fluorine atom and the $^{31}P\{^1H\}$ NMR spectrum displays a singlet at δ = 25.1 ppm.

Single crystals suitable for X-ray diffraction analysis of **3** were obtained by slow diffusion of pentane into a concentrated THF solution. Compound **3** crystallises in the monoclinic space group $P2_1/n$. The asymmetric unit contains one molecule of $IrF(C_8H_{12})(PPh_3)$ and half a solvent molecule of THF. Figure 1 shows the molecular structure of $IrF(C_8H_{12})(PPh_3)$ (**3**) along with selected bond lengths and angles. As expected from the larger *trans* influence of PPh_3 with respect to F^-, the Ir(1)−C(5) and Ir(1)−C(6) distances are longer than the Ir(1)−C(1) and Ir(1)−C(2) ones (Figure 1). The Ir(1)−F(1) bond length of 201.3(5) pm in **3** is shorter than those in iridium d^6 compounds, e.g. Cp* $IrF(Ph)(PMe_3)$ 206.9(4) pm,[5] $Ir(Cl)F(NSF_2)(CO)(PPh_3)_2$ 208.9(4),[6] $[IrF(\eta^2\text{-}NH{=}NC_6H_3\text{-}2\text{-}CF_3)(CO)(PPh_3)_2][BF_4]$ 221(4) pm,[7] and $Ir(FBF_3)Me_2(PMe_2Ph)_3$ 238.9(7) pm.[8] This might be due to π back-donation of the olefin ligand in **3**, causing stabilisation of such complexes.[4] The only exception is the iridium(III) fluoro complex $[Ir\{C(F)O\}F(CO)_2(PEt_3)_2][BF_4]$ with an Ir−F separation of 199.8(3) pm.[9] Complex **3** represents the first crystal structure to be determined for an organoiridium(I) fluoro complex.

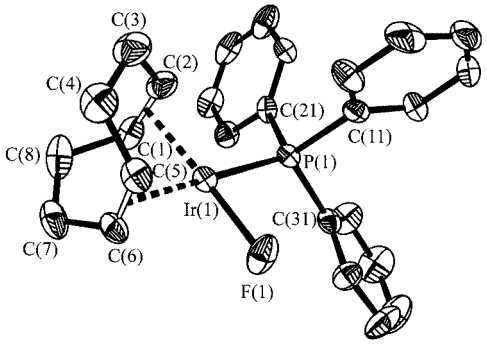

Figure 1. Molecular structure of $IrF(C_8H_{12})(PPh_3)$ (**3**) (without THF) with 50% probability ellipsoids and the labelling scheme; selected bond lengths (pm) and angles (°): Ir(1)−F(1) 201.3(5), Ir(1)−C(1) 209.3(9), Ir(1)−C(2) 208.7(8), Ir(1)−C(5) 218.9(8), Ir(1)−C(6) 217.2(7), C(1)−C(2) 140.0(13), C(5)−C(6) 139.3(12), Ir(1)−P(1) 231.93(19), P(1)−C(11) 181.9(7), P(1)−C(21) 181.7(7), P(1)−C(31) 181.8(8); F(1)−Ir(1)−C(1) 161.2(3), F(1)−Ir(1)−C(2) 157.9(3), F(1)−Ir(1)−C(5) 88.6(3), F(1)−Ir(1)−C(6) 86.6(3), F(1)−Ir(1)−P(1) 90.32(15), C(1)−Ir(1)−P(1) 97.8(2), C(2)−Ir(1)−P(1) 92.3(2), C(5)−Ir(1)−P(1) 159.0(2), C(6)−Ir(1)−P(1) 163.5(2)

However, treatment of **1** with aqueous HF carried out in glass vessels resulted in deep red crystals. This side product is insoluble in THF, but can be recrystallised from a dichloromethane/pentane mixture. This compound was unambiguously identified as the complex salt $[Ir(C_8H_{12})(PPh_3)_2][SiF_5]$ (**4**) by IR and NMR spectroscopy as well as single crystal structure analyses. The formation

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

of the cationic iridium complex $[Ir(C_8H_{12})(PPh_3)_2]^+$ in the presence of weakly coordinating anions is well-known.[14] In addition, the appearance of the $[SiF_5]^-$ anion is not unexpected, if reactions involving HF are carried out in glass vessels.[20] Thus, the reaction of **1** in THF with an excess of aqueous HF in a glass vessel affords **4** in quantitative yield, after two equiv. of triphenylphosphane were added (Scheme 1). The ^{1}H NMR spectrum of **4** shows three resonances of equal intensity for the protons of the cyclooctadiene ligand [δ = 4.20 (br. s, 4 H), δ = 2.33 (m, 4 H) and δ = 1.97 ppm (m, 4 H)]. These values are similar to δ = 4.14 (s, 4 H) and δ = 2.12 ppm (m, 8 H) found in $[Ir(C_8H_{12})(PPh_3)_2][BF_4]$.[24] The formation of the cationic bisphosphane complex is best documented by its ^{13}C NMR spectrum. The resonance for the carbon atoms of the =*C*H− groups of the cyclooctadiene ligand appears as a triplet [δ = 87.40 ppm (t, *J* = 5.58 Hz)] indicative of coupling to two phosphorus nuclei, whereas the −*C*H$_2$− groups show a singlet at δ = 31.37 ppm. In the ^{19}F NMR spectrum a broad resonance (δ = −139.1 ppm) is observed. This is in good agreement with that reported (δ = −139 ppm) for the $[SiF_5]^-$ anion in $[Au(PPh_3)_3][SiF_5]$.[18] The ^{31}P NMR resonance is shifted upfield in comparison to that of compound **3** and appears as a singlet at δ = 17.4 ppm. Compound **4** gives rise to bands in the infrared spectrum at ($\tilde{\nu}$ = 879, 790, 479 and 448 cm^{-1} CsI plates), due to Si−F modes similar to those reported in the literature.[16]

Single crystals suitable for X-ray diffraction analyses of **4** were obtained by slow diffusion of pentane into a concentrated CH_2Cl_2 solution. Compound **4** crystallises in the monoclinic space group $P2_1/c$. A structure determination showed one $[Ir(C_8H_{12})(PPh_3)_2]^+$ cation, one non-coordinated $[SiF_5]^-$ anion and a solvent molecule CH_2Cl_2 in the asymmetric unit. The cation is depicted in Figure 2 together with selected bond lengths and angles. The iridium-phosphorus bond lengths [Ir(1)−P(1) 233.1(3) and Ir(1)−P(2) 235.3(3) pm] are similar to those of Ir−P(1) 236.7(2) and Ir−P(2) 232.6(3) pm found in $[Ir(C_8H_{12})(PPh_3)_2][PF_6]$.[14]

The $[SiF_5]^-$ anion is not coordinated to an iridium atom (shortest Ir···F distance is 461.1 pm). The geometry of the silicon atom is regular bipyramidal. The Si−F$_{eq}$ bond lengths are Si(1)−F(1) 158.4(10), Si(1)−F(3) 159.8(10) and Si(1)−F(5) 158.3(10) pm. The Si−F$_{ax}$ distances are longer, with values of Si(1)−F(2) 162.3(10) and Si(1)−F(4) 162.5(11) pm. The bond lengths and angles for the $[SiF_5]^-$ anions in the compounds $[Au(PPh_3)_3][SiF_5]$, $[Ir(CO)_2(PtBu_2Ph)_2][SiF_5]$ and $[Ir(H)_2(CO)_2(PtBu_2Ph)_2][SiF_5]$, are in the same range as those for compound **4**.[18,19]

Once compound **3** has been isolated it does not interact with the glass surface. Evidence for that is derived from NMR and IR spectroscopic data obtained from the oily residue, formed in a glass vessel, as a result of the decomposition of **3** after some weeks. In the ^{19}F NMR spectrum a triplet (δ = −256.3 ppm, t, *J* = 28.8 Hz) and in the ^{31}P{H} NMR spectrum a doublet (δ = 24.5 ppm, d, *J* = 28.7 Hz) suggest the formation of a complex, which has one fluorine atom and two phosphane groups bonded to the iridium atom. The IR spectrum exhibits a band at 1945 cm^{-1} attributable to a $\tilde{\nu}_{CO}$ mode. These data lead to the assumption that one of the products of the decomposition of **3** is the Vaska complex $IrF(CO)(PPh_3)_2$. The formation of a carbonyl complex is in agreement with reports of the ability of rhodium(I) systems to abstract carbon monoxide from oxygen-containing organic solvents.[25]

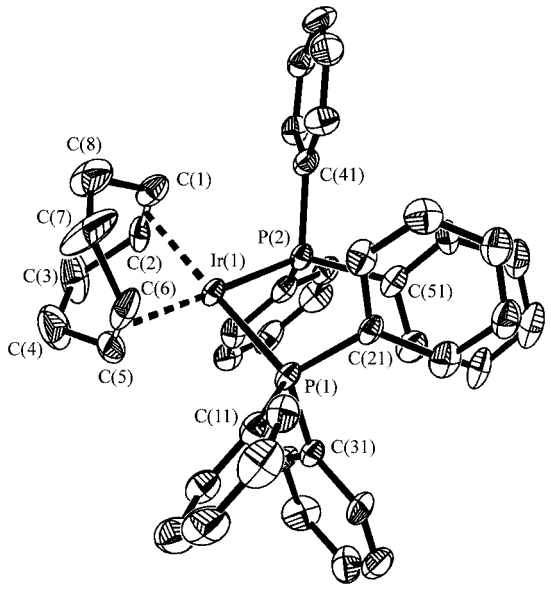

Figure 2. Molecular structure of the $[Ir(C_8H_{12})(PPh_3)_2]^+$ cation in **4** with 50% probability ellipsoids and the labelling scheme; selected bond lengths (pm) and angles (°): Ir(1)−C(1) 221.5(11), Ir(1)−C(2) 223.5(10), Ir(1)−C(5) 216.5(11), Ir(1)−C(6) 219.5(11), Ir(1)−P(1) 233.1(3), Ir(1)−P(2) 235.3(3), C(1)−C(2) 140.8(16), C(5)−C(6) 132.3(19), P(1)−C(11) 184.1(11), P(1)−C(21) 180.6(11), P(1)−C(31) 181.4(10), P(2)−C(41) 183.0(11), P(2)−C(51) 184.3(10), P(2)−C(61) 183.9(11); C(1)−Ir(1)−P(1) 153.7(3), C(2)−Ir(1)−P(1) 168.7(3), C(5)−Ir(1)−P(1) 95.6(3), C(6)−Ir(1)−P(1) 89.5(3), C(1)−Ir(1)−P(2) 93.9(3), C(2)−Ir(1)−P(2) 86.7(2), C(5)−Ir(1)−P(2) 152.0(4), C(6)−Ir(1)−P(2) 170.4(4), P(1)−Ir(1)−P(2) 94.43(9)

Conclusion

The present study describes the synthesis and characterisation of $IrF(C_8H_{12})(PPh_3)$ and provides the first crystallographic data for an organoiridium(I) fluoro complex. The reaction of $[Ir(\mu\text{-}OH)(C_8H_{12})]_2$ with concentrated aqueous HF yields the fluoro complex, only in Teflon tubes, whereas the use of glass vessels led to $[Ir(C_8H_{12})(PPh_3)_2][SiF_5]$. The X-ray diffraction analysis of this iridium(I) complex salt shows that the rather unstable $[SiF_5]^-$ anion can be trapped.

Experimental Section

General Remarks: Solvents were dried and distilled under nitrogen prior to use. All reactions were carried out under dry nitrogen, using standard Schlenk techniques. NMR spectra were recorded using a Bruker Avance 200, Bruker MSL 400 or a Bruker Avance 500 spectrometer and referenced to the resonances of the residual protons in deuterated benzene or CD_2Cl_2. ^{1}H NMR: external

standard TMS. ^{13}C NMR: external standard TMS. ^{19}F NMR: external standard CCl_3F. ^{31}P NMR: external standard 85% H_3PO_4. Infrared spectra were recorded on a BIO-RAD Digilab FTS 7 spectrometer. [Ir(μ-OH)(C_8H_{12})]$_2$ (**1**) was prepared by literature methods.[21] All other materials used in the syntheses were reagent grade chemicals and used without further purification.

IrF(C_8H_{12})(PPh_3) (3): Aqueous HF (50.0 μL, 2.00 mmol, 73%) solution was added to a solution of **1** (0.63 g, 1.00 mmol) in THF (10 mL). The reaction mixture was allowed to stand overnight to form a yellow insoluble precipitate **2,** which was filtered off and dried in vacuo. The solid was treated with a solution of PPh_3 (0.52 g, 2.00 mmol) in THF (10 mL) and the mixture was stirred until all solids had dissolved. The resulting reddish solution was layered with pentane (40 mL). After standing overnight orange crystals had formed which were filtered off and dried under reduced pressure. The product was recrystallised from THF/pentane (0.83 g, 71%). M.p. 218 °C (decomp.). $C_{26}H_{27}FIrP$ (581.68): calcd. C 53.69, H 4.68; found C 53.47, H 4.81. ^{1}H NMR (300.13 MHz, C_6D_6): δ = 1.40 (m, 4 H, CH_2), 2.05 (m, 4 H, CH_2), 2.59 (m, 2 H, CH), 5.42 (m, 2 H, *CH*), 7.08 (m, 9 H, C_6H_5), 7.93 (m, 6 H, C_6H_5) ppm. ^{19}F NMR (188.27 MHz, CCl_3F): δ = −219.3 (s, IrF) ppm. ^{31}P NMR (121.50 MHz, C_6D_6): δ = 25.1 (s, IrP). EIMS 70 eV, *m*/*z* (rel. int.): 582 [M] (5), 262 [M − Ir−C_8H_{12}−F] (100), 108 [M − Ir−P(C_6H_5)$_3$−F] (20).

[Ir(C_8H_{12})(PPh_3)$_2$][SiF_5] (4): Aqueous HF (0.50 mL, 20.0 mmol, 73%) solution was added to a solution of **1** (0.63 g, 1.00 mmol) in THF (10 mL) in a glass vessel . The reaction mixture was allowed to stand overnight to form a yellow insoluble precipitate, which was filtered off and dried in vacuo. The solid was treated with a solution of PPh_3 (1.05 g, 4.00 mmol) in THF (10 mL) and the mixture was stirred for 24 h. Deep red crystals formed which were filtered off and dried under reduced pressure. The product was recrystallised from CH_2Cl_2/pentane (1.80 g, 96%). $C_{44}H_{42}F_5IrP_2Si$ (948.05): calcd. C 55.74, H 4.47; found C 55.41, H 4.65. IR (CsI): $\tilde{\nu}$ = 879, 790, 479 and 448 cm^{-1} (SiF_5^-). ^{1}H NMR (300.13 MHz, CD_2Cl_2): δ = 1.97 (m, 4 H, CH_2), 2.32 (m, 4 H, CH_2), 4.20 (s, 4 H, CH), 7.39 (m, 15 H, C_6H_5) ppm. ^{13}C NMR (125.77 MHz, CD_2Cl_2): δ = 31.4 (s, C-3, C-4, C-7, C-8), 87.4 (t, *J* = 5.6 Hz, C-1, C-2, C-5, C-6), 128.9 (t, *J* = 5.2 Hz, C_6H_5), 131.7 (t, *J* = 1.0 Hz, C_6H_5), 134.6 (t, *J* = 5.5 Hz, C_6H_5) ppm. ^{19}F NMR (188.27 MHz, CCl_3F): δ = −139.1 (s, SiF_5) ppm. ^{31}P NMR (121.50 MHz, CD_2Cl_2): δ = 17.8 (s, IrP_2) ppm. FAB$^+$MS 70 eV, *m*/*z* (rel. int.): 825 [Ir(C_8H_{12})(PPh_3)$_2$] (100). FAB$^-$MS 70 eV, *m*/*z* (rel. int.): 123 [SiF_5] (100).

X-ray Crystallographic Study: The single crystals were mounted on a glass fibre in a frozen paraffin drop. Diffraction data were collected on a STOE AED2 four-circle diffractometer with graphite-monochromated Mo-K_α radiation (λ = 71.073 pm). The crystal structures were solved by direct methods using SHELXS-97[26] and refined with SHELXL-97[27] against F^2 for all data by full-matrix least-squares. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were included in the model at fixed positions. A summary of the crystal data is given in Table 1.

CCDC-228254 (for **3**) and -228255 (for **4**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Synthesis and Characterization of Ti Complexes Using 4-*tert*-Butyl-2,6-bis(hydroxymethyl)phenol: X-ray Structures of a Confacial Bioctahedron with Terminal Nucleophilic Phenylmethoxide Ligands, and a Ti_4O_{16} Core Protected by Two Hydrophobic Binding Pockets

Thorsten Glaser,*[a] Ioannis Liratzis,[a] Thomas Lügger,[a] and Roland Fröhlich[b]

Keywords: Tridentate ligands / O ligands / Titanium

Treatment of 4-*tert*-butyl-2,6-bis(hydroxymethyl)phenol (H_3L) with $[TiO(acac)_2]$ in protic solvents at elevated temperatures leads to the formation of the dinuclear complex $(Et_4N)[L_3Ti_2]$ **1**, whereas carrying out the reaction at room temperature or in aprotic solvents leads to the formation of the tetranuclear complex $(Et_4N)_2[L_2(HL)_4Ti_4O_2]$ **2**. Heating **2** in protic solvents leads to the formation of **1**, but **2** is stable in non-protic solvents such as THF even upon heating. Dissolving **1** in an aprotic solvent leads to the formation of **2**. The anion of **1** consists of a confacial bioctahedron with a $[(BzO)_3Ti^{IV}(\mu_2\text{-}OPh)_3Ti^{IV}(OBz)_3]^-$ core. The phenylmethoxide ligands (BzO^-), and the phenolato ligands are bound to the strong Lewis acid Ti^{IV}. The bond lengths are for Ti–OBz ca. 1.83 Å and for Ti–μ_2-OPh ca. 2.11 Å. Despite the highly covalent Ti–OBz bond, the phenylmethoxide ligands exhibit nucleophilic character, and a tendency to bridge two Ti^{IV} ions as demonstrated by the synthesis of the tetranuclear complex **2**. The dianion in **2** consists of a Ti_4O_{16} core with two hydrophobic half-bowl shaped pockets built from three *tert*-butylbenzene units each. The hydrophobic pockets allow access to the Lewis basic $\mu_3\text{-}O^{2-}$ ligands of the Ti_4O_{16} core. In the crystal structure of **2**·$2CH_3CN$, two Et_4N^+ cations occupy these two binding pockets.

Introduction

In 1970, Robson introduced the concept of dinucleating ligands (compartmental ligands, Robson type ligands).[1] Since then, there has been a steady increase in the number and type of such ligands synthesized in non-cyclic or macrocyclic versions. These ligands are based on the 2,6-bis(iminomethyl)phenol (**A**) and 2,6-bis(aminomethyl)-phenol (**B**) backbones (Scheme 1). The synthesis of homo- and hetero-dinuclear transition metal complexes enabled detailed investigations of their magnetochemical and electrochemical properties. Theses studies provided important insight into the molecular and electronic structure of dinuclear metallo-proteins, and into the cooperativity of such sites in catalysis.[2] The corresponding ligand system based on 2,6-bis(hydroxymethyl)phenol (**C**) (Scheme 1), however, has only recently been used for the synthesis of metal complexes.[3,4] Furthermore, a search of the Cambridge Structural Database indicates that the structural coordination chemistry of phenylmethoxide ligands has, in general, not been well explored.[5] We are interested in dinuclear face-sharing octahedral transition metal complexes (confacial bioctahedra) using ligands based on **C**, because this bridging mode provides short metal-metal distances giving rise to strong electronic communications. The corresponding ligands based on **A** and **B** have already been used for the synthesis of confacial bioctahedra with $N_3M(\mu_2\text{-}OPh)_3MN_3$[6] and $N_3M(\mu_2\text{-}SPh)_3MN_3$cores.[7] Due to their terminal facial $(R_nN)_3$ donor set (n = 1 or 2), these dinuclear complexes cannot be used as ′metal complexes as ligands′ (metallo-ligands). However, confacial bioctahedra with a $O_3M(\mu_2\text{-}OPh)_3MO_3$ core, where the terminal oxygen ligands represent monodentately coordinated alkoxide ligands, represent metallo-ligands, which can be used in a modular approach for the synthesis of larger molecules or even 1D coordination polymers.

Herein, we report on the rational synthesis of a confacial bioctahedron with nucleophilic terminal donors. Using the ligand 4-*tert*-butyl-2,6-bis(hydroxymethyl)phenol (H_3L), the complex $(Et_4N)[L_3Ti_2]$ (**1**) with a $[(BzO)_3Ti^{IV}(\mu_2\text{-}OPh)_3\text{-}Ti^{IV}(OBz)_3]^-$ core has been synthesized and characterized. The Ti^{IV} ions are strong Lewis acids. The terminal phenylmethoxide ligands, therefore, have to donate much of their charge to the coordinated Ti^{IV} ions. However, the terminally coordinated phenylmethoxide ligands still possess sufficient nucleophilicity to bridge two Ti^{IV} ions as demonstrated by the synthesis and characterization of $(Et_4N)_2[L_2(HL)_4Ti_4O_2]$ (**2**).

Results and Discussion

Synthesis and Characterization

Treatment of H_3L with $[TiO(acac)_2]$ in a 3:2 molar ratio in the presence of a stoichiometric amount of Et_3N in refluxing MeOH yielded, after addition of excess $(Et_4N)Cl$, filtration, and slow evaporation of the solvent, yellow crystals of **1**. The IR spectrum confirmed the presence of the ligand.[3] The absorptions at 2957, 2876, 1393, and 1363 cm^{-1} are characteristic of the *tert*-butyl groups of the ligand, and the symmetric ring stretch appears at 1479 cm^{-1}. Two strong absorptions for the stretching frequencies of the phenolic C−O bond can be observed at 1252 and 1212 cm^{-1} as well as one broad absorption of the benzylic C−O bond at 1041 cm^{-1}. Three strongly resolved absorptions at 613, 590, and 564 cm^{-1} [ν(Ti−O)][8] indicate the coordination of the ligand to titanium. The electrospray mass spectrum of **1** exhibits a prominent ion at a mass-to-charge ratio (*m*/*z*) of 717.6, with mass and isotope distribution patterns corresponding to $[L_3Ti_2]^-$ (calculated *m*/*z* of 717.2). The ^1H and ^{13}C NMR spectra correspond to a symmetrical coordination of one kind of trianionic ligand L^{3-}. These data are all in agreement with the formulation of **1** containing the symmetric bioctahedral $[L_3Ti_2]^-$ anion.

Treatment of H_3L with $[TiO(acac)_2]$ using similar conditions used for the synthesis of **1**, but stirring the reaction solution at room temperature, yielded yellow needles of **2**. The IR spectrum clearly shows, that this change in the reaction temperature affords a complex different from **1**. Characteristic absorptions show the presence of the ligand but a broad flat absorption at 2600−3200 cm^{-1} indicates, that the ligand is not completely deprotonated. The phenolic C−O stretching region exhibits four absorptions with a different intensity pattern compared with the two absorptions observed in the spectrum of **1**, while the absorption corresponding to the stretching frequency of the benzylic C−O bond at 1040 cm^{-1} becomes smaller and broader in the spectrum of **2**. The three sharp resolved absorptions of the ν(Ti−O) stretches in the spectrum of **1** are replaced by several unresolved transitions in this region in the spectrum of **2**. Thus, the IR spectrum of **2** indicates a more asymmetric coordination mode of the ligand compared with in **1**, and/or the occurrence of more than one set of ligands. This is corroborated by the ^1H NMR spectrum of **2**. The observation of three *tert*-butyl resonances and six different signals for the aromatic protons, demonstrates the presence of three distinguishable sets of ligand molecules in **2**. Additionally, two hydroxy proton resonances suggest, that only seven of the nine possible hydroxy groups of the three ligand molecules are deprotonated in **2**. The benzylic region shows a multitude of sharp signals indicating, that the two protons of each benzylic group are inequivalent, and that no fluxional interconversion occurs between them. Although the IR and NMR spectra of **2** show clear differences from the spectra of **1**, the electrospray mass spectrum of **2** in MeOH exhibits only a prominent ion at a mass-to-charge ratio (*m*/*z*) of 717.1 as in the spectrum of **1**, with mass and isotope distribution patterns corresponding to $[L_3Ti_2]^-$. This indicates the transformation of **2** into **1** under the conditions of the electrospray ionization (high temperature).

Single Crystal X-ray Diffraction Studies

Structure of $(NEt_4)[L_3Ti_2]$ (1)

The crystal structure of **1** consists of dinuclear anions $[L_3Ti_2]^-$ and well separated Et_4N^+ cations. Figure 1 shows two views of the molecular structure of the $[L_3Ti_2]^-$ anion in crystals of **1**, and the labeling scheme used. There is no crystallographic symmetry imposed on the anion. The anion consists of two titanium ions and three ligand molecules L^{3-}, which are the triply-deprotonated form of H_3L. Each ligand acts as a tridentate donor with two terminal phenylmethoxide donors (BzO^-), and one μ_2-bridging phenolato donor (PhO^-). The two titanium ions are bridged in a face-sharing fashion by the three phenolato donors giving rise to an overall bioctahedral core. However, the coordination geometry of the titanium ions deviates severely from octahedral symmetry. Table 1 summarizes selected interatomic distances and angles of the $O_3Ti(\mu_2\text{-}O)_3TiO_3$ core. The Ti−μ_2-OPh bond lengths are in the range of 2.10−2.13 Å while the Ti−OBz bond lengths are 0.3 Å shorter (1.81−1.84 Å). The Ti1···Ti2 distance is 3.04 Å. The short Ti−OBz bond lengths indicate a strong bond between the Lewis acidic Ti^{IV} ions and the Lewis basic BzO^-. The latter

exhibits no resonance stabilization of the negative charge compared with PhO^-.

An ideal bioctahedron would have all X−M−X angles equal to 90°, and all M−X_{br}−M (br denotes bridging ligand) angles equal to 70.53°. Distortions from this ideal geometry may be attributed to attractive or repulsive M-to-M forces.[9] In order to compare the structure of the anion in **1** with an ideal bioctahedron, four sets of angles have to be considered: Ti1−μ_2-OPh−Ti2 (β, ideal value 70.53°), PhO−Ti−OPh (α′, ideal value 90°), BzO−Ti−OBz (α″, ideal value 90°), and PhO−Ti−OBz (α‴, ideal value 90°). The respective mean values of these angles in **1** are: β = 92.2°, α′ = 73.7°, α″ = 96.2°, and α‴ = 95.0°. The increased value of β and the decreased value of α′ compared with the ideal values of 70.53 ° and 90 °, respectively, are clear evidence of an elongation of the bioctahedron along the C_3-axis, thus indicating repulsive electrostatic interactions between the two Ti^{IV} ions. To interpret the values of α″ and α‴, the steric constraints of the tridentate ligand L^{3-} must be considered. Similar constraints do not occur in confacial bioctahedra with only the monodentate ligands X, $X_3M(\mu_2\text{-}X)_3MX_3$. The steric constraint of the phenyl ring on the methoxide CH_2O^- units pushes the coordinated methoxide oxygen atom towards the phenyl plane of the ligand molecule (Figure 1, right). This is especially apparent with the occurrence of two different types of PhO−Ti−OBz angles (α‴). The mean value of these angles for benzylic and phenolic oxygen atoms belonging to the same ligand molecule is 85.4°, while for benzylic and phenolic oxygen atoms belonging to different ligand molecules it is 104.6°, demonstrating the steric stress on the phenylmethoxide donors.

Structure of $(Et_4N)_2[L_2(HL)_4Ti_4O_2]\cdot 2CH_3CN$ (2·2CH$_3$CN)

The crystal structure of **2**·2CH_3CN consists of tetranuclear dianions $[L_2(HL)_4Ti_4O_2]^{2-}$, Et_4N^+ cations, and CH_3CN molecules. The asymmetric unit consists of one half of the dianion with the other half generated by a center of inversion. The titanium centers are in distorted octahedral coordination environments of six oxygen donors (Figure 2 and Table 2). Ti1 is coordinated by one μ_3-oxo ligand O1′, one non-bridging OPh O10, one μ_2-OPh O50, two non-bridging OBz centers O19 and O51, and one μ_2-OBz O31′, whereas Ti2 is coordinated by two μ_3-oxo ligands O1 and O1′, one non-bridging OPh O30, one μ_2-OPh O50, one non-bridging OBz center O59, and one μ_2-OBz O31. The mean bond lengths for the different kinds of Ti−O bonds are: Ti−OBz 1.86 Å, Ti−OPh 1.90 Å, Ti−μ_3-O 1.97 Å, Ti−μ_2-OBz 2.03 Å, and Ti−μ_2-OPh 2.08 Å. The terminal phenylmethoxide donors form the shortest Ti−O bonds, while the bridging phenolato donors form the longest Ti−O bonds. It is interesting to compare these values with the corresponding values for Ti−OBz (1.83 Å) and Ti−μ_2-OPh (2.11 Å) found in **1**. The Ti−OBz bonds are slightly shorter in **1** compared with those in **2**, and the Ti−μ_2-OPh bonds are slightly longer in **1** compared with those in **2**. There are two other trends observed in the bond lengths in **2**, namely (*i*) the Ti−O bond length of one type of oxygen donor decreases upon going from monodentate to bridging. A ligand bridging two metal ions has to donate charge to both metal ions compared with a monodentate ligand, which only donates charge to one metal ion. Although the bridging ligand donates more overall charge (i.e. the sum of both bonds), the charge donation per bond is less compared with the bond to a monodentate ligand.[10] This results in the observed increase in the bond lengths of the bridging ligand compared with the monodentate ligand. (*ii*) The Ti−O bond length of a phenylmethoxide donor is shorter than of a phenolato donor of the same coordination mode (OBz vs. OPh and μ_2-OBz vs. μ_2-OPh), which is consistent with the stronger donor ability of a phenylmethoxide ligand compared with a phenolato ligand due to the difference in resonance stabilizations of the respective anions.[11]

The three independent ligand molecules in **2** exhibit three different coordination modes. Ligand a (O10, O11, O19) acts as a bidentate chelating ligand via O10 (OPh) and O19 (OBz), while O11 is protonated and forms an intramolecular hydrogen bond with the terminally coordinated phenylmethoxide oxygen atom O59′ (2.83 Å). Ligand b (O30, O31, O39) also coordinates only in a bidentate fashion via O30 (OPh) and O31 (OBz) but the phenylmethoxide donor acts as a bridging ligand between two Ti^{IV} ions. The protonated O39 (BzOH) forms an intramolecular hydrogen bond with the terminally coordinated phenylmethoxide oxygen atom O19 (2.72 Å). The remaining ligand c (O50,

O51, O59) exhibits the same tridentate coordination mode as the ligands in **1**.

The structure of **2** may be regarded as consisting of a Ti_4O_{16} core enclosed by an organic shell [Figure 3 (a)]. The oxygen atoms are situated above and below a plane comprised of the four titanium ions. Two half-bowls each formed by three *tert*-butylbenzene moieties are positioned above and below this Ti_4-plane, respectively. Figure 3 (b) demonstrates that the hydrophobic half-bowl allows access to the μ_3-oxo ligand. Thus, two hydrophobic binding pockets for Lewis bases are provided by **2**. In the crystal structure of **2**·2CH_3CN, the two hydrophobic pockets of each dianion are occupied by the two Et_4N^+ cations [Figure 3 (c)]. The Ti_4O_{16} core found in the dianion of **2** represents a relatively common structural motif in Ti−oxygen chemistry since it has been observed in several complexes constructed from varying kinds of alkoxide ligands from monodentate to tridentate.[4,12] These compounds can be used as molecular precursors for metal oxides in sol-gel chemistry or for thin-film preparation.

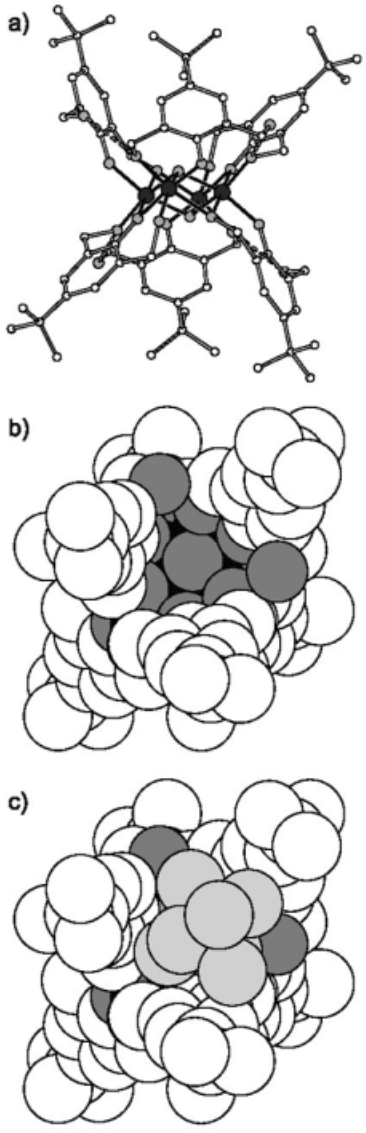

Figure 3. a) Sketch of the molecular structure of the dianion $[L_2(HL)_4Ti_4O_2]^{2-}$ **2**·2CH_3CN illustrating the Ti_4O_{16} core and the two hydrophobic half-bowls each formed by three *tert*-butylbenzene units; b) Space-filling model of this structure [rotated by 90° relative to the view in a)] illustrating the hydrophobic pocket, which allows direct access to the μ_3-oxo oxygen atom of the Ti_4O_{16} core; c) Space-filling model of the dianion, and one Et_4N^+ cation placed in the hydrophobic pockets of the dianion

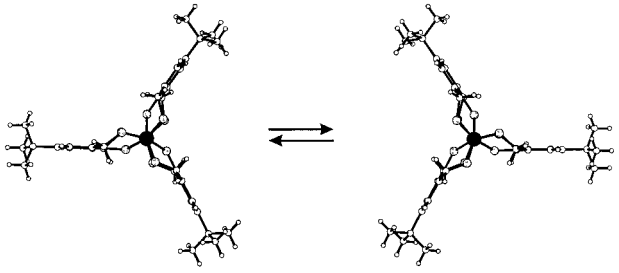
Solution Properties

The monoanion of **1** has an idealized C_{3h} symmetry in the solid state. If this symmetry were to be retained in solu-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

tion, two sets of signals would be expected for the benzylic protons in the ^{1}H NMR spectrum. However, the ^{1}H NMR spectrum of **1** in [D_6]DMSO exhibits only one broad resonance for the benzylic protons at $\delta = 5.17$ ppm. This indicates that a dynamic equilibrium exists between two forms with different orientations of the methoxide groups relative to the phenolic plane (Scheme 2). On the other hand, the ^{1}H NMR spectrum of **2** in [D_8]THF solution displays all signals predicted for the three different ligand molecules observed in the solid-state structure. This means, that the conformation of the tetranuclear dianion is fixed, which could be a consequence of the four intramolecular hydrogen bonds.



Scheme 2

The UV/Vis absorption spectra of acetonitrile solutions of H_3L, **1**, and **2** are shown in Figure 4. The protonated ligand exhibits absorptions at 309 nm (sh, ≈ 120 M^{-1} cm^{-1}) and 282 nm (2320 M^{-1} cm^{-1}). The spectrum of complex **1** exhibits absorption intensity, which starts to increase starting at ≈ 400 nm with no resolved transitions but shoulders at ≈ 288, 246, and 222 nm. The absorption of the tetranuclear complex **2** starts to increase at ≈ 450 nm with maxima at 333 nm (22200 M^{-1} cm^{-1}), 296 nm (21600 M^{-1} cm^{-1}), and 290 nm (21600 M^{-1} cm^{-1}). The strong low-energy absorptions in the spectra of **1** and **2** are oxygen-to-titanium charge transfer in origin. The main conclusion is that **1** and **2** are clearly distinguishable by their absorption spectra. The spectrum of **2** measured in THF is identical to that measured in CH_3CN.

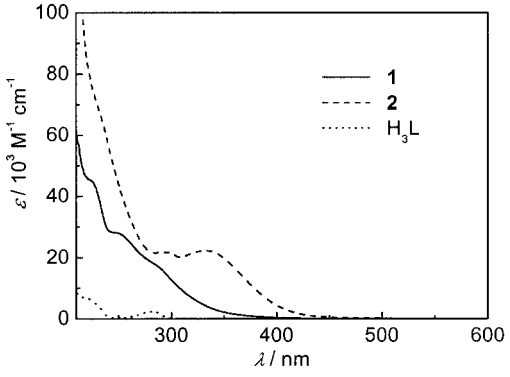


Figure 4. UV-Vis absorption spectra of acetonitrile solutions of H_3L, **1**, and, **2**

Heating **2** in protic solvents leads to the formation of **1**, an essential fact for the controlled synthesis of **1** and **2**, respectively. The reaction between the ligand and [$TiO(acac)_2$] in alcoholic solution at room temperature results in the formation of **2**, whereas **1** is formed by heating the reaction mixture to reflux. This is corroborated with the ESI mass spectrum of a methanolic solution of **2** which, due to heating of the solution in the ESI process, exhibits only the signal corresponding to the anion of **1**. On the other hand, in non-protic solvents **2** is stable even upon heating. Storing the sealed NMR tube of the [D_8]THF solution of **2** at 70 °C overnight does not affect the ^{1}H NMR spectrum. Additionally, **1** can be converted back to **2**. Dissolving **1** in a CH_3CN/MeOH mixture (10:1) leads to the deposition of yellow crystals, which were shown to be pure **2** by FTIR spectroscopy and single-crystal X-ray diffraction. These observations are in agreement with the following equilibrium:

$$[L_2(HL)_4Ti_4O_2]^{2-} \rightleftarrows 2\,[L_3Ti_2]^- + 2\,H_2O$$

The cleavage of the titanium−oxo bond of the former titanyl unit requires some activation energy, and a protic solvent is needed for the formation of water. The dinuclear $[L_3Ti_2]^-$ complex seems to be more stable in protic solvents whereas the tetranuclear $[L_2(HL)_4Ti_4O_2]^{2-}$ complex seems to be more stable in aprotic solvents. The latter might indicate that the two Et_4N^+ cations remain in the hydrophobic binding pockets to give an overall neutrally charged ion triple.

Conclusions

We have shown by the synthesis of complex **1**, that 2,6-bis(hydroxymethyl)-4-*tert*-butylphenol is capable of forming a confacial bioctahedron with a $[(BzO)_3Ti^{IV}(\mu_2\text{-}OPh)_3Ti^{IV}(OBz)_3]^-$ core exhibiting a short Ti···Ti distance of ≈3.0 Å. The coordination of the terminal phenylmethoxide donors to the strong Lewis acid Ti^{IV} still leaves some nucleophilicity at the oxygen atoms. This has been demonstrated with the synthesis of complex **2**, which exhibits μ_2-bridging phenylmethoxide ligands. Work is in progress to prepare coordination polymers using the anion of **1** as a building block.

The tetranuclear dianion in **2** consists of a Ti_4O_{16} core protected by two hydrophobic pockets, which allow access to the μ_3-oxo ligand of the Ti_4O_{16} core. TiO_2 is known as a heterogeneous photocatalyst, e.g. for the oxidation of ethanol.[13] Studies on the binding of ethanol to **2** are in progress to evaluate the potential of **2** as a homogeneous photocatalyst utilizing the strong LMCT absorption band at 333 nm.

Experimental Section

General Methods and Materials: Infrared spectra (400−4000 cm^{-1}) of solid samples were recorded in KBr disks using a Bruker Vector

22 spectrometer. UV/Vis/NIR-absorption spectra of solutions were measured on a Varian Cary 50 spectrophotometer in the range of 190−1100 nm at ambient temperature. ESI mass spectra were recorded on a Micromass Quattro LC mass spectrometer. ^{1}H and ^{13}C NMR spectra were obtained on a Bruker AC200 or on a Bruker ARX300 spectrometer using the solvent resonances as an internal standard in each case. The ligand H_3L was synthesized according to a published procedure.[3]

$(Et_4N)[L_3Ti_2]$ (1): To a stirred solution of H_3L (500 mg, 2.38 mmol) and $[TiO(acac)_2]$ (415 mg, 1.59 mmol) in MeOH (40 mL) was added Et_3N (1.00 mL, 7.13 mmol). The yellow solution was heated to reflux for 5 h. Addition of $(Et_4N)Cl$ (4.0 g), filtration, and slow evaporation of the solvent yielded yellow crystals of $(Et_4N)[L_3Ti_2]$ (350 mg, 52%). $C_{44}H_{65}NO_9Ti_2$ (847.77): calcd. C 62.34, H 7.73, N 1.65; found C 62.01, H 7.58, N 1.51. MS (ESI in MeOH/CH_3CN solution, negative ion mode): m/z = 749.6 $\{[L_3Ti_2]MeOH\}^-$, 717.6 $[L_3Ti_2]^-$. ^{1}H NMR (300 MHz, [D$_6$]DMSO, 25 °C): δ = 1.13 (t × t, $J_{H,H}$ = 7.4, J_{H-N} = 1.8 Hz, 12 H, NCH_2CH_3), 1.21 (s, 27 H, *tert*-butyl CH_3), 3.17 (q, 8 H, NCH_2CH_3), 5.17 (s, 12 H, br, benz. CH), 6.94 (s, 6 H, arom. CH). ^{13}C NMR (75 MHz, [D$_6$]DMSO, 25 °C): δ = 7.0 (NCH_2CH_3), 31.3 ($C(CH_3)_3$), 33.4 ($C(CH_3)_3$), 51.4 (t, J_{C-N} = 2.6 Hz, NCH_2CH_3), 71.0 (benz. CH_2), 122.2 (C_{Ar}-3), 127.8 (C_{Ar}-4), 139.8 (C_{Ar}-2), 154.5 (C_{Ar}-1). IR: $\tilde{\nu}$ = 2957 s, 2876 m, 2827 m, 1608 w, 1479 vs, 1451 s, 1393 w, 1363 w, 1252 vs, 1212 vs, 1041 vs/br, 871 w, 832 m, 765 m, 755 m, 668 m, 613 vs, 590 vs, 564 s cm^{-1}.

$(Et_4N)_2[L_2(HL)_4Ti_4O_2]\cdot 2EtOH\cdot 2H_2O$ ($2\cdot 2EtOH\cdot 2H_2O$): To a stirred solution of H_3L (500 mg, 2.38 mmol) and $[TiO(acac)_2]$ (415 mg, 1.59 mmol) in EtOH (45 mL) was added Et_3N (1.00 mL, 7.13 mmol). The yellow solution was stirred at room temperature for 5 h. Addition of $(Et_4N)Cl$ (4.0 g), filtration, and slow evaporation of the solvent yielded yellow needles of $(Et_4N)_2[L_2(HL)_4Ti_4O_2]\cdot 2EtOH\cdot 2H_2O$ (300 mg, 42%). $C_{88}H_{142}N_2O_{24}Ti_4$ (1803.61): calcd. C 58.60, H 7.94, N 1.55; found C 58.71, H 7.71, N 1.58. ^{1}H NMR (200 MHz, [D$_8$]THF, 25 °C): δ = 0.35 (m, 24 H, NCH_2CH_3), 1.19 (s, 27 H, *tert*-butyl CH_3), 1.23 (s, 27 H, *tert*-butyl CH_3), 1.25 (s, 27 H, *tert*-butyl CH_3), 3.88 (q, 16 H, NCH_2CH_3), 4.5−6.0 (m, 24 H, benz. CH), 6.8−7.2 (6s, 12 H, arom. CH), 7.87 (s, 2 H, BzOH), 8.42 (s, 2 H, BzOH). IR: $\tilde{\nu}$ = 2953 s, 2904 m, 2866 m, 1606 w, 1479 vs, 1393 w, 1364 w, 1305 w, 1275 s, 1262 s, 1218 vs, 1040 m/br, 1005 w, 877 w, 839 s, 768 m, 540−630 br cm^{-1}. X-ray quality crystals of $2\cdot 2CH_3CN$ were grown from MeOH/CH_3CN, 1:5.

Formation of Large Clusters in the Reaction of Lanthanide Cations with Heptamolybdate

Katja Burgemeister,[a] Daniel Drewes,[a] Eva Melanie Limanski,[a] Ina Küper,[a] and Bernt Krebs*[a]

Keywords: Lanthanides / Molybdenum / Polyoxometalates / Structural analysis

A series of new lanthanide polyoxomolybdates was synthesised by reaction of lanthanide cations with the heptamolybdate anion $(Mo_7O_{24})^{6-}$. The heteropolyanions $[Ln_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]^{14-}$ (Ln = La^{III}, Ce^{III}, Pr^{III}, Sm^{III}, Gd^{III}) were isolated as either their ammonium or tetramethylammonium salts and characterised by X-ray structure analysis, energy dispersive X-ray fluorescence analysis, and IR and Raman spectroscopy. The central $[Ln_4(MoO_4)(H_2O)_{16}]^{10+}$ core of the anion is coordinated by four heptamolybdate groups. Each Ln^{III} atom in the core exhibits ninefold coordination by oxygen atoms belonging to H_2O, $(MoO_4)^{2-}$ and $(Mo_7O_{24})^{6-}$ units; the central molybdenum atom is coordinated tetrahedrally by four oxygen atoms.

Introduction

Because of their multifunctional applications in the fields of catalysis, chemical analysis and medicine, the chemistry of polyoxometalates is a research area of growing interest.[1−3] The selective synthesis of heteropolymetalates is made difficult by the large number of equilibrium reactions during the formation of the resulting anions. The characterisation of novel compounds and functional investigations are required for identification of structural characteristics and for understanding the different mechanisms that are responsible for biological and catalytic activity.

In recent years, a number of very large polyoxomolybdate clusters have been synthesised and structurally characterised. The Müller group has reported several giant mixed-valence nano-structured polyoxomolybdates with well above one hundred molybdenum atoms.[4−7] In polyoxotungstate chemistry quite different structures have been described; the $[As_{12}Ce_{16}(H_2O)_{36}W_{148}O_{524}]^{76-}$ anion is the largest anion yet known.[8]

Lanthanide-containing polyoxometalates constitute a type of compound of great impact.[9] Structural studies of lanthanide polyoxotungstates have been investigated and a number of compounds, for example $Na_6H_2[Ce(W_5O_{18})_2]\cdot 30H_2O$,[10] $K_{16}[Ce(P_2W_{17}O_{61})_2]\cdot 50H_2O$[11] and $K_{15}H_3[Eu_3(H_2O)_3(W_5O_{18})_3(SbW_9O_{33})]\cdot 25.5H_2O$,[12] have been reported. In connection with the discovery of the anti-HIV activity of the polyoxometalate PM-104 by Yamase et al. and of the substances $K_{13}[Ln(SiW_{11}O_{39})_2]\cdot nH_2O$ and $K_{17}[Ln(P_2W_{17}O_{61})_2]\cdot nH_2O$, synthesised by Francesconi et al., investigations relating to structure-activity correlations were reported.[13,14]

There are still only a few crystal structure analyses of lanthanide-containing polyoxomolybdates. In 1991 Yamase et al. reported the synthesis and characterisation of the compound $(NH_4)_{12}H_2[Eu_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]\cdot 18H_2O$, the luminescence properties of which are of great interest.[15] A similar structure of nonluminescent dimeric $[Pr_4(MoO_4)(Mo_7O_{24})_4]_2^{28-}$ was reported in 1987.[16] The synthesis and crystal structure of the neodymium-containing compound $Na_4(NH_4)_{10}[Nd_4(MoO_4)(Mo_7O_{24})_4]\cdot 34H_2O$ was published in 1997.[17]

In this paper we report the syntheses and structural characterisation of five new lanthanide containing polyoxomolybdates of the general structure $[(CH_3)_4N]_x[NH_4]_{14-x}[Ln_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]\cdot nH_2O$. Polyoxoanions of this type, which are isotypic with Yamase's europium compound, were prepared for Ln = La^{III}, Ce^{III}, Pr^{III}, Sm^{III} and Gd^{III} and their complete crystal structures are reported here.

Results and Discussion

$[(CH_3)_4N]_x[NH_4]_{14-x}[Ln_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]\cdot nH_2O$ crystals (Ln = La^{III}, Ce^{III}, Pr^{III}, Sm^{III}, Gd^{III}) were obtained from aqueous solution at a pH of about 5. The syntheses succeeded in a direct and straightforward way from an aqueous solution of heptamolybdate by addition of salts of the trivalent lanthanides in water. The inserted amounts of

lanthanide ions in relation to heptamolybdate are not stoichiometric and vary from 1:5 for Ln = Sm^{III}, Ce^{III} and Pr^{III} to 2:5 for Ln = Gd^{III} and La^{III}. $[(CH_3)_4N]_{1.33}[NH_4]_{12.67}[La_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]\cdot 12H_2O$ (**1**), $[(CH_3)_4N]_{3.33}[NH_4]_{10.67}[Sm_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]\cdot 22H_2O$ (**4**) and $[(CH_3)_4N]_{3.33}[NH_4]_{10.67}[Gd_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]\cdot 16H_2O$ (**5**) crystallise in the cubic crystal system, space group $I\bar{4}3d$. The asymmetric unit consists of one quarter of the whole molecule, and the unit cell contains 12 anions. $[NH_4]_{14}[Ce_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]\cdot 36H_2O$ (**2**) crystallises in the triclinic crystal system, space group $P\bar{1}$, containing one formula unit per asymmetric unit and two formula units per unit cell. $[NH_4]_{14}[Pr_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]\cdot 29H_2O$ (**3**) crystallises in the monoclinic crystal system, space group $C2/c$. The asymmetric unit contains half a molecule and the unit cell includes four anions.

The five new heteromolybdate anions $[La_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]^{14-}$ (anion in compound **1**), $[Ce_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]^{14-}$ (anion in compound **2**), $[Pr_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]^{14-}$ (anion in compound **3**), $[Sm_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]^{14-}$ (anion in compound **4**) and $[Gd_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]^{14-}$ (anion in compound **5**) are isostructural to the europium-containing anion that is known from the literature.[15] Figure 1 shows the arrangement of the $[Ln_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]^{14-}$ anion seen from two different directions.

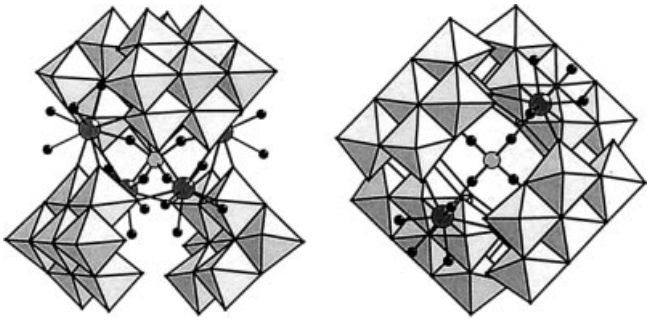

Figure 1. Polyhedron representation of the $[Ln_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]^{14-}$ anion viewed in two different projections

All the examples of this type contain a centered molybdenum atom (Mo1) that is coordinated tetrahedrally by four oxygen atoms. The O−Mo1−O bond angles differ only slightly from the perfect tetrahedral angle. The bond lengths between Mo1 and the four oxygen atoms [1.75(1)−1.77(1) Å] show that these bonds have partial double-bond character. Each oxygen atom of the central $(MoO_4)^{2-}$ unit is bonded to a lanthanide atom; the corresponding Mo1−O bond lengths show that an exchange of lanthanide atoms has no influence on the dπ-pπ bonding between molybdenum and oxygen atoms.

Each of the four lanthanide atoms in the $[Ln_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]^{14-}$ anion shows ninefold coordination by the oxygen atoms, approximating a tricapped trigonal prism, by attachment of one oxygen atom from the central $(MoO_4)^{2-}$ unit, four oxygen atoms from three $(Mo_7O_{24})^{6-}$ units and four oxygen atoms from four aqua ligands. The bond lengths and bond angles of the central $[Ln_4(MoO_4)(H_2O)_{16}]^{10+}$ unit (Ln = La^{III}, Ce^{III}, Pr^{III}, Sm^{III}, Eu^{III}, Gd^{III}) are given in Table 1 and 2. As shown in Table 2, all the lanthanide ions are coordinated by oxygen atoms in a very similar way. The observed decrease of Ln−O and Ln−OH_2 bond lengths in the series La > Ce > Pr > Sm > Eu > Gd is to be expected as an effect of the lanthanide contraction. The lanthanide atoms are well separated, with intramolecular Ln···Ln distances of between 6.28(1) and 7.67(1) Å for **1** and 6.15(1) and 7.50(1) Å for **5**. The decrease of these Ln···Ln distances is also an effect of the lanthanide contraction.

Figure 2 shows a schematic description of the $[Ln_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]^{14-}$ anion. Each $(Mo_7O_{24})^{6-}$ unit can be regarded as a tetradentate ligand bonded to three lanthanide atoms. Two of the seven MoO_6 octahedra of the $(Mo_7O_{24})^{6-}$ unit provide two terminal oxygen atoms for the Ln−O bonds.

It has been shown by Evans et al. that a characteristic feature of the heptamolybdate anion in $(NH_4)_6(Mo_7O_{24})\cdot 4H_2O$ is that all the MoO_6 octahedra contain two terminal or quasi-terminal bonds to oxygen atoms in *cis* positions.[18] This structural signature can also be found in the $(Mo_7O_{24})^{6-}$ units of all $[Ln_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]^{14-}$ anions. The short Mo−O_t bond lengths of the terminal and quasi-terminal oxygen atoms correspond well in the heptamolybdate anion and the $[Ln_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]^{14-}$ anions (Table 3). The coordination of the lanthanide cations by such terminal oxygen atoms does not lead to a significant expansion of these Mo−O bond lengths.

As well as the two short Mo−O bonds, each MoO_6 octahedron contains two intermediate Mo−O bonds and two long Mo−O bonds. The two long Mo−O bonds are located *trans* to the short Mo−O bonds and show Mo−O distances of between 2.09(1) Å and 2.51(1) Å (**1**−**5**) and 2.16(1) Å and 2.42(1) Å $[(NH_4)_6(Mo_7O_{24})\cdot 4H_2O]$. The intermediate Mo−O bonds show Mo−O distances of between 1.87(1) Å and 2.01(1) Å (compounds **1**−**5**) and 1.90(1) Å and 1.97(1) Å $[(NH_4)_6(Mo_7O_{24})\cdot 4H_2O]$.[18]

A comparison of the lanthanide-containing polyoxomolybdates **1**−**5** with the heptamolybdate anion in $(NH_4)_6(Mo_7O_{24})\cdot 4H_2O$ given in Table 3 shows rather similar distances within the limits of error. The variation of the lanthanide atoms belonging to the central $[Ln_4(MoO_4)(H_2O)_{16}]^{10+}$ unit has no significant influence on the coordinating heptamolybdate units.

According to the required charge balance, 14 cations per formula unit are needed. Compounds **2** and **3** contain only ammonium counterions. In this case, the cations cannot be distinguished crystallographically from the water molecules. To achieve better crystallisation, tetramethylammonium ions were added during the preparation of **1**, **4** and **5**. Compounds **4** and **5** contain 3.33 of these counterions each, with the lanthanum-containing compound **1** only having 1.33 tetramethylammonium ions. The fractional numbers result from the special positions of carbon and nitrogen atoms in the unit cell. Elemental analyses validate the content of

[a] Ow = oxygen atom of a water molecule.

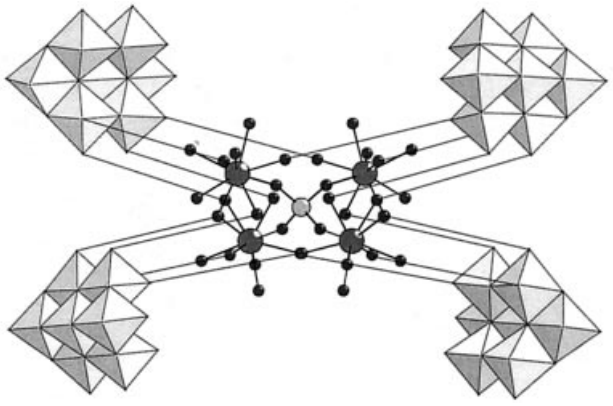

Figure 2. Schematic presentation of the $[Ln_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]^{14-}$ anion

ammonium and tetramethylammonium ions. There is no evidence for protonation of the crystal water molecules or the $[Ln_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]^{14-}$ anions.

The spectroscopic data of all $[Ln_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]^{14-}$ anions show great similarities in the most important bands of the IR and Raman spectra. The characteristic region of the Mo−O vibrations in the Raman spectra are observed in the region between 1000 and 800 cm^{-1} for all analysed compounds. In the IR spectra the characteristic $Mo-O_t$ bands are observed around 893 cm^{-1}.

Conclusion

The selective and aimed syntheses of five novel lanthanide-containing polyoxomolybdates $[(CH_3)_4N]_x[NH_4]_{14-x}[Ln_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]\cdot nH_2O$ **(1−5)** are reported.

Table 3. Mo−O-bond lengths with standard deviations of the heptamolybdate unit of the $[Ln_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]^{14-}$ anion with Ln = La^{III}, Ce^{III}, Pr^{III}, Sm^{III}, Eu^{III},[15] Gd^{III} and the heptamolybdate anion in $(NH_4)_6(Mo_7O_{24})\cdot 4H_2O$[18]

All compounds were completely characterised by X-ray structure analysis. The $[Ln_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]^{14-}$ clusters are built up by a central $[Ln_4(MoO_4)(H_2O)_{16}]^{10+}$ unit surrounded by four heptamolybdate groups, each of which can be regarded as a tetradentate ligand. The building blocks are connected by four lanthanide atoms which are coordinated by nine oxygen atoms. Investigations of the oxidation catalysis and anti-tumour and anti-HIV activity of the present compounds are in progress.

Experimental Section

Syntheses of Heteropolymolybdates: All starting materials and chemicals were used without further purification.

$[(CH_3)_4N]_{1.33}[NH_4]_{12.67}[La_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]\cdot 12H_2O$ (1): $(NH_4)_6(Mo_7O_{24})\cdot 4H_2O$ (0.93 g, 0.75 mmol) was dissolved in 20 mL of water, and 1 mL of CH_3OH was added. An aqueous solution (5 mL) containing $La(NO_3)_3\cdot 6H_2O$ (0.13 g, 0.3 mmol) was added dropwise to the above solution with stirring at room temperature. $(NMe_4)Br$ solution (0.5 mL; 1 M in water) was added to the resulting solution (pH ≈ 5). The reaction vessel was kept closed at room temperature for 48 h. Colorless single crystals were obtained from the solution. Yield: 0.37 g (86% based on La). $C_{5.33}H_{122.67}La_4Mo_{29}N_{14}O_{128}$ (5769.6): calcd. C 1.11, H 2.14, N 3.40; found C 1.06, H 2.22, N 3.43. IR data (KBr): $\tilde{\nu}$ = 3423 cm^{-1} (s) [ν(O−H)]; 1614 (s) [δ(N−H)]; 1389 (s) [δ(O−H)]; 941 (m); 893 (s) [ν(Mo-O_t)]; 621 (s) [ν(Mo-O)]; 488 (w). Raman data: $\tilde{\nu}$ = 946 cm^{-1} (s) (Mo-O_t); 891 (m); 863 (w); 363 (w); 222 (m). EDAX: calcd. Mo:La = 7.25:1; found Mo:La = 7.36:1.

$[NH_4]_{14}[Ce_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]\cdot 36H_2O$ (2): $(NH_4)_6(Mo_7O_{24})\cdot 4H_2O$ (0.93 g, 0.75 mmol) was dissolved in 9 mL of water, and 1 mL of CH_3OH was added. An aqueous solution (5 mL) containing $CeCl_3\cdot 7H_2O$ (0.056 g, 0.15 mmol) was added dropwise to the above solution with stirring at room temperature. The resulting solution (pH ≈ 5) was kept in a closed reaction flask at 278 K for 18 h. Red single-crystals were obtained from the solution. Yield: 0.18 g (78% based on Ce). $H_{160}Ce_4Mo_{29}N_{14}O_{152}$ (6132.5): calcd. H 2.63, N 3.20; found H 2.61, N 3.17. IR data (KBr): $\tilde{\nu}$ = 3142 cm^{-1} (s, br) [ν(O−H)]; 1620 (m) [δ(OH_2)]; 1401 (s) [δ(NH_4)]; 893 (s, br) [ν(Mo-O_t)]; 634 (m, br) [ν(Mo-O)]; 486 (w). Raman data: $\tilde{\nu}$ = 944 cm^{-1} (s) (Mo-O_t); 916 (m); 860 (w); 364 (w); 219 (m). EDAX: calcd. Mo:Ce = 7.25:1; found Mo:La = 6.56:1.

$[NH_4]_{14}[Pr_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]\cdot 29H_2O$ (3): This compound was prepared similarly to **2**, with $Pr(NO_3)_3\cdot 5H_2O$ (0.062 g, 0.15 mmol) instead of $CeCl_3\cdot 7H_2O$. Green single-crystals were ob-

Table 4. Crystallographic data for $[(CH_3)_4N]_{1.33}[NH_4]_{12.67}[La_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]\cdot 12H_2O$ (**1**), $[NH_4]_{14}[Ce_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]\cdot 36H_2O$ (**2**), $[NH_4]_{14}[Pr_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]\cdot 29H_2O$ (**3**), $[(CH_3)_4N]_{3.33}[NH_4]_{10.67}[Sm_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]\cdot 22H_2O$ (**4**) and $[(CH_3)_4N]_{3.33}[NH_4]_{10.67}[Gd_4(MoO_4)(H_2O)_{16}(Mo_7O_{24})_4]\cdot 16H_2O$ (**5**)

Instrumentation and Analytical Procedures: IR spectra were measured on a Perkin−Elmer 683 spectrometer as KBr pellets. Elemental analyses were carried out on an Elementar Vario EL III analyzer. The atomic ratios of the heavy elements were determined by energy-dispersive X-ray fluorescence analysis (EDAX).

Diffraction experiments were performed on a STOE IPDS imaging plate system (for **1**, **2** and **3**) and a Bruker Smart Apex diffractometer with CCD detector (for **4** and **5**), both using Mo-K_α radiation (λ = 0.71073 Å). Structures were solved by direct methods with SHELXS-97 and refined with SHELXL-97.[19] No hydrogen atoms were included. The nitrogen atoms of the ammonium cations were modeled as oxygen atoms because nitrogen atoms could not be distinguished from oxygen atoms.

All atoms except the oxygen atoms belonging to water molecules were refined anisotropically by full-matrix least-squares calculations based on F^2. As usual for polyoxometalates, the crystal structures show disorder in the counterions and crystal water part of the structure. The details of data collection and refinement are summarised in Table 4.

Further details on the crystal structure investigations may be obtained from the Fachinformationzentrum Karlsruhe, 76344 Eggenstein-Leopoldhafen, Germany [Fax: +49-(0)7247-808-666; E-mail: crysdata@fiz-karlsruhe.de], on quoting the depository number CSD-413732 (for **1**), -413730 (for **2**), -413733 (for **3**), -413734 (for **4**) or -413731 (for **5**).

Metal-Directed Self-Assembly: Two New Metal-Binicotinate Grid Polymeric Networks and Their Fluorescence Emission Tuned by Ligand Configuration

Benlai Wu,[a] Daqiang Yuan,[a] Feilong Jiang,[a] Ruihu Wang,[a] Lei Han,[a] Youfu Zhou,[a] and Maochun Hong*[a]

Keywords: Self-assembly / Binicotinic acid / Fluorescence / Coordination polymer / Chirality

Two new 2-D metal-binicotinate coordination polymers, namely, $[Cd^{II}(bpdc)]_n$ (**1**) and $\{[Zn^{II}_8(bpdc)_8(H_2O)_8](H_2O)_8\}_n$ (**2**) (H_2bpdc = binicotinic acid) have been synthesized using hydrothermal and three-layer diffusion methods, respectively. Single-crystal X-ray analyses revealed that both are extended grid networks of the (4,4) topology. Their structures alter with the configuration and function of bpdc. The achiral, free H_2bpdc has axial chirality induced by metal coordination in **1**, and bpdc connects to four metal centers forming a 2-D (4,4) net with three kinds of apertures generated through self-assembly. In **2**, however, bpdc connects to three metal centers, fabricating a microporous framework containing hydrophilic channels. Studies on the solid emission spectra of the free ligand, **1**, and **2** confirmed, that the configuration of bpdc resulting from metal-directed coordination has a profound effect on the fluorescence emissions of **1** and **2**.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

The construction of extended metal-organic networks, especially with micropores, is of current interest in the fields of supramolecular chemistry and crystal engineering, because of their exploitable magnetic,[1−3] catalytic,[4] optoelectronic,[5,6] and inclusive properties.[7] The self-assembly of suitable ligands and metal centers has been proved to be an efficient route for the formation of one- to three-dimensional networks with fascinating structural topologies.[8−11]

Recently, interest has increasingly been centered on self-assembly of metal ions with multi-pyridine and multi-carboxylate spacers.[12−15] As exemplified by the successful syntheses of porous networks, the rigid skeletons of multi-pyridine ligands always sustain the frameworks, and the diversely coordinating multi-carboxylate spacers can help enhance the stability of the resultant metal-organic networks.[16,17] The family of binicotinic acid ligands (H_2bpdc) bearing 2,2′-bipyridyl and dicarboxyl functional groups has received considerable attention in photochemistry and crystal engineering.[18−25] On the one hand, owing to the structural features of the strong chelating bipyridyl moiety and the adjacent carboxyl groups, these ligands often acts as bis(monodentate),[18] tridentate[19,20] or bis(bidentate)[20,21] bridging spacers, and facilitate the formation of 1-D catenopolymers, indicating ligand-directed synthesis. On the other hand, the configuration of bpdc can be greatly altered along the 1,1′ bond, while the pyridyl and carboxyl functional groups bind to the selected metal centers. This may also provide a route for metal-directed synthesis, something which has been rarely reported in the literature. In this work we selected Cd^{II} and Zn^{II} as metal nodes for assembly with Me_2bpdc (dimethyl 2,2′-bipyridine-3,3′-dicarboxylate) and H_2bpdc, respectively, and obtained two 2-D novel coordination polymers, namely, $[Cd^{II}(bpdc)]_n$ (**1**) and $\{[Zn^{II}_8(bpdc)_8(H_2O)_8](H_2O)_8\}_n$ (**2**). Complex **1**, which was assembled under hydrothermal conditions, has a (4,4) topological network with three-shaped apertures, while complex **2**, obtained through a three-layer diffusion method, exhibits a microporous framework containing hydrophilic channels.

We also report the interesting results of fluorescence emission experiments, which show that the configuration of bpdc resulting from metal-directed coordination has a profound effect on the emissions of **1** and **2**.

Results and Discussion

Using hydrothermal methods, the crystalline complex **1** was successfully obtained through the reaction of Me_2bpdc with $CdCl_2{\cdot}2.5H_2O$ (ratio 1:1) in the presence of triethylamine at 160 °C, under which conditions Me_2bpdc underwent hydrolytic decomposition to give bpdc. Substituting $CdCl_2{\cdot}2.5H_2O$ with $ZnCl_2$ under the same reaction conditions yielded only a white precipitate. Finally, single crys-

tals of compound **2** were obtained in a three-layer diffusion system with a aqueous solution of H_2bpdc as the bottom layer, a mixture of DMF, water, and methanol as the mesosphere, and a methanol solution of $ZnCl_2$ as the top layer.

Structural Description

A single-crystal X-ray diffraction analysis revealed, that complex **1** crystallizes in the tetragonal space group *P*4(2)/*mnm*, and possesses a 2-D framework with square, rectangular, and rhombohedral apertures (Figure 1). The local coordination geometry around each Cd^{II} center in **1** can be described as distorted trigonal prismatic (Figure 2), in which each Cd^{II} center is coordinated by four O atoms from the chelating carboxyl groups of two bpdc ligands and two N atoms from another two bpdc ligands to complete the coordination sphere. With its two chelating carboxyl groups and bridging 2,2′-pyridyl moiety (the dihedral angle of two pyridine rings being 93.7°), each bpdc is simultaneously bound to four Cd atoms (Scheme 1), resulting in the formation of a 2-D network with three different shaped apertures. To the best of our knowledge, the four-connecting hexadentate coordination pattern of bpdc is the first such example of its kind. The architecture of **1** with the 2,2′-bipyridyl moiety bridging divalent metal centers has rarely been reported.[18−22]

Symmetry codes: $A = 1 - y, 1 - x, 1 - z$; $B = y, x, 1 - z$; $C = x, y - 1, z$; $D = y - 1, x, 1 - z$ for 1; $A = x - 1, y + 1, z$; $B = x - 1, y, z$; $C = x, y + 1, z$; $D = x, y - 1, z$; $E = x + 1, y, z$; $F = x + 1, y - 1, z$ for 2.

The most interesting feature of **1** is that the achiral free H_2bpdc itself induces axial chirality upon metal coordination. Bpdc links to four metal centers, and exhibits a stereoselective configuration. As shown in Scheme 1, the deprotonated bpdc anions in complex **1** may exhibit (*R*) or (*S*) configurations. Each cadmium(II) center is ligated by two (*R*)-bpdc and two (*S*)-bpdc ligands. Unusually, ligands of the same configuration combine with metal nodes in the same line, so that the 2-D network is interweaved by -(*R*)-bpdc-Cd^{II}-(*R*)-bpdc- and -(*S*)-bpdc-Cd^{II}-(*S*)-bpdc- chains, as shown in Figure 1. Thus, the formation of the framework in **1** is a typical example of a metal-directed stereoselective supramolecular assembly.

In contrast to **1**, complex **2** crystallizes in the monoclinic space group *Pc*, and each asymmetric unit consists of 8 Zn^{II}, 8 bpdc, 8 H_2O, and 8 lattice H_2O units. There are two kinds of coordination geometries around the zinc(II) centers as shown in Figure 3. The Zn3 site exhibits a distorted octahedral geometry, which is surrounded by two nitrogen atoms from a bpdc bipyridyl group, four oxygen atoms from a bpdc monodentate carboxylate group, a bpdc chelating carboxylate group, and a water molecule. In contrast, the other zinc(II) centers, except for the slight difference in bond lengths and angles listed in Table 1, exhibit distorted trigonal bipyramidal environments each of which are surrounded by two nitrogen atoms from a bpdc bipyridyl group, three oxygen atoms from two other bpdc monodentate carboxylate groups, and a water molecule. The Zn−N and Zn−O distances are in the range of 2.077(8)−2.202(7) and 1.963(6)−2.443(10) Å, respectively. Unlike the four-connecting hexadentate pattern in complex **1**, each bpdc anion in complex **2** links three Zn^{II} centers with its chelating 2,2′-pyridyl moiety, asymmetrically chelating monodentate carboxyl groups, or its chelating 2,2′-pyridyl moiety and two monodentate carboxyl groups, displaying pentadentate or tetradentate three-connecting coordination modes

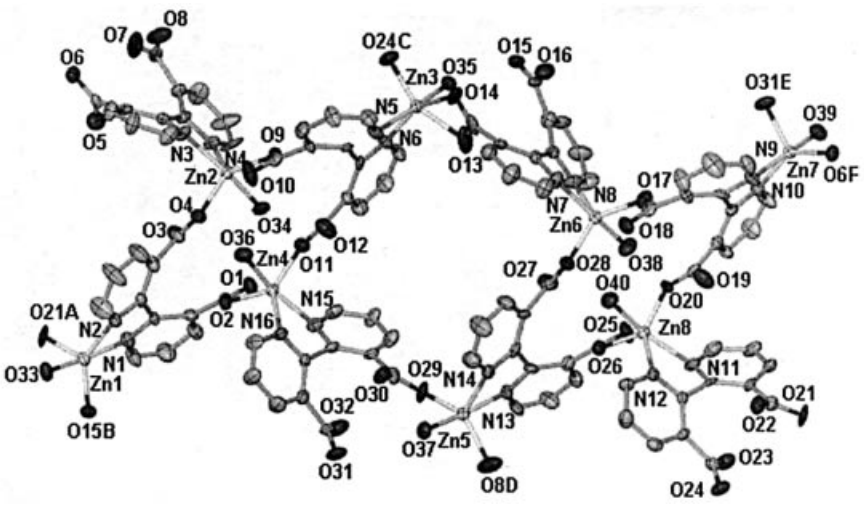

Figure 3. An ORTEP representation of the coordination geometry around the Zn^{II} centers in **2** (50% probability thermal ellipsoids); the solvent water molecules and hydrogen atoms have been omitted for clarity

due to the different coordination patterns of its carboxyl groups (see Scheme 1). The eight bpdc anions in the same asymmetric unit exhibit different distortions of the 2,2′-bipyridyl moiety along the 1,1′ bond, and the dihedral angles between their two pyridine rings are in the range of 30−45°.

The 2-D polymeric structure of **2** can be depicted as a porous grid topology. As shown in Figure 4, two triangular bpdc ligands coordinate to two Zn^{II} nodes with their carboxyl arms to form a rhombus, and further connect to Zn^{II} nodes of adjacent rhombuses with their 2,2′-bipyridyl moieties, resulting in an extended sheet along the *ab*-plane. Furthermore, cage-like pores with a diameter of about 1.2 nm are created through this regular combination of rhombuses. Through the face-to-face packing of 2-D grid sheets along *c*-axis, these cage-like pores run through each other and result in 1-D hydrophilic channels (Figure 5), where the guest water molecules reside. To the best of our knowledge, the framework architectures and unusual coordination modes of bpdc in **1** and **2** are new in the family of bpdc-containing complexes.

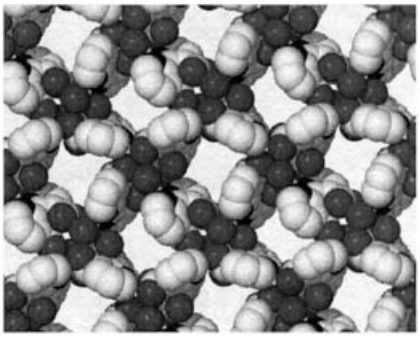

Figure 5. View of the 1-D hydrophilic tunnels along the *c* axis in **2** (guest water molecules have been omitted for clarity)

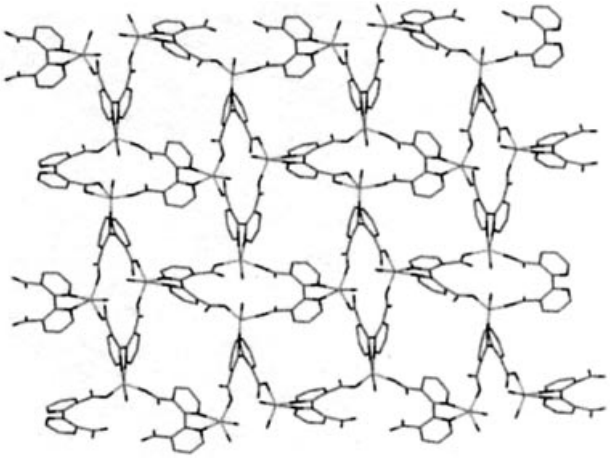

Figure 4. Perspective view of the 2-D network with square cavities and rhombuses in **2**

Fluorescence Properties

Investigations of the solid emissions of Me_2bpdc, **1**, and **2** indicate, that the intraligand fluorescence emission (IL) wavelength and intensity can be tuned by altering the configuration of bpdc, i.e. the dihedral angle between its pyridine moieties. The emissions of **1** [$\lambda_{max.}$ = 404 nm] and **2** [$\lambda_{max.}$ = 448 nm] can be tentatively assigned to the intraligand fluorescence emission, since a similar but weaker emission [$\lambda_{max.}$ = 443 nm for Me_2bpdc] can also be observed for the free ligand (Figure 6). Generally, the intraligand fluorescence emission wavelength of a multi-pyridine ligand is determined by the energy gap between the π and π* molecular orbitals of the free ligand, which is simply related to the extent of π conjugation in the system. For bpdc, however, whose 2,2′-bipyridyl moiety can rotate along the 1,1′ bond, the π and π* energy levels may be perturbed by the dihedral angle between the pyridine rings according to Perkovic's hy-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

pothesis.[23] The unexpected blue-shifted emission of **1** and the slightly red-shifted emission of **2** have been examined. As the dihedral angle of the 2,2′-bipyridyl moiety changes from 53.2° in Me_2bpdc to 93.7° in bpdc in complex **1**,[26] the energy gap between the π* and π molecular orbitals of bpdc increases. Thus, the maximum emission wavelength of **1** undergoes a blue-shift. However, as the dihedral angle of the 2,2′-bipyridyl moiety in **2** decreases to around 30−45°, the energy gap between the π* and π molecular orbitals of bpdc decreases, and the maximum emission wavelength of **2** undergoes a red-shift. The emission intensities of **1** and **2** increase relative to that of Me_2bpdc, and are approximately 1.6 and 1.3 times larger than that of Me_2bpdc, respectively. These enhancements perhaps result from the coordination of bpdc to Cd^{II} or Zn^{II}, which increases the conformational rigidity of the ligands, therefore reducing the non-radiative decay of the intraligand $^1(\pi$-$\pi^*)$ excited state. Similar enhancements of the intraligand fluorescence have also been found in polypyridyl cadmium(II) and polypyridyl zinc(II)polymers.[27−30]

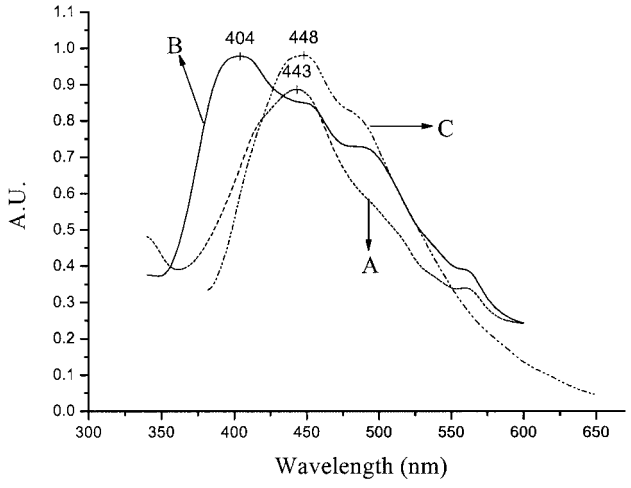

Figure 6. Fluorescence spectra of Me_2bpdc (A), **1** (B), and **2** (C) in the solid state at room temperature (the height of curve A has been reduced for clarity)

Conclusion

Based on the alteration of the configuration of bpdc induced by metal centers, two new 2-D coordination polymers have been obtained by self-assembly of bpdc with Cd^{II} or Zn^{II}. The achiral free H_2bpdc itself causes axial chirality by upon metal coordination in **1**, while in **2** it displays a different distortion of the 2,2′-bipyridyl moiety along the 1,1′ bond to meet the requirements of the final structural motif. Through tuning the configuration of bpdc, complexes **1** and **2** display stronger fluorescence emissions at different wavelengths, which may result in their exploitation in photo-materials.

Experimental Section

General Remarks: Except for binicotinic acid and dimethyl 2,2′-bipyridine-3,3′-dicarboxylate, which were synthesized by literature methods,[31] all other materials were used as received. The IR spectra in KBr disk were recorded with a Magna 750 FT-IR spectrophotometer. C, H and N elemental analyses were determined with an Elementary Vario ELIII elemental analyzer. Fluorescence spectra were measured with an Edinburgh FL-FS90 TCSPC system.

$[Cd^{II}(bpdc)]_n$ (1): Hydrothermal treatment of $CdCl_2{\cdot}2.5H_2O$ (0.2 mmol), Me_2bpdc (0.2 mmol), triethylamine (0.1 mL), and water (15 mL) at 160 °C for 5 days yielded colorless, crystalline blocks of **1** with only one pure phase. The yield of **1** was 55%. $C_{12}H_6CdN_2O_4$ (354.6): calcd. C 40.68, H 1.69, N 7.91; found C 41.10, H 1.44, N 7.91. IR (KBr): $\tilde{\nu}$ = 3093 cm^{-1} (w), 1616 (s), 1577 (s), 1566 (s), 1493 (sh, w), 1431 (m), 1400 (s), 1157 (m), 874 (m), 796 (s), 434 (m).

$\{[Zn^{II}_8(bpdc)_8(H_2O)_8](H_2O)_8\}_n$ (2): With a solution of H_2bpdc (0.2 mmol) in water (20 mL) as the bottom layer in a 50-mL tube, a mixture of water (5 mL), methanol (5 mL), and DMF (10 mL) was added dropwise to the tube along its wall to form a middle layer. A solution of $ZnCl_2$ (0.2 mmol) in methanol (10 mL) was then added as the top layer. After slowly diffusing for two weeks, colorless blocks of **2** appeared in the mesosphere and the yield of **2** was 40%. $C_{96}H_{80}N_{16}O_{48}Zn_8$ (2748.72): calcd. C 41.95, H 2.93, N 8.15; found C 41.70, H 2.84, N 8.18. IR (KBr): $\tilde{\nu}$ = 3461 cm^{-1} (br., s), 3096 (w), 3004 (w), 1653 (s), 1616 (s), 1582 (s), 1432 (m), 1381 (vs), 1161 (m), 1115 (w), 874 (m), 786 (s), 447 (m).

X-ray Crystallographic Determinations: A prismatic crystal of complex **1** with approximate dimensions of 0.46 × 0.28 × 0.04 mm, and a block crystal of complex **2** with approximate dimensions of 0.33 × 0.16 × 0.10 mm, respectively, were selected for X-ray diffraction analysis. The unit-cell parameters and intensities were collected at 298(2) K on a Siemens SMART CCD diffractometer with graphite-monochromated Mo-K_α radiation (λ = 0.71073Å) using the ω-scan mode. The structures were solved by direct methods, and refined on F^2 by full-matrix least-squares procedures using the SHELXTL software suite.[32] All non-hydrogen atoms were refined anisotropically. For complex **1**, no hydrogen atoms were theoretically located, and the maximum and minimum peaks in the final difference maps were 2.211 and −1.573 e·$Å^{-3}$ due to the statistical distribution of the pyridine rings. The largest residual density peak is close to the carboxyl group. For complex **2**, the positions of the hydrogen atoms in the pyridine rings were generated geometrically, and the maximum and minimum peaks in the final difference maps were 1.188 and −0.397 e·$Å^{-3}$ from the disordered solvent water molecule, respectively. The Flack x parameter of complex **2** is 0.3200 with an esd 0.0120 before a twin model refinement, and its absolute structural parameter is 0.00 in the final list of crystal and structural refinement data for complex **2**. A summary of the crystallographic data of complexes **1** and **2** is presented in Table 2, and their selected bond lengths and bond angles are listed in Table 1. CCDC-217300 and CCDC-223662 contain the supplementary crystallographic data for **1** and **2**, respectively. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Center, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) + 44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Film Polymerization − A New Route to the Synthesis of Insoluble Polyimides Containing Functional Nickel(II) Schiff Base Units in the Main Chain

Santo Di Bella,*[a] Giuseppe Consiglio,[b] Nicoletta Leonardi,[a] Salvatore Failla,*[b] Paolo Finocchiaro,[b] and Ignazio Fragalà[a]

Keywords: Coordination polymer / Nickel / Film polymerization / Nonlinear optics

The synthesis and characterization of a new, amino-derivatized functional bis(salicylaldiminato)Ni^{II} complex is reported. It is a useful and reactive precursor in the synthesis of polyimide thermosets. Thus, the first synthesis of a polyimide containing a nonlinear optical Ni^{II} Schiff base complex in the main chain is achieved by thermally controlled film polymerization. Polymerization was monitored on silicon substrates by FT-IR spectroscopy. The polymer film possesses characteristics analogous to those of the insoluble polymer obtained by polymerization in solution, as evidenced by FT-IR spectroscopy and TGA analysis. The present approach might represent a general strategy for achieving thin films of insoluble, functional polymers.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

The development of easily processable, functional molecular materials is of central interest in the emerging field of molecular electronics.[1] In this regard, functional polymers are amongst the most promising materials, by virtue of their facile processability into composites,[2] as well as in thin films.[3] The exploration of new polymers with functional transition metal complexes in the main chain is intriguing and the unique electronic properties associated with the metal center certainly deserve to be investigated, especially the distinct or combined, optical (linear and nonlinear), electrical, and magnetic properties.[4]

The very high thermal stability and high glass transition temperature of polyimides makes them well suited for plastic electronics,[2,3,5] although in some cases their low solubility prevents the application as thin-film materials. An alternative synthetic strategy to polyimides is the in situ film polymerization, with the potential to obtaining better thermal and mechanical characteristics of thin films. This strategy involves the choice of suitable and reactive monomers, in order to achieve a thermally controlled polymerization. The appropriate derivatization of starting monomers is thus of relevance for the design and synthesis of new functional thermoset materials.

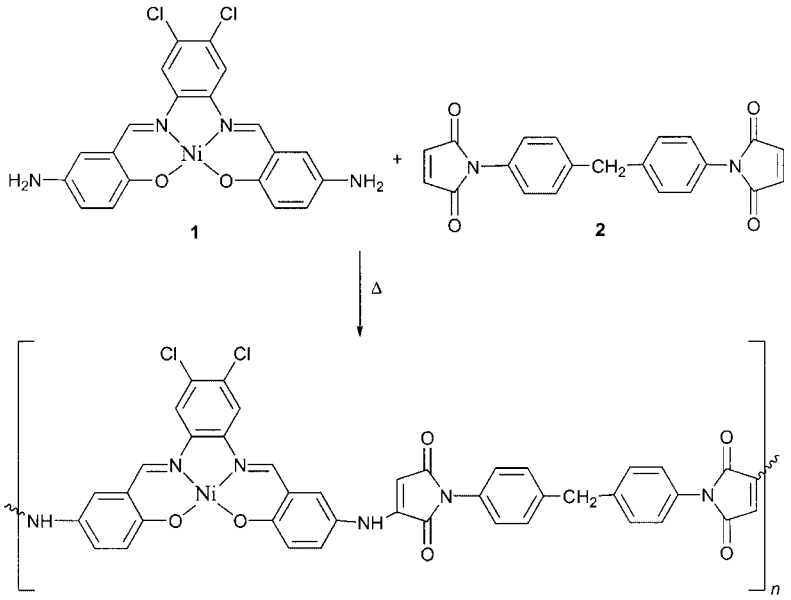
We report here on the synthesis and characterization of novel polyimide thermosets by thermally controlled, film polymerization, which might represent a general method for accomplishing films of insoluble, functional polymers. Moreover this contribution represents the first example of a co-polyimide containing a nonlinear optical Ni^{II} metal complex unit[6] in the main chain.[7,8] To this end, the amino-derivatized Schiff base bis(salicylaldiminato)Ni^{II} complex (**1**) and the bis(maleimide) (**2**) were chosen as starting monomers (Scheme 1).

Results and Discussion

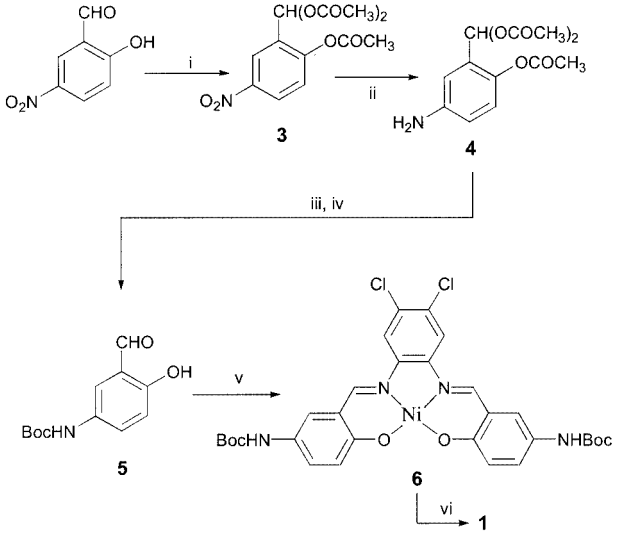
Synthesis of the Derivatized Schiff Base Complex 1

The synthesis of bis(salicylaldiminato), amino-derivatized compounds represents a difficult task. In fact, since these Schiff bases necessarily involve salicylaldehydes as starting compounds, the latter are chemically incompatible with the concurrent existence of free amines. On the other hand, nitrosalicylaldehydes, which could be used as starting materials, give rise to very low soluble Schiff bases. Actually, both the free ligand and the Ni^{II} complex of the related 5-nitro Schiff base, synthesized by standard procedures,[6b,6c] have a very low solubility in most solvents. Consequently, all attempts to obtain the diamine by reduction failed. We have thus developed an alternative route to the synthesis of amino-derivatized, Schiff base Ni^{II} complexes. The adopted synthetic approach is sketched in Scheme 2. It involves protection of the aldehyde function of the starting 5-nitrosalicylaldehyde by acetic anhydride to afford **3**; H_2-catalyzed reduction of the 5-nitro group to the free amine **4**; protection of the amine group with Boc_2O, followed by hydrolysis of the phenol and aldehyde func-



Scheme 1

tionalities with NaOH to get the salicylaldehyde derivative **5**; template reaction with the appropriate 1,2-diamine and Ni^{II} ion affords the 5-amino protected, Schiff base complex **6**; deprotection with trifluoroacetic acid of the amine groups of **6** leads to the 5-amino derivatized Schiff base Ni^{II} complex **1**. All these intermediate precursors **3**−**6**, as well as the amino-derivatized, Schiff base Ni^{II} complex **1**, were obtained in high yields (> 82%), except compound **5** (65%), and fully characterized by mass spectrometry and ^1H NMR spectroscopy, and gave satisfactory microanalyses.



Scheme 2. Reagents and conditions: (i) $(CH_3CO)_2O$, H_2SO_4 cat., room temp.; (ii) H_2 (45 psi), 10% Pd/C, EtOH; (iii) Boc_2O, CH_2Cl_2, room temp.; (iv) MeOH/H_2O, NaOH, reflux; (v) 4,5-dichloro-1,2-phenylenediamine, $NiOAc_2{\cdot}4H_2O$, MeOH; (vi) CF_3COOH, DCM, PhOMe, room temp.; then NaOH, H_2O

INDO/SCI-SOS calculations[9] on **1**, upon geometry optimization, indicate a molecular quadratic hyperpolarizability ($\beta_\mu = -22.8 \times 10^{-30}$ $cm^5{\cdot}esu^{-1}$), which can be compared with the calculated ($\beta_\mu = -17.3 \times 10^{-30}$ $cm^5{\cdot}esu^{-1}$)[6c] and experimental ($\beta_\mu = -20.5 \times 10^{-30}$ $cm^5{\cdot}esu^{-1}$)[6c] values for the unsubstituted Ni(salophen) derivative. The derivatized functional complex **1** is thus a potential candidate for nonlinear optical applications.

Polymerization in Solution

Polymerization was first carried out in solution. This allows for verification of the chemistry involved, by means of the synthesis and analysis of the prepolymer. Partial polymerization was performed by heating a solution of **1** and **2** (0.034 M in each component) in 1-methyl-2-pyrrolidone (NMP) for 1 h, at 90 °C. The prepolymer, that precipitated from chloroform, was analyzed by ^1H NMR and FT-IR spectroscopy. The 500 MHz ^1H NMR of the crude prepolymer in [D_6]DMSO solution shows a partial disappearing of the sharp resonance at $\delta = 7.15$ ppm (olefinic protons of **2**)[10] and the broad resonance (D_2O exchangeable) at $\delta = 4.57$ ppm, assigned to the primary amine protons of **1**. Moreover, the spectrum reveals the presence of new signals, with respect to the starting monomers. In particular, the peaks at $\delta = 2.80$, 3.85, 4.95, and 5.95 ppm, are evidence for the formation of the succinimide ring[11] and the secondary (−NH−) proton of the nitrogen bridge,[10] respectively (see Exp. Sect.). Along with the typical absorption bands,[12] the FT-IR spectrum of **2** also shows a strong absorption at 688 cm^{-1}, from the maleimide ring deformation, and the 1150 cm^{-1} absorption due to asymmetric C−N−C stretching. They represent the reference absorptions used to monitor the reaction between **1** and **2**. The comparison of the FT-IR spectrum of a 1:1 mixture of **1** and **2** with that of the prepolymer indicates an increase of the transmittance of bands at 688 and 1150 cm^{-1}, and the formation of a new band at 1175 cm^{-1} due to the asymmetric C−N−C

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

stretching of the succinimide ring.[13] In summary, both the ^{1}H NMR and FT-IR spectroscopic experiments on the prepolymer enable us to establish that the reaction between **1** and **2** involves a Michael addition reaction, as sketched in Scheme 1.

Polymerization was performed by curing a solution of the prepolymer in NMP for 2 h, at 140 °C. The resulting brown material has a low solubility in most solvents, typical of the polyimides, thus preventing, in principle, its application as a functional material. Longer reaction times and higher reaction temperatures did not result in appreciable changes in polymer properties (see infra). Thermogravimetric analysis of the polymer indicates a high thermal stability with a decomposition onset of 380 °C. In comparison with monomers (**2** melts at 157 °C, while **1** starts to decompose, without melting, at 330 °C) the higher thermal stability of the polymer is in agreement with its rigid structure. Accordingly, differential scanning calorimetry analysis indicates the absence of a transition glass temperature in the 30−400 °C range.

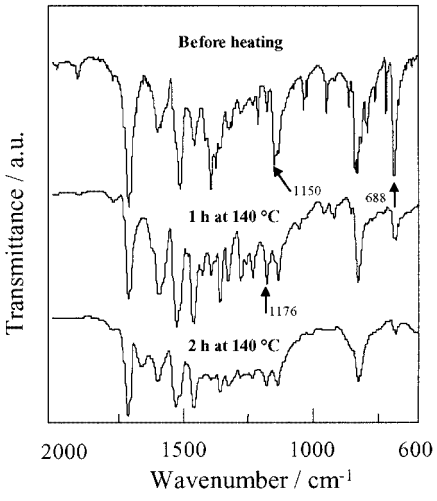


Figure 1. FT-IR spectra of a polyimide thermoset cast film on a silicon substrate at different polymerization stages, using as a reference sample the same substrate before casting. The arrows at 1176, and 1150, 688 cm^{-1} indicate the emerging succinimide function and the disappearing maleimide function, respectively

Film Polymerization

Casting of filtered chloroform solutions of **1** and **2** monomers (0.034 M in each component) on silicon substrates [Czochralsky-grown Si(100), optically transparent in the 600−4000 cm^{-1} IR region of interest, transmittance ≥ 0.90][14] followed by heating, allows the degree of film polymerization to be monitored by FT-IR analysis (Figure 1). When a film of cast monomers is heated at 140 °C for 1 h, the peaks at 688 and 1150 cm^{-1} associated with the maleimide ring decrease, while the peak at 1176 cm^{-1} associated with the succinimide function appears. After the polymer film is further heated at 140 °C for 2 h, the peak at 688 cm^{-1} almost completely disappears, and a band broadening in the range 1100−1600 cm^{-1} is observed, thus indicating an almost complete polymerization. This is also evident from the comparison of this spectrum with the almost identical one of the polymer obtained by polymerization in solution. The further heating of the film does not produce further changes in the FT-IR spectra. The polymer film possesses almost indistinguishable characteristics with respect those of the polymer obtained by polymerization in solution, as confirmed by the TGA analysis.

The polymer films were also characterized by optical spectroscopy. The optical absorption spectrum of the cast film, before heating, shows a band at 380 nm, and two shoulders at about 450 and about 560 nm (Figure 2). After polymerization is complete, the optical spectrum remains almost unchanged, except for a red-shift (≈ 10 nm) of the band at 380 nm along with a better defined structure. This is consistent with a more homogeneous film upon polymerization and good optical quality. These spectral features are similar to those of the optical spectrum of **1** in chloroform solution, thus indicating that the electronic structure of monomer **1** remains essentially unchanged upon polymerization.

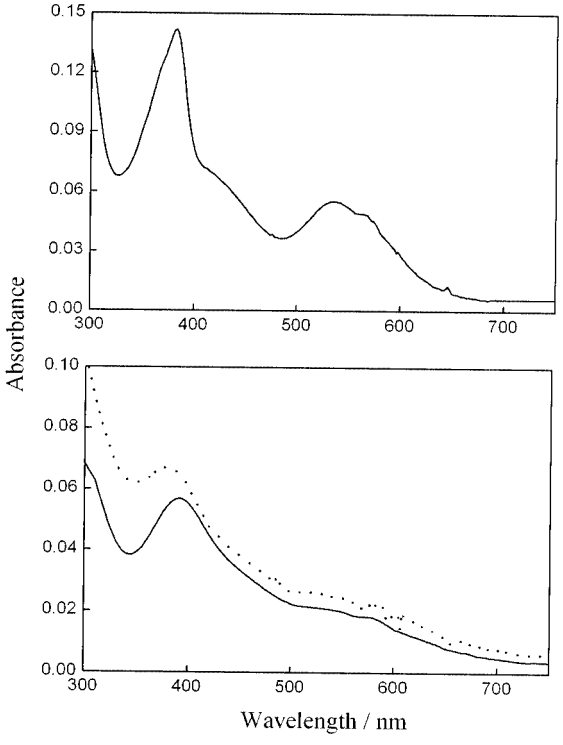

Figure 2. Optical absorption spectra (bottom) of a polyimide thermoset cast film on a glass substrate before heating (- - -) and after 3 h of heating at 140 °C (−). The absorption spectrum of complex **1** (top) in chloroform solution is reported for comparison

Conclusion

In this contribution we have achieved a convenient synthesis for novel functional, amino-derivatized Ni^{II} metal complexes. These complexes can be easily incorporated in the main chain of polyimides and *thermally controlled* film polymerization can be obtained by heating the monomers,

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

as monitored by FT-IR spectroscopy. Such an approach might represent a general method for accomplishing films of insoluble, otherwise rather intractable, functional polymers.

Further work is currently in progress with the aim of identifying more flexible monomers, in order to obtain copolymers with definite transition glass temperatures.

Experimental Section

Materials: Nickel(II) acetate tetrahydrate, 2-hydroxy-5-nitrobenzaldehyde, and all the other reagents (Aldrich) were used without purification. 4,5-Dichloro-1,2-phenylenediamine (Aldrich) was purified by sublimation in vacuo. 1,1′-(Methylenedi-4,1-phenylene)bis(maleimide) (**2**) (Aldrich), was purified by recrystallization from toluene. Dichloromethane (DMC) was distilled from CaH_2.

Physical Measurements

Elemental analyses were performed with a Carlo Erba 1106 elemental analyzer. ^{1}H NMR spectra were recorded with a Varian Unity Inova 500 MHz spectrometer, using TMS as internal standard. ESI MS were recorded with an Agilent 1100 Series ESI/MSD spectrometer. Experimental conditions were as follows: Capillary voltage, 3.5 kV; fragmentor, 100 V; source temperature, 350 °C; drying gas, N_2 (10 L/min), carrier solvent, methanol (0.4 mL/min). Samples were dissolved in methanol. For complex **1** the methanol solution was acidified with trifluoroacetic acid. Infrared spectra were recorded with a JASCO FT-IR spectrometer. Thermal measurements were performed with a Mettler Toledo TGA/SDTA85^e system. Thermal analyses were made both in air and under prepurified nitrogen (30 mL/min) using a 10 °C/min heating rate. DSC measurements were obtained from a Mettler DSC 20 calorimeter, under nitrogen atmosphere using a 20 °C/min heating rate. UV-vis spectra were recorded with a Beckman DU 650 spectrophotometer.

Syntheses

Acetyloxy(2-acetyloxy-5-nitrophenyl)methyl Acetate (3): A solution of 2-hydroxy-5-nitrobenzaldehyde (1.67 g, 10.0 mmol), acetic anhydride (50 mL), and H_2SO_4 (3 drops) was stirred under nitrogen for 1 h at room temperature. The solution obtained was poured into ice cold water (500 mL), and stirred for 30 minutes in order to hydrolyze the anhydride. The white solid was collected by filtration, air dried, and crystallized from an EtOAc/cyclohexane mixture to yield 2.55 g (82%) of a white crystalline solid (m.p. 113−115 °C). ESI MS: *m*/*z* (%) = 312 (23) $[MH]^+$. $C_{13}H_{13}NO_8$ (311.24): calcd. C 50.17, H 4.21, N 4.50; found C 50.23, H 4.19, N 4.53.

Acetyloxy(2-acetyloxy-5-aminophenyl)methyl Acetate (4): A solution of compound **3** (2.49 g, 8.00 mmol) in EtOH (40 mL) and THF (10 mL), was hydrogenated (H_2, 45 psi) using 10% Pd/C as catalyst (0.5 g). After 4 h, the filtrate was quickly concentrated to quantitatively give compound **4** (2.25 g) as light brown oil, which was used without any further purification.

***tert*-Butyl (3-Formyl-4-hydroxyphenyl)carbamate (5):** A solution of compound **4** (2.25 g, 8.00 mmol), and di(*tert*-butyl) dicarbonate (1.75 g, 8.00 mmol) in anhydrous DCM (15 mL), was stirred under nitrogen for 8 h. The solvent was evaporated under vacuum, and the oil obtained was dissolved in MeOH (10 mL). Sodium hydroxide (1.6 g, 40 mmol) and water (5 mL) were then added, and the resulting solution refluxed for 5 h. After cooling, the solution was neutralized, and the brown solid was collected by filtration, washed with water, and dried under vacuum. The solid was purified by column chromatography (SiO_2, $CHCl_3$, R_f = 0.22) and crystallized from cyclohexane, to yield 1.23 g (65%) of pale yellow needles (m.p. 122−123 °C). ^{1}H NMR (500 MHz, $CDCl_3$): δ = 10.75 (s, 1 H, O*H*), 9.84 (s, 1 H, C*H*O), 7.82 (d, J_{meta} = 2.8 Hz, 1 H, Ar*H*), 7.24 (dd, J_{ortho} = 9.0, J_{meta} = 2.8 Hz, 1 H, Ar*H*), 6.90 (d, J_{ortho} = 9.0 Hz, 1 H, Ar*H*), 6.39 (br. s, 1 H, N*H*), 1.49 (s, 9 H, CH_3C) ppm. ESI MS: *m*/*z* (%) = 238 (34) $[MH]^+$. $C_{12}H_{15}NO_4$ (237.25): calcd. C 60.75, H 6.37, N 5.90; found C 60.90, H 6.45; N 5.97.

{*N*,*N*′-Bis[5-(*tert*-butoxycarbonylamino)-2-hydroxybenzylidene]-4,5-dichloro-1,2-phenylene-diaminato}Ni^{II} (6): A solution of compound **5** (0.475 g, 2.00 mmol) in 4 mL of methanol was slowly added to a warm solution of 4,5-dichloro-1,2-phenylenediamine (0.177 g, 1.00 mmol) and nickel(II) acetate tetrahydrate (0.250 g, 1.00 mmol) in 10 mL of methanol. The brown suspension obtained was refluxed for 1 h, and then cooled to room temperature. The solid was filtered off, washed with methanol, and dried under vacuum, to yield 0.64 g (95%) of product as red-brown needles. ^{1}H NMR (500 MHz, [D$_6$]DMSO): δ = 9.11 (br. s, 2 H, N*H*), 8.87 (s, 2 H, C*H*=N), 8.57 (s, 2 H, Ar*H*), 7.86 (br. s, 2 H, Ar*H*), 7.22 (dd, J_{ortho} = 9.2, J_{meta} = 2.8 Hz, 2 H, Ar*H*), 6.80 (d, J_{ortho} = 9.2 Hz, 2 H, Ar*H*), 1.48 (s, 18 H, CH_3C) ppm. ESI MS: *m*/*z* (%) = 671 (12), 673 (13) $[MH]^+$. $C_{30}H_{30}Cl_2N_4NiO_6$ (672.18): calcd. C 53.61, H 4.50, N 8.33; found C 53.93, H 4.66, N 8.27.

[*N*,*N*′-Bis(5-amino-2-hydroxybenzylidene)-4,5-dichloro-1,2-phenylenediaminato]Ni^{II} (1): Trifluoroacetic acid (0.81 mL) was added to a suspension of compound **6** (0.540 g, 0.803 mmol) and anisole (0.4 mL) in DCM. The solution obtained was stirred under nitrogen for 24 h, at room temperature. The volatile material was removed under vacuum, and the red solid was collected and washed with diethyl ether. The solid was dissolved in 100 mL of water and filtered. Solid NaOH was added to the aqueous solution (pH ≈ 11), and the dark-brown powder that formed was collected by filtration, washed with water, and dried under high vacuum over P_2O_5, to yield 0.36 g (95%) of **1**. ^{1}H NMR (500 MHz, [D$_6$]DMSO): δ = 8.64 (s, 2 H, C*H*=N), 8.47 (s, 2 H, Ar*H*), 6.87 (d, J_{ortho} = 8.5 Hz, 2 H, Ar*H*), 6.72 (d, J_{ortho} = 8.5 Hz, 2 H, Ar*H*), 6.65 (s, 2 H, Ar*H*), 4.57 (br. s, 4 H, NH_2) ppm. ESI MS: *m*/*z* (%) = 471 (95), 473 (100) $[MH]^+$. UV/vis ($CHCl_3$): $\lambda_{max.}$ = 392, 440 (sh), 544 nm. TGA analysis: $T_{dec.}$ = 330 °C (onset). $C_{20}H_{14}Cl_2N_4NiO_2$ (471.95): calcd. C 50.90, H 2.99, N 11.87; found C 51.03, H 3.02, N 11.79.

Prepolymer: In a two-necked flask (100 mL), equipped with a reflux condenser, magnetic bar and a nitrogen inlet, a solution of **1** (0.25 g, 0.53 mmol) and **2** (0.19 g, 0.53 mmol) in NMP (16 mL) was stirred under nitrogen at 90 °C for 1 h. The mixture was poured into chloroform to give a brown solid, which was collected by filtration, washed with chloroform, several times, and then dried under vacuum (0.40 g). FT-IR (KBr pellet): $\tilde{\nu}$ = 3330 (br. m), 1710 (vs), 1598 (m), 1529 (s), 1460 (s), 1358 (m), 1175 (m), 1136 (m), 825 (s), 688 cm^{-1} (w). ^{1}H NMR (500 MHz, [D$_6$]DMSO), in the spectrum are present new peaks, with respect to the starting monomers: δ = 5.95 (s, D_2O exchangeable, Ar−NH succinimide), 4.95, 3.85 and 2.80 (m, succinimide H) ppm.

Polymer: A solution of **1** (0.25 g, 0.53 mmol) and **2** (0.19 g, 0.53 nmol) in NMP (16 mL) was placed into a two-necked flask (100 mL) equipped with a reflux condenser and a nitrogen inlet. The solution was stirred under nitrogen at 90 °C for 1 h. The temperature was then raised to 140 °C and stirring continued for 2 h. The dark mixture was cooled to room temperature, and then poured into chloroform to give a brown solid. The solid was collected by filtration, washed several times with chloroform, and then

Palladacyclopentadiene Complexes with Mono- and Didentate Imidato Ligands: Synthesis, Hemilabile Behaviour and Catalytic Application in the Stille Reaction

José Luis Serrano,*[a] Ian J. S. Fairlamb,*[b] Gregorio Sánchez,*[c] Luis García,[a] José Pérez,[a] Jorge Vives,[c] Gregorio López,[c] Catherine M. Crawforth,[b] and Richard J. K. Taylor[b]

Keywords: Catalysis / Cross-coupling / N,O ligands / Palladium / Stille reactions

The binuclear hydroxo complex $[NBu_4]_2[Pd_2\{C_4(COOMe)_4\}_2(\mu\text{-}OH)_2]$ (**1**) has been prepared by addition of two equivalents of NBu_4OH to polymeric $[Pd\{C_4(COOMe)_4\}]_n$. Complex **1** has been successfully employed as a precursor to three novel binuclear imidate-bridged complexes $[NBu_4]_2[Pd_2\{C_4(COOMe)_4\}_2(\mu\text{-imidate})_2]$ [imidate = succinimidate (suc) **2**, phthalimidate (pht) **3** or maleimidate (mal) **4**] in which the imidate group displays a bidentate *N*,*O*-coordination mode. The hemilabile behaviour of the imidate ligands has been investigated by reaction with a variety of P, N and S ligands, affording the corresponding mononuclear derivatives $[NBu_4][Pd\{C_4(COOMe)_4\}(imidate)L]$ [L = PPh_3 (**2a**, **3a** or **4a**), $P(p\text{-}C_6H_4F)_3$ (**2b**, **3b** or **4b**), PBu_3 (**2c**, **3c** or **4c**), py (**2d**, **3d** or **4d**), $p\text{-}MeC_6H_4NH_2$ (**2e**, **3e** or **4e**), tetrahydrothiophene (**2f**, **3f** or **4f**)] with terminal *N*-bonded imidate ligands. The characterization of the new complexes involved spectroscopic methods (IR, FAB, ^1H, ^{13}C, ^{19}F and ^{31}P NMR) and X-ray crystallographic analysis for **1**, **4b** and **4e**. The mononuclear derivatives are shown to catalyse the Stille cross-coupling of benzyl bromide **7** with ethyl *Z*-vinylstannyl carboxylate (**8**) in high yields. Yields and reaction times are dependent on the presence and type of imidate ligand, which suggests an important role for it in the catalytic cycle.

Introduction

Over the last twenty five years great advances in the development of palladium-catalysed carbon−carbon and carbon−heteroatom bond-forming processes have been observed.[1] Palladium-catalysed reactions, such as Stille[2] and Suzuki coupling, have made significant contributions to synthetic chemistry, not least in the synthesis of important natural products and materials.[3] For this reason, highly active, efficient and selective Pd catalysts are continually been sought after. The scope of the Suzuki and Stille reactions — the reaction of organohalides with organoboronic acids or organostannanes, respectively — has been substantially expanded upon in recent years. The design of electron-rich palladium species possessing strong σ-donor ligands that mediate mild cross-coupling reactions of activated and deactivated organohalide substrates with appropriate nucleophiles has contributed to this effort.[4] To date, however, palladacyclopentadiene complexes have not been used in classic carbon−carbon bond-forming processes, although they have been implicated in a number of other catalytic processes.[5]

In this paper, we wish to describe the synthesis of a new class of palladacyclopentadiene complexes that contain imidato ligands (succinimide, maleimide and phthalimide). We have studied in previous work[6] the hemilabile behaviour[7] of such ligands in complexes with a classical cyclometallated backbone. The precursors employed in this case were the well-known complexes with bridging acetate groups. However, regarding the desired palladacyclopentadiene compounds we envisaged that they could be synthesised from binuclear hydroxypalladium complexes, the chemistry of which has been studied recently,[8] by means of a simple acid-base reaction with protic electrophiles.[9] Thus, the preparation of the new organometallic di-μ-hydroxo complex **1** containing a palladacyclopentadiene backbone, its use as a precursor of binuclear di-μ-imidate palladacyclopentadiene complexes **2**−**4**, and their hemilabile behaviour towards monodentate ligands, such as acetonitrile,

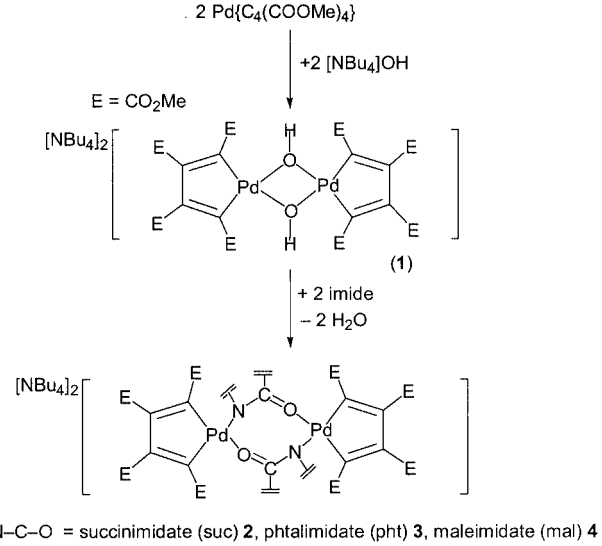
phosphanes [Ph_3P, (p-$C_6H_4F)_3P$ and nBu_3P], pyridine, p-toluidine and tetrahydrothiophene, are reported in detail herein. A comparison of the catalytic properties of the new di-μ-imidate palladacyclopentadiene complexes with [1,2,3,4-tetrakis(methoxycarbonyl)-1,3-butadiene-1,4-diyl]-palladium(II) (TCPC), [Pd($NCOC_2H_4CO$)(PPh_3)$_2$Br][10] (**5**) and [Pd($NCOC_2H_4CO$)(dppe)Br] (**6**) in the Stille reaction, is also presented. Fairlamb and Taylor[11] have recently disclosed the first application of imidato-based palladium pre-catalysts **5** and **6** in the Stille reaction,[12] where they found that allylic and benzylic substrates were coupled efficiently.[13] Here the succinimide ligand, a pseudohalide that can be viewed as a strong σ-acceptor and moderate π-donor (stronger π-donor than chlorine), plays an important role.[14] Thus, being able to compare the effect of the palladacyclopentadiene unit and the presence of an imidate ligand, is an important objective of this paper.

Results and Discussion

The novel anionic palladacyclopentadiene complex [Pd_2{C_4(COOMe)$_4$}$_2$(μ-OH)$_2$]$^{2-}$ (**1**) was conveniently prepared by reaction of the polymeric complex [Pd{C_4(COOMe)$_4$}]$_n$ (TCPC) with NBu_4OH in water (Scheme 1).[5d]



Scheme 1. Hydroxo- and imidate-bridged binuclear complexes

The analytical data for the hydroxo-bridged palladacyclopentadiene dimer **1** are consistent with the proposed formula. Negative-ion FAB mass spectrometry shows a signal at m/z = 725 due to the [Pd_2{C_4{$COOMe)_4$}{C_4{$COOMe}_3${CO}})(μ-$OH)_2$]$^-$ fragment. Evidence for the

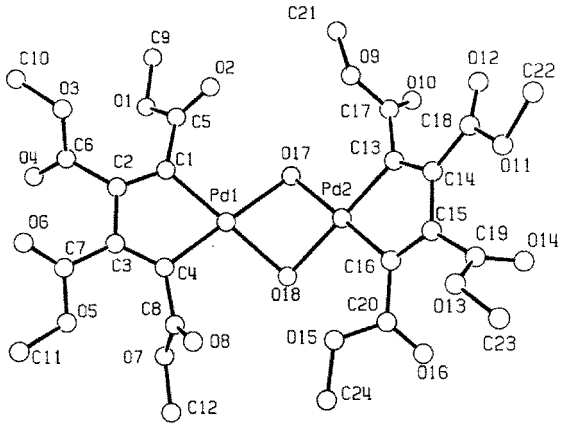


Figure 1. X-ray single-crystal structure of **1**

μ-OH ligand comes from the IR spectrum of **1**, which shows a stretching vibration at $\tilde{\nu}$ = 3600 cm^{-1}. A high-field shielded resonance is also seen at δ = −0.85 ppm in the ^{1}H NMR spectrum, which is attributable to this ligand. Two and four signals for the metallacycle moiety are found in the ^{1}H and ^{13}C NMR spectra, respectively. These attributes are consistent with the symmetrical nature of **1**. X-ray crystallographic analysis on a poor quality crystal of **1** allowed us to unambiguously define the connectivities of the atoms in the anion complex (Figure 1), confirming the proposed molecular structure and its similarity to previously reported halide complexes.[15] It was not possible to refine the structure with acceptable R-values to obtain an adequate data set for an accurate structure determination. Complex **1** crystallized from dichloromethane/diethyl ether as yellow crystals in the monoclinic space group $P2_1/c$ with cell parameters a = 12.8481(6) Å, b = 63.7441(30), c = 16.6102(8) Å, γ = 119.9433(9)°, V = 12618.0(17) Å^3, Z = 8, D_c = 1.369 g·cm^{-3}.

In acetone, **1** reacts with succinimide, phthalimide or maleimide to give the dinuclear complexes **2**, **3** and **4**, respectively, in which the imidato ligands replace the bridging hydroxo groups (as shown in Scheme 1). The imidate complexes are air-stable yellow solids, whose IR spectra exhibit strong bands between $\tilde{\nu}$ = 1700 ± 20 cm^{-1} and 1620 ± 20 cm^{-1}, that are characteristic of the carboxylate and imidate groups, respectively. The dinuclearity of these complexes was confirmed by FAB mass spectrometry. The negative FAB mass spectra of complexes **2**−**4** show peaks corresponding to [(NBu_4)Pd_2{C_4(COOMe)$_4$}$_2$(μ-suc)$_2$]$^-$ (m/z = 1220, **2**), [(NBu_4)Pd_2{C_4(COOMe)$_4$}$_2$(μ-phthal)$_2$-2]$^-$ (m/z = 1314, **3**) and [Pd_2{C_4(COOMe)$_4$}$_2$(mal)]$^-$ (m/z = 876, **4**). The dinuclear complexes **2**−**4** undergo rapid dissociation in acetonitrile to give mononuclear species. In CD_3CN, complex **2** exhibits four singlet resonances (δ = 3.36, 3.46, 3.49 and 3.60 ppm) in the ^{1}H NMR spectrum, which are attributable to the four methoxycarbonyl groups of the asymmetric [Pd{C_4(COOMe)$_4$}(suc)(CD_3CN)]$^-$ complex. Compounds **3** and **4** behave in a similar manner (see Exp. Sect.).

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

We have investigated the hemilabile behaviour of the imidato-bridged compounds toward neutral ligands, such as phosphanes, amines and tetrahydrothiophene. These reactions take place in acetone under mild conditions to give the corresponding anionic square-planar complexes $[Pd\{C_4\{COOMe)_4\}(N\text{-imidate})(L)]^-$ (**2a**−**f**, **3a**−**f**, **4a**−**f**, Scheme 2), which are air-stable pale-yellow solids. The IR spectra show bands characteristic of the palladacyclopentadiene backbone and imidate ligands (see Exp. Sect.).

Scheme 2. Mononuclear *N*-imidate complexes

With regard to the ^1H NMR spectra, the expected resonances of the palladacyclopentadiene, imidate and neutral ligands are seen. The resonances of the methoxycarbonyl groups on the carbons *trans* to the imidate units appear between $\delta = 3.25$ and 3.58 ppm, whilst the resonances of the methoxycarbonyl groups on the carbons *trans* to the neutral ligands occur at higher field, particularly in complexes containing PPh_3 and $P(p\text{-}C_6H_4F)_3$ ligands (between $\delta = 2.50$ and 2.62 ppm for complexes **2a**,**b**, **3a**,**b** and **4a**,**b**). The $^{31}P\{^1H\}$ NMR spectra of the phosphane complexes show a single resonance in the usual range for palladium(II) complexes (for PPh_3 (**2a**, **3a**, **4a**), $\delta = 28.1-28.7$ ppm; $P(4\text{-}F\text{-}C_6H_4)_3$ (**2b**, **3b**, **4b**), $\delta = 26.4-26.8$ ppm; $PnBu_3$ (**2c**, **3c**, **4c**), $\delta = 2.5-3.6$ ppm). The molecular structures of **4b** and **4e** were confirmed by X-ray single crystal diffraction (Figure 2 and 3, respectively; data collection and refinement information is given in the Exp. Sect.).

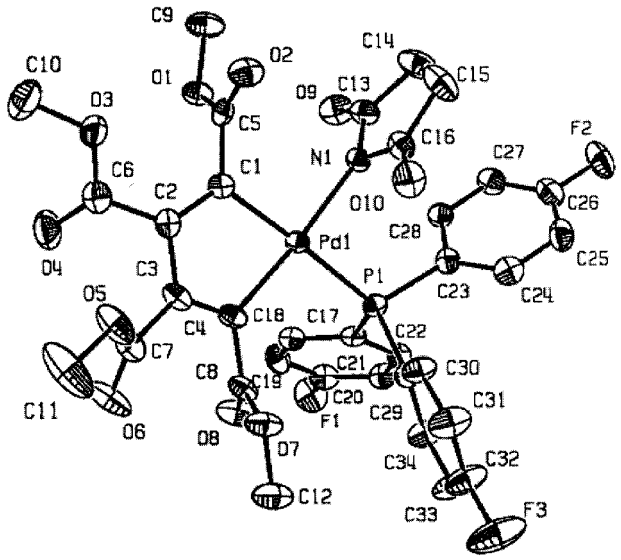

Figure 2. X-ray single crystal structure of **4b**

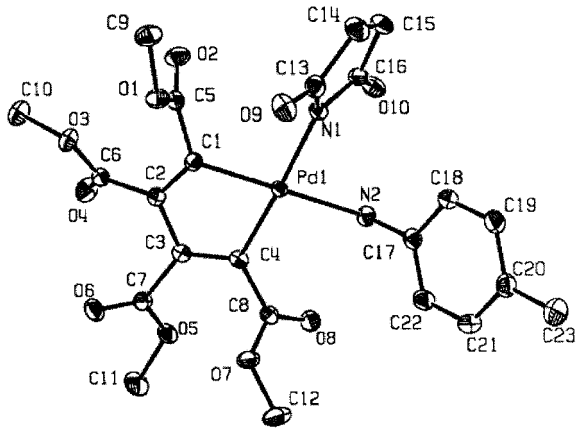

Figure 3. X-ray single crystal structure of **4e**

The X-ray data represent the first description of crystal structures in which the maleimidate ligand appears coordinated to a metal centre in a *N*-monodentate mode (η^2-alkene coordination is common for maleimide ligands).[16] Selected bond lengths and angles are given in Table 1.

The Pd(1)−N(1) distance and the C(1)−Pd(1)−C(4) angle are similar in both compounds and lie close to those determined for related structures.[5n] A slight tetrahedral distortion of the planar palladium environment is observed in **4b**, with torsion angles of −2.13° for P(1)−C(4)−C(1)−Pd(1) and −6.19° for N(1)−C(1)−C(4)−Pd(1).[17] In complex **4e** the coordination around the metal centre is characterised by a plane defined by the C(1)−C(4)−N(1)−Pd(1) atoms, with N(2) out of the plane [torsion angles of −0.30° for N(1)−C(1)−C(4)−Pd(1) and −9.40° for N(2)−C(4)−C(1)−Pd(1)]. Following the recent classification put forward by Dance and Scudder[18] for PPh_3, the conformation of the $Pd-P(p\text{-}C_6H_4F)_3$ group can be de-

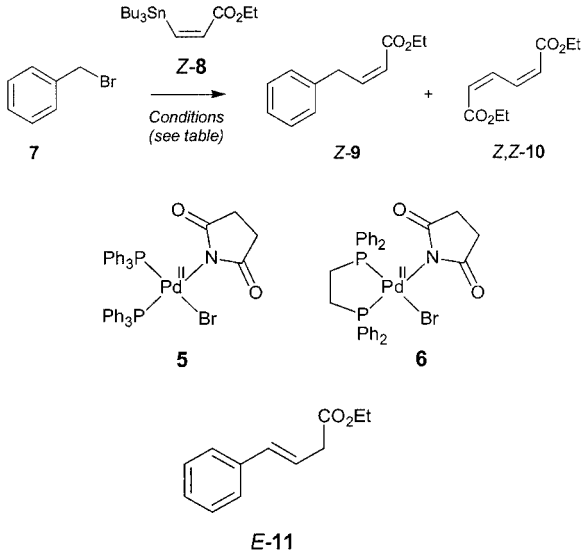
Catalytic Properties of the Mononuclear Imidate Complexes

The mononuclear palladacyclopentadiene complexes **2a**, **2d**, **2f**, **3a**−**3f**, **4a**, **4d** and **4f** were evaluated in the Stille coupling of benzyl bromide (**7**) with ethyl *Z*-vinylstannyl carboxylate (**8**) in dry toluene at 60 °C under an atmosphere of nitrogen (Table 2).



This was achieved under identical reactant concentrations and catalyst loadings to that reported in the successful Stille coupling using **5** and **6** as catalysts.[11] All of the mononuclear complexes were shown to catalyse the cross-coupling reaction. The particular type of imidate (succinimide, maleimide, phthalimide) and the neighbouring ligand attenuated the catalyst activity and overall yields of *Z*-**9**. The tetrahydrothiophene (tht) ligand proved to be the best for all of the imidate complexes, indicating that ligand dissociation is probably important (entries 5, 11 and 14). Credibility for this suggestion is gained by comparing the

pyridine and triphenylphosphane ligands (entries 3, 4, 6, 9, 12 and 13). The presence of a pyridine ligand in combination with a succinimide or phthalimide provides higher reaction rates than those catalysts containing phosphane ligands (entries 4 and 9). The reaction employing the maleimide-based complex **4d** was surprisingly sluggish and the overall yield was low (entry 13). With the exception of the phthalimide/triphenylphosphane derivative **3a** (entry 6), triphenylphosphane retards the reaction rate (entries 3 and 12). For a number of examples, regio- and/or stereoisomerisation was observed (entries 2−4, 6, 7 and 14) which is a common problem observed with this type of product.[11] We generally found that isomerisation occurs during the latter stages of the reaction (as judged by ^{1}H NMR spectroscopy and TLC analysis). In terms of isolated yields, **3b** is the best catalyst, providing *Z*-**9**/*E*-**11** in 99% combined yield, although extensive isomerisation was observed, which might be related to its high activity. The succinimido catalyst **2f** provided the product *Z*-**9** in 95% yield and no isomerisation was observed (entry 5). This catalyst reduces the reaction time by half in comparison to precatalyst **5** (entries 1 and 5) and is the catalyst of choice. As a control experiment, the TCPC complex was screened for catalytic activity (entry 15). Higher temperatures (100 °C) were required to facilitate the reaction, with the coupling product isolated in 68% yield after 15 h. The requirement for a higher temperature is presumably associated with the polymeric form of TCPC. Against a state-of-the-art catalyst system developed by Fu et al., namely the Pd/P(*t*Bu)$_3$ system,[19] our results compare well (entries 4, 5, 11). Employing an identical catalyst loading to that used in our studies (5 mol % Pd), the product *Z*-**9** was isolated in 71% yield after 1.5 h (entry 16). For catalyst **2f**, containing the tht ligand, lowering the catalyst concentration to 0.5 mol % gives the cross-coupled product in a 93% yield after only 3.25 h. Future studies will be focussed on assessing the effect and impact of catalyst loading on the reaction rates and yields of these reactions.

Generally, the results indicate that a phosphane ligand is *not* a prerequisite (it is usually required to promote the oxidative addition process). The type of imidate seems to affect the yields and reaction times, suggesting that it too plays an important role within the catalytic cycle. The substantially lower activity of TCPC in this reaction also suggests that the imidate and other ligands are important for catalysis. In consideration of the classic catalytic cycle, where a Pd^0/Pd^{II} or related anionic cycle is considered,[20] the palladacyclopentadiene unit would be reduced. However, we have yet to isolate any side-products related to the organic diene fragment of the palladacyclopentadiene unit. In the absence of phosphane ligand, reduction would be expected to release metallic palladium black, particularly towards the latter stages of the reaction when substrate concentration is low. In several reactions (entries 4, 5, 9 and 13, Table 2) small quantities of the homocoupled (self-coupled) product *Z*,*Z*-**10**, derived from the organotin reagent, *Z*-**8**, were isolated. The exact quantity of *Z*,*Z*-**10** varies, but it should be emphasised that we only begin to detect this during the latter stages of the reaction (by TLC).

Conclusion

The new di-μ hydroxo complex $[NBu_4]_2[Pd_2\{C_4(COOMe)_4\}_2(\mu\text{-}OH)_2]$ (**1**) has been synthesised and characterised. Its validity as a precursor in acid-base reactions has been demonstrated by preparation of new imidate-bridged complexes in which an *N*,*O*-bidentate coordination mode is exhibited. Bridge splitting with neutral ligands affords mononuclear *N*-bonded imidate complexes. Two *N*-bonded maleimidate complexes have been described and represent the first such examples where the maleimidate is *N*-bonded to a metal centre. These mononuclear complexes demonstrate very good catalytic properties in the Stille reaction and represent the first uses of anionic palladacyclopentadiene complexes in classical carbon−carbon bond-forming reactions. We intend to extend their use to other important reactions in synthesis, such as the Suzuki and Heck reactions. A number of complexes are more active than the previously described succinimido catalyst **5**. Complexes **2d**, **2f** and **3f** were the most efficient in this respect. Further studies are being carried out to probe whether these catalysts operate by classical or non-classical catalytic pathways, whether the palladacyclopentadiene unit is stable under the catalytic conditions, and which Pd complex is observed after catalysis. These results will be reported in due course.

Experimental Section

General Remarks: C, H, N and S analyses were carried out with a Carlo Erba model 1108 microanalyser. IR spectra were recorded on a Perkin−Elmer spectrophotometer 16F PC FT-IR, using Nujol mulls between polyethylene sheets. NMR spectroscopic data were recorded on a Bruker AC 200E or a Varian Unity 300 spectrometer. Mass spectrometric analyses were performed on a Fisons VG Autospec double-focusing spectrometer, operating in the negative mode. Ions were produced by fast-atom bombardment (FAB) with a beam of 25-KeV Cs atoms. The mass spectrometer was operated with an accelerating voltage of 8 kV and a resolution of at least 1000. The palladacyclopentadiene precursor (TCPC) was prepared by a published method.[4] Dry CH_2Cl_2 and toluene were distilled from calcium hydride. THF was distilled from sodium-benzophenone ketyl. Reagents were purchased from commercial sources and used directly unless stated otherwise in the text.

Catalysis: Nitrogen gas was oxygen-free and was dried immediately prior to use by passing over sodium hydroxide pellets. All TLC analysis was performed using Merck 5554 aluminium-backed silica plates. Compounds were visualised using UV light (254 nm) and either an acidic aqueous solution of vanillin, a basic aqueous solution of potassium permanganate, acidic DNP or iodine silica. Column chromatography was performed with Fisons matrix silica using the eluent specified in the text. The inorganic solutions used were either saturated (NaCl, KF) or of the approximate concentration indicated in the text. PE refers to petroleum ether 40−60 °C.

^{1}H and ^{13}C NMR spectra were recorded on a Jeol EX270 spectrometer operating at 270 and 67.9 MHz, respectively, on a Bruker AMX 500 at 500 and 125 MHz, respectively, or a Jeol EX400 spectrometer operating at 400 and 100 MHz. The solutions were prepared in suitable deuterated solvents. The spectra were referenced

to either TMS or residual protonated solvent. Proton assignments were based on coupling constants, integration and correlation tables. Carbon spectral assignments were aided using DEPT studies and correlation tables. All melting points were recorded on an Electrothermal IA9000 digital melting point apparatus and are uncorrected. Low- and high-field resolution electron ionisation (EI) and chemical ionisation (CI) mass spectrometry were performed by Dr. T. A. Dransfield and Mr. B. R. Glennie, using a Fisons analytical (VG) Autospec instrument. All values are reported in accordance with convention and high resolution molecular ions given are within ±5 ppm of the required molecular mass. Infrared spectroscopic data were obtained using an ATI Mattson Genesis FT-IR spectrometer. Samples were prepared for analysis as either neat films between NaCl plates, nujol mulls or solutions.

$[NBu_4]_2[Pd_2\{C_4(COOMe)_4\}_2(\mu\text{-}OH)_2]$ (1): $[NBu_4]OH$ (aq) (7.68 mL of 1 M solution, 7.68 mmol) was added to a suspension of $[Pd\{C_4\{COOMe)_4\}]_n$ (1.5 g, 3.84 mmol) in water (15 mL), with constant stirring for 30 min. The solvent was partly evaporated under reduced pressure until a yellow solid began to precipitate. The mixture was then stored overnight at ca. 4 °C and the solid was filtered off, washed with diethyl ether and air-dried. The compound was recrystallised from acetone/diethyl ether. Yield (1.972 g, 79%). M.p. 155 °C (dec.). $C_{56}H_{98}N_2O_{18}Pd_2$ (1300.2): calcd. C 51.7, H 7.6, N 2.1; found C 52.0, H 7.8, N 1.9. IR (nujol): $\tilde{\nu}$ = 3602m (νOH), 1686s (νCO), 1546s (νCO) cm^{-1}. ^1H NMR (200 MHz, $CDCl_3$): δ = −0.85 (s, 2 H, OH), 3.60 (s, 12 H, COOMe), 3.66 (s, 12 H, COOMe) ppm. $^{13}C\{^1H\}$ NMR (200 MHz, $CDCl_3$): δ = 50.5 (COO*Me*), 50.8 (COO*Me*), 50.8 (COO*Me*), 51.0 (COO*Me*) ppm. FAB-MS (negative mode): *m*/*z* = 784 $[Pd_2\{C_4(COOMe)_4\}\{C_4(COOMe)_3(CO)\}(\mu\text{-}OH)_2]^-$, 725 $[Pd_2\{C_4(COOMe)_4\}\{C_4(COOMe)_2(CO)\}(\mu\text{-}OH)_2]^-$, 407 $[Pd\{C_4(COOMe)_4O]^-$.

Complexes $[NBu_4]_2[Pd_2\{C_4(COOMe)_4\}_2(\mu\text{-imidate})_2]$ [imidate = succinimidate (suc) (2), phthalimidate (pht) (3) or maleimidate (mal) (4): These dinuclear complexes were obtained according to the following general method. A stoichiometric amount of imide (0.46 mmol) was added to an acetone solution of hydroxo complex **1** (0.3 g, 0.23 mmol). The solution was stirred at room temperature for 30 min and the solvent was partly evaporated under reduced pressure. Addition of a mixture of diethyl ether and hexane (1:1) caused the formation of yellow-orange solids, which were filtered off, washed with diethyl ether and air-dried. The compounds were recrystallised from acetone/diethyl ether.

Preparation of the Complexes [NBu$_4$][Pd{C_4(COOMe)$_4$}(mal)L] [L = PPh$_3$ (4a), P(*p*-C_6H_4F)$_3$ (4b), PBu$_3$ (4c), py (4d), *p*-Me$C_6H_4NH_2$ (4e), tetrahydrothiophene (4f)]: A stoichiometric amount of ligand (0.068 mmol) was added to a solution of the dinuclear complex [NBu$_4$]$_2$[Pd(C_4{COOMe}$_4$(μ-mal)]$_2$ (**4**; 0.05 g, 0.034 mmol) in acetone. The solution was stirred at room temperature for 30 min, and then the solvent was partly evaporated under reduced pressure to approximately one-third of the initial volume. The addition of diethyl ether caused the formation of yellow or pale-yellow solids, which were filtered off, washed with diethyl ether and air-dried. The compounds were recrystallised from dichloromethane/diethyl ether.

Preparation of Ethyl (*Z*)-3-(Tributylstannyl)propenoates (8): AIBN (0.073 g (0.4 mmol) was added to a neat mixture of ethyl propiolate (1.74 g, 17.7 mmol) and tributyltin hydride (5 mL, 18.6 mmol) and the mixture heated to 60 °C for 24 h. It was then allowed to cool to ambient temperature and purified by column chromatography using PE/EtOAc (95:5, v/v) as the eluent. This gave the *Z* isomer (2.72 g, 39%) and the *E* isomer (3.89 g, 56%), both as colourless oils. R_f = 0.70, PE/EtOAc (9:1, v/v). ^{1}H NMR (270 MHz, $CDCl_3$): δ = 0.85−0.99 (m, 18 H, 4 × CH_3 and 3 × CH_2), 1.24−1.32 (m, 6 H, 3 × CH_2), 1.43−1.56 (m, 6 H, 3 × CH_2), 4.21 (q, ^3J = 7.0 Hz, 2 H, CH_2), 6.72 (d, ^3J = 13.0 Hz, 1 H, *CH*), 7.15 (d, ^3J = 13.0 Hz, 1 H, *CH*) ppm. These data are consistent with those previously published.[21]

General Procedure for Stille Cross-Coupling: The specified catalyst (5 mol %) was added to a solution of benzyl bromide (0.5 mmol) and the stannane (0.6 mmol) in dry toluene (5 mL) and heated to 60 °C in the dark, under N_2 atmosphere, for the specified time. The reaction was allowed to cool to ambient temperature, then saturated aq. KF (5 mL) was added and the mixture stirred vigorously for 1 h. The mixture was filtered through Celite, washed with saturated aq. NaCl (2 × 5 mL) and dried ($MgSO_4$). Concentration in vacuo and subsequent purification by column chromatography using ethyl acetate/hexane mixtures (1:20 to 1:9, v/v) afforded the desired product along with some minor side-products.

Preparation of Ethyl (2*Z*)-4-Phenyl-2-butenoate (9): Obtained as a colourless oil. R_f = 0.51, PE/EtOAc (9:1, v/v). ^{1}H NMR (270 MHz, $CDCl_3$): δ = 1.32 (t, ^3J = 7.0 Hz, 3 H, CH_3), 4.03 (dd, ^3J = 7.5, 1.5, 2 H, CH_2), 4.22 (q, ^3J = 7.0 Hz, 2 H, CH_2), 5.86 (dt, ^3J = 11.5, ^4J = 1.5 Hz, 1 H, *CH*), 6.36 (dt, ^3J = 11.5, 7.5, 1 H, *CH*), 7.22−7.34 (m, 5 H, *Ph-H*) ppm. ^{13}C{^{1}H} NMR (67.9 MHz, $CDCl_3$): δ = 14.2 (CH_3), 35.1 (CH_2), 59.9 (CH_2), 119.9 (CH), 126.3 (CH), 128.7 (CH), 139.4 (C), 147.9 (CH), 166.3 (C) (*ipso* CH) ppm. These data are consistent with those previously published.[22]

Preparation of Ethyl (2*E*)-4-Phenyl-2-butenoate (9′): Obtained as a colourless oil. R_f = 0.30, PE/EtOAc (9:1, v/v). ^{1}H NMR (270 MHz, $CDCl_3$): δ = 1.27 (t, ^3J = 7.5 Hz, 3 H, CH_3), 3.52 (dd, ^3J = 7.0, 1.0, 2 H, CH_2) 4.18 (q, ^3J = 7.5 Hz, 2 H, CH_2), 5.81 (dt, ^3J = 15.5, ^4J = 1.0 Hz, 1 H, *CH*), 7.10 (dt, ^3J = 15.5, 7.0, 1 H, *CH*), 7.13−7.19 (m, 5 H, *Ph-H*) ppm. ^{13}C{^{1}H} NMR (67.9 MHz, $CDCl_3$): δ = 14.3 (CH_3), 38.6 (CH_2), 60.4 (CH_2), 122.5 (CH), 126.8 (CH), 128.8 (CH), 128.9 (CH), 137.8 (C), 147.4 (CH), 166.6 (C) ppm. These data are consistent with those previously published.[23]

Preparation of Diethyl (2*Z*,4*Z*)-2,4-Hexadienedioate (10): Obtained as a white solid. R_f = 0.10, PE/EtOAc (9:1 v/v). ^{1}H NMR (270 MHz, $CDCl_3$): δ = 1.30 (t, ^3J = 7.0 Hz, 6 H, CH_3), 4.21 (q, ^3J = 7.0 Hz, 4 H, CH_2), 5.52 (m, 2 H, *CH*), 7.89 (m, 2 H, *CH*) ppm. ^{13}C{^{1}H} NMR (100 MHz, $CDCl_3$): δ = 14.3 (CH_3), 61.0 (CH_2), 128.5 (CH), 140.9 (CH), 166.0 (C) ppm. These data are consistent with those previously published.[24]

Preparation of Diethyl (2*E*,4*E*)-2,4-Hexadienedioate (10′): Obtained as a white solid. R_f = 0.09, PE/EtOAc (9:1 v/v). ^{1}H NMR (400 MHz, $CDCl_3$): δ = 1.31 (t, ^3J = 7.0 Hz, 6 H, CH_3), 4.24 (q, ^3J = 7.0 Hz, 4 H, CH_2), 6.19 (m, 2 H, *CH*), 7.31 (m, 2 H, *CH*) ppm. ^{13}C{^{1}H} NMR (100 MHz, $CDCl_3$): δ = 14.3 (CH_3), 61.0 (CH_2), 128.5 (CH), 140.9 (CH), 166.0 (C) ppm. These data are consistent with those previously published.[25]

X-ray Crystallography: Crystals of **4b** and **4e** suitable for a diffraction study were grown from acetone/diethyl ether. Data collection for **4e** was performed at −173 °C on a Bruker Smart CCD diffractometer with a nominal crystal to detector distance of 4.5 cm. Diffraction data were collected based on a ω scan run. A total of 1371 frames were collected at 0.3° intervals and 10 s per frame. The diffraction frames were integrated using the SAINT package[26] and corrected for absorption with SADABS.[27] Data collection for **4b** was performed at −100 °C on a Siemens P4 diffractometer. The structures were solved by the Patterson (**4b**) or direct (**4e**) methods[28] and refined by full-matrix least-squares techniques using anisotropic thermal parameters for non-H atoms[28] (Table 3). Hydrogen atoms were introduced in calculated positions and refined during the last stages of the refinement.

CCDC-218969 (**4b**) and -218971 (**4e**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: + 44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Coordination Chemistry of 1,3-Bis(2-pyridylimino)- and 1,3-Bis-(2-thiazolylimino)isoindole Copper Complexes: Investigation of Their Catalytic Behavior in Oxidation Reactions

Markus B. Meder[a] and Lutz H. Gade*[a,b]

Keywords: Copper / Allylic peroxylation / Coordination polymers / Radical reactions / Oxidation

The copper complexes [Cu(4-MeBPI)(OAc)] (**4**), [Cu(4-Me-10-*t*BuBPI)(OAc)] (**5**) and [Cu(BTI)(OAc)] (**6**) [BPI = 1,3-bis(2-pyridylimino)isoindole, BTI = 1,3-bis(2-thiazolylimino)isoindole] were prepared by reaction of the protio ligands with copper(II) acetate. Compounds **4** and **6** were characterized by X-ray diffraction, establishing distorted square-planar coordination geometries of the copper ions. Two monoclinic modifications of **6** (**6a** and **6b**) were found, both crystallizing in the space group $P2_1/c$, but possessing different cell parameters. In contrast to **6a**, which is monomeric in the crystal, the second monoclinic modification **6b** has a more complicated crystal structure, which is composed of both monomeric complex units such as those found in **6a** and infinite chains of coordination polymers. The copper atoms in the polymeric chains of **6b** display fivefold coordination and a ligand polyhedron that is an intermediate form between a trigonal-bipyramidal and a square-pyramidal geometry. The allylic peroxylation of cyclohexene with *t*BuOOH (70% aqueous solution) catalyzed by **4** and **6** (0.17 mol %) gave *tert*-butylperoxy-3-cyclohexene with selectivities of 86% and 80% (based on cyclohexene) and turnover frequencies of 63 h^{-1} and 18 h^{-1}, respectively. The peroxylation reaction is thought to proceed according to a Haber–Weiss radical chain mechanism.

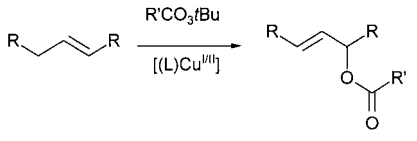
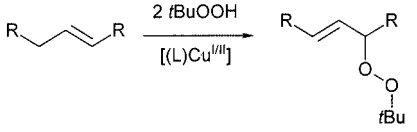
Introduction

The direct oxidation of C−H bonds is an important chemical transformation in organic synthesis. A preparatively useful example of such a conversion of hydrocarbons is the copper-catalyzed Kharasch−Sosnovsky reaction, i.e. the allylic acyloxylation of olefins [Equation (1)].[1] In the presence of chiral oxazoline-based ligands it has been possible to render this reaction enantioselective,[2] although a truly efficient asymmetric catalyst has not as yet been found. A much less studied variant of this oxidation is the allylic peroxylation, which is also catalyzed by Cu salts [Equation (2)]. The synthesis of dialkyl peroxides by the oxidation of cycloolefins with *tert*-butyl hydroperoxide, first reported by Kharasch,[3] has recently attracted renewed attention due to the high diastereoselectivity of the subsequent epoxidation or dihydroxylation of the C=C bond.[4] This gives rise to highly functionalized cyclohexane derivatives.



(1)



(2)

In the standard reaction protocols for allylic peroxylations, a Cu^I or Cu^{II} salt and, occasionally, an N-donor ligand are added to the reaction mixture which assemble to give the active catalyst, the nature of which is generally not unambiguously established.

In this paper we report the synthesis and structural characterization of several Cu^{II} complexes containing 1,3-bis(2-pyridylimino)isoindole (BPI) and 1,3-bis(2-thiazolylimino)isoindole (BTI) ligands, and their use as selective catalysts in the allylic peroxylation of cyclohexene. First reported in the 1950s,[5] such tridentate ligands have more recently been employed by Siegl and co-workers in the tran-

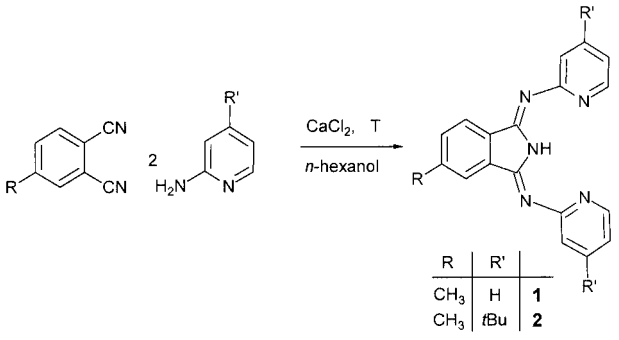
sition-metal (mainly cobalt) catalyzed oxidation of saturated hydrocarbons.[6,7] In a systematic study of the cobalt-catalyzed oxidation of cyclohexane and cyclohexene, Mimoun et al. employed *tert*-butyl hydroperoxide as the oxidizing reagent;[8] furthermore, the photoactivation of this kind of BPI-metal peroxo complex for the oxidation of hydrocarbons has also been reported.[9] Given the facile accessibility of well-defined BPI and BTI transition metal complexes and the previous results on copper-catalyzed allylic peroxylations, copper complexes of isoindole-derived tridentate ligands appear to be promising candidates for this type of transformations.

Results and Discussion

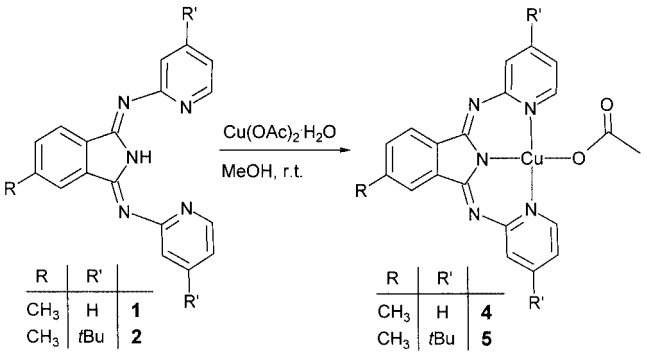
Synthesis of the Bis(2-pyridylimino)isoindole (BPI)- and Bis(2-thiazolylimino)isoindole (BTI)-Copper Complexes

For the synthesis of the bis(2-pyridylimino)isoindole and bis(2-thiazolylimino)isoindole ligand precursors, the method previously reported by Siegl was employed.[6,7,10] The phthalodinitrile starting materials were treated with an excess of the corresponding 2-aminopyridines or 2-aminothiazole in the presence of a catalytic amount of $CaCl_2$ (Scheme 1). The use of 1-hexanol as solvent instead of 1-butanol, as is reported in the literature for this type of conversion, gave significantly improved yields of the ligand precursors 4-MeBPI (**1**), 4-Me-10-*t*BuBPI (**2**) and BTI (**3**).

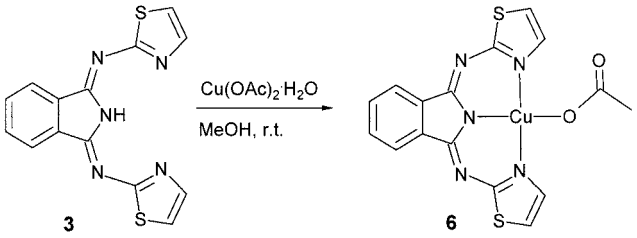


Scheme 1. Synthesis of the BPI ligands **1** and **2**

The BPI- and BTI-copper complexes [(4-MeBPI)-Cu(OAc)] (**4**), [(4-Me-10-*t*BuBPI)Cu(OAc)] (**5**), and [(BTI)-Cu(OAc)] (**6**) were prepared as previously published for similar complexes (Scheme 2 and Scheme 3);[11,12] compound **6** is the first BTI copper complex to be reported. To avoid the formation of the symmetric complexes $[Cu(BPI)_2]$ or $[Cu(BTI)_2]$, the exact metal−ligand stoichiometry was chosen, and the reaction temperature kept below 300 K. The formulation and the identity of **4**−**6** were confirmed by IR spectroscopy and elemental analysis.



Scheme 2. Synthesis of the (acetato)(BPI)copper complexes **4** and **5**



Scheme 3. Synthesis of the (acetato)(BTI)copper complex **6**

Structural Characterization of 4, 6a and 6b

Whereas a considerable number of X-ray diffraction studies have been carried out for transition-metal complexes of BPI, there are only a few previously determined structures for copper complexes. Gagné reported the dimeric structure of a (carbonato)(BPI)copper complex and the molecular structure of a μ-oxo-copper pentamer,[11] while Bereman, in a study aimed at modeling the coordination sphere of the Cu^{II} site in galactose oxidase, reported the crystal structure analysis of a pentacoordinate (acetato)(BPI)-copper complex.[13]

X-ray diffraction studies of both BPI copper compounds **4** and **5** were carried out. However, severe disorder of the *tert*-butyl groups in **5**, as well as disordered solvent in the unit cell, precluded a complete structure analysis of the latter (although the gross structural features displayed in Scheme 2 were confirmed). A single-crystal X-ray structure analysis of complex **4** established the structural details of this class of compounds. Its molecular structure is displayed in Figure 1, along with the principal bond lengths and bond angles.

As is apparent from Figure 1, the molecular structure of **4** is distorted from an ideal square-planar geometry. For instance, the N(1)−Cu−N(5) angle was found to be 158.8(1)°, which is significantly more acute than the corresponding bond angle found by Bereman et al. in the pentacoordinate complex [(10-MeBPI)Cu(OAc)(H_2O)] (169.4°).[13] The acetato ligand is monodentate and the Cu−O(1) distance of 1.956(2) Å is in the expected range.[14] The carboxyl group is arranged orthogonally to the metal complex plane due to steric repulsion with the pyridyl rings. This leads to an axial disposition of the O(2) atom of the carboxyl unit relative to the copper atom. However, the

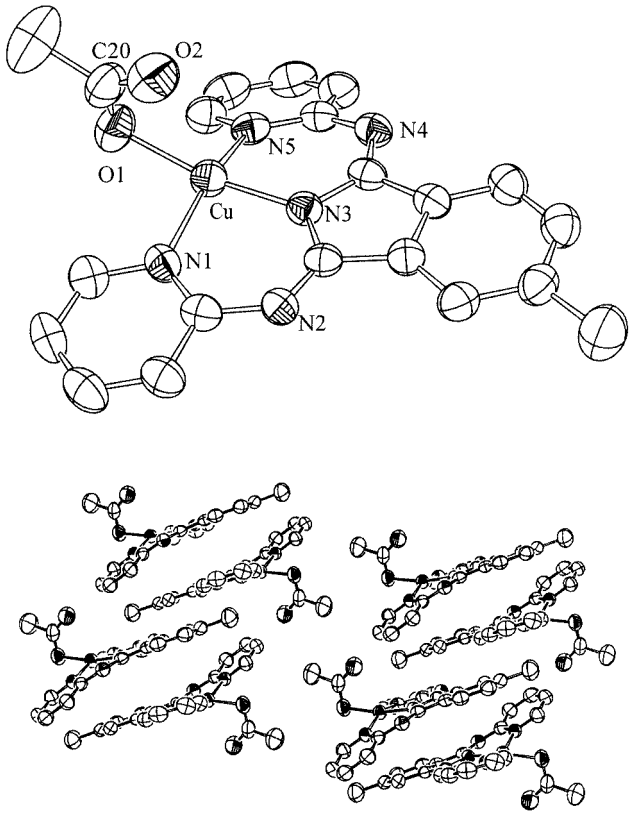

Figure 1. Molecular structure of complex **4** (top); selected bond lengths (Å) and angles (°): Cu−N(1) 2.023(3), Cu−N(3) 1.884(3), Cu−N(5) 2.014(3), Cu−O(2) 2.601(3), Cu−O(1) 1.956(2), C(20)−O(1) 1.249(5), C(20)−O(2) 1.245(5), N(1)−Cu−N(3) 90.6(1), N1−Cu−N5 158.2(1), N(1)−Cu−O(1) 93.3(1), N(3)−Cu−N(5) 89.3 (1), N(3)−Cu−O(1) 166.1(1), N(5)−Cu−O(1) 91.9(1), O(1)−C(20)−O(2) 122.9(4); view of the molecular packing of **4** in the unit cell (bottom)

Cu−O(2) distance of 2.601 Å does not support a significant bonding interaction and should be compared with the Cu−O bond length of 2.466 Å for the weakly axially coordinated water molecule in Bereman's complex.[13] A view of the packing of complex **4** in the unit cell clearly indicates that there are no bridging interactions of the acetato groups between the molecular units that stack in a head-to-tail fashion (Figure 1, bottom).

Since there is no previous report of a fully structurally characterized BTI complex, attempts were made to crystallize compound **6** in order to carry out an X-ray diffraction study. Two monoclinic crystalline modifications, the habits of which differed only marginally and which possessed identical analytical properties, were obtained in varying ratios on slow diffusion of *n*-hexane into a toluene solution of **6**. Mechanical separation of one type of crystal habit and subsequent recrystallization again gave both crystalline forms. Single-crystal X-ray structure analysis of both crystalline modifications **6a** and **6b** were carried out in order to establish the details of the molecular structure of **6** and its arrangement in both solid forms. The molecular structure of **6a** and its molecular packing pattern is displayed in Figure 2, while the principal bond lengths and bond angles are listed in Table 1.

