Isopropylamine (100 mmol, 5.911 g) was mixed with hydrochloric acid (16.0 cm^3), deionized water (20 mL) and phosphorous acid (400 mmol, 32.8 g). The mixture was allowed to reflux at 120 °C for 1 h, paraformaldehyde (300 mmol, 9 g) was then added in small portions over a period of 1 h, and the mixture was refluxed for one additional hour. Removal of solvents afforded 16.8 g of a white powder of H_4L^1 (yield 68.1%). Its purity was confirmed by NMR spectroscopic measurements and elemental analysis. ^{31}P NMR spectroscopy shows a single peak at 9.50 ppm. ^1H NMR: $\delta = 1.37$ (CH_3, d, 6 H, $J_{H-H} = 5.5$ Hz), 3.57 ($N-CH_2-PO_3$, d, 4 H, $J_{H-P} = 12.5$ Hz), 4.16 (Me_2-CH-N, sept., 1 H) ppm. Elemental analysis for H_4L^1, $C_5H_{15}NO_6P_2$ (247.12): calcd. C 24.86, H 6.62, N 4.88; found C 24.29, H 6.07, N 5.67.

H_4L^2 was obtained in a yield of 77.5% by a Mannich type reaction using cyclohexylamine (100 mmol, 9.92 g), hydrochloric acid (16.0 cm^3), deionized water (20.0 mL), phosphorous acid (400 mmol, 32.8 g) and paraformaldehyde (300 mmol, 9.0 g), in a similar method to that of H_4L^1. ^{31}P NMR spectroscopy shows a single peak at 8.75 ppm. ^1H NMR: $\delta = 1.16$, 1.36, 1.67, 1.91 and 2.06 (for five CH_2- groups of cyclohexyl, d), 1.51 (CH- of cyclohexyl, t, 1 H), 3.51 ($N-CH_2-PO_3$, d, 4 H, $J_{H,P} = 13.0$ Hz) ppm. Elemental analysis for H_4L^2, $C_8H_{19}NO_6P_2$ (288.54): calcd. C 33.24, H 6.81, N 4.59; found C 33.45, H 6.62, N 5.33.

$Pb_7(3\text{-}O_3S-C_6H_4-CO_2)(L^1)_3(H_2O)_2\cdot 2H_2O$ (1) and $Pb_3(HL^2)(H_2L^2)(H_2BTC)(H_2O)\cdot H_3BTC\cdot H_2O$ (2): A mixture of $PbCO_3$ (1.0 mmol, 0.267 g), H_4L^1 (0.5 mmol, 0.124 g), 3-sulfobenzoic acid monosodium salt (0.5 mmol, 0.112 g) and deionized water (10 mL) was sealed into a bomb equipped with a Teflon liner (20 mL), and then heated at 180 °C for 5 days. Colorless prismatic crystals of complex **1** were recovered in ca. 71% yield based on Pb. Elemental analysis for **1**, $C_{22}H_{45}N_3O_{27}P_6Pb_7S$ (2451.82): calcd. C 10.67, H 1.38, N 1.82; found C 10.77, H 1.84, N 1.71%. IR data (KBr, cm^{-1}): $\tilde{\nu}$ = 3406 (s), 2962 (m), 2933 (m), 2875 (m), 2798 (m), 2407 (m), 1732 (m), 1651 (m), 1587 (m), 1531 (s), 1419 (s), 1383 (s), 1302 (m), 1200 (m), 1084 (vs), 1032 (vs), 966 (vs), 839 (m), 752 (m), 679 (m), 588 (s), 557 (s), 507 (m), 480 (m).

A mixture of $PbCO_3$ (1.0 mmol, 0.267 g), H_4L^2 (0.5 mmol, 0.144 g), 1,3,5-benzenetricarboxylic acid (0.5 mmol, 0.105 g) and deionized water (10 mL) was sealed into a bomb equipped with a Teflon liner (20 mL), and then heated at 180 °C for 5 days. Prismatic colorless crystals of complex **2** were recovered in ca. 60% yield based on Pb. Elemental analysis for **2**, $C_{34}H_{48}N_2O_{26}P_4Pb_3$

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

(1646.19): calcd. C 23.93, H 2.42, N 1.62; found C 24.79, H 2.92, N 1.70%. IR data (KBr, cm^{-1}): $\tilde{\nu}$ = 3428 (s), 3021 (s), 2979 (s), 2940 (s), 2862 (s), 2648 (s), 2542 (s), 1878 (m), 1722 (vs), 1614 (s), 1576 (s), 1454 (s), 1381 (s), 1281 (vs), 1111 (vs), 1051 (vs), 987 (s), 933 (s), 777 (m), 744 (s), 692 (s), 621 (m), 526 (m), 442 (m).

Crystal Structure Determination: Single crystals of complexes **1** and **2** were mounted on a Siemens Smart CCD diffractometer equipped with a graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å). Intensity data were collected by the narrow frame method at 293 K. The data sets were corrected for Lorentz polarization, as well as for absorption, by ψ scan technique. Both structures were solved by direct methods and refined by full-matrix least-squares fitting on F^2 by SHELX-97.[15] All non-hydrogen atoms, except for N(2), C(2), C(3), C(14), C(15), C(22) and C(23) in complex **1**, and C(23) in complex **2,** were refined with anisotropic thermal parameters. Those atoms refined with isotropic thermal parameters were non-positive if refined anisotropically; this was caused by the problem resulting from correcting the absorption due to the presence of very heavy Pb atoms. The final difference Fourier maps showed featureless residual peaks of 3.16 e·$Å^{-3}$ (for complex **1**, 0.91 Å from Pb(2) atom) and 3.56 e $Å^{-3}$ (for complex **2**, 1.02 Å from Pb(1) atom), respectively. All hydrogen atoms were located at geometrically calculated positions. The hydrogen atoms for the water molecules were not included in the refinements. The large standard deviations for the bond lengths in complex **1** are due to the poor quality of the single crystals, which is very common for metal phosphonates; efforts were made to isolate better quality crystals, however they were unsuccessful. Crystallographic data and structural refinements are summarized in Table 3. Important bond lengths and angles are listed in Tables 1 and 2 for complexes **1** and **2**, respectively.

The Construction of P−O/P−N Ligands on Platinum and Palladium[‡]

Paola Bergamini,*[a] Valerio Bertolasi,[a] and Federico Milani[a]

Keywords: Template synthesis / Ligand design / P ligands / Platinum / Palladium

A variety of diphenyldiphosphinites have been prepared in a very stable form as Pt^{II} or Pd^{II} complexes by adding diols to a solution containing *cis*-[$MCl_2(PPh_2Cl)_2$] (M = Pt or Pd) preformed in situ from *cis*-[MCl_2(1,5-COD)] (M = Pt; M = Pd) and PPh_2Cl. This synthetic pathway can be used for diphosphinites derived from aliphatic 1,2 and 1,3 diols and also from the aromatic catechol. Besides the P–O bond, it is also shown here that the P–N bond can also be formed via nucleophilic attack of an amine group on coordinated PPh_2Cl in the presence of a base resulting in some AMPP and BAMP complexes of Pt^{II} and Pd^{II}. The X-ray crystal structures of the [*cis*-1,2-cyclohexanediyl bis(diphenylphosphinite)]platinum dichloride, of the AMPP palladium complex from (1*R*,2*S*)-(−)-norephedrine and of the BAMP palladium complex [*P*,*P*′-diphenyl-1,2-cyclohexanediylbis(imino)bisphosphane]-palladium dichloride have been determined. The chemical and optical stabilities of many complexes in solution have been monitored by ^{31}P NMR spectroscopy.

Introduction

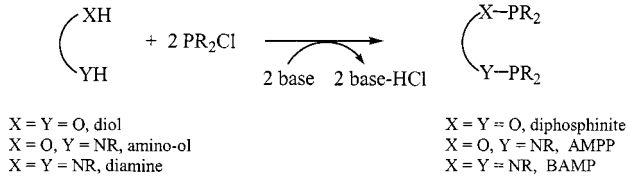
P-donor chiral ligands are widely used in metal-based asymmetric catalysis, because of the intrinsic ability of phosphorus to favour the substrate coordination, to stabilise intermediates of various processes and to provide selectivity through steric effects.[2] So far the most significant success is still represented by the asymmetric hydrogenation of prochiral olefins using Rh^{I} complexes of chiral diphosphanes.[3]

Research in this field has been developed since the early seventies and a large variety of chiral diphosphanes have been prepared and tested. Although great success has been achieved in the enantioselective conversion of some substrates, a few problems still remain unsolved:

i) Rh or Ru/chiral diphosphane catalysts are very efficient but their activity is restricted to a narrow group of transformations because only highly functionalised substrates (e.g. amino acids precursors) undergo coordination, the primary step of the process.

ii) The synthesis of chiral diphosphanes is often expensive and time consuming and requires delicate and awkward reactants.[4]

For these reasons the design and preparation of new ligands for chiral catalysts is still a lively topic and groups of phosphorated compounds other than diphosphanes have been taken into consideration. In particular chiral diphosphinites,[5] AMPP ("aminophosphanes-phosphinites") and BAMP ["bis(amino)phosphanes"][6] have been recently considered particularly for their synthetic accessibility based on the reaction of chlorophosphanes with diols, amino-ols and diamines (Scheme 1).



Scheme 1

The wide variety of asymmetric precursors belonging to these groups, especially from the natural chiral pool, enormously extends the number of easily accessible structural variations on the basic structure of these ligands.

Although the classical preparation of 1,2-(diphenyl)diphosphinites from diols and chlorodiphenylphosphane has been described in some papers as an easy clean process,[7] some problems have been raised[8] and in our hands this reaction gave poor and variable results because of the tendency of both the reagent chlorodiphenylphosphane and of the reaction products to undergo oxidative processes giving a variety of P^{V} species. On the other hand we noticed that 1,2-diphenylphosphinites are greatly stabilised by coordination to metal ions and therefore we have recently proposed an alternative synthetic pathway where a few examples of diphosphinite ligands were built up in the coordination sphere of Pt^{II} or Pd^{II} acting as templates.[1]

[‡] Part 2. Part 1: Ref.[1].

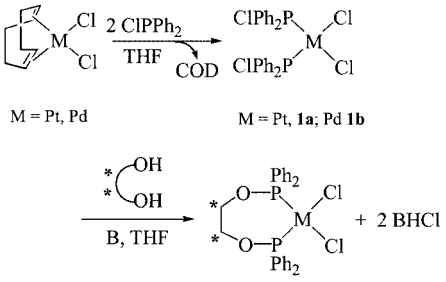
With the aim to demonstrate the generality of the above metal template method, in this paper we extend its application to the preparation of different kinds of coordinated diphosphinites, and also show that the P−N bond can be formed by nucleophilic substitution on coordinated chlorophosphane by an amine group leading to aminophosphane-phosphinites (AMPP) or bis(amino)phosphanes (BAMP).

Results and Discussion

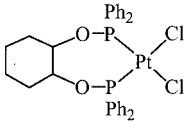
i) Preparation of Coordinated Diphosphinites

In our previous paper we showed that 1,2- and 2,3-bis(diphenylphosphinito)butanediols and isopropyl bis(diphenylphosphinito)tartrate can be prepared as coordinated ligands on Pt and Pd by a two-step process, starting from $[MCl_2(1,5\text{-COD})]$ (M = Pt, Pd), whose reaction with chlorodiphenylphosphane gave the intermediate complexes *cis*-$[MCl_2(PPh_2Cl)_2]$ (**1a**, M = Pt; **1b,** M = Pd), characterised in situ by ^{31}P NMR spectroscopy and converted into the relative diphenylphosphinite complex by addition of the corresponding diols in the presence of a base (Scheme 2).[1]



Scheme 2

In this paper we show that this template synthesis can be extended to other ligands: in particular we prepared the diphenylphosphinite from *cis*-1,2-cyclohexanediol in the platinum-coordinated form. This ligand is the optically inactive form derived from (1*R*,2*S*)-cyclohexanediol, and is the diastereomeric form of the optically active (1*R*,2*R*) or (1*S*,2*S*)-cyclohexane-1,2-diyl bis(diphenylphosphinite), which have already been tested in asymmetric catalysis.[9]



2a

Complex **2a** co-precipitated with py·HCl from the reaction mixture in THF and was purified by extraction with water and dichloromethane.

Due to the equivalence of the two phosphorus atoms, the ^{31}P NMR of **2a** shows a broad single signal at δ = 87.9 ppm, with satellites and $^1J_{Pt,P}$ = 3995 Hz, a typical value for a phosphorus atom *trans* to a chloride atom. The broadness of the signal is due to the fast equilibrium between two conformational forms where one P atom occupies the equatorial position while the other one is axial and vice versa.

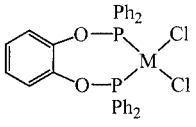
A variable-temperature experiment showed, at low temperature (− 55 °C), two distinct signals with satellites (δ_{P_A} = 74.8 ppm, $^1J_{Pt,P_A}$ = 3834 Hz, δ_{P_B} = 98.7 ppm $^1J_{Pt,P_B}$ = 4149 Hz), which coalesce at 25 °C into the above described broad singlet, which becomes sharper at +55 °C.

Solutions of **2a** in pure chloroform or in a $CHCl_3$/acetone mixture, examined by ^{31}P NMR, did not show any sign of decomposition even in the presence of oxygen and/or water after five days.

A recrystallisation of **2a** at room temperature from dichloromethane and diethyl ether gave crystals for X-ray crystal structure determination.

In order to demonstrate also that aromatic bis(diphenylphosphinites) can be formed on Pt, complex **3a** derived from catechol was prepared. The functionalisation of catechol can be proposed as a simple model for more complicated and more relevant aromatic systems like calixarenes.[10]

The ^{31}P spectrum of **3a** in $CHCl_3$ is a sharp singlet with satellites at δ = 93.4 ppm ($^1J_{Pt,P}$ = 4043 Hz); when the solution was treated with an excess of soluble CN^-, the spectrum changed into a singlet at δ = 114.1 ppm, due to the free ligand **3**. The following addition of $[PdCl_2(1,5\text{-COD})]$ to this solution gave the Pd analogue **3b** in situ, showing a singlet shifted to δ = 122 ppm. This chemical shift trend, with the Pd complex downfield and the Pt complex upfield, relative to the free ligand, has been found in general for the diphosphinites we have considered here and for the previously reported analogues.[1]



M = Pt, **3a**
M = Pd, **3b**

Using the optically active (*R*,*R*)-(−)-2,4-pentanediol, which gave the optically active Pt and Pd complexes **4a** and **4b**, we succeeded in demonstrating that it is possible to obtain eight-membered rings by this route.

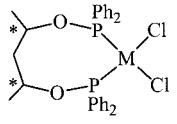
The platinum complex **4a** has been obtained from $[PtMe_2(1,5\text{-COD}]$ by treatment with PPh_2Cl to give the dimethyl intermediate, which is then treated with (*R*,*R*)-(−)-2,4-pentanediol, giving the immediate precipitation of **4a**.

The reaction occurs via nucleophilic attack of both the OH groups on the phosphorus atoms. The outgoing HCl causes the protonolysis of the two Pt−Me groups giving rise to the final dichloro complex. The use of the dimethyl intermediate is very convenient because it avoids the use of the base and produces volatile CH_4 as the only side product.

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

Because of the instability of the corresponding precursor [$PdMe_2$(1,5-COD)], the corresponding palladium complex **4b** was obtained from [$PdCl_2$(1,5-COD)].

The complete characterisation of **4a** and **4b** is reported in the Exp. Sect. It is worth noting that for **4a** the value of $^1J_{Pt,P}$ = 4176 Hz, is more than 100 Hz larger than the corresponding coupling constant in seven-membered ring complexes.



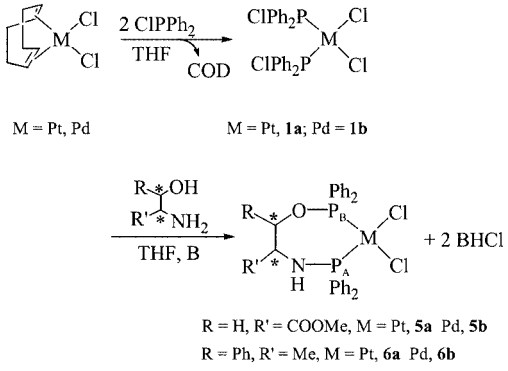
M = Pt, **4a**
M = Pd, **4b**

ii) Preparation of Coordinated AMPP

After the preparation of a series of bis(diphenylphosphinites) we reasoned that X−P bonds other than O−P could be conveniently built by nucleophilic substitution of chloride on the coordinated phosphorus centre.

Due to the interest in the catalysis of both aminophosphane-phosphinites (AMPP) and bis(amino)phosphanes (BAMP),[6] we tried to use amino groups (NH_2 or NHR) as nucleophiles in order to form N−P bonds.

By adding 1,2-amino-ols to a solution containing the preformed intermediates **1a** or **1b**, we succeeded in obtaining some examples of coordinated AMPP (Scheme 3).



M = Pt, Pd M = Pt, **1a**; Pd = **1b**

R = H, R' = COOMe, M = Pt, **5a** Pd, **5b**
R = Ph, R' = Me, M = Pt, **6a** Pd, **6b**

Scheme 3

By following the reactions using ^{31}P NMR spectroscopy, we noticed that the formation of the O−P bond is the first step occurring in a few minutes, followed by the slow making of N−P, with ring closure.

In this case it is necessary to assist the reaction using NEt_3, which is a stronger base than the $-NH_2$ group, in order to avoid the protonation of the amine group, which will make it unreactive.

We chose the methyl ester of the natural occurring amino acid L-serine, bearing an OH group in the β position, for this reaction and we obtained the Pt complex **5a** and the Pd analogue **5b**.

The ^{31}P NMR spectrum of **5a** shows two doublets of doublets with satellites at δ = 43.5 ppm (P_A, $^1J_{Pt,P_A}$ = 3887 Hz; $^2J_{P_BP_A}$ = 12 Hz) and 94.7 ppm (P_B, $^1J_{Pt,P_B}$ = 4075 Hz; $^2J_{P_AP_B}$ = 12 Hz) in the ranges expected for aminophosphane and phosphinites respectively.

The palladium complex **5b** presents two doublets at δ = 67.8 ppm (P_A, $^2J_{P_BP_A}$ = 32 Hz) and 124.9 ppm (P_B, $^2J_{P_AP_B}$ = 32 Hz) both at lower fields with respect to the corresponding peaks in **5a**.

Another example of optically active AMPP complexes, **6a** and **6b**, have been obtained via template synthesis using the optically active amino alcohol (1*R*,2*S*)-(−)-norephedrine.

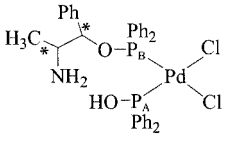
In ^{31}P NMR, **6a** is characterised by two doublets with satellites, due to the aminophosphinic moiety 45.9 ppm (P_A, $^1J_{Pt,P_A}$ = 3917 Hz and $^2J_{P_BP_A}$ = 11 Hz) and the phosphinitic group at 93.8 (P_B, $^1J_{Pt,P_B}$ = 4104 Hz and $^2J_{P_AP_B}$ = 11 Hz) ppm. ^{1}H NMR spectroscopy is very useful for checking the identity of the product and its purity (see Exp. Sect. for complete assignments): in particular at δ = 2.0 ppm a singlet is visible with satellites ($^3J_{PtH}$ = 55 Hz) belonging to the nitrogen bonded proton.

The palladium complex **6b**, obtained by treatment of **1b** with (1*R*,2*S*)-(−)-norephedrine and NEt_3 in benzene, shows two doublets at δ = 70.5 ppm (P_A, $^2J_{P_BP_A}$ = 35 Hz) and 123.6 ppm (P_B, $^2J_{P_AP_B}$ = 35 Hz). Its X-ray crystal structure has been determined (see further).

In these reactions the use of NEt_3 as a base affects the purity of the products, always contaminated by NEt_3HCl, which therefore require purification procedures.

In order to avoid salt contamination we reasoned that the use of a heterogeneous base could be convenient. With this aim, we tried to add solid $NaHCO_3$ to the reaction mixture in THF, together with a water sequestrating agent (e.g. anhydrous Na_2SO_4). Under these conditions, the reaction between **1b** and (1*R*,2*S*)-(−)-norephedrine gave complex **7b**, where the O−P bond is formed while the second-coordinated PPh_2Cl has been hydrolysed to PPh_2OH by the equivalent of water resulting from the reaction of $NaHCO_3$ with HCl. This indicates that the dehydrating agents (Na_2SO_4 or molecular sieves) that we tried, in order to avoid this hydrolytic process, are not efficient in comparison with the competing hydrolysis of the homogeneous coordinated PPh_2Cl.

Complex **7b** contains a coordinated monodentate aminophosphinite (AMP), a type of ligand mentioned previously for its ability to give P/N six-membered chelate rings of interest in catalysis.[6]

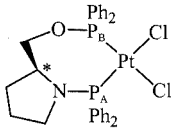


7b

The reaction of preformed **1a** with the aminoalcohol L-prolinol bearing a secondary amino group gave complex **8a**.

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

The NMR spectroscopic data of **8a** are consistent with the data previously reported for the same complex obtained by the classical synthetic procedure from the preformed ligand.[11]



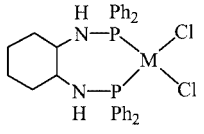
8a

iii) Preparation of Coordinated BAMP

Finally we have considered the possibility of extending the metal template method to the preparation of BAMP ligands.

The most interesting member of this group is the *N*,*N*′-bis(diphenylphosphanyl)-1,2-diaminocyclohexane ($DACHP_2$), whose palladium complex has recently been described as an efficient tool for the resolution of racemic amino acids.[12]

The platinum complex has been obtained from [$PtMe_2$(1,5-COD] by treatment with PPh_2Cl to give the dimethyl intermediate, which is then treated with (1*R*,2*R*)-*trans*-diaminocyclohexane, resulting in the immediate precipitation of **9a**. The corresponding palladium complex **9b** was obtained starting from [$PdCl_2$(1,5-COD)] (see Exp. Sect.). We determined the X-ray crystal structure of **9b**, recrystallised from dichloromethane and diethyl ether.



M = Pt, **9a**
M = Pd, **9b**

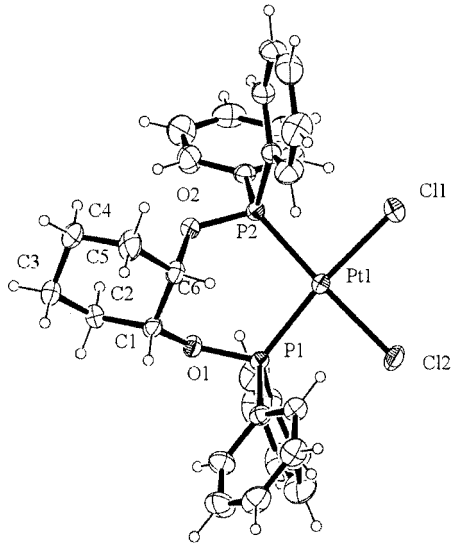


Figure 1. ORTEP view of compound **2a** showing the thermal ellipsoids at 30% level of probability

iv) X-ray Crystal Structures of 2a, 6b and 9b

By the slow diffusion of Et_2O into CH_2Cl_2 solutions, crystals suitable for structure diffractometric analysis were obtained for one member of each group: diphosphinites (**2a**), AMPP (**6b**) and BAMP (**9b**).

An ORTEP[13] view of each structure (**2a**, **6b** and **9b**) is given in Figure 1−3 and a selection of bond lengths and angles is reported in Table 1. All the complexes present a slightly distorted square-planar geometry with the metal centre bonded to two chloride and two phosphorus atoms belonging to the ligand. The seven-membered chelate rings resemble twisted half-chair conformations.

enantiomers. The C1 and C2 atoms in complex **6b** are in configurations (*S*) and (*R*), respectively. In complex **9b** both C1 and C6 atoms display the (*R*) configuration. The molecules in the crystals are coupled by means of two N2−H···Cl1 and N1−H···Cl2 hydrogen bonds: N2···Cl1(x + 1, y, z) = 3.236(3) Å and N1···Cl2(x+ 1, y, z) = 3.348(3) Å.

Conclusions

The preparation of a variety of Pt^{II} and Pd^{II} complexes through the metal template procedure proves that this new method can be proposed as an easy and accessible general synthetic pathway to P−O and P−N containing ligands, which are obtained in a convenient metal-stabilized form.

Experimental Section

All reactions and manipulations were routinely performed under dry nitrogen by using standard Schlenk-tube techniques. Tetrahydrofuran was bi-distilled over $LiAlH_4$, while diethyl ether and benzene were purified by distillation over sodium/benzophenone. Pyridine and triethylamine were distilled and stored over KOH. $CDCl_3$, used as solvent for NMR spectra, was dried with molecular sieves (4 Å).

PPh_2Cl (d = 1.23 g·mL^{-1}) was purified by distillation under nitrogen, stored at −15 °C and checked by ^{31}P NMR spectroscopy before use. All the other solvents and chemicals were reagent grade and, unless otherwise stated, were used as received from commercial suppliers. ^1H and ^{31}P NMR spectra (always ^1H decoupled) were recorded with a Bruker AC200 spectrometer operating at 200.13 MHz (^1H) and 81.01 MHz (^{31}P). Peak positions are given in ppm relative to tetramethylsilane (^1H) and to external 85% H_3PO_4 (^{31}P). Elemental analyses (C,H,N) were performed using a Carlo Erba model 1106 elemental analyser. Optical rotations were obtained with a Perkin−Elmer 241 at 25 °C.

Literature methods were used for the preparation of [$PtCl_2$(1,5-COD)],[14] [$PtMe_2$(1,5-COD)][15] and [$PdCl_2$(1,5-COD)].[16]

Synthesis of 2a: PPh_2Cl (144 μL, 0.802 mmol) was added dropwise, whilst stirring at room temperature, to a suspension of [$PtCl_2$(1,5-COD)] (0.150 g, 0.401 mmol) in THF (25 mL) placed in a Schlenk flask. The immediate formation of the dichloro diphosphane complex **1a** was unambiguously confirmed by ^{31}P NMR spectroscopy (δ =73.4 ppm, $^1J_{Pt,P}$ = 4069 Hz [1]).
The addition of pyridine (65 μL, 0.802 mmol) and *cis*-1,2-cyclohexanediol (0.047 g, 0.401 mmol) gave a cloudy mixture, which persisted whilst stirring at room temperature for 18 h. The white precipitate, composed of **2a** and pyridinium chloride, was then filtered, re-dissolved in CH_2Cl_2 and the solution was washed with 10 mL of water three times, dried with Na_2SO_4 and then taken to dryness under vacuum to give pure **2a** as a white solid. Yield 0.170 g (56%). $C_{30}H_{30}Cl_2O_2P_2Pt$ (750.5): calcd. C 48.01, H 4.03; found C 47.95, H 4.31. ^1H NMR (200 MHz, $CDCl_3$, 25 °C): δ = 1.2−1.5 (m, 4 H, CH), 1.6−1.9 (m, 4 H, CH), 4.5 (m, 2 H, CH−O), 7.3−7.9 (m, 20 H, Ph) ppm. ^{31}P NMR (81.01 MHz, $CDCl_3$, 25 °C): δ = 87.9 ppm (br. s, $^1J_{Pt,P}$ = 3995 Hz). Recrystallisation of crude **2a** from dichloromethane/ethanol gave crystals suitable for diffractometric study.

Synthesis of 3a: Complex **3a** was prepared in the same way as above using catechol (0.044 g, 0.401 mmol). After 18 h a small amount of

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

pyridinium chloride was filtered off, while the product remained in solution. The product was confirmed by ^{31}P NMR spectroscopic inspection. The solution was taken to dryness under vacuum and the oily residue was redissolved in CH_2Cl_2 (1 mL). Pure **3a**, as a white solid, was precipitated by addition of Et_2O (15 mL) and separated by filtration; yield 0.270 g (90%). $C_{30}H_{24}Cl_2O_2P_2Pt$ (744.4): calcd. C 48.40, H 3.25; found C 47.91, H 3.35. ^1H NMR (200 MHz, $CDCl_3$, 25 °C): δ = 6.1 (m, 2 H, CH), 6.85 (m, 2 H, CH), 7.4−8.1 (m, 20 H, Ph) ppm. ^{31}P NMR (81.01 MHz, $CDCl_3$, 25 °C): δ = 93.7 (s, $^1J_{Pt,P}$ = 4043 Hz) ppm.

Synthesis of 4a: [$PtMe_2$(1,5-COD)] (0.100 g, 0.300 mmol) was dissolved in bi-distilled THF (20 mL) and PPh_2Cl (108 μL, 0.600 mmol) was added. After checking the complete formation of the Pt containing intermediate [$PtMe_2(PPh_2Cl)_2$] by ^{31}P NMR spectroscopy (δ =100.3 ppm, $^1J_{Pt,P}$ = 1915 Hz), the solution was treated with (2*R*,4*R*)-(−)-pentanediol (0.031 g, 0.300 mmol). The initially clear solution was kept at room temperature for three days and during this time the progressive precipitation of a white solid was observed. Later the pure solid product was filtered away and dried under vacuum over P_2O_5. Yield 0.140 g (63%). $C_{29}H_{30}Cl_2O_2P_2Pt$ (738.5): calcd. C 47.17, H 4.09; found C 46.88, H 4.24. ^1H NMR (200 MHz, $CDCl_3$, 25 °C): δ = 0.8 (d, $^3J_{H,H}$ = 7.3 Hz, 6 H, CH_3), 1.8 (t, $^3J_{H,H}$ = 7.3 Hz, 2 H, CH_2), 4.35 (m, 2 H, CH), 7.3−8.1 (m, 20 H, Ph) ppm. ^{31}P NMR (81.01 MHz, $CDCl_3$, 25 °C): δ = 91.8 ppm (s, $^1J_{Pt,P}$ = 4176 Hz). $[\alpha]_D^{25}$ = −42.6 (*c* = 0.55, CH_2Cl_2).

Synthesis of 4b: PPh_2Cl (126 μL, 0.700 mmol) was added to [$PdCl_2$(1,5-COD)] (0.100 g, 0.350 mmol) suspended in 25 mL of dry THF: the solution turned yellow and the presence of **1b** was checked by ^{31}P NMR spectroscopy (δ =96 ppm, broad singlet) .[1] At this point pyridine (57 μL) and (2*R*,4*R*)-(−)-2,4-pentanediol (0.036 g, 0.350 mmol) were added to the solution which became cloudy. After stirring for 24 h the solid (**4b** and pyHCl) was filtered, redissolved in 1 mL of CH_2Cl_2 and extracted three times with water (10 mL). The organic phase was taken to dryness, resulting in **4b** as a yellow powder. Yield 0.100 g (44%). $C_{29}H_{30}Cl_2O_2P_2Pd$ (649.8): calcd. C 53.60, H 4.65; found C 53.80, H 4.73. ^1H NMR (200 MHz, $CDCl_3$, 25 °C): δ = 0.75 (d, $^3J_{H,H}$ = 7.3 Hz, 6 H, CH_3), 1.8 (t, $^3J_{H,H}$ = 7.3 Hz, 2 H, CH_2), 4.35 (m, 2 H, CH), 7.5−8.2 (m, 20 H, Ph) ppm. ^{31}P NMR (81.01 MHz, $CDCl_3$, 25 °C): δ = 121.8 (s) ppm. $[\alpha]_D^{25}$ = −61.4 (*c* = 0.5, CH_2Cl_2).

Synthesis of 5a: PPh_2Cl (96 μL, 0.535 mmol) was added dropwise whilst stirring at room temperature to a suspension of [$PtCl_2$(1,5-COD)] (0.100 g, 0.267 mmol) in THF (25 mL), resulting in **1a**. The addition of triethylamine (0.802 mmol) and L-serin methyl ester hydrochloride (0.042 g, 0.267 mmol) gave a cloudy mixture due to the formation of partially insoluble NEt_3 hydrochloride.
After 2 hours, another 50 mL of THF was added and the solution was stirred for a further two hours. The white precipitate was then filtered away and the solution, containing the impure product was taken to dryness. The residue was dissolved in CH_2Cl_2 and water was added in order to eliminate NEt_3HCl. The organic layer was finally dried with Na_2SO_4 and then taken to dryness under vacuum to give pure **5a** as a white solid. Yield 0.090 g (45%) $C_{28}H_{27}Cl_2NO_3P_2Pt$ (753.5): calcd. C 44.64, H 3.61, N 1.86; found C 44.60, H 3.80, N 1.89. ^1H NMR (200 MHz, $CDCl_3$, 25 °C): δ = 3.4 (br. s, $^3J_{PtH}$ = 45 Hz, 1 H, NH), 3.75 (s, 3 H, CH_3O), 4.0 (m, 1 H, CH−N), 4.4 (m, 2 H, C-CH_2O), 7.3−8.0 (m, 20 H, Ph) ppm. ^{31}P NMR (81.01 MHz, $CDCl_3$, 25 °C): δ = 43.6 (d, P_A, $^1J_{Pt,P_A}$ = 3885, $^2J_{P_BP_A}$ = 12 Hz), 94.9 (d, P_B, $^1J_{Pt,P_B}$ = 4074, $^2J_{P_AP_B}$ = 12 Hz) ppm. $[\alpha]_D^{25}$ = −20.8 (*c* = 0.58, CH_2Cl_2).

Synthesis of 6a: This complex was prepared in the same manner as **5a**, but by replacing L-serin methyl ester hydrochloride with (1*R*,2*S*)-(−)-di(norephedrine) (0.041 g, 0.267 mmol). The reaction gave **6a** as a white solid. Yield 0.096 g (46%). $C_{33}H_{31}Cl_2NOP_2Pt$ (785.5): calcd. C 50.46, H 3.98, N 1.78; found C 49.96, H 4.03, N 1.98. ^1H NMR (200 MHz, $CDCl_3$, 25 °C): δ = 0.95 (d, $^3J_{H,H}$ = 7.3 Hz, 3 H, CH_3), 2.0 (br. s, $^3J_{PtH}$ = 55 Hz, 1 H, NH), 4.0 (br. s, 1 H, CH−N), 5.35 (m, 1 H, CH−O), 6.8−8.2 (m, 25 H, CH arom.) ppm. ^{31}P NMR (81.01 MHz, $CDCl_3$, 25 °C): δ = 45.9 (d, P_A, $^1J_{Pt,P_A}$ = 3917, $^2J_{P_BP_A}$ = 11.3 Hz), 93.8 (d, P_B, $^1J_{Pt,P_B}$ = 4104, $^2J_{P_AP_B}$ = 11.5 Hz) ppm. $[\alpha]_D^{25}$ = −42.8 (*c* = 0.54, CH_2Cl_2).

Synthesis of 6b: [$PdCl_2$(1,5-COD)] (0.150 g, 0.525 mmol) was suspended in distilled benzene (25 mL) and PPh_2Cl (189 μL, 1.050 mmol) was added to give the immediate formation of the yellow soluble intermediate **1b**. Triethylamine (147 μL, 1.050 mmol) and (1*R*,2*S*)-(−)-norephedrine (0.080 g, 0.525 mmol) were added in sequence, followed by the precipitation of NEt_3HCl. After 18 hours of stirring, the solution containing **6b** was separated by filtration, and taken to dryness. The yellow-orange solid product was purified by recrystallisation from CH_2Cl_2 and diethyl ether Yield 0.215 g (59%). $C_{33}H_{31}Cl_2NOP_2Pd$ (696.9): calcd. C 56.88, H 4.48, N 2.01; found C 56.54, H 4.48, N 1.91. ^1H NMR (200 MHz, $CDCl_3$, 25 °C): δ = 0.95 (d, $^3J_{H,H}$ = 7.3 Hz, 3 H, CH_3), 2.0 (br. s, 1 H, NH), 3.9 (br. s, 1 H, CH−N), 5.2 (m, 1 H, CH−O), 6.8−8.2 (m, 25 H, Ph) ppm. ^{31}P NMR (81.01 MHz, $CDCl_3$, 25 °C): δ = 70.5 (d, P_A, $^2J_{P_BP_A}$ = 35 Hz), 123.6 (d, P_B, $^2J_{P_AP_B}$ = 35 Hz) ppm. $[\alpha]_D^{25}$ = −13.2 (*c* = 0.53, CH_2Cl_2). Recrystallisation of crude **6b** from dichloromethane/diethyl ether gave crystals suitable for a diffractometric study.

Synthesis of 7b: PPh_2Cl (189 μL, 1.050 mmol) was added to a suspension containing [$PdCl_2$(1,5-COD)] (0.150 g, 0.525 mmol) in 25 mL of bi-distilled THF: the mixture became clear and yellow and the complete formation of **1b** was checked by ^{31}P NMR spectroscopy. A large excess (0.500 g each) of $NaHCO_3$ and Na_2SO_4, previously dried at 120 °C for 10 h, was suspended in this solution, followed by the addition of (1*R*,2*S*)-(−)-norephedrine (0.079 g, 0.525 mmol). After stirring vigorously for 24 h, the salts were eliminated by filtration and the solution was taken to dryness, giving a solid residue of **7b**; yield 0.220 g (59%), which was recrystallised with CH_2Cl_2 and diethyl ether. $C_{33}H_{33}Cl_2NO_2P_2Pd$ (714.9): calcd. C 55.44, H 4.65, N 1.96; found C 55.72, H 4.90, N 2.01. ^1H NMR (200 MHz, $CDCl_3$, 25 °C): δ = 1.1 (d, $^3J_{H,H}$ = 7.3 Hz, 3 H, CH_3), 3.0 (m, 2 H, NH_2), 3.2 (br. s, 1 H, CH−N), 4.6 (m, $^3J_{H,H}$ = 8.2 Hz, 1 H, CH−O), 7.0−8.0 (m, 25 H, Ph) ppm. ^{31}P NMR (81.01 MHz, $CDCl_3$, 25 °C): δ = 63.2 (d, P_A, $^2J_{P_BP_A}$ = 15 Hz), 115.4 (d, P_B, $^2J_{P_AP_B}$ = 15 Hz) ppm.

Synthesis of 8a: PPh_2Cl (144 μL, 0.802 mmol) was added dropwise, whilst stirring at room temperature, to a suspension of [$PtCl_2$(1,5-COD)] (0.150 g, 0.401 mmol) in THF (25 mL), resulting in **1a**. The addition of triethylamine (112 μL, 0.802 mmol) and 40 μL of L-prolinol (0.401 mmol, *d* = 1.025 g·mL^{-1}) gave a cloudy mixture due to the formation of partially insoluble triethylamine hydrochloride. After stirring for 24 h at room temperature the salt was filtered away and the solution treated as above (see preparation of **5a**) to obtain **8a** as a white solid; yield 0.153 g (52%). $C_{29}H_{29}Cl_2NOP_2Pt$ (735.5): calcd. C 47.36, H 3.97, N 1.90; found C 46.96, H 4.12, N 1.89. ^1H NMR (200 MHz, $CDCl_3$, 25 °C): δ = 1.5−4.0 (m, 6 H, CH_2), 3.3−3.8 (m, 2 H, CH_2−O), 4.9 (br. s, 1 H, CH−N), 7.0−8.0 (m, 25 H, Ph) ppm. ^{31}P NMR (81.01 MHz, $CDCl_3$, 25 °C): δ = 51.3 (d, P_A, $^1J_{Pt,P_A}$ = 4030, $^2J_{P_BP_A}$ = 14 Hz), 80.7 (d, P_B, $^1J_{Pt,P_B}$ = 3941, $^2J_{P_AP_B}$ = 14 Hz) ppm. $[\alpha]_D^{25}$ = +17.8 (*c* = 0.53, CH_2Cl_2).

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

Synthesis of 9a: The complex was prepared from [$PtMe_2$(1,5-COD)] (0.100 g, 0.300 mmol), following the same procedure described above for **4a**, replacing the diol with (1*R*,2*R*)-*trans*-diaminocyclohexane (0.034 g, 0.300 mmol). The precipitation of **9a** occurred within five minutes as a white solid, which was filtered and dried with P_2O_5; yield 0.170 g (77%). $C_{30}H_{32}Cl_2N_2P_2Pt$ (748.5): calcd. C 48.14, H 4.31, N 3.74; found C 47.88, H 4.38, N 3.67. ^{1}H NMR (200 MHz, CD_2Cl_2, 25 °C): δ = 0.6−1.0 (m, 4 H, CH), 1.5 (m, 2 H, CH), 1.7 (d, 2 H, CH), 2.4 (s, $^3J_{PtH}$ = 32 Hz, 2 H, NH), 3.3 (br. s, 2 H, CH−N), 7.3−8.0 (m, 20 H, Ph) ppm. ^{31}P NMR (81.01 MHz, CD_2Cl_2, 25 °C): δ = 40.6 (s, $^1J_{Pt,P}$ = 4003 Hz) ppm.

Synthesis of 9b: This palladium complex was prepared as described above for **6b**, using THF as solvent and replacing the amino-ol with (1*R*,2*R*)-*trans*-diaminocyclohexane (0.060 g, 0.525 mmol). The product co-precipitated with NEt_3HCl in two hours and after filtration was re-dissolved in CH_2Cl_2 and extracted three times with water. The organic phase, taken to dryness, gave pure **9b** as a yellow solid; yield 0.160 g (46%). $C_{30}H_{32}Cl_2N_2P_2Pd$ (659.9): calcd. C 54.61, H 4.89, N 4.25; found C 54.68, H 4.70, N 4.55. ^{1}H NMR (200 MHz, CD_2Cl_2, 25 °C): δ = 0.6−1.0 (m, 4 H, CH), 1.5 (m, 2 H, CH), 1.7 (d, 2 H, CH), 2.3 (s, 2 H, NH), 3.3 (br. s, 2 H, CH−N), 7.3−8.0 (m, 20 H, Ph) ppm. ^{31}P NMR (81.01 MHz, CD_2Cl_2, 25 °C): δ = 65.9 ppm (s). $[\alpha]_D^{25}$ = +32.8 (*c* = 0.54, CH_2Cl_2). Recrystallisation of crude **9b** from dichloromethane/diethyl ether gave crystals suitable for a diffractometric study.

Removal of Coordinated Ligands from Platinum and Their Transfer to Palladium: This experiment was performed with the platinum complexes **4a**, **5a**, **6a** and **8a**. In a typical experiment, an excess of tetrabutylammonium cyanide (5 equiv.) was added to a solution containing the Pt complex (0.010 g) in $CDCl_3$ (0.8 mL). The progress of the reaction was monitored by ^{31}P NMR spectroscopy. After 15 min the spectrum showed the signals of the free ligand:

4: δ = 105.8 ppm (s)

5: δ = 116.9 ppm (s)

6: δ = 112.8 ppm (s) (PO), 38.8 ppm (s) (PN)

8: δ = 114.1 ppm (s) (PO), 46.4 ppm (s) (PN).

At this point an excess (2 equiv.) of [$PdCl_2$(1,5-COD)] was added to the solution and after ten minutes the signals of the corresponding palladium dichloride complex were visible in the ^{31}P NMR spectrum.

In an analogous manner the treatment of the palladium complex **9b** with tetrabutylammonium cyanide in $CDCl_3$, followed by the addition of [$PtCl_2$(1,5-COD)], allowed the observation of the spectrum of ligand **9** (δ = 33.6 ppm, s) and then of **9a**, assigned by comparison with a genuine sample.

The palladium complex **7b**, containing the monodentate aminophosphinite ligand **7**, after addition of CN^-, also gave the free ligand [δ = 111.5 ppm (s), PO] together with another unidentified phosphorus containing product [δ = 62.7 ppm (s)].

Chemical Stability Tests: In a typical experiment, 10^{-2} M solutions of the complex in $CDCl_3$, CH_2Cl_2, THF and benzene were prepared without exclusion of air and the ^{31}P NMR spectrum monitored after 30 min, 5 h and after 3 days. No changes were observed. A few drops of water were then added to each solution and the spectrum checked after 3 min and then after 24 h. Under these conditions all of the spectra were also found to be unchanged.

Optical Stability Tests: The values of $[\alpha]_D^{25}$ were determined for solutions of complexes **4a**, **4b**, **5a**, **6a**, **6b**, **8a** and **9b** as reported above. The optical rotations were redetermined for the same solutions after 3 days and each value was found unchanged.

X-ray Crystal Structure Determinations: X-ray diffraction data for compounds **2a**, **6b** and **9b** were collected on a Nonius Kappa CCD diffractometer, at room temperature (*T* = 295 K), with graphite monochromated Mo-K_α radiation (λ = 0.7107 Å) and corrected for Lorentz polarization and absorption (SORTAV)[17] effects. The structures were solved by direct methods (SIR97)[18] and refined (SHELXL-97)[19] by full-matrix least-squares with anisotropic non-hydrogen and hydrogen atoms on calculated positions, riding on their carrier atoms.

Crystal Data. 2a: $C_{30}H_{30}Cl_2O_2P_2Pt{\cdot}CH_2Cl_2$; trigonal, space group $P3_2$, *a* = 9.8264(1), *c* = 29.2991(2) Å, *V* = 2450.04(4) Å^3, *Z* = 3, $D_{calcd.}$ = 1.699 g·cm^{-3}. Intensity data collected with θ ≤ 30°; 9447 independent reflections measured; 8644 reflections observed [$I > 2\sigma(I)$]. Final *R* (observed reflections) = 0.028 and *Rw* (all reflections) = 0.063, *S* = 1.026, Flack parameter [20] = −0.012(3).

6b: $C_{33}H_{31}Cl_2NOP_2Pd{\cdot}1/2CH_2Cl_2$; triclinic, space group *P*1, *a* = 11.6343(2), *b* = 14.3753(3), *c* = 20.3486(4) Å, α = 93.0527(7), β = 92.4847(7), γ = 91.6164(9)°, *V* = 3393.6(1) Å^3, *Z* = 4, $D_{calcd.}$ = 1.447 g·cm^{-3}. Intensity data collected with θ ≤ 27°; 26342 independent reflections measured; 20677 reflections observed [$I > 2\sigma(I)$]. Final *R* = 0.098 (observed reflections) and *Rw* = 0.281 (all reflections), *S* = 1.029, Flack parameter = 0.03(4). The asymmetric unit contains four independent molecules of the complex and two molecules of dichloromethane.

9b: $C_{30}H_{32}Cl_2N_2P_2Pd$; monoclinic, space group $P2_1$, *a* = 7.5164(1), *b* = 16.2585(3), *c* = 12.4538(2) Å, β = 96.4409(7)°, *V* = 1512.32(4) Å^3, *Z* = 2, $D_{calcd.}$ = 1.449 g·cm^{-3}. Intensity data collected with θ ≤ 30°, 7940 independent reflections measured; 7416 reflections observed [$I > 2\sigma(I)$]. Final *R* = 0.039 (observed reflections), *Rw* = 0.101 (all reflections), *S* = 1.043, Flack parameter = 0.00(2).

Configuration of Octahedral Metal Compounds − Equilibrium, Crystal and Molecular Structure of Nickel(II) Complexes of Linear N_2O_4, N_4S_2 or N_6 Donors Set Atoms Ligands

Aminou Mohamadou,*[a] Caroline Jubert,[a] Nathalie Gruber,[b] and Jean-Pierre Barbier[a]

Keywords: Configuration determination / N,O ligands / N,S ligands / Nickel / Potentiometry

Two new nickel(II) complexes of symmetric hexadentate mixed-ligand N,O [1,12-bis(2-pyridyl)-5,8-dioxa-2,11-diazadodecane (pydado)] and N,S [1,12-bis(2-pyridyl)-5,8-dithia-2,11-diazadodecane (pydadt)] donor atoms have been synthesised as perchlorate salts and characterised by X-ray crystallography and ligand-field spectroscopy. In both complexes the Ni^{2+} ion is hexacoordinate. The cation $[Ni(pydado)]^{2+}$ is pseudo-octahedral with the two pyridyl groups in *trans* position; all Ni–N and Ni–O bond lengths are practically equivalent. In $[Ni(pydadt)]^{2+}$ complex, however, the size of the thioether sulfur atoms imposes a C_{2v} symmetry; the pyridyl groups and the sulfur atoms are in *trans* positions and all Ni–N bond lengths are equivalent. The comparison of these structures with those of octahedral cobalt, copper and zinc complexes with the same ligands shows that their configurations depend not only on the nature of the two central donor atoms of the ligand, but also on the nature of the metallic ion. In aqueous solution, the stability constants of the Ni^{II} chelates with these two ligands, determined by potentiometry, show the formation of $[Ni(LH)]^{3+}$ and $[NiL]^{2+}$ species in all cases. The chelating power of the pydadt ligand is slightly greater than that of pydado.

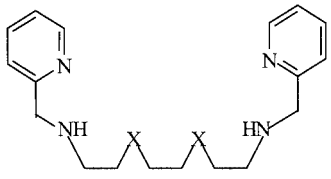
Introduction

The bioinorganic chemistry of the transition metal complexes has become increasingly important since the discovery that metal ions are found at the active site of several very important classes of metalloenzymes.[1] The catalytic activity of these compounds depends on the nature of the donors atoms of the ligand[2] and the configuration of the complex.[3] In this case, considerable interest has developed in nickel complexes with mixed-donor ligands in order to elucidate the relationship between the donor atoms of the ligand and the geometry around the metal ion.[4]

Nickel(II) complexes of linear ether or thioether ligands with different numbers of oxygen or sulfur donor atoms and a heterocyclic nitrogen have attracted attention recently.[5] In order to elucidate the effects of the distinctive structural features of the ligands on the properties of the resulting complexes, we described earlier the coordination complexes of cobalt, copper and zinc with three linear hexadentate ligands [1,12-bis(2-pyridyl)-2,5,8,11-tetraazadodecane (pytrien), 1,12-bis(2-pyridyl)-5,8-dioxa-2,11-diazadodecane (pydado) and 1,12-bis(2-pyridyl)-5,8-dithia-2,11-diazadodecane (pydadt)].[6,7] These ligands contain ether oxygen or thioether donors as well as aliphatic and aromatic nitrogen donors in the their ligand framework (Scheme 1).



X = O (pydado)
X = S (pydadt)
X = NH (pytrien)

Scheme 1

As a continuation of our interest in the study of complexes that model the active sites in metalloproteins and to better understand the physicochemical properties of such complexes, especially the stereochemistry of the metallic centre, we present here the thermodynamic constants of the metal chelates formed by these ligands in aqueous solution as well as the syntheses of the nickel(II) complexes. Their configuration has been investigated by crystal structures and compared to those described earlier.[6−8]

Results and Discussion

Synthesis

The violet nickel(II) complex of pydado was synthesised by the treatment of an aqueous solution of the ligand hydrochloride salt with tetramethylammonium hydroxide and one equivalent of nickel(II) perchlorate hexahydrate. The pink nickel(II) compound of pydadt was obtained by treating an ethanolic suspension of the ligand hydrochloride salt and four equivalents of sodium acetate with nickel(II) perchlorate hexahydrate. The two complexes were obtained as perchlorate salts, as confirmed by the presence of a strong band at 1090 cm^{-1} in the IR spectra. The chromatography studies of each nickel(II) complexes indicate the presence of only one diastereoisomer. Crystals suitable for structure determination were obtained by recrystallisation from water (compound **1**) or from a water/ethanol (1:2, v/v) mixture (compound **2**) by slow evaporation of the solvent at room temperature.

Solution Equilibria: Metal Chelate Formation Constants

The ligand equilibrium constants of the ligands pytrien,[9] and pydado and pydadt were determined previously.[7] The thermodynamic constants for the two ligands studied are listed in Table 1.

Table 1. Protonation constants ($\log K^n_H$), stability constants ($\log\beta$) and deprotonation constants ($\log K$) for Ni^{2+} complexes of pydado and pydadt (I = 1 M KNO_3 and 20 °C)[a]

	Ligands[b]				Complexes		
	$\log K^1_H$	$\log K^2_H$	$\log K^3_H$	$\log K^4_H$	$\log\beta_{110}$	$\log\beta_{111}$	$\log K$
pydado	8.63(3)	7.76(4)	2.36(4)	1.5(6)	12.85(1)	15.38(7)	2.53
pydadt	8.32(5)	7.58(4)	2.40(6)	1.6(5)	13.88(2)	16.24(5)	2.36

[a] Values in parentheses represent 1σ standard deviation for the last significant digit. [b] From ref.[7]

Complexation of Ni^{2+} with pydado and pydadt occurs below pH 3. The NiL species with these two ligands are completely formed at pH 5.5 (pydado) and pH 4.5 (pydadt). The protonated metal chelate Ni(HL) is formed in small amounts: a maximum of 10% of the analytical Ni^{2+} concentration with pydadt at pH 2.6, and a third, along with Ni^{2+} and NiL species, with pydado at pH 3.1.

The stability constants $\beta = |MHL^{3+}|/|M^{2+}||L||H^+|$ for the equilibrium in Equation (1) for nickel(II) complexes of pydado and pydadt appear in Table 1. The stability constants of the complex with pydado are smaller than those with pydadt. These results are in good agreement with those described by Martell and co-workers[10] in the coordination of pyridyl ligands possessing ether (O) or thioether (S) donor atoms. A thioether donor coordinates more strongly to divalent transition metals than an ether donor. The preference of these metals to bind to the softer thioether may be also explained by the larger size of the sulfur atom, allowing it to approach the metal ion more closely, with less contraction of the ligand backbone.[11] The stability constants for the nickel(II) complex with pytrien are higher than those with pydado and pydadt; this is in agreement with the chelating power of nitrogen atom with regard to ether oxygen or thioether sulfur atoms.

$$M^{2+} + L + H^+ \rightleftarrows M(HL)^{3+} \quad (1)$$

The chelate protonation constants for the equilibrium in Equation (2), defined as $K = [MHL^{3+}]/[ML^{2+}][H^+]$, also appear in Table 1.

$$ML^{2+} + H^+ \rightleftarrows MHL^{3+} \quad (2)$$

The protonation constant of $[NiL]^{2+}$ (L = pydado and pydadt) is close to the protonation constant K^3_H. Therefor, the K values do not allow the determination of the protonated nitrogen atom.

X-ray Diffraction Studies

The structures of complexes $[Ni(pydado)](ClO_4)_2\cdot H_2O$ (**1**) and $[Ni(pydadt)](ClO_4)_2$ (**2**) were determined by single-crystal X-ray diffraction. Pertinent crystallographic and refinement details are reported in Table 2.

[Ni(pydado)][ClO_4]$_2\cdot H_2O$ (1)

The molecular structure of this complex consists of $[Ni(pydado)]^{2+}$ cations and ClO_4^- anions. The two perchlorate anions are both ordered, with Cl−O bond lengths (average, 1.399 Å) and O−Cl−O bond angles (average 110.9°) similar to those reported earlier.[6,7] A view of the cation with the labelling scheme is shown in Figure 1.

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

Principal bond lengths and angles are listed in Table 3. The nickel(II) centre is coordinated by two aromatic nitrogens [N(1) and N(4)], two secondary amine nitrogens [(N2) and N(3)] and two ether oxygens [O(1) and O(2)]. Though several isomers can be obtained with a linear hexadentate ligand, the one observed here has the pyridine nitrogen atoms in the *trans* positions; the same isomer have been found for a zinc(II) complex.[7]

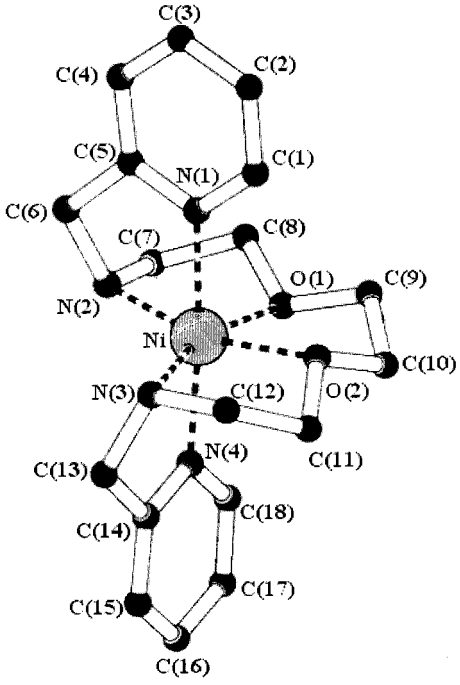

Figure 1. A PLUTON projection of the cation $[Ni(pydado)]^{2+}$ and the atom labelling-scheme; hydrogen atoms are omitted for clarity

The N(1)−Ni−N(4), N(2)−Ni−O(2) and N(3)−Ni−O(1) bond angles are 175.3(1)°, 159.8(1)° and 160.2(2)°, respectively. All nickel-donor atom bond lengths are slightly different [$Ni-N_{amine}$ (average 2.076 Å), $Ni-O_{ether}$ (average 2.084 Å) and $Ni-N_{pyridyl}$ (average 2.090 Å)]. Thus, the coordination geometry around the nickel atom is described as a slightly distorted octahedron, which is occupied by N(2), O(1), O(2) and N(3) at the equatorial sites and N(1) and N(4) at the axial sites. The two oxygen donor atoms are practically in the equatorial plane [N(1)−Ni−O(1): 92.8° and N(1)−Ni−O(2): 90.4°], whereas the two secondary amine nitrogen atoms are located below and above this plane, respectively [N(1)−Ni−N(2): 80.4° and N(1)−Ni−N(3): 96.9°].

Compared to the $[Zn(pydado)]^{2+}$ complex described earlier,[7] all metal-donor atom bond lengths in the nickel complex are smaller than those in the zinc complex, which is consistent with the larger radius of Zn^{II}. Conversely, the five chelate bond angles of 79.4(1)−83.3(2)° [average 81.4°] subtended by the ligand at the nickel atom are larger than their analogues of 74.1(1)−81.2(2)° [average 77.7°] in the zinc complex, in agreement with a smaller distortion in the nickel compound.

N(4)−Ni(1)−S(2)	166.39(9)	N(8)−Ni(2)−S(4)	164.40(9)
S(1)− Ni(1)−S(2)	85.18(4)	S(3)−Ni(2)−S(4)	85.73(4)

The crystal structure of complex **1** shows two, three-centre bifurcated H-bonds[12] between each secondary amine hydrogen and two oxygen atoms of each perchlorate anion [H(01)···O(4): 2.558 Å, H(01)···O(6): 2.416 Å and H(02)···O(7): 3.501 Å, H(02) ··O(9): 2.125 Å]. In the lattice of this complex, the intermolecular distances between the oxygen atom of the water of crystallisation and two oxygen atoms of one of the two perchlorate anions [O(11)···O(3): 3.217 Å and O(11)···O(5): 3.372 Å] are less than the sum of their van der Waals radii. This suggests that these species are also involved in hydrogen bonding interactions.

$[Ni(pydadt)][ClO_4]_2$ (2)

Compound **2** crystallises in a triclinic system with eight molecules in the unit cell. In the crystal lattice, the two enantiomeric isomers of the $[Ni(pydadt)]^{2+}$ cations are present in equal parts, giving a racemate. Three of the four ClO_4^- anions are ordered, whereas the fourth, in which each oxygen atom occupies two sets of positions, is disordered. Each perchlorate anion forms a two-centre chelate H-bond[12] between one oxygen atom and each of two secondary amine hydrogens (O···HN, average 2.132 Å). A per-

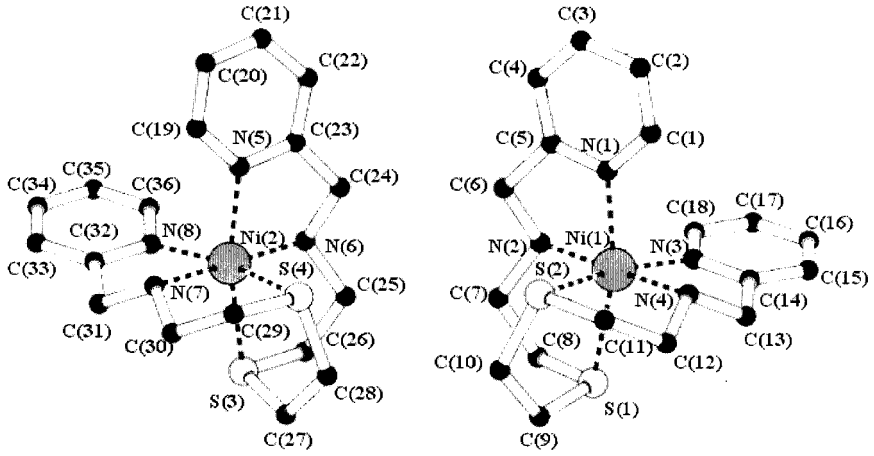

Figure 2. A PLUTON projection of the two enantiomeric cations of $[Ni(pydadt)]^{2+}$ and the atom labelling-scheme; hydrogen atoms are omitted for clarity

spective drawing of the two enantiomers cations with atom labelling is illustrated in Figure 2, relevant bond lengths and angles are given in Table 3.

The molecular structure of complex **2** shows that each $[Ni(pydadt)]^{2+}$ cation is hexacoordinate, with the two aromatic nitrogen atoms in the *cis* positions, whereas the two amino nitrogen atoms are in the *trans* positions. In each enantiomer, the bond lengths of the same donor atoms (N or S), while not always exact, are quite close [Ni(1)−N: average 2.085 Å; Ni(1)−S: 2.470 Å; Ni(2)−N: average, 2.101 Å], with the exception of the isomer labelled Ni(2), where the two Ni−S bond lengths are different [Ni(2)−S(3): 2.440 Å and Ni(2)−S(4): 2.463 Å]. In addition, the variation of the Ni−N and Ni−S bond lengths is opposite in the two enantiomers: the Ni(1)−N bond lengths are slightly shorter than Ni(2)−N (−0.016 Å), while the Ni(1)−S bonds are slightly longer than Ni(2)−S (average +0.018 Å). The $N_{py}-Ni-S$ (average 165°) and $N_{amino}-Ni-N_{amino}$ (average 179°) bond angles, which are practically the same in the two enantiomers, are not very close to those of an ideal octahedral geometry. According to the result obtained from ligand field spectroscopy (see below), complex **2** has C_{2v} symmetry.

Absorption Spectra

The electronic spectra of the two nickel(II) compounds (**1** and **2**) in the solid state are no different to those obtained in aqueous solution. The absorption spectra for these compounds exhibit essentially similar patterns in the 250−500 nm region, with two strong bands possibly due to intraligand[13] and charge-transfer transitions.

In the visible region, $[Ni(pydado)](ClO_4)_2$ (**1**) displays two bands at 890 nm and 560 nm. These two bands arise from $^3A_{2g}\rightarrow{}^3T_{2g}$ and $^3A_{2g}\rightarrow{}^3T_{1g}(^3F)$ transitions. The third band at higher energy is completely obscured by a metal-ligand charge transfer. These observations are consistent with an octahedral geometry around the Ni^{2+} ion. The ligand-field parameters were calculated using the energy levels given by Lever: 10 Dq = 11230 cm^{-1}, Racah parameter B = 860 cm^{-1}. These parameters, and those of the octahedral $[Ni(pytrien)](ClO_4)_2$ complex (10 Dq = 12360 cm^{-1}, B = 826 cm^{-1}),[8] are in agreement with NiN_4O_2 and NiN_6 chromophores, respectively.

The spectrum of $[Ni(pydadt)](ClO_4)_2$ (**2**) shows two more-intense absorption bands centred around 890 nm and 540 nm. Each band present shoulders, which indicates a lowering of the symmetry around the Ni^{2+} ion. These two absorption envelopes could be cleanly resolved into just three (10360 cm^{-1}, 11560 cm^{-1} and 12050 cm^{-1}) and two (16950 cm^{-1} and 18800 cm^{-1}) Gaussian components, respectively. The corresponding energy levels[14a] for these transitions are given in Figure 3; they are in agreement with those calculated for a C_{2v} symmetry,[14b] and described by Meredith and Palmer[15] for a $[Ni(histidine)_2(OH_2)_2]$ complex.

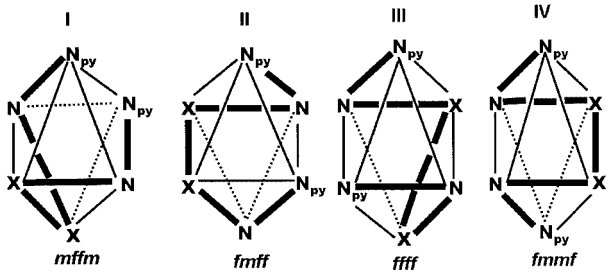
Configuration of the Octahedral Complexes

We have studied the coordination of first-row transition metals (cobalt, nickel, copper and zinc) with the linear hexadentate ligands pytrien,[6] pydado[7] and pydadt,[7] which possess two central N, O and S donors, respectively. These ligands, with three different donor atoms, are of the type A B C C B A, in which A represents a pyridyl nitrogen atom, B a secondary amine nitrogen atom and C the central heteroatom (N, O or S). Disregarding isomerism due to the fact that the secondary amine nitrogen donor can became stereogenic, and the non-planarity of the chelate rings formed upon complexation, there are many possibilities of ligand arrangement, meaning that there are four pairs of enantiomers possible with these $A_2B_2C_2$ donor sets. Generally, only one pair of enantiomers, which were resolved, was observed, indicating a stereoselectivity introduced by the different ligating atoms.[16]

All possible diastereoisomers of our complexes with linear hexadentate ligands are shown in Scheme 2. When dealing with this kind of octahedral compound, the α (or β)-*cis* or *cis-trans-cis* types of nomenclature are not adequate to describe the geometry of the complex, as they do not differentiate between the wrapping of the ligand around the metal ion in all the isomers; for example, the two configurations I and III (Scheme 2) are both *cis-trans-cis*. Therefore the extension of the Saito method,[17] introduced by Hartshorn and House,[18] was used to describe the configuration of the octahedral complexes obtained with these three linear hexadentate ligands; for each sequence of three donor atoms, the descriptors m and f indicate meridional and facial ligand segments, respectively. Consequently, each isomer of octahedral complexes with a linear hexadentate ligand can be described with four characters, with pairs of enantiomers having the same labelling.



Scheme 2

The X-ray crystal structures of the cobalt, nickel, copper and zinc complexes with the three hexadentate ligands show that the four compounds isolated with each ligand crystallise in the same diastereoisomer as the four described above. $[M(pytrien)]^{n+}$ (n = 3 for Co and n = 2 for Ni, Cu and Zn), $[M(pydado)]^{2+}$ and $[M(pydadt)]^{2+}$ have the configuration II, IV and I, respectively (Figure 4). As the only difference between these ligands is the two central heteroatoms, the stereoselectivity of these complexes is introduced by the central ligating atoms. In the crystal lattice, $[Cu(pydado)]^{2+}$ or $[Ni(pydadt)]^{2+}$ are racemates, whereas the others complexes have only one of the two enantiomers for the corresponding configurations. With each ligand, disregarding the

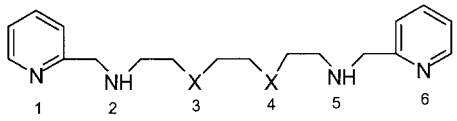
Figure 4. The configurations of cobalt, nickel, copper and zinc complexes with pytrien, pydado and pydadt ligands

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

nature of the metal ion, the cobalt and zinc compounds are always enantiomers, while the nickel complexes have either the enantiomeric configuration of the cobalt or the zinc complex.

A comparison of all octahedral metal complexes of pytrien and pydado shows that the donor atoms 5 and 6 (Scheme 3) are reversed in the octahedron. The absolute configuration of the stereogenic amine nitrogen atom 2 is retained for the two cobalt (*R*) and the two zinc (*S*) complexes, whereas it is inverted in the nickel compounds.



Scheme 3

The large size of the sulfur donor atoms of the pydadt ligand does not allow the facial coordination of the heteroatoms 1, 2 and 3 (Scheme 3) around the metal ion. Therefore, an mffm configuration is imposed for all $[M(pydadt)]^{2+}$ cations, so that the bulky pyridyl groups and the larger thioether sulfur atoms are in *trans* positions.

Conclusion

The equilibrium constants of the Ni^{II} chelates with pydado and pydadt determined by potentiometry show the formation of $[NiLH]^{3+}$ and $[NiL]^{2+}$ species in all cases; $[NiLH]^{3+}$species are present in small amounts around pH 3, while $[NiL]^{2+}$ are fully formed in neutral medium. The stability constants of the $[Ni(pydadt]^{2+}$ species are slightly greater than those of $[Ni(pydado]^{2+}$, in agreement with analogous ligands described by Martell and co-workers.[10,11] Comparison of the thermodynamic constants of these nickel(II) complexes and the other M^{II} complexes (M = cobalt, copper and zinc) of the same ligands,[7] shows that the values of the stability constants follow the Irving−Williams series.

X-ray crystallographic studies show that the Ni−N and Ni−O bond lengths in $[Ni(pydado]^{2+}$ cation are practically identical, and this is in good agreement with the electronic spectrum, which is easily interpreted in O_h symmetry. However, the presence of the thioether sulfur atoms in the $[Ni(pydadt]^{2+}$ complex, in which the Ni−S bond lengths are always longer than Ni−N (+0.376 Å), leads to a large distortion around the nickel ion, with the bulky pyridyl groups and sulfur donor atoms in *trans* positions. This distortion is corroborated with the nature of the electronic spectrum of $[Ni(pydadt]^{2+}$ complex, characteristic for C_{2v} symmetry.

The crystal structures of some octahedral first-row transition metal complexes with these kinds of symmetrical linear hexadentate ligands show clearly that the two central heteroatom donors introduce a stereoselectivity of the complexes obtained and therefore dictate their configuration. Conversely, the central metal ion imposes their conformation; for example, cobalt and zinc always have an inverse conformation.

Experimental Section

Chemicals and Starting Materials: All solvents were purified by conventional procedures[20] and distilled prior to use. Chemicals commercially available (Aldrich) were used as supplied without further purification. The ligands, 1,12-bis(2-pyridyl)-5,8-dioxa-2,11-diazadodecane (pydado) and 1,12-bis(2-pyridyl)-5,8-dithia-2,11-diazadodecane (pydadt) were obtained as tetrahydrochloride salts from the condensation of 2-pyridine carboxaldehyde and triethylene dioxa(or dithia)diamine, as described previously.[7]

CAUTION: *Although we have experienced no problems while handling any of the perchlorate substances described herein, readers are advised to handle these compounds as potentially explosive compounds.*

Elemental analyses (C, H and N) were carried out on a Perkin−Elmer 2400 C, H, N element analyser in our university. The metal analysis was performed on an ICP AES Liberty Series II Varian apparatus. Magnetic susceptibilities were determined at room temperature (20 °C) using $HgCo(SCN)_4$ as a calibrant; diamagnetic susceptibility corrections were calculated from Pascal's constants.[21]

Potentiometry: All chemicals used were of analytical grade. HNO_3 and KOH were purchased from Prolabo. KNO_3 and $Ni(NO_3)_2{\cdot}3H_2O$ were purchased from Fluka. The metal ion solutions were prepared (ca. 0.01 M) and standardised with $Na_2H_2edta{\cdot}2H_2O$. All measurements were performed in a thermoregulated cell at (20.0 ± 0.1) °C, under N_2 to prevent absorption of CO_2, as described previously.[7]

The measurement apparatus consist of a microprocessor burette (Metrohm Dosimat 665) and a pH meter (Metrohm 713) equipped with a combined pH glass electrode (Metrohm AG 9101) linked to a PC. The stability constants were calculated and refined with the computer program PROTAF.[22]

Spectroscopy: The UV/Vis. spectra were recorded on a Perkin−Elmer Lambda 6 spectrophotometer. Gaussian deconvolution of visible absorption spectra were performed using an application developed under "QUATTRO PRO" by J. Rimbault in our laboratory. IR spectra were obtained in KBr pellet.

$[Ni(pydado)](ClO_4)_2{\cdot}H_2O$ (1): A solution of tetramethylammonium hydroxide 0.5 M was added dropwise to an aqueous solution (30 mL) of pydado·4HCl (0.49 g, 1 mmol) and nickel(II) perchlorate hexahydrate (0.36 g, 1 mmol) to adjust the pH to around 8. Slow evaporation of the solvents at room temperature yielded violet crystals, suitable for X-ray diffraction studies, after two months. Yield: ca. 75%; m.p. 255 °C. $C_{18}H_{28}Cl_2N_4NiO_{11}$: calcd. C 35.7, H 4.6, N 9.2, Ni 9.7; found C 35.8, H 4.3, N 9.3, Ni 9.5. $\chi_M = 4310 \times 10^{-6}$ uem cgs, $\mu_{eff} = 3.18\ \mu_B$. UV/Vis (H_2O): λ_{max} (ε) = 890 nm (12 $mol^{-1}{\cdot}L{\cdot}cm^{-1}$), 560 (13).

$[Ni(pydadt)](ClO_4)_2$ (2): A mixture of sodium acetate trihydrate (0.54 g, 4 mmol) and the ligand pydadt·4HCl (0.54 g, 1 mmol) in absolute ethanol (30 mL) was stirred, whilst boiling, for 10 min in a water bath. The mixture was then cooled and the sodium chloride that precipitated was filtered. Nickel perchlorate hexahydrate

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

(0.36 g, 1 mmol) in absolute ethanol (20 mL) was added dropwise to the filtrate and the solution was stirred for 2 h at room temperature. The mauve powder formed was filtered off and washed with ethanol. Recrystallisation from water/ethanol (1:5) gave pink crystals suitable for X-ray diffraction after three weeks. Yield: ca. 70%; m.p. 270 °C. $C_{18}H_{26}Cl_2N_4NiO_8S_2$: calcd. C 34.9, H 4.2, N 9.0, Ni 9.5; found C 34.7, H 3.9, N 8.9, Ni 9.1. $\chi_M = 4550 \times 10^{-6}$ uem cgs, $\mu_{eff} = 3.27\ \mu_B$. UV/Vis (H_2O): λ_{max} (ε) = 965 nm sh, 890 (40 $mol^{-1}\cdot L\cdot cm^{-1}$), 830 sh; 570 sh, 540 (23).

Crystal Structure Determinations: The crystal data were collected on a Kappa CCD diffractometer using monochromatic Mo-K_α radiation (λ = 0.71073Å). The structures were solved by direct methods. After refinement of the non-hydrogen atoms, Fourier difference maps revealed maxima of residual electron density close to positions expected for hydrogen atoms. Hydrogen atoms were introduced as fixed contributors at calculated positions [C−H = 0.95 Å; B(H) = 1.3 Beq]. Final difference maps revealed no significant maxima. All calculations were performed with the Nonius OpenMoleN package.[23] Neutral-atom scattering factor and anomalous dispersion coefficients were taken from a standard source.[24] Molecular drawings were produced with the PLUTON software package.[25]

CCDC-213876 [for Ni(pydado)]$(ClO_4)_2\cdot H_2O$] and -213877 [for Ni(pydadt)]$(ClO_4)_2$] contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Acknowledgments

We are grateful to Prof. J. G. Fischer and Dr. A. De Cian (Université Louis Pasteur, Strasbourg, France) for the single-crystal X-ray analyses. We thank Dr. R. M. Hartshorn, University of Canterbury, for his advice on the geometrical configurations. C. Jubert thanks la Region Champagne-Ardenne for the award of a fellowship.

Neutral and Cationic Methylaluminium Complexes of 2-Anilinotropone Ligands: Synthesis, Characterization, and Reactivity toward Ethylene

Daniela Pappalardo,*[b] Mina Mazzeo,[a] Pasquale Montefusco,[a] Consiglia Tedesco,[a] and Claudio Pellecchia[a]

Keywords: Aluminium / N,O ligands / Alkenes / Cations / Polymerizations

Some new aluminium complexes bearing bidentate monoanionic 2-anilinotroponate ligands have been synthesized and characterized. Reaction of 2-(2,6-diisopropylanilino)tropone or 2-(perfluoroanilino)tropone with $AlMe_3$ (1 equiv.) gave, by methane elimination, compounds [2-(2,6-diisopropylanilino)tropone]$AlMe_2$ (**1**) and [2-(perfluoroanilino)-tropone]$AlMe_2$ (**2**), respectively, as yellow solids. Reaction of **1** with 1 equiv. of the ligand furnished, by protodealumination of a second Al–CH_3 bond, the [2-(2,6-diisopropylanilino)tropone]$_2$AlMe derivative **3**. The structure of **3** has been determined by single-crystal X-ray diffraction, showing a five-coordinate aluminium atom with a distorted trigonal-bipyramidal geometry. Compounds **1** and **3** underwent methyl abstraction reactions with $B(C_6F_5)_3$; the resulting cationic species was trapped in the presence of THF in dichloromethane solution. The reactivity of the synthesized compounds in ethylene polymerisation has also been explored.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

Organometallic aluminium complexes are widely employed in organic synthesis and in catalysis.[1] In particular, organoaluminium compounds are currently used in polymerisation chemistry, e.g. in cationic,[2,3] anionic,[4−6] and ring-opening polymerisation.[7] In addition, alkylaluminium complexes have long been known to catalyse olefin oligomerizations,[8] and are the preferred cocatalysts in various important industrial processes catalysed by transition metals, such as the Ziegler−Natta olefin polymerisation,[9] the Wilke alkene dimerization[10] and the Ziegler nickel effect.[11]

The disclosure by Coles and Jordan in 1997 that certain cationic methylaluminium amidinate compounds promote ethylene polymerisation, although with low activity,[12] has encouraged a growing interest in exploring the reactivity of various aluminium compounds. Dialkylaluminium compounds bearing monoanionic chelating ligands, such as the *N*,*N* bidentate aminotroponiminate,[13] the tridentate *N*,*N*,*N* pyridylaminoamide[14] or the tridentate *O*,*N*,*N* and *O*,*N*,*O* pendant arm Schiff-base ligands[15] showed, after activation with the ionising agents traditionally used in homogeneous Ziegler−Natta catalysis {i.e. $B(C_6F_5)_3$ or $[(C_6H_5)_3C][B(C_6F_5)_4]$}, some activity for ethylene polymerisation catalysis. In this regard, we reported recently the synthesis of alkylaluminium compounds bearing phenoxy-imine or *N*,*N* imino-amide ligands that undergo decomposition reactions after alkyl abstraction with $B(C_6F_5)_3$; the cationic species were instead obtained in the presence of THF. Toluene solutions of the aluminium salicylaldiminate compounds, if activated with $B(C_6F_5)_3$, polymerise ethylene to solid polyethylene with low activity.[16] Furthermore, the simple bis(dichloroaluminium)ethane[17] and alkylaluminium compounds themselves,[18] activated with ionising agents, can catalyse the polymerisation of ethylene, also with low activity.

Although cationic alkyl complexes have been isolated and characterized, it is still unclear if they are directly responsible for the catalytic activity. Monitoring the reaction of alkylaluminium aminotroponiminate cationic complex with [D_4]ethylene, Jordan excluded that intact cationic species are the active ethylene polymerisation catalysts, while their main reaction is a β-H transfer to generate the corresponding cationic aluminium hydride.[13b] In fact, according to recent theoretical studies on ethylene polymerisation at aluminium centres, mononuclear aluminium species are unlikely to produce polymers, because chain transfer is too easy relative to propagation.[19] Therefore, more complex structures for the active species have to be considered. Computational studies showed that dinuclear species could be involved and, recently,[19c] an aluminium bis(iminophosphorano)methanediide complex, based on a spirocyclic carbon centre subtended by two $AlMe_2$ units, was shown to polymerise ethylene with higher activity.[20]

We report here the synthesis and characterization of some new aluminium complexes carrying bidentate monoanionic anilinotropone ligands[21] (Scheme 1), along with their reactivity with ion-generating activators, and some preliminary data on their reactivity in ethylene polymerisation.

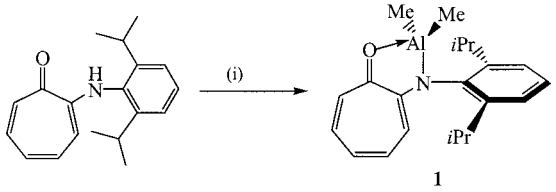
Results and Discussion

Synthesis of [2-(Anilino)tropone]$AlMe_2$ Derivatives

Recently, Brookhart has described neutral anilinotropone-based nickel(II) compounds[22] that can polymerise ethylene in the absence of an activator, with an activity higher than the analogous neutral nickel salicylaldiminate compounds reported by Grubbs.[23] We therefore synthesized the [2-(anilino)tropone]dimethylaluminium derivatives **1** and **2** to test their reactivity with olefins.

Treatment of 2-(2,6-diisopropylanilino)tropone[21] with $AlMe_3$ (1 equiv.) in toluene at 0 °C for 2 h produces [2-(2,6-diisopropylanilino)tropone]$AlMe_2$ (**1**) as a yellow solid. The reaction proceeds by protodealumination of the Al−CH_3 bond, with concomitant elimination of methane (Scheme 2), as evidenced by ^{1}H and ^{13}C NMR analysis. In the ^{1}H NMR spectrum ([D_6]benzene, room temperature) the N*H* singlet (δ = 8.86 ppm) of the ligand disappears, while a new singlet appears at high field [δ = −0.21 ppm (6 H)] accounting for the AlMe_2 protons. Similarly, in the ^{13}C NMR spectrum ([D_6]benzene, room temperature) a new signal at δ = −8.3 ppm is observed, which is attributable to AlMe_2 carbon atoms. The signal of the carbonyl carbon atom shifts from δ = 177.3 ppm in the free ligand to δ = 173.7 ppm in the aluminium compound **1**, indicating a change in electronic density after coordination to Al. The ^{1}H NMR spectrum has one signal for the AlMe_2 protons, one multiplet for C*H*Me_2 [δ = 3.09 ppm (2 H)] and two doublets for the methyl groups of CHMe_2 [δ = 1.21 ppm (6 H) and 0.89 ppm (6 H)]. The ^{13}C NMR spectrum confirms this picture: one signal for *C*HMe_2 (δ = 28.7 ppm), two signals for the methyl carbon atoms of CHMe_2 (δ = 25.9 and 24.5 ppm), one signal for the AlMe_2 groups. This pattern is compatible with a mirror symmetry passing through the tropone seven-membered ring, and perpendicular to the 2,6-disubstituted phenyl group; the AlMe_2 groups are equivalent, therefore they should lie symmetrically above and below the plane. Thus, the molecule belongs to the C_s symmetry group.



1

Scheme 2. Reaction conditions: (i): $AlMe_3$, toluene, 0 °C

The compound was further characterized by both FT-IR spectroscopy and EI mass spectrometry. The slight difference in the FT-IR spectrum between the stretching frequency of the carbonyl group in **1** (1598 cm^{-1}) and in the ligand (1601 cm^{-1}) could be explained by considering that in **1** the carbonyl group is reasonably coordinated to the metal atom while in the free ligand the C=O group is involved in hydrogen bonding with the NH group. The molecular ion peak in the EI mass spectrum is at m/z = 336.

The reaction of 2-(perfluoroanilino)tropone with $AlMe_3$ (1 equiv.) in toluene, at 0 °C, proceeds similarly (Scheme 3), affording [2-(perfluoroanilino)tropone]$AlMe_2$ (**2**) as a yellow solid, which has been characterized by ^{1}H and ^{13}C NMR analysis and EI mass spectrometry. The NMR spectroscopic data are compatible with a mirror symmetry passing through the seven-membered tropone ring and perpendicular to the perfluorophenyl group, as hypothesized for **1**.

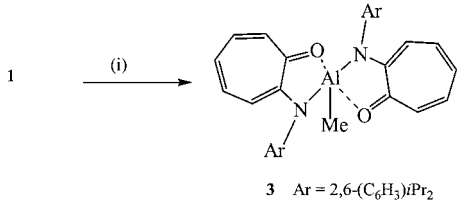
Scheme 3. Reaction conditions: (i): $AlMe_3$, toluene, 0 °C

Synthesis of [2-(2,6-Diisopropylanilino)tropone]$_2$AlMe (3)

The title compound was initially obtained as a secondary product in a preparation of **1**, upon accidentally using an excess of ligand, and was identified by NMR spectroscopy in [D_6]benzene solution. Compound **1** can be converted quantitatively into **3** by simply adding 1 equiv. of the ligand in toluene solution at room temperature (Scheme 4).



3 Ar = 2,6-(C_6H_3)*i*Pr_2

Scheme 4. Reaction conditions: (i): 2-(2,6-diisopropylanilino)tropone, toluene, room temperature

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

Compound **3** has been fully characterised by ^1H and ^{13}C NMR spectroscopy, elemental analyses, EI MS, FT-IR spectroscopy, and single-crystal X-ray diffraction. Diagnostic signals in the ^1H NMR spectrum ([D_6]benzene, room temperature; Figure 1) are a singlet at $\delta = -0.06$ ppm (3 H), attributable to the Al*Me* protons, four doublets at $\delta = 0.99, 1.03, 1.06, 1.48$ ppm (6 H each) that are attributable to the CH*Me*$_2$ protons, and two multiplets for C*H*Me$_2$ at $\delta = 3.07$ (2 H) and 3.37 ppm (2 H). The ^{13}C NMR spectrum exhibits resonances for the corresponding carbon atoms: one signal at $\delta = -6.7$ ppm, attributable to Al*Me*, four signals for the methyl carbon atoms at $\delta = 23.9, 25.4, 25.5$ and 26.5 ppm, and two signals at $\delta = 28.8$ and 29.8 ppm for the *C*HMe$_2$ carbon atoms. This picture is consistent with a C_2 symmetry of the molecule in solution.

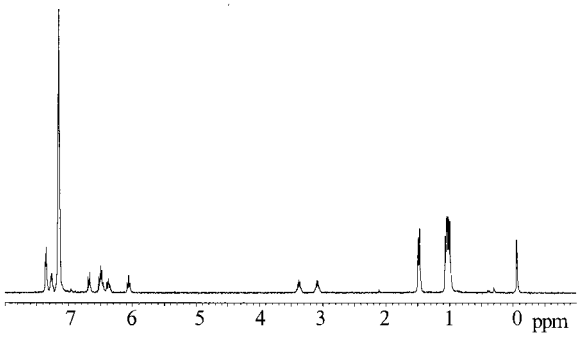


Figure 1. ^1H NMR spectrum of **3** (C_6D_6, room temperature)

The compound was further characterized by EI mass spectrometry, which shows the molecular ion peak at $m/z = 603$ $[M]^+$ and a peak at $m/z = 587$ $[M - CH_3]^+$. In the FT-IR spectrum, the stretching frequency of the carbonyl group appears at 1597 cm^{-1}.

Complex **3** crystallized as regular yellow prisms from toluene at −20 °C. The molecular structure of **3** (Figure 2) and the corresponding selected interatomic distances and angles (Table 1) are reported here. The X-ray structure determination shows that the space group is *C*2/*c*, with a crystallographic twofold axis parallel to the *b* axis and passing through the Al atom and methyl group C atom. Therefore the C_2 molecular axis, observed in solution, is preserved in the crystal. The unit cell contains four molecules of **3** and eight molecules of toluene disordered over a mirror plane; this feature affects the overall quality of the structural data.

The compound contains a five-coordinate Al atom with a highly distorted, approximate trigonal-bipyramidal geometry (tbp).[24] The O atoms occupy the apical positions, while the N atoms and the methyl group carbon atom lie in the equatorial plane; the C_2 molecular axis bisects the angle between the two N atoms.

The seven-membered tropone ring is almost planar with rmsd 0.024 Å; carbon atoms C1 and C7 deviate most from the seven-atoms least-squares plane by 0.039(4) and −0.034(4) Å, respectively. A comparison between the carbon−heteroatom bond lengths in compound **3** and in the free ligand[22] evidenced that the C1−O1 bond [1.292(5) Å] is longer than in the free ligand (1.252 Å), while C7−N1 [1.335(5) Å] is statistically almost the same as in the free ligand (1.355 Å). Some contribution from resonance form B in Scheme 5 cannot be excluded.

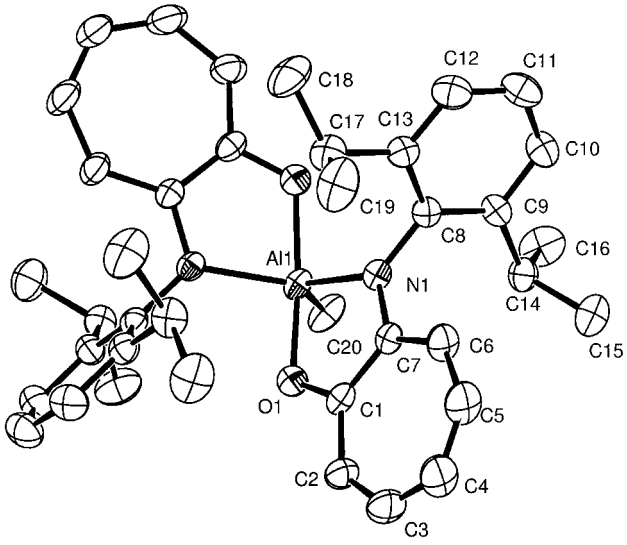

Figure 2. Molecular structure of **3**; thermal ellipsoids are drawn at 20% probability; H atoms omitted for clarity

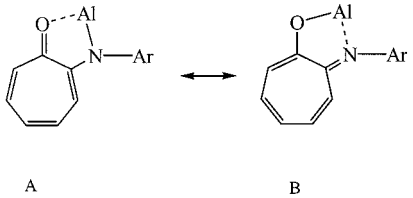

Scheme 5

The aniline six-membered ring is almost perfectly planar (rmsd 0.005 Å), with the N1, C14, and C17 atoms practically lying in the same plane. The aniline ring forms a dihedral angle of 58.6(1)° with the plane defined by the tropone seven-membered ring.

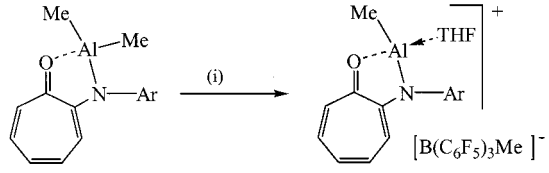
Five-coordinate aluminium complexes play an important role as initiators for the controlled polymerisation of polar monomers. Complexes bearing tetradentate macrocyclic or chelating ligands (such as porphyrins,[25] salen-type ligands[26]), or bulky monoanionic bidentate ligands,[27] catalyse the living ring-opening polymerisation of propene oxide. The generation of highly electrophilic cationic species and their catalytic application has also been explored.[7b,28]

Generation of Cationic Species and Their Reactivity Toward Ethylene

For catalytic applications, cationic aluminium species are more attractive than neutral ones, because of their increased Lewis acidity. The stability of group-13 alkyl cations depends strongly on the ancillary ligand and the kind of counter anion. Bochmann has described the preparation of the bis(cyclopentadienyl)aluminium cation from the corresponding methyl compound after reaction with $B(C_6F_5)_3$;[3] however, simple alkylaluminium compounds, if treated with the activators commonly used in homogeneous olefin polymerisation catalysis {i.e. $B(C_6F_5)_3$ or $[(C_6H_5)_3C][B(C_6F_5)_4]$}, undergo degradation reaction with cleavage of a $B-C_6F_5$ bond.[29] The cationic alkylaluminium species was trapped in the presence of bases[7a] or using coordinating solvents, such as diethyl ether and THF.[30]

We have generated cationic complexes from the synthesized aluminium compounds by NMR tube reactions with $B(C_6F_5)_3$. When **1** and $B(C_6F_5)_3$ are mixed in C_6D_6 at room temperature, a brown oil precipitates, thus preventing NMR solution analysis. The reaction was consequently studied in CD_2Cl_2 solution. After in situ treatment of **1** with of $B(C_6F_5)_3$ (1 equiv.), the ^1H NMR spectrum shows a resonance at $\delta = +0.45$ ppm, which is attributable to the *free* anion $[MeB(C_6F_5)_3]^-$,[31] therefore indicating that the main reaction is methyl abstraction by $B(C_6F_5)_3$. The initially formed cationic species is degraded rapidly, generating a mixture of unidentified organometallic species. Ethylene was added to a freshly prepared solution of **1** and $B(C_6F_5)_3$ in CD_2Cl_2; monitoring the reaction at room temperature showed that ethylene was consumed and that a solid polymer was formed.

Attempts to isolate and better characterize the cationic species in the absence of bases were unsuccessful. Trapping of the cationic species was instead achieved in the presence of THF. When $B(C_6F_5)_3$ (1 equiv.) was added to a CD_2Cl_2 solution of **1** containing THF (1 equiv.), the THF-coordinated methyl cation of {[2-(2,6-diisopropylanilino)-tropone]AlMe(THF)}$^+$[MeB$(C_6F_5)_3]^-$ (**1a**) was formed (Scheme 6). Characteristic ^1H NMR resonances are the signals at $\delta = -0.27$ ppm for Al*Me*$^+$ (3 H) and at $\delta =$ 0.45 ppm for B*Me* (3 H). The pattern of signals in the ^1H NMR spectrum is consistent with the C_1 symmetry group (i.e. two signals for the C*H*Me$_2$ groups and four doublets for the methyl groups of CH*Me*$_2$). Accordingly, the THF methylenic hydrogen atoms in α-positions with respect to the oxygen atom are diastereotopic, and appear as two multiplets at $\delta = 4.40$ (2 H) and 4.26 ppm (2 H); the β-hydrogen atoms, instead, appear as a multiplet centred at $\delta =$ 2.25 ppm (4 H). After addition of a further equivalent of THF, the THF methylenic hydrogen atoms in α-positions with respect to the oxygen atom coalesce in a multiplet centered at $\delta = 4.20$ ppm, and the numbers and multiplicity of the signals are the same as in the neutral starting compound, i.e. one signal for the C*H*Me$_2$ and two doublets for the methyl groups of the CH*Me*$_2$. Such behaviour can, probably, be explained by assuming, in the presence of excess THF, there is a rapid exchange process between free and bound THF.

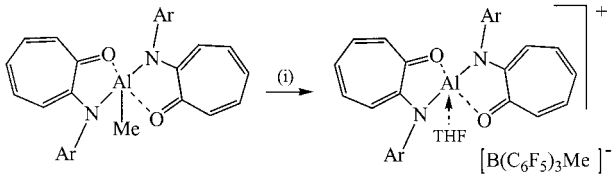


1 Ar = 2,6-(C_6H_3)*i*Pr$_2$ **1a** Ar = 2,6-(C_6H_3)*i*Pr$_2$

Scheme 6. Reaction conditions: (i): $B(C_6F_5)_3$, THF in CD_2Cl_2

Attempts to generate clean cationic species from the monomethylaluminium compound **3** with $B(C_6F_5)_3$ in the absence of coordinating agents were unsuccessful, leading always to a mixture of unidentified species. Addition of ethylene to a freshly prepared solution of **3** and $B(C_6F_5)_3$ did not result in monomer consumption or production of solid polymer, unlike the behaviour of **1** in the analogous experiment (see above). Since compounds **1** and **3** were prepared using the same reagents, but in different stoichiometric ratios, the implication of some metal impurity in the polymerization activity of the aluminium species **1** can be ruled out.[19] In fact, while the reaction of **1** with $B(C_6F_5)_3$ (1 equiv.) generates a cationic methylaluminium compound, abstraction of the methyl group from **3** generates a cationic species that lacks any Al−C bond suitable for chain growth by ethylene insertion.

The cationic species {[2-(2,6-diisopropilanylino)tropone]$_2$-Al(THF)}$^+$[MeB$(C_6F_5)_3]^-$ (**3a**) was cleanly generated by the reaction of **3** with of $B(C_6F_5)_3$ (1 equiv.) in the presence of THF (1 equiv.) in CD_2Cl_2 (Scheme 7). The product was characterized by ^1H and ^{13}C NMR spectroscopy at room temperature.



3 Ar = 2,6-(C_6H_3)*i*Pr$_2$ **3a** Ar = 2,6-(C_6H_3)*i*Pr$_2$

Scheme 7. Reaction conditions: (i): $B(C_6F_5)_3$, THF in CD_2Cl_2

In the ^1H NMR spectrum, the singlet of Al*Me* of the neutral starting compound **3** disappears, while a new signal appears at $\delta = 0.45$ ppm, which is attributable to the "free" anion $[MeB(C_6F_5)_3]^-$, indicating that alkyl abstraction has

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

occurred. The numbers of signals (i.e. four doublets for the CH*Me*$_2$ protons, and two multiplets for C*H*Me$_2$ in the ^{1}H NMR spectrum; four signals for the methyl carbon atoms and two signals for the isopropylic *C*HMe$_2$ carbon atom in the ^{13}C NMR spectrum) indicate that the cation preserves the C_2 symmetry observed in solution in the neutral compound. Integration shows that the cation is supported by one molecule of coordinated THF. Interestingly, the THF methylenic hydrogen atoms in α-positions with respect to the oxygen atom, being diastereotopic, appear as two multiplets at δ = 4.38 (2 H) and 3.93 ppm (2 H); the β-hydrogen atoms, instead, appear as a multiplet centred at δ = 2.13 ppm (4 H) (Figure 3). This suggests that the THF molecule substitutes the methyl group of the corresponding neutral compound, and therefore is situated on the C_2 symmetry axis.

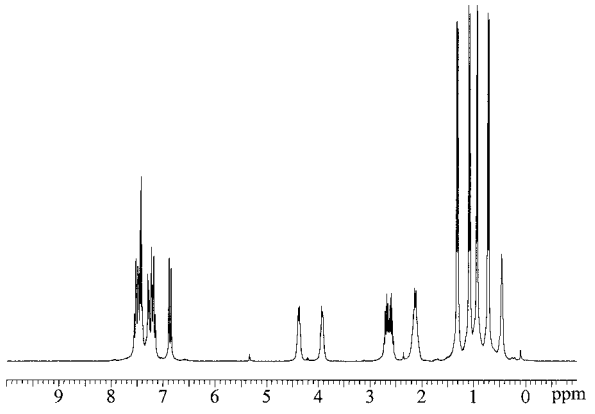


Figure 3. ^{1}H NMR spectrum of **3a** (CD_2Cl_2, room temperature)

Conclusions

Two new 4-coordinate aluminium complexes, namely [2-(2,6-diisopropylanilino)tropone]AlMe$_2$ (**1**) and [2-(perfluoroanilino)tropone]AlMe$_2$ (**2**), have been synthesized. A five-coordinate bis[2-(2,6-diisopropylanilino)tropone]AlMe derivative (**3**) has also been synthesized and characterized by single-crystal X-ray diffraction studies, which indicate a distorted trigonal-bipyramidal geometry around Al. Compounds **1** and **3** undergo methyl abstraction reactions with B(C_6F_5)$_3$; the resulting cationic species are stable in the presence of THF in dichloromethane solution. The reactivity of the synthesized compounds in ethylene polymerisation has also been explored. Interestingly, after reaction with B(C_6F_5)$_3$, compound **1** polymerizes ethylene to give a solid polymer, whereas compound **3** does not. This finding indicates that polymerization does not occur at a different metal contaminant.[19]

As Lewis acids, neutral, but especially cationic aluminium compounds, should be useful as catalysts to polymerize substrates containing a Lewis-basic atom. Experiments are in progress to ascertain if these compounds could be involved in the polymerization of polar monomers.

Experimental Section

General: Sensitive materials were manipulated under dry nitrogen using Schlenk or glove-box techniques. Toluene, heptane, and THF were heated under reflux in the presence of sodium and benzophenone and distilled under nitrogen prior to use. AlMe$_3$ was purchased from Aldrich and used as received. The 2-(2,6-diisopropylanilino)tropone and (perfluoroanilino)tropone ligands,[21] and B(C_6F_5)$_3$[30] were synthesized according to literature procedures. NMR spectra were recorded with a Bruker Avance 400 MHz spectrometer; chemical shifts were referenced to the residual protio impurity of the deuterated solvent. EI MS data were obtained with a Finnigan Thermoquest GCQ Plus 2000 spectrometer, using a direct exposure probe. Infrared spectra were recorded with a FT-IR Bruker Vector 22.

[2-(2,6-Diisopropylanilino)tropone]AlMe$_2$ (1): A toluene solution of 0.21 M AlMe$_3$ (4 mL, 0.85 mmol) was slowly added to a solution of 2-(2,6-diisopropylanilino)tropone (240 mg, 0.85 mmol) in toluene (15 mL) at 0 °C with stirring. The solution was then stirred for 2 h. Subsequently, the volatiles were removed under reduced pressure to give the product as an orange solid (yield 229 mg, 80%). ^{1}H NMR (400 MHz, C_6D_6): δ = 7.17 (d, 2 H, C*H*), 7.07 (d, 1 H, C*H*), 6.55 (m, 1 H, C*H*), 6.44 (d, 1 H, C*H*), 6.34 (m, 1 H, C*H*), 6.11 (t, 1 H, C*H*), 3.09 [m, 2 H, C*H*(CH$_3$)$_2$], 1.21 [d, 6 H, CH(C*H*$_3$)$_2$], 0.89 [d, 6 H, CH(C*H*$_3$)$_2$], −0.21 [s, 6 H, Al(C*H*$_3$)$_2$] ppm. ^{1}H NMR (400 MHz, CD_2Cl_2): δ = 7.38−7.28 (m, 3 H, C*H*), 7.28 (t, 2 H, C*H*), 6.87 (t, 2 H, C*H*), 6.57 (d, 1 H, C*H*), 2.93 [m, 2 H, C*H*(CH$_3$)$_2$], 1.20 [d, 6 H, CH(C*H*$_3$)$_2$], 0.99 [d, 6 H, CH(C*H*$_3$)$_2$], −0.74 [s, 6 H, Al(C*H*$_3$)$_2$] ppm. ^{13}C NMR (100 MHz, C_6D_6): δ = 173.7 (C=O), 167.4 (C−N), 144.4, 139.9 (*C*H), 138.4 (*C*H), 126 (*C*H), 125.7 (*C*H), 123.6 (*C*H), 122.3 (*C*H), 28.7 [*C*H(CH$_3$)$_2$], 25.9 [CH(*C*H$_3$)$_2$], 24.5 [CH(*C*H$_3$)$_2$], −8.3 [Al(*C*H$_3$)$_2$] ppm. EI MS (35 eV): *m*/*z* = 336 [M]$^+$, 324 [M − CH$_3$]$^+$. FT-IR: $\tilde{\nu}$ = 1598 (C=O) cm^{-1}. $C_{21}H_{28}AlNO$ (337.44): calcd. C 74.75, H 8.36, N 4.15; found C 74.54, H 8.56, N 4.29.

[2-(Perfluoroanilino)tropone]AlMe$_2$ (2): A solution of 2-(perfluoroanilino)tropone (300 mg, 1.04 mmol) in dry toluene (10 mL) was added dropwise to a toluene solution of 0.26 M AlMe$_3$ (10 mL, 1.14 mmol) at 0 °C. The solution was then stirred for 2 h and left to reach room temperature. The resulting solution was subsequently concentrated and cooled to −20 °C; compound then **2** precipitated as an orange powder; yield 150 mg (42%). ^{1}H NMR (400 MHz, C_6D_6): δ = 6.99 (d, 1 H, C*H*), 6.52 (t, 2 H, C*H*), 6.18 (t, 2 H, C*H*), −0.17 [s, 6 H, Al(C*H*$_3$)$_2$]. ^{13}C NMR (100 MHz, C_6D_6): δ = 175.1 (C-1), 165.8 (C-2), 139.7 (*C*H), 139.1 (*C*H), 126.2 (*C*H), 124.3 (*C*H), 118.9 (*C*H), −9.3 [Al(CH$_3$)$_2$] ppm. EI MS(35 eV): *m*/*z* = 346 [M]$^+$, 328 [M − CH$_3$]$^+$.

[2-(2,6-Diisopropylanilino)tropone]$_2$AlMe (3): [2-(2,6-Diisopropilanilino)tropone]AlMe$_2$ (82 mg, 0.24 mmol) was dissolved in dry toluene (10 mL). A solution of 2-(2,6-diisopropylanilino)tropone (68 mg, 0.24 mmol) in toluene (5 mL) was then added and the resulting solution stirred at room temperature for 2 h. The volatiles were then removed under reduced pressure to give the product as an orange solid in almost quantitative yield. ^{1}H NMR (400 MHz, C_6D_6): δ = 7.34 (d, 4 H, C*H*), 7.26 (m, 2 H, C*H*), 6.68 (d, 2 H, C*H*), 6.49 (m, 4 H, C*H*), 6.47 (t, 2 H, C*H*), 6.04 (t, 2 H, C*H*), 3.37 [m, 2 H, C*H*(CH$_3$)$_2$], 3.07 (m, 2 H, C*H*(CH$_3$)$_2$], 1.48 [d, 6 H, CH(C*H*$_3$)], 1.06 [d, 6 H, C*H*(C*H*$_3$)], 1.03 [d, 6 H, C*H*(C*H*$_3$)], 099 [d, 6 H, C*H*(C*H*$_3$)], −0.06 (s, 3 H, AlC*H*$_3$) ppm. ^{1}H NMR (400 MHz, CD_2Cl_2): δ = 7.32−7.03 (m, 10 H, C*H*), 6.70 (m, 4 H, C*H*), 6.46 (d, 2 H, C*H*), 3.05 [m, 2 H, C*H*(CH$_3$)$_2$], 2.77 [m, 2 H, C*H*(CH$_3$)$_2$],

1.27 [d, 6 H, CH(CH_3)], 1.16 [d, 6 H, CH(CH_3)], 1.05 [d, 6 H, CH(CH_3)], 0.78 [d, 6 H, CH(CH_3)], −0.83 (s, 3 H, AlCH_3) ppm. ^{13}C NMR (100 MHz, C_6D_6): δ = 175.2 (C=O); 166.6 (C−N); 144.4, 143.8, 142.3, 138.4, 137.5, 127.0, 125.5, 124.4, 124.1, 122.5, 121.1; 29.8 and 28.8 [*C*H(CH$_3$)$_2$]; 26.5, 25.5, 25.4, and 23.9 [CH(*C*H$_3$)$_2$]; −6.7 (Al*C*H$_3$) ppm. EI MS(35 eV): *m*/*z* = 603 [M]$^+$, 587 [M − CH$_3$]$^+$. FT-IR: $\tilde{\nu}$ = 1597 (C=O) cm^{-1}. $C_{39}H_{47}N_2O_2Al$ (602.79): calcd. C 77.71, H 7.86, N 4.65; found C 77.23, H 8.16, N 4.34.

Generation of {[2-(2,6-Diisopropylanilino)tropone]AlMe(THF)}$^+$-[MeB(C$_6$F$_5$)$_3$]$^-$ (1a): Compound **1** (17 mg, 50 μmol) was dissolved in CD_2Cl_2 (0.5 mL). THF (4 μL, 50 μmol) and B(C$_6$F$_5$)$_3$ (26 mg, 50 μmol) were then added sequentially, and the so-obtained solution was analysed by NMR spectroscopy at room temperature. ^{1}H NMR (400 MHz, CD_2Cl_2): δ = 7.76 (m, 2 H, C*H*), 7.66 (m, 1 H, C*H*), 7.46−7.35 (m, 4 H, C*H*), 6.99 (d, 1 H, C*H*), 4.40 (m, 2 H, OCH_2), 4.26 (m, 2 H, O-CH_2), 2.66 (m, 1 H, C*H*(CH$_3$)$_2$], 2.57 (m, 1 H, C*H*(CH$_3$)$_2$], 2.25 (s, 4 H, CH_2), 1.21 (d, 6 H, CHCH_3), 1.01 (d, 3 H, CHCH_3), 0.92 (d, 3 H, CHCH_3), 0.45 (s, 3 H, BCH_3), −0.27 (s, 3 H, AlCH_3) ppm. ^{13}C NMR (100 MHz, CD_2Cl_2): δ = 169.4 (C=O), 168.0, 144.4, 143.8, 142.3, 141.3, 134.5, 133.2, 129.5, 128.0, 126.6, 125.8, 125.3, 76.2 (O*C*H$_2$), 29.2 (2 peaks overlapped, *C*H), 25.9 (*C*H$_2$CH$_2$O), 25.0, 24.8, 23.9 (CH*C*H$_3$), 10.0 (B*C*H$_3$) ppm. Successively, one further eqivalent of THF was added to the solution, and the sample analysed by NMR spectroscopy at room temperature. ^{1}H NMR (400 MHz, CD_2Cl_2): δ = 7.65 (m, 2 H, C*H*), 7.55 (m, 1 H, C*H*), 7.46−7.27 (m, 4 H, C*H*), 6.90 (d, 1 H, C*H*), 4.20 (s, 8 H, OCH_2), 2.60 [m, 2 H, C*H*(CH$_3$)$_2$], 2.11 (s, 8 H, CH_2), 1.20 (d, 6 H, CHCH_3), 1.00 (d, 6 H, CHCH_3), 0.46 (s, 3 H, BCH_3), −0.48 (s, 3 H, AlCH_3) ppm. ^{13}C NMR (100 MHz, CD_2Cl_2): δ = 169.4 (C=O), 167.9, 144.0, 143.2, 142.2, 133.0, 129.4, 127.8, 126.2, 125.3, 125.2; 76.0 (O*C*H$_2$), 29.2 (*C*H), 25.7 (*C*H$_2$CH$_2$O), 25.4, 23.7 (CH*C*H$_3$), 10.2 (B*C*H$_3$), −14.0 (Al*C*H$_3$) ppm.

Generation of {[2-(2,6-Diisopropylanilino)tropone]$_2$Al(THF)}$^+$-[MeB(C$_6$F$_5$)$_3$]$^-$ (3a): Compound **3** (15 mg, 25 μmol) was dissolved in CD_2Cl_2 (0.5 mL). Dry THF (2 μL, 25 μmol) and B(C$_6$F$_5$)$_3$ (13 mg, 25 μmol) were then added sequentially, and the resulting solution was analysed by NMR spectroscopy at room temperature. ^{1}H NMR (300 MHz, CD_2Cl_2): δ = 7.60−7.10 (m, 14 H) and 6.85 (d, 2 H) (phenyl and tropone *H*), 4.38 (m, 2 H, OCH_aH$_b$), 3.93 (m, 2 H, OCH$_a$*H*$_b$), 2.67 [m, 2 H, C*H*(CH$_3$)$_2$], 2.59 [m, 2 H, C*H*(CH$_3$)$_2$], 2.13 (m, 4 H, CH_2), 1.32 [d, 6 H, CH(CH_3)], 1.08 [d, 6 H, CH(CH_3)], 0.93 [d, 6 H, CH(CH_3)], 0.72 [d, 6 H, CH(CH_3)], 0.45 (s, 3 H, BCH_3) ppm. ^{13}C NMR (75 MHz, CD_2Cl_2): δ = 169.9 (*C*=O), 167.4, 143.8, 143.2 (quaternary carbon atoms), 140.8 (*C*H), 140.2 (*C*H), 138.5 (quaternary carbon atom), 130.3 (*C*H), 128.3 (*C*H), 125.4 (*C*H), 123.9 (*C*H), 75.7 (OCH$_2$CH$_2$), 29.7 [*C*H(CH$_3$)$_2$], 29.2 [*C*H(CH$_3$)$_2$], 25.9 (OCH$_2$*C*H$_2$), 24.9 [CH(*C*H$_3$)], 23.7 [CH(*C*H$_3$)] ppm.

X-ray Crystallography: A prismatic yellow crystal of **3** (0.56 × 0.48 × 0.40 mm) was selected and mounted in a Lindemann capillary under an inert gas. Diffraction data were then measured at room temperature with a Rigaku AFC7S diffractometer using graphite-monochromated Mo-K_α radiation (λ = 0.71069 Å). Data reduction was performed with the crystallographic package TEXSAN.[32] The ψ-scan method was used to correct data for absorption. Structures were solved by direct methods using the program SIR92[33] and refined by means of full-matrix least squares based on F^2 including all diffraction data using the program SHELXL-97.[34] The electron density map revealed a disordered toluene molecule. A rigid body refinement was performed for the solvent molecule, considering two distinct toluene molecules with half occupancy. The hydrogen atoms of the methyl groups were assumed to be disordered over two sites rotated 60° to each other. Anisotropic displacement parameters were used for all non-hydrogen atoms except those belonging to the solvent molecule. Hydrogen atoms were positioned geometrically and refined using a riding model. Finally, a total of 226 parameters were refined considering 4174 intensity data. Maximum and minimum residual densities were 0.35 and −0.34 e·Å^{-3}, respectively. Final disagreement indices were R_1 = 0.0829 for 1336 reflections with $F_o > 4\sigma(F_o)$, R_1 = 0.255 and wR_2 = 0.146 for all 4174 data. ORTEP drawings performed by means of the program ORTEP32.[35] Crystallographic data for **3**: Formula: $C_{39}H_{47}AlN_2O_2{\cdot}2C_7H_8$, M = 787.03, system: monoclinic, space group *C*2/*c*, Z = 4; a = 18.321(6), b = 10.145(3), c = 25.506(7) Å; β = 91.40(3)°, V = 4739(2) Å^3, D_x = 1.103 g·cm^{-3}, $\mu_{calcd.}$ = 0.08 mm^{-1}. Crystallographic data (excluding structure factors) have been deposited with the Cambridge Crystallographic Data Centre as supplementary publications no. CCDC-204539. Copies of the data may be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 EZ, UK [Fax: (internat.) + 44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Acknowledgments

Keywords: Cyclopentadienyl ligands / Half-sandwich complexes / N ligands / Niobium / Tantalum

The preparation of a family of dinuclear monocyclopentadienyl imidoniobium and -tantalum complexes was achieved by two different synthetic routes. The diimido complexes [{M(Cp′)Cl_2}$_2$(μ-1,*i*-NC_6H_4N)] [Cp′ = η^5-$C_5H_4SiMe_3$, M = Nb, *i* = 4 (**1**); Cp′ = η^5-$C_5H_4SiMe_3$, M = Nb, *i* = 3 (**2**); Cp′ = η^5-$C_5H_4SiMe_3$, M = Nb, *i* = 2 (**3**); Cp′ = η^5-C_5Me_5, M = Nb, *i* = 4 (**4**); Cp′ = η^5-C_5Me_5, M = Nb, *i* = 3 (**5**); Cp′ = η^5-$C_5H_4SiMe_3$, M = Ta, *i* = 4 (**6**); Cp′ = η^5-$C_5H_4SiMe_3$, M = Ta, *i* = 3 (**7**)] were prepared by the reaction of one equivalent of the trichloro precursor [{MCl_3}$_2$(μ-1,*i*-NC_6H_4N)] (M = Nb, Ta, *i* = 4, 3 or 2) with two equivalents of either $C_5H_4(SiMe_3)_2$ or C_5Me_5-($SiMe_3$). Complexes **1**–**7** can also be prepared by the reaction of two equivalents of [MCp′Cl_4] (Cp′ = η^5-$C_5H_4SiMe_3$, M = Nb, Ta; Cp′ = η^5-C_5Me_5, M = Nb, Ta) with one equivalent of the corresponding aniline compound, *N*,*N*,*N*′,*N*′-tetrakis(trimethylsilyl)-1,4-, -1,3-, or -1,2-phenylenediamine, respectively. The synthesis of [{Ta(Cp′)Cl_2}$_2$(μ-1,*i*-NC_6H_4N)] [Cp′ = η^5-C_5Me_5, *i* = 4 (**8**); Cp′ = η^5-C_5Me_5, *i* = 3 (**9**)] was only successful with the second preparative method. The reaction of **1**, **2** and **8** with alkylating reagents gave the corresponding tetraalkyl derivatives, [{M(Cp′)R_2}$_2$(μ-1,*i*-NC_6H_4N)] [Cp′ = η^5-$C_5H_4SiMe_3$, M = Nb, R = Me, *i* = 4 (**10**); Cp′ = η^5-$C_5H_4SiMe_3$, M = Nb, R = CH_2SiMe_3, *i* = 4 (**11**); Cp′ = η^5-$C_5H_4SiMe_3$, M = Nb, R = CH_2Ph, *i* = 4 (**12**); Cp′ = η^5-$C_5H_4SiMe_3$, M = Nb, R = Me, *i* = 3 (**13**); Cp′ = η^5-$C_5H_4SiMe_3$, M = Nb, R = CH_2SiMe_3, *i* = 3 (**14**); Cp′ = η^5-$C_5H_4SiMe_3$, M = Nb, R = CH_2Ph, *i* = 3 (**15**); Cp′ = η^5-C_5Me_5, M = Ta, R = Me, *i* = 4 (**16**); Cp′ = η^5-C_5Me_5, M = Ta, R = CH_2SiMe_3, *i* = 4 (**17**); Cp′ = η^5-C_5Me_5, M = Ta, R = CH_2Ph, *i* = 4 (**18**)]. The alkylated complexes with other stoichiometries, [{M(Cp′)(Me)(X)}$_2$(μ-1,4-NC_6H_4N)] [Cp = η^5-$C_5H_4SiMe_3$, M = Nb, X = Cl (**19**); Cp = η^5-$C_5H_4SiMe_3$, M = Nb, X = NMe_2 (**20**); Cp = η^5-C_5Me_5, M = Ta, X = Cl (**21**)], were also prepared. The molecular structures of complexes **1**, **8** and **17** were determined by single-crystal X-ray diffraction studies.

Introduction

Imido derivatives of early transition metals have been widely studied and, in particular, a large number of well-established imido compounds of the d^0 metals niobium and tantalum are known.[1] For example, half-sandwich imido compounds of Nb and Ta of general formula M(η^5-C_5R_5')(NR)X_2 are well documented[2] and these are of considerable interest since an "isolobal" relationship between [M(η^5-C_5R_5')(NR)] (M = group 5 metal) and [M(η^5-C_5R_5')$_2$] (M = Group 4 metal) fragments has been established.[3] In fact, it has been claimed that monocyclopentadienyl imido group 5 metal complexes could behave in a similar manner to metallocenes of group 4 metals in olefin polymerisation catalytic processes.[2g] However, to date several species of this type have been used as catalysts without much success.[4] Two main preparative pathways have been employed in the synthesis of half-sandwich imido group 5 metal complexes. Firstly, reaction of the appropriate cyclopentadienide reagent with imido-containing [M(NR)Cl_3L_2] (M = Nb, Ta) precursors[5] has been employed and, sec-

ondly, the most general method involves the introduction of the imido group into precursors containing the cyclopentadienyl ligand.[6] On considering the different possible pathways to achieve this transformation, the one that is particularly noteworthy is that in which the imido group is incorporated by breaking the Si−N bond of a silylamine or -amide derivative.[7] The use of this last method, developed by our research group, gives rise to an interesting series of organo-diimido complexes [{Nb(L)$_2$Cl$_3$}$_2$(μ-1,*i*-NC$_6$H$_4$N)] (L = CH$_3$CN or *t*Bupy) by reaction of NbCl$_5$ with the appropriate aniline *N*,*N*,*N*′,*N*′-tetrakis(trimethylsilyl)-1,4-, -1,3-, or -1,2-phenylenediamine in the presence of CH$_3$CN or *t*Bupy.[8] As a continuation of our research in this field[9] we are currently interested in the preparation of half-sandwich diimidoniobium and -tantalum complexes in order to synthesise new types of dinuclear complexes in which the two metal centres are linked by conjugated π-systems. This class of diimido complex is rare, particularly with an aryl ligand.[10] The work described in this paper focuses on the synthesis and structural characterisation of half-sandwich imidoniobium and -tantalum complexes, and some aspects of their reactivity.

Results and Discussion

The preparation of derivatives [{M(Cp′)Cl$_2$}$_2$(μ-1,*i*-NC$_6$H$_4$N)] (Cp′ = η^5-C$_5$H$_4$SiMe$_3$, η^5-C$_5$Me$_5$; M = Nb, Ta; *i* = 3, 4) was initially undertaken by reaction of the appropriate complex [{M(L)$_2$Cl$_3$}$_2$(μ-1,*i*-NC$_6$H$_4$N)] (L = CH$_3$CN; M = Nb, Ta; *i* = 3, 4)[8] with different cyclopentadienide reagents, namely M(C$_5$H$_4$SiMe$_3$) (M = Li, Na, K) or K(C$_5$Me$_5$), in several solvents and under different experimental conditions. However, in all cases an intractable mixture of products was obtained. As an alternative method to prepare the aforementioned complexes, we decided to use milder cyclopentadienyl transfer reagents, such as the silylated compounds C$_5$H$_4$(SiMe$_3$)$_2$ and C$_5$Me$_5$(SiMe$_3$). This method has previously been used by Green et al.[11] to prepare cyclopentadienyl-imido complexes with constrained geometry and by Maatta et al.[12] for the preparation of imido-containing monocyclopentadienyl vanadium derivatives. However, the trichloro complexes [{M(L)$_2$Cl$_3$}$_2$(μ-1,*i*-NC$_6$H$_4$N)] (L = CH$_3$CN; M = Nb, Ta; *i* = 3, 4), do not react with the silylated cyclopentadienyl reagents. This lack of reactivity is probably due to the presence of two additional ligands (L) in the coordination sphere which diminishes the acidity of the metal centre making the elimination of the expected SiMe$_3$Cl by-product unfavourable. In order to increase the reactivity of the diimidoniobium and -tantalum precursors towards the cyclopentadienyl reagents, alternative compounds without donor ligands were employed, namely [{MCl$_3$}$_2$(μ-1,*i*-NC$_6$H$_4$N)] (M = Nb, Ta), which were prepared from the reaction of MCl$_5$ with the appropriate *N*,*N*,*N*′,*N*′-tetrakis(trimethylsilyl)phenylenediamine in CH$_2$Cl$_2$.[8] When these diimido complexes were reacted with the appropriate silylated cyclopentadienyl reagents in a 1:2 molar ratio in CH$_2$Cl$_2$ at 90 °C (see Exp. Sect.), the cyclopentadienyl-containing dinuclear species [{M(Cp′)Cl$_2$}$_2$(μ-1,*i*-NC$_6$H$_4$N)] [Cp′ = η^5-C$_5$H$_4$SiMe$_3$, M = Nb, *i* = 4 (**1**); Cp′ = η^5-C$_5$H$_4$SiMe$_3$, M = Nb, *i* = 3 (**2**); Cp′ = η^5-C$_5$H$_4$SiMe$_3$, M = Nb, *i* = 2 (**3**); Cp′ = η^5-C$_5$Me$_5$, M = Nb, *i* = 4 (**4**); Cp′ = η^5-C$_5$Me$_5$, M = Nb, *i* = 3 (**5**); Cp′ = η^5-C$_5$H$_4$SiMe$_3$, M = Ta, *i* = 4 (**6**); Cp′ = η^5-C$_5$H$_4$SiMe$_3$, M = Ta, *i* = 3 (**7**)] were isolated (Scheme 1).

A number of reactions did not, however, give the desired products. These involved tantalum derivatives formed from C$_5$Me$_5$(SiMe$_3$) and the derivatives [{MCl$_3$}$_2$(μ-1,2-NC$_6$H$_4$N)] (M = Nb, Ta) formed from the reagents C$_5$Me$_5$(SiMe$_3$) and C$_5$H$_4$(SiMe$_3$)$_2$. This procedure has provided a useful synthetic route to dinuclear monocyclopentadienyl imido species of these metals, particularly with the reagent C$_5$H$_4$(SiMe$_3$)$_2$, in high yields (about 80% for the tantalum

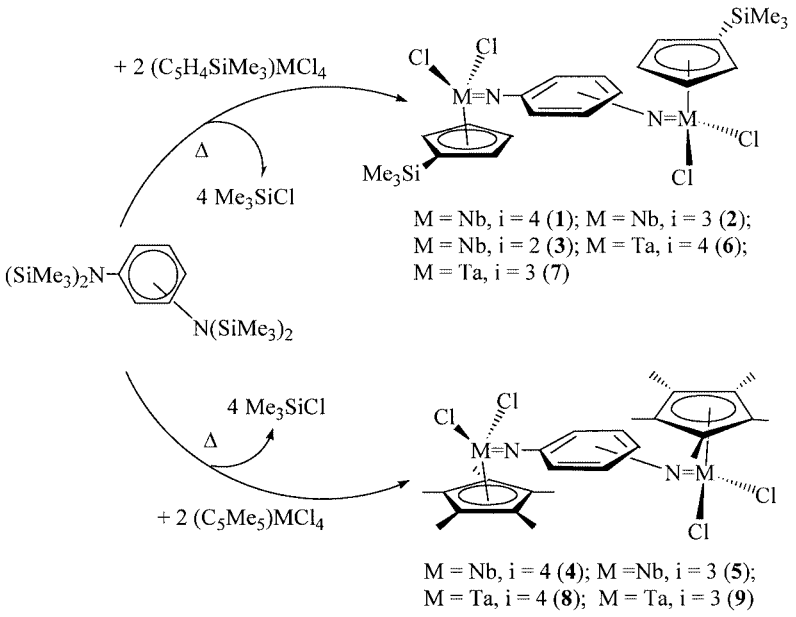

Scheme 2

complexes and quantitative yields for the niobium complexes). The overall reactions for the tantalum species require long reaction times of about one week. In order to improve this, an alternative method was considered to prepare the complexes. This method consisted of the reaction of the appropriate $MCp'Cl_4$ precursor (Cp′ = η^5-$C_5H_4SiMe_3$, η^5-C_5Me_5; M = Nb, Ta) with the corresponding *N*,*N*,*N*′,*N*′-tetrakis(trimethylsilyl)phenylenediamine derivative (Scheme 2).

This synthetic route, which is an adaptation of that previously described by Gibson et al.[3a] for the preparation of imido-containing niobium complexes, is an easy way to prepare cleanly (by elimination of $SiMe_3Cl$) the corresponding diimidoniobium and -tantalum complexes **1**−**7** as well as the new tantalum complexes [{Ta(η^5-C_5Me_5)Cl_2}$_2$(μ-1,*i*-NC_6H_4N)] [*i* = 4 (**8**), *i* = 3 (**9**)] in quantitative yields (see Exp. Sect.). On using this method the reaction times for the preparation of tantalum complexes are considerably shortened (to about 30 h). In wet solvents the materials evolve to the appropriate oxo-containing complexes with elimination of the corresponding diamine.[13] For example, solutions of **8** or **9** in wet CH_2Cl_2 give rise to the oxo complex [{Ta(η^5-C_5Me_5)Cl_3}$_2$(μ-O)].[14] Complexes **1**−**9**, as well as other complexes described in this work, were characterised by ^{1}H, ^{13}C NMR and IR spectroscopy (see Exp. Sect.). The ^{1}H and ^{13}C NMR spectra of **1**−**9** exhibit the characteristic signals for both the cyclopentadienyl and phenylene groups. This observation agrees with a structural situation where a diimidophenylene group bridges two metal atoms, which are, in turn, located in the plane formed by this ligand, in a three-legged piano-stool geometry around each metal centre (see Scheme 1). Free rotation around the N−C bond would be expected in solution and, for this reason, although a *trans*-disposition of both cyclopentadienyl ligands was considered in Scheme 1, alternative dispositions corresponding to other rotamers should also be considered.

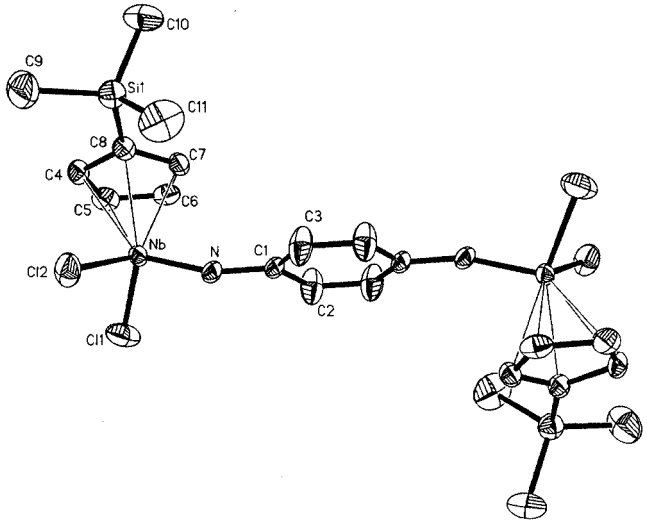

Figure 1. Molecular structure and atom-labelling scheme for [{Nb(η^5-$C_5H_4SiMe_3$)Cl_2}$_2$(μ-1,4-NC_6H_4N)] (**1**), with thermal ellipsoids at 30% probability

Complexes **1**−**9** were analysed by variable-temperature ^{1}H NMR spectroscopy in order to study this proposed dynamic behaviour. However, even at −90 °C there was no evidence of restricted rotation, probably due to the low energy value for the rotation barrier. The IR spectra of each complex contains a band between 1300−1370 cm^{-1}, which is characteristic of the terminal imido ligand.[3a] Several vibrational spectroscopic studies of group 5 imido complexes have been carried out.[15] In order to establish unequivocally the structural disposition of these complexes, an X-ray molecular analysis of compounds **1** and **8** was carried out. The molecular structures and atomic numbering schemes are shown in Figure 1 and 2, respectively. Selected bond lengths and angles for **1** and **8** are given in Table 1.

M−C5	2.47(1)	2.478(7)
M−C6	2.39(1)	2.382(7)
M−C7	2.36(1)	2.365(6)
M−C8	2.42(1)	2.382(6)
N−C1	1.39(1)	1.377(7)
N−M−Cl1	101.7(3)	102.3(2)
N−M−Cl2	103.5(3)	104.3(2)
Cl1−M−Cl2	106.0(1)	105.4(1)
M−N−C1	161.0(7)	166.4(5)

The structures of **1** and **8** consist of dinuclear complexes of niobium and tantalum, respectively. The metal atoms are bound to the cyclopentadienyl ring in an η^5 mode, to two chlorine atoms and to the nitrogen from the imido group in a three-legged piano-stool conformation. The cyclopentadienyl rings are in a *trans* disposition with respect to each other. The metal atom is out of the plane defined by N, C1, C2 and C3 by 0.54(2) and 0.39(1) Å for complexes **1** and **8**, respectively.

The metal-nitrogen distances lie within the range expected for a triple bond[3a,16,17] [1.776(8) and 1.783(5) Å for **1** and **8**, respectively]. The M−N−C1 angles of 161.0(7)° for **1** and 166.4(5)° for **8** deviate slightly from linear. Such deviations are normally in the range 12−15° (see Table 2). In the case of [Nb(=NPh)(η^5-$C_5H_4SiMe_3$)$_2$Cl] extended-Hückel molecular-orbital calculations established that the imido bond angles for "linear imide" in this class of complex can vary up to 140° with little effect on the Nb−N bonding.[18] Therefore we propose that in **1** and **8** the nitrogen atom is sp hybridized.

The cyclopentadienyl group is in a typical[3a] eclipsed fashion with respect to the imido group for both complexes (see Figure 3a). The slight lengthening of the M−C4 [2.468(9) and 2.468(7) Å for **1** and **8**, respectively] and M−C5 [2.47(1) and 2.478(7) Å for **1** and **8**, respectively] distances with respect to other M−C ring distances may be due to the *trans* influence of the imido group.

The second part of this work involves the study of alkylation reactions of complexes **1**, **2** and **8**. The reaction of alkylating reagents, MeLi, Me_3SiCH_2MgCl or $Mg(CH_2C_6H_5)_2(THF)_2$, in a 1:4 molar ratio with **1**, **2** or **8** afforded the per-alkylated complexes, [{M(Cp′)R_2}$_2$(μ-1,*i*-NC_6H_4)] [Cp′ = η^5-$C_5H_4SiMe_3$, M = Nb, R = Me, *i* = 4 (**10**); Cp′ = η^5-$C_5H_4SiMe_3$, M = Nb, R = CH_2SiMe_3, *i* = 4 (**11**); Cp′ = η^5-$C_5H_4SiMe_3$, M = Nb, R = CH_2Ph, *i* = 4

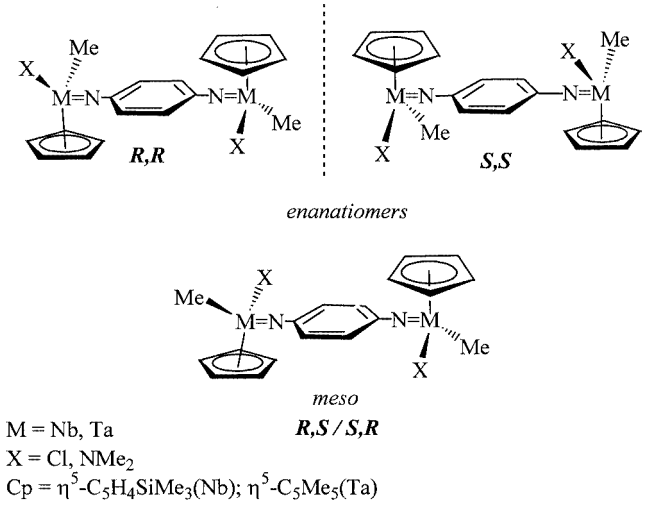
complex [{Nb(η^5-$C_5H_4SiMe_3$)(Me)(NMe_2)}$_2$(μ-1,4-NC_6H_4N)] (**20**).

The ^{1}H and ^{13}C NMR spectra for complexes **10**−**18** are similar to those found for the parent complexes with regards to both the cyclopentadienyl and phenylene groups (see Exp. Sect.). In addition, the spectra also contain the resonances due to the alkyl groups attached to the metal centre. In these complexes the four alkyl groups are both chemically and magnetically equivalent and only one set of signals for these groups is present. For example, one singlet corresponding to methyl groups for complexes **10**, **13** and **16** was observed in the ^{1}H NMR spectra. Furthermore, in all the complexes the metal atom is a pro-chiral centre and so the protons of the methylene groups (for CH_2SiMe_3 or CH_2Ph) for complexes **11**, **12**, **14**, **15**, **17** and **18** are diastereotopic and, therefore, give rise to two doublets of an AB spin-system in their ^{1}H NMR spectra (see Exp. Sect.). For **19**−**21** the two metal atoms of the binuclear moiety are chiral centres and the stereoisomer the *meso*-(*R*,*S*) and the enantiomers *rac*-(*R*,*R*) and -(*S*,*S*) are formed (see Scheme 4). The ^{1}H and ^{13}C NMR spectra of these complexes exhibit two sets of signals in a 1:1 ratio, corresponding to the presence of both diastereomers (*R*,*R*/*S*,*S*) and (*R*,*S*) (see Exp. Sect.).



Scheme 4

The IR spectra of complexes **10**−**21** show a band at ca. 1300−1350 cm^{-1}, which is characteristic of the terminal imido ligand.[3a] In accordance with the different spectroscopic data described for alkyl-containing complexes, a structural disposition similar to that found for the chloro complexes can be expected (see Scheme 3). The X-ray crystal-structure determination for **17** confirmed this situation. The molecular structure and atomic numbering scheme are shown in Figure 4. Selected bond lengths and angles for **17** are given in Table 3.

Table 3. Selected bond lengths (Å) and angles (°) for **17**

M−N	1.794(5)
M−C4	2.473(7)
M−C5	2.533(6)
M−C6	2.492(7)
M−C7	2.397(7)
M−C8	2.428(7)
M−C9	2.149(6)
M−C10	2.193(7)

M−N−C1	167.4(5)

The structure of **17** consists of a dinuclear complex where the metal atoms are bound to the cyclopentadienyl rings in an η^5 mode. In addition, the tantalum atoms are linked to two methylene groups from CH_2SiMe_3 and to the nitrogen atom from the imido group. Complex **17** adopts a three-legged piano-stool conformation about the metal centres. The cyclopentadienyl rings are in a *trans* disposition with respect to each other. The metal atom is out of the plane defined by N, C1, C2 and C3, by 0.36(1) Å. The metal-

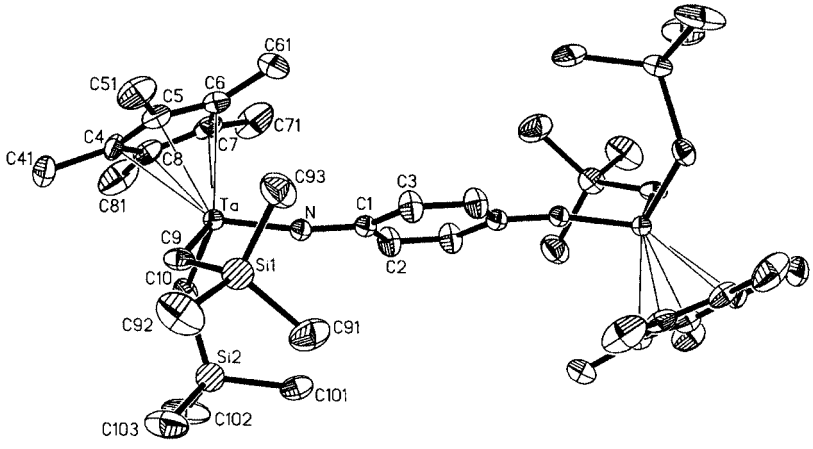

Figure 4. Molecular structure and atom-labelling scheme for [{Ta(η^5-C_5Me_5)(CH_2SiMe_3)$_2$}$_2$(μ-1,4-NC_6H_4N)] (**17**), with thermal ellipsoids at 30% probability

nitrogen distance of 1.794(5) Å and the M−*N*−C1 angle of 167.4(5)° lie within the range expected for a triple bond (see Table 2).[3a,16,17]

The cyclopentadienyl group in **17** is in a staggered disposition with respect to the imido group (Figure 3b), in contrary to the eclipsed disposition observed in **1** and **8** (Figure 3a). The slight lengthening of the M−C4 [2.473(7) Å] and M−C5 [2.533(6) Å] distances is probably due to the *trans* influence of the imido group.

Conclusions

In this paper we report the synthesis of new dinuclear monocyclopentadienyl imidoniobium and -tantalum complexes and their reactivity towards different alkylating agents. The molecular structures of several of these complexes have been determined by single-crystal X-ray diffraction studies.

Experimental Section

General Remarks: All reactions were performed using standard Schlenk-tube techniques under an atmosphere of dry nitrogen. Solvents were distilled from appropriate drying agents and degassed before use. Literature methods were employed for the synthesis of the following compounds: *N*,*N*,*N*′,*N*′-tetrakis(trimethylsilyl)phenylenediamine,[19] $[Nb(\eta^5\text{-}C_5H_4SiMe_3)Cl_4]$,[20] $[\{NbCl_3\}_2(\mu\text{-}1,i\text{-}NC_6H_4N)]$ (*i* = 4, 3 or 2),[8a] $C_5H_4(SiMe_3)_2$,[21] $[Ta(\eta^5\text{-}C_5H_4SiMe_3)Cl_4]$,[22] $[\{TaCl_3\}_2(\mu\text{-}1,i\text{-}NC_6H_4N)]$ (*i* = 4 or 3),[8b] $[Ta(\eta^5\text{-}C_5Me_5)Cl_4]$,[23] $C_5Me_5(SiMe_3)$,[24] $[Nb(\eta^5\text{-}C_5Me_5)Cl_4]$,[25] and $[Mg(CH_2Ph)_2(THF)_2]$.[25] All commercial products were purchased from Aldrich and were used without further purification: LiMe, $Mg(CH_2SiMe_3)Cl$, $ZnMe_2$ and $LiNMe_2$. IR spectra were recorded on a Perkin−Elmer 883 and Perkin−Elmer IR-FT Spectrophotometer 2000. ^1H and ^{13}C NMR spectra were recorded on a Gemini-200 and/or UNITY-300 (Varian) spectrometer. Chemical shifts were measured relative to residual ^1H and ^{13}C resonances for $[D_1]$chloroform and $[D_6]$benzene as solvents. C, H and N analyses were carried out with a Perkin−Elmer 240−13, Perkin−Elmer 240 C and/or Heraeus-CHN−O-Rapid microanalyzer.

Preparation of $[\{Nb(\eta^5\text{-}C_5H_4SiMe_3)Cl_2\}_2(\mu\text{-}1,4\text{-}NC_6H_4N)]$ (1), $[\{Nb(\eta^5\text{-}C_5H_4SiMe_3)Cl_2\}_2(\mu\text{-}1,3\text{-}NC_6H_4N)]$ (2) and $[\{Nb(\eta^5\text{-}C_5H_4SiMe_3)Cl_2\}_2(\mu\text{-}1,2\text{-}NC_6H_4N)]$ (3). Method A: CH_2Cl_2 (70 mL) was added to a mixture of $[Nb(\eta^5\text{-}C_5H_4SiMe_3)Cl_4]$ and the corresponding *N*,*N*,*N*′,*N*′-tetrakis(trimethylsilyl)phenylenediamine in a Teflon valve ampoule. The ampoule was placed in an oil bath and heated at 65 °C for 24 h. The solvent was removed under vacuum and the solids obtained were identified as **1**, **2** and **3**, respectively.

Complex 1: From $[Nb(\eta^5\text{-}C_5H_4SiMe_3)Cl_4]$ (1.15 g, 3.09 mmol) and 1,4-$\{(Me_3Si)_2N\}_2C_6H_4$ (0.61 g, 1.54 mmol). 1.08 g of a red solid was obtained (Yield: 100%).

Complex 2: From $[Nb(\eta^5\text{-}C_5H_4SiMe_3)Cl_4]$ (1.05 g, 2.83 mmol) and 1,3-$\{(Me_3Si)_2N\}_2C_6H_4$ (0.56 g, 1.41 mmol). 1.0 g of a red solid was obtained (Yield: 100%).

Complex 3: From $[Nb(\eta^5\text{-}C_5H_4SiMe_3)Cl_4]$ (1.01 g, 2.72 mmol) and 1,2-$\{(Me_3Si)_2N\}_2C_6H_4$ (0.54 g, 1.36 mmol). 0.96 g of a dark brown solid was obtained (Yield: 100%).

Method B: CH_2Cl_2 (60 mL) was added to the corresponding complex $[\{NbCl_3\}_2(\mu\text{-}1,i\text{-}NC_6H_4N)]$ (*i* = 4, 3 or 2) in a Teflon valve ampoule. $C_5H_4(SiMe_3)_2$ was added to this green suspension and the ampoule was placed in an oil bath and heated at 90 °C for 24 h. The initial green suspension changed to a red solution. The solvent was removed under vacuum and the solids obtained were identified as **1**, **2** and **3**, respectively.

Complex 1: From $[\{NbCl_3\}_2(\mu\text{-}1,4\text{-}NC_6H_4N)]$ (0.80 g, 1.59 mmol) and $C_5H_4(SiMe_3)_2$ (0.74 mL, 3.18 mmol). 1.12 g of a red solid was obtained (Yield: 100%). ^1H NMR (300 MHz, $CDCl_3$, 25 °C): δ = 0.26 (s, 18 H, 2 × $C_5H_4Si\mathit{Me}_3$), 6.60 and 6.75 (2m, each 4 H, 2 × $C_5\mathit{H}_4$), 6.89 (s, 4 H, $C_6\mathit{H}_4$) ppm. $^{13}C\{^1H\}$ NMR (75 MHz, $CDCl_3$, 25 °C): δ = −0.5 ($C_5H_4Si\mathit{Me}_3$), 114.7, 122.0 and 125.9 (C^{ipso}; $\mathit{C}_5H_4SiMe_3$) 124.3 and 153.9 (C^{ipso}; C_6H_4) ppm. IR (CsI/Nujol): $\tilde{\nu}$ = 3090m, 1483s, 1395m, 1370s, 1311vs, 1253vs, 1172s, 1099m, 1074w, 1045s, 1004w, 990m, 903s, 840vs, 764m, 703w, 635w, 530w, 423m, 380s and 330m cm^{-1}. $C_{22}H_{30}Cl_4N_2Nb_2Si_2$ (706.3): calcd. C 37.41, H 4.28, N 3.97; found C 37.05, H 4.48, N 4.08.

Complex 2: From $[\{NbCl_3\}_2(\mu\text{-}1,3\text{-}NC_6H_4N)]$ (0.71 g, 1.41 mmol) and $C_5H_4(SiMe_3)_2$ (0.66 mL, 2.82 mmol). 1.0 g of a red solid was obtained (Yield: 100%). ^1H NMR (300 MHz, $CDCl_3$, 25 °C): δ = 0.29 (s, 18 H, 2 × $C_5H_4Si\mathit{Me}_3$), 6.62 and 6.76 (2m, each 4 H, 2 × $C_5\mathit{H}_4$), 6.62 (1 H), 6.72 (2 H) and 7.13 (1 H) (3m, $C_6\mathit{H}_4$) ppm. $^{13}C\{^1H\}$ NMR (50 MHz, $CDCl_3$, 25 °C): δ = −0.5 ($C_5H_4Si\mathit{Me}_3$), 114.4, 122.2 and 126.3 (C^{ipso}; $\mathit{C}_5H_4SiMe_3$), 118.9, 122.1, 128.3 and 155.6 (C^{ipso}; C_6H_4) ppm. IR (KBr): $\tilde{\nu}$ = 3093m, 2953m, 2598m, 1567s, 1462s, 1410m, 1370m, 1332m, 1306m, 1283m, 1250s, 1170s, 1047s, 1036s, 971w, 903s, 839vs, 780s, 757s, 694s, 680m, 630s, 419w and 374s cm^{-1}. $C_{22}H_{30}Cl_4N_2Nb_2Si_2$ (706.3): calcd. C 37.41, H 4.28, N 3.97; found C 37.40, H 4.55, N 3.68.

Complex 3: From $[\{NbCl_3\}_2(\mu\text{-}1,2\text{-}NC_6H_4N)]$ (0.77 g, 1.53 mmol) and $C_5H_4(SiMe_3)_2$ (0.72 mL, 3.06 mmol). 1.08 g of a red solid was obtained (Yield: 100%). ^1H NMR (300 MHz, $CDCl_3$, 25 °C): δ = 0.28 (s, 18 H, 2 × $C_5H_4Si\mathit{Me}_3$), 6.68 and 6.76 (2m, each 4 H, 2 × $C_5\mathit{H}_4$), 6.93 (m, 4 H, $C_6\mathit{H}_4$) ppm. $^{13}C\{^1H\}$ NMR (75 MHz, $CDCl_3$, 25 °C): δ = −0.6 ($C_5H_4Si\mathit{Me}_3$), 114.1, 124.2 and 125.9 (C^{ipso}; $\mathit{C}_5H_4SiMe_3$), 125.5, 126.1, and 150.1 (C^{ipso}; C_6H_4) ppm. IR (CsI/Nujol): $\tilde{\nu}$ = 3101w, 1577w, 1436m, 1395w, 1371m, 1328m, 1315m, 1253s, 1170m, 1115w, 1048m, 1039w, 987w, 966(md), 933w, 903s, 842vs, 754s, 748s, 632w, 398m, 379s and 336m cm^{-1}. $C_{22}H_{30}Cl_4N_2Nb_2Si_2$ (706.3): calcd. C 37.41, H 4.28, N 3.97; found C 36.62, H 4.06, N 4.06.

Preparation of $[\{Nb(\eta^5\text{-}C_5Me_5)Cl_2\}_2(\mu\text{-}1,4\text{-}NC_6H_4N)]$ (4). Method A: Dichloromethane (60 mL) was added to a mixture of $[\{NbCl_3\}_2(\mu\text{-}1,4\text{-}NC_6H_4N)]$ (0.62 g, 1.23 mmol) and $C_5Me_5(SiMe_3)$ (0.60 mL, 2.47 mmol) in a Teflon valve ampoule. The ampoule was placed in an oil bath and heated to 90 °C for 24 h. The resulting solution was allowed to cool down to room temperature, filtered and the solvent removed under vacuum to give 0.83 g of **4** as a purple, analytically pure, crystalline solid. (Yield: 100%).

Method B: A Teflon valve NMR tube was charged with a solution of $[Nb(\eta^5\text{-}C_5Me_5)Cl_4]$ (15 mg, 0.04 mmol) and [1,4-$\{(SiMe_3)_2N\}_2C_6H_4$] (8 mg, 0.02 mmol) in $CDCl_3$. The mixture was placed in an oil bath, heated to 65 °C and monitored by ^1H NMR spectroscopy. After 24 h the reaction was complete and gave **4** as the only product. ^1H NMR (300 MHz, $CDCl_3$, 25 °C): δ = 2.07 (s, 30 H, 2 × $C_5\mathit{Me}_5$), 6.79 (s, 4 H, $C_6\mathit{H}_4$) ppm. $^{13}C\{^1H\}$ NMR (75 MHz, $CDCl_3$, 25 °C): δ = 11.8 ($C_5\mathit{Me}_5$), 123.9 (C_5Me_5) 125.1 and 151.1 (C^{ipso}; C_6H_4) ppm. IR (CsI/Nujol): $\tilde{\nu}$ = 1476s, 1311s, 1262w, 1094w, 1022m, 1003w, 990w, 840m, 799w, 488w, 393m and

366m cm^{-1}. $C_{26}H_{34}Cl_4N_2Nb_2$ (702.2): calcd. C 44.47, H 4.88, N 3.99; found C 44.04, H 4.92, N 4.22.

Preparation of [{Nb(η⁵-C_5Me_5)Cl_2}$_2$(μ-1,3-NC_6H_4N)] (5): The synthesis of **5** was carried out in an identical manner to **4**.

Method A: [{$NbCl_3$}$_2$(μ-1,3-NC_6H_4N)] (1.42 g, 2.82 mmol) and $C_5Me_5(SiMe_3)$ (1.38 mL, 5.63 mmol). 1.98 g of **5** was obtained as a pink solid (Yield: 100%).

Method B: [Nb(η⁵-C_5Me_5)Cl_4] (17 mg, 0.046 mmol) and [1,3-{$(SiMe_3)_2N$}$_2C_6H_4$] (9 mg, 0.023 mmol). (Yield: 100%). ^{1}H NMR (300 MHz, $CDCl_3$, 25 °C): δ = 2.09 (s, 30 H, 2 × C_5Me_5), 6.43 (1 H), 6.60 (2 H) and 7.08 (1 H) (3m, C_6H_4) ppm. $^{13}C\{^1H\}$ NMR (75 MHz, $CDCl_3$, 25 °C): δ = 11.9 (C_5Me_5), 124.0 (C_5Me_5) 120.2, 122.2, 128.2 and 153.6 (C^{ipso}; C_6H_4) ppm. IR (CsI/Nujol): ṽ = 1566s, 1415m, 1338m, 1284s, 1236s, 1149w, 1079w, 1026m, 971w, 897w, 865m, 847w, 791m, 687w, 485w, 469w, 402m and 362s cm^{-1}.$C_{26}H_{34}Cl_4N_2Nb_2$ (702.2): calcd. C 44.47, H 4.88, N 3.99; found C 44.21, H 5.06, N 4.07.

Preparation of [{Ta(η⁵-$C_5H_4SiMe_3$)Cl_2}$_2$(μ-1,4-NC_6H_4N)] (6) and [{Ta(η⁵-$C_5H_4SiMe_3$)Cl_2}$_2$(μ-1,3-NC_6H_4N)] (7). Method A: CH_2Cl_2 (40 mL) was added to a mixture of [Ta(η⁵-$C_5H_4SiMe_3$)Cl_4] and the corresponding *N*,*N*,*N*′,*N*′-tetrakis(trimethylsilyl)phenylenediamine in a Teflon valve ampoule. The ampoule was placed in an oil bath and heated at 70 °C for 16 h. The resulting deep-red solution was allowed to cool down to room temperature. The solution was filtered and the solvent removed under reduced pressure. The final products obtained were identified as **6** and **7**, respectively.

Complex 6: From [Ta(η⁵-$C_5H_4SiMe_3$)Cl_4] (0.81 g, 1.76 mmol) and 1,4-{$(Me_3Si)_2N$}$_2C_6H_4$ (0.35 g, 0.88 mmol). 0.78 g of a red solid was obtained (Yield: 100%).

Complex 7: From [Ta(η⁵-$C_5H_4SiMe_3$)Cl_4] (0.81 g, 1.76 mmol) and 1,3-{$(Me_3Si)_2N$}$_2C_6H_4$ (0.35 g, 0.88 mmol). 0.78 g of a yellow oil was obtained (Yield: 100%).

Method B: CH_2Cl_2 (40 mL) was added to the corresponding [{$TaCl_3$}$_2$(μ-1,*i*-NC_6H_4N)] (*i* = 4 or 3) in a Teflon valve ampoule. $C_5H_4(SiMe_3)_2$ was added to this red suspension and the ampoule was placed in an oil bath and heated at 90 °C for 72 h. The resulting red solution was filtered and the solvent was removed under vacuum. The final products were washed several times with hexane at −40 °C and identified as **6** and **7**, respectively.

Complex 6: From [($TaCl_3$)$_2$(μ-1,4-NC_6H_4N)] (1.71 g, 2.52 mmol) and $C_5H_4(SiMe_3)_2$ (1.30 mL, 5.02 mmol). 1.72 g of a red solid was obtained (Yield: 78%). ^{1}H NMR (300 MHz, $CDCl_3$, 25 °C): δ = 0.25 (s, 18 H, 2 × $C_5H_4SiMe_3$), 6.59 and 6.71 (2m, each 4 H, 2 × C_5H_4), 6.75 (s, 4 H, C_6H_4) ppm. $^{13}C\{^1H\}$ NMR (75 MHz, $CDCl_3$, 25 °C): δ = −0.4 ($C_5H_4SiMe_3$), 114.3, 120.6 and 123.1 (C^{ipso}; $C_5H_4SiMe_3$) 125.0 and 153.0 (C^{ipso}; C_6H_4) ppm. IR (CsI/Nujol): ṽ = 3090w, 1491s, 1333vs, 1254s, 1172m, 1043m, 905s, 841vs and 413m cm^{-1}. $C_{22}H_{30}Cl_4N_2Si_2Ta_2$ (882.4): calcd. C 29.95, H 3.43, N 3.17; found C 29.62, H 3.61, N 3.15.

Complex 7: From [($TaCl_3$)$_2$(μ-1,3-NC_6H_4N)] (1.71 g, 2.52 mmol) and $C_5H_4(SiMe_3)_2$ (1.30 mL, 5.02 mmol). 1.57 g of a yellow oil was obtained (Yield: 71%). ^{1}H NMR (300 MHz, $CDCl_3$, 25 °C): δ = 0.28 (s, 18 H, 2 × $C_5H_4SiMe_3$), 6.60 and 6.72 (2m, each 4 H, 2 × C_5H_4), 6.26 (1 H), 6.39 (2 H) and 7.17 (1 H) (3m, C_6H_4) ppm. $^{13}C\{^1H\}$ NMR (75 MHz, $CDCl_3$, 25 °C): δ = −0.4 ($C_5H_4SiMe_3$), 113.9, 120.8 and 123.6 (C^{ipso}; $C_5H_4SiMe_3$), 121.9, 122.7, 127.1 and 154.9 (C^{ipso}; C_6H_4) ppm. IR (CsI/Nujol): ṽ = 3098w, 1573vs, 1470vs, 1320vs, 1252vs, 1171s, 905s, 840vs and 417m cm^{-1}. $C_{22}H_{30}Cl_4N_2Si_2Ta_2$ (882.4): calcd. C 29.95, H 3.43, N 3.17; found C 29.76, H 3.65, N 3.31.

Preparation of [{Ta(η⁵-C_5Me_5)Cl_2}$_2$(μ-1,4-NC_6H_4N)] (8): Dichloromethane (40 mL) was added to a mixture of [Ta(η⁵-C_5Me_5)Cl_4] (1.72 g, 3.76 mmol) and [1,4-{$(SiMe_3)_2N$}$_2C_6H_4$] (0.75 g, 1.88 mmol) in a Teflon valve ampoule. The ampoule was placed in an oil bath and heated to 90 °C for 48 h. The resulting solution was allowed to cool down to room temperature, filtered and the solvent removed under vacuum to give 2.00 g of **8** as a red, analytically pure, crystalline solid. (Yield: 100%). An X-ray-quality sample was obtained from a saturated dichloromethane solution at −40 °C. ^{1}H NMR (300 MHz, $CDCl_3$, 25 °C): δ = 2.16 (s, 30 H, 2 × C_5Me_5), 6.65 (s, 4 H, C_6H_4) ppm. $^{13}C\{^1H\}$ NMR (75 MHz, $CDCl_3$, 25 °C): δ = 11.4 (C_5Me_5), 121.6 (C_5Me_5) 125.4 and 150.7 (C^{ipso}; C_6H_4) ppm. IR (CsI/Nujol): ṽ = 1485vs, 1338vs, 1091m, 1028s, 995m and 844s cm^{-1}. $C_{26}H_{34}Cl_4N_2Ta_2$ (878.3): calcd. C 35.56, H 3.90, N 3.19; found C 35.50, H 4.07, N 3.47.

Preparation of [{Ta(η⁵-C_5Me_5)Cl_2}$_2$(μ-1,3-NC_6H_4N)] (9): The synthesis of **9** was carried out in an identical manner to **8**, from [Ta(η⁵-C_5Me_5)Cl_4] (0.81 g, 1.75 mmol) and [1,3-{$(SiMe_3)_2N$}$_2C_6H_4$] (0.35 g, 0,88 mmol). 0.96 g of **9** was obtained as an orange solid (Yield: 100%). ^{1}H NMR (300 MHz, $CDCl_3$, 25 °C): δ = 2.18 (s, 30 H, 2 × C_5Me_5), 6.11 (1 H), 6.28 (2 H) and 7.10 (1 H) (3m, C_6H_4) ppm. $^{13}C\{^1H\}$ NMR (75 MHz, $CDCl_3$, 25 °C): δ = 11.5 (C_5Me_5), 121.8 (C_5Me_5) 122.4, 122.5, 127.0 and 153.7 (C^{ipso}; C_6H_4) ppm. IR (CsI/Nujol): ṽ = 1568vs, 1315vs, 1026s, 864m and 351s cm^{-1}. $C_{26}H_{34}Cl_4N_2Ta_2$ (878.3): calcd. C 35.56, H 3.90, N 3.19; found C 35.23, H 4.00, N 3.19.

Preparation of [{Nb(η⁵-$C_5H_4SiMe_3$)Me_2}$_2$(μ-1,4-NC_6H_4N)] (10) and [{Nb(η⁵-$C_5H_4SiMe_3$)Me_2}$_2$ (μ-1,3-NC_6H_4N)] (13): MeLi was added at −78 °C to a suspension of complex **1** or **2** in hexane (50 mL). The mixture was allowed to warm up to room temperature and was stirred for 5 h. The solution was filtered and the residue extracted with hexane (2 × 20 mL). The extracts and the solution were combined and the solvent was removed in vacuo to give a solid, which was identified as **10** or **13**, respectively.

Complex 10: From [{Nb(η⁵-$C_5H_4SiMe_3$)Cl_2}$_2$(μ-1,4-NC_6H_4N)] (0.85 g, 1.20 mmol) and MeLi (3.44 mL, 4.81 mmol). 0.70 g of a brown solid was obtained (Yield: 93%). ^{1}H NMR (300 MHz, C_6D_6, 25 °C): δ = 0.09 (s, 18 H, 2 × $C_5H_4SiMe_3$), 0.77 (s, 12 H, 4 × Nb-*Me*), 5.91 (m, 8 H, 2 × C_5H_4), 7.19 (s, 4 H, C_6H_4) ppm. $^{13}C\{^1H\}$ NMR (75 MHz, C_6D_6, 25 °C): δ = −0.1 ($C_5H_4SiMe_3$), 37.8 (Nb-*Me*), 113.0, 113.1 and 116.7 (C^{ipso}; $C_5H_4SiMe_3$) 125.4 and 153.7 (C^{ipso}; C_6H_4) ppm. IR (CsI/Nujol): ṽ = 1477m, 1407m, 1317m, 1251s, 1174m, 1091w, 1046m, 982w, 904m, 879w, 838vs, 807m, 756m, 695w, 631w, 493w and 422w cm^{-1}. $C_{26}H_{42}N_2Nb_2Si_2$ (624.6): calcd. C 50.00, H 6.78, N 4.48; found C 50.15, H 6.70, N 4.26.

Complex 13: From [{Nb(η⁵-$C_5H_4SiMe_3$)Cl_2}$_2$(μ-1,3-NC_6H_4N)] (1.66 g, 2.35 mmol) and MeLi (6.71 mL, 9.40 mmol). 1.35 g of a brown solid was obtained (Yield: 92%). ^{1}H NMR (300 MHz, C_6D_6, 25 °C): δ = 0.10 (s, 18 H, 2 × $C_5H_4SiMe_3$), 0.75 (s, 12 H, 4 × Nb-*Me*), 5.89 and 5.93 (2m, each 4 H, 2 × C_5H_4), 7.02 (3 H) and 7.30 (1 H) (2m, C_6H_4) ppm. $^{13}C\{^1H\}$ NMR (50 MHz, C_6D_6, 25 °C): δ = −0.2 ($C_5H_4SiMe_3$), 38.1 (Nb-*Me*), 112.6, 113.2 and 117.4 (C^{ipso}; $C_5H_4SiMe_3$), 121.1, 121.3, 128.0 and 157.4 (C^{ipso}; C_6H_4) ppm. IR (CsI/Nujol): ṽ = 1567s, 1409m, 1338m, 1303m, 1250s, 1174m, 1150m, 1045m, 956w, 904m, 838vs, 780m, 757m, 693w, 632w and 495w cm^{-1}. $C_{26}H_{42}N_2Nb_2Si_2$ (624.6): calcd. C 49.97, H 8.17, N 3.07; found C 49.41, H 8.18, N 3.24.

Preparation of [{Nb(η^5-$C_5H_4SiMe_3$)(CH_2Ph)$_2$}$_2$(μ-1,4-NC_6H_4N)] (12) and [{Nb(η^5-$C_5H_4SiMe_3$)(CH_2Ph)$_2$}$_2$(μ-1,3-NC_6H_4N)] (15): Diethyl ether (60 mL) was added at −78 °C to a mixture of complex **1** or **2** and [$Mg(CH_2Ph)_2(THF)_2$]. The mixture was allowed to warm up to room temperature and was stirred overnight. The solution was filtered and the residue was extracted with diethyl ether (2 × 20 mL). The extracts and the solution were combined. The solvent was removed to give a yellow and a pale yellow solid, respectively, and these were identified as the corresponding compounds **12** and **15**.

Complex 12: From **1** (0.75 g, 1.06 mmol) and [$Mg(CH_2Ph)_2(THF)_2$] (0.74 g, 2.12 mmol). 0.88 g was obtained (Yield: 90%). ^{1}H NMR (300 MHz, C_6D_6, 25 °C): δ = 0.11 (s, 18 H, 2 × $C_5H_4Si\mathit{Me}_3$), 1.55 and 2.13 (2d, $^2J_{H,H}$ = 8.1 Hz, each 4 H, 4 × $C\mathit{H}_2Ph$), 5.63 and 5.72 (2m, each 4 H, 2 × $C_5\mathit{H}_4$), 6.79 (s, 4 H, $C_6\mathit{H}_4$), 6.81−7.07 (m, 20 H, 4 × $CH_2\mathit{Ph}$) ppm. ^{13}C{^{1}H} NMR (75 MHz, C_6D_6, 25 °C): δ = 0.1 ($C_5H_4Si\mathit{Me}_3$), 43.4 ($\mathit{C}H_2Ph$), 111.6, 112.5 and 112.2 (C^{ipso}; $\mathit{C}_5H_4SiMe_3$) 124.9 and 153.5 (C^{ipso}; C_6H_4), 125.4, 129.0, 130.5 and 138.9 (C^{ipso}; $CH_2\mathit{Ph}$) ppm. IR (CsI/Nujol): ṽ = 1594m, 1477s, 1408m, 1314s, 1250s, 1205m, 1176s, 1093m, 1035s, 1004w, 995w, 985m, 920w, 902m, 885w, 835vs, 817vs, 760s, 750s, 696vs, 632w, 537w, 515w, 446w and 428w cm^{-1}. $C_{50}H_{58}N_2Nb_2Si_2$ (929.0): calcd. C 64.64, H 6.29, N 3.02; found C 65.33, H 6.94, N 2.74.

Complex 15: From **2** (0.75 g, 1.06 mmol) and [$Mg(CH_2Ph)_2(THF)_2$] (0.74 g, 2.12 mmol). 0.85 g was obtained (Yield: 86%). ^{1}H NMR (300 MHz, C_6D_6, 25 °C): δ = 0.15 (s, 18 H, 2 × $C_5H_4Si\mathit{Me}_3$), 1.70 and 2.11 (2d, $^2J_{H,H}$ = 8.1 Hz, each 4 H, 4 × $C\mathit{H}_2Ph$), 5.64 and 5.79 (2m, each 4 H, 2 × $C_5\mathit{H}_4$), 6.612 (2 H), 6.73 (1 H) and 7.16 (1 H) (3m, $C_6\mathit{H}_4$), 6.85−7.08 (m, 20 H, 4 × $CH_2\mathit{Ph}$) ppm. ^{13}C{^{1}H} NMR (75 MHz, C_6D_6, 25 °C): δ = 0.2 ($C_5H_4Si\mathit{Me}_3$), 43.6 ($\mathit{C}H_2Ph$), 111.9, 112.3 and 112.9 (C^{ipso}; $\mathit{C}_5H_4SiMe_3$) 119.8, 120.7, 128.0 and 157.3 (C^{ipso}; C_6H_4), 125.5, 129.1, 130.6 and 138.8 (C^{ipso}; $CH_2\mathit{Ph}$) ppm. IR (CsI/Nujol): ṽ = 1592s, 1565s, 1549m, 1513w, 1484s, 1409m, 1367m, 1343m, 1304s, 1290s, 1251s, 1234s, 1207m, 1177m, 1159w, 1123w, 1084w, 1043m, 1025m, 995w, 901m, 837vs, 820s, 805s, 784w, 758s, 695m, 686m, 633w, 541w, 516w, 499w, 443w and 430w cm^{-1}. $C_{50}H_{58}N_2Nb_2Si_2$ (929.0): calcd. C 64.64, H 6.29, N 3.02; found C 64.69, H 6.85, N 2.88.

Preparation of [{Ta(η^5-C_5Me_5)Me_2}$_2$(μ-1,4-NC_6H_4N)] (16): A solution of MeLi (2.28 mmol) diluted in Et_2O (10 mL) was added dropwise, at −78 °C, to a suspension of complex **8** (0.5 g, 0.57 mmol) in hexane (50 mL). The mixture was stirred overnight at room temperature. The resulting yellow solution was filtered and the residue extracted with hexane (2 × 25 mL). The solvent was removed in vacuo to give 0.36 g of a yellow solid, which was identified as complex **16** (Yield: 80%). ^{1}H NMR (300 MHz, $CDCl_3$, 25 °C): δ = 0.01 (s, 12 H, 4 × Ta-Me), 1.96 (s, 30 H, 2 × $C_5\mathit{Me}_5$), 6.68 (s, 4 H, $C_6\mathit{H}_4$) ppm. ^{13}C{^{1}H} NMR (75 MHz, $CDCl_3$, 25 °C): δ = 10.7 ($C_5\mathit{Me}_5$), 46.5 (Ta-Me), 115.9 (C_5Me_5) 125.0 and 151.9 (C^{ipso}; C_6H_4) ppm. IR (CsI/Nujol): ṽ = 1493s, 1332vs, 1086m, 1026m, 1007m, 835s, 804m and 500m cm^{-1}. $C_{30}H_{46}N_2Ta_2$ (796.6): calcd. C 45.23, H 5.82, N 3.52; found C 44.82, H 5.79, N 3.36.

Preparation of [{Ta(η^5-C_5Me_5)(CH_2SiMe_3)$_2$}$_2$(μ-1,4-NC_6H_4N)] (17): A solution of $Mg(CH_2SiMe_3)Cl$ (2.28 mmol) diluted in Et_2O (10 mL) was added dropwise, at −78 °C, to a suspension of complex **8** (0.5 g, 0.57 mmol) in hexane (50 mL). The mixture was stirred overnight at room temperature. The resulting yellow solution was filtered and the residue was extracted with hexane (2 × 25 mL). The solvent was removed in vacuo to give 0.53 g of a yellow solid, which was identified as complex **17** (Yield: 86%). ^{1}H NMR (300 MHz, $CDCl_3$, 25 °C): δ = 0.04 (s, 36 H, 4 × $CH_2Si\mathit{Me}_3$), −1.14 and 0.21 (2d, $^2J_{H,H}$ = 11.9 Hz, each 4 H, 4 × $C\mathit{H}_2SiMe_3$), 1.97 (s, 30 H, 2 × $C_5\mathit{Me}_5$), 6.63 (s, 4 H, $C_6\mathit{H}_4$) ppm. ^{13}C{^{1}H} NMR (75 MHz, $CDCl_3$, 25 °C): δ = 2.8 ($CH_2Si\mathit{Me}_3$), 11.1 ($C_5\mathit{Me}_5$), 58.5 ($\mathit{C}H_2SiMe_3$), 115.6 (C_5Me_5) 125.1 and 151.7 (C^{ipso}; C_6H_4) ppm. IR (CsI/Nujol): ṽ = 1489s, 1332vs, 1241s, 1089m, 1024m, 962m, 850vs and 465m cm^{-1}. $C_{42}H_{78}N_2Si_4Ta_2$ (1085.3): calcd. C 46.48, H 7.24, N 2.58; found C 46.46, H 7.28, N 2.96.

Preparation of [{Ta(η^5-C_5Me_5)(CH_2Ph)$_2$}$_2$(μ-1,4-NC_6H_4N)] (18): A solution of $Mg(CH_2Ph)_2(THF)_2$ (0.4 g, 1.14 mmol) diluted in Et_2O (20 mL) was added dropwise, at −78 °C, to a solution of complex **8** (0.5 g, 0.57 mmol) in Et_2O (30 mL). The mixture was stirred overnight at room temperature. The solvent was removed in vacuo and the resulting yellow residue was extracted with CH_2Cl_2 (2 × 15 mL). The filtrate was placed in a freezer at −40 °C to afford 0.44 g of **18**, after 16 h, as a yellow crystalline solid. The product contained ca. 0.25 equivalents of residual CH_2Cl_2 (by ^{1}H NMR spectroscopy and elemental analysis). Yield: 68%. ^{1}H NMR (300 MHz, $CDCl_3$, 25 °C): δ = 1.35 and 2.06 (2d, $^2J_{H,H}$ = 11.3 Hz, each 4 H, 4 × $C\mathit{H}_2Ph$), 1.94 (s, 30 H, 2 × $C_5\mathit{Me}_5$), 6.40 (s, 4 H, $C_6\mathit{H}_4$), 6.90−7.10 (m, 20 H, 4 × $CH_2\mathit{Ph}$) ppm. ^{13}C{^{1}H} NMR (75 MHz, $CDCl_3$, 25 °C): δ = 11.0 ($C_5\mathit{Me}_5$), 67.5 ($\mathit{C}H_2Ph$), 115.3 (C_5Me_5) 124.7 and 151.2 (C^{ipso}; C_6H_4), 123.2, 127.9, 129.7 and 144.6 (C^{ipso}; $CH_2\mathit{Ph}$) ppm. IR (CsI/Nujol): ṽ = 1593s, 1483vs, 1332vs, 1200m, 1024m, 835s, 742s and 452m cm^{-1}.

this was vindicated by the success of the subsequent solutions and refinements. Empirical absorption correction was performed for compound **17**. Intensities for **8** were measured on a Nonius-KappaCCD diffractometer at low temperature and treated with Scalpack and DENZO routines.[27] The crystal data and details of data collection and structure analyses are summarised in Table 4.

All structures were solved by direct methods using the SHELXS computer program[28] and refined in F^2 by a full-matrix least-squares procedure (SHELXL-97).[29] All non-hydrogen atoms were refined with anisotropic thermal parameters for all compounds. The hydrogen atoms were included in calculated positions and were refined with an overall isotropic temperature factor using a riding model. Weights were optimised in the final cycles.

CCDC-205739 (for **1**), -205740 (for **8**) and -205742 (for **17**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Synthesis, Structure and Magnetic Properties of a μ-Carboxylato-Bridged Ferromagnetic Trinuclear Copper(II) Complex with Lariat Tetraazacrown Ether as Ligand

Shu-Lan Ma,[a] Wen-Xiang Zhu,*[a] Song Gao,[b] Qian-Ling Guo,[a] and Miao-Qiong Xu[a]

Keywords: Copper / Macrocyclic ligands / X-ray diffraction / Magnetic properties

Four *o*-toluic acid pendant groups have been attached to a tetraaza crown ether to prepare the novel tetraazamacrocyclic ligand H_4L, 4,7,13,16-tetrakis(2-carboxybenzyl)-1,10-dioxa-4,7,13,16-tetraazacyclooctadecane. The trinuclear copper(II) complex of the ligand, $[Cu_3L{\cdot}2H_2O]^{2+}{\cdot}2NO_3^-{\cdot}2H_2O$, has been newly synthesized, and its subsequent structural characterization has revealed that it consists of three Cu^{II} cores with a isosceles triangular array and that there is a two-fold rotation axis that passes through the Cu2 center. The complex contains two symmetry-related CuN_2O_3 cores in a distorted square-pyramidal geometry and one CuO_4 core in a distorted square-plane geometry. The two μ-bidentate *syn-anti* carboxylate groups bridge Cu1 with Cu2, and Cu1A with Cu2. The trinuclear copper(II) complex units are connected in a one-dimensional zigzag chain via μ-H_2O–NO_3^--bridged hydrogen bonds. Variable-temperature susceptibility measurements (2–300 K) reveal a ferromagnetic coupling, J_a = 8.08 cm^{-1}, between the μ-carboxylato-bridged Cu1 and Cu2, or Cu1A and Cu2, and a weak antiferromagnetic interaction, J_b = –0.40 cm^{-1}, between Cu1 and Cu1A.

Introduction

Multimetallic complexes are of great interest due to the special chemical and physical properties that result from the mutual interaction of two or more metal centers.[1] Trinuclear transition metal complexes have received increasing attention recently, partly because of the lack of metallobiomolecules for which the trinuclear core can act as a synthetic analogue. Polynuclear copper(II) complexes possess potential applications as, for example, molecular magnets and as models of metal enzymes.[2] The recent discovery of a ferromagnetically coupled Cu^{II} triad in a subunit of methane mono-oxygenase,[3] and an X-ray structure analysis of ascorbate oxidase from zucchini, which revealed an angled trimeric Cu^{II} unit,[4] have all stimulated an increasing interest in trinuclear copper systems. To date, the magnetic properties of many trinuclear copper(II) compounds have been reported, most of which exhibit antiferromagnetic interactions,[5−12] except for a few examples with ferromagnetic exchange.[13−16]

The acetate ion can provide a strong superexchange path in copper compounds. This is illustrated by an early study on hydrated copper acetate.[17] The carboxylate groups can bridge the metal cores through monodentate, and *syn-syn*, *syn-anti* and *anti-anti* bidentate coordination modes. Both *syn-syn*[17−20] and *anti-anti* modes[21,22] may promote an antiferromagnetic interaction, but the *syn-anti* bridging mode may cause either ferromagnetic[18,22−25] or antiferromagnetic interaction.[26,27] Complexes with s*yn-syn*-bridged carboxylate groups are very common, but those with *syn-anti* modes are very few.

Many reported polyazamacrocyclic copper(II) complexes are mononuclear and the carboxylate groups nearly all have a monodentate coordination mode,[28−31] with only a few showing bidentate modes.[32] The synthesis of polynuclear complexes of polyazamacrocycles is more difficult and challenging primarily due to a lack of suitably characterized ligands. For $[Cu_2(OAc)_2L]_n(ClO_4)_{2n}$, where L is a hexaazamacrocyclic ligand, *syn-anti* acetate bridges result in a pseudodinuclear structure,[26] but the acetate ions are not attached to the macrocyclic crown ether. Surprisingly, we succeeded in preparing a tetraazamacrocyclic ligand, 4,7,13,16-tetrakis(2-carboxybenzyl)-1,10-dioxa-4,7,13,16-tetraazacyclooctadecane), and prepared its novel trinuclear complex, $[Cu_3L(H_2O)_2]^{2+}{\cdot}2NO_3^-{\cdot}2H_2O$. Here we report the crystal structure and magnetic property of the complex, which involves both *syn-anti* μ_2-*O*,*O′* bidentate and monodentate carboxylate groups and exhibits a ferromagnetic exchange interaction.

Results and Discussion

IR Spectrum

The band at 1121 cm^{-1}, assigned to ν_{C-O-C} for the free ligand, is shifted to 1086 cm^{-1} in the complex, indicating the complexation of the ether oxygen atoms to the Cu^{2+} ion. The complex exhibits strong bands corresponding to ν_{as}(COO) at 1595 and 1567cm^{-1}, and ν_s(COO) at 1426 and 1366 cm^{-1}. Since the carboxylate group can coordinate to the metal ion in either bidentate or monodentate fashion, the "$\Delta\nu$ criterion" [$\Delta\nu = \nu_{asymm}(COO) - \nu_{symm}(COO)$] was employed to determine the coordination mode of the carboxylate group. The $\Delta\nu$ value of 168 and 201 cm^{-1} in our complex are very similar to that reported for the copper(II) complexes with both bidentate μ_2-*O*,*O*′ and monodentate carboxylate groups,[33] thus indicating the carboxylate groups behave both as bridging bidentate ligands between Cu^{II} atoms,[14,15] and as monodentate ligands. In addition, the band at 1384 cm^{-1} reveals the free nitrate in the complex. A broad band centered at 3426 cm^{-1} for the complex can be assigned to the ν_{O-H} stretch of coordinated or uncoordinated water molecules.

Description of the Structure

The complex consists of a discrete $[Cu_3L(H_2O)_2]^{2+}$ cation, two lattice water molecules and two uncoordinated nitrate anions. The cation of the complex with the atomic labeling scheme (Figure 1) and selected bond lengths and bond angles (Table 1) are given here. The molecule has a twofold symmetry, and the twofold rotation axis passes through the Cu2 center. The complex contains two symmetry-related CuN_2O_3 cores in a distorted square-pyramidal geometry and one CuO_4 core in a distorted square-planar geometry. The two μ-bidentate *syn-anti* carboxylate groups, O4−C22−O5 and O4A−C22A−O5A, bridge Cu2 with the crystallographically equivalent Cu1 and Cu1A cores at 4.554 Å, forming an isosceles triangle. The Cu1 and Cu1A ions are placed on the triangle base, with a longer distance of 4.852 Å connected by the N−$(CH_2)_2$−O spacer. The overall result is a 16-membered ring Cu3 cluster (Figure 2).

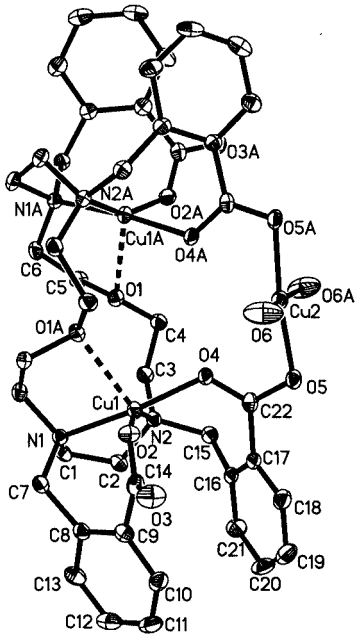

Figure 1. Thermal ellipsoids plot of the cation of $[Cu_3L{\cdot}2H_2O]^{2+}$ with labeling of selected atoms; ellipsoids shown at the 30% probability level

The distorted square-pyramidal Cu1 core consists of N1, N2, O2, O4, and O1A, in which N1, N2, O2 and O4 form the basal plane, and the apical positions are occupied by O1A. The distorted square-pyramidal Cu1A core consists of N1A, N2A, O2A, O4A and O1. The N1, N2, N1A, N2A, O1 and O1A atoms are all from the crown ether ring. O2 and O2A are from two carboxylate groups with a monodentate coordination mode, while O4 and O4A are from two other carboxylate groups with bidentate mode. Unlike Cu1 or Cu1A, the Cu2 ion is tetracoordinated to O5 and O5A, from the other oxygen atom of two μ_2-bidentate carboxylate groups, and O6 and O6A, from two water molecules. The deviations from the mean square-plane defined by Cu2, O5, O5A, O6 and O6A are −0.0951, 0.0225, 0.0225, 0.0251 and 0.0251 Å, respectively. Thus, the Cu2 ion is slightly above the basal square plane.

The complex obviously has a different structure from that of other reported macrocyclic polyazapolycarboxylato copper(II) complexes.[28−31] The nearly equal bond lengths of C22−O4 [1.263(4) Å] and C22−O5 [1.258(4) Å] show the bidentate coordination mode, while the significantly different lengths of C14−O2 [1.280(5) Å] and C14−O3 [1.241(5) Å] confirm its monodentate mode. The Cu−O bond lengths of the carboxylate group that bridges Cu1 and Cu2, 1.953(3) and 1.955(3) Å for Cu1−O4 and Cu2−O5, respectively, are nearly equal, but the Cu−O−C−O−Cu superexchange path is not symmetric. The crown ether ring is severely twisted to meet the requirement of the coordination geometry. The six donor atoms of crown ring, N 1, N2, N1A, N2A, O1 and O1A, are not coplanar and roughly adopt a boat conformation, which is in contrast with the chair conformation of the tetrakis(2-cyanobenzyl)-substituted tetraazacrown ether **2** in the solid state.[34] This may be due to steric hindrance from the four bulk pendant arms and the coordination requirement of the trinuclear complex.

Because of the limited cavity size of the parent macrocyclic free base (1,10-dioxa-4,7,13,16-tetraazacyclooctadecane) there are only two dinuclear complexes with its derivative ligand containing four (2-pyridyl)methyl pendant arms, from which the pyridyl nitrogen atoms are coordinated with the central metal atoms.[35,36] To our knowledge, the present complex is the first trinuclear complex of this tetraazamacrocyclic ligand.

There are intermolecular hydrogen bonds in the crystal of the complex. Oxygen atoms from the water molecule (O10) and the disordered nitrate anion (O7 and O9′) act as hydrogen-bond acceptors for the coordinated water mol-

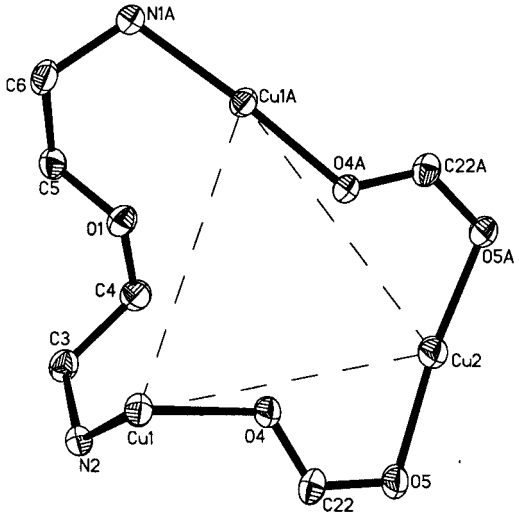

Figure 2. The 16-membered ring, showing the triangular Cu_3 skeleton and bridges

ecule involving O6. The water molecule involving O10, also as a hydrogen donor, is hydrogen-bonded to the uncoordinated oxygen atom (O3) of the carboxylate group, as well as to O8 and O8′ of its adjacent nitrate anion. Moreover, the nitrate anion is also hydrogen-bonded to the coordinated water molecule of the adjacent $[Cu_3L(H_2O)_2]^{2+}$ unit. Interatomic distances and bond angles are listed in Table 2. These hydrogen bonds form a μ-H_2O−NO_3^- "band" consisting of four water molecules and two nitrate ions to tie the molecules together, forming a one-dimensional zigzag chain in the unit cell (Figure 3). In addition, the adjacent chains are linked by a π-π stacking interaction between the phenyl rings C8−C13 and C8B−C13B (related by $-x + 1/2$, $-y + 1/2$, $-z + 1$). The interacting rings are strictly coplanar by symmetry and are separated by 3.356 Å, with their centroids being offset by 1.85 Å. The complex may thus be stabilized by both the hydrogen bonding and π-π stacking interaction.

Magnetic Properties

The variable-temperature magnetic susceptibility χ_m per trinuclear Cu^{II} unit has been measured. At room temperature $\chi_m T$ is 1.27 $cm^3\ mol^{-1}$ K, which is slightly higher than the expected 1.12 $cm^3\ mol^{-1}$ K for three uncoupled spin-only Cu^{II} ions ($S = 1/2$, $g = 2$). $\chi_m T$ increases upon cooling, reaching 1.88 $cm^3\ mol^{-1}$ K at 2.14 K (Figure 4). A plot of ${\chi_m}^{-1}$ versus T is essentially linear, and least-squares fitting of the data to the Curie−Weiss law gave $C = 1.24$ $cm^3\ mol^{-1}$ K and $\theta = +1.16$ K. The increase of $\chi_m T$ upon cooling, and the small positive Weiss constant suggest a ferromagnetic interaction between Cu^{II} ions in the trimer.

To estimate the magnitude of the magnetic coupling in the trinuclear complex, an isotropic Heisenberg−Dirac−van Vleck (HDVV) Hamiltonian [Equation (1)] was used:

$$H = -2J_{12}(S_1 \cdot S_2) - 2J_{13}(S_1 \cdot S_3) - 2J_{23}(S_2 \cdot S_3) \quad (1)$$

where $J_{12,}$ J_{13} and J_{23} are the exchange coupling constants (negative for an antiferromagnetic AF interaction, positive for a ferromagnetic F interaction) and $S_1 = S_2 = S_3 = {}^1/_2$ for the three Cu^{II} centers. For the geometry of an isosceles triangle with C_{2c} symmetry, two coupling constant are in-

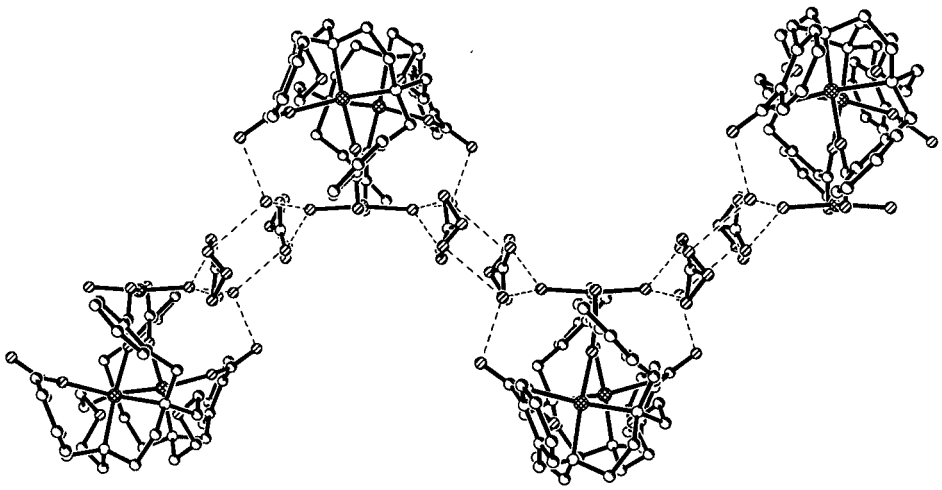

Figure 3. One-dimensional chain structure in the crystal linked by hydrogen bonding (viewed along the *a* axis, hydrogen atoms omitted for clarity)

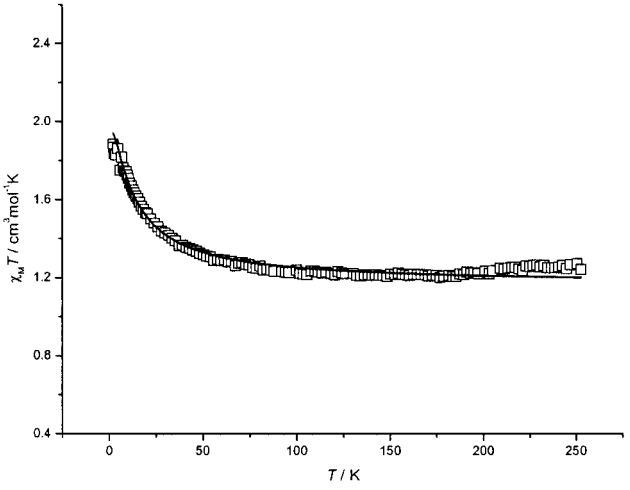

Figure 4. Temperature dependence of $\chi_m T$ of the complex, measured at 10 kOe; solid line corresponds to the best theoretical fitting (see text)

volved.[37] Thus, we employed Equation (2) to describe the low-lying electronic states:

$$H = -2J_a(S_1 \cdot S_2 + S_1 \cdot S_3) - 2J_b(S_2 \cdot S_3) \quad (2)$$

where $J_a = J_{12} = J_{13}$ is the coupling constant between bidentate carboxylato-bridged Cu2 and Cu1, or Cu2 and Cu1A, while $J_b = J_{23}$ is that between Cu1 and Cu1A, which are connected by the N−$(CH_2)_2$−O spacer (Figure 2). Application of van Vleck's susceptibility equation, and adding the Zeeman term to the preceding Hamiltonian (considering equal and isotropic *g* values for the three copper ions), gives Equation (3) for the molar susceptibility:

$$\chi_m = \frac{Ng^2\beta^2}{4kT} \frac{10\exp(J_a + 2J_b)/kT + \exp(-2J_a + 2J_b)/kT + 1}{2\exp(J_a + 2J_b)/kT + \exp(-2J_a + 2J_b)/kT + 1} \quad (3)$$

The best fit of the data through Equation (3) gives $g = 2.04$, $J_a = 8.08\ cm^{-1}$ and $J_b = -0.40\ cm^{-1}$. The reliability factor, defined as $R\ (\chi_m T) = (\chi_m T_{obs} - \chi_m T_{calcd.})^2/(\chi_m T_{obs})^2$, is 4.02×10^{-4}. The calculated data curve (solid line in Figure 4) matches the experimental magnetic data well. The positive J_a and the small negative J_b imply a ferromagnetic exchange interaction between the μ-carboxylato-bridged Cu2 and Cu1, or Cu2 and Cu1A, with a weak antiferromagnetic exchange interaction between Cu1 and Cu1A.

The magnetization measured at 1.84 K increases with the field, and reaches 3.25 Nβ per Cu_3 at 70 kOe, which is slightly higher than the expected saturation value of 3 Nβ for three spin-only Cu^{II} ions with $S = {}^1/_2$, $g = 2.0$ (Figure 5).

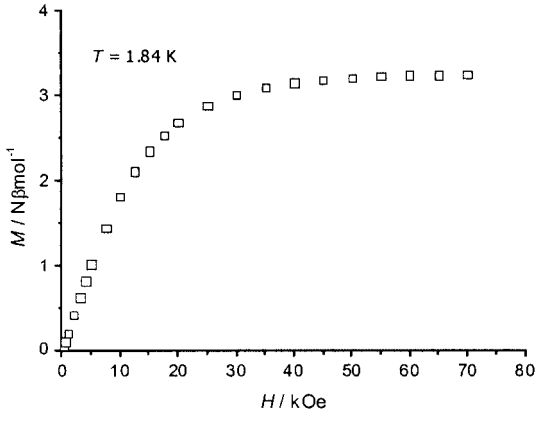

Figure 5. Magnetization versus field up to $H = 70$ kOe (at 1.84 K)

The exchange coupling in acetato- and related carboxylato-bridged complexes is largely determined by the conformation of the bridge and the interaction between the d orbitals of the metal ion and the bridge. In complexes where the metal ions are bridged in a *syn-syn* manner, the Cu−Cu distances are very small (e.g. 2.64 Å[38]) and the

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

exchange coupling constants are very large, and nearly all with antiferromagnetic interaction. The dimeric complex $Cu_2(OAc)_4{\cdot}2H_2O$ ($2J = -286\ cm^{-1}$) is one example of such bridging.[39] As previously noted, the magnitude of the antiferromagnetic interaction depends on the overlap of the magnetic orbitals centered on nearest-neighbor copper ions. In such complexes, the acetato ligands interact directly with the d orbitals of the copper ions. However, in complexes containing *syn-anti* type bridges, the exchange coupling constants ($J \approx 4-7\ cm^{-1}$) are usually smaller and the exchange is ferromagnetic.[22−25] This might be because the *syn-anti* bridging carboxylate groups bind copper ions with a Cu−Cu distance that is too long to form a direct interaction (such as the Cu−Cu distance of 4.554 Å in the present complex). For the *syn-anti* conformation of the Cu−O−C−O′−Cu′ bridges, the 2p orbitals of O and O′ belonging to the magnetic orbitals centered on Cu and Cu′, respectively, are unfavorably oriented to give a strong overlap. This reduces the antiferromagnetic contribution, which would lead ultimately to an overall ferromagnetic behavior.[25]

Rodríguez-Fortea et al. have recently reported a theoretical study of the exchange coupling through *syn-anti* bridging carboxylate groups.[40] Their computational study showed that the calculated coupling constant in the *syn-anti* case is weakly ferromagnetic ($+10.2\ cm^{-1}$). Because of the rareness of the *syn-anti* case, the authors can only compare their results with the one available compound with a *syn-anti* coordination mode. The coupling constant of $+8.08\ cm^{-1}$ in our present compound agrees well with the result above, providing an important *syn-anti* case.

Conclusion

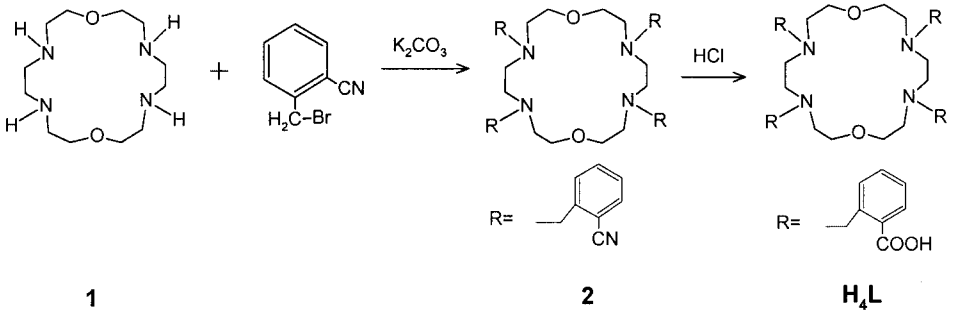
The novel tetraazamacrocyclic ligand containing four pendent *o*-toluic acid groups has been prepared by the hydrolysis of the cyano groups. Because of the strong coordinating ability of the carboxylate groups and the large steric hindrance from the four bulk *o*-toluic acid pendant arms, we obtained its trinuclear copper(II) complex. For the complex, the three Cu^{II} cores are in an isosceles triangular arrangement and adjacent copper ions are connected by μ_2-didentate *syn-anti* carboxylate groups and an $N-(CH_2)_2-O$ spacer. The trinuclear copper(II) complex units are connected into a one-dimensional zigzag hydrogen-bonding chain. Magnetic property studies revealed a ferromagnetic interaction, which corresponds with the magnetic coupling observed for other *syn-anti*-bridged complexes.

Experimental Section

General Remarks: All commercially available chemicals were of analytical grade and were used as received. C, H and N were determined using an Elementar vario EL elemental analyzer. The IR spectra were recorded with a Nicolet-AVATAR 360 FT-IR spectrometer using KBr pellets in the 4000−400 cm^{-1} regions. Variable-temperature magnetic susceptibility data for a crystalline sample of complex were obtained in an external field of 10.0 kG with an Oxford Maglab 2000 system magnetometer from 300 to 2 K. 1,10-Dioxa-4, 7,13,16-tetraazacyclooctadecane (**1**) was prepared according to a literature procedure.[41]

4,7,13,16-Tetrakis(2-cyanobenzyl)-1,10-dioxa-4,7,13,16-tetraazacyclooctadecane (2): To prepare compound **2** (Scheme 1) a mixture of azacrown ether **1** (0.26 g, 1 mmol) and anhydrous K_2CO_3 (1.10 g, 8 mmol) was heated under reflux in acetonitrile (15 mL) for 4 h, and then an acetonitrile solution (15 mL) of 2-(bromomethyl)benzonitrile (0.78 g, 4 mmol) was added. The resultant mixture was heated under reflux for a further 20 h. The so-obtained precipitate was then filtered off and the mother liquor was cooled slowly to room temperature. After 2 h, colorless plate crystals of **2** formed from the mother liquor. Mp 119−121°C. $C_{44}H_{48}N_8O_2$ (720.9): calcd. C 73.29, H 6.66, N 14.89; found C 73.10, H 6.39, N 14.79. ^1H NMR (500 MHz, $CDCl_3$): δ (ppm): = 2.79−2.83 (m, 16 H, NCH_2), 3.56−3.58 (t, $J_{H,H}$ = 5.5 Hz, 8 H, OCH_2), 3.80 (s, 8 H, CH_2), 7.31−7.34 (t, $J_{H,H}$ = 7.7 Hz, 4 H, ArH), 7.49−7.53 (m, 4 H, ArH), 7.59−7.61 (d, $J_{H,H}$ = 7.7 Hz, 8 H, ArH) ppm. IR (KBr pellet): $\tilde{\nu}$ = 2223 s, 1596 m, 1483 m, 1447 s, 1363 m, 1350 m, 1310 m, 1284 m, 1121 s, 1063 s, 1051 s, 937 m, 772 m, 561 w cm^{-1}.

4,7,13,16-Tetrakis(2-carboxybenzyl)-1,10-dioxa-4,7,13,16-tetraazacyclooctadecane Tetrahydrochloride ($H_4L{\cdot}4HCl$): A solution of azacrown ether **2** (0.72 g, 1.0 mmol) in 4 M aqueous HCl (30 mL) was heated under reflux overnight (see Scheme 1). The solvent was then removed by evaporation on a water bath. The resultant residue was dissolved in aqueous HCl (1:1, 10 mL) and heated at 70−80°C. After cooling, plate crystals were obtained as the tetrahydrochloride salt. $C_{44}H_{56}Cl_4N_4O_{10}$ (942.4): calcd. C 56.05, H 5.94, N 6.79;



1 **2** **H_4L**

Scheme 1

found C 55.87, H 6.13, N 6.41. IR (KBr pellet): $\tilde{\nu}$ = 3390 s, 1704 s, 1600 m, 1579 m, 1449 s, 1399 s, 1300 s, 1230 s, 1119 m, 1081 m, 971 w, 745 m, 650 m cm^{-1}.

$[Cu_3L{\cdot}2H_2O]^{2+}{\cdot}2NO_3^-{\cdot}2H_2O$: $Cu(NO_3)_2{\cdot}3H_2O$ (0.04 g, 0.15 mmol) was added to a water/methanol (1:4, 10 cm^3) solution of the ligand $H_4L{\cdot}4HCl$ (0.047 g, 0.05 mmol). The pH of the reaction solution was adjusted to 5 with triethylamine. Subsequent slow concentration at room temperature afforded blue crystals suitable for X-ray determination. $C_{44}H_{56}Cu_3N_6O_{20}$ (1179.57): calcd. C 44.76, H 4.75, N 7.12; found C 44.51, H 4.41, N 7.35. IR (KBr pellet): $\tilde{\nu}$ = 3429 m, 1608 m, 1594 s, 1567 s, 1457 m, 1426 s, 1384 s, 1365 s, 1336 s, 1285 w, 1086 m, 991 w, 745 m cm^{-1}.

X-ray Crystallographic Study: An X-ray diffraction analysis of a crystal (0.60 × 0.26 × 0.22 mm) was preformed with a Bruker SMART 1000 CCD diffractometer at 293 K with graphite-monochromatized Mo-K_α radiation (λ = 0.71073 Å). Semiempirical absorption corrections were applied using the SADABS program. The structure was solved by direct methods and refined by full-matrix least squares on F^2 using the SHELXS-97 and SHELXL-97 programs.[42] All non-hydrogen atoms were refined with anisotropic displacement parameters. The hydrogen atoms were generated geometrically and treated by a mixture of independent and constrained refinements. Disorder of the nitrate anion was found in the crystal. The site occupation factor for each nitrate anion was refined to 70.4 and 29.9%, respectively. Crystallographic data and details of the structure refinements are summarized in Table 3. CCDC-205577 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge, CB2 1EZ, UK [Fax: (internat.) + 44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Table 3. Crystal data and structure refinement details for the complex

Empirical formula	$C_{44}H_{56}Cu_3N_6O_{20}$
Formula mass	1179.57
Temperature	293(2) K
Wavelength	0.71073 Å
Crystal system, space group	monoclinic, *C*2/*c*
Unit cell dimensions	*a* = 29.454(16) Å
	b = 9.756(6) Å
	c = 17.473(10) Å
	β = 110.157(9)°
Volume	4713(4) $Å^3$
Z, calculated density	4, 1.662 Mg/m^3
Absorption coefficient	1.430 mm^{-1}
F(000)	2436
Crystal size	0.60 × 0.26 × 0.22 mm
θ range for data collection	2.21−25.00°
Limiting indices	$-34 \le h \le 32$, $-11 \le k \le 11$, $-10 \le l \le 20$
Reflections collected/unique	9907/4119 [*R*(int) = 0.0464]
Completeness to θ = 25.00°	99.2%
Absorption correction	semiempirical from equivalents
Max. and min. transmission	1.000000 and 0.747142
Refinement method	full-matrix least squares on F^2
Data/restraints/parameters	4119/93/371
Goodness of fit on F^2	1.020
Final *R* indices [$I > 2\sigma(I)$]	*R*1 = 0.0417, *wR*2 = 0.0827
Extinction coefficient	0.00043(7)
Largest diff. peak/hole	0.432/−0.425 e·$Å^{-3}$

A Series of Transition Metal Bis(dicyanobenzenedithiolate) Complexes [M(dcbdt)$_2$] (M = Fe, Co, Ni, Pd, Pt, Cu, Au and Zn)

Helena Alves,[a] Dulce Simão,[b] Isabel Cordeiro Santos,[a] Vasco Gama,[a] Rui Teives Henriques,[a,b] Horácio Novais,[b] and Manuel Almeida*[a]

Keywords: Coordination chemistry / EPR spectroscopy / Magnetic properties / S ligands / Transition metals

A series of new M[(dcbdt)$_2$]$^{-z}$ complexes of the dicyanobenzodithiolate (dcbdt) ligand with a range of transition metals (M = Co, Pd, Pt, Cu, Au and Zn) in different oxidation states (z = 0.4, 1, 2) were prepared as their nBu$_4$N salts and characterised by X-ray diffraction, cyclic voltammetry, EPR and static magnetic susceptibility. Their properties are discussed in comparison with the Ni and Fe analogues described by us recently. The structures of these complexes belong to four distinct groups: i) the Zn^{II} compound **10** is triclinic $P\bar{1}$ with the metal in a tetrahedral coordination geometry; ii) other M^{II} complexes [M = Pt (**8**), Pd (**7**), Co (**3**) and Cu (**5**)] are monoclinic $C2/m$, and are isostructural with the Ni^{II} analogue, presenting a perfectly planar square geometry; iii) the Co^{III} compound **4** is triclinic $P\bar{1}$, and isostructural with the Fe and Ni analogues, with a strong dimerisation of the M(dcbdt)$_2$ units and the metal in a square-pyramidal coordination geometry; iv) the M^{III} salts with M = Au (**2**), Cu (**6**) and Pt (**9**) are monoclinic $P2_1/c$ and the complexes are arranged as pseudo-dimers. The EPR and static magnetic-susceptibility measurements show that the Co^{II} (**3**), Cu^{II} (**5**), Pt^{III} (**9**) and Co^{III} (**4**) complexes are paramagnetic corresponding to an S = 1/2 state, except for Co^{III}, which is in a high-spin S = 1 configuration. The solid state EPR spectra of the Co^{II} compound presents a hyperfine structure typical of the I = 7/2 ^{59}Co. The temperature dependence of the paramagnetic susceptibility of the Pt^{III} compound follows a singlet-triplet model with a dimer antiferromagnetic coupling, J, of 984 K.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

During the last few years there has been a renewed interest in the study of transition metal bis(dithiolene) complexes which, in their square-planar coordination geometry, can be used as building blocks for conducting and or magnetic molecular materials.[1] These complexes can be seen as the inorganic analogues of TTF-type donors, which so far have provided the largest number of known organic conductors and superconductors, where the central C=C bond is replaced by a transition metal. In fact these inorganic complexes have frontier orbitals that are isolobal with the corresponding TTF analogues. Depending on the metal and on the oxidation state, these complexes can present different magnetic moments. Furthermore, the choice of the transition metal provides access to a diversity of different ground states. These are important features for the study and design of molecular materials with specific magnetic properties.

Bis(dithiolene) complexes based on extended and delocalised π-ligands are expected to be more promising for conducting materials due to the accessibility of a wider range of oxidation states and the possibility of larger solid-state interactions.[1−4] Although bis(dithiolene) complexes of metals from groups 10 and 11 tend to adopt a square-planar geometry, favourable for extended π-π interactions and electron delocalisation in stacked structures, in some cases, namely for Fe and Co, other structures and different metal coordination environments are possible. All known Fe^{III} bis(dithiolene) complexes are dimeric with a square-pyramidal coordination geometry.[5,6] For Co^{III}, further to this dimeric structure, examples of trimeric[7] or even polymeric structures are also known.[8]

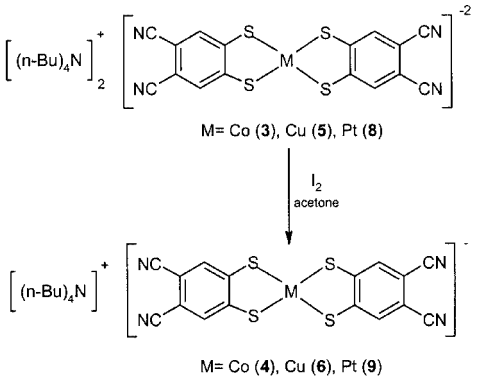
Recently, after the synthesis of the new extended aromatic ligand 4,5-dicyanobenzene-1,2-dithiolate (dcbdt), we have reported a study of the nickel complexes [Ni(dcbdt)$_2$]$^{z-}$, which can exist in a variety of different, easily accessible oxidation states (z = 0.4, 1, 2).[9] The Ni^{III} complex with this ligand and z = 1 was found to present a strongly dimerised geometry, rare for Ni, and the salt (nBu$_4$N)$_2$[Ni(dcbdt)$_2$]$_5$, with segregated stacks of partially oxidised Ni complexes, is a semiconductor with relatively high electrical conductivity. As judged from preliminary data published on the gold analogue (nBu$_4$N)$_2$-[Au(dcbdt)$_2$]$_5$,[10,11] the partially oxidised state, [M(dcbdt)$_2$]^z

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim DOI: 10.1002/ejic.200300476

with $z = 0.4$, seems to be a general feature of complexes with this ligand.

More recently the iron complex $[Fe(dcbdt)_2]_2^{2-}$ was also described and it presents a similar dimerised structure, with magnetic properties similar to the Ni analogue.[12] Thus, both for fundamental reasons and also in order to evaluate their possible use as building blocks for conducting or magnetic materials, it appears of obvious interest to study similar complexes with different transition metals.

In this paper we report a comparative study of a diversity of $[M(dcbdt)_2]^z$ complexes with different transition metals: M = Fe, Co, Ni, Cu, Zn, Pd, Pt and Au.



Scheme 2

Results and Discussion

Synthesis

The synthesis of the different metal complexes was performed following a general common procedure, similar to that previously described for nickel[9] and using the ligand 4,5-dicyanobenzene-1,2-dithiol (**1**) obtained from the aromatic dibenzyl sulfide 1,2-bis(benzylthio)benzene-4,5-dicarbonitrile. The benzothiol **1** was reacted, in a basic medium, with chloride salts of the different metals and the resulting metal complex precipitated as a tetrabutylammonium salt by addition of $(n\text{Bu})_4\text{Br}$ (Scheme 1).

The oxidation state of the resulting complex depends on the starting metal salt, the reaction conditions and the redox stability of the final product. The dianionic complexes were obtained from MCl_2 salts, with final yields in the range of 25−65% after recrystallisation from acetone, as deep-blue crystals for cobalt(II) (**3**), as orange crystals for palladium(II) (**7**) as red crystals for platinum(II) (**8**), as brown crystals for copper(II) (**5**) and as orange crystals for zinc(II) (**10**).

With exception of Pd and Zn, the monoanionic complexes could be obtained by oxidation of the corresponding dianions with iodine in acetone solution, as summarised in Scheme 2, leading to crystals of cobalt(III) (**4**), platinum(III) (**9**) and copper(III) (**6**) complexes, all of which are different shades of green. Attempts to oxidise the palladium(II) complex with iodine, or other oxidising agents, always led to decomposition.

The monoanionic complexes could be obtained directly after complexation for gold(III) (**2**), as green crystals, from the $KAuCl_4$ salt and also, as described previously, for iron(III) from $FeCl_3$.[12] For cobalt, the monoanionic complex $[Co(dcbdt)_2]^-$ (**4**) could also be obtained directly, starting from $CoCl_2$ and oxidation by prolonged exposure to air.

All complexes were characterised by elemental analysis (C, H, N, S) and by IR and UV/Visible spectroscopy. ^1H and ^{13}C NMR spectra were also recorded, giving rise to the expected peak-intensity ratios, according to the molecular structure and stoichiometry, for compounds **2**, **6**, **7**, **8** and **10**. For the paramagnetic compounds **4**, **5** and **9**, only the peaks of the tetrabutylammonium ion could be observed.

The cyclic voltammograms of $(n\text{Bu}_4\text{N})[M(dcbdt)_2]$ (M = Au, Co, Cu, Pt) and $(n\text{Bu}_4\text{N})_2[M(dcbdt)_2]$ (M = Pd, Zn) complexes were recorded in acetonitrile with reference to Ag/AgCl. The redox potentials observed are summarised in Table 1 together with those previously reported for the Ni and Fe compounds.

At lower potentials a redox process associated with the couple $[M(dcbdt)_2]^{2-}/[M(dcbdt)_2]^-$ is usually observed. This is reversible for M = Co ($E_{1/2} = -0.20$ V), Cu ($E_{1/2} = -0.07$ V) and Pd ($E_{1/2} = 0.36$ V), quasi-reversible for Pt ($E_{1/2} = 0.06$ V, with $\Delta E = 0.13$ V) and was not observed for Zn in the range of the experiment. An irreversible reduction wave of $[M(dcbdt)_2]^-$ to $[M(dcbdt)_2]^{2-}$ is observed for Au at −1.33 V and at −0.44 V for Fe. The difference in the oxidation potentials of the different complexes explains their chemical behaviour during the synthesis: the salts of Co, Pt, Cu, Pd, Zn are obtained in their dianionic form, $[n\text{Bu}_4\text{N}]_2[M(dcbdt)_2]$, while those of iron and gold, with

very negative potentials for the process $[M(dcbdt)_2]^{2-}/[M(dcbdt)_2]^{-}$, are obtained in the monoanionic form $(n\mathrm{Bu_4N})[M(dcbdt)_2]$. The synthesis of the monoanionic complexes $(n\mathrm{Bu_4N})[M(dcbdt)_2]$ [M = Co (**4**), Pt (**9**) and Cu (**6**)] requires an additional oxidation step. The high redox potential for this process in the palladium complex explains the difficulty to obtain to the Pd^{III} species employing common oxidising agents. The platinum complex is also difficult to oxidise, in comparison with the other salts, which is consistent with the slightly positive potential presented. As previously found for $[Ni(dcbdt)_2]$,[9] the redox potentials of these dcbdt complexes are significantly higher than the corresponding ones in complexes with the more simple bdt (1,2-benzenedithiolate) ligand. This feature is a consequence of the electron-withdrawing nature of the CN groups, which stabilises the dianionic state. As an example, we found a potential of −0.07 V for $[Cu(dcbdt)_2]^{2-}/[Cu(dcbdt)_2]^{-}$ versus Ag/AgCl, while the corresponding potential for $Cu(bdt)_2$ is −0.56 V.[13] A similar difference in redox potentials is found for other metals.

At higher positive potentials, a series of complex oxidation processes with larger current waves occur, showing, in general, two superimposed waves, which can be associated with a multielectron transfer process leading to the formation of $[M(dcbdt)_2]_5^{2-}$ (Scheme 3), similar to previous observations for M = Ni.[9]

$$5[M(dcbdt)_2]^{-} \rightleftharpoons [M(dcbdt)_2]_5^{2-} + 3e^{-}$$

Scheme 3

In fact, the compounds $(n\mathrm{Bu_4N})_2[M(dcbdt)_2]_5^{2-}$ (M = Au and Ni) have already been obtained by electrocrystallisation,[9,10] and a study of similar compounds, with different transition metals, will be reported in a subsequent publication.[14]

X-ray Diffraction Studies

The crystals obtained for compounds **3**, **4**, **7**, **8** and **10** enabled their crystal structure determination by X-ray diffraction. The refinement of the crystal structures of compounds **2**, **6** and **9** was limited by a small degree of disorder affecting only the cation. The reduced diffraction power of the crystals of compound **5** allowed only the determination of the lattice parameters, which are similar to those of Pt, Pd and Co. Crystallographic data of these compounds are listed in Table 2 and 3.

The structures observed can be classified into the following four groups: *i*) the Zn^{II} compound is triclinic, $P\bar{1}$, with the metal in a tetrahedral coordination geometry; *ii*) the other M^{II} complexes (M = Pt, Pd, Co and Cu) are monoclinic, $C2/m$, and isostructural with the Ni^{II} analogue described previously,[9] presenting a perfectly square-planar geometry; *iii*) the Co^{III} compound is triclinic, $P\bar{1}$, and isostructural with the Fe[12] and Ni[9] analogues, with a strong dimerisation of the M(dcbdt)$_2$ units and the metal in a square-pyramidal coordination geometry; *iv*) the M^{III} complexes with M = Au, Cu and Pt are monoclinic, $P2_1/c$, and present the complexes as pseudo-dimers.

Among the M^{II} complexes, the crystal structures of the (nBu$_4$N)$_2$[M(dcbdt)$_2$] salts with M = Co (**3**), Pd (**7**), Pt (**8**), and Zn (**10**) were determined by X-ray diffraction and their crystallographic data are listed in Table 2. For M = Cu (**5**) only the unit-cell parameters could be obtained, monoclinic, $C2/m$, with a = 19.753 Å, b = 13.440 Å, c = 9.792 Å, β = 93.44°, indicating a structure similar to those of Pt, Pd and Co. These compounds are isostructural with (nBu$_4$N)$_2$-[Ni(dcbdt)$_2$], described previously.[9]

Figure 1 presents the ORTEP diagrams of the complex anions in compounds **3**, **4**, **6** and **10**, showing the atomic labelling scheme, which is the same in the analogous compounds **2**, **7**, **8**, **9** with different metals; selected bond lengths and angles for these compounds are presented in Table 4 and Table 5.

In compound **10**, the [Zn(dcbdt)$_2$]$^{2-}$ anion is located in a general position and the metal has a tetrahedral coordination geometry. The average Zn−S bond length (2.316 Å) is similar to those found in many other Zn^{II} bis(dithiolate) complexes.[15−17] The ligands preserve their planarity (rms atomic deviations are 0.008 and 0.011 Å) but they present a dihedral angle of 78.28°. The Zn atom is significantly deviated (0.337 Å) from the average plane of the ligand containing S1 and S2, while it is much less deviated (0.028 Å) from the average plane of the second ligand containing S3 and S4. This distortion is imposed by the crystal packing, in which the anionic complexes are well separated by the cations, as shown in Figure 2. There are several hydrogen bonds between cation and anion units but this alternating packing prevents any possible interaction between the anion units.

In compounds **3**, **7** and **8** the transition metal atom is located at an inversion centre and the [M(dcbdt)$_2$]$^{2-}$ dianion presents a perfectly planar geometry, since all atoms lie in a mirror plane. The crystal structure of these compounds is made up of [M(dcbdt)$_2$]$^{2-}$ layers containing mirror planes at y = 0 and y = 1/2. These layers are separated by cation layers, as shown in Figure 3 for M = Co, thus preventing any short anion-anion interactions.

In **4** the Co^{III} complex presents a strong dimerisation of the [Co(dcbdt)$_2$]$^-$ units that are related by an inversion centre (iv in Figure 1) located between the two cobalt atoms. In the [Co(dcbdt)$_2$]$_2^{2-}$ units, besides the equatorial Co−S bonds, with distances Co−S(1) 2.1780(13) Å, Co−S(2) 2.1902(13) Å, Co−S(3) 2.1823(12) Å and Co−S(4) 2.2000(13) Å, there are two apical Co−S(3)* bonds at 2.3638(13) Å with a Co−Co* distance of 3.1534(10) Å. This dimerisation is typical of many Co^{III} bisdithiolene complexes,[5,6,18−20] with the metal presenting a square-pyramidal coordination geometry, with a metal-over-sulfur overlap mode, equatorial Co−S distances typically in the range 2.16−2.19 Å and apical Co−S bond lengths varying

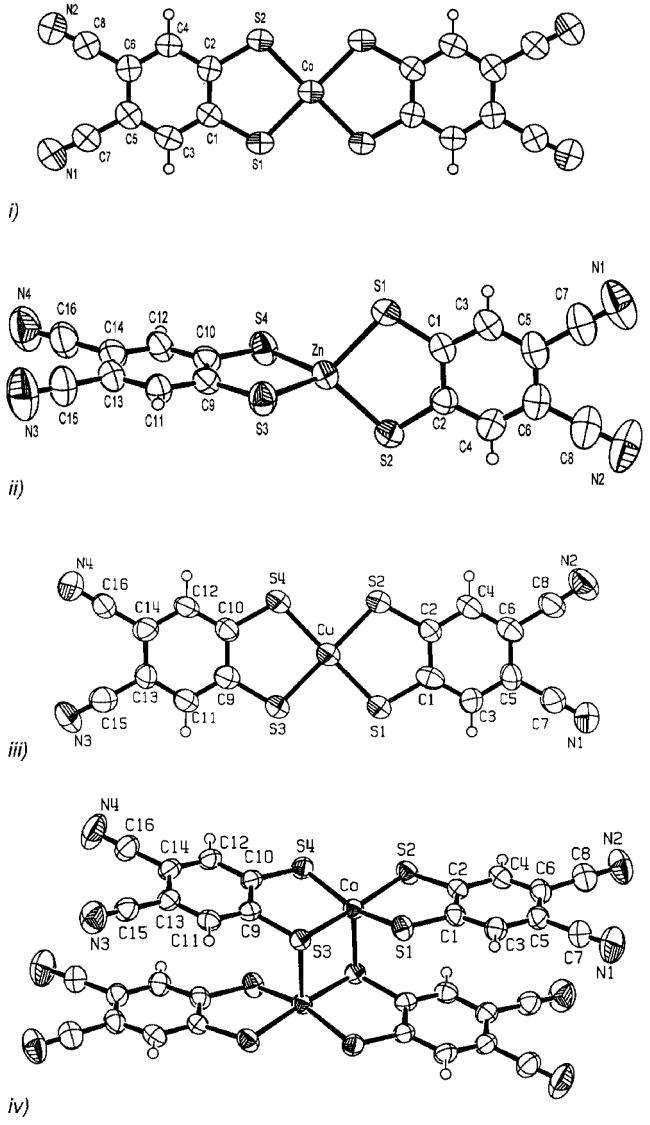

Figure 1. ORTEP diagrams: (i) $[Co(dcbdt)_2]^{2-}$ dianion in **3**, (ii) $[Zn(dcbdt)_2]^{2-}$ dianion in **10**, (iii) $[Cu(dcbdt)_2]^{-}$ monoanion in **6** and (iv) $[Co(dcbdt)_2]_2^{2-}$ in **4**; the diagrams are drawn with 50% probability thermal ellipsoids; the adopted numbering scheme is the same in isostructural compounds **2**, **7**, **8** and **9**

from 2.38 to 2.43 Å. As shown in Figure 4 (see a) the ligands are slightly distorted, repelling each other and making the distance between their mean planes larger than the central Co−S distance.

The crystal structure of **4** is identical to those of the Ni and Fe analogues previously described by us.[9,12] Along the *c* and *b* axes the dimerised anions and the cations are alternating, whereas along the *a* axis the $[Co(dcbdt)_2]_2^{2-}$ dimers are arranged in chains due to several weak interactions connecting two side-by-side $[Co(dcbdt)_2]^{-}$ units of adjacent dimers, namely the hydrogen bonds N(4)···H(4*) and N(4*)···H(4) at 2.609 Å and 156°, S(4)···H(12) at 3.248 Å and a short S(4)···S(4*) contact at 3.817 Å (see Figure 5).

In the other M^{III} complexes with M = Au (**2**), Cu (**6**) and Pt (**9**), the anions are located in a general position near the inversion centres and therefore form pseudo-dimers, as

shown in Figure 6 for **9**. The values of the M−S bond lengths in these complexes, presented in Table 5, are similar to the values published for other monoanionic bis(dithiolene) complexes. A remarkable common feature of these pseudo-dimers is that the complex units deviate only slightly from planarity in such a way that the ligands are closer than the central MS_4 atoms (Figure 4; see b for **6**, c for **2** and d for **9**). In fact, the distance between the average planes defined by the benzene rings of neighbouring complex units is about 3.43 Å, and almost the same for all three metal complexes, whereas the planes of the central MS_4 atoms within the dimer are further apart by 0.15 Å, 0.20 Å, and 0.23 Å for Cu, Pt, and Au, respectively (see Table 6). This is at variance with the strong Co, Fe and Ni dimers previously described, where there are two short M−S central bonds and a distortion of the ligands separating their extremities from each other (Figure 4, a).

