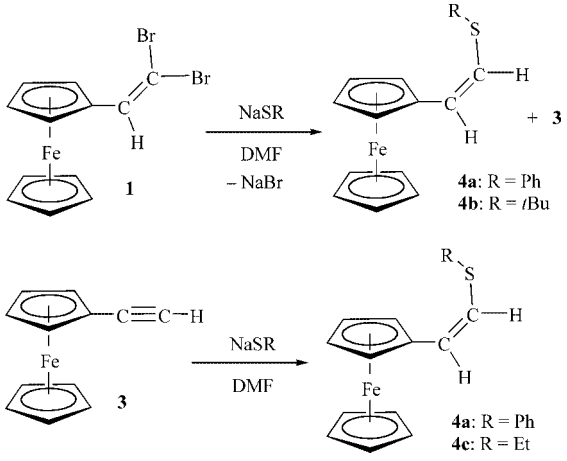
data of **4a** did not match the expected values for [(PhS)(Br)-C=C(H)–Fc] but instead suggested the formulation (*Z*)-[(PhS)(H)C=C(H)–Fc] (**4a**; Scheme 2). Treatment of **1** with an excess of NaS*t*Bu in dmf also did not lead to the anticipated dithioether compound [(*t*BuS)$_2$C=C(H)–Fc]. Instead, analysis of the crude product by TLC indicated the presence of (*Z*)-[(*t*BuS)(H)C=C(H)–Fc] (**4b**) together with a large amount of ethynylferrocene (**3**). The formation of ethynylferrocene, which was isolated by column chromatography, was unambiguously confirmed by an X-ray diffraction analysis.



Scheme 2.

The (*Z*) stereochemistry about the vinylic double bond of **4b** and the unexpected replacement of the Br substituent by an H atom were also confirmed by X-ray diffractometry. As illustrated in Figure 3, the crystallographic data unambiguously confirm the replacement of one bromine atom in the (*Z*) position relative to the ferrocene unit by an S*t*Bu group and replacement of the second bromine atom by a hydrogen atom. The Cp ring bearing the vinyl group and the thioether function are almost coplanar, with a C(10)–C(11)–C(12)–S torsion angle of 2.8°. We were unable to synthesise the corresponding SEt derivative (*Z*)-[(EtS)(H)-C=C(H)–Fc] (**4c**) by this method as, except for some minor amounts of the dithioether compound (*Z*)-[(EtS)(H)-C=C(SEt)–Fc] (**5c**; see below), only ethynylferrocene (**3**) could be isolated from this reaction. X-ray checks carried out on several differently shaped crystals and full analysis of one sample always showed the presence of ethynylferrocene.[23,24]

A related structural motif was recently crystallographically established for the vinylferrocene derivatives **A** and **B**, which were obtained after hydrolysis or alcoholysis of 2,3-diferrocenyl-1-(methylthio)cyclopropenylium iodide (Scheme 3).[25]

The formation of large amounts of ethynylferrocene can be rationalised by a dehydrobromination reaction induced by the basic thiolate reagent. It is well established that addition of thiolates (or thiols under basic conditions) across the C≡C bond of alkynes leads to vinyl thioethers.[26–30] For example, treatment of phenylacetylene with sodium *p*-

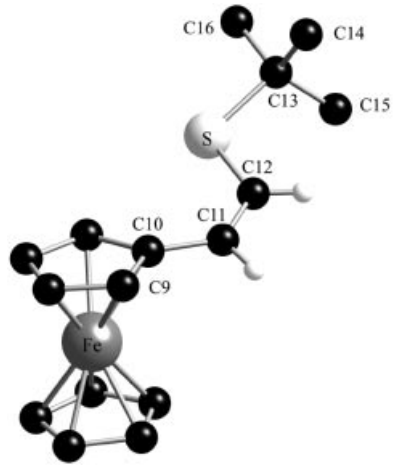


Figure 3. Ball-and-stick view of the molecular structure of **4b** showing the (*Z*) configuration around the C=C bond. For clarity, only the vinylic hydrogen atoms are shown. Selected bond lengths [Å] and angles [°]: C(10)–C(11) 1.458(7), C(11)–C(12) 1.351(8), C(12)–S 1.749(5), C(13)–S 1.845(5), C(13)–C(14) 1.545(7); C(9)–C(10)–C(11) 123.1(5), C(10)–C(11)–C(12) 128.8(5), C(11)–C(12)–S 125.0(4), C(12)–S–C(13) 103.0(3), C(14)–C(13)–S 110.1(3), C(15)–C(13)–S 110.8(4), C(16)–C(13)–S 103.5(4).

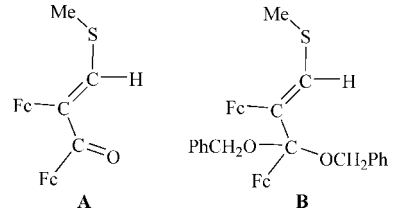

Scheme 3.

toluenethiolate in dmf produces (*Z*)-1-phenyl-2-(*p*-tolylmercapto)ethene in a stereospecific manner. According to the kinetics of the reaction, a stepwise mechanism has been suggested for this addition which is initiated by nucleophilic attack of SR$^-$ at the β-carbon atom of Ph–C≡C–H, followed by protonation of the resulting carbanionic intermediate.[27] We therefore attempted an alternative synthesis of **4c** along this route by treating Fc–C≡C–H (**3**) with NaSEt in dmf at room temperature. Indeed, **4c** was now accessible in 78% isolated yield as a red crystalline solid after workup in aqueous solution. An X-ray diffraction study confirmed the (*Z*) disposition of the Fc moiety and the SEt substituent about the C=C bond (see Figure 4). As in **4b**, the Cp ring bearing the vinyl group and the thioether function are almost coplanar, with a C(10)–C(11)–C(12)–S torsion angle of 2.7°. The Cp rings of **4c** are again placed in an eclipsed conformation.

The complex (*Z*)-[(PhS)(H)C=C(H)–Fc] (**4a**) is also accessible by this route. The (*Z*) arrangement of the two vinylic hydrogen atoms of **4a** is corroborated by the $^1$H NMR spectrum, which exhibits an AB pattern centred at $\delta$ = 6.31 ppm with a typical vicinal (*Z*) coupling constant of 10.1 Hz. Similar values ($\delta$ = 6.45 ppm, $^3J_{A,B}$ = 10.8 Hz) were recently reported for (*Z*)-[(PhS)(H)C=C(H)–C$_6$H$_4$O-Me].[31a] In contrast, a $^3J_{H,H}$ coupling constant of 15.3 Hz

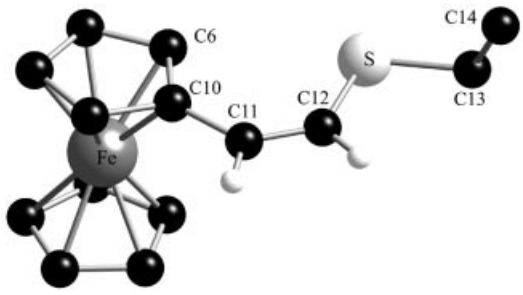

Figure 4. Ball-and-stick view of the molecular structure of **4c**. Selected bond lengths [Å] and angles [°]: C(10)–C(11) 1.463(7), C(11)–C(12) 1.314(7), C(12)–S 1.750(4), C(13)–S 1.789(6), C(13)–C(14) 1.522(5); C(10)–C(11)–C(12) 129.6(4), C(11)–C(12)–S 126.8(4), C(12)–S–C(13) 101.6(2), C(14)–C(13)–S 114.3(3).

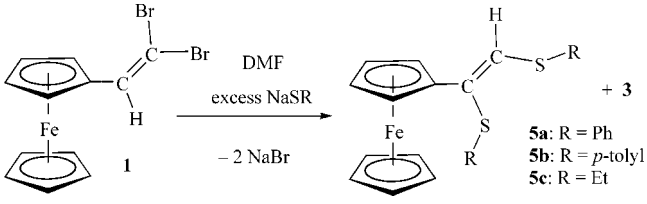
has been reported for (*E*)-[(PhS)(H)C=C(H)–Ph], which was obtained by Rh-catalysed hydrothiolation of phenylacetylene.[31b] The NOESY spectrum (see Supporting Information) reveals a weak correlation between the unresolved Cp signal at $\delta$ = 4.62 ppm and the vinylic resonance at $\delta$ = 6.35 ppm, thereby proving the existence of a weak $^4J_{H,H}$ "W-coupling".

With the aim of synthesising ferrocene-based dithioether ligands, complex **1** was treated with an excess of aromatic thiolate (10 equiv.) at room temperature. Although the vinylic dithioether complexes (*Z*)-[(ArS)(H)C=C(SAr)–Fc] (**5a**,**b**) were formed as orange-red solids, albeit in moderate yields (46–51%) due to a competing elimination reaction that produces ethynylferrocene (**3**; Scheme 4), a closer look at the NMR spectra of **5a**,**b** and the X-ray data for the heterodinuclear compound **6** (see Figure 5 for the rhenium dithioether complex) revealed that a rearrangement reaction again occurred.[32] The overall yield of **5c** was lower still (22%) with the more basic ethyl thiolate as nucleophile, giving **3** in more than 50% yield as the main product.



Scheme 4.

A literature survey indicates that this rearrangement has a precedent in organic chemistry. Thus, the mechanistic investigations of Truce and Boudakian on the reactivity of 1,1-dichloroethylene towards an excess of sodium *p*-toluenethiolate in EtOH demonstrate that this reaction affords exclusively (*Z*)-1,2-bis(*p*-tolylmercapto)ethene. The intermediacy of an alkyne species ArS–C≡CH was suggested to rationalize this interesting addition/elimination sequence.[33] Another research group later independently confirmed these findings with NaSPh as nucleophile and dmf as solvent.[34]

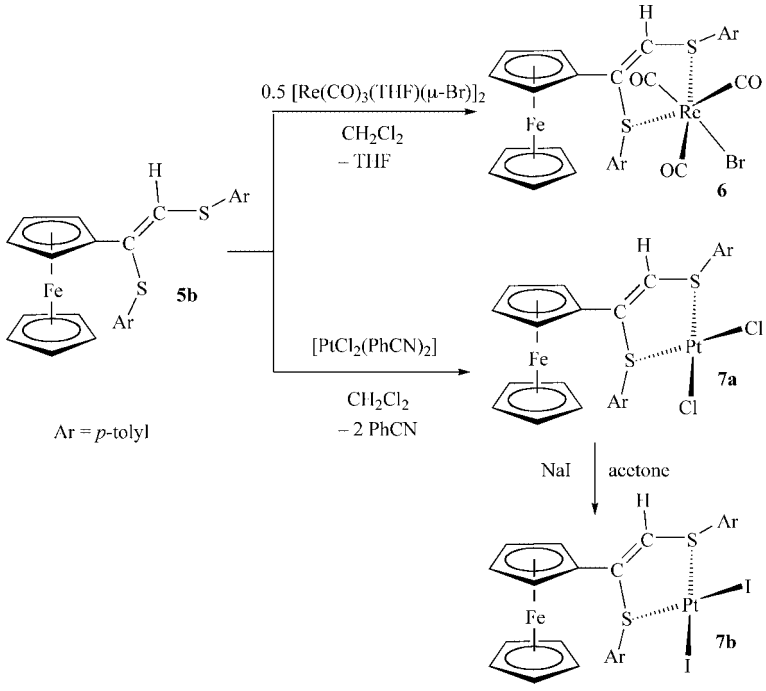
## Coordination Chemistry of the Dithioether Ligand 5b

Preliminary studies demonstrated that dithioether compounds **5** can be used as chelating ligands to assemble heterodinuclear compounds.[35] Thus, reaction monitoring by IR spectroscopy revealed that treatment of dimeric $[Re(thf)(CO)_3(\mu\text{-}Br)]_2$ with 2 equiv. of **5b** in $CH_2Cl_2$ solution led to formation of the brick-red complex [Fc{C(S–*p*-tolyl)=C(S–*p*-tolyl)(H)}–Re(Br)(CO)$_3$] (**6**; Scheme 5) almost quantitatively, within 15 min. The facial arrangement of the carbonyl groups of air-stable **6** can be deduced from the observation of three ν(CO) vibrations in KBr at 2031, 1958 and 1930 cm$^{-1}$.

The rearrangement discussed above, which results in a (*Z*) substitution of C(11) and C(12) by S–*p*-tolyl groups, was corroborated by an X-ray diffraction study. Figure 5 reveals that the octahedral coordination around the Re centre is achieved by three carbonyl groups, a chelating dithioether ligand and a bromo ligand, thus conferring an 18-electron count at the Re$^{I}$ centre. The bromo substituent and the ferrocenyl moiety of the dithioether ligand are directed in the same sense. The dithioether ligand forms a five-membered ring with mean Re–S bond lengths of 2.4807 Å, which are somewhat shorter than those found for *fac*-[{$(PhSCH_2)_2SiPh_2$}Re(Br)(CO)$_3$] (2.515 Å).[36] Like in the latter compound, the aryl rings of the thioether groups are

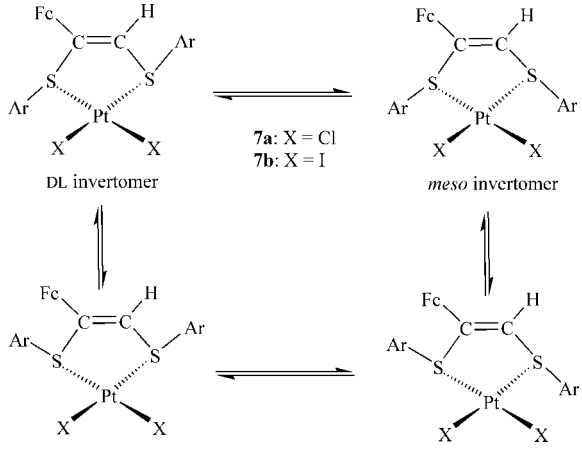
 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 



Scheme 5.

both *syn*-orientated and form a *meso* invertomer, although they point in the opposite direction to the bromo ligand.[36,37]

Similarly, treatment of $[PtCl_2(PhCN)_2]$ with a slight excess of **5b** yielded the brownish air-stable square-planar dithioether complex [Fc–{C(S–*p*-tolyl)=C(S–*p*-tolyl)-(H)}$PtCl_2$] (**7a**). The spectroscopic and elemental analysis data are in agreement with a bidentate chelating coordination mode of **5b** at the platinum atom, similar to that encountered in *cis*-$[MCl_2(MeSCH=CHSMe)]$ (M = Pd, Pt) and other related $Pd^{II}$ and $Pt^{II}$ compounds.[38] Metathesis with NaI in acetone solution converted **7a** into red-brown [Fc–{C(S–*p*-tolyl)=C(S–*p*-tolyl)(H)}$PtI_2$] (**7b**), whose $FAB^+$ mass spectrum displays the peak for the molecular ion. The $^1H$ NMR spectrum of **7a** recorded at 293 K displays a rather broad unresolved signal between $\delta$ = 4.80 and 4.10 ppm for the Cp resonances; the vinylic proton gives rise to a very broad hump centred at $\delta$ = 6.41 ppm. At 213 K, the vinylic proton appears sharper at $\delta$ = 6.54 ppm and the Cp protons give rise to several signals in the range $\delta$ = 4.58–3.92 ppm. This temperature-dependent behaviour is most probably due to a pyramidal inversion process operating for the two sulfur atoms that gives rise to *meso* and DL invertomers, as outlined in Scheme 6. Since this phenomenon has been studied by us and several other groups in the past,[20a,21a,36a,39] we did not undertake a detailed kinetic variable-temperature study. In contrast, the diiodo analogue **7b** displays well-resolved signals at room temperature, which barely sharpen upon heating to 313 K. This indicates a fast exchange such that only one "averaged planar" conformation is observed on the NMR timescale.



Scheme 6.

The vinylic proton signal at $\delta$ = 6.32 ppm exhibits a $^3J_{Pt,H}$ coupling of 73 Hz, and two distinct singlets are observed at $\delta$ = 2.41 and 2.34 ppm in a 1:1 ratio for the methyl groups of the *p*-tolyl rings. We and others have previously noted this finding for various $PtX_2$ complexes ligated with chelating dithioethers. The enhanced thermodynamic *trans* influence of I over Cl elongates the Pt–S bonds (as corroborated by several X-ray structures), and the concomitant weakening of the metal–sulfur bonds accounts for the lower activation barrier of the inversion process.[20a,20b,21,39]

## Electrochemistry

The anodic sweep of **1** in MeCN between –0.25 and +0.75 V vs. $Ag/Ag^+$ on a Pt electrode leads to a totally re-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

versible peak in the cyclic voltammogram (CV), even for low scan rates (i.e. 100 mV s$^{-1}$). The separation between the anodic and cathodic peaks is about 60 mV, which indicates a fast electron transfer. The peak potential for **1** is about +0.25 V vs. Ag/Ag$^+$. In comparison with the corresponding peak values measured for the non-substituted ferrocene/ferrocenium couple ($E_p$ = 0.21 V vs. Ag/Ag$^+$) or the vinylferrocene/ferrocenium couple ($E_p$ = 0.24 V vs. Ag/Ag$^+$), the introduction of the CH=CBr$_2$ group does not significantly change the oxidation peak potential.[40a]

The CV of **2** in MeCN exhibits a reversible one-electron oxidation peak at +0.08 V vs. Ag/Ag$^+$ ($i_{pc}/i_{pa}$ = 1, $\Delta E$ = 60 mV; see Supporting Information). This oxidation is "easier" (i.e. occurs at lower positive potential) than that for precursor **1** due to the electronic communication with the electron-rich Pd(PPh$_3$)$_2$Br moiety. A contribution from a Pd(PPh$_3$)$_2$Br motif was recently observed in (vinylferrocene)Pd$^{II}$ complexes containing thiophene spacers of the type [(C$_5$H$_5$)Fe(C$_5$H$_4$CH=CH–th–Pd(PPh$_3$)$_2$(Br)] (th = 2,5-disubstituted thiophene).[41] The potentials of these complexes were reported to be lower than those without an end-capping Pd(PPh$_3$)$_2$Br unit, thereby implying the delocalisation of Pd electron density into the spacer chain through a dπ→pπ interaction. This behaviour is also observed for dithioether **5b**. The CV of **5b** between –0.25 and +0.50 V vs. Ag/Ag$^+$ on a Pt electrode at 100 mV s$^{-1}$ reveals the presence of a reversible peak also involving a fast electron transfer (see Supporting Information). Since this ferrocene derivative bears two electron-donating substituents, the oxidation is "easier" than that for **1**. The potential of the reversible peak for **5b** ($E_p$ = 0.19 V vs. Ag/Ag$^+$) is lower than that for **1**. Oxidation of **7a** between 0.00 and +0.60 V vs. Ag/Ag$^+$ on a platinum electrode at 100 mV s$^{-1}$ again leads to a reversible signal (see Supporting Information). Actually, the complexation of **5b** with a PtCl$_2$ fragment decreases the electronic density on the ferrocene moiety and the oxidation peak is therefore shifted towards higher oxidation potentials with respect to that for **1** and **5b**. The $E^0$ value ($E_p$ = 0.39 V vs. Ag/Ag$^+$) is larger than that for compound **1**. This behaviour is also observed for compound **6**. The $E^0$ value for the couple **6**/**6**$^{\cdot+}$ ($E_p$ = 0.33 V vs. Ag/Ag$^+$) is in the same range as that for the couple **7a**/**7a**$^{\cdot+}$ ($E_p$ = 0.39 V vs. Ag/Ag$^+$). A shift after complexation with metal centres has also been noted previously for other ferrocene-based thioether ligands.[35e]

The CV of **5b** between –0.40 and +2.00 V vs. Ag/Ag$^+$ on a Pt electrode at 100 mV s$^{-1}$ reveals a different shape of the voltammogram curve (Figure 6). Thus, we now observe three irreversible waves at 0.19, 1.16 and 1.29 V vs. Ag/Ag$^+$. The first irreversible wave corresponds to the oxidation of the ferrocene moiety. Surprisingly, the lifetime of the ferrocenium radical cation formed during the oxidation in this experiment is not long enough to be observed during the reversible scan. This behaviour is usually not observed for ferrocenium radical cations. This phenomenon is probably due to the low scan rate and the high value of the final potential. Partial peak reversibility is again observed when we increase the scan rate to 200 mV s$^{-1}$. The CV of **7a** between –0.40 and +2.00 V vs. Ag/Ag$^+$ at a Pt electrode at 100 mV s$^{-1}$ leads to a voltammogram similar to that of **5b** (see Supporting Information). However, the two irreversible peaks in this voltammogram obtained after oxidation of the two S-*p*-tolyl substituents are less well-defined than that for **5b**. Moreover, the ferrocenium radical cation of **7a** is more stable than the corresponding radical cation of **5b**. In fact, we observe a partial reversibility of the first oxidation peak, even at low scan rate (100 mV s$^{-1}$).

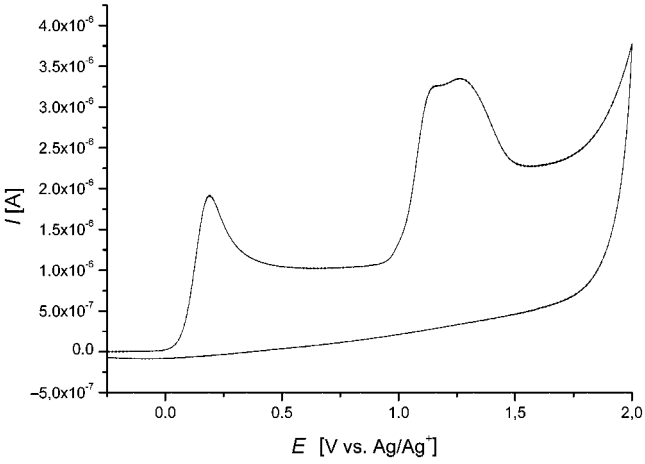


Figure 6. CV of **5b** (1 mM) in $CH_2Cl_2$ + $Bu_4NPF_6$ (0.1 M) at 100 mV s$^{-1}$ at a platinum electrode.

The same electrochemical measurements were also performed using glassy carbon electrodes. All voltammograms are very similar. The only difference observed between platinum and carbon electrodes concerns the value of $E_p$ (Table 1).

Table 1. Values of standard potentials or peak potentials for monomer/radical cation in dichloromethane (vs. Ag/Ag$^+$) deduced from CV measurements.

| Compound | $E_p$ [V] on Pt electrode | $E_p$ [V] on C electrode |
|---|---|---|
| **1** | 0.25 | 0.25 |
| **2** | | 0.08 |
| **5b** | 0.19, 1.16, 1.19 | 0.13, 1.21 |
| **6** | 0.33, 1.61 | 0.32, 1.59 |
| **7** | 0.39, 1.72 | 0.36, 1.59 |

### Solid-State Luminescence of 5b and 6

When excited at 270 nm, the solid-state emission spectra of **5b** and the heterometallic system **6** (Figure 7) at room temperature are quite similar, with a broad band at 668 and 670 nm, respectively. This band is tentatively assigned to an intraligand transition. More importantly, the incorporation of ferrocene and its derivatives in a luminescent system produced effective quenchers of excited states by energy-transfer processes.[42a] These compounds are known for their capacity to inhibit the lowest energy states of a number of molecules frequently used as photosensitizers.[42b,42c] This finding may also explain the luminescence quenching of the rhenium fragment in compound **6**.

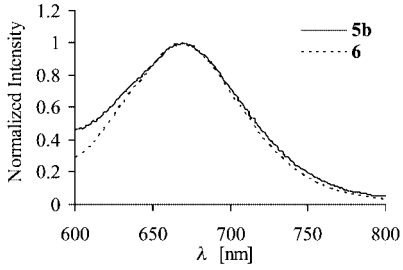

Figure 7. Corrected and normalised solid-state luminescence spectra recorded at room temperature for compounds **5b** (solid) and **6** (dotted).

## Conclusion and Perspectives

This study has demonstrated that the reactivity of **1** towards thiolates is not trivial. We are currently investigating these rearrangement reactions in more detail {isolation of intermediates, influence of temperature and solvent, utilisation of [$Cl_2C$=C(H)–Fc] instead of [$Br_2C$=C(H)–Fc] as starting material, use of other aromatic substrates such as (dibromovinyl)[2.2]paracyclophane, …} to develop a clear mechanistic understanding of these interesting transformations. Moreover, the preparation of π-conjugated thioether ligands **4** and **5** allows a promising development in organometallic coordination chemistry. We are currently working on the synthesis, reactivity and electrochemical investigation of other neutral and ionic complexes ligated by **4** and **5**. Furthermore, the substitution of the bromo substituents of **1** by $^-$OR, $^-NR_2$ or $^-PR_2$ may also lead to promising new ligand systems.

## Experimental Section

**General:** All reactions were performed using a conventional vacuum/argon line with standard Schlenk techniques. (2,2-Dibromovinyl)ferrocene (**1**), [$Pd(PPh_3)_4$], [$Re(\mu\text{-}Br)(CO)_3(thf)]_2$ and [$PtCl_2(PhCN)_2$] were prepared according to literature methods.[13,43] Thiophenol, *p*-thiocresol, 2-methyl-2-propanethiol and ethanethiol were purchased from commercial sources and used without further purification. All solvents were distilled from appropriate drying agents. IR spectra were recorded with a Nicolet Nexus 470 spectrometer. All NMR spectra were recorded in $CDCl_3$ with a Bruker AC 300 ($^1$H: 300.13 MHz; $^{13}$C: 75.48 MHz; $^{31}$P: 121.49 MHz) using the solvent as reference, except for $^{31}$P, where the chemical shifts are quoted relative to 85% $H_3PO_4$ in $D_2O$. UV/Vis spectra were recorded with a Varian Cary 50 spectrophotometer. The solid-state emission spectra were recorded at room temperature with a Jobin–Yvon Fluorolog-3 spectrometer using a cylindrical quartz capillary (diameter: 0.5 cm) with a scan speed of 1 nm s$^{-1}$. Intensity scales are presented in arbitrary units. The FAB$^+$ mass spectrum of **7b** was obtained with a VG Autospec spectrometer using NBA as matrix.

**Electrochemical Setup:** Analytical experiments were performed in a three-compartment cell fitted with an $AgClO_4$ (0.1 M in $CH_3CN$)| Ag reference electrode, a glassy carbon electrode (diameter: 3 mm) or a Pt electrode (diameter: 1 mm) and a platinum counter electrode. The electrochemical apparatus was an Autolab PGSTAT 20 Potentiostat Galvanostat (Ecochemie). The solvent was spectroscopic grade $CH_2Cl_2$ or acetonitrile with [$Bu_4N$][$PF_6$] (TBAF) as supporting electrolyte. The concentration of the monomeric substrate was $10^{-3}$ M. Under these conditions, the $E_{1/2}$ of $Cp_2Fe^{+/0}$ was found to be 0.21 V ± 0.01 V ($CH_2Cl_2$) vs. an Ag reference.

**Preparation of *trans*-[$(PPh_3)_2$PdBr{C(Br)=C(H)–Fc}] (2):** Compound **1** (185 mg, 0.5 mmol) was added to a suspension of [$Pd(PPh_3)_4$] (520 mg, 0.45 mmol) in toluene (15 mL) and the mixture was warmed to 60 °C for 1 d. The resulting clear, red solution was then concentrated to 8 mL and layered with heptane. Complex **2** crystallised as red needles after storing this solution in a refrigerator overnight. Yield: 76% (380 mg). $^1$H NMR: $\delta$ = 7.77 (m, 10 H, Ph), 7.17–7.41 (m, 20 H, Ph), 6.09 (s, 1 H, $H_{vinyl}$), 3.93 (m, 2 H, Cp), 3.81 (m, 2 H, Cp), 3.72 (s, 5 H, Cp) ppm. $^{31}$P{$^1$H} NMR: $\delta$ = 22.7 (s) ppm. UV/Vis ($CH_2Cl_2$): $\lambda_{max}$ ($\varepsilon$) = 229 nm (62800 M$^{-1}$ cm$^{-1}$), 310 (13100), 365 (13600). $C_{48}H_{40}Br_2FeP_2Pd$ (1000.9): calcd. C 57.60, H 4.03; found C 57.48, H 4.09.

**Typical Procedure for the Conversion of the Dibromo Olefin 1 into 4a–c and 5a–c:** Compound **1** (1 mmol) was stirred with an excess of thiolate (10 mmol) in dry dmf (10 mL) at room temperature for 1 d. The reaction mixture was then poured into water (10 mL). The organic layer was extracted with $Et_2O$ (2 × 25 mL), washed with brine (20 mL) and water (2 × 25 mL) and dried with $Na_2SO_4$. Evaporation of the solvents gave the crude products. Purification was carried out by chromatography on silica gel. In the case of treatment of **1** with 4 equiv. of thiolates, the ratios of thioether compounds **4a/3** and **4b/3** were both 25%/75%.

**FcCH=CH(SPh) (4a):** Eluent: $CH_2Cl_2$/petroleum ether (1:9). M.p. 50 °C. $^1$H NMR: $\delta$ = 7.25–7.52 (m, 5 H, Ph), 6.35 (d, $^3J_{H,H}$ = 10.1 Hz, 1 H, $H_{A,vinyl}$), 6.26 (d, $^3J_{H,H}$ = 10.1 Hz, 1 H, $H_{B,vinyl}$), 4.62 (br. s, 2 H), 4.27 (br. s, 2 H, Cp), 4.16 (s, 5 H, Cp) ppm. $^{13}$C{$^1$H} NMR: $\delta$ = 68.9, 69.2, 69.3, 80.8 (*Cp*HC=), 121.0 (CpH*C*=), 126.5, 126.8, 129.0, 129.3 [C-14, C-15, C-16, C-17, C-18, =*C*H(SPh)], 136.6 (C-13) ppm. $C_{18}H_{16}FeS$ (320.23): calcd. C 67.51, H 5.04, S 10.01; found C 67.42, H 5.74, S 9.80.

**FcCH=CH(S*t*Bu) (4b):** Eluent: $CH_2Cl_2$/petroleum ether (1:9). Yield: 52% (156 mg). M.p. 50–52 °C. $^1$H NMR: $\delta$ = 6.19 (d, $^3J_{H,H}$ = 10.0 Hz, 1 H, $H_{A,vinyl}$), 6.11 (d, $^3J_{H,H}$ = 10.0 Hz, 1 H, $H_{B,vinyl}$), 4.58 (br. s, 2 H, Cp), 4.23 (br. s, 2 H, Cp), 4.15 (s, 5 H, Cp), 1.43 (s, 9 H, $CH_3$) ppm. $^{13}$C{$^1$H} NMR: $\delta$ = 30.9 ($CH_3$), 43.8 [*C*-($CH_3$)$_3$], 68.5, 69.1, 69.2, 81.9 (*Cp*HC=), 119.5 (CpH*C*=), 124.1 [=*C*H(S*t*Bu)] ppm. UV/Vis ($CH_2Cl_2$): $\lambda_{max}$ ($\varepsilon$) = 229 (16200), 251 (10500), 298 (9100), 351 (7100), 452 nm (3900 M$^{-1}$ cm$^{-1}$). $C_{16}H_{20}FeS$ (300.23): calcd. C 64.00, H 6.67, S 10.67; found C 63.98, H 6.58, S 10.62.

**FcCH=CH(SEt) (4c):** Eluent: petroleum ether. M.p. 38–39 °C. $^1$H NMR: $\delta$ = 6.14 (d, $^3J_{H,H}$ = 10.4 Hz, 1 H, $H_{A,vinyl}$), 5.95 (d, $^3J_{H,H}$ = 10.4 Hz, 1 H, $H_{B,vinyl}$), 4.32 (br. s, 2 H, Cp), 4.24 (br. s, 2 H, Cp), 4.12 (s, 5 H, Cp), 2.75 (q, $^3J_{H,H}$ = 7.4 Hz, 2 H, SC$H_2$CH$_3$), 1.22 (t, $^3J_{H,H}$ = 7.4 Hz, 2 H, SCH$_2$C$H_3$) ppm. UV/Vis ($CH_2Cl_2$): $\lambda_{max}$ ($\varepsilon$) = 229 (11500), 250 (9200), 298 (10900), 351 (550), 452 nm (350 M$^{-1}$ cm$^{-1}$). $C_{14}H_{16}FeS$ (272.18): calcd. C 61.76, H 5.88, S 11.76; found C 61.68, H 5.73, S 11.67.

**Alternative Preparation of 4a and 4c:** Ethynylferrocene (210 mg, 1 mmol) was added to a stirred solution of thiolate (10 mmol) in dmf (10 mL). The solution was stirred at room temperature for 1 d and then poured into water. The organic layer was extracted with diethyl ether, washed with water (5 mL) and brine (2 × 5 mL) and dried with $Na_2SO_4$. Solvent evaporation provided the crude products. Column chromatography with petroleum ether as eluent afforded 207 mg of **4a** (yield: 76%) and 249 mg of **4c** (yield: 78%).

**FcC(SPh)=CH(SPh) (5a):** Obtained by column chromatography on silica gel with petroleum ether as eluent (197 mg, 46%). $^1$H NMR:

$\delta$ = 4.17 (s, 5 H, Cp), 4.23 (s, 2 H, Cp), 4.48 (br. s, 2 H, Cp), 7.13 (s, 1 H, $H_{vinyl}$), 7.23–7.52 (m, 10 H, Ph) ppm. $^{13}C\{^1H\}$ NMR: $\delta$ = 69.3, 69.8, 70.1 (C-1–C-9), 79.7 (C-10), 123.5, 125.6, 127.1, 127.3, 127.4, 129.0, 129.2, 129.9, 130.1, 130.7, 132.2, 134.7, 135.0, 135.5, 135.9, 141.2 (C-11–C-24) ppm. $C_{24}H_{20}FeS_2$ (428.39): calcd. C 67.29, H 4.67, S 14.95; found C 67.18, H 4.59, S 14.83.

**FcC(S–*p*-tolyl)=CH(S–*p*-tolyl) (5b):** Eluent: petroleum ether/$CH_2Cl_2$ (9:1). Yield: 51% (230 mg). M.p. 135–136 °C. $^1H$ NMR: $\delta$ = 7.30–7.00 (m, 9 H, $C_6H_4$ + $H_{vinyl}$), 4.40 (br. s, 2 H, Cp), 4.15 (br. s, 2 H, Cp), 4.09 (s, 5 H, Cp), 2.31 (s, 3 H, $CH_3$), 2.24 (s, 3 H, $CH_3$) ppm. $^{13}C\{^1H\}$ NMR: $\delta$ = 21.3, 21.4 ($CH_3$), 67.2, 69.2, 69.9 (Cp), 87.5 (CpH*C*=), 128.0, 128.1, 128.9, 130.1, 130.3, 130.9, 132.4, 132.8, 133.2, 135.8 ($C_6H_4$), 137.7 [=*C*($SC_6H_4CH_3$)$_2$] ppm. UV/Vis ($CH_2Cl_2$): $\lambda_{max}$ ($\varepsilon$) = 229 (64100), 257 (32200), 330 nm (9100 $M^{-1}cm^{-1}$). $C_{26}H_{24}FeS_2$ (456.44): calcd. C 68.42, H 5.30, S 14.05; found C 68.48, H 5.38, S 14.12.

**FcC(SEt)=CH(SEt) (5c):** Obtained by column chromatography on silica gel with petroleum ether as eluent (134 mg, 22%). $^1H$ NMR: $\delta$ = 6.26 (s, 1 H, $H_{vinyl}$), 4.53 (br., 2 H, Cp), 4.29 (s, 2 H, Cp), 4.11 (s, 5 H, Cp), 2.85 (m, 4 H, S*C*$H_2$CH$_3$), 2.77 (m, 4 H, SC$H_2$CH$_3$), 1.29 (m, 3 H, $SCH_2CH_3$), 1.27 (m, 3 H, $SCH_2CH_3$) ppm. $C_{16}H_{20}FeS_2$ (332.31): calcd. C 57.83, H 6.07, S 19.30; found C 57.78, H 5.93, S 19.18.

**[FcC(S–*p*-tolyl)=C(H)(S–*p*-tolyl)$_2$Re(Br)(CO)$_3$] (6):** [Re(μ-Br)(CO)$_3$-(thf)]$_2$ (127 mg, 0.15 mmol) was added in several portions to a solution of **5b** (136 mg, 0.3 mmol) in $CH_2Cl_2$ (5 mL). The reaction mixture was stirred at room temperature for 2 h and then concentrated to 3 mL under reduced pressure. Layering with heptane gave red needles after several days at 5 °C. Yield: 92% (119 mg). IR (KBr): ν(CO) = 2031 (vs), 1958 (s), 1931 (vs) $cm^{-1}$. $^1H$ NMR: $\delta$ = 7.37–7.27 (m, 8 H, $C_6H_4$), 7.07 (s, 1 H, $H_{vinyl}$), 4.83 s, (br., 2 H, Cp), 4.45 (br. s, 2 H, Cp), 4.55 (s, 5 H, Cp), 2.40 (s, 3 H, $CH_3$), 2.37 (s, 3 H, $CH_3$) ppm. UV/Vis ($CH_2Cl_2$): $\lambda_{max}$ ($\varepsilon$) = 231 (47800), 300 (16100), 382 (2200), 482 nm (1700 $M^{-1}cm^{-1}$). $C_{29}H_{24}BrFeReO_3S_2{\cdot}0.5CH_2Cl_2$ (849.09): calcd. C 41.72, H 2.95; found C 41.85, H, 3.00.

**[FcC(S–*p*-tolyl)=C(H)(S–*p*-tolyl)PtCl$_2$] (7a):** [$PtCl_2$(PhCN)$_2$] (127 mg, 0.3 mmol) was added in several portions to a solution of **5b** (136 mg, 0.3 mmol) in $CH_2Cl_2$ (8 mL). The reaction mixture was stirred at room temperature for 4 h and then concentrated to 5 mL under reduced pressure. Addition of light petroleum gave an orange powder, which was filtered off and dried under vacuum. Yield: 91% (197 mg). $^1H$ NMR (213 K): $\delta$ = 7.79–7.30 (m, 8 H, $C_6H_4$), 6.54 (br. s, 1 H, $H_{vinyl}$), 4.58–3.92 (m, 9 H, Cp), 2.40 (br. s, 3 H, $CH_3$), 2.36 (br. s, 3 H, $CH_3$) ppm. UV/Vis ($CH_2Cl_2$): $\lambda_{max}$ ($\varepsilon$) = 228 (69500), 295 (20200), 382 (2400), 487 nm (1600 $M^{-1}cm^{-1}$). $C_{26}H_{24}Cl_2FePtS_2$ (722.43): calcd. C 43.23, H 3.35, S 8.88; found C 43.02, H 3.12, S 8.54.

**[FcC(S–*p*-tolyl)=C(H)(S–*p*-tolyl)PtI$_2$] (7b):** NaI (150 mg, 10 mmol) was added to a solution of **7a** (72 mg, 0.1 mmol) in acetone (5 mL). The reaction mixture was stirred at room temperature for 1 d and then the solvent was evaporated under reduced pressure. Extraction of the crude product with $CH_2Cl_2$ (4 mL) and addition of heptane gave an orange powder, which was filtered off and dried under vacuum. Yield: 90% (76 mg). $^1H$ NMR: $\delta$ = 7.68–7.19 (m, 8 H, $C_6H_4$), 6.32 (br. s, $^3J_{Pt,H}$ = 73 Hz, 1 H, $H_{vinyl}$), 4.53–4.09 (m, 9 H, Cp), 2.41 (s, 3 H, $CH_3$), 2.34 (s, 3 H, $CH_3$) ppm. FAB$^+$ (NBA): *m*/*z* = 906.1 [M$^+$]. $C_{26}H_{24}FeI_2PtS_2$ (905.34): calcd. C 34.49, H 2.67; found C 34.12, H 2.76.

**X-ray Crystallography:** Crystal data and experimental details are given in Table 2. Data for **2** and **6** were collected with a Stoe IPDS diffractometer at 173(2) (**2**) and 193(2) K (**6**). The intensities were determined and corrected with the program INTEGRATE in IPDS (Stoe & Cie, 1999). An empirical absorption correction was employed using the FACEIT program in IPDS (Stoe & Cie, 1999). Data for **1** and **4b**,**c** were collected with a Bruker APEX-CCD (D8

three-circle goniometer, Bruker AXS) at 173(2) K; data collection, cell determination and refinement: Smart version 5.622 (Bruker AXS, 2001); integration: SaintPlus version 6.02 (Bruker AXS, 1999); empirical absorption correction: Sadabs version 2.01 (Bruker AXS, 1999). All structures were solved applying direct and Fourier methods, using SHELXS-90 and SHELXL-97.[44] For each structure, the non-hydrogen atoms were refined anisotropically. All of the hydrogen atoms were placed in geometrically calculated positions and each was assigned a fixed isotropic displacement parameter based on a riding model. Refinement of the structures was carried out by full-matrix least-squares methods based on $F_o^2$ using SHELXL-97. CCDC-644866 to -644869 (for **1**, **2**, **4c**, **6**), -646158 (for **3**), and -650184 (for **4b**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

**Supporting Information** (see footnote on the first page of this article): Crystallographic data and view of the structure and packing of **3** (Figure S1). Cyclic voltammograms of **2**, **5b** and **7a** are depicted in Figures S2–S5. Figures S6–S10 show the thermal ellipsoid plots of **1**, **2**, **4b**, **4c** and **6**. The NOESY $^1$H NMR spectrum of **4a** is shown in Figure S11.

## Acknowledgments

We are grateful to the French Ministère de la Recherche et Technologie for a PhD grant for S. C. Financial support from the Région of Franche-Comté for the fluorescence spectrometer is also gratefully acknowledged. We thank Dr. A. Khatyr for recording the emission spectra and Dr. Harmel N. Peindy (University of Bochum, Germany) for recording the FAB$^+$ mass spectrum of **7b**.

# Electrochemical Synthesis of Mono- and Disubstituted Diiron Dithiolate Complexes as Models for the Active Site of Iron-Only Hydrogenases

**Didier Morvan,[a] Jean-François Capon,[a] Frederic Gloaguen,*[a] Philippe Schollhammer,[a] and Jean Talarmin[a]**

**Keywords:** Biomimetic catalysis / Iron-only hydrogenases / Diiron dithiolate / CO substitution / Electrochemistry / Proton reduction

$[Fe_2(S_2C_3H_6)(CO)_5\{P(OMe)_3\}]$ (**2**) and $[Fe_2(S_2C_3H_6)(CO)_4\{P(OMe)_3\}_2]$ (**3**) were selectively prepared by the electrochemical reduction of $[Fe_2(S_2C_3H_6)(CO)_6]$ (**1**) in the presence of trimethyl phosphite ligand. Electrochemical data indicate a CO-displacement reaction catalyzed by electron transfer. Complexes **2** and **3** were characterized by X-ray crystallography, which shows that in the solid state, the trimethyl phosphite ligands lie in the apical configuration. NMR suggests that multiple isomers exist in solution. Both **2** and **3** exhibit a primary reduction step that involves two electrons. No stable hydride derivatives could be isolated by the reaction of **2** or **3** with strong acid. However, for both **2** and **3**, proton reduction catalysis was detected at a potential less negative than that of the reduction of the diiron complex working as catalyst. The proposed mechanism involves a protonation of the diiron complex in the vicinity of the electrode, which is triggered by the more facile reduction of the protonated form (CE mechanism). The protonation and reduction steps are followed by a bimolecular reaction that regenerates the starting complex.

## Introduction

Hydrogenases are nickel- and iron-based enzymes that control the hydrogen production and uptake in a wide variety of microorganisms. These biomolecules have long interested biologists and chemists, as they might hold the key to a competitive hydrogen economy.[1] Recently, the active site of the iron-only hydrogenases was structurally characterized and shown to contain a dithiolate-bridged diiron moiety with carbonyl and cyanido ligands.[2] This has opened the way for the synthesis of organometallic models that could eventually work as cheap and efficient proton reduction catalysts.[3–11] The First structural models were readily accessed by the substitution of two CO ligands with two $CN^-$ ligands in $[Fe_2(S_2C_3H_6)(CO)_6]$ (**1**).[12–14] Several structural aspects of the iron-only hydrogenase active site have been modeled by diiron complexes bearing azadithiolate and related bridges,[15–18] a 2Fe3S core,[19,20] or chelating ligands.[21–26] Mimicking the catalytic activity of the hydrogenases turns out to be far more challenging. For the all-carbonyl complex **1**, the catalysis of proton reduction in acidified acetonitrile solution requires potentials more negative than –1.6 V[27,28] (all potentials in this paper are referenced to that of the reversible oxidation of ferrocene, $E_{1/2}^{ox}$ = 0.4 V vs. NHE). The substitution of one or two CO ligands by good donor ligands such as cyanido, phosphane, and/or *N*-heterocyclic carbene (NHC) yielded better functional models.[21,29–33] Good donor ligands increase the basicity of the iron–iron bond, and thus render it susceptible to protonation by relatively strong acids ($pK_a < 10$).[34,35] On protonation, the reduction potential of the complex is positively shifted by about 1 V, and catalytic hydrogen evolution can be detected at potentials around –1.4 V.[29,30] This obviously suggests that advances in designing an efficient proton reduction catalyst will follow from a greater balance between the basicity and the reduction potential of the diiron center. There are several examples of $[Fe_2(SR)_2(CO)_{6-x}L_x]$ ($x$ = 1, 2) complexes with ligands L that have a relatively modest donor ability such as phosphite or isocyanide.[36–40] However, the electrochemistry of these compounds and their reactivity toward protons have so far received little attention. In addition, they were generally prepared in rather low yields by thermal activation to give a mixture of mono-, di-, and trisubstituted derivatives. On the other hand, it was shown that electron transfer (reduction or oxidation) could also lead to substituted diiron dithiolates.[38,41,42] For example, the formation of $[Fe_2(S_2C_2H_4)(CO)_5\{P(OMe)_3\}]$ by an electron-transfer-catalyzed chain reaction was detected upon the electrochemical reduction of the all-CO parent compound in the presence of $P(OMe)_3$.[41] A similar approach allowed us to

selectively prepare $[Fe_2(S_2C_6H_4)(CO)_5\{P(OMe)_3\}]$ in good yield.[43]

We now describe the selective synthesis of $[Fe_2(S_2C_3H_6)(CO)_5\{P(OMe)_3\}]$ (**2**) and $[Fe_2(S_2C_3H_6)(CO)_4\{P(OMe)_3\}_2]$ (**3**) by bulk electrolysis of the all-CO parent compound **1** in the presence of $P(OMe)_3$. The purpose of this preliminary study was to determine whether electrochemical methods could be used as a general route for the selective preparation of mono- and disubstituted diiron dithiolates. The crystallographic and spectroscopic characterization and the electrochemical properties of complexes **2** and **3** are also reported.

## Results and Discussion

### Preparation and Characterization of Complexes 2 and 3

IR spectra recorded over a period of several hours showed that a $CH_3CN$ solution of the all-CO compound **1** was not reactive toward the addition of 1.1 molar equiv. of $P(OMe)_3$ at room temperature. However, electrolysis of this solution at a potential slightly more negative than the reduction potential of **1** readily gave the monosubstituted derivative **2**. The disubstituted complex **3** was similarly obtained by bulk electrolysis of a solution of **1** with 2.1 molar equiv. of $P(OMe)_3$ at a potential slightly more negative than the reduction potential of **2**. In each case, IR spectra indicated total consumption of **1** in 45–60 min. The charge passed in the course of electrolysis was about 0.7 F per mol of **1**, which indicates that CO-displacement reactions catalyzed by electron transfer occur (see Supporting Information).[41,43]

Compounds **2** and **3** were characterized by IR and NMR spectroscopy, elemental analysis, mass spectrometry, and X-ray crystallography. The shift in the $\nu_{CO}$ bands is considered a useful indicator of the variation in electron density in diiron models of the hydrogenase active site. The average values for the IR bands in the carbonyl stretching region are lowered by 47 and 79 $cm^{-1}$ for the monosubstituted compound **2** ($\tilde{\nu}_{CO}$: 2048, 1991, 1976, 1938 $cm^{-1}$) and the disubstituted compound **3** ($\tilde{\nu}_{CO}$ = 2004, 1966, 1937, 1917 $cm^{-1}$), respectively, relative to those in the all-CO compound **1** ($\tilde{\nu}_{CO}$: 2073, 2033, 1999 $cm^{-1}$). The redshifted values for **2** and **3** indicate that the electron-donating ability of $P(OMe)_3$ is comparable to that of $PPh_3$ and slightly better than that of $P(OEt)_3$ and *t*BuNC.[39,40] The difference in wavenumber between the highest and lowest band ($\Delta\tilde{\nu}_{CO}$ = 87 $cm^{-1}$) in **3** is smaller than that in the monosubstituted complex **2** ($\Delta\tilde{\nu}_{CO}$ = 110 $cm^{-1}$), which indicates that **3** is a symmetric diphosphite derivative.[25]

Evidence for monosubstitution in **2** was provided by $^{13}C$ NMR spectroscopy. The spectrum of **2** displays two carbonyl resonances: a doublet at $\delta$ = 211.9 ppm assigned to the two carbonyl ligands of the $Fe(CO)_2[P(OMe)_3]$ moiety and a singlet at $\delta$ = 209.6 ppm assigned to the three carbonyl ligands of the $Fe(CO)_3$ moiety. The $^{13}C$ NMR spectrum of the disubstituted complex **3** shows only one doublet at $\delta$ = 213.5 ppm for the carbonyl ligands.

The dynamic properties of complexes **2** and **3** were investigated by variable temperature $^{31}P$ NMR spectroscopy. At room temperature, the NMR spectrum of complex **2** displays one signal at $\delta$ = 177.0 ppm, which splits at 183 K into four sharp resonances (186.4, 184.4, 178.0, and 177.1 ppm, Figure 1a). This indicates that the dynamic site exchange

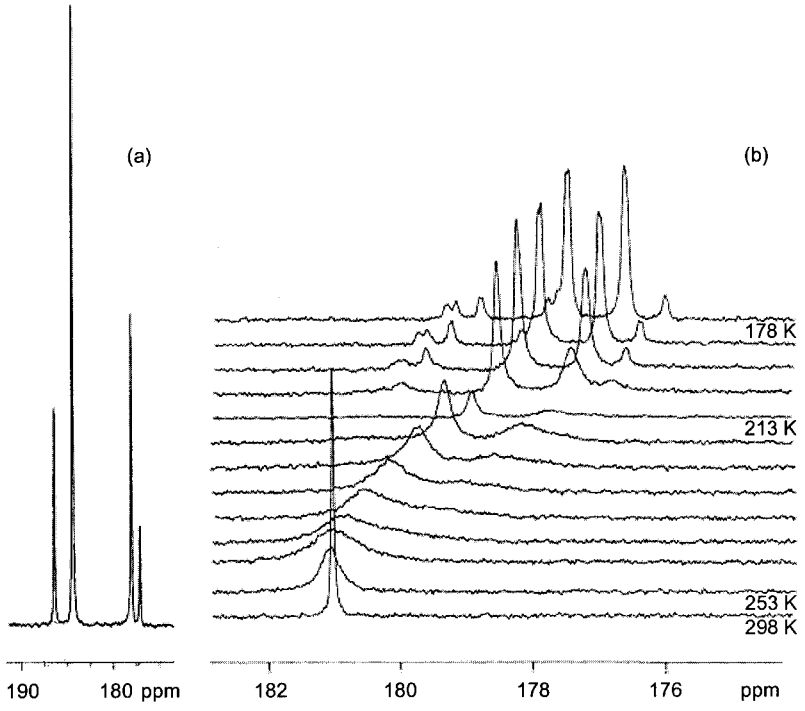

Figure 1. $^{31}P$ NMR spectra of (a) compound **2** at 183 K and (b) compound **3** at variable temperatures from 298 K to 178 K.

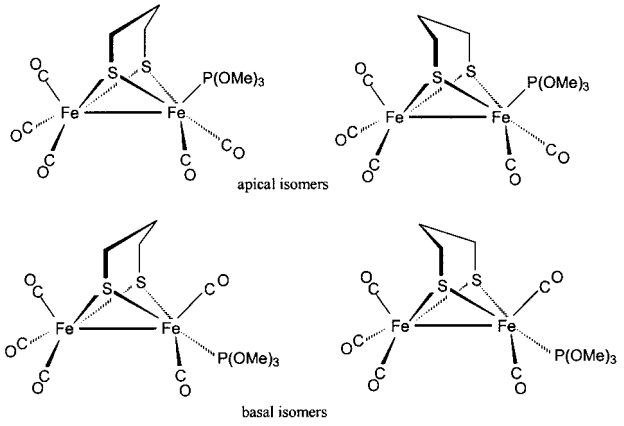
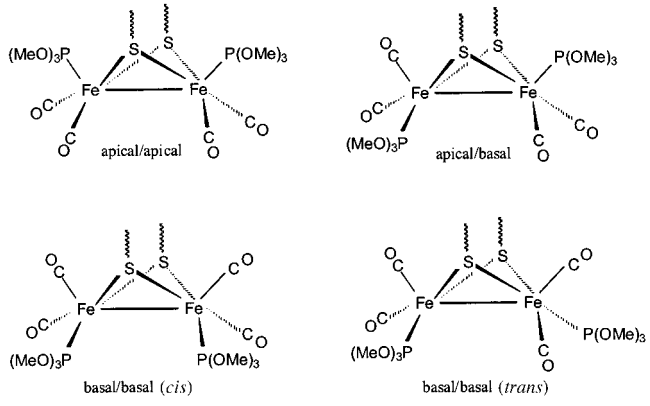
 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

processes at low temperature are sufficiently slow on the NMR timescale to allow the detection of the four isomers expected for a monosubstituted derivative (Scheme 1). The fluxional processes that occur in solution are a basal/apical rotation of the phosphite and carbonyl ligands along with a flipping of the methylene group of the propanedithiolate ligand.[44,45]



Scheme 1.

At room temperature, the $^{31}P$ NMR spectrum of **3** displays one signal at $\delta$ = 180.4 ppm (Figure 1b). The $^{31}P$ NMR pattern at 183 K suggests the presence of the four expected isomers, relative to the position of the phosphite ligands (Scheme 2). The major isomer (75%) displays four poorly resolved signals of nearly equal intensity in the range of 184.3 to 182.9 ppm. This is indicative of an apical/basal form, in which the two phosphorus atoms are nonequivalent. This observation is consistent with density functional theory calculations, which indicate that the most stable structure for $[Fe_2(S_2C_2H_4)(CO)_4(PH_3)_2]$ is the apical/basal isomer, even though the difference in energy between each isomer is weak.[46]



Scheme 2.

The structure of **2** in the solid state was determined by X-ray diffraction and confirms the presence of one phosphite ligand bonded to an iron atom in an apical position (Figure 2). Such an apical orientation for the incoming ligand was previously reported in $[Fe_2(S_2C_3H_6)(CO)_5L]$ when L = $PPh_3$, $PMe_2Ph$, $POEt_3$,[40] NHC,[21,32,33] and $PPh_2\{C_6H_4$-$CCSi(CH_3)_3\}$,[47] whereas the basal position was occupied when L = $P(NC_4H_8)_3$,[48] PTA (1,3,5-triaza-7-phosphaadamantane),[31] $\eta^1$-$Ph_2P$-$CH_2$-$PPh_2$,[23] and $H_2NPr$.[49] Each iron atom in **2** displays the usual pentacoordinate square-pyramidal structure, where both metal centers are displaced from the basal plane toward the apical position by 0.37 Å for Fe(1) and by 0.41 Å for Fe(2).

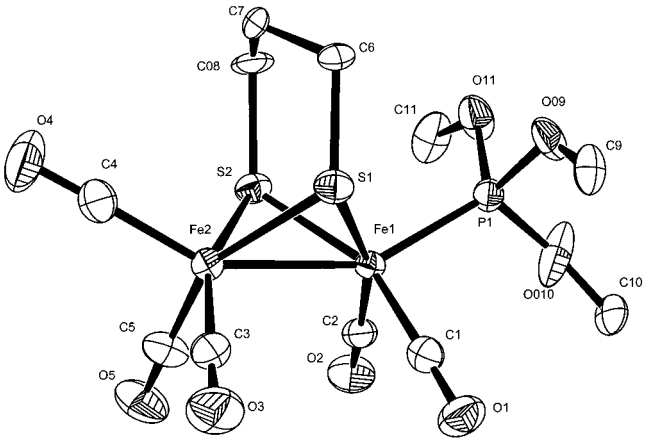


Figure 2. ORTEP diagram of compound **2** depicted with 50% thermal ellipsoids. Selected bond lengths [Å] and angles [°]: Fe(1)–Fe(2) 2.5098(12), Fe(1)–C(1) 1.777(2), Fe(1)–C(2) 1.785(2), C(1)–O(1) 1.144(3), C(2)–O(2) 1.140(3), C(3)–O(3) 1.139(3), Fe(1)–P(1) 2.1618(6), Fe(1)–S(1) 2.2595(6), C(2)–Fe(1)–P(1) 96.89(7), C(1)–Fe(1)–P(1) 97.80(7), P(1)–Fe(1)–S(1) 101.64(2), P(1)–Fe(1)–Fe(2) 150.73(4).

Crystallization of **3** afforded crystals suitable for X-ray diffraction and resulted in the formation of only one isomer in which both phosphite ligands are coordinated in an apical position (Figure 3). It is worth noting that the electrochemically synthesized complex **3** is a *symmetrically* disubstituted diiron compound, as are those prepared by the thermally-activated CO-displacement reaction. Ligand coordination in an apical/apical fashion was previously reported in complexes of type $[Fe_2(S_2C_3H_6)(CO)_4L_2]$, where L = *t*BuNC,[39] $PMe_2Ph$,[40] and $PPh_2(C_6H_4Br)$.[47] In analo-

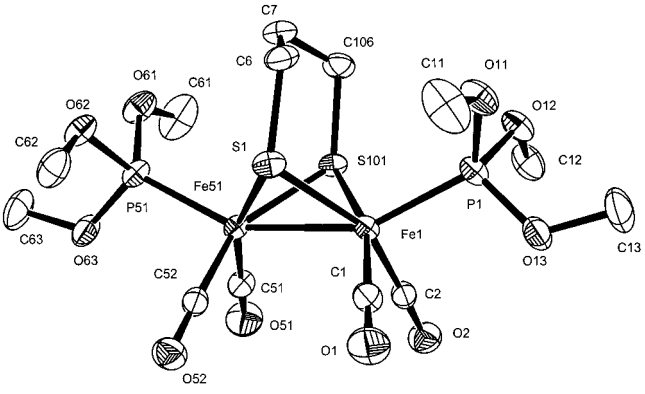

Figure 3. ORTEP diagram of compound **3** depicted with 50% thermal ellipsoids.  © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

gous disubstituted complexes, basal/basal *trans* isomers have also been observed in the solid state when L = $PMe_3$[50] and L = PTA,[31] while L = $CN^-$[14] and L = NHC[32] led to basal/apical isomers. These results show that the ligand size is not the determining factor that affects the structure of $[Fe_2(S_2C_3H_6)(CO)_4L_2]$ complexes in the solid state.[36]

The electrochemical properties of organometallic models are one of the interesting features that may lead to a better understanding of the structure–function relationships in the hydrogenase active site. Cyclic voltammetry of **2** and **3** was carried out in $CH_3CN/Bu_4NPF_6$ solution. The monosubstituted complex **2** exhibits two reductions at –1.98 V and –2.29 V and one oxidation at +0.37 V. The primary reduction and oxidation processes of **2** are chemically irreversible. The disubstituted complex **3** exhibits a chemically irreversible reduction at –2.30 V and a chemically reversible oxidation event at 0.12 V. In comparison to **1**, the first reduction processes of compounds **2** and **3** are negatively shifted by 0.31 V and 0.63 V, respectively, which is consistent with the increase in the electron density when one or two CO ligands are replaced by more electron-donating phosphite ligands (see IR data). Another interesting feature of these systems is that the oxidation of phosphite-disubstituted derivatives such as complex **3** and $[Fe_2(S_2C_3H_6)(CO)_4\{P(OEt)_3\}_2]$[40] is a chemically reversible process, while the oxidation of isocyanide- and phosphane-disubstituted derivatives is an irreversible process.[37,39] There is so far no clear agreement on the number of electrons involved in the reduction step of $[Fe_2(S_2C_3H_6)(CO)_{6-x}L_x]$ complexes. For example, Heinekey and co-workers[39] reported that the reduction of $[Fe_2(S_2C_3H_6)(CO)_4(t\text{BuNC})_2]$ is apparently a two-electron process, whereas Sun and co-workers[40] ascribed the first reduction peak of $[Fe_2(S_2C_3H_6)(CO)_{6-x}L_x]$ [L = $PPh_3$, $PMe_2Ph$, $P(OEt)_3$; $x$ = 1,2] to a one-electron process. To determine the number of electrons involved in the reduction and oxidation of **2** and **3**, respectively, we used $[Fe_2(S_2C_3H_6)(CO)_4(I_{Me}CH_2I_{Me})]$ ($I_{Me}$ = 1-methylimidazol-2-ylidene) as an internal standard (see Supporting Information). The chelated dicarbene derivative exhibits a diffusion-limited, reversible, one-electron oxidation process,[26] and its diffusion coefficient should be close to that of **2** and **3**. The voltammetric peak current ($I_p$) for the oxidation of **3** varies linearly with the square root of the potential scan rate ($v$) in the range of 0.02 to 2 $V s^{-1}$. Additionally, the slope of the $I_p$ vs. $v^{1/2}$ plot is more than twice that calculated for the chelated carbene-disubstituted derivative at the same concentration. This clearly demonstrates that the oxidation of **3** is a diffusion-limited, two-electron process. The same procedure allowed us to conclude that the reduction processes of **2** and **3** involve in each case two electrons.

## Protonation Study of Complexes 2 and 3

Before evaluating the electrocatalytic properties of **2** and **3** for proton reduction, it is important to check their reactivity toward protons. The all-CO compound **1** is not reactive toward strong acids such as $HBF_4{\cdot}Et_2O$. However, it is well known that in $[Fe_2(SR)_2(CO)_{6-x}L_x]$ ($x$ = 1,2), the donor ability of the ligand L has a great influence on the nucleophilicity of the $Fe^I$–$Fe^I$ bond.[34] The IR spectrum of a $CH_3CN$ solution of **2** with excess $HBF_4{\cdot}Et_2O$ remains unaltered, which indicates that the replacement of one CO ligand with one $P(OMe)_3$ ligand does not noticeably increase the basicity of the metal–metal bond. Treatment of a $CH_3CN$ solution of **3** with 10 molar equiv. $HBF_4{\cdot}Et_2O$ led to an IR spectrum that displays new $\tilde{\nu}_{CO}$ bands at 2070, 2050, and 2010 $cm^{-1}$. The positive shift of about 80 $cm^{-1}$ is characteristic of the formation of a $Fe^{II}(\mu\text{-H})Fe^{II}$ species.[34] Protonation is, however, very slow since $\nu_{CO}$ bands corresponding to the starting compound **3** were still observed one hour after excess acid was added. The $^1H$ NMR spectrum of **2** recorded at room temperature in the presence of excess $HBF_4{\cdot}Et_2O$ shows a triplet at $\delta$ = –14.8 ppm ($J_{PH}$ = 26.6 Hz) in the high field region, which confirms the formation of a bridging hydride complex.