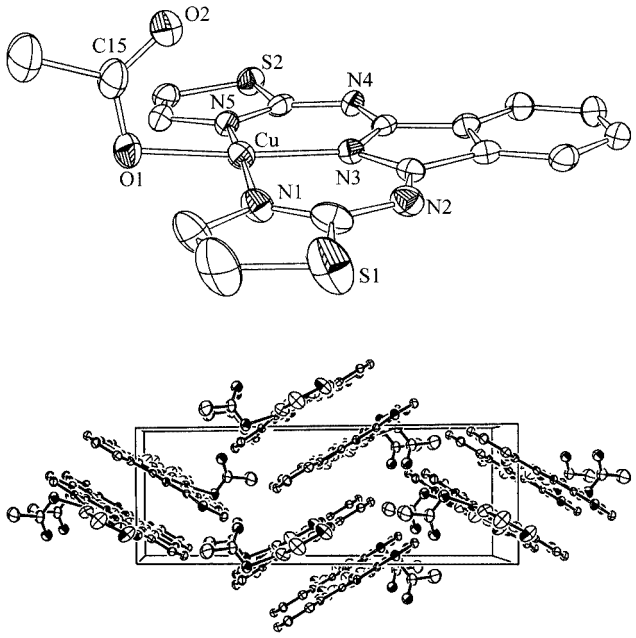

Figure 2. Molecular structure of **6a** (top); selected bond lengths and angles are given in Table 1; view of the molecular packing of **6a** in the unit cell (bottom)

Table 1. Comparison of selected bond lengths (Å) and angles (°) of **6a** and **6b**

	6a	**6b**
Cu−N1	1.991(3)	1.94(1)
Cu−N3	1.931(3)	1.98(1)
Cu−N5	1.989(3)	1.95(1)
Cu−O1	1.948(3)	2.08(1)
Cu−O2	2.595	2.54
Cu−O2′	–	2.23(1)
N1−Cu−N3	89.7(1)	89.1(5)
N1−Cu−N5	172.7(1)	173.0(5)
N3−Cu−O1	175.3(1)	154.2(5)
N3−Cu−O2	–	120.6(5)
O1−Cu−O2′	–	85.2
Cu−O1−C15	104.8(2)	101(1)
O1−C15−O2	122.8(4)	123(1)

The replacement of the pyridyl units by thiazolyl groups leads to a different orientation of the neutral N-donor functions and leaves a more open space for the acetate ligand than in **4**. These two factors lead to a complex geometry, which deviates less from the idealized planar structure than that found for **4**. The angles N(1)−Cu−N(5) and N(3)−Cu−O(1) are 172.7(1) and 175.3(1)°, respectively. Whereas the metal−N distance of the formally anionic donor atom is 0.05 Å greater than in **4** [**6a**: 1.931(3), **4**: 1.884(3) Å], the copper−thiazolyl-N bond lengths are about 0.03 Å shorter than the corresponding bond lengths in the BPI complex. The view of the molecular packing in **6a**, which is displayed in Figure 2, indicates a molecular head−tail stacking with interlayer distances of about 3.7

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

Å. There is no indication of bonding interactions through bridging acetato ligands in this structure.

In contrast to **6a**, the second monoclinic modification **6b** has a more complicated crystal structure composed of both monomeric complex units such as those found in **6a** and infinite chains of coordination polymers. A segment of such a chain structure is displayed in Figure 3, while the parameters of the complex within the polymeric structure are listed in Table 1 (those of the monomers are essentially identical to **6a**).

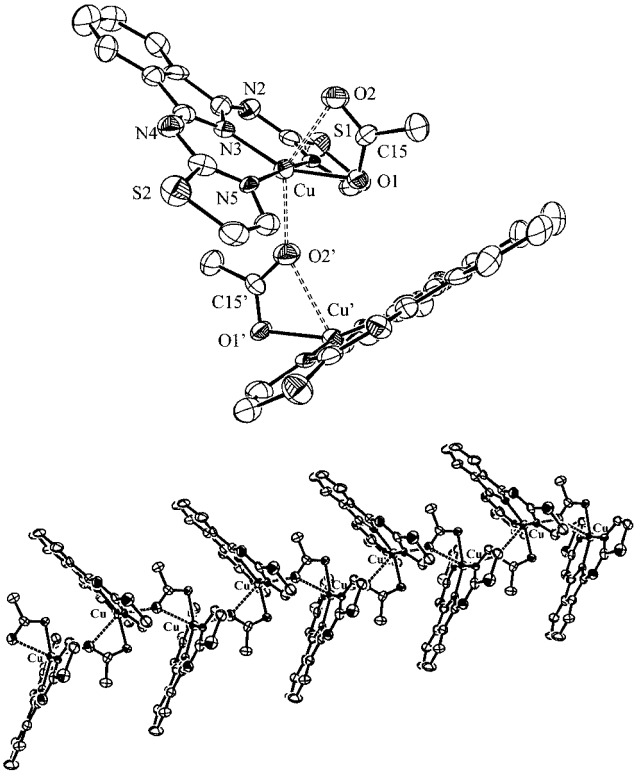

Figure 3. A segment of the chain structure in **6b** (top); selected bond lengths and angles are given in Table 1; polymeric chain structure of the (acetato)(BTI)copper complex in **6b** (bottom)

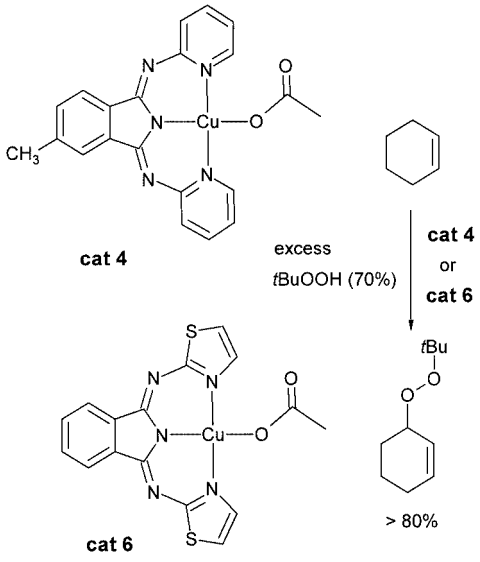
In contrast to the almost ideally planar four-coordinate structure of **6a**, the copper atoms in the polymeric chains of **6b** display fivefold coordination and a ligand polyhedron which is an intermediate form between a trigonal-bipyramidal and a square-pyramidal geometry. While the arrangement of the three heterocycles of the BTI ligand remains almost planar [N(1)−Cu−N(5), 173.0(5)°], the acetato ligand is tilted out of this plane [N(3)−Cu−O(1), 154.2(5)°], therefore making space for the coordination of the second acetato oxygen atom of a neighboring (acetato)(BTI)copper coordination unit. Significantly, the Cu−O(1) bond length of 2.08(1) Å is longer than in the square-planar monomer, and the Cu−O(2′) distance of 2.23(1) Å is indicative of substantial intermolecular bonding, leading to the polymeric complex. Similar Cu−O bond lengths were reported for two BPI copper complexes: a dimeric carbonato- and an oligomeric hydroxo-bridged complex.[12]

It should be pointed out that upon redissolution of either of the two crystalline modifications of compound **6** and subsequent recrystallization of the material, crystals of both monoclinic forms reprecipitated. The sole species in solution is therefore thought to be the monomer, as observed in **6a**. Exclusive formation of either **6a** or **6b** was not achieved by variation of either the solvent system or the temperature of crystallization.

Allylic Peroxylation of Cyclohexane Catalyzed by Complexes 4−6

In order to assess the catalytic activity of the copper complexes in the allylic peroxylation of alkenes, the Cu^{II}-catalyzed reaction of *t*BuOOH with cyclohexene was studied. In contrast to a previous study on the analogous Co-catalyzed reaction by Mimoun et al., who employed the oxidant in very high concentrations (96%),[8] we chose the commercial aqueous solution of 70% *t*BuOOH. Remarkably, all three complexes gave the dialkyl peroxide, *tert*-butylperoxy-3-cyclohexene, very selectively (Scheme 4). Conversions to this major product (based on cyclohexene) were in the range of 80−90%.



Scheme 4. Allylic peroxylation of cyclohexene catalyzed by complexes **4** and **6** giving the dialkyl peroxide in over 80% yield

The principal difference between the three catalysts was the activity observed: the two BPI derivatives display the same catalytic activity and are significantly more active than the BTI complex as is shown in Figure 4 for catalysts **4** and **6**. Both reactions were carried out with a catalyst loading of 0.17 mol %. Considering the nearly linear part of the conversion curves between 10% and 75%, the turnover frequencies amount to 63 h^{-1} for **4** and 18 h^{-1} for the BTI complex **6**. The maximum conversions of 86% observed for complex **4** and 80% for complex **6** correspond to turnover numbers of 505 and 470, respectively. The reaction product *tert*-butylperoxy-3-cyclohexene was isolated by distillation

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

and fully characterized. In order to exclude the possibility that a simple copper salt acts as a catalytic species after initial degradation of the ligands, analogous catalytic runs using the identical reaction parameters were carried out with copper acetate. Very slow oxidation of cyclohexene was observed with low chemoselectivity; the conversion of the starting material was variable, but in all cases well below 10% after 1500 minutes (the time frame of the experiments represented in Figure 4). Thus, for the results presented in this work, the background activity of nonligated copper salts is insignificant.

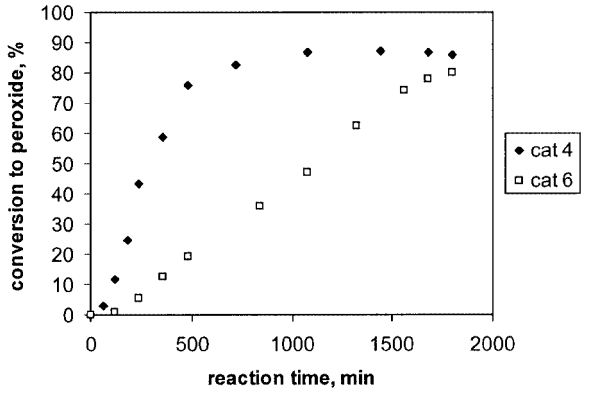


Figure 4. Peroxidation of cyclohexene with the catalysts **4** and **6**

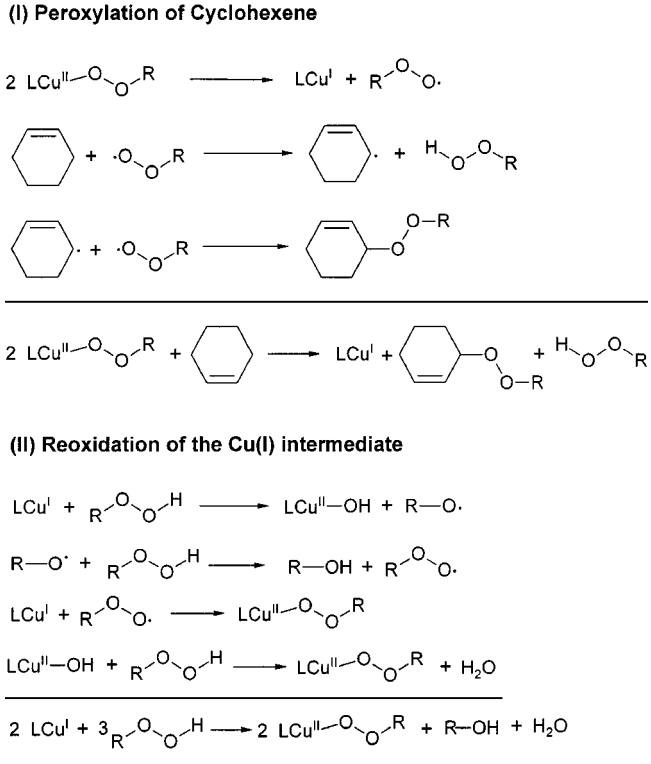
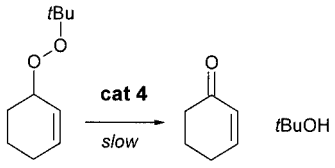


Scheme 5. Postulated Haber−Weiss mechanism for the Cu-catalyzed peroxylation: generation of the alkylperoxycopper(II) complexes as the active species and their degradation to the Cu^{I} species with concomitant transfer of the peroxyl group to the allylic position of cyclohexene

The catalytic reaction most probably proceeds according to a Haber−Weiss chain mechanism, as has been suggested previously, and which depicted in Scheme 5.[15] The active species is the copper(II) *tert*-butyl peroxide complex which thermally decomposes to the Cu^{I} complex and a peroxyl radical. This radical intermediate abstracts a hydrogen atom from the allylic position of cyclohexene, and the cyclohexenyl radical then recombines with a second peroxyl radical generated in the same way. The Cu^{I} product is then re-oxidized by the alkyl hydroperoxide in several steps generating *tert*-butanol and water as reduced products.

When the reaction product *tert*-butylperoxy-3-cyclohexene was exposed to the copper complexes over a longer period of time (> 20 h for **4** and **5** and > 35 h for **6**), slow conversion of the dialkyl peroxide to cyclohexenone and *tert*-butanol was observed (Scheme 6). This slow secondary reaction limits the yields of the dialkyl peroxide which can be isolated from the copper-catalyzed peroxylation described in this work. It was also observed by the addition of the Cu complexes to pure, isolated dialkyl peroxide.



Scheme 6. Copper-catalyzed slow conversion of *tert*-butylperoxy-3-cyclohexene to cyclohexenone and *tert*-butanol

Conclusion

In this work we have presented a detailed study of the coordination chemistry of three BPI and BTI copper complexes and their activity as catalysts for the allylic peroxylation of cyclohexene as substrate of reference. Using the hydroperoxide oxidant as an aqueous solution with a concentration of 70% gave the *tert*-butyl cyclohexenyl peroxide with high selectivity. Other previously described reaction products such as 3-cyclohexenol, 3,3′-dicyclohexenyl were not observed, even in traces, while exposure of the dialkyl peroxide to the copper catalysts for an extended period of time led to a very slow degradation to cyclohexenone as a secondary product. The high selectivity of the peroxylation on use of the BPI copper compounds and the relatively high turnover numbers obtained render these systems competitive catalysts for peroxylation reactions. We are currently studying the regioselectivity of the peroxide formation for nonsymmetrical olefins in order to assess the general applicability of this method.

Experimental Section

All manipulations were performed under a nitrogen atmosphere in standard (Schlenk) glassware. Solvents were dried according to standard procedures and saturated with nitrogen. The deuterated

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

solvents used for NMR spectroscopic measurements were degassed by three successive "freeze-pump-thaw" cycles and dried using standard techniques.

The ^1H and ^{13}C NMR spectra were recorded using an AMX 400 FT NMR spectrometer and infrared spectra on a Perkin−Elmer 1600 FT-IR spectrometer. Elemental analyses were carried out in the microanalytical laboratories of the chemistry departments at Würzburg (Germany) and Strasbourg (France). The compounds 2-amino-4-*tert*-butylpyridine[16] and 4-methylphthalonitrile[17] were prepared according to published methods. All other chemicals used as starting materials were obtained commercially and used without further purification.

Preparation of the Ligands: The synthesis of the ligand precursors was carried out by a modified protocol based on the method which was originally published by Siegl.[7,10] This modified reaction protocol will be exemplified for the synthesis of the novel derivative 4-Me-10-*t*BuBPI (**2**).

4-Me-10-*t*BuBPI (2): A suspension of 4-methylphthalonitrile (1.50 g, 10.6 mmol), 2-amino-4-*tert*-butylpyridine (3.96 g, 26.1 mmol) and $CaCl_2$ (0.16 g, 1.36 mmol) in 1-hexanol (50 cm^3) was refluxed for 18 h. After cooling to room temperature, the yellow compound which precipitated was filtered, washed with water (500 cm^3) and dried in vacuo. Yield: 2.53 g (56%). M.p. 204 °C. ^1H NMR (400.16 MHz, C_6D_6, 295 K): δ = 1.1, 1.2 (2 × s, 2 × 9 H, 10-*t*Bu), 2.05 (s, 3 H, 4-CH_3), 6.84 (m, 2 H, 11-H), 6.94 (br. d, $^3J_{H,H}$ = 7.9 Hz, 1 H, 5-H), 7.72 (m, 2 H, 9-H), 8.02 (br. s, 1 H, 3-H), 8.12 (d, $^3J_{H,H}$ = 7.9 Hz, 1 H, 6-H), 8.60 (d, $^3J_{H,H}$ = 5.3 Hz, 2 H, 12-H), 11.91 (br. s, 1 H, N−H). $\{^1H\}^{13}C$ NMR (100.6 MHz, C_6D_6, 295 K): δ = 21.6 (4-*C*H_3), 30.4 (10-C(*C*H_3)$_3$], 34.5 (10-*C*(CH$_3$)$_3$], 117.7 (C-11), 121.1 (C-9), 122.9 (C-5), 123.6 (C-6), 132.8 (C-3), 137.2 (C-1, C-2), 141.9 (C-4), 148.1 (C-12), 154.1 (C-7), 161.8 (C-8, C-10) ppm. IR (KBr): $\tilde{\nu}$ = 3237 (m, br), 2962 (m), 2867 (w), 1633 (m), 1590 (s), 1534 (w), 1477 (w), 1401 (w), 1365 (w), 1354 (w), 1310 (vw), 1285 (w), 1265 (w), 1219 (w), 1201 (vw), 1180 (vw), 1108 (vw), 1037 (vw), 928 (m), 890 (m), 826 (m), 716 (m) cm^{-1}. $C_{27}H_{31}N_5$ (425.57 g mol^{-1}): calcd. C 76.2, H 7.3, N 16.5; found C 76.5, H 7.4, N 16.3.

Preparation of the Copper Complexes

[Cu(4-MeBPI)(OAc)] (4): A suspension of **1** (87.0 mg, 0.28 mmol) was added to a stirred suspension of $Cu(OAc)_2{\cdot}H_2O$ (0.11 g, 0.56 mmol) in 10 mL of methanol at room temperature. After stirring for 16 h at room temperature, the reaction mixture was filtered and the resulting deep brown solution was concentrated in vacuo. The crude product was suspended in toluene and filtered with Celite. Evaporation of the solvent afforded a green-brown solid, which was recrystallized from toluene/*n*-hexane. Yield: 87.0 mg (71%). Green-brown crystals suitable for X-ray diffraction were grown by the slow diffusion of *n*-hexane into a saturated solution of **4** in toluene at room temperature. M.p. 116 °C. IR (KBr): $\tilde{\nu}$ = 2925 (w), 1628 (m), 1597 (m), 1573 (s), 1531 (m), 1467 (m), 1460 (m), 1431 (m), 1398 (vw), 1365 (w), 1280 (w), 1184 (w), 1135 (m), 1077 (w), 1012 (w), 786 (w), 755 (w) cm^{-1}. $C_{21}H_{17}CuN_5O_2$ (434.95 g mol^{-1}): calcd. C 58.0, H 3.5, N 16.1; found C 58.1, H 3.5, N 15.9%.

[Cu(4-Me-10-*t*BuBPI)(OAc)] (5): A suspension of **2** (80.0 mg, 0.19 mmol) was added to a stirred suspension of $Cu(OAc)_2{\cdot}H_2O$ (75.0 mg, 0.38 mmol) in 10 mL of methanol at room temperature. After stirring for 16 h at room temperature, the reaction mixture was filtered and the resulting deep brown solution was concentrated in vacuo. The crude product was suspended in toluene and filtered with Celite. Evaporation of the solvent afforded a green-brown solid, which was recrystallized from toluene/*n*-hexane. Yield: 82.0 mg (79%). M.p. 124 °C. IR (KBr): $\tilde{\nu}$ = 2965 (w), 1671 (m), 1573 (s), 1507 (m), 1478 (m), 1403 (m), 1360 (m), 1326 (w), 1248 (w), 1182 (m), 1143 (m), 1112 (m), 1082 (w), 946 (w), 918 (w), 885 (w), 828 (w), 729 (w) cm^{-1}. $C_{29}H_{33}CuN_5O_2$ (547.15 g mol^{-1}): calcd. C 63.7, H 6.1, N 12.8; found C 63.9, H 6.2, N 12.4%.

[Cu(BTI)(OAc)] (6a) and [Cu(BTI)(OAc)]$_\infty$ (6b): A suspension of BTI (**3**) (0.12 g, 0.38 mmol) in methanol was added to a suspension of $Cu(OAc)_2{\cdot}H_2O$ (0.15 g, 0.76 mmol) in methanol (10 mL). After stirring for 12 h at room temperature, the reaction mixture was dried in vacuo and the residue was redissolved in toluene. After filtration with Celite, the solution was concentrated and the crude product was recrystallized from toluene/*n*-hexane. Orange (**6a**) and yellow (**6b**) crystals suitable for X-ray diffraction were grown by slow diffusion of *n*-hexane into a saturated solution of **6** in toluene at room temperature. Yield: 0.13 g (81%). M.p. 121 °C. IR (KBr): $\tilde{\nu}$ = 3107 (w), 2965 (vw), 1583 (m), 1542 (s), 1494 (m), 1469 (w), 1383 (m), 1308 (w), 1298 (w), 1240 (m), 1190 (m), 1102 (s), 1071 (m), 916 (vw), 877 (m), 813 (vw), 715 (m), 682 (vw) cm^{-1}. $C_{16}H_{11}CuN_5O_2S_2$ (432.97 g mol^{-1}): calcd. C 44.4%; H 2.6%; N 16.2; found C 44.7%; H 2.7%; N 15.9%.

Catalytic Peroxylation of Cyclohexene: The catalytic peroxylations were carried out in neat cyclohexene with catalyst concentrations of 0.17 mol % and a twofold excess of *tert*-butyl hydroperoxide. Samples of ca. 10 μL were taken at the intervals indicated in Figure 4 and dissolved in 2 mL of toluene. The solution was then injected into a Shimadzu GC-17A/GCMS-QP5050A instrument. The measured ratio of the substrate and products was calibrated by comparative measurements with known ratios of pure substances. The conversion (%) generally refers to the generation of *tert*-butyl cyclohex-2-en-1-yl peroxide based on the substrate cyclohexene. The data displayed are average values of two runs.

The reaction product *tert*-butyl cyclohex-2-en-1-yl peroxide was isolated after filtration of the product mixture through a pad of Celite and removal of the solvent in vacuo. The crude product was subjected to a Kugelrohr distillation at 1 mbar (b.p. ca. 60 °C). ^1H NMR (400.16 MHz, $CDCl_3$, 295 K): δ = 1.25 (s, 9 H), 1.56 (m, 1 H), 1.73 (m, 2 H), 1.94 (m, 2 H), 2.06 (m, 12 H), 4.40 (m, 1 H), 5.74 (m, 1 H), 5.95 (m, 1 H). $\{^1H\}^{13}C$ NMR (100.6 MHz, $CDCl_3$, 295 K): δ = 18.8, 25.7, 26.8, 27.3, 76.7, 80.0, 124.5, 133.7 ppm. MS (EI): 170.1 [M^+].

X-ray Diffraction Study of 4, 6a and 6b: The crystal data were collected on a Nonius−Kappa CCD diffractometer at −100 °C and transferred to a DEC Alpha workstation; for all subsequent calculations the Nonius OpenMoleN package was used.[18] The structures were solved by direct methods, and absorption corrections were part of the scaling procedure of the data reductions. After refinement of the heavy atoms, difference Fourier maps revealed the maxima of residual electron density close to the positions expected for the hydrogen atoms; they were introduced as fixed contributors in the structure factor calculations with fixed coordinates (C−H: 0.95 Å) and isotropic temperature factors [B(H) = 1.3 B_{eqv}(C) Å^2], but not refined. Full least-square refinements on F^2. A final difference map revealed no significant maxima of electron density. The scattering factor coefficients and the anomalous dispersion coefficients were taken from the literature.[19] Crystal data and experimental details for the crystals of **4**, **6a** and **6b** are given in Table 2.

Can the *cyclo*-P_5 Ligand Introduce Basicity at the Transition Metal Center in Metallocenes? A Hybrid Density Functional Study on the *cyclo*-P_5 Analogues of Metallocenes of Fe, Ru and Os

E. J. Padma Malar[a]

Keywords: Basicity / Density functional calculations / Electronic structure / Metallocenes / Natural charge / Transition metals

Density functional theory (DFT) calculations and natural population analysis (NPA) performed on metallocenes of Fe, Ru and Os triad reveal that the *cyclo*-P_5 ligand introduces basicity at the metal center. All-electron calculations at the B3LYP/6-311+G* level yield NPA charges of 0.28, –0.28 and –0.91 at the iron center in [$FeCp_2$], [$FeCp(\eta^5\text{-}P_5)$] and [$Fe(\eta^5\text{-}P_5)_2$], respectively. The same trend in the charges is observed even when the core electrons of the metal are replaced by effective core potentials (ECPs). The accumulation of negative charge at the metal center is found to be similar in the *cyclo*-P_5 analogues of ruthenocene and osmocene. Thus, for example, the net NPA charges on Ru and Os in the decaphosphametallocenes are predicted to be –0.6 to –0.9, respectively, at different levels of calculations involving ECPs. The natural orbital populations show a small transfer of electron density from each phosphorus atom to the metal center, leading to a significant build-up of negative charge on the metal in [$M(\eta^5\text{-}P_5)_2$]; this is a new feature observed in the transition metals bound to *cyclo*-P_5 ring. This finding is indeed supported by the indirect evidence observed by Scherer and coworkers from the diamagnetic behavior in an iridium derivative of $Fe(P_5)$, that the Fe atom is negatively charged while one of the P atoms is positively charged. Natural bond orbital analysis reveals that the extent of covalent bond formation between the metal and the ligand is more pronounced for the *cyclo*-P_5 than the cyclopentadienyl ligand. While Cp retains 56–68% of aromaticity, the P_5 ring exhibits 26–51% aromaticity as compared to the free anionic rings.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

Cyclopentadienyl, C_5H_5 (Cp), is a very common and versatile ligand in the field of organometallic chemistry.[1–4] The inorganic ring *cyclo*-P_5, also known as pentaphospholyl or pentaphosphacyclopentadienyl, is π isoelectronic with Cp and is known to form complexes with several transition metals.[5–7] The first carbon-free entirely inorganic sandwich complex $[Ti(\eta^5\text{-}P_5)_2]^{2-}$ was synthesized and characterized in 2002 by Urnezius et al.[8] The crystal-structure analyses of mixed metallocenes $[M(\eta^5\text{-}C_5Me_4R)(\eta^5\text{-}P_5)]$ (M = Fe, Ru; R = Me, Et) and $[Ti(\eta^5\text{-}P_5)_2]^{2-}$ show a sandwich structure with two parallel η^5- or π-bonded rings.[6a,6b,8] Besides the pentaphospolyl ligand, inorganic rings of the type E_n (E = As, P; $n = 3-6$) are also known to form complexes with transition metals.[7] Numerous transition metal complexes have been studied with heterocyclic ligands of the type $P_n(CH)_{5-n}$ ($n = 1-4$).[9–11] Phosphorus heterocycles are also known to form sandwich complexes with some lanthanides.[10] The similarity between *cyclo*-P_5 and the Cp ligands towards complex formation is a manifestation of the "diagonal relationship" of the elements carbon and phosphorus in the Periodic Table; they have similar electronegativity values.[7,11] In recent years the role of planar aromatic heterocycles possessing novel structural and bonding features in catalysis has been recognised.[12]

Although experimental studies illustrate the potential of the P_5 ring as a ligand and can lead to a wealth of interesting complexes, there is still not much known about the structure and bonding in complexes containing a P_5 ring. Semiempirical and ab initio molecular orbital studies show that *cyclo*-P_5^- is aromatic in nature.[13–15] Early investigations[16] on bonding and stabilities in the pentaphospholyl complexes of iron were based on the extended Hückel theory. A number of studies document the importance of electron-correlation methods in obtaining reliable predictions in transition metal compounds.[17–19] Recent studies show that density functional theory (DFT)[20] calculations are remarkably successful in predicting a variety of properties to an accuracy which rivals that of more expensive correlated ab initio methods. Several recent works reveal that the DFT method provides reliable results in the case of transition metal and lanthanide complexes.[21] DFT analysis

of the electronic structure and bonding in some azaferrocenes and phosphaferrocenes by Frison et al.[22] has revealed the role of the heteroatom electronegativity as well as the shape of the lone pair in bonding. Frunzke et al.[23] have shown that in the ferrocene analogues $[Fe(\eta^5\text{-}E_5)_2]$ (E = N, P, As, Sb), bis(pentaphospholyl)ferrocene $[Fe(\eta^5\text{-}P_5)_2]$ exhibits the strongest bonding. A DFT study of Lein et al.[24] has shown that the metal−ligand bonding in $[Ti(\eta^5\text{-}E_5)_2]^{2-}$ (E = N, P, As, Sb) is more covalent than electrostatic. In addition to the complexes containing phosphorus rings, those of the analogous aza-rings have also received attention in recent years.[25] The recent DFT study of Malar[26] reveals novel structural and bonding features in the metallocenes of lithium and beryllium containing the *cyclo*-P_5 ligand. In the lowest energy structure, *cyclo*-P_5 exhibits η^1-coordination with the metal center and is perpendicular to the second ligand, which is η^5-coordinated. The absence of a metal−dπ interaction with the ligand results in a tilting of the *cyclo*-P_5 ring such that it becomes perpendicular to the second ligand. The above study shows that the *cyclo*-P_5 ligand behaves as a better donor than Cp and results in a lowering of the net charges on the lithium and beryllium centers.[26] It is of interest to know the influence of *cyclo*-P_5 on the electronic population of the metal centers in the title compounds.

The present study is aimed at getting detailed information on the molecular and electronic structures and the nature of the bonding in metallocenes of Fe, Ru and Os containing the *cyclo*-P_5 ligand. Both the mono- and bis-(*cyclo*-P_5) analogues of ferrocene, ruthenocene and osmocene are examined by hybrid DFT calculations. The electronic structures, properties and stabilities of these compounds are compared with those of the carbocyclic metallocenes Cp_2M, which are well characterized experimentally and theoretically.

Results and Discussion

Energetics

The relative stabilities of the complexes with reference to their ionic components are shown in Table 1. The binding energies ΔE are calculated with reference to the metal dication and the two anionic Cp/P_5 rings using the equation $\Delta E = E(LML') - E(L^-) - E(L'^-) - E(M^{2+})$. The heterolytic dissociation energy in the metallocene is given by $-\Delta E$.

The heterolytic dissociation energy of 615 kcal/mol predicted for the eclipsed geometry of ferrocene, based on the present B3LYP/6-311+G* analysis, agrees very closely with the observed value of 635 ± 15 kcal/mol.[27] Table 1 shows that the binding energies of ferrocene and its *cyclo*-P_5 analogues predicted by Type-II and -III basis sets are close to those of the all-electron 6-311+G* results. Type-I calculations deviate significantly from the B3LYP/6-311+G* values, though the trends in the stabilities are similar. Examination of the present results show that the predictions based on B3LYP/Type-III calculations, which use triple-split valence basis on the metal, agree better with those of the all-electron calculations at the B3LYP/6-311+G* level for ferrocene and its analogues. Although the all-electron calculations are more accurate, in systems with Ru or Os centers that require the use of ECPs, B3LYP/Type-III results are expected to be reliable. The dissociation energies predicted in this work by B3LYP/Type-I, B3LYP/Type-II, B3LYP/Type-III, and B3LYP/6-311+G* for ferrocene (608−638 kcal/mol) show better agreement with the experimental results than the value of 663 kcal/mol reported using the B_PW91 method of density functional theory.[21d] Our study shows that in a series of analogous metallocenes, the heterolytic dissociation energy increases in the order ferrocene < ruthenocene < osmocene; thus osmocenes are pre-

Table 1. Binding energies (kcal/mol) of the metallocenes at the eclipsed and staggered geometries; relative energies are given in parentheses

dicted to be more stable than the corresponding ferrocenes and ruthenocenes. This is in agreement with the earlier observation of Mayor-López et al[21d] that ruthenocene has a higher heterolytic dissociation energy than ferrocene. The present work shows that the stability of the *cyclo*-P_5 analogues of the metallocenes follows the order: MCp_2 > $MCpP_5$ > $M(P_5)_2$. In the pentaphosphaferrocene [$FeCp(\eta^5$-$P_5)$], the magnitude of the binding energy is 31−35 kcal/mol lower than in ferrocene when Type-II, Type-III, and 6-311+G* basis sets are used. However there is a more pronounced lowering of stability in the carbon-free metallocene [$Fe(\eta^5$-$P_5)_2$], by about 53 kcal/mol relative to the pentaphospha analogue. A similar but less marked lowering in the stabilities of the *cyclo*-P_5 analogues of ruthenocene and osmocene is evident from Table 1. The heterolytic dissociation energies of [$M(\eta^5$-$P_5)_2$] (M = Fe, Ru and Os) are lower than the corresponding values for MCp_2 by 85, 55, and 41 kcal/mol, respectively, according to Type-III calculations. A similar trend in the relative stabilities is also observed in penta- and decaphospha analogues of beryllocene using B3LYP/6-31G*, B3LYP/6-31+G*//B3LYP/6-31G*, B3LYP/6-311+G**//B3LYP/6-31G* and B3LYP/LANL2DZ calculations.[26] The prediction based on the present B3LYP/6-311+G* analysis, that [$Fe(\eta^5$-$P_5)_2$] is about 84 kcal/mol less stable than ferrocene towards heterolytic cleavage, contradicts the conclusion of Frunzke et al.[23] that the former is as stable as ferrocene.

The bonding in metallocenes is generally explained on the basis of interaction between the occupied π-orbitals of the ligands and the vacant d_{xz} and d_{yz} orbitals of the metal, which leads to stabilization of the bonding e_1'' orbitals and destabilization of the antibonding $(e_1'')^*$ orbitals. The earlier study of Mayor-López et al.[21d] on the electronic structures of ferrocene and ruthenocene showed that the HOMO−LUMO gap is about 0.8 eV larger for the latter than for the former. This led the authors to conclude that metal-ligand covalency, and hence the binding energy, is greater in ruthenocene than in ferrocene. Figure 1 depicts the energetics of the highest occupied and lowest vacant MOs generated by the B3LYP/6-311+G* method in the eclipsed structure of ferrocene analogues. The HOMO−LUMO energy gap follows the order $FeCp_2$ (5.09) > $FeCp(P_5)$ (4.35) > $Fe(P_5)_2$ (3.12). The lower HOMO−LUMO gap in the phospha analogues indicates that the interaction between the ligand π-orbitals and the vacant metal orbitals is smaller and it may account for their lower binding energies. The trends in the MO energies in ferrocene and its *cyclo*-P_5 analogues appear to be very similar to those of the beryllocenes with eclipsed structures.[26] The HOMO−LUMO energy gap in the beryllocenes is $BeCp_2$ (6.53) > $BeCp(P_5)$ (3.83) > $Be(P_5)_2$ (2.99) by the B3LYP/6-31G* method.[26] The resemblance in the MO energetics in the two different classes of metallocenes with sandwich structures reveals that the nature of the orbital interactions is quite similar irrespective of the type of the metal center. It is apparent that the ligand donor π-orbitals play a major role in the stabilization of the bonding and the destabilization of the antibonding MOs in these metallocenes.

The relative energies shown in parentheses in Table 1 reveal that the eclipsed sandwich arrangement is more stable than the staggered geometry by 0.3−1.7 kcal/mol. The small energy difference between the eclipsed and staggered arrangements is in agreement with the ^{13}C NMR study of ferrocene at cryogenic temperatures, which shows that ferrocene is freely rotating about its fivefold symmetry axis above 45−50 K.[21b] An eclipsed structure for ferrocene and ruthenocene was confirmed by an electron-diffraction study[28] and a crystal-structure analysis.[29] Negligibly small energy difference between the staggered and eclipsed geometries have been reported in different DFT studies of carbocyclic metallocenes MCp_2 [21b−21g] and in aza- and phosphaferrocenes.[22,23] Analysis of the vibrational frequencies in the present work reveals that all values are real

in the eclipsed structure and it is thus a minimum in the potential energy surface. However, the staggered sandwich structure exhibits one imaginary vibrational frequency in the range 20−50 i cm^{-1}, which indicates that the staggered arrangement is not a potential minimum and is likely to be the rotational transition state. In a recent study using different DFT methods, Schaefer and co-workers[21g] found that the eclipsed sandwich structure is the global minimum in the metallocenes of the first transition metal series. These authors have reported that the staggered structure of ferrocene is 0.75−1.13 kcal/mol higher in energy than the eclipsed geometry and is in agreement with the present results.

Geometries of Ferrocene, Ruthenocene and Osmocene and their *cyclo*-P_5 Analogues

Table 2−4 display selected geometrical parameters in the optimized eclipsed sandwich structures. It is found that the structural parameters of the ligands and the metal−ligand separations are nearly identical in both the eclipsed sandwich and the staggered sandwich arrangements. In a given system, the calculations at the different levels yield structures that vary only marginally. The predicted values are found to be closer to experimental results in Type-III calculations when ECPs are used. The computed ring bond lengths for the C−C and P−P bonds in the metallocenes are in the ranges 1.43−1.44 and 2.14−2.16 Å, respectively, and agree satisfactorily with the available experimental and the reported DFT studies.[21b−21d,21g,22−24] Although the C−C and P−P bonds in these complexes are characteristic of aromatic bonds, the present results show that the ligand rings expand along the series Fe, Ru, and Os. Thus the C−C and P−P lengths are the longest in osmium metallocenes. The present P−P bond lengths are very similar to the observed mean value of 2.154(9) Å[8] in the decaphosphatitanium complex $[Ti(\eta^5\text{-}P_5)_2]^{2-}$.

The distance between the metal and the center of the Cp ring (d_C; Table 2) in ferrocene is predicted to be 1.686−1.687 Å and it is 0.026 Å longer than the experimental value of 1.66 Å reported by Haaland.[28] In ruthenocene, there is an elongation of about 0.18 Å in the metal−ring distance as compared to that in ferrocene; this value is similar to the experimental increase of about 0.16 Å. However, the calculations predict that the d_C values are quite similar in $RuCp_2$ and $OsCp_2$. Similar trends in d_C are also maintained in the pentaphosphametallocenes. The longer separation between the metal and Cp ligands in ruthenium and osmium metallocenes leads to an increase of about 0.15 Å in Ru−C and Os−C bond lengths as compared to those of the Fe−C bonds.

The distance between the metal and the center of the P_5 ring, d_P, is shorter than the M−Cp(centre) in pentaphosphametallocenes. The experimental d_P values in the alkyl derivatives of pentaphosphametallocenes are 1.55, 1.65 and 1.66 Å for M = Fe, Ru and Os, respectively.[6a,6b] These values are about 0.20 Å shorter than the corresponding d_C values. The d_P values predicted by B3LYP are 1.597, 1.716 and 1.711 Å in $MCpP_5$ (M = Fe, Ru, Os) by Type-III calculations. The metal−Cp separations are longer than d_P and the values are 1.712, 1.888, and 1.897 Å, respectively. The distances between the metal and P_5 center in decaphosphametallocenes are 1.693, 1.788 and 1.788 Å for Fe, Ru

	Os−P	2.570 (0.377)	2.569 (0.382)	2.562 (0.408)	
	d_P	1.796	1.795	1.788	

and Os, respectively, according to B3LYP/Type-III calculations. These values are longer than those in the pentaphosphametallocenes by 0.07−0.10 Å. The d_P values in the decaphospa analogues of Ru and Os closely resemble the value of 1.797 Å observed in $[Ti(\eta^5\text{-}P_5)_2]^{2-}$.[8]

The theoretical lengths for d_C, d_P, metal−carbon, and metal−phosphorus deviate from the experimental values by about 0.05 Å. The Ru−P distance in $RuCpP_5$ exhibits a maximum deviation of about 0.08 Å. The experimental data shown in Table 3 are from the crystal structure of the alkyl

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

derivatives of $MCpP_5$ that exhibit staggered geometries, and thus a comparison with these values may not be appropriate.

Even though the B3LYP geometries deviate from the experimental results, they nevertheless reveal the right trend regarding the changes in lengths among the homologues. The results obtained are helpful to understand the nature of bonding in these metallocenes.

The complete structural analysis shows that the hydrogen atoms in the Cp ring move away from the plane of the carbon atoms, in agreement with different experimental and theoretical observations in metallocenes of main group elements and transition metals.[31] The bend angle, θ, given in Table 2 and 3 reveals that the hydrogens of the Cp ring are bent away from the metal (θ negative) except in ferrocene and pentaphosphaferrocene. In these two systems, the hydrogens are bent towards Fe by about 1.5°, which results in a lowering of the d_H distance by about 0.02−0.03 Å (Table 2 and 3). Experimental studies show that the hydrogen atoms are bent out of the Cp plane towards the metal center in metallocenes such as $FeCp_2$, $CrCp_2$ and $NiCp_2$ by 3.0−6.5°.[28,31b−31h] The present study predicts the right direction of bending of the hydrogens in ferrocene and the magnitude of the bend angle is also close to the value of 1.6(0.4)° reported in a neutron diffraction study.[32] The hydrogens in ruthenocene and osmocene and their pentaphospha analogues bend away from the metal center and the bend angle is smaller in magnitude (<1°).

Nature of the Bonding in the Complexes

The force constant of the Cp−M stretching vibration is considered to be one of the most important parameters to assign the character of the Cp−M bonding.[18h] NMR and Mossbauer spectroscopic studies of ferrocene and related complexes have shown the covalent nature of the Fe-ligand bonding, originating essentially from the π-contribution of the ligands.[33−35]

The covalent bond orders for the C−C bonds in the different MCp_2 and $MCpP_5$ complexes under study are in the range 1.25 −1.29 (Table 2 and 3). Comparison of these values with the B3LYP/6-31G* and B3LYP/6-311+G* C−C bond orders of 1.406 and 1.405 in the free cyclopentadienyl anion shows that the covalent bonding is reduced in the Cp unit of the complexes studied. The calculations reveal that the build-up of covalent bonding between the metal and the ligand carbons, with M−C bond orders in the range 0.25−0.35, is at the expense of bonding within the ligand. The highest M−C bond order of 0.34−0.35 is observed in osmocene, which has the lowest C−C bond order of 1.25−1.26. The B3LYP/Type-III predicted M−C bond orders of 0.29, 0.31, and 0.35 in ferrocene, ruthenocene and osmocene, respectively, reflect that the metal−ligand covalency increases in the Fe triad, as predicted by Mayor-López et al.[21d]

The M−P bond indices in the metallocenes of *cyclo*-P_5 are in the range 0.37−0.50 (Table 3 and 4). The ligated P_5 rings have P−P bond orders of 1.14−1.23, which are significantly lower than the value in the *cyclo*-P_5 anion (1.409 and 1.406 at B3LYP/6-31G* and B3LYP/6-311+G* levels, respectively). The bond orders for the M−P bonds in $MCpP_5$ are more pronounced than those of the M−C bonds. This is reflected in the shorter separation between the metal and P_5 ring as compared to that of M−Cp(centre), in agreement with the observed distances. The present analysis also reveals that the metal−P_5 covalent bonding increases along the iron triad.

Natural Population and Net Atomic Charges

The natural population of the valence orbitals of the metal and the ligand atoms and their net NPA charges obtained from the NBO analysis are shown in Table 5. It can be seen that the total population on the transition metal on the metallocene $(Cp)_2M$ is less than the free-atom value of eight electrons and that the metal center exhibits a small positive charge of 0.16−0.28 at the different levels of calculations, in agreement with earlier observations.[23] However, the metal d-population increases in the order $MCp_2 < MCpP_5 < M(P_5)_2$. The ns and np valence orbital populations of the metal also increase in the above order, although the contribution of the np orbital is very small. According to B3LYP/Type-III calculations on the decaphosphametallocenes, 0.42, 0.41 and 0.50 electrons populate the ns orbitals in Fe, Ru and Os, respectively. The population of the metal d-orbitals exceeds eight electrons on the Fe and Ru centers and the total valence populations are 8.92, 8.88 and 8.56 for Fe, Ru, and Os, respectively. Thus, the population analysis reveals a significant accumulation of negative charges of −0.92, −0.88 and −0.56 on Fe, Ru and Os, respectively, in the decaphosphametallocenes. In these complexes, the 3s populations of phosphorus are 1.67, 1.68 and 1.69, while the corresponding 3p populations are 3.23, 3.23 and 3.25, respectively. Thus it is seen that the total valence orbital populations of the phosphorus atoms in the above complexes are lower than the free-atom value of five electrons, which indicates a small transfer of electron density from each phosphorus to the metal center. This leads to positive charges of 0.09, 0.09, and 0.06 on the phosphorus atoms of bis(*cyclo*-P_5) metallocenes of Fe, Ru and Os, respectively. Consequently the novel situation arises in which the metal attains significant negative charge (Fe: −0.92; Ru: −0.88; Os: −0.56). The present work establishes the fact that the *cyclo*-P_5 ligand is responsible for accumulation of excess electron density on the transition metal center by a small transfer of electron density from each P atom. This is also observed at B3LYP/Type-I and B3LYP/Type-II levels and even when ECPs are used for phosphorus atoms at the B3LYP/LANL2DZ level. The more reliable B3LYP/6-311+G* study on ferrocenes corroborates this finding. A small negative charge of −0.05 on Fe in both mono- and bis(*cyclo*-P_5) ferrocenes has been reported by Frunzke et al.[23] Our recent work on the phosphorus analogues of lithocene anion and beryllocene also supports the fact that the P_5 ring transfers significant electron density to the metal center.[26] In these cases the metal center becomes less positive when the Cp ligand in the carbocyclic metallocene is replaced by *cyclo*-P_5 ligand. The present calculations

[a] Numbers in normal typeface correspond to the 6-311+G* basis set; bold values and those in italics correspond to Type-II and Type-III calculations, respectively.

on the mono(*cyclo*-P_5) metallocenes of Fe, Ru and Os also show that the phosphorus atoms exhibit a small positive charge and the metal center attains a negative charge, although it is less pronounced. Thus the B3LYP/Type-III calculations on $CpMP_5$ yield net charges of −0.40, −0.08 and −0.08 on Fe, Ru and Os, respectively. This finding corroborates the experimental observation of diamagnetic behavior in an iridium derivative of $Fe(P_5)$, which led Scherer and co-workers to conclude that the Fe atom is negatively charged while one of the P atoms is positively charged.[7g] The observation that the metal center is electron rich and the P_5 ring is electron deficient in $M(P_5)_2$ may have an impact in catalysis, since the heterocyclic complexes are increasingly used as catalysts.[12]

Aromaticity in the Ligand Species

There has been a recent surge of interest in the aromaticity of heterocycles containing phosphorus with different coordination numbers.[36] The *cyclo*-P_5 anion contains six π-electrons in the ring and is classified as aromatic, similar to the Cp anion, based on its UV spectrum[5b] and according to geometric, energetic and magnetic criteria of aromaticity.[13−15] However, the change in the degree of aromaticity in the Cp and P_5 ligands in metal complexes has not been explored so far. Knowledge of the degree of aromaticity in the ligand moieties in the complexes will aid in the understanding of the bonding in the metallocenes. The ring expansion and the consequent weakening of ring bonds in the Cp and *cyclo*-P_5 ligands in the different complexes under study shows that the aromaticity of the ligand moieties is lower than in the free anions of Cp and P_5, respectively. We have estimated the relative aromaticity RI_x of the Cp and P_5 rings in the complexes with reference to the free Cp and P_5 anions, respectively, using the relationship

$$RI_x = \frac{I_x\,(\text{complex}) - I_{\text{ethane}}}{I_x\,(\text{anion}) - I_{\text{ethane}}}$$

where x denotes the Cp or P_5 ring and I_x denotes the aromaticity index. Although different geometric, energetic and magnetic criteria are widely used to quantify aromaticity in cyclic systems,[37−41] in the present analysis the aromaticity index is taken as the lowest ring bond-order, in accordance with the ring-current definition of Jug.[37a] I_{ethane} is the C−C bond order in the archetypal nonaromatic compound ethane. The bond orders obtained from the NBO analysis were used in the comparison. Since bond orders are less sensitive to the basis sets than the bond lengths (Table 2−4), meaningful estimates of relative aromaticity can be obtained from this analysis. Table 6 lists the relative aromaticity in the ligands obtained using bond orders at the same level of the theory. These results indicate that the Cp ring retains 56−68% of aromaticity in the complexes MCp_2 and $MCpP_5$ (M = Fe, Ru, Os), and that the aromaticity of the Cp ligand is highest when the central metal is Fe and lowest when it is Os. A similar trend exists in the relative aromaticity of the P_5 ring in the complexes $MCpP_5$ and $M(P_5)_2$ (M = Fe, Ru, Os) but the magnitude is considerably lower (26−51%).

In the metallocenes under study, the decrease of aromaticity is more pronounced in the P_5 ring than in the Cp

Table 6. Relative aromaticitiy (in %) of Cp and P_5 ligands in the metallocenes of Fe, Ru and Os in an eclipsed sandwich (D_{5h}/C_{5v}) arrangement

[a]	Cp ligand				P_5 ligand			
	Type I	Type II	Type III	6-311+G*	Type I	Type II	Type III	6-311+G*
$FeCp_2$	67.9	67.2	66.1	66.4				
$FeCpP_5$	66.0	65.8	64.7	65.3	50.5	45.6	42.5	43.9
$Fe(P_5)_2$					51.1	47.0	44.8	45.1
$RuCp_2$	64.9	64.1	63.3					
$RuCpP_5$	66.3	65.8	64.7		44.0	40.0	36.3	
$Ru(P_5)_2$					47.3	43.9	40.3	
$OsCp_2$	58.6	57.6	55.9					
$OsCpP_5$	63.3	62.4	61.9		32.6	28.5	25.9	
$Os(P_5)_2$					38.0	34.9	33.5	

[a] C−C bond orders: B3LYP/6-31G*: Cp^- = 1.406; ethane = 1.041; B3LYP/6-311+G*: Cp^- = 1.405; ethane = 1.051. P−P bond orders in P_5 anion: B3LYP/6-31G*: 1.409; B3LYP/6-311+G*: 1.406.

ring. This situation is compensated by stronger metal−P_5 bond formation, as observed earlier. It is evident from the significant bond indexes for M−C and M−P bonds that considerable π-electron density of the ligand moiety is directed towards bonding with the central metal. Even though the ligands are weakened, the complex gains stability due to covalent bonding of the ligand atoms with the central atom.

Conclusions

The present study reveals that the metal attains a negative charge of about one unit in the decaphosphametallocenes [M(η^5-P_5)$_2$] (M = Fe, Ru and Os). The natural population analysis establishes the fact that the *cyclo*-P_5 ligand is responsible for an accumulation of excess electron density on the transition metal center by a small transfer of electron density from each P atom. The observation that the metal center is electron rich and the P_5 ring is electron deficient in $M(P_5)_2$ may have an impact in catalysis, since the heterocyclic complexes are increasingly being used as catalysts.

The B3LYP/6-311+G* bond-dissociation energy of 615 kcal/mol in ferrocene agrees very well with the experimental value of 635 ± 15 kcal/mol. The calculations reveal that the build-up of covalent bonding between the metal and the ligand is at the expense of bonding within the ligand. The present analysis also shows that both the M−Cp and M−P_5 covalent bonding increases along the iron triad.

Computational Aspects

All computations reported in this study were carried out using the Gaussian 03 suite of programs.[42] Hybrid Hartree−Fock−DFT calculations were performed with Becke's three parameter hybrid-exchange functional and the gradient-corrected nonlocal correlation functional of Lee, Yang and Parr (B3LYP).[43] We performed all-electron calculations on ferrocene and its *cyclo*-P_5 analogues [FeCp(η^5-P_5)] and [Fe(η^5-P_5)] with a triple-split valence basis set, which includes polarization and diffuse functions on the heavy atoms, at the B3LYP/6-311+G* level.[44] The calculations make use of the McLean−Chandler[44b,44c] (12s,9p) → (621111, 52111) basis set ("negative-ion" basis set) for phosphorus atoms. The Watchers−Hay all-electron basis set,[44d,44e] including the scaling factor of Raghavachary and Trucks,[44f] was used for the iron center. In the metallocenes of Ru and Os, the calculations invoked an electron core potential (ECP) approximation for the chemically inactive core electrons of the metal. Three different types of calculations were performed using the ECPs: in Type-I, the ligand atoms (H, C, and P) were treated with the split valence basis set including polarization at the 6-31G* level; in Type-II and Type-III, the 6-311+G* basis set was used for the ligand atoms. The core electrons of the metal were treated, in these three types of calculations, by the Los Alamos small-core potentials (LanL2)[45a] which incorporate some relativistic effects for post third-row atoms and are found to be the "best known" ECPs.[44a] In Type-I and Type-II, the metal valence electrons are treated by the double-zeta basis set of Hay and Wadt (LanL2DZ).[45a] The Type-III calculations invoke the Stevens−Basch−Krauss triple-split valence basis[45b−45d] for the valence electrons of the metal. Complete structural optimization was carried out for the eclipsed sandwich (D_{5h}/C_{5v}) and the staggered sandwich (D_{5d}/C_{5v}) geometries of the metallocenes.

Vibrational frequencies were calculated at the optimized geometries and the total energies were corrected for zero-point vibrational energy (ZPE). A scaling factor of 0.98 for ZPE, which is reported to be suitable for B3LYP/6-31G* calculations,[46] was used in the present work. The dications of the metals were calculated at their ^{5}D ground state. The total energies of the complexes E(LML′) and their ionic components E(L^-), E(L'^-) and E(M^{2+}) are included in the Supporting Information (Table S1).

The bonding in the metallocenes was examined by natural atomic orbital (NAO) and natural bond orbital (NBO) analyses using the NBO program incorporated in the Gaussian package.[47] Natural Population Analysis (NPA) performed in the NAO basis is well known to yield reliable estimates of atomic charges, in contrast to the Mulliken Population Analysis (MPA) charges, which are highly sensitive to the basis sets employed.[48] The extent of covalent bond formation between the metal and the ligand atoms was analyzed using bond orders[49] calculated in terms of natural atomic orbitals.

Acknowledgments

Keywords: Hybrid materials / Organometallic compounds / Polyoxometalates / Self assembly / Tungsten

We report on the hybrid organic-inorganic 2-D materials $(CsNa_2[\{Sn(CH_3)_2\}_3(H_2O)_4(\beta\text{-}AsW_9O_{33})]\cdot 7H_2O)_\infty$ (**1a**) and the isomorphous $(CsNa_2[\{Sn(CH_3)_2\}_3(H_2O)_4(\beta\text{-}SbW_9O_{33})]\cdot 7H_2O)_\infty$ (**2a**) which crystallize in the orthorhombic system, space group $Pna2_1$, with identical unit cell parameters a = 26.118(2) Å, b = 16.064(1) Å, c = 13.776(1) Å, and Z = 1. Compounds **1a** and **2a** have been synthesized in good yield by crystallization from a reaction mixture of dimethyltin dichloride and $Na_9[\alpha\text{-}XW_9O_{33}]$ (X = As^{III}, Sb^{III}) in aqueous, acidic medium. We have shown by multinuclear NMR spectroscopy (^{183}W, ^{119}Sn, ^{13}C, ^{1}H) that **1a** and **2a** decompose in solution leading to the monomeric species $[\{Sn(CH_3)_2(H_2O)_2\}_3(\beta\text{-}XW_9O_{33})]^{3-}$ [X = As^{III} (**1**), Sb^{III} (**2**)]. Polyanions **1** and **2** consist of a $(\beta\text{-}XW_9O_{33})$ fragment stabilized by three dimethyltin units. The dimethyltin groups are grafted onto the polyanion by two Sn–O(W) bonds on the side of the heteroatom lone pair. Compounds **1** and **2** are rare examples of discrete polyoxoanions which polymerize upon crystallization leading to a 2-D solid-state structure with inorganic and organic surface regions.

Introduction

Polyoxometalates are of interest because they exhibit a tremendous structural variety and useful properties in different fields, including catalysis and medicine.[1−6] This is most likely the reason why the number of researchers actively involved in polyoxoanion chemistry has increased significantly over the last couple of decades. A study of the literature reveals that the vast majority of reports is devoted to catalytic studies of polyoxoanion salts and acids.

Most likely this is a result of the fact that the synthesis of novel polyoxoanion architectures is not trivial. Although the template effect seems to play an important role during the formation process of polyoxoanions, the detailed mechanism of formation is far from being understood. This is even more surprising as the first polyoxoanions were reported almost two centuries ago.[7] However, it took another 100 years for the first structure (the Keggin ion) to be determined.[8]

It is known that the size, shape and charge density of many polyoxoanions are of interest for pharmaceutical applications (e.g. antiviral, antitumor).[1−6,9] However, the mechanism of action of many polyoxoanions is not selective towards a specific target. In order to improve selectivity it often appears desirable to modify a given polyoxoanion core structure slightly. However, such attempts result frequently in a different polyoxoanion framework. Therefore the most straightforward and promising approach towards systematic derivatization of polyoxoanions involves attachment of organic groups to the surface of the metal-oxo framework. In order to be attractive for pharmaceutical applications the functionalized polyoxoanions should be water soluble and fairly stable at physiological pH.

To date the number of water-soluble polyoxoanions with tightly bound organic functions is rather small. Pope and co-workers were the first to study the interaction of monoorganotin groups with polyoxoanions. They reacted different organotin halide precursors (e.g. $nC_4H_9SnCl_3$, $C_6H_5SnCl_3$) with a large number of lacunary heteropolytungstates in aqueous solution and were able to identify novel, mostly dimeric polyoxoanion structures.[10] Single-crystal X-ray diffraction studies revealed that these products contain tightly anchored organotin fragments. The compounds were also studied in solution by multinuclear NMR spectroscopy. This technique is also very valuable in the evaluation of the stability of polyoxoanions in low concentration at physiological pH for medicinal applications. Liu and co-workers have also synthesized some monoorganotin-substituted polyoxotungstates. They introduced ester functionalities to the organotin fragment and tested the biological (antitumor) activity of their products.[11] Very recently Hasenknopf et al. used the same methodology to introduce peptide functions into organotin units which were incorporated in the monolacunary Wells−Dawson deriva-

tive $[x\text{-}P_2W_{17}O_{61}]^{10-}$ ($x = \alpha_1, \alpha_2$).[12] Haiduc et al. have also reported some monoorganotin derivatives of polyoxotungstates.[13] However, the proposed structures of Liu and Haiduc need to be confirmed by X-ray diffraction. To date, only a few monoorganotin-substituted polyoxomolybdates and -vanadates are known.[14]

Interestingly there are no reports on diorganotin-substituted polyoxotungstates. Such species could allow for more flexibility regarding the interaction with, and binding to, organic compounds and biomolecules. Therefore we decided to investigate the interaction of dimethyltin groups with lone-pair-containing heteropolytungstates in some detail.

Results and Discussion

Here we report on the novel and isostructural polyoxoanion-based 2-D materials $(CsNa_2[\{Sn(CH_3)_2\}_3(H_2O)_4(\beta\text{-}XW_9O_{33})]\cdot 7H_2O)_\infty$ (X = As, **1a**; Sb, **2a**; see Figure 1). The structure of **1a** and **2a** is best described as a polymeric network composed of $[\{Sn(CH_3)_2\}_3(H_2O)_4(\beta\text{-}XW_9O_{33})]^{3-}$ building blocks ($X = As^{III}, Sb^{III}$) that are linked by Sn−O(W′) bridges. This leads to a 2-D surface which is not planar, but could be described as a ladder with a zig-zag backbone where the individual levels are decorated by methyl groups (see Figure 2). Clearly, the solid-state structure of **1a** and **2a** is governed by the organotin functionalities.

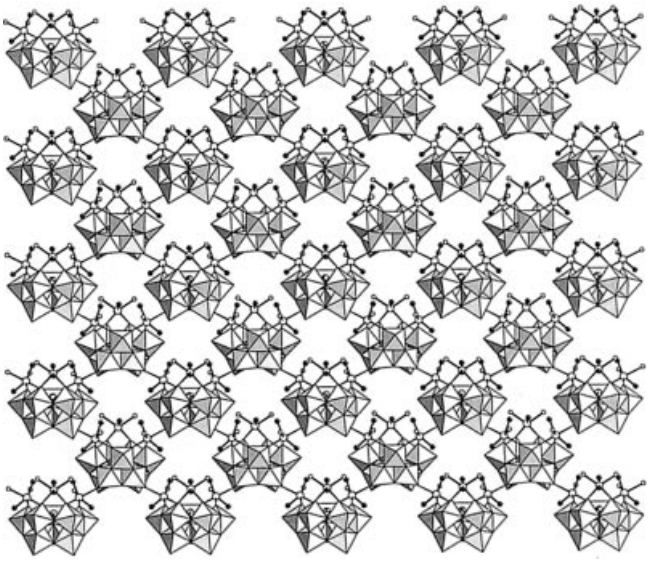

Figure 1. Combined polyhedral/ball-and-stick representation of the 2-D solid-state structure of $(CsNa_2[\{Sn(CH_3)_2\}_3(H_2O)_4(\beta\text{-}XW_9O_{33})]\cdot 7H_2O)_\infty$ (X = As, **1a**; Sb, **2a**); the octahedra represent WO_6 and the balls are tin (diagonally hatched), arsenic/antimony (crosshatched), oxygen (white) and carbon (black); hydrogen atoms are omitted for clarity

Compounds **1a** and **2a** are isostructural, which means that the different sizes of the As and Sb heteroatoms with their associated lone pairs have no significant effect on the solid-state structures.

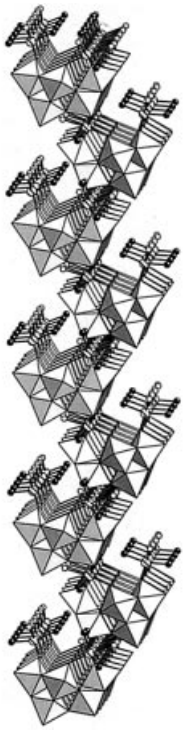

Figure 2. Side view of the 2-D solid-state structure of **1a** and **2a**; the code is the same as in Figure 1

The three organotin groups attached to each monomeric unit of **1a** and **2a** contain tin centers that are octahedrally coordinated by four oxo and two methyl groups which are positioned *trans* to each other. However, only two organotin groups are structurally equivalent and different from the third. The molecular formulae and charges of **1a** and **2a** are supported by bond-valence calculations, which indicate that all terminal oxygen atoms bound to the tin atoms are diprotonated.[15]

Close inspection of **1a** and **2a** indicates that the C−Sn−C bond angles are significantly smaller than 180°, indicating that the interior methyl groups still experience some degree of repulsion (see Figure 1). The C−Sn−C bond angles of the two equivalent organotin groups are very similar for **1a** [149(1)°, 152(1)°] and **2a** [150(1)°, 151(1)°]; however, the C−Sn−C bond angle of the unique organotin unit is distinctly larger in polyanion **1a** [166(1)°] than in **2a** [162(1)°]. This observation reflects (a) the smaller size of the As^{III} atom compared to Sb^{III}, (b) the shorter As^{III}−O bond lengths compared to Sb^{III}, and (c) the smaller size of the As^{III} lone-pair compared to Sb^{III}.

It is known that the α to β isomerization of $[\alpha\text{-}AsW_9O_{33}]^{9-}$ and $[\alpha\text{-}SbW_9O_{33}]^{9-}$ is facilitated in an acidic, aqueous medium.[16,17] This is in complete agreement with the synthetic conditions for **1a** and **2a**, which were isolated at pH 3. The $(\beta\text{-}AsW_9O_{33})$ fragment has so far only been observed in two different polyoxoanion structures.[16,18] The large tungstoarsenate(III) $[As_6W_{65}O_{217}(H_2O)_7]^{26-}$ is the only example of a polyanion that contains both $(\alpha\text{-}AsW_9O_{33})$ and $(\beta\text{-}AsW_9O_{33})$ isomers in the same structure.[18]

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

The fact that no cations are involved in the exclusively covalent 2-D network of **1a** and **2a** requires it to possess a negative charge. Indeed the appropriate number of cations (1 Cs, 2 Na) for each polyanionic unit was found by X-ray diffraction and elemental analysis. Therefore **1a** and **2a** are best described as polymeric polyanion salts. This view is further supported by our observation that **1a** and **2a** are soluble in water upon heating.

Clearly, in solution the polymeric structure of **1a** and **2a** decomposes and we identified the likely sites: the very long Sn−O(W′) bonds in **1a** [2.607(3), 2.656(3) Å] and **2a** [2.559(3), 2.633(3) Å]. The question now arises in which form **1a** and **2a** are present in solution: oligomeric or monomeric. The latter requires the existence of the hypothetical, monomeric polyanion $[\{Sn(CH_3)_2(H_2O)_2\}_3(\beta\text{-}XW_9O_{33})]^{3-}$ [X = As^{III} (**1**), Sb^{III} (**2**)]. Polyanion **1** consists of a (β-AsW_9O_{33}) fragment which is stabilized by three dimethyltin fragments, and polyanion **2** represents its antimony derivative (see Figures 3 and 4). The three dimethyltin groups of **1** and **2** are grafted onto the polyanion by two Sn−O(W) bonds each on the side of the heteroatom lone pair.

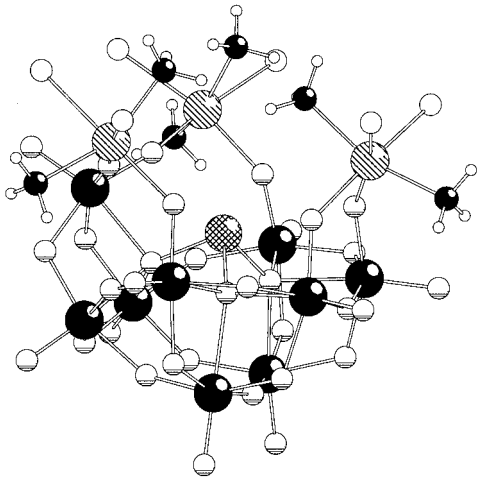

Figure 3. Ball-and-stick representation of $[\{Sn(CH_3)_2(H_2O)_2\}_3(\beta\text{-}XW_9O_{33})]^{3-}$ (X = As^{III}, **1**; Sb^{III}, **2**); the balls represent tungsten (black), tin (diagonally hatched), arsenic/antimony (crosshatched), oxygen (white with shadow), carbon (black) and hydrogen (small white); water molecules are shown as white balls

Solution NMR spectroscopy is the most elegant technique to prove the existence of **1** and **2** in solution. It is well-known that NMR of the addenda atoms (in this case tungsten) is the most sensitive analytical tool to obtain structural information of polyoxoanions in solution. Compounds **1a** and **2a** are ideal for a multinuclear NMR study because they are diamagnetic and contain several NMR-active, spin 1/2 nuclei. Therefore we performed ^{183}W, ^{119}Sn, ^{1}H and ^{13}C NMR studies on (a) freshly synthesized solutions of **1a** and **2a** (see Exp. Sect.) and (b) solid **1a** and **2a** redissolved in water. Interestingly we obtained exactly the same NMR results in both cases.

The ^{183}W NMR spectrum shows five peaks (intensity ratios 2:1:2:2:2) for **1a** at δ = −130.5, −135.2, −138.1, −142.5 and −146.2 ppm and for **2a** at δ = −108.1, −117.4, −120.1, −127.1 and −134.7 ppm (see Figure 5). The latter spectrum shows an additional, very small peak at δ = −124.6 ppm for which we do not yet have a good explanation. We also recorded a ^{119}Sn NMR spectrum and observed two peaks with an intensity ratio of 1:2 at δ = −175.9, −200.0 ppm (**1a**) and δ = −164.6, −205.2 ppm (**2a**), respectively (see Figure 6). Interestingly both signals for **1a** are somewhat broader than those for **2a**. The ^{13}C NMR spectrum shows only one peak for **1a** at δ = 8.5 ppm and for **2a** at δ = 8.7 ppm. As expected, the ^{1}H NMR spectrum also shows only one peak at δ = 4.7 ppm for **1a** and **2a**. All these results indicate that a species with C_s symmetry is present in solution and prove the existence of the discrete, monomeric polyanions **1** and **2**. Furthermore, the above NMR spectra do not change for several months; indicating that the dimethyltin groups are tightly bound to the tungsten-oxo fragment.

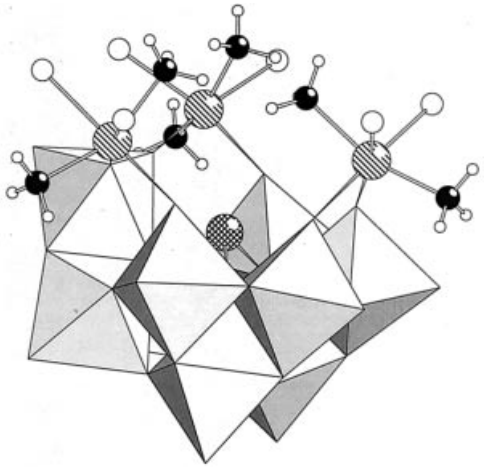

Figure 4. Combined polyhedral/ball-and-stick representation of **1** and **2**; the code is the same as in Figure 3

Polyoxoanions **1** and **2** were synthesized by heating an aqueous solution containing dimethyltin dichloride and $Na_9[\alpha\text{-}XW_9O_{33}]$ (X = As^{III}, Sb^{III}) in the appropriate stoichiometric ratio (3:1) in an aqueous, acidic medium (pH 3). From this solution the polymeric materials **1a** and **2a** were formed upon crystallization and both products could be isolated in good yield (see Exp. Sect.).

Interestingly, formation of **1** and **2** is accompanied by the isomerization (α-XW_9O_{33}) → (β-XW_9O_{33}) (X = As, Sb), and it is likely that steric interactions of the methyl groups do not allow formation of the hypothetical trisubstituted α-derivative $[\{Sn(CH_3)_2(H_2O)_2\}_3(\alpha\text{-}XW_9O_{33})]^{3-}$ (X = As^{III}, Sb^{III}). More precisely, the three "internal" methyl groups would come very close to each other if they were grafted onto a (α-AsW_9O_{33}) or (α-SbW_9O_{33}) fragment (see Figures 3 and 4). Furthermore the lone pair of electrons on the heteroatom may exhibit a repulsive effect on the internal methyl groups. Rotation of one W_3O_{13} triad by 60° results in the β-isomer and then all three dimethyltin units can be bound without steric hindrance, resulting in a stable structure. The terminal oxygens of all tin atoms in **1** and **2** are

almost certainly diprotonated. The presence of labile water ligands explains the tendency of **1** and **2** to polymerize in the solid state.

Conclusions

Our work has shown that diorganotin fragments can be incorporated into polyoxotungstates. Polyanions **1** and **2** represent (a) novel examples of hybrid organic-inorganic polyoxoanions, (b) the first examples of diorganotin-substituted polyoxoanions, (c) the first monomeric organotin derivatives of lone-pair-containing polyoxoanions, and (d) the first organotin derivatives of $[\beta\text{-}AsW_9O_{33}]^{9-}$ and $[\beta\text{-}SbW_9O_{33}]^{9-}$. The compounds presented here are rare examples of discrete polyoxoanions which polymerize upon crystallization, leading to a 2-D structure with inorganic and organic surface regions. We plan to prepare derivatives of polyanions **1** and **2** by attaching organic functional groups (e.g. COOH, NH_2, OH, SH) and chiral subunits (e.g. amino acids) to the organotin fragments. Such species would be of major interest for catalytic and medicinal applications (e.g. stabilization of metal nanoparticles, interaction with biomolecules).

Currently we investigate the possibility of grafting diorganotin units on other lacunary polyoxotungstates.

Experimental Section

The lacunary precursors $Na_9[\alpha\text{-}AsW_9O_{33}]$ and $Na_9[\alpha\text{-}SbW_9O_{33}]$ were synthesized according to published procedures and their purity was confirmed by infrared spectroscopy.[17,20] All other reagents were used as purchased without further purification.

All elemental analyses were performed by Kanti Labs Ltd. in Mississauga, Canada. The IR spectra were recorded on a Nicolet Avatar FTIR spectrophotometer in a KBr pellet. All NMR spectra were recorded, on a 400 MHz JEOL ECX instrument. The ^{183}W NMR measurements were performed at 16.656 MHz in 10 mm tubes and the ^{119}Sn, ^{13}C, and ^{1}H spectra were recorded in 5 mm tubes at 149.081, 100.525 and 399.782 MHz, respectively. The chemical shifts for unbound dimethyltin dichloride at pH 3 are at $\delta = -243.7$ ppm (^{119}Sn), 12.2 ppm (^{13}C) and 0.84 ppm (^{1}H).

$(CsNa_2[\{Sn(CH_3)_2\}_3(H_2O)_4(\beta\text{-}AsW_9O_{33})]\cdot 7H_2O)_\infty$ (1a): $Sn(CH_3)_2Cl_2$ (0.58 g, 2.64 mmol) was dissolved in 40 mL of H_2O and then $Na_9[\alpha\text{-}AsW_9O_{33}]$ (2.00 g, 0.80 mmol) was added. This solution (pH 3) was heated to 80 °C for 1 h and then cooled to room temperature and filtered. A few drops of 0.1 M CsCl were added and then the solution was allowed to evaporate in an open beaker at room temperature. After 1−2 days a white crystalline product started to appear. Evaporation was allowed to continue until the solvent level had approached the solid product, which was filtered off and air-dried. A total of 1.9 g (yield 76%) of crystalline product was obtained. **1a** (3081.0): calcd. Cs 4.3, Na 1.5 Sn 11.6, As 2.4, W 53.7; found Cs 4.0, Na 1.8, Sn 10.9, As 2.1, W 54.0. An Energy Dispersive X-ray Diffraction Study of Dioxouranium(VI) in 1 M Lithium Citrate

Ermanno Vasca,[a] Giuseppe Palladino,[a] Carla Manfredi,[b] Cecilia Fontanella,[a] Claudia Sadun,[c] and Ruggero Caminiti*[c]

Keywords: X-ray Diffraction / Solution / Uranium / Lithium citrate

An Energy Dispersive X-ray Diffraction (EDXD) study of 0.3 M dioxouranium(VI) in 1 M lithium citrate at pH = 5 is reported. The data are in accordance with the existence of a predominately polynuclear complex containing four U atoms, concluded from potentiometric measurements. The uranium atoms lie at the corners of two triangles sharing one edge. Five O atoms surround each uranyl group, the uranium coordination polyhedron being a pentagonal bipyramid; four U atoms are linked through double or single O bridges. The U–U distances are 3.95 Å and 4.65 Å.

Introduction

Speciation of dioxouranium(VI) in the presence of organic ligands containing at least one carboxylate group is a topic that is extremely relevant to the safe disposal of nuclear wastes resulting from the use of fission technologies. Actually, modeling the migration of radionuclides in the environment requires an extensive and accurate knowledge of the equilibria involving the contaminating ion, both in solution and at the solid−solution interface. The solution chemistry of highly radioactive actinides, which may be difficult to investigate directly, is frequently simulated by means of the thermodynamic data existing for uranium in the same oxidation state; so, as an example, UO_2^{2+} is often assumed to closely follow the chemical behavior of the NpO_2^{2+} and PuO_2^{2+} ions. Besides the well-established importance of their mononuclear complexes, with a unique or with different ligands, the formation of polynuclear complexes may substantially influence the speciation involved under specific thermodynamic conditions typical of the environment, for instance by enhancing the solubility of a solid phase. In connection with this, the most instructive example is probably represented by the $[(UO_2)_3(CO_3)_6]^{6-}$ complex, which has been since the determination of its formation constant through potentiometry,[1] extensively investigated by a large number of different techniques.[2,3,4] Similar investigations are still performed, first potentiometrically and then by other methods, on the complexes between UO_2^{2+} and acetate, UO_2^{2+} and oxalate, and UO_2^{2+} with ligands containing at least one carboxylic group.

Much interest has also been devoted to the dioxouranium(VI) citrate system,[5] in which the existence of polynuclear species of general stoichiometry $H_x(UO_2)_yL_z^{(x+2y-3z)+}$ (L indicates the citrate ion, $C_6H_5O_7^{3-}$) with different (x,y,z) coefficients [5−11] has been demonstrated. Nevertheless, despite large experimental efforts, the actual composition of polynuclear species with $y > 2$ and $z > 2$ is still a controversial topic: amongst the stoichiometries suggested on the basis of data from potentiometry, spectroscopy and other techniques (e.g. Electrospray Mass Spectrometry) there are $(x,2,1)$,[12] $(x,6,6)$,[7] $(x,3,2)$, and $(x,3,3)$.[11] The problem must certainly be tackled by combining a multiplicity of techniques. Electrochemical methods (mainly potentiometry) can be of fundamental importance in determining the stoichiometry and the formation constants of the complexes existing under different analytical conditions. On the other hand, spectroscopic methods may help to determine the actual structure of the species in solution.

The aim of the present work is to explore the possibility of studying the dioxouranium(VI) citrate system by using an approach like the one just described, by combining potentiometry and the Energy Dispersive X-ray Diffraction (EDXD) technique. The main difficulty lies in needing to work at dioxouranium(VI) concentrations (0.1 mol/dm^3 − 0.3 mol/dm^3) which are about one order of magnitude different from those usually used in each technique. A further goal of this work is to determine if the X-ray diffraction

pattern of relatively concentrated (about 0.3 molar) uranyl solutions in the presence of a threefold concentration of citrate can be interpreted by assuming the U–U and U–O distances previously reported by a number of authors.[13–16]

1. Results and Discussion

The analysis of the experimental data was performed using the *difference method*. This method has been successfully applied to liquid systems, in neutron diffraction and isotopic substitutions.[17–22] Here the assumption has been made that the perturbations induced by the presence of the solute has a limited influence on the bulk lithium citrate and perchloric acid solution. The structure of the lithium citrate and perchloric acid solution was mainly preserved because it is three times more concentrated than the solute uranyl perchlorate. The experimental curves from the lithium citrate and perchloric acid solutions were then subtracted from the dioxouranium(VI) experimental curves. In so doing all the interactions occurring in both solutions were cancelled, i.e. water–water, water–lithium citrate and perchlorate, lithium citrate–lithium citrate and perchlorate, and perchlorate–perchlorate. It was then possible to exclusively focus attention onto the interactions of the uranyl–uranyl and uranyl–other constituent in solution .The concentrations of the two solutions that were analyzed are reported in Table 1.

In the following the observed structure functions are reported [in the form $qi(q)M(q)$, in Figure 1, along with the radial distribution functions (*rdf*), in the form $D(r)_{\text{difference}} = D(r) - 4\pi r^2(\rho_0)$ for the water citrate solution and the citrate dioxouranium(VI) solution measured under the same experimental conditions.

The main features emerging from a qualitative analysis of both structure functions and radial distribution functions are significant and the presence in the dioxouranium(VI) solution of evident peaks at high values of r, implies an increase of order in solution for the lithium citrate and perchloric acid solution.

This pattern is particularly evident in the $D(r)_{\text{difference}}$ curves. As shown in Figure 1, the lithium citrate and perchloric acid solution (solution **A**) exhibits a large main peak at 2.5–6.0 Å and a second peak at 6.0–8.0 Å. In the dioxouranium(VI) solution *rdf* (solution **B**), we can discern peaks positioned at the same values of those present in the first solution rdf. This is expected because the concentration

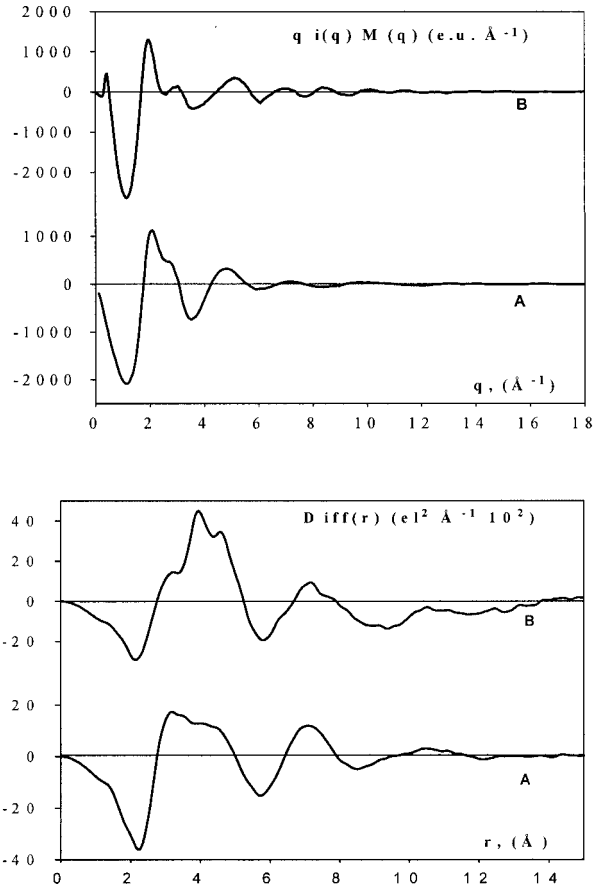

Figure 1. Top: experimental structure function in the form $q\ i(q)\ M(q)$: (**A**) Lithium citrate and perchloric acid solution, (**B**) dioxouranium(VI) solution; bottom: experimental radial distribution function in the form $D(r)_{\text{difference}} = D(r) - 4\pi r^2\rho$: (**A**) lithium citrate and perchloric acid solution, (**B**) dioxouranium(VI) solution

of lithium citrate is equal in the two solutions, and the concentration of ClO_4^- ions of the solution containing perchloric acid (solution **A**) is equivalent to the concentration of ClO_4^- ions due to the presence of dioxouranium(VI) perchlorate in the second solution (solution **B**). In the dioxouranium(VI) solution new peaks appear, namely the peak at 3.95 Å due to the interactions of the U atoms between themselves and between the constituent of the solution: water, lithium, citrate and perchlorate ions.

The features discussed above were used to build a structural model, the theoretical structure function and the theoretical distribution function, which best explained the

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

experimental data. Theoretical peaks were calculated by the Fourier transformation of a model structure function obtained by the Debye Equation (1) for pairs of interactions using the same sharpening factor, the same $q_{max.}$ value as for experimental data and assuming σ_{mn} to be the root mean square (r.m.s.) variation in the interatomic distance.

$$i_{mn}(q) = \{f_m \cdot f_n \cdot [\sin(r_{mn} \cdot q)/r_{mn} \cdot q] \cdot \exp(-1/2 \cdot \sigma^2_{mn} q^2)\} \quad (1)$$

Instead of using a σ_{mn} value for each distance r_{mn}, the number of the parameters has been reduced, by assuming the same σ value for distances within predefined ranges; predefined ranges used are reported in Table 2.

Table 2. Final values of the adjusted r.m.s. σ for the model used

σ Values (Å)	Distance range (Å)
0.05	$0.0 < r \leq 1.9$
0.13	$1.9 < r \leq 3.0$
0.20	$3.0 < r \leq 5.6$
0.25	$5.6 < r \leq 9.0$
0.30	$r > 9.0$

As previously noted, the "*difference method*" was used to test the experimental data. The experimental $D(r)$ curves of both solutions, namely (**A**) lithium citrate and perchloric acid solution and (**B**) dioxouranium(VI) solution, and the difference curve between the two experimental $D(r)$ curves are reported in Figure 2.

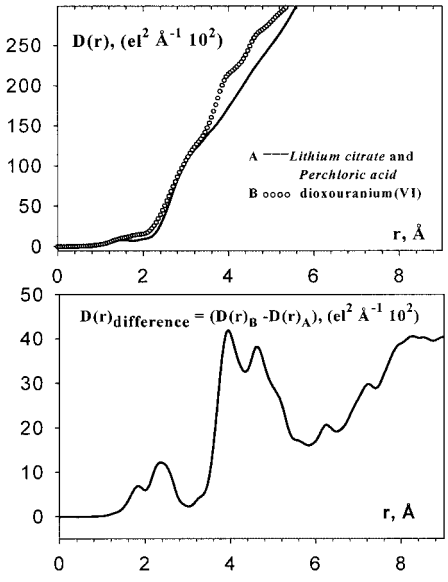

Figure 2. Top: experimental radial distribution function in the form $D(r)$; (**A**) lithium citrate and perchloric acid solution, (**B**) dioxouranium(VI) solution; bottom: experimental difference curve between the experimental radial distribution functions of solution (**B**) [dioxouranium(VI) solution], and solution (**A**) (lithium citrate and perchloric acid solution)

The experimental $D(r)$ difference curve only contains the interactions involving the UO_2^{2+} ions and the other constituent of solution **B**. Thus all the interactions which are also present in solution **A** have been eliminated from solution **B**. In fact the first peak in the difference curve occurs at 1.78 Å and corresponds to the U−O distances in the UO_2^{2+} ion and there are no peaks at lower distances due to the bond lengths in the citrate and perchlorate ions. Hence the first peak is exactly reproduced, in the theoretical peak shape function; on the basis of the two interactions U−O at 1.78 Å, with a σ value 0.05, it can be assumed that the second peak at 2.4 Å represents only the metal O coordination peak. The coordination number has been determined as five; the U−O distances are not equal for all the interactions, but are in the range 2.35−2.50 Å, i.e. two O atoms are coordinated at 2.35 Å, two at 2.40 and one at 2.50, with an average value of 2.40 Å: all these considered distances are in the range 1.9−3.0 Å to which a σ value 0.20 is attributed. The theoretical functions and the experimental one are shown in Figure 3.

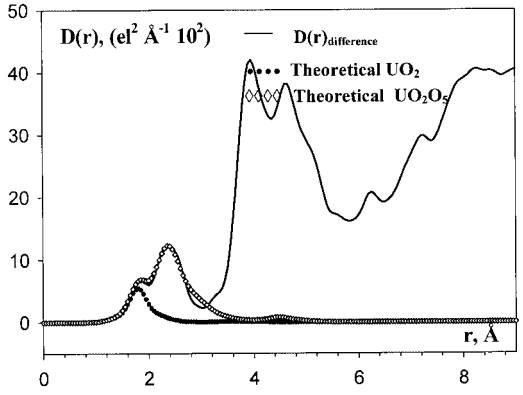

Figure 3. Experimental radial distribution functions difference curve $D(r)_{difference}$ (−−), the theoretical peak shape function of U−O interactions in UO_2^{2+} ion (solid circles), and the theoretical peak shape function of U−O interactions the in UO_2^{2+} ion coordinating five O atoms (open diamonds)

The bond lengths, and their spatial disposition are in good agreement with the literature data: dioxouranium(VI), in solution and in the solid state, is coordinated with five neighbors; the uranium atoms are at the centers of neighboring pentagonal bipyramids.[14]

The large peak at about 3.95Å indicates that the five O atoms, positioned on the equatorial plane of the pentagonal bipyramid, do not belong to the citric anions present in solution. The contributions of the five C atoms, bound to the O atoms, are altogether inadequate to fit the experimental peak.

On the basis of the literature data, tests have been performed for the presence of polynuclear complexes in solution. The first hypothesis tested, was the presence of binuclear complexes; two uranyl groups bonded by two bridging O atoms, with the uranium atoms at the center of neighboring pentagonal bipyramids having one common edge, with an usual U−U distance of 3.95 Å. Calculating the theoretical peak shape function, by a dimeric compound model, with a σ value of 0.20, a peak positioned at

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

3.95Å appears, but is still largely inadequate to reproduce the experimental one, as is shown in Figure 4.

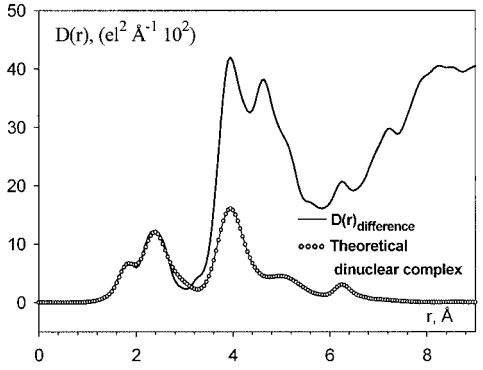

Figure 4. Experimental radial distribution functions difference curve $D(r)_{difference}$ (−−), the theoretical peak shape function of U−O interactions in binuclear complex $[(UO_2^{2+})O_5]_2$ (open circles)

The theoretical peak shape function was calculated for a model containing only the U−O interactions. The model of the binuclear complex is shown in Figure 5. Adding the U−C interactions, arising from the citric anions, bound to the O atoms, the experimental peak height is not reached.

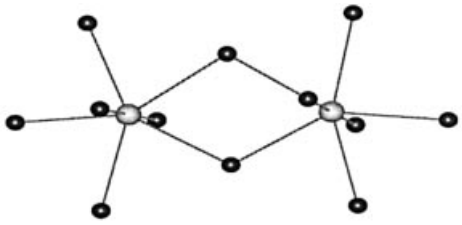

Figure 5. Picture of the model of the binuclear complex

A trinuclear model was successively tested. The position of the three U atoms, in a triangular unit, was supposed to be both symmetric and asymmetric; each U atom was considered to be surrounded by seven O atoms, and the coordination polyhedron was a pentagonal bipyramid, with the two apical O atoms belonging to the uranyl atoms. The model was constructed imposing the distance values previously obtained; 1.78 Å for the uranyl U−O distance and an average value of 2.42 Å, with a variation from 2.35 to 2.50 Å, for the remaining five O atoms. The three U atoms were positioned at the corner of an equilateral triangle with an edge length of 3.95 Å, or at the corner of a scalene triangle with an average edge length of 3.95 Å. The theoretical peak shape function obtained applying the model previously described only reproduces the experimental one with regards to the peak at 3.95. Adding the interactions arising from the citrate anions, belonging to the oxygen atoms that are free in the trinuclear complex, the height of the successive peak in the experimental function is not reached.

On the basis of the former considerations and of the potentiometric results it was supposed that a tetranuclear complex is present in solution of. The complex had to maintain the distorted pentagonal bipyramidal configuration around the U atoms, three U−U interactions at 3.95 Å and it had to create U−U interactions at 4.65 Å.

The structure of the tetramer is shown in Figure 6. The four uranium atoms lie at the corners of two isosceles triangles, with two edge length of 3.95 Å and the other edge length of 4.65 Å. The two triangles share one of the edges measuring 3.95 Å. They are not coplanar showing a dihedral angle of 35.30°. Each uranyl group is surrounded by five O atoms, as in dinuclear and trinuclear tested complexes.

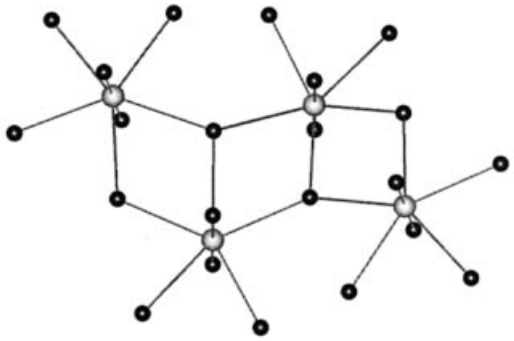

Figure 6. Picture of the model of the tetranuclear complex

In Figure 7 the experimental radial distribution function in the difference form $D(r)_{difference}$ is compared to the theoretical one, obtained from the model shown in Figure 6.

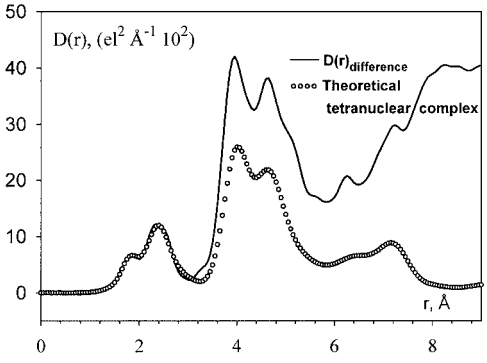

Figure 7. Experimental radial distribution functions difference curve $D(r)_{difference}$ (−−), the theoretical peak shape function of U−O interactions in tetranuclear complex $[(UO_2^{2+})_4O_{14}]$ (open circles)

Even if the trend of the theoretical curve, calculated with the tetranuclear model, is analogous to that of the experimental curve, it is not reproduced. The theoretical peaks are remarkably lower than the experimental ones. For this reason models obtained from a larger number of UO_2 units have been tested. Pentanuclear and esanuclear complexes, arranged according to various geometries, have been tried. The models were constructed imposing the distance values previously obtained (1.78 Å uranyl U···O distance and an average value of 2.42 Å for the remaining five O atoms). The five or six U atoms were positioned at the corners of various geometrical figures with edge lengths of 3.95 Å, or

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

4.65 Å opportunely distributed, in order to reproduce the experimental curve. It turns out that these models are not acceptable since the heights of the obtained peaks, in the theoretical peak shape function, were much too high, with respect to the experimental ones, in order to allow for the presence of a second sphere of coordination around the atom of uranium.

Therefore it was decided to return to the study of the tetranuclear complexes, and to reconsider the second coordination sphere. Since the concentration of citrate anions is three times higher than the concentration of the uranyl cations, it was assumed that at least one oxygen atom, between those bound to the uranyl, belong to a citrate carboxylic group. The theoretical peak shape function, calculated by this model, still did not give a good agreement with the experimental data. Models with a greater number of citrate interactions were tested, but these gave way to theoretical functions that exceeded the experimental ones, especially for the peak at 3.95 Å.

Therefore a further hypothesis was considered; that the contributions that were still lacking came from water molecules and due to hydrogen bonds with the oxygen atoms of the uranyl group a first coordination sphere of the complex could still be considered.

The model was constructed with the geometry parameters previously reported when only the U−O interactions were considered. The four O atoms bridging the four uranyl cations belong to OH^- groups that, with the four citrate anions, neutralize the positive charge of the uranyls. The possible model of the citrate coordination in the tetranuclear complex is shown in Figure 8 (see a). Six water molecules supplying the other O atoms that surround the U atoms and sixteen water molecules are bound to the eight O atoms of the uranyl cations by hydrogen bond with a O−O distance of about 2.86 Å and OÔU angle of about 115°.

In order to simplify the model construction, the tetranuclear complex was considered to have a symmetry center and the citrate anions to have the same spatial configuration. This conformational restriction, regarding the citrate anions, leads to the theoretical function not perfectly reproducing the experimental one. Different citrate anion conformations would allow a greater variability of the distances and therefore a better agreement between the experimental data and the theoretical peak shape function.

In Figure 9, the comparison between the experimental function and the theoretical one, calculated for the model previously described, is shown.

On the basis of NMR literature data, the possibility of the hydroxy group and the α-carboxyl group being involved in coordination was tested. The comparison between the experimental function and the theoretical one, calculated for the model proposed by NMR spectroscopic data, maintaining the uranyl first coordination sphere, unaltered with respect to the previously tested model, shows comparable concordance, Figure 9. For this model, the tetranuclear complex was also considered to have a symmetry center, but the conformational restrictions are superior with respect to the other model due to the five atom ring formation, Figure 8 (b). The X-ray diffraction in this case, is unable to discriminate between the two citrate coordination manners: for this purpose the information supplied from NMR spectroscopy may be fundamental. A better agreement between the experimental data and the theoretical function was not attempted since a refined structural analysis exceeded the main interest of this study, whose aim was to determine which form had the prevailing polynuclear uranyl citrate complexes.

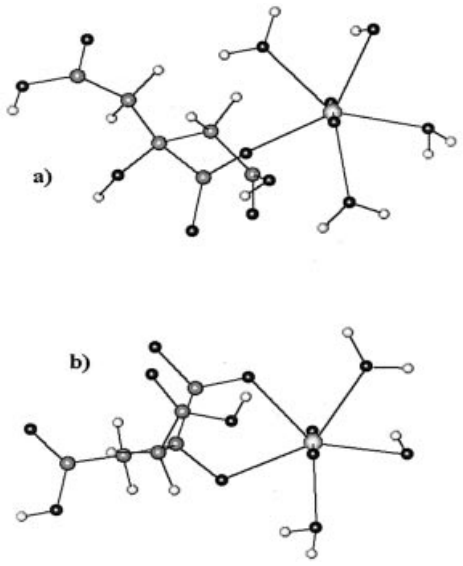

Figure 8. Picture of the models of the citrate coordination in tetranuclear complex: a) $[(UO_2^{2+})_4Cit_4O_6]\cdot 16H_2O$ and b) $[(UO_2^{2+})_4Cit_4O_2]\cdot 16H_2O$

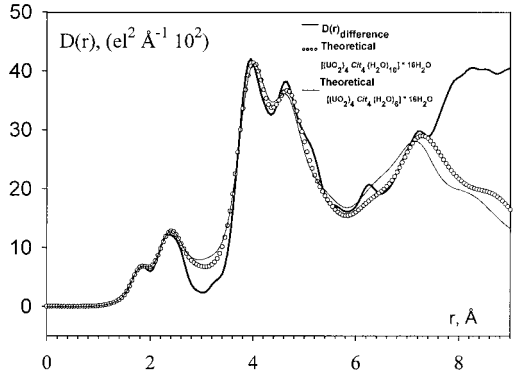

Figure 9. Experimental radial distribution functions difference curve $D(r)_{difference}$ (bold line), the theoretical peak shape functions of the tetranuclear complex $[(UO_2^{2+})_4Cit_4(H_2O)_{10}]\cdot 16H_2O$ (open circles) and $[(UO_2^{2+})_4Cit_4(H_2O)_6]\cdot 16H_2O$ (----)

2. Conclusions

A structural study on a uranyl perchlorate diluted solution in 1 M lithium citrate, with a ratio [total citrate]/[U^{VI}] > 3, has been carried out by means of X ray diffraction, on

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

the basis of a preliminary speciation study of the solution performed potentiometrically. The experimental data, treated and interpreted using the *differences method*, shows the occurrence of tetranuclear dioxouranium(VI) citrate complexes in solution. Further data, both potentiometric and spectroscopic, will be needed in order to unequivocally describe the citrate coordination around the dioxouranium(VI) polynuclear complexes.

3. Experimental Section

3.1 Sample Preparation. Reagents and Materials: All the solutions analyzed, Table 1, were prepared by using doubly distilled water. The uranyl perchlorate stock solution was prepared and standardized, with an accuracy of 0.3%, as suggested in ref.[1] starting from $UO_2(NO_3)_2{\cdot}6H_2O$ (Fluka p. a.). Perchloric acid solutions at different concentrations, prepared by diluting the 70% product from Fluka, were standardized using both $KHCO_3$ or HgO as primary standards (Fluka analytical grade) and methyl red or phenolphthalein, respectively, as indicators; analyses agreed within 0.1%. Concentrated lithium citrate and sodium citrate solutions were prepared from $Li_3C_6H_5O_7{\cdot}4H_2O$ (> 99.5%, Fluka) and $Na_3C_6H_5O_7{\cdot}2H_2O$ (> 99.5%, Fluka) respectively, which were not further purified. Sodium perchlorate was prepared and standardized as described elsewhere.[1]

The pH of solution **B** was 5.10±0.02 at 18 °C. It was measured with a Metrohm 691 pH-meter equipped with a 6.0232.100 glass combined electrode (Metrohm); the electrode was calibrated with IUPAC pH standards. The potentiometric data were recorded around the clock using Metrohm 6.0123.100 and 6.0726.100 electrodes, a 34970A Data Acquisition/Switch Unit pursued by Agilent Technologies and automatic burettes 715 Dosimat from Metrohm. Impedance adaptors were used to collect the data with a precision of 0.01 mV. The software TITPOT (by InLab, www.inlab.it) was used to control the experiments through a personal computer.

3.2 Potentiometric Measurements: Potentiometry was used to study the speciation of the uranyl ion in the presence of citrate. While the system is quite well-known at dioxouranium(VI) concentrations lower that 10 mM a preliminary experiments were performed at higher metal concentrations, in order to better define the stoichiometry of the polynuclear complexes other than the dimer. The results of a preliminary experiment are presented here, which is part of a more systematic investigation now in progress.

The experiment has been performed as a potentiometric titration. An accurately known volume of the test solution TS [TS: 0.100 M $UO_2(ClO_4)_2$, 0.100 M $HClO_4$, 2.700 M $NaClO_4$] placed into a vessel thermostatted at (25.00±0.02) °C, has been titrated in the dark, under a nitrogen stream, with known volumes, V_T, of the solution T (T: 0.100 M $UO_2(ClO_4)_2$, 0.700 M Na_3L, 0.150 M NaOH, 2.800 M $NaClO_4$). After each addition the $[H_3O^+]$ was determined from the EMF, E_I (in mV), of the cell (I). Cell I: Glass Electrode/Test Solution/Reference Electrode by using the Nernst Equation (2).

$$E_I = E^0 + 59.16{\cdot}\log[H_3O^+] + Ej \qquad (2)$$

In Equation (2) the cell constant E^0 was determined in two separate experiments performed before and after the titration, while the liquid junction potential Ej was evaluated as described elsewhere.[23] A second type Ag,AgCl electrode was used as the reference electrode; it was external to the cell but in electrical contact with TS through a salt bridge: 3.000 M $NaClO_4$/0.010 M $AgClO_4$, 2.990 M $NaClO_4$/AgCl,Ag.

The primary (V_T, E_I) data collected allowed us to span the $1.14 < -\log[H_3O^+] < 4.34$ range, and was processed using the least-squares program Hyperquad[24] in order to determine the equilibrium constant, β_{xyz}, of the general reaction (3)

$$x{\cdot}[H^+] + y{\cdot}[UO_2^{2+}] + z{\cdot}[L^{3-}] = [H_x(UO_2)_yL_z]^{(x+2y-3z)+} \qquad (3)$$

Several models have been tested. On the basis of the literature data,[5] under the experimental conditions chosen it is expected that the concentration of mononuclear complexes is very small, and hence negligible. In Table 3 the results that gave the least standard deviation are reported, while in Table 4 the proposed model with the formation constant of each species is presented.[25−27]

Table 3. Survey of the standard deviation of different speciation models

Model	σ (mV)
(0,1,1), (0,2,2), (1,3,3), (−2,4,4)	0.2299
(0,2,2), (2,3,2), (1,3,3), (−2,4,4)	0.2254
(1,1,1), (0,2,2), (1,3,3), (−2,4,4)	0.1593
(0,2,2), (0,3,2), (1,3,3), (−2,4,4)	0.1456
(0,2,2), (1,3,2), (1,3,3), (−2,4,4)	0.1158

Table 4. Formation constants of the $H_x(UO_2)_yL_z^{(x+2y-3z)+}$ species at 25 °C in 3 M $NaClO_4$

(*x*,*y*,*z*)	$\log\beta_{xyz} \pm 3\sigma$
(0,2,2)	17.96 ± 0.01
(1,3,2)	20.95 ± 0.06
(1,3,3)	30.19 ± 0.01
(−2,4,4)	28.50 ± 0.02

Owing to the high citrate concentration of the titrant solution, the ionic strength of the titrated solution increased from 3.1 M to about 4.2 M; nevertheless, the actual ionic strength variations are probably smaller, owing to the fact that part of the citrate is not present as the trivalent anion but is in the form of the polynuclear uranyl complexes, variously protonated. Thus the overall accuracy of the reported data is estimated to be of about 2−3%.

Table 5. Auxiliary data used for the calculation of the distribution diagram of Figure 1

Reaction	log *K*	Ref.
$H_2O = H^+ + OH^-$	−14.22	[25]
$H^+ + L^{3-} = HL^{2-}$	5.16 ± 0.03	[26]
$2H^+ + L^{3-} = H_2L^-$	9.46 ± 0.03	[26]
$3H^+ + L^{3-} = H_3L$	12.70 ± 0.04	[26]
$UO_2^{2+} + H_2O = UO_2OH^+ + H^+$	−5.03 ± 0.06	[27]
$2UO_2^{2+} + 2H_2O = (UO_2)_2(OH)^{2+} + 2H^+$	−6.01 ± 0.02	[27]
$3UO_2^{2+} + 5H_2O = (UO_2)_3(OH)_5^+ + 5H^+$	−16.13 ± 0.03	[27]

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

By using the set of constants of Table 4 and the auxiliary data of Table 5 the distribution diagram presented in Figure 10 was constructed. The diagram has been calculated by assuming $[U^{VI}] = 0.3$ M and [total citrate] = 1 M.

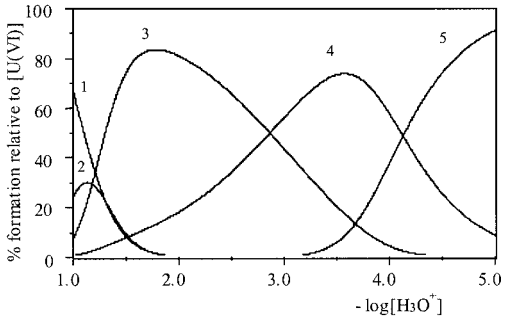

Figure 10. Distribution diagram of the uranyl citrate system; the curves have been calculated by using the data set reported in Tables 3 and 4, and assuming $[U^{VI}] = 0.3$ M and [total citrate] = 1 M; L represents the citrate anion, $C_6H_5O_7^{3-}$; the numbers on the curves indicate the following species: UO_2^{2+} (curve 1); $H(UO_2)_3L_2^{+}$ (curve 2); $H(UO_2)_3L_3^{2-}$ (curve 3); $(UO_2)_2L_2^{2-}$ (curve 4); $(UO_2)_4(OH)_2L_4^{6-}$ (curve 5)

The results of the potentiometric titration suggested the best experimental conditions for the X-ray measurements: a solution containing 0.3 mol dioxouranium(VI) and 1 mol citrate per dm^3, in which sodium should rather be substituted by lithium, because the Li−O distances interfere less with the other ones expected in the system.

3.3 EDXD Measurements: Several examples of the application of Angle Dispersive, or Energy Dispersive X-ray Diffraction to pure liquids and solutions of metal ions in various solvents can be found in the literature.[28−32]

In the present work, the Energy Dispersive X-ray Diffraction (EDXD) technique has been used. Compared with traditional ADXD (angular dispersion), it has several advantages:[33−38] Diffraction patterns are collected in a much shorter period of time, using only a few reflection angles, but still covering q ranges equal to or larger than those obtained by AD; samples are stored in sealed cells, which avoid evaporation and contamination by moisture in the air.

Experiments were performed by using the noncommercial energy-scanning diffractometer built at the Department of Chemistry, Rome University. Detailed descriptions of the instrument and the technique can be found elsewhere.[35−37]

Transmission geometry has been employed. The White Bremsstrahlung component of the radiation emitted by a tungsten tube working at 50 kV and 40 mA was used. Scattered intensities for the samples and the empty cell were measured at seven different angles. This choice allowed us to cover a wide range of the scattering variable q, namely between 0.23−18 $Å^{-1}$. The measuring time at each angle was set so as to obtain a minimum of 1000000 counts per experimental point for $q > 5$ $Å^{-1}$ and 300000 for $q < 5$ $Å^{-1}$, where q is given by Equation (4)

$$q = 4\pi\cdot\sin\theta/\lambda = 1.014\cdot E\cdot\sin\theta \quad (4)$$

When E is expressed in keV and q in $Å^{-1}$, measurement angles, the energy range used and scattering parameters are reported in Table 6.

Table 6. Scattering parameters associated with the energy range used (13.0 −43.7 keV) for each measurement angle

Scattering angles (degree)	q range ($Å^{-1}$)
24.0	5.36−18.00
15.5	3.52−11.84
8.0	1.83−6.17
5.0	1.15−3.86
3.0	0.69−2.32
2.0	0.46−1.55
1.5	0.34−1.16
1.0	0.23−0.77

The primary beam intensity $I(E)$ was measured directly using the same voltage, by reducing the tube current to 10 mA at a zero scattering angle without the sample. Transmission of the sample was measured under the same conditions. Both quantities are needed to carry out necessary conditions to observed scattered intensities.[35−38] After correction of experimental data for escape peak suppression,[35−38] the various angular sets were combined and the re-scaled intensity, in electron units (e. u.), was normalized to a stoichiometric unit volume containing one Li atom. Such correction is performed using our program DIF1, written ad hoc. Detailed description of procedures and formulae used can be found in refs.[25−28]. The atomic and water concentrations, together with stoichiometric volume and density, are reported in Table 1 (in $mol^{-1}\cdot Å^3$ and g/cm^3, respectively). The "static" structure function $I(q)$ was constructed according to Equation (5), where f_i are the atomic scattering factors, x_i are the number of concentrations of i-type atoms in the stoichiometric unit, $I_{e.u.}$ is the observed intensity in electron units.

$$i(q) = I_{e.u.} - \Sigma x_i f_i^2 \quad (5)$$

Fourier transformation of $i(q)$ led to radial distributions (rdf)

$$D(r) = 4\pi r^2\cdot\rho_0 + (2r/\pi)\int_0^{q\,max} qi(q)M(q)\sin(rq)dq \quad (6)$$

In Equation (6) ρ_0 is the bulk number density of stoichiometric units and

$$M(q) = [f_U^2(0)/f_U^2(q)]\exp(-0.01q^2) \quad (7)$$

is the sharpening factor; the value of 18 $Å^{-1}$ was used as the upper limit of integration.

Supporting Information: Primary potentiometric data are available (see footnote on the first page of this article).

Synthesis and Characterization of a Series of Lanthanide Complexes Constructed from Orotic Acid

Xing Li,[a] Qian Shi,[a] Daofeng Sun,[a] Wenhua Bi,[a] and Rong Cao*[a]

Keywords: Lanthanides / O ligands / Polymers / Solvothermal synthesis

The solution reaction of orotic acid (2,6-dioxo-1,2,3,6-tetrahydropyrimidine-4-carboxylic acid, H_3dtpc) and $Ln(NO_3)_3 \cdot 6H_2O$ (Ln = La, Ce) or Ln_2O_3 (Ln = Pr, Nd) yielded five complexes $[\{Ln(^aH_2dtpc)_2(^bH_2dtpc)(H_2O)_4\} \cdot H_2O]_n$ (Ln = La **1**, Ce **3**), $[La(^aH_2dtpc)_2(^cH_2dtpc)(H_2O)_6] \cdot 4H_2O$ (**2**), and $[Ln(^aH_2dtpc)_2(OH)(H_2O)_6] \cdot (H_3dtpc)_2 \cdot 7H_2O$ (Ln = Pr **4**, Nd **5**). Complexes **1** and **3** possess 1D chain structures, **2** is a mononuclear structure, and **4** and **5** are mononuclear complexes that are extended into infinite honeycomb structures through hydrogen bonding interactions. The hydrothermal reaction of orotic acid and Ln_2O_3 (Ln = La, Nd, Eu, Gd, Er) produced five polymeric complexes $[Ln(^dHdtpc)(OH)(H_2O)]_n$ (Ln = La **6**, Nd **7**, Eu **8**, Gd **9**, Er **10**), which contain isostructural 3D frameworks with ladder-like chains formed by Ln^{III}, a μ_3-OH bridge and an orotate spacer.

Introduction

Lanthanide complexes are of great interest because of their various potential applications in magnetic materials, Ln-doped semiconductor technology, nonlinear optical devices, catalysts, molecular sensors and probes.[1−6] Due to the unique nature of lanthanide ions, such as their large radius, high coordination number and the existence of many single electrons the assembly of lanthanide complexes possessing novel structures and special properties offers great challenges and opportunities in terms of controlling their shapes and dimensions. The selection of an appropriate organic ligand along with different synthetic methods is a key step for the construction of lanthanide complexes with the desired features. It has been proved that ligands containing a combination of nitrogen and oxygen donor atoms are good building blocks for the formation of lanthanide coordination polymers;[7,8] orotic acid (2,6-dioxo-1,2,3,6-tetrahydropyrimidine-4-carboxylic acid, H_3dtpc) may therefore be a good ligand for the construction of lanthanide complexes. Aside from its significance in biological systems,[9] orotic acid possesses a fascinating coordination behavior with potential hydrogen-bonding interactions, such as asymmetric geometry and multiple coordination sites.[10] However, previous studies on the coordination chemistry of orotic acid mainly focused on transition metals[11−19] or alkali metals;[20−22] the lanthanides have been neglected. Recently we began to use orotic acid as an organic ligand for the synthesis of lanthanide complexes with the aim of studying the coordination chemistry of the lanthanide-orotic acid system and to obtain some novel structures. We have successfully synthesized two novel lanthanide polymers containing orotic acid by employing a hydrothermal technique.[23,24] This paper reports systematic studies on the synthesis and characterization of a series of lanthanide-orotic acid complexes. We will show that the structures of lanthanide-orotic acid complexes are influenced by the synthetic methods, the lanthanide contraction and the pH.

Results and Discussion

Preparation of the Complexes

The coordination chemistry of H_3dtpc with transition metals has been studied in detail in recent years,[11−19] although systematic studies on lanthanide systems have received scant attention. Our aim was to investigate the coordination chemistry of Ln-orotate (Ln is a lanthanide metal) and hoped to obtain novel structures with special properties as well as to study the effects of the lanthanide contraction and acidity on the structure formation. Ten complexes with four kinds of structures were successfully isolated by employing different synthetic techniques.

The solution reactions of lanthanide nitrate or oxide and orotic acid generated the lanthanum complexes **1** and **2** (pH 4−5), the cerium complex **3** (pH 4−5), the praseodymium complex **4** (pH 3−4), and the neodymium complex **5** (pH 3−4). The successful isolation of **1**−**5** prompted us to ex-

Supporting information for this article is available on the WWW under http://www.eurjic.org or from the author.

tend our work to other metals of the lanthanide series. However, when we carried out similar reactions of $Ln(NO_3)_3{\cdot}nH_2O$ or Ln_2O_3 (Ln = Sm−Lu) and orotic acid in water, only uncharacterized precipitates were obtained, which may be due to the effects of the lanthanide contraction. The lanthanide contraction from La to Lu results in a gradual decrease of the ionic radius and of the pH value of the incipient precipitate with increasing atomic number.[25] We therefore tried to lower the pH value to 2 or 1 by addition of dilute HCl or HNO_3, but only single crystasl of orotic acid itself were isolated,[26] probably because orotic acid is not deprotonated at such low pH values and therefore cannot coordinate to lanthanide ions.

In order to investigate the effects of the lanthanide contraction and acidity on structure formation, similar experiments were carried out under hydrothermal conditions. The hydrothermal reaction of Ln_2O_3 (Ln = La, Nd, Ea, Gd, Er) and orotic acid (1:2) in aqueous solution (pH 7) yielded complexes **6**−**10**, which are all unexpectedly isomorphous. Taking account of the deprotonation process

$$H_3dtpc \rightleftarrows H_2dtpc^- + H^+ \rightleftarrows Hdtpc^{2-} + 2\,H^+ \rightleftarrows dtpc^{3-} + 3\,H^+$$

we tried to lower pH values of the reaction systems, hoping to obtain different structures. However, similar results were obtained although the yields or purity of the products were different. This result illustrates that complexes **6**−**10** are the most stable form under hydrothermal condition and their structures are not affected by the pH values of the reaction systems and lanthanide contraction, in contrast to previous observations.[8a,27]

It is interesting that the pH and the lanthanide contraction do, however, have an effect on the structures observed from the solution reactions: the La and Ce complexes were isolated at pH 4−5 and the Pr and Nd complexes were isolated at pH 3−4; no complexes suitable for X-ray analyses were successfully isolated from the solution reactions for the lanthanide elements heavier than neodymium. The different results between the solution and hydrothermal reactions may be caused by different reaction mechanisms:[28] the hydrothermal reaction mechanism is shifted from the thermodynamic to the kinetic domain when compared to a high-temperature solid-state reaction or from the kinetic to the thermodynamic domain when compared to a conventional solution reaction. Thus, the compounds obtained from hydrothermal reactions are often different to those obtained from conventional solution reactions.

Crystal Structures

X-ray diffraction studies revealed that complexes **1** and **3** are allomers with one-dimensional chain structures. Two types of coordination modes of orotate ligands are present in the structures: one adopts a monodentate fashion to coordinate one Ln^{III} ion through its carboxylate group ($^aH_2dtpc^-$, a in Scheme 1), and the other one acts as a μ_3-bridge to link three Ln^{III} atoms, in which a deprotonated carboxylic group bridges two Ln^{III} ions and the carbonyl oxygen atom connects to another Ln^{III} ion ($^bH_2dtpc^-$, b in Scheme 1). The central La or Ce is coordinated by four carboxylate oxygens and one carbonyl oxygen from different orotate ligands, and four oxygen atoms from coordinated water molecules (see **a** in Figure 1), with the Ln−O distances ranging from 2.497(4) to 2.626(4) Å and from 2.484(2) to 2.598(3) Å for **1** and **3**, respectively. Two Ln^{3+} ions are linked by two bridging carboxylate groups of $^bH_2dtpc^-$ to form a binuclear unit $[Ln_2(^aH_2dtpc)_4(^bH_2dtpc)_2(H_2O)_8]$, which can be viewed as the basic building block for the two complexes. Every two such blocks are connected by $Ln-O_{carbonyl}$ bonding to yield a 1D chain (Figure 2). The chains are further joined by different kinds of hydrogen bonding to generate the final 3D framework (Figure 3).

Complex **2** has a mononuclear structure (see **b** in Figure 1) in which the orotate ligands have two types of modes: one binds in a monodentate fashion to coordinate one Ln^{III} ion through its carboxylate group ($^aH_2dtpc^-$, **a** in Scheme 1), and the other one coordinates to a Ln^{III} ion through its carbonyl oxygen atom ($^cH_2dtpc^-$, **c** in Scheme 1). It should be noted that the carboxylate oxygen atoms in $^cH_2dtpc^-$ remain free and do not coordinate to metal ions; this is the first observation of such an interesting coordination mode for the orotate ligand. The La^{III} atom is nine-coordinate, with bonds to two carboxylate and one carbonyl oxygen atoms of different orotate ligands, and six coordinated water oxygen atoms, with La−O distances ranging from 2.486(4) to 2.610(4) Å. The hydrogen bonding provided by the isolated water molecules in the crystal lattice extends complex **2** into a 3D structure (Figure 4).

Complex **4** is also mononuclear, and each local coordination unit around the metal ion contains four orotate ligands (see **c** in Figure 1), two of which are not engaged in coordination to the metal ion as they are not deprotonated; the other two coordinate to the Pr^{III} ion through the deprotonated carboxylic oxygen atoms ($^aH_2dtpc^-$, **a** in

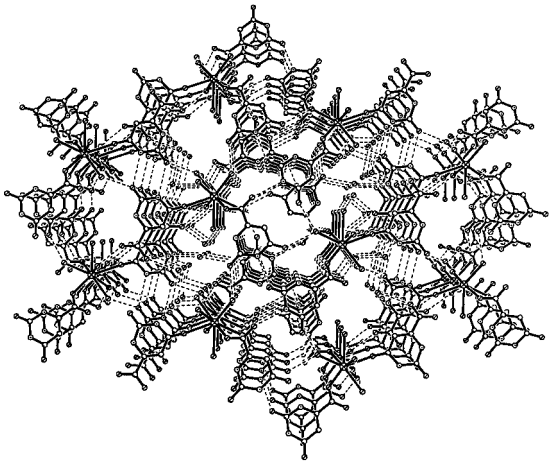

Figure 4. Packing structure along the *a* axis of **2**

Scheme 1). The Pr^{III} ion is nine-coordinate, with bonds to two carboxylate oxygen atoms from different orotate ligands, one oxygen atom from a hydroxyl group and six oxygen atoms from coordinated water molecules, with Pr−O distances ranging from 2.473(6) to 2.620(6) Å. Two coordinated units form a pore-like structure through hydrogen-bonding interactions between orotate ligands and metal ions; such pore-like units are further extended into 2D framework in the *ab* plane. The uncoordinated orotate li-

gands are located between two neighboring 2D layers, and strong π-π stacking interactions between the heterocyclic rings of uncoordinated and coordinated orotate ligands are observed, with distances from 3.20 to 3.60 Å.

The presence of this intermolecular hydrogen bonding and the π-π stacking interaction finally results in a honeycomb-like 3D structure along the *c* axis with unique quasi-channels (see **a** in Figure 5) accommodating a great number of guest water molecules; the free orotate and coordinated orotate ligands are arranged alternately in the 3D framework (see **b** in Figure 5). Because the hydrogen atoms on the isolated water and coordinated water molecules cannot be assigned completely from the Fourier peaks, the potential hydrogen bonding for complexes **4** and **5** is not discussed.

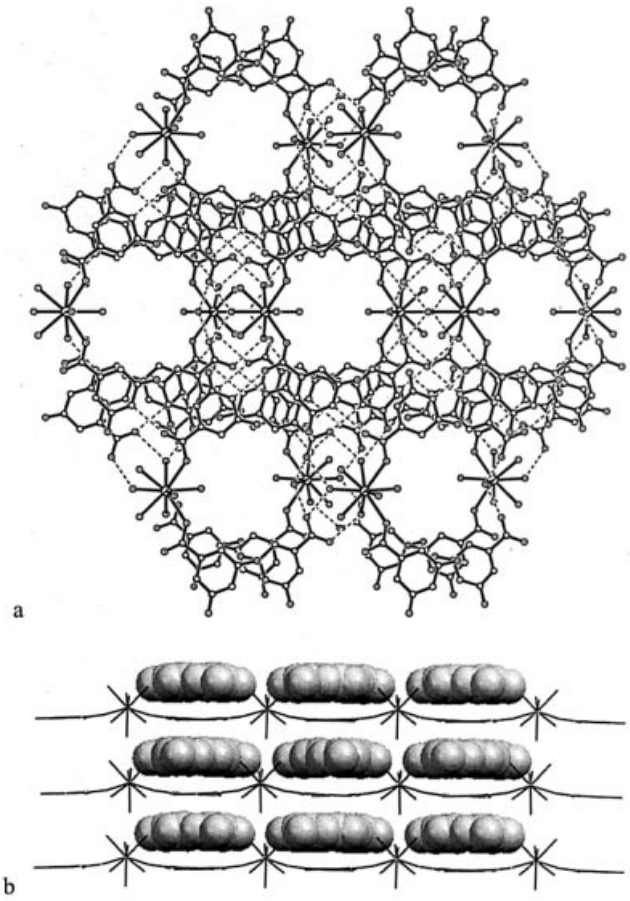

Figure 5. (a) the honeycombed structure with quasi-channels along the *c* axis for **4** and **5**, guest water molecules are omitted for clarity; (b) 3D packing structure along the *b* axis for **4** and **5**, space-filingl sphere (uncoordinated orotate ligands), wire-frame (coordinated orotate ligands)

The crystal structure of **5** is isomorphous to that of **4**; the local coordination environment around the Nd^{III} ion is shown in Figure 1 (see **c**). The Nd^{III} ion is nine-coordinate, with bonds to two carboxylate oxygen atoms from different orotate ligands, one oxygen atom from a hydroxyl group and six oxygen atoms from coordinated water molecules. Hydrogen bonding and π-π stacking interactions between neighboring heterocyclic rings of uncoordinated and coordinated orotate ligands, with distances from 3.22 to 3.61 Å, extend complex **5** into a honeycombed structure with unique quasi-channels accommodating guest water molecules.

It is interesting to observe the effect of the lanthanide contraction on the structures of complexes **1**−**5**. La^{3+} forms one-dimensional, mononuclear structures and Ce^{3+} also forms a one-dimensional structure. However, because of their smaller atomic sizes, Pr^{3+} and Nd^{3+} only form mononuclear structures. This is similar to the observation of Li and co-workers, who have reported the effect of the lanthanide contraction on crystal structure dimensions.[8a]

Complexes **6**−**10** are isostructural, possessing three-dimensional network structures constructed by eight-coordinate Ln^{III} centers. As shown in Figure 6, the Ln^{III} ion is coordinated by one nitrogen and seven oxygen atoms, of which three oxygen atoms come from OH^- groups, three oxygen atoms from different orotate ligands, and one oxygen atom from a coordinated water molecule. The carboxylic group and the adjacent nitrogen of orotic acid are deprotonated during the formation of **6**−**10**, and each orotate ligand acts as a tetradentate ligand linking three metal atoms in a chelating-bridging mode through one carboxylate oxygen, two carbonyl oxygens and the deprotonated nitrogen ($^{d}Hdtpc^{2-}$, d in Scheme 1). Each hydroxyl group acts as a μ_3-bridge linking three Ln^{III} ions (e in Scheme 1). Orotic acid usually acts as a bidentate dianionic ligand chelating to one metal ion through the deprotonated carboxylic group and the adjacent nitrogen atom; the two carbonyl oxygen atoms usually do not engage in coordination owing to their weak coordination ability. Although several examples show the coordination of a carbonyl oxygen,[10a,23,24] at least one of them remains free. In **6**−**10** both carbonyl oxygen atoms engage in coordination to Ln^{III}, and this unusual coordination mode may be ascribed to the high affinity of lanthanide ions for oxygen.

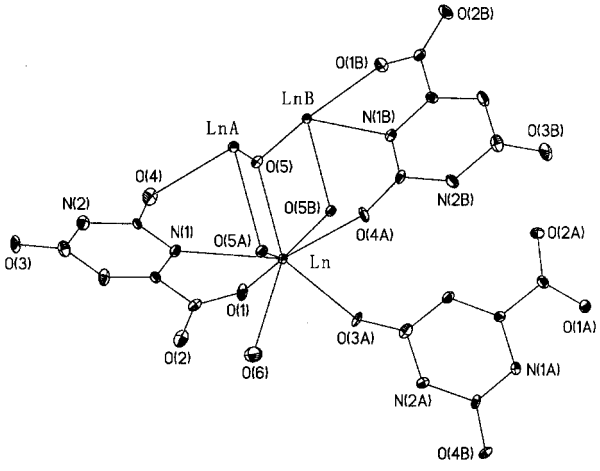

Figure 6. Local coordination environment around metal ions in **6**−**10**

[Ln(Hdtpc)(OH)(H_2O)] can be viewed as the basic building block for complexes **6**−**10**. Every two such blocks are connected by a shared orotate ligand and a μ_3-OH moiety

to give rise to a zig-zag lathanide chain (Figure 7) with Ln−Ln distances of 4.0065(1) Å for **6**, 3.9117(7) Å for **7**, 3.8466(1) Å for **8**, 3.824(2) Å for **9**, and 3.752(2) Å for **10**. The chains are further joined by the remaining carbonyl oxygen of the orotate ligands in a different direction to complete the eight-coordinate environment of Ln^{III}, forming the final three-dimension frameworks along the *c* axis (Figure 8). In other words, the structures of **6**−**10** can also be regarded as ladder-like chains formed by Ln^{III}−OH and orotate spacers

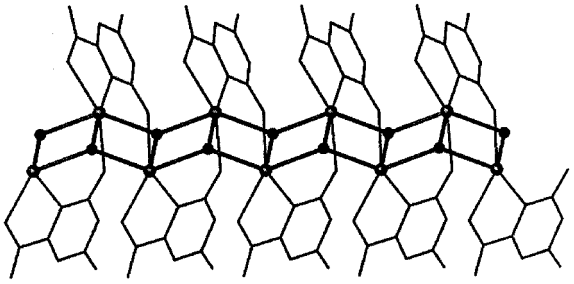

Figure 7. The zig-zag lanthanide chain formed by orotate ligands, μ_3-OH bridges in **6**−**10**

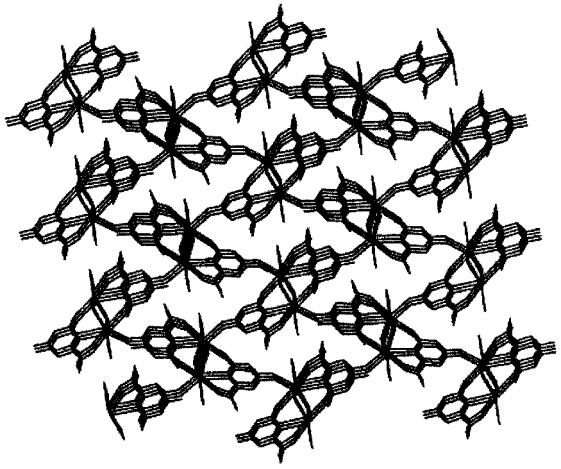

Figure 8. Packing structure along the *c* axis of **6**−**10**

Conclusions

In conclusion, ten lanthanide complexes have been prepared from orotic acid and the appropriate lanthanide salt. Lanthanide complexes with different structures were isolated from aqueous solution due to the effects of the lanthanide contraction. Nevertheless, the same geometries of complexes **6**−**10** were obtained with the hydrothermal method, which implies that the effects of the lanthanide contraction and the solution pH on crystal formation can be ignored in Ln-orotate hydrothermal reactions. The different results between solution and hydrothermal condition may be due to their different reaction mechanisms.

Experimental Section

Preparation of Complexes

General: All chemicals were used as purchased without purification prior to reaction. The infrared spectra were recorded as KBr pellets in the 4000−400 cm^{-1} region on a Magna 750 FT-IR spectrophotometer. The C, H and N microanalyses were carried out with a Perkin−Elmer 240-element analyzer in this institute.

$[\{La(^aH_2dtpc)_2(^bH_2dtpc)(H_2O)_4\}\cdot H_2O]_n$ (1): A mixture of $La(NO_3)_3\cdot 6H_2O$ (0.13 g, 0.3 mmol), H_3dtpc (0.104 g, 0.6 mmol), H_2O (20 mL) and EtOH (10 mL) was heated to boiling with stirring for 30 min. The solution was adjusted to pH 4−5 with 12 M aqueous NH_4OH and allowed to cool to room temperature. After two days colorless sheet-like crystals were obtained. Yield: 65%. $C_{15}H_{19}LaN_6O_{17}$ (694.3): calcd. C 25.95, H 2.76, N 12.11; found C 26.29, H 2.78, N 12.20. IR (KBr): $\tilde{\nu}$ = 1676 cm^{-1} (vs), 1479 (m), 1431 (m), 1379 (s), 1014 (w), 928 (w), 856 (w), 773 (m), 760 (w), 546 (m), 430 (w).

$[La(^aH_2dtpc)_2(^cH_2dtpc)(H_2O)_6]\cdot 4H_2O$ (2): A mixture of $La(NO_3)_3\cdot 6H_2O$ (0.11 g, 0.25 mmol), H_3dtpc (0.044 g, 0.25 mmol), and H_2O (20 mL) was heated in a 25 mL Teflon-lined bomb at 110 °C for 3 days to yield a colorless solution (pH 4−5). After evaporation for several days at room temperature, colorless sheet-like crystals were obtained. Yield: 30%. $C_{15}H_{29}LaN_6O_{22}$ (784.3): calcd. C 22.97, H 3.73, N 10.71; found C 23.17, H 3.61, N 10.93. IR (KBr): $\tilde{\nu}$ = 1705 cm^{-1} (vs), 1635 (vs), 1597 (s), 1491 (m), 1431 (m), 1373 (s), 1012 (w), 935 (w), 868 (w), 777 (w), 648 (w), 550 (m), 517 (w), 426 (w).

$[\{Ce(^aH_2dtpc)_2(^bH_2dtpc)(H_2O)_4\}\cdot H_2O]_n$ (3): A mixture of $Ce(NO_3)_3\cdot 6H_2O$ (0.087 g, 0.2 mmol), H_3dtpc (0.07 g, 0.4 mmol), H_2O (20 mL), and EtOH (10 mL) was heated to boiling with stirring for 30 min. The solution was adjusted to pH 4−5 with 12 M aqueous NH_4OH mixture and allowed to cool slowly to room temperature. After two days colorless sheet-like crystals were obtained. Yield: 60%. $C_{15}H_{19}CeN_6O_{17}$ (695.5): calcd. C 25.91, H 2.75, N 12.08; found C 26.13, H 2.68, N 12.17. IR (KBr): $\tilde{\nu}$ = 1709 cm^{-1} (vs), 1628 (vs), 1439 (s), 1390 (s), 1313 (m), 1018 (w), 856 (w), 931(W), 798 (m), 559 (m), 451 (w).

$[Pr(^aH_2dtpc)_2(OH)(H_2O)_6]\cdot(H_3dtpc)_2\cdot 7H_2O$ (4): A mixture of Pr_2O_3 (0.068 g, 0.2 mmol), H_3dtpc (0.14 g, 0.8 mmol), and water (30 mL) was heated to boiling with stirring for 30 min, the pH was adjusted to 3−4 by addition of 6 M aqueous H_2SO_4 and the mixture was then filtered. The filtrate was allowed to cool to room temperature. After two days light-blue crystals were obtained. Yield: 65%. $C_{20}H_{41}N_8O_{30}Pr$ (1014.5): calcd. C 23.67, H 4.07, N 11.04; found C 23.75, H 3.98, N 11.09. IR (KBr): $\tilde{\nu}$ = 1736 cm^{-1} (vs), 1635 (vs), 1489 (m), 1408 (vs), 1383 (s), 1011 (w), 931 (w), 814 (m), 754 (m), 544 (s), 432 (m).

$[Nd(^aH_2dtpc)_2(OH)(H_2O)_6]\cdot(H_3dtpc)_2\cdot 7H_2O$ (5): This complex was prepared as above by using Nd_2O_3 instead of Pr_2O_3. Yield: 65%. $C_{20}H_{41}N_8NdO_{30}$ (1017.8): calcd. C 23.60, H 4.06, N 11.01; found C 23.77, H 4.01, N 11.16. IR (KBr): $\tilde{\nu}$ = 1739 cm^{-1} (vs), 1670 (vs), 1635 (vs), 1489 (m), 1410 (vs), 1383 (vs), 1011 (w), 930 (w), 818 (m), 754 (m), 544 (s), 432 (m).

$[La(^dHdtpc)(OH)(H_2O)]_n$ (6): A mixture of La_2O_3 (0.0325 g, 0.1 mmol), H_3dtpc (0.035 g, 0.2 mmol) and water (15 mL) was placed in a 25 mL stainless reactor fitted with a Teflon liner and heated to 160 °C for 72 hours. It was then cooled to room temperature, and colorless needle-like crystals were obtained. Yield: 80%.

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

$C_5H_5LaN_2O_6$ (328.0): calcd. C 18.31, H 1.54, N 8.54; found C 18.82, H 1.46, N 8.76. IR (KBr): $\tilde{\nu}$ = 1664 cm^{-1} (vs), 1641 (vs), 1581 (s), 1558 (s), 1485 (m), 1407 (s), 1373 (s), 1335 (s), 1011 (m), 955 (w), 845 (m), 575 (m), 540 (w), 426 (w).

[Nd(^{d}Hdtpc)(OH)(H_2O)]$_n$ (7): This complex was prepared in a similar manner to **6** but with Nd_2O_3 instead of La_2O_3. Light-red crystals were obtained in 85% yield . $C_5H_5N_2NdO_6$ (333.3): calcd. C 18.02, H 1.51, N 8.40; found C 18.35, H 1.44, N 8.60. IR (KBr): $\tilde{\nu}$ = 1643 cm^{-1} (vs), 1487 (m), 1412 (s), 1336 (s), 1012 (s), 957 (w), 847 (m), 806 (m), 577 (m), 430 (w).

[Eu(^{d}Hdtpc)(OH)(H_2O)]$_n$ (8): This complex was prepared in a similar manner to **6** but with Eu_2O_3 instead of La_2O_3. Colorless crystals were obtained in 80% yield. $C_5H_5EuN_2O_6$ (341.1): calcd. C 17.61, H 1.48, N 8.21; found C 17.36, H 1.43, N 8.34. IR (KBr): $\tilde{\nu}$ = 1672 cm^{-1} (vs), 1649 (vs), 1487 (m), 1417 (s), 1340 (s), 1157 (w), 1014 (m), 958 (w), 808 (m), 771 (m), 434 (w).

[Gd(^{d}Hdtpc)(OH)(H2O)]$_n$ (9): This complex was prepared in a similar manner to **6** but with Gd_2O_3 instead of La_2O_3. Colorless crystals were obtained in 85% yield. $C_5H_5GdN_2O_6$ (346.4): calcd. C 17.34, H 1.46, N 8.09; found C 16.97, H 1.36, N 7.79. IR (KBr): $\tilde{\nu}$ = 1674 cm^{-1} (vs), 1651 (vs), 1579 (s), 1489 (m), 1417 (s), 1342 (s), 1014 (m), 958 (w), 810 (m), 579 (w), 436 (w).

[Er(^{d}Hdtpc)(OH)(H_2O)]$_n$ (10): This complex was prepared in a similar manner to **6** but with Er_2O_3 instead of La_2O_3. Colorless crystals were obtained in 85% yield. $C_5H_5ErN_2O_6$ (356.4): calcd. C 16.85, H 1.41, N 7.86; found C 16.93, H 1.37, N 7.95. IR (KBr): $\tilde{\nu}$ = 1655 cm^{-1} (vs), 1585 (s), 1487 (m), 1421 (s), 1016 (m), 962 (w), 820 (m), 623 (m), 579 (w), 436 (w).

X-ray Crystallography: Single crystals of complexes **1**−**10** with dimensions 0.8 × 0.16 × 0.1 (**1**), 0.8 × 0.26 × 0.2 (**2**), 0.8 × 0.24 × 0.12 (**3**), 0.6 × 0.24 × 0.16 (**4**), 0.6 × 0.20 × 0.12 (**5**), 0.36 × 0.24 × 0.04 (**6**), 0.24 × 0.08 × 0.06 (**7**), 0.4 × 0.24 × 0.04 (**8**), 0.4 ×

0.36 × 0.04 (**9**), 0.24 × 0.05 × 0.03 mm^3 (**10**) were selected for crystal structure analyses. Data collection for complexes **1**−**5** and **7**−**10** was performed at 293 K on a Siemens Smart CCD diffractometer with graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å). Empirical absorption corrections were applied using the SADABS program. Data collection for **6** was performed at 293 K on a CAD4 four-cycle diffractometer with graphite-monochromated Mo-K_α radiation (λ = 0.71073Å). Corrections for Lorentz polarization factors and empirical absorption were applied to the data. The structures of **1**−**10** were solved by direct methods; the heavy atoms were located from the E-maps; other non-hydrogen atoms were derived from the successive difference Fourier syntheses. All non-hydrogen atoms were refined by full-matrix, least-squares minimizations of $\Sigma(F_o - F_c)^2$ with anisotropic thermal parameters for **1**−**5** and **7**. The metal atoms were refined anisotropically while all other non-hydrogen atoms were refined isotropically for **6**, **8**, **9** and **10** in order to obtain a reasonable data/parameter ratio. One free water molecule (O14) in **4** and **5** was disordered over two sets of positions refined with restraints. The calculations were performed with the SHELXTL-97 program package.[29] The hydrogen atoms were located from the difference Fourier map and refined isotropically. Table 1 summarizes the important crystal data for **1**−**5** and Table 2 the data for **6**−**10**. The selected bond lengths and angles for **1**−**10** are provided in Table S1 in the Supporting Information.

CCDC-202618−202627 (for **1**−**10**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: +44 1223 336 033; E-mail: deposit@ccdc.cam.ac.uk].

Keywords: Cluster compounds / Copper / Nonlinear optics / Polymers / Tungsten

The self-assembly reaction of $(NH_4)_2(WOS_3)$ with CuBr in the presence of PCy_3 (PCy_3 = tricyclohexylphosphane) in MeCN gives rise to a novel 1D polymeric compound $[W_2O_2S_6Cu_4(NCMe)_4]_n$ (**1**) with solvent MeCN coordinated to the copper atom. This situation is unprecedented in the W(Mo)/Cu/S system. The excited state absorption and refraction of **1** in CH_3CN solution were studied by using the Z-scan technique with laser pulses of 40 ps pulse-width at a wavelength of 532 nm. The compound possesses an optical self-focusing performance. The positive nonlinear refraction is attributed to population transitions between singlet states. Compound **1** displays a strong excited-state absorption, which induces an asymmetry between the peak and valley.

Introduction

Polymeric transition-metal chalcogenides have attracted much attention because of their possible applications as catalysts or nonlinear optical devices directly derived from their peculiar solid-state structures.[1,2] Compared with polyoxometalates, polythiometalates are still in their infancy.[3−5] Mo(W)/Cu/S polymeric clusters are scarce and only a few structures have been reported. For example, the linear one-dimensional chains in $[\{WS_4Ag\}\{[H_3NC(CH_2OH)_3\}_n(dmf)_{2n}]$,[6a] $[\{(\eta^5\text{-}C_5Me_5)WS_3\}_2Ag_3(CN)\}_n]$[6b,6c] or $[WOS_3Cu_3(CN)(py)_4]_n$ (M = Mo, W),[7] the two-dimensional framework in $[\{NEt_4\}\{Mo_2O_2S_6Cu_6I_3(4,4'\text{-bipy})_5\}\cdot MeOH\cdot H_2O]_n$,[8a] $[(PPh_4)_2\{(CuNCS)_4WS_4\}]_n$ [8b] or the three-dimensional cross-framework in $[\{NEt_4\}_2\{(\mu_4\text{-}WSe_4)Cu_4(CN)_4\}]_n$.[9] We report here the synthesis and crystal structure of a novel 1D polymeric cluster $[W_2O_2S_6Cu_4(NCMe)_4]_n$ (**1**) with a novel zigzag chain configuration along the *c* axis and solvent as a ligand. Additionally, the excited state nonlinear refraction and absorption of compound **1** were investigated by using the Z-scan technique with picosecond pulses. We also propose a steady-state model of singlet excited state nonlinear refraction, which agrees well with experimental results of the excited-state refraction and absorption.

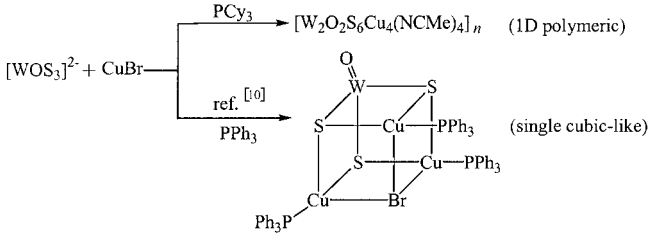
Results and Discussion

Synthesis of Compound 1

The reaction of $(NH_4)_2(WOS_3)$ and CuBr in the presence of PCy_3 (molar ratio of 1:2:2) in MeCN solution led to deep-red crystals of $[W_2O_2S_6Cu_4(NCMe)_4]_n$ (**1**) in 65% yield after allowing the orange-red filtrate to stand under an oxygen-free atmosphere for several days. Surprisingly, the PCy_3 ligand is not present in **1**, and solvent MeCN molecules are the only additional co-ligands present. This differs from our previously reported results when an analogous ligand, PPh_3, was used in place of PCy_3. As shown in Scheme 1, reaction of $[WOS_3]^{2-}$ with CuBr and PPh_3 produced a single cubic-like compound $[WOS_3Cu_3(PPh_3)_3Br]$.[10] When the reaction was performed in the absence of PCy_3 we could not isolate compound **1** or obtain good quality crystals, de-



Scheme 1

spite several attempts. It is possible that PCy_3 plays a role in the crystal growth.

Single-Crystal X-ray Diffraction Studies

Compound **1** crystallizes in the monoclinic system with space group $P2_1/c$. An ORTEP drawing is shown in Figure 1. The configuration of the polymeric compound can be viewed as a helical chain which is propagated along the crystallographic *c* axis. For clarity, a simplified diagram is shown in Figure 2, with S atoms omitted; the packing diagram of the unit cell is shown in Figure 3. It should be noted that the chain turns at each W atom. The main core in compound **1** may be described as containing a nest-shaped $W_2S_6Cu_4$ fragment, which has been previously been observed in $[(C_7H_7)_3P]_4Cu_4W_2S_6O_2$ [11] and $[Et_4N]_4[Mo_2S_6Cu_6O_2I_6]$.[12] Each approximately tetrahedral W atom is coordinated by one terminal O and three μ_3-S atoms with angles subtended at W of 108.61(10)−110.8(3)°. However, the coordination tetrahedron around the Cu(1) atom, formed by two μ_3-S and two N atoms from MeCN, is much more distorted, the angles of Cu ranging from 105.14(11)° to 116.0(3)°. The average W−Cu−W and Cu−W−Cu angles are 177.05(6)° and 85.80(2)°, respectively. The W=O bond length of 1.718(8) Å is typical of a double bond and is similar to those observed in $[(C_7H_7)_3P]_4Cu_4W_2S_6O_2$,[11] and $[(PPh_3)_4(SCMe_3)_2Cu_6W_2S_6O_2]$.[13] The W−$\mu_3$-S bond lengths are 2.244(2), 2.245(3), and 2.238(3) Å.

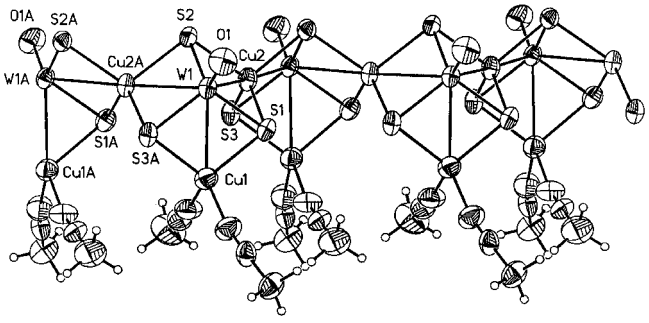

Figure 1. ORTEP drawing of a portion of the anion of $[W_2O_2S_6Cu_4(NCMe)_4]_n$ (**1**) with atomic labeling (30% displacement ellipsoids)

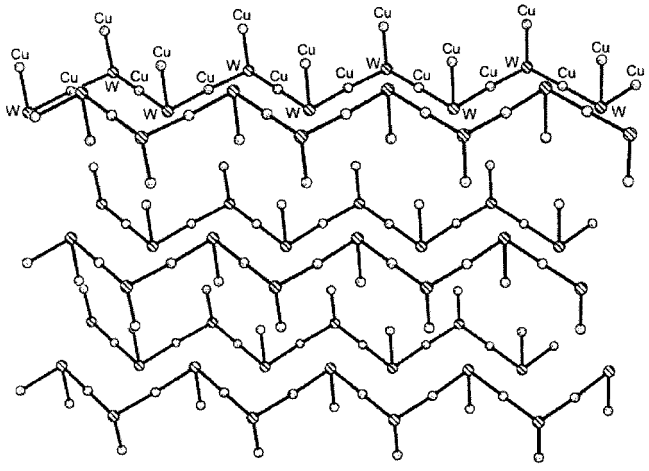

Figure 2. Simplified diagram of the anionic helical chain of **1**; sulfur atoms omitted for clarity

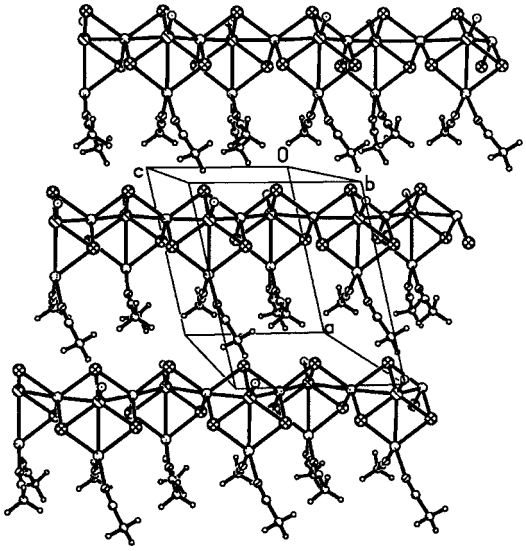

Figure 3. Packing drawing of the unit cell of **1** viewed along the *b* axis

There are two types of copper atoms in the $W_2S_6Cu_4$ core. The Cu(1) atom is tetrahedrally coordinated by two μ_3-S atoms and two nitrogen atoms of the MeCN ligands, resulting in a $(\mu_3\text{-S})_2Cu(NCMe)_2$ arrangement, while the Cu(2) atom is tetrahedrally coordinated by the four μ_3-S atoms resulting in a $(\mu_3\text{-S})_4Cu$ arrangement. Owing to the different coordination modes of the copper atoms, the W−Cu lengths are slightly different; for example, the W1−Cu1 bond length [2.6999(16) Å] is shorter than those for the W1−Cu2 bonds [av. 2.7489(15) Å]. The Cu−S distances also reflect the different coordination modes of the copper atoms, the Cu(2)−S bonds [av. 2.3264(3) Å] are longer than those for Cu(1) [av. 2.292(3) Å]. Selected bond lengths and angles are listed in Table 1.

Nonlinear Optical Properties

The UV/Vis spectrum of the polymeric compound **1** is depicted in Figure 4. It shows two absorption peaks with the first maximum located at 367 nm. The polymer has a relatively low linear absorption in the visible and near-IR regions. Indeed, the solution is nearly transparent in the visible and near infrared range, which qualifies the cluster as a potential optical limiting material.

The open-aperture Z-scan results are shown in Figure 5. The nonlinear transmittances of the sample are dependent only on the incident intensity for nanosecond and picosecond laser pulses, which indicates that the metal cluster possesses excited state absorption and not two-photon absorption. The details will be reported elsewhere. The nonlinear absorption of about 90% at the focus shows that the metal cluster possesses strong excited state absorption and a large optical limiting response. The normalized closed-aperture Z-scan curve (Figure 6) has a pair of sharp peaks and valley and the occurrence of the peak at positive Z indicates that

the cluster possesses positive nonlinear refraction or is self-focusing. Both the peak and the valley are asymmetric, and the width of the valley is widened. The asymmetry of the peak and valley of the normalized Z-scan curve is caused by the strong excited-state absorption. The excited-state optical nonlinearity can be studied by excited-state theory.

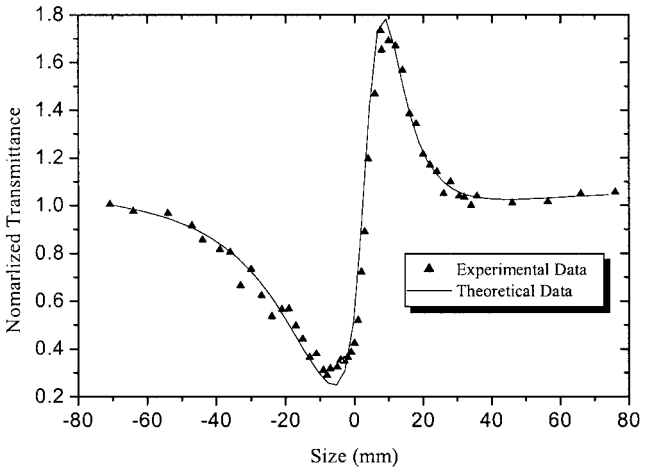

Figure 6. The Z-scan results of compound **1** observed under a closed-aperture configuration divided by those obtained under the open-aperture configuration

Under the excitation of picosecond laser pulses, the contribution of population of the singlet states to optical nonlinearities predominate and that of the triplet is negligible.[14] The nonlinear absorption index and refraction index can be written as shown in Equation (1)[15]

$$\begin{cases} \alpha = \alpha_0 + N_0\sigma_0 + N_1\sigma_S \\ \beta = \beta_0 + N_0\eta_0 + N_1\eta_S \end{cases} \quad (1)$$

where α_0 and α are the absorption coefficients of solvent and solute, respectively, σ_0 and σ_S are the absorption cross-sections of the ground and first singlet excited states, respectively, β_0 and β are the refractive indices of solvent and solution, respectively, and η_0 and η_S are the refrangibilities of the ground and first singlet excited states, respectively.

The light propagation equations are shown in Equation (2)

$$\begin{cases} \frac{\partial I}{\partial z} = -\alpha I \\ \frac{\partial \phi}{\partial z} = k\beta \end{cases} \quad (2)$$

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

where k is the wave vector and I is the incident laser density. We performed a Z-scan measurement using TEM_{00}-mode laser pulses with a beam-waist radius of ω_0, a Gaussian temporal profile of duration τ, and a propagation direction along positive z. The irradiance I thus varies with z, r, and t according to Equation (3)

$$I(z,r,t) = \frac{\omega_0^2}{\omega^2(z)} I_{00} \exp\left[-\left(\frac{t}{\tau}\right)^2\right] \exp\left[-\left(\frac{2r^2}{\omega^2(z)}\right)\right] \quad (3)$$

where $\omega(z) = \omega_0[1 + (z/z_0)^2]^{1/2}$ is the beam waist radius at z, $z_0 = \pi\omega_0^2/\lambda$ is the diffraction length of the beam, and I_{00} is the on-axis peak irradiance at the focus.

The lifetime of the second excited singlet-state is of the order of sub-picosecond, and is much shorter than the duration of the picosecond pulses. Hence this problem can be dealt with by a stable-state approximation. For the sake of simplicity, only the case of steady state is considered. In this event, the outcome may be expressed by Equation (4)

$$\begin{cases} \alpha = \alpha_0 + \dfrac{1 + K_a \dfrac{I}{I_s}}{1 + \dfrac{I}{I_s}} \sigma_0 N \\ \beta = \beta_0 + \dfrac{1 + K_r \dfrac{I}{I_s}}{1 + \dfrac{I}{I_s}} \eta_0 N \end{cases} \quad (4)$$

where $I_S = (\eta\nu)/(\sigma_0\tau_{S0})$ is a saturable intensity, and K_a and K_r are defined by $K_a = \sigma_S/\sigma_0$ and $K_r = \eta_S/\eta_0$, which are the ratios of the singlet excited-state absorption cross section and refrangibility to those of the ground state, respectively.

From Equations (1)−(4) we studied the nonlinear optical properties of the excited state of metal clusters, and successfully fitted the experimental results shown in Figure 5 and 6 (solid lines). The ratios K_r and K_a are calculated to be 1.1 and 18 by the fitting curve for picosecond pulses. It can be seen that the ratio of refraction volumes of the singlet excited-state to the ground-state is greater than one for picosecond pulses, so it is self-focusing. The ratio of the singlet excited-state absorption cross-section to the ground-state is very large, so the compound possesses a strong excited-state absorption, which induces the asymmetry of the peak and valley.