The relatively short distance between the benzene rings clearly denotes the existence of a significant ligand−ligand interaction in the present complexes. In this respect it is worthwhile to mention that in **9** the overlap mode between the two closest $M(dcbdt)_2$ units is obtained by a small shift along the short axis of the complexes, leading to a more direct metal−metal interaction, while for **6** and **2** the overlap is obtained by shifts along both the long and short axes, leading to both metal−metal and metal−sulfur interactions.

It is also worthwhile to note that while along the *b* and *c* axes the dimers alternate with cations without any short

inter-dimer contacts in the *b*,*c* plane, along *a* they are connected in chains through short S2−S3* contacts at 3.692(4) Å and hydrogen bonds N2−H3* and N3−H12* at 2.628(11) Å and 2.554(11) Å, respectively, as shown in Figure 7 for **9**. The interplanar distances and the short inter- and intra-dimer distances observed for **2**, **4**, **6** and **9** are given in Table 6.

Magnetic Properties

The M^{II} complexes of Co (**3**) and Cu (**5**), as d^7 and d^9 species respectively, and the Pt^{III} (**9**) complex, as a d^7 system, are expected to be paramagnetic with one unpaired electron. The Ni^{III} and the Fe^{III} complexes were previously described as paramagnetic with $S = 1/2$.[9,12] The remaining complexes of this family presented in this paper are expected to be diamagnetic. These expectations were con-

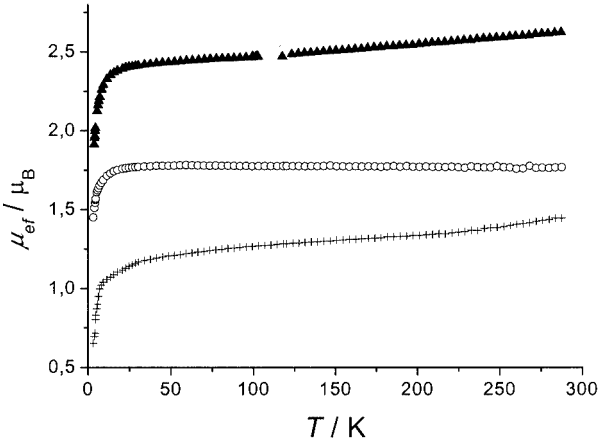

Figure 8. Effective magnetic moments as a function of temperature of $(n\mathrm{Bu_4N})_2[\mathrm{Cu(dcbdt)_2}]$ (**3**) (circles), $(n\mathrm{Bu_4N})_2[\mathrm{Co(dcbdt)_2}]$ (**4**) (triangles) and $(n\mathrm{Bu_4N})_2[\mathrm{Co(dcbdt)_2}]_2$ (**5**) (crosses)

firmed by EPR spectroscopic and static magnetic susceptibility measurements, with the exception of the $\mathrm{Co^{III}}$ complex which, as a d^6 system, seems to have a high-spin $S = 1$ configuration.

The EPR spectrum of an acetone solution of **5** at room temperature exhibits a quadruplet of lines, centred at $g = 2.045$ with an average hyperfine field constant of, a_o, of 80.8 G, due to the hyperfine interaction of the electron spin with the nuclear $I = 3/2$ spin of the copper nuclides. The powder EPR spectrum presents a pattern typical of a system with axial symmetry ($g_{\|} = 2.082$ and $g_{\perp} = 2.024$).

The static paramagnetic susceptibility, χ_P, of **5**, calculated from raw data assuming a diamagnetic contribution of -6.14×10^{-4} emu/mol, as estimated from tabulated Pascal constants, leads to an effective magnetic moment, $\mu_{eff.}$, of 1.77 μ_B. As shown in Figure 8, this value remains fairly constant above 20 K, (Figure 8) and is very close to the one

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

expected for an $S = 1/2$ system with $g = 2$. Below 20 K there is a reduction of μ_{eff}, denoting the presence of minor antiferromagnetic interactions.

Single crystals of $(n\mathrm{Bu_4N})_2[\mathrm{Co(dcbdt)_2}]$ (**3**) at room temperature present a complex EPR signal of an octet of lines with variable separation, depending on the crystal orientation (Figure 9). This type of spectra is typical of the hyperfine structure due to the $I = 7/2$ spin of ^{59}Co.[21−23] However this hyperfine structure is observed only for particular orientations and the signal presents a strong g-factor anisotropy.

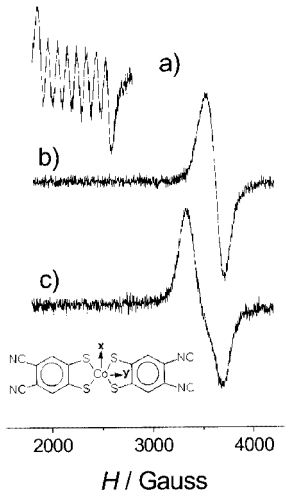

Figure 9. EPR spectra of a single crystal of $(n\mathrm{Bu_4N})_2[\mathrm{Co(dcbdt)_2}]$ (**4**) at 300 K, with the magnetic field in the b,c plane for two orientations 90° apart: a) along the long axis of the complex, b) along the short axis in the plane of the complex, c) perpendicular to the plane of the complex

A study of the EPR spectra with oriented single crystals allowed us to deduce an almost uniaxial rhombic anisotropy related to the symmetry axes of the complex as well as the anisotropy of the hyperfine tensor a_0. The principal axes of the a_0- and g-tensors are expected to coincide. As previously discussed in the crystallographic section, the Co^{II} complex is planar and lies parallel to the a,c plane, with the long axis making an angle of approximately 29° with a. The narrowest signal, with an apparent single EPR line with a peak-to-peak width of 14.6 mT, and the minimum g value at $g_x = 1.936$ is observed when the magnetic field is along the short axis in the plane of the complex (Figure 9, a). Along this direction the hyperfine coupling constant is negligible ($A_x < 2$ mT).

When the magnetic field is along the long axis in the plane of the complex, the maximum width is observed in the EPR signal that presents an octet extending over 73.4 mT and centred at $g_y = 3.156$ (Figure 9, a). Deviations of ±40° from this g_{max} orientation still present an octet with negligible extent variations of only ±1 mT. An octet is observed over all this angular range, corresponding to a hyperfine coupling constant, A_y, of 9.2 mT.

An intermediate situation is observed when the magnetic field is perpendicular to the plane of the complex (along the b axis). For this orientation an EPR signal with no resolved octet but well-separated maxima and minima, corresponding to a linewidth of 35.7 mT, is observed centred at $g_z = 1.994$. This suggests a small hyperfine component for this direction of $A_z = 4.5$ mT.

To the best of our knowledge this is the first example of a pure Co compound in which hyperfine structure is observed in the solid state. The hyperfine structure can be observed without the interference of significant dipolar interactions thanks to the large separation of the complexes in the structure, where the closest Co−Co distance is 9.76 Å along c, without any contact between the anions, and 12.4 Å between different layers separated by the cations. A detailed analysis of the observed anisotropy in the A and g-tensors in terms of the metal and ligand orbitals involved in the SOMO will be the subject of a subsequent publication.

The static paramagnetic susceptibility of **3** leads, in a similar way, to an effective magnetic moment, μ_{eff}, significantly larger than that of the Cu analogue (Figure 8). At room temperature μ_{eff} is about 2.55 μ_B, which decreases almost linearly with temperature upon cooling to 2.40 μ_B at 20 K. Below this temperature a more drastic reduction of μ_{eff} is observed. This larger magnetic moment is in fair agreement with the larger average g-value observed in the EPR spectrum, since for $g = 2.82$ and $S = 1/2$ a μ_{eff} value of 2.44 μ_B is expected. The small linear decrease of the effective moment observed between room temperature and 20 K most probably denotes the presence of a non-negligible temperature-independent paramagnetism.

Compound **9** is EPR silent at room temperature, as is also the case for the Ni and Fe analogues. Below 110 K a signal starts to appear, as shown in Figure 10 for a powder at 60 K. This signal can be described as coming from a doublet $S = 1/2$ state showing rhombic anisotropy with $g_x = 2.246$, $g_y = 2.054$ and $g_z = 1.785$. The more intense lines correspond to $I = 0$ platinum isotopes (66.2% natural

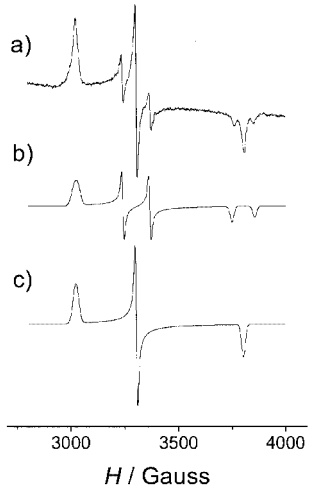

Figure 10. Experimental EPR spectra of $(n\mathrm{Bu_4N})[\mathrm{Pt(dcbdt)_2}]$ (**9**) as a polycrystalline sample at 60 K: (a) simulated spectra for 33.8% natural abundance of ^{195}Pt isotope with $I = 1/2$, and $A_x = 0$ mT, $A_y = 13$ mT and $A_z = 9.3$ mT (b), and 66.2% of Pt isotopes with $I = 0$ (c), both with $g_x = 2.246$, $g_y = 2.054$, $g_z = 1.785$

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

abundance), and the satellites around the medium- and high-field components are due to the 33.8% natural abundance of the ^{195}Pt isotope with $I = 1/2$. The anisotropic hyperfine coupling tensor has $A_x < 4$ mT (the satellites are not resolved for this component), $A_y = 13$ mT and $A_z = 9.3$ mT. Assuming a situation similar to $Pt(mnt)_2^-$, and the same coordinate system,[24] x is the shortest axis in the plane of the complex, y the longest and z is normal to the plane of the complex.

As, in this compound, the magnetic susceptibility follows a single-triplet model due to the dimerisation of $[Pt(dcbdt)_2]^-$, we looked for a possible signature of the $S = 1$ state in the EPR spectrum. The half-field signal corresponding to the forbidden $\Delta M_S = 2$ transition, was only visible at 4.2 K as a weak signal. Other signals coming from the triplet $S = 1$ state, if existing, are obscured by the spectrum of the doublet state described above.

The observation of an EPR signal of the triplet state in metal complexes is, in general rare, and most dimerised complexes are EPR silent, as reported for $(n\mathrm{Bu_4N})[Ni(dcbdt)_2]$[9] and $(n\mathrm{Bu_4N})[Fe(dcbdt)_2]$;[12] the number of Pt^{III} complexes studied by EPR spectroscopy is small. The $[Pt(dmit)_2]^-$ species, which is isolated and undimerised, presents a smaller g anisotropy than the present compound, with a hyperfine coupling being detected.[25] $[Pt(mnt)_2]^-$, also an undimerised species, studied by Kirmse et al. as a diluted paramagnetic centre in a diamagnetic host, shows a large anisotropy of the hyperfine coupling tensor, with $A_x = 0$.[24] In the *cis*-diammineplatinum α-pyridone complex, a mixed-valence compound, there is dimer formation, with the Pt−Pt distance of 2.7745 Å, much shorter than in **9**. No hyperfine interactions were observed in the single-crystal spectrum.[26]

The paramagnetic susceptibility of **9**, calculated after a correction for diamagnetism estimated from tabulated Pascal's constants as -4.3×10^{-4} emu/mol, is quite similar to that of the Ni analogue (Figure 11). At room temperature the paramagnetic susceptibility is 3.6×10^{-4} emu/mol, and it decreases upon cooling to about 100 K, where it reaches a minimum. At lower temperatures the magnetic susceptibility becomes dominated by a Curie tail of impurities or defects and increases again. The EPR spectra suggest that these impurities are defects of undimerised $Pt(dcbdt)_2^-$ units. Taking into account the structure with dimers of paramagnetic $Pt(dcbdt)_2^-$ units, this behaviour can be described by a singlet-triplet model of antiferromagnetically coupled $S = 1/2$ dimers[27] and a low-temperature Curie tail, [Equation (1)], as previously done in the case of the Ni and Fe compounds.[9,12]

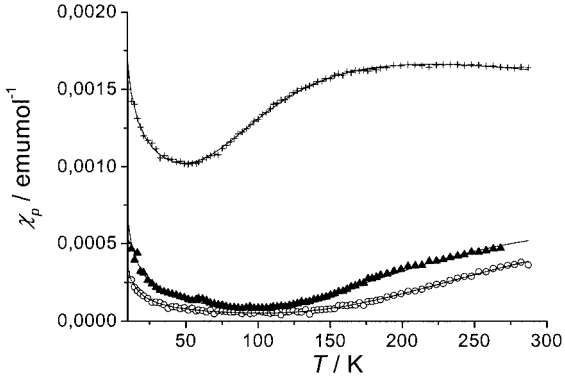

Figure 11. Magnetic susceptibility of $(n\mathrm{Bu_4N})[Pt(dcbdt)_2]$ (**9**) (circles), $(n\mathrm{Bu_4N})[Fe(dcbdt)_2]$ (squares)[12] and $(n\mathrm{Bu_4N})[Ni(dcbdt)_2]$ (triangles),[9] as a function of temperature; the line is a fit to Equation (1)

$$\chi_P = A + C/T + (Ng^2\mu_B^2/k_BT)[\exp(-2J/k_BT) + 3]^{-1} \quad (1)$$

A reasonable fit to Equation (1) was obtained with $J = 984$ K, $g = 2.9$, $A = 4 \times 10^{-5}$ emu/mol and a Curie tail corresponding to 1.5% of $S = 1/2$ spins. This g-value is certainly unrealistic because it is significantly larger than the highest g-value observed in the EPR spectra. This disagreement is probably due to the rather low temperature range of the experimental susceptibility data (when compared with the J value), which is inappropriate to obtain accurate fitting parameters.

Many Co^{III} bis(dithiolene) complexes are diamagnetic, but with some ligands, namely substituted benzodithiolates, high-spin $S = 1$ configurations are known.[13] The $[Co^{III}(dcbdt)_2]_2^{2-}$ compound (**5**) was found to be paramagnetic and its effective magnetic moment is also plotted in Figure 8 as a function of temperature. This paramagnetic behaviour demonstrates that the $[Co^{III}(dcbdt)_2]^-$ anions are in a high-spin $S = 1$ configuration. The effective magnetic moment observed is, however, significantly lower than the $S = 1$ value, demonstrating the presence of strong antiferromagnetic interactions. In spite of the crystal structure, with $[Co^{III}(dcbdt)_2]^-$ anions as dimers, packed side by side along a, the magnetisation data could not be fitted to any dimer or alternating-chain model.

Conclusion

In conclusion we have prepared and characterised several new members of the series of complexes $M(dcbdt)_2$ with different transition metals. These complexes are characterised by relatively low oxidation potentials, due to the extended nature of the ligands, and, as already described for M = Ni and Au, are expected to lead easily to partially oxidised, potentially electrically conducting. The Co^{II} complex is the first example of a pure Co compound in which hyperfine structure is observed in the solid state; the Co^{III} complex presents a high-spin configuration. The fuller use of these complexes in the preparation of conducting or magnetic molecular materials is presently under way.

Experimental Section

General: DMF, acetonitrile and dichloromethane were distilled from over phosphorus pentoxide and benzene was distilled from over sodium. Other chemicals were commercially obtained and

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

used without any further purification. 4,5-Dicyanobenzene-1,2-dithiol (**1**) was synthesised as described previously.[9] Elemental analyses were performed by the analytical services of IST and ITN. ^{1}H and ^{13}C NMR: Varian (300 MHz), [D$_6$]DMSO as solvent, and TMS as internal standard. IR: Perkin-Elmer 1330 spectrophotometer. VIS-UV-NIR: Cary 5G Varian spectrophotometer. Cyclic voltammetry data were obtained using a CV-50 W BAS Voltammetric Analyser. The measurements were performed at room temperature in acetonitrile solutions containing nBu$_4$ClO$_4$ as supporting electrolyte, with a scan rate of 100 mV/s, platinum working- and counter- electrodes and using a Ag/AgCl reference electrode.

EPR spectra in the range 4−300 K were obtained with an X-Band Bruker ESP 300E spectrometer equipped with a microwave bridge ER041XK, a rectangular cavity operating in T102 mode, a Bruker variable-temperature unit, an Oxford ESR-900 cryostat and a field controller ER 032M system. The modulation amplitude was kept well below the linewidth and the microwave power well below saturation.

Magnetic susceptibility measurements in the range 2−300 K were performed using a longitudinal Faraday system (Oxford Instruments) with a 7 T superconducting magnet, under a magnetic field of 5 T and forward- and reverse-field gradients of 1 T/m. Polycrystalline samples (10−15 mg) were placed inside a previously calibrated thin wall Teflon bucket. The force was measured with a microbalance (Sartorius S3D-V). Under these conditions the magnetisation was found to be proportional to the applied magnetic field.

Tetrabutylammonium Salt of Gold(III) Bis(4,5-dicyanobenzene-1,2-dithiolate) (nBu$_4$N)[Au(dcbdt)$_2$] (2): Compound **1** (0.2 g, 1.04 mmol) was dissolved in 5 mL of aqueous NaOH (5%). A solution of nBu$_4$NBr (0.17 g, 0.52 mmol) in EtOH/H$_2$O (1:1; 5 mL) was added, followed by a solution of KAuCl$_4$ (0.22 g, 0.52 mmol) in the same solvent. The mixture was stirred and a green precipitate was formed almost immediately. The solution was filtered and the precipitate was washed with EtOH. The crude material was recrystallised from acetone/iBuOH to give **2** as light-green needles (0.1 g, 1.2 mmol, 25%). M.p. 249−250 °C. ^{1}H NMR (300 MHz, [D$_2$]DCM, 25 °C, TMS): δ = 1.00 (t, J = 8.4 Hz, 12 H, CH$_3$), 1.41 (m, 8 H, CH$_2$), 1.59 (m, 8 H, CH$_2$), 3.07 (t, J = 7.2 Hz, 8 H, CH$_2$), 7.50 (s, 4 H, Ar−H) ppm. ^{13}C NMR (300 MHz, [D$_2$]DCM, 25 °C, TMS): δ = 13.77, 20.09, 24.26, 59.57, 113.77, 116.80, 132.98, 143.24) ppm. IR (KBr pellet): $\tilde{\nu}$ = 3060 (w, Ar−H), 2960−2860 (m, C−H), 2220 (s, C≡N), 1550 (w, C=C), 350 (w, S−Au) cm^{-1}. UV/Vis (CH$_2$Cl$_2$): λ_{max} (ε) = 264.2 (8500), 304.3 (34800), 367.6 (3300 mol^{-1} dm^3 cm^{-1}). C$_{32}$H$_{40}$AuN$_5$S$_4$ (820.02): calcd. C 46.87, H 4.93, N 8.54, S 15.64; found C 47.09, H 4.86, N 8.33, S 15.56.

Tetrabutylammonium Salt of Cobalt(II) Bis(4,5-dicyanobenzene-1,2-dithiolate) (nBu$_4$N)$_2$[Co(dcbdt)$_2$] (3): Compound **1** (0.48 g, 2.50 mmol) was dissolved in 5 mL of aqueous NaOH (5%). A solution of nBu$_4$NBr (0.80 g, 2.50 mmol) in EtOH/H$_2$O (1:1; 5 mL) was added, followed by a solution of CoCl$_2$·6H$_2$O (0.30 g, 1.26 mmol) in the same solvent. The mixture was stirred and a dark-blue precipitate was formed almost immediately. The solution was filtered and the precipitate was washed with EtOH. The crude material was recrystallised from acetone/iBuOH to give **3** as dark-blue crystals (0.64 g, 0.693 mmol, 55%). M.p. 254−255 C. IR (KBr pellet): $\tilde{\nu}$ = 3060 (w, Ar−H), 2960−2860 (m, C−H), 2220 (s, C≡N), 1550 (w, C=C), 530 (w, S−Co) cm^{-1}. UV/Vis (CH$_2$Cl$_2$): λ_{max} (ε) = 293.1 (91300), 322.0 (72600), 364.3 (41700), 589.0 (6700), 645.1 nm (17800 mol^{-1} dm^3 cm^{-1}). C$_{48}$H$_{76}$CoN$_6$S$_4$ (924.34): calcd. C 62.37, H 8.28, N 9.09, S 13.87; found C 61.10, H 8.13, N 9.42, S 14.94.

Tetrabutylammonium Salt of Cobalt(III) Bis(4,5-dicyanobenzene-1,2-dithiolate) (nBu$_4$N)[Co(dcbdt)$_2$] (4): A solution of I$_2$ (47.7 mg, 0.18 mmol) in acetone was added to a solution of **3** (0.17 g, 0.18 mmol) in acetone (50 mL). The solution was stirred until a colour change to dark green was observed. Ethanol was added and the solution was slowly evaporated to give **4** as dark-green needles (54.5 mg, 0.08 mmol, 46%). This compound can be also prepared directly from the ligand and CoCl$_2$ in the presence of air as follows: Compound **1** (0.17 g, 0.89 mmol) was dissolved in 5 mL of aqueous NaOH (5%). A solution of nBu$_4$NBr (0.14 g, 0.44 mmol) in EtOH/H$_2$O (1:1) (5 mL) was added, followed by a solution of CoCl$_2$·6H$_2$O (0.11 g, 0.44 mmol) in the same solvent. The mixture was stirred for 2 hours while a dark green precipitate was formed. The solution was filtered and the precipitate was washed with EtOH. The crude material was recrystallised from EtOH to give **4** as black/green crystals (77.3 mg, 0.11 mmol, 26%). M.p. 288−289 °C. ^{1}H NMR (300 MHz, [D$_6$]DMSO, TMS): δ = 0.90 (s, 12 H, CH$_3$), 1.27 (m, 8 H, CH$_2$), 1.49 (m, 8 H, CH$_2$), 3.08 (s, 8 H, CH$_2$) ppm. ^{13}C NMR (300 MHz, [D$_6$]DMSO, TMS): δ = 18.52, 24.21, 28.03, 62.50) ppm. IR (KBr pellet): $\tilde{\nu}$ = 3060 (w, Ar−H), 2980−2880 (m, C−H), 2220 (s, C≡N), 1560 (w, C=C), 430 (w, S−Co) cm^{-1}. UV/Vis (CH$_2$Cl$_2$): λ (ε) = 285.3 nm (8100 mol^{-1} dm^3 cm^{-1}), 318.0 (7000), 364.0 (4300), 411.9 (2100), 645.0 (1500). C$_{32}$H$_{40}$CoN$_5$S$_4$ (681.87): calcd. C 56.35, H 5.93, N 10.28, S 18.83; found C 57.23, H 6.22, N 10.25, S 18.84.

Tetrabutylammonium Salt of Copper(II) Bis(4,5-dicyanobenzene-1,2-dithiolate) (nBu$_4$N)$_2$[Cu(dcbdt)$_2$] (5): Compound **1** (0.30 g, 1.56 mmol) was dissolved in 5 mL of aqueous NaOH (5%). A solution of nBu$_4$NBr (0.51 g, 1.56 mmol) in EtOH/H$_2$O (1:1; 5 mL) was added, followed by a solution of CuCl$_2$·2H$_2$O (0.13 g, 0.78 mmol) in the same solvent. The mixture was stirred and a brown precipitate was formed almost immediately. The solution was filtered and the precipitate was washed with EtOH. The crude material was recrystallised from acetone to give **5** as brown needles (0.19 g, 0.20 mmol, 26%). M.p. 243−245 °C. ^{1}H NMR (300 MHz, [D$_6$]DMSO, 25 °C, TMS): δ = 0.99 (s, 24 H, CH$_3$), 1.48 (m, 16 H, CH$_2$), 1.86 (m, 16 H, CH$_2$), 3.59 (m, 16 H, CH$_2$) ppm. ^{13}C NMR (300 MHz, [D$_6$]DMSO, 25 °C, TMS): δ = 15.32, 20.55, 24.55, 50.49 ppm. IR (KBr pellet): $\tilde{\nu}$ = 3060 (w, Ar−H), 2960−2860 (m, C−H), 2220 (s, C≡N), 1540 (w, C=C), 430 (w, S−Cu) cm^{-1}. UV/Vis (CH$_2$Cl$_2$): λ (ε) = 320.1 nm (72500 mol^{-1} dm^3 cm^{-1}), 386.5 (18800). C$_{48}$H$_{76}$CuN$_6$S$_4$ (928.95): calcd. C 62.05, H 8.26, N 9.05, S 13.81; found C 61.74, H 7.98, N 8.90, S 14.13.

Tetrabutylammonium Salt of Copper(III) Bis(4,5-dicyanobenzene-1,2-dithiolate) (nBu$_4$N)[Cu(dcbdt)$_2$] (6): A solution of I$_2$ (51.9 mg, 0.20 mmol) in acetone was added to a solution of **5** (0.17 g, 0.18 mmol) in acetone (50 mL). The solution was stirred until a colour change to green was observed. Ethanol was added and the solution was slowly evaporated to give **6** as dark-green needles (90.2 mg, 0.13 mmol, 64%). M.p. 233−234 °C. ^{1}H NMR (300 MHz, [D$_6$]acetone, 25 °C, TMS): δ = 0.98 (t, J = 7.2 Hz, 12 H, CH$_3$), 1.44 (m, 8 H, CH$_2$), 1.84 (m, 8 H, CH$_2$), 3.45 (t, J = 8.6 Hz, 8 H, CH$_2$), 7.51 (s, 4 H, Ar−H) ppm. ^{13}C NMR (300 MHz, [D$_6$]acetone, 25 °C, TMS): δ = 13.91, 20.41, 24.44, 59.39, 114.22, 126.73, 131.33, 143.73 ppm. IR (KBr pellet): $\tilde{\nu}$ = 3060 (w, Ar−H), 2980−2880 (m, C−H), 2220 (s, C≡N), 1510 (s, C=C), 420 (w, S−Cu) cm^{-1}. UV/Vis (CH$_2$Cl$_2$): λ (ε) = 300.1 nm (137600), 395.0 (58200 mol^{-1} dm^3 cm^{-1}). C$_{32}$H$_{40}$CuN$_5$S$_4$ (686.49): calcd. C 55.99, H 5.87, N 10.20, S 18.68; found C 55.03, H 6.47, N 9.91, S 19.19.

Tetrabutylammonium Salt of Palladium(II) Bis(4,5-dicyanobenzene-1,2-dithiolate) (nBu$_4$N)$_2$[Pd(dcbdt)$_2$] (7): Compound **1** (0.41 g, 2.13 mmol) was dissolved in 5 mL of aqueous NaOH (5%). A solu-

tion of nBu$_4$NBr (0.70 g, 2.17 mmol) in EtOH/H$_2$O (1:1; 5 mL) was added, followed by a solution of K_2PdCl_4 (0.33 g, 1.01 mmol) in the same solvent. The mixture was stirred and an orange precipitate was formed almost immediately. The solution was filtered and the precipitate was washed with EtOH. The crude material was recrystallised from acetone/iBuOH to give **7** as red crystals (0.62 g, 0.64 mmol, 63%). M.p. 263−264 °C. ^{1}H NMR (300 MHz, [D$_6$]DMSO, 25 °C, TMS): δ = 0.93 (t, J = 7.2 Hz, 24 H, CH$_3$), 1.31 (m, 16 H, CH$_2$), 1.56 (m, 16 H, CH$_2$), 3.32 (t, J = 6.0 Hz, 16 H, CH$_2$), 7.28 (s, 4 H, Ar−H) ppm. ^{13}C NMR (300 MHz, [D$_6$]DMSO, 25 °C, TMS): δ = 14.17, 19.88, 23.74, 58.24, 96.41, 116.02, 131.49 ppm. IR (KBr pellet): ν̃ = 3060 (w, Ar−H), 2980−2840 (m, C−H), 2200 (s, C≡N), 1530 (m, C=C), 430 (w, S−Pd) cm^{-1}. UV/Vis (CH$_2$Cl$_2$): λ_{max} (ε) = 300.7 nm (53800), 345.0 (72300), 425.2 (13800 mol^{-1} dm^3 cm^{-1}). $C_{48}H_{76}N_6PdS_4$ (971.81): calcd. C 59.32, H 7.88, N 8.64, S 13.20; found C 58.51, H 8.11, N 8.86, S 13.05.

Tetrabutylammonium Salt of Platinum(II) Bis(4,5-dicyanobenzene-1,2-dithiolate) (nBu$_4$N)$_2$[Pt(dcbdt)$_2$] (8): Compound **1** (0.28 g, 1.46 mmol) was dissolved in 5 mL of aqueous NaOH (5%). A solution of nBu$_4$NBr (0.47 g, 1.46 mmol) in EtOH/H$_2$O (1:1; 5 mL) was added, followed by a solution of K_2PtCl_4 (0.52 g, 1.25 mmol) in the same solvent. The mixture was stirred and a red precipitate was formed almost immediately. The solution was filtered and the precipitate was washed with EtOH. The crude material was recrystallised from acetone/iBuOH to give **8** as red crystals (0.38 g, 0.36 mmol, 35%). M.p. 270−271 °C. ^{1}H NMR (300 MHz, [D$_2$]DCM, 25 °C, TMS): δ = 0.92 (t, J = 5.3 Hz, 24 H, CH$_3$), 1.28 (m, 16 H, CH$_2$), 1.53 (m, 16 H, CH$_2$), 3.15 (s, 16 H, CH$_2$), 7.36 (s, 4 H, Ar−H) ppm. ^{13}C NMR (300 MHz, [D$_2$]DCM, 25 °C, TMS): δ = 12.13, 17.85, 21.73, 56.17, 96.74, 111.48, 130.20, 143.11 ppm. IR (KBr pellet): ν̃ = 3060 (w, Ar−H), 2960−2860 (m, C−H), 2210 (s, C≡N), 1525 (m, C=C), 530 (m, S−Pt) cm^{-1}. UV/Vis (CH$_2$Cl$_2$): λ_{max} (ε) = 230.4 nm (42400), 279.0 (38300), 382.3 (31900), 449.8 (7800 mol^{-1} dm^3 cm^{-1}). $C_{48}H_{76}N_6PtS_4$ (1060.50): calcd. C 54.36, H 7.22, N 7.92, S 12.09; found C 55.73, H 7.61, N 8.12, S 12.74.

Tetrabutylammonium Salt of Platinum(III) Bis(4,5-dicyanobenzene-1,2-dithiolate) (nBu$_4$N)[Pt(dcbdt)$_2$] (9): A solution of I$_2$ (45.0 mg, 0.18 mmol) in acetone was added to a solution of **8** (0.38 g, 0.36 mmol) in acetone (100 mL). The solution was stirred until a colour change to green was observed. Ethanol was added and the solution was slowly evaporated to give **9** as dark-green needles (99.0 mg, 0.12 mmol, 33%). M.p. 250−251 °C. ^{1}H NMR (300 MHz, [D$_2$]DCM, 25 °C, TMS): δ = 0.94 (t, J = 7.1 Hz, 12 H, CH$_3$), 1.32 (m, 8 H, CH$_2$), 1.58 (m, 8 H, CH$_2$), 3.18 (s, 8 H, CH$_2$) ppm. ^{13}C NMR (300 MHz, [D$_2$]DCM, 25 °C, TMS): δ = 13.39, 18.89, 23.54, 53.79 ppm. IR (KBr pellet): ν̃ = 3060 (w, Ar−H), 2960−2860 (m, C−H), 2220 (s, C≡N), 1550 (w, C=C), 420 (w, S−Pt) cm^{-1}. UV/Vis (CH$_2$Cl$_2$): λ_{max} (ε) = 280.2 (80600), 347.1 nm (20400 mol^{-1} dm^3 cm^{-1}). $C_{32}H_{40}N_5PtS_4$ (818.03): calcd. C 46.98, H 4.94, N 8.56, S 15.68; found C 48.40, H 4.91, N 8.48, S 15.14.

Tetrabutylammonium Salt of Zinc(II) Bis(4,5-dicyanobenzene-1,2-dithiolate) (nBu$_4$N)$_2$[Zn(dcbdt)$_2$] (10): Compound **1** (0.14 g, 0.73 mmol) was dissolved in 5 mL of aqueous NaOH (10%). A solution of nBu$_4$NI (0.26 g, 0.73 mmol) in EtOH/H$_2$O (1:1; 5 mL) was added, followed by a solution of $ZnCl_2$ (0.05 g, 0.36 mmol) in the same solvent. The mixture was stirred and an orange precipitate was formed almost immediately. The solution was filtered and the precipitate was washed with EtOH. The crude material was recrystallised from acetonitrile/iBuOH to give **10** as orange crystals (0.22 g, 0.24 mmol, 65%). M.p. 205−206 °C. ^{1}H NMR (300 MHz, [D$_6$]acetone, 25 °C, TMS): δ = 0.96 (t, J = 7.4 Hz, 24 H, CH$_3$), 1.41 (m, 16 H, CH$_2$), 1.76 (m, 16 H, CH$_2$), 3.39 (m, 16 H, CH$_2$), 7.69 (s, 4 H, Ar−H) ppm. ^{13}C NMR (300 MHz, [D$_6$]acetone, 25 °C TMS): δ = 13.83, 20.31, 24.43, 59.36, 104.15, 114.02, 118.46, 132.88 ppm. IR (KBr pellet): ν̃ = 3040−3090 (w, Ar−H), 2960−2860 (m, C−H), 2240 (s, C≡N), 1540 (s, C=C), 420 (w, S−Zn) cm^{-1}. UV/Vis (CH$_2$Cl$_2$): λ_{max} (ε) = 310.3 (43400), 385.5 nm (20500 mol^{-1} dm^3 cm^{-1}). $C_{48}H_{76}N_6S_4Zn$ (930.79): calcd. C 61.94, H 8.23, N 9.03, S 13.78; found C 61.87, H 8.92, N 2.3, S 13.78.

X-ray Crystallographic Study: All diffraction measurements were made at room temperature with the crystals mounted in a glass capillary. An Enraf−Nonius TURBO CAD4 diffractometer equipped with graphite monochromated Cu-K_α radiation (λ = 1.5418 Å) was used for measurements of compounds **3** and **6**. All the other crystals were measured on an Enraf−Nonius CAD4 diffractometer using graphite-monochromated Mo-K_α radiation (λ = 0.71069 Å) in the ω-2θ scan mode. Lorentz, polarisation effects and empirical absorption correction based on psi-scan were applied to the collected intensities. The structures were solved by direct methods using SIR97[28] and refined by full-matrix least-squares methods using the program SHELXL-97[29] and the winGX software package.[30] All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were placed in calculated positions. In the compound (nBu$_4$N)[Cu(dcbdt)$_2$] (**6**) the cation unit was found to be disordered and was refined over two positions with occupancy factors of 0.608 and 0.392, respectively. The cation disorder of compounds **2** and **9** could not be fitted by any model. Molecular graphics were prepared with ORTEP3[31] and SCHAKAL-97.[32] Crystal data and structure refinement details are summarised in Table 1 and Table 2.

CCDC-213103, -213104, -213105, -213106, -213107, -213108, -213109 and -213110 for compounds **2**, **4**, **6**, **9**, **3**, **7**, **8** and **10**, respectively, contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Aminomethyl and Aminoacetyl Complexes of Palladium(II), Platinum(II), Iron(II) and Rhenium(I) with *N*-Phthaloyl as Amino Protecting Group and Mechanistic Studies on the Palladium-Catalyzed Amidocarbonylation

Armin Enzmann,[a] Markus Eckert,[b] Walter Ponikwar,[a][‡] Kurt Polborn,[a][‡] Stefan Schneiderbauer,[a][‡] Matthias Beller,*[b] and Wolfgang Beck*[a]

Dedicated to Dr. Hachiro Wakamatsu

Keywords: Amidocarbonylation / Iron / Palladium / Platinum / Rhenium

New aminomethyl and aminoacetyl complexes with *N*-phthaloyl as the amino protecting group were synthesised by oxidative addition of *N*-phthaloylmethyl or -acetyl halide to carbonylmetallates or to $Pd(PPh_3)_4$ or $[Pt(C_2H_4)(PPh_3)_2]$ to give $[Re\{C(O)CH_2N\text{-phthaloyl}\}(CO)_5]$ (**1**), $[FeCp(CH_2N\text{-phthaloyl})(CO)_2]$ (**2**), $[FeCp\{C(O)CH_2N\text{-phthaloyl}\}(CO)_2]$ (**3**), *trans*-$[PdBr(CH_2N\text{-phthaloyl})(PPh_3)_2]$ (**4**) and *trans*-$[Pd\{C(O)CH_2N\text{-phthaloyl}\}(X)(PPh_3)_2]$ (X = Br, Cl; **5**, **6**). The bis(phosphane) complexes $[Pd(CH_2N\text{-phthaloyl})(X)(R_2PCH_2CH_2PR_2)]$ and $[Pd\{C(O)CH_2N\text{-phthaloyl}\}(X)(R_2PCH_2CH_2PR_2)]$ (X = Cl, Br; R = Ph, C_6H_{11}) **8**–**13** were obtained by ligand exchange from **4**, **5** or **6** with the corresponding bis(phosphanes). Halide abstraction from **4**, **5**, **6**, **10**, **11** or **12** gives the cationic complexes **14** and **15** with formation of a five-membered chelate ring which includes one carbonyl atom of the phthaloyl group. The reaction of **6** with the tridentate ligand $PhP(CH_2CH_2PPh_2)_2$ affords the five-coordinate complex **16** and from $[Pt(C_2H_4)(PPh_3)_2]$ and organic halides the platinum(II) complexes *trans*-$[Pt(CH_2N\text{-phthaloyl})(Cl)(PPh_3)_2]$ (**17**) and $[PtC(O)CH(CH_2Ph)N\text{-phthaloyl}(Cl)(PPh_3)_2]$ (**18**) were isolated. The structures of **2**, **11**, **14**, **15** and **16** were determined by single-crystal X-ray analysis. The mechanism of the palladium-catalysed amidocarbonylation was studied using phthalimide, formaldehyde and CO as a model system which gives *N*-phthaloylglycine in good yield. The proposed elementary steps in the palladium-catalysed amidocarbonylation could be verified by use of the possible intermediates phthaloyl-NCH_2OH and phthaloyl-NCH_2Br as substrates, by oxidative addition of phthaloylmethyl bromide to Pd^0, by insertion of CO into the palladium-carbon-bond of **4** and **8** with formation of **5** or **9**, respectively, and by use of the isolated possible intermediates **4**, **5** and **14** as catalysts. Thus, all crucial steps of the palladium-catalysed amidocarbonylation with the model system phthalimide/formaldehyde/CO have been verified for the first time.

Introduction

Aminomethyl and aminoacyl complexes are possible intermediates in the metal-catalysed amidocarbonylation, i.e. the formation of α-amino acids from aldehydes, amide and carbon monoxide. This three component reaction was discovered by Wakamatsu et al.[1] using octacarbonyldicobalt as a catalyst and was more recently developed into a highly efficient process with palladium catalysts.[2] Here we report on the synthesis of new aminomethyl and aminoacetyl metal complexes with *N*-phthaloyl as the *N*-protecting group,[3] on their role and use as catalysts in amidocarbonylation reactions and on experiments which support the mechanism of the palladium-catalysed amidocarbonylation.

Several η^1- and η^2- (side-on) coordinated aminomethyl complexes are formed from methylene immonium salts $[H_2C{=}NR_2]^+ X^-$ and organometallic compounds.[4] η^1-Aminomethyl complexes of cobaloxime result from the reduced form of bis(dimethylglyoximato)cobalt(II), formaldehyde and aniline.[5] An interesting formation of η^2-$(CHR\text{-}NH_2)$ metal complexes is the photochemical decarboxylation of α-aminocarboxylatocobalt(III) complexes.[6] The insertion of imines into the palladium−acyl bond gives *N*-acyl-aminomethyl chelate complexes, a reaction which may provide a route for the palladium-catalysed formation of polypeptides.[7] Metalated α-amino acid derivatives of

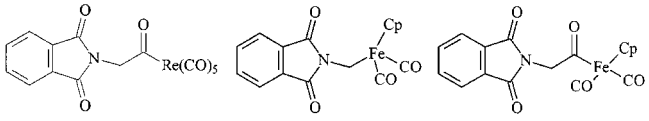
nickel,[8] palladium[7] and manganese[9] of the form L_nM-$C(O)CR_2$-N(*R*)-C(O)R have also been obtained by sequential insertion of carbon monoxide and imine into metal-carbon σ-bonds,[7−9] and recently an interesting palladium-catalysed synthesis of Münchnones (1,3-oxazolium 5-oxides, first isolated by Huisgen et al.[10]) and of α-amino acid derivatives from imines, CO and acyl chloride building blocks has been developed.[11] Its mechanism is similar to that of amidocarbonylation. Rhodium complexes with *N*-protected aminomethyl ligands have been prepared from $[RhCp(CH_2I)(I)(PMe_3)]$ and amides.[12] A general method for the preparation of η^1-aminomethyl and -aminoacetyl complexes with a protected amino group is the reaction of anionic organometallic compounds [Co(dimethylglyoximate)]$^-$ [13] or of metal carbonyls[14,15] with phthaloylmethyl halide, phthaloylglycyl chloride or with mixed anhydrides of *N*-protected α-amino acids.[16,17] The *N*-protected aminomethyl and aminoacetyl metal carbonyls can be interconverted by CO insertion[14,15] or decarbonylation,[14,15,17] respectively, and could be useful for the synthesis of peptides.[14]

Phthalimidomethyl and -acetyl Complexes of Iron and Rhenium Carbonyls

In continuation of our recent work,[14] new examples of metal carbonyls with *N*-protected η^1-aminomethyl and -aminoacetyl ligands (**1**−**3**) were obtained by reactions of the metal carbonyls $[FeCp(CO)_2]^-$ and $[Re(CO)_5]^-$ with phthaloylmethyl chloride and phthaloylacetyl chloride, respectively.



1 **2** **3**

Compounds **1**−**3** show the characteristic M(CO) and MeC=O absorptions in their IR spectra (see Exp. Sect.). The ^1H and ^{13}C NMR spectra of **1**−**3** exhibit the expected signals.

Crystals of **1** suitable for X-ray diffraction were obtained by layering a frozen solution of **2** in CH_2Cl_2 with *n*-pentane. The molecule of **2** (Figure 1) has the classic "piano stool" structure as, for example, in $[FeCp(COCH_3)(CO)(PPh_3)]$.[18] The Fe1−C8 distance [2.042(3) Å] is typical for an iron-carbon σ-bond and of similar length as in $[Co(CH_2$*N*-phthaloyl$)(CO)_4]$ from Marko and co-workers[15] and in $[FeCp(CH_3)(CO)\{Ph_2PN(CH_3)CH(CH_3)Ph\}]$.[19] In the crystal, the Cp rings of different molecules of **1** are arranged in a parallel fashion. Metzler-Nolte et al.[20] have reported the synthesis and structure of $[MoCp(CH_2CH_2$-*N*-phthaloyl$)(CO)_3]$ which is a homologue of the corresponding aminomethyl complex.[14]

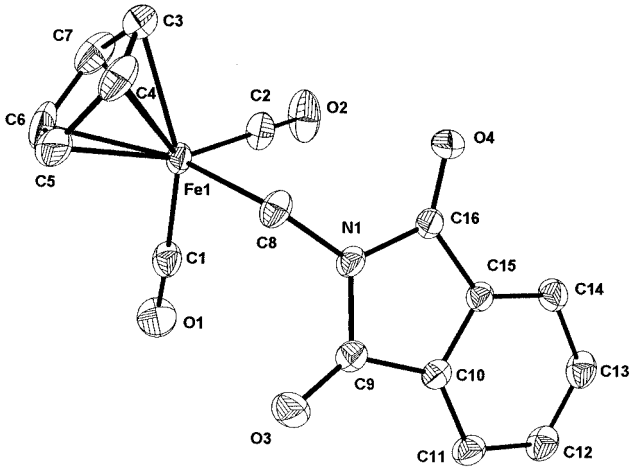


Figure 1. Molecular structure of **2** in the crystal; selected bond lengths (Å) and bond angles (°): Fe(1)−C(1) 1.755(3), O(3)−C(9) 1.204(3), Fe(1)−C(2) 1.750(3), O(4)−C(16) 1.208(3), Fe(1)−C(8) 2.042(3), N(1)−C(8) 1.450(3), O(1)−C(1) 1.144(3), N(1)−C(9) 1.395(3), O(2)−C(2) 1.140(3), N(1)−C(16) 1.391(3); C(2)−Fe(1)−C(1) 93.71(14), O(1)−C(1)−Fe(1) 176.0(3), C(1)−Fe(1)−C(8) 92.77(12), O(2)−C(2)−Fe(1) 177.3(3), C(2)−Fe(1)−C(8) 92.07(12), N(1)−C(8)−Fe(1) 119.7(2), C(16)−N(1)−C(9) 111.4(2), O(3)−C(9)−N(1) 124.9(2), C(16)−N(1)−C(8) 124.1(2), O(4)−C(16)−N(1) 124.6(2), C(9)−N(1)−C(8) 124.2(2)

Synthesis of Phthaloylmethyl and -acetyl Complexes of Palladium(II) and Platinum(II)

Palladium Complexes

The oxidative addition of organic halides to zero-valent palladium and platinum complexes is a general method for the synthesis of σ-bonded organometallic complexes.[21] This method was successfully applied for the synthesis of the *N*-phthaloylaminomethyl- and -acetylpalladium complexes **4**−**6**, which were prepared from $Pd(PPh_3)_4$ and *N*-phthaloylaminomethyl bromide, *N*-phthaloylaminoacetyl chloride or bromide, respectively. The formation of **4** takes several days (as expected, the methyl bromide is less reactive than the acetyl halides) and here the phosphonium salt **7** is formed as a by-product. A smaller quantity of $Pd(PPh)_4$ than stoichiometrically needed proved to be favourable for good yields of **4**. In a separate experiment it was shown that **7** does not react with $Pd(PPh_3)_4$.

Complexes **4**−**6** decompose slowly in solution. *N*-Phthaloylglycine is formed from **5** and **6** in the presence of moisture. It is interesting to note that complexes **4**−**6** react with the bis(phosphanes) $R_2P(CH_2)_2PR_2$ (R = Ph, C_6H_{11}) to give the complexes **8**−**13**. These reactions proceed by a *trans* → *cis* rearrangement.

In the IR spectra of **4**−**13** the phthaloyl absorptions at 1720 and 1770 cm^{-1} are characteristic. The acetyl carbonyl band of **5**, **6**, **9**, **10**, **12** and **13** is observed between 1660 and 1680 cm^{-1}. In the ^{31}P NMR spectra of **4**−**6** only one signal

is found, i.e. these complexes are formed as single *trans*-isomers. The X-ray structure determination of **11** (Figure 2) gave bonding parameters which lie in the usual range. Abstraction of halide ions from complexes **4**–**6** and **10**–**12** gives the cationic chelate complexes **14** and **15** in which coordination of one carbonyl oxygen atom of the phthaloyl group takes place.

Interestingly, complexes **14** and **15** are formed from the aminoacetyl complexes **5**, **6**, **11** and **12** by spontaneous decarbonylation, which is probably due to the stability of the formed five-membered chelate ring in **14** and **15** and which should involve alkyl migration.[22] In light of this, the reactions of **5** and **6** to **14** — the *trans* → *cis* isomerisation — can also be understood as being due to an alkyl migration.

The structures of **14** and **15** were confirmed by X-ray diffraction (Figure 3 and 4, respectively). The chelate ring in **14** and **15** has the same structural feature as in the palladium and platinum complexes obtained by oxidative addition of α-bromohippuric acid ester to Pd^0 or Pt^0 and subsequent reaction with $AgBF_4$.[23] An analogous chelate ring is also formed by insertion of imines into the metal–acetyl bond.[7–9] A similar chelate ring is formed from Ni^0 imine complexes and carbon dioxide.[24] The C–Pd–O bite angles in **14** and **15** (82–83°) are very similar to that of the above-mentioned complexes.[7,8,23] The Pd–C bonds in **14** and **15** (2.07–2.08 Å) are longer than that in [Pd{O=C(Ph)NHCHCO$_2$Me}(bipy)]$^+$ [23] which is due to the strong *trans*-influence of the phosphane ligand.

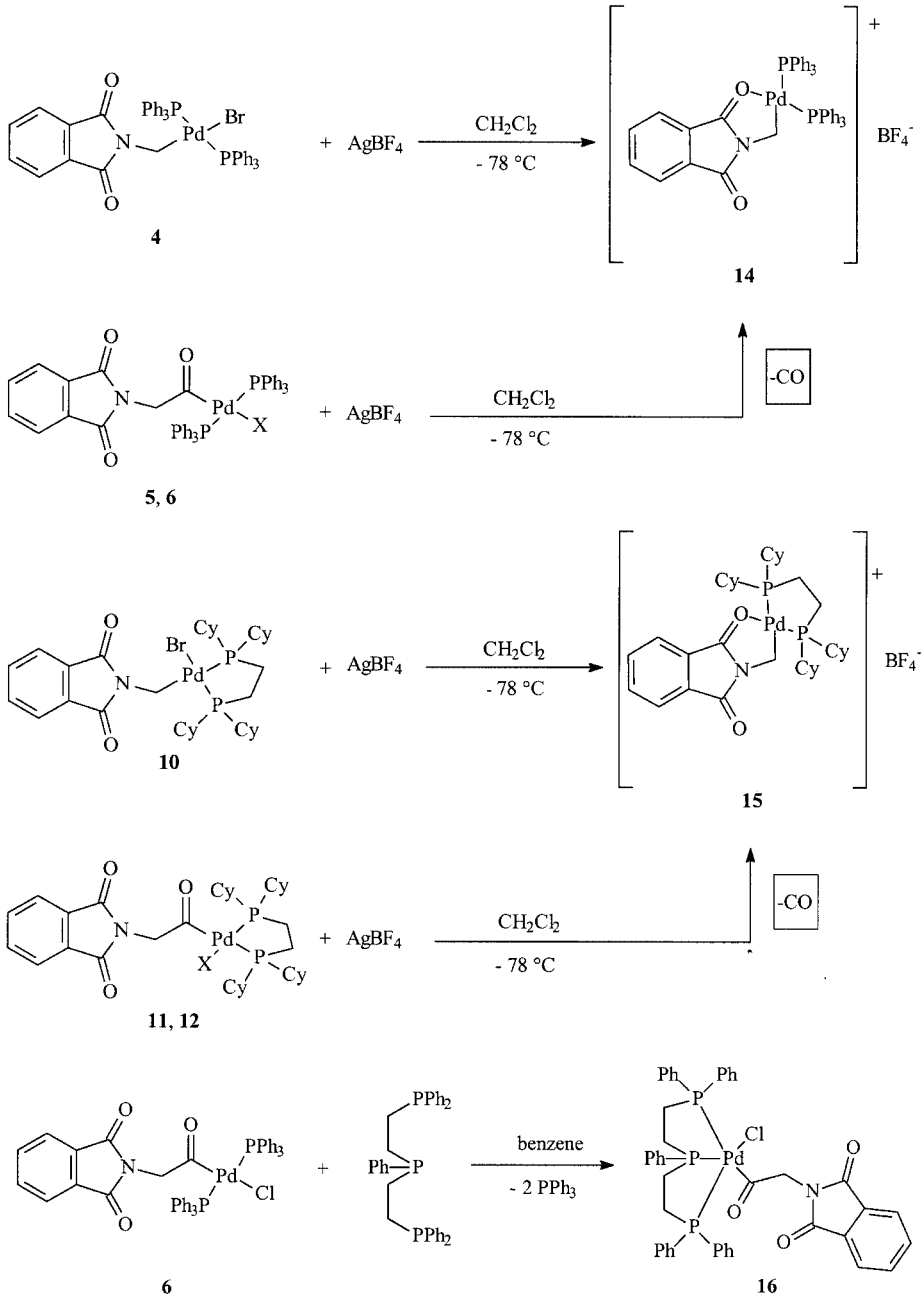
Figure 2. The reaction of **6** with the tridentate ligand $PhP(CH_2CH_2PPh_2)_2$ affords the five-coordinate, 18-electron aminoacetylpalladium complex **16**. The X-ray structure determination (Figure 5) shows the molecule of **16** as a dis-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim



torted trigonal bipyramid with P(1) and P(3) in the axial positions. The P(1), P(3) and Cl(1) atoms lie in a plane (sum of angles 360°). The unusually long Pd−Cl(1) bond (2.69 Å) is remarkable. In the crystal of **16** there are large voids which are occupied by solvent molecules (dichloromethane and *n*-pentane).

Similar five-coordinate palladium and platinum complexes are intermediates in many catalytic reactions,[25] and a series of such complexes with chelate ligands has been isolated and structurally characterised.[25−27]

Platinum Complexes

The platinum complexes **17** and **18** were obtained by oxidative addition of *N*-phthaloylglycyl chloride or *N*-phthaloylphenylalanyl chloride to $[Pt(C_2H_4)(PPh_3)_2]$. The

Experiments on the Mechanism of the Palladium-Catalyzed Amidocarbonylation

The proposed mechanism of the palladium-catalysed amidocarbonylation with aldehydes, amides and CO is shown in Scheme 1.[3]

In order to study the elementary steps of the mechanism the palladium-catalysed formation of phthaloylglycine from phthalimide, formaldehyde and CO was chosen as a model system. In the absence of CO and Pd^{2+}, phthalimide reacts with formaldehyde to give *N*-(hydroxymethyl)phthalimide.[13] The chosen reactants seemed to be favourable because phthalimide cannot form an oxazolone ring as side-product and the aldehyde does not carry β-hydrogen atoms. Hence, β-hydride elimination is not possible and a satisfying yield of 55% of the glycine derivative was achieved at 120 °C and 60 bar CO using 0.25 mol % $PdBr_2$ and 0.5 mol % PPh_3 as catalyst in the presence of 35 mol % LiBr and 1 mol % H_2SO_4. The yield strongly decreases at lower temperature (Table 1).

The following results confirm the previously proposed mechanism:[2]

1) With (hydroxymethyl)phthalimide or (bromomethyl)phthalimide as substrate the same yield of phthaloylglycine (55%) is obtained as with phthalimide and paraformaldehyde (Table 1). In many experiments[2] the temperature of 120 °C proved to be favourable. Experiments 3 and 4 in Table 2 demonstrate the need for halide and acid as cocatalysts.

2) Oxidative addition of the organic halide to Pd^0 was verified by the isolation of complex **4** from the reaction of (bromomethyl)phthalimide and $Pd(PPh_3)_4$.

3) The insertion of carbon monoxide into the aminoalkyl−palladium bond (which may occur via alkyl

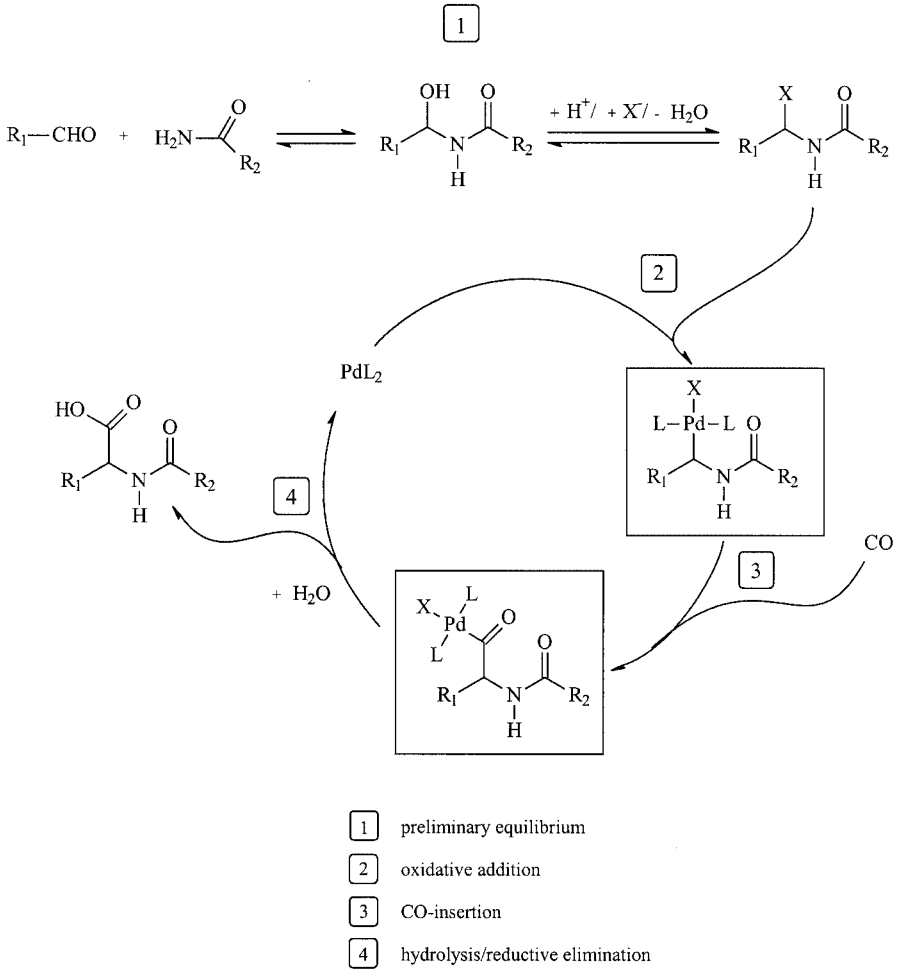
Figure 4. migration[22]) has been realized with the alkyl complexes **4** and **8** in CD_2Cl_2 solutions. The reaction was followed by ^{31}P NMR spectroscopy in a high pressure NMR tube. With **4** at 60 °C and 50 bar CO after 180 min the signal (δ = 19.7 ppm) of the acetyl complex **6** was detected (besides



Scheme 1

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

that of **7** at δ = 21.9 ppm). Similarly, with **8** at 50 bar CO and 130 °C after 1 h two ^{31}P NMR doublets were observed (with low intensity) which correspond to **9**. Obviously the CO insertion is more difficult with **8**, which has a bis(phosphane) chelate ligand.

The reverse decarbonylation reaction has been observed in CH_2Cl_2 solution of **12** where, after 1−2 days at 20 °C, the ^{31}P NMR signals of **11** appeared. Also, the spontaneous decarbonylation of **5**, **6**, **11** and **12** when treated with Ag^+ should be mentioned here.

4) The final step of the catalytic cycle — the hydrolysis of the acetylpalladium complex and formation of palladium(0) and phthaloylglycine — is supported by the observation that *N*-phthaloylglycine and palladium black are formed from solutions of **5** and **6** in CH_2Cl_2 in contact with air. It is remarkable that in entry 6 (Table 2) without addition of water phthaloylglycine was not formed from phthaloylmethyl bromide. Addition of methanol (entry 7, Table 2) gave *N*-phthaloylglycine (20%) and *N*-(methoxy)methylphthalimide (65%) as products.

5) Finally, the complexes **4**, **5** and **14**, which are possible intermediates in the amidocarbonylation, were used as catalysts for the reaction of phthalimide with paraformaldehyde. Under standard conditions (0.25 mol % complex, 120 °C, 60 bar CO, in NMP, 12 h) *N*-phthaloylglycine was obtained in yields of 48, 45 or 51% which corresponds to the activity of the normal catalyst $PdBr_2{\cdot}2PPh_3$.

In summary, all critical steps of the palladium-catalysed amidocarbonylation (Scheme 1) have been fully established for the model system phthalimide/formaldehyde/CO.

Experimental Section

The complexes $Pd(PPh_3)_4$,[28] $[Pt(C_2H_4)(PPh_3)_2]$[29] *N*-phthaloylglycyl chloride, *N*-phthaloylglycyl bromide[30] and *N*-phthaloylphenylalanyl chloride[31] were prepared according to the literature. The other starting materials were used as purchased.

Pentacarbonyl(*N*-phthaloylaminoacetyl)rhenium(I) (1): Dirheniumdecacarbonyl (700 mg, 1.1 mmol) was added to a mixture of 20.1 g of Na/Hg (6.63 mmol Na) and 25 mL of THF while stirring and cooling to −78 °C. After 1 h, the mixture was allowed to warm up to room temperature and was stirred for 2 h. The dark-red solution was removed with a syringe and added slowly to a solution of 380 mg of *N*-phthaloylglycyl chloride in 15 mL of THF at −78 °C. After 2 h of stirring at room temperature, the suspension was filtered and the filtrate was concentrated in vacuo. The resulting residue was washed several times with water, dried in vacuo and crystallised from CH_2Cl_2/*n*-pentane to give 735 mg of the colourless product (84% yield). ^1H NMR (270 MHz, 25 °C, $CDCl_3$): δ = 7.85−7.60 (m, 4 H, C_6H_4), 4.46 (s, 2 H, CH_2) ppm. $^{13}C\{^1H\}$ NMR (100.5 MHz, 25 °C, $CDCl_3$): δ = 246.3 [ReC(O)R], 181.9 [$Re(CO)_5$], 180.7 [$Re(CO)_5$], 167.9 (CON), 134.0, 132.3, 123.4 (C_6H_4), 69.4 (CH_2) ppm. IR (Nujol): $\tilde{\nu}$ = 2141 m, 2066 s, 2039, 2012 s, 1774 w, 1713 s, 1619 s cm^{-1}. $C_{15}H_6NO_8Re$ (514.4): calcd. C 35.02, H 1.18, N 2.72; found C 34.57, H 1.26, N 2.69.

Dicarbonyl(cyclopentadienyl)(*N*-phthaloylaminomethyl)iron(II) (2): Na/Hg (10.24 g, 3.3 mmol Na) was treated with a solution of bis(dicarbonylcyclopentadienyliron) (400 mg, 1.1 mmol) in 20 mL of THF at −78 °C. While stirring, the mixture was allowed to warm up to room temperature. After 3 h, the solution was removed with a syringe and added slowly to a solution of bromomethylphthalimide (456 mg, 1.9 mmol) in 15 mL of THF at −78 °C. The resulting dark red solution was stirred for 2 h at −78 °C and 3 h at room temperature. The colourless precipitate was separated by centrifugation. The dark red solution was concentrated in vacuo and the residue was crystallised from a CH_2Cl_2/*n*-pentane mixture. One of the resulting yellow crystals was selected for X-ray analysis. The rest of the product was dried in vacuo. Yield: 423 mg (66%). ^1H NMR (270 MHz, 25 °C, $CDCl_3$): δ = 7.80−7.20 (m, 4 H, C_6H_4), 4.94 (s, 5 H, C_5H_5), 3.99 (s, 2 H, CH_2) ppm. $^{13}C\{^1H\}$ NMR (100.5 MHz, 25 °C, $CDCl_3$): δ = 215.8 [$Fe(CO)_2$], 168.7 (CON), 133.7, 133.4, 122.7, (C_6H_4), 85.4 (C_5H_5), 11.2 ($FeCH_2$) ppm. IR (Nujol): $\tilde{\nu}$ = 2002 s, 1960 s, 1770 m, 1708 s cm^{-1}. $C_{16}H_{11}FeNO_4$ (337.1): calcd. C 57.01, H 3.29, N 4.15; found C 56.83, H 3.24, N 4.14.

Dicarbonyl(cyclopentadienyl)(*N*-phthaloylaminoacetyl)iron(II) (3): Na/Hg (3.66 g, 1.1 mmol Na) was treated with a solution of bis(dicarbonylcyclopentadienyliron) (140 mg, 0.4 mmol) in 15 mL of THF at −78 °C. While stirring, the mixture was allowed to warm up to room temperature. After 3 h, the solution was removed with a syringe and added slowly to a solution of *N*-phthaloylaminoacetyl chloride (180 mg, 0.8 mmol) in 15 mL of THF at −78 °C. The resulting dark solution was stirred for 1 h at −78 °C and 1 h at room temperature. The colourless precipitate was separated by centrifugation. The dark red solution was concentrated in vacuo and the residue was crystallised from a CH_2Cl_2/*n*-pentane mixture to afford 222 mg of yellow crystals (76% yield). ^1H NMR (270 MHz, 25 °C, $CDCl_3$): δ = 7.80−7.50 (m, 4 H, C_6H_4), 4.94 (s, 5 H, C_5H_5), 4.56 (s, 2 H, CH_2) ppm. IR (Nujol): $\tilde{\nu}$ = 2016 s, 1963 s, 1773 w, 1708 s, 1665 s cm^{-1}. $C_{17}H_{11}FeNO_5$ (365.1): calcd. C 55.92, H 3.04, N 3.84; found C 55.52, H 3.10, N 3.96.

***trans*-Bromo(*N*-phthaloylaminomethyl)bis(triphenylphosphane)-palladium(II) (4):** (Bromomethyl)phthalimide (200 mg, 0.83 mmol) was dissolved in 30 mL of benzene and $Pd(PPh_3)_4$ (960 mg, 0.83 mmol) was added at room temperature. After stirring for 2 days the resulting precipitate was separated by centrifugation, and

X-ray Structure Determination: The data in Table 3 were collected on an Enraf Nonius CAD 4 diffractometer (**2**), a Siemens P4 diffractometer (for **11**, **14**) or a Siemens P4 diffractometer with a SMART area detector (for **15**, **16**). CCDC-153852 (**2**), -226832 (**11**), -226831 (**14**), -226833 (**15**) and -226834 (**16**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Amidocarbonylation Experiments

The general procedure is described in ref.[2]

1. *N*-Phthaloylglycine: Phthalimide (3.68 g, 25 mmol), paraformaldehyde (0.76 g, 25 mmol), $PdBr_2$ (16.7 mg, 0.0625 mmol) and PPh_3 (33 mg, 0.125 mg, 0.5 mol %) in 25 mL of *N*-methylpyrrolidine were reacted at 120 °C under 60 bar CO in a 300 mL high-pressure reactor for 12 h. The product was recrystallised from water/2-propanol. Isolated yield: 2.82 g (55%); m.p. 193 °C. ^1H NMR (400 MHz, 25 °C, [D$_6$]DMSO): δ = 13.0 (br. s, 1 H, COO*H*), 7.85−7.97 (m, 4 H, *H*-aromat.), 4.32 (s, 2 H, *H*-2) ppm. $^{13}C\{^1H\}$ NMR (100 MHz, 25 °C, [D$_6$]DMSO): δ = 169.0 (*C*OOH), 167.4 (C-4), 134.9 (*C*-4′), 131.5 (*C*-6), 123.5 (*C*-5), 39.8 (*C*-2) ppm. IR (KBr): $\tilde{\nu}$ = 2985 m, 2936 w, 1773 s, 1724 s, 1416 s, 1247 s cm^{-1}. MS (CI, 70 eV): *m*/*z* = 206 [M + H$^+$], 188 [M + H$^+$ − H_2O], 160 [M$^+$ − CO_2H], 133, 103.

2. Reaction of *N*-(bromomethyl)phthalimide with Methanol and Carbon Monoxide: *N*-(Bromomethyl)phthalimide (1.48 g, 20 mmol), methanol (1 mL, 25 mmol) in 25 mL of NMP, $PdBr_2$ (13.5 mg, 0.05 mol, 0.25 mol %) and PPh_3 (27 mg, 0.1 mmol, 0.5 mol %) were reacted at 120 °C under 60 bar CO for 12 h. The volatile components were removed in vacuo and the residue was taken up in a saturated aqueous solution of $NaHCO_3$, which was then extracted twice with ethyl acetate. The combined organic phases were dried over $MgSO_4$ and the solvent was removed in vacuo. A sample of 1.0 g of the product (3.5 g) was purified by chromatography on silica (100 g, elution with hexane/ethyl acetate, 7:3).

Methyl *N*-Phthaloylglycinate: R_f = 0.28; isolated yield 0.25 g (20%). ^1H NMR (400 MHz, 25 °C, [D$_6$]DMSO): δ = 7.90−8.05 (m, 4 H, *H*-aromat.), 4.50 (s, 2 H, *H*-2), 3.72 (s, 3 H, OC*H*$_3$) ppm. $^{13}C\{1H\}$ NMR (100 MHz, 25 °C, [D$_6$]DMSO): δ = 168.1 (*C*OOH), 167.1 (*C*-4), 134.9 (*C*-4′), 131.4 (*C*-6), 123.5 (*C*-5), 52.5 (O*C*H$_3$), 38.8 (*C*-2) ppm. IR (KBr): $\tilde{\nu}$ = 3475 w, 2977 w, 1774 m, 1751 s, 1727 s, 1423 s, 1399 m, 1374 m, 1224 s cm^{-1}. MS (CI, 70 eV): *m*/*z* = 219 [M$^+$], 188 [M + H$^+$ − CH_3OH], 160 [M$^+$ − CO_2CH_3], 133, 104, 76.

***N*-(Methoxymethyl)phthalimide:** R_f = 0.5; isolated yield 0.70 g (65%). ^1H NMR (400 MHz, 25 °C, [D$_6$]DMSO): δ = 7.88−7.93 (m, 4 H, *H*-aromat.), 4.95 (s, 2 H, *H*-2), 3.28 (s, 3 H, OC*H*$_3$) ppm. $^{13}C\{1H\}$ NMR (100 MHz, 25 °C, [D$_6$]DMSO): δ = 167.8 (*C*-4), 134.9 (*C*-4′), 131.4 (*C*-6), 123.6 (*C*-5), 68.4 (*C*-2), 52.5 (O*C*H$_3$) ppm. MS (CI, 70 eV): *m*/*z* = 191 [M$^+$], 160, 133, 104, 76.

(Nitrido)ruthenium(VI) and -osmium(VI) Complexes with Catecholate Auxiliaries: Synthesis, Structure, and Conversion into a (Phosphoraniminato)osmium(V) Complex

Guo-Su Fang,[a,b] Jie-Sheng Huang,[b] Nianyong Zhu,[b] and Chi-Ming Che*[a,b]

Keywords: Nitrides / O ligands / Ruthenium / Osmium / Structure elucidation

Treatment of $[NnBu_4][M^{VI}NCl_4]$ (where M = Ru, Os) with catechol (H_2Cat) and 3,5-di-*tert*-butylcatechol (H_2DBCat) in the presence of 2,6-dimethylpyridine (2,6-Me_2Py) gave $[NnBu_4][M^{VI}N(Cat)_2]$ (where M = Ru **1a**, Os **1b**) and [2,6-Me_2PyH][$M^{VI}N(DBCat)_2$] (where M = Ru **2a**, Os **2b**), respectively, in 75–90 % yields. Reaction of **2b** with triphenylphosphane afforded the (phosphoraniminato)osmium(V) complex $[Os^{V}(NPPh_3)(DBCat)_2(PPh_3)]$ (**3**) in 90 % yield. X-ray crystal structure determinations on **1a**, **1b** and **3** reveal M≡N distances of 1.603(4) and 1.641(8) Å (for **1a** and **1b**, respectively) and an Os–N($NPPh_3$) distance of 2.077(3) Å (for **3**). The C–O distances in the three complexes range from 1.341(4) to 1.374(7) Å, indicating that the coordinated catecholate ligands adopt the catecholate(2–) state, rather than the semiquinonate(1–) or quinone states.

Introduction

(Nitrido)ruthenium and -osmium complexes are among the most extensively studied high-valent ruthenium and osmium compounds.[1] Stable mononuclear species with Ru≡N or Os≡N bonds have become accessible through many types of auxiliary ligands, including halides,[2] phosphanes/arsanes/stibanes[3−5] silyloxy,[6] alkyl,[6−8] thiocyanate,[7] thiolate or dithiolene,[7,9−11] ammine,[12,13] cyanide,[14] pyridine or polypyridine,[4,15−18] ureato,[19] cysteine(2−),[20] alkoxide,[21] diamine,[22] *N*-pyridinecarbonyl and/or *N*-hydroxybenzoyl diamide,[23] hydrotris(pyrazolyl)-borate,[24−27] trispyrazolylmethane,[28,29] imidodiphosphanylchalcogenido,[30,31] Schiff bases,[32] *meso*-octamethylporphrinogen,[33] porphyrin,[34,35] and aryl/alkyl acetylide.[36] The ruthenium and osmium ions in these nitrido complexes have exclusively a high oxidation state of +6 and therefore demonstrate the remarkable ability of the nitrido group to stabilize ruthenium(VI) and osmium(VI) species.

We have recently been interested in exploring the chemistry of (nitrido)ruthenium and -osmium complexes bearing catecholate ligands (the oxygen analogues of dithiolenes such as 1,2-benzenedithiolates), which is an important type of non-innocent ligands known to have three oxidation states, namely, catecholate(2−), semiquinonate(1−), and quinone, in complexes with metal ions.[37,38] We envisage that this new class of (nitrido)ruthenium and -osmium complexes may exhibit rich redox chemistry. The different oxidation states of the coordinated catecholate ligands, if achievable, would significantly regulate the reactivity of the Ru≡N and Os≡N functional groups. On the other hand, given the remarkable ability of the nitrido group to stabilize ruthenium(VI) and osmium(VI) species and the ambiguity in charge distribution in ruthenium and osmium catecholate complexes such as $[Os(Cat)_3]$ (H_2Cat = catechol), $[Ru(DBCat)_3]$ (H_2DBCat = 3,5-di-*tert*-butylcatechol), and $[Os(DBCat)_3]$,[39,40] a ruthenium(VI)/osmium(VI) catecholate complex with clear charge distribution might be obtained by introducing a nitrido group in the complex. The structure determination of the (nitrido)metal catecholates may provide a unique opportunity to examine the structural features of genuine Ru^{VI}- or Os^{VI}-catecholate(2−) bonds.

In the present work, we report on the synthesis of (nitrido)ruthenium(VI) and -osmium(VI) complexes $[M^{VI}N(L)_2]^-$ (where L = Cat, M = Ru **1a**, Os **1b**; L = DBCat, M = Ru **2a**, Os **2b**) and the crystal structures of $[NnBu_4][Ru^{VI}N(Cat)_2]$ (**1a**) and $[NnBu_4][Os^{VI}N(Cat)_2]$ (**1b**). These, to the best of our knowledge, are the first examples of isolated mononuclear (nitrido)metal complexes containing catecholate auxiliaries. Prior to this work, only dinuclear (μ-nitrido)metal complexes, such as the Fe(μ-N)Fe complexes prepared by Wieghardt and co-workers,[41,42] were known to contain catecholate ligands. Interestingly, the (nitrido)osmium complex $[Os^{VI}N(DBCat)_2]^-$ reacted with tri-

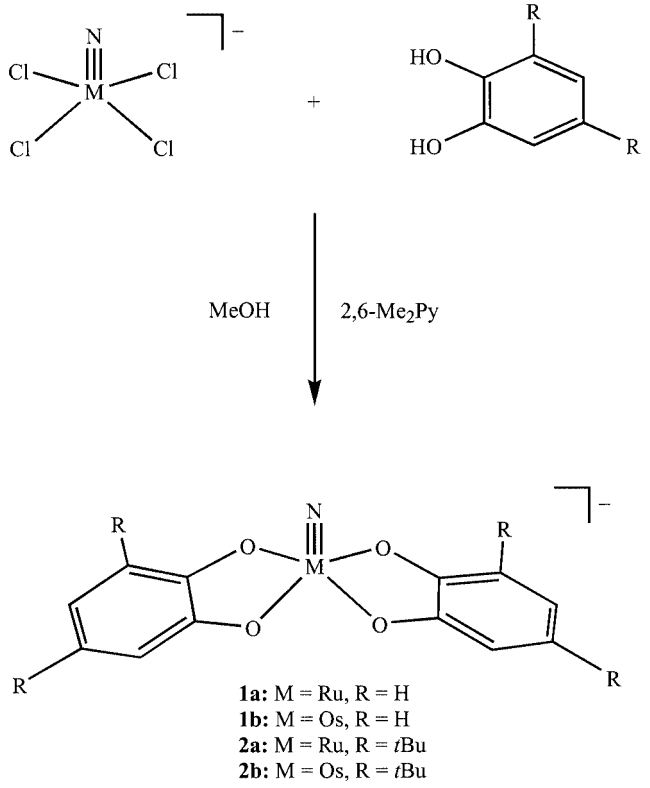
phenylphosphane to afford an unprecedented (phosphoraniminato)osmium(v) complex, $[Os^{V}(NPPh_3)(DBCat)_2(PPh_3)]$ (**3**). This unusual reaction, along with the crystal structure of **3**, is also described here.

Results and Discussion

Synthesis and Characterization of $[M^{VI}N(Cat)_2]^-$ and $[M^{VI}N(DBCat)_2]^-$ (M = Ru, Os)

Treatment of $[NnBu_4][M^{VI}NCl_4]$ (M = Ru/Os) with two equivalents of catechol in methanol in the presence of 2,6-dimethylpyridine readily gave a solution containing mainly the (nitrido)ruthenium/osmium catecholate complex **1a/1b** (see Scheme 1), which was isolated in approximately 80 % yield upon workup. By employing 3,5-di-*tert*-butylcatechol instead of catechol, the same reactions afforded **2a/2b** as a precipitate (Scheme 1, note that **2a/2b** could have two geometrical isomers but only one of them is shown), which can be readily separated from the reaction mixtures by filtration. An NMR-pure product of **2a/b** was obtained in up to 90 % yield after washing with diethyl ether and drying. The counter-cation in **1** is tetrabutylammonium $[NnBu_4]^+$, as could be expected. However, we were surprised to find that **2** took $[2,6\text{-}Me_2PyH]^+$ (which was generated during the reaction) as a counter-cation, as revealed by ^1H NMR measurements (see below). This might result from a supramolecular interaction/recognition between $[M^{VI}N(DBCat)_2]^-$ and $[2,6\text{-}Me_2PyH]^+$ ions or from a low solubility of the $[2,6\text{-}Me_2PyH]^+$ salts of $[M^{VI}N(DBCat)_2]^-$ in methanol.



Scheme 1. Syntheses of **1** and **2**

Complexes **1a**, **1b**, **2a** and **2b** are diamagnetic, air-stable solids, having good solubility in common organic solvents, such as dichloromethane, acetonitrile, and tetrahydrofuran. In solution at room temperature, **1a** and **1b** are stable for months. The solutions of **2a** and **2b** can be stored at −20 °C for several weeks.

The ^1H NMR spectra of **1a** and **1b** both show two well-resolved multiplets with δ = 6.62, 6.89 ppm (for **1a**) and 6.71, 7.00 ppm (for **1b**), together with the normal signals of $[NnBu_4]^+$. The spectrum of **1a** is shown in Figure 1a as an example. There are no $[NnBu_4]^+$ signals in the ^1H NMR spectra of **2a** and **2b**. Instead, a set of signals at δ = 2.8, 7.5, and 8.2 ppm, assignable to $[2,6\text{-}Me_2PyH]^+$, was observed (see Figure 1b,c). Note that although **2a/2b** may have two geometric isomers (with C_s and C_2 symmetries, respectively), only a single set of the coordinated catecholate signals was located in the spectrum. Probably, only one of the isomers is present in solution, or the signals of the two isomers are not different enough to be clearly resolved.

Negative-ion FAB mass spectra of **1a**, **1b**, **2a** and **2b** show intense cluster peaks assignable to $[M^{VI}N(Cat)_2]^-$ or

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

$[M^{VI}N(DBCat)_2]^-$; the observed and simulated isotope-distribution patterns are virtually identical.

In the IR spectra of **1a**, **1b**, **2a** and **2b**, sharp and intense bands, ascribable to $\nu_{Ru\equiv N}/\nu_{Os\equiv N}$ appear at 1049 (**1a**) and 1051 cm^{-1} (**2a**) for the ruthenium species and at 1093 (**1b**) and 1097 cm^{-1} (**2b**) for the osmium species. The $\nu_{M\equiv N}$ frequency of **1a**/**1b** is appreciably higher than the corresponding frequency of the sulfur analogues $[NnBu_4][M^{VI}N(S_2C_6H_4)_2]$ (M = Ru, Os; $S_2C_6H_4$ = 1,2-benzenedithiolate; $\nu_{Ru\equiv N}$ = 1024 cm^{-1}, $\nu_{Os\equiv N}$ = 1063 cm^{-1}) reported by Sellmann and co-workers.[10] The study of the effect of catecholate auxiliaries on the M≡N bond by comparing the $\nu_{M\equiv N}$ frequencies of **1a** and **2a**, or **1b** and **2b**, is complicated by the different counter-cations in the nitrido complexes.

Structures of $[NnBu_4][M^{VI}N(Cat)_2]$ (M = Ru, Os)

Complexes **1a** and **1b** are isostructural and they both crystallize in the monoclinic space group *C*2/*c*, with very similar unit-cell dimensions (see Table 1). This resembles their sulfur analogues $[NnBu_4][M^{VI}N(S_2C_6H_4)_2]$ (M = Ru, Os),[10] which are also isostructural and have similar unit-cell dimensions, except that the 1,2-benzenedithiolate complexes both crystallize in the orthorhombic space group $Pna2_1$. Figure 2 shows the ORTEP drawings of the $[M^{VI}N(Cat)_2]^-$ anions of **1a** and **1b** with atom-numbering schemes. Selected bond lengths and angles for the two (nitrido)metal catecholate complexes are given in Table 2.

As shown in Figure 2 and Table 2, the $[M^{VI}N(Cat)_2]^-$ anions of **1a** and **1b** feature a slightly distorted square-pyramidal coordination geometry with the nitrido group situated at the apical position (ca. 0.62 Å above the basal plane constituted by the four oxygen atoms of the catecholate ligands) as in their sulfur analogues $[M^{VI}N(S_2C_6H_4)_2]^-$ (M = Ru, Os; the nitrido groups are ca. 0.69 Å above the basal plane).[10] However, contrary to the lack of symmetry of $[Ru^{VI}N(S_2C_6H_4)_2]^-$ and $[Os^{VI}N(S_2C_6H_4)_2]^-$ in the corresponding crystal structures, the structures of **1a** and **1b** have a C_2 axis along the M≡N bond of $[M^{VI}N(Cat)_2]^-$. The

[a] C(6)−O(2). [b] Os(1)−O(2)−C(6).

Ru≡N distance in **1a** is 1.603(4) Å, slightly shorter than the Os≡N distance in **1b** [1.641(8) Å]. These Ru≡N/Os≡N distances are similar to those reported for $[NnBu_4][Ru^{VI}N(S_2C_6H_4)_2]$ [1.613(5) Å] and $[NnBu_4][Os^{VI}N(S_2C_6H_4)_2]$ [1.64(1) Å].[10] The average values of the N−M−O angles in **1a** and **1b** are 108.3 and 108.7°, respectively and are larger than the average N−M−S values in $[NnBu_4][Ru^{VI}N(S_2C_6H_4)_2]$ (107.6°) and $[NnBu_4][Os^{VI}N(S_2C_6H_4)_2]$ (107.2°), suggesting a greater repulsion between the π-electrons of the M≡N bond and the bonding electrons of the M−O bonds.[10]

The M−O distances in **1a** [1.954(3) and 1.962(2) Å] and **1b** [1.971(4) Å] fall in a narrower range than those in

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

[Ru(DBCat)$_3$] [1.941(10)−1.997(10) Å] and [Os(DBCat)$_3$] [1.947(7)−1.984(7) Å], reported by Pierpont and co-workers.[40] The C−O distances of **1a** [1.352(4), 1.366(4) Å] and **1b** [1.370(7), 1.374(7) Å] are significantly longer than those in the [Ru(DBCat)$_3$] [1.299(5), 1.319(6) Å] and [Os(DBCat)$_3$] [1.32(1) Å] complexes.[40] Since metal catecholate complexes typically feature C−O distances of, for example, 1.281(3) and 1.334(13) Å when the coordinated catecholate ligands adopt the semiquinonate(1−) and catecholate(2−) states, respectively,[40] the long C−O distances in **1a** and **1b**, together with their short M−O distances, should reveal a clear charge distribution in the two nitrido complexes, that is, the coordinated catecholate ligands are all in the catecholate(2−) state and their ruthenium and osmium ions are both in an oxidation state of +6.

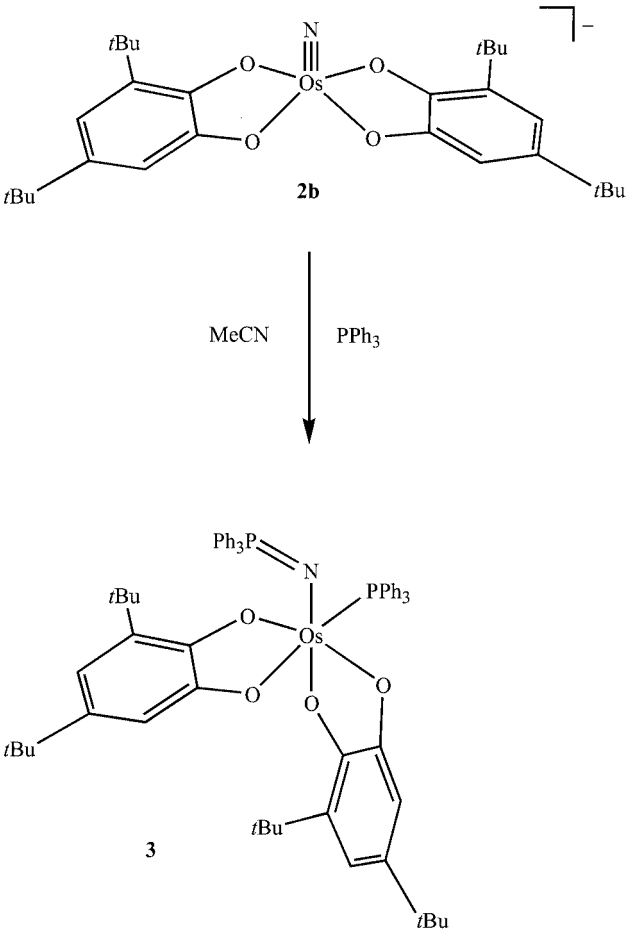
Note that high-valent ruthenium(VI)/osmium(VI) catecholate complexes are still sparse. Besides the Os^{VI} species [Os(Cat)$_3$] and [Os(DBCat)$_3$],[39,40] several (oxo)osmium(VI) complexes bearing catecholate auxiliaries have been prepared and characterized by Griffith and co-worker through spectroscopic means.[43] Complexes **1a** and **1b** reported in this work are, to the best of our knowledge, the only ruthenium(VI)/osmium(VI) complexes with catecholate ligands whose charge distribution has been confirmed by X-ray structure determination.

Reaction of $[Os^{VI}N(DBCat)_2]^-$ with Triphenylphosphane to Form $[Os^{V}(NPPh_3)(DBCat)_2(PPh_3)]$

The (nitrido)ruthenium/osmium complexes **1a**, **1b**, **2a** and **2b** are reactive toward PPh_3. Treatment of **2b** with PPh_3 in acetonitrile at room temperature for 0.5 h afforded the (phosphoraniminato)osmium(V) complex $[Os^{V}(NPPh_3)(DBCat)_2(PPh_3)]$ (**3**) in 90 % yield (see Scheme 2). However, the products of the reactions of **1a**, **1b** and **2a** with PPh_3 remain to be identified.

Complex **3** is a paramagnetic solid, stable toward moist air both in solid state and in solution. The ESR spectrum of **3** in solid state shows a single signal with a *g* value of 1.99, resembling the spectrum of a ruthenium(V) species (g = 2.11).[44] This indicates that the osmium(V) in **3** adopts a low-spin state, as is usual for heavy transition-metals.[44] The positive-ion FAB mass spectrum of **3** is dominated by an intense cluster peak at m/z = 1172, which can be attributed to the protonated parent ion ($[M + H]^+$).

The formation of a (phosphoraniminato)osmium(V) complex from the reaction of a (nitrido)osmium(VI) complex with phosphane is unusual. Previous reactions of (nitrido)osmium(VI) complexes, such as $[Os^{VI}NX_4]^-$ (X = Cl, Br),[3,4] $[Os^{VI}N(tpy)Cl_2]^+$ (tpy = 2,2′:6′,2′′-terpyridine),[45] $[Os^{VI}N(L)Cl]$ (L = salen and its derivatives),[32] and $[Os^{VI}N(L)Cl_2]$ (L = $[Co(\eta^5\text{-}C_5H_5)\{PO(OEt)_2\}_3]^-$)[31,46] all gave (phosphoraniminato)osmium(IV) and, much less frequently, (phosphoraniminato)osmium(III) complexes. Meyer and co-workers reported that electrochemical oxidation of *trans*-$[Os^{IV}(NPPh_3)(tpy)Cl_2]^+$ presumably gave *trans*-$[Os^{V}(NPPh_3)(tpy)Cl_2]^{2+}$ but this (phosphoraniminato)osmium(V) species was not isolated or characterized. The remarkable stability of complex **3** might arise from the unique binding behavior of the 3,5-di-*tert*-butylcatecholate ligands.



Scheme 2. Reaction of **2b** to form **3**

Stable osmium(V) complexes are not unprecedented in the literature.[1] We once isolated and structurally characterized several (oxo)osmium(V) complexes.[1] Recently, Meyer and co-workers prepared and characterized the (imido)osmium(V) complex $[Os^{V}(NH)(Tp)Cl_2]$ [Tp = hydrotris(pyrazol-1-yl)borate].[47] The coordination of phosphanes to high-valent osmium, as in the case of **3**, is much less common than that to low-valent osmium. A few (dioxo)osmium(VI) complexes, *trans*-$[Os^{VI}O_2X_2(PR_3)_2]$, were prepared by Walton and co-workers in early 1980s.[48]

Structure of $[Os^{V}(NPPh_3)(DBCat)_2(PPh_3)]$

Complex **3** crystallized in the orthorhombic space group $Pna2_1$. The ORTEP drawing of the complex is depicted in Figure 3. A surprising feature in this structure is the helical Os(DBCat)$_2$ arrangement, coupled with the *cis* arrangement of the $NPPh_3$ and PPh_3 groups. Such groups are expected to be *trans* to each other according to the structure of the nitrido precursor **2b** (which we were unable to determine by X-ray crystallography but should be similar to the structure of **1b**, shown in Figure 2). Probably, a *trans* arrangement of the $NPPh_3$ and PPh_3 groups would suffer

[a] The values for $[Os^{IV}(DBCat)_2(PPh_3)_2]$ (from ref.[49]) are in square brackets. [b] Os(1)−P(2).

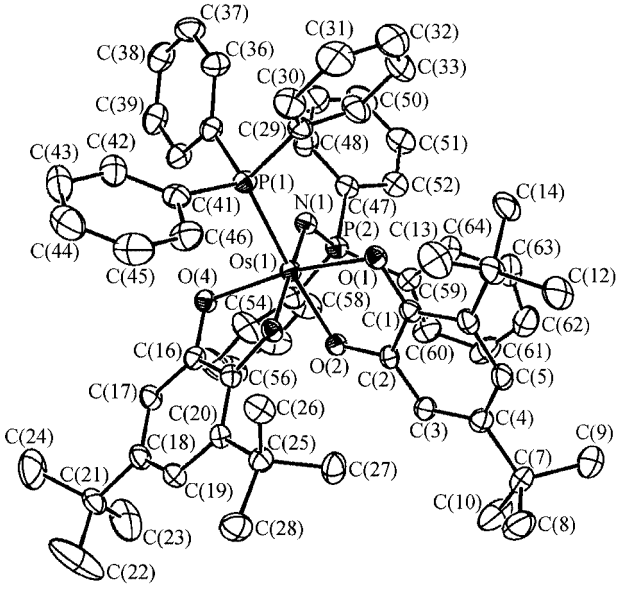

Figure 3. ORTEP drawing of **3** with omission of hydrogen atoms (thermal ellipsoid probability level: 30 %)

from significant steric interaction between the coordinated PPh_3 group and the *t*Bu groups of the bound catecholate ligands. Indeed, the structure of $[Os^{IV}(DBCat)_2(PPh_3)_2]$, reported by Pierpont and co-workers,[49] has also a helical $Os(DBCat)_2$ arrangement and *cis* PPh_3 ligands. Table 3 shows the selected bond lengths and angles for **3**; the corresponding geometric parameters of $[Os^{IV}(DBCat)_2(PPh_3)_2]$ are also given in the table for comparison.

It can be seen that both **3** and $[Os^{IV}(DBCat)_2(PPh_3)_2]$ have an $[Os(DBCat)_2(PPh_3)]$ moiety. However, the orientations of the coordinated catecholate ligands in the two complexes are different (see Table 3). A comparison between the geometrical parameters of **3** and $[Os^{IV}(DBCat)_2(PPh_3)_2]$ reveals additional differences in the $[Os(DBCat)_2(PPh_3)]$ moieties of the two structures. First, the Os−P(phosphane) distance in **3** is appreciably shorter than that in $[Os^{IV}(DBCat)_2(PPh_3)_2]$ [2.297(1) vs. 2.357(2) Å]. Second, the P(1)−Os(1)−O(2) moiety in $[Os^{IV}(DBCat)_2(PPh_3)_2]$ is more bent than that in **3** [164.7(1) vs. 175.96(8)°].

The OsO_4NP core in **3** can be best described as a distorted octahedron with the P(1) and O(2) atoms situated at the axial positions. The Os(1) atom and the four equatorial atoms O(1), O(3), O(4), and N(1) are basically co-planar, and the axial P(1)−Os(1)−O(2) moiety is almost linear [with an angle of 175.96(8)°]. One of the major distortions of the OsO_4NP core from a regular octahedron lies in a significant lengthening of the axial bond at the P(1) side [cf. Os(1)−P(1) 2.297(1) Å, Os(1)−O(2) 2.061(2) Å].

The Os−O distances in **3** range from 1.962(3) to 2.061(2) Å, which compare well with those in $[Os^{IV}(DBCat)_2(PPh_3)_2]$ [1.982(4)−2.048(5) Å], except that the average distance in **3** [2.008(3) Å] is slightly shorter than that in $[Os^{IV}(DBCat)_2(PPh_3)_2]$ [2.018(5) Å]. The C−O distances in **3** [1.341(4)−1.351(4) Å] are similar to, or even longer than,

those in $[Os^{IV}(DBCat)_2(PPh_3)_2]$ [1.321(7)−1.341(8) Å], consistent with the $DBCat^{2-}$ state of the coordinated catecholate ligands in **3**.

Complex **3** has an Os(1)−N(1) distance of 2.077(3) Å and an N(1)−P(2) distance of 1.616(3) Å. These Os−N(phosphoraniminato) and N−P distances are similar to those in *trans*-$[Os^{IV}(NPPh_3)(tpy)Cl_2]PF_6$ and *cis*-$[Os^{IV}(NPPh_2Me)(tpy)Cl_2]PF_6$,[45] but considerably longer than those in $[Os^{IV}(NPPh_3)(salophen)Cl]$[32] and $[Os^{IV}(NPPh_3)(L)Cl_2]$[46] (see Table 4). The Os−*N*−PPh_3 angle in **3** is 128.7(2)°. As shown in Table 4, this is the smallest Os−*N*−PR_3 angle ever found in the crystal structures of (phosphoraniminato)osmium complexes.

Conclusion

We have prepared several (nitrido)ruthenium(VI) and -osmium(VI) complexes bearing catecholate auxiliaries, which constitute a new class of mononuclear (nitrido)metal complexes. X-ray structure determinations on $[NnBu_4][Ru^{VI}N(Cat)_2]$ and $[NnBu_4][Os^{VI}N(Cat)_2]$ confirm that the catecholate ligands in these (nitrido)ruthenium(VI) and -osmium(VI) complexes all adopt the catecholate(2−) state, rather than the semiquinonate(1−) or quinone states. The structure determinations on $[NnBu_4][Ru^{VI}N(Cat)_2]$ and $[NnBu_4][Os^{VI}N(Cat)_2]$, together with those on their 1,2-benzenedithiolate counterparts reported by Sellmann and co-workers,[10] allow for a direct comparison between the effects of oxygen and sulfur donors on the structures of (nitrido)metal complexes. Incorporation of 3,5-di-*tert*-butylcatecholate auxiliaries into a (nitrido)osmium species results in an unusual reactivity of the nitrido complex toward tertiary phosphane, affording an unprecedented (phosphoraniminato)osmium(V) complex.

Experimental Section

General Remarks: All solvents were purified by standard methods before use. Catechol, 3,5-di-*tert*-butylcatechol, 2,6-dimethylpyridine, and triphenylphosphane (Aldrich) were used as received. $[NnBu_4][M^{VI}NCl_4]$ (M = Ru, Os) were prepared according to the reported procedures.[2] ^{1}H NMR spectra were recorded on a Bruker DPX-300 or −400 FT-IR spectrometer (chemical shifts, δ, are relative to tetramethylsilane). Infrared spectra were recorded on a Bio-Rad FTS-165 spectrometer. Fast atom bombardment (FAB) mass spectra were obtained on a Finnigan Mat 95 mass spectrometer. The ESR spectrum was recorded on a Bruker EMX100 ESR spectrometer. Elemental analyses were performed by the Institute of Chemistry, the Chinese Academy of Sciences.

Preparation of $[NnBu_4][M^{VI}N(Cat)_2]$ (M = Ru 1a, Os 1b): Several drops of 2,6-dimethylpyridine were added under nitrogen to a solution of H_2Cat (22 mg, 0.2 mmol) in methanol (5 mL). After being stirred for 0.5 h, the mixture was treated with $[NnBu_4][M^{VI}NCl_4]$ (0.1 mmol) and further stirred for 0.5 h. Slow evaporation of the solvent led to precipitation of the desired product as a microcrystalline solid, which was collected by filtration, washed with diethyl ether, and dried in vacuo.

$[NnBu_4][Ru^{VI}N(Cat)_2]$ (1a): Yield: 48.8 mg (85 %). ^{1}H NMR (400 MHz, $CDCl_3$): δ = 0.95 (t, 12 H), 1.34 (m, 16 H), 2.92 (t, 8 H), 6.62 (m, 4 H), 6.89 (m, 4 H) ppm. IR (Nujol): 1049 cm^{-1} ($\nu_{Ru\equiv N}$). FAB MS: *m*/*z* = 332 $[Ru^{VI}N(Cat)_2]^-$. $C_{28}H_{44}N_2O_4Ru$ (573.7): calcd. C 58.62, H 7.73, N 4.88; found C 58.20, H 7.42, N 4.53.

$[NnBu_4][Os^{VI}N(Cat)_2]$ (1b): Yield: 49.7 mg (75 %). ^{1}H NMR (400 MHz, $CDCl_3$): δ = 1.00 (t, 12 H), 1.46 (m, 16 H), 3.15 (t, 8 H), 6.71 (m, 4 H), 7.00 (m, 4 H) ppm. IR (Nujol): 1093 cm^{-1} ($\nu_{Os\equiv N}$). FAB MS: *m*/*z* = 422 $[Os^{VI}N(Cat)_2]^-$. $C_{28}H_{44}N_2O_4Os{\cdot}H_2O$ (680.9): calcd. C 49.39, H 6.81, N 4.11; found C 49.79, H 6.50, N 3.91.

Preparation of $[2,6\text{-}Me_2PyH][M^{VI}N(DBCat)_2]$ (M = Ru 2a, Os 2b): Several drops of 2,6-dimethylpyridine were added under nitrogen to a solution of H_2DBCat (445 mg, 2 mmol) in methanol (20 mL). After being stirred for 0.5 h, the mixture was treated with $[NnBu_4][M^{VI}NCl_4]$ (1 mmol), which resulted in precipitation of the desired product immediately. The precipitate was collected by filtration, washed with diethyl ether, and dried in vacuo.

$[2,6\text{-}Me_2PyH][Ru^{VI}N(DBCat)_2]$ (2a): Yield: 598 mg (90 %). ^{1}H NMR (300 MHz, $CDCl_3$): δ = 1.25 (s, 36 H), 2.84 (s, 6 H), 6.69 (s, 2 H), 6.80 (s, 2 H), 7.51 (d, 2 H), 8.18 (t, 1 H) ppm. IR (Nujol): 1051 cm^{-1} ($\nu_{Ru\equiv N}$). FAB MS: *m*/*z* = 556 $[Ru^{VI}N(DBCat)_2]^-$. $C_{35}H_{50}N_2O_4Ru{\cdot}0.5CHCl_3$ (723.5; a sample recrystallized from chloroform/diethyl ether): calcd. C 58.93, H 7.03, N 3.87; found C 59.36, H 6.88, N 4.15.

$[2,6\text{-}Me_2PyH][Os^{VI}N(DBCat)_2]$ (2b): Yield: 602 mg (80 %). ^{1}H NMR (300 MHz, $CDCl_3$): δ = 1.26 (d, 36 H), 2.89 (s, 6 H), 6.69 (d, 2 H), 6.94 (d, 2 H), 7.58 (d, 2 H), 8.25 (t, 1 H) ppm. IR (Nujol): 1097 cm^{-1} ($\nu_{Os\equiv N}$). FAB MS: *m*/*z* = 646 $[Os^{VI}N(DBCat)_2]^-$. $C_{35}H_{50}N_2O_4Os{\cdot}H_2O$ (771.0): calcd. C 54.52, H 6.80, N 3.63; found C 54.55, H 6.44, N 3.80.

Reaction of $[2,6\text{-}Me_2PyH][Os^{VI}N(DBCat)_2]$ (2b) with Triphenylphosphane: A mixture of **2b** (180 mg, 0.2 mmol) and PPh_3 (130 mg, 0.5 mmol) in acetonitrile (10 mL) was stirred for 0.5 h and gave a purple-red solution. After removal of the solvent, the residue

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

was transferred onto an alumina column with dichloromethane as an eluent. The purple-red band was collected and concentrated to dryness by rotary evaporation to give a purple-red solid, which was identified as $[Os^{V}(NPPh_3)(DBCat)_2(PPh_3)]$ (**3**).

$[Os^{V}(NPPh_3)(DBCat)_2(PPh_3)]$ (3): Yield: 210 mg (90 %). FAB MS: m/z = 1172 $[M + H]^+$. $C_{64}H_{70}NO_4OsP_2$ (1169.4): calcd. C 65.73, H 6.03, N 1.20; found C 65.77, H 5.92, N 1.05.

X-ray Crystallographic Study: Diffraction-quality crystals of **1a** and **1b** were obtained by slow evaporation of their methanol solutions at room temperature, whereas those of **3** were obtained by slow evaporation of its acetonitrile/diethyl ether (3:1, v/v) solution at −20 °C. Crystals of the dimensions of 0.6 × 0.2 × 0.1 (**1a**), 0.2 × 0.15 × 0.1 (**1b**), and 0.7 × 0.5 × 0.4 mm (**3**) mounted in glass capillaries were used for data collection at −20 °C on a MAR diffractometer with a 300 mm image plate detector using graphite-monochromatized Mo-K_α radiation (λ = 0.71073 Å). The data were collected with 2.5° (**1a**), 3° (**1b**), and 1.5° (**3**) oscillation steps of φ, 480 s (**1a** and **1b**) and 240 s (**3**) exposure time and 120 mm scanner distance. Eighty (**1a**), 50 (**1b**), and 123 (**3**) images were collected. The images were interpreted and intensities integrated using the DENZO[50] program. The structures were solved by direct methods by employing the SIR-97[51] program on PC. The ruthenium/osmium and many other non-hydrogen atoms were located according to the direct methods and the successive least-square Fourier cycles. The positions of the remaining non-hydrogen atoms were found after successful refinement by full-matrix least-squares using the SHELXL-97[52] program on PC. In the case of **1a**, one methyl group of the *n*Bu moiety was disordered into two positions.

CCDC-216402 (**1a**), CCDC-216401 (**1b**), CCDC-216403 (**3**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

The Solid-State Lanthanoid-Assisted Hydrolysis of the Solvolytically "Inert" $[AsF_6]^-$ Ion

Maja Ponikvar,*[a] Borka Sedej,[a] and Joel F. Liebman[b]

Keywords: Arsenic / Hydrolysis / $LnF_n(AsF_6)_{3-n}$ compounds / Rare-earth elements / Solid-state reactions

Results of elemental chemical analyses of the coordination compounds of the type $LnF_n(AsF_6)_{3-n}$ (Ln = Y, La, Ce, Pr, Nd, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Yb and Lu) indicated unexpectedly low stability of the generally highly hydrolytically stable $[AsF_6]^-$ ion. Experiments conducted on model compounds of the type $NdF_n(AsF_6)_{3-n}$ have shown that hydrolysis proceeded instantaneously during the reaction of the solid compound with water. The ligand substitution catalysis of the compounds is explained in terms of the distortion of the $[AsF_6]^-$ octahedra earlier shown by vibrational spectroscopy. The study contrasts formally related reactions on the solid–solvent interface as opposed to those in homogeneous solution. A new look at some long studied and well-known inorganic species is offered.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

The rare earth(III) fluoroarsenates(V) [$LnF_n(AsF_6)_{3-n}$ compounds] were isolated in the system LnF_3/AsF_5/aHF at room temperature and characterized by: (1) X-ray powder diffraction analysis; (2) spectroscopic methods (Infrared and Raman spectroscopy); (3) monitoring mass balances throughout the experiments; and (4) chemical analyses.[1] The results of elemental chemical analyses indicated the presumed composition of the obtained compounds.[1] Crystal structure data are still lacking for these compounds.

As reported in the literature, the $[AsF_6]^-$ ion is highly stable towards hydrolysis[2,3] and can be determined gravimetrically.[4,5] Klapötke confirmed the stability towards aqueous hydrolysis also for coordinated $[AsF_6]^-$ ions.[6] As part of their study, Clark and Jones[7] suggested that the $[AsF_6]^-$ ion partially hydrolyses through hard acid−hard base interactions. Ghorab and Winfield[8] studied ^{18}F exchange processes of this and other hexafluoropnictates in acetonitrile.

The results of chemical analyses of the $[AsF_6]^-$ ion in $LnF_n(AsF_6)_{3-n}$ compounds synthesized and characterized in our laboratories were low, irreproducible and in disagreement with the calculated amounts of the metal Ln^{III}, total fluoride $(F^-)_t$ and arsenic(V) (results of the determinations of $[AsF_6]^-$ were not reported or interpreted because of lack of the material for supporting experiments).

The aim of the current paper is to demonstrate the instantaneous process of hydrolysis of the generally highly hydrolytically stable $[AsF_6]^-$ ion in $NdF_n(AsF_6)_{3-n}$ compounds during suspension of these solid compounds in water and to offer a plausible interpretation of the obtained results.

Results and Discussion

The results of the determination of the $[AsF_6]^-$ ion in $LnF_n(AsF_6)_{3-n}$ compounds[1] were lower than theoretically calculated values and did not agree with the amount of determined Ln^{III} and $(F^-)_t$ ions [the following abbreviations are used within this paper: $(F^-)_t$ = total fluoride, $(F^-)_P$ = total fluoride in the precipitate, $(F^-)_F$ = free fluoride in the filtrate, $(F^-)_f$ = free fluoride in solution]. Moreover, repetition with several weights of the sample after suspension in water showed that the results were irreproducible. The amount of free fluoride $(F^-)_f$ [9] after suspending these solid compounds in water was also determined. The results of these analyses are presented in Table 1.

Judging by the results presented in Table 1, the differences between two independent parallel determinations of $[AsF_6]^-$ ions seem to increase with increasing fluoroacidity[1,10,11] of the rare-earth trifluorides along the series. The determined amounts of $(F^-)_f$ were abnormally high since binary compounds of the type LnF_3 do not release fluoride ions, as determined in aqueous suspension of the sample directly with a fluoride-ion-selective electrode. The amount of $(F^-)_f$ ions determined in these (binary) compounds was not higher than 0.1−0.2 % of the expected amount, that is, in the range of experimental error of the analytical procedure for fluoride ions.[12]

Table 1. Results of $[AsF_6]^-$ and $(F^-)_f$ analyses for in the coordination compounds of the type $LnF_n(AsF_6)_{3-n}$

Compound	$[AsF_6]^-$ [%] Calcd.	Found[a] 1	$(F^-)_f$ [%] 2	Found
$YF(AsF_6)_2$	77.78	67.9	68.3	5.1
$La(AsF_6)_3$	80.32	67.9	/	1.9
$CeF(AsF_6)_2$	70.37	68.6	68.6	0.5
$PrF(AsF_6)_2$	70.26	62.4	/	0.9
$PrF(AsF_6)_2$	70.26	68.1	68.0	0.5
$NdF(AsF_6)_2$	69.83	66.0	66.0	1.4
$SmF(AsF_6)_2$	69.05	63.3	63.1	1.0
$EuF(AsF_6)_2$	68.85	63.9	63.2	0.7
$GdF(AsF_6)_2$	68.19	58.6	59.2	/
$TbF(AsF_6)_2$	67.68	57.1	/	4.4
$DyF(AsF_6)_2$	67.55	55.3	56.6	6.7
$HoF(AsF_6)_2$	67.26	52.7	59.9	5.8
$ErF(AsF_6)_2$	66.98	59.2	60.2	4.8
ErF_2AsF_6	47.93	47.1	43.7	4.0
$TmF(AsF_6)_2$	66.78	62.2	65.1	2.5
$Tm_2F_3(AsF_6)_3$	58.94	53.5	49.8	5.5
$Yb_2F_3(AsF_6)_3$	58.44	51.5	50.9	4.5
$Lu_2F_3(AsF_6)_3$	58.21	52.8	51.2	3.9

[a] Amount of $[AsF_6]^-$ determined in two separate weights of the sample.

To explain the obtained results, ligand substitution catalysis through solution-phase hard acid−hard base interactions[7,8] was studied. Experiments conducted by using solid $KAsF_6$, solid lanthanide trifluorides or standard solutions of trivalent lanthanide salts revealed that addition of Ln^{III} or LnF_3 to acidic (HCl) aqueous solutions of $KAsF_6$ [with or without addition of solid NaF that represented a source of $(F^-)_f$] did not catalyze the fluoride exchange process in $[AsF_6]^-$ ions. The amounts of the $[AsF_6]^-$ ion determined (ranging from 82.2−82.6 %) in such samples agreed well with theoretically calculated amounts (82.85 %). The possibility of solution-phase catalysis was thus rejected.

The stability of the $[AsF_6]^-$ ion in coordination compounds of the type $LnF_n(AsF_6)_{3-n}$ in aqueous media was further studied in the neodymium model compounds $NdF(AsF_6)_2$ and $Nd(AsF_6)_3$ synthesized for this purpose in our laboratories. Elemental chemical analyses were conducted for both compounds. The results obtained are presented in Table 2.

The results revealed high precision of the obtained results for the determination of Nd^{III} and $(F^-)_t$ ions and high purity of the synthesized compounds, although the stoichiometry was not exact. However, for the purpose of our experiment, the stoichiometry of $NdF(AsF_6)_2$ and $Nd(AsF_6)_3$ was not important. The amount of $[AsF_6]^-$ ion was also determined (see Table 3). The results of these determinations were too low and irreproducible. It was obvious that during the process of suspending the solid compounds in water, the $[AsF_6]^-$ ion decomposed into the fluorohydroxyarsenic(v) species.

Table 3. Results of parallel determinations of $[AsF_6]^-$ in $NdF(AsF_6)_2$ and $Nd(AsF_6)_3$ including the results of determination of the amount of total fluoride in the precipitate $(F^-)_P$ and free fluoride in filtrate $(F^-)_F$

Compound	$[AsF_6]^-$ [%] Calcd.	Found	$(F^-)_P$ [%] Calcd.	Found	$(F^-)_F$ [%] Found
$NdF(AsF_6)_2$	69.83	61.2	19.93	19.6	9.3
		63.2		19.5	8.6
$Nd(AsF_6)_3$	79.71	66.3	19.93	19.5	9.5
		60.5		19.6	11.6
		62.2		19.6	10.6

As reported along with $[AsF_6]^-$, $[AsF_5OH]^-$ can also be determined gravimetrically by precipitation with tetraphenylarsonium chloride (TPAC).[5] Therefore, we investigated whether the precipitate formed was pure or whether $[AsF_5OH]^-$ coprecipitated with $[AsF_6]^-$. In this way, the amount of total fluoride ions in the precipitates $(F^-)_P$ and the amount of fluoride in the filtrates $(F^-)_F$ collected during the filtration of the precipitates were determined. The results are presented in Table 3.

These results indicated that the precipitates formed during the reaction of TPAC with $[AsF_6]^-$ ions in strongly acidic (HCl) media were pure and did not include any TPA-AsF_5OH. In Table 4, the sums of the amounts of fluoride present in the precipitates (calculated from the amount of determined $[AsF_6]$) and the filtrates in individual samples arecompared with the amount of $(F^-)_t$ determined.

As seen from the results, the differences between the sum of $(F^-)_P$ and $(F^-)_F$ and $(F^-)_t$ ranged from 0.8−2.2 %. Considering that precipitation is performed in hot (ca. 70−80 °C), strongly acidic (HCl) solution from which fluoride is lost in the form of relatively volatile HF, these differences are negligible. This indicates that during the initial stage of reaction of the sample with water, the strongly distorted AsF_6 unit partially decomposes. As a result, the fluorohydroxyarsenic(v) species are formed, which decom-

Table 2. The results of elemental chemical analysis of $NdF(AsF_6)_2$ and $Nd(AsF_6)_3$ compounds synthesized in our laboratories

Compound	Nd^{III} [%] Calcd.	Found	RSD[a] [%]	$(F^-)_t$ [%] Calcd.	Found	RSD [%]	As^V [%] Calcd.	Found	RSD [%]
$NdF(AsF_6)_2$	26.66	25.60	0.23	45.65	47.60	0.00	27.69	26.70	1.72
$Nd(AsF_6)_3$	20.29	20.60	0.28	48.10	50.30	0.11	31.61	27.30	1.48

Table 4. Sum of fluoride determined in the precipitate and in the filtrate compared to the amount of determined total fluoride

Compound	(F^-) in AsF_6^- [a] [%]	$(F^-)_F$ [%]	Sum [%]	Difference [%][b]
$NdF(AsF_6)_2$	36.9	9.3	46.2	−1.4
	38.1	8.6	46.7	−0.9
$Nd(AsF_6)_3$	40.0	9.5	49.5	−0.8
	36.5	11.6	48.1	−2.2
	37.8	10.6	48.4	−1.9

[a] The theoretical amount (%) of fluoride in $[AsF_6]^-$ is 60.34 %. [b] The amount of $(F^-)_t$ determined in $NdF(AsF_6)_2$ was 47.6 % and in $Nd(AsF_6)_3$ 50.3 % (see Table 1).

pose to a hydrated arsenic(V) species and fluoride and are subsequently determined in the filtrate according to the [Equation (1)].

$$[AsF_6]^- + 2\,nH_2O \rightarrow [AsF_{6-n}(OH)_n]^- + nF^- + nH_3O^+ \quad (1)$$

The amount of fluoride in the filtrates was determined in two ways: (1) after total decomposition with alkali hydroxide fusion; and (2) directly without prior decomposition. It is interesting to note that the amount of $(F^-)_F$ determined by the two ways was in agreement. This indicated that all the fluoride ions in the filtrate were present as free fluoride ions that can be determined by a fluoride-ion-selective electrode. Therefore, in a separate experiment with $Nd(AsF_6)_3$, we determined the amount of $(F^-)_f$ ions as a function of the pre-treatment conditions of an aliquot of the aqueous filtered suspension of the sample. Subsequently, the amount of $(F^-)_f$ was determined. The results are listed in Table 5.

Table 5. The amount of $(F^-)_f$ determined in $Nd(AsF_6)_3$ as a function of pre-treatment conditions of the sample

Pre-treatment conditions	$(F_f)^-$ [%]
Aqueous filtered suspension	1.6
An aliquot was heated to boiling	1.6
Conc. HCl (0.2 mL) was added to an aliquot	1.8
Conc. HCl (0.2 mL) was added to an aliquot and heated to boiling	9.2

The results indicated that the amount of $(F^-)_f$ determined in the filtered suspension of the sample increased in acidic (HCl) solution at higher temperatures. This observation is in agreement with previously conducted experiments. The covalently bonded fluorides in $LnF_n(AsF_6)_{3-n}$ compounds are therefore released into the solution under conditions of gravimetric determination of $[AsF_6]^-$.

Plausible Interpretation

In the vibrational spectra of rare earth(III) fluoroarsenates(V) more bands were observed than would be expected for a regular $[AsF_6]^-$ anion with O_h symmetry. Additionally, the strongest Raman (697−711 cm^{-1}) and the strongest infrared bands (765−768 cm^{-1}) are shifted to higher frequencies than that of the strongest band of the octahedral $[AsF_6]^-$ ion in $CsAsF_6$ [13] in which Raman-active symmetrical stretching, $\nu_1(A_{1g})$ appears at 685 cm^{-1} and infrared-degenerate stretching $\nu_3(F_{1u})$ at 699 cm^{-1}.[1]

The composition of rare earth(III) fluoroarsenates(V) and the fluorine acceptor abilities of AsF_5 suggests formation of a fluorine bridge between the Ln and As atoms (in agreement with the expected shifts in electron density according to "Gutmann's second rule" [14]). Consequently, the distorted octahedral $[AsF_6]^-$ ions of maximally C_{4v} symmetry are anticipated. The observed number of bands in vibrational spectra of rare earth(III) fluoroarsenates(V) support that assumption and indicate a covalent contribution to the bonding between LnF_3 and AsF_5 through fluorine bridges.[1]

Molecules undergo whatever distortion necessary to maximize the stability of the entire species (cations + anions). However, that the anion is distorted makes it easier for a positive, protic hydrogen to pull off a fluorine atom from the $[AsF_6]^-$ ion (presumably, at least one F has a longer Ln−F bond and so is enroute to dissociation) when suspending these solid compounds in water. Additionally, the arsenic atom has been made more vulnerable to attack by solvent H_2O or added $[OH]^-$ or other nucleophiles such as $[CO_3]^{2-}$, because the irregular octahedron provides more space around the As center, either because of stretched bonds or opened angles or both. Our suggested mechanism of the solid state F^-/OH^- exchange is schematically shown in Figure 1.

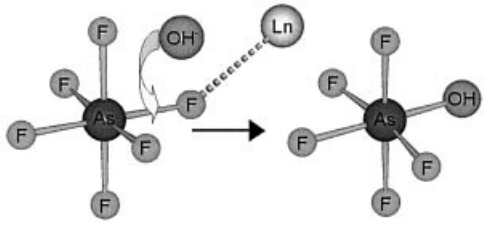

Figure 1. Schematic presentation of our suggested mechanism of the solid state F^-/OH^- exchange (Ln = Y, La, Ce, Pr, Nd, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Yb, Lu)

This reasoning that the distortion is stabilized by the rare-earth element is reminiscent of the generally accepted explanation for enzyme activity in terms of the enzyme stabilizing the transition state of the reaction.[15,16,17] The rare-earth ion stabilizes a distorted $[AsF_6]^-$ ion and so the energy of activation of hydrolysis is reduced relative to the

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

free, undistorted anion. The Ln^{3+} cation may bind the F^- anion so strongly that the $[AsF_6]^-$ hydrolysis is not catalyzed; instead a complex was formed and the reaction is merely accelerated. This too, has counterparts in terms of some modes of enzyme inhibition.

In contrast to the observed process of hydrolysis of rare earth(III) fluoroarsenates(V) after suspension of the solid compounds in water, we noted no acceleration of the hydrolysis of the $[AsF_6]^-$ ion in a homogeneous aqueous solution to which a rare-earth trifluoride or a dissolved rare-earth ion had been added. This observation is explained by coordinative saturation of Ln^{III} (completely and strongly complexed or solvated) by either a F^- anion or a water molecule; the anion is thus protected from hydrolysis. The difference is analogous to inner- and outer-sphere electron transfer and the ease of redox reactions. We close by noting that solvation of the $[AsF_6]^-$ ion by neutral water as opposed to complexation with some cation will also kinetically stabilize this anion. Disappointingly, literature spectroscopic and structural data needed to further corroborate our understanding are lacking.

Experimental Section

General: All reagents were of analytical grade and all solutions were prepared using double-distilled water.

Sample Preparation: Coordination compounds of the general type $LnF_n(AsF_6)_{3-n}$ are sensitive to traces of moisture.[1] Therefore, test samples for determination of the total amount of each element, the $[AsF_6]^-$ ion, and free fluoride $(F^-)_f$ were prepared by weighing in a dry box, with a precision of ± 0.05 mg into air- and moisture-tight Teflon containers. The containers were cooled in liquid nitrogen in order to moderate subsequent reaction with water (20 mL) during suspension in a closed Erlenmeyer flask.

Analyses: Accurate and precise results of chemical analyses with an absolute error of less than 0.2−0.3 % for the determination of the Ln^{III} cation and the $[AsF_6]^-$ anion were obtained by the use of classical analytical methods;[18] a modified analytical technique with a fluoride-ion-selective electrode that enabled us to achieve an absolute error of analysis of less than 0.3 %[12] was applied to the determination of the fluoride anion. The amount of the $[AsF_6]^-$ anion was determined gravimetrically by precipitation with TPAC.[19] The amounts of $(F^-)_t$ and total fluoride in the precipitate $(F^-)_P$ were determined after total decomposition of the sample with alkali carbonate fusion using solid $KNaCO_3$. The amounts of $(F^-)_f$ and free fluoride $(F^-)_F$ in the filtrate after precipitation of the $[AsF_6]^-$ ions were estimated in aqueous suspension and acidic solution of the sample, respectively.[3,12] The analyses were performed by direct potentiometry with a fluoride-ion-selective electrode.[12] The amounts of rare earths(III) were determined by complexometric titrations with EDTA.[20,21,22] Solid $KAsF_6$ (Ozark Mahoning), solid LnF_3 (all from Alfa; the experiment with TmF_3 has not been conducted), standard solutions of Ln^{III} [C = 1000 mg/L, all from Merck, the Y^{III}, La^{III}, Ce^{III} and Tb^{III} standard solutions are declared as nitrates(V) in 2−3 % HNO_3 and the Ce^{III}, Pr^{III}, Nd^{III}, Sm^{III}, Eu^{III}, Gd^{III}, Dy^{III}, Ho^{III}, Er^{III}, Yb^{III} and Lu^{III} standard solutions are declared as the trivalent oxides in 2−3 % HNO_3], solid NaF (Merck), and $NdF(AsF_6)_2$ and $Nd(AsF_6)_3$ synthesized in our laboratories were used during the study of the stability of $[AsF_6]^-$ species.

Acknowledgments

J. F. L. thanks the American Chemical Society for funding for his European travel through its education division, international activities programs. We are grateful to Dr. David Berne (O.B.M.), Dr. Anna Berne, Prof. Boris Žemva, Prof. James S. Vincent and Prof. Ralph M. Pollack for their helpful comments related to this study and to Dr. Zoran Mazej for the preparation of the model compounds. We gratefully acknowledge the financial support of the Ministry of Education, Science and Sport of the Republic of Slovenia.

COVER PICTURE

The cover picture shows how removal of interlayer water from a Zn–Al layered double hydroxide pillared by 1,1′-ferrocenedicarboxylate anions results in reorientation of the guest species and formation of a collapsed phase. Exposure of the collapsed phase to moist air leads to rapid recovery of the expanded phase. A material containing ferrocenecarboxylate anions has also been prepared and found to exhibit a basal spacing of 20.0 Å in the fully hydrated form, consistent with the presence of a bilayer of organometallic guest species. Details of the synthesis and characterization of these compounds are given in the article by M. Pillinger, I. S. Gonçalves et al. on p. 1389 ff.

Metal Telluride Clusters — From Small Molecules to Polyhedral Structures

Joachim Wachter[a]

Dedicated to Professor Dr. Henri Brunner on the occasion of his retirement

Keywords: Niobium / Tellurium / Polymetallic complexes / Clusters / Structures / Reactivity

Niobocene ditelluride complexes [(tBuC$_5$H$_4$)$_2$Nb(Te$_2$)H] (**1**) and [(C$_5$Me$_5$)$_2$Nb(Te$_2$H)] (**2**) are useful starting materials for the synthesis of heterometallic telluride complexes and clusters. The presence of free electron pairs, the propensity for Te–Te bond cleavage and the ability to eliminate Te ligands allow stepwise formation of polyhedral structures in reactions with binary transition metal carbonyl complexes or reactive organometallic fragments. Among the products are the first examples of organometallic derivatives of the elusive [MTe$_4$]$^{2-}$ ion. Ligand cross-transfer (CO versus Te) from one metal center to the other and subsequent charge separation lead to the formation of anionic metal telluride clusters and cationic carbonylniobocene species. The latter play a decisive role in tuning the electronic properties of the cluster units. Whereas the 17-electron fragment (tBuC$_5$H$_4$)$_2$Nb(CO) is directly anchored at the cluster cores by Te bridges, the 18-electron cation [Cp*$_2$Nb(CO)$_2$]$^+$ (Cp* = C$_5$Me$_5$) formed in situ is able to stabilize large and differently charged cluster anions. This is particularly the case in cobalt telluride cluster chemistry which is characterized by hexacapped cubic Co@Co$_8$ or heptacapped pentagonal-prismatic Co@Co$_{10}$ polyhedra. These compounds exhibit pronounced electron-sponge behavior, and crystallographic studies of differently charged clusters allow a correlation of different cluster charges and bond parameters important for understanding electronic structures.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

Metal telluride complexes are characterized by a wide and impressive structural variety[1] and recent developments focus on their ability for cluster aggregation.[2,3] Our interest in tellurium complex chemistry stems from the chemistry of chalcogen-rich organometallic complexes and the diversity of sulfur- and selenium-derived ligands.[4] During these studies we have found that bent dicyclopentadienylmetal fragments of the early transition metals are ideal organometallic substrates for the incorporation of chalcogenide ligands.[5] However, only a few comparative investigations have been carried out in which the coordination behavior of different chalcogens has been studied with the same transition metal,[6] although they reveal gradual but distinct changes when going from sulfur to tellurium.

It is a particular feature of the heavier group 5 metallocene fragments that they incorporate two chalcogenide ligands along with hydrogen in different coordination modes **A**–**C** (Scheme 1).[7,8] Obviously, the assembly of the main-group ligands not only depends on the nature of the chalcogen, but also on the substituents at the cyclopentadienyl ligand. Ligand rearrangements by breaking chalcogen–hydrogen and/or chalcogen–chalcogen bonds may lead to interconversion of one form into another. For example, [Cp*$_2$Nb(η-Se$_2$H)] (form **A**) may be easily converted by light into the corresponding forms **B** and **C**.[8b]

The presence of free electron pairs in metallocene dichalcogenides is an important prerequisite for the formation of

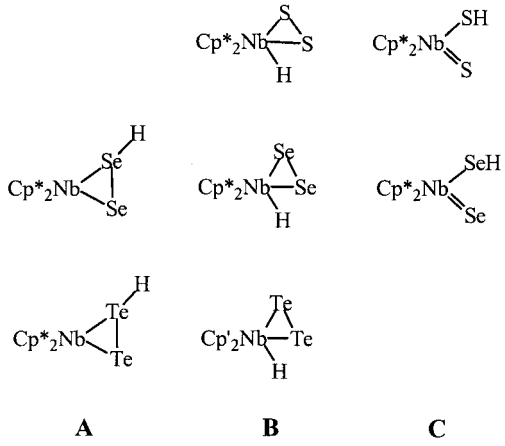
Joachim Wachter passed his Ph.D. in 1976 at the Universität Regensburg under the supervision of Prof. Dr. H. Brunner, after studying chemistry at the Universität München. In 1978/1979 he spent a year as a postdoctoral researcher with Prof. J. G. Riess in Nice. Since 1977 he has conducted research at the Universität Regensburg, which has led to more than 120 publications. His main scientific interests are the organometallic chemistry of the chalcogens, mixed ligands of the Group 15 and 16 elements, and the chemistry of metal telluride clusters.

MICROREVIEWS: This feature introduces the readers to the authors' research through a concise overview of the selected topic. Reference to important work from others in the field is included.

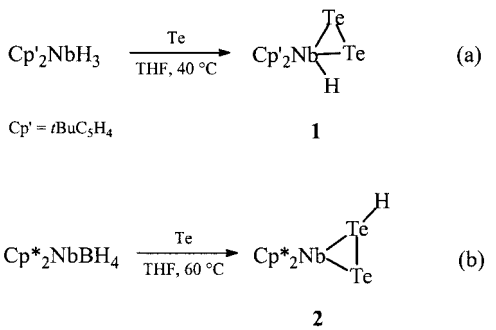


Scheme 1. Examples of the coordination modes of dichalcogenide ligands in $[Cp^*_2NbX_2H]$ complexes ($Cp^* = C_5Me_5$; X = S, Se, Te) and $[(t\text{BuC}_5H_4)_2Nb(Te_2)H]$

polymetallic compounds,[9] whereas the role of the different coordination modes of the hydrogen ligands is not yet fully understood. A specific feature, particularly in niobocene ditelluride chemistry, is the elimination of Te^0 or Te^{2-} building blocks and their transfer onto reactive organometallic compounds followed by the assembly of polyhedral clusters. The diversity of the obtained results is summarized in this microreview.

Activation of Elemental Tellurium in Hydridic Niobocene Derivatives

Convenient synthetic methods involve the use of hydride or boranate ligands containing alkyl-substituted niobocene derivatives. In both cases identical results are obtained. Thus, reaction of $[(t\text{BuC}_5H_4)_2NbH_3]$ or $[(t\text{BuC}_5H_4)_2NbBH_4]$ with elemental tellurium in THF forms $[(t\text{BuC}_5H_4)_2Nb(Te_2)H]$ (**1**) in good yields [Equation (1a)].[10] Replacement of the $t\text{BuC}_5H_4$ ligand by the more electron-rich peralkylated Cp* ligand in the analogous reactions gives $[Cp^*_2Nb(Te_2H)]$ (**2**) in excellent yields [Equation (1b)].[11] These results show that the formation of the structure types **A** or **B** for **1** and **2** depends more on the nature of the cyclopentadienyl ligands than on the nature of the hydride source.



(1)

NMR spectroscopy alone is not suitable to assign complexes **1** and **2** to one of the structural types shown in Scheme 1. However, the presence of a Te_2 ligand along with a hydride ion in the dark orange $[(t\text{BuC}_5H_4)_2Nb(Te_2)H]$ (**1**) follows definitively from the crystal structure of $[(t\text{BuC}_5H_4)_2Nb(Te_2)H{\cdot}Cr(CO)_5]$ (**3**), which is the product of the addition of the Lewis acid fragment $Cr(CO)_5$ to **1** (Scheme 2a). Structural analogues of **1** are $[Cp^*_2Nb(S_2)H]$,[7] $[(t\text{BuC}_5H_4)_2Ta(S_2)H]$,[12] and $[Cp^*_2Ta(Te_2)H]$.[13]

The orange complex $[Cp^*_2Nb(Te_2H)]$ (**2**) exhibits in its ^{1}H NMR spectrum a hydride resonance at $\delta = -3.55$ ppm, whereas in the ^{125}Te NMR spectrum only one resonance ($\delta = -207.9$ ppm) is found, probably due to partially relaxed scalar ^{125}Te-^{93}Nb interactions.[11] The ^{1}H NMR spectrum of $[(C_5Me_4Et)_2Nb(Te_2H)]$ exhibits a symmetrical 14-line signal for the diastereotopic CH_2 protons of both ethyl groups, in agreement with a chiral center at one of the Te atoms.[14] A nearly identical pattern has been observed in $[(C_5Me_4Et)_2Nb(Se_2H)]$.[8b]

Polymetallic Telluride Complexes from $[(t\text{BuC}_5H_4)_2Nb(Te_2)H]$

As already noted, $[(t\text{BuC}_5H_4)_2Nb(Te_2)H]$ reacts with $[Cr(CO)_5THF]$ to give the dimetallic adduct $[(t\text{BuC}_5H_4)_2Nb(Te_2)H{\cdot}Cr(CO)_5]$ (**3**) in 90% yield. The crystal structure of **3** provides evidence for the presence of a $\mu,\eta^{1:2}$-Te_2 ligand and allows unambiguous localization of the hydride ion directly bonded to the Nb center (Figure 1).[10] Therefore, complex **3** is one of the few structurally characterized ditelluride complexes of the structural type **B**. The Te−Te distance of 2.695(1) Å is similar to those in other complexes containing side-on coordinated η^2-Te_2.[6b,6e,15]

A side-product in the synthesis of **1** is the homonuclear polymetallic complex $[(t\text{BuC}_5H_4)_6Nb_4Te_4O]$ (**4**), the formation of which depends on the residual concentration of air in the reaction mixture. Small amounts of **4** also form upon heating solutions of **1** (Scheme 2b).

The crystal structure of **4** shows two planar Nb_2Te_2 rings (Figure 2) connected by a linear oxygen bridge. Each of the "outer" Nb atoms [Nb(1), Nb(4)] is part of a niobocene fragment, whereas the coordination sphere of the "inner" Nb atoms [Nb(2), Nb(3)] is completed by only one ($t\text{BuC}_5H_4$) ligand. The linearity of the Nb−O−Nb bridge [angle (Nb−O−Nb) = 177.1(1)°] and the electron deficiency of the "inner" Nb atoms [Nb(2), Nb(3)] suggests the contribution of p_π oxygen orbitals. A similar structure has been found in $[(t\text{BuC}_5H_4)_6V_4S_4O]$.[16]

Formally, complex **4** contains four Nb^{IV} centers, but ^{1}H NMR spectroscopy indicates the diamagnetic nature of the molecule. This behavior seems to be characteristic for compounds with four-membered Nb_2Te_2 rings and may be explained by through-space Nb−Nb coupling (see below). In the case of **4** the Nb−Nb distances (3.43 Å) are only slightly longer than those in the related diamagnetic complex $[(C_5H_5)_2Nb(\mu\text{-}S)]_2$ [*d*(Nb−Nb) 3.2340(8) Å].[17]

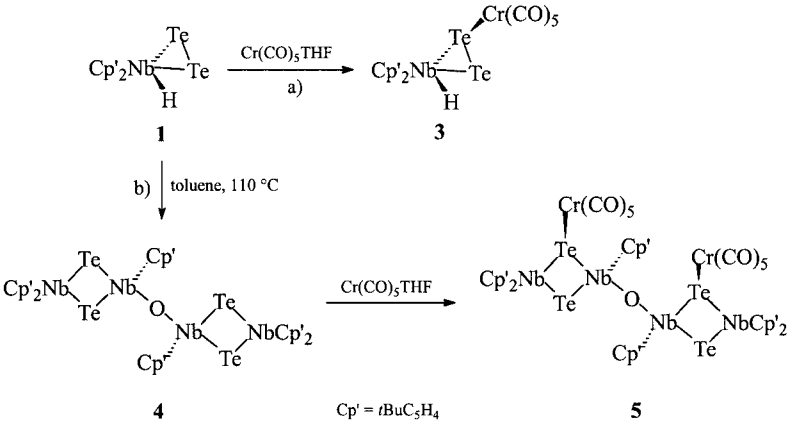

Scheme 2

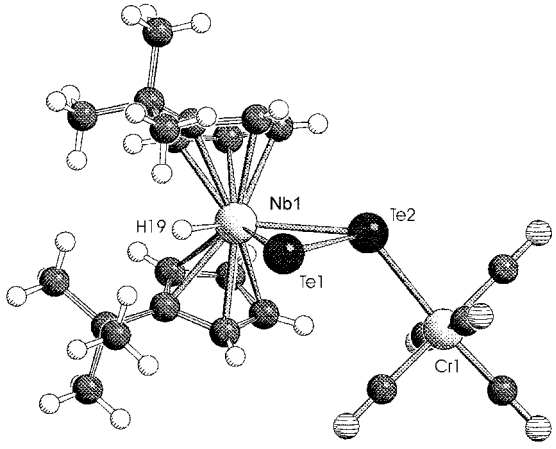

Figure 1. Molecular structure of $[(t\mathrm{BuC_5H_4})_2\mathrm{Nb(Te_2)H{\cdot}Cr(CO)_5}]$ (**3**)

The Te bridges of **4** are still accessible for the addition of two $Cr(CO)_5$ fragments although the steric situation of the bridges seems to be rather crowded (Scheme 2b). In the resulting complex $[(t\mathrm{BuC_5H_4})_6\mathrm{Nb_4Te_4O{\cdot}2Cr(CO)_5}]$ (**5**) the overall geometry of the starting complex has been preserved, but now the bulky $Cr(CO)_5$ groups are able to block the rotation around the Cp′−Nb bonds at room temperature, as follows from ^{1}H NMR spectroscopy.[10]

The reaction of $[(t\mathrm{BuC_5H_4})_2\mathrm{Nb(Te_2)H}]$ (**1**) with $[Fe_2(CO)_9]$ formally proceeds with insertion of an $Fe_2(CO)_6$ unit into the Te−Te bond of **1** (Scheme 3).[18] The resulting heterotrimetallic compound $[\{(t\mathrm{BuC_5H_4})_2\mathrm{NbH(Te)_2}\}\mathrm{Fe_2(CO)_6}]$ (**6**) forms the monoadduct $[\{(t\mathrm{BuC_5H_4})_2\mathrm{NbH(Te)_2Fe_2(CO)_6}\}{\cdot}\mathrm{Cr(CO)_5}]$ (**7**) with $[Cr(CO)_5THF]$ in nearly quantitative yield. ^{1}H NMR investigations reveal the presence of two isomers at room temperature in nearly equal amounts. Crystallization at −24 °C affords separation of the sterically more crowded *vic*-**7**. Its crystal structure (Figure 3) proves that the incoming $Cr(CO)_5$ fragment is

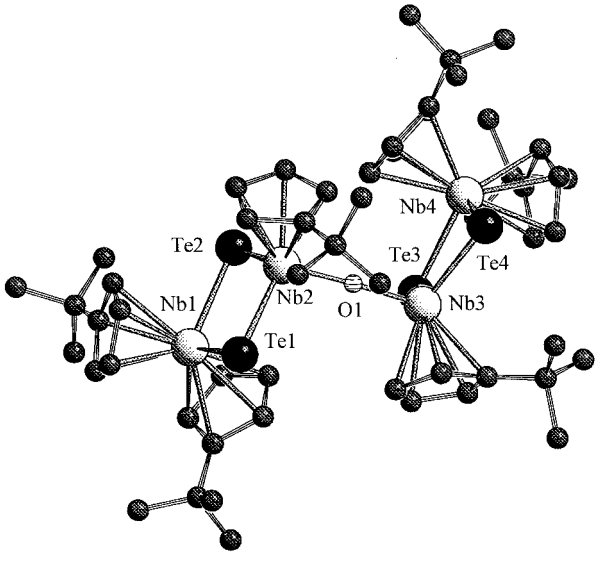

Figure 2. Molecular structure of $[(t\mathrm{BuC_5H_4})_6\mathrm{Nb_4Te_4O}]$ (**4**)

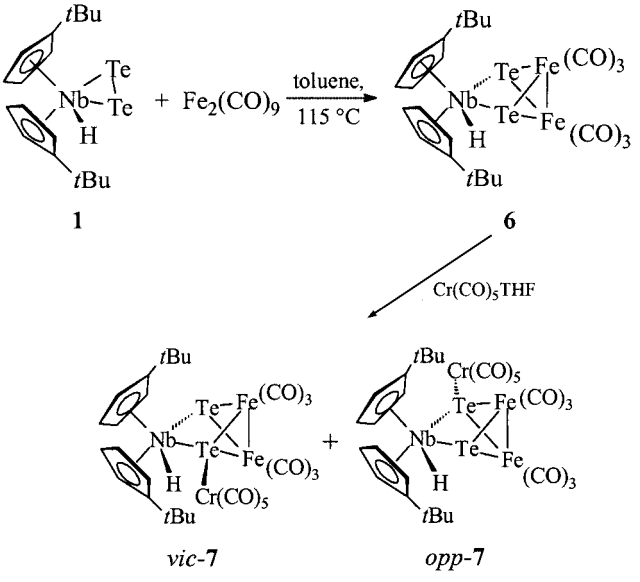

Scheme 3

attached at the central Te atom and in the vicinity (*vic*) of the Nb−H moiety. Although the latter could not be localized directly, its presence follows from its stereochemical activity in the structure and from the ^{1}H NMR spectra.

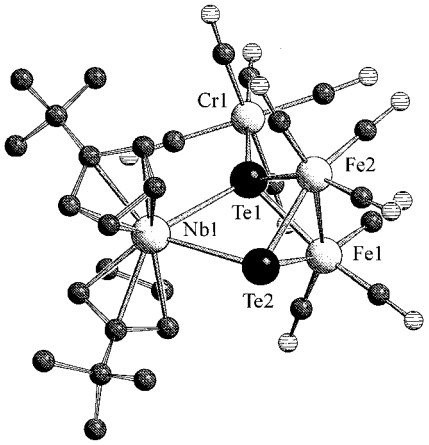

Figure 3. Molecular structure of *vic*-[{(tBuC$_5$H$_4$)$_2$-NbH(Te)$_2$Fe$_2$(CO)$_6$}·Cr(CO)$_5$] (*vic*-**7**); the hydrogen atom at Nb(1) may be located close to Te(1)[18]

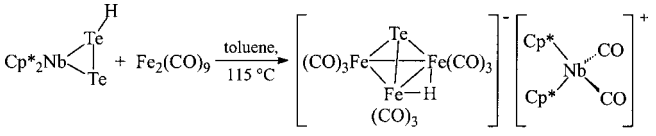
Complexes **6** and **7** are some more examples of compounds with an Fe_2Te_2 core.[19] Generally, such derivatives are formal insertion products of a two-electron metal fragment into the Te−Te bond of [Fe$_2$(μ-Te$_2$)(CO)$_6$].[20]

The stability of the $NbTe_2Fe_2$ framework in **6** and **7** occurs for different reasons, because replacement of tBuC$_5$H$_4$ by the Cp* ligand results in a ligand (CO, Te) cross-transfer from one metal center to the other. A concomitant charge separation leads to the formation of distinct [Cp*$_2$Nb(CO)$_2$]$^+$ and [Fe$_3$H(μ$_3$-Te)(CO)$_9$]$^-$ ions [Equation (2)].[21] CO-containing intermediate products, which may be analogues of **6**, can be observed by IR spectroscopy, but they are not stable enough for isolation.



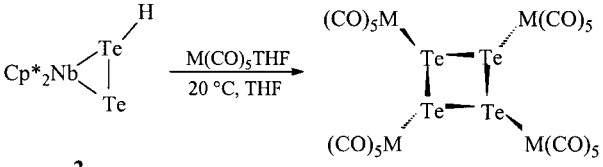
2 **8** (2)

Oxidative Elimination of Active Te^0 from [Cp*$_2$Nb(Te$_2$H)] (2)

Solutions of **2** are stable towards rearrangement into structural forms **B** and **C**. They are also stable with respect to spontaneous Te elimination, but with PPh_3 the corresponding phosphane oxide and elemental tellurium are formed, probably due to the presence of traces of air. No proof has been found for the existence of pseudo-tetrahedral [Cp*$_2$Nb(=Te)H], although the structurally related [Cp*$_2$Ta(=Te)H] is accessible in a similar reaction from [Cp*$_2$Ta(Te$_2$)H].[13]

In the presence of reactive transition metal fragments there is no precipitation of grey tellurium. Instead, depending on the reaction conditions a series of homo- and heterometallic telluride complexes or even clusters is formed which are the subject of the following sections.

A nice example of the elimination of Te^0 from [Cp*$_2$Nb(Te$_2$H)] is its reaction with an excess of [M(CO)$_5$(THF)] (M = Cr, W).[11] The resulting red-brown compounds *cyclo*-Te$_4$[M(CO)$_5$]$_4$ (**8**) are the first organometallic derivatives of a neutral molecular tellurium ring [Equation (3)].[12] The central feature of the structure of **8**-Cr is a Te$_4$ ring [d(Te−Te) = 2.854(3) Å mean], which is forced by the attached Cr(CO)$_5$ fragments into D_{2d} butterfly geometry (Figure 4). EHMO calculations carried out on the free hypothetical *cyclo*-Te$_4$ ring show that the square-planar (D_{4h}) structure is only 0.2 eV less favorable in total energies than the folded (D_{2d}) structure.[11]



2 **8** (3)

M = Cr, W

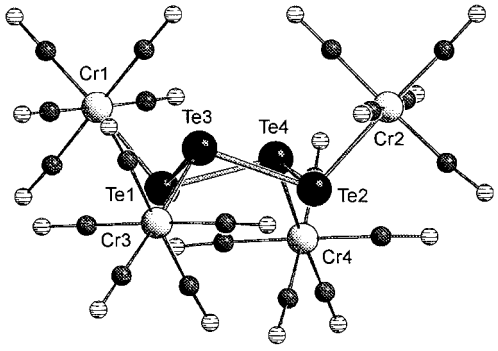


Figure 4. Side view of the structure of *cyclo*-Te$_4$[Cr(CO)$_5$]$_4$ (**8**-Cr)[11]

Another example of the incorporation of Te^0 from **2** into a Lewis acid metal fragment was observed in the reaction of **2** with [(C$_5$H$_5$)Mn(CO)$_2$(THF)], which gave [{(C$_5$H$_5$)Mn(CO)$_2$}$_3$(μ$_3$-Te)] in 80% yield.[25] This complex, which was first synthesized 1983 by Herberhold et al., possesses a trigonal-planar Te center.[26]

Interestingly, [Cp*$_2$Nb(Se$_2$H)], which is isostructural with **2**, gives a completely different result under identical reaction conditions: the carbonyl-free heterotrimetallic complex **9** is formed as the final product [Equation (4)],[23] which belongs to the class of *pseudo*-tetrahedral MX_4 compounds and which will be discussed shortly.[23,24] The observation of CO absorptions during the reaction by IR spectroscopy may be a hint for the addition of Cr(CO)$_5$ to one or more lone-pair electrons of the Nb(Se$_2$H) moiety [Equation (4)]. By contrast, the sterically less demanding tBuC$_5$H$_4$ ligand in **1** allows formation of a stable Cr(CO)$_5$ adduct

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

(Scheme 2). The related complex $[(t\mathrm{BuC_5H_4})_2\mathrm{Ta(S_2)H}]$ can even add two $Cr(CO)_5$ fragments.[9]

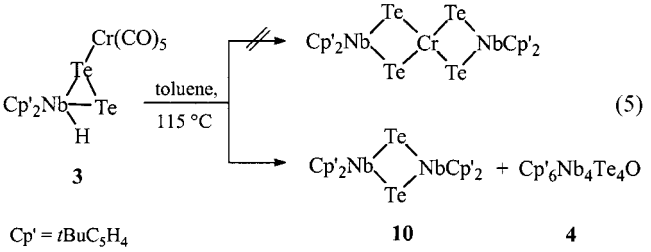
9

The Quest for Derivatives of the Tetratellurometalate Ion

Molecular polymetallic chalcogenido complexes containing a central *pseudo*-tetrahedral MX_4 (X = S, Se) unit show interesting electronic and optical properties.[27,28] Although it is known that replacement of sulfur by selenium increases nonlinear optical properties by a heavy metal effect,[29] the corresponding tetratellurometalates are still unknown. Examples of tellurometalates with coordination number four, in which the metal center is surrounded by polytelluride ligands, like in $[AuTe_7]^{3-}$, are known.[30]

Dimetallic tetrathio- and tetraselenometalates of the type $[(Cp^*_2Nb)_2MX_4]$ (M = Cr, Mo; X = S, Se) may be prepared from $[Cp^*_2Nb(\eta^2\text{-}X_2)H]$ derivatives and binary carbonyl transition metal complexes {e.g. $[M(CO)_6]$, $[Fe_2(CO)_9]$, $[Co_2(CO)_8]$} in boiling toluene.[23,24] An alternative route is the thermal decomposition of solutions of $[(t\mathrm{BuC_5H_4})_2\mathrm{Ta(S_2)H{\cdot}Cr(CO)_5}]$,[9] $[Cp^*_2\mathrm{Nb(S_2)H{\cdot}Cr(CO)_5}]$,[31] and the elusive $[Cp^*_2\mathrm{Nb(Se_2)H{\cdot}Cr(CO)_5}]$, respectively [Equation (4)].

Attempts to convert solutions of **3** in boiling toluene into $[(Cp^*_2Nb)_2CrTe_4]$ end up with green-black $[(t\mathrm{BuC_5H_4})_4\mathrm{Nb_2Te_2}]$ (**10**) along with small amounts of **4** [Equation (5)]. Complex **10** may be obtained in still better yield from the reaction of **1** with $[Cr(CO)_6]$ in boiling toluene.[31] The crystal structure of **10** contains a planar rhombohedral Nb_2Te_2 core to which four Cp′ ligands are coordinated. The conformation of the $(t\mathrm{BuC_5H_4})$ ligands is that of the achiral *meso* diastereomer (Figure 5). ^{1}H NMR spectroscopic investigations reveal a restricted rotation around the $(t\mathrm{BuC_5H_4})$–Nb bonds at −90 °C. Although a similar conformation has been found in the related complex $[(t\mathrm{BuC_5H_4})_4\mathrm{Zr_2Te_2}]$, there is no spectroscopic evidence for a restricted rotation around the $(t\mathrm{BuC_5H_4})$–Zr axis.[32]



(5)

3 **10** **4**

Cp′ = $t\mathrm{BuC_5H_4}$

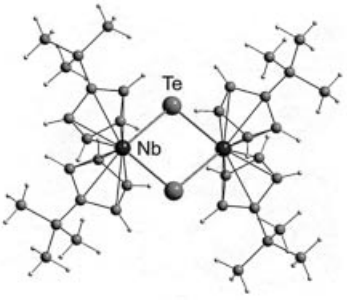


Figure 5. Molecular structure of $[(t\mathrm{BuC_5H_4})_4\mathrm{Nb_2Te_2}]$ (**10**)[31]

The bonding system within the four-membered Nb_2Te_2 ring in **10** is defined by a long transannular Te–Te distance [d = 4.262(1) Å] of nonbonding character and an Nb–Nb distance [3.647(1) Å], which is still longer than d(Nb–Nb) in **4**, but which is again consistent, according to DFT calculations,[10] with a through-space Nb–Nb coupling.

The μ_2-Te bridges in **10** exhibit nucleophilic character. Thus, reaction of **10** with MeI gives the violet salts $[(t\mathrm{BuC_5H_4})_4\mathrm{Nb_2Te(MeTe)}]\mathrm{I}$ or $[\mathrm{Cp'_4Nb_2(MeTe)_2}]\mathrm{I_2}$ according to the employed stoichiometry (1 or 2 equiv. of MeI).[10] Crystallographic studies of the cations reveal that addition of the electrophiles does not significantly affect the intraannular forces between opposite atoms in the Nb_2Te_2 ring.

Whereas reaction of **1** with $[Cr(CO)_6]$ in boiling toluene gives chromium-free **10** [Equation (6)], $[W(CO)_6]$ does not react under similar conditions. However, in decane at 140 °C the red tetrametallic complex $[\{(t\mathrm{BuC_5H_4})_4\mathrm{Nb_2WTe_4}\}\mathrm{W(CO)_4}]$ (**11**) is formed in 54% yield [Equation (6)].[31] According to X-ray crystallography, complex **11** contains a slightly distorted WTe_4 tetrahedron to which two niobocene fragments are coordinated (Figure 6). A $W(CO)_4$ fragment is inserted between two of the Te bridges of the central WTe_4 tetrahedron. Formally, complex **11** may be described as an organometallic derivative of the hitherto unknown $[WTe_4]^{2-}$ ion. This view is in agreement with W–Te bond lengths [average 2.574(2) Å] around W(1) in the range of W–Te double bonds and a *pseudo*-tetrahedral arrangement of the Te atoms around W(1).[33] Accordingly, the distances W(2)–Te(2) and W(2)–Te(3) are longer by 0.25 Å. The description of the entire metal–ligand bond system needs to take into account delocalization over the heavy atom skeleton, except for W(2).[31]

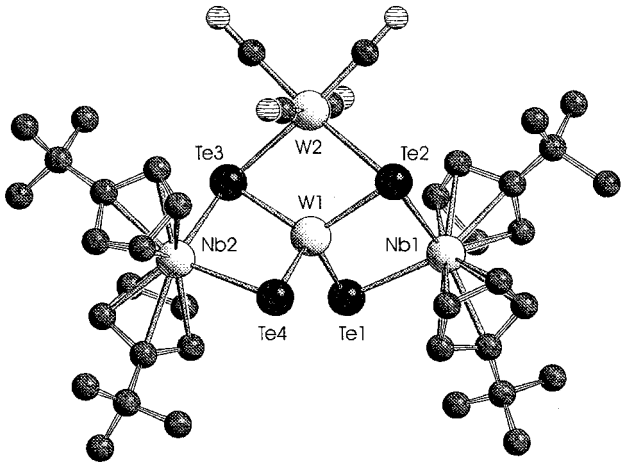

Figure 6. Molecular structure of $[\{(t\mathrm{BuC_5H_4})_4Nb_2WTe_4\}W(CO)_4]$ (**11**)[31]

A second example of a tetratellurometalate complex is $[(Cp^*_2Nb)_2NiTe_4]$ (**12**). The black-violet diamagnetic compound is accessible from the reaction of $[Ni(COD)_2]$ with $[Cp^*_2Nb(Te_2H)]$ in boiling toluene. The reaction with $[(t\mathrm{BuC_5H_4})_2Nb(Te_2)H]$ under analogous conditions does not give well-defined products.[34]

At first glance the molecular structure of **12** resembles those of the above-described bis(niobocene) tetrachalcogenidometalates. However, there is a remarkable distortion of the central $NiTe_4$ tetrahedron (Figure 7). This is expressed by Te−Ni−Te angles which split into three different groups between 78.2(1) and 139.2(1)° when compared to the WTe_4 core in **11**. The distortion is also expressed by interannular Te1···Te3 and Te2···Te4 distances of 3.100(7) and 3.122(7) Å, which may even be bonding interactions. In contrast, the transannular Te···Te distances within each of the $NiNbTe_2$ cycles are much longer (4.19 Å mean). Interestingly, complexes involving Ni_2Te_2 four-membered rings, like $[\{(\mathrm{triphos})Ni\}_2(\mu\text{-}Te)_2]$ [d(Te−Te) = 2.802(1) Å][35] and $[\{(C_5H\mathit{i}Pr_4)Ni\}_2(\mu\text{-}Te)_2]$ [d(Te−Te) = 3.052(5) Å] exhibit Te−Te distances that clearly have bonding character.[36]

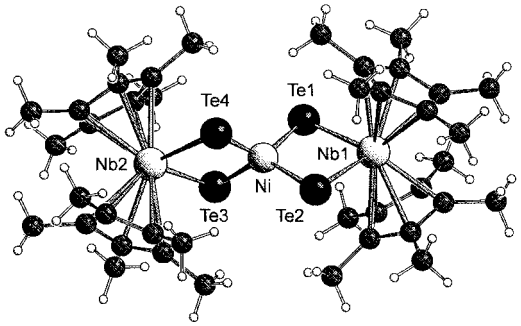

Figure 7. Molecular structure of $[(Cp^*_2Nb)_2NiTe_4]$ (**12**)[34]

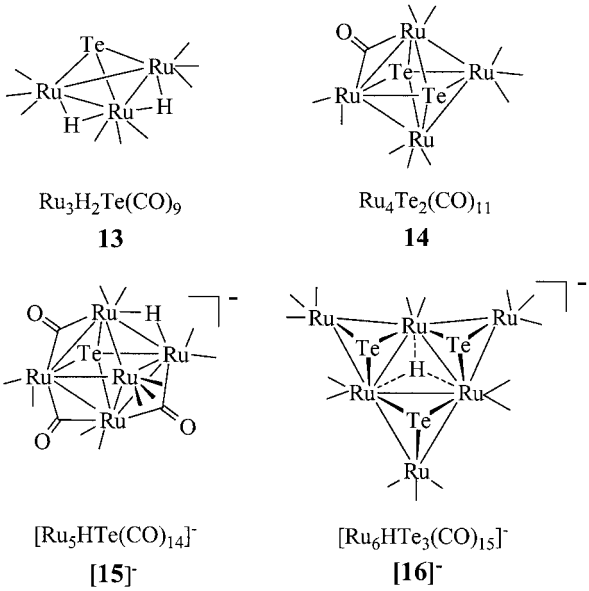
Like $[(Cp^*_2Nb)_2CrSe_4]$ (**9**),[23] complex **12** is able to undergo two reversible oxidation steps and two reversible reduction steps in cyclic voltammetry.[37] The corresponding paramagnetic cation $[\mathbf{12}]^+$ has been obtained by oxidation of **12** with $[C_5H_5)_2Fe]^+$, but only in the presence of a chemically relatively inert anion, like $[BPh_4]^-$.

Formation of Metal Telluride Clusters

It has already been shown that insertion of an $Fe_2(CO)_6$ unit from $[Fe_2(CO)_9]$ into the Te−Te bond of **1** gives the heterotrimetallic complex **6** (Scheme 3). However, the $NbTe_2Fe_2$ framework seems to be destabilized by introduction of the Cp* ligand. Thus, reaction of **2** with $[Fe_2(CO)_9]$ finally results in a reductive elimination of Te^{2-}, which serves as a glue for the formation of the $[Fe_3H(\mu_3\text{-}Te)(CO)_9]^-$ cluster anion [Equation (2)].[19b,19g,38] The counterion is the rather stable $[Cp^*_2Nb(CO)_2]^+$ ion, which may have been formed by CO ligand transfer from enneacarbonyldiiron onto the niobocene fragment. In the following sections we will show that the in situ formation of this Nb^{III} cation exerts a considerable stabilization effect on anionic transition metal telluride clusters. It is striking that a corresponding $[(t\mathrm{BuC_5H_4})_2Nb(CO)_2]^+$ ion has not yet been observed thus far.

The reaction of **2** with $[Ru_3(CO)_{12}]$ in boiling toluene gives a rather heterogeneous mixture of neutral and salt-like carbonylruthenium clusters with tellurido and hydrido ligands (Scheme 4).[39] $[Ru_3(\mu_2\text{-}H)_2(\mu_3\text{-}Te)(CO)_9]$[40] (**13**; 11% yield) has been characterized indirectly by crystallography of $[Ru_3(\mu_2\text{-}H)_2(\mu_3\text{-}Te)(CO)_7(\mathrm{dppm})]$, which is a CO substitution product from the reaction of **13** with bis(diphenylphosphanyl)methane (dppm). Along with the already known cluster $[Ru_4(\mu_4\text{-}Te)_2(CO)_{11}]$ (**14**; 27%),[41] $[Cp^*_2Nb(CO)_2][Ru_5H(\mu_4\text{-}Te)(CO)_{14}]$ {$[Cp^*_2Nb(CO)_2]$[**15**]; 31%} and $[Cp^*_2Nb(CO)_2][Ru_6H(\mu_3\text{-}Te)_3(CO)_{15}]$ {$[Cp^*_2Nb(CO)_2]$[**16**]; 4%} have been isolated and characterized by X-ray crystallography. Cluster **14** exhibits inter-



Scheme 4. Neutral and anionic clusters from the reaction of **2** with $[Ru_3(CO)_{12}]$ in boiling toluene; the corresponding cation in the case of $[\mathbf{15}]^-$ and $[\mathbf{16}]^-$ is $[Cp^*_2Nb(CO)_2]^+$

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

esting redox properties: The reversible uptake of up to four electrons may be accompanied by structural rearrangements as suggested by theoretical studies.[39]

These structural motifs extend the knowledge of carbonylruthenium chalcogenide clusters.[42] The structure of the 74-electron anion $[\mathbf{15}]^-$ may be described by a slightly distorted Ru_5 square pyramid spanned by a μ_4-Te ligand. Thus, it belongs to the class of $[Ru_5X(CO)_{15}]$ clusters (X = S, Se, Te), of which only $[Ru_5S(CO)_{15}]$ has been synthesized thus far.[43] The triangular structure of $[\mathbf{16}]^-$ is mainly composed of three edge-linked Ru_3Te tetrahedra, in close analogy to the structure of $[Ru_6HS_3(CO)_{15}]^-$.[44]

It is striking that the CO/Ru ratio in all compounds is much higher than two, although attempts to increase the tellurium content by varying the stoichiometry and reaction conditions were not successful. The origin of the hydrido ligands in **13**, $[\mathbf{15}]^-$ and $[\mathbf{16}]^-$ may rather be ascribed to abstraction from the solvent[40,45] than hydrogen transfer from **2**. In this context it may be of interest that $[(t\mathrm{BuC_5H_4})_2\mathrm{Nb(Te_2)H}]$ does not give reasonable results under analogous reaction conditions.[46]

Another still more complex system concerns the reaction of $[\mathrm{Cp^*_2Nb(Te_2H)}]$ {or $[(\mathrm{C_5Me_4Et})_2\mathrm{Nb(Te_2H)}]$ for the purpose of better crystallization} with $[Co_2(CO)_8]$. This reaction is temperature-dependent and, contrary to other systems, it has been possible to isolate intermediate products, such as **17** and **18**, at 0 °C. These disappear at higher temperatures forming highly connected and symmetric molecular carbonylcobalt telluride cluster anions (Scheme 5).[47]

The bicapped trigonal-bipyramidal cobalt telluride cluster **17** consists of a triangular 47-electron $Co_3(CO)_6Te_2$ core [d(Co−Co) = 2.513(3) Å] to which a 17-electron $\mathrm{Cp^*_2Nb(CO)}$ fragment is attached by a covalent Te−Nb bridge (Figure 8). This structural motif is more current for niobocene derivatives comprising the $t\mathrm{BuC_5H_4}$ ligand, as will be shown later. Cluster **17** is the only example of an intermediate in which peralkylated niobocene telluride and carbonylcobalt building blocks are arranged together into a small covalent cluster. For this reason it may also be considered as the first step en route to polyhedral structures or even solid-state compounds.[48]

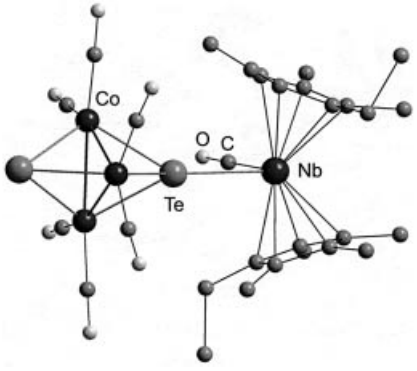


Figure 8. Molecular structure of $[(\mathrm{C_5Me_4Et})_2\mathrm{NbTe_2Co_3(CO)_7}]$ (**17**)[47]

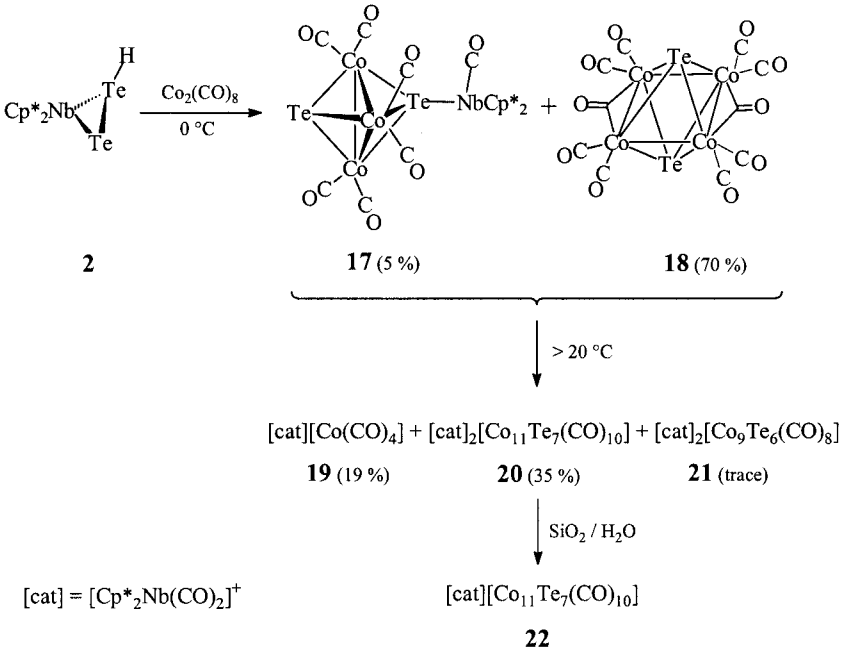
The second product is the already known tetragonal-bipyramidal $[Co_4(\mu_4\text{-Te})_2(\mu_2\text{-CO})_2(CO)_8]$ (**18**),[49] which forms in remarkably good yield. However, at room temperature there is a considerable decrease of the yields of **17** and **18** and the ionic compounds **19**−**21**, the formation of which is completed by refluxing the mixture in toluene for 3 h, are formed instead (Scheme 5). From the fact that **18** does not react with **2** in an independent experiment one may conclude that as-yet-unidentified reactive niobocene telluride particles exist in solution and that these are responsible for the disappearance of **18** when raising the temperature.



Scheme 5

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

The mixture of **19**, **20** and **21** was separated by fractional crystallization and the resulting crystals were examined by X-ray crystallography. The structure of the yellow salt **19** consists of distinct $[Cp^*_2Nb(CO)_2]^+$ and $[Co(CO)_4]^-$ ions in a 1:1 ratio, whereas the cation/anion ratio is 2:1 in **20** and **21**. The structure of the dianion in **20** resembles that of the monoanion (see below). It may be described by a heptacapped pentagonal-prismatic Co_{10} polyhedron (Figure 9), while that in **21** is a hexacapped Co_8 cube (Figure 10). In addition, each of the two polyhedra contains an interstitial Co atom.[47]

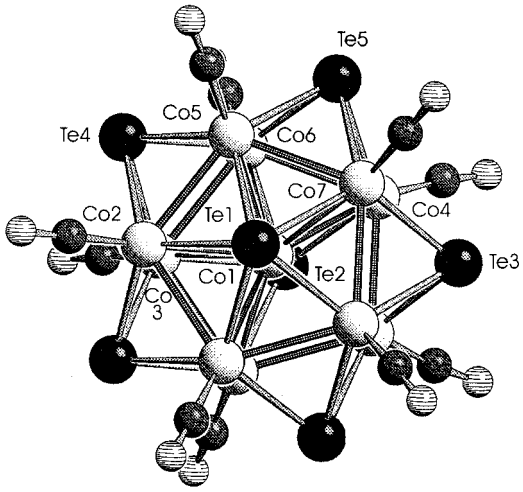


Figure 9. Structure of the $[Co_{11}Te_7(CO)_{10}]^-$ ion in **22**[47]

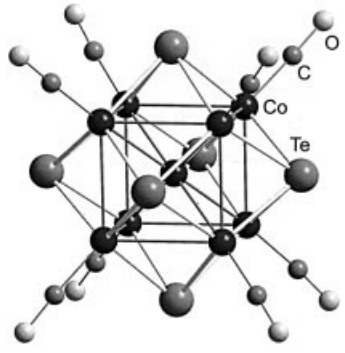

Figure 10. Structure of the $[Co_9Te_6(CO)_8]^{2-}$ ion in **21**[47]

The omnipresence of the $[Cp^*_2Nb(CO)_2]^+$ cation in the structures of compounds **19**−**22** is striking. The remarkably stable Nb^{III} derivative extends the series of dicarbonyl early transition metallocene complexes, for example $[Cp^*_2M(CO)_2]$ (M = Ti, Zr, Hf)[50] and $[(C_5H_5)_2V(CO)_2]^+$.[51] Furthermore, it takes the role of an organometallic template in the formation of cluster anions.

Although the cluster salt **21** is formed in only trace amounts its existence is important because it contains the first cobalt- and tellurium-containing representative in the class of metal-centered hexacapped $[M_9(\mu_4\text{-}E)_6L_8]$ clusters (M = Ni, Pd; E = GeEt, As, Te).[3a,52] According to various combinations of metals and ligands metal valence electron (MVE) counts of between 120 and 130 MVEs have been realized. No cluster has been described in different oxidation states thus far.[53] The anion in **21** contains 123 MVEs, but other electron counts have been realized by varying the cluster charges, as will be shown below.

Compound **20** contains the same dianion $[Co_{11}Te_7(CO)_{10}]^{2-}$ as has already been found in $[Ph_4P]_2$-$[Co_{11}Te_7(CO)_{10}]$. This compound was synthesized from $[Co_2(CO)_8]$, Na_2Te_2 and Ph_4PCl in methanol under solvothermal conditions.[54] Chromatography of **20** results in the formation of $[Cp^*_2Nb(CO)_2][Co_{11}Te_7(CO)_{10}]$ (**22**; Scheme 5). The loss of one $[Cp^*_2Nb(CO)_2]^+$ ion during the transfer **20** → **22** corresponds to a one-electron oxidation of $[Co_{11}Te_7(CO)_{10}]^{2-}$ by H^+. Electrochemical investigations confirm three reversible electron-transfer steps regardless of the charge of the anions (Scheme 6).[47] Concomitantly, the ν(CO) frequencies are a function of cluster charge *n* and decrease from 1961 (*n* = −1) to 1897 (*n* = −3) cm^{-1}, whereas the neutral species (*n* = 0) is too unstable in solution.

The redox behavior of the anions $[Co_{11}Te_7(CO)_{10}]^{1-,2-}$ is in agreement with considerable metallic interactions within the cluster core, which is also expressed by the small HOMO−LUMO gaps for both compounds.[47] According to DFT calculations the oxidized product (*n* = 0) should be less stable than the anions.

The structure of the $[Co_{11}Te_7(CO)_{10}]^-$ ion in **22** is that of a pentagonal prism formed by ten Co atoms in the center of which resides a further Co atom (Figure 9). All faces are capped by Te bridges. Alternatively, the $Co_{11}Te_7$ cage may be thought to be composed of five edge-sharing Co_5Te octahedra which are arranged around the fivefold Te(1)−Co(1)−Te(2) axis, with Co(1) as common vertex. These octahedra are nearly perfect, with Co−Te and Co−Co bond lengths of approximately equal order (between 2.50 and 2.61 Å).

Neutral clusters comprising the intact $Co_{11}Te_7$ cage are accessible by the reaction of phosphanes L with the salts **20** or **22** and subsequent chromatography on silica gel. In a very complex reaction the substituted clusters $[Co_{11}Te_7(CO)_{10-m}L_m]$ (*m* = 3, 4, 5) are formed, regardless of the charge of the initial cluster anion.[55] Electrochemical studies of the reaction of **22** with L = PMe_2Ph reveal that there is a stepwise substitution of CO groups, in which differently substituted cluster anions $[Co_{11}Te_7(CO)_{10-m}(PMe_2Ph)_m]^{n-}$ (*m* = 1−5, *n* = 1, 2) may be formed as intermediate products. Each of these intermediates exhibits at least three electron-transfer processes, leading to a total of 21 redox couples with 27 electroactive species. It is noteworthy that each replacement of a CO ligand by PMe_2Ph in $[\mathbf{1}]^-$ causes a shift of about 200 mV towards more negative potentials (Scheme 7).[55] As a consequence, reduction becomes more difficult and oxidation easier. Traces of oxygen or water (from SiO_2) are thought to be responsible for the oxidation.

The molecular structure of $[Co_{11}Te_7(CO)_5(PMe_2Ph)_5]$ contains the same cluster geometry as the precursor anion $[Co_{11}Te_7(CO)_{10}]^-$.[55] The replacement of five π-acceptor

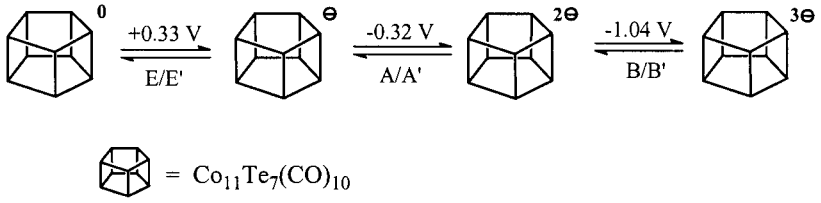
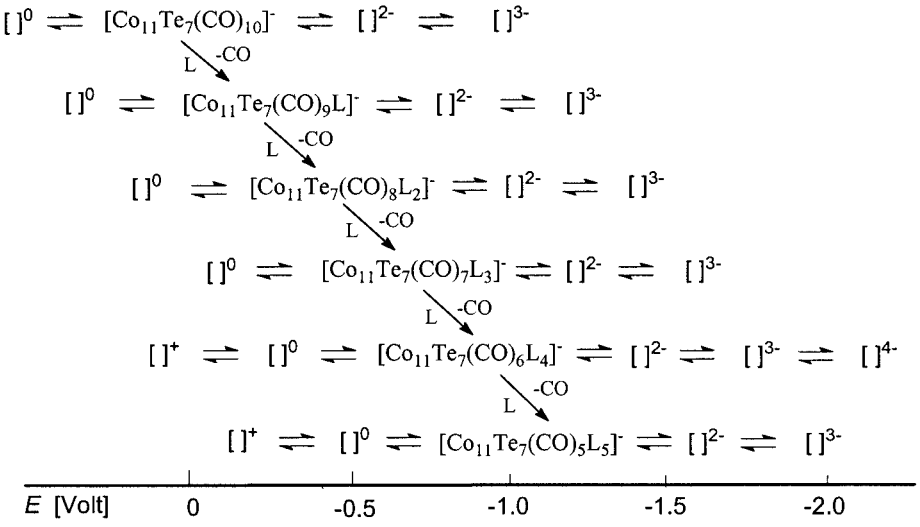


Scheme 6. Schematic representation of the electrochemistry of the $[Co_{11}Te_7(CO)_{10}]^{n-}$ anions ($n = 0-3$)



Scheme 7. Schematic summary of the electrochemical studies of the system $[Cp^*_2Nb(CO)_2][Co_{11}Te_7(CO)_{10}]/L$ (L = PMe_2Ph); compounds $[Co_{11}Te_7(CO)_{10-m}L_m]^0$ ($m = 3, 4, 5$) are accessible by synthetic means[55]

CO ligands by PMe_2Ph and the oxidation of the cluster core by one electron do not affect significantly the bond parameters in the $Co_{11}Te_7$ core when compared to the parent cluster anions. This is again in agreement with a *quasi-metallic* electron distribution within the cluster skeleton.

The rich redox chemistry of the $Co_{11}Te_7$ core resembles to some extent the electron-sink behavior of homoleptic carbonylmetal cluster anions.[56] A similar behavior may be expected for the cubic Co_9Te_6 core in **21** (Figure 10). This compound is not available in sufficient amounts (Scheme 5), but if $[(t\text{BuC}_5\text{H}_4)_2\text{Nb}(\text{Te}_2)\text{H}]$ (**1**) is used as starting material instead of **2** the neutral cluster $[\{(t\text{BuC}_5\text{H}_4)_2\text{Nb}(\text{CO})\}_3\text{Co}_9\text{Te}_6(\text{CO})_8]$ (**23**) forms in good yield (Scheme 8a).[57] This product contains a Co_9Te_6 core, to which three 17-electron $(t\text{BuC}_5\text{H}_4)_2\text{Nb}(\text{CO})$ fragments are attached by three of the six μ_4-Te ligands. No charge separation into distinct ionic building blocks, as described in Scheme 5, is observed. Interestingly, the reaction seems to proceed at 0 °C in an analogous manner to that of peralkylated **2** (Scheme 5). Accordingly, $[(t\text{BuC}_5\text{H}_4)_2\text{NbTe}_2\text{Co}_3(\text{CO})_7]$, an analogue of **17**, and $[Co_4Te_2(CO)_{10}]$ (**18**) are formed, although in low yields.[57][58]

For the purpose of crystallization it was necessary to treat **23** with $[Cr(CO)_5\text{THF}]$ (Scheme 8a). The central feature of the structure of the resulting cluster **24** is a $Co@Co_8$ cube. Its faces are bridged by six Te ligands to which three $(t\text{BuC}_5\text{H}_4)_2\text{Nb}(\text{CO})$ and three $Cr(CO)_5$ fragments are coordinated in a meridional manner with respect to the Te_6 octahedron (Figure 11).[57] The resulting outer octahedral shell of metal atoms has an average diameter of 11.6 Å, which means an expansion of the inner cubic shell by about 6.7 Å.

A somewhat different result is obtained when **1** is reduced with NaH. It is not yet clear if this reaction proceeds with hydride abstraction or with cleavage of the Te−Te bond. In the subsequent reaction of the obtained solution with $[Co_2(CO)_8]$ at 20 °C dark-brown $Na[Co_9Te_6(CO)_8]$ (**25**) is formed (Scheme 8b). Compound **25** crystallizes with THF as salt **26**, which is composed of $[Co_9Te_6(CO)_8]^-$ and $[Na(THF)_6]^+$ ions in a 1:1 ratio.[59] This means that **26** con-

Figure 11. Molecular structure of $[\{(t\mathrm{BuC_5H_4})_2\mathrm{Nb(CO)}\}_3\mathrm{Co_9Te_6(CO)_8}\{\mathrm{Cr(CO)_5}\}_3]$ (**24**); two of the $\mathrm{Cr(CO)_5}$ fragments, attached at the "free" μ_4-Te ligands, are omitted for the sake of clarity[57]

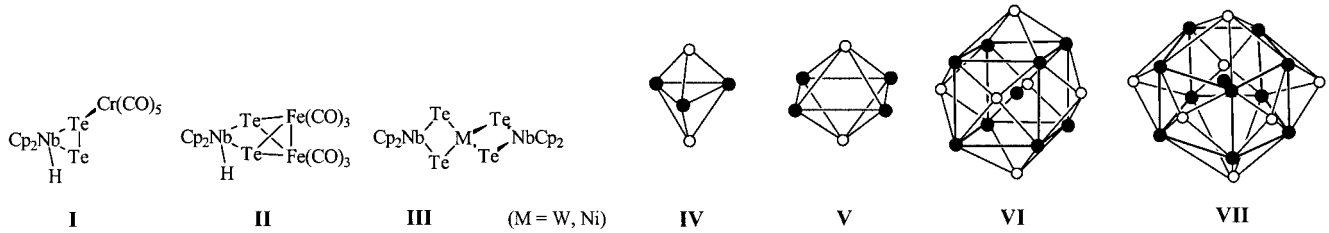
tains an oxidized form (122 MVEs) of the Co_9Te_6 cage with respect to that in **21** (123 MVEs). The metric parameters of both cubes and of the $Co@Co_8$ cage in **24** (124 MVEs) are very similar. This fact is currently under investigation from a theoretical point of view.

Conclusions

This microreview deals with synthesis and structure of niobocene ditelluride complexes and their application in cluster synthesis. The presence of free electron pairs, the propensity for Te−Te bond cleavage and the ability to eliminate Te^0 or Te^{2-} make them ideal molecular building blocks for the synthesis of polymetallic telluride complexes and clusters. Thus, in reactions with several binary carbonyl transition metal complexes a series of new homo- and heterometallic complexes and cluster compounds are formed, which range from simple adducts to polyhedral cluster frameworks (Scheme 9).

The stepwise build-up of telluride clusters may be facilitated by ligand (CO, Te) cross-transfer from one metal atom to the other. The carbonylniobocene species $[(t\mathrm{BuC_5H_4})_2\mathrm{Nb(CO)}]$ and $[\mathrm{Cp^*_2Nb(CO)_2}]^+$, the formation of which is directed by the organic substituents, play a decisive role in tuning the electronic properties of the cluster units: Whereas the 17-electron fragment may be directly anchored to the cluster core by Te bridges, the in situ formed 18-electron cation is able to stabilize large and differently charged cluster anions. An outstanding property of clusters derived from all-capped $Co@Co_8$ (type **VI**) and $Co@Co_{10}$ (type **VII**) polyhedra is their pronounced electron-sponge behavior. Crystal structure analyses allow correlation of cluster charge and bond parameters, and theoretical studies will provide insights into their electronic structures.

It has already been demonstrated that metal telluride complexes may be an important molecular basis for the preparation of binary solid-state phases such as β-CoTe[3b] and NiTe.[3a] Another area of interest may be the extension of polyhedral structures into supramolecular architectures. In this context it was suggested as early as 1985 to combine "discrete clusters into small aggregates" by means of covalent bridges that exist in the solid state.[60] This idea has been stimulated by the observation that the discrete cubic cluster $[Co_8S_6(SPh)_8]^{4-,5-}$ may be considered as a small solubilized fraction of the solid-state structure of pentlandite minerals, in which Co_8S_6 cubes are linked together by octahedral Co centers and sulfide bridges. Very recently it has been observed that octahedral $[Re_6(\mu_2\text{-}Se)_8]^{2+}$ core-containing clusters bearing ligands susceptible for self-organization of functional groups by hydrogen bonds arrange into zigzag chains of hydrogen-bonded cluster polymers.[61] A realization of these ideas with respect to our metal telluride clus-



Scheme 9. Examples of heteropolymetallic telluride complexes (**I**−**III**) and cobalt telluride cluster frameworks (**IV**−**VII**; o = Te, • = Co)

ters may envisage the facile CO substitution in the cluster anions in **20** and **22**. Thus, it should be possible to connect individual polyhedra by appropriate bifunctional donor ligands. On the other hand, reaction of the nucleophilic Te vertices with tellurophilic metal cations[2] may lead to the formation of inorganic networks.

Acknowledgments

I wish to thank my co-workers, who are cited in the literature section, for their numerous contributions and Prof. Yves Mugnier and his co-workers for their extremely valuable electrochemical studies. I am particularly indebted to Prof. Dr. H. Brunner for his continuous and generous support. I am also grateful to the Deutsche Forschungsgemeinschaft and the Deutscher Akademischer Auslandsdienst and the Ministère des Affaires Etrangères (program PROCOPE) for financial support.

C−C Bond Variation in the 1-Phenyl-*o*-carborane: Steric versus Electronic Effects

Ivan V. Glukhov,[a] Mikhail Yu. Antipin,[a] and Konstantin A. Lyssenko*[a]

Keywords: Ab initio calculations / Atoms in molecules theory / C−C bond elongation / Carboranes / Electron density / Hydrogen bonds

Using the "Atoms in molecules" topological theory the nature of the C_{carb}–C_{carb} bond variation in 1-phenyl-*o*-carborane upon rotation of the phenyl ring was investigated within B3LYP/6-31G** calculations. Despite the low barrier to the rotation of the phenyl ring, the bond paths linking hydrogen atoms of the phenyl ring and the ones of the carborane cage were found for all conformations. The length of the C_{carb}–C_{carb} bond increases by 0.031 Å without large energetic inputs due to back-donation of the π-density of the phenyl ring to the antibonding C_{carb}–C_{carb} orbital.

Introduction

The C_{carb}−C_{carb} bond in icosahedral *o*-carboranes (i.e., that between two carbon atoms of the icosahedron) is characterized by several unusual features, among which its high "plasticity", which is reflected in significant variation of its length in organic and organometallic derivatives, can be especially emphasised.[1−3] In the case of metallacarboranes this can lead to the formation of pseudocloso structures[4] in which two carbon atoms of the cage are not chemically bonded. This is important not only from a theoretical point of view but also for understanding the isomerisation process that occurs between the *ortho*-, *meta*- and *para*-isomers of the carboranes. The plasticity of the C_{carb}−C_{carb} bond is in line with its low force constant[5] as well as with the intermediate type of interatomic interaction [positive value of the Laplacian of the electron density in the critical point (3,−1)] found for the homopolar C_{carb}−C_{carb} bond in the crystal of 8,9,10,12-tetrafluoro-*o*-carborane.[6]

Three factors are usually considered to be the main ones that influence the C_{carb}−C_{carb} distance in the *o*-carborane derivatives: steric repulsion between one or two substituents, an electronic effect due to electronegativity differences between the hydrogen atom and the substituent group and, finally, stereoelectronic effects as a result of charge transfer from the electron lone-pair or occupied orbital of a substituent to the antibonding orbital of the C_{carb}−C_{carb} bond.[3] The role of the latter can be dominant, as was demonstrated previously in the case of *o*-carborane dithia, diaryl- and dialkylphosphanyl derivatives.[3] In particular, in 1,2-$(SPh)_2$-*o*-carborane the charge transfer from the sulfur lone-pair to the antibonding orbital of the C_{carb}−C_{carb} bond leads to a C_{carb}−C_{carb} bond elongation of up to 1.798(3) Å.[3a] It should be noted that a similar C_{carb}−C_{carb} bond elongation (1.720 Å and 1.733 Å) was found in 1,2-diphenyl-*o*-carborane,[7] in which the possibility of charge transfer from the phenyl group to the C_{carb}−C_{carb} bond of the icosahedron is not so evident.

In order to study whether the bond elongation in diphenyl-*o*-carborane is the result of steric effects[1] or electronic ones, in this paper we have chosen 1-phenyl-*o*-carborane (**1**) as a model compound. Despite the fact that this compound is not sterically overcrowded with respect to the pure *o*-carborane we cannot exclude the influence of intramolecular H···H contacts on the molecular geometry. Such interactions are important in the formation of host-guest complexes of carboranes.[8] So, in addition to analysis of the phenyl interaction with the C_{carb}−C_{carb} bond, we paid great attention to the nature of the C_{ph}−H···H−B and C_{ph}−H···H-C_{carb} contacts.

According to the theoretical and experimental studies, the replacement of CH by a CPh group in the *o*-carborane has a small electronic influence on the cage, but results in significant steric changes in the molecule due to H···H contacts.[1] It was found that in the isolated molecule **1**, there is an optimum value of the torsion angle θ [C(2)−C(1)−C(13)−C(14)], equal to 25°,[9] defining the conformation of the ring with respect to the carborane cage (see Figure 1). Although the H···H contacts in all conformations are substantially shorter than the sum of the van der Waals radii the barrier to rotation of the phenyl ring according to the HF/6−31G* calculations is very small (2.1 kJ·mol^{-1}). This low barrier was also found in the gas phase by electron diffraction and in the solid state.[9] Compound **1** has two polymorphs with two and one independent molecules in the unit cells, respectively[9,10] (α and β forms). The molecules in these forms differ in the orientation of the phenyl ring, with θ values equal to 22.2° and 18.3° in the α and β forms, respectively. It should be noted that in the α form one of the independent molecules is disordered due to the superposition of different conformations.[9]

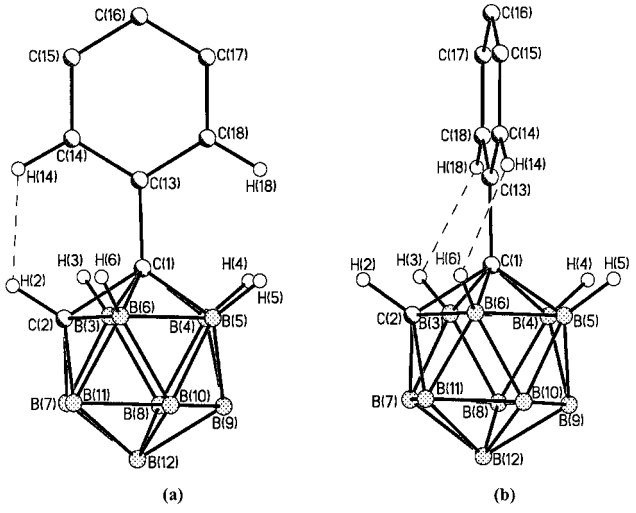

Figure 1. The general view and the numbering scheme of two limiting conformations of **1** with θ angles equal to 0° (a) and 90° (b); hydrogen atoms that do not participate in H···H contacts are omitted for clarity

Clearly, due to the low barrier of rotation, no significant back-donation from the phenyl group is expected, although we cannot exclude that this effect may be noticeable in the conformation with θ = 90° because, in this case, the π-density of the phenyl ring is positioned right above the $C_{carb}-C_{carb}$ bond, which makes charge transfer from the phenyl π-system to the antibonding orbital of the $C_{carb}-C_{carb}$ bond possible.

Results and Discussion

To investigate the nature of the $C_{carb}-C_{carb}$ bond elongation in mono- and diaryl-substituted *o*-carboranes we traced the changes in the icosahedron structure accompanying the phenyl ring rotation. We used a potential energy surface (PES) scan with the density functional B3LYP method at the 6−31G** level of theory along the coordinate corresponding to the above-mentioned torsion angle, changing from 0° to 90° in 10° steps with a full optimization of other geometric parameters at each step. The electron density distribution (EDD) properties and the most important bond lengths are summarized in Table 1.

The global minimum on the PES corresponds to the structure with θ = 30.2° which is close to the value obtained from the HF calculation (25°)[9] and is in good agreement with the experimental values (18° and 22°).[9,10] The geometry of the icosahedron obtained from the B3LYP calculation, in contrast to the HF one, is in excellent agreement with the X-ray diffraction data for the β form. In particular, the C(1)−C(2) bond length, according to HF and DFT calculations, and X-ray diffraction data, is equal to 1.626, 1.645 and 1.640 Å, respectively.

The estimated barrier to rotation of the phenyl ring is even lower (about 1.2 kJ·mol^{-1}) than reported earlier and the energy difference for the ideally eclipsed conformation (θ = 0°) and the conformation with θ = 90° becomes as low as 0.152 kJ·mol^{-1} (see Table 1).

To analyze the peculiarities and the nature of the intramolecular interactions in **1** we performed topological analysis of the EDD function $\rho(r)$ within Bader's "Atom in Molecules" theory (AIM).[11] Among the benefits of the AIM theory in analysis of the nature of the interactions is the availability of a clear definition of the chemical bonds and their properties in terms of the topological properties of the $\rho(r)$ function.

The characteristic set of critical points (CPs) contains CPs (3,−1) in the interatomic area of all expected chemical bonds, namely B−B, $C_{carb}-B$, $C_{carb}-C_{carb}$, $C_{ph}-C_{carb}$, $C_{ph}-H$, $C_{carb}-H$ and B−H. In addition, in line with the Poincaré−Hopf relationship[11] CPs (3,+1) were found for all triangular faces of the carborane icosahedron and in the center of the phenyl ring and, finally, CP (3,+3) was found in the center of the cage. Taking into account that in all bonds (with the exception of the $C_{carb}-B$ bonds, where the boron atom is bonded to one carbon atom), the Laplacian of the electron density $\nabla^2\rho(r)$ in CPs (3,−1) is negative, we may conclude that these bonds correspond to "shared-type" interatomic interactions. The other $C_{carb}-B$ bonds are characterized by the positive values of the $\nabla^2\rho(r)$ (0.1161−0.1511 a.u.)[12] in the CPs (3,−1). Taking into account the negative values of the electron energy density $h_e(r)$ [13] (−0.1022 to −0.1017a.u.) for these bonds, they may be considered as corresponding to the "intermediate type" of interatomic interactions.[11a] It should be noted that the values of the electron density in CPs (3,−1) for the $C_{carb}-B$ (0.1170−0.1214 a.u.) and B−B (0.1156−0.1235 a.u.) bonds are close to the corresponding values in CP (3,+1) (0.1099−0.1160 a.u.) for the triangular edges. For the $C_{carb}-C_{carb}$ bond the electron density is noticeably higher (0.1799 a.u.), as was found earlier for both small carboranes and icosahedral ones.[6,14,15] For comparison, the values of

$\rho(r)$ (0.3082−0.3136 a.u.) in CPs (3,−1) for $C_{ph}-C_{ph}$ bonds are significantly higher than the corresponding values in CP (3,+1) (0.0202 a.u.) in the center of the phenyl ring.

At the same time, as a result of the forced H···H interactions between the hydrogen atoms of the phenyl ring and the carborane cage, some additional critical points appear. Starting from θ = 0° we found CP (3,−1) between the H(2) and H(14) atoms. Also, one CP (3,+1) appears as the result of the six-membered-ring formation. The distance between the hydrogen atoms is 2.007 Å. Although other H···H contacts H(4)···H(18) and H(5)···H(18) are about 0.4 Å longer (2.424 Å each) they do not correspond to attractive interactions. Rather small values of $\rho(r)$, positive values of $\nabla^2\rho(r)$ and positive values of $h_e(r)$ point to a "closed-shell" type of interaction for these two contacts.

The value of $\rho(r)$ in the CP (3,−1) for the H(2)···H(14) contact, equal to 0.0117 a.u., and other topological EDD parameters are close to those obtained for similar H···H interactions found in the biphenyl molecule [the $\rho(r)$ value is equal to 0.0136 a.u.][16a] and different polybenzoid compounds.[17] In spite of the fact that the validity of the analysis of $\rho(r)$ within AIM theory for weak interactions was at one point debatable,[16] later comparison of the $\rho(r)$ topology and potential energy density distribution function resolved this controversy:[11b] it was demonstrated by Bader that each bond path in the electron density is mirrored by the virial path, a line of maximum potential energy density, which, in turn, indicates that the presence of the bond path or critical point (3,−1) between the pair of atoms in question is the "universal indicator of bonding between atoms".[11b] Thus, H···H interactions observed both for the $\rho(r)$ and potential energy density functions lead to additional stabilization of the molecules (up to 46.9 kJ·mol^{-1} in chrysene).[17] The barrier to rotation of the ring in biphenyl is about 6.7 kJ·mol^{-1},[16a] which is only slightly higher than in **1**.

In this paper we have traced in detail the changes in the intramolecular contact network as a result of the phenyl ring rotation. For all conformations investigated intramolecular H···H distances that are significantly shorter than the sum of the van der Waals radii[18] were found. Surprisingly, the shortest H···H contact (2.007 Å) was observed for the $C_{carb}-H\cdots H-C_{ph}$ interaction at θ = 0°, while the minimum value for the H···H distance among all $C_{ph}-H\cdots H-B$ contacts is 2.023 Å at θ = 70° (see Table 2). At θ = 30° the $C_{carb}-H\cdots H-C_{ph}$ contact disappears and only $B-H\cdots H-C_{ph}$ contacts are present. The possibility of $B-H\cdots H-C_{ph}$ contact formation is more evident because the difference in the atomic charges of the hydrogen atoms in this case is higher than that for the $C_{carb}-H\cdots H-C_{ph}$ contact.

We also determined the contact interatomic separation (CIS) — the distance between two nuclei at which a "fold catastrophe" occurs.[16a] At the CIS distance the values of the electron density and its Laplacian become equal in the CPs (3,−1) and (3,+1), leading to loss of the interatomic

interaction line. Because of the large value of the increment used during the PES scan we could not determine precisely the CIS value for the B−H···H−C_{ph} interaction. Nevertheless, according to our estimations its value is about 2.27 Å, which is higher than the corresponding value obtained for the corresponding contact in biphenyl (2.179 Å).[16a,17] This can be explained by an increase of the electron density near the H atom of the B−H group in comparison to the C_{carb}−H one. This result confirms the supposition of other authors about the nontransferability of these values between different systems.[16a]

As concerns the X−H···H and H···H−C_{ph} bond angles of the X−H···H−C_{ph} (X = B or C_{carb}) interactions, they vary in the range 111.7−129.0° for the H···H−C angle and 99.8−118.8° for the X−H···H one. These values may be compared to those obtained for the intermolecular contacts of the B−H···H−N type for which the B−H···H angles are 95−115° and the N−H···H angles are equal to 150−170°.[19]

Despite almost unrestricted rotation of the phenyl ring and variation of the strength and number of the H···H contacts, we noticed some other changes in the carborane-cage geometry, accompanying the rotation of the phenyl group. The most dramatic change is the increase of the C(1)−C(2) bond length from 1.641 Å at θ = 0° to 1.672 Å at θ = 90°; the C(2)−B(3) and C(2)−B(6) distances decrease by only 0.009 Å each. Other bonds, including the C(1)−C(13) one, do not vary so significantly (only within 0.004 Å) and the C(14)−C(13)−C(18) *ipso* angle increases by 0.2°. Despite these geometric changes, the character of the chemical bonding for the C_{carb}−C_{carb} bond remains invariable [the value of $\nabla^2\rho(r)$ varies from 0.1816 to 0.1703 a.u.].

In contrast to these data, the C(2)−B(3) and C(2)−B(6) bonds are more sensitive to changes in the icosahedron. At a θ value close to 90°, the $\nabla^2\rho(r)$ values in CPs (3,−1) are close to zero (0.0016 and 0.0023 a.u.). This result suggests a change of the bonding nature from the shared type to an intermediate one, thus indicating that small variations of the C_{carb}−C_{carb} bond strength are sufficient for the change of the B−C_{carb} bonding type.

At the same time the C_{carb}−C_{carb} bond elongation causes not only an expected decrease of the $\rho(r)$ and the absolute $\nabla^2\rho(r)$ values but also a substantial increase of its ellipticity from 0.79 at θ = 0° to 0.96 at θ = 90°. The difference between the C_{carb}−C_{carb} bond path length and the corresponding interatomic distance is less than 0.001 Å at θ = 0° and does not increase at θ = 90°. The same difference for the C_{carb}−B_{carb} bonds is substantially bigger and, for instance, at θ = 90° it is equal to 0.114 Å. Thus, the C_{carb}−C_{carb} bond lengthening does not lead to a shift of the CP from the interatomic line; the high ellipticity value indicates either "banana bonding" or a substantial contribution of the π component.[20]

The minimum on the PES corresponding to the structure with θ = 30.2° is characterized by only one intramolecular B(4)−H(4)···H(18)−C(18) closed-shell interaction, with an interatomic separation equal to 2.106 Å. The phenyl ring is slightly inclined away from the contacting hydrogen atoms, with the B(4)−C(1)−C(13) angle equal to 118.2° The value of $\rho(r)$ at the CP (3,−1), equal to 0.0115 a.u., is slightly less than that in the biphenyl (0.0136 a.u.). At θ = 70° the corresponding interaction is even stronger, as is clear from the shorter distance between the hydrogen atoms (2.023 Å) and the maximum value of $\rho(r)$ (0.0139 a.u.). This conformation, however, does not correspond to the local minimum on the PES. Evidently, the total energy decrease related to this interaction is neutralized by energy inputs related to the lengthening of the C_{carb}−C_{carb} bond.

What is the reason for this C_{carb}−C_{carb} elongation? Starting with a θ value equal to 40°, at which the substantial growth of the C_{carb}−C_{carb} bond occurs (see Figure 2), the back-donation of the π-electron density of the phenyl ring to the anti-bonding C_{carb}−C_{carb} orbital becomes geometrically possible. It should be noted that the lengthening of the C_{carb}−C_{carb} bond is accompanied by an increase of its ellipticity, which can be explained by an increase of the π-bond contribution. At the same time the C_{carb}−C_{ph} distance and the *ipso* angle do not change, which allows us to conclude that the extent of such an interaction is rather small.

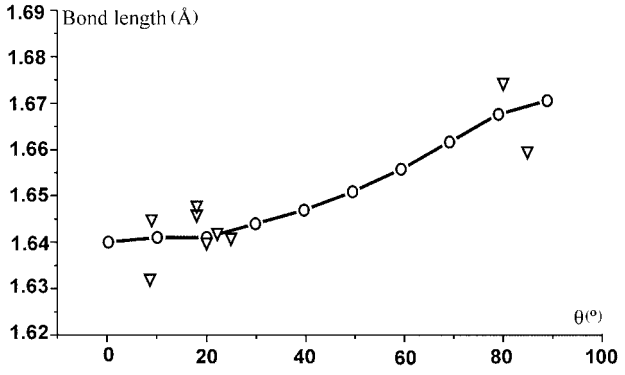

Figure 2. A plot of C_{carb}−C_{carb} bond length values vs. θ angles: the theoretical curve (circles) and the experimental data for phenyl-substituted *o*-carboranes (triangles)

To estimate if it is really observable we performed additional calculations on two derivatives of **1** with substituents in the phenyl ring in the *para* position with respect to the carborane cage. Two compounds were studied: with positive [NH_2 (**2**)] and negative [NO_2 (**3**)] mesomeric effects, their optimization was performed at the same level of theory using the same basis set for the conformation with a θ angle equal to 90°. The obtained data confirm the presence of the charge transfer from the phenyl ring to the antibonding orbital of the C−C bond. Thus, according to our calculations, at θ = 90° the C_{carb}−C_{carb} bond length in **2** is higher (1.680 Å), and in **3** is lower (1.669 Å) than in **1** (1.672 Å). It should be noted that the bond ellipticities for these derivatives also differ and are equal to 1.01 and 0.93 for **2** and **3,** respectively (in **1** at θ = 90° it is equal to 0.96). It should be noted that this effect cannot be explained by the alternation of the inductive effect of the substituted phenyl group that was checked for compounds **2** and **3** in the con-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

formation with θ = 0°. In this case, the value of the $C_{carb}-C_{carb}$ bond length coincides with that in **1**.

Using ellipticity values for the $C_{carb}-C_{carb}$ bond in **1** at different values of the θ angle and the same values in **2** and **3** at θ = 90° we found a linear correlation between the bond length and its ellipticity (see Figure 3). Such a correlation is characteristic of multiple bonds but not banana bonds, as in cyclopropane for example.[20] The observed ellipticity increase with the increase of the $C_{carb}-C_{carb}$ bond length is quite surprising and points to the unusual character of the bonding in *o*-carboranes.

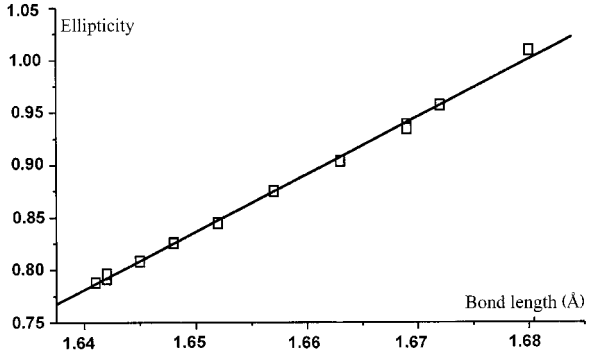

Figure 3. A plot of $C_{carb}-C_{carb}$ bond ellipticity vs. length; the dependence can be approximated by the linear function $y = 5.49105x - 8.22407$; the extrapolation to zero ellipticity gives a value of 1.50 Å for the bond length

Taking into account the low barrier to the rotation of the phenyl ring in **1** it is possible to suggest that the observed $C_{carb}-C_{carb}$ bond alternation accompanying rotation of the phenyl ring should also be observed in the crystal structures of different derivatives containing such a fragment.

To check our supposition we performed a search in the Cambridge Crystallographic Data Base[21] for ordered structures containing Ph-*o*-carborane fragment without other substituents in the carborane icosahedron, and with an *R* factor lower than 10% (five structures were found with REFCODEs FOSSIP,[22] NURLER,[23] TAVNAF,[24] ZUHTOL[10] and ZUHTOL1;[9] eight values were used). All analyzed values (bond lengths vs. θ angles) were found to be in good agreement with the theoretical curve, except for one value (not shown) in the crystal structure of FOSSIP, where the abnormally short $C_{carb}-C_{ph}$ bond length points to possible unresolved disorder of the phenyl ring. In Figure 2 the experimental and theoretical values are plotted against θ. It can be seen that a direct correlation exists between these values that allows one to predict the bond length value if the torsion angle, θ, is known.

Thus, both the theoretical and experimental data point to the fact that the dependence of the $C_{carb}-C_{carb}$ bond length on the torsion angle is caused by charge transfer from the phenyl ring to the antibonding orbital of this bond. A further question then arises: what can these results contribute to an explanation of the $C_{carb}-C_{carb}$ bong length elongation in 1,2-diphenyl-*o*-carborane (**4**)? Taking into account that the phenyl rings in **4** are almost perpendicular to the $C_{carb}-C_{carb}$ bond (θ values are equal to 81.5°/84° and 84°/89° for two independent molecules), and assuming that electron transfer has an additive effect, we obtain a value of 0.06 Å for the lengthening of this bond. Assuming also the inductive effect of the substituent replacement of the CH by the CPh group in the *o*-carborane according to B3LYP calculation,[25] which leads to an increase of the $C_{carb}-C_{carb}$ bond by approximately 0.02 Å at θ = 0°, we obtain a total value of 0.1 Å as the bond length difference between these compounds. Adding this value to the one for the $C_{carb}-C_{carb}$ distance in *o*-carborane (1.619 Å) leads to the bond length 1.720 Å, which is close to the experimental values for **4**.[7] At the same time, the difference in the $C_{carb}-C_{carb}$ bond in **4** [1.720(3) and 1.733(3) Å] can also be explained by the difference in the torsion angles: the shorter value is observed for the molecule with θ values deviating more from 90°.

Thus, the present study with the use of computational methods clearly shows that charge transfer from the phenyl ring to the carborane icosahedron exists and allows us to conclude that the $C_{carb}-C_{carb}$ bond in the *o*-carborane is characterized by a rather high π-component and that the bond length variation is caused not only by steric reasons but also electronic ones.

The presence of such an interaction is of interest from both theoretical and practical points of view. In particular, taking into account the high thermal stability of the carboranes, similar systems are of great interest for creation of new NLO materials.[26] Preliminary estimations show that the values of the first molecular hyperpolarizability for **2** is only slightly smaller than that in *p*-nitroaniline.[27] The study of 1,2-diaryl-*o*-carborane derivatives, like triazinyl-*o*-carboranes [the $C_{carb}-C_{carb}$ bond length is 1.712(3) Å],[28] in which the position of the aryl groups is constrained due to steric effects, might be promising for the design of NLO materials, and this will be the subject of our further investigations.

Computational Details

Ab initio calculations of **1**−**3** were performed with the Gaussian 98 program package[29] at the B3LYP level of theory. A potential-energy scan with C_1 symmetry of the molecules was carried out constraining one torsion angle and with full optimization of the other geometric parameters, with the 6−31G(d,p) basis set starting from the X-ray diffraction geometry. The torsion angle was changed in 10° steps starting from 0° up to 90°, except for 30°, because the value of 30.2° corresponds to the global minimum. As convergence criteria the normal threshold limits of 4.5×10^{-4} and 1.8×10^{-3} a.u. were applied for the maximum force and displacement, respectively. To enhance the B3LYP calculation accuracy the pruned (99,590) grid (keyword Grid=Ultrafine) was used. Topological analysis of the $\rho(r)$ function was performed using the MORPHY 98 program[30] based on the wavefunctions obtained from the B3LYP calculations.

[12] Here and further on values are given for the conformation with $\theta = 30.2°$.

[13] According to the AIM theory, interatomic interactions fall into "shared" and "closed-shell" types. Shared interactions are characterized by negative $\nabla^2\rho(r)$ values and high $\rho(r)$ values in CP (3,−1), while in the case of closed-shell interactions (ionic bonds, some van der Waals complexes, etc.) the value of $\nabla^2\rho(r)$ is positive and the total $\rho(r)$ in CP (3,−1) is small. However, a positive $\nabla^2\rho(r)$ value is not a unique criteria of the closed-shell interaction. The necessary condition for realization of this type of interaction is a positive value of the energy density, which is related to $\nabla^2\rho(r)$ by the equation $h_e(r) = v(r) + g(r) = g(r) - 1/4\nabla^2\rho(r)$, where $v(r)$ and $g(r)$ are the potential and kinetic energy density, respectively. The value of $h_e(r)$ may still be negative if the potential energy density (a priori negative) exceeds the kinetic one in absolute value. Therefore, bonds that are characterized by a positive value of $\nabla^2\rho(r)$ and a negative value of $h_e(r)$ are referred to as an intermediate type of interatomic interaction.

Synthesis and Structure of an Unprecedented Layered Vanadate Complex Containing Double-Helical Chains: $[\{Co^{III}(phen)_2\}_2V_8O_{23}]$

Dongrong Xiao,[a] Yan Xu,[b] Yu Hou,[a] Enbo Wang,*[a] Shutao Wang,[a] Yangguang Li,[a] Lin Xu,[a] and Changwen Hu[a]

Keywords: Vanadium / Helical structures / Hydrothermal synthesis

A novel two-dimensional organic–inorganic hybrid vanadate complex $[\{Co^{III}(phen)_2\}_2V_8O_{23}]$ has been hydrothermally synthesized and characterized by elemental analyses, IR spectroscopy, XPS spectroscopy, TG analysis and single-crystal X-ray diffraction. The single-crystal X-ray diffraction analysis reveals that compound **1** contains an unprecedented neutral 2D framework constructed of 4,10,12-net sheets. To the best of our knowledge, compound **1** represents the first example of 2D layered vanadium oxide complex constructed of 4,10,12-net sheets. Furthermore, the title compound consists of left-handed and right-handed helical chains, which are further interconnected to form the double-helical chains. (© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2003)

Introduction

A current focus on the chemistry of polyoxovanadates is the rational design and synthesis of organic−inorganic hybrid vanadium oxides in order to explore their potential applications in catalysis, medicine, biology, electron conductivity, magnetism and photochemistry.[1−4] Recently, the introduction of hydrothermal techniques and the use of organic−templating agents have led to the production of various organic−inorganic hybrid vanadium oxides with discrete clusters, one-dimensional (1D), two-dimensional (2D), and three-dimensional (3D) structures.[5−8] Typically, the organic substituents have been presented as charge-compensating cations and structural filling agents, such as organoammonium units. More recently, an important advance in this field is that the organic components directly coordinate to the inorganic vanadium oxide scaffoldings or to secondary metal centers.[3,4] The introduction of transition metal−ligand units will not only enrich the frameworks of vanadium oxides, but also improve their electronic and magnetic properties.[3−5] Based on this strategy, a large variety of organic−inorganic hybrid materials belonging to the $\{M_xL_yVO\}$ system (M = transition metal, L = organic ligand) have been isolated.[2−7]

Among the large amount of reported work, the design and synthesis of organic−inorganic materials with helical structures are of particular interest and great challenge.[9−12] It is well-known that vanadium exhibits a variety of coordination geometries, which can be used for the synthesis of double-helical structures.[12] We report the hydrothermal synthesis and crystal structure of an unprecedented layered solid-state vanadium oxide complex, $[\{Co^{III}(phen)_2\}_2V_8O_{23}]$ (**1**; phen = 1,10-phenanthroline), which consists of left-handed and right-handed helical chains. Furthermore, **1** represents the first example of a 2D layered vanadium oxide complex constructed of 4,10,12-net sheets.

Results and Discussion

The asymmetric unit of **1** (Figure 1) shows four crystallographically independent V atoms and one crystallographically independent Co atom. All vanadium sites exhibit distorted tetrahedral coordination geometries [V−O 1.589(5)−1.852(4) Å]. Each of the V(1), V(2) and V(3) atoms has a terminal vanadyl group (V=O), while V(4) has two terminal vanadyl groups. Moreover, V(2) and V(3) share oxygen atoms with one CoN_4O_2 octahedron and two VO_4 tetrahedra, while V(1) and V(4) only share oxygen atoms with VO_4 tetrahedra. The Co^{III} center adopts an octahedral geometry, being coordinated by four nitrogen donors [Co−N 1.929(4)−1.953(4) Å] of phen groups, and two oxygen atoms [Co−O 1.886(3)−1.898(4) Å] from the VO_4 units, which adopt *cis* orientation.

Single-crystal X-ray diffraction analysis reveals that compound **1** consists of an unprecedented neutral 2D frame-

work with $[Co^{III}(phen)_2]^{3+}$ coordination complex cations covalently linked to the vanadium oxide (V_8O_{23}) chains. Each V_8O_{23} chain is composed of alternating V_4O_{12} tetramer rings and V_4O_{13} units, which are linked by corner-sharing oxygen atoms. The V_4O_{12} tetramer rings and V_4O_{13} units of neighboring V_8O_{23} chains are further connected by $[Co^{III}(phen)_2]^{3+}$ fragments to form an extended 2D network with a unique 4,10,12-net structure (Figure 2 and Figure S1, see Supporting Information). To the best of our knowledge, compound **1** represents the first example of a 2D layered vanadium oxide complex that is constructed of 4,10,12-net sheets. The most interesting structural feature of compound **1** is that the CoN_4O_2 octahedra and VO_4 tetrahedra are connected to each other by corner-sharing oxygen atoms to form the right- and left-handed helical chains, which are further interconnected through oxygen atoms to produce the double-helical chains (Figure 3).

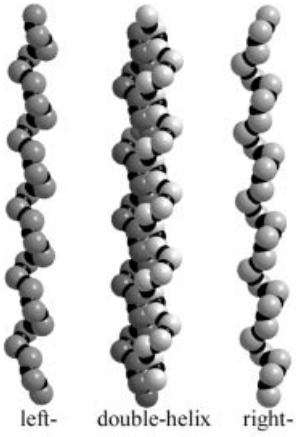

Figure 3. Space-filling view of the left-handed, right-handed, and double helices

It is striking that the adjacent layers are stably packed together, exhibiting an interesting three-dimensional supramolecular architecture through two types of supramolecular interactions. One interaction is the significant hydrogen bonding interaction between the hydrogen atoms of the phen groups and the unshared oxygen atoms of the inor-

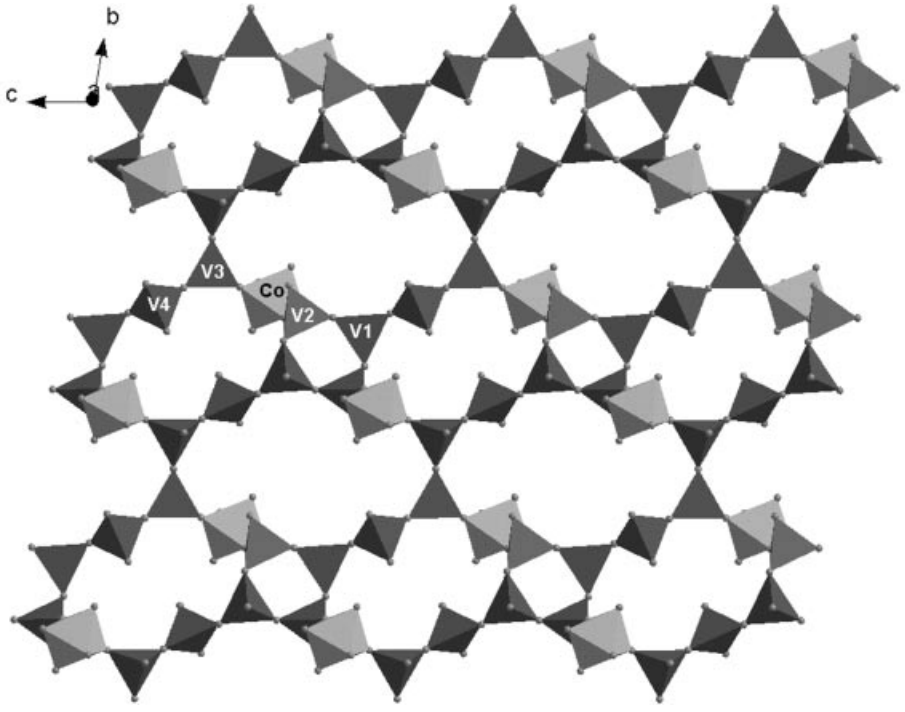

Figure 2. Polyhedral representation of compound **1** packed along the *a* axis; all C and H atoms are omitted for clarity

 © 2003 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

ganic layers (Figure S3, see Supporting Information).The typical hydrogen bonds are C(1)−H(1)···O(5) 2.305 Å, C(3)−H(3)···O(6) 2.415 Å, and C(21)−H(21)···O(4) 2.562 Å (Table S1, see supporting information). The other interaction is the aromatic π−π stacking interactions of the phen groups between adjacent layers; the close-contact distance between adjacent phen rings is 3.40−3.43 Å (Figure S2, see Supporting Information).

The bond valence sum calculations[14a] indicate that all V metal centers are in the +5 oxidation state and the Co metal center is in the +3 oxidation state within compound **1**. No signal was found in the EPR spectrum, which confirms that all cobalt atoms in **1** are in the +3 oxidation state and all vanadium atoms are in the +5 oxidation state. The X-ray photoelectron spectrum (XPS) of compound **1** in the energy regions of V_{2p} shows one peak at 516.7 eV, attributable to V^{5+} (Figure S4, see Supporting Information).[14b] It is noteworthy that compound **1** is the first vanadate complex containing cobalt in the +3 oxidation state.

The TG curve of compound **1** (Figure S5, see Supporting Information) is divided into two stages. The first mass loss is equal to 6.12 % from 335 to 440 °C and the second mass loss is equal to 37.69 % from 445−630 °C. These two continuous mass loss regions are ascribed to loss of the phen groups. The total mass loss (43.81 %) is in agreement with the calculated value (44.66 %). The sample does not lose mass at temperatures higher than 630 °C.

The variable-temperature magnetic susceptibility of compound **1** was measured from 2 to 300 K at 5000 Oe and are displayed in Figure 4, plotted as the thermal variation of χ_M and $\chi_M T$. At 300 K, the $\chi_M T$ value is 3.527 emu·K·mol^{-1}, which is slightly higher than that of an isolated spin-only Co^{3+} ion (3.00 emu·K·mol^{-1}, S = 2, g = 2.0) with diamagnetic V^{5+} ions (S = 0). It gives g = 2.18 if we assume the Co^{3+} ions are uncoupled. As T is lowered, $\chi_M T$ decreases continuously to a value of 0.173 emu·K·mol^{-1} at 2 K. This behavior of the $\chi_M T$ curve indicates that antiferromagnetic interactions exist in **1**. The effective magnetic moment at 300 K, 5.35 μ_B, is in the range of experimentally observed values for Co^{3+} ions. The magnetism of a Co^{3+} ion in molecular compounds is fairly complex because of the combined effects of spin−orbit coupling and the distortion of the octahedral crystal field. The consequence is that $\chi_M T$ deviates from the Curie law for an isolated Co^{3+} ion as it decreases with temperature.[15]

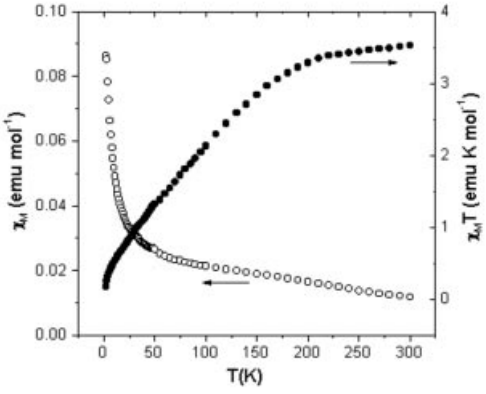

Figure 4. Thermal variation of χ_M and $\chi_M T$ for compound **1**

Conclusion

We have prepared the first vanadate complex with 4,10,12-net structure, in which the phen ligands coordinated to the cobalt−vanadate backbone. The title compound consists of left-handed and right-handed helical chains, which are further interconnected to form double-helical chains. The successful isolation of **1** confirms the observation that the transition-metal-complex moieties may profoundly influence the structure of the vanadium−oxide frameworks.

Experimental Section

Materials and General Methods: All chemicals were commercially purchased and used without further purification. Elemental analyses (C, H and N) were performed with a Perkin−Elmer 2400 CHN Elemental Analyzer. Co and V were determined by a PLASMASPEC(I) ICP atomic emission spectrometer. EPR spectrum was recorded with a Japanese JES-FE3AX spectrometer at 293 K. XPS analysis was performed with a VG ESCALABMKII spectrometer using an Mg-K_α (1253.6 eV) achromatic X-ray source. The vacuum inside the analysis chamber was maintained at 6.2×10^{-6} Pa during the analysis. IR spectrum was recorded in the range 400−4000 cm^{-1} with an Alpha Centaurt FT/IR Spectrophotometer using KBr pellets. TG analysis was performed with a Perkin−Elmer TGA7 instrument in a stream of N_2 with a heating rate of 10 °C·min^{-1}. X-ray powder diffraction (XRPD) patterns were recorded with a Siemens D5005 diffractometer with Cu-K_α (λ = 1.5418 Å) radiation. Variable-temperature magnetic susceptibility was measured (SQUID, Quantum Design) in the temperature range of 2−300 K at 5000 Oe.

Synthesis: In a typical synthesis procedure for **1**, a mixture of $Co(NO_3)_2{\cdot}6H_2O$ (0.25 mmol), V_2O_5 (0.65 mmol), H_2O_2 (30 %, 4 mL), phen (0.5 mmol) and H_2O (6 mL) was stirred in air for 30 min. The mixture was then sealed in an 18-mL Teflon-lined autoclave, which was heated to 170 °C for 120 h. After slow cooling to room temperature, the resulting purple block crystals **1** were filtered off, washed with distilled water, and dried at ambient temperature (yield: ca. 0.16 g, 80 % based on cobalt). Powder X-ray diffraction patterns of the bulk product are in good agreement with the calculated pattern base on the results from single-crystal X-ray diffraction (Figure S7, see Supporting Information). The use of NH_4VO_3 as an alternative vanadium source also leads to the same product (yield: ca. 0.13 g, 65 % based on cobalt). In the reaction, the role of H_2O_2 as oxidant is critical in the formation of compound **1**.[13] Elemental analyses results of the purple crystals are consistent with the stoichiometry of **1**. $C_{48}H_{32}Co_2N_8O_{23}V_8$ (1614.2): calcd. C 35.7, H 2.0, Co 7.3, N 6.9, V 25.2; found C 35.5, H 1.9, Co 7.5, N 7.0, V 25.0. FT/IR: $\tilde{\nu}$ = 3056 (w) cm^{-1}, 1605 (w), 1582 (w), 1518 (m), 1491 (w), 1460 (w), 1426 (m), 1343 (w), 1228 (w), 1148 (w), 1111 (w), 1038 (w), 982 (s), 961 (s), 926 (s), 866 (m), 853 (m), 793 (s), 750 (s), 703 (s), 526 (m), 445 (w).