The electrocatalytic activity of complexes **2** and **3** for proton reduction was investigated in $CH_3CN/Bu_4NPF_6$ solutions with increasing concentrations of toluenesulfonic acid (HOTs, p$K_a$ ca. 8). The addition of HOTs to a solution of **2** triggers the appearance of a new reduction process, noted as B in the cyclic voltammograms in Figure 4. This process occurs at a potential less negative than that of the

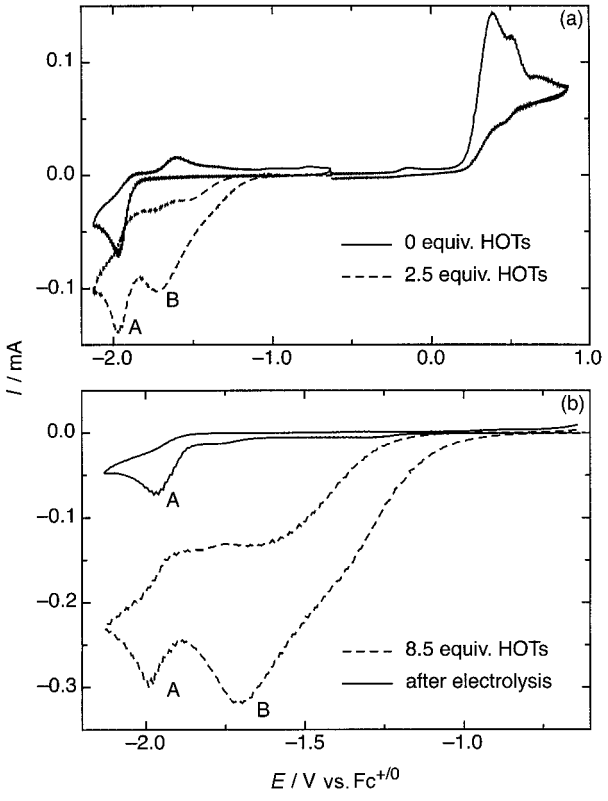

Figure 4. Cyclic voltammograms of compound **2** in $CH_3CN/Bu_4NPF_6$ (a) before and after addition of 2.5 molar equiv. HOTs and (b) after addition of 8.5 molar equiv. HOTs and after electrolysis at –1.65 V. Experimental conditions: $v$ = 0.1 $V s^{-1}$; [**2**] = 2.1 mM; glassy carbon electrode 0.071 $cm^2$ in surface area.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

reduction of **2**, noted as A in the same Figure. The onset of wave B is at about –1.1 V, and a maximum in height is reached at about –1.7 V. The height of wave B is responsive to the acid concentration. It increases by a factor of three upon increasing the [HOTs]/[**2**] ratio from 2.5 to 8.5 (Figure 4b). Since **2** does not readily react with protons under the present conditions (see IR data above), it is most probable that wave B is due to the reduction of $\mathbf{2}H^+$ generated at the electrode according to the CE mechanism shown in Equations (1), (2), and (3).

$$\mathbf{2} + H^+ \rightleftarrows \mathbf{2}H^+ \quad (1)$$

$$\mathbf{2}H^+ + e^- \rightleftarrows \mathbf{2}H \quad (2)$$

$$2 \times \mathbf{2}H \rightarrow 2 \times \mathbf{2} + H_2 \quad (3)$$

$\mathbf{2}H^+$ does not exist in an appreciable amount in the bulk of the solution, but its reduction at the electrode displaces the protonation equilibrium to the right [Equation (1)]. The amount of acid in solution has a similar effect on this equilibrium, which explains the dependence of the height of wave B on the proton concentration. It is relevant to note that the height of peak A, which corresponds to the reduction of **2**, remains unaffected upon addition of acid. This suggests not only that all the protons available in the diffusion layer are consumed in wave B, but also that the reduction of $\mathbf{2}H^+$ regenerates the unprotonated complex **2**, likely by the release of $H_2$ [Equations (3)]. To support the proposed mechanism, we carried out an electrolysis at –1.65 V of a solution of **2** with 8.5 molar equiv. of HOTs. The charge passed after a period of 120 min was 8.2 F per mol of **2**, consistent with the stoichiometry of one electron and one proton per mol of **2** as proposed in Equations (1)–(3). Gas evolution was observed over the course of the electrolysis, which is consistent with the production of molecular hydrogen, and this has previously been reported for the electrochemical reduction of diiron complexes in the presence of acid.[17,27,29] Cyclic voltammograms recorded after the electrolysis confirms the consumption of almost all of the protons without any noticeable decomposition of **2** (Figure 4b). Despite the presence of excess acid, the hydrogen production seems to proceed through a bimolecular reaction as in Equation (3) and not through the subsequent protonation and reduction of **2**H (i.e. $\mathbf{2}H + H^+ + e^- \rightarrow \mathbf{2} + H_2$). This is most certainly because of the weakly basic character of **2**H, which is either too slowly protonated by HOTs or not protonated at all.

As in the case of compound **2**, the addition of HOTs to a solution of **3** triggers the appearance of a new reduction process, noted as D in the cyclic voltammograms in Figure 5. This process occurs at a potential less negative than that of the reduction of **3**, noted as C in the same Figure. The height of wave D is responsive to the concentration of acid, which indicates proton reduction catalysis (Figure 5b). The onset of this catalysis by **3** occurs at a potential approximately 0.4 V more negative than that for **2**, which parallels the shift in reduction potential. Although **3** seems to be a less efficient catalyst than **2** on the voltammetric timescale, bulk electrolysis at –1.90 V of a solution of **3** containing 8.3 molar equiv. HOTs consumed 8.0 F per mol of **3** over a period of about 120 min. The voltammograms in Figure 5b show that most of the protons were consumed by electrolysis, which suggests that, as in the case of **2**, the catalysis by **3** involves a bimolecular reaction [see Equation (3)].

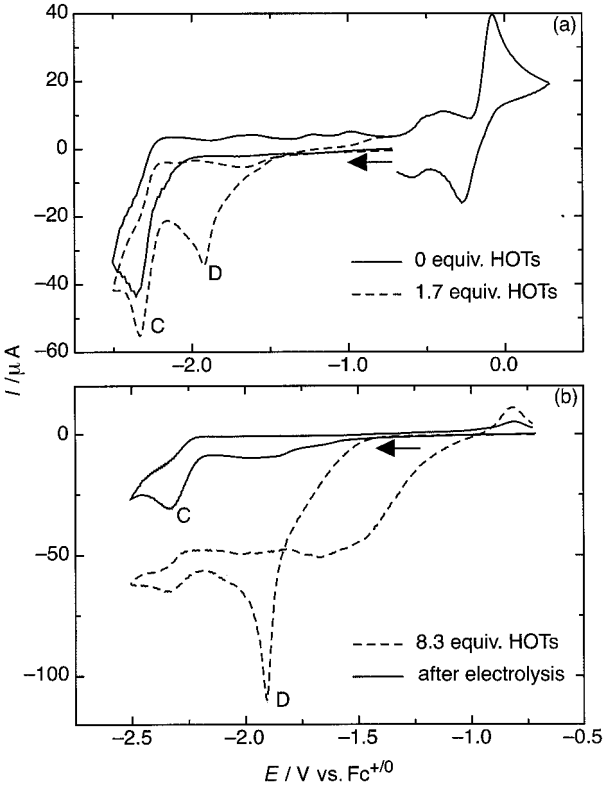

Figure 5. Cyclic voltammograms of compound **3** in $CH_3CN/Bu_4NPF_6$ (a) before and after addition of 1.7 molar equiv. HOTs and (b) after addition of 8.3 molar equiv. HOTs and after electrolysis at –1.9 V. Experimental conditions: $v$ = 0.1 V s$^{-1}$; [**3**] = 2.1 mM; glassy carbon electrode 0.071 cm$^2$ in surface area.

## Conclusions

To summarize our results, we have shown that the electrochemical route represents a convenient method for the selective synthesis of mono- and disubstituted derivatives of diiron dithiolates. We are currently extending this approach to introduce more elaborate ligands (e.g. bidentate ligands) into the coordination sphere of diiron complexes.

Substitution of one CO ligand by one $P(OMe)_3$ ligand shifts the reduction potential of the complex by about 0.3 V. This modification has little effect on the thermodynamics of proton binding. Nevertheless, the voltammogram of **2** in the presence of acid exhibits a reduction wave that does not have a counterpart in the voltammogram of **1**. This is ascribed to proton binding by **2** in the vicinity of the electrode, which is triggered by the more facile reduction of $\mathbf{2}H^+$ relative to that of **2** (CE mechanism). We are presently not able to determine whether the protonation is metal- or ligand- (e.g. sulfur) centered. Bulk electrolysis experiments

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

confirm the occurrence of a CE process and indicate that the proton reduction catalysis occurs most likely by a bimolecular reaction even in the presence of a large excess of acid. It is relevant to note that **2** appears to be a more efficient catalyst in terms of turnovers than the corresponding benzenedithiolate-bridged derivative, whereas the latter works at a significantly less negative potential.[43] This suggests that a careful tailoring of both the bridging and terminal ligands may well lead to an efficient proton reduction catalyst working at a mildly negative potential.

## Experimental Section

**General Procedures:** All reactions were performed under an atmosphere of argon or nitrogen by using conventional Schlenk techniques. Solvents were deoxygenated and dried by standard methods. Literature methods were used for the preparation of $[Fe_2(S_2C_3H_6)(CO)_6]$.[37] All other reagents were commercially available. Bulk electrolysis and cyclic voltammetry experiments were carried out as described elsewhere.[51] Chemical analyses were performed by the Service Central d'Analyse du CNRS (France). IR spectra were recorded in $CH_3CN$ solution with a Nicolet Nexus Fourier transform spectrometer. NMR spectra were recorded with Bruker AMX 3–400 and DRX 500 spectrometers. Single-crystal X-ray diffraction data were collected at 170 K on an X-CALIBUR-2 CCD diffractometer (Oxford Diffraction) with graphite-monochromated Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 Å). The structures of **2** and **3** were solved by direct methods and refined by full-matrix least-squares on $F^2$.[52] Complete crystal data and parameters for data collection and refinement are listed in Table 1. CCDC-49699 and CCDC-649700 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

Table 1. Crystallographic data and processing parameters for complexes **2** and **3**.

| Complex | **2** | **3** |
|---|---|---|
| Empirical formula | $C_{11}H_{15}Fe_2O_8PS_2$ | $C_{13}H_{24}Fe_2O_{10}P_2S_2$ |

**Electrochemical Synthesis of $[Fe_2(S_2C_3H_6)(CO)_5\{P(OMe)_3\}]$ (2):** In a typical procedure, $[Fe_2(S_2C_3H_6)(CO)_6]$ (70 mg, 0.181 mmol) was dissolved in a $N_2$-purged $CH_3CN/Bu_4NPF_6$ solution (15 mL). $P(OMe)_3$ (24 μL, 1.1 molar equiv.) was added by using a microsyringe. Bulk electrolysis was carried out at –1.75 V under vigorous agitation. The color of the solution changed rapidly from orange to brown. After 45–60 min, the quantity of electricity passed reached a plateau value, and the IR spectrum confirmed the total consumption of the starting hexacarbonyl compound. After evaporation of $CH_3CN$ under vacuum, complex **2** was purified by column chromatography on silica gel with hexane/$CH_2Cl_2$ (8:2) as eluent. Yield: 74 mg (85%). IR ($CH_3CN$): $\tilde{\nu}_{CO}$ = 2048 (s), 1991 (vs), 1976 (s), 1938 (w) cm$^{-1}$. $^1$H NMR ($CD_2Cl_2$, 298 K): $\delta$ = 3.75 [d, $^3J_{PH}$ = 11.3 Hz, 9 H, P(O*Me*)$_3$], 2.05 {s br., 4 H, [S-(C*H*$_2$)$_3$-S]}, 1.75 {s br., 1 H, [S-(C*H*$_2$)$_3$-S]}, 1.54 {s br., 1 H, [S-(C*H*$_2$)$_3$-S]} ppm. $^{13}$C{$^1$H} NMR ($CDCl_3$, 298 K): $\delta$ = 211.90 (d, $^2J_{PC}$ = 20.5 Hz, {Fe(*C*O)$_2$[P(OMe)$_3$]}), 209.59 [Fe(*C*O)$_3$], 52.09 [P(O*Me*)$_3$], 30.26, 22.88 [S-(*C*H$_2$)$_3$-S] ppm. $^{31}$P{$^1$H} NMR ($CD_2Cl_2$, 298 K): $\delta$ = 177.04 [*P*(OMe)$_3$] ppm. $^{31}$P{$^1$H} NMR ($CD_2Cl_2$, 183 K): $\delta$ = 186.4 (17%), 184.4 (50%), 178.0 (25%), 177.1 (8%), [*P*(OMe)$_3$] ppm. LSMIS: *m*/*z* calcd. for [M]$^+$ 481.9; found 481.9. $C_{11}H_{15}Fe_2O_8PS_2$ (482.02): calcd. C 27.41, H 3.14; found C 27.90, H 3.40.

**Electrochemical Synthesis of $[Fe_2(S_2C_3H_6)(CO)_4\{P(OMe)_3\}_2]$ (3):** Complex **3** was prepared as described for complex **2** except that the amount of added $P(OMe)_3$ was 2.1 equiv. and that the electrolysis potential was set to –2.0 V. Yield (starting from 70 mg **1**): 71 mg (68%). IR ($CH_3CN$): $\tilde{\nu}_{CO}$ = 2004 (s), 1966 (vs), 1937 (s), 1917 (w) cm$^{-1}$. $^1$H NMR ($CDCl_3$, 298 K): $\delta$ = 3.77 [d, $^3J_{PH}$ = 11.7 Hz, 18 H, 2 P(O*Me*)$_3$], 1.94 {m br., 4 H, [S-(C*H*$_2$)$_3$-S]}, 1.70 {s br., 2 H, [S-(C*H*$_2$)$_3$-S]} ppm. $^{13}$C{$^1$H} NMR ($CDCl_3$, 298 K): $\delta$ = 213.50 (d, $^2J_{PC}$ = 17 Hz, {Fe(*C*O)$_2$[P(OMe)$_3$]}), 51.67 [P(O*Me*)$_3$], 29.94, 22.03 [S-(*C*H$_2$)$_3$-S] ppm. $^{31}$P{$^1$H} NMR ($CD_2Cl_2$, 298 K): $\delta$ = 180.40 [*P*(OMe)$_3$] ppm. LSMIS: *m*/*z* calcd. for [M]$^+$ 577.9; found 577.9. $C_{13}H_{24}Fe_2O_{10}P_2S_2$ (578.08): calcd. C 27.01, H 4.18, P 10.72; found C 27.04, H 4.16, P 10.32.

**Supporting Information** (see footnote on the first page of this article): Plots as a function of the potential scan rate of the oxidation current of compound **3** and $[Fe_2(S_2C_3H_6)(CO)_4(I_{Me}CH_2I_{Me})]$ ($I_{Me}$ = 1-methylimidazol-2-ylidene) used as an internal standard, cyclic voltammetry of **1** and **2** in the presence of added $P(OMe)_3$, along with the kinetic analysis of the charge-transfer-catalyzed substitution process, are presented.

# Nickel(II), Palladium(II) and Rhodium(I) Complexes of New NHC-Thioether Ligands: Efficient Ketone Hydrosilylation Catalysis by a Cationic Rh Complex

**Joffrey Wolf,[a] Agnès Labande,*[a] Jean-Claude Daran,[a] and Rinaldo Poli[a]**

**Keywords:** N-Heterocyclic carbenes / S ligands / Nickel / Palladium / Rhodium

Five new, bifunctional imidazolium–thioether ligands of the general formula $RS(CH_2)_n(imidazolium)^+ArBr^-$ ($n$ = 2 or 3, R = Et or *t*Bu, Ar = 2,4,6-trimethylphenyl or 2,6-diisopropylphenyl) have been synthesised in good overall yields by a general method and used as N-heterocyclic carbene precursors for complexation studies on various transition metals ($Ni^{II}$, $Pd^{II}$ and $Rh^{I}$). Sulfur does not coordinate the nickel centre, whereas the two functional groups bind the palladium centre to form a dinuclear compound. Cationic rhodium(I) complexes have also been prepared and preliminary catalytic tests show that they have good activity for the hydrosilylation of ketones.

## Introduction

N-Heterocyclic carbenes (NHC) have been thoroughly studied over the last 15 years.[1] Whereas the high strength of metal–NHC bonds has yielded new classes of robust catalysts,[2–4] the combination of NHCs and less strongly binding heteroatom donors has been investigated in order to combine robustness and activity in the corresponding complexes. Thus NHC–phosphane[5–10] and NHC-N donor[11,12] or NHC-O donor[13] ligands have been developed. Thioethers are soft donor ligands and have been successfully used in catalysis, mostly in combination with other donors such as phosphanes.[14] In combination with NHCs, they could provide potentially useful catalytic properties. A few NHC–thioether precursors have already been described, but they have mainly been used as bioactive compounds (antibacterials, fungicides)[15] or for heavy metal extraction from water.[16] Few carbene–thioether complexes have been isolated and characterised, respectively, by Seo et al. in 2003[9] and Ros et al. recently[17,18] (Figure 1). NHC–furan and NHC–thiophene ligands have also been described, but only the NHC moiety coordinates the metal centre.[19] We have recently described an efficient synthetic pathway for phosphane–imidazolium compounds, using 1-bromoalkyl-3-arylimidazolium bromides as key intermediates.[5,6] We have now extended this methodology to the synthesis of NHC–thioether precursors and report here the characterisation of these new ligands, as well as representative products of their complexation to various metals of interest in catalysis: nickel(II), palladium(II) and rhodium(I).

## Results and Discussion

### Ligand Syntheses

Compounds **5**–**7** were obtained from 1-(2-bromoethyl)-3-arylimidazolium bromides **1** and **2**, and compounds **8** and **9** from 1-(3-bromopropyl)-3-arylimidazolium bromides **3** and **4**, by nucleophilic substitution with lithium alkylthiolates (Scheme 1). An optimisation study has been carried out on the reaction of compound **1** with lithium *tert*-butyl

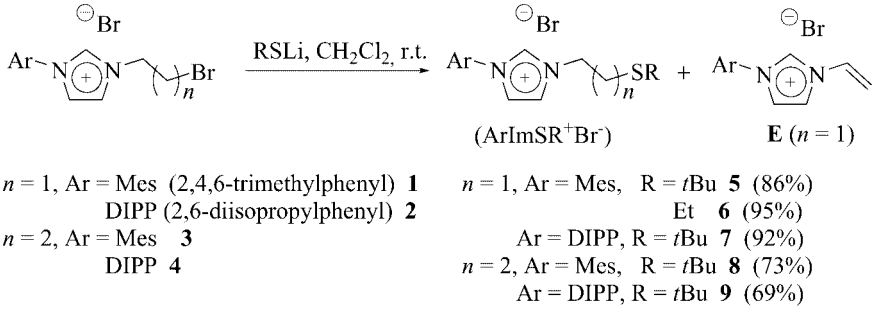

Scheme 1. Nucleophilic substitution on **1**–**4** bromides by lithium alkylthiolate reagents.

thiolate (Table 1). Alcohols and water are commonly used solvents for nucleophilic substitution reactions with thiolates,[20] whereas acetone and DMF are employed with phenolates.[21] Ethanol and DMF produced homogeneous mixtures with our substrates, contrary to acetone and dichloromethane. Our first attempt in ethanol at 60 °C, however, gave 62% of an elimination product, **E**, and only 7% of the expected compound. The temperature was lowered to 25 °C in order to improve the selectivity in favour of the substitution product: compound **5** was obtained in 14% yield, but again with 57% of elimination product (entry 1). A systematic study of the reaction conditions showed that the reaction is highly solvent-dependent, ethanol and acetone leading to substantial amounts of elimination product **E**, whereas dichloromethane and DMSO yield greater selectivity in favour of the substitution product but at slower rates. The conversion was also greatly improved when the reactions were carried out in more dilute media (entries 4 and 6). Under optimised reaction conditions (entry 6), **5** was obtained in very good yields (Scheme 1). These conditions were successfully applied to other substrates to afford thioethers **6**–**9** in good yields.

Table 1. Solvent and concentration screening for ligand **5** synthesis.[a]

| Entry | Solvent | Solvent amount (mL) | **1**/**E**/**5**[b] |
|---|---|---|---|
| 1 | EtOH | 2 | 29/57/14 |
| 2 | $Me_2CO$ | 2 | 38/50/12 |
| 3 | DMSO | 2 | 85/00/15 |
| 4 | DMSO | 3 | 60/00/40 |
| 5 | $CH_2Cl_2$ | 2 | 74/07/19 |

[a] **1** (0.5 mmol), *t*BuSLi (0.55 mmol), 17 h at room temperature. [b] Ratio determined by ethylene signal integration in $^1$H NMR spectra of crude products.

The $^1$H NMR signals of the acidic imidazolium protons are observed between 10.03 and 10.28 ppm for compounds **5**, **6** and **8**, and at $\delta$ = 9.87 ppm for compounds **7** and **9**, which denotes a greater shielding effect of the bulky DIPP compared to the mesityl group. Compounds **5** and **6** were analysed by single-crystal X-ray diffraction. The structures (Figure 2) show hydrogen bonds, as is typically observed for imidazolium bromides,[22] between the bromide anion and the C1 proton (Br1···H1–C1 2.637 Å for **5**, 2.624 Å for **6**).

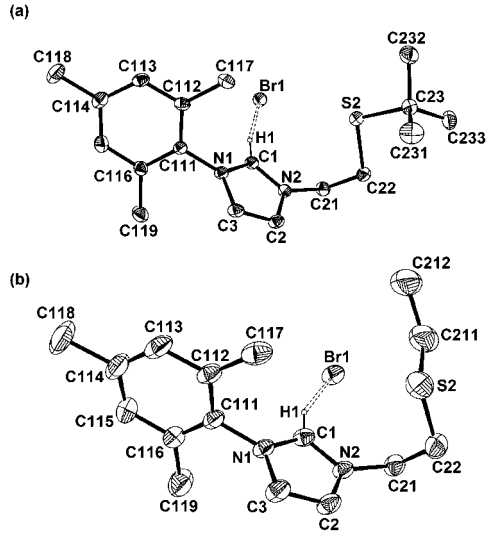

Figure 2. ORTEP views of **5** (a) and **6** (b). Ellipsoids are shown at the 30% probability level. All hydrogen atoms except H(1) and the solvent molecule ($CH_2Cl_2$) which co-crystallised with **5** are omitted for clarity.

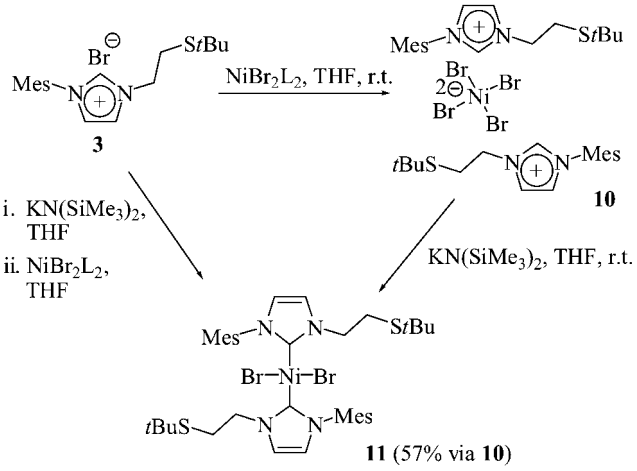
## Nickel Complexes

Preliminary complexation studies were carried out with the catalytically relevant metals nickel, palladium and rhodium. Our previous studies of the coordination of phosphane-imidazolium salts to $Ni^{II}$ complexes of type $NiX_2L_2$ led to the isolation of zwitterionic compounds of the formula [$NiX_3(PPh_2ImAr)$], where ImAr is as defined in Scheme 1.[5,6] The analogous reaction of **5** with 1 equiv. of $NiBr_2$(DME) did not give the corresponding zwitterionic species with sulfur coordination. A $NiBr_4^{2-}$ species with two imidazolium/thioether counterions, **10**, was obtained instead (Scheme 2). Deprotonation of **10** with *t*BuOK led to the biscarbene complex **11**, with no sulfur coordination onto the nickel centre. The alternative strategy consisting of initial deprotonation of ligand **5** with a strong base, followed by reaction of the resulting free carbene with $NiBr_2$(DME), also led to the same product. The absence of sulfur coordination has two possible explanations: the bulkiness of the *tert*-butyl group prevents the coordination on the nickel, or the sulfur donor power is insufficient to compete with bromide for coordination. In order to con-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

firm one of these hypotheses, we added 1 equiv. of **6**, which contains a less bulky ethyl substituent, to 1 equiv. of $NiBr_2(MeCN)_2$. During the treatment, unreacted nickel corresponding to half of the starting material was recovered. This result would be more in favour of the second hypothesis, although we have no further evidence to validate it.



Scheme 2. Nickel(II) complex synthesis.

The crystal structure of compound **11** has been resolved by X-ray analysis (Figure 3). As the nickel atom is located on an inversion centre, the geometry around it is perfectly square-planar. The imidazol-2-ylidene ring is planar [maximum deviation of 0.005(1) Å for atom N2] and is approximately perpendicular [angle of 75.06(5)°] to the coordination plane, thus limiting steric interactions. This was already observed for other previously described $Ni^{II}$–bis(NHC) complexes.[23] The mesityl ring forms an angle of 77.63(6)° with the NHC ring, and we can notice the existence of an interaction between a hydrogen from methyl C119 and Br1 (C119···Br1$^{i}$ 2.75 Å). Selected bond lengths and angles are listed in Table 2.

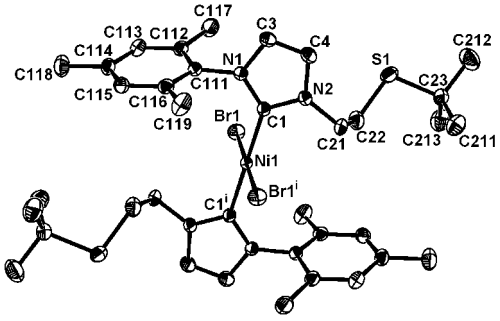


Figure 3. An ORTEP view of compound **11**. Ellipsoids are represented at the 50% probability level. Hydrogen atoms are omitted for clarity.

Although only one isomer is present in the crystal, analysis by $^1H$ and $^{13}C$ NMR revealed a mixture of two distinct isomers in solution in a ratio of 1:1.27. We believe that these

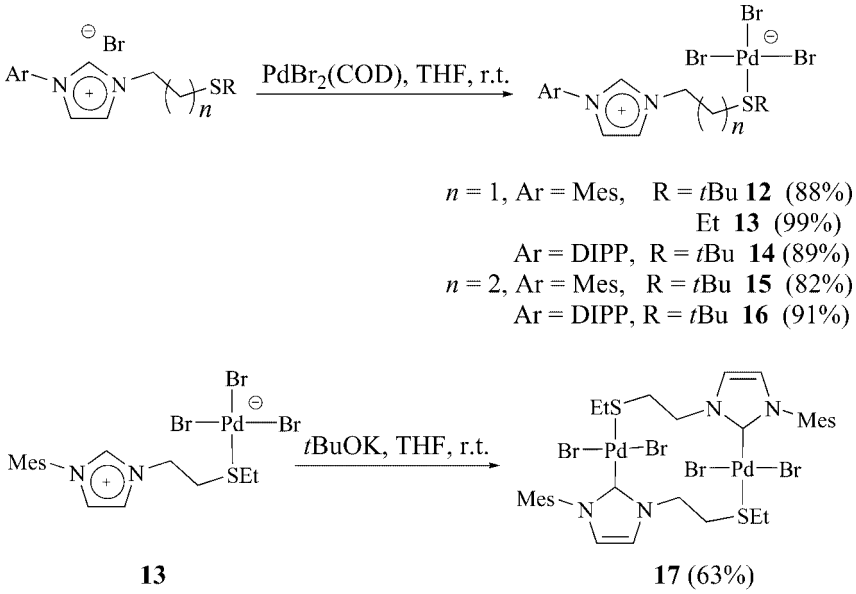
[a] L = 1,3-dicyclohexylimidazol-2-ylidene.

are conformational isomers. In the crystalline compound, the aryl and thioether alkyl chains of the two imidazol-2-ylidene groups are mutually *anti* to afford a head-to-tail arrangement, which minimises steric interactions. Strong steric interactions between the N-substituents in a bis-NHC-$Ni^{II}$ complex have been observed for $NiCl_2$[1,3-bis(2,6-diisopropylphenyl)imidazol-2-ylidene]$_2$, resulting in a significant deviation from coplanarity for the two NHC rings.[24] For our compound, it is possible to envisage that the different N-substituents adopt a *syn* orientation in the second isomer and that there is a significant barrier for the 180° rotation that is required to interconvert them. Recent work by Gomes et al.[25] has shown that the energy barrier for a 180° rotation of a N-heterocyclic carbene along the C–Ni axis, in allyl $Ni^{II}$ complexes, is 14–15 kcal mol$^{-1}$ for NHCs bearing methyl substituents and becomes >18 kcal mol$^{-1}$ with *tert*-butyl substituents. In our case, the imidazole-2-ylidene bears a bulky mesityl group on one side and a functionalised alkyl chain on the other side. Therefore it becomes possible to independently observe two conformational isomers.

## Palladium Complexes

Contrary to the nickel system, addition of ligands **5**–**9** to $PdBr_2$(COD) led to the expected coordination of the sulfur and bromine atoms, leading to the zwitterionic complexes **12**–**16** in good yields (Scheme 3). A zwitterionic structure for these complexes, with a coordinated thioether function and a dangling imidazolium group, is suggested by the spectroscopic data. The typical signal of the acidic imidazolium proton is still present in the $^1H$ NMR spectra of all complexes and is situated between 9.00 and 9.61 ppm. Likewise, the elemental analyses of the complexes are in agreement with the calculated values. Subsequent deprotonation of **13** (Scheme 3) led to NHC complex **17**. The $^1H$ and $^{13}C$ NMR properties are consistent with the expected stoichiometry, as for the related phosphane-carbene complexes previously

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 



Scheme 3. Synthesis of palladium(II) complexes.

described by Danopoulos et al.[7] and Lee et al.[26] The $^{13}C$ NMR signal of the carbene C atom is observed at $\delta$ = 155.75 ppm in the case of **17**, and respectively at $\delta$ = 157.2 and 162.4 ppm for the above-mentioned phosphane-carbene complexes. Moreover, the $^{1}H$ NMR spectrum of **17** only shows two protons for the imidazole cycle, appearing as doublets, and a 2D HMBC NMR experiment confirms the existence of a long-range coupling between these protons and the carbene C atom.

However, the X-ray structure (Figure 4) reveals that **17** is a dinuclear complex where each palladium centre displays a slightly distorted square-planar coordination environment. The two square-planar moieties are located face to face and the two NHC–thioether ligands span the metal centres in a relative *trans* arrangement. Pd–C and Pd–S bond lengths are comparable to the usual NHC–$Pd^{II}$ and thioether–$Pd^{II}$ bonds.[7,26,27] A similar arrangement is adopted by related NHC–oxazoline derivatives. Only three X-ray structures of $Pd^{II}$ complexes possessing a chelating NHC–thioether ligand have been described:[17,18] in these cases, the sulfur atom is situated *cis* to the NHC moiety, with Pd–C and Pd–S distances of, respectively, 2.036–2.063 Å and 2.326–2.367 Å. Mass spectrometry analyses (FAB technique) confirm the existence of a dinuclear compound.

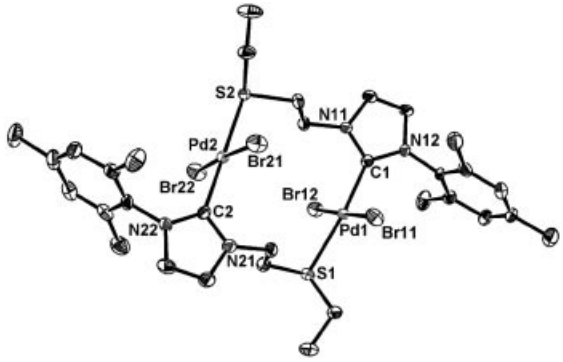


Figure 4. An ORTEP view of compound **17**. Ellipsoids are represented at the 30% probability level. Hydrogen atoms and a co-crystallised THF molecule are omitted for clarity. Selected bond lengths [Å] and angles [°]: Pd1–C1 1.990(4), Pd2–C2 1.983(4), Pd1–S1 2.3731(9), Pd2–S2 2.3622(9), Br21–Pd2–Br22 175.50(2), C1–Pd1–S1 173.10(12).

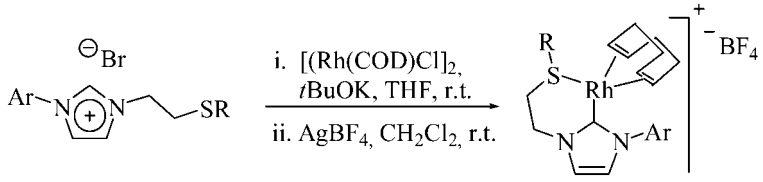
## Rhodium Complexes

Addition of compounds **5**–**7** to $[Rh(COD)Cl]_2$ in the presence of a strong base (Scheme 4) led, after halide abstraction, to the formation of NHC derivatives **18**–**20**. The



R = *t*Bu, Ar = Mes **18** (81%)
Ar = DIPP **19** (79%)
R = Et, Ar = Mes **20** (76%)

Scheme 4. Synthesis of rhodium(I) complexes.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

nature of these products, as salts of typical square-planar $Rh^I$ complexes with *cis* chelating NHC–thioether ligands, is consistent with the spectroscopic characterisation. The $^{13}C$ NMR signals of the carbene C atoms appear around 173 ppm, which is the expected value for cationic NHC–$Rh^I$ complexes.[10,18,28] The sulfur coordination on rhodium is suggested by the downfield shift (about 7 ppm) of the quaternary carbon on sulfur for complexes **18** and **19**, and of the S–$CH_2CH_3$ carbon signal (about 6 ppm) for complex **20**.[29]

The square-planar coordination environment in complexes **18**–**20** was confirmed by X-ray diffraction studies (Figure 5). Selected bond lengths and angles are listed in Table 3. The structures reveal slightly shorter Rh1–C1 bond lengths than in Seo's NHC–thioether complex. Rh1–S1 distances are within the same range, except compound **20**, for which we observe a shorter bond of 2.351(2) Å. The Rh1–C(COD) bonds *trans* to NHC are longer than the bonds *trans* to sulfur, which indicates a stronger *trans* influence of the NHC moiety. A boat-like conformation of the six-membered metallacycle is a common feature for all these structures. In the case of compound **20**, the deviation from the ideal 90° value of the C1–Rh1–S1 angle [82.5(2)°] could be because of a close contact between the methylene of the ethyl arm on sulfur (C311) and the COD ligand [intramolecular distances: C5–C311 3.45(1) Å and H5–H31A 2.36 Å; C6–C311 3.52(1) Å and H6–H31B 2.30 Å]. This value is consistent with the previously reported data for similar complexes.[10,18,30] This distortion cannot be observed in **18** and **19**, which have a bulky *tert*-butyl substituent on sulfur.

**Catalytic Hydrosilylation of Methyl Aryl Ketones**

The catalysed hydrosilylation of ketones has attracted a lot of attention for many decades as it is an efficient synthetic alternative to the reduction of the carbonyl group by main group hydrides and catalytic hydrogenation.[31] Rhodium is the favoured catalytic metal for this process, even though other metals have been used. Neutral precatalysts derived from $RhCl(PPh_3)_3$,[32,33] $[RhCl(olefin)_2]_2$ [olefin = ethylene, cyclooctene; or $(olefin)_2$ = 1,5-cyclooctadiene, norbornadiene],[33–36] $RhH(PPh_3)_4$[37] or $RhCl_3L_3$[38] derivatives have most commonly been used to generate the active catalyst, but a few processes using cationic precursors have also been reported.[39,40] It has also been reported that the assistance of AgX (X = $OSO_2CF_3$, $BF_4$) is required in some cases to improve the catalytic activity,[38,41] presumably through transformation into a more active cationic species. The typical supporting ligands, including chiral versions for the enantioselective hydrosilylation of prochiral ketones, are based on P or N donors. Although several catalysts have shown outstanding activities,[36,41,42] the issue of catalyst stability and deactivation may hamper extension to large-scale production. As NHC ligands are likely to be solidly anchored to the metal centre, they may be expected to impart activity and stability to the catalytic system. Previous reports of ketone hydrosilylation using NHC ligands are limited.[12,43,44] For these reasons, we considered it of interest to test the catalytic activity of the cationic rhodium complexes **18**–**20**.

Preliminary catalytic tests have shown that these complexes are indeed active in the hydrosilylation of acetophenone and its derivatives (Tables 4 and 5, Scheme 5). The reactions were followed by TLC and the silylated intermediate was hydrolysed with MeOH before $^1H$ NMR analysis. The reactions were first carried out with 2 mol-% of **18**, in dichloromethane or THF. The yield of the expected alcohol reached 90% in dichloromethane in 17 h (Table 4, entry 1), whereas it was quantitative in THF (Table 4, entry 2). The catalyst loading was thus lowered to 1 mol-%. With a concentration of 1 M in acetophenone in THF, the yield reached 90% after 24 h. However, working in a more concentrated medium allowed us to get a total conversion of the substrate into the alcohol in only 4 h (entry 4). A similar result was obtained with complex **19** (Table 4, entries 5 and 6). Finally, complex **20** proved to be the most active, with a quantitative yield of alcohol in only 1 h at room temperature (Table 4, entry 7). The same trend was observed with 4-methoxyacetophenone (Table 5, entries 1–5): increasing the concentration allowed us to get a total conversion of the substrate into the desired alcohol in a reduced time, while **20** showed a better activity than **18** and **19**. Similar results were obtained with 4-fluoroacetophenone, bearing an electron-withdrawing substituent (Table 5, entries 6–8). The introduction of a methyl group *ortho* to the halide, however, slowed the reaction down. As an example, the reaction with **18** did not go to completion after 6 h, with only 78% conversion (Table 5, entry 9). Thus steric factors seem to have more influence than electronic factors on the issue of the reaction. Finally, no reaction occurred when other silanes ($Et_3SiH$, $MeEt_2SiH$ and $HSiCl_3$) were used with acetophenone.

Table 4. Hydrosilylation of acetophenone.[a]

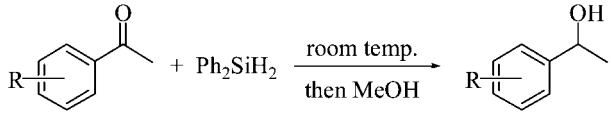
[a] Ketone (1 equiv.), diphenylsilane (1.1 equiv.), room temperature, 1 mol-% catalyst, THF, then hydrolysis with MeOH. [b] Determined by integration of signals in $^1H$ NMR spectra of crude products. [c] The reaction was stopped before completion.



Scheme 5. Hydrosilylation of acetophenone and its derivatives with $Rh^I$ complexes.

The activity of our complexes compares well with previously reported $Rh^I$ systems bearing bifunctional NHC-oxazoline ligands. Thus, Bolm et al. obtain excellent yields of 1-phenylethanol with their system, using 2 mol-% of catalyst in THF at room temperature or at 0 °C.[44] Unfortunately there is no indication of reaction times, which does not allow a direct comparison with our results. On the other hand, César et al. report the hydrosilylation of acetophenone with diphenylsilane using 1 mol-% catalyst in dichloromethane at room temperature. In their case, the $Rh^I$ complexes tested give from 70% to 93% yield in a maximum of 5 h.[12]

The higher catalytic activity observed at higher ketone concentration is in agreement with previous reports of a saturation effect: the reaction was found to be first order in ketone at low concentrations, but eventually became [ketone] independent at high concentrations.[35,40]

## Conclusions

In conclusion, we have described a general and simple method for the preparation of new NHC–thioether precursors and explored their coordination chemistry. The coordination of sulfur on nickel was not observed, yielding complex **11** where the two ligands are monodentate through the NHC function and the thioether function is dangling. In the case of palladium(II), a dinuclear complex with *trans* carbene and sulfur coordination, **17**, was obtained. Rhodium(I) complexes with chelating carbene/thioether ligands were finally prepared in good yields. Preliminary catalytic studies have shown that these complexes are very active for the hydrosilylation of acetophenone and its derivatives. The asymmetric version of this reaction, as well as other catalytic reactions, is now under investigation, and the results will be published in due course.

## Experimental Section

**General Methods:** Reactions involving air- or moisture-sensitive reagents and products were carried out under dry argon using Schlenk glassware and vacuum line techniques, and dry, purified solvents. All other steps were done without particular precautions. Elemental analyses were carried out by the Service d'Analyse du Laboratoire de Chimie de Coordination in Toulouse. $^1$H and $^{13}$C{$^1$H} NMR spectroscopic data were recorded with a Bruker AV-500 spectrometer, operating at 500 MHz for $^1$H and 125.8 MHz for $^{13}$C and on a Bruker AV-200 spectrometer operating at 188 MHz for $^{19}$F. The spectra were referenced internally using the signal from the residual protiosolvent ($^1$H), the signals of the solvent ($^{13}$C) or the signal of trifluoroacetic acid, 10% in $C_6D_6$ ($^{19}$F). Mass spectra (ESI) were obtained from acetonitrile or methanol solutions on a TSQ 7000 (Thermo Electron) and (FAB) from DMSO or DMF solutions on a Nermag R10-10 instrument. Electrospray high-resolution mass spectra were performed by the Service de spectroscopie de masse CESAMO de l'université de Bordeaux I. Chromatographic work was performed on silica gel 60 Å. $PdBr_2(COD)$,[45] 1-(2-bromoethyl)-3-(2,4,6-trimethylphenyl) imidazolium bromide **1**,[6] 1-(2-bromoethyl)-3-(2,6-diisopropylphenyl)imidazolium bromide **2**[6] and 1-(3-bromopropyl)-3-(2,4,6-trimethylphenyl)imidazolium bromide **3**[6] were prepared as described in the literature. Both lithium alkylthiolates were prepared by action of methyllithium on the corresponding thiols and used rapidly after their preparation. Other reagents were obtained from commercial sources and used as received.

**1-[2-(*tert*-Butylthio)ethyl]-3-(2,4,6-trimethylphenyl)imidazolium Bromide (5):** *t*BuSLi (170 mg, 1.77 mmol) was added to a solution of **1** (610 mg, 1.63 mmol) in $CH_2Cl_2$ (10 mL). The mixture was stirred for one day at room temperature. $CH_2Cl_2$ (20 mL) was added and the mixture was washed with water (10 + 5 mL). The organic phase was dried ($MgSO_4$), filtered and concentrated under vacuum to give a white, hygroscopic solid. Yield 535 mg (86%). Suitable X-ray colourless crystals were obtained by slow diffusion of diethyl ether in a $CH_2Cl_2$ solution. # Synthesis and Structure of Tetrameric Gallium(I) Amides

**Annekathrin Seifert[a] and Gerald Linti*[a]**

**Keywords:** Gallium / Amides / Cluster compounds / X-ray structures / Density functional calculations

The amino substituted gallatetrahedranes described herein, $Ga_4(tmp)_4$ [tmp = 2,2,6,6-(tetramethylpiperidino)] and $Ga_4[N(SiMe_3)dipp]_4$ (dipp = 2,6-diisopropylphenyl), are the first oligomeric gallium(I) amides to be reported. These compounds are formed in a facile manner from "GaI". A new hexagallane with an unusual structure is also described. The clusters were characterized by NMR and UV/Vis spectroscopy, single-crystal X-ray crystallography, and DFT calculations.

(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2007)

## Introduction

The cluster chemistry of gallium seems to be dominated by metal-rich compounds.[1] Prominent examples include $[Ga_8\{Si(CMe_3)_3\}_6]^{x-}$, ($x$ = 0, 2),[2] $[Ga_9\{Si(SiMe_3)_3\}_6]^-$,[3] $[Ga_{10}\{Si(SiMe_3)_3\}_6]$,[4] $Ga_{11}(C_6H_3\text{-}2,6\text{-}Mes_2)_4$,[5] $[Ga_{12}(fluorenyl)_{10}]^{2-}$,[6] $[Ga_{13}\{Si(CMe_3)_3\}_6]$,[4] $[Ga_{22}R_8]$ [R = $Si(SiMe_3)_3$],[7] $Ge(SiMe_3)_3$,[8] $Si(CMe_3)_3$,[9] $[Ga_{26}\{Si(SiMe_3)_3\}_8]^{2-}$,[10] $[Ga_{84}\{N(SiMe_3)_2\}_{20}]^{4-}$,[11] and $Ga_{23}[N(SiMe_3)_2]_{11}$.[12]

Known gallium(I) derivatives are either cluster compounds, $(GaR)_n$ where $n$ = 4–9, or monomeric species. Examples of cluster compounds are $Ga_4R_4$ [**1a** R = $C(SiMe_3)_3$,[13] **1b** $Si(SiMe_3)_3$,[14] **1c** $Si(CMe_3)_3$[15]], $Ga_6[SiMe(SiMe_3)_2]_6$,[16] and $[Ga_9(CMe_3)_9]$.[17,18] For $(GaR)_n$ clusters, $n$ skeletal electron pairs are counted, these clusters may hence be termed *hypercloso* clusters. $[Ga_6[Si(CMe_3)_3]_4(CH_2Ph)_2]^{2-}$[16] and $[Ga_8(fluorenyl)_8]^{2-}$[19] have two more electrons in their cluster core; therefore, they are *closo*-type clusters according to the Wade rules.[20–23] More bulky substituents stabilize less aggregated compounds such as the dimeric compound $[Ga(2,6\text{-}dipp_2\text{-}C_6H_3)]_2$.[24] GaCp* is monomeric in the gas phase and in solution, but it forms a weakly bound hexameric crystal structure.[25–27] [Ga{2,6-$iPr_2C_6H_2NC(CH_3)_2\}_2CH$][28] and the recently reported gallium amide $[GaN(SiMe_3)(2,6\text{-}Mes_2C_6H_3)]$ (**2**)[29] are monomers with a broad scope of applications. A very versatile starting material into this chemistry has been "GaI".[30,31]

Gallium(I) amide species are still rare. The parent compound, $GaNH_2$, has been studied in a matrix.[32] As a whole, amino groups are investigated less frequently as cluster-stabilizing substituents; with the exception of the $(Me_3Si)_2N$ group, which is used to synthesize metalloid clusters.

Here we report on reactions of "GaI" with bulky lithium amides to obtain tetrahedral clusters of gallium.

## Results and Discussion

By treating "GaI"[30] with equimolar amounts of Li[N(2,6-$iPr_2C_6H_3$)($SiMe_3$)] [Equation (1)] in a toluene/thf mixture (2:1) at –78 °C, [Ga{N(2,6-$iPr_2C_6H_3$)($SiMe_3$)}]$_4$ (**3**) is obtained. In a comparable manner, $[Ga(tmp)]_4$ (**4**) was synthesized by reaction of "GaI" and Li(tmp) [tmp = 2,2,6,6-(tetramethylpiperidino)]. Compounds **3** and **4** were isolated in moderate yields of 24% and 34%, respectively. The reactions described here allow synthetically useful amounts of material to be prepared from "GaI", whereas other reactions starting from "GaI" form a mixture of products simultaneously and mostly in very low yields, as a result of disproportionation and redox reactions that in-

volve the reagent LiR. This difference may be due to the lower reductive ability of amides compared to that of silanides.

Nevertheless, the formation of elemental gallium points to accompanying redox reactions. No products could be isolated, but in the case of the tmp derivative, NMR spectra of the reaction mixture indicated the formation of Ga(tmp)$_2$I[33] and Ga$_2$(tmp)$_4$,[34] which are expected byproducts. Gallium(I) amides **3** and **4** are yellow and very soluble in *n*-hexane, toluene, and tetrahydrofuran. Compound **3** is tetrameric in benzene solution, as determined by cryoscopy. Temperature-dependent NMR spectroscopic studies (20–70 °C) suggest a tetramer/monomer equilibrium in solution (see below).

In the case of LiN(SiMe$_3$)$_2$, the tetrameric species [GaN(SiMe$_3$)$_2$]$_4$ was not observed, and only the disproportionation product **5** was isolated in minor yields [Equation (2)]. This is partly in line with the results observed for the reaction of metastable GaX solutions with LiN(SiMe$_3$)$_2$, which lead to the higher metalloid Ga$_{23}$ and Ga$_{84}$ clusters. In a similar reaction, with only toluene as solvent, the only observed products were gallium and Ga[N(SiMe$_3$)$_2$]$_3$. The source of the oxygen atom that bridges two gallium atoms in **5** was not clear. Either thf was cleaved by the Lewis acidic Ga[N(SiMe$_3$)$_2$]I units or Ga[N(SiMe$_3$)$_2$]I was hydrolyzed by traces of water. Compounds **5** and **5a**, a derivative of **5** in which Li(thf) is replaced by a LiILi(thf)$_3$ unit (see Supporting Information), were formed reproducibly. This might be indicative of thf as the oxygen source.

$$\text{"GaI"} + \text{LiN(SiMe}_3\text{)}_2 \xrightarrow[-78\,^\circ\text{C}\ -\text{Ga}\ -\text{LiI}]{\text{toluene/thf}} \underset{\mathbf{5}}{\text{[Li(thf)][Ga}_6\text{IO\{N(SiMe}_3\text{)}_2\}_6\text{]}} \quad (2)$$

## Spectroscopic Characterization

Both compounds **3** and **4** were fully characterized by $^1$H-, $^{13}$C-, $^{29}$Si NMR and UV/Vis spectroscopy and elemental analyses as well as X-ray structure analysis. The signals in the proton and carbon NMR spectra were associated by HMBC correlation. For **3**, a characteristic signal for the SiMe$_3$ group was found at $\delta$ = 0.09 ppm. The proton resonance of the isopropyl moiety was detected as one set of doublets at $\delta$ = 1.26 ppm (CH$_3$) and a septet at $\delta$ = 3.4 ppm (CH). The coincidence of the diastereotopic methyl groups is indicative of a similar environment and thus of free rotation around the Ga–N bonds. The singlet observed at $\delta$ = 3.2 ppm for the SiMe$_3$ group at 293 K by $^{29}$Si NMR spectroscopy was the most characteristic for **3**. Upon heating to 333 K, a new signal at 1.4 ppm appeared, but it disappeared again upon cooling. This is indicative of the dissociation of **3** in solution. A $\Delta G$ value of 20 kJ/mol for the dissociation of **3** into monomers was derived from the NMR spectroscopic data. Quantum chemical calculations (see below) predict low tetramerization energies for GaNR$_2$ and are in line with this observation.

The $^1$H NMR spectrum for **4** shows three signal groups. The methyl groups resonate at $\delta$ = 1.65 ppm, the protons of the six-membered piperidine ring give rise to multiples at $\delta$ = 1.32 and 1.55 ppm. The carbon atoms in the ring resonate at 18.7 (C-4), 41.3 (C-3,5), and 55.6 (C-2,6) ppm in the $^{13}$C NMR spectrum, as expected. The resonance signal for the methyl groups is at $\delta$ = 36 ppm. The chemical shift for C-2,6 is typical for Ga(tmp) derivatives and is shifted to higher frequencies compared to tmpH. For comparison, the formal oxidation product of **4**, [Ga(tmp)S]$_4$, shows a signal for C-2,6 at $\delta$ = 54.9 ppm.[35] Here, too, the observation of only one set of tmp signals is indicative of free rotation around the Ga–N bond.

The mass spectra of **3** and **4** do not have the molecular peak characteristic for the tetramers. In the case of **4**, the peak at highest mass, at *m*/*z* = 419, corresponds to [Ga$_2$(tmp)$_2$]$^+$, from which one Ga is lost to give [Ga(tmp)$_2$]$^+$ at *m*/*z* = 349.

Solutions of **3** and **4** absorb in the UV range at 280 and 268 nm, respectively. The extinction coefficients suggest a weak transition. In contrast, the intensively colored silyl and organyl substituted gallatetrahedranes show absorption bands at about 500 nm.

## Crystal Structure Analyses

Tetragallane **3** crystallizes from *n*-hexane at –30 °C as yellow crystals in the monoclinic space group $P2_1c$ (Table 1), while **4** crystallizes in the monoclinic space group *Cc*. The molecular structures of molecules **3** and **4** are presented in Figure 1 and Figure 2.

The cores of **3** and **4** are distorted tetrahedra of gallium atoms. The gallium–gallium distances in **3** spread over a range of 10 pm [$d_{Ga-Ga}$ = 258.6(1)–268.5(1) pm], those for **4** cover a range of 6 pm [$d_{Ga-Ga}$ = 258.4(1)–264.2(1) pm]. This is different from the results obtained for silyl and organyl substituted gallatetrahedranes, in which nearly regular tetrahedra were observed. Silyl substituted derivatives **1b** and **1c** have shorter gallium–gallium distances [$d_{Ga-Ga}$ = 258.4 pm, **1b**;[14] 257.2 pm, **1c**[15,36,37]] than organyl substituted ones [$d_{Ga-Ga}$ = 268.8 pm, **1a**].[13] Steric as well as electronic reasons for these differences have been discussed.[1] The gallium–nitrogen bond lengths in **3** and **4** are similar. The average Ga–N distances are 186.0 and 188.5 pm for **3** and **4**, respectively. The nitrogen atoms in **3** and **4** are coordinated in a nearly planar manner by a gallium atom and two carbon atoms (or a silicon atom). In **3**, the nitrogen atoms are less than 2 pm outside the corresponding Ga–Si–C-planes. In **4**, the deviation is slightly larger, with values between 5 and 15 pm. Nevertheless, the nitrogen atoms can be regarded as coordinated in a planar fashion. The N–Si–C bond lengths and the Ga–N–Si bond angle in **3** are very similar to those observed for **2**. The gallium–nitrogen bond lengths in **3** are similar to that in a N(SiMe$_3$)dipp derivative of gallium(III).[38] The gallium–nitrogen distances of **4** are in the typical range observed for Ga(tmp) compounds like Ga$_2$(tmp)$_4$ [$d_{Ga-N}$ = 190.1(4) pm] and Ga(tmp)$_2$Ph

[$d_{Ga–N}$ = 188.3(2) pm].[33] Gallium(I) amides with two- and three-coordinate gallium atoms have longer gallium–nitrogen distances, e.g. [{H(CMeCdipp$_2$N)$_2$}Ga][28] [$d_{Ga–N}$ = 205.4(2) pm], [dippNC(NCy$_2$)Ndipp]Ga[39] [$d_{Ga–N}$ = 209.1(2) pm], and Tp*t*Bu$_2$Ga [$d_{Ga–N}$ = 223.0(5) pm], where Tp*t*Bu$_2$ = tris(3,5-di-*tert*-butylpyrazolyl)hydroborato.[40] Even relative to the monomeric gallium(I) amide **2** [$d_{Ga–N}$ = 198.0(2) pm], the gallium–nitrogen bonds seem to be shortened by 10 pm. The gallium–nitrogen distances in the metalloid clusters Ga$_{23}$ and Ga$_{84}$ are in a similar range [$d_{Ga–N}$ = 186–190 pm]. A comparable shortening was observed on the tetramerization of [GaC(SiMe$_3$)$_3$].[13] The long Ga–X bonds in the monomer were explained by the influence of the lone pair. To determine whether this is valid for gallium(I) amides as well, DFT calculations were performed.

Compound **5** crystallizes in the triclinic space group $P\bar{1}$ together with a disordered molecule of tetrahydrofuran. Compound **5** (Figure 3) is a hexagallanate with six bis(trimethylsilyl)amino, one iodo, and one oxo substituents. The counterion is a lithium cation coordinated by a thf molecule. The lithium ion is bonded by a Li–O and a Li–N contact to the hexagallane core. This means that the $Ga_6X_9^-$ derivative has an intermediate formal oxidation state of 1.66, which is close to that of $Ga_4I_6$. The latter was synthesized directly from the elements[41] and could be identified[42] by means of Raman spectroscopy as a possible component of "GaI". Upon heating a suspension of "GaI" in toluene to about 100 °C for a week, crystals of $Ga_4I_6$ can be obtained.

The structure of **5** is best described as a central gallium atom coordinated by four gallium atoms in a distorted tetrahedron (angles Ga–Ga–Ga = 89.9–120.9°). Three of them are part of $GaX_2$ groups where $X_2$ is [N(SiMe$_3$)]$_2$, [N(SiMe$_3$)I], or [N(SiMe$_3$)]$_2$O$_{0.5}$. The fourth gallium atom is part of a $Ga_2$ unit and is ligated to a N(SiMe$_3$)$_2$ group and a [GaN(SiMe$_3$)$_2$O$_{0.5}$] group. Thus, a five-membered ring composed of four gallium atoms and one oxygen atom is formed in a slightly twisted conformation [torsion angles for Ga1–Ga5–Ga3–Ga2 and Ga5–Ga3–Ga2–O1 are –19.2° and 24.6°, respectively].

The iodine atom bonded to Ga4 is connected to Ga5 as well, which means that Ga5 is tetracoordinate, like the central Ga3. The gallium–iodine distances ($d_{Ga–I}$ = 289.2 and 299.0 pm) are relatively long compared to other compounds with four-membered $Ga_3I$ rings; for example, in {(Me$_3$Si)$_3$Si}$_4$Ga$_4$I$_3^-$ (**6**)[3] they are at 285 pm. The remaining gallium atoms are in a planar environment made up of their substituents. The nonplanar, four-membered $Ga_3I$ ring has an acute angle [angle (Ga–I–Ga) = 73.68(3)°] at the iodine atom. The remaining inner ring angles are between 89 and 92°. The ring is butterfly-like with a roof angle of 31.7°. Both rings are oriented orthogonally to one another. The gallium–gallium bond lengths range from 246.5 to 252.7 pm, which is typical for digallanes $R_4Ga_2$ and other oligogallanes,[1] which can be described by 2c2e gallium–gallium bonds. Also comparable is the subhalide $Ga_5Cl_7$·(OEt$_2$)$_5$,[43] in which a central gallium atom is tetrahedrally surrounded by four gallium atoms, and tetragallane **6**[3] [average $d_{Ga–Ga}$ = 253 pm].

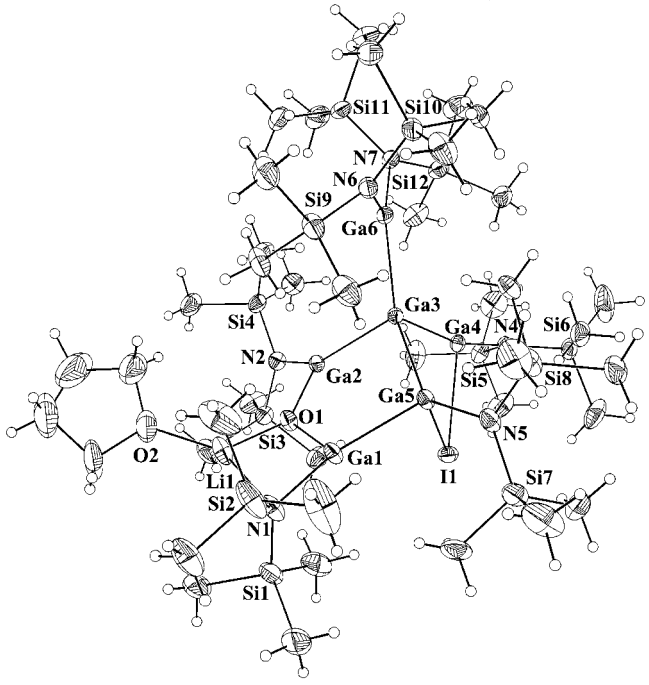

Figure 3. View of a molecule of **5**. Selected distances [pm] and angles [°]: Ga1–Ga5 250.00(9), Ga2–Ga3 250.59(8), Ga3–Ga4 246.49(8), Ga3–Ga5 248.8(1), Ga3–Ga6 252.7(1), Ga4–I1 289.2(1), Ga5–I1 299.04(9), Ga1–O1 185.1(2), Ga2–O1 185.1(2), Ga1–N1 196.8(3), Ga2–N2 190.0(3), Ga4–N4 186.4(3), Ga5–N5 190.4(3), Ga6–N6 190.0(3), Ga6–N7 191.2(3§), N–Si 174.2(3)–175.6(4); Ga2–Ga3–Ga4 96.65(3), Ga2–Ga3–Ga6 118.46(3), Ga4–Ga3–Ga6 120.88(3), Ga4–Ga3–Ga5 89.94(3), Ga6–Ga3–Ga5 128.77(3), Ga2–Ga3–Ga5 94.22(4).

The gallium–nitrogen bond lengths are between 186.4 and 196.8 pm. This is in the typical range for gallium–nitrogen bonds, e.g. Ga[N(SiMe$_3$)$_3$] [$d_{Ga–N}$ = 186.8(1) pm].[44–47] Bonds between gallium and nitrogen show considerable variations due to inductive and steric effects of gallium substituents. In general, electron-withdrawing substituents at gallium lead to shorter gallium–nitrogen bonds.[33] In **5**, the longest gallium–nitrogen bond is the Ga1–N1 bond, where N1 is coordinated to lithium. The shortest is the Ga4–N4 bond, where the gallium is also bonded to an iodine atom.

At the triply coordinated gallium centers Ga2 and Ga6, the $NSi_2$ planes are twisted by approximately 45° to the planes described by the adjacent gallium atom and its bonding partners. At the Ga1 center, the twist angle is larger (70°). This difference is due to the interaction of the nitrogen atom with the lithium ion and the resulting steric restrictions. At Ga4, the $NSi_2$ and Ga4–N4–I1–Ga3 planes are orthogonal. The N4–Ga4–Ga3 angle is very wide (165°). This might hint to an alternative description with a gallium(I) amide (Me$_3$Si)$_2$NGa as Lewis base adduct to a pentagallate residue, as depicted in Scheme 1. In line with this description are the short gallium–nitrogen bond to Ga4, the long gallium–iodine distance, and the large angle at Ga4.[44–47]

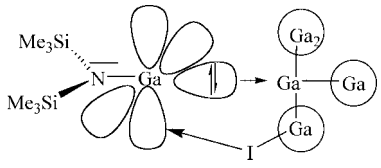

Scheme 1. Description of **5** as a gallium(I) adduct to a pentagallanate.