Conclusions

In summary, a novel 1D polymeric compound $[W_2O_2S_6Cu_4(NCMe)_4]_n$ (**1**) with solvent MeCN coordinated to the copper atom was obtained through the self-assembly reaction of $(NH_4)_2(WOS_3)$ with CuBr in the presence of PCy_3. Compound **1** exhibits a strong excited-state absorption performance, the ratio of absorption cross-section of the singlet excited-state to that of the ground-state was about 18. Compound **1** is therefore considered to be a promising candidate for picosecond optical-limiting. The ratio of refrangibility of the singlet excited-state to that of the ground state is about 1.1; thus, it possesses a self-focusing property with picosecond pulses. The asymmetry of the peak and valley of the Z-scan curve is caused by the excited-state absorption. The nonlinear refraction and absorption model of the excited-states is presented to simulate the experiment results.

Experimental Section

General: The reagent $(NH_4)_2(WOS_3)$ was prepared according to a literature procedure.[16] Other chemicals were of AR grade and used without further purification. Infrared spectra were recorded with a Fourier transform Nicolet FT-170SX spectrophotometer (KBr pellets). The electronic spectrum was taken on a Shimadzu UV-240 spectrophotometer and elemental analyses (C and H) were performed on a PE-240C elemental analyzer. The ^1H NMR spectra were recorded on a Bruker AC400 spectrometer.

Nonlinear Optical Measurements: The nonlinear optical properties of the metal cluster solution were measured by the Z-scan technique at 532 nm. A continuum ns/ps Nd:YAG laser system with a pulse width of 40 ps was used. The metal complex **1** in CH_3CN solution was filled into a 2-mm cuvette with a linear transmittance of 92%. The input and the output energies of beams were measured with energy meters (Laser Precision Corporation Rjp-735). The focal length of the lens was 90 mm. The laser beam waist was about 36 μm at focus point, and the corresponding Rayleigh length was thus much larger than the thickness of sample. The aperture diameter was 2 mm and this corresponds to a far-field transmittance of 9.8%. The experimental data were collected utilizing a single shot at a rate of 1 pulse per minute to avoid thermal effects. The input pulse energies were 700 μJ for picosecond pulses.

Preparation of Compound 1: A solution of PCy_3 (560 mg, 2 mmol) in MeCN (10 mL) was added to a mixture of $(NH_4)_2(WOS_3)$ (332 mg, 1 mmol) and CuBr (287 mg, 2 mmol) in MeCN (40 mL). The resulting mixture was stirred for 24 h and then filtered. The red filtrate was layered with hexane (20 mL) and allowed to stand at room temperature for several weeks. Deep-red crystals were obtained; yield: 65%. Characteristic infrared absorptions were found at 420 cm^{-1} and 440 cm^{-1} for ν(W−S), 910 cm^{-1} for ν(W−O), and 2100 cm^{-1} for ν(C≡N). ^1H NMR ([D$_6$]DMSO, 25 °C): δ = 1.93 (s, CH_3). $C_4H_6Cu_2N_2OS_3W$ (505.22): calcd. C 9.51, H 1.20, N 5.54; found C 9.21, H 1.23, N 5.32.

Crystal Structure Determination and Refinement: A well-developed single crystal of the polymeric compound with suitable dimensions was mounted on a glass fiber. Cell dimension measurements and data collection were performed on a Siemens Smart CCD diffractomer with graphite monochromatized Mo-K_α radiation (λ = 0.71073 Å) at 20 °C. Intensity data for the crystal were obtained in the range $4.56° < 2\theta < 50°$ using the ω-scan technique. The structure was solved by direct methods using SHELXTL software and refined by full-matrix least-square methods on F^2.[17] All H atoms were geometrically fixed and allowed to ride on their attached atoms. Selected bond lengths and angles are listed in Table 1 and details of the data collection and structure refinement are summarized in Table 2.

Synthesis and Characterisation of the First Three-Dimensional Mixed-Metal-Center Inorganic-Organic Hybrid Framework with *N*-(Phosphonomethyl)iminodiacetate

Filipe A. Almeida Paz,[a] Fa-Nian Shi,[b] Jacek Klinowski,[a] João Rocha,*[b] and Tito Trindade[b]

Keywords: Carboxylate ligands / Crystal engineering / Hydrothermal synthesis / N ligands / Organic-inorganic hybrid composites

Using crystal engineering concepts, the first three-dimensional (3D) mixed-metal-centre inorganic-organic hybrid frameworks incorporating *N*-(phosphonomethyl)iminodiacetate ($pmida^{4-}$) were synthesised under mild hydrothermal conditions (100 °C) and characterised structurally. The crystal structures, obtained by the displacement of the coordinated water molecules in $[Co_2V_2O_2(pmida)_2(H_2O)_{10}]\cdot 2(H_2O)$ (**1**) [$P2_1/c$ monoclinic space group, $Z = 2$, $a = 9.996(2)$ Å, $b = 14.854(3)$ Å, $c = 10.781(2)$ Å, $\beta = 110.90(3)°$ and $V = 1495.5(5)$ Å^3] by the rod-like bridging 4,4′-bipyridine (4,4′-bpy) ligand — $[CdVO(pmida)(4,4'\text{-bpy})(H_2O)_2]\cdot(4,4'\text{-bpy})_{0.5}\cdot H_2O$ (**2**) and $[CoVO(pmida)(4,4'\text{-bpy})(H_2O)_2]\cdot(4,4'\text{-bpy})_{0.5}$ (**3**) — are isostructural and were also determined in the $P2_1/c$ monoclinic space group ($Z = 4$) by single-crystal X-ray diffraction studies at low temperature (180 K): for **2**, $a = 9.1267(18)$ Å, $b = 17.610(4)$ Å, $c = 15.361(3)$ Å, $\beta = 93.06(3)°$ and $V = 2465.3(9)$ Å^3; for **3**, $a = 8.7734(18)$ Å, $b = 17.264(4)$ Å, $c = 15.507(3)$ Å, $\beta = 93.94(3)°$ and $V = 2343.2(8)$ Å^3. All the crystal structures contain centrosymmetric dimeric $[V_2O_2(pmida)_2]^{4-}$ units connected to neighbouring M^{2+} cations (Cd^{2+} for **2**, and Co^{2+} for **1** and **3**) through the phosphonate group. In **2** and **3**, extended two-dimensional $[MVO(pmida)(H_2O)_2]_n$ layers are formed, with the 4,4′-bpy molecules acting as pillars between adjacent layers, leading to porous 3D supramolecular structures, $[MVO(pmida)(4,4'\text{-bpy})(H_2O)_2]_\infty$, with a topology resembling that of the NbO net.

Introduction

Since Hoskins and Robson reported the first highly ordered organic-inorganic coordination frameworks,[1] there has been a widespread interest in the design, synthesis and characterisation of such compounds.[2,3] The driving force behind this work is the potential application of functional materials for reversible guest-exchange,[4,5] shape selectivity,[5] catalysis,[6] gas storage,[7] molecular recognition,[8] photoluminescence,[9] and/or unusual magnetic,[10−12] nonlinear[11] and semiconducting properties,[13] chirality[12,14] or clathration.[15] While considerable progress has been made in the understanding of the chemical self-assembly of the building blocks of such materials, reliable prediction of their final topology and chemical properties remains one of the greatest challenges to crystal engineers, since several supramolecular isomers of similar energies are usually formed.[3] However, by careful selection of metallic centres with specific coordination geometries and organic ligands with predictable coordination fashions, some supramolecular motifs can be predicted.

We have focused our research on the synthesis of novel highly crystalline organic-inorganic hybrid materials which incorporate, simultaneously, traditional and novel ligands to the field.[16−18] *N*-(Phosphonomethyl)iminodiacetic acid (H_4pmida) is a precursor of a multidentate organic ligand ($pmida^{4-}$) with interesting and flexible coordination properties: apart from the two carboxylic acid groups and the central N-donor atom, it contains a phosphonate group capable of coordinating to several metal centres and to eliminate available coordination sites. Surprisingly, searches in the literature and the Cambridge Structural Database produced only a handful of structures incorporating this organic molecule: $Na_4[V_2O_2(pmida)_2]\cdot 10H_2O$ and $Na_8[V_2O_2(pmida)_2]_2\cdot 16H_2O$;[19] $[Co_2(pmida)(H_2O)_5]\cdot H_2O$ and $[Zn_2(pmida)(CH_3CO_2H)]_2\cdot H_2O$;[20] several zirconium derivatives;[21] $\{K_2[CoO_3(pmida)]\}_6\cdot xH_2O$[22] and $[Pb_2(pmida)]\cdot 1.5H_2O$.[23] The structures reported by Crans and co-workers[19] contain a centrosymmetric dimeric $[V_2O_2(pmida)_2]^{4-}$ unit, in which $pmida^{4-}$ completely traps

the vanadium centres inside three five-membered rings formed by the two carboxylate groups and the phosphonate group, closely resembling what we have observed for the *N*′′-carboxymethyldiethylenetriamine-*N*,*N*,*N*′,*N*′′-tetraacetate[17] and nitrilotriacetate[18] ligands. We felt that the $[V_2O_2(pmida)_2]^{4-}$ unit could then be used as a robust building block to construct novel multi-dimensional hybrid materials by replacing the Na^+ counterions with transition metal cations such as Co^{2+} and Cd^{2+}. This was first achieved with Co^{2+} cations which, along with the $[V_2O_2(pmida)_2]^{4-}$ unit, formed centrosymmetric neutral $[Co_2V_2O_2(pmida)_2(H_2O)_{10}]$ species (present in the crystal structure of **1**). Interestingly, each Co^{2+} centre is coordinated to five water molecules, which led us to believe that such weakly bound molecules could be easily displaced by a multitopic rod-like bridging ligand, such as 4,4′-bipyridine (4,4′-bpy). Here, we wish to report the synthesis and structural characterisation of the first two three-dimensional mixed-metallic frameworks incorporating $pmida^{4-}$ and 4,4′-bpy: $[CdVO(pmida)(4,4'\text{-bpy})(H_2O)_2]\cdot(4,4'\text{-bpy})_{0.5}\cdot H_2O$ (**2**) and $[CoVO(pmida)(4,4'\text{-bpy})(H_2O)_2]\cdot(4,4'\text{-bpy})_{0.5}$ (**3**).

Results and Discussion

$[Co_2V_2O_2(pmida)_2(H_2O)_{10}]\cdot 2(H_2O)$ (**1**), $[CdVO(pmida)(4,4'\text{-bpy})(H_2O)_2]\cdot(4,4'\text{-bpy})_{0.5}\cdot H_2O$ (**2**) and $[CoVO(pmida)(4,4'\text{-bpy})(H_2O)_2]\cdot(4,4'\text{-bpy})_{0.5}$ (**3**) were synthesised under mild hydrothermal conditions (see Exp. Sect.) and characterised structurally by single-crystal X-ray diffraction (see Exp. Sect. for further details) [$pmida^{4-}$ = *N*-(phosphonomethyl)iminodiacetate and 4,4′-bpy = 4,4′-bipyridine]. Compounds **2** and **3** have almost identical frameworks, with the most important difference being the extra crystallisation solvent molecule present in **2**. The phase purity and homogeneity of the bulk samples were further confirmed by X-ray powder diffraction analysis and elemental composition studies (EDS and CHN elemental analyses).

All structures contain two crystallographically unique metal centres, M1 and V1 [where M = Co^{2+} (for **1** and **3**) or Cd^{2+} (for **2**)], both in a six-coordination geometry, $\{CoO_6\}$ (in **1**), $\{MO_3N_3\}$ (in **2**/**3**) and $\{VO_5N\}$ [see Figure 1 and (a) in Figure 2; Table 1 and 2]. V1 is always connected to one oxo group and to two $pmida^{4-}$ ligands, with the coordination geometry resembling the typical highly distorted octahedral environment of V^{4+} sites [angles varying from 74.66(8) to 169.94(9)° (for **1**), 75.78(11) to 172.65(13)° (for **2**), and from 75.64(10) to 172.97(12)° (for **3**)], with a short (V=O), four intermediate (V−O) and one long (V−N) bonds (Table 1 and 2), all within the expected ranges reported by Boudin et al.,[24] as found in related compounds. The same authors classify such coordination geometry for V^{4+} as 1+4+1 with, as observed in our struc-

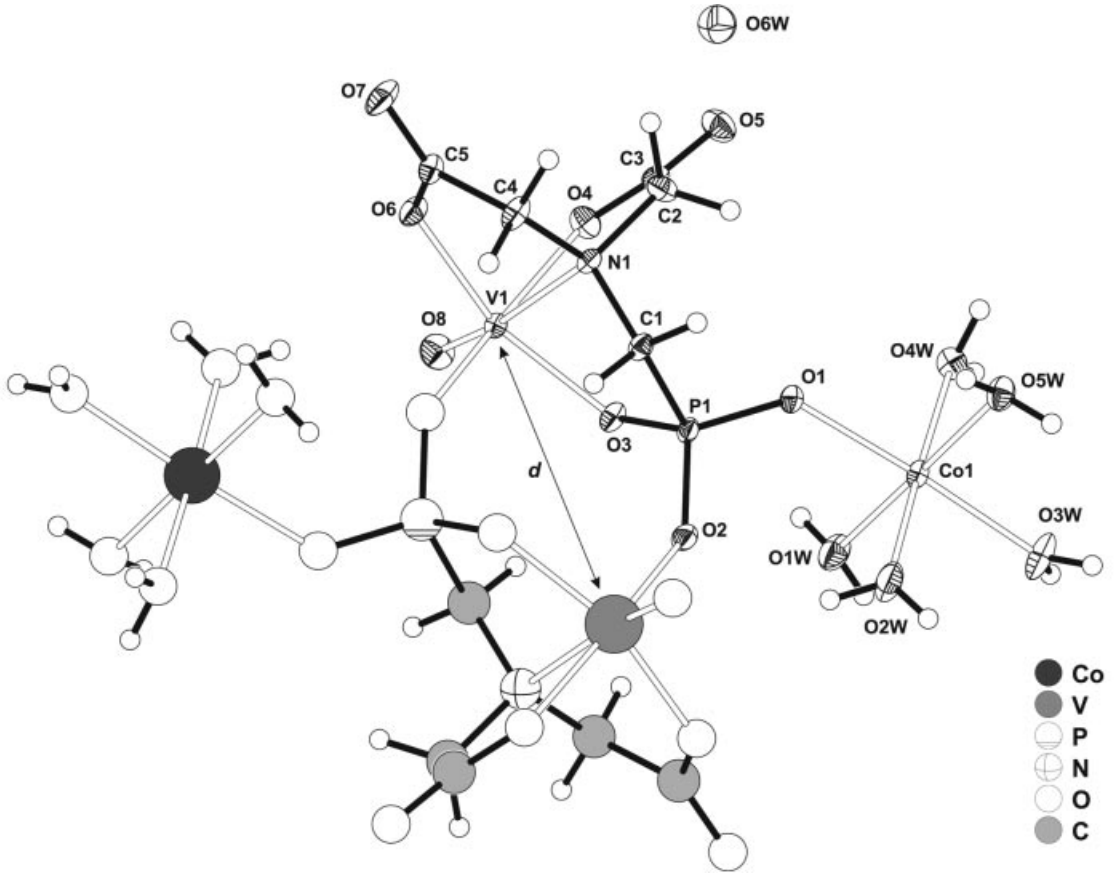

Figure 1. Molecular unit of **1**, showing the labelling scheme for all non-hydrogen atoms belonging to the asymmetric unit [*d* = 5.2285(13) Å]; displacement ellipsoids are drawn at the 50% probability level and H atoms are shown as small spheres; see Table 1 for bond lengths and angles

[a] Symmetry transformation used to generate equivalent atoms: (i) 2 − *x*, −*y*, 1 − *z*.

tures, the V=O being *trans* to V−N, showing a marked influence of the oxo ligand in the long V−N distance.[24] Such bonds, although longer than those found in compounds with a *trans* amine nitrogen donor atom bound to vanadium as, for example, complexes with nitrilotriacetic acid (2.17−2.30 Å),[25] *N*-(2-hydroxyethyl)iminodiacetic acid (2.17−2.31 Å),[26] *N*-(carbamoylmethyl)iminodiacetic acid (2.19−2.21 Å),[27] *N*-(carbamoylethyl)iminodiacetic acid (2.17−2.19 Å),[28] (*S*)-[1-(2-pyridyl)ethyl]iminodiacetic acid (2.26−2.29 Å)[29] and triethanolamine (2.15−2.28 Å),[30] are similar to the values found by Crans and co-workers for the vanadium compounds containing $pmida^{4-}$ ligands: {$Na_4[V_2O_2(pmida)_2]\cdot 10H_2O$ (**a**) and $Na_8[V_2O_2(pmida)_2]_2\cdot 16H_2O$ (**b**)}.[19] Since for each compound the four V−O bonds are statistically identical, the coordination geometry for V1 can be seen as a highly distorted octahedral environment (Table 1 and 2).

In **1**, the coordination environment of Co1 is composed of five water molecules and one O-donor atom from the phosphonate group (Figure 1), with a coordination geometry of an almost regular octahedron [bond lengths and angles varying from 2.0364(19) to 2.139(2) Å, and 87.57(9) to 179.29(8)°, respectively] (Table 1). As expected, the bridging rod-like 4,4′-bpy ligand has displaced the weakly bound water molecules, introducing significant structural changes in the final compounds. In **2** and **3**, M1 is now coordinated to six independent moieties (two water molecules, two $pmida^{4-}$ and two 4,4′-bpy ligands) with a coordination geometry of a slightly distorted octahedron [bond angles varying from 84.02(12) to 174.82(1)° (for **2**), and from 86.09(11) to 175.02(9)° (for **3**); see (a) in Figure 2 and Table 2]. Interestingly, each pair of ligand types is *trans*-coordinated in the axial positions, with the O-donor atoms

[a] Symmetry transformations used to generate equivalent atoms: (i) x, 1/2 − y, 1/2 + z; (ii) x + 1, 1/2 − y, 1/2 + z; (iii) 2 − x, −y, 1 − z; (iv) x, 1/2 − y, z − *1/2*; (v) x − 1, 1 − y, z − 1/2; (vi) −x, −y, 1 − z. M = Cd^{2+} or Co^{2+} for **2** and **3**, respectively.

from the two pmida^{4-} ligands being from different functional groups inside this molecule [O1 belongs to the phosphonate group, while O5 belongs to the bridging-η^2-*syn*, *anti*-bidentate C3 carboxylate group; see (a) in Figure 2]. The average M−O and M−N distances are 2.09/2.32/2.14 and 2.29/2.13 Å (for **1/2/3**), consistent with values found in similar structures.

The pmida^{4-} anion is a polydentate ligand that completely traps the vanadium centres inside three five-membered rings formed by the two carboxylate and phosphonate groups connected in an *anti*-unidentate coordinative fashion to the vanadium centres [pmida-V moiety; Figure 1 and (a) in Figure 2]. The average bite angles are ca. 76.7/76.8/76.2° (for **1/2/3**, Table 1 and 2), similar to the values for **a** and **b** (ca. 76.7 and 77.0°, respectively).[19] Interestingly, in **2** and **3** each carboxylate group from pmida^{4-} has a different coordination mode: while the C5 group is only coordinated to V1 by the O5 atom in an *anti*-unidentate mode, C3 also forms a bridge with a neighbouring M1 through a bridging-*syn*,*anti*-bidentate coordination mode [V1···Cd1^{i} 5.3463(11) Å, and V1···Co1^{ii} 5.2888(11) Å; symmetry codes: (i) x, 1/2 − y, −1/2 + z; (ii) x, 1/2 − y, 1/2 + z]. All carboxylate groups maintain approximately the equivalence in the C−O bonds, with the distances within the 1.239(3)−1.278(3) Å, 1.239(5)−1.277(5) Å and 1.240(4)−1.277(4) Å ranges for structures **1**−**3**, respectively. This is particularly unexpected for the carboxylate groups adopting the *anti*-unidentate coordinative fashion (C5 for all the structures, plus C1 in **1**), and can be explained by the extensive hydrogen-bonding network in the crystal struc-

tures (Table 3). As in **a** and **b**, the phosphonate group from pmida^{4-} establishes bridges between adjacent vanadium centres (through the O2 and O3 atoms), leading to the formation of a centrosymmetric dimeric unit consisting of two pmida-V moieties, $[V_2O_2(pmida)_2]^{4-}$, and imposing V1···V1$^{iii/iv}$ separations of 5.2285(13)/5.2545(17)/5.2128(16) Å (for **1**/**2**/**3**) [symmetry codes: (iii) $2 - x, -y, 1 - z$; (iv) $-x, -y, 1 - z$; see Figure 1 and (a) in 2].

In the structures reported by Crans and co-workers, the $[V_2O_2(pmida)_2]^{4-}$ dimeric units appear isolated in the crystal structure, interacting only with the neighbouring Na^+ cations and water molecules. Similarly, **1** can be described by the close packing of $[Co_2V_2O_2(pmida)_2(H_2O)_{10}]$ moieties, interacting through the extensive hydrogen-bonding network (not shown; Table 3). However, in **2** and **3** coordinative interactions with Cd^{2+} and Co^{2+} cations from adjacent moieties lead to the formation of extended two-dimensional (2D) $[MVO(pmida)(H_2O)_2]_n$ networks in the *bc* plane of the unit cell (Figure 3). In fact, apart from the bridge created by the C3 *syn*,*anti*-bidentate carboxylate group discussed previously, O1 is also connected to a neighbouring M1 centre, establishing the final tridentate coordination mode for the phosphonate group [V1···M1 6.2903(11)/6.1987(12) Å and M1···V1$^{iii/iv}$ 5.0474(11)/4.9696(11) Å for (**2**/**3**); symmetry codes: (iii) $2 - x, -y, 1 - z$; (iv) $-x, -y, 1 - z$].

As often occurs in other hybrid organic-inorganic materials, **2** and **3** can also be seen as modular structures assembled by the 3D repetition of a discrete hexametallic secondary building unit (SBU) composed of 4 M^{2+} and 2 V^{4+} centres (Figure 2 and 3). Taking the geometrical centres of the $[V_2O_2(pmida)_2]^{4-}$ units (denoted as A) and the M^{2+} metal centres (denoted as X; see Figure 2b and 3b) as network nodes, the $[MVO(pmida)(H_2O)_2]_n$ layers can be seen as undulating plane nets formed by distorted 4-gons assembled by 4- (A) and 2-connected nodes (X) [se (b) in Figure 3]. As expected for a typical AX_2 plane net, A and X are not co-planar, with rows of X-nodes placed above and below the plane of the A-nodes. Such a topological feature has direct consequences in the 3D structure of the compounds. In fact, ditopic bridging 4,4′-bpy molecules [with dihedral angles of ca. 42/44° (**2**/**3**) between the two 4-pyridyl groups; see (a) in Figure 2] establish physical links between consecutive M1 metal centres [see (b) in Figure 2], forming $[M(4,4'\text{-bpy})(H_2O)_2]_n^{2n+}$ cationic chains which run along the crystallographic *a* axis [see (a) in Figure 2 and Figure 4], and act as pillars between consecutive $[MVO(pmida)(H_2O)_2]_n$ layers [M1···M1^{v} 11.613(4)/11.308(4) Å for (**2**/**3**); symmetry code: (v) $1 + x, 1/2 - y, 1/2 + z$] (Figure 4).

The parallel stacking of 4,4′-bpy-pillared $[MVO(pmida)(H_2O)_2]_n$ layers leads to a porous 3D supramolecular structure, $[MVO(pmida)(4,4'\text{-bpy})(H_2O)_2]_\infty$ (Figure 4), with a topology resembling that of the NbO net (Figure 5).[31] This 3D structure contains rectangular channels which run along the *a* direction (average cross-section of ca. 5.0 × 4.0 Å^2), and stack in an [ABAB...] brick-wall-like fashion in the *bc* plane (Figure 6). A search for the solvent accessible voids for $[MVO(pmida)(4,4'\text{-bpy})(H_2O)_2]_\infty$ using the software package PLATON[32] (1.20 Å probe radius) gives 596.2/516.9 Å^3 (24.2/22.1% of the total volume of the unit cell) for **2**/**3**. These channels contain the extra crystallisation solvent molecule (in the case of **2**), and 4,4′-bpy molecules strongly hydrogen bonded to the framework, establishing further interactions between consecutive layers (Figure 6 and Table 3).

Thermal Analysis

The course of thermal decomposition of compounds **1**, **2** and **3** is similar. For **1** and **2**, two mass losses in the 54−336 and 30−280 °C temperature ranges, respectively, correspond to the release of all the water molecules from the crystal structure: for **1**, the combined mass losses (24.2%) are in good agreement with the calculated value (23.8%) for the release of the twelve crystallographic water molecules; for **2**, some lattice water is gradually released between 30 and 180 °C (1.4% observed, 2.6% calculated); between 180 and 280 °C all the remaining water molecules are released in a one-step process (7.5% observed, 7.8% calculated).

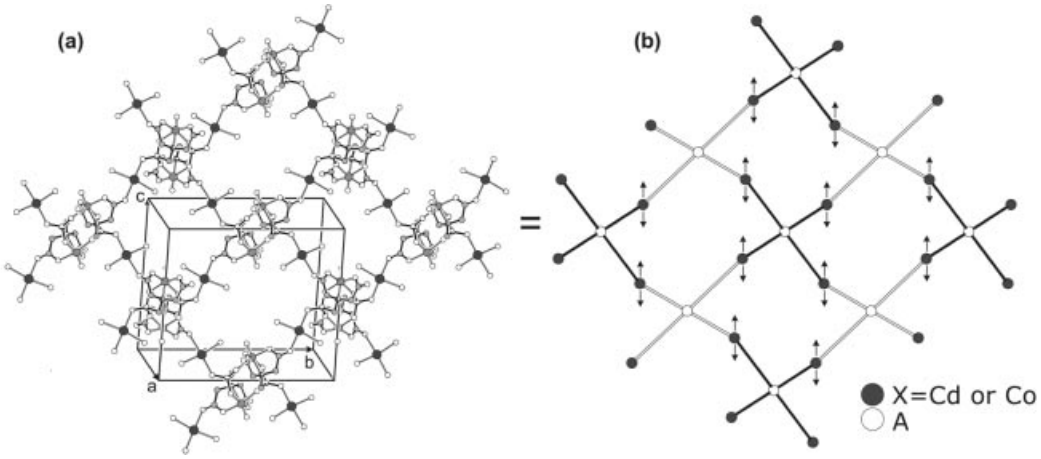

Figure 3. (a) Ball-and-stick and (b) topological representations of 2D $[MVO(pmida)(H_2O)_2]_n$ undulated network; all hydrogen atoms have been omitted for clarity; arrows indicate the ditopic bridging 4,4′-bpy ligands and thus the direction of the $[M(4,4'\text{-bpy})(H_2O)_2]_n^{2n+}$ cationic chains which connect neighbouring $[MVO(pmida)(H_2O)_2]_n$ layers (M = Cd^{2+} and Co^{2+} for **2** and **3**, respectively)

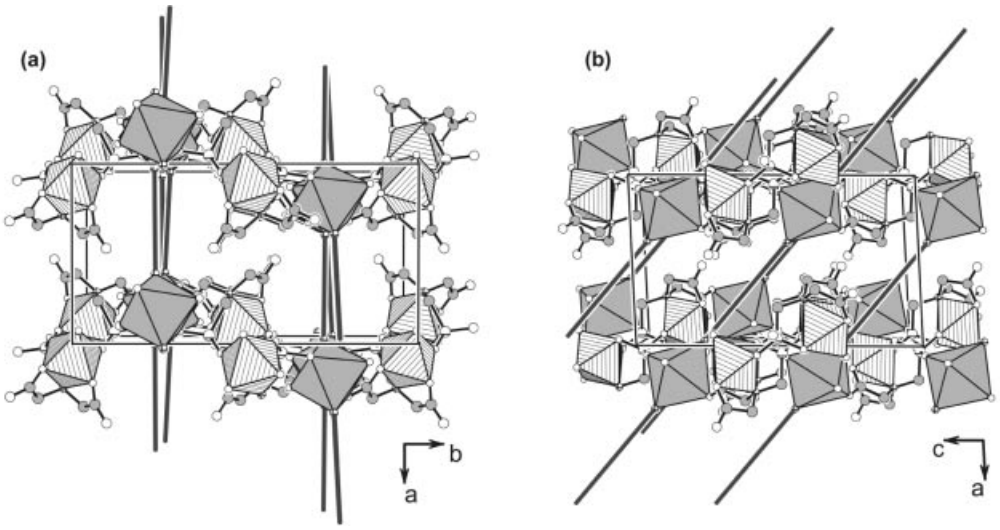

Figure 4. Perspective views along the (a) *c* and (b) *b* crystallographic axes of two consecutive $[MVO(pmida)(H_2O)_2]_n$ layers (M = Cd^{2+} and Co^{2+} for **2** and **3**, respectively), which pack in a parallel fashion along the *a* direction (one layer per *a* axis); the bridging 4,4′-bpy ligands (represented as grey-filled rods) act as pillars between the layers; V^{4+} and M^{2+} centres are represented as white- and grey-filled octahedra, respectively; all hydrogen atoms have been omitted for clarity

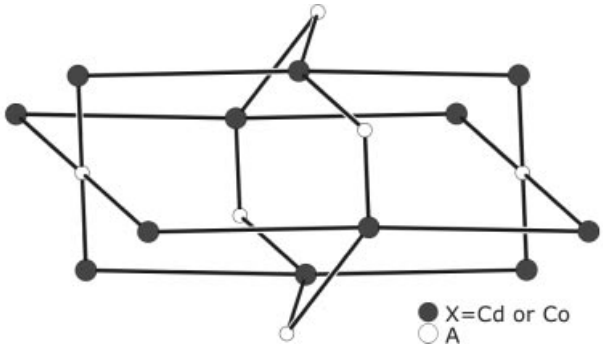

Figure 5. Topological representation of a portion of the $[MVO(pmida)(4,4'\text{-bpy})(H_2O)_2]_\infty$ network (M = Cd^{2+} and Co^{2+} for **2** and **3**, respectively), showing a topology resembling that of the NbO net[31]

Interestingly, in compound **3** the release of the two molecules per formula unit is significantly faster, with the majority of the water molecules being liberated between 30 and 149 °C (4.9% observed, 5.8% calculated). Although the steric hindrance created by the presence of the 4,4′-bpy molecules within the channels is almost the same for **2** and **3**, the hydrogen bonds caused by the presence of extra lattice water in **2** appear to be responsible for the slow kinetics of the dehydration process (Table 3 and Figure 6).

Up to 606 °C, 520 °C and 655 °C total mass losses of 46.6%, 55.7% and 60.9% are registered for **1**, **2** and **3**, respectively, which is attributed to the thermal decomposition of the organic component, leading to the formation of the mixed oxo-metallic phosphates, MVO_2PO_4 (**1**: 52.1% calculated and 53.4% observed residues; **2**: M = Cd^{2+}, 42.2% calculated and 44.3% observed residues; **3**: M = Co^{2+}, 38.3% calculated and 39.1% observed residues).

Vibrational Spectra

FT-IR spectroscopy confirms the presence of the organic ligands used in the synthesis (see Exp. Sect.). The presence of hydrogen-bonding networks is evident from the spectra, not only through the presence of the typical O−H stretching vibrations for water molecules (very broad bands), but also to in-plane (δ) and out-of-plane (γ) O−H···O deformations (see Exp. Sect.). The characteristic antisymmetric and symmetric stretching bands for carboxylate ions are also present, with the corresponding $\Delta[\nu_{assym}(CO_2^-) - \nu_{sym}(CO_2^-)]$ values being 218 cm^{-1}, 246 and 189 cm^{-1}, and 250 and 192 cm^{-1} for **1**, **2** and **3**, respectively. These values are a clear indication of the presence of carboxylate groups in the *anti*-unidentate and bridging-η^2-*syn*,*anti*-chelate coordination modes, respectively, as observed in the crystal structures (Figure 1 and 2).[33] The *anti*-unidentate coordination mode for the carboxylate groups is clearly observed in the IR spectra from the typical stretching vibration for C−O groups (found at 1685, 1670 and 1697 cm^{-1} for structures **1**−**3**, respectively).

Conclusion

Crystal Engineering concepts have been used to examine the assembly of ordered 3D solid organic-inorganic hybrid materials containing $[V_2O_2(pmida)_2]^{4-}$ moieties [where $pmida^{4-}$ is *N*-(phosphonomethyl)iminodiacetate]. Two novel isostructural mixed-metal materials containing Cd^{2+} or Co^{2+} have been prepared by using the rod-like 4,4′-bipyridine ligand to establish physical bridges between adjacent $[M_2V_2O_2(pmida)_2]$ moieties. The 3D structures contain pores along the *a* direction of the unit cell that are filled with uncoordinated 4,4′-bipyridine and solvent molecules.

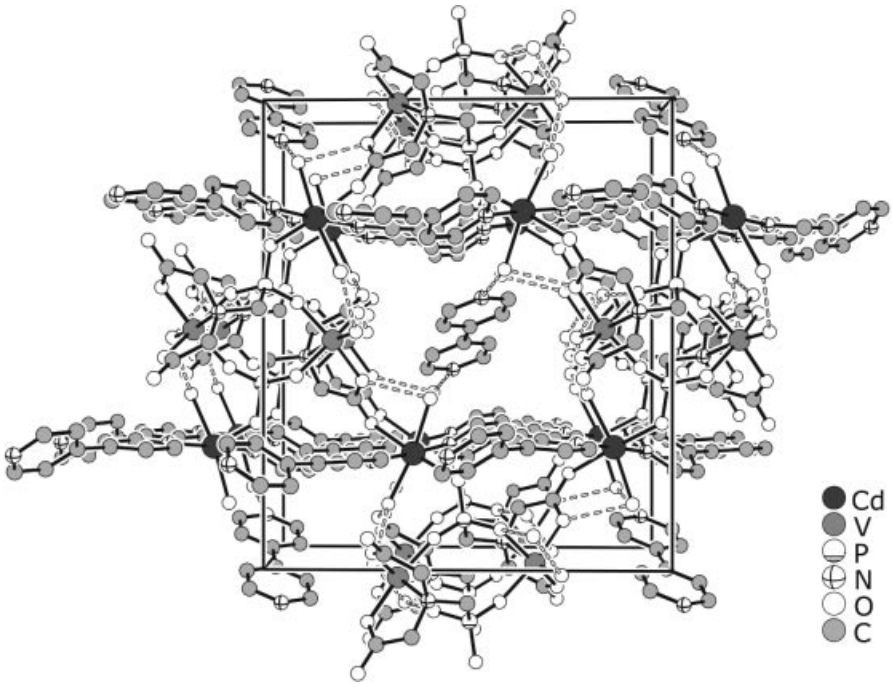

Figure 6. Perspective view along the *a* direction of the unit cell of **2**; hydrogen bonds are represented as white-filled dashed lines (for hydrogen-bonding geometry see Table 3); all hydrogen atoms have been omitted forclarity

Current work is focused on functionalising such materials by selectively controlling the organic pillars and the metal cations bridging adjacent $[V_2O_2(pmida)_2]^{4-}$ moieties.

Experimental Section

General: All reagents were readily available from commercial sources and were used as received without further purification. Syntheses were carried out in PTFE-lined stainless-steel reaction vessels (40 mL) under autogenous pressure and static conditions at 100 °C in a preheated oven. Reactions took place over a period of 4 days after which the vessels were removed from the oven and left to cool to ambient temperature before opening. All compounds proved to be air- and light-stable, and insoluble in water and common organic solvents such as methanol, ethanol, acetone, dichloromethane, toluene, DMSO and chloroform.

Characterisation: Elemental analyses for C, H and N were performed on an Exeter Analytical CE-440 Elemental Analyzer (University of Cambridge). Samples were combusted under oxygen at 975 °C, with He as the purge gas. FT-IR spectra were measured from KBr disks (Aldrich, 99%+, FT-IR grade) on a Matson 700 FTIR spectrometer. Thermogravimetric analyses (TGA) were carried out using a Shimadzu TGA-50, with a heating rate of 10 °C/min, under nitrogen atmosphere with flow rate of 20 mL/min.

Preparation and Structural Characterisation of $[CoVO(pmida)(H_2O)_5]_2\cdot 2(H_2O)$ (1): A mixture of vanadium(IV) oxide sulfate pentahydrate ($VOSO_4\cdot 5H_2O$; 0.40 g, 99% Sigma-Aldrich), cobalt acetate tetrahydrate ($CoC_4H_6O_4\cdot 4H_2O$; 0.620 g, 99.0% Fluka), *N*-(phosphonomethyl)iminodiacetic acid hydrate (H_4pmida; 0.400 g, 97% Fluka), and imidazole ($C_3H_4N_2$; 0.200 g, 99.0% Panreac) in about 8 mL of distilled water, was stirred thoroughly for 30 min at ambient temperature yielding a suspension with a molar composition of 1.00:1.56:1.19:1.86:281, respectively. After the reaction a large amount of big purple crystals of **1** (ca. 0.50 g) were isolated by vacuum filtering, washed with large amounts of distilled water (3 × ca. 50 mL), and air-dried at ambient temperature. Large single-crystals of **1** could also be formed by the slow evaporation of water from the autoclave mother liquor. $C_{10}H_{32}Co_2N_2O_{28}P_2V_2$ (910.06) (based on single-crystal data): calcd. C 13.14, H 3.97, N 3.06; found C 13.63, H 3.72, N 2.89. TGA data (mass losses): 54−169 °C 18.8% (DTG peak at 142 °C); 169−336 °C 5.4% (DTG peak at 171 °C); 336−440 °C 20.4% (DTG peaks at 379 and 403 °C); 440−606 °C 2.0% (DTG peak at 501 °C). Selected FT-IR data (cm^{-1}): ν(O−H, lattice and coordinated water) = 3384 vs (very broad); ν_{sym}(C−H in CH_2) = 2962 m; ν_{asym}(C−H in CH_2) = 2925 m; ν(C−O) = 1695 m; $\nu_{asym}(CO_2^-)$ = 1622 vs; δ(CH_2) = 1427 m; $\nu_{sym}(CO_2^-)$ = 1404 s; δ(O−H···O) = 1389 s and 1343 m; ν(C−O) = 1254 m; δ(C−C−N, amines) = 1145 vs and 1116 s; ν(N−C) = 1103s; ν(P−O) = 1061 vs; ν(V−O) = 955 s; γ(O−H···O) = 909 m; ν(P−C) = 774 m; γ(C−O) = 737 m.

Preparation and Structural Characterisation of $[CdVO(pmida)(4,4'\text{-bpy})(H_2O)_2]\cdot(4,4'\text{-bpy})_{0.5}\cdot H_2O$ (2): A mixture of vanadium(IV) oxide sulfate pentahydrate ($VOSO_4\cdot 5H_2O$; 0.40 g, 99% Sigma−Aldrich), cadmium oxide (CdO; 0.470 g, 99% Fluka), *N*-(phosphonomethyl)-iminodiacetic acid hydrate (H_4pmida; 0.560 g, 97% Fluka) and 4,4′-bipyridine (4,4′-bpy; 0.190 g, 99% Fluka) in about 15 mL of distilled water, was stirred thoroughly for 30 min at ambient temperature yielding a suspension with a molar composition of 1.30:2.77:2.04:1.00:685, respectively. After the reaction the resulting mixture consisted of two distinct phases: a large amount of light-blue crystals of **1** (ca. 0.20 g), and a residual amount of a white powder of unknown composition. The two components were readily separated by vacuum filtering and washing with large amounts of distilled water (3 × ca. 50 mL). Crystals of **2** were manually harvested and then air-dried at 70 °C. $C_{20}H_{22}CdN_4O_{11}PV$ (688.73) (based on single-crystal data): calcd. C 34.78, H 3.50, N 8.11; found C 33.72, H 3.32, N 7.72. TGA data (mass losses): 30−180 °C 1.4% (DTG peak at 50 °C); 180−280 °C 6.1% (DTG peak at 216 °C);

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

280−520 °C 48.2% (DTG peaks at 366 °C and 430 °C). Selected FT-IR data (cm^{-1}): ν(O−H, lattice and coordinated water) = 3381 vs (very broad); 3140 vs (very broad); ν(C−H, aromatic compounds) = 3055 s; 3036 s; ν_{sym}(C−H in CH_2) = 2963 m; ν_{asym}(C−H in CH_2) = 2917 m; overtones and combination bands for 4-monosubstituted pyridines = 1966 w and 1940 w; ν(C−O) = 1670 sh; $\nu_{asym}(CO_2^-)$ = 1632 vs and 1601 vs; interactions between ν(C−C) and ν(C−N) for 4-monosubstituted pyridines = 1565 m and 1489 m; ν(C−H, aromatic compounds) = 1535 m; δ(CH_2) = 1428 m; $\nu_{sym}(CO_2^-)$ = 1412 s and 1386 s; δ(O−H···O) = 1343 m and 1325 m; ν(C−O) = 1266 m and 1254 m; δ(C−H, 4-monosubstituted pyridines) = 1219 m and 1099 s; ρ(C−H) = 1160 s and 1050 s; δ(C−C−N, amines) = 1123 s and 1113 s; ν(N−C) = 1098 vs and 1075 vs; ν(P−O) = 1050 vs; interactions between ν(C−C) and ν(C−N) for 4-monosubstituted pyridines = 992 m; ν(V−O) = 946 s; γ(O−H···O) = 911 m; γ(=C−H, 4-monosubstituted pyridines) = 855 m and 805 s; ν(P−C) = 783 vs; γ(C−O) = 732 m; δ(C−N−C, tertiary amines) = 556 m (very broad); ρ[(C−O)−O] 490 m and 514 m.

Preparation and Structural Characterisation of [CoVO(pmida)(4,4′-bpy)(H_2O)$_2$]·(4,4′-bpy)$_{0.5}$ (3): A mixture of vanadium(IV) oxide sulfate pentahydrate ($VOSO_4·5H_2O$; 0.40 g, 99% Sigma−Aldrich), cobalt acetate tetrahydrate ($CoC_4H_6O_4·4H_2O$; 0.310 g, 99.0% Fluka), *N*-(phosphonomethyl)iminodiacetic acid hydrate (H_4pida; 0.280 g, 97% Fluka), 4,4′-bipyridine (4,4′-bpy; 0.100 g, 99% Fluka), and sodium hydroxide (NaOH; 0.20 g, 98.0% Panreac) in ca. 10 g of distilled water, was stirred thoroughly for 30 min at ambient temperature yielding a suspension with a molar composition of 2.47:1.94:1.94:1.00:7.81:867, respectively. After the reaction the resulting mixture consisted of three distinct phases: a large amount of big purple-pink crystals of **2** (ca. 0.21 g), and a residual amount of small mixed particles of unknown microcrystalline compounds. These components were readily separated by vacuum filtering and washing with large amounts of distilled water (3 × ca. 50 mL). Crystals of **3** were manually harvested and air-dried at ambient temperature. $C_{20}H_{22}CoN_4O_{10}PV$ (619.26) (based on single-crystal data): calcd. C 38.79, H 3.58, N 9.05; found C 38.23, H 3.56, N 8.83. TGA data (mass losses): 30−149 °C 4.9% (DTG peak at 119 °C); 215−265 °C 4.7% (DTG peak at 250 °C); 265−335 °C 18.3% (DTG peak at 301 °C); 335−366 °C 10.5% (DTG peak at 343 °C); 366−478 °C 8.0% (DTG peaks at 377 and 400 °C); 478−655 °C 14.5% (broad DTG peak at 575 °C). Selected FT-IR data (cm^{-1}): ν(O−H, lattice and coordinated water) = 3395 vs (very broad); ν(C−H, aromatic compounds) = 3063 s; 3044 s; ν_{sym}(C−H in CH_2) = 2962 m and 2953 m; ν_{asym}(C−H in CH_2) = 2923 m and 2912 m; ν(C−O) = 1697 m; $\nu_{asym}(CO_2^-)$ = 1651 vs and 1610 vs; interactions between ν(C−C) and ν(C−N) for 4-monosubstituted pyridines = 1578 m and 1491 m; ν(C−H, aromatic compounds) = 1536 m; δ(CH_2) = 1428 m; $\nu_{sym}(CO_2^-)$ = 1418 s and 1401 s; δ(O−H···O) = 1358 m and 1336 m; ν(C−O) = 1261 m and 1249 m; δ(C−H, 4-monosubstituted pyridines) = 1221 m and 1205 m; δ(C−C−N, amines) = 1128 s and 1117 s; ν(N−C) = 1103 vs and 1095 vs; ν(P−O) = 1062 vs and 1049 s; ν(V−O) = 949 s; γ(O−H···O) = 910 m; γ(=C−H, 4-monosubstituted pyridines) = 862 m, 821 vs, 800 s; ν(P−C) = 787 m; γ(C−O) = 733 m; δ(ring, 4-monosubstituted pyridines) = 635 s.

X-ray Crystallographic Studies: Suitable single crystals of [$Co_2V_2O_2$(pmida)$_2$(H_2O)$_{10}$]·2(H_2O) (**1**), [CdVO(pmida)(4,4′-bpy)(H_2O)$_2$]·(4,4′-bpy)$_{0.5}$·H_2O (**2**) and [CoVO(pmida)(4,4′-bpy)(H_2O)$_2$]·(4,4′-bpy)$_{0.5}$ (**3**) were mounted on a glass fibre using perfluoropolyether oil.[34] Data were collected at 180(2) K on a Nonius−Kappa charge-coupled device (CCD) area-detector diffractometer (Mo-K_α graphite-monochromated radiation, λ = 0.7107 Å), equipped with an Oxford Cryosystems cryostream and controlled by the Collect software package.[35] Images were processed with Denzo and Scalepack,[36] and the data were corrected for absorption by using the empirical method employed in Sortav.[37] Structures were solved by the direct methods of SHELXS-97,[38] and refined by full-matrix least-squares on F^2 using SHELXL-97.[39] All non-hydrogen atoms were directly located from difference Fourier maps and refined with anisotropic displacement parameters.

In **2** and **3**, the crystallographically unique 4-pyridyl group from the uncoordinated 4,4′-bpy molecule was found to be affected by thermal disorder, with the last difference Fourier map syntheses showing a large residual electron density around the aromatic ring: for **2**, the highest peak (2.661 e·Å^{-3}) was located at 0.67 Å from C17, and the deepest hole (−2.660 e·Å^{-3}) at 0.17 Å from C16; for **3**, the highest peak (1.737 e·Å^{-3}) was located at 0.57 Å from C16, and the deepest hole (−1.079 e·Å^{-3}) at 0.46 Å from C16. In **2**, only N4 was satisfactorily refined using anisotropic treatment, with all the carbon atoms receiving a single common isotropic displacement parameter; in **3**, atoms from the uncoordinated 4-pyridyl group were generally refined using an anisotropic treatment, with the exception of C16 and C17, for which a common isotropic displacement parameter was used instead. AFIX 66 instruction was also applied in the earlier stages of the refinement in order to ensure a reasonable geometry for the uncoordinated 4-pyridyl aromatic rings.

The hydrogen atoms attached to carbon were located at their idealised positions, and included in the refinement in a riding-motion approximation with an isotropic thermal displacement parameter fixed at 1.2-times U_{eq} of the atom to which they are attached. Hydrogen atoms from coordinated water molecules were directly located from difference Fourier maps and refined using independent isotropic displacement parameters. The O−H and H···H distances were restrained to 0.84(2) and 1.37 Å, respectively, to ensure a chemically reasonable geometry for the water molecules. These O−H bonds are intended to provide the best fit for the X-ray data, but they do not reflect the true position of the hydrogen nucleus. For **1** and **2**, the crystallisation water molecules were also directly located from difference Fourier maps. Although in **1** the O-atom could be successfully refined using anisotropic thermal displacement parameters, in **2** such treatment gave large tensors in more than one direction, suggesting that the atom is affected by thermal disorder (the atom was instead refined with isotropic thermal displacement parameters). No attempt was made to place the hydrogens on these oxygen atoms and, consequently, the empirical formulae are four and two H atoms short per formula unit, for **1** and **2**, respectively.

All cavity dimensions were calculated by overlapping rigid spheres with van der Waals radii for each element: O 1.52 Å, N 1.55 Å, C 1.7 Å, Cd 2.2 Å, Co 2.0 Å, V 2.0 Å and P 1.8 Å (hydrogen atoms were omitted in all cases for simplicity). Information concerning crystallographic data collection and structure refinement for structures **1** to **3** is summarised in Table 4. Selected bond lengths and angles are given in Table 1 (for **1**) and 2 (for **2** and **3**), and hydrogen-bonding geometry in Table 3.

CCDC-220439 (for **1**), -214332 (for **2**) and -219881 (for **3**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: +44 1223 336 033; E-mail: deposit@ccdc.cam.ac.uk].

Chloride as Supramolecular Glue: Anion-Directed Assembly of a 2D Network of Mn^{III} Complexes

Manuel R. Bermejo,*[a] M. Isabel Fernández,[b] Ana M. González-Noya,[b] Marcelino Maneiro,[b] Rosa Pedrido,[a] M. Jesús Rodríguez,[b] and Miguel Vázquez[a]

Keywords: Supramolecular chemistry / Manganese / Schiff bases / Hydrogen bond / Self-assembly

The Schiff base H_4L [where H_4L = *N*,*N*′-bis(3-hydroxysalicylidene)ethane-1,2-diamine], containing six potential donor atoms, is able to induce the formation of a novel $[Mn^{III}(H_2L)(CH_3OH)_2]Cl$ (**1**) complex, which was characterized by elemental analysis, FAB mass spectrometry, IR, ^1H NMR and electronic spectroscopy, magnetic measurements, X-ray diffraction techniques and conductivity measurements. The study of its redox properties by cyclic and normal pulse voltammetry is also reported. The crystal structure of **1** is formed by monomeric cationic Mn^{III} complexes, where the manganese ion is in an octahedral environment and is coordinated in the equatorial plane to the N_2O_2 donor set of the inner Schiff-base compartment. The neutral condition of the complex is achieved with the presence of the chloride counterion, which behaves as a multiple acceptor of hydrogen bonds. The chloride is involved in four O–H···Cl bonds, connecting three neighbouring cationic complexes. To the best of our knowledge, this constitutes the first example of self-assembly of discrete units of Mn^{III} complexes in a 2D network in the solid state through hydrogen bonding, where the anion is acting as a supramolecular glue.

Introduction

Of the first-row transition metals, manganese has a particularly appealing coordination chemistry due to its rich redox behaviour, as demonstrated by the variety of structures and oxidation states in polynuclear manganese complexes.[1−3] In particular, manganese(III) derivatives from tetradentate Schiff-base ligands have a clear tendency to form infinite linear or helical chains, due to the predisposition of these ligands to occupy a planar configuration in an octahedral coordination geometry, leaving the axial positions free to develop polymerization through bidentate bridges.[4,5] Occasionally manganese−Schiff-base complexes can produce dimeric structures with μ-phenoxo[4b,4f,5] or μ-oxo bridges with the ligand in the equatorial plane around each metal centre[6] or, alternatively, μ-oxo bridges with the two ligands bridging both metal ions.[4b,4e,8] Moreover, some 2D polymerization processes via coordinative bonding have been reported.[9] In contrast, the aggregation of manganese(III) discrete complexes or infinite chains in multidimensional frameworks by metal-free supramolecular interactions (hydrogen bonding, π-π stacking, and so forth) are particularly rare.[10]

In the last years, part of our research program has been focused on reproducing the reactivity of some manganese redox enzymes, and we have reported an important number of active synthetic models of Mn^{III} systems derived from Schiff-base ligands. With the skill and the motivation acquired due to our recent successes in the construction of very appealing supramolecular architectures,[11] we are now interested in investigating the overlooked supramolecular chemistry of manganese(III). In particular, our new scheme consists in obtaining the aggregation of discrete manganese(III) complexes into multidimensional arrays through metal-free self-assembly.

In this paper we describe the results of this research work. We believed that the insertion of extra donor atoms out of the classical tetradentate compartment of a salen-type ligand would favour the aggregation of neighbouring complexes through hydrogen bonding. This represents a class of weaker, non-covalent interactions that not only induce supramolecular arrays through self-organization of molecules, but also plays a crucial role in fundamental biological processes, such as the expression and transfer of genetic information, and is essential for molecular recognition between receptors and substrates.[12] For this purpose, we designed the ligand H_4L that contains six potential donor atoms: two imine nitrogen and four phenolic oxygen atoms. The reaction of H_4L with manganese(II) chloride, in fact,

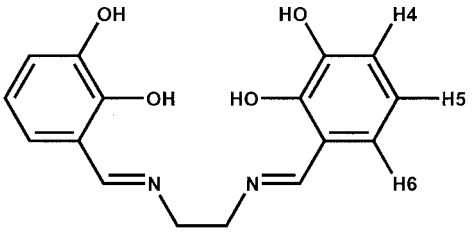
yields a supramolecular system, which we report herein and where the main intermolecular interactions come from the special role of the halide counterion as a kind of supramolecular glue. This type of networks, which have the ability to bind negatively charged ions, also constitute a hot subject of research in recent years due to their potential ability and selectivity to recognize anion receptors in solution.[13,14]

Results and Discussion

The hexadentate Schiff base, H_4L (see Scheme 1), reacts with the manganese(II) chloride salt to yield a black crystalline complex with the formula $[Mn(H_2L)(CH_3OH)_2]Cl$ (**1**), in accordance with the elemental analysis. The solid appears to be stable in the solid state and in solution; it melts at over 300 °C and is insoluble or sparingly soluble in water and also in common organic solvents, but quite soluble in MeOH, DMF and DMSO.



Scheme 1. Structure of the Schiff-base ligand H_4L

Spectroscopy techniques verified the coordination of the ligand to the manganese ion. Thus, the IR spectrum of **1** shows the shift of the $\nu(CN_{imine})$ band to lower frequency (-13 cm^{-1}) and a positive shift of the $\nu(CO_{phenol})$ mode ($+13$ cm^{-1}) with respect to the free ligand. These data suggest the coordination of the Schiff base in its dianionic form through the inner phenol oxygen and the imine nitrogen atoms.[14] The absence of ν(Mn−Cl) bands in the far IR spectrum indicates that the metal is not coordinated to the chloride, as confirmed by the crystal structure of this complex. The FAB mass spectrum shows a peak due to the fragment $[Mn(H_2L)]^+$, which thus further corroborates coordination of the ligand to the manganese ion.

The room temperature magnetic moment of **1** is 4.8 B.M., close to the spin-only value of 4.9 B.M., as expected for a high-spin magnetically diluted d^4 manganese(III) ion. The magnetic behaviour obeys the Curie−Weiss law in the range 40−300 K, showing little or no antiferromagnetic interaction between neighbouring metal centres. The electronic spectrum in methanol solution is also typical of a manganese(III) ion in an octahedral environment. On other hand, the conductivity measurements in DMF give a Λ_M value of 90 μS cm^{-1} for **1**, indicating behaviour that is attributable to 1:1 electrolytes.[16]

X-ray Diffraction Studies

Single crystals of $[Mn(H_2L)(CH_3OH)_2]Cl$ (**1**), suitable for X-ray diffraction studies were obtained as detailed in the Exp. Sect. An ORTEP view of **1**, together with the atomic numbering scheme, is shown in Figure 1. Experimental details are given in Table 1. Main bond lengths and angles are listed in Table 2. This structure reveals the existence of a cationic octahedral $[Mn(H_2L)(CH_3OH)_2]^+$ complex; the neutral condition is achieved by the presence of a chloride anion, which acts as a counterion despite the known tend-

ency to appear coordinated to the metal ion in similar Mn^{III} compounds.[4b,17]

The structure of discrete mononuclear $[Mn(H_2L)(CH_3OH)_2]^+$ cations comprises the planar Schiff-base ligand tightly bound to manganese(III) through the inner N_2O_2 compartment through the N_{imine} and O_{phenol} atoms ($Mn-N_{imine}$ bond lengths of 1.9809(17) Å and $Mn-O_{phenol}$ 1.8755(14) Å, typical of such complexes).[4,18] The coordination spheres of the slightly distorted octahedral manganese centres are then completed by capping *trans* methanol molecules [$Mn-O_{methanol}$ 2.2675(19) Å]. The elongation in the *trans* $Mn-O_{methanol}$ bonds is usually attributed to a Jahn−Teller distortion for a d^4 high-spin Mn^{III} system but in this case the poor donor strength of the methanol molecules may also contribute to this elongation. The MnN_2O_2 core forms two six-membered chelate rings, which are nearly planar [maximum deviation of any atom from its least-squares calculated plane is −0.1170(11) Å, with the manganese atom 0.1027(09) Å above this plane]. This indicates a slight distortion from the ideal geometry. The slight distortion of the octahedron is also shown by the angles between the manganese and adjacent donor atoms, which range from 81.96(11)° to 94.06(9)°. The angle between the metal atom and the *trans* donor atoms is 176.48(9)°. All distances and angles lie in the range expected for this type of Mn^{III} complexes;[4,17,18] the N(1)−C(7) bond length of 1.277(3) Å suggests a double bond, which is confirmed by the IR spectrum with a strong vibration band at 1620 cm^{-1}.

The $[Mn(H_2L)(CH_3OH)_2]^+$ cations are interconnected through the chloride anions by hydrogen bonds yielding a supramolecular structure. Each chloride anion is involved in four O−H···Cl hydrogen bonds with four different hydroxy groups from three neighbouring cationic complexes (see Figure 2).

Two of these interactions are in the range of strong hydrogen bonds with an almost linear angle O−H···Cl, and involve the hydroxy groups from the axial methanol ligands of two different complexes [H(1S)···Cl(1) 2.35(3), O(1S)···Cl(1) 3.081(2) Å and O(1S)−H(1S)···Cl(1) 178(3)°] (see Table 2).

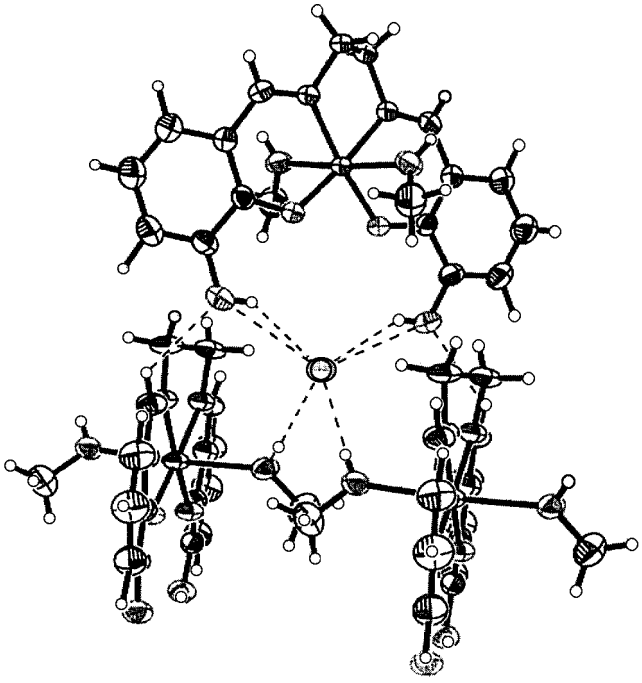

Figure 2. Part of the unit cell of **1**, exhibiting the net of interactions between three neighbouring cationic complexes; the chloride anion is tetra-coordinated to four hydroxy groups through hydrogen bonding

The other two intermolecular contacts imply the outer hydroxy groups of the third complex [H(2A)···Cl(1) 2.55(3), O(2)···Cl(1) 3.218(2) Å and O(2)−H(2A)···Cl(1) 146(2)°], and can be categorized as intermediate in strength,[19] prob-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

ably because of the additional interaction of these outer hydroxy groups with the inner hydroxy groups through intramolecular hydrogen bonding [H(2A)···O(1) 2.31(3), O(2)···O(1) 2.668(2) Å and O(2)−H(2A)···O(1) 103.6(10)°].

This rich supramolecular structure is completed and further stabilized with intermolecular hydrogen bonds between carbon atoms from imine groups and oxygen atoms from the free phenolic sets of adjacent molecules. In this case the H(7)···O(2) distance is of 2.51(7) Å, the C(7)···O(2) distance is of 3.143(3) Å, and the C(7)−H(7)···O(2) angle is 130.6(2)°.

The packing of **1** determines the existence of a supramolecular structure in which the chloride counterions are acting as multiple acceptors, connecting three neighbouring complexes through very different hydrogen bonding. However, the Mn···Mn distances of 7.67(9) Å are too long to establish intermetallic interactions between neighbouring manganese ions, which is in accordance with the non-antiferromagnetic behaviour showed by the magnetic studies.

These multiple intermolecular interactions are extended into the solid to form an infinite array (see Figure 3) constituting, to the best of our knowledge, the first example of an anion-directed assembly of a 2D network of manganese(III) complexes.

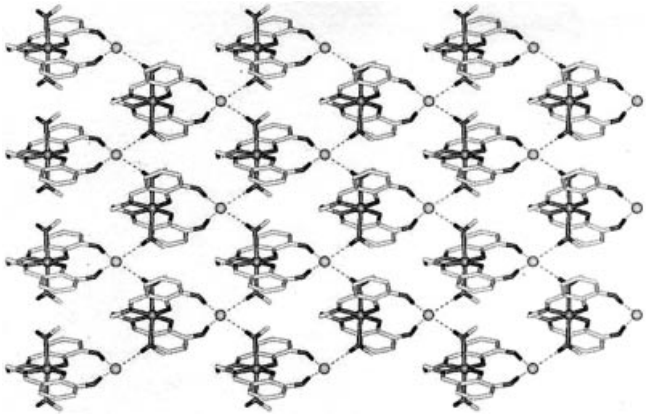

Figure 3. Perspective view of the 2D network formed, which shows the chloride′s role as supramolecular glue in the assembly of the manganese(III) complexes

^{1}H NMR Studies

Paramagnetic ^{1}H NMR studies of **1** were undertaken using [D_6]DMSO as a solvent, and the data serve to substantiate the formation of the manganese(III) complex. The spectrum of **1** is essentially as would be expected, in accordance with the assignments proposed by Pecoraro[20] and also from our own results.[4d,18] The spectrum contains two upfield proton resonances at −16.3 and −28.1 ppm that lie outside the diamagnetic region (δ ca. 0−10) and must arise from the H5 and H4 protons of the aromatic rings, respectively.[4d]

Electrochemical Studies

The electrochemical behaviour of **1** in DMF solution was studied by cyclic and normal pulse voltammetry (see Figure 4). The oxidation state +III for the manganese ion in DMF solutions of **1** is determined by NPV, as it exhibited anodic and cathodic currents when an anodic potential scan was performed (Figure 4b), but when a cathodic potential scan was used, only cathodic current was observed (Figure 4c). This behaviour suggests that only the oxidized form of the implied redox system $Mn^{II}-Mn^{III}$ is present in solution, as we have previously reported.[4b]

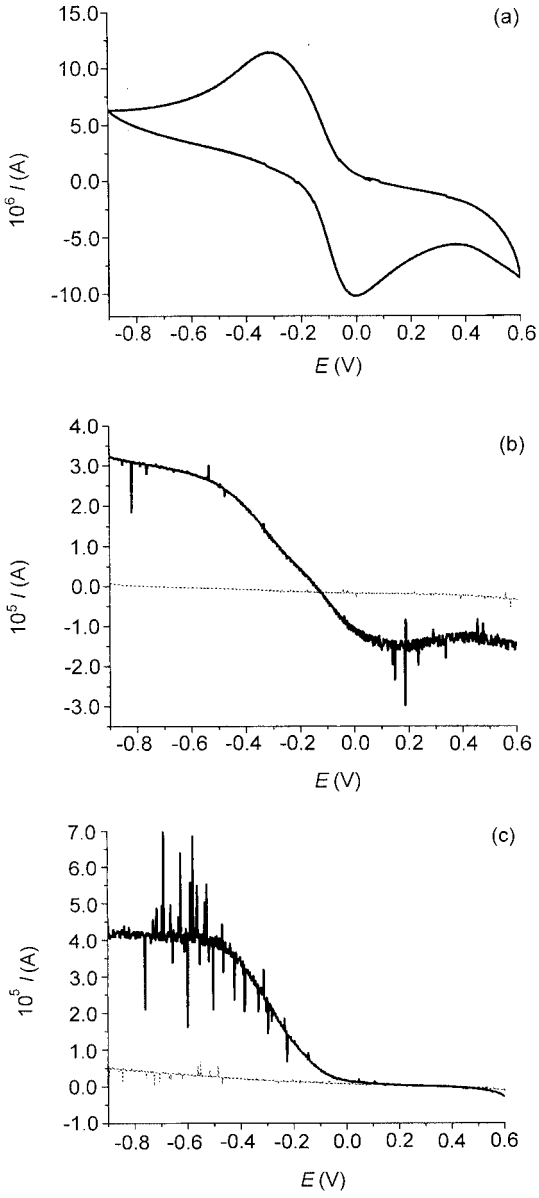

Figure 4. Cyclic voltammogram for **1** at a scan rate of 0.02 V s^{-1} (a); normal pulse voltammogram (NPV) with anodic scan of **1** (b); NPV with cathodic scan of **1** (c)

CV of **1** exhibits a quasi-reversible one-electron reduction−oxidation wave (Figure 4a) centred at $E_{1/2}$ = −0.159 V (versus saturated calomel electrode, SCE). Although this negative potential belongs to the range which would favour the potential catalytic activity, as we have previously reported for other manganese(III)−Schiff base systems,[4g] the peak-to-peak separation of 0.318 V (E_{ox} =

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

0.007 V; E_{red} = −0.311 V) becomes a significant handicap for the possible use of this complex in catalysis.

Conclusion

In the present work, we have shown how a ligand such as H_4L is able to induce, simultaneously, the formation of a manganese(III) complex and its aggregation into an infinite 2D array in the solid state through hydrogen bonding. The chloride anions, contrary to their typical behaviour, are not directly coordinated to the manganese atom at the first coordination sphere, but they act as multiple hydrogen-bonding-acceptor counterions as a kind of supramolecular glue, promoting the assembly of the Mn^{III} complexes. Finally, it must be noted that the development of molecular and supramolecular systems, such as this one, with the ability to bind negatively charged ions could play an important role in biology, medicine and the environment.

Experimental Section

General: Elemental analyses were performed on a Carlo Erba EA 1108 analyser. NMR spectra were recorded on a Bruker AC-300 spectrometer using [D_6]DMSO (296 K) as a solvent. Infrared spectra were registered as KBr pellets on a Bio-Rad FTS 135 spectrophotometer in the range 4000−200 cm^{-1}. Fast atom bombardment (FAB) mass spectra were obtained on a Kratos MS-50 mass spectrometer, employing Xe atoms at 70 KeV in *m*-nitrobenzyl alcohol as a matrix. Room-temperature magnetic susceptibilities were measured using a digital measurement system MSB-MKI, calibrated using tetrakis(isothiocyanato)cobaltate(II). Magnetic susceptibility measurements in the 40−300 K temperature range were obtained using a SQUID-QUANTUM model MPMS magnetometer operating at 5000 G. Electronic spectra were recorded on a Cary 230 spectrometer. Conductivities of 10^{-3} M solutions in DMF were measured on a Crison microCM 2200 conductivimeter.

Electrochemical Measurements: Measurements were performed using an EG&G PAR model, 273 potentiostat, controlled by an EG&G PAR model, 270 software. A Metrohm model, 6.1204.000 graphite disc, coupled to a Metrohm model, 628−10 rotating electrolyte device, was used as a working electrode. A saturated calomel electrode was used as a reference and a platinum wire as an auxiliary electrode.
Measurements were made with ca. 10^{-3} M solution of 1 in dimethylformamide using 0.1 M tetraethylammonium perchlorate as a supporting electrolyte. Cyclic voltammetry measurements were performed with a static graphite electrode, whilst direct-current and pulse voltammograms were recorded with the graphite disc rotating at 2000 revolutions per minute.

Syntheses: All solvents, 2,3-dihydroxybenzaldehyde (Maybridge), ethylenediamine (Aldrich), manganese(II) chloride tetrahydrate (Aldrich), and ABTS (Aldrich) were used as received without further purification.

Ligand Synthesis: Ethylenediamine (14.48 mol, 0.97 mL) was added to a methanolic solution (120 mL) of 2,3-dihydroxybenzaldehyde (28.96 mmol, 4 g).[21] This mixture was refluxed in a round bottomed flask fitted with a Dean−Stark trap to remove the water produced during the reaction. After refluxing for 3 h, the solution was concentrated to yield a yellow solid. The product was collected by filtration, washed with diethyl ether and dried in air. The yield was almost quantitative; M.p. 240 °C. $C_{16}H_{16}N_2O_4$ (300.2): calcd. C 63.9, H 5.4, N 9.3; found C 63.3, H 5.6, N 9.4. MS FAB (*m*/*z*): 301.1. IR (KBr): ν(O−H) 3258, 3389 (m), ν(C=N) 1633 (vs), ν(C−O) 1246 (s) cm^{-1}. ^1H NMR ([D_6]DMSO): δ = 3.93 (s, 4 H), 6.65 (t, 2 H), 6.82 (d, 2 H), 6.85 (d, 2 H), 8.54 (s, 2 H), 8.97 (br. s, 2 H), 13.46 (br. s, 2 H) ppm. ^{13}C NMR ([D_6]DMSO): δ = 58.0 (CH_2), 116−122 (C_{ar}), 145.8 (C-OH_{inner}), 151.0 (C-OH_{outer}), 167.2 (C=N) ppm.

Synthesis of the Complex $[Mn(H_2L)(CH_3OH)_2]Cl$ (1): H_4L (1.0 mmol, 0.30 g) was dissolved in methanol (40 mL) and $MnCl_2·4H_2O$ (1.0 mmol, 0.20 g), dissolved in methanol was added to the initial yellow solution, which changed to green. After stirring for 10 min, NaOH (2 mmol, 0.08 g), dissolved in a small quantity of water, was added and the mixture turned dark. The reaction mixture was refluxed for 2 hours, and then concentrated in vacuo to half its volume. The complex was obtained as black crystals, suitable for single X-ray-diffraction studies, after slow concentration of the solution. These crystals were isolated by filtration, washed with diethyl ether and dried in air, yield: 0.23 g, 50 %. $C_{18}H_{22}ClMnN_2O_6$ (452.77): calcd. C 47.7, H 4.9, N 6.2; found C 47.5, H 4.7, N 6.3. MS FAB (*m*/*z*): 353 {$Mn(H_2L)$}, 705 {$Mn_2(H_2L)_2$}. IR (KBr): ν(O−H) 3414 (br), ν(C=N) 1620 (vs), ν(C−O) 1259 (s) cm^{-1}. Magnetic moment μ_{eff} = 4.8 B.M. ^1H NMR (300 MHz, [D_6]DMSO): δ = −28.1, −16.3 ppm. Conductivity (in DMF) Λ_M = 90 μS cm^{-1}. E_{ox} = 0.007 V, E_{red} = −0.311 V, $E_{1/2}$ = −0.159 V.

X-ray Crystallographic Studies: Crystals of **1**, suitable for X-ray diffraction studies, were obtained as described above. Data were collected with a Smart CCD-100 Bruker diffractometer employing graphite-monochromated Mo-K_α (λ = 0.71073 Å) radiation. The structure was solved by direct methods[22] and finally refined by full-matrix least-squares base on F^2. An empirical absorption correction was applied using SADABS.[23] All non-hydrogen atoms were anisotropically refined, and all hydrogen atoms were included in the model at geometrically calculated positions. Detailed data collection and refinement of the compound are summarized in Table 1.
CCDC-212667 contains the supplementary crystallographic data for **1**. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html (or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Syntheses and Crystal Structures of Diorganotin Derivatives of 2,5-Dimercapto-1,3,4-thiadiazole

Chunlin Ma,*[a,b] Junhong Zhang,[a] Feng Li,[a] and Rufen Zhang[a]

Keywords: Macrocyclic ligands / N ligands / Oxo ligands / S ligands / Tin

Two novel trinuclear tin oxo clusters $[(C_2S_3N_2)R_6Sn_3O(OH)Y]\cdot L$ [R = CH_3, Y = OH, L = $1\cdot5H_2O$ (**1**); R = $PhCH_2$, Y = OEt, L = 0 (**2**)], a pentanuclear tin macrocycle $[(CH_3)_2Sn(C_2N_2S_3)]_5\cdot CH_2Cl_2\cdot3H_2O$ (**3**) and $[(PhCH_2)_4Cl_2Sn(C_2S_3N_2)]$ (**4**) have been synthesized by the reaction of 2,5-dimercapto-1,3,4-thiadiazole with dialkyltin dichloride in ethanol (95%) or dichloromethane. Complexes **1**–**4** have been characterized by elemental analysis and IR, ^1H, ^{13}C and ^{119}Sn NMR spectroscopy. The structures of **1**–**3** have been determined by X-ray crystallography. Complexes **1** and **2** display a unique tricyclic structure consisting of fused five-membered Sn_2ON_2 and four-membered Sn_2O_2 rings that form a planar $N_2Sn_3O_2$ skeleton, with a distorted trigonal bipyramidal coordination at tin. Complex **3** is a pentanuclear 35-membered tin macrocycle containing the crown thioether-type ligand in which all five tin atoms bond to the sulfur and nitrogen atoms with distorted octahedral geometries. The structures of complexes **1** and **3** are stabilized by hydrogen bonds or intermolecular non-bonding S···S interactions.

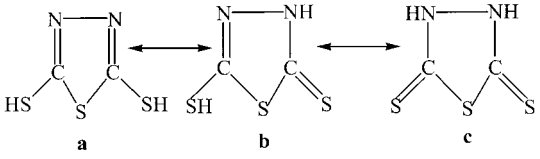
Introduction

Recent developments in coordination chemistry have produced numerous supermolecular and macrocyclic complexes through the appropriate combination of organometallic complexes and various organic ligands.[1−6] Organotin macrocycles are attracting more and more attention for their potential industrial applications and biological activities.[7,8] In these metallomacrocyclic systems, ligands with multiply coordinating donor atoms and particular stereochemistry may lead to different specific architectures. Heterocyclic thionate ligands,[5] which contain at least one deprotonated heterocyclic thioamide group $(N-C-S)^-$ and can act as monodentate, chelating or bridging ligands are particularly important.[9] In our previous work, we studied the ligand 2-mercaptonicotinic acid (Hmnc), which possesses one deprotonated heterocyclic thioamide group $(N-C-S)^-$, and found that the primary bond of the ligand to the tin atoms occurs through sulfur rather than through nitrogen. Moreover, different coordination patterns of the ligand in the thiolic form have been found.[10,11]

To continue our study in this field, we chose another ligand: 2,5-dimercapto-1,3,4-thiadiazole (H_2dmt), which possesses a more complex deprotonated heterocyclic thioamide group $(S-C-N-N-C-S)^{2-}$ than Hmnc. The heterocycle of H_2dmt, with four available donors all of which can be utilized in bonding in varying combinations, as shown in Scheme 1),[12] may act as a fulcrum about which lattice construction is orchestrated in two or more dimensions.



Scheme 1. Tautomeric forms of H_2dmt

In our previous work we reported a pentanuclear tin macrocycle[13] in which the coordination of H_2dmt is through two sulfur atoms of the thiol (**a**) rather than the thione (**c**) tautomer. While continuing our research on other diorganotin complexes of H_2dmt, we surprisingly obtained four novel complexes $[(C_2S_3N_2)(CH_3)_6Sn_3O(OH)_2]\cdot1.5H_2O$ (**1**), $[(C_2S_3N_2)\{(PhCH_2)_6Sn_3O(OH)(OEt)\}]$ (**2**) $[(CH_3)_2Sn(C_2N_2S_3)]_5\cdot CH_2Cl_2\cdot3H_2O$ (**3**) and $[(PhCH_2)_2ClSn(S-C_2SN_2-S)SnCl(PhCH_2)_2]$ (**4**). It is worthwhile to note that complexes **1** and **3** were obtained by the same reactants in different solvents, and the complexes **2** and **4** were obtained by the same reactants in different solvents, too, and that H_2dmt shows different coordination to the tin(IV) atom. All four complexes **1**−**4** were characterized by elemental analysis and IR, ^1H, ^{13}C and ^{119}Sn NMR spec-

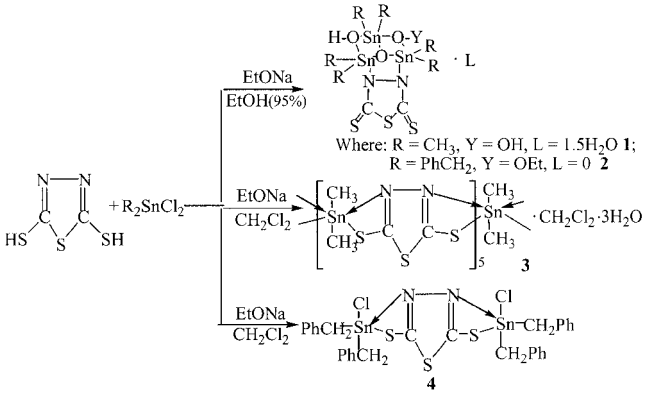
troscopy and the structures of **1**, **2** and **3** were determined by X-ray crystallography.

Results and Discussion

Complexes **1**−**4** were prepared by the reaction of dimethyltin dichloride or dibenzyltin dichloride with 2,5-dimercapto-1,3,4-thiadiazole in either EtOH (95%) or CH_2Cl_2. The reaction procedures are shown in Scheme 2.



Scheme 2

When the reaction solvent is EtOH (95%), the complexes **1** and **2** were obtained. In view of the results of our present studies[10,14] and those of earlier work,[15] the possible mechanism of formation of complexes **1** and **2** is as follows. Firstly, a hydrolysis reaction of R_2SnCl_2 occurs to form $R_2(Cl)Sn(OH)$, which is then further hydrolyzed to produce $[R_2(OH)SnY]$ (Y = OH or OEt). Two $R_2(Cl)Sn(OH)$ molecules then condense to form $[R_2(Cl)Sn]_2O$, which then reacts with $[R_2(OH)SnY]$ to produce $[R_6Sn_3O(Cl)_2(OH)Y]$.[14] Finally, the two chlorine atoms of $[R_6Sn_3O(Cl)_2(OH)Y]$ are substituted by two nitrogen atoms of the sodium salt of H_2dmt $[Na_2(C_2N_2S_3)]$ to produce the title complexes **1** and **2**. As shown in Scheme 2, the H_2dmt acts as tautomer **c**, bonding to tin(IV) through two nitrogen atoms in both complexes **1** and **2**.

When the reaction solvent was replaced by CH_2Cl_2 we obtained complexes **3** and **4**. In this case the hydrolysis of R_2SnCl_2 does not occur and the ligand coordinates to the tin(IV) center, through two sulfur atoms, as the thiol tautomer (**a**).

Moreover, in complex **4**, the spatial resistances of two benzyl groups are strong enough to prevent another H_2dmt ligand chelating to the central tin atom, which is well consistent with the sequence of steric constraints phenyl ≈ benzyl > *n*-butyl > methyl: the larger the steric constraint of the R groups, the more difficult the substitution of the chlorine atoms.[16]

Description of the Structures

[(C2S3N2)(CH3)6Sn3O(OH)2]·1.5H2O (1) and [(C2S3N2)(PhCH2)6Sn3O(OH)(OEt)] (2)

The molecular structures and unit cells of complexes **1** (Figure 1 and 2) and **2** (Figure 3 and 4) are shown below; selected bond lengths and angles are collected in Table 1 and 2, respectively. Like other trinuclear organotin oxo clusters,[17] complex **1** contains a tricyclic system formed by an N_2Sn_2O ring and two Sn_2O_2 rings, in which the $N_2Sn_3O(OH)_2$ structural motif is almost planar with a mean deviation of ±0.0452 Å. All three tin atoms show severely distorted trigonal bipyramidal configurations.

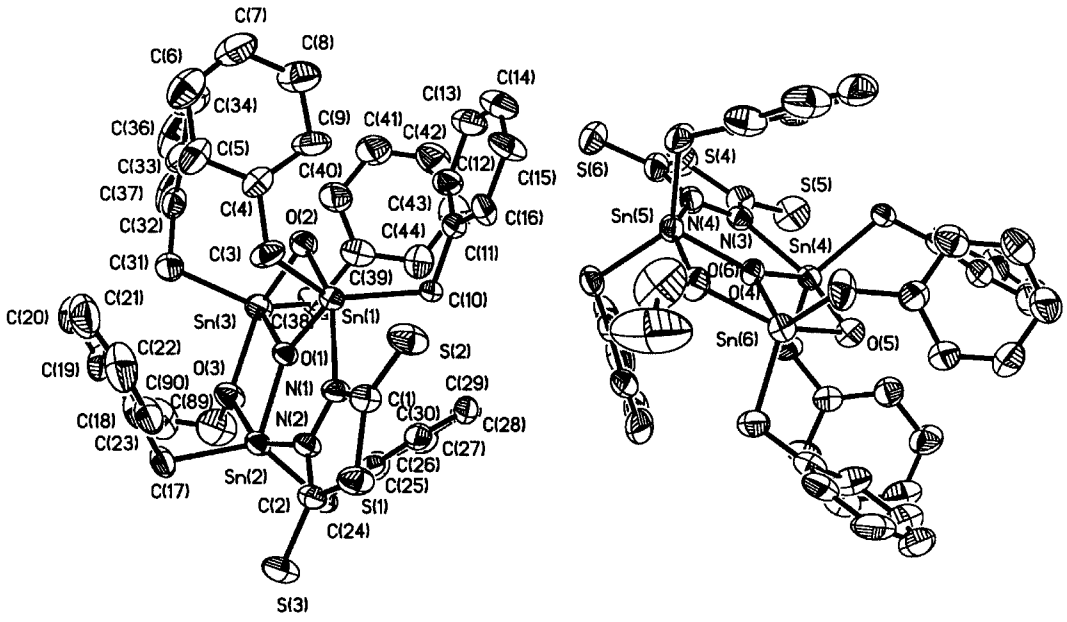

Figure 3. Molecular structure of complex **2**; ellipsoids at 30% probability

Sn(1) and Sn(3) have the same environment, where one μ_3-O atom and two C atoms of the methyl groups occupy the equatorial positions [C(3), C(4) and O(2) for Sn(1); C(7), C(8) and O(2) for Sn(3)], and the axial positions are occupied by one N atom of the H_2dmt and one O atom of the hydroxyl group [N(1) and O(1) for Sn(1); N(2) and O(3) for Sn(3)]. The geometry of Sn(2) is *cis*-R_2SnO_3, in which the axial positions are occupied by the O(3) and O(1) atoms of hydroxyl groups, and two C(5) and C(6) atoms of methyl groups and one μ_3-O(2) atom occupy the equatorial plane. The distortion of the axial angles is very large at the three tin atoms [O(1)−Sn(1)−N(1) 150.4(2)°, O(3)−Sn(3)−N(2) 150.0(2)° and O(3)−Sn(2)−O(1) 144.1(2)° respectively] compared to the ideal angle of 180°.

With regard to the hydrolysis, three [$(CH_3)_2$Sn] units are bridged by one μ_3-O atom and two O atoms of hydroxyl groups, and thus form a trinuclear complex containing two Sn_2O_2 rings. Three Sn atoms and three O atoms [Sn(1), Sn(3), O(2), Sn(2), O(1), O(3)] comprise a fused ring system and are nearly coplanar, with a mean deviation of ±0.0326 Å, which is similar to traditional hydrolytic products with a ladder-type arrangement,[18] but different from the staircase structure of $[Me_4Sn_2(OSiMe_3)_2O]_2$.[19] The Sn−O distances between μ_3-O atom and the tin atoms are similar [Sn(3)−O(2) 2.037(5) Å, Sn(2)−O(2) 2.051(5) Å and Sn(1)−O(2) 2.032 (5) Å], but other Sn−O lengths between the O atoms of the hydroxyl and the tin atoms [Sn(1)−O(1) 2.150(5) Å, Sn(2)−O(1) 2.106(5) Å, Sn(2)−O(3) 2.094(6) Å, Sn(3)−O(3) 2.129(6) Å] are slightly longer, and similar to the Sn−O bonds in the ladder structure $[Me_2ClSnOSnMe_2Cl]_2$ [2.115(9) Å].[20] All of the above indicates that a strong oxo bridge exists in complex **1**.

The two nitrogen atoms of the H_2dmt ligand, which is a five-membered ring, bond to tin atoms to form another five-membered N_2Sn_2O ring. The dihedral angle between the two rings is 1.2°, which indicates that all the atoms of the two rings are almost planar. The Sn−N bond lengths [Sn(1)−N(1) 2.274(6) Å and Sn(3)−N(2) 2.246(7) Å] are similar to the sum of the covalent radii of Sn and N (2.15 Å) and much shorter than the sum of the van der Waals radii of tin and nitrogen atoms (3.74 Å),[21] which proves that the nitrogen atoms coordinate to tin by strong chemical bonds. Furthermore, the C−S bonds [S(2)−C(1) 1.701(10) Å, S(3)−C(2) 1.668(10) Å] are similar to those in thiourea (1.681 Å),[22] suggesting that they are C=S double bonds and therefore retain the thione form. All of above proves

[a] Symmetry transformations used to generate equivalent atoms: (i) $x, -y, z + 1/2$; (ii) $-x + 1/2, y, z + 1/2$; (iii) $-x + 1, y, -z + 3/2$.

indirectly that H_2dmt bonds to tin as the nitrogen tautomer **c** and not the sulfur tautomer.

As can be seen in Figure 2, molecules of **1** are joined into a network of 2D dimers in a head-to-tail fashion by intermolecular hydrogen bonds. Each monomeric unit forms two weak hydrogen bonds between the O atom of the hydroxyl and the uncoordinated S atom of a neighboring molecule of H_2dmt [O(1)−H(1) 0.897 Å, H···S(2) 2.302 Å, O(1)···S(2) 3.178, O(1)−H(1)···S(2) 174.32°; O(3)−H(2) 0.886 Å, H···S(3) 2.364 Å, O(3)···S(3) 3.206 Å, O(3)−H(2)···S(3) 158.81°]. Moreover, S···S weak intermolecular non-bonding interactions also help to stabilize the structure. The S(3)···S(3) distance of 3.274 Å is significantly shorter than the sum of the van der Waals radii of two sulfur atoms (3.7 Å).[23] Therefore in these two cases hydrogen bonds and intermolecular non-bonding interactions lead to aggregation and formation of a supramolecular assembly.[24]

The tin environment in complex **2** is the same as that of complex **1**. The Sn−N distance [Sn(1)−N(1) 2.224(7) Å, Sn(2)−N(2) 2.230(7) Å], the C−S bonds [S(2)−C(1) 1.673(9) Å, S(3)−C(2) 1.688(9) Å] and the Sn−O distance

[from 2.047 Å to 2.224(6) Å] are all similar to those found in complex **1**, which indicates that the $(PhCH_2)_2SnCl_2$ was also hydrolyzed and the ligand coordinates to tin(IV) through two nitrogen atoms as the tautomer **c**. The difference between complexes **1** and **2** lies in the co-ligands formed during the hydrolysis reaction. As shown in Figure 1 and 3 the products of the hydrolysis reaction are $[(CH_3)_2Sn(OH)_2]$ for complex **1** and $[(PhCH_2)_2Sn(OH)(OEt)]$ for complex **2**, respectively. Such a difference may be due to the larger steric constraints of $PhCH_2$ groups than CH_3.

[(CH$_3$)$_2$Sn(C$_2$N$_2$S$_3$)]$_5$·CH$_2$Cl$_2$·3H$_2$O (3)

The molecular structure and unit cell of complex **3** are shown in Figure 5 and 6, respectively; Figure 7 shows the crystal structure of the same component with all co-crystallized solvent molecules omitted. Selected bond lengths and angles are listed in Table 3.

As shown in Figure 5, the coordination of H_2dmt in complex **3** is different from that in complex **1**, but is similar to our previously reported complex $(Bu_2SnC_2N_2S_3)_5$;[13] the ligand is found as the thiol tautomer **a** when bonded to tin. The pentanuclear tin complex is characterized by a 35-membered $C_{10}S_{10}N_{10}Sn_5$ macrocycle ring system with all ten sulfur atoms pointing to the exterior of the cavity, thereby acting as a crown thioether.[25] All five tin atoms have the same arrangement — they are hexacoordinate with

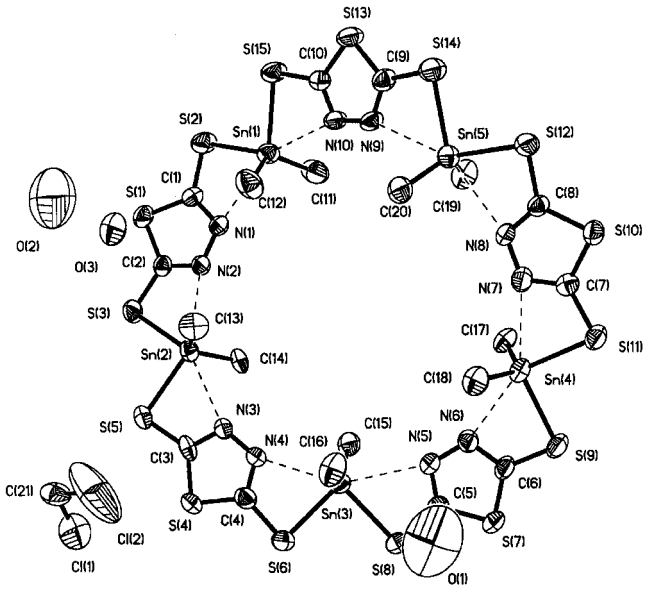

Figure 5. Molecular structure of complex **3**; ellipsoids at 30% probability

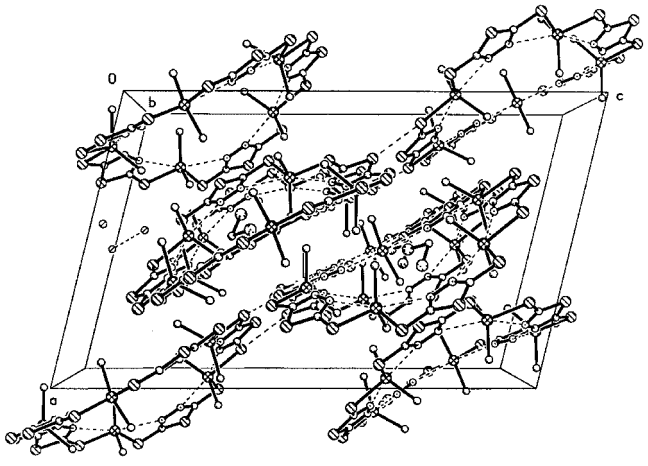

Figure 6. Unit cell of complex **3**

distorted octahedral geometries. Two sulfur atoms and two carbon atoms occupy the equatorial positions and the axial positions are occupied by two azole-N atoms. The deviation from an ideal octahedron is manifested by the bond angles N(1)−Sn(1)−N(10) [149.5(2)°], N(2)−Sn(2)−N(3) [148.7(2)°], N(4)−Sn(3)−N(5) [150.3(2)°], N(6)−Sn(4)−N(7) [147.0(3)°] and N(8)−Sn(5)−N(9) [149.0(2)°], all of which deviate from the ideal value of 180°.

The Sn···S (from 2.483 Å to 2.502 Å) and Sn···N distances (from 2.701 Å to 2.890 Å) are similar to those in the reported complex $(Bu_2SnC_2N_2S_3)_5$ (average value: 2.494 Å and 2.762 Å, respectively).[13] The longest Sn−S distance is slightly longer than the sum of the covalent radii of Sn and S (2.44 Å),[26] but consistent with Sn−S in $tBu_2Sn(S_2CNEt_2)_2$ (2.554 Å),[27] and is much shorter than the sum of the van der waals radii of 4.0 Å.[28] This proves that the sulfur atoms coordinate to the tin atoms by strong

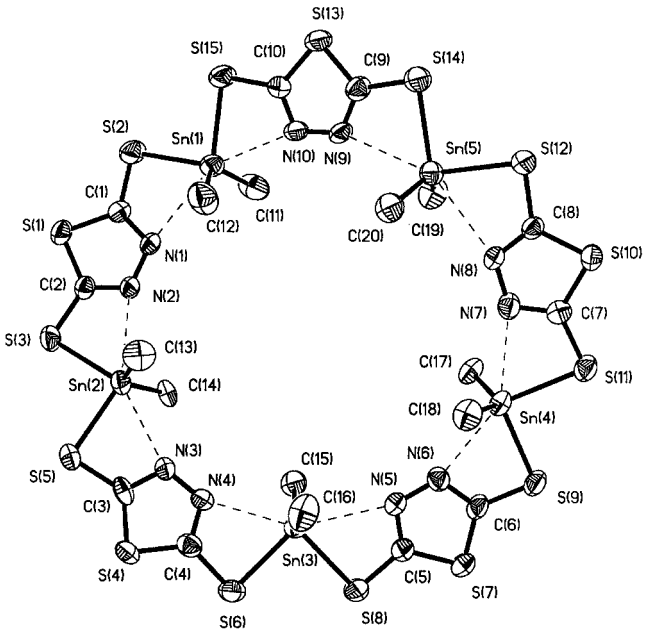

Figure 7. Molecular structure of complex **3** (all solvent molecules omitted)

chemical bonds. The average Sn−N bond length (2.778 Å) is much longer than that in complex **1**, but is similar to the Sn←N (2.787 Å) intermolecular bond found in the trimeric $[Me_3SnSCN_4Ph]_3$ unit.[29] All the Sn−N distances are midway between the covalent radii and the sums of the van der Waals of Sn and N (2.15 and 3.74 Å)[21] and can be regarded as weak coordination bonds. Thus the coordination number of the tin atom is increased to six through Sn←N intermolecular bonds. All above information suggests that the primary bonds of the H_2dmt ligand to tin atoms are through sulfur atoms with the ligand appearing as the thiol tautomer **a**. This situation is similar to that in the reported complex $(Bu_2SnC_2N_2S_3)_5$.[13]

The C−S bond lengths are in the range from 1.695 to 1.750 Å with an average value of 1.723 Å for the chelating ligands, similar to the C−S single bond (1.724 Å) in triphenyltin benzoxazole-2-thiolate,[30] thereby confirming the above proposal.

It is worthwhile to note that the critical cross-ring interatomic distances of the cavity are 10.904 Å [N(1)···Sn(4)] and 10.897 Å [N(4)···Sn(5)], which are larger than those found in dimethyl- and di-*n*-butyltin(IV) complexes with phthalic and isophthalic acid.[8] Furthermore, as shown in Figure 5, there are weak intermolecular non-bonding S···S interactions between the coordinated S atom and the uncoordinated S atom of the neighboring ligand. The S···S distances [S(1)···S(8) 3.489 and S(9)···S(15) 3.449] are all shorter than the sum of the Van der Waals radii of two sulfur atoms (3.7 Å),[23] which indicate that these intermolecular non-bonding interactions lend the crystal stability and compactness and result in a one-dimensional supramolecular polymers arrangement.[5]

Spectroscopic Data

IR Spectra

The strong broad bands in the IR spectra of complexes **1**−**3** in the region 3440−3000 can be attributed to the O−H stretching vibration. A medium-strength band of δ(H−O−H) is also present at about 1650 cm^{-1} in complexes **1** and **3**; the strong absorption at 1286 cm^{-1} in complex **2** is attributed to the C−O vibration of the EtO group. The main feature in the infrared spectra of complexes **1**−**4** is the absence of a band in the region 2550−2430 cm^{-1}, which appear in the free ligand as the ν(S−H) vibration. In complexes **1** and **2**, the absorption at 1210 cm^{-1} is assigned to the C=S vibration[31] and the new medium-strength band at 445 cm^{-1} for **1** and 480 cm^{-1} for **2** is assigned to the Sn−N stretching,[32] both of which indicate that the $(dmt)^{2-}$ coordinates to tin through its nitrogen atoms as tautomer **c**. The strong absorptions at 597 cm^{-1} for **1** and 627 cm^{-1} for **2** are assigned to Sn−O−Sn stretching. In the far-infrared spectra a strong absorption at 317 cm^{-1} for **3** and 321 cm^{-1} for **4**, which are absent in the spectrum of the ligand, are assigned to the Sn−S stretching vibration. These values are consistent with those reported for a number of organotin(IV) sulfur derivatives.[16,33] The ν(Sn−Cl) absorption at 277 cm^{-1} in complex **4** is close to that found in trichloromethylbis(imidazole)tin·H_2O (275 cm^{-1}).[34] The middle-intensity bands observed at 1635 cm^{-1} in complexes **3** and **4** are assignable to ν(C=N) according to the literature,[35] which suggests that the coordination of dmt to tin is through the sulfur atoms of the thiol tautomer **a**, as reported previously.[36]

NMR Spectra

In the ^1H NMR spectra of complexes **1**−**4** the signal at δ = 1.6 ppm for the -SH protons of the ligand are absent, thus demonstrating that the ligand is deprotonated.

In the ^{13}C NMR spectra of complexes **1**−**4** the chemical shifts of the signals are quite similar to those of the parent ligand. Only a shift in the positions of two carbon atoms in the deprotonated group $(S-C-N-N-C-S)^{2-}$ of H_2dmt are seen; these data reflect the differences between the thiol-C and thione-C atoms. The thiol-to-thione evolution is responsible for the marked deshielding of thione-C,[37] which further proves that the coordination between complexes **1**, **2** and **3**, **4**.

For the methyl derivatives **1** and **3**, substitution of the $^2J_{^{119}Sn,^1}$ (83.2 and 78.1 Hz, respectively) and $^1J_{^{119}Sn,^{13}C}$ values (618.4 and 595.0 Hz, respectively) into the corresponding Lockhart−Manders equations[38] (empirical relationship between the coupling constants and the C−Sn−C angle) gives C−Sn−C angles of 135.0° and 131.5° for complex **1** and 128.5° and 129.0° for complex **3**. These values indicate that the data are reliable.

The ^{119}Sn chemical shifts of tin complexes appear to depend not only on coordination number, but also on the type of donor atoms bonded to the metal ion.[39] As reported in the literature,[40] chemical shifts in the range $\delta = -210$ to

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

−400 ppm, −90 to −190 ppm and 200 to −60 ppm have been associated with six-, five- and four-coordinate tin centers, respectively. The value of $\delta = -121.2$ ppm for complex **1**, $\delta = -179.6$ ppm for **2** and $\delta = -187.8$ ppm for **4** are within the range expected for five-coordinate complexes. The chemical shift for complex **3** in $CDCl_3$ indicates a change to a lower coordination than in the solid state, as the value of $\delta = -83.6$ ppm seems to indicate tetracoordination (Me_2S_2)[41] instead of hexacoordination. This change could be explained by the rupture of the weak Sn−N bonds in solution, these bonds being longer than those in other previously published complexes with S,N ligands.[42]

Experimental Section

Materials and Methods: Dimethyltin dichloride (Aldrich) and 2,5-dimercapto-1,3,4-thiadiazole (H_2dmt) were used as received. Dibenzyltin dichloride was prepared by a standard method reported in the literature.[43] The melting points were obtained with a Kofler micro melting point apparatus and are uncorrected. IR spectra were recorded on a Nicolet-460 spectrophotometer using KBr discs and sodium chloride optics. ^{1}H, ^{13}C and ^{119}Sn spectra were recorded on a Bruker AMX-300 spectrometer operating at 300, 75.3 and 111.9 MHz, respectively. The spectra were acquired at room temperature (298 K) unless otherwise specified; ^{13}C spectra are broadband proton decoupled. The chemical shifts are reported in ppm with respect to the references (external tetramethylsilane (TMS) for ^{1}H and ^{13}C NMR and neat tetramethyltin for ^{119}Sn). Elemental analyses were performed with a PE-2400II apparatus.

[{$C_2S_3N_2(CH_3)_2Sn$}$_2$O$(CH_3)_2Sn(OH)_2$]·1.5H_2O (1): Sodium ethoxide (0.136 g, 2 mmol) was added to a solution of 2,5-dimercapto-1,3,4-thiadiazole (0.150 g, 1 mmol) in 95% ethanol (25 mL) and the mixture was stirred for 30 min. $(CH_3)_2SnCl_2$ (0.659 g, 3 mmol) was then added to the mixture, continuing the reaction for 10 h at 40 °C. After cooling to room temperature, the mixture was filtered and the solvent was gradually removed by evaporation under vacuum to give the solid product. The solid was then recrystallized from ethanol to give colorless crystals of **1**. Yield, 80%. m.p. > 220 °C (dec.). IR (KBr): $\tilde{\nu}$ = 3410 (s, O−H), 2923 (m, C−H), 1210 (w, C=S), 561 (m, Sn−C), 597 (s, Sn−O−Sn), 445 (m, Sn−N) cm^{-1}. ^{1}H NMR ($CDCl_3$/D_2O, 300 MHz): δ = 5.15 (s, 2 H, O−H), 0.96 (s, 18 H, CH_3, $^2J^{119}_{Sn,^1}$ = 83.2 Hz) ppm. ^{13}C NMR ($CDCl_3$, 300 MHz): δ = 173.2 (C-1), 173.2 (C-1′), 6.3 [CH_3, $^1J^{119}_{Sn,^{13}C}$ = 618.4 Hz] ppm. ^{119}Sn NMR ($CDCl_3$): $\delta = -121.2$ ppm. $C_8H_{23}N_2O_{4.5}S_3Sn_3$ (671.53): calcd. C 14.31, H 3.45, N 4.20; found C 14.34, H 3.42, N 4.17.

[{$C_2S_3N_2(PhCH_2)_2Sn$}$_2$O$(PhCH_2)_2$Sn(OH)(OEt)] (2): The synthesis procedure was the same as complex **1**. H_2dmt (0.150 g, 1 mmol), sodium ethoxide (0.272 g, 4 mmol), and $(PhCH_2)_2SnCl_2$ (1.116 g, 3 mmol) in 95% ethanol (30 mL); reaction time 10 h; temperature 40 °C. Recrystallized from ethanol as colorless crystals. Yield, 89%. m.p. >200 °C(dec.). IR (KBr): $\tilde{\nu}$ = 3420 (O−H), 3021 (w, Ph−H), 2923 (m, C−H), 1631, 1597, 1491, 1451 (m, Ph), 1286 (s, C−O), 561 (m, Sn−C), 627 (s, Sn−O−Sn), 513 (s, Sn−OR), 480 (m, Sn−N). ^{1}H NMR ($CDCl_3$): δ = 7.15−7.56 (m, 30 H, Ph), 5.15 (s, 1 H, O−H), 3.75 [q, ^3J(^{119}Sn−^{1}H) = 5.8 Hz, 2 H, O−CH_2], 2.28 (m, 12 H, CH_2−Ph, $^2J^{119}_{Sn,^1}$ = 86 Hz,), 1.25 [t, ^4J(^{119}Sn−^{1}H) = 1.2 Hz, 3 H, CH_3] ppm. ^{13}C NMR ($CDCl_3$, 300 MHz): δ = 173.4 (C-1), 173.4 (C-1′), 37.5 [CH_2−Ph, $^1J^{119}_{Sn,^{13}C}$ = 624.1 Hz], 127.4 (*m*-C), 128.2 (*p*-C), 129.3 (*o*-C), 135.2 (*i*-C) ppm. ^{119}Sn NMR ($CDCl_3$): $\delta = -179.6$ ppm. $C_{46}H_{48}N_2O_3S_3Sn_3$ (1129.1): calcd. C 48.93, H 4.29, N 2.48; found C 48.82, H 4.28, N 2.50.

[$(CH_3)_2Sn(C_2N_2S_3)]_5$·CH_2Cl_2·3H_2O (3): The reaction was carried out under nitrogen atmosphere with use of standard Schlenk techniques. H_2dmt (0.30 g, 2 mmol) was added to a solution of dichloromethane (40 mL) and sodium ethoxide (0.272 g, 4 mmol), and the mixture was stirred for 30 minutes. $(CH_3)_2SnCl_2$ (0.439 g, 2 mmol) was then added to the mixture, continuing the reaction for 16 h at 30 °C. After cooling to room temperature the mixture was filtered. The solvent of the filtrate was gradually removed by evaporation under vacuum until a solid product was obtained. The solid was then recrystallized from dichloromethane/ethanol (95%) to give colorless crystals of **3**. Yield, 72%. m.p. > 240 °C (dec.). IR (KBr): $\tilde{\nu}$ = 3430 (s, O−H), 2923 (m, C−H), 1635 (m, C=N), 701 (s, C−S), 563 (m, Sn−C), 317 (m, Sn−S) cm^{-1}. ^{1}H NMR ($CDCl_3$/D_2O): δ = 0.95 [t, 30 H, CH_3, $^2J^{119}_{Sn,^1}$ = 78.1 Hz] ppm. ^{13}C NMR ($CDCl_3$): δ = 168.0 (C-1), 168.0 (C-1′), 5.8 [CH_3, $^1J^{119}_{Sn,^{13}C}$ = 595.0 Hz]. ^{119}Sn ($CDCl_3$): $\delta = -83.6$ ppm. $C_{26}H_{38}Cl_2N_{10}O_3S_{15}Sn_5$ (1683.9): calcd. C 18.55, H 2.27, N 8.32; found C 18.52, H 2.25, N 8.31.

[$(PhCH_2)_2SnCl$(S-C_2SN_2-S)SnCl$(PhCH_2)_2$] (4): The synthesis procedure was the same as that of complex **3**. H_2dmt (0.30 g, 2 mmol) was added to a solution of dichloromethane (40 mL) and sodium ethoxide (0.272 g, 4 mmol), and the mixture was stirred for 30 minutes. $(PhCH_2)_2SnCl_2$ (0.744 g, 2 mmol) was then added; reaction time 16 h; temperature 30 °C. Recrystallized from ether/dichloromethane. M.p. 196−198 °C. Yield, 72%. IR (KBr): $\tilde{\nu}$ = 1635 (C=N), 701 (s, C-S), 561 (m, Sn−C), 321 (m, Sn−S), 277 (m, Sn−Cl) cm^{-1}. ^{1}H NMR ($CDCl_3$): δ = 7.32−7.86 (m, 20 H, aromatic-H), 3.26 [s, 8 H, CH_2−Ph, $^2J^{119}_{Sn,^1}$ = 79.0 Hz] ppm. ^{13}C NMR ($CDCl_3$): δ = 168.5 (C-1), 168.5 (C-1′), 38.5 (CH_2−Ph, $^1J^{119}_{Sn,^{13}C}$ = 546 Hz), 125.4 ($^4J^{119}_{Sn,^{13}C}$ = 30 Hz, *m*-C), 127.0 ($^5J^{119}_{Sn,^{13}C}$ = 26 Hz, *p*-C), 130.5 ($^3J^{119}_{Sn,^{13}C}$ = 44 Hz, *o*-C), 139.0 ($^2J^{119}_{Sn,^{13}C}$ = 36 Hz, *i*-C) ppm. ^{119}Sn NMR ($CDCl_3$): $\delta = -187.8$ ppm. $C_{30}H_{28}Cl_2N_2S_3Sn_2$ (821): calcd. C 43.89, H 3.43, N 3.07; found C 43.86, H 3.40, N 3.05.

Crystal Structures of Complexes 1, 2 and 3: All X-ray crystallographic data were collected on a Bruker SMART-1000-CCD diffractometer. A criterion of observability was used for the solution and refinement. The structure was solved by direct methods and refined by a full-matrix least-squares procedure based on F^2 using the SHELXL-97 program. All data were collected at 298(2) K using graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å) and corrected for Lorentz and polarization effects but not for absorption. All non-H atoms were included in the model at their calculated positions. The positions of the hydrogen atoms were calculated, and their contributions in structural factor calculations were included. Table 4 lists the crystal data and structure refinement parameters.

CCDC-215777 (for **1**), -183604 (for **2**) and -215778 (for **3**) contain the supplementary crystallographic data for this paper. These data can be obtained free of the charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Center, 12 Union Road, Cambridge, CB2 1EZ, UK; Fax: +44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

On the Electronic Structure of Mesitylnickel Complexes of α-Diimines — Combining Structural Data, Spectroscopy and Calculations

Axel Klein,*[a][‡] Martin P. Feth,*[b] Helmut Bertagnolli,[b] and Stanislav Záliš[c]

Keywords: Density functional calculations / Electronic structure / EXAFS / Nickel / Raman spectroscopy

New organometallic nickel complexes of the type [(α-diimine)-Ni(Mes)Br] and [(α-diimine)Ni(Mes)$_2$] (Mes = mesityl = 2,4,6-trimethylphenyl) were prepared and characterised spectroscopically in detail. A combination of spectroscopic techniques (XRD, EXAFS, absorption, resonance Raman) and quantum chemical (DFT) calculations reveals the interplay of the diimine ligands and the mesityl or bromine co-ligands with the nickel centre. The low-lying electronic transitions are assigned as mixed MLCT/L′LCT or MLCT/XLCT due to low-lying accepting π*-orbitals centred on the diimine ligands and mixed metal/co-ligand MOs as donor levels.

Introduction

Organometallic nickel complexes with α-diimine ligands like 2,2′-bipyridine (bpy), 1,10-phenanthroline (phen) or diazabutadienes (R-DAB) have gained an enormous interest in the last decade. This is mainly due to their success as effective catalysts in olefin polymerisation or olefin/CO copolymerisation.[1−9] It has been established, mainly by Brookhart, that methylnickel complexes with carefully designed diazabutadiene ligands exhibit higher activities than the classical Ziegler catalysts combined with a greatly reduced sensibility towards poisoning by polar functions. Detailed investigations on the activities of various derivatives on polymerisation,[1a] theoretical calculations on the mechanisms and energetics[2] and the use of these compounds for other catalytic purposes[10−13] have been published so far.

In the 1960s these compounds were already known as darkly coloured very reactive materials.[14−17] Detailed investigation of their structures and electronic properties, however, were scarce[15,18−20] until Yamamoto et al. recently reported and discussed the optical spectra of some alkyl and aryl complexes with 2,2′-bipyridine (bpy).[21] In this report the spectra were mainly used to monitor elimination processes. In order to fill that gap we initiated a detailed and combined research project using various spectroscopic techniques (absorption, emission and resonance Raman) and quantum chemical calculations, with a focus on the optical properties.

One reason why such investigations have not been performed so far is probably the high sensitivity of such alkylnickel complexes towards oxygen or moisture.[19] They also easily undergo thermal decomposition by reductive elimination.[21,22] Aryl derivatives are much more inert towards water or oxygen, although the threat of reductive elimination (forming biaryls) remains.[22] We have recently shown that introducing the bulky mesityl co-ligand (Mes = 2,4,6-trimethylphenyl) results in very stable mesityl- and dimesitylnickel complexes[23] of 2,2′-bipyridine, and, with the proper choice of ligands, compounds such as [(N^N)Ni-(Mes)Br] (N^N = α-diimine) have allowed us to carry out a detailed study of the ligand-exchange behaviour of these complexes using EXAFS and spectroscopic techniques like NMR or absorption spectroscopy.[24]

In this paper we wish to report the synthesis and detailed spectroscopic and structural (EXAFS + XRD) characterisation of a series of bromomesityl- and dimesitylnickel complexes of various diimine ligands together with the results of a detailed study of the electronic properties of selected samples using a combination of spectroscopy (absorption, resonance Raman) and quantum chemical calculations. The latter were based on the molecular structures established by single-crystal XRD measurements and EXAFS spec-

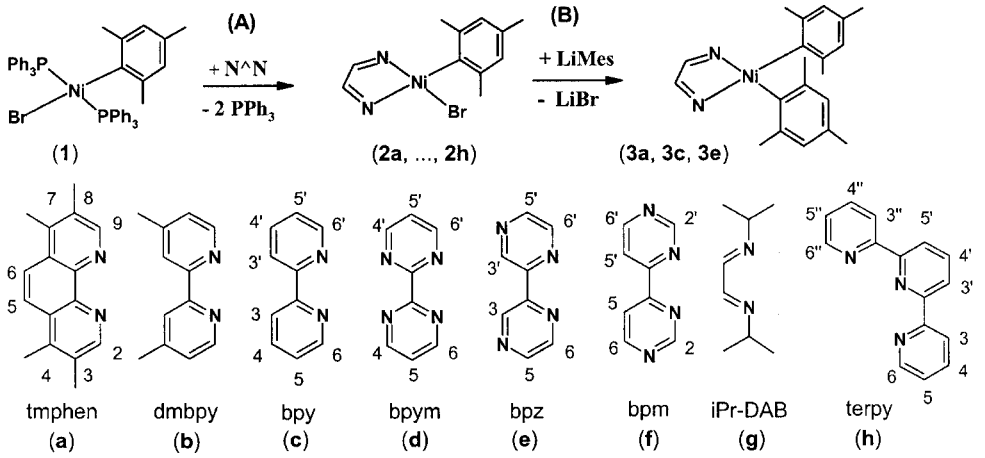

Scheme 1. Preparation of the α-diimine complexes with numbering; tmphen = 3,4,7,8-tetramethyl-1,10-phenanthroline, dmbpy = 4,4′-dimethyl-2,2′-bipyridine, bpy = 2,2′-bipyridine, bpym = 2,2′-bipyrimidine, bpz = 2,2′-bipyrazine, bpm = 4,4′-bipyrimidine, *i*Pr-DAB = *N*,*N*′-diisopropyl-1,2-ethanediimine (*N*,*N*′-diisopropyl-1,4-diazabutadiene), terpy = 2,2′,6′′-terpyridine

troscopy. The compounds under study are bromomesityl complexes of the type [(N^N)Ni(Mes)Br] (N^N = diimine ligands, Mes = mesityl = 2,4,6-trimethylphenyl) with various α-diimine ligands and, additionally, selected dimesityl complexes [(N^N)Ni(Mes)$_2$] (see Scheme 1).

Results and Discussion

Synthesis and General Properties

The neutral complexes [(N^N)Ni(Mes)Br] (N^N = diimine ligands) were synthesised from the precursor complex [(PPh$_3$)$_2$Ni(Mes)Br] (**1**) by ligand-exchange reactions in acetone or toluene solution [see Scheme 1 (A)] and were analysed by ^{1}H and ^{13}C NMR spectroscopy and elemental analysis (see Table 1).

For rather basic diimine ligands like bpy or tmphen reaction A proceeds very smoothly with high yields. The less basic the diimine ligands are (e.g. bpz or bpm) the more the equilibrium tends towards the starting materials. For *i*Pr-DAB the procedure had to be varied to obtain reasonable yields (see Exp. Sect.). With the very weakly basic ligand *N*,*N*′-di(2,6-xylyl)-1,2-ethanediimine (Xyl-DAB) no product was formed upon reaction with [(PPh$_3$)$_2$Ni(Mes)Br] (**1**). Once formed, and in the absence of PPh$_3$ or other strong ligands, the compounds are stable in solvents like CH_2Cl_2, THF, toluene or acetone towards ligand-exchange reactions.[24] The complex [(terpy)Ni(Mes)]Br (**2h**) was prepared following the same method. The ^{1}H NMR spectroscopic data reveal that all three pyridine units bind to nickel and that Br serves only as a counteranion to the cationic complex. The dimesityl complexes [(N^N)Ni(Mes)$_2$] (**3**) were prepared for selected samples by reacting the bromomesityl complexes with mesityllithium as shown in Scheme 1 (B).

The NMR spectroscopic data reflect the geometric properties of the compounds. The bromomesityl complexes

give full sets of ^1H and ^{13}C resonances (see Table 1 and Supporting Information) for the chelate ligands, confirming the planar geometry and C_S symmetry. For the dimesityl complexes C_2 symmetry can be deduced from the NMR spectra.

Structures

The structures of the investigated complexes are essential for the discussion of electronic properties since the molecular entity must be unequivocal. Also, the optical spectroscopy might be affected by intermolecular interactions like stacking and, finally, they serve as a basis for the quantum chemical calculations. Selected samples were therefore submitted to single-crystal XRD or powder EXAFS study.

XRD

The crystal structures of two examples of the series [(N^N)Ni(Mes)Br] with N^N = bpy (**2c**) or *i*Pr-DAB (**2g**)[24] and the structure of [(bpy)Ni(Mes)$_2$] (**3c**)[23] have recently been published. In this paper we report the crystal structure of [(tmphen)Ni(Mes)$_2$] (**3a**; Figure 1). The reason for adding this structure to the series is because of the special character of the tmphen ligand. In the series shown in Scheme 1 tmphen is the most basic ligand and, more importantly, it is a much more rigid ligand than bpy or the bidiazines. This has a strong impact on the molecular structure since previous studies have revealed that the steric demand of two *cis* oriented mesityl substituents in square-planar complexes of nickel, palladium or platinum leads to marked deviations not only in the coordination sphere but also within the diimine ligands.[23–25] This rigidity also has a strong impact on the optical properties, as we will see later.

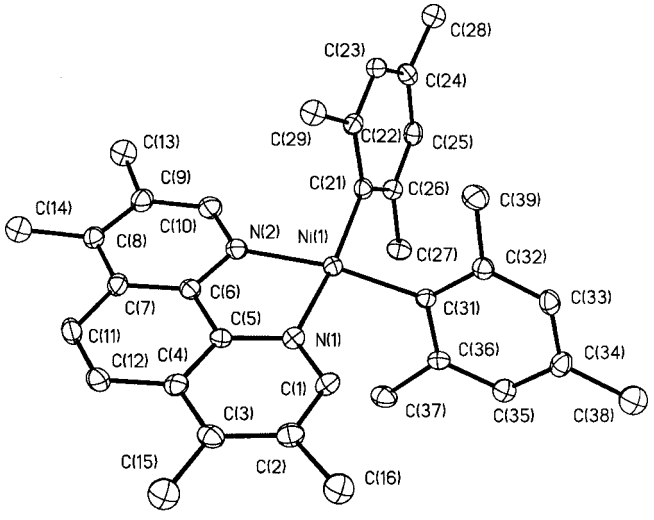

Figure 1. Molecular structure of **3a** (50% probability ellipsoids; H atoms omitted for clarity); selected bond lengths (Å) and angles (deg): Ni−N(1) 1.975(4), Ni−N(2) 1.960(4), Ni−C(11) 1.911(4), Ni−C(21) 1.914(4), N(1)−C(1) 1.337(6), N(2)−C(10) 1.333(6), N1−C(5) 1.345(13), N2−C(6) 1.385(12); N(1)−Ni−N(2) 82.55(16), C(11)−Ni−C(21) 90.47(18), N(1)−Ni−C(11) 94.01(17), N(1)−Ni−C(21) 168.30(17), N(2)−Ni−C(21) 94.79(17), N(2)−Ni−C(11) 169.65(18)

The structure was solved in the orthorhombic *Pbca* space group (for details see Exp. Sect.). A solution in $P2_1/n$, which is the space group obtained for the bpy derivative **3c**, gave slightly worse *R* values. The crystal structure reveals that the complex forms dimers in the unit cell which are π-stacked in a non-graphite-like fashion, with an interplanar distance of 3.49(1) Å. As displayed in Figure 2 the two central rings overlap but are not completely eclipsed (shift of 0.69 Å). The interplanar distance is similar to that in the recently studied isoleptic complex [(tmphen)Pt(Mes)$_2$],[25d] but longer than the distance found in graphite (3.354 Å). For the platinum complex a similar distance of 3.52(1) Å was found but the ligands stack in a staggered fashion and are also not back-to-back, but offset.

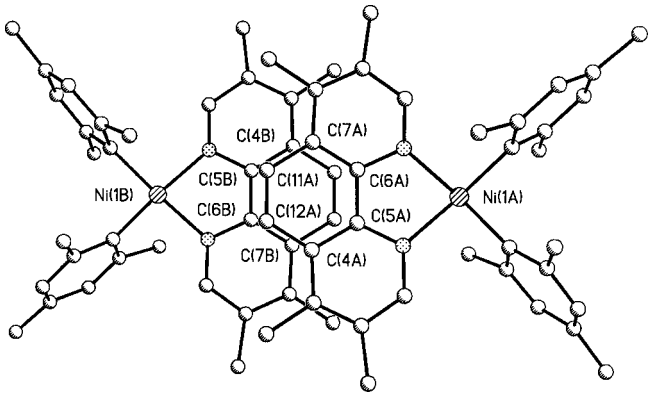

Figure 2. Stacking of two molecules of **3a** in the unit cell

The molecular structure of **3a** resembles in many respects that of the bpy derivative **3c**. The essential distances, for example Ni−N or Ni−C, and the chelate bite angle (around 82°) are very similar. The distortion of the square-planar coordination plane is higher (15.1° vs. 12.4°), as expected. In both cases the distortion of the diimine ligand is quite small (2.8° vs. 3.1°). The mesityl substituents are tilted towards the coordination plane [C(21)−N(2)−Ni(1)−N(1)−C(31)] by 70.0(6)° and 69.0(6)°, respectively, as was observed for other square-planar dimesityl complexes.[23,25] In the related complex [(bpy)Ni(C$_6$F$_5$)$_2$][22a] the C$_6$F$_5$ co-ligands are oriented almost perpendicular to the coordination plane and both the Ni−N distances [1.938(3) and 1.935(3) Å] and the Ni−C distances [1.903(3) and 1.907(3) Å] are markedly shorter. The N−Ni−N bite angle (82.9°) lies in the normal range whereas the C−C bond between the two pyridyl units is noticeably elongated to 1.477(7) Å. The latter is a clear indication of reduced back-bonding to the diimine ligand due to the fact that the fluoroaryl co-ligands donate much less electron density than their mesityl counterpart in the complexes **3a** and **3c**. This is also the reason for the different Ni−C bond lengths in the two types of arylnickel complexes. We thus conclude that the aryl co-ligand strongly governs the geometry around the nickel atom (and also the electron distribution).

EXAFS Spectroscopy

In the Ni-K edge XANES spectra of all complexes the typical two pre-edge peaks of square-planar Ni^{II} complexes can be observed.[26] The pre-peak at about 8333 eV can be assigned to a 1s→3d electron transition, while the second peak, which occurs at about 8337 eV, is due to a 1s→$4p_z$ transition with shakedown contributions.[26a]

The obtained structural parameters of the investigated complexes determined by curve fitting analysis of the EXAFS spectra at the Ni-K and Br-K edge are summarised in Table 2. [(dmbpy)Ni(Mes)Br] (**2b**), [(bpym)Ni(Mes)Br] (**2d**) and [(bpz)Ni(Mes)Br] (**2e**) show very similar EXAFS functions at the Ni-K and Br-K edge, leading to almost identical structural parameters, which are in very good agreement with values found from single crystal XRD and from the EXAFS analysis of the complex [(bpy)Ni(Mes)Br] (**2c**).[24] As an example, Figure 3 shows the k^3-weighted EXAFS spectra coupled with the magnitudes of the Fourier transforms of **2e** at the Ni-K (a and b) and at the Br-K edge (c and d) The fitting of the Ni-K edge EXAFS spectra was performed using a three-shell model in which the first coordination shell at about 1.9 Å consists of the two coordinating nitrogen atoms of the diimine ligand and the carbon atom of the mesityl group, the second shell contains the bromine backscatterer at about 2.3 Å and the third coordination shell at about 2.8 Å contains the further backbone-carbon atoms of the mesityl and diimine ligand. Because of the quite equal distances and backscatter behaviour of the nitrogen and carbon backscatterers in the first coordination shell, only one shell was fitted with nitrogen amplitude- and phase-functions. The Br-K edge EXAFS spectra were fitted with one coordination shell of nickel at about 2.3 Å. In complex **2a** a slightly higher Ni−C/N distance (1.97 Å) of the first coordination shell was detected, although the Ni−Br distance is of the same order of magnitude.

In Figure 4 (a) a comparison of the experimental k^3-weighted EXAFS functions of [(tmphen)$Ni(Mes)_2$] (**3a**), [(bpy)$Ni(Mes)_2$] (**3c**) and [(bpz)$Ni(Mes)_2$] (**3e**) at the Ni-K edge is shown. The spectra of **3a**, **2h**, **3c** and **3e** were fitted with a two-shell model: the first shell is due to the carbon and nitrogen atoms of the imine and mesityl ligands coordinating directly to the nickel centre atom and the second shell consist of the backbone carbon atoms of the ligands. The structural parameters of **3a**, **2h** and **3c** determined by EXAFS are very similar.

At first sight the complex [(bpz)$Ni(Mes)_2$] (**3e**) seems to deviate from **3a**, **2h** and **3c**. The peak of the first coordination shell in the Fourier-transformed EXAFS spectrum

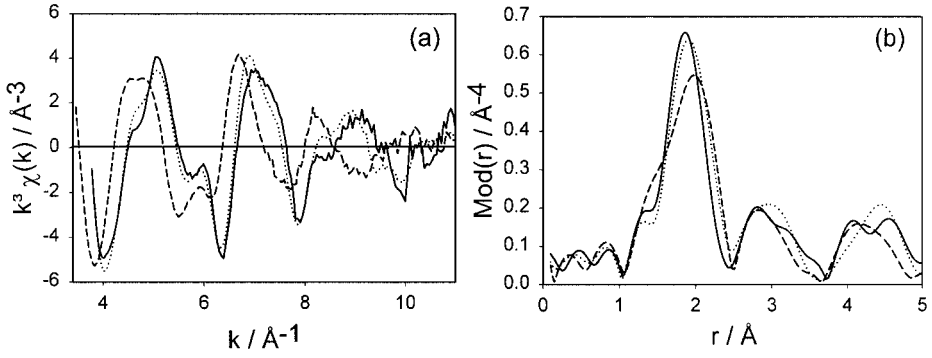

Figure 4. Comparison of the experimental k^3 χ(k) functions (a) and their Fourier transforms (b) of solid [(tmphen)Ni($Mes)_2$] (**3a**) (solid line), solid [(bpy)Ni($Mes)_2$] (**3c**) (dotted line) and solid [(bpz)Ni($Mes)_2$] (**3e**) (dashed line) (Ni-K edge)

of **3e** shows a clear asymmetry, indicating longer and shorter bonded backscatterers in the local environment of the Ni central atoms. However, a fit of two separate coordination shells did not lead to a satisfying result, thus only one coordination shell for the direct environment of nickel was fitted. The determined Ni−C/N distance of 2.01 Å for this shell is significantly longer than in the other dimesityl complexes, such as in [(bpy)Ni($Mes)_2$] (**3c**) (Ni−C/N distance of 1.94 Å). Comparing the bpy complex with the tmphen derivative reveals slightly longer averaged distances for the former. In this series of ligands tmphen represents the high-basicity end and bpy is therefore less basic. Bpz is a much better π-acceptor but therefore a much weaker base, and this gives rise to the lengthening of the Ni−N bonds. The consequences of the basicity of the various ligands for the preparation of the complexes has already been discussed. For the bromomesityl complexes this trend is reversed — the longest average distances are found for the tmphen derivative. This can be explained in the following way. Assuming that the Ni−C and Ni−N bond *trans* to Mes are essentially the same as for the dimesityl complexes, and that the Ni−Br distances are more or less constant, the length of the Ni−N bond *trans* to Br must be the reason for the observed trend. Br is a π-donor which is best accommodated by a good π-acceptor diimine ligand and tmphen in that sense is the worst in our series, whereas bpz is the best.

Optical Spectroscopy and Calculations

Absorption Spectroscopy and Calculations

Both dimesityl and bromomesityl nickel complexes are brightly coloured, ranging from orange to green in the solid as well as in solution. The absorption spectra (see Figure 5) are dominated by two broad bands of medium intensity in the visible region and an intense band in the UV region. Additional weak, very-long-wavelength bands appear as shoulders in the near IR (NIR) region which, in most cases, are only clearly visible in apolar solvents (Table 3). The two broad bands show a strong negative solvatochromism (see for example Table 4−7) they are red-shifted for the dimesityl complexes relative to their bromomesityl analogues, and in apolar solvents they are partly structured. The UV band is solvent invariant and appears to be characteristic of the ligand.

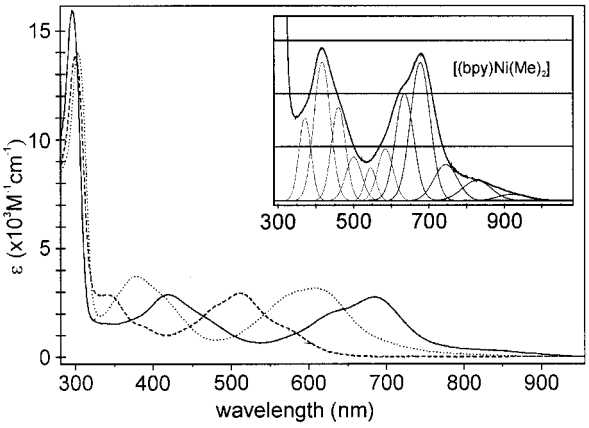

Figure 5. Absorption spectra of [(bpy)Ni(Me$_2$)] (solid line), [(bpy)-Ni(Mes)$_2$] (dotted line) and [(bpy)Ni(Mes)Br] (dashed) in toluene solution; the insert depicts the spectral deconvolution for [(bpy)-Ni(Me)$_2$]

In agreement with recent work by Yamamoto[21] we can assign the two long-wavelength bands to charge-transfer transitions (CT) to the π* orbitals of the diimine ligands and the UV bands to ligand-centred π-π* transitions. In view of the observed solvatochromism of the extremely long-wavelength bands an assignment of these bands to metal-centred (LF) transitions is unlikely.

A closer look at the solvatochromism data (Table 4) reveals that the extent, as derived from the differences of the observed maxima in pentane and DMF solution, increases with the absolute energy, which parallels the series of increasing basicity (or decreasing π-acceptor character; Table 3). Generally the bromomesityl complexes exhibit stronger solvatochromism than the dimesityl derivatives and there is no marked difference between the dimethyl complex [(bpy)Ni(Me)$_2$] and its mesityl analogue. Extreme values are found for **2a**, underlining the special character of the tmphen ligand mentioned above, and for **3e**. All these findings are in full agreement with the simple model of a more or less strong polarisation $M^{(\delta-)}\leftarrow L^{(\delta+)}$ in the ground state, which is transformed to a rather apolar M←L excited state by an MLCT excitation.[28] Strongly basic ligands favour more pronounced polarisation, whereas the donating Mes co-ligands prevent the negative polarisation of the metal by the diimine ligand.

Recently we have discussed the occurrence of mixed MLCT/L′LCT (ligand-to-ligand charge transfer) transitions (instead of pure MLCT transitions) due to contributions of the co-ligands to the frontier orbitals in related diarylplatinum complexes.[29] To probe for such contributions from the mesityl or the bromine co-ligands we have examined the dimesitylnickel complex, the dimethylnickel complex and the bromo(mesityl)nickel complex of 2,2′-bipyridine in a combined spectroscopic and quantum chemical study.

First of all the molecular structures were calculated by both ADF/BP and G03/B3LYP methods. Both methods re-

produce the experimentally obtained bond lengths and angles well. The biggest difference between the two methods was observed for the Ni–C bond, where ADF/BP gave a value of 1.930 Å and G03/B3LYP yielded 1.906 Å for the dimethyl complex compared to the experimental value of 1.923(4) Å.[30] Approximately the same was found for the dimesityl derivative. For the bromomesityl complex ADF/BP also gave a far more accurate Ni–Br distance (2.324 Å) compared with the experimental value of 2.300(1) Å (G03/BLYP gave 2.399 Å). Comparing the experimental data of the dimethyl derivative [(bpy)Ni($Me)_2$] (monoclinic $P2/c$, $Z = 4$)[30] with all the so far structurally characterised

mesitylnickel complexes reveals markedly shorter Ni−C bonds for the latter. This is in contrast to what would be expected on steric grounds. The C−Ni−C angles in the dimesityl derivatives are slightly enlarged to more than 90° (86.6° for the dimethyl derivative). The N−Ni−N chelate bite and the Ni−N bonds, however, do not differ. As a consequence, it seems that in [(bpy)Ni(Me)$_2$] the inter-ring distance between the pyridine rings is elongated (1.485 Å) which normally means reduced back-bonding. ADF/BP gives a value of 74.4° for the N1−Ni−C11−C12 tilt angle of the mesityl co-ligands (74.9° by G03/B3LYP) and we feel that from these structural data there is already evidence for a notable co-ligand (Mes) contribution to the electronic transitions. The Mes co-ligand therein could act either as a π-donor or π-acceptor. Furthermore, from the EXAFS measurements we have evidence of a strong π-donating interaction of the bromine co-ligand with the nickel atom. Both types of co-ligand contributions will be substantiated by a view of the calculated frontier orbitals. The ground-state one-electron energies and percentage composition of selected highest occupied and lowest unoccupied molecular orbitals have been calculated by DFT methods and the results are shown qualitatively in Figure 6.

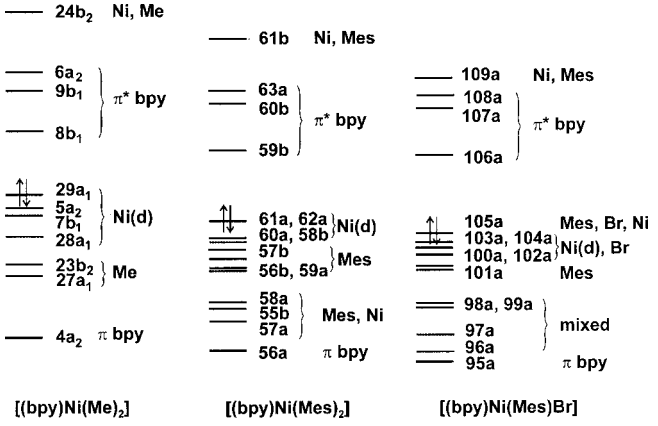

Figure 6. Qualitative MO schemes [(bpy)Ni(Me)$_2$], [(bpy)Ni(Mes)$_2$] (**3c**) and [(bpy)Ni(Mes)Br] (**2c**) based on ADF/SAOP calculated one-electron energies and percentage composition of selected frontier molecular orbitals

The labelling and relative position of ADF/SAOP calculated frontier molecular orbitals is depicted in Figure 6. The calculated composition is available in the Supporting Information. The figure illustrates how the replacement of Mes by other co-ligands influences the composition of the frontier MOs. The character of the LUMO is only moderately influenced by the variation of the co-ligand R.

More substantial changes are observed in the composition of the set of HOMOs which, in the case of [(bpy)Ni(Mes)$_2$] (**3c**), have large contributions of the Mes co-ligand. This is different for [(bpy)Ni(Me)$_2$], where the lower lying occupied orbitals are formed by Me sp^3 orbitals interacting with central metal orbitals. Both ADF/BP and DFT/B3LYP give qualitatively the same composition for the HOMO and LUMO of [(bpy)Ni(Me)$_2$], and the composition of the other frontier orbitals does not differ substantially either. In the case of [(bpy)Ni(Mes)Br] (**2c**) bromine p orbitals contribute to a large extent to the HOMOs whereas the contributions of the mesityl co-ligands are lower than for the dimesityl derivative.

To gain insight to the electronic transitions, lowest TD DFT singlet excitation energies have been calculated and compared to experimentally observed absorption maxima. The results are summarised in Tables 5−7. To this end the absorption spectra of the three compounds have been submitted to a spectral deconvolution, as shown in Figure 5. However, the results of the deconvolutions were not unambiguous since both multiple electronic transitions and vibrational progression could contribute to the various maxima observed as shoulders in the spectra.

All calculated transitions have mixed character. They can be characterised as MLCT excitations for [(bpy)Ni(Me)$_2$], whereas for [(bpy)Ni(Mes)$_2$] (**3c**) and [(bpy)Ni(Mes)Br] (**2c**) the contribution from the Mes or Br co-ligands cannot be neglected and the corresponding transitions should be assigned as mixtures of MLCT/L′LCT [ligand (Mes)-to-li-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

gand charge transfer] or MLCT/XLCT (halogen-to-ligand charge transfer), respectively. Both co-ligands thus act as π-donors. In the bromomesityl complex the donor character of the mesityl group is lower than the dimesityl derivative. The transition energies agree qualitatively quite well with experimental ones for the dimesityl and dimethyl derivatives (Table 5 and 6). Note that the solvatochromic effects are enormous for most absorption bands. Generally, G03/B3LYP predicts larger transition energies than ADF/SAOP, as shown in Table 7. For **2c** the ADF/SAOP calculations predict very low-energy transitions around 1.64 eV (750 nm), which cannot be found in the absorption spectra; the TD-DFT method using "pure" functionals underestimates the transitions energies also in the case of other halide complexes.[31] The transitions calculated at higher energies fit better to experimentally found ones; however the intensity pattern is not reproduced well. G03 calculations using hybrid B3LYP functionals give transitions with high bromine contributions closer to the experimentally measured weak, low-lying absorption bands.

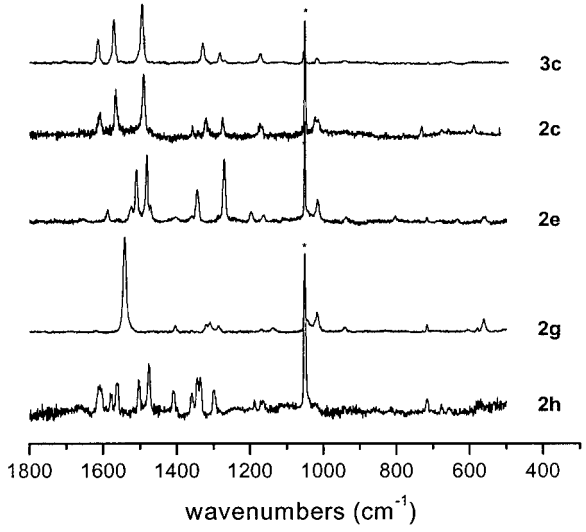

Figure 7. Resonance Raman spectra of the nickel complexes [(bpy)Ni(Mes)$_2$] (**3c**; λ_{ex} = 542 nm), [(bpy)Ni(Mes)Br] (**2c**; λ_{ex} = 488 nm), [(bpz)Ni(Mes)Br] (**2e**; λ_{ex} = 592 nm), [(*i*Pr-DAB)Ni(Mes)Br] (**2g**; λ_{ex} = 598 nm) and [(terpy)Ni(Mes)]Br (**2h**; λ_{ex} = 457.9 nm), obtained from KNO_3 pellets upon irradiation into the long-wavelength absorption bands; * denotes the 1051 cm^{-1} resonance of NO_3^-

Resonance Raman Spectroscopy

In many cases the character of the excited states of transition metal complexes has been studied by emission spectroscopy.[32] However, of the present nickel complexes only **2a**, **2b**, **2h** and **3a** show very weak emission in the solid or solution; the others do not emit either in the solid or in solution, even at 110 K. Additionally, for the weakly emitting compounds the obtained results are ambiguous. We therefore embarked on a combination of resonance Raman (rR) spectroscopy and quantum chemical calculations to probe the character of the excited states. The rR technique allows us to draw direct conclusions about the character of the electronic transitions since it is based on the presumption that only those Raman bands due to vibrations that are influenced by the electronic transition that is excited are enhanced in intensity.[33] The rR spectra of the dimesityl complexes and selected bromomesityl complexes dispersed in KNO_3 were recorded after irradiation of their lowest-energy absorption bands; examples are displayed in Figure 7. Selected data are collected in Table 8 (see also Supporting Information) in comparison to DFT calculated Raman active vibrations for the model system [(bpy)Ni(Me)$_2$] and the resonances of free bpy.[34]

Based on these calculations and data the resonances observed for [(bpy)Ni(Mes)$_2$] (**3c**) at 1608, 1561, 1485, 1322, 1277, 1167, 1015, 655 and 370 cm^{-1} can be assigned to the normal modes of the bpy ligand. They have been observed previously in rR experiments with a number of bpy complexes upon excitation into their metal-to-ligand(bpy) charge-transfer bands.[35] The resonance at highest energy is assigned to the ν(C=N) vibration. Its energy decreases along the series tmphen > bpy > bpz which is caused by the increasing π-accepting abilities from tmphen to bpz. Resonances at 426, 343 and 241 cm^{-1} were assigned to the metal-ligand modes ν(Ni−C), ν(Ni−N) and δ(Ni−N), respectively. For the other diimine ligands the assignment is based on comparison with the bpy analogue.

At first sight (e.g. in Figure 7 for the two bpy complexes) the rR spectra of the bromomesityl complexes of the aromatic diimine ligands are much the same as those recorded for the dimesityl complexes. For the *i*Pr-DAB complex assignment of the observed resonances at 1542 cm^{-1} ν(C=N), or 1170, 1138 and 1020 cm^{-1} ν(C−C) was facilitated by comparison with recently examined organoplatinum(II) and -platinum(IV) complexes.[29b,36] A closer look at the data reveals that in the dimesityl complexes some resonances are observed that do not appear for the bromomesityl derivatives, for example for bpy: 1263, 1114 and 941 and 740 cm^{-1} (marked in italics in Table 8). Such resonances are characteristic of ν(C=C$_{ring}$) or δ$_{ring}$ vibrations and could be assigned to the mesityl co-ligands. They appear only for the dimesityl complexes because the contribution of the mesityl co-ligands to the excited state is markedly higher (mixed MLCT/L′LCT) than for the bromomesityl complexes (mixed XLCT/MLCT) thus supporting the results from quantum chemical calculation (vide supra). The mentioned resonances might also be interpreted as bpy-centred resonances and their occurrence explained by the differences in symmetry between dimesityl (C_2) and bromomesityl (C_s). However, it is unlikely that the higher-symmetry molecules exhibit more resonances than the lower-symmetry ones.

Support for the partial XLCT character of the excited states in the bromomesityl complexes could not be obtained from rR spectra. The only relevant vibration, ν(Ni-Br), which occurs around 160−170 cm^{-1}, is quite weak and therefore hard to detect in the rR experiment due to the closeness to the excitation line. Furthermore, it is also possible that the Ni−Br σ-bond is not much distorted upon π-

donation by the bromine atom and therefore not resonantly enhanced.

Conclusion

Quantum chemical calculations have revealed the interplay of the metal centre, the chelating diimine ligand and the co-ligands methyl, mesityl or bromine to form the frontier orbitals relevant for the optical transitions and excited states. Strong experimental evidence for the π-accepting mode of the chelate ligand and the π-donating modes of the mesityl and bromine co-ligands comes from a combination of spectroscopic methods. A structural study using EXAFS spectroscopy shows some clear trends for the metal–ligand distances that can be explained by varying σ-donor and/or π-acceptor ability through the series of diimine ligands and π-donating contributions from the bromine co-ligand. Support for a specific electronic contribution from the mesityl co-ligand comes from XRD results. The absorption spectra agree qualitatively well with the calculated transitions. Resonance Raman spectroscopy strongly supports the π-accepting character of the diimine ligands. The evidence for the co-ligand contributions is less strong and should be further substantiated by rR studies on structurally varied derivatives (H/D exchange, other aryl co-ligands, Cl/Br/I exchange). Such studies are already underway.

Experimental Section

Instrumentation: ^{1}H NMR spectra were recorded on Bruker AC250 or AM200 spectrometers. UV/Vis absorption spectra were recorded on Bruins Instruments Omega 10, Hewlett–Packard 8453 Diode Array and Varian Cary 4E spectrophotometers. Resonance Raman spectra of the complexes dispersed in KNO_3 pellets were recorded on a Dilor XY spectrometer equipped with a Wright Instruments CCD detector, using a Spectra Physics 2040E Ar^+ and Coherent CR490 and CR590 dye lasers (with Coumarin 6 and Rhodamine 6G dyes) as excitation sources. Emission spectra were recorded on a Perkin–Elmer LS5B spectrophotometer.

Computational Details: Ground-state electronic structure calculations on complexes [(bpy)Ni(R)$_2$] and [(bpy)Ni(Mes)Br] (**2c**) have been done on the base of density-functional theory (DFT) methods using the ADF2002.03[38] and Gaussian 03[39] program packages. The lowest excited states of the closed-shell complexes were calculated by the time-dependent DFT (TD DFT) method (both ADF and G03 programs).

Within the ADF program, Slater-type orbital (STO) basis sets of triple-ζ quality with polarisation functions were employed; methyl groups on the Mes co-ligands were described by basis sets of double-ζ quality with polarisation functions. The inner shells were represented by a frozen core approximation (1s for C, N, 1s-3p for Br and 1s-3p for Ni were kept frozen). The following density functionals were used within ADF: the local density approximation (LDA) with VWN parametrisation of electron gas data or the functional including Becke's gradient correction[40] to the local-exchange expression in conjunction with Perdew's gradient correction[41] to the LDA expression (ADF/BP). The scalar relativistic (SR) zero-order regular approximation (ZORA) was used within this study. Compositions and energies of molecular orbitals and electronic transition energies and compositions were calculated by the asymptotically correct SAOP functional,[42] which is suitable also for higher-lying MOs and electronic transitions. Core electrons were included in ADF/SAOP calculations.

Within Gaussian 03 6-31G* polarized double-ζ basis sets[43] for C, N, H and Ni atoms; effective core pseudopotentials with corresponding optimised set of basis functions for Br atom[44] were used

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

for geometry optimisation and frequency calculations. Correlation consistent polarized double-ζ basis sets[45] (cc-pVDZ) within TD-DFT calculations. Hybrid Becke's three parameter functional with Lee, Yang and Parr correlation functional (B3LYP)[46] was used in Gaussian 03 calculations (G03/B3LYP). Gaussian 03 was also used for the calculations of the vibrations at G03/B3LYP optimised geometries.

The calculations on [(bpy)Ni(Me)$_2$] and [(bpy)Ni(Mes)$_2$] (**3c**) were performed in a C_{2v} or C_2 constrained symmetry, respectively. The z axis is coincident with the C_2 symmetry axis; the central atom and bpy ligand lie in the y,z plane. All results discussed correspond to optimised geometries. The calculations on [(bpy)Ni(Mes)Br] were done without any symmetry constrains.

Crystal Structure Analysis for [(tmphen)Ni(Mes)$_2$] (3a): Data collection was performed at T = 173(2) K on a Siemens P4 diffractometer with Mo-K_α radiation (λ = 0.71073 Å). The structure was solved by direct methods using the SHELXTL-PLUS package[47] and refinement was carried out with SHELXL-97 employing full-matrix least-squares methods on F^2 with $F_o^2 = -3\sigma(F_o^2)$. Formula (M_W) $C_{34}H_{38}N_2Ni_1$ (533.37); cell dimensions (Å): a = 16.297(3), b = 16.578(3), c = 20.732(4); V = 5601.3(19) Å^3; Z = 8; Abs. coefficient = 0.718 mm^{-1}; F(000) = 2272; GooF at F^2 = 1.174; R values [$I > 2\sigma(I)$]: $R1$ = 0.0801, $wR2$ = 0.1679; R values (all data): $R1$ = 0.164, $wR2$ = 0.2076; max./min. 0.609/−0.508 e·Å^{-3}. Empirical absorption correction was performed using Ψ-scans. All non-hydrogen atoms were treated anisotropically, hydrogen atoms were included by using appropriate riding models.

CCDC-226909 (for **3a**) contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: +44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

EXAFS Measurements: The XANES and EXAFS measurements were performed at the beamlines X1.1 (RÖMO II) and E4 at the Hamburger Synchrotronstrahlungslabor des Deutschen Elektronensynchrotrons (HASYLAB at DESY, Hamburg, Germany), at beamline 2−3 at the Stanford Synchrotron Radiation Laboratory (SSRL) at SLAC (Stanford, USA) or at the newly designed EXAFS-beamline KMC-2 at the Berliner Elektronenspeicherring-Gesellschaft für Synchrotronstrahlung m.b.H (BESSY II, Berlin, Germany).

For the measurements at the Ni-K edge (8332.8 eV) a Si(111) double crystal monochromator was used at the SSRL and at DESY. For the measurements at the Br-K edge (13474.0 eV) at beamline X1.1 a Si(311) double crystal monochromator was used. At BESSY a SiGe(220) double graded-crystal (0.5% Ge/cm) monochromator was used for the nickel and the bromine edge. The synchrotron beam current was between 80 and 100 mA at HASYLAB (positron energy 4.45 GeV), between 100 and 250 mA at BESSY (electron energy 1.7 GeV) and between 80 and 100 mA at the SSRL (electron energy 1.7 GeV).

All the experiments were carried out under ambient conditions at 25 °C. The tilt of the second monochromator crystal was set to 30% harmonic rejection. Energy resolution was estimated to be about 0.7−2.0 eV for the Ni-K edge and 4.0 eV for the Br-K edge. The spectra were collected in transmission mode with ion chambers. All ion chambers were filled with nitrogen in the case of the measurements at the Ni-K edge, and the second and third chamber with argon in the case of the measurements at the Br-K edge. Energy calibration was performed with nickel metal foil in the case of measurements at the Ni-K edge and lead metal foil (Pb L_{III}-edge) in the case of the Br-K edge. The solid complexes were embedded in a polyethylene matrix and pressed to pellets. The concentration of all samples was adjusted to yield an absorption jump, $\Delta\mu d$, of about 1.5.

Data evaluation started with background absorption removal from the experimental absorption spectrum by subtraction of a Victoreen-type polynomial. Then, the background-subtracted spectrum was convoluted with a series of increasingly broader Gauss functions and the common intersection point of the convoluted spectra was taken as energy E_0.[48] To determine the smooth part of the spectrum, corrected for pre-edge absorption, a piecewise polynomial was used. It was adjusted in such a way that the low-R components of the resulting Fourier transform were minimal. After division of the background-subtracted spectrum by its smooth part, the photon energy was converted into photoelectron wavenumbers k. The resulting EXAFS function was weighted with k^3. Data analysis in k-space was performed according to the curved wave multiple scattering formalism of the program EXCURV92 with XALPHA phase and amplitude functions.[49] The mean-free path of the scattered electrons was calculated from the imaginary part of the potential (VPI was set to −4.00) and an overall energy shift (ΔE_0) was assumed. The Amplitude Reduction Factor (AFAC) was set to a value of 0.8 in the case of the Ni-K as well as the Br-K edge.

Materials and Procedures: The precursor complex [(PPh$_3$)$_2$Ni(Mes)Br] (**1**) [23] and the ligands bpm,[50] bpz,[51] and *i*Pr-DAB[52] were obtained following literature procedures. Mesityllithium was prepared according to the method of Biali et al.[53] Other reagents were commercially available and used without further purification. All preparations and physical measurements were carried out in dried solvents under an argon atmosphere, using Schlenk techniques.

Preparation of [(N^N)Ni(Mes)Br] (2) [N^N = tmphen (a), dmbpy (b), bpy (c), bpym (d), bpz (e) bpm (f), and terpy (h)]: In a typical reaction 2 g of [(PPh$_3$)$_2$Ni(Mes)Br] (**1**) (2.56 mmol) were suspended in 250 mL of toluene, 1.1 equivalents of the ligand was added and the solution stirred overnight at ambient temperature. The reaction volume was then reduced to 20 mL and the resulting solids were filtered off. They were washed with small amounts of toluene (2 × 5 mL) and *n*-pentane (3 × 20 mL) and dried. For bpz and bpm the products were recrystallised twice from a mixture of CH_2Cl_2 and *n*-heptane (1:8). From the filtrates only small amounts of clean products could be isolated after evaporation to dryness and recrystallisation from CH_2Cl_2/*n*-heptane (1:8). For analytical data see Table 1 and Supporting Information.

Preparation of Bromo-1,4-diisopropyl-1,4-diazabutadienemesitylnickel(II), [(*i*Pr-DAB)Ni(Mes)Br] (2g): *i*Pr-DAB (250 mg, 1.78 mmol) was added to a vigorously stirred suspension of [(PPh$_3$)$_2$Ni(Mes)Br] (**1**; 250 mg, 0.32 mmol) in 500 mL of *n*-pentane. After a few minutes the yellow suspension dissolved leaving a violet voluminous precipitate that was finally filtered off. The obtained violet solid was recrystallised from CH_2Cl_2/*n*-heptane (1:8) and dried, yielding 112 mg of dark-violet microcrystalline material. For nalytical data see Table 1 and Supporting Information.

Preparation of the Dimesitylnickel Complexes 3a, 3c, 3e: The dimesitylnickel complexes [(N^N)Ni(Mes)$_2$] were prepared as described for the bpy complex[23] from the bromomesityl complexes and mesityllithium.

3a: Yield 88%, dark violet powder. $C_{34}H_{38}N_2Ni_1$ (533.40): calcd. C 76.56, H 7.18, N 5.25; found C 76.59, H 7.23, N 5.27. ^{1}H NMR ([D$_6$]DMSO): δ = 8.26 (s, 2 H, H5,6), 7.64 (s, 2 H, H2,9), 6.45 (s, 4 H, *m*-H), 2.67 (s, 6 H, $H_3C^{4,7}$), 2.64 (s, 12 H, *o*-CH_3), 2.29 (s, 6

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

H, $H_3C^{3,8}$), 2.13 (s, 6 H, *p*-CH_3) ppm. ^{13}C NMR (CD_2Cl_2): δ = 157.2, 150.5, 142.6, 127.3, 122.7 (all tmphen); 144.9 (Mes-1), 144.1 (Mes-2), 130.9 (Mes-4), 125.3 (Mes-3), 27.3 (*o*-CH_3), 20.8 (*p*-CH_3), 18.1 ($H_3C^{4,7}$), 14.9 ($H_3C^{3,8}$) ppm.