X-ray Crystallography: The structure of compound **1** was determined by single-crystal X-ray diffraction. A purple single crystal of **1** with dimensions 0.581 × 0.498 × 0.418 mm was mounted onto a glass fiber. Data were collected with a Rigaku R-AXIS RAPID

IP diffractometer using monochromated Mo-K_α (λ = 0.71073 Å) radiation at 293 K in the range of $1.59° < \theta < 27.48°$. Empirical absorption correction (ψ scan) was applied. The structure was solved by the direct method and refined by the full-matrix least-squares method on F^2 using the SHELXTL-97 software.[16] All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were located from difference Fourier maps. A total of 8823 (5797 unique, R_{int} = 0.0526) reflections were measured. Structure solution and refinement based on 5797 independent reflections with $I > 2\sigma(I)$ and 403 parameters gave $R_1(wR_2) = 0.0560$ (0.1516) $\{R_1 = \Sigma||F_o| - |F_c||/\Sigma|F_o|$; $wR_2 = \Sigma[w(F_o^2 - F_c^2)^2]/\Sigma[w(F_o^2)^2]^{1/2}\}$. CCDC-215475 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Synthesis and Properties of Zn−Al Layered Double Hydroxides Containing Ferrocenecarboxylate Anions

Sandra Gago,[a] Martyn Pillinger,*[a] Teresa M. Santos,[a] João Rocha,[a] and Isabel S. Gonçalves*[a]

Keywords: Hydroxides / Layered compounds / Ferrocene / Host-guest systems / Organic-inorganic hybrid composites

Zn–Al layered double hydroxides (LDHs) intercalated by ferrocenecarboxylate (FcCOO) and 1,1′-ferrocenedicarboxylate [$Fc(COO)_2$] anions have been prepared by co-precipitation from aqueous solution. The Zn/Al ratio in the final materials was in the range of 1.8–1.9. Powder X-ray diffraction (XRD) indicates that the material Zn_2Al–$Fc(COO)_2$ contains a monolayer of guest anions resulting in a basal spacing of 15.5 Å. The material Zn_2Al–FcCOO exhibits a basal spacing of 20.0 Å, consistent with the formation of a bilayer of organometallic guest species. FTIR, FT Raman and ^{13}C MAS NMR spectroscopy confirm the presence of structurally intact ferrocenecarboxylate and 1,1′-ferrocenedicarboxylate anions. The nature of the Al centers in the samples was probed by 1- and 2-D (triple-quantum) ^{27}Al MAS NMR spectroscopy. Thermal properties were studied by thermogravimetric analysis and by measuring powder XRD patterns at increasing temperatures in the range of 25–450 °C. Up to 160 °C the materials lose interlayer water molecules. Dehydration of Zn_2Al–$Fc(COO)_2$ prompts reorientation of the ferrocene guest anions, resulting in the formation of a collapsed phase with an interlayer separation of 12.3 Å. The structural transformation is fully reversible upon hydration. Heat treatment of Zn_2Al–FcCOO only resulted in a gradual contraction of the interlayer separation and not the formation of a collapsed phase.

Introduction

Layered double hydroxides (LDHs), also known as anionic clays or hydrotalcite-like compounds, are an important class of ionic lamellar solids.[1] The structures of LDHs consist of positively charged mixed metal hydroxide layers separated by charge-balancing anions and water molecules. A broad range of compositions of the type $[M^{2+}_{1-x}M^{3+}_{x}(OH)_2](A^{m-})_{x/m}\cdot nH_2O$ (M^{2+} = Mg^{2+}, Zn^{2+}, Ni^{2+} etc., M^{3+} = Al^{3+}, Cr^{3+}, Ga^{3+} etc.) are possible, in which the M^{2+} and M^{3+} metal ions occupy octahedral positions in the hydroxide layers. The gallery anions A^{m-} are exchangeable, giving rise to a rich intercalation chemistry,[2] and the guest species may be organic or inorganic, simple or complex.[3] LDHs find uses as catalysts and catalyst supports,[4] adsorbents, anion scavengers, anion exchangers, polymer stabilizers, and antacids.[1] The synthesis of LDHs intercalated by metal coordination compounds and oxometalates was reviewed recently.[3b] Apart from cyano complexes, e.g. $Fe(CN)_6^{3-}$ and $Fe(CN)_6^{4-}$, there are few examples of LDHs intercalated by organometallic anions, especially those containing cyclopentadienyl (Cp = η^5-C_5H_5) and η^6-arene groups. Two exceptions are LDH intercalates containing ferrocenesulfonate[5] and ferrocenebutyrate anions,[6] and their use in clay-modified electrodes. These hybrid materials may also exhibit interesting photochemical or photophysical properties.[7] In the present work, Zn−Al LDHs intercalated by ferrocenecarboxylate and 1,1′-ferrocenedicarboxylate anions have been synthesized directly by co-precipitation from aqueous solution. The materials were characterized by powder X-ray diffraction, FTIR and Raman spectroscopy, magic-angle-spinning NMR (^{13}C, ^{27}Al) spectroscopy, and thermogravimetric analyses (TGA). As will be described, the interlayer arrangement of organometallic anions depends on a number of factors, including the presence of one or two carboxylate substituents in the guest molecules and the degree of hydration of the LDH. Such factors have previously been shown to be important for LDHs intercalated by organic carboxylic acids.[8,9] In this paper comparison will be made with these studies, in particular those concerning the aromatic guests terephthalate and benzoate.

Results and Discussion

Structural and Compositional Analysis

The structural formulae of the synthesized samples $Zn_2Al-Fc(COO)_2$ and $Zn_2Al-FcCOO$ conform to the de-

Table 1. Chemical compositions and diffraction data for the LDH intercalates

Composition	x[a]	d(003) [Å]	c[b] [Å]	a (Å)	A_c[c] [Å^2/e]	t[d] [Å]
$Zn_{3.8}Al_2(OH)_{11.6}[Fc(COO)_2]\cdot 7H_2O$	0.345	15.5	46.35	3.04	23.2	115
$Zn_{3.5}Al_2(OH)_{11}[FcCOO]_2\cdot 8H_2O$	0.364	20.0	60.05	3.04	22.0	233

[a] Molar ratio $x = Al^{3+}/(Zn^{2+} + Al^{3+})$. [b] Lattice parameters a and c calculated from d(110) and d(003) planes, respectively. [c] Area per unit charge in the brucite-like layer, $A_c = (a^2\sin 60)/x$. [d] Average crystallite sizes calculated from the (003), (006), (009), (0012) and (0015) planes employing the Debye−Scherrer equation.

sired stoichiometric compositions except that the final Zn/Al atomic ratios are slightly lower than the value of 2.0 used in the starting solution (Table 1). This indicates an incomplete precipitation of the divalent cation, possibly due to the fact that the final pH used in the syntheses (7−8) is at the low end of the range appropriate for the synthesis of Zn−Al LDHs (7−9).[1]

The powder XRD patterns of $Zn_2Al-Fc(COO)_2$ and $Zn_2Al-FcCOO$, recorded at ambient temperature in the range of 3−70 °2θ, are typical of reasonably well-crystallized hydrotalcite-type compounds (Figure 1). Indexing was based on rhombohedral symmetry (polytype $3R_1$). The (00l) basal reflections can be easily identified as a series of symmetric, equally spaced peaks at angles below 30 °2θ. The high intensities combined with broad line-shapes indicate that the materials are of relatively high crystallinity but form as small crystallites. Furthermore, the alternation of the intensities of successive 00l reflections is indicative of a high concentration of electron density in the midplane of the interlayer region.[8a] The average crystallite sizes in the z direction were estimated from the (003), (006), (009), (0012) and (0015) planes using Scherrer's equation $L = 0.9\lambda/\beta_c\cos\theta$, where L is the crystallite size in Å along a line normal to the reflecting plane, λ is the wavelength of the radiation used, β_c is the instrument-corrected width of a reflection at half-height expressed in radians of 2θ, and θ is the Bragg diffraction angle. Values of 115 and 233 Å were found for $Zn_2Al-Fc(COO)_2$ and $Zn_2Al-FcCOO$, respectively (Table 1). The powder XRD patterns of the two LDHs also contain broad, asymmetric (*hkl*) reflections above ca. 2θ ≥ 30°, characteristic of turbostratic layered structures. Many organic-anion-pillared LDHs exhibit similar structural features.[10] The turbostratic effect is caused by a decrease in the ordering along the stacking axis due to the loss of van der Waals interactions between adjacent layers and the absence of a densely packed interlayer space formed by high charge density anions such as carbonate. On comparing the powder XRD patterns shown in Figure 1, it is evident that $Zn_2Al-FcCOO$ exhibits increased turbostratic disorder because the *hkl* reflections are broader and less intense, and in fact several are not observed. These differences are understandable when we consider the two types of guest species and the corresponding interlayer arrangements (see below).

The lattice parameter a, which corresponds to the average metal-metal distance in the layers, was calculated to be 3.04 Å for both samples ($a = 2d_{110}$). The parameter c was calculated as three times the spacing of the diffraction maximum

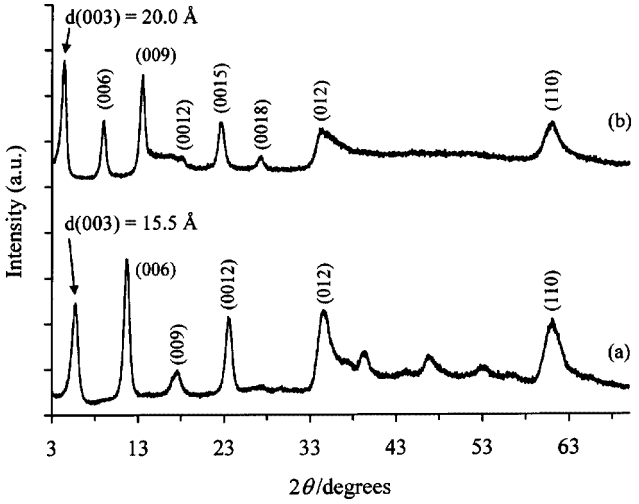

Figure 1. Powder XRD patterns at room temperature of (a) $Zn_2Al-Fc(COO)_2$ and (b) $Zn_2Al-FcCOO$

corresponding to planes (003), leading to values of 46.35 Å for $Zn_2Al-Fc(COO)_2$ and 60.05 Å for $Zn_2Al-FcCOO$. If the thickness of the brucite-like layer is taken as 4.77 Å, the gallery heights are 10.7 Å and 15.2 Å, respectively. In this work, the dimensions of the guest molecules have been estimated by using the structures of the heterobimetallic compounds $[LaL^1_3(CH_3OH)_4]_\infty$ (L^1 = 1,1′-ferrocenedicarboxylate) and $La_2L^2_6(CH_3OH)_2(H_2O)_5$ (L^2 = ferrocenecarboxylate), reported by Qing-jin and co-workers.[11] In $[LaL^1_3(CH_3OH)_4]_\infty$, two types of ferrocenedicarboxylato(2−) ligands exist, differing in their conformations. One of these is antiperiplanar with a torsion angle of 180°. The longest dimension of this molecule corresponds to one of the O···O distances and is equal to 7.48 Å. Taking into account the van der Waals radius of oxygen, this distance becomes 10.52 Å which is very similar to the observed gallery height. It is therefore reasonable to assume that the interlayer of $Zn_2Al-Fc(COO)_2$ consists of a monolayer of guest species with the longest dimension of each anion perpendicular to the brucite-like layers, as depicted in Figure 2. In this orientation, the area occupied by each molecule in the xy plane is equal to about 40 Å^2. The area per unit charge of the host lattice is given by $A_c = (a^2\sin 60)/x$, where a is the lattice parameter and x is the molar ratio of trivalent to total cations. For $Zn_2Al-Fc(COO)_2$, a = 3.04 Å and x = 0.345, and so A_c = 23.2 Å^2 (Table 1). Hence, the area available per divalent anion is approximately 46.4 Å^2. It follows that in a monolayer of 1,1′-ferrocenedicarboxyl-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

ate anions, the host layer charge can be balanced although relatively close packing of guest molecules is required.

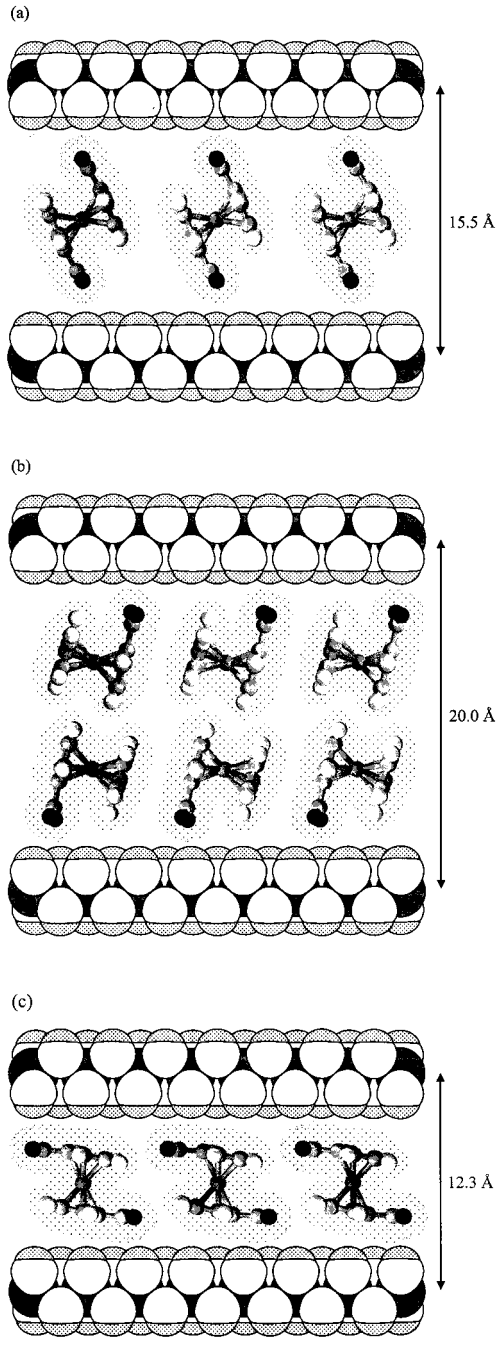

Figure 2. Models for the interlayer arrangement of guest species in (a) $Zn_2Al-Fc(COO)_2$ (fully hydrated sample = expanded phase), (b) $Zn_2Al-FcCOO$ (fully hydrated sample) and (c) $Zn_2Al-Fc(COO)_2$ (dehydrated sample = collapsed phase)

It is clear from the above calculations that the ferrocenecarboxylate anion would not be capable of spatially balancing the host layer charge of a Zn_2Al LDH, if arranged in a monolayer. The observed gallery height of $Zn_2Al-FcCOO$ is 15.2 Å, which suggests that a bilayer-like structure exists within the gallery. Figure 2(b) shows a possible arrangement of guest anions for which the calculated basal spacing exactly matches the observed value. Morlat-Thérias et al. reported Zn−Cr LDHs pillared by ferrocene mono- and disulfonate anions.[6] The basal spacings observed for their materials (20.0 and 15.0 Å, respectively) are very similar to those found in the present work for the corresponding carboxylate derivatives. It is worth noting that the interlayer arrangements for LDHs intercalated by mono- and disubstituted ferrocenes are similar to those usually reported for LDHs pillared by benzoate and terephthalate anions, respectively (with $M^{2+}/M^{3+} \approx 2$). Like 1,1′-ferrocenedicarboxylate, terephthalate anions tend to adopt a vertical orientation within the interlayer, at least under fully hydrated conditions.[3a,8,12] Benzoate anions form bilayer-like structures[8b] or monofilms of interdigitated species as found for methyl orange.[13] In all these LDH intercalates, the preferred orientation of the guest species permits a maximum interaction with the layers through hydrogen bonding with the layer hydroxyl groups, and at the same time the hydrophobic aromatic groups are located within the center of the galleries, as far apart as possible from the hydrophilic layer hydroxyls.

The organometallic-LDHs were further characterized by FTIR, Raman and MAS NMR spectroscopy. In the high frequency region (4000−2000 cm^{-1}), the IR spectra are dominated by broad bands at about 3410 cm^{-1}, attributable to the O−H stretches of weakly hydrogen-bonded water molecules and layer hydroxyl groups. A weak shoulder at about 3090 cm^{-1} (only observed for $Zn_2Al-FcCOO$) can be assigned to the C−H stretch of the cyclopentadienyl (Cp) rings of the guest. This band is stronger in the Raman spectra, and is located at 3108 cm^{-1} for $Zn_2Al-FcCOO$ and 3117 cm^{-1} for $Zn_2Al-Fc(COO)_2$. In the IR spectra, the C−C stretching vibration for the Cp rings appears at 1472 cm^{-1} for $Zn_2Al-FcCOO$ and 1487 cm^{-1} for $Zn_2Al-Fc(COO)_2$, weakly shifted compared with the corresponding bands for ferrocenecarboxylic acid (1475 cm^{-1}) and 1,1′-ferrocenedicarboxylic acid (1492 cm^{-1}). The two acids display strong bands in the solid state at about 1665 and 1300 cm^{-1}, due to C=O and C−O stretches. These bands are not observed in the spectra of the LDH intercalates, indicating that the guest species are deprotonated. This is confirmed by the presence of strong peaks at 1525 and 1391 cm^{-1} for $Zn_2Al-FcCOO$, and 1554 and 1401 cm^{-1} for $Zn_2Al-Fc(COO)_2$, assigned to $\nu_{as}(OCO)$ and $\nu_s(OCO)$, respectively. Below 750 cm^{-1}, the IR spectra of the two LDHs contain some bands due to the guest species (515 and 485 cm^{-1}) in addition to peaks arising from the host lattice. A broad band at about 630 cm^{-1} is due either to a vibrational mode of the hydroxyl groups and water or to a metal−oxygen vibration $\nu(M-O)$.[14] Two peaks at about 560 and 427 cm^{-1} can be attributed to $\nu(M-O)$ and $\delta(M-O-M)$, respectively. In the Raman spectra, the low frequency region is dominated by the intense ν_1 skeletal frequency at 324 cm^{-1} for $Zn_2Al-Fc(COO)_2$ and 314 cm^{-1} for $Zn_2Al-FcCOO$, both of which are weakly shifted compared with the corresponding bands for $Fc(COOH)_2$ and FcCOOH.

Figure 3 shows the ^{13}C CP MAS NMR spectra of $Fc(COOH)_2$, FcCOOH and the corresponding organometallic-LDHs. Ferrocenecarboxylic acid gives rise to peaks at δ = 180.7 ppm due to the carboxyl carbon and δ = 70.8 ppm (with shoulders) due to the Cp carbons. A resolved shoulder at δ = 72.7 ppm can be attributed to the Cp carbon atom that is attached to the carboxylic acid group (*ipso* carbon). Similarly, 1,1′-ferrocenedicarboxylic acid gives rise to peaks at δ = 175.1 and 73.2 ppm, although in this case no resolved shoulder was observed for the *ipso* carbon. The main difference between these spectra and those of the organometallic-LDHs is that the peaks due to the *ipso* carbon atoms are shifted considerably to lower field, presumably due to deprotonation of the carboxylic acid groups. The ^{27}Al MAS NMR spectrum of $Zn_2Al-Fc(COO)_2$ contains a sharp peak at δ = 14 ppm with a broad low-frequency shoulder, assigned to octahedral aluminium (see a in Figure 4). Similar spectra have been reported in the literature for $Zn-Al-CO_3$ and $Mg-Al-CO_3$ LDHs.[15,16] The sheared triple-quantum ^{27}Al MAS NMR spectrum of this sample clearly shows the existence of two distinct Al sites (overlapping resonances S1 and S2, see b in Figure 4). The peak S1, at δ ca. 16 (F1) [δ ca. 14 (F2)], displays a distribution of isotropic chemical shifts. We speculate that this may be due to the presence of a range of slightly different local Al environments generated by the random insertion of Al in the layers.[16] The low-frequency F2 shoulder (S2) is essentially undistributed but it has an average quadrupole coupling constant larger than S1. Similar 1-D and 2-D spectra were obtained for $Zn_2Al-FcCOO$ (not shown).

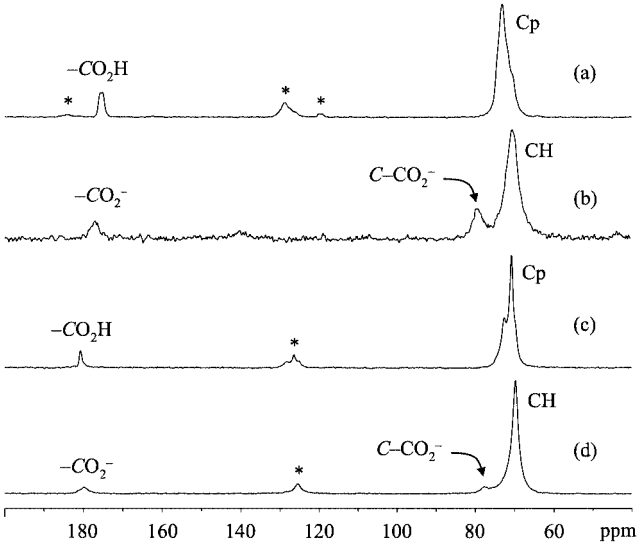

Figure 3. ^{13}C CP MAS NMR spectra of (a) $Fc(COOH)_2$, (b) $Zn_2Al-Fc(COO)_2$, (c) FcCOOH and (d) $Zn_2Al-FcCOO$; spinning side-bands are indicated with an asterisk

Thermal Properties

The TGA traces for $Zn_2Al-Fc(COO)_2$ and $Zn_2Al-FcCOO$ indicate three general regions of mass loss

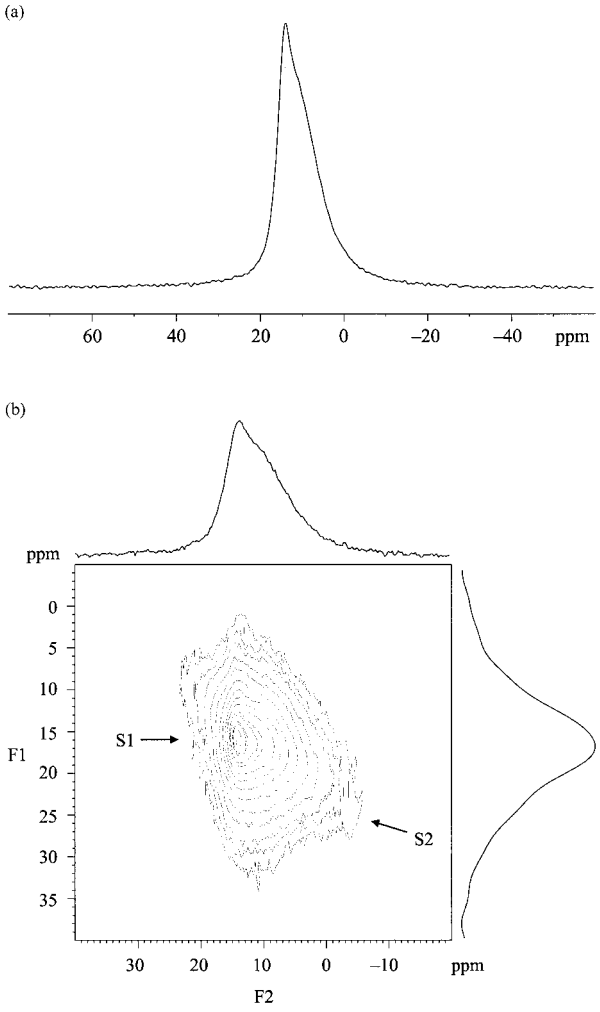

Figure 4. (a) ^{27}Al MAS NMR spectrum of $Zn_2Al-Fc(COO)_2$ and (b) sheared 3Q ^{27}Al MAS NMR spectrum of $Zn_2Al-Fc(COO)_2$

(Figure 5), the first two of which overlap to some extent. The first step, corresponding to removal of interlayer water, extends from room temperature to approximately 180 °C for $Zn_2Al-Fc(COO)_2$ (13.1% mass loss, DTG_{max} = 140 °C) and 160 °C for $Zn_2Al-FcCOO$ (10.6% mass loss, DTG_{max} = 80 °C). The second step, which takes place in the 180–240 °C range for $Zn_2Al-Fc(COO)_2$ (DTG_{max} = 214 °C) and 160–230 °C for $Zn_2Al-FcCOO$ (DTG_{max} = 196 °C), can be assigned to partial dehydroxylation of the double hydroxide layers.[17] The third step extends from about 280 °C to 520 °C and can be attributed to complete dehydroxylation and partial elimination/decomposition of the organometallic anions. The mass loss in this range is higher for $Zn_2Al-FcCOO$ (28.1%) than for $Zn_2Al-Fc(COO)_2$ (20.2%), consistent with the fact that the former has approximately double the number of intercalated ferrocenyl units due to the lower anion charge.

Powder XRD diagrams of $Zn_2Al-Fc(COO)_2$, recorded at increasing temperatures in the range of 25–450 °C, are shown in Figure 6. Only the basal reflections are displayed from which the interlayer spacing of the LDH may be deduced. As described above, the synthesized

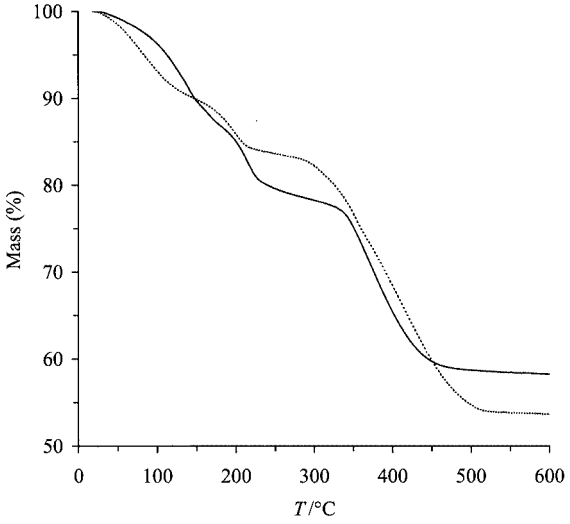

Figure 5. TGA curves for $Zn_2Al-Fc(COO)_2$ (——) and $Zn_2Al-FcCOO$ (− − −)

$Zn_2Al-Fc(COO)_2$ consists of a single expanded phase at room temperature characterized by a basal spacing of 15.5 Å. At 120 °C, the expanded phase can still be identified, although the basal reflections are reduced in intensity and shifted slightly to higher angles. In addition to this phase, a new "collapsed phase" is present characterized by a basal spacing of 12.3 Å. At this temperature, the water content was estimated to be 59% of the initial total. Further heating to 160 °C resulted in complete transformation of the expanded phase to the collapsed phase (water content = 19% of initial total). The basal spacing of 12.3 Å suggests a gallery height of 7.5 Å which fits very well with a model where the shortest dimension of the guest molecules is nearly perpendicular to the host layers (see c in Figure 2). We therefore conclude that removal of interlayer water is accompanied by a reorientation of the organometallic anions.[18] It can be assumed that the ferrocenyl units do not lie completely flat but are tilted slightly with respect to the host layers in order to maintain a hydrogen-bonding interaction between the carboxyl groups and hydroxide layers. The (003) reflection of the collapsed phase did not change much up to 300 °C, despite partial dehydroxylation of the layers. Transformation to an amorphous phase occurred above this temperature, i.e. during the third stage of weight loss observed by TGA. In a separate experiment, a sample of $Zn_2Al-Fc(COO)_2$ was heated to 160 °C and, after measuring the powder XRD pattern at this temperature, cooled to room temperature over ca. 15 min (under moist air), and the powder XRD pattern measured again (Figure 7). The results show complete recovery of the expanded phase, indicating that the structural transformation is fully reversible upon hydration. A TGA of the sample after measuring the powder XRD indicated that the total water content was equal to the initial value, within experimental error. The recovery of the expanded phase demonstrates that heat treatment (up to 160 °C) does not result in covalent grafting of the anions to the hydroxyl layers. These results are similar to those reported by Kooli et al. for a Mg_2Al-TA LDH (TA = terephthalate) prepared by co-precipitation at constant pH.[8b] Thus, it was found that the terephthalate anion initially adopts a vertical orientation between the layers, but above 150 °C the expanded structure collapses, with a shift in the position of the (003) reflection from 14.6 to 8.9 Å suggesting a horizontal arrangement for the anion. Cooling of the sample to room temperature under moist air led to complete recovery of the vertical arrangement.

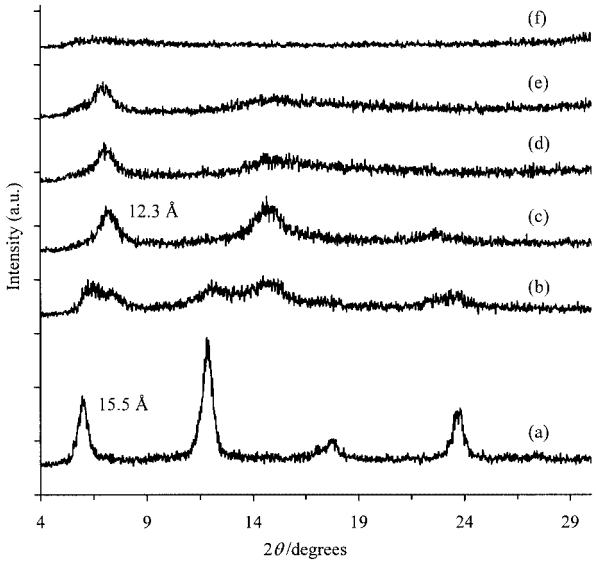

Figure 6. Powder XRD patterns of $Zn_2Al-Fc(COO)_2$ recorded at (a) room temperature, (b) 120 °C, (c) 160 °C, (d) 230 °C, (e) 300 °C and (f) 450 °C; the *d*(003) spacings for the expanded (15.5 Å) and collapsed (12.3 Å) phases are indicated

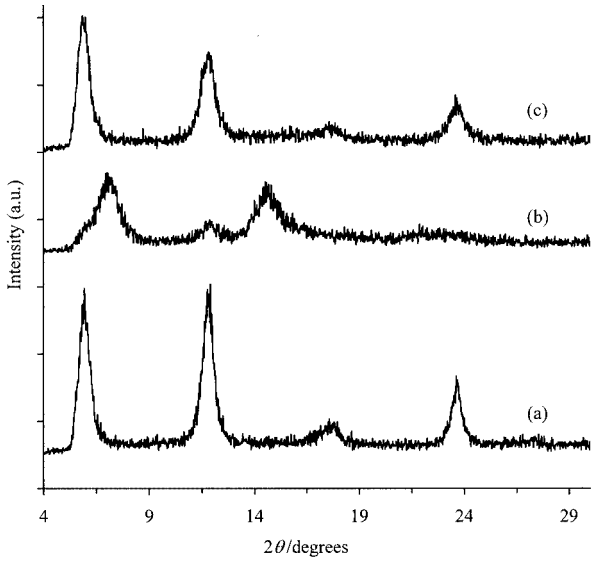

Figure 7. Powder XRD patterns of $Zn_2Al-Fc(COO)_2$ recorded at (a) room temperature, (b) 160 °C and (c) room temperature (after cooling the sample from 160 °C under moist air)

Powder XRD diagrams of $Zn_2Al-FcCOO$, recorded at increasing temperatures in the range of 25−450 °C, did not indicate the formation of a new collapsed phase (Figure 8). Instead, there was a gradual contraction of the interlayer separation up to 160 °C, as evidenced by a slight shift of the basal reflections to higher 2θ values [the (003) peak was not clearly observed in these diffraction patterns, probably due to the nature of the sample holder]. At 230 °C, the (00*l*) reflections had disappeared and only a very broad weak feature was observed between 13 and 20 °2θ. The layered structure was therefore severely disrupted by the partial dehydroxylation which, as revealed by the TGA results, took place in the range 160−230 °C. Transformation to an amorphous phase was complete at 300 °C and no further change took place up to 450 °C.

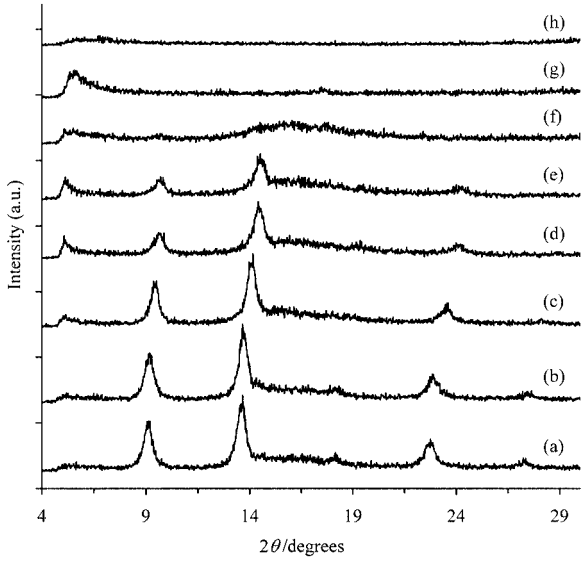

Figure 8. Powder XRD patterns of $Zn_2Al-FcCOO$ recorded at (a) room temperature, (b) 50 °C, (c) 80 °C, (d) 120 °C, (e) 160 °C, (f) 230 °C, (g) 300 °C and (h) 450 °C

Concluding Remarks

Zn−Al layered double hydroxides intercalated by ferrocene guests anions have successfully been prepared by co-precipitation from aqueous solution. In the case of 1,1-ferrocenedicarboxylate, the interlayer separation for the fully hydrated material indicates that the guest species adopt an antiperiplanar conformation and are arranged in a monolayer with the longest dimension perpendicular to the host layers. As observed for many organic-anion-pillared LDHs, water plays a critical role in stabilizing the expanded structure. Heat treatment results in a reorientation of the guest species such that the shortest dimension is nearly perpendicular to the host layers. The resultant collapsed phase is quite stable − the layered structure can still be identified by powder XRD after heat treatment at 300 °C. In the case of ferrocenecarboxylate guest anions, we conclude that bilayer structures are formed in the interlayer. The carboxyl groups are probably linked by hydrogen bonding to the hydroxide sheets with the aromatic groups located within the center of the gallery. Such an arrangement would result in a hydrophobic membrane-like region. This material may therefore have interesting adsorption properties, e.g. the ability to take up organic molecules (and swell in a direction perpendicular to the layers). The interlayer region may also provide a novel environment for photochemical reactions of photoactive molecules. These studies are currently under way in our laboratories in addition to efforts to prepare LDHs containing other types of organometallic anions.

Experimental Section

Materials and Methods: The reagents $Zn(NO_3)_2{\cdot}6H_2O$ (Riedel-de Haën), $Al(NO_3)_3{\cdot}9H_2O$ (Riedel-de Haën), 50% aqueous NaOH (Aldrich), 1,1′-ferrocenedicarboxylic acid [$Fc(COOH)_2$, Fluka] and ferrocenecarboxylic acid (FcCOOH, Fluka) were obtained from commercial sources and used as received.

Microanalyses for CHN were carried out at the Instituto de Tecnologia Química e Biológica, Oeiras, Portugal. Zn, Al and Fe were determined by ICP-OES at the Central Laboratory for Analysis, University of Aveiro (E. Soares). Room temperature powder XRD data were collected on a Philips X'pert diffractometer with a curved graphite monochromator (Cu-K_α radiation) in a Bragg−Brentano para-focusing optics configuration. Samples were step-scanned in 0.02 °2θ steps with a counting time of 1 s per step. The XRD measurements as a function of temperature were carried out in situ using the same diffractometer equipped with an Anton-Parr GmbH HTK16 high temperature chamber containing a Pt heating filament and a Pt−Pt/Rh (10%) thermocouple. The powdered sample was deposited on the filament which also acts as the sample holder. Heating rates of 10 °C min^{-1} were used. At a given temperature, samples were step-scanned in 0.02 °2θ steps with a counting time of 0.6 s per step. TGA studies were performed using a Shimadzu TGA-50 system at a heating rate of 5 °C min^{-1} under nitrogen.

IR spectra were obtained with KBr pellets using an FTIR Mattson-7000 infrared spectrophotometer. Raman spectra were recorded on a Bruker RFS100/S FT instrument (Nd:YAG laser, 1064 nm excitation, InGaAs detector). Solid-state NMR spectra were measured at 100.62 MHz for ^{13}C and 104.26 MHz for ^{27}Al with a (9.4 T) wide bore Bruker Avance 400 spectrometer. ^{13}C CP MAS NMR spectra were acquired with a 4 μs 90° proton pulse and 2 ms contact time with spinning rates of 7−8.5 kHz and 4 s recycle delays. Chemical shifts are quoted in ppm relative to TMS. Single-quantum ('conventional') ^{27}Al MAS NMR spectra were acquired using short and powerful radio-frequency pulses (0.6 μs, corresponding to π/12 pulses), a spinning rate of 14 kHz and a recycle delay of 1 s. Chemical shifts are quoted in ppm relative to $Al(H_2O)_6^{3+}$. The two-dimensional triple-quantum (3Q) ^{27}Al MAS NMR spectra were acquired using the three pulse z-filter sequence.[19,20] The lengths of the two hard pulses were 2.4 μs and 0.7 μs (radio-frequency magnetic field amplitude ν_1 = 150 kHz), and the length of the soft pulse was 11 μs (ν_1 = 7.5 kHz). The MAS rate was 14 kHz. 114 data points were acquired in the t_1 domain in increments of $(1/2\nu r)$ = 35.71 μs. The ppm scale of the sheared spectra was referenced to ν_0 frequency in the ν_2 domain and to $1.42\nu_0$ in the ν_1 domain (high-resolution dimension after shearing). The reference was $Al(H_2O)_6^{3+}$.

Sample Preparation: The LDHs were prepared by a co-precipitation method similar to that described by Drezdon.[12] Reactions were carried out under nitrogen, using distilled deionized water which was freshly de-carbonated prior to use by vigorously boiling for 15 minutes. As an example, a solution of $Zn(NO_3)_2{\cdot}6H_2O$ (2.97 g, 10 mmol) and $Al(NO_3)_3{\cdot}9H_2O$ (1.88 g, 5 mmol) in decarbonated water (20 mL) was added dropwise to a solution of 1,1′-ferrocenedicarboxylic acid (1.37 g, 5 mmol) and 50% NaOH (3.25 g, 40 mmol) in decarbonated water (35 mL) with efficient mixing. Once addition was complete, the resultant light brown gel-like slurry was stirred for 48 h at 75 °C. The solid was isolated by filtration, washed several times with de-carbonated water and dried at room temperature under reduced pressure in a vacuum desiccator. This material is referred to as $Zn_2Al-Fc(COO)_2$. The same general method was used for the synthesis of $Zn_2Al-FcCOO$ (10 mmol ferrocenecarboxylic acid). In both cases, the pH at the end of the reaction was in the range of 7−8.

$Zn_2Al-Fc(COO)_2$: $Zn_{3.8}Al_2(OH)_{11.6}[Fc(COO)_2]{\cdot}7H_2O$ (897.87): calcd. Zn 27.68, Al 6.01, Fe 6.22, C 16.05; found Zn 27.60, Al 6.04, Fe 6.22, C 15.29. TGA up to 180 °C revealed a sample weight loss of 13.1% (calcd: for loss of $7H_2O$, 14.0%; for loss of $6H_2O$, 12.3%). IR (KBr): $\tilde{\nu}$ = 3420 cm^{-1} (br), 2370 (w), 1554 (s), 1487 (m), 1460 (m), 1401 (m), 1389 (m), 1364 (m), 1347 (sh), 1260 (sh), 1193 (w), 1053 (sh), 1026 (m), 821 (m), 798 (m), 625 (m), 564 (m), 518 (m), 485 (w), 427 (s). Raman (cm^{-1}): 3362, 3117, 1480, 1459, 1392, 1367, 1195, 1070, 1034, 922, 569, 504, 324. ^{13}C CP MAS NMR: δ = 70.7 (*C*H), 79.5 (*C*−CO_2^-), 177.0 (C−*C*O_2^-). ^{27}Al MAS NMR: δ = 14.1 ppm.

$Zn_2Al-FcCOO$: $Zn_{3.5}Al_2(OH)_{11}[FcCOO]_2{\cdot}8H_2O$ (1072.1): calcd. Zn 21.34, Al 5.03, Fe 10.42, C 24.65; found Zn 21.40, Al 4.97, Fe 10.80, C 25.79. TGA up to 150 °C revealed a sample weight loss of 10.6% (calcd: for loss of $8H_2O$, 13.4%; for loss of $6H_2O$, 10.4%). IR (KBr): $\tilde{\nu}$ = 3407 cm^{-1} (br), 3086 (sh), 2924 (sh), 2861 (sh), 2367 (w), 2342 (w), 1525 (s), 1472 (m), 1391 (m), 1361 (m), 1347 (sh), 1266 (sh), 1211 (sh), 1187 (w), 1105 (w), 1024 (m), 1005 (w), 918 (w), 841 (sh), 819 (m), 793 (m), 637 (m), 554 (m), 510 (m), 485 (m), 429 (s). Raman (cm^{-1}): 3390, 3108, 1473, 1411, 1392, 1361, 1188, 1107, 1060, 1032, 918, 560, 504, 382, 314. ^{13}C CP MAS NMR: δ = 69.8 (*C*H), 77.8 (*C*−CO_2^-), 179.9 (C−*C*O_2^-). ^{27}Al MAS NMR: δ = 14.6 ppm.

[18] A referee suggested that the observed collapse of the interlayer distance for $Zn_2Al-Fc(COO)_2$ upon heating could be due to the removal of water molecules present between the carboxylate groups and the positive charges. Based on the agreement between calculated and experimental interlayer spacings, we firmly believe that the collapse is due to a reorientation of guest species (analogous to that reported in the literature for LDHs pillared by terephthalate anions).

Tetranuclear (Borole)rhodium Clusters with Hydrido and Methylthiolato Ligands − Structures of $[\{Rh(C_4H_4BMe)\}_4(\mu_3\text{-}H)(\mu_3\text{-}I)_3]$ and of $[\{Rh(C_4H_4BPh)\}_2(\mu\text{-}SMe)(\mu_3\text{-}SMe)]_2$ (2 *Rh−Rh*)[‡]

Gerhard E. Herberich,*[a] Hartmut J. Eckenrath,[a,b] Trixie Wagner,[a,c] and Ruimin Wang[a]

Keywords: Boron / Borole / Hydride ligands / Rhodium / S ligands

The heterocubanes $[Rh(C_4H_4BR)(\mu_3\text{-}I)]_4$ (**1a**: R = Ph; **1b**: R = Me) can be hydrogenated in THF (suspension, 1 bar H_2, 20 °C) to give the μ_3-hydrido clusters $[\{Rh(C_4H_4BR)\}_4(\mu_3\text{-}H)(\mu_3\text{-}I)_3]$ (**2a**,**b**). The structure of **2b** consists of a $Rh_4(\mu_3\text{-}H)(\mu_3\text{-}I)_3$ core with idealized C_{3v} symmetry and four capping η^5-borole ligands. The Rh–Rh distances within the $Rh_3(\mu_3\text{-}H)$ cluster unit amount to 2.9448(6), 2.9647(6), and 2.9724(6) Å; the μ_3-H ligand is 0.064(5) Å above the Rh_3 plane with a mean Rh–H bond length of 1.83(5) Å. The tris(acetonitrile) salts $[Rh(C_4H_4BR)(NCMe)_3]BF_4$ (**4a**,**b**) react with NaSMe to give the methylthiolato complexes $[Rh(C_4H_4BR)(SMe)]_x$ (**3a**,**b**). In the crystal **3a** possesses a centrosymmetric stepped-ladder structure $[\{Rh(C_4H_4BPh)\}_2(\mu\text{-}SMe)(\mu_3\text{-}SMe)]_2$ (2*Rh–Rh*) (**3a**-Rh_4), with a Rh–Rh bond length of 2.9233(11) Å. In solution a dissociation equilibrium is observed with a predominating dinuclear complex $[Rh(C_4H_4BPh)(\mu\text{-}SMe)]_2$ (**3a**-Rh_2); in pyridine a closely related solvate $[Rh(py)(C_4H_4BPh)(\mu\text{-}SMe)]_2$ (**5**) with a static $Rh_2(\mu\text{-}SMe)_2$ core is formed.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

The recently described heterocubanes $[Rh(C_4H_4BR)(\mu_3\text{-}I)]_4$ (**1a**,**b**) are readily accessible[2a] and display a rich reaction chemistry.[2b] They possess a total of 72 valence electrons, with five electrons counted per μ_3-iodide ligand. Hence the Rh centers obey the 18-electron rule and therefore the complexes **1** are cage compounds. As they have no metal−metal bonds, they are not clusters in the sense of the widely accepted definition of a cluster given by Cotton.[3] The heterocubanes **1a** and **1b** undergo an exchange of (borole)rhodium vertices which is fast on the NMR timescale at ambient temperature,[2a] possibly via a dissociation−association equilibrium between tetra- and dinuclear species.

We have tried to vary the bridging ligand in these cage compounds in a number of ways,[4] and report here on two results. Homogeneous hydrogenation of the heterocubanes **1a**,**b** (R = Ph and Me, respectively) produces novel tetranuclear μ_3-hydrido clusters $[\{Rh(C_4H_4BR)\}_4(\mu_3\text{-}H)(\mu_3\text{-}I)_3]$ (**2a**,**b**), and treatment with NaSMe affords the methylthio complexes $[Rh(SMe)(C_4H_4BR)]_x$ (**3a**,**b**). In the case of **3b** a tetranuclear complex with a partially opened structure is found in the crystal and a dissociation−association equilibrium in solution.

Results and Discussion

Hydrogenation and Synthesis of Hydrido Clusters

The heterocubanes **1** readily react with dihydrogen in THF (1 bar, 20 °C, 3 h) to produce the μ_3-hydrido clusters **2** (Scheme 1) The basicity of the THF seems to be essential since no reaction is observed when dichloromethane is used as solvent. The products can be isolated as dark red crystals by cooling concentrated dichloromethane solutions. In solution they are slightly sensitive to air. They do not react with triethylamine or with iodomethane at ambient temperature and are decomposed by CF_3CO_2D in $CDCl_3$. We mention in passing that attempted hydrogenation of **1a**,**b** with $NaBHEt_3$ was unsuccessful and seemed to result in reductive decomposition.

The ^{1}H NMR spectra of the product complexes **2a**,**b** display a quadruplet at high field [e.g. for **2a**: $\delta = -10.27$ ppm, $^1J_{Rh,H} = 21.5$ Hz] indicating the presence of a triply bridging hydrido ligand in a $Rh_3(\mu_3\text{-H})$ arrangement. The $Rh_3(\mu_3\text{-H})$ structural element was first found in the Fischer/Wawersik complex $[(RhCp)_3(\mu_3\text{-H})(\mu_3\text{-Cp})]$ [$\delta = -12.47$ ppm, $^1J_{Rh,H} = 26.5$ Hz],[5] and is known from a few other structurally characterized complexes,[6,7] including, for instance, the tetranuclear complex $[(RhCp^*)_4(\mu_3\text{-H})_4](BF_4)_2$[7b,7c] and the trimethylenemethane complex $[\{Rh(COD)\}_3(\mu_3\text{-H})\{\mu_3\text{-C}(CH_2)_3\}]$.[7a] We also see two types of borole ligands in a 3:1 ratio. In combination with the elemental analysis these observations define the formula and constitution of the clusters **2**.

Structure of the Hydrido Cluster 2b

Because of the novelty of these hydrido compounds we decided to characterize **2b** by an X-ray structure determination. Complex **2b** crystallizes in the monoclinic space group $P2_1/n$ with $Z = 4$ (Figure 1; produced with the Platon software package[8]). The central core of **2b** is a trigonal $Rh_4(\mu_3\text{-H})(\mu_3\text{-I})_3$ unit with idealized C_{3v} symmetry, and each Rh vertex is capped by a borole ligand. Note that the apical vertex (with Rh1) is similar to the vertices of **1b**, while the basal vertices belong to a true cluster unit $(\mu_3\text{-H})Rh_3$.

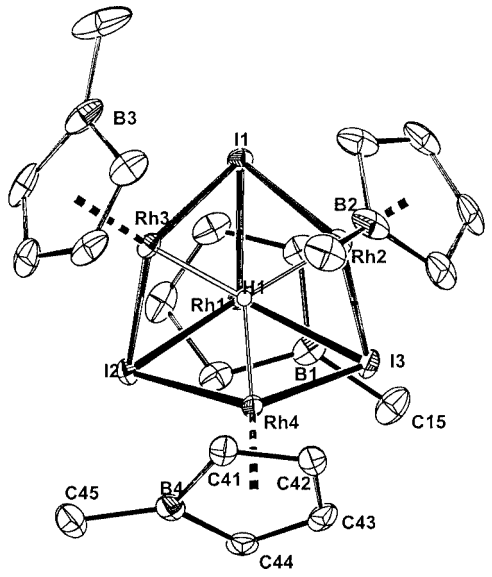

Figure 1. Molecular structure (PLATON plot,[8] at the 30% probability level) of **2b** in the crystal; see text for Rh−Rh interactions in the cluster; selected bond lengths (Å) and bond angles (°): I1−Rh1 2.7420(5), I1−Rh2 2.7181(6), I1−Rh3 2.7309(6), I2−Rh1 2.7272(6), I2−Rh3 2.7170(5), I2−Rh4 2.7285(6), I3−Rh1 2.7626(6), I3−Rh2 2.7398(6), I3−Rh4 2.7626(6), Rh1···Rh2 3.956(1), Rh1··Rh3 3.905(1), Rh1···Rh4 3.973(1), Rh2−Rh3 2.9647(6), Rh2−Rh4 2.9448(6), Rh3−Rh4 2.9724(6), Rh2−H1 1.82(5), Rh3−H1 1.82(5), Rh4−H1 1.83(5); I1−Rh1−I2 87.81(2), I1−Rh1−I3 85.87(2), I1−Rh2−I3 86.78(2), I1−Rh3−I2 88.24(2), I2−Rh1−I3 86.17(1), I2−Rh4−I3 86.14(1), Rh1−I1−Rh2 92.85(2), Rh1−I1−Rh3 91.06(2), Rh1−I2−Rh3 91.68(2), Rh1−I2−Rh4 93.47(2), Rh1−I3−Rh2 91.93(2), Rh1−I3−Rh4 91.95(1), Rh2−I1−Rh3 65.92(1), Rh2−I3−Rh4 64.71(2), Rh3−I2−Rh4 66.16(1)

The Rh−Rh distances between the apical Rh atom and the basal Rh centers amount to more than 3.90 Å and thus are nonbonding. The basal Rh atoms form a nearly regular triangle with Rh−Rh distances of 2.9448(6)−2.9724(6) Å. Known complexes with all-18e configurations and two center, two electron Rh−Rh bonds typically display Rh−Rh bond lengths of 2.72 Å,[5,6] while electron-deficient examples[7] tend to have longer bonds, with Rh−Rh distances up to about 3.0 Å.[9]

The Rh−I bond lengths average 2.737 Å [2.7170(5)−2.7626(6) Å] and are similar to those in **1a** and **1b** [2.7049(9)−2.777(1) Å],[3] while the Rh−(μ_2-I) distances [2.715−2.741 Å] seem to be marginally shorter.[10] The borole ligation to the metal is not detailed here. We only note that the Rh−B distances [2.307(6)−2.348(6) Å] are in the expected range (cf. the Rh−B bond lengths in the heterocubanes **1a**,**b**, which average to 2.325 Å[2a]).

The hydride ligand could be localized in the structure analysis and was refined isotropically. It lies 0.64(5) Å above the Rh_3 plane, and the Rh−H bond lengths observed average to 1.83(5) Å. This result is in reasonable agreement with the data for the cluster $[(RhCp^*)_4(\mu_3\text{-H})_4](BF_4)_2$ (as determined by neutron diffraction).[7b]

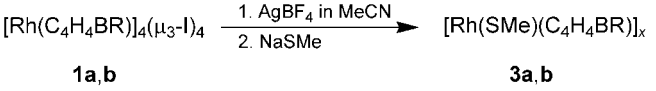
The hydrido clusters $[\{Rh(C_4H_4BR)\}_4(\mu_3\text{-H})(\mu_3\text{-I})_3]$ (**2a,b**) possess a total of 68 valence electrons, four less than the cage complexes **1**. Formally removing one iodo ligand from the cages **1** generates a $[\{Rh(C_4H_4BR)\}_4(\mu_3\text{-I})_3]^+$ fragment with three empty, metal-centered orbitals ready for σ-bonding. In C_{3v} symmetry these σ-orbitals combine to an a_1 and an e set of orbitals. Interaction with the 1s orbital of the hydrido ligand results in bonding of the hydrido ligand and metal-metal bonding, in other words, in a four center, two electron bond within the $(\mu_3\text{-H})Rh_3$ tetrahedron. The e set of MOs remains empty and accounts for the reduced electron count of **2a**,**b**.

Synthesis of Methylthiolato Complexes

The anionic ligand of the cage complexes **1** may be substituted in a two-step procedure, first removing the halide ligand by dehalogenation with silver salts such as $AgBF_4$ in acetonitrile, and then introducing a new ligand. Thus, the reaction of the tris(acetonitrile) salts **4a**,**b** with sodium methylthiolate in acetonitrile smoothly affords the robust, high-melting methylthiolato complexes **3a**,**b** (Scheme 2). The phenyl complex **3a** can be crystallized from hot toluene, while the methyl complex **3b** is scarcely soluble, even in toluene or CH_2Cl_2.

Structure of the Methylthiolato Complex 3a in the Crystal

The low-temperature NMR spectra of complex **3a** indicate that this compound is not of the heterocubane type.



Scheme 2. Synthesis of the methylthiolato complexes $[Rh(SMe)(C_4H_4BR)]_x$ (**3a**,**b**)

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

The X-ray single-crystal structure determination revealed that complex **3a** consists of tetranuclear [{Rh-(C_4H_4BR)}$_2$(μ-SMe)(μ$_3$-SMe)]$_2$ (2 *Rh*−*Rh*) (**3a**-Rh_4) molecules which display a crystallographic center of symmetry (Figure 2). The structure observed may formally be deduced from a cubanoid structure analogous to **1a**. Opening the heterocubane cage gives a stepped ladder, and coordinative unsaturation of the outer Rh centers is avoided by formation of dative Rh−Rh bonds [Rh1−Rh2 2.9233(11) Å]. Some additional stabilization by π-interactions with the sulfur lone-pairs may also be present. While the central rhombus is planar (as implied by the centrosymmetry of the molecule), the outer tetragons are folded along the line Rh1,Rh2 with a folding angle (between the plane Rh1,Rh2,S1 and Rh1,Rh2,S2) of 68.38(9)° in such a way that S2 is moved toward the central rhombus. Finally, we note that the molecule **3a**-Rh_4 may be viewed as a dimer of a dinuclear species **3a**-Rh_2. This view is supported by the fact that the connecting Rh2−S1′ and Rh2′−S1 bonds are markedly longer [2.461(2) Å] than the other Rh−S bonds in the same molecule [cf. Rh1−S1 2.326(2), Rh1−S2 2.303(3) Å and Rh2−S1 2.400(2), Rh2−S2 2.405(3) Å].

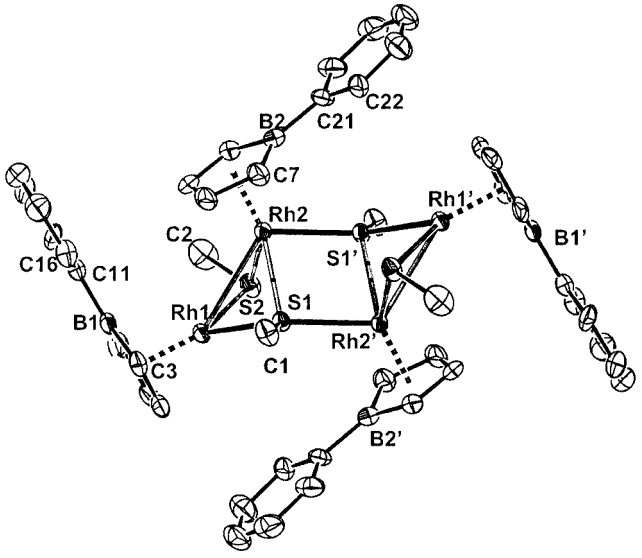


Figure 2. Molecular structure (PLATON plot,[8] at the 30% probability level) of **3a** in the crystal; selected bond lengths (Å) and bond angles (°):Rh1−Rh2 2.9233(11), Rh1−S1 2.326(2), Rh1−S2 2.303(2), Rh2−S1 2.400(2), Rh2−S2 2.405(3), Rh2−S1′ 2.461(2), S1−C1 1.818(8), S2−C2 1.826(10); Rh1−Rh2−S1 50.67(5), Rh1−Rh2−S2 50.06(6), Rh2−Rh1−S1 52.92(5), Rh2−Rh1−S2 53.21(7), S1−Rh1−S2 82.78(8), S1−Rh2−S2 79.14(8)

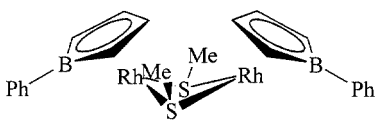


3a-Rh_2

Opening of heterocubane structures is also known from the family of complexes [$MX(PR_3)$]$_4$,[11] and small metal centers and bulky counter-ligands favor stepped-ladder structures. For instance, while the chloro complex [$CuCl(PPh_3)$]$_4$ is a heterocubane, the phenylthiolate adopts a [{$Cu(PPh_3)$}$_2$(μ-SPh)(μ$_3$-SPh)]$_2$ structure closely akin to that of **3a**. This structural difference is probably related to the bulkiness of the phenylthiolato ligands.

The Rh−S bond lengths in **3a** (2.32−2.46 Å) are shorter than the Rh−I bond lengths in **1a** (2.73−2.77 Å). The opening of the cubanoid structure to the stepped-ladder structure may again be caused by steric congestion. A detailed molecular modeling study would require a fully parametrized force-field to deal with the η^5-bonded phenylborole ligands. We therefore recurred to the following simplified approach for the generation of a hypothetical μ$_3$-SMe bridged heterocubane: Starting with the structure of **1a** the distances between the Rh centers and the heteroatoms were reduced to 2.35 Å (for pertinent reference data see ref.[10]), and the methyl groups were placed at an S−C distance of 1.8 Å in the radial direction. No conformational changes and no optimizations of the whole structure were performed. The resulting molecule exhibited prohibitively short C···H (1.9 Å), C···C (2.8 Å), and H···H (1.9 Å) interactions between the S−Me and B−Ph groups. On the basis of MM2 van der Waals parameters[12] an estimated destabilization of the cubanoid structure by approximately 100 kJ/mol was calculated.

Structure of the Methylthiolato Clusters 3a,b in Solution

The low-temperature ^{1}H NMR spectrum of **3a** (500 MHz, CD_2Cl_2, −80 °C) displays eight multiplets of equal intensity for the borole protons. This observation strongly suggests that the same structure that was found in the crystal is also present in the low-temperature solution. The stepped-ladder molecule **3a**-Rh_4 is a *meso* species with two chemically different borole ligands, both of which are in a chiral environment. Two sharp singlets are seen for the SMe groups, again in agreement with the assumption of a stepped-ladder structure in solution.

^{1}H NMR measurements at ambient temperature or above (in CD_2Cl_2, $CDCl_3$, or 1,1,2,2-$C_2D_2Cl_4$) produced spectra corresponding to effective C_{2v} symmetry. Using a 500 MHz spectrometer the signals were broad and blurred; on an 80 MHz machine the same solutions gave sharp, well-resolved signals with the characteristic hyperfine structure of the borole AA′BB′ four-spin system. Only one type of borole ligand and one type of SMe ligand were left. The chemical shifts are temperature dependent up to about 80 °C and then remain constant up to 120 °C (in 1,1,2,2-$C_2D_2Cl_4$), the highest temperature reached. These observations are readily explained by the assumption of a dissociation/association equilibrium between the tetranuclear species **3a**-Rh_4 and the dinuclear species **3a**-Rh_2, which was already mentioned above in the structural discussion (Scheme 3). We mention in passing that dinuclear species such as **3a**-Rh_2 could, in principle, form three stereoisomers, two *syn*-stereoisomers and one *anti*-stereoisomer, although only one species is seen in the NMR spectra. A comparison of the chemical shifts of the tetranuclear species from the spectrum measured at

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

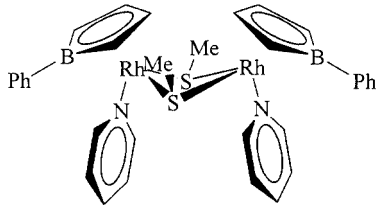
−80 °C and of the dinuclear species **3a**-Rh_2 exclusively present above 80 °C shows that at ambient temperatures **3a**-Rh_2 is already the predominant species. It is interesting to note here that the electronically related ruthenium complexes $[(RuCp^*)_2(\mu\text{-}SR)_2]$ are dinuclear, as confirmed by an X-ray structure determination of $[\{Ru(C_5Me_4Et)\}_2(\mu\text{-}SEt)_2]$.[13]

$[\{Rh(C_4H_4BPh)\}_2(\mu\text{-}SMe)(\mu_3\text{-}SMe)]_2 \rightleftharpoons 2\ [Rh(C_4H_4BPh)]_2(\mu\text{-}SMe)_2$

3a-Rh_4 **3a**-Rh_2

Sdheme 3. The dissociation equilibrium of the tetranuclear complex $[\{Rh(C_4H_4BR)\}_2(\mu\text{-}SMe)(\mu_3\text{-}SMe)]_2$ (2 *Rh*−*Rh*) (**3a**-Rh_4)

In the presence of pyridine complex **3a** shows a somewhat enhanced solubility, and in neat $[D_5]$pyridine it is moderately soluble. The ^1H NMR spectrum of this solution shows effective C_{2v} symmetry. The SMe groups appear as a sharp triplet not seen in the equilibrium mixture of Scheme 3. The triplet results from coupling with two Rh centers and indicates the formation of a new dinuclear species **5**, presumably of the formula $[\{Rh(py)(C_4H_4BPh)\}_2(\mu\text{-}SMe)_2]$. On attempted isolation complex **5** lost the pyridine completely, re-forming the cluster **3a**. The observation of the sharp triplet demonstrates that **3a**-Rh_2 cannot dissociate into a mononuclear species, not even in the presence of a good donor ligand. On the other hand, it also suggests that the tetranuclear species **3a**-Rh_4 is no longer present as it would, very likely, cause blurring of the hyperfine structure of the signal.



5

The analogous 1-methylborole complex **3b** poses the same structural problems. Because of the low solubility of this complex only ^1H NMR spectra could be measured and low-temperature measurements were not possible. Comparison of ^1H NMR measurements at 500 MHz and at 80 MHz revealed chemical-shift differences, suggesting that the methyl compound **3b** is also involved in a dissociation equilibrium in solution. An attempted X-ray structure determination showed the crystals to be polysynthetic twins, and no structure solution could be obtained. Thus the nuclearity of **3b** remains an open question.

Conclusion

The triple-decker complexes $[\{Rh(C_4H_4BR)\}_2(\mu\text{-}C_4H_4BR)]$ (R = Ph, Me) are among the most easily accessible borole complexes,[14] and therefore have been the starting point of a variety of studies.[1,2,15] In this paper we have described the first true cluster compounds with (borole)rhodium vertices. In preceding work we speculated that the fast exchange of (borole)rhodium vertices observed for the heterocubanes **1a**,**b** could occur via a dissociative formation of dinuclear intermediates.[2a] It was therefore particularly satisfying to find compelling evidence for the existence of the dinuclear species **3a**,**b**-Rh_2 in equilibrium with the tetranuclear clusters **3a**,**b**-Rh_4.

Experimental Section

General: Reactions were carried out under an atmosphere of dinitrogen by means of conventional Schlenk techniques. Hexane was distilled from potassium, CH_2Cl_2 from CaH_2, and THF and Et_2O from sodium benzophenone ketyl.

Secondary ion mass spectra (SIMS) were recorded on a Finnigan MAT-95 spectrometer. NMR spectra were recorded on a Varian Unity 500 spectrometer (^1H: 499.6 MHz; $^{13}C\{^1H\}$: 125.6 MHz; $^{11}B\{^1H\}$: 160.3 MHz). Chemical shifts are given in ppm; they were measured at ambient temperature and are relative to internal TMS for ^1H and ^{13}C and relative to $BF_3{\cdot}OEt_2$ as external reference for ^{11}B.

$[\{Rh(C_4H_4BPh)\}_4(\mu_3\text{-}H)(\mu_3\text{-}I)_3]$ (2a): The heterocubane $[Rh(C_4H_4BPh)(\mu_3\text{-}I)]_4$ (**1a**; 830 mg, 0.561 mmol) was suspended in THF (60 mL). A slow stream of hydrogen was passed through the flask with stirring for 3 h. Complex **1b** slowly dissolved as the reaction proceeded. The volatiles were then removed under vacuum. The residue was dissolved in CH_2Cl_2 (50 mL); the solution was filtered through a frit covered with kieselguhr, concentrated to a small volume (5 mL), and kept at −30 °C for 24 h. After removal of the mother liquor the crystals were washed with diethyl ether (2 × 5 mL) and dried under vacuum to give **2a** (560 mg, 74%) as dark red crystals, m.p. 212 °C (dec.); in solution somewhat sensitive to air, soluble in CH_2Cl_2, slightly soluble in benzene, insoluble in hexane, Et_2O and acetonitrile. $C_{40}H_{37}B_4I_3Rh_4$ (1353.3): calcd. C 35.50, H 2.76; found C 35.18, H 2.71. SIMS (NBA; negative ions): *m*/*z* (%) = 1110 (14) $[Rh_3I_3(C_4H_4BPh)_3]^-$, 497 (24) $[RhI_2(C_4H_4BPh)]^-$, 357 (27) $[RhI_2]^-$, 127 (100) $[I^-]$. ^1H NMR ($CDCl_3$): δ = −10.27 (q, $^1J_{Rh,H}$ = 21.5 Hz, μ_3-H), 3.84 (m, $N = {}^3J_{23} + {}^4J_{24}$ = 5.5 Hz, borole 2-/5-H), 4.49 (m, *N* = 5.5 Hz, 3 × borole 2′-/5′-H), 4.91 (m, *N* = 5.2 Hz, borole 3-/4-H), 5.11 (m, *N* = 5.2 Hz, 3 × borole 3′-/4′-H), 7.31−7.39 (m, $H_p + 3\ H_{p'} + 2\ H_m + 6\ H_{m'}$), 7.57 (m, 2 H_o), 7.62 (m, 6 $H_{o'}$) ppm. $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 71.8 (br., borole C-2,5), 75.0 (br., borole C-2′,5′), 88.49 [d, $^1J_{Rh,C}$ = 9.3 Hz, borole C-3,4], 90.19 (d, $^1J_{Rh,C}$ = 8.3 Hz, borole C-3′,4′) 127.68 (C_m), 127.60 ($C_{m'}$), 129.09 ($C_{p'}$), 129.11 (C_p), 135.82 ($C_o + C_{o'}$), 136.7 (C_i), 137.08 ($C_{i'}$) ppm. $^{11}B\{^1H\}$ NMR ($CDCl_3$): δ = 20 ppm.

$[\{Rh(C_4H_4BMe)\}_4(\mu_3\text{-}H)(\mu_3\text{-}I)_3]$ (2b): The heterocubane $[Rh(C_4H_4BMe)(\mu_3\text{-}I)]_4$ (**1b**, 200 mg, 0.162 mmol) was dissolved in THF (20 mL) and hydrogenated as described above for **1a**. The raw product was dissolved in CH_2Cl_2 (10 mL); the solution was filtered through a frit covered with kieselguhr, concentrated to a small volume (1 mL), and kept at −30 °C for 24 h. After removal of the mother liquor the crystals were washed with hexane (2 × 5 mL) and dried under vacuum to give **2b** (148 mg, 82%) as dark red crystals, m.p. 155 °C (dec.); in solution somewhat sensitive to air, soluble in CH_2Cl_2, tetrahydrofuran and toluene, moderately soluble in Et_2O, insoluble in hexane. Crystals suitable for a single-crystal

$[Rh(SMe)(C_4H_4BMe)]_x$ (3b): A solution of $AgBF_4$ (221 mg, 1.135 mmol) in acetonitrile (10 mL) was added with stirring to a suspension of **1b** (350 mg, 0.284 mmol) in acetonitrile (10 mL), and stirring was continued for 30 min. The resulting reaction mixture was filtered through a frit covered with kieselguhr into a flask containing a stirred suspension of NaSMe (79.5 mg, 1.134 mmol) in acetonitrile (5 mL). After stirring the reaction mixture for 60 min, the microcrystalline product was collected on a frit covered with kieselguhr and washed with acetonitrile (5 × 10 mL). It was then eluted with CH_2Cl_2. The solvent was evaporated under vacuum, and the resulting solid was washed with acetone (2 × 5 mL) and dried under vacuum to afford **3b** (180 mg, 70%) as blackish red microcrystals, m.p. 227 °C; not air-sensitive, slightly soluble in $CHCl_3$, CH_2Cl_2 and toluene, insoluble in diethyl ether, acetone, acetonitrile. ^{1}H NMR (80 MHz, $CDCl_3$, 25 °C): δ = 0.31 (s, B-Me), 2.83 (s, S-Me), 3.77 (m, N = 5.7 Hz, borole 2-/5-H), 5.24 (m, N = 5.8 Hz, borole 3-/4-H) ppm. ^{1}H NMR (500 MHz, $CDCl_3$, 25 °C): δ = 0.32 (s, Me), 2.71 (s, SMe), 3.69 (m, borole 2-/5-H), 5.22 (m, borole 3-/4-H) ppm.

X-ray Crystal Structure Determinations: The data collection was performed on an ENRAF-Nonius CAD4 diffractometer with Mo-K_α radiation for **2b** and Cu-K_α radiation for **3a** (where the crystals were small and the unit cell comparatively large) using a graphite monochromator. Crystal data, data collection parameters, and convergence results are given in Table 1. In the case of **3a** all residual electron density greater than 0.55 e/Å^3 was close to the two Rh atoms.

CCDC-216303 (for **2b**) and -216302 (for **3a**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) + 44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Amino-Substituted Ferra-bis(tricarbollides) − Metallatricarbaboranes Designed for Linear Molecular Constructions

Bohumír Grüner,*[a] Jaroslav Bačkovský,[a] Reijo Sillanpää,[b] Raikko Kivekäs,[c] Ivana Císařová,[d] Francesc Teixidor,[e] Clara Viñas,[e] and Bohumil Štíbr[a]

Keywords: Boranes / Carboranes / Metallacarboranes / Metallatricarbaboranes / Metallatricarbollides

Reactions between high purity $FeCl_2$ and the anion [*nido*-7-(*t*BuHN)-7,8,9-$C_3B_8H_{10}$)]$^-$ (**1**$^-$) have been used for efficient syntheses of the twelve-vertex double-cluster metallatricarbollide complexes of the *para*,*para* (*p*,*p*) type [*closo*-9,9′-$(RHN)_2$-*commo*-2,2′-Fe^{II}-1,7,9-($C_3B_8H_{10}$)-1′,7′,9′-($C_3B_8H_{10}$)] (**2**) (**2a**, R = *t*Bu and **2b**, R = H) (yields 42–45% for **2a**). Compound **2b**, which contains two reactive amino substituents conveniently attached to the tricarbollide subclusters in *p*-positions with respect to the metal center, was prepared via facile cleavage of the *t*Bu substituent in **2a** either by $AlCl_3$ or by thermal means. The structure of **2b** constitutes a good setting for the synthesis of building blocks for constructing linear metallatricarbollide rods of high stability. Two isomeric compounds of the *para*,*meta* (*p*,*m*) type **3**, [*closo*-9,10′-$(RHN)_2$-*commo*-2,2′-Fe-1,7,9-($C_3B_8H_{10}$)-1′,7′,10′-($C_3B_8H_{10}$)] (where R = *t*Bu **3a** and/or H **3b**), were isolated in smaller yields from reactions of high purity $FeCl_2$ with **1**$^-$ at higher temperatures. Also reported is the characterization of the *m*,*m*-type complex, [*closo*-10,10′-(*t*BuHN)$_2$-*commo*-2,2′-Fe^{II}-1,7,10-($C_3B_8H_{10}$)-1′,7′,10′-($C_3B_8H_{10}$)] (**4a**), and the two zwitterionic species of the new 7-L-7,8,10-$C_3B_8H_{10}$ type (**6**) [L = Me_3N **6a** and *t*Bu(Me)HN **6b**] isolated in moderate yields from the reaction of reagent grade $FeCl_2$ with **1**$^-$. The molecular structures of **2b**, **3a**, and **6b** were determined by single-crystal X-ray diffraction studies. Multinuclear (^1H and ^{11}B), two-dimensional [^{11}B-^{11}B]-COSY, and $^1H\{^{11}B$(selective)} magnetic resonance measurements enabled complete assignments of all resonances for all compounds and are in excellent agreement with the structures proposed.

Introduction

The first venture into the area of twelve-vertex metallatricarbollide chemistry was the synthesis of the mixed-sandwich cyclopentadienyl-ferratricarbollide analogues of ferrocene, the *closo* complexes [9-R-2-(η^5-C_5H_5)-2,1,7,9-$FeC_3B_8H_{10}$] [where R = H_2N, CH_3NH, $(CH_3)_2N$, *t*BuHN, and *t*BuCH$_3$N][1] and of the isomeric [10-R-2-(η^5-C_5H_5)-2,1,7,10-$FeC_3B_8H_{10}$] (where R = H_2N, CH_3NH, $(CH_3)_2N$, and *t*BuHN)[2] species. In contrast to double-cluster metal dicarbollide "full" sandwiches, which are quite common and easily available,[3] we have found that the corresponding metallatricarbollide counterparts cannot be prepared under comparable conditions. Finally it was recognized that such complexes could be synthesized only under forcing reaction conditions. In a preliminary communication[4] we reported a low-yield isolation of the first representatives of the double-cluster metallatricarbollide family, [*closo*-9,9′-(*t*BuHN)$_2$-*commo*-2,2′-M^{II}-1,7,9-($C_3B_8H_{10}$)-1′,7′,9′-($C_3B_8H_{10}$)], where M = Fe and Ru (yields 4% and 9%, respectively). In this paper we report full experimental details on substantially improved, simple and good yielding syntheses of the isomeric ferra-bis(tricarbollides) containing amine functionalities, (*t*BuHN or H_2N) in *m*- and *p*-positions with respect to the Fe center. Also reported are compounds of the still unknown 7-L-7,8,10-$C_3B_8H_{10}$ (L = amine) type which are formed by metal-promoted isomerization reactions. Structures are presented in a simplified manner: unmarked vertices in Schemes 1 and 2 stand for cluster BH units, while C denotes the CH vertex if no substituent is attached to it. General structures of individual types of compounds discussed in this work are in the Structures diagram.

Results and Discussion

Syntheses

As shown in path i) of Scheme 1, the reaction between Tl[7-(*t*BuHN)-7,8,9-$C_3B_8H_{10}$] Tl(**1**$^-$) and an excess of highly pure $FeCl_2$ (99.99%) in a diglyme-mesitylene mixture led to formation of [*closo*-9,9′-(*t*BuHN)$_2$-*commo*-2,2′-Fe^{II}-1,7,9-($C_3B_8H_{10}$)-1′,7′,9′-($C_3B_8H_{10}$)] (**2a**). Complex **2a** was isolated as a single metallacarborane product in a significantly improved yield (43%, cf. a 4% yield in the previous method).[4]

Higher overall yields of the ferra bis(tricarbollides) (up to 62%) have been obtained when Na[7-(*t*BuH$_2$N)-7,8,9-$C_3B_8H_{10}$]$^-$ Na(**1**$^-$) was heated to reflux in diglyme in the presence of an excess of high-purity $FeCl_2$ (path ii) of Scheme 1). In this case, however, the main product **2a** (yield 45%) was always accompanied by the isomeric compound [9,10′-(*t*BuHN)$_2$-*commo*-2,2′-Fe-*closo*-1,7,9-($C_3B_8H_{10}$)-1′,7′,10′-($C_3B_8H_{10}$)] (**3a**) (yield 17%). The advantage of the Na(**1**$^-$) reaction is the good total yield of the sandwich compounds, but the presence of **3a** substantially complicates the isolation of **2a** since the mixture of **2a** and **3a** must be then separated by preparative liquid chromatography. Attempts at carrying out the reaction in a mesitylene-diglyme mixture or decreasing the reaction temperature led to similar isomeric mixtures and also to a substantial decrease in the total yield of **2a** and **3a** (ca. 25%). On the other hand, if the process was directed to obtain products with bare NH_2 groups (**2b** and **3b**), the pre-purified mixture of **2a** and **3a** could be first conveniently treated to remove the butoxide function (see text below), and the resultant products could be separated more easily.

Complex **3a** apparently originates from *dsd* isomerization on one of the tricarbollide ligands of **2a** in the reaction mixture as the concentration of **3a** increases with the reaction time. This observation is consistent with the similarly anomalous $p \rightarrow m$ isomerization path reported for the mixed-sandwich metallatricarbollide series.[2]

Consistent with the previously reported findings[2] are the isobutylene elimination reactions leading to H_2N derivatives in the series of bis(tricarbollide) iron sandwiches reported in this work. The reactions of both **2a** and **3a** with anhydrous $AlCl_3$ in hexane at reflux removes the *t*Bu substituent to give the complexes [*closo*-9,9′-(H_2N)$_2$-*commo*-2,2′-Fe^{II}-1,7,9-($C_3B_8H_{10}$)-1′,7′,9′-($C_3B_8H_{10}$)] (**2b**) and [*closo*-9,9′-(H_2N)$_2$-*commo*-2,2′-Fe^{II}-1,7,9-($C_3B_8H_{10}$)-1′,7′,10′-($C_3B_8H_{10}$)] (**3b**), respectively (yields of 82% and 80%, respectively, see paths iii) and ix) of Scheme 1). For the preparation of **3b**, it was convenient to apply the $AlCl_3$ reaction on a mixture of **2a** and **3a** obtained from the complexation of Na(**1**$^-$) as outlined above, which resulted typically in a total yield of 79% of the H_2N- derivatives **2b** and **3b**. The advantage of this approach is that the mixture of compounds **2b** and **3b** could be easily separated by conventional column chromatography. Alternatively, the isobutylene elimination, giving **2b**, could be achieved by briefly heating **2a** at 210 °C in vacuo (see path xi) of Scheme 1). This thermal cleavage is, however, accompanied by simultaneous formation of the isomeric [*closo*-9,10′-(H_2N)$_2$-*commo*-2,2′-Fe^{II}-1,7,9-($C_3B_8H_{10}$)-1′,7′,10′-($C_3B_8H_{10}$)] (**3b**) which, depending on reaction time, accompanies the main

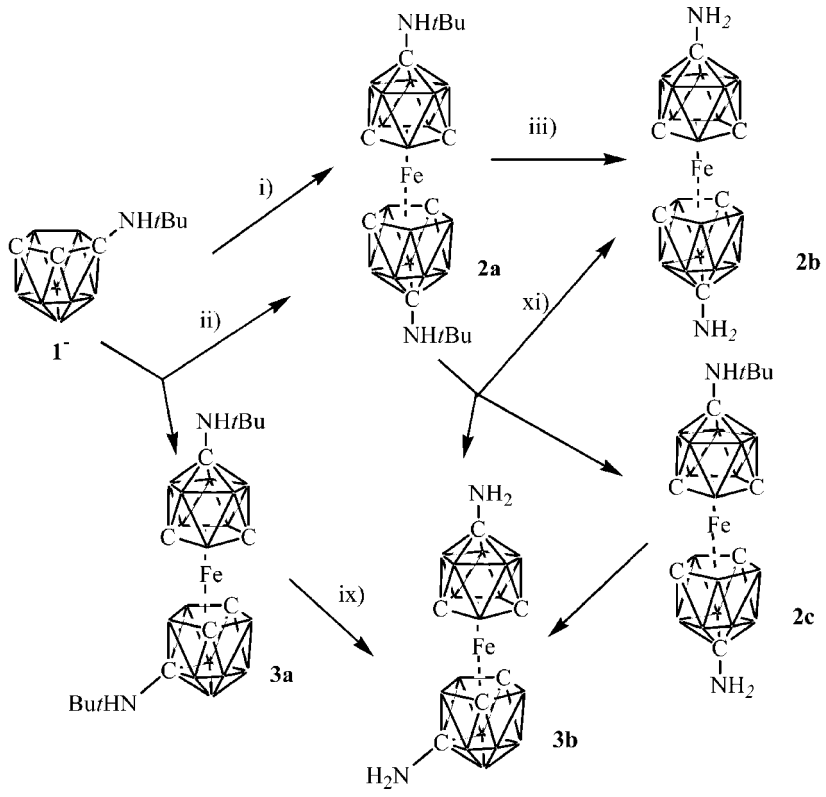

Scheme 1. Formation of ferratricarbollides, their thermal rearrangements and cleavage of their butyl groups. i) Tl(**1**$^-$), $FeCl_2$ (99.99%), diglyme/mesitylene (1:4), reflux. ii) Na(**1**$^-$), $FeCl_2$ (99.99%), diglyme, reflux. iii), ix) $AlCl_3$, hexane, reflux. xi) 210 °C, 15 min

product in small to moderate yields. Another by-product of this thermal cleavage is the linearly shaped [*closo*-9-(*t*BuHN),9′-(H_2N)-*commo*-2,2′-Fe^{II}-1,7,9-($C_3B_8H_{10}$)-1′,7′,10′-($C_3B_8H_{10}$)] (**2c**) (yield 20%). Complex **2c** evidently arises from one-side loss of a butyl group from **2a**. These side isobutylene-elimination reactions are the reason why **3a** cannot be obtained in good yields by thermal rearrangement of **2a**.

It should be noted that the iron complexation reactions outlined above are rather sensitive to the purity of the $FeCl_2$ employed since the reagent grade $FeCl_2$ used in the preliminary communication[4] provided completely different reaction products. This original reaction[4] has now been studied in more detail and has been found to be very complex. Based on multiple experiments, it was found that prolonged treatment of 7-(*t*BuH_2N)- *nido*-7,8,9-$C_3B_8H_{10}$ (**1**) with NaH and an excess of the reagent-grade $FeCl_2$ in diglyme at reflux (path i) of Scheme 2), followed by chromatographic separation, resulted in the isolation of complexes **2a** and **3a** in yields 4 and 6%, respectively. The reaction also gave trace amounts of the third *m*,*m*-substituted isomer, [*closo*-10,10′-(*t*BuHN)$_2$-*commo*-2,2′-Fe^{II}-(1,7,10-$C_3B_8H_{10}$)$_2$] (**4a**). Nevertheless, the formation of these three iron complexes represents only a side reaction mode (path ii) of Scheme 2). The main reaction mode (path iii) of Scheme 2) is, however, associated with the recently reported metal-promoted rearrangement of anion **1**$^-$ giving at lower temperatures (DME at reflux) the [8-*t*BuNH-*nido*-7,8,9-$C_3B_8H_{10}$]$^-$ (**5**$^-$) anion [and finally the neutral compound 8-*t*BuNH-*nido*-7,8,9-$C_3B_8H_{11}$ (**5**) upon protonation].[5] Under the reaction conditions now employed (diglyme at reflux) compound **5** was isolated in only trace amounts and the main reaction products were identified as 7-Me_3N-*nido*-7,8,10-$C_3B_8H_{10}$ (**6a**) and 7-*t*Bu(Me)HN-*nido*-7,8,10-$C_3B_8H_{10}$ (**6b**) (yields of 14 and 17%, respectively). These compounds are representatives of the zwitterionic 7-L-7,8,10-$C_3B_8H_{10}$ (**6**) family and it is reasonable to suppose that their formation is associated with further cage rearrangement of anion **5**$^-$, followed by in situ *N*-methylation by the solvent methyl groups (diglyme) (path ix) of Scheme 2). The rearrangement is evidently associated with the migration of the unsubstituted cage carbon C7 in **5**$^-$ into the C10 position. A similar rearrangement of the [7,8,9-$C_3B_8H_{11}$]$^-$ and 7-(CH_3)$_3$N-7,8,9-$C_3B_8H_{10}$ *nido*-tricarbollide compounds into their isomeric congeners, [7,8,10-$C_3B_8H_{11}$]$^-$ and 10-(CH_3)$_3$N-7,8,10-$C_3B_8H_{10}$, has already been subject of theoretical and experimental studies.[6,7]

X-ray Diffraction Studies

The structure of compound **2a** has already been determined by an X-ray diffraction study published in a preliminary communication.[4] The results of the X-ray diffraction analysis of the bis-tricarbollide complex [*closo*-9,9′-(H_2N)$_2$-*commo*-2,2′-Fe^{II}-1,7,9-($C_3B_8H_{10}$)-1′,7′,9′-$C_3B_8H_{10}$)] (**2b**) resulting from cleavage of the *t*Bu end groups is shown in Figure 1. As follows from the comparison of the crystallo-

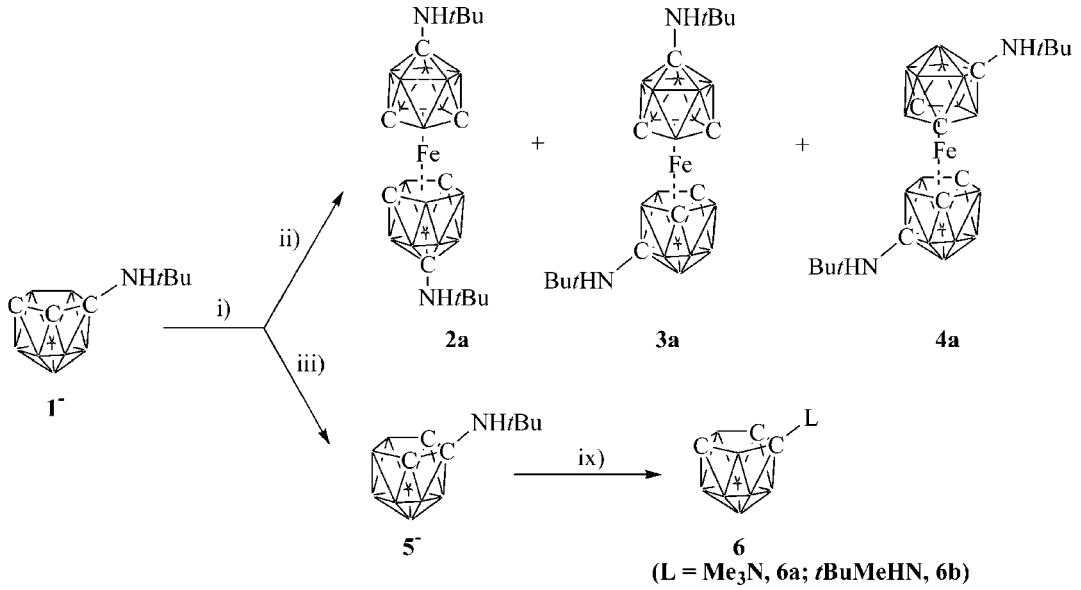

Scheme 2. Reactions with reagent grade $FeCl_2$ (metal-promoted rearrangements) i) Na(**1**$^-$), $FeCl_2$ (98%), diglyme, reflux. ii) side formation of ferratricabollides. iii) main reaction mode, the formation of zwitterions of the 7-L-7,8,10-$C_3B_8H_{10}$ type (**6**) (L = Me_3N **6a** and *t*Bu(Me)HN **6b**)

graphically determined structures of **2a**[4] and the structurally similar **2b**, a change in the *t*BuHN substituent for the unsubstituted H_2N group has no significant effect either on the N−C9 or C9−B distances. In contrast to **2a**, however, the molecules of **2b** are symmetrical, with two independent molecules in the unit cell. The iron atoms in both molecules are situated at the center of symmetry and the mutual configuration of the C_2B_3 pentagons is therefore exactly staggered. This means the C_2B_3 pentagonal planes flanking the metal center are parallel and the arrangement of the C9, Fe, and C9^i atoms is linear in both molecules. An interesting feature is that the two molecules form dimeric assemblies via a weak hydrogen bond N1−H1A−N2 with the N1−N2 distance being 3.378(2) Å and the N1−H1A−N2 angle being 172°.

The results of the X-ray diffraction analysis of the bis(tricarbollide) complex [*closo*-9,10′-(*t*BuHN)$_2$-*commo*-2,2′-Fe-1,7,9-($C_3B_8H_{10}$)-1′,7′,10′-($C_3B_8H_{10}$)] (**3a**) are shown in Figure 2. The tricarbollide subclusters in **3a** are different and Figure 2 shows *p*-substitution in one of the tricarbollide subunits and *m*-substitution in the second. However, no marked differences can be seen in the corresponding bond parameters between the cages. The mutual configuration of the C_2B_3 pentagons is staggered and the torsion angles are very close to the ideal value of 36° for a perfectly staggered conformation. As expected, the mean C_2B_3 pentagonal planes flanking the metal center in **3a** are very close to parallel, the dihedral angle between the planes being 2.25(1)°, and the C9−Fe2−B9′ jack-knife angle at 179.02(1)° is essentially linear. The disposition of the C9, Fe2, and C10′ atoms is reflected by the C9−M2−C10′ angle of 154.83(1)°.

The structure of 7-*t*Bu(Me)HN-*nido*-7,8,10-$C_3B_8H_{10}$ (**6b**), shown in Figure 3, confirms the 7,8,10 arrangement of the cage carbon atoms and the C7 substitution by the

associated with the upper C_3B_2 pentagon brought by the substituent. The largest differences can be seen for the longer inter-atomic distances B9−C10 [1.673(6) Å] and C10−B11 [1.609(6) Å] found in the structure of the symmetrically substituted derivative 10-Me_3N-*nido*-7,8,10-$C_3B_8H_{10}$. There is, however, some uncertainty due to the disorder in this structure.[6f]

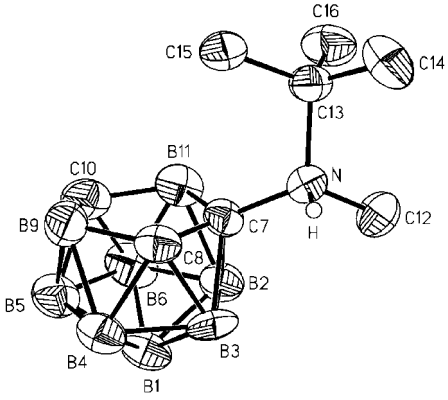

Figure 3. Molecular structure of **6b** with selected bond lengths (Å): N−C(7) 1.517(4), C(7)−C(8) 1.543(5), C(7)−B(11) 1.590(6), C(8)−B(9) 1.593(6), C(10)−B(9) 1.596(7), C(10)−B(11) 1.623(7). Hydrogen atoms omitted for clarity. Thermal ellipsoids are drawn at the 50% probability level

NMR Spectroscopy

Figure 4 shows simplified stick diagrams comparing the ^{11}B chemical shifts for selected complexes of types **2** and **3** with those of the structurally related mixed-sandwich *closo* compounds [9-*t*BuHN-2-(η^5-C_5H_5)-2,1,7,9-$FeC_3B_8H_{10}$][1] and [10-*t*BuHN-2-(η^5-C_5H_5)-2,1,7,10-$FeC_3B_8H_{10}$].[2] The NMR spectroscopic data are also consistent with the structures for the *p, p* substituted complexes of type **2** determined crystallographically. The ^{11}B NMR spectra of compounds **2a**[4] and **2b** show very similar 4:2:4:2:4 patterns of doublets with only slight differences. The same intensity patterns apply to the corresponding BH resonances in the ^1H NMR spectra, in which one singlet resonance of intensity 4, assigned to the magnetically equivalent CH cage units, was also clearly found. As seen in Figure 4, the ^{11}B NMR spectra are very similar to that of [9- *t*BuHN-2-(η^5-C_5H_5)-*closo*-2,1,7,9-$FeC_3B_8H_{10}$][1] which exhibits a general upfield shift of the all resonances in comparison with those of compounds of type **2**.

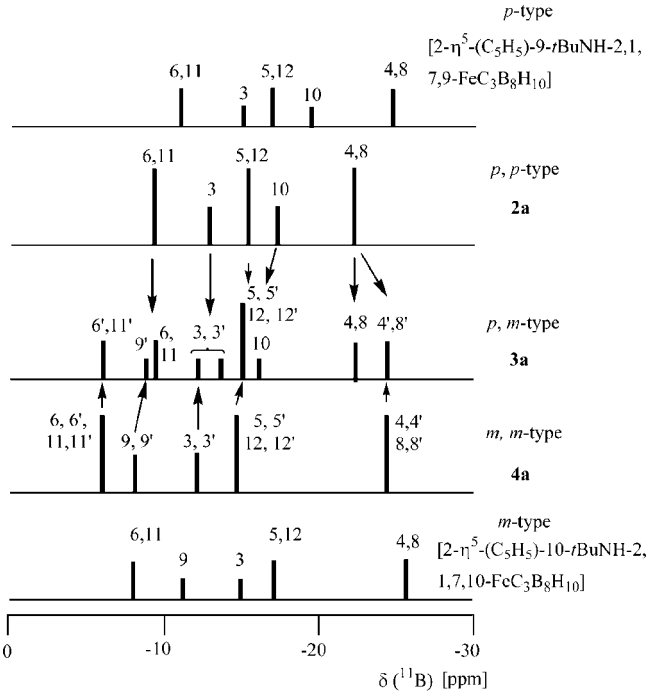

Figure 4. Stick representation and comparison of the ^{11}B NMR shifts for the *t*BuNH-substituted mixed sandwiches (data from ref.[1b,2]) and double-cluster ferratricarbollides **2a**, **3a**, and **4a**

Two sets of slightly shifted resonances with the same spectral patterns can be observed in the ^{11}B NMR spectrum of **2c**, those due to B10,10′ and B5,12,5′,12′ being coincidentally overlapping. The $^1H\{^{11}B\}$ NMR spectrum of **2c** contains two nonequivalent CH signals and also two related sets of resonances for each subcluster with coincidental overlaps for H6,11,6′,11′ and H3,3′. The ^{11}B NMR spectrum of **4a** (see Figure 4) with the *m,m* configuration of both ligands consists of 4:2:2:4:4 patterns of doublets as does the spectrum of the corresponding mixed-ligand complex [10-*t*BuHN-2-(η^5-C_5H_5)-*closo*-2,1,7,9-$FeC_3B_8H_{10}$].[2] The ^{11}B NMR spectra of the *p,m* type complexes **3a** and **3b** consist of two series of signals clearly attributable to those of the two nonequivalent tricarbollide ligands with *p*- and *m*- positioned substituents. The signals associated with the nonequivalent tricarbollide ligands can be clearly distinguished due to close similarities with the corresponding ^{11}B patterns found for **2b** and **4a**. The same similarities can be also found in the corresponding $^1H\{^{11}B\}$ NMR spectra of complexes **3a** and **3b**.

In accord with the absence of symmetry, the ^{11}B NMR spectra of the zwitterionic tricarbollide derivatives **6a** and **6b** consist of eight different signals with two coincidental overlaps found in the spectrum of **6b**. As shown in Figure 5,

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

the ^{11}B NMR patterns show very close similarities with those of the structurally related anion [7-Me-*nido*-7,8,10-$C_3B_8H_{10}]^-$.[7] The ^{11}B NMR spectra of **6a** and **6b** themselves exhibit only slight differences in chemical shifts. Also eight singlets corresponding to BH signals were found in the $^1H\{^{11}B\}$ spectra of both compounds along with two different CH signals for each derivative. The respective ^1H NMR signals corresponding to Me_3N- and *t*Bu(Me)HN-substitution in **6a** and **6b** were clearly identified.

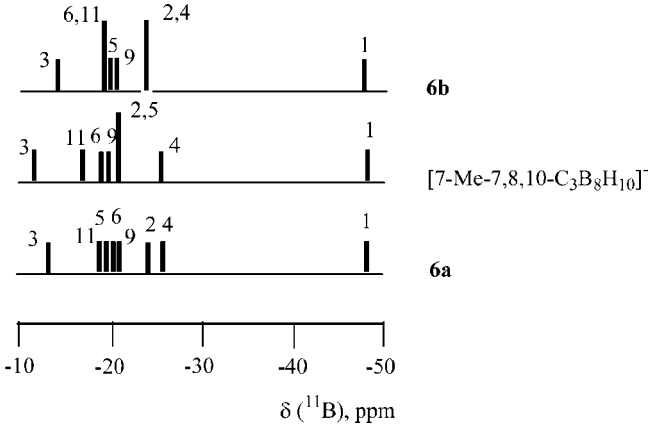

Figure 5. Stick representation and comparison of the ^{11}B NMR shifts for the zwitterions of the 7-L-7,8,10-$C_3B_8H_{10}$ type **6** (L = Me_3N **6a** and *t*Bu(Me)HN **6b**) with those for the [7-Me-*nido*-7,8,10-$C_3B_8H_{10}]^-$ anion (data from ref.[7])

Mass spectra of all the newly prepared compounds of types **2**, **3**, **4**, and **6** show theoretical cut-offs in their molecular-ion envelopes.

Conclusions

This work has opened up efficient preparative routes to the ferra bis(tricarbollides) of which compounds of type **2** with *p*,*p* orientation of the two reactive amino functionalities are the most important. These complexes are neutral and highly stable 26-cluster-electron *closo* complexes, perfect tricarbollide analogues of ferrocene. Optimization of the synthetic procedures has made these compounds generally feasible for their future synthetic use as metallacarborane building units for chemical constructions of linearly shaped oligomeric rod molecules. It was also demonstrated that cage isomerization of these compounds leads to *p*,*m* and *m*,*m* oriented shapes, which offers another modification in the area of structurally designed cluster chemistry. Moreover, it can be anticipated that the amine functions attached to the subclusters can be modified via analogous organic reactions, which should lead to other stable molecules with variable substituents. An important aspect of this work is that metal complexation reactions can be significantly affected by the purity of the metal reagent, which may significantly influence the nature of reaction products. This was documented by the metal-promoted isomerization reactions leading to new types of zwitterionic tricarbaborane compounds of type **6**. Aspects of this metallacarborane chemistry will be further developed and relevant experimental work in this area is in progress.

Experimental Section

General Procedures: All reactions were carried out with use of standard vacuum or inert-atmosphere techniques as described by Shriver[8] although some operations, such as preparative TLC, were carried out in air. The starting compound **1** was prepared according to the literature.[6g] Diethylene glycol dimethyl ether (diglyme) from Aldrich, 1,3,5-trimethylbenzene, benzene and hexane were dried with sodium wire and freshly distilled prior to use, the former being distilled at reduced pressure from sodium diphenylketyl. Dichloromethane was dried with CaH_2 and distilled before use. Aldrich anhydrous $FeCl_2$ of the three different purity grades 99.998% (H_2O < 10 ppm), 99.99% (H_2O < 100 ppm) and 98% was used. High-surface dry 96% NaH (prepared in this laboratory) was used. Other chemicals were reagent or analytical grade and were used as purchased. Preparative liquid chromatography was carried out using Aldrich silica gel (60−230 mesh) as the stationary phase under nitrogen. The mixtures of the isomeric derivatives **2a** and **3a** were separated by semi-preparative low-pressure chromatography on a pre-packed Merck Lobar® column LiChroprep® Si 60 (40−63μm), using hexane/CH_2Cl_2 (3:1, v/v) as the mobile phase, flow rate 7 mL/min, detection visual (the red bands) and by UV at 295 nm.

The purities of individual chromatographic fractions were checked by analytical TLC on Macherey−Nagel plates with UV indicator (silica gel on aluminium foil; detection by UV 254 nm followed by 2% aqueous $AgNO_3$ spray) and for the compounds of types **2** and **3** also by HPLC (see below). Melting points were measured in sealed capillaries and are uncorrected. Analyses were performed in the I.I.C. analytical laboratories using standard procedures. Low-resolution mass spectra were obtained using a Finnigan MAT MAGNUM ion trap quadrupole mass spectrometer equipped with a heated inlet option, as developed by Spectronex AG, Basle, Switzerland (70 eV, EI ionisation). Proton (^1H) and boron (^{11}B) NMR spectroscopy were performed at 11.75 Tesla with a Varian UNITY-500 instrument. The [^{11}B-^{11}B]-COSY[9] and $^1H\{^{11}B$(selective)$\}$[10] NMR experiments were essentially as described in other related papers from our laboratories.[11] Chemical shifts are given in ppm to high-frequency (low field) of Ξ = 160 MHz (nominally $F_3B{\cdot}OEt_2$ in $CDCl_3$) for ^{11}B (quoted ± 0.5 ppm) and Ξ = 500 MHz ($SiMe_4$) for ^1H (quoted ± 0.05 ppm), Ξ being defined as in ref.[12] Residual solvent ^1H resonances were used as internal secondary standards. Coupling constants $^1J_{BH}$ are taken from resolution-enhanced ^{11}B spectra with a digital resolution of ± 1 Hz. Analytical HPLC was used for monitoring the ratio of **2a** and **3a** or **2b** and **3b**. The system consisted of a Merck−Hitachi 6200 Intelligent pump, D-6000 Interface, Rheodyne 7125 injection valve with a 20-μL sample loop and a L 7450 Diode Array detector with 7000 Manager Software 2.1. Chromatographic conditions: analytical separation on a 4 × 250 mm I.D. steel column (LiChrosorb SI 60 (10 μm), Merck Darmstadt, packed by Labio Ltd., Prague), detection by Diode Array 200−300 nm, sensitivity range 0−2.0 A.U.F.S. Chromatographic data for the separation of **2a** and **3a**: hexane/CH_2Cl_2 (75:25, v/v) as the mobile phase, flow rate 1.0 mL/min, capacity factors (k'), selectivity (α) and resolution (*Rs*) for analytical separations were: **2a:** k_2' = 3.09 **3a**: $k_{3'}$ = 4.25, α = 1.38, *Rs* = 3.72; chromatographic conditions for the separation of **2b** and **3b**: CH_2Cl_2/CH_3CN (97:3, v/v) as the mobile phase, flow rate 1.0 mL/min, capacity factors (k') k_7' = 5.65 $k_{8'}$ = 10.4, α = 1.85, *Rs* = 5.3.

[*closo*-9,9′-(*t*BuHN)$_2$-*commo*-2,2′-Fe^{II}-1,7,9-($C_3B_8H_{10}$)-1′,7′,9′-($C_3B_8H_{10}$)] (2a) and [*closo*-9,10′-(*t*BuHN)$_2$-*commo*-2,2′-Fe^{II}-1,7,9-($C_3B_8H_{10}$)-1′,7′,10′-($C_3B_8H_{10}$)] (3a): a) The starting salt $Tl^+\mathbf{1}^-$ [1b] (2.50 g, 6.11 mmol) was stirred in a mesitylene/diglyme solvent mixture (40 mL, 25:75, v/v), $FeCl_2$ (99.99%, 1.60 g, 12.7 mmol) was then added and the mixture heated and stirred under gentle reflux for 8 h. After cooling to room temperature, water (2 mL) was added dropwise and the solvents were removed by rotary evaporation. The dark residue was digested with Et_2O (20 mL) and 1 M HCl (10 mL). The organic layer was then separated and the aqueous phase extracted with two additional portions of diethyl ether (20 mL). The combined organic extracts were evaporated and the reddish solid was treated with three portions of hexane (15 mL), filtered, and the combined red hexane extracts were evaporated. Crude complex **2a** (680 mg, 49% yield) was then isolated by repeated extraction of the solid residue with hexane, filtration of the combined extracts, and evaporation of the solvent. The compound was purified by flash chromatography on a silica gel column (2.5 × 35 cm) by elution with hexane/benzene (65:35, v.v.) to isolate 602 mg (43%) of **2a** as a red, semi-crystalline material. An analytical sample was crystallized from a concentrated petroleum ether solution at ca. 5 °C (red needles) and identified by NMR spectroscopy as reported earlier.[4] b) Compound **1** (1.01 g, 4.91 mmol) was stirred in diglyme (15 mL), dry NaH (0.22 g, 9.17 mmol) was added, and the slurry was stirred at room temperature for 1 h and then heated at 80 °C (bath temperature) for 30 min. After cooling, $FeCl_2$ (99.99%, 1.33 g, 10.49 mmol) was added and the reaction mixture heated under gentle reflux for 3 h with stirring. The mixture was then worked-up as in the preceding experiment giving a mixture of compounds **2a** and **3a**. This was separated by semi-preparative liquid chromatography on a pre-packed Merck Lobar® column (see above) to separate two red bands of R_f = 0.25 and 0.20 (TLC in 25% CH_2Cl_2 in hexane), from which compounds **2a** and **3a** were obtained in respective yields of 514 mg (45%) and 194 mg (17%) after evaporation. Compound **3a** was crystallized from a warm pentane solution by cooling to 5 °C. **3a:** R_f = 0.20 (CH_2Cl_2/hexane, 25: 75, v/v); m.p. 152−155 °C. ^{11}B NMR (160.4 MHz, 25 °C, $CDCl_3$): δ = −6.6 [d, ^1J(B,H) = 174 Hz, 2 B, B6′,11′], −8.3 (d, 1 B, B9′), −9.2 [d, ^1J(B,H) = 153 Hz, 2 B, B6,11], −12.3 [d, ^1J(B,H) = 170 Hz, 1 B, B3′], −13.4 [d, ^1J(B,H) = 168 Hz, 1 B, B3], −15.2 [d, ^1J(B,H) = 174 Hz, 4 B, B5,12,5′,12′] −16.9 [d, ^1J(B,H) = 177 Hz, 1 B, B10], −22.4 [d, ^1J(B,H) = 177 Hz, 2 B, B4,8], −24.05 [d, ^1J(B,H) = 161 Hz, 2 B, B4′,8′] ppm, all theoretical [^{11}B-^{11}B] cross-peaks observed. ^{1}H{^{11}B} NMR (500 MHz, 25 °C, $CDCl_3$): δ = 3.78 (s, 1 H, H 3′), 3.66 (s, 1 H, H3), 3.32 (s, 2 H, H6′,11′), 3.05 (s, 1 H, H9′) 2.98 (s, 2 H, H6,11], 2.49 (s, 4 H, H5,12,5′,12′), 2.35 (s, 2 H, H4,8), 2.30 (m, 1 H, N*H*-*t*Bu), 2.12 (s, 1 H, H10), 2.07 (s, 4 H, cage C*H*), 1.52 (s, 2 H, H4′,8′), 1.22 and 1.19 (s, 18 H, *t*Bu) ppm. IR (KBr): $\tilde{\nu}$ = 2534 (B−H) cm^{-1}. MS (70 eV, EI): *m*/*z* (%) = 468 (4) [M$^+$], 465 (100) [M$^+$ − 3H]. $C_{14}H_{30}B_{16}FeN_2$ (465.30): calcd. B 37.17, N 6.01; found B 36.86, N 5.94.

[*closo*-9,9′-(H_2N)$_2$-*commo*-2,2′-Fe^{II}-1,7,9-($C_3B_8H_{10}$)-1′,7′,9′-($C_3B_8H_{10}$)] (2b) and [*closo*-9,10′-(H_2N)$_2$-*commo*-2,2′-Fe^{II}-1,7,9-($C_3B_8H_{10}$)-1′,7′,10′-($C_3B_8H_{10}$)] (3b): Compound **2a** or **3a** (200 mg, 0.57 mmol) was dissolved in hexane (20 mL) and $AlCl_3$ (800 mg, 6.0 mmol) was then added in one portion. The reaction slurry was stirred under gentle reflux for 2 h. After cooling, the reaction slurry was treated with water (10 mL) and the solvents were evaporated. The solid residue was treated with 10% aqueous KOH (15 mL), extracted with CH_2Cl_2 (2 × 15 mL), the organic portion was separated, and the solvent evaporated to give 124 mg (82%) of **2b** or 121 mg (80%) of **3b**. For the preparation of **3b**, it is convenient to apply the $AlCl_3$ reaction on a mixture of **2a** and **3a** obtained in the preceding experiment, which results typically in a total yield of 79% of the H_2N- derivatives **2b** and **3b**. The isomers were then separated by chromatography on a silica gel column (1.5 × 25 cm), using a CH_2Cl_2/MeCN mixture (95:5, v/v) as the mobile phase.

2b: R_f = 0.24 (CH_2Cl_2); m.p. >360 °C. ^{11}B NMR (160.4 MHz, 25 °C, $CDCl_3$): δ = −8.6 [d, ^1J(B,H) = 154 Hz, 2 B, B6,11], −12.6 [d, ^1J(B,H) = 169 Hz, 1 B, B3], −15.6 [d, ^1J(B,H) = 170 Hz, 2 B, B5,12], −17.3 [d, ^1J(B,H) = 165 Hz, 1 B, B10], −22.7 [d, ^1J(B,H) = 177 Hz, 2 B, B4,8] ppm, all theoretical [^{11}B-^{11}B] cross-peaks observed. ^{1}H{^{11}B} NMR (500 MHz, 25 °C, $CDCl_3$): δ = 4.09 (s, 1 H, H3), 2.92 (s, 2 H, H6,11), 2.44 (br. s, 1 H, N*H*), 2.33 (s, 2 H, H5,12), 2.26 (s, 2 H, H4,8), 1.97 (s, 1 H, H10), 1.86 (s, 2 H, cage C*H*) ppm. cooling, reagent grade $FeCl_2$ (98%, 1580 mg, 12.5 mmol) was added and the mixture gently heated to reflux for 24 h with stirring. After cooling to room temperature, water (5 mL) was added dropwise and the diglyme removed by rotary evaporation. The dark residue was digested with Et_2O (50 mL) and 1 M HCl (40 mL). The organic layer was separated and the aqueous phase extracted with two additional 20 mL portions of Et_2O. The combined organic extracts were evaporated, the reddish solid was treated with three 20 mL portions of hexane and the solution thus obtained was filtered and the solvents evaporated to give a mixture of compounds **2a** and **3a**. The mixture was separated by preparative liquid chromatography on a silica gel column (25 × 1.5 cm), using 25% CH_2Cl_2 in hexane as the mobile phase to separate the red bands of R_f (anal., 25% CH_2Cl_2 in hexane) 0.25, 0.20, and 0.15. The first fractions contained trace quantities of compound **5**, which was identified from its NMR spectra.[5] Complexes **2a** (22 mg, 4%), **3a** (26 mg, 5%), and **4a** (12 mg 2%) were then isolated from individual fractions and purified by crystallization from concentrated petroleum ether at ca. 0 °C. The pale brown solid residue after hexane extraction was dissolved in 5% MeCN in CH_2Cl_2 and chromatographed on a silica gel column (25 × 1.5 cm), using CH_2Cl_2 and finally a CH_2Cl_2/MeCN (4:1, v/v) mixture (TLC monitoring). Evaporation of the two last fractions resulted in the isolation of compounds **6a** (66 mg, 14%) and **6b** (92 mg, 17%), which were recrystallized from hot CH_2Cl_2.

4a: R_f (CH_2Cl_2/hexane, 25:75, v/v) 0.16. ^{11}B NMR (160.4 MHz, 25 °C, $CDCl_3$): δ = −6.5 [d, ^1J(B,H) = 153, 4 B, B6,11,6′,11′], −8.1 (d, 2 B, B9,9′), −12.2 [d, ^1J(B,H) = 165, 2 B, B3,3′], −14.7 [d, ^1J(B,H) = 174, 4 B, B5,12,5′,12′], −23.7 [d, ^1J(B,H) = 165, 4 B, B4,8,4′,8′] ppm, all theoretical [^{11}B-^{11}B] cross-peaks observed. $^1H\{^{11}B\}$ NMR (500 MHz, 25 °C, $CDCl_3$): δ = 3.56 (s, 2 H, H3,3′), 3.42 (s, 4 H, H6,11,6′,11′), 3.13 (s, 2 H, H9,9′), 2.61 (s, 2 H, N*H*), 2.59 (s, 4 H, H5,12,5′,12′), 2.27 (s, 4 H, cage C*H*), 1.57 s (s, 4 H, H4,8,4′,8′), 1.25 (s, 18 H, *t*Bu) ppm. X-ray Crystallography

Crystallographic Data for 2b: A red crystal of **2b** of dimensions 0.3 × 0.3 × 0.25 mm was mounted on a glass fiber with epoxy cement and placed on a four-circle Nonius−KappaCCD diffractometer equipped with a CCD area detector at 150(2)K with Mo-K_α radiation. The crystallographic details are summarized in Table 1. The structure was solved by the direct methods (SIR97)[13] and refined by a full-matrix least-squares procedure based on F^2 (SHELXL-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

97).[14] The hydrogen atoms were found on a difference Fourier map, but some of them behaved erroneously during refinement and were therefore fixed in idealized positions (riding model) and assigned temperature factors $H_{iso}(H) = 1.2U_{eq}$ (pivot atom). The final difference map displayed no peaks of chemical significance.

Crystallographic Data for 3a and 6b: A pale red crystal of **3a** and a colorless crystal of **6b** were analyzed at 294 K with a Rigaku AFC5S diffractometer with Mo-K_α radiation. The crystallographic details are summarized in Table 1. The structures were solved by the direct method and refined on F^2 with the SHELXL-97 program.[14] For **3a**, boron atoms were refined isotropically but the rest of the non-hydrogen atoms were refined with anisotropic thermal displacement parameters. Hydrogen atoms were placed in calculated positions and were treated as riding atoms using the SHELX97[14] default parameters. For **6b**, the reflection power of the crystal steeply dropped at high reflection angles and therefore the data collection was limited to $2\theta_{max.} = 45°$. The non-hydrogen atoms were refined with anisotropic thermal displacement parameters. Hydrogen atoms of the carborane cage were found from a difference Fourier map and refined with fixed *U*. The hydrogen atoms of the methyl groups were placed in calculated positions and treated as riding atoms. The final difference maps of **3a** and **6b** displayed no peaks of chemical significance.

CCDC-215766, -215767 and -215768 contain the supplementary crystallographic data of the compounds **3a**, **6b** and **2a** for this paper. These data can be obtained free of charge at wwww.ccdc.cam.ac.uk/conts/retrieving.hmtl [or from Cambridge Crystallographic Data Center, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Acknowledgments

We thank Drs. Z. Plzák and J. Fusek for MS and NMR measurements, respectively. Support from the Grant Agency of the Czech Republic (Grant No. 203/00/1042) and the Ministry of Education Youth and Sport of the Czech Republic (Project LN00A0028) are appreciated. Early stages of this work were also supported by the Spanish project AMB1999-1810-Ce and Generalitat de Catalunya (grant no 1996-SGR-00038 to B. G.).

Structure, Electrochemistry and Hydroformylation Catalytic Activity of the Bis(pyrazolylborato)rhodium(I) Complexes [RhBp(CO)P] [P = $P(NC_4H_4)_3$, PPh_3, PCy_3, $P(C_6H_4OMe\text{-}4)_3$]

Keywords: Rhodium / N ligands / Electrochemistry / X-ray diffraction / Hydroformylation

Rhodium complexes of formula [RhBp(CO)P] [Bp = bis(pyrazolylborate), P = $P(NC_4H_4)_3$ **1**, PPh_3 **2**, PCy_3 **3**, $P(C_6H_4OMe\text{-}4)_3$ **4**] have been prepared by exchange of the acetylacetonate ($acac^-$) ligand in [Rh(acac)(CO)P] complexes. The spectroscopic and electrochemical properties as well as X-ray data of [Rh(acac)(CO)P] and [RhBp(CO)P] complexes have been compared with the aim to estimate the relative donor properties of both anionic ligands ($acac^-$ and Bp^-). The cyclic voltammetric results indicate that the Bp^- ligand behaves as a much stronger electron donor than $acac^-$ and a value of the Lever E_L ligand parameter identical to that of the pyrazolate ligand (–0.24 V vs. NHE for each coordinating arm) is proposed for the bis- and tris(pyrazolyl)borate ligands, whereas $P(C_6H_4OMe\text{-}4)_3$ is also shown to have an identical E_L value (0.69 V) to that of $P(NC_4H_4)_3$. An improved linear relationship between the oxidation potential and the sum of the ligand E_L values for square-planar Rh^I complexes is also obtained and adjusted values for the Lever S_M and I_M parameters for the Rh^I/Rh^{II} redox couple are given. The *trans* influence of phosphanes was not observed in crystals of complexes **2** and **3**, in contrast to analogous acetylacetonato complexes in which the Rh–O bonds differ by ca. 0.04–0.06 Å. Complexes **1**–**4** are very attractive precursors for hydroformylation catalysts and yields of aldehydes of 80–87% have been obtained with all complexes without extra phosphane as co-catalyst. During the hydroformylation reaction, however, small amounts of a catalytically inactive $[RhBp(CO)_2]$ complex were formed.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

The exceptionally high catalytic activity of rhodium complexes in the hydroformylation of unsaturated compounds is well known.[1] Among the large number of rhodium catalyst precursors, the acetylacetonato complexes $[Rh(acac)(CO)_2]$, [Rh(acac)(CO)P] or $[Rh(acac)P_2]$ (acac: acetylacetonato, P: phosphorus ligands) are used very often, both in the laboratory and in industrial processes.[2−4] Many studies have shown that the acetylacetonato ligand is easily removed from the coordination sphere of rhodium in the presence of CO and H_2, facilitating the formation of active hydrido-carbonyl complexes.[5,6] In contrast to rhodium complexes with anionic oxygen-containing ligands, there are very few data reporting the application of rhodium complexes containing nitrogen ligands as catalyst precursors. The few known examples, including the active rhodium pyrazolylborate complexes in the high pressure hydroformylation of propylene (60−80 atm of H_2/CO) and 1-hexene (30−50 atm of H_2/CO), have been patented.[7]

Tris(pyrazolylborato) ligands are very often compared with cyclopentadienyl ligands in view of their similar electronic structure and steric properties.[8,9]

In this paper we report the results of structural as well as catalytic studies of rhodium bis(pyrazolylborate) complexes of the type [RhBp(CO)P] [Figure 1; Bp: bis(pyrazolylborate), P: $P(NC_4H_4)_3$ **1**, PPh_3 **2**, PCy_3 **3**, $P(C_6H_4OMe\text{-}4)_3$ **4**].

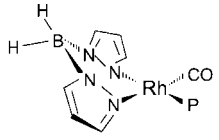

Figure 1. Structure of [RhBp(CO)P] complexes

We were also interested in comparing the properties of these complexes with those of a known family of square-

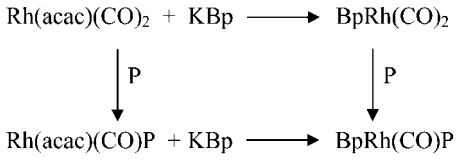
planar rhodium complexes of formula [Rh(acac)(CO)P] (P: phosphorus ligand). In both types of complexes the rhodium(I) ion is coordinated by the chelating ligand through two nitrogen or oxygen atoms, forming a six-membered ring. Rhodium(I) complexes with β-diketonate ligands are known as model groups of rhodium complexes for which the *trans* effect, the effect of the steric and electronic properties of the phosphorus ligands, as well as the electrochemical, thermochemical and kinetic properties, have been discussed.[10−14] However, rhodium(I) complexes with bis(pyrazolylborato) ligands, although known for a long time, have not received any special attention.

Results and Discussion

Strategy of Synthesis

Complexes **1** and **4** were prepared and characterized for the first time in this paper (details in Exp. Sect.). Complex **2** was obtained earlier by reaction of $[RhCl(CO)_2]_2$ with KBp.[15,16] We adapted the other method of synthesis of [RhBp(CO)P] complexes, reported recently for $[RhTp^{Ph,Me}(CO)_2]$ and $[RhTp^{Ph,Me}(CO)(PPh_3)]$, based on the replacement of an $acac^-$ ligand by a bis(pyrazolylborate).[17] The reactions were performed with isolated [Rh(acac)(CO)P] complexes, at room temperature, and were complete in ca. 30 min, giving satisfactory yields of pure products.

Alternatively, the complexes [Rh(acac)(CO)P] were prepared "in situ" from $[Rh(acac)(CO)_2]$ and the appropriate amount of the phosphorus ligand P and further used for the substitution of anionic ligands ($acac^-$ for Bp^-; Scheme 1).



Scheme 1. Synthesis of [RhBp(CO)P] complexes

The third method of synthesis of the complexes consisted of the reaction of $[Rh(acac)(CO)_2]$ with KBp to give $[RhBp(CO)_2]$, followed by replacement of CO by the phosphane P. Independent of the reaction pathway, the [RhBp(CO)P] complexes were isolated as final products with yields of 70−90%.

IR and ^{31}P NMR Spectra

The ν(CO) frequencies in the IR spectra of [RhBp(CO)P] complexes are summarized in Table 1, where the IR data of analogous [Rh(acac)(CO)P] complexes are also presented for comparison. The ν(CO) frequencies in the bis(pyrazolylborato) complexes decrease with an increase of the σ/π-donor properties of the P ligands in the order $P(NC_4H_4)_3 > PPh_3 > P(C_6H_4OMe\text{-}4)_3 > PCy_3$. Similar changes of ν(CO) frequencies were observed in the IR spectra of [Rh(acac)(CO)P] and [Rh{$CF_3C(O)CHC(NH)Me$}(CO)P] complexes.[18] The highest ν(CO) frequencies were found for complexes with the Bp^- ligand, if rhodium compounds with the same phosphane ligand were compared. The positions of the IR bands suggest a weaker σ/π-donor character of the *N*,*N*-Bp^- ligand in comparison with *O*,*O*-$acac^-$ and *N*,*O*-bonded ones (β-ketoiminate). However, a more detailed analysis of the $J_{Rh,P}$ coupling constants in the ^{31}P NMR spectra leads to another conclusion. The $J_{Rh,P}$ coupling constants determined for [RhBp(CO)P] complexes are similar to those for β-ketoiminato complexes but lower than the corresponding $J_{Rh,P}$ values for acetylacetonato complexes (Table 1). Usually, $J_{Rh,P}$ decreases when the ligand σ/π-donor character increases. Therefore, according to this criterion, the *N*,*N*-Bp^- ligand should be a more effective donor than the *O*,*O*-acetylacetonato ligand, which is in agreement with the electrochemical results discussed below.

Following Tolman's rule for complexes in which the electronic effect dominates, the $J_{Rh,P}$ values decrease with a decrease of ν(CO) frequencies.[19] Such a dependence has been observed previously for both [Rh(acac)(CO)P] and [RhBp(CO)P] complexes (Figure 2). However, the plot of the experimental data fits not one curve but two almost parallel ones.

^1H NMR Spectra

The ^1H NMR spectra of complexes **1**−**4** contain six signals due to the inequivalent protons of the pyrazolyl rings. All resonances are located in the δ = 5.7−7.6 ppm range, similar to what was observed for other bis(pyrazolylborato) rhodium complexes (Table 2). The two signals of the 4-H protons are shifted upfield with respect to the remaining signals and are observed at ca. δ = 6 ppm. In all spectra

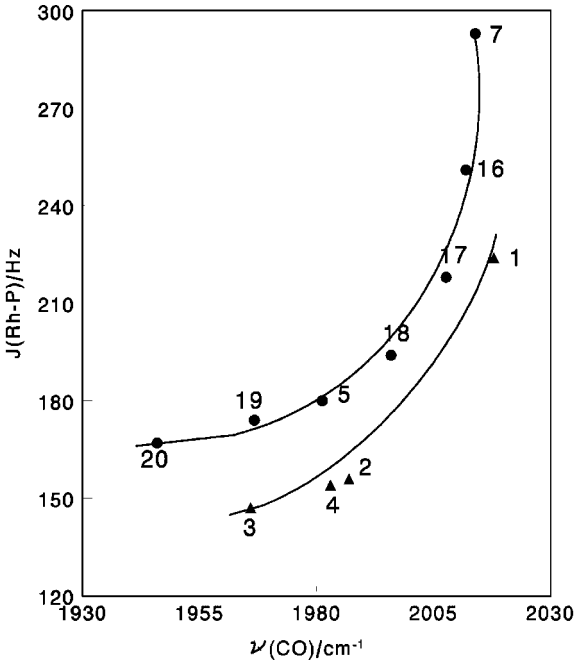

Figure 2. Plot of J(Rh-P) (^{31}P NMR) versus ν(CO) (IR) for RhBp(CO)(P) and Rh(acac)(CO)(P) complexes; RhBp(CO)(P): P = $P(NC_4H_4)_3$ **1**, PPh_3 **2**, PCy_3 **3**, $P(C_6H_4OMe\text{-}4)_3$ **4**; Rh(acac)(CO)(P): P = PPh_3 **5**, $P(OPh)_3$ **7**, $P(NC_4H_4)_3$ **16**, $PPh(NC_4H_4)_2$ **17**, $PPh_2(NC_4H_4)$ **18**, $P(C_6H_4OMe\text{-}4)_3$ **19**, PCy_3 **20**

Table 2. ^{1}H NMR spectroscopic data of bis(pyrazolylborato) ligands in complexes [RhBp(CO)P] (**1**−**4**) measured in $CDCl_3$

Complex	4-H	4′-H	3- or 5-H	3- or 5-H	3′- or 5′-H	3′- or 5′-H
1	5.95	6.27	6.78	7.57	7.63	7.67
2	5.69	6.19	6.29	7.41	7.42	7.56
3	6.06	6.13	7.36	7.46	7.49	7.52
4	5.70	6.18	6.32	6.91	6.94	7.42

(of complexes **1**−**4**) the signals arising from one pyrazolyl ring are better resolved than those in the second ring because of the higher values of the $J_{H,H}$ coupling constants (ca. 2.3 Hz).

The resonances of the 3-H and 5-H protons are observed at δ = 7.3−7.6 ppm, except in the spectra of **2** and **4**, in which one doublet (3-H or 5-H) is present at δ = 6.29 or 6.32 ppm, respectively. In Figure 3 the effect of temperature (in the temperature range from 20 to −60 °C) on the ^{1}H NMR spectra of **2** is presented.

The signals of the 4-H and 4′-H protons (δ = 5.69 and 6.19 ppm) do not change their positions when the temperature is lowered. In contrast, the resonance at δ = 6.29 ppm (3-H or 5-H) is shifted upfield and that at δ = 7.5 ppm (3′-H or 5′-H) is shifted downfield. The dynamics observed can be related only to small changes in the conformation of the pyrazolylborato ligand, because in bis(pyrazolylborato) complexes a change of coordination mode is not expected. The fluxional behaviour of tris(pyrazolylborato) complexes is well documented and is interpreted in terms of a $\kappa^2 \rightarrow \kappa^3$ equilibrium[9,20,21] (N,N-Tp$^-$ or N,N,N-Tp$^-$, respectively).

Electrochemical Behaviour of the Rhodium(I) Complexes [RhBp(CO)P]

The cyclic voltammograms of the rhodium(I) complexes [RhBp(CO)P] were run in 0.2 M $[NBu_4][BF_4]/CH_2Cl_2$ (or NCMe), at a Pt- or C-disc electrode. They exhibit, at 200 mV s^{-1} (Table 3), an irreversible oxidation wave (I) at $^{I}E^{ox}_{p/2}$ in the range 0.63−0.95 V vs. NHE, which is followed, at a higher potential ($^{II}E^{ox}_{p/2}$ in the 1.0−1.6 V range), by a second irreversible wave (wave II), with a higher peak-current intensity (Figure 4, for complex **3**). In one case (compound **2**) the shape of the cyclic voltammogram changed rapidly with time, as shown by the alteration of the relative intensities of waves I and II, which is indicative of the instability of the complex in solution.

The oxidation potential of wave I is always substantially lower than that of the free bis(pyrazolylborate) (1.20 V for the KBp salt) and its electrode process is expected[11] to

Table 3. Cyclic voltammetric data for the rhodium(I) complexes [RhBp(CO)P][a]

Complex	P	NCMe		CH_2Cl_2	
		$^{I}E_{p/2}^{ox}$	$^{II}E_{p/2}^{ox}$	$^{I}E_{p/2}^{ox}$	$^{II}E_{p/2}^{ox}$
1	$P(NC_4H_4)_3$	0.95	1.57	1.25	1.69
2	PPh_3	0.80	1.07[b]	0.74	1.27
3	PCy_3	0.63[c]	1.03	0.84[d]	1.20
4	$P(C_6H_4OMe\text{-}4)_3$	0.95[e]	1.44	0.93	1.67
	$[H_2Bp]H$[f]	1.14	–		
	$[H_2Bp]K$[g]	1.20	1.56		

[a] Potentials ($E_{p/2}$ = half-peak potential) in V ± 0.02 vs. NHE measured at a scan rate of 0.2 V s^{-1}, in 0.2 M $[NBu_4][BF_4]$/NCMe or CH_2Cl_2 at a Pt or C electrode. [b] Upon anodic scan, an irreversible cathodic wave is detected at 0.09 V vs. NHE. Relative peak currents of waves I and II change rapidly with time. By CPE (with strong passivation) a total of 4 faraday/mol was obtained (initial step approx. 1.5e). [c] CPE at a potential slightly above that of wave I led to the consumption of only 0.23 faraday/mol, with the disappearance of both waves I and II and the appearance of another wave at E_p^{ox} = 1.57 V. [d] For scan rates higher than 0.6 V/s the wave shows some reversibility. [e] For scan rates higher than 10 V/s the wave shows some reversibility. At 350 V/s it is the only wave detected. [f] Cathodic wave at E_p^{red} = −0.48 V due to H^+ reduction. [g] Cathodic wave at E_p^{red} = −1.53 V which, upon scan reversal, leads to an oxidation wave at 0.26 V.

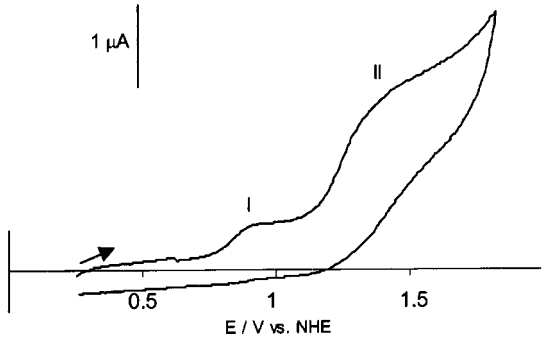

Figure 4. Cyclic voltammogram of complex **3** (2.4 mmol dm^{-3} in CH_2Cl_2 with 0.2 mol dm^{-3} $[NBu_4][BF_4]$) at a carbon disc (d = 0.5 mm) working electrode and at a scan rate of 0.2 V s^{-1}

involve, as the first step, the metal-centered, single-electron $Rh^I \rightarrow Rh^{II}$ oxidation. However, the overall number of electrons involved in each oxidation wave could not be measured due to the strong electrode passivation associated with the electrode processes.

Such an oxidation potential is also much lower (by ca. 0.5−0.7 V) than that exhibited[11] by the corresponding acetylacetonato complexes [Rh(acac)(CO)P], indicating a much stronger electron-donor character of the bis(pyrazolyl)borate ligand than that of acetylacetonate. In fact, the first oxidation potential should reflect the relative electron donor/acceptor abilities of the ligands as measured by the electrochemical E_L ligand parameter proposed by Lever, for which the empirical linear correlation [Equation (1)] has been shown to be applicable to many redox couples.[22,23] The redox potential of the complex (E) is expressed in V vs. NHE, ΣE_L is the sum of the E_L values (V vs. NHE) for all the ligands (additive effects), whereas S_M and I_M (V vs. NHE) depend upon the metal and redox couple, the spin state and the stereochemistry.

$$E = S_M \times (\Sigma E_L) + I_M \quad (1)$$

The E_L value for the bis(pyrazolylborate) ligand (for each of its 2e-donor *N*-coordinating arms) was assumed to be identical to those of the pyrazolate ligand (−0.24 V[22,23]) and of the related hydrotris(pyrazolyl)borate ligand (Tp′; −0.23 V for each of its 2e-donor *N*-coordinating arms) estimated in this study by taking into consideration the oxidation potential data reported[25] for the tetracoordinate Rh^I compounds [Rh(κ²-Tp′)(CO)(P)] [Tp′ = HBR_3 (R = 3,5-dimethylpyrazolyl); P = PPh_3, PCy_3, $P(NMe)_3$, $P(C_6H_4Me\text{-}4)_3$ or $P(C_6H_4Me\text{-}3)_3$] as well as Lever's previously established[11] linear relationship expressed by Equation (1), in which S_M = 1.93 and I_M = −1.29 V.[24] The E_L value thus estimated for Tp′ (−0.23 V for each N-ligating arm) is identical to that of pyrazolate (E_L = −0.24),[22,23] indicating that the pyrazolylborate group has a negligible influence on the σ/π-donor/acceptor properties of the pyrazolate ligand.

This E_L value (−0.24 or −0.23 V for each *N*-coordinating arm) is much lower than that reported for the acetylacetonate ligand (−0.08 V for each *O*-coordinating arm),[22] showing that pyrazolate, and bis- and tris(pyrazolylborate) ligands are much stronger electron-donor ligands than $acac^-$, in agreement with the above-mentioned conclusion based on the much lower oxidation potentials of the Bp^- complexes in this study in comparison with the analogous $acac^-$ complexes.

The order of the measured first oxidation potential values of the complexes (**3** < **2** < **1**, **4**) follows the expected reverse order of the electron-donor ability of the phosphane, i.e. $PCy_3 > PPh_3 > P(C_6H_4OMe\text{-}4)_3$, $P(NC_4H_4)_3$. Since complexes **1** and **4** have an identical oxidation potential, the tris(4-methoxyphenyl)phosphane ligand is pro-

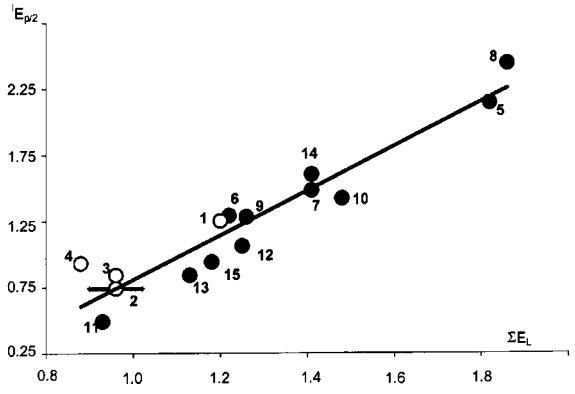

Figure 5. Plot of $^{I}Ep/2^{ox}$ (V versus NHE, measured in CH_2Cl_2) versus ΣE_L (V versus NHE) for [RhBp(CO)(P)] [P = $P(NC_4H_4)_3$ **1**, PPh_3 **2**, PCy_3 **3**, $P(C_6H_4OMe\text{-}4)_3$ **4**] (o) and for other tetracoordinate Rh^I complexes published elsewhere (see text) (•);[11,24] the E_L(L) value of CO taken from the literature (0.99 V) and that of Bp considered (see text) as that of pyrazolate (−0.24 V);[22,23] for $P(C_6H_4OMe\text{-}4)_3$ (complex **4**) the E_L value for tritolylphosphane was considered (0.37 V);[22,23] for PPh_3 an error bar comprising the E_L value taken from the literature (0.39 V)[22,23] and the one estimated from previous data (0.51 V)[11] is presented

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

posed to exhibit an E_L value identical to that (0.69 V) we have obtained previously[11] for the *N*-pyrrolylphosphane $P(NC_4H_4)_3$.

The rhodium complexes of this study with ligands with known E_L values [**1**, **2** and **3**; for **4** the E_L value of tri(tolyl)-phosphane was taken for $P(C_6H_4OMe\text{-}4)_3$] fit the roughly linear plot of ${}^{I}E^{ox}_{p/2}$ vs. ΣE_L (Figure 5), which also contains the data reported by us[11] for the Rh^I complexes [Rh(O∩O)(CO)L] [O∩O = acac, L = CO **5**, PPh_3 **6**, $P(OPh)_3$ **7**; O∩O = PhC(O)CHC(O)Me (bac), L = CO **8**, PPh_3 **9**; O∩O = PhC(O)CHC(O)CF_3 (bta), L = PPh_3 **10**], as well as those reported by Werner et al. for [RhCl(L)[P*i*Pr_3)$_2$] [L = CPh_2 **11**, C=CPh_2 **12**, C=C=CPh_2 **13**, CO **14** and C_2H_4 **15**].[24]

The novel relationship expressed by Equation (2) (r = 0.95), considering also the complexes in the present study (Figure 6), allows the adjustment of S_M and I_M for the square-planar Rh^I/Rh^{II} redox couples: S_M = 1.68 and I_M = −0.87 V. Values of S_M = 1.93 and I_M = −1.29 V vs. NHE have been proposed previously[24] on the basis of the then available data.

$$E^{ox}_{p/2} = 1.68 \times \Sigma E_L - 0.87 \quad (2)$$

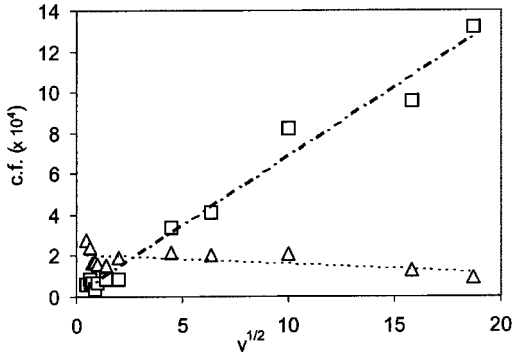

Figure 6. Plot of the current-function $i_p \cdot C^{-1} \cdot v^{-1/2}$ ($A \cdot M^{-1} \cdot V^{-1/2} s^{1/2}$) versus the square root of the scan rate ($V\ s^{-1}$), for waves I (□) and II (Δ) of complex **4** (Scheme 2)

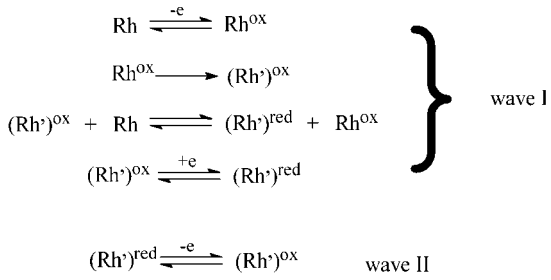
In spite of the above-mentioned strong electrode passivation that normally precluded the controlled-potential electrolysis, in one of the cases (compound **3**) this could be achieved at the anodic wave I, leading to the total disappearance of both oxidation waves of the complex with the consumption of much less than 1 F/mol (ca. 0.2 F/mol). In addition, the reversibility of wave I in compound **4** and its current-function $i_p \cdot C^{-1} \cdot v^{-1/2}$ (i_p = peak current intensity, C = concentration, v = scan rate) increases with the scan rate, with concomitant disappearance of wave II (Figure 6). These observations suggest that wave II may result from the oxidation of a species generated in situ upon oxidation, at wave I, of the starting complex according to an Electron-Transfer-Chain-Catalysis (ETCC)-type process,[34,35] in which $E^0[(Rh')^{ox}/(Rh')^{red}] > E^0[Rh^{ox}/Rh]$, as shown in Scheme 2.



Scheme 2

X-ray Crystal Structures of 2, 3 and [Rh(acac)(CO)PCy_3] (20)

The molecular structures of the complexes [RhBp(CO)PPh_3] (**2**) and [RhBp(CO)PCy_3] (**3**) are shown in Figure 7 and 8, respectively, and selected bond lengths and angles are listed in Tables 4 and 5, respectively. The geometry about the rhodium atoms in both complexes is square planar, as expected for four-coordinate d^8 species, and the two nitrogen atoms of the bis(pyrazolylborato) anion, the carbonyl ligand and the P atom (from phosphane

C7−Rh−P	90.27(6)	89.63(14)	C6−Rh−P	88.93(10)

ligand) are located approximately in the same plane. The Rh−N distances are equal [2.0963(16), 2.0891(15) Å in **2** and 2.087(3), 2.099(3) Å in **3**] within the experimental error (4σ). The Rh−N bonds lengths are similar to those in other complexes with Bp ligands {[RhBp$^{3,5\text{-Me}}{}_2$(C$_2$H$_4$)$_2$] 2.108(5), 2.106(6) Å[26] and [RhBp(PPh$_3$)$_2$] 2.130(2), 2.102(2) Å[26]} and in complexes with κ^2-Tp ligands {[RhTp^{Ph,Me}(CO)PPh$_3$] 2.099(2), 2.120(2) Å[25] and [RhTp^{Me,Me}(CO)PMe$_3$] 2.113(3), 2.101(3) Å[21]}. In β-ketoiminato complexes the Rh−N bonds are significantly shorter (Table 4).

The N1−Rh−N3 angles are slightly different [87.26(6) and 84.83(13)° in **2** and **3**, respectively], which can be explained by the bulkiness of PCy$_3$, represented by a cone angle (Θ) of 170° versus 145° for PPh$_3$.[19]

It is interesting to note that the *trans* effect of the phosphane is not observed, in contrast to [Rh(acac)(CO)PPh$_3$] and **20** (Figure 9) in which the two Rh−O bonds differ by ca. 0.06 Å[27] and 0.04 Å, respectively.

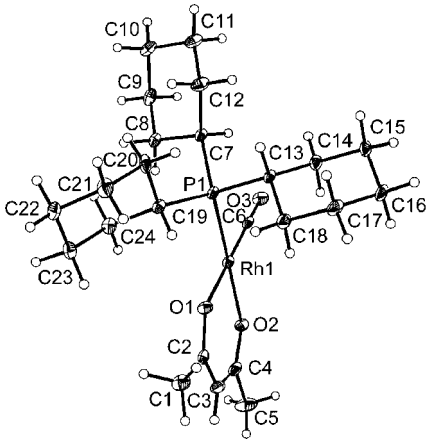

Figure 9. Molecular structure of Rh(acac)(CO)PCy$_3$ (**20**)

The Rh−P bond is longer in complex **3** [2.280(1) Å] than in complex **2** [2.2614(5) Å], as is common for rhodium complexes with PPh$_3$ and PCy$_3$ ligands. The Rh−PPh$_3$ bond in complex **2** [2.2614(5) Å] is longer than those in the related complexes [RhBp(PPh$_3$)$_2$] [2.2261(9) and 2.2503(10) Å][26] and [Rh(acac)(CO)PPh$_3$] [2.244(2) Å],[27] but shorter than that in [RhTp′(CO)PPh$_3$] [2.272(2) Å].[28] The Rh−PCy$_3$ bond in **3** [2.2613(10) Å] is relatively short when compared with the Rh−PCy$_3$ bonds in [RhBp(CO)PCy$_3$] [2.2808(12) Å], [RhTp′(CO)PCy$_3$] [2.292(1) Å],[28] [HRh(CO)(PCy$_3$)$_2$] [2.290(1), 2.297(1) Å][29] and in other acetylacetonatorhodium complexes: [Rh(acac){(*E*)-CH=CHCy}(PCy$_3$)$_2$]BF$_4$ [2.336(3), 2.357(3) Å][30] and [Rh(acac){CH=C=CPh$_2$}(PCy$_3$)$_2$]BF$_4$ [2.285(2) Å].[31] Such a short Rh−PCy$_3$ bond has, until now, only been reported for [Rh(acac)(PCy$_3$)$_2$] [2.252(1), 2.260(1) Å].[30]

A very interesting feature observed in complex **3** is that the angle formed by the rhodium, phosphorus and a carbon atom of one of the cyclohexyl rings [Rh−P−C7 117.53(10)°] differs distinctly from the two remaining angles [Rh−P−C13 110.72(11)° and Rh−P−C19 108.98(12)°]. The same effect has been observed in rhodium complexes with the β-ketoiminate ligand [Rh{CF$_3$C(O)CHC(NH)Me}(CO)PCy$_3$] and [Rh{CF$_3$C(O)CHC(NH)CMe$_3$}(CO)PCy$_3$],[18] and was explained as the result of an interaction between the cyclohexyl ring and the carbonyl ligand. In rhodium-triphenylphosphane complexes, the Rh−P−C(Ph) angles are less differentiated, and in [Rh(acac)(CO)PPh$_3$] they are equivalent.[27] One of the angles between a phosphorus atom and two carbons of one of the cyclohexyl rings in the Rh−PCy$_3$ complexes is also noticeably greater: in **3** the C7−P−C13 and C13−P−C19 angles are ca.104°, whereas the C7−P−C19 angle is ca. 111°. Similar values for the corresponding angles were found for [RhBp(CO)PCy$_3$] and for two complexes with β-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

ketoiminate ligands: [Rh{$CF_3C(O)CHC(NH)Me$}(CO)-PCy_3] and [Rh{$CF_3C(O)CHC(NH)CMe_3$}(CO)PCy_3].[18] In analogous complexes with PPh_3 all (Ph)C−P−C(Ph) angles are of similar magnitude.[18]

Catalytic Activity

Complexes **1**−**4** were tested as catalysts in 1-hexene hydroformylation under standardized reaction conditions (80 °C, 10 atm $H_2/CO = 1$) and at different catalyst concentrations and reaction times depending on the catalyst activity observed. The results presented in Table 6 demonstrate the generally high catalytic activity of all complexes, which produce ca. 80% of aldehydes and ca. 20% of 2-hexene when used without any additional free phosphane (the hydroformylation reaction yield increases in the presence of a phosphane co-catalyst[1]). To obtain the best results it is necessary to use a relatively high concentration of catalyst, expressed by a 1-hexene:Rh ratio of 280. However, with complex **3** a 1-hexene:Rh ratio of 800 gave the aldehyde in 78% yield. In reactions with catalysts **1**, **2** and **4** the yield of aldehydes increases with an increase of catalyst concentration. The increase of hydroformylation reaction yield with decrease of the 1-hexene:Rh ratio may be explained as an effect of the competition of the olefin and CO for access to rhodium: at higher concentrations of 1-hexene isomerization is dominant and the main reaction product is 2-hexene. It is interesting to note that the ratio of normal to branched aldehydes (*n*/*iso*) is only slightly dependent on the kind of phosphane coordinated to rhodium — it differs from 1.3 for **3** to 2.8 for **4**. The low *n*/*iso* ratio for **3** could be expected because of the rather strongly basic properties of PCy_3.[19] However, by comparison with results obtained for [Rh(acac)(CO){$P(NC_4H_4)_3$}],[5] one could expect a much higher *n*/*iso* ratio for **1**.

Table 6. Products of 1-hexene hydroformylation catalyzed by complexes **1**−**4**[a]

Catalyst	[1-hexene]/[Rh]	*t* (h)	Aldehydes (%)	2-Hexene (%)	*n*/*iso*
1	800	5	28	70	2.1
	400	3	73	27	2.0
	280	3	86	13	2.3
2	800	5	11	78	2.4
	400	3	37	19	2.6
	280	5	80	20	2.5
3	800	3	78	12	1.3
	280	2	87	11	1.3
4	800	5	44	32	2.8
	400	3	79	21	2.7

[a] Reaction conditions: 80 °C, 10 atm $CO/H_2 = 1$.

The second interesting feature of bis(pyrazolylborato)rhodium catalysts is the relatively high stability of the Rh−N bond under these reaction conditions. This is demonstrated by the presence of [$RhBp(CO)_2$] in all the post-reaction mixtures, as confirmed by the IR spectra, in which two strong ν(CO) bands are observed at 2019 and 2078 cm^{-1}, identical to [$RhBp(CO)_2$] prepared separately.[15] In contrast to [Rh(acac)$(CO)_2$], which reacts easily with CO/H_2 to produce [$Rh_4(CO)_{12}$] and [$Rh_6(CO)_{16}$], [$RhBp(CO)_2$] is not changed when heated at 80 °C under 10 atm CO/H_2 for 5 h. Both dicarbonyl complexes also exhibit different reactivity towards 1-hexene under hydroformylation reaction conditions: [Rh(acac)$(CO)_2$] produces ca. 90% of 2-hexene, and unchanged 1-hexene was found after the reaction with [$RhBp(CO)_2$].

We did not succeed in the isolation of catalytically active forms of rhodium complexes, however at this moment we cannot exclude that rhodium complexes with coordinated pyrazolylborate participate in the catalytic cycle.

Experimental Section

[Rh(acac)$(CO)_2$] was synthesized according to the method described previously.[32] [Rh(acac)(CO)PPh_3] and [Rh(acac)-(CO)PCy_3] (**20**) were obtained from the reaction of [Rh(acac)$(CO)_2$] with an equimolar amount of phosphane in hexane. Crystals of **20** suitable for X-ray analysis were obtained by recrystallization of the complex from toluene/hexane solution. 1-Hexene (Fluka) and toluene were distilled before use.

The electrochemical experiments were performed on an EG & G PAR 273 potentiostat/galvanostat connected to a PC computer through a GPIB interface (National Instruments PC-2A) or on an EG & G PAR 173 potentiostat/galvanostat and an EG & G PARC 175 Universal programmer. Cyclic voltammetry was performed in a two-compartment, three-electrode cell, at a platinum- or carbon-disc working electrode ($d = 0.5$ mm), probed by a Luggin capillary connected to a silver-wire pseudo-reference electrode; a platinum auxiliary electrode was employed. Controlled potential electrolysis was carried out in a two-compartment, three-electrode cell with platinum gauze working and counter electrodes in compartments separated by a glass frit; a Luggin capillary, probing the working electrode, was connected to a silver-wire pseudo-reference electrode. The experiments were performed under an inert atmosphere (N_2) at room temperature, the potentials were measured in 0.2 M $[NBu_4][BF_4]/CH_2Cl_2$ (or NCMe) in the presence of ferrocene as the internal standard, and the redox potential values are quoted relative to the normal hydrogen electrode (NHE) by using the $[Fe(\eta^5\text{-}C_5H_5)_2]^{0/+}$ couple with $E^{ox}_{1/2} = 0.77$ or 0.66 V vs. NHE in 0.2 M $[NBu_4][BF_4]/CH_2Cl_2$ or NCMe, respectively (values obtained relative to NHE by adding +0.24 V[33] to those we measured relative to the SCE). The controlled-potential electrolysis experiments were monitored regularly by cyclic voltammetry, thus assuring that no significant potential drift occurred along the electrolyses. Due to the strong working electrode passivation, the electrolyses had to be interrupted frequently for cleaning of this electrode.

FT-IR spectra were recorded on a Nicolet Impact 400 spectrometer and ^1H NMR spectra on a Bruker 300 MHz, or a Bruker 500 MHz spectrometer. Chemical shifts are referenced to TMS. GC-MS was performed on a Hewlett−Packard 8452A spectrometer.

Synthesis of [RhBp(CO)$P(NC_4H_4)_3$] (1): A mixture of [Rh(acac)$(CO)_2$] (0.11 g, 4.2×10^{-4} mol) and KBp (0.17 g, $9.1 \cdot 10^{-3}$ mol) in benzene (6 mL) was stirred for ca. 1 h. The precipitate of Kacac was separated by filtration, $P(NC_4H_4)_3$ (0.121 g, 5.3×10^{-4}) was added to the filtrate and the solution was stirred for 1 h. The solvent was removed under vacuum and the pale yellow

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

product was obtained with 89% yield. $C_{19}H_{20}N_7BOPRh$ (507.10): calcd. C 47.94, H 4.20, N 20.16.; found C 47.64, H 4.47, N 19.74. IR (KBr): ν_{CO} 1987 vs; ν_{BH} 2411 m, 2362 m, 2326 w, 2272 w cm^{-1}.

Synthesis of [RhBp(CO)PPh$_3$] (2): KBp (0.06 g, 3.26×10^{-4} mol) was added to a solution of [Rh(acac)(CO)PPh$_3$] (0.107 g, 2.18×10^{-4} mol) in CH_3CN (3 mL). After stirring the mixture for ca. 15 min, the white precipitate of Kacac was removed by filtration. The clear filtrate was evaporated in vacuo giving the orange product in 76% yield. Crystals of **2** were obtained by slow evaporation of the solvents from a toluene/hexane solution. $C_{25}H_{23}N_4BOPRh$ (540.16): calcd. C 55.56, H 4.26, N 10.47; found C 55.71, H 4.30, N 11.00. IR (KBr): ν_{CO} 1987 vs; ν_{BH} 2411 m, 2362 m, 2326 w, 2272 w cm^{-1}. UV/Vis (CH_2Cl_2): λ (ε) = 266 (8500 $M^{-1}\cdot cm^{-1}$), 306 (4100), 360 (2000) nm; (toluene): 308 (4800 $M^{-1}\cdot cm^{-1}$), 360 (2400), 412 (1300) nm.

Synthesis of [RhBp(CO)PCy$_3$] (3): KBp (0.05 g, 2.98×10^{-4} mol) was added to a solution of [Rh(acac)(CO)PCy$_3$] (0.148 g, 2.98×10^{-4} mol) in CH_2Cl_2 (3 mL). After stirring the mixture for ca. 15 min, the white precipitate of Kacac was removed by filtration. The clear filtrate was evaporated in vacuo giving the yellow product in 68% yield. Crystals of **3** were obtained by slow evaporation of the solvents from a benzene/hexane solution. $C_{25}H_{41}N_4BOPRh$ (558.32): calcd. C 53.76, H 7.35, N 10.04; found C 54.09, H 7.53, N 9.69. IR (KBr): ν_{CO} 1966 vs; ν_{BH} 2411 m, 2368 m, 2328 w, 2268 w cm^{-1}. UV/Vis (CH_2Cl_2): λ = 270, 316, 362 nm.

Synthesis of [RhBp(CO){P(C$_6$H$_4$OMe-4)$_3$}] (4): A mixture of [Rh(acac)(CO)$_2$] (0.11 g, 4.2×10^{-4} mol) and KBp (0.17 g, 9.1×10^{-3} mol) in benzene (6 mL) was stirred for ca. 1 h. The precipitate of Kacac was separated by filtration, P(C$_6$H$_4$OMe-4)$_3$ (0.26 g, 7.4×10^{-4} mol) was added to the filtrate and the solution was stirred for 1 h. The solvent was removed under vacuum and the pale yellow product was obtained in 75% yield. $C_{28}H_{29}N_4BO_4PRh$ (630.25): calcd. C 53.38, H 4.60, N 8.89; found C 53.25, H 5.07, N 8.42. IR (KBr): ν_{CO} 1983 vs; ν_{BH} 2421 m, 2418 m cm^{-1}.

Hydroformylation of 1-Hexene: Hydroformylation was carried out at 80 °C in a steel autoclave (50 mL) containing a mixture of 1-hexene and toluene (1.5 mL each). The appropriate amount of catalyst was weighed in a small Teflon vessel and introduced into the autoclave under a nitrogen atmosphere. After introduction of the reagents, the autoclave was closed and filled with an equimolar H_2/CO mixture. The mixture was stirred magnetically and after 2−5 h the autoclave was cooled down. The organic products were separated by vacuum transfer and analysed by GC-MS.

X-ray Studies: Crystal data are given in Table 7, together with refinement details. X-ray data were collected at low temperature using an Oxford Cryosystem device on a Kuma KM4CCD κ-axis diffractometer with graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å). Crystals were positioned at 65 mm from the CCD camera. 612 Frames were measured at 0.75° intervals with a counting time of 20 sec. Accurate cell parameters were determined and refined by a least-squares fit of 1900−2700 of the strongest reflections. The data were corrected for Lorentz and polarization effects. No absorption correction was applied. Data reduction and analysis were carried out with the Oxford Diffraction (Poland) Sp. z o.o (formerly Kuma Diffraction Wrocław, Poland) programs. Structures were solved by direct methods (program SHELXS-97[36]) and refined by the full-matrix least-squares method on all F^2 data using the SHELXL-97[37] programs. Non-hydrogen atoms were refined with anisotropic displacement parameters; hydrogen atoms were included from geometry of molecules and Δρ maps. During refinement they were fixed.

CCDC-215750 (for **20**), -215751 (for **2**) and -215752 (for **3**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Synthesis, Characterization and in Vitro Study of the Cytostatic and Antiviral Activity of New Polymeric Silver(I) Complexes with Ribbon Structures Derived from the Conjugated Heterocyclic Thioamide 2-Mercapto-3,4,5,6-tetrahydropyrimidine

Panagiotis C. Zachariadis,[a] Sotiris K. Hadjikakou,*[a] Nick Hadjiliadis,*[a] Stavroula Skoulika,[b] Adonis Michaelides,[b] Jan Balzarini,[c] and Erik De Clercq[c]

Keywords: Bioinorganic chemistry / Silver / X-ray diffraction / Cytostatic activity / Antiviral activity

Silver(I) bromide reacts with 2-mercapto-3,4,5,6-tetrahydropyrimidine (StpmH$_2$, $C_4H_8N_2S$) in DMSO with an excess of triethylamine to give a water-insoluble complex of formula $[Ag_6(\mu_2\text{-}Br)_6(\mu_2\text{-}StpmH_2)_4(\mu_3\text{-}StpmH_2)_2]_n$ (**1**), while the reaction of silver(I) nitrate with StpmH$_2$ under the same conditions gives a water-insoluble complex of formula $[\{Ag_4(\mu_2\text{-}StpmH_2)_6\}(NO_3)_4]_n$ (**2**). The products were characterized by elemental analyses, and FT-IR far-IR, UV/Vis, ^{1}H and ^{13}C NMR spectroscopy. Crystal structures of complexes **1** and **2** were determined by X-ray diffraction. Complex **1**, $C_{24}H_{48}Ag_6N_{12}S_6$, crystallizes in the triclinic system space group $P\bar{1}$, a = 8.041(1) Å, b = 12.838(4) Å, c = 13.281(2) Å, α = 68.40(1)°, β = 72.97(1)°, γ = 87.80(2), Z = 2, forming a one-dimensional infinite ribbon structure by strong interatomic interactions of two μ_2-Br bonds with Ag(1). Complex **2**, $C_{24}H_{48}Ag_4N_{16}O_{12}S_6$, crystallizes in the orthorhombic system, space group $Cmc2_1$, and a = 32.148(3) Å, b = 9.461(2) Å, c = 7.234(1) Å, $\alpha = \beta = \gamma$ = 90°, Z = 8, forming infinite Ag–S–Ag chains which are bridged to each other by a sulfur atom of μ_2-StpmH$_2$ ligands. Complexes **1** and **2** were studied for their cytostatic activity against murine leukemia (L1210) and human T-lymphocyte (Molt4/C8 and CEM) cells and for their antiviral activity against a wide variety of viruses. They are markedly cytostatic at 50% inhibitory concentration (IC_{50}) values ranging from 3 to 17 μg/mL. None of the compounds showed appreciable antiviral activity at subtoxic concentrations.

Introduction

Research towards the design of infinite molecular components with specific chains and networks is a matter of great current interest.[1] This self-assembly process between metal ions and ligands is known to depend on the steric and interactive information stored in the ligand and also by the metal ions through their coordination geometry demands.[1b,1c] From this point of view, the ability of silver(I) thiolate or thionate complexes to adopt geometries with variable nuclearities and structural diversity makes the study of silver(I) chemistry very attractive.[2,3] Silver(I) complexes with sulfur-containing ligands exhibit a wide range of applications in medicine, in analytical chemistry or in the polymer industry.[2,3] The biomedical applications and uses of silver(I) complexes are related to their antibacterial action,[4] which appears to involve interaction with DNA.[5] The molecular design and structural characterization of silver(I) complexes is therefore an intriguing aspect of bioinorganic chemistry and metal-based drugs.[6]

A great deal of work has also been devoted to the study of thioamides because of their tendency to bridge metal centers forming oligo- and polynuclear species with potential usage as functional solid materials.[7] Furthermore, 2-mercapto-3,4,5,6-tetrahydropyrimidine can coordinate up to three metal centers at short distances, offering the possibility of studying the metal-metal interaction of d^{10} systems which have attracted considerable attention.[8] Such metal-metal interactions have been observed for silver(I) complexes containing aromatic heterocyclic thioamides like 2-mercaptopyridine,[1a,7] 2-mercaptonicotinic acid,[6b,9] 3-(*tert*-butyldimethylsilyl)pyridine-2-thione and 3,6-bis(*tert*-butyldimethylsilyl)pyridine-2-thione,[10a] 2-(triorganosilyl)-thiophenols and 2,6-bis(triorganosilyl)thiophenols,[10b] and 2-(triorganosilyl)methanethione[10c] and -thiophenol.[11] It is noteworthy that in all cases of complexes with a short sil-

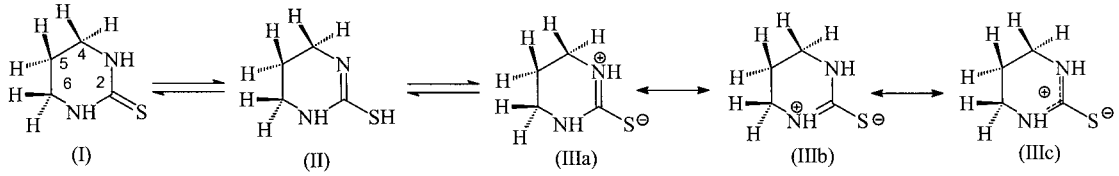

Figure 1. Tautomeric forms of 2-mercapto-3,4,5,6-tetrahydropyrimidine (thione I, thiol II and zwitterionic salt III)

ver(I)-silver(I) distance [shorter than twice the van der Waals radius for silver (3.44 Å)[6b]] there is no halogen atom in the coordination sphere of the metal center.

In this paper, we report the structural and spectroscopic characterization of two new silver complexes with the heterocyclic thioamide 2-mercapto-3,4,5,6-tetrahydropyrimidine (Figure 1) of formulae $[Ag_6(\mu_2\text{-}Br)_6(\mu_2\text{-}StpmH_2)_4(\mu_3\text{-}StpmH_2)_2]_n$ (**1**) and $[\{Ag_4(\mu_2\text{-}StpmH_2)_6\}(NO_3)_4]_n$ (**2**). The cytostatic activity of complexes **1** and **2** against murine leukemia (L1210) and human T-lymphocyte (Molt4/C8 and CEM) cells, and their antiviral properties, have also been studied.

Results and Discussion

General Aspects

The synthesis of complexes **1** and **2** was carried out in DMSO with an excess of triethylamine according to the reactions shown in Equation (1) and (2).

$$6n\ AgBr + 6n\ StpmtH_2 \xrightarrow[DMSO]{Et_3N} \{[Ag_6(\mu_2\text{-}Br)_6(\mu_2\text{-}StpmtH_2)_4(\mu_3\text{-}StpmtH_2)_2]_n\} \quad (1)$$

$$4n\ AgNO_3 + 6n\ StpmtH_2 \xrightarrow[DMSO]{Et_3N} \{[Ag_4(\mu_2\text{-}StpmtH_2)_6](NO_3)_4\}_n \quad (2)$$

No deprotonation of the thioamide ligand was observed, even though an excess of triethylamine was used. When 2-mercaptonicotinic acid was allowed to react with silver(I) chloride under the same reaction conditions, a hexanuclear, water-soluble aggregate of formula $[\{Ag_6(\mu_3\text{-}Hmna)_4(\mu_3\text{-}mna)_2\}^{2-}\cdot\{(Et_3NH)^+\}_2\cdot(DMSO)_2\cdot(H_2O)]$ was formed.[9] Complexes **1** and **2** have infinite ribbon structures (vide infra) which consist of Ag_3S_3 six-membered rings bridged by Br atoms in the case of **1** and two infinite Ag−S−Ag chains bridged by S atoms in the case of **2**. It is noteworthy that the geometry around the silver(I) ions in **1** is tetrahedral while for **2** the geometry around the silver(I) ions is trigonal.

The formulae of molecules **1** and **2** were first deduced from elemental analysis and spectroscopic data. Complexes **1** and **2** are soluble in DMSO and DMF. Crystals of the complexes are stable in air but were stored in darkness. The infinite-ribbon structures of complexes **1** and **2** seem to persist in DMSO solution, since the specific conductivity for complex **1** is $k = 16.15$ μs/cm at 22 °C and does not change up to 38 °C (see also ^{13}C NMR spectra). Complex **2**, on the other hand, has a specific conductivity of 162.45 μs/cm at 22 °C, increasing to 218.8 μs/cm at 38 °C due to the free NO_3^- counteranions.

With 3-(*tert*-butyldimethylsilyl)pyridine-2-thione, 3,6-bis-(*tert*-butyldimethylsilyl)pyridine-2-thione,[10a] 2-(triorganosilyl)thiophenols, 2,6-bis(triorganosilyl)thiophenols,[10b] or 2-(triorganosilyl)methanethione[10c] as ligands towards silver(I) ions, Zubieta et al.[10] have established that the extent of the association of silver(I) ions in their clusters depends intimately on the nature of thioamide. Thus, silver(I) with unbranched linear thiolate ligands are highly polymeric as silver(I) is unprotected from the approach of additional bridging thiolate groups, while bulky ligands such as substituted thiolates increase the aggregation degree of $[Ag(LS)]_n$ compounds.[10] In accordance with the above findings an aggregate of formula $[\{Ag_6(\mu_3\text{-}Hmna)_4(\mu_3\text{-}mna)_2\}^{2-}\cdot\{(Et_3NH)^+\}_2\cdot(DMSO)_2\cdot(H_2O)]$[9] was recently synthesized with the branched substituted 2-mercaptonicotinic acid. When the unbranched, non-aromatic 2-mercapto-3,4,5,6-tetrahydropyrimidine was used for the synthesis of complexes **1** and **2**, highly polymeric structures were obtained.

Infrared Spectroscopy

The infrared spectra of complexes **1** and **2** show distinct vibrational bands at 1559, 1214 cm^{-1} and 1564, 1221 cm^{-1}, respectively, which were assigned as the vibrations of the C−N bond (thioamide I and II bands) and at 1063, 619 cm^{-1} and at 1038, 627 cm^{-1}, respectively, which were attributed to the C−S bond vibrations (thioamide III and IV bands). The corresponding thioamide bands of the free 2-mercapto-3,4,5,6-tetrahydropyrimidine ligand are found at 1557, 1206, 1067 and 644 cm^{-1}, respectively. The new bands at 133 and 139 cm^{-1} in the far-IR spectra of complexes **1** and **2** were assigned to the vibrations of the Ag−S bond,[12] while bands also appear at 178, 137 cm^{-1} in the far-IR spectrum of **1** that can be attributed to the vibration of the Ag−Br bonds.

NMR Spectroscopy

The ^1H NMR spectrum of the free ligand $StpmH_2$ in $[D_6]$DMSO solution shows resonance signals at δ = 7.86 ppm for the amide proton and at δ = 3.20 and 1.75 ppm for the -CH_2- a and b protons. The signal of the amide protons is shifted to δ = 8.50 and 8.76 ppm, respectively, in the ^1H NMR spectra of complexes **1** and **2** in $[D_6]$DMSO solution, confirming the N/S-metal coordination.

The ^{13}C NMR peak assignments of complexes **1** and **2** were based on those of the free ligand, which shows signals

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

at δ = 175.7 ppm for C(=S) (C^2, Figure 1), δ = 40.1 ppm for the two CH_2(-N) equivalent carbon atoms (C^4 and C^6, Figure 1) and at δ = 19.5 ppm for CH_2(-CH_2) (C^5, Figure 1). Complex **1** shows signals at δ = 169.9 ppm for C^2(=S), at δ = 40.7 and 40.3 ppm for C^4(-N) and C^6(-N), respectively, and at δ = 19.5 ppm for C^5. The corresponding signals for complex **2** are at δ = 169.4 ppm for C^2(=S), at δ = 41.4 and 41.0 ppm for C^4(-N) and C^6(-N), respectively, and at δ = 19.1 ppm for C^5. The presence of two signals for C^4 and C^6 of the ligand in both complexes, in contrast to the one in the case of the free ligand, indicates two different coordination modes in the complexes, in accordance with the structures determined by X-ray crystallography (see also conductivity measurements), and suggests that the infinite ribbon structures are persistent in DMSO solutions.

Crystal and Molecular Structures of Complexes $[Ag_6(\mu_2\text{-}Br)_6(\mu_2\text{-}StpmH_2)_4(\mu_3\text{-}StpmH_2)_2]_n$ (1) and $[\{Ag_4(\mu_2\text{-}StpmH_2)_6\}(NO_3)_4]_n$ (2)

Schakal diagrams of complexes **1** and **2** are shown in Figure 2 and 3, respectively, while selected bond lengths and angles are given in Table 1 and 2.

In complex **1**, three sulfur atoms bridge three silver(I) ions, forming a six-membered ring. Strong μ-S and μ-Br intramolecular interactions bridge two six-membered rings (R^1, R^2) through two silver(I) ions while this unit is also bridged by a third six-membered ring (R^3) through the remaining silver(I) ion, two strong μ-Br interactions and so on. Thus, a one-dimensional infinite ribbon structure is formed with strong interatomic interactions (Figure 4).

The Ag−S bond lengths are Ag(1)−S(2) = 2.504(2), Ag(1)−S(1) = 2.522(2), Ag(2)−S(2) = 2.562(2), Ag(2)−S(3) = 2.666(2), Ag(3)−S(1)^b = 2.4832(2), Ag(3)−S(3)^b = 2.554(2) and Ag(3)−S(3) = 2.949(2) Å (^{b}: $-x + 1, -y + 1, -z$). These values are similar to those measured in complexes with infinite ribbon structures, such as $[Ag_6(\mu_3\text{-}pyS)_4(\mu_4\text{-}pyS)_2]_n$ [1a] [pySH = 2-mercaptopyridine, Ag−S = 2.456(5)−2.959(5) Å], $[Ag_5(pyS)_4(pySH)BF_4]_n$ [7] (pySH = 2-mercaptopyridine, Ag−S = 2.45−2.90 Å),

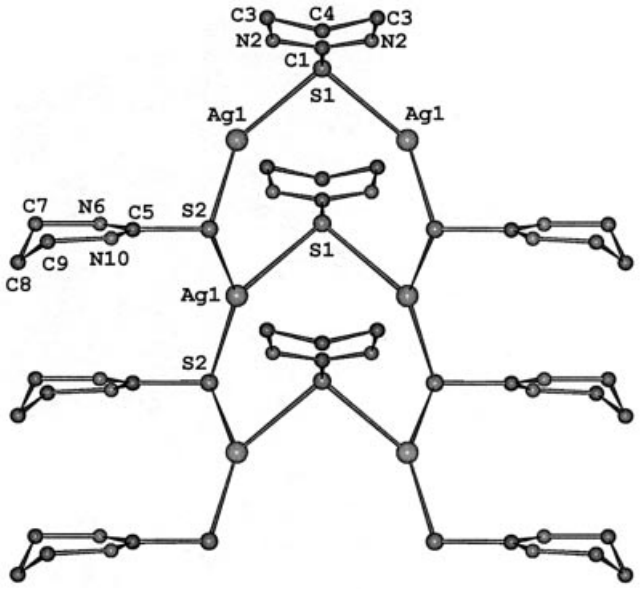

Figure 3. Schakal diagram of the crystal structure of complex **2**; the NO_3^- counterions are omitted for clarity

$[\{Ag_6(SPh)_8\}(Me_4N)_2]$[11] [Ag−S = 2.431(3)−2.878(2) Å], and in $[Ag(\mu_2\text{-}pyS)]_n$ [1a] [pySH = 2-mercaptopyridine, Ag−S = 2.587(4) and Ag−S(a) = 2.502 Å].

The Ag···Ag distances in **1** are Ag(2)−Ag(3) = 3.063(1) and Ag(3)−Ag(3)^b = 2.963(2) and are shorter than twice the van der Waals radius for silver (3.44 Å),[6b] indicating a strong Ag···Ag interaction. Other compounds with strong Ag···Ag interactions include $[Ag_6(\mu_3\text{-}pyS)_4(\mu_4\text{-}pyS)_2]_n$,[1] (pySH = 2-mercaptopyridine) with Ag···Ag = 2.959(2) Å, the neutral cluster $[Ag_6(\mu_3\text{-}Hmna)_6\cdot 8DMSO]$ (H_2mna = 2-mercaptonicotinic acid),[6b] with Ag···Ag = 2.911(1) Å, $[Ag_5(pyS)_4(pySH)BF_4]_n$ (pySH = 2-mercaptopyridine),[7] with Ag···Ag = 2.995 Å, $[\{Ag_6(\mu_3\text{-}Hmna)_4(\mu_3\text{-}mna)_2\}^{2-}\cdot\{(Et_3NH)^+\}_2\cdot(DMSO)_2\cdot(H_2O)]$,[9] with Ag···Ag = 2.916 Å, and $[\{Ag_6(SPh)_8\}\cdot(Me_4N)_2\}]$,[11] with Ag···Ag = 2.959(1) Å. It is noteworthy that in all these complexes with

a short silver(I)−silver(I) distance there is no halogen atom in the coordination sphere of the metal center. Complex **1** is therefore the first example of a silver(I) cluster containing a bromide ion in the coordination sphere of the metal center with an Ag···Ag interaction.

The C−S bond lengths found in complex **1** are S(1)−C(1) = 1.707(8), S(2)−C(7) = 1.734(8) and S(3)−C(13) = 1.732(7) Å, with a partial double-bond character, while the C−N bond lengths are C(1)−N(6) = 1.312(10), C(1)−N(2) = 1.320(10), C(7)−N(8) = 1.305(11), C(7)−N(12) = 1.328(10), C(13)−N(14) = 1.313(9) and C(13)−N(18) = 1.318(9) Å. These bond lengths, as well as the C−*N*−C and N−C−S bond angles, which are around 123° and 120°, respectively, indicate that the ligand coordinates to the silver(I) ion through its zwitterionic form IIIc (Figure 1).

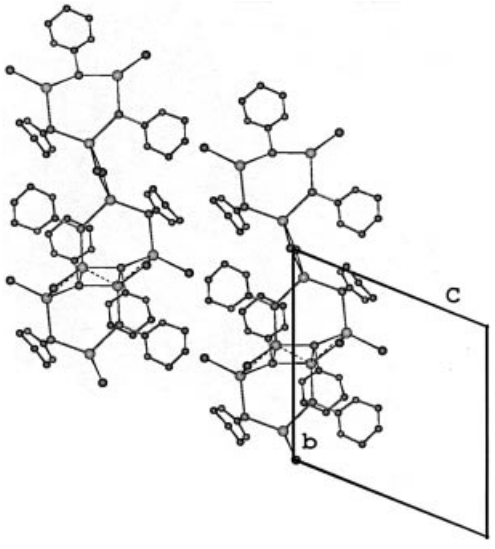

Figure 4. *bc* Projection of the crystal structure of complex **1**; part of the 1-D ribbon structure is presented

Complex **2** consists of two infinite Ag−S−Ag chains, parallel to the *c* axis, which are bridged to each other by a

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

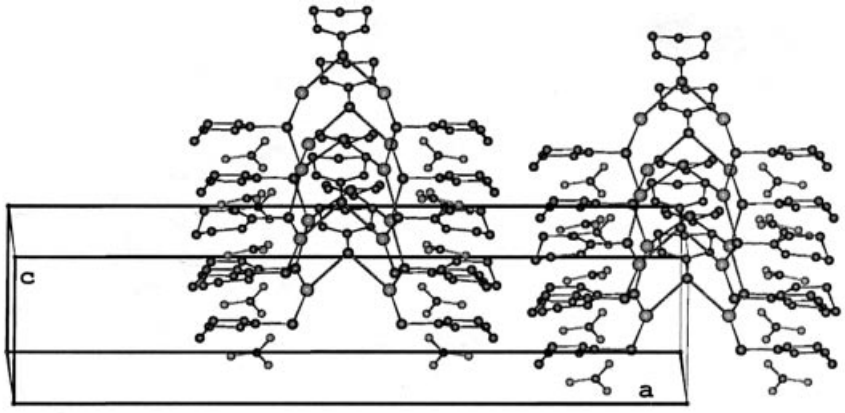

Figure 5. *ac* projection of the crystal structure of complex **2**; the NO_3^- counterions are shown

sulfur atom of the μ_2-StpmH$_2$ ligands. In this way, a one dimensional structure is obtained (Figure 5). A mirror plane parallel to the *bc* plane of the unit cell passes through atoms S(1), C(1) and C(4). The silver(I) ions are three-coordinate while the charge of the Ag^I ion is counterbalanced by a nitrate counterion.

The Ag−S bond lengths are Ag(1)−S(2) = 2.499(5), Ag(1)−S(2)^a = 2.554(4) and Ag(1)−S(1) = 2.669(5) Å (^{a}: x, $-y$, $-z + {}^1/_2$). The Ag−S bond lengths are similar to those found in **1**. No Ag···Ag interaction is observed in **2** [Ag(1)−Ag(1b) = 3.666 and Ag(1)−Ag(1c) = 3.954 Å, both of which are longer than the sum of the Van der Waals radii of two silver atoms]. The C−S bond lengths found in complex **2** are S(1)−C(1) = 1.76(2) and S(2)−C(5) = 1.769(14) Å, which correspond to a C−S single bond, while the C−N bond lengths are C(1)−N(2) = 1.314(14), C(5)−N(6) = 1.307(19) and C(5)−N(10) = 1.30(2) Å. Thus, both ligands have two equivalent short C−N bonds and a C−S single bond, forming the zwitterion IIIc (Figure 1) upon coordination to the silver(I) ion. This is further supported by the values of the C−*N*−C and N−C−S angles, which are around 123° and 120°, respectively. Therefore, a second coordination mode of the ligand is observed in complex **2** from the partial thionic form which is found in complex **1**. Moreover, although a tautomeric zwitterionic form is known to exist in the case of aromatic thioamide ligands,[1a,7,13] complex **2**, with a 2-mercapto-3,4,5,6-tetrahydropyrimidine ligand, is the first example of a coordination mode of S^-−Ag^+ and HN^+ counterbalanced by NO_3^- ions, i.e. with the ligand in its zwitterionic form. A possible charge distribution on the atoms of the unit cell in complex **2** is shown in Figure 6.

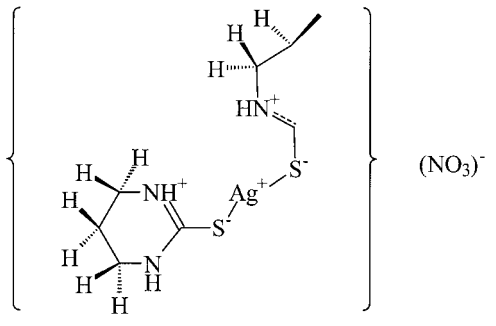

Figure 6. A possible charge distribution on the atoms in complex **2**

Biological Tests

Complexes **1** and **2** were evaluated for their inhibitory activity against the proliferation of murine leukemia (L1210) and human T-lymphocyte (Molt4/C8 and CEM) cells. Table 3 presents the antiproliferative effects of complexes **1** and **2**, as well as the activity of the ligand, as 50% inhibitory concentration (IC_{50}) values:

Table 3. Cytostatic activity of complexes **1** and **2** as 50% inhibitory concentration (IC_{50}) values against murine leukemia (L1210) and human T-lymphocyte (Molt4/C8 and CEM) cells

Compound	IC_{50} (μg/mL)		
	L1210	Molt4/C8	CEM
StpmH$_2$	>200	>200	>200
1	3.4 ± 0.1	3.6 ± 0.3	14 ± 5
2	3.5 ± 0.1	4.1 ± 1.1	17 ± 0

These findings indicate that complexes **1** and **2** show a pronounced cytostatic activity against the tumor cell-lines studied. None of the compounds show a pronounced activity against a wide spectrum of viruses (see Exp. Sect.) at subtoxic concentrations (3.2 μg/mL for **1** and 0.64−3.2 μg/mL for **2** in HEL and Vero cell cultures; data not shown).

Experimental Section

Materials and Instruments: All solvents used were of reagent grade. Silver(I) halides were freshly prepared by mixing aqueous solutions of $AgNO_3$ (Riedel) with the appropriate amount of NaBr (Merck or Aldrich). The precipitate was filtered off, washed with diethyl ether and dried in vacuo. 2-Mercapto-3,4,5,6-tetrahydropyrimidine (Aldrich) was used with no further purification. Elemental analyses for C, H, N, and S were carried out with a Carlo Erba EA model 1108 elemental analyzer. Melting points were measured in open tubes with a Stuart scientific apparatus and are uncorrected. Con-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

ductivity measurements were performed on a CONSORT C 831 conductometer, in DMSO solutions. IR spectra in the region of 4000−370 cm^{-1} were obtained from KBr discs, while far-IR spectra in the region of 400−30 cm^{-1} were obtained from polyethylene discs, with a Perkin−Elmer Spectrum GX FT-IR spectrophotometer. A Jasco UV/Vis/NIR V 570 series spectrophotometer was used to obtain the electronic absorption spectra. The ^1H and ^{13}C NMR spectra were recorded on a Bruker AC250 MHFT NMR instrument in [D_6]DMSO solutions. Chemical shifts are given in ppm referenced to internal TMS.

Synthesis and Crystallization of $[Ag_6(\mu_2\text{-}Br)_6(\mu_2\text{-}StpmH_2)_4(\mu_3\text{-}StpmH_2)_2]_n$ (1) and $[\{Ag_4(\mu_2\text{-}StpmH_2)_6\}(NO_3)_4]_n$ (2): Silver(I) bromide (1 mmol, 0.188 g) or silver(I) nitrate (0.170 g) were added to a clear solution of 2-mercapto-3,4,5,6-tetrahydropyrimidine (2 mmol, 0.2324 g) in 7 mL of DMSO. After stirring for 30 min, triethylamine (3.6 mmol, 0.5 mL) was added to the clear solution. The solution was then filtered and the filtrates were kept in darkness at room temp. After a few days colorless crystals of complex **1** or **2** suitable for crystallographic single crystal analysis were obtained.

1: Yield: 0.067 g (25%); m.p. 176−178 °C. $C_{24}H_{48}Ag_6Br_6N_{12}S_6$ (1823.7): calcd. C 15.81, H 2.65, N 9.22, S 10.55; found C 16.13, H 2.52, N 9.92, S 10.36. IR: $\tilde{\nu}$ = 3258 vs cm^{-1}, 2966 m, 1559 vs, 1432 m, 1362 vs, 1317 vs, 1215 vs, 1199 vs, 1072 m, 808 s, 694 s, 598 s, 566 s; far-IR: 178 m cm^{-1}, 133 m, 118 m, 111 m, 104 m. UV/Vis (DMSO): λ_{max} (log ε) = 263.5 nm (4.19). ^1H NMR (DMSO): δ = 8.572 (s, NH), 3.219 [t, $^3J_{HH}$ = 7.40 Hz, CH_2, -C(4)], 1.812−1.770 [q, $^3J_{HH}$ = 6.0 Hz, CH_2, -C(5)] ppm.

2: Yield: 0.034 g (10%); m.p. 209−211 °C. $C_{24}H_{48}Ag_4N_{16}O_{12}S_6$ (1376.5): calcd. C 20.94, H 3.51, N 16.28, S 13.97; found C 21.51, H 3.64, N 16.73, S 13.60. IR: $\tilde{\nu}$ = 3381 s cm^{-1}, 3229 s, 2965 m, 1564 vs, 1383 vs, 1309 s, 1221 s, 1196 s, 1073 m, 1038 m, 970 m, 815 m, 751 m, 627 m, 566 m, 519 m; far-IR: 286 m cm^{-1}, 282 m, 276 m, 273 m, 253 m, 246 m, 228 m, 222 m, 207 s, 199 m, 193 m, 175 m, 170 s, 158 m, 155 m, 147 m, 139 m, 128 s, 117 s, 112 m. UV/Vis (DMSO): λ_{max} (log ε) 257.5 nm (4.69). ^1H NMR (DMSO): δ = 8.76 (s), 3.25 (m), και 1.80 (m) ppm.

Cytostatic Activity Assays: To each well of a 96-well microtiter plate was added 5 × 10^4 L1210 or 7.5 × 10^4 Molt4/C8 or CEM cells and a given amount of the test compound dissolved in DMSO. The cells were allowed to proliferate for 48 hours (L1210) or 72 hours (Molt4/C8 or CEM) in a humidified, CO_2-controlled atmosphere. At the end of the incubation period, the cells were counted with a Coulter Counter. The IC_{50} (50% inhibitory concentration) is defined as the concentration of compound that reduced the number of living cells by 50%.

Inhibition of HIV-Induced Cytopathicity in CEM Cells: Human CEM (approx. 3 × 10^5 cells·mL^{-1}) cells were infected with 100 $CCID_{50}$ (1 $CCID_{50}$ being the viral dose required to infect 50% of the cell cultures) of HIV-1 (III_B) or HIV-2 (ROD) per milliliter and seeded in 200-μL wells of 96-well microtiter plates, containing appropriate dilutions of the test compounds. After 4 days of incubation at 37 °C, CEM giant-cell formation was examined microscopically.

Antiviral Activity Assays: The antiviral, other than *anti*-HIV, assays were based on inhibition of virus-induced cytopathicity in either human embryonic lung (HEL) [HSV-1, HSV-2, vaccinia virus, vesicular stomatitis virus (VSV), varicella-zoster virus, cytomegalovirus], human cervix carcinoma (HeLa) (VSV, Coxsackie virus B4, respiratory syncytial virus) or simian kidney (Vero) (parainfluenza-3 virus, reovirus-1, Sindbis virus, Coxsackie B4 virus and Punta Toro virus) cell cultures. Confluent cell cultures in microtiter 96-well plates were inoculated with 100 $CCID_{50}$ of virus [for CMV 100 plaque-forming units (PFU) and for VZV 20 PFU were used]. After a one to two hour virus-adsorption period, residual virus was removed, and the cell cultures were incubated in the presence of varying concentrations (400, 200, 100, ... μg/mL) of the test compounds. Viral cytopathicity was recorded as soon as it reached completion in the control virus-infected cell cultures that were not treated with the test compounds.

X-ray Structure Determination: Data were collected at room temperature on a Bruker P4 diffractometer, with graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å), in the θ−2θ scan mode (1.93° < 2θ < 25.03° for **1** and 2.24° < 2θ < 24.98° for **2**). The structures were solved with SHELXS-97 and refined with SHELXL-97.[14] All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were located by difference maps and refined isotropically. Relevant crystallographic data together with data collection and structure refinement details for both complexes are listed in Table 4.

CCDC-222599 (**1**) and -222600 (**2**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Synthesis and Characterization of the Diastereomers Λ- and Δ-[Ru(bpy)$_2$-(m-bpy-Gly-L-His-L-Lys)]Cl$_2$ − ^{1}H NMR Studies on Their Interactions with the Deoxynucleotide Duplex d[(5′-CGCGAATTCGCG-3′)$_2$]

Alexandra Myari,[a] Nick Hadjiliadis,*[a] and Achilleas Garoufis*[a]

Keywords: Metallopeptides / Oligonucleotides / Ruthenium / Chemical nucleases / Groove

The synthesis and characterization of the diastereomeric complexes Λ- and Δ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$, (GHK = glycine-L-histidine-L-lysine, m-bpy = 4|-methyl-2,2|-bipyridine) as well as their binding properties to the deoxynucleotide duplex d(5′-CGCGAATTCGCG-3′)$_2$ studied by means of NMR, ESI-MS and CD spectroscopy, are reported. The ROESY spectrum of Λ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$ shows intramolecular cross peaks between the bpy H3 or H3′ protons and the aromatic H2 and H5 of the histidine imidazole ring, indicating that the peptide adopts an orientation with the imidazole ring close to the bpy ligand, possibly interacting by π-stacking. The absence of intramolecular cross peaks between the peptide and the bipyridine ligands in the ROESY spectrum of Δ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$ on the other hand, shows that in this case the peptide is far from the two bpy ligands, having a different orientation from the Λ isomer. The isomers interact with the oligonucleotide duplex differently. Δ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$ binds in the oligonucleotide major groove close to the central part of the sequence. Λ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$ binds, probably non selectively, approaching the helix from the minor groove. It can be concluded that the peptide (GHK) binding leads the rest of the isomer to interact with the oligonucleotide in the case of the Δ isomer.

1. Introduction

The idea that low-molecular mass organic compounds (e.g., DNA targeting drugs) may bind selectively to DNA was raised several years ago.[1] There is evidence for ligands exhibiting antiviral activity and antineoplastic properties[2] or catalyzing the hydrolysis of DNA phosphodiesteric bonds (chemical nucleases).[3] The ways that such molecules bind to DNA are known and include covalent and noncovalent binding (intercalation, groove binding and electrostatic interactions). Some of them bind in specific domains of the DNA (sequence selectivity) or selectively from the major or minor groove depending on the relation of ligand−DNA recognition. Consequently, the structure of the incoming molecule is important due to different dimensions of the two DNA grooves when it approaches the bases. From the point of view of inorganic chemistry it is interesting to study the binding properties of the metal complexes of such ligands that may potentially combine the properties of the metal and the ligand. For instance the complex [Pt(net)$_2$(NH$_3$)$_2$]$^{2+}$ preserves the selective binding of netropsin (net) and binds in the AT rich region from the minor groove but induces DNA-cleavage near the binding sites upon X-ray irradiation.[4] On the other hand, the complex of the peptide GGKGGG with Cu^{2+} conjugated to netropsin binds to DNA in the same manner as the antibiotic alone, i.e. from the minor groove, assisted by the complex−peptide moiety through electrostatic and van der Waals interactions.[5,6] This compound generates oxygen active species upon activation by a mild oxidizer and induces cleavage in a specific DNA sequence region. Using photophysical techniques, Barton and co-workers have shown DNA sequence recognition by the metal peptide complex [Rh(phi)$_2$(phen′)]$^{3+}$ (phen′ = 1,10 phenanthroline conjugated with a 14/peptide and phi = phenanthrenequinonediamine) which binds at the 5′-ACAA-3′ region.[7] It is worth mentioning that the complex of Cu^{2+} with bis(salicylideneethylenediamine) (salen) conjugated with distamycine (DNA minor groove binder in AT rich regions) binds rather selectively to DNA. Upon activation, however, the cleavage is nonspecific.[8]

Ruthenium polypyridine complexes are undoubtedly the main class of molecules which may bind to DNA through intercalation, inducing cleavage of the DNA backbone through photoxidation.[9] The sequence specificity of these complexes has been investigated with known sequence oligonucleotides, mainly by means of NMR techniques, but no general rules about such selectivity have been

suggested.[10−15] Our efforts are focused on the design and synthesis of ruthenium polypyridyl complexes able to recognize and bind to a specific DNA sequence. Peptides are important biological ligands having the functional groups essential for the formation of sequence specific contacts such as hydrogen bonds and van der Waals contacts. Hence, the incorporation of a peptide sequence may be an asset in the design of sequence specific binders. Our design of such complexes involves a Ru^{II} ion surrounded by polypyridine ligands, one of which is conjugated to the peptide sequence (Figure 1).

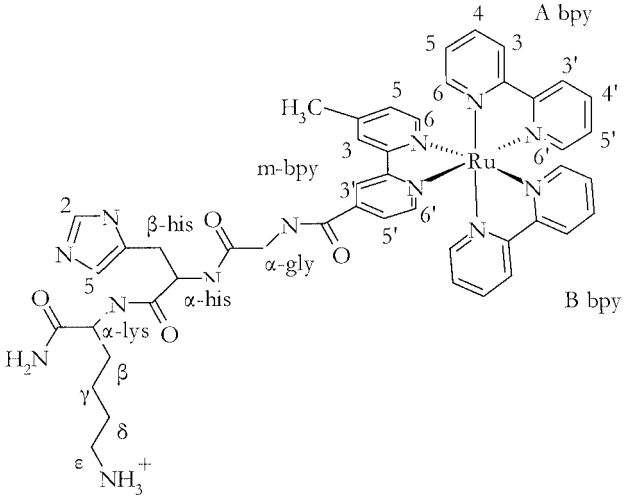

Figure 1. Structure of the complex Δ-$[Ru(bpy)_2(m\text{-}bpy\text{-}GHK)]^{2+}$ with atom numbering

Recently, we have focused our attention on the tripeptide Gly-His-Lys (GHK) related to GGH. Its Cu^{2+} complex conjugated with netropsin contributes to the binding reaction with the DNA from the minor groove in AT rich domains.[5,6] The DNA binding properties of the complex we designed were tested on the spectroscopically and crystallographically characterized Dickerson−Drew dodecamer, d(5′-CGCGAATTCGCG-3′)$_2$ which forms a self-complementary duplex the structure of which is known.[16,17] This paper describes the synthesis and characterization of the diastereomeric complexes Λ- and Δ-$[Ru(bpy)_2(m\text{-}bpy\text{-}GHK)]Cl_2$, derived from the compounds Λ- and Δ- *cis*-$[Ru(bpy)_2(py)_2]A$ (where A = *O*,*O*′-dibenzoyltartaric acid)[18,19] by a substitution of the two py molecules with the chelate ligand m-bpy-COOH followed by a solid-phase peptide synthesis. This was also our first attempt to investigate, by means of NMR, ESI-MS and CD spectroscopic techniques, their binding properties with the deoxynucleotide duplex d(5′-CGCGAATTCGCG-3′)$_2$. The possible selective cleavage of the oligonucleotide by these complexes is under investigation and the results will appear in a later publication.

2. Results and Discussion

2.1. Synthesis and Characterization of the $[Ru(bpy)_2(m\text{-}bpy\text{-}GHK)]Cl_2$ Isomers

2.1.1. Synthesis

The synthesis of the diastereomers Λ- and Δ-$[Ru(bpy)_2(m\text{-}bpy\text{-}GHK)]Cl_2$ was based on the enantiomerically pure complexes Λ- and Δ-*cis*-$[Ru(bpy)_2(py)_2]^{2+}$ as building blocks. These complexes were used as precursors for the synthesis of the tris(chelates) Λ- and Δ-$[Ru(bpy)_2(m\text{-}bpy\text{-}COOH)]^{2+}$.[20,21] Both pyridine molecules in the complex *cis*-$[Ru(bpy)_2(py)_2]^{2+}$ were substituted by the chelate ligand m-bpy-COOH (m-bpy-COOH = 4′-methyl-2,2′-bipyridine-4-carboxylic acid), the optical purity being retained in the resultant compounds. The carboxyl group of the ligand (m-bpy-COOH) remained free due to the higher propensity of the phenanthroline nitrogen donor atoms over the oxygen atoms for coordination to the Ru^{II} ion[24] assisted by the formation of a very stable five-membered chelate ring. These enantiomers were isolated as their $[PF_6]^-$ salts by the addition of HPF_6 (pH = 1) thus keeping the carboxyl group protonated. The tripeptide (GHK) was then conjugated to the m-bpy-COOH molecule through the solid state method SPPS, using the 2-chlorotrityl-H-Fmoc-resin by activation of the carboxyl group with succinic acid and DCC.[25] The isomers were isolated as TFA salts and then converted in to their water-soluble chlorides with LiCl in acetone.[15] The total procedure is detailed in Scheme 1.

2.1.2. Electrospray Ionization Mass Spectrometry

Positive electrospray spectra for both Λ- and Δ-$[Ru(bpy)_2(m\text{-}bpy\text{-}GHK)]Cl_2$ in aqueous media were recorded using the time-of-flight method to register all ions simultaneously without scanning.[26] Both spectra were generally the same, showing mainly two peaks of high intensity at 474.58 and 316.74 *m*/*z* arising from $[RuC_{46}H_{49}N_{13}O_4]^+$ (948.30 *m*/*z*) at doubly and triply charged states correspondingly. The very weak intensity of the peak at *m*/*z* = 948.30 indicates that the abundance of the peptide which is deprotonated both to the lysine terminal amino group and probably to any peptidic NH group or to the terminal amide group $[Ru(bpy)_2(m\text{-}bpy\text{-}CO\text{-}Gly\text{-}His\text{-}LysCONH_2)H^+]^+$ is very low. Indeed, a relatively high intensity peak that was observed at 474.58 *m*/*z* may be assigned to the doubly charged cation $[Ru(bpy)_2(m\text{-}bpy\text{-}CO\text{-}Gly\text{-}His\text{-}LysCONH_2)]^{2+}$ with all the peptidic NH groups being protonated. Finally the main peak of the spectrum at *m*/*z* = 316.74 can be assigned to the triply charged cation $[Ru(bpy)_2(m\text{-}bpy\text{-}CO\text{-}Gly\text{-}His\text{-}LysCONH_2)]^{3+}$ where the lysine terminal amino group (p*K*a = 10.4) [27] is protonated (Figure 2).

2.1.3. Circular Dichroism Spectroscopy

The CD spectra of the Δ- and Λ-diastereomers are not mirror images of each other as expected (Figure 3) since the presence of another chiral center in the peptide moiety

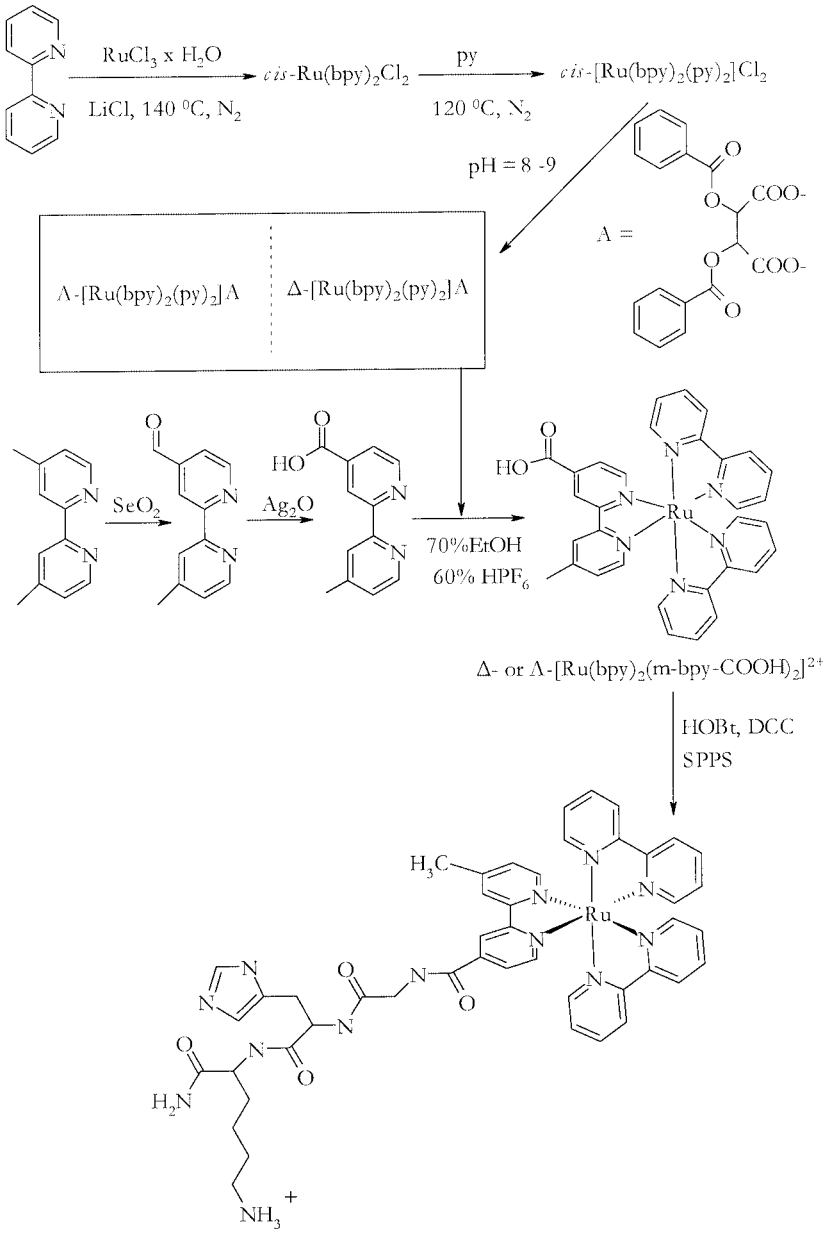

Scheme 1

besides the metal results in diastereomers. Assignments were made by comparison with similar complexes of known configuration.[20,28] The spectra of the isomers exhibit $\lambda_{max.}$ (nm) with $\Delta\varepsilon$ ($M^{-1}cm^{-1}$) at 479 nm (+6.7), 422 (−9.6), 295 nm (+90.1), 278 (−36.9) 226 nm (−13.5), 205 nm (+11.7), 195 nm (−14.8) for the Λ isomer and at 479 nm (− 4.6) 421.5 nm (+6.4), 295 nm (−60.8), 278 nm (+22.6), 225 nm (+5.2), 204 nm (−18.6), 190 nm (−11.5) for the Δ isomer.

2.1.4. NMR Spectroscopy

^{1}H NMR resonances of the diastereomers Λ- and Δ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$ were assigned based on homo and heteronuclear 2-D COSY and TOCSY experiments. In the spectra of both isomers only one set of proton signals for the two bpy ligands were observed. The influence of the third non-symmetric ligand m-bpy-GHK on the bpy proton signals is insignificant and the differences in their magnetic environments are non-detectable. Similar behavior was also observed in the complexes [Ru(bpy)$_2$(HPIP)]$^{2+}$ [15] and [Ru(bpy)$_2$(pqx)]$^{2+}$,[29] where HPIP {HPIP is 2-(2-hydroxyphenyl)imidazo[4,5-*f*][1,10] phenanthroline} and pqx [pqx is 2-(2′-pyridyl)quinoxaline] are non-symmetric chelate ligands. On the other hand, the ligand m-bpy-GHK exhibits one set of proton resonances for each pyridine ring which differ significantly from each other. The pyridine ring, which is substituted by a methyl group at the 4th position, exhibits similar chemical shifts with the pyridine residues of the other two bpy ligands with the protons at the neighbor-

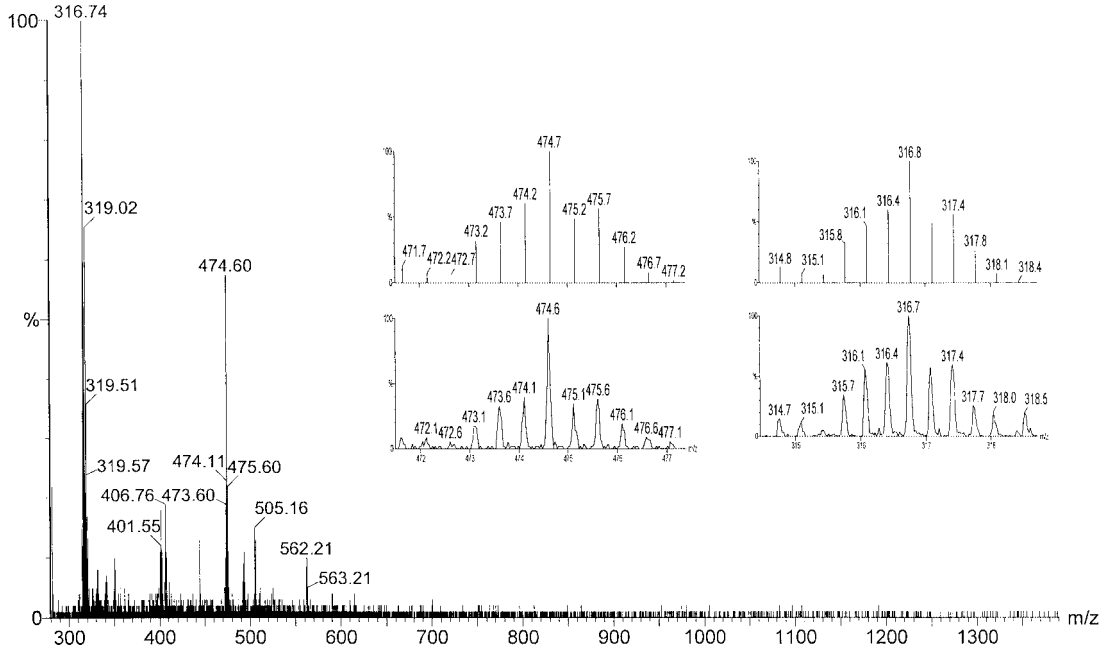

Figure 2. A typical electrospray mass scan of Λ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$ in the positive mode. Insets, the calculated spectrum in comparison with the observed peaks for the cations Λ-[Ru(bpy)$_2$(m-bpy-GHK + H$^+$)]$^{3+}$ (*m*/*z* 316.74) and Λ-[Ru(bpy)$_2$(m-bpy-GHK)]$^{2+}$ (*m*/*z* 474.58)

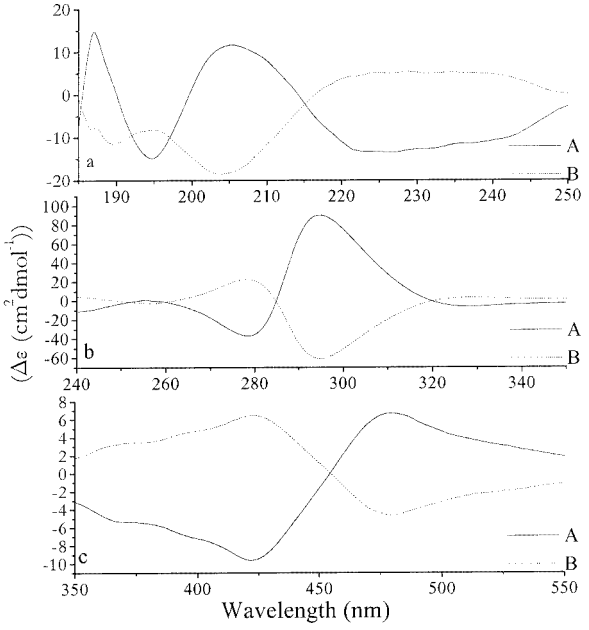

Figure 3. The CD spectra of A = Λ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$ and B = Δ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$ in the region (a) (190−250 nm), (b) (240−350 nm) and (c) (350−550 nm)

ing 3rd and 5th positions shifted upfield only by δ = −0.06 and −0.04 ppm respectively. In contrast, the protons H3′ and H5′ of the other pyridine ring of the m-bpy group are shifted downfield by about δ = +0.29 ppm (H3′) and δ = +0.78 ppm (H5′), indicating that the CO-GHK substitution at the 4th position provides a deshielding effect on these protons reducing the electron density of this pyridine ring.[30]

The chemical shifts of the peptide protons are similar for the diastereomers Λ- and Δ-[Ru(bpy)$_2$ (m-bpy-GHK)]Cl$_2$, differing only slightly (about ±0.01 ppm). The one exception being H2 of the histidine imidazole ring of the Λ- isomer which is shifted upfield by δ = −0.16 ppm compared with the shift of the equivalent resonance in the Δ isomer. This effect probably arises from a different configuration of the peptide in the isomers, with the histidine's imidazole ring being closer to the aromatic pyridine moieties in the case of the Λ isomer (Figure 4). A qualitative approach to the observed shielding by −0.16 ppm based on a method proposed by Cheney results in a distance of about 4 to 5 Å between the plane of one of the pyridine rings and H2 of the imidazole.[31] The ROE spectra of both isomers are similar as the cross peaks in the ROE map indicate. These can be assigned to dipolar interactions between the pyridine ring protons of rings on the same or adjacent metal bipyridine units. Additionally, two new cross peaks were observed in the spectrum of the Λ isomer (Figure 4), which we have assigned to the interaction of the bpy H3 or H3′ protons with both the aromatic protons H2 and H5 of the histidine imidazole ring. This indicates that it has a different orientation in the two diastereomers. Such a geometry will direct the imidazole ring in the case of Λ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$ close to the bpy ligand possibly resulting in a π-stacking interaction. This would not be the case in the Δ isomer (Figure 4).

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

(b) The same part of the ROESY spectrum under the same conditions for Λ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$, following a qualitative model of the peptide orientation. The labeled cross peaks correspond to ROE contacts assigned to the protons: (A) hisH2-bpyH3H3′, (B) hisH2-bpyH4H4′, (C) hisH5-bpyH6H6′

2.2. Interactions of the Diastereomers [Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$ with the DNA Dodecamer Duplex [d(5′-CGCGAATTCGCG-3′)$_2$]

2.2.1 Assignments of the Proton Resonances of [d(5′-CGCGAATTCGCG-3′)$_2$]

1-D-NOE (Nuclear Overhauser Effect) experiments in 90% H_2O/10% D_2O were used to assign the amino and the imino resonances of the duplex. Five signals in the imino region (δ = 14 ppm) of the NMR spectrum of the dodecanucleotide were observed, indicating that only the terminal C···G bases do not form stable Watson−Crick hydrogen bonding. The two most downfield shifted resonances were identified as T7N3-H and T8N3-H in the A···T pairs and the other three as G2N1-H, G10N1-H and G4N1-H in the G···C pairs, typical for B-type DNA structures in aqueous solution.[32] In addition, the signals of the hydrogen-bonded exocyclic amino groups of the purines and pyrimidines were observed in the region of δ = −9.5 ppm, in contrast to the resonances of the non hydrogen-bonded amino groups C1-NH_2 and G12-NH_2 located at a higher field (δ ≈ 6 ppm).

Assignments of all non-exchangeable protons of the oligonucleotide were achieved by using the standard DQF COSY technique[33] and two-dimensional NOE spectroscopy.[34] Small differences in the proton assignments of the dodecamer exist between our findings and those reported in literature,[35] probably due to the slightly different conditions and the high field ^{1}H NMR (500 MHz) instrument used. In the NOESY map of [d(5′-CGCGAATTCGCG-3′)$_2$] the sequential assignments for the *n*H6/H8 → *n*H1′ => (*n* + 1)H6/H8 → (*n* + 1)H1′ (where the different arrows → and => denote *intra* and *inter* nucleotide distances-cross peaks, respectively) system

were observed for all the bases of the sequence.[36,37] Moreover, NOE cross peaks from each H8/H6 to its own H2′ and H2′′ are consistent, as expected, with a B-type right-handed DNA duplex.[37]

2.2.2 1-D ^{1}H NMR Spectroscopy

Table 1 and 2 show the ^{1}H NMR chemical shift data of the free oligonucleotide, the complexes Δ- and Λ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$ and the changes induced by addition of the isomers to the oligonucleotide.

The ^{1}H NMR spectra of the samples containing the oligonucleotide and the Δ or the Λ isomer in molar ratios of 1:0.5 and 1:1 show only one set of resonances in all cases. This behavior indicates fast exchange (on the NMR time scale at ambient temperature) between the bound form(s), the free oligonucleotide, and the metal complex.

Upon decreasing the temperature to 283 K, a slight broadening of the signals was observed indicating that the fast exchange changes slowly to intermediate. Moreover, decreasing the temperature close to the solvent's freezing point did not yield separate resonances (coalescence point). Under these conditions only average NMR results of the bound form(s) could be observed. This clearly means that the NMR observations do not necessarily belong to only one single species but may be the average of different bound forms in a non-specific binding of the diastereomers to the oligonucleotide. Each NMR signal in the fast exchange kinetics represents a statistical average for all species present and the extracting of specific information is difficult. However, the achievement of slow exchange conditions is rather scarce even for highly specific compounds such as distamycine.[38] In such cases, the NMR results can only be considered as a qualitative analysis of the binding. The majority of Ru^{II} polypyridine complexes bind to DNA with fast to intermediate kinetics and conformational predictions have been given using additional methods such as molecular mechanics (MM) and molecular dynamics (MD) calculations, coupled with some of the NOE results as distance constraints.[11−15,39,40]

Upfield changes in the bpy proton signals of both diastereomers were observed which were largest in the case of the Δ isomer. In particular, the protons located at the end of the one pyridine ring of bpy namely H3′ and H4′ were shifted by δ = − 0.19 and − 0.17 ppm respectively. These values, followed by smaller but significant changes in chemical shifts of all other bpy protons, indicate that the ligand clearly binds to the oligonucleotide without intercalating between the bases. Intercalation would cause large upfield changes in the resonances of the ligand protons (δ = 0.3−1.0 ppm) and significant broadening of the signals due to intermediate exchange.[11] The observed electronic shielding of the H3′ and H4′ bpy protons from the DNA bases is close to the lower limit for binding by intercalation, showing that the vertical distance between these protons and the base planes is not very high.[41] According to Pullman and co-workers, the induced shielding effect for a five or a six membered aromatic ring from the DNA bases is a function of distance.[41,42] The observed 0.2 ppm upfield shift corresponds to a vertical distance between the base planes and H3′/ H4′ of the bpy aromatic ring system of about 5 Å which is not enough to cause intercalation. These slight changes in the chemical shifts of the complex protons are more consistent with other modes of binding, such us groove binding. In general, molecules which bind in the DNA grooves interact with the edges of the bases causing zero or insignificant shielding of the molecule's protons.[43] Complexes with ligands similar to bpy, as in the case of [Ru(Me$_2$bpy)$_2$}$_2$(μ-bpm)]$^{4+}$ (μ-bpm = 2,2′-bipyrimidine), associate in the minor groove of the DNA and induce very small changes in the ligand proton resonances (less than 0.1 ppm).[14] Small changes were observed in the pyridyl and aliphatic proton chemical shifts for the complex Δ-*cis*-α-[Ru{*R*,*R*)-picchxnMe$_2$}(phen)]$^{2+}$ (< 0.2 ppm) which binds selectively at the minor groove of the oligonucleotide [d(CGCGATCGCG)$_2$] and the [d(ATATCGATAT)$_2$] duplex.[39] This type of DNA−metal complex interaction is also known for the complex [Ru(bpy)$_3$]$^{2+}$ which binds to the DNA without intercalation.[44] In the case of Λ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$ the changes observed were in the range of δ = −0.06 to −0.03 ppm for the bpy protons, sug-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

gesting a weak association with the oligonucleotide or a non-specific binding. The diffusion of shielding or deshielding effects induced by the interaction of the metal complex with DNA, for all proton signals of the Λ-[Ru(bpy)$_2$(m-bpy-GHK)] with approximately similar shifts, could be explained as being due to a non specific binding of this isomer.

The aromatic protons of the m-bpy-GHK ligand show small upfield shifts (less than 0.1 ppm) for both isomers. In addition, the peptide protons were shifted upfield except the lysine side chain protons Hα (shifted upfield in both isomers), Hβ (shifted downfield in both isomers) and Hγ (shifted downfield in both isomers). The Hδ proton, which is very close to the terminal amino group, was shifted slightly downfield and upfield in the Δ and Λ isomers, respectively, indicating that it probably interacts either with the charged phosphate groups of the DNA or with the aromatic π system of the bpy ligands. Similar results were observed in the case of the binding of the tripeptide Lys-Tyr-Lys to the tetranucleotide [d(5′-GCGC-3′)]$_2$, where the positively charged amino group of the lysine side chain interacts electrostatically with the phosphodiester backbone of the DNA.[45] Furthermore, the binding of Lys-Trp-Lys with the DNA involves electrostatic interactions between the lysine residues and the DNA backbone.[46]

The influence of the binding of the Δ isomer on the oligonucleotide proton resonances is focused on the protons located at the major groove, namely H2′ and H2′′ of the sugar moieties which are shifted more than the minor groove proton H1′. The highest shifts were observed for A5 H2′′ and A6 H2′′ and for C3 H5. The base C3 is located opposite G10 and probably H5 is affected by a complex binding close to the T8C9 base sequence. Thus, the most affected part of the oligonucleotide is the region from A5 to G10 in the major groove.

In an attempt to further investigate the binding modes of the peptide moiety of the complexes to the synthetic DNA fragment, all spectra were recorded in 90% H_2O /10% D_2O in order to observe the exchangeable amino and imino protons. The assignments in Table 3 were aided by the use of

NOE spectroscopy and by data available in the literature.[47−49]

The H8 proton (neighboring N7) of the guanine or the adenine residues of the oligonucleotide do not shift significantly in the presence of the diastereomers thus excluding any possibility of participation of this nitrogen in hydrogen bonding with the peptide complexes. O6 of guanine is also a good candidate but such interactions would affect the GO6···H4NC proton signal, which is not the case ($\Delta\delta$ = 0.02 to 0.03 ppm for both isomers). The other non-hydrogen bonded protons of the exocyclic amino group of C3, C9 and C11, (CN4-H) are shifted by about 0.1 ppm due to their interactions with both isomers (Figure 5). This downfield shift is significant but clearly not large enough to conclude that these protons participate in hydrogen bonding. This observation could, however, be due to hydrogen bonds which are bifurcated and longer than normal or indeed van der Waals interactions between the peptide residue of the complexes and the CN4-H protons of C3, C9 and C11.[50] A similar example is the interaction of the same DNA sequence with the drug *Distamycin A*, where small downfield shifts were observed for both protons of the adenine ring

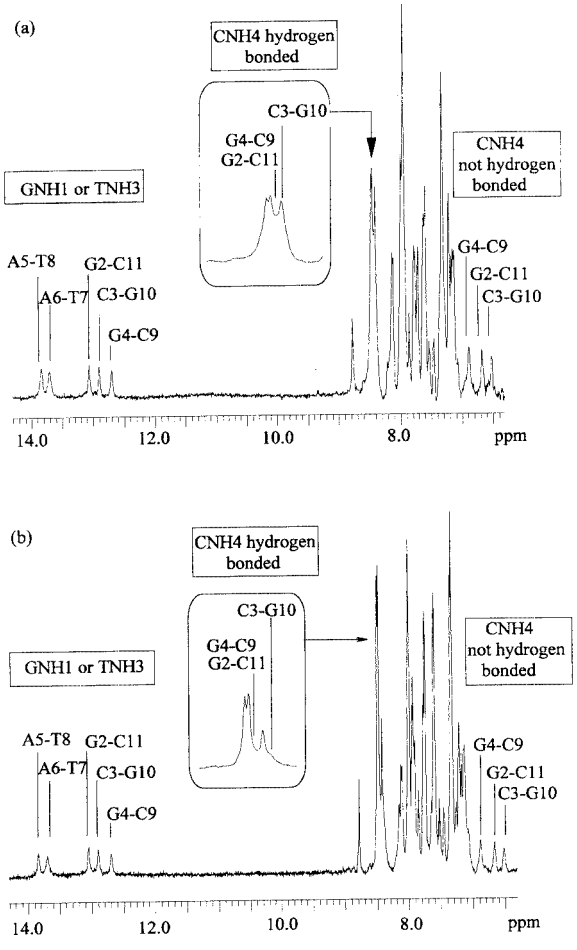

Figure 5. Part of the ^{1}H NMR spectra of the diastereoisomers showing the influence of (a) Δ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$ and (b) Λ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$ to the hydrogen bonds of GNH1, TNH3 and CNH4 in the base pairs CG and AT of the oligonucleotide duplex

and the NH of the drug's pyrrole groups[50] suggesting a groove interaction. The hydrogen-bonded proton of the AT base pair *A*N6-H···O4*T* does not seem to be affected by the binding because the neighboring proton signals of the thymine methyl group do not shift upfield. This excludes the possibility of interaction of these sites with the peptide. The A5H2 that shifts downfield by about 0.05 ppm reflects a possible association of the peptide with the A5N3 position.

Of the exchangeable peptide protons only the NH proton of the His group was shifted upfield by about −0.13 ppm in both diastereomers, suggesting that this site or the neighboring carbonyl (>C=O) participates in the binding of the complex to DNA.

2.2.3 2-D ^{1}H NMR Spectroscopy

Table 4 shows selected NOESY cross peaks observed between the isomers Λ- and Δ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$ and [d(5′-CGCGAATTCGCG-3′)$_2$].

Table 4. Selective NOE cross peaks observed between the protons of the diastereomers Λ- and Δ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$ and [d(5′-CGCGAATTCGCG-3′)$_2$] at a metal complex/duplex ratio of 1:1 in 100 mM phosphate buffer (pH = 7.01) at 303 K

Δ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$	Λ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$
(m-bpy-GHK)H3 → C9H2′′(W)	
(m-bpy-GHK)H3′ → C9H2′′ (S)	
(m-bpy-GHK)H5′ → C9H2′′ (S)	(m-bpy-GHK)H3′ → A6H1′(M)
	(m-bpy-GHK)H5′ → C9H1′ (W)
(bpy)H3′ → C9H2′′ (S)	
(bpy)H6H6′ → C1H2′ (M)	
(His)HA → A5H1′(W)	
	(Gly)NH → T8H1′(W)
(Lys)NH → A5A6H2′′ (M)	
(His)NH → T7T8H2′′ (M) → MeT8 (M)	

The NOE contacts, originating from the duplex conformation (B-form), are intact but the cross peak intensities of some of them are decreased indicating small perturbations of the helix conformation.[51] This observation allowed us to consider a "fix" B-DNA structure for the binding models. In addition, we observed a number of cross peaks between the ligand protons of the diastereomers. Intermolecular NOE effects were also observed between the diastereomeric complex protons and the dodecanucleotide (see Figure 6 and 7).

In the case of Δ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$, distances of less than 5Å were observed between the aromatic protons of the ligands m-bpy and bpy with the H2′′ proton of C9 and T8 facing the major groove of the helix. The exchangeable NH protons of the peptide backbone, which extend from the 4th position of the ligand m-bpy, show cross peaks with protons that are also accessible from the major groove such as H2′′ of T7 and T8 and the thymine T8 methyl group. A few very weak intensity intermolecular NOE effects were observed between the lysine aliphatic side chain and the oligonucleotide protons indicating that this part of the peptide is located across the major groove of the helix.