### Quantum Chemical Calculations

Geometry optimizations at the RI-DFT[44] level with the BP86-functional and def-SVP base sets for all atoms have been performed for monomeric gallium(I) amides **7**–**10** and the tetrameric species **11**–**14** (Table 2). The calculated structural parameters for **13** are similar to those observed for **3**, but the bonds are all a little bit elongated ($d_{Ga–Ga}$ = 263.5–272.2 pm, $d_{Ga–N}$ = 192.3 pm, $d_{N–Si}$ = 179.0 pm). Compared to the monomer **9**, the gallium–nitrogen bonds in **13** are shortened only by 2 pm. For gallium organyls, a larger shortening of the Ga–N bonds by nearly 10 pm was observed experimentally. Even the gallium–hydrogen bond lengths in GaH were calculated to be shortened by 9 pm upon tetramerization to $Ga_4H_4$. The silicon–nitrogen and nitrogen–carbon bonds were affected slightly [**9**: $d_{N–Si}$ = 179.9 pm, $d_{N–C}$ = 143.3 pm; **13**: $d_{N–Si}$ = 179.0 pm, $d_{N–C}$ = 144.0 pm]. The Si–N–C angles are 3° smaller than those in the monomer. A comparison of **9** with **2**[29] shows that the gallium–nitrogen bond is shorter in **9**. Calculations for monomeric gallium(I) amides reported previously[29,32] and in this work demonstrate quite strong gallium–nitrogen bonds, with minor participation from Ga–N π bonds. This is documented by an Ahlrichs–Heinzmann population analysis, which gives an SEN value of 1.4 to 1.6 for these amides.[45] Values of about 1.4 are typical for Ga–N single bonds.

The HOMO–1 orbitals for **7**–**10** are mainly Ga 4s orbitals, the LUMO and LUMO+1 orbitals have mainly Ga 4p character. The HOMO orbitals indicate a π bond, which is polarized to nitrogen. In the tetrameric compounds **11**–**14**, the SEN values for the gallium–nitrogen bonds are smaller, indicating the loss of π-bond participation. The HOMO of cluster **12** (Figure 4) has mainly nitrogen-pair character and gives no hint of any interaction, either stabilizing or destabilizing, between the lone pairs and the cluster core.

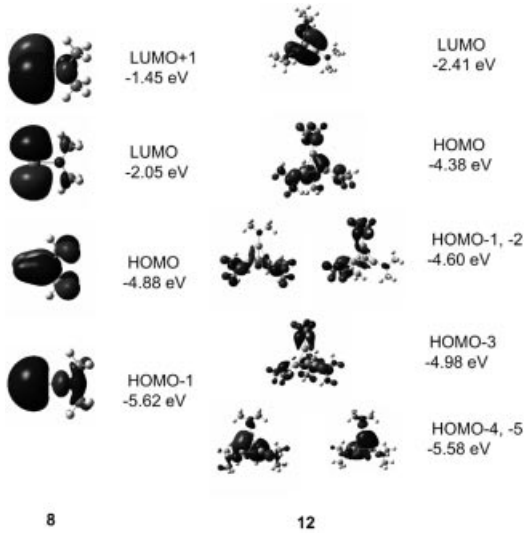

Figure 4. Kohn–Sham frontier orbitals for $GaNMe_2$ and $Ga_4(NMe_2)_4$.

The calculated HOMO–LUMO gaps of about 2.4 eV fit well with the observed absorption bands in the visible spectral region of **1** but not with those measured for **3** and **4**. Inspection of the LUMO and HOMO of **12** makes clear that population of the LUMO would weaken the cluster bonding, because the LUMO is a cluster antibonding orbital, whilst the HOMO has, as stated before, essentially lone-pair character. A more reasonable excitation of an electron from a cluster-binding orbital like HOMO–4 into the LUMO could explain the UV-absorption bands of **3** and **4** much better. The monomer would also give rise to absorptions around 300 nm. The tetramerization energy of the gallium amides ($E_{tetra}$ = 150–170 kJ/mol) is much lower than those calculated for gallium silyls ($E_{tetra}$ = 300–400 kJ/mol) and organyls ($E_{tetra}$ ≈ 200 kJ/mol). This is a consequence of the Ga–N π bond in monomeric gallium(I) amides, which has to be broken upon tetramerization. A hypothetical dimer should have a very long Ga–Ga distance [$d_{Ga–Ga}$ = 299.5 pm] and a very low dimerization energy of 16 kJ/mol. A trimer $[Ga(tmp)]_3$ is calculated to have a irregular triangular $Ga_3$ core [$d_{Ga–Ga}$ = 261.0–280.3 pm, $d_{Ga–N}$ = 193.0 pm] and has a trimerization energy of 58 kJ/mol.

The HOMO of tetramer **11** is higher in energy than that of the monomer. A similar situation is found for gallium organyls, where monomerization in gas phase and solution is easy. For gallium silyls, the HOMO energies for tetrahedral clusters are lower than those for the monomers. Compound **12** is a distorted tetrahedron, thus the HOMO is a nondegenerate molecular orbital, in contrast to the regular tetrahedral clusters with $T_d$ symmetry, where the HOMO is of the $t_2$ type.

## Conclusions

The facile synthesis of the first amino-substituted gallium(I) clusters, with functional groups attached to cluster cores, opens new reaction possibilities, which might lead to novel cluster types and give insight into cluster formation reactions.

## Experimental Section

**General Remarks:** All experiments were performed under purified argon or in vacuo with Schlenk techniques. All yields are referenced to "GaI" as starting material. Elemental analyses were performed in the microanalytical laboratory of Ruprecht-Karls-University of Heidelberg. NMR: Bruker AV400–600; The UV/Vis spectra were measured at 18 °C with a JASCO V-570 UV/Vis/NIR Spectrophotometer, using a Suprasil quartz cell (10 mm transition thickness) in n-hexane as solvent. Quantum chemical calculations: TURBOMOLE[44,47,48] and G03/GaussView.[49]

### X-ray Crystallography

Suitable crystals were mounted with a perfluorinated polyether oil on the tip of a glass fiber and cooled immediately on the goniometer head. Data collection was performed with Mo-$K_\alpha$ radiation (graphite monochromator) on a STOE IPDSI diffractometer. Structures were solved by direct methods and refined by full-matrix least-squares against $F^2$. All non-hydrogen atoms were given anisotropic displacement parameters. Hydrogen atoms were included in calculated positions. Calculations were performed by using the SHELXTL package.[46] Crystals of **3** were weakly diffracting; no reflections could be observed at $2\theta > 40°$.

CCDC-641586 (**3**), -641585 (**4**), -641587 (**5**), -650747 (**5a**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from the Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

**[Ga{N(2,6-*i*Pr$_2$C$_6$H$_3$)(SiMe$_3$)}]$_4$ (3):** Into a vigorously stirred suspension of freshly prepared "GaI" (0.61 g, 3.9 mmol) in toluene (20 mL) at –78 °C was added a solution of Li[N(2,6-*i*Pr$_2$C$_6$H$_3$)-(SiMe$_3$)] (1.10 g, 4.3 mmol) in thf (8 mL). After slow warming to room temperature, the mixture was stirred for an additional hour. All volatiles were removed in vacuo. The residue was extracted with *n*-hexane (30 mL). The yellow solution was concentrated to about 10 mL. At –30 °C, yellow crystals of compound **3** were isolated. Yield 0.30 g, 0.24 mmol (24%). $^1$H NMR ($C_6D_6$): $\delta$ = 0.09 (s, 9 H, SiC$H_3$), 1.26 [d, $^3J_{HH}$ = 6.9 Hz, 12 H, CH(C$H_3$)$_2$], 3.44 [sept, 2 H, C$H$(CH$_3$)$_2$], 7.07 (m, 3 H, CH arom.) ppm. $^{13}$C NMR ($C_6D_6$): $\delta$ = 0.8 (SiCH$_3$), 23.8, [CH(*C*H$_3$)$_2$], 28.4 [*C*H(CH$_3$)$_2$], 123.3 (m-C), 124.0 (*p*-C), 139.8 (*o*-C), 144.6 (*i*-C) ppm. $^{29}$Si NMR ($C_6D_6$): $\delta$ = 3.26 ppm. UV/Vis (*n*-hexane): $\lambda_{max}$ ($\varepsilon$, L mol$^{-1}$ cm$^{-1}$) = 280 (996) nm. $C_{60}H_{104}Ga_4N_4Si_4$ (1272.7): calcd. C 56.62, H 8.24, N 4.40; found C 54.95, H 8.23, N 4.39.

**[Ga(tmp)]$_4$ (4):** Into a vigorously stirred suspension of freshly prepared "GaI"[30] (0.99 g, 51 mmol) in toluene (20 mL) at –78 °C was added a solution of Li(tmp) (0.82 g, 55 mmol) in thf (8 mL). After slow warming to room temperature, the mixture was stirred for 1 h. All volatiles were removed in vacuo. The residue was extracted with *n*-hexane (30 mL). The orange solution was concentrated to a volume of 5 mL. At –30 °C yellow crystals of compound **4** were isolated; yield 0.37 g, 0.44 mmol (34%). $^1$H NMR ($C_6D_6$): $\delta$ = 1.32 [m, 4 H, (CH$_3$)$_2$CC$H_2$], 1.55 (m, 2 H, CH$_2$C$H_2$CH$_2$) ppm. 1.65 [s, 12 H, C(C$H_3$)] ppm. $^{13}$C NMR ($C_6D_6$): $\delta$ = 18.8 (CH$_2$*C*H$_2$CH$_2$), 36.6 [C(*C*H$_3$)$_2$], 41.3 (*C*H$_2$CH$_2$*C*H$_2$), 55.6 [*C*(CH$_3$)$_2$] ppm. UV/Vis (*n*-hexane): $\lambda_{max}$ ($\varepsilon$, L mol$^{-1}$ cm$^{-1}$) = 268 (155) nm. $C_{36}H_{72}Ga_4N_4$ (839.8): calcd. C 51.48, H 8.64, N 6.64; found C 50.46, H 8.46, N 6.35.

**Ga$_6$[N(SiMe$_3$)$_2$]$_6$IOLi.thf (5):** Into a vigorously stirred suspension of freshly prepared "GaI" (0.66 g, 3.35 mmol) in toluene (20 mL) at –78 °C was added a solution of LiN(SiMe$_3$)$_2$ (0.62 g, 3.68 mmol) in thf (8 mL). After slow warming to room temperature, the mixture was stirred for an additional hour. All volatiles were removed in vacuo. The residue was extracted with *n*-hexane (30 mL). The remaining solid was not soluble in any common solvent and consisted mainly of LiI and elemental gallium. The orange solution was concentrated to a volume of 5 mL. At –30 °C, some yellow crystals of compound **5** were isolated.

**Supporting Information** (see footnote on the first page of this article): Crystal data, structure refinement, and selected bond lengths and bond angles for **5a**.

## Acknowledgments

We thank the Deutsche Forschungsgemeinschaft for financial support and Philipp Butzug for making the crystallographic measurements.

# (Benzimidazolylmethyl)cyclen: A Potential Sensitive Fluorescent PET Chemosensor for Zinc

**Abir El Majzoub,[a] Cyril Cadiou,[a] Isabelle Déchamps-Olivier,[a] Françoise Chuburu,*[a] and Michel Aplincourt[a]**

**Keywords:** Zinc / Macrocyclic ligands / X-ray diffraction / UV/Vis spectroscopy / Fluorescent probes / Fluorimetric titrations

A new fluorescent probe for $Zn^{2+}$, methylbenzimidazole-pendant cyclen [LH: 1-(benzimidazol-2-ylmethyl)-1,4,7,10-tetraazacyclododecane] was designed and synthesized. The protonation constants of (benzimidazolylmethyl)cyclen and the stability constants of the corresponding zinc complex were determined by potentiometric titrations. The single-crystal X-ray diffraction analysis showed that LH and $Zn^{2+}$ form a 1:1 complex $[ZnLH]^{2+}$. The results of potentiometric, $^1H$ NMR and UV titrations indicated that above pH 8, $[ZnLH]^{2+}$ mainly deprotonates into $[ZnL]^+$. On addition of successive amounts of $Zn^{2+}$ at pH 10.4 ($2 \times 10^{-2}$ mol L$^{-1}$ CAPS, 25 °C), the fluorescence emission of cyclen(methylbenzimidazole) increases linearly by a factor of 3.

## Introduction

The design and synthesis of fluorescent chemosensors is an active field of research and is of particular significance in analytical chemistry since fluorimetric analysis offers a simple method for detecting chemical species in solution.[1] Thus, the development of selective analytical reagents, which allows the quantitative analysis of trace metal ions, is very important for environmental and biological applications. Fluorescent chemosensors developed for the detection of pH and metal cations in aqueous solution generally comprise a fluorophore covalently linked to an ionophore that can bind $H^+$ or metal cations.[2–5] The principle on which the so-called fluoroionophore works is based on an enhanced or quenched fluorescence of the system when the ionophore units bind $H^+$ or metal ions. Among the metal ions, the detection of biologically important divalent cations is of great importance to elucidate their physiological roles. In particular, the detection of $Zn^{2+}$, which is the second most abundant transition metal, following iron, in biological systems, is of interest.[6,7] The most important and best-known role for zinc is as a structural cofactor in metalloproteins. Many zinc proteins possessing one or more zinc motifs have been identified.[8] In these different structures, the zinc environment is usually tetracoordinate {i.e. $[Zn(Cys)_4]$, $[Zn(Cys)_3(His)]$, $[Zn(Cys)_2(His)_2]$}. A catalytic role was also demonstrated for zinc, for instance, in carbonic anhydrase or carboxypeptidase.[9,10] The main difference in the coordination sphere of zinc when its catalytic function is involved is the existence of a vacant coordination site. Recently, the neurological roles of zinc have attracted much attention.[11] A disorder in the metabolism of zinc is closely associated with neurological diseases such as Alzheimer's disease, amyotrophic lateral sclerosis, Parkinson's disease and epilepsy. Thus, there is a great interest in developing zinc sensors, and since, unlike biological metal ions, $Zn^{2+}$ does not give any spectroscopic or magnetic signals (as a result of its $d^{10}$ configuration), fluorescence spectroscopy stands out as a method of choice. Up to now, the reported zinc sensors are chelation-enhanced fluorescent probes.[12–17] Among them, Zn-chelating macrocyclic compounds such as cyclen (1,4,7,10-tetraazacyclododecane) form stable $Zn^{II}$ complexes in aqueous solution at neutral pH. Moreover, by comparison with quinoline-based compounds such as TSQ [6-methoxy-8-(*p*-toluenesulfonamido)-quinoline] and zinquin,[12,13a] for which zinc complexation at neutral pH is not stoichiometric (mixture of ZnL and $ZnL_2$ complexes can be obtained), cyclen derivatives such as anthracene-pendant cyclen,[14] dansylamide-pendant cyclen,[15] (anthrylmethylamino)ethyl cyclen,[16] 2-[8-hydroxy-5-(dimethylaminosulfonyl)quinolinyl]methyl cyclen[17] complex with almost 100% of $Zn^{II}$ to form ZnL under physiological conditions (at pH 7.4, $10.7 < \log K_{app}$, $[ZnL] < 14.1$, where L represents the ligand and $K_{app[ZnL]} = [ZnL]/[L]_{free}[Zn]_{free}$). The $\log K_{app[ZnL]}$ value depends whether $Zn^{2+}$ is coordinated to the fluorescent unit. Furthermore, from the fluorescent point of view, comparison of the efficiency of the sensors indicates that coordination of the fluorophore to the metal improves the signal.

LH Cyclen $L^2$ $L^3$

Scheme 1.

Therefore, on the basis of this analysis, we present here a new fluorophore, LH (Scheme 1), in which the ionophore unit is cyclen; according to the affinity for the imidazole of histidine units in metalloenzymes of zinc, we have chosen a benzimidazole moiety as the fluorophore. This paper describes the synthesis and the coordination properties of the resulting (benzimidazolylmethyl)cyclen; protonation and coordination properties towards $Zn^{2+}$ are studied. Spectrophotometric and spectrofluorimetric investigations of the ligand in the presence of $Zn^{2+}$ are also reported in order, first, to test whether the benzimidazole moiety is a good candidate for the detection of zinc and, second, whether the system is responsive in the biological pH window.

## Results and Discussion

The ligand LH was prepared following the bisaminal methodology.[18]

### Acidity Constants of LH Determined by Potentiometric pH, UV and $^1$H NMR Titrations

Typical potentiometric pH titration curves of a mixture of (LH) $2 \times 10^{-3}$ mol L$^{-1}$ and ($HNO_3$) $10^{-2}$ mol L$^{-1}$ with $I$ = 1 ($KNO_3$) at 25 °C were analysed for acid–base equilibrium [Equation (1)]. Four protonation constants were determined for LH by using the PROTAF software (Table 1).[19] The LH macrocyclic cavity protonation assignment was made on the basis of the variation in the cyclen protonation constants upon *N*-functionalisation in relevant ligands $L^2$ and $L^3$[20,21] (Table 1). Since the presence of electron-withdrawing pendant groups results in the lowering of the cyclen protonation constants $\log K_{011}$ and $\log K_{012}$, one can conclude that the second and the third protonations of LH ($\log K_{012}$ = 10.21 and $\log K_{013}$ = 9.01) correspond to those of the macrocycle. The fourth protonation constant ($\log K_{014}$ = 4.55) cannot be associated to the cyclen moiety but to the benzimidazole ring. Effectively, this $\log K$ value has to be compared to the $\log K$ value determined for protonation of the pyrrole nitrogen atom in the benzimidazole ring [$\log K_{012}$ (benzimidazole BIH ⇆ benzimidazolium $BIH_2^+$) ≈ 5.6, see Scheme 2].[22,23] Furthermore, this value is close to that determined for the protonation of the exocyclic pyridine or acridine nitrogen atom of $L^2$ and $L^3$, respectively ($\log K_{013}$ = 3.42 and 4.44, respectively, Table 1).[21] In order to get a more precise insight into the acid–base properties of LH before pH 6, the UV absorption changes that take place upon protonation of the macrocyclic nitrogen atoms and/or the benzimidazole moiety were investigated in the 250–340 nm range (Figure 1). In this range and at pH = 6, the electronic spectrum is characteristic of the benzimidazole moiety, and two main absorptions are centred at 273 and 280 nm.[24] This absorption pattern ressembles that of a substituted benzene derivative: two absorption bands are observed in the near UV region that can be assigned to the $\pi^* \leftarrow \pi$ singlet–singlet transitions[25]($^1L_a \leftarrow S_0$ and $^1L_b \leftarrow S_0$, where $^1L_a$ and $^1L_b$ correspond to the two excited states[25c]). The extinction coefficients ($\varepsilon_{max}$ = 6700 mol$^{-1}$ L cm$^{-1}$ at 273 and 280 nm) are in agreement

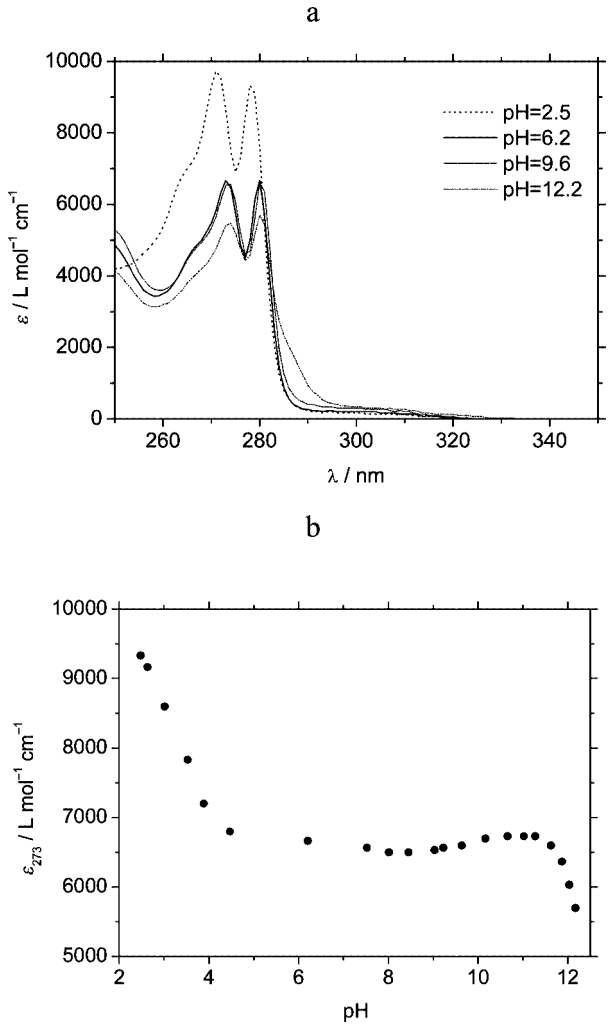

Figure 1. (a) Spectrophotometric titration of LH with KOH (0.1 mol L$^{-1}$): [LH] = $3 \times 10^{-5}$ mol L$^{-1}$ in HCl ($10^{-2}$ mol L$^{-1}$), $T$ = 25 °C, path length = 1 cm; (b) $\varepsilon_{273}$ (mol$^{-1}$ L cm$^{-1}$) as a function of pH.

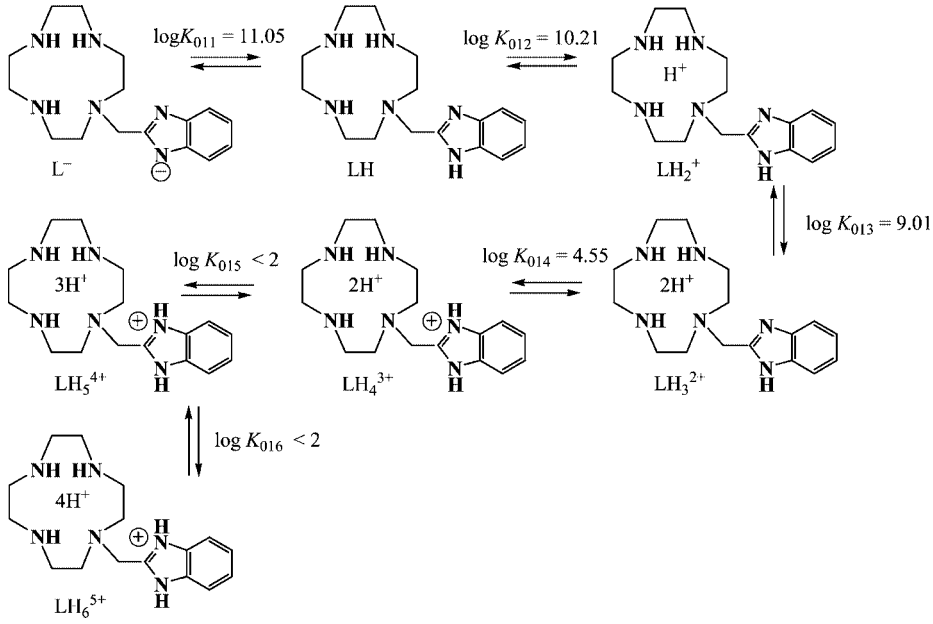
with those obtained in bis(benzimidazole) macrocycles.[25,26] Acidification of the medium down to pH = 6 induces perturbations in the spectra: the previous bands undergo a slight blue shift ($\lambda$ = 2 nm) similar to that observed for the free benzimidazole under acidic conditions.[24] This slight shift is accompanied by a strong hyperchromic effect, which results in an approximately 50% increase in the parent extinction coefficient (Figure 1b). This effect can be compared to the hyperchromic effect observed under similar conditions on the $\pi^* \leftarrow \pi$ transition of cyclen- and cyclam–pyridine.[21a] This result is characteristic of the formation of a benzimidazolium cation. This analysis can be consolidated by the change in the $^1$H chemical shifts of $H_\alpha$ and $H_\beta$ of the benzimidazole moiety (for the numbering see Scheme 1) in the pH range 6.2–2.5 in $D_2O$ (Supporting Information Figure S1). The decrease in pH is accompanied with a downfield shift of the signals of the aromatic protons as expected for protonation of the aromatic ring.[21a] These convergent observations imply that the log $K$ value of 4.55 can be attributed to protonation of the benzimidazole group.

Finally, the first protonation constant (log $K_{011}$ = 11.05) determined for (benzimidazolylmethyl)cyclen LH cannot be attributed to the cyclen moiety but to the benzimidazole ring. This is supported by UV and $^1$H NMR spectroscopic experiments above pH 9. The increase in pH is accompanied by an upfield shift in the NMR spectrum of the signals for the aromatic protons (Supporting Information, Figure S1). Accordingly, in the range 250–290 nm in the absorption spectrum, a hypochromic effect is observed with a slight red shift of the bands (Figure 1), and a low-energy shoulder appears at 287 nm. These data are in agreement with the formation of a benzimidazolate species (Scheme 2).[24,27] From the sigmoidal curve observed in the plot of $\varepsilon_{273}$ versus pH (Figure 1b), one can estimate the corresponding log $K$ value to be 11, which agrees well with the



Scheme 3.

$\log K_{011}$ value obtained from the potentiometric pH titration. On the basis of these results, the acid–base behaviour of LH is summarised in Scheme 3.

### Zinc(II) Complex of LH

#### *Synthesis and Solid-State Structure of [ZnLH](ClO$_4$)$_2$*

[ZnLH]$X_2$, where X = $NO_3$ and $ClO_4$, were synthesised by reacting one equivalent of the ligand and one equivalent of the $ZnX_2{\cdot}nH_2O$ salt in a methanolic solution. Colorless single crystals were obtained only for [ZnLH](ClO$_4$)$_2$ by diffusion of diethyl ether in an acetonitrile solution of the complex. Selected geometrical parameters for [ZnLH](ClO$_4$)$_2$ are given in Table 2. The X-ray structure of $[ZnLH]^{2+}$ shows that the metal ion lies inside a square-based pyramid (Figure 2) and that the coordination sphere of the zinc centre consists of the four macrocyclic nitrogen atoms (N1–N4) and the imine nitrogen atom of the benzimidazole ($N_{im}$). The $Zn^{II}$ cation lies 0.781 Å above the macrocyclic nitrogen square in this distorted square-based pyramid geometry. The Zn–N(secondary) bonds (2.104–2.116 Å) are shorter than the Zn–N(tertiary) bond (2.236 Å): tertiary nitrogen atoms are not as good donors as secondary nitrogen atoms.[28–30] The $N_{im}$ atom is coordinated to the zinc cation. This type of coordination in which the imidazole is linked to the metal cation through the imine nitrogen atom and the hydrogen atom of the secondary amine nitrogen atom remains is well known for histidine and nucleoside bases such as adenine and guanine.[10] The Zn–$N_{im}$ bond of 1.982 Å is shorter than the Zn–N(cyclen) bonds, which indicates a strong interaction between the $N_{im}$ and $Zn^{II}$ atoms. This feature has already been reported for a Zn–guanidinyl cyclen complex in which the Zn–N(guanidyl) bond[31] (1.95 Å) is shorter than the average Zn–N(cyclen) bonds (2.16 Å). For $[ZnLH]^{2+}$ in the solid state, an efficient five-membered chelate ring is formed, as the $N_{im}$–Zn–N4 angle of 80.6° is noticeably smaller than the other three $N_{im}$–Zn–N angles (104.6–138.2°). This indicates that electron donation from the imine nitrogen lone pair of the benzimidazole moiety to the $Zn^{II}$ ion is strong. Furthermore, comparison of the C–N bond lengths in the imidazole ring of $[ZnLH]^{2+}$ (C2–$N_{im}$: 1.324 Å and C2–$N_{am}$: 1.347 Å) and in free benzimidazole[32] (C2–$N_{im}$: 1.297 Å and C2–$N_{am}$: 1.344 Å) shows that the C2–$N_{im}$ distance is elongated by coordination. This indicates an electronic delocalisation through the imidazole ring,[33] which results in the reinforcement of the electronic density at the $N_{im}$ nitrogen atom (Scheme 4). The driving force of this phenomenon is the $Zn^{II}$ Lewis acidity. Finally, to ensure the cohesion of the solid-state structure, hydrogen bonds between $ClO_4^-$ oxygen atoms and N1, N3 and $N_{am}$ hydrogen atoms are present.[34]

Table 2. Selected bond lengths [Å] and angles [°] for $[ZnLH]^{2+}$.

| | | | |
|---|---|---|---|
| Zn–N1 | 2.1049(15) | N1–Zn–N2 | 83.25(6) |
| Zn–N2 | 2.1147(15) | N1–Zn–N3 | 133.47(6) |
| Zn–N3 | 2.1163(16) | N1–Zn–N4 | 81.22(6) |
| Zn–N4 | 2.2369(15) | N1–Zn–$N_{im}$ | 114.79(6) |

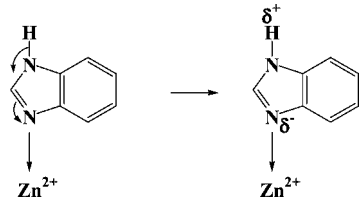

Scheme 4.

#### *Thermodynamic Stability of the Zn$^{II}$-LH Complex – Potentiometric pH, UV and $^1$H NMR Titrations*

At first, direct pH titrations of LH in the presence of one equivalent of $Zn^{2+}$ and a strong acid in excess were carried out following a published procedure for similar compounds.[35] By using this method with LH, we encountered some problems because $Zn^{2+}$complexation is very slow at low pH. This can be attributed to the protonation of the ligand nitrogen atoms (the macrocyclic nitrogen atoms and the pyrrole nitrogen atom in the benzimidazole ring). In order to counteract this drawback in acidic medium, the "batch method", which involves the preparation of LH/

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

$Zn^{2+}/HNO_3/KOH$ mixtures at each pH value, was then used.[36] This method was implemented up to pH 7, after which carbonation cannot be avoided. Direct KOH titrations of synthesised $[ZnLH]^{2+}$ were also carried out in the pH range 5–12. For comparison, similar titrations were performed with pendantless cyclen. From the analysis of the titration data, the speciation diagram of the $Zn^{2+}/LH$ system was obtained (Figure 3), and the values for the overall complexation constants of the 1:1 $Zn^{II}$ complex ($\log\beta_{mlh}$) calculated (Table 3). Firstly, the speciation diagram indicates that there is no formation of the $Zn^{II}$ complex with $LH_4^{3+}$ in acidic medium. This is confirmed by spectroscopy: the UV (Figure 4) and/or $^1H$ NMR (Figure 5 and Supporting Information Figure S2) experiments show that, under acidic conditions, the presence of the metal does not affect the signal, since the ligand is the only species detected. Secondly, the diagram indicates that at pH 3, the $[ZnLH]^{2+}$ complex starts to form: this is confirmed by $^1H$ NMR spectroscopy, since in the $^1H$ NMR spectrum, a second set of signals at $\delta$ = 7.64, 7.38 and 4.28 ppm increasingly appears, while the signals for LH collapse (from pH 3.7). Comparison of the LH and cyclen affinities for $Zn^{2+}$ before pH 4 (Supporting Information Figure S3) indicates, moreover, that the presence of the benzimidazole moiety on the cyclen framework promotes $Zn^{2+}$ complexation in acidic medium. The speciation diagram highlights that the 1:1 $Zn^{II}$ complex is quantitatively obtained between pH 5–7. In this pH range, the UV and $^1H$ NMR spectra remain unchanged. From the $\log\beta_{111}$ value and the first protonation constant, $\log K_{011}$, of the ligand, the stepwise formation constant of the species $[ZnLH]^{2+}$ was calculated to be 16.13 (Table 3). This value is higher than that of the cyclen complex $\{\log K_{[Zn(cyclen)]} = 14.20\}$. The affinity of LH for $Zn^{2+}$ is greater than that of cyclen over the whole pH range (Supporting Information Figure S3). Usually, the *N*-functionalisation of the tetraazamacrocycle induces a decrease in the stability of the complexes, which results mainly because of the poor σ-donor ability of tertiary amines relative to that of secondary amines.[16,30,38,39] Here, the enhanced stability of $[ZnLH]^{2+}$ must be due to the presence of an additional stabilising interaction, probably between the benzimidazole ring and the metal through a supplementary five-membered ring chelate. This also suggests that the solid-state structure remains in solution. Although lower, the stability of $[ZnLH]^{2+}$ compares well with that determined for the [{(anthrylmethylamino)ethyl}cyclen]$Zn^{II}$ complex ($\log K$ = 17.6).[16] This stability is even lower than that of the [{8-hydroxy-5-(dimethylaminosulfonyl)quinolin-2-

Table 3. Stability constants for the $Zn^{II}$/LH and $Zn^{II}$/cyclen systems.

ylmethyl}cyclen]$Zn^{II}$ complex ($\log K$ = 22.4).[17] It can be assumed for the latter that the enhanced stability is due to the fact that the metal ion is six-coordinate rather than five-coordinate. Another way to compare the thermodynamic behaviour of different systems is to calculate the apparent complexation constant $\log K_{app}$ at a given pH. The $\log K_{app}$ value is calculated from the potentiometric pH titration results, according to $\log K_{app} = \log([ZnLH]/[Zn]_{free} \times [L]_{free})$ with $[L]_{free} = \sum_n [H_nL]_{free}$ ($n$ = 0–4 for LH) and for an equimolar mixture of $5 \times 10^{-6}$ mol $L^{-1}$ LH and $Zn^{2+}$. At pH 7.4, in the medium of the biological pH window, the $\log K_{app[ZnLH]}$ value is calculated to be 11.71. This value is between those calculated under the same conditions for [{(anthrylmethylamino)ethyl}cyclen]$Zn^{II}$ complex ($\log K_{app[ZnL]}$ = 10.7)[16] and for [{8-hydroxy-5-(dimethylaminosulfonyl)quinolin-2-ylmethyl}cyclen]$Zn^{II}$ complex ($\log K_{app[ZnL]}$ = 14.1).[17] Finally, above pH 8, the deprotonation of $[ZnLH]^{2+}$ was confirmed by $^1H$ NMR and UV spectroscopy. Thus, around pH 8.5, the $^1H$ signals for $H_\alpha$, $H_\beta$ and $N_{cyclen}CH_2$ are shifted upfield [Figure 5: $\Delta(\delta)$ = 0.15 ppm for $H_\alpha$, 0.25 ppm for $H_\beta$ and 0.3 ppm for $N_{cyclen}CH_2$]. This shielding indicates a decrease in the overall charge of the complex. Accordingly, on increasing the pH up to 12, the UV bands of the benzimidazole unit are perturbed and undergo a slight red shift of about 5 nm (Figure 4b). As indicated for the ligand, this is characteristic of deprotonation at the imidazole ring.[24] Moreover, a new band appears at 282 nm from pH 8, and up to pH 12, the extinction coefficient of this band increases by about a factor of six. From the $\log \beta_{mlh}$ values, one can calculate the deprotonation constant of $[ZnLH]^{2+}$ ($\log K$ = –8.65), which, as suggested by the UV titration, corresponds to the ionisation of the pyrrole hydrogen of the benzimidazole moiety. This value is remarkably lower than that for the analogous equilibrium in LH, which means that in the presence of $Zn^{II}$, the benzimidazole pyrrole hydrogen is $10^{2.4}$ times more acidic. This is a consequence of the Lewis acidity of the $Zn^{II}$ ion, which operates predominantly through an inductive effect and strongly alters the benzimidazole acidity.[40]

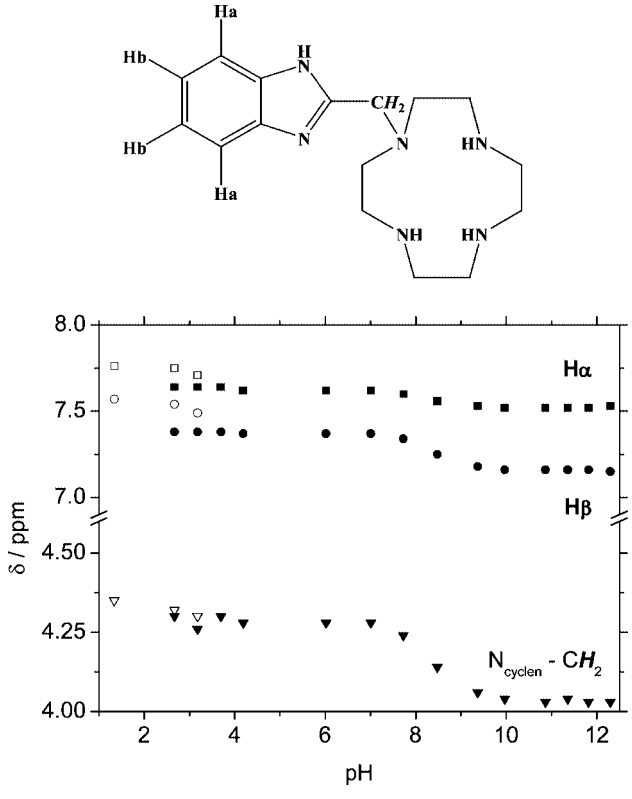

Figure 5. $^1H$ NMR chemical shifts plotted as a function of pH for a mixture of LH ($10^{-2}$ mol $L^{-1}$) and $Zn^{2+}$ ($10^{-2}$ mol $L^{-1}$) in the pH range 3.0–12.0 ($T$ = 25 °C, $D_2O$). The filled symbols correspond to the complex chemical shifts.

## Spectrofluorimetric Study of LH

The change in the fluorescent response of LH ($5 \times 10^{-7}$ mol $L^{-1}$) in the pH range 4–12 ($I$ = 0.1 $NaNO_3$) at 25 °C (excitation at 270 nm) is presented in Figure 6. Inspection of the LH deprotonation sequence indicates that the fully protonated species gives rise to the smallest emission intensity and that removal of the protons leads to an increase in the fluorescence emission intensity. Thus, as the pH is raised, emission at 301 nm increases following a sigmoidal curve with an inflexion point at pH 9. The fluorescence curve follows the formation of all the species in solution at pH > 8, i.e. $LH^{2+}$, LH and $L^-$. It is concluded that the break at pH 9 in Figure 6 denotes the $pK_{a4}$ for $LH_3^{2+} \leftrightarrows LH_2^+$. The further increase in the fluorescence emission (above pH 10.5) is due to deprotonation at the benzimidazole moiety. Consequently, the quantum yield $\Phi$ of (benzimidazolylmethyl)cyclen increases with the pH from 0.21 at pH 10.4 to 0.30 at pH 12. The enhanced effect of the fluorescence emission can be explained in terms of an intramolecular electron-transfer process from the macrocycle to the excited benzimidazole (PET process).[41] Such a mechanism involves the deactivation of the excited state of the fluorophore by addition of one electron to one of its excited-state frontier orbitals. This leaves the fluorophore in a reduced, nonemissive state. Among factors responsible for intramolecular electron transfer, the overlap S between the electron donor (macrocycle) and acceptor (benzimidazole) orbitals is, of course, crucial, and it is obvious that S is optimum when both parts of the fluoroionophore are in close proximity and in a suitable orientation. In functionalised macrocycles, it has already been shown that protonated forms of the macrocycle are stabilised by intramolecular hydrogen bonds between the cavity and the pendant arm when the latter has coordinating atoms.[21a,42] Furthermore, deprotonation at the cavity induces conformational modifications in the ligand that lead to an outward orientation of the pendant arm relative to the macrocyclic cavity. If we assume that similar conformational changes occur during deprotonation of LH, in particular between the $LH_3^{2+}$, $LH_2^+$ and LH species, then an increase in the distance between the cavity and the benzimidazole moiety results. One can then

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

explain the fluorescence enhancement observed during the deprotonation sequence by the reduced overlap of the orbitals of both parts of the fluoroionophore, which favours the emissive deactivation of benzimidazole over the PET process.

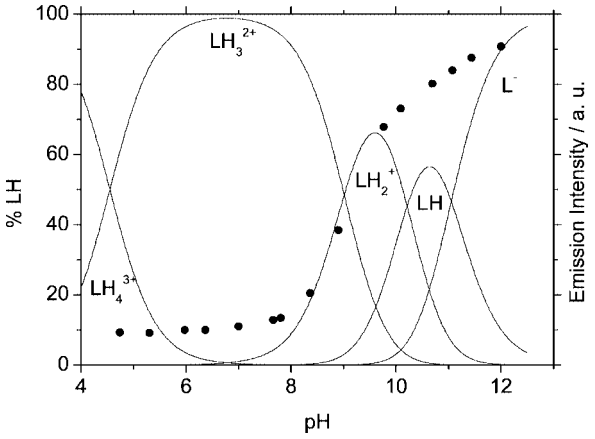

Figure 6. Speciation diagram of the LH system as a function of pH in the pH range 4.0–12.0, and the fluorescent response of LH ($5 \times 10^{-7}$ mol L$^{-1}$).

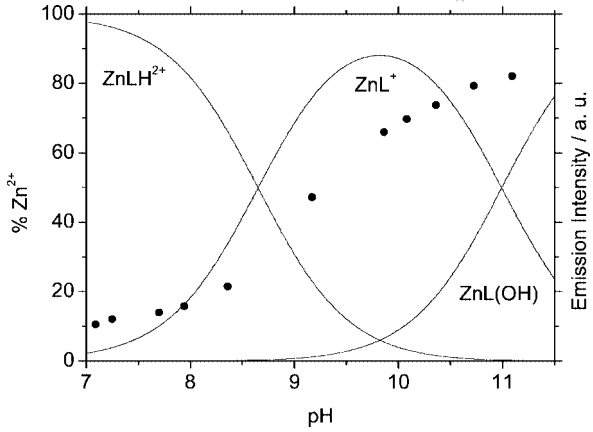

Figure 7. Speciation diagram of the LH/$Zn^{2+}$ system as a function of pH in the pH range 7.0–12.0, and fluorescent response of LH/$Zn^{2+}$.

Moreover, once formed $[ZnL]^+$ is so stable that even at such concentrations, the 1:1 complex does not dissociate and the $Zn^{2+}$-dependent fluorescence is unaffected by excess amounts of $Zn^{2+}$.

### Fluorescence of $[ZnLH]^{2+}$ and Titration of LH with $Zn^{2+}$

The change in the fluorescence emission of the zinc complex ($5 \times 10^{-7}$ mol L$^{-1}$) as a function of pH is presented in Figure 7. The fluorescence curve follows the formation of all the species in solution at pH >8, i.e. $ZnL^+$, ZnL(OH). The sensitivity of the fluorescence in the complex implicates deprotonation at the benzimidazole moiety. This behaviour should be compared with that of [(dansylamidoethyl)-cyclen]Zn.[15] Moreover, the emission of LH increased by about a factor of three with increasing $[Zn^{2+}]$ (quantum yield $\Phi$ 0.21 → 0.63). This chelation-enhanced fluorescence can be explained as follows: the metal coordination induces an energetic modification of the molecular orbitals between the free macrocycle and the corresponding $Zn^{II}$ complex that leads to the stabilisation of the HOMO. Consequently, the Zn-cyclen subunit is a less efficient donor towards the benzimidazole fluorophore than the cyclen unit in LH towards the same benzimidazole moiety. This makes PET-type fluorescence quenching less probable, and the native fluorescence of the fluorophore is thus restored.[43]

In order to test the response of LH in the presence of $Zn^{2+}$, it is then necessary to follow the fluorescence emissionat pH 10.4 where, first, a significant alteration in the signal intensity in response to the binding unit is expected, and, second, the complexation kinetics is fast. The change in fluorescence upon addition of $Zn^{2+}$ to (benzimidazolylmethyl)cyclen is presented in Figure 8. Upon excitation at 270 nm, an increase in emission is observed. The response of the system at 301 nm is linear between $5 \times 10^{-8}$ and $5 \times 10^{-7}$ mol L$^{-1}$, until a 1:1 [LH]/$[Zn^{2+}]$ ratio is reached. This implies that the increase in fluorescence is stoichiometric and is due to total formation of the $[ZnL]^+$ complex.

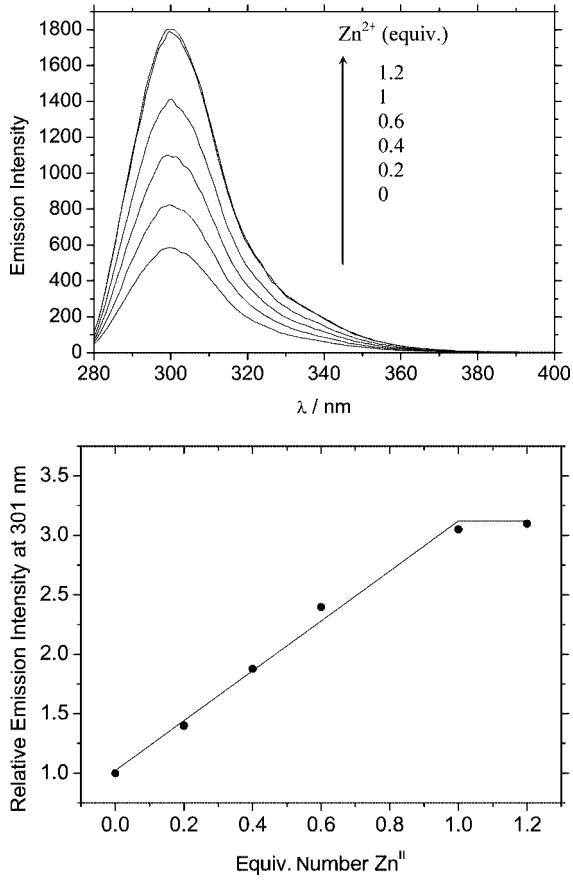

Figure 8. Change in the fluorescent response of LH ($5 \times 10^{-7}$ mol L$^{-1}$) upon addition of $Zn^{2+}$ at pH 10.4 [CAPS ($2 \times 10^{-2}$ mol L$^{-1}$), $I$ = 1 ($NaClO_4$), $T$ = 25 °C, excitation at 270 nm].

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

To determine whether LH works as a selective chemosensor for $Zn^{2+}$, the LH fluorescent spectra were recorded in the presence of various metal ions at pH 10.4 (some first-row transition metals, $Cd^{II}$ and biologically relevant alkali and alkaline earth ions, Figure 9). The fluorescent intensities slightly increase by addition of ions that are found in high concentrations in cells, such as $K^+$, $Mg^{2+}$ and $Ca^{2+}$. The selectivity of $Zn^{2+}$ over alkali or alkaline earth cations comes from the inherent binding properties of macrocyclic polyamines. Addition of transition metals such as $Mn^{2+}$ and $Fe^{3+}$ does not significantly increase the fluorescent response of (benzimidazolylmethyl)cyclen. This test also indicates that the cadmium complex is less fluorescent than the ligand (which allows $Zn^{2+}$ and $Cd^{2+}$ to be distinguished), while the copper complex does not fluoresce at all. For these two cations, the decrease in fluorescence is due to a quenching mechanism.[44]

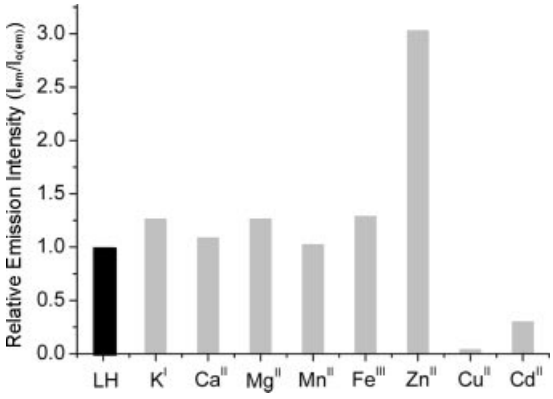

Figure 9. Relative fluorescence of LH at 301 nm responding to 1 equiv. of the metal ions at pH 10.4 [CAPS ($2\times10^{-2}$ mol L$^{-1}$), $I$ = 1 (NaCl), $T$ = 25 °C, excitation at 270 nm]. $I_{0(em)}$ is the emission intensity of LH ($5\times10^{-7}$ mol L$^{-1}$) at 301 nm in the absence of metal ions.

In comparison with the results reported for cyclen fluorophores,[15–17] the fluorimetric titration of $Zn^{2+}$ with LH shows that LH does not respond to $Zn^{2+}$ at neutral pH, which is a disadvantage. This point has to be improved in order to envisage a use under biological conditions. For that, the key mechanistic feature is the decoupling of macrocyclic electron-donor nitrogen atoms from resonance with the fluorophore. In light of the behaviour of the anthracene-pendant cyclen probe, which responds to $Zn^{2+}$ for pH values >12,[14] and the {(anthrylmethylamino)ethyl}-cyclen probe, which responds to $Zn^{2+}$ at neutral pH,[16] the introduction of an aminoethyl spacer between the macrocycle and the methylbenzimidazole moiety is to be studied. The introduction of a supplementary amine function on the spacer is expected to sufficiently change the electronic nature of the ligand and complex structures at neutral pH to be able to detect $Zn^{2+}$ under better conditions.

## Conclusions

We have designed a new ligand LH for complexation with $Zn^{2+}$ and that can be detected by fluorescence spectroscopy. The zinc(II) complex is stable and quantitatively formed at pH 5, which is comparable to zinc(II) complexes obtained from (dansylamidoethyl)cyclen[15] or {(anthrylmethylamino)ethyl}cyclen.[16] The complexation induces a PET-retarded fluorescence, which is responsible for the fluorescence enhancement in the presence of $Zn^{2+}$. Thus, in CAPS buffer and upon addition of increasing amounts of $Zn^{2+}$, the fluorescent emission of LH linearly increases. The detection limit of LH ($5\times10^{-7}$ mol L$^{-1}$) is [$Zn^{2+}$] = $5\times10^{-8}$ mol L$^{-1}$ at pH 10.4. The LH fluorescent response to $Zn^{2+}$ has to be improved in order to allow $Zn^{2+}$ detection at neutral pH. On the basis of the modification of the ligand already proposed by Aoki and al.,[16] it is envisaged that the introduction of an aminoethyl spacer between the macrocycle and the methylbenzimidazole moiety will help towards this end.

## Experimental Section

**General Information:** All solvents were HPLC grade. The metals salts were purchased from Aldrich. The other reagents (highest commercial quality) were used without further purification.

**Ligand Synthesis:** The ligand LH was synthesised according to a published procedure[18] by alkylation of the cyclen glyoxal ligand (5.1 mmol, 1.00 g) with 2-(chloromethyl)benzimidazole (5.3 mmol, 0.89 g) in thf. The solution was stirred for 6 h, after which a pale yellow precipitate forms, which corresponds to the alkylated bisaminal monosalt. This was separated from the mother solution by filtration. This salt was then deprotected with hydrazine monohydrate for 3 h at 100 °C. After cooling, a brown oil precipitates, which was collected by filtration and washed several times with ethanol. The ligand LH was finally obtained after purification in methanol in 53% yield (0.87 g). $^{13}$C NMR (62.9 MHz, $D_2O$): $\delta$ = 44.5, 45.4, 51.4, 52.8 and 73.7 ($CH_2N$), 115.2, 123.2, 118.1 and 153.9 ($C_{Ar}$) ppm. $C_{16}H_{26}N_6\cdot0.25CH_3OH\cdot0.5H_2O$ (319.44): calcd. C 61.10, H 8.84, N 26.31; found C 61.09, H 9.14, N 26.67%.

### Preparation of the Zinc Complexes

**[Zn(cyclen)$(NO_3)_2$]:** A methanolic solution of $Zn(NO_3)_2\cdot4H_2O$ (0.61 mmol, 0.16 g, 5 mL) was added dropwise to a solution of the ligand (cyclen: 0.60 mmol, 0.11 g) in methanol (10 mL). The colourless solution was heated at reflux for 4 h and concentrated by evaporation. A white powder was precipitated by addition of diethyl ether solution (0.16 g, 74%). $C_8H_{20}N_4Zn(NO_3)_2$ (361.67): calcd. C 26.57, H 5.57, N 23.24; found C 26.71, H 5.66, N, 23.39%. ESI-MS: $m/z$ calcd. for $[Zn(C_8H_{20}N_4)(NO_3)]^+$ 298.1; found 298.0.

**[ZnLH]$(NO_3)_2$:** A methanolic solution of $Zn(NO_3)_2\cdot4H_2O$ (0.68 mmol, 0.18 g, 5 mL) was added dropwise to a solution of the ligand (LH: 0.66 mmol, 0.21 g) in methanol (10 mL). The colourless solution was heated at reflux for 4 h and concentrated by evaporation. A white powder was precipitated by addition of diethyl ether solution (0.19 mg, 58%). $^{13}$C NMR (62.9 MHz, $CD_3OD$): $\delta$ = 45.1, 42.3, 47.4, 52.2 and 53.9 ($CH_2N$), 113.5, 118.5, 125.2, 125.8, 135.6, 139.3 and 153.3 ($C_{Ar}$). $C_{16}H_{26}N_6ZnN_2O_6\cdot0.25CH_3OH$ (499.83): calcd. C 39.05, H 5.44, N 22.42; found C 38.92, H 5.26, N 22.49%.

**[ZnLH]$(ClO_4)_2$:** A methanolic solution of $Zn(ClO_4)_2\cdot6H_2O$ (0.41 mmol, 0.15 g, 5 mL) was added dropwise to a solution of the ligand (LH: 0.35 mmol, 0.11 g) in methanol (5 mL). The colourless solution was heated at reflux for 4 h and concentrated by evapora-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

tion. A white powder was precipitated by addition of diethyl ether (0.10 g, 50%). $C_{16}H_{26}N_6ZnCl_2O_8{\cdot}0.5H_2O$ (575.72): calcd. C 33.38, H 4.73, N 14.60; found C 33.62, H 4.76, N 14.42%. ESI-MS: *m*/*z* calcd. for $[Zn(C_{16}H_{26}N_6)(ClO_4)]^+$ 465.1; found 465.1. This solid was further dissolved in acetonitrile, and after slow diffusion of diethyl ether, white monocrystals of $[ZnLH](ClO_4)_2{\cdot}CH_3CN$ suitable for X-ray analysis were produced.

CAUTION: Perchlorate-containing complexes are potentially explosive and appropriate precautions should be in place for their preparation, handling and storage.

**Potentiometric Measurements:** Potentiometric titrations were carried out with an automatic titrator composed of a microprocessor burette (Metrohm dosimat 665) and a pH meter (Metrohm 713) connected to a computer. The titration procedure was fully automated.[19] All measurements were performed within a thermoregulated cell at 25.0 ± 0.1 °C under an argon stream to avoid the dissolution of carbon dioxide. The ionic strength was adjusted to 1 with potassium nitrate. The combined Type "U" glass electrode (Metrohm) used had a very low alkaline error. The complex formation constants were determined according to the "batch method". Equimolar mixtures of $Zn^{2+}$ and ligand [$2 \times 10^{-3}$ mol L$^{-1}$ in $10^{-2}$ mol L$^{-1}$ $HNO_3$ , $I$ = 1 ($KNO_3$)] were prepared in 30 stoppered flasks at different pH values by microaddition of KOH [$10^{-1}$ mol L$^{-1}$, $I$ = 1 ($KNO_3$)]. These solutions were stored under argon and placed in a thermoregulated enclosure at 40 °C for two, four or six weeks. Before pH measurements, these solutions were allowed to reach equilibrium temperature (25 °C) for 48 h. The deprotonation of the [(benzimidazolylmethyl)cyclen]zinc complex was determined by a pH titration of a complex solution [$2 \times 10^{-3}$ mol L$^{-1}$, $I$ = 1 ($KNO_3$)] prepared from the solid $[ZnLH](NO_3)_2$ monohydrate complex previously described.

The protometric data were processed by using the PROTAF program[19] to obtain the best-fit chemical model and refined overall constants, $\beta_{mlh}$.

$$mM + lL + hH^+ \rightleftharpoons M_mL_lH_h$$

$$\beta_{mlh} = \frac{[M_mL_lH_h]}{[M]^m[L]^l[H^+]^h}$$

A negative $h$ value refers to the hydroxide ion.

The stepwise protonation constants ($K_{0lh}$) related to equilibrium (1) are defined by Equation (2) and are deduced from the refined $\beta_{0lh}$ values by Equation (3).

$$LH_{h-1}^{(h-1)+} + H^+ \overset{K_{0lh}}{\rightleftharpoons} LH_h^{h+} \quad (1)$$

$$K_{0lh} \frac{[LH_h^{h+}]}{[LH_{h-1}^{(h-1)+}][H^+]} \quad (2)$$

$$\beta_{0lh} = \prod_{i=1}^{h} K_{0li} \quad (3)$$

**Spectroscopic Measurements:** $^1$H and $^{13}$C NMR spectra were recorded with a Bruker DRX 500 spectrometer. $^1$H–$^1$H and $^1$H–$^{13}$C 2D correlation experiments were performed to assign the signals. In $^1$H NMR titrations, the pD was adjusted by additions of small amounts of a 4-% diluted NaOD solution or a 3.5-% diluted DCl solution to $D_2O$ solutions containing the ligand LH ($10^{-2}$ mol L$^{-1}$). The pH was calculated from the measured pD values by using Equation (4):[26]

$$pH = pD - 0.40 \quad (4)$$

For both ligands, NMR measurements were performed after an equilibration time of one day. Mass spectra in methanol were recorded on a Micromass Q-TOF electrospray positive ionisation instrument. For both ligand and complex $[ZnLH](ClO_4)_2{\cdot}H_2O$ ($3 \times 10^{-5}$ mol L$^{-1}$), the UV spectrophotometric titrations were recorded at 25 °C in the range 200–400 nm with a thermoregulated Shimadzu UV 2401 PC spectrophotometer. For the UV pH titrations, the pH was adjusted by addition of small amounts of KOH ($10^{-1}$ to $10^{-3}$ mol L$^{-1}$) and HCl solutions ($10^{-1}$ to $10^{-2}$ mol L$^{-1}$).

**Crystal Structure Determination:** The crystal diffraction data were collected at 120 K with a Kappa CCD diffractometer (Centre de Diffractométrie X, Univ. Rennes, France) by using monochromated Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 Å). Data collection was performed with the COLLECT program.[45] Frame integration and data reduction procedures were realised with the DENZO and SCALEPACK programs of the KappaCCD software package, respectively,[46] for the [ZnLH] compound and with EVAL[47] and SADABS[48] programs, respectively. The structure was solved by using the direct methods program SIR97,[49] which revealed all non-hydrogen atoms. SHELXL97[50] was used to refine the structure. Finally, hydrogen atoms were placed geometrically and held in riding mode in the least-squares refinement procedure. Final difference maps revealed no significant maxima (Table 4). CCDC-648571 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

**Spectrofluorimetric Measurements:** Fluorescence emission spectra were recorded at 25 °C with a Perkin–Elmer LS50B spectrofluorimeter equipped with a Hammamastu R928 photomultiplier. The lin-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

earity of the fluorescence emission versus the concentration was checked in the concentration range 0 to $10^{-6}$ mol L$^{-1}$. Emission spectra were normalised by the manufacturer-supplied correction curves. Quantum yields were determined by comparison of the integrated corrected emission spectrum of standard quinine sulfate[51] [the quantum yield ($\Phi$) is 0.55]. Spectrofluorimetric pH titrations of the ligand and the complex were performed as follows: the stock solutions of the ligand or the complex (ca. $3\times10^{-5}$ mol L$^{-1}$) were prepared by dissolving an appropriate amount of the ligand in a 50-mL volumetric flask and by diluting with degassed water under an argon atmosphere. The titration solution {[LH] = $5\times10^{-7}$ mol L$^{-1}$} was prepared by appropriate dilution of the stock solution. The response of LH to increased amounts of $Zn^{2+}$ was checked as follows: successive volumes of $Zn(ClO_4)_2\cdot6H_2O$ ($1.2\times10^{-3}$ mol L$^{-1}$) were added to ligand solutions ($3\times10^{-5}$ mol L$^{-1}$) for a constant pH value [CAPS buffer solution ($2\times10^{-2}$ mol L$^{-1}$)]. These solutions were further diluted in CAPS buffer in order to reach a LH concentration of $5\times10^{-7}$ mol L$^{-1}$. The emission spectra of ligand and complex solutions were recorded after excitation at a wavelength of $\lambda$ = 270 nm in the range 275–400 nm (slit width of 5 nm).

**Supporting Information** (see footnote on the first page of this article): The $^1$H NMR spectra of LH as well as the $^1$H NMR spectra of a mixture of LH and $Zn^{2+}$ as a function of pH. A comparison of the affinities of LH and cyclen for $Zn^{II}$ is also reported.

## Acknowledgments

We thank H. Ballia and D. Harakat (Université de Reims Champagne Ardenne, France) for their help with the NMR 2D measurements and with ESI-MS measurements, respectively. T. Roisnel is gratefully acknowlegded for the crystal structure determination. Prof. S. Aoki (Tokyo University of Science), Dr. C. Picard (Université Paul Sabatier, Toulouse, France) and Prof. J. Rimbault (Université de Reims Champagne Ardenne, France) are gratefully acknowledged for helpful discussions.

# Mixed-Valence Cobalt(II/III) Carboxylate Clusters: $Co^{II}_4Co^{III}_2$ and $Co^{II}Co^{III}_2$ Complexes from the Use of 2-(Hydroxymethyl)pyridine

**Theocharis C. Stamatatos,[a] Athanassios K. Boudalis,[b] Konstantina V. Pringouri,[a] Catherine P. Raptopoulou,[b] Aris Terzis,[b] Joanna Wolowska,[c] Eric J. L. McInnes,*[c] and Spyros P. Perlepes*[a]**

*Dedicated to the late F. Albert Cotton for his important contributions to Inorganic Chemistry*

**Keywords:** Mixed-valence cobalt complexes / [2-(Hydroxymethyl)pyridine]metal complexes / Linear trinuclear cobalt complexes / Hexanuclear cobalt clusters / Q-band electron paramagnetic resonance

Aerobic reactions of $Co(O_2CR)_2$ with 2-(hydroxymethyl)pyridine (hmpH), in the presence of $ClO_4^-$ counterions give the hexanuclear, mixed-valence clusters $[Co^{II}_4Co^{III}_2(O_2CR)_4(hmp)_8](ClO_4)_2$ [R = Me (**1**), Ph (**2**)] which possess the unprecedented $[Co^{II}_4Co^{III}_2(\mu_3\text{-}OR')_4(\mu\text{-}OR')_4]^{6+}$ [R′ = (2-pyridyl)-$CH_2$-] core. Replacement of $ClO_4^-$ by $N_3^-$ in the reaction mixture that gives **1** leads to the linear complex $[Co^{III,II,III}_3(O_2CMe)_2(N_3)_2(hmp)_4]$ (**3**). Q-band EPR spectra and variable-temperature magnetic susceptibility studies for **1** and **2** provide strong evidence that the $Co^{II}$ ions are antiferromagnetically coupled.

## Introduction

There is currently an intense interest in the synthesis and study of polynuclear 3d-metal complexes (clusters). Among the diverse reasons for this is the discovery that 3d-metal molecular clusters can show slow relaxation of magnetisation under certain circumstances. These molecular species, named "single-molecule magnets" (SMMs),[1] have attracted great interest from both a technological viewpoint – in that such single molecules represent the smallest conceivable memory devices – and from a fundamental scientific perspective, as those clusters have allowed studies of quantum mechanichal phenomena such as tunneling.[1a,1b,1d] There thus continues to be a need for new synthetic methods[2] to such molecules.

Ligands used in synthesising 3d-metal clusters are however comparatively restricted[3] and thus discovery of new combinations ("blends") of ligands remains important in the field. With this aim, we have been exploring "ligand blend" reactions involving carboxylates ($RCO_2^-$) *and* anionic bridging-chelating ligands (i.e. bridging ligands that simultaneously form chelating rings), *with* or *without* additional inorganic anions ($Cl^-$, $Br^-$, $NO_3^-$, $N_3^-$, $SCN^-$). Our results with the anionic *gem*-diol derivatives of di-2-pyridyl ketone,[4] various 2-pyridyloximates[5] and a plethora of derivatized salicylaldoximates[6] have been very encouraging, and a series of Cr, Mn, Fe, Co, Ni and Cu carboxylate clusters with nuclearities ranging from 3 to 20 and with interesting properties (including high-spin molecules[7] and SMMs[6,8]) have been prepared.