3c: Yield 84%, dark violet powder. $C_{28}H_{30}N_2Ni_1$ (453.27): calcd. C 74.20, H 6.67, N 6.18; found C 74.35, H 6.65, N 6.22. ^1H NMR ([D_6]acetone): δ = 8.38 (d, $^3J_{H3,H4}$ = 8.02 Hz, 2 H, H3,3′), 8.12 (dd,$^3J_{H4,H5}$ = 6.90 Hz, 2 H, H4,4), 7.54 (d, $^3J_{H5,H6}$ = 4.84 Hz, 2 H, H6,6′), 7.44 (dd, 2 H, H5,5′), 6.37 (s, 4 H, *m*-H), 2.53 (s, 12 H, *o*-CH_3), 2.08 (s, 6 H, *p*-CH_3) ppm. ^{13}C NMR ([D_6]acetone): δ = 157.4 (bpy-2,2′), 149.9 (bpy-6,6′), 144.1 (Mes-2), 138.1 (bpy-4,4′), 136.6 (Mes-1), 130.9 (Mes-4), 127.6 (bpy-3,3′), 126.0 (Mes-3), 122.0 (bpy-5,5′), 27.3 (*o*-CH_3), 20.8 (*p*-CH_3) ppm.

3e: Yield 78%, dark green microcrystalline powder. $C_{26}H_{28}N_4Ni_1$ (455.25): calcd. C 68.60, H 6.20, N 12.31; found C 68.72, H 6.22, N 12.41. ^1H NMR ([D_6]acetone): δ = 9.54 (s, 2 H, H3,3′), 8.75 (s, 2 H, H5,5′), 7.53 (s, 2 H, H6,6′), 6.49 (s, 4 H, *m*-H), 2.45 (s, 12 H, *o*-CH_3), 2.28 (s, 6 H, *p*-CH_3) ppm.

Supporting Information: Fourteen tables with comparisons between calculated and experimental structural data for **2c**, **3c**, and [(bpy)-Ni(Me)$_2$]; details of the crystal structure of **3a**; ^{13}C NMR spectroscopic data of selected complexes and absorption spectroscopic data are also given. Furthermore, eight figures are provided showing additional EXAFS spectra and the XANES spectra of **2e** and **2d** and a view of the unit cell of **3a** from the crystal structure determination (see also the footnote on the first page of this article).

Acknowledgments

We wish to thank HASYLAB at DESY (Hamburg, Germany), the SSRL at SLAC (Stanford, USA) and BESSY (Berlin, Germany) for providing synchrotron radiation. The SSRL is operated by the U.S. Department of Energy, Office of Basic Energy Science. Ministry of Education of the Czech Republic and the COST Action D14 is gratefully acknowledged.

COVER PICTURE

The cover picture shows the rearrangement of *N*-imidoyl-*N*-heterocyclic carbenes as well as a crystal structures of a palladium complex of a derivative of one of the rearranged carbene ligands. This work was supported by the polymer laboratory of BASF AG, Ludwigshafen, Germany, in search of new imino-*N*-heterocyclic carbene late transition metal complexes as novel polymerization catalysts. Details are discussed in the article by B. Bildstein et al. on p. 2827 ff.

Solvothermal Synthesis of Paramagnetic Molecular Clusters

Rebecca H. Laye[a] and Eric J. L. McInnes*[a]

Keywords: Solvothermal synthesis / Hydrothermal synthesis / Clusters / Single-molecule magnets

A brief overview is given of the literature of the use of solvothermal techniques – chemistry in superheated solvents – towards paramagnetic cluster synthesis. Although these techniques have been used extensively to prepare infinite lattice magnetic materials, there is much less work on preparing discrete molecular clusters other than the polyoxovanadates and -molybdates. This microreview details some of our early success in using these techniques towards high-nuclearity vanadium(III), chromium(III), manganese(II/III), iron(III) and nickel(II) clusters, including some very high spin ground state clusters ($S \leq 25$), and therefore demonstrates the potential in the synthesis of molecular materials such as single-molecule magnets.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

Interest in polymetallic cluster complexes of paramagnetic transition metal ions has increased hugely since the discovery of "single-molecule magnets" (SMMs).[1] This remarkable class of molecules displays magnetic bistability that is entirely of a molecular origin, and arises from the combination of a high ground state electron spin (S, resulting from the magnetic exchange interactions between the individual ions within the cluster), and a large negative zero-field splitting (D) within this ground state.[2] The first SMM discovered was the dodecametallic, mixed-valence manganese(III/IV) cluster[1] $[Mn_{12}O_{12}(O_2CMe)_{16}(H_2O)_4]$, trivially known as "Mn12", that has an $S = 10$ ground state. Magnetic hysteresis (due to retention of magnetisation in the absence of an applied magnetic field) in SMMs is only observed below a certain blocking temperature, and in Mn12 this is ca. 4 K − this is still the highest recorded for an SMM. The blocking temperature is controlled in part by the product DS^2. Clearly, if SMMs are to be exploited in, for example, memory devices there is a need to synthesise new SMMs with higher blocking temperatures. Thus, the primary challenge in this field is still the synthesis of new cluster molecules.

The vast majority of paramagnetic cluster compounds have been synthesised by what might be termed "conventional" coordination chemistry techniques − a source of metal ion and bridging and terminal ligands in a common solvent at temperatures limited by the boiling point of that solvent at atmospheric pressure. Although these methods have been superbly successful in producing a bewildering array of clusters (see ref.[3] for a recent review of structures

Rebecca Laye has been a post-doctoral researcher with Eric McInnes in the Department of Chemistry at The University of Manchester since 2002. She completed her PhD under the supervision of Prof. Jon A. McCleverty and Prof. Michael D. Ward at the University of Bristol in 2002, and obtained her MChem. in Chemistry at Bristol in 1999. In 2004 she was awarded a Ramsey Fellowship.

Eric McInnes has been a Lecturer in the Department of Chemistry at The University of Manchester since 2000. Prior to this he was a post-doctoral researcher in the School of Chemical Sciences at the University of East Anglia with Prof. Andrew J. Thomson FRS and Prof. Annie K. Powell, and in Manchester with Dr. Frank E. Mabbs and Dr. David Collison. He completed his PhD in 1995 under the supervision of Dr. Lesley J. Yellowlees at the University of Edinburgh, where he also obtained his BSc in 1992.

MICROREVIEWS: This feature introduces the readers to the author's research through a concise overview of the selected topic. Reference to important work from others in the field is included.

with more than 6 metal ions), there is no reason to confine synthetic methods to this limited temperature/pressure regime as this can only limit the range of products available. A few groups have explored higher temperature routes to clusters − for example, high-nuclearity chromium(III) clusters, including very high spin ground state examples,[4] have been made by solid-state thermolysis reactions followed by extraction into a suitable solvent and crystallisation.[5] Although these results demonstrate the possibilities of higher temperature routes, they lack the advantages of solution chemistry, most importantly the direct crystallisation of products. We were inspired by the pioneering work of Zubieta and co-workers in the hydrothermal synthesis of high-nuclearity, high-valent (alkoxo)polyoxovanadates and -molybdates[6] to investigate the use of solvothermal techniques in the synthesis of large paramagnetic clusters of the 1st row transition metal ions. This Microreview summarises the important literature to date, and highlights some of our early successes in this area demonstrating the applicability of these techniques in cluster chemistry of metals across the 1st row, with examples of vanadium(III), chromium(III), manganese(II/III), iron(III) and nickel(II) chemistry, including some of the highest spin ground state molecules known.

Solvothermal Synthesis

Hydrothermal or, more generally, solvothermal techniques involve heating a reaction mixture in a sealed vessel such that reaction temperatures greater than the boiling point of the solvent can be reached (typically between 100 and 250 °C in hydrothermal chemistry), typically under autogenous pressure. [Note that some authors reserve the term hydro(solvo)thermal to refer to supercritical conditions − in this work we merely imply heating beyond the boiling point.] Superheated solvents exhibit (i) reduced viscosity (and therefore enhanced diffusion of chemical species) and (ii) very different solubilising properties (e.g. the dielectric constant of water decreases rapidly with increasing temperature)[7] compared to ambient conditions. These factors can lead to very different chemistry. For example, (ii) can lead to otherwise insoluble reagents being solubilised (which can be exploited to overcome solubility differences between metal salts and ligands), and (i) can lead to enhanced crystal growth from reaction solutions. Furthermore, the temperature regime available in solvothermal techniques, intermediate between low-temperature solution chemistry and high-temperature solid-state chemistry, can favour the formation of metastable kinetic products rather than the thermodynamic products (e.g. metal oxides) favoured at higher temperatures. All these features of hydrothermal chemistry have long been exploited in materials chemistry, e.g. in the preparation of zeolites, and there are several excellent reviews in this area.[7,8] More recently, these techniques have been employed extensively in the synthesis of coordination polymers (or metalorganic frameworks),[9] including magnetic materials.[10]

However, there is much less literature on the solvothermal synthesis of *discrete molecular clusters*, despite the fact that all the above advantages are equally applicable. In particular, the propensity to crystallise products direct from reaction solution is invaluable because product identification in cluster chemistry relies almost entirely on single-crystal X-ray diffraction given the complexity, and unpredictability,[11] of the materials being formed. The literature on solvothermal cluster synthesis is dominated by Zubieta's systematic exploration of the hydrothermal synthesis of polyoxo/alkoxovanadates,[6] although there is also a significant body of work involving metal chalcogenide clusters.[12] Zubieta's work highlights another important advantage of solvothermal conditions for cluster synthesis. From a very simple set of reagents − for example, a source of vanadium(III) (V_2O_3) and vanadium(V) [V_2O_5 or $(NH_4)VO_3$], a bridging ligand (tri- or tetraalcohol, which are readily deprotonated to alkoxides), and a mineraliser salt and source of counterion (alkylammonium halide salt) in superheated water (150−210 °C) − a vast array of vanadium(IV/V) clusters can be formed: for example, $[V_6O_7\{EtC(CH_2O)_3\}_4]^{2-}$ (based on a V_6 octahedron, see Figure 1),[13] $[V_{10}O_{16}\{EtC(CH_2O)_3\}_4]^{2-/4-}$, $[V_{10}O_{13}\{EtC(CH_2O)_3\}_5]^{-}$ (based on V_{10} edge-sharing bioctahedra),[14] and $[V_{16}O_{20}\{CH_2(OH)C(CH_2O)_3\}_8(H_2O)_4]$,[15] amongst many others. Thus, because solvothermal conditions facilitate the isolation of metastable species, the nature of the product (nuclearity, oxidation states, topology) is very sensitive to the specific reaction conditions and there is a vast "parameter space" to explore over and above the obvious variables of reagents and solvent, viz. stoichiometery, temperature, pressure, pH, mineralisers, fill volume of the reaction vessel, etc. O'Hare has also recently highlighted this in hydrothermal syntheses of uranyl-based coordination polymers.[9c]

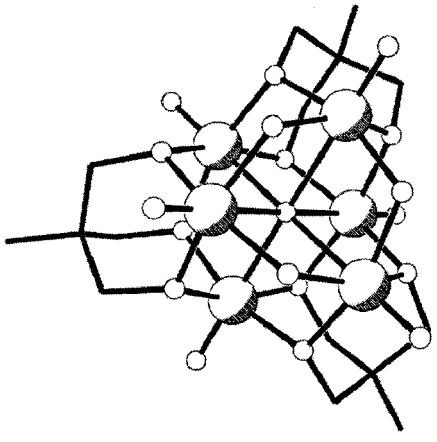

Figure 1. Structure of Zubieta's $[V_6O_7\{MeC(CH_2O)_3\}_4]^{2-}$ anion, after ref.[13]; scheme: V (large shaded circles), O (small open), C (connectivity only), H omitted for clarity

There is now a very large amount of literature on hydrothermally prepared polyoxometallate clusters of the vanadium group − in addition to Zubieta's alkoxide-based work (reviewed in detail elsewhere),[6] there are many polyoxovanadates exploiting inorganic (borate, phosphonate, arsenate, germanate) templates,[16] and several heterometallic vanadate/molybdates[17] and tungstates.[18] (Alkoxo)po-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

lyoxovanadate[19] and -molybdate[20] clusters-of-clusters with nuclearities up to 18 and 42, respectively, have also been prepared by hydrothermally induced condensation of smaller, preformed clusters.

All this work is based on vanadium and molybdenum in the +4 or +5 oxidation state, and even in the fully reduced M^{IV} forms these clusters only have one unpaired electron per metal centre. In our work, where we are targeting very high spin ground state clusters, we require transition-metal ions with several unpaired electrons; thus, we are utilising later transition ions or lower oxidation states of the early transition metals. There are very few solvothermally prepared clusters with later transition ions, but there are a few important examples. Secondary metals − Co^{II}, Mn^{II}, Cu^{II} and Zn^{II} − have been introduced into polyoxovanadates and -molybdates.[21] More significantly in the context of this article, Zubieta has recently extended his poly(alkoxide) work to Fe^{III} in $[\{Fe(OH)(MeCN)_2\}Fe_6OCl_6\{CH_2(OH)C(CH_2O)_3\}_4]$ (based on a face-capped Fe_6 octahedron), $[Fe_{10}O_2Cl_8\{EtC(CH_2O)_3\}_6]$ and the heterometallic $[(VO)_2Fe_8O_2Cl_6\{EtC(CH_2O)_3\}_6]$ (both structurally related to the edge-sharing bioctahedral V_{10} clusters, above) all synthesised from mixtures of $FeCl_2$, V_2O_5 and tri- or tetra-alcohol ligand in MeCN at 120−150 °C.[22] In addition, two hexametallic Co^{II} clusters have been reported by solvothermal routes: Wood et al. prepared the Co_6 ring $[Co_6\{O_3PCH_2N(CH_2CO_2)_2\}_6]^{12-}$ from the potassium salt of the ligand and $Co(NO_3)_2$ in MeOH at 200 °C,[23] while Ōkawa's $[Co_6(OH)_2(phenylcinnamate)_{10}]$ is prepared from the organic acid, $Co(NO_3)_2$ and base in water at 170 °C.[24] It is perhaps significant that several of these latter examples use organic solvents rather than water, as these less polar solvents have been suggested to favour formation of clusters rather than infinite solids under solvothermal conditions,[23] presumably due to the effectively limitless source of O^{2-}/OH^- available in hydrothermal synthesis favouring the formation of polymers.[23]

Our Work

Our rationale was to use the simple triangular clusters $[M_3O(O_2CR)_6L_3]^{n+}$ (Figure 2) as our source of metal ion, in superheated alcohols as solvent and source of bridging ligand. The "basic metal carboxylates"[25] have several advantages as precursors: (i) they are small clusters themselves, (ii) they are known for the 1st row transition metals from vanadium to cobalt, (iii) homovalent M^{III}_3 ($n = 1$) and heterovalent $M^{III}_2M^{II}$ ($n = 0$) triangles are available for V, Mn, and Fe, (iv) heterometallic triangles are known, (v) they can be prepared with a wide range of carboxylates and terminal ligands (L), (vi) the central oxide and bridging carboxylates provide sources of ligands with several potential bridging modes. Hence, these simple metal triangles have been used extensively as precursors to higher nuclearity clusters, particularly with manganese and iron by "conventional" synthetic methods (for example, Mn12 derivatives can be prepared by oxidation of $[Mn_3O(O_2CR)_6L_3]^+$),[1a] and with chromium(III) by high-temperature solid-state routes.[5] There is much less literature[21c,22,23,26] on solvothermal synthesis with alcohols than with water. However, in addition to (perhaps) favouring cluster formation (see above), alcohols obviously provide a source of alkoxide that can bridge in μ_2 and μ_3 modes, thus providing further scope for extensive metal aggregation.

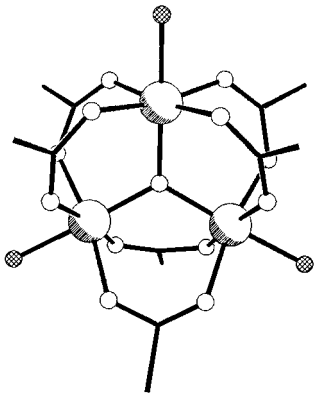

Figure 2. Structure of $[M_3O(O_2CMe)_3L_3]^{+/0}$; scheme: M (large shaded circles), terminal ligands L (cross-hatched circle), others as in Figure 1

Our first efforts employed this simple reaction system of metal triangle in alcohols with no additional source of bridging ligand. For example, reaction of $[Cr_3O(O_2CMe)_6(H_2O)_3]Cl$ in MeOH or EtOH at 200 °C yields the decametallic clusters $[Cr_{10}(OR)_{20}(O_2CMe)_{10}]$, which have a cyclic structure with respect to the metal ions where neighbouring ions are bridged by a μ_2-acetate and two μ_2-alkoxides (Figure 3).[27] Thus, in this example extensive bridging of metal ions has occurred, utilising ligands from both the metal precursor and deprotonated solvent as we had hoped. Furthermore, otherwise identical reactions under reflux only give recrystallised versions of the starting triangle (although Bino has reported that refluxing $[Cr_3O(O_2CMe)_6(H_2O)_3]Cl$ in H_2O yields the octametallic $[Cr_8(OH)_{12}(O_2CMe)_{12}]$)[28]. Therefore, the superheated conditions have allowed us to overcome the kinetic inertness of the Cr^{III} ion to form larger clusters. Alternative routes to Cr^{III} clusters have also been by high temperatures for this reason. For example, heating $[Cr_3O(O_2CCMe_3)_6(H_2O)_3]NO_3$ in the solid state at 300 °C, followed by extraction with and crystallisation from *n*PrOH, gives $[Cr_{12}O_9(OH)_3(O_2CCMe_3)_{15}]$,[5] and refluxing $[Cr_3O(O_2CMe)_6(H_2O)_3]Cl$ in a high-boiling solvent, PhCN at 188 °C, in the presence of 2,2′-bipyridine (bipy) gives the butterfly tetramers $[Cr_4O_2(O_2CMe)_7(bipy)_2]Cl$.[29]

The magnetic properties of the $[Cr_{10}(OR)_{20}(O_2CMe)_{10}]$ clusters are highly unusual.[27] $[Cr_{10}(OEt)_{20}(O_2CMe)_{10}]$ is weakly antiferromagnetically coupled ($J = -0.9$ cm^{-1}), leading to an $S = 0$ ground state. This is the norm for paramagnetic "molecular wheels" in the literature, albeit the magnitude of $|J|$ is small compared to other (octametallic) Cr^{III} examples.[3] However, $[Cr_{10}(OMe)_{20}(O_2CMe)_{10}]$ is weakly ferromagnetically coupled ($J = +4.5$ cm^{-1}). The logical consequence of this is an $S = 15$ ground state, which

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

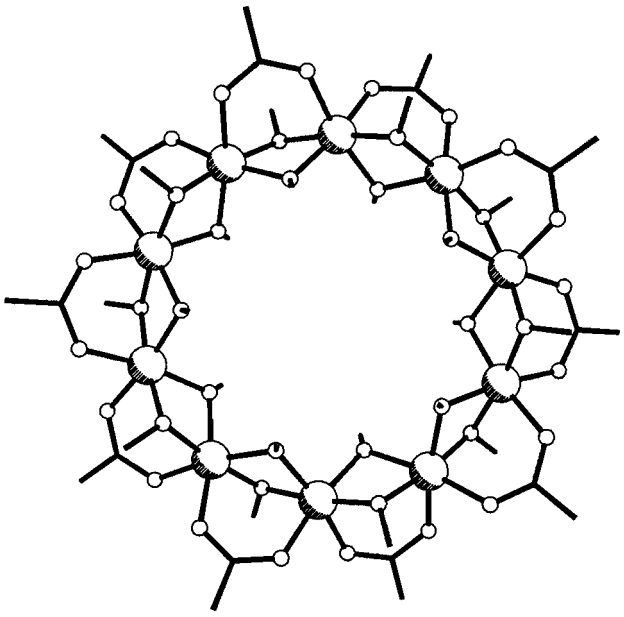

Figure 3. X-ray structure of a molecule of $[Cr_{10}(OMe)_{20}(O_2CMe)_{10}]$; scheme: Cr (large shaded circles), others as in Figure 1

is the highest know for a Cr-based cluster, and among the highest for any metal ion.[30] We have recently confirmed this by inelastic neutron scattering (INS) measurements on $[Cr_{10}(OCD_3)_{20}(O_2CCD_3)_{10}]$,[31] prepared by reaction of $[Cr_3O(O_2CCD_3)_6(H_2O)_3]NO_3$ in CD_3OD at 200 °C. The simplicity of the solvothermal route and the high yield (60−80%) of these clusters is vital in preparing the gram-scale quantities of per-deuterated complex required for INS studies at reasonable cost. This remarkable change from an $S = 0$ to an $S = 15$ ground state by changing the alkoxide bridge is simply a consequence of a small shift in J (ca. 6 cm^{-1}) that happens to cross $J = 0$. The small decrease in the antiferromagnetic contribution to J on changing from OEt to OMe is rationalisable in terms of the decrease in electron density at the bridging atom and consequent poorer overlap of magnetic orbitals, and similar shifts in J have been observed in Cr^{III} dimers.[32] We have now prepared a large family of these compounds $[Cr_{10}(OR)_{20}(O_2CR')_{10}]$ (R′ = Me, Et, $CCMe_3$; R = Me, Et) by the same route, and for each R′ the R = Me species are less antiferromagnetically coupled than the R = Et ones, including a second ferromagnetically coupled example, $[Cr_{10}(OMe)_{20}(O_2CCMe_3)_{10}]$.[31]

The analogous Fe^{III} wheels are known, the first known example being Lippard's $[Fe_{10}(OMe)_{20}(O_2CCH_2Cl)_{10}]$ "ferric wheel",[33] and can be prepared under much more facile conditions reflecting the greater kinetic lability of the ferric ion. Under solvothermal conditions we have only prepared insoluble powders from $[Fe_3O(O_2CMe)_3L_3]X$ in alcohols. Similar results have been reported by others from reactions under reflux − continuous extraction of this mixture is one of the routes to isolating the parent ferric wheel $[Fe_{10}(OMe)_{20}(O_2CMe)_{10}]$.[34] Nevertheless, the isolation of $[M_{10}(OR)_{20}(O_2CR')_{10}]$ with Fe^{III} and Cr^{III} indicates that this should be a stable molecule for a range of M^{III} ions, and indeed we have recently prepared the dark-green V^{III} analogue $[V_{10}(OMe)_{20}(O_2CMe)_{10}]$ by reaction of $[V_3O(O_2CMe)_6(pyridine)_3][ReO_4]$ (we have been exploring perrhenate as a non-explosive analogue of perchlorate) in MeOH at 150 °C (equivalent reactions under reflux only give pale-yellow powders).[35] There is very little V^{III} cluster chemistry in the literature because of the readily oxidisable nature of this ion, and $[V_{10}(OMe)_{20}(O_2CMe)_{10}]$ is the highest nuclearity example reported to date. Here we have exploited the reducing nature of alcohols under solvothermal conditions to stabilise the V^{III} ion − others have used this effect to reduce V^V precursors to make V^{IV} clusters,[36] and V^{III} coordination polymers have also been prepared from VCl_3 under hydrothermal conditions.[37] Similar reactions of $[V_3O(O_2CR')_6L_3]^+$ with carboxylates other than acetate in superheated ROH lead to the formation of the octametallic V^{III} rings $[V_8(OH)_4(OR)_8(O_2CR')_{12}]$ with alternate $(\mu_2\text{-}OH)(\mu_2\text{-}O_2CR')_2$ and $(\mu_2\text{-}OR)_2(\mu_2\text{-}O_2CR')$ bridging (Figure 4) − this is in contrast to the analogous Cr^{III} chemistry where the decametallic wheel is always formed.[35,38] V^{III} clusters are an appealing goal since some V^{III} dimers exhibit very strong ferromagnetic coupling[39] and if this could be introduced into larger clusters it would generate the well-isolated, large spin states necessary for SMM behaviour. Although both the eight and ten-membered V^{III} wheels are antiferromagnetically coupled, the establishment of a reliable synthetic route to high-nuclearity V^{III} clusters is an important step forward.

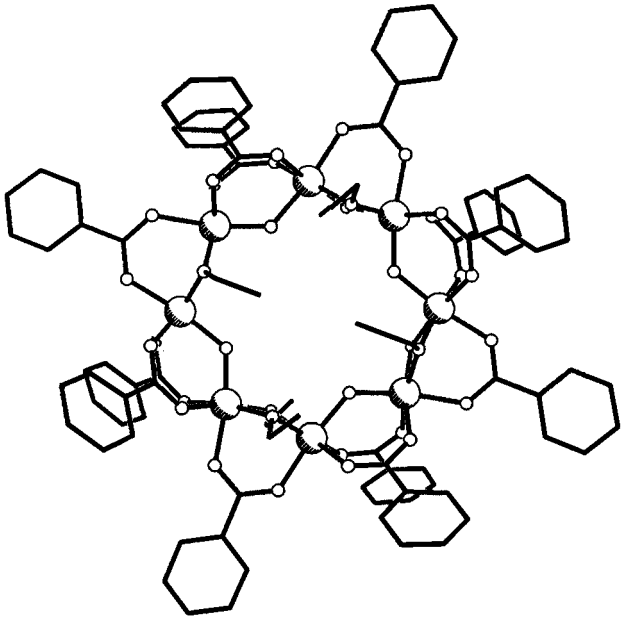

Figure 4. X-ray structure of a molecule of $[V_8(OH)_4(OEt)_8(O_2CPh)_{12}]$; scheme: V (large shaded circles), others as in Figure 1

This simple reaction fails with Mn^{III} for the very reason that it works for V^{III}. The Mn^{III} ions in $[Mn_3O(O_2CR)L_3]X$ (X = anion) are reduced to Mn^{II} in superheated alcohol solutions and only pale-pink solutions are formed. How-

ever, by changing to a more inert solvent we have shown that solvothermal techniques are also applicable to manganese cluster synthesis. For example, reaction of the mixed-valent $[Mn_3O(O_2CPh)_6(py)_2(H_2O)]$ (py = pyridine) in MeCN at 100 °C gives the hexametallic $[Mn_6O_2(O_2CPh)_{12}(py)_2]$.[40] In contrast to the alcohol-based reactions above, there is very little rearrangement of the precursor, simply a dimerisation of triangle with loss of terminal ligands. The $\{Mn_6O_2\}^{12+}$ core (Figure 5) consists of two planar $\{Mn_3O\}^{6+}$ units linked by four μ_3-carboxylates. Christou has previously shown that the same precursor can undergo thermally induced aggregation by reflux in a relatively high-boiling solvent (PhCN at 188 °C) to give an alternative hexametallic species, $[Mn_6O_2(O_2CPh)_{10}(py)_4]$, based on an edge-sharing bitetrahedral $\{Mn_6O_2\}^{10+}$ core.[41] This higher temperature, but non-solvothermal, reaction has led to more substantial rearrangement, and reduction, of the precursor − the related cluster $[Mn_6O_2(O_2CCMe_3)_{10}(HO_2CCMe_3)_4]$ has also been prepared by reflux in other relatively high-boiling solvents (toluene at 110 °C, dioxane at 100 °C).[42] This illustrates the importance of the temperature regime in cluster formation, and therefore the advantages of the greater range of this parameter in a wider range of solvents afforded by the solvothermal methodology. In this example we have prepared a product of the same nuclearity as higher temperature, non-sovothermal reactions, but with different metal topology and oxidation states. This leads to very different magnetic behaviour − $[Mn_6O_2(O_2CPh)_{10}(py)_4]$ has an S = 0 ground state, while $[Mn_6O_2(O_2CPh)_{12}(py)_2]$ has S = 3 (the parent monomer has an S = 3/2 ground state, so this can be considered as a simple ferromagnetic coupling of the two "halves" in the hexametallic cluster).[40]

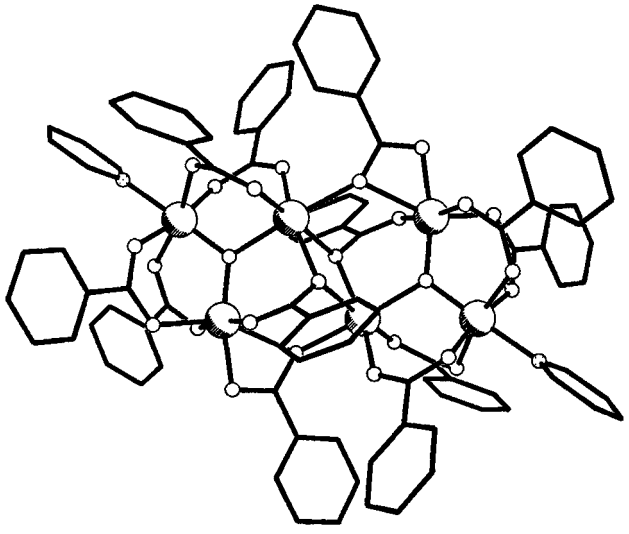

Figure 5. X-ray structure of a molecule of $[Mn_6O_2(O_2CPh)_{12}(py)_2]$; scheme: Mn (large shaded circles), others as in Figure 1

In the examples above we have taken very simple reaction systems involving only a triangular precursor and a solvent. We are now starting to explore analogous reactions but with additional ligands with potential for extensive metal bridging and possible structure-directing properties. For example, we have already shown that reaction of M^{III} acetate triangles in methanol leads to formation of $[M_{10}(OMe)_{20}(O_2CMe)_{10}]$ wheels. If we add an additional ligand which competes with the alkoxides, we should prevent formation of the metal wheels and thus force the formation of clusters of different shape and size. For example, reaction of $[Fe_3O(O_2CMe)_6(H_2O)_3]Cl$ in MeOH at 100 °C, in the presence of benzotriazole (btaH), yields the tetradecametallic Fe^{III} cluster $[Fe_{14}(bta)_6O_6(OMe)_{18}Cl_6]$ (Figure 6).[43] The structure is based on a hexa-capped hexagonal bipyramid of Fe^{III} ions with the caps on alternate faces (Figure 7). The bta^- ligands coordinate in their maximal μ_3-mode to form two $\{Fe_4(bta)_3\}$ moieties (Figure 6b) which sandwich a central Fe_6 ring, bridged by 18 μ_2-methoxides and six μ_4-oxides. The $\{M_4(bta)_3\}$ fragment is well known in M^{II} chemistry in the centred tetrahedral clusters $[M_5(bta)_6(diketonate)_4]$;[44] thus, its formation here is not unexpected and in this case has capped the growth of the iron oxide/alkoxide cluster. However, the absence of carboxylate in the structure is totally unexpected. As with all the reactions above, the product is crystallised directly from the reaction solution. The equivalent reaction under reflux gives only solutions from which we have failed to crystallise any cluster products.

$[Fe_{14}(bta)_6O_6(OMe)_{18}Cl_6]$ has one of the largest ground state spins yet observed, with initial magnetisation data suggesting S = 23 but possibly as high as 25.[43] This higher value can be easily rationalised from competing *anti*ferromagnetic interactions within the cluster: the relative magnitude of the four chemically distinct nearest-neighbour exchange pathways, via μ_2-O(Me) and/or μ_4-O, can be predicted on the basis of the Fe−O−Fe angles (Figure 7). The Fe(apex)−Fe(face cap) (J_1) and Fe(apex)−Fe(ring) (J_3) interactions are expected to be the most antiferromagnetic because of the largest angles, and therefore dominate over the much weaker antiferromagnetic Fe(face cap)−Fe(ring) (J_2) and Fe(ring)−Fe(ring) (J_4) interactions. This would lead to a very simple spin structure in the ground state with the two apical iron ions of the bipyramid "spin up" and all other ions "spin down". Conventional fitting of the experimental magnetic susceptibility data to a spin Hamiltonian to derive the four distinct J values is not possible for this system of 14 S = 5/2 spins. However, density functional theory calculations in tandem with Monte Carlo simulations of the experimental magnetic data to estimate the J values supports this simple model with values of $J_1 = -22$ cm^{-1}, $J_2 = -8.7$ cm^{-1}, $J_3 = -29.7$ cm^{-1} and $J_4 = -3.7$ cm^{-1}.[45] Scheme 1 summarises the clusters prepared above from simple $[M_3O(O_2CR)_6L_3]X$ precursors.

Finally, we give an example of the solvothermal synthesis of a late transition ion cluster, namely nickel(II). The typically large zero-field splitting of Ni^{II} makes this ion a promising building block for SMMs.[46] Since Ni^{II} cannot form M_3 triangles, we have used simple [Ni(diketonate)$_2$] monomers as our precursors − these are known to form heterocubane $[Ni_4(OR)_4(diketonate)_4]$ species in alcohols under

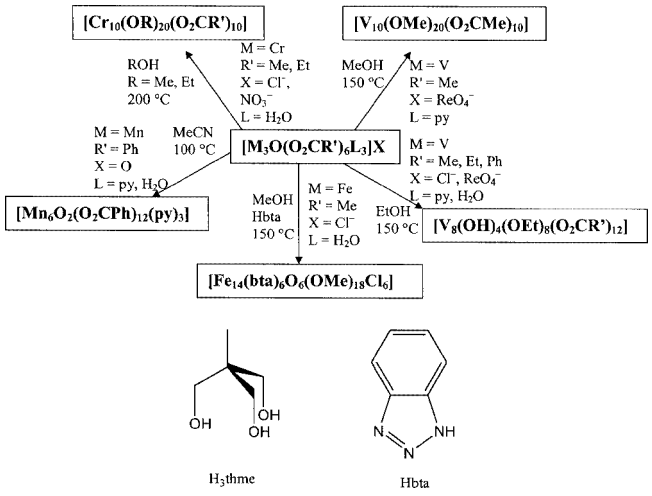

Scheme 1. Summary of clusters prepared solvothermally from $[M_3O(O_2CR)_6L_3]X$ precursors, and structures of the ligands benzotriazole (Hbta) and 1,1,1-tris(hydroxymethyl)ethane (H_3thme)

reflux.[46a] Analogous reactions under solvothermal conditions give identical products. However, in the presence of a competing ligand larger clusters can be obtained. For example, reaction of $[Ni(dbm)_2]$ (Hdbm = dibenzoylmethane) in EtOH at 150 °C with the triol 1,1,1-tris(hydroxymethyl)-ethane (H_3thme) gives the decametallic Ni^{II} cluster $[Ni_{10}(O)(thme)_4(dbm)_4(O_2CPh)_2(EtOH)_6]$ (Figure 8a: note the solvothermal conditions have led to the partial degradation of the diketonate to carboxylate − the cluster can be prepared more rationally with carboxylate as an additional reagent).[47] The analogous reaction under reflux gives only heterocubanes − the solvothermal conditions are essential for preventing the formation of this very stable product. The cluster core is a very regular Ni_{10} supertetrahedron, centred on a μ_6-O, where each (near equilateral) triangular Ni_6 face is bound by a single, fully deprotonated $thme^{3-}$ (Figure 8b). The disposition of the three alkoxide arms of $thme^{3-}$, investigated extensively by Zubieta in polyoxovanadate chemistry (see above), is known to favour the formation of triangular M_3 fragments (with each arm μ_2, the ligand overall being μ_3, for example see Figure 1), which can then condense to form larger clusters (hence the preponderance of clusters based on triangular faces with this ligand − octahedral, edge-sharing bioctahedra, etc.).[6] Hence, this could be anticipated with Ni^{II}. However, the formation of the expanded M_6 triangles, allowing formation of the supertetrahedron, is unprecedented. We have also found that other ligands with a potentially similar trigonal arrangement of alcohol groups can form analogous clusters under solvothermal conditions, e.g. *cis*,*cis*-1,3,5-cyclohexanetriol.[47] The magnetic properties of the Ni_{10} cluster are dominated by the antiferromagnetic exchange interactions across the linear Ni−μ_6-O−Ni groups. Magnetic ordering phenomena below 20 K prevent full characterisation of the molecular behaviour, which is unfortunate because the supertetrahedral topology should lead to extensive spin frustration effects.

Conclusions

The work above illustrates some of the advantages of solvothermal synthetic techniques in the synthesis of paramagnetic cluster complexes. In every example above, these products are *only* isolated under solvothermal conditions − under less forcing conditions (ambient or under reflux) either no product is isolated or different products are formed. In addition, in each case the products crystallise directly from the reaction solutions as the only solid product, and in the majority of cases in yields of greater than 50% based on total metal content. Over and above these massive advantages, we also have shown examples of exploiting the solvothermal regime (allowing high-temperature reactions in low-boiling solvents) to overcome the kinetic inertness of Cr^{III}, and to isolate clusters in relatively unusual oxidation states such as V^{III} (exploiting the enhanced reducing nature of alcohols under these conditions). Moreover, several of the clusters we are preparing have interesting magnetic properties including some of the highest ground state spins known. Thus, solvothermal techniques will be an important tool in the synthesis of new SMMs and related materials, alongside the more established synthetic routes.

Acknowledgments

We are grateful to The Leverhulme Trust, the EPSRC and the European Community for funding our research, and to several collaborators including Prof. H. U. Güdel (Berne), Prof. R. Sessoli (Firenze), Dr. T. Mallah (Paris-Sud) and Dr. S. Teat (Daresbury). The benzotriazole and triol work is the result of collaboration with our colleagues Dr. E. K. Brechin and Dr. D. Collison at Manchester.

An Easy Route to Monofunctionalized Organoimido Derivatives of the Lindqvist Hexamolybdate

Pingfan Wu,[a,c] Qiang Li,[b] Ning Ge,[a] Yongge Wei,*[a] Yuan Wang,[a] Ping Wang,[b] and Hongyou Guo*[b]

Keywords: Organoimido Derivatives / Polyoxometalates / Acid Catalysis / Dehydration / Organic−inorganic hybrid

In the presence of a carbodiimide (DCC) a proton can dramatically speed up the reaction of α-$[Mo_8O_{26}]^{4-}$ with aromatic amines under mild conditions and convenient bench manipulations, which results in the easy synthesis of monofunctionalized organoimido derivatives of $[Mo_6O_{19}]^{2-}$ even bearing an electron-withdrawing group such as bromo or chloro groups.

Introduction

The surface modification of polyoxometalates, that is, the substitution of a terminal oxo or M=O group with organic species,[1,2] has received increasing interest in recent years because it can afford a way to conveniently and effectively construct novel organic−inorganic hybrid materials[3−9] with the so-called "value-adding properties"[10] and possible synergistic effects.[11] Organoimido derivatives,[8,9,11−24] which were first reported by E. A. Maatta et al.,[15] are amongst the most important organic derivatives of polyoxometalates obtained by surface modification, since the π electrons in the organic component may extend their conjugation to the inorganic framework and thus dramatically modify the electronic structure and redox properties of the corresponding parent polyoxometalates.[10−12] In addition, organoimido derivatives of polyoxometalates with a remote, active functional group may be exploited to prepare covalently-linked nano-dumbbells,[13,14] polymeric chains[9] and even networks of polyoxometalates in more controllable manners.

So far, the synthesis of organoimido derivatives of polyoxometalates has focused mainly on Lindqvist polyoxometalates such as the hexamolybdate ion, $[Mo_6O_{19}]^{2-}$, the hexatungstate ion, $[W_6O_{19}]^{2-}$, and the pentatungstenmolybdate ion, $[MoW_5O_{19}]^{2-}$, obtained by reactions with phosphinimines,[15,16] isocyanates[17−19] or aromatic amines.[20,21] As we know, it is very difficult to prepare organoimido derivatives of polyoxometalates bearing an electron-withdrawing group in reasonable yield and high purity using the three approaches mentioned above. However, one of us, together with his co-workers[22,23] at UMKC, has recently developed an efficient and convenient reaction protocol to give monofunctionalized arylimido derivatives of polyoxometalates with a carbodiimide, that is, DCC (*N*,*N*′-dicyclohexylcarbodiimide), as the dehydrating agent. Furthermore, a first attempt to modify the α-octamolybdate ion, α-$[Mo_8O_{26}]^{4-}$, with this approach resulted in the selective synthesis of bifunctionalized arylimido derivatives of hexamolybdate, in a degradation and re-assembly process, with reasonable yield and high purity.[9] However, under such active reaction conditions, it was still not possible to functionalize polyoxometalates with aromatic amines bearing electron-withdrawing groups, for example, bromo and chloro groups, because of the weak nucleophilicity and easy oxidization of these kinds of amines. In this communication, we report our recent discovery that a proton can dramatically speed up the reaction of α-$[Mo_8O_{26}]^{4-}$ with aromatic amines under much milder conditions and, in the meanwhile, monofunctionalized organoimido derivatives of $[Mo_6O_{19}]^{2-}$, bearing even electron-withdrawing groups such as *para*-chloroaniline, *meta*-chloroaniline, *ortho*-chloroaniline and *para*-bromoaniline, are selectively synthesized in high purity and moderate yield with easy bench manipulations. As examples, the synthesis and structural characterization of five arylimido derivatives, $(Bu_4N)_2[Mo_6O_{18}(=NAR)]$, (where AR = *o*-$CH_3C_6H_4$ **1**, AR = *p*-ClC_6H_4 **2**, AR = *o*-ClC_6H_4 **3**, AR = *m*-ClC_6H_4 **4**, AR = *p*-BrC_6H_4 **5**) will be introduced here.[25]

Results and Discussion

When a mixture of $(Bu_4N)_4$·[α-Mo_8O_{26}], an aromatic amine and its hydrochloride salt, and DCC or other carbodiimides is refluxed in anhydrous acetonitrile under nitrogen, the corresponding monofunctionalized organoimido derivative of $[Mo_6O_{19}]^{2-}$ is formed and this reaction is usually complete in about six hours. However, under the same conditions, no anticipatory dehydrating reaction was observed for $(Bu_4N)_2$·$[Mo_6O_{19}]$. Instead, it was reduced, while the aromatic amine was oxidized. The key role of DCC here is to act as a special dehydrating agent with an activating effect on the terminal Mo−O bond, which is similar to its activating effect on the carboxyl group in the synthesis of amide or peptides.[22] In our tests, the amount of DCC is equivalent to, or slightly higher than that of the water needed to be removed from the reaction system because excess DCC usually results in unexpected side reactions and reduces the yield of the products.[22]

It was observed that no hydrochloride salt is present, *o*-toluidine or other active aromatic amines with an electron-donating group, react with α-$[Mo_8O_{26}]^{4-}$ to produce only the bifunctionalized arylimido derivatives of hexamolybdate.[9] On the other hand, under the same conditions, no reaction occurs between α-$[Mo_8O_{26}]^{4-}$ and *para*-chloroaniline or other inert aromatic amines with an electron-withdrawing group, except for the oxidation of the corresponding amines. However, for both types of aromatic amines, the addition of hydrochloride salts to the reaction mixture results in the formation of monofunctionalized organoimido derivatives of hexamolybdate, for instance, **1** and **2**. Moreover, the reaction can be speeded up by increasing the amount of hydrochloride salts. It is also worth pointing out that this novel routine can be carried out even at room temperature. The hydrochloride salt is, in fact, a proton carrier that introduces the proton into the reaction mixture. While more work needs to be done to shed light on the detailed reaction mechanism, the likely role of the proton is to complex with DCC and hence to increase the electrophilic ability of DCC to attack the oxo group of Mo−O. Additionally, it also promotes the conversion of the octamolybdate into the hexamolybdate through a degradation and re-assembly process since in an acidic organic solvent, hexamolybdates and its derivatives are much more stable than octamolybdates.[9]

The optimum reaction conditions, including the amount of each raw material and the reaction time, can be obtained by monitoring the reaction system by TLC, UV or ^{1}H NMR technology and a favorable routine is given in the Exp. Sect. Compared to previous methods presented in the literature,[15−23] this novel reaction route has many advantages: it is faster and is usually complete in less than 6 h, it is more efficient with easy bench manipulations, and the reaction conditions are much milder. Best of all, this approach tolerates electron-withdrawing functional groups such as chloro and bromo. With aromatic amine chlorides or bromides easily accessible, a great number of organoimido derivatives of hexamolybdate bearing halogen groups can now be easily synthesized in reasonable yield. Thus, this reaction opens alternative ways to make organic−inorganic hybrids based on polyoxometalates in a much more controlled fashion.[24] Related work is underway in our laboratory and will be published in subsequent papers.

The composition and structures of compounds **1**, **2**, **3**, **4**, and **5** were initially obtained according to elemental analysis, and IR, ^{1}H NMR, and UV/Vis spectroscopy studies. The IR spectra of the compounds are similar to those of previously reported mono organoimido derivatives, and the strong shoulder peak near 974 cm^{-1} proves them to be the mono-organoimido substitution derivatives.[15,16,21,26] Compared to the ^{1}H NMR spectra of corresponding free amine ligands, the protons of **1**, **2**, **3**, **4**, and **5**, except for those in the tetrabutylammonium cation, all exhibit significantly downfield chemical shifts, indicating that the shielding nature of $[Mo_5O_{18}(Mo{\equiv}N-)]^{2-}$ is much weaker than that of the amino group NH_2-. The fact that the chemical shifts of the aromatic protons in **2**, **3**, **4**, and **5** are higher than in **1** implies that the Mo≡N bond in **2**, **3**, **4**, and **5** is more electron withdrawing than in **1**, which is in good agreement with the electronic character of their imido ligands: **1** has an electron-donating methyl group (CH_3) whereas **2**, **3**, **4**, and **5** have an electron-withdrawing halogen group (Cl or Br). The lowest energy L→M electronic transition at 325 nm in $[Mo_6O_{19}]^{2-}$ is bathochromically shifted by more than 20 nm and becomes considerably more intense in **1** (350 nm), **2** (346 nm), **3** (345 nm), **4** (344 nm), and **5** (345 nm), which indicates that the Mo−N π-bond is formed in these organoimido derivatives. The bathochromic shift on going from **2**, **3**, **4**, and **5** to **1** is consistent with the trend in the π-donor ability of imido ligands.

The molecular structures of **1** and **2** have also been confirmed by single-crystal X-ray diffraction analysis[27] and their cluster anions are shown in Figure 1. In both struc-

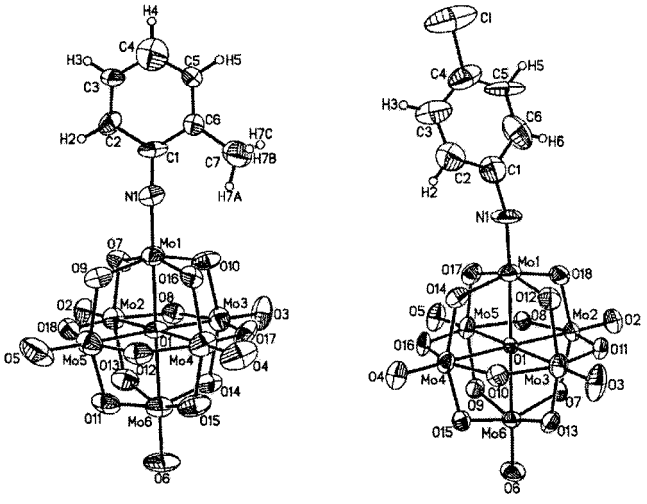

Figure 1. ORTEP drawings of the cluster anions of **1** and **2**

1 **2**

Figure 2. Showing of the dimer structure of cluster anions of **1** and **2**

tures, the arylimido ligands are indeed bound to a terminal position of the hexamolybdate in a monodentate fashion. The short Mo−N bond lengths [1.772(18) Å in **1** and 1.686(5) Å in **2**] and the C−N−Mo bond angles close to 180° (173.9° for **1** and 163.6° for **2**) are typical of organoimido groups bound to an octahedral d^0 metal center and are consistent with a substantial degree of Mo≡N triple bond character.[28] The C(1)−N(1)−Mo(1) bond angle of **2** is in agreement with angles of other derivatives bearing *para*-only-replaced phenylimido ligands and substantially smaller than the angles of **1** and other derivatives bearing *ortho*-replaced phenylimido ligands. Since the shortening of the Mo≡N bond is not observed for *ortho*-replaced phenylimido ligands derivatives, and **2** and other derivatives with *para*-only replaced phenylimido groups all crystallize in the same monoclinic space group of No. 14, this difference is probably due to the force of the crystal packing. Compared to the hexamolybdate and other derivatives, the bond lengths of the five terminal oxo ligands of **1** and **2** do not vary appreciably. The Mo(1)−O(1) distances between the Mo-bearing imido group and the central oxygen atom within the cluster anion cage are both significantly shorter than the other Mo−O(1) distances. An analogous contraction was noticed in the structures of other monofunctionalized imido derivatives of Lindqvist polyoxometalates reported in the literature,[11−24] which implies that there are no appreciable differences in their molecular structures. However, an important feature that should be pointed out here is the dimerization of cluster anions of **1** and **2** in the solid state through the π-π stacking of parallel phenyl rings of two neighboring cluster anions (see Figure 2). The existence of supramolecular π-π interactions between the pairs of cluster anions is clearly indicated by the short vertical phenyl ring separation of 3.136 and 3.796 Å in **1** and **2**, respectively. Such a structural feature has not been mentioned before in the reported mono phenylimido derivatives of hexamolybdate.[11−24]

Conclusion

In summary, we have developed a novel reaction route to give organonimido derivatives of Lindqvist polyoxometalates by introducing a proton. Compared to literature methods, even in the case of aromatic amines with an electron-withdrawing halogen group, this new method allows the reaction to be carried out under much milder conditions, even at room temperature, with much faster reaction rates and reasonable yield. With aromatic amine chlorides or bromides widely accessible and much cheaper than the corresponding iodides, this new approach provides an alternative way to efficiently construct novel, hybrid molecular materials containing covalently-bonded metal−oxygen clusters and organic conjugated segments. Extension of this approach to other polyoxometalates is still under study in our laboratory.

Experimental Section

A typical synthesis is as follows: a mixture of $(Bu_4N)_4$·[α-Mo_8O_{26}] (1.0 mmol), DCC (3.4 mmol), aromatic amine (1.34 mmol) and its salt (1.34 mmol) was refluxed under nitrogen in anhydrous acetonitrile (10 mL) for about 6 h. During the course of the reaction the color of the solution changed into red-brown, and some white precipitates (*N*,*N*′-dicyclohexylurea) were formed. The resulting dark-red solution was cooled down to room temperature and the white precipitates were removed by filtration. While most of the acetonitrile evaporated slowly in the open air, the product precipitated from the filtrate as a red colloid-like solid. The product was collected by filtration, washed successively with EtOH or benzene and Et_2O for several times, and then recrystallized twice from the mixture of acetone and EtOH (1:1), the product deposited as orange crystals usually in moderate yield of ca. 40 to 50 %.

Structural Characterization of Bismuth(III) and Antimony(III) Chlorotriflates: Key Intermediates in Catalytic Friedel–Crafts Transformations

Stéphane Mazières,*[a] Christophe Le Roux,*[a] Magali Peyronneau,[a] Heinz Gornitzka,[a] and Nicolas Roques[b]

Keywords: Bismuth / Antimony / Triflate / X-ray diffraction / Friedel–Crafts reactions

Chlorotriflates of antimony and bismuth $Cl_nM(OSO_2CF_3)_{3-n}$ (n = 1 or 2) are believed to be metallic intermediates of major importance in Friedel–Crafts reactions that use $Bi(OSO_2CF_3)_3$, $Sb(OSO_2CF_3)_3$, the systems $BiCl_3/CF_3SO_2OH$ or $SbCl_3/CF_3SO_2OH$ as catalysts. Unknown until now, the compounds $ClBi(OSO_2CF_3)_2$ (**1**) and $Cl_2Sb(OSO_2CF_3)$ (**2**) have been synthesized by reaction of MCl_3 (M = Bi, Sb) with triflic acid. After crystallization from THF, **1** and **2** were investigated in the solid state by X-ray crystallography. Their use as catalysts in benzoylation of toluene, acylation of *m*-xylene, and sulfonylation of toluene led to conclusive results, thus giving weight to their key role as intermediates in Friedel–Crafts reactions.

Introduction

The number of bismuth compounds structurally characterized by X-ray crystallographic methods has greatly increased over the past decades, showing the growing interest in these structures.[1] For our topic, we will focus on Bi^{III} and also Sb^{III} halides, which are found to be useful in a number of applications;[2] of major interest is the use of bismuth or antimony derivatives in catalysis. For Friedel–Crafts acylations, reactions which are mainly developed on an industrial scale using at least a stoichiometric amount of a Lewis acid such as $AlCl_3$ or $TiCl_4$,[3] $BiCl_3$ and recently bismuth(III) trifluoromethanesulfonate (triflate) appeared to be among the best catalysts for the acylation of aromatic compounds.[4–6] In 1988, Olah had already showed the catalytic activity of boron(III), aluminium(III) and gallium(III) triflates in alkylation and acylation reactions with 50mol % metallic triflates.[7] Later various metallic salts of triflic acid such as rare earth[8–11] and antimony(III) triflates[12,13] were reported. The catalytic efficiency of bismuth(III) triflate was confirmed, especially in the sulfonylation of arenes,[14] a reaction that belongs to the most important group of aromatic electrophilic substitutions.[3,4] In the present work we describe the preparation of mixed chlorotriflates of bismuth and antimony, which are involved in the process of acylation and sulfonylation of aromatic compounds that use Bi^{III} and Sb^{III} triflate based catalysts, and their direct use as catalysts in these reactions.

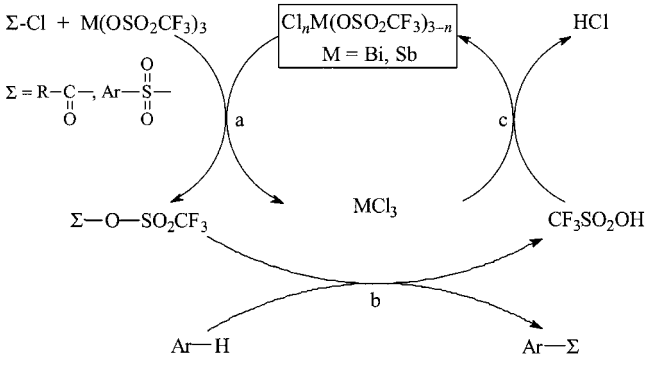
Results and Discussion

In the mechanism for both acylation and sulfonylation reactions,[6,8–13] it clearly appears that the main electrophilic agent is a mixed anhydride such as trifluoromethanesulfonic carboxylic- or trifluoromethanesulfonic arenesulfonic anhydrides ($RCO-O-SO_2CF_3$ or $ArSO_2-O-SO_2CF_3$), which are known to be strong acylating or sulfonylating reagents.[15] The formation of mixed anhydrides results from ligand exchanges at the metal (Scheme 1, path a).



Scheme 1

Following the formation of the anhydride and its reaction with the aromatic compound (Scheme 1, path b), the

mechanism involves the reaction of the metal(III) chloride with triflic acid (CF_3SO_2OH), leading to the mixed metallic intermediate (Scheme 1, path c). The metal acts as a shuttle for the triflic acid. Such types of mixed compounds have been previously related with fluorosulfonic acid and result from the reaction of $BiCl_3$ and fluorosulfonic acid; however, they have been poorly characterized.[16] In fact, it appears that these metallic intermediates play a key role with regard to the entire mechanism. Until now their existence was postulated,[8–13] but no real proof was given for their exact structure. One goal was to isolate such mixed metallic chlorotriflates. The reaction between the metal(III) chloride and an excess of triflic acid did not lead to metal tristriflate[17] but to compounds **1** and **2** in appreciable yields (Scheme 2).

$$MCl_3 + x\,CF_3SO_2OH \xrightarrow[110\ ^\circ C]{C_6H_5CH_3} Cl_nM(OSO_2CF_3)_{3-n}$$

M = Bi, Sb $x > 3$ $n = 1$: M = Bi **1** (89%) $n = 2$: M = Sb **2** (61%)

Scheme 2

With bismuth, the only product is the chlorobistriflate **1**, while antimony leads exclusively to the dichlorotriflate **2**. It appears that the trifluoromethanesulfonate ligand exhibits a strong electronic effect, which modifies the strength of the remaining M–Cl bonds. Only one ligand exchange occurred with antimony, while two with bismuth. **1** is stable up to 250 °C,[18] and this thermostability can indicate the strength of the bonds involved.

In the synthesis of these compounds, the use of toluene as solvent proved to be crucial; while $BiCl_3$ is mainly soluble in π-donor solvents, the solvation of $SbCl_3$ with donor solvents can be greatly compromised by strong complexation, which inhibits further reactivity. Indeed, these complexes known as Mentshutkin complexes[19,20] are responsible for the inefficiency of $SbCl_3$ in the catalysis of Friedel- Crafts reactions of activated aromatics.[21] Compounds **1** and **2** are crystalline, and their THF adducts were obtained from a THF/pentane solution. Single crystals suitable for an X-ray structure determination were grown at −20 °C.

The structure analysis of the THF complexes in the solid state shows a monomeric form in the case of the bismuth compound and a dimeric form for the antimony compound (Figure 1 and Figure 2). In both compounds, primary M–Cl bonds (Bi–Cl1 2.465 Å and Sb–Cl1 2.362 Å, Sb–Cl2 2.363 Å) appear shorter than M–Cl bond lengths in MCl_3 or MCl_3 with oxygen donor interactions;[22] this is in accordance with the observed stability of these M–Cl bonds. For the THF adduct of **1**, the chlorine atom, in good approximation, occupies the axial position of a distorted pentagonal bipyramid (Figure 1).

The two triflate ligands are connected to the bismuth atom through oxygen atoms, Bi–O1 2.386 Å and Bi–O4 2.613 Å, the latter bond length is longer, probably due to another weak interaction (Bi–O5 2.879 Å) which destroys the ideal geometry of the bipyramid.

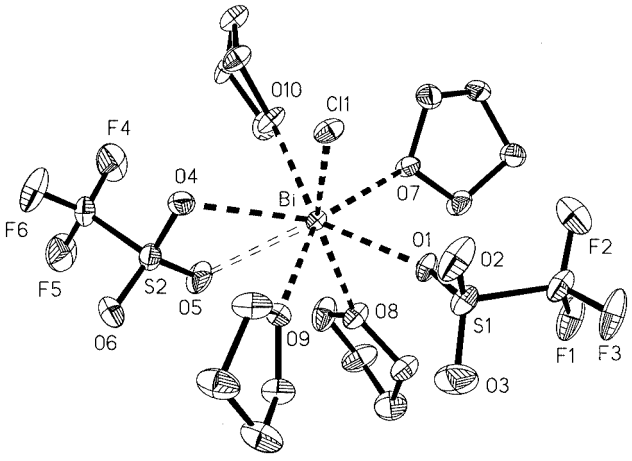


Figure 1. Molecular structure of **1**·4THF in the solid state; selected distances (Å) and angles (°): Bi–Cl1 2.465(4), Bi–O1 2.386(11), Bi–O4 2.613(13), Bi–O5 2.879(15), Cl1–Bi–O8 156.4(3), Cl1–Bi–O4 80.4(3), Cl1–Bi–O5 131.2(3)

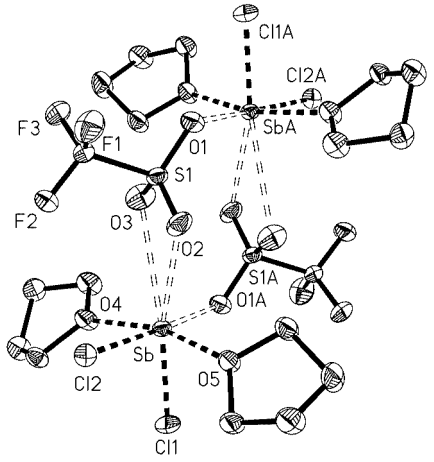

Figure 2. Molecular structure of **2**·2THF in the solid state; selected distances (Å) and angles (°): Sb–Cl1 3.3628(8), Sb–Cl2 2.3629(8), Sb–O1A 2.876(3), Sb–O2 2.911(3), Sb–O3 3.084(3), Cl1–Sb–Cl2 92.75(3), Cl1–Sb–O1A 82.57(5), Cl1–Sb–O2 158.83(5), Cl1–Sb–O3 153.55(5)

The structure of the THF adduct of **2** may be best described as a distorted octahedron in which one SO_2 group occupies an axial position (Figure 2). This structure is associated into dimeric units through two weak coordinations by two triflate ligands of different units thereby bridging the two Sb centers. The antimony atoms are thus seven-coordinate.

These newly synthesized and fully characterized mixed chlorotriflates are believed to be the mixed metallic intermediates involved in the mechanism, but nothing is known about the real mixture in solution during the process. By changing the stoichiometry of the reactants, triflic acid and metal chloride, it was not possible to isolate or even characterize $Cl_2Bi(OSO_2CF_3)$ or $ClSb(OSO_2CF_3)_2$ in solution; this is probably due to their lack of stability. In both cases we only obtained products **1** and **2**.

Finally, experiments were performed in which **1** and **2** were used as catalysts in benzoylation, acylation and sulfon-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

Table 1. Catalytic activity of **1** and **2** in benzoylation, acylation and sulfonylation reactions

Entry	Reaction	Catalyst	Mol (%)	Yield (%)	*o*/*m*/*p*
1	benzoylation of toluene	$Bi(OSO_2CF_3)_3$	10	95[6]	22/2/76
2		**1**	10	60	21/2/77
3	acylation of *m*-xylene	$Sb(OSO_2CF_3)_3$	10	77[13]	
4		**2**	30	74	
5	sulfonylation of toluene	**1**	5	99	39/6/55
6		$BiCl_3/CF_3SO_2OH$	5/10	95[23]	39/6/55
7		**2**	5	99	40/6/54
8		$SbCl_3/CF_3SO_2OH$	5/5	99	38/6/56

ylation of aromatic compounds (Table 1). In these catalytic systems, the ratio of triflate ligand, which leads to the mixed anhydride (Scheme 1, path a) is the main factor that influences the efficiency of the catalytic process.

For the benzoylation of toluene (Table 1, entries 1 and 2), the use of $ClBi(OSO_2CF_3)_2$ **1** at 10 mol % led to 60% yield, and gave a similar result to that obtained with $Bi(OSO_2CF_3)_3$.[6] The yield for **1** is lower, but **1** only has two triflate ligands instead of three as is the case for $Bi(OSO_2CF_3)_3$.

$Cl_2Sb(OSO_2CF_3)$ **2** provided identical results (74% yield) for the acylation of *m*-xylene (Table 1, entries 3 and 4) with *n*-pentCOCl to that obtained by the catalytic system described by Kobayashi.[13] For the sulfonylation of toluene (Table 1, entries 5 to 8), where the mixed species play a key role, a 99% yield of tolylphenylsulfones was obtained with **1** [similar to that obtained by the catalytic system $BiCl_3/CF_3SO_2OH$ (5 mol %/10 mol %)],[23] and a 99% yield was also obtained with **2** [the same as that obtained by the catalytic system $SbCl_3/CF_3SO_2OH$ (5 mol %/5 mol %)]. In addition, all the selectivities proved to be similar.

With regard to the yields and the selectivities, the results for the catalytic activity of **1** and **2** are conclusive, and these mixed metallic chlorotriflates are strongly believed to be the key intermediates in these Friedel−Crafts reactions.

Experimental Section

Syntheses of **1** and **2** were performed under a dry and oxygen-free argon atmosphere. Solvents were dried by appropriate methods. Melting points were determined in capillaries sealed under argon and are uncorrected.

$ClBi(OSO_2CF_3)_2$ (1): Triflic acid (10.5 g, 70.0 mmol) was added dropwise at 0 °C to a solution of bismuth(III) chloride (9.1 g, 28.9 mmol) in toluene (60 mL). The reaction mixture was then stirred for 10 min at room temperature and heated to 110 °C for 90 min. After cooling, the mixture was filtered, and the residue was washed twice with dichloromethane (100 mL). Solvents were removed in vacuo, and **1** was obtained as a white powder (14.0 g, 89% yield) and was recrystallized from a THF/pentane solution at −20 °C. M.p. >250 °C. ^{13}C NMR (100.6 MHz, [D$_6$]DMSO, TMS): δ = 125.9 (q, $^1J_{C,F}$ = 322 Hz) ppm. ^{19}F NMR (376.4 MHz, CD_3CN, CF_3COOH): δ = 0.9 ppm. IR (CH_3CN): $\tilde{\nu}$ = 635, 585, 515 (S−O in OSO_2CF_3), 310 (Bi−Cl) cm^{-1}. RAMAN: $\tilde{\nu}$ = 307 (Bi−Cl) cm^{-1}. MS (DCI/CH_4): *m*/*z* = 543 (4) $[MH]^+$, 507 (5) $[M - Cl]^+$, 393 (8) $[M-Cl-OSO_2CF_3]^+$. $C_2BiClF_6O_6S_2$ (542.57): calcd. C 4.43, Cl 6.53, F 21.01, S 11.82; found C 4.43, Cl 6.05, F 21.09, S 11.87.

$Cl_2Sb(OSO_2CF_3)$ (2): The same procedure was used as for **1**, and the reaction mixture was heated at 110 °C for 5 h. **2** (4.6 g, 61% yield) was recrystallized from a THF/pentane solution at −20 °C. M.p. 61 °C(decomp.). ^{13}C NMR (100.6 MHz, [D$_6$]DMSO, TMS): δ = 120.5 (q, $^1J_{C,F}$ = 322 Hz) ppm. ^{19}F NMR (376.4 MHz, [D$_6$]DMSO, CF_3COOH): δ = 1.5 ppm. IR (CH_3CN): $\tilde{\nu}$ = 588, 515 (S−O in OSO_2CF_3), 353 (Sb−Cl) cm^{-1}. RAMAN: $\tilde{\nu}$ = 356 (Sb−Cl) cm^{-1}. MS (DCI/CH_4): *m*/*z* = 343 (16) $[MH]^+$, 193 (19) $[M - OSO_2CF_3]^+$. It was not possible to obtain satisfactory elemental data.

Benzoylation of Toluene: PhCOCl (1.97 g, 14 mmol), toluene (2.58 g, 28 mmol), and catalyst (14 mmol) were added together in a 20 mL flask. After 5 h at 110 °C, dichloromethane (20 mL) was added, and the organic layer was extracted with a 6% aqueous HCl (2 × 10 mL), dried ($MgSO_4$), and concentrated. After purification by flash chromatography (silica, pentane/ether, 9:1), methylbenzophenones were isolated. The use of 10 mol % of $Bi(OSO_2CF_3)_3$ led to 95% yield (*o*/*m*/*p*, 22/2/76)[6] and 10 mol % of **1** led to 60% yield (*o*/*m*/*p*, 21/2/77).

Acylation of *m*-Xylene: Following the procedure described by Kobayashi,[13] *n*-pentCOCl (0.20 g, 1.49 mmol), *m*-xylene (4.69 g, 44.2 mmol), and $Sb(OSO_2CF_3)_3$ (83 mg, 1.46 mmol) were added together, and the mixture was heated at 100 °C. After 24 hours, 1-(2,4-dimethylphenyl)hexan-1-one was obtained in 77% yield. With the same procedure, the use of 30 mol % of **2** led to 74% yield.

Sulfonylation of Toluene: (a) **1** as the catalyst: following the procedure described in ref. 23, 99% yield (*o*/*m*/*p*, 39/6/55) was obtained using 5 mol % of **1**, the system $BiCl_3/CF_3SO_2OH$ (5 mol %/10 mol %) provided 95% yield (*o*/*m*/*p*, 39/6/55). (b) **2** as the catalyst: following the typical procedure, $PhSO_2Cl$ (3.25 g, 18.4 mmol), toluene (3.39 g, 36.8 mmol) and catalyst (5 mol %, 0.92 mmol) were heated at 110 °C for 12 hours. Dichloromethane (40 mL) was then added, and the organic layer was extracted with aqueous HCl (40 mL of a 2 N solution), neutralized by saturated $NaHCO_3$ solution (40 mL), and analyzed by GC with tetradecane as external standard.

X-ray Structure Determination for the THF Adducts of 1 and 2: Crystal data were collected at low temperatures [*T* = 193(2) K] using an oil-coated shock-cooled crystal on a Bruker-AXS CCD 1000 diffractometer with Mo-K_α radiation (λ = 0.71073 Å). Semi-empirical absorption corrections were employed.[24] The structures were solved by direct methods (SHELXS-97)[25] and refined using the least-squares method on F^2.[26] Experimental details are given in Table 2.

[1,2]-Rearrangement of Imino-*N*-heterocyclic Carbenes − Synthesis and Structures of Chelating Iminoimidazole Pd and Ni Complexes

Georg Steiner,[a] Alexander Krajete,[a] Holger Kopacka,[a] Karl-Hans Ongania,[b] Klaus Wurst,[a] Peter Preishuber-Pflügl,[c] and Benno Bildstein*[a]

Keywords: N ligands / Carbenes / Chelates / Transition metals / Rearrangement

Imidazolium and benzimidazolium salts with an *N*-iminoyl and an *N*′-alkyl group are potential precursors for new bidentate [*N*,*C*] ligands which are of interest as novel steering ligands for applications of their metal complexes in homogeneous catalysis. Deprotonation of these azolium salts with potassium hydride does indeed occur, however, the initially formed imino-*N*-heterocyclic carbenes rearrange spontaneously under migration of the *N*-iminoyl group from the nitrogen to the former carbene carbon with the formation of 2-iminoyl(benz)imidazoles. These rearranged compounds are new [*N*,*N*] ligand systems, which can also be synthesized by aluminum-assisted condensation of anilines with the corresponding 2-acylimidazoles. Palladium and nickel [*N*,*N*] complexes have been prepared, characterized by single-crystal X-ray analysis, and briefly evaluated for their catalytic performance in ethylene polymerizations and in Suzuki cross-coupling reactions.

Introduction

Soon after Arduengo and co-workers[1] isolated the first stable imino-*N*-heterocyclic carbene (NHC) in 1991, the chemistry of these nucleophilic species attracted the interest of many chemists due to their very rich coordination chemistry with almost all elements of the periodic table, and due to the possibility of employing modified and optimized NHC's as steering ligands in metal complexes with catalytic applications, i.e. for carbon-carbon cross-coupling reactions, olefin metathesis, and other reactions.[2] From a historic perspective,[3] metal complexes of simple (in situ generated) NHC's have been studied for over 40 years by the groups of Wanzlick,[4] Lappert,[5] Raubenheimer,[6] Öfele and Herrmann.[2b][2c]

The most common *N*-heterocyclic carbenes are imidazol-2-ylenes containing various *N*-substituents, usually simple alkyl or aryl groups.[2] In recent years tailor-made heterotopic chelating NHCs containing an additional donor functionality gained more and more importance, due to the general focus on applications of NHC metal complexes in catalysis.[2b] Chart 1 gives an overview of selected, recent examples from the current literature[7−9] of [*N*,*C*] and [*C*,*N*,*C*] metal complexes. In addition to the NHC donor, in all reported [*N*,*C*] ligand systems the *N*-donor is part of a planar heterocycle, i.e. pyridine and oxazoline, respectively. To the best of our knowledge, no other *N*-donor functionalities have been investigated as components of heterotopic [*N*,*C*] ligands for potential catalytic applications of their metal complexes, except for one very recent example,[10] published during the preparation of this manuscript.

Conceptually, our motivation for the work reported here is based on the following considerations: We have a general interest in the development of new and improved olefin polymerization catalysts.[11] Up to now, however, there are no NHC metal complexes as olefin polymerization precatalysts, only oligmerization catalysts have been reported.[12] In contrast, ring opening olefin metathesis polymerization (ROMP) is one of the most prominent uses for NHC ruthenium complexes.[13,14] The NHC ligands reported in the literature thus far are not suitable as steering ligands for late transition metal olefin polymerization catalysts based on iron or nickel,[15] because the planar *N*-donor (e.g. pyridine, compare Scheme 1) prevents the axial shielding resulting in suppressed chain termination pathways at the active metal site. The most active non-cyclopentadienyl late transition metal polymerization catalysts are [*N*,*N*,*N*] bis(imino)pyridine iron and [*N*,*N*] bisimine nickel complexes with peripheral sterically demanding *N*-aryl substituents (Scheme 2).[15] We therefore anticipate that [*N*,*C*] and [*N*,*C*,*N*] ligand systems where one *N*-donor is replaced by an NHC moiety will be very promising novel ligands for

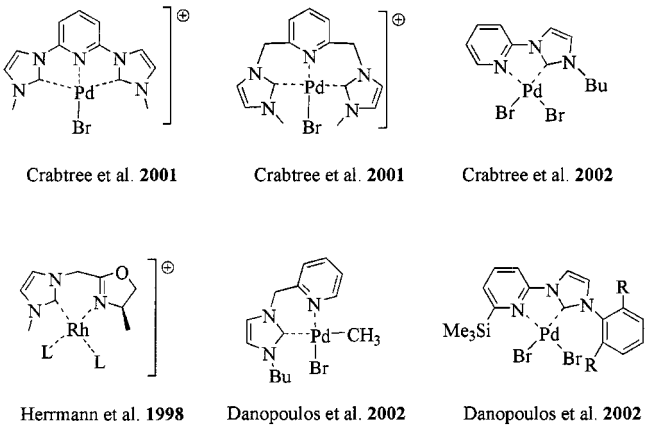
new olefin polymerization precatalysts. In this contribution, we summarize our results on the chemistry of such imino-NHCs and of their metal complexes.

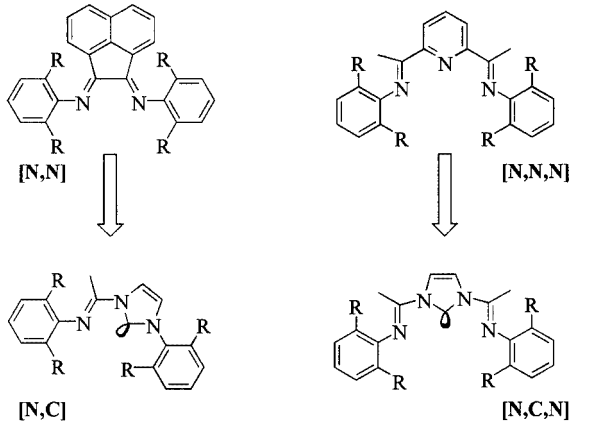


Scheme 1. Recent examples[7−9] of [*N*,*C*] chelating NHC metal complexes

Results and Discussion

The most versatile and common route to imino-*N*-heterocyclic carbenes consists of deprotonation of their corresponding (benz)imidazolium salts by suitable strong bases.[2] Simple azolium salts are easily accessible by alkylation or arylation of the parent heterocycles, whereas introduction of an additional *N*-donor with sterically demanding substituents is more challenging.

In a first approach, one might assume that condensation of known *N*,*N*′-dibenzoylbenzimidazolium salts[16] with anilines might give access to tridentate [*N*,*C*,*N*] ligand precursors (compare Scheme 2). However, it proved impossible to convert mono- or bis-acylated azolium salts into the corresponding iminoyl derivatives under a variety of experimental conditions. Therefore we chose an alternate synthetic strategy which introduces the imino functionality at an early stage in the synthetic sequence (Scheme 3).



Scheme 2. Design concept for new [*N*,*C*] and [*N*,*C*,*N*] ligands

In other work[11b] we found that iminoyl chlorides **1**[17] are very convenient and useful electrophilic reagents which react quantitatively with *N*-H nucleophiles. They also convert imidazole and benzimidazole to the corresponding *N*-iminoyl heterocycles **2a** and **2b** in very good yield. Both compounds are yellow air-stable organic materials with properties in line with their structure (for details see Exp. Sect.). Spectroscopically, the imine group is clearly evident from a strong stretching vibration in the IR spectrum (**2a**: $\nu_{C=N}$ = 1652 cm^{-1}; **2b**: $\nu_{C=N}$ = 1651 cm^{-1}) and from a low-field ^{13}C chemical shift of the imine carbon (**2a**: δ = 148.6 ppm; **2b**: δ = 149.9 ppm).

Monoiminoylazoles **2a** and **2b** already contain one sterically bulky *N*-arylated donor − in this case 2,6-diisopropylphenyl − in agreement with the design concept outlined in the introduction. To obtain access to azolium precursors for [*N*,*C*] and [*N*,*C*,*N*] ligands according to Scheme 2, either a simple alkylation step or a second acylation with iminoyl chloride is all that is formally needed.

The attempt at forming *N*,*N*′-bisiminoylazolium salts by reaction of **2a** and **2b** with a second equivalent of iminoyl chloride **1** gave inconclusive results: a reaction did occur but the very air-sensitive product could not be characterized and its follow-up chemistry ruled out the formation of an azolium precursor to a [*N*,*C*,*N*] ligand. After half a year of trying to improve reaction conditions and workup procedures we finally concluded that such tridentate ligand systems are unfortunately not accessible due to fragmentation of the precursor imidazolium species.

On the other hand, the use of azolium salts as the required starting materials for [*N*,*C*] ligands produces no major problems: alkylation at the *N*′-position of **2a** and **2b** is indeed possible using methyl triflate as a highly electrophilic reagent, affording *N*-iminoyl-*N*′-methyl-azolium salts **3a** and **3b**, respectively, in high yield (**3a**: 100%; **3b**: 77%). Other, more common alkylating agents like iodomethane yielded no reaction at all under a variety of experimental conditions, including forced conditions like sealed-tube reactions using excess methyl iodide as solvent and reagent. Both azolium salts are yellow, slightly air-sensitive compounds of surprising stability. Key spectroscopic data include the observation of molecular ions of the cations in the positive mode FAB mass spectra (**3a**: *m*/*z* = 346; **3b**: *m*/*z* = 396), detection of the low-field NMR signal of the azolium hydrogen in the 2-position of the heterocycle [**3a**: δ(^{1}H) = 9.09 ppm; **3b**: δ(^{1}H) = 9.50 ppm], and observation of the *N*-methyl NMR signals [**3a**: δ(^{1}H) = 4.08 ppm, δ(^{13}C) = 37.6 ppm; **3b**: δ(^{1}H) = 4.25 ppm, δ(^{13}C) = 34.8 ppm]. Interestingly, the ^{13}C chemical shifts of the imine carbon are almost identical to those of the non-cationic non-methylated starting materials **2a** and **2b** suggesting that the positive charge predominantly located at the *N*-methyl nitrogen. In the case of **3b** suitable crystals for an X-ray structure analysis were obtained (Table 1, Figure 1). In the solid state, the cation of **3b** has a conformation where the imine functionality is oriented away from the 5-ring *N*-heterocycle. Due to steric crowding, the aryl substituents are tilted with respect to the plane of the benzimidazole-imine

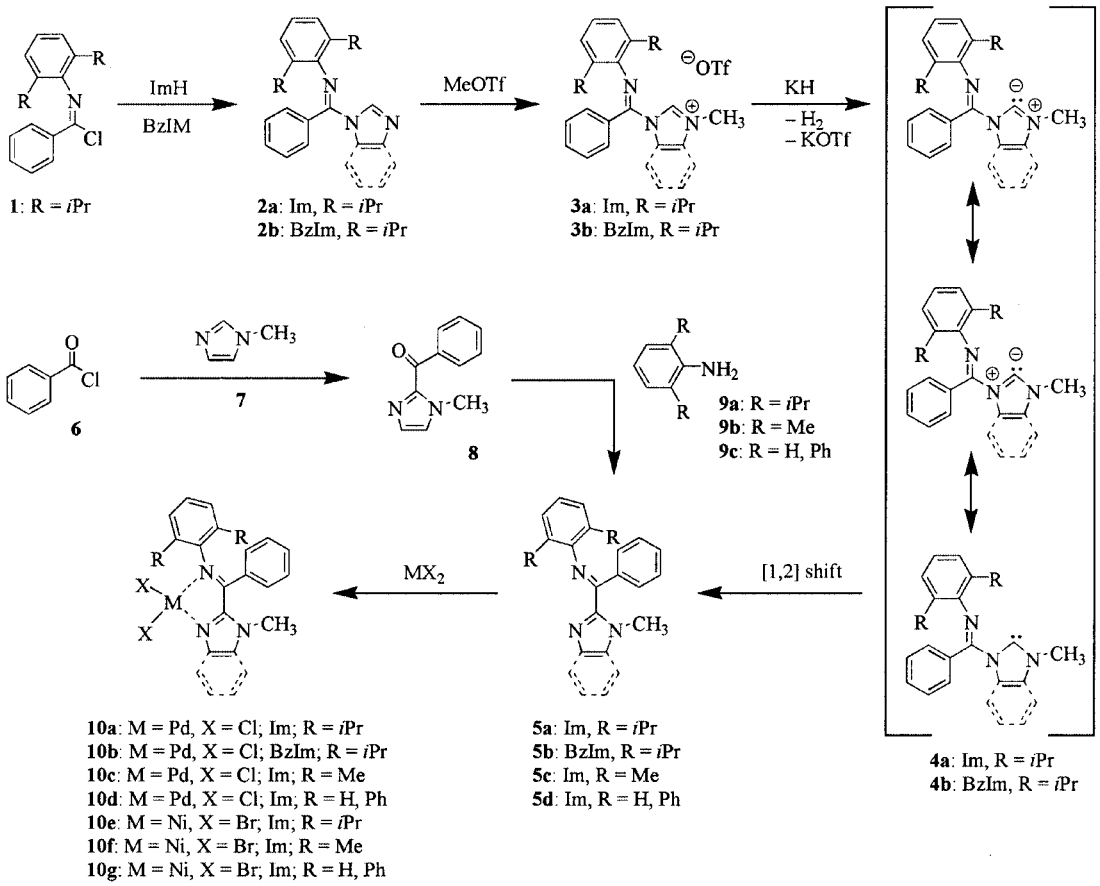

Scheme 3. Synthesis of compounds **2**–**10** (ImH = imidazole, BzImH = benzimidazole, *i*Pr = isopropyl, Me = methyl, Ph = phenyl)

moiety by 39.8° (phenyl group) and 76.6° (2,6-diisopropylphenyl group), respectively. The unsymmetric charge distribution indicated by the NMR spectroscopic data in solution is also evident in the crystalline state: The bond length of C(14)–N(2) equals 133.8(4) pm, slightly longer than the value of C(14)–N(3) with 132.0(4) pm, suggesting more double-bond character to this latter bond and more positive charge on the nitrogen N(3) of the *N*-methyl group.

Both azolium salts **3a** and **3b** serve as the key precursors for the corresponding [*N*,*C*] carbenes **4a** and **4b**, respectively (Scheme 3). Reaction of THF solutions of **3a** or **3b** with potassium hydride as base led to the evolution of H_2 gas, indicating deprotonation at the imidazole C(2) carbon. Subsequent reaction of these deprotonated (benz)imidazolium species with $PdCl_2$ afforded stable palladium complexes, as anticipated, but their properties and structures (vide infra) were not consistent with [*N*,*C*]$PdCl_2$ complexes. It soon became clear that the initial carbenes **4a** and **4b** must have rearranged by a 1,2-iminoyl shift to C(2)-substituted iminoyl(benz)imidazole **5a** and **5b**, and with "regular" [*N*,*N*] ligands easily formed the [*N*,*N*]$PdCl_2$ complexes **10a** and **10b**, respectively. Low temperature reactions aimed at trapping the initial carbenes **4a** or **4b** failed in all cases, suggesting that this 1,2-rearrangement is an unavoidable process under normal experimental conditions, thereby more or less ruling out the existence of iminocarbenes **4a** and **4b** in the condensed phase. The 1,2-shift of the iminoyl moiety of carbenes **4a** or **4b** is reminiscent of the Stevens rearrangement[18] of acceptor-substituted ammonium salts, but to the best of our knowledge no such migration has ever been described for ylides derived from (benz)imidazolium salts.

In addition we report that the attempted preparation of a Pd complex of **4a** by Raubenheimer's methodology[6] was equally unsuccessful: deprotonation of **2a** followed by complexation with $PdCl_2$ and subsequent methylation with methyl triflate did not afford the desired [*N*,*C*]$PdCl_2$ complex, instead a regular non-chelating imidazole–Pd complex was formed.[19]

The rearrangement of [*N*,*C*] carbenes **4a** and **4b** to [*N*,*N*] ligands **5a** and **5b** prompted us to look for a more versatile synthetic route for this potentially useful ligand framework. To this end, benzoyl chloride **6** was reacted with methylimidazole **7** to afford 2-benzoyl-*N*-methylimidazole (**8**) by a published procedure (Scheme 3).[20] Introduction of the imine functionality was achieved with aluminum-metalated

anilines **9a**, **9b**, and **9c** in yields of 68%-85%, thereby allowing steric fine-tuning of these [*N*,*N*] ligand systems. The aluminum-assisted condensation of carbonyl functionalities with primary amines is a very convenient method,[11a,21] which is especially useful for electronically deactivated and sterically crowded systems. Mechanistically it involves a metalation of aniline with trimethylaluminum and sequential formation of the hemiaminal and aminal of the carbonyl moiety, driven by the high oxophilicity of aluminum and by the formation of the thermodynamically very stable Al−O−Al bond of tetramethylaluminoxane.[11a,21] This aluminum-assisted formation of **5a**−**5d** is a necessary synthetic protocol for the chemistry reported in this paper, because standard condensation procedures of **8** with anilines (e.g. acid-catalyzed condensation with aceotropic removal of water) gave only partial conversion into the product in non-useful preparative yields. Compounds **5a**, **5c**, and **5d** are air-stable viscous oils with spectroscopic properties in accordance with their structure (for details see Exp. Sect.). During the course of this work an analogous [*N*,*N*] ligand has been claimed in a patent,[22] although without a phenyl substituent on the imine carbon and without a *N*′-alkyl group. Otherwise the only comparable bidentate *N*-hetero-

cyclic imine ligands reported in the literature are pyridinylimines published three years ago.[23]

Reaction of **5a**, **5c** and **5d** with either $PdCl_2$ or $NiBr_2$ afforded the [*N*,*N*]MX_2 complexes **10a**, **10c**−**10g**, respectively, in isolated yields of 65−99% (Scheme 3). Complex **10b** with a benzimidazole backbone has been prepared in 85% yield by the one-pot sequence **3b-4b-5b-10b** (vide supra). All four palladium compounds **10a**−**10d** are orange, air-stable and diamagnetic complexes, indicating the expected regular square-planar coordination geometry at the palladium center. In contrast, all three nickel complexes **10e**−**10f** are green-brown, highly air-sensitive and strongly paramagnetic compounds, suggesting a tetracoordinate tetrahedrally distorted geometry in the case of monomeric complexes, or a bromine-bridged pentacoordinate coordination sphere in the case of dimeric complexes. The paramagnetism of these nickel compounds prevented NMR spectroscopic characterization, on the other hand it is clear evidence for the "designed" steric bulk of the [*N*,*N*] ligands **5a**, **5c** and **5d**.

The different substitution patterns of the *N*-aryl groups of palladium complexes **10a**−**10d** is obviously responsible for varying solubility in this series of complexes: compounds **10a** and **10c** are soluble in common organic solvents, allowing their routine characterization by NMR spectroscopic analysis, but complexes **10b** and **10d** showed only insufficient solubilities even in polar solvents like acetonitrile, acetone and dimethyl sulfoxide, preventing detection of their NMR signals. For compounds **10a** and **10c** the ^{13}C signal of the imine carbon (**10a**: $\delta_{C=N}$ = 165.7 ppm; **10c**: $\delta_{C=N}$ = 167.5 ppm) is shifted to lower field by approximately 7 ppm in comparison with the non-complexed free ligands **5a** and **5c**.

Single crystals for X-ray analyses were obtained for complexes **10a**−**10c** (Table 1, Figures 2−4). Overall, all three compounds show the expected square-planar coordination geometry at the palladium centers, deviations from the ideal 90° angle are most pronounced for the structurally enforced [*N*,*N*] chelate (angle N−Pd−N; **10a**: 79.7°, **10b**: 79.8°, **10c**: 79.6°) whereas all other angles are, more or less, close to the ideal value (**10a**: 91.3°-97.4°, **10b**: 89.1°-95.8°, **10c**: 92.2°-95.7°). On the other hand, due to steric crowding, the phenyl groups and the peripheral *N*-aryl groups show large tilt angles of 71.9° to 87.4° in relation to the coordination plane. Clearly visible in Figures 2−4 is the different steric shielding of the palladium metal centers by the differently substituted *N*-aryl groups, indicating "steric control" in these precatalysts by employment of different building blocks. The lengths of the Pd−Cl bonds (226.9−228.4 pm) and of the Pd−N bonds (199.1−207.8 pm) are unexceptional. The bond lengths of the coordinated imine moieties are distinctly shorter (129.7−130.3 pm) in comparison with those of the coordinated N=C double bonds (132.7−133.4 pm) of the (benz)imidazole rings.

Some preliminary catalytic screenings were performed with these new palladium and nickel precatalysts. Ethylene polymerization experiments with methylaluminoxane (MAO) activated nickel complexes **10e**−**10g** in homogeneous solution (70 °C, 20 bar ethylene pressure) showed only very low activities, indicating the predominance of chain termination processes. This result is not too unexpected, because axial shielding of the active metal site in these nickel complexes is insufficient due to the sterically "open"

Figure 2. imidazole side of the bidentate iminoylimidazole ligands. On the other hand, palladium complexes **10a**, **10c**, **10d** are efficient catalysts for Suzuki carbon-carbon cross-coupling reactions: aromatic boronic acids are quantitatively coupled with aryl bromides without formation of undesired homo-coupled products. However, only bromo electrophiles are sufficiently activated for this reaction, attempts to cross-couple boronic acids with the industrially more important chloro aromatics gave no conversion at all.

Conclusion

The work reported in this contribution is motivated by the search for novel bidentate [*N*,*C*] ligand systems as steering ligands for late transition metal complexes with applications in polymerization catalysis and fine chemical synthesis. Conceptually, the new ligands should contain one imine donor with a sterically demanding *N*-aryl substituent and a *N*-heterocyclic carbene (NHC) as the second donor site. Synthetically, imidazole and benzimidazole are *N*-derivatized with iminoyl chloride followed by *N′*-alkylation with methyl triflate, affording novel iminoyl(benz)imidazolium salts of surprising stability. An X-ray structure and NMR spectroscopic data of benzimidazolium triflate indicate that the positive charge resides predominantly at the *N′*-methyl side, suggesting that the *N*-iminoyl moiety is in a "normal" chemical environment, thereby explaining the unusual stability of this azolium salt. Deprotonation of these (benz)imidazolium triflates at the (benz)imidazole C(2) carbon using potassium hydride as base is successful, however, the initially formed imino-NHC rearranges by a Stevens 1,2-shift to 2-iminoyl(benz)imidazoles which are new [*N*,*N*] ligand systems. These are also synthesized by an alternate synthetic route, which introduces the *N*-aryl group by an aluminum-assisted condensation of anilines with 2-benzoyl-1-methylimidazole. The [*N*,*N*] palladium complexes derived from these ligands are regular square-planar, diamagnetic complexes, as shown by single-crystal structure analysis of three representatives. In contrast, the [*N*,*N*] nickel complexes are highly air-sensitive and strongly paramagnetic complexes, due to ligand induced distortions. Preliminary catalytic tests of olefin polymerizations and of C−C cross-coupling reactions are performed, showing that the palladium complexes are useful catalysts for Suzuki reactions, but the nickel complexes are only poor catalysts for MAO-cocatalyzed ethylene polymerizations.

Experimental Section

General: Commercially available starting materials were used as obtained. Solvents were dried, deoxygenated and saturated with argon according to standard procedures in organometallic chemistry. Reactions of air-sensitive materials were performed in Schlenk glassware in an atmosphere of argon by techniques common in inorganic/organometallic chemistry. New compounds were characterized by MS and IR and NMR spectroscopy, etc by current state of the art procedures, details of instrumentation have been published previously.[24]

Imidazole 2a: A Schlenk tube was charged with imidazole (1.76 g, 25.8 mmol) and dry dichloromethane (40 mL). *N*-(2,6-diisopropylphenyl)benziminoyl chloride[11b,16] **1** (12.3 mmol) dissolved in dichloromethane (30 mL) was added to this solution. Imidazolium chloride immediately precipitated, indicating fast formation of the product. Stirring at ambient temperature was continued for 3 hours. Workup: 150 mL of water was added to the mixture to dissolve and remove the imidazolium chloride, the organic product was extracted with three portions of dichloromethane, the combined organic layers were washed with a brine solution, the dichloromethane solution of the product was dried with Na_2SO_4 and concentrated in vacuo to a volume of approximately 5 mL. After an equal volume of *n*-hexane was added, 3.30 g **2a** crystallized in the form of a yellow, microcrystalline solid in 81% yield, m.p: 112−115 °C. IR (KBr): $\tilde{\nu}$ = 2969 (w), 2962 (m), 1652 (s), 1602 (w), 1590 (m), 1515 (m), 1469 (s), 1439 (s), 1376 (s), 1364 (m), 1333 (m), 1314 (s), 1297 (s), 1283 (m), 1239 (s), 1160 (s), 1059 (s), 1023 (s), 940 (m), 918 (s), 835 (s), 706 (s), 700 (s) cm^{-1}. MS (FAB): *m*/*z* = 331 $[M]^+$. ^1H NMR (300 MHz, $CDCl_3$): δ = 0.89 [d, $^3J_{H,H}$ = 6.6 Hz, 6 H, $CH(CH_3)_2$], 1.07 [d, $^3J_{H,H}$ = 6.6 Hz, 6 H, $CH(CH_3)_2$], 2.82 [2 H, sept., 2 × $CH(CH_3)_2$], 6.65−7.71 (m, 10 H, C_6H_5, C_6H_3, $C_3H_3N_2$), 7.91 (s, 1 H, $C_3H_3N_2$) ppm. ^{13}C NMR (75.432 MHz, $CDCl_3$): δ = 21.7, 23.8, 28.4 [$CH(CH_3)_2$], 118.0, 122.8, 124.1, 128.3, 128.9, 129.9, 130.2, 130.7, 136.6, 137.3, 141.9 (C_6H_5, C_6H_3, $C_3H_3N_2$), 148.6 (C=N) ppm. $C_{22}H_{25}N_3$ (331.46): calcd. C 79.72, H 7.60, N 12.68; found C 80.00, H 7.63, N 12.63.

Benzimidazole 2b: A Schlenk tube was charged with benzimidazole (761 mg, 6.44 mmol) and dry dichloromethane (70 mL). *N*-(2,6-diisopropylphenyl)benziminoyl chloride[11b,17] **1** (3.07 mmol) dissolved in dichloromethane (8 mL) was added to this solution.

Benzimidazolium chloride immediately precipitated, indicating fast formation of the product. Stirring at ambient temperature was continued for 4 hours. Workup: 150 mL of water was added to the mixture to dissolve and remove the benzimidazolium chloride, the organic product was extracted with three portions of dichloromethane, the combined organic layers were washed with a brine solution, the dichloromethane solution of the product was dried with Na_2SO_4 and concentrated in vacuo to a volume of approximately 5 mL. After an equal volume of *n*-hexane was added, 1.12 g **2b** crystallized in the form of a yellow, microcrystalline solid in 96% yield. m.p.: 123−127 °C. IR (KBr): $\tilde{\nu}$ = 2963 (w), 2867 (m), 1651 (s), 1609 (s), 1588 (s), 1493 (s), 1451 (s), 1369 (s), 1290 (m), 1217 (s), 1161 (m), 1057 (m), 931 (s), 800 (s), 764 (s), 708 (s), 698 (s) cm^{-1}. MS (FAB): *m*/*z* = 381 $[M]^+$. ^1H NMR (300 MHz, $CDCl_3$): δ = 0.95−1.27 [m, 12 H, $CH(CH_3)_2$], 2.92−3.19 [m, 2 H, 2 × $CH(CH_3)_2$], 7.02−8.07 (m, 12 H, C_6H_5, C_6H_3, $C_7H_5N_2$) ppm. ^{13}C NMR (75.432 MHz, $CDCl_3$): δ = 21.8, 24.2, 28.4, 28.8 $[CH(CH_3)_2]$, 115.3, 120.4, 122.9, 123.5, 124.0, 124.7, 127.2, 128.6, 128.9, 130.8, 131.7, 136.7, 142.2, 143.0, 146.4 (C_6H_5, C_6H_3, $C_7H_5N_2$), 149.9 (C=N) ppm. $C_{26}H_{27}N_3$ (381.52): calcd. C 81.85, H 7.13, N 11.01; found C 81.98, H 7.15, N 10.97.

Imidazolium Triflate 3a: A Schlenk tube was charged with **2a** (150 mg, 0.453 mmol) and dry dichloromethane (40 mL). The solution was cooled to −80 °C and methyltrifluoromethansulfonate (50 µL, 0.453 mmol) was added via a syringe. After 20 minutes stirring at −80 °C, the cooling bath was removed and the mixture was stirred for a further 2 hours, resulting in a clear bright yellow solution. Thin layer chromatography (TLC) indicated complete reaction, all starting material had been consumed with the formation of a polar non-eluting product. Workup: all volatile materials were removed on a vacuum line, the solid yellow residue was washed with two portions of dry diethyl ether and dried in vacuo, affording 224 mg **3a** as a yellow, moderately air-sensitive powder in 100% yield. MS (FAB): *m*/*z* = 346 [M of cation]$^+$. ^1H NMR (300 MHz, CD_2Cl_2): δ = 0.93 (d, $^3J_{H,H}$ = 6.9 Hz, 6 H, $CH(CH_3)_2$], 1.12 [d, $^3J_{H,H}$ = 6.6 Hz, 6 H, $CH(CH_3)_2$], 2.81 (m, 2 H, 2 × $CH(CH_3)_2$], 4.08 (s, 3 H, CH_3), 7.07−7.87 (m, 10 H, C_6H_5, C_6H_3, $C_3H_3N_2$), 9.09 (s, 1 H, $C_3H_3N_2$) ppm. ^{13}C NMR (75.432 MHz, CD_2Cl_2): δ = 21.9, 24.1, 28.8 $[CH(CH_3)_2]$, 37.6 (N−CH_3), 118.9, 120.5, 123.7, 124.9, 125.8, 129.4, 129.5, 132.7, 136.9, 137.0, 140.8 (C_6H_5, C_6H_3, $C_3H_3N_2$), 147.3 (C=N) ppm. $C_{24}H_{28}F_3N_3O_3S$ (495.56): calcd. C 58.17, H 5.70, N 8.48; found C 58.08, H 5.72, N 8.43.

Benzimidazolium Triflate 3b: A Schlenk tube was charged with **2b** (214 mg, 0.561 mmol) and dry dichloromethane (40 mL). The solution was cooled to −80 °C and methyltrifluoromethansulfonate (62 µL, 0.561 mmol) was added via a syringe. After 20 minutes stirring at −80 °C, the cooling bath was removed and the mixture was stirred for a further 2 hours, resulting in a clear bright yellow solution. Thin layer chromatography (TLC) indicated complete reaction, all starting material had been consumed with the formation of a polar non-eluting product. Workup: all volatile materials were removed on a vacuum line, the solid yellow residue was washed with two portions of dry diethyl ether and dried in vacuo, affording 236 mg **3b** as a yellow, moderately air-sensitive powder in 77% yield. MS (FAB): *m*/*z* = 396 [M of cation]$^+$. ^1H NMR (300 MHz, CD_2Cl_2): δ = 0.95 (d, $^3J_{H,H}$ = 6.9 Hz, 6 H, $CH(CH_3)_2$], 1.14 [d, $^3J_{H,H}$ = 6.6 Hz, 6 H, $CH(CH_3)_2$], 2.92 [m, 2 H, 2 × $CH(CH_3)_2$], 4.25 (s, 3 H, CH_3), 7.11−8.09 (m, 12 H, C_6H_5, C_6H_3, $C_7H_5N_2$), 9.50 (s, 1 H, $C_7H_5N_2$) ppm. ^{13}C NMR (75.432 MHz, CD_2Cl_2): δ = 21.9, 24.4, 28.8 $[CH(CH_3)_2]$, 34.8 (N−CH_3), 113.7, 117.4, 123.7, 125.8, 128.5, 128.9, 129.6, 129.7, 130.7, 132.7, 136.9, 141.1, 143.2 (C_6H_5, C_6H_3, $C_3H_3N_2$), 149.1 (C=N) ppm. $C_{28}H_{30}F_3N_3O_3S$ (545.62): calcd. C 61.64, H 5.54, N 7.70; found C 61.53, H 5.57, N 7.66. Single crystal X-ray structure: Table 1, Figure 1.

Ketone 8:[20] A round-bottom flask was charged (without protection from air) with 1-methylimidazole **7** (10 mL, 0.125 mol) and acetonitrile (125 mL). The stirred solution was cooled to 0 °C and benzoyl chloride **6** (14.6 mL) was added from a dropping funnel within a period of 15 minutes, followed by addition of triethylamine (17.5 mL, 0.125 mol). The mixture was stirred overnight at ambient temperature, resulting in a yellow solution and a white precipitate of triethylammonium chloride. The ammonium salt was filtered off, solvents and other volatile materials were removed on a rotary evaporator, affording crude **8** as a yellow oil. Distillation in an oil pump vacuum gave 17.5 g (75%) pure **8** as a yellow viscous liquid, b.p. 120−125 °C. MS (EI): *m*/*z* = 186 $[M]^+$. ^1H NMR (300 MHz, CD_2Cl_2): δ = 4.03 (s, 3 H, CH_3), 7.13−7.18 (d, 2 H, $C_3H_2N_2$), 7.45−7.58 (m, 3 H, C_6H_5), 8.26−8.29 (d, 2 H, C_6H_5) ppm. ^{13}C NMR (75.432 MHz, CD_2Cl_2): δ = 36.6 (N−CH_3), 127.3, 128.2, 129.3, 131.1, 132.8, 137.8, 143.5 (C_6H_5, $C_3H_2N_2$), 184.1 (C=O) ppm. ^1H NMR spectroscopic data and the boiling point concur with published data.[20]

Imidazole 5a: A Schlenk tube was charged with 2,6-diisopropylaniline **9a** (2 mL, 10.6 mmol), toluene (40 mL), and 5.3 mL of a 2.0 molar toluene solution of trimethylaluminum (10.6 mmol). The stirred solution was heated to 80 °C. After 90 minutes methane evolution was completed and the solution was cooled to ambient temperature. Under protection from air, (1-methyl-2-imidazolyl)-phenylketone (**8**) (986 mg, 5.30 mmol) was added in one portion, and an immediate color change from yellow to burgundy red was observed. The mixture was stirred overnight at ambient temperature and heated to 80 °C for a further three hours, affording a bright yellow solution. Workup: the solution was cooled to 0 °C, the mixture was carefully hydrolyzed with crushed ice, the organic product was extracted with three portions of diethyl ether, the combined organic layers were washed with one portion of a 5% aqueous NaOH solution, the diethyl ether solution was washed with two portions of water, the organic phase was dried with Na_2SO_4, and all volatile materials were removed in vacuo on a rotary evaporator, affording the crude product together with 2,6-diisopropylaniline. Chromatography on alumina with diethyl ether/*n*-hexane (v/v, 1:1) as eluent afforded 1.45 g pure **5a** in 79% yield as a yellow oil. MS (EI): *m*/*z* = 345 $[M]^+$. ^1H NMR (300 MHz, $CDCl_3$): δ = 0.89 [d, $^3J_{H,H}$ = 6.9 Hz, 6 H, $CH(CH_3)_2$], 1.10 [d, $^3J_{H,H}$ = 6.6 Hz, 6 H, $CH(CH_3)_2$], 2.87 [m, 2 H, 2 × $CH(CH_3)_2$], 4.08 (s, 3 H, N−CH_3), 6.98−7.17 (m, 10 H, C_6H_5, C_6H_3, $C_3H_2N_2$) ppm. ^{13}C NMR (75.432 MHz, $CDCl_3$): δ = 21.6, 24.3, 28.2 $[CH(CH_3)_2]$, 36.8 (N−CH_3), 122.6, 123.5, 125.4, 127.3, 128.4, 129.0, 129.2, 134.8, 135.5, 144.6, 144.9 (C_6H_5, C_6H_3, $C_3H_2N_2$), 158.5 (C=N) ppm. $C_{23}H_{27}N_3$ (345.49): calcd. C 79.96, H 7.88, N 12.16; found C 80.05, H 7.86, N 12.12.

Imidazole 5c: A Schlenk tube was charged with 2,6-dimethylaniline (**9b**) (2.5 mL, 20.3 mmol), toluene (40 mL) and 10.2 mL of a 2.0 molar toluene solution of trimethylaluminum (20.3 mmol). The stirred solution was heated to 80 °C. After 90 minutes methane evolution was completed and the solution was cooled to ambient temperature. Under protection from air, (1-methyl-2-imidazolyl)-phenylketone (**8**) (1.89 g, 10.2 mmol) was added in one portion, and an immediate color change from yellow to burgundy red was observed. The mixture was stirred over the weekend at ambient temperature, affording a bright yellow solution. Workup: the solution was cooled to 0 °C, the mixture was carefully hydrolyzed with crushed ice, the organic product was extracted with three portions of diethyl ether, the combined organic layers were washed with one

portion of a 5% aqueous NaOH solution, the diethyl ether solution was washed with two portions of water, the organic phase was dried with Na_2SO_4, and all volatile materials were removed in vacuo on a rotary evaporator, affording the crude product together with 2,6-dimethylaniline. Chromatography on alumina with diethyl ether/*n*-hexane (v/v, 1:1) as eluent afforded 2.0 g pure **5c** in 68% yield as a yellow oil. MS (EI): m/z = 289 $[M]^+$. ^1H NMR (300 MHz, CD_2Cl_2): δ = 2.09 (s, 6 H, CH_3), 4.15 (s, 3 H, N−CH_3), 6.82−7.24 (m, 10 H, C_6H_5, C_6H_3, $C_3H_2N_2$) ppm. ^{13}C NMR (75.432 MHz, CD_2Cl_2): δ = 18.8 (CH_3), 37.6 (N−CH_3), 123.2, 125.9, 126.1, 127.6, 127.9, 128.5, 128.9, 129.3, 136.7, 144.8, 148.4 (C_6H_5, C_6H_3, $C_3H_2N_2$), 159.8 (C=N) ppm. $C_{19}H_{19}N_3$ (289.38): calcd. C 78.86, H 6.62, N 14.52; found C 78.99, H 6.62, N 14.48.

Imidazole 5d: A Schlenk tube was charged with 2-aminobiphenyl (**9c**) (1.9 g, 11.2 mmol), toluene (40 mL), and 5.6 mL of a 2.0 molar toluene solution of trimethylaluminum (11.2 mmol). The stirred solution was heated to 80 °C. After 90 minutes methane evolution was completed and the solution was cooled to ambient temperature. Under protection from air, (1-methyl-2-imidazolyl)phenylketone (**8**) (1.05 g, 5.61 mmol) was added in one portion, and an immediate color change from yellow to burgundy red was observed. The mixture was stirred for 48 hours at ambient temperature, affording a bright yellow solution. Workup: the solution was cooled to 0 °C, the mixture was carefully hydrolyzed with crushed ice, the organic product was extracted with three portions of diethyl ether, the combined organic layers were washed with one portion of a 5% aqueous NaOH solution, the ether solution was washed with two portions of water, the organic phase was dried with Na_2SO_4, and all volatile materials were removed in vacuo on a rotary evaporator, affording the crude product together with 2-aminobiphenyl. Chromatography on alumina with diethyl ether/*n*-hexane (v/v, 1:1) as eluent afforded 1.61 g pure **5d** in 85% yield as a yellow oil. MS (EI): m/z = 337 $[M]^+$. ^1H NMR (300 MHz, $CDCl_3$): δ = 2.69, 4.15 (s, 3 H, N−CH_3, *E*/*Z* isomers in 1:2 ratio), 6.59−7.72 (m, 16 H, C_6H_5, $C_{12}H_9$, $C_3H_2N_2$) ppm. ^{13}C NMR (75.432 MHz, $CDCl_3$): δ = 33.3, 37.2 (N−CH_3, *E*/*Z* isomers in 1:2 ratio), 120.8, 121.2, 124.2, 125.1, 125.9, 127.0, 127.8, 128.2, 128.8, 128.9, 129.2, 129.4, 129.6, 129.8, 130.4, 131.4, 132.9, 133.5, 135.4, 138.3, 140.1, 140.4, 142.2, 144.8, 147.7, 148.2, 158.3 (C_6H_5, $C_{10}H_9$, $C_3H_2N_2$), 160.2 (C=N) ppm. $C_{23}H_{19}N_3$ (337.42): calcd. C 81.87, H 5.68, N 12.45; found C 81.96, H 5.71, N 12.39.

Palladium(II) Complex 10a. **Method A:** A Schlenk tube was charged with **3a** (145 mg, 0.293 mmol), THF (40 mL), and an excess of potassium hydride (25 mg, 0.62 mmol). H_2 evolution commenced immediately and the mixture was stirred for 3 hours at ambient temperature, after this time no more gas evolution was observed. The slightly yellow suspension was filtered under protection from air through a short plug of glass wool to remove excess KH and most of the potassium trifluoromethanesulfonate. Palladium dichloride (52 mg, 0.293 mmol) was added to the resulting slightly turbid solution and the mixture was stirred at room temperature for 20 hours, resulting in a brown suspension. Workup: the volatiles were removed on a rotary evaporator, the brown residue was chromatographed on alumina with dichloromethane and acetonitrile as eluent, the brown fraction was decolorized with activated charcoal, and the solvents were removed in vacuo, affording 100 mg of **10a** as a tan solid in 65% yield.

Method B: A Schlenk tube was charged with **5a** (630 mg, 1.82 mmol), acetonitrile (30 mL) and $PdCl_2$ (323 mg, 1.82 mmol). The mixture was stirred overnight at ambient temperature to afford an orange solution. Workup: the solution was filtered through celite and chromatographed on silica with dichloromethane and acetonitrile as eluent, the orange fraction was collected, solvents were removed on a rotary evaporator, and the product was dried in vacuo, yielding 800 mg (84%) **10a** as an orange powder.

Data for 10a: MS (FAB): m/z = 522 $[M]^+$ was not observed, due to clustering signals of higher masses were detected. ^1H NMR (300 MHz, CD_2Cl_2): δ = 1.05 [d, $^3J_{H,H}$ = 6.6 Hz, 6 H, $CH(CH_3)_2$], 1.46 (d, $^3J_{H,H}$ = 6.9 Hz, 6 H, $CH(CH_3)_2$], 3.21 [m, 5 H, 2 × $CH(CH_3)_2$, N−CH_3], 6.98−7.93 (m, 10 H, C_6H_5, C_6H_3, $C_3H_2N_2$) ppm. ^{13}C NMR (75.432 MHz, CD_2Cl_2): δ = 23.3, 24.7, 29.1 [$CH(CH_3)_2$], 37.5 (N−CH_3), 123.6, 127.7, 127.9, 128.4, 128.8, 129.5, 129.7, 132.3, 140.3, 140.8, 146.3 (C_6H_5, C_6H_3, $C_3H_2N_2$), 165.7 (C=N) ppm. $C_{23}H_{27}Cl_2N_3Pd$ (522.81): calcd. C 52.84, H 5.21, N 8.04; found C 52.76, H 5.20, N 8.10. Single-crystal X-ray structure: Table 1, Figure 2.

Palladium(II) Complex 10b: A Schlenk tube was charged with **3b** (165 mg, 0.302 mmol), of THF (40 mL) and an excess of potassium hydride (25 mg, 0.62 mmol). H_2 evolution commenced immediately and the mixture was stirred for 3 hours at ambient temperature, after that period no more gas evolution was observed. The slightly yellow suspension was filtered under protection from air through a short plug of glass wool to remove excess KH and most of the potassium trifluoromethanesulfonate. $PdCl_2$ (65 mg, 0.363 mmol) was added to the resulting slightly turbid solution and the mixture was stirred at room temperature for 24 hours, resulting in a brown suspension. Workup: the volatiles were removed on a rotary evaporator, the brown residue was chromatographed on alumina with dichloromethane and acetonitrile as eluent, the brown fraction was decolorized with activated charcoal, and the solvents were removed in vacuo, affording 147 mg of **10b** as a yellow solid in 85% yield. IR (KBr): $\tilde{\nu}$ = 2961 (m), 2869 (m), 1588 (m), 1487 (s), 1410 (m), 1385 (m), 1346 (s), 1011 (s), 789 (m), 746 (s), 713 (s) cm^{-1}. MS (FAB): m/z = 573 $[M]^+$ was not observed, due to clustering signals of higher masses were detected. ^1H and ^{13}C NMR spectroscopy were attempted in deuterated acetonitrile, acetone, and dimethyl sulfoxide, respectively, but the solubility of **10b** was insufficient to obtain meaningful NMR spectroscopic data. $C_{27}H_{29}Cl_2N_3Pd$ (572.87): calcd. C 56.61, H 5.10, N 7.33; found C 56.48, H 5.07, N 7.38. Single crystal X-ray structure: Table 1, Figure 3.

Palladium(II) Complex 10c: A Schlenk tube was charged with **5c** (710 mg, 2.45 mmol), acetonitrile (30 mL), and $PdCl_2$ (435 mg, 2.45 mmol). The mixture was stirred overnight at ambient temperature to afford an orange solution. Workup: the solution was filtered through celite and chromatographed on silica with dichloromethane and acetonitrile as eluent, the orange fraction was collected, solvents were removed on a rotary evaporator, the product was dried in vacuo, and recrystallized from acetonitrile, yielding 1.03 mg (90%) **10c** as orange crystals. MS (FAB): m/z = 467 $[M]^+$ was not observed, due to clustering signals of higher masses were detected. ^1H NMR (300 MHz, CD_3CN): δ = 2.22, 2.34 (6 H, 2 × s, CH_3), 3.11 (s, 3 H, N−CH_3), 6.89−7.47 (m, 10 H, C_6H_5, C_6H_3, $C_3H_2N_2$) ppm. ^{13}C NMR (75.432 MHz, CD_3CN): δ = 19.4 (CH_3), 37.3 (N−CH_3), 127.5, 127.9, 128.2, 128.5, 128.7, 129.8, 130.9, 131.9, 132.5, 144.1, 147.4 (C_6H_5, C_6H_3, $C_3H_2N_2$), 167.5 (C=N) ppm. $C_{19}H_{19}Cl_2N_3Pd$ (466.71): calcd. C 48.90, H 4.10, N 9.00; found C 49.10, H 4.15, N 8.94. Single crystal X-ray structure: Table 1, Figure 4.

Palladium(II) Complex 10d: A Schlenk tube was charged with **5d** (545 mg, 1.62 mmol), acetonitrile (30 mL) and $PdCl_2$ (286 mg, 1.62 mmol). The mixture was stirred overnight at ambient temperature to afford an orange solution. Workup: the solution was filtered through celite and chromatographed on silica with dichlorometh-

ane and acetonitrile as eluent, the orange fraction was collected, solvents were removed on a rotary evaporator, the product was dried in vacuo, and recrystallized from a mixture of dichloromethane and acetonitrile, yielding 835 mg (98%) **10d** as orange crystals. MS (FAB): m/z = 515 $[M]^+$ was not observed, due to clustering signals of higher masses were detected. ^1H and ^{13}C NMR spectroscopy were attempted, but the solubility of **10d** was insufficient to obtain meaningful NMR spectroscopic data. $C_{23}H_{19}Cl_2N_3Pd$ (514.47): calcd. C 53.67, H 3.72, N 8.16; found C 53.37, H 3.75, N 8.21.

Nickel(II) Complex 10e: A Schlenk tube was charged with **5a** (787 mg, 2.28 mmol), acetonitrile (30 mL) and $NiBr_2$ (550 mg, 2.52 mmol). The mixture was stirred overnight, giving a green suspension. Workup: acetonitrile was removed on a vacuum line, the residue was dissolved in dry dichloromethane, the solution was filtered through a Schlenk frit to remove excess $NiBr_2$, and the solution was evaporated to dryness on a vacuum line, affording 1.22 g (95%) **10e** as a green-brown, paramagnetic, air-sensitive powder. ^1H NMR in deuterated dimethyl sulfoxide showed only very broad signals. $C_{23}H_{27}Br_2N_3Ni$ (563.98): calcd. C 48.98, H 4.83, N 7.45; found C 48.70, H 4.89, N 7.58.

Nickel(II) Complex 10f: A Schlenk tube was charged with **5c** (510 mg, 1.76 mmol), dichloromethane (40 mL) and $NiBr_2$·DME (544 mg, 1.76 mmol). The mixture was stirred for 48 hours at room temperature, giving a brown solution. Workup: dichloromethane was removed on a vacuum line, affording 814 mg (91%) **10f** as a brown, paramagnetic, air-sensitive powder. ^1H NMR spectra, in deuterated dimethyl sulfoxide, showed only very broad signals. $C_{19}H_{19}Br_2N_3Ni$ (507.88): calcd. C 44.93, H 3.77, N 8.27; found C 44.54, H 3.67, N 7.96.

Nickel(II) Complex 10g: A Schlenk tube was charged with **5d** (480 mg, 1.42 mmol), dichloromethane (40 mL) and $NiBr_2$·DME (439 mg, 1.42 mmol). The mixture was stirred for 48 hours at room temperature, giving a green solution. Workup: dichloromethane was removed on a vacuum line, affording 790 mg (99%) **10g** as a green, paramagnetic, air-sensitive powder. ^1H NMR spectra, in deuterated dimethyl sulfoxide, showed only very broad signals. $C_{23}H_{19}Br_2N_3Ni$ (555.92): calcd. C 49.69, H 3.44, N 7.56; found C 49.21, H 3.51, N 7.42.

X-ray Crystallography: Single-crystal X-ray measurements and structure determinations of **3b, 10a, 10b, 10c** (Table 1, Figures 1−4): The data collection was performed on a Nonius Kappa CCD equipped with graphite-monochromatized Mo-K_α-radiation (λ = 0.71073 Å) and a nominal crystal to area detector distance of 36 mm. Intensities were integrated using DENZO and scaled with SCALEPACK.[25] Several scans in the φ and ω directions were made to increase the number of redundant reflections, which were averaged in the refinement cycles. This procedure replaces an empirical absorption correction. The structures were solved with direct methods (SHELXS-86) and refined against F^2 (SHELX-97).[26] Hydrogen atoms at carbon atoms were added geometrically and refined using a riding model. All non-hydrogen atoms were refined with anisotropic displacement parameters.

CCDC-216464 (for **3b**), -216465 (for **10a**), -216466 (for **10b**), -216467 (for **10c**) contain the crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Acknowledgments

We thank BASF Aktiengesellschaft, Ludwigshafen, Germany for financial support and for preliminary ethene polymerizations as well as for investigations of C−C cross-coupling Suzuki reactions.

Synthesis and Characterization of $[OsCl_2(=C=CHR)(PPh_3)_2]$ and Related Complexes

Ting Bin Wen,[a] Wai Yiu Hung,[a] Zhong Yuan Zhou,[b] Man Fung Lo,[a] Ian D. Williams,[a] and Guochen Jia*[a]

Keywords: Carbyne ligands / Osmium / Vinylidene ligands

Treatment of $[OsCl_2(PPh_3)_3]$ with HC≡CR (R = Ph, *p*-tolyl, CMe_3) in the presence of HCl gives the corresponding trichloro(carbyne) complexes $[OsCl_3(\equiv CCH_2R)(PPh_3)_2]$ in good yields. The vinylidene complexes $[OsCl_2(=C=CHR)(PPh_3)_2]$ (R = Ph, *p*-tolyl, CMe_3) are, in turn, prepared from the reactions of the carbyne complexes $[OsCl_3(\equiv CCH_2R)(PPh_3)_2]$ with NEt_3. These new vinylidene complexes are hygroscopic and react with H_2O to give (aqua)(vinylidene) complexes $[OsCl_2(H_2O)(=C=CHR)(PPh_3)_2]$. The structures of several of these new complexes have been determined by X-ray diffraction studies.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

(Vinylidene)ruthenium complexes[1] of the type $[RuCl_2(=C=CHR)(PR'_3)_2]$ have attracted attention because they are catalytically active for olefin metathesis,[2a−2c] dimerization and carboxylation of terminal alkynes,[2d] and they can be used as precursors to other vinylidene complexes.[2d,2e] A number of such complexes have been prepared from the reactions of HC≡CR with dichlororuthenium complexes such as $[RuCl_2(PPh_3)_3]$,[3,4] $[RuCl_2H_2(PR'_3)_2]$ (R′ = Cy, *i*Pr),[5] $[RuCl_2(PiPr_3)_2]_n$,[6] $[RuCl_2(MeCN)_2(PiPr_3)_2]$,[6] $[RuCl_2(p\text{-cymene})]_2/PR'_3$[6] and $[\{RuCl_2(TPPMS)_2\}Na_2]_2{\cdot}4H_2O$ [TPPMS = $Ph_2P(2\text{-}OSO_2C_6H_4)Na$][7] or from the reaction of $[RuCl_2(=CHPh)(PCy_3)_2]$ with 1,2-propadiene.[2a]

In contrast to ruthenium, the chemistry of related (vinylidene)osmium complexes of the type $[OsCl_2(=C=CHR)(PR'_3)_2]$ is still underdeveloped, despite the fact that a large number of other (vinylidene)osmium complexes have been prepared.[8−21] To the best our knowledge, only $[OsCl_2(=C=CHPh)(PiPr_3)_2]$, which was produced by elimination of the imine ligands from the (imine)(vinylidene) complexes $[OsCl_2(=C=CHPh)(NH=CR_2)(PiPr_3)_2]$ [CR_2 = CMe_2, $C(CH_2)_5$] in refluxing toluene, has been reported by Esteruelas and co-workers.[13]

Prompted by the facile preparation of the (vinylidene)ruthenium complex $[RuCl_2(=C=CHCMe_3)(PPh_3)_2]$ from the reaction of $HC\equiv CCMe_3$ with $[RuCl_2(PPh_3)_3]$, we have attempted to prepare analogous (vinylidene)osmium complexes $[OsCl_2(=C=CHR)(PPh_3)_2]$ from the reactions of $[OsCl_2(PPh_3)_3]$ with HC≡CR. However, it was found that the expected vinylidene complexes $[OsCl_2(=C=CHR)(PPh_3)_2]$ could not be isolated from the reactions of $[OsCl_2(PPh_3)_3]$ with HC≡CR (R = CMe_3,[22] $SiMe_3$ [23]). Instead, the reactions afford a series of complexes including carbyne complexes $[OsCl_3(\equiv CCH_2R)(PPh_3)_2]$, osmabenzyne complexes, and vinyl(vinylidene) complexes $[OsX\{C(C\equiv CR)=CHR\}(=C=CHR)(PPh_3)_2]$ (X = Cl, C≡CR).[22,23] It was suggested that these complexes are formed via vinylidene intermediates $[OsCl_2(=C=CHR)(PPh_3)_2]$, although attempts to isolate them from the reactions failed. In this report, we will show that the vinylidene complexes $[OsCl_2(=C=CHR)(PPh_3)_2]$ can be obtained from the deprotonation reactions of (carbyne)osmium complexes $[OsCl_3(\equiv CCH_2R)(PPh_3)_2]$.

Results and Discussion

Preparation of Carbyne Complexes $[OsCl_3(\equiv CCH_2R)(PPh_3)_2]$

We have previously shown that the carbyne complexes $[OsCl_3(\equiv CCH_2CMe_3)(PPh_3)_2]$ (**4**) and $[OsCl_3(\equiv CCH_3)(PPh_3)_2]$ (**5**) are formed as one of the products from the reaction of $[OsCl_2(PPh_3)_3]$ (**1**) with $HC\equiv CCMe_3$ and $HC\equiv CSiMe_3$, respectively.[22,23] It was suspected that the carbyne complexes were produced by protonation of the vinylidene intermediates $[OsCl_2(=C=CHR)(PPh_3)_2]$ with HCl generated in situ. Thus, it was expected that carbyne

Kowloon, Hong Kong, P. R. China

complexes $[OsCl_3(\equiv CCH_2R)(PPh_3)_2]$ might be readily prepared from the reaction of $[OsCl_2(PPh_3)_3]$ (**1**) with HC≡CR in the presence of HCl. Indeed, treatment of $[OsCl_2(PPh_3)_3]$ (**1**) with HC≡CR (R = Ph, *p*-tolyl, CMe_3) and HCl gave exclusively the corresponding (carbyne)trichloro complexes $[OsCl_3(\equiv CCH_2R)(PPh_3)_2]$ (**2**−**4**) in good yields [Equation (1)].

$$OsCl_2(PPh_3)_3 + H{\equiv}R \xrightarrow[\text{benzene, } -PPh_3]{\text{HCl (ether solution)}} Cl{-}Os(Cl)(PPh_3)_2{\equiv}C{-}CH_2{-}R \quad (1)$$

1 → **2**, R = Ph; **3**, R = *p*-tolyl; **4**, R = CMe_3

The analogous reaction of **1** with $HC{\equiv}CSiMe_3$ in the presence of HCl led to the known desilylated (carbyne)-trichloro complex $[OsCl_3(\equiv CCH_3)(PPh_3)_2]$ (**5**), which was isolated as a yellow solid in 71% yield [Equation (2)]. It is assumed that reaction of **1** with $HC{\equiv}CSiMe_3$ initially generates the vinylidene intermediate $[OsCl_2(=C=CHSiMe_3)(PPh_3)_2]$, which reacts with HCl to give the (carbyne)-trichloro complex $[OsCl_3(\equiv CCH_2SiMe_3)(PPh_3)_2]$. Desilylation of the later carbyne complex by electrophilic reagents (e.g. HCl or H_2O) produces the carbyne complex **5**. There are many reports on the cleavage of Si−C bonds by H_2O or acids to give C−H bonds.[24−27]

$$OsCl_2(PPh_3)_3 + H{\equiv}SiMe_3 \xrightarrow[\text{benzene, } -PPh_3]{\text{HCl (ether solution)}} Cl{-}Os(Cl)(PPh_3)_2{\equiv}C{-}CH_3 \quad (2)$$

1 → **5**

The new complexes **2** and **3** were characterized by multinuclear NMR spectroscopy. The $^{31}P\{^1H\}$ NMR spectra (in $CDCl_3$) of complexes **2** and **3** display singlet ^{31}P signals at $\delta = -12.9$ and -12.1 ppm, respectively. The ^1H NMR spectra (in $CDCl_3$) display the $\equiv CCH_2$ proton signals at $\delta = 1.77$ (for **2**) and 1.72 ppm (for **3**). The $^{13}C\{^1H\}$ NMR spectra (in CD_2Cl_2) exhibit the resonances of the C-α atoms of the carbyne ligands as a triplet at $\delta = 278.2$ (**2**) and 280.1 ppm (**3**) and the signals of the CH_2 carbon atoms as a singlet at $\delta = 57.3$ (**2**) and 57.1 ppm (**3**). The $^{31}P\{^1H\}$ and $^{13}C\{^1H\}$ NMR spectroscopic data suggest that the two PPh_3 ligands in **2** and **3** are *trans* to each other and that the carbyne ligand is *trans* to a chloro ligand.

The structure of **2** was confirmed by an X-ray diffraction study. A view of the molecular geometry of **2** is shown in Figure 1. Selected bond lengths and angles are given in Table 1. Similarly to **4**,[22] the geometry around the osmium atom in **2** can be viewed as a distorted octahedron with two PPh_3 ligands at the axial positions and the three chlorides and the carbyne ligand in the equatorial plane. The Os−C(1)−C(2) unit in **2** is almost linear with a bond angle of 174.8(3)°. The Os−C(carbyne) bond length in **2** [1.734(3) Å] is nearly identical to that in **4** [1.728(3) Å],[22] and is within the range of those reported previously for other (carbyne)osmium complexes.[10,16,18,22,24,25,27−34] As expected, the Os−Cl(1) bond [2.4621(8) Å] is significantly longer than the mutually *trans* bonds Os−Cl(2) [2.4105(7) Å] and

Os−Cl(3) [2.3874(8) Å], due to the strong *trans* influence of the carbyne ligand.

The structure of **5** has been previously assigned on the basis of NMR spectroscopic data.[23] Its structure was now also confirmed by an X-ray diffraction study. A view of the molecular geometry of **5** is shown in Figure 2. Selected bond lengths and angles are given in Table 1. Overall, the structural features of **5** are similar to those of **2** and **4**.

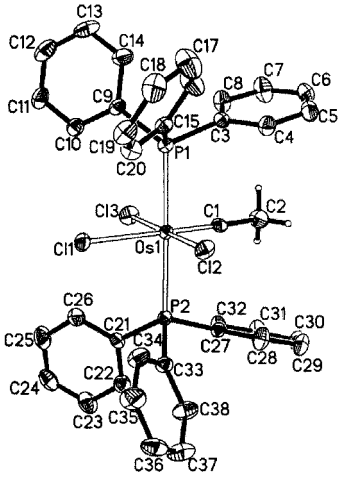

Figure 2. Molecular structure for [$OsCl_3(\equiv CCH_3)(PPh_3)_2$] (**5**)

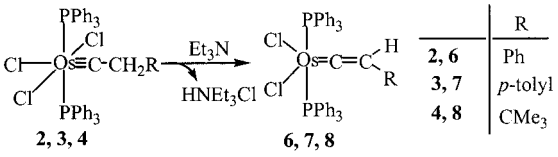
The chemistry of (carbyne)osmium complexes has received considerable attention, especially in recent years.[8,10,13,15−19,20a,20c,20d,20e,21−25,28−38] Reported compounds closely related to **2**−**5** include [$OsCl_3(\equiv CPh)(PPh_3)_2$],[35] [$OsCl_2(SCN)(\equiv CC_6H_4NMe_2)(PPh_3)_2$],[35] [$OsHCl_2(\equiv CR')(PR_3)_2$] (R = Cy, *i*Pr),[19,24,25,36] [$OsHCl(OPh)(\equiv CMe)(P{i}Pr_3)_2$],[19] and [$OsCl_2(\equiv C-CH=CRPh)[P(iPr)_2CH_2CO_2Me)[P(iPr)_2CH_2CO_2)]$] (R = Ph, Me).[34] The analogous carbyne complex [$OsCl_3(\equiv CPh)(PPh_3)_2$] was previously obtained from the reaction of HCl with [$OsCl(\equiv CPh)(O_2CO)(PPh_3)_2$], which was in turn prepared from the reaction of [$OsCl(\equiv CPh)(CO)(PPh_3)_2$] with O_2.[35b] Thus, the reactions reported here represent a much simpler route to (carbyne)osmium complexes of the type [$OsX_3(\equiv CR')(PR_3)_2$] (X = halide).

Preparation of Vinylidene Complexes [$OsCl_2(=C=CHR)(PPh_3)_2$]

Deprotonation of (carbyne)metal complexes is one of the common routes to prepare vinylidene complexes. For example, deprotonation of [$CpOsH(\equiv CCH_2Ph)[P(iPr_3)]BF_4$, [$OsH(OAc)(\equiv CCH_3)(P{i}Pr_3)_2]BF_4$, [$OsHCl_2(\equiv CCH_2Ph)(P{i}Pr_3)_2$], and [$CpMn(\equiv CCH_3)(CO)_2]BCl_4$ produces the vinylidene complexes [$CpOsH(=C=CHPh)(P{i}Pr_3)$],[17] [$OsH(OAc)(=C=CH_2)(P{i}Pr_3)_2$],[21] [$OsHCl(=C=CHPh)(P{i}Pr_3)_2$][37] and [$CpMn(=C=CH_2)(CO)_2$],[39] respectively. Thus, it was reasoned that the vinylidene complexes [$OsCl_2(=C=CHR)(PPh_3)_2$] might be obtained by treatment of the easily accessible (carbyne)trichloro complexes [$OsCl_3(=CCH_2R)(PPh_3)_2$] with bases. Indeed, the (carbyne)-trichloro complexes **2**−**4** were readily deprotonated by NEt_3 to give the corresponding moisture-sensitive dichloro(vinylidene) complexes **6**−**8**, which can be isolated in good to excellent yields [Equation (3)].



(3)

Our attempt to isolate the vinylidene complex [$OsCl_2(=C=CH_2)(PPh_3)_2$] from the deprotonation reaction of the (carbyne)trichloro complex [$OsCl_3(\equiv CCH_3)(PPh_3)_2$] (**5**) failed, however. The in situ $^{31}P\{^1H\}$ NMR spectrum for the reaction of **5** with NEt_3 in CD_2Cl_2 also showed a new broad peak at $\delta \approx 3.7$ ppm, which is similar to those observed for the in situ reactions of [$OsCl_3(\equiv CCH_2R)(PPh_3)_2$] (R = Ph or *p*-tolyl, CMe_3) with NEt_3, indicative of the formation of the vinylidene complex [$OsCl_2(=C=CH_2)(PPh_3)_2$]. However, after workup with a procedure similar to that used for the isolation of **6**−**8**, the isolated solid showed the $^{31}P\{^1H\}$ NMR signal of **5** and several unidentified broad peaks. Apparently, the initially formed vinylidene complex decomposes during workup.

The solid-state structure of the vinylidene complex **8** was determined by an X-ray diffraction study. A view of the molecular geometry of **8** is shown in Figure 3. Selected bond lengths and angles are given in Table 2. The geometry around the osmium atom in **8** may be described as a distorted trigonal bipyramid with two PPh_3 ligands at the axial positions and the other three ligands in the equatorial plane. The deviation is reflected by the P(1)−Os−P(2) angle [168.13(2)°] (which is bent away from the vinylidene ligand) and the Cl(1)−Os−Cl(2) angle [149.31(2)°]. The Cl−Os−Cl angle is close to that calculated for the model complex [$OsCl_2(=C=CH_2)(PH_3)_2$] (146.9°)[40] and the X−M−X angles observed in the analogous compounds

As mentioned previously, (vinylidene)osmium complexes with the general composition $[OsCl_2(=C=CHR)(PR_3)_2]$ are still very rare. Esteruelas et al. recently reported the vinylidene complex $[OsCl_2(=C=CHPh)(PiPr_3)_2]$, which was prepared by elimination of the imine ligands from the (imine)(vinylidene) complexes $[OsCl_2(=C=CHPh)(NH=CR_2)(PiPr_3)_2]$ [CR_2 = CMe_2, $C(CH_2)_5$] in a refluxing toluene solution.[13] As far as we know, complex **8** is the first structurally characterized osmium complex of this kind. Other reported five-coordinate (vinylidene)osmium complexes include $[OsHCl(=C=CHR)(PR'_3)_2]$ (PR'_3 = PCy_3, $PiPr_3$],[19,24,37,42] $[OsCl(=N=CR_2)(=C=CHPh)(PiPr_3)_2]$,[13] $[OsCl(=C=CHR)(2,6\text{-}[P(tBu)_2CH_2]_2C_6H_3)]$,[11] [Os[C(≡CR)=CHR)Cl(=C=CHR)$(PPh_3)_2$][22,23] and $[Os(CH=CHSiMe_3)Cl(=C=CHPh)(PiPr_3)_2]$.[43] These compounds adopt a Y-shaped geometry around the osmium atom.

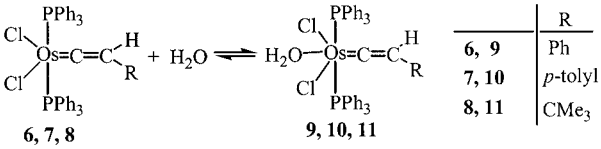
Consistent with the solid-state structure, a freshly prepared and vacuum-dried sample of **8** in freshly distilled dry CD_2Cl_2 at room temperature shows a singlet $^{31}P\{^1H\}$ signal at δ = 3.4 ppm. The ^1H NMR spectrum in CD_2Cl_2 exhibits a triplet at δ = 1.20 ppm with a P-H coupling constant of 3.6 Hz for the vinylidene =CH proton and the $^{13}C\{^1H\}$ NMR spectrum displays two triplets at δ = 274.1 ($J_{P,C}$ = 12.5 Hz) and 120.5 ppm ($J_{P,C}$ = 5.5 Hz), which are due to C-α and -β of the vinylidene ligand, respectively.

Complexes **6** and **7** presumably have similar structures, as indicated by their NMR spectroscopic data. Freshly prepared and vacuum-dried samples of **6** and **7** in freshly distilled CD_2Cl_2 at room temperature show the $^{31}P\{^1H\}$ signals at δ = 9.6 and 9.2 ppm, respectively. The ^1H NMR spectra exhibits triplets at δ = 2.56 and 2.46 ppm for the vinylidene =C*H* protons of **6** and **7**, respectively. The $^{13}C\{^1H\}$ NMR spectra displays C-α signals of the vinylidene ligands at δ = 280.8 and 281.0 ppm for **6** and **7**, respectively.

Preparation of (Aqua)(vinylidene) Complexes $[OsCl_2(H_2O)(=C=CHR)(PPh_3)_2]$

During the process of recording the $^{31}P\{^1H\}$ NMR spectra of the vinylidene complexes **6** and **7** with commercially available CD_2Cl_2, it was found that the chemical shifts of the signals of the vinylidene complexes changed with different batches of solvent and with time when a non-sealed NMR tube was used. It was suspected that this change might be caused by coordination of water present in solution to give the (aqua)(vinylidene) complexes $[OsCl_2(H_2O)(=C=CHR)(PPh_3)_2]$, which equilibrate with $[OsCl_2(=C=CHR)(PPh_3)_2]$. As a result of fast dissociation and association of water, only one ^{31}P signal with an average ^{31}P shift is observed at room temperature. Different amounts of water present in the solution will therefore affect the relative amounts of the five-coordinate vinylidene complexes and the corresponding six-coordinate (aqua)(vinylidene) complexes, therefore resulting in different ^{31}P chemical shifts in the NMR spectra. This speculation was confirmed by experiments. At low temperature, the $^{31}P\{^1H\}$ NMR spectra in commercial CD_2Cl_2 show two singlets. The chemical shift of one of the ^{31}P signals is close to that of $[OsCl_2(=C=CHAr)(PPh_3)_2]$ in freshly dried CD_2Cl_2. The other signal can therefore be attributed to $[OsCl_2(H_2O)(=C=CHR)(PPh_3)_2]$. Treatment of a blue solution of **6** or **7** in CD_2Cl_2 in an NMR tube with a drop of water gave an orange solution immediately, the $^{31}P\{^1H\}$ NMR spectra of which shows sharp singlets at $\delta \approx -3.6$ or -3.8 ppm, respectively. The chemical shifts are very close to those of the ^{31}P signals suspected for the (aqua)(vinylidene) complexes observed at low temperature. The possibility of isomerism arising from the rotation of the vinylidene group at low temperature can be excluded because such a rotation does not generate two different electronically favourable conformers.

The (aqua)(vinylidene) complexes $[OsCl_2(H_2O)(=C=CHPh)(PPh_3)_2]$ (**9**) and $[OsCl_2(H_2O)(=C=CH\text{-}p\text{-}tolyl)(PPh_3)_2]$ (**10**) were isolated as orange solids on a preparative scale by treatment of **6** and **7** with excess water [Equation (4)]. Orange solids of **9** and **10** were also obtained when blue solids of **6** and **7** were exposed to air for 18 h.



(4)

The solid-state structure of **9** (Figure 4) was confirmed by an X-ray diffraction study. Selected bond lengths and angles are given in Table 3. The geometry around the osmium atom in **9** can be viewed as a distorted octahedron with two PPh_3 ligands *trans* to each other lying in the axial

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

positions. The equatorial plane is formed by two chloro, the vinylidene and water ligands with the coordinated water molecule *trans* to the vinylidene ligand [O(1W)−Os−C(1) = 175.8(2)°]. The two mutually *trans*-disposed chloro ligands severely bend away from the vinylidene ligand and toward the water molecule with a Cl(1)−Os−Cl(2) angle of 158.56(5)° and Cl(1)−Os−O and Cl(2)−Os−O angles of 81.13(11)° and 77.53(11)°, respectively. These angles deviate greatly from the ideal value of 180° for a *trans* angle and 90° for a *cis* angle. The vinylidene ligand is bound to the metal atom in a nearly linear fashion with an Os−C(1)−C(2) angle of 174.7(6)°. The Os−C(1) [1.812(7) Å] and C(1)−C(2) [1.298(8) Å] bond lengths are similar to those of **8**, and compare well with those observed in other (vinylidene)osmium complexes.[8−16] The Os−O bond length is 2.289(4) Å, which is close to those in [OsCl(=C=CHPh)(NH=CMe_2)(H_2O)($PiPr_3$)$_2$]OTf [2.281(6) Å],[14] [OsCl(=CHPh)(H_2O)(CO)($PiPr_3$)$_2$]BF_4 [2.182(5) Å],[44a] [OsMe(H_2O)(CO)$_2$(PMe_3)$_2$]OTf [2.155(6) Å],[44b] [Cp*Os(η^3-C_4H_7)Me(H_2O)]BF_4 [44c] [2.158(5) Å] and [$OsCl_2$(H_2O)(≡CCH=CPh_2)(PPh_3)$_2$]BF_4 [2.209(5) Å].[45]

The water in **9** and **10** is only weakly bound to the metal center. Thus, when the orange solids of **9** or **10** are placed under vacuum for 3 h, the color changed to blue, indicating the reformation of **6** or **7**. Similarly, if the isolated orange solids of **9** or **10** are redissolved in CD_2Cl_2, the $^{31}P\{^1H\}$ NMR spectra at room temperature show a broad signal with a chemical shift significantly downfield from those observed in the presence of added water, indicating that water is partially dissociated and the equilibrium shown in Equation (4) occurs in solution. Thus, the NMR spectroscopic data of **9** and **10** have to be collected in the presence of added water. The $^{13}C\{^1H\}$ NMR spectrum of **9** in a CD_2Cl_2 solution saturated with H_2O shows the Os=C $^{13}C\{^1H\}$ signal as a triplet at δ = 289.1 ppm ($J_{P,C}$ = 11.4 Hz). The ^1H NMR signal of =C=CH_2 of **9** is observed at δ = 2.48 ppm at room temp. and at δ = 2.61 ppm at 211 K. The ^1H NMR signal of H_2O is observed at δ = 1.95 ppm at 211 K**.** The NMR spectroscopic data of **9** are consistent with the solid-state structure. Complex **10** presumably has a structure similar to that of **9**, as judged by its spectroscopic data.

As indicated by NMR experiments, complex **8** also reacts with water to give the (aqua)(vinylidene) complex [$OsCl_2$(H_2O)(=C=CHCMe_3)(PPh_3)$_2$] (**11**). Thus, the $^{31}P\{^1H\}$ NMR spectrum of a sample of **8** in commercially available CD_2Cl_2 at room temperature shows a singlet at δ = 2.8 ppm which is slightly upfield from that obtained with dry CD_2Cl_2. At 188 K, this singlet splits into two peaks at δ = 3.6 and −10.2 ppm, which can be attributed to [$OsCl_2$(=C=CHCMe_3)(PPh_3)$_2$] (**8**) and [$OsCl_2$(H_2O)-(=C=CHCMe_3)(PPh_3)$_2$] (**11**), respectively. Similarly, the ^1H NMR spectrum in CD_2Cl_2 at room temperature shows one C=CH signal at δ = 1.17 ppm and at 188 K two C=CH signals at δ = 1.50 and 0.91 ppm, which can be assigned to **8** and **11**, respectively. The water proton signal appears as a broad peak at δ = 2.12 ppm at room temperature, which sharpens at low temperature with a similar chemical shift and gives a relative integration of 2:1 with the less-intense vinylidene signal of **11**. As further evidence for the formation of **11**, addition of a drop of water to a solution of **8** in commercial CD_2Cl_2 in an NMR tube causes the ^{31}P signal to shift from δ = 2.8 ppm to −5.8 ppm, and the ^1H signal of =CCH to shift from δ = 1.17 ppm to 0.91 ppm. The upfield shift of the ^{31}P signal is expected because the relative amount of **11** is increased when the concentration of water in the solution is increased. However, the ^{31}P shift cannot, even in the presence of excess water, reach the value of δ = −10.2 ppm observed for **11** at low temperature, suggesting that the equilibrium constant is small (see below).

During the process of the NMR study, it was found that these vinylidene species (**8** and **11**) are unstable in solution, especially in the presence of added water. The major decomposition product is the carbyne complex **4**. Other detectable decomposition species include a small amount of PPh_3 and others showing unidentified doublet and triplet signals. The decomposition is likely initiated by the protonation of the vinylidene ligand of **11** with water present in the solution. Owing to the instability and incomplete

conversion of **8** to **11**, even in the presence of excess water, complex **11** could not be isolated.

NMR Study of the Equilibria

We carried out variable-temperature $^{31}P\{^1H\}$ and ^1H NMR experiments to study the dynamic process between $[OsCl_2(=C=CHR)(PPh_3)_2]$ and $[OsCl_2(H_2O)(=C=CHR)(PPh_3)_2]$. As an illustration, the $^{31}P\{^1H\}$ NMR spectra of a sample of **6** in wet CD_2Cl_2 (the Os/H_2O molar ratio in solution is 1:0.2) at different temperatures are shown in Figure 5. At room temperature (298 K), the ^{31}P signal is a singlet at δ = 9.1 ppm, which broadens and shifts upfield upon decreasing the temperature to 239 K. The upfield shift of the ^{31}P signal on lowering the temperature indicates that the equilibrium is shifted toward the formation of the (aqua)(vinylidene) complex **9** at lower temperature. The singlet separates into two peaks with unequal intensities when the temperature is lowered below 217 K. At 198 K, two sharp singlets in about a 5:1 ratio at δ = 11.6 and −3.4 ppm are observed, due to the ^{31}P signals of **6** and **9**, respectively. Similarly, in the ^1H NMR spectrum in CD_2Cl_2 at room temperature, the Os=C=CH vinylidene proton displays only one triplet at δ = 2.54 ppm with a P-H coupling constant of 3.3 Hz. This signal is somewhat broader when the temperature is lowered and at 190 K gives rise to two broad singlets (the broadening is probably due to unresolved coupling with the ^{31}P nuclei) at δ = 2.71 and 2.65 ppm in an approximate ratio of 5:1. The water proton signal at 190 K appears as a singlet at δ = 1.88 ppm with a relative integration of 2:1 with the less-intense vinylidene signal at δ = 2.65 ppm. The water content in the solution affects the appearance of the variable-temperature spectra. Thus, when a solution with an Os/H_2O molar ratio of 1:1.6 was used in the variable-temperature experiments, the NMR spectra show a singlet ^{31}P signal with a chemical shift between those of **6** and **9** at room temperature, as one might expect, but only show the signal of the (aqua)(vinylidene) complex **9**, while the signal of **6** cannot be detected, when the temperature is lowered below 255 K, due to the higher affinity of the metal center for H_2O at low temperature. The variable-temperature spectra of **7/10** and **8/11** show spectroscopic features similar to those of **6** and **8**.

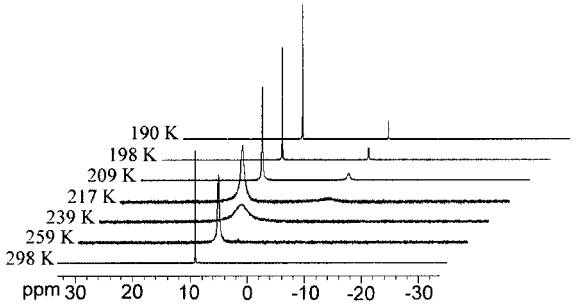

Figure 5. The variable-temperature $^{31}P\{^1H\}$ NMR spectra of $[OsCl_2(=C=CHPh)(PPh_3)_2]$ (**6**) and $[OsCl_2(H_2O)(=C=CHPh)(PPh_3)_2]$ (**9**) in wet CD_2Cl_2 (Os/H_2O molar ratio in solution = 1:0.2) at 121.5 MHz

The equilibrium constants at several temperatures (between 298 and 270 K) were estimated on the basis of variable-temperature $^{31}P\{^1H\}$ and ^1H NMR measurements of samples of **9**, **10** and **11** in CD_2Cl_2. The relative amounts of the five-coordinate vinylidene complexes and their corresponding (aqua)(vinylidene) complexes were calculated from the average ^{31}P chemical shifts assuming that the chemical shifts of five-coordinate vinylidene complexes and their corresponding (aqua)(vinylidene) complexes do not change with temperature.[46] The relative concentrations of coordinated and free water in the solution can be obtained from the integrals of the H_2O signals in the ^1H NMR spectra and the concentrations of the aqua complexes. The equilibrium constants at different temperatures calculated based

on these data are summarized in Table 4. A plot of $\ln K$ against reciprocal absolute temperature gave a straight line. According to the equation $\ln K = -(\Delta H^0/R)(1/T) + \Delta S^0/R$, the standard enthalpy and the standard entropy change of the reaction can be calculated from the slope of the straight line and the intercept, respectively. Approximate values of $\Delta H^0 = -22.7$ kcal·mol^{-1} and $\Delta S^0 = -70.96$ cal·mol^{-1}·K^{-1} were calculated for the equilibrium between **8** and **11** in CD_2Cl_2, and the value of ΔG^0 at 298 K was −1.62 kcal·mol^{-1}. For the equilibrium between **6** and **9** in CD_2Cl_2, the relevant values were calculated to be $\Delta H^0 = -15.7$ kcal·mol^{-1}, $\Delta S^0 = -42.3$ cal·mol^{-1}·K^{-1} and $\Delta G^0_{(298)} = -3.15$ kcal·mol^{-1}. These results indicate that formation of the (aqua)(vinylidene) is exothermic and that the equilibria are shifted to the (aqua)(vinylidene) complexes when the temperature is lowered, as mentioned previously.

As can be seen from Table 4, the equilibrium constant at room temperature for **6/9** is similar to that of **7/11** and is about 13 times as large as that of **8/11**, indicating that [$OsCl_2(=C=CHAr)(PPh_3)_2$] (**6** and **7**) have a higher affinity for H_2O than [$OsCl_2(=C=CHCMe_3)(PPh_3)_2$] (**8**). This difference may be related to that fact that CMe_3 is more electron-donating than Ar, thus the Lewis acidities of **6** and **7** are higher than that of **8**.

Conclusions

Reaction of [$OsCl_2(PPh_3)_3$] with terminal acetylenes HC≡CR (R = Ph, *p*-tolyl, CMe_3) in the presence of HCl readily produced the carbyne complexes [$OsCl_3(\equiv CCH_2R)(PPh_3)_2$]. Due to the acidic nature of the protons α to the carbyne carbon atom, the vinylidene complexes [$OsCl_2(=C=CHR)(PPh_3)_2$] (R = CMe_3, Ph, *p*-tolyl) can be easily prepared from these carbyne complexes by treatment with NEt_3. Interestingly, these vinylidene complexes are hygroscopic and react with water to give [$OsCl_2(H_2O)(=C=CHR)(PPh_3)_2$] reversibly. Dynamic NMR studies show that the vinylidene complexes [$OsCl_2(=C=CHR)(PPh_3)_2$] (R = Ph, *p*-tolyl) have a higher tendency to form the aqua complexes than does [$OsCl_2(=C=CHCMe_3)(PPh_3)_2$]. Thus, the (aqua)(vinylidene) complexes [$OsCl_2(=C=CHR)(H_2O)(PPh_3)_2$] (R = Ph, *p*-tolyl) could be isolated by treatment of the anhydrous vinylidene complexes with water.

Experimental Section

General: All manipulations were carried out at room temperature under nitrogen using standard Schlenk techniques, unless otherwise stated. Solvents were distilled under nitrogen from sodium/benzophenone (hexane, diethyl ether, THF, benzene) or calcium hydride (dichloromethane, $CHCl_3$). The starting material [$OsCl_2(PPh_3)_3$][47] was prepared according to literature methods. Microanalyses were performed by M-H-W Laboratories (Phoenix, AZ). ^{1}H, ^{13}C{^{1}H} and ^{31}P{^{1}H} NMR spectra were collected with a Bruker ARX-300 spectrometer (300 MHz) or a JOEL EX-400 spectrometer (400 MHz). ^{1}H and ^{13}C NMR chemical shifts are relative to TMS, and ^{31}P NMR chemical shifts are relative to 85% H_3PO_4.

[$OsCl_3(\equiv C-CH_2Ph)(PPh_3)_2$] (2): HCl·$OEt_2$ (1.00 mL,1.0 M in diethyl ether solution, 1.0 mmol) and HC≡CPh (0.32 mL, 2.9 mmol) were added to a solution of [$OsCl_2(PPh_3)_3$] (0.50 g, 0.48 mmol) in benzene (15 mL). The reaction mixture was stirred at room temperature for 6 h to give a yellow microcrystalline solid, which was collected by filtration, washed with diethyl ether (2 × 20 mL) and dried under vacuum (0.33 g). The filtrate was concentrated to ca. 5 mL, and addition of diethyl ether (20 mL) to the residue produced additional yellow solid, which was collected by filtration, washed with diethyl ether (2 × 20 mL), and dried under vacuum overnight (0.05 g). Total yield: 0.38 g (86%). ^{1}H NMR (399.65 MHz, $CDCl_3$): δ = 1.77 (s, 2 H, Os≡CCH_2), 6.46 (d, $J_{H,H}$ = 7.1 Hz, 2 H, *o*-C_6H_5), 7.08 (t, $J_{H,H}$ = 7.6 Hz, 2 H, *m*-C_6H_5), 7.19 (t, $J_{H,H}$ = 7.6 Hz, 1 H, *p*-C_6H_5), 7.29−7.38 (m, 18 H, P*Ph*$_3$), 7.81−7.86 (m, 12 H, P*Ph*$_3$) ppm. ^{13}C{^{1}H} NMR (100.4 MHz, CD_2Cl_2): δ = 278.2 (t, $J_{P,C}$ = 11.1 Hz, Os≡*C*), 134.9−125.0 (m, C_6H_5, PPh_3), 57.3 (s, Os≡C*C*H_2) ppm. ^{31}P{^{1}H} NMR (121.5 MHz, $CDCl_3$): δ = −12.9 (s) ppm. $C_{44}H_{37}Cl_3OsP_2$ (924.3): calcd. C 57.18, H 4.04; found C 57.35, H 4.19.