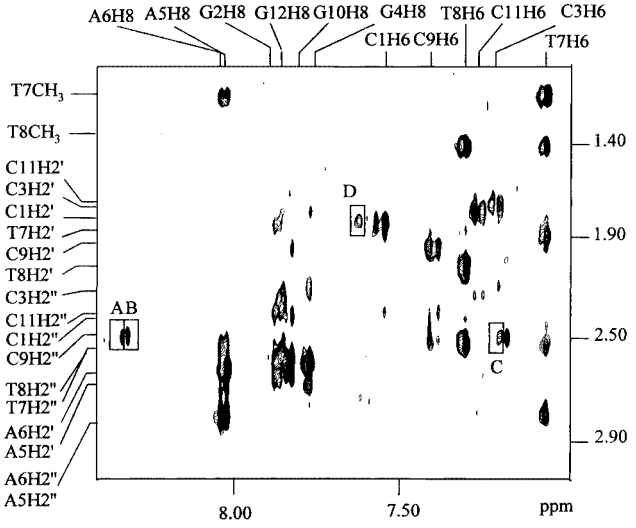

Figure 6. Part of the ^{1}H NOESY spectrum (τ_m = 400 ms) of the Δ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$−[d(CGCGAATTCGCG)$_2$] adduct at a 1:1 molar ratio at 303 K with the oligonucleotide assignments of the base's aromatic protons (F2) and the major groove sugar protons H2′ and H2′′ for the bases adenine, thymine and cytosine (F1). The labeled cross peaks correspond to NOE contacts between the protons: (A) m-bpyH3′-C9H2′′, (B) bpyH3−C9H2′′, (C) m-bpyH5′-C9H2′′ (D) bpyH6H6′-C1H2′

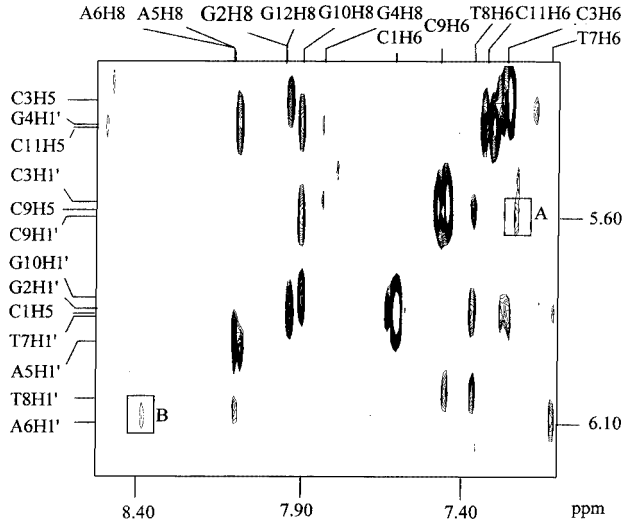

Figure 7. Part of the ^{1}H NOESY spectrum (τ_m = 400 ms) of the Λ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$−[d(CGCGAATTCGCG)$_2$] adduct at a 1:1 molar ratio at 303 K with the oligonucleotide assignments of the base's aromatic protons (F2) and the minor groove sugar proton H1′ (F1). The labeled cross peaks correspond to NOEs between the protons: (A) m-bpyH5′-C9H1′, (B) m-bpyH3′-A6H1′

On the other hand, the intermolecular NOE contacts between Λ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$ and the oligonucleotide are significantly less than in the case of the Δ isomer, suggesting a looser or non-specific binding of the isomer. A few of these take place between the ligand m-bpy protons H5′and H3′ with C9H1′ and the peptide backbone Gly-NH with the sugar proton H1′ of the base T8, all located in the helix minor groove. In contrast to the Δ isomer, no cross peak was observed between the other two bpy ligand protons of the complex and the oligonucleotide indicating that only the m-bpy-GHK moiety of the complex is close to [d(5′-CGCGAATTCGCG-3′)$_2$].

2.2.4 Binding Models

It is not possible to develop quantitative 3-D models of the way the diastereomers bind to the oligonucleotide duplex in the Ru^{II}complex/d[(CGCGAATTCGCG)$_2$] due to the fast exchange kinetics of the system, which does not allow taking all NOE results as distance constraints. Taking in to account (i) that there is no significant perturbation to the DNA helix (according to NOE's and the *inter* and *intra*-strand connectivity of the oligonucleotide protons), (ii) that the geometry around the Ru^{II} coordination sphere is fixed and (iii) that using selective NOE's that are not geometrically in disagreement, we have constructed simple binding models that are consistent with the observations from 1-D and 2-D NMR spectroscopy (Figure 8 and 9). The complexes manually docked at distances are consistent with the inter-proton NOE in many different combinations and the geometries of the complexes were optimized with respect to the "freeze" geometry of the Ru^{II} coordination sphere (angles and bond lengths) and the DNA structure. The structures which are more consistent with the NMR observations are presented in Figure 8 and 9.

The molecular model of the Δ-[Ru(bpy)$_2$(m-bpy-GHK)]$^{2+}$/d[CGCGAATTCGCG)$_2$] system shows the two bpy ligands of the complex close to the DNA bases, in agreement with the observed ≈0.2 ppm upfield shift changes of H3′ and H4′ in the 1-D NMR spectra. The location of the complex is also consistent with the small changes in the aromatic proton chemical shifts of the m-bpy-GHK ligand, oriented out of the helix groove and with the observed upfield shifts of the protons A5A6H2′, A5A6H2′′ and C3H5 (opposite G10), since the complex is located close to this part of the oligonucleotide. In the model of the Λ isomer (Figure 9), the bpy ligands are far from the DNA bases and the terminal positive amino group of the lysine is close to DNA phosphates, as has already been suggested based on the 1-D NMR spectra. The resultant model located Λ-[Ru(bpy)$_2$(m-bpy-GHK)]$^{2+}$ at the helix minor groove.

It is known that ruthenium tris-chelates involving 2,2′-bipyridine or 1,10-phenanthroline ligands bind at the DNA grooves. For example [Ru(phen)$_3$]$^{2+}$ [10] binds in the minor groove and [Ru(bpy)$_2$(phen)]$^{2+}$ shows a similar binding geometry.[52] In all cases, however, where the Ru^{II} complex comprises an intercalative ligand [e.g. dipyridophenazine (dppz)] together with two bpy or phen ligands, the complex binds to DNA through intercalation of this ligand between the bases and leads the other two ligands into the oligonucleotide minor groove (e.g. Δ-[Ru(phen)$_2$(dpq)]$^{2+}$,[12] Δ-[Ru(Me$_2$phen)$_2$(dppz)]$^{2+}$ [13] and [{Ru(Me$_2$bpy)$_2$}(μ-bpy)]$^{4+}$ [14]). Sometimes the "leader" ligand intercalates from the major groove as in the case of Δ-[Ru(phen)$_2$(dppz)]$^{2+}$ leading the phenanthroline molecules to be located next to the major groove.[11] The questions which thus arises are, what makes an octahedral Ru^{II} com-

plex approach from the minor or the major groove of the DNA helix? Is the intercalative ligand responsible for this?

In the case of Δ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$ a non-intercalative and flexible ligand (m-bpy-GHK) which binds to the DNA major groove has been used, showing that it is probably the peptide which leads the other two bpy ligands of the isomer to interact with the major groove. In other words, the peptide affinity for the major groove is higher than that of Δ-[Ru(bpy)$_2$] for the minor. In contrast, the same ligand does not follow the same way of binding in the case of the Λ isomer. For this complex, the different orientation of the peptide (see Figure 4) from that in the Δ isomer gives the main role to the bpy ligands that lead the complex into the minor groove. In particular, in this context, the major groove binding of Δ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$ is consistent with (i) the relative dimensions of the complex and the oligonucleotide major groove (estimated dimensions of the complex are 22 Å long and 11 Å wide, while the size of the major groove is 11.6 Å × 8.5 Å and the minor is 6.0 Å × 8.2 Å [53]), (ii) the formation of hydrogen bonds between the peptide backbone and the non-hydrogen bonded protons of the cytidine exocyclic NH_2 group, which was deduced from the 1-D NMR spectra, can be explained by an approach of the oligonucleotide by the complexes from the major groove, (iii) the fact that the major groove is rich in negatively charged phosphates and for this reason it prefers the positively charged cationic complex and the lysine's terminal NH_3^+ group as well. It seems that the peptide determines the way that the complex binds to the oligonucleotide followed by a possible binding of the other ligands.

In the case of the Λ isomer, weak intensity cross-peaks were observed only between the glycine NH with the H1′ of T8 and H3′/H5′, located on the one pyridine ring of the m-bpy ligand, with the A6 and C9H1′, indicating that only the m-bpy ligand of the complex interacts with the oligonucleotide probably from the minor groove.

3. Conclusion

In summary, it is concluded from the 1-D and 2-D NMR spectroscopic data that (i) the diastereomers bind to the oligonucleotide differently. The Δ isomer binds from the helix major groove, close to the central part of the sequence while the peptide moiety extends across the major groove from the base T8 to C11. The Λ isomer probably binds non-selectively, approaching the helix from the minor groove. (ii) The peptide binding, it would appear, leads the rest of the Δ isomer to interact with the oligonucleotide and thus may explain why the two bpy ligands were found to be located in the major groove in the case of the Δ isomer. The detection of sequence selectivity binding requires further studies with different DNA sequences. This work together with photo cleavage experiments of the oligonucleotides by such complexes is in progress.

4. Experimental Section

4.1. Starting Materials: All chemicals and solvents were of reagent grade and were used without further purification. The deoxynucleotide [d(5′-CGCGAATTCGCG-3′)] was purchased from OSWEL DNA (University of Southampton U.K.) and purified by chromatography on a 120 × 2.5 cm Sephadex G-25 superfine column, using distilled water as the eluent and lyophilized to dryness. The complexes *cis*-[Ru(bpy)$_2$Cl$_2$][18] Λ- and Δ-[Ru(bpy)$_2$(py)$_2$]A (where A = *O*,*O*′-dibenzoyltartaric acid) ,[19,20] and the ligand 4′-methyl-2,2′-bipyridine-4-carboxylic acid (m-bpy-COOH) were synthesized according to literature.[21]

4.2. Synthesis of the Peptide Conjugated Ru^{II} Complexes

Λ-, Δ-[Ru(bpy)$_2$(m-bpy-COOH)](PF$_6$)$_2$: Solid Λ- or Δ-[Ru(bpy)$_2$(py)$_2$]A (0.38 g) and m-bpy-COOH (0.105 g) were suspended in 70% ethanol in water (10 mL) and the mixture was heated to reflux overnight. The reaction mixture was cooled to room temperature and the solvent was reduced with a rotary evaporator to approximately 3 mL. After standing overnight, the mixture was filtered and the remaining solid was washed with water. The filtrate was acidified to pH = 1 by dropwise addition of aqueous 60% HPF_6 with vigorous stirring. The solid was collected on a fine-porosity glass filter, washed with water (2 × 5 mL), diethyl ether (2 × 5 mL) and oven dried at 110 °C overnight to provide pure Λ- or Δ-[Ru(bpy)$_2$(m-bpy-COOH)](PF$_6$)$_2$ as a red solid. Yield 0.30 g (82%). **Δ-[Ru(bpy)$_2$(m-bpy-COOH)](PF$_6$)$_2$:** $C_{32}H_{26}F_{12}N_6O_2P_2Ru$: calcd. C 41.9, H 2.9, N 9.2; found C 41.2, H 2.9, N 9.3. **Λ-[Ru(bpy)$_2$(m-bpy-COOH)](PF$_6$)$_2$:** $C_{32}H_{26}F_{12}N_6O_2P_2Ru$: calcd. C 41.9, H 2.9, N 9.2; found C 41.1, H 2.9, N 9.2.

Λ-, Δ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$: Solid-phase peptide synthesis was used for peptide conjugation. The Fmoc strategy was followed using 2-chlorotrityl-H-Linker-Fmoc resin as the solid support. Piperidine was used as a deprotection reagent. DCC and HOBt were used as coupling reagents. The cleavage from the resin and the final deprotection of peptide side chain protecting groups were performed in one step by shaking with a 90% TFA solution in DMF. Anisol was used as a scavenger. The final products Λ- or Δ-[Ru(bpy)$_2$m-GHL]$^{2+}$ were isolated as trifuoroacetate salts which are insoluble in water. The trifluoroacetate anion was replaced by a chloride anion by mixing an acetone solution of the ruthenium peptide derivative with an excess of LiCl. [Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$ precipitated as an orange water soluble solid. The product was purified by reverse-phase HPLC using a DIONEX chromatograph and a Waters C18 column. Chromatography solvents were HPLC grade acetonitrile and water both containing 0.1% TFA. Yield approximately 30%. **Δ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$:** ^{1}H NMR (500 MHz, D_2O, 10 mM, in 100 mM phosphate buffer, pH = 7.01, 303 K): δ = 8.83 (s, 1 H, m-bpy H3′), 8.54 (d, $^3J_{H,H}$ = 8.1 Hz, 4 H, bpy H3H3′), 8.48 (s, 1 H, m-bpy H3), 8.05 (t, $^3J_{H,H}$ = 7.5 Hz, 4 H, bpy H4H4′), 8.00 (d, $^3J_{H,H}$ = 5.8 Hz, 1 H, m-bpy H5), 7.79 (s, 1 H, His H2), 7.80 (d, $^3J_{H,H}$ = 5.7 Hz, 4 H, bpy H6H6′), 7.37 (t, $^3J_{H,H}$ = 6.3 Hz, 4 H, bpy H5H5′), 7.65 (d, $^3J_{H,H}$ = 5.8 Hz, 2 H, m-bpy H6H6′), 7.53 (s, 1 H, His H5), 7.27 (d, $^3J_{H,H}$ = 5.8 Hz, 1 H, m-bpy H5′), 4.63 (d, $^3J_{H,H}$ = 4.1 Hz, 1 H, His *a*-CH), 4.25 (d, $^3J_{H,H}$ = 4.2 Hz, 1 H, Lys *a*-CH), 4.17 (d, $^3J_{H,H}$ = 4.2 Hz, 1 H, Gly *a*-CH), 2.88 (t, $^3J_{H,H}$ = 7.5 Hz, 2 H, Lys ε-CH), 3.15 (m, $^3J_{H,H}$ = 7.5 Hz, 2 H, His β-CH), 2.49 (s, 3 H, m-bpy CH_3), 1.80 (m, 2 H, Lys β-CH), 1.67 (t, $^3J_{H,H}$ = 6.3 Hz, 2 H, Lys δ-CH), 1.37 (m, 2 H, Lys γ-CH), ppm. **Λ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$:** ^{1}H NMR (500 MHz, D_2O, 10 mM, in 100 mM phosphate buffer, pH = 7.01, 303 K): δ = 8.83 (s, 1 H, m-bpy H3′), 8.54 (d, $^3J_{H,H}$ = 8.6 Hz, 4 H, bpy H3H3′),

4.3. Physical Measurements

4.3.1 NMR Spectroscopy

Measurements were made with a Varian Unity-500 MHz instrument. 1-D ^{1}H NMR spectra were recorded at 303 K into 4096 data points, with a 6024 Hz spectral width after 128 transients. The water resonance was suppressed with a time-shared Redfield "2-1-4"-pulse. ^{1}H NOESY spectra were recorded in phase sensitive mode with a total 2048 × 256 points for a mixing time of 200 to 400ms, while ^{1}H ROESY spectra had mixing times (τ_m) of 60−120 ms. ^{1}H DQFCOSY spectra were collected using the TPPI method with a spectral width of 3125 Hz with a total of 2048 × 256 points and a relaxation delay of 1.5 s.

The amounts of the oligonucleotide were estimated by weighing, and the concentration of the sample was determined using its absorption at 260 nm .[22] In all NMR experiments carried out, a 100 mM Na_2HPO_4/NaH_2PO_4 (pH = 7.00) buffer was used. The lyophilized samples were dissolved in D_2O (99.96) and lyophilized again to dryness. These samples were finally dissolved in D_2O (99.996, 0.4 mL) and transferred to 5 mm NMR tubes.

The 1-D ^{1}H NMR spectra were recorded with sample concentration ≈ 100 OD_{260} units while 2-D NOE experiments were carried out in more concentrated samples (≈ 300 OD_{260}). ^{1}H NMR spectra of the labile oligonucleotide protons were recorded in 90% H_2O 10% D_2O (field-frequency lock). No internal chemical shift reference was added to the samples.

4.3.2 Electrospray Mass Spectrometry

ESI mass spectra were acquired with a Micromass Q-Tof quadrupole MS instrument. All spectra were recorded in TOF (time of flight) mode with a source temperature of 80 °C, and low cone voltage (ΔCS = 100−120V) to obtain gentle interface conditions.

4.3.3 CD spectroscopy

CD spectra were recorded with a Jasco J-720 spectropolarimeter. A 0.1-cm path length cuvette was used for the 190−250 nm region while a 2-cm path length cuvette was used for the 250−540 nm region. The blank was subtracted from the CD spectrum of the sample. Smoothing of the curves was performed using the Adjacent Averaging method from Microcal Origin 6.0.

4.4. Molecular Modeling

The 3-D binding models were constructed using the HyperChem. v. 6.0 molecular modeling software. The model of the oligonucleotide [d(CGCGAATTCGCG)$_2$] duplex was based on a standard B-type structure with a C2′ *endo* sugar conformation using the database of the program. The Ru^{II} complex was constructed in two steps. Firstly, the coordination sphere of the ruthenium was constructed using crystal structure data of similar complexes [23] and secondly, the peptide was conjugated at the 4th position of the ligand m-bpy. The complex was then manually docked close to the oligonucleotide duplex with respect to the observed NOE contacts, which were inserted as distance restraints. The NOE cross peaks were classified into three categories: weak (5 Å), medium (4 Å) and strong (3 Å) relative to the volume integral of the cytosine CH5/CH6 cross peak. Selective NOEs from the nine observations (Table 4) for Δ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$ were inserted as distance restraints and the complexes were selectively and briefly energy minimized in the presence of the oligonucleotide using the AMBER force field. Several structures from different combinations of the intermolecular NOEs were observed and the most consistent one with the NMR spectroscopic data was presented as a possible binding model of the complex to the oligonucleotide duplex. In the case of Λ-[Ru(bpy)$_2$(m-bpy-GHK)]Cl$_2$, a similar procedure was followed and a structure that was more consistent with the NMR observations was maintained. Graphical outputs were obtained from the selected structures with the RasMol v. 2.6 software.

Hydrolytic Cleavage of DNA by Ternary Amino Acid Schiff Base Copper(II) Complexes Having Planar Heterocyclic Ligands

Pattubala A. N. Reddy,[a] Munirathinam Nethaji,[a] and Akhil R. Chakravarty*[a]

Keywords: Copper / Synthetic hydrolase / X-ray diffraction / Schiff bases / Phenanthroline bases

The ternary copper(II) complexes [Cu(salgly)L] (L = phen, **1**; dpq, **2**), [Cu(salala)L] (L = phen, **3**; dpq, **4**) and [Cu(salphe)L] (L = phen, **5**; dpq, **6**), where salgly, salala and salphe are tridentate Schiff-base ligands derived from the condensation of salicylaldehyde with glycine, L-alanine and L-phenylalanine, respectively, are prepared and their nuclease activity studied (phen, 1,10-phenanthroline; dpq, dipyridoquinoxaline). The crystal structure of **3** displays a distorted square-pyramidal (4+1) coordination geometry in which the ONO-donor Schiff base is bonded to the metal atom in the basal plane. The chelating phen ligand displays an axial–equatorial mode of bonding. The complexes exhibit a d–d band near 670 nm and a charge transfer band near 370 nm in methanol. The one-electron paramagnetic complexes display axial EPR spectra in DMF glass at 77 K, indicating a $\{d_{x^2-y^2}\}^1$ ground state. The complexes are redox-active and exhibit a quasi-reversible Cu^{II}/Cu^{I} couple in DMF at approximately –0.6 V vs. SCE. They show catalytic activity in the oxidation of ascorbic acid by molecular oxygen. The ability of the complexes to bind calf thymus (CT) DNA follows the order: **2** ≈ **4** ≈ **6** > **1** ≈ **3** ≈ **5**. Complexes **1**–**6** show oxidative DNA cleavage activity in the presence of mercaptopropionic acid as a reducing agent. All the complexes show hydrolytic cleavage activity in the absence of light or any reducing agent. The oxidative and hydrolytic DNA cleavage efficiencies follow the order: **2** ≈ **4** ≈ **6** > **1** ≈ **3** ≈ **5**. The dpq complexes, which have a greater DNA binding ability, display enhanced nuclease activity than their phen analogues. The hydrolytic DNA cleavage rate of 1.8 h^{-1}, observed for **2**, is significantly high relative to most of the known copper-based synthetic hydrolases. Mechanistic pathways involved in the nuclease activity of the complexes are discussed.

Introduction

Designing metal complexes suitable for cleaving DNA under hydrolytic conditions is of considerable importance considering the advantages of a process that produces fragments similar to those formed by the restriction enzymes, relative to other nucleolytic processes, viz. oxidative cleavage of DNA in the presence of additives or photo-induced DNA cleavage.[1–10] While photo-cleavers require the presence of a photo-sensitizer that can be activated on irradiation with UV or visible light, the redox-active "chemical nucleases" are effective cleavers of DNA in the presence of a reducing agent or H_2O_2 as an additive.[11–21] The mechanistic pathways in the oxidative process generally involve abstraction of sugar hydrogen, electron transfer, or guanine base oxidation, depending on the reaction conditions. The oxidative processes form cleaved products that are not readily amenable to further enzymatic manipulations, and thus have limited use in molecular biology. The synthetic metallohydrolases, on the other hand, follow a mechanistic pathway targeted at the phosphodiester bonds linking the nucleosides, and involves metal-promoted acid/base catalysis which leads to the formation of fragments that can be used for further enzymatic religation. Among several types of transition metal complexes used as synthetic hydrolases, copper(II) and zinc(II) complexes are better suited for the hydrolysis of DNA due to the strong Lewis acid properties of these metal ions.

The present work stems from our interest to design ternary copper(II) complexes with amino acid based Schiff-base ligands and planar NN-donor heterocyclic ligands. While 1,10-phenanthroline (phen) and dipyridoquinoxaline (dpq) are used for binding to DNA, the Schiff bases containing different α-amino acids are designed to participate in the acid/base activity through their potentially labile carboxylate and/or phenolate oxygen atom binding site(s). We have synthesized a series of new ternary complexes, viz. [Cu(salgly)(L)] (L = phen, **1**; dpq, **2**), [Cu(salala)(L)] (L = phen, **3**; dpq, **4**) and [Cu(salphe)L] (L = phen, **5**; dpq, **6**), where salgly, salala and salphe are tridentate Schiff-base ligands derived from the condensation of salicylaldehyde with glycine, L-alanine and L-phenylalanine, respectively (Scheme 1). Complex **3** has been structurally characterized by X-ray crystallography. An important observation from

Results and Discussion

Synthesis and General Aspects

Complexes **1** and **2** have been prepared in high yields by the reactions of [Cu(salgly)(H_2O)]·0.5H_2O with 1,10-phenanthroline (phen) and dipyridoquinoxaline (dpq), respectively. Complexes **3**−**6** have been synthesized by the reactions of copper(II) acetate hydrate with the Schiff base H_2salala or H_2salphe in the presence of phen or dpq. The ternary complexes are stable in the solid state and moderately stable in solution. They have been characterized by elemental analysis, and from spectral and magnetic data (Table 1).

The non-electrolytic and one-electron paramagnetic ($\mu_{eff} \approx 1.8\ \mu_B$ at 25 °C) complexes show infrared spectral features that are characteristic of the Schiff base and the heterocyclic ligand. The carboxyl C=O stretch of the Schiff base is observed in the range 1620−1650 cm^{-1}. The electronic spectra of the complexes in methanol display a d-d band near 670 nm. In addition, the complexes exhibit a charge transfer (CT) transition at ca. 370 nm. They present an axial EPR spectrum in DMF-glass at 77 K, with a $g_{\|}$ value of ca. 2.22 ($A_{\|} \approx 170 \times 10^{-4}\ cm^{-1}$) and a $g_{\perp}$ value of 1.98, suggesting a $\{d_{x^2-y^2}\}^1$ ground state and a tetragonally distorted geometry for the complexes.[22] The Schiff bases H_2salala and H_2salphe are optically active. Complexes **3** and **4**, containing the dianionic salala ligand, are found to be optically active. In contrast, complexes **5** and **6** with the salphe ligand do not show any optical rotation; racemization could possibly have taken place as a result of complexation with the metal ion. A similar process has been reported earlier for phenylalanine-based Schiff-base complexes.[23,24]

Crystal Structure

Complex **3** has been characterized by single-crystal X-ray diffraction. The ORTEP view of the complex is shown in Figure 1. Selected bond lengths and angles are given in Table 2. The complex crystallizes in the monoclinic space group C_2 with two complexes and ten water molecules in the crystallographic asymmetric unit. The α-carbon atom of the amino acid Schiff base has an (*S*) configuration in both molecules. Based on the structural data, the complex has been formulated as [Cu{sal-(*S*)-ala}(phen)]·5H_2O. The crystal structure of the complex reveals the presence of a ternary structure consisting of a tridentate ONO-donor Schiff base, a bidentate N,N-donor heterocyclic base and a copper(II) center in the discrete monomeric species.[24] In the five-coordinate structure, the Schiff base is situated in the basal plane. The phen ligand displays axial-equatorial coordination. The distortion from the square-pyramidal geometry can be estimated from the τ values, 0.23 and 0.2, for two independent molecules in the asymmetric unit.[25] Significant hydrogen-bonding interactions involving the water molecules are observed. The complex displays intermolecular π-π stacking interactions of the phenolate phenyl moieties.

Redox and Catalytic Properties

The electron transfer behavior of complexes **1**−**6** was studied by cyclic and differential pulse voltammetric techniques using a glassy carbon working electrode in dimethylformamide (DMF); 0.1 M TBAP was used as the electrolyte. The electrochemical data are given in Table 1. The complexes exhibit a quasi-reversible cyclic voltammetric response near −0.6 V vs. SCE in DMF, with large ΔE_p values at a scan rate of 50 $mV \cdot s^{-1}$. The redox process is assigned to the Cu^{II}/Cu^{I} couple. The reduced species is unstable in the voltammetric time scale as can be seen from the i_{pa}/i_{pc} ratio which is less than 1 (i_{pa} and i_{pc} are the anodic and cathodic peak currents, respectively).

Complexes **1**−**6** react readily with ascorbic acid (H_2A) in aqueous methanol to form an unstable brown copper(I) species, which readily converts to the parent copper(II) complex. The complexes retain the structure during the catalytic reaction with a H_2A/complex molar ratio of ca 30:1. Excess addition of H_2A leads to the formation of an inactive oxalato species, analyzed as [CuL(ox)] (ox = oxalate dianion). Oxalic acid is formed from the oxidation of the dehydroascorbate species (A).[26] The reduced copper(I) complex converts to the moderately stable bis(phen)- or bis(dpq)copper(I) species under an inert gas.

Oxidative Cleavage of DNA

The ability of the complexes **1**−**6** in inducing DNA cleavage has been studied by gel electrophoresis using supercoiled pUC19 DNA in 50 mM Tris-HCl/50 mM NaCl buffer (pH = 7.2). On reaction with SC DNA in the presence of mercaptopropionic acid (MPA), complexes **1**−**6** show nuclease activity (Figure 2). Control experiments using only complex **2** or MPA do not show any apparent DNA cleavage under similar experimental conditions. Complexes such as $[Cu(salgly)(H_2O)]$[27] and $[Cu(salgly)(bpy)]$[24] also do not cleave DNA in the presence of MPA. This indicates the necessity of planar heterocyclic bases such as phen or dpq for oxidative DNA cleavage. The DNA cleavage efficiencies of the complexes follow the order: **2** ≈ **4** ≈ **6** > **1** ≈ **3** ≈ **5**. The % DNA cleaved observed for the dpq complexes in the presence of MPA is similar to that observed for the bis(phen)copper(II) complex which is used as a standard (Table 3).[28] A 40 μM concentration of the dpq complex **2** showed complete conversion of the initial SC form to the NC form, while for the phen analogue, only 38% conversion of the SC form was seen. The similar values for the % DNA cleaved by the three dpq complexes suggests only a minor effect of the organic moieties, such as the methyl or benzyl group of the amino acid based Schiff bases, on the cleavage efficiency. Mechanistic studies involving the addition of the minor groove binder distamycin showed complete inhibition of the cleavage process, suggesting the minor groove binding preference of the complexes.[29] Fluorescence spectral studies using ethidium bromide as a probe shows a greater DNA binding ability of the dpq complexes than their phen analogues. The binding ability of the dpq complexes is similar to that observed for the bis(phen)copper(II) complex under similar experimental conditions. The hydroxyl radical scavenger DMSO completely inhibits the cleavage reaction. This indicates the possible involvement of the hydroxyl radical and/or the reactive copper−oxo species in the cleavage pathway. A similar pathway was pro-

Figure 2. [a] Complex concentration is 40 μM. Incubation period: 1 h

posed by Sigman and co-workers for the oxidative cleavage reaction of the bis(phen)copper complex.[15]

Hydrolytic Cleavage of DNA

In the absence of any reducing agent or light, the complexes are found to cleave DNA hydrolytically (Table 4). At a concentration of 1.0 mM and an incubation time of 2 h, complex **1** which contains the ligand phen cleaves 55% of SC DNA, while complete cleavage is observed for the dpq complex **2** (Figure 3, a). Complexes [Cu(salgly)(H_2O)] and [Cu(salgly)(bpy)], which do not bind DNA, do not show any hydrolytic cleavage activity under similar conditions. The cleavage efficiency follows the order: **2** ≈ **4** ≈ **6** > **1** ≈ **3** ≈ **5**. To ascertain the hydrolytic nature of the DNA cleavage process, reactions were performed in the presence of DMSO and in the absence of oxygen in dark [Figure 3 (a), lanes 9 and 10]. The cleavage efficiency does not change in the presence of DMSO. This rules out the involvement of any radical hydroxyl species in the strand cleavage. The absence of smear in the gels for an incubation time of up to 6 h also precludes any radical cleavage. Once again, the extent of DNA cleavage is found to be the same under argon, suggesting the oxygen-independent cleavage pathway. This indicates the non-oxidative nature of the DNA cleavage. The cleavage reactions have also been studied using different complex concentrations and incubation times. The % DNA cleavage for complex **2** is 52, 91 and 100% after 1.5, 6 and 10 h incubation time, respectively, at a concentration of 500 μM. The data reveal the essential role of the α-amino acid Schiff bases in promoting the Lewis acid/base activity for the enhancement of the hydrolytic cleavage, while the primary role of the heterocyclic base is to bind DNA in the minor groove.[30]

The plot showing the extent of DNA cleavage by [Cu(salgly)(dpq)] (**2**) with reaction time is displayed in Figure 4. The decrease in form I (SC) and the formation of form II (NC) of DNA with time show the expected exponential nature of the curves. The plot of log (% SC-DNA) with time gave a linear fit from which the hydrolytic pseudo-first-order rate constant ($k_{obsd.}$) is obtained (5.0×10^{-4}·s^{-1} or 1.8 h^{-1}), using a complex concentration of 1 mM (Figure 4, inset). Ito and co-workers have reported a copper(II) complex

(0.095 mM) of *cis,cis*-1,3,5-triaminocyclohexane that has been shown to cleave DNA hydrolytically with a rate constant of 4.3 h^{-1}.[31] The rate of DNA hydrolysis by complex **2** is lower than this complex, but significantly higher than other copper(II) amine complexes, which have rate constants in the range 0.04−0.25 h^{-1}.[32−37] These studies were carried out under excess catalyst (pseudo-Michaelis−Menten) conditions and do not represent multiple turnover activity. The copper(II)−L-histidine complex is known to cleave DNA hydrolytically, however, at a rate of 0.76 h^{-1} with a complex concentration of 1.0 mM.[38] We have studied the saturation kinetics by varying the concentrations of both SC DNA (40−125 μM) and the complex (0.1−4.0 mM). Under Michaelis−Menten conditions, a 1.0 mM concentration of **2** is found to show saturation with a DNA concentration of 66.6 μM (Figure 5). The $k_{cat.}$ value obtained from the plot is 1.71 h^{-1} (2.85 × 10^{-2} min^{-1}).

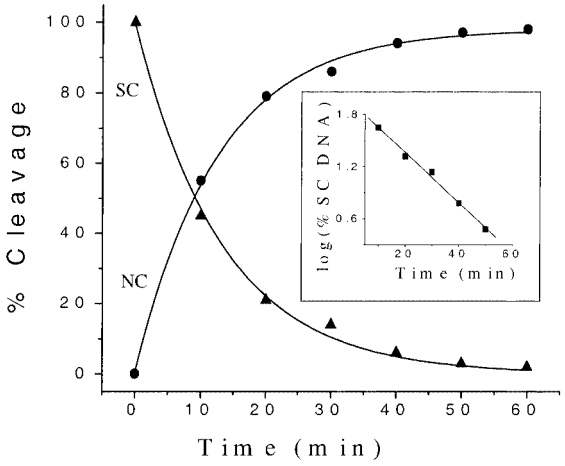

Figure 4. Hydrolytic cleavage of SC pUC19DNA (ca. 0.5 μg) showing the decrease in form I (SC DNA) and the formation of form II (NC DNA) with the incubation time (in the dark) using 1.0 mM concentration of **2**; inset shows the plot of log (% SC DNA) vs. time for complex **2** (1.0 mM) at 37 °C at pH = 7.2 for an incubation period of 10−60 min

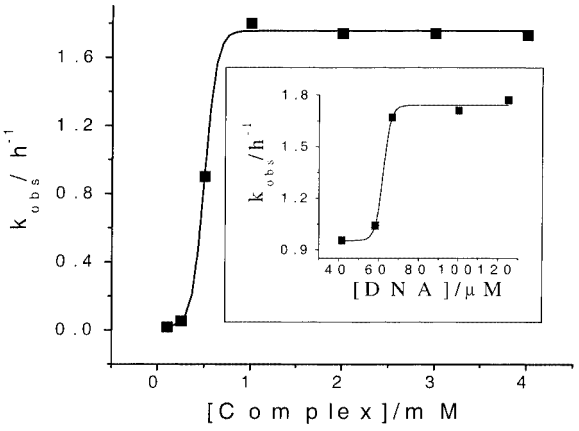

Figure 5. Saturation kinetics for the cleavage of SC pUC19 DNA (ca. 0.5 μg) by **2** at pH = 7.2 and 37 °C; inset displays the variation of the observed rate constant with SC DNA concentration (concentration of complex **2** is 1.0 mM)

Conclusion

Ternary copper(II) complexes having tridentate ONO-donor α-amino acid salicylaldimine Schiff bases and planar NN-donor heterocyclic bases are prepared and characterized. The crystal structure of **3** shows a CuN_3O_2 square-pyramidal (4+1) coordination. The complexes show efficient oxidative and hydrolytic cleavage activities. The dpq complexes, with higher DNA-binding abilities, exhibit efficient hydrolytic cleavage activities in the absence of any reducing agent and light. Mechanistic studies reveal the minor groove binding of the complexes and the involvement of the hydroxyl radical in the oxidative cleavage reactions. Hydrolytic cleavage occurs in the presence of DMSO and in the absence of oxygen. The role of heterocyclic base in complexes **1**−**6** is primarily to bind DNA at the minor groove. The amino acid Schiff bases with labile carboxylate and/or phenolato oxygen sites could be responsible for promoting the hydrolytic cleavage of DNA by utilizing the strong Lewis acid properties of copper in the +2 oxidation state. The observed DNA hydrolysis rate (1.8 h^{-1}) for **2** provides further scope for designing analogous amino acid or peptide-based copper(II) complexes or their hybrids to increase cleavage activity by enhancing the Lewis acid property of the metal ion, as well as for cellular use.

Experimental Section

Materials and Physical Measurements: All chemicals and reagents were purchased from commercial sources and were used without further purification. Glycine, L-alanine, L-phenylalanine, L-ascorbic acid and 2,2′-bipyridine were obtained from SD Fine Chemicals, Mumbai. Copper(II) acetate hydrate was bought from BDH (India). The solvents were purified by standard procedures.[39] The precursor complex [Cu(salgly)(H_2O)]·0.5H_2O, where salgly is the *N*-salicylideneglycinato dianion, was prepared by a literature method.[27] The other Schiff bases, viz. *N*-salicylidene-L-alanine

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

(H_2salala) and *N*-salicylidene-L-phenylalanine (H_2salphe), were prepared by the condensation of salicylaldehyde with the respective L-amino acid in the presence of LiOH according to a reported procedure.[40] The dipyrido[3,2-*d*:2′,3′-*f*]quinoxaline (dpq) ligand, [Cu(salgly)(bpy)] and $[Cu(phen)_2(H_2O)](ClO_4)_2$ were prepared according to literature methods.[24,41,42] Calf thymus (CT) DNA and super-coiled (SC) pUC19 DNA were purchased from Bangalore Genie (India). Agarose (molecular biology grade) and ethidium bromide were from Sigma (USA). All solvents were purified before use as per standard procedures. The Tris-HCl buffer solution was prepared using deionized, sonicated triple distilled water.

Syntheses

Preparation of [Cu(salgly)(phen)] (1) and [Cu(salgly)(dpq)] (2): An aqueous methanolic solution (30 mL, 1:5 v/v) of $[Cu(salgly)(H_2O)]\cdot 0.5H_2O$ (0.39 g, 1.1 mmol) was treated with the heterocyclic base (0.22 g phen or 0.26 g dpq, 1.1 mmol) whilst stirring at 25 °C for 1 h. The product was isolated as a dark green solid in ca. 80% yield on evaporation of the solvent. The complex was crystallized by slow concentration of an aqueous methanolic solution at 5 °C. **1:** $C_{21}H_{15}CuN_3O_3$ (420.5): calcd. C 59.93, H 3.57, N 9.99; found C 59.67, H 3.88, N 9.86. IR (KBr phase): $\tilde{\nu}$ = 3417 br, 1642 s, 1595 s, 1359 m, 1199 m, 1122 m, 849 w, 719 m cm^{-1}. **2:** $C_{23}H_{15}CuN_5O_3$ (472.5): calcd. C 58.41, H 3.17, N 14.81; found C 58.18, H 3.09, N 14.75. IR (KBr disc): $\tilde{\nu}$ = 3427 br, 1642 s, 1605 s, 1528 s, 1455 m, 1342 m, 1122 m, 1086 m, 736 w, 436 w cm^{-1}.

Preparation of [Cu(salala)(phen)] (3), [Cu(salala)(dpq)](4), [Cu(salphe)(phen)] (5) and [Cu(salphe)(dpq)] (6): The complexes were prepared by a general method. An aqueous methanolic solution (20 mL, 1:4 v/v), containing copper(II) acetate hydrate (0.2 g, 1.0 mmol) and the heterocyclic base (0.22 g phen or 0.26 g dpq, 1.1 mmol), was treated with a methanolic solution (5 mL) of the Schiff base (0.19 g H_2salala or 0.27 g H_2salphe, 1.0 mmol) whilst stirring at 25 °C for 1 h. The color of the solution turned to dark green. Slow evaporation of the solvent at 5 °C gave the analytically pure product in ca. 70% yield; dark green crystalline blocks were obtained. The solid was isolated, washed with hexane and dried in vacuo over P_4O_{10}. **3:** $C_{22}H_{17}CuN_3O_3$ (434.5): calcd. C 60.76, H 3.91, N 9.67; found C 60.55, H 4.08, N 9.95. Polarimetric data: $[\alpha]_{589}$ = +26 (*c* = 10 mg/ml, MeOH). IR (KBr phase): $\tilde{\nu}$ = 3417 br, 1635 s, 1596 s, 1449 s, 1393 m, 1109 m, 1022 m, 915 m, 768 w cm^{-1}. **4:** $C_{24}H_{19}CuN_5O_3$ (488.5): calcd. C 58.96, H 3.89, N 14.33; found C 59.13, H 4.04, N 14.39. Polarimetric data: $[\alpha]_{589}$ = +29 (*c* = 10 mg/ml, MeOH). IR (KBr phase): $\tilde{\nu}$ = 3387 br, 1605 s, 1575 s, 1472 s, 1389 s, 1086 m, 822 m, 766 w, 736 w, 443 w cm^{-1}. **5:** $C_{28}H_{20}CuN_3O_3$ (509.5): calcd. C 65.95, H 3.93, N 8.24; found C 66.17, H 4.16, N 7.99. IR (KBr phase): $\tilde{\nu}$ = 3390 br, 1625 s, 1595 s, 1445 s, 1349 s, 1199 m, 1152 m, 849 m, 766 w, 499 w cm^{-1}. **6:** $C_{30}H_{20}CuN_5O_3$ (561.5): calcd. C 64.11, H 3.56, N 12.47; found C 64.30, H 3.92, N 12.27. IR (KBr phase): $\tilde{\nu}$ = 3430 br, 1636 s, 1599 s, 1450 s, 1383 s, 1129 m, 1022 m, 915 w, 768 w cm^{-1}.

DNA Binding and Cleavage Experiments: The concentration of the CT DNA, used for the binding experiments studied by spectroscopic methods, was determined by recording the absorption intensity at 260 nm with a known molar extinction coefficient of 6600 $dm^3\ mol^{-1}\ cm^{-1}$.[43] In order to compare the relative binding of complexes **1**−**6** to DNA with respect to the analogous phen complex, an ethidium bromide bound CT DNA solution in Tris-HCl / NaCl buffer (pH = 7.2) was treated with an increasing amount of the complex solution. The fluorescence intensities at 601 nm (510 nm excitation) of ethidium bromide (EB) in the bound form were plotted against the complex concentration. Competitive binding studies were done using an EB-bound DNA which show an enhanced emission intensity relative to free EB.[44,45] Binding of the complex resulted in the displacement of DNA-bound EB molecules, with a reduction of emission intensity due to fluorescence quenching of free EB by the solvent molecules.[46] The extent of complex binding to DNA was estimated from the relative decrease of the emission intensity of EB on addition of the complex. Bis(phen)copper(II) complex was used as a standard in the binding studies. The cleavage of DNA was monitored using agarose gel electrophoresis. Supercoiled pUC19 DNA (6μL, ca. 500 ng) in Tris-HCl buffer (50 mM) with 50 mM NaCl (pH = 7.2) was treated with the metal complex (40 μM in DMF) and 3-mercaptopropionic acid (2 μL, 100 μM), followed by dilution with the Tris-HCl buffer to a total volume of 20 μL. The samples were incubated at 37 °C for 1 h. A loading buffer containing 25% bromophenol blue, 0.25% xylene cyanol and 30% glycerol (3 μL) was added. Electrophoresis was performed at 60 V for 2 h in TAE buffer using 0.8% agarose gel containing 1.0 μg/mL ethidium bromide. Bands were viewed by UV light and photographed. The cleavage efficiency was measured by determining the ability of the complex to convert the supercoiled (SC) DNA to nicked circular form (NC). After electrophoresis, the proportion of DNA in each fraction was estimated quantitatively from the intensities of the bands using the UVITEC Gel Documentation System. The fraction of the original supercoiled DNA that was converted into the NC form at the end of the reaction was calculated after correcting for the low level of NC present in the original sample and the low affinity of ethidium bromide for SC relative to NC and linear forms of DNA.[47] For hydrolytic cleavage, DNA and complex were added in the dark and incubated for longer than required. Inhibition reactions were carried out by adding different reagents such as distamycin (200 μM) and DMSO (4 μL) prior to the addition of the complex.

X-ray Crystallography: Complex **3** was crystallized on slow concentration of an aqueous methanolic solution at room temperature. A crystal of approximate size 0.54 × 0.38 × 0.28 mm was mounted on a glass fiber with epoxy cement. All geometric and intensity data were collected using an automated Enraf−Nonius CAD4 diffractometer equipped with Mo-K_α radiation (λ = 0.71073 Å). The intensity data, collected using the ω-scan technique for 4550 reflections in the range $1.4° < \theta < 25°$, were corrected for Lorentz polarization effects and for absorption.[48] Structure determination was carried out using 3511 data with $I > 2\sigma(I)$ and 608 parameters using the SHELX system of programs[49] by a combination of Patterson and Fourier techniques and refined by full-matrix least squares on F^2. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were fixed in their calculated positions and were refined using a riding model. The perspective view of the molecule was obtained using ORTEP.[50] Selected crystal data are given in Table 5. CCDC-214929 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Keywords: Chiral ligands / Enantioselectivity / Hydroformylation / Palladium / Platinum / Rhodium

The new short-bite chiral ligands (S_c)-*N*,*N*-bis(diphenylphosphanyl)-*sec*-butylamine [(S_c)-**1**], (R_a,R_a)-*N*,*N*-bis(binaphthylphosphonito)phenylamine [(R_a,R_a)-**2**] and (R_a,S_c)-*N*-(diphenylphosphanyl)-*N*-(binaphthylphosphonito)-*sec*-butylamine [(R_a,S_c)-**3**] have been treated with rhodium(I), palladium(II) and platinum(II) substrates. The (S_c)-**1** ligand reacts with [Pd(C_6H_5CN)$_2$Cl$_2$], [Pt(COD)Cl$_2$] and [Rh(COD)(THF)$_2$]PF$_6$ to afford the products [Pd(S_c-**1**)Cl$_2$] (**4**), [Pt(S_c-**1**)Cl$_2$] (**5**) and [Rh(COD)(S_c-**1**)]PF$_6$ (**6**), respectively, in high yields. By bubbling CO to a CH_2Cl_2 solution of **6**, we formed the dicarbonyl species [Rh(CO)$_2$(S_c-**1**)]PF$_6$ (**7**), which is stable only in solution under CO. Compounds **4** and **5** were characterized additionally by X-ray diffraction studies. The ligand (R_a,R_a)-**2** reacts with [Pd(C_6H_5CN)$_2$Cl$_2$] and [Pt(COD)I$_2$] to give [Pd(R_a,R_a-**2**)Cl$_2$] (**8**) and [Pt(R_a,R_a-**2**)I$_2$] (**9**), respectively; the reaction with [Rh(CO)$_2$Cl]$_2$ or [Rh(COD)(THF)$_2$]PF$_6$ affords a mixture of mono- and binuclear compounds, in which the ligand is oxidized to the corresponding phosphonate or is partially hydrolysed. The compounds [Pd(R_a,S_c-**3**)Cl$_2$] (**10**) and [Pt(R_a,S_c-**3**)I$_2$] (**11**) were obtained in the analogous reactions using the asymmetric (R_a,S_c)-**3** ligand. This ligand reacted with [Rh(CO)$_2$Cl]$_2$ in a 2:1 molar ratio in hexane to give a mixture of products in almost equal amounts. The $^{31}P\{^1H\}$ NMR spectrum recorded in $CDCl_3$ allowed us to identify the chelate [Rh(R_a,S_c-**3**)(CO)Cl] (**12**); the nature of the accompanying dinuclear species **13** is not clear. The catalytic systems formed by [Rh(acac)(CO)$_2$] and the ligands (R_a,R_a)-**2** and (R_a,S_c)-**3**, at ligand/metal ratios of 1:1 and 1:2, were unstable under the experimental conditions used (CO/H_2 pressure of 50 atm and temperature of 40 °C) for the hydroformylation of styrene; instead, metallic rhodium was afforded together with unidentified decomposition products.

Introduction

The design and synthesis of new chiral ligands remains a significant research subject for the development of transition metal-catalysed asymmetric syntheses. Satisfactory enantioselectivities have been obtained when many families of ligands, with very different features, have been prepared and applied in asymmetric catalytic reactions.[1] Among these ligands, the widest range of applications have been found for those containing atropisomeric C_2-symmetric moieties.[2]

Recently, we began[3] synthesising chiral short-bite ligands that resemble the well-known bis(diphenylphosphanyl)methane (dppm), phenylpyrophosphite, and phenylaminobis(diphenylphosphane) (dpppa), but contain atropisomeric C_2-symmetric binaphthyl moieties bonded to the phosphorus donor atoms rather than the phenyl groups. We have also reported[3] the application of these ligands in palladium−allyl-catalysed reaction of 1,3-diphenylallyl acetate with dimethylmalonate. Owing to their favourable structural features, short-bite ligands have been widely used in organometallic chemistry.[4] These bidentate ligands have their donor-atoms separated by one spacer atom; their coordination to a metal centre can produce either chelated mononuclear or bridged dinuclear complexes. In the mononuclear complexes, the short-bite ligand forms a strained four-membered ring with a very narrow bite angle; in the dinuclear complexes, two metal centres are held in close proximity by the features of the bridging short-bite ligand and can cooperate to activate a substrate. This property of the dinuclear complexes has been found to operate during homogeneous catalysis.[5]

When using short-bite chiral ligands, both coordination modes (chelated mononuclear or bridged dinuclear complexes) can, in principle, produce beneficial effects during

catalytic enantioselective processes. In fact, the reduced number and rigidity of the conformational isomers formed by a strained four-membered metallacycle can induce a minor number of processes having different activation energies. For the bridged dinuclear complexes, novel modes of reactivity can be achieved for the activation of a substrate as a consequence of cooperative interactions between the metal centres.

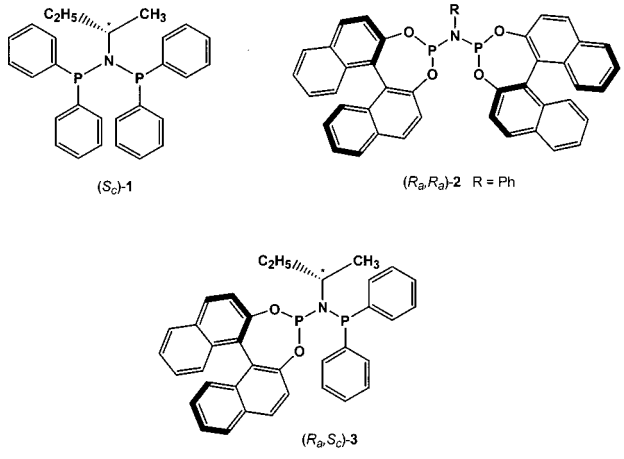
As far as we know, only a few chiral, optically pure, short-bite ligands have been reported; of these ligands, only the diphosphane MiniPHOS has been explored as a catalyst precursor in asymmetric synthesis and it affords excellent enantioselectivities in representative carbon−carbon bond-formation reactions.[6]

Prior to studying catalytic systems formed from a metal substrate and a chiral P−N−P short-bite ligand in conventional metal-catalysed asymmetric carbon−carbon bond formation, we explored the coordinating properties of the synthesized (S_c)-*N*,*N*-bis(diphenylphosphanyl)-*sec*-butylamine, (R_a,R_a)-*N*,*N*-bis(binaphthylphosphonito)phenylamine and (R_a,S_c)-*N*-(diphenylphosphanyl)-*N*-(binaphthylphosphonito)-*sec*-butylamine.

Results and Discussion

Ligands

Scheme 1 presents the new short-bite chiral P−N−P ligands used in the reactions with rhodium(I), palladium(II) and platinum(II) substrates.



Scheme 1

These ligands were designed so that we could verify the effects that the position, nature, absolute configuration and number of stereogenic centres have on the enantioselective catalysis. The ligands were synthesized[3] by reacting the corresponding primary amine RNH_2 [R = Ph, (S_c)-(+)-*sec*-$C_2H_5CHCH_3$] with the chlorodiphenylphosphane or the phosphorochloridite derived from (R_a)-binaphthol in a 1:2 molar ratio in toluene at 0 °C in the presence of an excess of NEt_3. Ligands similar to (S_c)-**1** have been reported previously,[7] but their coordination chemistry has not been explored extensively. The ligands (S_c)-**1**, (R_a,R_a)-**2** and (R_a,S_c)-**3** should behave, in principle, either as chelating, originating, four-membered metallacycles or as bridging ligands giving dimetalllic species. Literature reports indicate that the presence of an alkyl or aryl group on the nitrogen atom favours the formation of a four-membered strained ring when the ligand coordinates to a metal centre.[8]

Reactions with Rhodium(I), Palladium(II) and Platinum(II) Substrates

The reaction of $[Pd(C_6H_5CN)_2Cl_2]$ with (S_c)-**1** in a 1:1 molar ratio in CH_2Cl_2 afforded $[Pd(S_c\text{-}\mathbf{1})Cl_2]$ (**4**) in high yield as a yellow orange solid that is stable to air and moisture for a long period of time. This complex was characterized by elemental analysis and ^1H and $^{31}P\{^1H\}$ NMR spectra; an X-ray diffractometric study established its nature as a mononuclear complex, with (S_c)-**1** chelating to the palladium(II) centre. The $^{31}P\{^1H\}$ NMR spectrum of **4** in $CDCl_3$ displays a singlet at δ = 29.6 ppm; in the ^1H NMR spectrum, the chiral moiety provides the signals at δ = 0.43 (t, $^3J_{H,H}$ = 7 Hz, CH_3), 0.79 (d, $^3J_{H,H}$ = 7 Hz, CH_3), 1.29 and 0.95 (m, diastereotopic CH_2) and 3.28 (m, CH) ppm.

Similarly to $[Pd(C_6H_5CN)_2Cl_2]$, $[Pt(COD)Cl_2]$ reacted with an equimolar amount of (S_c)-**1** in toluene to give $[Pt(S_c\text{-}\mathbf{1})Cl_2]$ (**5**) as a white microcrystalline solid that is stable to air for a long time in the solid state and in solution. An X-ray diffractometric study indicated that **5** is isostructural with **4**. In its $^{31}P\{^1H\}$ NMR spectrum in $CDCl_3$, the phosphorus atom resonance of **5** appears as a singlet at δ = 15.5 ppm having ^{195}Pt satellites ($^1J_{Pt,P}$ 3285 Hz); in the ^1H NMR spectrum, the pattern of the chiral moiety CHMeEt is the same as that obtained for **4**, except that it shows additional peaks due to ^{195}Pt satellites.

The addition of a THF solution of (S_c)-**1** to an equimolar solution of $[Rh(COD)(THF)_2]PF_6$, obtained in situ from $[Rh(COD)Cl]_2$ and NH_4PF_6, in THF, readily gave $[Rh(COD)(S_c\text{-}\mathbf{1})]PF_6$ (**6**) as an orange solid. Analytical and conductivity data, together with CO reactivity and NMR spectroscopic data, support this formulation. In fact, the $^{31}P\{^1H\}$ NMR spectrum in $CDCl_3$ displays a doublet at δ = 50.1 ppm ($^1J_{RhP}$ = 134 Hz). Upon bubbling CO into a CH_2Cl_2 solution of **6**, displacement of COD occurs readily with formation of the dicarbonyl species $[Rh(CO)_2(S_c\text{-}\mathbf{1})]PF_6$ (**7**) [$\tilde{\nu}_{CO}$ (CH_2Cl_2) = 2059 and 2098 cm^{-1}] together with small amount of another carbonyl compound, which is very likely to be the five-coordinate species $[Rh(CO)_3(S_c\text{-}\mathbf{1})]PF_6$; compound **7** requires a CO atmosphere and can be handled only in solution.

The ligand (R_a,R_a)-**2** reacts in solution with $[Pd(C_6H_5CN)_2Cl_2]$ and $[Pt(COD)I_2]$ to give $[Pd(R_a,R_a\text{-}\mathbf{2})Cl_2]$ (**8**) and $[Pt(R_a,R_a\text{-}\mathbf{2})I_2]$ (**9**), respectively, as yellow-orange solids (Scheme 2).

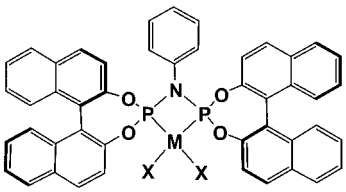

Scheme 2

These formulations are based on analytical and NMR spectroscopic data. The resonances of the phosphorus atoms appear in the $^{31}P\{^1H\}$ NMR spectra, recorded in $CDCl_3$, as singlets at higher fields than the free ligand, at δ = 82.1 and 94.5 ppm ($^1J_{Pt,P}$ = 5296 Hz) for **8** and **9**, respectively. Both **8** and **9** are moderately stable to air and moisture.

The reaction of (R_a,R_a)-**2** with $[Rh(CO)_2Cl]_2$ or $[Rh(COD)(THF)_2]PF_6$ leads to the formation of a mixture of compounds in which the ligand is oxidized to the corresponding phosphonate or is partially hydrolysed. We were not able to obtain fully characterized products from these mixtures.

The asymmetric (R_a,S_c)-**3** ligand reacts in CH_2Cl_2 with $[Pd(C_6H_5CN)_2Cl_2]$ in a 1:1 molar ratio to afford [Pd(R_a,S_c-**3**)Cl_2] (**10**) together with small trace amounts of **4**. The formation of **4** by $N-P_{Phosphonite}$ bond cleavage of **10** in the presence of trace amounts of H_2O[9] is very unlikely; most probably the formation of **4** is due to the presence of trace amounts of (S_c)-**1** as an impurity in the sample of the (R_a,S_c)-**3** ligand we used. Compound **10** is a yellow solid that is moderately stable in the presence of air or moisture; it was isolated in low yield after column chromatography. Its formulation is supported by the presence of two doublets in the $^{31}P\{^1H\}$ NMR spectrum recorded in $CDCl_3$ at δ = 81.8 and 39.9 ppm, with $^2J_{P,P}$ = 17 Hz, which correspond to the phosphonito and phosphino phosphorus atoms, respectively.

Similarly to $[Pd(C_6H_5CN)_2Cl_2]$, $[Pt(COD)I_2]$ reacted with (R_a,S_c)-**3** in a 1:1 molar ratio in toluene to give the product [Pt(R_a,S_c-**3**)I_2] (**11**) as a white microcrystalline solid that is moderately stable to air in the solid state and in solution. Its formulation is supported by the presence of resonances in the $^{31}P\{^1H\}$ NMR spectrum, recorded in $CDCl_3$, that correspond to phosphonito and phosphino phosphorus atoms, together with peaks due to ^{195}Pt satellites.

The reaction of (R_a,S_c)-**3** with $[Rh(CO)_2Cl]_2$ in a 2:1 molar ratio in hexane led to a mixture of products in almost equal amounts. The $^{31}P\{^1H\}$ NMR spectrum of the crude product, recorded in $CDCl_3$ (see a in Figure 1), allows us to identify the chelate [Rh(R_a,S_c-**3**)(CO)Cl] (**12**) and a dinuclear species **13**, the nature of which we are not able to fully explain.

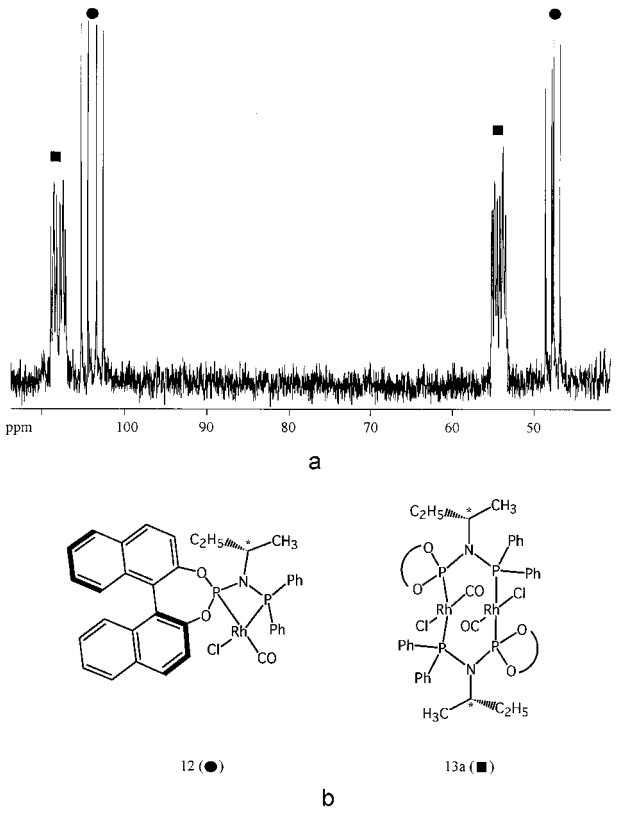

Figure 1. $^{31}P\{^1H\}$ NMR spectrum in $CDCl_3$ at 298 K: filled black square: compound **13**, filled black circle: compound **12**

The formulation of compound **12** as a chelated mononuclear species is supported by the pattern of the phosphorous atom resonances in the $^{31}P\{^1H\}$ NMR spectrum and the $^1J_{RhP}$ values. As expected for the proposed structure, compound **12** exhibits two doublets of doublets in the $^{31}P\{^1H\}$ NMR spectrum, recorded in $CDCl_3$, centred at δ = 103.9 ppm (dd, $^1J_{RhP}$ = 222, $^2J_{P,P}$ = 98 Hz) and at δ = 47.7 ppm (dd, $^1J_{RhP}$ = 122, $^2J_{P,P}$ = 98 Hz) for the phosphonito and phosphino phoshorus atoms, respectively; the value of $\tilde{\nu}_{CO}$ at 1990 cm^{-1} (nujol mull) in the IR spectrum supports a structure in which the carbonyl unit is in a trans position to the higher-trans-influence phosphonito group. As shown in Figure 1 (a), the NMR spectrum of the crude product also indicates, in the region of the phosphonito and phosphanyl phoshorus atom resonances, well-resolved signals at δ = 108.0 (ddd, $^1J_{RhP}$ = 133, $^2J_{P,P}$ = 46, $^2J_{P,P}$ = 35 Hz) and 54.4 ppm (ddd, $^1J_{RhP}$ = 124, $^2J_{P,P}$ = 46, $^2J_{P,P}$ = 35 Hz) arising from AA′BB′XX′ systems. These spectroscopic data allow us to assign a dinuclear structure to **13**, but they are not sufficient to fully characterize it. On the basis the $^{31}P\{^1H\}$ NMR spectroscopic data, we tentatively propose for **13** the dinuclear head-to-tail structure, **13a** (see b in Figure 1).[10] The large decrease in the value of $^1J_{RhP}$ on proceeding from **12** to **13** can also suggest an oxidation process from Rh^I to Rh^{II} and propose an $Rh^{II}-Rh^{II}$ undefined dimer formulation.[11,12] We have ascertained that **12** and **13** do not interconvert; the bulkiness of the binaphthyl

moiety probably prevents the exchange reaction between **12** and **13**.

Crystal and Molecular Structure of [Pd(S_c-**1**)Cl_2] (**4**) and [Pt(S_c-**1**)Cl_2] (**5**)

Compounds **4** and **5** are isostructural. In the crystals of **4** (and of **5**), two crystallographically independent, but very similar, complexes of [Pd(S_c-**1**)Cl_2] (and of [Pt(S_c-**1**)Cl_2]) are present. ORTEP views of one of the two molecules of the complexes **4** and **5** are shown in Figure 2 and 3, respectively.

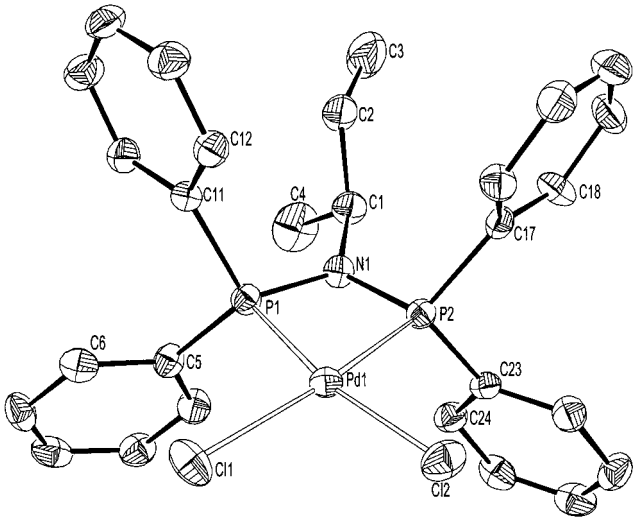

Figure 2. View of one of the two independent molecules of **4**, together with the atomic numbering system. Thermal ellipsoids are drawn at the 30% probability level

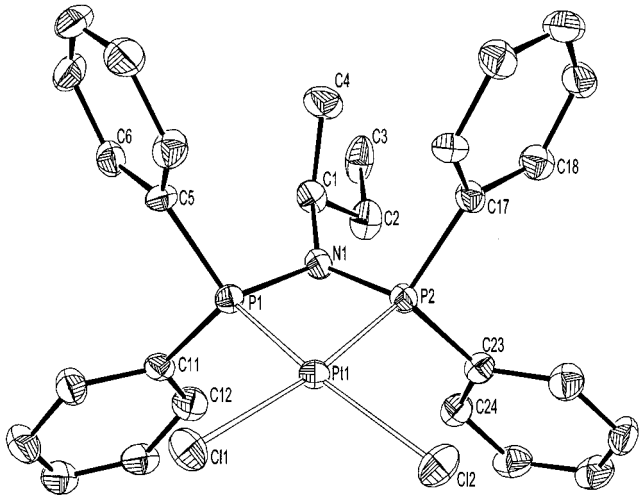

Figure 3. View of one of the two independent molecules of **5**, together with the atomic numbering system. Thermal ellipsoids are drawn at the 30% probability level

Lists of selected bond lengths and angles of **4** and **5** are given in Table 1 and 2, respectively.

The metal center is in a slightly distorted square-planar environment, being coordinated by two chlorine atoms and two phosphorous atoms of the chelating (S_c)-**1** ligand. The chelating ligand forms a four-membered ring with the N1 atom deviating by ca. 0.15 Å from the plane formed by the P1, P2 and Pd1 (or Pt1) atoms. The P1−Pd1−P2 and P1−Pt−P2 bite angles are 71.7 and 72.0° in **4** and **5**, respectively. The absolute configuration of the chiral carbon atom C1 is confirmed to be *S*.

Catalysis

We used the catalytic systems formed by [Rh(acac)$(CO)_2$] and ligands (R_a,R_a)-**2** and (R_a,S_c)-**3**, at ligand-to-metal ratios of 1:1 and 1:2, in the hydroformylation of styrene. The catalytic runs were carried out in benzene solutions using an equimolar mixture of hydrogen and carbon monoxide gases. The catalytic systems so formed were unstable under the experimental conditions (using a CO/H_2 pressure of 50 atm and a temperature of 40 °C) and afforded metallic rhodium together with unidentified decomposition products. Thus, the ligands (R_a,R_a)-**2** and (R_a,S_c)-**3** are unsuitable for the enantioselective rhodium-catalysed hydroformylation of styrene.

Experimental Section

The ligands (S_c)-**1**, (R_a,R_a)-**2** and (R_a,S_c)-**3** were prepared as reported in the literature.[3] All other reagents were purchased from Sigma−Aldrich and Strem and used as supplied. All reactions were performed under dry nitrogen in a vacuum system or in Schlenk apparatus. All solvents were purified by conventional procedures and freshly distilled prior to use. For column chromatography, we used silica gel 60 (220−440 mesh) purchased from Fluka. IR spectra were obtained from Nujol mulls on KBr plates using a Perkin−Elmer FTIR 1720 spectrometer. ^{1}H and ^{31}P{^{1}H} NMR spectra were recorded with a Bruker AMX R300 instrument. ^{1}H NMR spectra were referenced to internal tetramethylsilane and ^{31}P{^{1}H} spectra to external 85% H_3PO_4; positive chemical shifts for all nuclei are at relatively higher frequencies. Elemental analyses were performed by Redox s.n.c., Monza, Milano.

[Pd(S_c-1)Cl$_2$] (4): Solid (S_c)-**1** (0.46 g, 1.04 mmol) was added to a solution of [Pd(PhCN)$_2$Cl$_2$] (0.40 g, 1.04 mmol) in CH_2Cl_2 (30 mL).The mixture was stirred at room temperature for about 30 min. During this time, the solution became turbid and its colour switched from dark- to bright-orange. After filtration, evaporation of the solvent under reduced pressure yielded a solid that was washed twice with hexane and crystallized from CH_2Cl_2/petroleum ether (3:1, 15 mL) to obtain an orange-yellow crystalline solid. Yield: 73% (0.470 g, 0.76 mmol). ^{1}H NMR ($CDCl_3$): δ = 8.02−7.55 (m, 20 H, Ar−H), 3.28 (m, 1 H, CH), 1.29 (m, 1 H, CH_2), 0.95 (m, 1 H, CH_2), 0.79 (d, ^3J = 7 Hz, 3 H, CH_3), 0.43 (t, ^3J = 7 Hz, 3 H, CH_3) ppm. ^{31}P{^{1}H} NMR ($CDCl_3$): δ = 29.6 (s) ppm. $C_{28}H_{29}Cl_2NP_2Pd$ (618.80): calcd. C 54.35, H 4.72, Cl 11.46, N 2.26; found C 54.26, H 4.68, Cl 11.70, N 2.14.

[Pt(S_c-1)Cl$_2$] (5): Following the same procedure used for the synthesis of **4**, compound **5** was obtained as a white crystalline solid by reacting [Pt(COD)Cl$_2$] (0.50 g, 1.33 mmol) and (S_c)-**1** (0.59 g, 1.33 mmol). Yield: 82% (0.777 g, 1.09 mmol). ^{1}H NMR ($CDCl_3$): δ = 8.00 (m, 10 H, Ar−H), δ = 7.50 (m, 10 H, Ar−H), 3.20 (m, 1 H, C*H), 1.02 (m, 1 H, CH_2), 0.87 (m, 1 H, CH_2), 0.77 (d, ^3J = 7 Hz, 3 H, CH_3), 0.41 (t, ^3J = 7 Hz, 3 H, CH_3) ppm. ^{31}P{^{1}H} NMR ($CDCl_3$): δ = 15.5 (t, $^1J_{Pt,P}$ = 3285 Hz) ppm. $C_{28}H_{29}Cl_2NP_2Pt$ (707.49): calcd. C 47.54, H 4.13, Cl 10.02, N 1.98; found C 47.50, H 3.98, Cl 9.94, N 1.89.

[Rh(COD)(S_c-1)]PF$_6$ (6): NH_4PF_6 (0.260 g, 1.6 mmol) was added to a solution of [Rh(COD)Cl]$_2$ (0.400 g, 0.8 mmol) in THF (25 mL). The bright-yellow solution was stirred at room temperature for 30 min. Upon adding the solid ligand (S_c)-**1** (0.706 g, 1.6 mmol), an instantaneous change of colour occurred from yellow to orange, together with formation of an orange precipitate. The solvent was evaporated under reduced pressure and the residual solid was washed three times with hexane to afford the pure title complex **6** as an orange powder. Yield: 65% (0.830 g, 1.04 mmol). ^{1}H NMR ($CDCl_3$): δ = 7.80−7.40 (m, 32 H, Ar−H), 3.06 (m, 1 H, C*H), 0.82 (m, 1 H, CH_2), 0.71 (m, 1 H, CH_2), 0.64 (d, ^3J = 7 Hz, 3 H, CH_3), 0.34 (t, ^3J = 6.8 Hz, 3 H, CH_3) ppm. ^{31}P{^{1}H} NMR ($CDCl_3$): δ = 50.1 (d, $^1J_{RhP}$ = 134 Hz), −143.9 (PF_6) ppm. $C_{36}H_{41}F_6NP_3Rh$ (797.55): calcd. C 54.22, H 5.18, F 14.29, N 1.76; found C 53.92, H 5.22, F 14.15, N 1.73.

[Pd(R_a,R_a-2)Cl$_2$] (8): A solution of (R_a,R_a)-**2** (0.563 g, 0.78 mmol) in toluene (10 mL) was added dropwise to a solution of [Pd(PhCN)$_2$Cl$_2$] (0.300 g, 0.78 mmol) in the same solvent (20 mL) that was cooled in an ice bath. The reaction mixture was stirred for 30 min; during this time, precipitation of an orange solid occurred. The solid was separated by filtration, washed a few times with petroleum ether and then dried under reduced pressure to give the product **8** as an orange solid. Yield: 74% (0.519 g, 0.58 mmol). ^{1}H NMR ($CDCl_3$): δ = 8.33−7.28 (m, 29 H, Ar−H) ppm. ^{31}P{^{1}H} NMR ($CDCl_3$): δ = 82.1 (s) ppm. $C_{46}H_{29}Cl_2NO_4P_2Pd$ (899.0): calcd. C 61.46, H 3.25, Cl 7.89, N 1.56; found C 61.36, H 3.15, Cl 8.02, N 1.50.

[Pt(R_a,R_a-2)I$_2$] (9): A solution of ligand (R_a,R_a)-**2** (0.130 g, 0.18 mmol) in toluene (10 mL) was added dropwise at room temperature to a solution of [Pt(COD)I$_2$] (0.100 g, 0.18 mmol) in the same solvent (20 mL). After 1 h, the bright-yellow solution was concentrated under reduced pressure until the volume was ca. 5 mL; after the addition of pentane (30 mL), a deep-yellow solid precipitated. This solid was crystallized from CH_2Cl_2/pentane (3:1, 10 mL) to obtain the pure complex **9** as a yellow powder. Yield: 79% (0.166 g, 0.14 mmol). ^{1}H NMR ($CDCl_3$): δ = 8.49 (m, 6 H, Ar−H), 8.04−7.95 (m, 11 H, Ar−H), 7.51−7.31 (m, 4 H, Ar−H), 6.89 (m, 4 H, Ar−H), 6.80−6.75 (m, 4 H, Ar−H) ppm. ^{31}P{^{1}H} NMR ($CDCl_3$): δ = 94.5 ($^1J_{Pt,P}$ = 5296 Hz) ppm. $C_{46}H_{29}I_2NO_4P_2Pt$ (1170.59): calcd. C 47.20, H 2.50, I 21.68, N 1.20; found C 46.98, H 2.58, I 21.48, N 1.26.

[Pd(R_a,S_c-3)Cl$_2$] (10): A solution of ligand (R_a,S_c)-**3** (0.108 g, 0.189 mmol) in CH_2Cl_2 (10 mL) was added to a solution of [Pd(PhCN)$_2$Cl$_2$] (0.073 g, 0.189 mmol) in the same solvent (25 mL). The reaction mixture was stirred for 30 min at room temperature. The solution was concentrated under reduced pressure until the volume was ca. 5 mL; after the addition of pentane (30 mL), a yellow solid precipitated. This solid was crystallized from CH_2Cl_2/pentane (3:1, 10 mL), washed twice with petroleum ether and then dried under vacuum to give compound **10**. Yield: 68% (0.101 g, 0.13 mmol). ^{1}H NMR ($CDCl_3$): δ = 8.04−7.95 (m, 22 H, Ar−H),

3.15 (m, 1 H, CH), 1.18 (m, 1 H, CH_2), 0.82 (m, 1 H, CH_2), 0.73 (d, ^3J = 7 Hz, 3 H, CH_3), 0.41 (t, ^3J = 7 Hz, 3 H, CH_3) ppm. $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 81.8 (d, $^2J_{P,P}$ = 17 Hz), 39.9 (d, $^2J_{P,P}$ = 17 Hz) ppm. $C_{36}H_{31}Cl_2NO_2P_2Pd$ (784.91): calcd. C 57.74, H 4.17, Cl 9.47, N 1.87; found C 57.84, H 4.21, Cl 9.62, N 1.77.

[Pt(R_a,S_c-3)I$_2$] (11): Following the same procedure used for the synthesis of **10**, compound **11** was obtained as a white solid after reacting [Pt(COD)I_2] (0.094 g, 0.168 mmol) and solid (R_a,S_c)-**3** (0.096 g, 0.168 mmol) in CH_2Cl_2. Yield: 67% (0.115 g, 0.11 mmol). ^1H NMR ($CDCl_3$): δ = 8.04−7.95 (m, 22 H, Ar−H), 3.08 (m, 1 H, CH), 1.14 (m, 1 H, CH_2), 0.75 (m, 1 H, CH_2), 0.61 (d, ^3J = 7 Hz, 3 H, CH_3), 0.35 (t, ^3J = 7 Hz, 3 H, CH_3) ppm. $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 98.3 (d, $^2J_{P,P}$ = 19, $^1J_{Pt,P}$ 4876 Hz), 45.8 (d, $^2J_{P,P}$ = 19, $^1J_{Pt,P}$ 3218 Hz) ppm. $C_{36}H_{31}Cl_2NO_2P_2Pt$ (1020.50): calcd. C 42.37, H 3.06, I 24.87, N 1.37; found C 42.34, H 3.01, I 24.69, N 1.31.

Reaction of [RhCO)$_2$Cl]$_2$ with (R_a,S_c)-3: Solid (R_a,S_c)-**3** (0.320 g, 0.56 mmol) was added at room temperature to a stirred solution of [Rh(CO)$_2$Cl]$_2$ (0.112 g, 0.288 mmol) in hexane (30 mL). After the addition, precipitation of a yellow compound was observed. The mixture was stirred for 30 min at room temperature, and then the solvent was evaporated under reduced pressure. The solid was washed with hexane (3 × 10 mL) until the filtered solution was colourless, i.e., indicating that the excess of [Rh(CO)$_2$Cl]$_2$ had been separated. The $^{31}P\{^1H\}$ NMR spectrum of the crude product (Figure 1), recorded in $CDCl_3$, indicated the presence of both [Rh(R_a,S_c-**3**)(CO)Cl] (**12**) and [Rh(μ-R_a,S_c-**3**)(CO)Cl]$_2$ (**13**) together with other species at very low concentrations. We failed to obtain compounds **12** and **13** as analytically pure solids, either by using column chromatographic methods or differences in their solubilities. The reaction of [RhCO)$_2$Cl]$_2$ with (R_a,S_c)-**3** in a 1:2 molar ratio also afforded a mixture of **12** and **13**. **Compound [Rh(R_a,S_c-3)(CO)Cl] (12):** IR (KBr, Nujol): $\tilde{\nu}_{CO}$ = 1990 cm^{-1}. ^1H NMR ($CDCl_3$): δ = 8.04−6.95 (m, 22 H, Ar−H), 2.66 (m, 1 H, CH), 1.23 (m, 1 H, CH_2), 0.81 (m, 1 H, CH_2), 0.49 (d, ^3J = 6 Hz, 1 H, CH_3), 0.23 (t, ^3J = 7 Hz, 3 H, CH_3) ppm. $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 103.9 (dd, $^1J_{RhP}$ = 222, $^2J_{P,P}$ = 98 Hz), 47.7 (dd, $^1J_{RhP}$ = 122, $^2J_{P,P}$ = 98 Hz) ppm. **Compound [Rh(μ-R_a,S_c-3)(CO)Cl]$_2$ (13):** ^1H NMR ($CDCl_3$): δ = 8.04−6.95 (m, 44 H, Ar−H), 2.90 (m, 2 H, CH), 1.18 (m, 2 H, CH_2), 0.72 (m, 2 H, CH_2), 0.78 (d, ^3J = 7 Hz, 6 H, CH_3), 0.43 (d, ^3J = 7 Hz, 6 H, CH_3) ppm. $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 108.0 (ddd, $^1J_{RhP}$ = 133, $^2J_{P,P}$ = 46, $^2J_{P,P}$ = 35 Hz), 54.4 (ddd, $^1J_{RhP}$ = 124, $^2J_{P,P}$ = 46, $^2J_{P,P}$ = 35 Hz) ppm.

X-ray Data Collection, Structural Solution and Refinement for Compounds 4 and 5: The intensity data of compound **4** and **5** were collected at room temperature on a Bruker Smart 1000 single-crystal diffractometer. Crystallographic and experimental details for the structures are summarized in Table 3.

The structures were solved by Patterson and Fourier methods and refined by full-matrix least-squares procedures (based on F_o^2)[13] with anisotropic thermal parameters used in the last cycles of refinement for all the non-hydrogen atoms.

The hydrogen atoms were introduced into geometrically calculated positions and refined riding on the corresponding parent atoms. In the final cycles of refinement, we used a weighting scheme: $w = 1/[\sigma^2F_o^2 + (0.0069\ P)^2]$ (**4**, **Pd**), $w = 1/[\sigma^2F_o^2 + (0.0454\ P)^2]$ (**5**, **Pt**), where $P = (F_o^2 + 2\ F_c^2)/3$.

CCDC-215879 (for **4**) and -215878 (for **5 Pt**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) + 44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Synthesis, Structural Characterizations and Magnetic Properties of a Series of Mono-, Di- and Polynuclear Manganese Pyridinecarboxylate Compounds

Deguang Huang,[a] Wenguo Wang,[a] Xiaofeng Zhang,[a] Changneng Chen,[a] Feng Chen,[a] Qiutian Liu,*[a] Daizheng Liao,[b] Licun Li,[b] and Licheng Sun[c]

Keywords: Carboxylate ligands / Coordination polymers / Magnetic properties / Manganese / X-ray diffraction

Seven new manganese(II, III, IV) pyridinecarboxylate compounds $(Et_4N)[MnCl_2(pic)_2]$ (**1**, Hpic = picolinic acid) $[MnCl(pic)_2(H_2O)]\cdot H_2O$ (**2**), $[MnCl(pic)(H_2O)_2]_n$ (**3**), $[Mn(pic)_2]_n$ (**4**), $[MnCl(pic)]_n$ (**5**), $[MnCl_2(4\text{-}C_5H_4NHCOO)]_n$ (**6**) and $[Mn_2O_2(pic)_4]$ (**7**) were synthesized and structurally characterized. The picolinate ligand coordinates to the Mn ion forming a chelating five-membered ring which constructs diverse architectures by various bridging modes, such as μ-Cl, $\mu_{1,1}$- and $\mu_{1,3}$-carboxylate bridges (*syn-syn* and *syn-anti* modes). The interaction between the pyridyl rings is discussed, displaying a face-to-face π-π stacking for complex **6** and a T-shaped C–H···π attraction for complex **4**. Complex **3** has an infinite zigzag chain structure in which two neighboring Mn ions are linked by a carboxylate bridge in a *syn-anti* mode. In complex **4**, the $Mn(pic)_2$ fragments are joined to each other by double $\mu_{1,1}$-carboxylate bridges, forming a 2D layer structure. Complex **5** contains Mn_4O_4 square subunits which are connected by double μ-Cl bridges to form a grid-like 2D structure. The isonicotinate complex **6** has a zigzag chain structure containing mixed double μ-Cl and $\mu_{1,3}$-carboxylate bridges in a *syn-syn* mode. Protonation at the pyridyl-N position was found and identified by the IR and magnetic properties of **6**. The participation of an oxidizing agent like MnO_4^- leads to complexes containing higher valent manganese (**1**, **2** and **7**). The IR spectra of these complexes are discussed and found to be consistent with the structural features. The magnetic properties of complexes **4**, **5** and **6** have been investigated. Antiferromagnetic coupling interactions were observed and satisfactory fitting results were obtained with *J* values ranging from –0.63 cm^{-1} to –2.35 cm^{-1}. The magnetic parameters of these complexes, together with the parameters of other Mn complexes with comparable structures, are compared and discussed based on the bridging modes.

Introduction

Metal-ligand coordination polymers are attracting increasing attention owing to their potential applications as novel functional materials in catalysis, magnetism, molecular recognition and other fields.[1] Meanwhile, the increasing interest in the coordination chemistry of manganese also stems from the involvement of manganese in several biological redox-active systems,[2,3] especially in the oxygen-evolving complex[4] (OEC) of photosystem II (PS II), which is believed to be a tetranuclear $Mn^{II,III,IV}$ aggregate[5] with O- and N-donors from a carboxylate group and a histidine, respectively.[6] The binding[7] of water to the Mn site and the presence[8] of chloride anion are important structural features of the OEC.

Three isomers of pyridinecarboxylic acid, which contains both O- and N-donors, exhibit remarkable coordination modes to metal ions. Picolinic acid is the most commonly used to obtain metal complexes — its different coordination modes are shown in Scheme 1 — in which a chelating five-membered ring is always found. A number of Mn picolinate complexes with nuclearity[9–12] from 1 to 10 or with a polymeric structure[13] have been reported in the past two decades. However, only a few of these Mn complexes possess a polymeric structure[13] or contain a chloride ligand.[11]

Compared to the coordination modes of the picolinate, there is an obvious difference for 3-, and 4-pyridinecarboxylates, which do not form a chelate ring when they coordinate to metals. Mn complexes[14,15] of these ligands with a polymeric structure are also rare. In order to develop the diversity of the architectures in Mn pyridinecarboxylate chemistry, especially picolinate chemistry, we are interested in the preparation of Mn/pyridinecarboxylate complexes containing a chloride anion, to see what fascinating network topologies are obtained. In this work several Mn com-

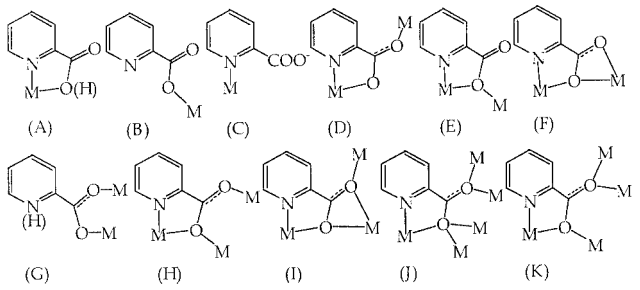

Scheme 1. Possible coordination modes of picolinate to metal ions; modes **A**, **D**, **E**, **H** and **I** have been found in Mn picolinate complexes

plexes with the Mn oxidation states from II to IV are reported, of which four complexes possess a chain-like structure and five contain Mn−Cl ligation.

Results and Discussion

Synthesis

Hundreds of manganese complexes containing Mn−Cl bonds have been reported, of which more than one hundred contain both O- and N-donors from a Schiff base and a nitrogen-containing heterocycle. In this work pyridinecarboxylic acid and $MnCl_2{\cdot}4H_2O$ were used to provide the O- and N-donors and the Cl, respectively. Complexes **1**−**7** were obtained by both conventional solution synthesis and solvothermal methods. Complex **5**, containing an Mn−Cl bond, was obtained in DMF by a solvothermal method, while with a similar molar ratio of reagents and the same reaction temperature to those used for preparing **5** (see Exp. Sect.), complex **4** was synthesized and was found not to contain an Mn−Cl component. This difference is considered to arise from the polarity of the solvents adopted for the syntheses of **4** and **5**. Depending on the polarity of the solvent, DMF or H_2O gives rise to the dissociation of the Mn−Cl bond, leading to the disappearance of the Cl component in complex **4**, while solvents with lower polarity favor the retention of the Mn−Cl bond in **5**. The participation of an oxidizing agent (MnO_4^-) results in the formation of complexes with higher valent manganese. Compounds **1**, **2** and **7** containing Mn^{III} and Mn^{IV} were obtained in the presence of the oxidizing agent or after a prolonged exposure to air. The dinuclear Mn^{IV} compound **7** has been obtained in other laboratories by different methods[10,16] with a difficulty in crystallizability. We have improved the synthesis by reducing the $KMnO_4$:$Mn(OAc)_2$ ratio to avoid the large amount of insoluble precipitates. A co-product, $Mn(pic)_3$, was obtained and isolated, leading to an improved crystallization of complex **7**.

Structure

The structures of mononuclear **1** and **2** are shown in Figure 1 and 2, respectively. Their structures contain an Mn unit together with a counterion for **1** or a solvate molecule for **2**. The Mn atom in both the compounds has a distorted octahedral coordination geometry, whilst Mn1 in complex **1** lies on a crystallographically imposed inversion centre. Both the chelating five-membered rings lie in the equatorial plane, with largest deviations of 0.1067 Å and 0.1447 Å for the constituent atoms of **1** and **2**, respectively. Two terminal *trans*-ligands coordinate to the Mn ion forming linear Cl−Mn−ClA (180° for **1**) and Cl−Mn−O5 [177.60(11)° for **2**] arrays. The Mn−Cl [2.504(1)−2.525(1) Å] and the $Mn-O_{H_2O}$ [2.324(4) Å] bond lengths are obviously lengthened, indicating a Jahn−Teller elongation of high spin d^4 Mn^{III} along the axial direction for the two Mn^{III} complexes. Consequently the $Mn^{III}-Cl$ and $Mn^{III}-O_{H_2O}$ bonds are longer than those found in the Mn^{II} complexes **3**−**6** (Table 1). This Jahn−Teller elongation has previously been observed in other Mn^{III} complexes, in which $Mn^{III}-Cl$ bond lengths of 2.510−2.541 Å were observed.[17] There was still some doubt as to whether the ligand is picolinic acid rather than picolinate. A bond valence sum (BVS) analysis[18] was therefore performed to calculate the oxi-

dation state of the metal centre. The bond valences (s) were calculated according to Equation (1), where r is the observed bond length and r_0 and B are empirically determined parameters.[18]

$$s = exp[(r_0 - r)/B] \quad (1)$$

This BVS analysis did not support an Mn^{2+} oxidation state. X-band EPR spectra were recorded on a Bruker-ER420 spectrometer for complexes **1** and **2** as solid samples. No signals were observed, which could be an indication of the Mn^{III} ion since the EPR signal is very difficult to observe with traditional perpendicular polarization EPR spectroscopy at X-band for the spin $S = 2$ Mn^{III} ion. An obvious difference between **1** and **2** is that the terminal water ligand gives rise to extended hydrogen bonding interactions between neighboring molecules of **2**, such as O5···Cl [3.272(5) Å] and $O5\cdots O_{carboxyl}$ [2.736(5) and 2.873(6) Å], giving a one-dimensional chain structure. In contrast, the structure of complex **1**, with two chloride ligands, contains only the discrete ions.

Compound **3** has an infinite zigzag chain structure in which the Mn ions are linked to each other by $\mu_{1,3}$-OCO bridges in a *syn-anti* mode, as shown in Figure 3. The Mn ion is located at the center of a distorted octahedron and the picolinate chelate ring forms the equatorial plane together with Cl and the symmetrically related O1A atoms. All the bond lengths [2.170(2), 2.171(2), 2.176(2) and 2.209(2) Å for Mn−O; 2.275(2) Å for Mn−N; 2.492(1) Å for Mn−Cl] were used for the BVS analysis.[18] The BVS of Mn was calculated to be 2.097 by summing the values of *s*, which supports the oxidation state of the Mn^{II} ion. Interestingly, except for the O3 and O4 atoms, which lie in the axial direction, all the other atoms are coplanar, with the largest deviation from the least-squares plane being 0.0197 Å. Consequently, the zigzag chain contains all the atoms in the common plane except for the axial atoms. The O3−Mn−O4 axis [178.51(8)°] is perpendicular to the plane, with bond angles (O3−Mn−X and O4−Mn−X, X = N, O, Cl) ranging from 89.21(7)° to 90.49(11)°. Figure 4 shows a packing diagram of the compound, in which hydrogen bonding interactions of the type $O_{carboxylate}\cdots H-O_{aqua}$ [2.830(3) and 2.821(3) Å] and $Cl\cdots H-O_{aqua}$ [3.144(2) and 3.153(2) Å] link the neighboring parallel zigzag chains, constructing a two-dimensional double-layer network. Rectangular channels are observed in the polymeric structure, with dimensions of 3.22 × 4.16 Å. However, these channel dimensions are measured between atom centers. In a space-filling plot (Figure 4B) taking into account the van der Waals radii, there is only a small channel left. It should also be pointed out that no π-π stacking is observed between the pyridyl rings since their separation is too large (> 3.8 Å)[19] for a van der Waals interaction; the pyridyl rings are found in a parallel and face-to-face alignment.

The structure of compound **4** is shown in Figure 5. The BVS of the central Mn ion is calculated[18] to be 2.028, indicating an Mn^{II} oxidation state and the ligand to be a picolinate anion. In the $Mn(pic)_2$ fragment, the two chelating five-membered rings are nearly perpendicular to each other,

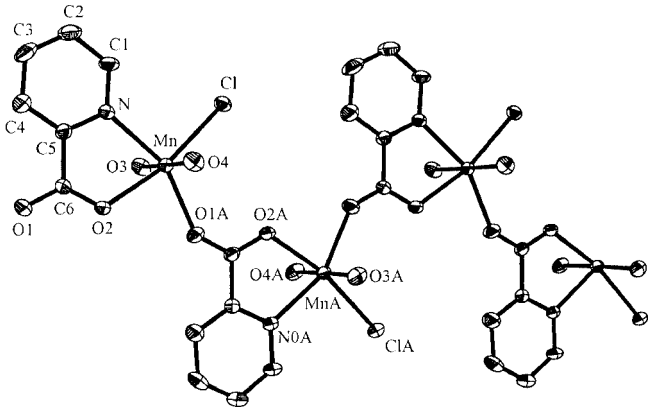

Figure 3. ORTEP representation of compound **3** showing 30% probability displacement ellipsoids and the atom numbering

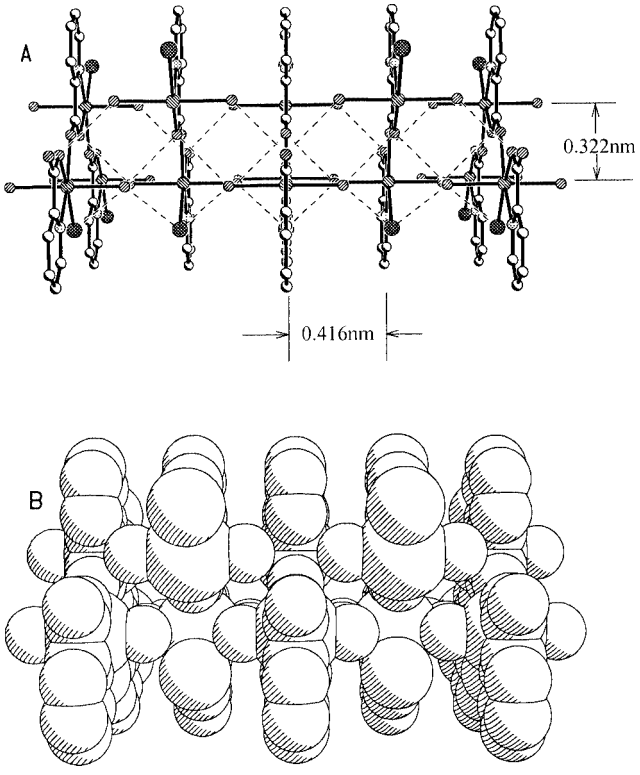

Figure 4. Packing diagram (A) of **3** showing the rectangular channels; hydrogen bonding interactions are shown by dotted lines; (B) space-filling plot to show the small channel space

with a dihedral angle of 85.2°. These fragments are linked pairwise by double μ-$O_{carboxylate}$ bridges to form [Mn_2(pic)$_4$] subunits, with an Mn···Mn distance of 3.507 Å. All the bond angles around the Mn ion range from 145.34(8)° to 160.00(9)° for *trans* angles and from 71.63(8)° to 115.63(10)° for the others, indicating a seriously distorted octahedral geometry. The picolinate anions link the Mn^{II} ions through a $\mu_{1,3}$-OCO bridge in a *syn-anti* mode together with an η^1-monodentate mode to construct a two-dimensional layer structure, as shown in Figure 6, in which π-π stacking has not been observed owing to the large separation between the parallel displaced pyridyl rings. However, a point-to-face (T-shape) interaction — a C−H···π attraction[19] — appears to exist between the pyridyl rings that are perpendicular to each other with a separation of 3.7 Å (Figure 6). An isostructural 2-pyrazinecarboxylate Mn^{II} complex[20] has been reported to have almost the same crystallographic data to that of **4**.

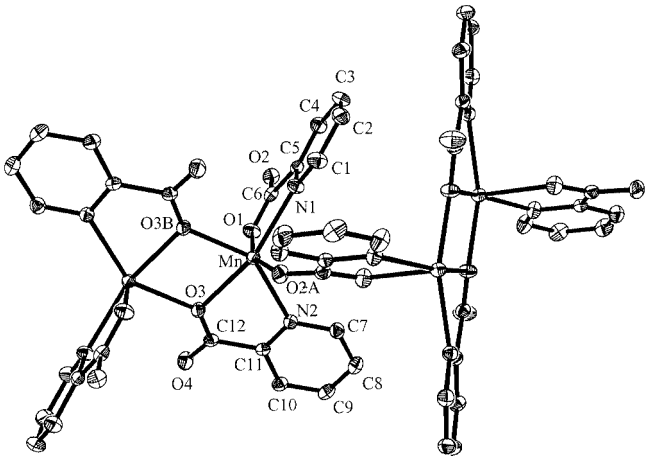

Figure 5. ORTEP representation of compound **4** showing 30% probability displacement ellipsoids and the atom numbering.

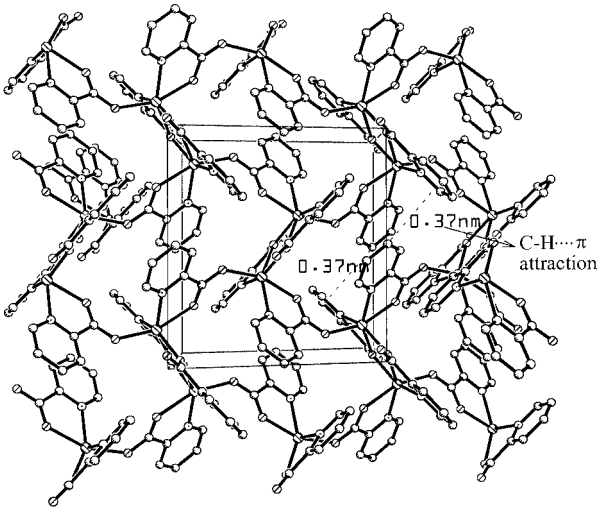

Figure 6. The 2D layer structure of compound **4** along the *a* axis

Complex **5** contains the simplest unit [Mn(pic)Cl], where the picolinate coordinates to the Mn center according to the coordination mode F (Scheme 1) to link two neighboring Mn atoms in the space group $P4_2/n$. The fragments combine, leading to a tetra-manganese [Mn_4(pic)$_4$] subunit, which has an alternating [Mn−O]$_4$ eight-membered ring that looks like a distorted square, as shown in Figure 7, with an Mn···Mn separation of 4.425 Å for each Mn···Mn edge and an O−Mn−O angle of 88.3°. The Mn−O [2.190(2), 2.342(2) and 2.232(2) Å], Mn−N [2.227(2) Å] and Mn−Cl [2.500(1), 2.501(1) Å] bond lengths were used for the BVS calculation[18] and the sum of the values of *s* is 1.98, indicating the Mn^{II} oxidation state. Two kinds of carboxylate bridges of the picolinate anion — a $\mu_{1,1}$-OCO

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

bridge and a $\mu_{1,3}$-OCO bridge in a *syn-anti* mode — link simultaneously the Mn ions to form five- and four-membered chelating rings by O,N- and O,O-donors. A small dihedral angle of 4.0° for the two chelating rings indicates an approximate coplanarity of the picolinate ligand and the two Mn ions, as shown in Figure 7. Around the $[Mn-O]_4$ square, the neighbouring picolinates are perpendicular to each other with a dihedral angle of 89.0°, while the opposite ones are approximately parallel, with a dihedral angle of 11.9°.

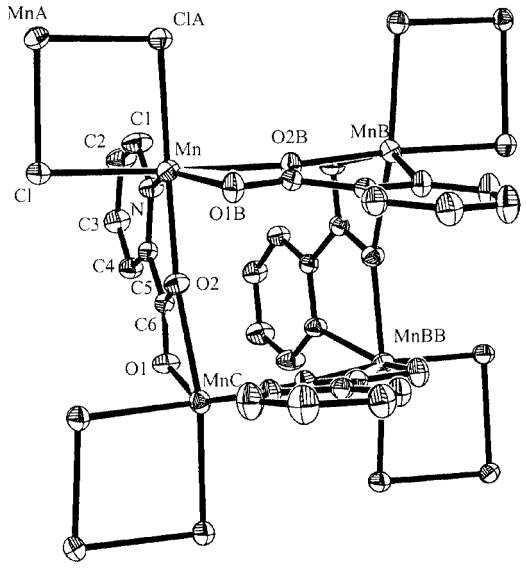

Figure 7. The unit structure of compound **5** showing 30% probability displacement ellipsoids and the atom numbering; a tetramanganese subunit $[Mn(pic)]_4$ is presented

The above $[Mn-O]_4$ squares are connected by double μ-Cl bridges forming the second type of $[Mn(\mu_2\text{-}Cl)_2Mn]$ square-like units, with an Mn−Cl distance of 2.501 Å and angles of 87.6−91.6°. An isostructural Cu analogue $[CuCl(pic)]_n$ has been reported to have similar metal-ligand square-like units.[21] The two types of squares are alternately linked by sharing the Mn ions to form a 2-D Mn_nCl_n quasi-planar grid-like sheet (Figure 8), while the picolinate planes protrude perpendicularly on both sides of the sheet. From the packing diagram (Figure 9), it can clearly be noticed that these salients interpenetrate to give a tightly packed structure without any hydrogen-bonding interactions.

The structure of the isonicotinate complex **6** is composed of a one-dimensional $[Mn(\mu\text{-}C_5H_4NHCOO)(\mu\text{-}Cl)_2]_n$ chain; the $Mn(C_5H_4NHCOO)Cl_2$ unit is shown in Figure 10. A carboxylate bridge in a *syn-syn* mode and double μ-Cl bridges exist between neighboring Mn ions. This is a novel coordination mode for Mn isonicotinate complexes. This is also the first example of a metal complex that contains mixed double Cl and single $\mu_{1,3}$-OCO bridges, the only similar bridging mode was found in $\{Hg_3(L)Cl_6\}_n$ [22] [L = 2,5-bis(pyridino)adipate] containing mixed single Cl and single $\mu_{1,3}$-OCO bridges. In addition, protonation at the pyridyl-N atom was found and was identified by IR spectroscopy (vide infra). A similar proton shift has been observed in a

few metal isonicotinate complexes.[23] The ESR spectra of **6** were recorded on a Bruker-ER420 spectrometer at X-band at room temperature and at 77 K as solid samples, showing strong signals at $g = 2$ and implying the existence of Mn^{II}

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

species with spin $S = 5/2$. A BVS calculation[18] for the Mn ion gives the sum of the *s* values to be 1.99, confirming the Mn^{II} oxidation state. The Mn^{II} ion lies at a centre of symmetry, forming a slightly distorted octahedron with O−Mn−Cl angles ranging from 87.83(5)° to 92.17(5)°. Parallel pyridine rings are alternately insert between the neighboring zigzag chains (Figure 11) with a ring separation of 3.621 Å that is slightly larger than the sum of the van der Waals contact radii (3.4 Å) for two C atoms, showing a face-to-face π-π stacking interaction. Owing to the restriction by this arrangement, the pyridine rings cannot be coplanar with the carboxylic group, and the dihedral angle was observed to be 67.2° between the carboxylate group and the pyridyl ring. Hydrogen-bonding interactions (N−H···Cl) exist between the neighboring chains to construct a 2D layer structure.

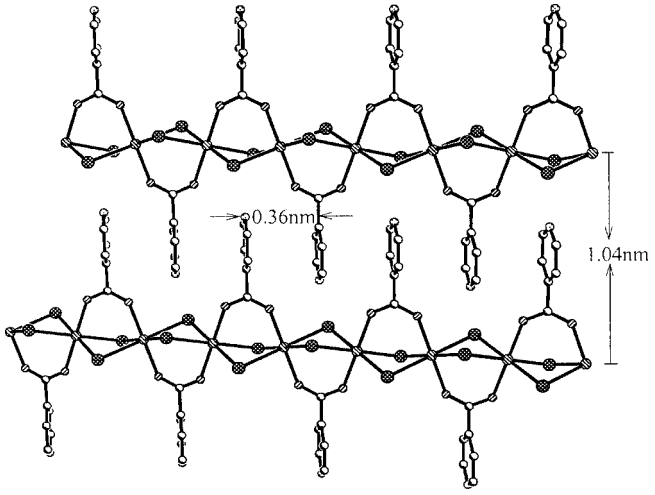

Figure 11. The 1D zigzag chain of complex **6**

Compound **7** contains Mn ions and double oxo-bridges as well as the picolinate ligands. It should be pointed out that the first such complex $[Mn_2O_2(pic)_4]\cdot CH_3CN$ was reported by Christou.[10] Similar structural parameters to those of $[Mn_2O_2(pic)_4]\cdot CH_3CN$, and the BVS of 4.1,[18] indicate that the Mn atom is definitely tetravalent in **7**. An interesting difference between both structures is the lower symmetry of **7** than that of $[Mn_2O_2(pic)_4]\cdot CH_3CN$. The structure of **7** is shown in Figure 12. A twofold axis passes through the Mn1 and Mn2 ions with an Mn−Mn bond length of 2.701(1) Å. Both the octahedral Mn ions coordinate differently to the picolinate ligands. Two nitrogen atoms are located in the *trans*-positions for the Mn1 ion, with an N1−Mn1−N1′ angle of 166.91(9)°, while they are in the *cis*-positions for Mn2, with an N2−Mn2−N2′ angle of 94.26(9)°. A similar situation is also observed for the carboxylate oxygen atoms: O1−Mn1−O1′ of 92.37(10)° and O4−Mn2−O4′ of 164.82(9)°. This is an important difference between **7** and $[Mn_2O_2(pic)_4]\cdot CH_3CN$, as in the latter both N atoms are axially arranged in the octahedron of any Mn ion.

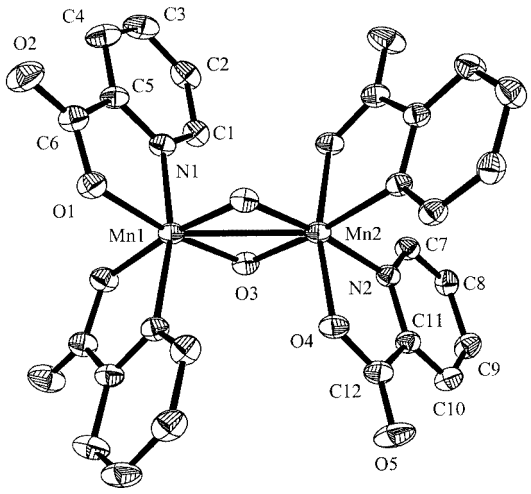

Figure 12. ORTEP representation of **7** showing 30% probability displacement ellipsoids and the atom numbering; Mn···Mn distance 2.701 Å

IR Spectroscopy

In agreement with previously published data,[9,10] the IR spectra of the Mn picolinate complexes (**1**−**5** and **7**) in the 400−4000 cm^{-1} region only exhibit signals related to the picolinate ligand, for example 1649, 1309, 1049 and 764 cm^{-1} for **1**; similar signals are found for the other complexes. The signals in the range from 1610 cm^{-1} to 1682 cm^{-1} can be assigned to the asymmetric stretching vibrations for the COO^- groups, and the signals between 1446 and 1497 cm^{-1} correspond to the symmetric stretching vibrations $\nu_s(COO^-)$. The isonicotinate signals for complex **6** are also similar to those reported previously.[15] The carboxylate in **6** exhibits similar asymmetric and symmetric stretching vibrations to those of other picolinate complexes. The N−H stretching frequency is observed at 3217 cm^{-1}, suggesting[24] protonation at the nitrogen atom of the pyridyl. Complexes **1** and **7** contain the carboxylate groups in unidentate coordination mode, and the separation (Δ) between $\nu_{as}(COO^-)$ and $\nu_s(COO^-)$ is 209 cm^{-1}, which is consistent with the generally accepted value[25] ($\Delta > 200$ cm^{-1}) for a unidentate-coordinated carboxylate, while complexes **5** and **6** give a separation value of less than 200 cm^{-1}, which is considered to correlate to a chelating carboxylate in **5** ($\Delta = 135-164$ cm^{-1}) or a bridging bidentate ligand in a *syn-syn* configuration in **6** ($\Delta = 174-197$ cm^{-1}). The strong and broad band centered at 3385 cm^{-1} for **3** is assigned to the H−O−H stretching vibration of the water ligand on the basis of the known structure. Medium-intensity absorptions are observed in the range from 3080 to 3120 cm^{-1} and can be attributed to the δ(CH) of the pyridyl.

Magnetic Properties

The magnetic properties of Mn complexes are often important. Complexes **1** and **2**, however, are mononuclear, and complex **3** has an Mn···Mn separation too large to permit magnetic exchange, while the magnetic properties have already been reported for $[Mn_2O_2(pic)_4]\cdot CH_3CN$.[10] There-

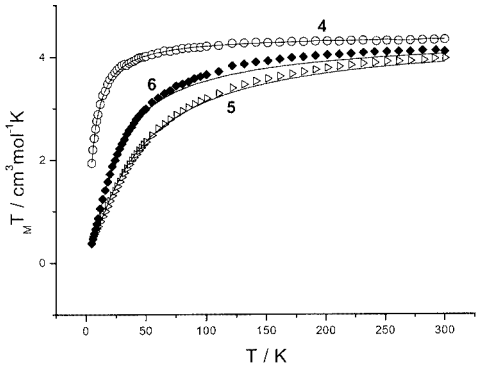

Figure 13. Thermal variations of the $\chi_M T$ product for **4** (circle), **5** (triangle) and **6** (square); the solid lines represent the best-fit curves

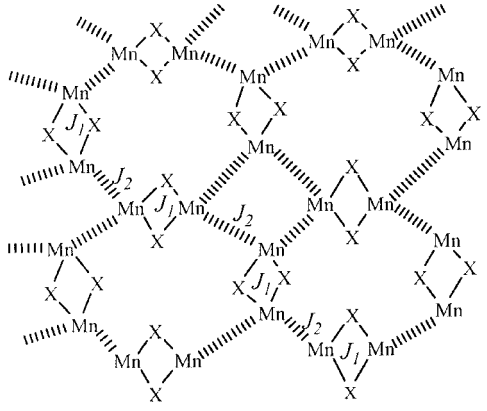
fore we report here the magnetic behavior of complexes **4**, **5** and **6**. Figure 13 shows the temperature dependence of the product ($\chi_M T$) of molar susceptibility and the temperature for the three complexes. For **4**, the value of μ_{eff} at 300 K amounts to 5.88 μ_B, close to the spin-only value of 5.92 μ_B for $S = 5/2$. For **5**, the value of μ_{eff} at 300 K amounts to 5.63 μ_B which is slightly lower than the spin-only value for $S = 5/2$. The effective magnetic moment smoothly decreases with a decrease of the temperature, indicating an antiferromagnetic interaction between neighboring magnetic species for both the complexes. Figure 6 and 8 show the 2D layer structures of **4** and **5**, which contain the [$Mn_2(\mu\text{-}O_{carboxylate})_2$] and [Mn2($\mu_{1,3}$-OCO)] moieties for **4**, and the [$Mn_2(\mu\text{-}Cl)_2$] and $Mn-O_{carboxylate}-Mn$ moieties for **5**. These moieties are arranged alternately to construct alternating chains along two directions, therefore an alternating chain with a classical spin S_{eff} is suggested as a model to analyze the magnetic data for both complexes (Scheme 2). The susceptibilities of the chains are obtained from Equation (2), which was deduced by Rojo[26] and is suitable for the fitting of an alternating chain model.



4: X = $O_{carboxylate}$ ⫶⫶⫶⫶⫶ = $\mu_{1,3}$–OCO

5: X = Cl ⫶⫶⫶⫶⫶ = μ–$O_{carboxylate}$

Scheme 2. An alternating chain ($J_1 - J_2$) with a classical spin S_{eff} is shown; the interactions between the S_{eff} chains are treated further according to a uniform chain

$$\chi_{chain} = \frac{Ng'^2\beta^2}{3kT}\left(\frac{1+u_1+u_2+u_1u_2}{1-u_1u_2}\right)$$

$$\text{where} \quad u_1 = Coth\left(\frac{J_1}{kT}\right) \qquad u_2 = Coth\left(\frac{J_2}{kT}\right) - \frac{kT}{J_2} \tag{2}$$

$$J_1 = J_1 S(S+1) \qquad g' = g[S(S+1)]^{1/2}$$

The magnetic interactions between the chains are treated based on the assumption that the alternating chain can be seen as an entity with classical spin S_{eff}. The S_{eff} should obey the Curie expressions [Equation (3)].

$$S_{eff}(S_{eff}+1) = 3k(\chi_{chain}T)/Ng^2\beta^2 \tag{3}$$

These S_{eff} entities are connected by $\mu_{1,3}$- or $\mu_{1,1}$-carboxylate bridges and can be treated as a uniform chain. Consequently, the magnetic susceptibilities of the systems can be calculated by Equation (4) for a classical chain.[27]

$$\chi_M = [Ng^2\beta^2 S_{eff}(S_{eff}+1)/3kT](1+u)/(1-u)$$

$$\text{where} \quad u = Coth[J_2 S_{eff}(S_{eff}+1)/kT] - kT/J_2 S_{eff}(S_{eff}+1) \tag{4}$$

The least-squares fitting results of the experimental data are: $g = 2.02$, $J_1 = -0.63$ cm^{-1}, $J_2 = -0.14$ cm^{-1} and $R = 4.63 \times 10^{-5}$ for **4**, and $g = 2.00$, $J_1 = -0.6$ cm^{-1}, $J_2 = -2.7$ cm^{-1} and $R = 4.92 \times 10^{-4}$ for **5**, where $R = \Sigma[(\chi_M)^{cal} - (\chi_M)^{obs}]^2/[(\chi_M)^{obs}]^2$.

The μ_{eff} value at 300 K for **6** amounts to 5.72 μ_B, close to the spin-only value of 5.92 μ_B for Mn^{II} with $S = 5/2$, supporting the protonation of the nitrogen atom in $C_5H_4N^+HCOO^-$. A uniform Mn chain model [Mn(μ-Cl)$_2$($\mu_{1,3}$-OCO)]$_n$ was used to fit the magnetic data of **6** and the magnetic susceptibility was calculated by Equation (5) for a uniform chain:[28]

$$\chi_M = \left(\frac{Ng^2\beta^2}{kT}\right)[A + Bx^2][1 + Cx + Dx^3]^{-1} \tag{5}$$

where $x = |J|/kT$, $A = 2.9167$, $B = 208.04$, $C = 15.543$ and $D = 2707.2$. These coefficients for magnetic susceptibility expressions for Heisenberg chains with $S = 5/2$ have beenused previously.[28] The least-squares fitting leads to $g = 2.00$, $J = -1.1$ cm^{-1} and $R = 2.4 \times 10^{-5}$.

Table 2 lists the magnetic parameters for the three complexes together with the parameters of other Mn complexes with similar structures. Complex **7**, containing the $Mn_2(\mu\text{-}O_{oxo})_2$ unit, shows the largest $|J|$ value among all the complexes in Table 2, which is believed to be correlated to the strong $Mn^{IV}-Mn^{IV}$ bonding interaction. Magnetically active chloride-bridged systems have been reported previously. Complexes containing an $Mn_2(\mu\text{-}Cl)_2$ unit reveal the exchange interactions via double μ-Cl bridges in the range $|J| = 0.2-16$ cm^{-1}, as shown in Table 2. The angular de-

[a] Magnetic exchange interaction through μ-Cl and $\mu_{1,3}$-OCO mixed bridges. [b] Magnetic exchange interaction through single atom μ-Cl or μ-O bridge. [c] Magnetic exchange interaction through $\mu_{1,3}$-OCO bridge. [d] This work. [e] **A**: $[Mn(pyz)_2]n$, pyz = 2-pyrazinecarboxylate. **B**: $[MnCl(MeCp)(PEt_3)]_2$. **C**: $[ppn]_2[Mn_2Cl_6]$. **D**: $[Mn(H_2dapd)C1_2]n$, H_2dapd = 2,6-diacetylpyridine dioxime. **E**: $[MnCl(pyz)(H_2O)]n$, **F**: $[\{Mn(bic)(H_2O)\}_2{\cdot}2Br]n$ (bic = bicinate).

pendence of the strength and nature of the magnetic coupling in M(μ-X)M systems has been studied in detail for Cu^{II}_2 and Cr^{III}_2 systems.[34] The Mn−Cl−Mn angle obviously plays an important role in determining the nature and strength of the chloride-mediated coupling. Complexes **5**, **6** and $[MnCl(MeCp)(PEt_3)]_2$ (**B**) have Mn−Cl−Mn angles very close to 90° in their $Mn_2(\mu\text{-}Cl)_2$ units and exhibit an antiferromagnetic coupling, while complexes **D** and **E** have angles larger than 90° and have weak ferromagnetic interactions. It seems that a smaller separation of the Mn^{II} ions (and/or smaller Mn−Cl−Mn angle) results in a larger $|J|$ value, implying that greater overlap between the magnetic orbitals in the $Mn_2(\mu\text{-}Cl)_2$ unit favors the antiferromagnetic exchange of the paramagnetic sites. Complexes **4** and $[Mn(pyz)_2]_n$ (**A**, pyz = 2-pyrazinecarboxylate), which are isostructural, both have an $Mn_2(\mu\text{-}O_{carboxylate})_2$ unit in their structures and exhibit a weak antiferromagnetic coupling. It should also be noted that magnetic coupling through a $\mu_{1,3}$-carboxylate bridge is dependent on the coordination mode of the carboxylate to the paramagnetic centers. There is an efficient overlap between the 3d magnetic orbital of the Mn^{2+} center and the 2p magnetic orbital of the carboxylate group in the order *syn-syn* > *anti-anti* > *syn-anti*.[35] Complexes **4** and **A** have the $\mu_{1,3}$-carboxylate bridges in a *syn-anti* mode, and are therefore less capable of transmitting magnetic interactions ($J_{\mu\text{-}OCO}$ = −0.14 cm^{-1}) than complex **6**, with the carboxylate in a *syn-syn* mode and double Cl bridges. In our work, the transfer pathway via a single-atom (O or Cl) bridge seems to be better than via a $\mu_{1,3}$-carboxylate bridge, $|J_{\mu\text{-}O}|$ or $|J_{\mu\text{-}Cl}| > |J_{\mu\text{-}OCO}|$. However, this is not general since exceptions have been reported by Nagata.[36] A larger $|J_{\mu\text{-}O}|$ value (−2.35 cm^{-1}) was observed for complex **5**, in spite of the larger Mn···Mn separation (4.425 Å). The only comparable complex is $[\{Mn(bic)(H_2O)\}_2{\cdot}2Br]_n$ [bic = bicinate = *N,N*-bis(2-hydroxyethyl)glycinate],[33] in which an Mn···Mn separation of 4.41 Å and Mn−O−Mn angle of 151° were found. It is thought that a linear Mn−O−Mn array may lead to an efficient overlap of the magnetic orbitals between the 3d magnetic orbitals of the Mn^{2+} and the 2p magnetic orbitals of the carboxylic oxygen atom. Consequently, complex **5** has a $|J_{\mu\text{-}O}|$ value larger than that of **4**. However, additional examples are required before such arguments can be considered valid.

Conclusion

Six new manganese picolinate or isonicotinate complexes were synthesized and structurally characterized. The chelating five-membered rings of the Mn picolinate construct diverse architectures, such as the zigzag chain of **3**, the 2D layer structure of **4** or the grid-like 2D structure of **5**, by $\mu_{1,3}$-OCO bridges in a *syn-anti* mode, and $\mu_{1,1}$-carboxylate or μ-Cl bridges, respectively. The isonicotinate complex **6** contains $MnCl_2(4\text{-}C_5H_4NHCOO)$ units which form an infinite zigzag chain by double μ-Cl and $\mu_{1,3}$-OCO bridges in a *syn-syn* mode.

In the syntheses of these complexes, the participation of an oxidizing agent leads to complexes with higher-valent manganese (III or IV for **1**, **2** and **7**). The removability of the chloride anion depends on the polarity of the solvent. Strongly polar DMF or H_2O allow the dissociation of the Mn−Cl bond, while other solvents favor the retention of the Mn−Cl bond in the products. This removability may be related to the doubts over whether the Cl^- ion is a ligand of the Mn site in OEC. We have assumed that the Cl^- ion is removable outside or inside the coordination sphere of the Mn ions.[37]

The IR spectra were discussed and various separations [$\Delta = \nu_{as}(COO) - \nu_s(COO)$] were obtained for these complexes, indicating unidentate, bidentate bridging or chelating coordination modes for the carboxylate groups. This is consistent with the structural features of the complexes. The

N−H stretching frequency at 3217 cm^{-1} supports the structural analysis for complex **6**, with protonation at the nitrogen atom of the pyridyl unit.

Complexes **4**, **5** and **6** exhibit antiferromagnetic coupling interactions with J values ranging from -0.63 cm^{-1} to -2.35 cm^{-1}. Comparison of the magnetic parameters with those of other Mn complexes with comparable structures indicates the angular dependence of the strength and the nature of the magnetic coupling in M(μ-Cl)M systems: a smaller Mn−Cl−Mn angle results in a larger $|J|$ value.

Experimental Section

General: All manipulations were performed under aerobic conditions, and all commercially available reagents were used as received, except for the complex Et_4NMnO_4 which was prepared according to a literature procedure.[38] IR spectra were recorded on a Magna-75 FT-IR spectrophotometer as KBr pellets. The variable-temperature susceptibility was measured on a model CF-1 superconducting magnetometer with crystalline sample kept in a capsule at 5−300 K. Diamagnetic corrections were made with Pascal's constants for all the constituent atoms of the complexes determined. Elemental analyses were performed with an Elemental Analyzer Vario EL III.

$(Et_4N)[MnCl_2(pic)_2]$ (1): Tetraethylammonium hydroxide (25% in methanol; 0.5 mL) was added to a solution of picolinic acid (0.123 g, 1 mmol) in 10 mL of CH_2Cl_2/MeCN (1:1, v/v). The solution was stirred for 15 minutes and then $MnCl_2{\cdot}4H_2O$ (0.198 g, 1 mmol) was added. The reaction solution was refluxed for 18 h. After filtration, the filtrate was allowed to stand for one month at room temperature to deposit light-red crystals, which were collected, affording 0.068 g of complex **1**. Yield: 27% based on Hpic. $C_{20}H_{28}Cl_2MnN_3O_4$ (500.29): calcd. C 48.02, H 5.64, N 8.40, Mn 10.98; found C 48.48, H 5.72, N 8.73, Mn 11.05. IR (KBr): $\tilde{\nu}$ = 3080 (w) cm^{-1}, 2987 (w), 2922 (w), 1682 (vs), 1645 (m), 1606 (s), 1497 (m), 1473 (m), 1309 (s), 1275 (s), 1257 (s), 1236 (m), 1142 (s), 1049 (m), 764 (s).

$[MnCl(pic)_2(H_2O)]{\cdot}H_2O$ (2): $MnCl_2{\cdot}4H_2O$ (0.198 g, 1 mmol) was added to a solution of picolinic acid (0.123 g, 1 mmol) in 25 mL of CH_3OH and the solution was stirred for 30 minutes. Then, Et_4NMnO_4 (0.062 g, 0.25 mmol) was added in small portions to the reaction solution to give a dark-red solution. The mixture was filtered and the filtrate was evaporated at room temperature to yield green crystals, which were collected to afford 0.019 g of complex **2** with a yield of 10% based on Hpic. $C_{12}H_{12}ClMnN_2O_6$ (370.63): calcd. C 38.89, H 3.26, N 7.56, Mn 14.82; found C 39.97, H 3.31, N 7.66, Mn 14.90.

$[MnCl(pic)(H_2O)_2]_n$ (3): $MnCl_2{\cdot}4H_2O$ (0.594 g, 3 mmol) was added to a solution of picolinic acid (0.185 g, 1.5 mmol) in 40 mL of CH_3OH/CH_2Cl_2/MeCN (1:1:2, v/v/v) and the solution was refluxed for 24 h. After filtration light red crystals deposited from the filtrate at room temperature. The crystals were collected, affording 0.075 g of complex **3** with a yield of 20% based on Hpic. $C_6H_8ClMnNO_4$ (248.52): calcd. C 29.00, H 3.24, N 5.64, Mn 22.11; found C 29.28, H 3.27, N 5.77, Mn 22.24. IR (KBr): $\tilde{\nu}$ = 3385 (s) cm^{-1}, 3086 (w), 1610 (s), 1587 (s), 1566 (s), 1475 (m), 1446 (m), 1394 (s), 752 (s).

$[Mn(pic)_2]_n$ (4): A slurry composed of $MnCl_2{\cdot}4H_2O$ (0.198 g, 1.00 mmol) and picolinic acid (0.123 g, 1 mmol) in 12 mL of DMF (or CH_3OH/H_2O) was sealed into a 25-mL stainless steel reactor with a Teflon liner and heated at 145 °C for 72 h under autogenous pressure. After cooling the reactor, brown-red crystals were collected to afford 0.085 g of complex **4** with a yield of 57% based on Hpic. $C_{12}H_8MnN_2O_4$ (299.14): calcd. C 48.18, H 2.70, N 9.37, Mn 18.37; found C 48.33, H 2.76, N 9.48, Mn 18.46. IR (KBr): $\tilde{\nu}$ = 3089 (w) cm^{-1}, 3064 (w), 3020 (w), 1659 (s), 1624 (s), 1570 (m), 1408 (m), 1350 (s), 781 (m).

$[MnCl(pic)]_n$ (5): A slurry composed of $MnCl_2{\cdot}4H_2O$ (0.198 g, 1.00 mmol) and picolinic acid (0.123 g, 1 mmol) in 19 mL of MeCN (or EtOH) was sealed into a 25-mL stainless steel reactor with a Teflon liner and heated at 145 °C for 72 h under autogenous

C 33.92, H 1.90, N 6.59, Mn 25.85; found C 34.10, H 1.95, N 6.68, Mn 25.99. IR (KBr): $\tilde{\nu}$ = 3120 (w) cm^{-1}, 3080 (w), 1610 (s), 1587 (s), 1566 (s), 1475 (m), 1446 (m), 1396 (s), 1296 (m), 752 (s).

$[MnCl_2(4\text{-}C_5H_4NHCOO)]_n$ (6): A solution of $MnCl_2{\cdot}4H_2O$ (0.198 g, 1 mmol) in 10 mL of CH_3OH was added to a solution of isonocotinic acid (0.246 g, 2 mmol) in 20 mL of H_2O and the solution was refluxed for 14 h. After filtration the filtrate was allowed to stand for three weeks at room temperature to deposit light red crystals, which were collected, affording 0.039 g (yield 16%) of complex 7. $C_6H_5Cl_2MnNO_2$ (248.95): calcd. C 28.92, H 2.01, N 5.62, Mn 22.09; found C 30.01, H 2.36, N 5.28, Mn 21.46. IR (KBr): $\tilde{\nu}$ = 3217 (s) cm^{-1}, 1614 (vs), 1591 (s), 1495 (m), 1417 (s), 1188 (m), 764 (s), 673 (s), 428 (s).

$[Mn_2O_2(pic)_4]$ (7): Glacial acetic acid (4 mL) and picolinic acid (0.492 g, 4 mmol) were added to a solution of $Mn(CH_3COO)_2{\cdot}4H_2O$ (0.490 g, 2 mmol) in 25 mL of CH_3OH/H_2O (4:1, v/v) to give a light brown solution. After 5 minutes, $KMnO_4$ (0.087 g, 0.55 mmol) in 10 mL of water was slowly added dropwise to the solution, which was then filtered. The solvents were evaporated from the filtrate at room temperature to yield red crystals, which were separated by filtration and identified to be $Mn(pic)_3$, a known compound. The filtrate was allowed to stand to deposit black crystals, which were collected to afford 0.158 g of complex **7** with a yield of 25% based on total available Mn. $C_{24}H_{16}Mn_2N_4O_{10}$ (630.29): calcd. C 45.74, H 2.56, N 8.89, Mn 17.43; found C 45.90, H 2.62, N 8.94, Mn 17.55. This complex has been prepared by other workers.[17] Similar IR data were observed to those[10] of a complex $[Mn_2O_2(pic)_4]{\cdot}CH_3CN$ with different crystallographic data.

X-ray Crystallography: Single crystals of complexes **1**−**7** were coated with epoxy resin and mounted on a glass fiber for X-ray diffraction. Refraction data were collected on Siemens Smart CCD diffractometer with Mo-K_α radiation (λ = 0.71073 Å) at 293 K using the ω-2θ scan mode for all the complexes except for **7**, which was scanned on a Weissenberg IP diffractometer. Metal ions together with the chloride ions were first located and other non-hydrogen atoms were found in subsequent difference Fourier syntheses. Hydrogen atoms were located by geometric calculations, except those in water ligands, but their positions and thermal parameters were fixed during the structure refinement. Further crystallographic details are given in Table 3. Selected bond lengths and angles are listed in Table 1. Structure solution and refinement were carried out by standard methods using the SHELXTL-97 program package[39] on a DELL™ personal computer.

CCDC-210998 to -211004 (for **1**−**7**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) + 44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Syntheses, Crystal Structures and Electrospray Mass Spectra of Coordination Polymers of an *N*,*N*′-Bis(3-pyridylmethyl)-1,4-benzenebis(methylamine) Ligand and Silver(I) Salts

Hui-Fang Zhu,[a] Ling-Yan Kong,[a] Taka-aki Okamura,[b] Jian Fan,[a] Wei-Yin Sun,*[a] and Norikazu Ueyama[b]

Keywords: Coordination polymers / Crystal engineering / Pi interactions / Silver / Supramolecular chemistry

Four new coordination frameworks $\{[Ag_2(L1)](NO_3)_2{\cdot}2H_2O\}_n$ (**1**), $\{[Ag(L1)](CF_3COO){\cdot}2.5H_2O\}_n$ (**2**), $\{[Ag_2(L1)_2][1,4\text{-}C_6H_4(COO)_2]{\cdot}7H_2O\}_n$ (**3**) and $\{[Ag(L1)]ClO_4\}_n$ (**4**) were obtained by the reaction of *N*,*N*′-bis(3-pyridylmethyl)-1,4-benzenebis(methylamine) (L1) with the corresponding silver(I) salts. X-ray diffraction analyses reveal that complex **1** has an infinite 1D chain structure, in which L1 acts as a tetradentate ligand. Complexes **2**, **3** and **4** have 2D network structures, and the L1 ligands in these complexes adopt two different coordination modes: one kind of ligand coordinates four silver(I) atoms using its four N atoms, and the other kind of ligand connects only two silver(I) atoms with the two N atoms of the benzenebis(methylamine) unit, while the pyridine units remain free of coordination. Complex $\{[Ag(L2)]ClO_4\}_n$ (**5**) was synthesized by reaction of *N*,*N*′-bis(3-pyridylmethyl)-1,4-benzenebis(methyleneamine) (L2) with silver(I) perchlorate. It has a novel 1D chain structure, which is different from that of **4** due to the different flexibility of the ligands L1 and L2. All of these complexes form 2D or 3D structures stabilized by hydrogen bonding, C–H···π and π-π interactions. The results revealed that the nature of the counteranions and the flexibility of the ligand have an impact on the structure of the supramolecular architectures. The complexes were also characterized by electrospray mass spectrometry.

Introduction

The crystal engineering of coordination polymeric networks based on multidentate ligands is a growing area of coordination and supramolecular chemistry. Many efforts have been devoted to the use of flexible ligands to achieve supramolecular arrays, due to the unpredictable nature of such systems.[1] A variety of networks can be expected since the flexible ligands can adopt different conformations according to the different geometry requirements of the metal ions.[2] It has been reported that chain-like bidentate ligands have the ability to form unique interwoven extended structural motifs such as polycatenanes, polyrotaxanes and helices.[3] Compared with bidentate ligands, long chain-like multidentate ligands are less documented. The silver(I) ion exhibits a diverse coordination geometry due to its variable coordination number. When flexible ligands react with silver(I) salts, interesting and unusual structures are often generated, such as helices, boxes, and brick walls.[4]

In our laboratory, we focus our attentions on the reactions of silver(I) salts with flexible multidentate ligands based on (pyridylmethyl)amine or (pyridylmethylene)amine groups linked by an ethylene spacer (e.g. L3−L6 in Scheme 1), and have obtained various frameworks with interesting structures.[5] For example, 1,2-bis(4′-pyridylmethyleneamino)ethane (L5) reacts with AgOTf or $AgNO_3$ to give a double-stranded helix chain and a 2D network, respectively.[5a] In order to further study the influence of multidentate organic ligands on the formation of the resultant structures, we use two multidentate ligands *N*,*N*′-bis(3-pyridylmethyl)-1,4-benzenebis(methylamine) (L1) and *N*,*N*′-bis(3-pyridylmethyl)-1,4-benzenebis(methylene)amine (L2) (Scheme 1) in this study. In these two ligands, a 1,4-benzenedimethyl or 1,4-benzenedimethylene group was employed, instead of the ethylene group of L3−L6, to examine the influence of the size and flexibility of the spacer group on the structure of the frameworks. Five non-interpenetrated complexes, $\{[Ag_2(L1)](NO_3)_2{\cdot}2H_2O\}_n$ (**1**), $\{[Ag(L1)](CF_3COO){\cdot}2.5H_2O\}_n$ (**2**), $\{[Ag_2(L1)_2][1,4\text{-}C_6H_4(COO)_2]{\cdot}7H_2O\}_n$ (**3**), $\{[Ag(L1)]ClO_4\}_n$ (**4**) and $\{[Ag(L2)]ClO_4\}_n$ (**5**) were synthesized by reactions of L1 and L2 with the corresponding silver(I) salts. The complexes

Results and Discussion

Preparation of Compounds

The title complexes were readily prepared by reaction of L1 or L2 with silver(I) salts in the dark by layering (**1** and **3**), slow evaporation (**2** and **4**) and diffusion (**5**) methods at room temperature. The elemental analyses and X-ray crystal structure analyses confirmed the chemical formulation of these complexes. The complexes of L1 with different anions were found to show remarkable differences in solubility. Complex **2**, with the CF_3COO^- anion, is soluble in organic solvents such as methanol, ethanol, acetonitrile and has moderate solubility in water, while **1**, **3** and **4** are almost insoluble in water and have low solubility in organic solvents. Complex **5**, with L2, has almost no solubility in water and methanol but reasonable solubility in acetonitrile.

Crystal Structure Description

{[Ag$_2$(L1)](NO$_3$)$_2$·2H$_2$O}$_n$ (1)

When the flexible ligand L1 reacts with silver(I) nitrate, a new coordination polymer **1** is obtained and its structure was determined by X-ray crystallography. As shown in Figure 1a, the asymmetric unit of **1** consists of half a molecule of $[Ag_2(L1)](NO_3)_2]\cdot 2H_2O$. Each silver(I) atom is coordinated by two N atoms with an almost linear coordination geometry [N−Ag−N bond angle is 156.97(9)°, Table 1], one of which is from the benzenedimethylamine unit and the other one is from the pyridine unit of another L1 ligand. Each L1 ligand, in turn, coordinates four silver(I) atoms to generate an infinite 1D chain structure. It is noteworthy that C−H···π interactions[6] associate the 1D chains into a 2D network structure as illustrated in Figure 1b. Such an interaction occurs between the hydrogen atom (H5) bound to C10 (methylene directly attached to the benzene ring) and the pyridine group of a neighboring chain. The C10−H5−X (X refers to the centroid of the pyridine group) angle is 117° and the H···X distance is 2.88 Å. From the crystal-packing diagram of **1** (Figure S1 in the Supporting Information), it can be seen that the nitrate anions are connecting 2D cationic sheets through four C−H···O hydrogen bonds to form a 3D framework. The solvated water molecules are located in the 3D structure by forming one N−H···O(water) hydrogen bond with a cationic chain and three (water)O−H···O(nitrate anion) hydrogen bonds. The hydrogen bonding data are summarized in Table 2.

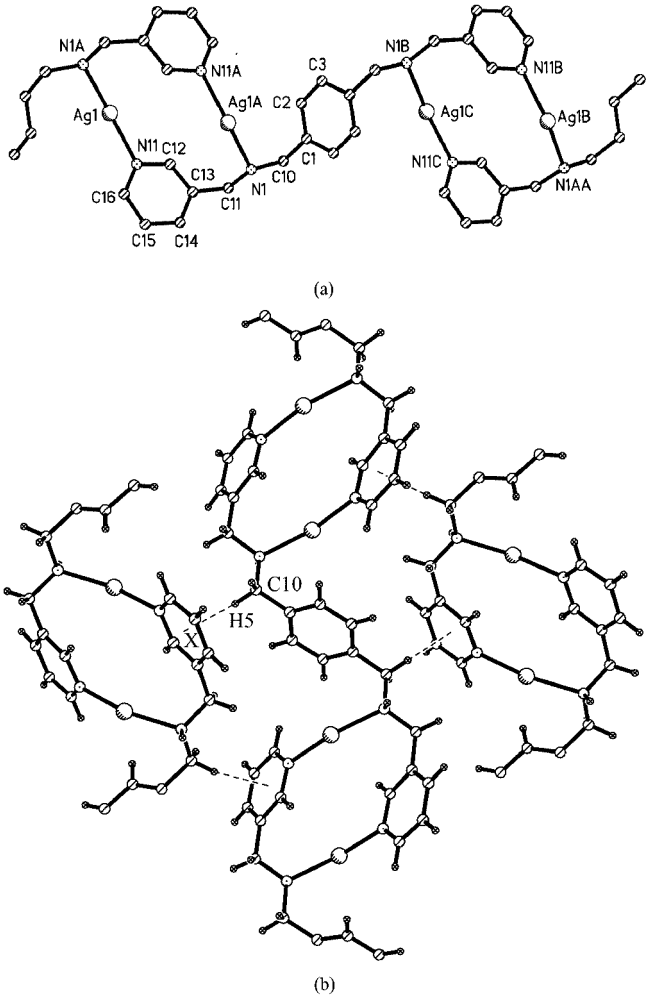

Figure 1. (a) One-dimensional chain structure of complex **1**; water molecules, hydrogen atoms and anions are omitted for clarity; (b) view of 2D cationic sheet of **1** with the C−H···π interactions indicated by dashed lines

In **1** two N atoms of each benzenebis(methylamine) unit in the L1 ligand coordinate to two Ag^I atoms, respectively, while in the reported metal complexes with ligands L3−L6 (Scheme 1) the two N atoms of each ethylenediamine or ethylenediimine unit coordinate to one metal atom in a chelate fashion.[5] This is due to the bulky and rigid 1,4-benzenedimethyl spacer in L1.

{[Ag(L1)](CF₃COO)·2.5H₂O}ₙ (2) and {[Ag₂(L1)₂][1,4-C₆H₄(COO)₂]·7H₂O}ₙ (3)

The same space group and the similar cell parameters (see Exp. Sect.) indicate that complexes **2** and **3** are isomorphous and isostructural. As a typical example, the structure of complex **2** is described here in detail. In complex **2**, the amount of disordered water molecules was confirmed by elemental analysis and thermogravimetric analysis. The TGA data of **2** show an initial weight loss of 7.6% (calcd. 7.7%) from 20 to 80 °C, representing the loss of uncoordinated water molecules; no further weight loss was observed over the temperature range 80–170 °C. The crystal structure of complex **2** (cationic part) is shown in Figure 2a with the atom numbering scheme. Each silver(I) atom is coordinated by two N atoms of the benzenebis(methylamine) units from two different L1 ligands, and one N atom of the pyridine unit of the third L1 ligand. The coordination environment of the silver(I) atom can be described as a triangle, with the N–Ag–N coordination angles varying from 102.81(9)° to 134.30(10)° (Table 1). The average Ag–N bond length of 2.271(3) Å in **2** is similar to those of reported silver(I) complexes with the same AgN_3 binding site, for example $[Ag_3(py\text{-}hep)_2](ClO_4)_3{\cdot}0.5CH_3CN$ [py-hep = 1,6-bis(4′-pyridyl)-2,5-diazahexane] exhibits an average Ag–N bond length of 2.297(5) and 2.314(5) Å for the two crystallographically independent silver atoms.[7] The remarkable structural feature of **2** is that the flexible ligand L1 adopts two different coordination modes at the Ag^I atoms: one kind of ligand coordinates four silver(I) atoms as a tetradentate ligand, and the other kind coordinates only two silver(I) atoms with the N atom of the benzenebis(methylamine) unit as a bidentate ligand, while the pyridine units remain free of coordination. In the reported metal complexes with L4 and L6 the ligands are all tetradentate and each ligand coordinates three different metal atoms.[5b,5d–5f] The whole structure of **2** can be described as the silver(I) atoms being bridged by the tetradentate L1

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

ligands to form 1D chains, which are further linked by the bidentate L1 ligands to generate a wavelike 2D network structure (Figure 2b). In each 2D sheet, there are two kinds of macrometallacyclic rings: the smaller, 12-membered one contains two Ag^I atoms and two L1 ligands and the larger, 44-membered one is made up of two bidentate L1 ligands, two tetradentate L1 ligands and four three-coordinate silver(I) atoms. In addition, the large ring adopts a "chair" conformation to make the uncoordinated pyridine groups point inside of the ring; the large void space of the 44-membered ring is filled by uncoordinated pyridine groups, which may prevent the occurrence of interpenetration. Furthermore, these uncoordinated pyridine groups are stabilized in the large ring by C−H···π interactions.[8] For example as exhibited in Figure 2b, the C12−H9−X (X refers to the centroid of the uncoordinated pyridine group) angle is 142° and the H···X distance is 2.88 Å. The wavelike 2D networks are held together by hydrogen bonds to form a 3D structure (Figure S2). The trifluoroacetate anions and water molecules are sandwiched between the cationic 2D layers and are held there by two N−H···O, one O−H···O and one C−H···F hydrogen bonds (Table 2).

Similar C−H···π interactions (the C112−H19-centroid angle is 137° and the H···centroid distance is 2.88 Å) and crystal packing were found for complex **3**. The uncoordinated 1,4-benzenedicarboxylate anions and water molecules are also located in the voids between the 2D cationic layers and 3D structure is formed by two N−H···O and five C−H···O hydrogen bonds (Figure S3, Table 2).

{[Ag(L1)]ClO$_4$}$_n$ (4) and {[Ag(L2)]ClO$_4$}$_n$ (5)

As described above, the complex with a nitrate anion has a 1D chain structure while those with trifluoroacetate or 1,4-benzenedicarboxylate anions show a 2D network structure. To further investigate the influence of the anion on the structure of Ag^I complexes of L1, the reaction of silver(I) perchlorate with ligand L1 was carried out and complex **4** was isolated and characterized by X-ray crystallography. As shown in Figure 3a, the asymmetric unit of **4** consists of one molecule of [Ag(L1)]ClO_4. Each silver(I) atom is coordinated by two N atoms from the benzenebis(methylamine) units of two different L1 ligands, with an N−Ag−N angle of 157.98(7)°. In addition, an Ag−N distance of 2.436(2) Å indicates the occurrence of a weak interaction between the silver(I) atom and the N atom of the pyridine unit. Thus, the coordination environment of the silver(I) atom in **4** can be regarded as a T-shaped coordination mode, while the Ag^I atoms in **2** and **3** have a triangular coordination geometry. Similar T-shaped silver(I) atoms have been observed in Ag^I complexes with flexible bis(thioether) ligands.[4e] The L1 ligand in **4** adopts the same kind as in **2** and **3**, and in the 2D network structure of complex **4**, 12- and 44-membered macrometallacyclic rings similar to those observed in complexes **2** and **3** were also found. However, there is an obvious difference between the structures of **4** and **2** (**3**): the perchlorate anions are located in the voids of the 44-membered rings and held there through N−H···O and C−H···O hydrogen bonds (Table 2), while in the case of

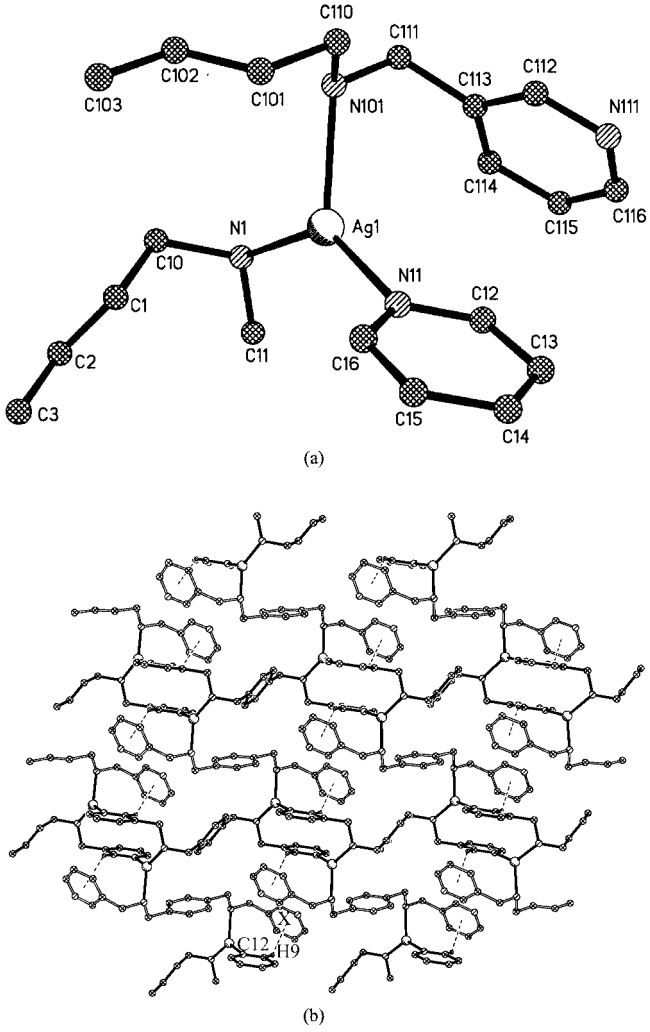

Figure 2. (a) Molecular structure of the asymmetric unit of complex **2**; (b) 2D cationic network structure of complex **2** with the C−H···π interactions indicated by dashed lines; the 1D chain substructure of complex **2** is indicated by solid lines, and the bidentate L1 ligands connecting the 1D chains are indicated by open lines.

complexes **2** and **3**, the anions occupy the void between the 2D cationic layers. This difference in the location of the anions in **4** and **2** (**3**) is caused by the different size of the anions. $CF_3CO_2^-$ and 1,4-$C_6H_4(COO)_2^{2-}$ in **2** and **3** are too large to fit in the void of the 44-membered ring, while the smaller perchlorate anion in **4** can. In addition, C−H···π interactions[9] in **4** occur between the benzene ring groups, rather than the pyridine groups observed in **2** and **3**. For example, the distance between the hydrogen atom (H5) bound to C5 (located at the benzene group of the bidentate ligand) and the centroid of the benzene group of the adjacent tetradentate ligand is 2.55 Å and the C5−H5−centroid angle is 155°. The uncoordinated pyridine rings of the bidentate ligand are parallel to each other and located above and below the 12-membered ring of the 2D network (Figure 3, b and c). The centroid-centroid separation of 3.66 Å between the uncoordinated and adjacent coordinated pyridine groups indicates the presence of π-π interactions.

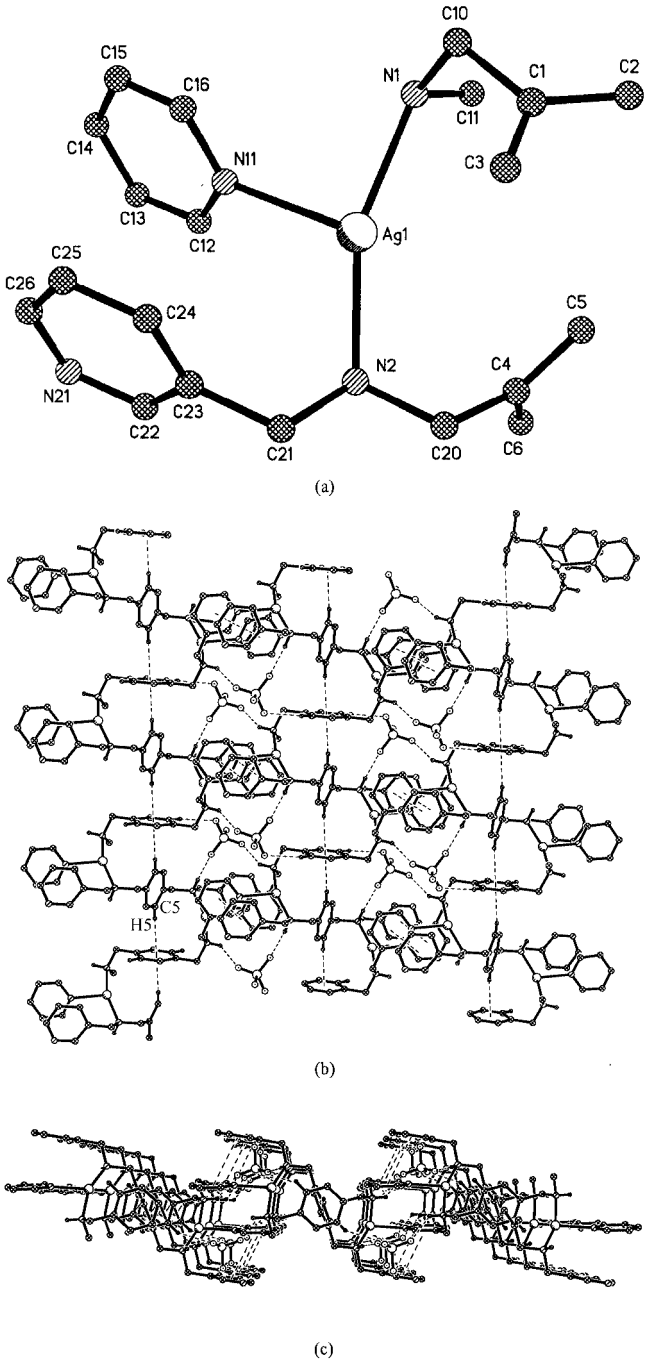

Figure 3. (a) Molecular structure of the asymmetric unit of complex **4**; (b) top and (c) side views of the 2D structure of **4** with the hydrogen bonds, π···π and C−H···π interactions indicated by dashed lines

In order to investigate the effect of the nature of the organic ligand on the structure of the complex, we prepared a Schiff-base ligand L2 by reducing the flexibility of the ligand L1. Reaction of L2 with silver(I) perchlorate gave an unexpected coordination polymer $\{[Ag(L2)]ClO_4\}_n$ (**5**) with a 1D chain structure. The coordination environment of the silver(I) atom is shown in Figure 4a with the atom numbering scheme. Each silver(I) atom in complex **5** is threefold coordinated by two pyridine N atoms from two different L2 ligands and one imine N atom of the other ligand, with Ag···N distances ranging from 2.272(3) to 2.320(2) Å and N−Ag−N bond angles in the range 115.84(9)−120.34(9)° (Table 1). There is only one kind of coordination mode for the L2 ligand in **5** as opposed to the two kinds of coordination modes for the L1 ligand in **2**, **3** and **4** as mentioned above. In addition to the 12-membered macrometallacyclic rings in **5**, which are the same as those in complexes **2**−**4**, there are also 34-membered rings formed by two L2 ligands bridging two silver(I) atoms, with an intra-ring Ag···Ag distance of 16.74 Å. These large 34-membered rings are linked by two Ag−N coordination bonds (N atom of imine group of other rings) to give the 12-membered ring and form a cationic 1D chain. It is interesting to note that three of the four N atoms of each L2 ligand participate in the coordination with three Ag^I atoms; the remaining imine N atom remains uncoordinated. In the reported metal complexes of L3 and L5, each ligand coordinates to two or three different metal atoms as bidentate, tridentate or tetradentate ligands, and the two imine N atoms in one ligand either both participate in coordination or both remain uncoordinated.[5a,5c,5e] For example, each L5 ligand in $[Cu(L5)(CH_3CN)]NO_3$ connects two Cu^I atoms using its two imine N and one pyridine N atoms, another pyridine

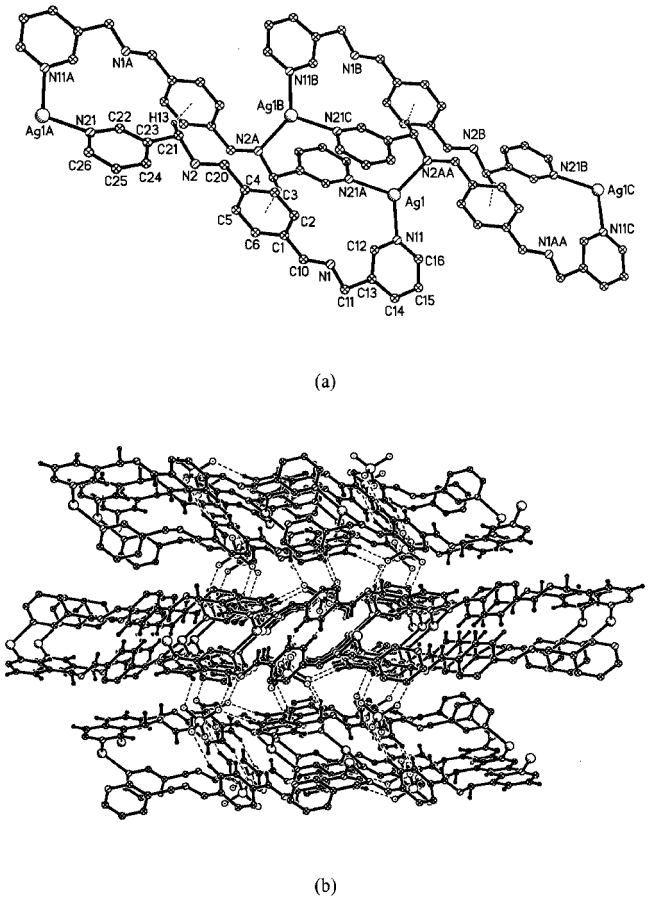

Figure 4. (a) 1D chain structure of complex **5** in which the C−H···π interactions are indicated by dashed lines; (b) crystal packing diagram of **5** with the hydrogen bonds indicated by dashed lines

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

N atom of L5, rather than one of the imine N like for L2 in **5**, remains uncoordinated.[5e] As reported previously, the imine groups (i.e. -C=N-) in L2 ligand may conjugate with the central benzene ring group thereby decreasing the electron density around the imine N atoms. As a result the electron-donating ability of the imine group is reduced and the N atom of imine group is thus difficult to coordinate to a metal atom.[10] In the case of complex **5**, the imine group containing the N1 atom almost conjugates with the central benzene ring group, since the N1−C10−C1−C2 torsion angle is 0.6(4)°, and therefore the N1 atom does not coordinate to the silver(I) atom, whereas the N2−C20−C4−C5 torsion angle is 16.6(4)°, which means that the imine group containing the N2 atom does not strictly conjugate with the central benzene ring, and, consequently, the N2 atom coordinates to the silver(I) atom. Such a difference between the N1 and N2 imine groups may be caused by the π-π and C−H···π interactions since such interactions are related with the pyridylmethyl group on the N2 side; no such interactions were detected for the pyridylmethyl group on the N1 side. The centroid-centroid distance of 4.17 Å between the two pyridine groups within the 12-membered ring implies the existence of weak π-π interactions. In addition, there are C−H···π interactions[11] in the 34-membered ring, for example between the hydrogen atom (H13) bound to C21 (the methylene directly connecting pyridine group) and the benzene group of another ligand within the same ring (Figure 4, a). The H···centroid distance is 2.96 Å and the C−H−centroid angle is 150°. The Ag−N (N atom of the coordinated imine group) bond length is 2.295(3) Å (Table 1), which is shorter than those observed in the complexes $[Ag_2(L5)_2](CF_3SO_3)_2·H_2O$ and $[Ag_3(L5)_2](NO_3)_3·H_2O$ with the corresponding Ag−N bond lengths ranging from 2.328(2) to 2.405(2) Å and from 2.331(4) to 2.407(3) Å, respectively.[5a]

From the crystal-packing diagram of complex **5** shown in Figure 4 (see b) it can be seen that the cationic 1D chains and uncoordinated perchlorate anions are held together by five C−H···O hydrogen bonds (Table 2).

Electrospray (ES) Mass Spectra

Complexes **1**−**5** were further characterized by ES mass spectrometry and the spectroscopic data are summarized in Table 3. As revealed by X-ray analysis, complexes **1**−**4** are composed of the same ligand and metal atom, and each Ag^I atom is coordinated by at least two L1 ligands. Hence it is reasonable that the same three peaks at *m*/*z* = 319.2, 425.3, 744.8, corresponding to $[HL1]^+$, $[AgL1]^+$ and $[Ag(L1)_2]^+$ species, respectively, appear in the ES mass spectra of these complexes. In addition, there are peaks at *m*/*z* = 913.9, 964.7 and 950.8 corresponding to $[Ag_2(L1)_2(NO_3)]^+$, $[Ag_2(L1)_2(CF_3CO_2)]^+$ and $[Ag_2(L1)_2(ClO_4)]^+$ species in the ES mass spectra of **1**, **2** and **4**, respectively. As an example, the ES mass spectrum of complex **2** is shown in Figure 5. All the assignments are ensured by good agreement between the observed and calculated isotopic distributions. Figure 5 (see b) shows a typical example of a comparison between the experimental and calculated isotopic distributions for the peak at *m*/*z* = 964.7. The observation of mono- and dinuclear cationic species in the ES-MS spectra of complexes **1**−**5** (Table 3) confirms the coordination of the ligand to the Ag^I atom and suggests the presence of polymeric species in solution under the ES mass experimental conditions.

Conclusion

The present study shows that the reactions of the multidentate ligand L1 with various silver(I) salts can afford a variety of polymeric frameworks and that C−H···π interactions play an important role in the crystal structures. Furthermore, the results of the present study show that the nature of the counteranions has a great impact in determining the structure of the coordination polymers in this system.[12] Complex **1** contains two-coordinate silver(I) and a tetradentate L1 ligand, which may be responsible for the formation of the 1D chain structure. The 2D structures of complexes **2**, **3** and **4** all contain 12- and 44-membered macrometalla-

cyclic rings, although the structure of complex **4** is different from that of complex **2** or **3**. In **2** and **3**, the anions [$CF_3CO_2^-$ in **2** and 1,4-$C_6H_4(COO)_2^{2-}$ in **3**] are too large to fill the void of the 44-membered macrometallacyclic rings, whereas in **4**, the size of the perchlorate anion allows it to be accommodated in the void of the 44-membered ring by forming N−H···O and C−H···O hydrogen bonds. These results show that the size of the counteranions plays a key role in the construction of such coordination polymers. In complex **5**, due to the presence of the −C=N− imine group in the L2 ligand, a 1D chain structure is formed rather than a 2D network like **4**. The results show that the nature of ligand has a remarkable impact on the structure of the frameworks in this system.

Experimental Section

General: All commercially available chemicals were of reagent grade and used as received without further purification. Elemental analyses for C, H and N were carried out on a Perkin−Elmer 240C elemental analyzer at the Analysis Center of Nanjing University. Thermogravimetric and differential thermal analyses were taken on a simultaneous SDT 2960 thermal analyzer under N_2 with a heating rate of 10 °C/min. The electrospray mass spectral (ES-MS) measurements of the complexes were carried out on an LCQ System (Finnegan MAT, USA) using a mixing solution of methanol and water (1:1) as mobile phase. The samples for ES-MS measurements were prepared by redissolving the final isolated compounds in methanol (**1**−**4**) or in methanol and acetonitrile (1:1; for **5**). Ligands L1 and L2 were prepared by procedures reported previously.[10] All procedures for the synthesis and measurement of the silver(I) complexes were carried out in the dark.

Caution: *Perchlorate salts of metal complexes with organic ligands are potentially explosive and should be handled with care.*

Synthesis of $\{[Ag_2(L1)](NO_3)_2\cdot 2H_2O\}_n$ (1): Complex **1** was synthesized by the layering method. A solution of L1 (31.8 mg, 0.1 mmol) in ethanol (5 mL) was carefully layered over a solution of $AgNO_3$ (17.0 mg, 0.1 mmol) in water (10 mL). Colorless crystals were isolated in 61% yield by filtration after two weeks at room temperature. $C_{20}H_{26}Ag_2N_6O_8$: calcd. C 34.60, H 3.78, N 12.11; found C 34.63, H 3.76, N 11.94.

Synthesis of $\{[Ag(L1)](CF_3COO)\cdot 2.5H_2O\}_n$ (2): An aqueous (5 mL) solution of L1 (31.8 mg, 0.1 mmol) and a solution of CF_3COOAg (22.1 mg, 0.1 mmol) in water (5 mL) were mixed and allowed to stand in air at room temperature for about fifteen days. Light-brown crystals were obtained in 76% yield. $C_{22}H_{27}AgF_3N_4O_{4.5}$: calcd. C 45.22, H 4.66, N 9.59; found C 45.35, H 4.65, N 9.50.

Synthesis of $\{[Ag_2(L1)_2][1,4\text{-}C_6H_4(COO)_2]\cdot 7H_2O\}_n$ (3): A solution of L1 (31.8 mg, 0.1 mmol) in methanol (5 mL) was carefully layered over an aqueous solution of freshly prepared $[Ag(Py)_2]_2[1,4\text{-}C_6H_4(COO)_2]$ (Py = pyridine; 0.025 mmol mL^{-1}, 2 mL). Colorless crystals appeared within two weeks at room temperature in 43% yield. $C_{48}H_{62}Ag_2N_8O_{11}$: calcd. C 50.45, H 5.47, N 9.81; found C 50.48, H 5.51, N 9.73.

Synthesis of $\{[Ag(L1)]ClO_4\}_n$ (4): A methanol (5 mL) solution of L1 (31.8 mg, 0.1 mmol) and an acetonitrile (5 mL) solution of $AgClO_4\cdot H_2O$ (22.5 mg, 0.1 mmol) were mixed and allowed to stand at room temperature for ten days. Light-brown crystals were obtained in 63% yield. $C_{20}H_{22}AgClN_4O_4$: calcd. C 45.69, H 4.22, N 10.66; found C 45.60, H 4.30, N 10.58.

Synthesis of $\{[Ag(L2)]ClO_4\}_n$ (5): An aqueous (3 mL) solution of $AgClO_4\cdot H_2O$ (22.5 mg, 0.1 mmol) was added dropwise to a solution of L2 (31.4 mg, 0.1 mmol) in CH_3OH (6 mL) with stirring. The resulting precipitate was isolated and then dissolved in CH_3CN (8 mL) to give a clear solution. Crystals were obtained in 46% yield by slow diffusion of diethyl ether into the clear solution at room temperature for about two days. $C_{20}H_{18}AgClN_4O_4$: calcd. C 46.04, H 3.48, N 10.74; found C 46.24, H 3.68, N 10.75.

X-ray Crystal Structure Determination: The intensity data for complexes **1**−**5** (Table 4) were collected on a Rigaku RAXIS-RAPID Imaging Plate diffractometer at 200 K, using graphite-monochromated Mo-K_α radiation (λ = 0.7107 Å). The structures were solved by direct methods with SIR92,[13] and expanded using Fourier techniques.[14] All non-hydrogen atoms were refined anisotropically by the full-matrix least-squares method on F^2. The hydrogen atoms, except those from water molecules, were generated geometrically. The F1, F2 and F3 atoms in **2** have two positions with site occupation factors of 0.815(8) and 0.185(8), respectively. The O4, O5 and O6 atoms in **2** have site occupation factors of 0.429(13), 0.571(13) and 0.571(13), and the O2, O3 and O4 atoms in **4** are disordered over two positions with site occupation factors of

The First Silver(I) Side-On η^2-Coordination Network Formed by Self-Assembly of Bis(pyrrol-2-ylmethylene)hydrazine

Lanying Yang,[a] Xufeng Shan,[b] Qingqi Chen,[c] Zhengping Wang,[b] and Jin Shi Ma*[a]

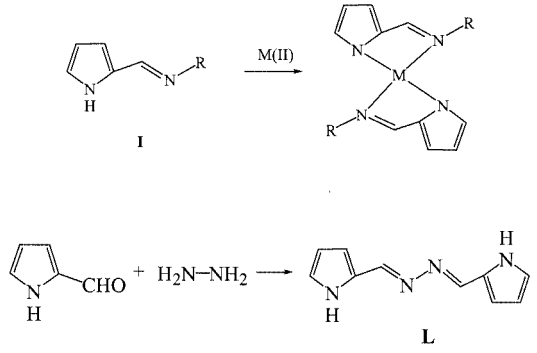
Keywords: Coordination polymers / Hydrogen bonding / Schiff bases / Self-assembly / Silver

This paper reports the first silver(I) network polymer formed by the self-assembly of bis(pyrrol-2-ylmethylene)hydrazine with silver nitrate, in which the silver centers are bonded to the C–N bonds of the pyrrole rings in an η^2-fashion. An X-ray crystal structure analysis revealed that the self-assembly of the bis(pyrrol-2-ylmethylene)hydrazine ligand with Ag^I gives a 2D sheet, which is further assembled to form a 3D network through weak intermolecular hydrogen bonding between the protons of the pyrrole rings and the oxygen atoms of the nitrate ions.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

The design and synthesis of supramolecular coordination polymers has attracted increasing attention during the last decade due to their potential applications as functional materials.[1,2] Multidimensional networks based on ligands with a rigid bridging spacer[3] or a flexible bridging spacer[4] have been reported. Coordination networks containing π-sandwiched silver(I) complexes with polycyclic aromatic compounds,[5] cyclopentadienyl rings,[6] and phenyl rings,[7] have been described. Small π-sandwiched silver(I) complexes have been reported recently[8] in which the silver centers are doubly sandwiched. In this paper we report a novel three-dimensional silver(I) coordination network formed by self-assembly of bis(pyrrol-2-ylmethylene)hydrazine with silver nitrate, in which the silver center, unlike its more common sandwich coordination, is side-on η^2-coordinated to the pyrrole ring. To the best of our knowledge, this is the first example of a silver(I) side-on η^2-complex with pyrrole.

Our group is currently exploring the use of pyrrole-based Schiff bases, such as the (pyrrol-2-ylmethylene)amine ligands **I**, as building blocks for supramolecular architectures. By varying the length and geometric arrangement of the bridging spacer, the bis(pyrrol-2-ylmethylene)hydrazines could form dinuclear double-stranded helicates,[9] trimeric triangles, or tetrameric squares.[10] To further explore the application of the (pyrrol-2-ylmethylene)amine ligand **I** in supramolecular self-assembly, we are interested in investigating the self-assembly of bis(pyrrol-2-ylmethylene)hydrazine (**L**), in which two (pyrrol-2-ylmethylene)amine units are directly linked between two imine N atoms. Bis(pyrrol-2-ylmethylene)hydrazine was synthesized by a simple condensation of 2-formylpyrrole with hydrazine, as shown in Scheme 1. Among the many metal ions attempted, Ag^I was found to form complex **1** with ligand **L**, which was stable enough to allow successful isolation and crystallization.



Scheme 1

Results and Discussion

Complex Analysis

The polymer **1**, prepared by simply treating ligand **L** with silver nitrate, has a melting point of 140 °C (dec.), and is insoluble in most common solvents, such as $CHCl_3$, CH_2Cl_2, THF, acetone, ethyl acetate and CH_3OH. The IR analysis confirms the formation of complex **1**, in which the

peak for nitrate is at 1382 cm^{-1} and is more intense than in **L**, the peak for ν_{N-H} is slightly shifted to a higher frequency (3222 cm^{-1}) with less intensity, while the peak for $\nu_{C=N}$ is not shifted (1631 cm^{-1}) but becomes much weaker than in the free ligand **L**. Attempts to analyze the polymer **1** by ^1H NMR spectroscopy in [D_6]DMSO or [D_5]pyridine failed since **1** decomposed.

X-ray Crystallographic Characterization

Complex **1** has the chemical formula $[Ag_2\mathbf{L}(NO_3)_2]_n$, indicating that two N−H protons remain in the ligand **L**, which is unique and surprising because the protons of pyrrolic NH groups in the (pyrrol-2-ylmethylene)amine ligands are usually removed upon coordinating to metal ions such as Zn^{II}, Ni^{II}, Cu^{II}, Co^{III}, Hg^{II}, Mn^{II} and Mn^{II}.[9−12]

The crystallographic study revealed that each ligand interacts symmetrically above and below the ligand plane in a di-η^2-fashion with two Ag^I ions, which coordinate to two imine-N atoms of two nearby ligands, resulting in an infinite one-dimensional (1D) stair-like polymeric structure as shown in Figure 1 (bottom). Due to an interaction between Ag^I and the five-membered rings in an η^2-fashion, the C5−N3 bond is found to be longer (1.413 Å) than the other four bonds (1.327−1.395 Å) in the pyrrole ring. The Ag1−N3 and Ag1−C5 (2.631 and 2.690 Å, respectively) bond lengths are within the normal range found in silver(I) sandwich complexes (2.47−2.92 Å),[5−8] indicating a moderate interaction between Ag^I and the pyrrole ring.

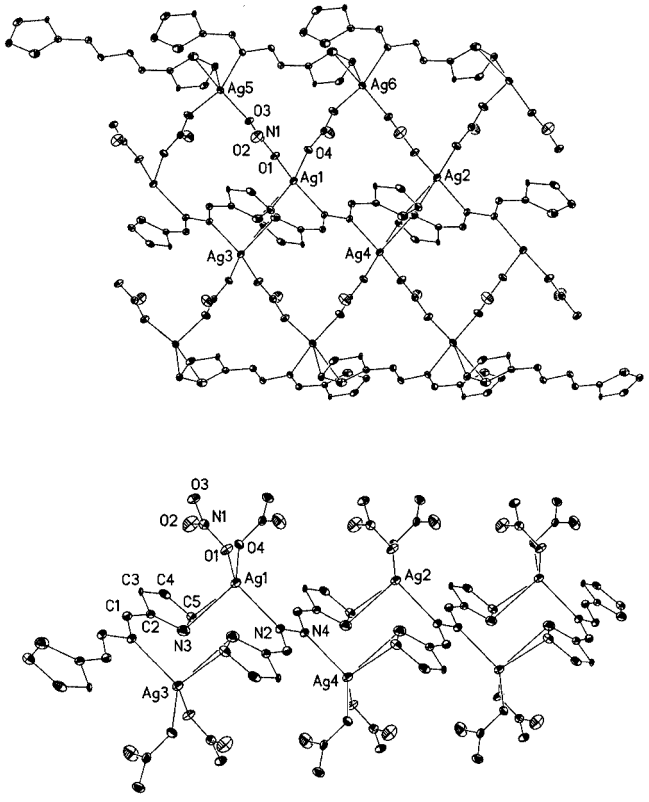

Figure 1. Perspective view of the 2D silver(I) polymer sheet of **1** (top), and the stair-like structure, with emphasis on the side-on η^2-coordination (bottom); hydrogen atoms are omitted for clarity

The adjacent 1D structures are assembled into a two-dimensional (2D) polymeric structure through the linkage of two silver atoms bridged by one nitrate group, with an Ag···Ag separation of 5.639 Å (Figure 1, top). In the 2D polymer sheet of **1**, the bis(pyrrol-2-ylmethylene)hydrazine ligands are arranged in rows in two directions, and the dihedral angle defined by the planes of the ligands in the two adjacent rows is 37.6°.

Each Ag^I center is four-coordinate to a nitrogen donor from the imine group of ligand **L**, a pyrrole ring of another ligand **L** in a side-on η^2-fashion, specifically with the C5−N3 bond (see Figure 1, bottom), and two oxygen atoms of two distinct nitrate ions. In turn, each nitrate ion is bound to two distinct Ag^I centers, while each ligand links four distinct Ag^I centers. This forms a unique stair-like Ag^I coordination polymer, in which the ligand **L** remains neutral, similar to the situation in silver(I) complexes with polycyclic aromatic compounds.[5]

The two (pyrrol-2-ylmethylene)amine units in ligand **L** adopt a *trans* arrangement about the N2−N4 bond, and are coplanar (σ = 0.019 Å). Ag1 and Ag4, bonded to two imine-N atoms of the ligand, are coplanar with ligand **L**. The Ag^I ions in **2** are also arranged into rows with a separation of 6.946 Å for the same row (e.g. Ag1−Ag2), and 4.828 Å for the adjacent separation (e.g. Ag1−Ag3).

The 2D sheets are further assembled to form a three-dimensional (3D) network through weak hydrogen bonding between the H atoms in the C3 and C4 positions of the pyrrole ring and the oxygen atoms of the nitrate ions in the two adjacent sheets (Figure 2). The C(pyrrole)−H···O(nitrate) angles are 154.2 and 142.1°, with an H···O separation (*d*) of 2.379 and 2.108 Å, respectively. These data fall in the range associated with weak hydrogen bonding.[13]

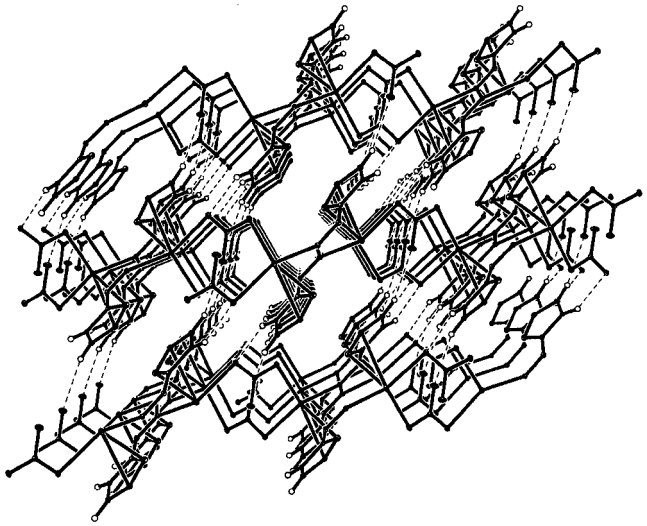

Figure 2. Perspective view of the three-dimensional network of **1** formed by weak intermolecular hydrogen bonding, viewed along the crystallographic *b* axis

In conclusion, a 2D polymer sheet of **2** is formed through self-assembly of bis(pyrrol-2-ylmethylene)hydrazine with silver nitrate. This is the first example of a 2D network

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

polymer where the Ag^I center is side-on coordinated with a pyrrole ring in an η^2-fashion. The 2D sheet polymer is further assembled to form a 3D network through weak intermolecular hydrogen bonding of the type C(pyrrole)−H···O(nitrate).

Experimental Section

General Methods: Pyrrole-2-carbaldehyde was synthesized according to a literature method.[14] All reagents for syntheses and analyses were of analytical grade and used as received. Melting points were determined with a Yanaco MP-500 micro-melting point apparatus and are uncorrected. IR spectra were recorded with a Tensor 27 spectrometer. Raman spectra were recorded with an RFS100 spectrometer. ^{1}H NMR spectra were recorded with a Bruker Avance dpx 400 MHz instrument using TMS as internal standard. Elemental analyses were performed with Carlo Erba-120 elemental analyzer.

Preparation of Bis(pyrrol-2-ylmethylene)hydrazine (L): Pyrrole-2-carbaldehyde (0.95 g, 10 mmol) and hydrazine hydrate (0.25 g, 5 mmol) were dissolved in ethanol (15 mL). The mixture was stirred while a few drops of glacial acetic acid were added. After a few seconds, a yellow precipitate was observed. The suspension was stirred at room temperature for 1 h. The yellow solid was collected by suction filtration, washed with cold ethanol and dried under vacuum to give the expected product. An analytical sample was purified by recrystallization from ethanol. Yield: 0.56 g (60%). Mp. 186−187 °C. Selected FT-IR peaks (KBr pellets): $\tilde{\nu}$ = 3217s cm^{-1} (NH), 3105w (=CH), 3066w (=CH), 1632s (C=N), 1541w (ring), 1409s (ring), 1132m (ring CH), 1029m (ring CH). Raman: $\tilde{\nu}$ = 1584s cm^{-1} (C=N), 1532m (C=N), 1422m (ring), 1347m (ring), 1017s (ring). ^{1}H NMR (400 MHz, $CDCl_3$, 25 °C, TMS): δ = 6.30 (s, 2 H, pyrrole-H), 6.62 (s, 2 H, pyrrole-H), 6.98 (s, 2 H, pyrrole-H), 8.37 (s, 2 H, imine-H), 9.33 (br., 2 H, NH) ppm. UV/Vis (DMSO): λ = 357 nm (ε = 46500). $C_{10}H_{10}N_4$ (186.09): calcd. C 64.50, H 5.41, N 30.09; found C 64.72, H 5.55, N 30.47.

Preparation of $[Ag_2L(NO_3)_2]_n$ (1): Crystals of **1** were prepared by slow diffusion of a solution of $AgNO_3$ (34 mg, 0.2 mmol) in CH_3OH (6 mL) into a solution of **L** (18.6 mg, 0.1 mmol) in $CHCl_3$ (10 mL) in a sealed tube. After one week, light-yellow crystals of **1** suitable for X-ray analysis were obtained. Yield: 29 mg (55%). M.p. > 140 °C (decomp.). Selected FT-IR peaks (KBr pellet): $\tilde{\nu}$ = 3221m cm^{-1} (NH), 3138w (=CH), 3108w (=CH), 1630s (C=N), 1541w (ring), 1410sh (ring), 1382vs (NO_3^-), 1361s (ring), 1129m (ring CH), 1032m (ring CH). Raman: $\tilde{\nu}$ = 1576s cm^{-1} (C=N), 1441w (ring), 1362w (ring), 1012w (ring). $C_{10}H_{10}Ag_2N_6O_6$ (525.98): calcd. C 22.84, H 1.92, N 15.98; found C 22.75, H 1.87, N 15.68.

X-ray Data Collection and Structure Solution and Refinements: Single-crystal X-ray diffraction measurements were carried out with a Rigaku R-axis RAPID IP diffractometer. Determination of the unit-cell parameters and data collection were performed with Mo-K_α radiation (λ = 0.71073 Å) and unit-cell dimensions were obtained by least-squares refinement. The structure was solved by direct methods and empirical absorption corrections were applied using the ψ-scan method. The final refinement was carried out by full-matrix least-squares methods with anisotropic thermal parameters for non-hydrogen atoms on F^2. The hydrogen positions were calculated and refined as riding on the concerned atoms with fixed thermal factors. A total of 2754 reflections were measured in the range 2.52° ≤ θ ≤ 27.48° (*hkl* range indices: −12 ≤ *h* ≤ 12, −8 ≤ *k* ≤ 8, −14 ≤ *l* ≤ 14) with 1638 unique reflections [*R*(int) = 0.0303]. The structure was solved with SHELX-97[15] and refined with SHELX-97.[16] The details for structure analysis are summarized in Table 1. Selected bond lengths and angles are given in Table 2. CCDC-208538 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at at www.ccdc.cam.ac.uk/conts/retrieving.html. [or from the Cambridge Crystallographic Data Centre, 12 Union Road,-Cambridge CB2 1EZ, UK; Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Self-Assembly of Bis(pyrrol-2-ylmethyleneamine) Ligands with Cu^{II} Controlled by Bridging [−$(CH_2)_n$−] Spacers and Weak Intermolecular C−H···Cu Hydrogen Bonding

Lanying Yang,[a] Qingqi Chen,[b] Yan Li,[a] Shaoxiang Xiong,[a] Genpei Li,[c] and Jin Shi Ma*[a]

Keywords: Copper / Helical structures / Hydrogen bonding / N ligands / Schiff bases / Self-assembly

Bis(pyrrol-2-ylmetyhleneamine) ligands linked by alkyl spacers between the imine nitrogens are shown to give dinuclear dimers or mononuclear monomers, depending on the length of the alkyl linker, upon coordination with Cu^{II}. Ligands containing ethylene or hexylene linkers –$(CH_2)_n$– (n = 2, 6) give dinuclear dimers **5** and **8**, while propylene and butylene chains (n = 3, 4) give mononuclear monomers **6** and **7**. X-ray crystal structural analysis reveals that **5** exists as two very similar isomers **5a** and **5b**, in which the two ligands are bound to two Cu^{II} centers to form a distorted helical conformation. In the unit cells of **8**, two entirely different isomers **8a** and **8b** are found. In **8a** two ligands are side-by-side bound to two Cu^{II} centers to form a rectangular macrocycle, while in **8b** they are bonded to two Cu^{II} centers to form a distorted double-stranded helix. Moreover, X-ray structural analysis reveals that complexes **5**–**8** are further assembled into one-dimensional polymers through weak, intermolecular C–H···Cu hydrogen bonding, which plays a crucial role in stabilizing the crystal lattice.

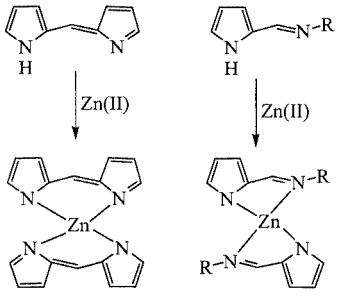
Introduction

Metal-ion-assisted self-assembly is one of most powerful approaches to supramolecular architectures.[1] This strategy typically utilizes metal-ligand interactions to organize small molecules into large assemblies. Obviously the ligands are the key to such research. The dipyrrin ligands **I**, which are important synthetic precursors for porphyrins, bile pigments, and linear and cyclic polypyrroles,[2] were recently used for metal-ion-assisted self-assembly.[3,4] One of the advantages of using dipyrrins as a building block for self-assembly is their ability to form neutral complexes, meaning that counterions are not required, which makes it particularly convenient to purify the complexes by column chromatography since the complexes are not charged and are generally the least-polar component in the reaction mixtures.[3,4] This may also avoid the disordering problem in the solid state caused by counterions.



I Dipyrrin **II** Schiff-base Ligand

However, the use of dipyrrin for constructing supramolecular architectures by self-assembly is also limited by their availability and solubility in organic solvents. Spacer-bridged linear bis- or tris-dipyrrins are usually difficult to synthesize.[2,5] Moreover, linear poly(dipyrrin)s, such as tetradipyrrins, hexadipyrrins, have been reported to have limited solubility in common solvents.[5]

Having examined the chemical structure of dipyrrin **I**, we assumed that its simpler analogues **II** may possess similar coordinating properties to **I**, and may therefore be an ideal building block for supramolecular architectures. Ligands **II**, a pyrrol-2-yl Schiff base or pyrrol-2-ylmethyleneamine, could easily be prepared by condensation of 2-formylpyrrole with a primary amine. Complexes formed by **II** and

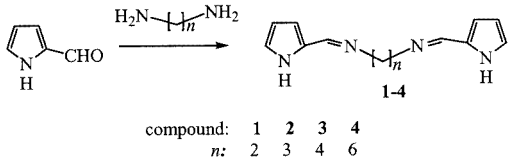
metal ions have been known for a long time,[6] and macrocycles containing pyrrol-2-ylmethyleneamine units, such as texaphyrins and expanded porphyrins,[7] have been extensively investigated. Linear spaced bis(pyrrol-2-ylmethyleneamine) and their complexes with metal ions have been reported,[8] which shows that both the preparation of ligands and the complexes are highly efficient, and that the metal complexes formed by pyrrol-2-ylmethyleneamines possess good solubility in common solvents. Attracted by those properties, our group recently investigated the use of pyrrol-2-ylmethyleneamine ligands for self-assembly.[9−11] By varying the spacers between two pyrrol-2-ylmethyleneamine units, a two-dimensional network polymer,[9] dinuclear dimeric helicates,[10,11] trinuclear trimeric triangle[11] and tetranuclear tetrameric square[11] complexes were generated, which demonstrated that pyrrol-2-ylmethyleneamine ligands are ideal building blocks for self-assembly. Relative to its close analogues — pyridine-imine ligands[12] — the pyrrole-Schiff-base ligand can form neutral complexes, which allows a simpler purification and characterization. In this paper we report the self-assembly of bis(pyrrol-2-ylmethyleneamine) ligands controlled by the length of the bridging spacers and an "unconventional" weak intermolecular C−H···Cu hydrogen bonding, which is found in all the four copper complex crystals. This weak hydrogen bonding plays a crucial role in the architecture of the chain or 1D network polymers.

Results and Discussions

Structural Characterization

The bis(pyrrol-2-ylmethyleneamine) ligands **1**−**4** were synthesized in high yields by condensation of alkyl diamines with 2-formyl-1*H*-pyrroles in ethanol (Scheme 1). They are symmetrical in chemical structure, possess two Schiff-base units, and have good solubility in common solvents. Their structures were fully characterized by ^{1}H and ^{13}C NMR spectroscopy, and mass spectrometry.



Scheme 1

The Cu^{II} complexes **5**−**8** were prepared in yields of 55−75% by reaction of each of ligands **1**−**4** with Cu^{II} (Scheme 2). Complexes **5**−**7** possess good solubility in common solvents such as dichloromethane, chloroform, THF, and DMF, but are less soluble in methanol, ethanol, acetone, hexane, benzene, toluene and water. Complex **8** is insoluble in most solvents. Crystals of compounds **5**−**8** are

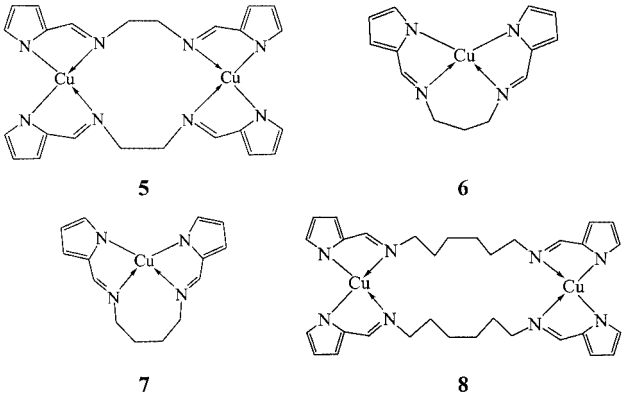
stable for several months under cold and dark conditions. Their solutions in dichloromethane or chloroform were found to slowly decompose upon exposure to light and air.



5 **6** **7** **8**

Scheme 2

Mass spectrometry was found to be especially informative in identifying the above reaction products. Analysis of the complexes, primarily by MALDI-TOF mass spectrometry, revealed that the molecular ions (*m*/*z*) observed in the mass spectra of **5** and **8** are 628 [M^+ + Cu] and 663 [M^+ + H], respectively, which were therefore assigned as dimeric complexes with a ligand:metal ratio of 2:2, while those of **6** and **7** are 289 [M^+] and 303 [M^+], respectively, which were assigned to the corresponding mononuclear monomeric complexes.

Crystal Structures

Crystals of **5**−**7** suitable for X-ray analysis were obtained by recrystallization from CH_2Cl_2/MeOH, whereas single crystals of **8** were prepared by layering a solution of $Cu(OAc)_2$ in CH_3OH upon a solution of **4** in $CHCl_3$ in a sealed tube with very careful diffusion. A summary of the crystal data of complexes **5**−**8** is given in Table 1.

By varying the length of the bridging −$(CH)_n$− spacer between the pyrrol-2-ylmethyleneamine units, self-assembly of bis(pyrrol-2-ylmethyleneamine) alkane ligands with Cu^{II} could offer mononuclear monomeric or dinuclear dimeric complexes. When n = 2, the self-assembly products are two very similar dinuclear dimeric complexes **5a** and **5b**, while in the case of n = 3 and 4, the products are the mononuclear monomeric complexes **6** and **7**, respectively, due to the greater flexibility of the spacer between the pyrrol-2-ylmethyleneamine units, which allows ligands **2** or **3** to coordinate to the same metal center. The tension of the shorter chain in ligand **1** makes it more likely to form a dinuclear dimeric complex. When n = 6, the complexation gives two

Table 4. The dihedral angles between two Cu−N−N terminal planes

	5a	5b	6	7	8a	8b
Dihedral angles (°)	33.8 (Cu1) 35.1 (Cu2)	36.9 (Cu3) 36.9 (Cu4)	12.3	22.6	37.4 (Cu1) 35.3 (Cu2)	20.6 (Cu3) 27.3 (Cu4)

dinuclear dimeric isomers — a side-by-side conformer (**8a**) and helical conformer (**8b**) — thus avoiding the steric crowding of six CH_2 groups constrained in a relatively small space which would be the case for a mononuclear monomer conformation. The crystallographic data show that the tetrahedral sp^3 angles in the spacers of all complexes are close to 109.5°, which also suggests that the dinuclear dimeric complexes **5** and **8** and mononuclear monomeric complexes **6** and **7** are stable species.

The Cu^{II} centers have a distorted square-planar geometry for complexes **5**−**8**. Each Cu^{II} center is tetracoordinate to four N atoms from two pyrrol-2-ylmethyleneamine units. The covalent Cu−N distance is in the range of 1.910−1.981 Å, while the dative Cu−N separation is between 1.940 and 2.083 Å. These distances are similar to the length range of Cu−N bonds found in the literature.[13] Selected bond lengths and angles for complexes **5**−**8** are shown in Table 2 and Table 3, respectively.

The dihedral angles, which are defined by the intersection of two pyrrol-2-ylmethyleneamine planes at the copper center, are in the range of 12.3−37.4°, indicating that the copper centers of complex **6** have the smallest deviation from the square-planar coordination geometry (see Table 4).

In the crystal of complex **5**, it was found that the unit cell contains two different isomers, **5a** and **5b**, both of which adopt a double-stranded helical conformation[13a,14] (Figure 1). However, **5b** has D_2 symmetry while **5a** has C_2 sym-

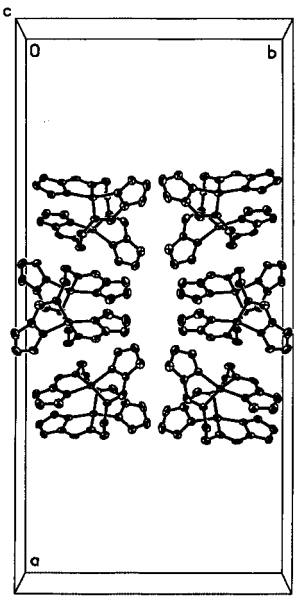

Figure 2. The enantiomer pairs of **5a** and **5b** arranged in the crystal; protons are omitted for clarity

metry. In addition, the torsion angles of the N(imine)−CH_2−CH_2−N(imine) groups in **5a** is −58.4° (N4−C18−C19−N6) and −56.8° (N2−C6−C7−N8) while the corresponding angle in **5b** is −61.8°.

In both **5a** and **5b**, two pyrrol-2-ylmethyleneamine units of the same ligand are found to adopt a *cis* arrangement, which is different from the *trans* arrangement of the Zn^{II} analogue and other bis(pyrrol-2-ylmethyleneamine)zinc(II) complexes.[9−11] This may be due to the geometry requirement of the different metal centers. The Cu···Cu distances are 3.242 Å and 3.257 Å for **5a** and **5b**, respectively. Interestingly, the *M* and *P* helical enantiomers of **5a** and **5b** are found in the crystal (see c and d in Figure 1) and they are arranged alternately (Figure 2).

Unlike complex **5**, complexes **6** and **7** are mononuclear complexes and each ligand uses all its N atoms to bind to the same metal center. The structures of complex **6** and **7** are very similar. However, the dihedral angles between the two Cu−N−N terminal planes are 12.3° and 22.6° for **6** and **7**, respectively, indicating that the Cu center in complex **6** is closer to an ideal square-planar geometry (Figure 3 and 4). Like complex **5**, *M* and *P* helical enantiomers are found for complexes **6** and **7** (Figure 3 and 4).

Interestingly, two different molecules (**8a**, **8b**) were found in the unit cell of complex **8**, which is similar to Dietrich-Buchecker's observations[15b] in solution. In **8a**, two pyrrol-2-ylmethyleneamine units in the same ligand adopt a *cis* arrangement along the hexylene chain (Figure 5). Two ligands are bound parallel to two copper centers to form an 18-membered rectangular macrocycle with cavity dimensions of approximately 7.7 × 3.9 Å. In **8b**, two pyrrol-2-ylmethyleneamine groups in the same ligand adopt a *trans* arrangement along the hexylene bridging chain, forming a distorted double-stranded helical configuration. As a result, this pattern of self-assembly also gives an 18-membered, distorted square-shaped macrocycle with cavity dimensions of approximately 6.4 × 6.1 Å.

The Cu···Cu distances are 8.405 Å for **8a** and 7.744 Å for **8b**, which are much longer than the corresponding distances

in complex **5** due to the longer spacer of the ligand in complex **8**. In **8a**, the dihedral angles at the Cu centers are 37.4° [Cu(1)] and 35.3° [Cu(2)], which are very close to the value for complex **5**, but larger than that in **8b** (Table 4). Unlike complexes **5**−**7**, there is no enantiomer pair found in the crystal of complex **8**.

Weak Hydrogen Bonding

Weak hydrogen bonding has been known to play a crucial role in chemical and biological systems.[15] Interestingly, the crystallographic characterization suggests that the Cu^{II} centers in complexes **5**−**8** participate in weak hydrogen bonding, which plays a crucial role in the formation of chain-type polymers or 1D networks. Although regular weak hydrogen bonding is very common,[16] weak hydrogen bonding with Cu^{II} is rare.[16b] However, copper is an electron-rich metal atom with filled *d*-orbitals that is capable of forming hydrogen bonds with a suitable donor to form a three-center, four-electron interaction (3*c*-4*e*).[16b,16c,16f] In complexes **5**−**8**, the H···Cu separation (d) is in the range of 2.804−3.018 Å, the C−H···Cu separation (D) is in the range of 3.637−3.921 Å and the C−H···Cu angle (θ) is between 84.9 and 168.0° (Table 5), which are similar to the values for weak hydrogen bonding found in the literature.

In complex **5**, a hydrogen atom from the CH_2 group in one molecule is bound to the Cu^{II} center of the second molecule (Figure 6, a). As a result, a triple-row 1D network is formed though weak C−H···Cu interactions with a row of **5a** on each side and **5b** in the middle (see b and c in Figure 6).

Unlike complex **5**, in complexes **6** and **7** the hydrogen atom at the 3-position of the pyrrole ring in one molecule is bound to the Cu^{II} center of the second molecule to form 1D extended chains (Figure 7). Interestingly, in the packing diagram of **6**, the *M* and *P* isomers are arranged in alternating rows when viewed along the *c* axis (Figure 7, a). However, in the packing diagram of **7** the *M* and *P* enantiomers are arranged alternately in the same chain (Figure 7, b). The Cu···H distances (d), C−H···Cu distance (D) and C−H···Cu angles (θ) are 3.018 Å, 3.637 Å and 84.9°, respectively, for **6**, and 2.842 Å, 3.637 Å and 144.1°, respectively, for **7**, indicating a stronger interaction in **7** than in **6**.

Table 5. Parameters for C−H···Cu intermolecular hydrogen bonding in complexes **5**−**8**

	d (Å)	*D* (Å)	θ(C−H···Cu) (°)
5	2.993[a]	3.671[a]	133.7[a]

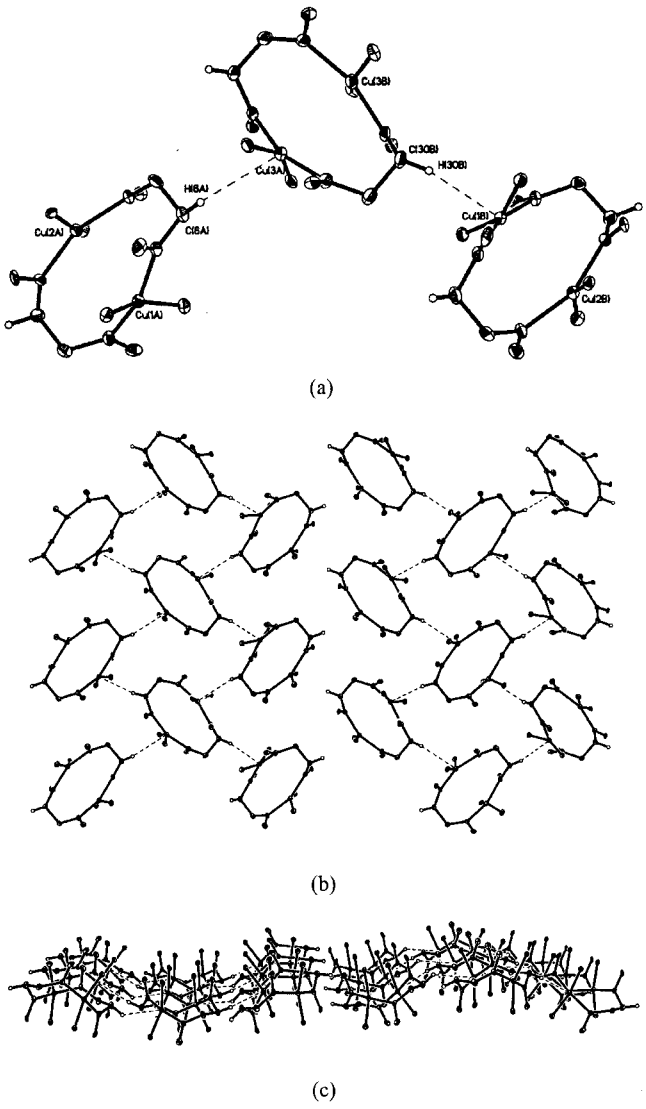

Figure 6. Weak hydrogen bonding in complex **5**; carbon atoms of the pyrrole ring are omitted for clarity: (a) weak C−H···Cu hydrogen bonding between **5a**−**5b**−**5a**; (b) view of triple-row 1D network along the *b* axis; (c) view of the triple-row 1D network along the *c* axis

Like complex **5**, one H atom of the CH_2 group in the bridge of each ligand is weakly bound to the Cu^{II} center from another molecule to form a 1D chain for complex **8**. However, unlike the interaction pattern in **5**, in which each molecule offers a hydrogen donor and a Cu^{II} acceptor to form the 1D networks, and also unlike the interaction pattern in **6** and **7**, in which each molecule acts as both acceptor and donor to form 1D chains, in complex **8** each helical conformer (**8b**) offers two hydrogen atoms from two different ligands and binds to two Cu^{II} centers of two side-by-side conformers (**8a**; Figure 8). In other words, **8b** acts only as a donor and **8a** acts only as an acceptor.

In conclusion, the self-assembly of bis(pyrrol-2-ylmethyleneamine) ligands with Cu^{II} gives mononuclear monomeric complexes or dinuclear dimeric complexes depending on the bridging spacer between the two pyrrol-2-ylmethyleneamine units. In all cases, the metal centers are four-coordinate with

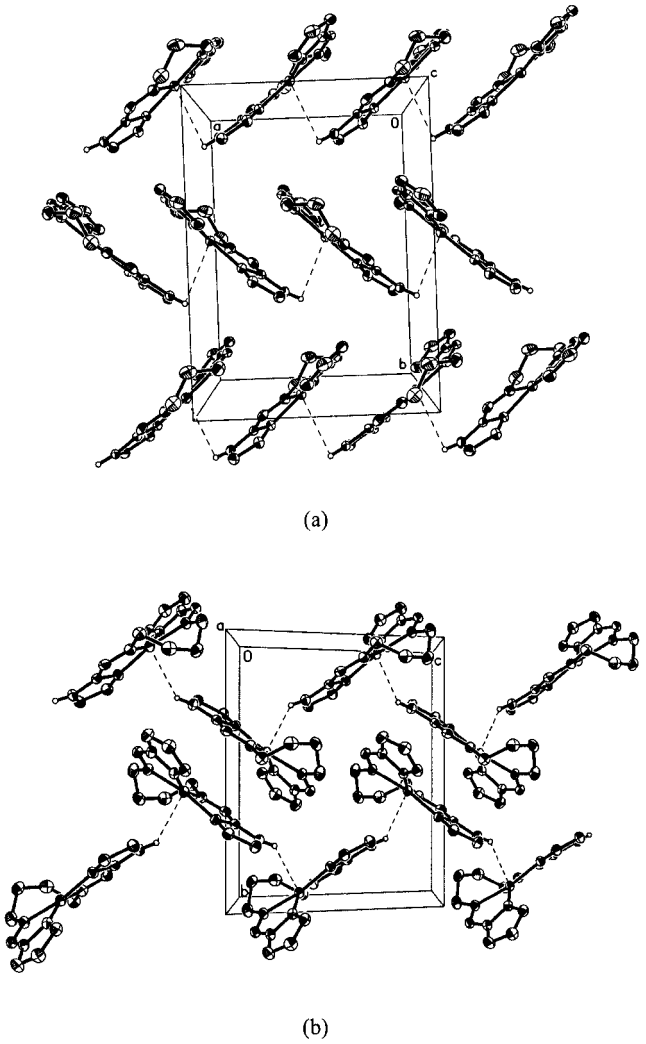

Figure 7. 1D chains formed through weak hydrogen bonding in complexes **6** and **7**: (a) one enantiomer of complex **6** in each row is ordered parallel through weak C−H···Cu hydrogen bonding, and the rows are arranged in a zigzag pattern; (b) 1D chains constructed through weak C−H···Cu hydrogen bonding in **7**

a distorted planar conformation. Moreover, the bis(pyrrol-2-ylmethyleneamine) ligands are doubly deprotonated, which allows the formation of neutral complexes in high yields. By varying the length of the bridging $-(CH)_n-$ spacer between the pyrrol-2-ylmethyleneamine units, self-assembly of bis(pyrrol-2-ylmethyleneamine)alkane ligands with Cu^{II} could offer mononuclear monomeric or dinuclear dimeric complexes. The self-assembly, which changes with the bridging spacers, reflects the steric requirement of the complexation. Intermolecular weak C−H···Cu hydrogen bonding is found in all complexes **5**−**8** and plays a major role in constructing 1D chains or network polymers.

In light of the high yields of the neutral complexes, their excellent solubility, the easy synthesis of the ligands and their great flexibility to generate supramolecules with interesting geometric structures, pyrrol-2-ylmethyleneamine has been demonstrated to be an ideal building block for supramolecular architectures through self-assembly. Our future work will be focused on the design, synthesis and self-assembly of ligands containing multiple pyrrol-2-ylmethyleneamine units.

Experimental Section

All reagents for syntheses and analyses were of analytical grade and used as received. Melting points were determined on a Yanaco MP-500 micro-melting point apparatus. NMR spectra were recorded on a Bruker Avance dpx 400 MHz instrument using TMS as internal standard. Mass spectra were obtained on Bruker APEX II and KYKY-ZHP-5 spectrometers. IR spectra were recorded on a BIO-RAD FT-165 IR spectrometer. Elemental analyses were performed on a Carlo Erba-120 elemental analyzer.

General Procedure for the Synthesis of Ligands 1−4: Pyrrol-2-carbaldehyde (1.9 g, 20 mmol) and the linear diaminoalkane (10 mmol) were dissolved in ethanol (20 mL). The mixture was stirred for a while and then a few drops of glacial acetic acid were added. After a few seconds a white precipitate was observed. The suspension was stirred at room temperature for 2 h. The white solid was collected by suction filtration, washed with cold ethanol and dried under vacuum to give the expected product. The analytic sample was purified by re-crystallization from ethanol.

1,2-Bis(pyrrol-2-ylmethyleneamine)ethane (1): Yield: 1.61 g, 75%; m.p. 178−181 °C. ^{1}H NMR (400 MHz, $CDCl_3$, 25 °C, TMS): δ = 3.78 (s, 4 H, CH_2), 6.23 (dd, J = 3.5, 3.5 Hz, 2 H, pyrrole-H), 6.47 (dd, J = 3.5, 1.3 Hz, 2 H, pyrrole-H), 6.89 (m, 2 H, pyrrole-H), 8.04 (s, 2 H, imine-H) ppm. ^{13}C NMR (100 Hz, $CDCl_3$): δ = 61.4, 109.8, 114.5, 122.0, 130.1, 152.8 ppm. FAB-MS: *m*/*z* (%) =215 (30) [M^+ + H]. FT-IR (KBr pellet): $\tilde{\nu}$ = 3178, 3088, 2974, 2943, 2870, 1641, 1424, 1317, 1130, 1048, 1014, 828, 736 cm^{-1}.

1,3-Bis(pyrrol-2-ylmethyleneamine)propane (2): Yield: 1.44 g, 65%; m.p. 119−120 °C. ^{1}H NMR (400 MHz, $CDCl_3$, 25 °C, TMS): δ = 1.96 (t, *J* = 7.0 Hz, 2 H, CH_2), 3.58 (t, *J* = 7.0 Hz, 4 H, CH_2), 6.21 (t, *J* = 3.2 Hz, 2 H, pyrrole-H), 6.45 (d, *J* = 3.2 Hz, 2 H, pyrrole-H), 6.86 (m, 2 H, pyrrole-H), 8.01 (s, 2 H, imine-H) ppm. ^{13}C NMR (100 Hz, $CDCl_3$): δ = 32.7, 58.3, 109.7, 114.2, 121.9, 130.4, 152.1 ppm. FAB-MS: *m*/*z* (%) = 229 (30) [M^+ + H]. FT-IR (KBr pellet): ν̃ = 3117, 3062, 2966, 2943, 2850, 1637, 1445, 1420, 1314, 1131, 1097, 1033, 989, 750 cm^{-1}.

1,4-Bis(pyrrol-2-ylmethyleneamine)butane (3): Yield: 1.89 g, 78%; m.p. 178−179 °C. ^{1}H NMR (400 MHz, $CDCl_3$, 25 °C, TMS): δ = 1.73 (m, 4 H, CH_2), 3.55 (t, *J* = 3.8 Hz, 4 H, CH_2), 6.25 (dd, *J* = 3.4, 3.2 Hz, 2 H, pyrrole-H), 6.52 (dd, *J* = 3.4, 1.0 Hz, 2 H, pyrrole-H), 6.94 (m, 2 H, pyrrole-H), 7.99 (s, 2 H, imine-H) ppm. ^{13}C NMR (100 Hz, $CDCl_3$): δ = 28.7, 59.8, 110.2, 115.3, 122.9, 129.7, 151.6 ppm. FAB-MS: *m*/*z* (%) = 243 (70) [M^+ + H]. FT-IR (KBr pellet): ν̃ = 3164, 2970, 2928, 2897, 2848, 1644, 1424, 1360, 1136, 1099, 1035, 995, 829, 728 cm^{-1}.

1,6-Bis(pyrrol-2-ylmethyleneamine)hexane (4): Yield: 2.16 g, 80%; m.p. 131−132 °C. ^{1}H NMR (400 MHz, $CDCl_3$, 25 °C, TMS): δ = 1.36 (m, 4 H, CH_2), 1.61 (m, 4 H, CH_2), 3.50 (t, *J* = 6.7 Hz, 4 H, CH_2), 6.22 (t, *J* = 2.9 Hz, 2 H, pyrrole-H), 6.47 (dd, *J* = 2.9, 1.3 Hz, 2 H, pyrrole-H), 6.86 (m, 2 H, pyrrole-H), 8.03 (s, 2 H, imine-H) ppm. ^{13}C NMR (100 Hz, $CDCl_3$): δ = 27.1, 31.3, 60.7, 109.5, 114.2, 122.0, 130.4, 152.1 ppm. FAB-MS: *m*/*z* (%) = 271 (30) [M^+ + H]. FT-IR (KBr pellet): ν̃ = 3166, 3096, 2972, 2932, 2899, 2851, 1646, 1424, 1367, 1319, 1362, 1098, 1019, 959, 830, 728, 605cm^{-1}.

General Procedure for the Synthesis of 5−7: A solution of $Cu(OAc)_2{\cdot}H_2O$ (0.2 g, 1 mmol) in methanol (20 mL) was added to a solution of ligand (**1**−**3**, 1 mmol) in methanol (10 mL). A yellow-green precipitate appeared quickly. After 1.5 h the precipitates were collected by suction filtration and washed with methanol. Crystals suitable for X-ray analysis were obtained by recrystallization from CH_2Cl_2/CH_3OH with a yield of 65−75%.

Cu^{II} Complex of 1,2-Bis(pyrrol-2-ylmethyleneamine)ethane (5): Yield: 193 mg, 70%; m.p. > 210 °C (decomp.). IR (KBr pellet): ν̃ = 3442, 3093, 2905, 1587, 1443, 1391, 1345, 1309, 1035, 738 cm^{-1}. MALDI-TOF-MS: 628 *m*/*z* = [M^+ + Cu]. $C_{24}H_{24}Cu_2N_8$ (551.59): calcd. C 52.26, H 4.39, N 20.31; found C 52.36, H 4.41, N 19.99.

Cu^{II} Complex of 1,3-Bis(pyrrol-2-ylmethyleneamine)propane (6): Yield: 188 mg, 65%; m.p. > 185 °C (decomp.). IR (KBr pellet): ν̃ = 3444, 3089, 2900, 2838, 1600, 1514, 1439, 1395, 1033, 735 cm^{-1}. MALDI-TOF-MS: *m*/*z* = 289 [M^+]. $C_{13}H_{14}CuN_4$ (289.82): calcd. C 53.87, H 4.87, N 19.33; found C 53.65, H 4.85, N 19.08.

Cu^{II} Complex of 1,4-Bis(pyrrol-2-ylmethyleneamine)butane (7): Yield: 227 mg, 75%; m.p. 160−161 °C. IR (KBr pellet): ν̃ = 3430, 3090, 2928, 2854, 1601, 1513, 1440, 1393, 1363, 1089, 1033, 744 cm^{-1}. MALDI-TOF-MS: *m*/*z* = 303 [M^+]. $C_{14}H_{16}CuN_4$ (303.85): calcd. C 55.34, H 5.31, N 18.44; found C 55.07, H 5.29, N 18.19.

Synthesis of Cu^{II} Complex of 1,6-Bis(pyrrol-2-ylmethyleneamine)-hexane (8): This complex was prepared by laying a solution of $Cu(OAc)_2{\cdot}H_2O$ (39 mg, 0.2 mmol) in CH_3OH (6 mL) on top of a solution of **4** (54 mg, 0.2 mmol) in $CHCl_3$ (8 mL) in a sealed tube. After several days, crystals of **8** suitable for X-ray analysis were obtained. Yield: 182 mg, 55%. m.p. > 250 °C (decomp.). FT-IR (KBr pellet): ν̃ = 3443, 3093, 2929, 2853, 1593, 1515, 1441, 1391, 1341, 1313, 1034, 740 cm^{-1}. MALDI-TOF-MS: *m*/*z* = 663 [M^+ + H]. $C_{32}H_{40}Cu_2N_8$ (663.81): calcd. C 57.90, H 6.07, N 16.88; found C 58.14, H 6.15, N 16.92.

X-ray Crystallography: Crystals suitable for X-ray diffraction studies were obtained as described above. Accurate unit cell parameters were determined by a least-squares fit of 2θ values, measured for 200 strong reflections, and intensity data sets were measured on a Bruker Smart 1000 CCD or Rigarku Raxis Rapid IP diffractometer with Mo-K_α radiation (λ = 0.71073 Å) at room temperature. The intensities were corrected for Lorentz and polarization effects, but no corrections for extinction were made. All structures were solved by direct methods. The non-hydrogen atoms were located in successive difference Fourier synthesis. The final refinement was performed by full-matrix least-squares methods with anisotropic thermal parameters for non-hydrogen atoms on F^2. The hydrogen atoms were added theoretically and treated as riding on the concerned atoms. Crystallographic data and experimental details for structure analyses are summarized in Table 1.

CCDC-209047 ... -209050 (for **5**−**8**, respectively) contain the supplementary crystallographic data for this paper. Syntheses and Structural Characterization of Ag^{I} Complexes with the *N*,*N*′-Di(2-pyridyl)oxamide Ligand

Yi-Fen Hsu[a] and Jhy-Der Chen*[a]

Keywords: Silver / Nitrogen heterocycles / Coordination polymers / Trinuclear complexes

A series of the silver(I) complexes $\{[Ag(\mathbf{L})][NO_3]\}_\infty$ (**1**), $\{[Ag(\mathbf{L})(CH_3CN)][ClO_4]\}_\infty$ (**2**), $\{[Ag_2(\mathbf{L})_3(CH_3CN)_2][PF_6]_2\}_\infty$ (**3**), and $[Ag_3(\mathbf{L})_4(CH_3CN)_4][BF_4]_3$ (**4**) [where **L** = *N*,*N*′-di(2-pyridyl)oxamide] have been prepared by the reactions of AgX (X = NO_3^-, ClO_4^-, PF_6^- and BF_4^-) with **L**. All the complexes have been structurally characterized by X-ray crystallography, confirming that **1**–**3** are coordination polymers whereas **4** is a trinuclear complex. Complex **1** forms helical chains which are interlinked through a series of Ag···O interactions and C–H···O hydrogen bonds. In complexes **2** and **3**, a new set of interactions involving two Ag···O interactions and self-complementary double N–H···O hydrogen bonds were found to link the linear chains and ladder structures into polymer pairs (for **2**) and molecular sheets (for **3**). In complex **4**, the molecules are interlinked by extensive Ag···N interactions and π–π stacking interactions to form molecular bands.

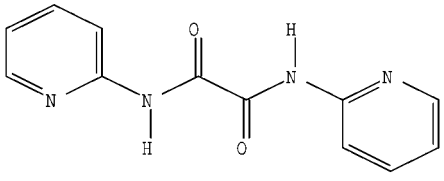
Introduction

Recently, a great deal of effort has been devoted to the self-assembly of organic and inorganic molecules in the solid state, because it extends the range of new solids which can be designed to have particular physical and chemical properties.[1] Among the various types of interactions employed to create larger molecular arrays, covalent and hydrogen bonds are the most widely used.[2] The use of metal ions to link organic molecules is an alternative method for the design of inorganic supramolecules. The range and variety of self-assembling inorganic structures that can be constructed relies on the presence of suitable metal−ligand interactions and hydrogen bonds. We have recently reported the self-assembly of molecules through N−H···Cl[3a] and N−H···Br[3a] interactions.

Many topologically promising Ag^{I}-containing architectures have been constructed with nitrogen-containing bidentate building blocks.[4] These polymers include 1-D, 2-D and 3-D network structures.[4b] Despite some recent progress, the ability to predict and control the supramolecular assembly of molecules remains elusive, and much more work is required to understand the inter- and intramolecular forces that determine the patterns of molecular structure and crystal packing in the solid state. During our study on the reactions of Ag^{I} ion with the bidentate ligand *N*,*N*′-di(2-pyridyl)oxamide (**L**), (which contains both amide and pyridyl groups) we found that it can form coordination polymers capable of self-assembling into 2-D molecular structures through a series of interactions involving Ag···O weak covalent bonds and self-complementary double N−H···O hydrogen bonds.[5] It was also found that changing the counterion of Ag^{I} had a drastic effect on the structures of the Ag^{I} coordination polymer. The syntheses and structural characterization of Ag^{I} complexes of the types $\{[Ag(\mathbf{L})][NO_3]\}_\infty$, $\{[Ag(\mathbf{L})(CH_3CN)][ClO_4]\}_\infty$, $\{[Ag_2(\mathbf{L})_3(CH_3CN)_2][PF_6]_2\}_\infty$ and $[Ag_3(\mathbf{L})_4(CH_3CN)_4][BF_4]_3$ form the subject of this report.



L

Results and Discussion

Syntheses

The ligand *N*, *N*′-di(2-pyridyl)oxamide (**L**) was prepared by reaction of 2-aminopyridine and oxalyl chloride in CH_2Cl_2, in accordance with a literature procedure.[6] The reactions of **L** with AgX (X = NO_3^-, ClO_4^-, PF_6^- and BF_4^-) in refluxing CH_3CN afforded the complexes $\{[Ag(\mathbf{L})][NO_3]\}_\infty$ (**1**), $\{[Ag(\mathbf{L})(CH_3CN)][ClO_4]\}_\infty$ (**2**), $\{[Ag_2(\mathbf{L})_3(CH_3CN)_2][PF_6]_2\}_\infty$ (**3**) and $[Ag_3(\mathbf{L})_4(CH_3CN)_4][BF_4]_3$ (**4**), respectively. All these complexes were structurally characterized by X-ray crystallography. Complexes **1**−**4** were insoluble in most organic solvents; crystals suitable for X-ray diffraction studies were obtained by layering their CH_3CN solutions with diethyl ether.

Structure of the Ligand L

The crystal structure of the ligand belongs to the space group $P4bar2_1/c$ with eight molecules in each unit cell. Figure 1 shows the packing of these molecules. It can be seen that the ligand forms one dimensional chains in the solid state, and the molecules are held together by a series of donor-acceptor-donor-acceptor (DADA) quadruple hydrogen bonds and donor-acceptor (DA) double hydrogen bonds. The one dimensional chains interact with each other through extensive C−H···O interactions (H···O: 2.576 Å; ∠ C−H···O: 149.9°). The centrosymmetric DADA:ADAD self-complementary interaction involves two strong N−H···N and two weak C−H···O hydrogen bonds. The H···N distance in the N−H···N interaction is 2.220 Å, with an N−H···N angle of 153.2°, whereas the H···O distance in the C−H···O interaction is 2.451 Å, with a C−H···O angle of 121.3°. The centrosymmetric DA:AD double hydrogen bonds involve two N−H···N interactions; the H···N distance and N−H···N angle are 2.203 Å and 161.5°, respectively. Noticeably, this DADA:ADAD system involves two N−N, two N−C, and two N−C secondary interactions,[5c] which are all repulsive. This system is in marked contrast to the DADA:ADAD system (which has two strong N−H···N and two strong O−H···O interactions) found for 6-methyl-2-butylureidopyrimidone, in which four N−N and two N−O repulsive secondary interactions were observed.[7]

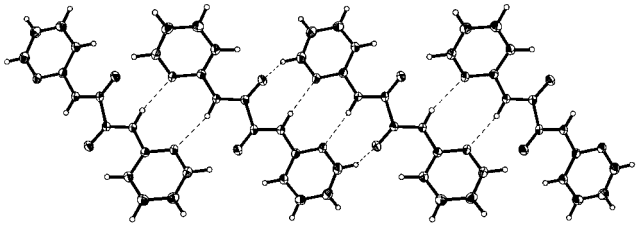

Figure 1. An ORTEP diagram of **L** showing the interactions among the ligands

Structure of 1

The single-crystal X-ray structure of complex **1** shows that the silver atom is bound to the nitrogen atoms of two symmetry-related **L** ligands [Ag−N(2): 2.183 (4), Ag−N(5A): 2.198 (3) Å] in a distinctly non-linear geometry [N(2)−Ag−N(5A): 154.95(13)°]. Selected bond lengths and angles are listed in Table 1. As illustrated in Figure 2 (a), the asymmetric unit of **1** consists of one [Ag(**L**)][NO_3] subunit, which under an appropriate symmetry operation produces the polymeric structure, Figure 2 (b). It is interesting to note that the bidentate ligand **L** in each cation is not flat, but twisted around the C−N bond, with a dihedral angle of 47.0° between the planes of the two pyridine rings, resulting in a series of single-twist helicates. Each single-twist helix contains two Ag^I−**L** units, as shown in Figure 2 (b). The helical chains are interlinked through a series of Ag···O−C (Ag···O: 3.567 Å) interactions and C−H···O (H···O = 2.555 Å, ∠ C−H−O: 144.2°) hydrogen bonds. The nitrate ions form bridges between adjacent chains through all three oxygen atoms [Figure 2 (c)] and link the cations through a series of Ag···O interactions (Ag···O: 2.695−3.336 Å) and N−H···O (H···O: 2.280 and 2.296 Å, ∠ N−H···O: 140.3 and 162.1°, respectively) hydrogen bonds. In addition to the weak interactions mentioned above, the **L** ligands in each helix experience π−π interactions, with interplanar distances of 3.905 Å between the pyridine rings.

Structure of 2

The asymmetric unit and infinite molecular structure of **2** are depicted in Figure 3 (a and b), respectively. Selected bond lengths and angles are listed in Table 1. Figure 3 (b) shows that **2** is a coordination polymer of [Ag(**L**)(CH_3CN)][ClO_4]. The Ag metal centres possess two types of geometries. One has a distorted tetrahedral geometry in which two CH_3CN ligands and two **L** ligands coordinate to the metal centre, whereas the other has an approximately linear geometry [N(3)−Ag(1)−N(2): 164.29(14)°] in which the metal is coordinated by two **L** ligands. The largest N(7)−Ag(2)−N(6) angle is 145.13(14)°, whereas the remaining five angles are in the range 97.30(17) to 103.68 (17)°. The bidentate **L** ligand in each cation is not

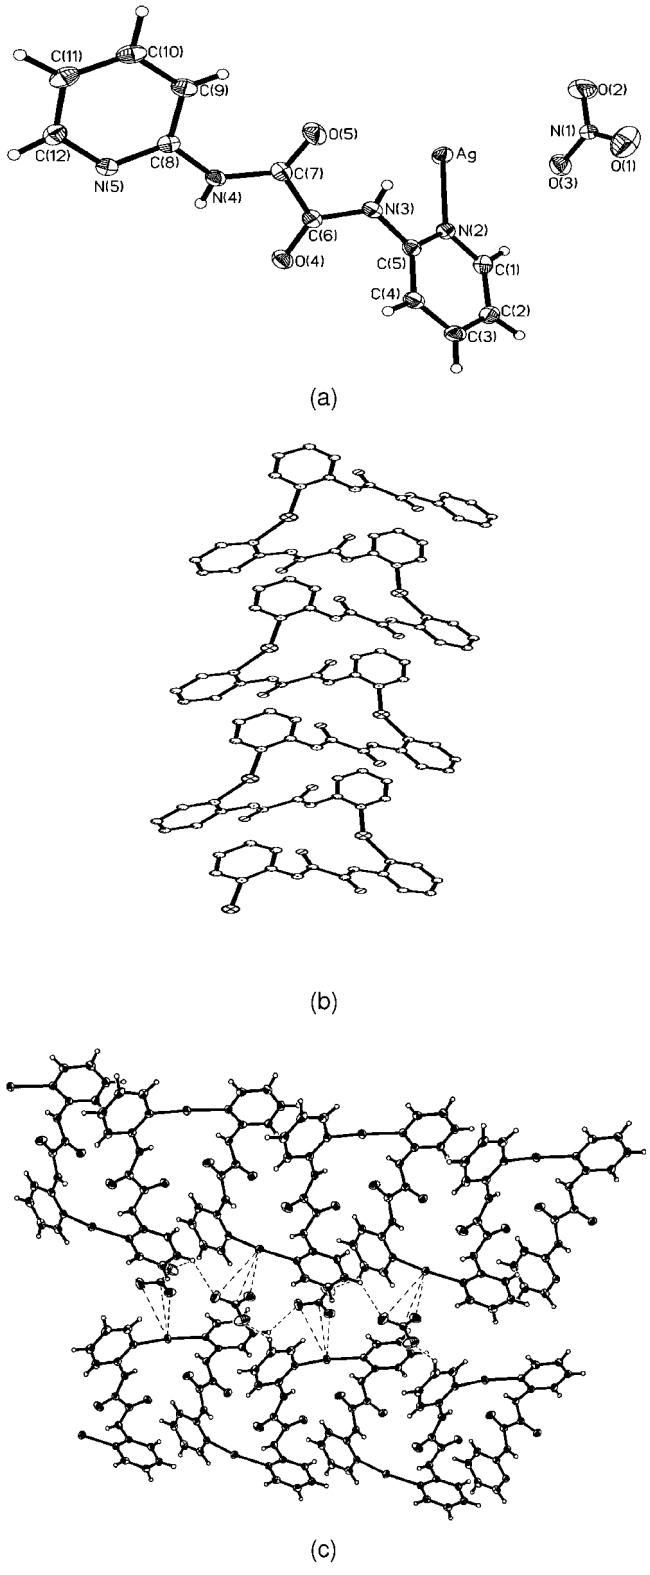

Figure 2. (a) The asymmetric unit of **1**; (b) an ORTEP diagram showing the helical structure of **1**; the hydrogen atoms are omitted for clarity; (c) the interactions between the anions and the cations

flat, but twisted around the C−N bonds, with a dihedral angle of 31.7° between the planes of the two pyridine rings. Most interestingly, each polymer chain is linked to the other through a series of self-complementary double hydrogen bonds and Ag···O interactions (Ag···O: 3.194 and 3.047 Å) to form polymer pairs. The DA:AD self-complementary interaction involves two strong N−H···O hydrogen bonds. The H···N distances are 2.474 and 2.422 Å and the corresponding angles are 132.6 and 141.4°, respectively. One of the ClO_4^- anions interacts with the methyl hydrogen of the CH_3CN ligand through two C−H···O hydrogen bonds (H···O: 2.302 and 2.544 Å and ∠ C−H−O: 139.5 and 133.3°, respectively); the other ClO_4^- anion interacts with the metal centre through a Ag···O interaction (Ag···O: 2.739 Å). The molecules are further linked through intermolecular π−π interactions, with interplanar distances of 3.859 Å between the pyridine rings.