As part of our continuing search for new preparative routes to polynuclear species, we have recently turned our attention to 2-pyridyl alcohols that present a kind of structural similarity to 2-pyridyl oximes; our goals are to investigate to what extent the use of such ligands might affect the identity of the obtained products compared with 2-pyridyl oximes and to what extent this might thus prove to be a route to new cluster types. In the present work, we report interesting clusters from the use of 2-(hydroxymethyl)pyridine (hmpH) in cobalt carboxylate chemistry. Cobalt(II), which has a large single-ion anisotropy due to the orbitally degenerate ground state, may potentially be a good candidate for making SMMs, and there are few reports in the literature of $Co^{II}$-based SMMs.[9] The ligand hmpH has been used extensively in the synthesis of Fe,[10] Mn[11] and Cu[12] clusters, but has been sparingly used with other 3d-metals. The deprotonated $hmp^-$ group has been used previously in $Co^{II}$ chemistry by Christou and Hendrickson,[9a] who reported the cubane cluster $[Co^{II}_4Cl_4(hmp)_4(MeOH)_4]$;

this cluster proved to be the first cobalt SMM. No cobalt carboxylate clusters containing hmp$^-$ have been reported. We suspected that there might be a number of Co/$RCO_2^-$/hmp$^-$ cluster species accessible and have therefore been investigated the reactions of hmpH with $Co^{II}$ carboxylate sources under a variety of conditions.

## Results and Discussion

### Synthesis and IR Characterisation

Aerobic reactions of $Co(O_2CMe)_2{\cdot}4H_2O$ and $Co(O_2CPh)_2$ with hmpH, in the presence of $NaClO_4$ (1:1:1 molar ratio), in a solvent mixture comprising MeCN and MeOH (3:1, v/v) at room temperature led to dark red solutions, from which were subsequently isolated crystals of $[Co_6(O_2CMe)_4(hmp)_8](ClO_4)_2{\cdot}$MeOH (**1**·MeOH) and $[Co_6(O_2CPh)_4(hmp)_8](ClO_4)_2{\cdot}2$(*n*-hex) [**2**·2(*n*-hex)], respectively, upon conventional workup (*n*-hex = *n*-hexane). The formation of **1** and **2** can be represented by Equation (1).

$$6\ Co^{II}(O_2CR)_2 + 8\ hmpH + 2\ NaClO_4 + 1/2\ O_2 \xrightarrow{MeCN/MeOH} \mathbf{[Co^{II}_4Co^{III}_2(O_2CR)_4(hmp)_8](ClO_4)_2} + 6\ RCO_2H + 2\ NaO_2CR + H_2O \quad [R = Me\ (\mathbf{1}),\ Ph\ (\mathbf{2})] \tag{1}$$

The addition of the coordinating $N_3^-$ ions to the 1:1 Co$(O_2CMe)_2{\cdot}4H_2O$/hmpH (i.e. omission of $ClO_4^-$ ions) reaction mixture in MeCN/$H_2O$ (3:1, v/v), in the presence of atmospheric oxygen and layering of $Me_2CO$ onto the resulting green-brown solution gave dark red crystals of the neutral complex $[Co_3(O_2CMe)_2(N_3)_2(hmp)_4]{\cdot}H_2O$ (**3**·$H_2O$) in very good yield. The formation of **3** is summarised in Equation (2).

$$3\ Co^{II}(O_2CMe)_2{\cdot}4H_2O + 4\ hmpH + 2\ NaN_3 + 1/2\ O_2 \xrightarrow{MeCN/H_2O} \mathbf{[Co^{II}Co^{III}_2(O_2CMe)_2(N_3)_2(hmp)_4]}\ (\mathbf{3}) + 2\ MeCO_2H + 2\ NaO_2CMe + 13\ H_2O \tag{2}$$

The IR spectra of **1** and **2** exhibit bands at 1098–1092 and 628–624 $cm^{-1}$ assignable to the $\nu_3(F_2)[\nu_d(ClO)]$ and $\nu_4(F_2)[\delta_d(OClO)]$ modes, respectively, of the uncoordinated $T_d$ $ClO_4^-$ ions.[13] The spectrum of **3**·$H_2O$ exhibits an intense band centred at 2135 $cm^{-1}$ which is attributed to the asymmetric stretching mode of the coordinated azide.[13] Several bands appear in the 1610–1380 $cm^{-1}$ range in the spectra of the three complexes. Contributions from the carboxylate $\nu_{as}(CO_2)$ and $\nu_s(CO_2)$ modes are expected in this region, but overlapping with the stretching vibrations of the 2-pyridyl and benzoate (only for **2**) rings, and $\delta(CH_2)$ renders assignments tentative. The strong bands at 1574 (**1**), 1573 (**2**), 1574 (**3**·$H_2O$) and 1434 (**1**), 1438 (**2**), 1434 (**3**·$H_2O$) have $\nu_{as}(CO_2)$ and $\nu_s(CO_2)$ characters, respectively. The difference $\Delta$ [$\Delta = \nu_{as}(CO_2) - \nu_s(CO_2)$] is 140 $cm^{-1}$ for **1**, **3**·$H_2O$ and 135 $cm^{-1}$ for **2**, less than those for $NaO_2CMe$ (164 $cm^{-1}$) and $NaO_2CPh$ (184 $cm^{-1}$), as expected for the bridging mode of carboxylate ligation.[14]

### Description of Structures

The cations of **1** (Figure 1) and **2** (Figure 2) are structurally similar in many aspects and thus only the structure of complex **1**·MeOH (the quality of this structure is superior

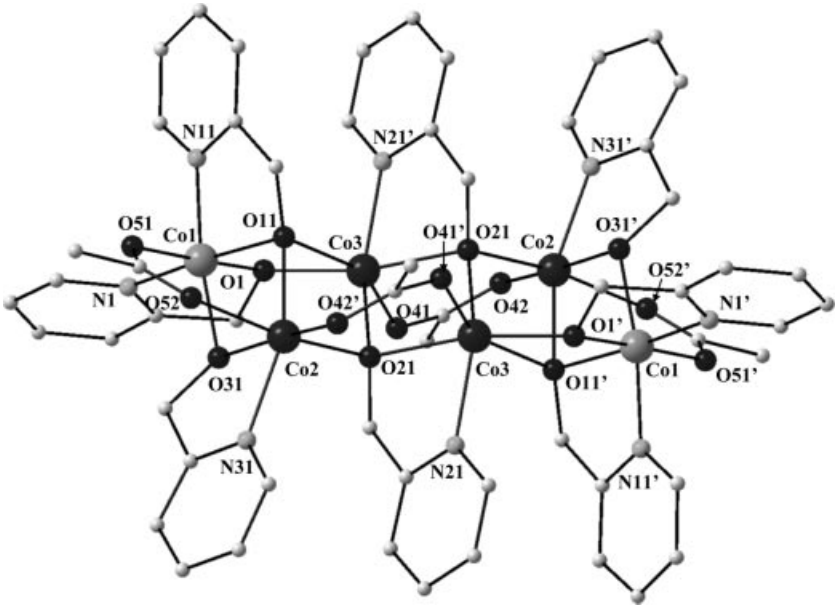

Figure 1. Partially labelled ball-and-stick presentation of the cation of **1**. H atoms are omitted for clarity. Primes are used for symmetry-related atoms.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

to that of the benzoate cluster) will be described in detail. Selected interatomic distances and angles for the two hexanuclear complexes are listed in Tables 1 and 2. The cation of **1** lies on a crystallographic inversion centre, and consists of six distorted octahedral metal ions held together by four 3.31 (Harris notation[15]) or $\eta^1{:}\eta^3{:}\mu_3$ hmp$^-$ ligands, four 2.21 or $\eta^1{:}\eta^2{:}\mu$ hmp$^-$ ligands (Scheme 1), two *syn*,*syn* 2.11 or $\eta^1{:}\eta^1{:}\mu$ $MeCO_2^-$ groups (those containing atoms O51/O52 and their symmetry equivalents) and two *syn*,*anti* 2.11 or $\eta^1{:}\eta^1{:}\mu$ $MeCO_2^-$ (those containing atoms O41/O42 and their symmetry equivalents). Harris notation[15] describes the binding mode as $X.Y_1Y_2Y_3\cdots Y_n$, where X is the overall number of metals bound by the whole ligand, and each value of Y refers to the number of metal ions attached to the different donor atoms. The ordering of Y is listed by the Cahn–Ingold–Prelog priority rules, hence here O before N. The chromophores are $Co(1)O_4N_2$, $Co(2)O_5N$ and $Co(3)O_5N$. Charge considerations require a $4Co^{II}$, $2Co^{III}$ oxidation-state description (mixed-valent complex). Cobalt–ligand distances fall into two well-separated groups with all distances from Co(1) being less than 1.93 Å, and those from Co(2) and Co(3) being at least 2.01 Å; thus,[16] Co(1) and its symmetry-related Co(1′) are assigned as the $Co^{III}$ ions. The core of the cluster (Figure 3) appears to be $[Co^{II}_4Co^{III}_2(\mu_3\text{-}OR')_4(\mu\text{-}OR')_4]^{6+}$, where R′ is the (2-pyridyl)$CH_2$- group. It can be conveniently described as consisting of two $[Co^{II}_2Co^{III}O_4]$ partial cubanes (cubanes missing a vertex). The linking of the partial cubane subunits is achieved via the alkoxide-type oxygen atoms O(21) and O(21′) which become $\mu_3$. The four $Co^{II}$ ions define a rhombus. The $Co^{II}_3$ triangular faces are each bridged by a $\mu_3$-oxygen [O(21), O(21′)]. An alternative description of the core is as containing a $[Co_6O_8]^{6+}$ rod- or ladder-like unit which consists of four edge-sharing triangles, with Co(1) and Co(1′), respectively, below and above (0.223 Å) the plane of the central four $Co^{II}$ ions. The Co(1)–(O,N) and Co(2,3)–(O,N) bond lengths agree well with values expected for low-spin $Co^{III}$ and high-spin $Co^{II}$, respectively, in octahedral environments.[16–18]

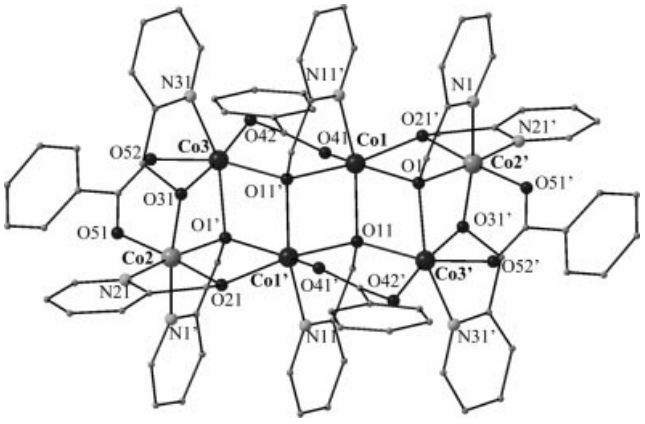

Figure 2. Partially labelled ball-and-stick presentation of the cation of **2**. H atoms are omitted for clarity. Primes are used for symmetry-related atoms.

Table 1. Selected interatomic distances [Å] and angles [°] for complex $[Co_6(O_2CMe)_4(hmp)_8](ClO_4)_2\cdot MeOH$ (**1**·MeOH).[a]

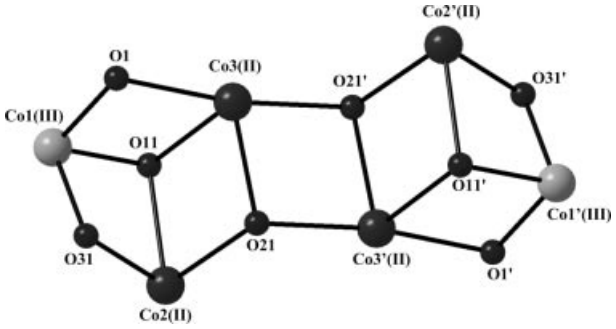

Figure 3. The $[Co^{II}_4Co^{III}_2(OR')_8]^{6+}$ core of complexes **1** and **2**.

The crystal structure of **3**·$H_2O$ reveals the formation of a linear trinuclear molecule (Figure 4). Selected interatomic distances and angles for this complex are listed in Table 3. The central metal ion, Co(1), which is located on a crystallographic inversion centre, is octahedrally coordinated by six-oxygen atoms belonging to four $hmp^-$ and two $MeCO_2^-$ ligands. The six sites on each of the distorted octahedral, terminal Co ions are occupied by the N,O-atoms [N(1), O(1), N(11), O(11)] that belong to the "chelating" part of two $hmp^-$ ligands, one N-atom [N(21)] of a terminal azido ligand and one O-atom [O(22′)] of a *syn*,*syn*-$\eta^1$:$\eta^1$:μ (2.11) $MeCO_2^-$ group. The three nitrogen atoms are in the facial configuration. The core appears to be $[Co^{II}Co^{III}_2(\mu\text{-}OR')_4]^{4+}$. Charge considerations require a formal $2Co^{III}$, $Co^{II}$ description of **3**, and the terminal metal ions are

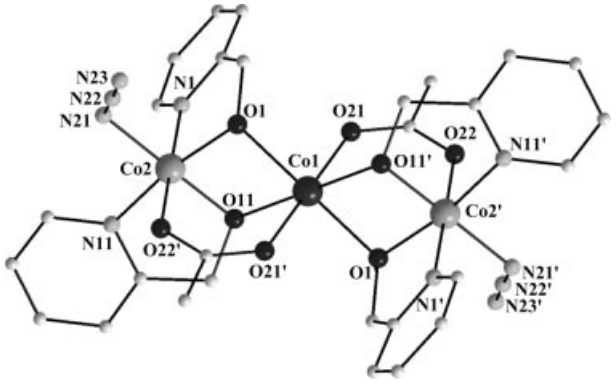

Figure 4. Molecular structure of the mixed-valence (III/II/III) complex **3** with selecting atom labelling. Primes are used for symmetry-related atoms.

clearly low-spin $Co^{III}$ ions based[16] on their Co–N,O bond lengths (all <1.95 Å) compared with those of the central Co(1) ion which has Co–O distances in the range 2.062(2)–2.097(2) Å, indicating that this is a $Co^{II}$ ion. The $hmp^-$ ions function as $\eta^1$:$\eta^2$:μ (2.21) ligands; each ligand chelates one $Co^{III}$ ion through the 2-pyridyl and the alkoxide oxygen forming a five-membered chelating ring and bridges this metal centre with the central $Co^{II}$ ion through the μ deprotonated oxygen atom (Scheme 1).

Complex **3** joins a handful of structurally characterised linear, valence-trapped $Co^{III}Co^{II}Co^{III}$ complexes[18] and an even smaller group of $Co^{II/III}$ clusters comprising both azido and carboxylate ligands.[19]

## Magnetic and EPR Studies

Magnetic susceptibility measurements were carried out on a polycrystalline sample of cluster **1** over 3–300 K and a magnetic field of 1 T (Figure 5). The $\chi_M T$ product at 300 K is 10.83 $cm^3 mol^{-1} K$, significantly higher than the spin-only value of 7.48 $cm^3 mol^{-1} K$ for four non-interacting $S$ = 3/2 ions (with $g$ = 2), and is due to the significant orbital contribution of $Co^{II}$ ions in octahedral environments. Assuming a $g_{av}$ value of 2.2, the theoretical $\chi_M T$ value is 9.08 $cm^3 mol^{-1} K$. $\chi_M T$ drops upon cooling, down to 2.12 $cm^3$ $mol^{-1}$ K at 3 K. The $(\chi_M)^{-1}$ vs. $T$ plot gives a Weiss constant of $\Theta$ = –11.5 K with $C$ = 11.2 $cm^3 mol^{-1} K$ (over the 20–300 K range). The room temperature $\chi_M T$ values of **2** at both 1 and 0.1 T are almost the same (≈ 11.0 $cm^3 mol^{-1} K$). There is a continuous decrease in $\chi_M T$ with decreasing temperature, which is more pronounced below ca. 50 K (as in **1**). The $\chi_M T$ product (1 T field) reaches the value of 2.20 $cm^3 mol^{-1} K$ at 2 K. In a 0.1 T field, however, this decrease is steeper (1.65 $cm^3 mol^{-1} K$ at 2 K). Because the data for **1** are available only at 1 T, the magnetic field effects are unknown for this compound.

Although single-ion spin-orbit coupling effects (giving a doublet ground state) could give rise to this qualitative behaviour,[17c] the low temperature $\chi_M T$ data for two hexanuclear clusters extrapolate to zero at 0 K suggesting a diamagnetic ground state and hence significant antiferromagnetic interactions. This is supported by Q-band EPR spectra for **1** at low temperature which show two features, at ca. 0 and 2 kG, which must arise from different low-lying spin

Table 3. Selected interatomic distances [Å] and angles [°] for complex $[Co_3(O_2CMe)_2(N_3)_2(hmp)_4]\cdot H_2O$ (**3**·$H_2O$).[a]

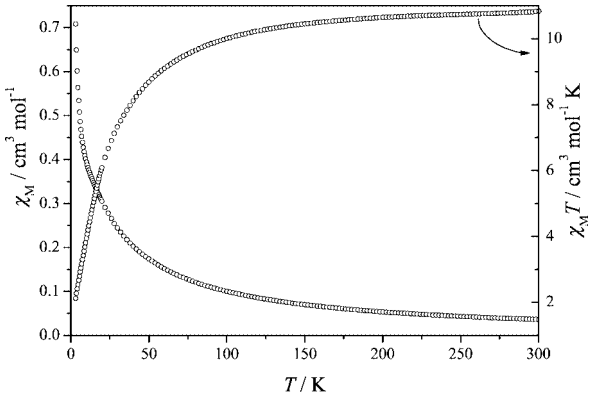

Figure 5. $\chi_M T$ vs. $T$ and $\chi_M$ vs. $T$ plots for complex **1**.

states as shown by their different temperature dependences (Figure 6). However, due to the complexity of systems comprising coupled $Co^{II}$ ions, a quantitative analysis of the susceptibility behaviour is not possible.

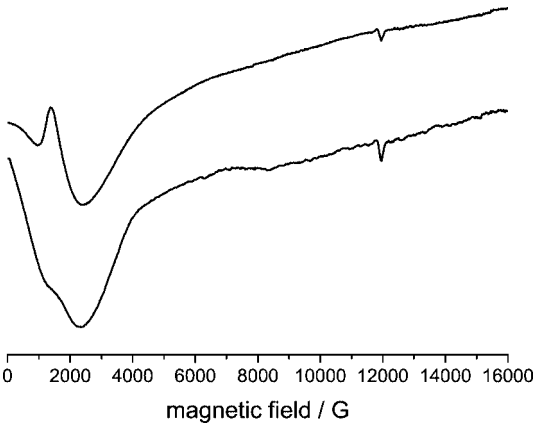

Figure 6. Q-Band (33.9 GHz) EPR spectra of a powder of **1** at 20 (top) and 5 K (bottom). The weak signal at 12000 G is most probably due to an impurity.

The room-temperature value of $\chi_M T$ for **3**·$H_2O$ at 0.1 T is 2.88 cm$^3$ mol$^{-1}$ K ($\mu_{eff}$ per $Co^{II}$ = 4.80 BM), to be compared with the spin-only ($g$ = 2) $\chi_M T$ value of 1.87 cm$^3$ mol$^{-1}$ K ($\mu_{eff}$ per $Co^{II}$ = 3.87 BM). This value is within the range observed for six-coordinate, high-spin cobalt(II) complexes.[18h,20] Because of the intrinsic orbital angular momentum in the octahedral ground state $^4T_{1g}$ (F), there is consistently a considerable orbital contribution, and effective magnetic moments for such compounds around room temperature are between 4.7 and 5.2 BM.[20] The $\chi_M T$ product decreases slowly to 2.13 cm$^3$ mol$^{-1}$ K ($\mu_{eff}$ per $Co^{II}$ = 4.13 BM) at around 25 K and then drops to 1.80 cm$^3$ mol$^{-1}$ K ($\mu_{eff}$ per $Co^{II}$ = 3.80 BM) at 3 K. This behaviour may be understood as arising from the combined effects of orbital degeneracy and zero-field splitting.[18h] The magnetic data confirm that complex **3**·$H_2O$ is in the mixed-valence state $Co^{III}$($S$ = 0) – $Co^{II}$($S$ = 3/2) – $Co^{III}$($S$ = 0) as suggested by the X-ray structural analysis.

## Conclusions and Perspectives

In summary, the initial use of the hmp$^-$/$RCO_2^-$ "blend" in Co chemistry has provided two $Co^{II}_4Co^{III}_2$ clusters with an unprecedented core and one linear $Co^{III}Co^{II}Co^{III}$ complex. The nuclearity of the mixed-valent cluster, [$Co_6$] or [$Co_3$], is controlled partly by the nature of the extra inorganic anion. Magnetic and Q-band EPR studies of the hexanuclear cobalt acetate cluster have provided preliminary useful insights into the complex interplay between single-ion properties and exchange interactions in polynuclear Co complexes. We stated in the Introduction that it was our suspicion that Co/$RCO_2^-$/hmp$^-$ chemistry might prove a rich new area for what is otherwise a well-studied metal. This work and a variety of unpublished results seem to suggest that our suspicions were correct.

## Experimental Section

**General:** All manipulations were performed under aerobic conditions using materials (Merck, Aldrich) as received. Elemental analyses (C,H,N) were performed by the University of Ioannina (Greece) Microanalytical Laboratory with an EA 108 Carlo–Erba analyzer. IR spectra (4400–450 cm$^{-1}$) were recorded from KBr pellets with a Perkin–Elmer PC 16 FTIR spectrometer. Variable-temperature magnetic susceptibility measurements were carried out at the Institute of Materials Science of the NCSR "Demokritos" on polycrystalline samples of complexes **1**–**3** in the 2.0–300 K temperature range using a Quantum Design MPMS SQUID susceptometer under magnetic fields of 1.0 and 0.1 T. Q-band (34 GHz) EPR spectra of **1** were obtained with a Bruker ESP300E spectrometer.

**Safety Note:** Perchlorate and azide salts are potentially explosive; such compounds should be synthesised and used in small quantities, and treated with utmost care at all times.

**Preparations**

**Synthesis of [$Co_6(O_2CMe)_4(hmp)_8$]($ClO_4$)$_2$·MeOH (1·MeOH):** A colourless solution of hmpH (0.10 mL, 1.00 mmol) in MeCN (5 mL) was added to a stirred pink suspension of $Co(O_2CMe)_2$·$4H_2O$ (0.26 g, 1.04 mmol) in MeCN (25 mL). The resulting purple suspension was stirred for 20 min, during which time a colourless solution of $NaClO_4$·$H_2O$ (0.14 g, 1.00 mmol) in MeOH (10 mL) was added in small portions to finally give a deep red slurry. The latter was stirred for a further 24 h, during which time all the solids were completely dissolved. The resulting deep red solution was filtered and layered with $Et_2O$ (90 mL). After 3 d dark orange-red crystals were obtained and collected by filtration, washed with cold MeOH (2 × 5 mL) and $Et_2O$ (2 × 5 mL), and dried in vacuo; the yield was 0.140 g (65% based on hmpH). The dried solid analysed as solvent-free. $C_{56}H_{60}Cl_2Co_6N_8O_{24}$ (1653.65): calcd. C 40.68, H 3.66, N 6.78; found C 40.43, H 3.81, N 6.81. Main IR data: IR (KBr): $\tilde{\nu}$ = 3428 (mb), 2920 (w), 2830 (w), 1574 (s), 1478 (m), 1434 (s), 1346 (w), 1286 (m), 1228 (w), 1092 (vs), 1044 (s), 760 (m), 728 (w), 674 (s), 628 (m), 546 (w), 494 (w) cm$^{-1}$.

**Synthesis of [$Co_6(O_2CPh)_4(hmp)_8$]($ClO_4$)$_2$·2(*n*-hex) [2·2(*n*-hex)]:** This complex was prepared in the same manner as complex **1**, except that $Co(O_2CPh)_2$ (0.31 g, 1.00 mmol) was used in place of $Co(O_2CMe)_2$·$4H_2O$, and the solution was layered with $Et_2O$/*n*-hexanes (1:1, v/v) instead of $Et_2O$. Dark orange crystals of the product were collected by filtration, washed with cold MeOH (2 × 5 mL) and

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

$Et_2O$ (2 × 5 mL), and dried in vacuo; the yield was 0.112 g (47% based on hmpH). The dried solid analysed as solvent-free. $C_{76}H_{68}Cl_2Co_6N_8O_{24}$ (1901.93): calcd. C 48.00, H 3.60, N 5.89; found C 48.17, H 3.81, N 5.94. Main IR data. IR (KBr): $\tilde{\nu}$ = 3430 (mb), 2923 (w), 2835 (w), 1573 (s), 1479 (m), 1438 (s), 1345 (w), 1284 (m), 1229 (w), 1098 (vs), 1041 (m), 763 (m), 729 (w), 674 (s), 624 (m), 543 (w), 492 (w) $cm^{-1}$.

**Synthesis of $[Co_3(O_2CMe)_2(N_3)_2(hmp)_4]\cdot H_2O$ (3·$H_2O$):** A colourless solution of hmpH (0.10 mL, 1.00 mmol) in MeCN (5 mL) was added to a stirred pink suspension of $Co(O_2CMe)_2\cdot 4H_2O$ (0.26 g, 1.04 mmol) in MeCN (25 mL). The resulting purple suspension was stirred for 20 min, during which time a colourless aqueous solution (10 mL) of $NaN_3$ (0.07 g, 1.00 mmol) was added in small portions to finally give a dark green slurry. The latter was stirred for a further 12 h and all the unreacted solids were completely dissolved. The resulting dark brown-green solution was filtered and layered with $Me_2CO$ (90 mL). After 6 d dark red crystals of the product were isolated and collected by filtration, washed with cold $Me_2CO$ (2 × 5 mL) and dried in vacuo over silica gel; the yield was 0.151 g (70% based on hmpH). The dried solid analysed as 3·$H_2O$. $C_{28}H_{32}Co_3N_{10}O_9$ (829.42): calcd. C 40.55, H 3.89, N 16.89; found C 40.33, H 4.00, N 17.24. Main IR data. IR (KBr): $\tilde{\nu}$ = 3428 (m), 2135 (vs), 1574 (s), 1478 (m), 1434 (s), 1346 (m), 1286 (m), 1044 (m), 760 (m), 728 (w), 686 (m), 628 (w), 546 (m), 494 (w) $cm^{-1}$.

**X-ray Crystallographic Studies:** Crystals of 1·MeOH, 2·2(*n*-hex), and 3·$H_2O$ were mounted in air and covered with epoxy glue. Diffraction measurements for 1·MeOH and 3·$H_2O$ were made with a Crystal Logic Dual Goniometer diffractometer using graphite-monochromated Mo-$K_\alpha$ radiation. The X-ray data set for 2·2(*n*-hex) was collected on a $P2_1$ Nicolet diffractometer upgraded by Crystal Logic using graphite-monochromated Cu-$K_\alpha$ radiation. Complete crystal data and parameters for data collection and refinement are listed in Table 4. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centred reflections in the ranges $11 < 2\theta < 23°$ (for 1·MeOH and 3·$H_2O$) and $22 < 2\theta < 54°$ [for 2·2(*n*-hex)]. Intensity data were recorded using the $\theta$–$2\theta$ scan method. Three standard reflections monitored every 97 reflections showed less than 3% variation and no decay. Lorentz, polarisation and $\Psi$-scan absorption corrections were applied using the Crystal Logic software package. For all the three structures, all hydrogen atoms were located by difference maps and were refined isotropically, except those of the methyl groups which were introduced at calculated positions as riding on bonded atoms. No H-atoms for the solvate methanol (for 1·MeOH), *n*-hexane [for 2·2(*n*-hex)] and water (for 3·$H_2O$) were included in the refinement. All non-hydrogen atoms were refined anisotropically, except of the carbon atoms of the benzoates and the solvate *n*-hexane molecules which were refined isotropically. The oxygen atoms of the perchlorate anion in 1·MeOH were found disordered and were refined over two positions with occupation factors of total sum one. All structures were solved by direct methods using SHELXS-86[21] and refined by full-matrix least-squares techniques on $F^2$ with SHELXL-97.[22]

CCDC-642412 (for 1·MeOH), -642411 [for 2·2(*n*-hex)] and -642410 (for 3·$H_2O$) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

Table 4. Crystal data and structure refinement for complexes $[Co_6(O_2CMe)_4(hmp)_8](ClO_4)_2\cdot$MeOH (1·MeOH), $[Co_6(O_2CPh)_4(hmp)_8](ClO_4)_2\cdot 2$(*n*-hex) [2·2(*n*-hex)], and $[Co_3(O_2CMe)_2(N_3)_2(hmp)_4]\cdot H_2O$ (3·$H_2O$).

# Efficient, Ultrafast, Microwave-Assisted Syntheses of Cycloplatinated Complexes

Nicolas Godbert,[a] Teresa Pugliese,[a] Iolinda Aiello,[a] Anna Bellusci,[a] Alessandra Crispini,[a] and Mauro Ghedini*[a]

**Keywords:** Cycloplatination / Microwave synthesis / Platinum / Antitumor agents / X-ray diffraction

Cyclometallated chloridoplatinum complexes containing neutral monodentate ligands such as 2-phenylpyridine (**1a**), 2-(2′-thienyl)pyridine (**1c**) or 4-methoxypyridine (**1d**), as well as the cyclometallated benzo[*h*]quinoline chlorido complex with 4-methoxypyridine (**2d**), can be synthesised in a few minutes by irradiating the reaction mixture with microwaves. The single-crystal X-ray molecular structures of the solvato complexes **1**·dmso and **2**·dmso as well as **1c**, **1d** and **2d** are reported. The availability of this class of complexes in a few minutes offers the possibility of a combinatorial approach for the preparation of libraries of homologous compounds of potential interest for applicative purposes.

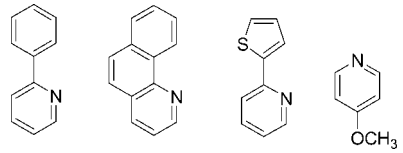
## Introduction

Significant research efforts are currently focused on the study of cycloplatinated complexes due to their potential antitumoural activity[1] as well as their photophysical[2] or mesomorphic[3] properties. The creation of a five-membered metallacycle and formation of the chlorido-bridged dimer $[LPt(\mu\text{-}Cl)]_2$ typically occur during standard cycloplatination reactions carried out with $K_2PtCl_4$ and a ligand HL.[4] Although cyclometallation has been extensively studied and applied, cycloplatination is not a straightforward reaction and often requires rather drastic conditions to take place.

In the last few years, "although microwave effects are still the subject of considerable current debate and controversy",[5] controlled microwave heating has been extensively used in organic synthesis to reduce reaction times and/or improve yields. Microwave-assisted reactions involving transition metals are mainly dedicated to catalytic processes[5,6] or the synthesis of coordination complexes mainly containing iridium[7] and ruthenium,[8] and there is only one example where microwave irradiation has been used to attempt cyclometallation in the synthesis of (2-arylpyridine)-iridium complexes.[9] To the best of our knowledge, cycloplatination has never been studied under microwave irradiation.

Herein we describe new synthetic protocols for the synthesis of dinuclear chlorido-bridged cycloplatinated complexes of the ligands 2-phenylpyridine and benzo[*h*]quinoline (**a** and **b**, respectively), which were selected as representative examples of species that can undergo cycloplatination with the assistance of microwaves.



a b c d

Motivated by literature data reporting the highly cytotoxic properties of a mononuclear $Pt^{II}$ complex bearing ligand **a** both as a cyclometallated and monodentate neutral ligand against some cisplatin-resistant cell lines,[10] this article presents new synthetic strategies for the preparation of mononuclear derivatives with a similar structure that are easily obtained from their corresponding dinuclear complexes. Several new mononuclear $Pt^{II}$ complexes are obtained by both conventional and microwave-assisted syntheses and fully characterised by standard spectroscopic techniques. In addition, the molecular structures of all new synthesised complexes have been determined by single-crystal X-ray analysis.

## Results and Discussion

### Conventional Synthesis of Cycloplatinated Complexes

Cycloplatination reactions were carried out by treating ligand **a** or **b** with $K_2PtCl_4$ according to a conventional synthetic procedure. Under the reaction conditions used [24 h in 2-ethoxyethanol (EGEE) at 65 °C], the nature of the products obtained depends on the ligand/salt molar ratio. Thus, with a 1:1 ratio of ligand/$Pt^{II}$ salt the expected cyclo-

platinated chlorido-bridged dimers **[1(μ-Cl)]$_2$** and **[2(μ-Cl)]$_2$** were obtained in good yields (95 and 75%, respectively), whereas with an excess of **a** (i.e. a molar ratio of 2:1 or even higher), the mononuclear cycloplatinated complex **1a**, which contains a coordinated molecule of **a**, formed almost quantitatively (95% yield). Ligand **b** gives rise exclusively to the dimeric derivative **[2(μ-Cl)]$_2$** irrespective of the ligand/salt ratio. Complexes **[1(μ-Cl)]$_2$**, **[2(μ-Cl)]$_2$** and **1a** have been reported previously,[11] although it is worthwhile noting that **1a** was either only isolated as a side product (10% yield)[12] or was obtained unexpectedly in a two-step reaction from cisplatin in rather poor overall yield.[9b]

Dissolving **[1(μ-Cl)]$_2$** or **[2(μ-Cl)]$_2$** in dmso gave the mononuclear derivatives **1**·dmso and **2**·dmso, which bear a solvent molecule as ancillary ligand.[13] The $^1$H NMR spectra of these complexes in $CDCl_3$ show the signal of the methyl protons of the coordinated solvent molecule ($\delta \approx 3.6$ ppm). Moreover, two characteristic doublets with broad $^{195}$Pt satellites ($^3J_{Pt,H}$ between 30 and 45 Hz) are observed due to the protons of the carbon atoms in the α-position with respect to the (N,C)Pt metallacycle nitrogen and carbon atoms ($\delta \approx 9.7$ and 8.4 ppm, respectively). The structures of **1**·dmso and **2**·dmso were unequivocally confirmed by single-crystal X-ray diffraction analysis (see below).

The reactivity of **[1(μ-Cl)]$_2$** and **[2(μ-Cl)]$_2$** towards the nucleophiles **a**–**d** (see above), which differ in their basicity and steric hindrance, was tested in bridge-splitting reactions to yield the corresponding monomeric adducts. Thus, refluxing **[1(μ-Cl)]$_2$** or **[2(μ-Cl)]$_2$** in 2-ethoxyethanol for 24 h with bases **a**–**d** gave complexes **1a**, **1c**, **1d** and **2d** in 95, 88, 92 and 98% yields, respectively. No complexes were formed when **[1(μ-Cl)]$_2$** and **[2(μ-Cl)]$_2$** were treated with the sterically more demanding base **b** even after longer reaction times. In particular, for **[2(μ-Cl)]$_2$**, due to the steric hindrance of the bridge itself, only the less encumbered base **d** led to the formation of a monomeric adduct **2d**.

### Microwave-Assisted Cycloplatinations

Since cycloplatinations still suffer from long reaction times of up to a week,[14] the reaction mixtures were irradiated with microwaves to try to reduce the reaction times. The Pt$^{II}$ precursor salts used in cycloplatination reactions are highly sensitive to the experimental conditions as they readily decompose at high temperature and in the presence of oxygen. In a very recent synthesis of (diimine)Pt$^{II}$ complexes,[15] the authors reported that microwave irradiation of a reaction mixture containing $K_2PtCl_4$ led to degradation to black Pt$^0$ within a few minutes after heating.

In order to overcome this limitation in the use of Pt$^{II}$ precursor salts, we decided to control the microwave heating by controlling the irradiation power during the synthesis of the new cycloplatinated species. The microwave oven was initially set to reach a maximum temperature of 65 °C after 150 W irradiation. However, this temperature was reached after only 1 min of irradiation; therefore, irradiation was automatically stopped to prevent the maximum temperature from being exceeded. Increasing the reaction time by using the oven cooling option allowed further irradiation of only 1 or 2 W instead of the expected 150 W. In order to prevent the reaction carrying on at 65 °C without microwave irradiation, the reaction vessel was cooled to room temperature in an ice bath and then re-inserted into the microwave oven to be irradiated once more. Three irradiation/cooling cycles of 1 min each were performed; the reaction times reported in Table 3 are quoted relative to the total amount of effective 150 W irradiation time. The bridged dimers **[1(μ-Cl)]$_2$** and **[2(μ-Cl)]$_2$** were obtained using a 1:1 molar ratio of ligand/metal salt according to this strategy in yields of 55–65%. These low yields are due to the formation of a small amount of black Pt$^0$.

When 2 equiv. (or more) of ligand **a** was used to reproduce the synthesis of complex **1a**, 250 W irradiation was used in order to work at a higher temperature (110 °C) than that used for the bridge dimers. This allowed quantitative conversion to the desired product **1a** in 1 min, with no sign of $K_2PtCl_4$ decomposition. Under the same experimental conditions (250 W, 110 °C), but with a smaller quantity of ligand **a**, $K_2PtCl_4$ salt decomposition was immediately observed.

As for the conventional heating synthesis, the only product isolated upon irradiation of a reaction mixture containing ligand **b** and the Pt$^{II}$ salt, irrespective of the ligand/salt ratio, is the dinuclear complex **[2(μ-Cl)]$_2$**, even after shorter reaction times (<1 min).

The microwave heating protocol was also applied to the bridge-splitting reactions between **[1(μ-Cl)]$_2$** and **[2(μ-Cl)]$_2$** and bases **a**–**d**, using 250 W of irradiation. Again, an irradiation/external cooling strategy was preferred in order to avoid temperatures higher than those previously established and to ensure that the reaction was performed under 250 W irradiation conditions. Even under these conditions only the mononuclear complexes **1a**, **1c**, **1d** and **2d** were obtained in a few minutes and in good yields (99, 74, 94 and 63% respectively). The spectroscopic characterisation of **1a**, **1c** and **1d** proved the presence of a single product in all cases. Their $^1$H NMR spectra show three characteristic doublets with broad $^{195}$Pt satellites due to the protons of the carbon atoms α to the Pt-coordinated atoms. The crude product resulting from the reaction between **d** and **[2(μ-Cl)]$_2$** contains a mixture of isomers and the $^1$H NMR spectrum of the crude product suggests a mixture of *trans*-*N*,*N* (**2d**) and *cis*-*N*,*N* (**2d′**) isomers. The clear separation of the distinctive doublets due to the protons of the carbon atoms α to the N–Pt-bonded atoms ($\delta$ = 9.82 ppm for **2d** and 9.35 ppm for **2d′**) allowed the relative ratio of the two isomers (85% of **2d** and 15% of **2d′**) to be determined. Recrystallisation of the crude reaction product from a dichloromethane/methanol solution allowed the separation of the *trans*-*N*,*N* isomer **2d**. Since this isomer is the only product formed from the reaction between **[2(μ-Cl)]$_2$** and **d** during the conventional heating routine, it can be inferred that **2d** and **2d′**, which is observed only when the reaction is performed using microwave irradiation, are the thermodynamic and kinetic products, respectively.

## Crystal Structure Analysis

The mononuclear complexes **1**·dmso, **2**·dmso, **1a**, **1c**, **1d** and **2d** were characterised by single-crystal X-ray diffraction analysis (Figures 1 and 2). Selected bond lengths and angles are listed in Tables 1 and 2.

Complexes **1**·dmso and **2**·dmso are formed when the dinuclear precursors are dissolved in dmso and a molecule of solvent replaces one chlorido ligand in a bridge-splitting reaction. The platinum atom in both **1**·dmso and **2**·dmso is located in a slightly distorted square-planar environment and is surrounded by the C and N atoms of the cyclometallated ligand with the coordinated solvent molecule positioned *trans* to the N atom. The Pt–S distances of 2.21–

2.22 Å are similar to those found in a search of the CSD (Cambridge Structural Database, Version 5.26) for a Pt–dmso fragment with the S atom *trans* to an N atom.

The molecular structure of **1a** has already been reported in both its monoclinic and triclinic polymorphs.[9a,10b] The crystals of **1a** isolated here were found to be the triclinic polymorph from a determination of their unit cell parameters. The molecular structures of **1c**, **1d** and **2d** reveal the formation of square-planar derivatives with the nitrogen ligands **c** and **d** bound *trans* to the nitrogen atom of the cyclometallated ligands **a** (**1c** and **1d**) and **b** (**2d**).

The dihedral angles between the two aromatic rings of the cyclometallated ligand **a** in **1c** and **1d** are 2.7(2)° and 3.2(1)° (two molecules of **1c** in the asymmetric unit) and 2.4(2)°, respectively, thereby showing a certain degree of planarity. The pyridyl ring of the $Pt^{II}$-coordinated ligands **c** and **d** is almost perpendicular to the coordination plane in all cases. The Pt–Cl bond lengths (2.39–2.42 Å) confirm the *trans* influence of the cyclometallated carbon atom, as already observed in complex **1a**.[9a] The shortest value (2.39 Å) is found in complex **2d**, where the higher electron delocalisation of the cycloplatinated ring, and its planarity, result in a stronger Pt–Cl bond than in **1d**.

Analysis of the molecular packing showed the presence of weak hydrogen bonds of the C–H···Cl type. The presence of an oxygen atom in the methoxy substituent of **d** results in the presence of additional intermolecular C–H···O interactions, with distances of 2.7–2.8 Å, in complexes **1d** and **2d**, as shown in Figure 3a, b.

## Conclusions

The results obtained from the present comparative investigations, summarised in Table 3, show that microwave irradiation is an easy, efficient and quick way to obtain mononuclear cycloplatinated complexes. Accurate simultaneous control of both temperature and irradiation power is, however, required for these sensitive cycloplatination reactions. The effective irradiation time is an important parameter to be considered when using a controlled microwave heating oven to avoid working without irradiation once the maximum set-up temperature is reached. We found that working with irradiation/external cooling cycles of a few minutes is the best way to control both parameters as it leads to less degradation of the $Pt^{II}$ starting materials in the synthesis of the dinuclear complexes **[1(μ-Cl)]$_2$** and **[2(μ-Cl)]$_2$** and the absence of decomposition in the case of the mononuclear derivatives **1a**, **1c**, **1d** and **2d**.

As the only difference between the conventional and microwave heating procedures in bridge-splitting reactions of the dinuclear compounds **[1(μ-Cl)]$_2$** and **[2(μ-Cl)]$_2$** is the reaction time, the nature of the obtained products must depend on both the electronic effects exerted by the cyclometallated fragment and the nucleophilicity of the ancillary nitrogen ligands. In particular, the bridge cleavage of **[2(μ-Cl)]$_2$** is only possible with ligand **d** (to yield the expected complex **2d**), whereas with **a** and **c**, which react easily with **[1(μ-Cl)]$_2$** to form the derivatives **1a** and **1c**, no complexes were isolated. This behaviour can be explained on the basis of the metal-chelated ring aromaticity and the π back-bonding of the cyclometallated ligand.[16] The higher electron delocalisation of the cycloplatinated ring formed by **b**, as evidenced by the stronger Pt–Cl bond in **2d** than in **1d** (Table 2), is responsible for the higher stability of the dinuclear complex **[2(μ-Cl)]$_2$**. Consequently, only the smallest and more nucleophilic ligand (**d**) is capable of reacting with **[2(μ-Cl)]$_2$** to give the corresponding mononuclear species.

The synthesis of **1a**, which is quantitative in 1 min, is a large step forward in the preparation of highly cytotoxic compounds. Furthermore, due to their structural similarities to known cytotoxic compounds, complexes **1c**, **1d** and **2d** should also be of interest for potential therapeutic applications. The availability of this class of complexes in only a

few minutes by microwave-assisted synthesis is a considerable advantage as it offers the possibility of a combinatorial approach to the preparation of families of compounds for large-scale screening studies.[17]

## Experimental Section

**General:** 2-Phenylpyridine, benzo[*h*]quinoline, 2-(2′-thienyl)pyridine, 4-methoxypyridine, potassium tetrachloroplatinate and all solvents were obtained from Aldrich and used as received. Microwave reactions were performed using a CEM Discover Synthesis Unit (CEM Corp., Matthews, NC). This instrument consists of a continuous focused microwave power delivery system with operator-selectable power output (0–300 W). The reactions were performed in glass vessels (capacity 50 mL) equipped with a condenser under atmospheric pressure. The temperature of the contents of the vessel was monitored using an optical fibre inserted through a specially designed glass-tube directly into the centre of the reaction vessel. The contents of the vessel were stirred by means of a rotating magnetic plate located below the floor of the microwave cavity and a Teflon-coated magnetic stir bar in the vessel. $^1$H NMR (500 MHz) spectra were recorded with a Bruker Avance 500 spectrometer with tetramethylsilane (TMS) as internal standard. Elemental analyses were performed with a Perkin–Elmer 2400 analyzer. The thermal behaviour was monitored with a Zeiss Axioscope polarizing microscope equipped with a Linkam CO 600 heating stage.

**[1(μ-Cl)]$_2$. Conventional Heating Synthesis:** An aqueous degassed solution (5 mL) of potassium tetrachloroplatinate (500 mg, 1.2 mmol) was added, under $N_2$, to a stirred degassed solution of 2-phenylpyridine (**a**; 185 mg, 1.2 mmol) in 2-ethoxyethanol (15 mL) and the reaction mixture heated to 80 °C for 48 h. After cooling in an ice bath, distilled water was added. The obtained yellow-green precipitate was filtered, washed with ethanol and dried under vacuum. Yield: 435 mg (95%). **Microwave-Assisted Synthesis:** The product was synthesised by treating ligand **a** (224 mg, 1.4 mmol) with potassium tetrachloroplatinate (600 mg, 1.4 mmol) in a degassed solution ($N_2$) of 2-ethoxyethanol/$H_2O$ (3:1, v/v, 20 mL) and irradiating this mixture with 150 W of microwave radiation. The temperature was prevented from rising above 65 °C by stopping the irradiation and quickly cooling the reaction mixture. Three irradiation/cooling cycles of 1 min were performed. Upon completion, the black $Pt^0$ precipitate was filtered off and distilled water added. The yellow-green precipitate obtained was washed with dichloromethane and dried under vacuum. Yield: 305 mg (55%). $C_{22}H_{16}Cl_2N_2Pt_2$ (769.44): calcd. C 34.34, H 2.10, N 3.64; found C 34.73, H 1.98, N 3.61. M.p. > 350 °C. NMR spectroscopic data are not available because **[1(μ-Cl)]$_2$** is only soluble in solvents such as dmso or dmf in which bridge splitting occurs upon dissolution to give complexes containing a solvent molecule as ancillary ligand (for example **1**·dmso).

**[2(μ-Cl)]$_2$. Conventional Heating Synthesis:** The cycloplatination reaction of benzo[*h*]quinoline (**b**) was carried out as described for the preparation of **[1(μ-Cl)]$_2$**. Yellow-green solid. Yield: 365 mg (75%). **Microwave-Assisted Synthesis:** Complex **[2(μ-Cl)]$_2$** was prepared as described for **[1(μ-Cl)]$_2$**. Yellow-green solid. Yield: 383 mg (65%). $C_{26}H_{16}Cl_2N_2Pt_2$ (817.48): calcd. C 38.20, H 1.97, N 3.43; found C 38.49, H 2.01, N 3.09. Mp > 350 °C. NMR spectroscopic data are not available for the same reason as for **[1(μ-Cl)]$_2$**.

**1·dmso:** Distilled water was added to a solution of **[1(μ-Cl)]$_2$** (380 mg, 0.5 mmol) in dmso (10 mL). The resulting yellow-green powder was filtered off, dried under vacuum and recrystallised from dichloromethane/ethanol to yield **1**·dmso quantitatively (455 mg). M.p. 208 °C. $^1$H NMR (500 MHz, $CDCl_3$, 25 °C): $\delta$ = 9.60 (d with broad $^{195}$Pt satellites, $^3J_{H,H}$ = 4.5, $^3J_{Pt,H}$ = 33 Hz, 1 H), 8.32 (d with broad $^{195}$Pt satellites, $^3J_{H,H}$ = 7.5, $^3J_{Pt,H}$ = 37.5 Hz, 1 H), 7.85 (t, $^3J_{H,H}$ = 8 Hz, 1 H), 7.71 (d, $^3J_{H,H}$ = 8 Hz, 1 H), 7.50 (d, $^3J_{H,H}$ = 7 Hz, 1 H), 7.26–7.16 (m, 3 H) 3.65 (s, 6 H) ppm. $^{13}$C NMR (500 MHz, $CDCl_3$, 25 °C): $\delta$ = 166.0, 150.1, 144.4, 140.4, 140.2, 134.1, 130.8, 125.3, 123.8, 121.9, 118.6, 47.3 ppm. $C_{13}H_{14}ClNOPtS$ (462.85): calcd. C 33.73, H 3.05, N 3.03; found C 33.95, H 2.94, N 3.25.

**2·dmso:** Distilled water was added to a solution of **[2(μ-Cl)]$_2$** (408 mg, 0.5 mmol) in dmso (10 mL). The resulting yellow-green powder was filtered off, dried under vacuum and recrystallised from dichloromethane/ethanol to yield **2**·dmso quantitatively (485 mg). M.p. 227 °C. $^1$H NMR (500 MHz, CDCl3, 25 °C): $\delta$ = 9.80 (d with broad $^{195}$Pt satellites, $^3J_{H,H}$ = 5.5, $^3J_{Pt,H}$ = 30.5 Hz, 1 H), 8.51 (d with broad $^{195}$Pt satellites, $^3J_{H,H}$ = 6.5, $^3J_{Pt,H}$ = 43.5 Hz, 1 H), 8.35 (d, $^3J_{H,H}$ = 8 Hz, 1 H), 7.81 (d, $^3J_{H,H}$ = 8.5 Hz, 1 H), 7.69 (d, $^3J_{H,H}$ = 8 Hz, 1 H), 7.70–7.56 (m, 3 H) 3.71 (s, 6 H) ppm. $^{13}$C NMR (500 MHz, $CDCl_3$, 25 °C): $\delta$ = 178.0, 154.8, 143.9, 133.7, 127.0, 126.6, 124.8, 124.5, 122.7, 121.5, 118.2, 117.5, 115.4, 47.3 ppm. $C_{15}H_{14}ClNOPtS$ (486.87): calcd. C 37.00, H 2.90, N 2.88; found C 36.76, H 1.94, N 3.01.

**1a. Conventional Heating Synthesis:** An aqueous degassed solution of potassium tetrachloroplatinate (500 mg, 1.2 mmol in 3 mL of $H_2O$) was added to a stirred degassed solution of **a** (372 mg, 2.4 mmol) in 2-ethoxyethanol (9 mL) under $N_2$ and the reaction mixture heated to 80 °C overnight. After cooling in an ice bath, distilled water was added and the yellow precipitate produced was filtered off, washed with cold ethanol and dried under vacuum. Further crystallisation from a dichloromethane/ethanol solution yielded yellow crystals of **1a**. Yield: 615 mg (95%). **Microwave-Assisted Synthesis:** The product was synthesised by treating ligand **a** (340 mg, 2.2 mmol) with potassium tetrachloroplatinate (400 mg, 1 mmol) in a degassed solution ($N_2$) of 2-ethoxyethanol/$H_2O$ (3:1, v/v, 20 mL) and irradiating this mixture with 250 W of microwave radiation for 1 min (maximum temperature reached: 110 °C). The reaction mixture was then cooled rapidly and the yellow precipitate formed was filtered off. Recrystallisation from dichloromethane/ethanol solution yielded **1a** quantitatively (591 mg). M.p. 225 °C.

$^1$H NMR (500 MHz, $CDCl_3$, 25 °C): $\delta$ = 9.60 (d with broad $^{195}$Pt satellites, $^3J_{H,H}$ = 5, $^3J_{Pt,H}$ = 34 Hz, 1 H), 9.23 (d with broad $^{195}$Pt satellites, $^3J_{H,H}$ = 5.5, $^3J_{Pt,H}$ = 39 Hz, 1 H), 8.08 (m, 2 H), 7.92 (td, $^3J_{H,H}$ = 8, $^3J_{H,H}$ = 2 Hz, 1 H), 7.67 (td, $^3J_{H,H}$ = 8, $^3J_{H,H}$ = 2 Hz, 1 H), 7.47 (d, $^3J_{H,H}$ = 8 Hz, 1 H) 7.35–7.26 (m, 5 H), 7.03 (td, $^3J_{H,H}$ = 7.5, $^3J_{H,H}$ = 1.5 Hz, 1 H), 6.96 (td, $^3J_{H,H}$ = 7.5, $^3J_{H,H}$ = 1.5 Hz, 1 H) 6.86 (td, $^3J_{H,H}$ = 7.5, $^3J_{H,H}$ = 1.5 Hz, 1 H), 6.17 (d with broad $^{195}$Pt satellites, $^3J_{H,H}$ = 6.5, $^3J_{Pt,H}$ = 39 Hz, 1 H) ppm. $^{13}$C NMR (500 MHz, $CDCl_3$, 25 °C): $\delta$ = 167.2, 162.3, 154.4, 151.2, 144.2, 141.1, 139.9, 138.4, 137.7, 130.82, 129.8, 129.6, 129.3, 127.8, 127.3, 123.8, 123.2, 123.1, 121.7, 118.0 ppm. $C_{22}H_{17}ClN_2Pt$ (539.91): calcd. C 48.94, H 3.17, N 5.19; found C 48.78, H 3.25, N 5.33.

**1c. Conventional Heating Synthesis:** 2-(2′-Thienyl)pyridine (**c**; 400 mg, 2.5 mmol) was added to a stirred solution of **[1(μ-Cl)]$_2$** (765 mg, 1 mmol) in 2-ethoxyethanol (15 mL) and the reaction mixture heated to 80 °C overnight. The solvent was then evaporated and the resulting solid was dissolved in dichloromethane (5 mL). Addition of ethanol (15 mL) caused the formation of a precipitate. Recrystallisation of this precipitate from dichloromethane/ethanol gave yellow crystals of **1c**. Yield: 955 mg (88%). **Microwave-Assisted Synthesis:** This product was synthesised by treating ligand **c** (27 mg, 0.17 mmol) with the chlorido-bridged dimer **[1(μ-Cl)]$_2$** (63 mg, 0.08 mmol) in degassed ($N_2$) 2-ethoxyethanol (15 mL) and irradiating this mixture at 250 W for 2 min (maximum temperature reached: 110 °C). After each irradiation step, the mixture was cooled in an ice bath and the irradiation cycle repeated three times. Distilled water was then added and the resulting yellow precipitate filtered off and recrystallised from a dichloromethane/ethanol solution. Yield: 66 mg (74%). M.p. 258 °C (dec). $^1$H NMR (500 MHz, $CDCl_3$, 25 °C): $\delta$ = 9.70 (d with broad $^{195}$Pt satellites, $^3J_{H,H}$ = 5, $^3J_{Pt,H}$ = 35 Hz, 1 H), 9.24 (d with broad $^{195}$Pt satellites, $^3J_{H,H}$ = 5, $^3J_{Pt,H}$ = 45 Hz, 1 H), 8.01 (dd, $^3J_{H,H}$ = 4, $^3J_{H,H}$ = 1.5 Hz, 1 H), 7.90–7.79 (m, 3 H) 7.62 (d, $^3J_{H,H}$ = 7.5 Hz, 1 H), 7.41 (dd, $^3J_{H,H}$ = 7.5, $^3J_{H,H}$ = 1 Hz, 1 H), 7.38 (dd, $^3J_{H,H}$ = 8, $^3J_{H,H}$ = 1 Hz, 1 H), 7.26 (m, 1 H), 7.14 (td, $^3J_{H,H}$ = 7, $^3J_{H,H}$ = 1.5 Hz, 1 H), 7.04 (td, $^3J_{H,H}$ = 7.5, $^3J_{H,H}$ = 1 Hz, 1 H), 6.98 (dd, $^3J_{H,H}$ = 5, $^3J_{H,H}$ = 4 Hz, 1 H), 6.87 (td, $^3J_{H,H}$ = 7.5, $^3J_{H,H}$ = 1 Hz, 1 H), 6.21 (d with broad $^{195}$Pt satellites, $^3J_{H,H}$ = 7, $^3J_{Pt,H}$ = 42.5 Hz, 1 H) ppm. $^{13}$C NMR (500 MHz, $CDCl_3$, 25 °C): $\delta$ = 167.4, 155.4, 154.6, 151.4, 144.1, 141.6, 138.7, 137.6, 130.7, 130.2, 130.1, 129.5, 129.4, 127.0, 126.3, 123.5, 123.4, 123.3, 121.9, 118.2 ppm. $C_{20}H_{15}ClN_2PtS$ (545.94): calcd. C 44.00, H 2.77, N 5.13; found C 44.20, H 3.05, N 5.25.

**1d. Conventional Heating Synthesis:** The preparation of **1d** was carried out as described for **1c**. Yellow solid. Yield: 903 mg (92%). **Microwave-Assisted Synthesis:** Complex **1d** was prepared as described for **1c** from **[1(μ-Cl)]$_2$** and 4-methoxypyridine (**d**). Yellow solid. Yield: 76 mg (94%). M.p. 245 °C. $^1$H NMR (500 MHz, $CDCl_3$, 25 °C): $\delta$ = 9.70 (d with broad $^{195}$Pt satellites, $^3J_{H,H}$ = 5.5, $^3J_{Pt,H}$ = 31 Hz, 1 H), 8.78 (d with broad $^{195}$Pt satellites, $^3J_{H,H}$ = 7, $^3J_{Pt,H}$ = 39.5 Hz, 2 H), 7.81 (td, $^3J_{H,H}$ = 8, $^3J_{H,H}$ = 1.5 Hz, 1 H), 7.64 (d, $^3J_{H,H}$ = 8 Hz, 1 H), 7.47 (dd, $^3J_{H,H}$ = 7.5, $^3J_{H,H}$ = 1.5 Hz, 1 H), 7.14–7.08 (m, 2 H), 6.99 (td, $^3J_{H,H}$ = 7.5, $^3J_{H,H}$ = 1.5 Hz, 1 H), 6.92 (d, $^3J_{H,H}$ = 7 Hz, 2 H), 6.44 (d with broad $^{195}$Pt satellites, $^3J_{H,H}$ = 6.5, $^3J_{Pt,H}$ = 41.5 Hz, 1 H), 3.95 (s, 3 H) ppm. $^{13}$C NMR (500 MHz, $CDCl_3$, 25 °C): $\delta$ = 171.9, 152.5, 149.1, 140.4, 130.7, 127.2, 125.4, 124.9, 124.6, 123.1, 122.9, 120.9, 119.9, 110.6, 55.45 ppm. $C_{17}H_{15}ClN_2OPt$ (493.94): calcd. C 41.35, H 3.06, N 5.67; found C 41.38, H 3.29, N 5.98.

**2d. Conventional Heating Synthesis:** Complex **2d** was prepared as described for **1c** from **[2(μ-Cl)]$_2$** and **d**. Yellow solid. Yield: 1 g (98%). **Microwave-Assisted Synthesis:** The reaction was performed as described for **1c**. The $^1$H NMR spectrum of the crude reaction product shows signals for an isomeric mixture (see text) containing **2d** (85%) and **2d′** (15%). Recrystallisation of the crude yellow solid from a dichloromethane/ethanol solution allowed the major thermodynamic isomer **2d** to be separated. Yield: 53 mg (63%). M.p. 268 °C (dec). $^1$H NMR (500 MHz, $CDCl_3$, 25 °C): $\delta$ = 9.82 (d with broad $^{195}$Pt satellites, $^3J_{H,H}$ = 5.5, $^3J_{Pt,H}$ = 35 Hz, 1 H), 8.90 (d with broad $^{195}$Pt satellites, $^3J_{H,H}$ = 7, $^3J_{Pt,H}$ = 37.5 Hz, 2 H), 8.26 (dd, $^3J_{H,H}$ = 8, $^3J_{H,H}$ = 1 Hz, 1 H), 7.74 (d, $^3J_{H,H}$ = 9 Hz, 1 H), 7.58 (d, $^3J_{H,H}$ = 7.5 Hz, 1 H), 7.55 (d, $^3J_{H,H}$ = 8.5 Hz, 1 H), 7.47 (dd, $^3J_{H,H}$ = 8, $^3J_{H,H}$ = 5.5 Hz, 1 H), 7.35 (t, $^3J_{H,H}$ = 7.5 Hz, 1 H), 6.95 (d, $^3J_{H,H}$ = 7 Hz, 2 H), 6.71 (d with broad $^{195}$Pt satellites, $^3J_{H,H}$ = 7.5, $^3J_{Pt,H}$ = 37.5 Hz, 1 H), 3.96 (s, 3 H) ppm. $^{13}$C NMR (500 MHz, $CDCl_3$, 25 °C): $\delta$ = 166.4, 156.9, 154.8, 150.3, 141.6, 139.8, 137.6, 133.6, 129.3, 129.1, 127.9, 126.4, 123.5, 121.6, 120.9, 112.0, 56.1 ppm. $C_{19}H_{15}ClN_2OPt$ (517.87): calcd. C 44.07, H 2.92, N 5.41; found C 44.38, H 3.09, N 5.71.

**X-ray Diffraction Studies:** X-ray data were collected with a Bruker-Nonius X8 Apex CCD area detector equipped with a graphite-monochromated Mo-$K_\alpha$ radiation source ($\lambda$ = 0.71073). Data reduction was performed using the SAINT programs; absorption corrections based on multiscan techniques were performed with SADABS.[18] All structures were solved by the Patterson method (SHELXS/L program in the SHELXTL-NT software package)[19] and refined by full-matrix least-squares based on $F^2$. All non-hydrogen atoms were refined anisotropically and hydrogen atoms were included as idealised atoms riding on the respective carbon atoms with C–H bond lengths appropriate to the carbon atom hybridisation. CCDC-646172 to -646176 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

**Crystal Data for 1·dmso:** $C_{13}H_{14}ClNOPtS$, $M_r$ = 462.85 g mol$^{-1}$, size 0.28 × 0.20 × 0.02 mm, monoclinic, space group $P2_1/c$, $a$ = 9.6290(8), $b$ = 18.9145(1), $c$ = 7.3691(6) Å, $\beta$ = 91.238(3)°, $F$(000) = 872, $V$ = 1341.80 (2) Å$^3$, $T$ = 298 K, $Z$ = 4, $D_{calcd.}$ = 2.291 g cm$^{-3}$, $\mu$ = 10.798 mm$^{-1}$, $2\theta_{max}$ = 56.6°. The structure was solved by the Patterson method and refined on $F^2$ to $R_1$ ($wR_2$) = 0.0278 (0.0609) using 2916 reflections with $I > 2\sigma(I)$. GOF = 1.056.