[$OsCl_3\{\equiv C-CH_2(p\text{-tolyl})\}(PPh_3)_2$] (3): HCl·$OEt_2$ (1.00 mL, 1.0 M in diethyl ether solution, 1.0 mmol) and 4-ethynyltoluene (0.24 mL, 1.9 mmol) were added to a solution of [$OsCl_2(PPh_3)_3$] (0.50 g, 0.48 mmol) in benzene (15 mL). The reaction mixture was stirred at room temperature for 6 h to give a yellow microcrystalline solid, which was collected by filtration, washed with diethyl ether (2 × 20 mL) and dried under vacuum (0.32 g). The filtrate was concentrated to about 5 mL, and addition of diethyl ether (20 mL) to the residue produced additional yellow solid, which was collected by filtration, washed with diethyl ether (2 × 15 mL), and dried under vacuum overnight (31 mg). Total yield: 0.35 g (78%). ^{1}H NMR (399.65 MHz, $CDCl_3$): δ = 1.72 (s, 2 H, Os≡CCH_2), 2.22 (s, 3 H, $C_6H_4CH_3$), 6.21 (d, $J_{H,H}$ = 8.0 Hz, 2 H, C_6H_4) 6.79 (d, $J_{H,H}$ = 8.0 Hz, 2 H, C_6H_4), 7.30 (m, 18 H, PPh_3), 7.80 (m, 12 H, PPh_3) ppm. ^{13}C{^{1}H} NMR (100.4 MHz, CD_2Cl_2): δ = 280.1 (t, $J_{P,C}$ = 12.0 Hz, Os≡*C*), 138.0−122.1 (m, C_6H_5, PPh_3), 57.1 (s, Os≡C*C*H_2), 21.2 (s, C_6H_4-*C*H_3) ppm. ^{31}P{^{1}H} NMR (121.5 MHz, $CDCl_3$): δ = −12.1 (s) ppm. $C_{45}H_{39}Cl_3OsP_2$ (938.3): calcd. C 57.60, H 4.19; found C 57.40, H 4.34.

[$OsCl_3(\equiv CCH_2CMe_3)(PPh_3)_2$] (4): HC≡$CCMe_3$ (0.28 mL, 2.3 mmol) and HCl·OEt_2 (0.80 mL, 0.80 mmol, 1.0 M in diethyl ether solution) were added to a solution of [$OsCl_2(PPh_3)_3$] (0.40 g, 0.38 mmol) in benzene (15 mL). The reaction mixture was stirred at room temperature for 6 h to give a yellow microcrystalline solid, which was collected by filtration, washed with diethyl ether (2 × 20 mL) and dried under vacuum (0.20 g). The filtrate was concentrated to ca. 3 mL, and addition of diethyl ether (20 mL) to the residue produced additional yellow solid, which was collected by filtration, washed with diethyl ether (2 × 20 mL), and dried under vacuum overnight (0.08 g). Total yield: 0.28 g (82%). The spectroscopic data have been reported previously.[22]

[$OsCl_3(\equiv CCH_3)(PPh_3)_2$] (5): HC≡$CSiMe_3$ (0.27 mL, 1.9 mmol) and HCl·OEt_2 (1.20 mL, 1.0 M in diethyl ether solution, 1.2 mmol) were added to a solution of [$OsCl_2(PPh_3)_3$] (0.50 g, 0.48 mmol) in benzene (15 mL). The reaction mixture was stirred at room temperature for 8 h to give a yellow microcrystalline solid, which was collected by filtration, washed with diethyl ether (2 × 20 mL) and dried under vacuum (0.25 g). The filtrate was concentrated to ca. 3 mL, and addition of diethyl ether (20 mL) to the residue produced additional yellow solid, which was collected by filtration,

washed with diethyl ether (2 × 15 mL), and dried under vacuum overnight (0.04 g). Total yield: 0.29 g (71%). ^{1}H NMR (300.13 MHz, CD_2Cl_2): δ = 0.04 (t, $J_{P,H}$ = 2.5 Hz, 3 H, CH_3), 7.36−7.43 (m, 18 H, PPh_3), 7.89−7.96 (m, 12 H, PPh_3) ppm. ^{13}C{^{1}H} NMR (100.40 MHz, CD_2Cl_2): δ = 283.7 (t, $J_{P,C}$ = 12.3 Hz, Os≡*C*), 135.1−127.9 (m, PPh_3), 36.9 (s, Os≡C-*C*H_3) ppm. ^{31}P{^{1}H} NMR (121.5 MHz, CD_2Cl_2): δ = −13.5 (s) ppm. $C_{38}H_{33}Cl_3OsP_2$ (848.2): calcd. C 53.81, H 3.92; found C 53.60, H 4.18.

[$OsCl_2$(=C=CHPh)(PPh_3)$_2$] (6): NEt_3 (0.43 mL, 3.1 mmol) was added to a CH_2Cl_2 (40 mL) solution of [$OsCl_3$(≡CCH_2Ph)(PPh_3)$_2$] (0.57 g, 0.62 mmol). The reaction mixture rapidly changed color from yellow to blue. After stirring for 1 h, the solvent was removed completely under vacuum and the resulting blue solid was extracted with benzene (30 mL). The extract was filtered through Celite to remove the insoluble Et_3N·HCl. The filtrate was concentrated to ca. 1 mL and diethyl ether was slowly added to give a blue solid, which was collected by filtration, washed with diethyl ether (2 × 10 mL) and dried under vacuum overnight. Yield: 0.47 g (85%). ^{1}H NMR (300.13 MHz, freshly distilled CD_2Cl_2): δ = 2.56 (t, $J_{P,H}$ = 3.3 Hz, 1 H, Os=C=C*H*), 6.48 (d, $J_{H,H}$ = 7.4 Hz, 2 H, *o*-C_6H_5), 6.71 (t, $J_{H,H}$ = 7.4 Hz, 1 H, *p*-C_6H_5), 7.02 (t, $J_{H,H}$ = 7.4 Hz, 2 H, *m*-C_6H_5), 7.25−7.41 (m, 18 H, PPh_3), 7.57−7.64 (m, 12 H, PPh_3) ppm. ^{13}C{^{1}H} NMR (100.4 MHz, freshly distilled CD_2Cl_2): δ = 280.8 (br., Os=*C*), 135.0−124.3 (m, C_6H_5, PPh_3), 112.1 (t, $J_{P,C}$ = 4.8 Hz, Os=C=*C*H) ppm. ^{31}P{^{1}H} NMR (121.5 MHz, freshly distilled CD_2Cl_2): δ = 9.6 (s) ppm. $C_{44}H_{36}Cl_2OsP_2$ (887.8): calcd. C 59.53, H 4.09; found C 59.54, H 4.01.

[$OsCl_2${=C=CH(*p*-tolyl)}(PPh_3)$_2$] (7): NEt_3 (0.44 mL, 3.2 mmol) was added to a CH_2Cl_2 (40 mL) solution of [$OsCl_3${≡CCH_2(*p*-tolyl)}(PPh_3)$_2$] (0.50 g, 0.53 mmol). The reaction mixture rapidly changed color from yellow to blue. After stirring for 1 h, the solvent was removed completely under vacuum and the resulting blue solid was extracted with benzene (30 mL). The extract was filtered through Celite to remove the insoluble Et_3N·HCl. The filtrate was concentrated to ca. 1 mL and diethyl ether was slowly added to give a blue solid, which was collected by filtration, washed with diethyl ether (2 × 10 mL) and dried under vacuum overnight. Yield: 0.42 g (88%). ^{1}H NMR (300.13 MHz, CD_2Cl_2): δ = 2.39 (s, 3 H, $C_6H_4CH_3$), 2.46 (t, $J_{P,H}$ = 3.4 Hz, 1 H, Os=C=C*H*), 6.40 (d, $J_{H,H}$ = 8.0 Hz, 2 H, C_6H_4), 6.87 (d, $J_{H,H}$ = 8.0 Hz, 2 H, C_6H_4), 7.33−7.41 (m, 18 H, PPh_3), 7.59−7.62 (m, 12 H, PPh_3) ppm. ^{13}C{^{1}H} NMR (100.4 MHz, freshly distilled CD_2Cl_2): δ = 281.0 (br., Os=*C*), 135.0−124.9 (m, C_6H_4, PPh_3), 112.0 (t, $J_{P,C}$ = 4.5 Hz, Os=C=*C*H), 20.9 (s, C_6H_4-*C*H_3) ppm. ^{31}P{^{1}H} NMR (121.5 MHz, freshly distilled CD_2Cl_2): δ = 9.2 (s) ppm. $C_{45}H_{38}Cl_2OsP_2$ (901.8): calcd. C 59.93, H 4.25; found C 59.76, H 4.26.

[$OsCl_2$(=C=CHCMe_3)(PPh_3)$_2$] (8): NEt_3 (0.31 mL, 1.7 mmol) was added with stirring to a solution of [$OsCl_3$(≡CCH_2CMe_3)(PPh_3)$_2$] (0.50 g, 0.55 mmol) in CH_2Cl_2 (50 mL). The reaction solution changed color from orange to brown immediately. The reaction mixture was stirred at room temperature for 1 h and the solvent was removed completely under vacuum. The brown solid was extracted with benzene (15 mL) and the extract filtered through Celite to remove the insoluble Et_3N·HCl. The volume of the brown filtrate was reduced to ca. 1 mL. Addition of diethyl ether (20 mL) to the residue produced a purple solid, which was collected by filtration, washed with diethyl ether (2 × 10 mL) and hexane (20 mL) and dried under vacuum overnight. Yield: 0.29 g (61%). ^{1}H NMR (300.13 MHz, freshly distilled CD_2Cl_2): δ = 0.54 [s, 9 H, C(CH_3)$_3$], 1.20 (t, $J_{P,H}$ = 3.6 Hz, 1 H, Os=C=C*H*), 7.42−7.51 (m, 18 H, PPh_3), 7.66−7.71 (m, 12 H, PPh_3) ppm. The signal of H_2O appears at room temp. at δ = 1.73 ppm and at 211 K at δ = 1.86 ppm with an integral of 2:1 relative to that of the vinylidene signal. ^{13}C{^{1}H} NMR (100.40 MHz, freshly distilled CD_2Cl_2): δ = 274.1 (t, $J_{P,C}$ = 12.5 Hz, Os=*C*), 134.9−128.4 (m, PPh_3), 120.5 (t, $J_{P,C}$ = 5.5 Hz, Os=C=*C*H), 32.60 [s, C(*C*H_3)$_3$], 27.47 [s, *C*(CH_3)$_3$] ppm. ^{31}P{^{1}H} NMR (121.5 MHz, freshly distilled CD_2Cl_2): δ = 3.4 (s) ppm. FAB-MS (NBA): *m*/*z* = 868 [M^+]. $C_{42}H_{40}Cl_2OsP_2$ (867.8): calcd. C 58.13, H 4.65; found C 58.49, H 4.53.

[$OsCl_2$(H_2O)(=C=CHPh)(PPh_3)$_2$] (9): Water (0.2 mL) was added to a blue solution of [$OsCl_2$(=C=CHPh)(PPh_3)$_2$] (0.15 g, 0.17 mmol) in CH_2Cl_2 (10 mL). The solution turned orange immediately. After stirring for 20 min, the solvent was pumped off to give an orange paste. Diethyl ether (10 mL) was added to the residue to give an orange solid, which was collected by filtration, washed with diethyl ether (2 × 5 mL) and dried under vacuum for 30 min. Yield: 0.14 g (91%). ^{1}H NMR (300.13 MHz, CD_2Cl_2): δ = 2.48 (t, $J_{P,H}$ = 3.3 Hz, 1 H, Os=C=C*H*), 6.70 (d, $J_{H,H}$ = 7.2 Hz, 2 H, *o*-C_6H_5), 6.76 (t, $J_{H,H}$ = 7.4 Hz, 1 H, *p*-C_6H_5), 7.08 (t, $J_{H,H}$ = 7.4 Hz, 2 H, *m*-C_6H_5), 7.28−7.40 (m, 18 H, PPh_3), 7.70−7.76 (m, 12 H, PPh_3) ppm. The signal of H_2O appears at room temp. at δ = 1.77 ppm and at 211 K at δ = 1.95 ppm with an integral of 2:1 relative to that of the vinylidene =CH signal. ^{13}C{^{1}H} NMR (100.4 MHz, CD_2Cl_2): δ = 289.1 (t, $J_{P,C}$ = 11.4 Hz, Os=*C*), 134.7−123.8 (m, C_6H_5, PPh_3), 112.3 (t, $J_{P,C}$ = 4.4 Hz, Os=C=*C*H) ppm. ^{31}P{^{1}H} NMR (121.5 MHz, CD_2Cl_2 in the presence of a drop of water): δ = −3.6 (s) ppm. $C_{44}H_{38}Cl_2OOsP_2$ (905.8): calcd. C 58.34, H 4.23; found C 58.54, H 4.42.

[$OsCl_2$(H_2O){=C=CH(*p*-tolyl)}(PPh_3)$_2$] (10): Water (0.2 mL) was added to a blue solution of [$OsCl_2${=C=CH(*p*-tolyl)}(PPh_3)$_2$] (0.15 g, 0.17 mmol) in CH_2Cl_2 (10 mL). The solution turned orange immediately. After stirring for 20 min, the solvent was pumped off to give an orange paste. Diethyl ether (10 mL) was added to the residue to give an orange solid, which was collected by filtration, washed with diethyl ether (2 × 5 mL) and dried under vacuum for 30 min. Yield: 0.14 g (89%). ^{1}H NMR (300.13 MHz, CD_2Cl_2): δ = 2.38 (s, 3 H, $C_6H_4CH_3$), 2.42 (t, $J_{P,H}$ = 3.5 Hz, 1 H, Os=C=C*H*), 6.62 (d, $J_{H,H}$ = 8.0 Hz, 2 H, C_6H_4), 6.92 (d, $J_{H,H}$ = 8.0 Hz, 2 H, C_6H_4), 7.30−7.37 (m, 18 H, PPh_3), 7.70−7.73 (m, 12 H, PPh_3) ppm. The signal of H_2O appears at room temp. at δ = 1.73 ppm and at 190 K at δ = 1.86 ppm with an integral of 2:1 relative to that of the vinylidene =CH signal. ^{13}C{^{1}H} NMR (100.4 MHz, CD_2Cl_2): δ = 293.7 (t, $J_{P,C}$ = 14.1 Hz, Os=*C*), 135.1−125.4 (m, C_6H_4, PPh_3), 112.5 (t, $J_{P,C}$ = 4.5 Hz, Os=C=*C*H), 20.8 (s, C_6H_4-*C*H_3) ppm. ^{31}P{^{1}H} NMR (121.5 MHz, CD_2Cl_2): δ = −3.8 (s) ppm. $C_{45}H_{40}Cl_2P_2OOs$ (919.9): calcd. C 58.76, H 4.38; found C 58.63, H 4.12.

Observation of 11: Owing to the instability and incomplete conversion of **8** to **11**, **11** could not be isolated but could be detected when a solution of **8** in commercially available CD_2Cl_2 was monitored by variable-temperature ^{31}P{^{1}H} and ^{1}H NMR experiments. Characterization data of **11**: ^{1}H NMR (300.13 MHz, CD_2Cl_2, 188 K): δ = 0.91 (br. s, 1 H, Os=C=C*H*), 2.38 (br., 2 H, H_2O) ppm. ^{31}P{^{1}H} NMR (121.5 MHz, CD_2Cl_2, 188 K): δ = −10.2 (br. s) ppm.

Crystal-Structure Analyses: Crystals suitable for X-ray diffraction were grown by layering hexane on CH_2Cl_2 solutions of **2**, **5** and **8**, or cooling a warm solution of **9** in benzene. Data collection was performed with a Bruker Apex CCD Area Detector for **2** and **8** and with a Bruker SMART CCD Area Detector for **5** and **9**, using graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å) in all

cases. Empirical absorption corrections (SADABS)[48] were applied. All structures were solved by direct methods, expanded by difference Fourier syntheses and refined by full-matrix least-squares on F^2 using the Bruker SHELXTL (Version 5.10)[49] program package. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were introduced at their geometric positions and refined as riding atoms. Further details on crystal data, data collection and refinements are summarized in Table 5. CCDC-227451 (**2**·1.5C_6H_6), -227452 (**5**·CH_2Cl_2), -227453 (**8**) and -227454 (**9**·C_6H_6) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: + 44-1223-336033; E-mail: deposit@ccdc.cam.ac.uk].

3-D Water-Soluble Reversible Neodymium(III) and Lanthanum(III) Coordination Polymers

Tina Vermonden,[a] Wiebe M. de Vos,[a] Antonius T. M. Marcelis,*[a] and Ernst J. R. Sudhölter[a]

Keywords: Lanthanides / NMR spectroscopy / Self-assembly / Tridendate ligands / Viscosity

The formation of soluble supramolecular 3-D coordination polymers with Nd^{3+} and La^{3+} in aqueous solution has been studied for two bifunctional ligands consisting of two pyridine-2,6-dicarboxylate groups connected at the 4-position by $O(CH_2CH_2O)_4$ and $O(CH_2CH_2O)_6$ spacers (**C4** and **C6**, respectively). Viscosity measurements were used to monitor the network formation as a function of the ligand concentration, and the ratio between metal ions and ligands. For corresponding conditions **C4** solutions with Nd^{3+} always gave much higher viscosities than **C6** solutions with Nd^{3+}. **C6** is long, and flexible enough to bind with both chelating groups to only one metal ion (ring formation). This causes the polymers to stop growing, resulting in smaller average sizes of the 3-D polymers. The ring-structures could be demonstrated by ^1H NMR spectroscopy using **C6** and La^{3+} at low concentrations.

Introduction

In the past few decades, the field of supramolecular chemistry has grown into an important part of chemistry. Supramolecular structures can be built using several noncovalent intermolecular interactions such as hydrogen bonding, π−π-stacking interactions, van der Waals interactions, and coordinative bonding (metal−ligand bonding).[1]

Metal−ligand bond strengths span a wide range, with the strength depending on both the metal ion and the ligand. In some cases the bond strengths are comparable to covalent bonds, and the reversibility of the binding can be tuned by the choice of solvent.[1] When a coordinating solvent such as water or acetonitrile is used, the reversibility of the binding increases.

In a previous study, we reported the reversible formation of linear polymers in aqueous solutions of Zn^{2+} ions with bifunctional ligands, consisting of two terdendate pyridine-2,6-dicarboxylate groups connected through an $O(CH_2CH_2O)_4$ or $O(CH_2CH_2O)_6$ spacer, **C4** or **C6**, respectively.[2] The bifunctional ligands can form not only linear polymers through metal ion coordination, but also rings. The rings can be formed by one ligand molecule and one metal ion (monomer rings) if a long and flexible spacer links the ligand groups. If the spacer is shorter or less flexible, at least two ligand molecules and two metal ions are necessary to form rings (dimer and larger rings). We showed, that the amount of ring formation depends on spacer length, concentration, temperature, and the metal ion/ligand molecule (M/L) molar ratio.[2] The total amount of rings is much higher when the ligand is long enough to form monomeric rings than when only dimers and larger rings can be formed. The larger the rings become, the smaller the probability of them being formed. This implies, that the amount of small rings will always be higher than the amount of large rings. When the molecules are able to form monomeric rings, there will still be dimer and larger rings present in solution, but their relative amounts will be much smaller. This also means, that when two ligand molecules differing in spacer length are compared, the solutions with molecules able to form monomeric rings will show a greater overall formation of rings than the solution with molecules able to form only dimer and larger rings.

The rings are dominant at low concentrations, where the probability of meeting a ligand group of another molecule is smaller than at higher concentrations. On going from a low to a high concentration, mainly rings are formed in the first instance and, after reaching a critical concentration, linear polymers are formed in addition. The total amount of rings stays approximately the same, but the amount and average length of the linear polymers increases. By considering the relative amounts we can say, that rings play an important role at low concentrations, but can be ignored at high concentrations. This relation between the formation of rings and linear chains was also found for reversible hydrogen-bonded supramolecular polymers.[3]

Another very important role in the equilibrium between rings and linear polymers is the molar ratio between metal

ions and ligand molecules (M/L). The ideal ratio for forming linear polymers is 1, but this is also the ideal ratio for ring formation. Overall it can be said, that the influence of rings is largest at a molar ratio of unity and at low concentrations.[2]

In the field of coordination chemistry, interest in the lanthanide metal ions has grown considerably in the last two decades. Because of their large size, lanthanide ions can generally support higher coordination numbers than transition metal ions. Not many self-assembled structures of lanthanide ions in aqueous solution have been reported, although some lanthanide-containing helicates in water have been reported.[4−6] A few lanthanide coordination polymers having 3-D networks have also been reported, but only solid-state properties have been studied.[7−11]

In this paper we describe the reversible formation of 3-D polymers of the bifunctional ligands **C4** and **C6** with Nd^{3+} and La^{3+}. Neodymium(III) and lanthanum(III) are both lanthanide ions, and are large enough to form complexes with three terdendate ligands (9-coordination).[12] Compared with first-row transition metal ions such as Zn^{2+} or Ni^{2+}, which give 6-coordination with terdendate ligands, Nd^{3+} and La^{3+} can bind an additional ligand group by self-assembly, which makes the formation of a 3-D network possible. Additionally, we show that the possibility of ring formation also plays an important role in this system.

Results and Discussion

The ligands we used were **C4** and **C6**, these are represented in Figure 1. The complexing groups are based on 2,6-pyridinedicarboxylic acid. The complexation behavior of this group has been well studied with numerous metal ions. The complexation constants (p*K*) of the subsequent bindings of three 2,6-pyridinedicarboxylic acid molecules to one Nd^{3+} ion are 8.78, 6.72, and 5.06 as reported by Grenthe.[13]

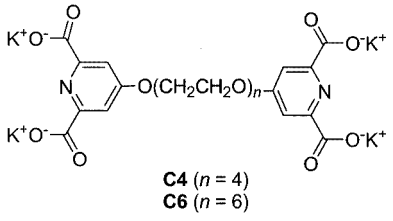

Figure 1. Schematic representation of the bifunctional ligands **C4** and **C6**

In our study we did not verify these stability constants but only the stoichiometry of binding. This was done using a monofunctional ligand with only an ethoxy group at the 4-position of the pyridine moiety in an isothermal titration calorimetric experiment (ITC). As can be seen in Figure 2, an inflection point was found at an Nd^{3+}/monoligand molar ratio of 0.33. This experiment confirms, that the Nd^{3+} center is surrounded by three terdendate monofunctional ligands.

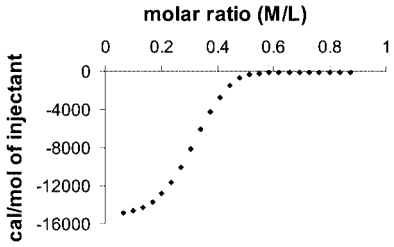

Figure 2. ITC curve of the monofunctional ligand 4-ethoxy-2,6-pyridinedicarboxylic acid (1.07 mM in cell) and $Nd(NO_3)_3$ (9.65 mM in burette) in a 0.1 M PIPES buffer of pH = 5.4 at 298 K

In a previous paper we showed, that **C4** and **C6** display different behavior towards Zn^{2+} although they differ only in spacer length [$O(CH_2CH_2O)_4$ versus $O(CH_2CH_2O)_6$].[2] One **C6** molecule is just long enough to form a ring around one zinc ion (monomer ring). On the other hand **C4** cannot form a monomeric ring, and needs at least two ligand molecules and two zinc ions to form a ring. This implies that the total amount of rings formed is much higher when **C6** is used instead of **C4** at all concentrations, as explained in the Introduction.

The situation is different when Nd^{3+} was used instead of Zn^{2+}. The ligands still form rings with the metal ion, and **C6** more so than **C4**, but the metal ion has still one binding site left. This makes the system more complicated. Although monomer rings alone will not be present anymore, they can act as chain stoppers as shown in Figure 3. **C4** is shorter, and therefore similar chain-stopping rings cannot be formed. The smallest possible rings do not prevent the polymer from growing longer as shown in Figure 3.

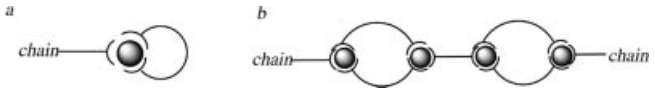

Figure 3. Schematic representation of the smallest possible rings for **C6** (a) and **C4** (b), and their influence on polymer formation

Viscosity measurements were used to study the solution properties as a function of the molar ratio. We titrated a ligand solution in a 0.1 M PIPES buffer of pH = 5.4 with an $Nd(NO_3)_3$ solution in the same buffer. A precipitate was always initially formed upon the addition of neodymium ions, but this completely dissolved after mixing. After each addition the viscosity was measured. Above an M/L molar ratio of 1, the precipitate did not dissolve anymore, and no viscosities could be measured above that ratio. At much larger ratios (M/L > 2) the precipitates dissolved easily again upon shaking. In Figure 4 the reduced viscosity of **C4** and Nd^{3+} has been plotted as a function of the molar ratio at three different concentrations of ligand (20.0 mm, 36.7 mm and 53.6 mm). We found a peak in the viscosity at

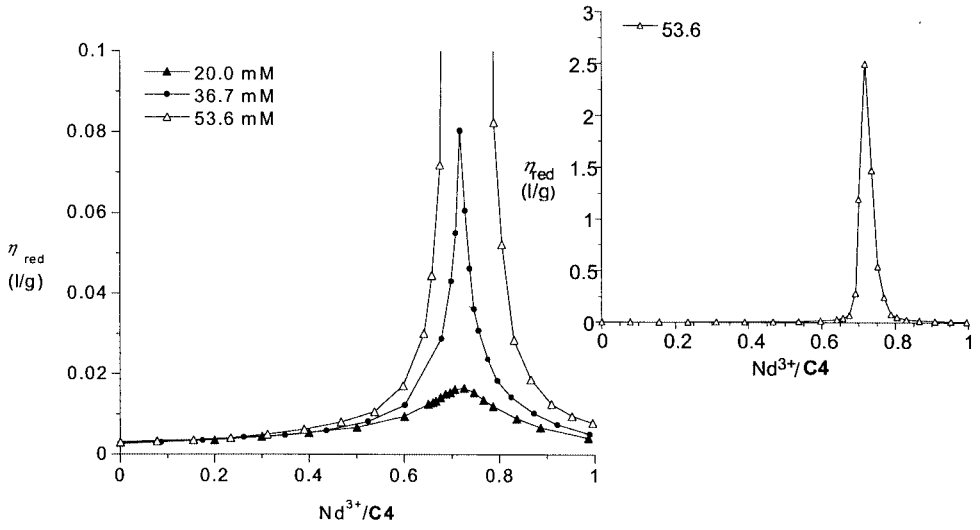

Figure 4. Reduced viscosity of **C4** as a function of molar ratio $Nd(NO_3)_3$/**C4** in a 0.1 M PIPES buffer of pH = 5.4 at 298 K at different concentrations

a molar ratio of about 2:3 (M/L), which can be expected when mixing a bifunctional ligand with a metal ion capable of binding three ligand groups. However, the most noticeable fact is the enormous effect of concentration. At the lowest concentration (20 mM), the highest reduced viscosity was 0.017 L/g. When the concentration was increased further to 37.6 mM, the highest reduced viscosity was already 0.071 L/g, and when the concentration was increased to 53.6 mM, the reduced viscosity went up to at least 2.5 L/g. This shows, that the size of the aggregates increases enormously with concentration through the formation of 3-D networks. The presence of a peak indicates, that the process is reversible. An excess of metal ions (> 0.67) causes the network to break down.

Upon close inspection of the graphs it can be seen, that the peak is shifted a little compared to the 2:3 ratio. With increasing concentration, the peak shifted to a slightly higher molar ratio. We will explain this after discussing the viscosity plots of **C6**.

Figure 5 shows the viscosity of **C6** and Nd^{3+} as a function of molar ratio at four different concentrations. Most noticeable here is, that although the viscosity increases with increasing concentration, this effect is much smaller than observed for **C4**. The curves are also much more asymmetric than those of **C4**. Another effect is the clear shift of the peak to higher molar ratios with increasing concentration. This shift is larger than for **C4**. The shifts of the peaks are plotted in Figure 6 for both ligands as a function of concentration.

The explanation for the low viscosity, asymmetric curves, and the large shift of the peak of **C6** compared with that of **C4** can only be found in the much stronger tendency of **C6** to form small rings. Since **C6** is able to form monomeric rings, which can act as chain stoppers (see Figure 3a), the structures cannot grow as large as for **C4**. This causes the much lower viscosity of **C6** and Nd^{3+} at all concentrations. The ideal molar ratio for formation of those rings is 0.67. At larger molar ratios (M/L), the amount of the rings de-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

creases, allowing the formation of longer chains, and therefore the highest reduced viscosity is reached at higher molar ratios. This also explains the asymmetric curves. At higher molar ratios (above 0.67) the rings open and become part of the 3-D polymers. This effect contributes to higher viscosities. At these higher molar ratios, however, the metal ions will not all be coordinated to three chelating groups, which causes the viscosity to drop. Both effects counteract each other, leading to a slower decrease in viscosity than expected based on only the explanation of the excess of metal ions.

C4 also shows a shift in the viscosity peak, but it is much smaller. The origin of the shift here can, however, not be found in end capping by ring formation, since the rings can be part of a polymer chain (see Figure 3b). Therefore, the shift found for **C4** has an explanation different from that for **C6**. The shift for **C4** may be explained by the fact, that more expanded structures can be formed when not every metal ion is complexed with three ligand groups. This expansion causes a higher viscosity even though the molar mass of the structures is not larger. This is also the case for conventional covalently bonded polymer solutions. Expanded polymers take a larger volume, and therefore their solutions give higher viscosities than solutions of polymers with the same length but which are more compact.

For **C4**, a concentration-dependent viscosity plot was also measured at a constant M/L molar ratio of 0.71, corresponding to the average molar ratio of the top of the peak at concentrations above 20 mM. Although the top of the peak for concentrations below 20 mM is lower than at M/L = 0.71, the influence of this is negligible due to the broadness of the peak at lower concentrations. This plot is shown in Figure 7 to illustrate the enormous effect of concentration on the viscosity, and thus on the sizes of the self-assembled structures. With increasing concentration, the influence of the rings becomes smaller, and the 3-D polymers become larger, resulting in the steep increase in viscosity (see Figure 8).

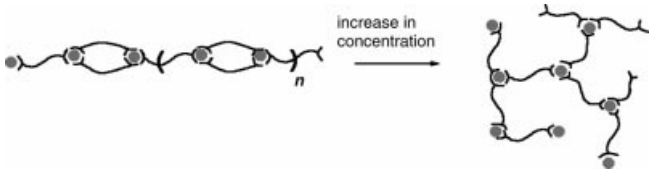

Figure 8. Changes in the structures of **C4**/Nd^{3+} coordination aggregates as a function of concentration

Some NMR experiments were performed in order to examine more closely the shifts of the peaks in the viscosity plots with respect to the molar ratio. The different causes for the shifts for **C6** and **C4** can be illustrated by ^1H NMR experiments. These experiments were performed using lanthanum(III) as the metal ion instead of neodymium(III), because neodymium broadens the signals in the spectrum; La^{3+} has properties similar to those of Nd^{3+}. They both belong to the lanthanides, and are known to exhibit 9-coordination.[12,13] The stoichiometry was checked by isothermal titration calorimetry and indeed showed, that three ligand groups are bound to one lanthanum ion. The curve was less steep than that shown in Figure 2 for neodymium due to lower complexation constants, which is in agreement with reported values in the literature. The reported complexation constants (pK) of La^{3+} with three dipicolinic acid molecules (structure of complexing group similar to the ones we use) are 7.98, 5.81, and 4.27.[13]

The reduced viscosity plots of both metal ions gave comparable results for both ligand molecules. At the measured concentrations, the shift in the molar ratio of the peak was found for both Nd^{3+} and La^{3+} and for both ligands. However, the viscosity of **C4** with lanthanum was found to be lower than for **C4** with neodymium at a concentration of 36.7 mM (Figure 9).

The NMR spectra in D_2O were recorded for both ligands as a function of concentration at an M/L ratio of 0.71, and as a function of the M/L ratio at a ligand concentration of 40 mM. A precipitate was also formed upon addition of La^{3+} ions to a ligand solution, but this subsequently dissolved after mixing. For ligand **C4** few changes occurred in the spectra when metal ions were added to a 40 mM solution in D_2O at pH = 5.8 (Figure 10). The signals between δ = 3.0 and 4.5 ppm originate from the OCH_2 protons in the spacer, the signal at δ ≈ 7.4 ppm originates from the aromatic protons in the pyridine ring. The signals became a little broader upon addition of La^{3+} ions, but no new signals appeared. The aromatic signal at δ = 7.35 ppm also shifted to 7.45 upon complexation, up to a molar ratio of 0.72. Above that ratio, the signal shifted back to δ = 7.40 ppm. The proton signals of the spacer shifted a little to high field. The broadening of signals instead of the formation of separated signals for free and coordinated ligand upon addition of metal ions, points to an exchange process between the ligand molecules at a moderate rate on the NMR time scale.[14]

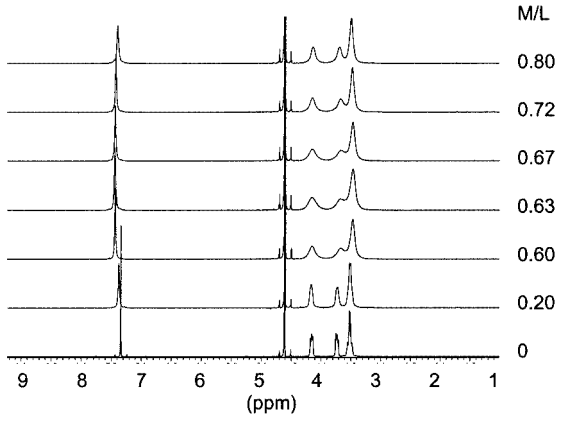

Figure 10. ^1H NMR spectra of compound **C4** with La^{3+} at 40 mM in D_2O at 298 K, pH = 5.8 at various molar ratios

No significant changes occurred in the ^1H NMR spectra upon dilution of a solution with a constant M/L ratio of 0.71 in D_2O (see Supporting Information). This implies that at all concentrations either the exchange between different species is fast, or that only one kind of species (3-D polymer) is present.

For **C6**, a new signal appears both in the molar ratio dependent spectra (Figure 11), and in the dilution spectra (Supporting Information). We observed the new signal as a broad bump in the molar ratio dependent series at δ = 3.1 ppm, with the highest intensity at a molar ratio of 0.67. The highest amount of small ring-like species would be expected at a molar ratio of 0.67, which is the ideal ratio for ring formation around metal ions with 9-coordination. These small structures containing many rings could, for example, look like the representation in Figure 12.

We indeed observed, that upon increasing the molar ratio, the bump became bigger up to a molar ratio of 0.67.

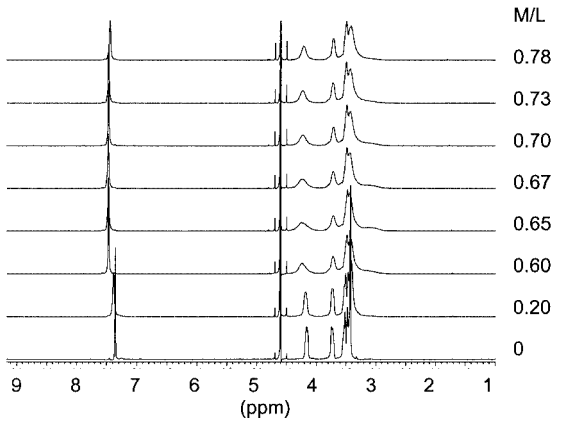

Figure 11. ^1H NMR spectra of compound **C6** with La^{3+} at 40 mM in D_2O at 298 K, pH = 5.8 at various molar ratios

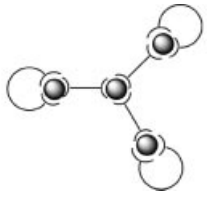

Figure 12. Schematic representation of an example of a small structure containing multiple rings, that can be formed by **C6** and La^{3+} ions at low concentrations and a molar ratio (M/L) close to 0.67

This signal in the NMR spectrum is, therefore, most likely caused by the structure of the rings. At higher ratios the height of the bump decreased rapidly because here, larger open structures are more dominant. The larger structures do not seem to give unique signals; they cause only broadening and slight shifting of the signals, which are also present without metal ions. The broadening of the signals is itself an indication of the formation of large structures. The disappearance of the "ring signal" at δ = 3.1 ppm at M/L > 0.67 is in agreement with the viscosity plots. Here the viscosity increased at a molar ratio of > 0.67 due to the opening of ring structures, which contribute to larger structures with higher viscosities.

Since we did not see this "ring signal" in the NMR spectra of **C4**, the presence of these kinds of structures can be ruled out here. This is logical, because **C4** is not long and flexible enough to act as a chain stopper.

In the dilution series (Supporting Information) no clear signal was found at δ = 3.1 ppm at 40 mM, but a broad bump appeared starting from about 20 mM, which became resolved into two peaks at 5 mM. Upon dilution, the only species that can become dominant in this system are chain-stopping rings. At low concentrations, the probability of a ligand meeting another metal ion is small, and therefore more rings are formed using only one metal ion to bind both chelating groups of a ligand molecule.

Conclusions

We have reported here the first water-soluble lanthanide-containing reversible 3-D coordination polymers, and the viscosities of their aqueous solutions as a function of both the concentration and the M/L molar ratio. The investigated bifunctional ligands self-assemble in aqueous solution in the presence of neodymium and lanthanum ions to give reversible networks. The use of these ligands in combination with lanthanide ions gives rise to much higher viscosities than when transition metal ions such as zinc are used, that yield linear coordination polymers.[2] A comparison of the viscosities and ^{1}H NMR spectra of **C4** and **C6** shows, that under the same conditions, **C6** always gives smaller structures with lanthanide ions than **C4**. Ligand **C6** has a long enough spacer to bend around one metal ion. In this way it can act as a chain stopper, which causes the structures to stop "growing" and remain small. The ideal M/L ratio for formation of these rings is 0.67. The opening of the rings at higher M/L ratios causes a rather asymmetrical curve, and a shift of the peak in the molar ratio dependent viscosity plots. The ring structures can also be seen in the ^{1}H NMR spectra of **C6** at low concentrations, and at a molar ratio close to 0.67, giving separate signals at $\delta \approx 3.1$ ppm. The ^{1}H NMR spectra of **C4** do not show this signal at any concentration or molar ratio. Also, in the viscosity plots, the shifts of the peaks with respect to the molar ratio are much smaller and the curves are more symmetrical, showing that rings acting as chain stoppers are not present. Coordination structures formed by **C4** and neodymium are therefore able to become much larger. The small shifts of the viscosity peaks here originate from expansion of the structures when metal ions are only slightly in excess.

Experimental Section

The syntheses of compounds **C4** and **C6** have been reported in a previous paper.[2] All commercial chemicals were obtained from Acros or Aldrich, and were used as received. ^{1}H NMR (200 MHz) spectra were recorded with a Bruker AC-E 200 spectrometer. Isothermal titration calorimetry measurements were performed with a Microcal MCS ITC with a cell volume of 1.353 mL. The experiments were performed using injections of 5 μL, 250 s between injections, and a reference offset of 60%. Viscosity measurements were performed in a 100 mM 1,4-piperazinebis(ethanesulfonic acid) buffer (PIPES) of pH = 5.4 with a Schott AVS 360 capillary viscometer. The reduced viscosity is defined as the specific viscosity divided by the ligand concentration C in g/L, i.e. $\eta_{red} = \eta_{sp}/C = (\eta_s - \eta_o)/(\eta_o \cdot C)$, with η_s being the viscosity of the sample, and η_o the viscosity of the solvent.

Nitroxide Radicals Interacting with Polyamine-Phenolic Ligands and Their Metal Complexes

Michela Cangiotti,[a] Mauro Formica,[a] Vieri Fusi,*[a] Luca Giorgi,[a] Mauro Micheloni,*[a] M. Francesca Ottaviani,*[a] and Sonia Sampaolesi[a]

Keywords: EPR / Macrocycles / Metal complexes / Nitroxide radicals / Polyamines

We have analyzed the interactions of a series of nitroxide radicals with ligands containing a phenol moiety coupled with different polyamine fragments, and their Cu^{II} and Zn^{II} complexes, by EPR experiments. Nitroxide radicals are good mimics of the properties of pollutant molecules, e.g., organic compounds having different polarities and charges, surfactants, and polyaromatics. Charged, polar, and low-polarity sites in the ligands and complexes are all available for interactions; in particular, the ability to entrap the radicals in a vice-like structure, by the formation of phenyl sandwich complexes, determines the type of selective interaction that occurs when a chain or planar aromatic structure is present. For closely packed complexes, Zn^{II} has a cooperative effect in the interaction with the radical; it allows both the entrance of low-polarity radicals at the low-polarity sites of the complex and the interactions of polar or charged radicals at the polar sites of the complexes. Conversely, Cu^{II} coordinates to the amino groups of the ligands and blocks the entry of radicals, which, thus, impedes their insertion into the structure of the complexes. The opposite behavior, with respect to that of Cu^{II} and Zn^{II}, was found for the complexes that have more open structures. The complexes that have cyclic ligands exhibit a poor ability to interact with radicals, but, for the ligands in the absence of the coordinating metals, the interactions are significantly enhanced as a result of the entrance of the radicals into the cyclic structures. In all cases, stronger interactions occur when both hydrophilic and hydrophobic sites are involved. The neutral-surfactant probe forms aggregates mainly with the cooperative effect of the copper complexes. UV/Vis measurements confirmed the results obtained by EPR and indicate that weak interactions occur between the radicals and the complexes or ligands; they also confirmed the formation of 1:1 adducts.

Introduction

Transition metal complexes can host and bind various organic and inorganic species, which, thus, allows their recognition, transport, and activation.[1−5] In this respect, the most important property of the metal complex is its readiness to interact with the host species through an unsaturated coordination site, which, in turn, is affected by the nature of the metal and the degree of preorganization of the complex that allows it to adapt to the presence of the new species. Because many natural biological sites, such as the active centers of various metalloenzymes, are produced by two transition metal ions, many dinuclear metal complexes have been synthesized and used successfully as devices for the recognition and assembly of external species that have different properties, e.g., inorganic and organic species; therefore, synthetic receptors for metal ions can be used to mimic enzymes' active centers.[6−10] Control over the distance between the two metal ions is crucial to allow the cooperation of both metal ions and, thus, the ability to mimic the reactions of active centers such as those present, for example, in oxygen receptors, activators, and carriers.[11,12] Moreover, the cooperation of the two metal ions permits a stronger complexation of the guest, which is usually coordinated by both metal centers.

Recently, we reported the synthesis and properties of several macrocyclic and noncyclic ligands containing a phenol moiety inserted into a polyamine skeleton.[13−17] Solid-state and solution studies highlighted the ability of these ligands to form complexes with M^{II} cations and, hence, to match the properties above; therefore, these systems may be suitable for interacting with secondary species that are extracted from the environment and then linked at the metal−ligand active sites. In particular, the dinuclear metal complexes we synthesized present the two transition metal ions in close proximity, which allows them to bind cooperatively to at least one substrate that is linked in a bridge disposition between them. In this paper, we report a series of ligands containing phenol moieties coupled with different polyamine fragments, which we term MODEN, DIDEN, ANIDEN, ANITR, and ANIPT (Scheme 1). With the exception of ANITR, which contains a tetraamine chain, these ligands are obtained from a combination of

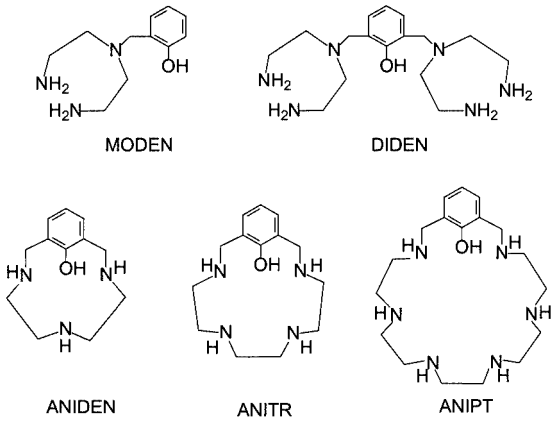
ottaviani@uniurb.it

one or two diethylentriamine (dien) chains linked in different positions to the 2,6-dimethylphenol moiety. For example, ANIDEN can be viewed as the macrocyclic counterpart of MODEN, while ANIPT is the macrocyclic counterpart of DIDEN. ANITR forms only mononuclear species with transition metal ions such as Cu^{II} or Zn^{II} in aqueous or alcoholic solution, whereas the other ligands mainly form dinuclear species that are the only species existing in alcoholic solution. The dinuclear species of ANIPT and DIDEN possess ligand/metal molar ratios of 1:2, while those for ANIDEN and MODEN are 2:2.



Scheme 1

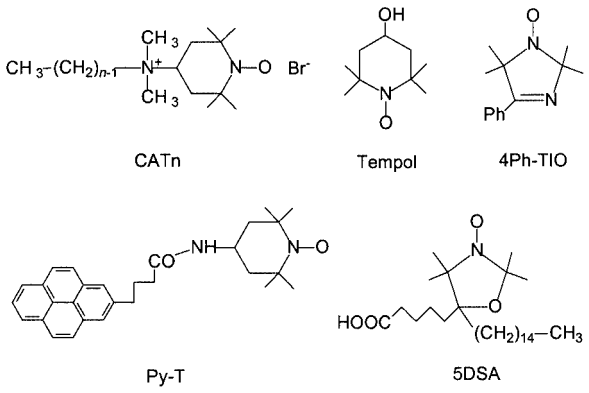
Electron paramagnetic resonance (EPR) spectroscopy is a powerful tool for the analysis of the binding of nitroxide radicals to coordination sites and ligand groups.[18,19] Several studies have dealt with the magnetic and structural properties of complexes formed from metal complexes and nitroxide radicals.[20−25] To the best of our knowledge, however, no efforts have as yet been devoted to studying the interactions of heterocyclic ligands, and their dinuclear metal complexes, with differently structured nitroxide radicals.

Therefore, in an effort to analyze the ability of these ligands — and, more specifically, their complexes with Cu^{II} or Zn^{II} — to interact with pollutant molecules extracted selectively from the environment, in this study we applied the EPR technique while using selected nitroxide radicals that mimic well the properties of pollutant molecules, e.g., organic species that have different polarities and charges, surfactants, and polyaromatics (their formulas and acronyms are presented in Scheme 2).

Results and Discussion

EPR Spectroscopy

Figure 1 shows examples of the EPR spectra obtained for the complexes in the presence of the CATn radicals (radical concentration, 1 mM; complex concentration, 8 mM) at 263 K: (a) CAT1 with DIDEN-Cu, DIDEN-Zn, MODEN-Cu, and MODEN-Zn and (b) CAT12 with DIDEN-Zn and MODEN-Zn. The full lines in the Figure are the experimental spectra and the dashed lines represent the computed ones. The computation of the spectral line shape was



Scheme 2

performed by means of a well-established procedure that was reported by Budil et al.[26] The **g** tensor components (for the coupling between the electron spin and the magnetic field) were assumed to be constants (g_{ii} = 2.009, 2.006, 2.003). The **A** tensor components (for the coupling between the electron spin and the nuclear spin of the nitrogen atom) mainly reflect the variations in polarity of the nitroxide environment: an increase in A_{ii} values (accuracy: 3%) corresponds to an increase in the environmental polarity. For instance, the A_{ii} values found for CAT1 are greater than those evaluated for CAT12; the presence of the hydrophobic chain attached to the positively charged CAT group favors the localization of the nitroxide group in a less polar environment. An increase in line width arises from spin−spin interactions; the presence of paramagnetic copper ions in the vicinity of the nitroxide moiety may be responsible for this effect. A partial self-aggregation of surfactant radicals is also responsible for spin-exchange interactions. The variation in line width among the samples is very small, between 1 and 2 G, which gives, on average, a value of 1.5 G (reported in Figure 1). This value indicates that the spin−spin effects are quite negligible in the CAT*n* samples that we analyzed in this study. The NO group, therefore, does not approach the paramagnetic Cu^{II} center.

A Brownian, or Jump, model for the diffusional rotation of the nitroxide unit was considered and provided the correlation-time components, perpendicular and parallel, of $\tau_i = 1/(6D_i)$ and $\tau_i = 1/D_i$, respectively. These values (accuracy of 3% on the basis of the computation) are the most important parameters for analyses of complex−radical interactions; indeed, an increase in the correlation time for motion reflects a decrease in the radical mobility that is due to the interaction between the radical and the complex, or the ligand. This interaction is mainly physical, that is, dipole−dipole and van der Waals interactions prevail, but ion−dipole interactions are certainly the main driving forces that move the radicals towards the ligand sites.

The spectra recorded at complex/radical molar ratios < 8:1 (not shown) present higher mobilities (lower correlation time for motion) than those recorded at an 8:1 ratio (Figure 1); molar ratios > 8:1 result in almost equivalent spectra (also not shown) as that at an 8:1 molar ratio. We found, however, that already at a 1:1 molar ratio between the com-

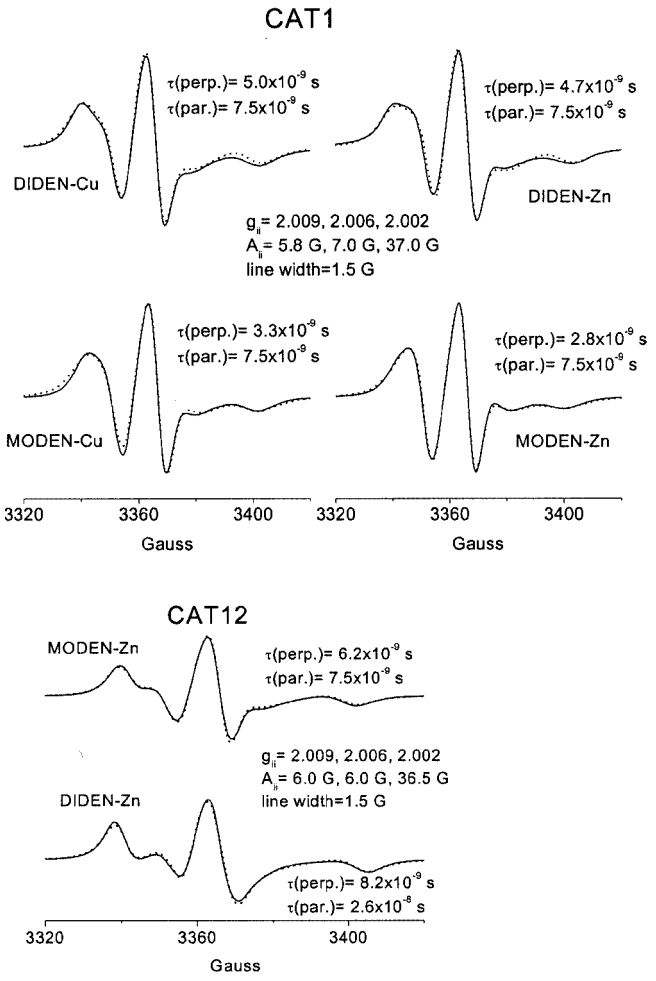

Figure 1. Examples of the EPR spectra obtained for the complexes in the presence of the CAT*n* radicals (radical concentration 1 mM; complex concentration 8 mM) at 263 K; (a) CAT1 with DIDEN-Cu, DIDEN-Zn, MODEN-Cu, and MODEN-Zn; (b) CAT12 with DIDEN-Zn and MODEN-Zn; the full lines in the figure are the experimental spectra, the dashed lines are the computed ones

plex and the radical, a small, but perceptible, quenching of the mobility occurs with respect to that of the radical in the absence of the complexes. On the other hand, we were mainly interested in the differences among the various systems (radicals + complexes or ligands), which showed equivalent trends at the different complex/radical molar ratios. For this reason, we simply compared the spectra obtained for the various radical/complex (or radical/ligand) systems at molar ratios of 1:8.

The first observation we made based on the parameters listed in Figure 1 was a decrease in the mobility on proceeding from CAT1 to CAT12, when comparing the same complex. It must be remembered that a similar difference in rotational mobility is found between the two probes in solution in the absence of the complexes, which occurs as a result of the different structures (size and shape) of the probes. In any case, this difference leads to a lower sensitivity of CAT12 with respect to its ability to differentiate among the various systems; when the interactions are strong, the mobility is very low and all the spectra appear to be similar. Computation of the line shape, however, easily reveals the differences. Problems may arise because the spectral computation of the different samples often requires a different anisotropy of motion, in which case a direct comparison of the perpendicular or parallel correlation times for motion does not work. Similarly, the average correlation time is not a good parameter for comparing the samples because different diffusional models yield different weights to the perpendicular and parallel components. Therefore, for an easier comparison, we simply used $2A_{zz}'$ splitting, i.e., the distance between the low- and high-field absorptions (in several cases, the second derivatives of the signals allowed more-accurate evaluations of this parameter: accuracy within 2−3%), which is related directly to the increased resolution of the anisotropic components of the hyperfine tensor; in turn this increased resolution is due to a progressive quenching of radical mobility: an increase in $2A_{zz}'$ reflects a decrease in mobility of the radical because of its interactions with the complexes or the ligands.

Figure 2 displays the variation of $2A_{zz}'$ for the various CAT*n* complex (or ligand) systems as histograms. Analyses of these histograms allowed us to define some general trends:

1. The DIDEN-Zn complex interacts the most with CAT*n*.
2. MODEN-Zn interacts less than does MODEN-Cu.
3. Cu complexes also interact more than do Zn complexes for the ANITR-M and ANIPT-M systems.
4. Conversely, DIDEN-Zn interacts more than does DIDEN-Cu.
5. ANITR-M and ANIPT-M interact less strongly than do the other complexes.
6. ANIDEN-Cu also interacts quite strongly.

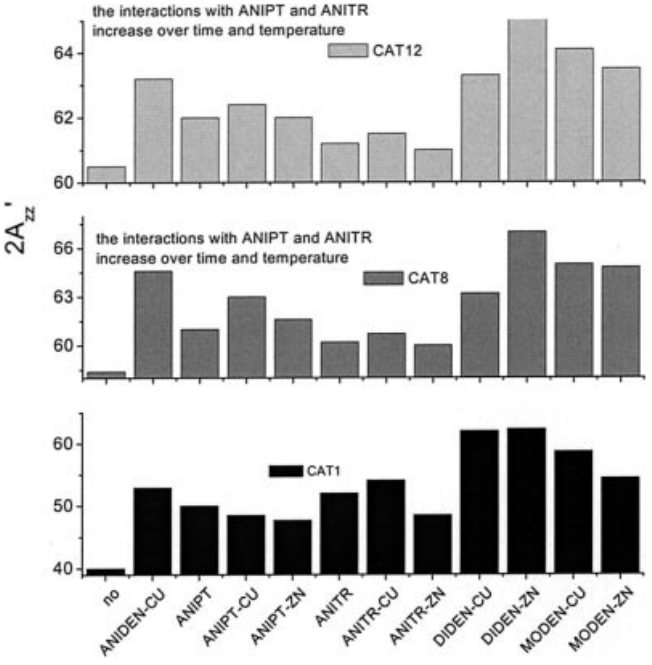

Figure 2. Histograms of the values of $2A_{zz}'$ for the various CAT*n* complex (or ligand) systems

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

Before discussing these results, we also stress that different behaviors were found for ANITR and ANIPT (the ligands lacking coordinated metal ions), which interact quite strongly with CAT1, but, initially, the interaction is relatively weak with CAT8 and CAT12. However, increasing the temperature or leaving the samples to equilibrate for longer times leads to a progressive increase in the strength of binding because of the slow kinetics of the interaction.

Since CAT1 behaved similarly to CAT8 and CAT12, we hypothesized that the interaction takes place mainly by means of the charged CAT group; the driving force for the interactions certainly can be ascribed to this moiety. Therefore, we supposed that the hydrophobic chains of CAT8 and CAT12 do not play a substantial role in the binding between the radical and the complexes, but rather they affect only the entrance of ANITR and ANIPT into the macrocycles, as indicated by the slow kinetics of the interactions. Consequently, it is surprising to note that the similar trends observed for CAT*n* also hold for the hydrophobic radicals Py-T and 4Ph-TIO, as is shown in the histograms in Figure 3. Nevertheless, the lower values of $2A_{zz}'$ arose from the much faster mobility of these radicals with respect to the CAT*n* radicals, because 4Ph-TIO is more mobile than Py-T. This faster rotational mobility, in turn, allows a better differentiation of one sample from another. Some further discrepancies were found, however, between the CAT*n* samples and the 4Ph-TIO and Py-T samples:

1. The difference in probe mobility between MODEN-Cu and MODEN-Zn is relatively high.
2. MODEN-Cu exhibits the maximum interaction with 4Ph-TIO.
3. ANITR-Zn interacts more strongly than does ANITR-Cu.
4. The interaction with the ligands ANITR and ANIPT is relatively strong and is constant over time and at different temperatures.

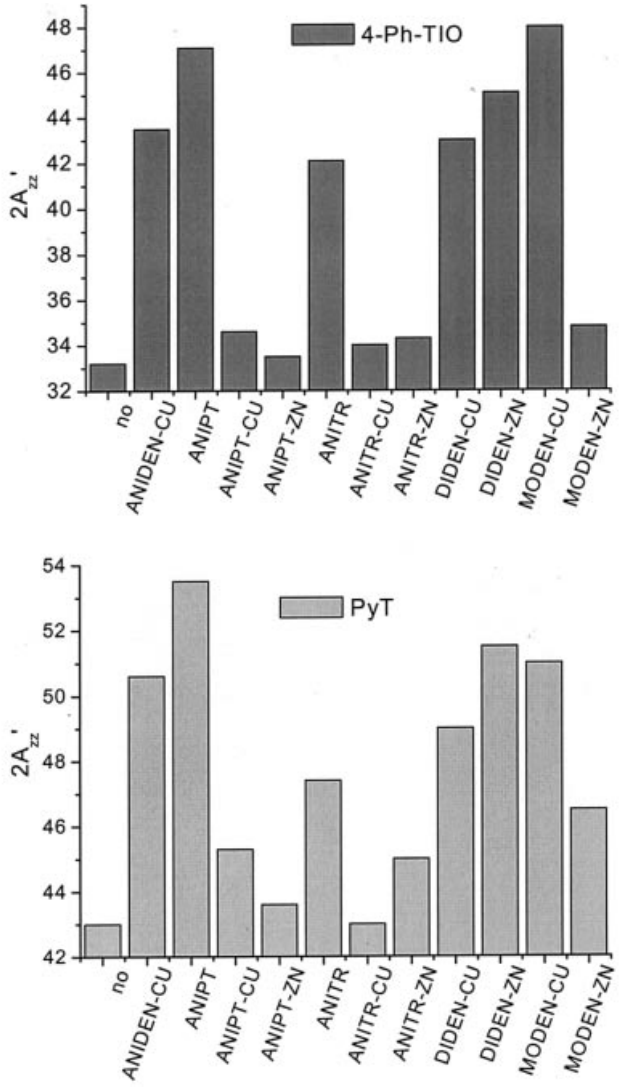

Figure 3. Histograms of the values of $2A_{zz}'$ for the Py-T and 4Ph-TIO complex (or ligand) systems

Before discussing the rationale implicit in these results, and the connections with the structures of the complexes, the results from the last two radicals shown in the histograms in Figure 4, 5DSA and Tempol, deserve separate considerations. First of all, the parameter used for describing the interaction with Tempol is not the $2A_{zz}'$ splitting, but rather the intensity ratio between the two components superimposing to form the overall signal (results not shown). These two components, which arise because the radicals exist in two motion regimes, simply termed fast and slow, originate from the two different radical environments, i.e., in water (bulk, not interacting radicals) and in the complexes (interacting radicals). As has already found in previous studies,[27] the increase in the intensity ratio between the slow and fast components (Is/If) can be interpreted as being due to the an increase in the interactions of the radicals with the complexes or the ligands. These intensities were calculated by a subtraction/addition procedure of the components themselves to separate them and obtain, by double integration, the values of their intensities. The histogram in Figure 4 for Tempol shows the values of Is/If for the different ligands and complexes. It is interesting that, on the basis of the higher Is/If ratio, the interaction of Tempol is stronger for DIDEN-Cu and ANITR-Zn, with respect to the other complexes; this finding is the opposite of the preferential interactions occurring for the other radicals and indicates that the mechanism of interaction is also different.

An introductory description is also needed for the results obtained from 5DSA. In this case, the self-aggregation ability of this radical provides a new contribution appearing as a single line (not shown for brevity). This component, termed the agg. component, arises from spin−spin exchange interactions due to the high local concentration of self-aggregating radicals; since this component is absent in the absence of the complex or the ligand, this observation implies that the complex or the ligand offers an aggregation site for these radicals. This behavior can be described in terms of a cooperative interaction in which the ligand or the complex, by interacting with the radicals, cooperates with them in the formation of the aggregates. This aggre-

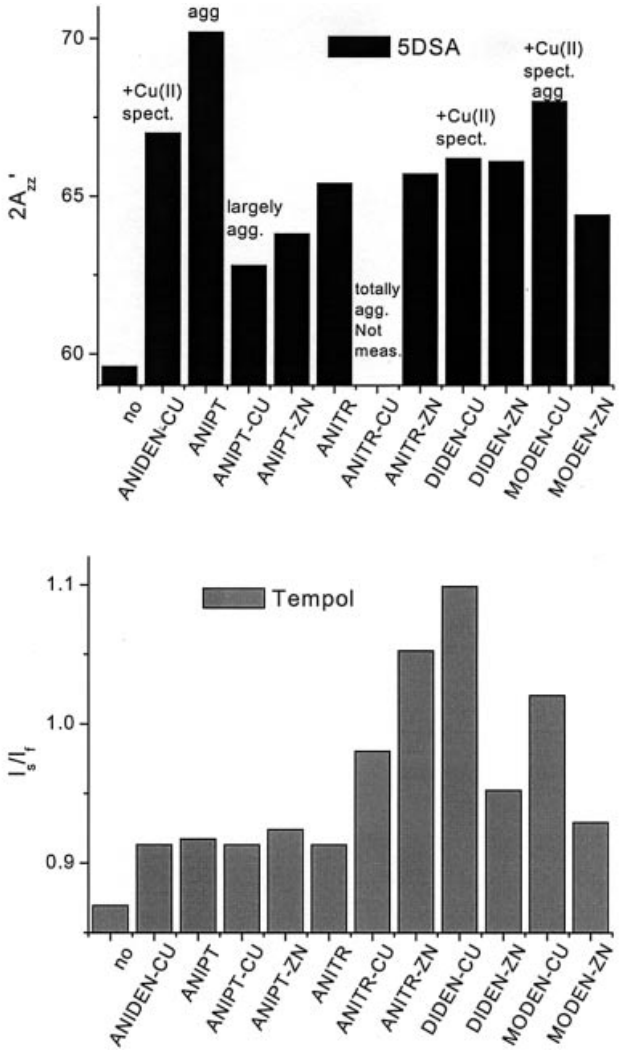

Figure 4. Histograms of the values of $2A_{zz}'$ for the 5DSA and Tempol complex (or ligand) systems

gation, however, is also favored by the repulsive effect of the charged metal sites: the hydrophobic chains escape from contact with the ions by forming aggregates. In cases in which the agg. component contributes to the EPR spectrum, we indicate the presence of aggregated surfactants by the "agg" label at the top of the pertinent bar in the histogram showing the $2A_{zz}'$ values for the different ligands or complexes (Figure 4). Although the strongest interaction for 5DSA is exhibited by ANIPT, which also shows the formation of 5DSA aggregates, the preferential formation of aggregates is presented by ANIPT-Cu and ANITR-Cu, which, conversely, show a weak interaction, as evidenced by the $2A_{zz}'$ values. This finding demonstrates that the mechanism of interaction of 5DSA with these complexes is different from that of the other complexes. Also, it is interesting that the interaction of the copper complexes with 5DSA leads to the appearance of a signal characteristic of monomeric copper complexes. This observation implies that, when interacting with the complex, this surfactant radical functions as a separator of the two Cu^{II} ions. This phenomenon may be related to both a physical separation and an electron transfer between the radical and Cu^{II}. This result holds true also for DIDEN-Cu and ANIDEN-Cu, which show the strongest interactions with the radical. For DIDEN-Cu, the high $2A_{zz}'$ value, the appearance of a signal from monomeric Cu^{II} complexes, and the presence of aggregates characterize the spectrum and are indicative of a very strong interaction.

This interaction can be understood quite easily by considering that it arises from an acid−base interaction between the COOH group of the probe and the amino groups of the ligand. Such an interaction may also involve the Cu^{II} ions, which coordinate well to deprotonated carboxylic groups, and, hence, may be responsible for the appearance of the monomeric copper complexes.

All of the results described above for the different radicals can be analyzed, for each complex or ligand, by proposing a suitable mechanism of interaction.

The structure of DIDEN-M characterizes a quite strong interaction with almost all the nitroxide radicals: charged, polar, and low-polarity interacting sites are all available for the interaction, but, mainly, the ability to entrap the radicals in a vice- or pliers-like structure determines the preferential interactions of the radicals with this complex. MODEN-M and ANIDEN-M may also create a similar interacting effect, but, in these cases, the possibility of forming phenyl sandwiches with the radicals also enhances the interactions.

Perhaps surprisingly, DIDEN-Zn generally interacts more readily than does DIDEN-Cu, whereas the opposite holds true for MODEN-M (i.e., the Cu complex interacts more readily than does the Zn complex). For DIDEN-Zn, the high ability to interact arises from two synergic effects: (1) Zn^{II} has a cooperative effect in the interaction with the radical and allows both the entrance of the low-polarity radicals at the low-polarity binding sites of the complex and (2) the interactions of the polar or charged radicals at the polar sites of the complex; conversely, Cu^{II} readily coordinates to the amino groups of the ligands and blocks the entrance of the radicals, which, thus, impedes their insertion in the complex structure. The Cu and Zn complexes of MODEN behave in an opposite way because the more open MODEN structure allows the entrance of the radicals into the structure of the Cu complex. Essentially, the coordinative requirement of Cu^{II} is not saturated by the donor atoms of the ligands and the radical behaves as an extra ligand. On the basis, however, of the strength of the interaction, as measured by EPR spectroscopy, the binding site of the radicals is not located directly at the NO moiety.

In the cases of ANITR and ANITP, their monomeric nature does not allow either a sandwich- or vice-like interaction. Therefore, the presence of the chain for the CAT or 5DSA does not favor the interaction and the ANITR-M and ANTP-M complexes show a weak interaction with the probes. Nevertheless, it is interesting that ANITP-M, which has the larger cycle, increases its interacting ability with respect to ANITR-M, by increasing the chain length of the

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

CAT*n* probes, because both hydrophilic and hydrophobic interactions become active.

Two other interesting features in the interactions of the radicals with the ANITR and ANITP ligands and complexes are noteworthy.

(a) Cu complexes are more interacting than Zn complexes for CAT*n*, but this trend is reversed for ANITR-M with respect to the hydrophobic probes (ANITR-Zn is more interacting than ANITR-Cu for 5DSA, Py-T, and 4Ph-TIO); this observation means that the mechanism of interaction is different because ANITR-Cu is more selective for the interaction with hydrophilic substances and ANITR-Zn is more selective in respect to the hydrophobic molecules. In relation to the different mechanisms of interaction of the copper and zinc complexes, the behavior of 5DSA is very informative: the copper complexes promote the self-aggregation of the probes, i.e., it is favored by repulsion of the charged copper site.

(b) In the absence of the metal ion, the ligands ANITR and ANIPT show a significant interaction with the hydrophobic probes; in these cases, the macrocycles offer a comfortable binding site for the probes that have a prevalently hydrophobic nature. The CAT*n* probes are less interactive, but it is interesting to note that, in the presence of the chain, a slow kinetic process (which takes hours at room temperature) allows the progressive entrance of these probes so that they can be hosted by the macrocycles. As expected, an increase in temperature accelerates this process.

With regard to the mechanism of the interaction process, further information was provided by Tempol, which, in several cases, behaved in a manner opposite to that of the CAT*n* probes. We propose that, for Tempol, the interactions occur through the hydroxyl moiety, whereas the CAT*n* probes promote the interactions via their positively charged group.

UV/Vis Spectroscopy

The interaction of the radicals with the metal complexes was also supported by UV/Vis spectroscopy experiments, in which we observed the d−d electronic transitions of the coordinated Cu^{II} chromophore in the complexes in the absence and presence of the radicals. Table 1 shows λ_{max} (nm) and $\varepsilon_{\lambda max}$ ($mol^{-1}dm^3cm^{-1}$) values of DIDEN-Cu in methanol solution in the absence and in the presence of Tempol, CAT1, and Py-T. This complex in methanol shows a band at λ_{max} = 623 nm for the d−d transitions (ε = 150 $mol^{-1}dm^3$ cm^{-1}), while a shift towards lower energy was observed in the presence of Tempol and, moreover, for CAT1, but the effect was lower for Py-T, which is in agreement with the EPR spectroscopic results. Figure 5 shows the UV/Vis electronic spectra of the system Tempol-DIDEN-Cu upon addition of different quantities of Tempol to a methanol solution of the DIDEN-Cu complex. A constant profile was obtained at high Tempol/DIDEN-Cu molar ratio, which indicates the weak complexation of Tempol by DIDEN-Cu, as we had found also by EPR spectroscopy. The increase in absorbance at 669 nm, as a function of the number of equivalents of Tempol added, provided evidence for the formation of a Tempol/DIDEN-Cu adduct having 1:1 stoichiometry. CAT1 and Py-T provided similar results to those obtained with Tempol, as a function of the relative molar ratio with respect to the complex.

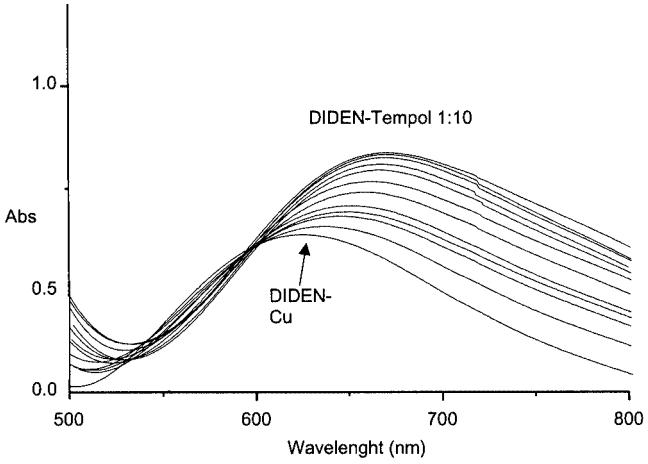

Figure 5. UV/Vis electronic spectra obtained upon addition of different quantities of Tempol to a methanol solution of the DIDEN-Cu complex; [DIDEN-Cu] = 5×10^{-3} M

The shift in the d−d band was slightly smaller for ANIPT-Cu and ANITR-Cu, with respect to those of DIDEN-Cu, ANIDEN-Cu and MODEN-Cu, but this variation was not as significant as expected on the basis of the EPR spectroscopy results, which indicates that the "copper side" (tested by the UV/Vis spectroscopic analysis) was less sensitive to the complexation behavior of the radicals with respect to the "radical side" (tested by the EPR analysis).

Conclusions

We have demonstrated that ligands containing a phenol moiety coupled to different polyamine fragments, namely DIDEN, MODEN, ANIDEN, ANIPT, and ANITR

(Scheme 1), and their Cu^{II} and Zn^{II} dinuclear complexes, bind differently to nitroxide radicals, namely Tempol, 4Ph-TIO, CAT1, CAT8, CAT12, 5DSA, and Py-T (Scheme 2), that mimic well the properties of pollutant molecules, e.g., organic species having different polarities and charges, surfactants, and polyaromatics.

Computer-aided analysis of the EPR spectra provided indications of the different strengths of interactions as a function of the complex or ligand structure, and of the structure, polarity, and charge of the radical. The interactions between the radicals and the complexes or the ligands were dynamic in nature.

The structure of DIDEN-M allows a quite strong interaction with almost all the nitroxide radicals: charged, polar, and low-polarity interacting sites are all available for the interaction, but, mainly, the ability to entrap the radicals in a vice- or pliers-like structure determines the preferential interaction of the radicals with this complex. Also, MODEN-M and ANIDEN-M may also create a similar interaction effect, but, in these cases, the possibility of phenyl sandwiches existing also enhances the interactions.

In DIDEN-Zn, the metal ion has a cooperative effect in the interaction with the radical and allows both the entrance of the low-polarity radicals at the low-polarity interacting sites of the complex and the interactions of polar or charged radicals at the polar sites of the complexes; conversely, in DIDEN-Cu, the metal readily coordinates the amino groups of the ligands and, because of the packing of the resulting structure, it blocks the entry of the radicals, which, thus, impedes their insertion into the structure of the complexes. The more open MODEN structure allows the entrance of the radicals in the structure of the Cu complex; MODEN-Cu is able to interact more strongly than is MODEN-Zn. Essentially, Cu^{II} presents a coordinative requirement that is not saturated by the donor atoms of the ligand and the radical functions as an extra ligand. On the basis of the strength of interaction as measured by EPR spectroscopy, however, the binding site of the radicals is not on the NO side.

ANITR-M and ANIPT-M complexes undergo weak interactions with the nitroxide probes. ANIPT-M, however, which has the larger cycle, has increased interacting ability with respect to ANITR-M when the chain length of the CAT*n* probes is increased, because, in these cases, both the hydrophilic and hydrophobic interactions become active. ANITR-Cu was revealed to be more selective for interactions with hydrophilic substances, whereas ANITR-Zn was more selective in interactions with hydrophobic molecules. For the ANITR and ANIPT ligands, in the absence of the coordinating metal ions, the interactions are significantly enhanced because of the entrance of the radicals in the cyclic structure. The kinetics of the entrance processes are slow (it takes hours at room temperature) for CAT8 and CAT12 radicals.

With the copper complexes of MODEN, DIDEN, and ANIDEN, the interaction of 5DSA induces the appearance of the EPR spectroscopic signal of a monomeric Cu complex, which is due to magnetic separation and/or electron transfer occurring at the two Cu^{II} ions. For the copper complexes of ANITR and ANIPT, the main effect of the ion is to promote the self-aggregation of the 5DSA radicals.

The interactions between Tempol and the complexes or the ligands are weak and occur through the hydroxyl moiety, which has a negative potential for interaction, whereas CAT*n* promotes interactions via the positively charged group.

The positively charged moiety of the radicals undoubtedly promotes the interactions with the complexes and the ligands, but stronger interactions occurred when both hydrophilic and hydrophobic sites were involved.

UV/Vis spectroscopic measurements confirmed the results obtained by EPR spectroscopy, i.e., they indicate that weak interactions occur between the radicals and the complexes or the ligands, and they also confirm the formation of 1:1 adducts.

Experimental Section

General: The ligands MODEN,[13] DIDEN,[14] ANIDEN,[15] ANITR,[16] and ANIPT[17] (Scheme 1) and their metal complexes used in the present study were synthesized as previously reported. 5-Doxylstearic acid (5DSA) and 4-hydroxy-2,2,6,6-tetramethylpiperidine-*N*-oxyl (Tempol) were purchased from Sigma and used without any further purification. 4-Trimethylammonio-Tempo bromide (CAT1), its derivatives bearing C_8 and C_{12} chains (CAT8 and CAT12, respectively), and pyrene-Tempo (Py-T) were kindly provided by Dr. X. Lei, Columbia University, NY. 4-Phenyl-2,2,5,5-tetramethyl-3-imidazolin-1-yloxy (4Ph-TIO) was kindly provided by Prof. L. Greci, University of Ancona, Italy. Methanol solutions of the complexes or the ligands (initial concentration: 0.05 M) and of the radicals (initial concentration: 5 mM; deoxygenated and stored in a refrigerator under nitrogen in the dark) were added together to obtain molar ratios, between the complex or ligand and the radical, from 1:1 to 10:1 at a constant radical concentration of 1 mM. The complex solutions in the absence of the radicals were also analyzed by EPR spectroscopy for the sake of comparison. The solutions were processed by EPR spectroscopy (glass tube: 2 mm diameter; sealed and inserted in the EPR spectrometer's cavity) immediately after preparation and 1 and 2 d after preparation. The EPR spectra were recorded with an EMX-Bruker spectrometer operating at the X band (9.5 GHz) and interfaced to a PC (Bruker software) for data acquisition and handling. The temperature was controlled by means of a Bruker ST3000 variable-temperature assembly. Experiments were carried out as a function of temperature (between 293 and 163 K) and a progressive quenching of the mobility was observed as the temperature decreased. The room-temperature spectra, however, did not indicate a significant variation in mobility among the various samples (results not shown), which suggests that the interactions between the complexes (or ligands) and the radicals were dynamic in nature, i.e., the radical undergoes fast exchange between the ligand site and the bulk solution, and/or the formed complex structure allowed fast rotation of the radical at the ligand site. The spectra recorded at 263 K, however, still do not indicate a frozen environment, but rather slow-exchange conditions that suggest a wide range of mobilities exist between samples; these spectra permitted an analysis of the behavior of the different interactions of the different samples. Both progressive cooling and direct cooling at 263 K in the EPR cavity were per-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

formed. The latter procedure ensured a reproducible response and, therefore, a better comparison could be made among the samples.

Electronic Spectroscopy: UV absorption spectra were recorded at 298 K with a Varian Cary-100 spectrophotometer equipped with a temperature control unit. The samples tested by UV/Vis spectroscopy were obtained using a constant concentration of the complex in methanol (between 1 and 5 mM) and variable concentrations of the radicals, which allowed us to obtain radical/complex molar ratios from 10:1 to 1:1.

Paramagnetic Chloro-, Alkoxo-, or Azidovanadium(IV) Complexes Supported by an [ONNO]-Type Amine Bis(phenolate) Ligand

Fabien Wolff,[a] Christian Lorber,*[a] Robert Choukroun,*[a] and Bruno Donnadieu[a]

Keywords: Vanadium / Amines / Paramagnetism

The reactions between $V(N_3)_2(NMe_2)_2$ or $V(OiPr)_4$ and the chelating dianionic bis(phenoxy)amine ligand $[ONNO]H_2$ afford complexes formulated as $[V(N_3)_2\{ONNO\}]$ (**1**) and $[V(OiPr)_2\{ONNO\}]$ (**2**). When refluxed in toluene with an excess of Me_3SiCl, compound **2** leads to mono- or dichloro derivatives $[V(Cl)(OiPr)\{ONNO\}]$ (**3**) and $[VCl_2\{ONNO\}]$ (**4**) depending on the experimental conditions. The crystal structures of complexes **1**–**4** were solved and show in all cases an [ONNO] ligand that has phenolate groups in a *trans* configuration, with both amino-nitrogen donor atoms of the ligand coordinated to the octahedral vanadium center. Complexes **1**–**4** were further characterized by EPR spectroscopy and susceptibility measurement studies typical of d^1-paramagnetic V^{IV} species.

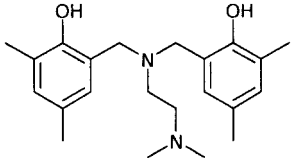
Introduction

In the past decade, ''non-metallocene'' complexes have attracted considerable attention due to their activity as α-olefin polymerization catalysts.[1] Chelating diamide,[1a,2–4] dialkoxide,[1a,5–6] or phenoxyimine[7,8] ligands in particular have been extensively studied as rigid supporting environments for group 4 transition metals. As a result a great deal of novel and useful chemistry has emerged, including the discovery of highly active olefin polymerization precatalysts. Among these new ligands, chelating dianionic [ONNO]-type amine bis(phenolate) ligands, recently introduced by Kol et al.[5] and associated to group 4 metal complexes, have proved to give highly active 1-hexene polymerization catalysts, and in some cases even isospecific living polymerization was possible.[5a] As our interest lies strongly in vanadium chemistry with various supporting ligand environments,[9] in particular those that could help stabilize the formal oxidation state (+III or +IV) of the vanadium center (and thus avoid the reduction to inactive V^{II} species by the alkylaluminum cocatalyst) during the vanadium-catalyzed polymerization of olefins,[10,11] we have recently described the synthesis of a series of oxovanadium(V) complexes with the ancillary amine bis(phenolate) [ONNO]-type ligand (Figure 1),[12] and demonstrated interesting features in the solution and the solid-state structure of these complexes. In the present article, we wish to report on the synthesis, structure, EPR spectroscopy, and magnetism of new d^1-paramagnetic vanadium(IV) complexes supported by the same [ONNO]-type bis(phenoxy)amine ligand.



[ONNO]H$_2$

Results and Discussion

1. Syntheses

In the past few years we have successfully used tetrakis(dialkylamido)vanadium(IV) $V(NR_2)_4$ as a precursor to various families of vanadium complexes.[9b,19,20] Logically, therefore, we first attempted the reaction between $V(NR_2)_4$

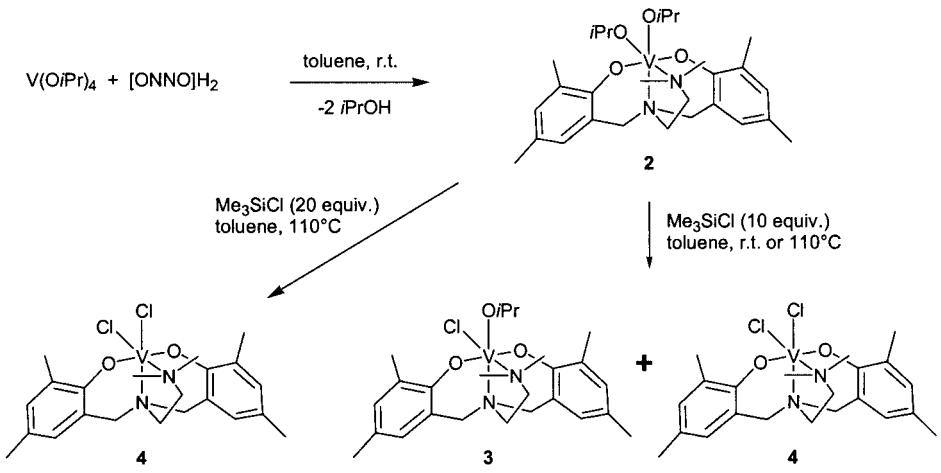

Scheme 2. Synthesis of alkoxo- and chloro- [ONNO] vanadium(IV) complexes

(R = Me; Et)[21] and an equimolar amount of the bisphenol ligand [ONNO]H_2, but although a reaction occurred we failed to isolate the pure [V(NMe_2)$_2${ONNO}] derivatives resulting from the amine elimination reaction. We then conducted the room temperature reaction of the new [V(N_3)$_2$(NMe_2)$_2$] complex (see Exp. Sect.) with [ONNO]H_2 in THF, which yielded the brown microcrystalline vanadium(IV) complex [V(N_3)$_2${ONNO}] (**1**) (yield: 40%) (Scheme 1). Brown crystals were further obtained by slow diffusion of pentane into a THF solution of **1**.

Reacting [ONNO]H_2 with an equimolar amount of V(O*i*Pr)$_4$ in toluene at room temperature for two hours afforded a dark red solution from which the complex [V(O*i*Pr)$_2${ONNO}] (**2**) was isolated with good yield (86%) as a dark red microcrystalline solid (Scheme 2). Compound **2** was recrystallized from a concentrated cold (−40 °C) pentane solution as dark red crystals.

Trimethylchlorosilane is known for its ability to substitute −NMe_2, −OR, or oxo groups by chlorine atoms in lanthanides [22] and in group 4−6 transition metal complexes;[3,4,9b,23] for vanadium complexes forcing conditions are generally required.[9b,20] We showed previously that Me_3SiCl could replace an azido group by a chlorine atom in oxo-vanadium(V) complexes,[12] and thus it was interesting to react the bis-azido complex **1** with Me_3SiCl. Unfortunately, the reaction did not proceed to completion even under forcing conditions in refluxing toluene.[24] However, when 10 equiv. of Me_3SiCl were used to chlorinate complex **2** in toluene at room temp. or 110 °C, a reaction occurred giving a mixture of the monochloro [V(Cl)(O*i*Pr){ONNO}] (**3**) and the dichloro [VCl_2{ONNO}] (**4**) derivatives. From that mixture of complexes, compound **3** was accidentally isolated as purple crystals (Scheme 2). In order to achieve a complete chlorination of **2**, a larger excess of Me_3SiCl (20 equiv.) was necessary, in dilute refluxing toluene solution, followed by slow cooling of the solution to room temperature, to afford dark blue crystals of the dichloro complex [VCl_2{ONNO}] (**4**) (yield: 96%) (Scheme 2).

In solution, [ONNO]-vanadium(IV) compounds **1**−**4** are all d^1-paramagnetic species presenting well-resolved electron paramagnetic resonance (EPR) spectra with the characteristic octet pattern at about g = 1.97 [A_{iso}(^{51}V) = 94.0 G (**1**), 70.9 G (**2**), 77.3 G (**3**), 82.7 G (**4**)] expected for the interaction of an unpaired electron of V^{IV} with the ^{51}V nucleus (I = 7/2). Accordingly, susceptibility measurements show magnetic moments consistent with a d^1 electronic configuration [μ_{eff} = 1.80 μ_B (**1**), 1.79 μ_B (**2**), 1.77 μ_B (**3**), 1.82 μ_B (**4**)].

Addition of pyridine or PMe_3 to complex **2** did not affect its EPR spectrum (in particular, no coupling with the ^{31}P phosphorus nucleus of PMe_3 was observed) or the color of the solution, suggesting that the sidearm NMe_2 group is sufficiently tightly bound to the metal not to be displaced by strong donors (as in our vanadium(V)[ONNO] complexes[12]).

2. Solid State Structures

In contrast to diamagnetic [ONNO]-vanadium(V) complexes for which ^{1}H NMR spectroscopy and NOESY experiments are very helpful tools in determining the structure in solution and in particular the conformation of the [ONNO] fragment, for paramagnetic d^1-vanadium(IV) species it is of tremendous importance to have a crystal structure in order to assess their formulation without ambiguity, as we have already stated in other articles dealing with vanadium(IV) complexes.[9a,9b]

Crystals suitable for X-ray structure determination were obtained for all complexes described in this article, either by diffusion of pentane into a THF solution of the complex (for **1** and **3**), cold pentane solution (for **2**), or slow cooling of a toluene solution from 110 °C to ambient temperature (for **4**). ORTEP drawings are given in Figure 2−5, with selected bond lengths and angles in Table 1 (complex **2** presents two independent molecules in the cell with very similar structural parameters, therefore only one of these molecules will be described here).

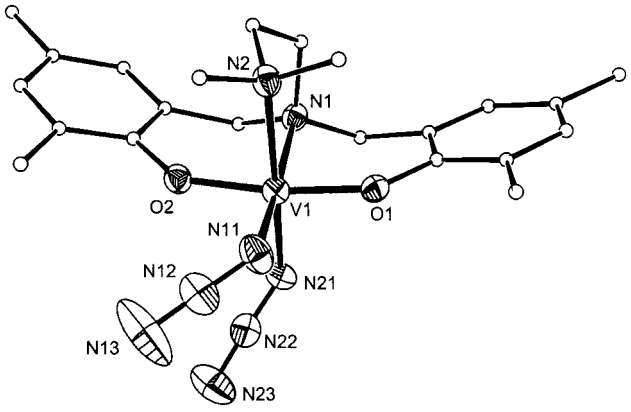

Figure 2. ORTEP drawing of the molecular structure of **1** showing 50% probability ellipsoids (except on C atoms for clarity) and partial atom-labeling schemes. Hydrogen atoms are omitted for clarity

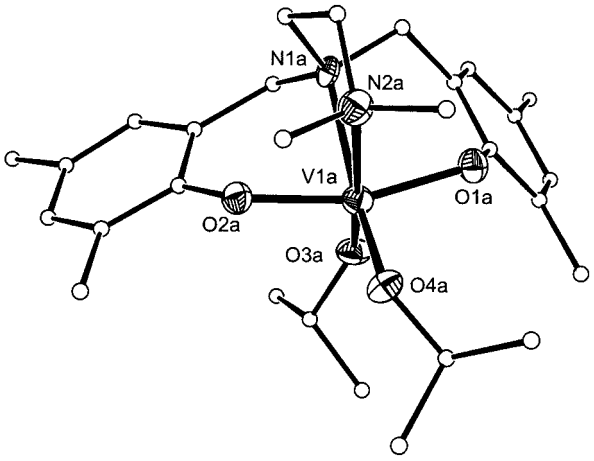

Figure 3. ORTEP drawing of the molecular structure of **2** (independent molecule A) showing 50% probability ellipsoids (except on C atoms for clarity) and partial atom-labeling schemes. Hydrogen atoms are omitted for clarity

The solid-state structures confirm our first formulation for complexes **1**−**4** as mononuclear vanadium complexes with one [ONNO] ligand in association with either two N_3 groups (**1**), two O*iPr* groups (**2**), two Cl groups (**4**), or one chlorine atom and one O*iPr* group (**3**). Furthermore, all complexes have a slightly distorted octahedral geometry with a *trans* configuration for the two phenolate rings of the [ONNO] ligand, as well as coordination of both amino-nitrogen donor atoms to the metal center, features that they share with their group 4 and oxo-[ONNO] vanadium(V) analogs.[5b,5d,5e,5f,12]

In contrast to the latter oxo complexes in which a *trans* effect due to the oxo ligand was observed, resulting in an elongated V−N bond of the amino-nitrogen atom of the [ONNO] ligand *trans* to the oxo group compared to the one in *cis*, here in the vanadium(IV) systems the two V−N bonds (formed between the metal center and the tripodal

amino-N atom and the dimethylamino sidearm N atom) have almost identical distances ranging from 2.19 to 2.31 Å. Short phenoxide V−O bond lengths of 1.78 to 1.82 Å are found in **1**, **3** and **4** (which correspond to the complexes that adopt a similar "symmetric" configuration, vide infra),[25] whereas they are about 0.1 Å longer in complex **2**. All other bonds are in the normal range; alkoxide V−O bond lengths are about 1.79 Å, V−Cl bond lengths are about 2.35 Å, and V−N_{azido} bond lengths are about 2.00 Å. V−O−$C_{phenolate}$ angles are around 141−143° in **1**, **3** and **4**, whereas for **2** they are 117−130° (vide infra). In **2**−**3**, V−O−C_{iPr} angles are between 132−134° which reflect only weak π interactions in the V−alkoxide bonds.

More importantly, if we have a closer look at the four crystal structures of **1**−**4** [see also Figure 6 that represents a view along the tripodal nitrogen atom N1−V−X axis for **1**−**4**, X being N11 (**1**), O4 (**2**), O3 (**3**), Cl2 (**4**)], in complexes **1**, **3** and **4** the [ONNO] fragment adopts the same, almost superimposable, configuration which is probably due to the very similar electronegativity of the chloride and azide ligands. Interestingly, the arrangement of the three groups attached to the tripodal N donor atom (the two benzylic groups and the ethylenic arm) is not helicoidal as observed in the crystal structure of **2**. As a result, the phenolate groups of the [ONNO] framework in **1**, **3** and **4** fold in towards the pendant (dimethylamino)ethyl sidearm, the angle between the two planes of the aromatic rings is about −148° (**1**), −149° (**3**) and −140° (**4**) (the minus sign refers to a folding towards the NMe_2 sidearm, in contrast to the folding away from the NMe_2 sidearm that has a positive sign), whereas in complex **2** the phenolate groups of the tetradentate ligand fold back away from the pendant (dimethylamino)ethyl sidearm, the angle δ between the two planes of the aromatic rings is about +106°. As a consequence, the V−$O_{phenolate}$ and V−N_{amino} bond lengths are longer by about 0.05−0.10 Å in **2** (compared to **1**, **3** or **4**), and the O1−V−O2 angle are smaller in **2** by about 5−10° as well as the V−O−$C_{phenolate}$ by 13° (V−O2−C8) to 26° (V−O1−C7).

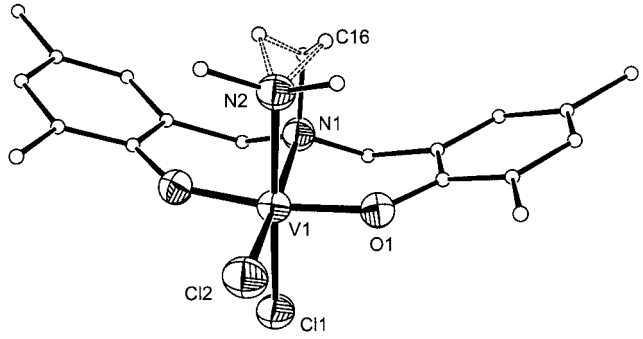

Figure 5. ORTEP drawing of the molecular structure of **4** showing 50% probability ellipsoids (except on C atoms for clarity) and partial atom-labeling schemes. Hydrogen atoms are omitted for clarity

A similar observation was already mentioned in our oxo-[ONNO]-vanadium(v) series of complexes in which, in the solid state and in solution, the amine(bisphenolate) ligand accommodates different arrangements that allows the aromatic rings to flip above and under the plane defined by the vanadium center, the tripodal N atom and the two phenolate O atoms. Now, on the basis of all the crystal structures collected on our [ONNO]-vanadium systems,[26] it ap-

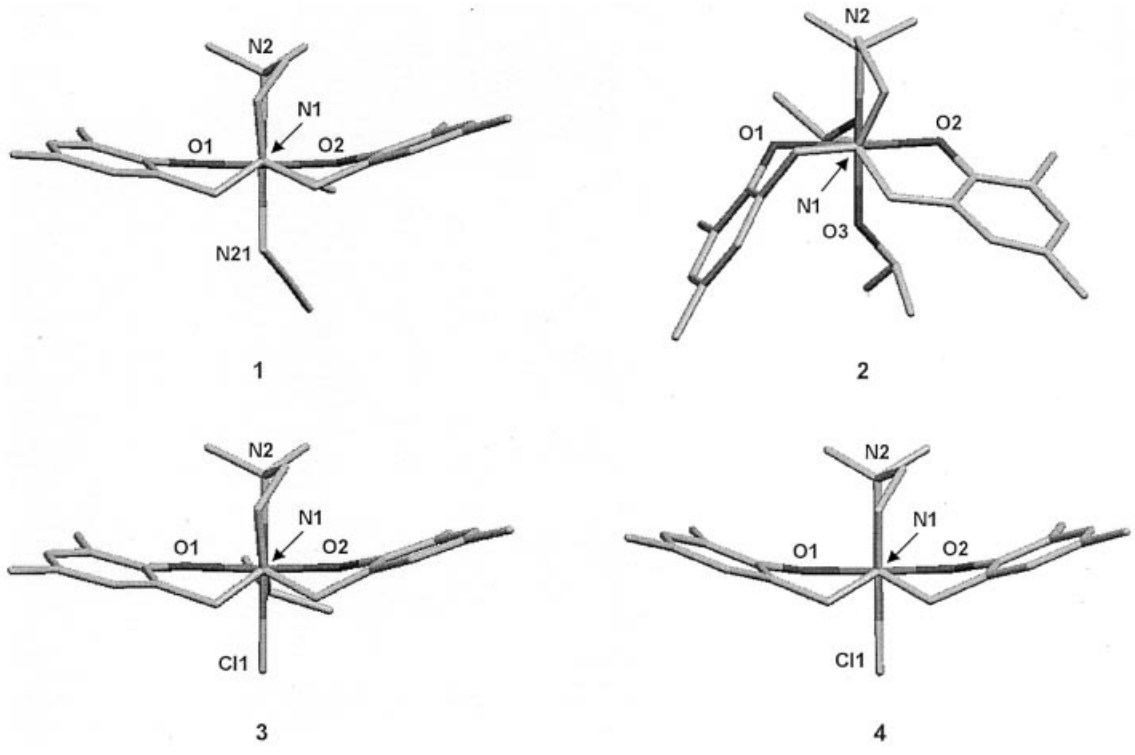

Figure 6. View along the tripodal N1−V−X axis of complexes **1**−**4** [X = N11 (**1**), O4 (**2**), O3 (**3**), Cl2 (**4**)]

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

pears that the "dissymmetric" configuration (never observed for group 4 metal complexes) in which the phenolate ligand folds back away from the pendant (dimethylamino)-ethyl sidearm (as in complex **2** and *cis*-[$V^{V}O(OiPr)\{ONNO\}$][12]) is due to the presence of an *O*-ligated anionic ligand (alkoxo, oxo, ···) *trans* to the (dimethylamino)ethyl sidearm nitrogen donor atom in these complexes.

Interestingly, we crystallized only one isomer for [V(Cl)(O*i*Pr){ONNO}] (**3**) although we could expect the formation of two isomers during the chlorination process with Me_3SiCl. Nevertheless, as the two groups (Cl and O*i*Pr) are *trans* to amino nitrogen donor atoms of similar electronic properties, there is probably no reason why in solution the two isomers would not coexist (and have not been distinguished by EPR spectroscopy).

Conclusion

New vanadium(IV) complexes **1**−**4** containing the amine bis(phenolate) [ONNO] ligand and additional azido, isopropoxo or chloro groups are reported. All complexes are d^1-paramagnetic species, whose crystal structures show an [ONNO] moiety that can adopt two different geometries depending on the nature of the ligand located *trans* to the NMe_2 sidearm nitrogen donor atom. Next, we will present the reactivity of these [ONNO]-vanadium complexes towards olefin polymerization.

Experimental Section

General Remarks: All manipulations were carried out using standard Schlenk line or drybox techniques under argon. Starting materials were purchased from Aldrich Inc. or Fluka Inc. and used without further purification. Solvents were refluxed and dried with appropriate drying agents under argon, collected by distillation and stored in a drybox over activated 4-Å molecular sieves. Trimethylchlorosilane and azidotrimethylsilane were distilled and stored over 4-Å molecular sieves under argon. $[ONNO]H_2$ and $V(OiPr)_4$ were prepared according to known procedures.[5e,13] EPR spectra were recorded on a Bruker ESP300E spectrometer. Infrared spectra were prepared as KBr pellets under argon in a glove box and were recorded on a Perkin−Elmer Spectrum GX FT-IR spectrometer. Infrared data are quoted in wavenumber (cm^{-1}). Elemental analyses were performed at the Laboratoire de Chimie de Coordination (Toulouse, France). Magnetic susceptibility data were collected on powdered samples of the different compounds using a homemade Faraday-type automatic magnetometer with mercury tetra(thiocyanato)cobaltate susceptibility (at 20 °C, 16.44×10^{-6} $cm^3 \cdot mol^{-1}$). Diamagnetic corrections were applied using Pascal's constants as described previously.[9b]

CAUTION: Organic and inorganic azides are potentially explosive compounds and should be handled with great care.[14]

$[V(N_3)_2(NMe_2)_2]$: A large excess of azidotrimethylsilane (2.5 g, 22.0 mmol) was added to a pentane solution (15 mL) of $V(NMe_2)_4$ (1.1 g, 5.0 mmol). The solution was kept at room temperature overnight without stirring. A brown-red microcrystalline solid was filtered off, washed with pentane and dried (yield 96%). IR: $\tilde{\nu}$ = 2050 (s, ν_{N3}) cm^{-1}. $C_4H_{12}N_8V$ (223.1): calcd. C 21.53, H 5.42; found C 21.51, H 5.25 (Caution: we encountered an explosion during the combustion analysis).

$[V(N_3)_2\{ONNO\}]$ (1): Solid $[ONNO]H_2$ ligand (195 mg, 0.45 mmol) was added at room temperature to a THF suspension (2 mL) of $[V(N_3)_2(NMe_2)_2]$ (100 mg, 0.45 mmol). The brown solution was stirred at room temperature for 2 h and a brown solid was filtered off (yield 40%). EPR (THF, 20 °C): g = 1.968, $A(^{51}V)$ = 94.0 G. IR: $\tilde{\nu}$ = 2057 (s, ν_{N3}) cm^{-1}. μ_{eff} (20 °C) = 1.80 μ_B. $C_{22}H_{30}N_8O_2V$ (489.5): calcd. C 53.98, H 6.18, N 22.89; found C 53.81, H 6.31, N 23.11.

$[V(OiPr)_2\{ONNO\}]$ (2): Solid $[ONNO]H_2$ ligand (125 mg, 0.35 mmol) was added at room temperature to a toluene solution (2 mL) of $V(OiPr)_4$ (100 mg, 0.35 mmol). The blue-green solution immediately turned dark red and was stirred at room temperature for 2 h. Removal of the volatiles under vacuum and washing with pentane afforded a dark red solid (yield 86%). EPR (pentane, 20 °C): g = 1.967, $A(^{51}V)$ = 70.9 G. μ_{eff} (20 °C) = 1.79 μ_B. $C_{28}H_{44}N_2O_2V$ (491.6): calcd. C 64.23, H 8.47, N 5.35; found C 63.97, H 8.40, N 5.49.

[V(O*i*Pr)(Cl){ONNO}] (3): An excess of Me_3SiCl (1.90 mmol) was slowly added at room temperature to a toluene solution (2 mL) of **2** (100 mg, 0.19 mmol). The reaction mixture was placed in a 25 mL screw-cap vial and heated at 110 °C for 14 h. Removal of the volatiles afforded a dark solid containing a mixture of **3** and **4** from which **3** could be recrystallized from a pentane/THF solution at room temperature giving 11 mg of **3** (yield 11%). EPR (CH_2Cl_2, 20 °C): g = 1.973, $A(^{51}V)$ = 77.3 G. μ_{eff} (20 °C) = 1.77 μ_B. $C_{25}H_{37}ClN_2O_3V$ (500.0): calcd. C 60.06, H 7.46, N 5.60; found C 59.72, H 7.51, N 5.44.

$[VCl_2\{ONNO\}]$ (4) (*CAUTION*: *closed flask heating*): A large excess of Me_3SiCl (3.80 mmol) was slowly added at room temperature to a toluene solution (4 mL) of $[V(OiPr)_2\{ONNO\}]$ (100 mg, 0.19 mmol). The reaction mixture was placed in a 25 mL screw-cap vial and heated at 110 °C for 14 h and then cooled to room temperature. Dark blue needles were filtered off, washed with pentane and dried under vacuum (yield 96%). EPR (CH_2Cl_2, 20 °C): g = 1.975, $A(^{51}V)$ = 82.7 G. μ_{eff} (20 °C) = 1.82 μ_B. $C_{22}H_{30}Cl_2N_2O_2V$ (476.3): calcd. C 55.47, H 6.35, N 5.88; found C 55.60, H 6.33, N 5.96.

Crystal Structure Determination of 1−4: For the four compounds, data were collected at low temperature (T = 180 K) on a Stoe Imaging Plate Diffraction System (IPDS), equipped with an Oxford Cryosystems Cryostream Cooler Device and using graphite-monochromated Mo-K_α radiation (λ = 0.71073Å). Final unit cell parameters were obtained by means of a least-squares refinement of a set of 8000 well-measured reflections. The crystal decay was monitored during data collection by measuring 200 reflections by image; no significant fluctuation of intensities was observed. Structures were solved by means of Direct Methods with the program SIR92.[15] Subsequent difference Fourier maps and models were refined by least-squares procedures on F^2 by using SHELXL-97[16] integrated in the package WINGX version 1.64,[17] and empirical absorption corrections were applied to the data.[18] All hydrogen atoms were located on difference Fourier maps, and introduced in the refinement as fixed contributors using a riding model with an isotropic thermal parameter fixed at 20% higher than those of the C sp^2 atoms and 50% for the C sp^3 atoms to which they were connected. The methyl groups were refined with the torsion angle as free variable. For the four compounds all non-hydrogens atoms were anisotropically refined, and in the last cycles of refinement weighting schemes were used, where weights were calculated from

Synthesis, Crystal Structure and Thermal Reactivity of New Copper(I) Halide Pyrimidine-Containing Coordination Polymers

Christian Näther*[a] and Inke Jeß[a]

Keywords: Coordination polymers / Copper / Halides / N ligands / Thermal properties

Reaction of copper(I) chloride with pyrimidine in acetonitrile leads to the formation of the ligand-rich 1:1 compound poly-[CuCl(μ_2-pyrimidine-*N*,*N*′)] (**1**). "Zig-zag"-like CuCl chains are found in the crystal structure that are connected by the pyrimidine ligands to form layers. This compound loses half of its ligands upon heating and transforms into the new l2:1 coordination polymer poly[$(CuCl)_2$(μ_2-pyrimidine-*N*,*N*′)] (**2**). In this structure, ladder-like CuCl double chains occur which are connected by the pyrimidine ligands to form layers. If copper(I) iodide is used in the synthesis, the new 1:1 coordination polymer poly[CuI(μ_2-pyrimidine-*N*,*N*′)] (**3**) forms. In contrast to compound **1**, CuI single chains and $(CuI)_2$ dimers are found as the CuX substructure, and these are connected by the ligands to form sheets. On heating this compound a similar behaviour as for compound **1** is observed, and a transformation into the new 2:1 compound poly[$(CuI)_2$(μ_2-pyrimidine-*N*,*N*′)] (**4**) occurs. This compound is not isotypic to **2** even though the topology of the coordination network is identical (CuI double chains are connected into layers by the pyrimidine ligands). The thermal behaviour of the known compounds poly[CuBr(μ_2-pyrimidine-*N*,*N*′)] (**5**) and poly-[$(CuBr)_2$(μ_2-pyrimidine-*N*,*N*′)] (**6**) was also investigated. A transformation of the ligand-rich 1:1 compound **5** into the 2:1 compound **6** is also observed in the thermal decomposition reaction.

Introduction

Inorganic-organic coordination polymers based on copper(I) halides or pseudohalides and aromatic nitrogen-donor ligands are well-known and several of them have been synthesised and structurally characterised in the past.[1−38] These compounds consist of CuX substructures such as four- or six-membered rings, "zig-zag"-like or helical single chains, or "ladder-like" double chains, which are connected by the nitrogen-donor ligands to give one-, two- or three-dimensional coordination polymers. For each combination of copper(I) halide or pseudohalide and nitrogen-donor ligand several different compounds are frequently found, each of which has a different ratio — 1:1, 1:2, 2:1, 3:2 or 4:1 — between the copper(I) halide or pseudohalide and the organic ligand. We have found that most ligand-rich copper(I) halide or pseudohalide compounds can be transformed into ligand-poorer compounds by thermal decomposition, whereas others loses all their ligands in one step forming the pure copper(I) halides or pseudohalides.[26−38] This method is therefore an alternative route for the preparation of new CuX (X = Cl, Br, I, SCN, CN) coordination polymers that cannot be prepared in solution or that are always obtained as mixtures. We have found, for example, no simple relationship between the structure of the starting compound and its thermal reactivity or the structure of the decomposition product.[26−38] However, our investigations do show that the product formation depends on the kinetics of all the reactions involved.[31] In some cases several ligand-poorer intermediates (2:1 or 4:1) or different polymorphic modifications can be isolated.[32−34] In order to investigate the influence of the coordination behaviour of the organic ligands on the structure and the thermal reactivity of these coordination polymers we have prepared and structurally characterised several of them. In most cases we have used small six-membered nitrogen heterocycles (e.g. pyrazine or its derivatives). To investigate the influence of the position of the nitrogen-donor atoms on the structure we were also interested in the pyridazine or pyrimidine coordination compounds. With pyrimidine only the 1:1 compound [CuBr(pyrimidine)][9] the 2:1 compound [$(CuBr)_2$(pyrimidine)][37] and the 2:1 compound [$(CuCN)_2$(pyrimidine)][18,24] have been structurally characterized. The amine-poorer compounds [$(CuX)_2$pyrimidine] (X = Cl, Br, I) were also prepared and characterised by elemental analysis and thermogravimetric measurements.[25] It was shown that these compounds lose all of the pyrimidine ligands in one step forming the pure copper(I)-halides. Here we report on the synthesis, the crystal structure and the thermal reactivity of CuX and $(CuX)_2$ pyrimidine-containing coordination polymers.

Results and Discussion

Crystal Structures

The 1:1 compound poly[CuCl(μ_2-pyrimidine-*N*,*N*′)] (**1**) crystallizes in the orthorhombic space group *Pma*2 with two formula units in the unit cell. The compound is not isotypic with the 1:1 coordination polymer poly[CuBr(μ_2-pyrimidine-*N*,*N*′)] (**5**), and the topology of the coordination network is also different.[9] The asymmetric unit consists of one copper and one chlorine atom as well as one pyrimidine ligand, all of which are located in special positions. Each copper(I) atom is coordinated by two chlorine atoms and two nitrogen atoms of pyrimidine ligands within a distorted tetrahedron (Figure 1, top).

The bond lengths and angles are similar to those of related compounds (Table 1). The copper atoms are connected through the chlorine atoms forming "zig-zag" CuCl chains in the direction of the crystallographic *b*-axis (Figure 1, bottom). These chains are connected by the pyrimidine ligands to form layers that are parallel to (001) (Figure 1, bottom).

The ligand-poorer 2:1 compound poly[$(CuCl)_2$(μ_2-pyrimidine-*N*,*N*′)] (**2**) crystallizes in the orthorhombic space group *Pnma* with four formula units in the unit cell. The asymmetric unit consists of one crystallographically independent Cu and Cl atom in general positions and one pyrimidine ligand which is located in a special position (Figure 2, top). The compound is not isotypic with the previously reported compound poly[$(CuBr)_2$(μ_2-pyrimidine-*N*,*N*′)] (**6**)[37] but contains an identical topology of the coordination network. The copper atoms are coordinated by three chlorine atoms and one nitrogen atom of the pyrimidine ligand within strongly distorted tetrahedra (Table 1). The Cu−N bond length is significantly shorter than that observed in compound **1**, whereas the Cu−Cl bond lengths are longer.

The CuX substructure consists of CuCl double chains which are connected by the pyrimidine ligands to form layers which are parallel to the *bc* plane (Figure 2, bottom). This topology of the coordination network is frequently found in such ligand-poorer 2:1 compounds.

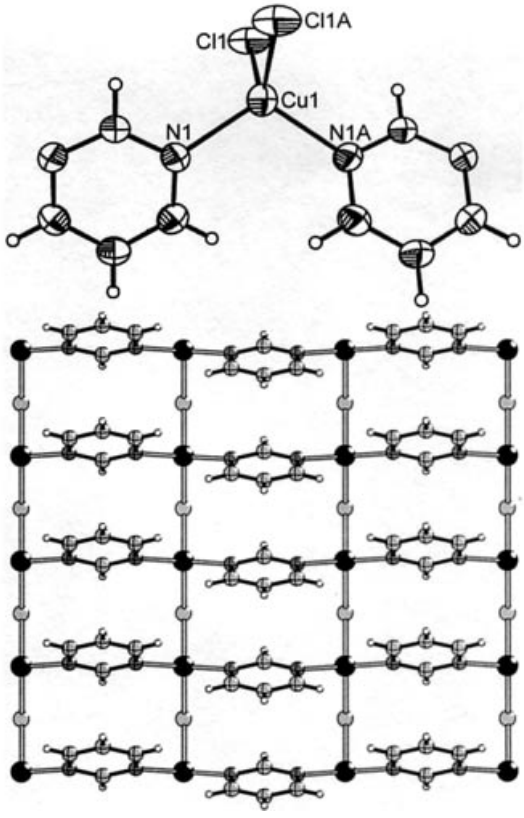

Figure 1. Crystal structure of poly[CuCl(μ_2-pyrimidine-*N*,*N*′] (**1**) showing the coordination sphere of the copper atoms with labelling and displacement ellipsoids drawn at the 50% probability level (top); view of the coordination network along the crystallographic *c*-axis (bottom)

The 1:1 compound poly[CuI(μ_2-pyrimidine-*N*,*N*′)] (**3**) crystallizes in the monoclinic space group $P2_1/c$ with eight formula units in the unit cell. The asymmetric unit consists

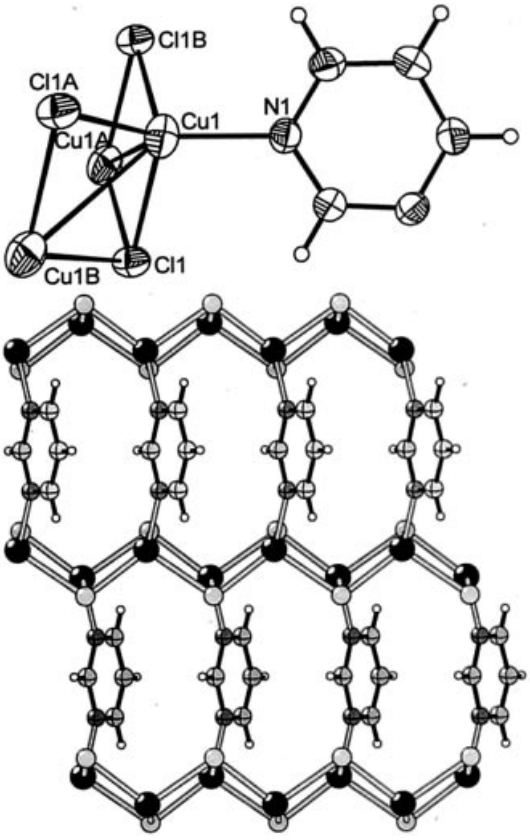

Figure 2. Crystal structure of poly[$(CuCl)_2(\mu_2$-pyrimidine-*N*,*N*′] (**2**) showing the coordination sphere of the copper atoms with labelling and displacement ellipsoids drawn at the 50% probability level (top); view of the coordination network along the crystallographic *a*-axis (bottom)

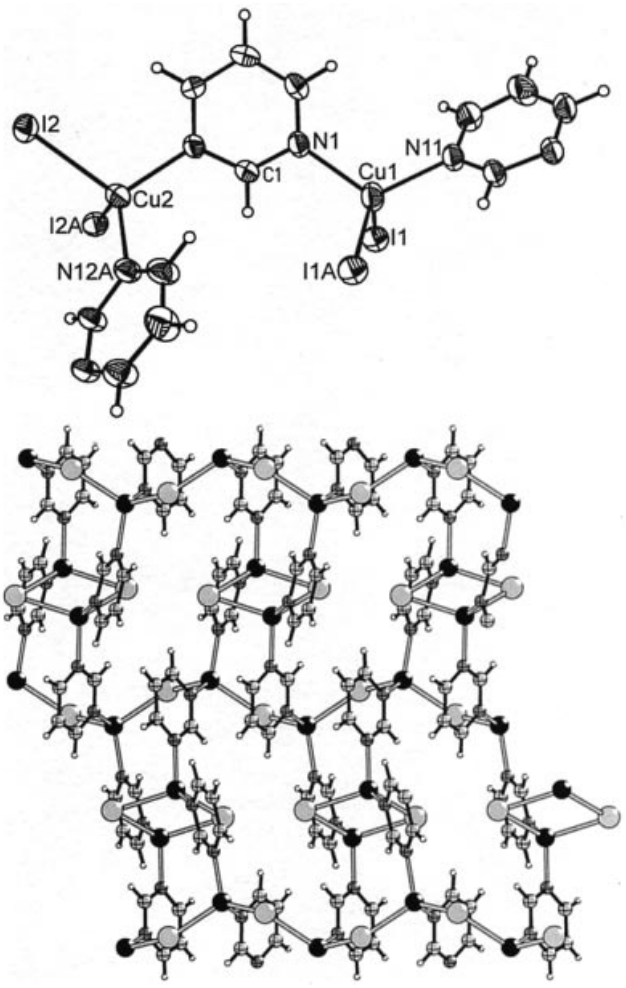

Figure 3. Crystal structure of poly[CuI(μ_2-pyrimidine-*N*,*N*′] (**3**) showing the coordination sphere of the copper atoms with labelling and displacement ellipsoids drawn at the 50% probability level (top); view of the coordination network along the crystallographic *a*-axis (bottom)

of two crystallographically independent Cu atoms and one I atom as well as two pyrimidine ligands located in general positions (Figure 3, top). This compound is isotypic to the 1:1 coordination polymer poly[CuBr(μ_2-pyrimidine-*N*,*N*′)] (**1**).[9] Each of the two crystallographically independent copper atoms is coordinated by two iodine atoms and two organic ligands within a distorted tetrahedra (Table 2 and Figure 3, top). In contrast to compound **1**, two different building units are found as the CuX substructure. Cu1 and I1 form coplanar $(CuI)_2$ dimers which are located on centres of inversion, whereas Cu2 and I2 are connected to "zig-zag"-like CuI single chains which propagate in the direction of the crystallographic *c*-axis (Figure 3, bottom). The dimers and single chains are connected by the pyrimidine ligands into corrugated layers in the *bc* plane.

The ligand poorer 2:1 compound poly[$(CuI)_2(\mu_2$-pyrimidine-*N*,*N*′)] (**4**) crystallizes in the monoclinic space group $P2_1/m$ with two formula units in the unit cell (Table 3). The asymmetric unit contains one copper atom and one iodine in general positions as well as one pyrimidine ligand which is located in the crystallographic mirror plane. The compound is isotypic with the previously reported coordination polymer poly[$(CuBr)_2(\mu_2$-pyrimidine-*N*,*N*′)] (**6**).[37] The copper atoms are surrounded by three iodine atoms and one nitrogen atom of the pyrimidine ligand within a distorted tetrahedron (Figure 4, top). The bond lengths and angles are similar to those observed in other ligand-poorer 2:1 CuX compounds. As in the CuCl compound **1** and the CuI compound **4**, CuX double chains are found as the CuX substructure, and these are connected to form layers by the pyrimidine ligands. Therefore, the topology of the coordination network is identical in all ligand-poorer 2:1 compounds.

If the crystal structures of the present pyrimidine compounds are compared with those of the previously reported pyrazine and pyridazine compounds some interesting features become obvious. The ligand-rich 1:2 coordination polymers with pyrazine have an identical topology of the coordination network to the present pyrimidine compounds. CuX single chains (X = Cl,[39] Br[15]) are observed as the CuX substructure, and these are connected into layers by the pyrazine ligands. If the N-donor atoms are located in the 1- and 2-positions, like in pyridazine, the topology of the coordination network in the 1:1 compounds is completely different.[9,34] Due to steric restrictions no layered structures can be formed and typical one-dimensional

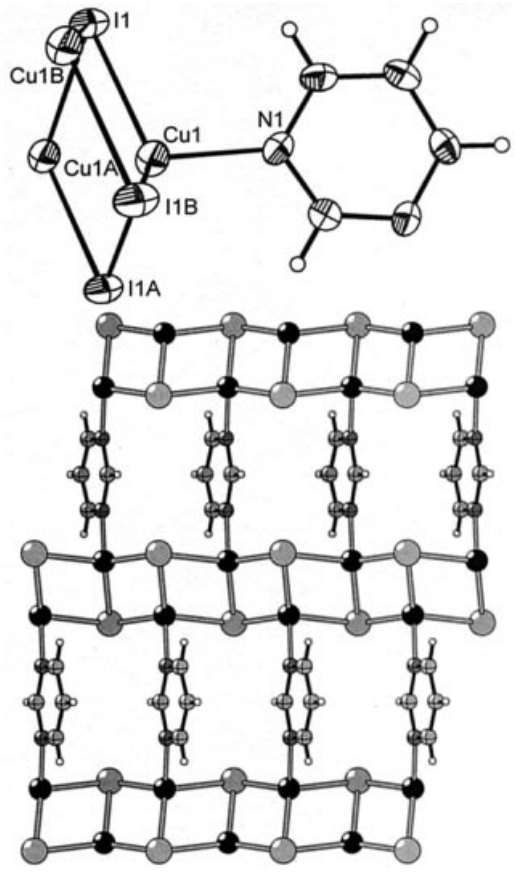

Figure 4. Crystal structure of poly[$(CuI)_2(\mu_2$-pyrimidine-*N*,*N*′] (**4**) showing the coordination sphere of the copper atoms with labelling and displacement ellipsoids drawn at the 50% probability level (top); view of the coordination network along the crystallographic *a*-axis (bottom)

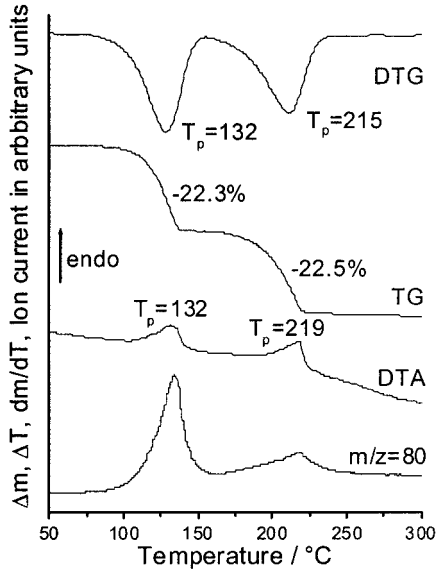

Figure 5. DTA, TG, DTG and MS trend scan curves for poly[CuCl(μ_2-pyrimidine-*N*,*N*′] (**1**) (weight: 19.98 mg; heating rate: 4 °C/min.; MS: m/z = 80 (pyrimidine); T_p = peak temperature)

structures result. A similar observation is made for the ligand-poorer 2:1 compounds. The topology of the structures with pyrazine is identical to that of the structures with pyrimidine. CuX double chains (X = Cl,[40] Br[11]) are observed that are connected to form layers. This arrangement cannot be formed with pyridazine as ligand and therefore completely different CuX substructures (X = Cl, Br,[34] I[9]) and a completely different coordination network result.

Thermal Properties

The thermal properties of compounds **1**−**5** were investigated by simultaneous differential thermoanalysis, thermogravimetry and mass spectrometry, as well as temperature-dependent X-ray powder diffraction.

On heating poly[CuCl(μ_2-pyrimidine-*N*,*N*′] (**1**) in a thermobalance two mass steps are observed, which are accompanied by two endothermic events in the DTA curve at peak temperatures of 132 and 219 °C (Figure 5).

The experimental mass-loss of 22.3 and 22.5% in both steps is in good agreement with that calculated for the removal of half of the pyrimidine ligands in each step [Δm_{theo} = 22.3%]. The DTG curve shows that both steps are well resolved and that only pyrimidine (m/z = 80) is emitted. The final product of this reaction was identified as $Cu^{I}Cl$ by X-ray powder diffraction. These results suggest that in the first step the ligand-poorer 2:1 compound poly[$(CuCl)_2(\mu_2$-pyrimidine-*N*,*N*′] (**2**) is formed, which on further heating loses its remaining pyrimidine ligands. The results found for the decomposition of the amine-poorer 2:1 compound are in agreement with those found by Mayer et al.[25]

To identify the intermediate after the first TG step a second TG experiment was performed which was stopped after the first TG step. The residue isolated was investigated by elemental analysis and X-ray powder diffraction. When this experimental powder pattern was compared with that calculated for the 2:1 compound **2** from single crystal data, it was confirmed that the ligand poorer coordination polymer **2** had formed (Figure 6).

On heating the 1:1 compound poly[CuI(μ_2-pyrimidine-*N*,*N*′] (**3**) a similar behaviour as for compound **1** was found. Two endothermic events were observed at peak temperatures of 110 and 215 °C which are accompanied by two well-resolved mass steps in the TG curve (Figure 7). The MS spectra show that in both steps only pyrimidine ligands are emitted and the experimental mass loss is in good agreement with that calculated for the emission of half of the pyrimidine ligands in each step (Δm_{theo} = 14.8%). Therefore, the first TG step should lead to the formation of the ligand-poorer compound **4**. The residue after the second TG step was identified as CuI by X-ray powder diffraction, which is in agreement with previous investigations.[25]

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

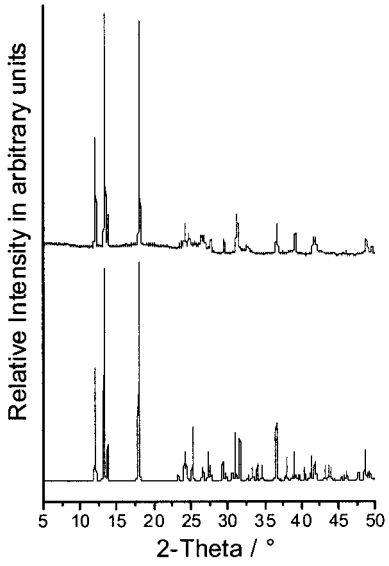

Figure 6. Powder pattern of the residue isolated after the first TG step during the thermal decomposition of poly[CuCl(μ_2-pyrimidine-*N*,*N*′] (**1**) (top), and calculated pattern for the ligand-poorer 2:1 compound poly[(CuCl)$_2$(μ_2-pyrimidine-*N*,*N*′] (**2**) (bottom)

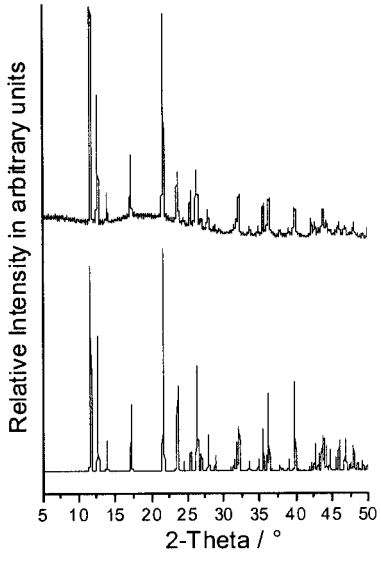

Figure 8. Powder pattern of the residue isolated after the first TG step during the thermal decomposition of poly[CuI(μ_2-pyrimidine-*N*,*N*′] (**3**) (top), and calculated pattern for the ligand-poorer 2:1 compound poly[(CuI)$_2$(μ_2-pyrimidine-*N*,*N*′] (**4**) (bottom).

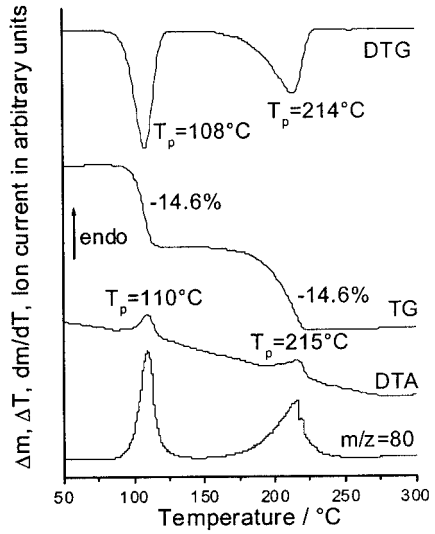

Figure 7. DTA, TG, DTG and MS trend scan curves for poly[CuI(μ_2-pyrimidine-*N*,*N*′] (**3**) (weight: 19.98 mg; heating rate: 4 °C/min.; MS: *m*/*z* = 80 (pyrimidine); T_p = peak temperature)

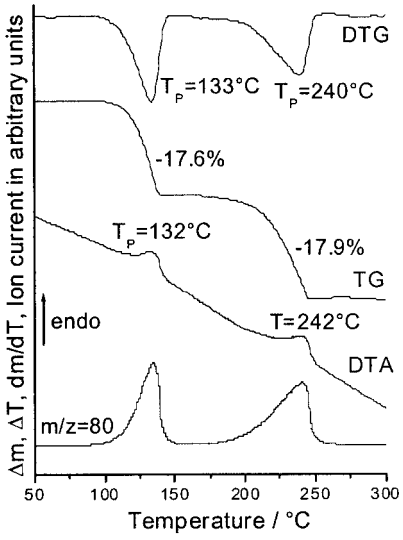

Figure 9. DTA, TG, DTG and MS trend scan curves for poly[CuBr(μ_2-pyrimidine-*N*,*N*′] (**5**) (weight: 19.98 mg; heating rate: 4 °C/min.; MS: *m*/*z* = 80 (pyrimidine); T_p = peak temperature)

In a second TG run the experiment was stopped after the first TG step and the intermediate was investigated by X-ray powder diffraction and elemental analysis. The CHN content is in agreement with that calculated for a ligand-poorer 2:1 compound and the experimental powder pattern is identical with that calculated for compound **4** (Figure 8).

If the known 1:1 compound poly[CuBr(μ_2-pyrimidine-*N*,*N*′)] (**5**) is heated in a thermobalance two well-resolved mass steps occur which are accompanied by two endothermic events in the DTA curve (Figure 9). The MS curve shows that only the N-donor ligands are removed and the experimental mass loss of 17.6 and 17.9% in both steps is in good agreement with that calculated for the removal of half of the pyrimidine ligands in each step (Δm_{theo} = 17.9%). The residue formed after the first TG step was identified as the ligand-poorer 2:1 compound poly[(CuBr)$_2$(μ_2-pyrimidine-*N*,*N*′)] (**6**; Figure 10).

Because in previous investigations we have shown that the product formation sometimes depends on the kinetics of all the reactions involved[31] heating-rate-dependent studies were performed for all compounds at rates of between 0.5 and 16 °C/min. However, these experiments showed no changes in the TG curves and gave no hints for the presence of additional intermediates during the thermal reactions.

To investigate if the reaction is more complex and, for example, different polymorphic modifications occur, temperature-dependent X-ray powder measurements were performed[33–35] (Figure 11).

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

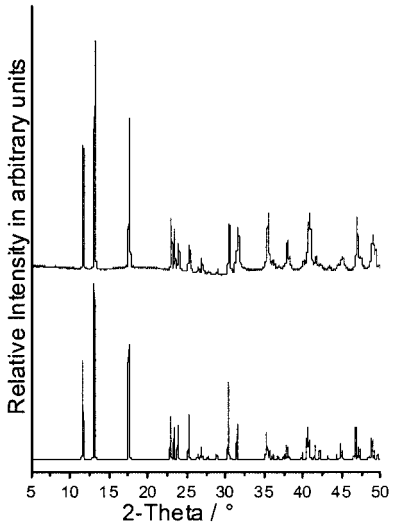

Figure 10. Powder pattern of the residue isolated after the first TG step during the thermal decomposition of poly[CuBr(μ_2-pyrimidine-*N*,*N*′] (**5**) (top), and calculated pattern for the ligand-poorer 2:1 compound poly[(CuBr)$_2$(μ_2-pyrimidine-*N*,*N*′] (**6**) (bottom)

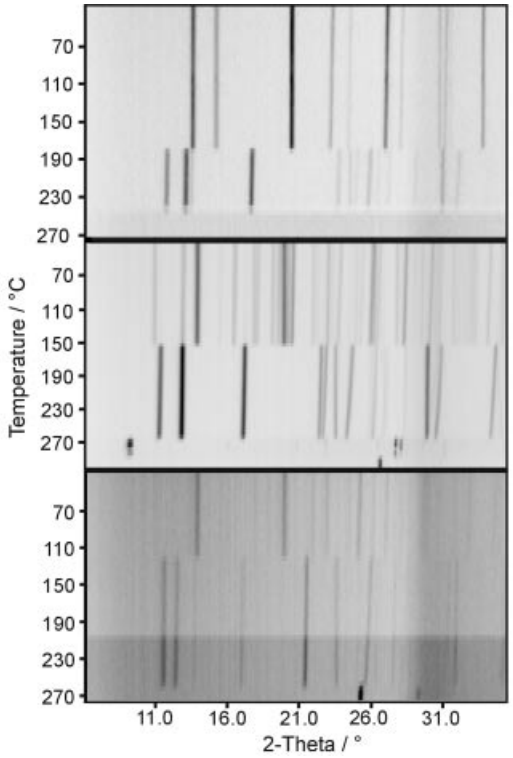

Figure 11. Temperature-resolved X-ray powder pattern for poly[CuCl(μ_2-pyrimidine-*N*,*N*′] (**1**) (top), poly[CuBr(μ_2-pyrimidine-*N*,*N*′] (**5**) (middle) and poly[CuI(μ_2-pyrimidine-*N*,*N*′] (**3**) (bottom); heating rate: 5 °C/min; the diffraction pattern was measured every 5 °C

It must be noted that the decomposition temperatures cannot be compared with those from the DTA-TG-MS measurements because different conditions, for example static or flowing atmosphere, are used. On heating the CuCl compound **1** the formation of the 2:1 compound is observed at about 180 °C, which is obvious from the dramatic change of the diffraction pattern (Figure 11, top). The 2:1 compound **2** is stable up to about 250 °C and then formation of CuCl is observed. The formation of CuCl is not visible in the presented pattern because in this experiment the gaseous product blows out the powder from the X-ray beam. However, this was proven in additional experiments. When poly[CuBr(μ_2-pyrimidine-*N*,*N*′] (**5**) was heated similar observations were made. The 1:1 compound is stable up to about 150 °C before the transformation into the 2:1 compound occurs. On further heating the ligand-poorer compound **6** decomposes at about 260 °C. Decomposition of the iodine compound **3** starts at about 120 °C (Figure 11, bottom). The 2:1 phase **4** is stable up to 260 °C and then the formation of CuI is observed. From these experiments there is no hint of additional intermediates or the occurrence of different polymorphic modifications. However, it should be noted that the stability range of the ligand-poorer 2:1 compounds increases from CuCl to CuI, whereas for the 1:1 compounds an opposite trend is observed. This is in agreement with previous results which shows that the stability of the ligand-poorer coordination polymers increases from CuCl to CuI.

Conclusion

In the present work we have prepared several new coordination polymers based on copper(I) halides and pyrimidine as the N-donor ligand. Comparison of these structures with those of the previously reported compounds with pyrazine and pyridazine as the organic ligands shows that the structure of these coordination polymers can be understand to some extent by taking into account the coordination behaviour of the N-donor ligands. However, the influence of the ligands on the actual CuX substructure is difficult to predict.

For all of these compounds ligand-poorer 2:1 compounds are observed during the thermal decomposition, which, on further heating, decompose to the pure copper(I) halides. The results observed for the amine-poorer 2:1 compounds are in agreement with those of previous investigations.[25] However, our investigations shows that this is a general phenomena and that there is no simple relationship between the structure of the ligand-rich phases and their thermal reactivity. Because the topology of the coordination network in the ligand-poorer coordination polymers is identical, whereas that of the ligand-rich coordination polymers is different, there is also no obvious relationship between the structures of the starting compounds and those formed by the thermal decomposition reaction. However, our investigation shows that new ligand-poorer coordination polymers can be prepared by thermal decomposition of suitable ligand-rich precursor compounds.

Experimental Section

Synthesis of poly[CuCl(μ_2-pyrimidine-*N*,*N*′)] (1): CuCl (49.5 mg, 0.5 mmol), pyrimidine (160 μL, 2 mmol) and 2 mL of acetonitrile

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

were placed into a glass ampoule which was sealed and heated for 1 week at 100 °C. The reaction mixture was cooled to room temp. and the orange-red residue was filtered off and washed with ethanol and diethyl ether. Yield: 79.3% based on CuCl. $C_4H_4ClCuN_2$ (179.08): calcd. C 26.8, H 2.2, N 15.6; found C 26.5, H 2.2, N 15.5.

Synthesis of poly[(CuCl)$_2$(μ$_2$-pyrimidine-*N*,*N*′)] (2): Single crystals were prepared by the reaction of CuCl (98.9 mg, 1.0 mmol), pyrimidine (40 μL, 0.5 mmol) and 2 mL acetonitrile in a glass ampoule which was sealed and heated for 4 days at 100 °C. The reaction mixture was cooled to room temp. and the yellow residue was filtered off and washed with ethanol and diethyl ether. Under these conditions the precipitate consists of a mixture of the 1:1 compound **1** and the 2:1 compound **2**. If an excess of CuCl is used the product is contaminated with a small amount of unchanged copper(I) chloride. However, this compound can be prepared in large amounts and very pure by thermal decomposition of **1**.

Synthesis of poly[CuI(μ$_2$-pyrimidine-*N*,*N*′)] (3): CuI (95.2 mg, 0.5 mmol), pyrimidine (160 μL, 2 mmol) and 2 mL of acetonitrile were stirred together at room temp. for 3 days. The yellow residue was filtered off and washed with ethanol and diethyl ether. Yield: 84.3% based on CuI. $C_4H_4CuIN_2$ (270.53): calcd. C 17.8, H 1.5, N 10.4; found C 17.7, H 1.4, N 10.3. Single crystals were prepared by the reaction of CuI (47.6 mg, 0.25 mmol) and pyrimidine (80 μL, 1 mmol) in 2 mL of acetonitrile. After 5 days yellow single crystals were grown.

Synthesis of poly[(CuI)$_2$(μ$_2$-pyrimidine-*N*,*N*′)] (4): CuI (190.5 mg, 1.0 mmol), pyrimidine (40 μL, 0.5 mmol) and 3 mL of acetonitrile were placed into a glass ampoule which was sealed and heated for 3 days at 110 °C. The reaction mixture was cooled to room temp. and the yellow residue was filtered off and washed with ethanol and diethyl ether. The product consists of yellow needles and a yellow microcrystalline powder. Yield: 84.5%. $C_4H_4Cu_2I_2N_2$ (460.97): calcd. C 10.4, H 0.9, N 6.1; found C 10.4, H 0.8, N 6.2.

Synthesis of poly[CuBr(μ$_2$-pyrimidine-*N*,*N*′)] (5): CuBr (71.7 mg, 0.5 mmol), pyrimidine (160 μL, 2 mmol) and 3 mL of acetonitrile were placed into a glass ampoule which was sealed and heated for 4 days at 100 °C. The reaction mixture was cooled to room temp. and the orange residue was filtered off and washed with ethanol and diethyl ether. Yield: 86.8%. $C_4H_4BrCuN_2$ (223.54): calcd. C 21.5, H 1.8, N 12.5; found C 20.4, H 1.8, N 12.4.

Single-Crystal Structure Analysis: All structure solutions were performed with direct methods using SHELXS-97.[41] Further details are given in Table 3. Structure refinement was done against F^2 using SHELXL-97.[42] All non-hydrogen atoms were refined with anisotropic displacement parameters. The C−H hydrogen atoms were positioned with idealised geometry and were refined with isotropic displacement parameters using the riding model. For compounds **1**, **3** and **4** a numerical absorption correction was performed using X-RED and X-SHAPE.[43] The absolute structure for compound **1** was determined and is in agreement with the selected setting [Flack *x* parameter = −0.047(15)]. In addition, refinement of the inverted structure leads to significant poorer reliability factors [*R*1 for 755 $F_o > 4\sigma(F_o)$ = 0.0440, *wR*2 for all 884 reflections = 0.1525, Flack *x* parameter = 1.026 (0.042)].
CCDC-226928 (for **1**), -226929 (for **2**), -226926 (for **3**) and -226927 (for **4**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: +44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

X-ray Powder Diffraction: X-ray powder diffraction experiments were performed using a STOE STADI P transmission powder diffractometer equipped with a 4° PSD (position sensitive detector) using Cu-K_α radiation (λ = 1.540598 Å). For the temperature-dependent X-ray powder measurements a 45° PSD and a graphite furnace from STOE & CIE were used. These measurements were carried out in glass capillaries under a static air atmosphere.

Differential Thermal Analysis, Thermogravimetry and Mass Spectrometry: DTA-TG-MS measurements were performed using an STA-409CD with Skimmer coupling from Netzsch, equipped with a quadrupole mass spectrometer QMA 400 (max. 512 amu) from Balzers. The MS measurements were performed in analog and trend scan mode, in Al_2O_3 crucibles under helium atmosphere (purity: 4.6) at heating rates of 4 °C/min. The heating-rate-dependent measurements were performed with the same instrument in a Pt-Rh furnace in flowing nitrogen (purity: 5.0). All measurements were performed with a flow rate of 75 mL/min. and were corrected for buoyancy and current effects. The instrument was calibrated using standard reference materials.

Elemental Analysis: C, H and N analysis was performed using a CHN-O-RAPID combustion analyser from Heraeus and EDAX was performed using a Philips XL30 Environmental Scanning Electron Microscope (ESEM) equipped with an EDAX system from Philips.

Ruthenium(II) Octaphenylporphyrazine Complexes with Mixed Axial Ligands: Peculiarities of Their Formation and Spectral Properties

Sergej Vagin,*[a,b] Ulrich Ziener,[a,c] Michael Hanack,*[a] and Pavel A. Stuzhin[b]

Keywords: Isocyanide ligands / N ligands / NMR spectroscopy / Porphyrinoids / Ruthenium / Self-assembly

A series of new axially bis-coordinated (octaphenylporphyrazinato)ruthenium(II) complexes {[(Ph_8Pz)RuL_2], L = cyclohexyl isocyanide, CyNC, (**1b**); 4,4′-bipyridine, bpy, (**2c**); *N*-methylimidazole, CH_3Im, (**3a**)} was prepared and characterized. The reaction of the bis-isocyanide adducts [(Ph_8Pz)Ru(*t*-BuNC)$_2$] (**1a**) or [(Ph_8Pz)Ru(CyNC)$_2$] (**1b**) with monodentate N-heterocycles gave, under certain conditions, the mixed-ligand complexes [(Ph_8Pz)Ru(Py)(*t*BuNC)] (**4a**), [(Ph_8Pz)Ru(Py)-(CyNC)] (**4b**) and [(Ph_8Pz)Ru(CH_3Im)(CyNC)] (**3b**). The reaction of **1a** or **1b** with an excess of bidentate 4,4′-bipyridine under the same conditions resulted in the formation of the corresponding dimeric species [(Ph_8Pz)Ru(*t*BuNC)]$_2$(μ-bpy) (**2a**) and [(Ph_8Pz)Ru(CyNC)]$_2$(μ-bpy) (**2b**) in high yield. The structures of all the complexes were unambiguously proved by ^{1}H NMR spectroscopy, and the possibility of their self-assembly is discussed. All mixed-ligand compounds were also characterized by UV/Vis and IR spectroscopy, as well as elemental analysis. The ^{1}H NMR spectra of these compounds are discussed in detail.

Introduction

The high interest in complexes of porphyrins (Por), and their analogues, with transition metals such as Co, Fe, Ru, Os, etc. has arisen, especially in recent years, due to their possible application in materials science and industry. Many peculiar properties of these compounds appear to be a consequence of their ability to bind additional axial ligands, as well as to change the oxidation state of the central metal relatively easily. In particular, a high catalytic activity in different processes — decarbonylation of aldehydes,[1a] isomerization of epoxides,[1b] oxidation of different organic substrates,[1c,1d] etc. — has been observed for transition-metal complexes with porphyrin-type macrocycles, including phthalocyanines (Pc).[1e] Polymeric axially linked complexes of iron, cobalt and ruthenium with phthalocyanines and naphthalocyanines (Nc) possess semiconducting properties in the solid state.[2] Porphyrin complexes of ruthenium and osmium have also been used to construct different self-organized multimacrocyclic assemblies through axial coordination,[3] in which energy- or electron-transfer effects can appear due to the special intramolecular interaction between face-to-face or side-to-face oriented macrocycles, leading to the possibility of light harvesting and efficient photocurrent generation by these systems.[4] Additionally, the important role played by porphyrin-like complexes with different transition metals, especially iron and cobalt, in many biological processes has led to a vast amount of research on analogous model compounds, including phthalocyanines. This research was aimed mainly at the investigation of the axial-ligand-exchange rules and mechanisms in macrocyclic systems.[5]

Complexes of alkyl- and aryl-substituted porphyrazines (Pz), which have an intermediate structure between porphyrins and phthalocyanines, have been less-well investigated and only a few studies on the synthesis and properties of these compounds are available. We have previously prepared and characterized a series of monomeric and oligomeric iron and ruthenium complexes with octaphenylporphyrazine (Ph_8Pz), containing different axial ligands,[6] and investigated the axial-ligand-exchange processes in [(Ph_8Pz)Fe(L)(L′)], where L and L′ are isocyanides or N-heterocycles.[7] Here we continue the study of axially coordinated complexes of octaphenylporphyrazine with iron subgroup metals. We have reported previously that "crude" [(Ph_8Pz)Ru], which can be prepared by template condensation of diphenylfumaronitrile and [$Ru(NH_3)_5(N_2)$]Cl_2,[6e] is a very convenient starting material for the synthesis of hexacoordinate (octaphenylporphyrazinato)ruthenium(II) complexes [(Ph_8Pz)RuL_2], where L is one of various N-heterocycles or isocyanides. Thus, refluxing crude [(Ph_8Pz)Ru]

in pyridine for 24 h gave the corresponding bis-pyridine adduct [(Ph_8Pz)Ru($Py)_2$] (**4c**) and heating [(Ph_8Pz)Ru] with *tert*-butyl isocyanide resulted in the formation of [(Ph_8Pz)-Ru(tBuNC)$_2$] (**1a**).[6c] A similar route was chosen in the present work to prepare bis adducts of (octaphenylporphyrazinato)ruthenium(II) with cyclohexyl isocyanide {[(Ph_8Pz)Ru-(CyNC)$_2$] (**1b**)}, 4,4′-bipyridine {[(Ph_8Pz)Ru(bpy)$_2$] (**2c**)} and *N*-methylimidazole {[(Ph_8Pz)Ru($CH_3Im)_2$] (**3a**)}. The bis-isocyanide complexes **1a** and **1b** were utilized to prepare the mixed axial ligand complexes [(Ph_8Pz)Ru(Py)(tBuNC)] (**4a**), [(Ph_8Pz)Ru(Py)(CyNC)] (**4b**), [(Ph_8Pz)Ru(CH_3Im)-(CyNC)] (**3b**), [(Ph_8Pz)Ru(tBuNC)$_2$(bpy) (**2a**) and [(Ph_8Pz)Ru(CyNC)]$_2$(bpy) (**2b**) shown in Scheme 1. The structure of these compounds was verified by means of UV/Vis, IR and NMR spectroscopy (see discussion below), as well as by elemental analysis. Mass spectrometry was found not to give enough information on the structure of axially coordinated ruthenium octaphenylporphyrazines due to a complete loss of axial ligands even under the relatively soft conditions of the FD technique.[6c] Therefore, we did not apply this method of analysis for the compounds reported here.

Results and Discussion

Ruthenium complexes of porphyrins or phthalocyanines are, in general, more stable towards the loss of axial ligands than their iron analogues.[5e,10] This is also true for octaphenylporphyrazine systems. For example, the complete substitution of axially coordinated isocyanides by pyridine, or vice versa, in iron complexes proceeds with rather high rates ($\tau_{1/2} \approx 1-10$ min) even at room temperature.[7] On the other hand bis-isocyanide adducts [(Ph_8Pz)Ru($RNC)_2$] with ruthenium as a central metal remain unchanged in pyridine solution at room temperature at least for several hours. Early investigations on axial-ligand-exchange in iron or ruthenium phthalocyanines allowed the proposal of a dissociative mechanism for these processes.[5] Additionally, in complexes with axial ligands that exhibit a strong *trans* effect, substitution usually proceeds in two well-separated steps, as shown in Scheme 2, where Pz is a porphyrazine-type macrocycle and M is iron or ruthenium. We have also observed this mechanism for the substitution of axially coordinated isocyanides by N-heterocycles in (octaphenylporphyrazinato)iron complexes.[7]

In this work we studied the substitution behavior of axially coordinated isocyanides in (octaphenylporphyrazinato)-ruthenium(II) complexes. Although these compounds remain spectroscopically unchanged at room temperature in pyridine solution for a relatively long time, as pointed out above, heating them to elevated temperatures (but below 100 °C) results in modest changes in their UV/Vis spectra (see **a** in Figure 1, dotted line), although the resulting spectra do not correspond to that of the bis-pyridine adduct **4c**. The spectra were, however, found to be similar to the spec-

tra of solutions of (octaphenylporphyrazinato)iron(II) complexes [(Ph_8Pz)Fe(L)(L′)] with two different axial ligands — one isocyanide and one nitrogen heterocycle, such as pyridine. These spectra were observed in our titration experiments on [(Ph_8Pz)Fe($RNC)_2$] with nitrogen heterocycles, in which we were not able to isolate the mixed-ligand compounds in the solid state due to their high lability.[7] Additionally, the formation of [(Ph_8Pz)Fe(L)(L′)] adducts from [(Ph_8Pz)Fe($RNC)_2$] was found to be so fast that we were not able to study the kinetics of this process by common spectroscopic techniques. In contrast, the reaction of [(Ph_8Pz)Ru(tBuNC)$_2$] with pyridine could be followed easily. The reaction was found to be first order in ruthenium complex {a linear dependence of ln(C^o/C) on reaction time was observed, where C^o and C are the starting and current concentrations of [(Ph_8Pz)Ru(tBuNC)$_2$] respectively} and zero order in pyridine (see Figure 2). This, and the observed spectral changes, allowed us to assume that under these reaction conditions only the first step shown in Scheme 2 {formation of the mixed-ligand complex [(Ph_8Pz)Ru(Py)(tBuNC)] (**4a**)} takes place. The activation energy of this process is rather high (see Table 1), which explains the observed high kinetic stability of ruthenium complexes **1a** and **1b** at room temperature. However, a comparison of the kinetic parameters of the described reaction with those of analogous reactions of [PcRu($BzNC)_2$] (Bz = benzyl) reveals a higher lability of the porphyrazine complex.[10] A similar trend was observed in our studies on (octaphenylporphyrazinato)iron complexes.[7]

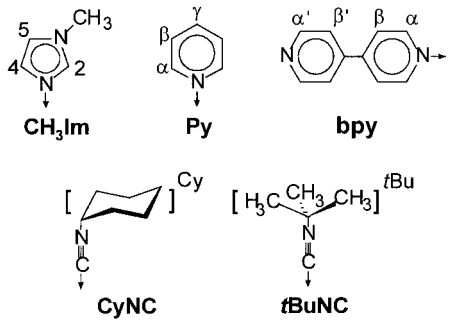
[(Ph_8Pz)Ru(Py)(tBuNC)] (**4a**) was isolated and its IR and NMR spectra were recorded. The obtained spectroscopic data proved the mixed-ligand nature of the compound. The analogous complexes of iron or ruthenium phthalocyanine or porphyrins have been described previously.[10] Several other compounds, such as CO, nitroso derivatives and phosphites,[10–12] can also be utilized as strong-field axial ligands to build similar mixed-ligand complexes. Here (octaphenylporphyrazinato)ruthenium mixed-ligand complexes with axially coordinated isocyanides and nitrogen heterocycles have been isolated and characterized for the first time.

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

It is remarkable that upon heating the reaction mixture above 100 °C in the presence of an excess of the nitrogen heterocycle the second step in Scheme 2 can also take place to yield the bis adduct of the corresponding heterocycle, which does not happen under milder conditions with the same concentration of heterocycle. Therefore, and in contrast to iron complexes, in the case of porphyrazinatoruthenium isocyanides the kinetic control of the substitution reaction becomes obvious. This allowed us to prepare and isolate mixed-ligand complexes of (octaphenylporphyrazinato)ruthenium(II) with axially coordinated alkyl isocyanides and nitrogen heterocycles, namely [(Ph_8Pz)Ru(Py)(CyNC)] (**4b**) and [(Ph_8Pz)Ru(CH_3Im)(CyNC)] (**3b**). Interestingly, the reaction of [(Ph_8Pz)Ru(RNC)$_2$] even with a large excess of 4,4′-bipyridine (see Exp. Sect.) under mild conditions results in an almost quantitative yield of the dimeric bipyridine-bridged complexes **2a** or **2b** with no monomeric mixed-ligand species. The structure of these self-assembled dimers was determined from their ^{1}H NMR spectra.

The position of the ^{1}H NMR resonances of the axial ligands depends strongly on the distance of the protons from the coordinating metal because of the different shielding effect of the porphyrazine macrocycle ring current. This allows, for example, to use iron and ruthenium phthalocyanines as shift reagents in NMR spectroscopy for some coordination compounds.[13a,13b] The protons closest to the center of the macrocycle undergo the strongest shielding ring-current effect, which can be as much as 9 ppm, as was observed, for example, for the α-protons in dioctylgermanium phthalocyanine.[13c] Dependence of the ring-current shielding effect on the position of the proton about phthalocyanines or naphthalocyanines was also calculated.[13d,13e] Accordingly, the observed ^{1}H NMR signals of coordinated axial ligands in different complexes of (octaphenylporphyrazinato)ruthenium(II) can be assigned as shown in Table 2. The signals of coordinated pyridine appear as three multiplets, which have slightly different positions for the bis-pyridine adduct **4c** and the mixed-ligand species **4a** and **4b**. The position of the α-proton signals was found to be the most sensitive to the nature of the *trans* ligand (see Table 2 and Scheme 3). The resonance of the α-proton in **4a**, for example, is shifted upfield by 0.28 ppm relative to **4c**. Therefore, taking into account also the integration, it can clearly be seen that the mixed-ligand complexes **4a** and **4b** do not contain any admixture of bis-pyridine adduct **4c** or of starting material **1a** or **1b** (see also **a** in Figure 3).