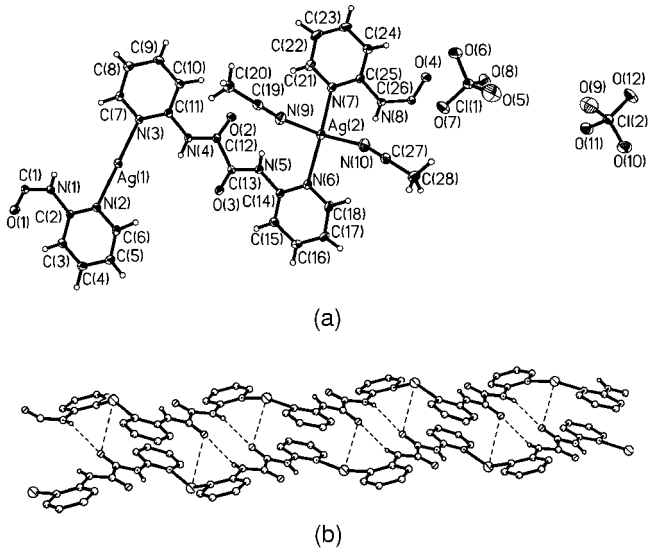

Figure 3. (a) The asymmetric unit of **2**; (b) the interactions between the cations; the pyridine hydrogen atoms are omitted for clarity

Structure of 3

The asymmetric unit of **3** is depicted in Figure 4 (a), and selected bond lengths and angles are listed in Table 1. The single-crystal X-ray structure of **3** shows that it is a coordination polymer consisting of $Ag_4(\mathbf{L})_4(CH_3CN)_2$ metallacycles, and forming a ladder-type structure [Figure 4 (b)]. The distorted tetrahedral coordination geometry of the Ag^I metal centre involves one CH_3CN ligand and three **L** ligands. The ladders are interlinked to each other through a series of self-complementary double N−H···O hydrogen bonds and Ag···O interactions (Ag···O: 3.085 Å) to form molecular sheets. The H···O distance in the strong N−H···O interaction is 2.290 Å, with an N−H−O angle of 161.6°. The PF_6^- anions interact with the pyridyl hydrogen atoms of the **L** ligands through C−H···F hydrogen bonds (H···F: 2.542 and 2.508 Å, with angles 143.4 and 152.7°, respectively). In marked contrast to the twisted conformations in complexes **1** and **2**, the bidentate **L** ligand in each cation of complex **3** is flat, with a dihedral angle of 0° between the planes of the two pyridine rings.

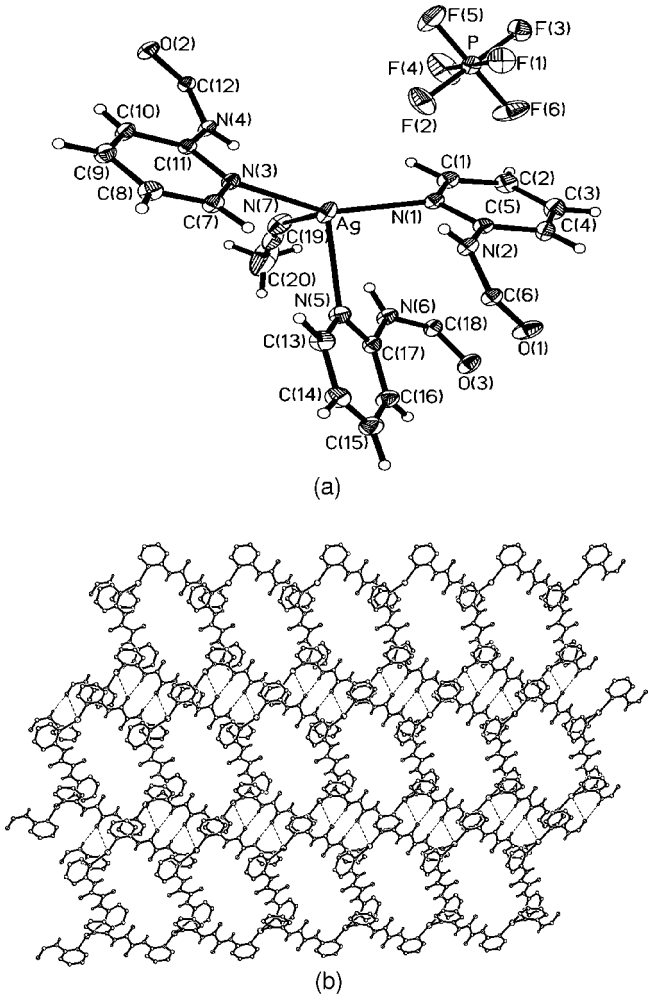

Figure 4. (a) The asymmetric unit of **3**; (b) an ORTEP diagram showing the ladder type structure of **3**; the CH_3CN molecules and the pyridyl hydrogen atoms are omitted for clarity

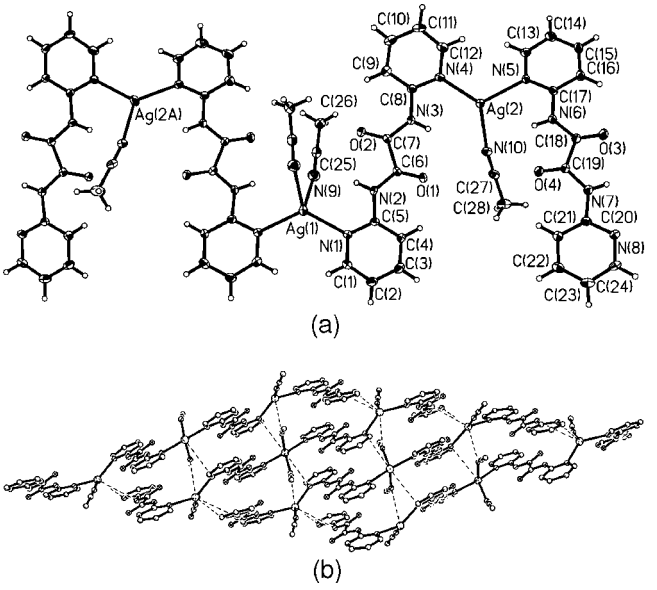

Figure 5. (a) An ORTEP diagram of **4**; (b) an ORTEP diagram showing the interactions among the molecules of **4**; the hydrogen atoms are omitted for clarity

In the structures of complexes **2** and **3**, a new set of interactions involving a pair of Ag···O interactions and self-complementary double N−H···O hydrogen bonds was found to self-assemble the coordination polymers into 2-D networks. By way of comparison, the complementary amide hydrogen bonds in the complexes $\{[AgL']X\}_\infty$ [L′ = *N*,*N*′-bis(3-pyridinecarboxamido)-1,2-ethane; X = ClO_4^-, $CF_3SO_3^-$ or NO_3^-][8] show H···O distances in the range 2.833 to 2.970 Å, which are significantly longer that those found for complexes **2** and **3** (2.290 to 2.474 Å).

Structure of 4

The ORTEP diagram of the trinuclear complex **4** and its packing diagram are depicted (see a and b in Figure 5), respectively. Selected bond lengths and angles are listed in Table 1. The single-crystal X-ray structure of **4** shows that the complex consists of a trinuclear cation $[Ag_3(\mathbf{L})_4(CH_3CN)_4]^{3+}$ and three BF_4^- anions. Two types of coordination geometries are observed for the metal centres. The Ag[I] ion, which is coordinated by two **L** ligands and one CH_3CN ligand, has a distorted triangular planar geometry, whereas the other, coordinated by two **L** and two CH_3CN ligands, has a distorted tetrahedral geometry. The dihedral angles between the planes of the two pyridine rings are 2.0 and 5.2°. The molecule is chiral with a C_2 axis bisecting the N(9)−Ag(1)−N(9A) angle. The trinuclear complexes are interlinked to each other through extensive Ag···N (Ag···N: 3.487 and 3.654 Å) and π−π stacking interactions to form molecular bands. These are interlinked by the BF_4^- anions through extensive C−H···F hydrogen bonds. The interplanar distances between the pyridine rings forming the π−π stacking interactions are 3.875, 3.619 and 3.783 Å, respectively.

In the four complexes mentioned above, the silver atoms of complexes **2**, **3** and **4** have distorted tetrahedral geometries, presumably due to the ligand constraints. Complex **3** has the greatest distortions, with the angles in the range 90.75(10) to 150.12(8)°. In complexes **2** and **4**, the tetrahedral silver atoms show a smaller degree of distortion, with angles in the range 97.30(17) to 145.13(14)° for **2** and 83.8(3) to 125.4(2)° for **4**.

Concluding Remarks

In this study, the coordination chemistry of AgX (X = NO_3^-, ClO_4^-, PF_6^- and BF_4^-) with *N*,*N*′-di(2-pyridyl)oxamide was investigated. Complex **1** is a coordination polymer which forms helical chains whereas complex **4** is a discrete trinuclear complex. In complexes **2** and **3**, a new set of interactions involving two Ag···O interactions and self-complementary double N−H···O hydrogen bonds was found, which link the linear chains and ladder structures of **2** and **3** into polymer pairs and molecular sheets, respec-

tively. Obviously, the *N*,*N*′-di(2-pyridyl)oxamide ligand is sufficiently flexible to adjust to the stereochemical requirements for the formation of complexes **1**−**4** by twisting about the C−N bonds. It is also shown that the self-assembly frameworks of these Ag^I coordination polymers can be altered by changing their counterions. These frameworks are also highly influenced by coordination of CH_3CN solvent molecules to the Ag^I centres.

Experimental Section

General Procedures: All manipulations were carried out under dry, oxygen-free nitrogen by using Schlenk techniques, unless otherwise noted. Solvents were dried and deoxygenated by refluxing over the appropriate reagents before use. *n*-Hexane and diethyl ether were purified by distillation from sodium/benzophenone, dichloromethane from P_2O_5, and acetonitrile from CaH_2. The visible absorption spectra were recorded on a Hitachi U-2000 spectrophotometer. IR spectra were obtained from a Jasco FT/IR-460 plus spectrometer. Elemental analyses were obtained from a PE 2400 series II CHNS/O analyzer or a HERAEUS VaruoEL analyzer.

Materials: The reagents AgX (X = NO_3^-, ClO_4^-, BF_4^- and PF_6^-) were purchased from Aldrich Chemical Co. The ligand *N*, *N*′-di(2-pyridyl)oxamide was prepared according to a literature procedure.[6]

Syntheses: The complexes were synthesized by reaction of AgX (X = NO_3^-, ClO_4^-, PF_6^- and BF_4^-) with *N*, *N*′-di(2-pyridyl)oxamide in CH_3CN.

$[Ag(L)(NO_3)]_\infty$ (1): $AgNO_3$ (0.050 g, 0.294 mmol) and *N*,*N*′-di(2-pyridyl)oxamide (0.142 g, 0.587 mmol) were added successively to a flask containing 15 mL of CH_3CN. The mixture was then refluxed for 24 h to yield a yellow solution, and diethyl ether added to induce precipitation. The precipitate was filtered and washed with diethyl ether and then dried under reduced pressure to give the light yellow product. Yield: 0.087 g (72%). UV/Vis (CH_3CN): λ = 299 nm. IR (KBr disk): ν̃ = 3168 (br), 1686 (s), 1592 (m), 1574 (m), 1497 (m), 1432 (s), 1384 (m), 1302 (m), 1152 (w), 777 (w), 553 (w) cm^{-1}. $C_{12}H_{10}AgN_5O_5$ (412.12): calcd. C 34.97, H 2.44, N 16.99; found C 35.01, H 2.20, N 17.01.

$[Ag(L)(CH_3CN)(ClO_4)]_\infty$ (2): Prepared as described for **1**. Yield: 65%. UV/Vis (CH_3CN): λ = 282 nm. IR (KBr disk): ν̃ = 3164 (br), 1686 (s), 1592 (m), 1575 (m), 1497 (m), 1433 (s), 1302 (m), 1087 (m), 778(w), 625(w), 552(w), 483(w), 418(w) cm^{-1}. $C_{28}H_{26}Ag_2Cl_2N_{10}O_{12}$ (981.23): calcd. C 34.27, H 2.67, N 14.27; found C 34.67, H 2.28, N 14.28.

$[Ag_2(L)_3(CH_3CN)_2(PF_6)_2]_\infty$ (3): Prepared as described for **1**. Yield: 58%. UV/Vis (CH_3CN): λ = 314 nm. Synthesis, Characterization and Reactivity of New (μ-Aminocarbyne)diruthenium Complexes Containing Alkynylimino Ligands

Luigi Busetto,*[a] Fabio Marchetti,[a] Stefano Zacchini,[a] and Valerio Zanotti[a]

Keywords: Ruthenium / Dinuclear complexes / Carbynes / C−C coupling / Alkynylimino ligands

Addition of acetylides R′C≡CLi [R′ = Tol, Ph, Me_3Si, *n*Bu, C(Me)=CH_2] to the diruthenium complexes [Ru_2{μ-CN(Me)(R)}(μ-CO)(CO)($NCCMe_3$)$(Cp)_2$]$^+$ (R = Xy, **2a**; Bz, **2b**; Me, **2c**) results in the formation of [Ru_2{μ-CN(Me)(R)}(μ-CO)(CO){N(H)=C(CMe_3)(C≡CR′)}$(Cp)_2$]$^+$ (R = Xy, R′ = Tol, **3a**; R = Bz, R′ = Tol, **3b**; R = Me, R′ = Tol, **3c**; R = Xy, R′ = Ph, **4a**; R = Bz, R′ = Ph, **4b**; R = Me, R′ = Ph, **4c**; R = Bz R′ = H, **5**; R = Xy, R′ = *n*Bu, **6**; R = Xy, R′ = [C(Me)=CH_2], **7**), which contain an alkynylimino ligand, formed from addition of the acetylide to the Me_3CCN ligand. Structural and spectroscopic studies show that all these complexes contain the two Cp ligands in a relative *cis* arrangement, whereas two isomers arise from the different orientation of the substituents on the bridging aminocarbyne μ-CN(Me)(R) when R ≠ Me. Addition of secondary amines to **3**–**7** results in a stereo- and regioselective *cis* amination of the C–C triple bond to give the new complexes [Ru_2{μ-CN(Me)(R)}(μ-CO)(CO){N(H)=C(CMe_3)C(H)=C(NMe_2)(Tol)}$(Cp)_2$]$^+$ (R = Xy, **8a**; Bz, **8b**; Me, **8c**), [Ru_2{μ-CN(Me)(Xy)}(μ-CO)(CO){N(H)=C(CMe_3)C(H)=C(NC_5H_{10})(Tol)}$(Cp)_2$]$^+$(**9**) and [Ru_2{μ-CN(Me)(Xy)}(μ-CO)(CO){N(H)=C(CMe_3)C(H)=C(NMe_2)C(Me)=CH_2)}$(Cp)_2$]$^+$ (**10**) containing the hitherto unknown new imino-2-en-3-amine ligand. The solid-state structures of these products have been analyzed by X-ray analysis and, in solution, by NOE spectroscopic studies.

Introduction

Transition metal complexes containing η^1-coordinated imines represent an important field in classical coordination chemistry and organometallic chemistry.[1−3] Several synthetic routes for their synthesis have been developed in the last decade, including displacement of a labile ligand by free imine and modification of coordinated ligands.[4] Among the latter, some interesting examples are: a) oxidation of coordinated amines;[5] b) condensation of coordinated amines with free aldehydes and ketones;[6] c) reduction of coordinated nitriles.[7,8] Only in a limited number of cases the imino ligands have been obtained via addition of a carbon nucleophile to coordinated nitriles.[8,9] We have recently reported a particular case of the latter procedure employing acetylides as carbon nucleophiles.[10] Thus, addition of TolC≡CLi (Tol = *p*-MeC_6H_4) to [Fe_2{μ-CN(Me)(Xy)}(μ-CO)(CO)($NCCMe_3$)$(Cp)_2$]$^+$ (Xy = 2,6-$Me_2C_6H_3$), followed by protonation, in THF at low temperature, resulted in the formation of the complex [Fe_2{μ-CN(Me)(Xy)}(μ-CO)(CO){N(H)=C(CMe_3)(C≡CTol)}$(Cp)_2$]$^+$, which contains the new alkynylimino ligand HN=C(CMe_3)(C≡CTol). Unfortunately, the reported reaction occurs only in the case described, and, depending on the experimental conditions, other products can be formed. Thus, we have decided to investigate analogous reactions of diruthenium complexes. As will be shown in this paper, the reaction for the synthesis of alkynylimino complexes of ruthenium is very general: aromatic, aliphatic and functionalized acetylides can be used, as well as different groups on the aminocarbyne. Moreover, the high unsaturation of the alkynylimino ligand offers the possibility to exploit it for further modification, and some studies on nucleophilic additions are reported here.

Results and Discussion

Synthesis and Characterization of the Nitrile Complexes [Ru_2{μ-CN(Me)(R)}(μ-CO)(CO)($NCCMe_3$)$(Cp)_2$]$^+$ (R = Xy, 2a; Bz, 2b; Me, 2c)

One CO ligand in the diruthenium aminocarbyne complexes [Ru_2{μ-CN(Me)(R)}(μ-CO)$(CO)_2(Cp)_2$]$^+$ [R = Xy, **1a**; CH_2Ph (Bz), **1b**; Me, **1c**] [11] can be easily replaced by Me_3CCN after treatment with Me_3NO in THF and a slight excess of the nitrile compound (Scheme 1). The resulting complexes [Ru_2{μ-CN(Me)(R)}(μ-CO)(CO)($NCCMe_3$)$(Cp)_2$]$^+$ (R = Xy, **2a**; Bz, **2b**; Me, **2c**), obtained in good yields (85−88%), have been spectroscopically characterized. The IR spectra of **2a**−**c** show the presence of a terminal and a bridging CO, whereas the ^{1}H and ^{13}C spectra show

R = Xy **1a**, Bz **1b**, Me **1c**

R = Xy **2a**, Bz **2b**, Me **2c**

Scheme 1

resonances due to two inequivalent Cp ligands. Moreover, resonances typical of the Me_3CCN ligand are present in both the ^1H and ^{13}C NMR spectra, confirming coordination of the nitrile group in complexes **2a**−**c**.

It is worth noting that in the case of **2a,b,** where the bridging aminocarbyne ligand is non-symmetrically substituted, two isomers are present in solution (see Scheme 2, where the two isomers have been labeled α and β; α/β = 1.5), as a consequence of the different orientation of the substituents in the μ-CN(Me)(R) ligand and hindered rotation around the C−N bond.

Another explanation deriving from a possible *cis*−*trans* isomerisation of the two Cp ligands with respect to the Ru_2C_2 plane, is ruled out by the observation of only one isomer in the case of **2c** (R = Me). It is worth noting that the starting compounds **1a**−**c** adopt a *cis*-arrangement,[11] and this is the preferred geometry for the analogous (aminocarbyne)diruthenium and -diiron complexes.[12−14] The fact that the two isomers are due to the orientation of the μ-CN(Me)(R) ligand has been further supported in the case of **2a** by NOE spectroscopic measurements. Some important results arise from these studies: 1) in both isomers, the NOE is mutually generated between the two Cp ligands, as expected for a *cis* geometry. 2) NOE is generated in the major isomer (but not in the minor) between the NMe group and the Me_3CCN ligand. Thus, it is possible to assign the α structure to the major isomer. 3) In perfect agreement with this, NOE is observed in the minor isomer between the protons of the Xy group and the Me_3CCN ligand (β structure). 4) In both the α and β isomers, the Cp resonating at lower frequencies (< 5 ppm) is the one on the same side of the Xy group. It is noteworthy that in **2b,c** both Cp ligands resonate above 5 ppm in the ^1H NMR spectra, suggesting that the shift at lower frequencies of one Cp in **2a** is due to the presence of Xy.

Synthesis and Characterization of the Alkynylimino Complexes $[Ru_2\{\mu\text{-}CN(Me)(R)\}(\mu\text{-}CO)(CO)\{N(H)=C(CMe_3)(C{\equiv}CR')\}(Cp)_2]^+$ (R = Xy, R′ = Tol, 3a; R = Bz, R′ = Tol, 3b; R = Me, R′ = Tol, 3c; R = Xy, R′ = Ph, 4a; R = Bz, R′ = Ph, 4b; R = Me, R′ = Ph, 4c; R = Bz, R′ = H, 5; R = Xy, R′ = *n*Bu, 6; R = Xy, R′ = [C(Me) = CH_2], 7)

The nitrile complexes **2a**−**c** react, in THF at low temperature, with different acetylides R′C≡CLi (R′ = Tol, Ph, Me_3Si, *n*Bu, C(Me)=CH_2) affording, in good yields (56−75%), the new $[Ru_2(\mu\text{-}CN(Me)(R)\}(\mu\text{-}CO)(CO)\{N(H)=C(CMe_3)(C{\equiv}CR')\}(Cp)_2]^+$ (R = Xy, R′ = Tol, **3a**; R = Bz, R′ = Tol, **3b**; R = Me, R′ = Tol, **3c**; R = Xy, R′ = Ph, **4a**; R = Bz, R′ = Ph, **4b**; R = Me, R′ = Ph, **4c**; R = Bz R′ = H, **5**; R = Xy, R′ = *n*Bu, **6**; R = Xy, R′ = [C(Me)=CH_2], **7**) which contain an alkynylimino ligand, formed from addition of the acetylide to the Me_3CCN ligand (Scheme 3). The hydrogen of the NH group probably arises from the CH_2Cl_2 used to solubilize the residue obtained after evaporation of the THF during the work-up of the reaction (see next section). Interestingly, when $Me_3SiC{\equiv}CLi$ is used, cleavage of the Si−C(sp) bond occurs and, thus, the final product contains a proton instead of $SiMe_3$. Unexpectedly, this is the only way to obtain **5**, since addition of HC≡CNa to **2b** results in decomposition products.

Scheme 3

Complexes **3**−**7** have been fully characterized by IR, ^{1}H and ^{13}C NMR spectroscopy; **3a** has also been characterized by X-ray crystallography, and **3b, 4b** and **5** by ESI MS. The mass spectra confirm the ionic nature of these complexes: a positive ion corresponding to the cation and a negative ion at *m*/*z* = 149, corresponding to $CF_3SO_3^-$ are, in fact, present. The IR spectra of **3**−**7** in CH_2Cl_2 show ν(CO) at ca. 1968 and 1810 cm^{-1} and bands at ca. 2200 cm^{-1} attributable to ν(C≡C); a broad signal at ca. 3320 cm^{-1} (in KBr) is a clear indication of the presence of the NH group. It is worth noting that in the ^{1}H NMR spectra of **3a, 4a, 6** and **7** (R = Xy), one Cp resonates below and one above δ = 5 ppm, whereas in the remaining alkynylimino compounds (R = Bz or Me) both resonances are above δ = 5 ppm, confirming the peculiar shielding effect of the Xy group on the closer Cp ligand. The ^{13}C NMR spectra show four high frequency resonances at δ ca. 310, 236, 202 and 184 ppm, in the typical regions for bridging aminocarbyne, bridging and terminal CO and imine carbon atoms, respectively.

As in **2c**, the NMR spectra of **3c** and **4c** show the presence in solution of only one species, whereas two isomers exist for all the complexes with R ≠ Me (see Scheme 4). The ratio of these isomeric forms is ca. 2:1 for complexes **3b**, **4b** and **5** (R = Bz), and increases up to 10−20:1 for **3a**, **4a**, **6** and **7** (R = Xy), in agreement with the different steric properties of the aminocarbyne substituents: thus, one isomer strongly predominates when the bulkier Xy group is present. Moreover, in all these cases, it can be assumed that the major species is the α-isomer, in which the bulky alkynylimino ligand is on the same side of the less bulky Me group.

The possible presence of *cis*-*trans* forms of the $Cp_2Ru_2(\mu\text{-}C)_2$ core, or of isomers deriving from the C=N iminic double bond, cannot be excluded, but they are less convincing since they would also entail the presence of isomers in the case of complexes with symmetrically substituted aminocarbyne. NOE measurements further support our hypothesis. For example, irradiation of the Cp resonance (δ = 5.46 ppm) of the major isomer of **3a** resulted in the enhancement of the resonances due to the other Cp ligand, the NMe group and some protons of the HN=C(CMe$_3$)(C≡CTol) ligand, in agreement with the proposed *cis*-α structure. Conversely, irradiation of the Cp resonating at lower frequency (δ = 4.95 ppm) affected only the resonance due to the other Cp (δ = 5.46 ppm) and the Xy group. Moreover, in the case of **3b**, because of the higher concentration of the minor isomer than in the case of **3a**, it has been possible to determine the relative orientation of the substituents in both the isomers via NOE measurements. The major isomer shows results similar to the ones reported for the major isomer of **3a**, indicating its *cis*-α structure. Conversely, in the minor isomer of **3b** it has been possible to detect an appreciable NOE between the two Cp ligands, between one Cp and the NMe group, and between the other Cp, the NBz and the alkynylimino ligand confirming a *cis*-β structure.

Further support is given to our stereochemical assignments from the X-ray structure of **3a**, which is reported in Figure 1, whereas relevant bond lengths and angles are reported in Table 1.

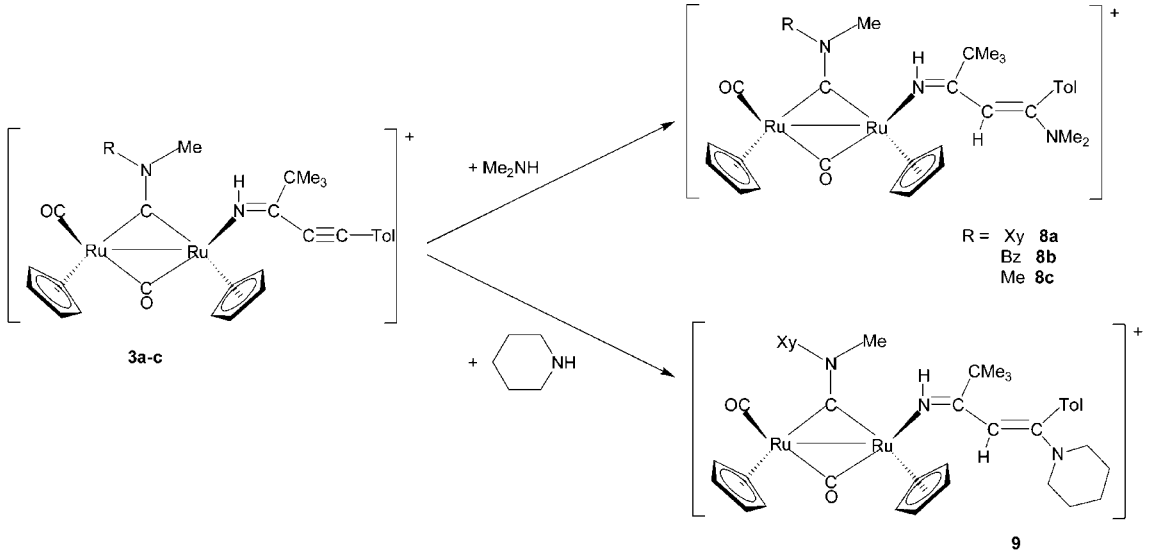
The molecular structure of **3a** is almost identical to the one previously reported for the analogous diiron complex $[Fe_2\{\mu\text{-}CN(Me)(Xy)\}(\mu\text{-}CO)(CO)\{N(H)=C(CMe_3)(C\equiv CTol)\}(Cp)_2]^+$,[10] and it can be better described as composed of two moieties, i.e. the $[Ru_2\{\mu\text{-}CN(Me)(Xy)\}(\mu\text{-}CO)(CO)(Cp_2)]$ unit and the alkynylimino ligand $HN=C(CMe_3)(C\equiv CTol)$. The Ru−Ru distance [2.7105(9) Å] is typical for a Ru−Ru single bond.[15−17] The C(13)−N(1) distance [1.328(11) Å] gives evidence of partial double bond character in the μ-CN(Me)(Xy) ligand, which could be alternatively described as a bridging iminium. The two Cp ligands lie on the same side of the mean plane determined by the inner Ru_2C_2 core in a mutual *cis*-position. Moreover, the bulky xylyl group on the bridging aminocarbyne ligand lies on the opposite side of the alkynylimino ligand. Thus, **3a** adopts, in the solid-state, a *cis*-α structure, which is also the predominant isomer revealed in solution by the NOE studies.

Reactions of $[Ru_2\{\mu\text{-}CN(Me)(R)\}(\mu\text{-}CO)(CO)\{N(H)=C(CMe_3)(C\equiv CR')\}(Cp)_2]^+$

Complexes **3a**−**c** react at room temperature in THF with an excess of Me_2NH or piperidine ($C_5H_{10}NH$) giving good yields (60−70%) of new products which show, from the ESI MS analyses, that the secondary amine has been added to **3a**−**c** without loss of the imino ligand. The ν(CO) and the disappearance of ν(C≡C) in the IR spectra suggests that addition has occurred on the C≡C bond; hence, the new products can be formulated as $[Ru_2\{\mu\text{-}CN(Me)(R)\}(\mu\text{-}CO)(CO)\{N(H)=C(CMe_3)C(H)=C(NMe_2)(Tol)\}(Cp)_2]^+$ (R = Xy, **8a**; Bz, **8b**; Me, **8c**) and $[Ru_2\{\mu\text{-}CN(Me)(Xy)\}(\mu\text{-}CO)(CO)\{N(H)=C(CMe_3)C(H)=C(NC_5H_{10})(Tol)\}(Cp)_2]^+$ (**9**) (Scheme 5).

Amination of alkynes is a widely used reaction in organic chemistry, and is promoted by a large variety of transition metals.[18] In our case, the reaction can be better viewed as the amination of an α,β-unsaturated imine η^1-coordinated to ruthenium. The reaction seems to be completely stereo- and regioselective. Amination of **3c**, which exists in solution as a single isomer, results in the formation of only a single species, whereas, amination of the complexes **3a,b**, which



Scheme 5

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

exist as two isomers (α and β) results in the formation of two products in the same ratio of the starting compounds (in the case of **8a** the concentration of the minor isomer is too low to be fully characterized).

In order to understand better the stereo- and regiochemistry of the addition, an X-ray study has been carried out on **8a**. The molecular structure of **8a** is reported in Figure 2, whereas the relevant bond lengths and angles are reported in Table 2. The molecule is chiral, but the racemic mixture is present within the crystal; two independent molecules are present in the asymmetric unit, with similar relative arrangement of the atoms, similar bond lengths and bond angles but opposite absolute structure. Differences are mainly attributable to packing effects and, in all cases, the parameters describing the bonds in the two molecules fall in the same ranges expected for a similar hybridization of the atoms and bond order. As in the case of **3a**, the structure of **8a** can be discussed in terms of two moieties, i.e. the $Ru_2\{\mu\text{-}CN(Me)(Xy)\}(\mu\text{-}CO)(CO)(Cp_2)$ unit and the new $HN{=}C(CMe_3)CH{=}C(NMe_2)(Tol)$ ligand. The former resembles the analogous unit in **3a** and does not need any further comments; it is, however, worth noting the fact that in this case the molecule also adopts a *cis*-α structure considering the relative position of the two Cp ligands and the orientation of the N(Me)(Xy) group on the aminocarbyne.

The new $HN{=}C(CMe_3)CH{=}C(NMe_2)(Tol)$ ligand is an imino-2-en-3-amine η^1-coordinated to one ruthenium atom via the imino nitrogen [Ru(1)−N(2) 2.077(13) and Ru(3)−N(5) 2.133(13) Å]. In agreement with this, the N(2)−C(13) [1.282(13) Å], N(5)−C(63) [1.248(13) Å], C(18)−C(19) [1.34(2) Å] and C(68)−C(69) [1.35(2) Å] distances are typical double bonds (compare 1.28 Å in free imines and oximes and 1.32 Å in ethylene for typical C=N and C=C, respectively),[19] whereas the C(13)−C(18) [1.493(14) Å] and C(63)−C(68) [1.502(15) Å] interactions are essentially single bonds {compare C(13)−C(14) [1.56(2) Å] and C(63)−C(64) [1.55(2) Å]}, suggesting the absence of conjugation between the imine and enamine. In fact, their two π-systems are nearly orthogonal [dihedral angles N(2)−C(13)−C(18)−C(19) −99.0(19)° and N(5)−C(63)−C(68)−C(69) 101(2)°]. The atoms of the enamine in the two molecules are nearly in the same plane [mean deviations 0.0510 and 0.0467 Å from the least-squares planes C(13)−C(18)−C(19)−N(3)−C(22) and C(63)−C(68)−C(69)−N(6)−C(72), respectively], and they all have sp^2 hybridization. These planes form relatively small angles with the planes of the NMe_2 units [i.e. 22.58(0.97) and 27.74(1.03)° for the two molecules], whereas the Tol groups lie considerably out of the enamine planes, with angles of 49.83(0.42) and 50.19(0.46)° for the two molecules, respectively.

On the basis of the X-ray analysis it is possible to conclude that the amination of the coordinated alkynylimine occurs in a *cis* fashion with the nucleophile adding regioselectively to the β-carbon. The nature of compound **8** and **9** has been further confirmed by IR and NMR spectroscopy. The IR spectra of **8** and **9** in CH_2Cl_2 show two ν(CO) at ca. 1965 and 1808 cm^{-1}, due to the terminal and bridging carbonyl, respectively, whereas a band at ca. 3325 cm^{-1} in the spectra in KBr is attributable to the NH stretching. The NMR spectra of **8** and **9** have been fully assigned using DEPT, gs-HSQC and gs-HMBC experiments.[20] The main features of the ^1H spectra are the presence of two inequiva-

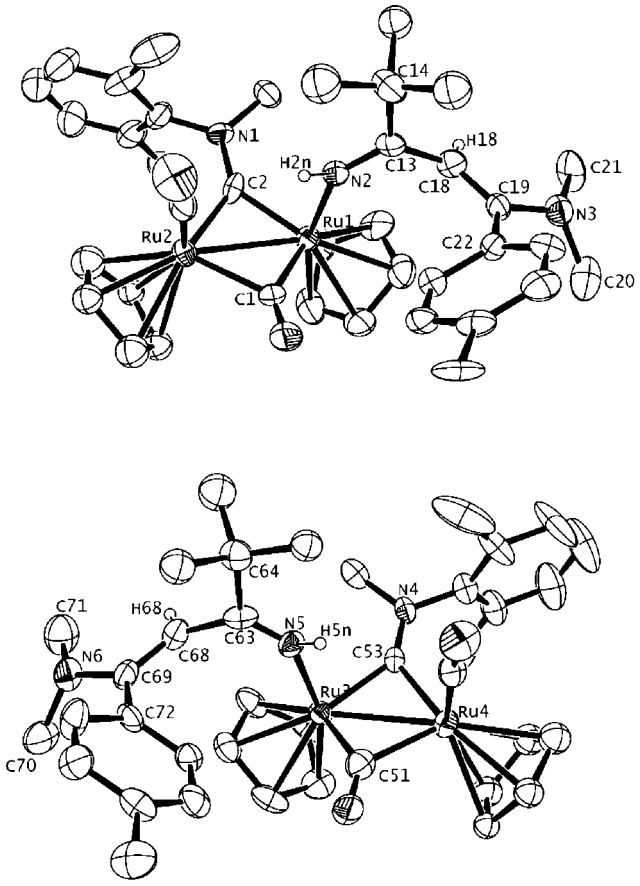


Figure 2. Molecular structure of the two independent molecules of **8a**, with key atoms labeled (all H atoms, apart from H2a, H18, H5n and H68 have been omitted). Displacement ellipsoids are at 30% probability level.

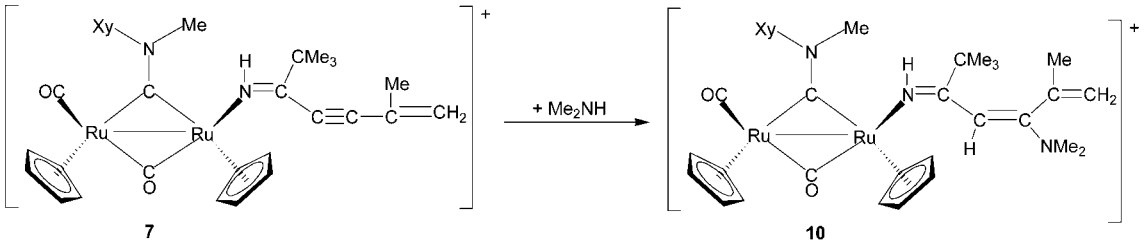


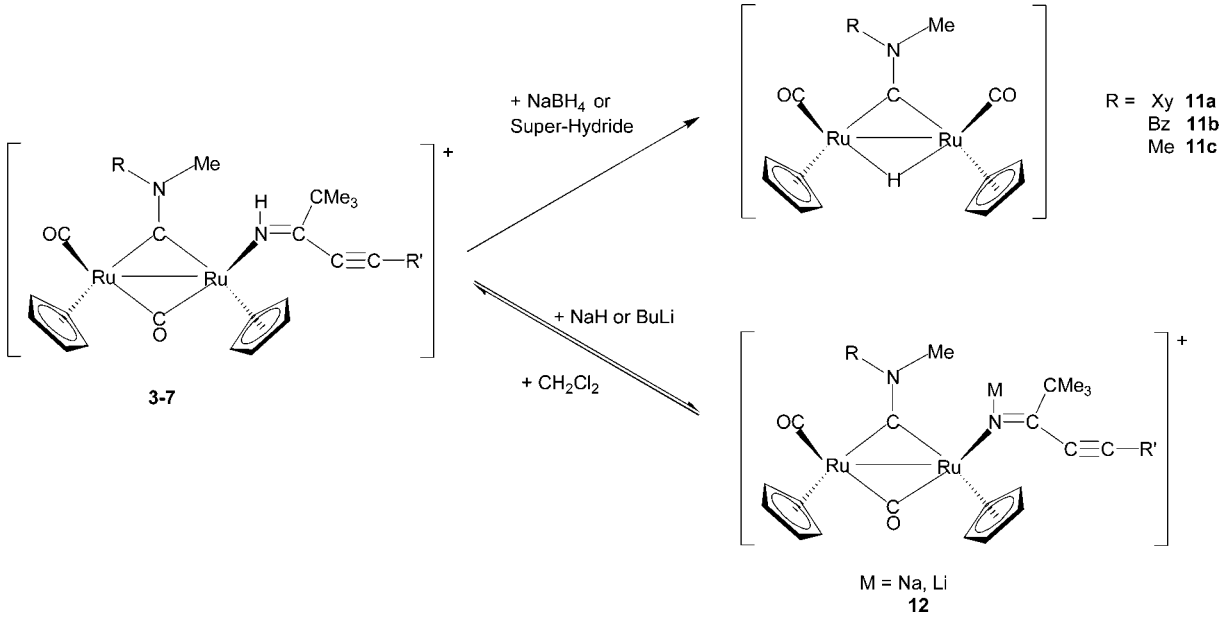
Scheme 6

lent Cp ligands, a broad resonance at δ ca. 6.5 ppm due to the iminic NH and a singlet at δ ca. 5 ppm due to the olefinic α-CH proton. Four different resonances at high frequency are present in the ^{13}C NMR spectra due to the bridging carbyne (ca. 310 ppm), the bridging CO (δ ca. 236 ppm), the terminal CO and the carbon of the imine (both at δ ca. 200 ppm). The α-CH olefinic carbon resonates at ca. 100 ppm, whereas the quaternary β-carbon resonates at δ = 155−156 ppm.

The NMR spectra of **8c** show the presence in solution of a single isomer, whereas two isomers are present in the case of **8a,b** and **9**, with ratios which perfectly correspond to the isomer ratios in the starting compounds **3a,b**. Therefore, it is possible to conclude that, in these cases, the two isomers present in solution are also the α and β isomers arising from the different orientation of the R- and Me groups on the aminocarbyne. The stereochemistry of all the addition products has been further confirmed by NOE experiments. For example, irradiation of the olefinic α-CH proton (δ = 5.20 ppm) of the major isomer of **9** resulted in the enhancement of the resonances due to the α-protons of the piperidine (δ = 3.11 ppm) and the Cp at higher frequency (δ = 5.38 ppm). In the same way, NOE was generated on the olefinic α-CH resonance, on the Cp resonating at δ = 4.98 ppm and in the aminocarbyne NMe resonance by irradiation of the Cp resonance at δ = 5.38 ppm. These data confirm that in this case the amination has occurred with a *cis* geometry and that the imino ligand in the major isomer is on the same side as the Me group of the aminocarbyne ligand (α isomer). Moreover, it is noteworthy that in this case the Cp resonating at lower frequency (δ = 4.98 ppm) is the one on the same side of the Xy group. The NOE observed on one Cp ligand when the other is irradiated agrees with a *cis* arrangement of the $Ru_2\{\mu\text{-}CN(Me)(Xy)\}(\mu\text{-}CO)(CO)(Cp)_2$ core.

Finally, the amination of **7**, which contains an iminoalkynyl ligand conjugated with an olefinic end group, i.e. $HN{=}C(CMe_3)C{\equiv}CC(Me){=}CH_2$, occurs regioselectively onto the C≡C bond affording the complex $[Ru_2\{\mu\text{-}CN(Me)(Xy)\}(\mu\text{-}CO)(CO)\{N(H){=}C(CMe_3)C(H){=}C(NMe_2)C(Me){=}CH_2\}(Cp)_2]^+$ (**10**) which contains the new 1-imino-2,4-dien-3-amine ligand $HN{=}C(CMe_3)CH{=}C(NMe_2)C(Me){=}CH_2$, in a 52% yield. In this case, the reaction is stereoselective, resulting only in the formation of the *cis* addition product (Scheme 6), as shown by NOE experiments.

Strong nucleophiles such as $NaBH_4$ or super-hydride ($LiBHEt_3$) react with **3**−**7** replacing the alkynylimino li-



Scheme 7

gand to give the hydrido complexes $[Ru_2\{\mu\text{-}CN(Me)(R)\}(\mu\text{-}H)(CO)_2Cp_2]$ (R = Xy, **11a**, Bz, **11b**; Me, **11c**),[21] whereas the reaction with nucleophiles having strong basic character such as NaH and *n*BuLi results in the almost quantitative formation of a new species, tentatively formulated as **12** (Scheme 7). Because of their instability, the latter compounds have not been isolated, but only characterised by IR spectroscopy. Compounds **12** show one terminal and one bridging ν(CO) absorption at wavenumbers similar to those of the cationic derivatives **3**−**7:** 1958 vs and 1803 s for the product obtained from **3a** and *n*BuLi, which should be compared with the IR spectrum of **3a** in THF (1961 vs, 1811 s). The reaction can easily be reversed by evaporation of the solvent in vacuo followed by dissolution of the residue in CH_2Cl_2. A simple explanation could be that metalation of the nitrogen of the imino ligand occurs and, thus, the new products can be formulated as $[Ru_2\{\mu\text{-}CN(Me)(R)\}(\mu\text{-}CO)(CO)\{N(M)=C(CMe_3)(C\equiv CR')\}(Cp_2)]^+$ (M = Li, Na, **12**). An alternative could be deprotonation of the NH instead of metalation, but this would afford a neutral azavinylidene species, in contrast with the IR data. It is noticeable that deprotonation of coordinated imines to give azavinylidene is quite well documented in the literature, whereas metalation is more rare.[4,22,23] Complexes of type **12** are also the product directly formed in THF during the reaction of **2a**−**c** with R′C≡CLi; the alkynylimino products **3**−**7** are, in fact, formed only after evaporation of THF and dissolution of the residue in CH_2Cl_2 (see above).

Conclusion

Nitriles are reported to be labile ligands and, therefore, very often used as intermediates for substitution reactions in organometallic chemistry. Nonetheless, addition of nucleophiles such as amines, alcohols and water have been extensively used for the synthesis of a large variety of metal complexes containing ligands such as azavinylidenes, amides, imidic esters and aminidines.[24,25] Addition of carbon nucleophiles is also known, although less common.[8,26] Despite our recent findings which demonstrated that the addition of acetylides to the nitrile ligand in (aminocarbyne)diiron complexes occurs only in one specific case,[10] we show here that the corresponding reaction is quite general for ruthenium: different substituents on the aminocarbyne have been used (i.e. Xy, Bz, Me) as well as aromatic and aliphatic acetylides. The alkynylimino complexes **3**−**7** are the only products formed in all the cases studied. Therefore, it seems that in the case of ruthenium there is no tendency at all for coupling between the imino and the aminocarbyne ligand, as found in the iron complex. Moreover, in the case of ruthenium it is not necessary to add strong acids, since the acidity of CH_2Cl_2 is sufficient for protonating the nitrogen, whereas the iron analogue requires the addition of strong acids. This suggests an enhanced basicity of the nitrogen in the case of ruthenium compared to iron, which could explain the different output of the two reactions.

The new alkynylimino ligand shows electrophilic properties. Nonetheless, it is not possible to use nucleophiles with a strong basic character, since they metalate the iminic nitrogen rather than adding to the triple bond. Conversely, strong nucleophiles such as $NaBH_4$ gives substitution and not addition. Thus, addition to the alkynylimino ligand can be achieved only using nucleophiles which are not too strong and not too basic, and here the case of secondary amines has been described. The reaction is completely regio- and stereoselective, resulting only in the addition to the β carbon of the ligand and protonation of the α carbon in a *cis* fashion. The resulting ligand can be described as an imino-2-en-3-amine ligand, which, as far as we know, has not been reported before. The procedure elaborated in this paper seems to be an interesting method of synthesizing new bimetallic complexes containing highly unsaturated ligands with heteroatoms.

Experimental Section

All reactions were carried out routinely under nitrogen using standard Schlenk techniques. Solvents were distilled immediately before use under nitrogen from appropriate drying agents. Infrared spectra were recorded with a Perkin−Elmer Spectrum 2000 FT-IR spectrophotometer and elemental analyses were performed on a ThermoQuest Flash 1112 Series EA Instrument. ESI MS spectra were recorded with a Waters Micromass ZQ 4000 with samples dissolved in CH_3CN. All NMR measurements were performed with Varian Gemini 300, Mercury 400 and Inova 600 instruments. The chemical shifts for ^1H and ^{13}C NMR spectra were referenced to internal TMS. The spectra were fully assigned via DEPT experiments and ^1H,^{13}C NMR spectra correlation through gs-HSQC and gs-HMBC experiments.[20] In some cases it has not been possible to assign all the resonances to the minor isomer, especially when it was present in very low concentration. NOE measurements were recorded using the DPFGSE-NOE sequence.[27] All chemicals were used as received from Aldrich Co., except $[Ru_2\{\mu\text{-}CN(Me)(R)\}(\mu\text{-}CO)(CO)_2(Cp)_2][CF_3SO_3]$ (R = Xy, **1a**; Bz, **1b**; Me, **1c**) which were prepared by published methods.[11] The acetylides R′C≡CLi [R′ = Tol, Ph, Me_3Si, *n*Bu, $C(Me)=CH_2$] were prepared just before use from the reaction of the appropriate alkyne R′C≡CH in THF at −50 °C with *n*BuLi (alkyne/*n*BuLi, 1.2).

$[Ru_2\{\mu\text{-}CN(Me)(R)\}(\mu\text{-}CO)(CO)(NCCMe_3)(Cp)_2][CF_3SO_3]$ (R = Xy, 2a; Bz, 2b; Me, 2c). General Procedure: Me_3NO (30.0 mg, 0.400 mmol) was added to a solution containing $[Ru_2\{\mu\text{-}CN(Me)(R)\}(\mu\text{-}CO)(CO)_2(Cp)_2][CF_3SO_3]$ (0.200 mmol) and Me_3CCN (0.1 mL, 0.905 mmol) in THF (5 mL). The resulting suspension was stirred at room temperature for 3 h and, then, the solid removed by filtration through a Celite pad. The solvent was removed under reduced pressure and the residue washed with petroleum ether (2 × 5 mL) and Et_2O (2 × 5 mL) affording the final product as a yellow-orange powder.

[Ru$_2${μ-CN(Me)(R)}(μ-CO)(CO){N(H)=C(CMe$_3$)(C≡CR′)}(Cp$_2$)]$^+$ (R = Xy, R′ = Tol, 3a; R = Bz, R′ = Tol, 3b; R = Me, R′ = Tol, 3c; R = Xy, R′ = Ph, 4a; R = Bz, R′ = Ph, 4b; R = Me, R′ = Ph, 4c; R = Bz, R′ = H, 5; R = Xy, R′ = *n*Bu, 6; R = Xy, R′ = [C(Me)=CH$_2$], 7). General Procedure: A solution of the appropriate acetylide R′C≡CLi (0.225 mmol) in THF (3 mL) was added dropwise to a solution of **2a−c** (0.150 mmol) in THF (6 mL) at −50 °C and the resulting red solution stirred at room temperature for 30 minutes. Then, the solvent was removed in vacuo and the residue dissolved in CH_2Cl_2 (5 mL) and chromatographed through an Al_2O_3 column. The final product was obtained as an orange fraction using CH_3CN as eluent.

X-ray Crystallographic Study: Compounds **3a[CF$_3$SO$_3$]** and **8a[CF$_3$SO$_3$]** were crystallized from CH_2Cl_2/Et_2O. Crystal data were collected at room temperature on a Bruker AXS SMART 2000 CCD diffractometer using Mo-K_α radiation. Intensity data were measured over full diffraction spheres using 0.3° wide ω scans, crystal-to-detector distance 5.2 cm. Cell dimensions and orientation

Table 3. Crystal data and experimental details for **3a[CF$_3$SO$_3$]** and **10a[CF$_3$SO$_3$]**

Complex	**3a[CF$_3$SO$_3$]**	**8a[CF$_3$SO$_3$]**
Empirical formula	$C_{37}H_{39}F_3N_2O_5Ru_2S$	$C_{39}H_{46}F_3N_3O_5Ru_2S$
Formula mass	882.90	927.99
T, K	293(2)	293(2)
λ, Å	0.71073	0.71073
Crystal system	orthorhombic	monoclinic
Space group	$P2_12_12_1$	Cc
a, Å	12.245(2)	12.925(3)
b, Å	14.179(3)	24.789(5)
c, Å	22.219(4)	26.031(5)
α, °	90	90
β, °	90	96.43(3)
γ, °	90	90
Cell volume, Å^3	3857.7(13)	8288(3)
Z	4	8
$D_{calcd.}$, g·cm^{-3}	1.520	1.487
μ, mm^{-1}	0.894	0.836
F(000)	1784	3776
Crystal size, mm	0.35 × 0.25 × 0.19	0.28 × 0.22 × 0.15
θ limits, °	1.70−25.03	1.57−25.03
Reflections collected	34166	36307
Independent reflections	6830 [*R*(int) = 0.0617]	14605 [*R*(int) = 0.1155]
Data/restraints/parameters	6830/ 211/417	14605/554/778
Goodness on fit on F^2	1.075	0.934
*R*1 [$I > 2\sigma(I)$]	0.0661	0.0725
*wR*2 (all data)	0.1756	0.1940
Largest diff. peak and hole, e·Å^{-3}	3.835/−0.837	1.094/−1.154

matrices were initially determined from least-squares refinements on reflections measured in 3 sets of 20 exposures collected in three different ω regions and eventually refined against all reflections. The software SMART [28] was used for collecting frames of data, indexing reflections and determination of lattice parameters. The collected frames were then processed for integration by the software SAINT and empirical absorption corrections were applied with SADABS.[29] Structures were solved by direct methods and structures refined by full-matrix least-squares based on all data using F^2.[30] Crystal data are listed in Table 3. Non-H atoms were refined anisotropically, unless otherwise stated. The hydrogen atoms were added in idealized positions except the ones attached to nitrogen atoms in **8a[CF_3SO_3]** which were located in the Fourier map and refined isotropically with isotropic thermal parameters defined as $U(H) = 1.2U_{eq}(N)$. The crystals of both **3a[CF_3SO_3]** and **8a[CF_3SO_3]** appeared to be racemically twinned with a refined Flack parameter of 0.47(7) and 0.41(7), respectively.[31] They were, therefore, refined using the TWIN refinement routine of SHELXTL. Some residual electron density peaks up to 3.835 e·Å^{-3} remain after refinement of **3a[CF_3SO_3]**, probably because of partial non-merohedral twinning. Different crystals of **3a[CF_3SO_3]** have been examined, and we have also tried to recrystallize them, without obtaining better results. Nonetheless, the data are fully consistent with the ones previously reported for the analogous complex [Fe_2{μ-CN(Me)(Xy)}(μ-CO)(CO){N(H)=C(CMe_3)(C≡CTol)}-$(Cp)_2$][CF_3SO_3].[10] One Cp ligand and the CMe_3 group in the unique molecule of **8a[CF_3SO_3]** are both disordered. Disordered atomic positions were split and refined isotropically using similar distance and similar U restraints and one occupancy parameter per disordered group.

CCDC-222309 and -222310 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) + 44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Synthesis, Structural and Spectroscopic Characterization of Four [(η^6-PAH)Cr(CO)$_3$] Complexes (PAH = Pyrene, Perylene, Chrysene, 1,2-Benzanthracene)

Aldo Arrais,[a] Eliano Diana,[b] Giuliana Gervasio,*[b] Roberto Gobetto,[b] Domenica Marabello,[b] and Pier Luigi Stanghellini*[a]

Keywords: Macrocyclic ligands / Chromium / X-ray diffraction / NMR spectroscopy / Vibrational spectroscopy / DFT calculations

The thermal reaction of hexacarbonylchromium with the polycyclic aromatic hydrocarbons (PAHs) pyrene, perylene, chrysene and 1,2-benzanthracene has afforded four organometallic complexes of the type [(η^6-PAH)Cr(CO)$_3$], whose unprecedented structures were obtained by single-crystal X-ray analysis. The topology of the coordination of the Cr(CO)$_3$ fragment and its asymmetry with respect to the coordinating ring may depend on the opportunity to maintain the maximum aromaticity of the complexed ligand. DFT calculations, ^{1}H NMR, FT-IR and Raman spectroscopy have been used to elucidate the type of interaction between the PAH ligand and the carbonylmetal moiety, giving insight into the ligand-to-metal donor capacity and the intra- and intermolecular interactions.

Introduction

Polycyclic aromatic hydrocarbons (PAHs) have long been investigated in diverse fields of research, ranging from astrophysics[1] to molecular biology.[2] [(PAH)Cr(CO)$_3$] complexes are efficient organometallic precursors for the organic synthesis of PAH derivatives by selective nucleophilic attack on the metallated ring.[3] Some can also exhibit chirality, which is useful in stereochemical reactions for drug design as, in vivo, PAHs have multiple well-documented carcinogenic effects.[4]

In the solid state, PAHs often assume a layered architecture;[5] which suggests that they have potential as synthons in crystal engineering and in preparing advanced molecular solids.[6] Actually, the large delocalization of π-electron density allows the formation of complexes where intermolecular coupling ranges from weak interactions to the formation of charge-transfer complexes.[7] Alongside the well-known adducts of PAHs with classical electron-transfer organic counterparts, such as tetracyanoethylene (TCNE),[8] tetracyanoquinodimethane (TCNQ)[9] and 2,3-dichloro-5,6-dicyano-*p*-benzoquinone (DDQ),[10] more recently a few organometallic complexes have appeared, such as the ferrocene−pyrene system.[11] Two promising examples of [(η^6-arene)Cr(CO)$_3$]- and [(η^6-PAH)Cr(CO)$_3$]-type structures have been reported, i.e. the non-centrosymmetrical complex (benzene)Cr(CO)$_3$/thiourea[12] and the complex (phenanthrene)Cr(CO)$_3$/1,3,5-trinitrobenzene.[13] Interest in the latter derivatives is strengthened by the presence of the metal atom, which can tune the electronic properties of the adducts and allow the isolation of materials displaying useful magnetic and optical properties.[14,15]

Carbonyl(PAH)chromium derivatives also tend to maintain, in the solid state, a face-to-face packing of the aromatic rings, and they can provide carbonyl groups that can interact through weak intermolecular interactions such as the C−H···O hydrogen bond, which is crucial in the design of suitable molecular building blocks in crystal engineering.[16]

From these perspectives, we attempted to synthesise [(η^6-PAH)Cr(CO)$_3$] complexes, including large polycyclic aromatic compounds, focusing upon four important PAH frameworks: pyrene, perylene, chrysene and 1,2-benzanthracene. There are few reports of such large complexed ligands,[17] the main published derivatives concerning instead the homologues of [(η^6-benzene)Cr(CO)$_3$].[18−22] In fact, only four examples of [(η^6-PAH)Cr(CO)$_3$] complexes, where PAHs are unsubstituted naphthalene,[23] an-

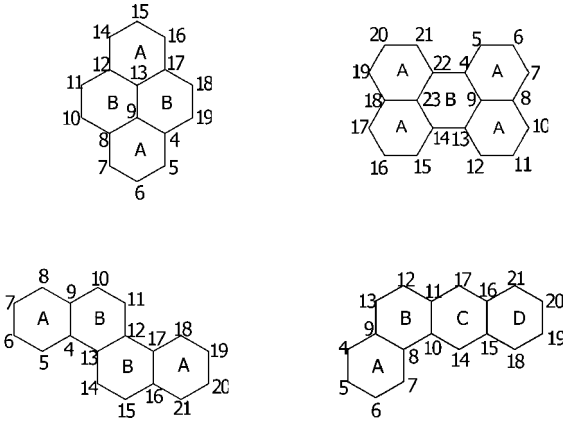
thracene,[24] phenanthrene[25] and triphenylene,[26] have been structurally determined.[27] For the former large PAH structures, however, a few metal coordination studies have been reported, with Ru,[28−31] Fe,[32,33] Mo[33,34] and Ti[35] as the η^6-bonded metal atoms. The PAH ligands used in the present work are illustrated in Scheme 1.



Scheme 1. Structure of the polycyclic aromatic hydrocarbon ligands pyrene, perylene, chrysene and 1,2-benzanthracene (the C atom numbering starts from C-4, as C-1, C-2 and C-3 always refer to carbonyl carbon atoms

Results and Discussion

Structure of the Complexes

(Pyrene)-, (perylene)-, (chrysene)- and (1,2-benzanthracene)tricarbonylchromium complexes (Figures 1−4) all coordinate the $Cr(CO)_3$ group on the face of a peripheral ring, with the metal atom ca. 1.74 Å from the ring centroid. The carbon atoms of the four ligands lie in a plane with a mean deviation from planarity of 0.021 (**1**), 0.028 (**2**), 0.029 (**3**) and 0.034 Å (**4**). The carbonyl groups lie between a staggered and an eclipsed orientation with respect to the carbon atoms of the coordinated ring. The plane formed by the three oxygen atoms is parallel to the plane of the coordinated ring; however, the chromium atom is not symmetrically linked to the six atoms of the aromatic ring, as occurs,

for example, in [{$C_6(CH_3)_6$}Cr(CO)$_3$].[36] The chromium atom is significantly farther from the carbon atoms connected to the condensed rings than the remaining Cr−C_{ring} distances (Table 1).

Coordination of a metal atom to an aromatic ring sometimes modifies the structure of the ring, typically by expansion of the ring, the loss of planarity of the ring and alternation of long and short C−C bonds.[37] In our case, the ligands are planar. Regular alternating of short/long C−C bonds of the coordinated ring may be observed in complexes **3** and **4** only where the coordinated ring is condensed to another ring.[38−41] In all complexes, however, the bonds adjacent to the coordinated rings are significantly long and therefore have a minor double-bond character. Further, C(10)−C(11) [1.327(3) Å] and C(18)−C(19) [1.324(3) Å] bonds in **1**, C(10)−C(11) [1.343(4) Å] and C(12)−C(13) [1.364(3) Å] bonds in **2**, C(10)−C(11) [1.332(3) Å] bond in **3** and C(12)−C(13) [1.326(3) Å] bond in **4** all show values corresponding to a double bond. Also, a set of short C−C bonds is located in the ligand on the opposite side with respect to the metal atom. We are confident of the accuracy of these values, even though the structural data of the complexes were collected at room temperature: in fact the estimated standard deviations (e.s.d.) of the C−C bond lengths are 0.003−0.004 Å.[42]

Considering the structural data, as expected there is no more than a negligible change in the PAH structures, owing to the very hard deformability of the fused rings. Variations of some structural parameters concerning the metal fragment and the relationship between the PAH and this fragment are expected to be more significant, such as (i) the average Cr−C_{CO} distance in the coordinated Cr(CO)$_3$ fragment and (ii) the distance between the chromium atom and the arene centroid. Table 2 collects these data, together with those of some other selected complexes with either greatly electron-releasing (diethylaminobenzene and hexamethylbenzene)[43] or electron-withdrawing (hexachlorobenzene)[44] arenes. Also included are some well-known [(PAH)Cr(CO)$_3$] complexes, together with [Cr(CO)$_6$] because of the exceptional electronic withdrawal of the (CO)$_3$ unit. The clear variation shown in Cr−C_{CO} is typical of an L−M−CO unit and of the well-known relationship between charge transfer and bond length. Thus, electron transfer from arene to Cr causes a significant shortening of the Cr−CO bond and vice versa a charge demand elongates this bond length. Accordingly, diethylaminobenzene shows the shortest distance[43] and hexachlorobenzene[44] {and, of course, [Cr(CO)$_6$]} the longest.[45] ν(CO) is another indirect, but sensible, parameter by which to measure this charge transfer.[46] Accordingly, the hexamethylbenzene complex shows the lowest and the hexachlorobenzene the highest value. The PAH ligands lie in between, showing a medium donating character; among them, pyrene is the best donating ligand, whereas perylene is the worst. The Cr−centroid distances [point (ii) above] are less significant in classifying charge-transfer effects, because arenes with substantial differences in donor−acceptor properties sometimes exhibit similar M−arene distances. Nevertheless, a long Cr−CO distance roughly corresponds to a short Cr−ring distance.

Bonding

The topology of the coordination of the Cr(CO)$_3$ fragment on the PAH ring is significant. Even if a statistical effect could be invoked for perylene, for all the other ligands

[a] The first value is the average Cr−C(ring-unsusbstituted) bond length, the second one is the average Cr−C(ring-junction) bond length.

the probability of the coordinating ring to bond the metal fragment is identical to that of any other ring types. The observed regioisomerism of the coordination could be explained by the different aromaticity between the free and the bonded PAH, which can be simply represented by the number of possible Kekulé covalent structures (KS).[47] In all cases KS decreases as a consequence of coordination. The real structure is that which, compared to the other possibilities, maintains the maximum aromaticity of the bonded ligand (Table 3). This simple approach agrees with the observed localized short and long C−C bond lengths found in the structures and also satisfactorily explains one of the most interesting stereochemical features of these complexes, that is the slipping of the $Cr(CO)_3$ fragment towards the unsubstituted carbon atoms of the arene ring and away from the ring junction carbon atoms.

Table 3. Number of the possible Kekulè structures (KS) of free and coordinated PAH ligands

Complex	**1**	**2**	**3**	**4**
Coordinating ring[a]	A B	A B	A B	A B C D
Number of KS	4 2	6 4	6 4	6 4 4 4
Number of KS of the free ligand	6	9	8	7
A[b]	1.5	1.5	1.3	1.2

[a] See Scheme 1. [b] Aromatic loss, i.e. the ratio between no. of KS of the free ligand with respect to the stable form of the coordinated ligand.

From another point of view, this agrees with the suggestion that, for non-symmetric aromatic rings, the metal atom should bind to the more electron-rich double bond.[48−49] The external C−C bonds have an overall double-bond character greater than that of the ring-junction C−C bond. Moreover, another effect can be present, which is a repulsion between the π-electron charge delocalized on the adjacent non-bonded rings and the negative charge induced on the Cr atom by the donation of the bonded ring. A closely related phenomenon has been evidenced in a series of [(substituted arene)$Cr(CO)_3$] complexes, where the electron repulsion tilts the arene substituents away from Cr.[21] If in the PAH ligand the adjacent ring can be viewed as a substituent of the bonded ring, as the overall structure is hardly deformable, it is the $Cr(CO)_3$ group that shifts towards the peripheral carbon atoms.[50]

To substantiate the previous simplified approach, a quantum mechanical calculation of the total energy has been performed.[51] The chosen model was complex **4**, which displays the highest number of possible regioisomers, named as the A, B, C and D complexes, according to the coordinating ring (Scheme 1). We made a single-point calculation on an idealized structure with the Cr atom perpendicular to the centre of the coordinating ring and the carbonyl groups in the staggered position with respect to the carbon atoms. For complex A, a calculation has also been carried out on the real structure: the difference is irrelevant. The B3LYP DFT method was used with a pseudopotential LANL2DZ basis set for the chromium atom and the 6-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

31G(d, p) basis for the other atoms. Figure 5 shows both the total energy and of the Mulliken charge on the Cr atom. Complex A is clearly the most stable conformation, as predicted by simple KS counting. The charge on the Cr atom can be related to the DFT-Mulliken mean charge density in the rings of the free 1,2-benzanthracene, which is D (−0.194) < A (−0.0368) < B (0.0254) < C (0.0327). As the main contribution to the PAH−Cr bond is the electron donation PAH→Cr, the most stable configuration should be given by the Cr coordination to the ring with the highest electron density. The A ring is preferred to the D ring, probably because of the maintenance of the maximum aromatic stabilisation energy.

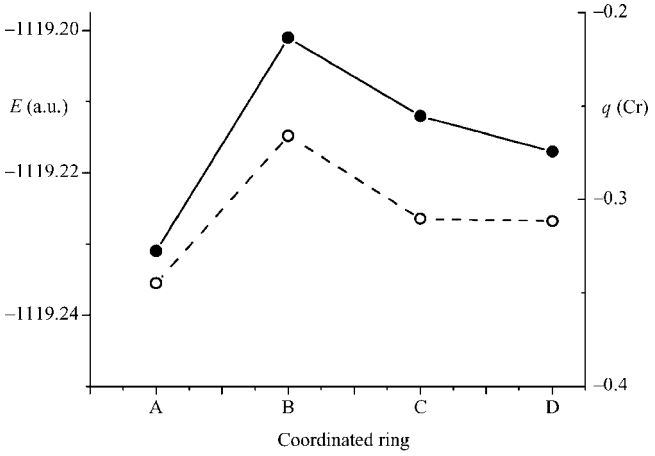

Figure 5. Total energy of the regioisomers of complex **4** (closed circles); Mulliken charge on the Cr atom (open circles)

Finally, the theoretical approach can be related to simple chemical properties of the complexes. For example, the linear PAHs, 1,2-benzanthracene in particular, whose aromaticity loss in the coordination is lower, are more stable and are obtained in better yield than the condensed PAHs.

Vibrational Analysis

The vibrational pattern of the [(PAH)Cr(CO)$_3$] complexes can be roughly divided into three types of modes, those of the PAH ligand, those of the Cr(CO)$_3$ unit and those derived by the interaction between the two fragments. In a first approximation the coupling between these sets of modes is negligible;[52] thus, a close comparison with the spectra of the free ligand is of significant help in the assignment. As an example, Figures 6 and 7 show the infrared and the Raman spectra of complex **1**, together with those of the ligand. The modes of the Cr(CO)$_3$ unit are immediately evident, as a very strong band in the 2000−1800 cm^{-1} region [ν(CO)] and in the 700−400 cm^{-1} region [δ(Cr−CO) and ν(Cr−CO)]. More doubtful is the assignment of the PAH−Cr modes, which lie below 300 cm^{-1} and are mixed with the ring deformation modes. Usually, only the PAH−Cr stretching can be assigned with some confidence to a medium-strong Raman band around 290 cm^{-1}. The remaining band pattern concerns the vibrations of the coordinated PAH ligand.

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

The infrared ν(CO) spectrum in aliphatic and aromatic hydrocarbon solutions shows the usual behavior of an $M(CO)_3$ group with a local C_{3v} symmetry: a medium-strong high-frequency band (A_1) and a strong, broad (sometimes split) band at lower frequency (E). Both the IR and Raman spectral patterns in the solid state are more complex, because of the site and/or factor group effects, and are shifted to lower frequencies by 15−25 cm^{-1}, with respect to those in solution (Figure 8). This is clear spectroscopic evidence of what has been observed in the crystal packing, i.e. many C−H···O interactions.

The modes of the coordinated and uncoordinated aromatic ligand lie in typical fingerprint regions,[53] corresponding to C−H stretching (3200−3000 cm^{-1}), in-plane C−C stretching and C−H bending (1600−900 cm^{-1}), to out-of-plane C−H bending (900−700 cm^{-1}) and to out-of-plane C−C bending (below 500 cm^{-1}). Significant changes are evident in the ν(CH) region: the modes of the coordinated PAH move up with respect to those of the free PAH. The Raman spectra, which give rise to medium-strong bands, are clear in this respect (Figure 9). Separation of the CH vibrations of the bonded ring from those of the non-bonded ring is inapplicable. As DFT calculations on the free PAH show that the CH vibrators are strongly coupled, the pattern has to be considered as a whole.

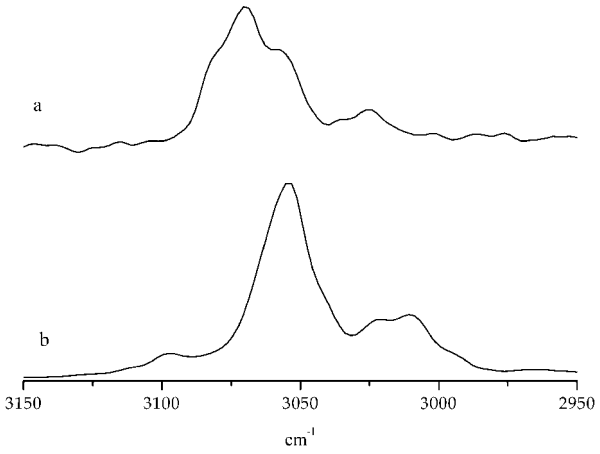

Figure 9. Solid-state Raman spectra of complex **1** (a), pyrene (b)

Even more interesting is the behavior of the γ(CH) modes, which are the most evident infrared fingerprint bands of the aromatic hydrocarbons, and are sensitive to the effect of metal coordination, usually reflected in an increase in the frequency.[52,54−56] For example, the IR spectrum of free pyrene shows two very strong bands at 838 and 748 cm^{-1}, easily assigned to the γ(CH) modes, which are clearly shifted to 855 and 796 cm^{-1} in complex **1**. The average shift (ca. 40 cm^{-1}) is similar to that found for perylene and complex **2** (ca. 30 cm^{-1}), but is definitely smaller than for the couple benzene/(benzene)$Cr(CO)_3$ ($\Delta\tilde{\nu} \approx 120$ cm^{-1}).[56] The γ(CH) modes have been separated into small sub-sets, corresponding to the vibrations of groups of adjacent H atoms (quadruplet, triplet, doublet and hydrogen solo).[53] Here too, DFT calculations show that this distinction is too rough and unacceptable, as the vibration of the CH units are all coupled. So the contribution to a γ(CH) mode is given by the vibration of all the CH units, belonging both to coordinated and to uncoordinated rings, and it is reasonable to expect that the last ones can attenuate the coordination effect. It could be relevant that with the linear PAH (chrysene and 1,2-benzanthracene) the attenuating effect of the uncoordinated part of the ligand is significant, because $\Delta\tilde{\nu}$ is very small (3 and 2 cm^{-1}, respectively).[57]

Usually, both ν(CH) and γ(CH) frequencies increase as a consequence of metal coordination, an explanation for which must include the extended framework of hydrogen bonds. This is an important factor in the rise of γ(CH), as a bending vibration that pulls the H atoms away from the equilibrium position is rendered more difficult by C−H···O interactions. The comparison between the spectra in the solid state and in solution is clear: in the last case rather small increases occur.[58] Presumably, the metal−ring interaction could also contribute to the shift − similar to the contributions observed in metallocene complexes.[52]

Conversely, the hydrogen interaction is expected to decrease ν(CH), so that the observed increase may be due to a simultaneous phenomenon that reinforces the C−H bond, thereby increasing the frequency. The π-donation from ring to metal atom might stabilize the σ frame, and so increase the C−C and C−H bond strengths. Owing to the small mass of hydrogen, ν(CH) values are particularly susceptible to small modifications of the C−H bond.

The vibrational pattern may also give some insight into the donor−acceptor properties of the PAH ligands. Theoretical and experimental infrared spectra have been reported to show significant differences in the intensity of the spectral regions between PAH molecules and the corresponding $[PAH]^+$ ions.[53][59] In particular, the latter exhibit an enhanced intensity in the ν(CC) and δ(CH) regions and a decreased intensity in the ν(CH) and γ(CH) regions with respect to the corresponding neutral molecule. On this basis an estimate of the intensity ratio $IR = \{I[\nu(CC) + \delta(CH)]/I[\nu(CH) + \gamma(CH)]\}$ for both free and complexed PAH could give information on the variation of the charge on the PAH as a consequence of coordination. Indeed, *IR* increases significantly from free to coordinated PAH for both pyrene (0.73 to 1.63) and chrysene (0.48 to 1.20), suggesting that these ligands are good donors, where the other two PAHs, which show the opposite trend (perylene: from 1.10 to 0.68; 1,2-benzanthracene: from 1.1 to 0.37), are bad donors.

NMR Analysis

VT ^1H NMR spectra can allow the assignment of the aromatic protons of the four complexes on the basis of simple chemical shift/scalar coupling considerations, double resonance measurements and 2D ^1H-^1H results.

In all cases, the coordination induces typical high-field shifts and a decrease of the scalar $^3J_{H,H}$ couplings. This upfield shift can be a combination of different effects such as partial sp rehybridization of the ring carbon atom, an increase in electron density on the aromatic ring, quenching of the ring current, or magnetic anisotropy of the

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

chromium−ligand bond, as previously discussed.[60−63] The maximum up-field shift due to interaction with the $Cr(CO)_3$ fragment ($\Delta\delta$) occurs for the inner protons belonging to the peripheral ring, which supports metal coordination ($\Delta\delta$ = 3.06, 2.27, 2.71 and 2.70 ppm for **1**−**4**, respectively). The other protons belonging to the coordinated ring show $\Delta\delta \approx$ 2 ppm, whereas the chemical shifts of the protons of the uncoordinated rings are very close to those corresponding to the free ligand ($\Delta\delta \approx 0.2-0.6$ ppm). Detailed data are reported in Table 1SI of the Supporting Information (see also the footnote on the first page of this article).

We also attempted to evaluate the possible migration of the $Cr(CO)_3$ fragment on the different aromatic rings. Thermally induced rearrangements have been previously detected in many π complexes, e.g. in monosubstituted [(naphthalene)$Cr(CO)_3$][64−66] and monosubstituted [(biphenyl)$Cr(CO)_3$][67] derivatives. Haptotropic rearrangements reportedly require substantial activation energies, except in the presence of a coordinating solvent.[68,69] We thus performed a ^{1}H NMR study of complexes **1**−**4**. However, under our experimental conditions (from −100 to +80 °C, deuterated toluene solutions, presence of the free ligand), no line broadening of the ^{1}H resonances was observed, ruling out a fast degenerate haptotropic shift. This is not so surprising if the large energy differences of the possible regioisomers are considered, as has been evaluated for complex **4** by DFT calculations. Spin saturation transfer experiments[70] were also performed with complex **2**, which shows no energy differences between the possible regioisomers. No decrease in the intensity of the aromatic resonances were observed at +80 °C under saturation of the protons 5, 6 and 7, ruling out any haptotropic motion.

Experimental Section

Reactants and Solvents: Pyrene, perylene, chrysene and 1,2-benzanthracene (Aldrich), hexacarbonylchromium (Fluka) were commercial products and were used without further purification. SilicaGel60 was purchased from Merck. The solvents, *n*-heptane, petroleum benzin and toluene (Riedel), were dried with sodium and kept under N_2.

Warning: *Chrysene and 1,2-benzanthracene are active carcinogenic agents. They must be handled using all possible safety precautions, avoiding any contact or exposure.*

Synthesis of the Complexes: The synthetic methods used for the four complexes are very similar. We report as an example the detailed synthesis of the pyrene complex; for the other complexes, basic data are given.

(a) [(Pyrene)Cr(CO)$_3$] (1): Pyrene (250 mg, 1.24 mmol) was dissolved in petroleum benzin (boiling range 100−140 °C; 40 mL) in a flask (250 mL) equipped with an inlet inert gas bubbler and a reflux condenser. An Hg outlet bubbler was used to prevent air entering during the reaction. A gentle flow of N_2 was maintained for a few minutes to purge air from the flask. Hexacarbonylchromium (1.25 g, 5.68 mmol) was then added and the mixture was heated to reflux under vigorous stirring. A slight flow of N_2 was used periodically to remove CO and to maintain the presence of an inert gas in the reaction flask. The initial pale yellow solution turned bright red, and the conversion was measured by checking the characteristic infrared ν(CO) stretching bands of the starting [$Cr(CO)_6$] and of the reaction product. The reaction reached a maximum product concentration after ca. 2 d, when some decomposition began to appear. Heating was then stopped, and the solvent was evaporated under vacuum in a warm bath (45−50 °C, 2500 Pa). The resultant residue was dissolved in toluene (a few mL) and the solution was chromatographed on a 25-cm column, with SilicaGel60 as stationary phase and toluene as eluent. The excess [$Cr(CO)_6$] rapidly eluted, whilst a pale yellow band due to the remaining pyrene partially overlapped the deep red band of complex **1**. This fraction was collected and reduced to ca. 5 mL under a gentle flow of N_2. Crystallization under N_2 at 0 °C gave rise to bright red needles of pure complex **1** in a yield of ca. 45% (with respect to the starting pyrene). The crystals are stable in air for weeks and quite stable in solution, provided they are kept under anaerobic conditions.

(b) [(Perylene)Cr(CO)$_3$] (2): Reactants: perylene (200 mg, 0.79 mmol) and hexacarbonylchromium (1.25 g, 5.68 mmol); reaction conditions: as before; product: bulky dark purple crystals in ca. 35% yield after 4−5 d standing at −30 °C. **2** is air-stable in the solid state for several days, rather stable in anaerobic hydrocarbon solutions, and very unstable when dissolved in halogenated solvents (CH_2Cl_2, CCl_4), even under the strictest anaerobic conditions.

(c) [(Chrysene)Cr(CO)$_3$] (3): Reactants: chrysene (200 mg, 0.88 mmol) and [$Cr(CO)_6$] (1 g, 4.54 mmol); reaction conditions: as before; product: bright bulky red crystals (yield ca. 55%), obtained after 3−4 d standing at −30 °C; the complex is very stable on air, and quite stable in anaerobic solutions. Because **3** co-crystallizes with toluene, to avoid crystal efflorescence the crystals must be stored in the presence of toluene vapor at low temperatures.

(d) [(1,2-Benzanthracene)Cr(CO)$_3$] (4): Reactants: 1,2-benzanthracene (150 mg, 0.66 mmol) and $Cr(CO)_6$ (1 g, 4.54 mmol); reaction conditions: as before; product: bright red needles (yield ca. 65%), obtained after dissolution of **4** in benzene and 15 d of standing at 7 °C. The complex is stable in air in the solid state, and quite stable in solution under anaerobic conditions.

X-ray Structure Analysis: X-ray data for complexes **1**−**4** were collected at room temperature, with a Siemens P4 diffractometer, equipped with an APEX CCD detector 6 cm from the crystal. Graphite-monochromatized Mo-K_α radiation was used with a generator working at 50 kV and 40 mA for **1** and **2** and 35 mA for **3** and **4**. To avoid the loss of solvent (toluene), the crystal of **3** was mounted in a Lindemann glass capillary, with a drop of mother solution inside. Unit cell parameters were obtained by least-squares refinement of 46 (**1**), 31 (**2**), 60 (**3**) and 60 (**4**) reflections in the 2θ range 10−45°. For data collection and refinement, the package of Bruker AXS programs (SMART, SAINT, SADABS, SHELXTL)[71] was used. Owing to the small dimensions and low diffraction power of some crystals, the exposure time of the frames for data collections was 30 (**1** and **2**), 20 (**3**) and 10 s (**4**). The reflections were collected using the ω-scan technique ($\Delta\omega$ = 0.3°) and the intensities were corrected for absorption with the multi-scan method (SADABS) for **1**, **3** and **4**, while for **2** the numerical crystal faces method was applied (XPREP). In complex **3** a disordered molecule of toluene, lying on the inversion centre, was located. The non-hydrogen atoms were anisotropically refined. High thermal parameters were found for the four complexes. Hydrogen atoms in calculated positions were refined riding on the corresponding carbon atom. Crystal data and refinement parameters are

reported in Table 4. CCDC-211599 to·-211602 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Vibrational Analysis: Infrared spectroscopy measurements were recorded in solutions of dried *n*-heptane and toluene or in KBr pellets with a Bruker FTIR Equinox 55 spectrophotometer (resolution 2 cm^{-1}). Raman measurements were performed on crystal samples, sealed in a glass capillary under Ar, with a Bruker RFS 100 spectrophotometer (resolution 4 cm^{-1}) equipped with a 1.064 nm Nd:YAG laser, irradiating the samples with an average power set in the range 30−45 mW. Ab initio calculations of the free PAH were performed by employing the DFT B3LYP method with the Gaussian 98[72] package on a personal computer. We used a 6-31G** basis set and the vibrational frequencies and intensities and normal coordinates were calculated at the respective optimised structure. For the 1700−100 cm^{-1} region we employed a scaling factor of 0.9614. Normal coordinates were visualized with the Moldraw package.[73] The accordance between the scaled DFT and experimental frequencies was very good, and the intensity vibrational pattern was well fitted.

NMR Spectra: All NMR data were acquired with a Jeol EX 400 operating at 399.6 MHz. One-dimensional ^1H spectra were recorded in deuterated benzene and toluene solutions, with 32 K data points and a sweep width of 5827 Hz giving a digital resolution of 0.35 Hz; 64 accumulations were acquired with an acquisition time of 2.8 s. Two-dimensional ^1H-^1H spectra were acquired with a spectral width of 5500 Hz, 512 t_1 points, 2 K data points in t_2 and 32 transients for each t_2 points. Chemical shifts were referenced to tetramethylsilane (TMS).

Acknowledgments

Hydrothermal Syntheses, Crystal Structures, Magnetism and Fluorescence Quenching of Oxamidato-Bridged Pentanuclear $Cu^{II}_4Ln^{III}$ Complexes Containing Macrocyclic Ligands (Ln = Eu, Tb) and the Crystal Structure of a Hexanuclear $Ni^{II}_5Sm^{III}$ Complex

Keywords: Hydrothermal synthesis / Macrocyclic ligands / Magnetic properties / Fluorescence

Three novel oxamidato-bridged complexes incorporating a macrocyclic oxamide of formula $[(CuL)_3\{CuL(C_2H_5OH)\}Eu(H_2O)](ClO_4)_3\cdot 1.5H_2O$ (**1**), $[(CuL)_3\{CuL(C_2H_5OH)\}Tb(H_2O)](ClO_4)_3\cdot 2H_2O$ (**2**) and $[(NiL)_5Sm](ClO_4)_3\cdot 2H_2O$ (**3**) (CuL and NiL, H_2L = 2,3-dioxo-5,6,14,15-dibenzo-1,4,8,12-tetraazacyclopentadeca-7,13-dien), have been hydrothermally synthesized and structurally characterized. In these complexes, the central Ln^{III} and external copper (or nickel) ions are bridged by macrocyclic oxamide groups. The Eu^{III} (or Tb^{III}) ion of **1** (or **2**) resides in a distorted tricapped trigonal prismatic environment surrounded by eight oxygen atoms from four oxamide groups and one oxygen atom from a water molecule, whereas the Sm^{III} ion of **3** resides in a distorted bicapped square antiprismatic environment surrounded by ten oxygen atoms from five oxamide groups. Furthermore, there are hydrogen bonding interactions in **1** and **2** between perchlorate, ethanol and water moieties. Especially for **1** and **2**, O–H···O and weak coordination of ClO_4^- groups link the pentanuclear fragments and perchlorate ions to form a 1-D supramolecular architecture. The fluorescence of Eu^{III} and Tb^{III} are almost completely quenched in **1** and **2**. The magnetic properties of **1** and **2** have been characterized. (© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2003)

Introduction

Molecular magnetism and macrocyclic compounds are two active fields of research encompassing chemistry, physics, biology, and material science.[1,2] The field of molecular-based magnetic materials has shown spectacular advances in the last two decades, especially for metal complex-based magnetic compounds.[2] Assembly of metal complexes which may act as light switchable magnets and single molecule magnets has attracted special attention in the latest decade.[3−5] The mechanisms responsible for the magnetic interactions between d ions are reasonably well understood, and efficient models have been proposed to rationalize the various types of magnetic behavior.[2,6] As far as magnetic coupling between f ions and d ions is concerned, the situation is much less advanced because the behavior of the Ln^{III} ion with a first-order orbital momentum is much more complicated. Indeed, the 4f configuration of a Ln^{III} ion is split into $^{2S+1}L_J$ states by the inter-electronic repulsion and the spin-orbit coupling. Each of these states is further split into Stark components due to the crystal field perturbation. It follows that it is in principle very difficult to determine not only the magnitude of the $Ln^{III}-Cu^{III}$ interactions but even their nature. It is therefore essential for further development of 3d-4f magnetochemistry in order to obtain accurate information on the 3d-4f magnetic interactions and a synthetic design without 3d-3d and 4f-4f magnetic interactions.[7,8] Since Gatteschi and co-workers discovered a ferromagnetic coupling between Cu^{II} and Gd^{III} ions in 1985,[9] the design and properties of molecular complexes simultaneously comprising lanthanide and transition metal ions[9−15] have been of considerable interest. However, most of the studies have been focused on the $Gd^{III}-Cu^{II}$ couple[9−15] which has been found to be directly ferromagnetic in most cases. In comparison, polynuclear complexes containing other $Ln^{III}-Cu^{II}$ couples have been poorly investigated.[12,16−18] In addition, the majority of the mixed metal complexes are bridged by polydentate Schiff bases, pyridonates, carboxylate or oxamide ligands.[12,13,19−21] In particular, the oxamide group has been noted as an efficient

mediator of magnetic exchange between 3d-3d centers. However, heterometallic complexes of the macrocyclic oxamide, especially of those containing 3d-4f metals, have been rarely prepared,[22] although metal complexes of macrocyclic ligands have been of great interest to coordination chemists for their special structures, properties, and/or functionalities.[1][8a,23]

On the other hand, investigations of the effect of metal complexes upon the fluorescence of rare earth ions will give basic and useful information for the development of fluorescent materials, since the metal complexes reported so far are beyond enumeration and show a great variety of characteristic colors. Recently, many complexes containing rare earth ions have been prepared, and their fluorescent proprieties have been studied,[24−27] but heterometallic complexes of this kind, especially those containing 3d-4f metals have been rarely investigated.[12,27]

With these facts in mind and in continuation of our work on polynuclear macrocyclic complexes,[20−22] the macrocyclic oxamido-copper (II) and oxamido-nickel(II) complexes were used as ligands to synthesize new complexes. The result is that two novel pentanuclear $Cu^{II}_4Ln^{III}$ complexes (Ln = Eu, Tb) and one hexanuclear $Ni^{II}_5Sm^{III}$ complex have been isolated and structurally characterized, the magnetic and fluorescent properties of **1** and **2** have also been subjected to a preliminarily investigation.

Results and Discussion

Synthesis

The hydrothermal technique not only provides a pathway to stable structures utilizing inorganic molecular units of a desired geometry or composition but also allows the introduction of a variety of inorganic cations to act as templates in directing the organization of the complexes. In those reactions the Ln(III) ions were used as templating reagents. Under appropriate conditions, large single crystals were obtained in high yield.

Structures

Description of the Structure of 1

Complex **1** consists of pentanuclear $[(CuL)_3\{CuL(C_2H_5OH)\}Eu(H_2O)]^{3+}$ cations, monovalent ClO_4^- anions, and water. A perspective view of the pentanuclear cation is depicted in Figure 1, and selected bond lengths and angles are listed in Table 1. The central europium and external copper ions are bridged by macrocyclic oxamide groups. The external Cu1 ion is coordinated by four nitrogen atoms from the macrocyclic organic ligand, with the $[Cu1N_4]$ chromophore exhibiting near planarity. The Cu1 ion is displaced from the least-square plane by +0.1130Å. The coordination environment of Cu2 is similar to that of Cu1. Cu3 is located in a slightly distorted square-based pyramidal environment with the basal plane composed of atoms N9, N10, N11 and N12 from the macrocyclic oxamide groups, the axial position is occupied by an ethanol molecule. The deviations of the four donor atoms (N9, N10, N11 and N12) from their mean plane are −0.1756, +0.1023, −0.1645 and +0.1607 Å, respectively, and Cu3 is located +0.1521Å out of the plane. Cu4 is also located in a slightly distorted square pyramidal environment with the basal plane composed of atoms N13, N14, N15 and N16 from the macrocyclic oxamide groups, the axial position is occupied by perchlorate weakly coordinated with Cu4, and the Cu4···O14 distance is 2.460 Å. The central europium atom resides in a distorted tricapped trigonal prismatic environment surrounded by eight oxygen atoms from four oxamide groups and the O1w atom of the water molecule. The O1w, O3 and O8 atoms are located on the respective caps. The trigonal prism is composed of O1, O2, O4, O5, O6 and O7, with one basal plane constructed from O4, O5, O6 and the other basal plane constructed from O7, O1 and O2. The flank of the trigonal prism is slightly distorted square-planar because the deviations of the four oxygen atoms (O6, O2, O4, O7 of one flank) are −0.0980, −0.1101, +0.1046 and +0.1035 Å, respectively, and the deviations of atoms from another flank (O1, O2, O4, O5) are −0.1284, +0.1397, −0.1228 and +0.1115 Å, respectively. Thus, the coordination geometry around the europium ion can be described as distorted tricapped trigonal prismatic. As depicted in Figure 2, the cations are alternately bridged by perchlorates to give infinite chains in which O−H···O interactions between coordinated ethanol and perchlorate ($d_{O\cdots O}$ = 2.855 Å), and ClO_4^-→Cu weak coordination pull the cations together ($d_{O\cdots Cu}$ = 2.558 Å). Furthermore, there are other O−H···O interactions between coordinated water and free water and free perchlorate, the O···O distances are 2.850 and 2.972 Å, respectively. In addition, there are π-π interactions between benzene rings of the CuL units of different cations in the cell which are parallel to each other

and the distance between carbon atoms is approximately 3.416 Å.

Description of the Structure of 2

X-ray structural analysis shows that the structure of the pentanuclear $[(CuL)_3\{CuL(C_2H_5OH)\}Tb(H_2O)]^{3+}$ cation is similar to that in **1** (Figure 3). There is an oxamide bridge between the Tb(III) and each Cu(II) ion. The coordination environments of the Cu1 and Cu2 ions are similar and slightly distorted square-planar with the basal planes composed of four nitrogen atoms from the macrocyclic oxamide groups with the axial positions occupied by perchlorates weakly coordinated to Cu1 and Cu2. The Cu3 ion is coordinated by four nitrogen atoms of the macrocyclic organic ligand with the $[Cu1N_4]$ chromophore exhibiting near planarity. Cu4 is located in a slightly distorted square pyramidal environment with the basal plane composed of atoms N13, N14, N15 and N16 from the macrocyclic oxamide groups, with the axial position being occupied by an ethanol molecule. The central terbium ion resides in a distorted tricapped trigonal prismatic environment surrounded by eight oxygen atoms from four oxamide groups and the O9 atom of a water molecule. The O9, O5 and O8 atoms are located on the respective caps, while the trigonal prism is composed of O1, O2, O3, O4, O6 and O7 with one basal plane constructed from O4, O2, O6 and the other basal plane constructed from O7, O1 and O3. As depicted in Figure 2, the cations are alternately bridged by perchlorates giving infinite chains in which the O−H···O interactions between coordinated ethanol and perchlorate groups ($d_{O\cdots O}$ = 2.825 Å), and $ClO_4^-\rightarrow$Cu weak coordination ($d_{O\cdots Cu}$ = 2.528 Å) pull the cations together. Furthermore, there are other O−H···O interactions between coordinated water and free water and free perchlorate and the O···O distances are 2.821 and 2.943 Å, respectively. In addition, there are π-π interactions between benzene rings of the CuL moieties of different cations in the cell which are parallel to each other and the distance between carbon atoms is approximately 3.400 Å (Table 2).

Description of the Structure of 3

Complex **3** consists of hexanuclear $[(NiL)_5Sm]^{3+}$ cations, monovalent ClO_4^- anions, and water. A perspective view of the hexanuclear cation is depicted in Figure 4, and selected bond lengths and angles are listed in Table 3. The central samarium and external nickel ions are bridged by

macrocyclic oxamide groups. The external nickel ions are coordinated by four nitrogen atoms from the macrocyclic organic ligand, with the $[NiN_4]$ chromophore exhibiting a distorted planar arrangement. The deviations of the four donor atoms (N1, N2, N3 and N4) from their mean plane are −0.2695, +0.2713, −0.2627 and +0.2699 Å, respectively, and Ni1 is located −0.0089 Å out of the plane. The central samarium ion resides in a distorted bicapped square antiprismatic environment surrounded by ten oxygen atoms from five oxamide groups. O6 and O9 are located on the respective caps. The square antiprism is composed of O1, O2, O3, O4, O5, O7, O8 and O10, with one basal plane constructed from O1, O3, O7 and O10 and the other basal plane constructed from O2, O4, O5 and O8. The deviations of the atoms of one basal plane (O1, O3, O7, O10) are −0.1697, +0.1269, −0.1097 and +0.1525 Å, respectively. Thus, the coordination geometry around the samarium ion can be described as distorted bicapped square antiprismatic. In addition, there are π-π interactions between benzene rings of the NiL units of different cations in the cell which are parallel to each other and the distance between carbon atoms is approximately 3.301 Å.

IR and Electronic Spectra

The IR spectra of **1, 2** and **3** show three strong bands at around 1639, 1610 and 1448 cm^{-1} which can be attributed to the υ(N−C−O) stretching bands and are characteristic of the bridging oxamide group.[28] The broad bands of **1, 2** and **3** around 1090 cm^{-1} in each case can be attributed to the ClO_4^- group.[29]

The electronic absorption spectra of the **1** and **2** were measured in DMF solution. In complexes **1** and **2**, a broad strong band centered at 613 nm can be attributed to the d-d transitions of five or six coordinate copper atoms,[30] the latter geometry being due to the fact that DMF is axially bound to the distorted square planar Cu(II) sites. All complexes exhibit intense bands below 550 nm, assignable to charge-transfer transitions in the [CuL] chromophores and/or intraligand π-π* interactions.[28] The hypersensitive transition bands of the rare earth metal ions were not observed.[31]

Fluorescence Properties

The fluorescence spectra of the $Cu^{II}_4Ln^{III}$ complexes (Ln = Eu, Tb) are given in Figure 5. The fluorescence spectra of $Ln(ClO_4)_3{\cdot}6H_2O$, which are included in Figure 5 were also measured for comparison. $Eu(ClO_4)_3{\cdot}6H_2O$ and $Tb(ClO_4)_3{\cdot}6H_2O$ exhibit fluorescence bands attributable to $^5D_0 \rightarrow {}^7F_1$ transitions in the 580−700 nm region and $^5D_4 \rightarrow {}^7F_1$ transitions in the 440−600 nm region, respectively. These fluorescence bands disappear almost completely in both complexes. According to the most probable quenching mechanism, we presume that the energy transfer occurs from the excited Ln(III) to the Cu(II) center through the oxamidic oxygen bridges.[24−27]

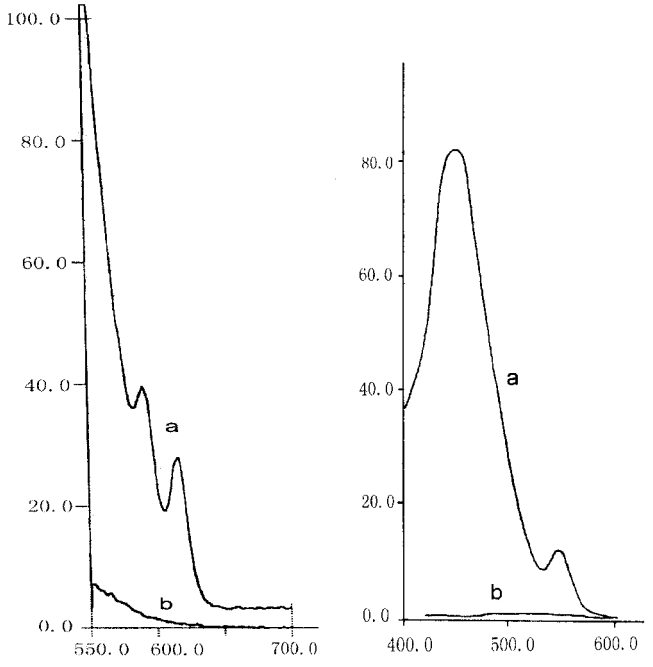

Figure 5. left: The fluorescence spectra of $Eu(ClO_4)_3{\cdot}6H_2O$ (a) and **1** (b), in DMF solution; the exciting wavelength is 394 nm; slim widths (excitation and emission sides) are 3 and 3 nm; ordinate scales are × 7 for (a) and for (b). right: The fluorescence spectra of $Tb(ClO_4)_3{\cdot}6H_2O$ (a) and **2** (b), in DMF solution; the exciting wavelength is 355 nm; slim widths (excitation and emission sides) are 2 and 2 nm; ordinate scales are × 8 for (a) and for (b)

Magnetic Properties

The magnetic susceptibilities (χ_M) of **1** was measured in the temperature range 2−300 K (Figure 6). The μ_{eff} value of 4.95 B.M. at room temperature continuously decreased with temperature to a value of 3.59 B.M. at 2 K. The μ_{eff} value is 3.59 B.M. at 2 K which is very close to the four copper(II)-only value(3.46 B.M.). This may be due to the thermal depopulation of excited levels ($J = 1-6$) of Eu(III), leading to the four copper(II)-only value since the $^7F_0$ ground state of Eu(III) is diamagnetic. As a first approach to simulating experimental magnetic behavior, the magnetic susceptibility of **1** was treated as sum of the contributions of one Eu(III) and four Cu(II) ions [Equation (1)].

$$\chi = 4\chi_{Cu} + \chi_{Eu} \tag{1}$$

where the first term $4\chi_{Cu}$ is the magnetic susceptibility for four Cu(II) ions [Equation (2)].

$$\chi_{Cu} = \frac{Ng^2\beta^2}{3KT}\frac{1}{2}\left(\frac{1}{2}+1\right) \tag{2}$$

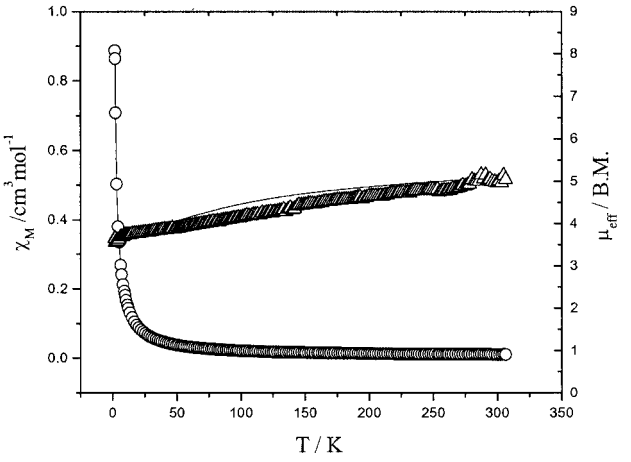

Figure 6. χ_M (circles) versus T and $\mu(T)$ (triangles) versus plots for the pentanuclear species **1**

The second term χ_{Eu} is the magnetic susceptibility for the Eu(III) ion. For the latter, the ^7F ground term is split by spin-orbit coupling into seven states, ^7F_J, with J taking integral values from 0 to 6. If the energy of the $^7F_0$ ground state is taken as the origin, the magnetic susceptibility may be expressed as in [Equation (3)].[32]

$$\chi_{Eu} = \frac{N\beta^2}{3KT}\frac{\left\{\begin{array}{l}144/x+(27/2-9/x)\exp(-x/6)+(135/2-15/x)\exp(-x/2)+\\(189-21/x)\exp(-2x)+(405-27/x)\exp(-10x/3)+(1485/2-\\33/x)\exp(-5x)+(2457/2-39/x)\exp(-7x)\end{array}\right\}}{\begin{array}{l}1+3\exp(-x/6)+5\exp(-x/2)+7\exp(-2x)+\\9\exp(-10x/3)+11\exp(-5x)+13\exp(-7x)\end{array}} \tag{3}$$

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

Where $x = \zeta/KT$, ζ is the spin-orbit coupling constant for Eu(III). Taking into account the interaction between Cu(II) and Eu(III) ions, a correction for a molecular field can be made [Equation (4)].

$$\chi_M = \frac{\chi}{1-(2ZJ'/Ng^2\beta^2)\chi} \quad (4)$$

The least-squares fit of Equation (4) to the data yielded the parameters $g = 2.13$, $\zeta = 1358$, $ZJ' = -0.12$, where the agreement factor defined as:

$$R = \Sigma[(\chi_M)^{Cal} - (\chi_M)^{obsd}]^2 / \Sigma[(\chi_M)^{obsd}]^2$$

is 8.40×10^{-3}.

The value of ZJ' reveals weak antiferromagnetic interaction between the Cu(II) ions and the Eu(III) ion.

The magnetic susceptibilities (χ_M) of **2** were measured in the temperature range 4−300 K (Figure 7). The observed μ_{eff} value for **2** was 10.54 B.M. at room temperature. This value is slightly higher than that expected if the metal centers are not interacting (for, **2**, 10.32 B.M., assuming $g_{Cu} = 2.0$, $g_{Tb} = 3/2$). For **2**, this values declines gradually between 300 and 8 K, where at the latter temperature the μ_{eff} value is 9.41 B.M. Below 8 K, it falls sharply reaching 8.84 B.M. at 4 K. In contrast to the Cu_4Eu case, a similar treatment of **2** does not give reasonable results. To gain some information concerning the interaction between Tb and Cu, Kahn and Costes et al. have developed an experimental approach. For this, it appeared necessary to synthesize an isostructural Ln^{III} complex with a diamagnetic surrounding.[7d,33] Unfortunately, for **2**, we have been unable to crystallized an isostructural series. However, we synthesized a hexanuclear Ni_5Ln (Ln = Sm) complex using $Ni^{II}L$ as a ligand. Thus, to get insight into the strength of these interactions, accurate models involving both the orbital contribution and the ligand field effect have to be developed.

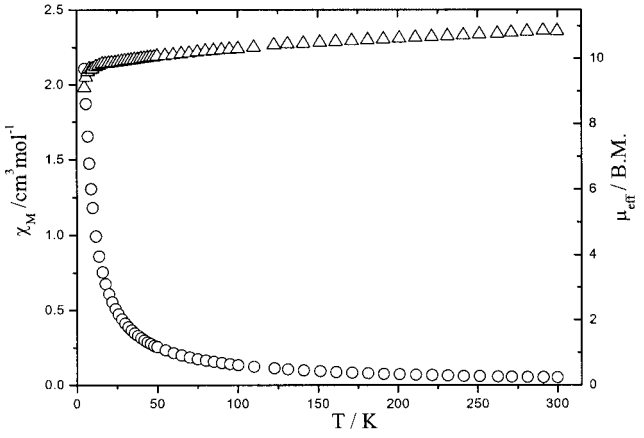

Figure 7. χ_M (circles) versus T and $\mu(T)$ (triangles) versus plots for the pentanuclear species **2**

Conclusion

Two novel oxamidato-bridged $Cu^{II}_4Ln^{III}$ pentanuclear complexes of formula $[(CuL)_3\{CuL(C_2H_5OH)\}Eu(H_2O)](ClO_4)_3\cdot1.5H_2O$, $[(CuL)_3\{CuL(C_2H_5OH)\}Tb(H_2O)](ClO_4)_3\cdot2H_2O$ and $[(NiL)_5Sm](ClO_4)_3\cdot2H_2O$ incorporating a macrocyclic oxamide have been hydrothermally synthesized and structurally characterized. The hydrogen bonds play an important role in the 1-D supramolecular architectures of **1** and **2**. The magnetic and fluorescent properties of **1** and **2** have also been characterized.

Experimental Section

Caution ! *Perchlorate salts of metal complexes with organic ligands are potentially explosive and should be handled very carefully and in small quantities.*

General Remarks: All the starting reagents were of A. R. grade and were used as purchased. The complex ligand CuL was prepared as described according to the literature.[34] The complex ligand NiL was prepared in the same way as CuL.

$[(CuL)_3\{CuL(C_2H_5OH)\}Eu(H_2O)](ClO_4)_3\cdot1.5H_2O$ (1): The complex was prepared by a hydrothermal reaction. A mixture of CuL, $Eu(ClO_4)_3\cdot6H_2O$, CH_3CH_2OH and H_2O in a molar ratio of 4.0:1.0:40:300 was sealed in an 18 cm^3 capacity Teflon-lined reactor which was kept at 160 °C for 72 h. Deep brown-green crystals of the compound were isolated (yield 89.5 % base on Eu) by filtering and washing with water. $C_{78}H_{75}Cl_3Cu_4EuN_{16}O_{23.5}$ (2125.0): calcd. C 44.09, H 3.56, N 10.55; found C 44.10, H 3.45, N 10.48. Main IR bands (KBr, cm^{-1}): $\tilde{\nu}$ = 3414 s (br), 1640 vs, 1610 vs, 1445 m, 1088 vs (br), 776 w, 620 w.

$[(CuL)_3\{CuL(C_2H_5OH)\}Tb(H_2O)](ClO_4)_3\cdot2.0H_2O$ (2): The complex was prepared in the same way as **1**, using terbium perchlorate instead of europium perchlorate. Deep brown-green crystals were obtained (yield 87 % based on Tb). $C_{78}H_{76}Cl_3Cu_4N_{16}O_{24}Tb$ (2141.0): calcd. C 43.76, H 3.58, N 10.47; found C 46.18, H 3.51, N 11.35. Main IR bands (KBr, cm^{-1}): $\tilde{\nu}$ = 3417 s (br), 1639 vs, 1615 vs, 1448 m, 1090 vs (br), 777 w, 623 w.

$[(NiL)_5Sm](ClO_4)_3\cdot2H_2O$ (3): The complex was prepared by a hydrothermal reaction. A mixture of NiL, $Sm(ClO_4)_3\cdot6H_2O$, CH_3CH_2OH and H_2O in a molar ratio of 4.0:1.0:40:300 was sealed in an 18 cm^3 capacity Teflon-lined reactor which was kept at 165 °C for 72 h. Deep brown-red crystals of the compound were isolated (yield 80.5 % base on Sm) by filtering and washing with water. $C_{95}H_{84}Cl_3N_{20}Ni_5O_{24}Sm$ (2440.1): calcd. C 46.76, H 3.47, N 11.48; found C 46.78, H 3.41, N 11.45. Main IR bands (KBr, cm^{-1}): $\tilde{\nu}$ = 3415 s(br), 1636 vs, 1611 vs, 1445 m, 1090 vs (br), 778 w, 621 w.

Physical Measurements: C, H and N analyses were determined on a Perkin−Elmer 240 Elemental analyzer. IR spectra were recorded in KBr discs on a Shimadzu IR-408 infrared spectrophotometer in the 4000−600cm^{-1} range. Electronic spectra in DMF were recorded on a Shimadzu UV-2101 PC scanning spectrophotometer. Variable-temperature magnetic susceptibilities were measured on an MPMS-7 SQUID magnetometer. Diamagnetic corrections were made with Pascal's constants for all the constituent atoms.[35]

X-ray Diffraction Data Collection and Structure Refinement − Crystallographic Studies: All data were collected on a Bruker Smart-1000-CCD area detector using graphite monochromated

Mo-K_α radiation (= 0.71073 Å). The structures were solved by direct method and subsequent Fourier difference techniques and refined using a full-matrix least-squares procedure on F^2 with anisotropic thermal parameters for all non-hydrogen atoms (SHELXS-97 and SHELXL-97).[36] Hydrogen atoms were added geometrically and refined with riding model positional parameters and fixed isotropic thermal parameters. Crystal data collection and refinement parameters are given in Table 4. CCDC 208850 (for **1**), 214752 (for **2**) and -218203 (for **3**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Center, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

sp^3-C^1-Bridged 1,3-Me_2Cp/Amido Titanium and Zirconium Complexes and Their Reactivities towards Ethylene Polymerization

Tae Ho Kim,[a] Young Chul Won,[a] Bun Yeoul Lee,*[a] Dong Mok Shin,[b] and Young Keun Chung[b]

Keywords: Cyclopentadienyl / Zirconium / Titanium / Polymerization / Homogeneous catalysis

sp^3-C^1-Bridged Cp/amido titanium and zirconium complexes are synthesized by using novel fulvenes that have substituents in the 1-, 4-, and 6-positions only. Thus, the nucleophilic attack of lithium *tert*-butylamide on 1,4-dimethyl-6-phenylfulvene, 6-(2-furyl)-1,4-dimethylfulvene and 6-cyclohexyl-1,4-dimethylfulvene, and subsequent aqueous workup, yields *t*BuN(H)–CHR–$C_5H_3Me_2$ (R = phenyl, **6**; R = 2-furyl, **7**; R = cyclohexyl, **8**) in 80, 88, and 60% yields, respectively. The reactions of the ligands with $M(NMe_2)_4$ (M = Ti or Zr) afford the desired bis(dimethylamido) complexes, which can be transformed by treatment with Me_2SiCl_2 to the dichloride complexes, (1,3-$Me_2C_5H_2$–CHR–N*t*Bu–κ*N*)MCl_2 (M = Ti, R = phenyl, **10**; M = Zr, R = phenyl, **11**; M = Ti, R = 2-furyl, **13**; M = Zr, R = 2-furyl, **14**; M = Zr, R = cyclohexyl, **15**). Complex **10** is very sensitive towards water, such that an oxo-bridged dimer, (1,3-$Me_2C_5H_2$–CHPh–NH*t*Bu)$ZrCl_2$–μO–$ZrCl_2$(1,3-$Me_2C_5H_2$–CHPh–NH*t*Bu) (**12**), is easily formed by the abstraction of water from the solvents. The solid structures of (1,3-$Me_2C_5H_2$–CHPh–N*t*Bu–κ*N*)$Zr(NMe_2)_2$, **10**, **11**, and **12** have been determined by X-ray crystallography. The complexes are active towards the polymerization of ethylene when activated with MAO. The activities are rather low and the molecular weight distributions are broad (M_w/M_n = 10–36).

Introduction

Various group 4 *ansa*-metallocene complexes, which have drawn attention as homogeneous Ziegler catalysts, can be synthesized from fulvenes. The C^1-bridged Cp/fluorenyl and C^1-bridged Cp/indenyl complexes are typical examples.[1] Some C^1-bridged Cp/Cp,[2] C^2-bridged Cp/Cp,[3] and C^3-bridged Cp/Cp complexes[4] are also obtained from fulvenes. Recently, Erker et al. reported on the syntheses of sp^3-C^1-bridged Cp/amido titanium and zirconium complexes using 6-*tert*-butylfulvene and 1,2,3,4-tetramethylfulvene.[5] Fulvenes are conventionally synthesized by the base-mediated coupling of cyclopentadiene with aldehydes or ketones.[6] If mono-substituted or 1,3-disubstituted cyclopentadienes are used, the substituents are located mainly in the 2-position or the 1,3-positions in the resulting fulvenes due to steric reasons. Recently, we reported on a synthetic route for the preparation of 1,4-dimethyl-6-phenylfulvene, which is a novel product as it has substituents in the 1-, 4-, and 6-positions only, and we demonstrated the synthesis of a C^1-bridged 1,3-Me_2Cp/fluorenyl zirconium complex using the fulvene.[7] Herein, we report on the syntheses and characterizations of C^1-bridged 1,3-Me_2Cp/amido zirconium and titanium complexes using fulvenes that have substituents in the 1-, 4- and 6-positions only. The complexes are characteristic since the methyl substituents on the cyclopentadienyl ligand are located next to the bridge.[8] In these complexes, the steric congestion at the reaction site is minimized, while an electronic effect is imposed by the substituents.[9]

Results and Discussion

Syntheses and Characterizations

6-(2-Furyl)-1,4-dimethylfulvene (**4**) and 6-cyclohexyl-1,4-dimethylfulvene (**5**) were synthesized by a similar method using the same conditions as that developed for the syn-

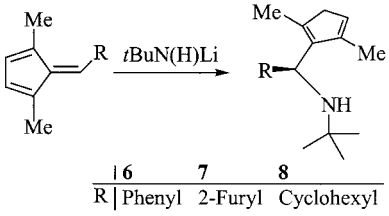
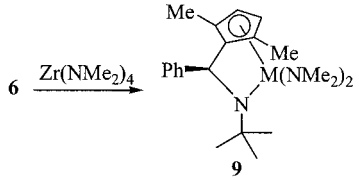
thesis of 1,4-dimethy-6-phenylfulvene (Scheme 1). The overall yields from the starting material **1** were 31% and 42% for **4** and **5**, respectively. The ^{1}H NMR spectra, ^{13}C NMR spectra, and the elemental analyses are in agreement with the fulvene structures of **4** and **5**.

The nucleophilic attack of lithium *tert*-butylamide on the fulvenes in THF, followed by aqueous workup, afforded the desired ligands **6**, **7**, and **8** in 80, 88, and 60% yields, respectively (Scheme 2). Substituted cyclopentadienes are frequently obtained as a set of isomers due to the rapid 1,5-sigmatropic rearrangement.[10] However, compounds **6**, **7**, and **8** were obtained as single isomers, as a result of the symmetry of the substituents, and were characterized unambiguously by ^{1}H and ^{13}C NMR spectroscopy. Comparison of the ^{13}C NMR spectra of the three compounds assists in the assignment of the signals. The signal at 125 ppm is assigned to Cp−*C*H and the signals for Cp−*C*(CH$_3$) are observed at 140−144 ppm. The signals assigned to Cp−*C*(bridgehead) and Cp−*C*H$_2$ are observed at 136−138 ppm and 44 ppm, respectively.



Scheme 2

The reaction of **6** with Zr(NMe$_2$)$_4$ at 100 °C for 2 days afforded the desired C^1-bridged 1,3-Me$_2$Cp/amido zirconium complex **9** (Scheme 3).[11] The dimethylamine formed was removed by a stream of nitrogen gas. When the reaction was carried out by heating without the stream of nitrogen, the reaction stops with the formation of unbridged tris(dimethylamido)Cp complex. The ^{1}H and ^{13}C NMR spectra support the structure shown in Scheme 3. Signals for the Cp protons are observed as a pair of doublets (J = 2.8 ppm) at 5.88 ppm and 5.48 ppm in the ^{1}H NMR spectrum (C$_6$D$_6$), and the methyl signals of the dimethylamido group are observed as a pair of singlets at 3.09 and 2.89 ppm. The signal for the bridgehead carbon on the Cp moiety is observed at 105.76 ppm in the ^{13}C NMR spectrum. Complex **9** is a solid, and single crystals suitable for X-ray crystallography were obtained by recrystallization in pentane at −30 °C. The X-ray crystallographic studies confirm the structure shown in Scheme 3. The thermal ellipsoid plot is shown in Figure 1.



Scheme 3

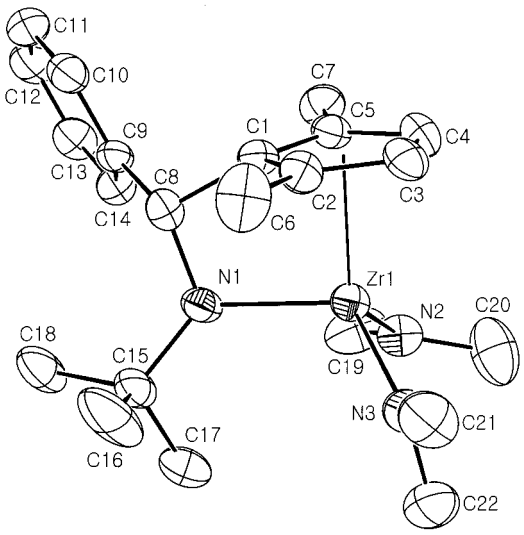


Figure 1. Thermal ellipsoid plot (30% probability level) of the structure of **9**

Similar reactions of **7** and **8** with Zr(NMe$_2$)$_4$, and reactions of **6** and **7** with Ti(NMe$_2$)$_4$, afforded the corresponding bis(dimethylamido) complexes. The reaction of **8** with Ti(NM$_2$)$_4$ was sluggish under identical conditions. The bis(dimethylamido) complexes are oily and therefore could not be purified by recrystallization; however, the ^{1}H and ^{13}C NMR spectra strongly support their formation. The crude products have been used for the proceeding chlorination reactions without further purification. The synthetic method described here is complementary to that developed by Erker, who obtained the Cp and tetramethylcyclopentadienyl analogues by treating the corresponding dilithium salts with TiCl$_2$(NMe$_2$) or ZrCl$_2$(NEt$_2$)$_2$(THF)$_2$.[5]

Erker attempted to convert (Me$_4$Cp−CH$_2$−N*t*Bu)Zr(NEt$_2$)$_2$ to (Me$_4$Cp−CH$_2$−N*t*Bu)ZrCl$_2$ by treatment with excess unpurified Me$_3$SiCl.[5] He unexpectedly obtained an μ-oxo complex, (Me$_4$Cp−CH$_2$−N*t*Bu)ZrCl$_2$−μO−ZrCl$_2$(Me$_4$Cp−CH$_2$−N*t*Bu). The yield of the μ-oxo complex was relatively low (40%), and a complicated mixture of unidentified products was observed in the ^{1}H NMR spectrum. When the reaction of two equivalents of carefully dried Me$_3$SiCl with the bis(dimethylamido) titanium complex of **6** in C$_6$D$_6$ was followed by ^{1}H NMR spectroscopy, it was seen that only one dimethylamido ligand was replaced by the chloride ligand giving (1,3-Me$_2$C$_5$H$_2$−CHPh−N*t*Bu−κ*N*)TiCl(NMe$_2$). Complete chlorination is achieved using Me$_2$SiCl$_2$.[12] Addition of four equivalents of Me$_2$SiCl$_2$ in C$_6$D$_6$ resulted in the formation of the desired dichloride complex **10** (Scheme 4). The ^{1}H and ^{13}C NMR spectra are in agreement with the structure of the dichloride complex. Single crystals of **10** suitable for X-ray crystallography were obtained in toluene at −30 °C and X-ray crystallographic studies confirm the dichloride structure (Figure 2).

Addition of two equivalents of Me$_2$SiCl$_2$ to the bis(dimethylamido)zirconium complex **9** in benzene and overnight stirring, resulted in the precipitation of a white solid. The ^{1}H and ^{13}C NMR spectra of the precipitate strongly sup-

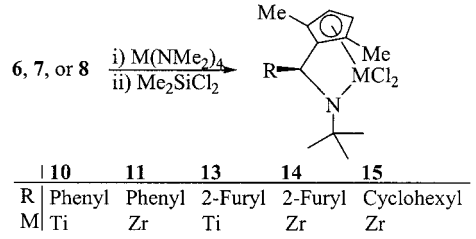

Scheme 4

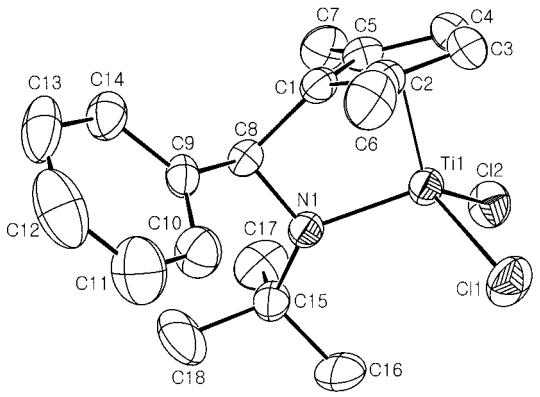

Figure 2. Thermal ellipsoid plot (30% probability level) of the structure of **10**

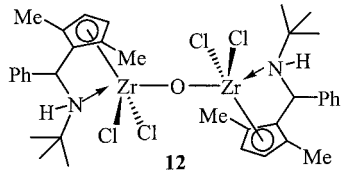
port the formation of the desired dichloride complex **11** (Scheme 4). The main features of the NMR spectra are almost identical to those observed for titanium complex **10**. However, X-ray crystallographic studies of a single crystal, which was obtained by dissolving the precipitate in benzene and by the slow addition of pentane vapor at room temperature, reveal the structure of an unexpected dinuclear μ-oxo complex, **12** (Figure 3). A similar dinuclear μ-oxo complex was observed by Erker when (Me_4Cp-CH_2-NtBu)$Zr(NEt_2)_2$ was treated with excess unpurified Me_3SiCl.[5]



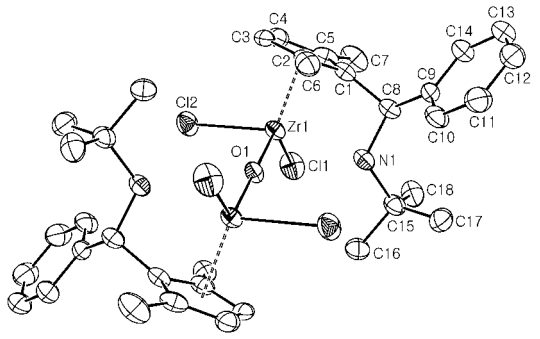


Figure 3. Thermal ellipsoid plot (30% probability level) of the structure of **12**

Since the ^1H and ^{13}C NMR spectra of the precipitate strongly support the structure of the desired mononuclear complex **11**, the formation of **12** may be attributed to the presence of water as an impurity in the recrystallization solvents. Single crystals suitable for X-ray crystallography were directly deposited when **9** and Me_2SiCl_2 were mixed in benzene and reacted without stirring for several days at room temperature. X-ray crystallographic studies of a single crystal obtained by this procedure reveal the desired structure of the mononuclear complex **11** (Figure 4). Complexes **13**–**15** were synthesized in a similar manner, by the reactions of two or three equivalents of Me_2SiCl_2 with the crude bis(dimethylamido) complexes, which are obtained by the reaction of **7** with $Ti(NMe_2)_4$ and reactions of **7** and **8** with $Zr(NMe_2)_4$ (Scheme 4).

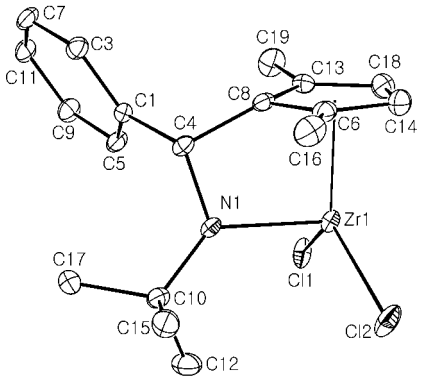

Figure 4. Thermal ellipsoid plot (30% probability level) of the structure of **11**

Crystal Structures of 9, 10, 11, and 12

The thermal ellipsoid plots of **9**, **10**, and **11** are shown in Figures 1, 2, and 4, respectively, and the selected bond lengths and angles are tabulated in Table 1. The crystal structures show the tetrahedral coordination geometry of the central zirconium or titanium atoms. The cyclopentadienyl ligands are η^5-coordinated, with a systematic increase in the Zr–C bond lengths on moving from the bridgehead carbon atom to the peripheral carbon atoms. The M–C distances observed for the titanium complex **10** are shorter than the corresponding distances observed for the zirconium complexes **9** and **11**, and the M–C distances observed for the bis(dimethylamido) complex **9** are longer than those observed for the dichloride complex **11**. A similar trend is observed for the M–N*t*Bu distances of **9**, **10**, and **11**. The Cl–M–Cl angle observed for the zirconium complex **11** [123.27(5)°] is greater than that observed for the titanium complex **10** [104.11(7)°], as well as for the N–Zr–N angle observed for **9** [104.56(16)°]. The bridge carbon atoms are out of the Cp planes, and consequently the $Cp^{centroid}-C^{bridgehead}-C^{bridge}$ bond angles deviate from the ideal value of 180°. The $Cp^{centroid}-C^{bridgehead}-C^{bridge}$ angle observed for the titanium complex **10** (152.1°) is smaller than those observed for the zirconium complexes **9** and **11** (156.2 and 155.8°, respectively), indicating that the bridge carbon atom is further out of the Cp plane in the

[a] Bond length with respect to the side to which the phenyl group is located. [b] Zr−O distance, 1.9526(5) Å.

titanium complex **10**. The $C^{bridgehead}$−C^{bridge}−N angles (100.9(3), 97(3) and 99.3(3) ° for **9**, **10**, and **11**, respectively) deviate from the ideal sp^3-tetrahedral angle (109.5°). The $Cp^{centroid}$−M−NC^{bridge} angles observed for **9**, **10**, and **11** are smaller than that observed for the related complex $(Me_4CpSiN)Zr(NR_2)_2$ (100.2°).[13] The $Cp^{centroid}$−M−NC^{bridge} angles observed for the zirconium complexes **9** and **11** (90.7 and 91.0°, respectively) are smaller than that observed for the titanium complex **10** (97.1°), reflecting that the constraint imposed by the Cp−C^{bridge}−N−M frame is larger in the zirconium complexes than in the titanium complex. The nitrogen atoms on the dimethylamido ligand in **10** form a perfect trigonal planar structure (sum of the bond angles are 359.1° and 359.9°). The nitrogen atoms bonded to the *tert*-butyl group in the dichloride complexes **10** and **11** also almost form a trigonal planar structure (sum of bonding angles, 357.0° and 357.9°, respectively), however, the corresponding nitrogen atoms in the bis(dimethylamido) complex **9** deviate from the trigonal planar structure (sum of the bond angles is 352.8°).

The thermal ellipsoid plot of **12** is shown in Figure 3 and the selected bond lengths and angles are tabulated in Table 1. The metrical parameters observed for **12** are very similar to those observed for $[Me_4Cp-CH_2-N(H)tBu]ZrCl_2-O-ZrCl_2[Me_4Cp-CH_2-N(H)tBu]$, with the exception of the Zr−O−Zr angle. A strictly linear Zr−O−Zr arrangement (180°) is observed for complex **12**, while a somewhat bent structure is observed for $[Me_4Cp-CH_2-N(H)tBu]ZrCl_2-O-ZrCl_2[Me_4Cp-CH_2-N(H)tBu]$ (the Zr−O−Zr angle is 168.2°).

Ethylene Polymerization Studies

The dichloride complexes **10**, **11**, and **13**−**15** are active towards the polymerization of ethylene when activated with MAO (Table 2). The activities are low compared with that of Cp_2ZrCl_2, but are similar to those of the cyclopentadienyl or tetramethylcyclopentadienyl analogues previously prepared by Erker.[5] The titanium complexes show higher activities relative to the zirconium complexes (entry 1 and 3 versus entry 2 and 4). The activity depends strongly on the substituent attached to the bridge carbon atom. The complexes that have the 2-furyl group show the highest activity (entry 3 and 4), and the activity of the zirconium complex that has the 2-furyl substituent is 10 times higher than the complex that has a phenyl substituent (entry 2 and 4). The complex *rac*-(EBI)$Zr(NMe_2)_2$ was reported to be less active than the corresponding dichloride complex when activated with MAO.[14] However, in this case, the bis(dimethylamido) complex **9** shows a higher activity than the corresponding dichloride complex **11** (entry 2 and 6). The titanium complex **13**, which shows the highest activity, produces a polymer with the highest molecular weight (M_w, 610,000). The molecular weight distributions are very broad (M_w/M_n = 10−36), indicating that there are several types of active species in the polymerization solution.

Table 2. Ethylene polymerization results

Entry	Compound[a]	Time (min)	Activity (kg/mol·h)	M_w[c]	M_w/M_n[c]

Conclusion

sp^3-C^1−bridged Cp/amido CGC complexes (1,3-$Me_2C_5H_2$−CHR−N*t*Bu−κ*N*)MCl_2 (M = Ti, Zr; R = phenyl, 2-furyl, cyclohexyl) have been synthesized using novel fulvenes that have substituents in the 1-, 4-, and 6-positions only. The bis(dimethylamido) complexes, which have been prepared by the reaction of $M(NMe_2)_4$ with *t*BuN(H)−CHR−$C_5H_3Me_2$, can be transformed to the dichloride complexes by treatment with Me_2SiCl_2. The complexes are active towards the polymerization of ethylene when activated with MAO. The titanium complexes show higher activities relative to the zirconium complexes, and the titanium complex that has a 2-furyl group on the bridge carbon atom shows the highest activity. The molecular weight distributions are broad (M_w/M_n, 10−36).

Experimental Section

General Remarks: All manipulations were performed under an inert atmosphere using standard glove box and Schlenk techniques. Toluene, pentane, THF, diethyl ether, and benzene were distilled from benzophenone ketyl. Toluene used for the polymerization reaction was purchased from Aldrich (anhydrous grade) and purified further over Na/K alloy. Dichlorodimethylsilane was dried over CaH_2. Ethylene was purchased from Conley Gas (99.9%) and purified by contactwith molecular sieves and copper overnight under a pressure of 150 psig. Methylaluminoxane (MAO) was purchased as a solution in toluene from Akzo (7.6 weight% of Al, MMAO type 4). The NMR spectra were recorded on a Varian Mercury plus 400 spectrometer. Elemental analyses were carried out at the Inter-University Center Natural Science Facilities, Seoul National University. Gel permeation chromatograms (GPC) were obtained at 140 °C in trichlorobenzene using a Waters Model 150-C+ GPC, and the data were analyzed using a polystyrene analyzing curve.

Compound 2: *n*BuLi (3.82 g, 2.5 M in hexane, 13.8 mmol) at −78 °C was added dropwise to a Schlenk flask containing **1** (3.00 g, 13.8 mmol) in THF (5 mL), and the solution was stirred for 1 hour at −78 °C. Furfural (1.32 g, 13.8 mmol) was added and the solution was stirred for 2 hours at −78 °C. The solution was poured into a separating funnel containing water (20 mL), and the product was extracted with ethyl acetate (10 mL × 5). The combined organic layer was shaken with aqueous HCl (1 N, 20 mL) for about 30 seconds, in which step the ketal group was deprotected to give a carbonyl compound. The organic layer was washed with concentrated aqueous $NaHCO_3$ solution (20 mL). The organic layer was collected and dried over anhydrous $MgSO_4$. The solvent was removed to give a residue, which was purified by column chromatography on silica gel eluting with hexane and ethyl acetate (v/v, 2:1) (white solid, 1.44 g, 54%). M.p. 74 °C. ^{1}H NMR (400 MHz, $CDCl_3$, 25 °C): δ = 2.10 (s, 3 H, CH_3), 2.44−2.48 (m, 2 H, CH_2), 2.58−2.63 (m, 2 H, CH_2), 4.64 (d, $^3J_{H,H}$ = 8.8 Hz, 1 H, OH), 5.60 (d, $^3J_{H,H}$ = 8.8 Hz, 1 H, OCH), 6.22 [dd, $^3J_{H,H}$ = 3.2, $^3J_{H,H}$ = 0.8 Hz, 1 H, furyl-C(4)−H], 6.31 [dd, $^3J_{H,H}$ = 3.2, $^4J_{H,H}$ = 2.0 Hz, 1 H, furyl-C(5)−H], 7.34 [dd, $^4J_{H,H}$ = 2.0, $^3J_{H,H}$ = 0.8 Hz, 1 H, furyl-C(3)−H] ppm. $^{13}C\{^1H\}$ NMR (100 MHz, $CDCl_3$, 25 °C): δ = 17.41 (CH_3), 32.18 (CH_2), 34.65 (CH_2), 64.28 (COH), 106.26 [furyl-C(3 or 4)], 110.23 [furyl-C(3 or 4)], 137.27 (C=C), 142.04 [furyl-C(5)], 154.57 [furyl-C(2)], 173.18 (C=C), 210.05 (carbonyl) ppm. IR (neat): ṽ = 1635 and 1673 (C=C−C=O), 3315 (br., OH) cm^{-1}. $C_{11}H_{12}O_3$ (192.21): calcd. C 68.7, H 6.31; found C 68.8, H 6.50.

Compound 3: This compound was synthesized according to a procedure similar to that of **2**. It was purified by column chromatography on silica gel eluting with hexane and ethyl acetate (v/v, 2:1) (oil, 82%). ^{1}H NMR (400 MHz, $CDCl_3$, 25 °C): δ = 0.19 (td, $J_{H,H}$ = 12.0, $J_{H,H}$ = 3.2 Hz, 1 H, Cy-H), 1.00 (td, $J_{H,H}$ = 12.0, $J_{H,H}$ = 3.2 Hz, 1 H, Cy-H), 1.08−1.84 (m, 9 H, Cy-H), 2.05 (s, 3 H, CH_3), 2.38−2.43 (m, 2 H, CH_2), 2.52−2.62 (m, 2 H, CH_2), 3.66 (d, $^3J_{H,H}$ = 10.0 Hz, 1 H, OH), 4.10 (dd, $^3J_{H,H}$ = 10.0, $^3J_{H,H}$ = 8.4 Hz, 1 H, OCH) ppm. $^{13}C\{^1H\}$ NMR (100 MHz, $CDCl_3$, 25 °C): δ = 17.72 (CH_3), 25.93 (Cy-CH_2), 26.10 (Cy-CH_2), 26.46 (Cy-CH_2), 29.30 (Cy-CH_2), 29.46 (Cy-CH_2), 31.94 (CH_2), 34.64 (CH_2), 43.79 (Cy-CH), 73.14 (COH), 139.49 (C=C), 171.91 (C=C), 210.88 (carbonyl) ppm. IR (neat): ṽ = 2850 and 2923 (C=C−C=O), 3446 (br., OH) cm^{-1}. $C_{13}H_{20}O_2$ (208.30): calcd. C 75.0, H 9.70; found C 75.3, H 9.52.

6-(2-Furyl)-1,4-dimethylfulvene (4): Compound **2** (1.44 g, 7.50 mmol) was dissolved in CH_2Cl_2 (10 mL). Dihydropyran (0.95 g, 11 mmol) and pyridinium *p*-toluenesulfonate (PPTS) (0.19 g, 0.75 mmol) were then added at room temperature. The solution was stirred for 4 hours and then diluted with diethyl ether (50 mL). The solution was washed with saturated aqueous NaCl solution. The organic phase was collected and dried over anhydrous $MgSO_4$. Removal of the solvent using a rotary evaporator gave a residue that was purified by column chromatography on silica gel eluting with hexane and ethyl acetate (v/v, 2:1). Signals of two diastereomers are observed in the ^{1}H NMR spectrum. The yield was 1.77 g (yield, 85%). The compound was dissolved in diethyl ether (5 mL), and MeLi (6.4 mL, 1.5 M in diethyl ether, 9.6 mmol) was added dropwise at −78 °C. The solution was allowed to warm to room temperature and stirred overnight. Water (10 mL) was then added. The diethyl ether was removed using a rotary evaporator. Ethyl acetate (30 mL) was added to the residue and the mixture was poured into a separating funnel. The aqueous layer was removed and aqueous HCl (2 N, 30 mL) was added. The mixture was shaken vigorously for 2.5 minutes. The aqueous layer was removed and the organic layer was washed with saturated aqueous $NaHCO_3$ solution (30 mL). The organic layer was collected and dried over anhydrous $MgSO_4$. The solvent was removed using a rotary evaporator, thus giving a residue. NaH (0.23 g, 9.6 mmol) and anhydrous THF (10 mL) was added to the residue under a nitrogen atmosphere. Methanol (1.0 mL) was added using a syringe, upon which hydrogen gas was evolved and the solution became red. The solution was stirred for 20 minutes at room temperature under nitrogen. The solution was poured into a separating funnel containing water (20 mL), and the red compound was extracted with ethyl acetate (50 mL). The organic layer was dried over anhydrous $MgSO_4$. Removal of the solvent gave a red residue that was purified by column chromatography on silica gel eluting with hexane and ethyl acetate (v/v, 20:1). The yield was 0.750 g (overall yield from **2**, 58%). ^{1}H NMR (400 MHz, $CDCl_3$, 25 °C): δ = 2.09 (s, 3 H, CH_3), 2.31 (s, 3 H, CH_3), 5.97 [s, 1 H, fulvene-C(2 or 3)-H], 6.11 [quadruplet, $^4J_{H,H}$ = 1.2 Hz, 1 H, fulvene-C(2 or 3)−H)], 6.51 [dd, $^3J_{H,H}$ = 3.2, $^3J_{H,H}$ = 1.6 Hz, 1 H, furyl-C(4)−H], 6.73 [d, $^3J_{H,H}$ = 3.2 Hz, 1 H, furyl-C(3)−H], 6.80 [(s, 1 H, fulvene-C(6)−H)], 7.56 [dd, $^3J_{H,H}$ = 1.6, $^4J_{H,H}$ = 0.4 Hz, 1 H, furyl-C(5)−H)] ppm. $^{13}C\{^1H\}$ NMR (100 MHz, $CDCl_3$, 25 °C): δ = 13.09 (CH_3), 17.42 (CH_3), 112.22 (furyl-CH), 116.84 (furyl-CH), 119.38 (furyl-CH), 126.29 [fulvene-C(2 or 3)], 129.38 [fulvene-C(1 or 4)], 131.68 [fulvene-C(2 or 3)], 134.05 [fulvene-C(1 or 4)], 141.77 [fulvene-C(5)], 144.49 [fulvene-C(6)], 151.28 [furyl-C(2)] ppm. $C_{12}H_{12}O_1$ (172.22): calcd. C 83.7, H 7.04; found C 83.6, H 7.00.

6-Cyclohexyl-1,4-dimethylfulvene (5): This compound was synthesized according to a procedure similar to that for **4**. It was purified by column chromatography on silica gel eluting with hexane and ethyl acetate (v/v, 50:1). A yellow oily compound was obtained in a 51% overall yield from **3**. ^{1}H NMR (400 MHz, $CDCl_3$, 25 °C): δ = 1.12−1.44 (m, 5 H, Cy-CH_2), 1.68−1.90 (m, 5 H, Cy-CH_2), 2.01 (s, 3 H, CH_3), 2.22 (s, 3 H, CH_3), 2.93 (qt, $^3J_{H,H}$ = 10.4, $^3J_{H,H}$ = 3.2 Hz, 1 H, Cy-CH), 5.92 [s, 1 H, fulvene-C(2 or 3)−H], 6.03 [quadruplet, $^4J_{H,H}$ = 1.2 Hz, 1 H, fulvene-C(2 or 3)−H], 6.11 [d, $^3J_{H,H}$ = 10.4 Hz, 1 H, fulvene-C(6)−H] ppm. $^{13}C\{^1H\}$ NMR (100 MHz, $CDCl_3$, 25 °C): δ = 12.68 (CH_3), 16.95 (CH_3), 25.79 (Cy-CH_2), 25.98 (Cy-CH_2), 33.12 (Cy-CH_2), 37.55 (Cy-CH), 125.34 [fulvene-C(2 or 3)], 130.03 [fulvene-C(1 or 4)], 130.28 [fulvene-C(2 or 3)], 133.43 [fulvene-C(1 or 4)], 142.65 [fulvene-C(5)], 144.10 [fulvene-C(6)] ppm. $C_{14}H_{20}$ (188.31): calcd. C 89.3, H 10.7; found C 89.0, H 10.5.

Substituted Cyclopentadiene (6): 1,4-Dimethyl-6-phenylfulvene (0.95 g, 5.21 mmol) was dissolved in cold THF (−30 °C, 40 mL) and lithium *tert*-butylamide (0.41 g, 5.21 mmol) was added. The solution was stirred overnight at room temperature. Water (20 mL) was added and the product was extracted with hexane (50 mL). It was purified by column chromatography on silica gel eluting with hexane and ethyl acetate (v/v, 10:1). The yield was 80% (1.06 g). ^{1}H NMR (400 MHz, $CDCl_3$, 25 °C): δ = 1.13 (s, 9 H, *t*Bu-H), 1.82 (quadruplet, $J_{H,H}$ = 2.0 Hz, 3 H, CH_3), 2.14 (s, 3 H, CH_3), 2.80 (quintet, $J_{H,H}$ = 2.0 Hz, 2 H, CH_2), 4.98 (s, 1 H, bridge-CH), 5.78 (d, $J_{H,H}$ = 2.0 Hz, 1 H, Cp-CH), 7.14 [t, $^3J_{H,H}$ = 8 Hz, 1 H, Ph-C(*para*)−H], 7.25 [t, $^3J_{H,H}$ = 8 Hz, 2 H, Ph-C(*meta*)−H], 7.46 [d, $^3J_{H,H}$ = 8 Hz, 2 H, Ph-C(*ortho*)−H] ppm. $^{13}C\{^1H\}$ NMR (100 MHz, $CDCl_3$, 25 °C): δ = 14.65 (CH_3), 15.92 (CH_3), 30.12 [C(*C*H_3)$_3$], 44.12 (CH_2), 51.41 [N*C*(CH_3)$_3$], 52.98 (NCH), 125.09 (Cp-CH), 125.69 [Ph-C(*para*)], 127.07 [Ph-C(*ortho* or *meta*)], 127.63 [Ph-C(*ortho* or *meta*)], 137.05 [Cp-C(bridgehead)], 143.02 [Cp-C(CH_3)], 143.11 [Cp-C(CH_3)], 145.66 [Ph-C(*ipso*)] ppm. $C_{18}H_{25}N_1$ (255.40): calcd. C 84.7, H 9.89, N 5.48; found C 84.6, H 10.1, N 5.15.

Substituted Cyclopentadiene 7: This compound was synthesized according to a procedure similar to that for **6**. It was purified by column chromatography on silica gel eluting with hexane and ethyl acetate (v/v, 50:1). The yield was 88%. ^{1}H NMR (400 MHz, $CDCl_3$, 25 °C): δ = 1.14 (s, 9 H, *t*Bu-H), 1.99 (quadruplet, $J_{H,H}$ = 2.0 Hz, 3 H, CH_3), 2.10 (s, 3 H, CH_3), 2.82 (quintet, $J_{H,H}$ = 2.0 Hz, 2 H, CH_2), 4.99 (s, 1 H, NCH), 5.83 (d, $J_{H,H}$ = 1.6 Hz, 1 H, Cp-CH), 6.10 [d, $^3J_{H,H}$ = 3.2 Hz, 1 H, furyl-C(3)−H], 6.28 [dd, $^3J_{H,H}$ = 3.2, $^3J_{H,H}$ = 2.0 Hz, 1 H, furyl-C(4)−H], 7.32 [d, $^3J_{H,H}$ = 2.0 Hz, 1 H, furyl-C(5)−H] ppm. $^{13}C\{^1H\}$ NMR (100 MHz, $CDCl_3$, 25 °C): δ = 14.32 (CH_3), 15.56 (CH_3), 29.87 [C(*C*H_3)$_3$], 44.15 (CH_2), 48.48 (NCH), 51.30 [N*C*(CH_3)$_3$], 105.49 [furyl-C(3 or 4)], 109.95 [furyl-C(3 or 4)], 124.79 (Cp-*C*H), 138.36 [Cp-C(bridgehead)], 140.49 [Cp-C(CH_3)], 140.75 [furyl-C(5)], 143.03 [Cp-C(CH_3)], 157.78 [furyl-C(2)] ppm. $C_{16}H_{23}O_1N_1$ (245.36): calcd. C 78.3, H 9.47, N 5.71; found C 78.2, H 9.50, N 5.83.

Substituted Cyclopentadiene 8: This compound was synthesized according to a procedure similar to that for **6**. It was purified by column chromatography on silica gel eluting with hexane and ethyl acetate (v/v, 30:1). The yield was 60%. ^{1}H NMR (400 MHz, $CDCl_3$, 25 °C): δ = 0.7−2.2 (m, 11 H, Cy-H), 1.00 (s, 9 H, *t*Bu-H), 1.94 (s, 3 H, CH_3), 2.10 (s, 3 H, CH_3), 2.65−2.82 (m, 2 H, Cp-CH_2), 3.34 (d, $J_{H,H}$ = 9.6 Hz, 1 H, NCH), 5.78 (s, 1 H, Cp-CH) ppm. $^{13}C\{^1H\}$ NMR (100 MHz, $CDCl_3$, 25 °C): δ = 14.33 (CH_3), 16.71 (CH_3), 26.66, 26.71, 26.83, 30.21 [C(*C*H_3)$_3$], 30.40, 32.11, 42.80, 43.62, 50.78, 55.89, 124.79 (Cp-CH), 136.70 [Cp-C(bridgehead)], 142.73 [Cp-C(CH_3)], 143.73 [Cp-C(CH_3)] ppm. $C_{18}H_{31}N_1$ (261.45): calcd. C 82.7, H 12.0, N 5.35; found C 82.9, H 12.1, N 5.40.

(1,3-$Me_2C_5H_2$-CHPh−N*t*Bu−κ*N*)Zr(NMe_2)$_2$ (9): Compound **6** (0.511 g, 2.00 mmol) and Zr(NMe_2)$_4$ (0.535 g, 2.00 mmol) were weighed in a flask and toluene (30 mL) was added. The solution was stirred for 2 days at 100 °C under a weak stream of nitrogen gas. The volatiles were removed to give a white oil, which was quite pure (analyzed by ^{1}H and ^{13}C NMR spectroscopy) (crude yield, 97%). Analytically pure single crystals suitable for X-ray crystallography were obtained in pentane at −30 °C. M.p. 135 °C. ^{1}H NMR (400 MHz, C_6D_6, 25 °C): δ = 1.24 (s, 9 H, *t*Bu-H), 1.54 (s, 3 H, CH_3), 2.19 (s, 3 H, CH_3), 2.89 (s, 6 H, NCH_3), 3.09 (s, 6 H, NCH_3), 5.48 (d, $^3J_{H,H}$ = 2.8 Hz, 1 H, Cp-H), 5.85 (s, 1 H, bridge-CH), 5.88 (d, $^3J_{H,H}$ = 2.8 Hz, 1 H, Cp-H), 7.13 [t, $^3J_{H,H}$ = 7.6 Hz, 1 H, Ph-C(*para*)−H], 7.25 [t, $^3J_{H,H}$ = 7.6 Hz, 2 H, Ph-C(*meta*)−H], 7.61 [d, $^3J_{H,H}$ = 7.6 Hz, 2 H, Ph-C(*ortho*)−H] ppm. $^{13}C\{^1H\}$ NMR (100 MHz, C_6D_6, 25 °C): δ = 13.52 (CH_3), 14.79 (CH_3), 32.24 [C(*C*H_3)$_3$], 43.58 [N(CH_3)$_2$], 47.37 [N(CH_3)$_2$], 56.20 [N*C*(CH_3)$_3$], 59.33 (bridge-CH), 105.76 [Cp-C(bridgehead)], 107.74 (Cp-CH), 112.60 (Cp-CH), 123.77 [Cp-C(CH_3)], 125.43 [Cp-C(CH_3)], 126.45 (Ph-C), 127.64 (Ph-C), 128.45 (Ph-C), 147.10 [Ph-C(*ipso*)] ppm. $C_{22}H_{35}N_3Zr$ (432.76): calcd. C 61.1, H 8.15, N 9.71; found C 61.3, H 8.23, N 9.65.

(1,3-$Me_2C_5H_2$−CHPh−N*t*Bu−κ*N*)$TiCl_2$ (10): The bis(dimethylamido) complex was synthesized according to a procedure similar to that of **9**, however, **6** (0.511 g, 2.00 mmol) and Ti(NMe_2)$_4$ (0.450 g, 2.00 mmol) were used. A deep red oil was obtained, which was quite pure (analyzed by ^{1}H and ^{13}C NMR spectroscopy). ^{1}H NMR (400 MHz, C_6D_6, 25 °C): δ = 1.28 (s, 9 H, *t*Bu-H), 1.44 (s, 3 H, CH_3), 2.13 (s, 3 H, CH_3), 3.01 (s, 6 H, NCH_3), 3.27 (s, 6 H, NCH_3), 5.44 (d, $^3J_{H,H}$ = 2.8 Hz, 1 H, Cp-H), 5.80 (s, 1 H, bridge-CH), 5.94 (d, $^3J_{H,H}$ = 2.8 Hz, 1 H, Cp-H), 7.12 [t, $^3J_{H,H}$ = 7.6 Hz, 1 H, Ph-C(*para*)−H], 7.24 [t, $^3J_{H,H}$ = 7.6 Hz, 2 H, Ph-C(*meta*)−H], 7.55 [d, $^3J_{H,H}$ = 7.6 Hz, 2 H, Ph-C(*ortho*)−H] ppm. $^{13}C\{^1H\}$ NMR (100 MHz, C_6D_6, 25 °C): δ = 13.76 (CH_3), 14.59 (CH_3), 32.11 [C(*C*H_3)$_3$], 48.42 [N(CH_3)$_2$], 52.65 [N(CH_3)$_2$], 59.95 [N*C*(CH_3)$_3$], 60.98 (bridge-CH), 103.29 [Cp-C(bridgehead)], 109.85 (Cp-CH), 115.62 (Cp-CH), 123.25 [Cp-C(CH_3)], 126.37 (Ph-C), 128.35 (Ph-C), 146.95 [Ph-C(*ipso*)] ppm. The crude residue was dissolved in toluene (12 mL) and dichlorodimethylsilane (1.03 g, 8.00 mmol) was added. The solution was stirred overnight. The volatiles were removed under a vacuum. The complex was dissolved in toluene and stored in a freezer (−30 °C) overnight to give red crystals which were suitable for X-ray crystallography (0.234 g, 37%). The major constituent of the mother liquor was the desired complex, but further isolation of the clean complex from the mother liquor was not achieved. M.p. 163 °C. ^{1}H NMR (400 MHz, C_6D_6, 25 °C): δ = 1.37 (s, 9 H, *t*Bu-H), 1.52 (s, 3 H, CH_3), 1.88 (s, 3 H, CH_3), 6.06 (d, $^3J_{H,H}$ = 3.6 Hz, 1 H, Cp-H), 6.08 (s, 1 H, bridge-CH), 6.20 (d, $^3J_{H,H}$ = 3.6 Hz, 1 H, Cp-H), 7.00−7.15 (m, 5 H, Ph-H) ppm. $^{13}C\{^1H\}$ NMR (100 MHz, C_6D_6, 25 °C): δ = 15.12 (CH_3), 17.88 (CH_3), 30.83 [C(*C*H_3)$_3$], 62.45 (bridge-CH), 63.76 [N*C*(CH_3)$_3$], 102.13 [Cp-C(bridgehead)], 122.14 (Cp-CH), 122.78 (Cp-CH), 127.76 (Ph-C), 127.92 (Ph-C), 128.44 (Ph-C), 138.47 [Cp-C(CH_3)], 138.79 [Cp-C(CH_3)], 141.43 [Ph-C(*ipso*)] ppm. $C_{18}H_{23}Cl_2NTi$ (372.15): calcd. C 58.1, H 6.24, N 3.76; found C 57.8, H 6.25, N 3.93.

(1,3-$Me_2C_5H_2$−CHPh−N*t*Bu−κ*N*)$ZrCl_2$ (11): Compound **9** (0.530 g, 1.22 mmol) was dissolved in toluene (20 mL) and dichlorodimethylsilane (0.315 g, 2.44 mmol) was added. The solution was stirred overnight, upon which a white solid precipitated. The solid was filtered and dried under vacuum. The yield was 44% (0.222 g).

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

The major constituent of the filtrate was the desired complex. The reaction for 4 days without stirring gave single crystals suitable for X-ray crystallography. M.p. 194 °C. ^{1}H NMR (400 MHz, C_6D_6, 25 °C): δ = 1.27 (s, 9 H, *t*Bu-H), 1.60 (s, 3 H, CH_3), 1.99 (s, 3 H, CH_3), 5.77 (d, $^3J_{H,H}$ = 3.2 Hz, 1 H, Cp-H), 5.91 (s, 1 H, bridge-CH), 5.95 (d, $^3J_{H,H}$ = 3.2 Hz, 1 H, Cp-H), 7.00−7.10 [m, 3 H, Ph-C(*meta* or *para*)−H], 7.10−7.22 [m, 2 H, Ph-C(*ortho*)−H] ppm. ^{13}C{^{1}H} NMR (100 MHz, C_6D_6, 25 °C): δ = 14.00 (CH_3), 16.58 (CH_3), 30.70 [C(*C*H$_3$)$_3$], 57.84 [N*C*(CH$_3$)$_3$], 59.65 (bridge-CH), 104.27 [Cp-C(bridgehead)], 116.17 (Cp-CH), 116.40 (Cp-CH), 127.56 (Ph-C), 128.29 (Ph-C), 128.49 (Ph-C), 132.17 [Cp-C(CH_3)], 132.25 [Cp-C(CH_3)], 142.21 [Ph-C(*ipso*)] ppm. $C_{18}H_{23}Cl_2NZr$ (415.51): calcd. C 52.0, H 5.59, N 3.37; found C 51.7, H 6.00, N 3.34.

[1,3-Me$_2$C$_5$H$_2$−CH(C$_4$H$_3$O)−N*t*Bu−κ*N*]TiCl$_2$ (13): The bis(dimethylamido) complex was synthesized according to a procedure similar to that for **9**. The reaction time was 4 days. A deep red oil was obtained. ^{1}H NMR (400 MHz, C_6D_6, 25 °C): δ = 1.26 (s, 9 H, *t*Bu-H), 1.75 (s, 3 H, CH_3), 2.07 (s, 3 H, CH_3), 3.04 (s, 6 H, NCH_3), 3.22 (s, 6 H, NCH_3), 5.50 (d, $^3J_{H,H}$ = 2.8 Hz, 1 H, Cp-H), 5.91 (s, 1 H, bridge-CH), 5.94 (d, $^3J_{H,H}$ = 2.8 Hz, 1 H, Cp-H), 6.15−6.20 [m, 2 H, furyl-C(3 and 4)−H], 7.17 [dd, $^3J_{H,H}$ = 1.6, $^4J_{H,H}$ = 0.8 Hz, 1 H, furyl-C(5)−H] ppm. ^{13}C{^{1}H} NMR (100 MHz, C_6D_6, 25 °C): δ = 13.50 (CH_3), 14.49 (CH_3), 31.27 [C(*C*H$_3$)$_3$], 48.35 [N(CH_3)$_2$], 52.40 [N(CH_3)$_2$], 54.94 (bridge-CH), 59.62 [N*C*(CH$_3$)$_3$], 102.26 [Cp-C(bridgehead)], 106.94 [furyl-C(3 or 4)], 109.31 (Cp-CH), 110.75 [furyl-C(3 or 4)], 115.68 (Cp-CH), 123.23 [Cp-C(CH_3)], 126.06 [Cp-C(CH_3)], 139.91 [furyl-C(5)], 158.57 [furyl-C(2)] ppm. Chlorination was accomplished using the method and conditions developed for **10**. A crude red oil, which is quite pure (analyzed by NMR spectroscopy), was obtained by evaporation of all the volatiles, in a 86% yield. An analytically pure compound was obtained by recrystallization in pentane at −30 °C. M.p. 117 °C. ^{1}H NMR (400 MHz, C_6D_6, 25 °C): δ = 1.33 (s, 9 H, *t*Bu-H), 1.82 (s, 3 H, CH_3), 2.01 (s, 3 H, CH_3), 5.97 [d, $^3J_{H,H}$ = 3.6 Hz, 1 H, furyl-C(3)−H], 6.00 [dd, $^3J_{H,H}$ = 3.6, $^3J_{H,H}$ = 1.6 Hz, 1 H, furyl-C(4)−H], 6.14 (s, 1 H, bridge-CH), 6.16 (d, $^3J_{H,H}$ = 3.6 Hz, 1 H, Cp-H), 6.17 (d, $^3J_{H,H}$ = 3.6 Hz, 1 H, Cp-H), 6.92 [dd, $^3J_{H,H}$ = 1.6, $^4J_{H,H}$ = 0.8 Hz, 1 H, furyl-C(5)−H] ppm. ^{13}C{^{1}H} NMR (100 MHz, C_6D_6, 25 °C): δ = 15.08 (CH_3), 18.12 (CH_3), 29.29 [C(*C*H$_3$)$_3$], 55.88 (bridge-*C*H), 63.09 [N*C*(CH$_3$)$_3$], 102.95 [Cp-C(bridgehead)], 109.36 [furyl-C(3 or 4), 110.95 [furyl-C(3 or 4)], 121.52 (Cp-CH), 122.68 (Cp-CH), 137.46 [Cp-C(CH_3)], 138.83 [Cp-C(CH_3)], 141.31 [furyl-C(5)], 152.64 [furyl-C(2)] ppm. $C_{16}H_{21}Cl_2NOTi$ (362.12): calcd. C 53.1, H 5.85, N 3.86; found C 52.8 (52.6), H 6.32 (6.30), N 3.80 (3.75).

[1,3-Me$_2$C$_5$H$_2$−CH(C$_4$H$_3$O)−N*t*Bu−κ*N*]ZrCl$_2$ (14): The bis(dimethylamido) complex was synthesized according to a procedure similar to that for **9**. The reaction time was 4 days. A white oil was obtained. ^{1}H NMR (400 MHz, C_6D_6, 25 °C): δ = 1.21 (s, 9 H, *t*Bu-H), 1.92 (s, 3 H, CH_3), 2.13 (s, 3 H, CH_3), 2.91 (s, 6 H, NCH_3), 3.04 (s, 6 H, NCH_3), 5.56 (d, $^3J_{H,H}$ = 2.8 Hz, 1 H, Cp-H), 5.87 (d, $^3J_{H,H}$ = 2.8 Hz, 1 H, Cp-H), 5.93 (s, 1 H, bridge-CH), 6.18−6.22 [m, 2 H, furyl-C(3 and 4)−H], 7.18 [dd, $^3J_{H,H}$ = 2.8, $^4J_{H,H}$ = 0.8 Hz, 1 H, furyl-C(5)−H] ppm. ^{13}C{^{1}H} NMR (100 MHz, C_6D_6, 25 °C): δ = 13.22 (CH_3), 14.01 (CH_3), 31.21 [C(*C*H$_3$)$_3$], 43.52 [N(CH_3)$_2$], 47.14 [N(CH_3)$_2$], 53.45 (bridge-CH), 55.86 [N*C*(CH$_3$)$_3$], 105.55 [Cp-C(bridgehead)], 107.12 (Cp-CH), 107.71 [furyl-C(3 or 4)], 110.72 [furyl-C(3 or 4)], 112.55 (Cp-CH), 123.91 [Cp-C(CH_3)], 125.29 [Cp-C(CH_3)], 140.00 [furyl-C(5)], 158.71 [furyl-C(2)] ppm. Chlorination was accomplished by stirring the crude bis(dimethylamido) complex with 3.0 equivalents of dichlorodimethylsilane in pentane overnight. The precipitated white solid was filtered and dried under vacuum. The yield was 47%. M.p. 128 °C. ^{1}H NMR (400 MHz, C_6D_6, 25 °C): δ = 1.23 (s, 9 H, *t*Bu-H), 1.96 (s, 3 H, CH_3), 2.15 (s, 3 H, CH_3), 5.92 (d, $^3J_{H,H}$ = 2.8 Hz, 1 H, Cp-H), 5.94 (d, $^3J_{H,H}$ = 2.8 Hz, 1 H, Cp-H), 5.98 (s, 1 H, bridge-CH), 6.01 [d, $^3J_{H,H}$ = 3.2 Hz, 1 H, furyl-C(3)−H], 6.04 [dd, $^3J_{H,H}$ = 3.2, $^3J_{H,H}$ = 1.6 Hz, 1 H, furyl-C(4)−H], 6.99 [d, $^3J_{H,H}$ = 1.6 Hz, 1 H, furyl-C(5)−H] ppm. ^{13}C{^{1}H} NMR (100 MHz, C_6D_6, 25 °C): δ = 14.08 (CH_3), 16.77 (CH_3), 29.11 [C(*C*H$_3$)$_3$], 53.30 (bridge-CH), 57.53 [N*C*(CH$_3$)$_3$], 105.13 [Cp-C(bridgehead)], 108.93 [furyl-C(3 or 4)], 110.88 [furyl-C(3 or 4)], 115.55 (Cp-CH), 116.43 (Cp-CH), 131.91 [Cp-C(CH_3)], 132.27 [Cp-C(CH_3)], 141.17 [furyl-C(5)], 153.82 [furyl-C(2)] ppm. $C_{16}H_{21}Cl_2NOZr$ (405.47): calcd. Ethylene Polymerization: In a dry box, toluene (30 mL) was added to a dried 70 mL glass reactor. The activated complex, prepared by mixing the complex (10 μmol) and MAO (Al/Zr or Ti = 500), was added to the reactor. The reactor was assembled and removed from the dry box. The reactor was immersed in an oil bath whose temperature had been set to 60 °C, and stirred for 15 minutes, at which time the solution temperature reached that of the bath. Ethylene was fed under the pressure of 100 psig. After the polymerization reaction was performed for the given time, it was quenched by venting ethylene gas and pouring the mixture into acetone. The white precipitates were collected by filtration and dried under vacuum. Table 2 summarizes the polymerization results.

X-ray Crystallographic Study: Crystals of **9**, **10**, and **12** were coated with grease (Apiezon N) and mounted inside a thin glass tube with epoxy glue and placed on an Enraf−Nonius CCD single-crystal X-ray diffractometer using graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å). The crystal of **11** was mounted onto a thin glass fiber with paratone and immediately placed in a cold nitrogen stream at 150 K on a MXC3 diffractometer (Mac Science) The structures were solved by direct methods (SHELXS-97)[15] and refined against all F^2 data (SHELXS-97). All non-hydrogen atoms were refined with anisotropic thermal parameters. The hydrogen atoms were treated as idealized contributions. The crystal data and

Macrocyclic and Open-Chain Cu^{II}-4f (4f = Gd^{III}, Ce^{III}) Complexes with Planar Diamino Chains: Structures and Magnetic Properties

Jean-Pierre Costes,*[a] Françoise Dahan,[a] Ghenadie Novitchi,[a,b] Vladimir Arion,[c] Sergiu Shova,[d] and Janusz Lipkowski[e]

Keywords: Heterometallic complexes / Copper / Lanthanides / Macrocyclic ligands / Template synthesis / Magnetic properties

Until now, the known structures of heterodinuclear Cu–Ln complexes involve compartmental Schiff-base ligands with saturated diamino chains. We report here two Cu–Ln complexes (Ln = Gd or Ce) which are the first structurally characterized Cu–Ln entities involving *S*-methylisothiosemicarbazide as the diamino bridge, with open chain and macrocyclic ligands. The macrocyclic Cu–Gd entity is a well isolated dinuclear complex whereas two hydrogen bonds join together a pair of binuclear Cu–Ce complexes to give tetranuclear {Cu–Ce···Ce–Cu} entities. The Cu–Gd complexes [H = -J($S_{Cu}S_{Gd}$)] exhibit ferromagnetic interactions between 5 and 5.5 cm^{-1}. Since the Cu–Ce complexes do not follow the Curie law due to the presence of orbital degeneracy, an analysis based on a simple spin-only Hamiltonian is not possible. Nevertheless, the EPR spectra of the Cu–Ce complexes do confirm the existence of magnetic interactions.

1. Introduction

Heteronuclear lanthanide (4f) and 3d metal coordination complexes are mainly studied for their interesting magnetic properties.[1−9] These bimetallic complexes are important for studying the nature of the magnetic exchange interactions between lanthanide and transition metal atoms, and they can potentially be used as magnetic materials[1−4] and high temperature superconductors.[10] Studies aimed at understanding the coupling mechanism in paramagnetic rare earth metal complexes with other spin carriers are mainly restricted to gadolinium(III) (S = 7/2) derivatives and S = 1/2 species such as copper(II)[5,6,11−24] or vanadyl(II)[25] metal centers. Consistently, in the great majority of Cu−Gd, VO−Gd, or radical−Gd species studied so far, the intramolecular interaction between the gadolinium ion and the 1/2 spin has been found to be ferromagnetic, but a few examples of complexes showing antiferromagnetic behavior do exist.[6,24−27] The most frequently used ligands are polydentate Schiff bases involving saturated diamino chains. In order to extend the number of known examples, we have considered simple Cu−Ln heterodinuclear complexes involving Schiff-base ligands with *S*-methylisothiosemicarbazide as the diamino chain. Indeed, the use of an unsaturated diamino chain introduces planarity into the five-membered metallacycle that can induce geometric modifications in the Cu−Ln bridge and, consequently, change the magnitude and/or the nature of the magnetic interaction. Keeping this in mind, we have also synthesized a macrocyclic Cu−Gd complex which should be more constrained. It should be stressed that these examples are the first structurally characterized Cu−Ln entities involving *S*-methylisothiosemicarbazide as the diamino bridge.

2. Results and Discussion

2.1 Synthesis of the Complexes

The reaction of 3-methoxysalicylaldehyde or 3-ethoxysalicylaldehyde with *S*-methylisothiosemicarbazide hydroiodide in a 2:1 molar ratio in methanol, followed by treatment with $AgNO_3$, removal of AgI and addition of $CuOAc_2·H_2O$ afforded red crystals of the **$CuL_A·(H_2O)$** and **$CuL_B·(H_2O)$** complexes, respectively (Scheme 1). The corresponding **H_2L_A** and **H_2L_B** ligands are represented in Scheme 2. **$CuL_C·2H_2O$** was obtained from $L_CCuBa(CF_3SO_3)_2$ by reaction with guanidinium sulfate in $CHCl_3/H_2O$ (1:1).[28]

The heterometallic complexes **I**−**V** were synthesized by reaction of the related copper complexes with $La(NO_3)_3{\cdot}6H_2O$, $Ce(NO_3)_3{\cdot}6H_2O$, or $Gd(NO_3)_3{\cdot}6H_2O$ in acetone, while **VI** was obtained by utilizing the same reaction in a mixture of dichloromethane and methanol.

2.2 Structures of the Complexes

2.2.1 $[L_ACuCe(NO_3)_3(H_2O)](CH_3)_2CO$ (II)

An X-ray crystallographic study of **II** shows that the unit cell contains two neutral dinuclear $[L_ACuCe(NO_3)_3(H_2O)]$

species and two acetone molecules which are not coordinated to the copper or cerium ions but involved in hydrogen bonding with the cerium-coordinated water molecule. A perspective drawing of the asymmetric unit appears in Figure 1. The molecular structure of **II** is very similar to those of analogous 3d−4f Schiff-base complexes studied earlier.[12−14] The Ce^{III} and Cu^{II} ions are connected by two bridging phenoxo oxygen atoms, with a Cu···Ce distance of 3.457(1) Å. The Ce^{III} ion is eleven-coordinate, bound to oxygen atoms from the two bridging phenoxo groups, two methoxy groups, three nitrate anions acting as η^2 chelating ligands and one aqua ligand. The Ce−O bond lengths range from 2.503(4) to 2.900(4) Å. As usual, the shortest bonds involve the bridging O(1) and O(2) oxygen atoms, the longest ones corresponding to the methoxy groups, are 2.900(4) and 2.787(4) Å. This can be easily explained because the cerium ion is displaced from the mean O_4 ligand coordination plane by 0.962(5) Å. The Ce−O nitrato bond lengths are within 2.540(4)−2.604(4) Å, except for Ce−O(9) which is longer [2.756(4) Å]. The short intramolecular O(9)···Cu(1) contact [2.706(4) Å] is probably responsible for this lengthening. The Cu^{II} ion is located in the inner N_2O_2 cavity of the Schiff-base ligand and has a square-pyramidal (4+1) geometry, with the nitrogen and oxygen atoms of the ligand in the basal plane and the nitrato oxygen atom in the apical position. The *S*-methylisothiosemicarbazide fragment was found to be disordered over two positions with occupancy factors of 0.57 and 0.43 for the S(1) and S(1*) atoms respectively (Figure 1). This feature is characteristic of the *S*-methylisothiosemicarbazone moiety and has already been observed in a large number of complexes.[29,30] The five-membered ring formed by the *S*-methylisothiosemicarbazone moiety coordinated to the copper ion is perfectly planar and induces planarity in the whole ligand, which implies a better electronic delocalization. As a consequence, the Cu−N and Cu−O bond lengths are practically equal [1.890(3)−1.909(4) Å range] and slightly shorter than in the previous structurally characterized Cu−Ce complex.[31]

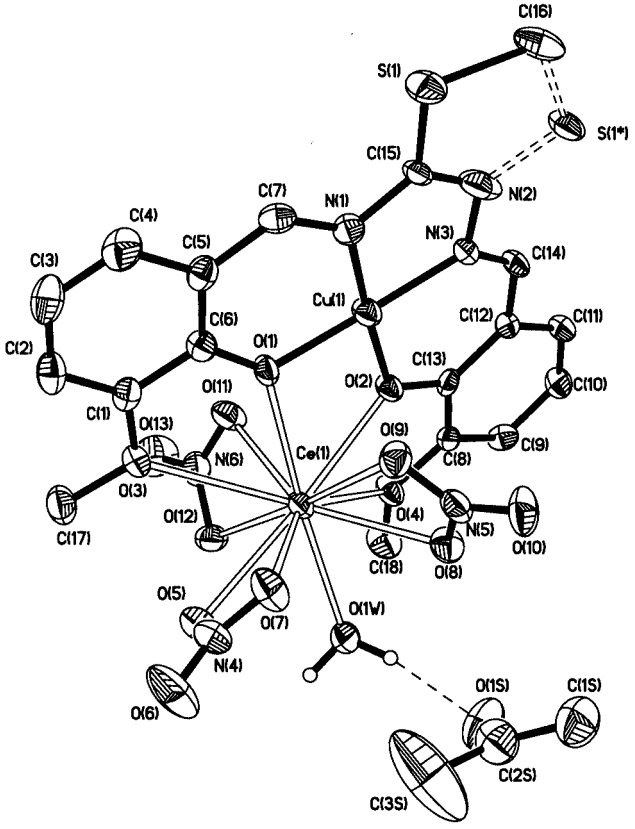

Figure 1. View of $[L_ACuCe(NO_3)_3(H_2O)](CH_3)_2CO$ (**II**); the thermal ellipsoids are drawn at the 50% probability level

A significant intermolecular interaction O(1*w*)−H···O(12)^i (*i*: 1 − *x*, −*y*, −*z*) between the coordinated water molecule O(1*w*) and the nitrato oxygen O(12) of the neighboring molecule with O(1*w*)−H: 0.86(1) Å, O(1*w*)−H···O(12): 1.99(2) Å, O(1*w*)···O(12)′: 2.831(6) Å and ∠O(1*w*)−H···O(12)′: 167(8)° should be mentioned. Two of the above mentioned H-bonds join together a pair

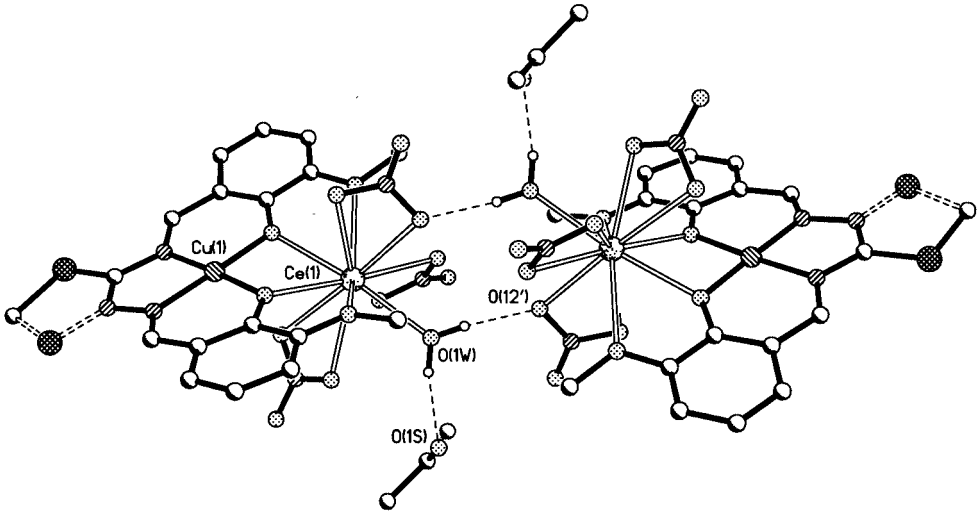

Figure 2. Structure of the tetranuclear entity $\{[L_ACuCe(NO_3)_3(H_2O)](CH_3)_2CO\}_2$

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

of binuclear complexes **II** to give tetranuclear Cu−Ce···Ce−Cu units. The coordinated water molecules are also hydrogen-bonded to the oxygen atom of an acetone molecule [O(1*w*)−H: 0.87(1) Å, O(1*w*)−H···O(1S): 1.90(1) Å, O(1*w*)···O(1S): 2.757(6) Å and ∠O(1*w*)−H···O(1S): 173(6)°]. The resultant tetranuclear entity, formulated as $\{[L_ACuCe(NO_3)_3(H_2O)](CH_3)_2CO\}_2$, is depicted in Figure 2. Furthermore, the centrosymmetrically related tetranuclear $\{[L_ACuCe(NO_3)_3(H_2O)](CH_3)_2CO\}_2$ species are linked through π−π interactions, giving two-dimensional layers oriented parallel to the *ac* plane of the crystal. The distances between the mean planes of neighboring overlapping aromatic rings vary from 3.45 to 3.52 Å.

2.2.2 $L_CCuGd(NO_3)_3$ (VI)

The asymmetric unit of the macrocyclic complex **VI** is shown in Figure 3. In contrast to **II**, the copper ion in **VI** has a square-planar geometry and only two nitrate ions act as η^2 chelating ligands, the third one being mono-coordinated to the gadolinium ion. The bridging network Cu(O,O)Ln is not planar. The dihedral angle between the planes O(1)−Cu−O(2) and O(1)−Ln−O(2) is larger in **II** [24.3(2)°] than in **VI** [18.9(1)°].

Interestingly, the gadolinium ion is eleven-coordinate, bound to five oxygen atoms from nitrate ions and six oxygen atoms from the macrocyclic ligand. As in **II**, the distances of the gadolinium ion to the oxygen atoms of the alkoxy groups are the longest. The shortest Gd−O bond [2.330(4) Å] involves the mono-coordinated nitrate ion. The bonds involving the bridging phenoxo oxygen atoms [2.465(3) and 2.477(3) Å] are larger than in other Cu−Gd complexes.[5,6,13,14] The *S*-methylisothiosemicarbazide fragment was again found to be disordered over two positions.

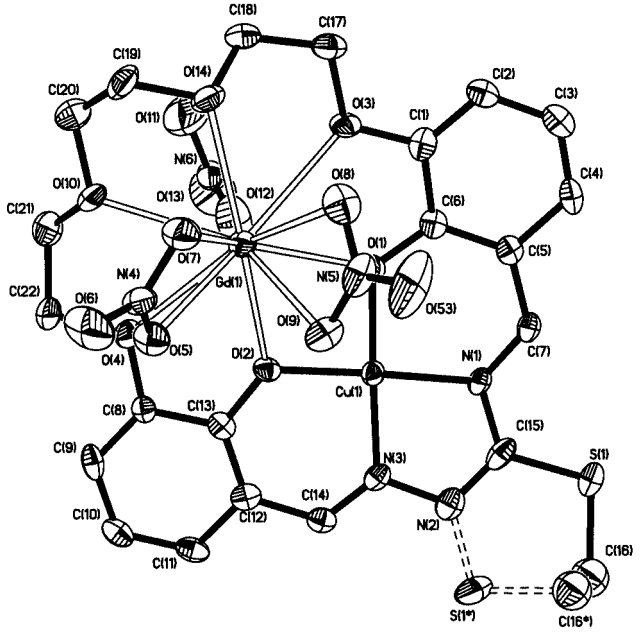

Figure 3. Molecular structure of $L_CCuGd(NO_3)_3$ (**VI**)

2.3. Magnetic Properties

Almost identical magnetic behavior is observed for compounds **I**, **III**, and **VI**. As an example, the data for **I** are quoted in Figure 4 in the form of the thermal variation of the $\chi_M T$ product, χ_M being the molar susceptibility corrected for diamagnetism. At 300 K, $\chi_M T$ for **I** is equal to 8.20 $cm^3mol^{-1}K$, which corresponds to the value expected for two uncoupled metal ions. Lowering the temperature causes $\chi_M T$ to increase to 9.89 $cm^3mol^{-1}K$ at 7 K. This value compares well with that (10.0 $cm^3mol^{-1}K$) expected for an $S = 4$ spin state resulting from ferromagnetic coupling between Cu^{II} ($S = 1/2$) and Gd^{III} ($S = 7/2$) and assuming $g_{Cu} = g_{Gd} = 2$. A quantitative analysis has been performed on the basis of an expression derived from the spin-only Hamiltonian $H = -J_{Cu\text{-}Gd}S_{Cu}S_{Gd}$. Taking into consideration the g values associated with the low lying levels $E(4) = 0$ [$g_4 = (7g_{Gd} + g_{Cu})/8$] and $E(3) = 4J$ [$g_3 = (9g_{Gd} - g_{Cu})/8$],[32] the following expression can be obtained [Equation (1)].

$$\chi T = N\alpha + \frac{4N\beta^2 T}{\kappa(T-\theta)} \cdot \frac{15g_4^2 + 7g_3^2 \cdot \exp(-\frac{4J}{kT})}{9 + 7 \cdot \exp(-\frac{4J}{kT})} \quad (1)$$

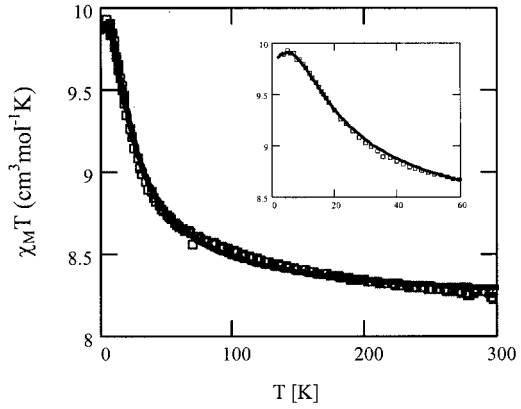

Figure 4. Thermal dependence of $\chi_M T$ for **I** at 0.1 T; the full line corresponds to the best data fit

Least-squares fitting of the experimental data led to the following set of parameters: $g_{Gd} = 1.99$, $g_{Cu} = 2.02$, $\theta = -0.02$ K, $J = 5.2$ cm^{-1} for **I**. The other two complexes give the following values: $g_{Gd} = 1.99$, $g_{Cu} = 2.01$, $\theta = -0.09$ K, $J = 5.5$ cm^{-1} for **III** and $g_{Gd} = 1.98$, $g_{Cu} = 2.02$, $\theta = -0.06$ K, $J = 4.98$ cm^{-1} for **VI**. The agreement factors $\Sigma(\chi T_{calc} - \chi T_{obs})^2/\Sigma(\chi T_{obs})^2$ are then respectively equal to $1\cdot10^{-5}$, $4\cdot10^{-5}$, and $2\cdot10^{-5}$. The small θ values suggest that second-order effects, such as intermolecular interactions or partial saturation at low temperature are, at best, very weak. The positive J value indicates a ferromagnetic coupling between Cu^{II} and Gd^{III}. This is further supported by the experimental values of the magnetization for **I** measured at 2.0 K which are correctly fitted by the Brillouin function

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

for an $S = 4$ spin state, which confirms the ferromagnetic nature of the Cu−Gd interaction. The magnitude of the Cu−Gd interaction does not differ widely from one compound to the others.

It has been reported that the J_{CuGd} values and Cu···Gd distances could be correlated using an exponential function.[33] More recently, from the magnetic properties of several Cu−Gd complexes, we have found a satisfying correlation between the absolute value of the ferromagnetic coupling constant J_{CuGd} and the dihedral angle α defined by the two OCuO and OGdO planes of the bridging network.[5] The value obtained for **VI** is in good agreement with our previously published values. This relation implies that the dihedral angle must be lower than 18.9(1)° in **I** and **III** for the J values associated with them are larger. Unfortunately, the structural parameters for these complexes are not available. However we know the dihedral angle [24.2(2)°] for the Cu−Ce complex **II**. Since there is a decrease in the ionic radius on going from Ce^{III} to Gd^{III}, a decrease of α from 24.2(2)° to a value slightly lower than 18.9(1)° may be reasonably expected.

The magnetic behavior of the Cu−Ce compound **II** is more complex since the cerium ion does possess an orbital contribution, so that the observed $\chi_M T$ decrease in Figure 5 may be due to two concomitant factors namely depopulation of the Stark levels as T decreases and a possible Cu−Ce antiferromagnetic interaction.[18,33,34] A semi-qualitative analysis would necessitate the synthesis of the equivalent Ni−Ce complex with the nickel ion in a low spin state in order to evaluate the contribution of the Stark effect.[33] Unfortunately we did not succeed in preparing this complex. To complete our study we have considered the EPR spectra of complexes **IV** and **V**. For **IV** we observed a strong feature at $g = 2.04$ and a four component hyperfine structure centered at $g = 2.19$, these features being attributable to isolated copper ions (Figure 6, a). The spectrum of **V** consists of a single signal at $g = 2.07$ (Figure 6, b). It is tempting to attribute the difference to the presence of a (Cu−Ce) exchange interaction in **IV** which has no counterpart in **V** due to the diamagnetism of the lanthanum ions. To support this hypothesis we refer to the early work of Bleaney[35] devoted to the systems made up from two ions with very different relaxation rates. A recent review focuses on this question and gives the relaxation times for monomeric systems involving copper (10^{-8}, 10^{-9} s) and cerium

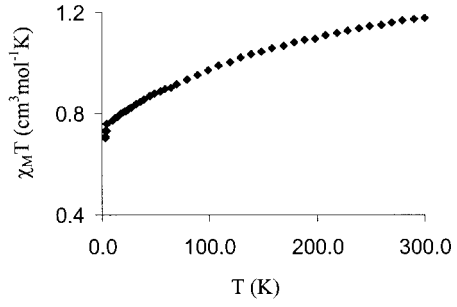

Figure 5. Thermal dependence of $\chi_M T$ for **$[L_A CuCe(NO_3)_3(H_2O)](CH_3)_2CO$ (II)**

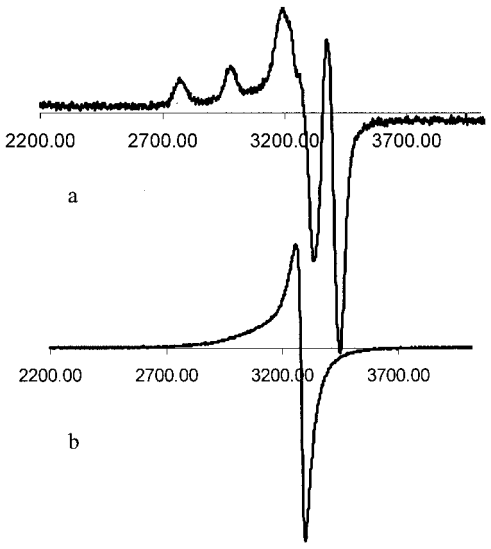

Figure 6. The solid state EPR spectra of (a) **$L_B CuCe(NO_3)_3(H_2O)$ (IV)** and (b) **$L_B CuLa(NO_3)_3(H_2O)$ (V)** at 90 K

ions (10^{-13} s).[36] In the case of complex **IV** the cerium resonance was not observed because the signals are strongly enlarged due to an abnormally low value of the spin lattice relaxation time. Contrary to the cerium ions, the copper ions have normal relaxation times that lead to an observable and even well-resolved spectrum. The absence or at least the lowering of the signal broadening would be due to a supplementary relaxation mechanism of the copper ions through the (Cu−Ce) exchange interaction. Due to the complexity of the relaxation mechanisms,[36] a more complete description of that behavior would necessitate further experimental data. Eventually this experimental evidence for a (Cu−Ce) exchange interaction gave no information concerning the sign of the interaction and we have to keep in mind that these interactions are very weak. Nevertheless, from the variation of the χT product at very low temperature for **II** (Figure 5) and from previous examples in literature,[31,34] it seems more likely that the Cu−Ce interaction is antiferromagnetic. Such an interaction is also present in **II**, but the π−π stacking present in this complex is responsible for the lower intensity of the parallel part of the spectrum.

3. Conclusion

The complexes considered in this work exhibit ferromagnetic $J_{Cu\text{-}Gd}$ interactions, as in the majority of previously published Cu−Gd complexes. Although the variation of the $J_{Cu\text{-}Gd}$ interactions is relatively limited, from 1.0 to 10.1 cm^{-1}, it appears that the decrease of the interaction parameter J can be related to an increase in the dihedral angle α defined by the two OCuO and OGdO planes of the bridging network.[5] The compounds described in this work fit in with the previous results. The best J values have been obtained with the most planar Cu−$(O)_2$−Gd cores corresponding to α angles near 0°. From a synthetic point of view, these complexes with *S*-methylisothiosemicarbazide as

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

diamino chains are the first examples of structurally characterized Cu−Ln heterodinuclear complexes with planar and unsaturated diamino chains. Thus, it was tempting to investigate if the use of more planar ligands could increase this *J* value. Unfortunately, other constraints coming from the macrocyclic structure or a greater rigidity of the ligand did not allow us to obtain higher *J* values. Furthermore, the EPR spectra of the Cu−Ce complexes have given a satisfying confirmation for the existence of magnetic interactions in these complexes that do not follow the Curie law due to the presence of orbital degeneracy.

4. Experimental Section

All starting materials and solvents were purchased from Aldrich and were used without further purification. *S*-methylisothiosemicarbazide hydroiodide was obtained by the reaction of thiosemicarbazide with methyl iodide in dry ethanol.[37] Elemental analyses (C, H, N) were carried out by the Service de Microanalyse du Laboratoire de Chimie de Coordination, Toulouse. Magnetic susceptibility data were collected on powdered samples of a SQUID-based sample magnetometer on Quantum Design model MPMS instrument. All data were corrected for the diamagnetism of the ligands estimated from Pascal's constants.[38] The Nα parameter, which is very weak, was omitted in our calculations.

$CuL_A \cdot H_2O$: To a methanolic solution (50 mL) of 3-methoxysalicylaldehyde (0.3 g 2.0 mmol) was added dropwise a solution of *S*-methylisothiosemicarbazide hydroiodide (0.23 g, 1.0 mmol) in CH_3OH (15 mL). The obtained mixture was carefully stirred at 50 °C for 2 h. The resultant pale-yellow solution was heated to reflux for a further 20 min. After cooling to room temperature, a solution of $AgNO_3$ (0.26 g, 1.0 mmol) in CH_3OH/H_2O (1:2, 15 mL) was added. The AgI was removed by filtration and a solution of $Cu(CH_3COO)_2 \cdot H_2O$ (0.2 g, 1.0 mmol) in CH_3OH (15 mL) was added in one portion to the filtrate. The red product which crystallized overnight was filtered and washed with a small amount of cold methanol. Yield 0.32 g (70%). $C_{18}H_{19}CuN_3O_5S$: calcd. C 47.73, H 4.23, N 9.28; found C 48.65, H 4.53, N, 9.32%.

The complex **$CuL_B \cdot H_2O$** was prepared using an analogous experimental procedure. Yield 0.25 g (55%). $C_{20}H_{23}CuN_3O_5S$: calcd. C 49.94, H 4.82, N 8.74; found C 50.03, H 4.83, N 8.90%.

$CuL_C \cdot 2H_2O$ was prepared as described elsewhere.[30]

$L_ACuGd(NO_3)_3 \cdot H_2O$ (I): $CuL_A \cdot H_2O$ (0.22 g 0.5 mmol) dissolved in acetone (50 mL) was slowly added to an acetone solution (20 mL) of $Gd(NO_3)_3 \cdot 5H_2O$ (0.23 g 0.5 mmol) with vigorous stirring. After partial evaporation of the solvent bright brown crystals were formed, separated by filtration, washed with cold acetone and air dried. Yield 0.28 g (70%). $C_{18}H_{19}CuGdN_6O_{14}S$: calcd. C 27.15, H 2.41, N 10.55; found C 27.44, H 2.46, N 2.52%.

$[L_ACuCe(NO_3)_3(H_2O)](CH_3)_2CO$ (II), **$L_BCuGd(NO_3)_3(H_2O)$ (III)**, and **$L_BCuCe(NO_3)_3(H_2O)$ (IV)** were prepared similarly. Single crystals of **II** suitable for X-ray diffraction study were obtained by slow evaporation of an acetone solution of **$CuL_A \cdot H_2O$** and $Ce(NO_3)_3 \cdot 6H_2O$.

$[L_ACuCe(NO_3)_3(H_2O)](CH_3)_2CO$ (II): Yield 0.20 g (50%). $C_{21}H_{25}CeCuN_6O_{15}S$: calcd. C 30.13, H 3.01, N 10.04; found C 30.70, H 3.25, N 9.98%.

$L_BCuGd(NO_3)_3(H_2O)$ (III): Yield 0.25 g (45%). $C_{20}H_{23}CuGdN_6O_{14}S$: calcd. C 29.14, H 2.81, N 10.20; found C 28.92, H 2.83, N 9.94%.

$L_BCuCe(NO_3)_3(H_2O)$ (IV): 0.32 g (75%). $C_{20}H_{23}CeCuN_6O_{14}S$: calcd. C 29.76, H 2.87, N 10.41; found C 30.42, H 2.93, N 10.35%.

$L_BCuLa(NO_3)_3(H_2O)$ (V): 0.35 g (80%). $C_{20}H_{23}CuLaN_6O_{14}S$: calcd. C 29.80, H 2.88, N 10.43; found C 29.42, H 2.81, N 10.25%.

$L_CCuGd(NO_3)_3$ (VI): To **$CuL_C \cdot 2H_2O$** (0.27 g, 0.5 mmol) in a dichloromethane/methanol mixture (3:2 ratio) (50 mL) was added $Gd(NO_3)_3 \cdot 6H_2O$ (0.29 g, 0.6 mmol) in methanol (20 mL). The solution was heated to reflux for 15 min until the crystallization of the product had begun. The solvent was evaporated to 15 mL and methanol (20 mL) was added. The dark-red product was filtered, washed with methanol and dichloromethane and dried in vacuo. Yield 0.34 g (40%). $C_{22}H_{23}CuGdN_6O_{15}S$: calcd. C 30.57, H 2.68, N 9.72; found C 30.46, H 2.85, N 9.57%.

X-ray Crystallographic Studies of $[L_ACuCe(NO_3)_3(H_2O)](CH_3)_2CO$ (II): Crystallographic measurements for **II** were carried out on a Nonius Kappa CCD diffractometer equipped with a graphite-monochromated Mo-K_α radiation source. Intensity data were collected at 150 K using θ rotations with 2degree scan and a detector-to-crystal distance of 35 mm. The unit cell determination and data integration were carried out using the program DENZO-SMN.[39] Data sets were corrected for Lorentz and polarization effects. The absorption correction was introduced by a semi-empirical method from symmetry equivalent reflections.[40] The structure was solved by direct methods with the program SHELXS-97.[41] Refinement was performed using full-matrix least-squares on F^2, with anisotropic displacement parameters for the non-hydrogen atoms using the program SHELXL-97.[42] The hydrogen atoms of the polydentate ligand and solvent molecule (acetone) were placed in calculated positions and given isotropic displacement parameters equal to $1.2 \times U_{eq}$ of the relevant carbon atom. Positional parameters of the H atoms of water molecules were obtained from difference Fourier syntheses and were verified by the geometric parameters of corresponding hydrogen bonds.

X-ray Crystallographic Studies of $L_cCuGd(NO_3)_3$ (VI): The selected crystal of **VI** (orange-red plate) was mounted on a Stoe Imaging Plate Diffractometer System (IPDS) equipped with an Oxford Cryosystems cooler device at 160 K using a graphite monochromator (λ = 0.71073 Å). The crystal-to-detector distance was 80 mm. Data were collected[43] with a φ rotation movement (φ = 0.0−249.6°, Δφ = 1.3°). Numerical absorption[44] corrections were applied. Maximum and minimum transmission factors were respectively 0.7576 and 0.3294. The structure was solved by direct methods using SHELXS-97[41] and refined by full-matrix least-squares on F_o^2 with SHELXL-97[42] with anisotropic displacement parameters for all non-hydrogen atoms. H atoms were introduced by calculations using the riding model with isotropic thermal parameters 1.1 times higher than those of the riding atom. Scattering factors were taken from ref.[45] The molecular plot was obtained using the ZORTEP program.[46]

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Center. Copies of the data (CCDC-215450 for **II** and CCDC-215647 for **VI**) can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) +44-1223/336-033, E-mail: deposit@ccdc.cam.ac.uk].

The Synthesis of Stable Intramolecularly Dialkylamino-Coordinated Silenes and Their Methyl Iodide Induced Isomerization into Cyclic Aminosilanes[‡]

Martin Mickoleit,[a] Kathleen Schmohl,[a] Manfred Michalik,[b] and Hartmut Oehme*[a]

Keywords: Rearrangement / Silaethenes / Silanes / Silenes / Silicon

The reaction of the (dichloromethyl)oligosilanes $R(Me_3Si)_2SiCHCl_2$ **4a–d** (**4a**: R = Me; **4b**: R = *t*Bu; **4c**: R = Ph; **4d**: R = $SiMe_3$) with 8-(dimethylamino)-1-naphthyllithium leads to the intramolecularly donor-stabilized silenes **1a–d**. Whereas **1a**,**b**, and **d** were isolated as thermally stable yellow crystalline compounds, **1c** could not be separated in a pure form but was characterized by NMR spectroscopy and mass spectroscopy as well as by its chemical reactivity with a variety of substrates. Dynamic ^1H NMR spectroscopic studies of **1a** and **1d** revealed coalescence of the signals of the two $CSiMe_3$ groups. In agreement with theoretical calculations, this effect was interpreted as the result of internal rotations about the silene double bond. These findings and the known relatively long Si=C distances for **1d**, **2** and **3** help establish the ylide-like nature of the silenes prepared. Treatment of **1a–d** with water produced the silanols **9a–d**. Treatment of **1a**,**b**, and **d** with methyl iodide caused a rearrangement of the silenes, one methyl substituent formally migrating from the coordinated dimethylamino group to the silene carbon atom producing the respective cyclic aminosilanes **11a**,**b**, and **d**. As the outcome of the reaction of **1d** with benzaldehyde, 2,2-bis(trimethylsilyl)vinylbenzene (**14**) and a mixture of the two isomers of the cyclodisiloxane **13** were obtained.

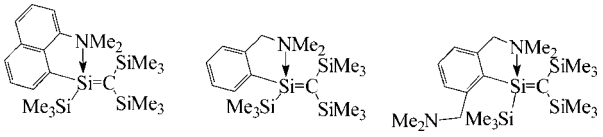
Introduction

Silenes, silicon derivatives with a Si=C double bond, are known as extremely reactive compounds, which in absence of scavenger reagents rapidly undergo dimerization or polymerization. Only very few kinetically stabilized silenes have been isolated and structurally characterized.[1] Coordination of amines, THF or fluoride ions to the electrophilic silene silicon atom leads to an effective stabilization of the compounds;[2a] Wiberg et al. have succeeded in the isolation of an amine adduct of a silene, which is unstable in the absence of a donor molecule.[2b] Recently we presented the synthesis, by a new pathway, isolation and structural characterization of the first intramolecularly donor-stabilized silenes **1d**, **2**, and **3**.[3] The compounds proved to be thermally stable up to 140 °C and, compared with uncomplexed silenes, their reactivity was also dramatically reduced.



1d **2** **3**

In this paper we report on the general applicability of the newly developed synthetic route, describe some further stable silenes, and discuss the results of recent studies characterizing their chemical behavior. Dynamic NMR studies in combination with quantum mechanical calculations give an insight into rotational processes about the Si=C bonds of these compounds. Furthermore, we describe an unexpected methyl iodide induced isomerization of intramolecularly amine-coordinated silenes into cyclic aminosilanes.

Results and Discussion

Synthesis of Intramolecularly Donor-Stabilized Silenes

As described previously, the silenes **1d**, **2**, and **3** are easily accessible in a one-pot reaction by treatment of (dichloromethyl)tris(trimethylsilyl)silane (**4d**, $R^1 = SiMe_3$) with two equivalents of 8-(dimethylamino)-1-naphthyllithium, 2-(dimethylaminomethyl)phenyllithium or 2,6-bis(dimethylami-

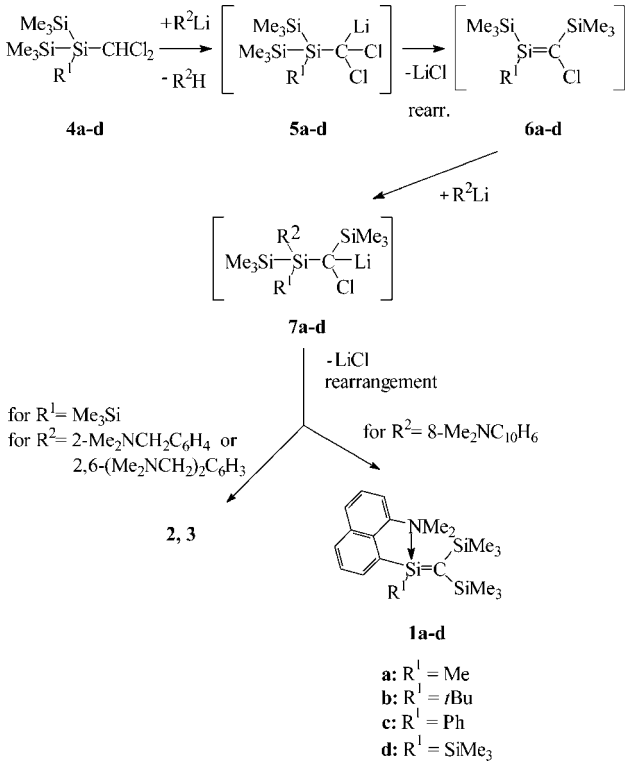

Scheme 1. The formation of the intramolecularly donor-stabilized silenes **1a**−**d**, **2**, and **3** by the reaction of the (dichloromethyl)oligosilanes **4a**−**d** with 8-(dimethylamino)-1-naphthyllithium, 2-(dimethylaminomethyl)phenyllithium and 2,6-bis(dimethylaminomethyl)phenyllithium, respectively (molar ratio 1:2)

nomethyl)phenyllithium, respectively, following the route outlined in Scheme 1.[3] The reaction path, which we have already discussed in detail,[3,4] involves the deprotonation of **4d**, lithium chloride elimination from **5d** and migration of one trimethylsilyl group from the central silicon atom to the neighboring carbon atom producing the transient silene **6d**. Subsequent addition of a second equivalent of the organolithium derivative across the Si=C double bond of **6d**, repeated elimination of LiCl, and a second trimethylsilyl migration leads to the formation of the silenes **1d**, **2**, and **3**. Whereas uncomplexed silenes, generated according to the same pattern by the reaction of **4d** with ordinary organolithium compounds (R^2Li = MeLi, PhLi, *n*BuLi, MesLi) immediately add excess R^2Li finally producing after hydrolysis the silanes $R^1R^2{}_2Si-CH(SiMe_3)_2$,[4] **1d**, **2**, and **3** proved to be stable with respect to the attack of an excess of the aryllithium compounds applied, could be isolated and structurally characterized. X-ray structural analyses were also performed. The high stability of these compounds can no doubt be attributed to the strong interaction between the amino groups and the silene silicon atoms, which dramatically reduces the electrophilic properties of the Si=C moieties of **1d**, **2**, and **3**.

The reaction path outlined involves the migration of two trimethylsilyl groups from the central silicon atom in **4d** (R^1 = $SiMe_3$) to the neighboring carbon atom replacing the two chlorine substituents and forming the $C(SiMe_3)_2$ unit in **1d**, **2**, and **3**. Consequently, one trimethylsilyl group of the original (dichloromethyl)tris(trimethylsilyl)silane (**4d**) can be replaced by any alkyl or aryl group, and treatment of these related (dichloromethyl)oligosilanes with dialkylaminoaryllithium compounds should produce stabilized silenes with a further carbon substituent at the silene silicon atom. We chose (dichloromethyl)methylbis(trimethylsilyl)silane (**4a**), *tert*-butyl(dichloromethyl)bis(trimethylsilyl)silane (**4b**), and (dichloromethyl)phenylbis(trimethylsilyl)silane (**4c**) and studied their reactions with 8-(dimethylamino)-1-naphthyllithium (molar ratio 1:2). The first experiments were unsuccessful, the main problem being the complete separation of the 1-(dimethylamino)naphthalene formed in the first step of the reaction by protonation of the aryllithium compound through the dichloromethylsilanes **4a**−**c**. As subsequently discovered, however, the high thermal stability of the products allowed the application of more aggressive purification methods. Thus, silene **1a** was generated by the reaction of **4a** with 8-(dimethylamino)-1-naphthyllithium (1:2) following the general procedure described for the synthesis of **1d**, **2**, and **3**;[3] to our surprise, this compound could be purified by distillation in vacuo (150 °C/0.0005 mbar) to give a yellow solid. Similarly, **1b** was obtained from **4b** and 8-(dimethylamino)-1-naphthyllithium (1:2). 1-(Dimethylamino)naphthaline was distilled from the product mixture (100 °C/0.01 mbar) and **1b** was obtained as an orange-yellow oil, which gradually solidified. Unfortunately, the crystal quality of **1a** was insufficient for an X-ray structural analysis, but extended NMR, IR, and MS spectroscopic studies as well as chemical reactions of **1a** and **1b** unambiguously confirmed the proposed structures. Particularly the ^{29}Si and ^{13}C chemical shifts of the silicon and carbon atoms of the Si=C groups in **1a** and **1b**, which are in good agreement with those of **1d**, **2**, and **3**,[3] characterize the compounds as intramolecularly donor-stabilized silenes (see Exp. Sect.).

Silene **1c**, the expected product of the reaction of **4c** with 8-(dimethylamino)-1-naphthyllithium (1:2) could not be obtained in a pure form. Aqueous workup of the reaction mixture, however, gave the silanol **9c** in a yield of approximately 80%. Similarly, treatment of the reaction mixture with methanol produced (8-dimethylamino-1-naphthyl)(methoxy)phenyl[bis(trimethylsilyl)methyl]silane **10** (78%). Both results indicate that silene **1c** was indeed formed and is indefinitely stable.

As expected for the magnetically non-equivalent $CSiMe_3$ groups of **1a**−**d**, two separate signals were observed in the ^1H NMR spectra at room temperature. For **1a** and **1d** dynamic ^1H NMR studies were performed, which revealed that at elevated temperatures coalescence of the signals of the two trimethylsilyl groups at the silene carbon atoms occurred. The data obtained were used for calculations of the rotational barriers about the Si=C bond in **1a** and **1d** (Table 1).

The assignment of the above-mentioned coalescence phenomena to rotation about the Si=C double bond is supported by theoretical calculations performed on **2** and a related silene bearing a methyl group at the silene Si instead of a Me_3Si group. These computations led to calculated

Table 1. Coalescence temperatures (T_c) and signal separations ($\Delta\nu_c$) of the $CSiMe_3$ groups and rotational barriers ($\Delta G_o^{\neq}$) about the Si=C bond in **1a** and **1d**

	T_c (K)	$\Delta\nu_c$ (Hz)	$\Delta G_c^{\neq}$[a] (kJ·mol^{-1})
1a	317	95	63.3
1d	353	98	71.0

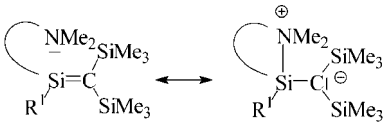
[a] The free energies of activation $\Delta G_c^{\neq}$ at the coalescence temperature were calculated from the Eyring equation.[5] The error limits were estimated to be $T_c = \pm 2$ K, $\Delta\nu_c = \pm 5\%$, and $\Delta G_c^{\neq} = \pm 1.0$ kJ·mol^{-1}.

values of the rotational barriers of the same order of magnitude as those found experimentally for **1a** and **1d**. These results will be communicated separately.[6]

The magnitude of the rotational barrier to isomer interconversion in uncomplexed silenes was found to be about 160 kJ·mol^{-1}.[1a] As expected, this figure is considerably lower than the height of the barrier to *cis*/*trans* isomerization in alkenes, which amounts to approximately 250 kJ·mol^{-1}.[7] The reported rotational barriers for the silene donor adducts THF·Me_2Si=$C(SiMe_3)SiMetBu_2$ and Me_3N·Me_2Si=$C(SiMe_3)SiMetBu_2$ of 50 kJ·mol^{-1} and 65 kJ·mol^{-1}, respectively,[8] are very close to those found for **1a** and **1d**. That means that the interaction of silenes with donor molecules leads to a weakening of the Si−C π-interaction, and **1a**−**d** as well as **2** and **3** may equally be described as ylidic compounds [Equation (1)].

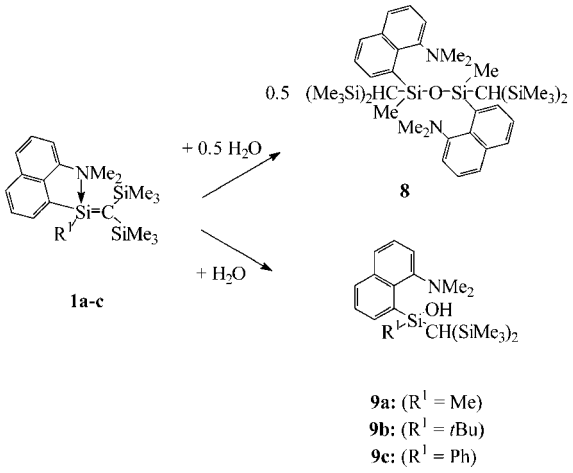
The Reactions of the Silenes 1a, 1b, and 1d with Water, Methyl Iodide and Benzaldehyde

The established pyramidalization at the silene silicon atoms of **1a**, **2**, and **3** in the solid state[3] and the relatively low rotational barriers of the Si=C bonds in **1a** and **1d** point to a pronounced ylid-like character of the compounds [Equation (1)]. Consequently, compared with uncomplexed silenes, enhanced nucleophilic properties of the silene carbon atoms of the intramolecularly donor-stabilized silenes would be expected. This was confirmed by studies of the behavior of **1a**, **1b**, and **1d** towards methyl iodide. The reactions of the newly synthesized silenes with water and benzaldehyde were also investigated as a further method of characterization.



1a-d, 2, 3 (1)

The addition of water or alcohols across the Si=C double bonds with formation of silanols or alkoxysilanes, respectively, is typical of silenes and is frequently used for their chemical characterization.[1] Compounds **1a**−**c**, after treatment with water or methanol, also gave the expected products. **1a** proved to be extraordinarily moisture sensitive. Wet solvents immediately decolorize the yellow solutions of the silene to give a mixture of the two diastereomeric forms of the disiloxane **8** (Scheme 2). Compounds **1b** and **1c** are less reactive, but with excess water **1b**,**c** as well as **1a** are converted into the silanols **9b**, **9c**, and **9a**, respectively. The conversion of **1d** into the silanol **9d** has been previously described.[3b] The formation of **8** can be understood as the result of the addition of silanol **9a** to the Si=C unit of **1a**. As expected, thermolysis of **9a** (heating to 120 °C) also formed the disiloxane **8**. As mentioned above, methoxysilane **10** was prepared by addition of methanol to the impure silene for the characterization of **1c**.



Scheme 2. The reaction of the intramolecularly donor-stabilized silenes **1a**−**c** with water.

The reaction of the stable amine-coordinated silenes with methyl iodide was expected to lead, after methylation of the nucleophilic $C(SiMe_3)_2$ group with H_3CI, to the intramolecularly donor-stabilized silylium iodides $[(Me_2NC_{10}H_6)R^1Si-CMe(SiMe_3)_2]^+ I^-$ or, alternatively, to the respective iodosilanes $(Me_2NC_{10}H_6)R^1SiI-CMe(SiMe_3)_2$. Hydrolysis of both products should then give the silanols $(Me_2NC_{10}H_6)R^1Si(OH)-CMe(SiMe_3)_2$. In fact, studies of the reaction of **1a**, **1b**, and **1d** with methyl iodide revealed an unforeseen rearrangement of the silenes finally producing the azasilaacenaphthenes **11a**, **11b**, and **11d**, respectively (Scheme 3). Formally, one methyl substituent migrates from the nitrogen atom to the silene carbon atom with simultaneous formation of a cyclic aminosilane. The rearrangement can be interpreted as an expected nucleophilic methylation of the silene carbon atoms by methyl iodide, but the resultant silylium salts are unstable, the iodide anion attacks one *N*-methyl group regenerating methyl iodide and forming an aminosilane function. The strong N→Si donor-acceptor interaction in **1a**, **1b**, and **1d** as well as in the intermediate silylium ions makes the nitrogen atom a good leaving group and the *N*-methyl substituent easily susceptible to a nucleophilic attack by the iodide anion. For

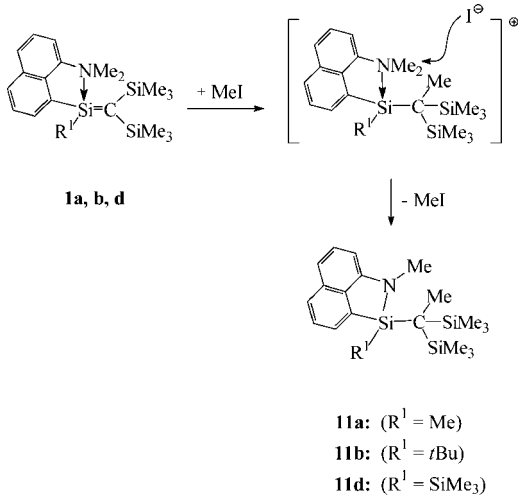
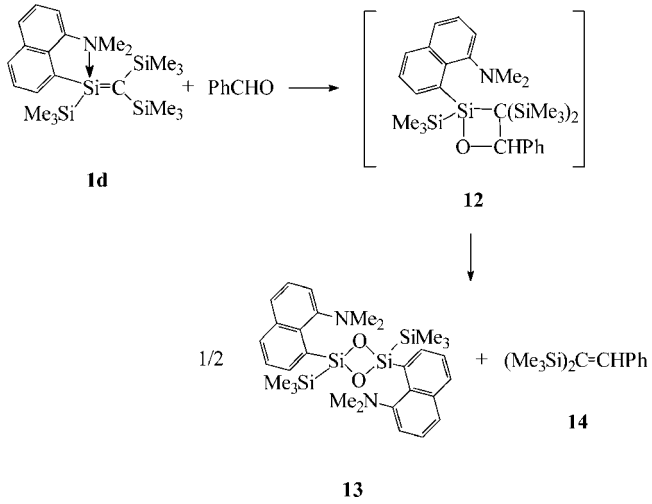


Scheme 3. The methyl iodide induced isomerization of the intramolecularly donor-stabilized silenes **1a**, **1b**, and **1d** into the cyclic aminosilanes **11a**, **11b**, and **11d**.



Scheme 4. The reaction of silene **1d** with benzaldehyde

a complete conversion of **1a**, **1b**, and **1d** into **11a**, **11b**, and **11d**, respectively, only catalytic quantities of methyl iodide were necessary. Indeed, the results of the experiments are independent of the molar ratio of silene to methyl iodide. In order to attempt to ethylate or allylate the silene carbon atom, **1d** was treated with ethyl iodide or allyl iodide, respectively. Surprisingly, however, even with excesses of these reagents only **11d**, the methylated derivative, could be isolated in high yield. The ethyl or allyl analogues of **11d** could not be detected. This indicates that the nucleophilic reaction of the silene with the liberated methyl iodide proceeds considerably faster than with ethyl iodide or allyl iodide.

The structures of **11a**, **11b**, and **11d** were elucidated on the basis of NMR and MS spectroscopic studies (see Exp. Sect.). The compounds proved to be stable towards water and solutions of **11a**, **11b**, and **11d** in THF/water remained unchanged.

Silenes normally react with carbonyl compounds to give an olefin and silanone oligomers.[1] In some cases 2-oxasiletanes and [2 +2] cycloadducts were isolated and, in particular, when aromatic ketones were used, [4 +2] cycloadducts and a variety of their isomerization products were also isolated.[1] Uncomplexed, kinetically stabilized 2,2-bis(trimethylsilyl)silenes, recently synthesized by the reaction of **4c** or **4d**, respectively, when treated with 2,4,6-triisopropylphenyllithium (1:2) afforded, after subsequent treatment with benzaldehyde, stable substituted 2-oxasiletanes.[4] Treatment of intramolecularly amine-coordinated silenes of the type described in this paper with carbonyl compounds are of particular interest, since this could be a promising route to intramolecularly donor-stabilized silanones.

Unfortunately, the reactivity of the intramolecularly donor-stabilized silenes towards carbonyl compounds proved to be rather low. In THF solution **1d** and **2**, which were chosen for these studies, did not react with benzaldehyde. The reaction of **1d** with benzaldehyde in heptane at room temperature required three days to proceed to completion; at 80 °C 5−6 h were needed. In both cases a colorless solid was obtained, which was identified as a mixture of the two isomeric forms of the cyclodisiloxane **13** (Scheme 4). Furthermore, 2,2-bis(trimethylsilyl)styrene (**14**) was isolated in an almost quantitative yield.

The suggested reaction path is outlined in Scheme 4 and is consistent with the standard course of the reaction of silenes with simple aromatic aldehydes.[1] The silene carbon atom attacks the carbonyl carbon atom and subsequent Si−O interaction leads to the formation of the oxasiletane **12**. The long reaction times are due to the strong nitrogen−silicon interaction in **1d** reducing the electrophilic properties of the silene silicon atom. Clearly, **12** is unstable and decomposes spontaneously producing the olefin **14** and a mixture of the two diastereomers of the cyclodisiloxane **13**, which may be considered as a dimer of an originally formed transient silanone. The two isomers of **13** could not be separated, but ^{1}H and ^{13}C NMR spectroscopic data as well as MS data of the mixture unambiguously confirmed the proposed structures. A comparable cyclodisiloxane was recently obtained by Belzner et al. as the result of an oxygen transfer from isocyanates to bis[2-(dimethylaminomethyl)-phenyl]silylene and was presumed to be the cyclodimer of an initially generated silanone.[9] The analytical data obtained for **14** proved to be identical to those reported for 2,2-bis(trimethylsilyl)styrene in the literature.[10] The reaction of **2** with benzaldehyde under comparable conditions similarly led to **14** but the respective disiloxane could not be identified.

Experimental Section

General: All reactions involving organometallic reagents were carried out under purified argon. NMR: Bruker AC 250 or Bruker ARX 300 instruments were used, temperature 30 °C, tetramethylsilane as internal standard. IR: Nicolet 205 FT-IR instrument. MS: Intectra AMD 402 spectrometer (EI with 70 eV or chemical ionization with isobutane). (Dichloromethyl)methylbis(trimethylsilyl)silane (**4a**),[4] *tert*-butyl(dichloromethyl)bis(trimethylsi-

lyl)silane (**4b**),[11] and (dichloromethyl)phenylbis(trimethylsilyl)silane (**4c**)[4] as well as 1-[8-(dimethylamino)-1-naphthyl)-1,2,2-tris(trimethylsilyl)silene (**1d**),[3a] and 1-(2-dimethylaminophenyl)-1,2,2-tris(trimethylsilyl)silene (**2**)[3b] were prepared as described previously. 8-(dimethylaminomethyl)-1-naphthyllithium was prepared following the procedure given by Corriu et al.,[12] but was isolated as a brown amorphous powder. All yields given refer to amounts obtained after chromatographic separation and purification or recrystallization. The results of the elemental analyses of the compounds prepared were unsatisfactory in some cases (SiC formation). Therefore, high resolution mass spectra were recorded.

1-[8-(Dimethylamino)-1-naphthyl]-1-methyl-2,2-bis(trimethylsilyl)-silene (1a): At −78 °C, **4a** (1.50 g, 5.4 mmol) was added gradually to a suspension of 8-(dimethylamino)-1-naphthyllithium−diethyl ether (3.00 g, 11.7 mmol) in diethyl ether (30 mL). After warming to room temperature and stirring overnight, the solvent was removed in vacuo. Pentane was added and LiCl separated by filtration. The orange-yellow filtrate was concentrated and 1-(dimethylamino)naphthalene was removed by distillation in vacuo (80 °C/$5\cdot10^{-4}$ mbar). The residue was purified by kugelrohr distillation (150 °C/$5\cdot10^{-4}$ mbar). Care has to be taken not to exceed a temperature of 155 °C, otherwise decomposition reactions take place. Silene **1a** was obtained as a glassy oil. Crystallization from pentane gave yellow crystals. Yield 1.83 g (52%); m.p. 140−142 °C. ^{1}H NMR ([D$_6$]benzene): δ = 0.23 and 0.57 [2 broad s, 2 × 9 H, Si(CH$_3$)$_3$], 0.34 (s, 3 H, SiCH$_3$), 2.27 and 2.52 (2s, 2 × 3 H, NCH$_3$), 6.63−7.82 (m, 6 H, aryl-H) ppm. ^{13}C NMR ([D$_6$]benzene): δ = 5.0 (C=Si*C*H$_3$), 7.6 and 8.0 (Si=CSi*C*H$_3$, broad), 14.5 (Si=C), 45.6 and 52.8 (NCH$_3$), 115.5, 125.8, 127.6, 127.7, 128.4 and 132.5 (arom. CH), 132.3, 132.9, 138.1 and 147.4 (quat. arom. C) ppm. ^{29}Si NMR ([D$_6$]benzene): δ = −16.1 and −7.0 (SiMe$_3$), 36.0 (Si=C) ppm. UV/Vis (*n*-heptane): λ_{max} (ε) = 304 nm (14800). MS (70 eV): *m*/*z* (%) = 372 (100) [MH]$^+$, 357 (14) [MH − CH$_3$]$^+$. C$_{20}$H$_{33}$NSi$_3$ (371.8): calcd. C 64.62, H 8.95, N 3.77; found C 64.18, H 8.92, N 3.74.

1-*tert*-Butyl-1-[8-(dimethylamino)-1-naphthyl]-2,2-bis(trimethylsilyl)silene (1b): As described for **1a**. Compound **4b** (1.63 g, 5.17 mmol) and 8-(dimethylamino)-1-naphthyllithium−diethyl ether (2.60 g, 10.33 mmol) afforded, after separation of 1-(dimethylamino)naphthalene, 0.85 g (41%) of oily **1b**, which gradually solidified. ^{1}H NMR ([D$_6$]benzene): δ = 0.34 and 0.68 (2s, 2 × 9 H, SiCH$_3$), 0.84 (s, 9 H, CCH$_3$), 2.48 and 2.52 (2s, 2 × 3 H, NCH$_3$), 6.50−7.94 (m, 6 H, aryl-H) ppm. ^{13}C NMR ([D$_6$]benzene): δ = 9.24 and 9.19 ppm (SiCH$_3$), 24.6 (*C*CH$_3$), 28.7 (Si=C), 29.4 (C*C*H$_3$), 43.8 and 56.2 (NCH$_3$), 109.2, 113.9, 125.3, 127.5, 127.8 and 132.5 (arom. CH), 133.7, 134.8, 136.3 and 148.4 (quat. arom. C) ppm. ^{29}Si NMR ([D$_6$]benzene): δ = −10.2 and −7.8 (SiMe$_3$), 43.6 (Si=C) ppm. UV/Vis (*n*-heptane): λ_{max} (ε) = 308 nm (40660). MS (70 eV): *m*/*z* (%) = 413 (8) [M]$^+$, 398 (26) [M − CH$_3$]$^+$, 356 (100) [M − C(CH$_3$)$_3$]. HRMS calcd. for C$_{23}$H$_{39}$NSi$_3$ 413.23904; found 413.23850.