**Crystal Data for 2·dmso:** $C_{15}H_{14}ClNOPtS$, $M_r$ = 486.87 g mol$^{-1}$, size 0.32 × 0.16 × 0.16 mm, orthorhombic, space group $Pnma$, $a$ = 11.2795(2), $b$ = 6.9794(1), $c$ = 18.399(3) Å, $F$(000) = 920, $V$ = 1448.5 (4) Å$^3$, $T$ = 298 K, $Z$ = 4, $D_{calcd.}$ = 2.233 Mg m$^{-3}$, $\mu$ = 10.009 mm$^{-1}$, $2\theta_{max}$ = 56.6°. The structure was solved by the Patterson method and refined on $F^2$ to $R_1$ ($wR_2$) = 0.0178 (0.0359) using 1768 reflections with $I > 2\sigma(I)$. GOF = 1.072.

**Crystal Data for 1c:** $C_{20}H_{15}ClN_2PtS$, $M_r$ = 545.94 g mol$^{-1}$, size 0.32 × 0.28 × 0.16 mm, monoclinic, space group $P2_1/n$, $a$ = 17.962(2), $b$ = 9.0825(1), $c$ = 22.107(3) Å, $\beta$ = 92.111(2)°, $F$(000) = 2080, $V$ = 3604.1(8) Å$^3$, $T$ = 298 K, $Z$ = 8, $D_{calcd.}$ = 2.012 g cm$^{-3}$, $\mu$ = 8.055 mm$^{-1}$, $2\theta_{max}$ = 56.6°. The structure was solved by the Patterson method and refined on $F^2$ to $R_1$ ($wR_2$) 0.0297 (0.0685) using 7268 reflections with $I > 2\sigma(I)$. GOF = 1.029.

**Crystal Data for 1d·CHCl$_3$:** $C_{18}H_{16}Cl_4N_2OPt$, $M_r$ = 613.22 g mol$^{-1}$, size 0.40 × 0.20 × 0.02 mm, triclinic, space group $P\bar{1}$, $a$ = 9.3783(7), $b$ = 9.4050(7), $c$ = 13.2499(9) Å, $\alpha$ = 73.945(3)°, $\beta$ = 82.691(3)°, $\gamma$ = 63.670(2)°, $F$(000) = 584, $V$ = 1006.57(13) Å$^3$, $T$ = 298 K, $Z$ = 2, $D_{calcd.}$ = 2.023 g cm$^{-3}$, $\mu$ = 7.511 mm$^{-1}$, $2\theta_{max}$ = 50.7°. The structure was solved by the Patterson method and refined on $F^2$ to $R_1$ ($wR_2$) 0.0272 (0.0559) using 3192 reflections with $I > 2\sigma(I)$. GOF = 1.076.

# 2-Chloro-1,3,2-diazaphospholenes – A Crystal Structural Study

**Sebastian Burck,[a] Dietrich Gudat,*[a] Kalle Nättinen,[b] Martin Nieger,[c] Mark Niemeyer,[a] and Dirk Schmid[a]**

**Keywords:** Phosphanes / Halides / X-ray diffraction / Substituent effects / Structure correlation

A series of 2-chloro-1,3,2-diazaphospholenes with different substitution patterns has been prepared from 1,4-diazabutadienes according to a general synthetic methodology. Subsequent chloride abstraction with Lewis acids affords the corresponding 1,3,2-diazaphospholenium salts. All products have been characterised spectroscopically and by single-crystal X-ray diffraction studies. A detailed analysis of trends in the structural parameters supports the interpretation that the unusual P–Cl bond lengthening in the diazaphospholenes is attributable to n(N)/σ*(P-Cl) hyperconjugation.

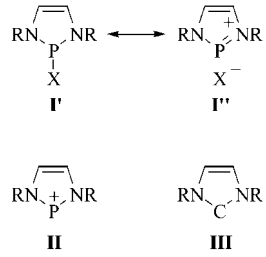
## Introduction

*P*-Functionalised 1,3,2-diazaphospholenes (**I**) are representatives of a class of N-heterocyclic phosphanes that have recently gained interest because of their unique reactivity. In particular, P–H-substituted compounds (**I**; X = H) are selective hydride-transfer reagents that allow reductive hydrogenation of element halides as well as aldehydes and aryl ketones,[1] and phosphanyl derivatives (**I**; X = $PR'_2$) react with alkenes and alkynes by diphosphination to give novel unsymmetrical 1,2-bisphosphanes.[2] This unique reactivity has, in both cases, been explained by a weakening and concomitant ionic polarisation of the P–X bonds which can be expressed in terms of bond/no-bond resonance between the canonical structures **I′** and **I′′** (Scheme 1).[3] The high weight of the ionic canonical structure **I′′** is intimately connected with the exceptional stability of the corresponding phosphenium ions **II**,[4] which are isoelectronic with imidazoyl carbenes **III**[5] and are stabilised by similar electronic factors.

Another type of functional 1,3,2-diazaphospholenes, namely *P*-chloro-substituted compounds (**I**; X = Cl),[4,6,7] are of interest not only from a synthetic point of view as precursors for the cations **II** and the aforementioned P–H and P-phosphanyl derivatives but they also provide evidence for the weakening and enhanced ionic polarisation of the exocyclic P–Cl bonds.[3] Despite the high intrinsic polarity of these bonds, these phenomena still exert a visible effect on the chemical reactivity and have, for example, been considered as crucial for the use of *P*-chlorodiazaphospholenes as organocatalysts in the P–C cross-coupling between alkyl chlorides and trimethylsilyl diphenylphosphane.[8] The P–Cl bond lengthening is also significant from a structural point of view and it has been argued that its occurrence is attributable to a high degree of aromatic stabilisation in the heterocyclic ring, which induces a concomitant spontaneous dissociation of the P–Cl bond.[4,7] Although this interpretation was subsequently discredited,[3] a precise analysis of the bonding situation in *P*-chlorodiazaphospholenes is still needed.



Scheme 1.

During our investigations of the chemistry of N-heterocyclic phosphanes we have developed a general synthetic method for the preparation of 2-chloro-1,3,2-diazaphospholenes and 1,3,2-diazaphospholenium ions with a wide range of substituent patterns.[1] In this work we will give a full account of this synthetic work, and we will report on the interpretation of trends in structural parameters which were obtained from X-ray diffraction studies on a comprehensive series of these compounds.

## Results and Discussion

### Syntheses and Spectroscopic Studies

Known synthetic routes to 2-chloro-1,3,2-diazaphospholenes (**I**; X = Cl) include base-induced condensations of

$PCl_3$ with 1,4-diazabutadienes,[6] salt-elimination reactions of $PCl_3$ with 1,4-diazabutadienide dianions[7] or metathesis reactions of $PCl_3$ with 1,3,2-diazasiloles.[4] The products can be converted into diazaphospholenium salts by subsequent treatment with Lewis acids such as $AlCl_3$, $GaCl_3$, $SbCl_5$ or $Me_3SiOTf$.[3,4,9] It was shown recently that triiodide or pentachlorostannate(IV) salts of cations **II** are also accessible in one step by a redox reaction between a diazabutadiene and $PI_3$ or a mixture of $PCl_3$ and $SnCl_2$, respectively.[10] The limitations of the existing methods are that their application may be restricted to the synthesis of heterocycles with specific substitution patterns, the yields of products may be low owing to the occurrence of side reactions or difficulties in purifying the products or intermediates, or that the possible redox activity of counter anions such as $I_3^-$ or $SnCl_5^-$ may limit the use of the product in further transformations. In order to circumvent these restrictions we have developed a simple protocol for the preparation of 2-chloro-1,3,2-diazaphospholenes starting from *N*-arylated 1,4-diazabutadienes.[1] We demonstrate here that the same procedure is also applicable for the synthesis of *N*-alkylated and *C*-alkylated heterocyclic rings.

The novel *P*-chlorodiazaphospholenes **3b**,**h** and **3d**–**f** are accessible in a similar way as the previously reported derivatives **3a**,**c**,**g**[1] in a cascade reaction involving reduction of the readily available 1,4-diazabutadienes **1a**–**h** with excess lithium, quenching the resulting dianions with triethylamine hydrochloride at –78 °C, and condensation of the products formed with $PCl_3$ at the same temperature. All subsequent reaction steps can be carried out in a one-pot procedure without isolation of any intermediates. The triethylamine introduced to protonate the diazadienide dianions is reused to scavenge the hydrogen chloride liberated in the last step. As reported earlier,[9,11] protonation of the diazadienide dianions yields either α-aminoaldimines **2a**–**c**,**g**,**h** or 2,3-diamino-2-butenes **2d**–**f** depending on whether the central carbon atoms in the dianions bear hydrogen or alkyl substituents, respectively; both types of intermediates can be isolated as stable compounds if desired. The 2-chloro-1,3,2-diazaphospholenes **3b**,**d**–**f**,**h** were isolated as off-white to orange, moderately moisture-sensitive solids in good to excellent yields of 75–92% after work up. Reports of 4,5-dialkylated 1,3,2-diazaphospholenes are rare, although some derivatives have been obtained by condensation of a diaminoethene with substituted phosphorus dihalides according to a similar reaction to that reported here.[12]

Compounds **3b**,**c**,**g** were converted into the 1,3,2-diazaphospholenium salts **4b**,**c**,**g** by treatment with $Me_3SiOTf$ by analogy to a previously reported method,[3] In a similar manner, **5f** was obtained by treatment of **3f** with $GaCl_3$.[13] All phosphenium salts were isolated after work-up as air- and moisture-sensitive powders in more than 90% yield.

All phosphorus heterocycles prepared were characterised by analytical data and spectroscopic techniques. The NMR spectroscopic data of both 2-chloro-1,3,2-diazaphospholenes and phosphenium salts are unremarkable and are similar to known literature data;[1,3,4,7,10] a discussion of trends in chemical shifts (including $^{35}Cl$ and $^{15}N$ NMR spectroscopic data) has been given elsewhere[3] and is not repeated here. Methylation in the 4,5-positions of the diazaphospholene ring induces a deshielding of the $^{31}P$ NMR signals of **3d**,**e** by some 15 ppm with respect to **3a**,**c**. As expected, both the $^{31}P$ and the $^{13}C$ NMR signals of the ring carbon atoms in the 1,3,2-diazaphospholenium salts **4b**,**c** and **5f** are deshielded with respect to the appropriate signals in the neutral precursors **3b**,**c**,**f**. The salt **4b** exhibits the largest $^{31}P$ NMR shift for a 1,3,2-diazaphospholenium cation observed so far ($\delta_{^{31}P}$ = 209.4 ppm).

## Crystal Structure Studies

Suitable crystals for single-crystal X-ray diffraction studies of the 1,3,2-diazaphospholenes **3b**–**h** and the 1,3,2-diazaphospholenium salts **4b**,**c**,**g** and **5f** were obtained by crystallisation of appropriate solutions at low temperature (see Scheme 2 and Exp. Sect. for further details). The salt **5f** crystallised as a solvate with one molecule of $CH_2Cl_2$ per formula unit.

The molecular structures of the *P*-chlorodiazaphospholene **3f** and the tetrachlorogallate salt **5f** are shown in Figures 1 and 2, respectively. The *tert*-butyl moieties in both

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

*N*-aryl substituents of **3f** are located on the same side of the diazaphospholene ring *trans* to the chlorine substituent, thereby suggesting that the direct steric interaction between the *tert*-butyl groups is lower than the repulsion between substituents at adjacent ring atoms. Interestingly, the arrangement of the *tert*-butyl groups in the cation of salt **5f** remains unchanged. As the distance between the phosphorus and the closest chlorine atom in the anion (3.75 Å) is close to the sum of the van der Waals radii (thus ruling out any substantial intermolecular interactions) and both nitrogen atoms still display planar coordination geometries [sum of bond angles of 359.4(6)° for N2 and 359.7(6)° for N5] it can be concluded that the steric strain between the bulky *N*-aryl substituents is negligible. The preference for the observed pseudo-$C_s$-symmetric conformation over a $C_2$-like conformation with *tert*-butyl moieties on opposite sides of the diazaphospholene ring is presumably due to the fact that it facilitates a closer stacking of molecules in the crystal.

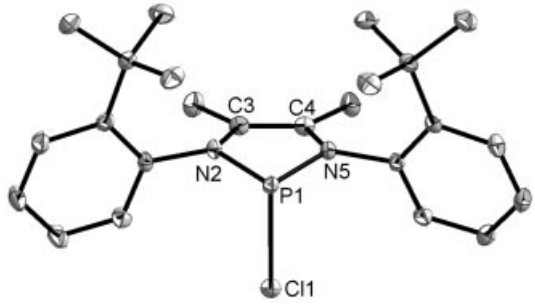

Figure 1. Molecular structure of **3f**. Thermal ellipsoids are drawn at the 50% probability level and H atoms have been omitted for clarity.

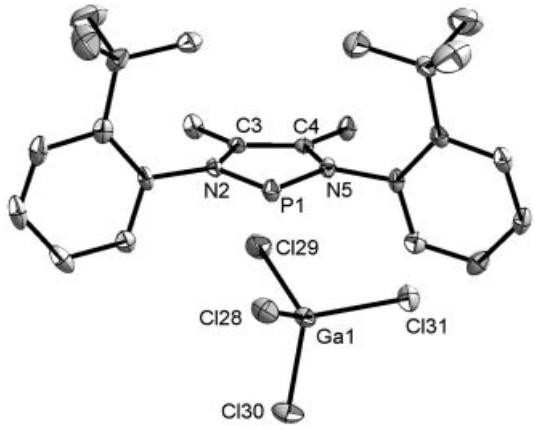

Figure 2. Molecular structure of **5f**. Thermal ellipsoids are drawn at the 50% probability level and H atoms have been omitted for clarity.

Selected bond lengths and angles of all neutral *P*-chlorodiazaphospholenes and the cations of phosphenium salts are summarised in Table 1 together with the previously reported structural data for **3a**,**g** and **4a**[3] for comparison. The five-membered rings of all *P*-chlorodiazaphospholenes feature a similar flat envelope conformation to that already found for **3a**,**g**,[3] while the rings of the cations display no significant deviations from planarity. All molecules exhibit only insignificant deviations between the two crystallographically independent P-N2/N5 and C3/4-N2/5 distances.

The endocyclic P–N and C–C bond lengths in all studied 2-chloro-1,3,2-diazaphospholenes are similar and match the values for **3a** and **3g**. The C–N bonds in **3b** and **3h** are likewise similar to those of **3a** and **3g** while the C-methylated derivatives **3d**–**f** display a small (1–2 pm) yet crystallographically significant bond lengthening. The most important variation is found for the exocyclic P–Cl bond lengths, which range from 2.243(1) Å in **3c** to 2.692(4) Å in **3g**. All distances are thus considerably longer than standard P–Cl bonds in diaminochlorophosphanes (2.13 ± 0.06 Å[14]), although the bond length in **3c**, which is the shortest P–Cl bond in a 2-chloro-1,3,2-diazaphospholene reported to date, comes quite close to the normal range. A comparison between compounds with N-Mes (**3a**,**d**) and N-DIPP (**3c**,**e**) substituents reveals that the P–Cl bonds in the latter are 3–8 pm shorter, although the reason for this effect is not obvious. The longest P–Cl bonds are found for the *N*-alkyl-substituted compounds **3g**,**h**.

Table 1. Selected bond lengths [Å] and angles [°] for the 2-chloro-1,3,2-diazaphospholenes **3a**–**h** and the cations of the 1,3,2-diazaphospholenium salts **4a**–**c**, **4g**, and **5f**.

The P–N bond lengths in the cations of the phosphenium salts **4a**–**c**,**g** and **5f** match the values in **3a**–**h** closely, whereas the adjacent C–N bonds are approximately 3 pm longer than in the neutral compounds. The C–C bonds in the cations are also longer than in **3a**–**h**, although the difference in this case is less pronounced (approx. 1 pm) and on the verge of being significant when compared with the magnitude of the estimated standard deviations (see data in Table 1). The cation of **5f** is an exception and displays a significant lengthening of the C–C bond length, which is possibly influenced by the presence of methyl substituents at both ring carbon atoms. Apart from this effect, the variation of bond lengths in the phosphenium cations shows no clear connection with the changes in the substituent pattern.

The existence of a series of crystal structure analyses of similar compounds stimulated us to attempt a discussion of common trends in the sense of a structure correlation. This principle, which was coined by Bürgi and Dunitz,[15] states that structural changes that occur during a chemical reaction can be manifested in the ground-state structure as deviations of bond lengths and angles from "normal values" along the reaction coordinate. In the case of *P*-chlorodiazaphospholenes the extraordinary P–Cl bond lengthening, which was first reported for **3g**, can be interpreted as a consequence of spontaneous bond heterolysis that is energetically driven by the aromatisation of the cyclic phosphenium cation fragment.[4,7] Given the validity of this hypothesis, the application of the structure-correlation principle implies that a comparison of the crystal structure data of all compounds included in this study might reveal a systematic correlation between the P–Cl bond lengthening, the lengthening of the C–C double bond, and a concomitant shortening of the C–N and P–N single bonds, respectively.

Inspection of a plot of the P–Cl versus average P–N distances for the diazaphospholenes **3a**–**h** (Figure 3) reveals that the P–Cl bond lengthening indeed appears to coincide with a general shortening of the P–N bonds. A linear regression analysis reveals that this correlation is not particularly strong, and the magnitude of the correlation coefficient ($r$ = 0.78) implies the presence of some scattering which suggests that additional factors also have a major impact on both bond lengths. If one considers that the individual compounds are not isostructural but crystallise in different space groups, and thus exhibit different types of crystal packing, the observed scattering is presumably due, at least in part, to variations in intermolecular interactions (the validity of this assumption is substantiated by the observed difference in P–Cl bond lengths between pure **3g** and its toluene solvate[3]). Even though an analysis of the crystallographic data of all diaminochlorophosphanes of the type $(R_2N)_2PCl$ (except **3a**,**g**) listed in the CSD data base reveals a similar relation between the changes in P–N and P–Cl bond lengths, the two regression lines deviate substantially from each other (Figure 3). In principle, this finding underlines, in a quantitative way, the previously mentioned hypothesis of the P–Cl bond in the N-heterocyclic derivatives **3a**–**h** being much "softer" (i.e. more easily polarisable) than in diaminochlorophosphanes in general.

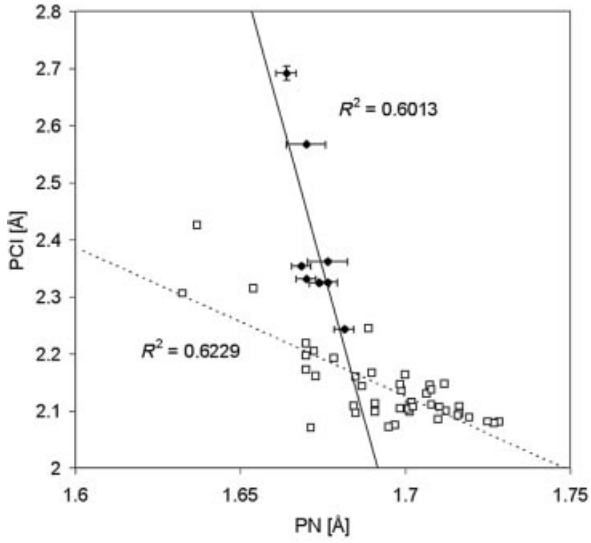

Figure 3. Plot of P–Cl distances [Å] vs. average P–N distances [Å] for **3a**–**h** (diamonds) and for all $(R_2N)_2PCl$ compounds (except **3a**,**g**) listed in the CSD data base (open squares). The solid and dashed lines represent the result of linear regression analyses. Error bars at the data points for **3a**–**h** denote a range of ±3σ, where σ is the estimated standard deviation. $R^2$ is the square of the correlation coefficient in the regression analysis.

An analysis of the trends in endocyclic P–N, N–C and C–C bond lengths in the diazaphospholenes **3a**–**h** and the salts **4a**–**c**,**g** and **5f** shows that the observed changes are essentially uncorrelated. A regression analysis of the changes in P–N and C–N distances for all compounds (Figure 4) gave a statistical correlation coefficient ($r$ = 0.41) which suggests no significant connection between both parameters. Furthermore, a positive slope for the computed regression curve indicates parallel trends of the lengths of

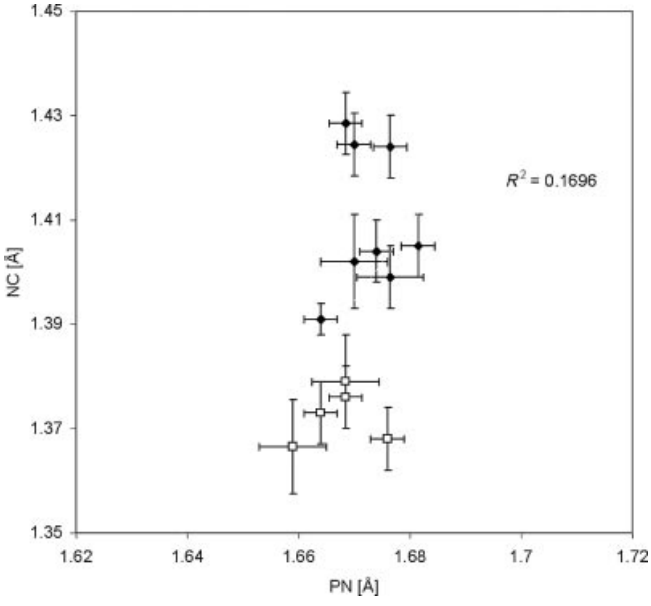

Figure 4. Plot of the average P–N distances [Å] vs. average C–N distances [Å] of **3a**–**h** (diamonds) and **4a**–**c**, **5f** (open squares). Error bars at each data point denote a range of ±3σ, where σ is the estimated standard deviation.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

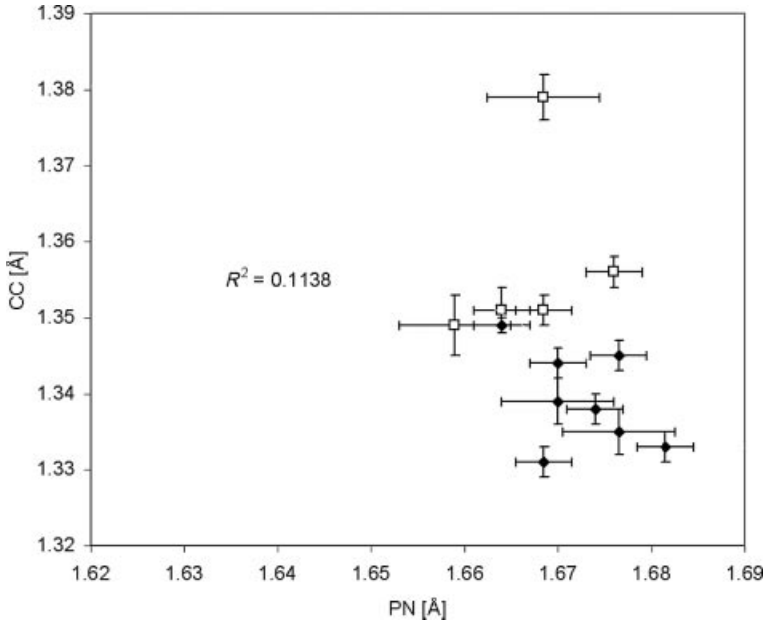

Figure 5. Plot of the average P–N distances [Å] vs. C–C distances [Å] of **3a**–**h** (diamonds) and **4a**–**c**, **5f** (open squares). Error bars at each data point denote a range of ±3σ, where σ is the estimated standard deviation.

both types of bonds, which is hardly compatible with a connection between P–Cl bond dissociation and increasing aromaticity in the ring.[4] A regression analysis of the connection between changes in P–N and C–C distances (Figure 5) indicated a statistically still weaker correlation ($r$ = 0.34), the physical interpretation of which is further complicated by the fact that the observed differences in C–C bond lengths are rather small when compared with the estimated standard deviations of the experimental data. Further regression analyses which included only data for neutral diazaphospholenes, or involved correlations between P–Cl and C–N/C–C bond lengths, gave similar or even lower values for the correlation coefficients.

On the whole, the regression analyses performed suggest a weak statistical correlation between P–Cl and P–N distances in the diazaphospholenes **3a**–**h**, whereas the variations in the endocyclic N–C and C–C bonds appear to be fairly uncorrelated. In contrast, inspection of Figures 3, 4 and 5 suggests that the data for the neutral compounds **3a**–**h** and the salts **4a**–**c**,**g** and **5f** lie in different regions of the scatter plots that are more or less well separated owing to systematic deviations in C–N and (less pronounced) C–C bond lengths between both types of compounds. All these features are very well compatible with the explanation of the bond lengthening in *P*-chlorodiazaphospholenes being due to n(N)/σ*(P-Cl) hyperconjugation, which has also been derived from earlier computational and experimental studies,[3] but do not support the interpretation as beginning P–Cl dissociation driven by increasing aromatic character of the diazaphospholene ring.

## Conclusions

We have shown that the previously reported one-pot route to 1,3,2-diazaphospholenes by reduction/protonation of 1,4-diazadienes and subsequent condensation with phosphorus trichloride offers a generally applicable and economic access to 2-chloro-1,3,2-diazaphospholenes with a wide range of substituents at both the ring nitrogen and carbon atoms. All products were obtained in high yields and purity and are suitable starting materials for further transformations.[1,3,16] In particular, subsequent Lewis acid-induced chloride abstraction permits the synthesis of N-heterocyclic phosphenium cations in overall yields that compare well with those of a recently reported one-step synthesis involving the redox reaction between a diazabutadiene and $PI_3$.[10] Systematic single-crystal X-ray diffraction studies have revealed that the P–Cl bond lengths in *P*-chlorodiazaphospholenes vary between 2.24 and 2.70 Å, with the *N*-alkyl derivatives showing systematically longer bonds than the *N*-aryl derivatives. An analysis of trends in the structural parameters underlines that the P–Cl bonds in diazaphospholenes are more easily polarised than in compounds of the type $(R_2N)_2PCl$ in general, but gives no evidence that the bond lengthening can be interpreted in terms of the onset of spontaneous bond heterolysis driven by an increase in the aromatic character of the diazaphospholene ring. This analysis supports the results of earlier experimental and computational studies which have explained this effect as being mainly the result of n(N)/σ*(P-Cl) hyperconjugation.

## Experimental Section

All manipulations were carried out under argon in flame-dried glassware. Solvents were dried prior to use according to common procedures. Compounds **1a**–**h** were synthesised according to literature procedures.[17] The synthesis of **3a**–**h** was carried out according

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

to the procedure reported in ref.[1] All other chemicals were purchased from commercial suppliers. NMR Spectra: Bruker Avance 400 ($^1$H: 400.13 MHz; $^{31}$P: 161.9 MHz; $^{13}$C: 100.4 MHz) at 30 °C; chemical shifts referred to ext. TMS ($^1$H, $^{13}$C) or 85% $H_3PO_4$ ($\Xi$ = 40.480747 MHz, $^{31}$P); positive signs of chemical shifts denote shifts to lower frequencies; coupling constants are given as absolute values; prefixes *i*-, *o*-, *m*-, *p*- denote atoms of aryl substituents. MS: Varian MAT 711, EI, 70 eV. Elemental analysis: Perkin–Elmer 2400CHSN/O analyser. Melting points were determined in sealed capillaries.

**1-[(2,6-Dimethylphenyl)imino]-2-[(2,6-dimethylphenyl)amino]ethane (2b):** Compound **1b** (18.5 g, 70 mmol) was dissolved in thf (200 mL), and lithium turnings (1.1 g, 150 mmol) were added. After stirring for 24 h the unreacted lithium was filtered off and the solution cooled to –78 °C. Triethylamine hydrochloride (15.1 g, 150 mmol) was added and the reaction mixture slowly warmed to room temperature. After the solution had become colourless all volatiles were removed in vacuo. The residue was dissolved in *n*-hexane (150 mL) and the precipitate filtered off. The solution was concentrated and the product crystallised at –20 °C. The yellow needles obtained were filtered off and dried in vacuo. Yield 12.0 g (65%), m.p. 136 °C. $^1$H NMR ($CDCl_3$): $\delta$ = 7.83 (t, $^3J_{H,H}$ = 2.1 Hz, 1 H, C*H*=N), 7.25–6.80 (m, 6 H, C*H*), 5.42 (s, 1 H, N*H*), 4.15 (d, $^3J_{H,H}$ = 2.1 Hz, 2 H, C$H_2$-N), 2.42 (s, 6 H, *o*-C$H_3$), 2.14 (s, 6 H, *o*-C$H_3$) ppm. $^{13}$C{$^1$H} NMR ($CDCl_3$): $\delta$ = 163.7 (s, *C*H=N), 150.2 (s, *i*-*C*), 146.4 (s, *i*-*C*), 128.9 (s, *m*-*C*), 128.2 (s, *o*-*C*), 128.0 (s, *m*-*C*), 126.8 (s, *p*-*C*), 123.8 (s, *o*-*C*), 121.3 (s, *p*-*C*), 52.9 (s, *C*$H_2$-N), 19.0 (s, *o*-*C*$H_3$), 18.2 (s, *o*-*C*$H_3$) ppm.

**1,4-Bis(2-*tert*-butylphenyl)-2,3-dimethyl-1,4-diazabuta-2-ene (2f):** Compound **1f** (10.4 g, 30 mmol) was dissolved in thf (300 mL), and lithium (0.5 g, 60 mmol) was added. The mixture was stirred for 24 h. The remaining lithium was filtered off, the solution cooled to –78 °C, and triethylamine hydrochloride (6.1 g, 60 mmol) was added. The reaction mixture was slowly warmed to room temperature, and all volatiles were removed in vacuo. The residue was dissolved in *n*-hexane (100 mL) and the insoluble portion filtered off. The filtrate was concentrated to 30 mL and stored at –20 °C. The yellow powder formed was filtered off and dried in vacuo. Yield 9.4 g (89%). $^1$H NMR ($CDCl_3$): $\delta$ = 7.27 (dt, $^3J_{H,H}$ = 7.8, $^4J_{H,H}$ = 1.7 Hz, 2 H, C*H*), 7.12 (dd, $^3J_{H,H}$ = 7.8, $^4J_{H,H}$ = 1.7 Hz, 2 H, C*H*), 6.83 (dt, $^3J_{H,H}$ = 7.8, $^4J_{H,H}$ = 1.7 Hz, 2 H, C*H*), 6.82 (dd, $^3J_{H,H}$ = 7.8, $^4J_{H,H}$ = 1.7 Hz, 2 H, C*H*), 5.29 (s, 2 H, N*H*), 1.91 (s, 6 H, C$H_3$), 1.37 (s, 18 H, C$H_3$) ppm. $^{13}$C{$^1$H} NMR ($CDCl_3$): $\delta$ = 143.2 (s, *i*-*C*), 138.0 (s, *o*-*C*), 126.7 (s, *o*-*C*H), 126.3 (s, *m*-*C*H), 122.2 (s, N-*C*CH$_3$), 119.9 (s, *m*-*C*H), 119.2 (s, *p*-*C*H), 34.4 (s, *C*), 30.0 [s, C(*C*H$_3$)$_3$], 15.7 (s, *C*H$_3$) ppm.

(30 mL) was cooled to –78 °C and trimethylsilyl trifluoromethanesulfonate (1.08 g, 5 mmol) was added. After stirring for 2 h at room temperature all volatiles were evaporated in vacuo and the residue dissolved twice in 15 mL of diethyl ether, followed by removal of the solvent. The product was dissolved in a mixture of *n*-hexane, toluene, and dichloromethane (5 mL/5 mL/1 mL) and crystallised at –28 °C. The colourless needles were filtered off and dried in vacuo. Yield 0.78 g (73%); m.p. 259 °C. $^1$H NMR ($CDCl_3$): $\delta$ = 8.62 (d, $^3J_{P,H}$ = 0.9 Hz, 2 H, N-C*H*), 7.64 (t, $^3J_{H,H}$ = 7.8 Hz, 2 H, *p*-C*H*), 7.43 (d, $^3J_{H,H}$ = 7.8 Hz, 4 H, *m*-C*H*), 2.50 (sept, $^3J_{H,H}$ = 6.8 Hz, 4 H, C*H*), 1.36 (d, $^3J_{H,H}$ = 6.8 Hz, 12 H, C$H_3$), 1.27 (d, $^3J_{H,H}$ = 6.8 Hz, 12 H, C$H_3$) ppm. $^{13}$C{$^1$H} NMR ($CDCl_3$): $\delta$ = 144.2 (d, $^2J_{P,C}$ = 3.6 Hz, *i*-*C*), 140.2 (s, *o*-*C*), 137.1 (s, *o*-*C*), 131.5 (d, $^2J_{P,C}$ = 1.2 Hz, N-*C*H), 128.3 (s, *m*-*C*), 127.5 (s, *m*-*C*), 124.6 (s, *p*-*C*), 124.2 (s, *p*-*C*), 30.9 (s, *C*H), 30.1 (s, *C*H), 24.5 (s, *C*$H_3$), 23.0 (s, *C*$H_3$), 21.9 (s, *C*$H_3$), 20.7 (s, *C*$H_3$) ppm. $^{31}$P{$^1$H} NMR ($CDCl_3$): $\delta$ = 205.0 (s) ppm. Storage of the solution at –35 °C afforded colourless crystals, which were filtered off and dried in vacuo. Yield 280 mg (95%). $^1$H NMR ($CD_3CN$): $\delta$ = 7.84 (dd, $^3J_{H,H}$ = 8.2, $^4J_{H,H}$ = 1.6 Hz, 2 H, o -C*H*), 7.65 (dddd, $^3J_{H,H}$ = 8.2, $^3J_{H,H}$ = 7.3, $^4J_{H,H}$ = 1.6, $^6J_{P,H}$ = 0.9 Hz, 2 H, *m*-C*H*), 7.48 (dddd, $^3J_{H,H}$ = 7.9, $^3J_{H,H}$ = 7.3, $^4J_{H,H}$ = 1.6, $^5J_{P,H}$ = 0.9 Hz, 2 H, *p*-C*H*), 7.28 (ddd, $^3J_{H,H}$ = 7.9, $^4J_{H,H}$ = 1.6, $^5J_{H,H}$ = 0.4 Hz, 2 H, m′-C*H*), 2.21 (d, $^4J_{P,H}$ = 1.8 Hz, 6 H, C$H_3$), 1.34 (s, 18 H, C$H_3$) ppm. $^{13}$C{$^1$H} NMR ($CD_3CN$): $\delta$ = 146.9 (d, $^2J_{P,C}$ = 3.4 Hz, *i*-*C*), 144.6 (s, *o*-*C*), 132.5 (d, $^4J_{P,C}$ = 1.3 Hz, *m*-*C*H), 132.1 (s, *m*-*C*H), 132.0 (d, $^2J_{P,C}$ = 5.5 Hz, N-*C*), 130.9 (s, *m*-*C*H), 128.8 (s, *p*-*C*H), 37.3 (d, $^4J_{P,C}$ = 0.8 Hz, 1 *C*), 32.7 (d, $^5J_{P,C}$ = 2.6 Hz, *C*$H_3$), 13.8 (d, $^3J_{P,C}$ = 3.9 Hz, *C*$H_3$) ppm. $^{31}$P{$^1$H} NMR ($CD_3CN$): $\delta$ = 205.8 (s) ppm. MS (EI): *m*/*z* (%) 379.2 (100.0) $[M - GaCl_4]^+$. $C_{24}H_{32}Cl_4GaN_2P$ (591.04): calcd. C 48.77, H 5.46, N 4.74; found C 48.49, H 5.39, N 4.74.

**Crystal Structure Studies:** Single-crystal X-ray diffraction studies were carried out at low temperatures on a Nonius Kappa-CCD diffractometer or a Siemens P3 or P4 diffractometer using Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 Å). Direct methods (SHELXS-97[18]) were used for structure solution and refinement (SHELXL-97,[19] full-matrix least-squares on $F^2$). An empirical absorption correction was applied for **5f**, and H atoms were refined using a riding model. The absolute structure of **3c** was determined by refinement of Flack's *x*-parameter [*x* = 0.04(4)].[20] Important data regarding the data collection and structure solution and refinement are listed in Tables 2 and 3.

# Speciation of Uranyl Nitrato Complexes in Acetonitrile and in the Ionic Liquid 1-Butyl-3-methylimidazolium Bis(trifluoromethylsulfonyl)imide

**Kelly Servaes,[a] Christoph Hennig,*[b] Isabelle Billard,[c] Clotilde Gaillard,[c] Koen Binnemans,[a] Christiane Görller-Walrand,[a] and Rik Van Deun*[a]**

**Keywords:** EXAFS spectroscopy / Ionic liquids / Uranium / UV/Vis spectroscopy / X-ray absorption spectroscopy

Complex formation between the uranyl ion and nitrate ions in acetonitrile and the ionic liquid 1-butyl-3-methylimidazolium bis(trifluoromethylsulfonyl)imide ($[C_4mim][Tf_2N]$) has been studied by absorption, magnetic circular dichroism (MCD) and uranium $L_{III}$ EXAFS spectroscopy. The experimental results point to the existence of a trinitrate species $[UO_2(NO_3)_3]^-$ with $D_{3h}$ symmetry in both solvents. The atomic distances in the uranium(VI) coordination sphere for the trinitrato complex in acetonitrile are $U–O_{ax}$ = 1.77 ± 0.01 Å and $U–O_{eq}$ = 2.48 ± 0.01 Å. EXAFS data show that the uranyl ion in the ionic liquid is surrounded by six oxygen atoms in the equatorial plane at a distance of 2.49 ± 0.01 Å. The U–N distance of 2.92 ± 0.01 Å indicates a bidentate coordination of the nitrate group in both solvents. A structural comparison is made between the uranyl trinitrato complex anion $[UO_2(NO_3)_3]^-$ and the uranyl tricarbonato complex anion $[UO_2(CO_3)_3]^{4-}$. No evidence is found for the presence of uranyl nitrato complexes in aqueous solution. The optical absorption, MCD and EXAFS spectra resemble those of the hydrated free uranyl ion. There are two axial oxygen atoms at 1.77 ± 0.01 Å and five equatorial oxygen atoms at 2.41 ± 0.01 Å. These values agree well with structural parameters obtained for the uranyl aqua ion.

## Introduction

The molecular structure of the uranyl trinitrate complex anion $[UO_2(NO_3)_3]^-$ is well known from X-ray diffraction studies.[1–3] Dieke and Duncan first recorded the absorption spectrum of a $Cs[UO_2(NO_3)_3]$ crystal with a spectrograph and identified the so-called "fluorescent series" and "magnetic series" in the spectrum.[4,5] The magnetic circular dichroism (MCD) spectra of $[UO_2(NO_3)_3]^-$ were first described by Brint and McCaffery[6] and subsequently reinvestigated by Görller-Walrand and Colen,[7] and the electronic transitions and vibrational progressions were first identified by Denning and co-workers by measuring the σ- and π-spectra of $Cs[UO_2(NO_3)_3]$ single crystals.[8] Kaplan and co-workers observed the typical UV/Vis absorption spectrum of the $[UO_2(NO_3)_3]^-$ complex anion in ketone solvents like acetone by adding tetrabutylammonium nitrate to a solution of $UO_2(NO_3)_2$ in these solvents.[9] They noticed a good agreement between the solution spectra and those of $Cs[UO_2(NO_3)_3]$ single crystals. In contrast, these authors could not find a proof for nitrate complex formation in aqueous solution.

Extended X-ray absorption fine structure (EXAFS) spectroscopy measurements on uranyl nitrato compounds are rather scarce, although Thompson and co-workers have investigated the uranyl trinitrato unit in solid $UO_2(NO_3)_2 \cdot 6H_2O$,[10] and the uranyl nitrate dimer in solid $Him_2[\{UO_2(\mu\text{-}OH)(NO_3)_2\}_2]$ (Him = imidazolium) has been studied by Barnes et al.[11] Solvent-extraction processes of uranyl nitrate solutions have been extensively studied because of their significance for nuclear waste treatment.[12–21] These research activities include EXAFS measurements of uranyl nitrate in trimethyl phosphate, tri-*n*-butyl phosphate, triisobutyl phosphate and triphenyl phosphate, which indicate a coordination of two bidentate nitrate groups and two monodentate organophosphate ligands.[20–22] All the experimental EXAFS data obtained to date suffer from competing scattering contributions that cover the important multiple scattering features within the nitrate group. So far, trinitratouranyl species in solution have not been studied in depth by EXAFS spectroscopy, although recently there has been a strong research interest in uranyl complexes, including uranyl nitrate complexes, in ionic liquids.[23–31]

The speciation of uranyl complexes in solution is not always straightforward. Unlike solid-state structures, which can be determined by X-ray diffraction of single crystals, the structure of solution species can be determined only by symmetry effects, for example by optical absorption spectra, or by limited structural parameters obtained, for example, from EXAFS spectra. Various conclusions have been drawn in the past from spectroscopic results, particularly absorption, luminescence and magnetic circular dichroism spectroscopy, and in a previous paper we have demonstrated the existence of a $[UO_2Cl_4]^{2-}$ complex anion with $D_{4h}$ symmetry in acetonitrile by a combination of optical absorption spectroscopy and uranium $L_{III}$ EXAFS spectroscopy.[32] An analogous investigation by the same complementary spectroscopic techniques presented in this paper points to the existence of the uranyl trinitrato complex anion in acetonitrile and the ionic liquid 1-butyl-3-methylimidazolium bis(trifluoromethylsulfonyl)imide ([$C_4$mim][$Tf_2$N]). Furthermore, both spectroscopic techniques provide evidence for the absence of a significant degree of complex formation between the uranyl ion and nitrate ions in aqueous solution.

## Results and Discussion

The UV/Vis absorption spectrum and the MCD spectrum of uranyl nitrate in the presence of tetrabutylammonium nitrate in acetonitrile are shown in Figure 1. No further changes were observed upon increasing the nitrate concentration above the ratio $[UO_2^{2+}]/[NO_3^-]$ = 1:3, which points to a maximal coordination of the uranyl ion. The most striking feature is the increase in intensity of four bands in the long-wavelength part of the absorption spectrum (21000–24000 $cm^{-1}$) with respect to the solvated uranyl ion in acetonitrile. These lines correspond to the "magnetic series" reported by Dieke and Duncan for the single-crystal spectra of $Cs[UO_2(NO_3)_3]$, in which the coordination polyhedron of the uranyl ion has a $D_{3h}$ symmetry.[4] The transitions belonging to the magnetic series give rise to very intense, negative A-terms in the MCD spectrum (Figure 1).[7] These MCD signals originate from the electronic transition between the totally symmetric ground state $A_1'$ ($\Sigma_g^+$ in $D_{\infty h}$) to the excited state E′ ($\Delta_g$ in $D_{\infty h}$).

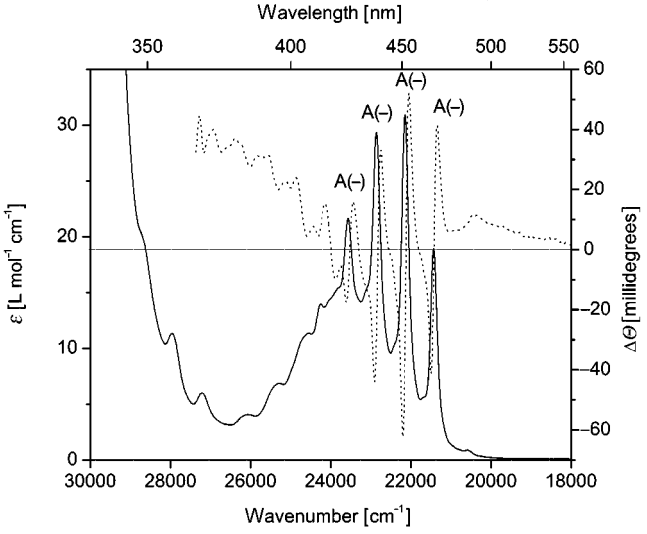

Figure 1. Optical absorption spectrum (solid line) and MCD spectrum (dotted line) of $[UO_2(NO_3)_3]^-$ in acetonitrile at room temperature. $[UO_2^{2+}]$ = 50 and $[NO_3^-]$ = 200 mM ($[UO_2^{2+}]/[NO_3^-]$ = 1:4).

The UV/Vis absorption spectrum and the MCD spectrum of uranyl nitrate in the presence of tetrabutylammonium nitrate in acetone are given as Supporting Information. These spectra are very similar to those recorded in acetonitrile. An overview of all the electronic transitions in the optical absorption spectrum of $[UO_2(NO_3)_3]^-$ in acetonitrile is given in Table 1. A detailed list of the transitions assigned for $[UO_2(NO_3)_3]^-$ in acetonitrile in $D_{3h}$ symmetry is available as Supporting Information. The presence of very intense, sharp peaks in the first part of the optical absorption spectrum is also characteristic of other complexes with $D_{3h}$ trigonal symmetry, such as $[UO_2(CO_3)_3]^{4-}$ and $[UO_2(CH_3COO)_3]^-$.[7,12,33,34]

The optical absorption spectrum and MCD spectrum of $UO_2(NO_3)_2{\cdot}6H_2O$ and $Bu_4NNO_3$ in the ionic liquid [$C_4$mim][$Tf_2$N] are given in Figure 2. The molar absorptivity in this ionic liquid solvent is of the same order of magnitude as that in acetonitrile. The absorption bands can all be assigned to transitions of the uranyl ion since [$C_4$mim][$Tf_2$N] does not absorb in this wavelength region.[35] The same typical spectroscopic features of the uranyl trinitrato complex in the range 20000–24000 $cm^{-1}$ (sharp, intense peaks in the optical absorption spectrum

Table 1. Observed electronic transitions for $[UO_2(NO_3)_3]^-$ in acetonitrile and [$C_4$mim][$Tf_2$N], assigned to $D_{\infty h}$ and $D_{3h}$ symmetry, compared with those of $Cs[UO_2(NO_3)_3]$ single crystals.[8] Energies are given in wavenumber units [$cm^{-1}$].

and very intense, negative A-terms in the MCD spectrum) as observed in acetonitrile are also observed in $[C_4mim][Tf_2N]$. Furthermore, the absorption maxima in acetonitrile and $[C_4mim][Tf_2N]$ agree well. The features in the long-wavelength part of the UV/Vis absorption spectrum and the MCD spectrum, as well as a comparison with the well-known $[UO_2(NO_3)_3]^-$ complex in ketone solvents, indicate the formation of a $[UO_2(NO_3)_3]^-$ species in $[C_4mim][Tf_2N]$. The energetic positions of the different electronic states of $[UO_2(NO_3)_3]^-$ in $[C_4mim][Tf_2N]$ are given in Table 1. A detailed assignment of the transitions of $[UO_2(NO_3)_3]^-$ in $[C_4mim][Tf_2N]$ is available as Supporting Information.

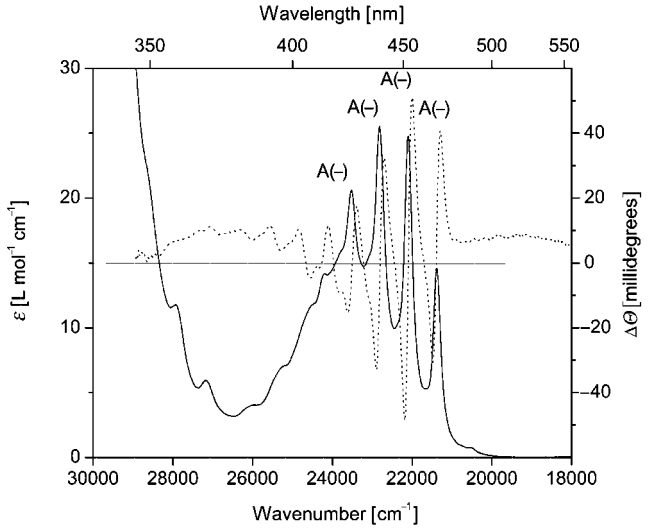

Figure 2. UV/Vis absorption spectrum (solid line) and MCD spectrum (dotted line) of $[UO_2(NO_3)_3]^-$ in $[C_4mim][Tf_2N]$ at room temperature. $[UO_2^{2+}]$ = 50 and $[NO_3^-]$ = 200 mM ($[UO_2^{2+}]/[NO_3^-]$ = 1:4).

An alternative way to obtain the trinitrato complex is to treat $UO_2$ with concentrated nitric acid in $[C_4mim][Tf_2N]$. However, nitrite ions are also formed in addition to the trinitrato complex, as evidenced by the bands in the region 25000–28500 $cm^{-1}$ in the UV/Vis absorption spectrum (given as Supporting Information). The UV/Vis spectra of nitrite ions and nitrous acid have been described by das Graças Gomes et al.[36] Nevertheless, the presence of the $[UO_2(NO_3)_3]^-$ moiety is also indicated in this case by the intense features in the long-wavelength part of the UV/Vis spectrum.

Spectroscopic measurements indicate that there is no significant complex formation between the uranyl ion and nitrate ions in aqueous solution. The optical absorption spectrum and the MCD spectrum of uranyl nitrate in water exhibit the same vibrational fine structure as that of the free uranyl ion (i.e. the hydrated uranyl ion) obtained by dissolving $UO_2(ClO_4)_2{\cdot}xH_2O$ in water (Figure 3). Moreover, no red- or blueshift of the absorption bands is observed. This similarity between the two spectra suggests that the hydrated uranyl ion is the dominant species in aqueous solution. The absorption spectra of uranyl nitrate $UO_2(NO_3)_2{\cdot}6H_2O$ in aqueous solution can be found in the Supporting Information. The typical sharp absorption bands of the uranyl trinitrato complex are absent in aqueous solution because nitrate ions form only weak complexes in this medium. The system can be characterized by three formation constants: $K_1$ = 0.5, $K_2$ = 1.0 and $K_3$ = 0.9 $L\,mol^{-1}$.[12,37] The formation constants $K_1$ and $K_2$ were determined in $NaClO_4$ medium at an ionic strength of 1.0 and $K_3$ in media of varying $HNO_3$ concentrations. The species distribution in an aqueous solution of $UO_2(NO_3)_2{\cdot}6H_2O$ (50 mM, pH = 2.4) is dominated by the uranyl aqua ion and the distribution coefficient of the nitrato species is low [94.8% $UO_2^{2+}$, 4.6% $UO_2NO_3^+$, 0.45% $UO_2(NO_3)_2$ and 0.04% $UO_2(NO_3)_3^-$]. The low-concentration nitrato species cannot be clearly distinguished by UV/Vis absorption spectroscopy. In a recent paper, Ruas and co-workers stated that the equilibrium constants for the 1:1 and 1:2 $UO_2^{2+}/NO_3^-$ complexes are low, which means that the uranyl trinitrato complex in water can be neglected in our case.[38]

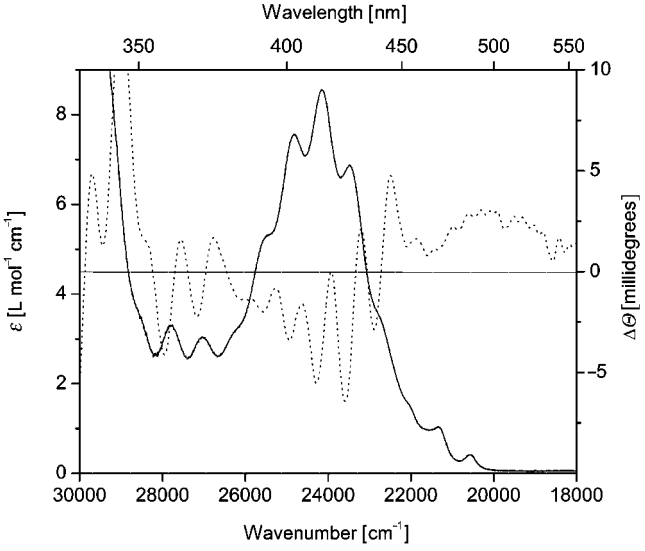

Figure 3. UV/Vis absorption spectrum (solid line) and MCD spectrum (dotted line) of $UO_2(NO_3)_2{\cdot}6H_2O$ in aqueous solution at room temperature. Uranyl concentration: 50 mM.

The UV/Vis absorption spectrum of the hydrated uranyl ion is well known,[5] although the coordination sphere of the hydrated free uranyl ion has always been a point of discussion. Models with four to six water molecules in the equatorial plane have been proposed,[39,40] although it is generally accepted that the uranyl ion is coordinated by five water molecules in the equatorial plane.[41–45]

EXAFS measurements of uranyl nitrate in the presence of tetrabutylammonium nitrate in acetonitrile as well as in $[C_4mim][Tf_2N]$ were performed to confirm the formation of a $[UO_2(NO_3)_3]^-$ species indicated by optical absorption spectroscopy. Furthermore, EXAFS can provide extra structural information, such as bond lengths, for the metal species in solution. Both the EXAFS spectra and corresponding Fourier transforms in acetonitrile and $[C_4mim][Tf_2N]$ exhibit the same structural features (Figure 4). Peaks in the Fourier transforms were not corrected

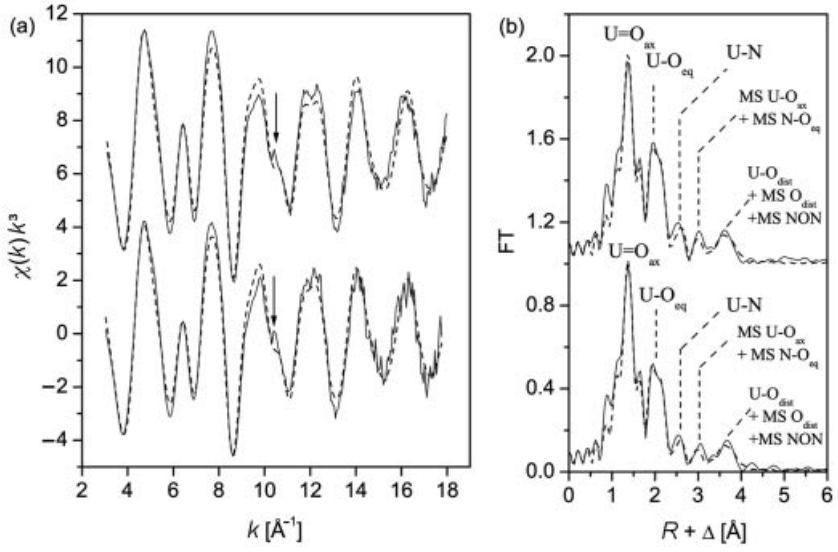

Figure 4. (a) Uranium $L_{III}$-edge $k^3$-weighted EXAFS data and (b) the corresponding Fourier transforms of $[UO_2(NO_3)_3]^-$ in acetonitrile (top) and in the ionic liquid $[C_4mim][Tf_2N]$ (bottom). Experimental data are presented as a continuous line and the theoretical curve as a dotted line. The multiple scattering path N–$O_{eq}$–N is abbreviated as MS NON. The arrow indicates a [2p4f] double-electron excitation.[57]

for the phase shift. The results of the shell-fitting procedure, including phase correction, are given in Tables 2 and 3. The coordination numbers of the equatorial oxygen atoms ($O_{eq}$) and nitrogen atoms were determined in an iterative manner by a free fit. These coordination numbers were subsequently fixed during the shell-fitting procedure in order to avoid correlation problems between $N$ and $\sigma^2$. The coordination number of the distal oxygen atoms was set equal to the coordination number of the nitrogen atoms. The fit results also indicate that three nitrate groups coordinate to uranium(VI) in a bidentate fashion, as shown in Figure 5. The U–$O_{eq}$ distance of 2.48–2.49 Å confirms the sixfold coordination of the uranyl ion as a U–$O_{eq}$ distance between 2.44 and 2.54 Å corresponds to a coordination number of six.[46] The weak peak due to nitrogen backscattering indicates a U–N distance of 2.94 Å (Figure 4). This U–N distance indicates a bidentate coordination of the $NO_3^-$ group and is in good agreement with the U–N distance in solid $Rb[UO_2(NO_3)_3]$ (2.88 Å).[3] The three coordinated nitrate ligands result in complex backscattering features mainly originating from a linear arrangement of the nitrogen atom and the distal oxygen atoms ($O_{dist}$) in each of the $NO_3^-$ ligands, with respect to the uranium atom. In this situation the scattering amplitude is greatly enhanced in the forward scattering direction due to focusing of the electron wave on the next neighbour. This effect is therefore called the "focusing effect". This focusing effect makes the distal oxygen atoms ($O_{dist}$) at a large distance of 4.16 (in acetonitrile) or 4.18 Å (in the ionic liquid $[C_4mim][Tf_2N]$) visible. A similar strong multiple scattering effect has been observed for the tricarbonato species $Ca_2[UO_2(CO_3)_3]$ in aqueous solution.[47] The amplitudes of the multiple scattering paths MS $O_{dist}$ (U–N–$O_{dist}$) and U–N–$O_{dist}$–N are much more pronounced than that of the single scattering path U–$O_{dist}$. It is interesting to note that the U–$O_{dist}$ distance in solution is slightly longer than in the solid {4.09 Å in solid $Rb[UO_2(NO_3)_3]$}.[3] The influence of the effective ligand charge on the bond lengths can be revealed by comparing uranium(VI) coordinated by nitrate and carbonate. The uranyl tricarbonato complex anion $[UO_2(CO_3)_3]^{4-}$ is isostructural with the trinitrato anion $[UO_2(NO_3)_3]^-$.[3,47] The U–$O_{eq}$ distance in the uranyl tricarbonato anion is shorter than that in the uranyl trinitrato anion (2.44 vs. 2.48–2.49 Å). Obviously, there is an influence of the U–$O_{eq}$ electron density on the U–$O_{ax}$ bond length, which results in a longer distance (1.81 Å) for the tricarbonato anion and a shorter one (1.77 Å) for the trinitrato anion.[48] The shorter U–$O_{ax}$ distance for the uranyl trinitrato anion can also be deduced from the ground-state vibrational frequencies. Thus, for the uranyl trinitrato anion the symmetric and asymmetric stretching vibrations are 884 and 956 $cm^{-1}$, respectively, compared to 808 and 856 $cm^{-1}$, respectively, for the tricarbonato anion. According to Badger's rule,[49,50] the U–$O_{ax}$ distance should therefore be smaller in the uranyl trinitrato anion.

[a] Errors in distances, $R$, are ±0.01 Å; errors in coordination numbers, $N$, are ±10%. [b] Value fixed during the shell-fitting procedure. $\Delta E$ = 3.85 eV. Weighted $F$-factor = 0.205.

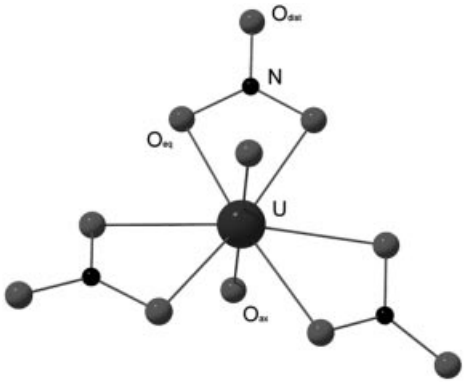

Figure 5. Ball-and-stick representation of the structure of $[UO_2(NO_3)_3]^-$.

The raw $k^3$-weighted EXAFS data of uranyl nitrate in water are shown in Figure 6. Like the optical absorption spectra, the EXAFS spectra of the aqueous solution show only the typical scattering features of the dominant hydrated uranyl ion. The largest peak in the Fourier transform represents the scattering contribution from the two axial oxygen ($O_{ax}$) atoms. The double peak at $R + \Delta$ = 1.8 Å arises from one single shell of equatorial oxygen ($O_{eq}$) atoms. This peak can be completely covered by including one single shell of equatorial oxygen atoms at 2.42 Å in the fitting procedure. The splitting of the $O_{eq}$ shell arises from a superposition of the $O_{ax}$ peak and the $O_{eq}$ peak. Due to the limited $k$-range, the Fourier transform peaks include small satellite peaks. The rather large satellite peak at high $R$-values of the $O_{ax}$ peak coincides with the $O_{eq}$ peak, which gives rise to this peak splitting.[51] Peaks in the Fourier transform were not corrected for the phase shift. The structural parameters of the EXAFS shell fitting, including phase correction, are summarized in Table 4. There are two axial oxygen atoms at 1.77 ± 0.01 Å and five equatorial oxygen atoms at 2.41 ± 0.01 Å. A fivefold coordination of the uranyl ion is characterized by a U–$O_{eq}$ distance between 2.34 and 2.42 Å.[46] These values agree well with the structural parameters obtained previously for the uranyl aqua ion in perchloric acid solution.[41,42]

Table 4. EXAFS structural parameters for uranyl nitrate in aqueous solution.

| | $R$[a] [Å] | $N$[a] | $\sigma^2$ [Å$^2$] |
|---|---|---|---|
| U–$O_{ax}$ | 1.77 | 2[b] | 0.0013 |
| MS U–$O_{ax}$ | 3.54 | 2[b] | 0.0026 |
| U–$O_{eq}$ | 2.41 | 4.9 | 0.0069 |

[a] Errors in distances, $R$, are ±0.01 Å; errors in coordination numbers, $N$, are ±10%. [b] Value fixed during the shell-fitting procedure. $\Delta E$ = 3.2 eV. Weighted $F$-factor = 0.273.

## Conclusions

We have shown that both UV/Vis absorption and EXAFS spectroscopy point unambiguously to the existence of a $[UO_2(NO_3)_3]^-$ coordination polyhedron ($D_{3h}$ sym-

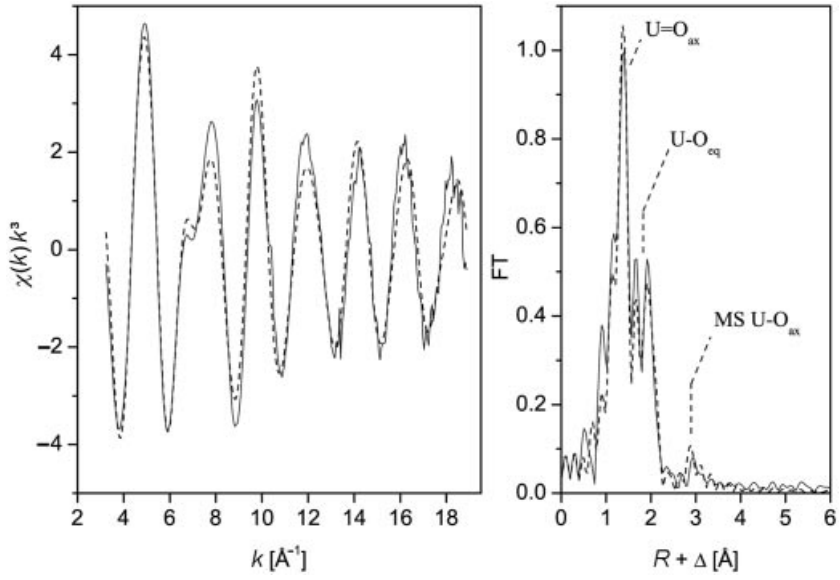

Figure 6. Uranium $L_{III}$-edge $k^3$-weighted EXAFS data (left) and the corresponding Fourier transform (right) of uranyl nitrate in aqueous solution. Experimental data are presented as a continuous line and the theoretical curve as a dotted line.

metry) for the uranyl nitrate complex in acetonitrile as well as in the ionic liquid [$C_4$mim][$Tf_2$N]. The sharp peaks in the long-wavelength part of the UV/Vis absorption spectra (21000–24000 $cm^{-1}$) are characteristic of a trigonal symmetry. The fit results of the EXAFS spectra and the corresponding Fourier transforms reveal the presence of six equatorial oxygen ($O_{eq}$) atoms with U–O bond lengths of 2.48–2.49 Å. The U–N distance of 2.92–2.93 Å points to a bidentate coordination of the $NO_3^-$ group. Furthermore, the distances in the equatorial plane around the uranyl ion for solution species are in good agreement with the distances in solid Rb[$UO_2(NO_3)_3$]. Only the U–$O_{dist}$ distance is slightly longer in solution. The increase in the coordination number from $N_{O_{eq}}$ = 5 (aqua ion) to $N_{O_{eq}}$ = 6 ([$UO_2(NO_3)_3]^-$) involves an increase of the U–$O_{eq}$ bond length from 2.41 to 2.48–2.49 Å. In contrast, no evidence has been found for the presence of uranyl nitrato species in aqueous solution under the given experimental conditions.