Scheme 3. Designation of protons in axially coordinated molecules used for ^{1}H NMR signals' assignment

Similarly, the proton signals of the coordinated *N*-methylimidazole undergo a noticeable upfield shift when going from the bis(*N*-methylimidazole) adduct **3a** to the mixed-ligand complex **3b** (see Table 2). Their shifts are even stronger than for the pyridine adducts. In contrast, the signals of coordinated alkyl isocyanides do not depend as strongly on the nature of the *trans* ligand. Thus, the difference in position of the singlet of coordinated *t*BuNC in **1a** and **4a** is only 0.04 ppm. The signals of coordinated CyNC appear as several broad multiplets in the region $\delta = -0.6$ to 0.9 ppm and their assignment is complicated because of

Table 2. ^{1}H NMR spectroscopic data of the prepared compounds; intervals are given for broad multiplets or groups of multiplets; middle position is given for narrow multiplets

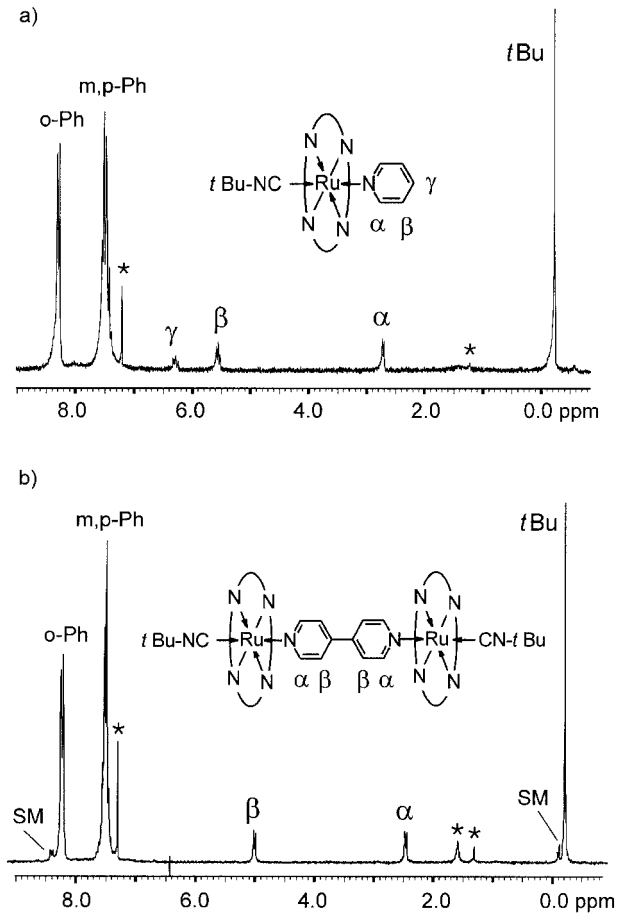

Figure 3. ^{1}H NMR spectra of [(Ph_8Pz)Ru(Py)(*t*BuNC)] (a) and [(Ph_8Pz)Ru(*t*BuNC)]$_2$(μ-bpy) (b) in $CDCl_3$ (250 MHz); signals of impurities ($CHCl_3$, H_2O etc.) are marked with an asterisk; signals of starting materials are denoted as SM

the different possible conformations of CyNC (axial and equatorial position of NC group, for example).

The upfield shift of the proton signals of nitrogen heterocycles upon *trans* substitution with isocyanide can be explained as an effect of the displacement of the central metal from the macrocycle plane towards a stronger coordinating axial ligand, which is an isocyanide in our case. The crystal-structure parameters summarized in ref.[10] clearly show, for example, a tendency of carbonyl coordinated *trans* to pyridine, THF or DMF in Fe, Ru or Os complexes to pull the metal out of the Por or Pc plane. In our case, the nitrogen heterocycle *trans* to the isocyanide ligand is closer to the macrocycle plane than in the bis-heterocycle adduct, and therefore is more strongly affected by the ring-current of the macrocycle. Additional effects of electron redistribution between axial ligands can also play a role. For example, the binding energy of isocyanide in these mixed-ligand complexes is higher than that in bis-isocyanide adducts due to the weaker *trans* effect of the nitrogen heterocycle, resulting in a stronger π-back bonding effect of isocyanide. Therefore, a shorter bond between the coordinating carbon of the isocyanide and the central metal should be expected. Indeed, an increase of the π-back bonding effect of the isocyanide in mixed-ligand complexes of (Ph_8Pz)Ru compared to the corresponding bis-isocyanide adducts can be observed as a lowering of the stretching vibration frequency of the NC group.[6c,14] Thus, ν_{NC} was found to be 2135 cm^{-1} and 2120 cm^{-1} for [(Ph_8Pz)Ru(*t*BuNC)$_2$] (**1a**) and [(Ph_8Pz)Ru(Py)(*t*BuNC)] (**4a**), respectively. Similarly, for cyclohexyl isocyanide-containing complexes **1b** and **4b** it is 2151 and 2128 cm^{-1}, respectively.

Products **2a** and **2b** from the reaction of 4,4′-bipyridine with bis-isocyanide adducts **1a** and **1b** exhibit an analogous decrease of the NC-group vibration frequency, indicating the substitution of one molecule of isocyanide. In their ^{1}H NMR spectra only two multiplets (doublets of doublets) belonging to the coordinated bipyridine were observed at approximately δ = 2.4 and 4.9 ppm, whereas in the ^{1}H NMR spectrum of the bis adduct **2c** with 4,4′-bipyridine four multiplets (doublets of doublets) of bipyridine were observed at δ = 3.14, 5.82, 6.67 and 8.28 ppm (α, β, β′ and α′ respectively, see Scheme 3). Additionally, integration of the signals in the ^{1}H NMR spectra of **2a** and **2b** shows that the ratio between the macrocycle and bipyridine in these compounds is 2:1. This allowed us to ascribe a dimeric structure to these compounds with bipyridine as bridging ligand (see **b** in Figure 3). For **2a** and **2b** the α and α′ protons become magnetically equivalent, as do the β and β′ protons, giving only two signals, α and β, for the coordinated bridging bipyridine. The shielding effect of two macrocycles towards the protons of the bridging ligand is almost additive, which can be seen as follows:

δ_d (β, β′) ≈ δ_m (β) − [δ_m (β′) − δ_m (β)], or 4.9 ≈ 5.82 − (6.67 − 5.82)

where δ_d is the chemical shift of the corresponding proton in the dimers **2a** and **2b** and δ_m is the chemical shift of the corresponding protons in the monomeric compound **2c**. This was also observed in our previous work on iron complexes of octaphenylporphyrazine with diisocyanodurole as axial ligand, where a mixture of corresponding linear oligomers was analyzed by means of ^{1}H NMR spectroscopy.[6d] In the present case, self-assembly of ruthenium porphyrazine complexes to give the dimeric structures **2a** or **2b** occurs, even in the presence of excess 4,4′-bipyridine, with practically no formation of monomeric mixed-ligand complexes, as was mentioned above and can also be seen from the ^{1}H NMR spectra of the products (see **b** in Figure 3 for example). This fact, to the best of our knowledge, has not been observed before for phthalocyanine complexes of ruthenium, although the preferential formation of a dimeric species upon interaction of *trans*-(ethanol)(carbonyl)(octaethylporphyrinato)ruthenium(II) with an excess of different diaza compounds has been reported previously.[15] In our case the self-assembly leading to the symmetric dimers **2a** or **2b** could be realized either during the reaction of bis-isocyanide adducts **1a** or **1b** with 4,4′-bipyridine (thermodynamically controlled possibility of error-correction towards more organized system[16]) or during purification of the reaction product, for example when removing the excess bipyridine and column chromatography (shifting the equilibrium towards dimeric species by removal of the excess of bridging ligand). However, for realization of the latter case it is

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

necessary that the corresponding monomeric mixed-ligand complexes [(Ph_8Pz)Ru(bpy)(RNC)] are labile enough towards splitting off the coordinated axial ligand (bipyridine) even at room temperature, which is not the case for the starting bis-isocyanide adducts **1a** and **1b**, as mentioned above. On the other hand, the additional forces leading to a stabilization of the dimeric structures **2a** and **2b** (e.g. van der Waals interaction of the macrocycles in the dimer) are required to shift the equilibrium from the monomeric towards the dimeric species.

The chemical shifts of the protons in the peripheral phenyl groups also depend on the structure of the complexes and the nature of the axial ligands. In general, in the spectra recorded at 250 MHz the phenyl protons appear as two multiplets: a downfield-shifted multiplet for the *ortho* protons, and a multiplet for the *meta* and *para* protons in the region $\delta = 7.4-7.6$ ppm. At 400 MHz these signals become better resolved giving three multiplets, which can be considered as a doublet (*ortho* protons) and two triplets (*meta* and *para* protons) showing an upfield shift of the same order. The chemical shift of the *ortho* protons appears to be the most sensitive to the nature of the axial ligands: axial ligands exhibiting stronger π-acceptor properties, such as isocyanides, lead to a slight downfield shift of the *ortho* proton signals. For example, their resonances in [(Ph_8Pz)Ru(*t*BuNC)$_2$] (**1a**), [(Ph_8Pz)Ru(Py)(*t*BuNC)] (**4a**), [(Ph_8Pz)Ru(Py)$_2$] (**4c**) and [(Ph_8Pz)Ru(CH_3Im)$_2$] (**3**) are observed at $\delta = 8.33$, 8.33, 8.25 and 8.18 ppm, respectively. In the dimeric species **2a** and **2b** they are shifted upfield because of the mutual shielding effect of the neighboring macrocycles and appear at $\delta = 8.17$ and 8.10 ppm, respectively (see Table 2).

No mutual co-facial electronic interaction of the neighboring macrocycles in the dimeric species **2a** and **2b** was observed in the UV/Vis spectra (no noticeable broadening or blue shift of the dimer's Q-band), probably due to the comparatively large distance between the macrocycles. The UV/Vis spectral pattern displayed by these compounds was found to be practically the same as that of the monomeric mixed-ligand complexes, such as [(Ph_8Pz)Ru(Py)(*t*BuNC)] (**4a**). The molar-absorption coefficients for the most intense bands are almost double those of the monomeric species.

The most noticeable changes in the UV/Vis spectra of all prepared compounds, caused by axial-ligand exchange, occur in the region of the B-band (350−360 nm) and charge-transfer (CT) band[6c] (400−500 nm). The Q-band experiences only a slight red shift if a strong π-accepting axial ligand is substituted by a weaker acceptor, whereas the B-band shifts noticeably to the blue if axially coordinated isocyanides are substituted by nitrogen heterocycles. The explanation for these observations is given in our previous work.[6c] The CT bands between 400 and 500 nm are perhaps the most sensitive to the nature of the axial ligands. Their intensity and bathochromic shift increase unambiguously with decreasing π-accepting properties of the axial ligands. However, even one coordinated molecule of isocyanide is enough to noticeably shift these CT-bands hypsochromically due to its pronounced π-accepting effect. Therefore, the position and intensity of the CT bands in mixed-ligand complexes is closer to those in bis-isocyanide adducts than in bis-heterocycle adducts (see Figure 1). The spectral changes shown in Figure 1 are typical for the whole series of adducts (bis-isocyanide → mixed-ligand → bis-heterocycle) and independent of the nature of the isocyanide or the heterocycle. This also allows us to see whether one or two isocyanide molecules are substituted by nitrogen heterocycles by UV/Vis spectroscopy. The obtained UV/Vis data for the prepared complexes are summarized in Table 3.

Experimental Section

The following equipment was used for the characterization of compounds: UV/Vis: Hitachi U-2000 and Specord M-40. IR: Specord M-80, Bruker IFS-48. ^1H and ^{13}C NMR: Bruker AC 250 and AC 400; elemental analysis: Carlo−Erba Elemental Analyzer 1104, 1106.

The kinetics of axial ligand substitution in [(Ph_8Pz)Ru(*t*BuNC)$_2$] was studied spectrophotometrically, registering the changes in optical density at the wavelength of the absorption maximum growth during the course of the reaction, using a computer-linked Hitachi U-2000 spectrophotometer with a thermostatted probe-holder. A series of experiments with constant concentrations of starting [(Ph_8Pz)Ru(*t*BuNC)$_2$] (approx. 2×10^{-5} M) in toluene and three different concentrations of pyridine in toluene were carried out at three different temperatures. Before mixing, the solutions of [(Ph_8Pz)Ru(*t*BuNC)$_2$] and pyridine were thermostatted separately. Toluene and pyridine for kinetic studies and for the syntheses were purified by standard procedures.[8] Other solvents were used without additional purification. Cyclohexyl isocyanide was prepared ac-

Table 3. UV/Vis data of the prepared compounds

Compound	Absorption maxima, nm (log ε)	Solvent
[(Ph_8Pz)Ru(*t*BuNC)$_2$] (**1a**)[6c]	276 (4.80); 364 (4.97); 421 (4.05); 443 (4.07); 540 (4.47); 585 (5.00)	CH_2Cl_2

cording to the literature procedure.[9] Other chemicals were acquired from commercial sources.

Synthesis of the starting material {"crude" [(Ph_8Pz)Ru]} for the preparation of the axially coordinated complexes [(Ph_8Pz)RuL_2], as well as the synthesis of [(Ph_8Pz)Ru(*t*BuNC)$_2$] (**1a**), have been described before.[6c] Other complexes were prepared as described below.

Bis(cyclohexyl isocyanide)(octaphenylporphyrazinato)ruthenium(II) [(Ph_8Pz)Ru(CyNC)$_2$] (1b): Crude [(Ph_8Pz)Ru] (65 mg) was refluxed in a mixture of cyclohexyl isocyanide (2 mL) and toluene (5 mL) for 24 h. After cooling, 100 mL of CH_2Cl_2 was added to the reaction mixture and stirred for 24 h to dissolve the product as completely as possible. The formed solution was filtered and chromatographed on Al_2O_3 with CH_2Cl_2 as eluent The blue-colored fraction was collected, the solvent was partially evaporated and methanol (ca. 100 mL) was added to precipitate the product, which was filtered off, washed with methanol and dried. Yield 37 mg (49%) of a dark-violet powder. IR (KBr): $\tilde{\nu}$ = 3048 w, 2936 m, 2856 w, 2152 vs, 1600 w, 1560 w, 1472 s, 1448 m, 1368 m, 1320 w, 1168 s, 1088 m, 992 s, 912 w, 888 w, 832 w, 768 w, 744 m, 696 s cm^{-1}. $C_{78}H_{62}N_{10}Ru$ (1240.5): calcd. C 75.52, H 5.04, N 11.29; found C 75.06, H 5.29, N 10.93.

Bis(4,4′-bipyridine)(octaphenylporphyrazinato)ruthenium(II) [(Ph_8Pz)Ru(bpy)$_2$] (2c): Crude [(Ph_8Pz)Ru] (150 mg) was stirred in molten 4,4′-dipyridine hydrate (4 g) at 130 °C for 10 h. After cooling, the reaction mixture was suspended in 200 mL of methanol. The insoluble residue was filtered off, washed thoroughly with methanol and chromatographed as described for [(Ph_8Pz)Ru(CyNC)$_2$]. Yield 120 mg (63%) of a dark-red powder. IR (KBr): $\tilde{\nu}$ = 3049 m, 1594 m, 1468 s, 1448 m, 1405 m, 1367 m, 1171 s, 1066 w, 1004 s, 991 s, 912 w, 887 w, 829 m, 808 m, 779 m, 770 m, 741 m, 693 s, 623 w, 608 m, 542 m cm^{-1}. $C_{84}H_{56}N_{12}Ru{\cdot}2H_2O$ (1334.5 + 36): calcd. C 73.61, H 4.41, N 12.26; found C 73.26, H 4.26, N 11.95.

Bis(*N*-methylimidazole)(octaphenylporphyrazinato)ruthenium(II) [(Ph_8Pz)Ru(CH_3Im)$_2$] (3a): Crude [(Ph_8Pz)Ru] (120 mg) and *N*-methylimidazole (1 mL) were refluxed in 15 mL of toluene for 24 h. After cooling, 25 mL of CH_2Cl_2 was added to the reaction mixture and the formed solution was chromatographed on Al_2O_3 with CH_2Cl_2 as eluent The first colored fraction was collected, diluted slightly with toluene and left to evaporate to dryness in the air at room temperature to give dark-violet rhombic crystals. Yield 45 mg (33%). IR (KBr): $\tilde{\nu}$ = 3129 w, 3047 w, 1601 m, 1575 w, 1534 w, 1495 w, 1468 s, 1448 m, 1420 w, 1368 m, 1287 w, 1241 w, 1174 s, 1107 m, 1094 m, 1066 w, 1028 w, 1004 s, 992 s, 911 w, 888 w, 829 m, 779 m, 768 m, 740 m, 693 s, 661 w, 616 w, 608 m, 542 m, 524 w, 467 w cm^{-1}. $C_{72}H_{52}N_{12}Ru{\cdot}2.5C_7H_8$ (toluene) (1186.4 + 230.4): calcd. C 75.88, H 5.12, N 11.86; found C 75.54, H 5.17, N 11.62.

***trans*-(*tert*-Butyl isocyanide)(octaphenylporphyrazinato)pyridineruthenium(II) [(Ph_8Pz)Ru(Py)(*t*BuNC)] (4a):** [(Ph_8Pz)Ru(*t*BuNC)$_2$] (**1a**; 64 mg, 54 μmol) in 15 mL of pyridine was heated at 80 °C for 8 h. After cooling, the pyridine was removed in vacuo and the residue was chromatographed as described for [(Ph_8Pz)Ru(CyNC)$_2$] (**1b**). Yield 53 mg (83%). IR (KBr): $\tilde{\nu}$ = 3048 w, 2120 s, 1600 m, 1576 w, 1472 s, 1368 s, 1168 s, 1064 w, 992 s, 912 m, 888 w, 832 m, 744 m, 692 s, 608 m, 544 s, 456 w cm^{-1}. $C_{74}H_{54}N_{10}Ru{\cdot}H_2O$ (1184.4 + 18): calcd. C 73.92, H 4.69, N 11.65; found C 74.18, H 4.61, N 11.58.

***trans*-(Cyclohexyl isocyanide)(octaphenylporphyrazinato)pyridineruthenium(II) [(Ph_8Pz)Ru(Py)(CyNC)] (4b):** [(Ph_8Pz)Ru(CyNC)$_2$] (**1b**; 50 mg, 40 μmol) was heated in 50 mL of pyridine at 100 °C for 5 h. After cooling, the reaction mixture was filtered and the product was isolated from solution as described for [(Ph_8Pz)Ru(Py)(*t*BuNC)] (**4a**). Yield 44 mg (88%). IR (KBr): $\tilde{\nu}$ = 3056 w, 2928 m, 2848 w, 2128 s, 1600 w, 1168 s, 992 s, 696 s cm^{-1}. $C_{76}H_{56}N_{10}Ru{\cdot}H_2O$ (1210.4 + 18): calcd. C 74.31, H 4.76, N 11.40; found C 73.93, H 4.70, N 11.71.

***trans*-(Cyclohexyl isocyanide)(*N*-methylimidazole)(octaphenylporphyrazinato)ruthenium(II) [(Ph_8Pz)Ru(CH_3Im)(CyNC)] (3b):** (Ph_8Pz)Ru(CyNC)$_2$ (**1b**; 25 mg, 20 μmol) and 1 mL of *N*-methylimidazole were heated in 50 mL of toluene at 80 °C for 10 h. The product was isolated as described for [(Ph_8Pz)Ru(Py)(CyNC)] (**4b**). Yield 15 mg (62%). $C_{75}H_{57}N_{11}Ru{\cdot}H_2O$ (1213.4 + 18): calcd. C 73.15, H 4.83, N 12.51; found C 73.51, H 5.25, N 12.88.

(μ-4,4′-Bipyridyl)bis[(*tert*-butyl isocyanide)(octaphenylporphyrazinato)ruthenium(II)] [(Ph_8Pz)Ru(*t*BuNC)]$_2$(μ-bpy) (2a): [(Ph_8Pz)Ru(*t*BuNC)$_2$] (**1a**; 100 mg, 84 μmol) and 4,4′-bipyridine (3 g) were heated in 30 mL of toluene at 90 °C for 16 h. The toluene was then removed under vacuum, and the excess of bipyridine was removed by washing with methanol. The residue was chromatographed (Al_2O_3, dichloromethane), precipitated with methanol and dried. Yield 80 mg (80%). $C_{148}H_{106}N_{20}Ru_2$ (2366.7): calcd. C 75.11, H 4.51, N 11.84; found C 74.79, H 4.90, N 12.02.

(μ-4,4′-Bipyridyl)bis[(cyclohexyl isocyanide)(octaphenylporphyrazinato)ruthenium(II)] [(Ph_8Pz)Ru(CyNC)]$_2$(μ-bpy) (2b): [(Ph_8Pz)Ru(CyNC)$_2$] (**1b**; 100 mg, 81 μmol) was used following the same procedure as described for **2a**. Yield 72 mg (73%). IR (KBr): $\tilde{\nu}$ = 3050 cm^{-1} w, 2931 m, 2853 w, 2135 s, 1602 m, 1470 s, 1448 m, 1365 m, 1168 s, 1004 s, 990 s, 829 m, 743 m, 692 s, 607 m, 543 m. $C_{152}H_{110}N_{20}Ru_2{\cdot}H_2O$ (2418.8 + 18): calcd. C 74.92, H 4.63, N 11.50; found C 75.08, H 5.03, N 11.25.

Phenyl 2-Pyridyl Ketone and Its Oxime in Manganese Carboxylate Chemistry: Synthesis, Characterisation, X-ray Studies and Magnetic Properties of Mononuclear, Trinuclear and Octanuclear Complexes

Constantinos J. Milios,[a] Theocharis C. Stamatatos,[a] Panayotis Kyritsis,[b] Aris Terzis,[c] Catherine P. Raptopoulou,[c] Ramon Vicente,*[d] Albert Escuer,*[d] and Spyros P. Perlepes*[a]

Keywords: Carboxylate ligands / Magnetic properties / Manganese / N,O ligands / X-ray crystallography

The use of phenyl 2-pyridyl ketone [(ph)(2-py)CO] and its oxime [(ph)(2-py)CNOH] in manganese benzoate chemistry has been investigated. The reaction of an excess of (ph)(2-py)CNOH with $Mn(O_2CPh)_2{\cdot}2H_2O$ affords the mononuclear complex $[Mn^{II}(O_2CPh)_2\{(ph)(2\text{-py})CNOH\}_2]{\cdot}1.2H_2O$ (**1**·1.2H_2O) in high yield. The Mn^{II} ion is coordinated by two monodentate benzoates and two *N,N′*-bidentate chelating (ph)(2-py)CNOH molecules in a *cis-cis-trans* fashion. The comproportionation reaction between $Mn(O_2CPh)_2{\cdot}2H_2O$ and N*n*Bu_4MnO_4 (3:1) in the presence of (ph)(2-py)CNOH in MeCN/EtOH/CH_2Cl_2 leads to the isolation of the mixed-valent cluster $[Mn_8O_2(OH)_2(O_2CPh)_{10}\{(ph)(2\text{-py})CNO\}_4]{\cdot}4CH_2Cl_2$ (**2**·4CH_2Cl_2) in about 55% yield. A second synthetic procedure that leads to pure **2** involves the reaction between the known starting material (N*n*Bu_4)$[Mn_4^{III}O_2(O_2CPh)_9(H_2O)]$ and four equivalents of the oxime ligand in CH_2Cl_2. The centrosymmetric octanuclear molecule contains four Mn^{II} and four Mn^{III} ions held together by two μ_4-O^{2-} ligands and two μ_3-OH^- ions to give the unprecedented $[Mn_8(\mu_4\text{-}O)_2(\mu_3\text{-}OH)_2]^{14+}$ core, with peripheral ligation provided by ten $PhCO_2^-$ (two η^1, four *syn,syn* $\eta^1{:}\eta^1{:}\mu_2$ and four $\eta^1{:}\eta^2{:}\mu_3$) and four $\eta^1{:}\eta^1{:}\eta^1{:}\mu_2$ (ph)(2-py)CNO^- ions. The 1:1 reaction between $Mn(O_2CPh)_2{\cdot}2H_2O$ and the ketone (ph)(2-py)CO affords the trinuclear complex $[Mn_3(O_2CPh)_6\{(ph)(2\text{-py})CO\}_2]$ (**3**) in more than 80% yield. As judged from single-crystal X-ray crystallography, the complex adopts a linear structure with one $\eta^1{:}\eta^2{:}\mu_2$ and two $\eta^1{:}\eta^1{:}\mu_2$ benzoates spanning each pair of metal ions. The terminal Mn^{II} ions are capped by bidentate chelating (ph)(2-py)CO ligands. The three complexes have been characterised by IR spectroscopy. The CV study of complex **2** in CH_2Cl_2 reveals irreversible reduction and oxidation processes. The magnetic properties of **2** and **3** have been studied by variable-temperature dc magnetic-susceptibility techniques. As the temperature approaches zero, the value of the $\chi_M T$ product for **2** approaches zero and, thus, the octanuclear complex has an $S = 0$ ground state. This $S = 0$ ground state is explained in terms of the magnetic behaviour of the central, butterfly-like $[Mn_4^{III}(\mu_3\text{-}O)_2]^{8+}$ subcore. The results for **3** reveal weak antiferromagnetic coupling, with $J = -2.7$ cm^{-1} for adjacent Mn^{II} ions.

Introduction

There are several reasons why manganese carboxylate chemistry is the focus of such great research interest at present. One such reason is that a tetranuclear Mn carboxylate cluster is an integral component of the photosystem II reaction centre of green plants (and cyanobacteria), where it is responsible for the light-driven oxidation of water to dioxygen gas.[1] This Mn_4 water oxidation complex (WOC) is the site of substrate (water) binding, deprotonation and oxidative coupling to O_2, although the exact structure of the cluster[2] and its precise mechanism[1] of action are currently unknown. The synthesis and structural/spectroscopic characterisation of Mn model complexes[1,3] have provided a wealth of data for comparison and contrast with the corresponding characteristics for the native WOC. In the last ten years, the synthesis and study of polynuclear Mn carboxylate complexes have also been stimulated by the discovery that some of them exhibit the new magnetic phenomenon of single-molecule magnetism.[4] This property is the ability of discrete molecules to exhibit the superparamagnet-like property of slow magnetisation relaxation and thus to behave as magnets below their blocking temperature by exhibiting magnetisation vs. field hysteresis. Such properties do not arise from intermolecular exchange interactions and long-range ordering, but instead from a combination of two intramolecular properties, namely a

large ground-state spin (S) and a significant magnetoanisotropy of the Ising (easy-axis) type, the latter being reflected in a large and negative value of the zero-field splitting parameter D.[4] The first single-molecule magnet (SMM) was $[Mn_{12}O_{12}(O_2CMe)_{16}(H_2O)_4]$, which possesses an $S = 10$ ground state,[5] and a number of other Mn_x carboxylate SMMs have since been discovered.[4,6] There is thus a continuing need to develop new synthetic methods for the preparation of new polynuclear Mn carboxylate compounds.

Among the many synthetic lines currently being pursued by our groups and others in this field is the reaction of a bridging ligand containing both chelating sites and ionizable hydrogens with a simple Mn carboxylate "salt" or a preformed Mn carboxylate cluster that does not already incorporate any chelating ligand.[6,8] As long as the RCO_2^-/bridging ligand ratio is high enough to leave an amount of non-protonated RCO_2^- ions in the reaction mixture, this approach normally leads to heteroleptic RCO_2^-/deprotonated bridging ligand metal clusters. One of the ligands that has previously proved to be useful in these syntheses, giving many new polynuclear complexes, is di-2-pyridyl ketone [$(2\text{-py})_2CO$; Figure 1]. Our groups have been exploring "ligand blend" reactions involving the monoanion $(2\text{-py})_2C(OH)O^-$ or the dianion $(2\text{-py})_2CO_2^{2-}$ of the *gem*-diol form of $(2\text{-py})_2CO$ (these anions are stabilized *only* in the presence of metal ions[8]) *and* carboxylates. These reaction schemes have led[9] to a variety of Fe, Co, Ni, Cu, Zn clusters with nuclearities ranging from three to twelve and with interesting magnetic properties, including SMM behaviour.[9j] In Mn carboxylate chemistry the most impressive cluster isolated[10] is $[Mn_{10}^{II}Mn_4^{III}O_4(O_2CMe)_{20}\{(2\text{-py})_2C(OH)O\}_4]$; the observed tetradecanuclearity is extremely rare in 3d-metal chemistry. Recently we have extended our efforts to ligands (Figure 1) that present a structural similarity to $(2\text{-py})_2CO$; our goals are to investigate to what extent the use of such ligands might affect the identity of the obtained products compared with $(2\text{-py})_2CO$ and to what extent this might thus prove to be a route to new cluster types. Our initial work was concentrated on di-2-pyridyl ketone oxime, $(2\text{-py})_2CNOH$, a ligand whose employment in Mn carboxylate chemistry gave the new family of valence-trapped, mixed-valence complexes[11] $[Mn_2^{II}Mn_2^{III}(O_2CR)_2X_2\{(2\text{-py})_2CNO\}_2\{(2\text{-py})_2CO_2\}_2]$, where X^- is Cl^-, Br^- or RCO_2^-; it has been of great interest that an appreciable quantity of the oxime ligand undergoes transformation to yield the coordinated dianion of the *gem*-diol form of $(2\text{-py})_2CO$. The mechanism of this transformation probably involves reaction(s) of the electrophilically activated coordinated oxime group. In attempting to extend the above-mentioned chemistry, and to create new topologies, we have begun reactions featuring phenyl 2-pyridyl ketone oxime, (ph)(2-py)CNOH, and its ketone, (ph)(2-py)CO. These ligands have different electronic properties to those of $(2\text{-py})_2CNOH$ and $(2\text{-py})_2CO$, respectively, and have never been employed in polynuclear 3d-metal chemistry.

Herein we describe our efforts toward the use of (ph)(2-py)CNOH and (ph)(2-py)CO in Mn benzoate chemistry. In particular, we report the synthesis, structure and characterisation of one mononuclear Mn^{II} complex, one trinuclear Mn^{II} complex and one octanuclear $Mn^{II/III}$ cluster featuring a novel core. A small portion of this work has been communicated previously.[10] There is currently a renewed interest in the coordination chemistry of oximes.[12] This interest is driven by a number of considerations.[12,13] In contrast to the great number of studies concerning metal complexes of single oximes and salicylaldoxime, little is known[12,13] about complexes of pyridyloximes, although this class of compounds could offer unique features in terms of structural and physical properties.

Results and Discussion

Synthesis

The initial reaction explored was that between $Mn(O_2CPh)_2{\cdot}2H_2O$ and one equivalent of (ph)(2-py)CNOH in MeCN/EtOH. The pale-orange solution obtained gradually turned brown due to slow oxidation of Mn^{II} under the normal laboratory atmosphere. Evaporation of the resulting solution under reduced pressure, redissolv-

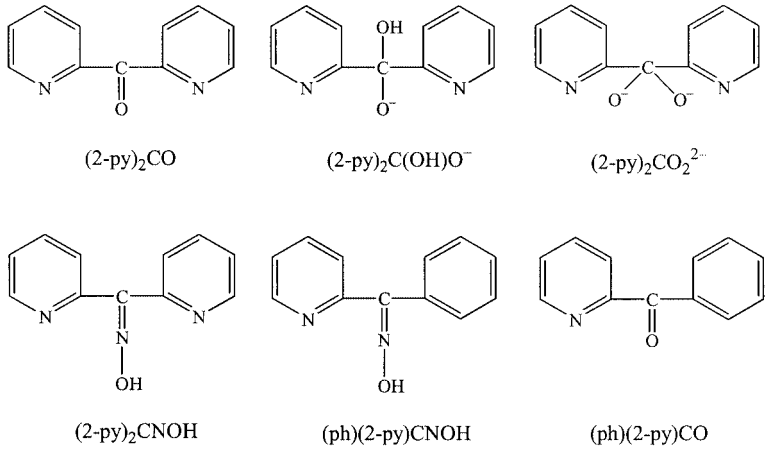

Figure 1. Some of the ligands discussed in the text; note that $(2\text{-py})_2C(OH)O^-$ and $(2\text{-py})_2CO_2^{2-}$ do not exist as free species — they exist only in their metal complexes

$$Mn(O_2CPh)_2{\cdot}2H_2O + 2\ (ph)(2\text{-}py)CNOH \xrightarrow{EtOH} [Mn(O_2CPh)_2\{(ph)(2\text{-}py)CNOH\}_2] + 2\ H_2O \quad (1)$$

1

ing the residue in CH_2Cl_2 and layering the solution with Et_2O/*n*-hexane gave a mixture of yellow and dark-brown crystals, which were readily separated manually and crystallographically identified as $[Mn(O_2CPh)_2\{(ph)(2\text{-}py)CNOH\}_2]{\cdot}1.2H_2O$ (**1**·$1.2H_2O$) and $[Mn_8O_2(OH)_2(O_2CPh)_{10}\{(ph)(2\text{-}py)CNO\}_4]{\cdot}4CH_2Cl_2$ (**2**·$4CH_2Cl_2$), respectively. The latter is a mixed-valence ($4Mn^{II}$, $4Mn^{III}$) complex (vide infra). With the identities of **1** and **2** established, alternative and convenient syntheses of pure materials were sought. The mononuclear product contains a (ph)(2-py)CNOH/Mn ratio of 2:1, whereas the reaction solution had a ratio of 1:1; thus, attempts to obtain pure **1** were made by increasing the ligand/Mn reaction ratio. The preparation of pure **1** *under aerobic conditions* was achieved by the reaction of $Mn(O_2CPh)_2{\cdot}2H_2O$ with an excess of oxime in EtOH [Equation (1)].

Two procedures were developed that lead to preparation of pure **2**. The first one involves a comproportionation reaction between $Mn(O_2CPh)_2{\cdot}2H_2O$ and NBu_4MnO_4 [14] in a 3:1 ratio in the presence of (ph)(2-py)CNOH. This ratio, on paper, gives an average Mn oxidation state in solution of $Mn^{+3.25}$, higher than that ($Mn^{+2.5}$) observed in solid **2**. The source of the reducing agent is probably EtOH from the solvent mixture, solvent impurities or excess ligand groups, facilitated by the strongly oxidizing nature of Mn^{III}.[15] It is also likely, as with many other reactions in higher oxidation state Mn chemistry, that the reaction solution contains a complicated mixture of several species in equilibrium, with factors such as relative solubility, lattice energies, crystallisation kinetics and others determining the identity of the isolated product.[16] Comproportionation reactions between Mn^{II} and Mn^{VII} sources have found extensive use to produce $Mn/O^{2-}/RCO_2^-$ clusters of various nuclearities.[15,16] Complex **2** was isolated from the above reaction solution in 55% yield. In an attempt to increase further the yield of the product, the Mn^{II}/MnO_4^- ratio was increased to that which would give an average Mn oxidation state of +2.5, as found in **2**, but this instead led to crystallisation of $[Mn_6O_2(O_2CPh)_{10}(MeCN)_4]$[17a] and/or $[Mn_6O_2(O_2CPh)_{10}(EtOH)_4(H_2O)]{\cdot}EtOH$[17b] containing $4Mn^{II}$, $2Mn^{III}$, and no bound (ph)(2-py)CNO^- groups. These and similar hexanuclear species differing in the identity of the bound neutral monodentate ligands have been previously observed and are common products at this oxidation level with benzoate groups.[17c] Attempts to obtain clusters with higher average Mn oxidation states were also made by decreasing the Mn^{II}/MnO_4^- ratio; for example, a ratio of 3:2 (this ratio on paper gives an average Mn oxidation state in solution of Mn^{4+}) again resulted in the isolation of **2** in low (< 30%) yields. The second procedure that leads to pure **2** involves the conversion of $(NBu_4)[Mn_4O_2(O_2CPh)_9(H_2O)]$ into a higher nuclearity product. The anion $[Mn_4O_2(O_2CPh)_9(H_2O)]^-$ contains only Mn^{III} ions, and only $PhCO_2^-$ and H_2O peripheral ligation.[15] The latter fact makes it especially useful for synthesising higher nuclearity products: it has, for example, permitted the isolation of $(NBu_4)[Mn_8O_6Cl_6(O_2CPh)_7(H_2O)_2]$,[18a] $(NBu_4)[Mn_8O_4(O_2CPh)_{12}(Et_2mal)_2(H_2O)_2]$[15] ($Et_2malH_2$ = 2,2-diethylmalonic acid) and $K_4[Mn_{18}O_{16}(O_2CPh)_{22}(phth)_2(H_2O)_4]$[18b] ($H_2phth$ = phthalic acid) when treated with Me_3SiCl, $Na_2(Et_2mal)$ and KH(phth), respectively. Treatment of complex $(NBu_4)[Mn_4O_2(O_2CPh)_9(H_2O)]$ with four equivalents of (ph)(2-py)CNOH in CH_2Cl_2 leads to subsequent isolation of pure crystalline **2** in acceptable yield (ca. 30%). The formation of **2** by this route can be summarised in Equation (2).

It seems that the core of **2** can be thought of as being derived from the "butterfly" $[Mn_4(\mu_3\text{-}O)_2]^{8+}$ core[15] of the starting tetranuclear material by dimerisation/reduction / protonation steps (the order is arbitrary). The $4Mn^{II}$, $4Mn^{III}$ description of **2** requires the reduction of four Mn^{III} ions to have occurred; as stated above, it is not uncommon to find Mn^{III} — a strong oxidizing agent — being reduced by ligand groups, solvent impurities, etc.[15] An alternative means for the generation of the Mn^{II} ions in **2** is disproportionation of Mn^{III}, in which case Mn^{IV}-containing species would be in the filtrate.[15] We have not attempted to identify the exact origin of the Mn^{II} ions in the product, nor would it be a simple matter to do so. The excess of (ph)(2-py)CNOH (oxime/Mn_4 = 4:1) is beneficial to the preparation, because use of a stoichiometric amount (oxime/Mn_4 = 2:1) yields an oxime-free product analysed as $[Mn_6O_2(O_2CPh)_{10}(H_2O)_x]$ (x = 2−3).

The structure of **2** was shown by crystallography (vide infra) to contain an octanuclear core in which two $[Mn_4(\mu_3\text{-}O)(\mu_3\text{-}OH)]$ units have been linked together. Although **2** is a new and interesting complex, the question that arose after its characterisation was whether a discrete tetranuclear product containing this unit might be attainable by suitable alteration of the reaction conditions. A number of such at-

$$2\ [Mn_4^{III}O_2(O_2CPh)_9(H_2O)]^- + 4\ (ph)(2\text{-}py)CNOH \xrightarrow{+4\ e} [Mn_4^{II}Mn_4^{III}O_2(OH)_2(O_2CPh)_{10}\{(ph)(2\text{-}py)CNO\}_4] + 2\ PhCO_2H + 6\ PhCO_2^- + 2\ H_2O \quad (2)$$

$$3\ Mn(O_2CPh)_2{\cdot}2H_2O + 2\ (ph)(2\text{-}py)CO \xrightarrow{MeOH} \underset{\mathbf{3}}{[Mn_3(O_2CPh)_6\{(ph)(2\text{-}py)CO\}_2]} + 4\ H_2O \quad (3)$$

tempts were made, but with no successful isolation of any other species; in particular, increasing the (ph)(2-py)CNOH/Mn_4 reaction ratio further still gives complex **2** as the isolable product. Thus, complex **2** remains the only polynuclear Mn/$PhCO_2^-$/(ph)(2-py)CNO^- species to have been identified to date.

The next goal of this work was to synthesise Mn complexes of the ketone of (ph)(2-py)CNOH, i.e., (ph)(2-py)CO (Figure 1). The reaction used to prepare the trinuclear manganese(II) complex $[Mn_3(O_2CPh)_6\{(ph)(2\text{-}py)CO\}_2]$ (**3**) is shown in Equation (3).

The "wrong" reaction ratio employed experimentally (Mn/ketone= 1:1), compared to the stoichiometric ratio (Mn/ketone= 1.5:1) required by Equation (3), obviously did not prove detrimental to the isolation of the trinuclear product. We have not explored reactions in any solvent (complex **3** can be isolated from a variety of solvents including EtOH, MeCN and CH_2Cl_2) using Mn^{II}:(ph)(2-py)CO ratios other than 1:1.

Attempts to oxidize one or more Mn^{II} ions of **3** failed to give a crystalline compound. Several 3:1 and 3:2 **3**/N*n*Bu_4MnO_4 reaction mixtures were studied under various conditions, but almost all led to a mixture of the starting trinuclear complex and an as-yet unidentified reddish, non-crystalline material; we did not study this material further. Thus, complex **3** does not appear promising for the isolation of other (possibly larger) Mn clusters. We also investigated in situ reactions between $Mn(O_2CPh)_2{\cdot}2H_2O$ and (ph)(2-py)CO in the presence of N*n*Bu_4MnO_4 at various Mn^{II}/Mn^{VII} ratios, but, somewhat to our surprise, the only isolable product remained complex **3**, thus proving the great thermodynamic stability of the $[Mn_3^{II}(\eta^1{:}\eta^1{:}\mu_2\text{-}O_2CR)_4(\eta^1{:}\eta^2{:}\mu_2\text{-}O_2CR)_2]$ core. Along these lines, it is worth noting that reactions of the preformed, mixed-valence compound $[Mn_3^{II,III,III}O(O_2CPh)_6(py)_2(H_2O)]$[19] (py = pyridine) and (ph)(2-py)CO led to fading of the reaction solutions and subsequent isolation of **3**.

X-ray Crystal Structures

$[Mn(O_2CPh)_2\{(ph)(2\text{-}py)CNOH\}_2]{\cdot}1.2H_2O$ (**1**·1.2H_2O)

A labelled plot of the structure of the mononuclear compound **1** is shown in Figure 2. Selected bond lengths and angles are listed in Table 1. The structure consists of well-separated $[Mn(O_2CPh)_2\{(ph)(2\text{-}py)CNOH\}_2]$ moieties and solvate H_2O molecules. The Mn^{II} atom is coordinated by two monodentate benzoates and two *N*,*N*′-bidentate chelating (ph)(2-py)CNOH molecules. The six-coordinate molecule is the *cis*-*cis*-*trans* isomer considering the positions of the oxygen, pyridyl nitrogen and oxime nitrogen atoms, respectively. An analogous *cis*-*cis*-*trans* arrangement has also been observed in the molecular structure of $[Mn(O_2CCF_3)_2\{(py)CHNOH\}_2]$,[13] where (py)CHNOH is 2-pyridinealdoxime. The molecule has no imposed sym-

metry, although it approximates closely to C_2 symmetry, with the C_2 axis bisecting the O(21)−Mn−O(31) angle. The four Mn−N bond lengths [2.255(3)−2.319(4) Å] are similar. The distortion from a perfect octahedral geometry is primarily a consequence of the small bite-angle of the chelating ligands, which leads to acute N(1)−Mn−N(2) and N(11)−Mn−N(12) angles of 70.6(1)° and 70.8(1)°, respectively. There are two strong intramolecular hydrogen bonds with the uncoordinated oxime oxygens as donors and the "free" carboxylate oxygens as acceptors. Their dimensions are: O(1)···O(22) 2.524 Å, H(O1)···O(22) 1.735 Å, O(1)−H(O1)···O(22) 169.4° and O(11)···O(32) 2.532 Å, H(O11)···O(32) 1.519 Å, O(11)−H(O11)···O(32) 153.1°. The existence of these strong hydrogen bonds most likely explains the isolation of the *cis-cis-trans* isomer.

$[Mn_8O_2(OH)_2(O_2CPh)_{10}\{(ph)(2\text{-py})CNO\}_4]\cdot 4CH_2Cl_2$ (**2**·4CH_2Cl_2)

A partially labelled plot of the octanuclear complex **2** is shown in Figure 3. Selected interatomic distances and angles are listed in Table 2. Complex **2**·4CH_2Cl_2 crystallises in the monoclinic space group *C*2/*c*. Its structure consists of the octanuclear $[Mn_8O_2(OH)_2(O_2CPh)_{10}\{(ph)(2\text{-py})CNO\}_4]$ moiety and solvate CH_2Cl_2 molecules; the latter will not be further discussed. The molecule lies on an inversion centre; it comprises eight Mn ions held together by two μ_4-O^{2-} ions [O(21), O(21′)] and two μ_3-OH^- ions [O(22), O(22′)] to give a $[Mn_8(\mu_4\text{-}O)_2(\mu_3\text{-}OH)_2]^{14+}$ core, with peripheral ligation provided by ten $PhCO_2^-$ groups and four (ph)(2-py)CNO^- ligands. Bond-valence sum (BVS) calculations[20] give values of 1.9 and 1.3 for O(21) and O(22), respectively, supporting their assignments as oxo [O(21), theoretical value: 2.0] and hydroxo [O(22), theoretical value: 1.0] oxygen atoms. The ten $PhCO_2^-$ groups are arranged in three classes: (i) two are monodentate with O(71) and O(71′) being the ligated atoms; (ii) four [those containing O(31)/O(32), O(41)/O(42) and their symmetry-related partners] bridge two Mn ions and are in their familiar *syn*,*syn*-$\eta^1{:}\eta^1{:}\mu_2$ binding modes; and (iii) four (the rest) are in the fairly rare $\eta^1{:}\eta^2{:}\mu_3$ modes, one O bridging two Mn ions and

[a] Primed atoms are related to the unprimed ones by the symmetry transformation $-x, y, -z - 1/2$.

the other O terminal to a third Mn ion, with the bridging carboxylate O atoms being O(51), O(51′), O(61) and O(61′). The four (ph)(2-py)CNO^- ions behave as $\eta^1{:}\eta^1{:}\eta^1{:}\mu_2$ ligands; each ligand chelates one metal ion through its nitrogen atoms forming a five-membered ring and bridges this metal ion with a second one through the terminally ligated, deprotonated O atom [O(1), O(1′), O(11), O(11′)]. For convenience, the six coordination modes exhibited by the four different ligands of **2** are presented in Figure 4.

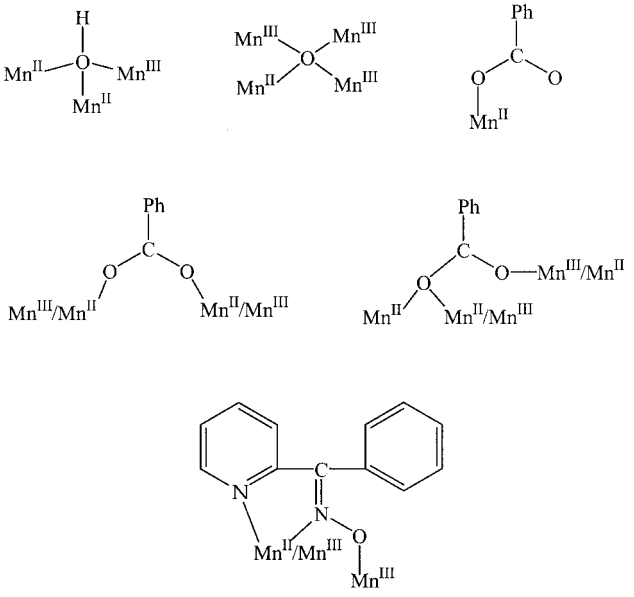

Figure 4. The crystallographically established coordination modes of the hydroxo, oxo, benzoato and phenyl 2-pyridyl ketone oximato ligands present in complex **2**

Mn(1) and Mn(3) are bound to an O_4N_2 set of donor atoms, while Mn(2) and Mn(4) are bound to an O_6 set. Charge considerations require a $4Mn^{II}$, $4Mn^{III}$ oxidation-state description, and Mn(2) and Mn(3) [and their symmetry related Mn(2′) and Mn(3′)] are assigned as the Mn^{II} ions on the basis of: (i) the longer average Mn−O bond lengths at these ions (average 2.190 Å and no individual value shorter than 2.07 Å) compared with those of the other Mn ions (average 2.010 Å), (ii) the clear presence of a Jahn−Teller (JT) axial elongation at Mn(1) and Mn(4) [and their symmetry-related partners], as expected for a high-spin d^4 ion in near-octahedral geometry; the JT elongation axes are O(21)−Mn(1)−N(11) and O(42)−Mn(4)−O(51′), with the axially elongated Mn−O bonds being longer than the equatorial Mn−O bonds by at least 0.21 Å, and (iii) BVS calculations[20] which give values of 3.21, 2.12, 1.75 and 3.20 for Mn(1), Mn(2), Mn(3) and Mn(4), respectively, in good agreement with the above assignments.

The above assignments of the Mn oxidation states reveal that the hydroxo ligand bridges two Mn^{II} and one Mn^{III} ions, while the oxo ligand bridges one Mn^{II} and three Mn^{III} ions (Figure 4). The four $\eta^1{:}\eta^1{:}\mu_2$ $PhCO_2^-$ groups separate further into two subclasses: The groups bearing O(31), O(32) and O(31′), O(32′) each bridge two Mn^{II} ions and those bearing O(41), O(42) and O(41′), O(42′) each bridge two Mn^{III} ions. Similarly, there are two types of $\eta^1{:}\eta^2{:}\mu_3$ $PhCO_2^-$ groups, which all bridge one Mn^{III} and two Mn^{II} ions: the μ_2-O [O(51), O(51′)] of the carboxylate groups bearing O(51), O(52) and O(51′), O(52′) bridges one Mn^{II} and one Mn^{III} ion, whereas the μ_2-O [O(61), O(61′)] of the

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

groups bearing O(61), O(62) and O(61′), O(62′) bridges two Mn^{II} ions. The four $\eta^1{:}\eta^1{:}\eta^1{:}\mu_2$ (ph)(2-py)CNO^- ligands also separate further into two subclasses: The anions bearing N(1), N(2), O(1) and their symmetry-related partners each bridge one Mn^{II} and one Mn^{III} ion, while those bearing N(11), N(12), O(11) and N(11′), N(12′), O(11′) each bridge two Mn^{III} ions; in both cases the deprotonated oximate oxygen atom is terminally ligated to a Mn^{III} ion (Figure 4).

The molecular structure of **2** leads to diverse Mn···Mn distances (Table 2), which depend on the number and nature of the bridges between the two metal centres and on the oxidation state of each Mn atom. The central Mn(4)···Mn(4′) separation is the shortest [2.791(3) Å]; this separation is almost identical to the Mn···Mn distances observed for other polynuclear complexes containing the $[Mn_2^{III}(\mu_4\text{-}O)_2]^{2+}$ subunit.[17] The other two $Mn^{III}\cdots Mn^{III}$ distances are 3.307(2) [Mn(1)···Mn(4)] and 3.945(2) Å [Mn(1)···Mn(4′)]; the shorter Mn···Mn separation corresponds to the pair bridged by one oxo, one $\eta^1{:}\eta^1{:}\mu_2$ benzoato and one oximato groups, whereas the larger distance corresponds to that linked by only one oxo group. The shortest $Mn^{II}\cdots Mn^{III}$ distance is Mn(2)···Mn(4′) [3.187(2) Å]; this pair is bridged by one oxo group and the μ_2-O of an $\eta^1{:}\eta^2{:}\mu_3$ benzoato group. The μ_2-benzoate oxygen atom O(61) [and O(61′)] does not bridge the two Mn^{II} ions symmetrically, and Mn(2)−O(61) [2.308(5) Å] is noticeably shorter than Mn(3)−O(61) [2.408(5) Å]. The Mn(2,3)−O(22) distances [2.155(5), 2.195(5) Å] are noticeably longer than the Mn(1)−O(22) distance [1.913(5) Å], consistent with the lower oxidation state in the former. Similarly, Mn(2,3)-carboxylate distances (average 2.190 Å) are longer than Mn(1,4)-carboxylate distances (average 2.090 Å). It is interesting that the μ_4-O^{2-} ions [O(21), O(21′)] bridge the Mn^{III} ions asymmetrically. Thus, Mn(4)−O(21) and Mn(4′)−O(21) are 1.872(5) and 1.898(5) Å, respectively, whereas Mn(1)−O(21) is much longer at 2.235(5) Å. This is the result of O(21) lying on the JT elongation axis of Mn(1); Mn^{III}−O^{2-} distances greater than 2.2 Å are extremely rare.[21] This JT-elongated Mn(1)−O(21) bond contributes to the relatively long Mn(1)···Mn(4′) distance [3.945(2) Å].

The uncoordinated O atoms of the monodentate $PhCO_2^-$ groups [O(72) and O(72′)] are hydrogen-bonded to the μ_3-OH^- ligands, with the O(72)···O(22) distance being 2.610 Å.

The novel Mn_8 topology in **2** can be described in a number of ways, but the following three are particularly useful. As is emphasised in Figure 5, the $[Mn_8O_2(OH)_2]^{14+}$ core can be conveniently described as two $\{Mn_2^{II}Mn_2^{III}(\mu_3\text{-}O)(\mu_3\text{-}OH)\}^{7+}$ units [atoms Mn(1)−Mn(4) and their symmetry-related partners] becoming linked through the μ_3-O^{2-} in each unit converting to a μ_4 mode and thus providing the two "inter-fragment' bonds Mn(4)−O(21′) and Mn(4′)−O(21). The four metal ions in each unit are nearly coplanar with the torsion angle Mn(1)−Mn(2)−Mn(3)−Mn(4) being 9.4°. Although tetranuclear complexes containing the $[Mn_4(\mu_3\text{-}O)_2]$ core, where the metals are arranged in either planar or nonplanar ("butterfly") fashion and the metal oxidation levels are $Mn_2^{II}Mn_2^{III}$,[22] $Mn^{II}Mn_3^{III}$ [23] or Mn^{III},[15,22] have been reported, the $\{Mn_2^{II}Mn_2^{III}(\mu_3\text{-}O)(\mu_3\text{-}OH)\}^{7+}$ unit present in **2** has not been observed either in a discrete tetranuclear complex or encountered as a recognizable sub-fragment of higher nuclearity Mn clusters. A second way of describing the core emphasises its "central" $\{Mn_2^{II}Mn_4^{III}(\mu_4\text{-}O)_2\}^{12+}$ subunit, which is the currently unknown (in either a discrete hexanuclear complex or in a higher nuclearity cluster) oxidized version of the familiar[17] $[Mn_4^{II}Mn_2^{III}(\mu_4\text{-}O)_2]^{10+}$ core; extension of the former at each end with an additional Mn^{II} ion through the μ_3-OH^- gives the core of **2**. In view of the magnetochemical discussion presented below (vide infra), it is of interest and beneficial to consider a third, alternate description of the core of complex **2** which emphasises its structural relationship to a well-known smaller nuclearity Mn/O unit. The molecule can be described as consisting of a central, butterfly-like[15,22] $[Mn_4^{III}(\mu_3\text{-}O)_2]^{8+}$ subunit [atoms Mn(1), Mn(1′), Mn(4), Mn(4′), O(21), O(21′); see Figure 5]. The $[Mn_8(\mu_4\text{-}O)_2(\mu_3\text{-}OH)_2]^{14+}$ core of **2** is then completed by the attachment of two additional $[Mn_2^{II,II}(\mu_2\text{-}OH)]^{3+}$ subunits to the butterfly-like central sub-core via the inter-fragment bonds Mn(1)−O(22), Mn(2)−O(21) and their symmetry equivalents. As a result, each OH^- ligand becomes μ_3, forming a bond with a "wing-tip" Mn^{III} ion [Mn(1), Mn(1′)], and each O^{2-} ligand is converted to μ_4, forming a bond with one of the Mn^{II} ions [Mn(2), Mn(2′)].

Complex **2** joins a very small family of Mn clusters of nuclearity eight, which currently comprise the metal oxi-

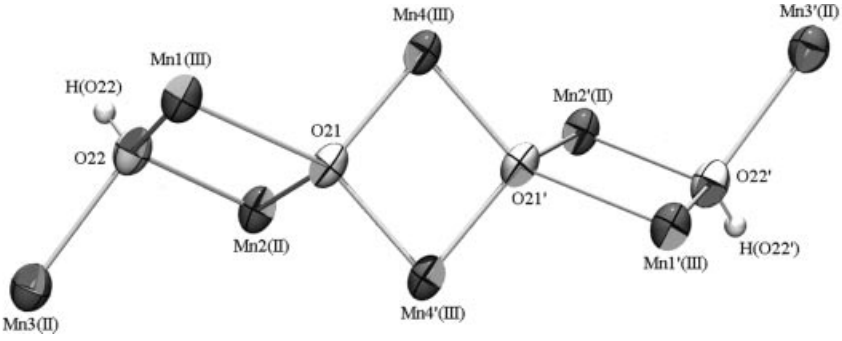

Figure 5. ORTEP representation of the $[Mn_4^{II}Mn_4^{III}(\mu_4\text{-}O)_2(\mu_3\text{-}OH)_2]^{14+}$ core of **2**

dation states Mn_8^{II},[24] $Mn_6^{II}Mn_2^{III}$,[6a,25] $Mn_2^{II}Mn_6^{III}$,[15,26] Mn_8^{III} [18a,27] and $Mn_2^{III}Mn_6^{IV}$,[28] and thus becomes the first member of the $Mn_4^{II}Mn_4^{III}$ subfamily. Since most of these were reported only recently, we felt it timely to collect the octanuclear $Mn^{II/III}$, Mn^{III} and $Mn^{III/IV}$ clusters in Table 3, together with their cores for convenient comparison; we have not included the Mn_8^{II} complexes. The $[Mn_4^{II}Mn_4^{III}(\mu_4\text{-}O)_2(\mu_3\text{-}OH)_2]^{14+}$ core of **2** bears some similarity to the $[Mn_2^{II}Mn_6^{III}(\mu_3\text{-}O)_2(\mu_4\text{-}O)_2]^{14+}$ core present[15] in the anion $[Mn_8O_4(O_2CPh)_{12}(Et_2mal)_2(H_2O)_2]^{2-}$, where Et_2mal is the dianion of 2,2-diethylmalonic acid; the former can be thought of as being derived from the latter by reduction/protonation steps. Complex **2** is also one of the rare examples of polynuclear Mn complexes that contain oxo and hydroxo bridges simultaneously,[29] other such complexes being $[Mn_8O_4(OH)_2(O_2CMe)_{12}(DMHP)_2(py)_2]$ (DMHP = 2,6-dimethyl-6-hydroxypyrimidine; py = pyridine),[26] $[Mn_4O_5(OH)(tame)_4](CF_3SO_3)_5$ [tame= 1,1,1-tris(aminomethyl)ethane],[30] $[Mn_4O_5(OH)(tacn)_4](ClO_4)_5$ (tacn = 1,4,7-triazacyclononane)[30] and $[Mn_{10}O_4(OH)_2(O_2CMe)_8(hmp)_8](ClO_4)_4$ [hmp = the anion of 2-(hydroxymethyl)pyridine].[16]

The Mn_8 nuclearity of **2** can be put into context by noting that the largest molecular Mn cluster currently known is $[Mn_{30}O_{24}(OH)_8(O_2CCH_2But)_{32}(H_2O)_2(MeNO_2)_4]$,[31a] followed by $[Mn_{26}O_{16}(OH)_{10}(OMe)_6F_{10}(bta)_2(btaH)_2(MeOH)_{13}(H_2O)]$, where btaH is benzotriazole;[31b] these two clusters are also mixed oxo/hydroxo species.

$[Mn_3(O_2CPh)_6\{(ph)(2\text{-}py)CO\}_2]$ (3)

A partially labelled plot of the trinuclear complex **3** is shown in Figure 6. Selected interatomic distances and angles are listed in Table 4. The complex crystallises in the monoclinic space group $P2_1/a$. The central metal ion, Mn(2), which is located on a crystallographic inversion centre, is coordinated octahedrally by six oxygen atoms belonging to six different benzoates. Thus, the trinuclear molecule adopts a linear structure, with one $\eta^1{:}\eta^2{:}\mu_2$ and two *syn*,*syn*-$\eta^1{:}\eta^1{:}\mu_2$ carboxylate groups spanning each pair of Mn^{II}. The termini of the $\{Mn(O_2CPh)_3Mn(O_2CPh)_3Mn\}$ unit are capped by bidentate chelating (ph)(2-py)CO ligands, resulting in six-coordination at these sites.

Table 3. Formulae, cores and core description for structurally characterised octanuclear $Mn^{II/III}$, Mn^{III} and $Mn^{III/IV}$ clusters

Complex[a]	Core	Core description	Ref.
$[Mn_8O_2(O_2CCH_2tBu)_{14}(ButCH_2CO_2H)_4]$	$[Mn_6^{II}Mn_2^{III}(\mu_4\text{-}O)_2(\mu_2\text{-}O)_8]^{10+}$[b]	extension of the $[Mn_4^{II}Mn_2^{III}(\mu_4\text{-}O)_2]^{10+}$ core at one end with two additional Mn^{II} ions	[25]
$[Mn_8O_2(O_2CEt)_8(py)_4(L)_2]^{2+}$	$[Mn_6^{II}Mn_2^{III}(\mu_4\text{-}O)_2(\mu_3\text{-}O)_4(\mu_2\text{-}O)_4]^{6+}$[c]	two distorted cubanes edge-linked together at two Mn−O edges	[6a]
$[Mn_8O_2(OH)_2(O_2CPh)_{10}\{(ph)(2\text{-}py)CNO\}_4]$	$[Mn_4^{II}Mn_4^{III}(\mu_4\text{-}O)_2(\mu_3\text{-}OH)_2]^{14+}$	two $\{Mn_2^{II}Mn_2^{III}(\mu_3\text{-}O)(\mu_3\text{-}OH)\}^{7+}$ units linked *via* the O^{2-} in each unit	this work
$[Mn_8O_4(OH)_2(O_2CMe)_{12}(DMHP)_2(py)_2]$	$[Mn_2^{II}Mn_6^{III}(\mu_3\text{-}O)_4(\mu_2\text{-}OH)_2]^{12+}$	two $[Mn^{II}Mn_3^{III}(\mu_3\text{-}O)_2]^{7+}$ "butterfly" units linked by the two μ_2-OH^- ligands	[26]
$[Mn_8O_4(O_2CPh)_{12}(Et_2mal)_2(H_2O)_2]^{2-}$	$[Mn_2^{II}Mn_6^{III}(\mu_4\text{-}O)_2(\mu_3\text{-}O)_2]^{14+}$	two $[Mn^{II}Mn_3^{III}(\mu_3\text{-}O)_2]^{7+}$ "butterfly" units linked by one O^{2-} in each unit	[15]
$[Mn_8O_4(O_2CMe)_{12}(pic)_4]$	$[Mn_4^{III}(\mu_3\text{-}O)_2]_2^{8+}$	two $[Mn_4^{III}(\mu_3\text{-}O)_2]^{8+}$ units linked through two picolinates bridges	[27a]
$[Mn_8O_6Cl_6(O_2CPh)_7(H_2O)_2]^-$	$[Mn_8^{III}(\mu_4\text{-}O)_2(\mu_3\text{-}O)_4(\mu_2\text{-}Cl)_2(\mu_3\text{-}Cl)(\mu_4\text{-}Cl)]^{8+}$	two $[Mn_4^{III}(\mu_3\text{-}O)_2]^{8+}$ "butterfly" units fused by sharing one "body" Mn; an eighth Mn^{III} ion is connected to the resultant $\{Mn_7O_7\}^{7+}$ unit by two additional bridging O^{2-} ions	[18a]
$[Mn_8O_4(piv)_{10}(thme)_2(py)_2]$	$[Mn_8^{III}(\mu_3\text{-}O)_4]^{16+}$	six edge-sharing triangles or three edge-sharing "butterfly" units (ladder-like unit)	[27b]
$[Mn_8O_4(O_2CPh)_{12}(dbm)_4(bpe)_2]$	$[Mn_4^{III}(\mu_3\text{-}O)_2]_2^{8+}$	two "butterfly" $[Mn_4^{III}(\mu_3\text{-}O)_2]^{8+}$ units with the two bpe ligands attached *syn* about the central $[Mn_2O_2]$ rhomboids	[27c]
$[Mn_8O_4(O_2CEt)_{14}(py)_4(L')_2]^{2+}$	$[Mn_4^{III}(\mu_3\text{-}O)_2]_2^{8+}$	two butterfly-like cores arranged face-to-face and bridged by two bis-bidentate L ligands	[27d]
$[Mn_8O_{10}(O_2CMe)_6(bpy)_2(H_2O)_2]^{4+}$	$[Mn_2^{III}Mn_6^{IV}(\mu_2\text{-}O)_8(\mu_3\text{-}O)_2]^{10+}$	five $[Mn_2O_2]$ rhombs linked and fused to give a core with a serpentine topology	[28]

[a] Counterions and solvate molecules omitted; bpe = *trans*-1,2-bis(4-pyridyl)ethene; bpy = 2,2′-bipyridine; dbm = the anion of dibenzoylmethane; DMHP = 2,6-dimethyl-6-hydroxypyrimidine; Et_2mal = the dianion of 2,2-diethylmalonic acid; L = the dianion of (6-hydroxymethylpyridin-2-yl)-(6-hydroxymethylpyridin-2-yl methoxymethanol); L′ = 1,2-bis(5-methyl-2,2′-bipyridyl-5-yl)ethane; pic = the picolinate anion; piv = the pivalate anion; py = pyridine. [b] The μ_2-O atoms belong to carboxylates. [c] The μ_3-O atoms belong to the L^{2-} ligands, while the μ_2-O atoms are from $EtCO_2^-$ ligands.

[a] Primed atoms are related to the unprimed ones by the symmetry transformation $-x, -y + 1, -z$.

The Mn(1) polyhedron is significantly distorted. The main distortions arise from the five-membered chelating ring with a narrow O(1)−Mn(1)−N(1) bond angle [70.4(1)°] and an acute O(41)−Mn(1)−O(42) angle [57.9(1)°]. The Mn−N and Mn−O bond lengths agree well with values expected for high-spin Mn^{II}.[13] The Mn(2)−O bond lengths are in the narrow 2.136(3)−2.240(3) Å range, with the Mn(2)−O(42) distance longer, as expected. The coordination of the bridging benzoate oxygen, O(42) [and O(42′)], is somewhat pyramidal [Σ°O(42) = 336.8°].

Complex **3** joins a small family[32−34] of trinuclear Mn^{II} carboxylate complexes containing the $[Mn_3(\eta^1{:}\eta^1{:}\mu_2\text{-}O_2CR)_4(\eta^1{:}\eta^2{:}\mu_2\text{-}O_2CR)_2]^0$ core. The members of this family are listed in Table 5. This structural motif was also confirmed[35] for complexes $[Mn_3(O_2CPh\text{-}3\text{-}Cl)_6(bpy)_2]$ and $[Mn_3(O_2CPh\text{-}3\text{-}Cl)_6(Me_2\text{-}bpy)_2]$ (Me_2-bpy = 4,4′-dimethyl-2,2′-bipyridine) by analysis of the XANES and EXAFS spectra at the Mn K-edge; since only average distances could be derived, these two complexes are not included in Table 5. Some of the listed complexes have been important in the establishment of the "carboxylate shift" model.[34] Of the various types of metal-carboxylate binding modes, monodentate(monoatomic) bridging between metal centres offers unique flexibility. Analysis[34] of the structural characteristics of discrete compounds containing monodentate (monoatomic) bridging carboxylates shows that they can be arranged into three classes, depending upon the strength of the interaction of the non-bridging, or dangling (O_d), oxygen atom [O(42) in complex **3**] with one of the bridged metal ions [Mn(1) in **3**]. The application of this analysis to trinuclear Mn^{II} carboxylate complexes is demonstrated in Figure 7 and Table 5. The monodentate bridging mode is postulated to be an important intermediate between the other, more common, carboxylate attachment modes, based on observed variations of the geometry for monodentate bridges in structurally characterised complexes. The movement from monodentate to these other binding modes has been termed the "carboxylate shift";[34] such a shift could be kinetically important in carboxylate-containing metalloproteins.

Complex **3** is characterised by a small *D* value, $B > D$, a rather large Mn···Mn distance, a small difference between $C-O_d$ and $C-O_b$ (indicating significant delocalisation of the double bond), a large tilt (α-β) of the $\eta^1{:}\eta^2{:}\mu_2$ carboxylate toward Mn(1) and a significant distortion of the coordination geometry of Mn(1). Thus, complex **3** has a

[a] See Figure 7 for the definition of the structural parameters given in this table. [b] Not reported. [c] Three isomers of $[Mn_3(O_2CMe)_6L_2]$ have been crystallised and structurally characterised; they are designated *anti* and *syn* based on the disposition of the L imidazole groups with respect to the best plane passing through the three metal ions and the two monodentate acetate oxygen bridges. The A designation indicates the *anti* isomer where the central metal is located on a crystallographic inversion centre; no such inversion centre exists in the B form. [d] Average value for one of the two crystallographically independent trinuclear molecules present in the unit cell. [e] Variable-temperature magnetic-susceptibility data are available for a bulk sample of $[Mn_3(O_2CMe)_6L_2]$ possibly containing all three isomers. [f] Average value. [g] The single-crystal structure of this complex was also reported by Miyamae and co-workers;[32f] the quoted bond lengths and angles do no differ much from those reported by Lippard and co-workers. [h] Variable-temperature magnetic susceptibility data are not available.

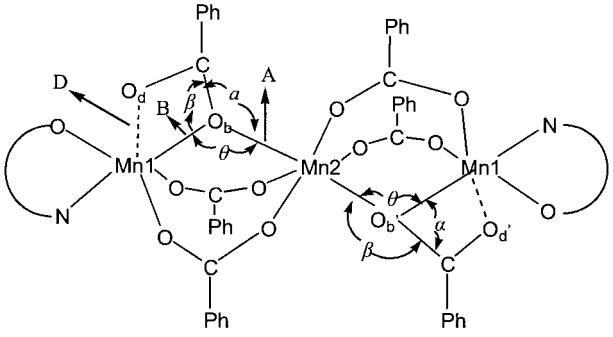

Figure 7. The schematic structure of complex **3** showing the dangling (O_d) and the bridging (O_b) oxygen atoms of the $\eta^1{:}\eta^2{:}\mu_2$ carboxylate groups, and defining the geometry of monoatomic carboxylate-bridged polymetallic centres in relation to the "carboxylate shift" mechanism proposed by Lippard;[32c,34] the values of the relevant structural parameters for **3** and other trinuclear complexes containing the $[Mn_3(\eta^1{:}\eta^1{:}\mu_2\text{-}O_2CR)_4(\eta^1{:}\eta^2{:}\mu_2\text{-}O_2CR)_2]^0$ core are listed in Table 5.

strong interaction between Mn(1) and O_d, i.e. O(42), and can be placed in class III in Lippard's classification scheme.[34]

IR Spectra

The presence of both neutral oxime and solvate H_2O molecules in **1**·1.2H_2O is manifested by a broad IR band of medium intensity at 3434 cm^{-1}, assigned to $\nu(OH)_{oxime}$ [13]/$\nu(OH)_{water}$.[36] The IR spectrum of **2** exhibits a medium band at 3438 cm^{-1} assignable[37] to $\nu(OH)_{OH^-}$; the broadness and relatively low frequency of this band are both indicative of strong hydrogen bonding.

The $\nu(C{=}O)$ mode is found at a lower wavenumber (1648 cm^{-1}) in the spectrum of **3** than for free (ph)(2-py)CO (1668 cm^{-1}); this shift is consistent with ketone-O coordination.[38]

Several bands appear in the 1610−1390 cm^{-1} range in the spectra of **1**−**3**. Contributions from the $PhCO_2^-$ $\nu_{as}(CO_2)$ and $\nu_s(CO_2)$ modes would be expected in this region, but overlap with the stretching vibrations of the aromatic rings and $\nu(C{=}N)_{oxime}$ (in **1** and **2**) renders assignments tentative and application of the spectroscopic criterion of Deacon and Phillips[39a] difficult. In all spectra, the very strong band at 1404−1400 cm^{-1} should have a high $\nu_s(CO_2)$ character.[13,39b]

A medium-intensity band at 606 cm^{-1} is present in the spectrum of **2**. This band is absent from the spectra of **1**·1.2H_2O and can be tentatively assigned to a vibration involving a $Mn^{III}-O^{2-}$ stretch.[40]

Magnetic Properties

Complex 2

Solid-state variable-temperature dc magnetic-susceptibility measurements were performed on a microcrystalline sample of **2** in a 0.1 T field in the range 2.0−300 K. The $\chi_M T$ vs. T and χ_M vs. T plots are shown in Figure 8. The value of $\chi_M T$ gradually decreases from 25.2 $cm^3{\cdot}mol^{-1}{\cdot}K$ at room temperature to 0.82 $cm^3{\cdot}mol^{-1}{\cdot}K$ at 2.0 K. The value of $\chi_M T$ at room temperature is lower than that expected for a cluster of $4Mn^{II}$ and $4Mn^{III}$ non-interacting ions (29.5 $cm^3{\cdot}mol^{-1}{\cdot}K$ for $g = 2$). A well-defined maximum of χ_M appears at 16 K. The $\chi_M T$ vs. T plot extrapolates to $\chi_M T \approx 0$ as the temperature approaches zero, indicating an $S = 0$ ground state. The intense drop of $\chi_M T$ with decreasing temperature reflects the presence of strong antiferromagnetic interactions within the cluster.

Complex **2** contains $4Mn^{II}$ and $4Mn^{III}$ centres, with total spin values ranging from 0 to 18. Owing to the size and low symmetry of the molecule, it is not possible to apply the Kambe method[41] or otherwise evaluate the individual

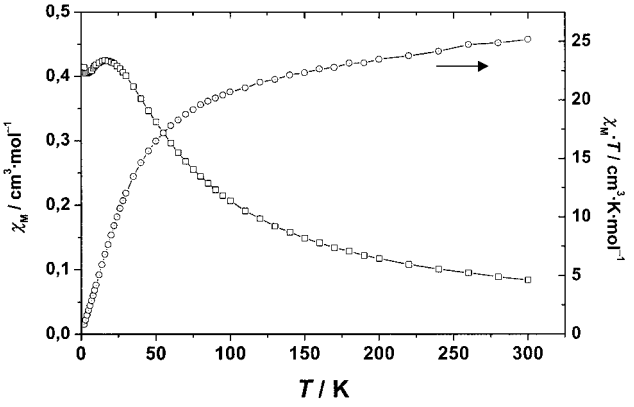

Figure 8. $\chi_M T$ vs. T and χ_M vs. T plots for complex **2**; the solid lines are guides for the eye

pairwise Mn_2 exchange interactions. Magnetisation data were collected in the magnetic field and temperature ranges 1−50 KG and 2.0−4.0 K, respectively. These measurements are poorly indicative, because they reveal a continuous increase of M with a change in the slope at 20 KG, up to an $M/N\beta$ value of 5.2 at 50 KG, far from saturation, indicating that several spin-states different from zero are very close to the ground state.

For the present $Mn_4^{II}Mn_4^{III}$ complex **2** it is important to rationalize the apparent $S = 0$. As indicated above, complex **2** can be described as arising from the linkage of the central $[Mn_4^{III}(\mu_3\text{-}O)_2]^{8+}$ subunit with two $[Mn_2^{II,II}(\mu_2\text{-}OH)]^{3+}$ subunits. Since $Mn^{II}\cdots Mn^{II}$ and $Mn^{II}\cdots Mn^{III}$ exchange interactions are typically weak and antiferromagnetic,[6a] the apparent $S = 0$ ground state of **2** can be rationalised taking as a starting point the well-established magnetic behaviour of the central, butterfly-like $[Mn_4^{III}(\mu_3\text{-}O)_2]^{8+}$ sub-core.

Table 6 conveniently summarises all previous magnetochemically characterised, *discrete* $[Mn_4^{III}(\mu_3\text{-}O)_2]^{8+}$ complexes.[22,42] There are two main exchange parameters: a body-body interaction parameter, J_{bb}, and a wing-tip-body parameter, J_{wb}. It has been found in all studied complexes that both types of interaction are antiferromagnetic and that $|J_{bb}|$ is appreciably larger than $|J_{wb}|$. In the format[42d] (S, S_{bb}, S_{ww}), the ground state of most complexes is (3, 1, 4). Even though both types of pairwise exchange interactions are antiferromagnetic, the ground state of these complexes has six unpaired electrons ($S = 3$). Because the J_{bb} interaction is greater than J_{wb} ($J_{bb}/J_{wb} = 3.0-5.0$), the spins on the two Mn_b ions have a greater tendency to pair up. Each Mn_w ion interacts with both the Mn_b ions and would align its spin antiparallel to both if possible, but it cannot do so. The net result is that the spin alignments of the Mn_w ions are frustrated. Overall, the unpaired electrons on the Mn_b ions are essentially paired up (actually the resultant spin vector S_{bb} is 1, not 0), and this leaves the unpaired electrons on the Mn_w ions. The S_{bb} resultant spin then couples with the $S_{ww} = 4$ to give the resultant $S = 3$ ground state of the complete molecule.[18a] The (3, 1, 4) ground state can be depicted diagrammatically as shown in **I** of Figure 9. In one complex, namely $[Mn_4O_2(O_2CEt)_7(bpya)_2](ClO_4)$ [bpya = bis(2-pyridyl)-amine],[42c] the J_{bb}/J_{wb} ratio is large (7.8) and there is also a very small J_{ww} interaction (-0.8 cm^{-1}); in this case, the spins of the Mn_b ions are fully antiparallel-aligned, i.e. $S_{bb} = 0$, and the ground state is then determined by the interaction of the Mn_w ions via the J_{ww} exchange, giving an $S = 0$ ground state since J_{ww} is antiferromagnetic (**II** in Figure 9). In effect, this (0, 0, 0) ground state can be described as the result of a weak, long-distance J_{ww} interaction between the wing-tip Mn^{III} ions through a strongly coupled, diamagnetic ($S_{bb} = 0$) central unit.[42c] In complex $[Mn_4O_2(O_2CPh)_6(dpm)_2]$ (dpm is the anion of dipivaloylmethane),[42d] the J_{bb}/J_{wb} ratio is much larger (ca. 70) and J_{ww} is negligible, i.e. $J_{ww} = 0$; the (n, 0, n) ground state is best described as fivefold degenerate (**III** in Figure 9). An alternative and completely equivalent description is to suggest that the ground state is composed of two non-interacting independent Mn^{III} ions.[42d]

The core of complex **2** (Figure 5) is more complicated than the $[Mn_4^{III}(\mu_3\text{-}O)_2]^{8+}$ core present in the *discrete* tetranuclear manganese(III) clusters mentioned above. However, the magnetic study of the latter has shown two important features. First, the J_{bb} coupling constant is always negative and relatively strong, and second, ground states with $S \neq 0$ are strongly dependent on the presence of competitive interactions in the coupling scheme. Complex **2** has two possible ligand types which may be involved in competitive interactions; these are the $\mu_4\text{-}O^{2-}$ and the $\mu_3\text{-}OH^-$ ligands. Spin frustration derived from competitive interactions involving the $\mu_4\text{-}O^{2-}$ ligand can be excluded because Mn(1) and Mn(2) are asymmetrically linked to the central Mn(4) and Mn(4′) ions, breaking the possible spin frustration. In fact, due to the fact that the oxo group O(21) lies on the JT

Table 6. Figure 9. The spin ground states established for *discrete* tetranuclear manganese(III) clusters containing the butterfly-like $[Mn_4^{III}(\mu_3\text{-}O)_2]^{8+}$ core (**I**, **II**, **III**) and a tentative coupling scheme for complex **2** (**IV**); the numbering scheme (in parentheses) for the Mn^{III} ions in the tetranuclear complexes is the same as that used for the central, Mn^{III}-containing subunit of complex **2** (see Figure 5), while the subscripts b and w denote body and wing-tip Mn^{III} ions, respectively; in **IV** the oxidation states of the Mn atoms are also denoted by superscripts

elongation axis of Mn(1), the interaction of Mn(1) with Mn(4′) should be very weak and clearly weaker than the interaction between Mn(1) and Mn(4) through the oximato/carboxylate bridges; an antiparallel alignment of the Mn(1) spin vector with respect to Mn(4) should be expected. Mn(2) is also asymmetrically linked to Mn(4) and Mn(4′) [for example, the Mn(2)−O(21)−Mn(4) bond angle is 118.8°, whereas the Mn(2)−O(21)−Mn(4′) one is 99.2°] and therefore different antiferromagnetic coupling with each of these Mn^{III} centres should be expected. These latter competitive interactions, combined with the antiferromagnetic coupling expected through the double oxo-hydroxo bridge within the Mn(2)···Mn(1) pair, make an antiparallel alignment of the Mn(2) spin vector with respect to Mn(1) reasonable. At this point, a reasonable coupling scheme for **2** can be as shown in **IV** of Figure 9, on the basis of the strong antiferromagnetic coupling within the Mn(4)···Mn(4′) pair (Table 6) and the expected antiferromagnetic interactions. The alignment of the Mn(3) spin vector, mainly determined by its interactions with Mn(1) and Mn(2) through the hydroxo oxygen [O(22), triangular arrangement], is not clear; however, for symmetry reasons, the orientation for Mn(3) and Mn(3′) should be related by the inversion centre of the molecule, resulting in an $S = 0$ ground state.

In summary, it is tempting to assume that the $S = 0$ ground state observed for **2** arises mainly from the reasonable antiferromagnetic interaction between Mn(1) and Mn(2) [and their symmetry-related partners], assuming a strongly coupled, diamagnetic ($S_{bb} = 0$) [Mn(4)Mn(4′)-O(21)O(21′)]$^{2+}$ central subunit and excluding the possibility of spin frustration due to the asymmetry of the interactions. We would like to emphasise that this discussion is only intended to qualitatively show a possible origin of the $S = 0$ ground state observed for complex **2**.

The $S = 0$ ground state is not uncommon in octanuclear Mn clusters and has been established in $[Mn_8O_2(O_2CEt)_8(py)_4(L)_2]^{2+}$,[6a] $[Mn_8O_2(O_2CCH_2But)_{14}(t\text{BuCH}_2CO_2H)_4]$[25] and $[Mn_8O_{10}(O_2CMe)_6(bpy)_2(H_2O)_2]^{4+}$.[28]

Complex 3

The variable-temperature magnetic-susceptibility data for compound **3** also reveal an overall antiferromagnetic behaviour. The $\chi_M T$ vs. T plot is shown in Figure 10. The value of $\chi_M T$ decreases from 12.1 $cm^3 \cdot mol^{-1} \cdot K$ at room temperature to 4.6 $cm^3 \cdot mol^{-1} \cdot K$ at 6.0 K. The room-temperature $\chi_M T$ value is slightly lower than the expected value $\chi_M T = (N\beta^2/3k)3g_i^2S_i(S_i + 1) = 13.125$ $cm^3 \cdot mol^{-1} \cdot K$ for three uncoupled Mn^{II} ions with $S_i = 5/2$ and $g_i = 2$ each. This value is already indicative of substantial antiferromagnetic coupling. The antiferromagnetic behaviour is further confirmed by the dramatic decrease of $\chi_M T$ when T decreases. At low temperature, the value of $\chi_M T$ almost corresponds to the expected value $\chi_M T = (N\beta^2/3k)g_i^2S(S + 1) = 4.375$ $cm^3 \cdot mol^{-1} \cdot K$ for an $S = 5/2$ spin state with $g = 2$.

Taking into account the molecular structure of **3**, the Kambe vector-coupling scheme shown in Figure 11 was considered. The spin Hamiltonian that describes the low-lying electronic states is given by Equation (4), where S_i is

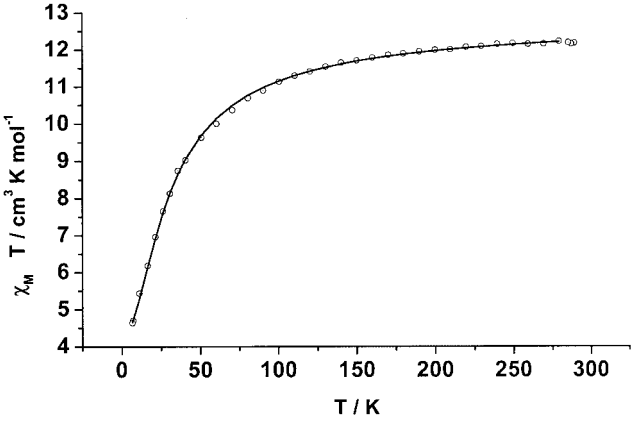

Figure 10. $\chi_M T$ vs. T plot for complex **3**; the solid line is the best theoretical fit to the data (see text for details)

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

the spin of the Mn^{II} ion with number i (Figure 11) and $J_{12} = J_{21'} = J$.

$$H_s = -J(S_1S_2 + S_2S_{1'}) - J_{11'}S_1S_{1'} \quad (4)$$

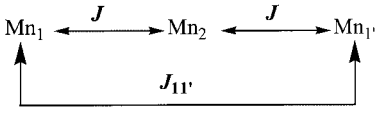

Figure 11. The Kambe vector-coupling scheme used for the interpretation of the magnetic behaviour of complex **3**

The experimental data were fitted with the susceptibility expression derived from the Van Vleck formula for three $S = 5/2$ spins. The best fit was obtained for $J = -2.74$ cm^{-1}, $J_{11'} = 0.7$ cm^{-1} and $g = 1.99$. The agreement between this calculation and experimental data is excellent, as can be judged from Figure 10. The agreement factor, defined as $R = \Sigma(\chi_M^{calcd.} - \chi_M^{exp})^2/\Sigma(\chi_M^{exp})^2$ is 4×10^{-4}. The J value obtained leads to a total-spin ground state of $S = 5/2$. The system can be reasonably fitted with only one J value ($J_{11'} = 0$) but this gives a worse agreement with experimental data. We refrain from analyzing further the magnetic properties of **3**, since detailed studies are available[32a,32b,35] for trinuclear Mn^{II} carboxylate complexes with similar structures.

The J value of **3** is well within the reported range (-5.6 to -1.9) reported for other trinuclear manganese(II) complexes containing the $[Mn_3(\eta^1{:}\eta^1{:}\mu_2\text{-}O_2CR)_4(\eta^1{:}\eta^2{:}\mu_2\text{-}O_2CR)_2]^0$ core[32] (see also Table 5). This indicates that weak antiferromagnetic coupling is mediated by the bridging carboxylate groups, which is as expected, since the Mn−O distances are relatively long in such compounds.[32] J values reported in the manganese(II) literature with *only* carboxylate groups as bridging ligands are always small and negative, between approximately -0.2 and -5 cm^{-1},[13] indicating weak antiferromagnetic coupling.

Electrochemistry of Complex 2

Complex **2** was investigated by cyclic voltammetry (CV), in CH_2Cl_2, and the corresponding voltammogram is shown in Figure 12. It should be stressed at this point that there is no actual proof that complex **2** retains its structure in solution. However, the non-coordinating nature of CH_2Cl_2 and the fact that solutions of **2** in CH_2Cl_2 are non-conducting both provide strong evidence that the structure of the complex is retained in solution. The cyclic voltammogram shows only broad, irreversible features — two oxidations at about 1.24 and 0.57 V, and three reductions at -0.69, 0.06, and 0.98 V, vs. a calomel electrode (4 M KCl). Since complex **2** is valence-trapped, probably owing to the increase in the barrier to intramolecular electron transfer resulting from the JT distortion of Mn^{III},[18a] it is likely that the reduction and oxidation of **2** will be centred at particular Mn ions. It is relatively rare for high-nuclearity $Mn/O/RCO_2^-$ aggregates to exhibit reversible redox processes, and thus the observed behaviour is typical of polynuclear Mn carboxylate complexes.[18a]

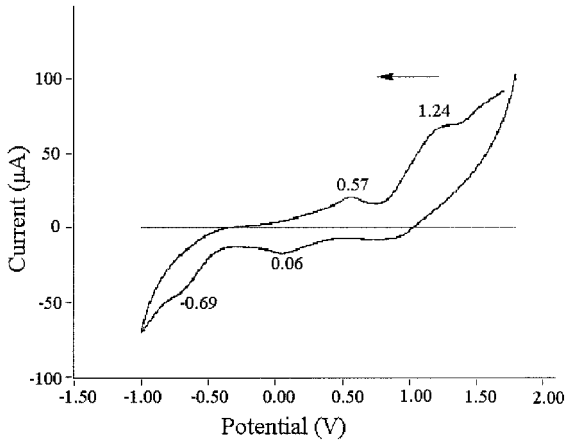

Figure 12. Cyclic voltammogram of complex **2** in CH_2Cl_2; scan rate: 100 mV s^{-1}; the potentials are given vs. a calomel electrode (4 M KCl)

Conclusions and Perspectives

The first use of (ph)(2-py)CNOH in Mn carboxylate chemistry has provided access to new complexes, one mononuclear (**1**) containing Mn^{II}, and the other octanuclear (**2**) with an unprecedented $[Mn_4^{II}Mn_4^{III}(\mu_4\text{-}O)_2(\mu_3\text{-}OH)_2]^{14+}$ core. In the former case, the ligand is neutral and chelates through its nitrogen atoms; in the latter case, the ligand is monoanionic chelating and bridging $Mn^{II}Mn^{III}$ or Mn_2^{III} pairs (Figure 4). Although the octanuclear cluster has been found to possess an $S = 0$ ground state, the bridging mode of (ph)(2-py)CNO^- nevertheless suggests possibilities for other Mn_x species that might exist (e.g. clusters containing the strongly coordinating inorganic anions NO_3^-, N_3^- and SO_4^{2-}) and which may have high-spin ground states. In addition, it provides encouragement for believing that a variety of carboxylate and non-carboxylate M_x^{II} and M_x^{III} clusters (M^{II} = Co^{II}, Ni^{II}; M^{III} = Cr^{III}, Fe^{III}) should also be accessible with this anionic ligand, leading to species with new topologies and exciting magnetic properties. Results with $Co^{II,II/III}$ and Ni^{II} at the time of writing reveal that the nature of (ph)(2-py)CNO^- makes it a versatile ligand for a variety of objectives/advantages, including μ_2 and μ_3 behaviour, high-nuclearity cluster formation, linking of clusters into polymeric arrays, 3d-4f mixed-metal chemistry and ferromagnetic exchange interactions. Clearly, the use of other pyridyl- or polypyridyl oximes offers a potential route to other new polynuclear metal complexes, and such studies are currently under progress.

Analogues of compound **2** with acetates or substituted benzoates are not known, at least to date, and it is currently not evident whether the preparation and the stability of this Mn_8 species are dependent on the particular nature of the $PhCO_2^-$ ligand.

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

Complex **3** is a new addition to the growing family of trinuclear complexes with the $[M_3(\eta^1{:}\eta^1{:}\mu_2\text{-}O_2CR)_4(\eta^1{:}\eta^2{:}\mu_2\text{-}O_2CR)_2]^0$ core (M = Mn, Fe, Co), providing a useful new datum point for the ongoing objective of fully understanding the ground-state spin value of transition metal carboxylate clusters as a function of metal, oxidation state and topology of the polynuclear metal core. The structural motif of the linear trinuclear $[M_3(O_2CR)_6]^0$ unit turns out to be as important as that of the triangular basic carboxylate motif, which is characteristic of the trivalent and mixed-valent $M^{II}M_2^{III}$ analogues. Clearly, the inability of phenyl 2-pyridyl ketone, (ph)(2-py)CO, to give the *gem*-diol form [(ph)(2-py)C(OH)$_2$] in solution in the presence of metal ions, restricts its utility to the synthesis of polynuclear metal complexes, in contrast with its bis(2-pyridyl) analogue, (2-py)$_2$CO.

Experimental Section

Materials and Physical Measurements: All manipulations were performed using materials (Merck, Aldrich) as received. Compounds $Mn(O_2CPh)_2{\cdot}2H_2O$,[15] N*n*Bu$_4$MnO$_4$ [14] and (N*n*Bu$_4$)[Mn$_4$O$_2$(O$_2$CPh)$_9$(H$_2$O)][15] were synthesised according to published methods. Elemental analysis (C, H, N) were performed by the University of Ioannina (Greece) Microanalytical Laboratory using an EA 108 Carlo Erba analyzer. IR spectra (4400−450 cm^{-1}) were recorded from KBr pellets on a Perkin−Elmer PC 16 FT-IR spectrometer. Magnetic susceptibility measurements in the range of 2−300 K and magnetisation measurements (2−4 K) in the field range of 0.1−5 T for complex **2** were performed with a Quantum Design SQUID magnetometer at the Magnetochemistry Service of the University of Barcelona. Magnetic susceptibility measurements for complex **3** were performed with a DSM8 pendulum-type susceptometer operating in the range 6−300 K at magnetic fields of approximately 1 T. All measurements were performed on polycrystalline samples. Data were corrected for diamagnetic contributions calculated from Pascal constants. The cyclic voltammogram of complex **2** was recorded on a AFCBP1 Biopotentiostat and a standard three-electrode assembly (glassy carbon working, platinum wire auxiliary, SCE reference) with 0.1 M N*n*Bu$_4$PF$_6$ in distilled CH$_2$Cl$_2$ as supporting electrolyte.

$[Mn(O_2CPh)_2\{(ph)(2\text{-}py)CNOH\}_2]{\cdot}1.2H_2O$ (1·1.2H$_2$O) and $[Mn_8O_2(OH)_2(O_2CPh)_{10}\{(ph)(2\text{-}py)CNO\}_4]{\cdot}4CH_2Cl_2$ (2·4CH$_2$Cl$_2$) as a Mixture: Treatment of a stirred, colourless solution of $Mn(O_2CPh)_2{\cdot}2H_2O$ (0.166 g, 0.50 mmol) in EtOH/MeCN (15 mL, 2:1 v/v) with solid (ph)(2-py)CNOH (0.099 g, 0.50 mmol) resulted in a pale-orange solution, which, upon slow evaporation at room temperature, turned brown due to slow oxidation of Mn^{II} under aerobic conditions. The resulting solution was evaporated to dryness under reduced pressure and the residue redissolved in CH$_2$Cl$_2$ (25 mL) to give a red-brown solution. This was layered with a mixture (50 mL, 1:1 v/v) of Et$_2$O and *n*-hexane. After several days yellow and dark-brown crystals were formed; they were carefully collected by filtration. The two products were readily separable manually, and the yellow and dark brown crystals proved by single-crystal crystallography to be complexes **1**·1.2H$_2$O and **2**·4CH$_2$Cl$_2$, respectively.

$[Mn(O_2CPh)_2\{(ph)(2\text{-}py)CNOH\}_2]{\cdot}1.2H_2O$ (1·1.2H$_2$O): A colourless solution of $Mn(O_2CPh)_2{\cdot}2H_2O$ (0.166 g, 0.50 mmol) in EtOH (10 mL) was treated with solid (ph)(2-py)CNOH (0.297 g, 1.50 mmol). The solid soon dissolved. The resulting yellow solution was stirred for about 10 min and was then allowed to stand undisturbed at 5 °C for several days. Well-formed yellow crystals appeared, which were collected by filtration, washed with Et$_2$O (2 × 5 mL) and dried in air. Yields (based on Mn^{II}) as high as 0.27 g (75%) were obtained. $C_{38}H_{32.4}MnN_4O_{7.2}$ (715.22): calcd. C 63.8, H 4.6, N 7.8; found C 64.1, H 4.6, N 7.7. Main IR data (KBr pellet): $\tilde{\nu}$ = 3434 (m, broad), 2924 (w), 1594 (m), 1538 (s), 1468 (w), 1436 (w), 1402 (s), 1332 (w), 1256 (w), 1190 (w), 1062 (m), 1026 (m), 965 (w), 834 (w), 792 (w), 776 (w), 722 (m), 706 (m), 674 (m), 636 (w), 500 (w) cm^{-1}.

$[Mn_8O_2(OH)_2(O_2CPh)_{10}\{(ph)(2\text{-}py)CNO\}_4]{\cdot}4CH_2Cl_2$ (2·4CH$_2$Cl$_2$). ***Method A*:** Treatment of a stirred, colourless solution of $Mn(O_2CPh)_2{\cdot}2H_2O$ (0.166 g, 0.50 mmol) in EtOH/MeCN (15 mL, 2:1 v/v) with N*n*Bu$_4$MnO$_4$ (0.060 g, 0.16 mmol) resulted in a dark-brown solution. Solid (ph)(2-py)CNOH (0.099 g, 0.50 mmol) was slowly added to this mixture, and it soon dissolved to give a solution of essentially the same colour. The solvents were then evaporated under reduced pressure. The obtained residue was dissolved in CH$_2$Cl$_2$ (25 mL), filtered, and the filtrate layered with a mixture of Et$_2$O and n-hexane (50 mL, 1:1 v/v); slow mixing gave dark-brown crystals of the product, which were collected by filtration, washed with cold CH$_2$Cl$_2$ (2 mL) and Et$_2$O (2 × 5 mL), and dried in vacuo over silica gel. Yield (based on the oxime): 0.17 g (55%). The dried solid analysed as CH$_2$Cl$_2$-free **2**. $C_{118}H_{88}Mn_8N_8O_{28}$ (2505.66): calcd. C 56.6, H 3.6, N 4.5; found C 57.0, H 3.5, N 4.6. The crystals of **2**·4CH$_2$Cl$_2$ were found to lose solvent readily, and they were kept in the mother liquor until a suitable crystal had been found for X-ray crystallography. Main IR data (KBr pellet): $\tilde{\nu}$ = 3438 (m, broad), 3060 (w), 1596 (s), 1552 (s), 1490 (m), 1468 (m), 1444 (m), 1404 (s), 1200 (w), 1174 (w), 1110 (w), 1094 (m), 1070 (s), 1026 (m), 978 (w), 818 (w), 788 (m), 744 (w), 716 (s), 676 (s), 638 (w), 606 (m), 552 (w) cm^{-1}.

***Method B*:** Treatment of a stirred, brown solution of (N*n*Bu$_4$)[Mn$_4$O$_2$(O$_2$CPh)$_9$(H$_2$O)] (0.110 g, 0.07 mmol) in CH$_2$Cl$_2$ (20 mL) with solid (ph)(2-py)CNOH (0.060 g, 0.03 mmol) gave a solution of essentially the same colour. The solution was stirred vigorously for about 45 min, and layered with a mixture of Et$_2$O and *n*-hexane (40 mL, 2:1 v/v) to give X-ray quality, dark-brown crystals of **2**·4CH$_2$Cl$_2$. The crystals were collected by filtration, washed with Et$_2$O (2 × 5 mL) and dried in vacuo over silica gel. The dried solid analysed satisfactorily as **2**. The identity of the product was confirmed by IR spectroscopic comparison with the authentic sample prepared according to Method A.

$[Mn_3(O_2CPh)_6\{(ph)(2\text{-}py)CO\}_2]$ (3): A colourless solution of (ph)(2-py)CO (0.090 g, 0.50 mmol) in MeOH (15 mL) was added to a colourless solution of $Mn(O_2CPh)_2{\cdot}2H_2O$ (0.166 g, 0.50 mmol) in the same solvent (15 mL). The resulting yellow solution was stirred for 1 h. Slow evaporation of this solution at room temperature gave large yellow needles suitable for crystallography. When precipitation was judged complete, the crystals were collected by filtration, washed with Et$_2$O and dried in air. Yields (based on Mn^{II}) as high as 0.18 g (85%) were obtained. $C_{66}H_{48}Mn_3N_2O_{14}$ (1257.88): calcd. C 63.0, H 3.9, N 2.2; found C 62.7, H 3.8, N 2.2. Main IR data (KBr pellet): $\tilde{\nu}$ = 3058 (w), 1648 (m), 1606 (s), 1566 (s), 1536 (s), 1448 (w), 1400 (s), 1316 (m), 1250 (m), 1170 (m, broad), 1068 (w), 1016 (m), 952 (m), 936 (w), 858 (w), 822 (w), 768 (w), 748 (sh), 718 (s), 700 (m), 674 (m), 656 (w), 572 (wb) cm^{-1}.

X-ray Crystallographic Studies: Crystals of **1**·1.2H$_2$O and **3** were mounted in air and covered with epoxy glue, while a crystal of **2**·4CH$_2$Cl$_2$ was mounted in a capillary filled with drops of mother liquor. Diffraction measurements for **1**·1.2H$_2$O and **3** were made

on a Crystal Logic Dual Goniometer diffractometer using graphite-monochromated Mo-K_a radiation. The X-ray data set for **2**·4CH_2Cl_2 was collected on a $P2_1$ Nicolet diffractometer upgraded by Crystal Logic using graphite monochromated Cu-K_a radiation. Complete crystal data and parameters for data collection and refinement are listed in Table 7. Unit-cell dimensions were determined and refined by using the angular settings of 25 automatically centred reflections in the ranges $11 < 2\theta < 23°$ (for **1**·1.2H_2O and **3**) and $22 < 2\theta < 54°$ (for **2**·4CH_2Cl_2). Intensity data were recorded using the θ-2θ scan method. Three standard reflections monitored every 97 reflections showed less than 3% variation and no decay. Lorentz, polarisation and Ψ-scan absorption corrections were applied using the Crystal Logic software package.

The structures were solved by direct methods using SHELXS-86[43a] and refined by full-matrix least-squares techniques on F^2 with SHELXL-93.[43b] For all three structures, all hydrogen atoms [except those of O(1) and O(11) for **1**·1.2H_2O and the μ_3-OH^- hydrogen for **2**·4CH_2Cl_2 which were located by difference maps and refined isotropically] were introduced at calculated positions as riding on their parent atoms. All non-hydrogen coordinated atoms of **1**·1.2H_2O were refined anisotropically. The solvate oxygen atoms were refined isotropically. Two of them were refined with occupation factors of a total sum one; the third one, sitting on an inversion centre of symmetry, was refined with a freely refined occupation factor of about 0.20. All non-hydrogen atoms of **2**·4CH_2Cl_2 and **3** were refined anisotropically.

CCDC-227429 (**1**·1.2H_2O), -195209 (**2**·4CH_2Cl_2) and -227430 (**3**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.hmtl [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: +44 1223 336033; E-mail: deposit@ccdc.cam.ac.uk].

EPR Insensitivity of the Metal-Nitrosyl Spin-Bearing Moiety in Complexes $[L_nRu^{II}\text{-}NO^{\cdot}]^k$

Stéphanie Frantz,[a] Biprajit Sarkar,[a] Monika Sieger,[a] Wolfgang Kaim,*[a] Federico Roncaroli,[b] José A. Olabe,*[b] and Stanislav Záliš[c]

Keywords: Density functional calculations / EPR spectroscopy / Nitric oxide / Radical complexes / Ruthenium

A survey of 18 paramagnetic species $[L_nRu(NO)]^k$, including seven new examples studied by in situ electrolysis, reveals a surprisingly narrow range of EPR parameters despite a wide variety of ligands such as pyridine, polypyridines, imines, amines, nitriles, phosphanes, carbonyl, cyclopentadienides, halides, hydride, hydroxide, thiocyanate or cyanide: g_1 = 2.015 ± 0.02, g_2 = 1.990 ± 0.015, g_3 = 1.892 ± 0.03, g_{av} = 1.968 ± 0.02, $\Delta g = g_1 - g_3 = 0.122 \pm 0.037$, $A_2(^{14}N) = 3.3 \pm 0.5$ mT. This rather small variability, smaller still if the organometallic compounds are excluded, differs from the wider range of EPR data reported for nitrosyliron species with $S = 1/2$; apparently, the $\{RuNO\}^7$ configuration involves a rather invariant and relatively covalent metal–NO interaction. DFT calculations were employed for $[(NC)_5Ru(NO)]^{3-}$ to reproduce the EPR data, to evaluate the spin distribution (58% spin density on NO), and to reveal structural changes on reduction such as the Ru–N–O bending and Ru–NO bond lengthening. In addition, the possibility of staggered and eclipsed conformations is discussed.

Introduction

The formation, reactivity, spectroscopy and structures of nitrosyliron complexes have been investigated for more than a century.[1−3] The question of the appropriate electronic description of such species in terms of oxidation and spin states has been highlighted recently by the examples of simple $[(H_2O)_5Fe(NO)]^{2+}$,[4] of complexes $[(L)Fe(NO)]^{n+}$ with multidentate N-, S- or O-donor ligands L,[5] and of nitrosyliron porphyrins inside or outside of heme proteins.[6,7] Various iron oxidation states, from −II[8] to +IV,[9] can be discussed in conjunction with nitrosonium (NO^+), nitric oxide ($NO^{\cdot}$) or nitroside (NO^-) ligands.[10] Paramagnetic neutral $NO^{\cdot}$ is of particular interest, and its presence has been observed frequently by vibrational or EPR spectroscopy.[11−13]

The current surge in such studies is attributed to the recognition of the essential role of iron−NO interactions in a physiological context,[13] including the formation,[14] binding, and release[15] of this ubiquitous messenger (neurotransmitter) molecule.[16] Copper-[17] or iron-coordinated NO also play an important role in the biological nitrogen cycle.[18] In yet another line of interest, the metal-influenced chemistry of NO is of relevance for catalytic exhaust-gas conversion.[19]

Recently, corresponding compounds of the higher homologue ruthenium have also been studied in the search for NO-scavenging[20] or NO-releasing (delivering) agents.[14,15,21] Scavenging by specifically designed ruthenium(III) aqua complexes containing polycarboxylate coligands was reported recently to involve a fast NO coordination, leading to formally $Ru^{II}(NO^+)$ complexes. However, the potential $Ru^{II}(NO^{\cdot})$ product accessible by electrochemically reversible reduction[20c] was not studied further.[20a]

Photochemical or electron-transfer activation can be envisaged for the labilization of bound NO from its usual, kinetically stable $Ru^{II}(NO^+) = \{RuNO\}^6$ configuration.[21] Following more recent assumptions[22] on the transition from $Ru^{II}-(NO^+)$ to $Ru^{II}-(NO^{\cdot})$ some EPR data on chemically generated $Ru^{II}(NO^{\cdot})$ species and pertinent quantum-chemical calculations have been published in the last few years.[21b,23−30] Herein we describe EPR results from the in situ reduction of several more such complexes $[L_nRu(NO)]^k$, we summarize and critically discuss the data of 18 different such species and compare the unexpectedly

uniform result with the situation in corresponding iron complexes. Results for the reduction and oxidation of $[Cl_5Ru(NO)]^{2-}$ are also presented, as are improved DFT calculations of the *g* and hyperfine properties of $[(NC)_5Ru(NO)]^{3-}$, including their orientation dependence (eclipsed vs. staggered conformation).

Results and Discussion

Although the new $Ru^{II}-(NO^+)$ precursor complexes referred to in the Exp. Sect. are reduced reversibly at room temperature, no EPR signals were detectable for the one-electron-reduced forms under those conditions. EPR silence at room temperature has been reported before for the related species from Table 1.[22−25] In glassy frozen solution a typical pattern[17,23−30] of rhombic *g* splitting with ^{14}N nitrosyl hyperfine coupling of the central component emerges, a representative spectrum from the in situ electrolysis of a precursor, $[(terpy)(bpz)Ru(NO)]^{3+}$, in CH_3CN/0.1 M Bu_4NPF_6, is shown together with a computer simulation in Figure 1.

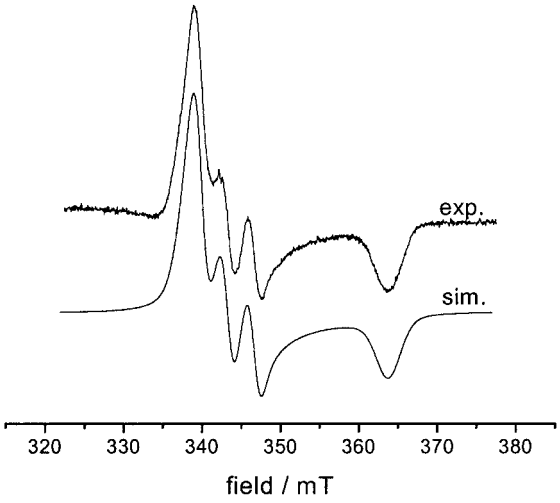

Figure 1. EPR spectrum of $[(terpy)(bpz)Ru(NO)]^{2+}$ at 110 K in CH_3CN/0.1 M Bu_4NPF_6 (top); computer simulation (bottom)

Conversion of commercially available $K_2[Cl_5Ru(NO)]$ into its tetrabutylammonium salt allowed us to additionally study its reduction behavior in acetonitrile. Even at −40 °C the electrochemical reduction proved to be irreversible,

presumably due to the facile dissociation of chloride. In contrast, reversible oxidation produced a species with an EPR signal ($g_{1,2}$ = 2.1075, g_3 = 2.0577) which will have to be analyzed further.

The results for the reversibly reduced systems are summarized, together with literature data, in Table 1; most previously reported species were obtained by chemical reduction with, for example, Zn/Hg[29] or Eu^{2+}.[21b,24,25b]

The spectra reported here were simulated without incorporating unresolved nitrosyl ^{14}N hyperfine splitting of the g_1 and g_3 components. Such incorporation has been reported in the literature;[25,29][30b] however, the corresponding values between 1 and 2 mT, or even below, may rather serve as an approximation or upper limit and they will not be discussed further. Accuracy of the g factors is assumed to be ±0.0005 (g_1), ±0.0002 (g_2) and ±0.001 (g_3); the A_2 values are given with a ±0.1 mT error margin.

Given the wide variety of ligands L for the species $[L_nRu(NO)]^k$ in Table 1 (L = pyridine, polypyridines, imines, amines, nitriles, phosphanes, carbonyl, cyclopentadienide, halides, hydride, hydroxide, thiocyanate, cyanide), the small degree of EPR parameter variation is surprising:
$g_1 = 2.015 \pm 0.02$, $g_2 = 1.990 \pm 0.015$, $g_3 = 1.892 \pm 0.03$, $g_{av} = 1.968 \pm 0.02$, $\Delta g = g_1 - g_3 = 0.122 \pm 0.037$, $A_2(^{14}N) = 3.3 \pm 0.5$ mT.

The variance is still smaller if organometallic derivatives[30] are excluded.

Paramagnetic nitrosyliron complexes, even those involving only low-spin systems,[4,5,7,31] exhibit a distinctly greater variation. In part this may reflect contributions from the more accessible valence-tautomeric $M^I(NO^+)$ state for M = Fe which has a $(d_z^2)^1$ configuration and leads to $g_{1,2} \approx 2.07$, $g_3 \approx 2.0$ and $g_{av} \approx 2.03$ for clearly established $Fe^I(NO^+)$ cases.[25,31b]

On average, the g anisotropy, $\Delta g = g_1 - g_3$, is about twice as large for the ruthenium complexes as for related nitrosyliron(II) species.[27] This is an immediate consequence of the higher spin-orbit coupling constant $\xi(Ru) \approx 2\xi(Fe)$.[32] The deviation of g from the free-electron value of 2.0023 results from admixtures of higher excited states with nonzero angular momentum; according to the approximation in Equation (1) the spin-orbit coupling constant, ξ, is a crucial factor.[33]

$$g = g_e - \frac{2}{3}\sum_i \sum_n \sum_{kj} \frac{\langle \psi_0 | \xi_k \mathbf{L} \delta_k | \psi_n \rangle \langle \psi_n | \mathbf{L}_{ij} \delta_j | \psi_0 \rangle}{E_n - E_0} = g_e + \Delta g \quad (1)$$

ξ: spin orbit coupling constant
L: angular momentum operator
E_0: energy of singly occupied molecular orbital (SOMO)

Unrestricted ADF/BP calculations for the most symmetric species $[(NC)_5Ru(NO)]^{3-}$ have confirmed the expected[11] and recently experimentally confirmed[30b] bending of the RuNO moiety to 146.1° [138.75(11)° for $[HCl(OC)(PiPr_3)_2Ru(NO)]$[30b]) and the lengthening of the Ru−NO bond by 0.128 Å to 1.899 Å [1.8566(11) Å for $[HCl(OC)(PiPr_3)_2Ru(NO)]$[30b]), in agreement with the established NO labilization on reduction for potential medical applications.[20,21] G98/B3LYP calculations give an RuNO angle of 146.7° and a Ru−NO bond length of 1.915 Å. ADF/SAOP calculations indicated about 29% metal and 58% NO contributions to the singly occupied molecular orbital (SOMO), suggesting $Ru^{II}-(NO^{\cdot})$ as the dominant oxidation state formulation, albeit with considerable mixing.[27] The lowest (completely) unoccupied molecular orbital (LUMO) is the second NO-based π* MO (25% metal and 62% NO contribution), originating from the degenerate e level of $[(NC)_5Ru(NO)]^{2-}$. The calculated values (g_n, A_n) are listed in Table 2.

Table 2. Comparison of experimental and calculated g values and hyperfine constants A (mT) for $[(NC)_5Ru(NO)]^{3-}$ at optimized geometry (eclipsed conformation)

[a] ADF/BP calculations: g values calculated using spin-restricted approach including spin-orbit coupling; A values calculated within the UKS-ZORA approach with core electrons included. [b] ADF/SAOP spin-restricted ZORA calculations including spin-orbit coupling. [c] UKS-Pauli approach. [d] Calculated from $<g> = [(g_1^2 + g_2^2 + g_3^2)/3]^{1/2}$.

The well-known bending of the M−N−O moiety in $\{MNO\}^7$ species with approximately octahedral configuration at M produces a conformational isomerism characterized by variations of the C(CN)−Ru−N−O dihedral angle, θ, with the eclipsed (θ = 0°) and staggered (θ = 45°) conformations as the two extreme cases (Scheme 1). G98/B3LYP geometry optimization shows the eclipsed conformation to be more stable by 0.041 eV (as in $[HCl(OC)(PiPr_3)_2Ru(NO)]$[30b]), the rotational barrier being highly dependent on the functional used. The calculated g_n, $A_n(^{14}N)$ and $A_n(^{101}Ru)$ parameters depend only slightly on the conformation.

The analysis of individual contributions to the Δg values was performed within the UKS-Pauli approach, indicating that the largest contribution arises from the paramagnetic orbital-orbital coupling between the SOMO and LUMO of the same spin polarization. The experimental g values are well reproduced by the calculations. Table 2 shows how the functional and the type of approach influence the calculated values. The best agreement between experimental and calculated g values was achieved using either the ADF/

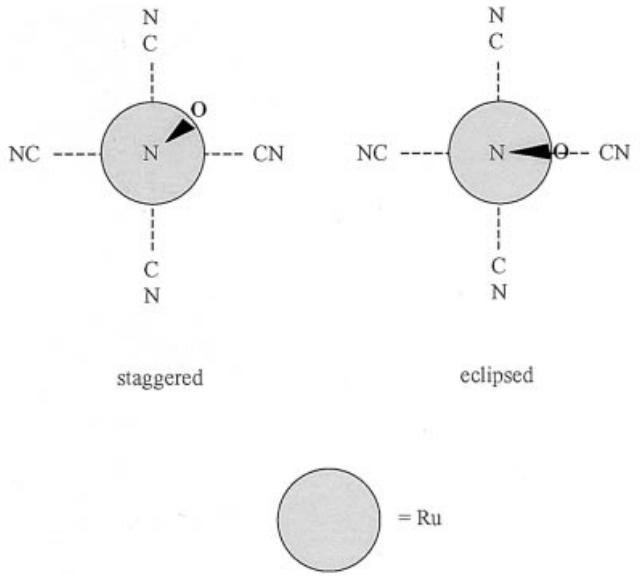

Scheme 1

SAOP spin-restricted ZORA spin-orbit calculation or the UKS-Pauli approach.

The spin distribution in complexes $[L_nRu(NO)]^k$ = $\{RuNO\}^7$ seems to be rather invariant throughout the complexes of Table 1, reflecting the high degree of covalency of the Ru−N bond in the $\{RuNO\}^{[7]}$ configuration with 19 valence electrons. Increasing covalency is also responsible for the general shift to higher g values on going from $Na^+-NO^{\cdot}$ via Cu^I complexes[34] to the Ru^{II} compounds summarized here. In comparison to the results given here, some other calculations[26,29] seem to underestimate the NO contributions. In that context, some conclusions based on very small ν(NO) shifts on reduction such as a $Ru^{III}(NO^{\cdot})$ formulation for $[(cyclam)ClRu(NO)]^{2+}$ or a ligand-delocalized description $(L^{\cdot-})Ru^{II}(NO^+)$ suggested for $[(bpydip)ClRu(NO)]^+$ [29] are not supported by the EPR data [cyclam = 1,4,8,11-tetraazacyclotetradecane; bypdip = *N*,*N*′-bis(7-methyl-2-pyridylmethylene)-1,3-diiminopropane].

Despite the rather uniform EPR results for the species in Table 1 there are some slight variations. The most symmetrical species $[(NC)_5Ru(NO)]^{3-}$ displays a g component splitting approaching the axial limit, with $g_{\perp} > g_{\|}$. The average value of g is smallest for this species whereas it is slightly larger (in 0.012) for $[(cyclam)ClRu(NO)]^+$; however, all $Ru^{II}(NO^{\cdot})$ complexes have g_{av} below 2, indicating the closeness of both π* orbitals of NO[27] and thus of both $^2\Pi_x$ and $^2\Pi_y$ states.[34,35] The presence of states lying close to the radical ground state is also responsible for the rapid relaxation as evident from the EPR silence at room temperature. The relatively large A_2 hyperfine value of 3.8 mT for $^{14}N(NO)$ may in part reflect the reluctance of negatively charged cyanide ligands in $[(NC)_5Ru(NO)]^{3-}$ to accommodate the unpaired electron. On the other hand, the A_2 values are smallest, at about 3.0 mT, for the series of complexes $[(py)_4XRu(NO)]^+$ with rather weak donor ligands (Table 1).

The total g anisotropy $\Delta g = g_1 - g_3$ is highest for the dinuclear complex $[(NC)(py)_4Ru(CN)(py)_4Ru(NO)]^{2+}$, possibly reflecting an effect of the second, non-NO-coordinating metal center with its high spin-orbit coupling constant. $[(NC)_5Ru(NO)]^{3-}$ and the phosphane-containing compound $[(depe)_2ClRu(NO)]^+$ [depe = 1,2-bis(diethylphosphanyl)ethane], both with strong σ donor/π acceptor ligation, display relatively small Δg values, indicating smaller metal contributions; this is also supported by rather high nitrosyl ligand coupling constants $A_2(^{14}N)$.

Changing the solvent from CH_3CN to DMF in the case of $[(py)_4ClRu(NO)]^+$ yielded identical EPR parameters. Although the cyanoiron compounds $[(NC)_5Fe(L)]^{2-}$ [L = NO^+ or *N*-methylpyrazinium (mpz)] can lose one cyanide ligand on reduction[36,37] we found no evidence for conversion into a five-coordinate complex in the paramagnetic ruthenium species studied here. The new calculated metal hyperfine coupling constants $A_n(^{101}Ru)$ (Table 2) confirm the failure to observe such splittings experimentally. Even the calculated A_2 value of 1.61 mT would be difficult to detect because of the line-width, the relatively low natural abundance of only 17% and the distribution of signal intensity over six lines (I = 5/2). The isotope ^{99}Ru (12.7% natural abundance, I = 5/2) has a 10% smaller hyperfine coupling[45] and would be still harder to detect. The maximum calculated isotropic hyperfine splitting of 0.94 mT according to Table 2 is only slightly larger than the $A_{iso}(^{101}Ru)$ parameters measured for radical complexes containing cyanoruthenium[37,38] (≤0.52 mT) or other ruthenium(II) complex fragments (≤0.86 mT).[39] Species with metal-centered spin containing ruthenium(I)[40] are expected to have isotropic metal coupling constants of several milliteslas.

In summary, the small variation in g tensor splitting and hyperfine coupling for all 18 compounds in Table 1 suggest very similar electronic structures, described essentially by the $Ru^{II}(NO^{\cdot})$ formulation. The surprising invariance of EPR parameters points to a higher degree of covalency in the $\{RuNO\}^7$ situation than in the corresponding $\{FeNO\}^7$ arrangements, the latter having more accessible options between the limiting structures $Fe^{II}(NO^{\cdot})$ and $Fe^{I}(NO^+)$ and between low-spin and high-spin states. Perspectives for future work will include nitrosylruthenium complexes with strongly dominant co-ligands such as porphyrins or other macrocycles[41] and the study of osmium analogues with their much higher spin-orbit coupling contributions from the 5d metal.

Experimental Section

Instrumentation: IR spectra were recorded with KBr pellets on a Thermo Nicolet model Avatar 320 FT-IR instrument. ^1H NMR spectra were obtained on a Bruker 500 MHz spectrometer. Electrochemical studies were performed with a Princeton Applied Research potentiostat 273A, by square-wave voltammetry (SWV) at 60 Hz, with vitreous carbon as working electrode and Ag/AgCl (3 M KCl) as reference. The electrolyte was an aqueous solution that was 1 M in NaCl and 0.01 M in HCl. Elemental analyses were done on a Carlo Erba elemental analyser, model 1106. EPR spec-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

troscopy: The nitrosylruthenium complexes were reduced for in situ EPR studies in a two-electrode capillary described earlier.[42] The electrolyte was CH_3CN/0.1 M Bu_4NPF_6. Whereas the brief (ca. 10 min) electrolysis was performed at 295 K, the EPR spectra were recorded at 110 K in glassy frozen solutions due to the EPR silence of the complexes at room temperature. A Bruker ESP 300 spectrometer was used. The *g* factor determination was carried out with a Bruker ER035M gaussmeter and a HP 5350B microwave counter. The spectra were simulated (program Bruker WinSimfonia) without incorporating the unresolved hyperfine splitting of the g_1 and g_3 components.

The complexes *trans*-$[(py)_4ClRu(NO)](PF_6)_2$,[43] *trans*-$[(py)_4(OH)Ru(NO)](PF_6)_2$,[43] *trans*-$[(py)_4(NH_3)Ru(NO)](BF_4)_3$,[44a] *cis*-$[(bpy)_2ClRu(NO)](PF_6)_2$,[23] *cis*-$[(bpy)_2(CH_3CN)Ru(NO)](PF_6)_2$[44b] and $[(terpy)(bpy)Ru(NO)](PF_6)_3$[45] were prepared as described previously.

[(terpy)(bpz)Ru(NO)](PF$_6$)$_3$: $[RuCl_3(terpy)]$[46] (100 mg, 0.227 mmol) and bpz (2,2′-bipyrazine, 60 mg, 0.379 mmol) were heated to reflux for 3 h in 50 mL of EtOH/H_2O (1:1). $NaNO_2$ (150 mg) was added to the red-brown solution and refluxing was continued for 2 h. The red solution was then filtered and a concentrated solution of NH_4PF_6 was added until complete precipitation of the product was ensured. The red solid was suspended in 3 M HCl and NH_4PF_6 was added in the same way as before to afford a brown solid. The product was further purified by recrystallization from acetonitrile/diethyl ether. IR: ν(NO) = 1957 cm^{-1}. $E_{1/2}$ = 0.46 V vs. Ag/AgCl. $C_{28}H_{17}F_{18}N_8OP_3Ru$ (957.40): calcd. C 28.85, N 1.79, N 11.71; found C 27.66, N 1.74, N 11.04. ^{1}H NMR (CD_3CN): δ = 10.12 (s, 1 H), 9.96 (s, 1 H), 9.51 (d, 1 H), 9.38 (d, 1 H), 8.99 (t, 1 H), 8.87 (d, 2 H), 8.82 (d, 1 H), 8.71 (d, 2 H), 8.47 (t, 2 H), 8.06 (d, 2 H), 7.73 (t, 2 H), 7.22 (t, 1 H) ppm.

***trans*-[(py)$_4$(SCN)Ru(NO)](PF$_6$)$_2$:** *trans*-$[(py)_4Ru(NO_2)_2]$[43] (100 mg, 0.0106 mmol) and NaSCN (300 mg, 3.7 mmol) were suspended in 20 mL of acetonitrile, and 0.5 mL of concentrated HPF_6 was added. After mixing, the sample was evaporated to dryness. The solid residue was suspended in water and filtered. 700 mg of NH_4PF_6 was added to the solution and a yellow solid was obtained. This compound was further purified by loading onto a DOWEX 50 WX2 cation exchanger (100−200 mesh) in acid form eluting with 1 M HCl. The main orange fraction was collected and precipitated with NH_4PF_6. $C_{21}H_{20}F_{12}N_6OP_2RuS$ (795.49): calcd. C 31.69, H 2.01, N 10.56, S 4.03; found C 31.90, H 2.27, N 10.12, S 3.63. IR: ν(NO) = 1902 cm^{-1}. $E_{1/2}$ = 0.12 V and −0.35 V vs. Ag/AgCl. ^{1}H NMR (CD_3CN): δ = 8.29 (t, 4 H, H^4), 8.26 (d, 8 H, $H^{2,6}$), 7.70 (t, 8 H, $H^{3,5}$) ppm.

DFT Calculations: Ground state electronic structure calculations on $[(NC)_5Ru(NO)]^{3-}$ have been done on the basis of density-functional theory (DFT) methods using the ADF2002.03[47,48] and Gaussian 98 program packages.[49]

Within the ADF program, Slater-type orbital (STO) basis sets of triple-quality with polarization functions were employed. Basis I was represented by the frozen-core approximation (1s for C, N O and 1s−3d for Ru), basis II also includes core electrons. The following density functionals were used within ADF: the local density approximation (LDA) with VWN parametrization of electron gas data or the functional including Becke's gradient correction[50] to the local exchange expression in conjunction with Perdew's gradient correction[51] to the LDA expression (ADF/BP). The scalar relativistic (SR) zero-order regular approximation (ZORA) was used within the geometry optimization. The *g*-tensor calculations were also performed using the asymptotically correct functional SAOP (statistical average of orbital potentials),[52] which gives better energies of the frontier MOs. Core electrons were included in the ADF/SAOP calculations.

The *g*-tensor was obtained from a spin-nonpolarized wave function after incorporating the spin-orbit (SO) coupling. *A* tensors and *g* tensors were obtained by first-order perturbation theory from the ZORA Hamiltonian in the presence of a time-independent magnetic field.[53,54] The analysis of individual contributions to the *g* tensor was done by the UKS-Pauli approach using gauge-including atomic orbitals.[55]

Within Gaussian-98 Dunning's polarized valence double-ζ basis sets[56] were used for the C, N and O atoms and the quasi-relativistic effective core pseudopotentials with a correspondingly optimized set of basis functions[57] for Ru. The hybrid Becke three-parameter functional with Lee, Yang and Parr correlation functional (B3LYP)[58] was used in the Gaussian-98 calculations (G98/B3LYP).

The geometry of $[(NC)_5Ru(NO)]^{3-}$ was optimized without any symmetry restrictions using the spin-unrestricted open-shell Kohn−Sham (UKS) approach.

Interface Synthesis, Characterization and Catalytic Properties of Dialkyldichlorotin and Tetraalkyl Distannoxane Functionalities Grafted to Insoluble Polystyrene Beads by a Hexamethylene Spacer

Monique Biesemans,*[a] Frédéric A. G. Mercier,[a] Manu Van Poeck,[a] José C. Martins,[b] Gilles Dumartin,[c] and Rudolph Willem[a]

Keywords: Catalysis / Heterogeneous catalysis / NMR spectroscopy / Transesterification / Tin

Insoluble polystyrene-grafted compounds of the type $[(P–H)_{(1-t)}\{P–(CH_2)_6SnBuCl_2\}_t]$ and $[(P–H)_{(1-t)}(\{P–(CH_2)_6SnBuX\}_2O)_{t/2}]$, where (P–H) represents a cross-linked polystyrene, X is Cl, OH or $OOCCH_3$, and t is the degree of functionalization, were synthesized from Amberlite XE-305, a polystyrene cross-linked with divinylbenzene. The compounds were characterized by elemental analysis, IR and Raman spectroscopy, solid-state ^{13}C and ^{117}Sn NMR spectroscopy and, where appropriate, by ^{119}Sn hr-MAS NMR spectroscopy. The influence of the variable t and tin functionality on the catalytic activity of these compounds was assessed in the transesterification reaction of ethyl acetate with octanol.

Introduction

While organotin compounds enjoy widespread use as versatile reagents or catalysts in a large variety of organic transformations,[1,2] their application is sometimes limited by their toxicity.[3,4] This adverse feature is further aggravated by the generally difficult quantitative removal of organotin reagents and their by-products from the reaction mixture,[5] often making them unsuitable for the synthesis of biological or pharmaceutical derivatives.[3,6] These concerns can be alleviated by grafting the organotin reagent onto a solid support, thereby creating so-called "clean" organotin reagents, which can be removed completely from reaction products by simple filtration. In a previous paper we reported on the synthesis[7] and characterization[7,8] of $[(P–H)_{(1-t)}\{P–(CH_2)_nSnBuX_2\}_t]$ (n = 4, 6; X = Ph, Cl; t (degree of functionalization) = 0.25–0.30]. The catalytic activity of these compounds in the transesterification reaction of ethyl acetate with simple alcohols such as octanol appeared reasonably good.[7] The work presented here describes the synthesis of analogues with a lower degree of functionalization, with the aim of evaluating the effect of t on the catalytic activity of these compounds. Furthermore, based on the work of Otera and co-workers,[9] which proposes the use of distannoxanes $[XR_2SnOSnR_2Y]_2$ (R = Bu, Me; X = Cl, NCS; Y = OH, Cl, NCS) as efficient catalysts in transesterification reactions, distannoxanes grafted to insoluble polystyrene, of the type $[(P–H)_{(1-t)}(\{P–(CH_2)_6SnBuX\}_2O)_{t/2}]$ (X = Cl, OH, $OOCCH_3$) were synthesized from the dialkyldichlorotin precursors. Their characterization and catalytic activity are also discussed.

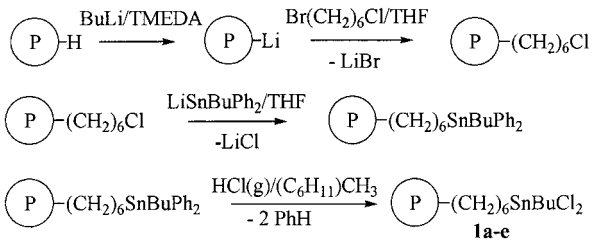
Results and Discussion

Synthesis and Characterization

A series of five dialkyldichlorotin compounds $[(P–H)_{(1-t)}\{P–(CH_2)_6SnBuCl_2\}_t]$ (**1a–e**) with t varying between 0.03 and 0.31 was synthesized[7,8] according to Scheme 1.



Scheme 1

Different degrees of functionalization were obtained by controlled variation of the amount of BuLi in the first lithiation step, resulting in five $(P-H)_{(1-t)}(P-Li)_t$ precursor compounds. The dependence of t on the BuLi/P−H molar ratio in this step is illustrated in Figure 1.

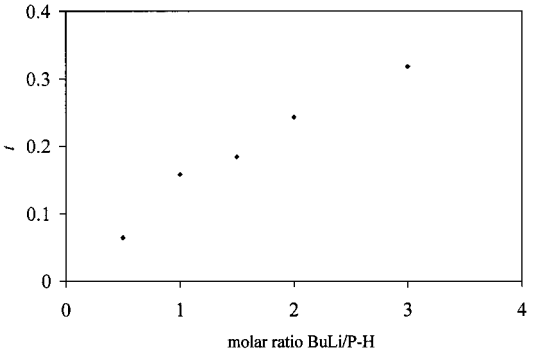

Figure 1. The experimental degree of functionalization (t) as a function of the molar ratio BuLi/P−H in the first reaction step of Scheme 1

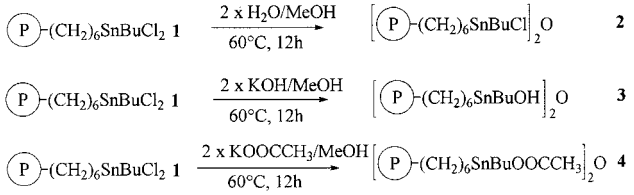
The substitution of the phenyl groups by chlorine in the last step of the reaction in Scheme 1, previously performed by reaction with HCl in methanol, suffered from sluggish reactivity leading to polymers with a slight but significant chlorine deficit.[7] In the present synthesis route, pure HCl gas is bubbled for 15 minutes through a suspension of beads of $[(P-H)_{(1-t)}\{P-(CH_2)_6SnBuPh_2\}_t]$ in methylcyclohexane at −80 °C. Using this new route, a better control over the desired substitution reaction was obtained, since less than 2% of grafted R_3SnCl side-functionality was obtained instead of 6−7 % by the HCl/CH_3OH method, as assessed by solid state ^{117}Sn MAS NMR spectroscopy and elemental analysis. Moreover, any possible inconvenience arising from moisture can be better avoided with the latter synthesis route. The determination of t of all precursor compounds and of **1a**−**e** (**1a**, t = 0.03; **1b**, t = 0.10; **1c**, t = 0.12; **1d**, t = 0.21; **1e**, t = 0.31) was performed, as described previously,[7] from experimentally obtained elemental mass fractions of all elements involved, using a mathematical non-linear least-squares procedure, minimizing the impact of the elements leading to larger uncertainty margins.

Since distannoxanes, with general formula $YR_2Sn-O-SnR_2Y$, have also proved to be efficient transesterification catalysts,[9] we were interested in the conversion of compounds **1a**−**e** into compounds of the type $[(P-H)_{(1-t)}(\{P-(CH_2)_6SnBuX\}_2O)_{t/2}]$ with X = Cl, OH, $OOCCH_3$. The synthetic procedures leading to the different Sn−O−Sn-bridged compounds are given in Scheme 2. The reactions were performed twice successively, in order to achieve full conversion as far as possible. IR and Raman spectroscopy were used to monitor the reactions: in the Raman spectra the evolution of the ν(Sn−Cl) band was monitored, while in the IR spectra the appearance of new bands characteristic of the different Sn−O−Sn-bridged compounds can be observed. The purity of the compounds in Scheme 2 was determined by elemental analysis, solid state ^{117}Sn MAS NMR spectroscopy and, where appropriate, by ^{119}Sn hr-MAS NMR spectroscopy. The latter technique is a high resolution liquid NMR technique that is used to obtain NMR spectra of tin-containing grafts dipped in solution, in situ at the solid−liquid interface, provided sufficient local rotational mobility can be achieved on the grafts through matrix pore swelling by the solvent.[8]



Scheme 2

Whereas the reaction with H_2O and KOH was complete for the compounds with high t value (0.31, compounds **2e** and **3e**), incomplete conversion was observed for the compounds with lower t value (0.03−0.21, compounds **2a**−**d**, **3a**−**d**). This was shown by the presence of residual ν(Sn−Cl) bands in the Raman spectra of **3a**−**d** and the detection of residual amounts of chlorine for **3a**−**d** or too high amounts for **2a**−**d** by elemental analysis; the conversion degree appears to be dependent on t, as illustrated in Figure 2 and 3.

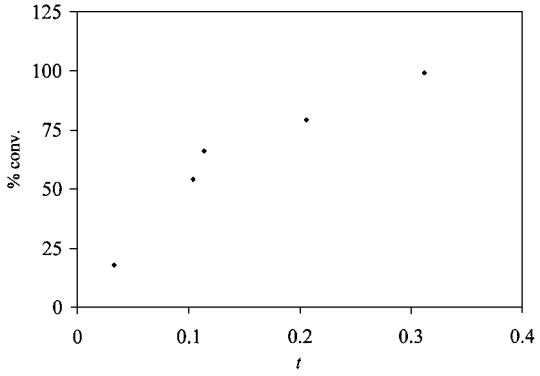


Figure 2. Percentage conversion of **1** into **2** as a function of t

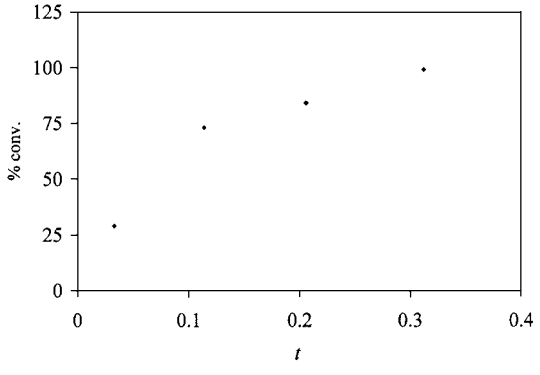

Figure 3. Percentage conversion of **1** into **3** as a function of t

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

The explanation for this observation is to be found in the lack of sufficient neighbouring grafted functionalities, which are necessary to generate Sn−O−Sn cross-links, in the compounds with low functionality.

Further evidence for residual $-SnCl_2$ functionalities was found in the ^{119}Sn hr-MAS spectra of **2a**−**d** and **3a**−**d**, which still show resonances for this functionality. This technique, which is used to obtain high resolution liquid-like ^{119}Sn NMR spectra of solvent-swollen beads of $[(P-H)_{(1-t)}\{P-(CH_2)_6SnBuCl_2\}_t]$,[8] in which the tin functionality acquires local rotational mobility, was disappointingly uninformative for **2e** and **3e**, where complete conversion was obtained. In fact, no ^{119}Sn NMR resonance could be generated, probably due to the rigidity of the distannoxane moiety by the additionally introduced Sn−O−Sn cross-linking, preventing sufficient rotational mobility necessary for this technique to be successful.

When reacting **1e** with CH_3COOK in methanol, it was unclear beforehand whether grafted tin compounds of the distannoxane type, $[P-(CH_2)_6SnBuOOCCH_3]_2O$, or of the tin dicarboxylate type, $P-(CH_2)_6SnBu[OOCCH_3]_2$, with both chlorides substituted by acetate, would be obtained, since the synthesis of a compound similar to the latter has already been described in the literature, although in this case the tin moiety is grafted directly to the phenyl rings of an insoluble polystyrene matrix.[10] Therefore, the theoretical mass fractions were calculated for both models using the functionalization degree of the precursor **1e**. When these calculated values were compared to those determined by elemental analysis, the mass fractions, especially the ones for carbon and tin calculated for the Sn−O−Sn model, fitted the experimental values better (see Table 1). Moreover, the positions of the ν(C=O) bands in the IR spectrum of **4e** differ from those of the model dicarboxylate compound $Bu_2Sn(OOCCH_3)_2$, while other characteristic bands of the latter are not found. This favours the proposal that the obtained compound is indeed of the distannoxane type, as is the case for those obtained by reaction of **1** with H_2O or KOH.

Table 1. Comparison of the experimental mass fractions of compound **4e** with the theoretical ones using different models

Model	γ_C (%)	γ_H (%)	γ_{Sn} (%)
Experimental mass fractions	68.80	7.54	18.50
$[P-(CH_2)_6SnBuOOCCH_3]_2O$	68.52	7.43	17.99
$P-(CH_2)_6SnBu[OOCCH_3]_2$	66.98	7.32	16.70

Catalytic Activity

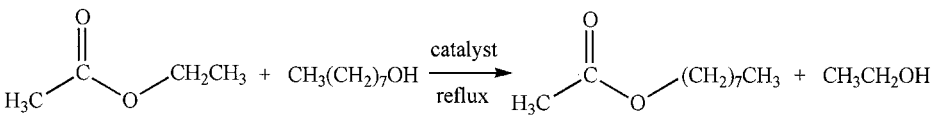
In order to evaluate the catalytic activity of the grafted organotins in **1**−**4**, the reaction between ethyl acetate and octanol (Scheme 3) was investigated. The degree of conversion was calculated from the ratio of initial alcohol to obtained ester by integration of the respective CH_2O ^{1}H NMR resonances. The results are summarized in Table 2.

For the compounds $[(P-H)_{(1-t)}\{P-(CH_2)_6SnBuCl_2\}_t]$ with variable functionalization degree, two types of experiments were performed. Entries 1−4 (type A) were carried out with a constant mass of catalyst (367 mg, corresponding to 1 mol % of **1e**), and consequently a variable molar amount of tin sites. Entries 5−7 (type B) describe reactions with 1 mol % of catalyst (% Sn with respect to octanol). In the first series reasonably good results were obtained for all compounds, with a maximum conversion obtained for t = 0.21, which appears to be the optimal functionalization degree for the catalytic activity (see Table 2). In the second series a slight decrease in conversion was observed with increasing t. Both data sets are in agreement with a better accessibility of the reagents to the catalytic centre at a moderate degree of functionalization, emphasizing the need to find the optimum compromise between having a sufficient number of catalytic sites and avoiding side-chain entanglement due to a too high degree of functionalization.

As far as the distannoxanes are concerned, the catalytic activity is reported for the functionally pure compounds **2e**, **3e** and **4e** only. Although a decreased molecular mobility of the grafted tin functionality is to be expected due to the introduction of Sn−O−Sn bridges, good conversion degrees, comparable (or slightly higher) to those of the precursor compound **1e**, were obtained when using these compounds as catalysts in the transesterification reaction of ethyl acetate with octanol (Table 2; entries 8−11).

The chemical stability of the catalysts under reaction was assessed by solid state ^{117}Sn CP-MAS NMR spectroscopy, at least within the signal-to-noise conditions under which the spectra were obtained. The spectra of compounds **1e** and **2e**, after their use as a catalyst, are reasonably superimposable on the spectra of the same compounds before catalysis. The isotropic chemical shift is found at the same position and no evidence for significant generation of new functionalities can be seen. By way of an example, Figure 4 shows the ^{117}CP-MAS spectrum of **2e** prior to and after a transesterification experiment for 48 hours.

In contrast, the grafted $HOSn-O-SnOH$ (**3e**) and $CH_3COOSn-O-SnOOCCH_3$ (**4e**) compounds are chemically modified during the reaction. Only very ill-defined noisy spectra of these compounds could be obtained, under



Scheme 3

Table 2. Catalytic activities of dialkyltin- and distannoxane-functionalized polystyrenes in the transesterification of ethyl acetate with octanol

Entry	Catalyst	Type[a]	t	Conv. after 24 h (%)	Conv. after 48 h (%)
1	**1b**	A	0.10	58	87
2	**1c**	A	0.12	65	88
3	**1d**	A	0.21	89	94
4	**1e**	A	0.31	74	89
5	**1c**	B	0.12	84	95
6	**1d**	B	0.21	80	94
7	**1e**	B	0.31	74	89
8	**2e**	B	0.31	78	96
9	**3e**	B	0.31	72	94
10	**4e**	B	0.31	54	90
11	**4e** (re-used)	B	0.31	58	87

[a] A: 367 mg of catalyst, corresponding to 1 mol % Sn with respect to octanol for **1e**, was used; B: 1 mol % Sn (variable mass) with respect to octanol.

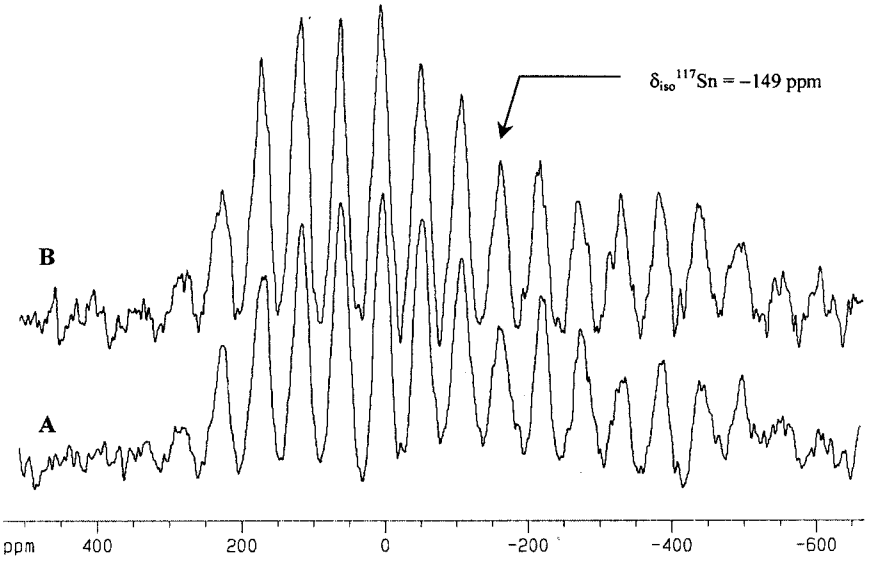


Figure 4. ^{117}Sn CP-MAS spectra of **2e** prior to (A) and after (B) a transesterification experiment

identical acquisition conditions as for the compound before its use as a catalyst, indicating that the organotin grafts are altered during the activation process. The identification of the distannoxane compounds was therefore impossible. Notwithstanding this observation, the catalyst was amenable to a second transesterification run to provide an identical conversion yield as in the first run within experimental error (entry 11 in Table 2). However, as they are chemically unstable, their potential as catalysts is less reliable than for **2e**, which appears to be both efficient and reasonably chemically stable, at least for the model reaction investigated during this work.

Conclusion

Dialkyldichlorotin-grafted polystyrene compounds were obtained with variable degree of functionalization. All compounds showed reasonable catalytic activity in the transesterification reaction of ethyl acetate with octanol. Evidence was found for the existence of an optimal degree of functionalization, interpreted as a compromise between having a sufficient number of catalytic sites and avoiding side-chain entanglement due to a too high degree of functionalization.

The dialkyldichlorotin-grafted polystyrenes were converted into three types of tetraalkyldistannoxanes by reaction with water, hydroxide or acetate. Complete conversion could only be obtained with a sufficiently high degree of functionalization. Their catalytic activity was similar to that of the dialkyldichlorostannanes.

Experimental Section

Synthesis of $[(P-H)_{(1-t)}\{P-(CH_2)_6SnBuCl_2\}_t]$ (1a−e): The polymers were synthesized as summarized in Scheme 1, following a procedure described previously,[7] modified in the last step to allow for a better control of possible side-reactions.[8] In all cases, a divi-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

nylbenzene cross-linked polystyrene, Amberlite XE305 (PolySciences Inc.), was used as the insoluble solid support P−H. In short, a hexamethylene spacer with terminal chloride was grafted onto the insoluble polystyrene P−H, preliminarily lithiated to different extents in the *para* position, by varying the amount of BuLi. In the next step a stannylation reaction with $Ph_2SnBuLi$ in THF substituted the chlorine atom for the $BuPh_2Sn$ group. The $BuCl_2Sn$ functionality in compound **1** was obtained by reaction with HCl gas at −78 °C in methylcyclohexane.[8] IR (cm^{-1}): $\nu_{(Sn-Cl)}$ 340 (m); $\nu_{sym(Sn-Bu)}$ 515 (w); $\nu_{asym(Sn-Bu)}$ 595 (w). $(C_8H_8)_{(1-t)}(C_{18}H_{28}Cl_2Sn)_t$ **1a** (t = 0.033): calcd. C 86.97, H 7.59, Cl 2.03, Sn 3.40; found C 86.96, H 7.78, Cl 3.07, Sn 2.63. **1b** (t = 0.104): calcd. C 78.42, H 7.34, Cl 5.33, Sn 8.92; found C 78.19, H 7.51, Cl 5.44, Sn 7.73. **1c** (t = 0.117): calcd. C 77.16, H 7.30, Cl 5.81, Sn 9.73; found C77.47, H 7.34, Cl 6.32, Sn 9.53. **1d** (t = 0.206): calcd. C 70.21, H 7.10, Cl 8.49, Sn 14.21; found C 70.34, H 7.19, Cl 7.86, Sn 14.46. **1e** (t = 0.312): calcd. C 64.50, H 6.93, Cl 10.68, Sn 17.88; found C 64.51, H 7.24, Cl 10.56, Sn 18.08. ^{119}Sn hr-MAS NMR: δ = 124 ppm.

Synthesis of $[(P-H)_{(1-t)}(\{P-(CH_2)_6SnBuCl\}_2O)_{t/2}]$ (2): Typically, 0.7 g of **1** was covered by MeOH (30 mL) and heated to 60 °C. Water (4 mL) was then added to the reaction mixture. The reaction mixture was stirred magnetically at 60 °C for 6 hours. The solution was removed with a capillary tube and then MeOH (30 mL) and water (4 mL) were again added successively to the polymer beads. The reaction mixture was kept at 60 °C for 18 hours. The obtained target polymer $[(P-H)_{(1-t)}(\{P-(CH_2)_6SnBuCl\}_2O)_{t/2}]$ (**2**) was washed 8 times with methanol (20 mL) and dried under vacuum at 60 °C. $(C_8H_8)_{(1-t)}(C_{18}H_{28}SnClO_{0.5})_t$ (t = 0.31): calcd. C 67.29, H 7.23, Cl 5.57, Sn 18.65; found C 66.98, H 7.32, Cl 6.13, Sn 18.30. IR (cm^{-1}): $\nu_{(Sn-Cl)}$ 337 (m); $\nu_{(Sn-O-Sn)}$ 602 (m); $\nu_{sym(SnBu)}$ 522(w); $\nu_{asym(SnBu)}$ 600 (w). ^{117}Sn MAS NMR: δ_{iso} = −149 ppm.

Synthesis of $[(P-H)_{(1-t)}(\{P-(CH_2)_6SnBuOH\}_2O)_{t/2}]$ (3): The procedure was identical to that described for **2**, but instead of water a solution of KOH (229 mg, 4.08 mmol) in MeOH (20 mL) was added to the reaction mixture. $(C_8H_8)_{(1-t)}(C_{18}H_{29}SnO_{1.5})_t$ (t = 0.31): calcd. C 69.37, H 7.61, Cl 0, Sn 19.15; found C 69.62, H 7.74, Cl 0.33, Sn 19.05. IR (cm^{-1}): $\nu_{(OH)}$ 3650 (w); $\nu_{(Sn-O)}$ 448 (w); $\nu_{asym(Sn-O-Sn)}$ 581 (w); $\nu_{sym(SnBu)}$ 506 (w); $\nu_{asym(SnBu)}$ 601 (w). ^{117}Sn MAS NMR: δ_{iso} = −171 ppm.

Synthesis of $[(P-H)_{(1-t)}(\{P-(CH_2)_6SnBuOOCCH_3\}_2O)_{t/2}]$ (4): The procedure was identical to that described for **2**, but instead of water a solution of CH_3COOK (400 mg, 4.08 mmol) in MeOH (20 mL) was added to the reaction mixture. $(C_8H_8)_{(1-t)}(C_{20}H_{31}SnO_{2.5})_t$ (t = 0.31): calcd. C 68.52, H 7.43, Cl 0, Sn 17.99; found C 68.80, H 7.54, Cl 0.40, Sn 18.50. IR (cm^{-1}): $\nu_{sym(CO)}$ 1319 (w); $\nu_{asym(CO)}$ 1630 (w); $\Delta\nu_{(CO)}$ = 311; $\nu_{(Sn-O)}$ 481 (m); $\nu_{asym(Sn-O-Sn)}$ 608 (w); $\nu_{sym(SnBu)}$ 517 (w); $\nu_{asym(SnBu)}$ 598 (w). ^{117}Sn MAS NMR: δ_{iso} = −167 ppm.

Catalysis Experiments on Transesterification Reactions: Ethyl acetate, used both as reactant ester and solvent, and 1-octanol (Aldrich) were used in a 7:1 molar ratio. A mixture of ethyl acetate (34.1 g, 388 mmol), octanol (7.2 g, 55 mmol) and insoluble Amberlite-supported catalyst (1 mol % Sn with respect to octanol; 367 mg for **1e**) was refluxed for 24 or 48 hours. The catalyst was filtered off and washed with $CHCl_3$, THF and ethanol. The ethyl acetate was distilled off from the reaction mixture. The ratio of initial alcohol to obtained ester was determined by integration (±1 %) of the respective CH_2O ^{1}H NMR resonances.

IR and Raman Spectra: IR spectra were recorded on a Perkin−Elmer System 2000 FT-IR spectrometer (MIR beam) from 200 mg dry KBr pellets containing about 5 mg of substance. The Raman spectra were recorded on a Perkin−Elmer 2000 NIR FT-RAMAN spectrometer using a Raman dpy2 beam with 310 mW power.

NMR Spectroscopic Data: Samples used for the determination of the initial alcohol to obtained ester ratio were prepared by dissolving about 10 mg of mixture in 0.5 mL of $CDCl_3$. Quantitative ^{1}H NMR spectra were recorded on a Bruker AMX500 instrument. The ^{119}Sn hr-MAS spectra were recorded on the same instrument (186.50 MHz) with a specially dedicated Bruker ^{1}H/^{13}C/^{119}Sn hr-MAS probe equipped with gradient coils, by using full rotors containing approximately 20 mg of resin beads, swollen in approximately 100 μL of $CDCl_3$ and spinning at 4000 Hz around the magic angle. External referencing with Ξ = 37.290665 MHz was used. The solid state (CP)-MAS spectra were recorded on a Bruker DRX250 spectrometer, operating at 62.90 and 89.15 MHz for ^{13}C and ^{117}Sn nuclei, respectively, using procedures described previously.[11,12] The solid state ^{117}Sn MAS NMR spectra were deconvoluted by total-lineshape (TLS) fitting[13,14] of the experimental spectra using the PERCH[15] software package.

Oxalato-Bridged [$Cu^{II}Cr^{III}$] and [$Mn^{II}Cr^{III}$] Binuclear Complexes: Synthesis, Crystal Structures, Magnetic and EPR Investigations

Gabriela Marinescu,[a,b] Diana Visinescu,[a,b] Andrei Cucos,[a] Marius Andruh,*[a] Yves Journaux,*[c] Victor Kravtsov,[d] Yurii A. Simonov,[d] and Janusz Lipkowski[e]

Dedicated to Professor Herbert W. Roesky

Keywords: Copper complexes / Magnetic properties / Manganese complexes / Oxalato bridges

Two new heterobinuclear complexes, [(bipy)(C_2O_4)Cr(μ-C_2O_4)Cu(Hfsaaep)(H_2O)]·2H_2O (**1**) and [(phen)(C_2O_4)Cr(μ-C_2O_4)Mn(phen)$_2$(N_3)]·H_2O (**2**) have been obtained by using bis(oxalato)chromium(III) anions, [Cr(AA)(C_2O_4)$_2$]$^-$, as building blocks [AA = 2,2′-bipyridine (bipy); 1,10-phenanthroline (phen)]. The crystal structures of the two complexes have been solved. These complexes comprise neutral oxalato-bridged Cr^{III}–Cu^{II} and Cr^{III}–Mn^{II} units. The [Cr(AA)(C_2O_4)$_2$]$^-$ anion acts as a bidentate ligand toward Cu^{II} in compound **1** and as a monodentate ligand toward Mn^{II} in compound **2**. The copper(II) ion in **1** exhibits a slightly distorted square bipyramidal stereochemistry, with the aqua ligand and one of the bridging oxalato oxygen atoms disposed in the apical positions [Cu(1)–O(1w) = 2.360(3) Å and Cu(1)–O(4) = 2.504(2) Å]. The second bridging oxalato oxygen atom [Cu(1)–O(2) = 2.0747(18) Å] and the *N*,*N*,*O*-type Hfsaaep ligand are located in the basal plane. The distance between the Cr^{III} and Cu^{II} ions across the bridging oxalate unit is 5.506 Å. The Mn^{II} ion in compound **2** is hexacoordinate (two chelating phen ligands, one oxalato bridging oxygen, and one terminal azido group). The intermolecular Cr^{III}···Mn^{II} distance is 5.257 Å. The magnetic properties of the two complexes have been investigated. The magnetic coupling between Cr^{III} and Cu^{II} in **1** was found to be ferromagnetic (J = +1.4 cm^{-1}). The nature of the ground state (S = 2) has been further confirmed by plotting the magnetization-versus-field curve. An antiferromagnetic interaction was found between Cr^{III} and Mn^{II} in compound **2** (J = –1.9 cm^{-1}). The magnetization-versus-field curve indicates the occurrence of a crossover between the Zeeman components: M_S = –1 (ground state S = 1), M_S = –2, from the first excited state (S = 2), and M_S = –3, from the second excited state. The EPR spectra of the two compounds are discussed.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

The ability of the oxalato anion to generate homo- and heteropolynuclear complexes with various nuclearities or dimensionalities is well known.[1] This chemistry has been stimulated mainly by the interesting magnetic properties exhibited by such compounds.[2] A plethora of oxalato-bridged homopolynuclear complexes has been characterized so far. These compounds are generally obtained through reactions involving a cationic complex, with potentially free coordination sites, and the oxalate anion. The presence of an ancillary ligand in the coordination sphere of the metallic ion, other than the water molecules, prevents the formation of the insoluble oxalates, and, moreover, influences the nuclearity, as well as the topology, of the metallic centers. As far as the heterometallic complexes are concerned, their synthesis raises an important point: the one-pot procedure, that is, the reaction of two different metal complexes with the oxalate anion, most frequently leads to mixtures of compounds and it is, therefore, inappropriate. To overcome this difficulty, an alternative synthetic approach has been developed: it employs anionic oxalato complexes as ligands toward the second metal ion ("complexes as ligands"; "building-block approach"). Particularly useful for the design of heterometallic systems are homoleptic and heteroleptic anionic complexes of chromium(III) containing potentially bridging oxalato groups. These sys-

tems are relatively stable towards substitution reactions and allow a good control over the reaction products. Three types of mononuclear chromium(III) oxalato complexes have been employed as building-blocks in obtaining heteropolynuclear systems: mono-oxalato, $[Cr(salen)(C_2O_4)]^-$ [H_2salen = *N*,*N*′-ethylenebis(salicylideneimine)][3] and $[Cr(acac)_2(C_2O_4)]^-$ (Hacac = acetylacetone),[4] bis(oxalato), $[Cr(AA)(C_2O_4)_2]^-$ [AA = 2,2′-bipyridine (bipy),[5] 1,10-phenanthroline (phen),[6] 2,2′-bipyrimidine (bpym),[7] and 2,2′-dipyridylamine (dpa)[8]], and tris(oxalato), $[Cr(C_2O_4)_3]^{3-}$, species.[9] While the homoleptic complex, $[Cr(C_2O_4)_3]^{3-}$, with three potentially bridging groups, is extensively used to generate two- or three-dimensional networks, the mono-oxalato species are appropriate for the synthesis of heterobinuclear complexes.