1,3-Bis[8-(dimethylamino)-1-naphthyl]-1,3-dimethyl-1,3-bis[bis(trimethylsilyl)methyl]disiloxane (8): Wet diethyl ether was added to a yellow ethereal solution of **1a** (2.0 g, 4.66 mmol) until the color had completely disappeared. After evaporation, the residue was recrystallized from acetone to give a mixture of two diastereomeric forms of **8** (ratio of 40:60). Yield 1.66 g (81%), m.p. 214−217 °C. The separation of the two diastereomers failed, but the NMR spectra of the mixture allowed the assignment of the signals of both forms. **Diastereomer 1:** ^{1}H NMR ([D$_6$]benzene): δ = −0.31, 0.48 [2s, 2 × 9 H, Si(CH$_3$)$_3$], 0.38 (s, 1 H, CH), 1.17 (s, 3 H, OSiCH$_3$), 2.15 and 2.60 (2s, 2 × 3 H, NCH$_3$), 7.05−8.75 (m,, 5 H aryl-H) ppm. ^{13}C NMR ([D$_6$]benzene): δ = 3.6 and 5.1 (SiMe$_3$), 4.3 (Si$_3$C), 9.1 (OSiCH$_3$),43.3 and 51.4 (NCH$_3$), 117.0, 125.3, 125.57, 125.63, 130.5 and 138.1 (arom. CH), 135.1, 136.3, 137.7 and 153.5 (quat. arom. C) ppm. ^{29}Si NMR ([D$_6$]benzene): δ = −5.5 (SiOSi), −1.0 and 0.8 (SiMe$_3$) ppm. **Diastereomer 2:** ^{1}H NMR ([D$_6$]benzene): δ = −0.07, 0.38 [2s, 2 × 9 H, Si(CH$_3$)$_3$], 0.44 (s, 1 H, CH), 0.75 (s, 3 H, OSiCH3], 2.32 and 2.46 (2s, 2 × 3 H, NCH$_3$), 7.05−8.75 (m, 5 H), aryl-Hppm. ^{13}C NMR ([D$_6$]benzene): δ = 3.9 and 5.4 (SiMe$_3$), 4.3 (Si$_3$C), 9.2 (OSiCH$_3$), 45.8 and 48.8 (NCH$_3$), 116.6, 124.9, 125.3, 126.0, 130.3 and 138.5 (arom. CH), 134.9, 136.1, 138.1 and 153.3 (quat. arom. C) ppm. ^{29}Si NMR ([D$_6$]benzene): δ = −5.3 (SiOSi), −0.6 and 0.8 (SiMe$_3$). **For the Mixture:** MS (70 eV): *m*/*z* (%) = 760 (38) [M]$^+$, 745 (5) [M − CH$_3$], 590 (16) [M − C$_{10}$H$_6$]$^+$, 372 (100) [(Me$_2$NC$_{10}$H$_6$)MeSiCH(SiMe$_3$)$_2$]$^+$. HRMS calcd. for C$_{40}$H$_{68}$N$_2$OSi$_6$ 760.39471; found 760.39430.

[8-(Dimethylamino)-1-naphthyl]methyl[bis(trimethylsilyl)methyl]-silanol (9a): An ethereal solution of **1a** (2.0 g, 4.66 mmol) was added to a mixture of THF/water (1:1). After a few minutes, the organic layer was separated and the solvents evaporated. The residue was purified by kugelrohr distillation (130 °C/$2\cdot10^{-2}$ mbar). Colorless oil, yield 1.04 g (57%). ^{1}H NMR ([D$_6$]benzene): δ = −0.14 (s, 1 H, CH), 0.00 and 0.27 [2s, 2 × 9 H, Si(CH$_3$)$_3$], 0.74 (s, 3 H, OSiCH$_3$), 2.28 and 2.39 (2s, 2 × 3 H, NCH$_3$), 6.32 (br.s, 1 H, OH), 6.92−7.91 (m, aryl-H) ppm. ^{13}C NMR ([D$_6$]benzene): δ = 3.2, 3.5, 6.1 and 7.74 (SiCH and SiCH$_3$), 44.6 and 48.3 (NCH$_3$), 116.9, 125.0, 125.4, 127.0, 130.4 and 136.0 (arom. CH), 134.1, 136.7, 139.8 and 151.5 (quat. arom. C) ppm. ^{29}Si NMR ([D$_6$]benzene): δ = −0.3 and 0.2 (SiMe$_3$), 3.0 (SiOH) ppm. IR (cap.): $\tilde{\nu}$ = 3439 cm^{-1} (br., OH$_{ass.}$). MS (70 eV): *m*/*z* (%) = 389 (100) [M]$^+$, 374 (23) [M − CH$_3$]$^+$, 230 (68) [M − CH(SiMe$_3$)$_2$]$^+$. C$_{22}$H$_{41}$NOSi$_4$ (389.8): calcd. C 61.63, H 9.05, N 3.59; found C 61.69, H 9.04, N 3.57.

***tert*-Butyl[8-(dimethylamino)-1-naphthyl][bis(trimethylsilyl)methyl]-silanol (9b):** As described for **1a**. Compound **4b** (1.1 g, 3.49 mmol) was treated with 8-(dimethylamino)-1-naphthyllithium−diethyl ether (1.75 g, 6.97 mmol), but silene **1b** was not isolated. Instead, after separation of LiCl, water was added to the pentane solution. Separation of the organic layer, evaporation of the solvent and kugelrohr distillation of the residue (140 °C/$2\cdot10^{-2}$ mbar) gave 0.80 g (53.1%) of **9b** in the form of a viscous oil. ^{1}H NMR ([D$_6$]benzene): δ = 0.06 and 0.45 (2s, 2 × 9 H, SiCH$_3$), 0.08 (s, 1 H, CH), 1.13 (s, 9 H, *t*Bu), 2.37 and 2.43 (2s, 2 × 3 H, NCH$_3$), 7.0−7.96 (m, 6 H, aryl-H), 10.0 (s, 1 H, SiOH) ppm. ^{13}C NMR ([D$_6$]benzene): δ = 4.7 and 5.2 (SiCH$_3$), 4.3 (CH), 22.1 (*C*CH$_3$), 28.7 (C*C*H$_3$), 46.9 and 47.4 (NCH$_3$), 119.4, 124.0, 125.3, 128.3, 128.8 and 131.0 (arom. CH), 136.6, 138.4, 151.6 and 154.2 (quat. arom. C) ppm. ^{29}Si NMR ([D$_6$]benzene): δ = −0.4 and 0.0 (SiMe$_3$), 5.4 (SiOH) ppm. MS (70 eV): *m*/*z* (%) = 431 (5) [M]$^+$, 416 (10) [M − CH$_3$]$^+$, 374 (100) [M − CMe$_3$]$^+$, 358 (4) [M − SiMe$_3$]$^+$. HRMS calcd. for C$_{23}$H$_{41}$NOSi$_3$ 431.24958; found 431.24913.

[8-(Dimethylamino)-1-naphthyl]phenyl[bis(trimethylsilyl)methyl]-silanol (9c): As described for **1a**. Compound **4c** (1.23 g, 3.6 mmol) was gradually added to a suspension of 8-(dimethylamino)-1-naphthyllithium−diethyl ether (2.00 g) in diethyl ether (60 mL) at −78 °C. After warming to room temperature and stirring overnight water (5 mL) was added. The organic layer was separated, evaporated and the residue was recrystallized from acetonitrile. Colorless crystals, m.p. 125−126 °C, yield 1.12 g (69%). ^{1}H NMR ([D$_6$]benzene): δ = 0.00 and 0.17 [2s, 2 × 9 H, Si(CH$_3$)$_3$], 0.11 (s, 1 H, CH), 1.74 and 2.35 (2s, 2 × 3 H, NCH$_3$), 6.83− 8.11 (11 H, aryl-H) ppm. ^{13}C NMR ([D$_6$]benzene): δ = 3.1 and 3.3 (SiCH$_3$), 7.5 (CH), 43.9 and 49.2 (NCH$_3$), 117.4, 124.6, 125.5, 127.3, 127.7, 129.0, 130.9, 134.9 and 137.0 (arom. CH), 134.2, 136.4, 137.3, 142.4 and

151.2 (quat. arom. C) ppm. ^{29}Si NMR ([D$_6$]benzene): δ = −5.2 (SiOH), 0.2 and 0.3 ($SiMe_3$) ppm. MS (70 eV): *m/z* (%) = 451 (54) $[M]^+$, 292 (100) $[M - CH(SiMe_3)_2]^+$. $C_{25}H_{37}NOSi_3$ (451.2): calcd. C 66.46, H 8.25, N 3.10; found C 65.63, H 8.25, N 3.10. HRMS calcd. for $C_{25}H_{37}NOSi_3$ 451.21829; found 451.21910.

[8-(Dimethylamino)-1-naphthyl](methoxy)phenyl[bis(trimethylsilyl)-methyl]silane (10): At −78 °C **4c** (1.3 g, 3.8 mmol) was added to a suspension of 8-(dimethylamino)-1-naphthyllithium−diethyl ether (2.1 g, 1.05 mmol) in diethyl ether (60 mL). After warming to room temperature and stirring overnight the solvent was replaced by pentane and lithium chloride was filtered off. Addition of methanol (2 mL) to this solution and evaporation gave a viscous oil which was purified by kugelrohr distillation (170−180 °C/4 × 10^{-2} mbar). Yield 1.4 g (83%). ^{1}H NMR ([D$_6$]benzene): δ = 0.04 and 0.08 ppm (2s, 2 × 9 H, $SiCH_3$), 0.70 (s, 1 H, CH), 1.99 and 2.30 (2s, 2 × 3 H, NCH_3), 3.51 (s, 3 H, OCH_3), 7.03−8.19 (m, 12 H, aryl-H) ppm. ^{13}C NMR ([D$_6$]benzene): δ = 3.1 (Si_3C), 3.9 and 4.2 ($SiCH_3$), 46.8 and 47.8 (NCH_3), 51.9 (OCH_3), 117.8, 125.1, 125.8, 126.2, 127.3, 128.6, 131.0, 135.4 and 138.5 (arom. CH), 132.9, 136.0, 136.1, 139.7 and 153.6 (quat. arom. C) ppm. ^{29}Si NMR ([D$_6$]benzene): δ = −5.6 (SiOMe), −1.2 and 0.4 ($SiMe_3$) ppm. IR (cap.): $\tilde{\nu}$ = 1101 cm^{-1} ($SiOCH_3$). MS (70 eV): *m/z* (%) = 465 (53) $[M]^+$, 450 (13) $[M - CH_3]^+$,388 (18) $[M - Ph]^+$, 306 (100) $[M - CH(SiMe_3)_2]^+$. HRMS calcd. for $C_{26}H_{39}NOSi_3$ 465.23395; found 465.22990.

1,2-Dimethyl-2-[1,1-bis(trimethylsilyl)ethyl]-1-aza-2-silaacenaphthene (11a): To a solution of **4a** (1.75 g, 4.70 mmol) in dichloromethane (20 mL) was added methyl iodide (1 mL, 1.53 g, 10.8 mmol) and the solution was stirred for 48 h at room temperature. Evaporation of the solution and purification of the residue by column chromatography (silica gel, heptane) gave a yellow oil, yield 0.7 g (40%). ^{1}H NMR ([D$_6$]benzene): δ = −0.13 ppm and 0.13 [2s, 2 × 9 H, $Si(CH_3)_3$], 0.35 (s, 3 H, $SiCH_3$), 1.22 (s, 3 H), $CCH_3$2.78 (s, 3 H, NCH_3), 6.34−7.74 (m, 6 H, arom. CH) ppm. ^{13}C NMR ([D$_6$]benzene): δ = −1.0, 0.5, 1.3 and 3.4 (SiC), 13.7 (CCH_3), 31.6 (NCH_3), 101.8, 115.2, 126.5, 128.5, 128.6 and 129.9 (arom. CH), 132.5, 134.4 and 152.3 (one signal hidden, quat. arom. C) ppm. ^{29}Si NMR ([D$_6$]benzene): δ = 2.6 and 3.9 ($CSiMe_3$), 10.4 (ring-Si) ppm. MS (70 eV): *m/z* (%) = 371 (100) $[M]^+$, 356 (28) $[M - CH_3]^+$, 298 (14) $[M - SiMe_3]^+$. HRMS calcd. for $C_{20}H_{33}NSi_3$ 371.19203; found 371.18654.

2-*tert*-Butyl-1-methy-2-[1,1-bis(trimethylsilyl)ethyl]-1-aza-2-silaacenaphthene (11b): 11b can be obtained from **1b** and methyl iodide as described for **11a**. It can be prepared more easily, however, by treatment of the crude product mixture obtained after treatment of **4b** with 8-(dimethylamino)-1-naphthyllithium. A typical procedure follows: **4b** (0.93 g, 2.94 mmol) was added at −78 °C to a suspension of 8-(dimethylamino)-1-naphthyllithium−diethyl ether (1.48 g, 5.89 mmol) in diethyl ether (30 mL). The mixture was warmed to room temperature and was stirred for 12 h. After replacement of the solvent by *n*-pentane, LiCl was separated, the yellow solution evaporated and 1-(dimethylamino)naphthalene was removed by distillation at 100 °C/10^{-2} mbar. The residue was dissolved in dichloromethane (20 mL), methyl iodide (2.0 g, 14 mmol) was added and the solution was stirred for 24 h. Evaporation and recrystallization from acetonitrile gave 0.75 g (62%) pale greenish crystals of **11b**, m.p. 129−132 °C. ^{1}H NMR ([D$_6$]benzene): δ = −0.02 ppm and 0.08 (2s, 2 × 9 H, $SiCH_3$), 0.96 [s, 9 H, $C(CH_3)_3$], 1.44 (s, 3 H, CCH_3), 2.90 (s, 3 H, NCH_3), 6.33−7.71 (6 H, aryl-H) ppm. ^{13}C NMR ([D$_6$]benzene): δ = 1.8 and 2.1 ($SiCH_3$), 4.3 (*C*Me), 13.9 (CCH_3), 25.1 (CMe_4), 28.2 (*t*Bu CH_3), 32.4 (NCH_3), 101.3, 115.1, 126.5, 128.3, 128.5 and 129.8 (arom. CH), 132.5, 134.3, 135.0 and 154.3 (quat. arom. C) ppm. ^{29}Si NMR ([D$_6$]benzene): δ = 3.4 and 4.1 ($SiMe_3$), 10.5 (ring-Si) ppm. MS (70 eV): *m/z* (%) = 413 (15) $[M]^+$, 398 (14) $[M - CH_3]^+$, 356 (100) $[M - CMe_3]^+$. HRMS calcd. for $C_{23}H_{39}NSi_3$ 413.23904; found 413.23692.

1-Methyl-2-trimethylsilyl-2-[1,1-bis(trimethylsilyl)ethyl]-1-aza-2-silaacenaphthene (11d): As described for **11a**. Compound **1d**[3a,3b] (2.0 g, 4.66 mmol) and methyl iodide (1 mL, 1.53 g, 10.8 mmol) were stirred in dichloromethane (20 mL) for 48 h at room temperature. After evaporation a solid was obtained, which was recrystallized from acetonitrile. Pale yellow crystals, yield 1.28 g (64%), m.p. 165 °C. ^{1}H NMR ([D$_6$]benzene): δ = −0.07, 0.02 and 0.12 (3s, 3 × 9 H, $SiCH_3$), 1.36 (s, 3 H, CCH_3), 2.84 (s, 3 H, NCH_3), 6.30−7.70 (m, 6 H, aryl-H) ppm. ^{13}C NMR ([D$_6$]benzene): δ = −0.2, 0.7 and 1.2 ($SiCH_3$), 4.8 (Si_3C), 14.2 (CCH_3), 33.0 (NCH_3), 101.4, 114.7, 126.7 128.6 and 129.6 (arom. CH, one signal hidden), 133.0, 135.6, 135.7 and 153.5 (quat. arom. C) ppm. ^{29}Si NMR ([D$_6$]benzene): δ = −17.2 ($SiSiMe_3$), 3.0, 4.1 and 4.4 ($CSiMe_3$ and ring-Si) ppm. MS (70 eV): *m/z* (%) = 429 (15) $[M]^+$, 414 (6) $[M - CH_3]^+$, 356 (100) $[M - SiMe_3]^+$. $C_{22}H_{39}NSi_4$ (429.9): calcd. C 61.47, H 9.14, N 3.26; found C 61.02, H 9.16, N 3.27.

The Reaction of 1d with Benzaldehyde: Benzaldehyde (1.18 g, 11.6 mmol) was added to a solution of **1d** (5.00 g, 11.6 mmol) in *n*-heptane (120 mL) and the mixture was stirred for 6 h at 80 °C. After cooling to room temperature 1,3-bis[8-(dimethylamino)-1-naphthyl]-1,3-bis(trimethylsilyl)cyclodisiloxan (**13**) in the form of the mixture of the two diastereomers crystallized from the solution and was separated by filtration (2.04 g, 61%). The filtrate was evaporated and the residue purified by column chromatography (silica gel, heptane) to give 2.77 g (96%) of 2,2-bis(trimethylsilyl)vinylbenzene (**14**).[10]

Attempts to separate the two diastereomers of **14** failed, but ^{1}H and ^{13}C NMR studies of the mixture (80:20) allowed the assignment of the signals to both forms. **Diastereomer 1:** ^{1}H NMR ([D$_6$]benzene): δ = −0.07 ppm [s, 9 H, $Si(CH_3)_3$], 2.75 and 2.92 (2s, 2 × 3 H, NCH_3) ppm. ^{13}C NMR ([D$_6$]benzene): δ = −0.3 ($SiMe_3$), 43.3 and 54.0 (NCH_3), 114.2, 125.5, 125.6, 125.8, 128.2, 128.7, 134.0, 135.9, 137.6 and 141.4 (arom. C) ppm. **Diastereomer 2:** ^{1}H NMR ([D$_6$]benzene): δ = 0.01 [s, 9 H, $Si(CH_3)_3$], 2.69 and 2.76 (2s, 2 × 3 H, NCH_3) ppm. ^{13}C NMR ([D$_6$]benzene): δ = 0.0 ($SiMe_3$), 43.4 and 53.2 (NCH_3), 114.3, 125.6, 125.8, 129.3, 134.8, 135.1, 136.5, 137.1 and 151.7 (one signal hidden, arom. C) ppm. **For the Mixture:** ^{1}H NMR ([D$_6$]benzene): δ = 6.91−8.86 (m, 6 H, arom. CH) ppm. ^{29}Si NMR ([D$_6$]benzene): δ = −35.9 and −35.4 (OSiO), −22.1 and −18.7 ($SiMe_3$). MS (CI, isobutane): *m/z* (%) = 575 (50) $[M + H]^+$, 559 (15) $[M - CH_3]^+$, 501 (100) $[M - SiMe_3]^+$. $C_{30}H_{42}N_2O_2Si_4$ (575.0): calcd. C 62.66, H 7.36, N 4.87; found C 62.31, H 7.21, N 4.53.

Acknowledgments

A New Family of Low-Spin Co^{III} Bis(amidate) Complexes with Two *cis* or *trans* Cyanides

Olaf Rotthaus,[a] Sophie LeRoy,[a] Alain Tomas,[b] Kathleen M. Barkigia,[c] and Isabelle Artaud*[a]

Keywords: Cobalt / Cyanides / N ligands

Four low-spin dicyanodicarboxamidocobalt(III) complexes have been prepared from *N*,*N*′-bis(8-quinolyl)malonamide derivatives, the malonyl fragment of which was either unsubstituted $(Et_4N)[Co(BQM)(CN)_2]$ (**3a**), monosubstituted by a benzyl group $(Et_4N)[Co(mono\text{-}BenzBQM)(CN)_2]$ (**3b**), or disubstituted by two benzyl or two phenylethyl groups, $(Et_4N)[Co(di\text{-}BenzBQM)(CN)_2]$ (**3c**) and $(Et_4N)[Co(di\text{-}PhEtBQM)(CN)_2]$ (**3d**), respectively. The X-ray crystal structures of **3a** and **3c** reveal that the tetradentate ligand adopts a helical or a planar configuration around the cobalt centre of **3a** and **3c**, respectively. Complexes **3a**–**3d** were characterised in solution by ^1H NMR spectroscopy by 1D and 2D COSY H-H techniques. The solid-state structures of **3a** and **3c** are retained in solution, and complexes **3b** and **3d** adopt structures similar to **3a** and **3c**, respectively, showing that the level of the malonic substitution determines the configuration of the tetradentate ligand around the cobalt centre and forces the cyanide ligands to adopt either *cis* or *trans* orientations.

Introduction

Prompted by the work of Collins' group showing the capacity of deprotonated amides to be strong metal donors and to stabilize high oxidation states,[1] this area of chemistry has received increased attention with the recent findings that amides from a peptide backbone could also be nitrogen donors to the metal centre of metalloproteins, such as the nitrogenase P-cluster[2] or the nitrile hydratase family.[3] Our group[4] and others[5,6] have synthesised iron and cobalt mimics of the nitrile hydratase active site. Our choice of N_2S_2 tetradentate ligands has illustrated the new properties of this series of complexes.[4] We are now aiming to develop nitrogen-containing ligands to prepare new mononuclear complexes that could be used as catalysts for oxidation reactions.

It is well-known that introducing one or more carboxamido nitrogens in the metal environment increases the stability of Fe^{III} or Co^{III} complexes[1,7] and provides catalysts with significant catalytic activity for the oxidation of olefins or hydrocarbons with *t*BuOOH or H_2O_2.[7,8] Tetradentate ligands containing two amides usually derive from picolinic acid and afford six-coordinate complexes with four nitrogens that occupy the equatorial plane and two exogenous ligands in the axial positions.[9] We report here the synthesis and characterisation of a new family of dicyano Co^{III} complexes of *N*,*N*′-bis(8-quinolyl)malonamide derivatives. We show that different substitutions of the malonic fragment control the coordination geometry of the four nitrogen donors to the metal centre. The tetradentate chelate adopts a planar or a helical configuration around the metal cation, providing two types of complexes with two *cis* or *trans* cyanides.

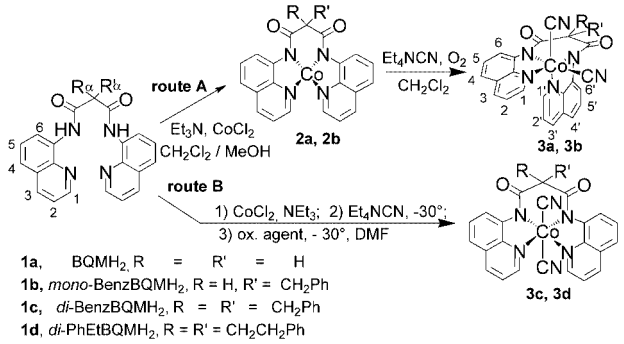
Results and Discussion

Synthesis of Co^{III} Complexes

We have prepared a series of *N*,*N*′-bis(8-quinolyl)malonamide (BQM) derivatives, shown in Scheme 1, containing a malonyl fragment that is either unsubstituted (**1a**), monosubstituted by a benzyl group (**1b**), or disubstituted by two benzyl (**1c**), or two 2-phenylethyl (**1d**) groups. These ligands were easily synthesised by condensing 8-aminoquinoline with malonyl dichloride derivatives, as previously reported for the disubstituted malonamide compounds.[10] Cobalt(II) was reacted with the ligands as $CoCl_2$ in the presence of triethylamine as a soft base. Depending on the ligand sub-

stitution, two different procedures were applied, as outlined in Scheme 1. For the unsubstituted or monosubstituted compounds **1a** and **1b**, the Co^{II} insertion was carried out in a mixture of CH_2Cl_2 and MeOH and led to the precipitation of the Co^{II} complex **2a** and **2b**, respectively. Complex **2a** precipitated readily from the solution, and **2b** precipitated after concentration in vacuo. Once isolated, the Co^{II} complexes are sparingly soluble in any solvent and were oxidized suspended in aerated CH_2Cl_2 after addition of two equivalents of tetraethylammonium cyanide to stabilize the Co^{III} complexes (Scheme 1, route A). Orange precipitates of the Co^{III} complexes **3a** and **3b** were obtained after partial removal of the solvent and addition of diethyl ether. The Co^{II} complexes of the disubstituted compounds **1c** and **1d** are highly soluble in CH_2Cl_2/MeOH and, consequently, more difficult to isolate. The one-pot synthesis of the dicyano Co^{III} complexes in DMF was therefore preferred. After preparing the Co^{II} complexes in solution, the cyanide ligands were added as Et_4NCN at −30 °C and the oxidation was performed with the one-electron oxidizing agent 4-fluorobenzenediazonium hexafluorophosphate[10] (Scheme 1, route B). After removing the solvent, the crude products were redissolved in CH_2Cl_2 and complexes **3c** and **3d** were precipitated by addition of diethyl ether and isolated as orange powders in good yields.



Scheme 1. Reaction pathways for the synthesis of the Co^{III} dicyano complexes

Characterisation of [Co^{II}(BQM)] (2a)

Co^{II} complexes were formed as intermediates during the synthesis of Co^{III} derivatives and, with the exception of **2a**, are not very stable under aerobic conditions, even as solids. Consequently, we characterised only **2a** to obtain some insight into the cobalt coordination. Its elemental analysis is in agreement with the formulation [Co^{II}(BQM)]. The IR spectrum of the ligand **1a** shows $\nu_{(N-H)}$ and $\nu_{(C=O)}$ vibrations at 3279 and 1646 cm^{-1}, respectively. The absence of the $\nu_{(N-H)}$ band and the shift of the $\nu_{(C=O)}$ band to a lower energy of 1605 cm^{-1} in the metal complex confirm that the amide nitrogens are coordinated to the Co in their deprotonated form. The X-band powder EPR spectrum at 4 K shows a single resonance at $g = 1.99$ characteristic of a low-spin Co^{II} state. This complex is four-coordinate and is probably square planar, as previously proposed for the Co^{II} complex of *N*,*N*′-bis(pyridin-2-ylmethylene)benzene-1,2-diamine, Co(bpb).[11] Co^{III} complexes with carboxamido nitrogen donors are typically six coordinate.[9] Thus, the oxidation was performed in the presence of cyanides to introduce two strong exogenous ligands to complete the cobalt coordination sphere and to stabilize the Co^{III} state.

X-ray Crystal Structure of (Et_4N)[Co(BQM)$(CN)_2$] (3a) and (Et_4N)[Co(di-BenzBQM)$(CN)_2$] (3c)

Crystals suitable for X-ray analysis were grown from CH_2Cl_2/hexane for **3a** and from acetonitrile/diethyl ether for **3c**. Views of the anions of **3a** and **3c** are presented in Figure 1 and 2. Selected bond angles and distances are listed in Table 1. In both structures the cobalt is six-coordinate in an octahedral environment to two deprotonated amide and two pyridyl nitrogens of the ligand and two exogenous cyanides. However, while the four nitrogen donors N1−N4 in **3c** (Figure 2) lie in the equatorial plane, with the two cyanides situated axially *trans* to each other, in **3a** (Figure 1) only three nitrogens (N1, N2 and N3) lie in the equatorial plane, with the fourth (N4) in an apical position and with the two cyanides occupying *cis* sites, one equatorial (C22−N5) and the other axial (C23−N6). Whereas in the *trans* configuration C11 deviates from the mean plane defined by N1N2C10C12N3N4 by 0.3 Å, the distortions are more important in the *cis* configuration. The angle between the planes N1N2N3 and N2C10C12N3 is 22° and the angle between C10C11C12 and N2C10C12N3 is 44°. Consequently the CH_2 fragment is in close proximity to the axial cyanide (C23N6).The distance between C11 of the CH_2 and C23 of the CN is 3.02 Å. This explains why a disubstituted derivative cannot adopt a *cis* configuration.

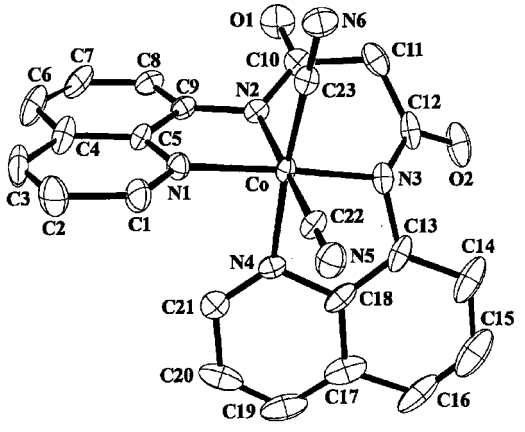


Figure 1. Thermal ellipsoid plot (50% probability level) of the anion of **3a**; H atoms are omitted for clarity

An unexpected aspect of the structure of **3a**, which crystallises with two water molecules per metal complex, is that the water molecules form an extended hydrogen-bonded network that links three chelates through the N5 nitrogens of the cyano group to the oxygens O1 and O2 of two additional ligands, as shown in Figure 3. The distance between the oxygen of a water and the cyano group (N5−O:

Solution Structure of $(Et_4N)[Co(BQM)(CN)_2]$ (3a) and $(Et_4N)[Co(di\text{-}BenzBQM)(CN)_2]$ (3c)

With the strong cyanide ligands, these complexes exist in a low-spin Co^{III} state. Their structures can be readily analysed by ^1H NMR spectroscopy. NMR assignments were based on 1D and 2D COSY H-H experiments. The spectrum of **3c**, shown in Figure 4, indicates a solution structure with a C_2 symmetry, as in the solid state (Figure 2). Both quinolyl rings are equivalent and the pyridyl proton spin system (H^1, H^2, H^3) appears as a set of three well-resolved resonances between δ = 7.7 and 9.0 ppm. The proton labelling is indicated in Scheme 1. The same NMR spectrum was obtained when compound **3c** was prepared according to the procedure following route A (Scheme 1), or when the NMR sample was heated up to 360 K. In contrast, the spectrum of **3a**, shown in Figure 4, exhibits a more complicated pattern indicative of the lack of any symmetry, as in the crystal structure (Figure 1). The quinolyl resonances are split into two spin systems H^1, H^2, H^3, H^4, H^5, H^6 and $H^{1'}$, $H^{2'}$, $H^{3'}$, $H^{4'}$, $H^{5'}$, $H^{6'}$. Correlations were made by a 2D COSY experiment. For the assignments, the protons of the quinolyl ring in the equatorial plane were assumed to appear at chemical shifts very close to those found in the *trans* complex **3c**. The two pyridyl systems are very different. The *ortho* and *meta* pyridyl protons in the axial position are shifted upfield relative to those in the equatorial plane ($H^{1'}$: δ = 6.17 ppm; H^1: δ = 9.07 ppm; $H^{2'}$: δ = 7.28 ppm; H^2: δ = 7.87 ppm). Finally, the two malonyl protons are inequivalent; their signals appeared at two chemical shifts (δ = 2.97 and 5.02 ppm) located apart from the value of the unique CH_2 resonance (δ = 3.87 ppm) found for the free ligand. These results show that the unexpected solid-state structure of **3a** is retained in solution.

Solution Structure of $(Et_4N)[Co(mono\text{-}BenzBQM)(CN)_2]$ (3b) and $(Et_4N)[Co(di\text{-}PhEtBQM)(CN)_2]$ (3d)

Since NMR spectroscopy proved suitable for the analysis of the two structurally related complexes **3a** and **3c**, we also used this technique to determine whether the cyanides in complexes **3b** and **3d** were orientated in a *cis* or a *trans* fashion. The aim was to determine the influence of the malonyl substitution level on the coordination geometry and, for the disubstituted derivatives, the effect of lengthening the chain by one C−C bond. The NMR spectra of **3d** (Figure 4) and **3c** are very similar, supporting a planar configuration of the tetradentate chelate and a *trans* coordination of the cyanides to the cobalt cation. In contrast, the NMR spectrum of the monobenzylated derivative **3b** (Figure 4) displays, as for **3a**, two quinolyl proton spin-systems. The $H^{1'}$ and H^1 resonances are located in the upfield and downfield regions at δ = 6.11 ppm and 9.06 ppm, respectively. The H^α malonyl proton signal appears at δ = 5.55 ppm, a value similar to that of the low-field resonance found for one of the two malonyl protons H^α and $H^{\alpha'}$ in **3a**. The benzylic resonance appears at δ = 3.18 ppm, showing that the benzylic protons in **3b** are slightly shielded relative to those in the *trans* complex **3c**. Thus, the monobenzylated

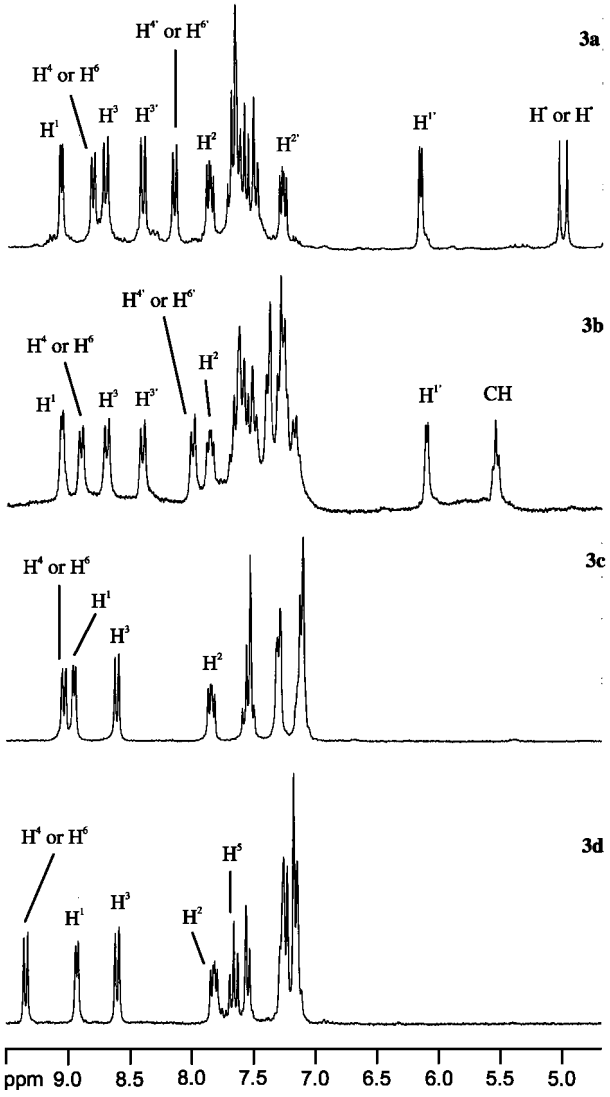

Figure 4. ^{1}H NMR spectra of the *cis*-**3a** and -**3b** and the *trans*-**3c** and -**3d** complexes at 250 MHz in [D_6]DMSO

and the unsubstituted complex, **3b** and **3a**, adopt the same helical arrangement of the N4 ligand and the same *cis* configuration of the cyanides.

It is noteworthy that while the NMR spectra of the two types of complexes are very different, their IR spectra do not reveal significant differences. They show a unique ν_{CN} stretching band at 2120 cm^{-1} suggesting that the two cyanides have the same surroundings. A similar observation has been reported for other *cis*-dicyano complexes such as *cis*-dicyanobis(1,10-phenanthroline)iron(II)[12] or bis(2,2′-bipyridine)-*cis*-dicyanoiron(III) perchlorate.[13]

Conclusion

In conclusion, we have prepared four new six-coordinate low-spin Co^{III} dicyano complexes that contain an *N*,*N*′-bis(8-quinolyl)malonamide ligand. Interestingly, the substitution level of the malonyl fragment determines whether the two cyanides are oriented *cis* or *trans* to the cobalt centre. The crystal structures of two representative complexes of this series have been solved. When unsubstituted or monosubstituted, the stable configuration is twisted with three nitrogens and one cyanide in the equatorial plane, and the fourth nitrogen and the second cyanide in apical positions. When disubstituted by two benzyl or two phenylethyl groups, the steric interaction of the malonyl substituent with the axial cyanide ligand destabilizes the *cis* configuration and forces the ligand to adopt a planar arrangement with two *trans* cyanides. Consequently, without changing the nature of the nitrogen donors, a disubstitution at the periphery of the ligand framework modulates the *cis* or *trans* coordination of the two exogenous ligands. Cyanides were introduced to facilitate the characterisation of the dicyano Co^{III} complexes, and therefore we next intend to introduce more labile exogenous ligands to compare the chemical reactivity of these complexes with the same nitrogen donor set and two *cis* or *trans* labile sites.

Experimental Section

Chemicals: All solvents and chemicals were purchased in analytical grade from SDS, Fluka or Aldrich. Sephadex LH-20 resin was purchased from Amersham Biosciences. Solvents were dried by standard procedures.

Spectroscopic Measurements: UV/Visible spectra were recorded at room temperature on a Safas UV *mc*^{2} spectrophotometer. X-band EPR spectra were recorded on a Bruker ESP300 spectrometer operating at a 9.5 GHz microwave frequency, with a 100 kHz modulation frequency and a 1 G modulation amplitude. ^{1}H NMR spectra were recorded at 300 K on a Bruker ARX-250 spectrometer. Chemical shifts are reported in ppm downfield from TMS. Infrared spectra were obtained with a Perkin−Elmer Spectrum One FT-IR spectrometer equipped either with a sample holder for KBr pellets or with a MIRacle™ single reflection horizontal ATR unit which allowed spectra of solid compounds to be recorded directly (marked as "neat"). Mass spectrometry (ESI^- and ESI^+) was performed on a Thermo Finnigan LCD Advantage spectrometer. Elemental analyses were carried out by the microanalysis service of Paris VI University.

***N*,*N*′-Bis(8-quinolyl)malonamide ($BQMH_2$) (1a):** Malonic acid chloride (972 μL, 9.5 mmol) was added under argon to a CH_2Cl_2 solution (100 mL) of 8-aminoquinoline (3.17 g, 22 mmol) and triethylamine (Et_3N, 3.0 mL, 20 mmoL). Then the mixture was stirred for 12 h at room temperature. After dissolution of all the precipitated condensation product by further addition of CH_2Cl_2 the solution was washed three times with water, then with saturated aqueous $NaHCO_3$ (30 mL each) and dried over $MgSO_4$. Removal of the solvent and recrystallisation of the product from CH_2Cl_2 afforded ligand **1a** as a white solid (1.32 g, 39%). $C_{21}H_{16}N_4O_2$ (356.13): calcd. C 70.78, H 4.49, N 15.73; found C 70.60, H 4.66, N 15.68. UV/Vis (CH_2Cl_2) λ_{max} (ε) = 243 (80000 $M^{-1}\cdot cm^{-1}$), 319 (13000) nm. IR (neat): $\tilde{\nu}$ = 3279 w (ν_{NH}) and 1646 s (ν_{CO}) cm^{-1}. ^{1}H NMR (250 MHz, $CDCl_3$): δ = 10.78 (s, 2 H, NH), 8.89 (dd, ^3J = 4.4, ^4J = 1.6 Hz, 2 H, H^1), 8.83 (dd, ^3J = 3.6, ^3J = 5.6 Hz, 2 H, H^5), 8.16 (dd, ^3J = 8.4, ^4J = 1.6 Hz, 2 H, H^3), 7.54 (d, ^3J = 3.6, 2 H, H^4 or H^6), 7.55 (d, ^3J = 5.6 Hz, 2 H, H^4 or H^6), 7.46 (dd, ^3J = 4.4, ^3J = 8.4 Hz, 2 H, H^2), 3.87 (s, 2 H, CH_2) ppm.

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

2-Benzyl(ethyl malonate): NaH (0.96 g, 40 mmol) and then benzyl bromide (4.7 mL, 40 mmol) were slowly added to a dried THF solution (80 mL) of diethyl malonate (6 mL, 40 mmol). The reaction mixture was refluxed for 24 h. Then, diethyl ether was added (120 mL) and the solution was washed three times with water (3 × 80 mL) and dried over $MgSO_4$. After evaporation of the solvent, the slightly yellow residue was distilled off as a clear oil (bp, 133−135 °C, P 0.6 Torr, 6.3 g, 63%). ^1H NMR (250 MHz, $CDCl_3$): δ = 7.30−7.15 (m, 5 H, H-Ph), 4.14 (q, ^3J = 7.1 Hz, 4 H, CH_2(OEt)), 3.63 (t, ^3J = 7.8 Hz, 1 H, CH), 3.20 (d, ^3J = 7.8 Hz, 2 H, CH_2), 1.19 [t, ^3J = 7.1 Hz, 6 H, CH_3(OEt)] ppm.

2-Benzylmalonic Acid: 2-Benzyl(ethyl malonate) (5.2 g, 21 mmol) was poured onto pulverized KOH (4.7 g, 94 mmol) in an ice/water bath. The mixture rapidly became highly viscous and ethanol (2 mL) and water (1.3 mL) were added to allow stirring. After 6 h of stirring at 90 °C, the suspension was dissolved in H_2O (30 mL) and twice washed with CH_2Cl_2 (3 × 10 mL) before concentrated HCl was added to reach pH 1. The reaction product was collected by washing with CH_2Cl_2 (5 × 20 mL). The solution was dried over $MgSO_4$, and evaporation of the solvent afforded 2-benzylmalonic acid (1.7 g, 41%). ^1H NMR (250 MHz, [D_4]MeOH): δ = 7.30−7.10 (m, 5 H, H-Ph), 3.62 (t, ^3J = 7.7 Hz, 1 H, CH), 3.15 (d, ^3J = 7.7 Hz, 2 H, CH_2) ppm.

2-Benzyl-*N*,*N*′-bis(8-quinolyl)malonamide (mono-BenzBQMH$_2$) (1b): Under argon, 2-benzylmalonic acid (0.25 g, 1.3 mmol) was dissolved in 4 mL of $SOCl_2$ and the mixture was stirred for 4 h at 60 °C. After removal of the excess thionyl chloride in vacuo, 2-benzyldiethylmalonic acid chloride was obtained as a yellow oil, which was directly converted into **1b**. Two equiv. of 8-aminoquinoline (0.37 g, 2.6 mmol) were added to the acid chloride dissolved in dry toluene (5 mL). The orange suspension was stirred for 1 h at room temperature, then Et_3N (0.33 mL, 2.5 mmol) was added and the mixture stirred overnight at 60 °C. Then, CH_2Cl_2 (20 mL) was added, the solution was washed with H_2O (4 × 10 mL) and the organic layer was dried over $MgSO_4$. After recrystallization from CH_2Cl_2 **1b** was obtained as a white solid (0.37 g, 63%). UV/Vis (CH_2Cl_2) λ_{max} (ε) = 248 (18800 $M^{-1}\cdot cm^{-1}$), 307 (11700) nm. IR (neat): $\tilde{\nu}$ = 3271 w (ν_{NH}) and 1666 s (ν_{CO}) cm^{-1}. ^1H NMR (250 MHz, $CDCl_3$): δ = 10.60 (s, 2 H, NH), 8.85−7.76 (m, 4 H, H^1 + H^5), 8.12 (d, ^3J = 8.2 Hz, 2 H, H^3), 7.55−7.48 (m, 4 H, H^4 + H^6), 7.43 (dd, ^3J = 8.2, ^3J = 4.2 Hz, 2 H, H^2), 7.38−7.05 (m, H-Ph, 5 H), 3.91 (t, ^3J = 7.6 Hz, 1 H, CH), 3.59 (d, ^3J = 7.6 Hz, 2 H, CH_2) ppm. MS: *m*/*z* (%) = 447 (100) $[M + H]^+$).

2,2′-Dibenzyl-*N*,*N*′-bis(8-quinolyl)malonamide (di-BenzBQMH$_2$; 1c) and 2,2′-Bis(2-phenylethyl)-*N*,*N*′-bis(8-quinolyl)malonamide (di-PhEtBQMH$_2$; 1d): The disubstituted ligands **1c** and **1d** were synthesised according to Hirose et al,[14] but the saponification of the malonic esters was carried out as reported by Maslak et al.[15]

[Co(BQM)] (2a): Et_3N (0.56 mL, 4.2 mmol) was added under argon to a solution of the $BQMH_2$ ligand (**1a**; 0.3 g, 0.84 mmol) in a CH_2Cl_2/MeOH mixture (30 mL/20 mL). Upon addition of a methanolic solution (10 mL) of $CoCl_2$ (0.12 g, 0.92 mmol) the mixture turned orange and within five minutes [Co^{II}(BQM)] precipitated as a completely insoluble orange solid that was washed with CH_2Cl_2, MeOH and diethyl ether (20 mL each) (0.3 g, 73%). $C_{21}H_{16}CoN_4O_2\cdot 1.5H_2O$ (440.06): calcd. C 55.89, H 3.65, N 12.40; found C 57.28, H 3.89, N 12.72. IR (KBr): $\tilde{\nu}$ = 1605 s (ν_{CO}) cm^{-1}. EPR (powder, 4 K) *g* = 1.99.

(Et$_4$N)[Co(BQM)(CN)$_2$] (3a): Complex **2a** (0.1 g, 0.24 mmol) was suspended in CH_2Cl_2 (2 mL). Addition of a CH_2Cl_2 solution (5 mL) of tetraethylammonium cyanide (Et_4NCN, 75 mg, 0.48 mmol) resulted in the dissolution of the complex. Exposure of the solution to air caused oxidation of the cobalt. Stirring was continued for 2 h, then half of the solvent was evaporated and the product was precipitated by addition of diethyl ether. Purification over LH-20 (30 g) with CH_2Cl_2/MeOH (8:2) as eluent, and precipitation from CH_2Cl_2/pentane afforded (Et_4N)[Co(BQM)$(CN)_2$] as an orange powder (70 mg, 50%). $C_{31}H_{34}CoN_7O_2\cdot H_2O\cdot CH_2Cl_2$ (697.17): calcd. C 55.02, H 5.48, N 14.04; found C 54.89, H 5.46, N 13.99. UV/Vis (MeOH) λ (ε) = 257 (29900 $M^{-1}cm^{-1}$), 380 (6040) nm. IR (KBr): $\tilde{\nu}$ = 2126w (ν_{CN}) and 1601s (ν_{CO}) cm^{-1}. ^1H NMR (250 MHz, [D_6]DMSO): δ = 9.07 (d, ^3J = 5.0 Hz, 1 H, H^1), 8.81 (d, ^3J = 7.1 Hz, 1 H, H^4 or H^6), 8.71 (d, ^3J = 8.2 Hz, 1 H, H^3), 8.41 (d, ^3J = 8.1 Hz, 1 H, $H^{3'}$), 8.15 (d, ^3J = 7.2 Hz, 1 H, $H^{4'}$ or $H^{6'}$), 7.87 (dd, ^3J = 8.2, ^3J = 5.0 Hz, 1 H, H^2), 7.75−7.40 (m, 4 H, H^5 + $H^{5'}$, H^4 or $H^{4'}$ and H^6 or $H^{6'}$), 7.28 (dd, ^3J = 8.1, ^3J = 4.9 Hz, 1 H, $H^{2'}$), 6.17 (d, ^3J = 4.9 Hz, 1 H, $H^{1'}$), 5.02 (d, ^2J = 15.1 Hz, 1 H, H^α or $H^{\alpha'}$), 2.97 (d, ^2J = 15.1 Hz, 1 H, H^α or $H^{\alpha'}$) ppm. MS: *m*/*z* (%) = 465 (100) $[Co(BQM)(CN)_2]^-$.

(Et$_4$N)[Co(mono-BenzBQM)(CN)$_2$] (3b): Under argon, the monosubstituted ligand mono-$BenzBQMH_2$ (**1b**) (0.1 g, 0.22 mmol) was dissolved in CH_2Cl_2 (30 mL) and Et_3N (0.15 mL, 1.1 mmol) was added, followed by a solution of $CoCl_2$ (32 mg, 0.24 mmol) in MeOH (5 mL). After removal of three quarters of the solvent [Co^{II}-(mono-BenzBQM)] (**2b**) precipitated as a yellow powder and was collected by filtration, then washed with CH_2Cl_2, MeOH and diethyl ether (50 mg, 45%). Like **2a**, it is insoluble. The oxidation procedure described for **2a** was applied to **2b** (20 mg, 0.04 mmol) with Et_4NCN (12.5 mg, 0.08 mmol). (Et_4N)[Co(mono-BenzBQM)$(CN)_2$] (**3b**) was obtained as an orange powder (18 mg, 65%). $C_{38}H_{40}CoN_7O_2$ (685.26): calcd. C 66.56, H 5.88, N 14.30; found C 66.06, H 5.85, N 14.20. UV/Vis (MeOH): λ_{max} (ε) = 259 (31300 $M^{-1}cm^{-1}$) and 387 (6230) nm. IR (KBr): $\tilde{\nu}$ = 2125 w (ν_{CN}) and 1618 s (ν_{CO}) cm^{-1}. ^1H NMR (250 MHz, [D_6]DMSO): δ = 9.06 (d, ^3J = 5.2 Hz, H^1, 1 H), 8.90 (dd, ^3J = 7.3, ^4J = 1.2 Hz, 1 H, H^4 or H^6), 8.69 (d, ^3J = 8.1 Hz, 1 H, H^3), 8.40 (d, ^3J = 8.0 Hz, 1 H, $H^{3'}$), 8.00 (d, ^3J = 7.1 Hz, 1 H, $H^{4'}$ or $H^{6'}$), 7.86 (dd, ^3J = 8.1, ^3J = 5.2 Hz, 1 H, H^2), 7.75−7.45 (m, 4 H, H^5 +$H^{5'}$, H^4 or $H^{4'}$ and H^6 or $H^{6'}$), 7.45−7.00 (m, 6 H, $H^{2'}$ and H-Ph,), 6.11 (d, ^3J = 4.6 Hz, 1 H, $H^{1'}$), 5.55 (t, ^3J = 6.5 Hz, 1 H, CH), 3.18 (d, ^3J = 6.5 Hz, 2 H, CH_2) ppm. MS: *m*/*z* (%) = 555 (100) [Co(mono-BenzBQM)$(CN)_2]^-$.

(Et$_4$N)[Co(di-BenzBQM)(CN)$_2$] (3c) and (Et$_4$N)[Co(di-PhEtBQM)-(CN)$_2$] (3d): A mixture of $CoCl_2$ (27 mg, 0.21 mmol) and the ligand di-$BenzBQMH_2$ (**1c**; 0.11 g, 0.21 mmol) or di-$PhEtBQMH_2$ (**1d**; 0.12 g, 0.21 mmol), respectively, was dissolved in dry DMF (10 mL) under argon. After addition of Et_3N (0.11 mL, 0.84 mmol) the solution turned orange. Stirring at room temperature was continued for 30 min before the solution was cooled to −30 °C. Et_4NCN (0.2 g, 1.3 mmol) in DMF (5 mL) was then added, and the solution was stirred for a further 30 min at this temperature. Oxidation to Co^{III} was performed by addition of the oxidizing agent $C_6H_4FN_2PF_6$[10] (1.5 equiv.), dissolved in DMF (2 mL). The reaction mixture was allowed to warm to room temperature and DMF was removed in vacuo. The brown/orange solid was dissolved in acetonitrile (20 mL), the remaining white residue — unconverted ligand — was filtered off. An orange product was obtained after evaporation of the solvent. The product was further purified over LH-20 (30 g) with MeOH and finally precipitated with diethyl ether as an orange powder (3c: 0.13 g, 79%; 3d: 59 mg, 35%).

3c: $C_{45}H_{46}CoN_7O_2\cdot 3H_2O\cdot 3MeOH\cdot 1.5MeCN$ (945.93): calcd. C 62.18, H 6.98, N, 11.10; found C 61.94, H 6.96, N 11.07. UV/Vis (MeOH): λ_{max} (ε) = 268 (26500 $M^{-1}\cdot cm^{-1}$) and 400 (6090) nm. IR

X-ray Crystallography: Crystal data for **3a** and **3c** are presented in Table 2. Data for **3a** were collected at beamline X7B (λ = 0.9376 Å) at the Brookhaven National Synchrotron Light Source with a MAR 345 image-plate detector and data for **3c** with an Excalibur system equipped with a CCD area detector. The structures were solved by use of isomorphous replacement for **3a**[16] and SHELXS 97[17] for **3c**. Refinement, based on F^2, was carried out by full-matrix least-squares with SHELXL-93[18] (**3a**) and SHELXL-97[19] (**3c**). Non-hydrogen atoms were refined anisotropically. The hydrogen atoms were positioned geometrically and refined riding on their carrier atom with isotropic thermal displacement parameters fixed at 1.2-times those of their parent atoms. The lattice of **3a** contains an extremely disordered molecule of solvation, which was unmodelable. The program SQUEEZE in the PLATON[20] suite of programs was used to treat this problem. The structure-factor calculation including SQUEEZE contribution for the final FCF file gave the following results: *R*1= 0.078 for 4366 reflections with $I > 2\sigma(I)$ and *wR*2 = 0.216 for 4614 reflections. ORTEP[21] diagrams of **3a** and **3c** are given in Figures 1 and 2.

CCDC-214648 (**3a**) and -211026 (**3c**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Mechanism of the Stepwise Dissociation of Fe^{III} Complexes with Tripodal Ligands as Siderophore Models

Guy Serratrice,*[a] Frédéric Biaso,[a] Fabrice Thomas,[a] and Claude Béguin[a]

Keywords: Tripodal ligands / Iron / Kinetics and mechanisms / Dissociation / Catechol / 8-hydroxyquinoline

The acid hydrolysis and formation kinetics of 1:1 ferric complexes with several tripodal hexadentate ligands were investigated over the $[H^+]$ range of 0.02–1.0 M at 25 °C and at an ionic strength of 2.0 M ($NaClO_4/HClO_4$). These ligands are based on a tris(2-aminoethyl)amine (TREN) spacer connected through a tris(amide) moiety to identical pendant bidentate chelating group arms such as catecholate (TRENCAMS, **L^3**), 8-hydroxyquinolinate (O-TRENSOX, **L^0**) or pyridinophenolate (TRENPYPOLS, **L^5**). Mixed ligands with chelating arms such as catecholate and 8-hydroxyquinolinate (TRENSOX2CAMS, **L^1** and TRENSOXCAMS2, **L^2**) were also investigated. An analogue of **L^0** (C-SOX, **L^4**) with a C-pivot scaffold instead of TREN was studied for comparison. The acid hydrolysis reaction was found to proceed in four kinetically distinguishable stages. A common mechanism in the series was followed when the ligand structure was varied. The first stage is very fast and can be attributed to the dissociation of one arm of the tripodal ligand. The second and third stages involve protonation of the complex which induces a change of coordination giving the corresponding tetracoordinated bis(salicylate) complex (coordination with carbonyl and *o*-hydroxy oxygen atoms). The final dissociation of the ligand proceeds in the fourth stage by one or two kinetically detectable steps. For the last step an important structural effect may be observed from 1.2×10^{-5} to 2.2×10^{-2} s^{-1} for the proton-independent step and from 1.2×10^{-6} to 0.18 $M^{-1}s^{-1}$ for the proton-dependent step. Differences in the rates and mechanism between the different tripodal ligands are discussed in terms of the global electrostatic charge of the ligand and the donor ability of the chelating subunit. The C–N bond rotation of the amide moiety and the importance, depending on the charge, of the H-bond network in the partially uncoordinated complexes have also been considered. The role of electrostatics in complex formation is discussed in relation to the Eigen-Wilkins mechanism.

Introduction

Microbial iron bio-availability is largely determined by the coordination chemistry of Fe^{III} with siderophores, a class of organic compounds having a high and specific chelating affinity for this cation.[1−3] Natural (siderophores) or synthetic Fe^{III} chelating agents can be used for therapeutic or agrochemical applications.[4,5] To gain a better understanding of the mechanism of Fe^{III} chelation and transport in biological systems, quantitative evaluations have been reported through measurements of the kinetics of the Fe^{III} uptake and release (through acid hydrolysis) in aqueous solution.[1] A better knowledge of the cleavage of the iron−oxygen bonds in iron chelates can help with the design of new biologically useful ligands, more precisely by improving iron exchange from ligands to proteins. Studying the sensitivity of the iron−oxygen bond to acid hydrolysis is also interesting since it is well known that, in some compartments of the cell (lysozomes for example), lower pH levels are present. There have been extensive kinetic studies of (hydroxamato)Fe^{III} complexes in relation to the predominance of the hydroxamate binding sites in siderophores.[6−13] The most studied, hexadentate desferrioxamine B (DFB, desferal), has three bidentate hydroxamate groups.[8,9] Fe^{III} complexes of dihydroxamate siderophores and siderophore models have been also investigated[7,10,11] but there are a few kinetic data available for the dechelation processes of complexes with other types of ligands.

In particular, numerous ligands having the tripodal structure have been synthesized and the thermodynamic data of their Fe^{III} complexes have been determined. The tripodal structure mimics the backbone of the tris(catecholate) siderophore enterobactin. It is based on tris(2-aminoethyl)amine (TREN) as a spacer. This central organizing unit is connected through a tris(amide) moiety to pendant arms each containing a bidentate chelating group such as catecholate (TRENCAM,[14] TRENCAMS[15]), hydroxamate (TRENDROX[16]), 8-hydroxyquinolinate (O-TRENSOX[17]), pyridinophenolate (TRENPYPOLS[18]) or hydroxypyridonate.[19] These ligands all exhibit strong complexing behavior towards Fe^{III}. Recently, we synthesized mixed tripodal li-

gands involving both catecholate and hydroxyquinolinate chelating subunits (TRENSOX2CAMS and TRENSOX-CAMS2[20]). They have been shown to be more effective at pH = 7.4 than the parent homopodal ligands TREN-CAMS and O-TRENSOX. Another series of tripodal ligands bearing a C-pivot scaffold with either 8-hydroxyquinoline (C-SOX,[21] COX[22]) or catechol subunits (Cac-CAM[23]) has also been developed in our laboratory. A C-pivot allows the grafting of any desired substituent, e.g. a polyoxyethylene chain, in order to modulate the hydrophile-lipophile balance or the fluorescent group used for labeling.

We previously investigated the dissociation, by acid hydrolysis, of the Fe^{III}-TRENCAMS[15] and Fe^{III}-O-TRENSOX[17b] complexes. Acid hydrolysis has been described by a stepwise mechanism producing the tetracoordinate bis(salicylate) complex and subsequently leading to its complete dissociation. In contrast to the 8-hydroxyquinoline groups, the catecholate groups have been found to be very labile. In this paper, we report an extensive kinetic study on the acid hydrolysis and formation kinetics of 1:1 ferric complexes with the ligands TRENSOX2CAMS (**L^1**), TRENSOX-CAMS2 (**L^2**), CSOX (**L^4**), and TRENPYPOLS (**L^5**). The structures of the ligands together with those of O-TRENSOX (**L^0**) and TRENCAMS (**L^3**) are depicted in Figure 1. The interesting feature of these ligands is the possibility of two modes of coordination for each arm of the ligand depending on the pH: a lowering of the pH leads to a switch from the coordination with the bidentate unit (8-hydroxyquinolinate or catecholate) to the so called salicylate-like mode in which protonation of the pyridine nitrogen atoms or *meta*-phenolic oxygen atoms induce their replacement by the amide carbonyl oxygen atoms (see for 8-hydroxyquinoline as example in Figure 2). Such a switch is proposed for the mechanism of iron release from enterobactin making reduction easier.[24] There are significant structural differences (bidentate subunit, spacer) between these tripodal ligands which therefore make a comparative study particularly interesting in order to elucidate electrostatic and structural factors affecting the dissociation and the formation of complexes. Furthermore, this kinetic investigation provides data necessary to formulate mechanisms by which the complexes are formed and dissociated.

Results

Acid Hydrolysis Kinetics

General Observations

All the studied Fe**L**^{n} complexes (n = 0−5 as shown in Figure 1) have been previously characterized by UV/Vis spectrophotometry which showed protonated [Fe**L**^{n}H$_m$] species as the pH was lowered with acidic media.[15,17b,18,20] The acid hydrolysis kinetics of the complexes were investigated in aqueous solution (ionic strength I = 2 M, 25 °C) by the pH jump method under pseudo-first-order conditions with an excess of [H$^+$] (varying generally over the range 0.02−1.0 M) for solutions containing Fe^{III} and the tripodal ligand in a 1:1 molar ratio at an initial pH = 5. The k_{obs} rate constants were determined from the absorbance data versus time at the λ_{max} of the [Fe**L**^{n}] complex. The absorption spectra were also monitored (λ range 300−700 nm) using a diode array device in order to provide additional information on the intermediate species. As the pH was lowered, the spectral changes observed were the result of the change of the number ligands at the iron center and their mode of coordination due to protonation of the coordination sites. The structures of the protonated complexes which were formed during the acid hydrolysis were supported by their absorption spectra.[15,17b,18,20] The acid hydrolysis reaction was found to proceed in three or four kinetically distinguishable stages depending on the ligand. All reaction steps in the first stage were found to occur rapidly and exhibited a loss of absorbance at all the wavelengths (20% of the initial absorbance amplitude for all of the spectrum). This process (denoted stage 1) was too fast to be monitored by stopped-flow measurements and it can been attributed to the dissociation of one arm of the tripodal ligand. The second and the third stages caused a striking change in the spectrum. They involve protonation of the di-coordinated arms which induces a change of coordination to a salicylate mode giving the bis(salicylate) (tetra-coordinated) complex which has been clearly identified from our previous spectrophotometric studies.[15,17b,18,20] Finally, the dissociation of the ligand occurs in the fourth stage in one or two kinetically detectable steps. The successive rate constants are noted k_i where i = 4 and 3 for stages two and three, respectively, i = 2 and 1 for the two steps of the fourth stage (1 is for the last step of the dissociation).

Fe^{III}-TRENSOXCAMS2 (FeL^2)

Four first-order kinetic processes were observed in the [H$^+$] range of 0.001−1 M (Figure 3). The spectrum recorded after the dead time is similar to that of the complex [Fe**L**^{2}H$_3$] with a hydroxyquinolinate and catecholate coordination (λ_{max} = 540 nm) indicating rapid dissociation of a catechol arm and protonation of the tertiary nitrogen atom (Figure , a) since the value of its pK_a = 3.4.[20] A first-order absorbance decay was then measured in the time range of seconds (stage 2). The corresponding pseudo-first-order constant k_4^{obs} was found to vary linearly with [H$^+$] as shown in Figure S1 of the Supporting Information which suggests the rate law (3). The UV/Vis spectra were recorded as a function of the time and the spectrum at the end of stage 2 (Figure 4, b) was found to be similar to the spectrum of the [Fe**L**^{2}H$_4$] species (λ_{max} = 570 nm) having a hydroxyquinolinate coordination and a salicylate coordination with one catecholate arm (through carbonyl and hydroxy oxygen atoms).[20]

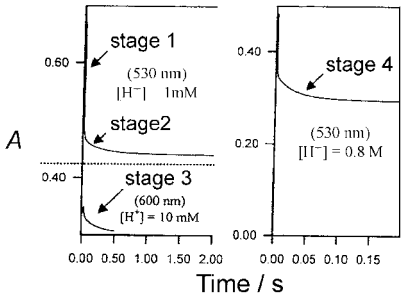

Figure 3. Acid hydrolysis kinetics of the Fe^{III}**L**^{2} complex: absorbance decay at λ = 530 or 600 nm; [Fe^{III}**L**^{2}] = 0.05 mM; [H$^+$] = 1 mM for stages 1 and 2, [H$^+$] = 10 mM for stage 3, [H$^+$] = 0.8 M for stage 4; solvent: water, I = 2 M (NaClO$_4$, HClO$_4$), 25 °C

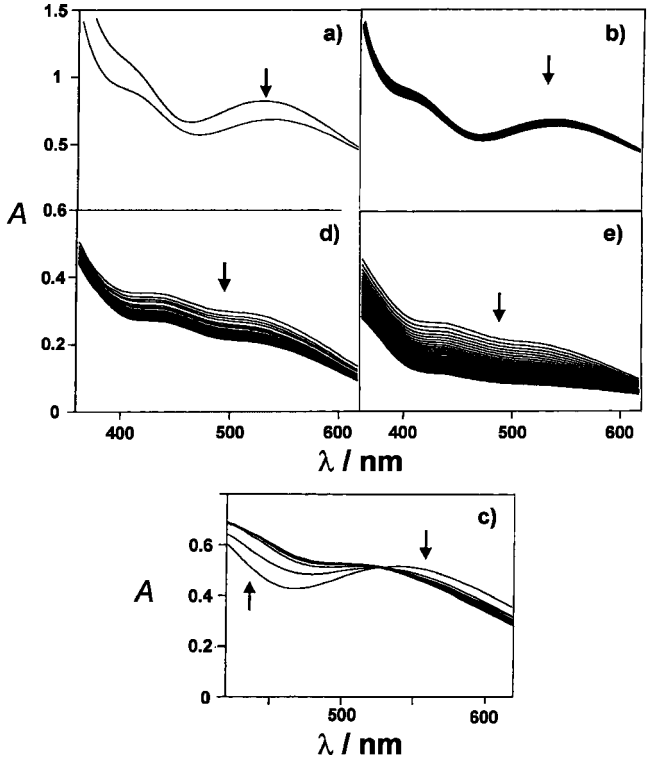

Figure 4. UV/Vis spectra recorded as a function of the time for the acid hydrolysis kinetics of the Fe^{III}**L**^{2} complex: (a) stage 1, 0−3 ms (b) stage 2, 0−1 s (c) stage 3, 0−500 ms (d) stage 4, step 1 0−0.5 s, (e) stage 4, step 2, 0.5−100 s; experimental conditions: see Figure 3; the arrow indicates the direction of change as the reaction proceeds

This is consistent with the following reactions (charges of the complexes and the ligand omitted) from which the

values $k_4 = 4440 \pm 180$ M^{-1} s^{-1} and $k_{-4} \approx 0$ s^{-1} could be deduced [Equations (1)−(3)].

$$Fe\mathbf{L^2} + 3\,H^+ \rightleftarrows Fe\mathbf{L^2}H_3 \text{ (fast)} \quad (1)$$

$$Fe\mathbf{L^2}H_3 + H^+ \rightleftarrows Fe\mathbf{L^2}H_4\ (k_4, k_{-4}) \quad (2)$$

$$k_4^{obs} = k_4\,[H^+] + k_{-4} \quad (3)$$

The third stage exhibited a single-exponential absorbance decay measured at $\lambda = 600$ nm and was monitored over the $[H^+]$ range 0.01−0.07 M. The spectra collected during this stage exhibited an isosbestic point at 525 nm and a decrease of λ_{max} (Figure 4, c) characteristic of the formation of the $Fe\mathbf{L^2}H_5$ species having a bis(salicylate) coordination.[20] The rate constant k_3^{obs} did not show a variation with $[H^+]$ (mean value ≈ 60 s^{-1}, see Figure S2 in the Supporting Information). By analyzing the absorbance data at the end of this stage as a function of $[H^+]^n$ in the form of a Hill plot, a linear plot was obtained for $n = 1$ (Figure S3 in the Supporting Information). These data suggest a saturation behavior with a fast acid-basic pre-equilibrium preceding the rate determining step as given by Equations (4)−(6).

$$Fe\mathbf{L^2}H_4 + H^+ \rightleftarrows Fe\mathbf{L^2}H_5{}^*\ (K_3') \quad (4)$$

$$Fe\mathbf{L^2}H_5{}^* \rightleftarrows Fe\mathbf{L^2}H_5\ (k_3, k_{-3}) \quad (5)$$

$$k_3^{obs} = k_3\,K_3'\,[H^+]/(1 + K_3'\,[H^+]) + k_{-3} \quad (6)$$

Our results imply that $K_3'\,[H^+] >> 1$, so that $k_3^{obs} \approx k_3 + k_{-3}$. Since $[H^+]$ spans the range 0.01−0.07 M, the lower limit for K_3' can be evaluated as ≈10^3 M^{-1}. Since the pK_a value of the equilibrium $Fe\mathbf{L^2}H_5/Fe\mathbf{L^2}H_4$ has been reported as 2.2,[20] it can be inferred that $k_3/k_{-3} < \approx 10^{-0.8}$ ($1/K_a = K_3'k_3/k_{-3}$) allowing evaluation of an upper limit for k_3 as ≈ 10 s^{-1} and k_{-3} as ≈ 50 s^{-1}. The chemical identity of $Fe\mathbf{L^2}H_5{}^*$ will be discussed later.

The spectral change observed during stage 4 showed an absorbance decrease in two steps at all wavelengths (Figure 4, d and e) in two time ranges which is consistent with complete dissociation of the ligand. Two well separated single-exponential absorbance decays (measured at 500 nm) were monitored in the time range of 0.5 s and 100 s over the $[H^+]$ range of 0.2 to 0.65 M. The rate constants k_2^{obs} and k_1^{obs} exhibited linear variations with $[H^+]$ (Figure S4). This result can be interpreted by the successive dissociation reactions. The faster involves dissociation of one arm of the tripodal ligand (charge omitted for $[Fe\mathbf{L^2}H_n]$) [Equations (7) and (8)] with $k_2 = 33.1 \pm 1.9$ M^{-1} s^{-1} and $k_{-2} = 11.2 \pm 1.4$ s^{-1} and the slower involves dissociation of the ligand via two parallel acid-dependent and acid-independent pathways to give free iron(III) in agreement with the dissociation pathways proposed for ferric complexes with the hydroxamate ligand [Equations (9)−(11)[24]][6] {$[FeOH]^{2+}$ for $[Fe(OH)(OH_2)_5]^{2+}$, Fe^{3+} for $[Fe(OH_2)_6]^{3+}$}.

$$Fe\mathbf{L^2}H_5 + H^+ \rightleftarrows Fe\mathbf{L^2}H_6\ (k_2, k_{-2}, K_2) \quad (7)$$

$$k_2^{obs} = k_2\,[H^+] + k_{-2} \quad (8)$$

$$Fe\mathbf{L^2}H_6 + H^+ \rightleftarrows Fe^{3+} + \mathbf{L^2}H_7\ (k_1, k_{-1}, K_1) \quad (9)$$

$$Fe\mathbf{L^2}H_6 + H_2O \rightleftarrows FeOH^{2+} + \mathbf{L^2}H_7\ (k_1', k_{-1}', K_1') \quad (10)$$

$$Fe^{3+} + H_2O \rightleftarrows FeOH^{2+} + H^+\ (K_{Fe} = 0.0015\text{ M}) \quad (11)$$

By assuming relaxation conditions for the reverse reactions, the experimental rate law can be expressed as Equation (12).

$$k_1^{obs} = k_1[H^+] + k_1' + (k_{-1} + k_{-1}'\,K_{Fe}/(K_{Fe} + [H^+])([Fe^{III}]_e + [\mathbf{L^2}H_7]_e) \quad (12)$$

$[Fe^{III}]_e$ and $[\mathbf{L^2}H_7{}^+]_e$ are the total equilibrium concentrations of ligand and metal under our experimental conditions (calculated from absorbances at equilibrium). The term in parentheses calculated using the value of k_{-1}' (2200 M^{-1} s^{-1}) determined from formation kinetics study (vide infra) was found to be negligible (assuming k_{-1} also to be negligible). The fitted values are $k_1 = 0.0137 \pm 0.0005$ M^{-1} s^{-1} and $k_1' = 0.00237 \pm 0.00025$ s^{-1}.

It was found that $K_1\,K_2 = K_1'\,K_2/K_{Fe} = 10^{-2.68}$ is in reasonable agreement with the value $10^{-2.27}$ determined from measurements at equilibrium and at an ionic strength of 0.1 M.[20]

Fe^{III}−TRENSOX2CAMS (FeL^1)

Three distinct first-order kinetic processes could be detected (Figure S5). The spectrum recorded after the dead time suggests a bis-8-hydroxyquinolinate coordination (Figure S6a in the Supporting Information)[20] indicating rapid dissociation of a catechol arm and the formation of the $[Fe\mathbf{L^1}H_3]$ species taking account of the protonation of the tertiary nitrogen. The spectral change observed during stage 2 reflects the change of coordination to a bis(salicylate) mode with the two hydroxyquinoline arms (Figure S6b) in the $[Fe\mathbf{L^1}H_5]$ species. This is clearly supported by its absorbance spectrum.[20] Contrary to the $Fe\mathbf{L^2}$ complex, only one absorbance increase was monitored at 435 nm, in the time range of deciseconds, over the $[H^+]$ range of 0.03 to 0.9 M (Figure S5). It was supposed that formation of the $[Fe\mathbf{L^1}H_4]$ species, corresponding to the change of coordination to a salicylate mode for one 8-hydroxyquinoline arm, was not detectable under our experimental conditions. The absorbance increase allowed determination the rate constant k_3^{obs}. The variation of k_3^{obs} with $[H^+]$ (Figure S7) is linear for $[H^+] > 0.4$ M and exhibits an inverse proton dependence for $[H^+] < 0.4$ M. This behavior can best be

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

explained by Equations (13)−(15), by analogy with Equations (9)−(11), yielding the rate expression according to Equation (16).

$$Fe\mathbf{L^1}H_4 + H^+ \rightleftarrows Fe\mathbf{L^1}H_5\ (k_3, k_{-3}) \quad (13)$$

$$Fe\mathbf{L^1}H_4 \rightleftarrows Fe\mathbf{L^1}H_4^*\ (k_3', k_{-3}') \quad (14)$$

$$Fe\mathbf{L^1}H_4^* + H^+ \rightleftarrows Fe\mathbf{L^1}H_5\ (K_3'', \text{fast}) \quad (15)$$

$$k_3^{obs} = k_3[H^+] + k_3' + (k_{-3}K_3''[H^+]) + k_{-3}')/(1 + K_3''[H^+]) \quad (16)$$

The non-linear fit of these data give the values $k_3 = 17.9 \pm 1.3$ M^{-1} s^{-1}, $k_{-3}' = 635 \pm 149$ s^{-1}, $K_3'' = 158 \pm 43$ M^{-1} (k_3' and k_{-3} could not be adjusted from the fit). The chemical identity of $Fe\mathbf{L^1}H_4$* and $Fe\mathbf{L^1}H_5$* will be discussed later.

The spectral change observed during stage 3 showed an absorbance decrease at all wavelengths (Figure S6c) and is consistent with dissociation of the ligand from the $Fe\mathbf{L^1}H_5$ species. A mono-exponential absorbance decay (measured at 435 nm) was monitored on a 1000 s time scale over the $[H^+]$ range of 0.2 to 1 M. The variation of k_1^{obs} vs. $[H^+]$ is shown in Figure 5. This can be interpreted by Equations (7) and (9)−(11) (replacing $\mathbf{L^2}$ for $\mathbf{L^1}$) and Equation (12) modified to give Equation (17) by considering Equation (7) as a fast pre-equilibrium.

$$k_1^{obs} = (k_1[H^+] + k_1')K_2[H^+]/(1 + K_2[H^+]) + [k_{-1} + k_{-1}' K_{Fe}/(K_{Fe} + [H^+])]([Fe^{III}]_e + [\mathbf{L^1}H_7]_e) \quad (17)$$

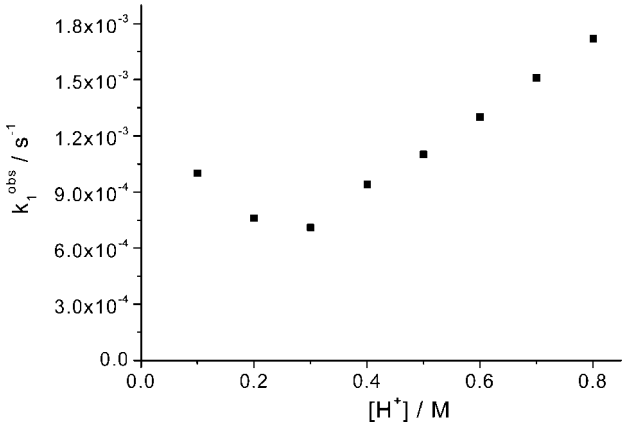

Figure 5. k_1^{obs} [s^{-1}] as a function of $[H^+]$ [M] in the acid hydrolysis kinetics of $Fe\mathbf{L^1}$; $[Fe\mathbf{L^1}] = 0.07$ mM; solvent: water, $I = 2$ M ($NaClO_4$, $HClO_4$), 25 °C

The term in parentheses was calculated using the value of k_{-1}' (1320 M^{-1} s^{-1}) determined from the formation kinetics study (vide infra) and assuming k_{-1} to be negligible. The fitted values are $k_1 = 0.0032 \pm 0.0004$ M^{-1} s^{-1} $k_1' \approx 0$ s^{-1} $K_2 = 1.70 \pm 0.55$ M^{-1}.

It was found that $K_1 K_2 \leq K_1' K_2/K_{Fe} = 10^{-3.55}$ (taking $k_1' \leq k_1/10$) which is in reasonable agreement with the value of $10^{-3.21}$ determined from measurements at equilibrium.[20]

Fe^{III}−CSOX (FeL^4)

Four distinct stages could be detected by measuring the absorbance decay at 600 nm (Figures S8 and S9). After the dead time, a bi-exponential decay of the absorbance was observed on a 10 s time scale with $[H^+]$ in the range of 0.02−0.1 M (stages 2 and 3). This decay could be fitted with a sum of two exponentials [Equation (18)].

$$A = A + A_1\exp(-k_4^{obs}\, t) + A_2\exp(-k_3^{obs}\, t) \quad (18)$$

The rate constants k_4^{obs} and k_3^{obs} vary apparently with $[H^+]$ with a non-zero intercept (Figure S10). This suggests two reversible elementary steps [Equations (19) and (20)].

$$Fe\mathbf{L^4}H_2 + H^+ \rightleftarrows Fe\mathbf{L^4}H_3\ (k_4, k_{-4}) \quad (19)$$

$$Fe\mathbf{L^4}H_3 + H^+ \rightleftarrows Fe\mathbf{L^4}H_4\ (k_3, k_{-3}) \quad (20)$$

The matrix formulation of the rate equations allows determination of analytical expressions for the observed rate constants. The following expressions can thus be deduced [Equations (21) and (22).

$$k_4^{obs} + k_3^{obs} = (k_4 + k_3)[H^+] + k_{-4} + k_{-3} \quad (21)$$

$$(k_4^{obs} - k_3^{obs})^2 = (k_4[H^+] + k_{-4})^2 + (k_3[H^+] + k_{-3})^2 + 2k_{-4}(k_3[H^+] - k_{-3}) - 2k_4(k_3[H^+] + k_{-3}) \quad (22)$$

The four microscopic constants were extracted from a non-linear least-squares refinement of the data according to Equations (21) and (22): $k_4 = 189 \pm 9$ M^{-1} s^{-1}, $k_{-4} = 10.0 \pm 0.4$ s^{-1}, $k_3 = 18.1 \pm 0.9$ M^{-1} s^{-1}, $k_{-3} = 1.20 \pm 0.05$ s^{-1}.

The spectral change observed during stage 4 showed an absorbance decrease at all wavelengths (Figure S9) and is consistent with dissociation of the ligand. A mono-ex-

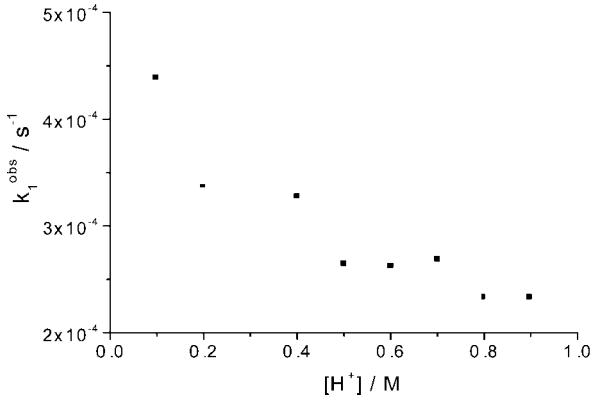

Figure 6. k_1^{obs} [s^{-1}] as a function of $[H^+]$ [M] in the acid hydrolysis kinetics of $Fe\mathbf{L^4}$; $[Fe\mathbf{L^4}] = 0.1$ mM; solvent: water, $I = 2$ M ($NaClO_4$, $HClO_4$), 25 °C

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

ponential absorbance decay (measured at 435 nm) was monitored on a 10000 s time scale over the $[H^+]$ range of 0.1−1 M. The variation of k_1^{obs} vs. $[H^+]$ is shown in Figure 6.

This can be interpreted by Equations (9)−(11) and Equation (12) (by replacing FeL^2H_5 for FeL^1H_6 and L^2H_7 for L^1H_6). The term in parentheses was calculated using the value of k_{-1}' (1750 M^{-1} s^{-1}) determined from the formation kinetics study (vide infra) and assuming k_{-1} to be negligible. The fitted values are: $k_1' = (2.0 \pm 0.2) \times 10^{-4}$ s^{-1} and $k_1 \approx 0$ M^{-1} s^{-1}.

Fe^{III}−O−TRENSOX (FeL^0)

The acid hydrolysis kinetics have been previously published.[17b] Only the last step of the dissociation was not described. As for **Fe^{III}−CSOX**, release of the ligand is very slow (20000 s time scale) even at high H^+ concentrations. It was observed at 435 nm as a mono-exponential absorbance decay. The variation of k_1^{obs} vs. $[H^+]$ is shown in Figure 7. The fitted values from Equation (13) are $k_1' = 1.0 \times 10^{-5} \pm 1.0 \times 10^{-6}$ s^{-1} and $k_1 \approx 0$ M^{-1} s^{-1} [the term in parentheses in Equation (12) was calculated using the value of 789 M^{-1} s^{-1} for k_{-1}' [17b] and assuming k_{-1} to be negligible].

Fe^{III}−TRENPYPOLS (FeL^5)

The absorbance change was measured at 470 nm. Three stages were observed in the $[H^+]$ range of 0.001−1 M (Figure S11). The spectrum change after the dead time resulted in a decrease of λ_{max} from 495 to 469 nm (Figure S12a) and was attributed to the formation of a tetra-coordinated complex with one arm of the tripodal ligand in the pyridinophenolate coordination mode and the other in the salicylate coordination mode.[18] This very fast process was followed by a slight increase in the absorbance at 470 nm (stage 2) in the time range of 200 ms. The UV/Vis spectra recorded as a function of the time (Figure S12b) exhibited an isosbestic point at 540 nm and the spectrum at the end of this stage is similar to that of the bis(salicylate) complex $[FeL^5H_5]$.[18] The corresponding pseudo first-order constant k_3^{obs} was found to vary linearly with $[H^+]$ (Figure S13).

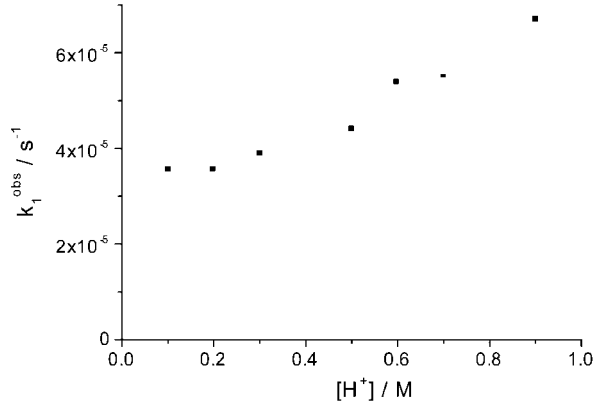

Figure 7. k_1^{obs} $[s^{-1}]$ as a function of $[H^+]$ [M] in the acid hydrolysis kinetics of FeL^0; $[FeL^0]$ = 0.07 mM; solvent: water, I = 2 M ($NaClO_4$, $HClO_4$), 25 °C

This is consistent with the reaction according to Equation (23) and and the rate law according to Equation (24) yielding the values $k_3 = 36 \pm 3$ M^{-1} s^{-1} and $k_{-3} = 18 \pm 1$ s^{-1}, respectively.

$$FeL^5H_4 + H^+ \rightleftarrows FeL^5H_5 \; (k_3, k_{-3}, K_3) \quad (23)$$

$$k_3^{obs} = k_3 [H^+] + k_{-3} \quad (24)$$

The spectral change observed during stage 3 showed an absorbance decrease at all wavelengths (Figures S12c and S12d) and resembles the spectra recorded for the formation reaction study. This is consistent with complete dissociation of the ligand. Two well-separated single-exponential absorbance decays (measured at 470 nm) were monitored in the time range of 5 s and 100 s over the $[H^+]$ range of 0.1−1 M. The rate constants k_2^{obs} exhibited linear variations with $[H^+]$ (Figure S14). The rate constants k_1^{obs} exhibited a linear proton dependence for $[H^+] > 0.2$ M and an inverse proton dependence for $[H^+] < 0.1$ (Figure 8). These successive dissociation reactions are consistent with reactions and rate laws according to Equations (7)−(12) (by replacing FeL^2H_5 with FeL^5H_5 and L^2H_7 with L^5H_7). The rate constants for Equation (7) have been determined as $k_2 = 4.9 \pm 0.2$ M^{-1} s^{-1}; $k_{-2} = 2.1 \pm 0.1$ s^{-1} and for Equations (9) and (10) the following could be evaluated from a non-linear least-squares fit of Equation (11) by taking for k_{-1}' the value of 514 M^{-1} s^{-1} determined from the formation kinetic studies (vide infra) and assuming k_{-1} to be negligible: $k_1 = (7.9 \pm 1.0) \times 10^{-3}$ M^{-1} s^{-1}; $k_1' = (9.6 \pm 5.7) \times 10^{-4}$ s^{-1}.

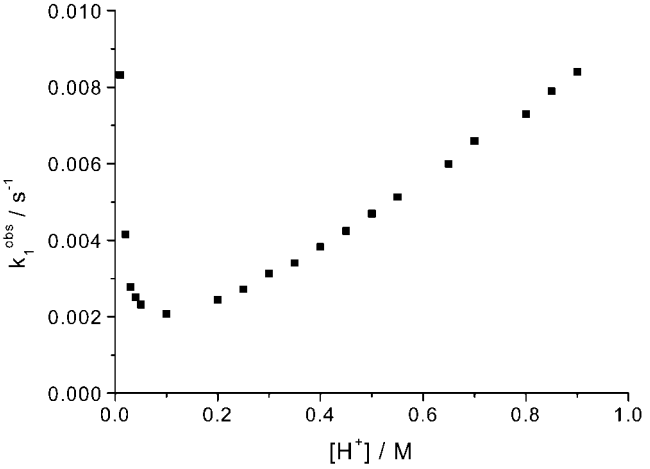

Figure 8. k_1^{obs} $[s^{-1}]$ as a function of $[H^+]$ [M] in the acid hydrolysis kinetics of FeL^5; $[FeL^5]$ = 0.2 mM; solvent: water, I = 2 M ($NaClO_4$, $HClO_4$), 25 °C

It was found that $K_1 K_2 = K_1' K_2 / K_{Fe} = 10^{-2.54}$ which is in reasonable agreement with the value of $10^{-1.79}$ determined from measurements at equilibrium.[18] The values of k_1, k_1', k_2, and k_{-2} for all the complexes are collected in Table 1.

Formation Kinetics

The kinetics of formation of the ferric complex with ligands $\mathbf{L^1}$, $\mathbf{L^2}$, $\mathbf{L^4}$ and $\mathbf{L^5}$ were investigated by a stopped-flow spectrophotometric method under pseudo-first-order conditions: [Fe^{III}] and [H$^+$] >> [$\mathbf{L}^n$] and at an ionic strength I = 2 M at 25 °C. The absorbance change vs. time at λ = 435 nm showed a single exponential curve indicating that the complex formation reaction proceeds through a single rate-limiting step. It should be noted that the spectra recorded with time using a diode array device were identical to those recorded for the final step of acid hydrolysis. It has been found that the pseudo-first-order rate constants k^{obs} at a given acidity level ([H$^+$] varied from 0.03 to 1 M) show a linear variation as a function of [Fe^{III}]$_{tot}$ with a zero intercept, and at a given concentration of Fe^{III} have a linear variation as a function of 1/[H$^+$] (Figure 9, a as an example). This suggests that the main reaction is the formation of the complex [Fe$\mathbf{L}^{n}H_6$] through the hydrolyzed ferric ion FeOH^{2+} {for [Fe(OH)(OH$_2$)$_5$]$^{2+}$} according to Equation (10) (formation is the reverse reaction). This leads to the observed pseudo-first-order rate constant given by Equation (25), where [Fe^{3+}] = [Fe^{3+}]$_{tot}$ – [FeOH]$^{2+}$ – 2 [Fe$_2$(OH)$_2$]$^{4+}$ and [H$^+$] takes into account the protons involved in formation of FeOH^{2+} [Equation (11)] and the dimer Fe$_2$(OH)$_2^{4+}$ {for [Fe$_2$(OH)$_2$(OH$_2$)$_8$]$^{4+}$} [Equation (26)].[25]

$$k_{obs} = k_{-1}' K_{Fe} [Fe^{3+}]/[H^+] + k_1' \quad (25)$$

$$2\ Fe^{3+} \rightleftarrows Fe_2(OH)_2^{4+} + 2\ H^+ \ (K_{DFe} = 0.0024\ M) \quad (26)$$

A linear variation of k_{obs} versus [Fe^{3+}]/[H$^+$] was observed (Figure 9, b for $\mathbf{L^1}$, Figure S15 for $\mathbf{L^2}$, Figure S16 for $\mathbf{L^4}$ and Figure S17 for $\mathbf{L^5}$). Least-squares fits of the data yielded the values of k_{-1}' 1320 ± 60, 2240 ± 120, 1750 ± 40 and 514 ± 8 M^{-1} s^{-1} for $\mathbf{L^1}$, $\mathbf{L^2}$, $\mathbf{L^4}$ and $\mathbf{L^5}$, respectively ($k_1' \approx 0$ s^{-1} for all cases). The values of k_{-1}' are collected in Table 1 together with the values previously determined for the formation of Fe$\mathbf{L^0}$ and Fe$\mathbf{L^3}$.

Figure 9. Discussion

Dissociation Kinetics

Rate constant data for the stepwise acid dissociation of the Fe$^{III}\mathbf{L}^{n}$ complexes are summarized in Tables 1 and 2, including data already published for O–TRENSOX[17b] ($\mathbf{L^0}$) and O–TRENCAMS[15] ($\mathbf{L^3}$). For easy comparison of the kinetic data of stages 1–3, we have reported in Table 2 the state of protonation of the tertiary nitrogen atom (for $\mathbf{L^0}$, $\mathbf{L^1}$, $\mathbf{L^2}$, $\mathbf{L^3}$ and $\mathbf{L^5}$) and the mode of coordination of Fe^{III} in the different species according to the state of protonation, the number of arms coordinated to the metallic cation and the bidentate coordination (8-hydroxyquinolinate or -catecholate or -salicylate). The following discussion suggests elementary reaction pathways as depicted in Figure 10 for Fe$\mathbf{L^2}$, Figure S18 for Fe$\mathbf{L^1}$ and Figure 14 of ref.[17b] for Fe$\mathbf{L^0}$, as examples.

[a] The different states of protonation during the pH jump (see text). [b] State of protonation of the anchor. [c] The coordination atoms of the three arms, separated by /, in the reverse order of the complete removal of the *n*th arm with Fe^{III}: "free" indicates an arm without a coordination bond to the iron atom, NO (NO*) refers to 8-hydroxyquinolinate (pyridinophenolate) bidentate coordination to Fe^{III}, OO refers to catecholate bidentate coordination to Fe^{III}, OOsal(ox) indicates salicylate bidentate coordination of a hydroxyquinoline arm to Fe^{III}, OOsal(cat) refers to salicylate bidentate coordination of a catechol arm to Fe^{III}, OO*sal represents salicylate bidentate coordination of a pyridinophenol arm to Fe^{III}.

Stage 1

On the basis of the spectral change, the reaction steps in this stage have been attributed to the dissociation of one arm of the ligand. This process is very fast whatever the type of chelating group. This suggests that the steric strain release in the complex may increase the rate of Fe−O and (or) Fe−N_{pyr} cleavage. We can also invoke, for the high kinetic lability of the hexacoordinate complex, the solvent rearrangement resulting from dissociation of the first bidentate group, as already supported for hydroxamate dissociation.[6] It can be suggested that the dissociated arm is maintained in proximity to the first coordination sphere of Fe^{III} through hydrogen bonds between the water molecules coordinated to Fe^{III} and the free arm. This results in a small motion of the arm as it dissociates from the Fe^{III} center

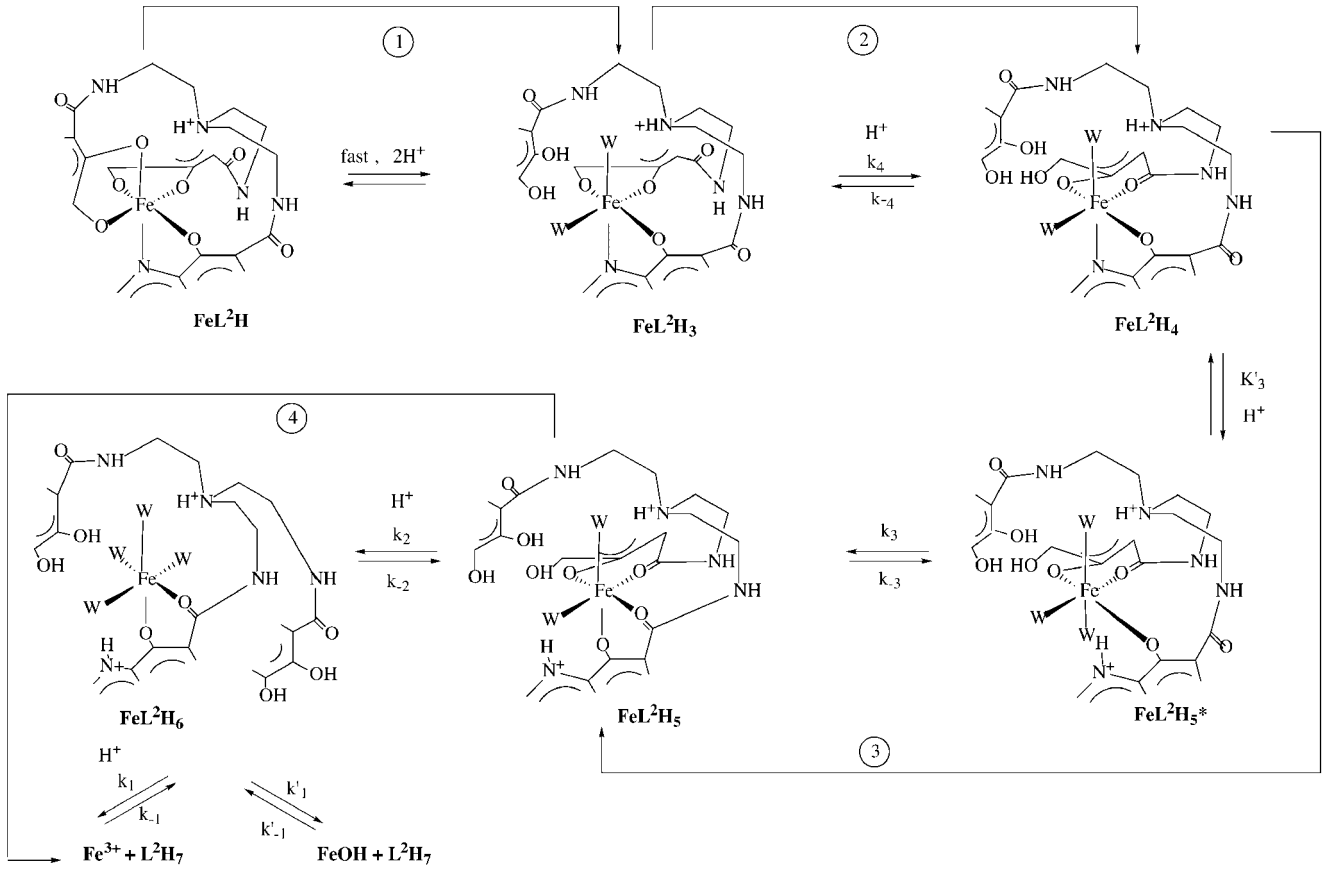

Figure 10. Proposed mechanism for the acid hydrolysis of the Fe$\mathbf{L^2}$H complex

and a slight solvent rearrangement. The reaction from the hexadentate to the tetradentate complex may therefore be a facile process.

Stages 2 and 3

Overall Scheme

These stages result in the formation of a bis(salicylate)-coordinated complex Fe$\mathbf{L}^n$H$_5$ (except Fe$\mathbf{L^4}$H$_4$) as clearly indicated by the spectra recorded at the end of stage 3 in agreement with the equilibrium studies previously published. Each stage is related to one arm of the ligand. It may involve the Fe−N$_{pyr}$ or Fe−O (depending on the type of bidentate group in $\mathbf{L}^n$) bond cleavage with protonation of N or O leading to an open-ring structure with the bidentate moiety, followed by the Fe−O(=C) bond closing the salicylate ring. It should be noted that this change of coordination requires conformational reorganization of the arm by rotation about the C−N amide bond in order to allow the carbonyl group to be in a suitable position favorable for salicylate coordination. Indeed, it has been shown that the carbonyl group is turned outside the Fe^{III} coordination sphere owing to hydrogen bond between the amide hydrogen atom and the *ortho*-oxygen atom (quinolinol or catechol or phenol) when Fe^{III} is coordinated with the bidentate group of each arm, as clearly evidenced.[22,26] We were able to obtain information on several elementary steps corresponding to stages 2 and 3 and rate constants k_4 and k_3, depending on the structure of the tripodal ligand, homopodand or heteropodand, and on the nature of the chelating subunit (catecholate, 8-hydroxyquinolinate, pyridinophenolate). Interesting correlations of the rate constants for same type of process with the chemical structures can be made.

Stages 2 and 3 for the Homopodate Fe$\mathbf{L}^n$H$_3$ Complexes (n = 0, 3, 4, 5)

The values of k_4 and k_3 clearly indicate the more labile character of the catechol arms (fast for the two arms in Fe$\mathbf{L^3}$H$_3$) compared with the pyridinophenol arms (first arm: fast, second arm: 36 M^{-1} s^{-1} in Fe$\mathbf{L^5}$H$_3$) and the 8-hydroxyquinoline arms (first arm: 643 and 189 M^{-1} s^{-1}, second arm: 5.7 M^{-1} s^{-1} and 18.1 M^{-1} s^{-1} in Fe$\mathbf{L^0}$H$_3$ and Fe$\mathbf{L^4}$H$_2$, respectively). This reflects (i) the higher donor strength of catecholate vs. pyridinophenolate and 8-hydroxyquinolinate which increases the electron density of the metal so that the bonds with the coordinated donor atoms are weakened; (ii) the chelate bulkiness which influences the rate of rotation about the C−N amide bond (pyridinophenol vs. catechol); (iii) the easier rotation of the am-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

ide bond in the catechol arm compared with in the 8-hydroxyquinoline arm that can be related to the electron-withdrawing effect of the 8-hydroxyquinoline group as clearly shown from the pK_a values of the carboxylic groups in the 2,3-dihydroxybenzoic acid (2.7) and in the 7-carboxy-8-hydroxyquinoline (1.9).[27]

Stages 2 and 3 for the Heteropodate FeL^nH_3 Complexes (n = 1, 2)

The reaction scheme developed from the analysis of the kinetic data is slightly different than for the homopodate complexes. For $\mathbf{L^1}$, only the stage $Fe\mathbf{L^1}H_4/Fe\mathbf{L^1}H_5$ was detected and can be described by Equations (13)−(15). This scheme, developed from an analysis of the kinetic data, has been proposed since the pK_a values of the tertiary amine nitrogen atom (1.9) and of the two hydroxyquinoline nitrogen atoms (2.4) are close.[20] We assumed a complicated kinetic pattern involving an acid-basic micro-equilibrium. A pictorial view of the proposed scheme is shown in Figure S18 (see also Table 2 for the state of protonation). The equilibrium between $Fe\mathbf{L^1}H_4$ and $Fe\mathbf{L^1}H_4$* [Equation (14)] involves proton transfer between the tertiary nitrogen atom and the quinoline nitrogen atom coordinated to the iron center, leading to the change of coordination of the 8-hydroxyquinoline moiety. The reaction according to Equation (15) involves the protonation of the tertiary amine nitrogen atom. The k_3 value (17.9 M^{-1} s^{-1}) is similar to the corresponding values determined for $Fe\mathbf{L^0}H_4$ (5.7 M^{-1} s^{-1}) and $Fe\mathbf{L^4}H_3$ (18.1 M^{-1} s^{-1}). The value of K_3'' (158 M^{-1}) is in agreement with the pK_a value (1.9) determined from static measurements at a 0.1 M ionic strength. The k_{-3}' value (635 s^{-1}) has no equivalent in the kinetic treatment to be related to the previously described micro-equilibrium. For $Fe\mathbf{L^2}H_3$ the value of k_4 (4440 M^{-1} s^{-1}) is consistent with the high lability of the catechol arm. For stage 3, we suggest that the pre-equilibrium [Equation (4)] is related to the Fe−N bond breaking of the 8-hydroxyquinoline arm leading to $Fe\mathbf{L^2}H_5$* (Figure 10) and that the last step [Equation (5)] is the change to the bidentate salicylate coordination of this arm ($Fe\mathbf{L^2}H_5$). The upper limit of 10 s^{-1} for k_3 is reasonable by comparison with the rate of rotation about the amide bond in hydroxamate ligands.[6]

Stage 4

In the last stage, leading from the tetradentate bis(salicylate) to the free ligand, at least two steps occur, corresponding to the Fe−O bond breakings of each salicylate arm. The rate constants for the leaving of the penultimate salicylate arms, k_2, could be measured only for $\mathbf{L^2}$ (33 s^{-1} M^{-1}) and $\mathbf{L^5}$ (4.9 s^{-1} M^{-1}). The smaller value for $Fe\mathbf{L^5}$ can be related to the bulkier access for the proton to the tetradentate complex with the pyridinophenol subunits in relation to the easy bond rotation between the pyridine and phenol moieties. The rate constants for the leaving of the last salicylate arm, k_1 (proton-dependent) and k'_1 (proton-independent) are well documented for all terms of the series (Table 2). About three orders of magnitude were observed, when measured, between k_2 and k_1 (or k'_1) for the release of two identical (salicylate) arms as already observed in related systems.[1]

Dependence of k_1 and k'_1 as a Function of Structure (Electrostatic Charge)

The important feature is that the rate constants k_1 and k_1' span over a range of several orders of magnitude: five orders for k_1 (184 to 0.0012×10^{-3} M^{-1} s^{-1}) and three and a half orders for k_1' (22 to 0.012×10^{-3} s^{-1}). Several trends in relation to the structure of the complex should be pointed out. The decrease of the rate constants k_1 and k_1' (except for $[Fe\mathbf{L^5}H_6]^{4+}$) in the series (Table 1) seems to be related mainly to the increase of the positive charges on the complexes evaluated without taking account of the sulfonate substituents, as in +3, +4, +5 and +6 for the iron(III) complexes with $\mathbf{L^3}$, $\mathbf{L^2}$, both $\mathbf{L^1}$ and $\mathbf{L^4}$ and $\mathbf{L^0}$, respectively. For the proton-dependent pathway (k_1) this is partly due to repulsion of the incoming H^+ by positive charges, suggesting that the dissociated 8-hydroxyquinoline arms of the ligand are maintained in proximity to the first coordination sphere of Fe^{III} probably through H-bonding between pyridinium nitrogen atoms and coordinated water molecules. It should be pointed out that k_1 for the complexes with the tris(8-hydroxyquinoline) ligands ($\mathbf{L^0}$ and $\mathbf{L^4}$) is 2 to 3 orders of magnitude slower than for the other complexes. This is probably due to enhanced repulsion for H^+ by positive charges suggesting a closer proximity for the dissociated arms than for the other ligands in $[Fe\mathbf{L^0}H_6]$ and $[Fe\mathbf{L^4}H_6]$. Indeed, pyridinium nitrogen atoms have been found to establish H-bonds with oxygen atoms coordinated to Fe^{III} in the structure of the tris(salicylate) complex with $\mathbf{L^0}$ forming a tight coordination sphere around the Fe^{III} center.[28] The value of 0.0079 M^{-1} s^{-1} for $[Fe\mathbf{L^5}H_6]^{4+}$ is high when compared with these highly charged complexes. This suggests a lower repulsion of the incoming H^+ by positive charges that are assumed to be far from the coordination sphere due to a free rotation of the pyridine ring relative to the phenol ring, thus disfavoring the formation of hydrogen bonds. For the proton-independent pathway, the decrease of k_1' parallels that of k_1.

Relationship between the Acid-Dependent and Acid-Independent Steps

The rate constants of these dissociations having acid-dependent and acid-independent steps vary in the same manner as a function of structure. We believe that this similarity is related to the structures of the transition states differing only by the presence of a proton. As the starting species is the same for these two steps, the transition state theory suggests a linear correlation between ln k_1 and ln k_1' [Equations (27) and (28)] as already discussed.[29,30]

$$\ln k_1 = \ln k_1' + \ln K_t \quad (27)$$

$$-\ln K_t = \Delta G_t^{\#}/RT \quad (28)$$

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

$\Delta G_t^{\#}$ is the free energy difference between the deprotonated and the protonated transition states, K_t may be considered as the protonation constant for the transition state and pK_{At} (= log k_1 − log k'_1) may be considered as a pseudo-pK_A of the transition state. A good correlation with a slope of 0.96 and an intercept $\ln K_t = 1.83$ ($pK_{At} = 0.80$) was obtained for the complexes with **L**[1], **L**[2], **L**[3] and **L**[5] (Figure 11). The correlation was not attempted for **L**[0] and **L**[4] since, for these ligands, k_1 values were only obtained as superior limits.

This correlation indicates that all the complexes follow the same dissociation mechanism from salicylate coordination. The protonation of the transition state is reasonably constant for this series. This implies that the hydroxy group is not implied in the transition state since its pK_a varies over a large range (5.6−9.23) in the free ligand. The Fe−O=C bond cleavage can therefore be suggested as the rate-limiting step for dissociation after a fast opening of the chelate ring as shown in Figure 12.

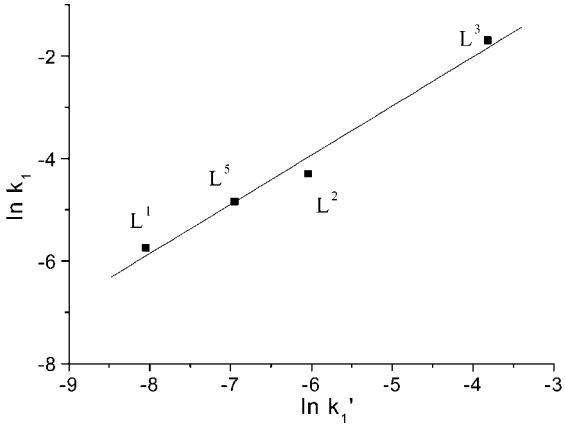

Figure 11. $\ln k_1$ vs. $\ln k_{-1}'$ for the final step dissociation of Fe**L**^{n} complexes; data were measured in aqueous 2.0 M $NaClO_4/HClO_4$ at 25 °C

Such a relationship has been observed for the dissociation of a large series of Fe^{III}-mono(hydroxamato) complexes yielding a slope of 0.9(1) in agreement with the theoretical value of 1, and an intercept $\ln K_1 = -0.6$ ($pK_{At} = -0.26$).[7] The correlation shows also that the transition state acidity of Fe^{III} (**L**[1] or **L**[2] or **L**[3] or **L**[5]) is lower than that of Fe^{III}(hydroxamic acid), i.e. that H^+ is more tightly bound in our series.

Linear Free Energy Relationships between k_1' and K_1'

The strong structural effect for the dissociation rate constants and the small dependence for the formation rate constants suggests a linear free energy relationships between $\ln k_1'$ and $\ln K_1'$ (K_1' has been calculated from k_1'/k_{-1}') [Equation (29)], where k_{-1}' (k_{-1}) is the formation rate constant when the active iron species is $FeOH^{2+}$ (Fe^{3+}). The theoretical basis for this correlation has been presented by Caudle and Crumbliss.[6]

$$\ln k_1' = \ln K_1' + \ln k_{-1}' \quad (29)$$

The plot $\ln k_1'$ vs. $\ln K_1'$ shown in Figure 13 (a) indicates a reasonably linear relation for the five complexes studied with a slope of 1.1 in agreement with the theoretical value of 1. This high degree of correlation suggests a similar mechanism in the final step of the dissociation. This implies a late transition state where the cleavage of the metal−ligand bonds are largely moved forward. The plot

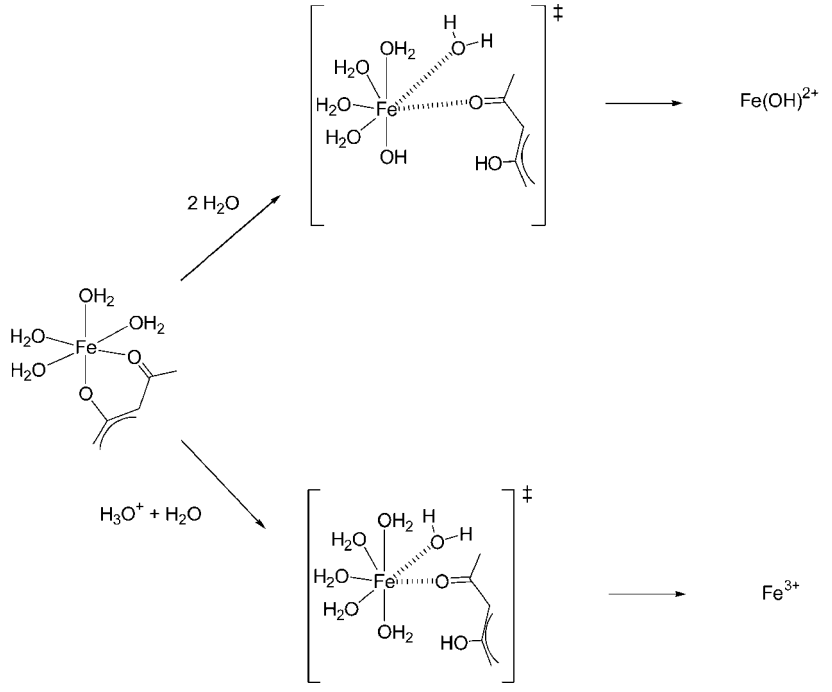

Figure 12. Transition states for proton-dependent and proton-independent dissociation of bidentate Fe−**L**^{n} complexes

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

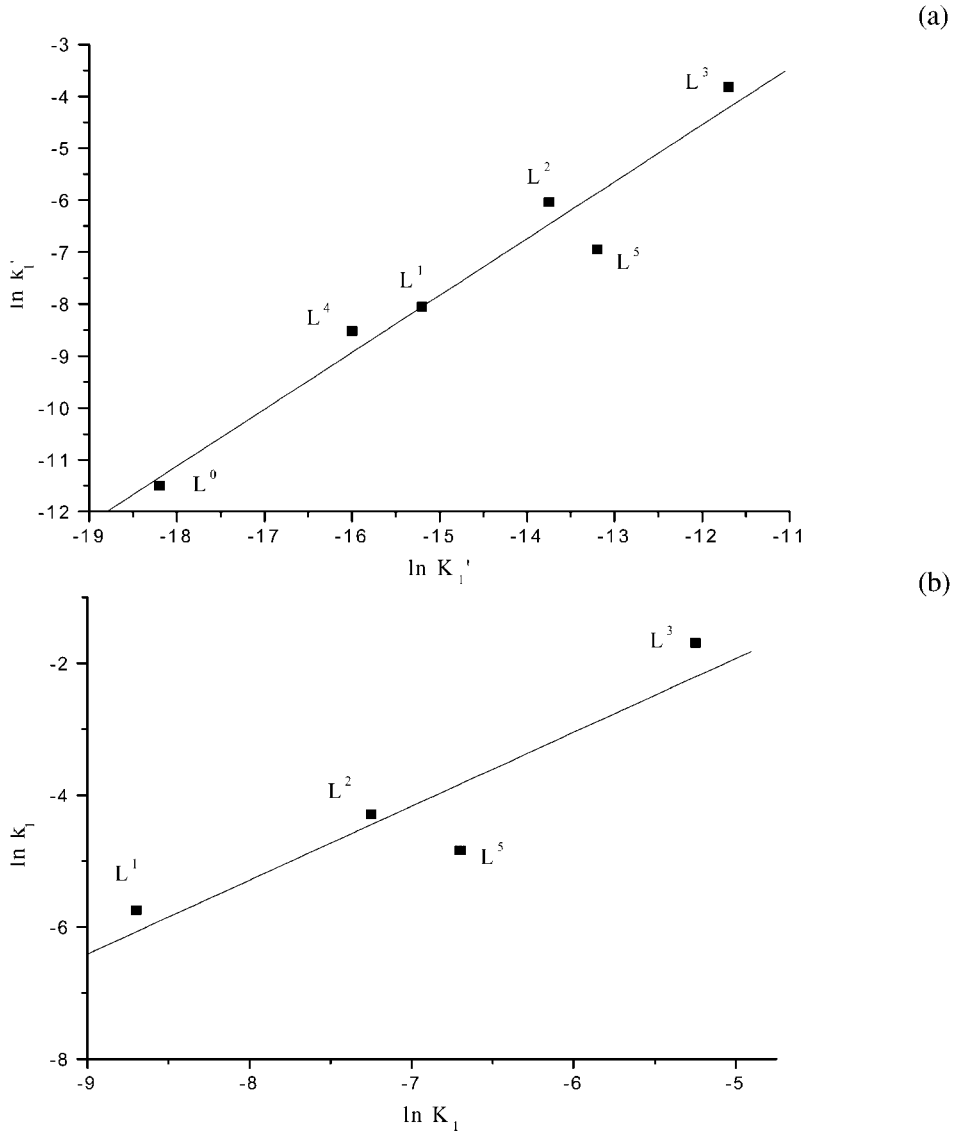

Figure 13. (a) ln k_1' vs. ln K_1' for proton-independent dissociation of bidentate Fe−**L**^{n} complexes; (b) ln k_1 vs. ln K_1 for proton-dependent dissociation of bidentate Fe−**L**^{n} complexes; data were measured in aqueous 2.0 M $NaClO_4/HClO_4$ at 25 °C

ln k_1 vs. ln K_1 (K'_1 calculated from K_1/K_{Fe}) also exhibits a reasonable correlation between data points for **L**^{1}, **L**^{2}, **L**^{3}, **L**^{5} with a slope of 1.1 (Figure 13, b) (a better correlation was obtained for the series **L**^{1}, **L**^{2}, **L**^{3}), as the correlation related to Equation (29) occurs. The proposed transition states are described in Figure 12.

Formation Kinetics

The rate-determining step is the coordination of Fe^{III} with one arm of the ligand through the salicylate coordination followed by a rapid coordination with a second arm of the ligand leading to the $[Fe\mathbf{L}H_5]^{n+}$ species. The spectra recorded during the formation of the complex using diode array device clearly show that coordination occurs through the 8-hydroxyquinoline arm for the mixed ligands **L**^{1} and **L**^{2}.

Ligand-substitution reactions at an iron center have been assumed to be controlled by water exchange from the inner coordination shell. The rate constants may be described according to the Eigen-Wilkins mechanism[31] with the fast formation step of an outer-sphere complex (K_{os}) followed by a rate-limiting step involving the water substitution of the monohydroxylated Fe^{III} species (k_{ex}) [Equation (30)], where S is a statistical factor to correct for the composition of the outer solvation shell.[6]

$$k_{-1}' = S\,K_{os}\,k_{ex} \tag{30}$$

The rate constant k_{-1}' was found to vary by a factor of about 5 for the six tripodal ligands studied. This result suggests charge effects of the ligand since increasing values for k_{-1}' were observed on going from $\mathbf{L^5}H_7^{4+}$, $\mathbf{L^0}H_7^{4+}$ to $\mathbf{L^1}H_7^{3+}$, $\mathbf{L^4}H_7^{3+}$, $\mathbf{L^2}H_7^{2+}$ and $\mathbf{L^3}H_7^{+}$ corresponding to a decreasing number of positive charges located on the N anchor and pyridine nitrogen atoms. The role of electro-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

statics in charge effect concerning complexation reactions with hydroxamate ligands has been largely discussed by Crumbliss and al.[6,32] with discussion involving the Fuoss equation and the Debye-Hückel interionic potential involving a', the distance between the center of the positive charge of the metallic cation and the center of the charge (positive or negative) on the ligand.[33−36] (see Supporting Information, S19). The calculated K_{os} values are, from these considerations, 0.024 M^{-1} for **L^0** and **L^5** (+2, +4), 0.039 M^{-1} for **L^1** and **L^4** (+2, +3), 0.062 M^{-1} for **L^2** (+2, +2) and 0.100 M^{-1} for **L^3** (+2, +1) and were found to exhibit a good correlation with the k_{-1}' rate constants determined for ligands with an 8-hydroxyquinoline group (for $\mathbf{L^0}H_7^{4+}$, $\mathbf{L^1}H_7^{3+}$, $\mathbf{L^2}H_7^{2+}$, $k_{-1}' = 789$, 1320, 2240 M^{-1} s^{-1}, respectively) (Figure S20). This indicates that the complex formation follows the Eigen-Wilkins model. By taking a water exchange rate constant of 1.2×10^5 s^{-1} [37,38] in Equation (30), an S value of 2/7 can be deduced for $\mathbf{L^0}H_7^{4+}$, $\mathbf{L^1}H_7^{3+}$ and $\mathbf{L^2}H_7^{2+}$ which is a reasonable statistical correction for solvent shell composition for this series of ligands with similar structures.[1,32]

Some comments for the other terms of the series can be made. For $\mathbf{L^3}H_7^{+}$, complex data point of the correlation that k_{-1}'/K_{os} falls slightly below the line defined by the $\mathbf{L^0}H_7^{4+}$, $\mathbf{L^1}H_7^{3+}$ and $\mathbf{L^2}H_7^{2+}$ complexes suggesting that K_{os} has probably been overestimated. A lower a' value is reasonable owing to the smaller catechol ring size in comparison with an 8-hydroxyquinoline ring. For $\mathbf{L^4}H_7^{3+}$ (C anchor) the k_{-1}' rate constant (1750 M^{-1} s^{-1}) is intermediate between those for $\mathbf{L^1}H_7^{3+}$ and $\mathbf{L^2}H_7^{2+}$. This may be due to a larger bulkiness of $\mathbf{L^4}H_7^{3+}$ leading to a higher value for a' and hence a higher value for K_{os} in comparison with $\mathbf{L^1}H_7^{3+}$. The tripodal anchor contains one additional CH_2 and does not allow hydrogen bonding with the carbonyl oxygen atoms similar to ligands with a Tren anchor, thus increasing the bulkiness of $\mathbf{L^4}H_7^{3+}$ with respect to $\mathbf{L^1}H_7^{3+}$. For $\mathbf{L^5}H_7^{4+}$ the k_{-1}' rate constant (514 M^{-1} s^{-1}) is lower than that for $\mathbf{L^0}H_7^{4+}$ (789 M^{-1} s^{-1}). A possible explanation could be that the entry of this ligand in the second coordination sphere of Fe^{III} is less favored owing to the flexibility of the binding cavity that allows rotation of the pyridine ring relative to the phenol ring and leads consequently to a smaller S value.

Conclusion

This work is the first report on the acid dissociation (and formation) kinetics of iron(III) complexes with a series of tripodal ligands, four homopodates [with two types of anchor (*tren* or C-anchor)], three types of arm (catechol or 8-hydroxyquinoline or pyridinophenol) and two heteropodates (mixing catechol or 8-hydroxyquinoline).

Analysis of kinetic data shows that there is a common mechanism in all the series when the ligand structure is varied. The mechanism of the dissociation is more complex than the successive departure of the three arms around the iron(III) as observed in the literature for linear ligands[1] (three successive bidentate moieties). The dissociation of the first arm (from a hexadentate to a tetradentate complex) is in all cases observed but too fast to be measured. The dissociation then follows a process going from the tetradentate complex with the originally di-coordination of the two concerned arms to the tetradentate bis(salicylate) complex. During this process, bond cleavage of Fe−N_{pyr} or Fe−O with protonation of N or O, followed by proton-independent Fe−O(=C) bond formation to close the salicylate ring could be characterized in most cases. The comparison of these reaction rate constants reflects the influence of chelate donor strength (catechol or pyridinophenol vs. 8-hydroxyquinoline) and the rate of rotation of the amide bond between the anchor and the arm in question. The rate constants for the leaving of the ultimate salicylate arm indicate a proton-dependent (k_1) and a proton-independent (k'_1) reaction. The rate constants k_1 and k_1' span over a range of several order of magnitude: five orders for k_1 (184 to 0.0012 $\times 10^{-3}$ M^{-1} s^{-1}) and three and a half orders for k'_1 (22 to 0.012 $\times 10^{-3}$ s^{-1}). The role of electrostatics in control of the dissociation rate of the last step is evidenced for the 8-hydroxyquinoline moieties. Interesting correlations could be obtained which yielded information on the transition states for the two mechanisms.

From thermodynamic and kinetic studies on aqueous solutions of such Fe^{III} complexes, we believe that analysis of rates of Fe−N or Fe−O bond cleavage of the species and the proposed structures for the transition states will help in the designing of new ligands for appropriate exchange of Fe^{III} in biological systems.

Experimental Section

Materials: All commercial reagents were of the highest purity grade and were used without further purification. Iron(III) stock solutions were prepared by dissolving the appropriate amount of ferric perchlorate hydrate (Aldrich) in standardized $HClO_4$ solution. The solutions were standardized for ferric ion concentration spectrophotometrically by using a molar extinction coefficient of 4160 M^{-1}·cm^{-1} at 240 nm.[39] The ligands were synthesized according to procedures previously described (**L^0**,[17a] **L^1**,[20] **L^2**,[20] **L^3**,[15] **L^4**,[40] **L^5**[18]).

Kinetics Studies: Kinetic measurements were performed with a KINSPEC UV (BIO-LOGIC Company, Claix, France) stopped-flow spectrophotometer equipped with a diode array detector (J & M) and connected to a microcomputer. The reported rate constants are the average of about 6 repeat determinations (standard deviation in the range 1−2%). The kinetic data were treated on-line with the commercial BIO-KINE program (BIO-LOGIC Company, Claix, France). The ionic strength was fixed at $I = 2$ M ($NaClO_4$, $HClO_4$) due to the H^+ concentrations which were up to 1 M. This allowed comparisons with literature data. Formation kinetics were carried out under pseudo-first-order conditions at 25 °C with Fe^{III} in excess with respect to the ligand. The Fe^{III} concentration spanned the range 5×10^{-3} to 3×10^{-3} M for each H^+ concentration which was over the range 0.03 to 0.1 M. A solution containing Fe^{III} and H^+ and a solution containing the ligand (1×10^{-4} M) at the same ionic strength were mixed on the stopped-flow apparatus. In each case, first order kinetics were observed. The acid

hydrolysis kinetics of the $Fe^{III}-\mathbf{L}^{n}$ complexes were studied under pseudo-first-order conditions in the presence an of excess protons ($[H^+]$ range 0.01 to 1 M) at 25 °C. The initial pH of the $Fe^{III}-\mathbf{L}^{n}$ solution (ca. 1×10^{-4} M) was ca. 5.

One- and Three-Dimensional Coordination Polymers Containing Organic Ligands Produced Through in situ Hydrothermal Reactions

Xi-Xue Hu,[a] Cheng-Ling Pan,[a] Ji-Qing Xu,*[a] Xiao-Bing Cui,[a] Guang-Di Yang,[b] and Tie-Gang Wang[a]

Keywords: Acylation / Coordination polymers / Hydrothermal synthesis / Cobalt

Two novel coordination polymers of cobalt(II), $[Co(\mu_3\text{-}H_2bbh)(phen)]_n$ (**1**) and $[Co(\mu_4\text{-}H_2bbh)(H_2O)_2]_n$ (**2**) (phen = 1,10-phenanthroline; H_4bbh = benzene-1,2,4,5-tetracarbo-1,2:4,5-dihydrazide), in which H_2bbh ligands are in situ generated by an acylation reaction of H_4bta (H_4bta = benzene-1,2,4,5-tetracarboxylic acid) with hydrazine hydrate under hydrothermal conditions have been synthesized and structurally characterized.

Introduction

The construction of metal-organic coordination polymers based on complexes of transition metals and multifunctional bridging ligands has proven to be an interesting field due to the intriguing network topologies and potential functions of this new class of materials.[1] Bridging ligands containing N-, and/or O-donors, for example multidentate aromatic polycarboxyl systems, including benzene-1,3-dicarboxylate,[2] -1,4-dicarboxylate,[1a,3] -1,2,3-tricarboxylate,[4] -1,2,4-tricarboxylate,[5] -1,3,5-tricarboxylate,[6] and especially benzene-1,2,4,5-tetracarboxylate,[7] have been widely used for hydrothermal syntheses of coordination polymers of metals,[8] and the syntheses occur mainly through direct interaction between the metal ion and the carboxylate group to construct one-, two- and three-dimensional networks in a variety of coordination modes. The hydro(solvo)thermal method has proved to be a promising technique in the preparation of highly stable, infinite metal−ligand frameworks[9] and the modification of organic ligands. So far, five types of organic ligand reactions under hydrothermal conditions have been uncovered, namely hydrolysis of ester or cyano groups into carboxylate groups,[8a,8c,9] substitution of a carboxylate group by a sulfonate group,[10] oxidative coupling of *o*-phenanthroline to generate a 2,2-biphenanthroline,[11] hydroxylation of aromatic rings[8b,12] and cycloaddition between the cyano group and the azide groups.[13] These reactions represent promising new routes for constructing novel coordination polymers under hydro(solvo)thermal condition.

We wanted to synthesize novel coordination polymers containing new ligands produced through an in situ reaction between the reactants under hydrothermal condition. Based on known reactions, it may be expected that generation of the target products could be achieved by utilizing an acylation reaction between benzene-1,2,4,5-tetracarboxylate and hydrazine hydrate.

Fortunately, we obtained two novel Co^{II} coordination polymers, $[Co(\mu_3\text{-}H_2bbh)(phen)]_n$ (**1**) and $[Co(\mu_4\text{-}H_2bbh)(H_2O)_2]_n$ (**2**). To the best of our knowledge, these are the first two examples in which new organic ligands have been generated by acylation and coordinated by transition metal ions to form novel polymers. Scheme 1 depicts equations representing the formation of the two compounds.

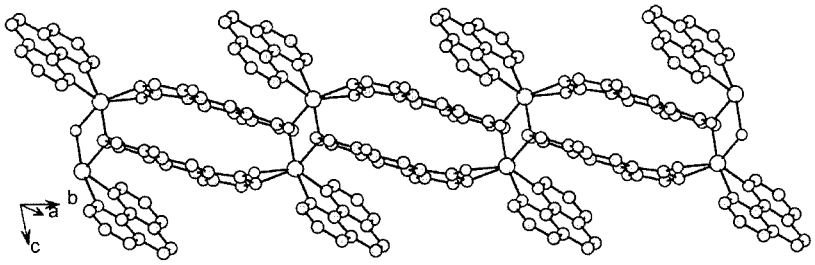

Figure 1. View of the double-chain structure of compound **1**

Results and Discussion

A single-crystal X-ray diffraction study revealed that compound **1** possesses a one-dimensional double-chain structure, as shown in Figure 1.

As shown in Figure 2, the coordination sphere of the Co^{II} site is defined by three acyl oxygen atoms O(2), O(3) and O(3A), one acylamino nitrogen atom N(5) and two nitrogen atoms N(1) and N(2) from phen, leading to a distorted octahedral geometry. In the coordination environment, N(5) and O(2), and N(1) and N(2) chelate the cobalt atom, while O(3) and O(3A) adopt a bidentate bridging mode connecting two cobalt atoms. The H_2bbh ligand shows a μ_3-coordination mode. No hydrogen atoms were found at N(3A) and N(5) by single-crystal X-ray analysis but the hydrogen atoms attached to C, N(4A) and N(6) were accurately located. The neighboring cobalt atoms are held together by the bridging acyl oxygen atoms with Co−Co(A) distances of 3.296(4) Å. It is very interesting that the Co_2O_2 cores including Co, Co(A), O(3) and O(3A) in adopting a parallelogram geometry are interconnected by H_2bbh bridging ligands to generate a centipede-like double-chain structure propagated along the *b* axis direction. In the double-chain, the planes of two H_2bbh ligands between each two Co_2O_2 cores are parallel to each other and perpendicular to the *bc* plane. The phen rings as auxiliary ligands on the same side of the chain are also parallel to each other.

As shown in Figure 3, the Co^{II} atom environment in **2** can be described as octahedral (Figure 3) with two acyl oxygen atoms [O(2) and O(2A)] from $[H_2bbh]^{2-}$ and two H_2O groups that comprise the equatorial plane, with the axial positions being occupied by two nitrogen atoms [N(1) and N(1A)] from $[H_2bbh]^{2-}$. The H_2bbh ligand displays a μ_4-coordination mode through an acyl oxygen atom and an acylamino nitrogen atom linking with four Co^{II} atoms.

Figure 4 shows the 3-D structure of compound **2** and Figure 5 shows a schematic representation revealing the 4-connected topology of the 3-D network of **2**. From these figures it can be seen that the Co atoms and H_2bbh ligands are alternately interconnected into 2-D sheets and these sheets are again interlinked to form the 3-D structure. Specifically, both the Co centers and the H_2bbh ligands can be divided into two classes. Each of the first type of Co atoms is connected to four H_2bbh ligands in the same layer, and each of the second type is connected to two H_2bbh ligands in the same layer and two H_2bbh groups in neighboring layers. Similarly, each of the first class of H_2bbh ligands is linked to four Co centers in the same layer, and each of the second type is linked to two Co centers in the

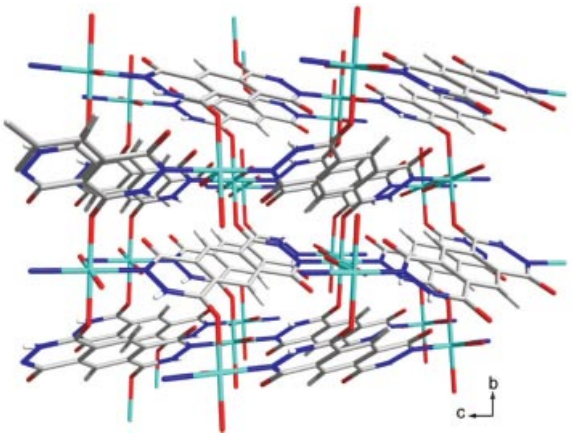

Figure 4. Packing diagram along the [100] direction for compound **2**

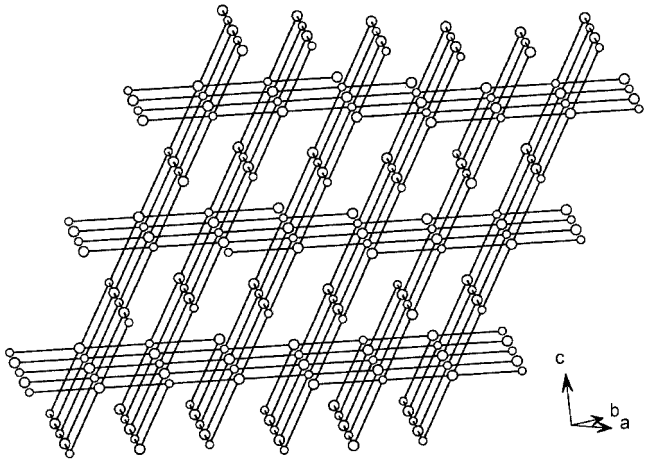

Figure 5. Representation showing the topology of the 3-D network for **2**; the H_2bbh ligands are shown as filled large circles and the cobalt atoms as open small cycles

same layer and two Co centers in neighboring layers. Through the second type of Co atoms and H_2bbh ligands, the layers are intergrated into the 3-D framework. Figure 4 indicates that in the solid state of **2**, there exist channels constructed of 22-membered rings consisting of three Co atoms and three H_2bbh ligands. In fact, the channels are intertwined in the 3-D network (Figure 5).

Compounds **1** and **2** were synthesized under similar conditions except for the use of phen in the preparation of **1** but not of **2**. However, **1** and **2** are of different structural types. The former is a chain while **2** displays a 3-D open framework. It is possible that the coordination ability and steric effect of the phen group are much larger than those of H_2O, resulting in th occurrence of this situation. This result clearly shows that auxiliary ligands, as well as bridging ligands, also play an important role in regulating the structures of synthesized compounds.

Preliminary magnetic studies of **1** and **2** show that the values of the effective magnetic moments μ_{eff} at room temperature are 4.50 μ_B and 4.53 μ_B per Co formula unit, respectively, while the spin-only magnetic moments are 3.87 μ_B with $S = 3/2$ and $g = 2.0$ $\{\mu_{eff} = g[s(s+1)]^{1/2}\mu_B\}$. The differences are due to additional orbital momentum. When the temperature was lowered, μ_{eff} gradually decreased from 4.50 μ_B and 4.53 μ_B at 300 K to 1.24 μ_B and 2.27 μ_B at 2.0 K for **1** and **2**, respectively. Both plots of $1/\chi_m$ vs. T obey the Curie−Weiss law $[\chi_m = C/(T - \theta)]$ at 5000 Oe with Weiss constants, $\theta_1 = -17.74$ K and $\theta_2 = -13.13$ K, and Curie constants, $C_1 = 2.668$ emu·mol^{-1}·K and $C_2 = 2.653$ emu·mol^{-1}·K for **1** and **2**, respectively, which indicates the occurrence of antiferromagnetic coupling between the Co^{II} atoms in **1** and **2**.

In conclusion, the reactivity of organic ligands under hydrothermal condition shows some differences from that under usual conditions, thus indicating that modification of organic ligands under hydrothermal conditions is very promising for the synthesis of useful new ligands. The work described herein once again provides strong evidence that a wide variety of new coordination polymers can be produced by hydrothermal generation of new bridging ligands in the presence of appropriate metal ions, although it remains a great challenge to develop this technique to a stage where a desired structure or crystal symmetry can be ensured.

Experimental Section

Syntheses of 1 and 2: Dark brown block crystals of **1** were synthesized hydrothermally from a mixture of $CoCl_2·6H_2O$, H_4bta, $N_2H_4·H_2O$, phen and H_2O (molar ratio 14:21:13: 8:1500) in a 30-mL Teflon-lined stainless steel autoclave (25 mL, capacity) under autogenous pressure heated to 170 °C for 4 d and cooled to room temperature. The crystalline product was filtered, washed with distilled water, and dried at ambient temperature to give 0.42 g of the compound (yield 41% based on cobalt). Orange block crystals of **2** (yield 46% based on cobalt) were obtained under the same reaction conditions and experimental procedures as those for **1** using a molar ratio of $CoCl_2·6H_2O/H_4$bta/$N_2H_4·H_2O/H_2O$ = 2.6:5:4.5:625.

COVER PICTURE

The cover picture shows a general cartoon of heterogeneous catalytic processes performed on Suzuki-type cross-coupling reactions. The submerged gear represents the hub in the system, holding the active sites of the catalysts which are triazatriolefinic palladium(0) complexes. The catalysts are anchored through oxidative electropolymerization of the pyrrole groups contained in their structures, and can be monitored through the electroactivity of additional ferrocene entities also present. Details are discussed in the article by A. Llobet, A. Roglans et al. on p. 1601 ff.

Perspectives in Inorganic Structural Genomics: A Trafficking Route for Copper

Fabio Arnesano,[a] Lucia Banci,[a] Ivano Bertini,*[a] and Simone Ciofi-Baffoni[a]

Keywords: Structural genomics / Copper / Metalloproteins / Chaperone proteins

Metal ions are essential for living organisms because they are involved in many fundamental biological processes. Increasing evidence indicates that there are no free copper ions in the cell; however, a recently discovered category of proteins (metallochaperones) is responsible for copper ion trafficking and delivery to either specific target enzymes or to membrane ATPases for metal translocation. A search in the available genomes for copper chaperones and soluble domains of the ATPases reveals a large variety of systems. In this Microreview, the example of copper transfer from outside a yeast cell into the Golgi organelle is considered, as well as related processes in other eukaryotes and in prokaryotes. The investigation of the structure and metal-binding properties of these proteins is crucial for understanding the process of copper trafficking at the molecular level and how coordination chemistry may contribute to the interpretation of the energetics of the metal environment.

Introduction

Life developed in an inorganic matrix, i.e. the Earth's crust. Living organisms have since learned how to acquire the correct amounts of essential inorganic elements and how to defend themselves from unnecessary or poisonous ones. Metal ions need a number of proteins both in order to be acquired/excreted, and in order to be transported from the outside of the cell to the final target, which is a metalloprotein.[1] Such processes are performed by soluble proteins[2−4] and membrane proteins, such as pumps[5−7] and permeases.[8] Such proteins are encoded in genomes or plasmids, but it is not obvious from a genome analysis which proteins are involved in the above processes. What can be done, however, is to search in the gene bank proteins similar to those already known to bind metal ions.[9,10] The identification of a metal-binding motif (i.e. a pattern of conserved amino acids acting as ligands) can be exploited in the search.[11] Another tool for the identification of proteins

Fabio Arnesano (far right) was born in Lecce, Italy in 1973. He studied Chemistry at the University of Florence where he received his laurea degree in 1997 and his Ph.D. in 2000. He is currently a postdoctoral fellow at the Magnetic Resonance Center of the University of Florence. His research is devoted to NMR spectroscopy and biophysical characterization of metalloproteins and protein complexes involved in electron transfer and metal-trafficking processes, with a focus on heme and copper proteins.

Lucia Banci (center left) is Professor of Chemistry at the University of Florence, Italy. Her research interests are devoted to structural characterization of biological molecules through NMR spectroscopy, the methodological aspects of its application to proteins containing paramagnetic metal ions, computational simulations of protein structure and dynamics, and genome browsing and functional genomics.

Ivano Bertini (center right) was born in 1940, obtained the Italian degree of Doctor in Chemistry at the University of Florence in 1964 and then the Libera Docenza in 1969. He became full professor in General and Inorganic Chemistry in 1975 at the University of Florence, where he is now. He received the Laurea Honoris Causa from the University of Stockholm in 1998, from the University of Ioannina in 2002 and from the University of Siena in 2003. He is a member of the Academia Europaea and of the Italian Accademia dei Lincei. Following his initial studies on theoretical/physical inorganic chemistry, he has, since 1975, been studying the structure-function relationships of metalloproteins. In 1994, he transformed his laboratory into an NMR laboratory for studying the structural biology of metalloproteins. He has pursued the advancements of technology for determination of solution structures (particularly of paramagnetic metalloproteins), and he has developed a molecular biology department for protein expression and purification.

Simone Ciofi-Baffoni (far left) was born in Florence, Italy in 1971. He obtained his Ph.D. degree from the University of Florence in 2000. He is now a postdoctoral fellow at the same university. His research interest is focused on the structural and dynamic characterization of metalloproteins through NMR spectroscopy. His current research is particularly devoted to copper trafficking proteins to elucidate molecular mechanisms of copper homeostasis.

MICROREVIEWS: This feature introduces the readers to the author's research through a concise overview of the selected topic. Reference to important work from others in the field is included.

involved in processing metal ions is that of looking at bacterial genomes — often proteins that interact with each other are close in these genomes or they are part of a segment of DNA — called an operon — which encodes a number of interacting proteins, plus their regulator(s) and promoter(s).[12,13]

An example of this is provided by the *cop* operon of *Enterococcus hirae*,[14] responsible for copper uptake, availability, and export in the bacterium by encoding a repressor (CopY), a copper chaperone (CopZ), and an import and an export copper ATPase (CopA and CopB, respectively).[14] Understanding of the mechanisms of metal transport and regulation at the molecular level is crucial in order to shed light on a number of biological processes, including the functional defects of genes. In so doing, a lot can be learned about this area of biological inorganic chemistry, which represents a window for the expansion of the field of inorganic chemistry. The most successfully studied system is that regarding copper — as a case study, this review will be devoted to one of its trafficking pathways.

Copper can adopt two distinct oxidation states, either oxidized (Cu^{II}) or reduced (Cu^{I}). Copper proteins are involved in vital processes such as respiration, iron transport, oxidative stress protection, blood clotting and pigmentation.[15] However, because of its redox activity, free copper would be highly toxic, even at low concentrations. Therefore, free intracellular copper is absent, and its concentrations need to be regulated within very narrow limits.[16] Disruption of copper homeostasis has recently been implicated in disease states and pathophysiological conditions.[17–19]

Results and Discussion

Copper in Yeast: From the Outside to the Multicopper Oxidase Fet3

Genetic experiments with baker's yeast *Saccharomyces cerevisiae* resulted in the cloning of the first gene encoding a cellular membrane protein associated with high-affinity Cu transport (Ctr), denoted Ctr1.[20] Indeed, yeast cells lacking a functional Ctr1 gene are unable to load Cu onto cytochrome *c* oxidase.[21] Copper uptake through Ctr1 is preceded by reduction of Cu^{II} to Cu^{I}, a process mediated by the cell surface metalloreductase Fre1[22] (Figure 1).

All members of the Ctr1 family of Cu transporters have three potential transmembrane domains, a hydrophilic amino terminus typically rich in methionine residues, and a number of other conserved residues of as yet unknown functional importance.[8] The amino-terminal region (located outside the cell) of baker's yeast Ctr1 harbors eight repeats of the putative Cu-binding motif MXMXXM (M = methionine, X = generic amino acid). The carboxy-terminal region (located inside the cell, in the cytosol) of Ctr1 is rich in charged amino acids and contains quite well conserved cysteines.[8] Thus far, studies reveal that both the yeast and human Ctr1 proteins are present as homo-multimeric proteins, with high affinity for Cu.[23,24]

Several proteins are, on the other hand, implicated in low-affinity trans-membrane copper uptake in baker's yeast, including Fet4 and Ctr2. Fet4 has no significant homology to the Ctr family of high affinity copper transporters. However, biochemical and genetic evidence suggests that Fet4 is able to transport both iron and copper.[25] Ctr2, which bears homology to Ctr1, may be localized in the membrane of organelles present inside the cell, and may play a role in the mobilization of copper ions[26] between different locations inside the cells.[27] O'Halloran et al. have demonstrated that there is no free copper in a cell,[16] and therefore copper, just like other metal ions, needs to be accompanied to different cell compartments or to its final destination by proteins called chaperones, responsible for copper distribution inside the cytoplasm.[2,3] The carboxy terminus of Ctr1 contains two CXC motifs which are proposed to bind Cu^{I} and exchange it with metallochaperones.[28] In support of this, it has been recently observed that a C-ter-

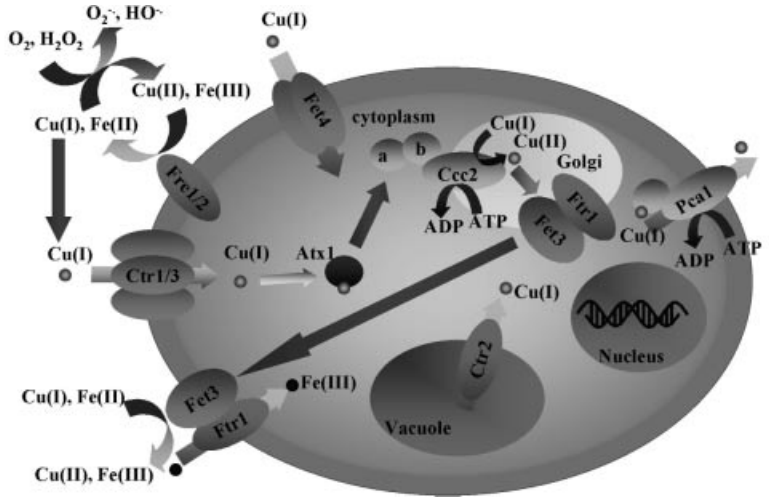

Figure 1. Some copper trafficking pathways in the yeast cell; depending on the extracellular copper concentration, copper can be transported inside the cell by two high-affinity copper transporters Ctr1 and Ctr3, or by a low-affinity Cu/Fe-transporter Fet4; Ctr2 could be involved in copper efflux from the vacuole; delivery of copper involves the metallochaperone Atx1 that shuttles copper to Ccc2, a P-type ATPase located in the trans-Golgi network, and is responsible for copper translocation; once copper is in the lumen of the secretory pathway, it is loaded onto Fet3, a multicopper-ferroxidase essential for high affinity iron uptake that partners with the Ftr1 protein

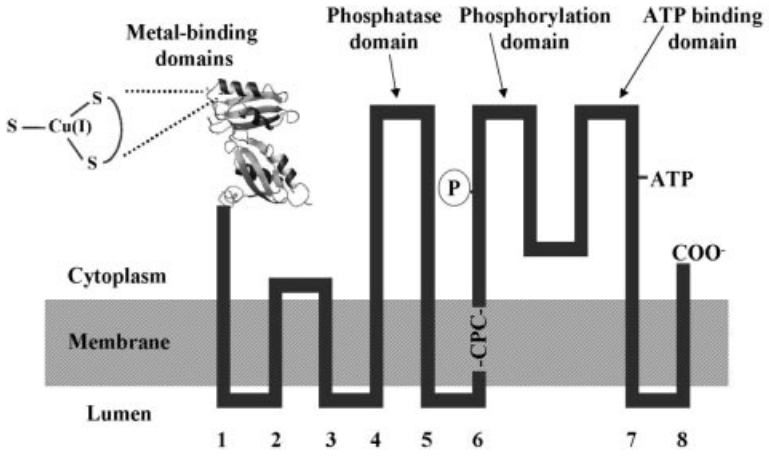

Figure 2. Schematic model of the copper-transporting ATPase Ccc2 from *S. cerevisiae*; the predicted transmembrane segments and the cytosolic domains are shown; "P" indicates a phosphate group; the copper binding motifs CXXC and CPC are also indicated; a similar structural organization is shared by all heavy metal P-type ATPases, but the number of N-terminal metal-binding domains is variable

minal domain of yeast Ctr1 exchanges Cu^{I} rapidly with the copper chaperone Atx1.[28] Atx1 delivers copper to the soluble copper domains of Ccc2, a P-type ATPase located in the Golgi membrane [29,30] (see Figure 1), which transfers copper to enzymes inside the Golgi organelle.[31] On the contrary, a different ATPase (Pca1), located on the cell membrane, appears to be involved in copper export from yeast.[32]

Ccc2 and Pca1 belong to the family of cation-transporting P-type ATPases (see Figure 2), which contain eight transmembrane segments, an ATP binding/phosphorylation domain (between transmembrane segments 6 and 7) and a phosphatase (or actuator) domain (between transmembrane segments 4 and 5).[5−7] Copper ATPases possess a variable number of N-terminal soluble metal-binding domains and a conserved CPx [C = cysteine, P = proline, x = C (cysteine) or H (histidine)] motif in transmembrane segment 6. Ccc2 has two soluble domains of about 70 amino acids, each containing a Cu^{I} binding CXXC motif. Pca1 contains only one domain preceded by a Cys-rich region of about 400 amino acids.[32]

Once Cu^{I} is bound to one or two soluble domains of Ccc2, it is transferred inside the Golgi organelle. It has been suggested that, during this transfer, Cu^{I} is oxidized to Cu^{II}, consistent with the more oxidizing environment of the Golgi organelle.[33] Copper is then loaded onto Fet3, a multicopper-ferroxidase essential for high-affinity iron uptake. When loaded with copper, Fet3 makes a complex with the iron transporter Ftr1[34] and, together, they move towards the cell membrane,[35] where Fet3 catalyzes the oxidation of Fe^{II} to Fe^{III}, which is then bound by Ftr1. Ftr1 and Fet3 are primarily expressed in oxygenated cultures, whereas anaerobic conditions induce the low affinity copper/iron transporter, Fet4.[36] Very recently, it has been observed that Fet3 also has a cuprous oxidase activity at the cell membrane, thus buffering the Cu^{I}/Cu^{II} ratio through an interplay with the cupric reductase Fre1.[37] By removing the Atx1 gene, iron uptake does not occur any more, as a consequence of failure to provide the metal cofactor to Fet3. These data, as well as other experimental evidence, point out at the tight interplay between copper and iron metabolisms. Figure 1 shows the mechanism by which Cu^{I} is acquired by Ctr1, taken by Atx1, released to the membrane protein Ccc2 and transferred to Fet3.

The structures of reduced apo- and Cu^{I}-loaded Atx1 were solved by NMR spectroscopy in Florence in collaboration with the Northwestern University[38] (Figure 3, top).

The solution structure of *S. cerevisiae* Cu^{I}-Atx1 exhibits a βαββαβ-fold with the Cu^{I} ion coordinated by two cysteine residues, Cys 15 (in loop 1) and Cys 18 (in helix α1), of a conserved CXXC motif. This fold is the same as that found by X-ray diffraction of the Hg^{II} derivative.[39] Atx1 shares significant sequence similarity (30 % residue identity) with a periplasmic mercury resistance protein, MerP.[40] Both the MerP solution structure[41] and the Hg^{II}-Atx1 crystal structure[39] show an Hg^{II} ion coordinated by the sulfur atoms of the two cysteines of the CXXC motif with a linear coordination geometry. In contrast, the solution structure of Cu^{I}-Atx1 has an average S−Cu−S angle of 120±40°, suggesting that Cu^{I} prefers a coordination number higher than two. EXAFS analyses of Cu^{I}-Atx1[42] and of its homologous protein, CopZ, from *Bacillus subtilis*[43] and *Enterococcus hirae*[44] showed that a third sulfur atom completes the coordination sphere of Cu^{I}, indicating its preference for a three-coordinate environment. A conserved Met residue, two residues upstream of the CxxC consensus motif, is a candidate for this third ligand. However, in the structures of Cu^{I}-Atx1 and Cu^{I}-CopZ from *B. subtilis*, the average positions of the Met sulfur atoms are 7.0±1 Å and 6.2±1 Å from copper, respectively, which rule their involvement in copper coordination.[38,45] Even in the Hg^{II}-Atx1 crystal structure[39] the Met sulfur is too far from copper (8.1 Å), suggesting it is not involved in metal coordination. The exposed location of the metal site suggests that the third ligand may be provided by an external thiol group.

These proteins are prepared by incubation of the apoprotein with a Cu^{I} complex in the presence of a thiol reductant, dithiothreitol (DTT).[29] In vivo, DTT is likely to be

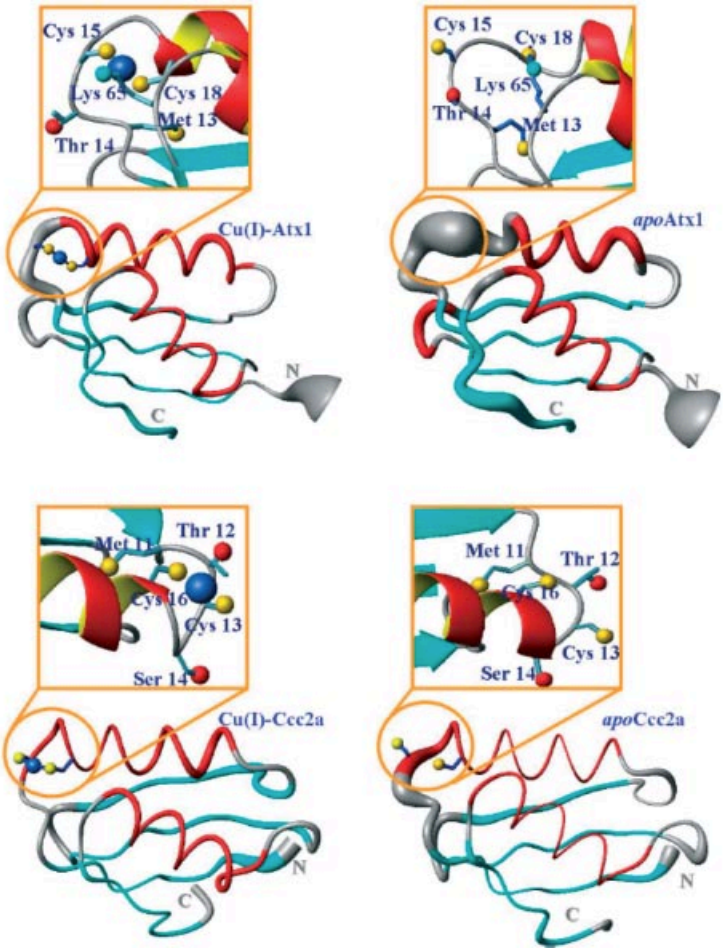

Figure 3. Solution structures of Cu^I- and apo-loaded Atx1 (top left and top right, respectively) and Cu^I- and apo-loaded Ccc2a (bottom left and bottom right, respectively); the structures are represented as a tube whose radius is proportional to the structural resolution; helices are colored in red and β-strands are colored in cyan; the insets show the copper binding site where copper is represented as a blue sphere; copper-binding cysteines and other neighbouring residues are also indicated

replaced by glutathione, which is present at high concentration (about 5 mM) inside the cell. When copper reduction is carried out with ascorbate, the EXAFS spectra of Cu^I-CopZ indicate that one oxygen atom of ascorbate is present in the first coordination sphere of copper, together with the two sulfur atoms of the Cys residues.[43] The three-coordinate environment of copper, with one ligand being exogenous and easily detectable, has a crucial role in the metal transfer process (see later).

The overall folding of apoAtx1 is essentially identical to that observed for the copper-bound form of the protein, with the exception of helix α1, which is shorter by one helical turn at the N-terminus.[38] Comparison of the Cu^I- and apo-conformations of the protein also reveals that the Cu^I-binding cysteines move from a buried site in the metal-bound form to a solvent-exposed conformation on the surface of the protein, after copper release (see Figure 3, top). Slight structural changes, involving both the charged and hydrophobic residues close to the metal-binding site,[38] may signal to the partner whether the metallochaperone is in the demetalated or in the copper-loaded form, and may trigger binding of Atx1 to Ccc2.

The structure of the first domain of Ccc2 (Ccc2a) was solved by NMR spectroscopy, and exhibits a βαββαβ, ferredoxin-like fold similar to that of its partner Atx1[46] (Figure 3, bottom). The overall fold of Ccc2a remains essentially unchanged upon copper loading. Unlike Atx1, only few conformational changes are observed in Ccc2a upon copper release, and the metal-binding region (including the conformation of the metal-binding cysteines), is well defined in both apo and holo forms, suggesting that the metal site in apoCcc2a is pre-organized to some extent to receive the copper ion.[46] Again, the structure indicates the copper environment is three-coordinate (S−Cu−S average angle 120±30°).

Modeling of the whole N-terminal region of Ccc2, encompassing the two soluble domains, was performed on the available structure of the homologous protein from *B. subtilis*,[47] and suggests that the two copper binding sites are far apart and cannot interact with each other. However,

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

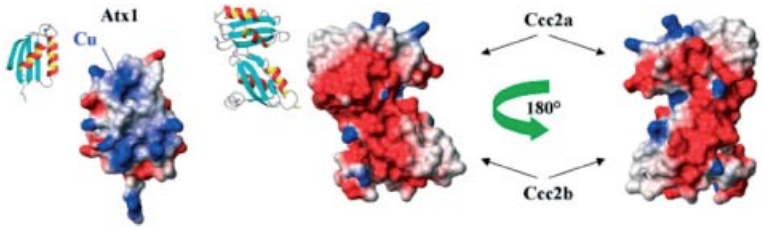

Figure 4. Electrostatic surface potential of Cu^{I}-Atx1 from *S. cerevisiae* and of a structural model of the two soluble domains of Ccc2 from *S. cerevisiae* based on the structure of CopAab from *B. subtilis*; the ribbon representations show the orientation of the two proteins; the copper binding cysteines of the CXXC motifs of Atx1 and Ccc2 domains are indicated in yellow; copper is shown as a blue sphere

they can interact with Atx1. Indeed, the surface of Atx1 is positively charged, whereas those of the Ccc2 domains are negative (Figure 4).[48] The electrostatic interaction is the long-distance driving force which brings the two partner proteins together.

The protein surface interacting with the partner can be monitored by NMR spectroscopy, through the mapping of $^{1}H/^{15}N$ chemical shift changes occurring in both proteins when titrated with the partner [Figure 5(A)].[48,49] These residues are located in loops 1 and 5, helix α1, and the C-terminal part of helix α2 in both proteins. Besides the metal-binding cysteines and the charged amino acids, some polar and hydrophobic residues are involved in interactions at the interface. As mentioned above, the hydrophobic patches at the protein interface are different between the apo and the copper-loaded forms of Atx1, whereas Ccc2a maintains a similar conformation and pattern of hydrophobic contacts around the metal-binding site, regardless the metalation state. Comparison with the structures of homologous proteins confirms that in most of the cases metal binding affects a hydrophobic patch around the metal site in metallochaperones, possibly for tuning and optimizing the hydrophobic interactions with the ATPase domains.[50]

Thermodynamic and kinetic considerations suggest that the copper chaperones are designed to increase significantly the rate of copper transfer between physiological partners and then to overcome the extraordinary copper chelation capacity of the eukaryotic cytoplasm. In this sense, metallochaperones work like enzymes, lowering the energetic barriers along a specific reaction pathway. The thermodynamic gradient for metal transfer between Atx1 and Ccc2 is shallow (K_{eq} = 1.5), establishing that transfer of copper from Atx1 to Ccc2 is not based on a higher copper affinity of the target domain.[51] Instead, Atx1 allows rapid metal transfer to the ATPase ($k_{ex} > 10^{3}\ s^{-1}$),[48] which, in turn, transfers copper across the membrane, thus driving the thermodynamic overall equilibrium. A low activation barrier for transfer between partners results from complementary electrostatic forces that orient the metal-binding loops of Atx1 and Ccc2 for formation of copper-bridged intermediates.[30,51]

As mentioned above, the exposed location of the metal-binding site allows copper to expand its coordination sphere, thus becoming three-coordinate. During the copper transfer process, the third labile copper ligand in Cu^{I}-Atx1 would be displaced by the first Cys of the CXXC motif on the partner molecule, to form a three-coordinate intermedi-

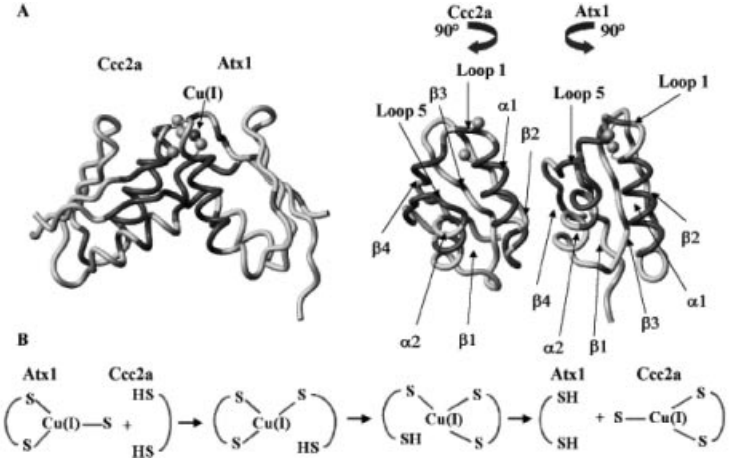

Figure 5. (A) The Ccc2a:Atx1 adduct model calculated using NMR chemical shift mapping; the view on the right-hand side shows the molecules rotated by 90° to expose the interaction surfaces; residues involved in the interaction are in dark grey; residues not involved in the interaction or not observed are in light grey; the copper ion is in dark grey and the sulfur atoms of the copper-binding cysteines are in light grey; secondary structure elements are indicated; (B) the proposed mechanism for copper transfer between Atx1 and a domain of the Ccc2 protein

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

ate. When the second Cys of Ccc2 binds copper, one Cys of Atx1 is detached, thus weakening the interaction of copper with Atx1. In the final step, the second Cys of Atx1 is detached, (probably) replaced by an exogenous ligand, and the metallochaperone leaves in its apo form (see B in Figure 5). These structural changes are accompanied by an increase in mobility of residues at the interface, which may favor complex dissociation after copper release.[48]

What Determines Metal Selectivity?

The βαββαβ structure containing a CXXC metal-binding motif has been adopted in nature to carry a variety of metal ions (Cu, Hg, Zn, Cd, Pb) with selective affinity.[52−54] Atx1 shares significant structure similarity with a periplasmic mercury resistance protein (MerP), which interacts with a membrane protein of the detoxification operon.[40] The solution structure of MerP[41] shows an Hg^{II} ion coordinated by the two cysteines of the CXXC motif, with a linear coordination geometry. It has also been shown that MerP is capable of binding to other divalent metal ions with lower affinities.[54,55] Similarly, the copper chaperone CopZ from *E. hirae* forms specific metal complexes with copper, mercury, cadmium and cobalt with the following order of affinity: $Cu^{I} > Hg^{II} > Cd^{II} >> Co^{II}$.[56] In addition, soluble domains of bacterial zinc-transporting[57] and cadmium-transporting ATPases,[58] either experimentally found[59] or predicted to have the βαββαβ fold, possess the CXXC binding motif. Therefore, it can be inferred that the metal-binding selectivity does not reside in the overall fold but in sequence variations close to the metal site.

For zinc ATPases, sequence analysis leads to the earlier suggestion that an Asp residue, which is found just before the N-terminal cysteine of the CXXC consensus motif, may modulate metal-binding affinity.[9] EXAFS data on the N-terminal domain of the zinc ATPase ZntA from *E. coli* indicate that Zn is coordinated by two sulfur atoms and two N/O atoms.[59] The structure of ZntA has been recently solved[59] and suggests that the conserved Asp residue can indeed coordinate zinc. The presence of three negative charges (one aspartate and two cysteines) ought to provide a more favourable electrostatic contribution for the binding of a Zn^{II} ion with respect to a Cu^{I} ion. Moreover, in terms of hard/soft acid-base theory, the Asp oxygen will stabilize binding of the harder (or less polarizable) Zn^{II} ion more than the highly polarizable Cu^{I} ion. In copper chaperone sequences, the position immediately preceding the N-terminal Cys in the metal-binding loop is often occupied by a Thr residue, which provides a second-shell interaction for copper.[60−62] These data suggest that the amino acid at this position plays a role in metal ion selectivity.

Other factors could determine metal selectivity of the CXXC metal-binding motif in a βαββαβ structure, such as the size of the binding pocket (which can be controlled by the tightness of the turn of the binding loop), or by electrostatics. The nature of the residues in the turn of the metal-binding loop affects their interactions with the solvent and with other protein residues, and can contribute to the turn tightness and/or to electrostatic properties.

Comparison of Homologous Proteins

The genome-sequencing projects developed in the last few years have made available the primary sequence of an enormous number of new genes. The draft sequence of the human genome[63] is now available, together with the complete genomes of many other organisms (see http://www.ncbi.nlm.nih.gov). Functional associations of neighboring genes can be detected by bioinformatic tools and can be used to identify potential protein partners.[12,13] This huge amount of incoming information has stimulated the development of Structural Genomics projects (http://www.spineurope.org/, http://www.nigms.nih.gov/psi/ and http://www.rsgi.riken.go.jp/), with the aim of elucidating the function of proteins through the determination of their three-dimensional structure. The idea can be translated in the motto: "*From sequence to function through structure*". Moreover, genome sequencing allows us to compare homologous sequences in different species, in an "orthologue" approach, and to model them when sequence identity with at least one protein of known structure is higher than 30 %.[64] Structure similarities allow the function of one family of proteins to be predicted from that of the other. In the case of metalloproteins, conserved residues forming the consensus motifs for metal binding can be used as selection criteria in a genome-wide search, together with sequence identity thresholds.[11] An orthologue search shows that proteins homologous to yeast Atx1 and Ccc2 are found in all the eukaryotes and in many bacteria.[9] Structural models can be calculated using the high-resolution solution structures of yeast proteins as templates, and structural modelling allows us to identify common structural features, such as the hydrophobic core, electrostatic potential surfaces and metal-binding site residues.

Searches have shown that bacteria are very diverse, and may develop alternative routes for copper homeostasis.[9] *B. subtilis* has a CopZ which acts as chaperone[45] as well as a CopA which is an ATPase containing two soluble metal-binding domains.[60] In this organism it has been shown that the CopZ-CopA interaction mechanism is used for copper excretion.[65] It is peculiar that CopZ has opposite overall charge with respect to its eukaryotic homolog Atx1 and, of course, opposite charges are displayed by the two metal-binding domains of the ATPase.[66] In *B. subtilis*, the first domain of CopA is not well folded in vitro, but a point mutation at position 46 is sufficient to fold the protein properly.[67] It is possible that the first domain is not folded in vivo or not used at all. Copper ATPases of other bacteria have indeed only one soluble domain. In *E. hirae* the homologous proteins are thought to function in copper uptake.[68] The *cop* operon of *E. hirae*, in addition to the CopA ATPase and the copper chaperone CopZ, consists of two more genes, one encoding a repressor (CopY), which, upon receiving copper from CopZ, breaks its interaction with DNA.[44,69] The other is a second P-type copper ATPase

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

(CopB), which is involved in the extrusion of copper when it reaches toxic levels[68] (Figure 6, top).

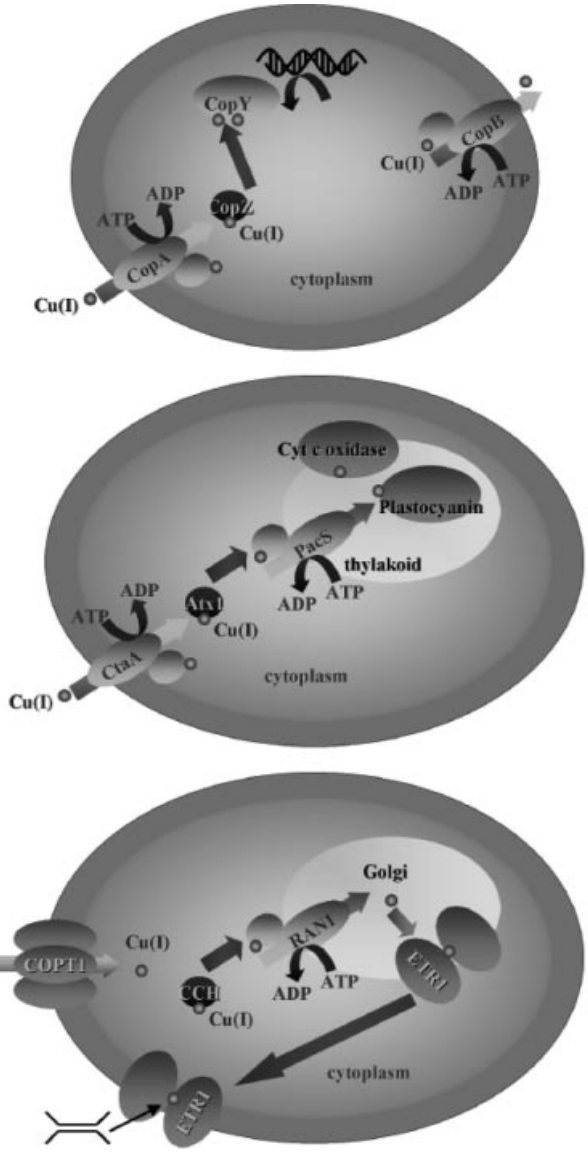

Figure 6. Copper-trafficking pathways in the bacterium *Enterococcus hirae* (top), in the cyanobacterium *Synechocystis* PCC 6803 (center) and in the plant *Arabidopsis thaliana* (bottom)

Some cyanobacteria have a peculiar cellular organization which involves organelles called thylakoids. These contain cytochrome *c* oxidase and plastocyanin, and both proteins require copper to function. In these bacteria, two copper-transporting ATPases are present, namely CtaA and PacS.[70] The former is located on the external cellular membrane and is involved in copper uptake, whereas the latter is on the thylakoid membrane and transports copper inside this organelle for its delivery to copper-requiring proteins.[71] Copper is shuttled between these two ATPases by a soluble small protein, which is able to interact with the soluble copper-binding domains of both ATPases.[70] Interestingly, this copper chaperone possesses a His residue on loop 5 in the position corresponding to Lys 65 in Atx1 from *S. cerevisiae*. The imidazole ring of the latter His is predicted to protrude from loop 5 of the cyanobacterial protein, providing a putative third copper ligand. This residue is proposed to influence the direction of metal transfer in the interaction of the chaperone with the amino-terminal domains of the two ATPases PacS and CtaA [72] (Figure 6, center).

Plants also need copper for a variety of functions. One of these functions is unique to this kingdom of life and involves binding of ethylene, an important endogenous plant hormone affecting many aspects of growth and development. Ethylene binding occurs through five copper-dependent ethylene receptors (ETR1, ERS1, ETR2, EIN4 and ERS2).[73] In *Arabidopsis thaliana*, one of the two plants for which the complete genome is available, a copper pathway similar to that of *S. cerevisiae* has been identified.[74] Using the yeast system as a guide, it has been postulated that copper enters the cell through COPT1, the homologue of yeast CTR2. Copper is shuttled by a soluble protein (CCH), the homologue of Atx1, to a copper ATPase (RAN1), which resides in the Golgi, like Ccc2.[74] Here, the ATPase delivers one copper ion to the ethylene receptors (ETR1 family), which thus become functional and move to the external cell membrane to sense ethylene concentrations.[74] Ethylene interacts with Cu^{I} in an electron-rich hydrophobic pocket formed by membrane-spanning helices of the ETR1 dimer[75] (Figure 6, bottom).

In humans, two P-type ATPases, Menkes (MNK)[76−78] and Wilson (WND)[79,80] proteins, and a copper chaperone (Hah1[81]), homologous to yeast Ccc2 and Atx1 respectively, are present. The key role of MNK and WND in the cellular copper trafficking is strongly determined by the intracellular localization mechanism by which these proteins manage to deliver copper to the recently synthesized copper proteins.[33,82] At low copper concentrations, both proteins are localized in the Golgi, where MNK transfers copper to lysyl oxidase, which is responsible for cross-linking collagen and elastin. At high copper concentrations, MNK moves to the external cell membrane and pumps out of the cell the excess of copper. When the intracellular copper levels are reduced, the protein returns to the Golgi membrane.[33] WND, also located in the Golgi membrane, incorporates copper (at low concentrations) into ceruloplasmin, a multicopper oxidase similar to Fet3. At high copper concentrations, WND moves from the Golgi membrane to a vesicular compartment where it releases copper. The copper-loaded vesicles are then discharged into the bile.[82]

Both proteins have six soluble metal-binding domains at the N-terminal region, in addition to an intramembrane potential metal-binding site containing a CPC motif. The soluble metal-binding domains were suggested to be involved in the copper-dependent regulation of WND. Indeed, the copper-bound N-terminal WND domains (1−6) interact with the ATP-binding domain less tightly than their apo forms, thus increasing the affinity of the domain for ATP.[83]

However, only binding of copper to the intramembrane CPC binding site is essential for the copper-dependent cata-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

lytic activity of the ATPase. This dependence is supported by the fact that mutations in the CPC motif destroy the activity,[84] whereas mutations in any or all of the six soluble domains do not.[85] It has been recently shown that affinity of the intramembrane copper-binding site is regulated by binding of copper to the 5th and 6th domains of WND, while the first four domains of WND are not involved in this process.[86] The need for six domains is not certain. Bacterial and yeast homologues have only one or two domains, suggesting that most of the metal-binding domains are not essential for the copper transport function.[9] A unique feature of mammalian copper-ATPases is their ability to undergo copper-dependent vesicular trafficking. Therefore, metal-binding domains 1−4 can be involved in the copper-dependent regulation of the ATPase subcellular localization, i.e. when copper concentration is increasing and all six metal-binding sites become occupied with the metal, the conformation of the N-terminal region changes,[87] thus inducing the translocation of the protein from the Golgi to the external cell membrane[88] or to a vesicular compartment.[89] Here, the copper ATPases act like their bacterial homologues, pumping excess copper out of the cytoplasm, thus detoxifying the cell.

The six metal-binding domains of MNK and WND are connected by linkers of different length. The longest flexible linker separates metal-binding domains 1−4 from domains 5 and 6.[9,90] Interestingly, it has been observed experimentally that the copper chaperone Hah1 interacts preferentially with domains 1−4 of WND.[53] It has been therefore proposed that domains 5 and 6 may receive copper from domains 1−4.[90] When Cu^{I}-Hah1 is added in large excess, copper is transferred to all six domains of WND, but Hah1 can also function as a regulator, by removing copper from N-terminal domains.[91] Although a slight excess of apo-Hah1 is sufficient to remove the first four copper atoms, removal of the other two copper atoms cannot be completed even using a large excess of apoHah1. It has been suggested that copper that is strongly bound to N-terminal domains of WND is essential for enzymatic activity, whereas exchangeable copper is bound to regulatory sites.[91]

The structures of a number of single metal-binding domains of MNK are available.[61,92] The other domains of MNK and WND have been modeled.[9] All the domains share a βαββαβ fold but display different surface charges. Interestingly, MNK possesses a seventh predicted βαββαβ domain between the first and the second metal-binding domains, but lacks a CXXC motif. In WND, only a short linker separates domains 1 and 2.[9] The arrangement of the last two soluble domains of MNK and WND, (i.e. those closest to the membrane) is thought to be similar to that of CopA from *B. subtilis* and Ccc2 (see above).[47]

Mutations and Illnesses

The advances in knowledge of the function of MNK and WND have been catalyzed by the fact that they are involved in two human disorders of copper transport.[93] Mutations of MNK in humans cause a copper deficiency disorder (Menkes' disease), and mutations of WND result in a Cu toxicity condition (Wilson's disease). The reason for different diseases caused by mutations in proteins of similar structure is related to the involvement of the two proteins in different patterns of cellular trafficking and their distinct pattern of tissue expression.[88,89] The Menkes gene is expressed in most tissues; the Wilson gene is expressed mainly in the liver, where it is responsible for biliary excretion of copper.

Different types of mutations have been identified which alter the copper metabolism in the Golgi (http://archive.uwcm.ac.uk/uwcm/mg/hgmd0.html). These mutations are mainly located in the transmembrane portion of the ATPases, with a few present in the soluble metal-binding and ATP-binding domains. One of the most common disease mutations, a H1069Q substitution, causes intracellular mislocalization of WND.[94] His 1069 is located in the ATP-binding domain of WND and is conserved in all copper-transporting ATPases from bacteria to mammals; experiments indicate that His 1069 is responsible for proper orientation of ATP in the catalytic site of WND prior to ATP hydrolysis.[95]

Several mutations found in Wilson's disease patients were shown to disrupt the ability of WND to interact with the soluble copper chaperone Hah1, which is homologous to yeast Atx1. Three disease-associated mutations (G85V, L492S, and G591D mutations) in the soluble metal-binding domains of WND, determine a marked reduction in interaction with Hah1, suggesting that the inability of Hah1 to deliver copper to WND constitutes the molecular basis of Wilson's disease in those patients harbouring these mutations.[96]

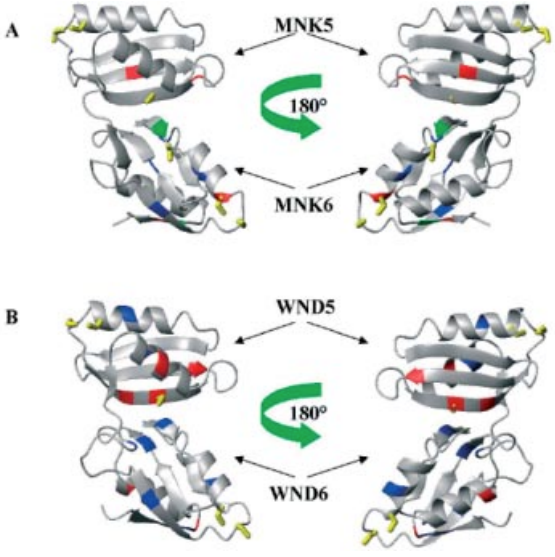

Figure 7. Structural models of the two linked soluble domains closest to the membrane (5 and 6) of the human Menkes (MNK) (A) and Wilson (WND) (B) proteins based on the structure of CopAab from *B. subtilis*; cysteine residues are indicated in yellow; mutations are coloured as follows: red = nucleotide substitutions (missense/nonsense), blue = small deletions, green = small insertions

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

The two domains closer to the membrane (5 and 6), have been shown to be essential for the functional activity of both MNK[97] and WND.[86,98] A structural model of these two domains can be obtained using the structure of CopAab from *B. subtilis*[47] as template. Significantly, although the length of the short linker between these two domains is not exactly the same for MNK/WND and CopAab,[9] residues at the interface between the two CopA domains are conserved in the last two soluble domains of both MNK and WND,[47] thus supporting a similar quaternary arrangement for this pair of domains. Mapping disease mutations on the models of these domains shows that some of them are farther from the two metal-binding sites, but they can affect the interaction between these two domains (Figure 7).

Concluding Remarks and Perspectives

The biochemistry of metal ions is becoming increasingly important, because of its tremendous implications in medicine and biology, as witnessed by the large number of proteins, emerging from genome sequencing and genetic studies, that are involved in diseases linked to metal ion homeostasis. Several copper-trafficking pathways involving metallochaperone-like proteins and P-type ATPases modulate copper ion homeostasis and delivery in bacteria and eukaryotes. These systems are at the boundary between inorganic chemistry and genomics, which has raised our interest as chemists working in the field of *inorganic structural biology*. Taking advantage of the large amount of structural information on yeast Atx1 chaperone and Ccc2 transporters and their interactions with metals, the field is moving towards a deeper understanding of homologous systems, with particular interest in the Menkes and Wilson ATPases involved in neurodegenerative disorders in humans. In these systems, it will be very useful to study the influence of the metal sites on the three-dimensional structures of proteins and multiple domain organization, in order to envisage the possible causes of degeneration and diseases. Finally, the mechanism of copper translocation across membranes needs to be fully elucidated.

Assembly of axially chiral (*S*)-2,2′-bis(3-pyridylmethyleneoxy)-1,1′-binaphthalene [(*S*)-L_1] and (*S*)-2,2′-bis(4-pyridylmethyleneoxy)-1,1′-binaphthalene [(*S*)-L_2] with $AgNO_3$ resulted in a double-stranded helical coordination polymer encapsulating guest water molecules and a helix-like complex with inter-immersion clefts, respectively, in which helical chirality is due to axial chirality of the 1,1′-bi-2-naphthol scaffold.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

The designed construction of supramolecular frameworks with helical morphology has made tremendous progress because of their practical application in functional materials and in the understanding of molecular self-assembly procedures.[1−6] The well-documented single-, double-, triple- and quadruple-stranded as well as circular and cylindrical helical complexes have been prepared from organic ligands and cleverly selected metal ions using metal-directed programmed self-assembly.[1−5] Recently, the stereoselective synthesis of homochiral helical complexes from enantiopure ligands has become an area of interest owing to their potential application in molecular recognition, asymmetric catalysis, optical materials and biomimetic chemistry.[3−5] In general, the metallo-helicated chirality in these complexes may be defined either by the chirality of at least one optically active carbon center[3d,3e] or by terminal axially chiral scaffolds in which transformation of chiral information on the helix can take place at a distance of up to 2 nm.[4] Thus, the axially chiral ligands may be used as starting materials for the design of new chiral ligands. Several helical frameworks have been constructed by introducing oligopyridine chelating groups into the axially chiral scaffolds,[4,5] but monopyridine-donor groups have been seldom employed.[6]

Optically active 1,1′-bi-2-naphthol (BINOL) has been widely used as a starting material and auxiliary in asymmetric synthesis[7] and chiral recognition[8] owing to its axial chirality and configurational stability. Based on chiral BINOL-derived ligands, Lin and co-workers have recently prepared a series of novel homochiral metallo-supramolecular complexes.[9] Several helical metal complexes based on binaphthyl chiral twisting have been also constructed by introducing the oligopyridine group into the 3,3′-[5a] and 6,6′-positions[5b] of BINOL, but helical metal-organic complexes from 2,2′-positions substituted BINOL derivatives have seldom been reported despite the fact that BINOL may form infinite helical chains through intermolecular O−H···O hydrogen bonds.[10] As an extension of our previous work[11] and with the aim of introducing valuable functional chiral spacers into pyridine-donor ligands, we have designed optically active *exo*-bidentate ligands (*S*)-2,2′-bis(3-pyridylmethyleneoxy)-1,1′-binaphthalene [(*S*)-L_1] and (*S*)-2,2′-bis(4-pyridylmethyleneoxy)-1,1′-binaphthalene [(*S*)-L_2]. Herein, we wish to report the syntheses and characterization of a double-stranded helical coordination polymer encapsulating guest water molecules $[Ag\{(S)\text{-}L_1\}(NO_3)\cdot H_2O]_n$ (**1**) and a helix-like complex with in-

terimmersion clefts $[Ag\{(S)\text{-}L_2\}(NO_3)]_n$ (**2**), assembled from (*S*)-L_1 and (*S*)-L_2 with $AgNO_3$, respectively (Scheme 1).

Results and Discussion

The chiral ligands (*S*)-L_1 or (*S*)-L_2 are readily prepared from commercially available (*S*)-BINOL and 3-picolyl chloride hydrochloride or 4-picolyl chloride hydrochloride in the presence of NaOH. (*S*)-L_1 and (*S*)-L_2 have five interesting characteristics as a result of incorporating the axially chiral 1,1′-binaphthol spacer into the pyridine-donor group: 1) the chirality of the ligands permits the formation of homochiral compounds; 2) the chiral twist of the binaphthyl group can be used to control the helical chirality; 3) the conformational rigidity of the binaphthyl group restricts its free rotation; 4) the divergency of the *exo*-bidentate pyridyl group prevents mononucleation of this ligand which is inclined to form a multinuclear complex or polymer; 5) the flexible rotation of the methylenepyridine unit may meet the requirement of the coordination environment of metal ions. Therefore, the linkage of the pyridyl group and the optically active BINOL scaffold affords the possibility of forming homochiral helical complexes.

(*S*)-L_1 and (*S*)-L_2 are soluble in most organic solvents; treating (*S*)-L_1 and (*S*)-L_2 with $AgNO_3$ in $MeCN/H_2O$ at 60 °C afforded colorless plate crystals of complexes **1** and **2**, respectively, in nearly quantitative yield. Complexes **1** and **2** are stable in air, and are insoluble in water and common solvents.

Single-crystal X-ray diffraction analysis reveals that complex **1** crystallizes in an orthorhombic space group $P2_12_12$ and has a double-helical structure with *M* (left-handed) configuration. As shown in Figure 1, each Ag^I center is coordinated by two nitrogen atoms from different (*S*)-L_1 ligands in a distorted linear geometry with the N(1)−Ag−N(2A) bond angle of 164.9(3)°. Bond lengths of Ag−N are 2.130(1) and 2.164(7) Å, which are typical values for Ag^I-N_{py} coordination distances.[11,12] Each (*S*)-L_1 ligand behaves in an *exo*-bidentate mode bridging a pair of adjacent Ag^I centers. The naphthyl rings are twisted with correspondingly linked pyridyl rings with dihedral angles between them of 8.6° and 33.4°. A dramatic twisting is observed between two naphthyl rings with a dihedral angle between them of 85.7°, which places the rings almost perpendicular to each other. The combination of these twistings results in the formation of the helical framework. The pyridyl and adjacent naphthyl rings from the other helical chain are approximately parallel with a dihedral angle between them of 7.5° and a distance between their centroids of 3.84 Å, indicating significant π−π interaction.[13] The intermolecular π−π interaction stabilizes the helical framework and produces a double-helical structure with an adjacent Ag···Ag separation of 4.29 Å between different helical chains. It is interesting to note that water molecules are encapsulated into the double helix as guest molecules (Figure 2). To the best of our knowledge, such a homochiral double-helical structure encapsulating guest water molecules is unprecedented.

Complex **2** crystallizes in the monoclinic space group C_2 and is a helix-like structure with *M* configuration. Similar to complex **1**, each Ag^I center is coordinated by two nitrogen atoms from different (*S*)-L_2 groups [Ag−N 2.195(4),

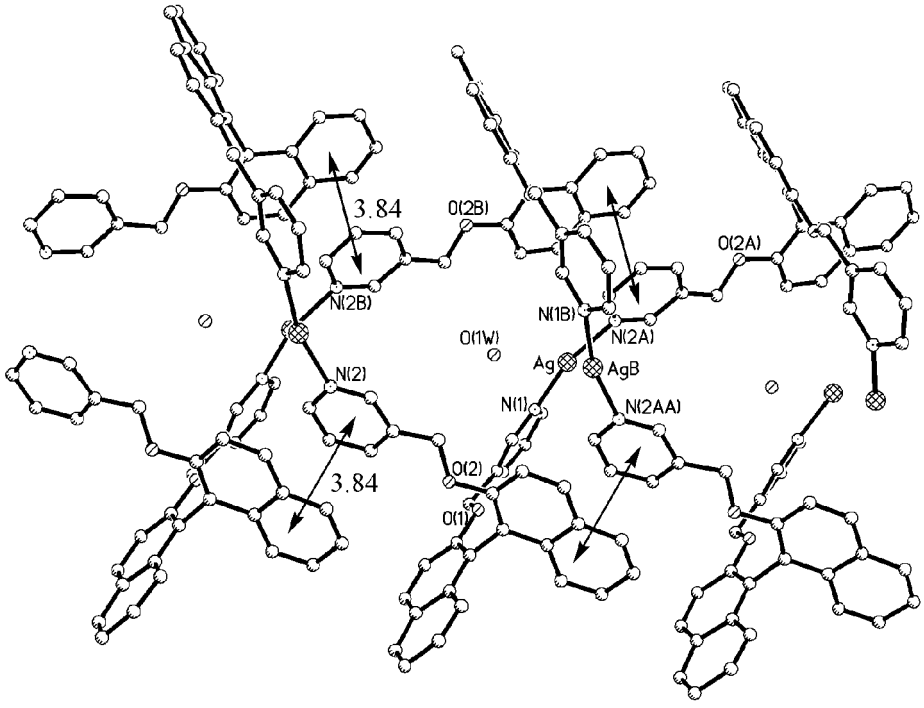

Figure 1. View of the double-helical chains encapsulating water molecules with counter anions, periphery water molecules and hydrogen atoms are omitted for clarity

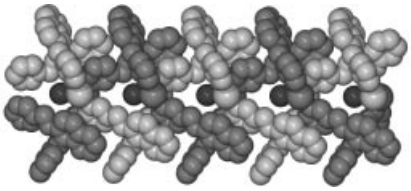

Figure 2. Space-filling diagram of the double-helical chains of **1** with counter anions, periphery water molecules and hydrogen atoms omitted for clarity

Ag−N 2.184(4) Å] in a distorted linear fashion with the N−Ag−N bond angle of 165.3(2)°. Three oxygen atoms from different $[NO_3]^-$ anions have weak interactions with the Ag^I center [Ag−O(12) 2.625(8), Ag−O(12 from complex A) 2.644(10), Ag−O(13 from complex B) = 2.859(9) Å]. Thus, the coordination environment of two N and 3 O atoms around the Ag^I centers can be best described as a slightly distorted triangular bipyramid. Two naphthyl rings with a twisting angle of 69.3° in *S*-L_2 have a smaller distortion than that in complex **1**, but the naphthyl rings and correspondingly linking pyridyl rings produce more twisting with dihedral angles between them of 42.3 and 85.4°, respectively, indicating that the metal coordination site at the 3-position of the pyridyl ring has more effect on the BINOL spacer than that at the 4-position. The interconnection of the *exo*-bidentate (*S*)-L_2 ligand and the Ag^I centers forms an infinite left-handed helix-like framework. The separations between two Ag^I centers bridged by the (*S*)-L_2 ligand and by the $[NO_3]^-$ anion (AgA−AgB) are

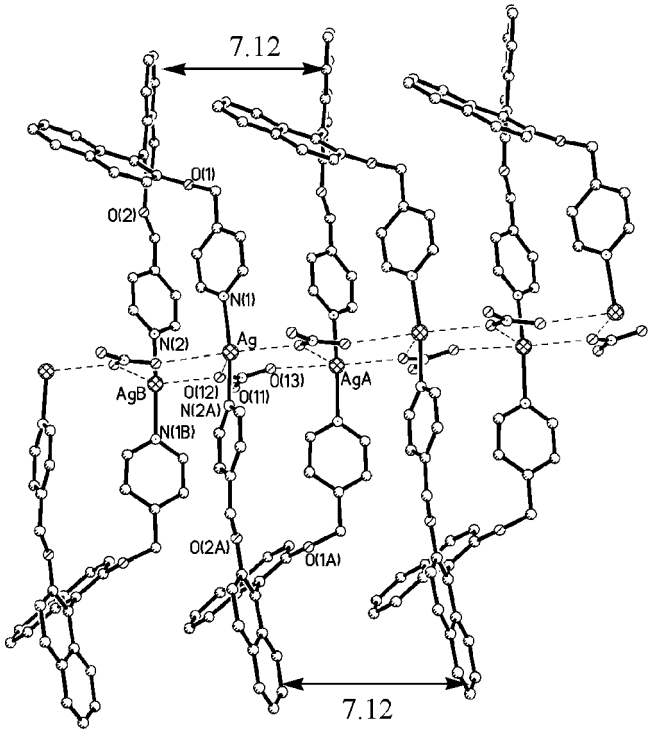

Figure 3. View of the helix-like chain of **2** with hydrogen atoms omitted for clarity

4.484 and 7.258 Å, respectively. It is worth noting that two adjacent ligands on the same side produce a cleft with a mean dimension of 7.12 Å (Figure 3). The (*S*)-L_2 moieties of adjacent helical chains are interimmersed into clefts of each other in an alternate fashion which effectively fills in the cleft void (Figure 4).[12]

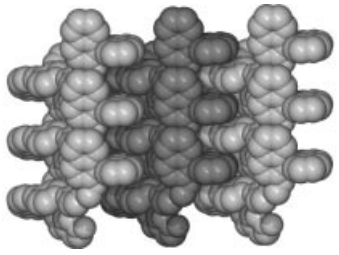

Figure 4. View of the pack diagram exhibiting interimmerse of clefts in **2**

It should be emphasized that the metal ions are not the center of chirality in complexes **1** and **2**. The chirality of the helical polymers is controlled by the inherently chiral twisting in the terminal BINOL spacer. Thus, the assembly of (*S*)-L_1 and (*S*)-L_2 with coordinatively flexible Ag^I centers results in the formation of the left-handed double-helical coordination polymer and the helix-like complex, respectively.

In conclusion, assembly of optically active (*S*)-L_1 and (*S*)-L_2 units with $AgNO_3$ produces a double-stranded helical coordination polymer encapsulating guest water molecules and a helix-like complex with interimmersion clefts, respectively, in which helical chirality is due to axial chirality of the BINOL scaffold. This research demonstrates that new types of homochiral helical complexes can be constructed through monopyridine-donor groups linking the 2,2′-positions of the terminal BINOL chiral scaffold. Moreover, the different orientation of the coordination sites in the pyridyl rings of such ligands can result in different structural motifs. Further investigations are in progress.

Experimental Section

General: (*S*)-1,1′-bi-2-naphthol, 3-picolyl chloride hydrochloride and 4-picolyl chloride hydrochloride were purchased from Acros. The other chemicals were commercially available and were used as purchased without further purification. The NMR spectra were recorded on a Varian Inova-500 spectrophotometer at room temperature and the chemical shifts were quoted in δ (ppm) relative to the deuterated solvent used. The optical rotation was measured with a Polarimeter 341. The mass spectra data were measured by the mass spectrometry laboratory at the Department of Applied Biology and Chemical Technology of The Hong Kong Polytechnic University and were recorded on a Fisons VG platform. The IR spectra were recorded as KBr disks on a Magna 750 FT-IR spectrophotometer. Elemental analyses were determined on an Elementar Vario ELIII elemental analyzer.

Synthesis of (*S*)-L_1: A mixture of (*S*)-1,1′-bi-2-naphthol (2.86 g, 10 mmol), 3-picolyl chloride hydrochloride (3.61 g, 22 mmol), and NaOH (1.76 g, 44 mmol) in acetone (50 mL) was stirred at reflux

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

under nitrogen for 3 days. After cooling to room temperature, the inorganic salt was removed by filtration and washed several times with acetone. From the combined solution, the solvents were evaporated under reduced pressure, and the red oily residue was dissolved in ethyl acetate, washed twice with water, and once with brine. The organic layer was dried over anhydrous Na_2SO_4 and filtered. After the removal of the solvent under reduced pressure, the residue was purified by chromatography on silica gel to afford a light yellow oil-like substance. Yield: 4.12 g (88 % based on BINOL). ^{1}H NMR (500 MHz, $CDCl_3$): δ = 8.35 (dd, *J* = 1.5, 4.5 Hz, 2 H, py), 8.20 (d, *J* = 2.0 Hz, 2 H, py), 8.07 (dd, *J* = 9.0 Hz, 2 H, bi), 7.96 (d, *J* = 7.5 Hz, 2 H, bi), 7.67 (d, *J* = 9.0 Hz, 2 H, bi), 7.36 (td, *J* = 1.5, 6.5 Hz, 15 Hz, 2 H, bi), 7.29−7.32 (m, 2 H, bi), 7.24−7.27 (m, 2 H, bi), 7.12 (dd, *J* = 4.5, 7.5 Hz, 2 H, py), 7.00 (d, *J* = 8.0 Hz, 2 H, py), 5.19 (s, 4 H, -CH_2-) ppm. ^{13}C NMR ($CDCl_3$, 125 MHz): δ = 153.3, 148.4, 147.9, 135.0, 134.8, 133.4, 132.9, 129.5, 129.0, 128.1, 126.5, 124.6, 123.6, 119.4, 115.5, 67.7 ppm. $[\alpha]_D^{20}$ = −99.2 (*c* = 1, DMSO). Calcd. for $C_{32}H_{25}N_2O_2$ (469.19): calcd. C 81.91, H 5.33, N 5.97; found C 81.96, H 5.35, N 5.94. ES-MS: *m*/*z* = 469 (M^+ + 1). HRMS: calcd. $C_{32}H_{25}N_2O_2$ (M^+ + 1): *m*/*z* = 469.1916; found: 469.1938.

Synthesis of (*S*)-L_2: The procedure was similar to the synthesis of (*S*)-L_1 except that 4-picolyl chloride hydrochloride was used instead of 3-picolyl chloride hydrochloride. Yield: 3.75 g (80 % based on BINOL). ^{1}H NMR (500 MHz, $CDCl_3$): δ = 8.28 (dd, *J* = 1.5, 4.5 Hz, 4 H, py), 8.07 (d, *J* = 8.5 Hz, 2 H, bi), 7.97 (d, *J* = 8.5 Hz, 2 H, bi), 7.59 (d, *J* = 9.0 Hz, 2 H, bi), 7.35−7.38 (m, 2 H, bi), 7.26−7.29 (m, 2 H, bi), 7.03 (d, *J* = 8.5 Hz, 2 H, bi), 6.94 (d, *J* = 6.0 Hz, 4 H, py), 5.24 (s, 4 H, -CH_2-) ppm. ^{13}C NMR ($CDCl_3$, 125 MHz): δ = 153.7, 149.6, 146.9, 134.3, 130.0, 129.8, 128.3, 127.0, 125.6, 124.5, 121.3, 120.7, 115.5, 69.6 ppm. $[\alpha]_D^{20}$ = −82.8 (*c* = 1, DMSO). $C_{32}H_{25}N_2O_2$ (469.19): calcd. C 81.91, H 5.33, N 5.97; found C 81.97, H 5.38, N 5.92. ES-MS: *m*/*z* = 469 (M^+ + 1). HRMS: calcd. $C_{32}H_{25}N_2O_2$ (M^+ + 1): *m*/*z* = 469.1916; found 469.1925.

Preparation of {Ag[(*S*)-L_1](NO$_3$)·H_2O}$_n$ (1): A solution of $AgNO_3$ (0.017 g, 0.1 mmol) in H_2O (5 mL) was added to a stirred solution of (*S*)-L_1 (0.047 g, 0.1 mmol) in MeCN (10 mL). The reaction mixture was stirred for 5 h at 60 °C, and the colorless solution was then filtered. Colorless crystals of complex **1** were obtained by allowing the filtrate to evaporate slowly in air for two weeks. Yield: 0.059 g (90 %). $C_{32}H_{26}AgN_3O_6$ (656.43): calcd. C 58.50, H 3.95, N 6.40; found C 58.39, H 3.98, N 6.37. IR (KBr pellet): $\tilde{\nu}$ = 3048 (m, C−H), 2962 (m, CH_2), 1742 (w), 1619 (s, C−C), 1587 (s, C−C), 1506 (s, C−C), 1458 (m, C−C), 1434 (m, C−C), 1360 (w), 1385 (s, N−O), 1232 (m, C−O), 1151 (w, C−H), 1090 (m, C−H), 1016 (m, C−H), 965 (w), 916 (w), 864 (w), 808 (m), 751 (m), 700 (m), 654 (w), 573 (w), 430 (w), 405 (w).

Preparation of [Ag{(*S*)-L_2}(NO$_3$)]$_n$ (2): The procedure was similar to the synthesis of complex **1** except that (*S*)-L_2 was used instead of (*S*)-L_1. Yield: 0.060 g (94 %). $C_{32}H_{24}AgN_3O_5$ (638.4): calcd. C 60.15, H 3.76, N 6.58; found C 60.16, H 3.78, N 6.61. IR (KBr pellet): $\tilde{\nu}$ = 3058 (m, C−H), 2925 (m, −CH_2−), 1619 (s, C−C), 1588 (s, C−C), 1561 (w, C−C), 1501 (s, C−C), 1505 (s, C−C), 1469 (w, C−C), 1446 (m, C−C), 1424 (m, C−C), 1385 (s), 1362 (w), 1266 (m, C−O), 1148 (m, C−H), 1095 (m, C−H), 1047 (m, C−H), 1019 (m, C−H), 959 (w), 911 (w), 858 (w), 804 (m), 743 (m), 670 (w), 619 (w), 527 (w), 485 (w).

X-ray Crystallography: The crystal data and structural determination summary for **1** and **2** are listed in Table 1. Intensity data for **1** and **2** were measured on a Siemens Smart CCD diffractometer with graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å) at 298 K. Empirical absorption corrections were applied by using the SADABS program.[14] The structures were solved by direct methods and all calculations were performed using the SHELXL PC program.[15] The positions of the H atoms were generated geometrically (C−H bond fixed at 0.96 Å), assigned isotropic thermal parameters, and allowed to ride on their parent carbon atoms before the final cycle of refinement. The structure was refined by full-matrix least-squares minimization of $\Sigma(F_o-F_c)^2$ with anisotropic thermal parameters for all atoms except the H atoms. CCDC-205478 and -205479 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) + 44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Syntheses, Structures and Redox Properties of New Macrocyclic Triazatriolefinic Pd^0 Complexes and Their Polypyrrole Modified Electrodes − Application to Heterogeneous Catalytic Suzuki Cross-Coupling Reactions

Antoni Llobet,*[a] Ester Masllorens,[a] Montserrat Rodríguez,[a] Anna Roglans,*[a] and Jordi Benet-Buchholz[b]

Keywords: Heterogeneous catalysis / Macrocyclic ligands / Palladium / Pyrroles / Modified electrodes / Electrochemistry

New triolefinic macrocyclic ligands of the type (*E,E,E*)-1,6,11-tris(arenesulfonyl)-1,6,11-triazacyclopentadeca-3,8,13-triene (aryl: **a** = ferrocenyl, **b** = 4-pyrrol-1-ylphenyl, **c** = 4-methylphenyl) and their Pd^0 complexes (**1aab**, **1abb** and **1bcc**) have been prepared and characterized. Further structural characterization in the solid state has also been performed by means of X-ray diffraction analysis for the complex **1bcc**. The redox properties of both the ligands and their Pd complexes have been studied using cyclic voltammetric and coulombimetric techniques. In particular, complexes and ligands containing the pyrrole group do polymerize upon exposure to sufficiently positive potentials, on glassy carbon electrodes, generating highly stable modified electrodes. The new modified electrodes are efficient and selective heterogeneous catalysts for Suzuki cross-couplings, benefiting from simple removal of the catalyst from the reaction vessel. As an example, more than $2 \cdot 10^5$ metal cycles are achieved at 65 °C in the coupling of phenylboronic acid and cinnamyl bromide. Iodoarenes and phenylboronic acid are also converted into biphenyls with relatively good conversions.

Introduction

Homogeneous catalysis using transition metal (TM) complexes is a topic of current interest from a basic organic synthetic perspective and also from an industrial point of view.[1] Highly efficient homogeneous catalytic systems have been described even though their potential industrial applications have been hampered by the cost and difficulty in recovering the TM catalyst and also because of the presence of trace amounts of the TM in the final product.

One of the main strategies designed to overcome the above mentioned drawbacks consists of making TM catalysts heterogeneous by incorporating them into solid materials. In this context, the development of highly efficient catalysts to compensate for TM complex cost and the fabrication of robust heterogeneous systems with negligible leaching, is essential in order to consider them as potential candidates for the scale up process at an industrial plant.

Different approaches for making TM catalysts heterogeneous have been recently reviewed.[1b,2] Very elegant strategies based on biphasic systems (aqueous-organic[2b,3] or fluorous-organic[4] systems) have been developed in the last decade. Organic[1b,5] and inorganic[1b,6] polymer matrices have also been extensively used to immobilize TM catalysts. Among them, pyrrole electropolymerization is an attractive and convenient method given the synthetic versatility of the monomers and the stability of the resultant polypyrrole films.[7] In general, these films attached to the electrode surface via an electropolymerization process are much more stable than those obtained by simple deposition on materials such as polystyrene,[8] Nafion[9] or carbon paste.[10] The stability of the film is an important factor since it minimizes potential leaching processes from the solid surface. Furthermore the high electrical conductivity of the polypyrrole films allows the use of the conveniently designed electroactive ancillary groups, which do not participate in the catalytic transformation, but allow important aspects of the process to be monitored and thus act as built in chemical sensors.

Given the many positive aspects of the polypyrrole films just described, it is striking that they have been scarcely used with carbon−carbon bond formation catalysts in order to introduce heterogeneity. In this context it is worth mentioning the work of Jugé et al.[11] in which they initially functionalized the polypyrrole backbone with phosphane ligands. Subsequently the catalyst was generated in situ upon adding an appropriate Pd^0 complex.

During the last two years, synthetic procedures for novel types of Pd^0-triazatriolefinic macrocyclic complexes such as (*E*,*E*,*E*)-1,6,11-tris(arenesulfonyl)-1,6,11-triazacyclopentadeca-3,8,13-trienepalladium(0), **1**, (see Scheme 1) have been reported.[12] These phosphane-free palladium(0) complexes are active and efficient catalysts for Suzuki cross-couplings,[13] butadiene telomerization,[14] and alkyne hydroarylation in ionic liquids.[15] They have also been anchored in polystyrene matrices allowing the catalyst to be separated from reaction products by simple filtration for subsequent re-use.[13]

We have recently reported[16] the preparation of related 15-membered macrocycles functionalized with ferrocenyl units at the sulfonamide groups, and their palladium(0) complexes. We have also reported[17] high activity and quantitative recovery of palladium(0) complexes, **1**, for the Heck reaction of diazonium salts with acrylates and styrene in a homogeneous phase.

Herein we present the synthesis, spectroscopic and electrochemical properties of new 15-membered triolefinic ligands containing pyrrole and/or ferrocene groups together with their corresponding Pd^0 complexes **1aab**, **1abb**, and **1bcc** (Scheme 1). Their redox properties as well as their chemical and electrochemical polymerization processes are also described. Finally the capacity of the corresponding modified electrodes to catalyze Suzuki cross-coupling reactions has been analyzed using two different substrates.

Results and Discussion

Synthesis and Structures

The preparation of the triaza olefinic ligands and their unsaturated 16-electron Pd^0 complexes, **1aab**, **1abb** and **1bcc**, is outlined in Scheme 1, according to the general method for the synthesis of related compounds.[12,16] Pd^0 complexes **1aab** and **1abb** were obtained in overall yields of 51% and 36%, respectively. The low yield for complex **1abb** was due to the poor solubility of several intermediates conferred by the two pyrrole groups. Complex **1bcc** was obtained in 8% overall yield by a different and more straightforward synthetic pathway (see Scheme 1). The main problem of this synthesis was that the bis(sulfonamide) **8cc** was obtained as the minor product, the major one (46% yield)

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

being the monosulfonamide, *N*,*N*-bis[(*E*)-4-bromo-2-butenyl](4-methylphenyl)sulfonamide. Optimization of this step was not successful.[12a]

This versatile synthetic route allowed the aromatic groups to be easily changed. Thus, these aromatic groups can be used as auxiliary substituents to perform specific functions without modifying the intrinsic coordinating properties of the ligand. In the present case, ferrocene was chosen since it acts as a quantitative electrochemical sensor. On the other hand, an *N*-bonded pyrrole group was also selected since it converts the Pd complex into a monomer which can be easily polymerized. At sufficiently positive anodic potentials the pyrrole group polymerizes, ejecting its α-hydrogen atoms,[7] while forming a relatively stable and insoluble conducting polypyrrole material. This material strongly adheres to the electrode surface to which the Pd-triolefinic complex has been covalently attached.

The crystal structure of complex **1bcc·CH_2Cl_2** was solved by means of a single-crystal X-ray diffraction analysis. Figure 1 presents the ORTEP diagram of the molecule including selected bond lengths and angles with the corresponding labeling scheme.

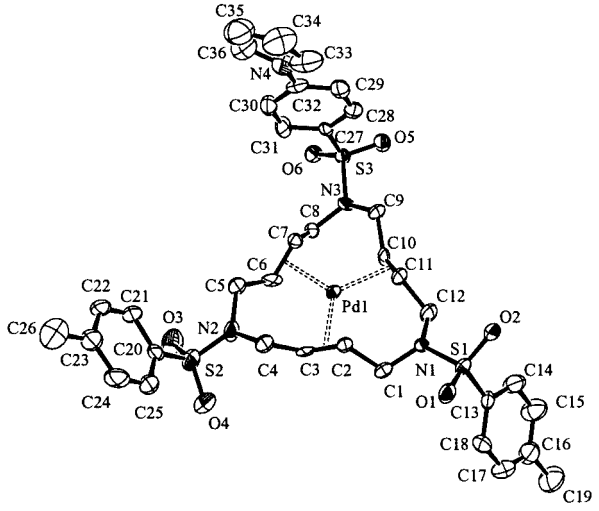

Figure 1. ORTEP plot (50 %) of complex **1bcc**, hydrogen atoms are omitted to fully appreciate the geometry of the complex; selected distances [Å] and angles [°]: Pd1−C2 2.196(6), Pd1−C3 2.216(7), Pd1−C6 2.164(17), Pd1−C7 2.214(9), Pd1−C10 2.186(7), Pd1−C11 2.187(7); C10−Pd1−C11 36.7(3), C10−Pd1−C6 115.9(4), C11−Pd1−C6 151.7(4), C10−Pd1−C2 121.9(3), C11−Pd1−C2 86.7(3), C6−Pd1−C2 121.6(4), C10−Pd1−C3 152.4(3), C11−Pd1−C3 122.5(3), C6−Pd1−C3 85.5(5), C2−Pd1−C3 37.0(2), C10−Pd1−C7 85.5(3), C11−Pd1−C7 117.9(3), C6−Pd1−C7 34.9(4), C2−Pd1−C7 151.6(3), C3−Pd1−C7 119.4(3), C3−C2−Pd1 72.3(4), C1−C2−Pd1 112.4(5), C2−C3−Pd1 70.7(4), C4−C3−Pd1 111.7(5), C5−C6−Pd1 114.4(10), C7−C6−Pd1 74.6(8), C8−C7−Pd1 111.3(7), C6−C7−Pd1 70.5(8), C11−C10−Pd1 71.7(4), C9−C10−Pd1 115.0(5), C10−C11−Pd1 71.6(4), C12−C11−Pd1 115.2(5)

The molecular structure of **1bcc** shows the macrocyclic ligand, **7bcc**, with all the olefinic *trans* double bonds coordinated to the palladium. The central point of the olefins and the palladium are all nearly situated in the same plane and thus the coordination of the palladium is slightly distorted trigonal planar. Bond lengths and angles are within the expected ranges for this type of complex.[12b] The three nitrogen atoms of the sulfonamides (N1, N2, N3) and the palladium center are also situated very close to a plane which will from now on be referred to as the main plane. The Pd−C bonds form a triangle with each olefinic group generating a three paddle helix centered at the palladium metal atom. It is also worth mentioning that the Pd complex suffers a slight disorder that is manifested in the chain of four carbon atoms (C5 to C8 with an occupancy factor of 80% and C5′ to C8′ with 20%) that links the amine atoms N2 and N3. For the molecular conformation with 80% occupancy, two of the paddles are oriented up (Pd1−C6−C7, Pd1−C10−C11) and one down (Pd1−C2−C3) if the helix is observed in a clockwise manner (following increasing values of the atom labeling scheme) with the helix parallel to the main plane, manifesting the asymmetry of the helix with regard to a hypothetical pseudo C_3 rotation axis perpendicular to the mentioned main plane. This relative orientation of the paddles is directly related to the conformation of the three six-membered rings fused to them containing N1 (Pd1, C11, C12, N1, C1, C2), N2 (Pd1, C3, C4, N2, C5, C6) and N3 (Pd1, C7, C8, N3, C9, C10), respectively. Thus when two neighboring paddles have different orientations, both a chair or a boat conformation are possible for the six member ring fused to them but when they have the same orientation then only a distorted chair or a distorted boat is possible. Indeed, two chair conformations were obtained for the six-membered rings containing the N1 and N2 atoms, respectively, whereas opposite orientations and a distorted boat was found for N3. The disordered atoms contained in the molecule with a 20% occupancy generate a paddle that has the opposite orientation with respect to that of the molecule with the 80% occupancy. The sulfonamides are oriented in such a way that the aromatic substituents are situated at 121.9° (C13−C18), 128.5° (C20−C25) and 97.3° (C27−C32) with regard to the main plane, with two of them directed over the plane, one up (S1, S3), and one down (S2). In the S3 case the *N*-pyrrolic substituent bonded to the phenyl ring is significantly rotated [C36−N4−C32−C30 torsion angle of −27.1°] to avoid steric interactions with its neighboring hydrogen atoms.

Redox Properties and Catalyst Immobilization

The redox properties of complexes **1aab**, **1abb** and **1bcc** were investigated by means of cyclic voltammetric and coulombimetric techniques. Figure 2 (A) shows the cyclic voltammograms of **1aab** in CH_2Cl_2+0.1 M nBu_4NPF_6 at a glassy carbon disk electrode using Ag/10 mM Ag^+ as the reference electrode in the dry box. By scanning anodically starting at 0.0 V a first wave was observed associated with the Fe^{III}/Fe^{II} couple at $E_{1/2}$ = 0.561 V ($E_{p,a}$ = 0.680 V, $E_{p,c}$ = 0.442 V, ΔE = 232 mV). The occurrence of a relatively high value of ΔE is a common phenomenon found in similar transition metal complex polymerization sys-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

tems,[18a] and is related to the intrinsic nature of the immobilized species as well as to the multiple processes which are taking place simultaneously.[7]

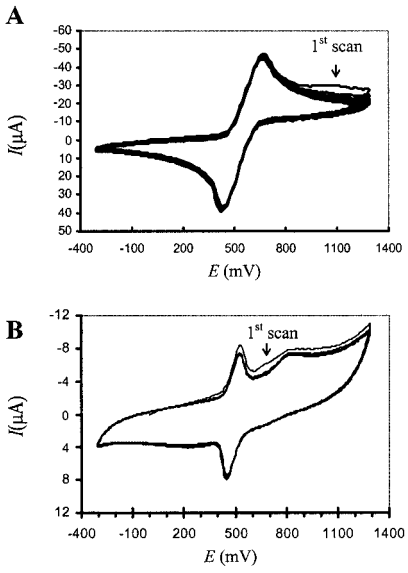

Figure 2. Top: Growth of a **C-glassy/poly-1aab** during the first 20 consecutive cyclic voltammetric scans on a glassy carbon disk electrode (3 mm diameter) in a 1 m M solution of **1** in CH_2Cl_2+0.1 M TBAP (υ = 0.1 V/s); bottom: cyclic voltammetric scan of **C-glassy/poly-1aab** ($\Gamma = 3.10 \times 10^{-10}$ mol cm^{-2}) upon transferring it to a blank electrolyte solution CH_2Cl_2+0.1 M TBAP (υ = 0.1 V/s); first and four consecutive scans

A second small and broad wave was also observed in the first scan with $E_{p,a}$ = 1.05 V which can be assigned to the irreversible oxidation of the pyrrole group with concomitant polymerization (the observation of this wave only in the first scan is typical for this kind of system and is related to the changes experienced on the electrode surface after the deposition of the first polypyrrole layer[7b,7c]). Modified electrodes, with units of the **1aab** monomer covalently bonded to the polypyrrole chain, can be obtained by scanning the potential region repeatedly from 0.0 V up to 1.30 V. This is depicted in Figure 2 (A) where, upon scanning 20 times over the indicated potential domain, a small but consistent increase of the intensity wave for the Fe^{III}/Fe^{II} couple was observed thus indicating the growth of the **C-glassy/poly-1aab** film on the electrode surface. Figure 2 (B) shows the cyclic voltammetric response of the film when transferred to a blank electrolyte solution. As in the previous case, a first wave due to the Fe^{III}/Fe^{II} couple can be observed ($E_{1/2}$ = 0.490 V, $E_{p,a}$ = 0.538, $E_{p,c}$ = 0.442, ΔE = 96 mV), as well as a second one, with $E_{p,a}$ = 0.83 V, that can be assigned to the electrochemically irreversible oxidation of palladium. The corresponding Pd^{II} reduction takes place through a broad wave found between 0 and 0.4 V. The electrochemical response of the Pd metal center can be determined from comparison of this system with the behavior shown in homogeneous phase by a family of related Pd complexes that we have described recently.[16] Also, the polymerization performed on the corresponding macrocyclic ligand **7aab** under equivalent conditions, does not show any significant wave around 0.8 V. This, together with the catalytic activity of the polymerized free ligands and complexes (vide infra), gives compelling evidence that the Pd metal remains coordinated to the triolefinic ligands in the generated modified electrodes containing the polypyrrolic films.

The films described here are highly stable. Upon scanning more than 40 times over the −2.0 to +2.0 V potential region in a fresh electrolyte solution, the decrease in charge under the Fe^{III}/Fe^{II} wave is insignificant. There is also some evidence for the preservation of the coordination environment of the Pd metal center in the complex structure, since the intensity of the anodic peak, corresponding to the $Pd^0 \rightarrow Pd^{II}$ transition, also maintains its intensity.

Similar films can also be built up by maintaining the electrode in the potential range 0.6−0.8 V with a potentiostat. As an example a film grown by maintaining E_{app} = 0.80 V, until a total charge of 7.22×10^{-3} C had passed, yielded a thin film with an apparent surface coverage of $\Gamma = 1.53 \times 10^{-9}$ mol/cm^2.

It is important to point out here that the whole process can be performed outside the dry box with carefully dried solvents under N_2 or Ar, but the Pd wave was only observed under rigorously anhydrous conditions in the dry box.

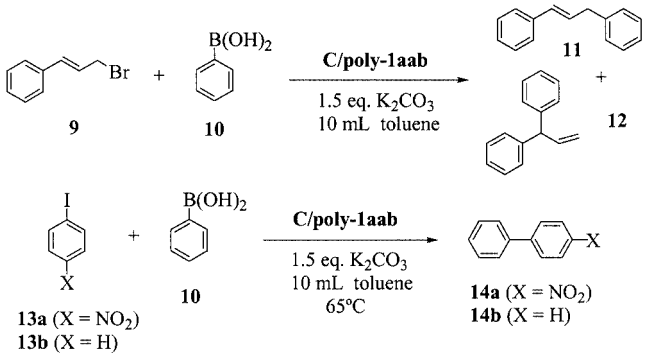
The polymerization process was also carried out for **1aab** utilizing carbon felt electrodes (1.0 × 0.5 × 0.5 cm), using the same protocols as with the glassy carbon electrodes previously described thus generating the corresponding **C-felt/poly-1aab**. Under these conditions, and using the voltamperometric methodology, different electrodes were generated with different amounts of deposited complex that, after proper cleaning, were used as catalysts. Their performance is described in the following section.

The redox properties of **1abb** parallel those of **1aab** except that the ferrocene waves have half the intensity observed in the previous case, as expected. For the complex **1bcc**, the absence of ferrocene substituents prevents the use of electrochemical monitoring since the polypyrrole backbone wave was not observed in our case, but they could also be used for catalytic purposes. The free ligands **7aab** and **7abb** can also be polymerized in the same manner as described for the Pd complex **1aab** generating very similar voltammograms except for the obvious absence of the wave due to the irreversible oxidation of Pd.

Catalytic Activity

To examine the catalytic efficiency and recovery of the **C-felt/poly-1aab** materials, two model Suzuki-type cross-coupling reactions were tested, namely the reaction of cinnamyl bromide, **9**, with phenylboronic acid, **10**, to afford *trans*-1,3-diphenylpropene, **11**,[19] together with minor amounts of regioisomer **12**,[20] and that of phenylboronic acid **10** with the iodoarenes **13a**−**b**, leading to the biphenyls **14a**−**b**[21] (see Scheme 2 and Table 1)

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim



Scheme 2. Suzuki-type cross-coupling reactions tested

Typically, the reaction was carried out by stirring a reaction mixture containing cinnamyl bromide, phenylboronic acid, potassium carbonate, and the catalyst immobilized onto the electrode surface in an anhydrous, degassed toluene solution under nitrogen. The electrode was recovered by removing it from the solution vessel, and washing with toluene before using it again in a new reaction.

Entry 1 in Table 1 shows that at 27 °C after a reaction time of 48 hours, up to 10 mL total volume of the system "**C-felt/poly-1aab**, 16.8·nmols/**9**, 15.0 mM; **10,** 22.5 mM/K_2CO_3, 22.5 mM/toluene", is capable of generating 10.50 mM *trans*-1,3-diphenylpropene, **11**, and 1.65 mM of its isomeric product 3,3-diphenylpropene, **12**. This implies a substrate conversion of 81% with a TON of 7200 cycles and a TOF of 150 cycles per hour at 48 h. When the catalytic material had been reused in a fresh system, a sharp decrease in its activity (entry 2) was observed due to partial deactivation of the supported catalyst by undesired side reactions. It is interesting to point out here that at this temperature the isomeric ratio (**11**:**12**) remains relatively constant in the range 5.0−7.0.

Entries 3−5 in Table 1 show a spectacular increase of the catalyst performance when the temperature and the Substrate/Cat ratio are increased from 27 to 65 °C and from 8930 up to 13800 respectively leaving the rest of the system parameters unchanged. In particular, entry 3 shows a substrate conversion of 96% in 24 h with an isomeric ratio of 15.0. This result clearly shows that upon increasing the temperature and the Substrate/Cat ratio, the pathways that lead

Table 1. Suzuki coupling between cinnamyl bromide, **9**, and the iodoarenes, **13a**−**b**, with phenylboronic acid **10**.

to **11** are kinetically favored with regard to those that lead to **12**. Entries 4 and 5 show the effect of reusing the catalyst after cleaning and soaking in a fresh solution with a slight decrease of the activity. Several experiments were performed in which the Substrate/Cat ratio was increased but the temperature was maintained at 65 °C. A 100% conversion and 100% isomeric purity was obtained although the deactivation became more severe upon reuse. Finally in entries 6−8 the Substrate/Cat ratio was strongly increased up to 107500. This decreased conversion to 89% and isomer selectivity to 16.8 but reduced the deactivation process on reuse (entries 7, 8) and generated an impressive overall TON of 223000. This is about an order of magnitude higher than had been described previously by anchoring similar Pd complexes but using polystyrene as a solid matrix.[13]

The results described above clearly show how, for the present system, the temperature and Substrate/Cat ratio are key parameters that strongly influence the catalytic performance. In particular the Substrate/Cat ratio can modulate: a) substrate conversion, b) isomer selectivity, c) reuse capacity and d) the TOF as well as the TON.

Iodoarene substrates were also tested for coupling reactions with phenyl boronic acid. Entries 9−16 in Table 1 show the results when **10** was treated with 4-iodonitrobenzene, **13a**, and iodobenzene, **13b**, respectively, using the similar catalytic system parameters as in the previous case i.e. at 65 °C and with a reaction time of 24 hours. In these cases conversions were lower (entries 9, 13), but the catalyst could be reused once without any significant loss of activity (entries 10, 14). In the second reuse (entries 11, 15) the catalyst activity was reduced to 50% of its initial performance and in the third (entries 12, 16) the activity was reduced dramatically until only 4% substrate conversion was observed.