## Experimental Section

**Samples:** $UO_2(NO_3)_2{\cdot}6H_2O$ and tetrabutylammonium nitrate ($Bu_4NNO_3$) were purchased from Merck and Fluka, respectively. Dry acetonitrile was purchased from Acros. An aqueous solution of uranyl nitrate (50 mM) was prepared by dissolving $UO_2(NO_3)_2{\cdot}6H_2O$ in distilled water. The pH of this solution was 2.4. Acetonitrile was used as solvent for measurements in non-aqueous solution instead of acetone because acetonitrile is more stable than acetone in the presence of uranyl ions. Tetrabutylammonium nitrate ($Bu_4NNO_3$) was added to a solution of $UO_2(NO_3)_2{\cdot}6H_2O$ (50 mM) in acetonitrile to give uranyl/nitrate ratios of beween 1:2 and 1:4. No further changes were observed in the optical absorption spectra at [$UO_2^{2+}$]/[$NO_3^-$] ratios higher than 1:3. To obtain the spectrum of the solvated uranyl ion ("free" or "bare" uranyl ion) in acetonitrile, a solution of $UO_2(ClO_4)_2{\cdot}xH_2O$ (50 mM) was prepared as described in ref.[32] 1-Butyl-3-methylimidazolium bis(trifluoromethylsulfonyl)imide ([$C_4$mim][$Tf_2$N]) was synthesized as described in ref.[35] To reduce the water content, [$C_4$mim][$Tf_2$N] was dried in vacuo at 70 °C before preparing the solutions. $UO_2(NO_3)_2{\cdot}6H_2O$ (50 mM) and tetrabutylammonium nitrate ($Bu_4NNO_3$; 100 mM) were dissolved in [$C_4$mim][$Tf_2$N] to give a total uranyl/nitrate ratio of 1:4. The dissolution of $UO_2(NO_3)_2{\cdot}6H_2O$ and $Bu_4NNO_3$ in [$C_4$mim][$Tf_2$N] took about 3 d and resulted in a transparent, yellow solution. Initial spectroscopic measurements on mixtures of $UO_2(NO_3)_2{\cdot}6H_2O$ and $Bu_4NNO_3$ in [$C_4$mim][$Tf_2$N] did not give the typical absorption spectrum of the uranyl trinitrato complex. However, the [$UO_2(NO_3)_3]^-$ absorption bands were clearly visible when these mixtures were remeasured after several days. This indicates that the kinetics of the formation of the trinitrato complex in the ionic liquid are slow.

**Optical Spectroscopy:** UV/Vis absorption spectra in aqueous solution, acetonitrile and [$C_4$mim][$Tf_2$N] were recorded at room temperature with a Varian Cary 5000 spectrophotometer in the wavelength interval 600–300 nm. Magnetic circular dichroism (MCD) spectra were recorded with an AVIV 62DS circular dichroism spectrometer equipped with an electromagnet (magnetic field strength: 0.9 T) to provide the longitudinal magnetic field.

**EXAFS Spectroscopy:** Uranium $L_{III}$-edge EXAFS spectra were collected at the Rossendorf Beamline at the European Synchrotron Radiation Facility (ESRF, Grenoble, France).[52] The measurements were carried out in transmittance mode using argon-filled ionization chambers at ambient temperature and pressure. Higher harmonics were rejected with two platinum-coated mirrors. The measurements were performed using a double-crystal Si(111) monochromator in equidistant $k$-steps of 0.05 $Å^{-1}$ across the EXAFS region. Three scans were recorded for each sample and then averaged. An yttrium metal foil (first inflection point at 17038 eV) was used for energy calibration. The uranium $L_{III}$ threshold energy, $E_{k=0}$, was defined at 17185 eV. EXAFS data were extracted from the raw absorption spectra by standard methods, including a spline approximation for the atomic background with the program EXAFSPAK.[53] Theoretical phase and amplitude functions were calculated with FEFF 8.2.[54] The scattering phase and amplitude functions were calculated using the crystal structure of uranyl dinitrate trihydrate, $[UO_2(NO_3)_2(H_2O)_2]{\cdot}H_2O$,[55] and the rubidium uranyl salt Rb[$UO_2(NO_3)_3$].[3] The amplitude reduction factor, $S_0^2$, was found to be 0.9 from the FEFF calculation and fixed to that value in the data fits. The coordination number of the uranyl oxygen atoms ($O_{ax}$) in all fits was kept constant at two. The main multiple scattering paths, with their relative importance, are defined according to the notation in Figure 5 and given in the Supporting Information. Hudson and co-workers have indicated that the scattering contributions from paths U–$O_{ax1}$–$O_{ax2}$ and U–$O_{ax1}$–U–$O_{ax1}$ tend to cancel each other out,[56] therefore the twofold-degenerate, four-legged multiple scattering path U–$O_{ax1}$–U–$O_{ax2}$ (abbreviated as MS U–$O_{ax}$) was included in the curve fit by constraining its Debye–Waller factor, $\sigma^2$, and its effective path length to twice the values of the corresponding, freely fitted U–$O_{ax}$ single scattering path. The degeneracy of the multiple scattering paths was included in the coordination numbers $N$, therefore the degeneracy of the dominating multiple scattering paths including the distal oxygen $O_{dist}$, namely U–N–$O_{dist}$–N and U–$O_{dist}$–N (abbreviated as MS $O_{dist}$), was fixed to twice the value of the number of distal oxygen atoms present. Furthermore, the distances and Debye–Waller factor for these multiple scattering paths were linked to $R$ and $\sigma^2$ of the single scattering path U–$O_{dist}$. The number of scattering paths of the three-legged multiple scattering path U–N–$O_{eq}$ was constrained to twice the coordination number of the equatorial oxygen atoms $O_{eq}$, whereas $R$ and $\sigma^2$ were kept free in the fit. Scattering contributions of less than 5% were not considered in the fitting procedure.

**Supporting Information** (see footnote on the first page of this article): Correlation table of the irreducible representations in the different $D_{nh}$ point groups; UV/Vis absorption spectrum and data of $UO_2(NO_3)_2{\cdot}6H_2O$ in water; UV/Vis absorption spectrum and observed vibronic transitions of [$UO_2(NO_3)_3]^-$ in acetonitrile, acetone, and [$C_4$mim][$Tf_2$N]; UV/Vis absorption spectrum of $UO_2$ powder dissolved in [$C_4$mim][$Tf_2$N] with the help of $HNO_3/H_2O$; MCD and UV/Vis absorption spectra of $Bu_4NUO_2(NO_3)_3$ in a PMMA matrix; principal scattering pathways of the photoelectron in the [$UO_2(NO_3)_3]^-$ unit.

## Acknowledgments

The EXAFS measurements were performed at the Rossendorf Beamline at the ESRF. K. S. is a research assistant and R. V. D. a postdoctoral fellow of the Fund for Scientific Research, Flanders (Belgium) (FWO-Vlaanderen). This project was financed by the FWO-Vlaanderen (project G.0508.07) and by the K. U. Leuven (projects GOA03/03 and IDO/05/005). R. V. D. acknowledges financial support from the FWO-Vlaanderen ("Krediet aan Navorsers" project 1.5.099.06) and C. H. acknowledges financial support from the DFG (HE 2297/2-1).

# Synthesis and Reactivity of Cobalt Complexes with Pendant Nitrogen Functional Groups

**Longjin Li,[a] Shuang Han,[b] Qiang Li,[a] Zhenxia Chen,[a] and Zhen Pang*[a]**

**Keywords:** Cyclopentadienylcobalt complexes / Carbonylcobalt complexes

Several derivatives of cyclopentadienylcobalt complexes having a pendant amino-functionalised side chain (Cp′) are described, the cyclopentadienyl ligands being (2-aminoethyl)cyclopentadienyl, (2-piperidinoethyl)cyclopentadienyl, 1-(2-piperidinoethyl)-2,3,4,5-tetraisopropylcyclopentadienyl and 2-picolylcyclopentadienyl. Chelation by the amino-functionalised side chain occurred when the Cp*-cobalt(I) dicarbonyl complexes **5**, **6**, **7** and **8** were oxidised by iodine, thereby forming the corresponding Cp*-cobalt(III) chelates **9**, **10**, **11** and **12**, respectively, through the diiodocarbonyl intermediates **5′**, **6′**, **7′** and **8′**, respectively. The stabilities of the intermediates differ greatly due to the different amino functions in the pendant side chain. Structural studies of **9**, **10** and **12** were carried out and the correlation of the I–Co–I angles and the repulsive forces from the amino-functionalised groups with the stabilities of the intermediates is discussed. The diiodocarbonyl-$\eta^5$-(2-piperidinylethyl)cyclopentadienylcobalt(III) intermediate **6′** becomes reduced to **6** by the CO released upon chelation of the former when the concentration of CO reaches about 0.088 mol L$^{-1}$. The chelated piperidine group in **10** could be easily replaced by triphenylphosphane to form the diiodotriphenylphosphanyl-$\eta^5$-(2-piperidinioethyl)cyclopentadienylcobalt(III) iodide dichloromethane solvate **13** in the presence of hydrogen iodide. A strong N–H···I hydrogen bond with an N···I distance of 3.414(14) Å and a D–H···A angle of 164.1° were found in **13**.

## Introduction

The cyclopentadienyl group is one of the most important ligands in organometallic chemistry.[1] Its derivatives with Lewis bases in a pendant side chain that are capable of binding to hard and soft centres in a hemilabile manner promise a rich coordination chemistry and unusual reactions at the metal centre.[2] The Lewis bases may included alkenes,[3] phosphorus atoms,[4] thioethers, ethers and ester groups.[5] N-Based Lewis bases tethered to the Cp ligand have been frequently used as hemilabile ligands. Such ligands can only weakly coordinate to late transition metal centres forming a chelate bond which can also be easily broken under mild conditions. Since the binding strength between the metal and the donor ligand can be controlled sterically or electronically, structural modification to such a pendant side chain can greatly influence the physical and chemical properties of these complexes[6] and some molecular switches, which have been designed, are based on this concept.[7,8] Furthermore, the weak coordinate bond in these complexes can be easily broken under mild condition thereby creating a vacant site on the metal and such complexes therefore have applications in catalysis. The reactivity of the active intermediate is strongly influenced by the changes in the electronic density on the metal centre and the steric nature of the chelating donor moiety. Thus, an improved understanding of the factors governing the chelation of the tethered functional group should lead to more control over the design of more efficient catalytic processes. Many complexes with a chelating pendant Lewis base tethered to a Cp ligand have be synthesised and studied.[9–22] We are interested in the chemistry of the half-sandwich type complexes with a pendant chelating functional group, especially those containing nitrogen atoms in the pendant side chain and in the factors which can influence the ability of the pendant group to chelate to the metal. In this paper we report the synthesis and reactivity of several cobalt complexes with nitrogen functionalised pendant side chain cyclopentadienyl ligands.

## Results and Discussion

Four compounds $C_5H_5CH_2CH_2NH_2$ (**1**), $C_5H_5CH_2CH_2NC_5H_{10}$ (**2**), $C_5(C_3H_7)_4HCH_2CH_2NC_5H_{10}$ (**3**) and $C_5H_5CH_2NC_5H_4$ (**4**) with a space of two carbon atoms between the nitrogen atom and cyclopentadienyl ring were all synthesized using a similar strategy, i.e. treatment of so-

Scheme 1.

dium cyclopentadienide with a suitable halogenated alkylamine followed by standard aqueous workup. Because of the good solubility of **1** in aqueous solution, strong acidic (pH $<$ 1) and basic (pH $>$ 14) conditions must be kept during the aqueous workup in order to increase the yield. The reaction of compounds **1**–**4** with $Co_2(CO)_8$ in dichloromethane in the presence of a sacrificial olefin 3,3-dimethyl-1-butene gave the substituted dicarbonylcyclopentadienylcobalt(I) complexes **5**–**8** in moderate yields, Scheme 1.[23] If the syntheses were to be done in a higher boiling point solvent, the yields should increase.

All the dicarbonylcobalt(I) complexes show two characteristic absorption bands in their IR spectra indicating that two terminal carbonyl groups are present and that the nitrogen atoms in the side chains do not coordinate to the cobalt atoms. No chelation was observed between the cobalt(I) and the nitrogen functional group except under irradiation of light.[24] The characteristic $\nu$(CO) data are listed in Table 1.

Complexes **5**–**8** can be easily oxidised by iodine to yield the corresponding cobalt(III) complexes.[25] It has been reported that when iodine is added to an ether solution of carbonyl cyclopentadienylcobalt(I) complexes with an N-donor function in the side chain, the corresponding chelated diiodo-cobalt(III) complexes precipitate spontaneously from the reaction mixture as black microcrystals.[24a] It is believed that the chelate is formed via the diiodocarbonyl complex (vide infra) since, when the CO-free chelate precipitates, the solution is still dark purple in colour indicating the presence of the monocarbonyl species and this is supported by $^1$H NMR spectroscopic observations. In our experiment, the observations made upon the addition of iodine to the dichloromethane solutions of **5**–**8** are consistent with the literature report because they show evidence of the appearance of a strong carbonyl absorption band at higher frequencies for the solutions which is in contrast to the two carbonyl stretching frequencies observed for the precursors. This carbonyl absorption must come from the reaction intermediates **5′**–**8′** as listed in Table 1. However, in all cases, the black purple precipitate appeared immediately after the addition of iodine and the isolated precipitates also showed one carbonyl absorption band. Elemental analyses and $^1$H NMR spectroscopy indicated that the isolated products were mixtures of the CO-free chelates **9**–**12** and their corresponding diiodocarbonyl complexes **5′**−**8′**. For example, the $^1$H NMR spectrum of the precipitate obtained from the solution of iodine and **5** shows three peaks at $\delta$ = 4.22, 3.60 and 2.42 ppm. The first and third peaks result from the methylene groups between the cyclopentadienyl and amino groups in chelate **9**. The peak of 3.60 ppm could also come from the dimethylene group but it is shifted 0.12 ppm downfield compared with the similar resonance in **5**, indicating a free side chain in the $Co^{III}$ product **5′**. A carbonyl stretching frequency at 2068 cm$^{-1}$ was found for the solid but its intensity diminished at room temperature after one weak indicating the existence of the unstable **5′** and, hence, the isolated solid was initially a mixture of **5′** and **9**. The carbonyl stretching frequency of the solid product isolated from a solution of iodine and **6** or **7** was found at 2060 or 2046 cm$^{-1}$, respectively, but the signal disappeared at room temperature after about one day indicating the isolated products to be mixtures of **6′** and **10** or **7′** and **11**, respectively. Only the precipitate isolated form a solution of iodine and **8** gave the pure chelated product **12**. The stability of the reaction intermediates is therefore of the order **5′** $>$ **6′**:**7′** $>$ **8′**. The oxidising process is illustrated in Scheme 2.

The crystal structures of the chelates **9**, **10** and **12** were determined and all of them show that the tethered amino group is intramolecularly coordinated to the cobalt atom. The ORTEP diagrams and the selected structural parameters of **9**, **10** and **12** are given in Figure 1, Figure 2 and Figure 3. The Co–N bond lengths in **9**, **10** and **12** were found to be 1.979(8), 2.097(3) and 1.956(6) Å, respectively. All of these bond lengths are slightly shorter than those in related tetramethyl-substituted diiodocyclopentadienylcobalt(III) complexes, e.g. 2.115(6) Å in diiodo-$\eta^5$:$\eta^1$-[l-(2-*N*,*N*-dimethylaminoethyl)-2,3,4,5-tetramethyl cyclopenta-

**12**, N-donor = $NC_5H_4$, R = H

Scheme 2.

dienyl] cobalt(III) ("aminoethyl")[24a] and 2.205(2) Å in diiodo-$\eta^5$:$\eta^1$-[l-[2-(dimethylamino)phenyl]-2,3,4,5-tetramethylcyclopentadienyl]cobalt(III) ("aminophenyl").[18] Considering that the alkyl ring of piperidine is an electron-releasing substituent, the nitrogen atom in the tethered side chain in **10** should be a stronger σ donor compared with that in **9** and **12** and the chelate bond in **10** would be expected to be the strongest one among the three analogues. However, the chelate bond in **10** was found to be the longest. For easy comparison between these analogues, some structural parameters are listed in Table 2. The average lengths of the Co–I bonds in **9**, **10** and **12** are 2.5979(10), 2.5865(3) and 2.5788(16) Å, respectively − all slightly shorter than 2.622(2) Å found in "aminoethyl" and 2.604(1) Å found in "aminophenyl". The average cobalt–carbon(ring) bond lengths show the same trend but all are still in the expected range. The I–Co–I bond angles are 96.50(5), 92.70(2) and 96.68(4) degrees in **9**, **10** and **12**, respectively. The corresponding values reported for "aminoethyl" and "aminophenyl" are 94.5(1) and 91.302(12)°, respectively. The I–Co–N bond angles found in **9**, **10** and **12** are 92.07(16), 100.32(8) and 95.12(18)°, respectively. A comparison of the above structural data indicates that a large repulsive force might exist in **10** between the iodine ligands and the methylene groups in the piperidine ring adjacent to the nitrogen atom which pushes the iodine ligands away from the piperidine moiety and leads to the smallest I–Co–I angle as well as the longest Co–N bond length among the three chelates.

Selected bond lengths [Å] and angles [°]: Average Co–C(ring) 2.039(8), Co(1)–N(1) 1.956(6), Co(1)–I(1) 2.5779(16), Co(1)–I(2) 2.5796(16), average C–C(ring) 1.403(14), N(1)–C(7) 1.351(10), N(1)–C(11) 1.327(10), C(7)–C(8) 1.392(12), C(8)–C(9) 1.360(14), C(9)–C(10) 1.370(14), C(10)–C(11) 1.365(12), I(1)–Co(1)–I(2) 96.68(4), I(1)–Co(1)–N(1) 95.12(18), I(2)–Co(1)–N(1) 95.12(19), Co(1)–N(1)–C(7) 116.9(5).

The COSY spectrum of **10** reveals that the methylene protons in the piperidine ring adjacent to nitrogen atom suffer large steric hindrance and retain their configuration in solution at room temperature (Figure 4). The methylene protons on the α carbon in the piperidine ring are split into two sets of signals. The signals of the protons in the *e* position at $\delta$ = 3.52 show a strong correlation with the methylene protons on the β carbon in the piperidine ring ($\delta$ = 1.72 ppm) and the signals of the protons in the *a* position at $\delta$ = 2.93 show a strong correlation with the methylene

Table 2. List of the structural parameters of the cyclopentadienylcobalt complexes with a nitrogen functional group in the pendant side chain.

| Chelates | I–Co−I [°] | Co–N [Å] | Co–$I_{av}$ [Å] | Co–$C(ring)_{av}$ [Å] |
|---|---|---|---|---|
| **9** | 96.50(5) | 1.979(8) | 2.5979(10) | 2.044(7) |
| **10** | 92.70(2) | 2.097(3) | 2.5865(3) | 2.055(4) |
| **12** | 96.68(4) | 1.956(6) | 2.5788(16) | 2.039(8) |
| **13** | 95.40(8) | 2.239(5) (Co–P) | 2.580(3) | 2.094(17) |
| Aminoethyl[24a] | 94.5(1) | 2.115(6) | 2.622(2) | 2.095(5) |
| Aminophenyl[15] | 91.302(12) | 2.205(2) | 2.604(1) | 2.080(3) |

protons on the ω carbon in the piperidine ring ($\delta$ = 1.22 ppm). The methylene protons on the β carbon in the piperidine are in a free-flipping motion and give rise to a broadened multiplet. We can deduce that the flipping of the methylene protons on the α carbon in the piperidine ring in **10** is prevented by steric hindrance in the chelated form. This steric hindrance results from the repulsive force of the iodine ligands which keeps the σ orbitals between cobalt and the amino nitrogen from fully overlapping and thus a longer chelate Co–N bond results. The side chains in **9** and **10** are coordinated to the cobalt in a zigzag fashion and, consequently, the latter can be expected to exist as chiral molecules. However, the very fast flip of the side chain makes the two enantiomers show only one set of signals in their $^1$H NMR spectra. Similar situations have also been found in "aminoethyl" and "aminophenyl" and by Wang et al. in the molybdenum complex $[C_5H_4CH_2CH_2NMe_2]$-$Mo(CO)_2I$.[26] In the crystal structure of **12**, an idealised mirror plane of the $Cp^*CoI_2$ fragment was found which almost coincides with the plane of the pyridine ring. The observed orientation allows the maximum overlap between the π system in pyridine and one of the two suitable d-type donor orbitals at the cobalt centre.[27] Pyridine is considered a moderate π acceptor because its LUMO is not as low in energy as, for example, that of pyrazine which is known as a good π acceptor.[28] Thus, besides the normal σ interaction, a weak π interaction between the metal and donor nitrogen is also possible. This binding pattern between the nitrogen and cobalt results in the shortest Co–N bond among the three. In the indenyl-nickel analogues reported by L. E. Groux and D. Zargarian,[30] N–C bond lengths and C–C bond lengths in the tethered pyridine moiety were found to be longer in the chelated form [average 1.354(3) Å and 1.376(3) Å, respectively] than in the non-chelated form [average 1.335(5) Å and 1.360(6) Å, respectively]. Thus a delocalisation of electron density from nickel to the pyridine π system could be assumed. The corresponding N–C bond lengths [average 1.339(10) Å] and the C–C bond lengths [average 1.372(13) Å] found in **12** are comparable with those of the chelated forms of the indenyl-nickel complexes. Comparing the slightly shorter C–C bond lengths in the Cp ring [average 1.403(14) Å] found in **12** with the corresponding data for **9** and **10** [average 1.4054(4) and 1.4084(6) Å, respectively], a possible delocalisation of electron density from cobalt to the pyridine π system is likely. The σ, π interaction between a donor atom possessing d orbitals (such as S and P from the ligand) and the metal in half-sandwich complexes is also known.[31,32] Although nitrogen does not have an available d orbital, the π system of pyridine makes the donor nitrogen atom in the tethered side chain of **12** undergo a stronger interaction with the metal compared with an S or P atom. Thus we may assert that there is a partial double bond in existence in **12** which leads to a shorter Co–N bond.

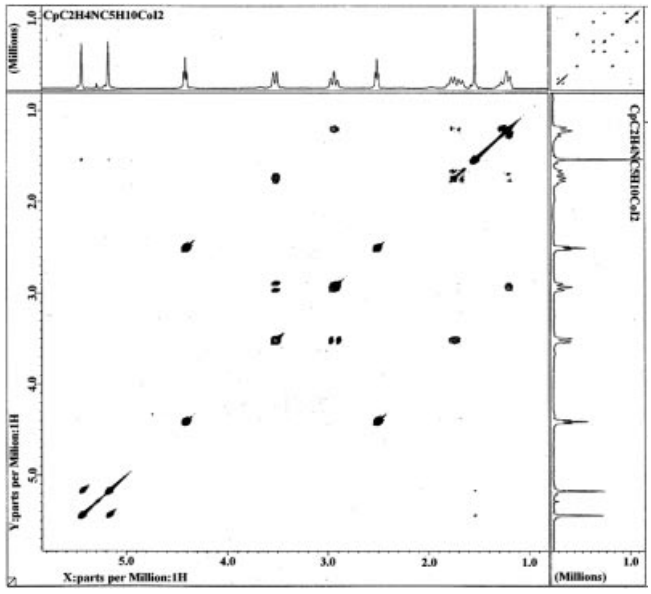

Figure 4. COSY spectrum of diiodo-$\eta^5$:$\eta^1$-(2-piperidinoethyl)cyclopentadienylcobalt(III) ($C_5H_4C_2H_4N_5H_{10}CoI_2$) (**10**) in $CDCl_3$ at 25 °C.

Since the metal–CO bond is weaker[25] for the cobalt(III) complex compared with that in the cobalt(I) complex, the amino nitrogen as a σ donor in the pendant side chain can replace the CO group in the oxidised diiodocarbonyl intermediates. Although there is greater steric hindrance around the donor atom in the piperidine moiety compared with the amino moiety, the formation of **10** was still found to be much faster than that of **9**. This phenomenon suggests that the rate of chelation might be determined by the strength of the Lewis basicity of the nitrogen atom in the donor function. However, by oxidation of **8** with iodine, pure **12** was obtained directly and we did not find a carbonyl adsorption band in the precipitate thus indicating the chelation here is the fastest among the four dicarbonyl reaction precursors. If the σ donor ability of the lone pair on the nitrogen atom in the pendant side chain were only determined by the hybridisation of the orbital, the rate of chelation in **8** should be slower than was observed in **6** or **7**. The

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

driving force for the faster rate of chelation can be attributed to the formation of a partial double bond between cobalt and nitrogen. The π interaction between cobalt(III) and nitrogen as well as the less steric hindrance and the low degree of freedom in the functionalised arm in **8** are more than enough to compensate for the lower σ donor ability of the N-based pendant function. Thus, the shortest lifetime of the diiodocarbonyl intermediate **8′** and the fastest rate of chelation observed during the oxidation process of **8** can be understood.

It has been demonstrated by Jutzi et al. that performing the reduction of diiodo cobalt(III) chelates with sodium amalgam under an atmosphere of carbon monoxide leads to the formation of dicarbonylcobalt(I) species. Without the presence of sodium amalgam, only diiodocarbonylcobalt(III) was formed in an equilibrium with the corresponding diiodo cobalt(III) chelate.[24,29] Irreversible displacement of the intramolecular coordinated ligand was only achieved under very drastic conditions. In our experiments, we found that carbon monoxide not only replaced the intramolecularly coordinated ligand but also reduced the cobalt(III) complex to a cobalt(I) complex. In a airtight reaction vessel, we observed that the reaction intermediate diiodocarbonyl-η$^5$-(2-piperidinylethyl)cyclopentadienylcobalt(III) **6′** was reduced to its corresponding dicarbonylcobalt(I) **6** by the CO released during the chelation of the tethered piperidinyl ligand as shown by the IR spectrum depicted in Figure 5. Since the decay of the adsorption of the metal–carbonyl bond at 2066 cm$^{-1}$ clearly shows the pattern of a first-order reaction and the plot of logA($\nu_{CO}$) vs. *t* has a good linear relationship ($R_2 > 0.999$) after an 882 s inducing period, the relationship between the concentration of the intermediate and time can be deduced. We estimated the initial absorbance (*t* = 0) of the diiodocarbonylcobalt(III) intermediate from the interception of the line with the ordinate by extrapolation. The carbonyl absorbance of **6** in dichloromethane was found obey the Lambert–Beer law quiet well within our experimental range. The concentration of each species at anytime can thus be calculated and such data are listed in Table 3. The reaction occurring in the IR cell can be described as shown in Scheme 3.

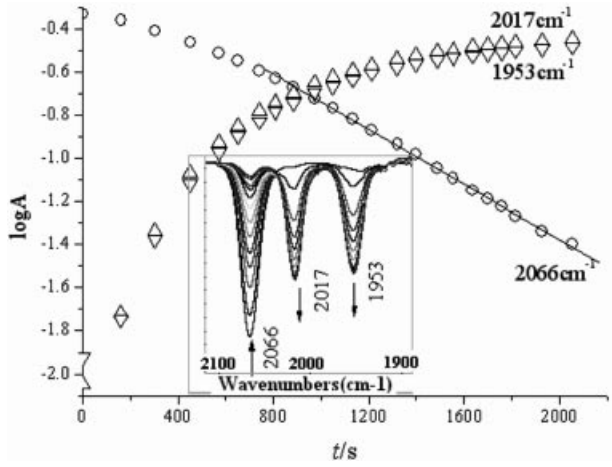

Figure 5. Reduction of diiodocarbonyl-η$^5$-(2-piperidinylethyl)cyclopentadienylcobalt(III) by carbon monoxide released via its own chelation. The inset IR spectra show the reducing *ν*(CO) of **6′** at 2066 cm$^{-1}$ and the increasing *ν*(CO) of **6** at 2017 and 1953 cm$^{-1}$, respectively.

Table 3. Changes of the carbonyl absorbance during the chelation of **6** after being oxidised by iodine in dichloromethane solution.

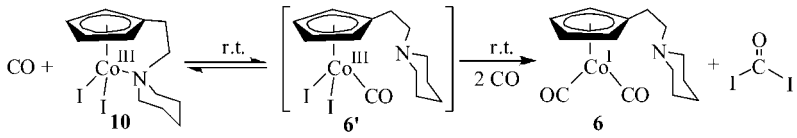

Scheme 3.

According to Scheme 3, each molecule of the diiodocarbonyl intermediate **6′** can provide one molecule of carbon monoxide after chelation. To produce each molecule of dicarbonylcobalt(I) **6** requires three molecules of carbon monoxide. The difference between the consumed molecules of diiodocarbonyl intermediate **6′** and the formed molecules of **6** is the free carbon monoxide that dissolves in solution as listed in Table 3. Based on these data, our calculations reveal that after the first 882 s induction period, the difference in the concentration of the cobalt(III) and (I) species determined by IR measurements at the same time remains a constant 0.088 mol $L^{-1}$. Since the solubility of carbon monoxide in organic solvents cannot reach such a high lever under normal conditions, bubbling carbon monoxide through a solution of a cobalt(III) chelate cannot produce an oxidation state +1. We did not observe such self-reduction in similar experiments with **5** and **8**. This can be attributed to the rate of chelation in **9** being too slow to allow a sufficiently high concentration of carbon monoxide to form in the reaction vessel and also because a small leakage of CO from the IR cell cannot be entirely prevented. On the other hand, the rate of chelation in **12** is too fast and the carbon monoxide had already escaped form the reaction solution after the iodine had been added.

It is interesting to compare the properties of the tethered functional side chains in "aminoethyl", **10** and "aminophenyl" since the stereochemical environments around the Co–N bonds are similar. The diiodomonocarbonyl precursor of "aminoethyl" reported could only exist in solution under an atmosphere of carbon monoxide whereas the diiodomonocarbonyl analogue of **10** could be isolated in the solid-state but could not be fully characterised because of its instability; completion of the chelation was observed after only about one day. The diiodomonocarbonyl analogue of "aminophenyl" was isolated from a solution after 16 h stirring at room temperature under $N_2$ and in a yield of 58%. The big difference in chelating ability is consistent with the repulsive force between the iodine ligands and the methyl (methylene) groups adjacent to the nitrogen atom. A comparison of the structural parameters of these analogues using the values of I–Co–I bond angles and the Co–N bond lengths found the largest in "aminoethyl" and the smallest in "aminophenyl".

Triphenylphosphane is known to be a better ligand for late transition metal complexes than amines. At room temperature, triphenylphosphane can replace the intramolecularly coordinated piperidine group in **10**. Since triphenylphosphane is easily oxidised by iodine to form $I_2PPh_3$ which is itself readily hydrolysed by moisture to generate hydrogen iodide and triphenylphosphane oxide, the formed diiodotriphenylphosphanyl-$\eta^5$-(2-piperidinoethyl)-cyclopentadienylcobalt(III) was thus protonated by hydrogen iodide to give the corresponding piperidinium salt **13**, crystals of which could be easily grown. From a crystal of suitable size we were able to determine the structure of **13**. The ORTEP diagram of **13** is given in Figure 6. It is interesting to find that the I–Co–I angle in **13** is 95.40(8)° and the I–Co–P angles are 91.57(14) and 92.79(14)°. Comparing the corresponding value of 92.70(2)° found in **10** suggests that the triphenylphosphane ligand experiences a smaller repulsive effect compared with the tethered intramolecular coordinated piperidine group. Triphenylphosphane is known as a ligand with a large stereochemical effect and has a cone angle of 143°.[33] However, as a strong σ donor ligand, triphenylphosphane still shows a larger *trans* effect than piperidine. The Co–C(5) bond *trans* to Co–P of 2.141(16) Å is 0.085 Å longer than the *cis* Co–C(3) bond which is 2.056(16) Å. For comparison, the Co–C(2) bond in **10** *trans* to Co–N is 2.086(4) Å, i.e. only 0.053 Å longer than the *cis* Co–C(5) bond which is 2.033(4) Å. There is one iodide counterion hydrogen bonded to the cation through N–H···I interactions with an N···I distance of 3.414(14) Å (Figure 7). This is an almost linear hydrogen bond with *d*(D–H) = 0.91 Å, *d*(H···A) = 2.53 Å and <D–H···A = 164.1°. A short contact between the iodide counterions and the hydrogen atom at C(12) adjacent to the nitrogen atom also exists and this should help the molecules pack in the crystal. To the best of our knowledge, this is one of the

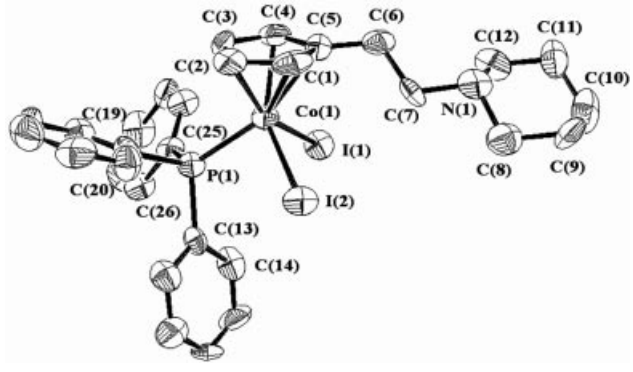

Figure 6. ORTEP diagram of **13** with the probability ellipsoids drawn at the 50% level. Hydrogen atoms, dichloromethane solvate molecule and iodide anion have been omitted for clarity. Selected bond lengths [Å] and angles [°]: Average Co–C(ring) 2.094(11), Co(1)–P(1) 2.239(5), Co(1)–I(1) 2.592(3), Co(1)–I(2) 2.568(2), average C–C(ring) 1.40(2), N(1)–C(7) 1.488(19), N(1)–C(12) 1.46(2), I(1)–Co(1)–I(2) 95.40(8), I(1)–Co(1)–P(1) 92.79(14), I(2)–Co(1)–P(1) 91.57(14), Co(1)–P(1)–C(13) 118.0(5), Co(1)–P(1)–C(19) 112.7(7), Co(1)–P(1)–C(25) 115.2(5).

strongest N–H···I hydrogen bonds found in the literature. A similar N–H···I hydrogen bond was found in crystals of $Me_3N{\cdot}HI$ and it was probably found to be linear with an N···I distance of 3.46(4) Å.[34] A further example can be seen in the crystal structure of the hexakis(*S*,*S*-diphenylsulfimide)cobalt(II) diiodide *S*,*S*-diphenylsulfimide acetonitrile solvate, $[Co(C_{12}H_{11}NS)_6]I_2{\cdot}C_{12}H_{11}NS{\cdot}2C_2H_3N$, in which two iodide counterions are hydrogen-bonded to the cation through N–H···I interactions, with N···I distances in the range of 3.7302(19)–3.8461(19) Å and D–H···A angles in the range of 156–172°.[35]

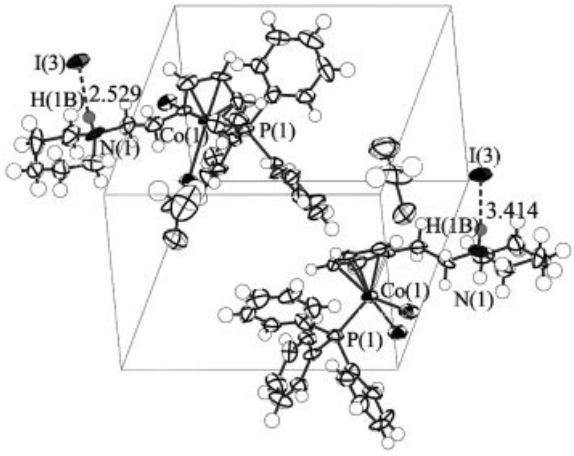

Figure 7. N–H···I hydrogen bonding in the unit cell of complex **13**.

## Conclusions

This paper reports the synthesis and reactivity of several cyclopentadienylcobalt complexes having a pendant amino-functionalised side chain. Intramolecular coordination by the pendant amino-functionalised side chain occurs when the oxidation state of the cobalt changes from +I to +III via a diiodocarbonyl intermediate. The stabilities of the intermediates differ greatly due to the different amino functions in the pendant side chains. Structural studies of chelates **9**, **10** and **12** have been carried out and these show that the Co–N bond length does not correlate with the stability of the diiodocarbonyl intermediate precursors but that there exists a correlation between the I–Co–I angles with the repulsive force from the methyl or methylene groups adjacent to the nitrogen atom. The intermediate diiodocarbonyl-$\eta^5$-(2-piperidinylethyl)cyclopentadienylcobalt(III) **6′** can be reduced to dicarbonylcyclopentadienylcobalt(I) **6** by the CO released due chelation of the former at a CO concentration of about 0.088 mol $L^{-1}$. The chelated piperidinyl group in **10** can easily be replaced by triphenylphosphane to form the diiodotriphenylphosphanyl-$\eta^5$-(2-piperidinioethyl)cyclopentadienylcobalt(III) iodide dichloromethane solvate **13** in the presence of hydrogen iodide. A strong N–H···I hydrogen bond with a N···I distance of 3.414(14) Å and a D–H···A angle of 164.1° was observed in **13**. It is one of the strongest N–H···I hydrogen bonds reported up to now.

## Experimental Section

**General:** All manipulations were carried out under an atmosphere of purified nitrogen using standard Schlenk techniques except where mentioned. All reagents were purchased from commercial sources (Acros Organics or Lancaster Synthesis Ltd) in the highest available purity and used as received. Solvents were purified by standard methods and distilled under nitrogen before use. Glassware was heated under vacuum and then flushed with $N_2$ prior to use. Alumina was heated at 300 °C under vacuum and then deactivated by addition of about 6 wt.-% of deoxygenated water before use.

Elemental analyses were performed on a Vario EL III Elemental Analyaer (Analysensysteme GmbH, Germany). IR spectra were recorded on a Nicolet Avatar-360 FTIR spectrometer in KBr pellets. A 0.2 mm NaCl IR cell was used to record the spectrum of solution samples. $^1$H NMR spectra were recorded on a Bruker Avance-DMX 500 NMR spectrometer or a JEOL ECA400 NMR spectrometer. The chemical shifts are reported in ppm relative to tetramethylsilane. Mass spectra were recorded on a Hewlett–Packard (USA) 6890/5073 gas chromatography–mass spectrometer. High resolution matrix assisted laser desorption ionisation mass spectra were recorded on an IonSpec 4.7 Tesla FTMS spectrometer at the Shanghai Institute of Organic Chemistry, Chinese Academy of Sciences, with 2,5-dihydroxybenzoic acid (DHB) serving as the absorbing matrix.

The crystal data were determined on a Bruker Smart-Apex CCD X-ray diffractometer equipped with a graphite monochromator. Data collection was performed with Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 Å) using the $\omega$-2$\theta$ scan technique to a maximum 2$\theta$ value of 26° at room temperature. The intensities were corrected for Lorentz polarisation effects and empirical absorption with the SADABS program.[36] Structures of the crystals were solved by direct methods and expanded using Fourier techniques. The non-hydrogen atoms were refined anisotropically with full-matrix least-squares methods. Hydrogen atoms were not included in the refinements. The final agreement factors are described with $R_1$ and $wR_2$ values for observed reflections. All calculations were performed on a PC computer using SHELX-97[37] the Bruker Smart program. Crystal data and experimental details for **9**, **10**, **12** and **13** are listed in Table 4 and selected bond lengths and angles are listed under the respective ORTEP diagrams.

### Synthesis of Compounds and Complexes

**2-Aminoethylcyclopentadiene (1):** Freshly distilled THF (50 mL) was added to a 250 mL Schlenk tube containing sodium sand (1.7835 g, 77.58 mmol) and the mixture was cooled in an ice-water bath. Freshly distilled cyclopentadiene (9 mL) was added dropwise and $H_2$ gas started to bubble out. After 30 min the bubbling stopped and the sodium sand had disappeared. The resultant pink solution was added by cannula to another 150 mL of Schlenk tube containing $BrCH_2CH_2NH_2{\cdot}HBr$ (4.1 g, 20.21 mmol) in THF (50 mL) which had already been cooled in an ice-water bath. The reaction mixture was then stirred at room temperature for 48 h during which time a white solid precipitated out from the solution. Water (50 mL) was added by cannula to the reaction mixture to dissolve the white precipitate. The organic layer was then separated. The aqueous phase was extracted with hexane (3 × 20 mL). The extract and the organic phase were combined and the volume was reduced to about 15 mL, cooled in an ice-water bath and acidified with aqueous HCl (concentrated HCl/water, 1:4). The separated aqueous phase was added directly to an ice-cold solution made from hexane (20 mL) and aqueous NaOH solution. The basic

aqueous phase (pH > 14) was extracted with hexane (3 × 20 mL). The organic phase and extract were combined, dried with anhydrous $MgSO_4$ and the solvents evaporated to give the product as an oily liquid (0.487 g, 4.46 mmol). Yield: 22.1%. The resultant oily product was identified as a 1:1 mixture of isomers. $^1$H NMR ($CDCl_3$): $\delta$ = 6.44 (d, *J* = 1.17 Hz, 1.5 H, =C*H*), 6.29 (d, *J* = 4.25 Hz, 0.5 H, =C*H*), 6.23 (s, 0.5 H, =C*H*), 6.09 (s, 0.5 H, =C*H*), 2.98 (s, 1 H, =CHC*H*−), 2.87–2.91 (m, 3 H, −C*H*), 2.56 (t, *J* = 6.7 Hz, 1 H, −C$H_2$), 2.51 (t, *J* = 6.7 Hz, 1 H, −C$H_2$) ppm. GCMS: *m*/*z* (%) = 109 (45) [M]$^+$, 80 (100) MH – $CH_2NH_2]^+$; retention times: 8.247, 8.327 min.

**(2-Piperidinoethyl)cyclopentadiene (2):** The compound was synthesised according to the reported procedure with little modification.[14] The product was purified on an alumina column. The resultant oily product was identified as a 1:1 mixture of isomers and a yield of 40% was redorded. $^1$H NMR ($CDCl_3$): $\delta$ = 6.45 (s, =C*H*), 6.42 (s, =C*H*), 6.27 (s, =C*H*), 6.19 (s, =C*H*), 6.05 (s, =C*H*), 3.59 (t, *J* = 7.34 Hz, 2 H, −C$H_2$−), 2.93 (d, *J* = 16.03 Hz, 1 H, −C*H*−), 2.69 (t, *J* = 7.35 Hz, 2 H, −C$H_2$N), 2.45 (m, 4 H, −NC$H_2$−), 1.60 (m, 4 H, −C$H_2$−), 1.46 (m, 2 H, −C$H_2$−) ppm. $^1$H NMR ([D$_6$]-acetone): $\delta$ = 6.42 (s, =C*H*), 6.21 (s, =C*H*), 6.03 (s, =C*H*), 5.94 (s, =C*H*), 5.47 (s, =C*H*), 5.11 (d, *J* = 14.41 Hz, 2 H, −C$H_2$−), 2.91 (d, *J* = 7.10 Hz, 1 H, −C*H*−), 2.50 (m, 2 H, −C$H_2$N), 2.42 (m, 4 H, −C$H_2$N), 2.12 (m, 2 H, −NC$H_2$−), 1.44 (m, 4 H, −C$H_2$−), 1.24 (m, 2 H, −C$H_2$−) ppm. $^{13}$C NMR ([D$_6$]acetone): $\delta$ = 146.58, 144.12, 133.74, 132.59, 131.37, 129.65, 125.82, 125.43, 123.92 (=*C*H), 58.52, 57.85, 56.79 (CpCH$_2$*C*H$_2$N−), 53.63 (α-N*C*H$_2$−), 42.48, 40.25, 33.29 (−*C*H$_2$−), 27.32, 26.79, 26.57 (Cp*C*H$_2$CH$_2$N−), 25.02, 23.46 (−*C*H$_2$−) ppm. GCMS: *m*/*z* (%) = 177 (25) [M]$^+$, 98 (100) [M – $C_5H_5CH_2]^+$, 80 (10) [MH – $CH_2NC_5H_{10}]^+$; retention times: 10.03, 10.15 min.

**1-(2-Piperidinoethyl)-2,3,4,5-tetraisopropylcyclopentadiene (3):** $C_5H_{10}NC_2H_4Cl$·HCl (5.174 g, 28.26 mmol) was added to an ice-cold mixture of hexane (30 mL) and aqueous KOH solution. The organic layer containing free $C_5H_{10}NC_2H_4Cl$ was separated and dried with $MgSO_4$. The volume was reduced to about 10 mL and THF (15 mL) was then added. The mixed solution was added by cannula to another 150 mL capacity Schlenk tube containing potassium tetraisopropylcyclopentadienide[19] (7.07 g, 25.8 mmol) and THF (60 mL). The resultant reaction mixture was heated to reflux for 24 h. The reaction was then quenched with water, extracted with hexane and eluted on an alumina column. A yellowish oil was obtained (3.5 g, 10.1 mmol) in a yield of 35.9%. $^1$H NMR ($CDCl_3$): $\delta$ = 3.16 (m, −C*H*C−), 2.74 (m, −C*H*C−), 2.46 (b, −C$H_2$N), 2.29 (b, −NC$H_2$), 1.87 (m, −C*H*Me$_2$), 1.62 (b, −C$H_2$−), 1.54 (b, −C$H_2$−), 1.39 (m, −CH*Me*$_2$), 1.19 (m, −CH*Me*$_2$), 1.12 (m, −CH*Me*$_2$), 1.01 (m, −CH*Me*$_2$) ppm. GCMS: *m*/*z* (%) = 345 (15) [M]$^+$.

**2-Picolylcyclopentadiene (4):** This compound was synthesised according to the reported procedure.[22] The product was separated on an alumina column. The resultant oily product was identified as 1:1 mixture of isomers. $^1$H NMR ($CDCl_3$): $\delta$ = 8.54 (t, *J* = 4.80 Hz, 1 H, =C*H*), 7.59 (m, 1 H, =C*H*), 7.17 (t, *J* = 6.88 Hz, 1 H, =C*H*), 7.11 (t, *J* = 4.60 Hz, 1 H, =C*H*), 6.44 (m, =C*H*), 6.29 (m, =C*H*), 6.23 (m, =CH), 6.10 (m, =C*H*), 3.94 (s, −C$H_2$−), 3.91 (s, −C$H_2$−), 3.00 (s, −C*H*−), 2.92 (t, −C$H_2$−) ppm.

**Dicarbonyl-η$^5$-(2-aminoethyl)cyclopentadienylcobalt(I) (5):** **1** (0.612 g, 5.61 mmol) was dissolved in $CH_2Cl_2$ (20 mL) containing 3,3-dimethyl-l-butene (5 mL) and the solution added by cannula to a $CH_2Cl_2$ solution (30 mL) containing $Co_2(CO)_8$ (0.6259 g, 1.83 mmol) at 0 °C. The deep red reaction mixture was stirred at ambient temperature and was inspected by observing the two characteristic $\nu_{CO}$ bands (2017, 1951 cm$^{-1}$) in the IR spectrum until their intensities became constant. This took about 24 h. The volume of the reaction mixture was reduced to about 2 mL under vacuum and the resultant solution was loaded on an alumina col-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

umn and rinsed with 1:1 solvent mixture of THF and hexane. A deep red band was collected and the solvent was evaporated in vacuo. A deep red oily product was obtained (0.34 g). Yield 42.0%. $^1$H NMR ($CDCl_3$): $\delta$ = 5.02 (s, 2 H, =C*H*), 4.92 (s, 2 H, =C*H*), 3.48 (m, 4 H, $-CH_2CH_2-$) ppm. IR (neat): $\tilde{\nu}_{max}$ = 3365, 2960, 2016 (C=O), 1951 (C=O), 1598, 1439, 1366, 1261, 1090, 1023, 898, 802 cm$^{-1}$.

**Dicarbonyl-η$^5$-(2-Piperidinoethyl)cyclopentadienylcobalt(I) (6):** A similar synthetic procedure was used as described for complex **5**. Thus $Co_2(CO)_8$ (0.976 g, 2.84 mmol) and **2** (1.43 g, 8.07 mmol) were stirred together for 20 h and the resultant mixture passed down an alumina column to produce a deep red oily product (0.226 g). Yield 13.7%. $^1$H NMR ($CDCl_3$): $\delta$ = 5.04 (s, 2 H, =C*H*), 4.90 (s, 2 H, =C*H*), 2.49 (2 H, $-CH_2N-$), 2.43 (4 H, $-NCH_2-$), 2.18 (2 H, $-CH_2-$), 1.60 (4 H, $-CH_2-$), 1.45 (2 H, $-CH_2-$) ppm. IR (neat): $\tilde{\nu}_{max}$ = 3401, 2935, 2854, 2800, 2766, 2019 (C=O), 1954 (C=O), 1603, 1445, 1373, 1352, 1262, 1155, 1114, 1039, 862, 802 cm$^{-1}$.

**Dicarbonyl-η$^5$-1-(2-piperidinoethyl)-2,3,4,5-tetraisopropylcyclopentadienylcobalt(I) (7):** A similar synthetic procedure was used as described for complex **5**. Thus $Co_2(CO)_8$ (0.4944 g, 1.45 mmol) and **3** (1.00 g, 2.90 mmol) were stirred under reflux for 24 h and the resultant mixture passed down an alumina column to produce a deep red oily product (0.785 g). Yield 59.0%. $^1$H NMR ($CDCl_3$): $\delta$ = 2.44 (s, 2 H, $-CH_2N$), 2.29 (b, 4 H, $-NCH_2$), 1.91 (m, 4 H, $-CHMe_2$), 1.87 (s, 2 H, $-CH_2-$), 1.54 (b, 6 H, $-CH_2-$), 1.26 (m, 6 H, $-CHMe_2$), 1.16 (m, 12 H, $-CHMe_2$), 1.11 (m, 6 H, $-CHMe_2$) ppm. IR (neat): $\tilde{\nu}_{max}$ = 3389, 2960, 2932, 2871, 2003 (C=O), 1942 (C=O), 1466, 1381, 1367, 1261, 1155, 1108, 1041, 861, 806 cm$^{-1}$.

**Dicarbonyl-η$^5$-2-picolylcyclopentadienylcobalt(I) (8):** A similar synthetic procedure was used as described for complex **5**. Thus $Co_2(CO)_8$ (0.1755 g, 0.513 mmol) and **4** (0.1585 g, 1.01 mmol) were stirred together for 13 h and the resultant mixture passed down an alumina column to produce a deep red oily product (0.098 g). Yield 35.6%. $^1$H NMR ($CDCl_3$): $\delta$ = 8.55 (s, 1 H, =C*H*−N), 7.64 (t, 1 H, =C*H*), 7.26 (t, 1 H, =C*H*), 7.14 (t, 1 H, =C*H*), 5.09 (s, 2 H, Cp), 4.93 (s, 2 H, Cp), 3.75 (s, 2 H, $-CH_2-$) ppm. IR (neat): $\tilde{\nu}_{max}$ = 3400, 3083, 3011, 2956, 2927, 2854, 2016 (C=O), 1948 (C=O), 1591 (C=N), 1570 (C=N), 1475, 1435, 1365, 1309, 1221, 1149, 1092, 1049, 995, 920, 820, 785, 749, 616 cm$^{-1}$.

**Diiodo-η$^5$:η$^1$-(2-aminoethyl)cyclopentadienylcobalt(III) (9):** To a solution of **5** (0.087 g, 0.39 mmol) in ether (15 mL) was slowly added a solution of iodine (1.00 g, 0.394 mmol) in ether with vigorous stirring. A black-purple precipitate immediately appeared. The reaction mixture was stirred for a further 1 h. The precipitate was filtered and washed with hexane (2× 10 mL) and dried in vacuo. A red-purple solid was obtained (0.171 g). Yield: 97.7%. The solid showed a strong $\nu_{CO}$ band at 2068 cm$^{-1}$ which disappeared after about one week. The solid was dissolved in dichloromethane and layered with hexane and a crystalline product was obtained (0.148 g). Yield 90.2%. Crystals suitable for X-ray crystallographic analysis were obtained from that crop. $C_7H_{10}CoI_2N$ (420.823): calcd. H 2.39, C 19.96, N 3.33; found H 2.44, C 19.86, N 3.41. $^1$H NMR ($CDCl_3$): $\delta$ = 5.51 (t, 2 H, =C*H*), 5.27 (t, 2 H, =C*H*), 4.22 (t, *J* = 5.48 Hz, 2 H, $-CH_2N-$),2.42 (t, *J* = 6.42 Hz, 2 H, $-CH_2N-$) ppm. MS (HiRMALDI): *m*/*z* (%): 573.2 (3.0) [M + DHB – H]$^+$, 545.2 (32) [M + DHB – $CH_2NH_2$]$^+$, 438.2 (8.0) [M + $H_2O$ – H]$^+$, 293.1 (26.0) [M – I – H]$^+$. IR (KBr pellet): $\tilde{\nu}_{max}$ = 3192, 2961, 1571, 1459, 1310, 1263, 1120, 1035, 1013, 840, 734, 700.2 cm$^{-1}$. UV/Vis ($CH_3CN$): $\lambda_{max}$ ($\varepsilon$) = 247 ($7.61\times10^3$), 290 ($1.04\times10^4$), 360 ($4.03\times10^3$), 585 ($4.53\times10^2$) nm.

**Diiodo-η$^5$:η$^1$-(2-piperidinoethyl)cyclopentadienylcobalt(III) (10):** A similar synthetic procedure was used as described for complex **9**. Thus **6** (0.226 g, 0.776 mmol) in ether (15 mL) was added to iodine (0.1985 g, 0.782 mmol) in ether (15 mL) and the solution stirred overnight. The resultant green-black precipitate was washed with hexane until the washings became colourless. The solid showed a medium strong $\nu_{CO}$ band at 2059 cm$^{-1}$ which disappeared after about 12 h. The solid was dissolved in dichloromethane and filtered through a pad of celite and the solvent was then evaporated. A green-black solid was obtained (0.204 g). Yield 53.8%. Crystals suitable for X-ray crystallographic analysis were obtained from a sample dissolved in dichloromethane and layered with hexane. $C_{12}H_{18}CoI_2N$ (489.02): calcd. H 3.71, C 29.47, N 2.86; found H 3.61, C 29.58, N 2.71. $^1$H NMR ($CDCl_3$): $\delta$ = 5.46 (s, 2 H, =C*H*), 5.19 (s, 2 H, =C*H*), 4.41 (t, *J* = 6.40 Hz, 2 H, $-CH_2N-$), 3.52 (d, *J* = 13.7 Hz, 2 H, $-NCH_eH_a-$), 2.93 (t, *J* = 13.7 Hz, 2 H, $-NCH_eH_a-$), 2.51 (t, *J* = 6.40 Hz, 2 H, $-CH_2-$), 1.72 (m, 4 H, $-CH_2-$), 1.22 (m, 2 H, $-CH_2-$) ppm. $^1$H NMR ([D$_6$]acetone): $\delta$ = 5.69 (s, 2 H, =C*H*), 5.11 (s, 2 H, =C*H*), 4.49 (t, *J* = 6.40 Hz, 2 H, $-CH_2N-$), 3.61 (d, *J* = 13.3 Hz, 2 H, $-NCH_eH_a-$), 2.81 (t, *J* = 13.3 Hz, 2 H, $-NCH_eH_a-$), 2.68 (t, *J* = 6.40 Hz, 2 H, $-CH_2-$), 1.90 (m, 4 H, $-CH_2-$), 1.13 (m, 2 H, $-CH_2-$) ppm. $^{13}$C NMR ([D$_6$]acetone): $\delta$ = 112.93 ($CpCH_2-$), 83.49 (Cp), 81.38 (Cp), 65.50 ($-CH_2CH_2N-$), 61.10 (*ortho*-$NCH_2-$), 25.39 ($CpCH_2CH_2N-$), 24.32, 22.30 ($-CH_2-$) ppm. MS (HiRMALDI): *m*/*z* (%): 514.9 (12.5) [M + DHB – I – H]$^+$, 422.9 (4.0) [M + $H_2O$ – $NC_5H_{10}$]$^+$, 379.1 (23) [M + $H_2O$ – I – H]$^+$, 362.0 (10) [M – I]$^+$. IR (KBr pellet): $\tilde{\nu}_{max}$ = 3076, 2932, 2856, 2801, 1726, 1603, 1468, 1443, 1393, 1353, 1309, 1261, 1101, 1025, 802 cm$^{-1}$. UV/Vis ($CH_3CN$): $\lambda_{max}$ ($\varepsilon$) = 248 ($1.01\times10^4$), 286 ($7.06\times10^3$), 587 ($5.79\times10^2$) nm.

**Diiodo-η$^5$:η$^1$-1-(2-piperidinoethyl)-2,3,4,5-tetraisopropylcyclopentadienylcobalt(III) (11):** A similar synthetic procedure was used as described for complex **9**. Thus **7** (0.786 g, 1.71 mmol) in ether (35 mL) was added to iodine (0.4456 g, 1.76 mmol) in ether (10 mL) and the resultant mixture stirred overnight. A red-purple solid precipitated which showed a medium-strong $\nu_{CO}$ band at 2046 cm$^{-1}$. The solid was dissolved in dichloromethane and filtered through a pad of celite and the solvent subsequently removed in vacuo. A solid was obtained (0.165 g). Yield 15%. $C_{24}H_{42}CoI_2N$ (657.35): calcd. H 6.44, C 43.85, N 2.13; found H 6.96, C 44.70, N 1.91. $^1$H NMR ($CDCl_3$): $\delta$ = 1.72 (d, 6 H, $-CH_3$), 1.70 (d, 6 H, $-CH_3$), 1.53 (d, $-CH_3$), 1.50 (d, 6 H, $-CH_3$), 2.05 (m, 4 H, $Me_2CH$), 3.83 (s, 2 H, $-CH_2N-$), 3.65 (s, 4 H, $-NCH_eH_a-$), 3.32 (s, 2 H, $-NCH_eH_a-$), 3.18 (s, 4 H, $-CH_2-$), 2.37 (m, 4 H, $-CH_2-$) ppm.

**Diiodo-η$^5$:η$^1$-2-picolylcyclopentadienylcobalt(III) (12):** A similar synthetic procedure was used as described for complex **9**. Thus complex **8** (0.098 g, 0.359 mmol) in hexane (10 mL) was added to iodine (0.097 g, 0.382 mmol) in hexane (10 mL) and the mixture stirred for 24 h. The resultant dark green precipitate was separated and washed twice with hexane and dissolved in dichloromethane. The solution was filtered and the solvent removed in vacuo. A dark green solid was obtained (0.1615 g). Yield 96.0%. Crystals suitable for X-ray crystallographic analysis were obtained from a sample dissolved in dichloromethane and crystallised by layering with hexane. $C_{11}H_{10}CoI_2N$ (468.831): calcd. H 2.15, C 28.16, N 2.99; found H 2.168, C 28.29, N 2.886. $^1$H NMR ($CDCl_3$): $\delta$ = 7.97 (s, 1 H, =C*H*−N), 7.70 (t, 1 H, =C*H*), 7.16 (d, 1 H, =C*H*), 7.00 (t, 1 H, =C*H*), 5.73 (s, 2 H, Cp), 5.38 (s, 2 H, Cp), 4.09 (s, 2 H, $-CH_2-$) ppm. MS (HiRMALDI): *m*/*z* (%): 341.9 (10.0) [M – I]$^+$. IR (KBr pellet): $\tilde{\nu}_{max}$ = 3090, 2960, 2924, 2858, 1605 (C=N), 1470, 1439, 1417, 1391, 1262, 1151, 1102, 1048, 1021, 846, 764 cm$^{-1}$. UV/

Vis ($CH_3CN$): $\lambda_{max}$ ($\varepsilon$) = 246 ($7.51 \times 10^3$), 286 ($5.28 \times 10^3$), 405 ($6.32 \times 10^2$), 593 ($5.63 \times 10^2$) nm.

**Diiodotriphenylphosphanyl-η$^5$-(2-piperidinioethyl)cyclopentadienylcobalt(III) Iodide ($C_5H_4C_2H_4NHC_5H_{10}CoI_2PPh_3)^+I^-\cdot CH_2Cl_2$ (13):** To a stirred solution of **6** (0.120 g, 0.412 mmol) in dichloromethane (10 mL) was added iodine (0.220 g, 0.887 mmol) in dichloromethane (10 mL) and the resultant mixture was stirred for 4 h. A solution of triphenylphosphane (0.2326 g, 0.885 mmol) in dichloromethane was then added at room temperature. The reaction mixture was stirred continuously for another 24 h under room temperature. The volume of the solvent was reduced in vacuo and hexane was layered over the remaining dichloromethane solution. Brown-black needle-shaped crystals formed several days later and 0.187 g of crystallised product was separated by filtration. Crystals suitable for X-ray crystallographic analysis were obtained. Structural analysis demonstrates that a solvent molecule of dichloromethane is incorporated in the crystal lattice. The resultant product was thus formulated as $(C_5H_4C_2H_4NHC_5H_{10}CoI_2PPh_3)^+I^-\cdot CH_2Cl_2$. Based on this composition, the yield was 47% $^1$H NMR ($CDCl_3$): $\delta$ = 7.23–7.90 (m, 15 H, Ph), 5.45 (s, 2 H, =CH), 5.30 (s, 2 H, C$H_2$Cl$_2$), 4.08 (m, 2 H, −C$H_2$N−), 3.97 (m, 2 H, −NC$H_2$−), 3.93 (s, 2 H, =C*H*), 3.82 (m, 2 H, −NC$H_2$−), 3.00 (m, 2 H, −C$H_2$−), 2.63 (s, 1 H, −N*H*−), 2.34 (m, 2 H, −C$H_2$−), 1.97 (m, 4 H, −C$H_2$−) ppm. IR (KBr pellet): $\tilde{\nu}_{max}$ = 3432, 3054, 2960, 2925, 2854, 1605, 1434, 1379, 1264, 1091, 1026, 800, 741, 697 cm$^{-1}$. UV/Vis ($CH_3CN$): $\lambda_{max}$ ($\varepsilon$) = 232 ($1.65 \times 10^4$), 279 ($7.70 \times 10^3$), 585 ($8.07 \times 10^2$) nm.