In a series of papers, it has been shown that bis-oxalato complexes of chromium(III), $[Cr(AA)(C_2O_4)_2]^-$ (AA = 2,2′-bipy, 1,10-phen, bpym, dpa), are extremely versatile building-blocks for the synthesis of heteropolynuclear complexes having a rich variety of structures.[5–8] The self-assembly processes between these species and mono- or dipositive hydrated cations led to two series of heteropolynuclear complexes: $[M^{I}Cr(bipy)(C_2O_4)_2(H_2O)_x]\cdot yH_2O$ (M = K, Na, Ag) and $[M^{II}Cr_2(bipy)_2(C_2O_4)_4(H_2O)_n]\cdot mH_2O$ (M = Ba, Mn, Co, Ni, Cu). Within each series, completely different structures have been obtained, according to the coordination algorithm of the assembling cation. We have also shown that the structures of the heterometallic complexes can be further influenced by using ancillary ligands attached to the assembling cation. For example, the reaction between Mn^{2+}(aq), 2,2′-bipyridine, and $[Cr(phen)(C_2O_4)_2]^-$ in the presence of sodium oxalate led to a tetranuclear [$Cr^{III}-C_2O_4-Mn^{II}-C_2O_4$-$Mn^{II}-C_2O_4-Cr^{III}$] complex.[6]

In this paper we report two new heterobinuclear complexes, which have been obtained by using bis-oxalato building blocks and ancillary ligands attached to the second metal ion: $[(bipy)(C_2O_4)Cr(\mu\text{-}C_2O_4)Cu(Hfsaaep)(H_2O)]\cdot 2H_2O$ {H_2fsaaep = 3-[*N*-2-(pyridylethyl)formimidoyl]salicylic acid} and $[(phen)(C_2O_4)Cr(\mu\text{-}C_2O_4)Mn(phen)_2(N_3)]\cdot H_2O$.

Results and Discussion

The complexes reported here have been obtained through reactions involving the $[Cr(AA)(C_2O_4)_2]^-$ building blocks and cationic complex species of Cu^{II} and Mn^{II}.

The [CuCr] complex has been synthesized by reacting the bis-oxalato chromium precursor, $[NaCr(bipy)(C_2O_4)_2(H_2O)]\cdot 2H_2O$[5c] with the binuclear chloro-bridged copper(II) complex, $[Cu(Hfsaaep)Cl]_2$ {H_2fsaaep is a Schiff base ligand derived from 3-formylsalicylic acid: 3-[*N*-2-(pyridylethyl)formimidoyl]salicylic acid}.[10] The chloro anion in the {Cu(hfsaaep)Cl} moiety was substituted by the $[Cr(bipy)(C_2O_4)_2]^-$ unit, resulting in a neutral [CuCr] heterobinuclear complex, **1**.

In the attempt to synthesize a $Mn^{II}_2Cr^{III}_2$ tetranuclear complex, with two different bridges connecting the metal ions (oxalato and azido), we have obtained a binuclear complex having an oxalato bridge between the two metal ions and a terminal azido ligand bound to manganese: $[(phen)(C_2O_4)Cr(\mu\text{-}C_2O_4)Mn(phen)_2(N_3)]\cdot H_2O$ (**2**). The phen:Mn^{II} molar ratio has been chosen to be 1:1 to prevent the formation of the tris-chelated manganese complex.

Description of the Structures

$[(Bipy)(C_2O_4)Cr(\mu\text{-}C_2O_4)Cu(Hfsaaep)(H_2O)]\cdot 2H_2O$ (1): The structure of **1** consists of neutral [CuCr] binuclear entities and uncoordinated water molecules (Figure 1). Crystal data, data collection parameters, and structure refinement details are given in Table 3. Selected bond lengths and angles are collected in Table 1. The $[Cr(bipy)(C_2O_4)_2]^-$ ion acts as a bidentate ligand toward the copper(II) ion, that is, one oxalato group acts simultaneously as a bidentate ligand toward chromium and copper. The distance between the Cr^{III} and Cu^{II} ions across the bridging oxalate is 5.506 Å. This distance is longer than those found in the trinuclear complex $[CuCr_2(bipy)_2(C_2O_4)_4(H_2O)_2]\cdot 1.5H_2O$ (Cu···Cr = 5.328 Å), where the two metal ions are bridged by a bis-chelating oxalato group,[5a] and in the binuclear $[(bipy)_2Cu(\mu\text{-}C_2O_4)Cr(C_2O_4)_2]^+$ species (5.056 Å).[11] We recall that in the last compound,[11] the oxalato group behaves as a monodentate ligand toward the copper and its bridging mode differs from that found in complex **1**. The copper atom is coordinated by two oxygen atoms arising from the oxalato bridge, one phenolic oxygen and two nitrogen atoms arising from the organic ligand (one nitrogen atom from the azomethine group, and the other one from the pyridyl ring), and one aqua ligand. The coordination polyhedron of the copper atom may be described as a distorted square-based bipyramid. The apical positions are occupied by the aqua ligand [Cu(1)–O(1w) = 2.360(3) Å] and one oxygen atom from the bridging oxalato group, Cu(1)–O(4) = 2.504(2) Å. The phenolic group of the Schiff base ligand is deprotonated, while the carboxylic group is protonated. The strong intramolecular hydrogen bond,

O(10)−H···O(9) (Table 2), binds this moieties and contributes to their planar arrangement.

The chromium atom is coordinated by two bipy nitrogen and four oxygen atoms, adopting a distorted octahedral geometry. The short bites of the bipy [78.95(8)°] and oxalato ligands [82.43(7) and 83.65(10)°] are the main factors responsible for the distortion of the $[CrN_2O_4]$ chromophore. The Cr−N bond lengths [2.057(2) and 2.064(2) Å] are somewhat longer than the Cr−O(ox) ones (Table 1). The Cr−O bond lengths are slightly shorter for the terminal oxalato ligand [1.939(2) and 1.941(2) Å] than for the bridging one [1.9720(17) and 1.9786(18) Å]. Both Cu^{II} and Cr^{III} ions reside close to the plane of the bridging oxalato ligand and deviate from it by 0.209(3) and 0.018(3) Å, respectively.

The heterobinuclear [CuCr] entities are interconnected through hydrogen bonding interactions involving the two water molecules, the oxygen atoms from the terminal oxalato group, and the aqua ligand coordinated to copper, which results in infinite chains (Figure 2). The distances associated with these interactions are summarized in Table 2. The chains are interconnected in a layer parallel to the (*ab*) crystallographic plane by week π−π stacking interactions (3.57 Å) between pyridine moieties of Hfsaaep and bifurcated O(3 W)···O(7), O(3 W)···O(8) hydrogen bonds (Table 2). The water molecules and hydrophilic fragments of **1** dwell inside such layers, while the hydrophobic bipy entities point outside. The bipy ligands from neighboring layers are arranged in a parallel mode and mutually intercalate with alternating spacings of 3.44 and 3.59 Å (Figure 3). These π−π stacking interactions between the bipy ligands act as a 2-D zipper and join the layers in the direction of the *c* axis (Figure 3).

$[(Phen)(C_2O_4)Cr(\mu\text{-}C_2O_4)Mn(phen)_2(N_3)]\cdot H_2O$ (2): The crystal structure of **2** consists of neutral [MnCr] heterobinuclear entities and crystallization water molecules. The $[Cr(phen)(C_2O_4)_2]^-$ ion acts as a monodentate ligand through an oxalato oxygen atom toward the $[Mn(phen)_2(N_3)]^+$ moiety (Figure 4). The intramolecular Cr···Mn distance is 5.257 Å. Selected bond lengths and angles are gathered in Table 1. The parameters of the hydrogen bonds are listed in Table 2. The manganese(II) ion is hexacoordinated by four nitrogen atoms arising from the phen molecules, one from the azido ion, and by one oxygen atom from the bridging oxalato group. The Mn(1)−N(phen) distances are in the range 2.2385(18)−2.2944(18) Å, while the Mn(1)−N(azido) bond is shorter [2.1592(19) Å]. The Mn−O(oxalato) distance is 2.1883(15) Å. The azido group is almost linear (the N−N−N angle is 178.4(2)°]. The connection between Mn and the azido ligand is bent: the value of the Mn(1)−N(7)−N(8) angle is 117.20(15)°. The bite angles of the phen ligands are 75.05(7) and 72.98(6)°.

As far as the chromium environment is concerned, it exhibits the same characteristic features observed for other compounds containing the $\{Cr(phen)(C_2O_4)_2\}$ moiety.[6] The dihedral angles between the plane of the 1,10-phenanthroline ligand and the planes of the bridging and terminal oxalato groups are 71.72(3)° and 85.13(4)°, respectively. The dihedral angle between oxalato groups is 85.07(4)°.

The 1,10-phenanthroline ligands associated with N(1)/N(2) and N(5)/N(6) atoms are almost parallel in complex **2** and partially overlap. The corresponding dihedral angle [12.51(6)°] and the interplanar spacing of 3.44−4.01 Å in the overlapped area suggest the possibility of intramolecular π−π stacking interactions, which seems to be an interesting characteristic feature of this complex.

Several $Mn^{II}-Cr^{III}$ oxalato-bridged complexes are known.[5a,6,9] To the best of our knowledge, this Mn^{II}−(μ-oxalato)−Cr^{III} binuclear complex is the first to be structurally characterized.

The intermolecular π−π stacking interactions play an important role in controlling the packing of compound **2** in the crystal. The phenanthroline ligands coordinated to the

manganese ions, associated with the N(3) and N(4) atoms, are partially overlapped. The small separation between these phen molecules (3.38 Å), which are related by a center of symmetry, indicate the occurrence of strong π−π interactions (Figure 5). In addition, the phen molecules coordinated to chromium and manganese atoms belonging to two different binuclear units also interact through π−π stacking. The interplanar spacing in this case is in the range of 3.17−4.14 Å. The convolution of the stacking interactions between the phenanthroline molecules coordinated to Mn and Cr atoms results in well-defined layers, which parallel the (*bc*) crystallographic plane (Figure 5). The repeating motif consists of four [MnCr] binuclear units that are interconnected through the aromatic−aromatic interactions established between six phenanthroline moieties. The water molecules occupy the space between the layers.

Magnetic Properties

The cryomagnetic properties of compounds **1** and **2** deserve to be deeply investigated for two special reasons. (i) Although the bridging mode of the oxalato ligand in compound **1** has been observed with several other [CuCr] complexes,[11−13] the axial coordination of the oxalato oxygen atom to the square-pyramidal copper(II) ion in such compounds leads to the lack of any exchange interaction between Cr^{III} and Cu^{II} ions. In compound **1**, one of the oxygen atoms arising from the oxalato group is coordinated in the basal plane of the coordination polyhedron of copper and can efficiently mediate the exchange interaction between the $d_{x^2-y^2}$ magnetic orbital of Cu^{II} and the magnetic orbitals of Cr^{III}. (ii) The low nuclearity of compound **2** makes it a good candidate for studying the magnetic interactions in Mn^{II}−(μ-oxalato)−Cr^{III} complexes, because the data on such compounds is rather scarce. The plots of $\chi_M T$ versus T for compounds **1** and **2** are given in Figures 6 and 7.

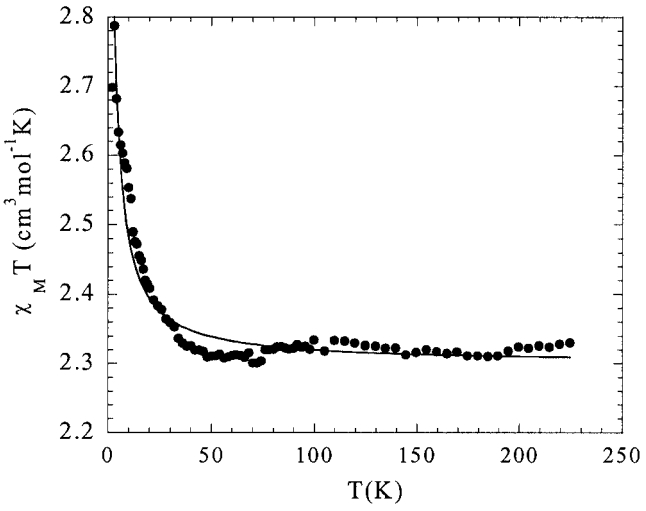

Figure 6. Plots of $\chi_M T$ vs. T for compound **1**; the solid line represents the curve of best fit

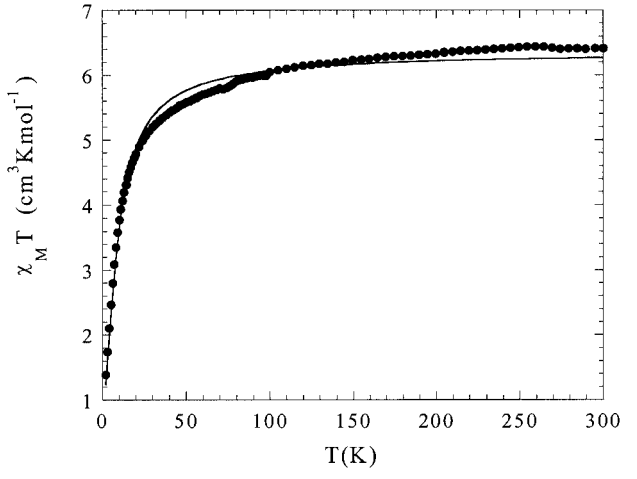

Figure 7. Plots of $\chi_M T$ vs. T for compound **2**; the solid line represents the curve of best fit

At 225 K the value of the $\chi_M T$ product for compound **1** is equal to 2.33 $cm^3 \cdot mol^{-1}K$, which corresponds to the ex-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

pected value for a spin doublet and spin quadruplet isolated magnetically (the calculated value is 2.25 $cm^3 \cdot mol^{-1}K$, assuming, in a first approximation, $g_{Cu} = g_{Cr} = 2$). By decreasing the temperature, $\chi_M T$ remains constant down to 50 K and then it increases, reaching a value of 2.7 $cm^3 \cdot mol^{-1}K$ at 2 K. This behavior indicates a ferromagnetic intramolecular interaction. For the Cu^{II} ($S = 1/2$)−Cr^{III} ($S = 3/2$) system, the energies of the low-lying spin states are obtained by using the isotropic spin Hamiltonian: $\boldsymbol{H} = -J\boldsymbol{S}_{Cu}\mathbf{S}_{Cr}$, which leads to Equation (1) describing the temperature dependence of the $\chi_M T$ product, where $g_1 = (5g_{Cr} - g_{Cu})/4$ and $g_2 = (3g_{Cr} + g_{Cu})/4$.

$$\chi_M T = \frac{2N\beta^2}{k}\frac{5g_2^2 + g_1^2 e^{-2J/kT}}{5 + 3e^{-2J/kT}} \quad (1)$$

Least-squares fitting to the data leads to the following values: $J = +1.4\ cm^{-1}$; $g_{Cr} = 1.99$ (fixed); $g_{Cu} = 2.1$, with $R = 2.2 \times 10^{-4}$ {R is the agreement factor defined as $\Sigma_i[(\chi_M T)_{obsd.}(i) - (\chi_M T)_{calcd.}(i)]^2/\Sigma_i[(\chi_M T)_{obsd.}(i)]^2$}.

To confirm the nature of the ground state, we investigated the variation of the magnetization, M, with respect to the field, at 2 K (Figure 8). The $M = f(H)$ curve closely follows the Brillouin function for a $S = 2$ system, and it is situated above the Brillouin function constructed for two independent $S = 1/2$ and $S = 3/2$ systems.

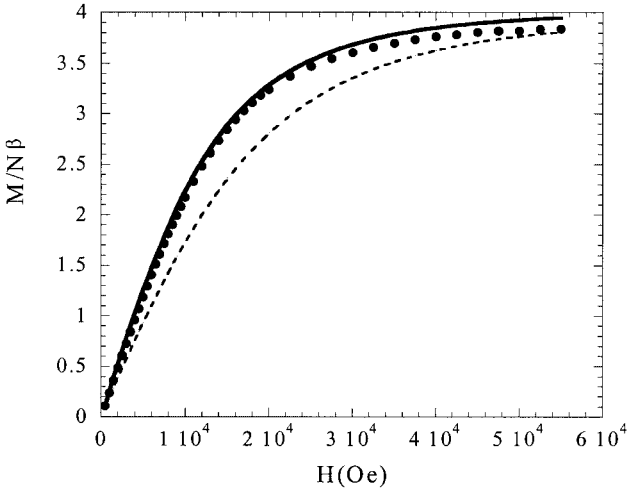

Figure 8. Magnetization-vs.-field curve for compound **1**; solid line: the Brillouin function for $S = 2$; dashed line: Brillouin functions for $S = 1/2$ and $S = 3/2$

Most of the μ-oxalato Cr^{III}−Cu^{II} complexes reported in the literature[5a,11,13] show either no or antiferromagnetic interactions. Only **1** and the Cu^{II}-(μ-oxalato)-Cr^{III} complexes reported by Okawa et al.[3b][3c] show a ferromagnetic interaction. For the latter two compounds, the copper $d_{x^2-y^2}$ orbital interacts with the σ-type orbitals of the oxalato group; on the other hand, the t_{2g} metallic orbitals of the Cr^{III} ions interact with the π-type orbitals of the oxalato bridge, leading to the classical example of ferromagnetic coupling due to the strict orthogonality of the magnetic orbitals. For the other Cr^{III}−Cu^{II} complexes described in the literature, the symmetry conditions are not fulfilled and the interaction is antiferromagnetic.

The value of the $\chi_M T$ product at room temperature for compound **2** is 6.41 $cm^3 \cdot mol^{-1}K$. This value corresponds to the one expected for two uncoupled Mn^{II} and Cr^{III} ions. Upon decreasing the temperature, $\chi_M T$ decreases, reaching a value of 1.38 $cm^3 \cdot mol^{-1}K$ at 2 K. This behavior indicates the occurrence of an antiferromagnetic coupling between Mn^{II} and Cr^{III}. The data were fitted using Equation (2), which gives the temperature dependence of the $\chi_M T$ product:

$$\chi_M T = \frac{2N\beta^2 g^2}{k}\frac{e^{-21J/4kT} + 5e^{-13J/4kT} + 14e^{-J/4kT} + 30e^{15J/4kT}}{3e^{-21J/4kT} + 5e^{-13J/4kT} + 7e^{-J/4kT} + 9e^{15J/4kT}} \quad (2)$$

Least-squares fitting leads to the following values: $J = -1.9\ cm^{-1}$ and $g = 2.01$, with $R = 5.6 \times 10^{-4}$. This value of the J parameter is close to the one found for a tetranuclear μ-oxalato Mn^{II}−Cr^{III} complex ($J = -1.1\ cm^{-1}$).[6]

The magnetization curve, $M = f(H)$, for compound **2**, recorded at 2 K (Figure 9), looks unusual: when increasing the field, instead of reaching the saturation corresponding to $S = 1$, M increases continuously to a value of 5 $N\beta$ at 6 T. This behavior can be explained by the crossover between the Zeeman components $M_S = -1$ (ground state $S = 1$), $M_S = -2$, from the first excited state ($S = 2$), and $M_S = -3$ from the second excited state (Figure 10). The crossover of the first two states occurs at $H = -2J/g\beta$, while that of the $M_S = -1$ and $M_S = -3$ occurs at $H = -3J/g\beta$. Least-squares fitting of the $M = f(H)$ curve, using a model taking into account all of the levels, leads to the following parameters: $J = -1.6\ cm^{-1}$ and $g = 1.99$. These values are in reasonable agreement with those found by the fitting of the magnetic susceptibility data.

EPR Spectra

The X-band powder spectra for **1** were recorded between 5 K and room temperature. The spectrum at 5 K, depicted in Figure 11, exhibits features between 0 and 1100 mT. Upon increasing the temperature, the resonances detected at 5 K vary in their relative intensities, especially the signal around 320 mT, which, in contrast to the others signals, increases in intensity between 5 and 10 K. This behavior clearly indicates that this signal belongs to the excited triplet state. The EPR spectra of **1** are difficult to interpret because, even at 5 K, there are two EPR-active states and only one signal can be attributed without doubt to a precise state (triplet state). Moreover, these two states are separated only by 3.8 cm^{-1} and the strong exchange limit condition ($J >> D$) is probably not fulfilled and additional transitions could be observed. Nevertheless we tried to treat the triplet and the quintet states independently and, in a first step, we also assumed that the anisotropy of the two states comes from the zero field splitting of the chromium ion. Starting from the line at 320 mT, we tried to determine the D_1 value of the triplet state. Several possibilities can be considered to label this signal. The presence of high-field transition precludes the solutions that correspond to a small D_1 value. Furthermore, solutions with D_1 values > 1 cm^{-1} do not give satisfactory simulation. Only the solutions with D_1 values in the range from 0.6 to 0.68 cm^{-1} are able to reproduce the lines in the low- and high-field regions. The former value corresponds to axial symmetry and the latter to the rhombic one. The D_1 value of the triplet state is expected to be three-times larger than the D_2 value of the quintet state:[14a]

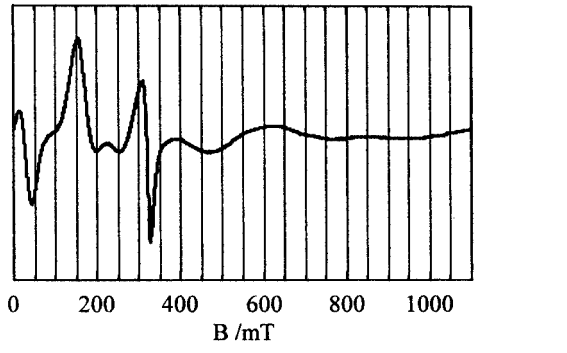

Figure 11. EPR spectrum for compound **1** at 5 K

$$D_1 = 3D_2 = \frac{3D_{cr}}{2} \quad (3)$$

From this formula, we calculate the D_2 value using the previous range for the D_1 values and simulate the spectra of the quintet state. In all cases, the combined spectra of the simulated quintet- and triplet-states spectra do not correspond to the experimental one. In particular, the intense lines at 45 and 150 mT are not well reproduced. Only D_2 values close to 0.15 cm^{-1} are able to reproduce these lines. This finding clearly indicates that there is another contribution to the D values of the two states, namely the anisotropic exchange interaction. Taking this interaction into account, D_2 and D_1 are given by the following relationships:[14a]

$$D_1 = \frac{3D_{cr}}{2} - \frac{D_{CuCr}}{4} \quad (4)$$

$$D_2 = \frac{D_{Cr}}{2} + \frac{D_{CuCr}}{4} \quad (5)$$

These relationships show that the anisotropic exchange provides opposite contributions to the quintet and the triplet states, and this feature could explain why $D_2 < D_1/3$. Because of the large number of parameters to optimize (g_{Cu}, g_{Cr}, D_{Cr}, and D_{CuCr} tensors, and their orientations) we obtained only a rough agreement between our simulation and the experimental spectrum with D_{Cr} and D_{CuCr} values around 0.4 cm^{-1} and -0.15 cm^{-1}, respectively. Nevertheless, it seems impossible to get a good simulation without a noticeable value for the anisotropic exchange. It is well established that the anisotropic exchange in a pair is pro-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

portional to the exchange interaction in an excited state of the pair, where one ion is in its fundamental state and the other in an excited state.[14b,15] In **1**, because of the relative orientation of the magnetic orbitals in the excited state, for which one electron of the chromium ion is in the d_{xy} orbital, there is a strong overlap between this orbital and the $d_{x^2-y^2}$ of the copper ion. This large antiferromagnetic interaction in an excited state of **1** leads to an important value of the anisotropic exchange in **1**.

The X-band powder spectra for **2** were recorded at several temperatures. The spectrum at 5 K exhibits a broad band at $g = 2.0$ and features of lower intensity between 0 and 1180 mT. An increase of the temperature does not induce any noticeable changes in the spectrum. The absence of thermal variation precludes any thorough analysis of the X-band powder spectra of **2**. The compounds discussed here illustrate once more that $[Cr(AA)(C_2O_4)_2]^-$ ions are very useful and versatile building blocks in designing heterometallic complexes.

Experimental Section

General Remarks: All the chemicals used for the present study were purchased from commercial sources and used without further purification. $Na[Cr(bipy)(C_2O_4)_2(H_2O)]\cdot 2H_2O$ and $Ba[Cr_2(phen)_2(C_2O_4)_4(H_2O)]\cdot H_2O$ were prepared as outlined in the literature.[5c,16] $[Cu(Hfsaaep)Cl]_2$ has been obtained as already reported.[17]

$[(Bipy)(C_2O_4)Cr(\mu\text{-}C_2O_4)Cu(Hfsaaep)(H_2O)]\cdot 2H_2O$ (1): A solution of $[Cu(Hfsaaep)Cl]_2$ (1 mmol) in methanol/water (1:1, 10 mL) was added to an aqueous solution of $Na[Cr(bipy)(C_2O_4)_2(H_2O)]\cdot 2H_2O$ (1 mmol, 10 mL). Slow evaporation of the resultant solution led to dark-blue single crystals of $[Cu(Hfsaaep)(H_2O)Cr(bipy)(C_2O_4)_2]\cdot 2H_2O$. IR data (KBr): $\tilde{\nu}$ = 3474 m, 3113 w, 1691 s, 1680 vs, 1639 s, 1565 m, 1447 m, 1395 s, 1383 s, 1324 w, 1238 m, 1027 w, 889 w, 810 m, 771 m, 667 w, 547 m cm^{-1}.

$[(Phen)(C_2O_4)Cr(\mu\text{-}C_2O_4)Mn(phen)_2(N_3)]\cdot H_2O$ (2): A suspension of $[BaCr_2(phen)_2(C_2O_4)_4(H_2O)]\cdot H_2O$ (1 mmol) in water (50 mL) was reacted with a stoichiometric amount of $MnSO_4\cdot 4H_2O$ (1 mmol) dissolved in water (10 mL). The resulting mixture was stirred for 4 h to promote the complete precipitation of barium sulfate, which was removed by filtration. An ethanolic solution of 1,10-phenanthroline (2 mmol, 10 mL), an aqueous solution of $MnCl_2\cdot 4H_2O$ (1 mmol, 10 mL), and aqueous sodium azide (2 mmol, 10 mL) were added successively to the red solution. Slow evaporation of the resultant solution led to orange-red single crystals of $[(phen)(C_2O_4)Cr(\mu\text{-}C_2O_4)Mn(phen)_2(N_3)]\cdot H_2O$. IR data (KBr): $\tilde{\nu}$ = 3479 m, 2038 s, 1705 s, 1679 vs, 1647 s, 1512 m, 1404 s, 1346 s, 1250 s, 1213 w, 1140 w, 1101 w, 851 m, 802 m, 724 s, 640 w, 482 m, 401 w cm^{-1}.

Physical Techniques: The IR spectra (KBr pellets) were recorded with a BIO-RAD FTS 135 spectrophotometer. UV/Vis spectra (diffuse reflectance technique) were recorded using a UV4 (Unicam) spectrophotometer and employing MgO as a standard. Magnetic measurements were carried out with a Quantum Design MPMS-5S SQUID magnetometer. The diamagnetic corrections for the compounds were estimated using Pascal's constants, and magnetic data were corrected for the diamagnetic contributions of the sample holder. EPR spectra were recorded using a Bruker Elexsys 500 spectrometer at the X band.

X-ray Crystallographic Study: X-Ray diffraction measurements were performed at room temperature and at 150 K for **1** and **2**, respectively, with a Nonius Kappa CCD diffractometer equipped with graphite-monochromated Mo-K_α radiation and using φ and ω scans. Crystal data, data collection parameters, and structure refinement details are given in Table 3. Lattice parameters were determined by the least-squares method from 8414 (**1**) and 5830 (**2**) reflections. The structures were solved by direct methods and refined by full-matrix, least-squares techniques based on F^2. The non-hydrogen atoms were refined using anisotropic displacement parameters. In all cases, hydrogen atoms on carbon atoms were calculated and allowed to ride. The other hydrogen atoms were found from difference Fourier maps and refined isotropically. Calculations were performed using SHELX-97 crystallographic software package.[18]

Homolysis of the Ln−N (Ln = Yb, Eu) Bond − Synthesis, Structure, and Catalytic Activity of Ytterbium(II) and Europium(II) Complexes Having (Dimethylamino)propyl- and (Dimethylamino)ethyl-Functionalized Indenyl Ligands

Enhong Sheng,[a] Shuangliu Zhou,[a] Shaowu Wang,*[a,b] Gaosheng Yang,[a] Yongyong Wu,[a] Yan Feng,[a] Lili Mao,[a] and Zixiang Huang[c]

Dedicated to Professor Changtao Qian on the occasion of his 70th birthday

Keywords: Catalyst / Homolysis / Organometallics / Polymer / Polymerization

We have synthesized a new series of ytterbium(II) and europium(II) complexes by tandem silylamine elimination/homolysis of Ln–N (Ln = Yb, Eu) bonds. The interaction of 2 equiv. of $C_9H_7CH_2CH_2CH_2NMe_2$ (**1**) with $[(Me_3Si)_2N]_3Ln(\mu\text{-}Cl)Li(THF)_3$ (Ln = Yb, Eu) in toluene under reflux produced lanthanide(II) complexes $[(\eta^5{:}\eta^1\text{-}C_9H_6CH_2CH_2CH_2NMe_2)_2\text{-}Ln]$ [Ln = Yb (**2**), Eu(**3**)] in 67 and 74% yields, respectively. Treatment of 2 equiv. of $Me_2Si(Me_2NCH_2CH_2C_9H_6)(NHtBu)$ with $[(Me_3Si)_2N]_3Eu(\mu\text{-}Cl)Li(THF)_3$ in toluene at 80 °C afforded a europium(II) complex $[\eta^5{:}\eta^1\text{-}Me_2Si(Me_2NCH_2\text{-}CH_2C_9H_5)(NHtBu)]_2Eu{\cdot}(OC_4H_8)_{0.5}$ (**4**) in 46% yield. The interaction of 2 equiv. of $Me_2NCH_2CH_2C_9H_6SiMe_3$ with $[(Me_3\text{-}Si)_2N]_3Eu(\mu\text{-}Cl)Li(THF)_3$ produced a europium(II) compound $[\eta^5{:}\eta^1\text{-}(Me_2NCH_2CH_2C_9H_5SiMe_3)]_2Eu$ (**5**) in 49% yield. Treatment of 2 equiv. of $Me_2NCH_2CH_2C_9H_7$ with $[(Me_3Si)_2N]_3Eu(\mu\text{-}Cl)Li(THF)_3$ in toluene gave a europium(II) complex $(\eta^5{:}\eta^1\text{-}Me_2NCH_2CH_2C_9H_6)_2Eu$ (**6**) in 57% yield. All the compounds were fully characterized by spectroscopic methods and elemental analyses. The structures of the complexes **4**, **5**, and **6** were determined by single-crystal X-ray analyses. The catalytic activities of organometallic complexes were examined; we found that all of the complexes can function as single-component MMA polymerization catalysts with good activity. We studied the effects of solvent and temperature on the catalytic activities and the stereochemistries of the polymers.

Introduction

Organolanthanide complexes have attracted much attentions for their potential applications as catalysts for olefins transformations.[1] The Ln−N bonds in lanthanide complexes have been demonstrated to exhibit unique reactivity and selectivity for chemo-, regio-, and enantioselective hydroamination of olefins and alkynes,[2] hydrosilylations of olefins,[3] and hydrophosphinations of olefins and alkynes,[4] as well as for olefin polymerization,[5] Tishchenko reactions,[6] ring opening polymerization of ε-caprolactone and δ-valerolactone,[7] and insertion reactions.[8] All of these reactions occur because of the heterolytic reactivity of Ln−N bonds.

We have reported that the interactions of (dimethylamino)ethyl-functionalized indene compounds with ytterbium(III) amide $[(Me_3Si)_2N]_3Yb(\mu\text{-}Cl)Li(THF)_3$ lead to the isolation and characterization of a new class of ytterbium(II) complexes having indenyl ligands; the interactions of methoxyethyl-functionalized indene compounds with $[(Me_3Si)_2N]_3Ln(\mu\text{-}Cl)Li(THF)_3$ (Ln = Yb, Eu) results in the synthesis of a new series of ytterbium(II) and europium(II) complexes.[9] On the basis of a mechanistic study, the pathway for the formation of the ytterbium(II) and europium(II) complexes is believed to proceed through tandem silylamine elimination[10]/homolysis of the Ln−N (Ln = Yb, Eu) bonds; this reaction provides a new methodology for the preparation of lanthanide(II) complexes. Extension of the process of homolysis of the Yb−N bond to europium chemistry, by studying the interactions of the indene compounds C_9H_6-1-R-3-$CH_2SiMe_2NC_4H_8$ (R = H, Me) with europium(III) amide $[(Me_3Si)_2N]_3Eu(\mu\text{-}Cl)Li(THF)_3$, has led to the isolation and characterization of novel europium(II) complexes.[11] The formation of different kinds

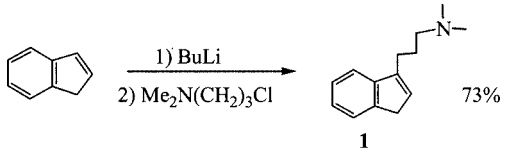
of lanthanide(II) complexes presumably is due to the ligands' effects on the reactivity. As part of our continued interest in the effects of ligands on the homolytic reactivity of Ln−N bonds, we have turned our attention to the interactions of (dimethylamino)propyl-functionalized indene compounds with $[(Me_3Si)_2N]_3Ln(\mu\text{-}Cl)Li(THF)_3$ (Ln = Yb, Eu) and the interactions of (dimethylamino)ethyl-functionalized indene compounds with europium(III) amide $[(Me_3Si)_2N]_3Eu(\mu\text{-}Cl)Li(THF)_3$.

Herein, we report that interacting (dimethylamino)propyl- and (dimethylamino)ethyl-functionalized indene compounds with $[(Me_3Si)_2N]_3Ln(\mu\text{-}Cl)Li(THF)_3$ (Ln = Yb, Eu) results in the isolation of a new series of ytterbium(II) and europium(II) complexes, which we have characterized. We propose that the pathway for the formation of the lanthanide(II) complexes proceeds through tandem silylamine elimination/homolysis of the Ln−N (Ln = Yb, Eu) bonds. The catalytic activity of the ytterbium(II) and europium(II) complexes as single-component MMA polymerization catalysts is also reported.

Results and Discussion

Synthesis of $Me_2NCH_2CH_2CH_2C_9H_7$ (1)

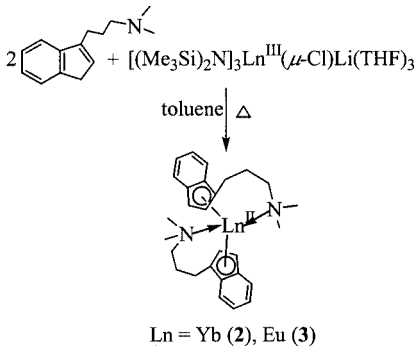
The interaction of C_9H_7Li with $Me_2NCH_2CH_2CH_2Cl$ in THF produced, after workup, the indene compound $Me_2NCH_2CH_2CH_2C_9H_7$ (**1**) in good yield (Scheme 1). The compound was fully characterized by spectroscopic methods and elemental analysis; the ^1H NMR spectrum showed that the substituent group connects to the sp^2-hybridized carbon atom of the five-membered ring of the indene compound.



Scheme 1

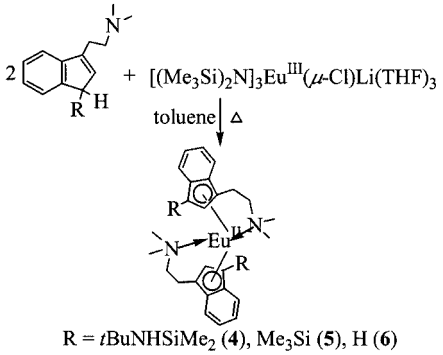
Reactions of the Indene Compounds with $[(Me_3Si)_2N]_3Ln(\mu\text{-}Cl)Li(THF)_3$ (Ln = Yb, Eu). Synthesis of Ytterbium(II) and Europium(II) Complexes

The interaction of 2 equiv. of $Me_2NCH_2CH_2CH_2C_9H_7$ (**1**) with lanthanide(III) amides $[(Me_3Si)_2N]_3Ln(\mu\text{-}Cl)Li(THF)_3$ (Ln = Yb, Eu) in toluene afforded, after workup, ytterbium(II) and europium(II) compounds $[(\eta^5{:}\eta^1\text{-}C_9H_6CH_2CH_2CH_2NMe_2)_2Yb]$ (**2**) and $[(\eta^5{:}\eta^1\text{-}C_9H_6CH_2CH_2CH_2NMe_2)_2Eu]$ (**3**) in 67 and 74% yields, respectively (Scheme 2). The complexes are sensitive to air and moisture, and they are soluble in THF, DME, and toluene. The complexes were fully characterized by spectroscopic methods and elemental analyses. A ^1H NMR spectroscopic study of complex **2** indicated the diamagnetic property of the complex and the +2 oxidation state of the ytterbium center. The results of elemental analyses are in agreement with the formulas of the ytterbium(II) and europium(II) complexes, which indicates that the reactions occur through a reductive process. All attempts to grow crystals suitable for X-ray analyses to confirm the structures of the complexes failed as a result the severe twinning problems. To overcome this difficulty and to extend the reaction chemistry, we studied the following reactions.



Scheme 2

Treatment of 2 equiv. of $Me_2Si(Me_2NCH_2CH_2C_9H_6)(NHtBu)$ with $[(Me_3Si)_2N]_3Eu(\mu\text{-}Cl)Li(THF)_3$ in toluene at 80 °C afforded, after workup, a europium(II) complex $[\{\eta^5{:}\eta^1\text{-}Me_2Si(Me_2NCH_2CH_2C_9H_5)(NHtBu)\}_2Eu]\cdot(OC_4H_8)_{0.5}$ (**4**) in 46% yield (Scheme 3). The complex is sensitive to air and moisture, and is soluble in THF, DME, pyridine, and toluene, but only slightly soluble in *n*-hexane. The compound was fully characterized by spectroscopic methods and elemental analysis. NMR spectra are not informative because of a lack of locking signals for the paramagnetic solutions of this compound. The elemental analysis of the product is in agreement with the formula of europium(II) complex being $Me_2Si(Me_2NCH_2CH_2C_9H_5)(NHtBu)]_2Eu$, which indicates that the reaction occurs through a reductive process. The structure of the europium(II) complex was confirmed by X-ray analysis. To extend the chemistry, we investigated the interaction of $Me_2NCH_2CH_2C_9H_6SiMe_3$ with $[(Me_3Si)_2N]_3Eu(\mu\text{-}Cl)Li(THF)_3$.



Scheme 3

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

Treatment of 2 equiv. of $Me_2NCH_2CH_2C_9H_6SiMe_3$ with $[(Me_3Si)_2N]_3Eu(\mu\text{-}Cl)Li(THF)_3$ produced a europium(II) compound $[\{\eta^5{:}\eta^1\text{-}(Me_2NCH_2CH_2C_9H_5SiMe_3)\}_2Eu]$ (**5**) in 49% yield (Scheme 3). The compound is sensitive to air and moisture, and is soluble in THF, DME, pyridine, and toluene, but is only slightly soluble in *n*-hexane. The complex was fully characterized by spectroscopic method and elemental analysis. Although NMR spectra are not informative because of the paramagnetic property of the complex, the elemental analysis of the complex is in agreement with the formula above; details of the structure were further confirmed by an X-ray diffraction study. These results suggest that the formation of the europium(II) complex occurs through a reductive reaction process. To probe the effects of the silyl substituent and the ligands on the reaction, we studied the interaction of $Me_2NCH_2CH_2C_9H_7$ with $[(Me_3Si)_2N]_3Eu(\mu\text{-}Cl)Li(THF)_3$.

Treatment of 2 equiv. of $Me_2NCH_2CH_2C_9H_7$ with $[(Me_3Si)_2N]_3Eu(\mu\text{-}Cl)Li(THF)_3$ in toluene gave the europium(II) complex $[(\eta^5{:}\eta^1\text{-}Me_2NCH_2CH_2C_9H_6)_2Eu]$ (**6**) in 57% yield (Scheme 3). The complex is sensitive to air and moisture; it is soluble in THF, DME, and pyridine, but it is only slightly soluble in toluene and insoluble in *n*-hexane. The complex was fully characterized by spectroscopic methods and elemental analysis. Although NMR spectra are not informative because of the paramagnetic property of the complex, the results of elemental analysis are in agreement with a monomeric europium(II) complex; the structure of this europium(II) complex was further confirmed by a X-ray diffraction study. The fact that a triple-decker tetranuclear europium(II) complex was not isolated as the product of the reaction between $C_9H_7CH_2SiMe_2NC_4H_8$ and europium(III) amide $[(Me_3Si)_2N]_3Eu(\mu\text{-}Cl)Li(THF)_3$ [11] may be due to the ligands' effects on the reactivity.

The formation of all of the ytterbium(II) and europium(II) complexes above is believed to occur through a reductive process. Several experiments were initiated to probe the reaction mechanism. The indene compounds, the amine $HN(SiMe_3)_2$, and the coupling product $[N(SiMe_3)_2]_2$ were detected by GC-MS analyses of the reaction mixtures after hydrolysis. The formation of the coupling product may be due to homolysis of the $Ln-N(SiMe_3)_2$ bond to produce the radical $N(SiMe_3)_2$, which then couples to give the coupling product; it should be noted, however, that the amount of coupling product $[N(SiMe_3)_2]_2$ is less than that expected, probably as a result of the free radical abstraction of a hydrogen atom from solvent. Homolysis of the Ln−N bond has not been observed, however, when heating the corresponding lanthanide(III) amides $[(Me_3Si)_2N]_3Ln(\mu\text{-}Cl)Li(THF)_3$ (Ln = Yb, Eu) in toluene under reflux for 2 days or when subliming the lanthanide(III) amides $[(Me_3Si)_2N]_3Ln(\mu\text{-}Cl)Li(THF)_3$ (Ln = Yb, Eu) at 100 °C and 10^{-4} Torr; instead, $[(Me_3Si)_2N]_3Ln$ was isolated,[5] indicating that homolysis of the $Ln-N(SiMe_3)_2$ bond occurs after the interaction of the indene compounds with $[(Me_3Si)_2N]_3Ln(\mu\text{-}Cl)Li(THF)_3$ (Ln = Yb, Eu). Our previous work has indicated that the interaction of 1,2-bis(indenyl)ethane with $[(Me_3Si)_2N]_3Yb(\mu\text{-}Cl)Li(THF)_3$ does not produce the ytterbium(II) compound: the ytterbium(III) amides, *meso*-$(EBI)Yb^{III}N(SiMe_3)_2$, were isolated,[9] which suggests an effect of the heteroatom on the reductive reaction.

On the basis of the evidence above, we propose the following pathway for the formation of the lanthanide(II) complexes: The interactions of the (dimethylamino)propyl- or (dimethylamino)ethyl-functionalized indene compounds with $[(Me_3Si)_2N]_3Ln(\mu\text{-}Cl)Li(THF)_3$ (Ln = Yb, Eu) produces the lanthanide(III) amides $(Indenyl')_2LnN(SiMe_3)_2$ [Indenyl' = (dimethylamino)ethyl- or (dimethylamino)propyl-functionalized indenyl ligands] as intermediates and $HN(SiMe_3)_2$ by a silylamine elimination reaction.[10] Coordination of the nitrogen atoms of the (dimethylamino)ethyl or (dimethylamino)propyl groups to the central lanthanide metal ions promotes homolysis of the Ln−N (Ln = Yb, Eu) bonds to give the lanthanide(II) complexes and the radical $N(SiMe_3)_2$, which then couples to form the coupling product (Scheme 4).

Molecular Structures of Complexes 4, 5, and 6

The structures of lanthanide(II) complexes **4** (Figure 1), **5** (Figure 2), and **6** (Figure 3) were determined by X-ray diffraction studies. X-Ray analyses revealed that the central metal ion of each complex exists in a +2 oxidation state. We found that there are two independent molecules in the unit cell of complex **6** that differ by the effects of the substituent groups of the indenyl ligands upon crystallization. The selected bond lengths and angles are listed in the Table 1. Some of the important structural parameters are compiled in Table 2 for a comparison of the structural parameters.

From Table 1 and 2, we see that the Eu−C bond lengths range from 2.827(10) to 2.944(11) Å, with an average of 2.883(11) Å in **4**; this distance is slightly different to those found in **5** [2.873(10) Å] and in **6** [2.841(7) Å]. Similarities are found in the average Eu−N bond lengths of **4** [2.748(9) Å], **5** [2.744(8) Å], and **6** [2.711(6) Å], which indicate the effect of the substituent groups on the bonding between the

ligands and the central metal ions. The N−Eu−N angle of 96.1(3)° in **4** is larger than the corresponding angle [92.9(3)°] in **5**, but it is smaller than these angles [102.1(2)° and 107.3(2)°] in **6**. Similar results have been found in the ytterbium(II) analogues (Table 2), suggesting an effect of the substituent groups on the configuration of the ytterbium(II) and europium(II) complexes. From Table 2, we see that, as the substituent groups on the indenyl rings change from *t*BuNHSiMe$_2$ to Me$_3$Si to H, the differences of either the average Ln−C or the average Ln−N bond lengths between **4** and **5**, **4** and **6**, and **5** and **6** are smaller than those values found in their ytterbium(II) analogues, which suggests that the effect of the substituent groups on the bonding between the ligands and the central metal ion becomes weaker as the ionic radii[12] of the central metal ion increases.

The average Eu−C distances found in **4** [2.883(11) Å], **5** [2.873(10) Å], and **6** [2.841(7) Å] are smaller than the corresponding value of 2.911(18) Å found in [(η^5:η^1-C$_9$H$_5$-1-Me-3-CH$_2$SiMe$_2$NC$_4$H$_8$)$_2$Eu], but are longer than the corresponding average values found in [{η^5:η^1-(MeOCH$_2$CH$_2$C$_9$H$_5$SiMe$_3$)}$_2$Yb] [**10**; 2.741(14) Å],[9b] [{η^5:η^1-Me$_2$Si(MeOCH$_2$CH$_2$C$_9$H$_5$)(NH*t*Bu)}$_2$Eu] [**11**; 2.858(8) Å],[9b] and [{η^5:η^1-(MeOCH$_2$CH$_2$C$_9$H$_5$-SiMe$_3$)}$_2$Eu] [**12**; 2.857(11) Å][9b] (Table 2); these difference may be due to steric effects and the different ionic radii. The average Eu−N distances found in **4** [2.748(9) Å], **5** [2.744(8) Å], and **6** [2.711(6) Å] are also smaller than the corresponding value of 2.754(16) Å found in [(η^5:η^1-C$_9$H$_5$-1-Me-3-CH$_2$SiMe$_2$NC$_4$H$_8$)$_2$Eu],[11] but are longer than the corresponding Ln−O bond lengths found in [η^5:η^1-(Me-

$OCH_2CH_2C_9H_5SiMe_3)]_2Yb$ [**10**; 2.462(9) Å],[9b] [{η^5:η^1-$Me_2Si(MeOCH_2CH_2C_9H_5)(NHtBu)$}$_2$Eu] [**11**; 2.559(6) Å],[9b] and [{η^5:η^1-$(MeOCH_2CH_2C_9H_5SiMe_3)$}$_2$Eu] [**12**; 2.588(8) Å][9b] (Table 2); these values reflect are steric and ionic radii effects on the bonding. The N−Eu−N angles in **4** [96.1(3)°], **5** [92.9(3)°], and **6** [102.1(2)° and 107.3(2)°] are smaller than the value of 110.19(15)° found in [η^5:η^1-C_9H_5-1-Me-3-$CH_2SiMe_2NC_4H_8)_2$Eu],[11] but are larger than the O−Ln−O (Ln = Yb, Eu) angles found in the methoxyethyl-functionalized (indenyl)ytterbium(II) and -europium(II) complexes[9b] (Table 2); these observations indicate that the substituent groups have an influence on the configuration of complexes having indenyl ligands.

MMA Polymerization

We have studied the activity of the complexes as single-component MMA polymerization catalysts by performing polymerizations in a series of solvents. The polymer products were quenched with acidified methanol after a fixed time and analyzed by obtaining ^{1}H NMR spectra of the microstructures.[13] We found that some polymers cannot be dissolved in THF or passed through GPC columns. We also found that all of the complexes can function as single-component MMA polymerization catalysts and that each has good catalytic activity. It is interesting to note that solvents influence the catalytic activity of the complexes: complexes **2** and **3** display catalytic activity in DME, THF, and toluene; complex **4** exhibits catalytic activity in THF; complexes **5** and **6** possess catalytic activity only in DME. The results are listed in Table 3.

We also examined the effects of temperature on the catalytic activities of the complexes. The catalytic activity of the complexes is temperature dependent: the catalytic activity of the complexes increases as the polymerization temperatures decrease; they possess poor catalytic activities in the temperature range 0−30 °C and exhibit relative higher catalytic activity at lower temperatures. These results are similar to those found when using other ytterbium(II) and eu-

ropium(II) catalyst systems.[9,11] We also found that the catalytic activity increases as the ionic radii of the catalysts' central metal ion increases; for example, the ytterbium(II) catalyst **2** displayed an activity of 2.5×10^5 g PMMA·mol^{-1}(cat)·h^{-1} in DME at −60 °C, but the europium(II) catalyst **3** bearing the same indenyl ligand exhibited an activity of 13.0×10^5 g PMMA·mol^{-1}(cat)·h^{-1} in the same solvent at the same temperature. These results also support the conclusion that the larger the substituent group of the indenyl ligand, the higher the catalytic activity of the catalyst.

The microstructures of the polymers were studied by ^{1}H NMR spectral analyses.[13] The spectra showed that a mostly syndiotactic polymers were obtained when using the ytterbium catalyst **2** in either polar (THF, DME) or nonpolar (toluene) solvents and when using the europium(II) catalyst **6** in the polar solvent DME. Almost a 1:1:1 ratio of isotactic, syndiotactic, and atactic polymers were obtained, however, when applying the europium(II) catalysts **3**, **4**, and **5** in polar solvents (DME, THF); in contrast, isotactic polymers dominated when using the europium(II) catalyst **3** in toluene. These findings indicate that the donor solvents have an effect on the stereochemistry of the polymers and that this phenomenon may arise from the donor solvents' effects on the epimerization process of the catalysts.[4b,14] The different tacticities of the polymers obtained when using the ytterbium(II) and europium(II) catalysts probably is due to the different ionic radii of the ytterbium(II) and europium(II) ions; these differences affect the epimerization process of the catalysts during the polymerization process.

The molecular weights of the polymers were analyzed by GPC; we found that the molecular weights of the polymers were dependent on the choice of catalyst, solvent, and polymerization temperature. The molecular weights of the polymers generally increase as the polymerization temperature decreases. The results of the polymer molecular mass studies support the supposition that initiation with a divalent lanthanidocence complex occurs through reductive dimerization of MMA to form a bis-initiator, comprising two lanthanide(III) enolates joined through their double-bond termini.[15] The fact that the values of M_w/M_n (1.80 to 3.36) are far from unity may be explained by the effect of partial chain termination caused by deactivation of the catalysts with trace amounts of impurities present in the system: lanthanide(II) complexes and their intermediates formed during the polymerization process are very sensitive to these impurities.

Conclusion

The interactions of the indene compound $Me_2NCH_2CH_2CH_2C_9H_7$ (**1**) with lanthanide(III) amides $[(Me_3Si)_2N]_3Ln(\mu\text{-}Cl)Li(THF)_3$ (Ln = Yb, Eu) and indene compounds $Me_2Si(Me_2NCH_2CH_2C_9H_6)NHtBu$, $Me_2NCH_2CH_2C_9H_6SiMe_3$, and $Me_2NCH_2CH_2C_9H_7$ with europium(III) amide $[(Me_3Si)_2N]_3Eu(\mu\text{-}Cl)Li(THF)_3$ resulted in the isolation of a series of new europium(II) complexes, which we characterized. The formation of the lanthanide(II) complexes is proposed to proceed through tandem silylamine elimination/homolysis of the Ln−N (Ln = Yb, Eu) bonds, as deduced by a mechanistic study. The lanthanide(II) complexes obtained from the reactions function as single-component MMA polymerization catalysts. We examined the effects of temperature, solvent, and substituent groups on the catalysts' activities and the polymers' stereochemistries, molecular weights, and molecular weight distributions.

Experimental Section

General Remarks: All the syntheses and manipulations of air- and moisture-sensitive materials were carried out using flamed Schlenk-type glassware on a Schlenk line. All the solvents were refluxed over and distilled from finely divided $LiAlH_4$ or sodium benzophenone ketyl under argon prior to use, unless otherwise noted. $CDCl_3$ was dried with activated 4-Å molecular sieves. MMA was dried with finely divided CaH_2 and distilled before use. $Me_2Si(Me_2NCH_2CH_2C_9H_6)NHtBu$,[9] $Me_2NCH_2CH_2C_9H_6SiMe_3$,[9] $Me_2NCH_2CH_2C_9H_7$,[16] and $[(Me_3Si)_2N]_3Ln(\mu\text{-}Cl)Li(THF)_3$ (Ln = Yb,[9] Eu[5h]) were prepared according to reported procedures. Elemental analyses were obtained with a Perkin−Elmer 2400 Series II Elemental Analyzer. IR spectra were recorded with a Perkin−Elmer 983(G) spectrometer (CsI crystal plate, Nujol and fluoroble mulls). Melting points were determined using sealed capillaries and uncorrected. GC-MS analyses were carried out with an Agilent 6890/Micromass GCT-MS instrument. ^{1}H NMR and ^{13}C NMR spectra were recorded with a Bruker AV-300 NMR spectrometer in C_5D_5N (pyridine-d_5) for lanthanide complexes and in $CDCl_3$ for polymers and indene compounds; the chemical shifts are listed relative to the internal solvent resonances. Gel permeation chromatography (GPC) analyses of polymer samples were performed at 30 °C using THF as the eluent on a Waters-150C instrument that was calibrated using monodisperse polystyrene (PS) standards at a flow rate of 1.0 mL·min^{-1}. Number-average molecular weights and polydispersities of polymers are given relative to PS standards. The polymers were analyzed according to the literature.[13]

$C_9H_7CH_2CH_2CH_2NMe_2$ (1): A 1.57 M hexane solution of *n*BuLi (54.0 mL, 85.2 mmol) was added slowly at 0 °C to a solution of indene (10.0 mL, 85.2 mmol) in THF (80.0 mL). The reaction mixture was stirred at room temperature overnight and then the solution was cooled to 0 °C and $Me_2NCH_2CH_2CH_2Cl$ (10.4 g, 85.2 mmol) was added in one portion. The reaction mixture was stirred at room temperature for 10 h and then it was hydrolyzed. The organic layer was separated and the aqueous layer was extracted with diethyl ether (2×15.0 mL). The organic fractions were combined and dried with anhydrous $MgSO_4$, filtered, and evaporated to dryness. The colorless oily product (12.5 mg, 73%) was obtained after distillation under reduced pressure. ^{1}H NMR (300.17 MHz, $CDCl_3$, 295 K): δ = 7.50 (d, J = 7.23 Hz, 1 H), 7.44 (d, J = 7.38 Hz, 1 H), 7.34 (m, 1 H), 7.24 (m, 1 H), 6.26 (s, 1 H) 3.36 (s, 2 H), 2.62 (m, 2 H), 2.42 (m, 2 H), 2.30 (s, 6 H), 1.94 (m, 2 H) ppm. ^{13}C NMR (75.48 MHz, $CDCl_3$, 295 K): δ = 145.55, 144.55, 144.38, 127.76, 126.76, 126.07, 124.58, 123.79, 119.04, 59.80, 45.66, 37.77, 26.25, 25.62 ppm. IR (Nujol and Fluroble mulls): $\tilde{\nu}$ = 3065 (m), 3017 (m), 2942 (s), 2857 (s), 2764 (s), 1881 (w), 1790 (w), 1682 (w), 1609 (m), 1460 (s), 1377 (m), 1264 (m), 1169 (m), 1097 (w), 1042 (m), 963 (m), 827 (w), 718 (m), 617 (w),

504 (w) cm^{-1}. $C_{14}H_{19}N$ (201.31): calcd. C 83.53, H 9.51, N 6.96; found C 83.15, H 9.45, N 7.02.

[(η⁵:η¹-$C_9H_6CH_2CH_2CH_2NMe_2$)$_2$Yb] (2): A solution of $C_9H_7CH_2CH_2CH_2NMe_2$ (**1**; 490 mg, 2.40 mmol) in toluene (10.0 mL) was added slowly to a solution of $[(Me_3Si)_2N]_3Yb(\mu\text{-}Cl)Li(THF)_3$ (1100 mg, 1.20 mmol) in toluene (50.0 mL) . The reaction mixture was stirred at room temperature for 6 h and then under reflux for 24 h. The color of the reaction mixture gradually changed from yellow to blue and finally to dark red. The solvent was evaporated to give a red solid that was washed with *n*-hexane (10.0 mL). The solid was extracted with toluene (2 × 15.0 mL); the extracts were combined and concentrated to ca. 15.0 mL. A red crystalline solid was obtained after cooling the solution to −10 °C. Yield: 460 mg (67%). M.p. 143−144 °C. ^{1}H NMR (300.17 MHz, C_5D_5N, 295 K): δ = 7.55 (m, 4 H), 7.35 (m, 4 H), 7.18 (m, 2 H), 6.16 (m, 2 H, C_9H_6), 3.24 (m, 4 H), 2.57 (m, 4 H), 1.81 (m, 4 H, $CH_2CH_2CH_2$), 2.13 [s, 12 H, $N(CH_3)_2$] ppm. IR (Nujol and Fluroble mulls): $\tilde{\nu}$ = 2947 (m), 2821 (m), 2777 (m), 1612 (m), 1461 (m), 1262 (m), 1152 (m), 1097 (m), 1042 (m), 965 (m), 914 (m), 769 (s), 719 (m), 411 (m) cm^{-1}. $C_{28}H_{36}N_2Yb$ (573.65): calcd. C58.63, H 6.33, N 4.88; found C 58.79, H 5.99, N 4.82.

[(η⁵:η¹-$C_9H_6CH_2CH_2CH_2NMe_2$)$_2$Eu] (3): This compound was prepared as a yellow crystalline solid in 74% yield from the reaction of $[(Me_3Si)_2N]_3Eu(\mu\text{-}Cl)Li(THF)_3$ (1.250 g, 1.40 mmol) and $C_9H_7CH_2CH_2CH_2NMe_2$ (570 mg, 2.80 mmol) in toluene at 50 °C by employing procedures similar to those used for the preparation of **2**. NMR spectra were not informative because of the lack of locking signals that arises from the paramagnetic property of the europium(II) complex. M.p. 335−337 °C (dec.). IR (Nujol and Fluroble mulls): $\tilde{\nu}$ = 3065 (m), 2954 (m), 2859 (m), 1789 (m), 1531 (m), 1460 (s), 1402 (s), 1265 (m), 1151 (m), 1042 (m), 963 (m), 847 (m), 769 (s), 719 (s), 412 (w) cm^{-1}. $C_{28}H_{36}EuN_2$ (552.57): calcd. C 60.86, H 6.57, N 5.07; found C 60.58, H 6.42, N 5.06.

[{η⁵:η¹-$Me_2Si(Me_2NCH_2CH_2C_9H_5)(NHtBu)$}$_2$Eu]·$(OC_4H_8)_{0.5}$ (4): This compound was prepared as yellow crystals in 46% yield from the reaction of $[(Me_3Si)_2N]_3Eu(\mu\text{-}Cl)Li(THF)_3$ (3.010 g, 3.38 mmol) and $Me_2Si(Me_2NCH_2CH_2C_9H_6)(NHtBu)$ (2.140 g, 6.76 mmol) in toluene at 60 °C by employing procedures similar to those used for the preparation of **2**. M.p. 252−254 °C. ^{1}H NMR (300.17 MHz, C_5D_5N, 295 K): δ = 7.54 (br. s, 4 H), 7.19 (br. s, 4 H), 6.57 (m, 2 H, C_9H_5), 4.00 (m, 4 H), 2.88 (m, 4 H, CH_2CH_2), 3.63 (s, 2 H, N*H*), 2.22 [br. s, 12 H, $N(CH_3)_2$], 1.18 [br. s, 18 H, $C(CH_3)_3$], −0.001 [br. s, 12 H, $Si(CH_3)_2$] ppm. IR (Nujol and Fluroble mulls): $\tilde{\nu}$ = 3377 (w), 3063 (w), 2963 (s), 2765 (m), 1600 (m), 1461 (s), 1377 (s), 1249 (s), 1097 (s), 1021 (vs), 864 (s), 764 (s), 721 (m), 615 (m), 435 (w) cm^{-1}. $C_{38}H_{60}EuN_4Si_2$ (**4**·0.5THF) (781.05): calcd. C 58.44, H 7.74, N 7.17; found C 58.05, H 7.76, N 6.90.

[{η⁵:η¹-$(Me_2NCH_2CH_2C_9H_5SiMe_3)$}$_2$Eu] (5): This compound was prepared as yellow crystals in 49% yield from the reaction of $[(Me_3Si)_2N]_3Eu(\mu\text{-}Cl)Li(THF)_3$ (6.870 g, 7.72 mmol) and $Me_2NCH_2CH_2C_9H_6SiMe_3$ (4.000 g, 15.44 mmol) in toluene at 60 °C by using procedures similar to those used for the preparation of **2**. ^{1}H NMR (300.17 MHz, C_5D_5N, 295 K): δ = 7.55 (br. s, 4 H), 7.18 (br. s, 4 H), 6.48 (m, 2 H, C_9H_5), 4.30 (m, 4 H), 2.90 (m, 4 H, CH_2CH_2), 2.24 [br. s, 12 H, $N(CH_3)_2$], 0.57 (br. s, 6 H), −0.03 [br. s, 12 H, $Si(CH_3)_3$] ppm. IR (Nujol and Fluroble mulls): $\tilde{\nu}$ = 3066 (w), 2954 (s), 1628 (m), 1455 (s), 1374 (m), 1260 (m), 1247 (vs), 1070 (m), 1018 (m), 838 (vs), 765 (m), 719 (m), 431 (w) cm^{-1}. $C_{32}H_{48}EuN_2Si_2$ (668.86): calcd. C 57.45, H 7.23, N 4.19; found C 57.02, H 6.93, N 4.02.

[(η⁵:η¹-$Me_2CH_2CH_2C_9H_6$)$_2$Eu] (6): This compound was prepared as yellow crystals in 57% yield from the reaction of $[(Me_3Si)_2N]_3Eu(\mu\text{-}Cl)Li(THF)_3$ (1.29 g, 1.91 mmol) and $Me_2NCH_2CH_2C_9H_7$ (720 mg, 3.82 mmol) in toluene under reflux by employing procedures similar to those used for the preparation of **2**. NMR spectra were not informative because of the lack of locking signals that arises from the paramagnetic property of the compound. IR (Nujol and Fluroble mulls): $\tilde{\nu}$ = 3180 (m), 2919 (vs), 1609 (m), 1459 (vs), 1375 (vs), 1265 (m), 1073 (m), 1018 (m), 863 (m), 769 (s), 718 (m), 386 (w) cm^{-1}. $C_{26}H_{32}EuN_2$ (524.50): calcd. C 59.54, H 6.15, N 5.34; found C 59.30, H 6.10, N 5.38.

High-Resolution GC-MS Analyses: Small portions of the reaction mixtures of the preparations of **2** to **6** were hydrolyzed and analyzed by GC-MS techniques. In addition to the corresponding indene compounds and $HN(SiMe_3)_2$, a small amount of coupling product $[(Me_3Si)_2N]_2$ was detected in each component. Retention time for $[(Me_3Si)_2N]_2$: 15.57 min; calcd. $[\{(Me_3Si)_2N\}_2 - Me]^+$ m/z = 306.1799; found 306.1838.

MMA Polymerization: MMA polymerization reactions were performed in a 50.0-mL Schlenk flask, placed in an external temperature-controlled bath, on a Schlenk line or in a glovebox. In a typical procedure, the catalyst (20−50 mg) was loaded into the Schlenk flask and the solvent was added. After the external bath temperature had stabilized, MMA was added through a gastight syringe. The polymerization was terminated by the addition of acidic methanol after a measured interval. The polymer product was precipitated into methanol (50.0 mL), washed with methanol, and then dried to a constant weight in a vacuum oven at 50 °C. The stereochemistry of the polymers and their molecular weights were analyzed by ^1H NMR spectroscopy and GPC techniques, respectively.

X-Ray Crystallography: Suitable crystals of the complexes **4**, **5**, and **6** were each mounted in a sealed capillary. Diffraction was performed on a Siemens SMART CCD-area detector diffractometer using graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å); temperature 293(2) K; φ and ω scan technique; SADABS effects and empirical absorption were applied in the data corrections. All structures were solved by direct methods (SHELXS-97),[17] completed by subsequent difference Fourier syntheses, and refined by full-matrix least-squares calculations based on F^2 (SHELXS-97).[17] See Table 4 for crystallographic data.

CCDC-229706 (for **4**), -195752 (for **5**), and -195751 (for **6**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: +44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Acknowledgments

This work was cosponsored by the National Natural Science Foundation of China (Project Nos. 20271003 and 20072001), the Excellent Young Scholars Foundation of Anhui Province, and a grants from the Anhui Education Department and the Anhui Normal University. We are grateful to Professors Jiping Hu and Baohui Du for their help in obtaining NMR and IR spectra.

Molecular Alloys: Syntheses and Structures of the Copper−Antimony Clusters $[Cu_{17}Sb_8(dppm)_6(Ph_2PCHPPh_2)]$ and $[Cu_{20}Sb_{10}(PCy_3)_8]$

Reinhart Ahlrichs,[a] Christopher E. Anson,[b] Rodolphe Clerac,[c] Dieter Fenske,*[b] Alexander Rothenberger,[b] Marek Sierka,[a] and Stephan Wieber[b]

Keywords: X-ray diffraction / Cluster compounds / Antimony / Copper

The syntheses, structures and theoretical investigations of the copper-antimony clusters $[Cu_{17}Sb_8(dppm)_6(Ph_2PCHPPh_2)]$ [**1**, dppm = bis(diphenylphosphanyl)methane] and $[Sb_{10}Cu_{20}(PCy_3)_8]$ (**2**, Cy = Cyclohexyl) are reported.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

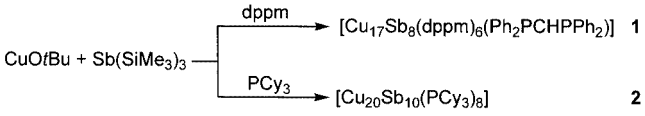
Over the last decade our major field of interest has been the synthesis and structural analysis of metal clusters in which metal atoms are bridged by main-group elements. Special focus was placed on Group 15 and Group 16 bridged metal arrangements, and examples for both cluster classes are numerous.[1] Examples of copper clusters bridged by higher homologues of Group 15 are scarce. Yamada et al. have studied cluster cations of the type $Cu_nSb_m^+$ produced by a gas aggregation source and found that the magic numbers [n, m = (4, 1), (5, 6), (6, 7)] reflect the stability of jellium-shell closings.[2] However, only recently were we able to synthesise and structurally characterise the first Cu−Sb cluster $[Cu_{10}(Sb_3)_2(SbSiMe_3)_2(dppm)_6]$ using Schlenk techniques.[3] All these Cu−Sb cluster species contain Sb−Sb bonds as a common structural motif.

Our approach to Group 15/coinage metal clusters generally involves the reaction of a metal salt MX (M = transition metal; X = halide, carboxylate, alkoxide) with a trimethylsilyl derivative of a main-group element in the presence of a tertiary phosphane. A second route is the metathesis reaction of a transition-metal salt with alkali-metallated Group 15 trimethylsilyl compounds.

Results and Discussion

During the course of the investigations into the syntheses of copper−antimony clusters we explored the potential of both routes. The compounds presented in this communication have all been prepared using the first route.

The reactions of dppm and PCy_3 with one equivalent of CuO*t*Bu and subsequent reaction with $Sb(SiMe_3)_3$ produced the copper−antimony clusters $[Cu_{17}Sb_8(dppm)_6(Ph_2PCHPPh_2)]$ **1** and $[Cu_{20}Sb_{10}(PCy_3)_8]$ **2** (Scheme 1).



Scheme 1. Syntheses of the Cu−Sb clusters in a THF/hexane solution

Compound **1** crystallizes in the triclinic space group $P\bar{1}$ with two molecules in the unit cell and nine lattice-bound THF molecules (Figure 1). The copper atoms are located on faces and edges of a central trigonal antiprismatic arrangement of Sb(2−7). The trigonal faces Sb(2,3,4) and Sb(5,6,7) are capped by Sb(1) and Sb(8). Cu(13) is located in the centre of a Sb(5,6,7) triangle. Cu(17) is the only copper atom in **1** that is coordinated to a carbon atom [Cu(17)−C(138) 2.08(2) Å] and does not bridge at least two Sb centres.[4] Observed Sb−Cu bond lengths and Cu···Cu distances of **1** are in the ranges 2.561(4)−3.086(4) and 2.515(4)−3.041(5) Å, respectively, and are similar to those observed in the cluster $[Cu_{10}(Sb_3)_2(SbSiMe_3)_2(dppm)_6]$ [Cu−Sb av. 2.60 Å, Cu···Cu 2.583(2)−2.675(2) Å].[3] It is noteworthy in this context that the short Cu···Cu distances of **1** (ca. 2.5 Å) are predominantly between tetrahedral and trigonal Cu centres, and are more likely to be the result of geometric requirements than of Cu−Cu bonding. During the course of the reaction partial deprotonation of dppm by CuO*t*Bu occurred, and the structure of **1** is composed

of a $[Cu_{16}Sb_8(dppm)_6]$ unit and metallated dppm [Cu(dppm)]. The structure of the $[Cu_{16}Sb_8(dppm)_6]$ unit in **1** is similar to the structure found for the Group 16 bridged copper cluster $[Cu_{16}Te_8(P^nPr_2Ph)_{10}]$, thus raising questions about the oxidation state of the metal atoms in **1**.[5] In the neutral copper cluster $[Cu_{16}Te_8(P^nPr_2Ph)_{10}]$ the situation is clear with eight formally Te^{2-} centres coordinated to 16 Cu^I centres.[5] The core of **1**, however, consists of eight Sb centres and sixteen Cu centres arranged in the subunit $[Cu_{16}Sb_8(dppm)_6]$. Additional [Cu(dppm)] gives the neutral complex $[Cu_{17}Sb_8(dppm)_6(Ph_2PCHPPh_2)]$ (**1**). The presence of both Cu^I and Cu^{II} centres in the structure cannot be detected. The UV spectra of brown crystals of **1** (200−900 nm) do not show charge-transfer bands similar to those observed in Cu−Te clusters or absorption maxima characteristic for Cu^{II} centres.[5] A similar situation was found for $[Cu_{20}Sb_{10}(PCy_3)_8]$ (**2**), which crystallizes in the monoclinic space group $P2_1/n$ with four molecules of THF as lattice-bound solvent (Figure 2).

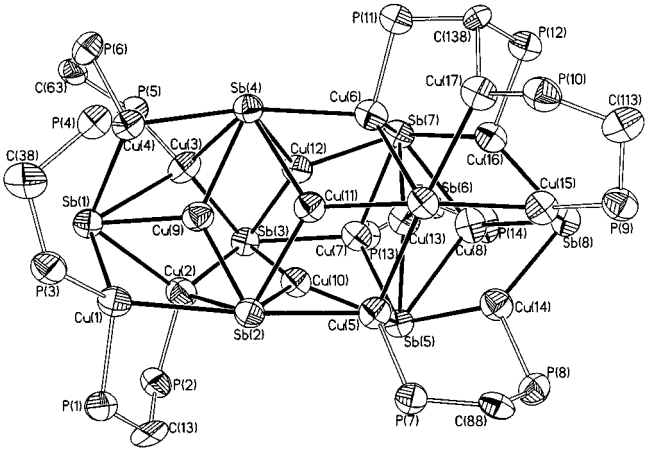

Figure 1. Molecular structure of $[Cu_{17}Sb_8(dppm)_6(Ph_2PCHPPh_2)]$ (**1**); phenyl groups have been omitted; ellipsoids at 50% probability level; selected bond lengths (Å): Cu−Sb 2.561(4) [Sb(2)−Cu(9)] to 3.086(4) [Sb(2)−Cu(2)], shortest Cu−Cu distance 2.515(4) [Cu(2)−Cu(9)], Cu(17)−C(138) 2.08(2), av. Cu−P 2.25

The solid-state structure of **2** consists of two distorted edge-sharing Sb_6 octahedra [Sb(2,3,3a,1,5a,4a) and Sb(4,5,1a,3a,3,2a)] in which the trigonal faces are capped by μ_3-Cu(1,5,6). In the centrosymmetric cluster **2**, the shared edge of the Sb_6 octahedra is bridged by Cu(3) [Cu(3)−Sb(3) 2.7009(19) Å]. The peripheral Cu(2,4,8,10) are coordinated by phosphane ligands. The cyclohexyl substituents of the phoshine ligands form an organic shell preventing the central $Cu_{20}Sb_{10}$ core from further aggregation. Cu(9) exhibits a distorted linear coordination environment [Sb(1A)−Cu(9)−Sb(5): 164.86(7)°] and would perhaps show a similar coordination environment to Cu(3) in a more extended solid-state structure than that of **2**. To elucidate the electronic structure and in particular the oxidation state of the copper atoms involved in the formation of **2**, further experiments (measurement of the temperature dependence of the magnetic susceptibility and of the field dependence of the magnetization between 1.83 K and 100 K) were carried out on polycrystalline samples of **2** (crystals of **1** are contaminated with an amorphous precipitate, so we focused on samples of **2**). As a result, we found that **2** has a diamagnetic ground state with an average susceptibility of −0.003 emu/mol (value in agreement with that expected for a diamagnetic material).

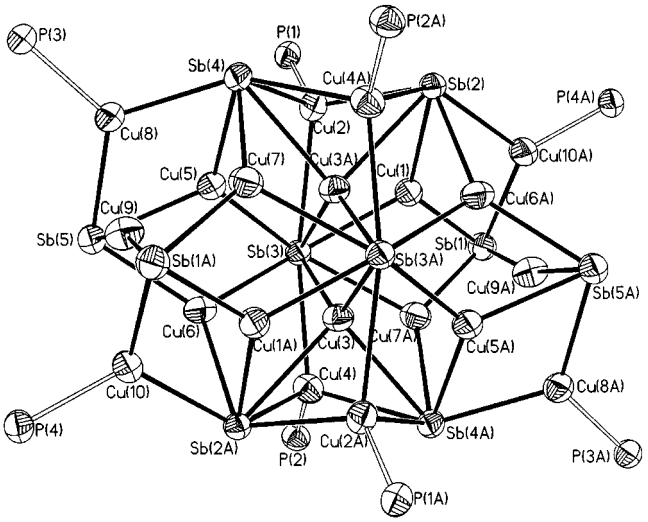

Figure 2. Molecular structure of $[Cu_{20}Sb_{10}(PCy_3)_8]$ (**2**); cyclohexyl groups have been omitted; ellipsoids at 50% probability level; selected bond lengths (Å): Cu−Sb 2.457(2) [Cu(9)−Sb(5)] to 3.106(2) [Cu(2)−Sb(3)], shortest Cu···Cu distance 2.517(2) [Cu(5)−Cu(6)], av. Cu−P 2.24

Independently, a DFT study was carried out to probe these findings.[6] To analyse the properties of the Cu−Sb bond we started with a set of small clusters Cu_nSb_m, n = 1−3; m = 1, 2 summarized in Table 1. Such clusters can provide information about the nature of the Cu−Sb bond with increasing cluster size and different compositions in the absence of ligand effects. Since the electronegativities of Cu and Sb are identical (Pauling scale), no significant charge transfer is expected upon formation of the Cu−Sb bond.[7] This is reflected by the results of Mulliken population analyses (Table 1), which predicts only negligible charge transfer in all small clusters. This confirms the covalent, alloy-like nature of the cores of the Cu−Sb compounds **1** and **2**.

Table 1. Calculated properties of small Cu−Sb clusters: spin state and molecular symmetry, Cu−Sb and Cu−Cu bond lengths (Å) and Mulliken atomic charges

	CuSb	Cu_2Sb	Cu_3Sb	Cu_3Sb_2
State (symmetry)	$^3\Sigma^-$	$^2B_2$ (C_{2v})	$^1A_1$ (C_{3v})	$^2B_2$ (C_{2v})
Cu−Sb	2.43	2.45	2.47	2.51; 2.60
Cu−Cu	−	2.49	2.50	2.55
q_{Cu}	0.07	0.03	0.005	0.02−0.03
q_{Sb}	−0.07	−0.06	−0.01	−0.04

To investigate the electronic properties of **2** we performed calculations on the model complex **2a** in which the PCy_3 ligands were replaced by PMe_3. The experimental structure of **2** shows a C_i molecular symmetry which was also kept during structure optimisations of **2a**. The calculated ground state of **2a** is ^1A_g with close-lying triplet ^3A_g (0.2 eV higher). Since the BP86 functional is known to stabilise lower spin states, this result just indicates singlet and triplet states that are similar in energy. However, the magnetic measurements indicate a diamagnetic nature of **2** and confirm the singlet ground state. The calculated structural parameters (Table 2) of **2a** are generally in good agreement with the experimental results for **2**.

Table 2. Comparison of selected calculated and experimental structural parameters of **2a** and **2**; bond lengths in Å and bond angles in degrees

Parameter	Calculated (**2a**)	Experimental (**2**)
Cu(3)−Cu(3A)	2.50	2.53
Cu(3A)−Cu(5)	2.61	2.63
Cu(9)−Sb(5)	2.53	2.46
Cu(3)−Sb(3)	2.75	2.70
Sb(1A)−Cu(9)−Sb(5)	171.6	164.9

Conclusion

Based on these results and the UV spectra we suggest that the concept of oxidation numbers and localised Cu^{II} and Cu^{I} centres cannot be applied to the Sb−Cu clusters presented here. Instead, **1** and **2** represent intermediates in the reaction of $Sb(SiMe_3)_3$ and Cu*O*t*Bu* that gives the Cu_2Sb alloy which is still under investigation.[8] The results presented here demonstrate that reactions of $Sb(SiMe_3)_3$ with Cu*O*t*Bu* in the presence of tertiary phosphanes can give rise to a class of Sb−Cu clusters that can be regarded as the first representatives of a possibly larger family of phosphane-stabilised molecular alloys with the metal composition $[Cu_2Sb]_n$.

Experimental Section

General Remarks: All operations were carried out in an atmosphere of purified argon. THF was refluxed over potassium and freshly distilled. Hexane was dried with $LiAlH_4$. $P(Cy)_3$ and dppm were purchased from Aldrich and used without further purification. $Sb(SiMe_3)_3$ was prepared according to a literature procedure.[9] Magnetic susceptibility measurements were performed using a Quantum Design SQUID magnetometer MPMS-XL. The magnetic data were corrected for the sample holder (plastic bag) and the diamagnetic contribution calculated from the Pascal constants.[10]

1: A solution of dppm (0.49 g, 1.27 mmol) in 3 mL THF was added to a solution of Cu*O*t*Bu* (0.27 g, 2.00 mmol) tin 5 mL THF. The brown solution was briefly heated to reflux and then allowed to cool down to room temperature. $Sb(SiMe_3)_3$ (3.85 mL, 0.66 mmol, 0.17 M in hexane) was then added at −78 °C. After storage at −40 °C for two weeks, the mixture was allowed to stand at room temperature for another two weeks to produce dark brown crystals of $[Cu_{17}Sb_8(dppm)_6(Ph_2PCHPPh_2)]$ **1** (nine molecules of THF as lattice-bound solvent) (0.10 g, 16%), decomposition at room temperature. The UV/Vis spectrum of **1** does not show any bands. $C_{211}H_{225}Cu_{17}O_9P_{14}Sb_8$:calcd. C 47.0, H 4.2; found C 44.1, H 3.4.

2: A solution of PCy_3 (0.56 g, 2.00 mmol) in 5 mL THF was added to a solution of Cu*O*t*Bu* (0.27 g, 2.00 mmol) *t*in 10 mL THF_3. The reaction mixture was briefly heated to reflux and then allowed to cool down to room temperature. $Sb(SiMe_3)_3$ (3.85 mL, 0.66 mmol, 0.17 M in hexane) was then added at −78 °C. After storage at −40 °C for two weeks, the mixture was allowed to stand at room temperature for another two weeks to produce dark brown crystals of **2** (0.15 g, 31%). The UV/Vis spectrum of **2** does not show any bands. $C_{304}H_{560}P_{16}Cu_{40}Sb_{20}O_4$: calcd. C 37.4, H 5.8; found C 37.0, H 5.7.

Deviations in the elemental analyses from the calculated values show loss of lattice-bound solvent. Crystals of **1** and **2** were dried under vacuum.

X-ray Crystallographic Study: Data for both compounds were collected on a Stoe IPDS II diffractometer using graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å). The structures were solved by direct methods and refined by full-matrix least-squares on F^2 (all data) using the SHELXTL software package.[11] Hydrogen atoms were placed in calculated positions, non-hydrogen atoms were assigned anisotropic thermal parameters.

Crystal data for 1: $C_{211}H_{225}Cu_{17}O_9P_{14}Sb_8$; M = 5392.67; triclinic, space group $P\bar{1}$, Z = 2; a = 17.503(2) Å, b = 22.469(3) Å, c = 29.642(4) Å, α = 80.80(1)°, β = 76.70(1)°, γ = 69.20(1)°; V = 10567(2) Å^3; T = 150(2) K; $F(000)$ = 5348; $D_{calcd.}$ = 1.695 g cm^{-3}. Of 38611 reflections measured 26935 were unique (R_{int} = 0.1025). 1655 parameters; final wR_2 = 0.2404 (all data); R_1 = 0.0974 [$I > 2\sigma(I)$]; largest difference peak and hole 1.44 and −1.26 e·Å^{-3}; disordered components were refined with isotropic thermal parameters.

Crystal data for 2: $C_{152}H_{280}Cu_{20}O_2P_8Sb_{10}$; M = 4875.82; monoclinic, space group $P2_1/n$; Z = 2; a = 15.984(3) Å, b = 28.640(6) Å, c = 19.444(4) Å, β = 100.60(3)°; V = 8749(3) Å^3; T = 123(2) K; $F(000)$ = 4836; $D_{calcd.}$ = 1.851 g·cm^{-3}. Of 30565 reflections measured 15110 were unique (R_{int} = 0.0681). 865 parameters; final wR_2 = 0.1472 (all data); R_1 = 0.0631 [$I > 2\sigma(I)$]; largest difference peak and hole 1.855 and −1.335 e·Å^{-3}.

CCDC-216800 and -216801 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (int.) +44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

The First Cyclometallated (1-Ferrocenylethanone thiosemicarbazone)-palladium(II) Compounds − Crystal and Molecular Structure of [Pd{(η^5-C_5H_5)Fe(η^5-C_5H_3)C(Me)=NN=C(S)NHMe}(PPh_3)]

José M. Vila,*[a] Eduardo Gayoso,[a] M. Teresa Pereira,[a] Juan M. Ortigueira,[a] Gemma Alberdi,[a] Marta Mariño,[a] Reyes Alvarez,[a] and Alberto Fernández[b]

Keywords: C−H activation / Ferrocene / Thiosemicarbazone / Palladium / X-ray diffraction

Treatment of the 1-ferrocenylethanone thiosemicarbazone ligands (η^5-C_5H_5)Fe(η^5-C_5H_4)C(Me)=NN(H)C(=S)NHR [R = H (**a**), Me (**b**)] with $K_2[PdCl_4]$ gave the novel heterometallic octanuclear palladium(II) compounds [Pd{(η^5-C_5H_5)Fe(η^5-C_5H_3)C(Me)=NN=C(S)NHR}]$_4$ [R = H (**1a**), Me (**1b**)] as tetramers, after deprotonation of the NH group, with the ligands acting as terdentate donors through the [C,N,S] atoms. Treatment with nucleophiles cleaves the tetrameric clusters giving compounds in which splitting only of the Pd–$S_{bridging}$ bonds has occurred. The strength of the Pd–$S_{chelating}$ bond hinders its cleavage. Thus, treatment of **1a** or **1b** with $Ph_2P(CH_2)_nPPh_2$ [*n* = 2 (dppe), 3 (dppp), 4 (dppb)] in a 1:2 molar ratio gave the tetranuclear species **2a**–**4a** and **2b**–**4b**, respectively, and treatment with PPh_2R gave the dinuclear compounds **5a**–**7a** and **5b**–**6b** [R = Ph (**5a**, **5b**), Et (**6a**, **6b**), Me (**7a**)]. The complexes described are the first fully characterized cyclometallated palladium(II) complexes with 1-ferrocenylethanone thiosemicarbazone ligands. The crystal and molecular structure of compound **5b** have been determined by X-ray crystallography.

Introduction

The synthesis, isolation and characterization of ferrocene[1] marked an important milestone in the evolution of modern organometallic chemistry. One of the developments in this area over the last two decades has been the cyclometallation of ferrocene derivatives. The cyclometallation reaction has been widely investigated in view of the growing chemistry[2] and the novel and outstanding applications which the resultant compounds present. To name but a few examples: the synthesis of new organometallic and organic compounds, many of which can be obtained by insertion reactions of unsaturated species to the metal−carbon bond,[3] the design of complexes with specific antitumor activity towards some forms of cancer[4] or their promising properties as liquid crystals,[5] and their use in the isolation of enantiomerically pure chiral compounds[6] or as efficient catalytic materials.[7]

In the past years, great efforts have been made in order to achieve the isolation and characterization of palladacycles derived from [C,N,X] terdentate ligands (C = phenyl C; X = N,[8] P,[9] O,[10] S[11]), mainly due to the potential hemilability of the Pd−X bond in these systems, which plays an important role in homogeneous catalysis.[12] The reported examples of those complexes containing terdentate [$C_{ferrocene}$,N,X] ligands are scarce, and only compounds with X = N have been described.[13] In some instances potentially terdentate [C,N,N] ferrocenyl ligands do not undergo cyclometallation reactions and only complexes with *N*,*N*-coordination could be isolated.[14] More recently, insertion of alkynes into the $C_{ferrocene}$−Pd bond has given new insights into the chemistry of cyclometallated ferrocene compounds such as the influence of the binding mode of the ferrocenyl ligand.[15]

As a continuation of our studies related to cyclometallated compounds with terdentate [C,N,S] ligands, we have extended our work in this area aimed at incorporating the −C(Me)=NN(H)C(=S)NHR system into the ferrocene ring, to give (η^5-C_5H_5)Fe(η^5-C_5H_4)C(Me)=NN(H)C(=S)-NHR (R = H, Me), with the purpose of producing the hitherto unknown cyclometallated 1-ferrocenylethanone thiosemicarbazone complexes by treatment with an appropriate palladium(II) salt. These compounds turned out to be octanuclear species, and we wished to further explore their reactivity with tertiary mono- and diphosphane ligands which affords the corresponding dinuclear and tetranuclear complexes, respectively. Our report includes a description of the first known crystal structure of this kind of compounds.

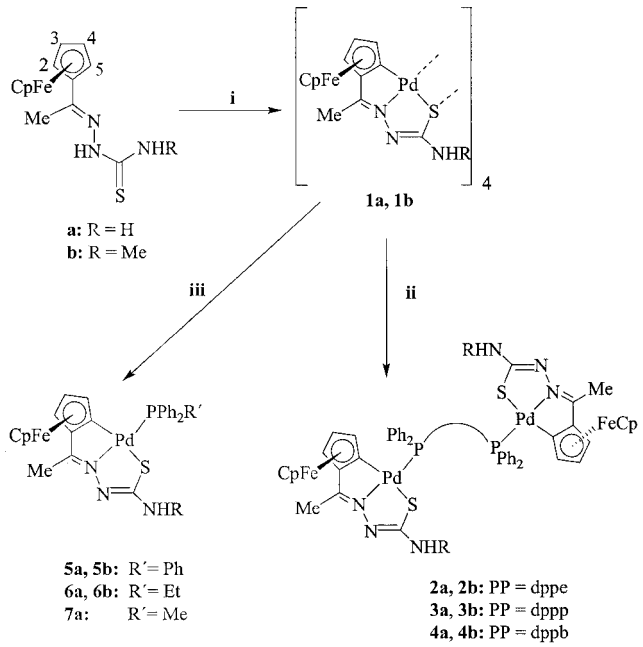
Results and Discussion

For convenience, the compounds and reactions are shown in Scheme 1. The compounds described in this paper were characterized by elemental analyses (C, H, N, S), mass spectrometry (in part), IR spectroscopy, and ^1H and $^{31}P\{^1H\}$ NMR spectroscopy (data in the Exp. Sect.).



Scheme 1. i) K_2PdCl_4, ethanol/water; ii) $Ph_2P(CH_2)_nPPh_2$ (n = 2, 3, 4), 1:2 ratio, acetone; iii) PPh_2R' (R′ = Me, Et, Ph), 1:4 ratio, acetone

The 1-ferrocenylethanone thiosemicarbazones[16] **a** and **b** were prepared by treatment of thiosemicarbazide or 4-methylthiosemicarbazide, respectively, with acetylferrocene in water in the presence of a few drops of hydrochloric acid, and obtained as air-stable solids, which were fully characterized (see Exp. Sect.). In particular, the IR spectra showed the typical ν(C=N) and ν(C=S) stretches,[17] and the ^1H NMR spectra revealed the NH resonances at δ = 7.38 (**a**) and 6.20 (**b**) ppm.

Cyclopalladated compounds derived from ferrocenyl ligands may be prepared by cyclomercuration and ulterior transmetallation reactions or by direct treatment with a palladium salt. The additional presence of a base such as NaOAc may be necessary.[13f] In the latter case, M_2PdCl_4 (M = Li, Na, K) proved to be a convenient reagent, as well as in the synthesis of cyclopalladated compounds derived from thiosemicarbazone ligands. Thus, treatment of a suspension of potassium tetrachloropalladate in ethanol/water with the corresponding 1-ferrocenylethanone thiosemicarbazone ligand yielded complexes **1a** and **1b** as brown air-stable solids, with the ligand in an (*E*,*Z*) configuration and the sulfur atom of each cyclometallated moiety displaying two different coordination modes: chelating, as part of the Pd*N*NC(NHR)*S* coordination ring, and bridging, linking two cyclometallated moieties through the metal atoms. We tentatively assigned a tetrameric structure for these species in accordance with the results reported by us[18] and others[19] in related complexes derived from terdentate [C,N,S] ligands, as shown by the spectroscopic data. Hence **1a** and **1b** should be considered as novel octanuclear cyclometalled palladium(II) compounds.

The IR spectra showed, as the main difference from the starting material, the disappearance of the ν(N−H) bands due to the −NH group[20] and the ν(C=S) band at 900−800 cm^{-1}, which indicated deprotonation and loss of the C=S double bond character, respectively. The position of the NH_2 and NH bands showed that the former group was not coordinated. The displacement of the ν(C=N) band towards lower wavenumbers upon complex formation[21] is in contrast with other thiosemicarbazone complexes in which the shift is towards higher wavenumbers, probably due to the presence of the five-membered metallacycle in compounds **1a** and **1b**.[22] No ν(Pd−Cl) band was found in the IR spectra of the compounds, indicating the absence of a chloride ligand in the coordination sphere of the metal center. The FAB mass spectra of **1a** and **1b** showed clusters of peaks, centered at 1622 and 1678 amu, which both correspond to $[M]^+$.[23] The ^1H NMR spectra showed only one set of signals, although the activation of the $C_{ferrocene}-H$ bond promotes planar chirality (R_s or R_p) in the ferrocenyl moiety.[24] This issue has been dealt with elsewhere.[25] In the ^1H NMR spectra, the absence of the −NH proton resonance confirms deprotonation as observed in other coordination and organometallic compounds with similar ligands.[26] Broad signals at δ ≈ 6.60 ppm were assigned to the NH_2 (**1a**) and N*H*Me (**1b**) proton resonances, shifted upfield with respect to their positions in the free ligands. A group of three signals at δ ≈ 4.50−4.10 ppm, integrating for one proton each, and a singlet at δ = 4.22 ppm assigned to the C_5H_5 group in each case were consistent with 1,2-disubstituted ferrocenes.[27] These facts provided evidence of metallation of the ligand. Variable-temperature NMR experiments did not produce any significant changes in the spectra.

Treatment of **1a** or **1b** with $Ph_2P(CH_2)_nPPh_2$ [n = 2 (dppe), 3 (dppp), 4 (dppb)] in a 1:2 molar ratio gave the tetranuclear species **2a**−**4a** and **2b**−**4b**, respectively (see Scheme 1). These reactions confirm the different reactivities of the chelating and bridging Pd−S bonds, the former being retained in the final products, even when a large excess of diphosphane was used, whilst the latter was cleaved in all instances, in agreement with the tendency observed in other cyclometallated Pd_4 cluster complexes derived from thiosemicarbazone ligands, indicating once again the greater strength of the $Pd-S_{chelating}$ bond.[18] All compounds were fully characterized by elemental analyses, and by IR and NMR spectroscopy. The ^1H NMR spectra showed only one set of signals in each case. The metallated cyclopentadienyl ring protons appeared as three signals at δ ≈ 4.67−3.48 ppm, with the 4-H proton resonance experiencing an upfield shift and appearing at lower frequency values than the C_5H_5 signal (see Exp. Sect.), due to the shielding effect of the phosphane phenyl rings, consistent with a P

trans to N arrangement within the terms of the "transphobic effect".[28] Unfortunately, the coupling constants to the phosphorus nuclei could not be assigned, in contrast with related complexes with diphosphane ligands.[29] The $^{31}P\{^{1}H\}$ NMR spectra showed singlets for the two equivalent phosphorus nuclei, shifted to higher frequency compared with those in the spectrum of the free phosphane, in agreement with the phosphorus atom coordinating to the metal center.[30] Based on the ^{1}H and $^{31}P\{^{1}H\}$ NMR spectroscopic data we propose a centrosymmetric arrangement for the compounds (see Scheme 1). Variable-temperature NMR experiments failed to show any noteworthy changes in the spectra. Also, the ^{1}H NMR spectra for compounds **2a**−**4a** and **2b**−**4b** were recorded in the presence of an NMR shift reagent {tris[3-heptafluoropropylhydroxymethylene-*d*-camphorato]europium(III), [Eu(hfc)$_3$]} and the appearance of the resultant spectra in terms of the positions of the signals and the presence of new signals remained unchanged upon varying the quantity of the chiral ligand.

Treatment of **1a** and **1b** with PPh_2R gave the dinuclear air-stable solids **5a**−**7a**, **5b**−**6b** [R = Ph (**5a**, **5b**), Et (**6a**, **6b**), Me (**7a**)] (see Scheme 1). Characteristic microanalytical, IR and NMR spectroscopic data are given in the Exp. Sect. Important spectroscopic features include the absence of the ν(NH) and ν(C=S) bands in the IR spectra (vide supra), the shift of the 4-H signal in the ^{1}H NMR spectra, which appears to high field of the non-substituted C_5H_5 resonance, and the chemical shift value of the ^{31}P singlets in the $^{31}P\{^{1}H\}$ NMR spectra, the latter two being consistent with a P *trans* to N geometry (vide supra). The molecular structure of compound **5b** has been determined by a single-crystal X-ray diffraction analysis.

Molecular Structure of Complex 5b

Suitable crystals of **5b** were grown by slowly concentrating a chloroform solution. The crystal structure has been determined (Figure 1) and confirms the geometry predicted from spectroscopic studies. Selected bond lengths and angles are listed in Table 1. The structure is comprised of a molecule of **5b** per asymmetric unit, with discrete molecules separated by van der Waals distances. Chirality is introduced in the complex due to activation of the C(sp^2)−H bond. The centrosymmetric space group of the crystal structure, however, indicates that both enantiomers are present in the solid state. The palladium atom Pd(1) is in an approximately square-planar coordination environment (r.m.s. = 0.0845 Å, plane 1) bonded to a terdentate 1-ferrocenylethanone thiosemicarbazone ligand through the ferrocene carbon atom C(1), the nitrogen atom N(1) of the C=N moiety, and the thioamide sulfur atom S(1), all of which pertain to the thiosemicarbazone ligand, with the remaining site occupied by the phosphorus atom P(1) of the triphenylphosphane group. Each molecule contains a [5,5,5] tricyclic system which includes the three fused ferrocenyl, cyclometallated and chelate rings, with the *C*,*N*-metallacycle and the *N*,*S*-chelate rings sharing the Pd(1) atom. The cyclometallated [Pd(1),C(1),C(5),C(11),N(1), plane 2], coordination [Pd(1),N(1),N(2),C(12),S(1), plane 3] and metallated ferrocenyl [C(1)−C(5), plane 4] rings are also planar (r.m.s. = 0.0208, 0.0076 and 0.0039 Å, respectively) and coplanar with the palladium coordination plane (angles between planes: 1/2 = 6.2°, 1/3 = 5.5°, 2/3 = 1.2°, 1/4 = 9.5°, 2/4 = 3.8°, 3/4 = 5.0°). The angles between adjacent atoms in the coordination geometry of the metal atom are close to the expected value of 90°, with the most noticeable distortion in the P(1)−Pd(1)−S(1), C(1)−Pd(1)−N(1) and N(1)−Pd(1)−S(1) angles of 103.47(8), 81.0(3) and 81.3(2)°, respectively. The sum of the angles around the palladium atom is approximately 360°. All bond lengths are within the expected ranges, allowing for the strong *trans* influence of the phosphorus donor ligand,[18] which is reflected in the Pd(1)−N(1) distance of 2.067(6)Å (cf. sum of the covalent radii for palladium and nitrogen, 2.01 Å[31]). The Pd(1)−C(1) bond of 2.001(8) Å is shorter than the expected value of 2.081 Å based on the sum of the covalent radii of carbon (sp^2) and palladium, 0.771 and 1.31 Å, respectively,[31] but similar to values reported for other cyclometallated complexes.[25,32] The Pd(1)−P(1) distance, 2.245(2) Å, is also shorter than the expected value of 2.41 Å.[31] The S(1)−C(12) bond length of 1.764(8) Å, and the N(2)−C(12) length of 1.305(9) Å, are consistent with increased single- and double-bond character, respectively, resulting from deprotonation of the ligand. The two C_5H_5 rings are parallel with a tilt angle of 0.8°. They are also nearly eclipsed, being skewed 8.9° form an eclipsed conformation.

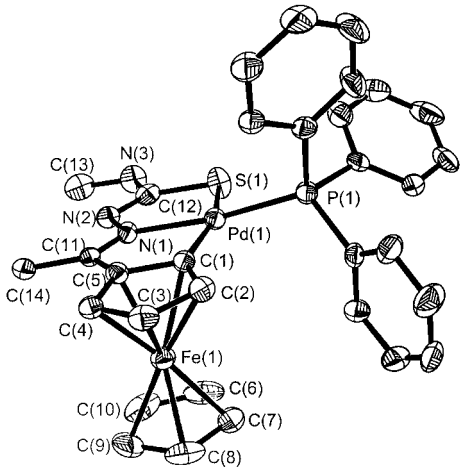

Figure 1. Molecular structure of [Pd{(η^5-C_5H_5)Fe(η^5-C_5H_3)C(Me)=NN=C(S)NHMe}(PPh_3)] (**5b**) with labeling scheme; hydrogen atoms have been omitted for clarity

Experimental Section

General Remarks: All solvents were distilled prior to use from appropriate drying agents.[33] Chemicals were used as supplied from commercial sources. Elemental analyses (C, H, N, S) were carried out at the Servicio de Análisis Elemental at the University of Santiago de Compostela using a Carlo−Erba Elemental Analyzer, model 1108. IR spectra were recorded as KBr discs or Nujol mulls with a Perkin−Elmer 1330 spectrophotometer. NMR spectra were recorded with a Bruker WM250 or AMX-300 spectrometer in $CDCl_3$ and were referenced to $SiMe_4$ (^1H) or 85% H_3PO_4 ($^{31}P\{^1H\}$). The FAB mass spectra were recorded with a Fisons Quatro mass spectrometer with a Cs ion gun; 3-nitrobenzyl alcohol was used as the matrix.

Synthesis of $(\eta^5\text{-}C_5H_5)Fe(\eta^5\text{-}C_5H_4)C(Me)=NN(H)C(=S)NH_2$ (a): A suspension of thiosemicarbazide (0.19 g, 2.19 mmol) and hydrochloric acid (0.1 mL) in water (40 mL) was stirred at room temperature. Acetylferrocene (0.5 g, 2.19 mmol) was added and the mixture stirred for 4 h, filtered and the resultant orange solid dried in vacuo. Yield 603.8 mg, 91.2%. $C_{13}H_{15}FeN_3S$ (301.2): calcd. C 51.8, H 5.0, N 13.9, S 10.7; found C 52.2, H 4.9, N 13.6, S 10.5. IR: $\tilde{\nu}$ = 3406 s, 3221 s [ν(N−H)], 1590 s [ν(C=N)], 819 m [ν(C=S)] cm^{-1}. ^1H NMR ($CDCl_3$): δ = 8.54 (br., 1 H, NH), 7.38 (br., 1 H, NH_2), 6.20 (br., 1 H, NH_2), 4.57 [d, ^3J(HH) = 1.6 Hz, 2 H, 2-H, 5-H], 4.39 (br., 2 H, 3-H, 4-H), 4.16 (s, 5 H, C_5H_5), 2.18 (s, 3 H, Me).

Synthesis of $(\eta^5\text{-}C_5H_5)Fe(\eta^5\text{-}C_5H_4)C(Me)=NN(H)C(=S)NHMe$ (b): Thiosemicarbazone **b** was synthesized as an orange solid in a similar fashion. Yield 673 mg, 97.4%. $C_{14}H_{17}FeN_3S$ (315.2): calcd. C 53.3, H 5.4, N 13.3, S 10.2; found C 53.2, H 5.3, N 12.9, S 9.9. IR: $\tilde{\nu}$ = 3361 s, 3235 m [ν(N−H)], 1663 w [ν(C=N)], 897 m [ν(C=S)] cm^{-1}. ^1H NMR ($CDCl_3$): δ = 8.23 (br., 1 H, NH), 7.64 (br., 1 H, N*H*Me), 4.55 (br., 2 H, 2-H, 5-H), 4.37 (br., 2 H, 3-H, 4-H), 4.14 (s, 5 H, C_5H_5), 3.34 [d, ^3J(HH) = 3.9 Hz, 3 H, NH*Me*], 2.26 (s, 3 H, Me).

Preparation of $[Pd\{(\eta^5\text{-}C_5H_5)Fe(\eta^5\text{-}C_5H_3)C(Me)=NN=C(S)NH_2\}]_4$ (1a): To a stirred solution of potassium tetrachloropalladate (0.2 g, 0.61 mmol) in water (6 mL) were added ethanol (40 mL) and ligand **a** (0.2 g, 0.67 mmol) and the mixture was stirred at room temperature for 24 h. The dark brown precipitate was filtered, washed with cold ethanol and dried in vacuo. Yield 581.3 mg, 58.7%. $C_{52}H_{52}Fe_4N_{12}Pd_4S_4$ (1622.4): calcd. C 38.5, H 3.2, N 10.4, S 7.9; found C 38.3, H 3.1, N 10.2, S 7.7. IR: $\tilde{\nu}$ = 3434 s [ν(N−H)], 1569 w [ν(C=N)] cm^{-1}. ^1H NMR ($CDCl_3$): δ = 6.50 (br., 2 H, NH_2), 4.45 (br., 1 H, 2-H), 4.32 (br., 1 H, 3-H), 4.22 (s, 5 H, C_5H_5), 4.12 (br., 1 H, 4-H), 2.13 (s, 3 H, Me) ppm. FAB-MS: *m*/*z* = 1622 $[M]^+$.

Preparation of $[Pd[\{\eta^5\text{-}C_5H_5)Fe(\eta^5\text{-}C_5H_3)C(Me)=NN=C(S)NHMe\}]_4$ (1b): Complex **1b** was prepared as a brown solid in a similar manner. Yield 678.2 mg, 66.2%. $C_{56}H_{60}Fe_4N_{12}Pd_4S_4$ (1678.5): calcd. C 40.1, H 3.6, N 10.0, S 7.6; found C 40.0, H 3.4, N 9.8, S 7.8. IR: $\tilde{\nu}$ = 3402 m [ν(N−H)], 1588 s [ν(C=N)] cm^{-1}. ^1H NMR ($CDCl_3$): δ = 6.78 (br., 1 H, N*H*Me), 4.45 [d, ^3J(HH) = 1.1 Hz, 1 H, 2-H], 4.33 (br., 1 H, 3-H), 4.22 (s, 5 H, C_5H_5), 4.11 (br., 1 H, 4-H), 2.73 [d, ^3J(H,H) = 4.6 Hz, 3 H, NH*Me*], 2.16 (s, 3 H, Me) ppm. FAB-MS: *m*/*z* = 1678 $[M]^+$.

Preparation of $[\{Pd[(\eta^5\text{-}C_5H_5)Fe(\eta^5\text{-}C_5H_3)C(Me)=NN=C(S)NH_2]\}_2\{\mu\text{-}Ph_2P(CH_2)_2PPh_2\}]$ (2a): 1,2-Bis(diphenylphosphanyl)ethane (14.7 mg, 0.037 mmol) was added to a suspension of **1a** (30.0 mg, 0.0185 mmol) in acetone (8 mL). The mixture was stirred for 24 h and the resultant orange solid filtered and dried. Yield 28.7 mg, 64.2%. $C_{52}H_{50}Fe_2N_6P_2Pd_2S_2$ (1209.6): calcd. C 51.6, H 4.2, N 6.9, S 5.3; found C 51.5, H 4.2, N 6.9, S 5.5. IR: $\tilde{\nu}$ = 3428 s [ν(N−H)], 1572 sh [ν(C=N)] cm^{-1}. ^1H NMR ($CDCl_3$): δ = 5.78 (br., 2 H, NH_2), 4.54 [d, ^3J(HH) = 1.7 Hz, 1 H, 2-H], 4.40 (br., 1 H, 3-H), 4.14 (s, 5 H, C_5H_5), 4.01 (br., 1 H, 4-H), 2.01 (s, 3 H, Me) ppm. ^{31}P NMR ($CDCl_3$): δ = 58.7 (s).

Preparation of $[\{Pd[(\eta^5\text{-}C_5H_5)Fe(\eta^5\text{-}C_5H_3)C(Me)=NN=C(S)NH_2]\}_2\{\mu\text{-}Ph_2P(CH_2)_3PPh_2\}]$ (3a), $[\{Pd[(\eta^5\text{-}C_5H_5)Fe(\eta^5\text{-}C_5H_3)C(Me)=NN=C(S)NH_2]\}_2\{\mu\text{-}Ph_2P(CH_2)_4PPh_2\}]$ (4a), $[\{Pd[(\eta^5\text{-}C_5H_5)Fe(\eta^5\text{-}C_5H_3)C(Me)=NN=C(S)NHMe]\}_2\{\mu\text{-}Ph_2P(CH_2)_2PPh_2\}]$ (2b) $[\{Pd[(\eta^5\text{-}C_5H_5)Fe(\eta^5\text{-}C_5H_3)C(Me)=NN=C(S)NHMe]\}_2\{\mu\text{-}Ph_2P(CH_2)_3PPh_2\}]$ (3b), $[\{Pd[(\eta^5\text{-}C_5H_5)Fe(\eta^5\text{-}C_5H_3)C(Me)=NN=C(S)NHMe]\}_2\{\mu\text{-}Ph_2P(CH_2)_4PPh_2\}]$ (4b): Compounds **3a**, **4a** and **2b**−**4b** were synthesized as air-stable orange solids according to a similar procedure for the preparation of **1a**, but using the appropriate diphosphane ligand. In the case of **3a** and **3b** no solid precipitated and so the solvent was removed at reduced pressure from the resultant solution and the residue recrystallized from dichloromethane/hexane.

3a: Yield 30.8 mg, 68.0%. $C_{53}H_{52}Fe_2N_6P_2Pd_2S_2$ (1223.6): calcd. C 52.0, H 4.3, N 6.9, S 5.2; found C 51.9, H 4.0, N 6.7, S 5.3. IR: $\tilde{\nu}$ = 3443 s [ν(N−H)],] 1570 sh [ν(C=N) cm^{-1}. ^1H NMR ($CDCl_3$): δ = 5.81 (br., 2 H, NH_2), 4.46 [d, ^3J(HH) = 0.9 Hz, 1 H, 2-H], 4.35 (br., 1 H, 3-H), 4.12 (s, 5 H, C_5H_5), 3.83 (m, 1 H, 4-H), 2.29 (s, 3 H, Me) ppm. ^{31}P NMR ($CDCl_3$): δ = 5.8 s.

4a: Yield 36.1 mg, 78.9%. $C_{54}H_{54}Fe_2N_6P_2Pd_2S_2$ (1237.7): calcd. C 52.4, H 4.4, N 6.8, S 5.2; found C 52.3, H 4.3, N 6.5, S 5.1. IR: $\tilde{\nu}$ = 3439 m [ν(N−H)], 1570 m [ν(C=N)] cm^{-1}. ^1H NMR ($CDCl_3$): δ = 4.82 (br., 2 H, NH_2), 4.25 [d, ^3J(HH) = 2.3 Hz, 1 H, 2-H], 4.12 (br., 1 H, 3-H), 3.81 (s, 5 H, C_5H_5), 3.49 [d, ^4J(PH) = 1.9 Hz, 1 H, 4-H], 2.20 (s, 3 H, Me) ppm. ^{31}P NMR ($CDCl_3$): δ = 27.0 (s).

2b: Yield 41.2 mg, 93.2%. $C_{54}H_{54}Fe_2N_6P_2Pd_2S_2$ (1237.7): calcd. C 52.4, H 4.4, N 6.8, S 5.2; found C 52.6, H 4.3, N 6.7, S 5.1. IR: $\tilde{\nu}$ = 3376 m [ν(N−H)], 1628 sh [ν(C=N)] cm^{-1}. ^1H NMR ($CDCl_3$): δ = 5.81 (br., 1 H, N*H*Me), 4.61 [d, ^3J(HH) = 3.2 Hz, 1 H, 2-H], 4.13 (br., 1 H, 3-H), 4.06 (s, 5 H, C_5H_5), 3.99 (br., 1 H, 4-H), 2.87 [d, ^3J(HH) = 4.5 Hz, 3 H, NH*Me*], 2.37 (s, 3 H, Me) ppm. ^{31}P NMR ($CDCl_3$): δ = 62.9 (s).

3b: Yield 32.3 mg, 72.2%. $C_{55}H_{56}Fe_2N_6P_2Pd_2S_2$ (1251.7): calcd. C 52.8, H 4.5, N 6.7, S 5.1; found C 52.6, H 4.4, N 6.5, S 5.0. IR: $\tilde{\nu}$ = 3418 m [ν(N−H)], 1626 w [ν(C=N)] cm^{-1}. ^1H NMR ($CDCl_3$): δ = 6.01 (br., 1 H, N*H*Me), 4.67 [d, 1 H, 2-H, ^3J(HH) = 3.6 Hz], 4.31 (br., 1 H, 3-H), 4.17 (s, 5 H, C_5H_5), 3.81 (br., 1 H, 4-H), 2.99 [d, ^3J(HH) = 4.6 Hz, 3 H, NH*Me*], 2.16 (s, 3 H, Me) ppm. ^{31}P NMR ($CDCl_3$): δ = 3.71 (s).

4b: Yield 36.8 mg, 81.3%. $C_{56}H_{58}Fe_2N_6P_2Pd_2S_2$ (1265.7): calcd. C 53.1, H 4.6, N 6.6, S 5.1; found C 53.0, H 4.5, N 6.4, S 5.1. IR: ν(N−H) 3434 s, ν(C=N) 1629 w cm^{-1}. ^1H NMR ($CDCl_3$): δ = 4.67 (br., 1 H, N*H*Me), 4.25 (br., 1 H, 2-H), 4.10 (br., 1 H, 3-H), 3.82 (s, 5 H, C_5H_5), 3.48 (m, 1 H, 4-H), 2.97 [d, 3 H, NH*Me*, ^3J(HH) = 4.9 Hz], 2.24 (s, 3 H, Me) ppm. ^{31}P NMR ($CDCl_3$): δ = 24.7 (s).

Preparation of $[Pd\{(\eta^5\text{-}C_5H_5)Fe(\eta^5\text{-}C_5H_3)C(Me)=NN=C(S)NH_2\}(PPh_3)]$ (5a): Triphenylphosphane (19.4 mg, 0.0739 mmol) was added to a suspension of **1a** (30.0 mg, 0.0185 mmol) in acetone (8 mL). The mixture was stirred for 24 h and the resultant orange solid filtered and dried. The residue was recrystallized from dichloromethane/hexane. Yield 35.7 mg, 72.3%. $C_{31}H_{28}FeN_3PPdS$ (667.9): calcd. C 55.8, H 4.2, N 6.3, S 4.8; found C 55.5, H 4.1, N

X-ray Crystallographic Study:[34] Three-dimensional, room-temperature X-ray data were collected in the range 2.28° < θ < 25.87° with a Bruker CCD diffractometer using the ω-scan method. Reflections were measured from a hemisphere of data collected in frames each covering 0.3° in ω. The 5968 reflections measured were corrected for Lorentz and polarization effects and for absorption using a semiempirical correction based on symmetry-equivalent and repeated reflections (max/min transmissions: 0.95/0.63). The structure was solved by direct methods and refined by full-matrix least-squares unique data (354 parameters) with allowance for the thermal anisotropy of all non-hydrogen atoms. Hydrogen atoms were included in calculated positions and refined using the riding mode. The refinement was carried out taking into account the minor components of the disorder. Minimum/maximum final electron density: −1.204/0.564 e·Å^{-3}. The structure solution and refinement were carried out using the SHELX-97 program package.[35] Crystal data are given in Table 2.

Table 2. Crystal data and structure refinement data for compound **5b**

Empirical formula	$C_{32}H_{30}N_3Cl_2PSFePd$
Formula mass	681.87
Temperature	293(2) K
Wavelength	0.71073 Å
Crystal system	triclinic
Space group	$P\bar{1}$
Unit cell	a = 11.134(2) Å
	b = 11.807(3) Å
	c = 12.418(4) Å
	α = 75.781(19)°
	β = 75.92(2)°
	γ = 70.355(19)°
Volume	1467.1(7) Å^3
Z	2
Density (calculated)	1.544 Mg cm^{-3}
Absorption coefficient	1.259 mm^{-1}
F(000)	692
Crystal size	0.40 × 0.12 × 0.04 mm
θ range for data collection	2.28−25.87°
hkl	−13/0, −14/13, −15/14.
Number of reflections collected	5968
Number of independent reflections	5660 [R(int) = 0.0977]
Max/min transmission	0.422/1.0
Completeness to θ = 25.87°	99.4%
Refinement method	full-matrix least-squares on F^2
Data/restraints/parameters	5660/0/354
Goodness-of-fit	0.927
Final R indices [$I > 2\sigma(I)$]	R_1 = 0.0511, wR_2 = 0.0888
R indices (all data)	R_1 = 0.2655, wR_2 = 0.1229
Largest difference peak/hole	0.564/−1.203 e/Å^3

Acknowledgments

One-Dimensional Cd^{II} Coordination Polymers: Solid Solutions with Ni^{II}, Thermal Stabilities and Structures

Dejana Vujovic,*[a] Helgard G. Raubenheimer,[a] and Luigi R. Nassimbeni[b]

Keywords: Coordination polymers / Solid solutions / Cadmium complexes

Reactions of $Cd(NCS)_2$ with 2-, 3- and 4-aminobenzonitrile ligands (2ABN, 3ABN and 4ABN respectively) have produced one-dimensional chain polymers of the general formula $[M(NCS)_2(ABN)_2]_n$ with the metal centres linked by double NCS^- bridges. The three cadmium polymers $[Cd(NCS)_2(3ABN)_2]_n$ (**1**), $[Cd(NCS)_2(2ABN)_2]_n$ (**2**) and $[Cd(NCS)_2(4ABN)_2]_n$ (**3**) all differ in their hydrogen-bonding patterns. In terms of ABN coordination, both **1** and **2** exhibit terminal amine coordination while in **3** the ABNs are coordinated through the cyano groups. Crystalline solid solutions of **1** of general formula $[Cd_{1-x}Ni_x(NCS)_2(3ABN)_2]_n$, containing nickel and cadmium in varying proportions, have also been prepared in order to establish the influence of the metal ratio on the thermal stability and bonding parameters of the polymers. The coordination polymers are not good candidates for forming clathrates while their thermal stability (ranging between 147 and 244 °C) depends on the position of functional groups on the ABN ligands and on the Cd:Ni ratio in the solid solutions. The new polymers have been characterised by single crystal X-ray diffraction, X-ray powder diffraction, electron microscopy, infrared spectroscopy, thermogravimetry and differential scanning calorimetry.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

Self-assembled coordination polymers have attracted considerable recent interest due to both their many interesting architectures[1−6] and numerous applications.[7−9] Such systems are often tunable by making subtle changes to the reaction conditions, such as the choice of counterion and solution pH, that allow the deliberate design of compounds with luminescent,[10] superconducting[11,12] or magnetic properties[13,14] and also compounds that can be used as nanofibres,[15] in catalysis,[16] in separation processes,[17,18] for gas and liquid storage[19] and in nonlinear optics.[20,21]

We have prepared previously one-dimensional coordination polymers of Ni^{II} with aminobenzonitrile isomers and thiocyanate ions as ligands.[22] The structural features and thermal stability of the polymers were determined by the position of the functional groups on the ABN isomers as well as the introduction of guest molecules into the structures. Furthermore, the ABN isomers not only afford hydrogen-bonded networks, but also lead to the possible formation of 1-, 2- and 3-dimensional polymer networks due to different coordination preferences such as coordination to the metal centre in monodentate (albeit ambidentately using either amine or cyanide nitrogens), bidentate (2ABN) or in a bridging fashion (using both nitrogen donors).

Most studied coordination polymers are unimetallic. Addition of a second metal to inorganic compounds is a well-established procedure in industry to modify and improve material properties. Studies on bimetallic coordination polymers usually involve either two different metals in different[23] or similar[24] oxidation states or the same metal in two different oxidation states.[25] The resultant new structure usually differs significantly from the starting one, with the two metals located in different positions along the polymeric chain. Coordination compounds with both metals at the same site of an unchanged structure have also been investigated; this work also concentrates on such bimetallic compounds. Magnetic phase transition studies are an example of this type of work. They involve Hofmann-type clathrates of the general formula $M(NH_3)_2M'(CN)_4{\cdot}2G$ (where M and M′ are transition metals), the magnetic properties of which are affected by diluting one of the metal sites with another metal located at the same position in the overall structure.[26−29]

Extensive studies have been carried out over the past three decades on coordination compounds of SCN^- using various transition metals. Most early work again involved Hofmann-type compounds, which, over the years, has expanded to include the design of materials and architectures with specific properties. SCN^- is a highly versatile ligand with both terminal and bridging coordination possibilities. As a terminal ligand it is either *S*- or *N*-coordinated, while as a bridging ligand it is most often coordinated in a bidentate or tridentate fashion (however, 13 possible bonding

[a] Department of Chemistry, University of Stellenbosch, Private Bag X1, Matieland 7602, South Africa
[b] Department of Chemistry, University of Cape Town, Rondebosch 7701, South Africa

modes have been identified).[30] The result is a wide variety of possible complexes, clusters and polymers (1-D single, double and triple bridged chains and 2-D and 3-D networks).[31,32]

Here, as part of a continuing study, we report on the structural and thermal influence of a metal on coordination polymers. This has been achieved by (i) changing the metal centre from Ni^{II} to Cd^{II} and/or (ii) introducing both metals in different ratios into the starting mixtures. Changing the metal centre from Ni^{II} to Cd^{II} afforded dramatically different polymeric structures **2** and **3** with 2ABN and 4ABN ligands in the presence of thiocyanate. Conversely, when $Cd(NCS)_2$ is treated with 3ABN the resultant polymer **1** is isostructural with its nickel counterpart, giving the option of introducing both metals in different proportions into such structures. Crystal structures, thermodynamic stabilities and metal concentrations in structures of the general formula $[Cd_{1-x}Ni_x(NCS)_2(3ABN)_2]_n$ have been determined by experimental methods (**4**−**7**).

Results and Discussion

Crystal Structure Analysis

Crystalline samples of the cadmium polymers were prepared by slow evaporation of mixtures of ethanolic ABN and $Cd(NCS)_2$ solutions. The crystals grew over a period of 1−3 days. Salient crystal and experimental data (Table 1) and hydrogen-bonding details (Table 2) are summarised here.

Crystal structure analysis revealed that **1** is isostructural with its previously reported nickel analogue **8**.[22] One-dimensional, double-stranded chain polymers were formed with a metal-to-3ABN ratio of 1:2. Thiocyanate double bridges propagate the chain along the crystallographic *b*-axis with the amine-bonded 3ABN ligands at axial positions. Adjacent polymer units are hydrogen-bonded through their amine and nitrile moieties, producing sheets parallel to the (011) plane. The structure of the coordination polymer **1** is shown in Figure 1.

Polymers **2** and **3** are also one-dimensional chain structures with double thiocyanate bridges. 2ABN ligands in **2** are coordinated to the metal through the amine nitrogens and are disordered over two positions (Figure 2) while 4ABN molecules in **3** are coordinated to the cadmium centres through the cyanide nitrogens (Figure 3). The disordered 2ABN molecules have site occupancies of 50% for each of the two disordered positions, A and B, with the whole structure stabilised by inter- and intramolecular hydrogen bonding. When 2ABN are in position A, each amine group is hydrogen-bonded to two adjacent cyanide ni-

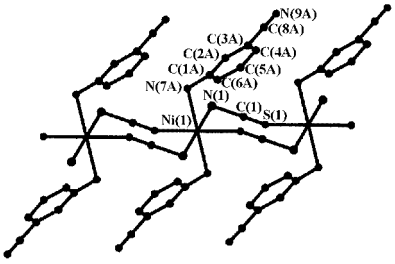

Figure 1. Section of the molecular structure of polymer **1**, showing the numbering scheme (the same numbering scheme was used for all compounds)

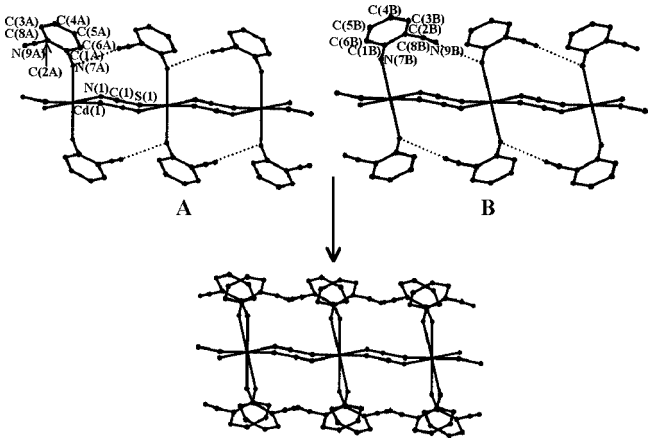

Figure 2. Section of the molecular structure of polymer **2**, showing disorder, hydrogen bonding and the numbering scheme

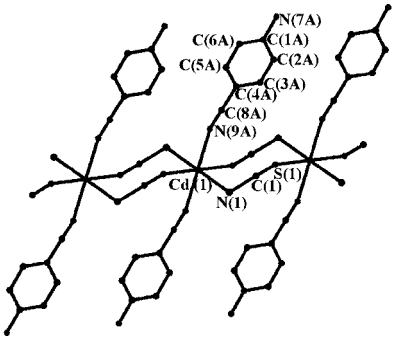

Figure 3. Section of the molecular structure of polymer **3**, showing the numbering scheme

trogens − one on the adjacent monomer unit of the same polymer strand and the other on a symmetry related strand. Intermolecular hydrogen bonding gives rise to the sheets parallel to the (110) plane. Position B only leads to intramolecular hydrogen-bonding. For **3**, only weak hydrogen bonds are present between the amine groups of one polymer strand and the thiocyanate sulfur atoms of another.

The introduction of several compounds (benzene, ABN, chloroform, toluene, naphthalene and linear and aromatic alcohols) into the respective starting mixtures afforded the polymers **1**−**6** (except for **7**) but gave no inclusion compounds. Thus, the cadmium-polymer formation is unaffected by potential guest molecules in the crystallisation medium. The only exception occurs for compound **7** when benzene is used as a guest and the nickel content in the mixed metal exceeds 75%. Here, two products are formed: the original Cd polymer **1** and the previously reported[22] nickel inclusion compound $[Ni(NCS)_2(3ABN)_2]_n$·(benzene). Interestingly, by changing the metal centre, we can suppress or activate the inclusion capability of a polymer. In addition, the introduction of a guest species in nickel polymers resulted in a structural change, due to differences in the modes of ligand coordination around the metal centre,[22] while the same was not observed with cadmium.

These results indicate different behaviours of cadmium and nickel in saturated solutions: nickel polymers can be tuned in terms of both their polymer structure and the formation of cavities, due to inclusion, while such a process is not useful for cadmium-containing compounds.

Solid solutions **4**−**7** were prepared as described in the Exp. Sect. The crystals are green, the colour intensity increasing with increasing concentration of nickel. Relatively large crystals of these bimetallic polymers were selected and then cut in two: one part for single-crystal X-ray analysis and the other for electron microscopy. This is important in avoiding ambiguous results as the ratio of each metal in the crystal could vary from batch to batch and also within the same batch. Crystals chosen for analysis were approximately 2.2 × 1.4 × 0.5 mm before cutting. The Cd:Ni ratio, determined at four sites for each crystal by electron microscopy, was reasonably homogeneous (Figure 4).

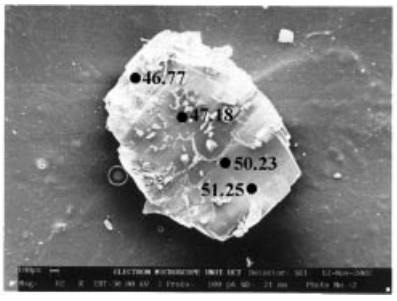

Figure 4. Electron microscopy image of a crystal of polymer **4**, showing the location and the results of measurements (as % Cd)

All four bimetallic compounds **4**−**7** are isostructural with the parent cadmium (**1**) and nickel (**8**) polymers, with the two metals occupying the same site. Structures were solved and refined by first locating all non-hydrogen atoms, then refining them anisotropically, and adding all the hydrogens to the final model. The relative metal composition in the structure was determined as the final part of refinement. The metal site was treated as being disordered as it may be occupied by a different metal atom in different unit cells. We attempted several different methods outlined in the literature:[33] (i) site occupancy values were allowed to refine while the displacement parameters remained fixed, having the same value; (ii) site occupancy values and the displacement parameters were refined simultaneously; (iii) once the site occupancy values were refined according to (i) the displacement parameters were also allowed to refine. All three

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

methods were unsuccessful in refining the four structures and, therefore, the following procedure was adopted: Site occupancies of the Ni and Cd atoms were systematically changed from 0 to 1 in 5% increments and the isotropic parameters were not constrained but instead allowed to refine. When these were in the range $0.01 < U_{iso} < 0.03$, the site occupancies were analysed in 1% increments. This technique allowed a final refinement in which the metal atoms had unconstrained anisotropic thermal parameters.

The Cd:Ni ratios determined by crystal structure refinement and electron microscopy are in very good agreement (Figure 5).

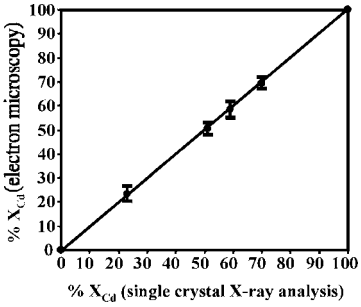

Figure 5. Percentage mol fraction cadmium, X_{Cd}, determined by electron microscopy and by single crystal X-ray diffraction refinement

For two isostructural parent compounds, where one ion is substituted by another at some sites, previous studies of inorganic solid solutions indicate that ions that can substitute one another[34] should not differ in size by more than 10−15%, so as to prevent drastic lattice distortions or changes in packing. These lattice distortions were not observed in our study even though the radii[35] of Cd^{2+} and Ni^{2+} are 0.95 and 0.69 Å, respectively, corresponding to a 38% difference in size. This could be because the volume occupied by the two metal atoms in the unit cell is relatively small compared with that of all the other atoms (in thiocyanate and 3ABN ligands).

Table 3. Selected bond lengths and angles

	Bond lengths (Å)			Bond angles (°)
	M−NCS	M−SCN	M−NH_2	N−M−S
1	2.293(1)	2.709(2)	2.389(2)	93.91(4)
2	2.313(1)	2.719(5)	2.391(5)[a] 2.445(6)[b]	91.03(4)
3	2.290(3)	2.722(1)	[c]	90.92(9)
4	2.215(3)	2.662(1)	2.320(2)	93.69(6)
5	2.158(4)	2.633(1)	2.273(3)	93.35(4)
6	2.159(2)	2.631(1)	2.272(2)	93.37(4)
7	2.065(1)	2.577(1)	2.188(1)	93.08(3)
8[22]	2.016(1)	2.544(1)	2.137(1)	92.98(3)

[a] Ring A. [b] Ring B. [c] Cd−NC = 2.341(3) Å.

Table 3 shows selected bond lengths and angles involving the metal centre; all values are typical for such types of interactions.

Vegard's Law[36] states that in solid solutions of isostructural compounds (i) the unit cell volume is proportional to the cube of the mean ionic radius and (ii) the unit cell dimensions (as well as mean bond lengths involving the metal atom) are linearly dependent on metal ion concentrations that are being substituted. We found that the unit cell dimensions (Table 1), unit cell volumes (Figure 6) and mean metal−ligand bond lengths (Figure 7) are indeed linearly dependent on the relative concentrations of the central cations, decreasing as Cd^{2+} is increasingly replaced by Ni^{2+}.

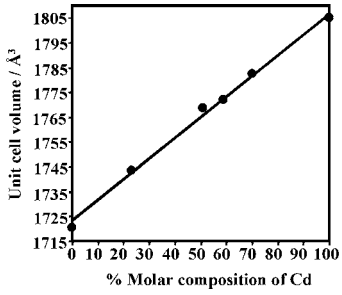

Figure 6. Unit cell volume vs. percentage molar composition of Cd

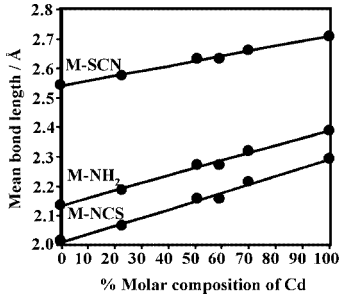

Figure 7. M−NCS bond length vs. percentage molar composition of Cd

We found parabolic behaviour instead of a linear correlation for the volume/ionic radii relationship (Figure 8). This has been observed in other situations before and is probably due the large difference in Cd and Ni ionic radii.[28]

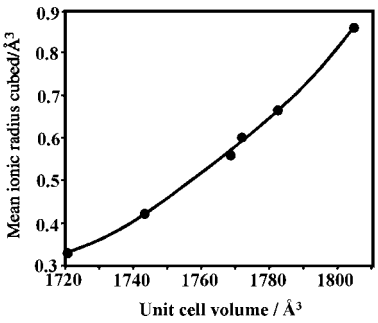

Figure 8. Cube of the mean ionic radii vs. unit cell volume

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

Infrared spectroscopy data substantiates a previous finding that NCS^- ligands acting as end-to-end bridging groups have CN stretching vibrations greater than 2100 cm^{-1}.[37] $\tilde{\nu}$(CN) for polymers **1**−**8** is 2124, 2125, 2123, 2124, 2122, 2121, 2118 and 2119 cm^{-1} respectively.

Elemental analysis results agree with the theoretical values. For **4**−**7**, calculated values were based on the relative amounts of cadmium and nickel determined by X-ray analysis, and were found to be in remarkably good agreement with the experimental values, indicating that the average composition of each batch is very close to that of the crystal chosen for X-ray analysis.

X-ray powder diffraction was used to confirm that all samples were uniform in that no structurally different compounds were present in the batch. In all instances, the calculated and experimental XRPD traces of product mixtures agreed; all peaks were present at the correct angular positions and with the correct relative intensities. For solid solutions **4**−**7** the calculated XRPD patterns are virtually identical, with only slight variations in some of the relative peak intensities. Therefore, this method was not sufficiently sensitive to differentiate between different ratios of the two metals present.

Thermal Analysis

Thermal analysis results are summarised in Table 4. For all compounds, the TG and DSC traces have the same profiles. TG traces consist of one-step mass losses due to the loss of two ABN ligands and a corresponding endotherm in the DSC trace. Experimental and calculated mass loss values are in good agreement (based on the composition determined by X-ray analysis).

We were able to determine the thermal stability of the polymers by measuring the onset temperature[38] (T_{on}) of decomposition due to the loss of two ABN ligands. The results show that thermal degradation of **1** and **2** occurs at the same onset temperature while polymer **3** is the most stable. For bimetallic polymers **4**−**7**, the results (Figure 9) indicate that their thermal stability is proportional to the amount of nickel present. This is to be expected as the higher percentage of cadmium causes the bonds (M−NCS, M−SCN and M−NH_2) around the metal centre to lengthen and, therefore, to weaken (Table 3). This result also accords with the rationalisation usually given for the relative positions of the main group cations in the Irving−Williams series.

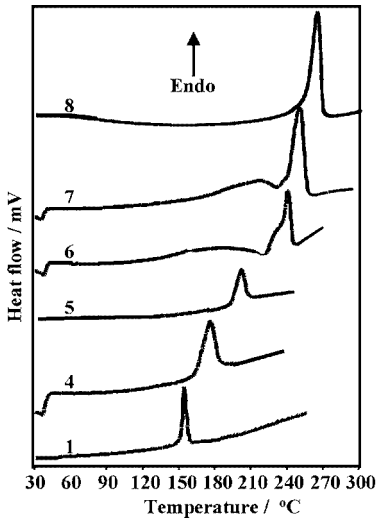

Figure 9. DSC results: migration of decomposition endotherm with changing Cd:Ni ratio

Conclusion

Aminobenzonitrile ligands can be used in the design and manipulation of new polymer architectures and their properties. In addition, the choice of metal ion influences the inclusion properties, thermal stability and structural features of the resultant coordination polymer. For example, at least one of the following is observed for the nickel and cadmium polymers (presented here and previously reported[22]): (i) the functionality through which ABNs are coordinated changes; (ii) both ABN and NCS^- ligands change their bonding environments from bidentate to monodentate coordination and vice versa; (iii) bridging and axial ligands are interchanged, (iv) inclusion properties are drastically affected and (v) thermal stability is influenced.

Comparison of all Ni and Cd polymer structures shows that, by changing the metal centre and/or adding a guest to the starting mixture, we can obtain three different polymer motifs (Scheme 1) that have different hydrogen-bonding capabilities, metal coordination environments and possible magnetic properties. [The nickel(II) coordination polymer, $Ni(NCS)_2(imidazole)_2$, which contains double thiocyanate bridges has been shown to exhibit long-range magnetic ordering.[39]]

Table 4. Thermal analysis data

	Polymer	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**[22]

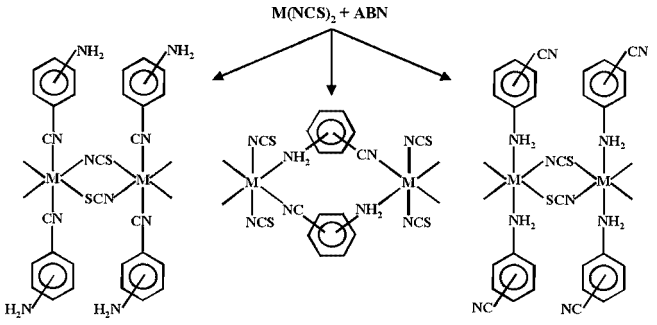

Scheme 1

By means of Vegard's Law,[36] it is possible to predict the composition of these solid solutions and, conversely, to ascertain their thermal stability from their composition.

We are currently attempting to develop a crystallisation methodology that would result in 2- and 3-dimensional ABN coordination polymers.

Experimental Section

Preparation of $[Cd(NCS)_2(3ABN)_2]_n$ (1), $[Cd(NCS)_2(2ABN)_2]_n$ (2) and $[Cd(NCS)_2(4ABN)_2]_n$ (3): The appropriate ABN isomer (0.047 g, 0.4 mmol) was dissolved in ethanol (0.5 mL) and added to ethanolic $Cd(NCS)_2$ solution (0.10 mmol·mL^{-1}, 1 mL). The resultant solution was then left to evaporate slowly, and gave colourless rectangular plate crystals within 24−72 h. Yield: **1**: 69%; **2**: 52%; **3**: 78%. **1:** $C_{16}H_{12}CdN_6S_2$; (464.84): calcd. C 41.34, H 2.60, N 18.08, S 13.80; found: C 41.34, H 2.41, N 18.06, S 13.73. **2**: $CdC_{16}H_{12}N_6S_2$ (464.84); for **2**: calcd. C 41.34, H 2.60, N 18.08 and S 13.80; found C 41.34, H 2.22, N 18.06, S 13.73. **3:** $CdC_{16}H_{12}N_6S_2$ (464.84):calcd. C 41.34, H 2.60, N 18.08, S 13.80 found C 41.35, H 2.52, N 18.10, S 13.77.

Preparation of Solid Solutions $[Cd_{1-x}Ni_x(NCS)_2(3ABN)_2]$ 4−7: 3ABN (0.35 g, 3.0 mmol) was dissolved in ethanol (3 mL) and added to solutions containing Ni^{II} and Cd^{II} in different ratios. To prepare the required metal ratios, ethanolic solutions of $Cd(NCS)_2$ (0.10 mmol·mL^{-1}) and $Ni(NCS)_2$ (0.20 mmol·mL^{-1}) were used. The solution of **4** contained $Ni(NCS)_2$ (1.25 mL) and $Cd(NCS)_2$ (7.50 mL) so that the Ni:Cd ratio was 25:75 while for **5** (Ni:Cd = 37:63) $Ni(NCS)_2$ (1.85 mL) and $Cd(NCS)_2$ (6.30 mL) were used. Compounds of **6** and **7** were prepared by adding $Ni(NCS)_2$ (2.50 and 3.75 mL) to $Cd(NCS)_2$ (5.0 and 2.5 mL) to give Ni:Cd ratios of 50:50 and 75:25 respectively. Crystals were obtained after 2−5 days for **4** and **5**, two weeks for **6** and approximately four weeks for **7**. The crystals varied from light green (**4**) to dark green (**7**) depending on the amount of nickel present. **4:** $C_{16}H_{12}Cd_{0.70}N_6Ni_{0.30}S_2$ (448.73): calcd. C 42.83, H 2.70, N 18.73, S 14.29; found C 42.72, H 2.58, N 18.69 and S 14.45. **5:** $C_{16}H_{12}Cd_{0.59}N_6Ni_{0.41}S_2$: (442.82): calcd. C 43.40, H 2.73, N 18.98, S 14.48; found C 43.21, H 2.52, N 19.05 and S 14.58. **6:** $C_{16}H_{12}Cd_{0.51}N_6Ni_{0.49}S_2$ (438.53): calcd. C 43.82, H 2.76, N 19.16, S 14.62; found C 43.94, H 2.48, N 19.24 and S 14.53. **7:** $C_{16}H_{12}Cd_{0.23}N_6Ni_{0.77}S_2$ (429.49): calcd. C 45.38, H 2.86, N 19.85, S 15.14; found C 45.62, H 2.52, N 19.58, S 15.26.

Thermal Analysis: Samples were crushed, blotted dry and sieved (Nybolt mesh) prior to analysis and then placed in open platinum pans for thermogravimetric (TG) experiments and in crimped but vented aluminium pans for differential scanning calorimetry (DSC). TG and DSC were carried out on a Perkin−Elmer PC7-Series system over the range 30−500 °C, at a heating rate of 20 °C min^{-1}, with a purge of dry nitrogen (30 mL·min^{-1}). Thermal analysis experiments depend on sample preparation, instrument geometry and heating rates. Particle size in particular can have a significant influence on the onset temperature of the thermal events[40]. Therefore, care was taken to prepare all samples in the same, reproducible manner. Each sample was sieved through a Nybolt mesh with a pore size of 17−80 μm.

Structure Determination: Cell dimensions were obtained from the intensity data measurements on a Nonius−Kappa CCD diffractometer using graphite-monochromated Mo-K_α radiation (λ = 0.71069 Å). The strategy for data collection was evaluated using the COLLECT[41] software. For all five structures, data were collected at 173(2) K using standard φ-scan and ω-scan techniques. All sets of data were scaled and reduced using DENZO-SMN.[42] Structures were solved by direct methods using SHELX-86[43] and refined by full-matrix least-squares with the program SHELX-97,[44] refining on F^2. The program X-Seed[45] was used as a graphical interface for structure solution and refinement using SHELX. No absorption corrections were necessary. Important crystal and experimental data for all five structures are given in Table 1.

Elemental Analysis: Elemental analyses to determine the percentages of C, H, N, and S were made on a Carlo−Erba 1106 Elemental Analyser. For each sample, the analysis was carried out in duplicate.

Infrared Spectroscopy: IR spectra were recorded using a Perkin−Elmer 983 IR spectrophotometer and NaCl plates. Samples were run as Nujol mulls over the range 4000−400 cm^{-1} and analysed for the mode of thiocyanate coordination.

Electron Microscopy: Single crystals were mounted using carbon glue and coated with a layer of pure carbon by vacuum evaporation. The analysis was performed on a Leo S440, fully analytical electron microscope with a KEVEX energy dispersive spectrometer. Data were collected at 30 kV with a beam current of 100 pA at a distance of 20 mm, tilt angle of 0° and a take-off angle of 35°. The results were analysed using the KEVEX Sigma Quasar Pro program.

X-ray Powder Diffraction (XRPD): X-ray powder diffraction patterns were measured using a Philips PW1050/25 goniometer with nickel-filtered Cu-K_α radiation. Samples were packed in aluminium sample holders and a step size of 0.1° at a scan rate of 1 s per step in the 2θ range 6−40° was employed for analysis. Calculated XRPD traces were generated for comparison purposes from the crystal structure results using the program LAZYPULVERIX.[46] CCDC-233623 to -233629 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Kinetics and Mechanism of Oxidation of Fe^{2+} by the Tris(biguanide)manganese(IV) Ion in Aqueous Acid Media

Basab Bijayi Dhar,[a] Ritam Mukherjee,[a] Subrata Mukhopadhyay,*[a] and Rupendranath Banerjee[a]

Keywords: Iron / Kinetics / Manganese / Mechanism / Redox chemistry

Tris(biguanide)manganese(IV), $[Mn(LH_2)_3]^{4+}$ (LH_2 = biguanide, $C_2N_5H_7$), quantitatively oxidises Fe^{2+} to Fe^{3+} and is itself reduced to Mn^{2+} with almost quantitative (> 95%) release of biguanide. The reaction rate strongly depends on added Fe^{3+}; in the presence of externally added Fe^{3+}, the reaction shows a clear first-order dependence in $[Mn^{IV}]$, whereas in the absence of any added Fe^{3+}, an initial quick loss of Mn^{IV} is associated with a subsequent very sluggish decay. Two consecutive one-electron transfer inner-sphere steps are proposed for the entire redox process where $[Mn(LH_2)_3]^{3+}$, the initial one-electron-reduced product of Mn^{IV}, is believed to be a steady-state intermediate.

Introduction

The aqueous solution chemistry of mononuclear Mn^{IV} is very scarce due to the extreme paucity of soluble Mn^{IV} species. However, the recently reported[1] tris(biguanide)-manganese(IV) complex $[Mn(LH_2)_3]^{4+}$ (**1**; Figure 1, LH_2 = biguanide, $C_2N_5H_7$) is structurally well characterised and is a rare example of a water-soluble mononuclear Mn^{IV} complex that is stable over a wide range of acidity (10^{-6} to 2 M). Figure 2 displays its UV/Vis spectrum at pH 2.0. Some oxo-bridged di-, tri- and tetranuclear Mn^{IV} complexes[2] are also stable in aqueous solution and have interesting solution chemistry,[3] but their mononuclear counterparts are unknown.

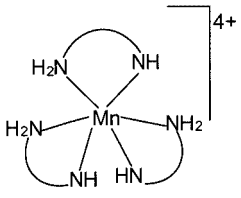

Figure 1. Structure of $[Mn(LH_2)_3]^{4+}$ (**1**)

We report here the kinetics of oxidation of Fe^{2+} by the title Mn^{IV} complex in aqueous acidic media to elucidate the mechanistic aspects of the process as a part of our continued interest[3] in the aqueous solution chemistry of higher-valent manganese species.

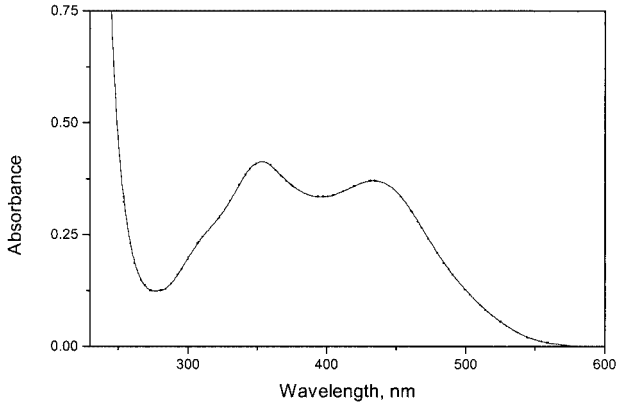

Figure 2. UV/Vis spectrum of 0.050 mM complex at pH 2.0

Results and Discussion

Equilibrium Studies

The built-in program of the Metrohm 736 GP Titrino autotitrator yielded two pK_a values for the title complex from the pH-titration curve: pK_{a1} = 5.30 ± 0.20 and pK_{a2} = 7.60 ± 0.30. The Mn^{IV} in the complex is coordinatively saturated and any deprotonation should thus arise from the ligand biguanide moiety, possibly from protons bound to sp^2 nitrogens as in an analogous Ag^{III} complex or in $[Co^{III}(am)(LH_2)_2]^{2+}$ (am = amino acids like glycine,

alanine, etc.).[4a,4b] In $[Co^{III}(LH_2)_2(H_2O)_2]^{3+}$, however, coordinated water is deprotonated.[4c] Table 1 summarises the known acidity constants of some biguanide complexes.

Table 1. Deprotonation constants of metal biguanide complexes[a]

Metal complex	pK_{a1}	pK_{a2}	Reference
$[Ag^{III}(enbbg)]^{3+}$	3.80	6.30	[4a]
$[Co^{III}(gly)(LH_2)_2]^{2+}$	9.06	10.4	[4b]
$[Co^{III}(L\text{-ala})(LH_2)_2]^{2+}$	9.07	10.4	[4b]
$[Co^{III}(LH_2)_2(H_2O)_2]^{3+}$	5.86	7.92	[4c]
$[Mn^{IV}(LH_2)_3]^{4+}$	5.30	7.60	this work

[a] enbbg = ethylenebis(biguanide), gly = glycine, L-ala = L-alanine.

Stoichiometry and Reaction Products

The results of the stoichiometry experiments (Table 2) yielded $\Delta[Mn^{IV}]/\Delta[Fe^{2+}] = 0.49 \pm 0.03$ and $\Delta[Mn^{IV}]/\Delta[Fe^{3+}] = 0.53 \pm 0.04$. The product solution, after removing iron, displays a typical six-line EPR spectrum of Mn^{II} ($I = 5/2$). Hence, Equation (1) describes the overall redox process.

$$Mn^{IV} + 2Fe^{2+} \rightarrow Mn^{II} + 2Fe^{3+} \quad (1)$$

Iodometric determination of copper in the cupric biguanide precipitated from the product solution indicated release of more than 95% of the biguanide.

Kinetics

The reaction of complex **1** reacting with excess Fe^{2+} does not represent well-behaved kinetics; an initial quick loss in absorbance of **1** is followed by a sluggish phase, and the absorbance vs. time data do not follow first-order kinetics, as shown in Figure 3. In the presence of added Fe^{3+}, the initial loss in absorbance is prevented and the whole reaction course follows first-order kinetics (Figure 3) — the $\ln(A_t - A_\infty)$ vs. time plots were found to be linear to more than 90% completion of the reactions. In all kinetic runs A_∞ values were less than 0.01. Most of the kinetics were therefore determined in the presence of added Fe^{3+}. The first-order rate constants, k_o, defined by Equation (2) were obtained from least-squares slopes of these plots and are presented in Table 3. Moreover, a tenfold variation in the initial Mn^{IV} concentration (0.02 −0.20 mM) gave no change in the k_o values within experimental uncertainty (± 5%). This indicates a first-order decay of Mn^{IV} concentration.

$$-d[Mn^{IV}]/dt = k_o[Mn^{IV}] \quad (2)$$

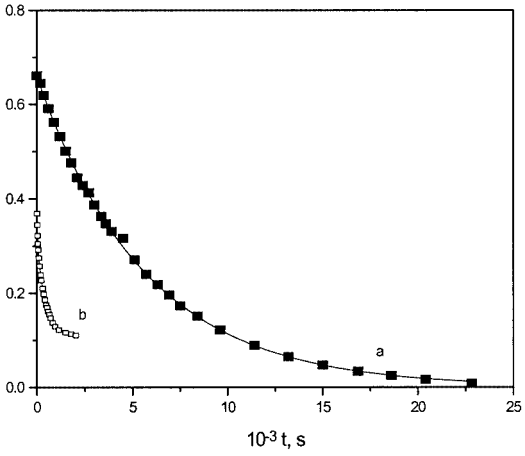

Figure 3. Absorbance vs. time graph for the reduction of $[Mn(LH_2)_3]^{4+}$ (0.10 mM) by Fe^{2+} (5.0 mM): a) in the presence of added Fe^{3+} (0.50 mM); b) in the absence of added Fe^{3+}; $[H^+]$ = 1.3 mM, I = 1.0 M, T = 25.0 °C

At fixed $[Fe^{3+}]_T$ (= $[Fe^{3+}]_{aq}$ + $[Fe(OH)^{2+}]_{aq}$) and $[H^+]$, the plot of $[Fe^{2+}]_T^2/k_o$ vs. $[Fe^{2+}]_T$, (= $[Fe^{2+}]_{aq}$ + $[Fe(OH)^+]_{aq}$) is a straight line with definite intercept and slope (Figure 4). Also, at fixed $[Fe^{2+}]_T$ and $[H^+]$, the plot of $1/k_o$ vs. $[Fe^{3+}]_T$ is a straight line with finite intercept. Plots of k_o versus $[H^+]$ at fixed $[Fe^{2+}]_T$ and $[Fe^{3+}]_T$ have a bell shape (Figure 5) indicating the involvement of at least two protic equilibria[5] in the reaction. We also observed that in the presence of 6% (v/v) acrylonitrile no polymeric products were formed, thus perhaps eliminating any detectable generation of free radicals during the reaction. Equations (3)−(8) provide a reasonable explanation of the kinetic observations.