To evaluate the degree of leaching during the catalytic experiments in the Suzuki cross-coupling reactions, a quantitative Pd analysis was carried out using Atomic Absorption Spectroscopy (AAS). It was shown that about 5% of the initial Pd had dissolved in the reaction solution during the first 24 h of the reaction. Nevertheless, this "leached Pd" does not significantly catalyze the Suzuki cross-coupling reaction, as verified by removing the **C-felt/poly-1aab** from a solution after a reaction time of 12 h and allowing the process to continue under the same conditions for a further 24 hours (see entry 9, Table 1). This experiment is thus evidence that the catalytic process proceeds in a true heterogeneous manner.[22]

Control experiments were carried out in the absence of the Pd complex. Suzuki coupling between cinnamyl bromide, **9**, and phenylboronic acid, **10**, under the same conditions as in entry 3 (Table 1) but without **C-felt/poly-1aab** ("**9**, 15.0 mM; **10**, 22.5 mM/K_2CO_3, 22.5 mM/toluene" up to 10 mL total volume at 65 °C for 24 h), afforded 4.65 m M of **11** and 0.3 m M of **12** (33% of conversion). The conversion between 4-iodonitrobenzene, **13a**, and phenylboronic acid, **10**, under similar conditions as in entry 9 ("**13a**, 78.7 mM; **10**, 118 mM/K_2CO_3, 118 mM/toluene" up to 10 mL total volume at 65 °C for 24 h) and without **C-felt/poly-1aab** is negligible.

Conclusion

New Pd^0 triolefinic complexes containing ancillary pyrrole and/or ferrocene groups have been prepared and characterized. These groups have been attached with the purpose of carrying out specific functions namely, electrochemical monitoring and anchoring via anodic electropolymerization, respectively. The new polypyrrole modified electrodes prepared in this way represent the first examples reported in the literature of a successful phosphane-free system, capable of efficiently catalyzing Suzuki cross-coupling reactions. The different parameters that govern system reactivity have been established putting forward the strong appeal of these new materials with regard to their high thermal and air stability as well as excellent solvent resistance.

Experimental Section

General Remarks: ^1H NMR (^{13}C NMR) spectra were recorded at 250 MHz (62.5 MHz) or at 200 MHz (50 MHz) using Me_4Si as internal standard. Chemical shifts are given in δ units. ESI mass spectra were acquired using a Navigator quadrupole instrument. The instrument was operated in the positive ion mode (ES+) at a probe tip voltage of 3 kV. HRMS and ICP analyses were obtained at "SCAI Unidad de Espectrometría de Masas de la Universidad de Córdoba", using a Micromass VG Mass Spectrometer and a Perkin−Elmer AA spectrophotometer respectively. Elemental analyses were determined at "Servei d'Anàlisi de la Universitat de Girona".

Cyclic voltammetric experiments and controlled-potential coulometry were carried out in a PAR 263A EG&G potentiostat using a three electrode cell. Glassy carbon disk electrodes (3 mm diameter) from BAS and carbon felt electrodes (0.5 × 0.5 × 0.5 cm) from SOFACEL were used as the working electrodes, platinum wires as auxiliary and Ag/10 mM Ag^+ as reference electrodes. Glassy carbon disk electrodes were routinely polished with 1 μm diamond paste. Cyclic voltammograms were performed in the dry box or outside with carefully dried solvents under N_2 or Ar, and at a potential scan rate of 100 mV/s. All electrochemical experiments were conducted in CH_2Cl_2 containing 0.1 M (nBu_4N)(PF_6) (TBAP) as the supporting electrolyte. All $E_{1/2}$ values reported were estimated from cyclic voltammetry as the average of the oxidative and reductive peak potentials ($E_{p,a}+E_{p,c}$)/2. Unless explicitly mentioned the concentration of the complexes was approximately 1 mM.

The protocol used for the preparation of the modified electrodes consisted of performing 20 repetitive CV scans at 100 mV/s from E_i = 0.0 V to E_{cl} = 1.3 V. Catalyst coverage for the modified electrodes was evaluated from the corresponding Fe^{III}/Fe^{II} wave charge.

Coupling product evolution was followed on a Hewlett−Packard 5890 gas chromatograph using naphthalene as an internal standard.

Palladium(0) complexes **1aab**, **1abb** and **1bcc** were prepared according to a previously reported method described for macrocycles containing different arene units.[12a,16] Physical properties and spectroscopic data for all new compounds are described below.

(4-Pyrrol-1-ylphenyl)sulfonamide (2b): Compound was prepared by heating to reflux sulfanilamide (2.01 g, 11.4 mmol) and 2,5-dimethoxytetrahydrofuran (1.52 mL, 11.4 mmol) in glacial acetic acid according to a method for aniline derivatives[23] (yield 1.95 g, 8.8 mmol, 75%). M.p. 246−247 °C. IR (KBr): $\tilde{\nu}$ = 3349, 3260, 1600, 1513, 1334, 1296, 1165 cm^{-1}. ^1H NMR (200 MHz, [D$_6$]DMSO): δ = 6.12 (t, *J* = 2.2 Hz, 2 H), 7.17 (s, 2 H), 7.29 (t, *J* = 2.2 Hz, 2 H), 7.67 (AA′ part of a AA′BB′ system, *J* = 8.8 Hz, 2 H), 7.58 (BB′ part of a AA′BB′ system, *J* = 8.8 Hz, 2 H). ^{13}C NMR (50 MHz, [D$_6$]DMSO): δ = 111.9, 119.4, 119.6, 127.9, 140.8, 142.5.

***N*-(*tert*-Butyloxycarbonyl)ferrocenylsulfonamide (3a):** Starting from **2a** (0.80 g, 3.0 mmol); orange solid (yield 1.10 g, 3.0 mmol, 100%). M.p. 149−151 °C.[16] IR (KBr): $\tilde{\nu}$ = 3247, 3103, 2977, 1730, 1435, 1339, 1243, 1133 cm^{-1}. ^1H NMR (200 MHz, $CDCl_3$): δ = 1.42 (s, 9 H), 4.39 (s, 5 H), 4.42−4.45 (m, 2 H), 4.80−4.82 (m, 2 H), 7.05 (broad s, 1 H). ^{13}C NMR (50 MHz, $CDCl_3$): δ = 27.9, 69.8, 70.9, 83.5, 85.8, 149.5. ESI-MS (*m*/*z*): 383 $[M + NH_4]^+$, 365 $[M]^+$. $C_{15}H_{19}FeNO_4S$ (365.23): calcd. C 49.33, H 5.24, N 3.83; found C 49.39, H 5.28, N 3.66.

***N*-(*tert*-Butyloxycarbonyl)(4-pyrrol-1-ylphenyl)sulfonamide (3b):** Starting from **2b** (0.50 g, 2.3 mmol); colorless solid (yield 0.68 g, 2.1 mmol, 94%). M.p. 162−163 °C. IR (KBr): $\tilde{\nu}$ = 3312, 1741, 1594, 1511, 1415, 1340, 1151 cm^{-1}. ^1H NMR (200 MHz, $CDCl_3$): δ = 1.42 (s, 9 H), 6.41 (t, *J* = 2.3 Hz, 2 H), 7.17 (t, *J* = 2.3 Hz, 2 H), 7.53 (AA′ part of the AA′BB′ system, *J* = 8.8 Hz, 2 H), 8.08 (BB′ part of the AA′BB′ system, *J* = 8.8 Hz, 2 H). ^{13}C NMR (50 MHz, [D$_6$]DMSO): δ = 27.5, 82.2, 111.7, 118.8, 119.1, 129.2, 135.3, 143.2, 149.8. ESI-MS (*m*/*z*): 340 $[M + NH_4]^+$, 323 $[M + H]^+$. $C_{15}H_{18}N_2O_4S$ (322.38): calcd. C 55.88, H 5.63, N 8.69; found C 55.52, H 5.60, N 8.49.

***N*-[(*E*)-4-Bromo-2-butenyl]-*N*-(*tert*-butyloxycarbonyl)ferrocenylsulfonamide (4a):** Starting from **3a** (1.05 g, 2.8 mmol); orange solid (yield 1.15 g, 2.3 mmol, 80%). Preparation of Modified Electrodes

C-felt/poly-1aab: Electrode coating was performed through cycling the potential as described previously using a carbon felt electrode (0.5 × 0.5 × 0.5 cm) used as the working electrode in a 1 mM solution of **1aab** in CH_2Cl_2 0.1 M TBAP. After electropolymerization, the modified electrode was transferred to a blank electrolyte solution and five more potential cycles were performed. The electrode was then soaked overnight in anhydrous toluene before using it as a heterogeneous catalyst.

Catalysis

1,3-Diphenylpropene, under Catalysis by C-felt/poly-1aab (11): To a degassed mixture of cinnamyl bromide **9** (0.030 g, 0.150 mmol), phenylboronic acid **10** (0.028 g, 0.225 mmol), anhydrous potassium carbonate (0.031 g, 0.225 mmol), and the electrode containing the immobilized Pd^0-catalyst, **C-felt/poly-1aab** (see Table 1 for Pd nmols) anhydrous toluene (10 mL) was added under N_2. The mixture was stirred at 65 °C for 24 hours. Product yield was calculated by GC using naphthalene as internal standard. 1,3-Diphenylpropene **11** has the same retention time as authentic material and the correct mass by GC/MS. ^{1}H NMR (200 MHz, $CDCl_3$): δ = 3.52 (d, J = 5.9 Hz, 2 H), 6.32−6.50 (m, 2 H), 7.15−7.37 (m, 10 H). 3,3-Diphenyl-1-propene **12**[24] has been identified by GC/MS analysis and by ^{1}H NMR spectrum. ^{1}H NMR (200 MHz, $CDCl_3$): δ = 4.70 (d, J = 7.2 Hz, 1 H), 4.98 (b d, J = 17.0 Hz, 1 H), 5.20 (b d, J = 9.2 Hz, 1 H), 6.30 (b abs, 1 H), 7.20−7.30 (m, 10 H). The heterogeneous catalyst was removed from the reaction vessel, washed by stirring it in toluene and reused.

4-Nitrobiphenyl, under Catalysis by C-felt/poly-1aab (14a), General Method: To a degassed mixture of 4-iodonitrobenzene **13a** (0.20 g, 0.79 mmol), phenylboronic acid **10** (0.15 g, 1.18 mmol), anhydrous potassium carbonate (0.17 g, 1.18 mmol), and the modified electrode, **C-felt/poly-1aab** (0.0015% molar) anhydrous toluene (10 mL) was added under N_2. The mixture was stirred at 65 °C for 24 hours. The product yield was calculated by GC using naphthalene as internal standard. 4-Nitrobiphenyl **14a** has the same retention time as authentic material and the correct mass by GC/MS. The elec-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

trode with the polymeric catalyst was removed from the reaction vessel, washed by stirring in toluene and reused.

X-ray Crystallographic Study

X-ray Structure Determination of 1bcc: Very small colorless and mostly twinned crystals of **1bcc·CH_2Cl_2** were grown by slow evaporation of a dichloromethane solution at room temperature. After different trials, a data set of moderate quality was acquired from a small crystal needle with the dimensions 44 × 14 × 6 μm. Molecular formula $C_{37}H_{42}Cl_2N_4O_6Pd_1S_3$, M = 912.23, triclinic, a = 11.1889(12), b = 14.1440(14), c = 14.4425(14) Å, α = 117.683(4)°, β = 100.507(4)°, γ = 90.266(3)°, V = 1979.5(3) Å^3, space group $P\bar{1}$, Z = 2, μ = 0.812 mm^{-1}, $d_{calcd.}$ = 1.530 g/cm^3. The measurements were made on a Siemens P4 diffractometer equipped with a SMART-CCD-1000 area detector, a MACScience Co. rotating anode with Mo-K_α radiation, a graphite monochromator and a Siemens low temperature device LT2 (T = −120 °C). The measurements were made in the range 1.63 to 27.50°. 24003 reflections were collected of which 8939 were unique (R_{int} = 0.1292) and 3783 observed [$F_o > 4\sigma(F_o)$]. Full sphere data collection was carried out using ω and scans. Programs used: Data collection Smart V. 5.060 (Bruker AXS, 1999), data reduction Saint + Version 6.02 (Bruker AXS 1999) and absorption correction SADABS (max./min. transmission: 1.000000/0.709584, Bruker AXS 1999). Structure solution and refinement using SHELXTL Version 5.10 (Sheldrick, University of Göttingen, Germany, 1998). The structure was solved by direct methods and refined by full-matrix least-squares against F^2. All calculated hydrogen positions were refined and constrained. Final R_1 [$I > 2\sigma(I)$] = 0.0698 and $wR(F^2)$ [$I > 2\sigma(I)$] = 0.1459. The number of refined parameters was 503.

CCDC-216129 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Center, 12, Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Acknowledgments

We thank Dr. Moreno-Mañas for helpful discussions and for useful suggestions. This research has been financed by MECYT of Spain (Project Nos. BQU2002−04002-C02 and BQU2000−0458 and predoctoral grant to E.M.) and by CIRIT "Generalitat de Catalunya" (Project No. SGR2001−00291). A.L. is also grateful to CIRIT for the Distinction award and to Johnson and Matthey for a precious metals loan.

[20] One possible mechanistic hypothesis for the formation of the two regioisomers, **11** and **12**, is that Pd^0 displace the bromide leaving group to form a π-allylpalladium complex intermediate. Reductive elimination after transmetallation takes place mainly at the less hindered site of the π-allyl intermediate yielding compound **11**. However, the reductive process at the most hindered site also occurs, affording small quantities of regioisomer **12**. A Series of Molybdenum(V) Complexes with the Oxalato Ligand Engaged in Different Binding Roles − An Unusual Staggered Conformation of the μ_4-Oxalate in $[\{Mo_2O_4(\eta^2\text{-}C_2O_4)_2\}_2(\mu_4\text{-}C_2O_4)]^{6-}$

Barbara Modec,*[a] Jurij V. Brenčič,[a] and Jože Koller[a]

Keywords: Coordination modes / Molybdenum / Oxo ligands / Oxalate / Polyoxometalates

Solvothermal reactions between mononuclear halooxomolybdates(V) and oxalic acid afforded smaller oligonuclear complexes with the oxalate ion engaged in different binding modes. The oxalate ion coordinates as a bidentate terminal ligand to each metal centre of the $\{Mo_2O_4\}^{2+}$ unit to form the anion of $(MeNC_5H_5)_2[Mo_2O_4(\eta^2\text{-}C_2O_4)_2py_2]$ (**1**; py = pyridine; $MeNC_5H_5^+$ = *N*-methylpyridinium cation). $(MeNC_5H_5)_6[\{Mo_2O_4(\eta^2\text{-}C_2O_4)_2\}_2(\mu_4\text{-}C_2O_4)]$ (**2**) with a tetradentate oxalate ion connecting two dinuclear subunits is a very rare example of a coordination compound with the oxalato ligand in a completely staggered conformation: the two CO_2 entities of the μ_4-oxalate ion are rotated by 90° with respect to each other. Ab initio MO calculations on $[\{Mo_2O_4(\eta^2\text{-}C_2O_4)_2\}_2(\mu_4\text{-}C_2O_4)]^{6-}$ revealed the isomer with the staggered conformation of the μ_4-oxalate ion to be of the lowest energy. The cyclic octanuclear anion of $(MeNC_5H_5)_2[Mo_8O_{16}(OMe)_8(\mu_8\text{-}C_2O_4)]$ (**3**) consists of four dinuclear subunits arranged around the central oxalate ion and additionally linked by pairs of methoxide bridges. Each oxygen atom of the oxalate ion bridges a pair of metal centres not connected by a metal–metal bond. The anionic part of $[MeNC_5H_2(Me)_3]_2[HNC_5H_2(Me)_3]_2[Mo_2O_3(\eta^2\text{-}C_2O_4)_4]$ (**4**) [$MeNC_5H_2(Me)_3^+$ = *N*-methylcollidinium cation; $HNC_5H_2(Me)_3^+$ = protonated 2,4,6-collidine] possesses an *anti*-$\{Mo_2O_3\}^{4+}$ structural fragment with a pair of bidentate oxalate ions coordinated to each molybdenum atom. The compounds were fully characterized by X-ray structural analysis and infrared spectroscopy.

Introduction

The continuous interest in polyoxometalates, in particular those with incorporated organic groups, is driven by their structural analogy to metal oxide surfaces, their use as models for the catalytic reactions taking place at these surfaces and also by the search for novel materials, distinguished by special structural and magnetic properties.[1] The mechanism of their formation is still not well understood. Mostly it is described as the self-assembly of known species. The basic building unit in the chemistry of molybdenum in the +5 oxidation state is a particularly stable dinuclear fragment, shown in Scheme 1 and henceforth symbolised by $\{Mo_2O_4\}^{2+}$. Its two d^1 metal centres are bridged by a pair of oxygen atoms. A single metal−metal bond with the usual length in the 2.5−2.6 Å range participates in the cohesion of the unit.[2] A set number of available coordination sites allows coordination of numerous ligands, while in their absence further aggregation takes place and larger, more stable assemblies are formed. The X-ray structure analyses of many $\{Mo_2O_4\}^{2+}$ compounds have shown that the structural integrity of the dinuclear unit remains intact irrespective of the nature of ligands completing the immediate environment of the metal atom.[2] Among the very diverse ligands which fulfil molybdenum's coordination demands, multidentate oxygen donor ligands have been used with the aim of assisting in the linkage of dinuclear blocks into polymeric materials. With only a few exceptions, the self-assembly process of dinuclear fragments prevailed, leading to discrete cluster species with the multidentate ligands incorporated into the metal oxide cores. As shown with some examples from the recent literature, various typical patterns of assembly can be recognized. For instance, the hexanuclear motif in $[(Mo_2O_4)_3(\mu_6\text{-}AsO_3)(\mu_2\text{-}SO_4)_3(\mu_2\text{-}OH)_3]^{6-}$,[3] $[(Mo_2O_4)_3(\mu_6\text{-}CO_3)(\mu_2\text{-}CO_3)_3(\mu_2\text{-}OH)_3]^{5-}$,[4] and $[(Mo_2O_4)_3(\mu_6\text{-}SO_3)(\mu_2\text{-}SO_3)_3(\mu_2\text{-}O)_3]^{8-}$,[5] is the same as first observed among the phosphomolybdates(V):[6] three $\{Mo_2O_4\}^{2+}$ building blocks are arranged around the central μ_6-bridging ligand [arsenate(III),[3] carbonate,[4] sulfate(IV)[5] or phosphate[6]] to form a planar hexanuclear moiety with three μ_2-bridging ligands [sulfate,[3] carbonate,[4] sulfate(IV)[5] or phosphate[6]] on its periphery. These hexanuclear moieties tend to aggregate even further: in

$\{Mn^{II}[P_4Mo_6O_{28}(OH)_3]_2\}^{16-}$ and $\{Co^{II}[P_4Mo_6O_{28}(OH)_3]_2\}^{16-}$,[7] two recent examples of the basic hexanuclear motif with bridging phosphate ions, the transition metal cation is sandwiched between two hexanuclear moieties to form a "dimer". These "dimers" are linked further through strong ionic interactions into polymeric materials. However, the mixed-valent $[(Mo_2O_4)_3(Mo^{VI}O_4)(O_3PCH_2PO_3)_3]^{8-}$ reveals a new pattern of assembly.[8] Rather than sharing edges as in the above-described examples, three pairs of octahedra arranged around the central molybdate(VI) share corners. Apparently, the larger size of the μ_6-bridging ligand, molybdate(VI) vs. phosphate, arsenate(III) etc., induces the change in the connectivity between the $\{Mo_2O_4\}^{2+}$ blocks. The sulfate(IV) ion has also been seen to connect six $\{Mo_2O_4\}^{2+}$ units into a bulky $[(Mo_2O_4)_6(\mu_2\text{-}SO_3)_{12}(\mu_3\text{-}SO_3)_4]^{20-}$ core.[5] Its structure resembles that of an ε-Keggin derivative.[9] Another example, $[(Mo_2O_4)_{10}(P_2O_7)_{10}(CH_3COO)_8(H_2O)_4]^{28-}$, with coordinated pyrophosphate and acetate ions features an even larger assembly of dinuclear blocks.[10] These are arranged into two groups, one of six and the other of four dinuclear blocks to form two non-equivalent interconnected rings.

In only three cases does the interaction between the $\{Mo_2O_4\}^{2+}$ unit and the multidentate ligand result in a true polymeric material: (i) $[Mo_2O_4(PO_4)(HPO_4)]_n^{3n-}$ with $\{Mo_2O_4\}^{2+}$ units linked in a complicated manner by bridging phosphate ions into a two-dimensional array;[11] (ii) $[Mo_2O_4(C_2O_4)_2(H_2PO_4)]_n^{3n-}$ where μ_2-phosphate ions link dinuclear units into polymeric chains;[12] and (iii) $[Mo_2O_4(\mu_2\text{-}C_2O_4)Cl_2]_n^{2n-}$, prepared in our laboratory, which has infinite chains containing alternating $\{Mo_2O_4\}^{2+}$ units and bis(bidentate) oxalate ions.[13] Our choice of the oxalate ion among many oxygen donor ligands was governed by its ability to adopt several coordination modes. The binding mode the ligand eventually adopts depends, to a certain extent, upon the ratio between the ligand and the central atom. Studies of the interaction between the oxalate ion and the molybdenum(V) starting material resulted, apart from the polymeric $[Mo_2O_4(\mu_2\text{-}C_2O_4)Cl_2]_n^{2n-}$, in a series of smaller $\{Mo_2O_4\}^{2+}$ assemblies. We report herein on the syntheses and the characterization of $(MeNC_5H_5)_2[Mo_2O_4(\eta^2\text{-}C_2O_4)_2py_2]$ (**1**), $(MeNC_5H_5)_6[\{Mo_2O_4(\eta^2\text{-}C_2O_4)_2\}_2(\mu_4\text{-}C_2O_4)]$ (**2**), $(MeNC_5H_5)_2[Mo_8O_{16}(OMe)_8(\mu_8\text{-}C_2O_4)]$ (**3**) and $[MeNC_5H_2(Me)_3]_2[HNC_5H_2(Me)_3]_2[Mo_2O_3(\eta^2\text{-}C_2O_4)_4]$ (**4**).

Results and Discussion

Structural Studies

Crystal Structure of $(MeNC_5H_5)_2[Mo_2O_4(\eta^2\text{-}C_2O_4)_2py_2]$ (1)

The crystal structure of **1** consists of $[Mo_2O_4(\eta^2\text{-}C_2O_4)_2py_2]^{2-}$ anions (Figure 1) and *N*-methylpyridinium cations. Selected bond lengths are given in Table 1. Two molybdenum atoms are bridged by a pair of oxygen atoms to form the $\{Mo_2O_4\}^{2+}$ structural moiety. Its geometry follows a well-established pattern.[2] The distance between

molybdenum atoms, 2.5468(4) Å, is shorter than those observed in larger $\{Mo_2O_4\}^{2+}$ assemblies (see Table 2). The $Mo(O_b)_2Mo$ ring is not planar, instead it is folded about the line connecting the bridging oxygen atoms (O_b). The dihedral angle between two $Mo(O_b)_2$ planes, commonly denoted as the fold angle,[2] is 149.62(6)°. The six-coordination of each molybdenum atom is completed with a bidentate oxalate ion and a pyridine ligand.

Dinuclear oxalato complexes of molybdenum(v) have been studied before.[18] Their dinuclear nature, initially formulated on the basis of spectroscopic data and diamagnetism, was first confirmed by the X-ray structure analysis of $Ba[Mo_2O_4(\eta^2\text{-}C_2O_4)_2(H_2O)_2]\cdot 3H_2O$,[19] which was also the first crystal structure of an $\{Mo_2O_4\}^{2+}$-containing compound. The literature also mentions the $[Mo_2O_4(C_2O_4)_2py_2]^{2-}$ species, although no X-ray structural data were given to support its formulation.[20] In $Ba[Mo_2O_4(\eta^2\text{-}C_2O_4)_2(H_2O)_2]\cdot 3H_2O$,[19] in contrast to the well-documented and uniform tendency of Mo=O bonds to weaken bonds *trans* to themselves, no significant *trans* influence was observed. The molybdenum-to-oxalato-oxygen bond length *trans* to the oxo ligand is 2.14(4) Å compared to 2.11(3) Å for the same bond in the *cis* position. The earlier belief that the oxalato ligand has a low *trans* susceptibility compared to other ligands[21] was ruled out by the later structural determinations of a series of compounds containing the $[Mo_2O_4(\eta^2\text{-}C_2O_4)_2(H_2O)_2]^{2-}$ anion, which clearly indicated the existence of a *trans* influence.[22] However, the effect was not equally conspicuous in all these compounds. In the anion of **1**, two sets of non-equivalent bond lengths are observed, Mo(1)−O(5) = 2.179(2) Å vs. Mo(1)−O(6) = 2.120(2) Å and Mo(2)−O(9) = 2.157(2) Å vs. Mo(2)−O(10) = 2.135(3) Å. Again, the differences are smaller than those observed in various compounds with an operating *trans* influence. For example, in $[\{Mo_2O_4(C_2O_4)_2(H_2O)_2\}_2\{[Ln(H_2O)_4]_2(C_2O_4)\}]\cdot 7H_2O$ (Ln = La^{3+}, Ce^{3+})[23] the bis(bidentate) oxalate ions link two Mo^V_2 entities and two rare earth cations with two distinctly different bond lengths, 2.244(7)−2.251(3) Å vs. 2.143(3)−2.159(7) Å. These observations imply that there are other factors that influence the molybdenum-to-oxalato bond lengths.

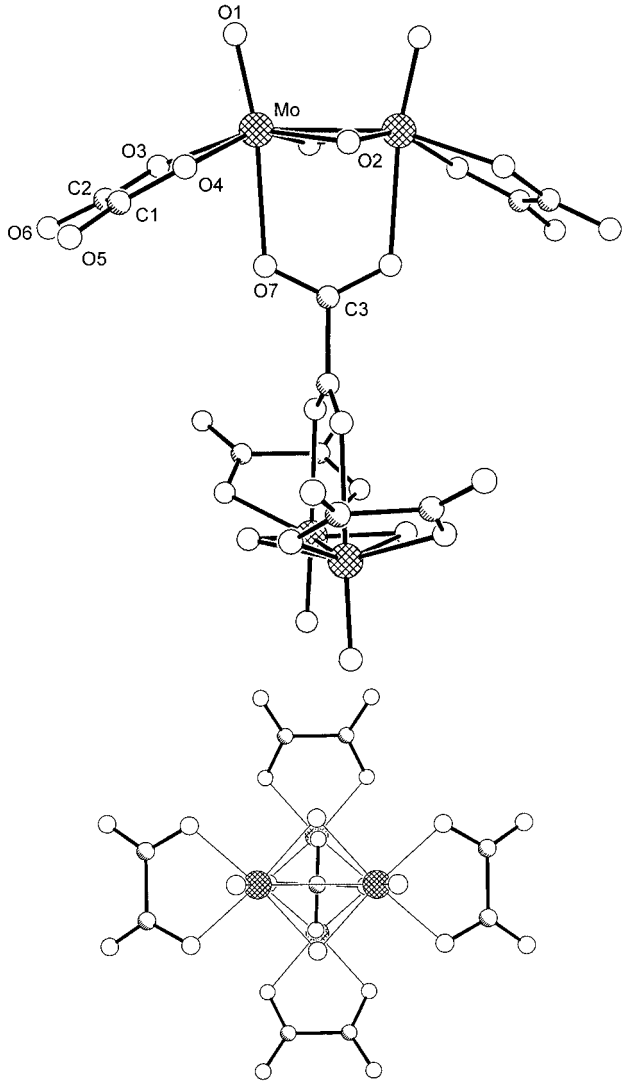

Figure 2. (a) (top) $[\{Mo_2O_4(\eta^2\text{-}C_2O_4)_2\}_2(\mu_4\text{-}C_2O_4)]^{6-}$, the anionic part of **2**, with the μ_4-oxalate ion in a staggered conformation; selected bond lengths [Å]: Mo−O(1) 1.678(2), Mo−O(2) 1.9397(18), Mo−O(2)[a] 1.9423(17), Mo−O(3) 2.0920(18), Mo−O(4) 2.0846(16), Mo−O(7) 2.3678(16), Mo−Mo[a] 2.5655(4), C(3)−O(7) 1.2548(19), C(3)−C(3)[b] 1.532(6); symmetry operations: [a] $-x, -y - 0.5, z$; [b] $-y - 0.25, x - 0.25, -z + 0.25$; (b) (bottom) the tetranuclear anion viewed along the improper fourfold axis

Crystal Structure of $(MeNC_5H_5)_6[\{Mo_2O_4(\eta^2\text{-}C_2O_4)_2\}_2(\mu_4\text{-}C_2O_4)]$ (2)

The crystal structure of **2** consists of tetranuclear $[\{Mo_2O_4(\eta^2\text{-}C_2O_4)_2\}_2(\mu_4\text{-}C_2O_4)]^{6-}$ anions (Figure 2) and *N*-methylpyridinium cations. The anion may be viewed as two $\{Mo_2O_4\}^{2+}$ subunits linked to each other through a μ_4-bridging oxalate ion. The Mo−Mo separation in the $\{Mo_2O_4\}^{2+}$ subunits, 2.5655(4) Å, is in agreement with the value expected for a single metal−metal bond. Each metal centre is attached to a bidentate oxalate ion, the corresponding molybdenum−oxygen distances are 2.0846(16) and 2.0920(18) Å. The terminal oxalate ions are tilted in an umbrella-like manner towards the other half of the anion, as if to shield the bridging oxalate ion. The relatively short distances, 2.7169(22) and 2.7359(23) Å, between a pair of coordinated oxygen atoms of the terminal oxalate ions to the oxygen atom of the μ_4-oxalate ion add support to this observation. This structural feature is readily apparent in Figure 2a. The four molybdenum atoms are related by an improper fourfold rotation axis, which passes through the C−C vector of the μ_4-oxalate ion and the centres of both $Mo(O_b)_2Mo$ rhombic units (Figure 2b). Consequently, the two metal−metal bond vectors are perpendicular to each other. Each oxygen atom of the bridging oxalate ion is coordinated to a different metal centre at a relatively long distance of 2.3678(16) Å. The lengthening of this bond when compared to the molybdenum-to-terminal-oxalate bond lengths may be explained in terms of the *trans* influence of

$[(Mo_2O_4)_3(\mu_6\text{-}CO_3)(\mu_2\text{-}CO_3)_3(\mu_2\text{-}OH)_3]^{5-}$ [4] [b]	2.5884(6)	carbonate	2.355(3)
$\{Na[(Mo_2O_4)_3(\mu_6\text{-}SO_3)(\mu_2\text{-}SO_3)_3(\mu_2\text{-}O)_3]_2\}^{15-}$ [5] [c]	2.597(5)	sulfate(IV)	2.36(2)
$[Mo_2O_4(\mu_2\text{-}SO_3)(SO_3)_4]^{8-}$ [5]	2.5872(18)	sulfate(IV)	2.27(1)
$[\{Mo_2O_4(\eta^2\text{-mal})_2\}_2(\mu_4\text{-mal})]^{6-}$ [25] [d]	2.555	malonate	2.321

[a] A multidentate oxygen donor ligand L coordinates to the dinuclear unit in all cited examples through two of its oxygen atoms, and to each metal centre with one. With the exception $[Mo_2O_4(\mu_2\text{-}SO_3)(SO_3)_4]^{8-}$, it binds in this manner to two or three $\{Mo_2O_4\}^{2+}$ units. [b] A μ_6-carbonate unit links three dinuclear units. [c] A μ_6-sulfate(IV) unit links three dinuclear units. [d] mal = $CH_2(COO)_2^{2-}$. A μ_4-malonate unit links two dinuclear units.

the terminal oxo group. A comparison with other $\{Mo_2O_4\}^{2+}$ compounds where multidentate oxygen donor ligands also coordinate to a pair of molybdenum atoms through two oxygen donor atoms in *trans* positions to the terminal oxo groups shows that the distances in **2** are within the normal range (Table 3).

The bridging oxalate ion is in a completely staggered conformation. The C−O distances of the μ_4-oxalate ion are equal, at 1.2548(19) Å, suggesting a bond character between a single and a double bond. For comparison, two sets of C−O distances are displayed within the bidentate oxalate ions, short ones, 1.216(3) and 1.219(3) Å, typical of localized double bonds, and longer ones, 1.291(3) and 1.294(3) Å. Hexaanions with two dinuclear subunits linked through a tetradentate oxalate ion have been observed before. Thio derivatives of the dinuclear unit, $\{Mo_2O_2(\mu_2\text{-}O)(\mu_2\text{-}S)\}^{2+}$ and $\{Mo_2O_2(\mu_2\text{-}S)_2\}^{2+}$, assemble in almost the same fashion as shown by $[\{Mo_2O_3S(\eta^2\text{-}C_2O_4)_2\}_2(\mu_4\text{-}C_2O_4)]^{6-}$ and $[\{Mo_2O_2S_2(\eta^2\text{-}C_2O_4)_2\}_2(\mu_4\text{-}C_2O_4)]^{6-}$, respectively.[26−28] The same structural type also occurs among very rare oxotungsten(V) compounds, such as $[\{W_2O_2S_2(\eta^2\text{-}C_2O_4)_2\}_2(\mu_4\text{-}C_2O_4)]^{6-}$.[28] Another example, $[Mo_4O_4S_2X_2(C_2O_4)_5]^{6-}$ (X = O or S), consists of one $\{Mo_2O_2(\mu_2\text{-}S)_2\}^{2+}$ unit, while the other displays a disorder in the double bridge.[29] The bridging atoms are partially oxygen and partially sulfur atoms. In contrast to a completely staggered configuration of the oxalate ion in **2**, the μ_4-oxalate ions in all the cited examples are planar. Ab initio MO calculations on the $[\{Mo_2O_4(\eta^2\text{-}C_2O_4)_2\}_2(\mu_4\text{-}C_2O_4)]^{6-}$ anion revealed the isomer with the staggered conformation of the oxalate ion to be the energetically more favoured one (Figure 3). The difference between the calculated energy of the anion with a staggered oxalate ion and that with a planar oxalate ion is 18 kcal/mol. AM1 and ab initio calculations on the oxalate dianion itself also indicated a slight preference for a completely staggered D_{2d} structure over a planar D_{2h} structure.[30] Bearing in mind that the bond lengths between the molybdenum atom and the oxalate oxygen atom in **2** are relatively long, this agreement is not surprising. The calculated barrier to rotation about the C−C bond in the oxalate dianion is smaller than in our case, ca. 5 kcal/mol. An oxalate ion coordinated to different metal ions usually adopts a planar or near-planar

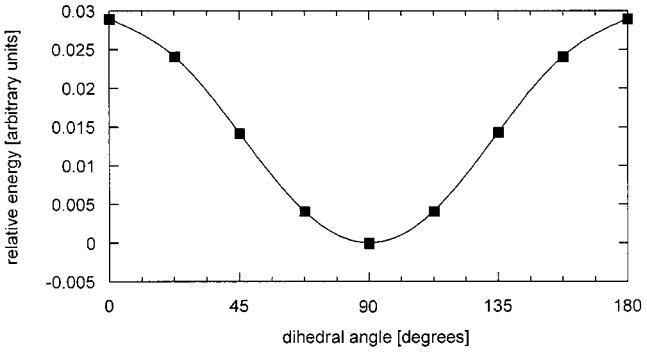

Figure 3. Relative energy of $[\{Mo_2O_4(\eta^2\text{-}C_2O_4)_2\}_2(\mu_4\text{-}C_2O_4)]^{6-}$ as a function of the dihedral angle in the μ_4-oxalate ion; 0.01 units correspond to 6.27 kcal/mol

form. Only a few deviations from planarity have been reported so far. In $[Ni(L1)(C_2O_4)]_n{\cdot}nH_2O$ (L1 represents a tetraaza macrocyclic ligand)[31] and $[Cu(C_2O_4)(H_2O)(4\text{-apy})_2]_n$ (4-apy = 4-aminopyridine)[32] the twist angles of the 1,1′-bis(monodentate) oxalate ion are 103° and 28°, respectively. In both these compounds the nonbonded oxalate oxygen atoms participate in significant hydrogen bonding interactions suggesting that these have an important influence over the ligand's conformation. In a recent study of the anhydrous alkali oxalates, in combination with K^+, Rb^+ and Cs^+ cations, both planar and staggered oxalate conformations were observed, showing that the conformation is determined mainly by packing effects.[33] On the other hand, the electronic structure calculations for the model compounds $[(HCOO)_3M_2(\mu_4\text{-}C_2O_4)M_2(HCOO)_3]$ ($HCOO^-$ stands for formate; and M_2 stands for pairs of Mo^{II} or W^{II} atoms linked by quadruple metal−metal bonds) employing density functional theory predicted the structure with the planar oxalate ion to be energetically more favoured than the one with the completely staggered oxalate ion by ca. 8 kcal/mol. This latter result is in line with the concept that the electronic coupling of M_2 units is maximized when the oxalate ion is in a planar conformation.[34]

Two other multidentate oxygen donor ligands, the malonate and sulfate ions, also form similar tetranuclear hexaanions in combination with the Mo^{V}_2 unit — $[\{Mo_2O_4(\eta^2\text{-}$

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

mal)$_2$}$_2$(μ_4-mal)]$^{6-}$,[25] and [{$Mo_2O_2S_2(\eta^2$-$SO_4)_2$}$_2$(μ_4-SO_4)]$^{6-}$.[35] The latter is the closest structural relative to the anion in **2**. The inherent improper fourfold rotation symmetry of the μ_4-SO_4^{2-} ligand leads to the perpendicular orientation of the two {$Mo_2O_2(\mu_2$-$S)_2$}$^{2+}$ subunits. The elongated Mo_4 tetrahedron has two short (approx. 2.8 Å) and four long (approx. 6.8 Å) Mo−Mo distances. The corresponding distances within the Mo_4 tetrahedron in **2** are 2.5655(4) Å and 7.5913(4) Å.[36]

The fold angle in **2**, 160.21(5)°, is larger than in other {Mo_2O_4}$^{2+}$ compounds (see Table 2). Keeping the metal−metal bond length within the normal range, the less folded bridging moiety, where the value of the fold angle is larger, induces changes in the angles within the $Mo_2(O_b)_2$ rhombus, especially in the O_b−Mo−O_b angles, which become larger. In some of the selected examples in Table 2, the {Mo_2O_4}$^{2+}$ units are fused together by sharing bridging oxygen atoms. It is pertinent to note that such an assembly also induces stress upon the internal dimensions of the constituent dinuclear blocks.

Crystal Structure of ($MeNC_5H_5$)$_2$[Mo_8O_{16}(OMe)$_8$(μ_8-C_2O_4)] (3)

This compound consists of cyclic octanuclear [$Mo_8O_{16}(OMe)_8(\mu_8$-$C_2O_4)$]$^{2-}$ anions and *N*-methylpyridinium cations. As the centre of the ring lies on an inversion centre, the asymmetric unit consists of one half of the anion. Four {Mo_2O_4}$^{2+}$ blocks are connected by pairs of methoxide ligands, forming a ring around the oxalate anion (Figure 4a). The methoxide ions fold out from the ring, whereas the oxo groups fold into the ring. Short metal−metal distances [2.5770(4) Å and 2.5786(4) Å] within the dinuclear blocks alternate with longer non-bonding Mo···Mo contacts [3.2577(4) and 3.2655(4) Å] between the neighbouring dinuclear blocks. Each of the molybdenum centres displays a pseudo-octahedral coordination sphere consisting of six oxygen atoms. The terminal oxygen atoms lie at 1.683(2)−1.688(2) Å, bridging oxygen atoms at 1.926(2)−1.946(2) Å, and bridging methoxide ligands at 2.084(2)−2.122(2) Å. An oxygen atom of the central oxalate ion occupies the position *trans* to the molybdenyl group at a significantly longer distance, 2.355(2)−2.395(2) Å. It also functions as a third bridge between a pair of molybdenum atoms linked by methoxide ligands. The fold angles of the {Mo_2O_4}$^{2+}$ units are 156.43(14)° and 156.83(18)°. All metal atoms, terminal oxo groups and the oxalate ion lie in the plane. One half of the bridging methoxide ions and the bridging oxo groups lie above, and the other half below this plane (Figure 4b). The central oxalate ion is disordered over two positions. The C−O distances of the oxalate ion are in the 1.287(6)−1.317(7) Å range.

The planar configuration of the ring in **3** contrasts with the puckered arrangement observed in [$Mo_8O_{16}(OMe)_8$(R-py)$_4$], with a vacant central cavity.[37] However, the Mo−Mo bond lengths and the Mo···Mo non-bonding contacts in the two are basically the same. The pair illustrates how the oxalate or pyridine ligands influence the conformation of the ring obtained upon the assembly of four {Mo_2O_4}$^{2+}$ building blocks.

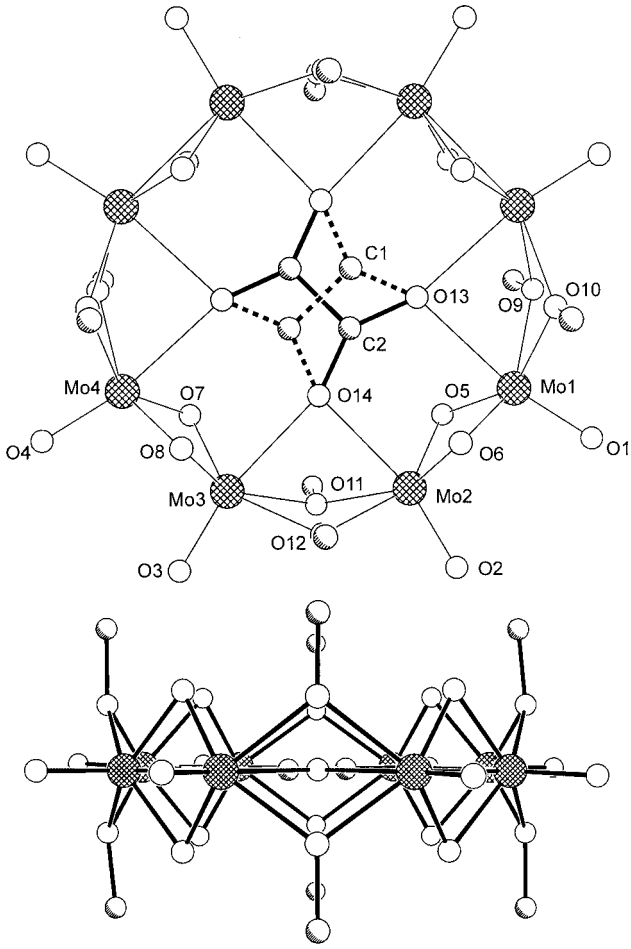

Figure 4. (a) (top) [$Mo_8O_{16}(OMe)_8(\mu_8$-$C_2O_4)$]$^{2-}$, the anionic part in **3**, with the oxalate ion disordered over two positions; selected bond lengths [Å]: Mo(1)−Mo(2) 2.5786(4), Mo(3)−Mo(4) 2.5770(4), Mo(1)−O(13) 2.386(2), Mo(2)−O(14) 2.355(2), Mo(3)−O(14) 2.373(2), Mo(4)−O(13)[a] 2.395(2); symmetry operation: [a] 2 − *x*, 1 − *y*, 2 − *z*; (b) (bottom) side view of the octanuclear anion showing the planar conformation of the ring

The anion [$Mo_8O_{16}(OMe)_8(\mu_8$-$C_2O_4)$]$^{2-}$ has been obtained before by the reaction of α-[(n-$C_4H_9)_4N]_4$[Mo_8O_{26}] with rhodizonic acid.[38] Its formation was explained in terms of a carbonyl insertion reaction coupled with ligand dissociation and redox processes. The same authors also reported the crystal structure of an ethoxide-bridged derivative, [$Mo_8O_{16}(OEt)_8(\mu_8$-$C_2O_4)$]$^{2-}$.[39] The same structural motif — four dinuclear building blocks forming a cycle — is also produced upon the linkage of {$Mo_2O_2(\mu_2$-$S)_2$}$^{2+}$ units through pairs of hydroxide bridges. The neutral cycle with the [$Mo_8S_8O_8(OH)_8$] composition can encapsulate various ligands, such as oxalate,[28,40a] molybdate(VI)[40b] or tungstate(VI) ions.[40c] The {$Mo_2O_2(\mu_2$-$S)_2$}$^{2+}$ unit forms in the presence of hydroxide ions even larger neutral cycles, which incorporate oxygen-donor guests with direct covalent interactions between the oxygen and molybdenum atoms. The inorganic backbone adapts its size and geometry to that of the guest anion. In the case of glutarate, a decanuclear ring

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

was obtained, while with larger anions such as pimelate and trimesate, dodecanuclear rings were formed.[40]

Crystal Structure of $[MeNC_5H_2(Me)_3]_2[HNC_5H_2(Me)_3]_2[Mo_2O_3(\eta^2\text{-}C_2O_4)_4]$ (4)

The dinuclear complex $[Mo_2O_3(\eta^2\text{-}C_2O_4)_4]^{4-}$ (**4**; Figure 5) displays a centrosymmetric structure consisting of an *anti*-$\{Mo_2O_2(\mu_2\text{-}O)\}^{4+}$ core (Scheme 2). *N*-methylated collidine and protonated collidine molecules serve as countercations. Two molybdenum atoms are connected by a single oxygen atom, O(2), lying on the inversion centre. Consequently, the Mo−O−Mo bridge is linear with symmetrical Mo−O(2) bond lengths of 1.8534(2) Å. The two terminal oxygen atoms are *trans* to each other. Insofar as the dimensions of the *anti*-$\{Mo_2O_2(\mu_2\text{-}O)\}^{4+}$ unit are concerned, these are similar to other compounds containing this fragment.[41] Two bidentate oxalate ligands complete a distorted octahedral environment of each metal atom. The coordinated oxygen atoms of one oxalate ion, with bond lengths to the molybdenum atom of 2.032(2) and 2.081(2) Å, are *cis* to the Mo=O group. The corresponding bite angle is 78.37(9)°. The other oxalate ion binds with two distinctly different bond lengths, 2.0869(19) and 2.217(2) Å. The longer one is, as expected, *trans* to the terminal oxo group. The oxalate bite angle is smaller, 73.87(7)°. The oxalate bite angles are largely determined by the metal−oxygen distances: when these are longer than 2.1 Å, the oxygen−metal−oxygen angles become smaller than 80°.[42]

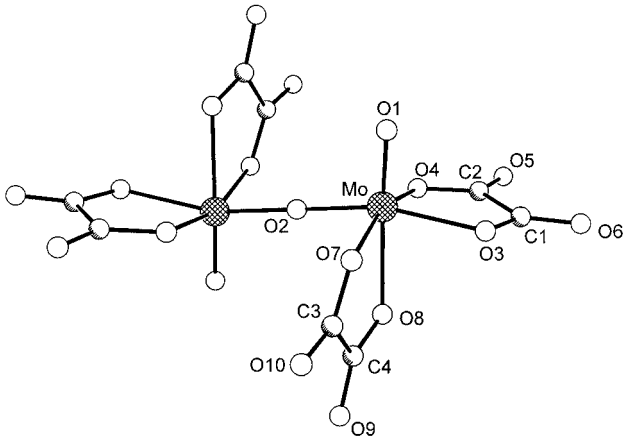

Figure 5. $[Mo_2O_3(\eta^2\text{-}C_2O_4)_4]^{4-}$ ion in **4**; selected bond lengths [Å]: Mo−O(1) 1.668(3), Mo−O(2) 1.8534(2), Mo−O(3) 2.081(2), Mo−O(4) 2.032(2), Mo−O(7) 2.0869(19), Mo−O(8) 2.217(2)

Vibrational Spectroscopy

Although the oxalate absorption bands in the infrared spectra reflect its binding modes,[43] the overlap of some with pyridine absorptions prevents straightforward assignations. Among three sets of the characteristic oxalate bands, ν_{as}(OCO), ν_s(OCO) and δ(OCO), the carbon−oxygen asymmetric and symmetric stretching frequencies show the highest sensitivity to the metal coordination and thus to the binding mode employed. In addition, the metal−oxygen bond lengths also affect the number of bands.[44] The influence of the asymmetric binding on the infrared bands is clearly observed in the infrared spectra of $(MeNC_5H_5)_{2n}[Mo_2O_4(C_2O_4)Cl_2]_n$ and $(3\text{-}MePyH)_{2n}[Mo_2O_4(C_2O_4)Cl_2]_n$ where the bis(bidentate) oxalate ion bridges two metal centres in a highly asymmetric fashion, 2.172(2) vs. 2.312(2) and 2.1684(15) vs. 2.3183(16) Å, respectively.[13] Two sets of ν_{as}(OCO) [at 1671 and 1633 cm^{-1} for the $MeNC_5H_5^+$ compound, and at 1671 and 1633 cm^{-1} for the $3\text{-}MePyH^+$ compound] and ν_s(OCO) bands [at 1354, 1306 and 1288 cm^{-1} for the $MeNC_5H_5^+$ compound, and at 1353, 1302 and 1264 cm^{-1} for the $3\text{-}MePyH^+$ compound] are observed.

In **3**, with one type of oxalate ligand, each of the oxalate oxygen atoms bridges two molybdenum atoms with metal−oxygen distances of approximately the same length. The bands at 1659, 1635 [ν_{as}(OCO)], 1336, 1290 [ν_s(OCO)] and 813 cm^{-1} [δ(OCO)] are in accordance with expectations.[43] The terminal, bidentate binding mode in **1** gives rise to bands at 1705, 1667, 1633 [ν_{as}(OCO)], 1372, 1287 [ν_s(OCO)] and at 780 cm^{-1} [δ(OCO)]. Their frequencies agree very well with those reported for $Ba[Mo_2O_4(C_2O_4)_2(H_2O)_2]\cdot 3H_2O$ {1710, 1680, 1653 [ν_{as}(OCO)]; 1430, 1289 [ν_s(OCO)]; 793 cm^{-1} [δ(OCO)]}[19] and other compounds containing a bidentate oxalate ion.[45] The occurrence of a bidentate oxalate ion is also evident in the spectrum of **4** where the bands occur at 1709, 1682, 1633 [ν_{as}(OCO)], 1337, 1259 ν_s[(OCO)] and 799 cm^{-1} [δ(OCO)]. A multitude of bands {1705, 1681, 1657, 1633, 1574 [ν_{as}(OCO)]; 1360, 1322, 1288 [ν_s(OCO)]; 828, 800 cm^{-1} [δ(OCO)]} in the spectrum of **2** indicates both the bidentate and tetradentate binding modes of the oxalate ion. These are similar to those observed in $[H_3N(CH_2)_3NH_3]_3[Mo_4S_4O_4(C_2O_4)_5]\cdot 4.5H_2O$ [bands at 1716, 1688, 1600, 1506 in the ν_{as}(OCO) region; 1391, 1321, 1242 in the ν_s(OCO) region and 830, 794 cm^{-1} in the δ(OCO) region].[28]

Bands in the 1000−900 cm^{-1} region are associated with the Mo=O stretching vibrations. These are seen as strong bands at 949, 939 and 927 cm^{-1} for **1**, 958, 942 and 903 cm^{-1} for **2**, and for **3** and **4** as a single band at 962 and 960 cm^{-1}, respectively.

General Considerations

As observed before,[13−15,46] methanol and pyridines provide a medium where the formation of the $\{Mo_2O_4\}^{2+}$ fragment from the mononuclear halooxomolybdate(v) is a fast and reproducible process. The dinuclear unit with three coordination sites per metal atom and the oxalate ion is a system where the variation of the amount of one with respect to the other can produce discrete clusters when the amounts of the oxalate ion are large, or a polymeric material when the amounts of the oxalate ion are small. In the

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

former case, $[Mo_2O_4(\eta^2\text{-}C_2O_4)_2py_2]^{2-}$ (**1**) and $[\{Mo_2O_4(\eta^2\text{-}C_2O_4)_2\}_2(\mu_4\text{-}C_2O_4)]^{6-}$ (**2**) were obtained. In **1** the oxalate ion occupies two out of three coordination sites of each metal atom in a bidentate fashion. One of the coordinated oxalate oxygen atoms is *cis* to the Mo=O group, and the other is in a less favourable *trans* position. Pyridine ligates to the remaining, third site. Considering both metal centres, two distinct geometries are possible. In **1**, the two pyridine ligands are on the opposite sides of the plane defined by a pair of Mo=O groups (*trans* to each other). The two pyridine ligands can also lie on the same side of the plane (*cis* to each other). The reaction conditions employed in the preparation of **1** apparently favour the *trans* isomer. Employing a huge excess of the oxalate ion afforded $[\{Mo_2O_4(\eta^2\text{-}C_2O_4)_2\}_2(\mu_4\text{-}C_2O_4)]^{6-}$ (**2**), where all three coordination sites of each metal centre are occupied with oxygen-donor ligands. Two belong to the bidentate oxalate ion and the third one to the bridging oxalate ion. Although the reaction medium for the preparation of **2** is mostly pyridine, pyridine does not coordinate. Reducing the ratio of oxalate vs. molybdate produces either a polymeric $[Mo_2O_4(C_2O_4)Cl_2]_n^{2n-}$, with one oxalate ion per dinuclear unit,[13] or a discrete octanuclear $[Mo_8O_{16}(OMe)_8(\mu_8\text{-}C_2O_4)]^{2-}$ (**3**) with one oxalate ion for every four dinuclear units, the major difference between the two synthetic procedures being the presence of pyridine. While the polymeric species is obtained in pyridine, the reaction mixture used in the case of **3** does not contain any. Methanol not only provides the reaction medium in the preparation of **3**, it is also a source of methoxide ions, which coordinate to the molybdenum atom and serve as bridges in the linkage of $\{Mo_2O_4\}^{2+}$ units. The role that methanol plays in the reaction mixtures merits additional comment as it is also consumed in the in situ formation of *N*-methylpyridinium cations. Their formation at elevated temperature requires apart from methanol, also pyridine and oxalic acid. *N*-Alkylation takes place when other pyridines are used as substrates as well, for example 2,4,6-collidine in the formation of **4**. The exact nature of this process is currently under investigation.[47] When no methanol is used, the only product isolated so far was $(PyH)_2[Mo_2O_4(\eta^2\text{-}C_2O_4)_2py_2]$, provided that a sufficient amount of the oxalate ion was present.

It is pertinent to mention briefly a series of structurally related species, dinuclear *cis*-$[Mo_2O_2(\mu_2\text{-}S)_2(\eta^2\text{-}C_2O_4)_2(H_2O)_2]^{2-}$, tetranuclear $[\{Mo_2O_2(\mu_2\text{-}S)_2(\eta^2\text{-}C_2O_4)_2\}_2(\mu_4\text{-}C_2O_4)]^{6-}$ and octanuclear $[Mo_8O_8S_8(OH)_8(\mu_8\text{-}C_2O_4)]^{2-}$, which are formed in the reactions between the thio-bridged dimer $\{Mo_2O_2(\mu_2\text{-}S)_2\}^{2+}$ and oxalate ions in aqueous media.[28,40e,40f] It was observed that the reaction products depend more upon the pH of the reaction medium than the stoichiometry. At pH ≈ 1.5, the dinuclear species is obtained, in less acidic medium, at pH ≈ 4, the tetranuclear one and at pH > 5, the octanuclear one. The binding modes of the oxalate ion were described as the competition between the chelating and the templating role of the ligand. The analogy between the thio-bridged species and the anions of **1**, **2** and **3** is unfortunately limited to their structures only. The same pattern of assembly of basic dinuclear units to form larger oligonuclear species can be recognized within the two series.

The preparation of **4** opens new perspectives. Similar amounts of the reagents were used as for the preparations of **1** or **2** with 2,4,6-collidine instead of pyridine. Given the low coordinating ability of 2,4,6-collidine due to methyl substituents in the *ortho* positions, the oxalate ion, as the only other ligand present in the reaction mixture, was forced to occupy more than two coordination sites in each metal atom environment. A singly oxo-bridged dimer, $\{Mo_2O_3\}^{4+}$, was formed. The four coordination sites of each metal atom are occupied by a pair of bidentate oxalate ions. It remains open for further studies to investigate how this system would respond to a reduced amount of oxalate ions, whether the oxalate ion would adopt the bis(bidentate) binding mode and as such connect dinuclear units, $\{Mo_2O_3\}^{4+}$ fragments in this case, into polymeric structures. It also seems feasible that the use of non-coordinating solvents could enable the coordination of the oxalate ion in less common binding modes and thus the synthesis of more complex architectures.

Conclusion

A series of discrete oxalato complexes of molybdenum(v) was accessed by solvothermal reactions of mononuclear halooxomolybdates(v) with oxalic acid. The oxalate ion binds to the dinuclear units, $\{Mo_2O_4\}^{2+}$ or $\{Mo_2O_3\}^{4+}$, as a terminal bidentate ligand as observed in $[Mo_2O_4(\eta^2\text{-}C_2O_4)_2py_2]^{2-}$ (**1**) and $[Mo_2O_3(\eta^2\text{-}C_2O_4)_4]^{4-}$ (**4**) or bridges two or four $\{Mo_2O_4\}^{2+}$ units as observed in $[\{Mo_2O_4(\eta^2\text{-}C_2O_4)_2\}_2(\mu_4\text{-}C_2O_4)]^{6-}$ (**2**) and $[Mo_8O_{16}(OMe)_8(\mu_8\text{-}C_2O_4)]^{2-}$ (**3**), respectively.

Experimental Section

General Remarks: Reactions were carried out in sealed glass tubes under autogenous pressure. Reagents were purchased from Aldrich and used without further purification. $(PyH)_2[MoOCl_5]$ and $(PyH)[MoOBr_4]$ were prepared by minor modification of a published procedure.[48] The IR and far-IR spectra were measured on solid samples as Nujol or poly(chlorotrifluoroethylene) mulls using a Perkin−Elmer 2000 series FT-IR spectrometer. Elemental analyses were performed by the Chemistry Department service at the University of Ljubljana.

$(MeNC_5H_5)_2[Mo_2O_4(\eta^2\text{-}C_2O_4)_2py_2]$ (1): A mixture of $(PyH)_2[MoOCl_5]$ (100 mg, 0.223 mmol), $H_2C_2O_4{\cdot}2H_2O$ (100 mg, 0.793 mmol), pyridine (4 mL), methanol (0.5 mL) and acetonitrile (0.5 mL) was placed in a glass tube which was sealed and subsequently heated in an electric oven maintained at 115 °C for 120 h. After cooling to room temperature, orange crystals of compound **1** were isolated in 40% yield (35 mg). IR: $\tilde{\nu}$ = 3047 (w), 2915 (w), 2851 (w), 1705 (vs), 1667 (vs), 1633 (vs), 1603 (vs), 1584 (s), 1494 (s), 1450 (s), 1372 (s), 1287 (m), 1254 (m), 1241 (m), 1216 (m), 1192 (m), 1163 (m), 1073 (m), 1015 (m), 949 (s), 939 (s), 927 (s), 897 (s), 780 (vs), 758 (vs), 734 (vs), 685 (vs), 649 (m), 639 (m), 524 (m), 482 (s), 451 (w), 435 (w), 348 (w), 320 (vs), 257 (s) cm^{-1}.

$[MeNC_5H_2(Me)_3]_2[HNC_5H_2(Me)_3]_2[Mo_2O_3(\eta^2\text{-}C_2O_4)_4]$ (4): A mixture of $(PyH)[MoOBr_4]$ (120 mg, 0.235 mmol), $H_2C_2O_4{\cdot}2H_2O$ (100 mg, 0.793 mmol), 2,4,6-collidine (4 mL), methanol (0.5 mL) and acetonitrile (0.5 mL) was placed in a glass tube which was sealed and subsequently heated in an electric oven maintained at 115 °C for 120 h. After cooling to room temperature, large black crystals of compound **4** were isolated in 47% yield (61 mg). IR: $\tilde{\nu}$ = 2920 (vs), 2849 (vs), 2671 (m), 2580 (m), 1912 (w), 1709 (vs), 1682 (vs), 1633 (vs), 1337 (m), 1274 (w), 1259 (m), 1224 (w), 1199 (m), 1171 (w), 1152 (w), 1039 (m), 997 (w), 960 (vs), 892 (m), 863 (w), 799 (vs), 786 (m), 721 (w), 535 (s), 517 (s), 477 (m), 445 (m), 366 (m), 350 (m), 312 (s), 264 (m), 220 (m), 193 (m). $C_{42}H_{52}Mo_2N_4O_{19}$ (1108.76): calcd. C 45.50, H 4.73, N 5.05; found C 45.68, H 4.59, N 4.97.

X-ray Crystallographic Study: The crystals were mounted on the tip of a glass fibre with a small amount of silicon grease and transferred to a goniometer head. Data were collected with a Nonius Kappa CCD diffractometer. For all compounds, data reduction and integration were performed with the software package DENZO-SMN.[49] Averaging of the symmetry-equivalent reflections largely compensated for the absorption effects. The coordinates of some or all of the non-hydrogen atoms were found by direct methods using the structure solution program SHELXS.[50] The positions of the remaining non-hydrogen atoms were located by use of a combination of least-squares refinement and difference Fourier maps with the SHELXL-97[50] program. Non-hydrogen atoms were refined with anisotropic displacement parameters. The hydrogen atoms were included in the structure factor calculations at idealized positions. The oxalate ion in **3** is disordered over two positions. The carbon atoms C(1) and C(2) of the disordered oxalate ion were refined anisotropically with the occupancy factors 0.51(1) and 0.49(1), respectively. Cell parameters and refinement results for compounds **1**−**4** are summarized in Table 4. CCDC-211525 (**1**), -211526 (**2**), -211527 (**3**) and -211528 (**4**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Computational Details: Ab initio MO calculations on the $[\{Mo_2O_4(\eta^2\text{-}C_2O_4)_2\}_2(\mu_4\text{-}C_2O_4)]^{6-}$ ion at the HF/3-21G* level were performed in order to determine its energy as a function of the dihedral angle in the μ_4-oxalate ion. The Gaussian 98 suite of programs was used.[51] No geometry optimization was applied. The

Absorption, Magnetic Circular Dichroism, IR Spectra, Electrochemistry, and Molecular Orbital Calculations of Monoaza- and Opposite Diazaporphyrins

Hiroshi Ogata,[a] Takamitsu Fukuda,[a] Katsunori Nakai,[a] Yuichi Fujimura,[a] Saburo Neya,[b] Pavel A. Stuzhin,[c] and Nagao Kobayashi*[a]

Keywords: Cyclic voltammetry / Density functional calculations / Magnetic circular dichroism / Porphyrinoids / UV/Vis spectroscopy

Electronic absorption, magnetic circular dichroism (MCD), IR spectra, and cyclic and differential pulse voltammograms of metal-free and copper monoaza- and opposite diazaporphyrins are reported, together with molecular orbital (MO) calculations using the density functional theory (DFT) method. Introduction of nitrogen atoms at the *meso* position of porphyrins caused a blue-shift of the B band and a red-shift of the Q band, with a concomitant decrease and increase of the apparent absorption coefficient, respectively. On going from monoaza to diaza species, the apparent bandwidth at half-height of the B band and the splitting of the Q band do not change significantly for metal-free species, but increase for the copper species. The MCD peaks and troughs correspond closely to the peaks of the absorption spectra, so that these are interpreted as the superimposition of Faraday *B* terms. The MCD sign pattern (minus-to-plus on going from longer to shorter wavelengths) substantiates experimentally that the splitting between the HOMO and HOMO–1 orbital is larger than that between the LUMO and LUMO+1. Of the copper complexes of octaethylporphyrin (OEP), monoaza- (MAP), diaza- (DAP) and tetraazaporphyrins (TAP), CuTAP is the easiest to reduce and hardest to oxidize. The potential differences between the first oxidation and reduction couples were about 2.1–2.4 V. MO calculations using DFT succeeded in reproducing some of the above spectroscopic and electrochemical characteristics. In addition, some of the IR bands were assigned on the basis of the DFT calculations.

Introduction

Azaporphyrins (APs) are porphyrins whose *meso*-carbon atoms have been replaced by nitrogen atoms to a varying degree. Monoaza- (MAP)[1−3] and diaza-porphyrins (DAP)[4] were first synthesized in the second half of the 1930s, and since then their improved synthesis,[5−13] and electronic absorption,[14−18] fluorescence,[19−21] IR,[6,16] NMR,[6,9,14−16,22] and EPR[15,16,23] spectra have been reported. While the spectroscopic changes due to the introduction of nitrogen atom(s) have often attracted the attention of physical chemists, to date no-one has applied magnetic circular dichroism (MCD) to these species. MCD spectroscopy[24] provides ground- and excited-state degeneracy information, which is needed to fully understand the electronic structure of high symmetry molecules. We, therefore, have applied this spectroscopy to various phthalocyanine (Pc)[25] and low symmetry Pc derivatives[26] and confirmed its utility in analyzing the electronic structure of these large aromatic metallocomplexes. In addition, no-one has attempted to interpret the IR spectra of these low-symmetry compounds by quantum mechanical calculations either. Electrochemical data on APs have also been rarely reported; the first oxidation potentials of a few MAPs in butyronitrile[16] and the first reduction potentials of MAP- and DAP-reconstituted hemoproteins[27] were recorded in a tris-buffer solution. Accordingly, no oxidation and reduction potentials have been reported for single AP derivatives. We therefore report here the electronic absorption, MCD and IR spectra, and electrochemistry of metal-free and copper MAP and DAP, together with results of quantum mechanical calculations.

tion and MCD spectra of the monoaza and diaza species, respectively.

Metal-Free Species

In the case of H_2MAP (Figure 2), the Q_{x00} and Q_{y00} bands appear at 612 and 536 nm, respectively. The wavelength of the former band is shorter than that of octaethylporphyrin (OEP)[28] by about 10 nm, while that of the latter is slightly longer by several nanometers. The splitting energy between the Q_{x00} and Q_{y00} bands is about 2320 cm^{-1}. The B band appears at 376 nm, which is shorter than that of OEP by more than 20 nm, while its shape is not symmetrical and the bandwidth is apparently larger than that of OEP. In H_2DAP, the two Q bands are red-shifted by about 11 nm, with a splitting energy of 2280 cm^{-1}, and are slightly more intense than in H_2MAP. The B band is only slightly blue-shifted, and the apparent absorption coefficient decreases.

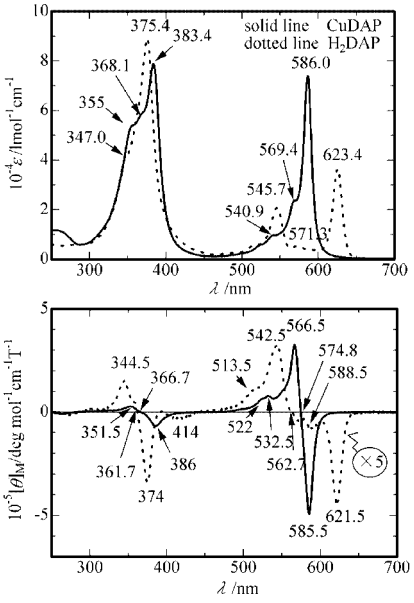

Figure 3. Electronic absorption (top) and MCD (bottom) spectra of CuDAP (solid lines) and H_2DAP (dotted lines) in chloroform; note the encircled magnification factor for the MCD of H_2DAP

The MCD peaks and troughs are observed roughly in the same positions as the absorption peaks and shoulders (Faraday *B* terms). In the Q-band region, the first and third peaks from the lower-energy side correspond to the Q_{x00} and Q_{y00} band for both H_2MAP and H_2DAP, since they show opposite signs. In the B region of H_2MAP, two dispersion curves appear, corresponding to the broad absorption spectra. These are considered to be due to pseudo-Faraday *A* terms produced by superimposition of at least four closely lying Faraday *B* terms.[30] In the B MCD of H_2DAP, the complexity of the spectra on the longer-wavelength side observed for H_2MAP decreases, and the most intense MCD trough and peak in this region appear to correspond to the absorption peak and shoulder, respectively.

Copper Species

The most intense Q- and B-band peaks of CuMAP appear at 570 and 389 nm, respectively. Since the corresponding bands of CuOEP occur at 560 and 399 nm, respectively,[28] the Q- and B-bands are shifted by about 10 nm to the red and blue, respectively, on introduction of one *meso*-nitrogen atom. In the case of CuDAP, the Q-band shifts further, to 586 nm, with an increase in intensity, while the B-band shifts to the blue, to 383 nm, with a loss of intensity. The apparent ratio of the absorption coefficient of the B-band to that of the Q-band [ε(B)/ε(Q)] decreases from about 12. 4 for CuOEP[28] to about 3.2 for CuMAP and further to about 1.1 for CuDAP, indicating that the Q-band becomes more intense with an increasing number of *meso*-nitrogen atoms.[29] In addition, the B-band is significantly broader than with CuMAP.

CuMAP shows dispersion-type MCD curves corresponding to the most intense Q- and B-band peaks. However,

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

these are considered to be pseudo-Faraday *A* terms produced by two *B* terms of opposite sign.[30] The MCD trough at 570 nm coincides with the absorption maximum, while the MCD peak at 558 nm corresponds to an absorption shoulder seen at the shorter-wavelength side of the absorption peak at 570 nm. The wavelength of the inflection point of the B MCD matches the absorption peak wavelength. These apparent *A* terms are produced, since the degeneracy of the LUMO is not lifted markedly by introduction of one *meso*-nitrogen atom. The Q MCD of CuDAP also has a dispersion-type curve. However, these are also Faraday *B* terms, since the Q MCD trough at 586 nm and the peak at 567 nm correspond closely to the absorption peaks at 586 and 569 nm, respectively. This feature is more clearly seen in the B MCD curve, which is weaker than that of CuMAP. The MCD trough and peak at 386 and 352 nm closely correspond to absorption peaks at 383 and 355 nm, respectively, and the shape of the inflection point is not as clear as for the Q band, indicating a significant splitting of the Soret band. Since both CuMAP and CuDAP display a negative-to-positive MCD pattern, it is experimentally suggested that the splitting of the LUMO is smaller than that between the HOMO and HOMO−1.[31]

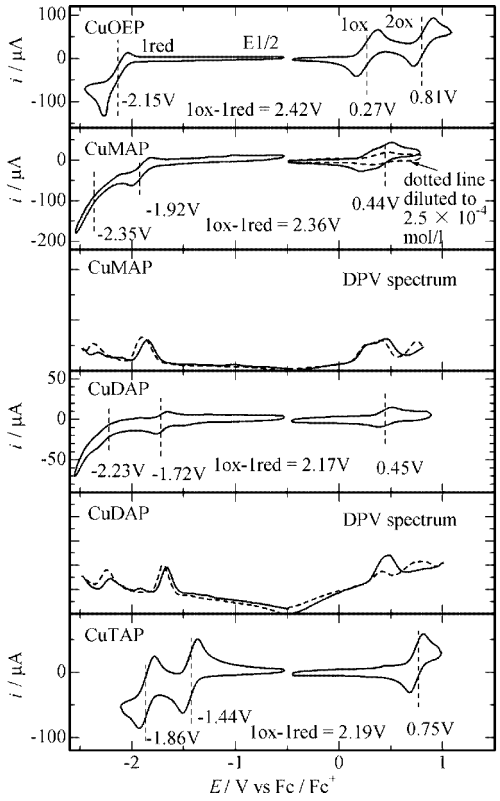

Figure 4. Cyclic and differential pulse voltammograms of CuOEP, CuMAP, CuDAP (opposite type), and CuTAP (from top to bottom) in *o*-DCB containing 0.1 mol/L TBAP

Electrochemistry

As described in the introductory portion, electrochemical data on MAP and DAP are still very rare, and even the first oxidation and reduction potentials of a single azaporphyrin derivative are not known. We therefore recorded the cyclic and differential pulse voltammograms of CuTAP and CuDAP, together with the CV curves of CuOEP and CuTAP in *o*-dichlorobenzene (*o*-DCB) (Figure 4). In the order OEP, MAP, DAP, and tetraazaporphyrin (TAP) — with increasing number of *meso*-nitrogen atoms — the first oxidation potential becomes more positive, since *meso*-nitrogen atoms withdraw electrons from the core of the skeleton, as follows: 0.27, 0.44, 0.45, 0.75 V, respectively. Similarly the first reduction potential varies as −2.15, −1.92, −1.72, −1.44 V, respectively, while the second reduction potential varies as (unmeasureable), −2.35, −2.23, −1.86 V, respectively. The potential difference between the first oxidation and reduction potentials of OEP derivatives is known to be 2.25 ± 0.15 V.[32] These values for CuMAP, CuDAP, and CuTAP are 2.36, 2.17, and 2.19 V, respectively, indicating that the introduction of *meso*-nitrogen atoms does not significantly affect the values. The slightly smaller value for CuDAP (2.17 V) is related to the appearance of the Q-band at longer wavelength due to its D_{2h} symmetry. The potential differences between the first and second reduction potentials for these species are 0.43, 0.51, and 0.42 V, respectively, in the above order, versus 0.42 ± 0.05 V reported for OEP derivatives.[32] These properties can be reproduced by MO calculations, as described in the next section.

MO Calculations

Orbital Energy

Molecular orbital calculations on a series of compounds between normal porphyrins and *meso*-azaporphyrins using CNDO/S Hamiltonian have been reported by Solovyov et al.[19,33] Important differences were found in the energies of the HOMOs between our results and those of Solovyov et al. Diamagnetic zinc was employed instead of paramagnetic copper as the central metal. As shown in Figure 5, the HOMO energy stabilizes moderately in contrast to almost no change reported by Solovyov et al., although the HOMO−1 orbital stabilizes significantly with increasing number of *meso*-nitrogen atoms, since this orbital has a large coefficient at the *meso* positions, as a_{2u} orbitals in D_{4h}-symmetric porphyrins and Pcs.

The LUMO also generally stabilizes with increasing number of *meso*-nitrogen atoms. Accordingly, these trends are in agreement with the observation (Figure 4) that both the first oxidation and reduction potentials become more positive with the introduction of *meso*-nitrogen atoms. As a result, the calculated energy differences between the HOMO and LUMO decrease in the order of OEP (3.027), MAP (2.939), DAP (2.690), and TAP (2.681 V), illustrating a good relationship with the experimental energy difference

between the first oxidation and reduction potentials (2.36, 2.17, and 2.19 V for CuMAP, CuDAP, and CuTAP, respectively). In addition, as suggested experimentally by a negative-to-positive MCD pattern for CuMAP and CuDAP, the calculated splitting between the HOMO and HOMO−1 is larger than that between the LUMO and LUMO+1 in these molecules. Thus, the calculated MO energies reproduce well the redox properties and one aspect of the MCD spectra.

Calculated Spectra

Table 1 summarizes the calculated absorption data of ZnMAP and ZnDAP. Not all the spectroscopic properties have been satisfactorily reproduced. However, the following results do reproduce the experimental trends. 1) The Q-band splitting is very small (less than 5 nm, ca. 150−180 cm^{-1}), as is discernible from the MCD of CuMAP and CuDAP (Figure 2 and 3). 2) The Q-band intensity is larger for the DAP species than for MAP. 3) Of the split Q-band, the one at longer wavelength is much stronger than that at shorter wavelength for the DAP species, as seen for CuDAP. 4) The purity of the Q-band increases with increasing number of *meso*-nitrogen atoms, since the energy difference between the HOMO and HOMO−1 increases. 5) The positions of the split Soret bands of DAP appear at shorter wavelength while their splitting is larger than for the MAP species. Judging from their configuration and intensity, the bands at 355 and 352 nm are the split Soret bands of ZnMAP, while the Soret bands of ZnDAP were estimated at 345 and 330 nm. On the other hand, the calculated features that do not agree with the experiments are as follows. 1) The Q-bands of the MAP species were calculated at slightly longer wavelength (510 and 506 nm) than those of the DAP species (505 and 500 nm). 2) Of the Q-bands of the MAP species, the band at longer wavelength is weaker than that at shorter wavelength. Thus, the calculations are able to roughly reproduce many of the experimental trends.

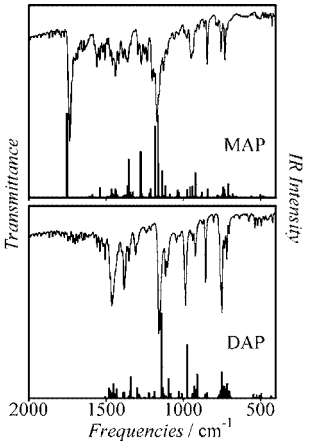

Figure 6. Experimental and calculated (bars) IR spectra of CuMAP (top) and CuDAP (bottom); in the calculation, Cu atoms were replaced by Zn

Structural Modelling and IR Spectra

Although the vibrational structures of tetraazaporphyrins (TAPs) and porphyrins (Pors) are expected to be similar because of the close resemblance of their skeletons, some differences were still detected between the experimental IR spectra of MAP and DAP, as depicted in Figure 6. One of the reasons for this obviously arises from the different substituents at the β-positions of the pyrroles. In order to eliminate the substituent effects and allow comparison of the IR spectra of MAP and DAP, quantum chemical calculations may be helpful. Accordingly, DFT calculations of IR spectra of MAP and DAP using the B3LYP[34] functional in combination with the 6−31G(d) basis set were performed, since this combination has been previously demonstrated to satisfactorily reproduce the experimental IR spectra of low symmetrical tetraaza-chlorin, bacteriochlorin, and isobacteriochlorin derivatives.[35,36] For simplicity of calculations, diamagnetic zinc was employed instead of paramagnetic copper as the central metal.

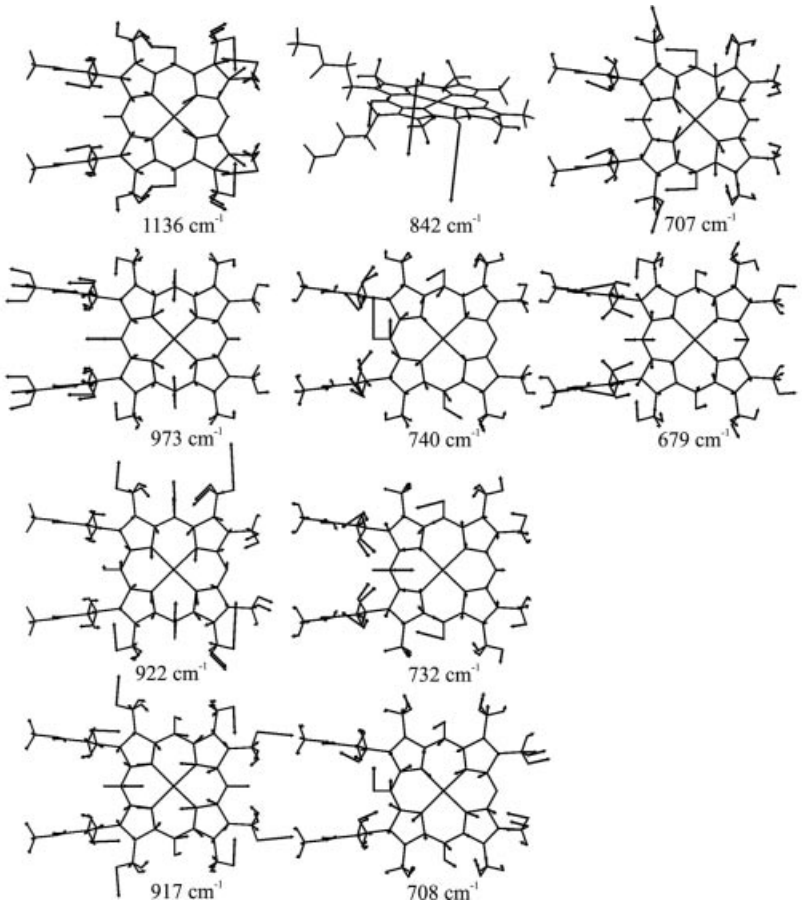

Figure 8. Atomic movements at the selected predicted frequencies of ZnMAP

MAP and DAP have planar skeletal structures with C_{2v} and D_{2h} symmetry, respectively. Table 2 presents selected bond lengths and angles obtained from the calculations (see also Figure 7). The lengths of the C−C and C−N bonds are 1.368−1.405 and 1.331 Å, respectively, which are within the typical values of aromatic compounds, implying a lack of strain in the molecules. The C−C−C and C−*N*−C angles are also normal. The $N_{pyrrole}-N_{pyrrole}$ distances across the azamethine group (i.e. N2−N3 for MAP and N2−N3 and N4−N1 for DAP) are shorter than the other $N_{pyrrole}-N_{pyrrole}$ distances (across the $C-H_{meso}$ group). This is simply because of the larger $C-C_{meso}-C$ bond angles than for the $C-N_{meso}-C$, and the central metal is, therefore, surrounded by the C_{2v}- and D_{2h}-type ligands, respectively.

The calculated harmonic vibrational frequencies (bars) are also listed in Figure 6. The calculated modes were assigned to experimental bands on the basis of both the frequency and intensity data. Some assignable vibrational modes are illustrated in Figure 8 and 9 using vector models. As shown, the correspondence between the experimental and calculated values is good, in particular in the energy region below 1200 cm^{-1}. An intense band at 1753 cm^{-1} for MAP obviously originates from the C=O stretching of the substituted esters. The other skeletal vibrations appear below about 1500 cm^{-1}. The out-of-plane motion of the hydrogens appears in the energy region below about 1000 cm^{-1}. In particular, the out-of-plane motion of the $C-H_{meso}$ groups was assigned to the peaks at 842 and 846 cm^{-1} for MAP and DAP, respectively, which demonstrates an independence of this type of vibration of the molecular structures. Although the intense bands at 1180 and 1163 cm^{-1} (MAP) and 1140 cm^{-1} (DAP) are energetically close, the former two bands originate from vibrations localized on the substituents, and the latter from inner skeletal vibrational modes. The effect of substituents was characterized by relatively intense bands. The in-plane motions of the skeleton are located at 1136, 973, 922, 917, 740, and 732 cm^{-1} for MAP and at 1340, 1132, 1094, 973, 928, 917, 910, 749, and 734 cm^{-1} for DAP. The above results illustrate that the DFT calculations are able to satisfactorily reproduce the experimental IR spectra.

Conclusion

Electronic absorption, MCD, and IR spectra, and redox potentials of metal-free and copper monoaza- and opposite diazaporphyrins have been reported, together with their molecular orbital (MO) and vibrational frequencies on the

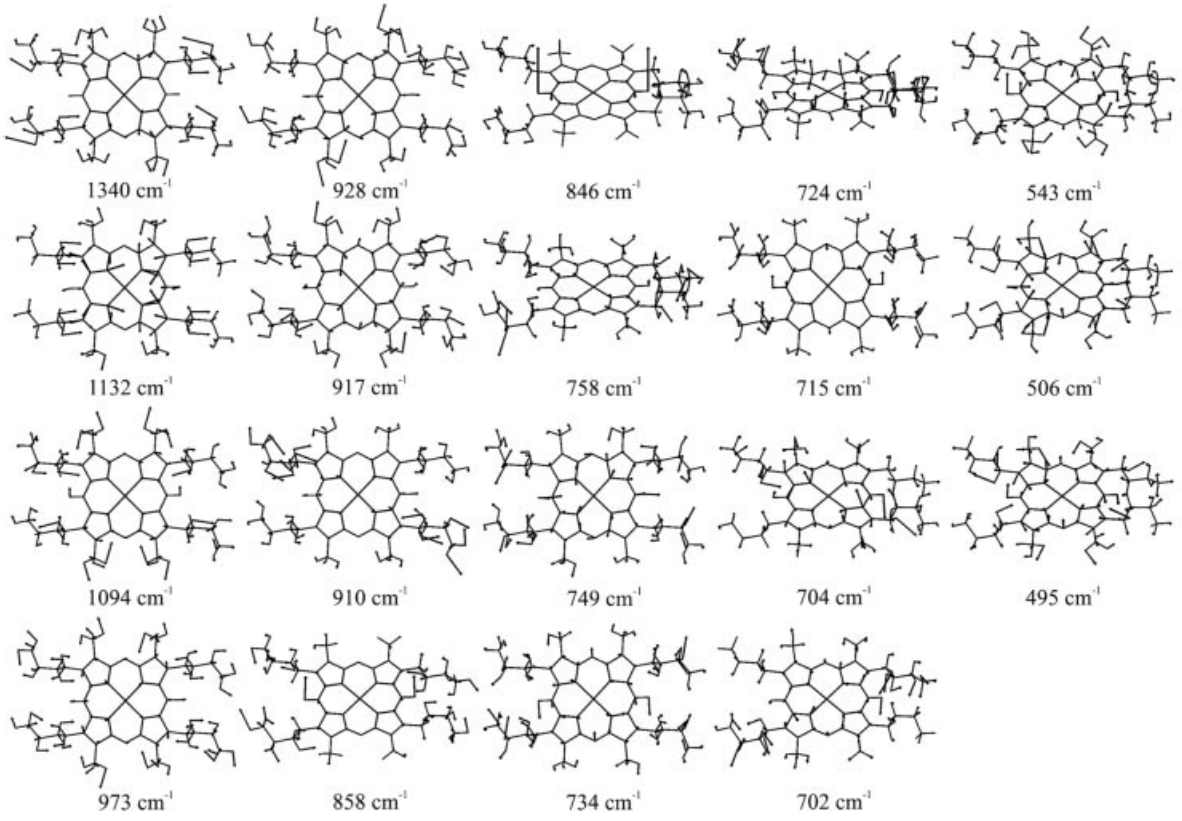

Figure 9. Atomic movements at the selected predicted frequencies of ZnDAP

basis of DFT calculations. The introduction of nitrogen atoms at the *meso* position of the porphyrins causes a blue-shift of the B-band and a red-shift of the Q-band with concomitant decrease and increase, respectively, of the apparent absorption coefficient. However, the bandwidth of the B-band and the splitting of the Q-band do not change systematically with the number of *meso*-nitrogen atoms. On going from monoaza to diaza species, the apparent bandwidth at half-height of the B-band and the splitting of the Q-band do not change significantly for metal-free species, although they increase for the copper species. All MCD curves are interpreted as the superimposition of Faraday *B* terms, since there is no orbital degeneracy in the excited states. The MCD sign pattern (minus-to-plus on going from longer to shorter wavelengths) substantiates experimentally that the splitting between the HOMO and HOMO−1 orbital is larger than that between the LUMO and LUMO+1. Of the copper complexes of octaethylporphyrin (OEP), monoaza- (MAP), diaza- (DAP) and tetraazaporphyrins (TAP), the first oxidation becomes more difficult, while the first reduction becomes easier with increasing number of *meso* nitrogen atoms. The potential differences between the first oxidation and reduction couples are about 2.1−2.4 V. MO calculations using DFT succeeded in reproducing some of the above spectroscopic and electrochemical characteristics. In addition, the good correspondence between the DFT calculations and experimental data enabled some IR bands to be assigned.

Experimental Section

Measurements: Mass spectra were obtained using a Micromass LCT Spectrometer (ESI-TOF mass). Electronic absorption spectra were recorded with a Hitachi U-3410 spectrophotometer using chloroform as solvent. Magnetic circular dichroism (MCD) measurements were made with a JASCO J-725 spectrophotometer equipped with a JASCO electromagnet that produces magnetic fields of up to 1.09 T. Its magnitude was expressed in terms of molar ellipticity per tesla, $[\theta]_M$/deg·mol^{-1}·dm^3·cm^{-1}·T^{-1}. IR spectra were recorded on a Shimadzu FTIR-8100M spectrometer using KBr disks. Cyclic voltammetry (CV) and differential pulse voltammetry (DPV) experiments were carried out with conventional three-electrode cells, in which a platinum wire auxiliary electrode, a glassy carbon working electrode (0.07 cm^2), and an Ag/AgCl wire reference electrode were employed. The solvent for electrochemical measurements, *o*-dichlorobenzene (*o*-DCB, Nacalai Tesque, specially prepared for HPLC) was used as supplied. Tetrabutylammonium perchlorate (TBAP) was used as an electrolyte. The ferrocenium/ferrocene (Fc^+/Fc) couple was used as an internal standard. In DCB containing 0.1 M TBAP, the Fc^+/Fc couple was observed at approximately +510 ± 20 mV vs. AgCl/Ag. All electrochemical work was carried out under an atmosphere of dry nitrogen. CV data were collected with a Hokuto Denko HA-501 potentiostat/galvanostat connected to a Hokuto Denko HB-104 function generator and a Graphtec WX1200 XY recorder. DPV data were collected with a Yanaco P-1100 polarographic analyzer connected to a Graphtec WX2400 XY recorder.

Materials: H_2DAP,[13] CuDAP,[12] and CuTAP[37] were synthesized as reported in our previous papers. CuMAP and CuOEP were ob-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

tained by reacting H_2MAP[38] or commercially available H_2OEP and $Cu(OAc)_2 \cdot H_2O$ in ethanol/dichloroethane (1:1 v/v) at 80 °C for 18 h, and subsequent purification using an alumina column and chloroform as eluent.

CuOEP: ESI-TOF: calcd. for $C_{36}H_{44}CuN_4$ 596.31; found 595.40. $C_{36}H_{44}CuN_4$ (596.31): calcd. C 72.51, H 7.44, N 9.40, found C 71.24, H 7.52, N 9.17.

CuMAP: ESI-TOF: calcd. for $C_{33}H_{35}N_5O_4Cu$ 629.21; found 629.24. $C_{33}H_{35}N_5CuO_4$ (629.21): calcd. C 62.99, H 5.61, N 11.13, found C 62.26, H 5.63, N 10.78.

Computational Methods: The Gaussian 98 program[39] running on an NEC TX7/AzusA computing system operated by Tohoku University Supercomputing System Information Synergy Center was used to perform DFT calculations of MOs (electron transitions) and frequencies. Since copper is paramagnetic, the central metal was taken to be zinc. B3LYP[34] with the 6−31G(d) basis set was used for all geometry optimization, MOs and frequency calculations. The transition energies and intensities of the lowest 30 singlet-singlet electronic transitions were determined by time-dependent DFT. An optimum scaling factor of 0.9613 was applied to the calculated frequencies in order to compare with the experimental data.[40]

One-Pot Synthesis of 1,6-Diiodo-2,3,4,5-tetracarba-*nido*-hexaboranes(6) and Mechanistic Studies on the Reaction System Alkynes/BI_3/$NaK_{2.8}$

Yong Nie,[a] Stefan Schwiegk,[a] Hans Pritzkow,[a] and Walter Siebert*[a]

Dedicated to Professor José Vicente on the occasion of his 60th birthday

Keywords: Boron / Boranes / Carboranes / Heterocycles / Iodine bridges

Attempts to prepare the tetracarba-*nido*-octaborane(8) derivative $(EtC)_4(BI)_4$ (**4**) by treatment of 3-hexyne with BI_3 (2 equiv.) and $NaK_{2.8}$ led to 2,3,4,5-tetraethyl-1,6-diiodo-2,3,4,5-tetracarba-*nido*-hexaborane(6) (**2a**) as the predominant product with trace quantities of **4** as well as 2,3-diethyl-1,4,5,6,7-pentaiodo-2,3-dicarba-*closo*-heptaborane(7) (**5**). Starting at –78 °C, reactions of 3-hexyne, 2-butyne or diphenylacetylene, respectively, with BI_3 (1 equiv.) and $NaK_{2.8}$ afforded the corresponding 1,6-diiodo-2,3,4,5-tetracarba-*nido*-hexaboranes(6) **2a**–**c** as the single carborane products. In the cases of 3-hexyne and diphenylacetylene, the formation of hexaorganylbenzene derivatives was also detected. To confirm the formation of **4** and **5**, the independent dehalogenation of *cis*-3,4-bis(diiodoboryl)-3-hexene (**3**) with $NaK_{2.8}$ has been studied, which indeed affords **4** and **5**, with the former being the predominant product. A mechanism for the formation of **2a** has been proposed, which involves iodoboration of the alkyne to give the borylalkene **1a**. This is followed by deiodination, presumably yielding the iodoborirene derivative **7**, which easily dimerizes to form the 1,4-diboracyclo-2,5-hexadiene derivative **8**. Subsequent rearrangement leads to the final C_4B_2-*nido*-carborane **2a**. To determine the stereochemistry of **1a**, its pyridine adduct **9** (and the isomer **9′**) and catechol derivative **10** (and the isomer **10′**), and the diisopropylamino derivative **11** have also been prepared. The new compounds have been characterized by MS and NMR spectroscopy, and the structures of **2a**, **3**, **9** and **9′** were confirmed by single-crystal X-ray analyses.

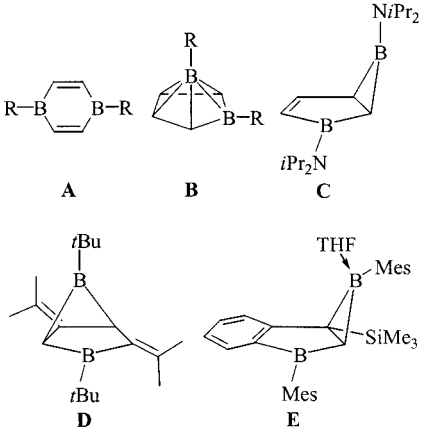
Introduction

The $(HC)_4(BR)_2$ organoborane/carborane system (**A**, **B**) has attracted considerable interest because the structures observed depend on the substituents (R) which attached to the boron atoms. Apart from the classical 1,4-diboracyclo-2,5-hexadienes **A**,[1] and non-classical 2,3,4,5-tetracarba-*nido*-hexaboranes(6) **B**,[2] the compounds **C**,[3a] **D**,[3b] **E**[3c] in between these two limits have also been reported. Peralkylated 2,3,4,5-tetracarba-*nido*-hexaboranes(6), known since the mid-1960s, are more stable than the parent compound $C_4B_2H_6$ [4] but their reactivities have only recently been studied.[5,6]

In order to investigate substitution reactions of **B**, functional groups (R) other than alkyl groups are needed at the boron atom(s). In 1994 we reported the formation of a 1,6-dichloro-2,3,4,5-tetracarba-*nido*-hexaborane(6)[7] derivative by photochemical transformation of 1,4-dichloro-2,3,5,6-tetrakis(isopropylidene)-1,4-diboracyclohexane. The low yield of the $(alkylC)_4(BCl)_2$ carborane did not allow further reactivity studies to be carried out. Wrackmeyer et al. were



able to obtain 1,6-dibromo-2,3,4,5-tetracarba-*nido*-hexaboranes(6)[5a] in high yield by treating 1,4,6,9-tetraalkyl-3,8-diethyl-2,7-bis(diethylboryl)-5-stannaspiro[4.4]nona-1,3,6,8-tetraenes with BBr_3. They also studied the reactions between the peralkylated 2,3,4,5-tetracarba-*nido*-hexaboranes(6) and an excess of BBr_3 (and BI_3), whereby the corresponding B6-halo substituted carboranes were formed.[5b] Nucleophilic substitution reactions of such B-halo carboranes were found to replace the basal B6-halogen atom to give the corresponding carboranes with organyl,[5c] stan-

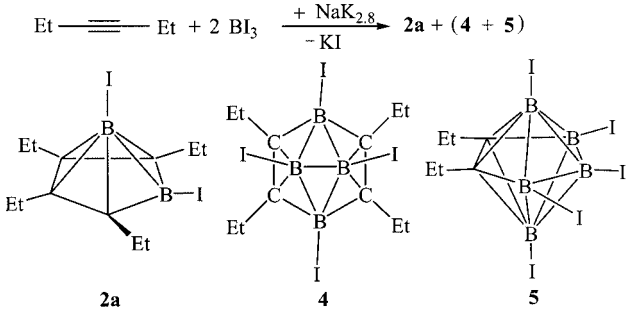
nyl[5d] and diphenylphosphanyl[5e] groups as well as, in the 1,6-dibromo case, an *N*-bonded $[Fe_2(CO)_6(\mu\text{-}SN)]$ substituent in the 6-position.[5f] Currently there is no easy pathway to such B-functionalized C_4B_2-*nido*-carboranes.

In our efforts to prepare the iodo analog of the tetracarba-*nido*-octaborane(8) $(EtC)_4(BCl)_4$ [8] we have developed a one-pot route to 1,6-diiodo-2,3,4,5-tetracarba-*nido*-hexaboranes(6) involving alkynes, BI_3 and $NaK_{2.8}$ alloy. In this paper we report the synthesis and characterization of the resultant C_4B_2-*nido*-carboranes, and a possible mechanism for their formation is proposed.

Results and Discussion

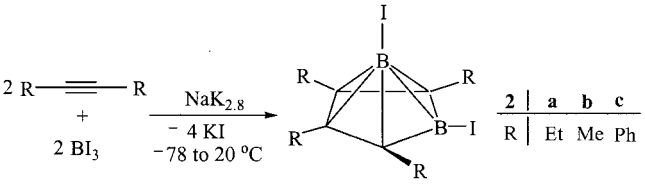
Synthesis of 1,6-Diiodo-2,3,4,5-tetracarba-*nido*-hexaboranes(6)

The reaction between 3-hexyne, BI_3 (2 equiv.) and $NaK_{2.8}$ alloy at room temperature, in a one-pot manner (Scheme 1), gave a mixture of products. Its ^{11}B NMR spectrum shows two dominant signals at $\delta = 5.5$ and -52.7 ppm in a 1:1 ratio, typical of C_4B_2-*nido*-carboranes[2] (type **B**). The EI-MS spectrum exhibits the molecular ion pattern with the correct isotopic distribution for the formula $(EtC)_4(BI)_2$ (**2a**). The other peaks can be assigned to *nido*-$(EtC)_4(BI)_4$ (**4**) and the novel species *closo*-$(EtC)_2(BI)_5$ (**5**), respectively, both exhibiting the expected isotopic patterns. Compounds **4** and **5** were formed only in trace amounts.



Scheme 1

Starting at low temperature (−78 °C) the same reaction gave **2a** as the single product in 51% yield as a yellow, sensitive and viscous oil. The yield can be increased to 66% when a 1:1 ratio of 3-hexyne and BI_3 was used (Scheme 2). In the latter case a very small amount of hexaethylbenzene could also be detected. The ^{11}B NMR spectrum of **2a** exhibits two signals at $\delta = 5.5$ and -52.5 ppm. The ^1H NMR spectrum shows an ABX_3 spin pattern for the methylene protons of the ethyl groups, and the ^{13}C NMR spectrum exhibits the corresponding four signals for the two different ethyl groups. The signals responsible for the skeletal carbon atoms non-adjacent to the basal boron were observed, while the signals for the other two skeletal carbon atoms (expected at ca. 105 ppm[5a]) were not observed. It should be noted that the formation of **2a** was first reported by Wrackmeyer et al.,[5a] (see Introduction) when they carried out reactions on a small scale for NMR spectroscopic studies. On standing at room temperature, yellow crystals of **2a** (vide infra) were obtained whereas the bromo compounds are oils.[5a,5b]



Scheme 2

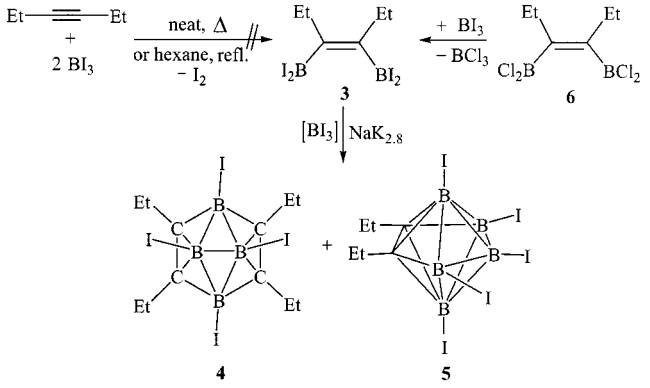
The analogous reaction with 2-butyne proceeded smoothly but the yellowish *nido*-$(MeC)_4(BI)_2$ (**2b**) was obtained only in low yield. The ^{11}B NMR spectrum exhibits two signals at $\delta = 5.7$, -48.6 ppm and the ^1H NMR spectrum shows two singlets for the two different methyl groups. The ^{13}C NMR spectrum gives the corresponding signals for the methyl and the skeletal carbon atoms non-adjacent to the basal boron, while the signal for the other two skeletal carbon atoms was not observed. In the mass spectrum the molecular ion peak with the expected isotopic pattern was found.

Whereas calculations[10] suggest that such *nido*-carboranes bearing halogen substituents at the boron atom(s) would prefer a classical type **A** structure, we have found that **2a** and **2b** are perfectly stable like the bromo analogs.[5a,5b] The reaction of diphenylacetylene with $BI_3/NaK_{2.8}$ also proceeds but the orange-yellow *nido*-$(PhC)_4(BI)_2$ (**2c**) was also obtained in low yield. It was characterized by ^{11}B NMR spectroscopy ($\delta = 7.9$, -50.1 ppm), and the high-resolution mass spectrum exhibits the molecular ion peak having the correct isotopic distribution. Unfortunately, the formation of a significant amount of hexaphenylbenzene hampered the successful isolation and the recording of satisfactory NMR spectra. Moreover, it was found to be unstable at room temperature even when stored under nitrogen, as indicated by its color which turned from orange-yellow to pale yellow. This instability is different from the cases of **2a** and **2b**, and reminiscent of the instability of the iodoboration product of diphenylacetylene with BI_3, which leads to a 9,10-dihydro-9-boraanthracene derivative.[9]

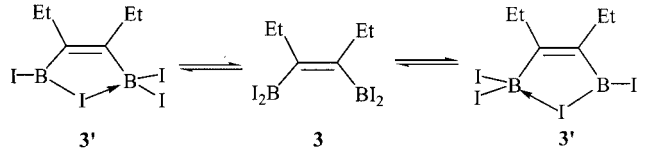
In order to verify the formation of compounds **4** and **5**, the independent dehalogenation of **3**[11a] (Scheme 3) was carried out. Attempts to obtain **3** through a redox reaction of 3-hexyne and two equivalents of BI_3 were not successful.[11b] However, the halogen exchange reaction of **6**[12] with BI_3 led to **3**, a yellow crystalline solid, which is extremely sensitive to air and moisture. In solution it exhibited a ^{11}B NMR signal at $\delta = 11.8$ ppm. No change in the chemical shift was observed upon cooling the sample to −30 °C but only broadening of the signal. The significant shift to high field compared with that of **6** ($\delta = 53.9$ ppm) indicates some additional intra- or intermolecular interaction. An X-ray structural determination revealed that **3** forms an intramolecular B−I−B bridge to yield **3′**. In solu-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

tion a fast equilibrium is present as shown in Scheme 4, which explains the single ^{11}B NMR signal.



Scheme 3



Scheme 4

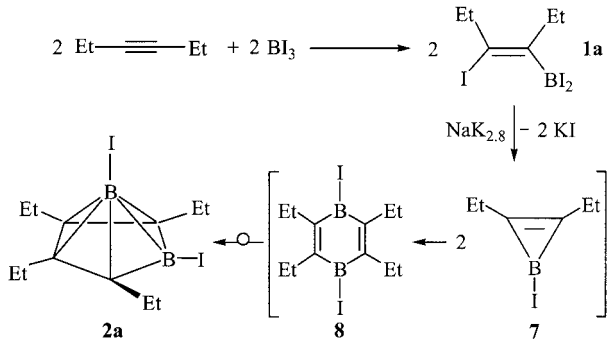
The dehalogenation of **3** starting at −65 °C gave compound **4** in 29% yield. When the same reaction was carried out at room temperature, the yield was lower. Compound **4** exhibits two ^{11}B NMR signals at δ = −10.5 and −13.4 ppm, which are shifted to lower frequencies in comparison with *nido*-$(EtC)_4(BCl)_4$ [8] (δ = −1.5 and −5.5 ppm). In the mass spectrum, the molecular ion at *m*/*z* = 716 is the base peak and has the correct isotopic distribution, while the formation of **5** was only detected by a cutoff peak at *m*/*z* = 771 [M^+] of very low intensity.

To further study the scope and limitations of this approach, a series of other alkynes has been studied using the same or similar procedures. In the cases of 5-decyne, di-*tert*-butylacetylene, bis(trimethylsilyl)acetylene, and di-*p*-tolylacetylene, all the reactions led to decomposition products. The debromination reaction of 3-hexyne and BBr_3 (1 equiv.) afforded the known *nido*-$(EtC)_4(BBr)_2$ [5a] in 49% yield, together with a small amount of hexaethylbenzene, while the analogous reaction using BCl_3 gave a mixture of unidentified boron-containing species, and a significant amount of hexaethylbenzene. Surprisingly, the reaction system of diphenylacetylene-/BBr_3/$NaK_{2.8}$ led only to decomposition irrespective of whether the one-step or stepwise procedures were used. Efforts to produce the corresponding *nido*-C_4B_2 carboranes with CH cluster atoms, starting from ethyne or phenylacetylene, and BI_3 (or BBr_3), respectively, were not successful.

Mechanistic Considerations

There have been two similar dehalogenation reactions reported. One is the early study of the diphenylacetylene/$PhBBr_2$/K system by Lappert et al.,[13] in which they claimed to have obtained a perphenylated 1,4-diboracyclohexadiene derivative or an unknown carborane species. These results, however, could not be reproduced by Eisch et al.[14] The other system involves the alkynes/$MeBBr_2$/C_8K reaction reported by van der Kerk et al.,[15] who claimed to have obtained stable peralkylated 1,4-diboracyclohexadiene derivatives as the main products through a borylene mechanism, while Wrackmeyer et al.[16] (in the cases of 3-hexyne and 5-decyne) obtained the corresponding C_4B_2-*nido*-carboranes. No 1,4-diboracyclohexadiene derivatives could be detected.

In order to get an insight into the formation of **2**, we selected **2a** as our target compound. A possible pathway to **2a** is shown in Scheme 5. Iodoboration of 3-hexyne with BI_3 afforded **1a**, its dehalogenation presumably yielded the iodoborirene intermediate **7**, which might dimerize[1d,17] to give 1,4-diboracyclohexadiene **8** or the bicyclic analog of type C (see Introduction) with iodine at boron and ethyl at carbon atoms as intermediates to rearrange to the carborane **2a**.

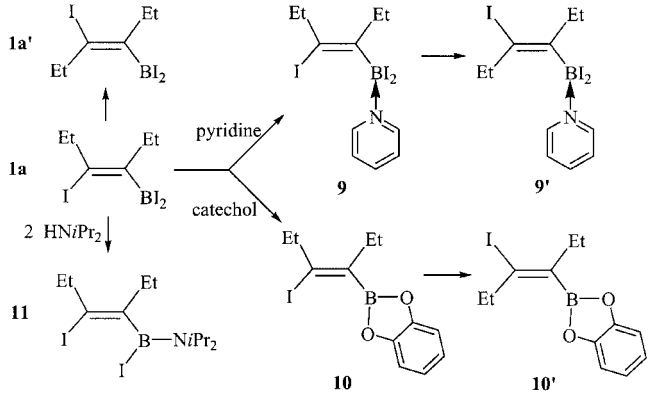


Scheme 5

The first step is the iodoboration of 3-hexyne to yield **1a**. In a study involving this step for the preparation of the 2,5-dihydro-1,2,5-thiadiborol,[9,18] the iodoboration product was reported to be a *cis*/*trans* mixture (ca. 2:3 *cis*/*trans* ratio) based on acetolysis which is an established method[19] for determining the stereochemistry of haloboration products (we repeated the acetolysis reaction and a ratio of 1:1 was obtained). The problem is that at room temperature the ^1H NMR spectrum shows two sets of ethyl signals and the ^{13}C NMR spectrum exhibits only six signals, whereas a *cis*/*trans* mixture should give more signals. Moreover, the ^{11}B NMR spectrum exhibits only one signal at δ = 40 ppm. As a result of this[20] some reactions were carried out with $[Fe_2(CO)_9]$ and Me_2S but unfortunately neither complexation nor adduct formation was observed. Later, the very similar reaction of 3-hexyne and BBr_3 was studied by Wrackmeyer.[21] Their results revealed that it is a stereoselective *cis*-addition, while the fast *cis*−*trans* isomerization led to a mixture. This allowed the assignment of both isomers by NMR spectroscopic methods. We tried to determine the stereochemistry of the present iodoboration products using a method more direct than acetolysis. It turned

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

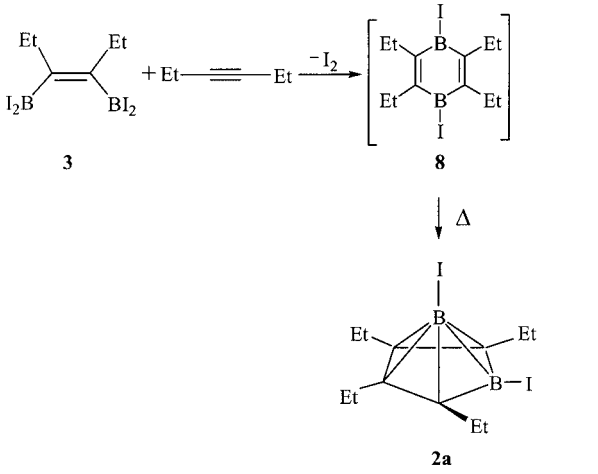
out, in agreement with Wrackmeyer's findings, that the reaction of 3-hexyne and BI_3 gave the *cis* isomer **1a** (Scheme 6), which underwent a slow isomerization to the thermodynamically more stable *trans* isomer **1a′**, thus allowing the characterization and even separation of both isomers. The pyridine adduct **9** and the catechol derivative **10** showed much faster *cis*−*trans* isomerizations than the parent **1a**, while the amino derivative **11** did not isomerize at room temperature even over a timescale of weeks. The X-ray structural analyses of **9** (*cis*) and **9′** (*trans*) unequivocally confirmed the stereochemical assignments.



Scheme 6

The second step in the formation of **2a** is the dehalogenation of **1a**. Apart form the one-pot reactions, the stepwise reaction (see Exp. Sect.) also afforded **2a** in a somewhat lower yield (43%). Although we do not have direct evidence for the formation of the borirene intermediate **7**, we found ^{11}B NMR signals for the reaction mixtures which may be assigned to the corresponding 1,4-diboracyclohexadiene **8** (broad signals at ca. 68 and 67 ppm in the formation of **2a** and **2b**, respectively), near to the expected region for 1,4-diboracyclohexadienes (55−65 ppm).[22]

The redox reaction of **3** with 3-hexyne shown in Scheme 7 (analogous to the preparation of the corresponding 1,3-diiodo-2,3-dihydro-1,3-diborol derivatives[23] and the 1,4-diiodo-1,4-diboracyclohexene compounds[24]) indeed afforded the expected carborane **2a**. The reaction mixture showed a broad ^{11}B NMR signal at $\delta = 66$ ppm. As suggested by Schleyer et al.[17] the straightforward intramolecular rearrangement of 1,4-diboracyclohexa-2,5-dienes into carboranes is forbidden by symmetry and our attempts to separate **8** by distillation led gradually to **2a**, as evidenced by ^{11}B NMR spectroscopy and EI-MS (see Exp. Sect.). Although this redox reaction (Scheme 7) represents a new route to the corresponding 1,4-diboracyclohexadienes/C_4B_2-*nido*-carboranes, the difficult access to the *cis*-1,2-diborylalkene **3** prevents its practical application.



Scheme 7

X-ray Structural Analyses of 2a, 3, 9 and 9′

The structures of the C_4B_2-*nido*-carboranes were previously examined by electron diffraction studies of the hexamethyl derivative $(MeC)_4(BMe)_2$,[25] and by microwave spectroscopy[26] of the parent derivative $(HC)_4(BH)_2$.[4] The structures were confirmed by X-ray diffraction analyses.[3c,5f] In 1992, Berndt et al.,[3c] reported the structure of a benzo-annelated derivative, and in 1996 Herberhold, Wrackmeyer et al.[5f] published the structure of the first example of an "undisturbed" pentamethyl-*nido*-C_4B_2 carborane with an *N*-bonded $[Fe_2(CO)_6(\mu\text{-NS})]$ complex fragment in the 6-position. Derivatives of a benzo compound[3c] with transition metal complex fragments coordinated to the benzene ring have also been synthesized.[6b]

The molecular structure of **2a** is shown in Figure 1. Its C_4B_2 skeleton adopts the expected *nido* structure (C_s symmetry) with an apical six-coordinate boron atom. The B−B bond length of 1.821 Å is similar to, but slightly shorter

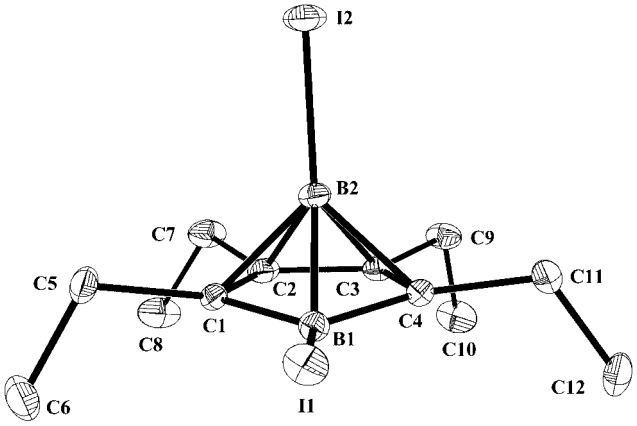


Figure 1. Molecular structure of **2a**, hydrogen atoms omitted for clarity, thermal ellipsoids are shown at the 40% probability level; selected bond lengths [A] and angles [°]: I1−B1 2.155(3), I2−B2 2.126(3), C1−C2 1.457(4), C2−C3 1.437(4), C3−C4 1.459(3), C1−B1 1.522(3), C4−B1 1.526(4), C1−B2 1.705(4), C2−B2 1.713(4), C3−B2 1.713(4), C4−B2 1.708(4), B1−B2 1.821(4); C2−C1−B1 108.3(2), C1−B1−C4 104.1(2), B1−C4−C3 107.9(2), C4−C3− C2 109.6(2), C3−C2−C1 109.2(2), B2−B1−I1 130.0(2), B1−B2−I2 140.1(2)

than, the corresponding distances in the above-mentioned $(MeC)_4(BMe)[B(\mu\text{-}NS)Fe_2(CO)_6]$[5f] (1.836 Å), in the benzo-annelated structure[3c] (1.870 Å) and in the parent derivative $(HC)_4(BH)_2$ [26] (1.886 Å). The B2−C distances vary within a narrow range (1.705−1.713 Å), and are also slightly shorter than the values in the examples mentioned[5f,3c] (1.720−1.743 and 1.673−1.865 Å, respectively), which can be attributed to the different steric environments around the skeleton. The skeletal C−C distances were found to be almost identical (av. 1.451 Å), and are also similar to the average of 1.438 Å in $(MeC)_4(BMe)[B(\mu\text{-}SN)Fe_2(CO)_6$. The four skeletal carbon atoms are in one plane, and the four *exo*-polyhedral carbon atoms C5, C7, C9, C11 are bent out of the C_4 plane towards B2 by an average of 0.24 Å. The five-membered C_4B open face is not planar, with B1 lying ca. 0.15 Å below the C_4 plane. The dihedral angle between the C_4 plane and the C_2B1 plane is ca. 9°. The B−I bond lengths are 2.126 and 2.155 Å, respectively, and are similar to the reported values in some other B-iodinated polyhedral borane and carborane clusters, for example 2.133 Å (av.) in $HNB_{11}Cl_5I_6$,[27a] 2.09−2.17 Å in polyiodinated *p*-carboranes,[27b] and also similar to that of 2.10(4) Å in BI_3.[28]

The molecular structure of **3** is shown in Figure 2. The two BI_2 groups are in a *cis* arrangement, and the I1 atom is intramolecularly coordinated to B1, forming a unique B−I−B bridge. The boron atom B2 is tri-coordinate and the B2−I4 bond length of 2.107 Å is typical of an I−B(sp^2) distance. B1 is four-coordinate, however, and the B1−I2 and B1−I3 distances are 2.231 and 2.201 Å, respectively, and are very similar to the reported values for I−B(sp^3) bonds, e.g. 2.21(1) Å (av.) in $[Ph_2PBI_2]_2$ [29a] and 2.229 Å (av.) in $(vi_3P)BI_3$ [29b] (where vi is vinyl). The B−I bond lengths involving the bridging I1 atom are 2.160 and 2.383 Å, respectively, and the latter is longer than the sum of the covalent radii of the two atoms, indicating that the interaction between B1 and I1 is weak.

Figure 3 (a and b) show the structures of **9** (*cis*) and **9′** (*trans*), respectively. In both structures the boron atom is four-coordinate, adopting a slightly distorted tetrahedral geometry. The bond lengths and angles in both structures are very similar. The B−I bond lengths are 2.269 and 2.306 Å in **9**, and 2.275(3) and 2.294(3) Å in **9′**, respectively, similar to the corresponding values in compound **3**. The corresponding B−N distances of 1.587 Å in **9** and 1.596 Å in **9′**, respectively, are similar to, but slightly shorter than, those found in other pyridine adducts.[30]

Figure 2. Conclusion

We have developed a one-pot synthesis of 1,6-diiodo-2,3,4,5-tetracarba-*nido*-hexaborane(6) derivatives involving disubstituted alkynes, BI_3 and $NaK_{2.8}$. Considering the ready availability of the starting materials and the product **2a**, it has been convenient to study the reactivities of such B−I functionalized carboranes and dehalogenation is a practical method for the preparation of carboranes. The formation of **4** from the dehalogenation of **3** confirms that bis(boryl-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

alkenes) are the precusors of *nido*-C_4B_4 carboranes. Such dehalogenation reactions at room temperature are more complex and give lower yields than at lower temperatures. A possible mechanism of the formation of C_4B_2-*nido*-hexaboranes(6) has been proposed and studied using **2a** as a representative example. The stereochemistry of the iodoboration product of the alkyne has been clarified as *cis*, using a more direct method than acetolysis, and the *cis*-*trans* isomerization exists in the addition product **1a** and some of the derivatives.

Experimental Section

All reactions and manipulations were performed in dry glassware under argon or nitrogen using standard Schlenk techniques. Solvents were dried, distilled, and saturated with nitrogen. NMR: Bruker DRX 200 spectrometer; $Et_2O{\cdot}BF_3$ was used as the external standard for ^{11}B NMR spectroscopy; as internal references for ^1H and ^{13}C NMR spectroscopy, the signals of the deuterated solvent ($CDCl_3$) were used and calculated relative to TMS. MS: ZAB-2F VH Micromass CTD spectrometer, and a JEOL MS Station JMS 700 spectrometer both using the EI ionization technique. Melting points (uncorrected) were measured with a Büchi apparatus, using capillaries which were filled under nitrogen and sealed.

2,3,4,5-Tetraethyl-1,6-diiodo-2,3,4,5-tetracarba-*nido*-hexaborane(6) (2a). Formation from 3-Hexyne, BI_3 (1 equiv.) and $NaK_{2.8}$

a) One-Pot Procedure: To a solution of BI_3 (872 mg, 2.23 mmol) in hexane (40 mL) at −78 °C was added 3-hexyne (190 mg, 2.3 mmol) dropwise, and $NaK_{2.8}$ (0.9 mL, excess) was then added with a syringe. The mixture was stirred for ca. 15 min, and the cooling bath was then removed. The reaction mixture was warmed to ambient temperature, stirred overnight, and then filtered (G4 frit) and the residue washed with hexane (2 × 15 mL). The solvent of the yellow filtrate was removed in vacuo, leaving a yellow viscous oil. Distillation at 80 °C/ 2×10^{-3} Torr gave **2a** (326 mg, 66%) as a yellow, air-sensitive oil, which slowly solidified. For reactions with up to 28 mmol of BI_3, longer reaction times (1 week) were needed (av. yield > 60%, m.p. 52 °C). ^1H NMR ($CDCl_3$, 200 MHz): δ = 1.20 (t, $^3J_{H,H}$ = 7.6 Hz, 6 H, CH_3), 1.26 (t, $^3J_{H,H}$ = 7.6 Hz, 6 H, CH_3), 1.87− 2.04 (m), 2.11− 2.38 (m, 8 H, CH_2) ppm. ^{11}B NMR ($CDCl_3$, 64 MHz): δ = 5.5 (s, B_{basal}, 1 B), −52.5 (s, B_{apical}, 1 B) ppm. ^{11}B NMR (C_6D_6, 64 MHz): δ = 5.9 (s, B_{basal}, 1 B), −52.4 (s, B_{apical}, 1 B) ppm. ^{13}C NMR ($CDCl_3$, 50 MHz): δ = 13.5, 14.2 (CH_3), 18.9, 20.4 (CH_2), 114.2 ppm (skeletal carbon atoms non-adjacent to the basal boron), the signals for the other basal carbon atoms not observed. EI-MS: *m*/*z* (%) = 440 (100) [M^+], 313 (20.3) [$M^+ - I$]. HR-MS (EI): *m*/*z* = 439.9842 [M^+]. Calcd. For $^{12}C_{12}{}^1H_{20}{}^{11}B_2{}^{127}I_2$ 439.9840 (Δ*m* = 0.2 mmu).

b) Stepwise Procedure: To a solution of BI_3 (2.165 g, 5.53 mmol) in hexane (50 mL) was added dropwise 3-hexyne (470 mg, 5.7 mmol) at −50 °C, and the resultant solution was warmed to ambient temperature. The resultant red solution (^{11}B NMR: δ = 40.5 ppm) was cooled to −60 °C again and $NaK_{2.8}$ (2 mL) was added with a syringe. The workup procedure which followed was similar to that of the one-pot procedure and yielded **2a** (520 mg, 43%).

Reactions of 3-Hexyne with BI_3 (2 equiv.) and $NaK_{2.8}$ at Different Temperatures

a): A solution of BI_3 (858 mg, 2.19 mmol) in hexane (35 mL) was added dropwise to a mixture of 3-hexyne (90 mg, 1.1 mmol) and $NaK_{2.8}$ (0.9 mL) at room temp. The reaction mixture became gray in ca. 20 min, and was stirred for 1 day, then filtered (G4 frit). The residue was washed with hexane (2 × 15 mL), and the slightly pink filtrate was dried in vacuo, leaving a red-brown oil (238 mg), which was a mixture of **2a**, **4** and **5**. EI-MS: *m*/*z* (%) = 440 (100) (**2a**), 716 (3.35) (**4**), and 771 (44.83) (**5**). HR-MS (EI): *m*/*z* = 439.9847 (**2a**); calcd. for $^{12}C_{12}{}^1H_{20}{}^{11}B_2{}^{127}I_2$ 439.9840 (Δ*m* = 0.6 mmu), *m*/*z* = 715.8150 (**4**); calcd. for $^{12}C_{12}{}^1H_{20}{}^{11}B_4{}^{127}I_4$ 715.8116 (Δ*m* = 3.4 mmu), *m*/*z* = 715.6464 (**5**); calcd. for $^{12}C_6{}^1H_{10}{}^{11}B_5{}^{127}I_5$ 715.6472 (Δ*m* = −0.8 mmu).

b): To a solution of BI_3 (3.126 g, 7.98 mmol) in hexane (30 mL) at −78 °C was added 3-hexyne (332 mg, 4.04 mmol) dropwise. The mixture immediately became yellow-brown, and $NaK_{2.8}$ (2 mL) was then added with a syringe. The reaction mixture was stirred at −78 °C for ca. 10 min, the cooling bath was removed, and the mixture was warmed to ambient temperature and stirred for 1 day. The mixture was then filtered (G4 frit), and the residue washed with hexane (2 × 15 mL). The yellow filtrate was dried in vacuo, leaving a yellow viscous oil, which was distilled to give **2a** (455 mg, 51%) as the single carborane product. In this case, no hexaethylbenzene was detected.

Formation of 2a from the Redox Reaction of 3-Hexyne and 3: 3-Hexyne (196 mg, 2.3 mmol) was added dropwise to a solution of **3** (1.357 g, 2.22 mmol) in hexane (25 mL) at −60 °C. The mixture was warmed to ambient temperature during which time it became deep brown indicating the formation of I_2. The ^{11}B NMR spectrum showed a signal at δ = 66 ppm. All the volatiles were removed in vacuo and the resultant red oil was distilled at 71 °C/ 8×10^{-2} Torr to give a yellowish oil (533 mg, 55%), which gradually became deep red. The ^{11}B NMR (C_6D_6, 64 MHz) data of the original distillate: δ = 57.6 (s), 45.7, 5.9, −9.0 (BI_3), −52.4 ppm; after three days, the corresponding signals were: δ = 57 (s), 32, 5.9, −52.4 ppm; after three weeks, there were only two ^{11}B NMR signals: δ = 5.9, −52.4 ppm (**2a**). The EI-MS spectrum was identical to that of authentic **2a**.

1,6-Diiodo-2,3,4,5-tetramethyl-2,3,4,5-tetracarba-*nido*-hexaborane(6) (2b): Same procedures as described for **2a**. 2-Butyne (426 mg, 7.9 mmol), BI_3 (3.09 g, 7.9 mmol), $NaK_{2.8}$ (2 mL). The final yellow viscous oil was distilled at 95 °C/ 3×10^{-2} Torr to give **2b** (225 mg, 15%) as a yellowish solid; m.p. 92−94 °C. ^1H NMR ($CDCl_3$, 200 MHz): δ = 1.72 (s, 6 H, CH_3), 1.87 (s, 6 H, CH_3) ppm. ^{11}B NMR ($CDCl_3$, 64 MHz): δ = 5.7 (s, B_{basal}), −48.6 (s, B_{apical}) ppm. ^{13}C NMR ($CDCl_3$, 50 MHz): δ = 11.29, 12.55 (CH_3), 110.7 ppm (skeletal carbon atoms non-adjacent to basal boron), the signals for the other basal carbon atoms not observed. EI-MS: *m*/*z* (%) = 384 (94) [M^+], 257 (100) [$M^+ - I$]. HR-MS (EI): *m*/*z* = 383.9218 [M^+]; calcd. for $^{12}C_8{}^1H_{12}{}^{11}B_2{}^{127}I_2$ 383.9215 (Δ*m* = 0.3 mmu).

1,6-Diiodo-2,3,4,5-tetraphenyl-2,3,4,5-tetracarba-*nido*-hexaborane(6) (2c): Same procedures as described for **2a**. Diphenylacetylene (1.38 g, 7.7 mmol), BI_3 (3.03 g, 7.7 mmol), $NaK_{2.8}$ (1.6 mL). The yellow filtrate was cooled, and some yellow solid (mainly hexaphenylbenzene) was filtered, and the yellow filtrate was dried in vacuo to give **2c** (147 mg, ca. 5%) and a small amount of hexaphenylbenzene as an orange yellow solid. ^{11}B NMR (CD_2Cl_2, 64 MHz): δ = 7.9 (s, B_{basal}), −50.1 (s, B_{apical}), (δ = 8.2 and −49.6 ppm in $CDCl_3$) ppm. EI-MS: *m*/*z* (%) = 632 (100) [M^+], 505 (69.6) [$M^+ - I$]. HR-MS (EI): *m*/*z* = 631.9855 [M^+]; calcd. for $^{12}C_{28}{}^1H_{20}{}^{11}B_2{}^{127}I_2$ 631.9841 (Δ*m* = 1.4 mmu).

***cis*-3,4-Bis(diiodoboryl)-3-hexene (3):**[11a] A portion of 3,4-bis(dichloroboryl)-3-hexene (**6**) (2.13 g, 8.7 mmol) was added to BI_3

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

(4.653 g, 11.9 mmol) at room temperature. The resultant dark brown solution was stirred at room temperature for ca. 2.5 h. The reaction flask was connected to a condensation apparatus, the trap cooled to −78 °C, and the system was kept at ca. 60 mbar overnight. All volatiles were then removed under high vacuum, and the resultant dark brown residue was recrystallized five times from hexane (ca. 20 mL), four times at −84 °C, and the last time at −28 °C. Compound **3** (2.53 g, 47.5%) was obtained as a yellow crystalline solid, which can be kept at −28 °C for a long period of time, m.p. 70−72 °C. ^{1}H NMR (C_6D_6, 200 MHz): δ = 1.02 (t, $^3J_{H,H}$ = 7.5 Hz, 6 H, CH_3), 2.29 (q, $^3J_{H,H}$ = 7.5 Hz, 4 H, CH_2) ppm. ^{11}B NMR (C_6D_6, 64 MHz): δ = 11.8 ppm. ^{13}C NMR (C_6D_6, 50 MHz): δ = 14.8 (CH_3), 26.2 (CH_2), 178.4 (C=C) ppm. EI-MS: *m*/*z* (%) = 485 (100) [M^+ − I]. HR-MS (EI): *m*/*z* = 484.8128 [M^+ − I]; calcd. For $^{12}C_6{}^1H_{10}{}^{11}B_2{}^{127}I_3$ 484.8103 (Δ*m* = 2.5 mmu). $C_6H_{10}B_2I_4$(611.4): calcd. C 11.79, H 1.65; found C 12.23, H 1.61.

Tetraethyltetraiodotetracarba-*nido*-octaborane(8) (4): To a solution of **3** (2.3 g, 3.76 mmol) in hexane (40 mL) at −65 °C was added $NaK_{2.8}$ (1.5 mL, excess) dropwise with a syringe. After ca. 1 h the cooling bath was removed, and the reaction mixture was warmed to room temperature and stirred for 3 days. The reaction mixture was filtered (G4 frit) and the residue washed with hexane (2 × 15 mL), the light yellow filtrate dried in vacuo, leaving a yellow viscous oil which slowly solidified, containing **4** (385 mg, 28.6%) and a trace amount of **5**. ^{11}B NMR ($CDCl_3$, 64 MHz): δ = −10.5 (s, 2 B), −13.4 (s, 2 B) ppm. EI-MS: *m*/*z* (%) = 716 (100) [M^+] (**4**), 589 (91.7) [M_1^+ − I]. 771(4.3) [M^+] (**5**). HR-MS (EI): *m*/*z* = 715.8112 [M_1^+]; calcd. For $^{12}C_{12}{}^1H_{20}{}^{11}B_4{}^{127}I_4$ 715.8117 (Δ*m* = −0.5 mmu). *m*/*z* = 771.6440 [M_2^+]; Calcd. For $^{12}C_6{}^1H_{10}{}^{11}B_5{}^{127}I_5$ 771.6471 (Δ*m* = −3.1 mmu).

***cis*-3-Diiodoboryl-4-iodo-3-hexene (1a):**[9,18] The procedure in the literature was slightly modified. To a solution of BI_3 (3.245 g, 8.3 mmol) in pentane (50 mL) was added 3-hexyne (681 mg, 8.3 mmol) dropwise at −25 °C. The red mixture was warmed to ambient temperature and the deep pink solution was transferred to another flask, leaving a little black solid on the wall of the original flask. The solution was dried in vacuo to give analytically pure **1a** almost quantitatively as a deep red liquid. ^{1}H NMR ($CDCl_3$, 200 MHz): δ = 1.08 (t, $^3J_{H,H}$ = 7.4 Hz, 3 H, CH_3), 1.22 (t, $^3J_{H,H}$ = 7.6 Hz, 3 H, CH_3), 2.15 (q, $^3J_{H,H}$ = 7.6 Hz, 2 H, CH_2), 2.62 (q, $^3J_{H,H}$ = 7.4 Hz, 2 H, CH_2) ppm. ^{11}B NMR ($CDCl_3$, 64 MHz): δ = 40.0 ppm. ^{13}C NMR ($CDCl_3$, 50 MHz): δ = 14.2, 15.0 (CH_3), 24.7, 33.3 (CH_2), 106.4 (=C-I), 157.6 (br., =C−B) ppm.

***trans*-3-Diiodoboryl-4-iodo-3-hexene (1a′):** Slow isomerization of **1a** (*cis*) at room temperature afforded **1a′** (not complete within 5 weeks as indicated by NMR in a $CDCl_3$ solution, with partial decompostion). ^{1}H NMR ($CDCl_3$, 200 MHz): δ = 1.08 (t, $^3J_{H,H}$ = 7.2 Hz, 3 H, CH_3), 1.15 (t, $^3J_{H,H}$ = 6.7 Hz, 3 H, CH_3), 2.2 (q, $^3J_{H,H}$ = 7.2 Hz, 2 H, CH_2), 2.61 (q, $^3J_{H,H}$ = 6.7 Hz, 2 H, CH_2) ppm. ^{11}B NMR ($CDCl_3$, 64 MHz): δ = 43.5 ppm. ^{13}C NMR ($CDCl_3$, 50 MHz): δ = 12.8, 14.0 (CH_3), 33.6, 39.1 (CH_2), 114.6 (=C−I), 158.1 (br., =C−B) ppm.

***cis*-3-Diiodoboryl-4-iodo-3-hexene−Pyridine Adduct (9):** Pyridine (223 mg, 2.8 mmol) was added dropwise to a solution of **1a** (1.33 g, 2.8 mmol) in hexane (25 mL) at −25 °C. The color immediately turned to deep red and a yellow precipitate then appeared. The mixture was warmed to room temperature, the solvent removed in vacuo, and an orange-yellow powder **9** was obtained quantitatively. The X-ray quality crystals were grown from a toluene solution at −28 °C. M.p. 30 °C. ^{1}H NMR ($CDCl_3$, 200 MHz): δ = 1.05 (t, $^3J_{H,H}$ = 7.4 Hz, 3 H, CH_3), 1.29 (t, $^3J_{H,H}$ = 7.4 Hz, 3 H, CH_3), 2.77 (q, $^3J_{H,H}$ = 7.4 Hz, 2 H, CH_2), 2.86 (q, $^3J_{H,H}$ = 7.4 Hz, 2 H, CH_2), 7.70 (m), 8.19(m), 9.39 (m) (py-H) ppm. ^{11}B NMR ($CDCl_3$, 64 MHz): δ = −13.9 ppm. ^{13}C NMR ($CDCl_3$, 50 MHz): δ = 14.4, 14.9 (CH_3), 32.4, 39.5 (CH_2), 115.2 (=C−I), 126.6, 142.4, 147.6 ppm (py-C), the signal of the boron-bound carbon was not observed.

***trans*-3-Diiodoboryl-4-iodo-3-hexene−Pyridine Adduct (9′):** Slow isomerization of **9** (*cis*) at room temperature afforded **9′** within one week as yellow crystals from a CH_2Cl_2 solution. Titanium Complexes Stabilized by a Sulfur-Bridged Chelating Bis(aryloxo) Ligand as Active Catalysts for Olefin Polymerization

Zofia Janas,[a] Lucjan B. Jerzykiewicz,[a] Katarzyna Przybylak,[a] Piotr Sobota,*[a] and Krzysztof Szczegot[b]

Keywords: Titanium / O,S,O ligands / Polymerization / X-ray diffraction / Aluminum

The mixed-ligand complexes $[Ti_2(\mu\text{-}OR)_2(OR)_2(\kappa^3\text{-}tbop)_2]$ (**1a**) for R = Me and (**1b**) R = Et were prepared by the reaction of $Ti(OR)_4$ and H_2tbop {H_2tbop = 2,2′-thiobis[4-(1,1,3,3-tetramethylbutyl)phenol]} in methanol. Treatment of **1a** and **1b** with $AlMe_3$ led to the substitution of terminal alkoxy groups to create the organometallic compounds $[Ti_2(\mu\text{-}OR)_2(\kappa^3\text{-}tbop)_2(Me)_2]$ (**2a**) for R = Me and (**2b**) for R = Et. Controlled hydrolysis of **2b** causes the evolution of methane and the formation of the titanoxane compounds $[\{Ti_2(\mu\text{-}OEt)_2(\kappa^3\text{-}tbop)_2\}_2(\mu\text{-}O)_2]\cdot 2CH_2Cl_2$ (**3**). Structures of **1a**, **1b**, **2a**, **2b**, and **3** were confirmed by NMR spectroscopy; **1b** and **3** were further investigated with X-ray crystallography. Compounds **1a**, **1b**, **2a**, and **2b** were supported on $MgCl_2$ and when activated with aluminum alkyls, found to effectively polymerize ethylene.

Introduction

Titanium complexes with the formula $[Ti(tbmp)X_2]$ which is derived from the sulfide-linked bis(phenol) H_2tbmp [tbmp = 2,2′-thiobis(6-*tert*-butyl-4-methylphenolato); X = Cl, O*i*Pr] and activated with methylaluminoxane (MAO), were first reported by Kakugo et al. to be highly active in the polymerization of ethylene, propylene, styrene, and dienes, as well as the copolymerization of ethylene with styrene.[1−3] These titanium complexes were found to be more active than the methylene-bridged chelating aryloxide complexes of the type $[Ti(mbmp)X_2]$ [mbmp = 2,2′-methylenebis(6-*tert*-butyl-4-methylphenolato)].[4] This is in qualitative agreement with theoretical studies that showed S-bridged chelating alkoxides to have lower insertion barriers than their methylene-bridged or directly bridged analogues.[5−7] Although the Ti−S interaction in $[Ti(tbmp)X_2]$ is weak, it is likely to be of importance in stabilizing the active cationic species, facilitating its formation from $[Ti(tbmp)X_2]$ and MAO, making the coordination of the counterion more flexible.[8] Titanium bis(phenolato) and bis(naphtholato) complexes are well characterized either structurally or spectroscopically in addition to the kinetics and thermodynamics of the intra- and intermolecular rearrangement in bis(naphtholates) which are also described.[9−10] It is worth noting that molybdenum derivatives containing these ligands have also been intensively investigated and employed for asymmetric olefin metathesis[11] as well as for various ring-closing reactions.[12] However, structural data on thio analogues, especially of their ligand modifications, are still limited.[5,13]

Our work is primarily concerned with the synthesis and structural characterization of titanium compounds with the tridentate (OSO-function) thiobis(phenolato) ligand: 2,2′-thiobis[4-(1,1,3,3-tetramethylbutyl)phenolato] (tbop; Scheme 1). Except for the S-bridge, the tbop ligand appeared to have an extra attractive feature, that is, the long sterically hindered auxiliary group 4-(1,1,3,3-tetramethylbutyl) on the thiobis(phenolato) ligand. This substituent sufficiently increases solubility of the catalyst in hydrocarbons. It was interesting for us to see whether these features of the tbop ligand would help create highly active catalytic systems in the heterogeneous ethylene polymerization process.

Results and Discussion

The thiobis(phenol) H_2tbop reacts smoothly with $Ti(OR)_4$ (R = Me, Et) in an appropriate alcohol producing **1a** and **1b**, which are sparingly soluble in alcohols, but readily soluble in common organic solvents (such as toluene, hexane, CH_2Cl_2 and tetrahydrofuran) to give yellow crystals of the complexes $[Ti_2(\mu\text{-}OR)_2(OR)_2(\kappa^3\text{-}tbop)_2]$ (**1a**) for R = Me, (**1b**) for R = Et (Scheme 1).

Compounds **1a** and **1b** are very stable and can be stored for a long time in air. The ^{1}H NMR spectra are invariant over a wide temperature range and show two singlets of OCH_3 (δ = 4.61, 4.29 ppm) for **1a** and two sets of CH_3

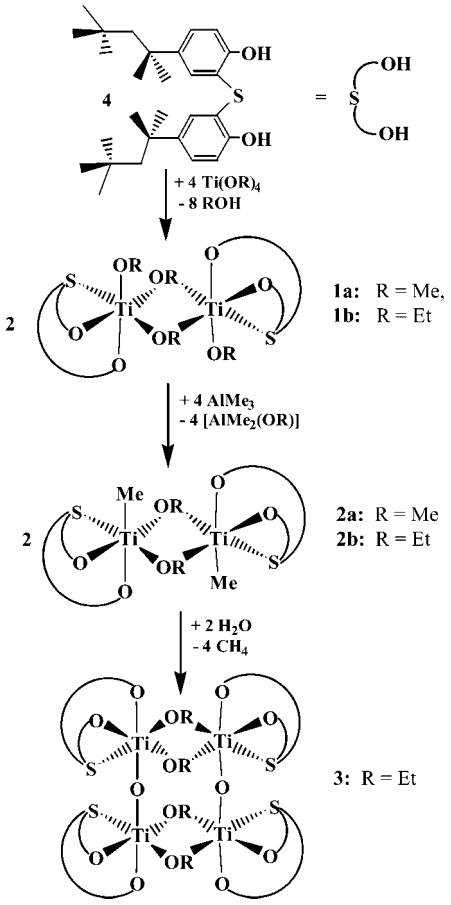

Scheme 1

(t, δ = 1.49; 1.37 ppm) and CH_2 (q, δ = 4.88; 4.78 ppm) resonances of OCH_2CH_3 for **1b** of terminal- and bridging-coordinated alkoxy groups , respectively, suggesting dimeric structures of these complexes exist in solution. A single-crystal X-ray diffraction study for **1b** in the solid state confirmed the structure deduced from ^{1}H NMR spectroscopy (Figure 1).

The crystal structure of **1b** comprises a centrosymmetric dimer with a planar Ti_2O_2 core. The coordination sphere around the titanium center can be described as octahedral with the oxygen atoms of the tbop ligand [O(11), O(21)] and of two bridging OEt groups [O(1), O(1)$^{(i)}$] forming the equatorial plane, while the O(2) oxygen atom of the terminal OEt ligand and the sulfur link of the tbop group occupy the apical sites. The two Ti−O(aryloxide) distances of 1.896(2) and 1.916(2) Å are in the expected range for Ti^{IV} complexes with nonbridging aryloxide ligands.[4] The Ti−O(ethoxide) distances of 1.762(2) and 2.009(2) Å are different according to their terminal and bridging nature, respectively, and are typical of $Ti_2(\mu\text{-}OR)_2(OR)$ moieties.[14] The Ti−S bond length of 2.800(1) Å is one of the longest so far reported in the literature;[15] this is substantially longer than Ti−S single bonds (typically 2.3−2.4 Å).[16] Shorter Ti−S bond lengths were reported in the following complexes: for example, $[Ti_2(\mu\text{-}O\textit{i}Pr)_2(O\textit{i}Pr)_2(\kappa^3\text{-tbmp})_2]$, where tbmp = 2,2′-thiobis(6-*tert*-butyl-4-methylphenolato) 2.719(1) Å, $[Ti(\kappa^3\text{-tbmp})\{\kappa^2\text{-}C_6H_4(CH_2NMe_2)_2\}Cl]$ 2.704(1) Å, and $[Ti(\kappa^3\text{-tbmp})Cl(O\textit{i}Pr)(HO\textit{i}Pr)]$ 2.693(1) Å.[5,13] The geometry of the Ti−S interaction in **1b** is characterized by the angle of 0.7° between the normal of the plane defined by S, C(12), C(22); the Ti−S direction is somewhat smaller than that found in $[Ti_2(\mu\text{-}O\textit{i}Pr)_2(O\textit{i}Pr)_2(\kappa^3\text{-tbmp})_2]$ (4°),[5] and is due to the interaction of one of the sulfur lone pairs with the electrophilic Ti atom. However, if the Ti−S interaction is disregarded the coordination can be described as a distorted square-based pyramid with an eight membered ring which has boat-boat conformation.

Reaction of complexes **1a** and **1b** with an excess of $AlMe_3$ in toluene produces light-yellow crystals of the thermally stable organometallic compounds $[Ti_2(\mu\text{-}OR)_2(\kappa^3\text{-tbop})_2(Me)_2]$ (**2a** for R = Me and **2b** for R = Et). Unfortunately, the poor quality of the X-ray data for **2b** prevents us from discussing the bond lengths and angles in detail.[17] Nonetheless, the central core of **2b** is clearly visible as a dimer similar to compound **1b** where the terminal ethoxides are substituted by methyl groups (Scheme 1). The $[Ti_2(\mu\text{-}OMe)_2(Me)_2]$ unit has been observed in the $[Ti_2(\mu\text{-}OMe)_2(tritox)_2(Me)_4]$ (tritox = tBu$_3$CO$^-$) complex obtained by controlled interaction of O_2 with the [Ti(tritox)$(Me)_3$] complex.[18] The presence of the Ti−C bonds was confirmed by the ^{1}H NMR spectra at room temperature as a singlet (δ = 2.22 ppm for **2a**; δ = 2.23 ppm for **2b**). For comparison, two singlets (δ = 1.38 and 1.36 ppm) of Ti−CH_3 for $[Ti(\kappa^2\text{-mbp})(CH_3)_2]$ [mbp = 2,2′-methylenebis(6-*tert*-butyl-4-methylphenolato)][4a] and one singlet (δ = 1.22 ppm) for $[Ti(CH_3)_4]\cdot Et_2O$ were detected.[19] Additional evidence for the formation of the Ti−C bond was achieved during controlled hydrolysis of **2b**. Treatment of **2b** with an excess of water in toluene resulted in the evolution of methane detected by GC-MS method and the changing color of the reaction mixture from yellow to orange-red. After workup of the post-reaction mixture, red crystals of $[\{Ti_2(\mu\text{-}OEt)_2(\kappa^3\text{-tbop})_2\}_2(\mu\text{-}O)_2]\cdot 2CH_2Cl_2$ (**3**) were isolated. The solid-state structure of **3** is shown in Figure 2.

Crystals of **3** consist of two $[Ti_2(\mu\text{-}OEt)_2(\kappa^3\text{-tbop})_2]$ units linked by two μ-O(oxo) atoms coordinated to the titanium atoms with two CH_2Cl_2 solvent molecules of crystallization. The four titanium atoms in **3** have equivalent distorted octahedral geometry. Also the individual Ti−μ-O(oxo) bond lengths are broadly similar and are in the range observed for titanoxanes; for example $[Ti_2(\mu\text{-}O)Cl_2(guaiacolato)_4]$,[20] $[Ti_4(\mu\text{-}O)_4(guaiacolato)_8]$,[20] and $[Ti_4(\mu\text{-}O)_4Cl_8(MeCN)_6]$[21] are formed in situ by controlled hydrolysis of the titanium species. The formation of compound **3** upon hydrolysis of **2b** with an excess of H_2O confirms particular stability of the μ-OR bridges. In contrast, upon deliberate hydrolysis of the monomeric compound [Ti(mbmp)$(O\textit{i}Pr)_2$] [mbmp = 2,2′-methylenebis(6-*tert*-butyl-4-methylphenolato)] with one equivalent of water, the formation of $[Ti(mbmp)_2]$ as a main product was observed and crystallographically confirmed.[4c]

Catalysts based on complexes **1a**, **1b**, **2a**, and **2b** are highly active systems for the polymerization of ethylene. They were prepared in *n*-hexane by milling (see Exp. Sect.) a slurry of $MgCl_2(THF)_2$ with one equivalent of the titanium compound and $AlEt_2Cl$ or $AlEt_2Cl/AlEt_3$ (1:1) as the cocatalysts. Ethylene polymerization results; the polymer characterization data are summarized in Table 1.

For comparison of catalyst activities, titanocene dichloride ($[Cp_2TiCl_2]$) was used as a reference under the same conditions (Table 1, Entry 9). It turned out that the catalyst based on the complex **2b** (Entry 7) exhibited the highest catalytic activity (204,760 g·PE·mmol^{-1}·h^{-1}) for ethylene polymerization. This is about fourfold more than with catalysts based on $[Ti_2(\mu\text{-}OEt)_2(OEt)_4(\kappa^2\text{-maltolato})_2]$ (54,630 g·PE·mmol^{-1}·h^{-1}, 50 °C, 0.5 MPa, catalyst 0.01 mmol, $AlEt_2Cl/AlEt_3$ 5 mmol, in *n*-hexane)[20] and the species formulated as $[Ti(tbmp)X_2]$ (47,620 g·PE·mmol^{-1}·h^{-1}; 20 °C, 3 MPa, catalyst 0.2 mmol, MAO 25 mmol, in toluene),[2b] but is less than for $[Ti(tbmp)X_2]$/MAO (390,476 g·PE·mmol^{-1}·h^{-1} for X = Cl and 356,315 g·PE·mmol^{-1}·h^{-1} for X = O*i*Pr; 20 °C, 3 MPa, catalyst 0.001 mmol, MAO 5.17 mmol, toluene) originally reported by Kakugo.[1b,1c] Molecular weights of the polymers produced employing complexes **1a**, **1b**, **2a**, and **2b** under these conditions range from 637,000 to 1,010,000. Polydispersities M_w/M_n for **1a**, **1b**, **2a**, and **2b** (see Table 1) are much narrower than those reported for ethylene polymerization with catalysts based on $[Ti_2(\mu\text{-}OEt)_2(OEt)_4(\kappa^2\text{-maltolato})_2]$ (6.11)[20] and $[Ti(tbmp)X_2]$ (11.9).[2b] It would appear that for polymerization of ethylene, activation at least those systems with $M_w/M_n < 3$ (Entries 3, 4, 7) does afford a single well-defined active species. This indicates that the cocatalyst does not abstract the tbop ligand from the titanium center. In fact, this was confirmed by the results of the interaction of **1a** and **1b** with $AlMe_3$ that showed only the migration of the terminal OR groups to aluminium atoms (Scheme 1). The

preliminary polymerization results on our Ziegler−Natta-like systems are promising on account of the production of a polymer with sufficiently narrow particle-size distributions. To obtain polymers with satisfactory polydispersity properties and high bulk densities we are now investigating the properties of the new catalysts based on modified titanium complexes described here.

Conclusions

The reaction of $Ti(OR)_4$ with H_2tbop in 1:1 molar ratio results in the formation of dimeric mixed-ligand complexes **1a** and **1b**. Treatment of **1a** and **1b** with an excess of $AlMe_3$ leads to the substitution of only terminal alkoxides by methyl groups to form organometallic compounds **2a** and **2b**. The Ti−C bond in **2a** and **2b** is thermally stable but very sensitive to moisture. The reaction of **2b** with water affords the titanoxane species **3**. In fact, the μ-OR bridges in **2a** and **2b** are very stable and do not undergo substitution either by $-CH_3$ groups or alkoxy oxygen atoms. Compounds **1a**, **1b**, **2a**, and **2b** supported on $MgCl_2$ and activated with $AlEt_2Cl$ or $AlEt_2Cl/AlEt_3$ show very high activity in ethylene polymerization. Narrow molecular weight distribution for these systems indicates that the operation of heterogeneous single-site catalysts occurs.

Experimental Section

General Remarks: All operations were carried out under dry nitrogen, using standard Schlenk techniques. All the solvents were distilled under nitrogen from the appropriate drying agents prior to use. The compounds $Ti(OMe)_4$, $Ti(OEt)_4$, $AlMe_3$, $AlEt_2Cl$, and 2,2′-

thiobis{4-(1,1,3,3-tetramethylbutyl)phenol} (H_2tbop) were obtained from the Aldrich Chemical Co. and used without further purification unless stated otherwise. Infrared spectra were recorded with a Perkin−Elmer 180 spectrophotometer as Nujol mulls. NMR spectra were performed with a Bruker ARX 300 spectrometer. Microanalysis were conducted with a ASA-1 (GDR, Karl- Zeiss-Jena) instrument (in-house).

Synthesis of $[Ti_2(\mu\text{-}OMe)_2(OMe)_2(\kappa^3\text{-}tbop)_2]$ (1a): $Ti(OMe)_4$ (1.40 g, 8.1 mmol) was added to a solution of H_2tbop (3.60 g, 8.1 mmol) in methanol (50 mL); the mixture was stirred at room temperature for 12 h . A yellow microcrystalline solid was filtered off, washed with methanol, and dried under vacuum. Yield 4.25 g (95 %). $C_{60}H_{92}O_8S_2Ti_2$: calcd. C 65.44, H 8.42, S 5.82; found C 65.12, H 8.25, S 6.12. IR (Nujol mulls, cm^{-1}): $\tilde{\nu}$ = 440 (w), 454 (w), 546 (vs), 576 (vs), 629 (s), 672 (s), 730 (s), 758 (s), 825 (vs), 866 (s), 880 (s), 888 (s), 1028 (s), 1070−1098 (br., s), 1122 (vs), 1208 (w), 1280 (w), 1249 (s), 1280 (vs), 1298 (vs), 1323 (w), 1362 (s), 1344 (w), 1396 (m), 1594 (w). ^{1}H NMR (300 MHz, C_6D_6, 25 °C): δ = 7.76−6.60 (12 H, C_6H_3), 4.61 (s, 6 H, μ-OCH_3), 4.29 (s, 6 H, OCH_3), 1.68 [s, 8 H, $C(CH_3)_2CH_2C(CH_3)_3$], 1.35 [s, 24 H, $C(CH_3)_2CH_2C(CH_3)_3$], 0.82 [s, 36 H, $C(CH_3)_2CH_2C(CH_3)_3$] ppm. ^{13}C NMR (300 MHz, C_6D_6, 25 °C): δ = 165.9, 142.2, 131.9, 129.8, 127.2, 115.9 (C_6H_3), 68.2, 63.0 (OCH_3), 57.1, 38.2, 32.5, 32.0, 31.8 [$C(CH_3)_2CH_2C(CH_3)_3$] ppm.

$[Ti_2(\mu\text{-}OEt)_2(OEt)_2(\kappa^3\text{-}tbop)_2]$ (1b): This compound was obtained in 90 % yield as a yellow crystalline solid from appropriate quantities of $Ti(OEt)_4$ and H_2tbop by a method similar to that of **1a**. Crystals suitable for the structure determination were obtained from the post-reaction mixture after standing for one day at room temperature. $C_{64}H_{100}O_8S_2Ti_2$: calcd. C 66.42, H 8.71, S 5.54; found C 66.93, H 8.98, S 6.12%. IR (Nujol mulls, cm^{-1}): $\tilde{\nu}$ = 310 (vw), 440 (w), 496 (s), 546 (vs), 580 (s), 622 (s), 680 (s), 740 (s), 764 (s), 834 (vs), 896 (vs), 930 (s), 976 (w), 1028 (s), 1070 (vs), 1122 (vs), 1208 (w), 1248 (s), 1282(vs), 1302 (vs), 1334 (s), 1544 (w), 1596 (m), 1652 (vw). ^{1}H NMR (300 MHz, C_6D_6, 25 °C): δ = 7.76−6.60 (12 H, C_6H_3), 4.98 (q, 4 H, μ-OCH_2CH$_3$), 4.71 (q, 4 H, OCH_2CH$_3$), 1.70 [s, 8 H, $C(CH_3)_2CH_2C(CH_3)_3$], 1.58 (t, 6 H, μ-OCH$_2$CH_3), 1.32 [m, 6 H, μ-OCH$_2$CH_3 and 24 H, $C(CH_3)_2CH_2C(CH_3)_3$], 0.82 [s, 36 H, $C(CH_3)_2CH_2C(CH_3)_3$] ppm. ^{13}C NMR (300 MHz, C_6D_6, 25 °C): δ = 166.3, 142.0, 131.9, 129.8, 127.3, 116.0 (C_6H_3), 76.8, 71.4 (OCH_2CH$_3$), 57.1, 38.1, 32.4, 31.9, 31.7 [$C(CH_3)_2CH_2C(CH_3)_3$], 18.9, 18.4 (OCH$_2$CH_3) ppm.

$[Ti_2(\mu\text{-}OMe)_2(Me)_2(\kappa^3\text{-}tbop)_2]$ (2a): $AlMe_3$ (0.26 g, 3.6 mmol) was added to an orange solution of **1a** (2.00 g, 1.8 mmol) in toluene (50 mL). The brown mixture was stirred for 24 h. The solvent was evaporated off to give an oily residue, after which addition of *n*-hexane (30 mL) and stirring gave a light yellow solid. This was filtered off, washed with *n*-hexane (3 × 5 mL) and dried in vacuo. Yield 1.43 g (74%). $C_{60}H_{92}O_6S_2Ti_2$: calcd. C 67.39, H 8.67, S 6.00; found C 67.12, H 8.62, S 5.89. IR (Nujol mulls, cm^{-1}): $\tilde{\nu}$ = 443 (w), 452 (w), 548 (vs), 572 (vs), 630 (s), 730 (s), 828 (vs), 867 (s), 882 (s), 1030 (s), 1073−1101(br., s), 1126 (vs), 1206 (w), 1282 (w), 1250 (s), 1278 (vs), 1294 (vs), 1320 (w), 1363 (s), 1340 (w), 1398 (m), 1594 (w). ^{1}H NMR (300 MHz, C_6D_6, 25 °C): δ = 7.88−6.69 (12 H, C_6H_3), 4.52 (s, 6 H, μ-OCH_3), 2.23 (s, 6 H, Ti−CH_3), 1.67 [s, 8 H, $C(CH_3)_2CH_2C(CH_3)_3$], 1.37 [s, 24 H, $C(CH_3)_2CH_2C(CH_3)_3$], 0.84 [s, 36 H, $C(CH_3)_2CH_2C(CH_3)_3$] ppm. ^{13}C NMR (300 MHz, C_6D_6, 25 °C): δ = 165.9, 142.2, 132.0, 130.0, 116.0 (C_6H_3), 68.4, (OCH_3), 57.1, 38.1, 32.4, 32.0, 31.8 [$C(CH_3)_2CH_2C(CH_3)_3$], 30.0 (T−CH_3) ppm.

$[Ti_2(\mu\text{-}OEt)_2(Me)_2(\kappa^3\text{-}tbop)_2]$ (2b): This compound was obtained in 59 % yield as a light yellow solid from appropriate quantities of **1b** and $AlMe_3$ by a similar method to that used to prepare **2a**. Crystals were obtained from the concentrated reaction mixture after standing for 3 days at room temperature. $C_{62}H_{96}O_6S_2Ti_2$: calcd. C 67.86, H 8.82, S 5.84; found C 67.25, H 8.68, S 5.28. $[\{Ti_2(\mu\text{-}OEt)_2(\kappa^3\text{-}tbop)_2\}_2(\mu\text{-}O)_2]\cdot 2CH_2Cl_2$ (3): To a solution of **2b** (1.10 g, 0.8 mmol) in toluene (30 mL), 0.03 mL (1.7 mmol) of H_2O was added in one portion. The evolution of a gas was identified as methane by the GC-MS method. The reaction mixture was stirred for 2 h and then all volatiles were evaporated under vacuum. The residue was dissolved in CH_2Cl_2 (10 mL), CH_3CN (5 mL) was added and the mixture was left in a refrigerator. After 2 days, orange-red crystals suitable for X-ray study were isolated. Yield 0.56 g (54%). $C_{122}H_{184}Cl_4O_{14}S_4Ti_4$: calcd. C 62.72, H 7.94, Cl 6.07, S 5.49; found C 63.58, H 8.29, Cl 7.12, S 5.94%. IR (Nujol mulls, cm^{-1}): $\tilde{\nu}$ = 302 (vw), 448 (w), 500 (w), 538 (s), 580 (s), 622 (w), 640 (vw), 680 (m), 736 (s), 758 (s), 808 (vs), 828 (vs), 844 (s), 882 (m), 966 (vw), 1028 (m), 1084 (w), 1148 (vw), 1208 (vw), 1252 (m), 1280(s), 1298 (s), 1324 (w), 1544 (vw), 1594 (vw), 1652 (vw). ^{1}H NMR (300 MHz, C_6D_6, 25 °C): δ = 7.63−6.88 (24 H, C_6H_3), 5.96 (s, 4 H, CH_2Cl_2), 4.89 (q, 8 H, μ-OCH_2CH$_3$), 1.57 [s, 16 H, $C(CH_3)_2CH_2C(CH_3)_3$], 1.49 (t, 12 H, μ-OCH$_2$CH_3), 1.26 [s, 48 H, $C(CH_3)_2CH_2C(CH_3)_3$], 0.72 [s, 72 H, $C(CH_3)_2CH_2C(CH_3)_3$] ppm. ^{13}C NMR (300 MHz, C_6D_6, 25 °C): δ = 165.8, 142.5, 133.0, 129.8, 127.3, 115.7 (C_6H_3), 76.5 (μ-OCH_2CH$_3$), 57.2, 37.9, 32.1, 32.1, 31.8 [$C(CH_3)_2CH_2C(CH_3)_3$], 19.3 (μ-OCH$_2$CH_3).

Polymerization Test: A slurry of $MgCl_2(THF)_2$ (30 mmol) in *n*-hexane was milled under argon in a glass mill (capacity 250 mL, with 20 balls of diameter 5−15 mm) at room temperature for 6 h. Then the titanium compound (5 mmol) and *n*-hexane (50 mL) were added, and the mixture was milled for a further 24 h. The sample of pro-catalyst suspension (containing 0.01 % titanium) was activated with $AlEt_2Cl$ or $AlEt_2Cl/AlEt_3$ (1:1 molar ratio; 20 mmol) for 15 min at 323 K under argon to form a highly active catalyst. The polymerization of ethylene was carried out in *n*-hexane at 323 K in a stainless steel reactor (1 L), equipped with a stirrer, at 0.5 MPa ethylene pressure. The polymerization was quenched with a 5 % solution of HCl in methanol and dried under vacuum.

X-ray Crystallographic Study for 1b and 3: Crystal data collection and refinement are summarized in Table 2. Preliminary examination and intensity-data collections were carried out on a KUMA KM-4 κ-axis diffractometer with graphite-monochromated Mo-K_α and with a scintillation counter (**1b**) or a CCD camera (**3**). All data were corrected for Lorentz and polarization effects. Data reduction and analysis were carried out with the Kuma Diffraction programs.[22−23] The structures were solved by direct methods,[24] and refined by the full-matrix least-squares method on all F^2 data using the SHELXL-97 software.[25] Carbon bonded hydrogen atoms were included in calculated positions and refined in the riding mode using SHELXL-97 default parameters. All non-hydrogen atoms were refined with anisotropic displacement parameters. In the structure of **1b** one carbon atom of an ethanol molecule is disordered between two sites — occupancy factors for these two positions were set as 0.65 and 0.35,

Pyrazolate-Based Dinucleating Ligands in L_2M_2 Scaffolds: Effects of Bulky Substituents and Coligands on Structures and M···H−C Interactions

Jens C. Röder,[b][‡] Franc Meyer,*[a] Elisabeth Kaifer,[b] and Hans Pritzkow[b]

Keywords: Nickel / Palladium / Dinuclear complexes / N-ligands / Pyrazole ligands

A series of nickel(II) and palladium(II) complexes $[L_2M_2]^{2+}$ have been prepared and structurally characterized, where L is a pyrazolate ligand with bulky 2,6-dimethyl- or 2,6-di(isopropyl)anilinomethyl side arms. Coordinating counter anions such as chloride can bind to axial sites of the dinickel species in a solvent-dependent process, giving rise to five-coordinate high-spin metal ions. In the case of weakly coordinating anions, the metal ions are found in roughly square-planar environments, and the structures are governed by the tendency of the bulky aryl groups to avoid each other, which forces the methyl or isopropyl substituents in the aryl 2- and 6-positions to approach the metal ions from the axial directions. This leads to drastic low-field shifts of the respective ^{1}H NMR signals, e.g. δ = 7.86 ppm for the isopropyl –CH which comes in close proximity to the low-spin nickel(II) center. The relevance of such low-field NMR resonances of protons close to the axial sites of d^8 metal ions for possible three-center four-electron M···H–C hydrogen bonds involving the filled d_z^2 orbital of the metal ion is discussed. In the present case, attractive M···H interactions are assumed to be of no major significance. This was corroborated by the structure of a further $[L_2Ni_2]^{2+}$ type complex where the anilinomethyl side arms bear only a single 2-isopropyl group, which was found rotated away from the metal. Additional spectroscopic and electrochemical properties of the various complexes are reported.

Introduction

At present, research on di- and oligonuclear transition metal complexes is a flourishing field with major interests focussed on biological mimicry and cooperative phenomena in catalysis and magnetism.[1–4] Among the diverse ligand frameworks that have been designed and employed in order to hold two metal centers in close proximity and to induce the sought-after cooperativity, pyrazole derived species appear particularly suited due to their well-known ability to span adjacent metal ions at a favorable distance of 2.4−4.6 Å.[5,6] Further control of the metal−metal separation, as well as of the steric and electronic properties of the individual metal ions, can be achieved by appropriate chelating side arms attached to the 3- and 5-positions of the heterocycle,[7,8] usually giving rise to either bis(μ-pyrazolato) bridged species L_2M_2 (**A**, Scheme 1)[9–15] or LM_2X complexes featuring secondary bridges within the dimetallic pocket (**B**).[16–24]

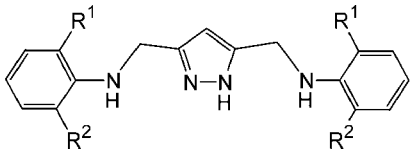

Scheme 2. Ligands used in this study[27]

In this contribution we report on the effects that coordinating versus non-coordinating co-ligands as well as bulky substituents at the chelating side arm donor atoms of L_2M_2 type compounds have on the solid-state structures, and we will particularly focus on unusual metal-ligand interactions that arise from the steric crowding in such systems. Nickel(II) and palladium(II) complexes of ligands $[L^1]^-$, $[L^2]^-$ and $[L^3]^-$ (Scheme 2) were initially prepared with the aim of providing diamine analogues of the bis(α-diimine) type dinuclear compounds **C**.[25,26] However, with $[L^1]^-$, $[L^2]^-$ and $[L^3]^-$, complexes of the type L_2M_2 (**A**) were favored in all cases, irrespective of the M:L ratio employed.

Results and Discussion

Syntheses of all complexes were readily achieved by deprotonation of the respective ligand precursor (HL^1, HL^2, or HL^3)[27] with one equivalent of KO*t*Bu in THF and subsequent addition of the respective metal salt.

Complexes of $[L^1]^-$: Solid-State Structures and Magnetic Properties

From the reaction between HL^1 and $NiCl_2{\cdot}6H_2O$, two structurally isomeric complexes $[L^1_2Ni_2Cl_2]$ (**1**) and $[L^1_2Ni_2]Cl_2$ (**2**) were obtained from acetone and CH_2Cl_2 solutions, respectively. The molecular structures of **1** and **2** are depicted in Figure 1 and 2 together with selected interatomic distances and bond angles.

In the green compound **1**, both nickel ions exist in roughly square-pyramidal coordination environments (τ = 0.11 and 0.18 for Ni1 and Ni2, respectively)[28] with the Cl ligands in axial positions. The metal ions are displaced slightly out of the planes of the basal N-donor atoms towards the axial ligands, which are located on opposite sides of the bimetallic framework defined by the two $\{N_4\}$ chelate ligands. As expected, the distances between the nickel and the coordinating amine N atoms are around 10% longer than the Ni−N(pyrazolate) distances [2.158(3) −2.224(3)Å versus 1.956(3) −1.978(3) Å]. The ligand side arm aryl substituents in **1** are oriented almost perpendicular to the plane of the pyrazolate, and hence perpendicular to the plane of the coordination framework. Due to the space required by the axial co-ligand, the adjacent aryl rings are pushed away from the chloride towards the back side of the dimetallic array. This situation has to balance two competing steric interactions: either some *ortho* methyl groups of the aryl substituents come quite close to the Cl atom [e.g. *d*(C21···Cl2) = 3.718 Å, *d*(C42···Cl1) = 3.942 Å], or the other *ortho* methyl groups are forced to approach the nickel ion from the reverse [C11, C41, C20, C32; *d*(Ni···C_{CH3}) = 3.482−3.783 Å]. In order to avoid an energetically unfavorable full eclipse of the opposing pairs of aryl rings, the respective five-membered chelate rings adopt different conformations (Scheme 3). For each nickel, one chelate ion is almost planar (at N3 and N4), while the second ring adopts an envelope conformation with the aryl groups in either an axial (N8) or an equatorial position (N7).

In the red compound **2**, the chloride ions are detached from their metal atoms, but they still remain associated with the complex via NH···Cl hydrogen bonds [*d*(N3···Cl5) =

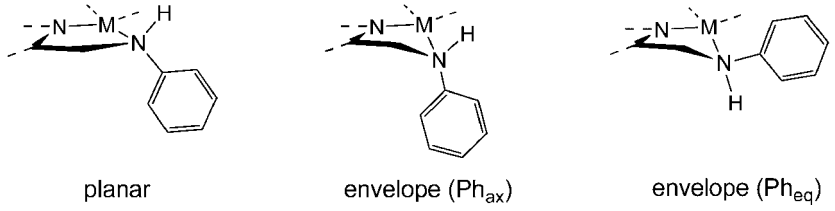

Scheme 3. Conformations of five-membered chelate rings

3.160 Å, *d*(N4···Cl5) = 3.229 Å]. The Ni···Cl distance is 3.214 Å [versus 2.339(1)/2.331(1) Å in **1**], i.e. clearly out of the bonding range, which leaves the metal ions in an approximately square-planar {N_4} environment and slightly decreases the Ni···Ni separation compared with **1** [3.830(1) Å versus 3.960(1) Å]. Due to the H-bonding pattern of the chloride ions, which are both located on one side of the bimetallic array, all aryl rings are directed downwards to the opposite side. Again, this forces two *ortho* methyl groups in close proximity to the metal ions [*d*(Ni···C12) = 3.417 Å, *d*(Ni···C20) = 3.284 Å]. Similar to the situation in **1**, the five-membered chelate rings feature different conformations in order to avoid a fully eclipsed stacking of the aryl groups. All Ni−N bond lengths are significantly shorter than in **1**, in accordance with the lower coordination number and the different spin state, i.e. a high-spin d^8 configuration in **1** compared with a low-spin configuration in **2**. It remains unclear, why the Cl^- ions in **2** are located on the same side of the bimetallic platform, while the Cl ligands in **1** are found on opposite sides.

The aryl rings facing each other in complexes **1** and **2** do not adopt an exact face-to-face alignment, but something of a slipped facial arrangement. To characterize the π-π stacking, one usually considers parameters such as the distance between, and the relative tilting of the planes of opposite aryl rings as well as the centroid−centroid distance (CC), and the angle between the centroid-centroid vector and the ring normal to one of the aryl planes.[29] In **1**, the planes are tilted by 4.3/5.1°, the CC distance is 3.81/4.15 Å, and the offset of the centroids is 1.41−2.13 Å, hence the distance between the centroid and the plane of the opposite aryl ring amounts to 3.49−3.57 Å. These latter values are in the typical range for interplanar distances of π-π stacked aromatic groups (3.3−3.8 Å).[29] In **2**, tilting of the aryl planes relative to each other is similar (6.2°), but the CC distance is somewhat shorter (3.55 Å) and the two rings are less displaced (offset 1.05/1.17 Å). Again, the interplanar separation of the aromatic groups (3.35/3.39 Å) is in the usual range.

The paramagnetic nature of **1** and the diamagnetic nature of **2** were confirmed by magnetic measurements. Temperature dependent data for the molar magnetic susceptibility and the effective magnetic moment of **1** are shown in Figure 3.

From ca. 4.7 B.M. at 300 K, the magnetic moment gradually decreases upon lowering the temperature, while the susceptibility curve exhibits a sharp maximum at around 60 K which is indicative of significant antiferromagnetic coupling between the two nickel(II) centers. Modeling the experimental data by the standard expression for the isotropic spin-Hamiltonian $H = -2J \cdot S_1 \cdot S_2$ (with $S_1 = S_2 = 1$) including a molar fraction p of uncoupled paramagnetic impurity [Equation (1)][4,30,31] yielded $J = -23.2\ cm^{-1}$, $g = 2.39$ and $p = 1.9\%$.

$$\chi = \chi_{dim}(1 - p) + 2\chi_{mono}p + 2N_{\alpha'} \quad (1)$$

The intra−dimer exchange term J proved to be the dominant contribution because a good quality fit was obtained despite the neglect of both a zero-field splitting parameter D as well as an inter−dimer interaction $z'J'$.[32] Relatively few bis(μ-pyrazolato)-bridged high-spin dinickel(II) complexes have been previously structurally charac-

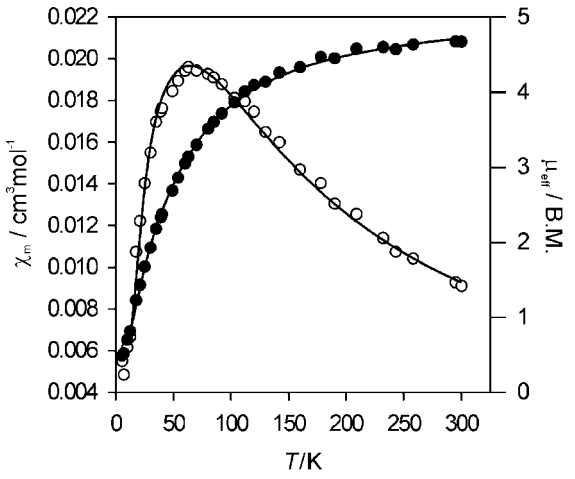

Figure 3. Temperature dependence of the molar magnetic susceptibility (open circles) and magnetic moment (solid circles) for **1**; the solid line represents the calculated fit (see text)

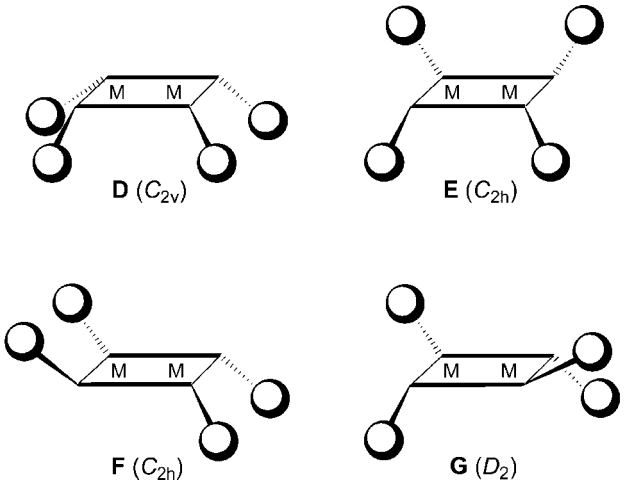
terized,[22,33,34] and even fewer have been studied with respect to their magnetic properties,[35] which precludes any definite magneto-structural correlations at the present stage. However, the rather large magnetic coupling in **1** is certainly due to the high degree of planarity of the $Ni(NN)_2Ni$ scaffold, in accordance with the magneto-structural trends observed in bis(μ-pyrazolato) dicopper(II) chemistry.[36,13]

The controlled synthesis of a complex with low-spin square-planar metal ions was achieved by treatment of $[L^1]^-$ with $[Ni(H_2O)_6](ClO_4)_2$. The molecular structure of the resultant compound **3**, obtained in crystalline form from acetonitrile/diethyl ether, is depicted in Figure 4.

The first coordination sphere of the nickel ions in **3** is quite similar to that in **2**, but less distorted with both metal centers nested within the plane of an overall planar framework. All five-membered chelate rings are roughly planar in this case. In the absence of any steric requirements of chloride counter-anions or co-ligands, the two aryl rings on both ends of **3** do not face each other, but one of them is pointing above and the other below the coordination plane. This gives rise to the sterically more favorable isomer **E** with approximate (non-crystallographic) C_{2h} symmetry (Scheme 4), in contrast to the C_{2v} isomer **D** that is imposed by the four NH···Cl bonds in **2** and the C_{2h} isomer **F** found for **1**. Note that the chiral D_2 isomer **G**, which should be quite similar to the C_{2h} isomer **E** in terms of steric effects, was not observed (neither were any isomers of lower symmetry). The C_{2h} isomer can be described as a *meso* form with an (*R*,*S*)(*S*,*R*) configuration of the four stereogenic N atoms, while the D_2 system represents a pair of enantiomers with (*R*,*R*)(*R*,*R*) or (*S*,*S*)(*S*,*S*) configurations. Interestingly, the *ortho* methyl groups in **3** are even closer to the nickel ions than in **2**, approaching from both axial directions [*d*(Ni···C11) = 3.033 Å, *d*(Ni···C32) = 3.110 Å].



Scheme 4. Different stereoisomers of the $[L_2M_2]^{2+}$ platform (M = Ni, Pd); the balls represent the bulky aryl substituents

The set of dinickel complexes **1**–**3** exemplifies the influence of co-ligands (in this case Cl^-) within the first or second coordination shell on the structural features of the bimetallic scaffold. The sequence given in Figure 5 may

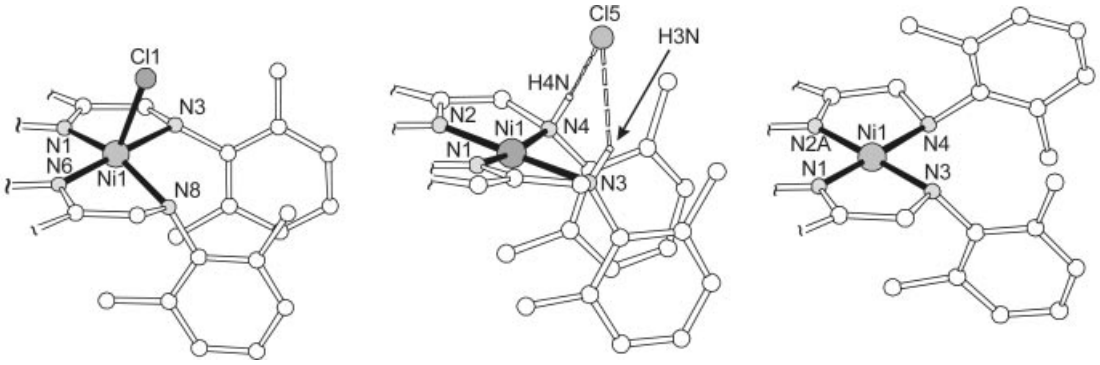

Figure 5. Comparative view of the Ni coordination in **1**, **2** and **3** with the chloride in the inner coordination sphere (**1**), outer coordination sphere (**2**), and without chloride (**3**)

then be viewed as a set of snapshots of the chloride dissociation process. The accompanying spectroscopic characteristics and solution properties of **1**−**3** are discussed below.

For comparison, a dipalladium complex **4** was prepared from $[L^1]^-$and $[Pd(NCMe)_4](BF_4)_2$ and crystallized (in low yield) from dichloromethane/light petroleum. The molecular structure of its cation is basically analogous to that of **3**. However, closer inspection reveals subtle differences which are revealed in Figure 6. In **4**, all chelate rings are more distorted towards an envelope conformation, which brings the adjacent aryl rings to partly stand opposite to each other and to move into the coordination plane. We believe two effects to be responsible for this. Firstly, the larger ionic radius of palladium(II) compared with nickel(II) (0.86 versus 0.72 Å) induces a larger separation between the aryl rings, allowing them to relax towards a more eclipsed stacking. Secondly, the larger palladium ion interferes more strongly with the *ortho* methyl groups, thus enforcing somewhat longer Pd···C distances (3.428 and 3.486 Å) in the axial positions of the metal center and pushing away the substituents. The parallel-displaced arrangement of the aromatic groups in these complexes (as well as in complexes **5**−**7**, see below) means that the interaction is more of the C−H···π type and driven by the known π-σ attraction, while π-π stacking is not favored.[29]

Complexes of $[L^1]^-$ in Solution

A solution of **1** (or, **2**) appears green in CH_2Cl_2 but red in MeCN, and dilution of a THF solution also causes a gradual change from green to red. This change in color is consistent with the crystallographic findings. In non-polar solvents and in concentrated solutions, the position of the equilibrium between **1** and **2** is shifted towards the neutral species $[L^1_2Ni_2Cl_2]$ and the more ionic $[L^1_2Ni_2]Cl_2$ is the less soluble compound that crystallizes from the solution. On the other hand, polar solvents such as MeCN or acetone favor the ionic form $[L^1_2Ni_2]Cl_2$, and the neutral **1** now becomes less soluble and precipitates first.

In order to obtain some further insight into these equilibria, a solution of the Cl-devoid complex **3** in CH_2Cl_2/MeCN (1:1) was titrated with $[(n\text{-hex})_4N]Cl$ and the mixture was analyzed by UV/Vis spectroscopy. Even in the presence of an excess of chloride, **3** was not fully converted into **1** in that solvent mixture. The absence of clear isosbestic points indicates the presence of more complex equilibria presumably involving, inter alia, species such as $[L^1Ni_2Cl]^+$.

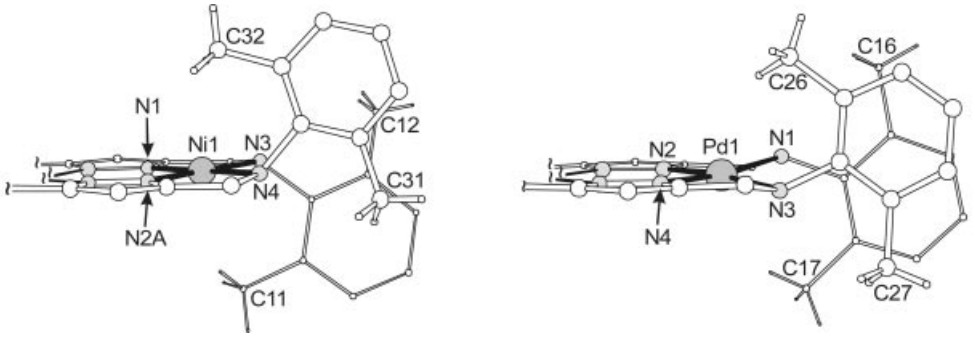

Figure 6. Comparative view of fragments of the molecular structures of **3** and **4**; in the interests of clarity only those hydrogen atoms bound to the methyl groups are shown; selected interatomic distances (Å) and bond angles for **4** are (°): Pd1−N2 1.969(2), Pd1−N4 1.970(2), Pd1−N1 2.110(2), Pd1−N3 2.123(2), Pd1···Pd1A 3.954, Pd1···C17 3.486, Pd1···C26 3.428; N4−Pd1−N1 173.49(8), N2−Pd1−N3 173.95(8)

Solid state UV/Vis/NIR spectra of **1**−**3** were recorded for comparison and are depicted in Figure 7. As expected for five-coordinate high-spin nickel(II) ions, **1** shows a series of absorptions, including the broad band at around 1980 nm, that should correspond to the $^3B_1 \rightarrow {}^3E$ transition in idealized C_{4v} symmetry. The two distinct bands at 328 and 502 nm for **3** can be assigned to the $^1A_{1g} \rightarrow {}^1B_{1g}$ and $^1A_{1g} \rightarrow {}^1A_{2g}$ transitions of low-spin nickel(II) in an idealized D_{4h} environment, where the latter gives a reasonable value of the ligand field splitting, $\Delta \approx 20000\ cm^{-1}$.[37] The similarity of the band positions for **1** and **3** in the range 300−1000 nm with those observed in solution confirms that the overall structures elucidated by X-ray crystallography are essentially retained in solution.

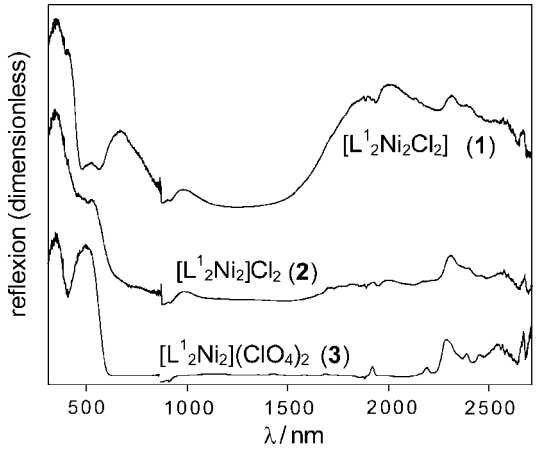

Figure 7. Solid state UV/Vis spectra of the dinickel complexes **1**, **2** and **3**

^1H NMR spectroscopy of diamagnetic **3** revealed unusual chemical shifts for the *ortho* methyl groups of the aryl rings (Figure 8; all signals have been unambiguously assigned by a series of 2D NMR experiments). While the CH_3 resonance appears at δ = 2.29 ppm in HL[1], the spectrum of **3** shows one signal shifted to higher field at δ = 1.08 ppm and two signals (of different intensities) at very low field, i.e. at δ = 4.17 and 4.20 ppm. These features can be rationalized by considering the positions of the methyl groups and, as is clearly seen in Figure 4, the high-field shifts of H12A−C and H31A−C are due to their location within the field of the ring current of the opposing aryl rings, while the deshielding of H11A−C and H32A−C results from their proximity to the filled d_z^2 orbital of the nickel(II) ion. The occurrence of two closely spaced resonances for the latter protons has been tentatively attributed to the presence of different isomers in solution, such as the C_{2h} and D_2 forms sketched in Scheme 4. These effects are even more pronounced in the case of complexes of $[L^2]^-$ and are discussed in more detail below. The diastereotopic nature of the CH_2 protons of the five-membered chelate rings is reflected by two well-separated sets of signals centered at δ = 3.43 and 4.15 ppm.

^1H NMR spectra of the palladium complex **4** in CD_2Cl_2 only show very broad resonances over a wide temperature range, presumably indicating a variety of dynamic and dissociative processes.

Complexes of $[L^2]^-$: Solid-State Structures and Spectroscopy

Similar to the preparation of **3** and **4**, the dinickel and dipalladium complexes $[L^2_2Ni_2](ClO_4)_2$ (**5**) and $[L^2_2Pd_2](BF_4)_2$ (**6**) were obtained by treatment of $[L^2]^-$ with $[Ni(H_2O)_6](ClO_4)_2$ or $[Pd(NCMe)_4](BF_4)_2$, respectively. Single crystals were grown from acetone/ethanol/light petroleum (**4**) or dichloromethane/light petroleum (**5**) and analyzed by X-ray crystallography. Both **5** and **6** crystallize in the triclinic space group $P\bar{1}$, and molecular structures of their cations are shown in Figure 9.

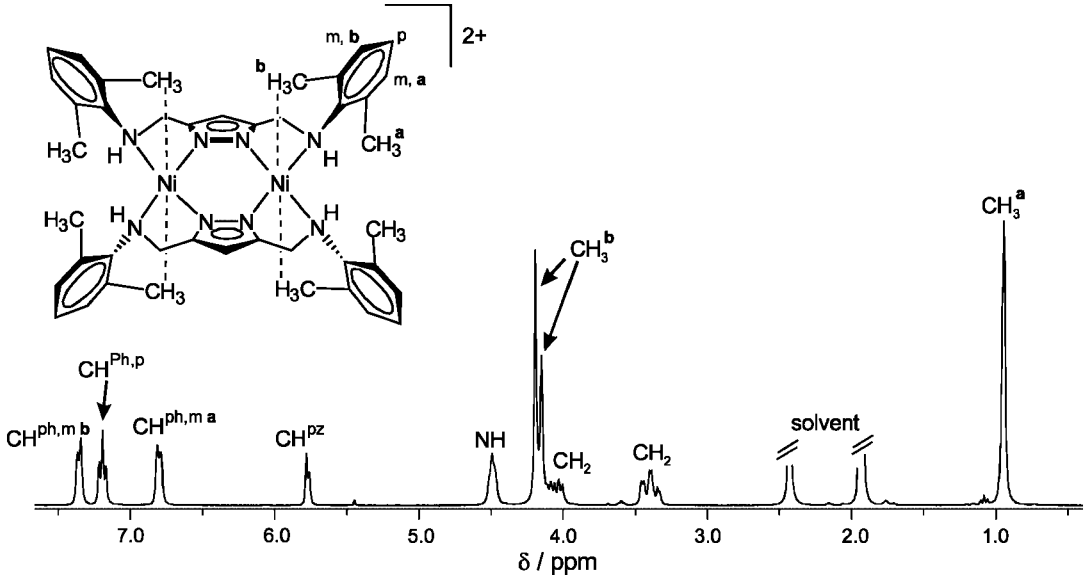

Figure 8. ^1H NMR spectrum of complex **3** in CD_3CN at 300 MHz and 293 K; the dashed lines in the graphical representation of **3** are not meant to indicate bonds

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

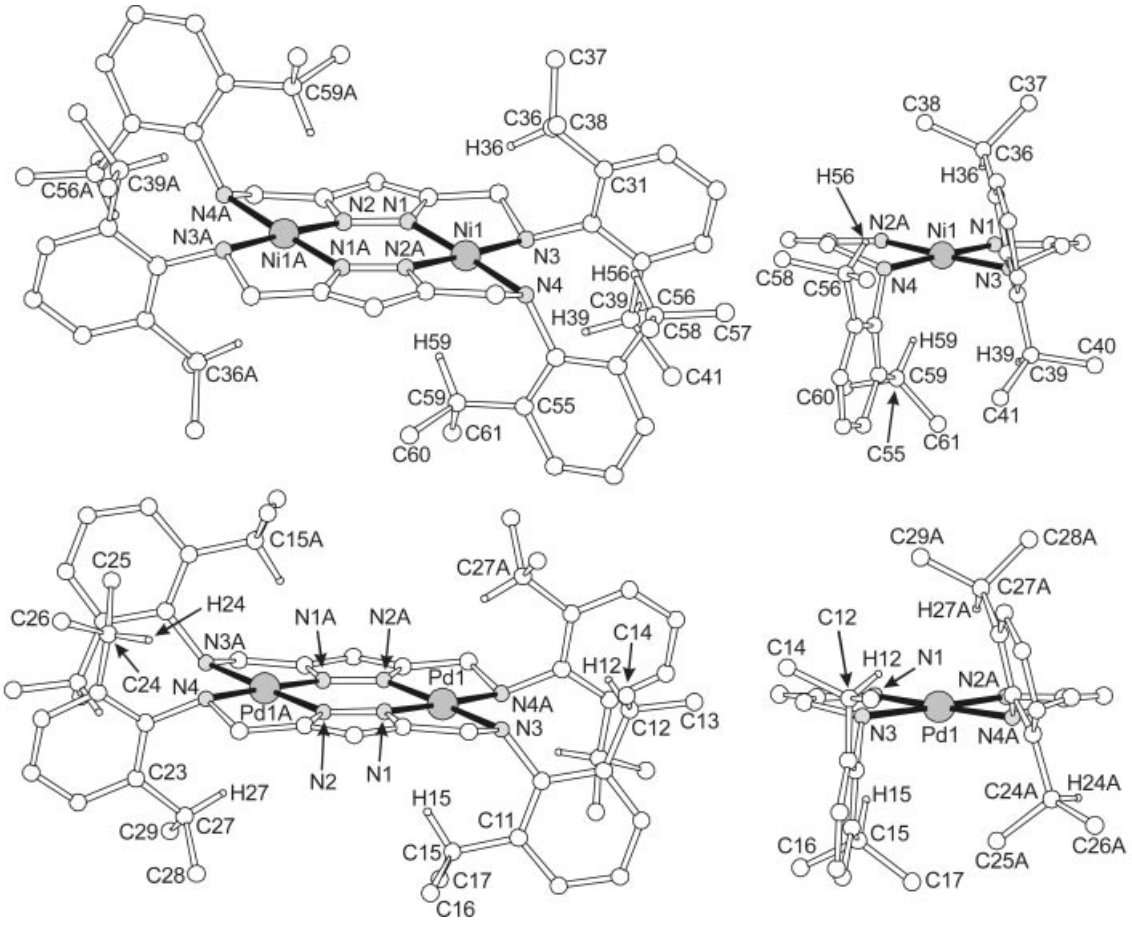

Figure 9. Molecular structures of the cations of **5** (top) and **6** (bottom); in the interests of clarity only a few hydrogen atoms are shown; selected interatomic distances (Å) and bond angles (°) for **5**: Ni1−N1 1.835(3), Ni1−N2A 1.848 (3), Ni1−N3 1.967(3), Ni1−N4 1.974(3), Ni1···Ni1A 3.842, C36···Ni1 3.269 C59···Ni1 3.114; N2A−Ni1−N3 177.25(11), N1−Ni1−N4 178.00(12); selected interatomic distances (Å) and bond angles (°) for **6**: Pd1−N1 1.968(3), Pd1−N2A 1.971(3), Pd1−N3 2.114(3), Pd1−N4A 2.123(3), Pd1···Pd1A 3.997, C15···Pd1 3.454, C27A···Pd1 3.377; N2A−Pd1−N3 176.09(12), N1−Pd1−N4A 176.19(12)

All metal ions are found in roughly SP-4 coordination environments. Due to the steric pressure exerted by the bulky 2,6-diisopropylphenyl substituents, however, the coordination planes of the metal ions are tilted by ca. 10° (**5**) or 8° (**6**) with respect to the planes of the pyrazolate heterocycles. The chelate rings adopt an envelope conformation with one aryl substituent in an axial position and one in an equatorial position for each half of the molecule (cf. Scheme 3). These structural features cause the methine proton of one isopropyl group of every aryl substituent to approach considerably close to the proximate metal ion from the axial direction [*d*(C36···Ni) = 3.269 Å and *d*(C59···Ni) = 3.114 Å in **5**, *d*(C15···Pd) = 3.454 Å and *d*(C27···Pd) = 3.377 Å in **6**]. The consequences for the ^{1}H NMR chemical shifts of these particular protons should be more pronounced than in **3**, since rotation is hindered for the isopropyl groups in **5**, while rotation of the methyl groups causes an averaging of the effect in **3**. The expected four CH_3 resonances for the non-equivalent isopropyl groups in **5** were seen in the low temperature (193 K) ^{1}H NMR spectrum in CD_2Cl_2 (Figure 10). Signals have been assigned based on a series of 2D NMR experiments ({^{1}H^{13}C}HSQC and {^{1}H^{13}C}HMBC), and the methine resonances of the isopropyl groups were found either at extremely low field (δ = 7.86 ppm; CH^B close to the nickel ion) or at very high field (δ = 1.86 ppm; CH^A opposing the proximate aryl ring) compared with the free ligand HL^2 (δ = 3.33 ppm at room temp.). At 193 K, the CH_2 protons at δ = 3.40 and 4.13 ppm showed a geminal coupling of ^2J = 10 Hz, in accordance with a fixed conformation of the five-membered chelate rings. At higher temperatures, a second set of resonances gradually developed, which were most clearly observed for the isopropyl-CH_3 groups and were also evident from the splitting of the signal at around 5.9 ppm for the pyrazolate H^4 proton (CH^{pz}). At 293 K, a 1:1 ratio of the two isomers was obtained. These different isomers have been tentatively assigned to the C_{2h} and D_2 forms of the bimetallic framework, where the two aryl substituents of each ligand are either on the same (C_{2h}) or on opposing sides (D_2). Interconversion was apparently rapid and may proceed either via a short-lived dissociation of the Ni−N bonds and inversion of the intermediate free amine, or via a sequence of deprotonation and inverse protonation of the *N*-bound protons.

In CD_3CN at higher temperatures all ^{1}H NMR signals of **5** became broad, except for the *para* protons of the aryl

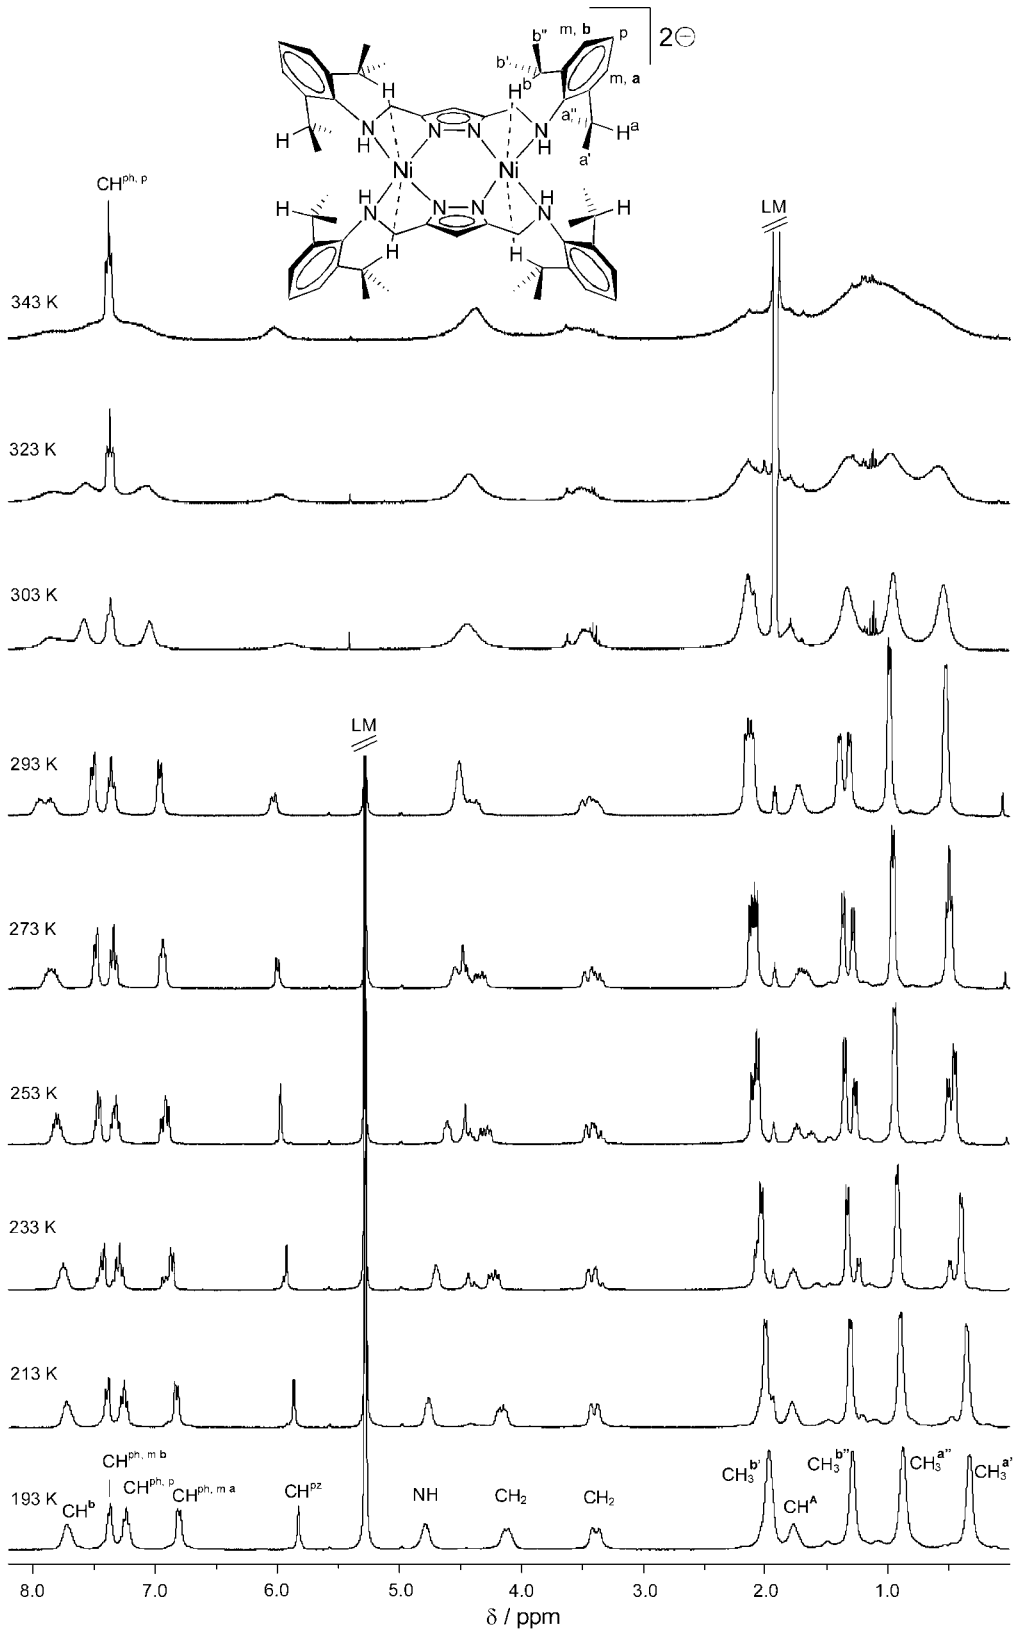

Figure 10. Temperature dependent ^{1}H NMR spectra of complex **5** in CD_3CN (303−343 K) and CD_2Cl_2 (193−293 K) at 300 MHz; the dashed lines in the graphical representation of **5** do not indicate bonds

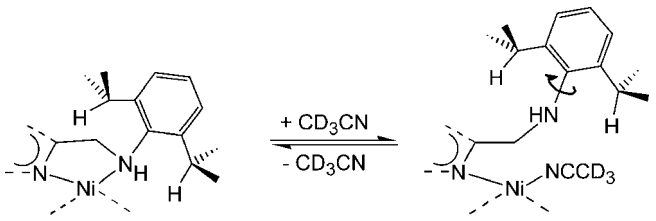
groups. We assume dissociative processes according to Scheme 5 to be responsible for this phenomenon, which may also support the former explanation for the stereoisomer interconversion discussed above. Similar characteristics were observed for the ^{1}H NMR spectrum of **6**, but with a somewhat less pronounced deshielding of its CH^B protons.

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim



Scheme 5. Possible solvent-assisted side arm dissociation

When **5** was treated with two equivalents of HL^1, formation of **3** and the heteroleptic complex $[L^1L^2Ni_2]$ $(ClO_4)_2$ (**7**) was observed within minutes. However, ligand exchange did not proceed to completeness, and equilibrium was reached at ca. 70% exchange. The mixed-ligand species **7** could be prepared directly by treatment of a 1:1 mixture of $[L^1]^-$ and $[L^2]^-$ with two equivalents of $[Ni(H_2O)_6](ClO_4)_2$. Single crystals were obtained from a MeCN/diethyl ether solution and were analyzed by X-ray crystallography. The molecular structure of the cation of **7** is depicted in Figure 11 together with selected atom distances and bond angles.

In **7**, the two nickel ions were found in subtly different environments. While the coordination sphere of Ni2 is almost square-planar, Ni1 shows a slight tetrahedral distortion. Five-membered chelate rings of all possible conformations (planar, λ-twist, δ-twist) are present in **7**. The two pyrazolate heterocycles are tilted by 12.1° with respect to each other.

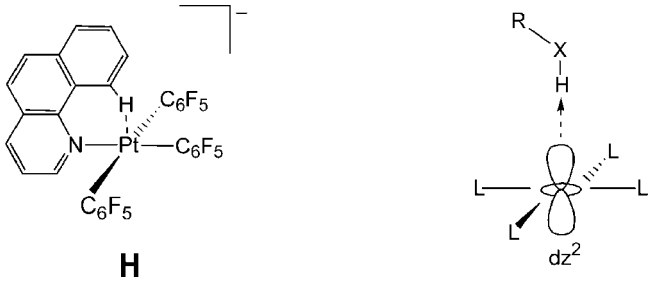
While the steric strain in **7** is somewhat relieved compared with **5**, the distances of the isopropyl CH atoms to the nickel ions are rather similar [*d*(Ni2···C48) = 3.230 Å and *d*(Ni···C32) = 3.200 Å versus 3.114 and 3.269 Å in **5**]. Also, the distances between the nickel atoms and the methyl groups of $[L^1]^-$ are similar to those in the homoleptic compound **3** (3.082 and 3.119 Å in **7** versus 3.033 and 3.110 Å in **3**).

The ^{1}H NMR spectrum of **7** is reminiscent of an overlay of the individual spectra of **3** and **5**. Chemical shifts of all signals assigned to the $[L^1]^-$ and $[L^2]^-$ ligand protons are quite similar to those in the homoleptic analogues. Deshielding of the isopropyl CH protons is only slightly less pronounced than in **5** (7.20 and 7.40 ppm versus 7.86 ppm; again, the two separate resonances are presumably due to the presence of different isomers in solution).

A ^{1}H NMR spectrum of the bulk crystalline material obtained from acetonitrile/diethyl ether by the synthetic procedure described above shows a $[L^1]^-$:$[L^2]^-$ ratio of approximately 2:1. We assume that **3**, **5** and **7** are initially formed in a statistical 1:1:2 mixture. Upon crystallization, however, both the less soluble **3** and **7** precipitate, while **5** remains in solution. As a consequence, the isolated crystalline material represents a 1:2 mixture of **3** and **7**, which gives rise to the observed 2:1 ratio of $[L^1]^-$:$[L^2]^-$ in the NMR spectroscopic analysis.

Comparative Discussion of Unusual ^{1}H NMR Shifts and Synthesis of a Complex of $[L^3]^-$

Close contacts between d^8 metal ions Pd^{II} and Pt^{II} in square-planar complexes and N−H or O−H bonds located above or below the coordination plane have been observed in several cases and investigated in detail.[38–41] Similar contacts with C−H bonds are less recognized and usually involve sp or sp^2 carbon atoms.[38,42–50] For some systems, these contacts have been interpreted in terms of three-center four-electron M···H−N and M···H−C hydrogen bonds involving the filled d_{z^2} orbital of the metal ion (Scheme 6), in contrast to three-center two-electron agostic interactions.



Scheme 6. Three-center four-electron M···H−X hydrogen bonds[50]

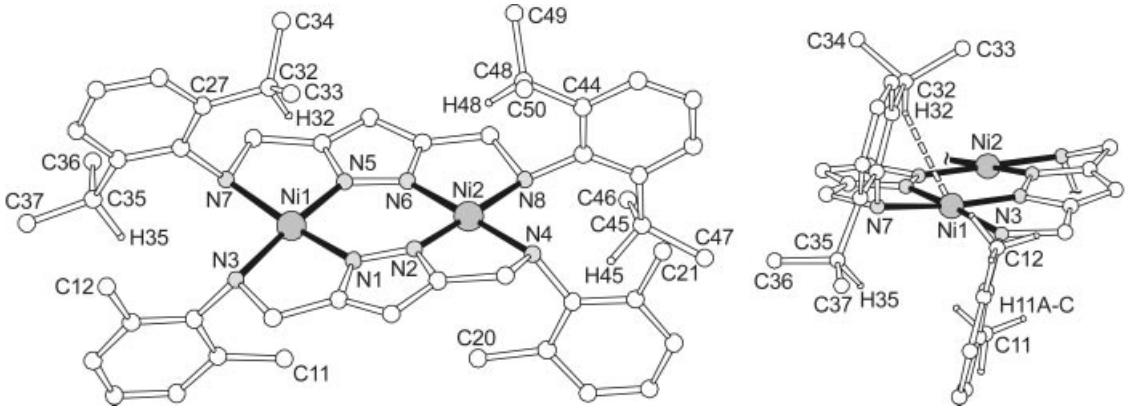


Figure 11. Molecular structure of the cation of **7**; in the interests of clarity only a few hydrogen atoms are shown; selected interatomic distances (Å) and range of selected bond angles (°): Ni1−N1 1.846(4), Ni1−N5 1.852(4), Ni1−N7 1.973(4), Ni1−N3 1.980(4), Ni2−N6 1.844(4), Ni2−N2 1.849(4), Ni2−N4 1.956(4), Ni2−N8 1.984(4), Ni1···Ni2 3.848, C32···Ni1 3.200, C11···Ni1 3.082, C20···Ni2 3.119; C48···Ni2 3.230; N1−Ni1−N7 173.5(2), N5−Ni1−N3 174.7(2), N6−Ni2−N4 178.6(2), N2−Ni2−N8 178.4(2)

While a significant downfield ^{1}H NMR shift for an H atom in the vicinity of the metal is characteristic for such contacts (agostic interactions are typified by a large upfield shift), it does not provide conclusive evidence for the presence of an attractive M···H interaction. ^{195}Pt−^{1}H coupling constants are a much better indicator, and large values for $^1J_{Pt,H}$ have been observed, e.g. $^1J_{Pt,H}$ = 69 Hz in **H**.[49] Unfortunately no stable, well-defined platinum(II) complexes $[L_2Pt_2]^{2+}$ could be isolated with $[L^1]^-$ and $[L^2]^-$.

Even in the possible presence of weak attractive M···H components, however, these hydrogen bonds have to be in balance with significant repulsive forces, and X-ray crystal structures for many of the systems reported in the literature reveal strained ligand geometries, often in order to relieve the interactions. A detailed molecular mechanics study has supported the view that the axial M···H interactions are mainly repulsive in nature.[51] While we cannot rule out a minor attractive contribution to the M···H−C interaction for the present pyrazolate-based dinuclear nickel(II) and palladium(II) complexes, we believe that the Ni···H and Pd···H interactions are basically repulsive and that the H atoms are forced to lie close to the metal ions simply because of geometric constraints due to the bulky ligand substituents. This has been further corroborated by the structure of the dinickel complex of $[L^3]^-$ described below. It should also be noted that the M−H−C angles in **1**−**7** (ca.140°) are more acute by 20°−30° than in those complexes with a confirmed M···H bonding interaction.[42]

Ligand $[L^3]^-$ which bears only a single *ortho* isopropyl substituent on all of its aryl groups was expected to provide clear evidence for the absence or presence of an attractive M···H−C interaction, since the isopropyl substituent might be oriented away from the metal ion or towards the axial coordination sites. The former proved to be the case, as revealed by the X-ray analysis of single crystals of $[L^3_2Ni_2](ClO_4)_2$ (**8**), which could be obtained from propionitrile/diethyl ether. In **8**, both nickel ions were again found in square planar $\{N_4\}$ coordination environments with almost planar five-membered chelate rings, and all bond lengths are in the expected regions (Figure 12). For each ligand $[L^3]^-$, the aryl substituents are on the same side of the coordination framework (isomer **E**, Scheme 4), and the isopropyl groups adopt the largest possible distance from the nickel ions. Due to the steric bulk of the isopropyl groups, opposing aryl rings are not fully parallel but are tilted by ca. 30 °C with respect to each other. Overall, the structure of **8** confirms that the system tends to relieve steric strain and to avoid any close M···H−C contacts if possible.

The ^{1}H NMR spectra of **8** in CD_3CN at 293−343 K revealed only very broad signals, indicative of a variety of dynamic processes in solution. The CH protons of the isopropyl groups resonate at ca. 2.3 ppm (at 293 K). Unfortunately, the poor solubility of **8** limits the range of solvents and temperatures for NMR spectroscopy, and satisfactory ^{13}C NMR spectra could not be obtained for **8**.

Electrochemistry

While no anodic processes were observed up to +1.8 V (all potentials relative to the SCE), the low-spin dinickel(II) complexes **3**, **5**, and **8** as well as the dipalladium complex **6** can be electrochemically reduced in acetonitrile or dichloromethane, respectively. Figure 13 depicts their cyclic voltammograms.

The dinickel complex **3** shows a reversible reduction at $E_{1/2}$ = −0.94 V, presumably giving the respective mixed-valent $Ni^{I}Ni^{II}$ compound. Further reduction is quasi-reversible with E_p^{red} = −1.25 V. The rather large separation of the two processes of around 130 mV (from an estimated "$E_{1/2}$" = −1.18 V for the second reduction wave) indicates significant stabilization of the mixed-valent species towards disproportionation ($K_{comp.}$ = 1.2 × 10^4).

Reduction of complexes **5** and **8** bearing isopropyl substituents at the aryl groups is quasi-reversible (E_p^{red} = −0.81 and −0.98 V, respectively), followed by a second irreversible process. The fully reduced species gives an oxidative wave at around −0.14 V or −0.30 V in the reverse scan. Apparently, the more sterically demanding isopropyl substituents lead to enhanced lability of the reduced compounds, and the methyl-substituted scaffold in **3** is best suited for accepting an additional electron in the antibonding nickel d_{xy} orbitals within the coordination plane.

The electrochemistry of the dipalladium complex **6** is quite similar to that of **5** (except for the lack of the oxidative wave in the back scan). Unexpectedly, however, the dipalladium complex **4** does not show any cathodic process

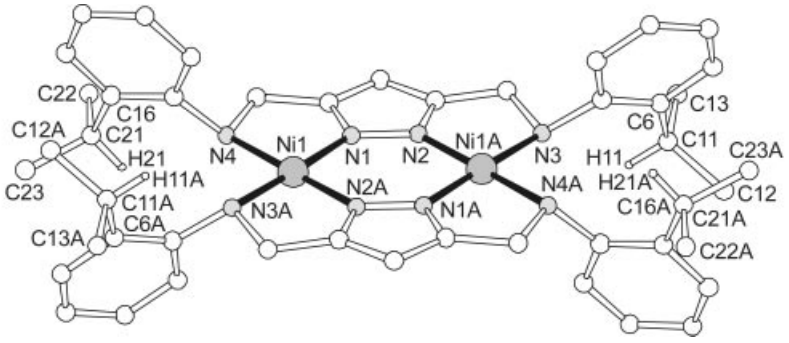

Figure 12. Molecular structure of the cation of **8**; in the interests of clarity only a few hydrogen atoms are shown; selected interatomic distances (Å) and bond angles (°): Ni1−N1 1.8364(12), Ni1−N2A 1.8372(12), Ni1−N3A 1.9697(12), Ni1−N4 1.9719(12), Ni1···Ni1A 3.853(2); N1−Ni1−N3A 178.69(5), N2A−Ni1−N4 176.84(5)

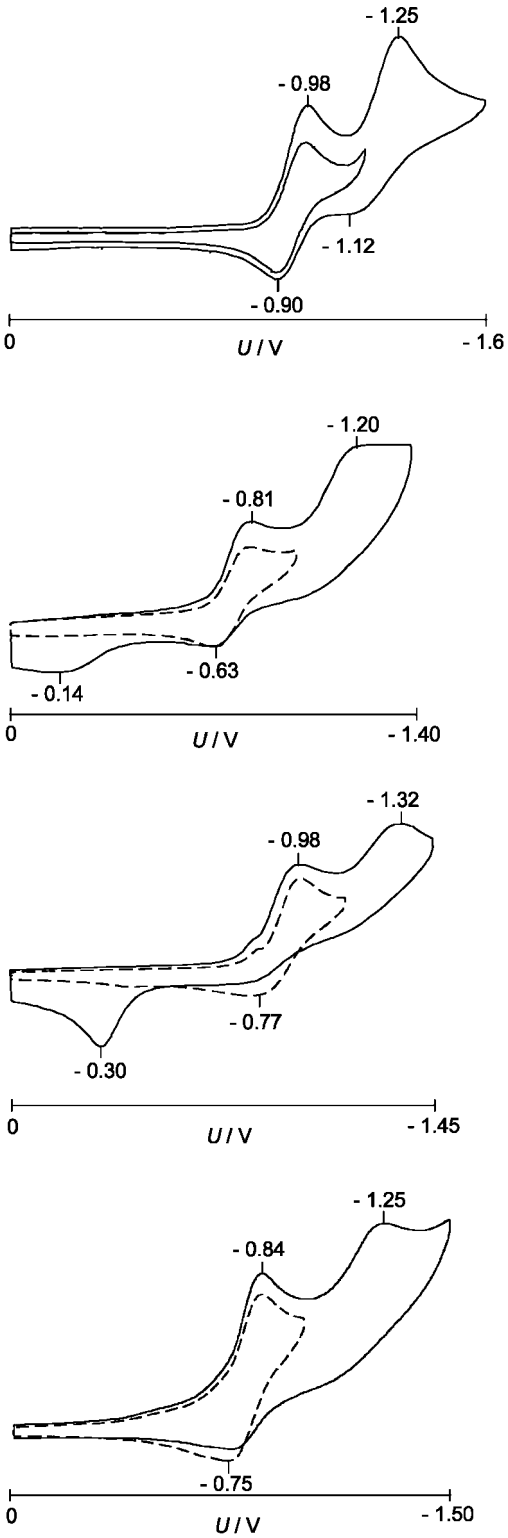

Figure 13. Cyclic voltammograms of **3** (top), **5** (second from top), **8** (second from bottom) and **6** (bottom) recorded on a platinum electrode in MeCN (**3**, **5**, **8**) or CH_2Cl_2 (**6**) containing 0.1 M $NnBu_4^+PF_6^-$; scan speed 200 mVs^{-1}

down to −2.5 V, but an irreversible oxidation at E_p^{ox} = +1.05 V. This corroborates the conclusions drawn from the NMR spectroscopic findings, i.e. the constitution of **4** in solution is most probably not identical to the structure observed in the solid state.

Conclusion

The anilinomethyl-appended pyrazolate ligands $[L^1]^-$, $[L^2]^-$ and $[L^3]^-$ yielded dinuclear type **A** complexes $[L_2M_2]^{2+}$ upon treatment with nickel(II) and palladium(II). Coordinating counter-anions such as chloride can bind to axial sites of the dinickel species in a solvent-dependent process, giving rise to five-coordinate metal ions. In the case of weakly coordinating anions, the metal ions were found in roughly square-planar environments with the structures being dictated by steric requirements due to the bulky aryl substituents. It is noteworthy that all complexes with four-coordinate (square planar) metal ions characterized crystallographically (i.e. complexes **3**, **4**, **5**, **6**, **7** and **8**) feature a (non-crystallographic) C_{2h}-type *meso* arrangement of the aryl groups, while the chiral D_2-type (compare Scheme 4) was not observed in the solid state. Only in the case of **2** was a less sterically favorable C_{2v} isomer enforced by the NH···Cl hydrogen bonds.

The tendency of the aryl groups to avoid each other and not to face each other in close proximity forces the methyl or isopropyl substituents in the aryl 2- and 6-positions to approach the metal ions from the axial directions. This leads to a drastic low-field shift of the respective ^{1}H NMR signals, e.g. δ = 7.86 ppm for the isopropyl-CH that come close to the low-spin nickel(II) ion in $[L^2_2Ni_2]^{2+}$ (**5**). In contrast, the remaining isopropyl-CH comes to lie within the field of the ring-current of the opposing aryl groups and resonates at very high field (δ = 1.86 ppm for **5**).

While the low-field NMR signature of protons close to the axial sites of d^8 metal ions has previously been considered indicative of three-center four-electron M···H−C hydrogen bonds involving the filled d_z^2 orbital of the metal ion, attractive M···H interactions were assumed not to be of major relevance in the present case. This was corroborated by the structure of $[L^3_2Ni_2]^{2+}$, where the single 2-isopropyl groups at each phenyl ring are rotated away from the metal. These phenomena and findings related to the sterically enforced proximity of aliphatic CH bonds to square-planar d^8 metal centers, as reported in the present work, may also be relevant to the characteristics of recent-generation late transition metal catalysts incorporating diamine and diimine ligands, which in many cases also bear bulky aryl substituents.

Experimental Section

General Remarks: Most manipulations were carried out under an dry nitrogen by employing standard Schlenk techniques. Solvents were dried according to established procedures. The ligands were synthesized according to the reported methods,[27] and all other chemicals were used as purchased. Microanalyses: Mikroanalytische Laboratorien des Organisch-Chemischen Instituts der Universität Heidelberg. IR spectra: Perkin−Elmer 983G; recorded as KBr

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

pellets. UV/Vis spectra: Perkin−Elmer Lambda 19. FAB-MS spectra: Finnigan MAT 8230. NMR spectra: Bruker AC 200 at 200.13 (^{1}H) and 50.32 (^{13}C) MHz, or Bruker DRX 300 at 300.13 MHz (^{1}H) and 75.47 (^{13}C) MHz; solvent signal as chemical shift reference (CD_3CN δ_H = 1.94, δ_C = 118.1/1.2 ppm); where necessary, assignments were based on a series of 2D experiments. Cyclic voltammetry: PAR equipment, (potentiostat/galvanostat 273), in 0.1 M NBu_4PF_6/CH_3CN. Potentials in V on a glassy carbon electrode, referenced to the SCE at ambient temperature. Magnetic measurements: Bruker magnet B-E 15 C8, field controller B-H 15, variable temperature unit ER 4111 VT, Sartorius microbalance M 25 D-S. Experimental susceptibility data were corrected for the underlying diamagnetism.

Caution! *Although no problems were encountered in this work, perchlorate salts are potentially explosive and should be handled with proper precautions.*

General Synthesis of Complexes: For the syntheses of the complexes, the respective ligand (HL^1, HL^2, HL^3; approximately 1 mmol) was dissolved in THF (50 mL) and deprotonated with one equivalent of KO*t*Bu. After the reaction mixture had been stirred for 30 min, one equivalent of the metal salt {$NiCl_2{\cdot}6H_2O$ or $[Ni(H_2O)_6](ClO_4)_2$ or $[Pd(CH_3CN)_4](BF_4)_2$} was added and stirring continued for 15 h. The solvent was then removed under reduced pressure and the residue washed with light petroleum. Pure compounds were obtained by crystallization, i.e. by slow diffusion of light petroleum or diethyl ether into a solution of the complex as detailed below.

Complex 1: Single crystals were obtained from acetone/light petroleum (yield of crystalline material 183 mg; 42%). IR (KBr): $\tilde{\nu}_{max.}$ = 3242 w, 2955 w, 1590 w, 1512 w, 1464 vs, 1436 s, 1379 m, 1302 s, 1251 w, 1191 s, 1093 s, 1042 w, 974 w, 924 m, 900 m, 761 s, 618 w cm^{-1}. M.p. > 240 °C. UV/Vis (CH_3CN): λ (ε) = 226 (16600), 290 sh (7040), 397 (610), 495 (155), 643 nm (35). MS (FAB): *m*/*z* (%) = 819 (30) $[L^1_2Ni_2Cl]^+$, 782 (100) $[L^1_2Ni_2]^+$. $C_{42}H_{50}Cl_2N_8Ni_2$ (855.20): calcd. C 58.99, H 5.89, N 13.10; found C 58.99, H 6.34, N 12.89.