**Reduction with CO:** Reaction intermediate **6′** was synthesised in situ. To a solution of **6** (0.157 g, 0.539 mmol) in dichloromethane (0.90 mL) was added iodine (0.141 g, 0.556 mmol) in dichloromethane (0.85 mL) with vigorous stirring for half a minute. The reaction mixture was then transferred to an IR cell which had been flushed with $N_2$ before use. The chamber of the IR cell was fully filled with the reaction mixture and tightly sealed with a Teflon stopper, no empty space was allowed. The first spectrum was measured 2 min after the iodine was added. The carbonyl absorption bands were monitored and the spectra were recorded. Plots of ln*A* vs. *t* for the absorbance of the monocarbonyl intermediate were linear over 2 half-lives [$\log A(2066\ cm^{-1}) = -0.0975 - 6.394 \times 10^{-4} t$, $R_2 = -0.9997$] after 882 s. From a another sample of **6** in dichloromethane, the absorbances of the carbonyl were found to be linear in the concentration range from 0.04 to 0.16 M [$A(2017\ cm^{-1}) = 0.00782 + 5.232(Co^I)$, $R_2 = 0.9999$; $A(1953\ cm^{-1}) = 0.00551 + 4.869(Co^I)$, $R_2 = 0.9999$]. The calculations of the concentrations of the diiodomonocarbonyl intermediate **6′** and the formed dicarbonyl product **6** listed in Table 3 are based on these linear relationships.

Crystallographic data have been deposited at the CCDC, 12 Union Road, Cambridge CB2 1EZ, U.K., and copies can be obtained on request, free of charge, by quoting the publication citation and the deposition numbers CCDC-615490 (for **9**), -615491 (for **10**), -615492 (for **12**) and -615489 (for **13**), respectively.

## Acknowledgments

Support for this work was provided by the National Natural Science Foundation of China, Grant No. 20471016. We also thank Prof. Linhong Weng for her excellent work on the X-ray crystallographic analysis.

# Displacement of Neutral Nitrogen Donors by Chloride in $AuCl_3$(3R-py) (3R-py = *meta*-Substituted Pyridine): Comparison between *meta*- and *para*-Substituted Pyridines by Kinetics and DFT Calculations

**Bruno Pitteri*[a] and Marco Bortoluzzi[a]**

**Keywords:** Gold / Kinetics / Nitrogen donors / Reaction Mechanism / DFT

The kinetics of the process $AuCl_3$(3R-py) + $Cl^- \rightarrow AuCl_4^-$ + 3R-py (3R-py = one of a number of *meta*-substituted pyridines covering a wide range of basicity) have been studied in methanol at 25 °C. The reactions obey the usual two-term rate law observed in the substitution reactions of square-planar complexes. The second-order rate constants, $k_2$, are very sensitive to the nature of the leaving group and plots of $\log k_2$ against the $pK_a$ of the conjugate acids are linear with the same slope of ca. –0.6 already found for *para*-substituted pyridines (4R-py). Until now the two groups of bases have been considered to behave in the same manner in their displacement from $Au^{III}$ and $Pt^{II}$ by various nucleophiles but, on the contrary, the reactivity of the two classes of N donors is slightly different and follows the order: 4R-py > 3R-py. This kinetic result is explained on the basis of an energetic difference between the frontier orbitals of the $AuCl_3$(3R-py) and $AuCl_3$(4R-py) derivatives.

## Introduction

The chemical features of (pyridine)gold(III) complexes are currently of interest from both a catalytic[1] and mechanistic point of view: in particular, the reactivity of gold(III)[2–5] in the reactions with N-donor bases has been widely studied, mainly involving pyridine and substituted pyridines (R-py) as entering or leaving groups. The same types of reactions have also been studied for platinum(II) derivatives[6–10] and it was observed that the substitution reactions (1), (2) and (3) take place with an associative mechanism, where the rate constants for the forward and the reverse reactions obey the general relationship $k_{obs} = k_1 + k_2$[nucleophile], which is usual for nucleophilic substitutions of planar four-coordinate $d^8$ metal complexes.[11]

$$AuCl_4^- + \text{R-py} \rightleftharpoons AuCl_3(\text{R-py}) + Cl^- \quad (1)$$

$$[LPtCl]^+ + \text{R-py} \rightleftharpoons [LPt(\text{R-py})]^{2+} + Cl^- \quad (2)$$

[L = 2,6-bis(methylsulfanylmethyl)pyridine,[5] bis(2-pyridylmethyl) sulfide,[7] 2,2′:6′,2′′-terpyridine,[9] biacetylbis(*N*-methyl-*N*-phenyl)-oxazone[8]]

$$LPtCl_2 + \text{R-py} \rightleftharpoons [LPt(\text{R-py})Cl]^+ + Cl^- \quad (3)$$

[L = 1,2-bis(phenylsulfanyl)ethane[6]]

The $k_1$ term is the first-order rate constant for the nucleophilic attack on the substrate by the solvent, whereas $k_2$ is the second-order rate constant for the nucleophilic attack on the substrate by the nucleophile. The $k_2$ constants are remarkably influenced by the nature of R-py, indicating that the discriminating ability of gold(III) and platinum(II) complexes is good. In both the forward and reverse reactions a linear free-energy relationship, $\log k_2 = \alpha pK_a$ + constant, occurs between the rate constant and the basicity of R-py, that is the $pK_a$ of the conjugated acid $[H(\text{R-py})]^+$. Steric retardation is observed for pyridines containing one or two *ortho* groups (usually called hindered pyridines) and these effects are in many cases approximately additive. Moreover, we studied the kinetics of the reaction $AuCl_3$(nu) + $Cl^- \rightarrow AuCl_4^-$ + nu (nu = five-membered N-donor heterocycles such as thiazole, oxazole, imidazole and their derivatives)[4] and the results were compared, under the same experimental conditions, with studies where the leaving groups are pyridines.[3] It was observed that the reactivity depends not only upon the ligand basicity but also upon the nature of the ligand in the order pyridines > five-membered heterocycles.

In recent work[5] involving reaction (1) we compared the lability of three different groups of N donors: (I) 4-substituted pyridines; (II) 4-substituted pyridines with a more extended π-system; and (III) $sp^3$ nitrogen-donor bases. The first group includes pyridine, 4-bromopyridine, 4-chloropyridine, 4-methylpyridine, 4-methoxypyridine, 4-aminopyridine and 4-(dimethylamino)pyridine, while the second group includes the derivatives of cyanopyridine, isonicotinic acid, methyl isonicotinate and 4-acetylpyridine. The lability

of these pyridines is considerably lower than that of the third group of derivatives, i.e. the $sp^3$ ligands piperidine, cyclohexylamine and morpholine. Pyridines I and II obey the linear relationship $\log k_2 = \alpha pK_a$ + constant with $\alpha \approx -0.6$, but the reactivity of the two groups differ by about 2.3 kJ mol$^{-1}$ in the order: pyridines I > pyridines II. These differences were attributed to a ground-state stabilization due to the π back-donation from the filled orbitals of the metal atom to the antibonding orbitals of the pyridine ligands.

In some kinetic studies involving reactions (1), (2) and (3)[2,3,7,8] *meta*-substituted pyridines (3R-py) were also considered and their reactivity appeared similar to that of group I pyridines, but during our latest work regarding reaction (1),[5] trying to study *meta*-substituted pyridines like 3-methylpyridine and 3-chloropyridine, we found kinetic data that was not completely comparable with those of *para*-substituted pyridines. In order to determine whether these differences have a chemical meaning, the kinetics of the displacement of the nitrogen ligand by chloride from $AuCl_3$(3R-py) substrates in methanol at 25 °C are reported and the results are compared with those of ref.[5] The discussion is supported by ground-state DFT calculations performed on the $AuCl_3$(3R-py) and $AuCl_3$(4R-py) derivatives and the different reactivity of the coordinated *meta*- and *para*-substituted pyridines is correlated with a slight, systematic difference between the energies of the frontier orbitals of the corresponding gold(III) complexes.

## Results and Discussion

When a methanolic solution of the neutral $AuCl_3$(3R-py) substrate was allowed to react with an appropriate excess of chloride, repetitive scanning of the spectrum in the region 240–360 nm showed that the reaction evolves with time in a first-order fashion leading to the substitution of the neutral base by a chloride ion. The presence of well-maintained isosbestic points, whose position depends only upon the spectrum of the starting compound, and the comparison of the final spectrum with that of original samples of the substituted products at the same concentration, clearly indicate a single reaction stage. Addition of $LiClO_4$ indicated that primary salt effects were absent and secondary effects were negligible; thus, no further attempt to maintain a constant ionic strength was made. The reactions were studied in the presence of 0.1 mol dm$^{-3}$ $CH_3SO_3H$. Preliminary experiments showed that, at constant chloride concentration, the rate of reaction was not dependent on the concentration of acid over the range 0.02–0.2 mol dm$^{-3}$. The acid simply serves to protonate the released ligand, to prevent the reverse reaction and to force the reaction to completion. All the reactions were studied in the presence of a sufficient excess of chloride over the substrate to provide pseudo-first-order conditions. It is to be noted that these experimental conditions are the same as those used in ref.[5] The rate constants were determined in the usual way from the change in absorbance as a function of time at a conve-

[a] The indicated errors were obtained from the nonlinear least-squares fit of the experimental data to $D_t = D_\infty + (D_0 - D_\infty)\exp(-k_{obs}t)$ ($D_0$ = absorbance after mixing the reactants, $D_\infty$ = absorbance at completion of reaction). Each experimental measurement was repeated at least twice.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

nient wavelength and the observed rate constants, $k_{obs}$, are collected in Table 1.

The observed rate constants, $k_{obs}$, obey the general relationship $k_{obs} = k_1 + k_2$[nucleophile], usually found for substitution in gold(III) complexes. The $k_1$ terms, which refer to the pathway in which the rate-determining step is the nucleophilic attack of the solvent followed by the rapid entry of chloride into the solvento complex,[12] are usually quite small and contribute little to the reactions. The $k_2$ terms are the second-order rate constants for the direct attack of the nucleophile, $Cl^-$, at the substrate and were determined by a linear regression of the $k_{obs}$ values vs. the chloride concentration. As expected from previous studies on gold(III) substitution reactions,[2–5] the pseudo-first-order rate constant values, $k_{obs}$, mainly depend upon the $k_2$ values, which are reported in Table 2 together with the p$K_a$ values of H[(3R-py)]$^+$ taken from ref.[13]

In Figure 1 the plots of log $k_2$ vs. p$K_a$ of the leaving 3R-py are shown, together with the data for the simple pyridine and the *para*-substituted pyridines 4R-py in the same p$K_a$ range (see ref.[5] for log $k_2$ and p$K_a$ values of these nitrogen donors).

As depicted in Figure 1, a linear relationship, log $k_2$ = αp$K_a$ + constant, is obeyed for both the *meta*-substituted (3R-py) and *para*-substituted (4R-py) pyridines, with $\alpha \approx -0.6$. Coordinated *meta*-substituted pyridines appear to be slightly less reactive than the *para*-substituted ones, even if the difference between the reactivity of the two groups of pyridines is quite small ($\Delta \approx 0.18$) and corresponds to about 1 kJ mol$^{-1}$. The chemical behaviour of the unsubstituted pyridine in its displacement by chloride from $Au^{III}$ is comparable to that of the *para*-substituted pyridines.

To explain the experimental data obtained from the kinetic measurements, ground-state DFT B3PW91 calculations were performed on $AuCl_3$(py), $AuCl_3$(3R-py) and $AuCl_3$(4R-py) derivatives. Particular interest was devoted to the frontier orbitals of the gold complexes and Table 3 reports the energy values of the HOMOs and LUMOs for all

Table 2. Second-order rate constants, $k_2$, and p$K_a$ values of [H(3R-py)]$^+$ for the reaction $AuCl_3$(3R-py) + $Cl^-$ → $AuCl_4^-$ + 3R-py in methanol at 25 °C (0.1 mol dm$^{-3}$ $CH_3SO_3H$).

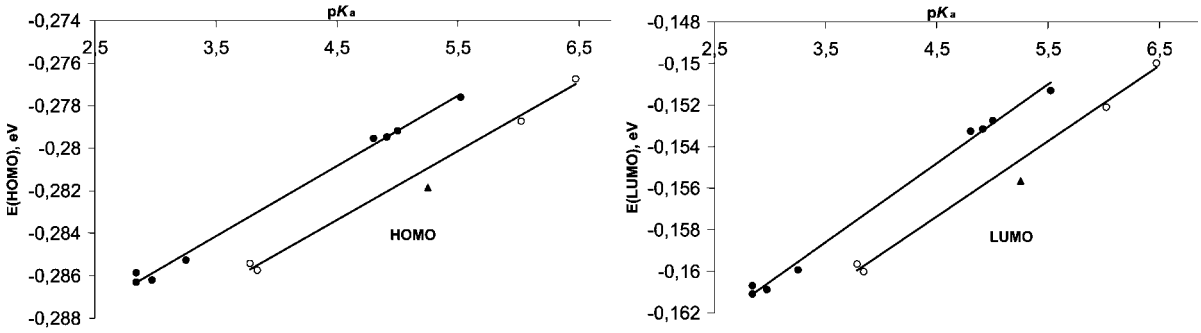

Figure 2. Plots of the (R-py) HOMO and LUMO energies against the p$K_a$ of $[H(R\text{-py})]^+$: (▲) R-py = pyridine; (○) R-py = 4-chloropyridine, 4-methoxypyridine, 4-methylpyridine, 4-bromopyridine; (●) R-py = 3-chloropyridine, 3-bromopyridine, 3-fluoropyridine, 3-iodopyridine, 3-methylpyridine, 3-phenylpyridine, 3-hydroxymethylpyridine, 3-methoxypyridine.

the considered species, while in Figure 2 the plots of HOMO and LUMO vs. p$K_a$ of the leaving 3R-py are shown.

Linear correlations between the frontier orbital energies and p$K_a$ values were found, in particular for the *para*-substituted pyridine (4R-py) derivatives where the equations are $E(\text{HOMO}) = 0.0032 \pm 0.0002\ \text{p}K_a - 0.2979 \pm 0.0008$ and $E(\text{LUMO}) = 0.0036 \pm 0.0002\ \text{p}K_a - 0.1737 \pm 0.0008$, while for the *meta*-substituted pyridine (3R-py) complexes the same equations are $E(\text{HOMO}) = 0.0031 \pm 0.0001\ \text{p}K_a - 0.2957 \pm 0.0004$ and $E(\text{LUMO}) = 0.0038 \pm 0.0001\ \text{p}K_a - 0.1719 \pm 0.0005$. As depicted in Figure 2, the gradients of the plots of the HOMO or LUMO energies vs. p$K_a$ are almost the same for both the 3R- and 4R-pyridines, while there is a significant difference (about 0.002 eV) in their intercepts. The computational results for the pyridine complex $AuCl_3$(py) are comparable to those of the $AuCl_3$(4R-py) derivatives, as was also the case with the chemical behaviour (see Figure 1). The comparison of Figure 1 and Figure 2 appears to indicate a relation between the kinetic and theoretical data, suggesting that the different reactivity of the two groups of ligands considered, 3R-py and 4R-py, could be ascribed to the different energies of the frontier orbitals depicted in Figure 2.

In the reaction studied, i.e. the nucleophilic attack of $Cl^-$ on $AuCl_3$(R-py) and the consequent displacement of the nitrogen ligand, a large role should be played by the lowest unoccupied molecular orbitals of the gold complexes and the filled atomic orbitals of the chloride ion. All the calculated LUMO energy values fall in the range –0.14997 eV to –0.16108 eV and the $AuCl_3$(3R-py) LUMOs are about 0.002 eV higher than those of the $AuCl_3$(4R-py) complexes. The three 3p atomic orbitals of $Cl^-$ have a calculated energy of –0.02709 eV, while the 3s atomic orbital corresponds to an energy value of –0.47949 eV (see Figure 3). On supposing that the observed minor reactivity of the $AuCl_3$(3R-py) complexes, compared to that of the $AuCl_3$(4R-py) derivatives, corresponds to a greater energy difference between the LUMOs of the $AuCl_3$(3R-py) species and the interacting $Cl^-$ atomic orbital, it is to be concluded that the 3s atomic orbital of the chloride ion plays an important role in the nucleophilic attack. Using a pseudo-Valence-Bond description to better explain this last conclusion regarding the reaction studied, $Cl^-$ appears to interact with the gold(III) complexes using a hybrid atomic orbital with a strong s character and, consequently, an energy value lower than those of the LUMOs of the gold complexes, as depicted in Figure 3.

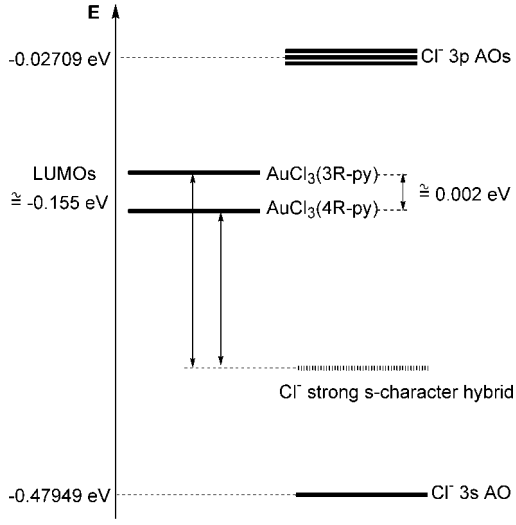

Figure 3. Plot of the $Cl^-$ 3s and 3p AOs and the $AuCl_3$(R-py) (R-py = 3R-py and 4R-py) LUMO energy levels.

## Concluding Remarks

The comparison of the results of the kinetic measurements on the process $AuCl_3(R\text{-py}) + Cl^- \rightarrow AuCl_4^- + R\text{-py}$, where R-py are *para*-substituted pyridines 4R-py and *meta*-substituted pyridines 3R-py, enabled the observation of a slightly different behaviour for these two types of pyridines, the latter type being less reactive. Moreover, by means of DFT calculations the kinetic results were correlated to a small energy difference of the frontier orbitals of the $AuCl_3$(4R-py) and $AuCl_3$(3R-py) derivatives.

## Experimental Section

**Materials:** Compound $KAuCl_4 \cdot 2H_2O$ was prepared from pure gold foil (99.99%). Pure reagent-grade products [LiCl, $LiClO_4$, $CH_3SO_3H$ (Aldrich)] were used without further purification. Pyridines were recrystallized or distilled before use when necessary. Anhydrous MeOH was obtained by distillation from Mg wires, but traces of water did not appear to have any appreciable effect upon the reactions. Acetone and dimethylformamide were pure reagent-grade products (Aldrich and BDH, respectively).

**Instruments:** Electronic spectra and kinetic measurements were obtained with a Perkin–Elmer Lambda 15 spectrophotometer. $^1H$ NMR spectra were obtained with Bruker Avance 300 and/or Bruker AC 200 spectrometers. COSY, NOESY and homonuclear decoupling experiments were performed to improve the characterization of the complexes. The conductivity of $1 \times 10^{-3}$ mol dm$^{-3}$ solutions in dimethylformamide at 25 °C was measured with a Radiometer CDM 83 instrument. Elemental analyses were performed by the Microanalytical Laboratory of the Faculty of Pharmaceutical Sciences of the University of Padua.

**Preparation of the Complexes:** Trichloro(3-methylpyridine)gold(III) was first characterized by Cattalini and Tobe,[3] but the preparation of the complexes of 3-fluoropyridine, 3-bromopyridine, 3-chloropyridine, 3-iodopyridine, 3-phenylpyridine, 3-(hydroxymethyl)pyridine and 3-methoxypyridine is described here for the first time. All the complexes were prepared by the following method: $KAuCl_4 \cdot 2H_2O$ (0.415 g, 1 mmol) was dissolved in water (20 mL) and an equimolar amount of the nitrogen-donor base, dissolved in a small volume of water (3 mL), was added dropwise whilst stirring. The yellow precipitate that formed almost immediately was filtered off, washed three times with water (10 mL) and dried in vacuo. The complexes were nonconductive in organic solvents. Yields were in all cases nearly quantitative (>95%). Analytical and $^1H$ NMR data are collected in Tables 4 and 5, respectively.

**Kinetics:** Reactions were initiated by adding a 0.015 mol dm$^{-3}$ acetone solution (10–20 μL) of the substrate complex, $AuCl_3$(3R-py), to a methanolic solution of chloride ion (3 mL) that had previously been brought to the reaction temperature (25 °C) in a thermostatted cell in the spectrophotometer. The concentration of the entering group was always large enough to provide pseudo-first-order conditions. After preliminary repetitive scan experiments in the range 240–360 nm to search for isosbestic points and spectral changes, the kinetics were studied by measuring the changing absorbance at a suitable wavelength (320 nm) as a function of time. Pseudo-first-order rate constants ($k_{obs}$ [s$^{-1}$]) were obtained either from the gradient of plots of $\log(D_t - D_\infty)$ vs. time or from a nonlinear least-squares fit of the experimental data to $D_t = D_\infty + (D_0 - D_\infty)\exp(-k_{obs}t)$, where $D_0$, $D_\infty$ and $k_{obs}$ are the parameters that have to be optimized ($D_0$ = absorbance after mixing the reactants, $D_\infty$ = absorbance at completion of reaction).

**Computational Details:** The computational geometry optimizations of the $AuCl_3$(3R-py) and $AuCl_3$(4R-py) complexes were performed in vacuo using the hybrid DFT B3PW91 method[14] without sym-

Table 4. Analytical data for the complexes (calcd. values in parentheses).

| Complex | C | H | N | Cl |
|---|---|---|---|---|
| $AuCl_3$(3-fluoropyridine) | 15.2 (15.0) | 1.27 (1.01) | 3.51 (3.50) | 26.5 (26.6) |

metry constraints, in combination with the polarized, single-ζ core, triple-ζ valence 6-311G** basis set on the elements of the first rows of the periodic table and the ECP-based SDD basis set on Au and I.[15] The "restricted" formalism was applied in all calculations. All the resultant stationary points were characterized as true minima (i.e. no imaginary frequencies). A B3PW91/6-311+G** calculation (the same was used for the complexes, with the addition of sp diffuse functions) was applied to obtain the energies of the filled atomic orbitals of the chloride ion. All calculations were carried out at CINECA (Centro Italiano di Supercalcolo, Bologna, Italy) using IBM p5-575 computers with 64-bit IBM Power5 processors operating at 1.9 GHz. The software used was the Gaussian 03 program.[16]

## COVER PICTURE

**The cover picture shows** the formation of deeply colored boronate ester polymers by three-component reactions of boronic acids with 1,2,4,5-tetrahydroxybenzene and dipyridyl compounds. The strong color of the polymers is due to efficient intrastrand charge transfer excitations from the tetraoxobenzene to the dipyridyl linker. Upon dissolution of the polymers in hot chloroform, most of the B−N connections are broken, which indicates that polymer formation is a reversible process. More details on these reactions are described in the article by K. Severin et al. on page 5177ff.

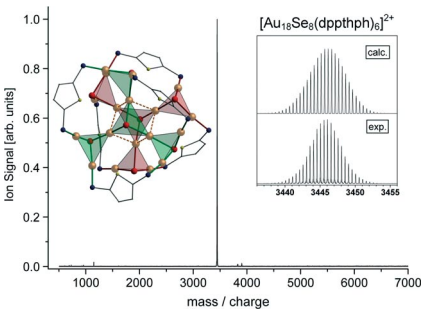
Synthesis, Characterization and Quantum Mechanical Calculations of $[Au_{18}Se_8(dppthph)_6]Cl_2$

**Keywords:** luster complexes / SCS-MP2 calculations / FT-ESI mass spectrometry / Gold / Photoluminescence measurements / Selenium



ESI MS demonstrates that in the gas phase the dimeric cation in $[Au_{18}Se_8(dppthph)_6]Cl_2$ is stabilized by six aurophilic Au···Au interactions. SCS-MP2 calculations predict a height of the Coulomb barrier for symmetric dissociation into two $[Au_9Se_2(dppthph)_3]^+$ subunits of 122 kJ/mol. In the solid state the compound crystallizes in two differently colored modifications.

### Haptotropic Rearrangement

## COVER PICTURE

**The cover picture shows** the formation of deeply colored boronate ester polymers by three-component reactions of boronic acids with 1,2,4,5-tetrahydroxybenzene and dipyridyl compounds. The strong color of the polymers is due to efficient intrastrand charge transfer excitations from the tetraoxobenzene to the dipyridyl linker. Upon dissolution of the polymers in hot chloroform, most of the B−N connections are broken, which indicates that polymer formation is a reversible process. More details on these reactions are described in the article by K. Severin et al. on page 5177ff.

# Synthesis, Characterization and Quantum Mechanical Calculations of $[Au_{18}Se_8(dppthph)_6]Cl_2$

**Paloma Sevillano,[a] Olaf Fuhr,[a] Oliver Hampe,[a] Sergej Lebedkin,[a] Christian Neiss,[a] Reinhart Ahlrichs,[a,b] Dieter Fenske,*[a,c] and Manfred M. Kappes[a,b]**

**Keywords:** Cluster complexes / SCS-MP2 calculations / FT-ESI mass spectrometry / Gold / Photoluminescence measurements / Selenium

The reaction of [Au(tht)Cl] (tht = tetrahydrothiophene) with 2,5-bis(diphenylphophanyl)thiophene (dppthph) and Se-$(SiMe_3)_2$ leads to the formation of $[Au_{18}Se_8(dppthph)_6]Cl_2$. This compound crystallizes in two modifications, both containing a cluster dication with nearly identical gold–selenium cores. The dication consists of two subunits only connected by six aurophilic interactions. ESI MS demonstrates that these facilitate cohesion of the cluster subunits even in the gaseous state. SCS-MP2 calculations show that the dimer is a metasable species, which is ultimately prevented from dissociation by a Coulomb barrier. In addition, photoluminescene measurements demonstrate that the small differences in the ligand shell of the cluster molecules lead to different photoluminescene properties of the two modifications. (© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2007)

## Introduction

During the last years much attention has been paid to the rich chemistry of ligand-stabilized gold-containing clusters, which has been extensively studied.[1,2] In previous works, we have reported about different gold cluster compounds containing elements from the groups 15 and 16. While the compounds containing selenium bridges seem to favor species containing 10 or 18 gold atoms, with $Au_3Se$ fragments as building blocks of the larger structures,[2a–2d] the clusters containing phosphorus and arsenic bridges show more versatile arrangements containing 10, 12, 17, 18 or 19 gold atoms and different building blocks like $Au_4P_2$, $Au_4As_2$ or $Au_7P_2$ in $[Au_{12}(PPh)_2(P_2Ph_2)_2(dppm)_4Cl_2]Cl_2$, $[Au_{17}(As\mathit{n}Pr)_6(As_2\mathit{n}Pr_2)(dppm)_6]Cl_3$ and $[Au_{18}(P)_2(PPh)_4(PHPh)(dppm)_6]Cl_3$, respectively.[2e–2g] In all these compounds, the building blocks are bridged by the diphosphane ligands with the length of their carbon chains being a determining factor affecting the final geometry of the cluster compound. In this work we report the synthesis and characterization of the compound $[Au_{18}Se_8(dppthph)_6]Cl_2$ (**1**) [dppthph = 2,5-bis(diphenylphosphanyl)thiophene].

## Results and Discussion

The reaction of the gold(I) complex [Au(tht)Cl] (tht = tetrahydrothiophene), the phosphane dppthph and Se-$(SiMe_3)_2$ leads to the formation of the compound $[Au_{18}Se_8(dppthph)_6]Cl_2$ (**1**). It crystallizes in two different space groups, $P\bar{1}$ (**1a**) and $P2_12_12_1$ (**1b**), which results in crystals with different appearance and colors: yellow rectangular plates and orange highly faceted hexagonal blocks, respectively (Scheme 1).

$$[Au(tht)Cl] + dppthph + Se(SiMe_3)_2 \xrightarrow{CH_2Cl_2} [Au_{18}Se_8(dppthph)_6]Cl_2\ (\mathbf{1a}\text{ and }\mathbf{1b})$$

Scheme 1. Preparation reaction of compound **1**.

Single-crystal X-ray analysis has been carried out for **1a** and **1b**. The results are shown in Figure 1.[3] Figure 1a shows a superposition of the $[Au_{18}Se_8(dppthph)_6]^{2+}$ cations in **1a** (blue) and **1b** (orange) indicating that the Au–Se cores are nearly identical concerning bond lengths and angles. One main difference in the molecular structures of **1a** and **1b** is the different orientation of the thiophene rings of the phosphane ligands (also the orientations of the phenyl rings – not shown in Figure 1 – differ, probably due to packing effects). Figure 1b shows a labelled model of the cation in **1a**. It consists of two separate $[Au_9Se_4(dppthph)_3]^+$ subunits, each of which is formed by four corner-sharing trigonal $Au_3Se$ pyramids (red and green polyhedra). This arrangement is typical for cluster compounds of the composition $[Au_{18}E_8(dppthph)_6]^{2+}$ (E: chalcogen; dppx: bidentate phosphane).[2a,4] All gold atoms in **1a** are almost linearly coordinated (bond angles between 167.5° and 177.2°) either by two selenium atoms or by one selenium atom and one phosphorus atom of the dppthph ligands. In the inner part of the cluster there are six relatively short Au···Au distances [294.5(1)–301.1(1) pm; indicated by dashed lines in Figure 1b] between gold atoms of different subunits (Au1–Au3

and Au10–Au12) forming an $Au_6Se_2$ heterocubane-like motif. A view from a different angle (Figure 1c, Au···Au not drawn) shows that there is no additional chemical bond between the two $[Au_9Se_4(dppthph)_3]^+$ fragments. In contrast to all other $\{[Au_9E_4(dppx)_3]\}_2^{2+}$ cations published so far, the two subunits in **1** are not interconnected in a catenane-like way. For comparison Figure 1d shows an analogous drawing of the core of $[Au_9Se_4(dppe)_3]_2^{2+}$ [dppe = bis(diphenylphosphanyl)ethane][2a] demonstrating the catenation of the two $[Au_9Se_4(dppe)_3]^+$ cations. Because of this significant difference it was particularly intriguing to employ electrospray mass spectrometry to gain insight into the relative stability of this dication. More specifically, we wondered whether this cluster dication can be observed both in solution and in the gas phase, what the possible fragmentation pathways are {e.g. scission into two singly charged $[Au_9Se_4(dppthph)_3]^+$ ions driven by Coulomb repulsion?} and how they compare to the related cluster $[Au_{18}Se_8(dppe)_6]^{2+}$ in which the two catenated $Au_9Se_4$ subunits are further clamped together by the bidentate ligands.[2a]

Figure 2 displays a positive-ion FT-ICR mass spectrum obtained upon electrospraying a solution of **1**: The virtually only ion signal obtained is found at $m/z \approx 3446.1$. On the basis of the exact mass and the isotopomer distribution (see inset in Figure 2) it can be clearly identified as the doubly charged species $[Au_{18}Se_8(dppthph)_6]^{2+}$. The stability of this

Figure 1.  © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

species was studied by means of collision-induced dissociation in the ICR cell of the FT mass spectrometer. Figure 3 shows the fragmentation mass spectra of the isolated parent ion $[Au_{18}Se_8(dppthph)_6]^{2+}$ at two different collision energies. At low collision energy – i.e. when fragmentation sets in and becomes observable – sequential loss of two dppthph ligands is observed (upper trace in Figure 3) without impairing the cluster's framework or charge. At somewhat higher collision energies (see lower trace of Figure 3) the framework of the cluster dication undergoes asymmetric scission according to Scheme 2.

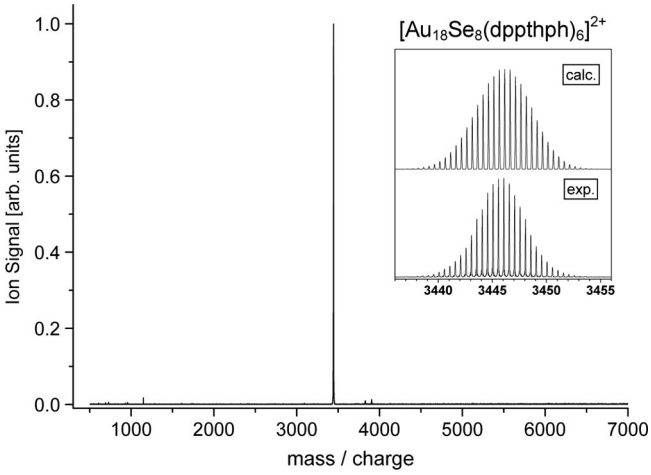

Figure 2. Positive-ion FT-ICR mass spectrum from an electrosprayed solution of **1**. The inset contrasts the experimental high-resolution signal at $m/z \approx 3446$ to the calculated isotopomer distribution for $[Au_{18}Se_8(dppthph)_6]^{2+}$.

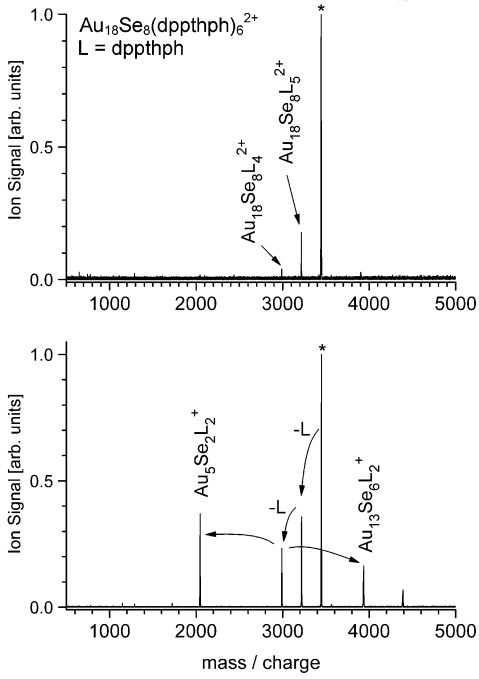

Figure 3. CID fragmentation spectra of the parent ion $[Au_{18}Se_8(dppthph)_6]^{2+}$ (marked with an asterisk) at low (upper trace) and high (lower trace) collision energies.

$$[Au_{18}Se_8(dppthph)_5]^{2+} \rightarrow [Au_{13}Se_6(dppthph)_3]^{+} + [Au_5Se_2(dppthph)_2]^{+}$$

$$[Au_{18}Se_8(dppthph)_4]^{2+} \rightarrow [Au_{13}Se_6(dppthph)_2]^{+} + [Au_5Se_2(dppthph)_2]^{+}$$

Scheme 2. Fragmentation channels observed upon collision-induced dissociation of isolated dications of **1** after loss of one and two dppthph ligands.

This is an intriguing result: Despite the two excess charges on the cluster and the known strong gold–phosphane bond,[5] loss of two neutral ligands is the primary (and therefore presumably energetically lowest-lying) fragmentation pathway before the cluster core dissociates at higher excess collision energies – presumably involving scission of the $Au_6Se_2$ heterocubane unit.

This observation and the rather small Au–Au average distance of 297 pm in the core immediately point towards a strong aurophilic interaction as discussed by, e.g., Schmidbaur[1a–1l] or Pyykkö[6] in detail. We investigated this question further by carrying out molecular electronic structure calculations. In a first attempt, the structures of the cluster **1b** (= dimer) and the monomer (= $[Au_9Se_4(dppthph)_3]^{+}$) were optimized by the density functional theory (DFT) level of theory, which predicted the cluster to be energetically unstable, with the monomers favored by 21 kJ/mol.[7] It is well known, however, that DFT is not able to describe van der Waals type interactions (to which aurophilic interactions belong) properly, and thus, DFT cannot be regarded reliable in this case.

Therefore, we investigated the bonding conditions adopting the SCS-MP2 (spin-component scaled Møller–Plesset perturbation theory of second order) level of theory as proposed by Grimme,[8] which gives more reliable results for gold cluster compounds than ordinary MP2,[9] which is known to overbind van der Waals complexes in general. In this part of the study we considered only the heterocubane core $(Au_3Se)_2^{2+}$ as illustrated in Figure 4, and computed the potential energy surface for pulling apart the two $Au_3Se^{+}$ subunits, which is also shown in Figure 4. Au–Se bond lengths and bonding angles were kept fixed to match the experimental ones.[10] With this simple model, we obtained a quite typical curve for the dissociation of multiply charged ions, revealing a Coulomb barrier height of 122 kJ/mol for symmetric dissociation with respect to the cluster. The minimum energy distance between the Se atoms is located at 476 pm and matches the experimentally observed result (crystal structure: **1a**: 478 pm, **1b**: 492 pm). The transition-state area is found to be around 680 pm. Moreover, the SCS-MP2 calculations support the finding of the DFT calculations that the dimer is only metastable with respect to the monomers, namely 102 kJ/mol, i.e. even more than predicted by DFT (albeit for a larger dication). To conclude, the observed stability of the cluster core is due to aurophilic interactions which are accompanied by a relatively high Coulomb barrier.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

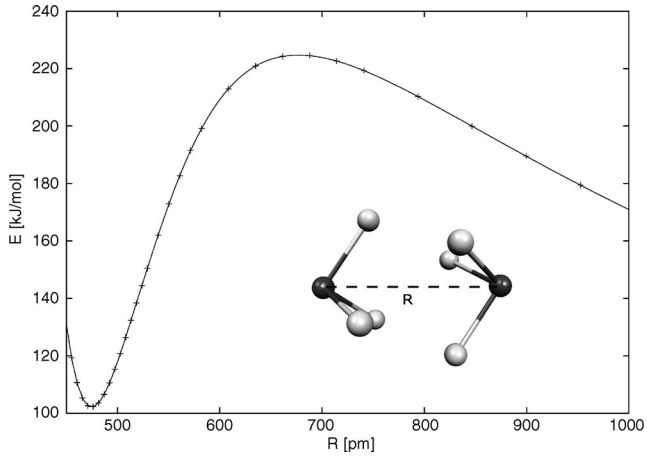

Figure 4. Potential energy surface for the symmetric dissociation and picture of the $(Au_3Se)_2^{2+}$ model complex at the SCS-MP2/QZVPP level of theory. The energy is relative to the completely separated monomers.

In accordance with the structural similarity of the two crystal modifications of **1**, we measured virtually identical FT-Raman spectra of **1a** and **1b**, particularly in the frequency range of $\geq 500\ cm^{-1}$, which is likely dominated by vibrational modes of the dppthph ligands. On the other hand, photoluminescence (PL) spectroscopy evidenced notable differences in the electronic structure and relaxation dynamics of **1a** and **1b**. Both crystals exhibited red emission under illumination in the UV/Vis spectral range, however, with distinct PL excitation (PLE) and emission spectra as shown in Figure 5. The emission maxima of **1a** and **1b** underwent uneven blueshifts from 647 and 660 nm, respectively, to 630 and 625 nm, respectively, by decreasing the temperature from 293 to 15 K (Figure 5). The PLE spectrum of **1b** is weakly structured as compared to **1a** and shows an additional shoulder at ca. 550–580 nm. The differences in the PLE spectra are consistent with the distinctly perceived colors of **1a** and **1b** (see above). PL quantum efficiency, $\phi_{PL}$, of **1a** and **1b** at ambient temperature was only $(3–4)\times10^{-2}$ and $(4–6)\times10^{-3}$, respectively, but it significantly increased by decreasing the temperature (Figure 5). The changes in $\phi_{PL}$ roughly correlate with the timescale of the PL decay (well fitted with biexponential curves). The latter occurred within tens (**1b**) and hundreds (**1a**) of nanoseconds at ambient temperature and slowed down to several microseconds at 15 K. The above deviations in the PL properties may be tentatively attributed to the different orientation of the ligands and "packing" of the cluster units in **1a** and **1b** and, correspondingly, to differences in the vibronic properties between them. In this context, the crystal modifications of **1** appear to be an interesting object for further comparative experimental and theoretical studies.

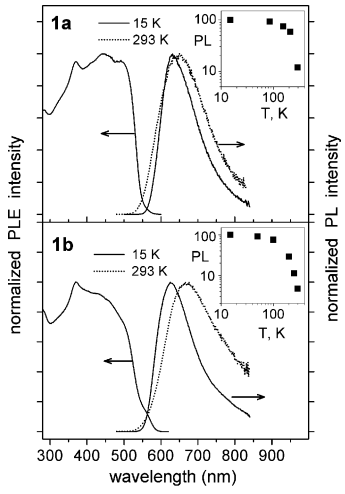

Figure 5. Normalized photoluminescence excitation (PLE) and emission (PL) spectra of crystals of **1a** (top) and **1b** (bottom) in nujol mull. The emission and excitation wavelengths for the PLE and PL spectra are 650 and 400 nm, respectively. The inserts show the temperature dependence of the integrated PL intensities.

## Conclusions

This report focuses on the aurophilic interactions in the dication $[Au_{18}Se_8(dppthph)_6]^{2+}$. In the solid state the compound $[Au_{18}Se_8(dppthph)_6]Cl_2$ crystallizes in two modifications (**1a** and **1b**) in which the cations have nearly identical cores but different orientations of the thiophene and phenyl groups in the ligand shell. This results in differences in the solid-state PL and PLE spectra of the two modifications. The dication in **1** consists of two $[Au_9Se_4(dppthph)_3]^+$ units interconnected by six aurophilic Au···Au contacts (av. distance 289 pm). These are strong enough to stabilize the dimeric cation even in the gas phase which was demonstrated by ESI MS. By SCS-MP2 calculations the height of Coulomb barrier for symmetric dissociation can be approximated as 122 kJ/mol.

## Experimental Section

**General:** All experiments regarding the synthesis were carried out under dry nitrogen. $CH_2Cl_2$ was dried with $P_2O_5$ and *n*-pentane with $LiAlH_4$. $Se(SiMe_3)_2$ was synthesized from $Me_3SiCl$ and $Na_2Se$ according to a published method.[11] [Au(tht)Cl] (tht = tetrahydrothphhene) was prepared according to standard procedures.[12]

**1:** To a solution of [Au(tht)Cl] (52 mg, 0.162 mmol) in $CH_2Cl_2$ (10 mL), dppthph (37 mg, 0.081 mmol) was added to give a colorless solution. After 30 min of stirring, $Se(SiMe_3)_2$ (0.020 mL, 0.081 mmol) was added to the former solution to give a yellow solution. This solution was layered with *n*-pentane, and a few days later yellow crystals of **1a** and orange crystals of **1b** had formed. For the spectroscopic measurements the crystals were separated manually.

**X-ray Structure Determination:** Data were collected with a STOE IPDS II diffractometer using Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 Å). Structure solution and refinement against $F^2$ were carried out using SHELXS and SHELXL software.[13] Further details are given in ref.[3]

**Mass Spectrometry:** Mass spectra were taken with a Fourier transform ion cyclotron resonance (FT-ICR) mass spectrometer (Bruker Daltonics, APEX II) equipped with a 7 T magnet and an electrospray ionization source (Analytica of Branford) with a set of home-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

built rf ion optics for improved sensitivity. Solutions from hand-picked crystals containing **1a** in dichloromethane ($CH_2Cl_2$) were prepared and sprayed using nitrogen as nebulizing gas at a flow rate of 300 μL/h. The desolvation capillary was typically heated to about 80 °C. Collision-induced dissociation was performed employing resonant dipolar rf excitation of the parent ion to variable kinetic energies in the ICR cell and using argon as collision gas at a typical pressure of $3 \times 10^{-7}$ mbar.

**Photoluminescence Spectroscopy:** Photoluminescence spectra of nujol mulls of crystals of **1a** and **1b** were measured with a Spex Fluorolog-3 spectrometer equipped with a closed-cycle optical cryostat (Leybold) operating at 15–293 K. Emission spectra were corrected for the wavelength-dependent response of the spectrometer.[2b] An integrating sphere was applied to estimate the PL quantum efficiency of **1a** and **1b** at ambient temperature according to a procedure described in ref.[2b] Emission decay traces were recorded using an $N_2$ laser (337 nm, ≤ 4 ns) for a pulse excitation.

**Calculations:** All calculations were carried out with the TURBOMOLE program suite.[14] Geometry optimizations[15] of the cluster and the monomer were performed by adopting the TPSS[16] density functional in combination with the def2-TZVP basis sets from the TURBOMOLE library and the RI-J approximation.[17] The reported potential energy surface was scanned at the SCS-MP2 level of theory[18] with the def2-QZVPP basis sets.[19] Basis set incompleteness problems were considered by adopting counterpoise corrections (to avoid basis-set superposition errors) and basis-set extrapolation on selected points of the potential surface, but it was found that these effects approximately cancel each other for the above-mentioned basis set. A relativistic small core pseudo potential for gold was used throughout.[20]

# Ring-Slipped (2,2′-Bipyridine)($\eta^3$-cyclopentadienyl)($\eta^5$-cyclopentadienyl)-vanadium(II) and Its Oxidation to (2,2′-Bipyridine)bis($\eta^5$-cyclopentadienyl)-vanadium(III) Tetraphenylborate

**Markus Jordan,[a] Wolfgang Saak,[a] Detlev Haase,[a] and Rüdiger Beckhaus*[a]**

**Keywords:** Coordination modes / Vanadium / Oxidation / Metallocenes / 2,2′-Bipyridine / Haptotropic rearrangement

Reaction of vanadocene(II) (**4**) with 2,2′-bipyridine (**5**) leads to (2,2′-bipyridine)vanadocene(II) (**6**), exhibiting a $\eta^3$,$\eta^5$-metallocene unit, proved by X-ray diffraction. By selective one-electron oxidation employing $[Cp_2Fe]BPh_4$ salts, the cationic (2,2′-bipyridine)vanadocene(III) derivative **7** is formed. It is characterized by a classical bent bis($\eta^5$-cyclopentadienyl)vanadium(III) structure. Characteristic structural details comparing changes in the oxidation states are discussed. The ring-slip parameters are compared to those of tungsten and other vanadium complexes.

## Introduction

Since the synthesis and characterization of ferrocene by Fischer and Wilkinson in 1952 the cyclopentadienyl unit has become one of the most important ligands in organometallic chemistry.[1,2] In addition to the common $\eta^5$-coordination mode (a), $\eta^3$- (b), $\eta^1$- (c), ionic (d) and bridging forms (e) are known (Figure 1).[3]

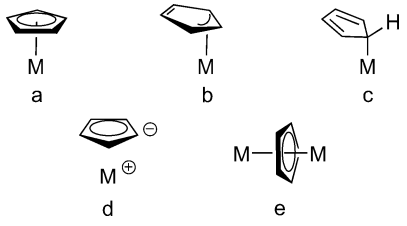

Figure 1. The most common of about ten bonding modes of the Cp ligand: (a) $\eta^5$, (b) $\eta^3$, (c) $\eta^1$, (d) ionic, (e) bridging.

Bonding modes of special interest are $\eta^3$-Cp and $\eta^1$-Cp due to their interconversion chemistry, the so-called "ring slippage".[3] Whereas the first $\eta^1$-Cp transition-metal complex was reported only three years after the characterization of ferrocene,[4] the $\eta^3$-coordination mode was discussed for several years. Generally, Cp-ligand isomerizations often play a significant role in the chemistry of their metal complexes.[5] Prominent examples of ring-slipped compounds are given in the case of complexes exhibiting an electron excess (> 18) like dicarbonyl($\eta^3$-cyclopentadienyl)($\eta^5$-cyclopentadienyl)tungsten (**1**),[6] or particularly for indenyl complexes such as those shown in Figure 2.[7]

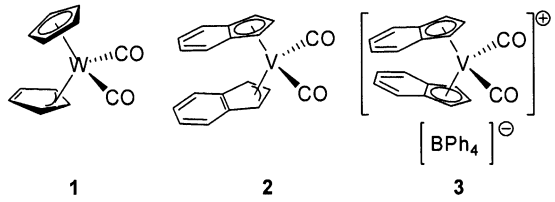

Figure 2. Prominent examples of stucturally characterized ring-slipped complexes: dicarbonyl($\eta^3$-cyclopentadienyl)($\eta^5$-cyclopentadienyl)tungsten (**1**),[6] dicarbonyl($\eta^3$-indenyl)($\eta^5$-indenyl)vanadium(II) (**2**)[7a] and the oxidized "non-slipped" form dicarbonylbis($\eta^5$-indenyl)vanadium(III) tetraphenylborate (**3**).[7b]

On the other hand, due to their electronic and steric versatility, aromatic *N*-heterocycles play an important role as classical ligands in coordination chemistry,[8] as bridging ligands in binuclear derivatives[9] and as building blocks for supramolecular compounds.[10] Beyond their capability to connect metal centres by forming ligand-to-metal bonds, they provide the opportunity of π-backbonding and thereby may affect delocalization and transport of electrons.[11] We have investigated the behaviour of bis(azine)s in the coordination sphere of low-valent titanium complexes, leading to bi-,[12] tri-,[12a,13] tetra-[12a,14] and up to octanuclear derivatives,[12a] accompanied by spontaneous C–C coupling reactions resulting from the strong reducing properties of titanium(II).[12a,13] Here we wish to report an example of the behaviour of 2,2′-bipyridine in the coordination sphere of vanadium(II) and vanadium(III). Floriani et al. described the formation of a [$Cp_2$V(2,2′-bipyridine)] derivative. However, because of the lack of structural data the authors assumed a monodentate coordination mode for the 2,2′-bipyridine ligand (17e$^-$ complex) (Figure 3).[15]

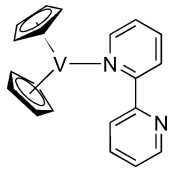

Figure 3. Assumed structure of [$Cp_2V$(2,2-bipyridine)] by Floriani et al.[15]

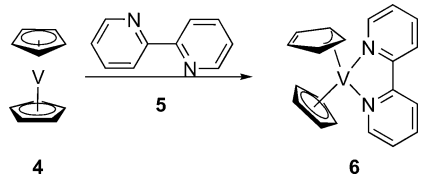
## Results and Discussion

First at all, we reproduced the reaction of vanadocene(II) (**4**) and 2,2′-bipyridine (**5**)[15] extended by the structural characterization of the reaction product **6**. In contrast to the proposed monodentate structure, the 2,2′-bipyridine ligand was found to act as a typical chelating unit. Additionally, one of the Cp rings exhibit an η³-coordination mode (ring slippage) (Scheme 1). Upon oxidation of complex **6** by ferrocenium tetraphenylborate, the Cp ring flips back to η⁵-coordination to form (2,2′-bipyridyl)bis(η⁵-cyclopentadienyl) vanadium(III) tetraphenylborate (**7**) (Scheme 2). A number of slip parameters were applied to these structures, and the results were compared with given examples of ring-slipped complexes such as **1** and **2**.



Scheme 1. Formation and structure representation of compound **6**.

### Synthesis and Characterization of (2,2′-Bipyridine)(η³-cyclopentadienyl)(η⁵-cyclopentadienyl)vanadium(II) (6)

Vanadocene(II) (**4**) and 2,2′-bipyridine (**5**) were dissolved in *n*-hexane, and the solution was stirred at room temperature overnight. The colour of the solution changed immediately from violet to black. The solution was cooled to –70 °C, and complex **6** precipitated in form of black crystals (53%).

Suitable crystals for X-ray diffraction became available by crystallization at –16 °C. Complex **6** crystallizes in the space group $R\bar{3}$; the trigonal unit cell contains 18 molecules of the compound. X-ray diffraction of these black flat prisms confirmed the bidentate chelate ligation of the 2,2′-bipyridine (**5**). However, one of the Cp rings offered only η³-coordination. This should be necessary to confirm the 18e⁻ rule in **6**. If both Cp rings were η⁵-coordinated, the complex would contain 19 electrons. With one η³-coordinated Cp ring, the preferred 17e⁻ structure of **6** was formed. The ORTEP plot (Figure 4) significantly shows the slippage of one Cp ring with respect to the other.

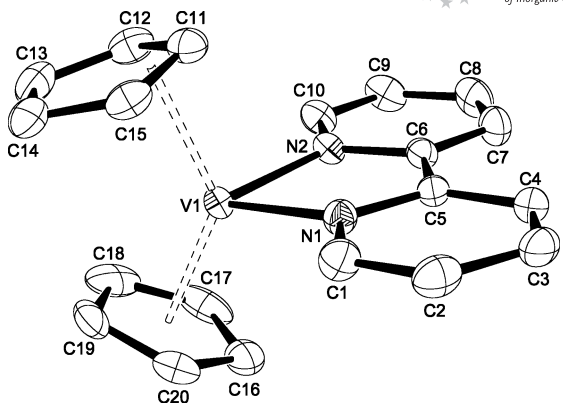


Figure 4. ORTEP plot of the solid-state molecular structure of compound **6**. Hydrogen atoms are omitted for clarity; thermal ellipsoids are drawn at the 50% probability level. Selected bond lengths [Å] and angles [°]: V1–N1 2.036(1), V1–N2 2.053(1), C5–C6 1.423(2), V1–Ct 2.01, N–V–N 76.89(5).

Furthermore the C11 atom slightly turns out of the plane formed by C12–C15 to distort the otherwise rather aromatic planar Cp ring to an envelope-like conformation. The angle $\Omega$ between plane C12–C13–C14–C15 and plane C11–C12–C15 is 8.3° and is defined by Faller, Crabtree and Habib as one of a number of slip parameters (Figure 5).[16]

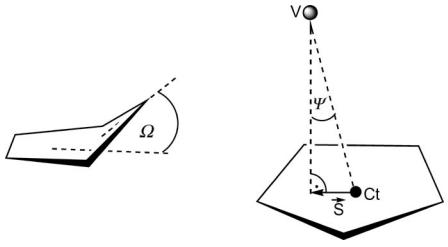

Figure 5. Graphical definition of the dihedral angle $\Omega$, the slip vector $\vec{S}$, whose norm is the slip distortion $\Delta$, and the angle slip $\Psi$, which is the angle between the plane normal and the centroid–metal vector.

This distortion seems to be typical for η³-coordinated cyclopentadienyl ligands, as can be seen in Table 1.[6,16] In contrast to that, the η⁵-coordinated Cp ring shows an angle $\Omega$ of only 1.2° between plane C17–C18–C19–C20 and plane C16–C17–C20, leading to the expected planarity of a Cp ring.

From the average of the M–C distances a further slip parameter, $\overline{\Delta M–C}$, can be calculated.[16] This parameter is a direct verification for the η³-coordinated Cp ligand. While every carbon atom is almost equidistant from the metal in η⁵-Cp, so that $\overline{\Delta M–C}$ is very small, in η³-Cp two carbons have a significantly elongated distance to the metal centre. This confirms the molecular structure of **6** in which ΔM–C of the η⁵-Cp is 0.04 Å, whereas the η³-Cp has a much higher value of 0.56 Å. Also the slip distortion $\Delta$ and the angle slip $\Psi$ (Figure 5) show clear indications for η³-coordination modes.[16]

For the 2,2′-bipyridine complex **6** and comparable derivatives (**1**,[6]**2**[7a]) selected structural ring-slip parameters are summarized in Table 1.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

Table 1. Slip parameters (see Figure 5) for compounds **6** and **7** and similar complexes.

| Compound | | Slip parameters | | | | Ref. |
|---|---|---|---|---|---|---|
| | | $\Delta = \lvert\vec{S}\rvert$ [Å] | $\Psi$ [°] | $\overline{\Delta M–C}$ [Å] | $\Omega$ [°] | |
| **1** | [$\eta^3$] | 0.928 | 23.4 | 0.62 | 19.7 | [6,16] |
| | [$\eta^5$] | 0.076 | 2.2 | 0.10 | (4.9)[a] | |
| **2** | [$\eta^3$] | 0.798 | 20.9 | 0.56 | – | [7a] |
| | [$\eta^5$] | 0.157 | 4.6 | 0.13 | – | |
| **6** | [$\eta^3$] | 0.876 | 21.9 | 0.56 | 8.3 | [c] |
| | [$\eta^5$] | 0.063 | 1.5 | 0.04 | 1.2 | |
| **7**[b] | [$\eta^5$] | 0.110 | 3.2 | 0.03 | 0.1 | [c] |

[a] The uncertainty for this value is large. [b] Slip parameters of only one Cp were calculated because of the disordering of the others. [c] This work.

The V–N bonds of **6** are shortened relative to the only known (2,2′-bipyridine)vanadocene complex (2,2′-bipyridine)bis($\eta^5$-cyclopentadienyl)vanadium(IV) ditriflate (**8**) of Ghosh et al.,[17] but the shortening of the C5–C6 bond of the 2,2′-bipyridine (**5**) in the complex relative to the free **5**[18] is more significant (Table 2). This shortening suggests the reduced nature of the ligand in complex **6**. In the neutral vanadium(II) complex **6** and the cationic vanadium(III) derivative **7** the bipyridine ligand is nearly located in the equatorial plane (N–V–N) with a deviation of 5.35° (**6**) and 2.25° (**7**), respectively. These values are significantly lower than the corresponding value of 23.09° in [$(Cp)_2$Ti(2,2′-bipyridine)].[19]

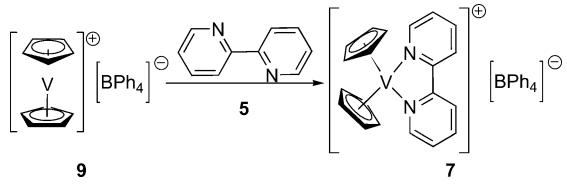
Table 2. Selected bond lengths [Å] for **5**, **6**, **7** and **8**.

| | **5** | **6** | **7** | **8** |
|---|---|---|---|---|
| V1–N1 | – | 2.036(2) | 2.161(2) | 2.129(2) |
| V1–N2 | – | 2.053(1) | 2.165(2) | 2.128(2) |
| C5–C6 | 1.490(3) | 1.423(3) | 1.466(4) | 1.465(4) |

### Synthesis and Characterization of (2,2′-Bipyridine)bis($\eta^5$-cyclopentadienyl)vanadium(III) Tetraphenylborate (7)

Direct oxidation of **6** with ferrocenium tetraphenylborate leads to products that are insoluble in common solvents. So recrystallization of red-violet ionic complex **7** was not successful. In contrast to that, vanadocenium tetraphenylborate (**9**), prepared by the reaction of **4** with ferrocenium tetraphenylborate,[20] is passably soluble in thf. But when **5** was added directly to **9**, an amorphous powder precipitated, too.

A successful procedure is layering of an *n*-hexane solution of **5** on a thf solution of **9** to form large red-violet needles of **7**,which were suitable for X-ray diffraction, in 44% yield at the phase interface (Scheme 2). The ionic compound crystallizes in the monoclinic space group $P2_1/c$; the unit cell contains eight ion pairs and there are two independent ion pairs in the asymmetric unit. Three of four Cp rings in an asymmetric unit are disordered; however, both rings in the cation are $\eta^5$-coordinated as can be seen in the ORTEP plot in Figure 6.



Scheme 2. Formation of compound **7**.

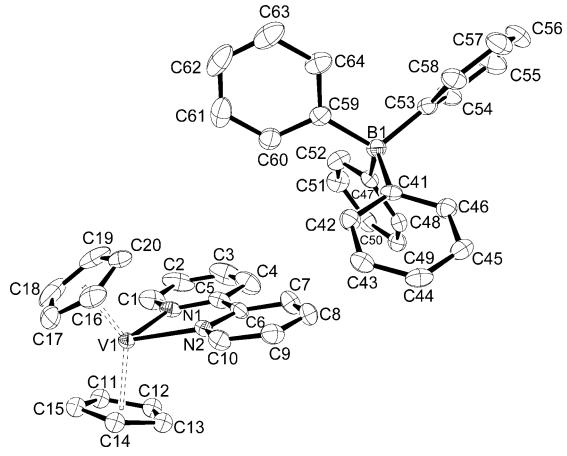


Figure 6. ORTEP plot of the solid-state molecular structure of **7** showing one ion pair of the asymmetric unit with idealized Cp rings, which are disordered in two positions and refined with isotropic coupled displacement parameters. Hydrogen atoms are omitted for clarity; thermal ellipsoids are drawn at the 50% probability level. Selected bond lengths [Å] and angles [°]: V1–N1 2.161(2), V1–N2 2.165(2), C5–C6 1.466(4), V1–Ct 1.95, B1–C 1.66, Ct–V1–Ct 135.4, N1–V1–N2 74.2.

Because of the disordering, the slip parameters for only one Cp ring, which is not disordered, were calculated (Table 1). The parameters are in good accordance with the slip parameters of the $\eta^5$-coordinated Cp rings of the other compounds in Table 1.

The V–Ct distances are insignificantly shorter than those in complex **6** (1.95 Å), but the V–N bonds as well as the connecting C5–C6 bond between the two heterocycles are lengthened relative to those in complex **6** (Table 2). In this case the heterocyclic ligand is not reduced by the metal centre. The V–N bond of **7** is a little longer relative to that in compound **8**, but the C5–C6 bond is almost equal in length (Table 2).[17]

## Conclusions

The reaction of **4** with **5** formed the 17e⁻ chelate complex (2,2′-bipyridine)($\eta^3$-cyclopentadienyl)($\eta^5$-cyclopentadienyl)-vanadium(II) (**6**) with one $\eta^3$-slipped Cp ring to avoid a 19e⁻ complex formation. Upon formal oxidation of **6**, the Cp ring flipped back to an $\eta^5$-coordination mode, forming the ionic 18e⁻ species (2,2′-bipyridine)bis($\eta^5$-cyclopentadienyl)vanadium(III) tetraphenylborate (**7**). To the best of our knowledge this is one of the rare examples of structurally characterized (cyclopentadienyl)vanadium complexes with a structurally verified $\eta^3$-ring-slippage.

## Experimental Section

**Reagents and General Techniques:** All operations were performed in a nitrogen atmosphere with rigorous exclusion of oxygen and moisture by using glovebox and Schlenk techniques. All chemicals used were of reagent grade or higher purity; they were purified according to standard protocols. Solvents were distilled from Na/K alloy and benzophenone under nitrogen. Chemical ionization (CI) mass spectra were taken with a Finnigan-MAT 95 spectrometer. Isobutane was used as the ionization gas. Electrospray ionization (ESI) mass spectra were recorded with a Finnigan-LCQ spectrometer. High-resolution electrospray ionization (HR-ESI) mass spectra were measured with a Micromass Premier quadrupole-time-of-flight (Q-TOF) instrument. IR spectra were recorded with a Bruker VECTOR 22 spectrometer by using KBr pellets. Elemental analyses were carried out by the Analytische Laboratorien GmbH, Lindlar (Germany). Melting points were determined by using a "Mel-Temp" by Laboratory Devices, Cambridge. 2,2′-Bipyridyl (**5**) was purchased from Merck. Vanadocene (**4**)[21] and vanadocenium tetraphenylborate (**9**)[20] were prepared according to literature procedures.