[a] Concentration of complex used: 0.10 mM. The k_o values calculated using Equation (9a) are given in parentheses.

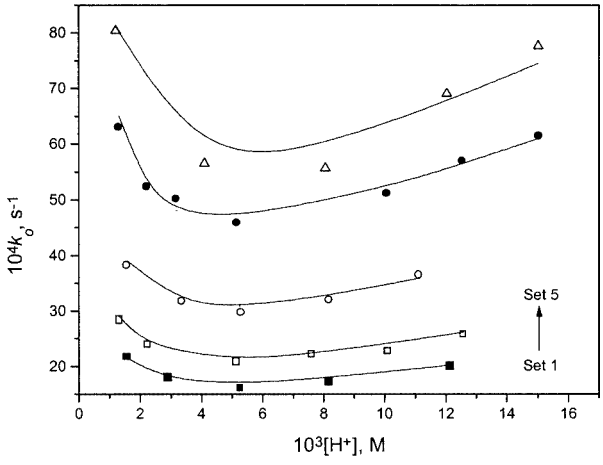

Figure 5. Plot of k_o vs. $[H^+]$; [complex] = 0.10 mM. set 1: $[Fe^{2+}]_T$ = 30.0 mM, $[Fe^{3+}]_T$ = 1.0 mM, $[H^+]$ = (1.5−12.2) mM; set 2: $[Fe^{2+}]_T$ = 30.0 mM, $[Fe^{3+}]_T$ = 0.50 mM, $[H^+]$ = (1.3−12.6) mM; set 3: $[Fe^{2+}]_T$ = 45.0 mM, $[Fe^{3+}]_T$ = 1.0 mM, $[H^+]$ = (1.5−11.2) mM; set 4: $[Fe^{2+}]_T$ = 60.0 mM, $[Fe^{3+}]_T$ = 0.50 mM, $[H^+]$ = (1.3−15.0) mM; set 5: $[Fe^{2+}]_T$ = 60.0 mM, $[Fe^{3+}]_T$ = 0.30 mM, $[H^+]$ = (1.2−15.0) mM. I = 1.0 M, T = 25.0 °C for all experiments

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

The plots of the left-hand-side of Equation (9) versus $[H^+]$ at different, fixed $[Fe^{2+}]_T$ and $[Fe^{3+}]_T$ are excellent straight lines (Figure 6; $r > 0.98$), which indicates that $C[H^+]^2 << (A + B[H^+])$ and $(E[H^+] + F[H^+]^2) << D$. Equation (9) therefore simplifies to Equation (10) as K_a $(= 10^{-8.1})$[6] $<<$ $[H^+]$.

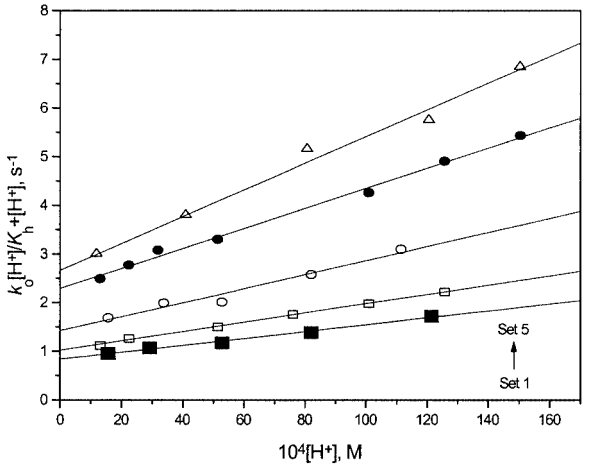

Figure 6. Plot of Y vs. $[H^+]$; [complex] = 0.10 mM; set 1: $[Fe^{2+}]_T$ = 30.0 M, $[Fe^{3+}]_T$ = 1.0 mM, $[H^+]$ = (1.5−12.2) mM; set 2: $[Fe^{2+}]_T$ = 30.0 mM, $[Fe^{3+}]_T$ = 0.50 mM, $[H^+]$ = (1.3−12.6) = mM; set 3: $[Fe^{2+}]_T$ = 45.0 mM, $[Fe^{3+}]_T$ = 1.0 mM, $[H^+]$ = (1.5−11.2) mM, Set 4: $[Fe^{2+}]_T$ = 60.0 mM, $[Fe^{3+}]_T$ = 0.50 mM, $[H^+]$ = (1.3−15.0) mM; set 5: $[Fe^{2+}]_T$ = 60.0 mM, $[Fe^{3+}]_T$ = 0.30 mM, $[H^+]$ = (1.2−15.0) mM. I = 1.0 M, T = 25.0 °C for all experiments

$$k_o[H^+]/(K_h + [H^+]) = (A + B[H^+])/D \quad (10)$$

The elaborated form of Equation (10) is:

LHS = Y (for example) = $[Fe^{2+}]_T^2\{K_a^2k_2k_4 + K_a(k_2k_3 + k_1k_4)[H^+]\}/[Fe^{3+}]_Tk_{-2}K_hK_a + [Fe^{2+}]_TK_hK_aK_4$

or

$$[Fe^{2+}]_T^2/Y = (k_{-2}K_hK_a/a)\,[Fe^{3+}]_T + (k_4K_hK_a/a)\,[Fe^{2+}]_T \quad (11)$$

where $a = K_a^2k_2k_4 + K_a(k_2k_3 + k_1k_4)[H^+]$. Equation (11) explains the observed linear plots of $[Fe^{2+}]_T^2/k_o$ versus $[Fe^{2+}]_T$ at fixed $[Fe^{3+}]_T$ and $[H^+]$ and also the linear plots of $1/k_o$ versus $[Fe^{3+}]_T$ at fixed $[Fe^{2+}]_T$ and $[H^+]$. From the linear plots of Y versus $[H^+]$ (Figure 6), the slopes and intercepts yielded, respectively, $B/D = \{[Fe^{2+}]_T^2(k_2k_3 + k_1k_4)/K_h([Fe^{3+}]_Tk_{-2} + [Fe^{2+}]_Tk_4)\}$ and $A/D = \{[Fe^{2+}]_T^2K_ak_4k_2/K_h([Fe^{3+}]_Tk_{-2} + [Fe^{2+}]_Tk_4)\}$. The slope/intercept of these plots yield B/A $[= (k_2k_3 + k_1k_4)/K_a\,k_2k_4] = 92.6 \pm 2.0\ M^{-1}$ at 25.0 °C and I = 1.0 M. We determined A/D and B/D values at different, fixed $[Fe^{2+}]_T$ and $[Fe^{3+}]_T$. These values were used to plot $[Fe^{2+}]_T/(A/D)$ vs. $[Fe^{3+}]_T/[Fe^{2+}]_T$ and $[Fe^{2+}]_T/(B/D)$ vs. $[Fe^{3+}]_T/[Fe^{2+}]_T$. As expected, these were found to be good straight lines ($r > 0.98$) and yielded k_{-2}/k_4 (= 28.0 ± 2.0) and k_2 $[= (1.28 \pm 0.1) \times 10^4\ M^{-1}s^{-1}]$ from their slopes and intercepts using known K_a and K_h $(= 10^{-2.7})$[7] values. The composite constants $(k_3k_2 + k_4k_1)/k_4$ $[= (1.0 \pm 0.01) \times 10^{-2}]$ and $(k_3k_2 + k_4k_1)/k_{-2}$ (= 3007 ± 150) were also determined from the slopes and intercepts.

Equations (12)−(16) can explain the kinetic observations equally well. Here, Fe^{2+} hydrolysis is neglected and replaced by the deprotonation equilibrium of **1**.

$$[Mn(LH_2)_3]^{4+} \underset{}{\overset{K_a}{\rightleftharpoons}} [Mn(LH_2)_2(LH)]^{3+} + H^+ \quad (12)$$
1 **1a**

$$[Mn(LH_2)_3]^{4+} + Fe^{2+}_{aq} \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} [Mn(LH_2)_3]^{3+} + Fe^{3+}_{aq} \quad (13)$$

$$[Mn(LH_2)_2(LH)]^{3+} + Fe^{2+}_{aq} \underset{k_{-2}}{\overset{k_2}{\rightleftharpoons}} [Mn(LH_2)_3]^{3+} + Fe(OH)^{2+}_{aq} \quad (14)$$
1a

$$Fe^{3+}_{aq} \overset{K_h}{\rightleftharpoons} Fe(OH)^{2+}_{aq} + H^+ \quad (15)$$

$$[Mn(LH_2)_3]^{3+} + Fe^{2+}_{aq} \xrightarrow{k_3} \text{Products} \quad (16)$$

Proceeding in the same way as above gives $k_1 = (1.0 \pm 0.01) \times 10^{-2}\ M^{-1}s^{-1}$, $k_2 = 21.5 \pm 0.5\ M^{-1}s^{-1}$ and $k_{-2}/k_3 = 28.0 \pm 2.0$.

Mechanism

We like to allow less importance to Equations (12)−(16) as it is unusual[8] that a deprotonated species of a higher valent transition metal complex is more reactive (k_2) than its conjugate acid (k_1). Further, this flouts the well-known fact that $Fe(OH)^+_{aq}$ is much more reactive than Fe^{2+}_{aq} in redox reactions and $Fe(OH)^+_{aq}$ is a kinetically reactive species even in moderately acidic media.[6]

The value of k_2 evaluated from Equations (3)−(8) indicates a very high reactivity of $Fe(OH)^+_{aq}$ in reducing the title Mn^{IV} complex. A similar situation has been found with the reduction of Ni^{IV}-oxime.[6] There, $Fe(OH)^+_{aq}$ is about 10^5 times more reactive than Fe^{2+}_{aq}. Although it was not possible to extract the absolute value of k_4, we expect it also to be high. Our results also indicate, at best, a poor contribution of Fe^{3+}_{aq} (k_{-1} path) in reoxidising the Mn^{III} species; $Fe(OH)^{2+}_{aq}$ (k_{-2} path) is almost wholly responsible for this. The pattern of reactivity established with Fe^{III}, Mn^{III}, Ag^{II} and Co^{III} as inner-sphere oxidants also revealed a significant contribution of the M−OH path to the overall rate.[9] In contrast, aqua complexes generally predominate for outer-sphere reactions, with little or no contribution from the M−OH path. In the present case, the hydroxo species $Fe(OH)^{2+}_{aq}$ and $Fe(OH)^+_{aq}$ are kinetically superior to their corresponding conjugate acids. Such a situation is likely with inner-sphere reactions, possibly by hydrogen bonding of the OH group to an NH or NH_2 group of the ligand biguanide.

Experimental Section

Materials: The complex salt $[Mn(C_2N_5H_7)_3]_2SO_4(NO_3)_6{\cdot}3H_2O$ was prepared by a known procedure.[1] The crystals obtained were sufficiently pure, as indicated by satisfactory elemental analysis (calcd. C 11.63, H 3.88, N 40.71; found C 11.3, H 3.9, N 39.9). A stock solution of $Fe(ClO_4)_2$ was prepared by dissolving pure iron powder (G. R., E. Merck) in a slight stoichiometric excess of $HClO_4$ under an N_2 atmosphere. These solutions were prepared just prior to use for kinetic measurements. This solution was estimated by the dichromate oxidation method.[10] $Fe(ClO_4)_3$ solutions were prepared by dissolving freshly precipitated $Fe(OH)_3$ in a stoichiometric excess of $HClO_4$. In solution, Fe^{3+} was estimated by measuring the absorbance of $[Fe(SCN)]_{aq}^{2+}$ (ε = 5000 $M^{-1}cm^{-1}$) at 460 nm after the addition of NH_4SCN solution.[11,12] The free-acid content in both of these iron solutions were measured by passing them separately through a Dowex 50 W X-8 strong cation-exchange resin in the H^+ form to obtain $[H^+]$ equivalent to the metal-ion concentration along with free acid and then subtracting the metal equivalent from these. An aqueous solution of $NaClO_4$ (G. R., E. Merck) was standardised by passing through a Dowex 50 W X-8 strong cation-exchange resin in the H^+ form and titrating the liberated acid with standard NaOH to a phenolphthalein end-point. The total acid content of the reaction mixtures was calculated as added acid plus that produced by the hydrolysis of ferric ion. All other chemicals were of reagent grade and used as received. Doubly distilled, freshly boiled water was used throughout.

Physical Measurements and Kinetics: All absorbances and electronic spectra were recorded with a Shimadzu (1601 PC) spectrophotometer using 1.00 cm quartz cells. The kinetics were monitored in situ in the "kinetic mode" of the instrument at 433 nm, one of the absorption peaks (Figure 2) of the complex **1**, in an electrically controlled thermostatted (25.0 ± 0.1 °C) cell housing (CPS-240A). For faster reactions, Fe^{2+} solution was injected directly into the spectrophotometer cell containing the other components of the reaction mixture. The desired concentration of the complex and the reducing agent was achieved after mixing. All kinetics were monitored in the presence of excess Fe^{2+} over **1** at an ionic strength 1.0 M ($NaClO_4$).

Stoichiometry and Reaction Products: The stoichiometry was measured by estimating unchanged Fe^{2+} spectrophotometrically. Reaction mixtures containing 4−10 times Fe^{2+} over **1** were allowed to react completely under an N_2 atmosphere until the solution turned colourless. Excess 1,10-phenanthroline was then added along with potassium hydrogen phthalate (pH ≈ 4). The red colour of $[Fe(phen)_3]^{2+}$ was then measured at 510 nm (ε = 11100 $M^{-1}cm^{-1}$).[11,13] In another aliquot of product solution, the Fe^{3+} produced was quantified by adding NH_4SCN and measuring the absorbance of $[Fe(SCN)]_{aq}^{2+}$ so formed at 460 nm.[11,12] A reaction mixture, initially containing 2.5 mM [Mn^{IV}], 100 mM [Fe^{2+}] and 10 mM [Fe^{3+}], stored till colourless (absorption < 0.01 at 433 nm), was treated with NaOH solution at about 50 °C with constant stirring. The pH was thus raised to about 5 and the solution was kept for about 24 hours, after which all the iron had precipitated as iron(III) hydroxide. This was removed by filtration. The pH of the resulting solution was lowered to about 1 to avoid the complexation of biguanide with Mn^{2+} and an EPR spectrum was recorded. The biguanide ligand in the product was quantitatively isolated as $[Cu(LH_2)_2]SO_4$ by the addition of $CuSO_4$. The amount of Cu^{II} thus held was determined iodometrically after decomposing the copper complex.[14]

Equilibrium Measurements: A 15 mL mixture of 1.00 mM complex and 3.00 mM $HClO_4$ was titrated with a standard NaOH solution to determine the acid dissociation constants of the title complex. The titration was carried out at 25.0 °C and I = 1.0 M ($NaClO_4$) with a Metrohm 736 GP Titrino autotitrator.

Covalent Bonding of Phosphonates of L-Proline and L-Cysteine to γ-Zirconium Phosphate

Kunlin Huang,[a] Jihong Yu,*[a] Guangmei Wang,[a] Yi Li,[a] and Ruren Xu*[a]

Keywords: Amino acids / Chirality / Phosphates / Phosphonates / Zirconium

This paper describes the synthesis and characterization of γ-zirconium phosphate-phosphonates based on chiral *N*-phosphonomethyl-L-proline [(–)-$HO_3PCH_2NHC_4H_7CO_2H$; H_3PMP] from L-proline, and *N*-phosphonomethyl-1,3-thiazolidine-4-carboxylic acid [(–)-$HO_3PCH_2NHCH_2SC_2H_3CO_2H$; H_3PMTA] from L-cysteine. Two compounds formulated as $[Zr(PO_4)(H_2PO_4)_{0.53}(H_2PMP)_{0.47}\cdot 2.0H_2O]$ [γ-ZrPMP (**1**)] and $[Zr(PO_4)(H_2PO_4)_{0.50}(H_2PMT)_{0.50}\cdot 1.6H_2O]$ [γ-ZrPMT (**2**)] were obtained by topotactic reaction of H_3PMP and H_3PMTA, respectively, with γ-ZrP in the presence of water/acetone. They possess intercalation capabilities and optical activities.

Introduction

Recently, there has been tremendous interest in the design and synthesis of chiral solids for their important applications in enantioseparation and asymmetric catalysis.[1] The chirality of these compounds mostly results from chiral organic groups,[2] therefore one strategy for obtaining solid materials with optical activity is to incorporate optically active organic moieties into the organic-inorganic hybrid frameworks.[1–3]

Zirconium phosphate (ZrP) derivatives incorporating organic functional groups are very promising materials.[4] The layered structure of ZrP provides a template surface where organic structures of virtually any nature can be chemically deposited in an orderly and predictable manner. Among the different zirconium phosphates, the high rigidity of the lamellae of γ-zirconium phosphate $[Zr(PO_4)(H_2PO_4)\cdot 2H_2O]$ allow the preparation of stable hybrid materials by topotactic exchange of dihydrogenphosphates with mono- or diphosphonic acids.[5] Their replacement may be total or partial, depending on the amount and steric volume of the phosphonate used in the topotactic exchange. Many functional groups, such as biphenylphosphonate,[6] poly(ethylene oxide) chains[7] and C_{60},[8] have been integrated into the frameworks. We therefore aimed to prepare functionalized layered γ-zirconium phosphate-phosphonates anchored with chiral groups.

Proline and its analogs or homologs are very important chiral sources that have wide applications, for instance in stereoselective synthesis,[2,9] enantioseparation[10] and biochemistry.[11] Phosphonic acid derivatives of proline are analogs of amino acids with biological activities.[12] Herein we wish to report the synthesis of functionalized γ-zirconium phosphate-phosphonates based on chiral *N*-phosphonomethyl-L-proline (H_3PMP), formed from L-proline, and *N*-phosphonomethyl-1,3-thiazolidine-4-carboxylic acid (H_3PMTA), formed from L-cysteine. The optical activity and intercalation properties are also discussed.

Results and Discussion

Preparation and Characterization of H_3PMP, H_3PMTA, γ-ZrPMP and γ-ZrPMT

The preparation of these compounds is outlined in Scheme 1. This method, which is based on a literature technique,[13] gave H_3PMP and H_3PMTA from the corresponding amino acids in a Mannich-type reaction in yields of 96% and 85%, respectively. γ-ZrP was prepared according to the reported procedure.[14] The specific rotations $[\alpha]_D$ of H_3PMP and H_3PMTA are −63 and −105, respectively, in aqueous solution 25 °C.

Highly crystalline $[Zr(PO_4)(H_2PO_4)_{0.53}(H_2PMP)_{0.47}\cdot 2.0H_2O]$ [γ-ZrPMP (**1**)] and $[Zr(PO_4)(H_2PO_4)_{0.50}(H_2PMT)_{0.50}\cdot 1.6H_2O]$ [γ-ZrPMT(**2**)] were prepared by treatment of H_3PMP or H_3PMTA with γ-ZrP in water/acetone (1:1, v/v) at 80 °C for 14 d, with a phosphonic acid to γ-ZrP ratio of 1. Their $[\alpha]_D$ values in HF/H_2O solution of are −16 and −21, respectively, at 25 °C.

The X-ray powder diffraction patterns of **1** and **2**, as shown in Figure 1b and c, are characteristic of layered structures[4] with a *d*-spacing of 14.2 Å and 14.1 Å, respectively.

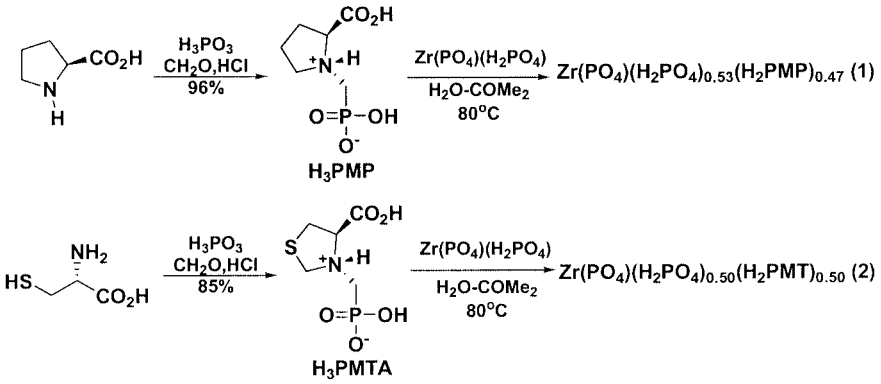

Scheme 1

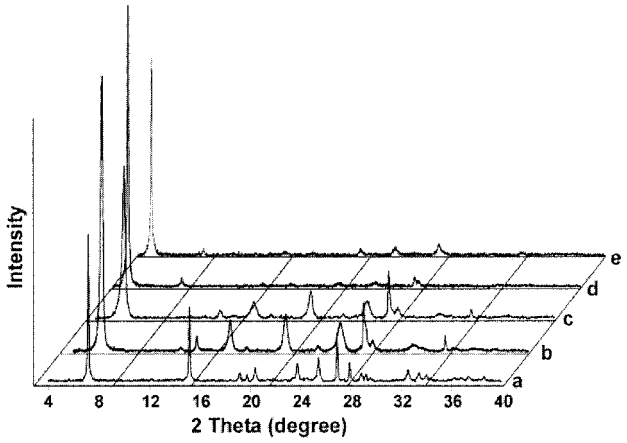

Figure 1. X-ray power diffraction patterns of: (a) γ-ZrP (*d*-spacing 12.2 Å), (b) γ-ZrPMP (**1**) (*d*-spacing 14.2 Å), (c) γ-ZrPMT (**2**) (*d*-spacing 14.1 Å), (d) **3** (*d*-spacing 21.65 Å) and (e) **4** (*d*-spacing 20.94 Å)

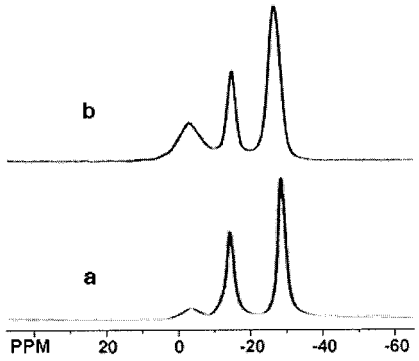

Figure 2. ^{31}P MAS NMR spectra of: (a) γ-ZrPMP (**1**) and (b) γ-ZrPMT (**2**) (δ = −28.8 ppm for PO_4^{3-}, −15.5 ppm for $H_2PO_4^-$, and −5.4 ppm for R-PO_3H^-)

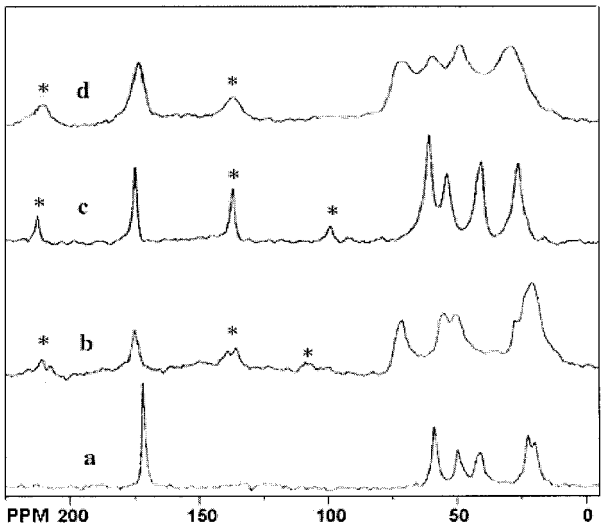

Figure 3. ^{13}C CP/MAS NMR spectra of: (a) H_3PMP, (b) γ-ZrPMP (**1**), (c) H_3PMTA, and (d) γ-ZrPMT (**2**) (asterisks denote spinning sidebands)

As shown in Figure 2, the ^{31}P solid-state MAS NMR spectra of **1** and **2** are similar: each shows three main resonances, one at δ = −28.8 ppm for PO_4^{3-}, one at δ = −15.5 ppm attributed to $H_2PO_4^-$ and one at δ = −5.4 ppm due to the phosphonate phosphorus atom. The ^{31}P MAS NMR spectra of **1** and **2** are similar to that observed for $[Zr(PO_4)(H_2PO_4)_{0.49}(C_6H_5PO_3H)_{0.51}]$.[15] Analyses on the basis of solid-state ^{31}P MAS NMR and high-resolution ^{31}P NMR spectroscopy give $H_2PO_4^-$ to R-PO_3H^- ratios of 1.13 and 1.01 for **1** and **2**, respectively.

The ^{13}C MAS NMR spectra of **1** and **2** indicate that COOH groups (δ = 173 ppm) exist inside the layers (Figure 3b and d). In the FT-IR spectra of **1** and **2**, the absorption at 1730 cm^{-1} is attributed to COOH (Figure 4d and e). The IR and Raman spectra are in good agreement with the ^{13}C MAS NMR spectra.

On the basis of X-ray diffraction data, inductively coupled plasma (ICP), elemental analysis, TGA data and the ^{31}P NMR spectra, **1** and **2** are formulated as (*S*)-$[Zr(PO_4)(H_2PO_4)_{0.53}(HO_3PCH_2NC_4H_7COOH)_{0.47}\cdot 2.0H_2O]$ (**1**; mol. wt. = 371.39) and (*R*)-$[Zr(PO_4)(H_2PO_4)_{0.50}(HO_3PCH_2NCH_2SC_2H_3COOH)_{0.50}\cdot 1.6H_2O]$ (**2**; mol. wt. = 376.52). The BET surface areas of **1** and **2** are 14 and 12 $m^2\cdot g^{-1}$, respectively. Such small surface areas indicate that organic groups are closely packed in the interlayer spaces of **1** and **2**.

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

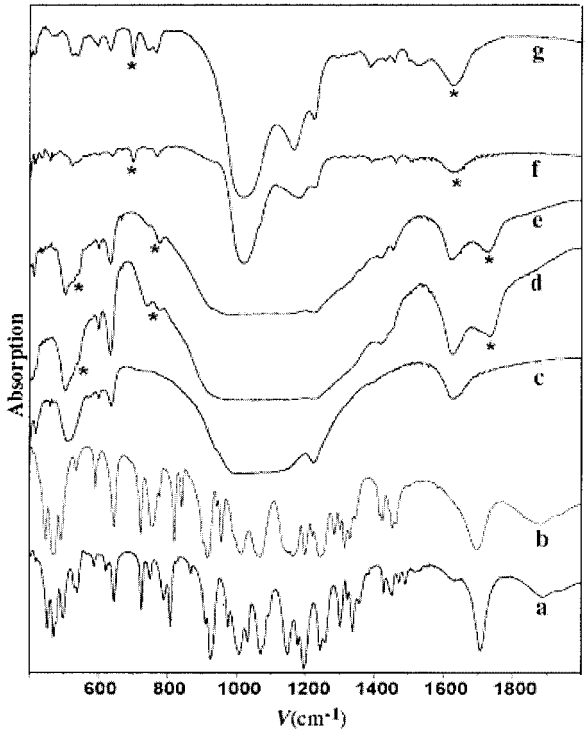

Figure 4. FT-IR spectra of: (a) H_3PMP, (b) H_3PMTA, (c) γ-ZrP, (d) γ-ZrPMP (**1**), (e) γ-ZrPMT (**2**), (f) **3** and (g) **4**; the bands at 1710 and 1730 cm^{-1} are attributed to CO_2H (a−e), and those at 1635 cm^{-1} to $-CO_2^-$ and 701 cm^{-1} to $C_6H_5CH(CH_3)NH_2$ (f and g)

Based on the above experimental data and the structure of γ-ZrP, a schematic representation of the proposed structural character of **2** is shown in Figure 5 (**1** is similar to **2**). In **2**, the nitrogen atoms are protonated by $H_2PO_4^-$ groups. These results are supported by the ^{13}C MAS NMR and IR spectra of **2** (Figures 3 and 4).

Molecule modeling of **2** is carried out based on γ-zirconium phosphate. Figure 6 shows the simulated structure model of **2**. This model shows that the heterocycles are closely packed, in good agreement with small BET surface areas.

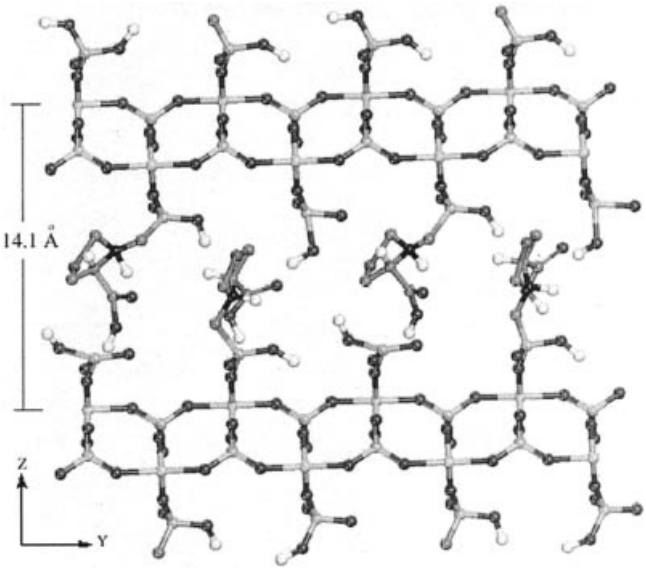

Figure 6. Simulated structural model of γ-ZrPMT (**2**) on the basis of γ-ZrP

Intercalation Capability and Optical Activity of γ-ZrPMP (1) and γ-ZrPMT (2)

A racemic mixture of 1-phenylethylamine [$C_6H_5CH(CH_3)NH_2$] (PEA) was used for the intercalation studies. The compounds $[Zr(PO_4)(H_2PO_4)_{0.53}(HO_3PCH_2NC_4H_7COOH)_{0.47}\cdot 0.56C_6H_5CH(CH_3)NH_2\cdot 0.75H_2O]$ (**3**) and $[Zr(PO_4)(H_2PO_4)_{0.50}(HO_3PCH_2NCH_2SC_2H_3COOH)_{0.50}\cdot 0.51C_6H_5CH(CH_3)NH_2\cdot 0.90H_2O]$ (**4**) were prepared from **1** and **2**, respectively, upon intercalation of PEA in ethanol solution at 55 °C for 24 h and 35 °C for 48 h, respectively. The *d*-spacings of intercalated **3** and **4** are 21.65Å and 20.94 Å, respectively (Figure 1d and e). In the IR spectra of **3** and **4**, the peaks at 1457, 1383 and 701 cm^{-1} are new and the

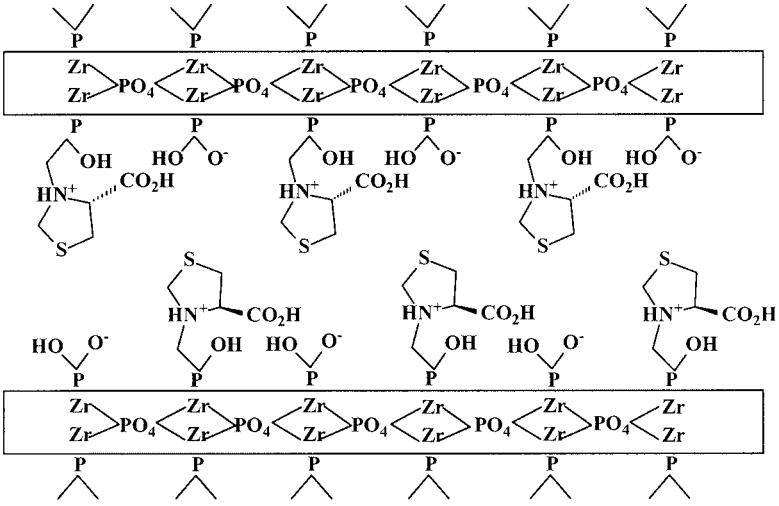

Figure 5. Schematic representation of the interlayer arrangement of γ-ZrPMT (**2**)

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

peaks at 1730 cm^{-1} disappear. (Figure 4f and g), which suggests that PEA exists inside the layers.[16]

Deintercalation was achieved by suspending **3** or **4** in 0.5 M HCl at 55 °C. The $[\alpha]_D^{25}$ values of deintercalated **3** and **4** are −15.6 and −21.2 (c = 1.3 in aqueous HF solution; pH ≈ 1.0), respectively. Compared to the $[\alpha]_D^{25}$ values of −16 for **1** and −21 for **2**, these results show that no racemization occurs during the whole experimental process.

Optical measurements show that the mother liquor obtained after the intercalation or deintercalation has no optical activity, which suggests that neither enantiomer is preferred under the above intercalation condition. In-depth studies of enantioseparation need appropriate guests and special techniques, such as high-performance liquid chromatography (HPLC).[3a,17]

Conclusion

In summary, two new compounds, formulated as $[Zr(PO_4)(H_2PO_4)_{0.53}(HO_3PCH_2NC_4H_7COOH)_{0.47}\cdot 2.0H_2O]$ (**1**) and $[Zr(PO_4)(H_2PO_4)_{0.50}(HO_3PCH_2NCH_2SC_2H_3COOH)_{0.50}\cdot 1.6H_2O]$ (**2**) were obtained. The host materials possess intercalation-deintercalation properties and optical activity.

Experimental Section

Materials and Methods: L-Proline, L-cysteine and 1-phenylethylamine $[C_6H_5CH(CH_3)NH_2]$ (PEA) were purchased from Acros, and used as received; PEA was racemic. The content of zirconium and phosphorus was analyzed with a Perkin−Elmer 3300 DV ICP analyzer, and C, H and N by a Perkin−Elmer 2400 analyzer. The IR spectra were recorded as KBr pellets with a Nicolet Impact 410 FT IR spectrometer. X-ray powder diffraction data were collected with a Siemens D5005 diffractometer with Cu-K_α radiation (λ = 1.54178 Å), a 0.03° 2θ-step size, and a 1-s counting time in the 3−40° 2θ range. Thermogravimetric analysis was performed with a NETZSCH STA 449C thermoanalyzer under a 20 mL min^{-1} air flow with a heating rate of 10 °C·min^{-1}. ^{13}C and ^{31}P MAS NMR spectra were recorded with a Bruker-MSL 400 MHz spectrometer. Solution ^{31}P NMR spectra were recorded with an AVANCE 500 spectrometer. BET was carried out under an N_2 flow with a Micro ASAP 2010 M at 77 K. Specific rotation was measured with a WWW-1S digital spectrometer. Solid **1** or **2** was dissolved in about 1.0 mL of HF (40% in water), and deionized water was added up to 50.0 mL. The path length was 20 cm.

Preparation of H_3PMP: This compound was obtained using our modified method based on a literature procedure.[13] CH_2O (40 mmol, 36% in water) was added dropwise to a mixture of L-proline (10 mmol), H_3PO_3 (11 mmol) and HCl (30 mL of a 6.0 M aqueous solution) under reflux. The resultant solution was then heated at reflux for a further 12 h. A white solid with a yield of 96% was recovered after removal of water, and recrystallized from an EtOH/propylene oxide (2:1, v/v) mixture. M.p. 257−259 °C. $C_6H_{12}NO_5P$ (209.14): calcd. C 34.44, N 6.69, H 5.74; found C 34.25, N 6.80, H 5.67. $[\alpha]_D^{25}$ = −63 (c = 1.6, in water). ^{31}P MAS NMR (161.9 MHz, 298 K): δ = 8.7 ppm.

Preparation of H_3PMTA: A mixture of L-cysteine (10 mmol), CH_2O (11 mmol, 36% in water) and HCl (10 mL of a 1.0 M aqueous solution) was allowed to stand at room temperature for 24 h. HCl (10 mL of a 6.0 M aqueous solution) and H_3PO_3 (11 mmol) were then added. CH_2O (40 mmol, 36% in water) was added dropwise to the resultant mixture at reflux over 5 min. The solution was then heated at reflux for a further 5 min. The product (yield: 85%) was recovered by removing the water. M.p. 198−200 °C. $C_5H_{10}NO_5PS$ (227.17): calcd. C 26.44, H 4.44, N 6.17, S 14.11; found C 26.49, H 4.62, N 6.01, S 13.95. $[\alpha]_D^{25}$ = −105 (c = 1.0, in water). ^1H NMR (D_2O + K_2CO_3, 500 MHz, 298 K): δ = 2.23−2.48 (m, 2 H), 3.02−3.20 (m, 2 H), 4.01 (d, $J_{H,H}$ = 6.50 Hz, 1 H), 4.12 (d, $J_{H,H}$ = 9.5 Hz, 1 H), 4.32 (d, J = 9.5 Hz, 1 H) ppm. ^{13}C NMR (D_2O + K_2CO_3, 125.8 MHz, 298 K): δ = 31.9, 53.1 (d, $J_{C,P}$ = 147.7 Hz), 60.3, 76.1, 178.9 ppm. ^{31}P NMR (D_2O, 202.4 MHz, 298 K): δ = 7.7 ppm (t, $J_{H,P}$ = 12.1 Hz). MS: calcd. 228.12 $[M + H]^+$; found 228.14.

Preparation of γ-ZrPMP (1): H_3PMP (0.17 g) and γ-ZrP (0.25 g) were added to a distilled water/acetone solution (1:1, v/v; 35 mL). The resultant solution was kept at 80 °C in a Teflon-lined container in an oil bath for 14 d. A white crystalline solid was recovered after washing with water and drying at room temperature. $Zr(PO_4)(H_2PO_4)_{0.53}(HO_3PCH_2NC_4H_7COOH)_{0.47}\cdot 2H_2O$ (371.39): calcd. C 9.11, H 2.75, N 1.77, P 16.69, Zr 24.56; found C 9.23, H 2.55, N 1.72, P 16.32, Zr 24.17. $[\alpha]_D^{25}$ = −16 (c = 1.2 in HF aqueous solution, pH = 1.5).

Preparation of γ-ZrPMT (2): The experimental procedure for the preparation of **2** was similar to that of **1**, but with H_3PMTA (0.19 g) instead of H_3PMP. $Zr(PO_4)(H_2PO_4)_{0.50}(HO_3PCH_2NCH_2SC_2H_3COOH)_{0.50}\cdot 1.6H_2O$ (376.52): calcd. C 7.97, H 2.31, N 1.86, P 16.47, S 4.25, Zr 24.23; found C 7.89, H 2.40, N 1.78, P 16.19, S 4.40, Zr 24.09. $[\alpha]_D^{25}$ = −21 (c = 1.4 in HF aqueous solution, pH = 1.5)

Intercalation and Deintercalation Studies with γ-ZrPMP (1). Formation of γ-ZrPMP·0.56$C_6H_5CH(CH_3)NH_2$ (3): Compound **1** (100 mg, 0.27 mmol) was intercalated with 1-phenylethylamine (0.14 mL, 1.08 mmol, c = 0.108 mol·L^{-1}) in ethanol solution (10 mL) at 55 °C for 24 h. Compound **3** (91 mg) was recovered by centrifugal separation, and dried at room temperature for 24 h. $Zr(PO_4)(H_2PO_4)_{0.53}(HO_3PCH_2NC_4H_7COOH)_{0.47}\cdot 0.56C_6H_5CH(CH_3)NH_2\cdot 0.75H_2O$ (416.88): calcd. C 21.01, H 3.33, N 3.46, P 14.87, Zr 21.88; found C 21.42, H 2.98, N 3.16, P, 15.03, Zr 22.41. Deintercalation was achieved by suspending **3** in 0.5 M HCl at 55 °C for 2 h. $[\alpha]_D^{25}$ = −15.6 (c = 1.3 in HF aqueous solution, pH ≈ 1.0).

Intercalation and Deintercalation Studies with γ-ZrPMT (2). Formation of γ-ZrPMT·0.51$C_6H_5CH(CH_3)NH_2$ (4): Compound **2** (102 mg, 0.27 mmol) was intercalated with PEA (0.14 mL, 1.08 mmol, c = 0.108 mol·L^{-1}) in ethanol solution (10 mL) at 35 °C for 48 h. Compound **4** (88 mg) was recovered by centrifugal separation, and dried at room temperature for 24 h. $Zr(PO_4)(H_2PO_4)_{0.50}(HO_3PCH_2NCH_2SC_2H_3COOH)_{0.50}\cdot 0.51C_6H_5CH(CH_3)NH_2\cdot 0.90H_2O$ (425.59): calcd. C 19.96, H 3.03, N 3.32, P 14.57, S 3.76, Zr 21.43; found C 20.21, H 2.80, N 3.11, P 14.91, S 3.32, Zr 21.31. Deintercalation was achieved by suspending **4** in 0.5 M HCl at 55 °C for 2 h. $[\alpha]_D^{25}$ = −21.2 (c = 1.3 in HF aqueous solution, pH ≈ 1.0).

Molecular Modeling: Computer modeling procedures were employed for the structure study. Using the Cerius² program,[18] a supercell was created including four cells of γ-ZrP (a = 5.3825, b = 26.5348, c = 12.4102 Å), and then 50% of $H_2PO_4^-$ was replaced

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

by H_2PMTA. The H_2O molecules were not taken into account in the modeling procedures. The lattice parameters *a* and *b* of the supercell were fixed, and *c* was changed to 14.1 Å on the basis of X-ray powder diffraction analysis. After fixing the inorganic matrix, the organic moieties were optimized to achieve the minimum geometry using the Universal Forcefield[18] supplied as part of the Cerius^2 program package.

Tris(trimethylsilyl)-Substituted Heavy Group 14-Element-Centered Anions: Unsolvated Trimeric Germyllithium and Solvated Dimeric Silyl- and Stannyllithiums

Masato Nanjo,*[a] Emi Nanjo,[a] and Kunio Mochida*[a]

Keywords: Germanium / Lithium / Silicon / Solid-state structures / Tin

Tris(trimethylsilyl)-substituted group 14-element-centered anion monomers [LiE($SiMe_3$)$_3$·3THF] (E = Si, Ge, and Sn) can be distilled under reduced pressure to give dimeric silyllithium **4** and stannyllithium **6**, and trimeric germyllithium **5** without pyrolysis products such as dilithiometallanes. The molecular structures of **4**, **5**, and **6** were unequivocally determined by X-ray diffraction. Dimer **4** has a symmetrical bent four-membered-ring structure consisting of two anionic silicon atoms and two cationic lithium atoms with coordinated THF molecules. Dimer **6** has an unsymmetrical distorted four-membered-ring structure consisting of two anionic tin atoms, a bridged unsolvated lithium atom, and a bridged lithium atom solvated by a THF molecule. Interestingly, **6** aggregates to form dimers of dimers by an intermolecular CH_3···Li interaction. Trimeric germyllithium **5** forms an equilateral triangular lithium cluster without solvation. Compound **5** has a crystallographic threefold axis with three anionic germanium atoms and three cationic lithium atoms lying in the same plane. The lithium atoms in **5** are stabilized by an intramolecular CH_3···Li interaction.

Introduction

Heavy group 14-element-centered anionic species, especially the lithium derivatives, are useful in some applications not only in organic synthesis but also in organometallic chemistry.[1] Despite the large number of reports on syntheses of silyl,[2] germyl,[3] and stannyl[4] anions, much less attention has been paid to their structural studies, which are of special interest for comparing with those of organolithium compounds.[5] Tris(trimethylsilyl)silyllithium (**1**), whose synthesis was first reported by Gilman and Smith in 1967[6] and then modified by Brook in 1982,[7] has been well studied from the viewpoint of its molecular structure,[8] NMR spectroscopic behavior,[9] and its application to the synthesis of the first stable silene species,[10] polysilane dendrimers,[11] and transition metal complexes.[12] Interestingly, thermolysis of **1** leads to the formation of bis(trimethylsilyl)dilithiosilane, which was trapped by [D_1]-ethanol and iodomethane to give the corresponding dideuteriosilane and dimethylsilane, respectively.[13] The structural studies on bis(trimethylsilyl)dilithiosilane were performed by mass spectrometry, suggesting that it forms both monomers and dimers, as determined by the molecular-ion peaks. Recently, the crystal structures of dilithiosilanes were revealed by X-ray diffraction method by using more bulky substituents at the anionic silicon center.[14]

Despite the large number of reports on silyllithium compounds, far less attention has been devoted to their germanium and tin analogues. Tris(trimethylsilyl)germyllithium (**2**) was first prepared by Brook et al. in 1986,[15a] and tris(trimethylsilyl)stannyllithium (**3**) by Preuss et al. in 1992.[16a] However, the solvent-separated ion pair [(Me_3Si)$_3$Ge][Li·[12]crown-4)$_2$][15b] and the monomeric solvated germyllithiums[15c] have only recently been reported by Stalke et al. More recently still, the solvated monomeric structure of the stannyllithium **3**·3THF has been published.[16b] However, the systematic study of lithium derivatives of the heavy group 14-elements is even more scarce. In the course of the thermolyses of [LiE($SiMe_3$)$_3$·3THF] (E = Si, Ge, Sn), we found the formation of aggregated structures of heavy group 14-element-centered anionic species, which include a rare trimeric structure of unsolvated germyllithium **5** and an unsymmetrical dimer of stannyllithium **6**. We report herein the structural study of **5** and **6** together with that of a solvated dimer of silyllithium **4**.

Results and Discussion

Synthesis of [LiE(Me_3Si)$_3$·3THF] (E = Si, Ge, and Sn)

[LiSi($SiMe_3$)$_3$·3THF] (**1**), was synthesized by a published procedure,[7] and was purified by recrystallization from *n*-pentane at −20 °C to give colorless crystals. Similarly,

$[LiGe(SiMe_3)_3 \cdot 3THF]$ (**2**)[15a] and $[LiSn(SiMe_3)_3 \cdot 3THF]$ (**3**)[16a] were also obtained as colorless crystals. The characterization of **1**−**3** was performed by ^1H, ^{13}C, ^{29}Si, and ^7Li NMR spectroscopy.

Tris(trimethylsilyl)silyllithium

The pyrolysis of **1** in an inert atmosphere at 140−150 °C leads to the formation of dilithiosilane $Li_2Si(SiMe_3)_2$ together with $(Me_3Si)_2$, $Si(SiMe_3)_4$, and $[Si(SiMe_3)_3]_2$, as reported by Lagow et al. in 1990.[13] We also examined the thermolysis of **1** under reduced pressure. Crystals of **1** were placed in a reaction vessel attached to vacuum line and heated slowly under reduced pressure (0.01 Torr). The crystals began to melt at 85 °C, and they completely melted at 100 °C. Bubbles from the interior of the liquid were observed. When the oil bath was heated to 150 °C, the oil of **1** boiled and we were able to obtain colorless crystals by distillation in vacuo. No pyrolysis products such as dilithiosilane, disilane, or tetrakis(trimethylsilyl)silane were detected in the ^1H NMR spectra. One THF molecule is coordinated to each $LiSi(SiMe_3)_3$ unit, as determined by ^1H NMR spectroscopy. The ^{29}Si NMR resonance of the central anionic silicon is observed at $\delta = -183.9$ ppm as a broad signal; this value is intermediate between the value of $\delta = -189.4$ ppm[8b] for monomeric silyllithium **1** and $\delta = -181.7$ ppm[9] for the unsolvated dimer $[(Me_3Si)_3Si(\mu\text{-}Li)]_2$.

The resulting crystals were recrystallized from *n*-hexane to give colorless single crystals. The distilled silyllithium was characterized by X-ray diffraction, and the molecular structure of $[(Me_3Si)_3Si(\mu\text{-}Li\cdot THF)]_2$ (**4**) is shown in Figure 1. The structural parameters are listed in Table 1. The silyllithium **4** is dimeric in the solid state, although the structure is different from that of the unsolvated dimer $[(Me_3Si)_3Si(\mu\text{-}Li)]_2$.[8d] Two lithium atoms bridge two anionic silicon atoms, and each lithium atom is coordinated by one THF molecule with an O(1)−Li(1) distance of 1.914(5) Å. The lithium-lithium distance is 2.695(9) Å. Up to now, six dimeric silyllithiums have been reported: $[(Me_3Si)_3Si(\mu\text{-}Li)]_2$,[8d] $[tBu_3Si(\mu\text{-}Li)]_2$,[17] $[(PhMe_2Si)_2MeSi(\mu\text{-}Li)]_2$,[18] $[(Me_3Si)_2PhSi(\mu\text{-}Li)]_2$,[18] $[(Me_3SiMe_2Si)_3Si(\mu\text{-}Li)]_2$,[19] and $[(tBuMe_2Si)_2HSi(\mu\text{-}Li\cdot THF)]_2$,[20] all of them containing planar four-membered rings consisting of two anionic silicon and two cationic lithium atoms. However, the silyllithium **4** possesses a folded four-membered ring. The sum of the angles of the tetragon is 354.6(4)° and the dihedral angle between the Li(1)−Si(1)−Li(1)* and Li(1)−Si(1)*−Li(1)* planes is 19°. Both the coordinated THF molecules lie on one side of the ring in order to avoid a steric repulsion of the bulky hypersilyl groups. The Li−O distance of 1.914(5) Å is somewhat shorter than that found in $[LiSi(SiMe_3)_3 \cdot 3THF]$ [1.94(1)−1.97(1) Å][8b][8c] and $[LiSi(SiMe_3)_3 \cdot DME]_2 \cdot (\mu\text{-}DME)$ [1.993(6)−2.003(5) Å].[8a] The Si−Si bond lengths of **4** [2.3406(9)−2.3509(9) Å] are normal. The angles around the anionic silicon atom are significantly contracted, the sum of the Si−Si−Si angles being only 307.68(9)°, a value that is closer to that in monomeric $[LiSi(SiMe_3)_3 \cdot 3THF]$ [307.9(3)°] than that in solvent-free dimeric $[LiSi(SiMe_3)_3]_2$ (322.5°).

Tris(trimethylsilyl)germyllithium

Colorless crystals of $[LiGe(SiMe_3)_3 \cdot 3THF]$ (**2**) were placed in a reaction vessel attached to a vacuum line and heated slowly under reduced pressure (0.01 Torr). The crystals began to melt at 90 °C, and they completely melted at 100 °C with bubbling from the interior of the liquid. Similar to the case of **4**, we distilled the liquid at 150 °C under reduced pressure (0.01 Torr) to give colorless crystals. The ^1H NMR spectrum of the crystals shows only a singlet at $\delta = 0.41$ ppm assigned to the $SiMe_3$ group; no resonance of coordinated THF molecules was detected. The ^7Li NMR sig-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

nal is observed at $\delta = 2.16$ ppm, which is different from that of **2** ($\delta = 0.58$ ppm), suggesting that the distillate is a solvent-free germyllithium. The resulting crystals were recrystallized from *n*-pentane at −20 °C to give single crystals suitable for X-ray crystallographic analysis.

The molecular structure of $[(Me_3Si)_3Ge(\mu\text{-}Li)]_3$ (**5**) is shown in Figure 2 and the structural parameters are listed in Table 2. Surprisingly, unsolvated germyllithium **5** is a trimeric aggregate in the solid state. The crystal system is hexagonal with the space group $P6_3/m$, and the trimer has a crystallographic threefold axis and a mirror plane. It should be noted that such a trimeric structure is the first such example among all structurally characterized heavy group 14-element-centered anionic species. Trimeric organolithium compounds in the solid state are scarcely known, to the best of our knowledge only three aryllithiums — 2,6-bis(dimethylamino)phenyllithium,[21a] 2,6-di-*tert*-butoxyphenyllithium,[21b] and 2-dimethylamino-6-*tert*-butoxyphenyllithium[21c] — have been characterized by X-ray diffraction. Each lithium atom in **5** is bridging, and three lithium atoms form an equilateral triangle with a Li···Li distance of 3.29(2) Å, which is somewhat longer than those in trimeric aryllithiums (2.96−3.17 Å). Substitution of a carbon in trimeric aryllithiums for a germanium should lead to expansion of the lithium core due to the increased bond length of Li−Ge compared with that of Li−C. Interestingly, each of the lithium atoms is coordinated by carbon atoms on the trimethylsilyl groups, with a C−Li distance of 2.587(10) Å. Although this value is longer than covalent C−Li bond lengths (2.13−2.48 Å) of typical organolithium compounds,[22] it is short enough to be a true CH_3···Li interaction between the lithium and carbon atoms. This is in contrast to the case of trimeric aryllithiums, which are stabilized by coordination of a lone pair of the alkoxy or amino group to the cationic lithium atoms. In **5** the three cationic lithium atoms and three anionic germanium atoms lie in the same plane and one of the trimethylsilyl groups (Si2) is also located in this plane as shown in Figure 2 (bottom). The geometry of the anionic germanium atoms is distorted trigonal bipyramid. The apical Si(2)−Ge(1)−Li(1)** bond angle is 177.6(3)° and equatorial Si(1)−Ge(1)−Li(1), Si(1)′−Ge(1)−Li(1), and Si(1)−Ge(1)−Si(1)′ bond angles are 120.1 (1)°, 120.1 (1)°, and 104.7 (1)°, respectively. The Si(1)−Ge(1)−Si(1)′ angle is very small due to a contribution of the *s*-characteristic anionic charge. The apical bonds Ge(1)−Si(2) and Ge(1)−Li(1)** are slightly longer than the equatorial bonds Ge(1)−Si(1) and Ge(1)−Li(1). The Ge(1)−Li(1) bond of 2.613(10) Å is slightly longer than that found in the monomeric germyllithium **2**.

Tris(trimethylsilyl)stannyllithium

Colorless crystals of $[LiSn(SiMe_3)_3 \cdot 3THF]$ (**3**) were placed in a reaction vessel attached to a vacuum line and

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

heated slowly under reduced pressure (0.01 Torr). The crystals began to melt with bubbling from the interior of the liquid and the colorless oil gradually changed to pale yellow. Colorless crystals were obtained by distillation under reduced pressure. From the ^{1}H NMR spectrum it was concluded that only one THF molecule is coordinated to the two $LiSn(SiMe_3)_3$ units. The ^{119}Sn NMR resonance is observed at $\delta = -878.2$ ppm as an unresolved multiplet due to coupling with the ^{7}Li nuclei. The resulting crystals were recrystallized from *n*-hexane at room temperature for an X-ray analysis. We also succeeded in the structural characterization of the distilled stannyllithium (**6**). The structural parameters are listed in Table 3.

The stannyllithium $\{[(Me_3Si)_3Sn]_2(\mu\text{-Li})(\mu\text{-Li}\cdot THF)\}$ (**6**) is dimeric in the solid state and the dimer has an unsymmetrical structure, as shown in Figure 3. Although each lithium atom is coordinated by a THF molecule in the case of silyllithium **4**, stannyllithium dimer **6** has only one THF molecule bound to Li(2), with an O(1)−Li(2) bond length of 1.907(17) Å. The two anionic tin and two cationic lithium atoms make a four-membered ring, which has a bent structure with a dihedral angle of 21° between the Sn(1)−Li(1)−Li(2) and Sn(2)−Li(1)−Li(2) planes. The Li(1)−Sn(1)−Li(2) and Li(1)−Sn(2)−Li(2) bond angles are 57.1(5)° and 58.2(4)°, respectively. These values are smaller than that found in silyllithium **4**. The sum of the three Si−Sn−Si angles in **6** is 303.8(3)° at Sn(1) and 303.4(2)° at Sn(2); these values are significantly contracted from the ideal tetrahedral value of 328.5° and are less than that found in silyllithium **4** [the sum of three angles of Si−Si−Si is 307.68(9)°]. However, they are larger than that found in the monomeric structure of **3** (total 296.2°).[16b] Of particular interest is the fact that two $[(Me_3Si)_3Sn(\mu\text{-Li})]_2$ dimers construct aggregates through short Li(1)···C(3)* and C(3)···Li(1)* interactions, as shown in Figure 4. The Li(1)···C(3)* distance of is 2.392(17) Å and the Si(1)−C(3)−Li(1)* angle is 175.7(7)°. These structures are therefore so-called "super-dimers"; super-dimeric structures of group 14-element-centered anionic species have also been observed in the series $[(Me_3Si)_3Si(\mu\text{-M})]_2$ (M = Li, Na, K, Rb, and Cs)[8d] and $[Ph(Me_3Si)_2Si(\mu\text{-Li})]_2$.[23] In his paper[8d] Klinkhammer described CH_3···M interactions, which include a dipole-ion component and C−H donor/M^+ − acceptor component. Although these CH_3···M interactions are weaker than the coordination of solvent molecules, they are strong enough to stabilize a naked lithium atom Li(1) in the case of **6**. The conformation of the trimethylsilyl groups at the anionic Sn(1) and Sn(2) centers is eclipsed. The Sn(1)−Li(2) [2.926(18) Å] and Sn(2)−Li(2) [2.857(17) Å] bond lengths are somewhat longer than those of Sn(1)−Li(1) [2.796(15) Å] and Sn(2)−Li(1) [2.764(17) Å] for steric reasons. The Sn(1)−Li(1)−Sn(2) angle of 122.8(5)° is larger than that of Sn(1)−Li(**2**)−Sn(2) [115.2(5)°].

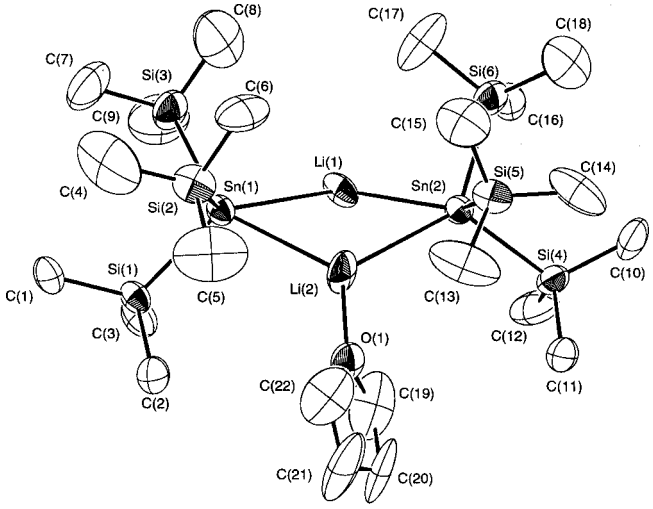

Figure 3. Molecular structure of **6** with 50% probability ellipsoids (H atoms omitted for clarity)

It is interesting that all three group 14-element-centered anionic species $LiE(SiMe_3)_3$ (E = Si, Ge, and Sn) **4**−**6** represent different aggregates in the solid state. It is not clear for the moment why they form different types of clusters. One of the possible reasons might be associated with the difference in Allred−Rochow electronegativities[24] of the central elements (Si = 1.74, Ge = 2.02, Sn = 1.72): the more electronegative germanium atom forms amore stable germyllithium, which does not require additional stabilization by a polar solvent (THF).

Conclusion

Tris(trimethylsilyl)-substituted group 14-element-centered anionic species $[LiE(SiMe_3)_3\cdot 3THF]$ (E = Si, Ge, Sn)

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

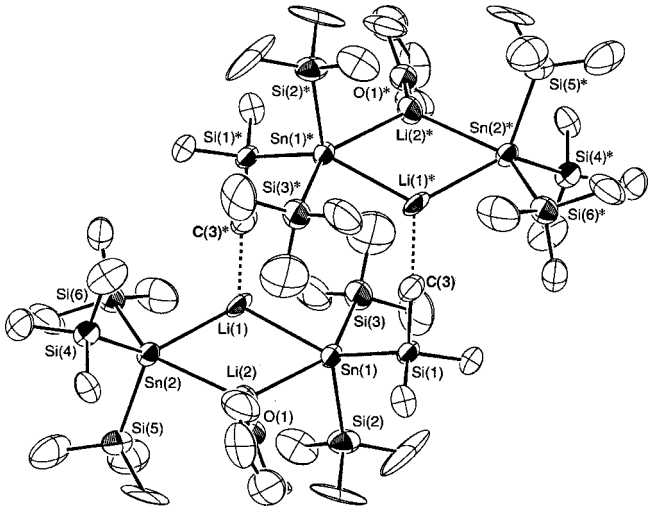

Figure 4. Formation of a dimer of dimers found in **6**; dotted lines indicate short intermolecular $CH_3\cdots Li$ interactions; C−Li distances are listed in Table 3

were heated at 150 °C under reduced pressure to give the corresponding aggregated anionic species with loss of coordinated THF molecules. The dimeric structures of silyllithium $[(Me_3Si)_3Si]_2(\mu\text{-Li}\cdot THF)_2$ (**4**) and stannyllithium $[(Me_3Si)_3Sn]_2(\mu\text{-Li})(\mu\text{-Li}\cdot THF)$ (**6**) and the trimeric strucrture of unsolvated germyllithium $[(Me_3Si)_3Ge]_3(\mu\text{-Li})_3$ (**5**) were unequivocally determined by X-ray crystallographic analyses. Silyllithium **4** and stannyllithium **6** contain distorted four-membered rings consisting of two anionic center atoms and two bridged lithium atoms. Both lithium atoms in **4** are coordinated by a THF molecule; **6** has only one coordinated THF molecule connected to a lithium atom and forms a dimer of dimers by an intermolecular $CH_3\cdots Li$ interaction. Trimeric germyllithium **5** has a crystallographic threefold axis and three anionic germanium atoms and three cationic lithium atoms lying in the same plane. The lithium atoms in **5** are stabilized by an intramolecular $CH_3\cdots Li$ interaction.

Experimental Section

General Procedure: All experiments were performed under an inert atmosphere of argon by standard vacuum-line techniques. *n*-Pentane and *n*-hexane were dried over potassium mirrors and degassed by freeze-pump-thaw cycles and then distilled prior to use. ^1H (400 MHz), ^{13}C (100 MHz), and ^7Li (155 MHz) NMR spectra were recorded on a Varian Inova 400 spectrometer, and ^{29}Si (60 MHz) and ^{119}Sn (112 MHz) NMR spectra were recorded on a JEOL AL-300 spectrometer. ^1H, ^{13}C, and ^{29}Si chemical shifts are referenced to $SiMe_4$ as an external standard. The chemical shifts in the ^7Li NMR spectra are referenced to external LiCl (1.0 M in methanol). The ^{119}Sn NMR chemical shifts are referenced to $SnMe_4$ as an external standard. Elemental analyses could not be performed because of the high instability of the anion species in air.

Preparation of $[(Me_3Si)_3Si(\mu\text{-Li}\cdot THF)]_2$ (4): Tris(tetrahydrofuran)-tris(trimethylsilyl)silyllithium (**1**)[7] (0.110 g, 0.234 mmol) was placed in a dry 6-mm diameter reaction vessel equipped with a side tube. After evacuation of the tube with a rotary pump, it was heated slowly in an oil bath to 150 °C in vacuo. Melting of **1** was observed at 85 °C, and bubbling from the interior of the liquid was observed at 100 °C. When the temperature of the oil bath had reached 150 °C, the vapor went to the top of the vessel and was cooled in the side tube to become a colorless oil, and then colorless crystals of **4** were obtained (0.066 g, 86%) at room temperature. The resulting crystals were recrystallized from *n*-hexane (0.15 mL) to give single crystals suitable for an X-ray crystallographic analysis. ^1H NMR ([D$_6$]benzene): δ = 0.46 (s, 54 H), 1.3−1.4 (m, 9.4 H, THF), 3.4−3.5 (m, 9.4 H, THF) ppm. ^7Li NMR ([D$_6$]benzene): δ = 1.99 ppm. ^{13}C NMR ([D$_6$]benzene): δ = 6.5, 25.2 (THF), 68.7 (THF) ppm. ^{29}Si NMR ([D$_6$]benzene): δ = −5.9 (Me_3Si), −183.9 (br., SiLi) ppm.

Preparation of $[(Me_3Si)_3Ge(\mu\text{-Li})]_3$ (5): Tris(tetrahydrofuran)tris-(trimethylsilyl)germyllithium (**2**)[15] (0.105 g, 0.204 mmol) was placed in a dry 7-mm diameter reaction vessel equipped with a side tube. After evacuation of the tube with a rotary pump, it was heated slowly in an oil bath to 150 °C in vacuo. Melting of **2** was observed at 90 °C, and bubbling from the interior of the liquid was observed at 100 °C. When the temperature of the oil bath had reached 140 °C, the vapor went to the top of the vessel and was cooled in the side tube to become a colorless oil, and then colorless crystals of **5** were obtained (0.060 g, 98%) at room temperature. The resulting crystals were recrystallized from *n*-pentane (0.3 mL) to give single crystals suitable for an X-ray crystallographic analysis. ^1H NMR ([D$_6$]benzene): δ = 0.41 (s, 27 H) ppm. ^7Li NMR ([D$_6$]benzene): δ = 2.16 ppm. ^{13}C NMR ([D$_6$]benzene): δ = 6.4 ppm. ^{29}Si NMR ([D$_6$]benzene): δ = −4.9 ppm.

Preparation of $\{[(Me_3Si)_3Sn]_2(\mu\text{-Li})(\mu\text{-Li}\cdot THF)\}$ (6): Tris(tetrahydrofuran)tris(trimethylsilyl)stannyllithium (**3**)[16] (0.130 g, 0.232 mmol) was placed in a dry 6-mm diameter reaction vessel equipped with a side tube. After evacuation of the tube with a rotary pump, it was heated slowly in an oil bath to 150 °C in vacuo. Melting of **3** was observed at 100 °C, and bubbling from the interior of the liquid was observed. When the temperature of the oil bath had reached 140 °C, the vapor went to the top of the vessel and was cooled in the side tube to become a colorless oil, and then colorless crystals of **6** were obtained (0.056 g, 63%) at room temperature. The resulting crystals were recrystallized from *n*-pentane (0.1 mL) to give single crystals suitable for an X-ray crystallographic analysis. ^1H NMR ([D$_6$]benzene): δ = 0.56 (s, 54 H). 1.2−1.3 (m, 4.6 H, THF), 3.5−3.6 (m, 4.6 H, THF) ppm. ^7Li NMR ([D$_6$]benzene): δ = 1.20 ppm. ^{13}C NMR ([D$_6$]benzene): δ = 7.3, 25.1 (THF), 69.2 (THF) ppm. ^{29}Si NMR ([D$_6$]benzene): δ = −12.4 ppm. ^{119}Sn NMR ([D$_6$]benzene): δ = −878.2 (br) ppm.

X-ray Crystal Structure Analyses for 4, 5, and 6: Crystal data for all structures are presented in Table 4. Data were collected with a MacScience DIP2030 imaging plate diffractometer employing graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å). The structures were solved by direct methods by means of SIR-92[25] (for **4** and **5**) and Multan78[26] (for **6**) refined with all data on F^2 by means of SHELXL-97.[27]

CCDC-225267, -225265, and -225266 (for **4**, **5**, and **6**, respectively) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: +44-1223-336033; E-mail: deposit@ccdc.cam.ac.uk].

Hydrothermal Syntheses, Structures, and Properties of Three 3-D Lanthanide Coordination Polymers that Form 1-D Channels

Xiang-Jun Zheng,[a] Zhe-Ming Wang,[b] Song Gao,[b] Fu-Hui Liao,[b] Chun-Hua Yan,[b] and Lin-Pei Jin*[a]

Keywords: Coordination polymer / Hydrothermal synthesis / Lanthanides / 2,6-Naphthalenedicarboxylate / X-ray diffraction

We report the hydrothermal synthesis and crystal structure of isostructural lanthanide coordination polymers $[Ln_2(NDC)_3(phen)_2]\cdot H_2NDC$ [Ln = Tb (**1**), Ho (**2**) and Yb (**3**)] that feature 2,6-naphthalenedicarboxylate (NDC) and 1,10-phenanthroline (phen) ligands. The NDC ligands bridge the lanthanide ions in two different modes to form a 3-D porous framework that accommodates large, neutral 2,6-naphthalenedicarboxylic acid molecules as guests in the channels, stabilized through O–H···O hydrogen bonds to the NDC ligand. The effective dimension of the channel is ca. 6.0×8.2 Å. Thermogravimetric analysis shows that complex **2** remains stable up to 330 °C, which we confirmed also by powder X-ray diffraction analyses. The framework collapsed upon the loss of the coordinating phen molecules. The Tb complex shows strong evidence of ferromagnetic coupling interactions.

Introduction

The synthesis of coordination polymers remains a subject of intense interest. Accordingly, a large number of coordination polymers of different dimensions and various topologies have been reported.[1−19] Recent research in this field has focused on producing materials designed to perform highly specific and cooperative functions.[20−25] Advances in the design and synthesis of metal-organic frameworks (MOFs) has led to numerous practical and conceptual developments in that direction.[26−30] Specifically, the chemistry of MOFs provides an extensive array of crystalline materials that have high stability, tunable metrics, organic functionalities, and porosity.[31] The wide variety of possible organic linkers and the multiple physical properties of inorganic metal ions make it feasible to modulate both the dimensions of the pores and the properties of the final porous coordination polymers. In such structures, organic species act as either pillars or linkers to arrange inorganic layers, chains, or clusters of transition or lanthanide ions.[32] Polycarboxylic acids are frequently utilized to construct microporous compounds.[33−36] In the study of lanthanide-organic frameworks, rigid polycarboxylic acids, especially dicarboxylic acids, are frequently used to link lanthanide ions[17,37] or lanthanide cubane-like clusters.[38,39] Considering the high coordination numbers of lanthanide ions, ancillary ligands also can be incorporated into the lanthanide coordination networks. Bulky ancillary ligands can occupy some coordination sites and reduce the interpenetration of frameworks, which results in an increase in the dimensions of the pores in the framework. 2,6-Naphthalenedicarboxylate is a rigid linear ligand whose transition metal coordination polymers, both binary and ternary, have been studied extensively,[40−46] but only three binary coordination polymers of its lanthanide analogues have been reported.[47−49] No ternary lanthanide coordination polymers of 2,6-naphthalenedicarboxylate have been described in the literature. In this study, we selected 2,6-naphthalenedicarboxylate as the linker and a chelating ligand, 1,10-phenanthroline, as the ancillary ligand to construct a ternary lanthanide-organic framework that is thermally stable and exhibits interesting magnetic behavior.

Results and Discussion

Synthetic Considerations

Dipotassium 2,6-naphthalenedicarboxylate readily forms a precipitate upon the addition of lanthanide chlorides. Therefore, for the preparation of our coordination polymers, first we acidified dipotassium 2,6-naphthalenedicarboxylate to prevent it from reacting too quickly with the lanthanide chloride; this process facilitates coordination of phen molecules and leads to the growth of crystals of the ternary complex. In this approach, some phen molecules

act as ligands to coordinate with lanthanide ions, while others act as mild organic bases that deprotonate H_2NDC units to give NDC ions that then coordinate with lanthanide ions.

Crystal Structures

The three complexes are isomorphous and isostructural; we describe in detail only the structure of complex **2**. The asymmetric unit of **2** consists of one Ho^{III} center, 1.5 NDC anions, one phen ligand, and 0.5 H_2NDC guest units. Around the central metal ion, there is a bidentate chelating phen ligand and four bridging NDC anions (Figure 1). The Ho^{III} ion is eight-coordinate with two ligating nitrogen atoms from a phen molecule and six oxygen atoms from four NDC anions; this arrangement results in a triangular dodecahedral coordination polyhedron. For convenience, the NDC anions having the oxygen atoms labeled O1, O3, and O5 (Figure 1) are named NDC1, NDC2, and NDC3, respectively. These structures represent the three orientations of NDC anions in the crystal; the dihedral angles between the naphthalene rings of NDC1 and NDC2, NDC2 and NDC3, and NDC1 and NDC3 are 108.2, 68.0, and 94.7 °C, respectively. In the title coordination polymers, the NDC anions adopt two coordination modes: bis(bridging bidentate) (I) and bis(chelating bidentate) (II), as depicted in Scheme 1. NDC1 ligands adopt the type I binding mode, whereas NDC2 and NDC3 ligands adopt type II binding.

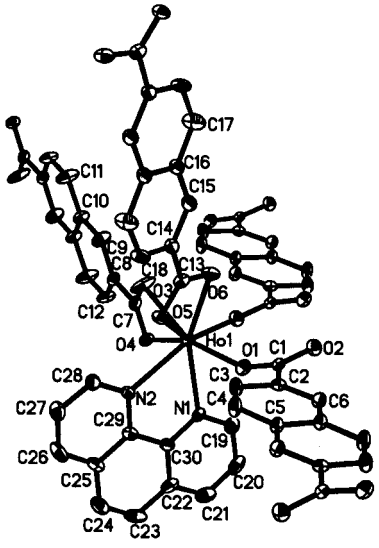

Figure 1. Coordination environment of complex **2**; the asymmetric unit and the related coordination atoms are labeled; guest molecules and all hydrogen atoms have been omitted for clarity; thermal ellipsoids are drawn at 30% probability

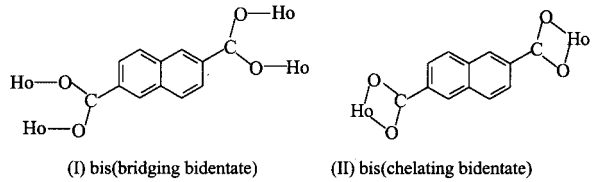

Scheme 1. Coordination modes of the NDC ligand in complex **2**

The framework structure of **2** is built from a dinuclear unit, $Ho_2(NDC)_3(phen)_2$, which results from the linking of two asymmetric units through two carboxylate units of two NDC1 anions. First, the NDC1 ligands link the dinuclear building units to form 1-D chains along the *c*-axis (Figure 2). The distance between the adjacent dinuclear units in the chain is 12.25 Å. Next, the NDC2 ligands link two Ho^{III} ions (Ho···Ho, 13.34 Å), in the [01$\bar{1}$] direction, of two adjacent chains to form 2-D layers that feature 44-membered

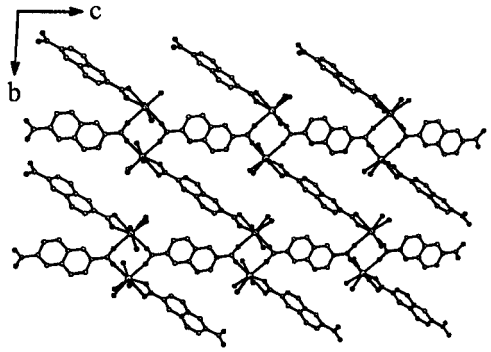

Figure 2. 2-D layers, viewed along the *a*-axis, featuring 44-membered ring channels constructed with Ho^{III}, NDC1, and NDC2 ligands

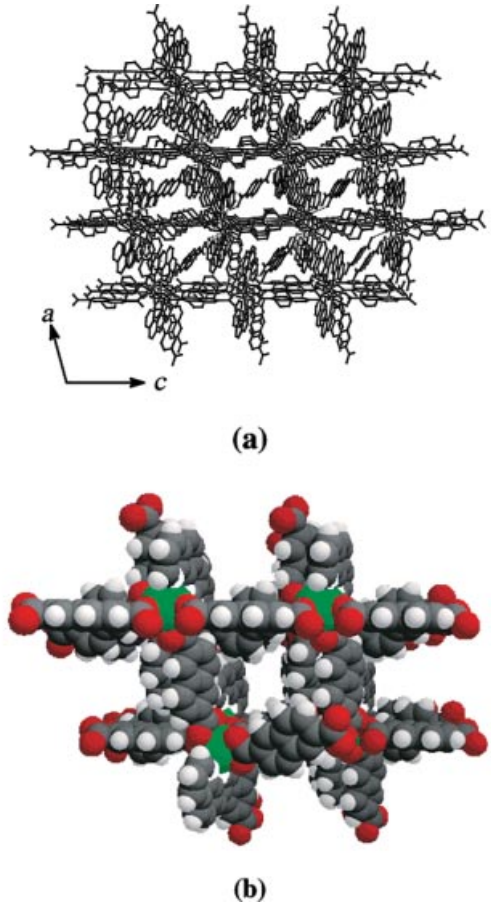

Figure 3. (a) 3-D porous framework of complex **2**, viewed along the *b*-axis, showing the guest molecules accommodated in the 1-D channels; all hydrogen atoms have been omitted for clarity; (b) space-filling model of complex **2** showing the 1-D channel; the guest molecules have been omitted for clarity

parallelogram channels (Figure 2). Finally, the NDC3 ligands, which act as pillars, link the Ho^{III} ions (Ho···Ho, 13.35 Å), in the [$\bar{1}$10] direction, from two adjacent layers to form the porous 3-D framework (Figure 3).

When viewed along the *b*-axis, complex **2** exhibits many 1-D channels. Despite the large dimensions of the cross-section of the channel (internuclear separation: 13.34 × 13.35 Å) arising from the long span of the NDC ligand (ca. 9.0 Å), the effective dimension of the channel is only 6.0 × 8.2 Å (van der Waals free space) because of the presence of the bulky phen molecules in the channel. The large neutral guest molecules (H_2NDC), which are hydrogen bonded to the coordinating oxygen atoms of the NDC3 ligands in the framework, are accommodated within the channels. The two carboxyl groups of the guest molecule are arrayed in the diagonal direction of the parallelogram channel. The geometries of the hydrogen bonds in complexes **1**, **2**, and **3** are listed in Table 1. Selected bond lengths within **1**, **2**, and **3** are listed in Table 2.

Analysis of the Thermal Stability of 2

The existence of guest molecules in the channels inspired us to investigate the thermal stability of the coordination polymers; we took complex **2** as a representative example to carry out the TG analysis. We observe from the thermogravimetric curve of **2** (Figure 4) that this complex remains stable up to 330 °C, at which temperature the first weight loss occured, i.e., loss of the H_2NDC guest molecule. A second weight loss occurred when the temperature reached 357 °C. The H_2NDC guest molecule was not completely removed before the loss of two coordinating phen molecules occurred. One H_2NDC guest molecule and two coordinating phen molecules were completely removed at 460 °C; this process occurs with a weight loss of 35.2% (calculated: 37.2%). The decomposition of the complex continued at

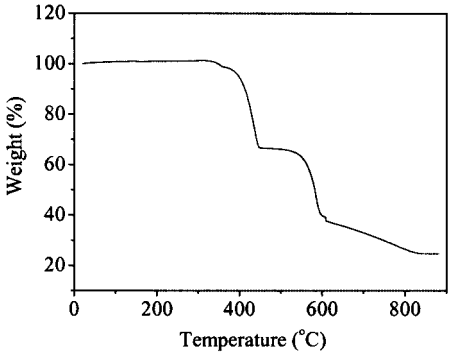

Figure 4. Thermogravimetric curve of complex **2**

491 °C and ended at 840 °C, at which point a residue, Ho_2O_3, was obtained in 24.8% yield (calculated: 24.4%).

To further test the thermal stability of **2**, we examined powder samples by variable-temperature X-ray diffraction analysis. The powder XRD patterns of **2** (Figure 5) at 27, 300, 350, 400, and 500 °C were recorded. We see in Figure 5 that when the temperature rose from 27 to 300 °C, the positions of the major peaks undergo no significant changes, but some peaks shift slightly to lower or higher 2θ values. This observation indicates that a possible distortion of the structure had occurred, but it did not affect the existence of the framework. The similarities between the powder XRD patterns obtained at 300 and 350 °C also suggest that the framework remains stable at 350 °C, i.e., when phen molecules are still present, which is in accordance with the results of the thermogravimetric analysis. Above 400 °C, however, the PXRD patterns are changed completely, which indicates that a collapse of the framework has occurred. The loss of the coordinating phen molecules may account for the framework's collapse, i.e., the presence of the coordinating phen molecules is required for a stabile framework.

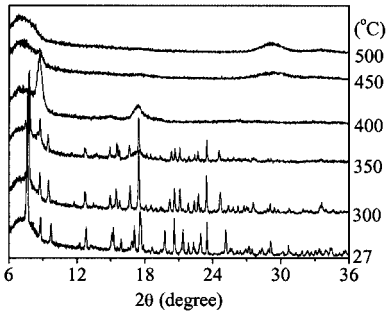

Figure 5. Powder X-ray diffraction patterns of **2** at different temperatures [the large broad peak at < 10° (2θ) arose from the use of the position scan detector]

Because of similarities between the frameworks of the title complexes, we deduced that **1** and **3** have stabilities similar to that of **2**.

Magnetic Properties

We investigated the magnetic properties of complexes **1** and **2** in the solid state at 1 T within the temperature range 2−300 K (Figure 6).

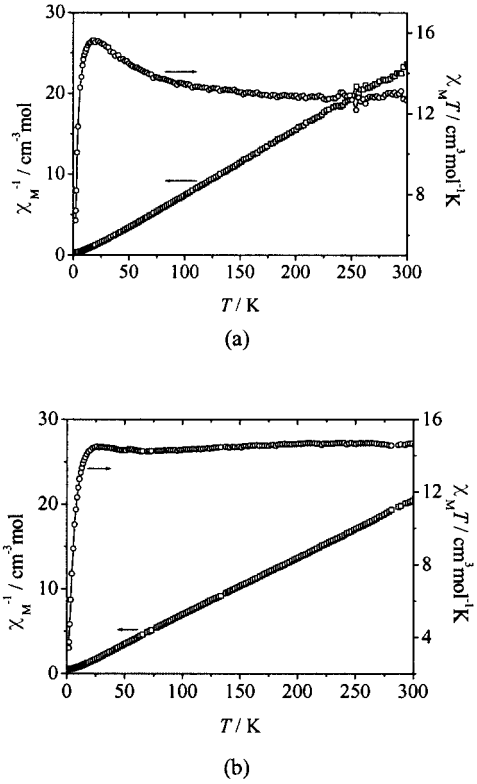

Figure 6. Plots of the temperature dependences of χ_M^{-1} (open squares) and $\chi_M T$ (open circles) for complexes **1** (a) and **2** (b)

For **1**, the observed value of $\chi_M T$ per [Tb] unit is 12.82 cm^3·K·mol^{-1} at room temperature (Figure 6a), which is slightly larger than the value expected for a free Tb^{3+} ion (11.82 cm^3·K·mol^{-1}).[50] Upon cooling, the value of $\chi_M T$ increases up to a maximum of 15.62 cm^3·K·mol^{-1} at ca. 18 K. The plot of χ_M^{-1} vs. T over the temperature range 30−300 K obeys the Curie−Weiss law [$\chi = C/(T - \theta)$] with C = 12.5 cm^3·K·mol^{-1} and θ = 6.5 K. All of these results indicate that there is ferromagnetic coupling between the Tb^{3+} ions. The value of $\chi_M T$ decreases abruptly at temperatures below 18 K to reach 6.70 cm^3·K·mol^{-1} at 2 K. This feature is due primarily to the splitting of the ligand field of the Tb^{3+} ion as a result of strong spin-orbital coupling. For **2**, the observed value of $\chi_M T$ per [Ho] unit is 14.65 cm^3·K·mol^{-1} at room temperature (Figure 6b), which is close to the value expected (14.07 cm^3·K·mol^{-1}) for a free Ho^{3+} ion.[50] The value of $\chi_M T$ decreases slowly as the temperature decreases to ca. 26 K (14.48 cm^3·K·mol^{-1}) and then it drops rapidly below 26 K to reach a value of 3.40 cm^3·K·mol^{-1} at 2 K. The plot of χ_M^{-1} vs. T over the temperature range 30−300 K obeys the Curie−Weiss law with C = 14.76 cm^3·K·mol^{-1} and θ = −2.21 K. The decrease of $\chi_M T$ and the negative value of θ are due primarily to splitting of the ligand field of the Ho^{3+} ion as a result of strong spin-orbital coupling, and is attributed partly to the poss-

Conclusion

We have synthesized novel 3-D porous lanthanide coordination polymers, $[Ln_2(NDC)_3(phen)_2]\cdot H_2NDC$ (Ln = Tb, Ho, and Yb), incorporating 2,6-naphthalenedicarboxylate and 1,10-phenanthroline units by hydrothermal reactions; we characterized the complexes by single-crystal X-ray diffraction analysis. The results show that the three complexes are isostructural and that the NDC^{2-} unit is a good spacer for the construction of porous lanthanide coordination polymers. Large, neutral guest molecules (2,6-naphthalenedicarboxylic acid units) are accommodated within the 1-D channels, which are rarely found in lanthanide coordination polymers. These lanthanide coordination polymers remain thermally stable up to ca. 330 °C.

Experimental Section

General Remarks: $TbCl_3\cdot 6H_2O$, $HoCl_3\cdot 6H_2O$, and $YbCl_3\cdot 6H_2O$ were each prepared by dissolving their respective oxides in concentrated hydrochloric acid and then evaporating the solvent to dryness. All the other reagents were commercially available and were used without further purification.

Instrumentation: Elemental analyses were obtained with an Elementar Vario EL analyzer. IR spectra were recorded with a Nicolet Avatar 360 FT-IR spectrometer by using the KBr pellet technique. Thermogravimetric analyses were performed with a TGA 951 thermogravimetric analyzer. The magnetic susceptibilities were obtained on crystal samples by using an Oxford MagLab System 2000 magnetometer. The experimental susceptibilities were corrected for the presence of the sample holder and the diamagnetism contributions were estimated from Pascal's constants. The powder X-ray diffraction patterns were recorded using a Bruker AXS D8 ADVANCE diffractometer.

$[Tb_2(NDC)_3(phen)_2]\cdot H_2NDC$ (1): Hydrochloric acid (1.65 mol·L^{-1}, 4 drops) was added with stirring to a mixture of dipotassium 2,6-naphthalenedicarboxylate (0.044 g, 0.15 mmol) and H_2O (10 mL). $TbCl_3\cdot 6H_2O$ (0.038 g, 0.1 mmol) and phen·H_2O (0.04 g, 0.2 mmol) were then added. The mixture was sealed in a 25-mL stainless steel reactor equipped with a Teflon liner and heated at 170 °C for 72 h. Light-yellow crystals of **1** were obtained (0.015 g, 26.0%). $C_{36}H_{21}N_2O_8Tb$ (768.47): calcd. C 56.27, H 2.75, N 3.65; found C 55.98, H 2.53, N 3.55. IR (KBr pellet): $\tilde{\nu}$ = 3433 m, 1705 m, 1617 m, 1548 m, 1493 m, 1422 s, 1362 m, 805 m, 792 m, 727 m cm^{-1}.

$[Ho_2(NDC)_3(phen)_2]\cdot H_2NDC$ (2): The same procedure was applied as that for **1**, but with the following quantities: dipotassium 2,6-naphthalenedicarboxylate (0.044 g, 0.15 mmol), H_2O (10 mL), hydrochloric acid (1.65 mol·L^{-1}, 4 drops), $HoCl_3\cdot 6H_2O$ (0.038 g, 0.1 mmol), and phen·H_2O (0.04 g, 0.2 mmol). Light-yellow crystals of **2** were obtained (0.018 g, 31.0%). $C_{36}H_{21}HoN_2O_8$ (774.48): calcd. C 55.83, H 2.73, N 3.62; found C 55.56, H 2.37, N 3.54. IR (KBr pellet): $\tilde{\nu}$ = 3439 m, 1705 m, 1619 m, 1552 m, 1494 m, 1423 s, 1362 m, 806 m, 792 m cm^{-1}.

$[Yb_2(NDC)_3(phen)_2]\cdot H_2NDC$ (3): The same procedure was applied as that for **1**, but with the following quantities: dipotassium 2,6-naphthalenedicarboxylate (0.044 g, 0.15 mmol), H_2O (10 mL), hydrochloric acid (1.65mol·L^{-1}, 4 drops), $YbCl_3\cdot 6H_2O$ (0.039 g, 0.1 mmol), and phen·H_2O (0.04 g, 0.2 mmol). Light-yellow crystals of **3** were obtained (0.016 g, 27.3%). $C_{36}H_{21}N_2O_8Yb$ (782.59): calcd. C 55.25, H 2.70, N 3.58; found C 55.63, H 2.91, N 3.72. IR (KBr pellet): $\tilde{\nu}$ = 3427 m, 1548 s, 1492 m, 1415 s, 1354 s, 1195 m, 921 w, 796 m, 775 m, 565 m cm^{-1}.

X-Ray Crystallography: The single-crystal X-ray data collection of complexes **1** and **3** was performed using a Nonius−Kappa CCD diffractometer, and that of **2** using a Bruker Smart 1000 CCD diffractometer, and graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å). Semiempirical absorption corrections were applied. The structures were solved by direct methods and refined by full-matrix least-squares methods on F^2 using the SHELXTL-97 program.[51] All non-hydrogen atoms were refined using anisotropic displacement parameters. The hydrogen atoms were generated geometrically and treated by a mixture of independent and constrained

Main Chain Ferrocenyl Amides from 1-Aminoferrocene-1′-carboxylic Acid

Katja Heinze*[a] and Manuela Schlenker[a]

Keywords: Metallocenes / Hydrogen bonds / Peptides / Conformation analysis

The non-natural amino acid 1-aminoferrocene-1′-carboxylic acid is synthesised from ferrocene in eight steps. The folding and association phenomena of amido-substituted ferrocenes in the crystal as well as in solution are studied by X-ray crystallography, IR and NMR spectroscopy and DFT calculations. The amino acid is selectively protected at the amino group with the use of the fluorenyl-9-methoxycarbonyl (Fmoc) group. An amide-linked ferrocene dimer is prepared using the HOBt/DCC protocol for amide formation. In the crystal the dimer forms a hydrogen-bonded sheet structure, while in solution dynamic intramolecular hydrogen bonds are observed by VT ^{1}H NMR and IR spectroscopy. The dynamic flipping process has been rationalised by DFT calculations.

Introduction

Natural materials are often superior to their artificial synthetic counterparts. The structural and functional variety of peptides is very impressive, especially when considering that only a few α-amino acids are incorporated. Introduction of non-natural amino acids into peptides may lead to novel biomaterials or hybrid materials with some properties that are similar to those of natural proteins such as folding, or with additional properties such as conductive, optical or magnetic properties.[1] The latter properties may be obtained through incorporation of transition metals in the main chain,[2] while folding and supramolecular organisation into stable conformations may be achieved by forming intra- and intermolecular hydrogen bonds to control morphological aspects e.g. formation of nanotubes,[3] fibres,[4] or hydrogels.[5]

Ferrocene derivatives[6] have advantageous characteristics such as excellent stability in water and air, and favourable electrochemical properties which have led to applications of ferrocene in molecular receptors, in sensor devices with electrochemical detection,[7−10] and in labelling of biomolecules.[11,12] Furthermore, the inter-ring separation of ferrocene of about 3.3 Å (close to the N···O distance in β-sheets of peptides) and the rotational freedom of the cyclopentadienyl rings has allowed to use ferrocene 1,1′-dicarboxylic acid as an organometallic β-turn mimetic in ferrocene conjugates of amino acids and peptides,[13−16] and as a molecular pair of scissors.[17]

In our approach peptides with ferrocene moieties in the backbone are sequentially built up by a stepwise synthesis giving a well-defined chain length and a primary structure of the peptide which allows full structural characterisation by NMR spectroscopic methods and X-ray crystallography, as well as high-level calculations. The key ferrocene building block is the non-natural amino acid 1-aminoferrocene-1′-carboxylic acid. Its optimised synthesis and the full characterisation of all intermediates using X-ray structural techniques, VT NMR spectroscopy[18] and DFT calculations is reported here, along with the application of fluorenyl-9-methoxycarbonyl (Fmoc)[19] solution-phase chemistry for *N*-protection and acid activation via benzotriazole ester.

Results and Discussion

Synthesis of 1-Aminoferrocene-1′-carboxylic Acid, Hydrochloride

In 1998 the first synthesis of 1-aminoferrocene-1′-carboxylic acid **9** was reported by Butler and Quayle.[20] However, the method yielded a mixture of compounds which could not be separated and purified. In the same year a different synthetic approach was used by Ueyama et. al, which gave pure 1-aminoferrocene-1′-carboxylic acid, hydrochloride **9** but in quite a low yield (28% from **6**[21]). As the yields of the reactions were unsatisfactory for a broader investigation and only few spectroscopic data were given,[20−22] we report on the optimised synthesis (51% from **6**) and detailed characterisation of **9** and all synthetic intermediates.

Scheme 1 summarises the reaction sequence starting from ferrocene **1** to give 1-aminoferrocene-1′-carboxylic acid, hydrochloride **9·HCl**. The key synthon in this synthesis is 1-aminoferrocene (**5**). Although aminoferrocene is a known compound, the main drawback for further preparative work is the tedious multistage preparation starting from ferro-

cene, with ferrocenylazide[23,24], *N*-ferrocenylacetamide[25] or *N*-ferrocenylphthalimide[26] as key intermediates. The best method for a multigram synthesis of aminoferrocene proves to be the Gabriel synthesis from *N*-ferrocenylphthalimide (**4**), although this route necessitates the synthesis of 1-haloferrocene or ferrocene boronic acid as precursors of **4**. A high-yield synthesis of iodoferrocene **3** has been reported by Bildstein et. al.[26] starting with the selective mono-lithiation of ferrocene **1** with *t*BuLi, then isolating the solid lithio-ferrocene **2** and quenching of **2** with iodine. The reaction in pyridine of **3** with phthalimide and Cu_2O as catalyst has been reported to give the *N*-ferrocenylphthalimide **4**.[26] However, the reaction is accompanied by the formation of biferrocenes by copper-mediated C−C coupling even in the presence of excess phthalimide. The product **4** is thus contaminated with biferrocenes and phthalimide which could not be removed. To circumvent these problems, **4** is prepared in the absence of solvent directly from **3** and pre-formed Cu−phthalimide.[27,28] Hydrazinolysis of **4** in ethanol gives pure **5**, which is then *N*-acetylated with acetic anhydride to form 1-(acetylamino)ferrocene **6**. The *N*-acetylamino group deactivates the substituted Cp ring, allowing the selective Friedel−Crafts acylation of **6** with 2,6-dichlorobenzoyl chloride[21,24,29] at the unsubstituted Cp ring giving 1-(acetylamino)-1′-(2,6-dichlorobenzoyl)ferrocene (**7**). Basic hydrolysis of **7** introduces the desired COOH group seen in **8**. However, the yield of this reaction depends highly on the exact stoichiometric amount of added water. Removal of the acetyl protection group with hydrochloric acid furnishes the ferrocene-containing amino acid **9** as the hydrochloride.[21]

molecules (Figure 1). Bond lengths and angles in this compound compare well with similar systems (Table 1).[30] The plane of the phthalimido ring system is slightly rotated out of the adjacent Cp ring plane (angle between planes 18°). In a similar ferrocenyl-(2,3-naphthalimide) system with a CH_2 link between ferrocene and the naphthalimide, the substituent ring plane is located almost perpendicular to the Cp ring plane.[30]

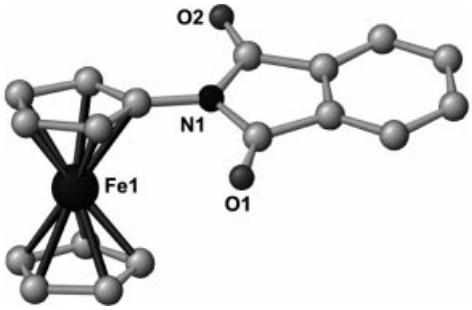

Figure 1. Molecular structure of **4** in the crystal

Aminoferrocene **5** crystallises in the tetragonal space group $I4_1/a$ (Figure 2). The bond lengths and angles are comparable with those found for 1,1′-diaminoferrocene (Table 1).[31] In the crystal the individual molecules of **5** are connected through N−H···N hydrogen bonds forming a helical arrangement along the crystallographic 4_1 screw axis (Figure 2) with a helical pitch of 5.93 Å (corresponding to the crystallographic *c*-axis). The N to N distance is 3.26 Å, and are in agreement with the distances found in the structure of 1,1′-diaminoferrocene (3.26, 3.10, 3.39 Å).[31]

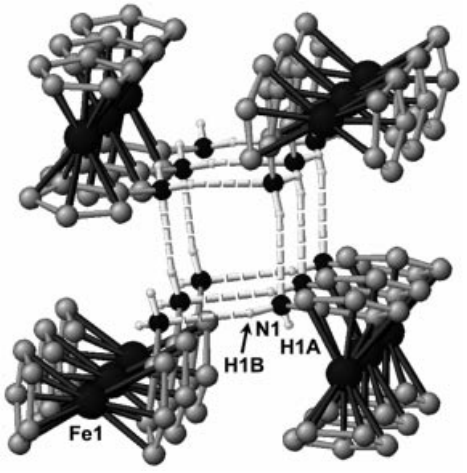

Figure 2. Hydrogen bonding of **5** in the crystal; view approximately along *c*

Compound **6** crystallises in the monoclinic space group $P2_1/n$ (Figure 3, Table 1). The molecules of **6** are connected through intermolecular N−H···O hydrogen bonds that connect the NH_{amide} group and the CO_{amide} group of a neighbouring molecule, forming chains along the *n* glide plane with a repeating distance of 9.54 Å (Figure 3). However, the $NH-CO-CH_3$ group is disordered over two positions, giving two different hydrogen bonds in the crystal: N1H1···O1X (N1 to O1X distance: 2.87 Å) and N1XH1X···O1 (N1X···O1 2.73 Å). A similar hydrogen-bonded chain has been observed in the related iodo-substituted complex $CpFeCpC(=O)NHCH_2I$ with a repeating distance of 9.55 Å and a N to O distance of 2.96 Å.[32]

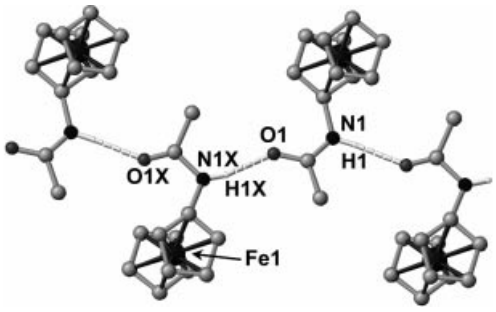

Figure 3. Hydrogen bonding of **6** in the crystal

The disubstituted ferrocene **7** crystallises in the monoclinic space group $P2_1/c$ (Figure 4, Table 1). Due to steric interactions the plane of the dichlorobenzene substituent is located almost perpendicular to the plane of the C6−C10 cyclopentadienyl ring (angle between planes: 82.9°). The molecules of **7** are connected through intermolecular N−H···O hydrogen bonds between the NH_{amide} group and the CO_{amide} group of a neighbouring molecule, forming chains along the 2_1 screw axis with a repeating distance of 9.02 Å; this is similar to that observed in structure **6** (Figure 3). The O1 to N1 distance is 2.88 Å and is similar to those found in **6** and the related complexes $H_3CC(=O)NHCpFeCpC(=O)NHCH_3$ (2.85 and 2.87 Å)[21] and $H_3CC(=O)NHCpFeCpC(=O)OCH_3$ (2.93 Å[33]).

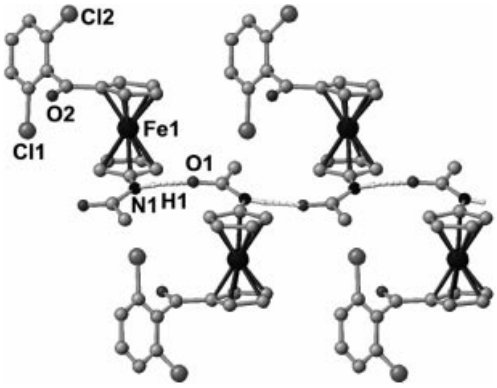

Figure 4. Hydrogen bonding of **7** in the crystal

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

The acid **8** crystallises in the orthorhombic space group *Pbca* with inclusion of one methanol molecule (Figure 5, Table 1). The ferrocene complexes are connected through O−H···O hydrogen bonds between the acid OH group (O3H6···O4; O3 to O4 distance: 2.56 Å) over the methanol and the amide CO group (O4H23···O1; O4 to O1 distance: 2.69 Å) to form a helical chain along a twofold axis (parallel to the *b* axis). These chains are further connected through NH···O hydrogen bonds between the amide NH group and the acid CO group (N1H1···O2; N1 to O2 distance: 2.91 Å). The same NH···O hydrogen-bonding motif has also been observed in the crystal structure of the corresponding methyl ester $H_3CC(=O)NHCpFeCp-C(=O)OCH_3$ that forms a dimer with an N to O distance of 2.93 Å.[33]

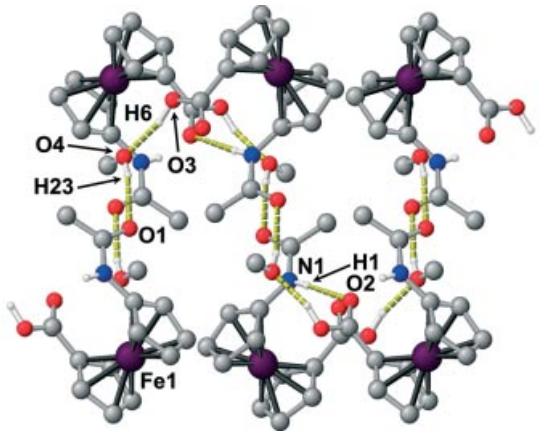

Figure 5. Hydrogen bonding of **8** in the crystal

Properties of 4−9

NMR spectroscopic data of compounds **4**−**13** are collected in Table 2 and Table 3, while UV/Vis spectroscopic and cyclic voltammetric data of **4**−**13** are given in Table 4.

In solution, the phthalimide substituent of **4** undergoes an easy torsional vibration around the C1−N1 bond leading to a time-averaged C_s symmetry of the molecule. Thus, in the ^1H and ^{13}C NMR spectra signal sets for a C_s-symmetric molecule are observed, e.g. only one ^{13}C resonance for the carbonyl carbon nuclei at δ = 167.0 is seen (Table 3; in contrast to the two erroneous reported values of δ = 165.1 and 167.0[26]). The IR absorption spectrum shows the signals assigned to the symmetric and asymmetric CO vibrations at 1778 cm^{-1} and 1717 cm^{-1}, respectively. In the UV/Vis spectrum of **4** bands corresponding to the ferrocene unit and to the phthalimide substituent are observed, and are in agreement with those reported for a similar ferrocenyl-1,8-naphthalimide (Table 4).[30] Further, the cyclic voltammogram of **4** displays waves corresponding to the oxidation of the ferrocene moiety at $E_{1/2}$ = 450 mV and the reduction of the phthalimide group at $E_{1/2}$ = −1470 mV (Table 4).[30]

The hydrogen bonding observed in the crystal of aminoferrocene **5** is also seen in the solid-state IR absorption spectrum: the signals for the NH stretching vibrations appear at 3400 cm^{-1} and 3336 cm^{-1}. The signal for the NH_2 deformation vibration is observed at 1621 cm^{-1}. In concen-

Table 5. Characteristic IR spectroscopic data of the amide groups of complexes **6**, **7**, **8**, **11**, **12** and **13**

	6	**7**	**8**	**11**	**12**	**13**
amide A (solid)[a]	3262	3275	3322	3359	3319	3327/3316
amide A (CH_2Cl_2)[a]	3435	3431	3303	3428/3363	3291	3430/3292
amide I (solid)[b]	1655	1659	1666	1682	1672	1660/1646
amide I (CH_2Cl_2)[b]	1685	1687	1691	1689	1677	1679/1660
amide II (solid)[c]	1580	1574	1569	1548	1569	1560
amide II (CH_2Cl_2)[c]	1532	1531	1557	1536	1526	1559/1529

[a] Amide A = $\tilde{\nu}_{NH,stretching}$. [b] Amide I = $\tilde{\nu}_{CO,stretching} + \tilde{\nu}_{NH,bending} + \tilde{\nu}_{CN,stretching}$. [c] Amide II = $\tilde{\nu}_{NH,bending} + \tilde{\nu}_{CN,stretching}$.

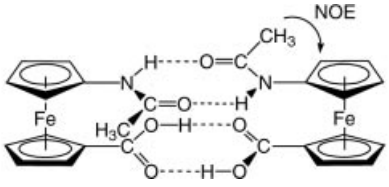
trated solutions the bands of the NH stretching vibrations are slightly shifted to 3425 and 3354 cm^{-1} showing the presence of hydrogen bonding (in dilute solutions these bands are observed at 3757 and 3692 cm^{-1})[24]. Compound **5** is oxidised at +130 mV (vs. SCE), a much more positive potential than 1,1′-diaminoferrocene (approximately −200 mV vs. SCE[31]). Obviously, the electron-donating effect of the amino groups to the metal centre is additive.[34]

In the solid-state IR absorption spectrum of **6** the characteristic amide vibrations confirm the presence of hydrogen bonds (Table 5). In dilute solutions, however, the bands assigned to amide A and amide I are shifted to higher energies, while that of amide II is shifted to a lower energy, suggesting that hydrogen bonding is absent (Table 5). This finding is also corroborated by the ^1H NMR spectrum of **6** as the signal for the amide proton appears at δ = 6.59 in CD_2Cl_2 at 293 K (Table 2). A weak temperature dependence is indicative of either a non-bonded hydrogen atom or a hydrogen atom involved in a locked hydrogen bond.[13,18] For **6**, the weak temperature dependence of $\Delta\delta_{NH} = -2.9$ ppb K^{-1} is interpreted in terms of the absence of hydrogen bonding (Table 2); thus, **6** is not associated in solution. The cyclic voltammogram of **6** shows that it is oxidised at +325 mV (vs. SCE), a much more positive potential than the amino compound **5** (Table 4).

An IR spectroscopic investigation of **7** shows the presence of hydrogen bonds in the solid state, while in solution no hydrogen bonding is detected (Table 5). This is also verified by the ^1H chemical shift of the amide proton resonating at δ = 6.73 with $\Delta\delta_{NH} = -3.4$ ppb K^{-1} in CD_2Cl_2 (Table 2). Thus, **7** like **6** does not associate in solution. The UV/Vis absorption band for the ferrocene unit of **7** at 480 nm is probably admixed with a charge transfer component (from the electron-rich ferrocene to the electron-deficient aromatic system), and thus appears at a relatively low energy and with a high intensity (Table 4).[35] The absorption band for the aromatic substituent appears at 358 nm. The ferrocene moiety is oxidised at 585 mV and the aromatic substituent is reduced at −1480 mV (Table 4).

The hydrogen bonding observed in the crystal of **8** is also apparent in the solid-state IR absorption spectrum (Table 5). In solution the IR absorption data suggest a hydrogen bond involving the amide hydrogen atom (Table 5). In the proton NMR spectrum a signal at δ = 7.15 in CD_2Cl_2 (δ = 8.40 in THF, Table 2) is observed which is assigned to the amide proton on the basis of the NOESY spectrum (correlation between NH and CH_3). This low-field chemical shift as well as the large temperature depen-

dence $\Delta\delta_{NH} = -12$ ppb K^{-1} confirm that the NH proton is involved in a dynamic hydrogen bond in solution, which can arise from either intermolecular association or intramolecular folding processes.[13,18] The characteristic signal for the vibration of the acid carbonyl group appears at 1715 cm^{-1} in CH_2Cl_2 and in THF, and is similar to that found for ferrocenedicarboxylic acid (1720 cm^{-1} in THF), and suggests the formation of carboxylic acid dimers. As both functional groups are involved in hydrogen bonding, a dynamic intermolecular aggregation in solution is proposed (Scheme 2). The *cis* orientation of the amide groups necessary for intermolecular dimerisation (Scheme 2) is confirmed by NOESY spectroscopy (correlation peak between the CH_3 group and Cp protons H-2/5).



Scheme 2

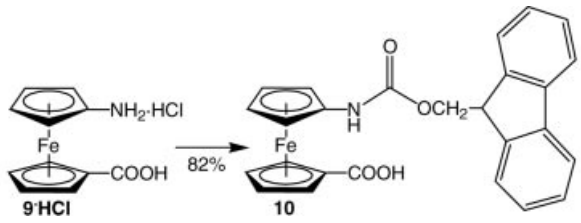
DFT calculations (see Supporting Information) on monomeric **8** show that the non-hydrogen-bonded structure is the global minimum and the $O_{acid}-H\cdots O_{amide}$ hydrogen-bonded structure is a local minimum 13 kJ mol^{-1} higher in energy, while no minimum is found for the $N_{amide}-H\cdots O_{acid}$ hydrogen-bonded structure. However, the dimeric fourfold hydrogen-bonded structure is calculated to be a minimum 73 kJ mol^{-1} more stable than two isolated molecules of **8** (although this might be an overestimated stabilisation energy due to the basis set superposition error BSSE[36]), confirming the presence of intermolecular hydrogen bonds.

The amino acid **9** can be isolated as the hydrochloride salt **9·HCl** which is soluble and stable in water and dimethyl sulfoxide. Neutralisation of an aqueous solution of **9·HCl** with sodium hydroxide immediately leads to the precipitation of the zwitterionic compound, which rapidly decomposes to a black material at pH > 7. The solid-state IR absorption spectrum of **9·HCl** shows absorption bands that are assigned to the NH and OH groups at 3366, 3177 and 3135 cm^{-1}, indicating extensive hydrogen bonding which is probably intermolecular in nature. The UV/Vis absorption band for the ferrocene moiety of **9·HCl** appears at 431 nm, and is blue-shifted by more than 500 cm^{-1} relative to the bands of e.g. **4**−**6** (441−443 nm) probably due to the cationic nature of the complex.

Peptide Chemistry

A) N-Protection, Crystal and Solution Structure of 10

Since the stability of **9** in alkaline solution is rather poor, *N*-protection of **9** with fluorenyl-9-methyl chloroformate (Fmoc-Cl) has been carried out in buffered solution (phosphate buffer, pH 7) to give the *N*-protected amino acid 1-[(fluoren-9-yl)methyloxycarbonylamino]ferrocene-1′-carboxylic acid (**10**) (Scheme 3).



Scheme 3

Compound **10** crystallises in the monoclinic space group $P2_1/c$ with the inclusion of half a molecule dichloromethane per molecule (Figure 6, Table 1). The asymmetric unit contains two independent molecules **10(A)** and **10(B)** which are connected through double O−H···O hydrogen bonds involving the carboxylic acid functions (O3H6···O102, O3···O102 distance: 2.63 Å; O103H106···O2, O103···O2 distance: 2.59 Å) and double N−H···O hydrogen bonds involving the *cis*-orientated urethane HNCO groups (N1H1···O101; N1···O101 distance: 2.83 Å; N101H101···O1; N101-to-O1 distance: 2.86 Å) to form a dimer of approximate C_2 symmetry (Figure 6). The same two eight-membered rings have been detected in the crystal structure of the related Boc-protected complex HOOC−CpFeCpNH(C=O)O*t*Bu (Boc = *tert*-butoxycarbonyl) with O···O distances of 2.66 and 2.66 Å and N···O distances of 2.83 and 2.85 Å.[37] The planes of the fluorenyl substituents are located almost perpendicular to the planes of the cyclopentadienyl rings to which they are attached [**10(A)**: 91.2°, **10(B)**: 83.4°].

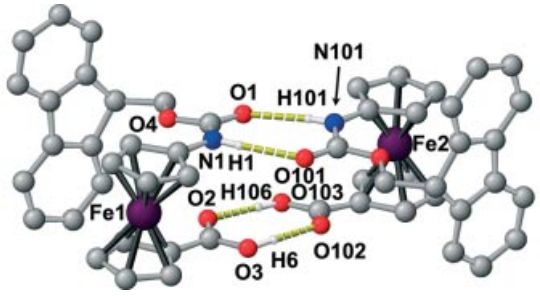


Figure 6. Hydrogen bonding of **10** in the crystal

The hydrogen bonding observed in the crystal of **10** is also confirmed by the IR absorption spectrum which shows the absorption bands assigned to the NH and OH groups between 3500−2800 cm^{-1}, signals for the carbonyl groups at 1707 (vs) and 1664 (s) cm^{-1}, and signals at 1560 (w) and 1544 (w) cm^{-1}. This pattern in the spectral region 1800−1500 cm^{-1} is in accordance with the pattern for a *cis*-orientation of the urethane moiety of **10** calculated by

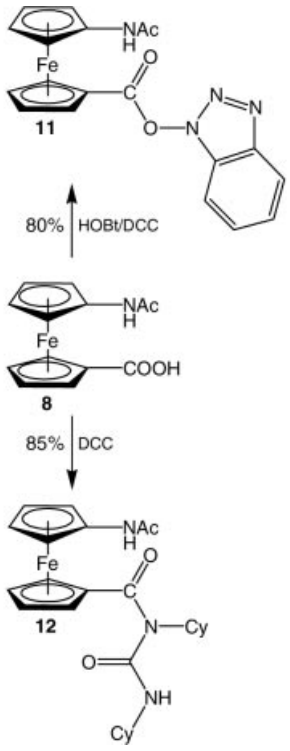
 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

DFT [1682 (1.00), 1668 (0.46), 1548 (0.11), 1510 (0.09) cm^{-1}; see Supporting Information].

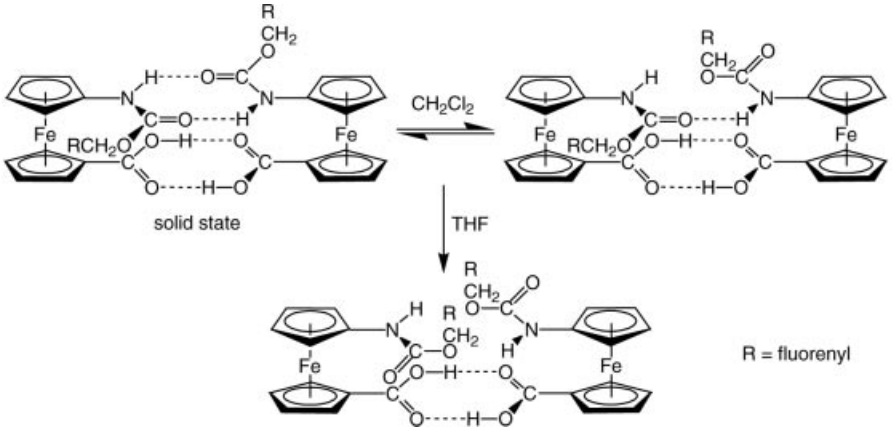
In CH_2Cl_2 solution two dominant bands are observed at 1707 (vs) and 1673 (s) cm^{-1} and two weak bands at 1570 and 1542 cm^{-1}, suggesting that a *cis*-urethane conformation is the major species. In addition, a shoulder at 1735 cm^{-1} is observed indicating the presence of another species in CH_2Cl_2 solution. In THF solution, however, a different pattern is observed: 1735 (s), 1716 (s) and 1563 (s) cm^{-1}. DFT calculations on **10** with a *trans*-orientated urethane group predict a comparable pattern: 1715 (0.78), 1694 (0.67), 1569 (0.73) cm^{-1} (see Supporting Information). Thus, **10** prefers the *cis*-conformation in CH_2Cl_2 solution and in the crystal and the *trans*-conformation in THF.[38,39] In all cases the acid group appears to be hydrogen bonded via carboxylic acid dimers. In the NH/OH region of the IR absorption spectrum bands are observed at 3266, 3316 and 3425 cm^{-1} in CH_2Cl_2 and at 3269, 3504 and 3573 cm^{-1} in THF. Thus hydrogen bonding involving the NH group exists in CH_2Cl_2 and is absent in THF. NMR spectroscopy supports this interpretation: in CD_2Cl_2 solution two resonances[38,39] assigned to the NH protons are observed at δ = 6.95 (free NH group; *trans* conformation; $\Delta\delta_{NH}$ could not be determined as the signal moves into the multiplet for the fluorenyl protons) and δ = 7.99 (hydrogen-bonded NH group; *cis* conformation; $\Delta\delta_{NH} = -7$ ppb K^{-1}) with equal intensity, together with a doubled signal set for all Cp protons and the CH_2 group, while in THF solution only a single signal set for the NH, Cp and CH_2 protons is observed (Table 2). Based on the experimental data, the proposed dynamic solution structure of **10** is depicted in Scheme 4. The *cis*-orientated species which has the opportunity to form hydrogen bonds is the dominant species in CH_2Cl_2, while the *trans*-orientated conformer without NH hydrogen bonds is the major species in THF. These bonding motifs can be derived from the crystal structure of **10** (Figure 6) by cleaving one and two N−H···O hydrogen bonds, respectively, concomitant with a *cis*/*trans* rearrangement. A similar type of aggregation − albeit more stable − has been proposed for the similar complex **8** (Scheme 2).

B) COOH Activation, Crystal and Solution Structures of 11 and 12

Reaction of the *N*-acetylated amino acid **8** with 1-hydroxybenzotriazole (HOBt) in the presence of 1,3-dicyclohexylcarbodiimide (DCC) leads to the formation of the isolable ferrocenoyl benzotriazole ester **11** (Scheme 5). This reaction is similar to that of ferrocene carboxylic acid with HOBt/DCC.[40] In the absence of HOBt **8** reacts with



Scheme 5



Scheme 4

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

DCC to give 1-[1′-(acetylamino)ferrocenylcarbonyl]-1,3-dicyclohexylurea (**12**) in a reaction similar to that of ferrocenecarboxylic acid with DCC.[41−43]

The activated ester **11** crystallises in the monoclinic space group $P2_1/n$ as discrete molecules (Table 1). The benzotriazole substituent is rotated out of the ester plane by 88.6°, similar to Fc-COOBt (96.6°[40]) but pointing in the opposite direction. This orientation allows for an intramolecular hydrogen bond from the amide NH to the central nitrogen atom of the Bt group (N1 to N3 distance: 3.06 Å, Figure 7).

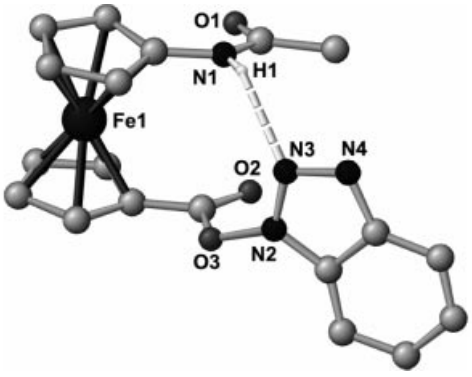


Figure 7. Molecular structure of **11** in the crystal

In the solid state the characteristic IR absorption bands of **11** appear at 3359 (amide A), 1764 (CO_{ester}), 1682 (amide I) and 1548 (amide II) cm^{-1}, while in solution these bands are shifted to 3428, 3363 (amide A), 1787 (CO_{ester}), 1689 (amide I) and 1536 (amide II) cm^{-1} (Table 5). These data show that in the solid state and in solution hydrogen bonding involving the NH part of the amide group occurs. DFT calculations suggest that the solution structure is identical to the crystal structure (Figure 8, see Supporting Information). This intramolecular hydrogen-bonded system is stabilised by 19 kJ mol^{-1} relative to the open form according to DFT calculations. The activation barrier for the hydrogen-bond dissociation is calculated to be 27 kJ mol^{-1}. This interpretation is supported by NMR spectroscopy: the signal for the amide proton appears at $\delta = 7.42$ in CD_2Cl_2 suggesting the presence of hydrogen bonding in dilute solution (Table 2). The signal is temperature dependent, with $\Delta\delta_{NH} = -3.4$ ppb K^{-1} when excluding intermolecular hydrogen bonding (a larger temperature dependence is expected when intermolecular hydrogen bonding is included[13,18]). In the VT-^{1}H NMR spectra the proton signals for the cyclopentadienyl rings H-2/5, H-3/4, H-7/10 and H-8/9 disappear at low temperature with a coalescence temperature (T_C) of 223, 213, 213 and 203 K, respectively, and reappear as separate signals with $\Delta\nu = 168$, 57, 39 and 9 Hz at lower temperature (Figure 8). This finding can be interpreted as a "frozen" interconversion of the enantiomeric hydrogen-bonded structures of **11** rendering the protons pairs H-2/5, H-3/4, H-7/10 and H-8/9 magnetically different (Figure 8). The activation barrier for this process can be estimated to be $\Delta G^{\neq}(T_C) = 43$ kJ mol^{-1}.

In the UV/Vis spectrum the absorption band for the ferrocene unit of **11** appears at 457 nm (probably admixed

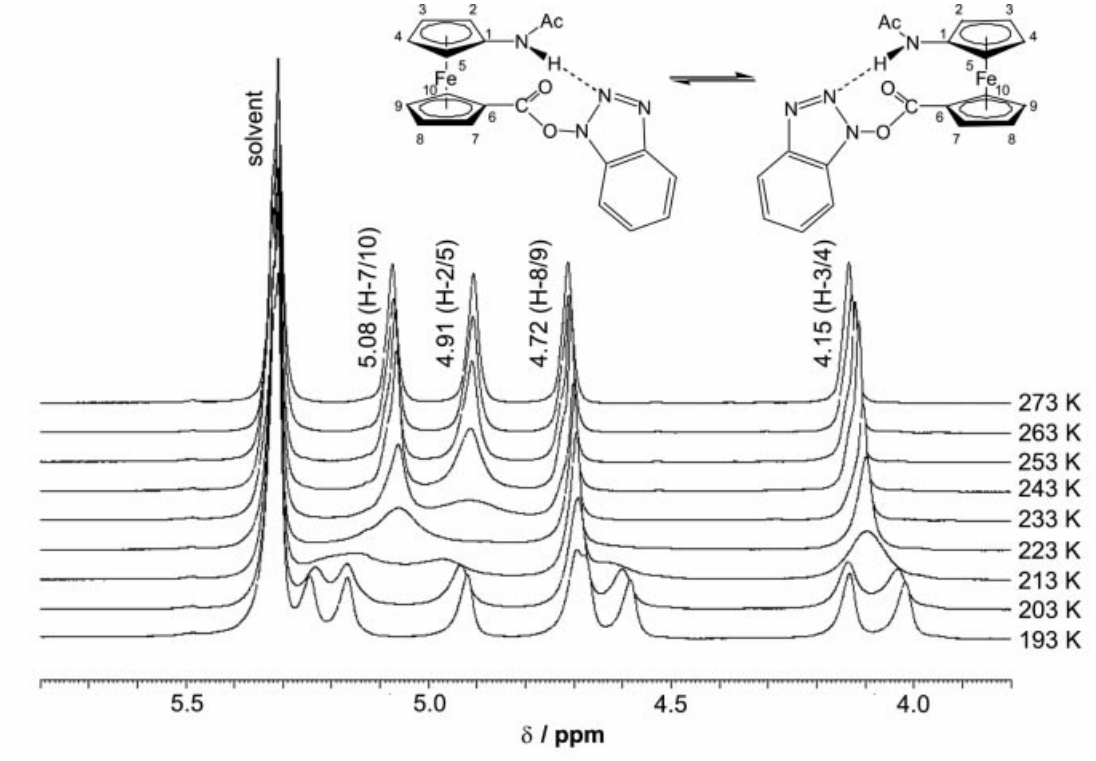

Figure 8. Partial VT-^{1}H NMR spectra of **11** (CD_2Cl_2, 500 MHz) and proposed interconversion of the enantiomeric hydrogen-bonded structures of **11**

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

with a charge-transfer component); the absorption band for the benzotriazole group is observed at 370 nm (Table 4). In the cyclic voltammogram the oxidation potential of the ferrocene moiety is 670 mV (Table 4).

The urea derivative **12** crystallises in the monoclinic space group $P2_1/c$ (Table 1). An intramolecular hydrogen bond from the amide proton (N1H1) to the carbonyl oxygen atom O2 is observed (N1···O2 distance: 3.02 Å, Figure 9). This intramolecular hydrogen bond in the crystal structure of **12** proves that such strongly bent connections are indeed possible (cf. proposed solution structures of **11** and **13** and the crystal structure of **11**). The molecules of **12** are connected through two different intermolecular hydrogen-bonding motifs (Figure 10): a centrosymmetric dimeric aggregate through double hydrogen bonds N1H1···O2 (N1···O2 2.96 Å), resulting in bifurcated hydrogen bonds at O2 and H1 and a connection of molecules along the *b*-axis through the NH group of urea (N3H6) and the carbonyl oxygen atom of the *N*-acetyl group (O1) with a donor acceptor distance N3···O1 of 2.95 Å.

The characteristic IR absorption bands in the solid state arise from the hydrogen-bonded NH groups (3319 cm^{-1}), CH_2 and CH groups of the cyclohexyl rings (2934, 2886 cm^{-1}), CO groups (1699, 1672, 1625 cm^{-1}) and CN groups (1569, 1543 cm^{-1}); this is consistent with the observed hydrogen bonding in the crystal structure (Table 5). In solution two absorption bands are observed for the NH stretching vibrations at 3426 and 3291 cm^{-1}. The former is assigned to the non-hydrogen-bonded NH group of the urea moiety and the latter to the hydrogen-bonded NH group of the *N*-acetyl group. Three signals assigned to the carbonyl vibrations appear at 1697, 1677 and 1619 cm^{-1}. The low-energy vibration is assigned the hydrogen-bonded carbonyl group C13−O2. Thus, the IR absorption data suggest a solution structure with an intramolecular hydrogen bond N1−H1···O2 similar to that found in the crystal (Figure 9). The IR spectroscopic data are also in agreement with the DFT-calculated frequencies of the hydrogen-bonded structure (see Supporting Information). NMR experiments confirm this proposed structure as two signals for the amide protons are observed at $\delta = 5.88$ (H^6, NOE correlation to cyclohexyl protons) and $\delta = 7.78$ (H^1), with temperature dependences of $\Delta\delta_{NH} = -13$ and -5.7 ppb K^{-1}, respectively. The large $\Delta\delta_{NH}$ observed for the urea proton H^6 is probably due to the start of intermolecular association at lower temperatures. A static structure as found for **11** was not observed for **12** in the NMR experiments at lower temperatures implying that the activation barrier for the analogous interconversion of hydrogen-bonded structures of **12** is smaller than 40 kJ mol^{-1}.

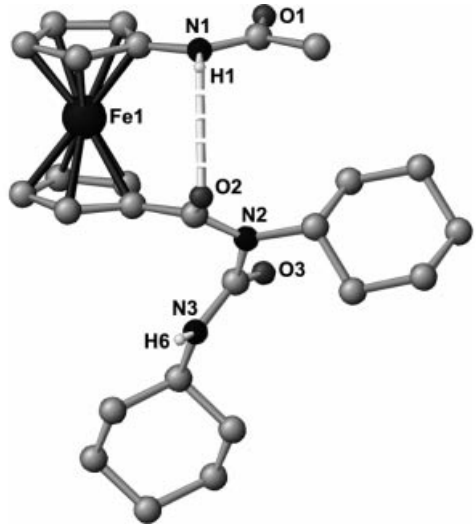

Figure 9. Molecular structure of **12** in the crystal

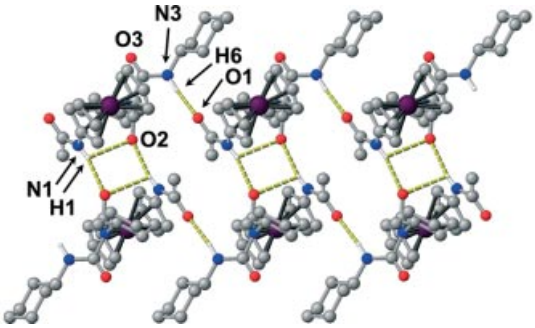

Figure 10. Hydrogen bonding of **12** in the crystal

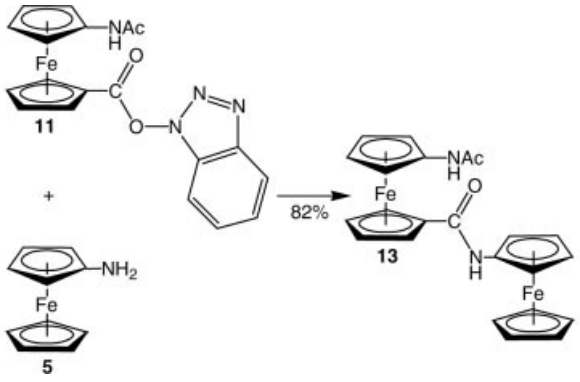
C) Amide Formation, Crystal and Solution Structure of 13

In the activated ester **11** the C−O ester bond to the benzotriazole is very long (1.423 Å), therefore allowing a facile reaction with amines. Thus, **11** cleanly reacts with aminoferrocene **5** to give the biferrocene **13** (Scheme 6).



Scheme 6

The diamide **13** crystallises in the polar orthorhombic space group $P2_12_12_1$ as a twinned racemic crystal (Figure 11). The individual molecules are connected through intermolecular hydrogen bonds between the NH-acetyl group and the amide carbonyl oxygen atom (N1···O2 distance: 3.04 Å) and between the NH-amide group and the carbonyl oxygen atom of the acetyl group (N2···O1 distance: 3.03 Å) resulting in a sheet structure (Figure 12).

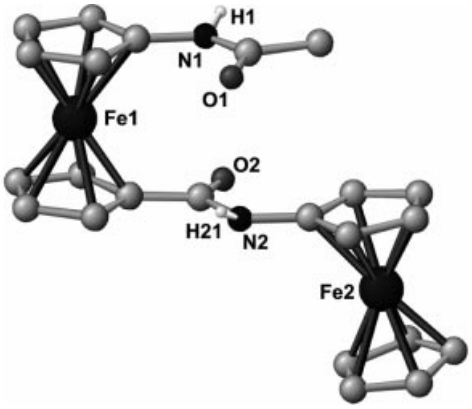

Figure 11. Molecular structure of **13** in the crystal

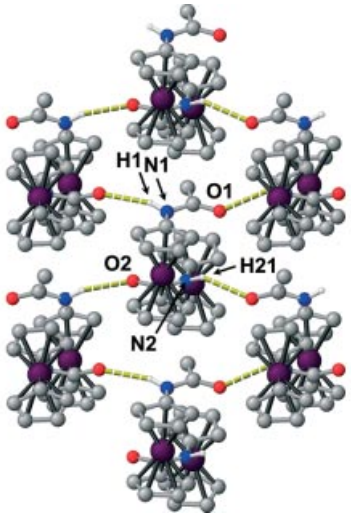

Figure 12. Hydrogen bonding of **13** in the crystal

In the solid-state IR absorption spectrum of **13** the characteristic absorption bands confirm a hydrogen-bonded structure involving all NH protons and all carbonyl groups

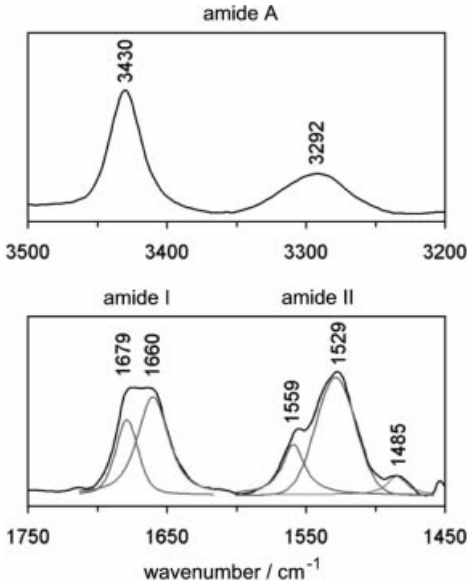

Figure 13. IR spectrum of **13** in CH_2Cl_2

(Table 5). In solution, however, one signal set for a hydrogen-bonded NHCO group (3292, 1660, 1559 cm^{-1}) and one set for a non-hydrogen-bonded NHCO group (3430, 1679, 1529 cm^{-1}) is observed (Table 5, Figure 13). These findings can be accounted for by one of the intramolecularly hydrogen-bonded structures **13a/13b**, as shown in Figure 14, or by a mixture of both structures which are indistinguishable by IR spectroscopy.

In the ^1H NMR spectrum of **13** in CD_2Cl_2 two NH resonances are observed at $\delta = 7.13$ and 8.33 with temperature dependences of $\Delta\delta_{NH} = -6.6$ and -11 ppb K^{-1}, respectively (Table 2). The former signal is assigned to the proton of the NH-acetyl group (NOESY correlation peak between CH_3 and NH) and the latter to the NH proton of the amide bond. The chemical shifts and their temperature dependences suggest that *both* protons are involved in *dynamic* hydrogen bonding. This can be rationalised by a flipping

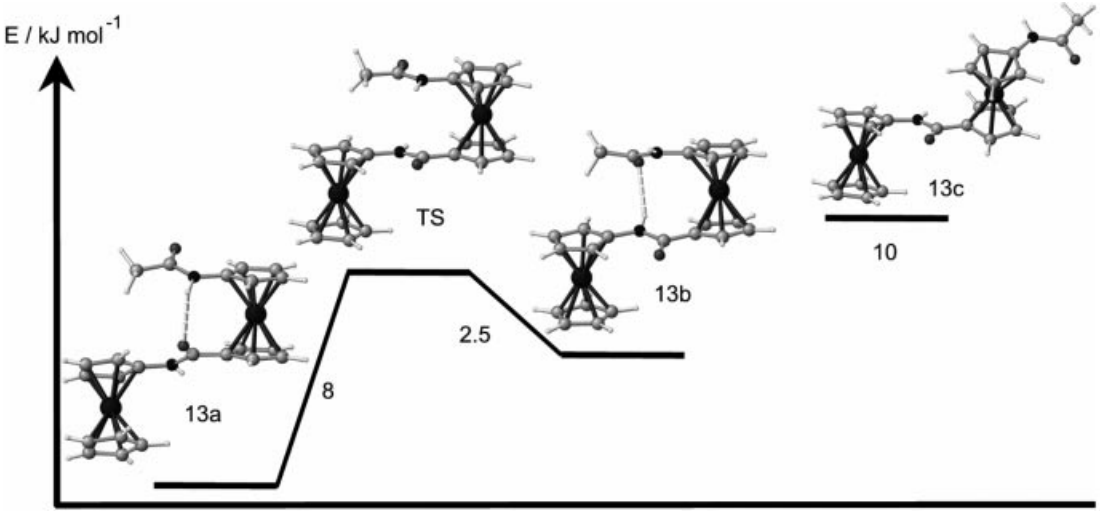

Figure 14. Interconversion of the two hydrogen-bonded structures of **13** (**13a/b**) and the extended form **13c** (DFT: B3LYP, LanL2DZ)

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

process that occurs between the two hydrogen-bonded structures **13a** and **13b**, as shown in Figure 14. This equilibrium is fast on the NMR time scale, averaging the NMR signals for free and hydrogen-bonded amide protons. DFT calculations on these two conformers confirm that both are minima on the potential energy surface with **13b** slightly higher in energy than **13a**. The activation barrier for the flipping process **13a** → **13b** is calculated to be only 8 kJ mol^{-1}, supporting the interpretation of a fast equilibrium (Figure 14, see Supporting Information). High-temperature NMR and IR studies show that the folded structures are stable up to 55 °C in chloroform. DFT calculations confirm the stability of **13a/13b** towards unfolding into the extended structure **13c** (Figure 14, $\Delta E_{\mathbf{13a/13c}}$ = 10 kJ mol^{-1}). From these energies, equilibrium compositions of 100:11:2 (**13a**:**13b**:**13c**) at 20 °C and 100:13:3 (**13a**:**13b**:**13c**) at 55 °C can be estimated which explain the experimental findings.

In addition to the folding characteristics imposed by the amide groups, the biferrocene compound **13** shows metal specific properties: (i) **13** absorbs at 451 nm with a small bathochromic shift relative to e.g. **12** (Table 4) and (ii) **13** can be oxidised in two reversible steps at 285 and 590 mV (Table 4). These values are different from the oxidation potentials of comparable mononuclear complexes e.g. **6** and **12** (Table 4). The constant for the comproportionation equilibrium K_C can be estimated to be 1.4×10^5, showing that $\mathbf{13^+}$ is stable towards disproportionation into **13** and $\mathbf{13^{2+}}$.

Conclusion

The optimised synthesis of the non-natural amino acid **9** reported here offers the possibility to incorporate ferrocenes in the main chain of peptides. Standard reactions of peptide synthesis (*N*-protection with Fmoc and acid activation with HOBt/DCC) have been applied to this ferrocene amino acid. The crystal structures of NHC(=O)R-substituted ferrocenes **6**−**13** have been determined by X-ray crystallography in order to elucidate hydrogen-bonding motifs. In most cases hydrogen bonding is found to be intermolecular, except in the case of the active ester **11** (only intramolecular) and the urea derivative **12** (both types). The solution structures have been investigated by a combination of IR and NMR spectroscopy, together with DFT calculations. In solution **6** and **7** are monomeric and non-hydrogen-bonded, **8** and **10** with C(=O)OH groups at the 1′ position form dimers via O−H···O and N−H···O hydrogen bonds, the active ester **11** forms an intramolecular hydrogen bond to the benzotriazole substituent, and **12** and **13** with C(=O)NRR′ groups at the 1′ position form intramolecular N−H···O hydrogen bonds. The structure of the diamide **13** in solution and in the crystal is reminiscent of the typical structures of peptides built from α-amino acids, i.e. α-helix and β-sheet structures, respectively.

This chemistry is currently extended to build ferrocene containing peptides in order to study their folding, electron-transfer and anion-sensing properties.[44]

Experimental Section

Unless noted otherwise, all manipulations were carried out under argon by means of standard Schlenk techniques. All solvents were dried by standard methods and distilled under argon prior to use. Iodoferrocene **3** was prepared by a literature method.[26] All other reagents were used as received from commercial sources. NMR spectra were recorded on Bruker Avance DPX 200 at 200.15 MHz (^{1}H), 50.323 MHz (^{13}C) at 303 K; chemical shifts (δ) in ppm with respect to residual solvent peaks as internal standards: CD_2Cl_2 (^{1}H: δ = 5.32; ^{13}C: δ = 53.5 ppm), $CDCl_3$ (^{1}H: δ = 7.24; ^{13}C: δ = 77.0 ppm), [D]$_6$DMSO (^{1}H: δ = 2.49; ^{13}C: δ = 39.7 ppm), [D]$_8$THF (^{1}H: δ = 1.73, 3.58; ^{13}C: δ = 25.5, 67.7), D_2O (^{1}H: δ = 4.65 ppm). Proton NMR spectra were measured at a concentration of 10 mM. Assignments are based on 2D NMR spectra and by comparison with spectra of similar compounds. IR absorption spectra were recorded on a BioRad Excalibur FTS 3000 spectrometer using CaF_2 cells (concentration < 10 mM) or CsI discs. UV/Vis/NIR spectra were recorded on a Perkin−Elmer Lambda 19, 0.2 cm cells (Hellma, suprasil). Cyclic voltammetry was performed using a glassy carbon electrode, a platinum electrode and a SCE electrode, 10^{-3} M in 0.1 M nBu$_4$NPF$_6$/CH_3CN, potentials are given relative to that of SCE. Mass spectra were recorded on a Finnigan MAT 8400 spectrometer, 4-nitrobenzyl alcohol (FAB). Elemental analyses were performed by the microanalytical laboratory of the Organic Chemistry Department, University of Heidelberg. Melting points were determined with a Gallenkamp capillary melting point apparatus MFB 595 010 and are uncorrected.

Computational Method: Density functional calculations were carried out with the Gaussian98/DFT[45] series of programs. The B3LYP formulation of density functional theory was used employing the LanL2DZ basis set.[45] Harmonic vibrational frequencies and infrared intensities were calculated by numerical second derivatives using analytically calculated first derivatives. Frequencies are not scaled.

Crystallographic Structure Determinations: The measurements were carried out on an Enraf−Nonius Kappa CCD diffractometer using graphite monochromated Mo-K_α radiation. The data were processed using the standard Nonius software.[46] All calculations were performed with the SHELXT PLUS software package. Structures were solved using direct or Patterson methods with the SHELXS-97 program and refined with the SHELXL-97 program.[47] Graphical handling of the structural data during refinement was performed using XMPA[48] and WinRay[49]. Atomic coordinates and anisotropic thermal parameters of the non-hydrogen atoms were refined by full-matrix least-squares calculations. Data relating to the structure determinations are collected in Table 6 and Table 7.

CCDC-225594−225602 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Copper Phthalimide: (modified literature procedure)[27,28] A solution of potassium phthalimide (20 g, 107 mmol) in water (50 mL) was added to an aqueous solution of $CuSO_4 \cdot 5H_2O$ (8 g, 32 mmol) in water (50 mL). The mixture was stirred for 30 min and the resulting light blue precipitate was filtered, washed with water and ethanol and dried in vacuo. Yield: 10.8 g (93%).

2-Ferrocenylisoindole-1,3-dione (4): Copper phthalimide (20 g) and iodoferrocene (7 g, 22 mmol) were made into a powder and heated

in vacuo at 135−140 °C for two hours. After cooling to room temperature, the mixture was washed with petroleum ether (boiling range 40−60 °C) to remove unchanged iodoferrocene. The residue was extracted with diethyl ether (5 ×). The combined extracts were evaporated in vacuo to give an orange solid. Yield: 6 g, 18 mmol (82%). $C_{18}H_{13}NO_2Fe$ (331.15): calcd. C 65.29, H 3.96, N 4.23; found C 64.88, H 4.06, N 4.87. IR (CsI): $\tilde{\nu}$ = 3095 (w, CH), 1778 (w, CO_{sym}), 1717 (vs, CO_{asym}), 1479 (s, CN) cm^{-1}. IR (CH_2Cl_2): $\tilde{\nu}$ = 1780 (w, CO_{sym}), 1720 (vs, CO_{asym}), 1484 (s, CN) cm^{-1}. MS (FAB): *m*/*z* (%) = 331 (100) [M$^+$], 266 (64) [M$^+$ − C_5H_5]. M.p. 148−151 °C.

1-Aminoferrocene (5): Compound **4** (3.57 g, 11 mmol) was dissolved in dry ethanol (50 mL). Hydrazine monohydrate (20 mL) was added and the mixture was heated under reflux for two hours. After cooling to ambient temperature, water (80 mL) was added

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

and the mixture was extracted with diethyl ether (3 ×). The combined organic phases were dried over Na_2SO_4, filtered and the solvents evaporated to dryness under reduced pressure to give a yellow solid which darkens on storage. Yield: 2.2 g, 10.9 mmol (99%). $C_{10}H_{11}NFe$ (201.05): calcd. C 59.74, H 5.51, N 6.97; found C 59.64, H 5.46, N 7.07. IR (CsI): $\tilde{\nu}$ = 3400, 3336 (w, NH), 3085 (w, CH), 1621 (br., NH_{2def}), 1500 (s, CN) cm^{-1}. IR (CH_2Cl_2): $\tilde{\nu}$ = 3425, 3354 (w, NH), 1616 (br., NH_{2def}), 1497 (s, CN) cm^{-1}. MS (EI): *m/z* (%) = 201 (100) [M^+], 121 (26) [$M^+ - CpNH_2$], 80 (24) [$C_5H_6N^+$].M.p. 153−155 °C.

1-(Acetylamino)ferrocene (6): Compound **5** (2.2 g, 10.9 mmol) was treated with acetic anhydride (20 mL) in the presence of sodium acetate (0.1 g, 1.2 mmol) for 18 hours. After removal of the solvent, the crude pale brown product was purified by recrystallisation from diethyl ether/petroleum ether (40:60) to give a golden powder. Yield: 2.5 g, 10.3 mmol (95%). $C_{12}H_{13}NOFe$ (243.09): calcd. C 59.29, H 5.39, N 5.76; found C 58.80, H 5.41, N 5.81. IR (CsI): $\tilde{\nu}$ = 3262, 3216 (m, NH), 3094, 2854 (w, CH), 1655 (s, CO), 1580 (s, CN) cm^{-1}. IR (CH_2Cl_2): $\tilde{\nu}$ = 3435 (m, NH), 1685 (s, CO), 1532 (s, CN) cm^{-1}. MS (FAB): *m/z* (%) = 243 (100) [M^+]. M.p. 169−171 °C.

1-(Acetylamino)-1′-(2,6-dichlorobenzoyl)ferrocene (7): A solution of **6** (4 g, 16 mmol) in dichloromethane (30 mL) was treated with 2,6-dichlorobenzoyl chloride (2.56 mL, 16 mmol) and $AlCl_3$ (3.06 g, 23 mmol) at 0 °C. The resulting blue solution was stirred for 30 minutes at 0 °C and for two hours at room temperature. The mixture was cooled by carefully adding cold water (50 mL). The colour of the solution turned red immediately. The aqueous solution was extracted with dichloromethane (3 ×) and the combined organic phases were washed with water and 10% NaOH (aq.). After drying over $MgSO_4$ and filtering, the solution was evaporated under reduced pressure to obtain a red oil. Repeated washing with diethyl ether gave a red microcrystalline product. Yield: 4.9 g, 11.8 mmol (74%). $C_{19}H_{15}Cl_2NO_2Fe$ (416.09): calcd. C 54.85, H 3.63, N 3.37; found C 54.78, H 3.81, N 3.35. IR (CsI): $\tilde{\nu}$ = 3275, 3223 (m, NH), 3105, 2853 (w, CH), 1659 (s, CO), 1638 (sh, CO), 1574 (s, CN) cm^{-1}. IR (CH_2Cl_2): $\tilde{\nu}$ = 3431 (w, NH), 1687 (s, CO), 1655 (s, CO), 1531 (s, CN) cm^{-1}. MS (EI): *m/z* (%) = 415 (100) [M^+], 373 (22) [$M^+ - C_2H_2O$], 293 (16) [$M^+ - CpNHCOCH_3$], 178 (100) [$M^+ - CpCOAr$]. M.p. 160 °C.

1-(Acetylamino)-ferrocene-1′-carboxylic Acid (8): A solution of **7** (3.5 g, 8.4 mmol) in 1,2-dimethoxyethane (20 mL) was added to a slurry of potassium *tert*-butoxide (3.8 g, 33 mmol) and water (0.15 mL) while cooling under ice. The red solution was heated under reflux for one hour. A colour change from red to brown was observed. After cooling to ambient temperature, water (20 mL) was added and the solution was washed with diethyl ether. The organic phase was back extracted with 10% NaOH (aq.) and water. The combined aqueous phases were acidified with dilute HCl. The crude product was obtained by extraction with ethyl acetate, drying over $MgSO_4$ and evaporation to dryness. After repeated washing with diethyl ether, an orange-brown product was obtained. Yield: 1.7 g, 5.9 mmol (70%). $C_{13}H_{13}NO_3Fe$ (287.10): calcd. C 54.39, H 4.56, N 4.88; found C 54.38, H 4.55, N 4.83. IR (CsI): $\tilde{\nu}$ = 3322, 3225 (m, NH), 3300−2500 (br., OH), 1698 (sh, CO), 1666 (s, CO), 1569 (s, CN) cm^{-1}. IR (CH_2Cl_2): $\tilde{\nu}$ = 3303 (w, NH), 3235 (w, OH), 1715 (s, CO), 1691 (sh, CO), 1557 (s, CN) cm^{-1}. MS (EI): *m/z* (%) = 287 (100) [M^+], 245 (4) [$M^+ - C_2H_2O$], 178 (28) [$M^+ - CpCOOH$], 165 (4) [$M^+ - CpNHCOCH_3$], 135 (22) [$M^+ - CpCOOH - C_2H_2O$]. M.p. 146−147 °C.

1-Aminoferrocene-1′-carboxylic Acid, Hydrochloride (9·HCl): Compound **8** (0.6 g, 2 mmol) was heated under reflux in 6 N HCl (aq.) (15 mL) for 30 minutes. The mixture turned to a clear brown solution. After filtration, the solvents were evaporated to dryness and the brown residue was washed with tetrahydrofuran and diethyl ether to obtain the product as a light brown solid. Yield: 0.55 g, 1.96 mmol (98%). $C_{11}H_{11}NO_2Fe$ (245.06)·2HCl·0.5H_2O: calcd. C 40.41, H 4.32, N 4.28; found C 39.98, H 4.52, N 4.78. IR (CsI): $\tilde{\nu}$ = 3366 (vs, OH), 3177, 3135, 3030 (m, NH_3^+), 1628 (m, CO) cm^{-1}. MS (FAB): *m/z* (%) = 245 (100) [M^+], 228 (24) [$M^+ - NH_4$]. M.p. 165 °C (dec.).

1-[(Fluoren-9-yl)methyloxycarbonylamino]ferrocene-1′-carboxylic Acid (10): 1-Aminoferrocene-1′-carboxylic acid, hydrochloride **9·HCl** (1.1 g, 3.9 mmol) was dissolved in phosphate buffer (20 mL) and the pH was adjusted to 7. 9-Fluorenylmethyl chloroformate (1.03 g, 3.98 mmol) dissolved in dioxane (10 mL) was added to the solution. A bright orange solid separated from the solution immediately after the addition. After stirring overnight, the precipitate was collected by filtration and washed twice with diethyl ether. Recrystallisation from dichloromethane gave an orange powder. Yield: 1.5 g, 3.2 mmol (82%). $C_{26}H_{21}NO_4Fe$ (467.30)·0.5CH_2Cl_2: calcd. C 62.44, H 4.35, N 2.75; found C 62.25, H 4.34, N 2.87. IR (CsI): $\tilde{\nu}$ = 3263, 3153 (m, NH), 3400−2800 (br., OH), 1707 (s, CO), 1664 (s, CO), 1560 (w, CN) cm^{-1}. IR (CH_2Cl_2): $\tilde{\nu}$ = 3425, 3316 (w, NH), 3266 (w, OH), 1735 (s, CO), 1707 (s, CO), 1673 (s, CO), 1570, 1544 (m, CN) cm^{-1}. IR (THF): $\tilde{\nu}$ = 3573, 3504 (w, NH), 3269 (w, OH), 1735 (s, CO), 1717 (s, CO), 1563 (m, CN) cm^{-1}. MS (FAB): *m/z* (%) = 467 (100) [M^+]. M.p. 118 °C.

Benzotriazol-1-yl 1-(Acetylamino)ferrocene-1′-carboxylate (11): Dicyclohexylcarbodiimide (0.86 g, 4.2 mmol) and *N*-hydroxybenztriazole (0.415 g, 4.2 mmol) was added to a solution of **8** (1.1 g, 3.8 mmol) in dichloromethane (10 mL). The mixture was stirred at room temperature overnight. After filtering, the solution was washed with aqueous $NaHCO_3$, saturated NaCl (aq.) and 2% HCl (aq.). After drying over $MgSO_4$, the solvent was removed in vacuo and the crude product was purified by column chromatography on silica gel with ethyl acetate as eluent. After removal of the solvent under reduced pressure an orange red powder was obtained. Yield: 1.23 g, 3.0 mmol (80%). $C_{19}H_{16}N_4O_3Fe$ (404.21): calcd. C 56.46, H 3.99, N 13.86; found C 57.13, H 4.47, N 13.17. IR (CsI): $\tilde{\nu}$ = 3359 (m, NH), 1764 (s, CO), 1682 (s, CO), 1548 (s, CN), 1491 (m) cm^{-1}. IR (CH_2Cl_2): $\tilde{\nu}$ = 3428, 3363 (w, NH), 1787 (s, CO), 1689 (s, CO), 1536 (s, CN),1485(m) cm^{-1}. MS (FAB): *m/z* (%) = 404 (100) [M^+]. M.p. 133 °C.

1-[1′-(Acetylamino)ferrocenylcarbonyl]-1,3-dicyclohexylurea (12): Compound **8** (1.02 g, 3.5 mmol) was dissolved in tetrahydrofuran (20 mL) and 1,3-dicyclohexylcarbodiimide (0.73 g, 3.5 mmol) was added to the stirred solution. After standing overnight at room temperature, the solvent was removed in vacuo and the crude product was purified by column chromatography on silica gel with ethyl acetate as eluent. The solvent was removed under reduced pressure and an orange-brown product was obtained. Yield: 1.46 g, 3.0 mmol (85%). $C_{26}H_{35}N_3O_3Fe$·0.18CH_2Cl_2 (493.43·0.18CH_2Cl_2): calcd. C 61.80, H 7.00, N 8.26; found C 61.84, H 6.75, N 7.85. IR (CsI): $\tilde{\nu}$ = 3319 (s, NH), 2934 (vs, CH_2), 2856 (s, CH), 1699 (s, CO), 1672 (vs, CO), 1625 (s, CO), 1569 (s, CN), 1541 (m, CN) cm^{-1}. IR (CH_2Cl_2): $\tilde{\nu}$ = 3426 (m, NH), 3291 (m, NH), 2936 (s, CH_2), 2858 (m, CH), 1697 (s, CO), 1677 (s, CO), 1619 (m, CO), 1526 (s, CN), 1510 (s, CN) cm^{-1}. MS (FAB): *m/z* (%) = 493 (20) [M^+], 368 (93) [$M^+ - CyNCO$], 178 (100) [FeCpNHAc]. M.p. 158 °C.

($CH_3CONH-C_5H_4$)Fe(C_5H_4-$CONH-C_5H_4$)Fe(C_5H_5) (13): Compound **11** (1.20 g, 2.9 mmol) and aminoferrocene **5** (0.59 g, 2.9 mmol) were dissolved in tetrahydrofuran (10 mL) and stirred

for 12 h at ambient temperature. The solvent was removed in vacuo and the residue was dissolved in dichloromethane. The solution was washed with water, aqueous $NaHCO_3$, saturated NaCl and 2% HCl. The organic layer was dried over $MgSO_4$ and the solvent was removed under reduced pressure. Recrystallisation from dichloromethane gave an orange-brown product. Yield: 1.1 g, 2.4 mmol (82%). $C_{23}H_{22}N_2O_2Fe_2$ (470.13): calcd. C 58.76, H 4.72, N 5.96; found C 58.51, H 5.53, N 6.40. IR (CsI): $\tilde{\nu}$ = 3327, 3316 (m, NH), 1660 (s, CO), 1646 (s, CO), 1560 (vs, CN) cm^{-1}. IR (CH_2Cl_2): $\tilde{\nu}$ = 3430, 3292 (w, NH), 1679, (s, CO), 1660 (s, CO), 1559, 1529 (s, CN), 1485 (w) cm^{-1}. MS (FAB): *m*/*z* (%) = 470 (100) [M^+], 405 (38) [M^+ − Cp]. M.p. 196 °C.

Acknowledgments

This work was supported by the Deutsche Forschungsgemeinschaft and the Fonds der Chemischen Industrie. The permanent, generous support from Prof. Dr. G. Huttner is gratefully acknowledged. We thank Simone Leingang for preparative assistance.