Complex 2: Single crystals were obtained from dichloromethane/light petroleum (yield of crystalline material 114 mg; 26%). IR (KBr): $\tilde{\nu}_{max.}$ = 2944 w, 1590 w, 1522 w, 1465 vs, 1439 s, 1380 m, 1307 s, 1172 s, 1095 s, 947 m, 902 w, 763 s, 724 w, 571 w cm^{-1}. M.p. > 240 °C. UV/Vis (CH_3CN): identical to the spectrum of **1**.

Complex 3: Single crystals were obtained from acetonitrile/diethyl ether (yield of crystalline material 430 mg; 88%). ^{1}H NMR (300 MHz, CD_3CN): δ = 1.08 (s, 12 H, CH_3), 3.37−3.49 (m, 4 H, CH_2), 4.08−4.30 (m, 4 H, CH_2), 4.17, 4.20 (s, 12 H, CH_3), 4.50 (s, 4 H, NH), 5.80 (s, 1 H, CH^{pz4}), 5.81 (s, 1 H, CH^{pz4}), 6.83 (m, 4 H, $CH^{Ph,m}$), 7.21 (t, ^3J = 7.5 Hz, 4 H, $CH^{Ph,p}$), 7.37 (d, ^3J = 7.5 Hz, 4 H, $CH^{Ph,m}$) ppm. ^{13}C NMR (300 MHz, CD_3CN): δ = 16.6 (CH_3), 21.9 (CH_3), 54.5 (CH_2), 97.0 (CH^{pz4}), 129.2 ($CH^{Ph,p}$), 130.1($CH^{Ph,m}$), 132.5 ($CH^{Ph,m}$), 132.9 ($CH^{Ph,m}$), 142.1, 142.4 (C^{ar}), 157.5, 157.6 ($C^{pz3/5}$) ppm. IR (KBr): $\tilde{\nu}_{max.}$ = 3349 m, 3226 m, 2951 m, 1622 m, 1463 m, 1443 m, 1382 w, 1366 w, 1308 m, 1259 w, 1214 w, 1137 vs, 1112 vs, 1084 vs, 951 w, 772 m, 624 s, 418 m cm^{-1}. M.p. > 240 °C. UV/Vis (CH_3CN): λ (ε) = 240 (14820), 300 (10560), 454 (185), 500 nm(175). MS (FAB): *m*/*z* (%) = 883 (90) $[L^1_2Ni_2ClO_4]^+$, 782 (100) $[L^1_2Ni_2]^+$. $C_{42}H_{50}Cl_2N_8Ni_2O_8$ (983.13): calcd. C 51.31, H 5.12, N 11.39; found C 50.83, H 5.41, N 11.44.

Complex 4: A few single crystals were obtained from dichloromethane/light petroleum. MS (FAB): *m*/*z* (%) = 877 (100) $[L^1_2Pd_2]^+$.

Complex 5: Single crystals were obtained from acetone/diethyl ether (yield of crystalline material 170 mg; 28%). ^{1}H NMR (300 MHz, CD_3CN, 233 K), only data for the major isomer are given: δ = 0.39 (d, ^3J = 6.0 Hz, 12 H, CH_3), 0.90 (d, ^3J = 6.0 Hz, 12 H, CH_3), 1.31 (d, ^3J = 6.0 Hz, 12 H, CH_3), 1.86 (sept, ^3J = 6.0 Hz, 4 H, CH*iPr*), 2.05 (d, ^3J = 6.0 Hz, 12 H, CH_3), 3.45 (dd, ^3J = 16.7/4.5 Hz, 4 H, CH_2), 4.31 (dd, ^3J = 16.7/7.8 Hz, 4 H, CH_2), 4.79 (br., s, NH), 5.75 (s, 2 H, CH^{pz4}), 6.98 (d, ^3J = 7.6 Hz, 4 H, $CH^{Ph,m}$), 7.35 (t, ^3J = 7.6 Hz, 4 H, $CH^{Ph,p}$), 7.55 (d, ^3J = 7.6 Hz, 4 H, $CH^{Ph,m}$), 7.86 (sept, ^3J = 6.0 Hz, 4 H, CH*iPr*) ppm. ^{13}C NMR (300 MHz, CD_3CN, 233 K): δ = 22.7 (CH_3), 25.4 (CH_3), 25.8 (CH_3), 26.0 (CH_3), 28.6 (CH*iPr*), 30.9 (CH*iPr*), 57.8 (CH_2), 99.0 ($CH^{pz,4}$), 126.0 ($CH^{Ph,m}$), 127.4 ($CH^{Ph,m}$), 130.2 ($CH^{Ph,p}$), 138.5 ($C^{Ph,1}$), 141.8 ($C^{Ph,2/6}$), 155.8 ($C^{pz3/5}$) ppm. Complex 8: Single crystals were obtained from acetonitrile/diethyl ether (yield of crystalline material 105 mg; 20%). ^{1}H NMR (300 MHz, $CDCl_3$, 333 K): δ = 1.03 (br. s, CH_3), 2.80 (br. s, CH*iPr*), 6.69 ($CH^{pz,4}$), 7.67, 7.96, 8.50 (br. s, CH^{Ph}) ppm, CH_2 not observed. ^{13}C NMR (300 MHz, $CDCl_3$): no signals observed. IR (KBr): $\tilde{\nu}_{max.}$ = 3425 w, 3226 s, 2935 s, 2921 m, 2879 w, 1484 s, 1437 m, 1383 m, 1359 w, 1312 s, 1237 w, 1112 vs, 1102 vs, 1088 vs, 1030 vs, 944 w, 929 w, 91 w, 763 s, 622 vs, 526 m, 461 w, 420 w cm^{-1}. M.p.> 240 °C. UV/Vis (CH_3CN): λ (ε) = 216 (28006), 242 (20310), 285 (7708), 477 (361). MS (FD): *m*/*z* (%) = 939 (100) $[L_2^3Ni_2(ClO_4)]^+$, 839 (10) $[L_2^3Ni_2]^+$. $C_{46}H_{58}Cl_2N_8Ni_2O_8$ (1039.29): calcd. C 53.16, H 5.63, N 10.78; found C 53.00, H 5.57, N 10.80.

X-ray Crystallographic Studies: The measurements for **1**, **2**, **3**, **4**, **5** and **7** were carried out with a Nonius Kappa CCD diffractometer and for **6** and **8** with a Bruker-AXS-CCD diffractometer, using graphite-monochromated Mo-K_α radiation. All calculations were performed using the SHELXT PLUS software package.[52] Structures were solved by direct methods with SHELXS-97 and refined with SHELXL-97. Atomic coordinates and thermal parameters of the non-hydrogen atoms were refined in fully or partially anisotropic models by full-matrix least-squares calculation based on F^2. In general the hydrogen atoms were placed in calculated positions and allowed to ride on the atoms to which they are attached. Table 1 and Table 2 shows a compilation of the data for the structure determinations.

CCDC-222584 (for **1**), -222585 (for **2**), -222586 (for **3**), -222587 (for **4**), -222588 (for **5**), -222589 (for **6**), -222590 (for **7**) and -222591 (for **8**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Center, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Acknowledgments

F. M. sincerely thanks Prof. Dr. G. Huttner for his generous support and Dr. S. Dechert for valuable discussions. Funding from the DFG (SFB, 247, Graduiertenkolleg-Fellowship to J. C. R.) and the Fonds der Chemischen Industrie (F. M.) is gratefully acknowledged.

Structural Study of Novel Graphite−Lithium−Calcium Intercalation Compounds

Sébastien Pruvost,[a,b] Claire Hérold,*[a] Albert Hérold,[a] and Philippe Lagrange[a,b]

Keywords: Calcium / Electron microscopy / Graphite / Intercalation / Lithium / X-ray diffraction

Three new layered compounds were synthesised by immersing a pyrographite platelet in a molten Ca–Li alloy creating a new graphite intercalation compound family. The samples were studied by X-ray and neutron diffraction, revealing that the intercalated sheets are polylayered. The study of the 00*l* reflections allowed us to establish the *c*-axis stacking of these three phases. The α-phase exhibits a five-layered intercalated sheet which has something in common with a Li–Ca–Li–Ca–Li slice cut in the $CaLi_2$ structure ($ThMn_2$ Laves phase type). The β-phase, which is richer in metallic elements and with a greater repeat distance, possesses seven-layered intercalated sheets due to the splitting of the middle lithium plane in three. The third phase is a pseudo-binary compound, containing monolayered sheets and with a formula close to CaC_6. Electron microdiffraction allowed us to determine the 2D unit cell for each compound, all of which were commensurate with that of graphite. Charge transfer from the intercalate to the host lattice was evaluated for the three phases from *hk*0 data, leading to high values.

Introduction

Graphite exhibits a lamellar structure containing two-dimensional Van der Waals gaps, and it therefore acts as a host lattice for numerous reagents. It turns out that the alkali metals are excellent electron donors in order to intercalate into graphite. The intercalation of the pure alkali metal was reported a long time ago;[1] it leads to binary compounds whose stage varies with metal content. Indeed, when potassium, rubidium and caesium react with graphite, it is very easy to prepare the pure first-stage MC_8 (M = K, Rb, Cs) compounds, which contain a monoatomic metal layer in each interlayer space. On the other hand, the behaviour of graphite changes radically when a less electropositive element is added to the reactive alkali metal. For example, when a graphite sample is immersed in liquid potassium containing a small amount of sulfur, a ternary compound is formed whose intercalated sheets are poly-layered with potassium atoms in contact with graphene planes.[2] Moreover, these potassium-rich compounds are very stable in air.

In the case of lithium, the binary first-stage compound is rather different from the previous ones:[3] its metal content is higher, since its chemical formula is LiC_6. This compound is of great interest, due to its widespread use as the negative electrode material in Li-ion batteries.[4] One way to improve the batteries' capacity could be to increase the lithium content of the negative electrode, although the co-intercalation of lithium with another element seems to be very difficult. The data concerning the structure and the properties of the LiC_6 compound, in comparison with those of the heavy alkali metal compounds, are unfavourable to this co-intercalation because the repeat distance would be increased and part of the strong Li−Li interactions along the *c*-axis would be destroyed. Moreover, the synthesis of a ternary alkali metal compound requires the melting of the M−E mixture (M = alkali metal, E = co-intercalated element) or the partial solubility of M−E in the liquid metal. The melting points of most M−E mixtures are very high and the attack of graphite by lithium is very fast above 600 °C, with formation of lithium acetylide (Li_2C_2) and, of course, destruction of the graphene planes. Numerous experiments have been carried out associating lithium with various elements but generally only binary compounds are obtained.[5] Consequently, we tried to co-intercalate lithium with some elements that are able to intercalate into graphite by themselves. We chose the alkaline earth metals because their intercalation into graphite leads to first-stage MC_6 compounds (M = Ca, Sr, Ba)[6] rather close to LiC_6, despite the fact that the reaction is markedly more difficult, especially with calcium. These experiments led to the isolation of the first ternary graphite−lithium−third-element compounds, that were obtained associating lithium and calcium.[7] We report three new intercalation compounds, called α, β and γ, and their description is given below.

Results and Discussion

Structure of the α Compound

The 00*l* diffraction diagram of this compound (Figure 1) gives a *c*-axis repeat distance of 776 pm. According to the dilatometric measurements, which give values of around 157%, it belongs to the first stage thus confirming the crystallographic data (the theoretical calculation leads to 132%). This difference is almost certainly due to the non-uniformity of the sample's faces. The repeat distance is quite characteristic of a poly-layered intercalated sheet. Indeed, the repeat distances are only 370 pm and 455 pm for both the binary compounds LiC_6 and CaC_6, respectively.[3,6]

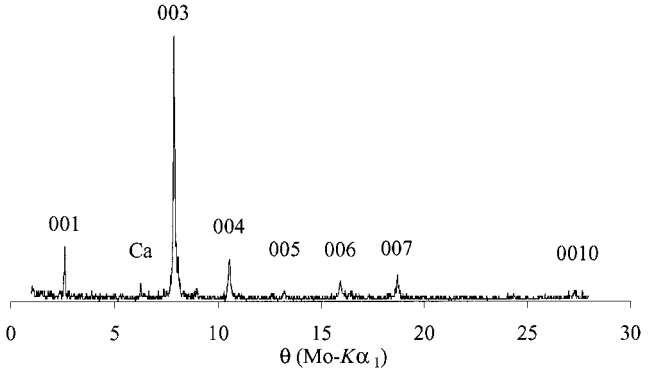

Figure 1. 00*l* X-ray diagram of the α compound

The study of lithium by X-ray diffraction is particularly difficult due to the presence of very few electrons in these atoms, therefore neutron diffraction experiments are often necessary in order to complete the data and allow us to calculate the *c*-axis atomic stacking.

Firstly, however, we will consider only the results obtained from the X-ray experiments. The Fourier transform of the 00*l* structure factors allowed us to produce the *c*-axis electronic density profile in the direct space. From a *c*-axis atomic stacking model, without taking the lithium atoms into account, we then plotted a second electronic density profile, which was compared to the previous one. When the best agreement had been obtained between both profiles (Figure 2), the atomic stacking model was considered to be a good description of the carbon and calcium positions along the *c*-axis. This model presents two superimposed symmetrical calcium layers in the graphitic interval, with a graphene—calcium layer distance of 238 pm, such that the calcium layer—calcium layer distance in the same graphitic interval reaches 300 pm. Moreover, the C/Ca ratio is equal to 2.3, in accordance with the results of the analyses.

Secondly, we used the neutron-diffraction data in order to take the lithium atoms into account. Using the same method, we obtained a final model with three additional lithium layers: one of them is placed at the centre of the

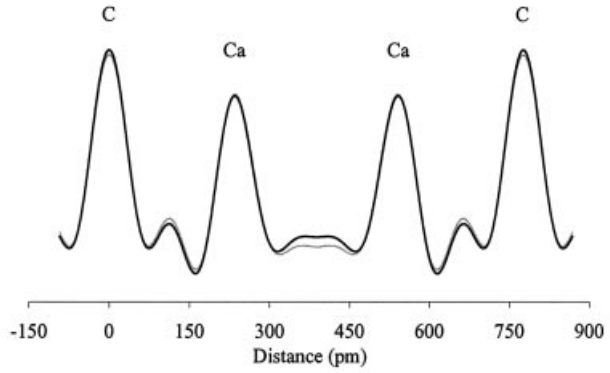

Figure 2. Electronic density profiles along the **c** axis of the α compound; black line: experimental data; grey line: calculated data; seven reflections are taken into account (residual factor R_{F00l} = 8.35%)

graphitic interval with two symmetrical layers between the graphene plane and the calcium layer. The graphite—lithium layer distance is estimated to be 160 pm. This result, nevertheless, remains qualitative, because it has been shown by nuclear microprobe analysis[8] that lithium distribution inside the compound is not really homogeneous. Consequently, it is not possible to attribute a well-defined metal content for each lithium layer. The lithium content is, however, higher in both of the symmetrical external layers.

Finally, the intercalated sheet appears as a five-layer, according to the Li−Ca−Li−Ca−Li sequence and we can clearly see that there are lithium atoms in contact with the graphene planes. Indeed, as is usual in these ternary compounds, the more electropositive element is localised close to the more electronegative one, in this case the carbon atoms.

The intercalation reaction into graphite is always an oxido-reduction. With electron donor species, graphite is reduced and the electron concentration of the graphene planes increases; the carbon−carbon distance simultaneously increases. The *hk*0 X-ray diagram allows us to determine this charge transfer between the intercalated species and the graphene layers, since measuring the angular position of the 110 reflection generated by the graphene planes very precisely is enough to be able to calculate this distance. Its value was compared to that of pristine graphite, and the increase of the carbon−carbon distance was deduced. For these measurements, diamond was used as an internal standard (the 220 reflection of the CFC diamond for our calculations). The d-spacing of the 110 reflection is equal to 125.2 pm for the ternary compound, whereas it only reaches 123 pm in pristine graphite. The corresponding increase of the C−C distance is of the order of 1.8%. Pietronero and Strässler[10] have established the following equation between this parameter and the charge transfer (f_c):

$$\Delta d_{C\text{-}C} = 0.157 f_c + 0.146 f_c^{3/2} + 0.236 f_c^2$$

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

According to this relation, the electronic transfer reaches 0.111 electrons per carbon atom for the compound. In comparison, the corresponding value is only 0.07 electrons per carbon atom in the LiC_6 compound. In spite of the very large amount of intercalated metal, the charge transfer remains moderate, so that it is probable that there are metallic bonds within the intercalated sheets. These bonds could explain the unusual hardness of the samples.

The 2D organisation of the compound was observed by several techniques, including TEM (transmission electron microscopy) and XRD (*hk*0 reflections). The TEM study was carried out in a single-crystalline area of the sample. In order to be sure that this area is well representative of the compound, it was systematically observed by EDS (electron dispersive spectroscopy) measurements. The electron microdiffraction images gave the symmetry and the parameters of the 2D unit cell: it is rectangular with $a = 2000$ pm and $b = 430$ pm, and it is commensurate with the graphitic one after taking the charge transfer into account. The 110 graphitic reflection becomes the 830 one in this unit cell. Furthermore, the a and b parameters can be respectively written as $8a_G$ and $\sqrt{3}{\cdot}a_G$. Of course, in these expressions the value of a_G is not that corresponding to pristine graphite, but that obtained from the expanded graphene planes present in the ternary compound. The particular values of these parameters lead to a 2D unit cell that contains exactly 32 carbon atoms (Figure 3).

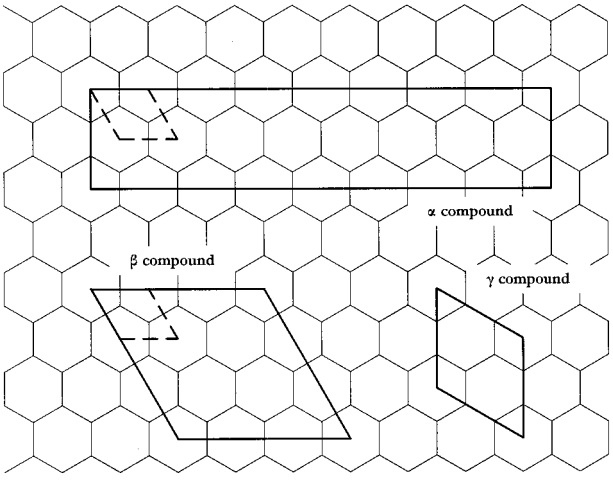

Figure 3. 2D unit cells of the α, β and γ compounds; dotted lines represent the 2D graphite unit cell

A rotating crystal image (Figure 4) allowed us to determine the value of the third parameter, which is twice the repeat distance, that is to say: $c = 1552$ pm. Consequently, the 3D unit cell of the compound is orthorhombic with the three previous parameters.

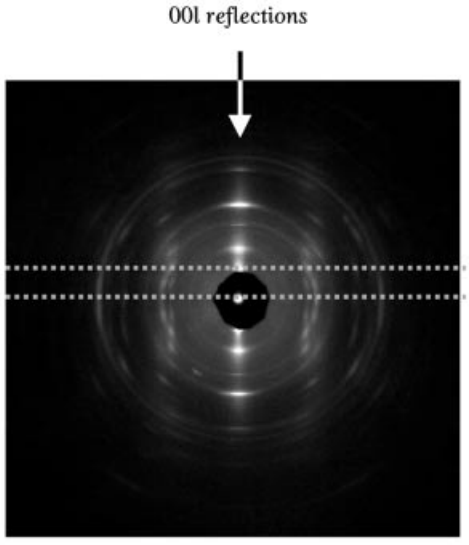

Figure 4. Rotating crystal image of the α compound; both dotted lines symbolise the equatorial stratum and stratum 2

It is interesting to compare the *c*-axis atomic stacking of the α ternary compound with the structure of the $CaLi_2$ binary solid alloy. $CaLi_2$ appears in the Ca−Li phase diagram[11,12] as the only definite compound. Its structure, first studied by Hellner and Laves[13] and later by Carfagno,[11] is hexagonal and isomorphic with the Laves's $ThMn_2$ phase with the following parameters: $a = 631.3$ pm and $c = 1028$ pm. Its space group is $P6_{3/m}mc$, with calcium atoms occupying the 4f sites and lithium atoms the 2a and 6h ones, such that each unit cell contains four $CaLi_2$ units. Along the *c*-axis, the structural arrangement of $CaLi_2$ can be described by a perfectly alternating sequence of calcium and lithium layers, in accordance with a Li−Ca−Li−Ca−Li five-layered intercalated sheet. As is shown in Figure 5, two possibilities exist in order to allow the formation of a *c*-axis five-layered sequence in the $CaLi_2$ solid alloy. The first slice (denoted A) seems to be more likely than the second one (denoted B) for two reasons. Firstly, in the A-slice the out-

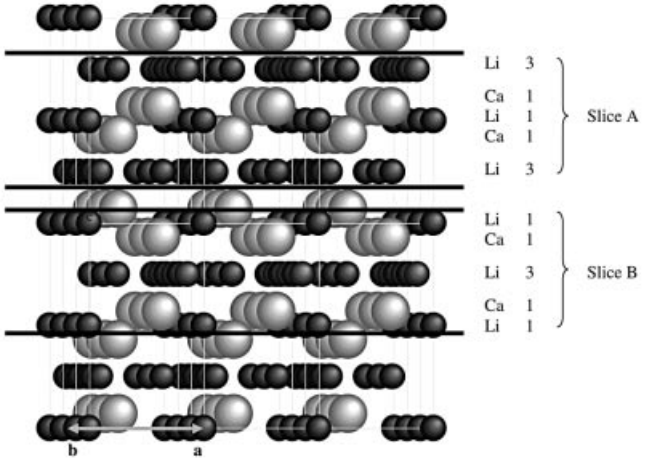

Figure 5. $CaLi_2$ structure and both possible slices

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

side lithium layers contain a larger number of atoms than the internal lithium plane — an identical distribution was observed in the intercalated sheet, according to the neutron-diffraction data — whereas in the B-slice the metal content of the internal lithium layer is particularly high. Secondly, the calcium atoms are exactly superimposed in the B-slice, while they are shifted in the A-slice, therefore it is likely that this second arrangement is more stable for a 2D slice intercalated between graphene planes.

These comments present a great interest because we can observe that the intercalation into graphite of binary species often allows a comparison between the sequence of the intercalated sheets and the structure of the free binary species. In spite of the stress applied by the graphene planes, the atomic stacking in the intercalation compound could be identical to a slice judiciously cut off in the structure. Similar results were previously observed in several cases, for example potassium sulfide,[14] potassium amalgam[15] and sodium peroxide.[16,17]

A mixture containing the second stage compound (α type) and CaC_6 was also obtained but it was not possible to isolate this ternary phase. The value of its repeat distance is 1100 pm, that is to say approximately (776 + 335) pm. Therefore, this compound exhibits alternating occupied graphitic intervals (with the same atomic stacking as in the first stage α phase) and empty ones along the *c*-axis.

Structure of the β Compound

As described above, the 00*l* X-ray diffraction diagram (Figure 6) gives the repeat distance of this first-stage compound. It is much higher for this phase, since it reaches 970 pm (instead of 776 pm for α compound). There is an obvious connection between this high value and the very large lithium content of the phase, which possesses a C/Li ratio slightly lower than 2.

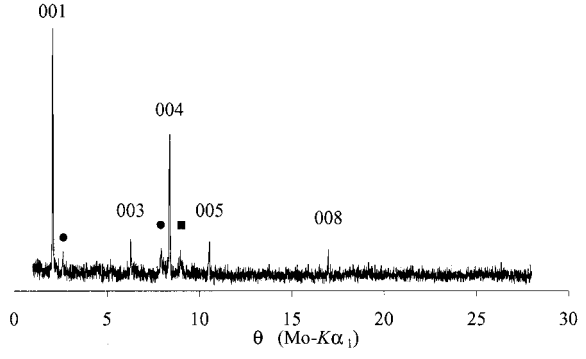

Figure 6. 00*l* X-ray diagram of the β compound; • α phase, ■ CaC_6

Using the previous method, it is possible to draw the experimental *c*-axis electronic density profile. This model then allows us to draw a second profile, and the comparison between both profiles leads to an improvement of this model until a better agreement was obtained. However, since this compound contains a lot of lithium, it is necessary in this case to take the lithium atoms into account. Indeed, their presence is clearly evident in Figure 7. The *c*-axis atomic stacking model contains seven layers, according to the Li−Ca−Li−Li−Li−Ca−Li sequence. The central lithium layer is very rich in metal (1.5 lithium atoms for every six carbon atoms), whereas the outer lithium planes (130 pm above and below) contain only 0.6 lithium atoms for every six carbon atoms. For this reason it is not easy to confirm the presence of these latter lithium layers by XRD, although the inter-calcium layer distance of 510 pm means that the calcium layers cannot surround only one lithium plane. This large value therefore confirms the presence of three central lithium layers. Both calcium planes contain 2.1 calcium atoms for every six carbons. Moreover, this very thick sheet is sandwiched between two lithium layers 650 pm away from one another, which contain one lithium atom for every six carbon atoms.

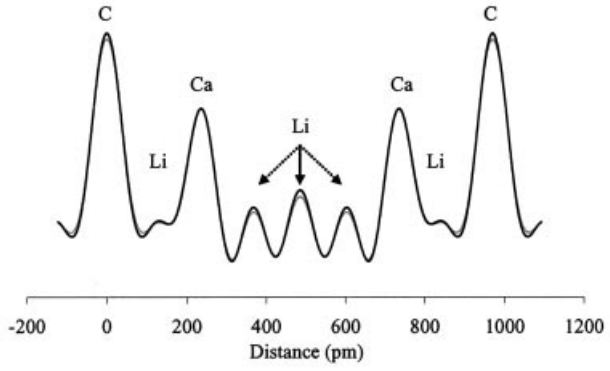

Figure 7. Electron-density profiles along the *c* axis of the β compound; black line: experimental data; grey line: calculated data; eight reflections are taken into account (residual factor R_{F00l} = 6.6%)

This intercalated sheet is extremely rich in metal and is consequently very thick. A similar phenomenon was observed previously in another system when we carried out the intercalation reaction of potassium−thallium alloys into graphite.[18] The amount of intercalated metal was also very high, as was the repeat distance, and the core of the intercalated sheet was also constituted by three metal layers, although with Tl−Tl−Tl stacking instead of Li−Li−Li stacking. In these cases it is generally not possible to establish a connection between the structure of the binary alloy and that of the poly-layered intercalated sheet.

The charge transfer between the graphene layers and intercalated species can also be measured by XRD using the positions of the *hk*0 reflections. In the graphene plane, the internal C−C distance reaches in this case 143.5 pm, instead of 142 pm in pristine graphite, meaning that the charge transfer is close to 0.07 electrons per carbon atom, which is about the same value as in LiC_6. This β ternary compound contains approximately five times as much metal as the binary compound, but nevertheless the electron transfer remains essentially unaltered. As above, this interesting result clearly emphasises the difficulty in correlating

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

both phenomena: a high metal content does not inevitably lead to a sizeable charge transfer, because there are automatically metallic bonds in the intercalated sheet in order to maintain its cohesion. These latter, of course, strongly reduce this transfer.

The 2D unit cell of the compound was obtained by TEM and XRD (*hk*0 reflections) techniques. Both methods give the same results: Figure 8 shows the *hk*0 diffraction diagram, for which all the reflections can be easily indexed in a hexagonal two-dimensional unit cell identical to the graphitic one. Indeed, the value of its parameter is 745 pm, that is to say $3a_G$. From this value, one can see that this unit cell contains 18 carbon atoms (Figure 3).

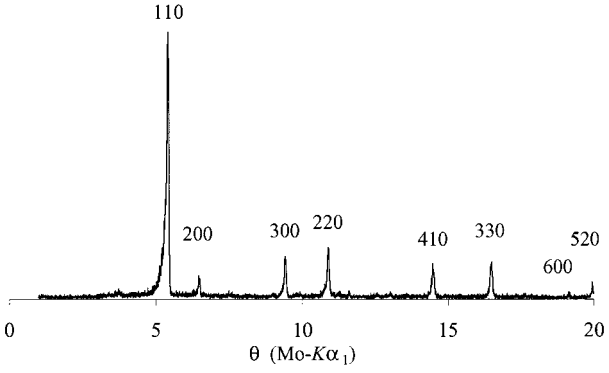

Figure 8. *hk*0 X-ray diagram of the β compound

Structure of the γ Compound

This first-stage compound exhibits a repeat distance that is much smaller than that of the previous ones (Figure 9). It has a value of only 454 pm, which is exactly the same as that of the CaC_6 binary intercalation compound. As expected, the study of the 00*l* reflections intensities (Fourier transform) shows unambiguously the presence of mono-layered intercalated sheets (Figure 10). This intercalated layer contains calcium atoms and its metal content corresponds accurately to a C/Ca ratio of six. It is basically the same compound as the CaC_6 binary, although it nevertheless contains a very small amount of lithium (1 atom-% of lithium), as was shown by nuclear microprobe measurements. This lithium amount is, of course, strictly invisible by XRD measurements. It is possible to consider this compound as a quasi-binary CaC_6 phase.

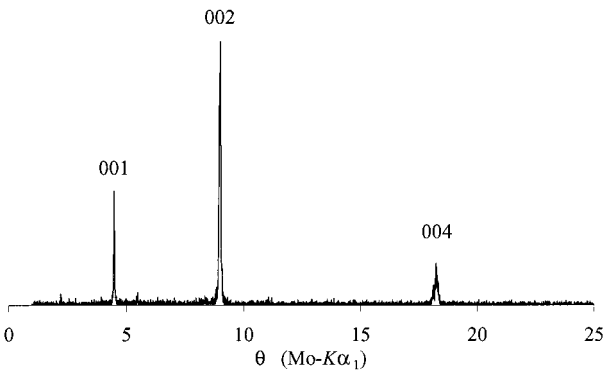

Figure 9. 00*l* X-ray diagram of the γ compound

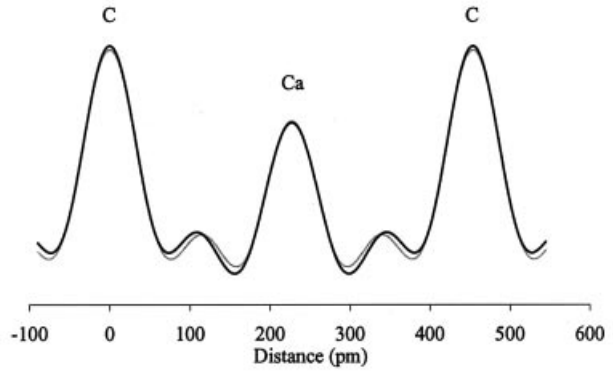

Figure 10. Electron-density profiles along the *c* axis of the γ compound; black line: experimental data; grey line: calculated data; five reflections are taken into account (residual factor R_{F00l} = 7.5%)

All its characteristics are exactly identical to that of the real binary.[6] The internal C−C distance of the graphene planes is equal to 125 pm, so that the charge transfer between the graphene and intercalated layers is close to 0.102 electrons per carbon atom. One can explain this high value for a binary compound as follows. Firstly, contrary to the alkali metals, calcium is divalent so that it is more easily able to release two electrons instead of one. Secondly, in a binary compound the intercalated sheet is mono-layered. Consequently the delocalised electrons, which are partially used in the ternaries in order to supply the internal cohesion of the poly-layered intercalated sheet by the means of metallic bonds, can in this case be wholly "absorbed" by the graphene layers. Indeed, the intercalated mono-layer does not need any internal cohesion, since it appears as a cation plane sandwiched between two macro-anionic planes: this situation is exactly the same as that observed in ionic salts, such as NaCl.

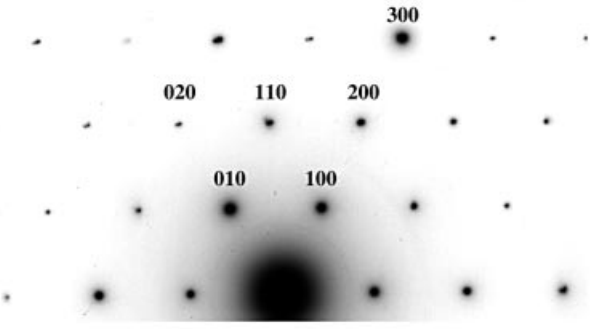

Figure 11. Electron-microdiffraction pattern of the γ compound; hexale lattice: *a* = 431 pm; the 110 reflection corresponds to the 100 reflection of graphite; the 300 reflection corresponds to the 110 reflection of graphite

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

Figure 11 shows the reciprocal lattice observed using a TEM technique. The two-dimensional unit cell of the compound is hexagonal with a parameter of 431 pm (Figure 3). It is the same as the graphitic one, since $a = 3d_{C-C} = \sqrt{3}\cdot a_G$. This classic 2D arrangement is known as the "hexal structure".[3]

As has been mentioned above, this compound is essentially the CaC_6 binary compound, since the lithium content is exceedingly low. However, this is the first time that the binary has been isolated. Its synthesis makes use of the reaction between graphite and calcium vapour at high temperature, so that the vapour pressure is sufficient, but nevertheless not so high as to allow the attack of the metal on graphite, leading to acetylides. The reaction is strongly limited by this range of temperatures, so that the formation of CaC_6 in that case is just superficial. But using a calcium-lithium liquid alloy, we have prepared this compound in the bulk of the sample.

Two hypotheses can explain this phenomenon. Firstly, the interstitial lithium (even though its content is extremely low) is necessary in order to carry out the intercalation right through to the core, so that thermodynamically its role is very significant. Secondly, this novel method is able to give a bulk CaC_6 sample and makes use of a liquid, and not a vapour, as reagent, so that the reaction can be undertaken at low temperatures (350 °C) with a very concentrated reagent. In these conditions, the carburisation by lithium or calcium is completely avoided and the intercalation reaction becomes total. The interstitial lithium is dragged towards the graphitic intervals by calcium during its intercalation, and after reaction it is trapped inside the intercalated sheet, but it does not play a role in the stability of the compound. This second explanation is probably the most likely.

This interesting synthesis technique has been used previously with another binary system: the reaction between graphite and lithium−sodium liquid alloys leads to the quasi-pure LiC_6 compound.[19] This latter, however, was isolated using the vapour method, although its preparation is much easier by this second method. On the contrary, for CaC_6, the liquid method is absolutely essential in order to isolate this compound.

Conclusion

It has been shown that the co-intercalation of lithium and another element into graphite is very difficult since the thermodynamic parameters are not favourable for such a reaction. However, the first ternary graphite intercalation compounds containing lithium and a second metal were prepared from lithium−calcium alloys.

Two novel first-stage graphite−lithium−calcium compounds were isolated and a structural study was carried out with samples prepared from pyrolytic graphite platelets. They are very rich in metal and one of them particularly in lithium. Both ternaries possess poly-layered intercalated sheets, with roughly an alternate sequence of lithium and calcium. Lithium, the more electropositive, builds two layers in contact with graphene planes, the more electronegative. Between these lithium layers are sandwiched two monoatomic calcium layers, which surround a central lithium sheet (mono- or three-layered according to the compound). This atomic stacking is typical for such ternary intercalation compounds. The charge transfer caused by the oxido-reducing character of the reaction takes place in the interfaces of the host structure and the intercalated species, that is to say between the graphene planes and adjacent lithium.

The α compound can be considered as a slice of $CaLi_2$ crystal alloy. Indeed, this latter consists of an alternating *c*-axis lithium−calcium stacking, exactly similar to that present inside the intercalated sheet of the ternary compound.

The two-dimensional unit cells of these ternaries were established: they are both identical to the graphitic one, with rectangular or hexagonal symmetry according to the compound. The 3D unit cell of one of them was found.

The third compound contains a very low amount of lithium, such that it appears as a quasi-binary phase, which could be identified as CaC_6. The liquid-solid reaction used for this synthesis appears to be a better method for the preparation and isolation of bulk CaC_6.

Experimental Section

Synthesis: The synthesis of these novel ternary graphite−lithium−calcium intercalation compounds requires a rigorous experimental process, including several successive steps: purification of the reagents, formation of the reactive alloy, reaction and sample recovery. All the steps must be done in a glove box, under a very pure argon atmosphere. The purity of the reagents is one of the main factors influencing the synthesis of the ternary graphite−lithium−calcium compounds. The dendritic calcium used was distilled and exhibited a purity of 99.99%. The lithium, with an initial purity of 99.95%, required a further purification step, which was carried out in the glove box, after melting of the metal. The formation of the alloy is tricky, because its good homogeneity is absolutely essential for the preparation of the ternary compounds. In order to obtain pure ternary phases, we use Ca−Li alloys whose composition is well defined and varies according to the nature of the ternary compound. Both metals were mixed carefully in order to obtain a molten alloy that is as homogeneous as possible (the binary phase diagram shows a complete miscibility in the liquid state). Then, the pyrographite platelet was immersed in this liquid mixture in a tightly closed reactor. Lastly, the temperature of the reagents was raised to the appropriate value for several days: 350 °C for ten days when using an equimolar Ca−Li alloy (α compound); 350 °C for ten days when using a $CaLi_2$ alloy (β compound); and 350 °C for ten days when using an alloy whose composition is included between Ca_3Li and Ca_4Li (γ compound). After reaction, the sample obtained after removal of the alloy was introduced into a Pyrex or a Lindemann capillary tube (according to the size of the sample), which was sealed for characterisation of the sample by X-ray diffraction (XRD). The chemical formulae of these compounds were established by nuclear microprobe measurements,[8] because it is difficult to determine lithium concentration and distribution by classical methods such as Castaing microprobe, SEM and TEM. The formulae, which represent the composition of the bulk samples, are $Li_{0.4}Ca_{2.7}C_6$ for the α compound, $Li_{3.1}Ca_{2.1}C_6$

for the β compound, and $Li_{0.07}CaC_6$ for the γ compound. It should be emphasised that the third compound (γ) has a very low lithium content, and it is so low that it appears to be almost a binary compound, close to the well-known CaC_6 phase.[6] On the other hand, the metal contents of the α and β compounds are much higher. The β compound in particular exhibits a very large lithium content (eight times richer than the α compound). It is probably the most metal-rich phase amongst the graphite intercalation compounds.

Structural Study: The compounds were studied by X-ray diffraction, using a specific technique because the samples are partially oriented. The host graphite sample used for the intercalation reaction is a platelet of highly oriented pyrolytic graphite (HOPG from Union Carbide). The *c*-axes of all elemental graphite crystals are mutually parallel but, within the graphene sheets, their *a* and *b* axes are randomly distributed. This structural particularity confers the properties of a single crystal along the *c* axis and the properties of a powder in the perpendicular plane. Consequently, it is very easy to observe the 00*l*, *hk*0 and *hkl* reflections with a device perfected in our laboratory.[9]

Acknowledgments

The authors wish to thank Sylvie Schneider for her contribution to X-ray diffraction measurements and especially for the rotating crystal image and Arsene Goukasov and Jean-Michel Kiat for neutron diffraction measurements.

Selective Reaction of Aminorhenium Complexes and the Formation of Cp-N-P Tridentate Complexes

Tein-Fu Wang,*[a] Tan-Ching Wang,[a] and Yuh-Sheng Wen[a]

Keywords: Rhenium / Cyclopentadienes / N ligands / P ligands / Tridentate ligands

Rhenium complexes containing cyclopentadienyl-aminophosphanyl tridentate ligands have been prepared starting from a cyclopentadienyl-amino bidentate complex in a controlled manner. Dehydrobromination of $[\eta^5{:}\eta^1\text{-}C_5H_4CH_2CH_2NH(CH_3)Re(CO)_2Br]^+$ (**2**) was carried out selectively at low temperature to give an exocyclic iminorhenium complex $[\eta^5{:}\eta^1\text{-}C_5H_4CH_2CH_2N(=CH_2)Re(CO)_2]$ (**5**). Selective *N*-methylation provided a cationic heterocyclopropane complex **8** which reacted with various nucleophiles (tBuNH$_2$, NaOCH$_3$, KPPh$_2$) to give precursors for tridentate complexes. A formal oxidation of the carbonyl ligand to a labile carbon dioxide ligand was accomplished by oxidation with peroxy acid. Intramolecular N ligand displacement furnished the Cp-N-P tridentate complex. The relative stability of the N, P and CO ligands was revealed when an η^3-allyl ligand was formed. The N ligand became detached from the metal rather than the P or CO ligands as the η^1-allyl was transformed to the corresponding η^3-allyl coordination mode.

Introduction

Transition metal Cp complexes containing an amino group functionalized side chain are of considerable current interest.[1] The majority of studies have concentrated on complex formation with early transition metals and their behavior as the ethylene polymerization catalysts.[2] Relatively little is known about the chemistry with low-valent transition metals. Amino groups have no π-acceptor capabilities, they coordinate only weakly to low-valent metals and form relatively labile complexes. Through chelation, several stable low-valent organometallic complexes have been realized.[3] With the strong electron donating amino group coordinated to the metal, the complexes show unprecedented chemical properties. We have reported aminorhenium complexes containing η^2-carbamoyl,[4] η^3-benzyl[5] and η^2-carbon dioxide[6] functionalities. These complexes are quite stable under ambient conditions and further exploration of the chemistry of this class of complexes is important.

In this study, we report some selective reactions of the aminorhenium complexes and ultimate conversion into the corresponding Cp-N-P tridentate complexes.[7] We introduce a new approach for promoting the carbonyl ligand substitution for the first time by an unprecedented peroxy acid oxidation. The synthesis and chemistry are reported herein.

Results and Discussion

Selective Reactions of Iminorhenium Complexes

We have previously reported that treatment of the aminorhenium bromide **2** with a base at room temperature afforded the η^2-carbamoyl complex **4**.[4] When the reaction was carried out at 0 °C, however, a significant amount of the iminorhenium complex **5** was isolated (Scheme 1). The reaction presumably proceeds via the neutral intermediate **3**, followed by two competitive pathways. Migratory CO insertion gave complex **4**, while dehydrobromination gave complex **5**. We assumed that the CO migratory insertion might be more temperature dependent than that of the dehydrobromination. Low temperature reactions were therefore tested. Indeed, when **2** was treated with base at −78 °C, only the dehydrobromination products **5** and **6** (≈ 3%) were isolated. The exocyclic imino complex **5** and the endocyclic imino complex **6** that were formed presumably *via* kinetic control, could be easily differentiated by their ^{1}H NMR spectra. There are two imino protons (δ = 7.90 and 7.79 ppm) for **5**, while only one imino proton (δ = 7.68 ppm) and a methyl group (δ = 3.81 ppm) for **6**.

Unlike the aminorhenium complex **1** in which the alkylation occurred selectively at the rhenium center,[8] the methylation of the exocyclic iminorhenium complex **5** turned out to be non-selective. Both *Re*- and *N*-methylation compounds **7** and **8** were obtained (Scheme 1). The formation of the *Re*-methylation compound is faster than that of the *N*-methylation compound. When the reaction mixture was stirred longer, however, the *N*-methylation compound **7** disappeared gradually by virtue of reversibility and finally the iminium complex **8** was isolated in good yield. The im-

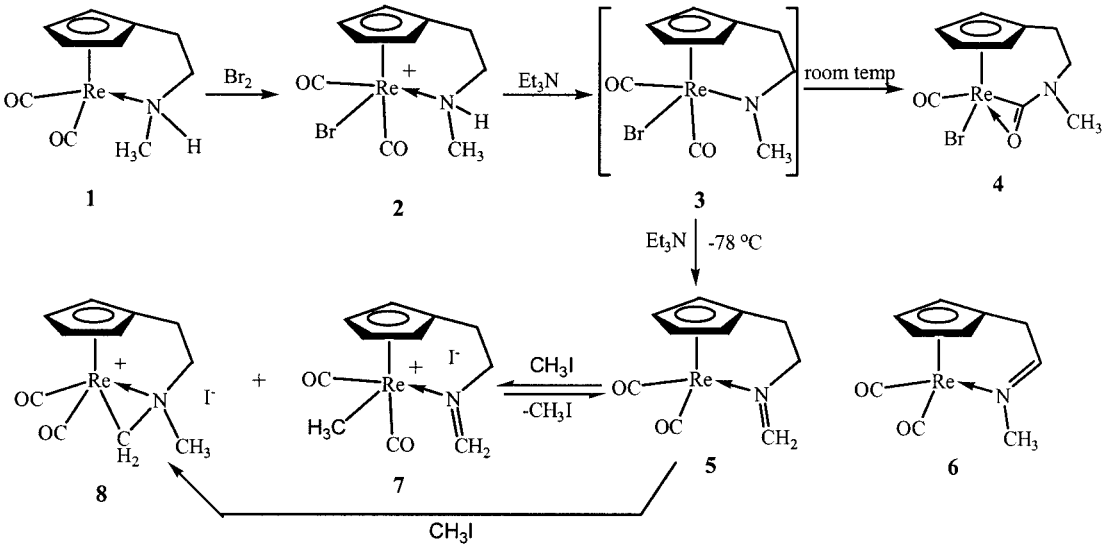
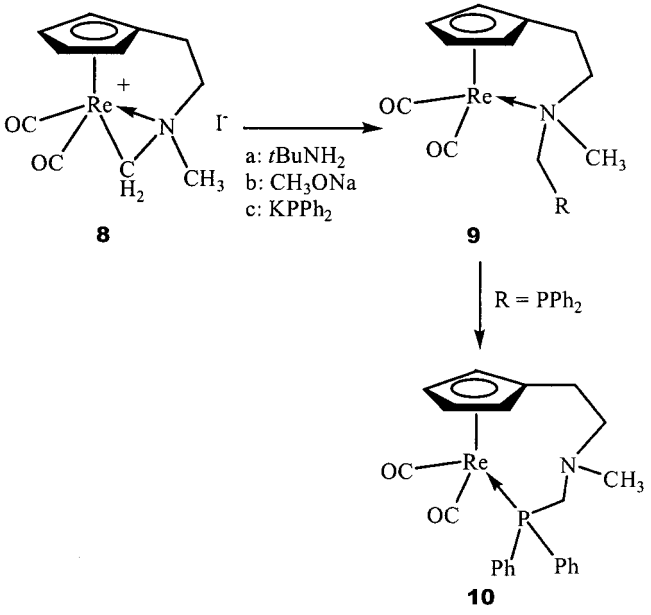


Scheme 1. Selective dehydrobromination and methylation

inium protons of **8** are shifted upfield to δ = 3.78 and 3.46 ppm, respectively, compared with δ = 8.42 and 8.11 ppm for complex **7**, suggesting that the iminium carbon is bonded to the metal center. The *N*-methyl resonance appeared at δ = 3.40 ppm indicating that the N ligand remains coordinated. The iminium ligand is therefore better viewed as a heterocyclopropane ring.

Reactions of the Cationic Complex 8 with Nucleophiles

Treatment of the cationic complex **8** with various nucleophiles (tBuNH$_2$, NaOCH$_3$) resulted in the opening of the heterocyclopropane ring to give the neutral complex **9** (Scheme 2). The physical properties of **9a** and **9b** are similar to those of *N*,*N*-disubstituted aminorhenium complexes that we have reported previously.[8] When **8** was treated with potassium diphenylphosphide, the phosphane-coordinated complex **10** was obtained. The terminal carbonyl stretching frequencies of **10** appeared at 1920 and 1848 cm^{-1} compared with 1894 and 1818 cm^{-1} in **9a**, and 1899 and 1823 cm^{-1} in **9b**. Higher energy shifts of the carbonyl stretching frequencies of **10** are consistent with the weaker electron donating ability of the phosphanyl group compared with that of the amino group. The *N*-methyl group of **10** appeared at δ = 2.30 ppm compared with δ = 3.08 ppm in **9a** and δ = 3.26 ppm in **9b** suggesting that the amino group of **10** is uncoordinated. The aminorhenium complex **9c** was assumed to be the initial reaction product. Phosphanyl groups are generally considered to be better ligands for low valent organometallic complexes than amino groups. The amino ligand of **9c** was therefore substituted intramolecularly by the newly generated phosphanyl group to give **10**. The intramolecular exchange of the two amino groups of **9a** was not observed. Unambiguous characterization of **10** was accomplished by a single-crystal X-ray diffraction study and Figure 1 shows an ORTEP diagram of **10**. The Re−P bond length is 2.331 Å, similar to those reported for neutral rhenium complexes (2.325−2.356 Å).[9] The carbonyl groups are bonded to the rhenium in a linear manner as indicated by the bond angles of 175.8° for Re−C10−O10 and 177.3° for Re−C11−O11.



Scheme 2. Reactions of the heterocyclopropane complex **8** with nucleophiles

Formation of Cyclopentadienyl-Nitrogen-Phosphorous Tridentate Complexes

Formation of a Cp-N-P tridentate complex from the rhenium phosphane compound **10** requires removal of a carbonyl ligand. Photochemical[10] and trimethylamine *N*-oxide promoted[11] CO expulsion have been commonly used for the removal of terminal carbonyl ligands. However,

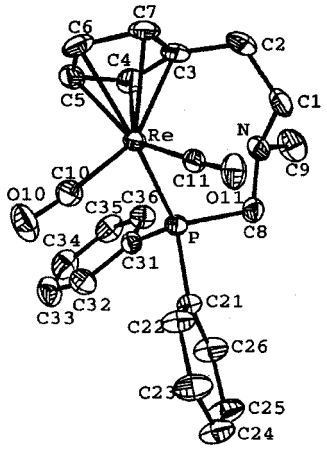

Figure 1. ORTEP diagram of **10**. Selective bond lengths (Å) and bond angles (°): Re−P 2.331(2), Re−C10 1.886(6), Re−C11 1.874(6); P−Re−C10 94.2(2), P−Re−C11 88.6(2), Re−C10−O10 175.8(6), Re−C11−O11 177.3(5)

these methodologies are not useful for complex **10**, owing to the relatively inert carbonyl groups (IR: $\tilde{\nu}$ = 1920, 1848 cm^{-1}). When **10** was treated with trimethylamine *N*-oxide or ultraviolet irradiation, only the starting material was recovered accompanied by some decomposition. It has been reported that an electron-rich aminorhenium complex such as **A** (Scheme 3), reacts with electrophilic peroxy acids to provide the CO_2 complex **B**.[6] Although the phosphanyl ligand is less electron donating than the amino ligand, we anticipated that the rhenium phosphane complex **10** would still be reactive enough with elctrophilic peroxy acids. Indeed, when **10** was treated with *m*-chloroperbenzoic acid, a carbonyl group disappeared immediately. Only one carbonyl stretch appeared at 1926 cm^{-1} in the resultant infrared spectrum. The resonance of the *N*-methyl group appeared at δ = 3.41 ppm in the ^1H NMR spectrum indicating that the amino group had become coordinated to the metal. A hydride appeared at δ = −6.15 suggesting that a Re−H bond had formed. The product was therefore proposed as the Cp-N-P tridentate complex **13** (Scheme 3). The reaction presumably proceeds through the rhenium carbon dioxide complex **11** followed by intramolecular amino group displacement of the labile CO_2 to give the neutral Cp-N-P tridentate complex **12**. The basic rhenium center picked up a proton and anion exchange furnished complex **13**.

Single crystals of **13** were obtained from a solution in acetone and methanol. An ORTEP drawing of **13** is shown in Figure 2. Both nitrogen and phosphorous are bonded to the metal with distances of 2.146 Å for Re−N and 2.363 Å for Re−P, respectively. The torsion angle of the heterocyclic 4−membered N−Re−P−C8 ring is 10.1°.

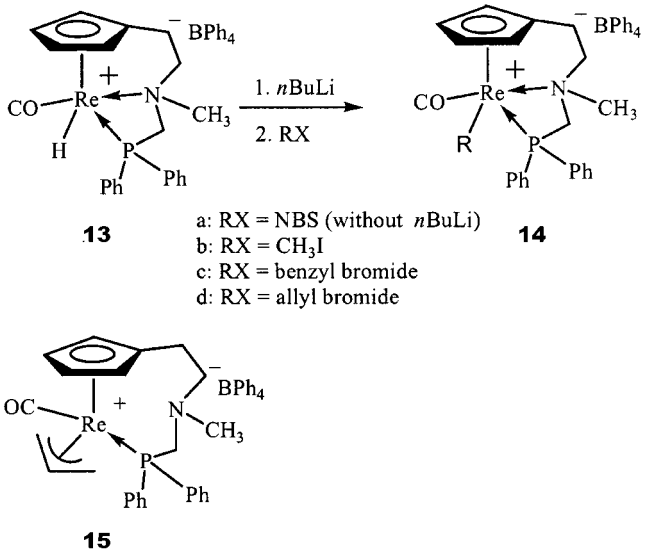
Reaction of the Cp-N-P Tridentate Complex with Electrophiles

The spontaneous protonation of the neutral Cp-N-P tridentate complex **12** to give the cationic complex **13** prompted us to investigate nucleophilic reactions of **12** (Scheme 3). Complex **12** was regenerated from the cationic **13** by deprotonation with *n*BuLi. Treatment of **12** with various electrophiles (*N*-bromosuccinimide, methyl iodide, benzyl bromide) gave the expected products **14a**−**c** in excellent yield (Scheme 4). The spectroscopic properties of **14a**−**c** appeared similar to those of **13**. The *N*-methyl groups appeared at δ = 3.36−3.52 ppm in the ^{1}H NMR spectra suggesting that the amino groups remained coordinated. The Re−CH_3 methyl protons of **14b** and the Re-benzyl methylene protons of **14c** show ^3J couplings with the phosphorous indicating that the alkylations were successful and that the phosphanyl ligands remain coordinated to the metal. The carbonyl stretching appeared at 1918 cm^{-1} for both **14b** and **14c**. A relatively higher stretching frequency appeared at 1953 cm^{-1} for **14a**, consistent with the presence of the electronegative bromine on the metal. Complex **14a** could also be obtained by direct treatment of **13** with *N*-bromosuccinimide.



Scheme 4. Reaction of the tridentate complex **13** and selective removal of the N ligand

The reaction of **12** with allyl bromide doesn't stop at the η^1-allyl complex **14d**, but proceeds further to give the η^3-allyl complex **15**. Examination of the ^{1}H NMR spectrum showed that the N−CH_3 group appeared at δ = 1.98 ppm, indicating that the amino group had become detached from the metal. A single-crystal X-ray analysis confirmed this assignment. Figure 3 shows an ORTEP diagram of **15**. The allyl group is bonded to the rhenium in an η^3-fashion with bond lengths of 2.257, 2.200 and 2.244 Å, respectively. The rhenium−phosphorous bond length is 2.414 Å, slight longer than those in complexes **10** and **13**. The amino group was generally thought to be a better ligand than that of the phosphanyl ligand towards the cationic metal center. To our surprise, however, the amino group was expelled in preference to the phosphanyl or the CO groups when the η^3-allyl complex was formed.

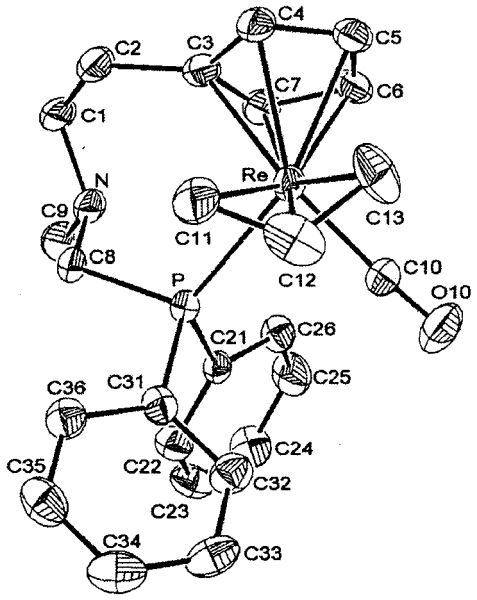


Figure 3. ORTEP drawing of the cationic part of **15**. Selective bond lengths (Å) and bond angles (°): Re−P 2.414(2), Re−C11 2.257(8), Re−C12 2.200(9), Re−C13 2.244(8); P−Re−C10 82.7(2), P−Re−C11 79.5(2), P−Re−C12 92.1(2), P−Re−C13 126.8(2), C11−C12−C13 119.0(8)

Conclusion

We have demonstrated that CO migratory insertion and dehydrobromination can be carried out selectively by temperature control. The CO migratory insertion of compound **3** was drastically reduced at low temperature thereby allowing selective dehydrobromination to give complex **5**. By learning that the rhenium-methylation is reversible, we successfully obtained the *N*-methylation complex **8** exclusively by prolonged reaction. Introduction of a P ligand was achieved by nucleophilic addition to the activated methylene group of the iminium ligand. Removal of a carbonyl ligand was demonstrated for the first time using a peroxy acid which formally oxidized the CO to a labile CO_2 ligand. Intramolecular ligand displacement furnished the Cp-N-P tridentate complex. It is worth noting that when the η^1-allyl was transformed to η^3-allyl, the N ligand of the cationic tridentate complex **14c** was detached from the metal to give **15**.

Experimental Section

General: Infrared solution spectra were recorded with a Perkin−Elmer 882 infrared spectrophotometer using 0.1 mm cells with CaF_2 windows. Melting points were determined using a Yanaco Model MP micro melting point apparatus and were uncor-

rected. ^{1}H NMR (300 MHz), ^{13}C NMR (75 MHz) and ^{31}P{^{1}H} NMR (121 MHz) were obtained with a Bruker AC-300 FT spectrometer. For the assignment of ^{1}H and ^{13}C NMR spectroscopic data, the carbon bound to the nitrogen was designated as C^1 and the hydrogens on C^1 were designated as H^{1a} and H^{1b}. The next carbon was designated as C^2, and the hydrogen atoms on C^2 were designated as H^{2a} and H^{2b}. ^{1}H and ^{13}C chemical shifts are reported in parts per million (ppm) relative to Me_4Si and ^{31}P chemical shifts are relative to 85% H_3PO_4. Elemental analyses were obtained on a Perkin−Elmer 2400 CHN elemental analyzer.

Preparation of [η^5:η^1-$C_5H_4CH_2CH_2N(=CH_2)Re(CO)_2$]: 5 To a stirred solution of complex **1** (3.44 g, 9.44 mmol) in CH_2Cl_2 (120 mL) at 0 °C was added a solution of bromine in CH_2Cl_2 (18.9 mL, 0.5 M) slowly over 15 min. After stirring for an additional 5 min, the resultant orange-red solution was cooled in a dry ice-acetone bath. A solution of triethylamine (4.5 mL) in CH_2Cl_2 (45 mL) was then added slowly over 1 h using a syringe pump. After addition, the cooling bath was removed and the solution was stirred at room temperature for 30 min. Solvents were then evaporated under reduced pressure. The brown solid residue was chromatographed on silica gel using 20% followed by 30% ethyl acetate in hexane as eluents. The first yellow band was collected and concentrated to give yellow crystalline **5** (2.406 g, 70% yield). A slightly more polar fraction was collected to give yellow crystalline **6** (0.112 g, 3% yield).

Complex 5: R_f = 0.57 (50% EtOAc in hexane). M.p. 169−171 °C. IR (CH_2Cl_2): $\tilde{\nu}$ = 1908 s, 1835 s cm^{-1}. ^{1}H NMR ($CDCl_3$): δ = 7.90 (dt, J = 12.9, 1.4 Hz, 1 H, imine), 7.79 (dt, J = 12.9, 1.4 Hz, 1 H, imine), 5.31 (t, J = 2.0 Hz, 2 H, Cp), 5.06 (t, J = 2.0 Hz, 2 H, Cp), 4.34 (tt, J = 6.6, 1.4 Hz, 2 H), 2.18 (t, J = 6.6 Hz, 2 H) ppm. ^{13}C NMR ($CDCl_3$): δ = 203.6 (CO × 2), 165.4 (CH_2, imine), 119.6 (C, Cp), 84.0 (CH_2), 80.4 (CH × 2, Cp), 77.1 (CH × 2, Cp), 26.7 (CH_2) ppm. $C_{10}H_{10}NO_2Re$ (362.40): calcd. C 33.14, H 2.78, N 3.86; found C 33.31, H 2.62, N 3.95.

Complex 6: M.p. 192−195 °C (dec). IR (CH_2Cl_2): $\tilde{\nu}$ = 1907 s, 1830 s cm^{-1}. ^{1}H NMR ($CDCl_3$): δ = 7.70−7.67 (m, 1 H, imine), 5.51 (t, J = 2.0 Hz, 2 H, Cp), 5.07 (t, J = 2.0 Hz, 2 H, Cp), 3.82−3.80 (m, 3 H, CH_3), 3.18−3.15 (m, 2 H) ppm. ^{13}C NMR ($CDCl_3$): δ = 205.2 (CO × 2), 181.2 (CH, imine), 115.7 (C, Cp), 79.3 (CH × 2, Cp), 77.8 (CH × 2, Cp), 60.8 (CH_3), 35.8 (CH_2) ppm. $C_{10}H_{10}NO_2Re$ (362.40): calcd. C 33.14, H 2.78, N 3.86; found C 33.15, H 2.88, N, 3.56.

Preparation of 8: A suspension of complex **5** (0.875 g, 2.41 mmol) in CH_3I (15 mL) was heated under reflux for 5 days. Excess CH_3I was evaporated. The solids was washed four times with CH_2Cl_2 (5 mL × 4) to give 0.852 g (72% yield) of **8** as a yellow powder. M.p. 90 °C (dec). IR (CH_3CN): $\tilde{\nu}$ = 2030 s, 1953 s cm^{-1}. ^{1}H NMR (CD_3CN): δ = 6.41−6.39 (m, 1 H, Cp), 6.37−6.35 (m, 1 H, Cp), 6.16−6.14 (m, 1 H, Cp), 5.66−5.64 (m, 1 H, Cp), 4.29−4.22 (m, 1 H, H^{1a}), 4.09−3.98 (m, 1 H, H^{1b}), 3.78 (d, J = 1.7 Hz, 1 H, Re−CH_2^a), 3.46 (d, J = 1.7 Hz, 1 H, Re−CH^{2b}), 3.40 (s, 3 H, N−CH_3), 2.21−2.15 (m, 2 H, $H^{2\prime}$s) ppm. ^{13}C NMR (CD_3CN): δ = 200.9 (CO), 196.8 (CO), 122.0 (C, Cp), 97.8 (CH, Cp), 92.9 (CH, Cp), 88.7 (CH, Cp), 84.6 (CH, Cp), 77.3 (CH_2, C^1), 58.4 (CH_3), 30.7 (CH_2, Re−CH_2), 22.4 (CH_2, C^2) ppm. $C_{11}H_{13}INO_2Re$ (359.12): calcd. C 26.20, H 2.60, N 2.78; found C 26.04, H 2.75, N 3.03.

Preparation of 9a: To a stirred suspension of **8** (0.149 g, 0.29 mmol) in CH_2Cl_2 (10 mL) was added *tert*-butylamine (2 mL). The mixture was stirred at room temperature for 17 h. The resultant yellow solution was concentrated and the residue was flash chromatographed on silica gel using 10% followed by 20% ethyl acetate in hexane as eluents. A yellow band which appeared at R_f = 0.65 (30% EtOAc/hexane) was collected and concentrated to give a yellow solid 0.122 g (94% yield) of **9a**. M.p. 147−150 °C (dec). IR (CH_2Cl_2): $\tilde{\nu}$ = 1894 s, 1818 s cm^{-1}. ^{1}H NMR ($CDCl_3$): δ = 5.23−5.21 (m, 1 H, Cp), 5.13−5.11 (m, 1 H, Cp), 4.92−4.90 (m, 1 H, Cp), 4.89−4.87 (m, 1 H, Cp), 3.90 (d, J = 11.5 Hz, 1 H, −NCH_2^aN−), 3.80 (d, J = 11.5 Hz, 1 H, −NCH_2^bN−), 3.40−3.22 (m, 2 H, H^1), 3.08 (s, 3 H, N−CH_3), 2.29−2.14 (m, 2 H, H^2), 1.10 (s, 9 H, *t*Bu) ppm. ^{13}C NMR ($CDCl_3$): δ = 205.4 (CO × 2), 119.9 (C, Cp), 81.5 (CH, Cp), 79.0 (CH_2, NCH_2N), 78.3 (CH, Cp), 75.5 (CH, Cp), 74.3 (CH, Cp), 73.6 (CH_2, C^1), 56.4 (CH_3, N−CH_3), 50.2 (C, *t*Bu), 29.6 (CH_3 × 3, *t*Bu), 24.6 (CH_2, C^2) ppm. $C_{15}H_{23}N_2O_2Re$ (449.57): calcd. C 40.07, H 5.16, N 6.23; found C 39.98, H 5.14, N 5.85.

Preparation of 9b: A solution of sodium methoxide in methanol (0.9 mL, 25 wt%) was added to a stirred solution of **8** (95 mg) in methanol (10 mL) at room temperature. After stirring for 1.5 h, methanol was evaporated under reduced pressure. The residue was extracted with CH_2Cl_2, concentrated and flash chromatographed on silica gel using 10% followed by 30% EtOAc in hexane as eluents. A yellow band appeared at R_f = 0.62 (50% EtOAc/hexane) which was collected and concentrated to give the yellow crystalline complex **9b** (70 mg, 90% yield). M.p. 98−103 °C. IR (CH_2Cl_2): $\tilde{\nu}$ = 1899 s, 1823 s cm^{-1}. ^{1}H NMR ($CDCl_3$): δ = 5.25−5.23 (m, 1 H, Cp), 5.13−5.11 (m, 1 H, Cp), 4.95−4.93 (m, 1 H, Cp), 4.87−4.85 (m, 1 H, Cp), 4.35 (d, J = 8.5 Hz, 1 H, −OCH_2^a), 4.28 (d, J = 8.5 Hz, 1 H, −OCH_2^b), 3.50−3.41 (m, 2 H, H^1), 3.37 (s, 3 H), 3.26 (s, 3 H), 2.21−2.12 (m, 2 H, H^2) ppm. ^{13}C NMR ($CDCl_3$): δ = 204.6 (CO), 204.5 (CO), 119.6 (C, Cp), 97.0 (CH2, OCH2N), 80.3 (CH, Cp), 79.0 (CH, Cp), 74.9 (CH, Cp), 74.7 (CH, Cp), 73.0 (CH_2, C^1), 57.5 (CH_3, CH_3), 56.6 (CH_3), 24.7 (CH_2, C^2) ppm. $C_{12}H_{16}NO_3Re$ (408.47): calcd. C 35.28, H 3.95, N 3.43; found C 35.29, H 3.70, N 3.30.

Preparation of Complex 10: To a stirred suspension of **8** (1.955 g, 3.987 mmol) in THF (40 mL) at 0 °C was added a red solution of potassium diphenylphosphide in THF (10.4 mL, 0.5 M) over 5 min. After addition, the cold bath was removed and the mixture was stirred at room temperature for 30 min. and then solvents were evaporated under reduced pressure. The residue was purified chromatographically on silica gel using 10% followed by 20% EtOAc in hexane as eluents. A yellow band appeared at R_f = 0.59 (20% EtOAc/hexane) which was collected and concentrated to give **10** (1.705 g, 80% yield) as a white solid. M.p. 145−149 °C. IR (CH_2Cl_2): $\tilde{\nu}$ = 1920 s, 1848 s cm^{-1}. ^{1}H NMR ($CDCl_3$): δ = 7.55−7.49 (m, 4 H, Ph), 7.39−7.32 (m, 6 H, Ph), 5.22−5.20 (m, 2 H, Cp), 5.05−5.03 (m, 2 H, Cp), 3.68 (s, 2 H, −PCH_2N), 2.75−2.71 (m, 2 H, H^1), 2.38−2.34 (m, 2 H, H^2), 2.30 (s, 3 H, N−CH_3) ppm. ^{13}C NMR ($CDCl_3$): δ = 203.2 (d, $J_{C,P}$ = 7.5 Hz, CO × 2), 138.8 (d, $J_{C,P}$ = 46 Hz, C × 2, Ph), 132.2 (d, $J_{C,P}$ = 9.6 Hz, CH × 4, Ph), 129.4 (CH × 2, Ph), 128.0 (d, $J_{C,P}$ = 9.3 Hz, CH × 4, Ph), 103.5 (C, Cp), 88.7 (CH × 2, Cp), 78.5 (CH × 2, Cp), 63.8 (CH_2, C^1), 62.9 (d, $J_{C,P}$ = 52 Hz, CH_2, PCH_2), 45.9 (d, $J_{C,P}$ = 10.4 Hz, CH_3, N−CH_3), 26.6 (CH_2, C^2) ppm. ^{31}P NMR ($CDCl_3$): δ = 26.0 (s) ppm. $C_{23}H_{23}NO_2PRe$ (562.62): calcd. C 49.10, H 4.12, N 2.49; found C 49.24, H 3.92, N 2.28.

Preparation of Complex 13: To a stirred solution of **10** (1.414 g, 2.66 mmol) in CH_2Cl_2 (35 mL) at 0 °C was added *m*-chloroperbenzoic acid (0.67 g, 80%, 1.2 equiv.) in 3 portions over 5 min. The initially colorless solution became yellow immediately. After stirring for an additional 20 min, CH_2Cl_2 was evaporated. The residue was dissolved in CH_3OH (15 mL) and a solution of $NaBPh_4$ (1.1 g) in CH_3OH (5 mL) was then added. The yellow solid was collected

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

using a centrifuge and washed three times with CH_3OH. The final yellow solid was recrystallized from a solution of acetone and methanol to give yellow crystalline **13** (1.377 g, 60%, yield). M.p. 190−196 °C. IR (acetone): $\tilde{\nu}$ = 1926 s cm^{-1}. ^1H NMR ([D$_6$]acetone): δ = 8.00−7.55 (m, 10 H, Ph), 7.36−7.30 (m, 8 H, Ph), 6.91 (t, *J* = 7.3 Hz, 8 H, Ph), 6.67 (t, *J* = 7.2 Hz, 4 H, Ph), 6.50 (dd, *J* = 15.3, 6.0 Hz, 1 H, PCH_2^a), 6.17−6.15 (m, 1 H, Cp), 5.76−5.67 (m, 3 H, Cp-H's and PCH_2^b), 4.95−4.93 (m, 1 H, Cp), 4.06−4.39 (m, 1 H, H^{1a}), 3.95−3.85 (m, 1 H, H^{1b}), 3.41 (s, 3 H, N−CH_3), 2.71−2.68 (m, 1 H, H^{2a}), 2.50−2.45 (m, 1 H, H^{2b}), −6.15 (d, *J* = 41 Hz, 1 H, Re−H) ppm. ^{31}P NMR ($CDCl_3$): δ = −42.7 ppm. $C_{46}H_{44}BNOPRe$ (854.86): calcd. C 64.63, H 5.19, N 1.64; found C 64.50, H 5.12, N 1.80.

Preparation of Complex 14a: To a stirred pale yellow solution of **13** (0.196 g, 0.23 mmol) in acetone (10 mL) at 0 °C was added *N*-bromosuccinimide (62 mg, 1.5 equiv.). After stirring for 5 min, the acetone was evaporated. The resultant solid was washed with diethyl ether several times and recrystallized from a solution of acetone and methanol to provide red crystals 168 mg (78% yield) of **14a**. M.p. 199−210 °C (dec). IR (acetone): $\tilde{\nu}$ = 1953 s cm^{-1}. ^1H NMR (CD_3CN): δ = 7.99−6.82 (m, 30 H, Ph), 6.63−6.61 (m, 1 H, Cp), 6.41−6.39 (m, 1 H, Cp), 5.92 (dd, *J* = 11.3, 4.2 Hz, 1 H, PCH_2^a), 5.65−5.63 (m, 1 H, Cp), 5.55−5.53 (m, 1 H, Cp), 5.48 (dd, *J* = 11.3, 4.5 Hz, 1 H, PCH_2^b), 3.82−3.77 (m, 1 H, H^{1a}), 3.62−3.56 (m, 1 H, H^{1b}), 3.36 (s, 3 H, N−CH_3), 2.30−2.26 (m, 2 H, $H^{2\prime}$s) ppm. ^{31}P NMR ([D$_6$]acetone): δ = −54.1 ppm. $C_{46}H_{43}BBrNOPRe$ (933.75): calcd. C 59.17, H 4.64, N 1.50; found C 59.20, H 4.42, N 1.72.

General Procedure for the Preparation of 14b and 14c: A solution *n*BuLi in hexane (1.6 M, 0.31 mL, 1.2 equiv.) was added to a stirred suspension of **13** (342 mg, 0.4 mmol) in THF (6 mL) at 0 °C over 1 min. After stirring for an additional 20 min, CH_3I (0.4 mL) or benzyl bromide (0.5 mL) was added to the resultant yellow-brown solution. The cooling bath was removed and the solution was stirred at room temperature for 1 h. The solution was concentrated under reduced pressure and the residues were washed twice with methanol then twice with diethyl ether. The solids were then recrystallized from a solution of acetone and hexane.

14b: Orange crystals, 271 mg (78% yield). M.p. 210−215 °C (dec.). IR (CH_3CN): $\tilde{\nu}$ =1918 s cm^{-1}. ^1H NMR ([D$_6$]acetone): δ = 8.10−7.31 (m, 18 H, Ph), 6.91 (t, *J* = 7.3 Hz, 8 H, Ph), 6.77 (t, *J* = 7.2 Hz, 4 H, Ph), 6.45 (dd, *J* = 15.1, 5.8 Hz, 1 H, PCH_2^a), 6.43−6.41 (m, 1 H, Cp), 6.34−6.32 (m, 1 H, Cp), 5.55 (dd, *J* = 15.1, 6.5 Hz, 1 H, PCH_2^b), 5.25−5.23 (m, 1 H, Cp), 4.88−4.86 (m, 1 H, Cp), 4.09 (br. dd, *J* = 12.1, 5.2 Hz, 1 H, H^{1a}), 3.90 (td, *J* = 12.1, 5.5 Hz, 1 H, H^{1b}), 3.52 (s, 3 H, N−CH_3), 2.67 (ddd, *J* = 14.4, 12.6, 5.2 Hz, 1 H, H^{2a}), 2.37 (ddd, *J* = 14.4, 5.4, 1.5 Hz, 1 H, H^{2b}), 0.48 (d, *J* = 12 Hz, 3 H, Re−CH_3) ppm. ^{31}P NMR ([D$_6$]acetone): δ = −36.6 ppm. $C_{47}H_{46}BNOPRe$ (868.88): calcd. C 64.97, H 5.34, N 1.61; found C 65.02, H 5.51, N 1.48.

14c: Orange crystals, 322 mg (85% yield). M.p. 165−170 °C (dec.). IR (CH_2Cl_2): $\tilde{\nu}$ =1918 s cm^{-1}. ^1H NMR ([D$_6$]acetone): δ = 8.22−6.72 (m, 35 H, Ph), 6.55−6.53 (m, 1 H, Cp), 6.48 (dd, *J* = 14.8, 5.6 Hz, 1 H, PCH_2^a), 6.29−6.27 (m, 1 H, Cp), 5.59 (dd, *J* = 14.8, 6.4 Hz, 1 H, PCH_2^b), 5.43−5.41 (m, 1 H, Cp), 4.10−4.06 (m, 1 H, H^{1a}), 3.98−3.92 (m, 1 H, H^{1b}), 3.65 (dd, *J* = 9.8, 7.3 Hz, 1 H, benzylic-H^a), 3.49 (s, 3 H, N−CH_3), 3.39−3.37 (m, 1 H, Cp), 2.78 (dd, *J* = 14, 9.8 Hz, 1 H, benzylic-H^b), 2.69−2.60 (m, 1 H, H^{2a}), 2.32−2.26 (m, 1 H, H^{2b}) ppm. ^{31}P NMR ($CDCl_3$): δ =

−36.5 ppm. $C_{53}H_{50}BNOPRe$ (944.98): calcd. C 67.36, H 5.33, N 1.48; found C 67.11, H 5.35, N 1.62.

Preparation of 15: A solution *n*BuLi in hexane (1.6 M, 0.13 mL, 1.2 equiv.) was added to a stirred suspension of **13** (144 mg, 0.168 mmol) in THF (3 mL) at 0 °C over 1 min. After stirring for an additional 20 min, allyl bromide (0.3 mL) was added to the resultant yellow-brown solution. The solution was stirred at room temperature for 1 h. Solvents were evaporated and the residues were washed twice with methanol. The solid obtained was recrystallized from a solution of CH_2Cl_2 (3 mL) and CH_3OH (5 mL) at room temperature. Pale yellow platelet crystals of the η^3-allyl complex **15** were collected (137 mg, 91% yield). M.p. 220−225 °C (dec.). IR (CH_2Cl_2): $\tilde{\nu}$ =1960 s cm^{-1}. ^1H NMR ([D_6]acetone): δ = 7.61−7.31 (m, 18 H, Ph), 6.91 (t, *J* = 7.4 Hz, 8 H, Ph), 6.76 (t, *J* = 7.2 Hz, 4 H, Ph), 6.40 (br., 1 H, Cp), 6.07 (br., 1 H, Cp), 5.90 (br., 1 H, Cp), 5.83 (br., 1 H, Cp), 4.20 (d, *J* = 14.5 Hz, 1 H, PCH_2^a), 4.00 (dd, *J* = 14.5, 1.5 Hz, 1 H, PCH_2^b), 3.14−2.79 (m, 9 H), 1.98 (s, 3 H, N−CH_3) ppm. ^{31}P NMR ([D_6]acetone): δ = 10.2 ppm. $C_{49}H_{48}BNOPRe$ (894.92): calcd. C 65.76, H 5.41, N 1.56; found C 65.58, H 5.70, N 1.62.

Crystal Structures of 10, 13 and 15: Single crystals of **10** were obtained from a solution of CH_2Cl_2 and hexane, **13** from a solution of acetone and methanol, and **15** from a solution of CH_2Cl_2 and methanol at room temperature, respectively. Diffraction measurements were made on an Enraf−Nonius CAD-4 automated diffractometer using graphite-monochromated Mo-K_α radiation (λ = 0.71069 Å) with the θ−2θ scan mode. The unit cells were determined and refined using 25 randomly selected reflections obtained with the automatic search, center, index, and least-squares routines. Lorentz/polarization and empirical absorption corrections based on three azimuthal scans were applied to the data. The space groups ($P2_1/c$ for both **10** and **15**, $P2_1$ for **13**) were determined from the systematic absences observed during data collection. All data reduction and refinements were carried out on a DecAlpha 3400/400 computer using the NRCVX program.[12] Structures were solved by direct methods and refined by a full-matrix least-squares routine[13] with anisotropic thermal parameters for all non-hydrogen atoms. The structures were refined by minimizing $\Sigma w|F_o - F_c|^2$, where $w = (1/\sigma^2)F_o$ was calculated from the counting statistics. Hydrogens were included in the structure factor calculations in their expected positions on the basis of idealized bonding geometries but were not refined in the least-squares procedure. The final cell parameters and data collection parameters are listed in Table 1.
CCDC-219541 (for **10**), -219542 (for **13**) and -219543 (for **15**) contain the supplementary crystallographic data for this paper. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

Strongly Nucleophilic Rh^I Centre in Square-Planar Complexes with Terdentate (κ^3) 2,2′:6′,2′′-Terpyridine Ligands: Crystallographic, Electrochemical and Density Functional Theoretical Studies

Boke C. de Pater,[a] Hans-Werner Frühauf,[a] Kees Vrieze,[a] René de Gelder,[b] Evert J. Baerends,[c] Drew McCormack,[c] Martin Lutz,[d] Anthony L. Spek,[d] and František Hartl*[a]

Keywords: Rhodium / Tridentate ligands / X-ray diffraction / Cyclic voltammetry / Density functional calculations

Rh^I-terpyridine complexes have been unambiguously formed for the first time. The 2,2′:6′,2′′-terpyridine (tpy), 4′-chloro-2,2′:6′,2′′-terpyridine (4′-Cl-tpy) and 4′-(*tert*-butyldimethylsilyl-*ortho*-carboranyl)-2,2′:6′,2′′-terpyridine (carboranyl-tpy) ligands were used for successful syntheses and characterisation of the corresponding Rh^I complexes with halide co-ligands, [Rh(X)(4′-Y-terpyridine)] (X = Cl, Y = H, Cl, carboranyl; X = Br, Y = H). All four neutral Rh-tpy complexes are square planar, with Rh–X bonds in the plane of the 4′-Y-terpyridine ligands. Full characterisation of these dark blue, highly air-sensitive compounds was hampered by their poor solubility in various organic solvents. This is mainly due to the formation of π-stacked aggregates, as evidenced by the crystal structure of [Rh(Cl)(tpy)]; in addition, [Rh(Cl)(carboranyl-tpy)] merely forms discrete dimers. The (bonding) properties of the novel Rh^I-terpyridine complexes have been studied with single-crystal X-ray diffraction, (time-dependent) density functional theoretical (DFT) calculations, far-infrared spectroscopy, electronic absorption spectroscopy and cyclic voltammetry. From DFT calculations, the HOMO of the studied Rh^I-terpyridine complexes involves predominantly the metal centre, while the LUMO resides on the terpyridine ligand. Absorption bands of the studied complexes in the visible region (400–900 nm) can be assigned to MLCT and MLCT/XLCT transitions. The relatively low oxidation potentials of [Rh(X)(tpy)] (X = Cl, Br) point to a high electron density on the metal centre. This makes the Rh^I-terpyridine complexes strongly nucleophilic and (potentially) highly reactive towards various (small) substrate molecules containing carbon–halide bonds.

Introduction

Transition metal complexes containing terdentate nitrogen ligands (N−N−N) are of great interest both in the field of supramolecular chemistry[1,2] and catalysis. For example,[3] $[Pd(Me)(N-N-N)]^+$ complexes react rapidly with CO and subsequently with norbornadiene to produce $[Pd\{C_7H_8C(O)Me\}(N-N-N)]^+$ on the road to metal-bound polyketone fragments. Notably, the highest insertion rates are for complexes containing highly rigid ligands, e.g. dipyrido[4,3-*b*;5,6-*b*]acridine.[4] According to theoretical calculations,[5] this is most probably due to the rigidity of the ligand causing an increased strain in the metal complex itself, thereby facilitating intermediate bidentate coordination of the N−N−N ligand. These interesting findings initiated investigation of isoelectronic Rh^I compounds. Haarman et al. reported novel compounds [Rh(Cl)(2,6-[$C(R^1)=N-R^2)_2C_5H_3N$], containing fairly flexible 2,6-diiminopyridine ligands.[6–8] These complexes react readily with alkyl halides and oxygen owing to a strongly nucleophilic Rh^I centre.[6] The present article extends these studies to complexes with stronger σ-donating[9] and more rigid terpyridine ligands.

Since the first report on 2,2′:6′,2′′-terpyridine (tpy) by Morgan and Burstall,[10,11] the coordination chemistry of this ligand and its derivatives has been widely studied. They exhibit variable coordination modes to transition metals, viz. terdentate,[1] bidentate,[1,2] or monodentate.[12] Although complexes with many late transition metals are known,[1] only a few Rh-terpyridine complexes have been prepared, all of which contain rhodium(II) or rhodium(III)

centres.[12−18] Electrochemical studies revealed stable rhodium(IV)- and oxorhodium(V)-terpyridine species.[16] Some rhodium(I) intermediates with terpyridine ligands have been proposed to participate in catalytic cycles,[19] but their formation has never been unambiguously established.

We report here, for the first time, syntheses, structures, spectroscopic, redox and bonding properties of four mononuclear square-planar Rh^I-terpyridine complexes. Due to the planar tpy skeleton, these compounds exhibit a strong tendency to π-stacking, which implies their low solubility. This is the main factor complicating their characterisation. Consequently, the bulky *tert*-butyldimethylsilyl-*o*-carboranyl group was placed at the C(4′)-position of the tpy ligand of the Rh^I-terpyridine species in the hope that such a sterically demanding substituent would lead to an increase in solubility.

Results

Syntheses of Complexes [Rh(X)(4′-Y-tpy)] (X = Cl, Y = H (1), Cl (3), *tert*-butyldimethylsilyl-*o*-carboranyl (4); X = Br, Y = H (2)]

The novel complexes **1**−**4** (Scheme 1) have been prepared by a ligand displacement reaction (Scheme 2). Characterisation by NMR techniques was problematic due to the poor solubility of the complexes. After scanning for 20 h (using C_6D_6 as solvent), only complex **4** gave an acceptable ^1H NMR spectrum (Figure 1). The C(6,6′′)-H signals of **4** were hidden under the benzene signal. The B−H signals, presumably spread over the range of 2−4 ppm, were not observable. The ^1H spectrum also contained additional signals of a minor species, probably a degradation product, since complex **4** is far less stable in organic solvents than **1**−**3**. The solubility of **1**−**4** in CD_3CN is lower than that in benzene and no acceptable ^1H NMR spectrum could be recorded. Finally, although the solubility of **1**−**4** in [D_6]EtOH and [D_6]DMF is similar to that in benzene, the ^1H NMR spectra only exhibited very broad signals.

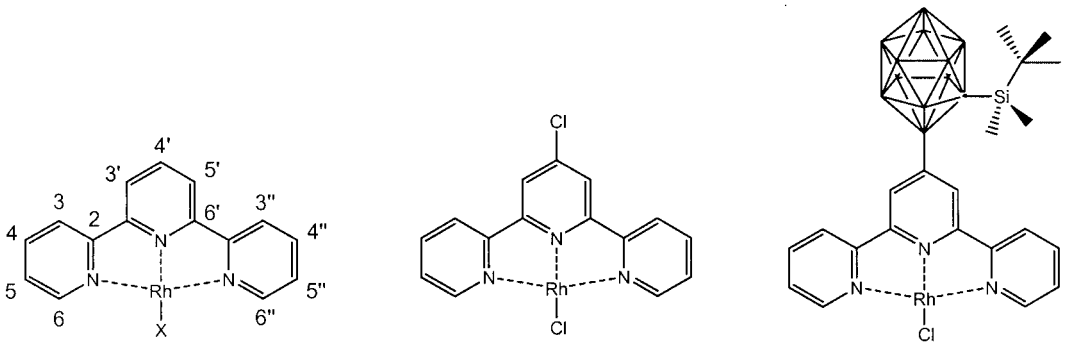
X-ray Structures of Complexes 1 and 4

Molecules of complex **1** (Figure 2) are arranged in sheets that run parallel with the crystallographic *b*-axis (Figure 3). The sheets are 3.508(12) Å apart, which is considered as the thickness of the molecules. Neighbouring molecules in different sheets are in a staggered arrangement close to inversion symmetry. The distance between the sheets strongly indicates the presence of π-stacking (Figure 4). Within the sheets, short intermolecular distances are found between the chlorine atom and H5′ and H3′′ of a neighbouring molecule: H···Cl are 2.79 and 2.85 Å, and C−H···Cl angles 167° and 169°, respectively (Figure 5). These short distances



Scheme 1

indicate "chelating" C−H···Cl hydrogen bonds that link the neighbouring molecules into a one-dimensional intermolecular hydrogen-bonding network. The hydrogen-bonded sheets are stacked in the crystallographic [101] direction (Figure 5). There are no short Rh−Rh′ contacts, the smallest distance being 4.896(2) Å. Selected bond lengths and angles in complex **1**, together with those in the ADF/BP-calculated complexes **1′** and **2′**, for comparison, are summarised in Table 1 and Table 2, respectively.

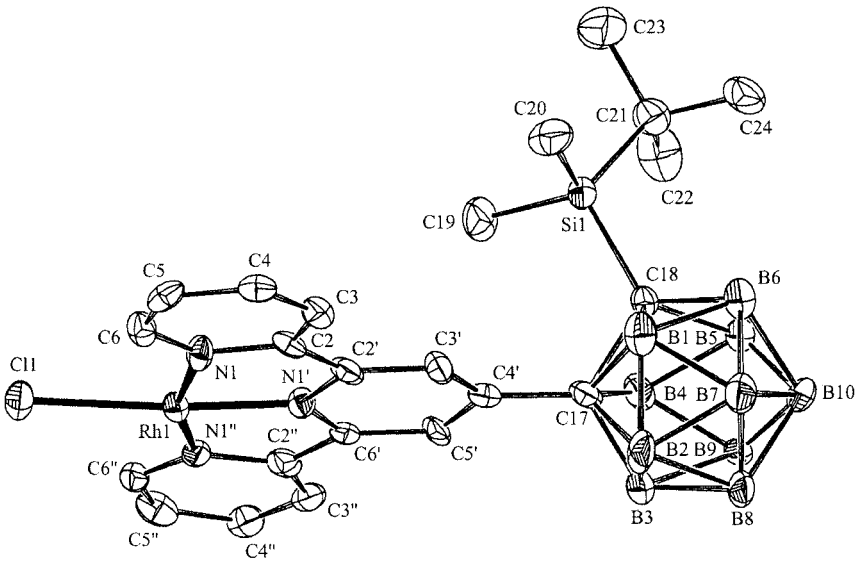

Figure 6. Displacement ellipsoid plot (50% probability level) of complex **4**. Hydrogen atoms and the disordered ethanol solvent molecule omitted for clarity

inversion centres (Figure 7), with Rh−Rh′ distances of 3.1503(13) Å. The packing of the dimers appears to be dominated by intermolecular hydrophobic interactions of the carborane residues, and by hydrophilic interactions of the Rh−Cl residues, with the disordered ethanol molecules also present in the structure. Apart from the interaction between the two halves of each dimer, no π-stacking is observed (Figure 8).

FIR Spectra of Complexes 1 and 2

Generally, the IR ν(Rh−X) (X = Cl, Br) modes of pseudooctahedral $Rh^{III}X_3$-terpyridine complexes are difficult to assign.[20] The complexity of the FIR spectra of these complexes is largely attributed to the coupling of ν(Rh−X) and ν(Rh−N) modes, and to the difference between the ν(Rh−X) modes of the cis and trans halides.

Conversely, analysis of the square-planar Rh^{I}(X)-terpyridine complexes is easier. The FIR spectra of complexes **1** and **2** are similar, except for the ν(Rh−Cl) and ν(Rh−Br) bands (Figure 9). Assignment of ν(Rh−X) (X = Cl, Br for **1** and **2**, respectively) is straightforward: ν(Rh−Cl) at 256−260 cm^{-1} and ν(Rh−Br) at 188 cm^{-1}. The assignment of ν(Rh−Cl) is also supported by the observation of chlorine isotope splitting; the experimental value of 4 cm^{-1} (256 and 260 cm^{-1} for ^{37}Cl and ^{35}Cl, respectively) is similar to the calculated isotope splitting of 5 cm^{-1} ($K = 6.33\cdot10^{28}$ dyn cm^{-1} for $^{103}Rh-^{37}Cl$; 1 dyn = 10^{-3} N m^{-1} = 10^{-3} J).

The band pattern observed for complex **1** at 129 and 138 cm^{-1} is also considerably shifted to smaller wavenumbers for complex **2** (85 and 96 cm^{-1}). These bands are probably Rh−X bending vibrations (out-of-plane and in-plane).

Other absorption bands for **1** at 300−320, 220−230 and 153 cm^{-1} show only a minor shift to smaller wavenumbers for **2**, viz. 295−302, 214−226 and 141 cm^{-1}, respectively. These bands are attributed, without detailed analysis, to Rh−N/tpy vibrations.

The DFT calculations prove that variation of the ligand X (Cl and Br for complexes **1** and **2**, respectively) produces only small differences in orbital characters and energies

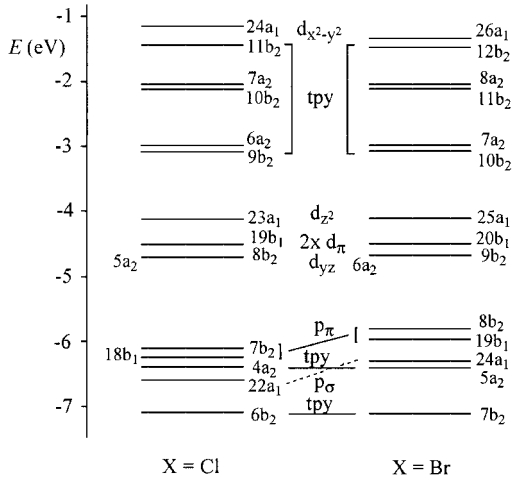

Figure 10. Relevant part of the MO diagrams of [Rh(X)(tpy)] (**1**: X = Cl; **2**: X = Br), as calculated with the ADF/BP program

(Table 3 and Figure 10). MO diagrams of complexes **1** and **2** clearly show that the comparable, predominantly Rh(d), orbitals of **1** and **2** (HOMO-1, -2, -3) have the same energies (except for empty $d_{x^2-y^2}$), which is also the case for the tpy-centred orbitals. Thus, the only comparable orbitals of **1** and **2** differing in energy are those with a predominant halide (p_π and p_σ) character (Figure 10). The variation of X in complexes **1** and **2** is reflected in the HOMO-4, HOMO-5 and HOMO-7 (X = Cl)/HOMO-6 (X = Br). These largely halide-based orbitals are ca. 0.3 eV lower in energy for complex **1** (X = Cl) than for **2** (X = Br).

According to the DFT calculations, the HOMO-1, HOMO-4 and HOMO-5 of **1** and **2** have significantly mixed X(p_π)/Rh(d_π) characters. Also, HOMO-2 of **1** and **2** is strongly mixed, tpy(π^*)/X(p_π)/Rh(d_π). In contrast, the HOMO and HOMO-3 of **1** and **2** are largely Rh(d_{z^2}) and Rh(d_{yz}), respectively, while HOMO-7 (X = Cl)/HOMO-6 (X = Br) has a predominantly halide (p_σ) character. As expected, the LUMO of **1** and **2** reside on the π^*(tpy) system, with some Rh(d_π) contribution. The higher-lying virtual orbitals of **1** and **2** are also almost exclusively localised on the π^*(tpy) system, except for LUMO+5, which is mainly Rh($d_{x^2-y^2}$).

Relevant electronic transitions (transition energies, wavelengths, oscillator strengths) of complexes **1** and **2** and their characters obtained from TD-DFT calculations are presented in Table 4 and Table 5, respectively. Apart from the first three excitations, only electronic transitions with oscillator strengths >0.015 have been incorporated.

The first seven single-electron transitions in Tables 4 and 5 are the same excitations from the comparable Rh(d) orbitals of complexes **1** and **2**. Single-electron transitions at higher energies are less similar owing to different characters of the molecular orbitals involved.

Experimental UV/Vis spectra and calculated electronic transitions for complexes **1** and **2** are shown in Figure 11 and Figure 12, respectively. The lowest seven single-electron transitions are highlighted, except for the forbidden transitions 1 of very low oscillator strengths.

Assignment of the absorption bands in the UV/Visible region (250−900 nm) is facilitated by the TD-DFT calculations. The calculated electronic transitions of complex **1** match fairly well the experimental electronic absorption spectrum, except for transition 7 (Table 4). For complex **2** the deviations in the UV region are larger. The intense ab-

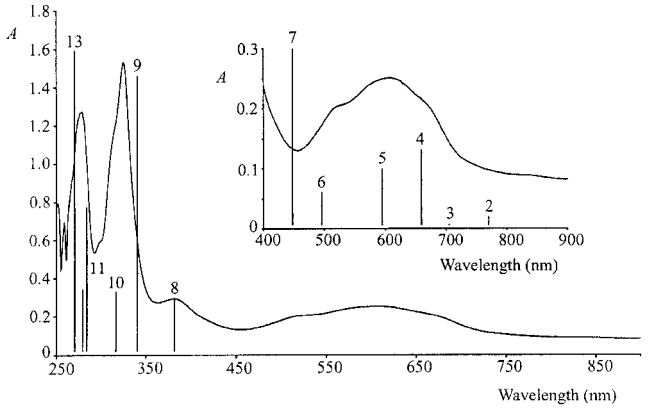

Figure 11. Electronic absorption spectrum of complex **1** (7.27×10^{-5} M) in EtOH. Major electronic transitions of complex **1**, as calculated by the ADF/BP method (Table 4)

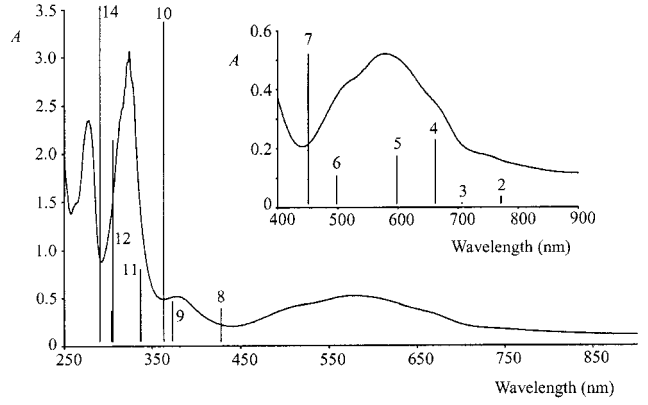

Figure 12. Electronic absorption spectrum of complex **2** (1.36×10^{-4} M) in EtOH. Major electronic transitions of complex **2**, as calculated by the ADF/BP method (Table 5)

sorption bands in the region 250−350 nm are predominantly due to intraligand tpy transitions. The pronounced composed absorption band in the 450−700 nm region encompasses mixed MLCT/XLCT (6, 5) and MLCT (4) transitions. Minor absorption bands in the region 700−900 nm belong to symmetry-forbidden (in a perfect square-planar coordination) MLCT (3), MLCT/XLCT (2) and MLCT (1; HOMO-to-LUMO) transitions.

Cyclic Voltammetry of Complexes 1 and 2

Solutions of complexes **1** and **2** in dry DMF, freshly prepared under an argon atmosphere, show very similar cyclic voltammograms. Therefore, only the cyclic voltammogram of complex **1** is depicted in Figure 13.

Electrochemical oxidation of complexes **1** and **2** is partly chemically reversible on the cyclic voltammetry time scale (ν = 100 mV s^{-1}) at room temperature (Figure 13). In accordance with DFT results (Table 3), this anodic process corresponds to a one-electron oxidation of the formal Rh^I centre to the corresponding Rh^{II} product. Further oxidation of $\mathbf{1}^+$ and $\mathbf{2}^+$ to the corresponding Rh^{III} species was not observed. The oxidation potentials of **1** and **2** show

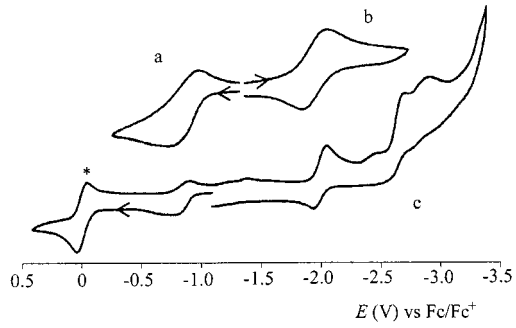

Figure 13. Cyclic voltammogram of complex **1** in DMF at a Pt disk electrode, ν = 100 mV s^{-1}: (a) Partly reversible one-electron oxidation of the Rh^I centre to Rh^{II} at T = 293 K; (b) reversible one-electron reduction of the tpy ligand at T = 233 K; (c) complete cyclic voltammogram at T = 293 K. Asterisk denotes the Fc/Fc^+ redox couple

negligible differences: $E_{1/2}$ (**1**) = −0.84 V vs. Fc/Fc^+; $E_{1/2}$ (**2**) = −0.83 V vs. Fc/Fc^+. This agrees with the DFT-calculated energies of the HOMO for both complexes, which differ merely by 0.01 eV (Table 3).

Electrochemical reduction of **1** and **2** is fully reversible on the cyclic voltammetry time scale at T = 233 K (ν = 100 mV s^{-1}) (Figure 13), being predominantly localised on the lowest π*(tpy) level (Table 3). Understandably, therefore, the reduction potentials of both complexes are nearly identical ($E_{1/2}$ (**1**) = −1.98 V and $E_{1/2}$ (**2**) = −1.97 V vs. Fc/Fc^+). The calculated LUMO energies of **1** and **2** differ to a slightly greater extent (0.036 eV).

Discussion

Syntheses of Complexes 1−4

Under the right reaction conditions, in particular with a suitable solvent, the studied Rh^I-terpyridine complexes are fairly simply synthesised, in nearly quantitative yields. The dark blue Rh^I-terpyridine products are highly air-sensitive and readily oxidise to yellow/red Rh^{III} species.

Having prepared complex **1** in toluene and washed it subsequently with hot THF, crystals were grown during gentle cooling of the combined THF phases. However, this method was unsuccessful for the crystallisation of the other studied Rh^I-terpyridine complexes. In contrast to complex **1**, complex **2** could not be synthesised in toluene; instead, only orange Rh^{III} species were formed. Complex **2** was only obtained in EtOH. Similar to complex **1**, complex **3** could be prepared in various organic solvents such as benzene, THF, Et_2O and EtOH. Attempts to synthesise the Rh−Br complex analogous to **3** only gave red oxidised products. Finally, despite the instability of the carboranyl-tpy unit in various organic solvents, complex **4** was stable for several weeks in EtOH and crystallised upon standing at room temperature.

X-ray Crystallographic Studies of Complexes 1 and 4

In contrast to the fairly facile syntheses of the studied Rh^I-terpyridine complexes, their characterisation is compli-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

cated by their low solubility in organic solvents. The crystal packing of various square-planar d^8 transition metal complexes containing rigid aromatic ligands is dominated by π−π stacking interactions,[21−23] leading to poor solubility and so hampering full characterisation. The distance between the sheets (3.508 Å) in the crystal of **1** is due to this type of π-stacking (Figure 3 and Figure 4).

Complex **4**, bearing the bulky carboranyl group,[24] was prepared to prevent such π-stacking. In the crystal, molecules of **4** are packed in discrete dimers with a Rh−Rh′ distance of 3.1503(13) Å, which is too long for a single bond but rather short for a non-bonding contact.[25] Clearly, the carboranyl group has resulted in a structure without strong π-stacking, the dimeric structure being apparently the highest degree of association possible with this ligand. Unfortunately, even this non-π-stacked complex does not dissolve well in organic solvents. Thus, preventing π-stacking is not a sufficient condition for increased solubility of Rh^I-terpyridine complexes.

Despite the dramatic difference in the packing of complexes **1** and **4**, the coordination geometries of the mononuclear units are very similar, and similar to isoelectronic Pd^{II} [26] and Pt^{II} [27] terpyridine complexes. The corresponding bond lengths (Table 1) and angles (Table 2) are almost the same. Rh−N distances for both **1** and **4** [1.891(6)−2.026(7) Å] are significantly shorter than (κ^1) Rh^{II}-terpyridine,[12] (κ^3) Rh^{II}-terpyridine[12] and (κ^3) Rh^I-diiminepyridine[6] complexes. For Rh^I-chloride complexes with the diiminepyridine ligands 2,6-bis(R^2-iminomethyl)pyridine and 2,6-bis(R^2-iminoethyl)pyridine (R^2 = *i*Pr, *t*Bu), Haarman et al. have shown that the angle between the N−N−N plane and the Rh−Cl axis is a useful measure of steric interactions between the R^2 groups and the chlorine atom.[6] In our study, these angles are 0.25(7)° for **1** and 3.4(3)° for **4**, which are much smaller than those found by Haarman et al. [5.34(16)−11.73(11)°]. We therefore conclude that steric interactions between the terpyridine ligand and the chlorine atom in complexes **1** and **4** are not significant.

FIR Spectra of Complexes 1 and 2

The Rh^I(X)-terpyridine complexes contain only a single Rh−X bond. This facilitates the analysis of their far-IR (FIR) spectra compared with those of $Rh^{III}(X)_3$-tpy[20] species. Assignment of ν(Rh−X) for **1** (256−260 cm^{-1}) and **2** (188 cm^{-1}) is straightforward. Bands at 129−138 cm^{-1} (**1**) and 85−96 cm^{-1} (**2**) are tentatively assigned to Rh−X bending vibrations. The influence of the Rh-metal oxidation state and of the absence/presence of axial halides on the ν(Rh−X) modes for Rh^I(X)-tpy and $Rh^{III}(X)_3$-tpy has not been thoroughly studied. Rh^I−X bonds are generally weaker than Rh^{III}−X bonds, due to stronger π-donation from X to Rh^{III} than to Rh^I metal ions. Therefore, the larger ν(Rh−X) wavenumbers reported for [$Rh(Cl)_3$(tpy)] (330−380 cm^{-1}) and [$Rh(Br)_3$(tpy)] (205−209 cm^{-1}) are reasonable.[20]

Bonding Properties of Complexes 1 and 2

The experimental and corresponding DFT calculated bond lengths and angles in complexes **1** and **2** (Table 1 and Table 2) are in good agreement. This confirms that the used GGA functional (Becke−Perdew), for geometry determination, and the chosen basis set for the DFT calculations, run by the ADF program, are adequate.

From the DFT calculations, the HOMO of complexes **1** and **2** is clearly located mainly on the Rh(d_{z^2}) orbital. This property, combined with the strong electron-donating nitrogen atoms coordinated at the Rh^I centre, makes complexes **1** and **2** extremely nucleophilic and, thereby, very reactive towards, e.g., oxygen and carbon−halogen bonds.[28] While the HOMO of **1** and **2** has a strong metal character, the LUMO is predominantly located on the π* system of the tpy ligand. The HOMO-1 and HOMO-2 can be characterised as antibonding combinations (π-interactions) of p(X) (X = Cl, Br) and d(Rh) orbitals. Both molecular orbitals are destabilised compared with the HOMO-3 that is mainly Rh(d_{yz}). HOMO-4 and HOMO-5 are bonding orbitals − π-interactions between p_π(X) and d_π(Rh) orbitals. HOMO-6 (X = Cl)/HOMO-7 (X = Br) have exclusively a ligand tpy character (like the HOMO-8). HOMO-7 (X = Cl)/HOMO-6 (X = Br) have predominantly a halide character (σ-interaction).

Complexes **1** and **2** feature comparable electronic transitions from orbitals of the same character (Table 4 and Table 5). The lowest seven excitations in both complexes correspond mutually very well. At higher energies, there is no longer a one-to-one relationship between the composition of the excited states of the Cl and Br complexes (**1** and **2**, respectively) in terms of one-electron transitions. After the seventh excitation, the Br p-orbitals play a more dominant role in the single-electron transitions for complex **2** than the Cl p-orbitals for complex **1**. This is mainly due to the difference in energy of the halide p-orbitals (Figure 10).

Regarding differences, for complex **2** an extra electronic transition (viz. 9, Table 5) has been calculated by the ADF/BP program, which has no counterpart in complex **1**. Furthermore, for complex **1**, the electronic transition 8 has a predominant MLCT character (Table 4), while the corresponding electronic transition 8 in complex **2** can better be assigned as XLCT (Table 5).

The MO diagrams of complexes **1** and **2** are very similar. Only the unoccupied predominantly Rh($d_{x^2-y^2}$) and occupied halide molecular orbitals of **1** and **2**, viz. LUMO+5, HOMO-4, HOMO-5 and HOMO-7 (X = Cl)/HOMO-6 (X = Br), slightly differ in energies (ca. 0.3 eV), as displayed by their molecular orbital diagrams in Figure 10. This rationalises the similar UV/Vis spectra and cyclic voltammograms of complexes **1** and **2**. Assignment of the UV/Vis absorption bands of **1** and **2** to particular types of electronic transitions is facilitated by the TD-DFT calculations. The most intense absorption bands in the UV region 250−350 nm are solely assigned as intraligand tpy transitions. The dominant and minor absorption bands and shoulders in the visible region 450−900 nm belong to mixed

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

electronic transitions that vary in nature from pure MLCT to mixed XLCT/MLCT charge transfers (Tables 4 and 5). The HOMO−LUMO transition is not symmetry allowed (Table 3), resulting in a very low oscillator strength (Tables 4 and 5). Exclusive Rh-centred (d−d, LF) transitions are not observed. The only notable d−d contribution, of limited significance (16% to transition 9) has been calculated for complex **1** (Table 4).

Complexes **1** and **2** have fairly negative oxidation potentials, strongly indicating that the Rh^I metal centres indeed accommodate high electron densities. The one-electron oxidation of formally Rh^I to Rh^{II} at room temperature is partly reversible on the time scale of seconds. The relative stability of the Rh^{II} species can be ascribed to the high electron-donating capacity of the coordinated tpy and halide ligands. Notably, the subsequent oxidation of Rh^{II} to Rh^{III} was not observed in the available potential window.

At room temperature, the initial one-electron reduction of complexes **1** and **2** in DMF is also partly chemically reversible. A fully reversible scan (ν = 100 mV/s) was achieved at T = 233 K. Long lifetimes of radical anions of **1** and **2** result from the accommodation of the added electron in the π*(tpy) LUMO, as evidenced by the DFT calculations. The subsequent thermal reaction of the radical anions most likely involves release of the halide ligand to compensate for the high electron density at the metal centre. Slow halide dissociation also occurs with the radical anion of the much less electron-rich complex [RhCl(CO)(*i*Pr_2Ph-BIAN)] [*i*Pr_2Ph-BIAN = *N*,*N*′-1,2-bis(2,6-diisopropylphenylimino)acenaphthene].[29,30]

Conclusions

We report the first successful syntheses, characterisation and determination of properties of neutral rigid square-planar Rh^I-terpyridine complexes **1**−**4**. For the syntheses, an appropriate solvent is of crucial importance for each complex. Characterisation is difficult, primarily due to the low solubility (formation of π-stacked aggregates and discrete dimers) and high reactivity of the complexes, promoted by the high electron density on the Rh centre. The Rh^I-terpyridine complexes show no steric repulsion between the halides and the tpy ligand, as evidenced by the crystal structures. Variation of the halide ligand in complexes **1** and **2** (Cl and Br, respectively) has no significant influence on the electronic structure. Their HOMO is predominantly localised on the Rh^I centre (d_{z^2}), and the LUMO resides on the tpy ligand.

Experimental Section

General Remarks: The syntheses of the Rh^I-terpyridine complexes under study and all manipulations with them were strictly performed under an inert atmosphere of purified dry argon or nitrogen, using standard Schlenk techniques. Solvents and reagents were dried and purified by standard procedures.[31] ^{1}H NMR measurements were carried out at 294 K with a Bruker AMX 300 spectrometer operating at 300 MHz. Fast Atom Bombardment (FAB^+) mass spectra were obtained with a JEOL JMS SX/SX102A four-sector mass spectrometer, coupled to a JEOL MS-7000 data system. Samples were loaded in a matrix phase (glycerol) on a stainless steel probe and bombarded with xenon atoms (3 keV). During the high-resolution FAB MS measurements a resolving power of 5000 (10% valley definition) was used. CsI and glycerol served as calibration standards. Elemental analyses were performed by H. Kolbe Mikroanalytisches Laboratorium (Mülheim an der Ruhr, Germany) and Analytische Laboratorien GmbH (Lindlar, Germany).

The tpy and 4′-chloro-2,2′:6′,2′′-terpyridine (4′-Cl-tpy) ligands are commercially available (Aldrich). Precursor complexes $[Rh(X)(COD)]_2$ (X = Cl, Br; COD = cycloocta-1,5-diene)[32] and the ligand 4′-(*tert*-butyldimethylsilyl-*o*-carboranyl)-2,2′:6′,2′′-terpyridine (carboranyl-tpy)[33] were synthesised according to literature procedures.

[Rh(Cl)(Tpy)] (1): Solutions of tpy (1.0 g, 4.3 mmol) and $[Rh(Cl)(COD)]_2$ (1.0 g, 2.0 mmol) in toluene (50 mL) were mixed and stirred together at room temperature. After five minutes, a dark blue precipitate of complex **1** was formed. The product was filtered off, washed with hot THF (3×20 mL) and dried under reduced pressure. Yield 0.7 g (95%). Gentle cooling of the collected THF phases afforded needle-shaped dark blue crystals suitable for X-ray diffraction studies. A small portion of the solid was recrystallised from hot benzonitrile as dark blue leaflets that were used for elemental analysis. FAB^+ MS: *m*/*z* = 371.98 [M^+]. $C_{15}H_{11}ClN_3Rh$ (370.97): calcd. C 48.48, H 2.98, Cl 9.54, N 11.31; found C 48.60, H 3.04, Cl 9.80, N 11.43.

[Rh(Br)(tpy)] (2): A solution of tpy (0.024 g, 0.10 mmol) and $[Rh(Br)(COD)]_2$ (0.03 g, 0.05 mmol) in EtOH (20 mL) was stirred at room temperature for 5 to 10 min, having afforded a dark blue suspension. After filtration, the so-obtained dark blue solid was washed with EtOH (3×10 mL), followed by pentane (3×10 mL). The product was then dried under reduced pressure. Complex **2** was collected as a dark blue powder in nearly quantitative yield (20 mg). FAB^+ MS: *m*/*z* = 414.92 [M^+]. $C_{15}H_{11}BrN_3Rh$ (414.92): calcd. C 43.30, H 2.66, Br 19.20, N 10.10; found C 43.28, H 2.66, Br 19.32, N 10.06.

[Rh(Cl)(4′-Cl-tpy)] (3): Solutions of 4′-Cl-tpy (0.045 g, 0.17 mmol) and $[Rh(Cl)(COD)]_2$ (0.04 g, 0.08 mmol) in toluene (10 mL) were mixed at room temperature. After stirring for 5 to 10 min, a dark blue solid precipitated that was filtered off, washed with toluene (3×10 mL), pentane (3×10 mL), and dried under reduced pressure. Complex **3** was collected as a dark blue powder in nearly quantitative yield (32 mg). FAB^+ MS: *m*/*z* = 404.93 [M^+]. $C_{15}H_{10}Cl_2N_3Rh$ (404.93): calcd. C 44.37, H 2.48, Cl 17.46, N 10.35; found C 44.26, H 2.55, Cl 17.55, N 10.18.

[Rh(Cl)(carboranyl-tpy)] (4): A solution of carboranyl-tpy (0.2 g, 0.41 mmol) and $[RhCl(COD)]_2$ (0.1 g, 0.20 mmol) in EtOH (100 mL) was stirred for 6 h at room temperature. After standing for three weeks and decanting the dark purple supernatant liquid, dark blue crystals of **4** were collected. Yield 0.11 g (90%). ^{1}H NMR (300 MHz, C_6D_6, 20 °C): δ (ppm) = 7.38 (s, 2 H), 7.09 [t, $^3J_{H,H}$ = 8 Hz, 2 H, C(5,5′′)−H], 6.94 [d, $^3J_{H,H}$ = 8 Hz, 2 H, C(3,3′′)−H], 6.84 [t, $^3J_{H,H}$ = 7 Hz, 2 H, C(4,4′′)−H], 0.65 (s, *t*Bu), −0.43 [s, −Si(Me)$_2$−]. $C_{23}H_{35}B_{10}ClN_3SiRh{\cdot}CH_3CH_2OH$ (675.27): calcd. C 44.54, H 6.13, N 6.23; found C 44.32, H 6.03, N 6.31.

Complexes **1** and **3** could also be synthesised in organic solvents other than toluene, such as benzene, THF, Et_2O and EtOH. In contrast, the syntheses of complexes **2** and **4** were only successful

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

in EtOH. Complexes **1**−**4** react rapidly with MeOH to produce unidentified red Rh^{III} species.

X-ray Structure Determination of Complexes 1 and 4: A dark blue single crystal was mounted on a capillary. Intensity data were collected at room temperature with an Enraf-Nonius CAD4 diffractometer, using the ω-2θ scan mode. Unit cell dimensions were determined from the angular setting of 25 reflections. Intensity data were corrected for Lorentz and polarisation effects. A semi-empirical absorption correction (ψ-scans)[34] was applied. The structures were solved by the program system DIRDIF,[35] using the program PATTY[36] to locate the rhodium atom, and refined with standard methods (refinement against F^2 of all reflections with SHELXL-97[37]), with anisotropic parameters for the non-hydrogen atoms. All hydrogen atoms were placed at calculated positions and refined riding on the parent atoms. A structure determination summary is presented in Table 6. PLATON[38] drawings of complexes **1** and **4** are shown in Figures 2 and 6, respectively. Selected bond lengths and angles for both crystal structures are given in Tables 1 and 2. CCDC-125107 (for **1**) and -125106 (for **4**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223-336-033; E-mail: deposit@ccdc.cam.ac.uk].

UV/Vis and FIR Spectra of Complexes 1 and 2: Electronic absorption spectra were measured with a HP 8453 diode-array spectrophotometer. Far-infrared (FIR) spectra were recorded between 75 and 375 cm^{-1} with a BOMEM DA3.02 FTIR spectrometer, using a polyethylene cell filled under an argon atmosphere. All FIR experiments used a globar light source and a helium-cooled germanium bolometer operating at 4.2 K. The spectra (128 scans) were recorded at 0.5 cm^{-1} resolution. Samples were dispersed in Nujol under an argon atmosphere.

Density Functional Theoretical (DFT) Study of Complexes 1 and 2: Density functional theory (DFT) was employed to determine the ground-state electronic structures of complexes **1** and **2**, and time-dependent density functional theory (TD-DFT) to describe the corresponding electronic transitions.[39−41] It is important to stress that the Kohn−Shan molecular orbitals, arising from DFT calculations, are physically meaningful,[42,43] and that the accuracy of excitation energies determined with TD-DFT is often similar to that of the most advanced ab initio methods.[44,45]

Calculations of geometry-optimised [Rh(Cl)(tpy)] (**1′**) and [Rh(Br)(tpy)] (**2′**) were performed with the Amsterdam Density Functional (ADF) program.[46] Crystallographic data of complex **1** were used to provide an initial estimate of the equilibrium geometry. Atomic coordinates were then projected onto a plane, and geometry optimisation was performed for the ground state. A separate optimisation was carried out for each molecule, with constrained planar geometry and C_{2v} symmetry.

For all calculations, including the geometry optimisation, the following basis sets were employed: for C, N, H, Cl and Br, an uncontracted triple-ζ Slater-type orbital (STO) basis with two polarisation functions; for Rh, an uncontracted triple-ζ STO basis with one polarisation function (5p). Core orbitals were frozen for C and N (1s), Cl (2s, 2p), Br (3s, 3p), and Rh (1s-3d).

To approximate the exchange-correlation potential, the generalised gradient approximation (GGA) was adopted, which employs the Becke gradient approximation for the exchange,[47] and Perdew approximation for correlation (ADF/BP).[48] After the geometry optimisation, calculations were performed for three different fragments of each complex molecule; the tpy ligand, Cl/Br and Rh. The ADF package allows the results of the fragment calculations to be used in ground-state calculations of each complete molecule, and the molecular orbitals (MOs) to be analysed in terms of the fragments' orbitals. In all calculations, C_{2v} symmetry was incorporated for the terpyridine ligand and the entire molecule. For the individual-atom fragments, spherical symmetry was imposed.

The ADF-RESPONSE module,[49] an extension of the ADF, was used to perform TD-DFT calculations, for the ground-state optimised geometry. These calculations provide excitation energies and relative contributions of individual occupied-to-virtual MO transitions to each excitation.

Cyclic Voltammetry of Complexes 1 and 2: Cyclic voltammetry was performed in a gas-tight cell under an inert atmosphere of dry argon. The cell was equipped with a Pt disk working electrode (apparent surface area of 0.42 mm^2), Pt wire auxiliary electrode, and Ag wire pseudoreference electrode. Before each experiment, the working electrode was carefully polished with a 0.25 μm grain diamond paste. Redox potentials are reported against the ferrocene/ferrocenium (Fc/Fc^+) redox couple, used as an internal reference standard.[50] Cyclic voltammetric experiments were performed with complexes **1** and **2** (10^{-4} M) in dry HPLC-grade dimethylformamide (DMF). The potential was controlled with a PAR Model 283 potentiostat equipped with positive feedback for ohmic drop compensation.

Acknowledgments

Prof. Anton W. Gal and Dr. Peter H. M. Budzelaar (University of Nijmegen) are thanked for their interest in this work and for their help with the syntheses.

Electrochemical Studies of Complexes with Oxo- or Hydroxo-Bridged $\{Mo_2(\mu\text{-}SMe)_3\}^+$ Centers: Cleavage of the Oxygen Bridge and Generation of Substrate-Binding Sites

Marc Le Hénanf,[a] Christine Le Roy,[a] Kenneth W. Muir,[b] François Y. Pétillon,[a] Philippe Schollhammer,[a] and Jean Talarmin*[a]

Keywords: Dinuclear complexes / Molybdenum / Electrochemical reduction / Oxo, hydroxo bridges / Protonations / Aqua ligands

The reduction of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}O)]^+$ (**1**$^+$) has been investigated by cyclic voltammetry and controlled-potential electrolysis in THF- and MeCN/NBu_4PF_6 without added acid or in the presence of various acids HX (HX: HTsO, CF_3CO_2H, HBF_4). Reduction in the presence of acid follows an $EC_{rev}E$ mechanism in which the intermediate chemical step is an acid-base equilibrium between **1** and $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}OH)]^+$ (**2**$^+$). This electrochemical process is followed by protonation of the neutral μ-hydroxo complex **2** to afford different products which depend both on the solvent (THF or MeCN) and on the nature of the acid. Controlled-potential electrolysis of **1**$^+$ in the presence of HX (2 equiv.) leads to the generation of binding sites and finally gives products identical to those obtained from protonation of **2** by HX. The complex $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}\eta^1,\eta^1\text{-}OCOCF_3)]$ (**3**) which can be obtained either by protonation of **2** by CF_3CO_2H or by reduction of **1**$^+$ in the presence of CF_3CO_2H, has been characterized crystallographically. In the presence of HBF_4 protonation of **1**$^+$ gives **2**$^{2+}$. The reactivity of **2**$^+$ and of the complexes $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(H_2O)(TsO)]$ (**4**) and $[Mo_2(cp)_2(\mu\text{-}SMe)_3(H_2O)L]^+$ (L = H_2O or THF) (**6**$^+$), all of which contain a terminal aqua ligand, has also been investigated.

Introduction

We have previously reported various aspects of the chemistry and electrochemistry of dinuclear complexes in which the metal centers are held together by thiolate bridges.[1] We have shown that the dinuclear $\{[Mo_2(Cp)_2(\mu\text{-}SMe)_3]^+\}$ entity can sustain progressive reduction of nitrogenous substrates thus modeling, in vitro, key steps of the nitrogen fixation process.[2−7] The same dinuclear center also permits the conversion of alkynes to carbyne and alkyl groups[8] and the partial reduction of C≡N bonds.[9] These transformations are facilitated by the ability of the $\{[Mo_2(Cp)_2(\mu\text{-}SMe)_3]^+\}$ core to adapt to the different modes of coordination required by different substrates. Recently, we turned our attention to oxygen-containing complexes such as $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}O)]^+$ (**1**$^+$) and $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}OH)]$ (**2**) (respectively isoelectronic with the imido and amido complexes we studied previously[5,6]) to see whether they had potential as precursors to species with sites able to bind and reduce nitrate and nitrite.[10]

Much of the published work on dinuclear complexes containing oxo- and/or hydroxo bridges has been prompted by the implication of such centers in various biological processes.[11] Electrochemical studies have been published for iron, ruthenium and manganese compounds.[12−14] In the case of molybdenum it has been reported that chemical reduction of a dinuclear complex with terminal and bridging oxo groups in acidic aqueous media affords complexes with hydroxo or aqua ligands,[15] and electrochemical studies of complexes with the $Mo_2O_2(\mu\text{-}O)_2^{2+}$ core in various aqueous buffers have shown that the terminal oxo groups are reduced to aqua ligands.[16]

In this paper, we report detailed electrochemical studies of the reactivity at the oxygen bridges in **1**$^+$ and **2**. We show that by protonation of **2** or reduction of **1**$^+$ in acidic solution it is possible to generate coordination sites suitable for occupation by oxygen-donor ligands such as the trifluoroacetate anion. Related to this, the crystal and molecular structures of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}\eta^1,\eta^1\text{-}OCOCF_3)]$ are described. The reactivity at the μ-oxo and μ-hydroxo ligands is shown to be strongly affected by the (formal) oxidation state of the metal centers in the $\{Mo(\mu\text{-}SMe)_3\}$ core. We believe that these results, obtained for dimolybdenum species, may also provide a more general insight into the reactivity of oxo and hydroxo groups when they act in a bridging role at a dinuclear metal center.

Results and Discussion

In order to examine the reactivity of the bridging oxo ligand the electrochemical reduction of $\mathbf{1}^+$ was investigated in the absence and presence of acid (tetrafluoroboric: HBF_4/H_2O or HBF_4/Et_2O; trifluoroacetic: CF_3CO_2H; *p*-toluenesulfonic: HTsO) using THF- or $MeCN/NBu_4PF_6$ as an electrolyte. Because the presence of acid is likely to lead to protonation at the oxygen bridge, we also investigated the reactivity of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}OH)]$ (**2**) with acids and its oxidative electrochemistry. For the sake of clarity, this topic is presented first.

1. Protonation and Oxidation of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}OH)]$ (2)

The μ-hydroxo complex **2** was prepared by our standard method[10] which involves treatment of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}Cl)]$[17] with an excess of KOH. This reaction produced samples of **2** contaminated with small amounts of other compounds. Repeated attempts to purify these samples failed because **2** has limited stability in solution and decomposes during column chromatography. The reactivity studies were therefore carried out with samples of **2** containing small quantities of impurities (see Figure 1,a).

Protonation of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}OH)]$, 2: Cleavage of the OH Bridge

The action of acid on **2** depends both on the solvent and on the nature of the acid. Addition of 1 equivalent of HBF_4 to a MeCN solution of **2** quantitatively[18] produced the known[4] bis(acetonitrile) complex $\mathbf{5}^+$, identified by its characteristic redox potentials (Scheme 1). Treatment of **2** with 1 equivalent of CF_3CO_2H in THF resulted in the quantitative[18] formation of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}\eta^1,\eta^1\text{-}OCOCF_3)]$ (**3**) (Scheme 1), which has been fully characterized (see Crystallographic and Experim. Sections). In both cases it is likely that initial protonation at the bridging hydroxide and binding of the conjugate base, or a solvent molecule, is followed by elimination of H_2O from the undetected aqua intermediate, $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(H_2O)(L/X)]^{n+}$ [X = CF_3CO_2, n = 0; L = MeCN, n = 1], to give the observed products. It should be noted that the ammine analogue of the intermediate can be obtained by protonation of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}NH_2)]$ by trifluoroacetic acid in THF but is also detectable by cyclic voltammetry as an intermediate on the path to $\mathbf{5}^+$ {obtained by protonation of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}NH_2)]$ by HBF_4 in MeCN}.[5] The different lifetimes of the aqua- and ammine-containing species suggest that H_2O is more labile than NH_3 at the $\{Mo_2(Cp)_2(\mu\text{-}SMe)_3\}$ site.

Complex **2** also reacted with HTsO (Scheme 1). The reaction product **4** was formed quantitatively[18] but could not be isolated or characterized. Complex **4** was formulated as $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(H_2O)(TsO)]$ by analogy with $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(NH_3)(TsO)]$ which is formed through protonation of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}NH_2)]$ by HTsO in THF.[5] Since there was a possibility that the TsO^- anion could occupy a bridging position (due to the lability of the aqua ligand compared with NH_3), we investigated the reactivity and electrochemistry of **4** in order to obtain more information about the nature of this complex.

Treatment of **4** with different substrates (MeCN, *t*BuNC, Cl^-, $CF_3CO_2^-$), respectively, produced $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(L)_2]^+$ (L = MeCN or *t*BuNC), $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}Cl)]$ or $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}\eta^1,\eta^1\text{-}OCOCF_3)]$

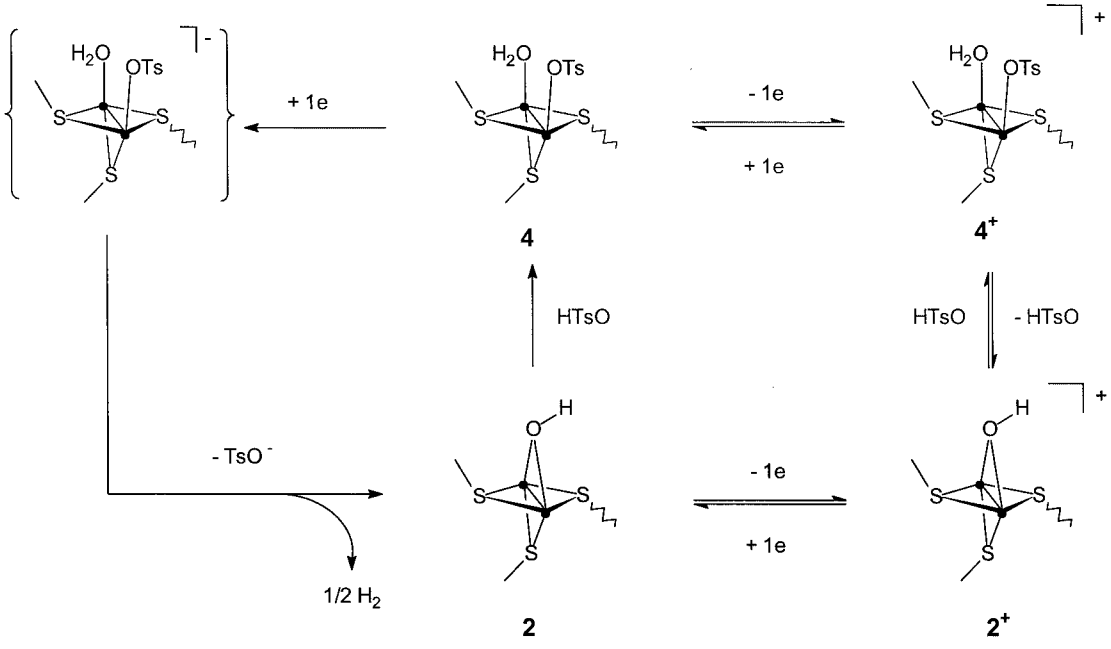
3	thf	−2.87 (irr)		−0.35	0.35
4	thf	−2.48 (irr)		−0.51	0.14
6$^+$	thf	−2.5 (irr)		−0.46	0.20

[a] Potentials were determined by cyclic voltammetry at a vitreous carbon electrode and a scan rate of 0.2 V·s^{-1}; irr: irreversible. [b] ΔEp in mV (average) measured at v = 0.2 V·s^{-1}.

(**3**). These products were characterized by their redox potentials (refs.[4,19] and Table 1) and, for the latter two complexes, by the NMR spectra of the solids isolated after completion of the reaction. This demonstrates that **4** retains the $\{Mo_2(Cp)_2(\mu\text{-}SMe)_3\}$ core.

The electrochemical study of **4** provided indirect evidence for the presence of an aqua ligand in the complex. Firstly, the electrochemical reduction of **4** (E_{el} = −2.6 V, Pt cathode, 1 F·mol^{-1} **4**) produced the hydroxo complex **2** (Scheme 2). This can be shown by comparing the CV[20] of the catholyte (Figure 2, b) with that of **2** in the presence of TsO^- (Figure 1, b). The shapes of the CV curves in Figure 1(b) and Figure 2(b) arose from the reaction of complex **2**$^+$ generated at the electrode with TsO^-. This will be detailed below. The fact that **2** is generated by a one-electron reduction of **4** is consistent with the occurrence of an aqua ligand in the latter, but cannot be reconciled with **4** being $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}OTs)]$. Secondly, the first oxidation of **4** ($E_{1/2}^{ox1}$ = −0.51 V, Table 1) shown in Figure 3(A) occurs according to an EC process[20,21] (the peak current ratio $(i_p^c/i_p^a)^{ox1}$ increases with increasing scan rates, and the product peak decreases accordingly). The product peak observed on the reverse scan can be suppressed in the presence of excess acid (Figure 3, B). This indicates that the electrochemical oxidation of **4** follows an EC_{rev} mechanism,[21] as shown in Scheme 2, the chemical step being a *reversible* proton loss from **4**$^+$. Since treatment of **2**$^+$ with HTsO afforded **4**$^+$ (see below), these results are entirely consistent with **4** being $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(H_2O)(TsO)]$.

Treatment of **2** with 1 equivalent of HBF_4/H_2O in THF resulted in partial oxidation of the starting material. When the reaction was monitored by voltammetry at a rotating disc electrode, a reduction current was detected thereby showing that some **2**$^+$ had been produced. However, **2** was not entirely converted into **2**$^+$. Cyclic voltammetry of a solution of **2** in the presence of increasing amounts of HBF_4/H_2O (1−5 equiv.) showed that new redox systems slowly increased at the expense of those due to the **2**$^{2+}$/**2**$^+$ and **2**$^+$/**2** couples (see below, oxidation of **2**). The new product **6**$^+$ ($E_{1/2}^{ox1}$ = −0.46 V and $E_{1/2}^{ox2}$ = 0.20 V, Table 1),



Scheme 2. • = Mo(Cp); methyl groups on the bridging S atoms are omitted

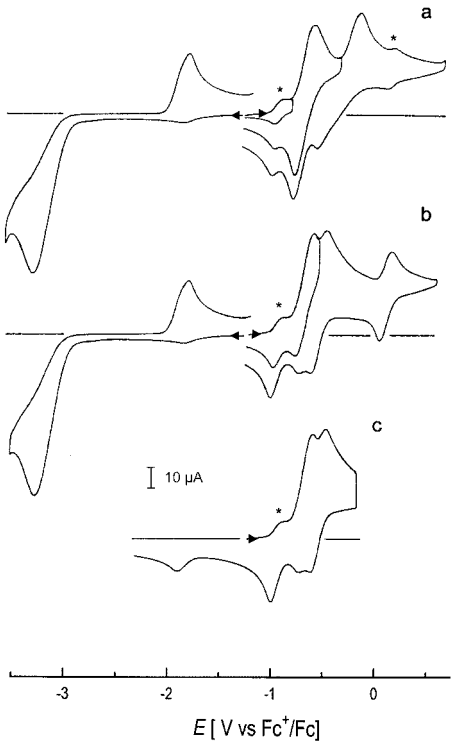

Figure 1. Cyclic voltammetry of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}OH)]$ **2** (ca. 1.2 mM) a) in the absence, and b) and c) in the presence of an excess NBu_4TsO. In scan c) the potential was held 10s at 0 V before scan reversal; under these conditions, the second (irreversible) reduction of $\mathbf{1}^+$ was observed on the reverse scan. The peaks marked with an asterisk are due to an impurity (THF/NBu_4PF_6; vitreous carbon electrode; scan rate $v = 0.2\ V{\cdot}s^{-1}$).

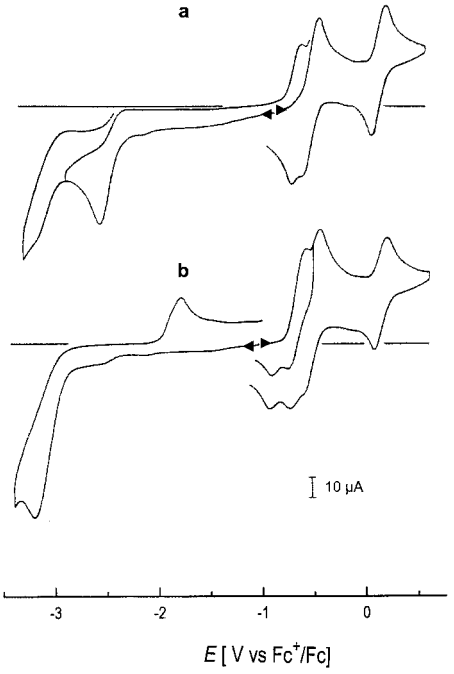

Figure 2. Cyclic voltammetry of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(H_2O)(TsO)]$ **4** (ca. 1.2 mM) a) before, and b) after electrolysis at −2.6 V (n = 1 $F{\cdot}mol^{-1}$ **4**) (THF/NBu_4PF_6; vitreous carbon electrode; scan rate $v = 0.2\ V{\cdot}s^{-1}$).

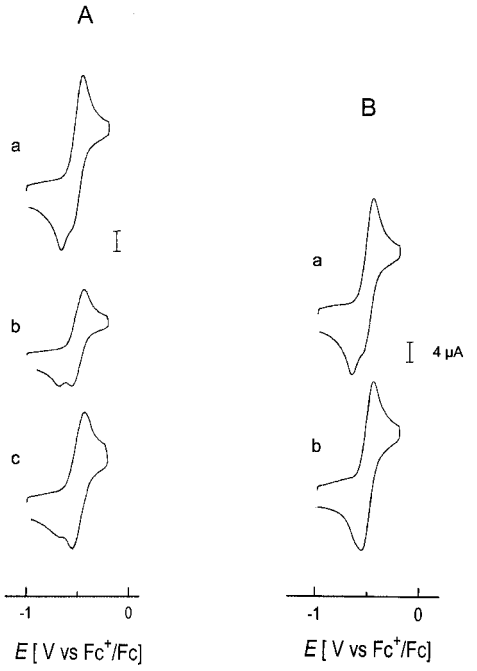

Figure 3. **A:** Cyclic voltammetry of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(H_2O)(TsO)]$ (**4**) (ca. 1.2 mM) at different scan rates a) 0.2 $V{\cdot}s^{-1}$, b) 0.5 $V{\cdot}s^{-1}$, c) 1 $V{\cdot}s^{-1}$; the current scale is 4 µA for a) and 10 µA for b) and c). **B:** Cyclic voltammetry of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(H_2O)(TsO)]$ (**4**) (ca. 1.2 mM) at $v = 0.2\ V{\cdot}s^{-1}$, a) in the absence and b) in the presence of an excess of HTsO (THF/NBu_4PF_6; vitreous carbon electrode)

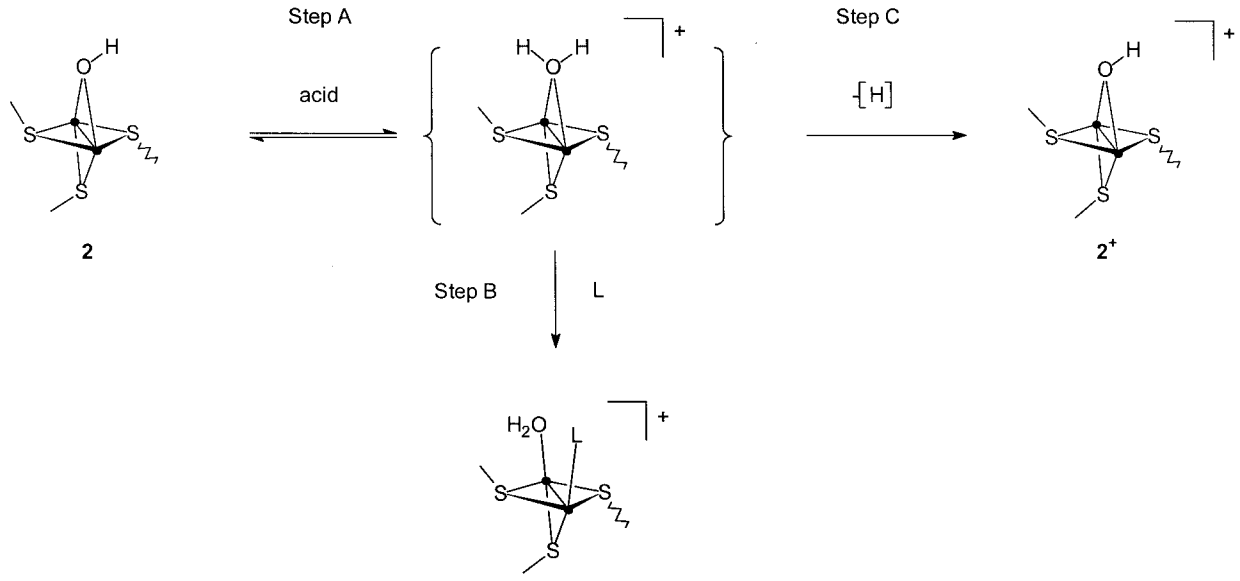
obtained as a mixture of $\mathbf{6}^+$ and $\mathbf{6}^{2+}$, formed faster when HBF_4/Et_2O replaced HBF_4/H_2O in the reaction with **2**. Complex $\mathbf{6}^+$ decomposed on workup and could not be isolated or characterized by analytical methods. However, its reactivity with different substrates demonstrated the presence of labile ligand(s) bound to the metal centers of the conserved $\{[Mo_2(Cp)_2(\mu\text{-}SMe)_3]^+\}$ core and showed a striking similarity to that of complex **4**. Addition of chloride, trifluoroacetate or acetonitrile causes the quantitative conversion[18] of $\mathbf{6}^+$ to $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}Cl)]$, **3** or $\mathbf{5}^+$, respectively. Furthermore, treatment of $\mathbf{6}^+$ with *t*BuNC produces the bis(isocyanide)[19] analogue of $\mathbf{5}^+$. Since the electrochemical behaviour of $\mathbf{6}^+$, and in particular its first oxidation step, is very similar to that of **4** (EC_{rev} process, see Scheme 2), and since treatment of $\mathbf{2}^+$ with HBF_4/H_2O afforded $\mathbf{6}^{2+}$ (see below), we have assigned $\mathbf{6}^+$ as $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(H_2O)(L)]^+$, where L could be a molecule of water or THF.

Protonation at the µ-OH ligand of **2** by HX could initially produce an intermediate with an aqua bridge (Scheme 3, step A). Subsequent coordination of the conjugate base X^- (or that of a substrate such as MeCN or *t*BuNC) would shift the H_2O ligand from a bridging to a terminal position (Scheme 3, step B). Protonation of a hydroxo bridge in tris-bridged cobalt complexes was similarly assumed to involve a µ-aqua intermediate on the path to the final product which contained terminally coordinated H_2O molecules.[22,23] Although we are not aware of stable

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim



Scheme 3. • = Mo(Cp); L = MeCN, *t*BuNC, THF or H_2O (see text); methyl groups on the bridging S atoms are omitted

Mo(μ-H_2O)Mo compounds, ruthenium,[24−26] cobalt,[27] and nickel[27] complexes containing bridging water molecule(s) have been characterized crystallographically. In these complexes, the aqua bridge appears to be stabilized via hydrogen bonds to the oxygen atom of terminally coordinated carboxylate ligands.[24−27]

Alternatively, protonation at the oxygen of **2** with concerted binding of X^- would afford directly $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(H_2O)(X)]$ (X = TsO or CF_3CO_2). This species was not detected when X = CF_3CO_2 but it was the final product **4** when X = TsO. In the absence of X^- or ligand L (protonation by HBF_4/H_2O in THF), treatment of **2** with protons led to two different types of reaction (oxidation and protonation). This suggests that two mechanisms are involved.

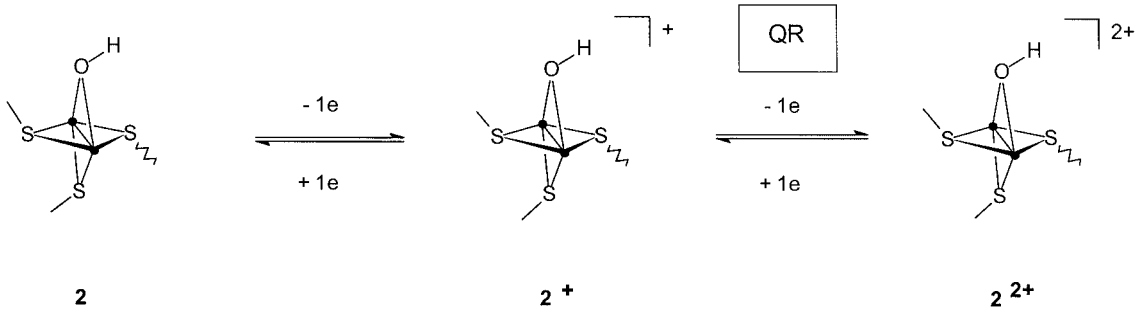
Although no kinetic measurements were performed, it appears that the rate of formation of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(H_2O)(L)]^+$ (Scheme 3), which is either a likely intermediate (L = MeCN, *t*BuNC) or the final product (L = H_2O or THF) of the protonation of **2** under different conditions, depends on the nature of both the acid (Scheme 3, step A) and of the nucleophile (Scheme 3, step B). The nature of the acid (HX) affects the concentration of the μ-aqua intermediate by perturbing the equilibrium constant [$K_{eq} = K_a^{HX}/K_a^{(\mu\text{-aqua})}$] and thus, the rate of the second-order reaction producing $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(H_2O)(L)]^+$ (Scheme 3, step B). This is shown by the fact that **6**$^+$ was obtained more rapidly when **2** was treated with HBF_4/Et_2O instead of HBF_4/H_2O. The effect of the nucleophile can be demonstrated by the fact that $[Mo_2(Cp)_2(\mu\text{-}SMe)_3L_2]^+$ (L = MeCN, *t*BuNC) was obtained "instantly" when a THF solution of **2** was treated by HBF_4/H_2O in the presence of L, while **6**$^+$ (L = H_2O or THF) was formed slowly upon treatment of **2** with HBF_4/H_2O in THF in the absence of MeCN or *t*BuNC, even though the former reaction involves a supplementary step (substitution of H_2O by a second L molecule) with respect to the latter. Substrate binding to the metal center, consecutive to (or concerted with) the cleavage of one Mo−O bond of the μ-aqua intermediate, was faster when L= MeCN or *t*BuNC than when L = H_2O or THF. The formation of **2**$^+$ observed in the latter situation could arise by loss of a hydrogen atom from the μ-aqua intermediate (Scheme 3, step C). The fate of the hydrogen atom is not known.[28]

Electrochemical Oxidation of [Mo₂(Cp)₂(μ-SMe)₃(μ-OH)], 2. Reactivity of 2⁺

With either THF or CH_2Cl_2 as solvent, complex **2** undergoes two oxidation steps; for both, the anodic-to-cathodic peak separation (ΔE_p[20]) is smaller in CH_2Cl_2 than it is in THF (Table 1, Figure 1, a). Comparison of the first oxidation peak current [$(i_p{}^a)^{ox1}$][20] for equimolar CH_2Cl_2 solutions of **2** and of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}Cl)]$ (which undergoes a reversible one-electron oxidation in this solvent[4]) indicates that the first oxidation of **2** at ca −0.6 V involves one electron on the CV timescale.[29]

The current of the second oxidation of **2** ($E_{1/2}{}^{ox2} = -0.34$ V in THF, −0.15 V in CH_2Cl_2) is lower than that of the first step in both solvents [$i_p{}^{ox2}/i_p{}^{ox1} = 0.6$ (average) in THF]. The second oxidation of **2** is quasi-reversible,[21] the large peak-to-peak separation [in THF: ΔE_p = 330 mV (average) at 0.2 V·s^{-1}][20] suggesting that a chemical reaction takes place along with the electron-transfer. The small value of the rate constant of the heterogeneous electron-transfer (k_e ca 6·10^{-4} cm·s^{-1} as estimated from CV simulations[40]) could indicate substantial structural reorganization without compositional change of the complex. Alternatively, a concerted reaction involving solvent-binding in THF is possible, since the potential and the CV peak separation of the second oxidation step are substantially affected by the nature of the solvent (Table 1). The dication cannot, however,

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim



Scheme 4. • = Mo(Cp); QR = quasi-reversible electron-transfer

be isolated. The nature of the chemical step thus remains speculative and 2^{2+} will therefore be represented formally with a bridging hydroxide group in Scheme 4 and in the rest of the paper.

The reduction peak of **2** was not altered by tosylate, thereby demonstrating that **2** and TsO^- do not react. In contrast, the oxidative part of the CV of **2** in THF was strongly affected by the presence of tosylate (Figure 1, b). Indeed, the second oxidation of **2** was not detectable when TsO^- was present. Key features of the oxidation of **2** in the presence of TsO^- include the detection of the two oxidation systems of **4** and of the reduction of the oxo complex $\mathbf{1}^+$ on the reverse scan (Figure 1, b and c). A rationalization of these features in terms of a reaction between TsO^- and electrogenerated $\mathbf{2}^+$ is presented in Scheme 5.

This has been checked independently by treating a THF solution of $\mathbf{2}^+$ electrogenerated from $\mathbf{1}^+$ in the presence of 1 equivalent of HBF_4/H_2O [see below and Figures 4(a) and 6(b)] with different substrates (MeCN, *t*BuNC, $CF_3CO_2^-$, TsO^-). The expected products, $[Mo_2Cp)_2(\mu\text{-}SMe)_3(L)_2]^+$ (L = MeCN, *t*BuNC), **3** and **4**, respectively, were obtained along with $\mathbf{1}^+$ in a ratio close to 1:1. The equilibrium in Scheme 5, formally a hydrogen atom transfer, probably arises from the deprotonation of $\mathbf{2}^+$, see below. Consistent with this, the CV of **2** in the presence of an excess of $CF_3CO_2^-$ in THF shows that the first one-electron oxidation of **2** is replaced by a reversible two-electron transfer at around −0.7 V. This is indicative of the $EC_{rev}E$ mechanism[21] shown in Scheme 6. Deprotonation of $\mathbf{2}^+$ by $CF_3CO_2^-$ produces the reduced oxo complex **1** which is oxidized at a potential more negative than that of **2** (ECE mechanism). The reversibility of the intervening chemical reaction (see below for the reduction of $\mathbf{1}^+$ in the presence of CF_3CO_2H) confers reversibility on the redox process and ensures that its potential is intermediate between those of $\mathbf{2}/\mathbf{2}^+$ and $\mathbf{1}/\mathbf{1}^+$.

Complex $\mathbf{2}^+$ could also be protonated. Addition of 1 equivalent of HTsO to a THF solution of $\mathbf{2}^+$ produced $\mathbf{4}^+$ (Figure 4). Similarly, treatment of $\mathbf{2}^+$ with HBF_4/H_2O led to $\mathbf{6}^{2+}$. These results demonstrate that $\mathbf{2}^+$ can behave both as an acid and as a base.

2. Reduction of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}O)]^+$ ($\mathbf{1}^+$)

In the Absence of Acid

Complex $\mathbf{1}^+$ undergoes an irreversible oxidation and two reduction steps in CH_2Cl_2-, THF-, or MeCN/NBu_4PF_6 (Figure 5, a). The irreversible reduction around $E_p^{red} = -1.9$ V and the irreversible oxidation were not investigated. The potential of the first reduction is essentially independent of the solvent (Table 1). From the usual diagnostic criteria ($i_p^{red1}/v^{1/2}$ independent of scan rate, v; $(i_p^a/i_p^c)^{red1}$ close

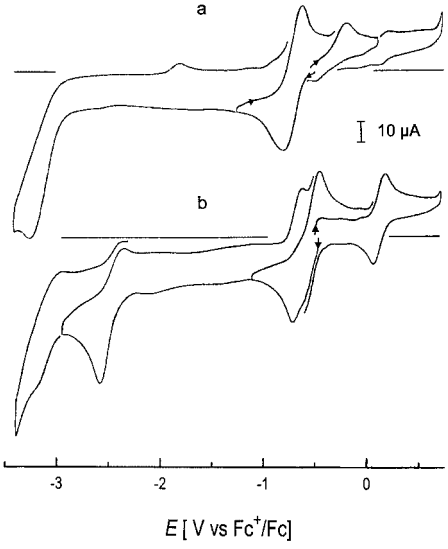

Figure 4. a) Cyclic voltammetry of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}OH)]^+$ ($\mathbf{2}^+$) generated by controlled-potential reduction (n = 1 F·mol^{-1} $\mathbf{1}^+$) of $\mathbf{1}^+$ (ca. 1.2 mM) in the presence of 1 equiv. HBF_4/H_2O; b) after addition of 1 equiv. HTsO to the solution in a). (THF/NBu_4PF_6; vitreous carbon electrode; scan rate v = 0.2 V·s^{-1})

vations have been made in the case of mononuclear imide and oxo complexes with the {Mo(dppe)$_2$} core.[30,31]

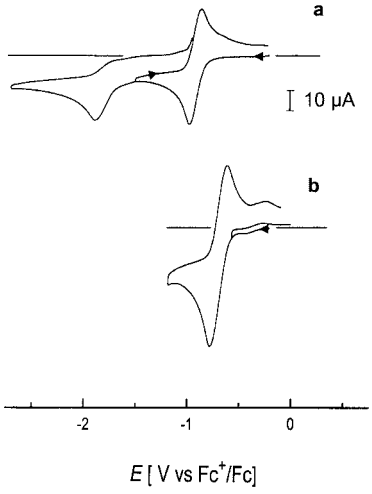

Figure 5. Cyclic voltammetry of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}O)]^+$ ($\mathbf{1}^+$) (ca. 1.5 mM) a) in the absence, and b) in the presence of 1 equivalent of HBF_4/H_2O (THF/NBu_4PF_6; vitreous carbon electrode; scan rate v = 0.2 V·s^{-1}).

to 1; ΔE_p ca 80mV),[21] the first reduction can be assigned to a reversible one-electron, diffusion-controlled step on the cyclic voltammetry timescale. The neutral oxo complex **1** is thus longer-lived than the isoelectronic imido derivative, since the reduction of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}NH)]^+$ was irreversible under the same conditions.[6] Similar obser-

Controlled-potential reduction of $\mathbf{1}^+$ in CH_2Cl_2/NBu_4PF_6 (E_{el} = −1.0 V, Pt cathode, n = 0.9 F·mol^{-1} $\mathbf{1}^+$ by coulometry) afforded **1** in essentially quantitative yield,[18] as shown by cyclic voltammetry of the catholyte. In contrast, **1** was not obtained in a THF electrolyte. Under these conditions electrolysis of $\mathbf{1}^+$ (ca. 1 F·mol^{-1} $\mathbf{1}^+$) afforded a product showing irreversible reduction and oxi-

dation processes ($E_p^{red} = -1.92$ V; $E_p^{ox} = -0.30$ V) which we have not attempted to characterize.

Reduction of 1⁺ in the Presence of Acid

The products of controlled-potential electrolyses of **1**$^+$ performed in THF and in MeCN electrolytes in the presence of acid (CF_3CO_2H, HTsO, HBF_4/H_2O) were the same as those obtained by protonation of **2** (Scheme 1). This suggested that **2** might be an intermediate in the reduction of **1**$^+$ in acidic media. However, when HTsO (in THF) or HBF_4/H_2O (in THF or in MeCN) were used, the same products as in Scheme 1 could also be obtained by controlled-potential reduction of **1**$^+$ at a potential where **2** could not be generated. The formation of these products by different pathways prompted us into a detailed investigation of the reduction mechanisms of **1**$^+$ in the presence of acid.

Addition of small amounts of HBF_4/H_2O (≤ 1 equiv.) to a solution of **1**$^+$ in THF/NBu_4PF_6 resulted in the presence of a new reversible reduction around -0.7 V. The corresponding current increased with increasing acid concentration. Comparison of the peak current of **1**$^+$ in the absence of acid (Figure 5, a) to that of the reversible system at $E_{1/2}^{red} = -0.7$ V in the presence of 1 equivalent of acid (Figure 5, b) showed that two electrons are involved in the latter reduction. This arises from the observation that complex **1** generated at the electrode is protonated to **2**$^+$, which is reducible at a less negative potential than **1**$^+$ (ECE process). The reversibility of the observed (overall) two-electron reduction and the intermediate position of its potential relative to those of the **1**$^+$/**1** and **2**$^+$/**2** couples indicates that the chemical step (protonation of **1**) is reversible and that an $EC_{rev}E$ mechanism is operative (Scheme 7, path B). In agreement with Scheme 7, compound **2**$^+$ can be generated almost quantitatively[18] by controlled-potential reduction of **1**$^+$ in the presence of 1 equivalent of HBF_4/H_2O (THF/NBu_4PF_6; $E_{el} = -0.9$ V; Pt or graphite cathode, electrolysis interrupted after the passage of 1 F mol^{-1} **1**$^+$) (Figure 6, b).

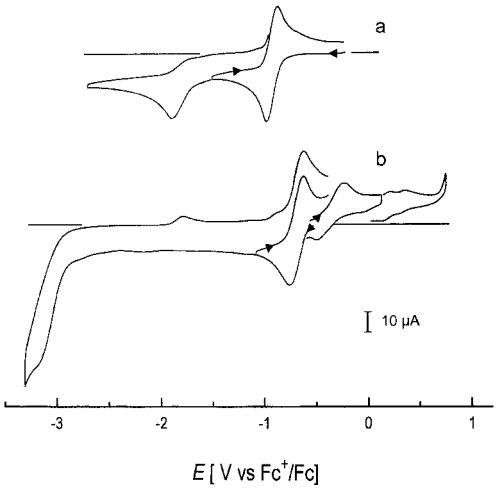

Figure 6. Cyclic voltammetry of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}O)]^+$ (**1**$^+$) (ca. 1.5 mM) a) before and b) after controlled-potential reduction ($E_{el} = -0.9$ V; $n = 1$ F·mol^{-1} **1**$^+$) in the presence of 1 equivalent of HBF_4/H_2O (see the solution in Figure 5,b) (THF/NBu_4PF_6; vitreous carbon electrode; scan rate $v = 0.2$ V·s^{-1}).

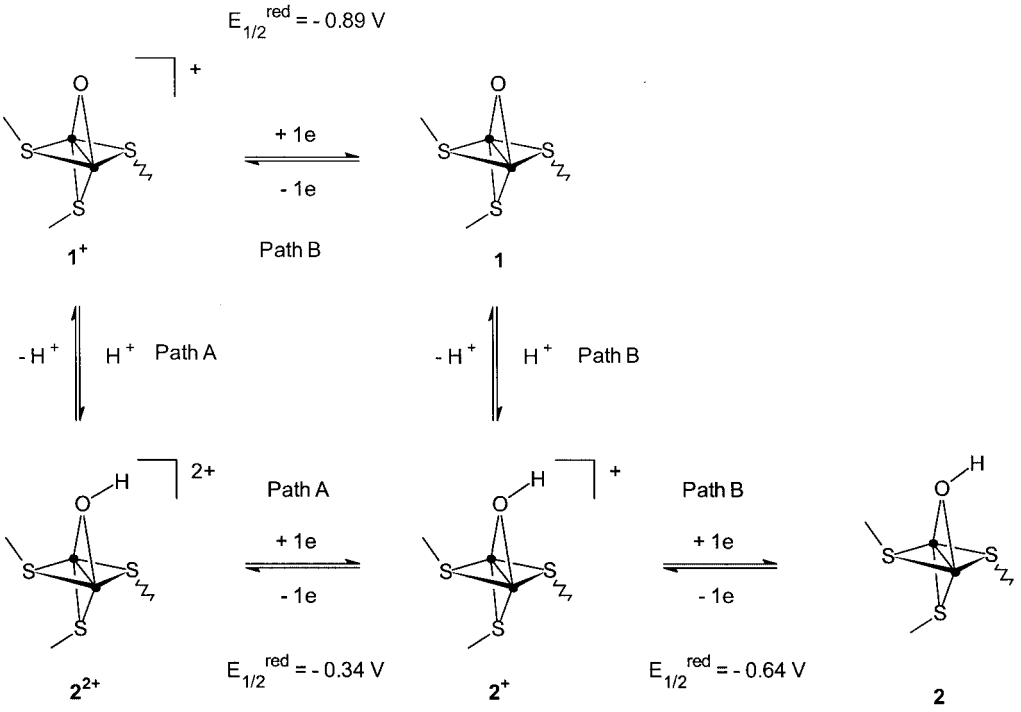
Further additions of HBF_4/H_2O (> 1 equiv.) to a THF solution of **1**$^+$ led to the increase of the quasi-reversible reduction of **2**$^{2+}$ at $E_{1/2}^{red} = -0.34$ V while the reversible couple was slightly suppressed (Figure 7). These obser-



Scheme 7. • = Mo(Cp); methyl groups on the bridging S atoms are omitted

vations demonstrate that $\mathbf{1}^+$ can be protonated by HBF_4/H_2O in THF (Scheme 7, path A), which is reminiscent of the behavior of the imide analogue of $\mathbf{1}^+$ in acidic media, since protonation of the imide cation to the amide dication was also observed.[6] The protonation of $\mathbf{1}^+$ is reversible, since it is still possible to detect the irreversible oxidation of $\mathbf{1}^+$ in the presence of acid, with little modification of the corresponding peak current. The first steps of the reduction mechanism of $\mathbf{1}^+$ in the presence of HBF_4/H_2O are presented in Scheme 7. We believe that the reactions of $\mathbf{2}^+$ with substrates, which are depicted as hydrogen atom transfers in Scheme 5, actually arise from the acid-base equilibrium in Scheme 7, path B. Complex **1** formed by deprotonation of $\mathbf{2}^+$ would be oxidized by $\mathbf{2}^+$ in a homogeneous redox reaction ($E_{1/2}^{red}$ $\mathbf{2}^+ = -0.64$ V; $E_{1/2}^{ox}$ **1** $= -0.89$ V) producing **2** and $\mathbf{1}^+$. Protonation of **2** would then afford the μ-aqua intermediate (Scheme 8). The overall reaction in Scheme 8 is equivalent to the equilibrium in Scheme 5.

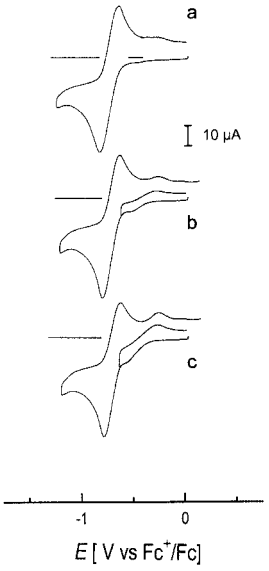


Figure 7. Cyclic voltammetry of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}O)]^+$ ($\mathbf{1}^+$) (ca. 1.4 mM) in the presence of a) 1 equivalent, b) 2 equivalents, and c) 3 equivalents of HBF_4/H_2O (THF/NBu_4PF_6; vitreous carbon electrode; scan rate $v = 0.2$ V·s^{-1}).

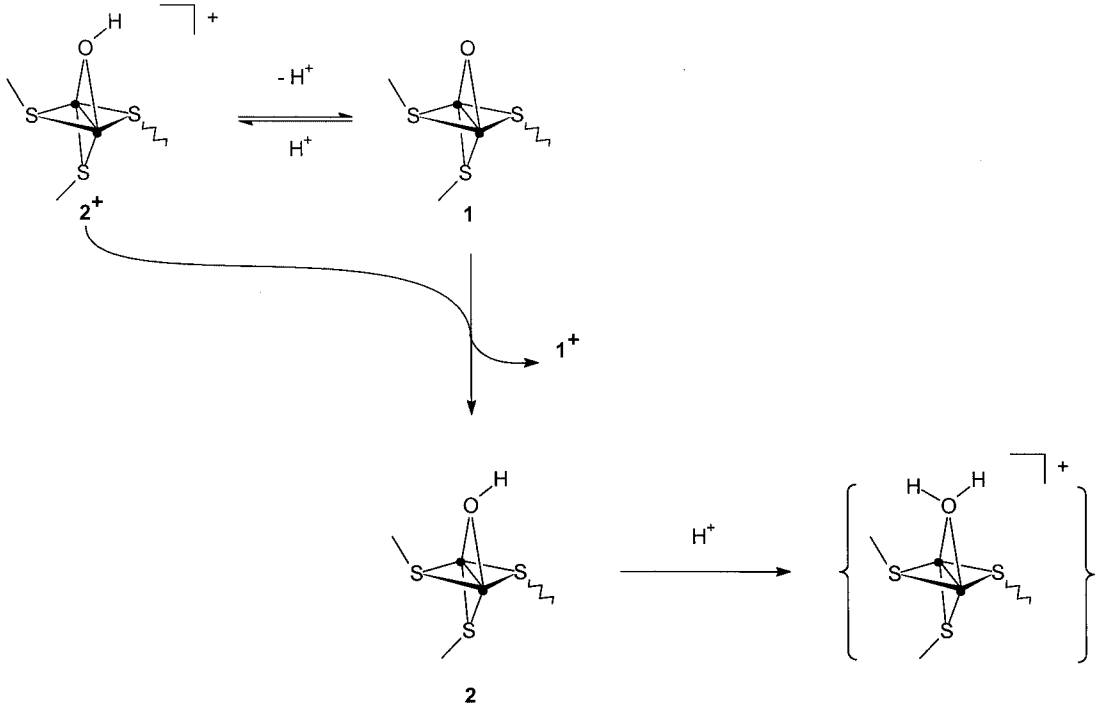
In addition to the increase of the $\mathbf{2}^{2+}/\mathbf{2}^+$ quasi-reversible reduction, addition of acid (> 2 equiv. HBF_4/H_2O) causes a gradual loss of reversibility of the two-electron reduction around −0.7 V, with $(i_p^a/i_p^c) < 1$ at slow scan rates. This shows the occurrence after the $EC_{rev}E$ mechanism of other chemical step(s) which eventually lead to $\mathbf{6}^+$. Controlled-potential electrolysis of $\mathbf{1}^+$ performed at −0.9 V (Pt cathode; $n = 2.2\pm0.2$ F·mol^{-1} $\mathbf{1}^+$ [32]) in the presence of an excess (> 3 equiv.) of HBF_4/H_2O effectively produces $\mathbf{6}^+$, characterized by two one-electron oxidation steps and by an irreversible reduction (Table 1). Electrolyses carried out at −0.5 V, a potential which does not permit the reduction of $\mathbf{2}^+$, also produced $\mathbf{6}^+$ after transfer of ca 2 F·mol^{-1} $\mathbf{1}^+$.[32] Under the latter conditions the formation of $\mathbf{6}^+$ occurs exclusively via reduction of $\mathbf{2}^{2+}$ and subsequent protonation of $\mathbf{2}^+$ (Schemes 7 and 9, path A). We have checked, in separate experiments, that addition of HBF_4/H_2O to a solution of $\mathbf{2}^+$ effectively produces $\mathbf{6}^{2+}$. The different mechanisms leading to the formation of the product, $\mathbf{6}^+$, are described by Schemes 7 and 9.

We have already mentioned that oxidation of $\mathbf{6}^+$ occurs according to an EC_{rev} process where the chemical step is a proton transfer. This protonation equilibrium (between $\mathbf{2}^+$



Scheme 8. • = Mo(Cp); methyl groups on the bridging S atoms are omitted

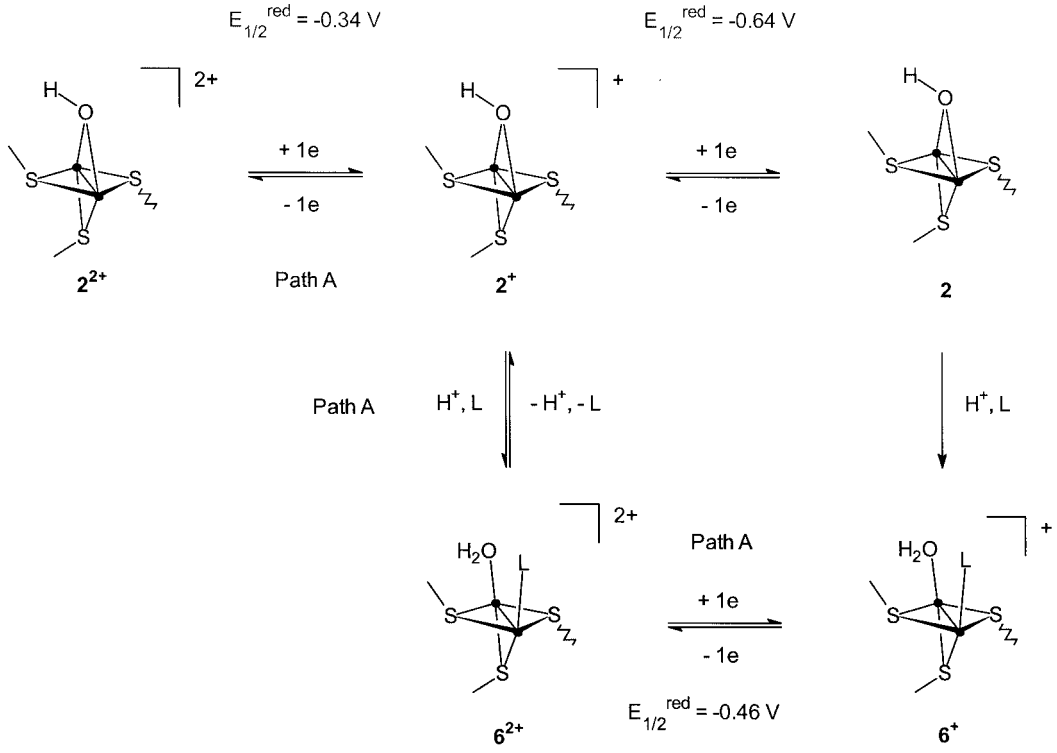

Scheme 9. • = Mo(Cp); methyl groups on the bridging S atoms are omitted

and $\mathbf{6}^{2+}$) is entirely consistent with the results of the electrochemical study of the reduction of $\mathbf{1}^{+}$ in the presence of HBF_4 (Scheme 9).

The electrochemical reduction of $\mathbf{1}^{+}$ in the presence of HBF_4/H_2O in MeCN follows the same type of mechanism as in THF (Schemes 7 and 9), except that the products $\mathbf{6}^{2+}$ and $\mathbf{6}^{+}$ are replaced by $\mathbf{5}^{2+}$ and $\mathbf{5}^{+}$, respectively.

In the presence of trifluoroacetic acid (2 equiv.; THF/NBu_4PF_6), the CV of $\mathbf{1}^{+}$ also shows a reversible overall two-electron reduction with $E_{1/2}^{red} = -0.72$ V, indicative of an $EC_{rev}E$ mechanism (see Scheme 6, Figure 8, a). The decrease of the anodic-to-cathodic peak current ratio $[(i_p^a/i_p^c)^{red}]$ with decreasing scan rates demonstrates that the $EC_{rev}E$ process is followed by one or more further chemical steps. Consistent with this observation, two reversible one-electron oxidations were detected at $E_{1/2}^{ox1} = -0.35$ V (Figure 8, a) and $E_{1/2}^{ox2} = 0.35$ V (not shown on Figure 8, a) on the reverse scan. These are due to $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}\eta^1,\eta^1\text{-}OCOCF_3)]$ (**3**) as is evident by comparison with the redox potentials of an authentic sample of this complex. Controlled-potential electrolysis performed under these conditions at the potential of the reduction step (Pt cathode, 1.6 F·mol^{-1} $\mathbf{1}^{+}$) produced **3** almost quantitatively[18] (Figure 8, b). The nature of the product was confirmed by comparison of the ^1H and ^{19}F NMR spectra of the solid isolated from the catholyte to those of an authentic sample of **3** prepared independently and characterized crystallographically (see below).

The reduction of $\mathbf{1}^{+}$ in the presence of HTsO was also investigated. Addition of 1 equivalent of acid resulted in the

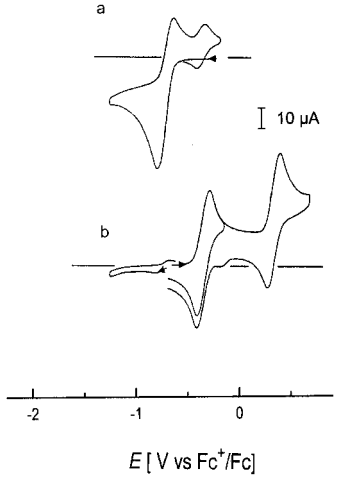

Figure 8. Cyclic voltammetry of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}O)]^{+}$ ($\mathbf{1}^{+}$) (ca. 1.4 mM) in the presence of 2 equivalents CF_3CO_2H a) before, and b) after controlled-potential reduction at −0.95 V (1.6 F·mol^{-1} $\mathbf{1}^{+}$) (THF/NBu_4PF_6; vitreous carbon electrode; scan rate $v = 0.2$ V·s^{-1})

presence of a reduction peak at −0.68 V. Comparison of the corresponding current with that of $\mathbf{1}^{+}$ in the absence of acid indicated that more than one electron is involved in the process. In contrast with the CV recorded in the presence of 1 equivalent of HBF_4/H_2O or CF_3CO_2H, the reduction is not fully reversible $[(i_p^a/i_p^c) < 1]$ and the redox systems of **4** were detected on the return scan. This is again consistent with an initial $EC_{rev}E$ mechanism, but in this case the prod-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

uct-forming reaction subsequent to the electrochemical process is faster than in previous examples. This might be due to two factors: (i) formation of the product requires less rearrangement for **4** than it does, for example, for **3** and (ii) formation of **4** is faster than that of $\mathbf{6}^+$ due to either a concerted attack of HTsO on **2** (and/or $\mathbf{2}^+$) or to a faster binding to the μ-aqua intermediate (see above) of TsO^- compared with L (L = H_2O or THF).

Controlled-potential electrolysis of $\mathbf{1}^+$ in the presence of 2 equivalents of HTsO produced **4** quantitatively[18] after transfer of ca 2 $F\cdot mol^{-1}$ $\mathbf{1}^+$. Since protonation of $\mathbf{2}^+$ by HTsO afforded $\mathbf{4}^+$ (Figure 4), two different pathways (similar to paths A and B in Scheme 9) can be followed. Evidence for the formation of $\mathbf{4}^+$ was obtained by voltammetry at the rotating disc electrode of the catholyte after the electrolysis was interrupted after passage of 1 $F\cdot mol^{-1}$ $\mathbf{1}^+$: this showed the presence of both **4** and $\mathbf{4}^+$ in the solution.

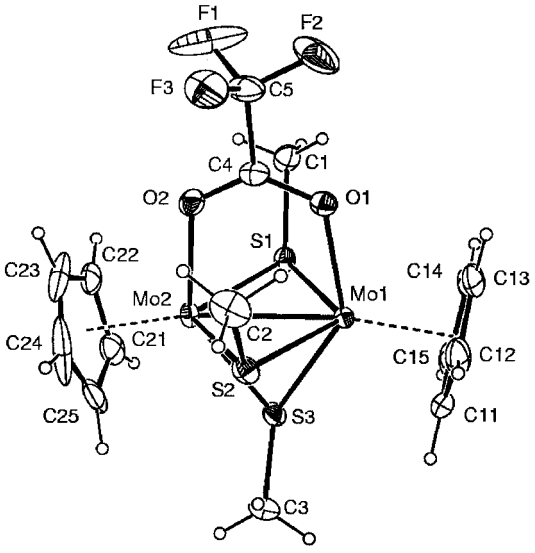

Figure 9. The molecular structure of $[Mo_2(cp)_2(\mu\text{-}SMe)_3(\mu\text{-}\eta^1,\eta^1\text{-}OCOCF_3)]$ (**3**) showing 20% ellipsoids

Solid State Structure of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}\eta^1,\eta^1\text{-}OCOCF_3)]$ (3)

The results of a single-crystal X-ray diffraction study of **3** (Figure 9, Table 2) confirmed the molecular structure proposed on the basis of the spectroscopic and analytical data presented in the Experim. Section. In particular, they demonstrate that the μ-hydroxo ligand in **2** has been replaced by a bridging trifluoroacetate group in **3**.

In the structure of **3** the two molybdenum atoms [Mo−Mo = 2.709(1) Å] are linked by four bridging ligands: three methylthiolates and a trifluoroacetate group. Each metal atom thereby attains a four-legged piano-stool coordination. This dinuclear structure is of a novel type in as much as that structurally characterized μ-carboxylato−Mo_2^{III} species are usually triply-bridged compounds with long Mo−Mo bonds e.g. in $[\{Mo_2(NC_6H_4CH_3)(S_2POEt_2)\}_2(\mu\text{-}S)(\mu\text{-}SR)(\mu\text{-}O_2CCF_3)]$ (R = H, Me),[33] and $[L_2Mo_2(\mu\text{-}O)(\mu\text{-}O_2CCH_3)_2]^{2+}$ (L = *N*,*N*′,*N*′′-trimethyl-1,4,7-triazacyclononane)[34] the Mo−Mo distances are 2.839(2), 2.844(1), and 2.885(1) Å, respectively. The Mo−Mo bond in the quadruply-bridged dinuclear molybdenum(IV) complex $[(Cp^*Mo)_2(\mu\text{-}O_2CMe)_2(\mu\text{-}PMe_2)(\mu\text{-}CH_3)]$ [Mo−Mo = 2.845(1) Å][35] is also significantly longer than that in **3**. However, Poli et al. recently reported a short Mo−Mo bond of 2.553(1) Å in the quadruply-bridged molybdenum(IV) complex $[(Cp^*Mo)_2(\mu\text{-}O)_2(\mu\text{-}O_2CMe)_2]$;[36] this contrasts with the long Mo−Mo bond [2.799(4) Å] found in the related triply-bridged molybdenum(IV) compound $[(Cp^*MoCl)_2(\mu\text{-}O)(\mu\text{-}Cl)(\mu\text{-}O_2COH)]$.[37] Metal−metal bonds in comparable thiolato-bridged bimetallic anions $[\{Mo(CO)_3\}_2(\mu\text{-}SR)_2(\mu\text{-}O_2CR')]^-$ {R = C_6H_5, *p*-ClC_6H_4; R′ = CMe_3, CF_3, $C(Me)=CH_2$}[38] where the molybdenum atoms are in low oxidation states (e.g. I) are much longer (ca. 2.91 Å) than that in **3**. It is clear, then, that the oxidation states of the metal atoms and the number and size of the bridging groups all play a part in bringing about the large variations

in the Mo-Mo distances found in these μ-carboxylato complexes.[33,38]

The mean Mo−S bond length in **3** (2.436 Å) is comparable with values for other acetato−thiolato-bridged compounds, such as $[\{Mo_2(NC_6H_4CH_3)(S_2POEt_2)\}_2(\mu\text{-}S)(\mu\text{-}SR)(\mu\text{-}O_2CCF_3)]$,[33] and $[\{Mo(CO)_3\}_2(\mu\text{-}SR)_2(\mu\text{-}O_2CR')]^-$[38] (average 2.456 Å). However, the shorter Mo−Mo bond in **3** requires the Mo−S−Mo angles to be more acute (average 67.5°) than those in the above mentioned compounds (average 72.0°).[33,38] The structural features of the CF_3CO_2 ligand, in particular the nearly equal C(4)−O(1) and C(4)−O(2) bond lengths of 1.258(5) and 1.245(5) Å, are unexceptional[33−38] and indicate π-electron delocalization over the O(1), O(2), and C(4) atoms. The Mo−O distances of 2.174(3) and 2.173(3) Å indicate single bonds. They are significantly shorter than values in neutral, triply-bridged dimolybdenum(III) complexes with acetate ligands (average 2.267 Å),[33] but are close to those in neutral, quadruply-bridged dimolybdenum(IV) compounds (average 2.161 Å).[36]

The heavy atom skeleton of **3**, excluding C3 and F1−F3, has approximate mirror symmetry: none of the nine atoms Mo1, Mo2, S3, O1, O2, C4, C5, C13, and C23 lie more than 0.04 Å from their common plane.

Conclusion

This work has illustrated the reactivity both of bridging oxo and hydroxo ligands in acidic media and of aqua ligands. It leads to four main conclusions.

(A) We have shown that protonation at a μ-OH ligand in a dimolybdenum complex is possible. Depending on the conditions (nature of the conjugate base, presence of a π-acid ligand L), the product can either retain the protonated OH bridge as a terminally bonded H_2O ligand or give rise to a disubstituted complex after elimination of a water molecule. It follows that protonation of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}OH)]$ gives ready access to one or more coordination sites at the metal centers.

(B) The reactivity of $\mathbf{2}^+$, due to its amphoteric nature, is also quite rich. Protonation of $\mathbf{2}^+$ by HTsO or HBF_4/H_2O in THF produces $\mathbf{4}^+$ or $\mathbf{6}^{2+}$, respectively. On the other hand, the products obtained on addition of CF_3CO_2H to $\mathbf{2}^+$, that is $\mathbf{1}^+$ and **3**, result from the reaction of the trifluoroacetate anion with the μ-aqua complex (see Scheme 5), rather than from protonation of the μ-hydroxo cation. The equilibrium in Scheme 5, which is formally a hydrogen atom transfer, could result from an acid-base equilibrium between $\mathbf{2}^+$ and **1**, coupled to a redox reaction between these species (Scheme 8).

(C) Both the oxo cation, $\mathbf{1}^+$, and its reduced form, **1**, can be protonated. The difference in pK_a between the $\mathbf{2}^{2+}$ and $\mathbf{2}^+$ forms can be estimated from the thermochemical cycle in Scheme 7. This ΔpK_a value, which is approximate because of the quasi-reversible nature of the $\mathbf{2}^{2+}/\mathbf{2}^+$ couple, is around 11 units in MeCN [$E_{1/2}(\mathbf{2}^{2+}/\mathbf{2}^+) = -0.24$ V; $E_{1/2}(\mathbf{1}^+/\mathbf{1}) = -0.89$ V] and about 9 units in THF [$E_{1/2}(\mathbf{2}^{2+}/\mathbf{2}^+) = -0.34$ V; $E_{1/2}(\mathbf{1}^+/\mathbf{1}) = -0.89$ V]. Similarly, the ΔpK_a between the $\mathbf{2}^+$ and **2** forms can be estimated using the redox potentials of the $\mathbf{2}^+/\mathbf{2}$ and $\mathbf{1}/\mathbf{1}^-$ reduction steps; in this case, ΔpK_a is about 20 units. Although this figure is at best a rough estimate since the $\mathbf{1}/\mathbf{1}^-$ irreversible reduction is shifted from the thermodynamic potential, it nevertheless illustrates the dramatic effect of the metal core oxidation state on the acidity of the μ-OH proton.

Since $\mathbf{1}^+$ can be protonated by HBF_4/H_2O to give $\mathbf{2}^{2+}$ it is possible to generate coordination sites (and access to $\mathbf{6}^+$ or products derived therefrom) at a potential ca 0.4 V less negative than would be required in the absence of such a protonation step. This conclusion is important for any consideration of biological processes involving redox enzymes since the range of potentials accessible to natural reductants is restricted.

(D) We have also shown that electrochemical reduction of a species containing a terminal aqua ligand leads to a hydroxo bridge (with elimination of a hydrogen atom). Oxidation of a compound containing terminally bonded water also affords a bridging hydroxide after the release of a proton. This kind of redox-induced reactivity at a terminal aqua ligand could also be relevant to different types of enzyme-driven reactions.

Experimental Section

Methods and Materials: All the experiments were carried out under an inert atmosphere using Schlenk techniques for the syntheses. Tetrahydrofuran (THF) was purified as described previously.[6] Acetonitrile (Merck, HPLC grade) was used as received. The acids, *p*-toluenesulfonic (Prolabo), trifluoroacetic (Aldrich), fluoroboric (diethyl ether complex and aqueous solution, Aldrich), were used as received. The preparation and purification of the supporting electrolyte NBu_4PF_6 and the configuration of the electrochemical equipment were as described previously.[6] All the potentials (text, tables, figures) are quoted relative to the ferrocene−ferrocenium couple. Ferrocene was added as an internal standard at the end of the experiments. ^1H NMR spectra were recorded on a Bruker AC300 spectrometer. Shifts are relative to tetramethylsilane as an internal reference. Chemical analyses were carried out at the Centre de Microanalyses du CNRS, Vernaison. Complexes $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}O)]^+$ ($\mathbf{1}^+$), $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}OH)]$ (**2**), and $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(L)_2]^+$ were synthesized as described previously.[4,10,19]

Synthesis of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}\eta^1,\eta^1\text{-}OCOCF_3)]$ (3): $[Mo_2(cp)_2(\mu\text{-}SMe)_3(MeCN)_2][BF_4]$ (100 mg, 0.158 mmol) and a 0.346 M solution (450 μL of) of $Et_4NCF_3CO_2/H_2O$ prepared by neutralization of a THF solution of CF_3CO_2H by Et_4NOH (40% in methanol) were added to THF (20 mL). After stirring for 5 minutes the dark red solution was evaporated to dryness. The residue was stirred with pentane (100 mL), the dark red solution was filtered, and pentane was evaporated under vacuum. After stirring in cold pentane and elimination of the solvent by filtration, the solid was vacuum dried. Yield 80 mg (0.139 mmol, 88%). C,H analysis for $C_{15}H_{19}O_2F_3S_3Mo_2$ (575.8): calcd. C, 31.3, H 3.3; found C 31.6, H 3.4. ^1H NMR, $(CD_3)_2CO$: δ = 5.36 (s, 10 H, C_5H_5), 1.53 (s, 3 H, SCH_3),1.38 (s, 3 H, SCH_3), 1.32 (s, 3 H, SCH_3). ^{19}F NMR $(CD_3)_2CO$: −73.9 (CF_3CO_2).

X-ray Analysis: Crystals of $[Mo_2(Cp)_2(\mu\text{-}SMe)_3(\mu\text{-}\eta^1,\eta^1\text{-}OCOCF_3)]$ (**3**) were obtained at room temperature from a pentane solution. Measurements were made with a plate-shaped crystal, 0.30 × 0.30 × 0.03 mm, on a Nonius CAD4 diffractometer with Mo-K_α X-rays, λ = 0.71073 Å. Intensities were estimated from ω/2θ scans and corrected empirically for absorption from ψ-scans (transmission factors 0.640−0.953). The structure was solved by Patterson methods and refined by full-matrix least-squares on F^2 using all independent reflections with $2\theta < 60°$.[39] Hydrogen atoms rode on their parent carbon atoms. A single orientation parameter was refined for each methyl group.

Crystal data for **3**, $C_{15}H_{19}F_3Mo_2O_2S_3$; M = 576.36, monoclinic, space group $P2_1/c$, a = 12.8796(5), b = 9.0131(5), c = 16.8558(5) Å, β = 91.411(3)°, V = 1956.11(14) Å^3, Z = 4, T = 20 °C, $\rho_{calcd.}$ = 1.957 g cm^{-3}, μ(Mo-K_α) = 1.636 mm^{-1}, F(000) = 1136, 7166 reflections collected, 5675 unique (R_{int} = 0.0240), 229 parameters refined, $R1$ = 0.0705 and $wR(F^2)$ = 0.0903 over all 5675 data used in refinement. Extreme Δρ values: 0.79−0.67 e·Å^{-3}.

CCDC-216408 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Center, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: + 44-1223-336-033; or E-mail: deposit@ccdc.cam.ac.uk.

[32] The fact that *n* is slightly larger than the theoretical value (2.0) when the electrolysis potential is −0.9 V can be attributed to the fact that small amounts of $\mathbf{2}^{+}$ produced by protonation of **2** (see Schemes 5 and 8) are reduced back to **2**. The extra charge consumed thus results in the reduction of H^{+} to H[28] via the $\mathbf{2}^{+}/\mathbf{2}$ couple. When the electrolysis is performed at a potential which does not allow the $\mathbf{2}^{+} \rightarrow \mathbf{2}$ reduction ($E_{el} = -0.5$V), the charge consumed is $n \leq 2$ F·mol^{-1} $\mathbf{1}^{+}$.

The First (Trisulfoxide)metal Complexes: Synthesis and Crystal Structures of the 1D Lanthanide Coordination Polymers $[Ln(L)(MeOH)(NO_3)_3]_n$ and $\{[La(L)(DMF)_5](ClO_4)_3\}_n$ [L = 1,3,5-Tris(ethylsulfinyl)-2,4,6-trimethylbenzene, Ln = La^{III} and Nd^{III}]

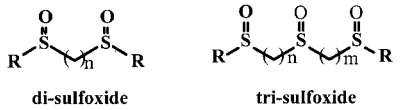
Jian-Rong Li,[a] Xian-He Bu,*[a,b] and Ruo-Hua Zhang[a]

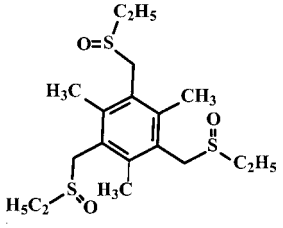
Keywords: Coordination polymers / Helical structures / Lanthanides / Sulfoxide

A new trisulfoxide ligand, 1,3,5-tris(ethylsulfinyl)-2,4,6-trimethylbenzene (L), was designed and synthesized, and treated with $Ln(NO_3)_3$ or $Ln(ClO_4)_3$ to produce three coordination polymers: $[Ln(L)(MeOH)(NO_3)_3]_n$ [where Ln = La^{III} (**1**); Nd^{III} (**2**)] and $\{[La(L)(DMF)_5](ClO_4)_3\}_n$ (**3**). Solid-state structures of all three complexes were determined by single-crystal X-ray diffraction. The three complexes have 1D helical-chain structures and complexes **1** and **2** are isostructural. To the best of our knowledge, these coordination polymers are the first examples of (trisulfoxide)metal complexes.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

Introduction

In recent years, much effort has been invested in attempts to design and synthesize metal-organic coordination polymers having specific network topologies and potential applicable properties.[1,2] In this regard, the studies performed by us and others[3] on the construction of coordination architectures using flexible disulfoxide ligands and metal ions as building blocks have acquired some interesting results. We are, therefore, interested in further exploiting the multisulfoxide ligands. Such ligands may produce interesting coordination polymers because of their multiple coordination modes. As a continuation of this study, we designed a new trisulfoxide ligand, 1,3,5-tris(ethylsulfinyl)-2,4,6-trimethylbenzene (L) (see structure shown below), which is a simple tridentate ligand. Since each S atom is an asymmetric center, the tridentate L molecule should be a chiral bridging ligand. Therefore, the ligand may be used to construct non-centric framework polymers (or chiral crystals). To the best of our knowledge, (trisulfoxide)metal complexes have not yet been reported and the lanthanide complexes presented here are the first structurally characterized examples of metal complexes with such ligands. Herein, we report the synthesis and crystal structures of three novel lanthanide complexes with L, $[Ln(L)(CH_3OH)(NO_3)_3]_n$ [where Ln = La (**1**); Nd, (**2**)] and $\{[La(L)(DMF)_5](ClO_4)_3\}_n$ (**3**).





L

Results and Discussion

Synthesis and General Characterization

The ligand L was synthesized according to a similar method used for the synthesis of disulfoxide[4] and the product might have been a mixture containing several isomers of the trisulfoxides. The attempts for separation were not successful so the mixture was used directly to prepare the metal complexes. The IR data of L show the characteristic band of the sulfinyl group (S=O) at 1022 cm^{-1} and the C−S stretching vibration at 756 cm^{-1}.[5]

The complexes **1**−**3** were prepared by the reaction of L with $Ln(NO_3)_3{\cdot}nH_2O$ or $Ln(ClO_4)_3{\cdot}nH_2O$ in the presence of triethyl orthoformate (see Scheme 1). The complexes are soluble in DMF and DMSO, and slightly soluble in CH_3OH and CH_3CN, but almost insoluble in H_2O and acetone. The IR spectrum of each complex has a $\nu_{S=O}$ band at around 1000 cm^{-1}, which is shifted to a lower frequency than that of the free ligand (1022 cm^{-1}), indicating that the

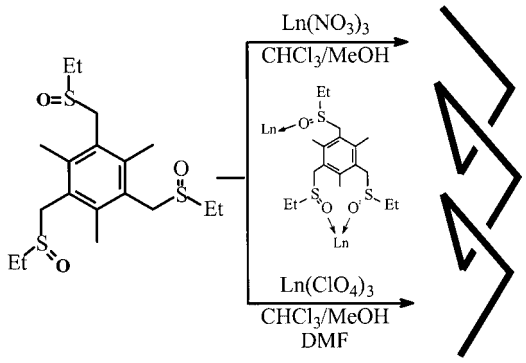
oxygen is coordinated to the Ln^{III} ions.[5] The existence of nitrate and perchlorate anions in the complexes was also confirmed by the IR spectra.



Scheme 1. Schematic representation of the formation of **1**−**3**

Description of the Crystal Structures

Complexes **1** and **2**, $[Ln(L)(CH_3OH)(NO_3)_3]_n$ [where Ln = La^{III} (**1**); Nd^{III} (**2**)], have isostructural, neutral helical-chain structures, with only minor differences in their geometry parameters, which reflect the normal lanthanide contraction. The coordination environments of the Ln^{III} centers in **1** and **2** are shown in Figure 1 (top, with **1** as a representative). Each Ln^{III} center is coordinated to three oxygen atoms of two distinct L ligands (one is mono-*O* and the other is chelating), six oxygen atoms of three bidentate nitrate groups and one oxygen atom of methanol to form a 4,4-bicapped square-antiprism geometry. Due to the small bite angle of the nitrate group, its oxygen atoms are closer than those of two independent L ligands, which makes their complexes have higher coordination numbers. In **1** and **2** the smallest chelating angles of the nitrate groups are 45.25° for **1** [O(9)−La(1)−O(7)] and 45.07° for **2** [O(32)−Nd(1)−O(31)]. Otherwise, one relatively short and one longer Ln−O (NO_3^-) bond [La(1)−O(9) = 2.629(6) Å and La(1)−O(7) = 2.926(7) Å for **1**, Nd(1)−O(32) = 2.541(6) Å and Nd(1)−O(31) = 2.947(6) Å for **2**] also show the binding of the oxygen atoms of this nitrate group, with the smaller chelating angle, to the Ln^{III} ions. In particular, for the La(1)−O(7) and Nd(1)−O(31) bonds, the interactions between the metal and the oxygen atom are week. The lengths of the bonds [2.436(6)−2.498(6) Å for **1** and 2.365(5)−2.437(5) Å for **2**] between the oxygen atoms of the sulfoxide moieties and the Ln^{III} ions are within the expected ranges and similar to those found in disulfoxide analogues,[3f] but significantly shorter than those of the nitrate groups [2.611(7)−2.926(7) Å for **1** and 2.541(6)−2.958(6) Å for **2**] or methanol [2.553(6) Å for **1** and 2.488(4) Å for **2**] in the same complex.

In **1** and **2**, each L links two adjacent Ln^{III} ions to form a 1D helical chain and the shortest Ln···Ln intrachain distance is 11.113 Å for **1** and 11.017 Å for **2**, as shown in Figure 1 (middle). In the chain the alternating Ln centers are located in a straight line and the alternating phenyl groups of the ligands are parallel to each other, while the

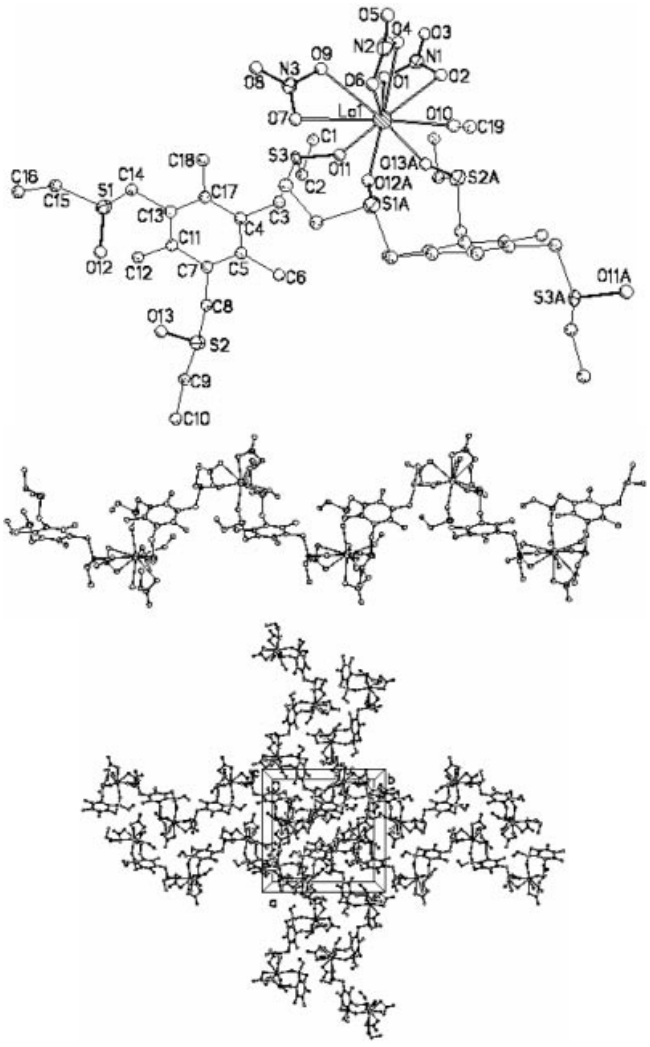


Figure 1. (Top) View of **1** showing the coordination environment of the center ion, (middle) the helical-chain structures of **1** (or **2**) and (bottom) crystal packing diagram in **1** (or **2**), only one position of the disordered sets of S atoms is shown

dihedral angle between two adjacent phenyl planes (namely, around one Ln center) is 66.6° for **1** and 64.5° for **2**, respectively. The 1D helical chain is related by a 4_1 helical axis, which passes through the alternating Ln^{III} ions. Furthermore, in the crystal packing of **1** and **2** the 1D chains are arranged parallel to each other in the *a* and *b* directions, respectively, to form planes. However, the chains in the adjacent planes are perpendicular to each other (see Figure 1 bottom).

The structure of **3** ($\{[La(L)(DMF)_5](ClO_4)_3\}_n$) consists of cationic, helical chains and perchlorate anions. Each chain contains the structural units $[La(L)(DMF)_5]^{3+}$, which are linked by L bridges. In each $[La(L)(DMF)_5]^{3+}$ unit, the La^{III} center is coordinated to eight oxygen atoms, of which three from two distinct L ligands and five from DMF (see Figure 2 top). The geometry of the La center approximates to a square antiprism. In **3** the La−O bond lengths are in the range of 2.4506(2)−2.5806(2) Å and are in the normal La−O bond-length range of eight-coordinate La^{III} com-

 © 2004 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim

plexes. The three distances of La−O(L) are basically equal and the average value is 2.4713(5) Å, which is slightly longer than that in **1** [2.4573(6) Å].

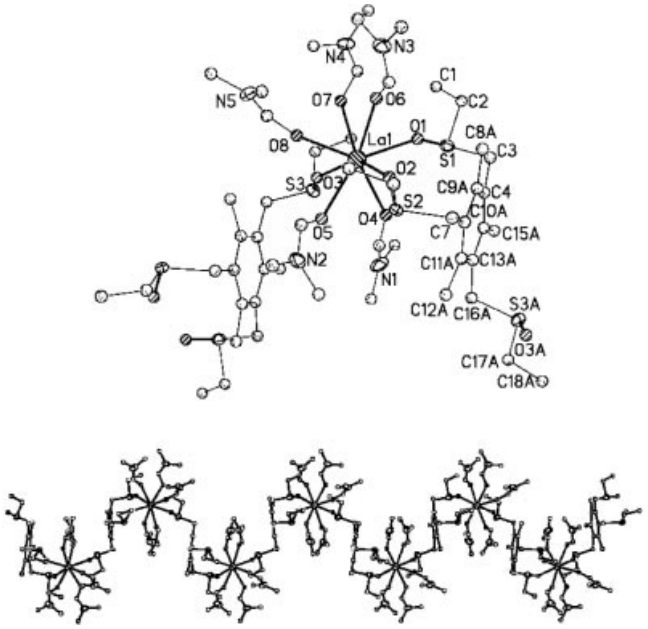

Figure 2. (Top) View of **3** showing the coordination environment of the center ion and (bottom) the helical-chain structure of **3**, only one position of the disordered sets of S atoms is shown

In **3**, the L ligands act as bridges that link adjacent metal ions to form a helical chain (see Figure 2 bottom) with an La···La separation of 10.313 Å. Within the chain, the alternating La^{III} ions are in a straight line, as in **1** and **2**, but all the phenyl groups are parallel to each other and related by a 2_1 helical axis, in contrast to **1** and **2**. Another difference is that in **3** all the chains are arranged parallel to each other along the *c* axis and the perchlorate ions are located among these chains.

In **1**−**3** the ligand is multidentate and displays two kinds of coordination mode: chelate bridging and mono-*O*-bridging. Each L ligand uses two of the sulfinyl moieties to chelate one Ln^{III} center to form a 10-membered ring and uses other one to bridge an adjacent Ln^{III} center. In **1**−**3**, although the trisulfoxide ligand is chiral due to its three S atoms displaying *S*,*R*,*R* (or *S*,*R*,*S*) configurations, in the crystal the presence of a 1:1 disorder for the sulfur atom (S, S′) of one of the sulfoxide moieties makes the configurations offset each other, which means that the complexes as a whole are not chiral. The S=O bond lengths are normal for sulfoxide moieties coordinated to metal ions and are similar to those in di- or mono-sulfoxide analogues.[6] In addition, and similarly to the lanthanide complexes with disulfoxide,[3c,3d] in **1**−**3** there are large M−O−S angles (140.1−168.8° for **1**, 143.6−156.1° for **2** and 147.1−150.6° for **3**) probably due to the high coordination number of the lanthanide ions, and the coordination configurations of the ligands are *trans*−*trans* (C−S−O−M torsion angles are 90−270°) as those in the previously reported disulfoxide lanthanide complexes.[3c−3g]

In summary, three 1D lanthanide-coordination polymers with trisulfoxide ligands were synthesized and structurally characterized. In the complexes, the trisulfoxide ligand shows tridentate linkage as well as mono-*O*-bridging and chelate-bridging coordination modes. Similarly to the disulfoxide ligands, the trisulfoxide ligands also act as bridges to link adjacent metal ions, which may allow the complexes to have higher dimensions. To the best of our knowledge, this is the first report on a trisulfoxide ligand used as a building block to construct coordination polymers. This study may not only open up a new researching domain for developing multisulfoxide-coordination chemistry, but will also offer a new type of organic building block for the construction of metal-organic coordination polymers.

Experimental Section

All the reagents used for synthesis and analyses were of analytical grade and used as received. Hydrated lanthanide nitrate and perchlorate were prepared from the corresponding oxides. Elemental analyses were performed on a Perkin−Elmer 240C analyzer. IR spectra (KBr pellets) were taken on an FT-IR 170SX (Nicolet) spectrometer. ^{1}H NMR spectra were measured on a Bruker AC-P500 spectrometer (300 MHz) at 25 °C with tetramethylsilane as the internal reference. The melting point measurement was taken on an X-4 melting point meter.

Syntheses of the Ligand: 1,3,5-Tris(bromomethyl)-2,4,6-trimethylbenzene was prepared according to a reported procedure.[7] 1,3,5-Tris(ethylthio)-2,4,6-trimethylbenzene was synthesized by the similar literature method.[8]

1,3,5-Tris(ethylsulfinyl)-2,4,6-trimethylbenzene (L): L was synthesized following a procedure similar to our previous work for synthesizing disulfoxides.[4] Nitric acid (63 %, 2 mL) was added dropwise to a vigorously stirred solution of 1,3,5-tris(ethylthio)-2,4,6-trimethylbenzene (10.3 g, 0.03 mol) in benzene (50 mL). After stirring for 24 h, the resulting mixture was added to a 15 % sodium hydrogen carbonate solution to adjust the pH value to ca. 7. The solid product was filtered and washed with distilled water, ethanol and diethyl ether successively. Yield 6.1 g, 52 %. M.p. 233−242 °C (mixture of isomers). $C_{18}H_{30}O_3S_3$ (390.15): calcd. C 55.35, H 7.74; found C 55.01, H 7.22. IR (cm^{-1}): 2887 (w), 2546 (w), 1455 (w), 1278 (m), 1022 (s), 962 (m), 864 (m), 756 (m), 689 (m), 639 (w), 580 (w). ^{1}H NMR (300 MHz): δ = 1.40 (t, 9 H, S−CH_2−CH_3), 2.82 (s, 9 H, Ph−CH_3), 4.04 (q, 6 H, S−CH_2−CH_3), 4.31 (s, 6 H, S−CH_2−Ph) ppm.

Preparation of Complexes: Caution! While we have experienced no problems in handling Ln^{III} perchlorates, these compounds should be handled with great caution because of their potential for explosion.

[Ln(L)(CH$_3$OH)(NO$_3$)$_3$]$_n$ [Ln = La (1); Nd (2)]: Triethyl orthoformate (3 mL) was added to a solution of L (117 mg, 0.3 mmol) in $CHCl_3$ (4 mL) and the mixture was stirred for ca. 20 min. Then $Ln(NO_3)_3{\cdot}nH_2O$ (0.2 mmol) in anhydrous methanol (4 mL) was added to the above mixture and further stirred at 70−80 °C for about 4 h. The mixture was cooled to room temperature and filtered. The filtrate was allowed to stand at room temperature for ca. one week and single crystals suitable for X-ray analysis were obtained. For **1**, yield 87 mg, 39 % based on L. $C_{19}H_{34}LaN_3O_{13}S_3$ (747.58): calcd. C 30.53, H 4.58, N 5.62; found C 30.11, H 4.27, N 5.40. IR (cm^{-1}):

2917 (m), 2426 (w), 1636 (m), 1456 (m), 1384 (s), 1043 (m), 1001 (s), 970 (m), 839 (w), 678 (m). For **2**, yield 77 mg, 34 % based on L. $C_{19}H_{34}NdN_3O_{13}S_3$ (752.91): calcd. C 30.31, H 4.55, N 5.58; found C 30.14, H 4.21, N 5.24. IR (cm^{-1}): 2941 (m), 2426 (w), 1638 (s), 1457 (m), 1384 (s), 1042 (m), 1000 (s), 970 (m), 637 (m).

$\{[La(L)(DMF)_5](ClO_4)_3\}_n$ (3): Triethyl orthoformate (2 mL) was added to a solution of L (78 mg, 0.2 mmol) in $CHCl_3$ (3 mL) and the mixture was stirred for 20 min. $La(ClO_4)_3{\cdot}nH_2O$ (0.2 mmol) in anhydrous methanol (3 mL) was added to the mixture and a precipitate immediately appeared. The mixture was further stirred at about 60 °C for 30 min. Then, DMF was slowly added until the precipitate dissolved and the solution was filtered. The slow diffusion of diethyl ether into the filtrate resulted in the formation of single crystals in 23 % yield. $C_{33}H_{65}Cl_3LaN_5O_{20}S_3$ (1193.34): calcd. C 33.21, H 5.49, N 5.87; found C 33.04, H 5.21, N 5.48. IR (cm^{-1}): 2981 (m), 1647 (m), 1457 (w), 1384 (m), 1141 (s), 1121 (s), 1086 (m), 1001 (s), 636 (m).

Crystal Structure Determinations: Single-crystal X-ray diffraction measurements of **1**−**3** were carried out at 293(2) K on a Bruker−Smart 1000 CCD area detector with Mo-K_α radiation (λ = 0.71073 Å). The structures were solved by direct methods and refined by full-matrix least-square methods based on F^2 using the SHELXS-97 program.[9] All non-hydrogen atoms were refined anisotropically and the hydrogen atoms were added theoretically. In **1**−**3** one of the three sulfur atoms in each crystallographic asymmetry unit displays positional disorder, and was refined in a statistical two-site occupancy. CCDC-217187 to -217189 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/conts/retrieving.html [or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; Fax: (internat.) +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

Crystal Data for 1: Tetragonal, space group $I4_1/cd$, $a = b =$ 18.215(4), c = 36.89(1) Å, V = 12241(5) Å^3, Z = 16, final refinement [$I > 2\sigma(I)$]: $R1$ = 0.0392, $wR2$ = 0.0882.

Crystal Data for 2: Tetragonal, space group $I4_1/cd$, $a = b =$ 17.9931(2), c = 36.7875(6) Å, V = 11910.0(3) Å^3, Z = 16, final refinement [$I > 2\sigma(I)$]: $R1$ = 0.0621, $wR2$ = 0.1565.

Crystal Data for 3: Monoclinic, space group $P2_1/c$, a = 11.897(4), b = 27.391(8), c = 16.288(5) Å, β = 91.841(5)°, V = 5305(3) Å^3, Z = 4, final refinement [$I > 2\sigma(I)$]: $R1$ = 0.0660, $wR2$ = 0.1417.

A Molecular Tool for Measuring the Electron-Acceptor Ability of Ligands from Crystallographic Data

Francesco P. Fanizzi,*[a] Nicola Margiotta,[b] Maurizio Lanfranchi,[c] Antonio Tiripicchio,[c] Gianfranco Pacchioni,[d] and Giovanni Natile*[b]

Keywords: Ab initio calculations / NMR spectroscopy / Pi ligands / Platinum / X-ray diffraction

A method is proposed for the direct measurement of the π-acidity of ligands coordinated to a metal center. The four-coordinate complex [PtI_2(Me_2-phen)] (Me_2-phen = 2,9-dimethyl-1,10-phenanthroline) is unique since it behaves as a molecular trap and, in the presence of a nucleophile (L), one end of it dissociates to allow the L ligand to coordinate *trans* to the monocoordinated diamine. The coordination of the free end of the phenanthroline is impeded by the filled d orbitals of the metal lying in the same plane as the phenanthroline (d_{yz} and d_z^2 electrons assuming as x-axis that of the I–Pt–I vector). However, if the L ligand is a π-acid able to remove electron charge from the yz plane, the second end of the phenanthroline will also be able to interact with platinum. A linear correlation is found between the crystallographic N–Pt–L angle (180° in ideal square-planar species and 143° in a trigonal bipyramid with a bite angle for bidentate Me_2-phen of 74°) and the π-acceptor capacity of the L ligand as estimated by ab initio calculations. Alkenes and alkynes are found to be among the best π-acids and lead to a regular trigonal-bipyramidal five-coordinate species. CO appears to be only halfway in between the best π-acceptor ligands and those with smallest π-acidity. P-, S-, and N-donor ligands follow in that order without significant differences between sulfides and sulfoxides or between aliphatic amines and pyridine. The very small difference between aliphatic amines and pyridine has been confirmed by investigation of the rate of exchange between the two ends for monocoordinated phenanthroline by ^{1}H NMR spectroscopy. The activation energy ($\Delta G^{\ddagger}$) was found to be equal, within the experimental error, for the two types of *trans* ligands.
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2004)

1. Introduction

The π-acceptor ability of a ligand is a key factor in determining its *trans* effect in substitution reactions involving square-planar complexes.[1] A π-acceptor ligand, one that is able to draw electron charge from the metallic center, stabilizes the trigonal-bipyramidal transition state in which the π-acceptor ligand, its *trans* ligand, and the incoming nucleophile share the trigonal plane. The accepted order of *trans*-labilizing ligands is: C_2H_4, CO > CN^- > NO_2^- > SCN^- > I^- > Br^- > Cl^- > NH_3 > OH^-.[2] This series has been derived mainly from kinetic experiments, however it would be highly desirable to have a direct means of measuring the ability of a ligand to favor the assembly of three ligands in the trigonal plane of a five-coordinate geometry.

In investigating the reaction of the sterically strained and highly reactive complexes [PtX_2(Me_2-phen)] (X = Cl, Br, I; Me_2-phen = 2,9-dimethyl-1,10-phenanthroline)[3,4] with an incoming nucleophile, it was found that, contrary to all expectations, no substitution takes place but, instead, simple addition of the extra ligand occurs, with formation of [PtX_2(Me_2-phen)(L)] species.[5–8] Depending upon the characteristics of the incoming ligand, the phenanthroline may become monodentate (and the platinum center still be four-coordinate) or can remain bidentate (and the platinum center become five-coordinate). Preliminary X-ray structural results concerning *trans*-[PtX_2(Me_2-phen)(L)] complexes (X = Cl, L = C_2H_4; X = I, L = CO, PPh_3, and PhNO) showed that the geometry of the complex can range from trigonal bipyramidal (L = ethylene) to square planar (L = PhNO).[5]

We have hypothesized that the structural data of this series of complexes can offer a direct way to rank the π-acceptor ability of L ligands and have extended the investigation to several L ligands comprising the most common S- (sulfides, sulfoxides) and N-donor ligands (aliphatic am-

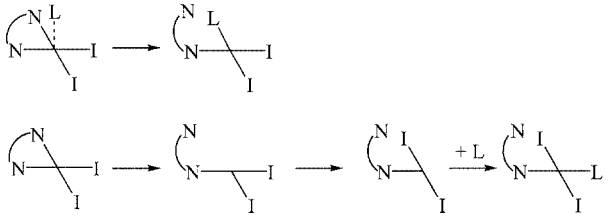
ines and pyridine). In this paper we combine accurate X-ray diffraction data of a wide series of *trans*-[$PtI_2(Me_2$-phen)(L)] complexes with the results of ab initio calculations to show that there is a linear relationship between the stereochemistry of the phenanthroline and the π-acidity of the *trans* ligand. The calculations are aimed at providing a quantum-mechanical rationale for the observed trends more than to give quantitative estimates of the observable properties.

The paper is organized as follows. In Section 2a we describe the synthesis and NMR studies of the complexes under investigation. Section 2b is dedicated to the structure of the complexes from X-ray diffraction measurements. Section 2c is devoted to the calculations and to the quantitative estimate of the π-acceptor ability of the L ligands. The existence of a direct correlation between the N−Pt−L angle and the π-acceptor ability is shown and discussed in the concluding Section 3.

2. Results

2a. Synthetic Aspects and NMR Measurements

[$PtI_2(Me_2$-phen)] (**1**) reacts instantaneously with an extra ligand (L) to give the corresponding addition product [$PtI_2(Me_2$-phen)(L)] (**2**). The addition reaction is quantitative for L = C_2H_4 (**a**), $C_2(C_6H_5)_2$ (**b**), CO (**c**), $P(C_6H_5)_3$ (**d**), $H_2(C_3H_7)N$ (**g**), and C_5H_5N (**h**). In the case of L = $(CH_3)_2SO$ (**e**) and $(CH_3)_2S$ (**f**) an excess of L ligand is required in order to obtain complete conversion into the addition product. The direct displacement of one end of the Me_2-phen ligand by the incoming ligand (L) by the usual S_N2 mechanism would place L *cis* to the monodentate Me_2-phen (upper row of Scheme 1). In some instances (L = PPh_3), such a species has been detected in solution, but not as the major reaction product. Moreover it is not an intermediate leading to the species with PPh_3 *trans* to monocoordinated Me_2-phen but it reacts further placing a second molecule of PPh_3 *trans* to the first one.[6] However, the L ligand is most commonly found *trans* to the monodentate Me_2-phen, an indication that one end of Me_2-phen is first released and the transient T-shaped three-coordinate species isomerizes from *cis* to *trans* conformation before addition of L (lower row of Scheme 1). Most of the data thus far accumulated indicate that such a dissociative mechanism can be operative even in four-coordinate square-planar complexes.[9−13]



Scheme 1

It has been found that, depending upon the nature of the L ligand, the phenanthroline can assume the whole range of positions spanning from pure monodentate to perfectly symmetrical bidentate coordination. This aspect will be treated in detail in Section 2b devoted to the crystal structure analysis. NMR spectroscopy is not very informative in this respect since, even in the case of monocoordinated Me_2-phen, a fast rate of exchange between the free and coordinated ends can render the two halves of the phenanthroline equivalent on the NMR timescale, as in the case of five-coordinate species. However in the case of pyridine and *n*-propylamine complexes, the single set of proton resonances observed for Me_2-phen at room temperature is split into two sets (one for each inequivalent half of Me_2-phen) by lowering the temperature to 210 K (Table 1). In these two cases dynamic NMR spectroscopy[14,15] allowed to calculate the rate constants (k) for the exchange between the free and coordinated ends of the phenanthroline and, from the dependence of the rate constants upon the temperature, it was possible to evaluate the activation parameters ($\Delta H^{\ddagger}$, $\Delta S^{\ddagger}$, and therefrom $\Delta G^{\ddagger}$ at a given temperature T, $\Delta G^{\ddagger}_T$). $\Delta G^{\ddagger}_T$ corresponds to the free-energy difference between the ground state (the four-coordinate species) and the transition state (the latter is likely to be close to a transition species with both ends of the phenanthroline symmetrically bound to platinum).

The NMR spectra of [$PtI_2(Me_2$-phen)(py)] (**2g**) recorded at different temperatures (black lines) overlapped by the simulated spectra (grey lines) are reported in Figure 1. Plots of $\ln(k/T)$ versus $1/T$ are reported in Figure 2. Values of $\Delta H^{\ddagger} = 57 \pm 2$ kJ·mol^{-1}, $\Delta S^{\ddagger} = 20 \pm 2$ J·mol^{-1}·K^{-1}, and $\Delta G^{\ddagger}_{295} = 51 \pm 2$ kJ·mol^{-1} were found for the pyridine complex **2g**, while values of $\Delta H^{\ddagger} = 56 \pm 2$ kJ·mol^{-1}, $\Delta S^{\ddagger} = 14 \pm 2$ J·mol^{-1}·K^{-1}, and $\Delta G^{\ddagger}_{295} = 52 \pm 2$ kJ·mol^{-1} were found for the *n*-propylamine complex **2h**. The very small difference between the $\Delta G^{\ddagger}_{295}$ values for compounds **2g** and **2h** indicates that the ability to stabilize the trigonal bipyramidal transition state, and hence their π-acceptor capacity towards electrons confined in the trigonal plane, can be considered equivalent for the two ligands and, in general, for aliphatic amines and pyridine.

2b. Crystal Structures of Complexes 2a, 2e, 2f, 2g, and 2h

The molecular structures of **2a** (L = C_2H_4), **2e** (L = DMSO), **2f** (L = DMS), **2g** (L = Py), and **2h** (L = NH_2nPr) are depicted in Figure 3, 4, 5, 6, and 7, respectively. Selected bond lengths and angles are summarized in Table 2 for all compounds.

In **2a** the Pt atom presents a trigonal bipyramidal coordination geometry in which the two N atoms of the bidentate Me_2-phen ligand and the double bond of the ethylene molecule are the equatorial donors and the two iodine atoms the axial ligands (Figure 3). The complex has pseudo-C_{2v} symmetry with the pseudo-twofold axis passing through the midpoint of the ethylene ligand and the Pt atom. The bond lengths and angles in the coordination sphere are normal

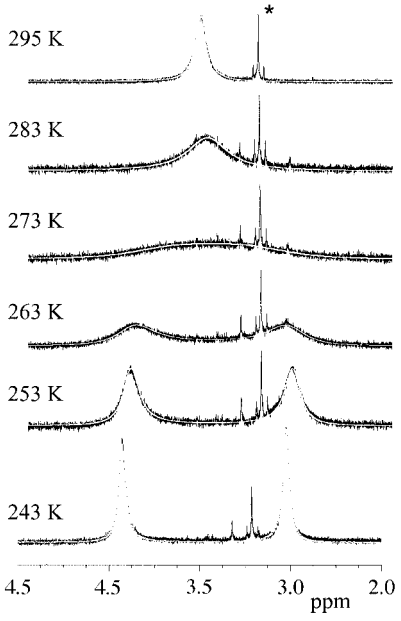

Figure 1. Experimental (black line) and simulated (grey line) ^{1}H NMR spectra (only the aliphatic region is shown) of [$PtI_2(Me_2$-phen)(py)] (**2g**) in $CDCl_3$ at different temperatures; the asterisk indicates the peak belonging to a small excess of the starting complex [$PtI_2(Me_2$-phen)] (**1**)

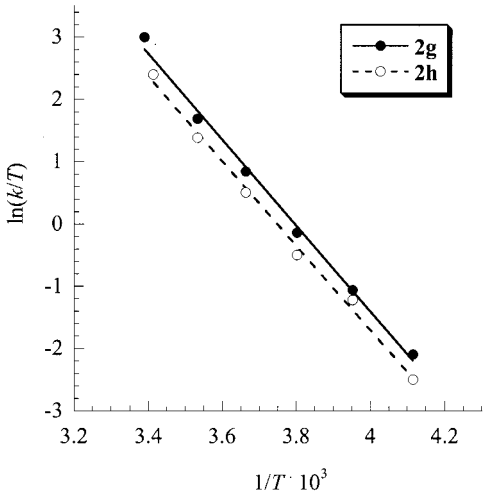

Figure 2. Plots of ln(*k*/T) as a function of 1/T for compounds **2g** and **2h** (*k* values obtained from the line shape analysis of the simulated NMR spectra)

and very similar to those found in the related dichloro derivative.[5]

In **2e** the L ligand is an S-coordinated DMSO molecule (Figure 4) while in **2f** it is dimethyl sulfide (Figure 5). In both complexes the Pt atom shows a slightly distorted square-planar coordination with the L ligand *trans* to the N1-coordinated phenanthroline; two *trans* iodo ligands complete the coordination sphere. In **2e** the orientation of the DMSO molecule is such that a methyl group is placed in the coordination plane [C(15)–S–Pt–I(1) torsion angle of 3.1(4)°] and is responsible for the increase in the S–Pt–I(1) angle with respect to the S–Pt–I(2) angle [96.47(8)° and 89.15(8)°, respectively]. The two Pt–I bond lengths are also significantly different [Pt–I(1) = 2.617(1) and Pt–I(2) = 2.650(1) Å]. A similar situation is found in **2f** [C(15)–S–Pt–I(1) torsion angle of 23.6(4)°, S–Pt–I(1) angle of 96.27(7)°, and S–Pt–I(2) angle of 85.90(7)°]. The phenanthroline is not perfectly planar but shows a certain degree of twist [displacements of the methyl carbon atoms C(13) and C(14) from the mean plane of the phenanthroline of 0.22(1) and −0.22(1) Å for **2e** and 0.25(1) and −0.18(1) Å for **2f**]. This type of phenanthroline deformation is also present in **2a**, but to a smaller extent [deviations from the mean plane of −0.16(1) and 0.14(1) Å for C(13) and C(14), respectively]. In both compounds **2e** and **2f** the Pt atom is slightly out of the mean coordination plane and displaced towards the N(2) atom of the phenanthroline [Pt···N(2) distance of 2.629(6) and 2.666(6) Å for **2e** and **2f**, respectively]. Thus the coordination can be defined as elongated square pyramidal (4+1). The degree of transition from four coordination to five coordination can be judged from the N(1)–Pt–S angle [170.58(17)° and 169.89(17)° for **2e** and