**X-ray Diffraction:** Single-crystal experiments were carried out with a STOE IPDS diffractometer with graphite-monochromated Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 Å). The structures were solved by direct phase determination and refined by full-matrix least-squares techniques against $F^2$ with the SHELXL-97 program system.[22] Crystallographic details are given in Table 3. CCDC-649843 (**6**) and -649844 (**7**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

# One-Pot Synthesis of an Enantiopure N,N,O Scorpionate Ligand Derived from (+)-Camphor

**Johannes Elflein,[a] Florian Platzmann,[a] and Nicolai Burzlaff*[a]**

*Dedicated to Professor Horst Kisch on the occasion of his 65th birthday*

**Keywords:** Chiral pool / Ligand design / Zinc / Rhenium / Camphor

A one-pot synthesis of the new enantiopure heteroscorpionate ligand HOPhbpm$^{3cam}$ (**3**) was described. Ligand **3** was obtained in a pyridine-catalysed Peterson rearrangement starting from camphorpyrazole, thionyl chloride, and salicylaldehyde. $\kappa^2$- and $\kappa^3$-coordination of the ligand was observed, and the ligand was shown to form a tetrahedral zinc complex [Zn-$\kappa^3$-(OPhbpm$^{3cam}$)$CH_3$] (**4**) as well as an octahedral rhenium complex [Re-$\kappa^3$-(OPhbpm$^{3cam}$)$(CO)_3$] (**6**).

## Introduction

During the last decade, various bis(pyrazolyl)methane-based "heteroscorpionate" ligands have been recognised as very versatile ligands for bioinorganic chemistry and organometallics.[1–3] Specifically, several achiral tripodal N,N,O and N,N,S ligands were reported by Carrano and coworkers that can be obtained from 1,1′-carbonylbis(pyrazole) and functionalised aldehydes.[3–5] This cobalt-catalysed reaction, in which $CO_2$ is released, is based on some early reports from the 1970s by Peterson and Thè[6] and was recently modified by Reger to involve aldehyde and 1,1′-sulfinylbis-(pyrazole).[7] First applications of group 4 metal complexes bearing these tridentate heteroscorpionate ligands consist of catalytic ethylene and propylene polymerisation.[8]

## Results and Discussion

Recently, we reported on a rather simple concept based on prochirality that allows us to synthesise enantiopure facially binding tripod ligands from $C_2$ symmetric precursors without any additional separation of enantiomers or diastereomers.[9] $C_2$ symmetry is a feature often used in enantiopure bidentate chelating ligands.[10] In many of these, two identical enantiopure donor groups, Y*, are connected by a tetrahedral bridging atom, for example, an $sp^3$ carbon atom. Any additional group, Z, at this atom will form a prochiral centre rather than an additional stereocentre (Figure 1).[11]

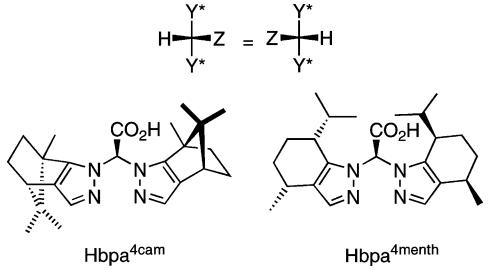

Figure 1. Prochirality in the enantiopure ligands Hbpa$^{4cam}$ and Hbpa$^{4menth}$.[9]

So far, two examples of enantiopure N,N,O tripod ligands based on this concept were published by our group, namely, bis(camphorpyrazol-1-yl)acetic acid Hbpa$^{4cam}$ and bis(menthylpyrazol-1-yl)acetic acid Hbpa$^{4menth}$ (Figure 1).[9] Other bis(pyrazolyl)methane-derived enantiopure tripod ligands were reported by Otero and coworkers recently.[12] Here we report on a one-step synthesis of an enantiopure N,N,O scorpionate ligand HOPhbpm$^{3cam}$ (**3**) derived from (+)-camphor by using a modified version of the Peterson cobalt rearrangement that does not require the cobalt catalyst.

Camphorpyrazole **1** [i.e. (4*S*,7*R*)-7,8,8-trimethyl-4,5,6,7-tetrahydro-4,7-methano-1(2)H-indazole] is an enantiopure pyrazole derived from the chiral pool that can be obtained easily and in high yield in a two-step synthesis starting from (+)-camphor.[13] Reaction of **1** with phosgene to afford 2,2′-carbonylbis(camphorpyrazole) (**2b**) was previously described in a footnote by Rebek and coworkers.[14]

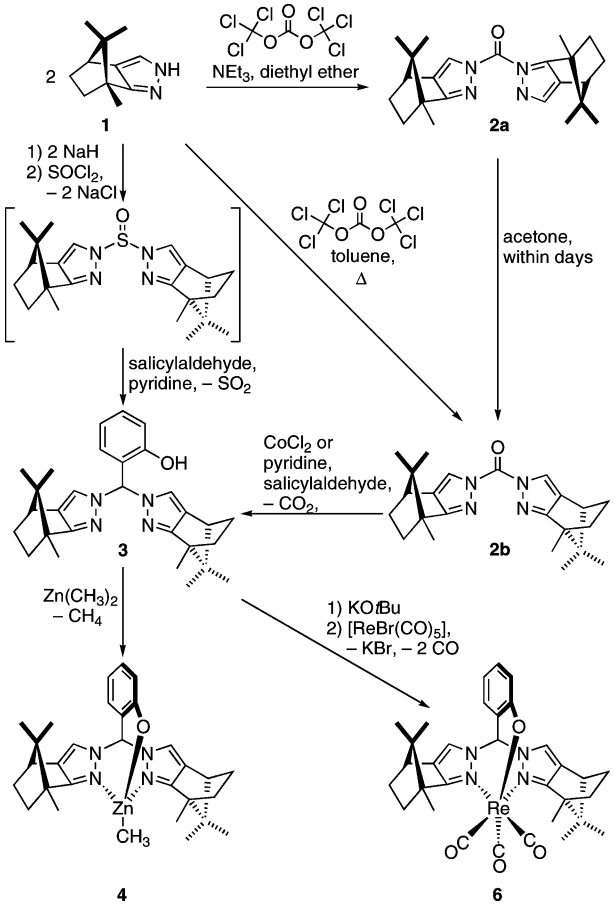
According to a very recent report by Artaud, phosgene can be replaced in such carbonylbis(pyrazole) syntheses by triphosgene.[15] We now found that reaction of **1** with triphosgene and triethylamine first gives the $C_1$ symmetrical isomer of 1,2′-carbonylbis(camphorpyrazole) (**2a**), which is transformed into the $C_2$ symmetrical 2,2′-carbonylbis(camphorpyrazole) (**2b**) upon standing in solution within some days (Scheme 1).



Scheme 1. Synthesis of homochiral heteroscorpionato complexes.

A reaction under reflux in toluene or benzene gives only the desired $C_2$ symmetrical 2,2′-carbonylbis(camphorpyrazole) (**2b**) in very high yield (Scheme 1). An X-ray structure determination of isomer **2b** (Figure 2) allows doubtless differentiation between the two isomers.

Furthermore, only one set of camphorpyrazole signals is observed in the $^1$H and $^{13}$C NMR spectra of **2b**, as to be expected for a $C_2$ symmetric compound, which is in contrast to the two sets of signals observed in the spectra of **2a**.

To test our concept of "prochirality-based" ligands with a new N,N,O tripod ligand, we then synthesised (*o*-hydroxyphenyl)bis(camphorpyrazol-1-yl)methane HOPhbpm$^{3cam}$ (**3**) by applying the cobalt-catalysed Peterson rearrangement of **2b** with salicylaldehyde.[16] Unfortunately, the yield of this reaction was quite erratic; this observation was also

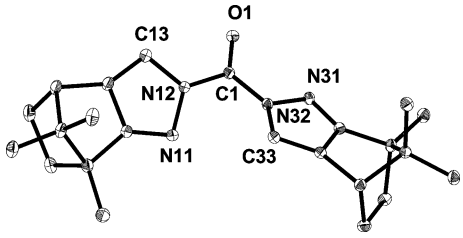


Figure 2. Molecular structure of 2,2′-carbonylbis(camphorpyrazole) (**2b**); thermal ellipsoids are drawn at the 50% probability level; hydrogen atoms are omitted for better clarity. Selected bond lengths [Å] and angles [°]: C1–O1 1.204(2), C1–N32 1.392(3), C1–N12 1.402(3), O1–C1–N32 123.93(19), O1–C1–N12 121.0(2), N32–C1–N12 115.07(18).

made by various other groups who used the Peterson rearrangement for their syntheses. We thus developed an alternative procedure for this reaction to which we were inspired by a publication of Canty and coworkers.[17] They reported on a coupling of 1,1′-carbonylbis(3,5-dimethylpyrazole) and pyridine-2-aldehyde without any cobalt catalyst.[17] Indeed, a similar reaction of **2b**, pyridine and salicylaldehyde yields the ligand (*o*-hydroxyphenyl)bis(camphorpyrazol-1-yl)methane HOPhbpm$^{3cam}$ (**3**) in reproducible yields up to 70% (Scheme 1) without the use of the cobalt catalyst. The synthetic procedure was modified further by us according to the version of Reger for the Peterson rearrangement, which we mentioned above, involving the aldehyde and 1,1′-sulfinylbispyrazole. Thereby, we finally developed a one-pot synthesis for (*o*-hydroxyphenyl)bis(camphorpyrazol-1-yl)methane HOPhbpm$^{3cam}$ (**3**) starting with the reaction of camphorpyrazole (**1**) with sodium hydride and thionyl chloride. Without any further purification, pyridine and salicylaldehyde were added to the resulting 2,2′-sulfinylbis(camphorpyrazole) to yield ligand **3** in yields up to 60%. After the reaction was scaled up, we were able to obtain up to 7 g of enantiopure ligand **3** in one run. Because of the loss of $C_2$ symmetry, the two pyrazole donors are no longer spectroscopically equivalent and two sets of signals in the $^1$H and $^{13}$C NMR spectra are exhibited.

Treatment of ligand **3** with dimethylzinc resulted in very pure monomethylzinc complex [Zn(OPhbpm$^{3cam}$)CH$_3$] (**4**) and methane without any formation of bis(ligand) complex [Zn(OPhbpm$^{3cam}$)$_2$]. In the NMR spectra, the methyl group in **4** ($^1$H NMR: $\delta$ = –0.60 ppm; $^{13}$C NMR: $\delta$ = –14.6 ppm) is observed at high field. This agrees well with the complex [Zn(bpa$^{Me_2,tBu_2}$)CH$_3$] reported recently by us and with the sterically hindered (*o*-hydroxyphenyl)bis(pyrazol-1-yl)methane zinc complex published by Carrano and coworkers.[4d,18]

In an attempt to synthesise the chlorido complex [Zn(κ$^3$-*N*,*N*,*O*-OPhbpm$^{3cam}$)Cl], colourless crystals of [Zn(κ$^2$-*N*,*N*-HOPhbpm$^{3cam}$)(Cl)$_2$] (**5**) were obtained from an acetonitrile solution.

The molecular structure (Figure 3) clearly shows κ$^2$-coordination of the ligand, similar to the achiral complex [Zn(κ$^2$-*N*,*N*-HOPhbdmpzm)(*I*)$_2$] [HOPhbdmpzm: *ortho*-(hydroxyphenyl)bis(dimethylpyrazol-1-yl)methane] recently

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

reported by Carrano and coworkers.[4d] The molecular structure of **5** is proof of the constitution of the HOPhbpm$^{3cam}$ ligand (**3**). It has to be emphasised that in this new ligand the chiral camphorpyrazolyl donors are pointing towards the zinc centre. This is different from our former ligands and makes this ligand a promising candidate for future enantioselective inductions.

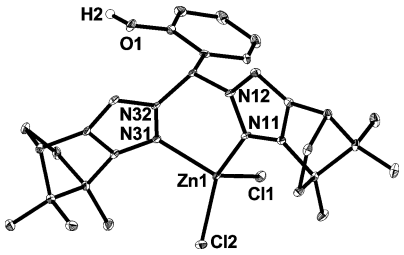

Figure 3. Molecular structure of [Zn(κ$^2$-*N*,*N*-HOPhbpm$^{3cam}$)(Cl)$_2$] (**5**); thermal ellipsoids are drawn at the 50% probability level; most hydrogen atoms are omitted for better clarity. Selected bond lengths [Å] and angles [°]: Zn–Cl1 2.2267(8), Zn–Cl2 2.2293(7), Zn–N11 2.053(2), Zn–N31 2.089(2), Zn–N31–N32 111.92(16), Zn–N11–N12 122.78(17), N11–Zn–N31 94.20(9), N11–Zn–Cl2 108.64(7), N31–Zn–Cl2 119.39(6), N11–Zn–Cl1 112.42(7), N31–Zn–Cl1 107.79(6), Cl2–Zn–Cl1 113.01(3).

Reaction of K[OPhbpm$^{3cam}$] with [ReBr(CO)$_5$] resulted in a complex [Re(OPhbpm$^{3cam}$)(CO)$_3$] (**6**). Elemental analysis, FAB MS [M + H]$^+$ peak and, pursuant to $C_1$ symmetry, three class A carbonyl vibrations at 2018, 1910 and 1881 cm$^{-1}$ indicate κ$^3$-coordination of the ligand and formation of an octahedral complex.

## Conclusions

Chiral modification of the well-established (2-hydroxyphenyl)bis(pyrazol-1-yl)methane ligands leads to the new enantiopure heteroscorpionate ligand (2-hydroxyphenyl)-bis(camphorpyrazol-1-yl)methane HOPhbpm$^{3cam}$ (**3**). This ligand provides similar coordination properties as its achiral analogues, which was proven by the synthesis of a tetrahedral monomethylzinc complex and an octahedral tricarbonylrhenium complex. The simple one-pot synthesis, starting from camphorpyrazole, thionyl chloride and salicylaldehyde, should allow broad application of this and related ligands in coordination chemistry, especially because the achiral analogues have already shown their potential for catalytic processes. Furthermore, it is obvious that in the future a broad spectrum of similar homochiral tripod ligands should be accessible by variations of this one-pot synthesis.

[16] To avoid extraordinarily long abbreviations, the abbreviation system for Tp and benzopyrazolylborate Tp$^{Bo}$ ligands introduced by Trofimenko was transferred to this manuscript. A superscript of 3 preceding "cam" indicates a 3,4-fusion of the camphor group to the pyrazole. This results in the abbreviation HOPhbpm$^{3cam}$ (**3**). For further details see: S. Trofimenko, *Scorpionates – The Coordination Chemistry of Polypyrazolylborate Ligands*, Imperial College Press, London, **1999**, p. 5.

# Formation of Boronate Ester Polymers with Efficient Intrastrand Charge-Transfer Transitions by Three-Component Reactions

Nicolas Christinat,[a] Emmanuel Croisier,[a] Rosario Scopelliti,[a][‡] Michele Cascella,[a] Ursula Röthlisberger,[a] and Kay Severin*[a]

**Keywords:** Boron / Charge transfer / Polymers / Self-assembly

The three-component reaction of aryl boronic acids with 1,2,4,5-tetrahydroxybenzene and 1,2-bis(4-pyridyl)ethylene or 4,4′-bipyridine leads to the formation of dark-purple boronate ester polymers. Crystallographic analyses show that the polymer strands have a zig–zag geometry, and the bis(dioxaborole) units are connected by dipyridyl linkers through dative B–N interactions. Upon dissolution of the polymers in hot chloroform, most of the B–N connections are broken, which indicates that polymer formation is a reversible process. A computational study provides evidence that the strong color of the polymers is due to efficient intrastrand charge-transfer excitations from the tetraoxobenzene to the dipyridyl linker.

## Introduction

Boronic acids are known to easily and reversibly condense with diols to form boronate esters. This type of reaction has been exploited extensively in carbohydrate chemistry where boronic acids are used as an integral part of receptors and sensors or as protecting groups.[1] The reversible formation of boronic esters has also been employed to build complex structures such as macrocycles,[2] dendrimers,[3] helicates,[4] nanotubes,[5] or porous covalent organic frameworks.[6] The labile boron–oxygen bonds are used here in a similar fashion to metal–ligand interactions in supramolecular coordination chemistry. Constitutional dynamic polymers[7] with boronate ester backbones represent another interesting class of compounds. Lavigne and coworkers showed that poly(dioxaborolane)s[8] and poly(dioxaborole)s[9] can be obtained by the condensation of diboronic acids with pentaerythritol or 1,2,4,5-tetrahydroxybenzene.[10] An interesting feature of these polymers is that hydrolytic degradation can be reversed by annealing under vacuum ("self-repairing polymers").[8] The polycondensation of diboronic acids with sugar derivatives as linkers has been investigated by the groups of Shinkai[11] and Shimizu.[12] Again it was found that the polymerization is a reversible process, which depends on the conditions.

An alternative way to generate dynamic polymers with boron centers in the backbone is the polymerization by dative B–N bonds. This was demonstrated by Wagner and coworkers who made polymers by the reaction of the borylated ferrocene [$(C_5H_4BMe_2)_2Fe$] with 4,4′-bipyridine or pyrazine[13] and by the group of Jäkle who assembled polymers with borane end groups by the reaction with 4,4′-bipyridine.[14,15] In the following we show that boronic acid–diol condensations can be used *in parallel* with dative B–N interactions to generate novel polymer architectures by three-component reactions. The resulting crystalline polymers are deeply colored due to efficient intrastrand charge-transfer transitions.

## Results and Discussion

To evaluate the possibility to generate boronate polymers with ditopic N-donor ligands, we heated a mixture of 1,2-bis(4-pyridyl)ethylene, two equivalents of 4-ethylphenylboronic acid, and one equivalent of 1,2,4,5-tetrahydroxybenzene in benzene with the use of a Dean–Stark trap. A slightly yellow solution was obtained, from which, upon cooling, a dark-purple solid (**1**) precipitated (Scheme 1). A similar behavior was observed when 4-*tert*-butylphenylboronic acid was employed: when the hot benzene solution was cooled, a dark precipitate formed (**2**).

At room temperature, products **1** and **2** were found to display low solubility in common organic solvents such as benzene, chloroform, acetonitrile, and tetrahydrofuran. Upon heating, however, it was possible to dissolve them in chloroform. This process was accompanied with a strong change in color: the dark-purple solids gave rise to weakly yellow solutions. When the hot chloroform solutions were cooled to room temperature, the purple polymers started to precipitate after a few minutes, which indicated that the color change was due to a reversible process.

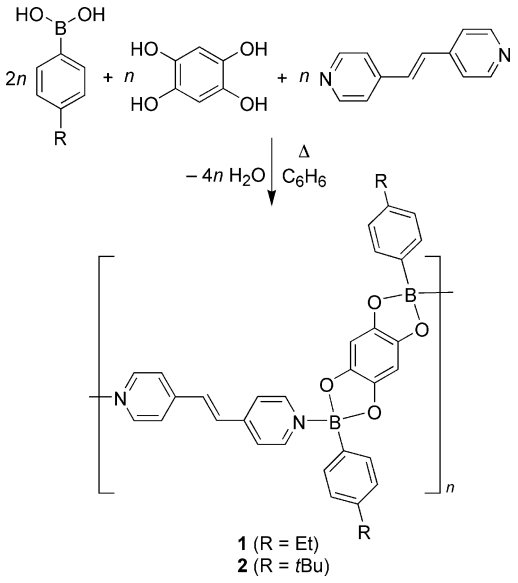
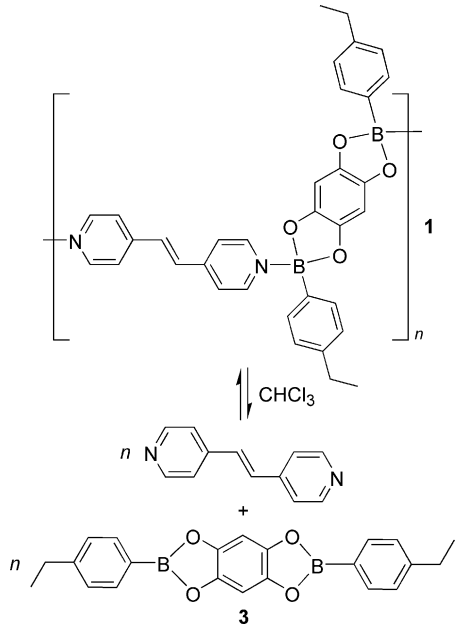


Scheme 1. Synthesis of polymers **1** and **2**.



Scheme 2. When dissolved in $CHCl_3$, polymer **1** splits into 1,2-bis(4-pyridyl)ethylene and bis(dioxaborole) **3**.

A $CDCl_3$ solution of polymer **1** was analyzed by $^1H$ NMR spectroscopy, and its spectrum was nearly a superposition to those of 1,2-bis(4-pyridyl)ethylene and bis(dioxaborole) **3** ($\Delta\delta < 0.15$ ppm). The latter compound was prepared for comparison by condensing 4-ethylphenylboronic acid with 1,2,4,5-tetrahydroxybenzene.[16] The $^{11}B$ NMR spectrum of **1** showed a peak at $\delta = 28.8$ ppm, which was similar to that of **3** ($\delta = 34.6$ ppm) and very distinct from the expected signal of a tetracoordinated boron center.[17] This data suggested that the chloroform solution of polymer **1** contained mainly dissociated 1,2-bis(4-pyridyl)-ethylene and bis(dioxaborole) **3** (Scheme 2). The small differences in chemical shifts can be explained by the formation of minor amounts of B–N adducts, which are in fast equilibrium with 1,2-bis(4-pyridyl)ethylene and **3**. A related situation was observed for the ferrocene polymers prepared by Wagner et al.: upon dissolution at high temperature, the polymer was split into its monomers, $[(C_5H_4BMe_2)_2Fe]$ and 4,4′-bipyridine.[13]

The reversible formation of **1** from 1,2-bis(4-pyridyl)-ethylene and **3** allowed single crystals to be obtained from $CHCl_3$/pentane solutions, and crystallographic analysis confirmed the polymeric structure (Figure 1). The ditopic 1,2-bis(4-pyridyl)ethylene acts as a bridge between the boronate esters. The average boron–nitrogen bond length of 1.677 Å is long relative to what was observed for other crystallographically characterized adducts between $sp^2$-nitrogen donors and tetracoordinated boron centers.[18] Accordingly, the tetrahedral character (THC)[18] of the boron center is relatively low ($THC_{av}$ = 72.5%). This data is in line with the results of the NMR spectroscopic experiments, which suggest that the dative B–N bond in **1** is weak. The B–O bonds ($B–O_{av}$ 1.479 Å) are, as expected, longer than what was observed for 1,2,4,5-tetrahydroxybenzene-based bis(dioxaborole)s with trigonal planar boron (B–O 1.388–1.395 Å).[14]

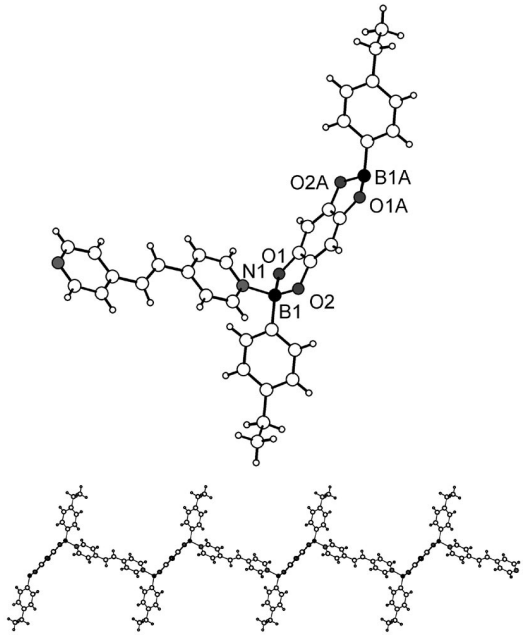


Figure 1. Molecular structure of polymer **1** in the crystal. Top: view of the repeating unit – only one of the two crystallographically independent subunits is shown; bottom: view of the polymer chain. The solvent molecule ($CHCl_3$) is not shown for clarity.

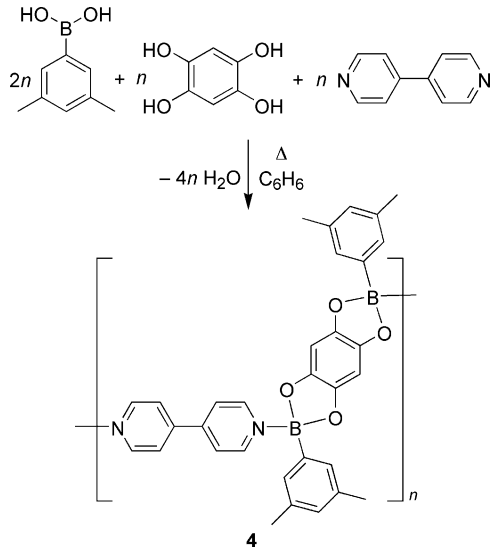
The modular nature of the three-component polymerization reactions offers structural flexibility as demonstrated by the formation of polymer **4**, which contains 4,4′-bipyridine instead of 1,2-bis(4-pyridyl)ethylene as the bridging N-donor ligand (Scheme 3). The physical properties of **4** are similar to those of **1** and **2**: the polymer has a dark-purple color and it splits into 4,4′-bipyridine and the respective boronate ester upon dissolution in hot chloroform.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 



Scheme 3. Synthesis of polymer **4**.

The molecular structure of polymer **4** in the crystal is depicted in Figure 2. As it was observed for **1**, a zig–zag chain is formed. With B1–N1 1.702(5) Å, B1–O1 1.470(4) Å, and B1–O2 1.479(4) Å, the bond lengths of **4** are very similar to those of **1**. Again, the long B–N bond correlates with a low tetrahedral character of 69.5%.

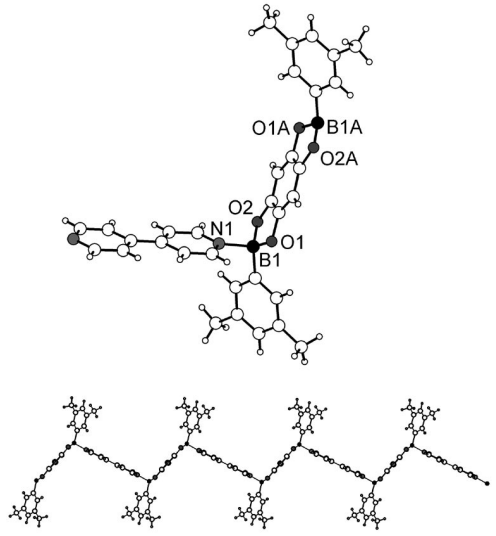


Figure 2. Molecular structure of polymer **4** in the crystal. Top: view of the repeating unit; bottom: view of the polymer chain.

The solid-state $^{11}B$ NMR spectra of polymers **1**, **2**, and **4** are in agreement with the depicted structures and show peaks around 10 ppm. An interesting difference was observed when we attempted to make a polymer from methyl boronic acid, 4,4′-bipyridine, and 1,2,4,5-tetrahydroxybenzene. Again, a dark-purple precipitate was formed (**5**), but its solid-state $^{11}B$ NMR spectrum showed two peaks at ca. 32 and ca. 9 ppm. The former peak is characteristic for a trigonal planar boron center.[16] We therefore propose that compound **5** is the monoadduct [MeB($C_6H_2O_4$)BMe(bipy)] with one trigonal and one tetragonal boron center. Apparently, the methyl boronate ester is not sufficiently Lewis acidic to promote extended polymerization.

A striking feature of polymers **1**, **2**, and **4** is their very dark-purple color. Because the color disappears upon dissolution in chloroform, it must be the fully assembled polymer, which gives rise to the strong absorption. To understand this phenomenon, we performed single-point second-order approximate coupled-cluster (CC2)[19] calculations of the electronic excitations on model systems of the acid and base pairs 1,2-bis(4-pyridyl)ethylene and 4,5-dihydroxyphenyl-4-ethylphenylborole and of their respective condensate in vacuo. Both the uncomplexed acid and base showed the first absorption peak in the near-UV region (4.2 and 3.8 eV, respectively), which is consistent with the finding that the solution containing nonassembled monomers is colorless. In contrast, the assembled acid–base complex showed one transition in the yellow-green region (2.2 eV), which is in agreement with the observed purple coloration of its crystals.

Decomposition of the optical excitation in the visible region onto a molecular orbital basis shows that it has an almost pure HOMO–LUMO π–π* character (88%). This transition corresponds to an intrastrand charge-transfer excitation from the hydroxy–phenyl ring of the dioxaborol moiety to the 1,2-bis(4-pyridyl)ethylene ring (Figure 3).[20] Charge-transfer transitions internal to the dioxaborol strand, specifically between the hydroxy–phenyl and the ethyl–phenyl rings, are not strongly affected by the presence of the pyridyl base; therefore, they do not contribute to the absorption in the visible region, and they remain confined in the UV region of the spectrum. Furthermore, it should be noted that there is no orbital contribution of boron and thus no extended conjugation as it was observed for polymers containing tricoordinate boron.[9b]

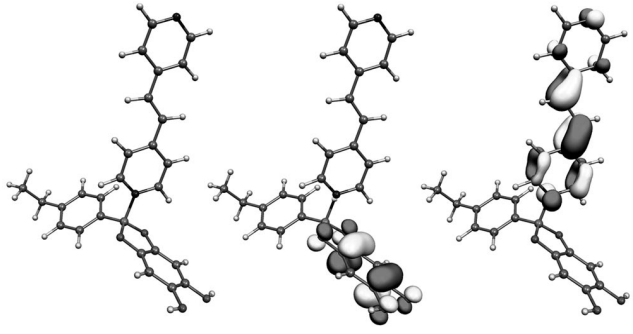

Figure 3. Left: Theoretical cluster-model of the polymeric acid–base pair. Center-right: HOMO–LUMO orbitals responsible for the charge-transfer optical transition in the yellow-green region.

## Conclusions

We showed that condensation reactions of aryl boronic acids with 1,2,4,5-tetrahydroxybenzene can be used *in parallel* with dative B–pyridyl interactions to generate novel polymer architectures by three-component reactions. The

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

resulting crystalline polymers are deeply colored due to efficient intrastrand charge-transfer transitions. An intrinsic advantage of the multicomponent assembly strategy is its modular nature, which allows structural modifications to be easily incorporated. This was evidenced by utilizing different boronic acids and dipyridyl linkers. Because of the weak B–N interaction, the polymers are not stable in solution. However, the reversible formation of the polymer backbone could be interesting from a processing point of view. Furthermore, single crystals can be grown and thus structural information can be obtained. Overall, the work further highlights the potential of boronic acids as building blocks for the generation of polymers with interesting new structures and properties.

## Experimental Section

**General:** 1,2-Bis(4-pyridyl)ethylene, 4,4′-bipyridyl, and the boronic acids were obtained from commercial sources. 1,2,4,5-Tetrahydroxybenzene was prepared as described in the literature.[21] All reactions were carried out under an atmosphere of dry nitrogen by using standard Schlenk techniques. The $^{1}H$, $^{13}C$ and $^{11}B$ spectra were recorded with a 400 MHz spectrometer by using the residual protonated solvents ($^{1}H$, $^{13}C$) as internal standards or $BF_3{\cdot}OEt_2$ ($^{11}B$) as an external standard. $^{1}H$ NMR spectra of the polymers were obtained by dissolving the samples in hot chloroform and then rapidly measuring the solutions before the polymers started to precipitate. The solid-state NMR spectra were recorded with a Bruker DRX 400 spectrometer with a 7.0-widebore magnet by utilizing a 3-mm CPMAS probehead. A solution of boric acid in $H_2O$ was used as the external standard ($\delta$ = 19.3 ppm).

**Polymer 1:** A suspension of 4-ethylphenylboronic acid (135 mg, 0.90 mmol), 1,2,4,5-tetrahydroxybenzene (64 mg, 0.45 mmol), and 1,2-bis(4-pyridyl)ethylene (82 mg, 0.45 mmol) in distilled benzene (90 mL) was heated under reflux with the use of a Dean Stark trap. After 8 h, the suspension was filtered hot, and the filtrate was cooled to room temperature. Upon cooling, a purple solid precipitated. The precipitate was filtered, washed with pentane, and dried under vacuum. Yield: 196 mg, 79%. $(C_{34}H_{30}B_2N_2O_4)_n$ (552.24)$_n$: calcd. C 73.95, H 5.48, N 5.07; found C 74.25, H 5.47, N 5.16. Crystals were obtained by slow diffusion of pentane into a solution of **1** in chloroform.

**Polymer 2:** A suspension of 4-*tert*-butylphenylboronic acid (160 mg, 0.90 mmol), 1,2,4,5-tetrahydroxybenzene (64 mg, 0.45 mmol), and 1,2-bis(4-pyridyl)ethylene (82 mg, 0.45 mmol) in distilled benzene (90 mL) was heated under reflux with the use of a Dean Stark trap. After 8 h, the suspension was filtered hot, and the filtrate was cooled to room temperature. Upon cooling, a purple solid precipitated. The precipitate was filtered, washed with pentane, and dried under vacuum. Yield: 222 mg, 81%. $(C_{38}H_{38}B_2N_2O_4)_n$ (608.34)$_n$: calcd. C 75.02, H 6.30, N 4.60; found C 75.18, H 6.39, N 4.39.

**Boronate Ester 3:** A suspension of 4-ethylphenylboronic acid (135 mg, 0.90 mmol) and 1,2,4,5-tetrahydroxybenzene (64 mg, 0.45 mmol) in distilled benzene (90 mL) was heated under reflux with the use of a Dean Stark trap. After 8 h, the suspension was filtered hot, and the filtrate was cooled to room temperature. Upon cooling, white crystals formed. The crystals were filtered, washed with pentane, and dried under vacuum. Yield: 93 mg, 58%. $^{1}H$ NMR (400 MHz, $CDCl_3$): $\delta$ = 1.29 (t, $^{3}J$ = 7 Hz, 6 H, $CH_3$), 2.73 (q, $^{3}J$ = 8 Hz, 4 H, $CH_2$), 7.31 (s, 2 H, phenyl), 7.34 (d, $^{3}J$ = 8 Hz, 4 H, phenyl), 8.00 (d, $^{3}J$ = 8 Hz, 4 H, phenyl) ppm. $^{13}C$ NMR (101 MHz, $CDCl_3$): $\delta$ = 15.45, 29.36, 98.36, 128.08, 135.15, 143.95, 149.18 ppm. $^{11}B$ NMR (128 MHz, $CDCl_3$): $\delta$ = 34.6 ($h_{1/2}$ = 870 Hz) ppm. $C_{22}H_{20}B_2O_4$ (370.01): calcd. C 71.41, H 5.45; found C 71.25, H 5.57.

**Polymer 4:** A suspension of 3,5-dimethylphenylboronic acid (135 mg, 0.90 mmol), 1,2,4,5-tetrahydroxybenzene (64 mg, 0.45 mmol), and 4,4′-bipyridyl (70 mg, 0.45 mmol) in distilled benzene (90 mL) was heated under reflux with the use of a Dean Stark trap. After 1 h, the suspension was filtered hot, and the filtrate was cooled to room temperature. Upon cooling, a purple solid precipitated. The precipitate was filtered, washed with pentane, and dried under vacuum. Yield: 176 mg, 74%. $(C_{32}H_{28}B_2N_2O_4)_n$ (526.20)$_n$: calcd. C 73.04, H 5.36, N 5.32; found C 72.62, H 5.43, N 5.45. Crystals were obtained by slow diffusion of pentane into a solution of **4** in chloroform.

**Adduct 5:** A suspension of methylboronic acid (54 mg, 0.90 mmol), 1,2,4,5-tetrahydroxybenzene (64 mg, 0.45 mmol), and 4,4′-bipyridyl (70 mg, 0.45 mmol) in distilled benzene (90 mL) was heated under reflux with the use of a Dean Stark trap. After 1 h, the suspension was filtered hot, and the filtrate was cooled to room temperature. Upon cooling, a purple solid precipitated. The precipitate was filtered, washed with pentane, and dried under vacuum. Yield: 110 mg, 71%. $C_{18}H_{16}B_2N_2O_4$ (345.95)$_n$: calcd. C 62.49, H 4.66, N 8.10; found C 62.03, H 4.46, N 7.82.

**X-ray Crystallography:** Details about the crystals and their structure refinement are listed in Table 1. Data collection was performed at 100(2) K by means of a Bruker APEX II CCD detector. Data reduction was carried out with EvalCCD.[22] Absorption correction

was applied to both data sets. Structure solution and refinement were performed with the SHELXTL software package, release 5.1.[23] The structures were refined by using the full-matrix least-squares on $F^2$ with all non-hydrogen atoms anisotropically defined. H atoms were placed in calculated positions by using the "riding model". CCDC-653486 and -653487 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

**Computational Section:** Vertical excitations for the 1,2-bis(4-pyridyl)ethylene, the (dioxaborole), and the Lewis condensate of the two species were computed at the single-point second-order approximate coupled-cluster (CC2)[17] level. Calculations were performed by using the TURBOMOLE 5.9 code,[24] within the resolution-of-the-identity (RI) approximation for the evaluation of the electron-repulsion integrals.[25] For all calculations a cc-pVDZ[26] basis set was used.

## Acknowledgments

We gratefully acknowledge the support of the Swiss National Science Foundation, the COST action D31, and the EPFL. We thank Dr. Anuji Abraham for measuring the solid-state $^{11}$B NMR spectra.

# Oxoethoxide Chlorides – Representatives of Oligonuclear Alkoxide Complexes of Gallium: Penta- and Dodecanuclear Molecules

**Evgeniya V. Suslova,[a] Vadim G. Kessler,*[b] Suresh Gohil,[b] and Nataliya Ya. Turova[a]**

**Keywords:** Gallium oxides / Sol–gel precursors / Oligonuclear complexes / X-ray / Mass spectrometry

Metathesis of solid $GaCl_3$ with NaOEt/EtOH (1:3) provided, after separation of the NaCl precipitate, a solution containing oxoalkoxide chloride complexes of gallium. Residues from evacuation of the latter were redissolved in either toluene/MeCN (solution 1) or toluene/pyridine (solution 2). Storage of the first solution provided crystals of $Ga_5(\mu_5\text{-}O)(\mu\text{-}OEt)_8Cl_5$ (**1**), and of the second solution – $[Ga_{12}(\mu_4\text{-}O)_2(\mu_3\text{-}O)_5(\mu\text{-}OEt)_{10}Cl_{12}Py_4]Py$ (**2**), both at room temperature and in relatively high yields. Compound **1** crystallizes as a vertically contracted tetragonal pyramid with the $\mu_5$-O ligand situated in the center of the equatorial plane defined by four trigonal bipyramidal coordinated gallium atoms. The axial Ga atom has octahedral coordination. All eight edges of the pyramid are capped by μ-OEt groups, and all the chloride ligands are situated in terminal positions. Crystals of $[Ga_{12}(\mu_4\text{-}O)_2(\mu_3\text{-}O)_5(\mu\text{-}OEt)_{10}Cl_{12}Py_4]Py$ (**2**) contain two $[Ga_5(\mu_4\text{-}O)(\mu_3\text{-}O)_2(\mu\text{-}OEt)_5Cl_5Py]$ fragments connected through a cyclic $[Ga_4(\mu_3\text{-}O)_5Cl_2Py_2]$ unit with a $\mu_3$-O ligand in its center. Of the metal atoms, three possess tetrahedral, seven trigonal bipyramidal, and two octahedral coordination. The mass spectrum of **1** contains penta- and tetranuclear fragments. The spectrum of **2** contains heptameric fragments in addition to the pentanuclear fragments that are analogous to those in the spectrum of **1**. The factors leading to formation of polymeric $M(OR)_n$ and related oligonuclear oxocomplexes are discussed.

## Introduction

The present interest to organic derivatives of gallium is related to the possibilities of their application as precursors of a series of complex oxide materials applied as gas sensors,[1,2] luminophores,[3] and solid electrolytes, on the one hand, and $M^{II}$-doped $LaGaO_3$[4] and catalysts with zeolyte-type structures on the other hand.[5] The oligonuclear molecular complexes of gallium are also very attractive as close structural analogs, diamagnetic models, and potential reagents for tuning the magnetic moment of the oligonuclear complexes of iron(III) for applications in the field of molecular electronics.[6] It appeared extremely interesting to get closer insight into the chemistry of gallium alkoxide complexes in view of their earlier postulated rendered kinetics (slow reaction rates in ligands exchange and core rearrangements) and polymerism (coexistence of different oligomers with the same chemical composition) in contrast to kinetically unhindered iron(III) alkoxides.[7]

Among the synthetic approaches to gallium alkoxides described in the literature, a considerable emphasis has always been put on the metathesis of gallium chloride with alkali alkoxides.[8–12] Our attempts to reproduce the proposed techniques, in particular those described for the synthesis of $Ga(OEt)_3$, led consequently to rather low yields of the desired products.[13]

In the present work we report the isolation of the products of interaction of solid $GaCl_3$ with a solution of NaOEt in ethanol (taken in the stoichiometric 1:3 ratio) and their structural characterization.

## Results and Discussion

Repeated trials of the metathesis of $GaCl_3$ with sodium ethoxide in 1:3 ratio according to the techniques proposed in refs.[10–11] for the synthesis of $Ga(OEt)_3$ resulted in the following observations: (1) Alcoholysis of the solid $GaCl_3$ – a quite strong Lewis acid – resulted, to a certain extent, in the evolution of hydrogen chloride, HCl, which reacted in turn with the alcohol (a process catalyzed by $MCl_n$) with the release of water; this resulted in the presence of oxo-derivatives in the reaction products.[13] (2) The stability of gallium oxoalkoxide halides is so high that even prolonged heating of the reaction mixture at reflux was unable to achieve their decomposition (the amount of NaCl precipitate constitutes only about 80% of the theoretically calculated yield).

It is important to mention that when a toluene solution of $GaCl_3$ is applied as the reagent in metathesis (i.e., by reducing the extent of the alcoholysis side reaction[13]), the process resulted in the formation of insoluble polymeric *or-*

*tho*-ethoxide $Ga(OEt)_3$, which displayed a layered $[Ga(OEt)_{4/2}(OEt)]_\infty$ structure.[14] Oxo complexes are most often more soluble due to their oligonuclear molecular structure.

Preparation of a crystalline sample suitable for single-crystal X-ray studies could be achieved only with the use of polar organic solvents such as acetonitrile or pyridine. Crystals of $Ga_5(\mu_5\text{-}O)(\mu\text{-}OEt)_8Cl_5$ (**1**) were formed from solution after 5 months of storage. Crystals of **1** comprise a flattened tetragonal pyramid of metal atoms, $Ga_5$, with an octahedrally coordinated metal atom $[Ga(\mu_5\text{-}O)(\mu\text{-}OEt)_4Cl]$ in the axial position and the trigonal bipyramidal coordinated ones $[Ga(\mu_5\text{-}O)(\mu\text{-}OEt)_3Cl]$ in the equatorial plane of the pyramid. A pentadentate oxo group is situated in the center of the pyramid, and all its edges are capped by eight μ-OEt groups. Four shorter bridges are placed between the apical hexacoordinate metal atom and the equatorial metal atoms (designated as $^{(5-6)}$ in Table 1), and the other four longer bridges bind the trigonal bipyramidal coordinated Ga atoms together in the equatorial plane (designated as $^{(5-5)}$ in Table 1), see Figure 1. The bonding parameters for **1** are practically identical to those of its structural analogs – derivatives of aluminium and iron(III),[15–19] see Table 1. The only (minor) difference between the compounds presented in Table 1 lies in the position of the $\mu_5$-O group: in **1** and $Fe_5O(OEt)_8(OEt)_5$[7,16] the oxo atom lies practically within the equatorial plane [the sums of the $M^5$–($\mu_5$-O)–$M^5$ angles are 356.3 and 357.5°, respectively, which corresponds to only ca. 0.02 Å distance from the $\mu_5$-O ligand to the equatorial plane]. The same type of $\mu_5$-O ligand placement can in fact be observed for the tetragonal pyramidal isopropoxide $M_5(\mu_5\text{-}O)(\mu_3\text{-}OR)_4)(\mu\text{-}OR)_4(OR)_5$ (M = In, Sc, Y, Ln) complexes, where all metal atoms are octahedrally coordinated and the alkoxide groups, which are situated between the axial and the equatorial metal atoms, are they cap the faces of the pyramid instead of the edges.[20–25]

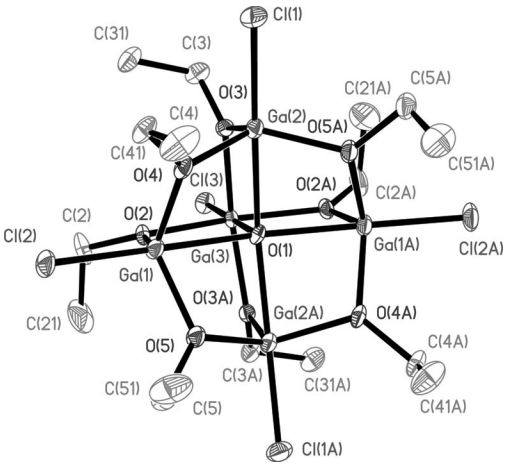

Figure 1. Molecular structure of $Ga_5(\mu_5\text{-}O)(\mu\text{-}OEt)_8Cl_5$ (**1**).

In the other molecules presented in Table 1, the sums of the equatorial angles at the $\mu_5$-O groups are ca. 331°, which corresponds to its distance to the equatorial plane of about 0.22 Å. An interesting peculiarity of all the compared structures is that the length of the bond between the $\mu_5$-O ligand and the axial, hexacoordinate, metal atom is considerably shorter than between this ligand and the pentacoordinate equatorial metal atoms, for gallium – 1.931(11) and 2.162(3) Å, respectively. This fact confirms that the central oxo atom is really involved in five bonds, and it is truly pentacoordinate. The values of the M–(μ-OC) angles in **1** (124.2–129.6°), as well as the corresponding angles for the alkoxide bridging groups in the other molecules in this fam-

Table 1. Comparison of the bonding parameters in the $[M_5(\mu_5\text{-}O)(\mu\text{-}OR)_8X_5]$ molecules ($M^6$ – octahedral coordinated, $M^5$ – trigonal bipyramidal coordinated). The molecules with closely related structures have recently been envisaged for a series of other alkoxides of iron(III) – $Fe_5O(OR)_{13}$ (R = *n*Pr, *i*Pr, *i*Bu, $CH_2CF_3$), and also $Fe_5O(O\textit{i}Pr)_{12}Cl$.[19]

ily, indicate certain contribution of the $d_\pi$–$p_\pi$ interaction and predominantly $sp^2$ hybridization for the oxygen atoms according to the well-established structural correlations.[13]

According to the mass spectrometric data, molecules of **1** are present in the gas phase (Figure 2) and are relatively stable to all types of decomposition (by chemical means on evaporation and also by electron impact – the fragmentation series for the pentanuclear species is the most intense in the spectrum). The major alternative in the decomposition of **1** on evaporation is provided by the loss of a $Ga(OEt)_2Cl$ molecule, which should lead to a symmetric tetrahedral $Ga_4O(OEt)_6Cl_4$ molecule, unknown in the condensed phase, but represented by its own fragmentation series in the mass spectrum. The first ion in the series is formed by further loss of a terminal chloride ligand from this molecule, $Ga_4O(OEt)_6Cl_3^+$. It is interesting to note that the most intense ion in the mass spectrum of iron(III) ethoxide is $Fe_4O(OEt)_9^+$ [*m*/*z* (%) = 645 (100)], which possesses most probably a symmetric tetrahedral structure of the same type containing nine ethoxide ligands in addition to the oxo one.[7] Further fragmentation is associated with the loss of two more ethoxide ligands apparently with conservation of the close-packed structure (Figure 3). The formation of the close-packed structures is very characteristic of the molecular alkoxide aggregates even in the solid state and in solution.[26,27] The ionization in a mass-spectrometric experiment occurs by collision of the sample with an electron beam with the energy of 70 eV (about 675 KJ mol$^{-1}$). This transfers the molecule into a virtual state, where all metal atoms, in a molecule such as **1** that has relatively high symmetry, become equivalent. The energy is then released through ionization and loss of a fragment. The structure of the formed ion corresponds to the energy minimum for the residual fragment, which is achieved by dense packing of the metal cations and residual donor atoms.

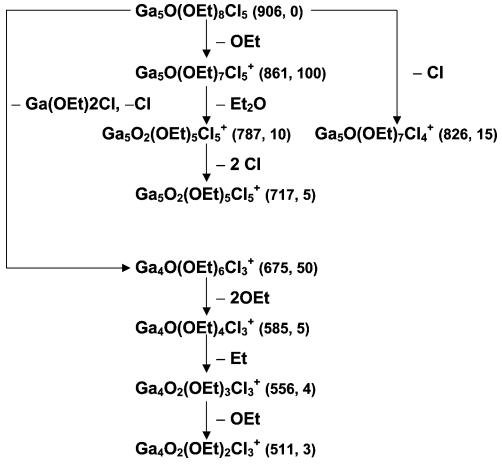

Figure 2. Mass-spectral fragmentation scheme for **1**.

The crystal structure of compound **2**, obtained from solutions of reaction products in toluene/pyridine, contains noncentrosymmetric dodecanuclear $[Ga_{12}(\mu_4\text{-}O)_2(\mu_3\text{-}O)_5(\mu\text{-}OEt)_{10}Cl_{12}Py_4]$ molecules and additional interstitial pyridine molecules in the cavities of the packing. The dodecanuclear molecules are constituted by two $[Ga_5(\mu_4\text{-}O)(\mu_3\text{-}O)_2(\mu\text{-}OEt)_5Cl_4Py]$ fragments connected to each other by a ClGaOpy unit (Figure 4). The molecule contains two octahedrally coordinated metal atoms, Ga8 and Ga9, seven trigonal bipyramidal coordinated Ga atoms – (number 1, 2, 3, 6, 10, 11, and 12), and also three tetrahedral coordinated ones. Two of the latter display a practically regular tetrahedral geometry, Ga4 and Ga7, and the third one is considerably distorted, Ga5, in the center of the molecule. Of the seven oxo groups, the two tetradentate ones, O1 and O7, have distorted tetrahedral coordination, and the four tridentate ones, O4, O6, O2, O8, are practically planar with the sums of the bonding angles of about 358°; the fifth oxo ligand, O5, in the center of the molecule has a pyramidal coordination (valence angle sum 335.6° in the $[OGa_3]$ fragment). All OEt groups are bidentate. In the center of each pentanuclear fragment one can find a planar tetragonal fragment, (Ga2–O7–Ga9–O9) and Ga1–O1–Ga8–O3), respectively.

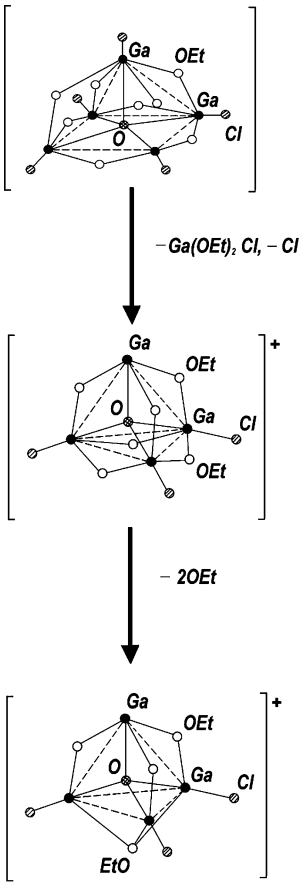

Figure 3. Partial decomposition of **1** in the gas phase.

The bond lengths of the Ga–O(oxo) fragments are independent of the coordination number of the metal atom and are determined exclusively by the bonding mode of the oxo groups. Thus, the tetradentate oxygen atoms O1 and O7 form two longer [2.037–2.367(16) Å] and two shorter bonds [1.858–2.007(16) Å]. The length of the latter is of the same order of magnitude as for the tridentate oxygen atoms O4,

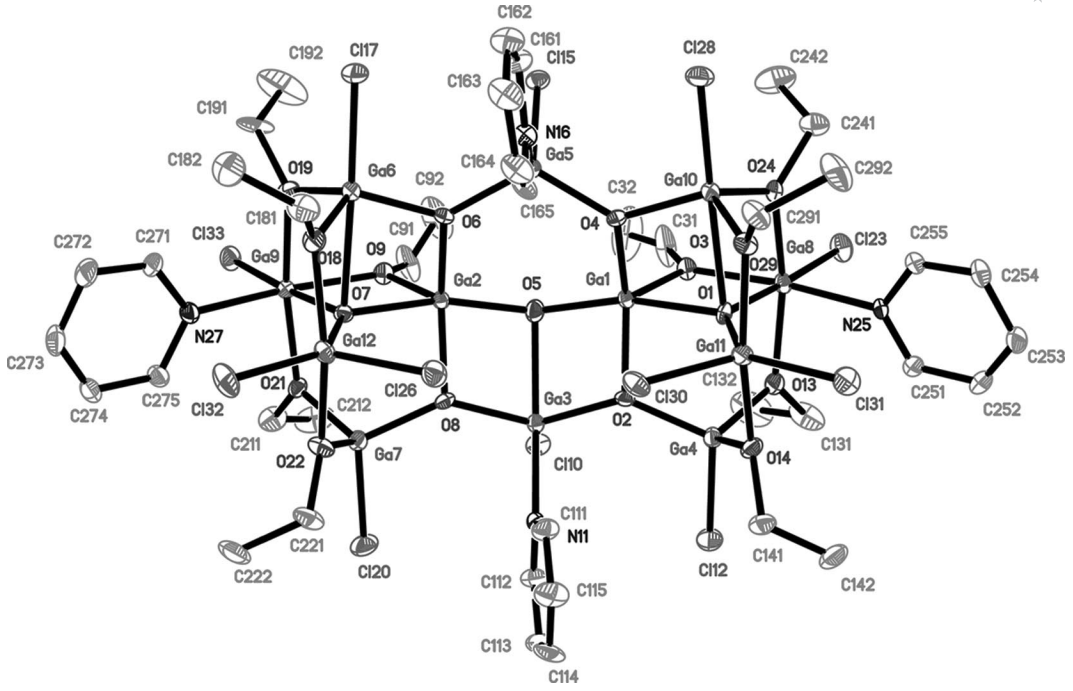

Figure 4. Molecular structure of $Ga_{12}(\mu_4\text{-}O)_2(\mu_3\text{-}O)_5(\mu\text{-}OEt)_{10}Cl_{12}Py_4$ (**2**).

O6, O2, O8–Ga [1.812–1.933(16) Å]. The only exclusion is represented by one of the bonds involving the central tridentate oxygen atom in the molecule, O5–Ga3 [2.161(18) Å]. The lengths of the Ga–(μ-OEt) bridges are within the interval 1.804–2.048(17) Å, and the distances to the terminal chloride ligands Ga–Cl is 2.113–2.236(8) Å, again independently of the coordination number of the metal atom. Only the distance to the terminal nitrogen atoms increases considerably from tetrahedral to octahedral coordination from 2.01(2) to 2.236(9) Å.

The first ions in the mass spectrum of **2** – $Ga_7O_5(OEt)_3Cl_7^+$ $Ga_7O_5(OEt)_2Cl_7^{++}$ – belong to the heptanuclear fragment and correspond to the loss of a pentanuclear core from the original molecule. The light ions correspond to those observed in the spectrum of **1**. It can be explained both by easy fragmentation of **2** into two structural fragments – pentanuclear and heptanuclear – but even possibly by partial decomposition on evaporation with formation of more volatile compound **1**.

The structure of **2** is closely related to the other chemically related oxoalkoxo complexes of aluminium and iron(III) – $[Fe_9O_3(OEt)_{21}]\cdot EtOH$,[28] $[Al_{10}O_4(OEt)_{22}]$,[29] and $[Al_{11}O_6(OnPr)_{10}(OiPr)_{10}(OR)(ROH)_2]$,[30] which have pentanuclear cores connected to each other through a common [M(μ$_3$-O)(μ-OR)] edge or through central [Al$_2$(μ$_3$-O)$_2$] or [Al(OR)(μ-O)$_2$(μ$_3$-O)$_2$][31] units (Figure 5). All the above-mentioned molecules contain tetrahedral [(μ$_4$-O)M$_4$] groups, to which an additional fifth metal atom is connected through oxo- or alkoxo bridges. In **2** these additional atoms, Ga4 and Ga7, are attached to the tetrahedral one through two μ-OR groups O13, O14 and O21, O22 and one μ$_3$-O group O2 and O8, respectively.

Gallium oxoalkoxides were synthesized in this work for the first time, but they definitely show close structural relationship to the derivatives of aluminium and iron. Easy transformations on evaporation trace a closer relationship

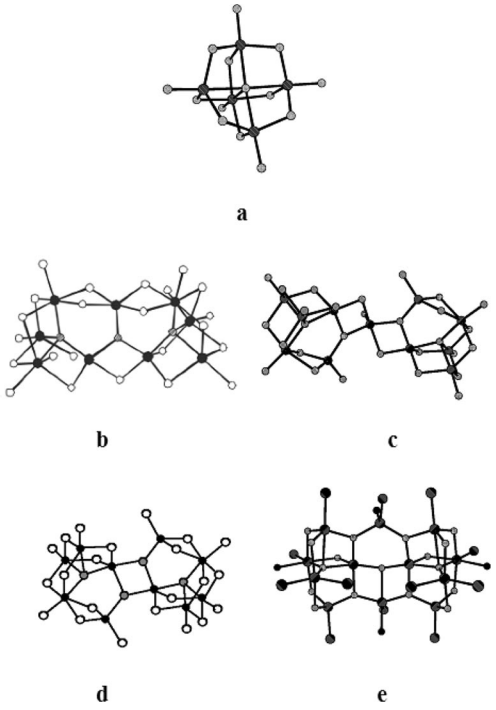

Figure 5. Comparison of the metal–ligand cores in the molecules of the penta-, nona- deca-, undeca-, and dodecanuclear oxoalkoxides: (a) $Fe_5O(OEt)_{13}$[7] or $Ga_5O(OEt)_8Cl_5$ (**1**); (b) $[Fe_9O_3(OEt)_{21}]\cdot EtOH$;[28] (c) $Al_{10}O_4(OEt)_{22}$;[29] (d) $Al_{11}O_6(OnPr)_{10}(OiPr)_{10}(OR)(ROH)_2$;[30] and (e) $Ga_{12}O_7(OEt)_{10}Cl_{12}Py_4$ (**2**).

to the derivatives of iron(III) and thus less kinetically hindered reactivity. The rearrangements of the gallium complexes appear to occur easily and follow the solution equilibria. It opens a way to potential new classes of gallium–iron(III) molecular aggregates, which are attractive for molecular electronic applications.[6]

## Experimental Section

All manipulations were carried out under a dry nitrogen atmosphere by using Schlenk techniques or in a glove box. Anhydrous $GaCl_3$ was purchased from Aldrich and used as received. Ethanol was dried by refluxing over $Ca(OEt)_2$ with subsequent distillation, and toluene was distillation from Na and $LiAlH_4$. Mass spectra were recorded with a JEOL JMS-SX/SX-102A mass spectrometer by applying electron beam ionization ($U$ = 70 eV) with direct-probe introduction. The reported masses of the ions were calculated for the $^{71}$Ga isotope. IR spectra were registered with a Perkin–Elmer Spectrum 100 instrument (as nujol or hexachlorobutadiene mulls). $^1$H NMR spectra were recorded in $CDCl_3$ solutions with a Bruker 400 MHz instrument at room temperature.

**Synthetic Procedure:** Sodium metal (1.22 g, 53 mmol) was dissolved in EtOH (27 mL) at room temperature. An solid $GaCl_3$ (2.85 g, 16.0 mmol) was then added to the solution. The process was strongly exothermic and accompanied by the evolution of visible amounts of HCl "mist" that was subsequently consumed by redissolution in the reaction mixture. The mixture was then heated at reflux for 5–6 h and then finally left for precipitation of NaCl (2.39 g, 41 mmol) overnight. The clear solution was removed by syringe, and the solvents were evaporated to dryness in vacuo. The residual solid was very sparingly soluble in toluene or alcohol even

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

on reflux. Its suspension in 3 mL of toluene was separated into a solution fraction and a sediment.

The sediment was treated with a mixture of MeCN (3 mL) and toluene (3 mL), which provided a dark-red solution that slowly lost its color on storage to produce colorless crystals of **1** with practically quantitative yield after 5 months. $^1$H NMR (400 MHz, $CDCl_3$): $\delta$ = 4.22 (q, $J$ = 6.5 Hz, 16 H, H-C$H_2$), 1.26 (t, $J$ = 6.0 Hz, 24 H, H-C$H_3$) ppm. $^{13}$C NMR (100 MHz, $CDCl_3$): $\delta$ = 59.6 (C-$CH_2$), 16.6 (C-$CH_3$) ppm. The presence of only one signal for each type of carbon or hydrogen atom indicates rather quick exchange under these conditions. IR (nujol): $\tilde{\nu}$ = 1302 (m), 1166.09 (m), 1093.74 (w), 1034.10 (w), 897.12 (w), 601.19 (w), 467.94 (m), 427.16 (m) cm$^{-1}$. MS: *m*/*z* (%) = 861(100) $[Ga_5O(OEt)_7Cl_5]^+$, 826 (15) $[Ga_5O(OEt)_7Cl_4]$, 787 (10) $[Ga_5O_2(OEt)_5Cl_5]^+$, 717 (5) $[Ga_5O_2(OEt)_2Cl_3]^+$, 675 (50) $[Ga_4O(OEt)_6Cl_3]^+$, 585 (5) $[Ga_4O(OEt)_4Cl_3]^+$,

556 (4) $[Ga_4O_2(OEt)_3Cl_3]^+$, 511 (3) $[Ga_4O_2(OEt)_2Cl_3]^+$. $C_{16}H_{40}Cl_5Ga_5O_9$ (902.33): calcd. C 21.29, H 4.43, Ga 38.88; found C 20.52, H 4.12, Ga 39.31.

The toluene solution was treated with pyridine (0.5 mL), which provided crystallization of a small crop (0.25 g) of crystals of **2**. Further storage of the mother liquor under septum resulted in its complete crystallization with the formation of needle-shaped crystals of [PyH][$GaCl_4$] (identified by single-crystal and powder X-ray studies). $^1$H NMR (400 MHz, $CDCl_3$): $\delta$ = 8.72 (m, 8 H, α-H-Py), 7.62 (t, $J$ = 4.7 Hz, 4 H, γ -H-Py), 7.44 (m, 8 H, β-H-Py), 4.31 (q, $J$ = 6.4 Hz, 8 H, H-C$H_2$-OEt), 4.20 (q, $J$ = 6.5 Hz, 8 H, H-C$H_2$-OEt), 3.51 (q, $J$ = 6.5 Hz, 4 H, H-C$H_2$-OEt), 1.46 (t, $J$ = 6.0 Hz, 6 H, H-C$H_3$-OEt), 1.28 (t, $J$ = 6.0 Hz, 12 H, H-C$H_3$-OEt), 0.74 (t, $J$ = 6.0 Hz, 12 H, H-C$H_3$-OEt) ppm. IR (nujol): $\tilde{\nu}$ = 1611 [vs (νPy)], 1573 [w (νPy)], 1479 (s), 1299 (w), 1218 [s (δPy)], 1156 (s), 1092 (vs), 1054 (vs), 1026 (vs, br.), 889 (vs), 887 (s), 742 (vs), 691 [vs (νGa–O)], 558 [vs, br. (νGa–O)], 452 (vs), 443 (vs), 403 (vs) cm$^{-1}$. MS: *m*/*z* (%) = 957 (20) $[Ga_7O_5(OEt)_3Cl_7]^+$, 912 (6) $[Ga_7O_5(OEt)_2Cl_7]^+$, the other ions are identical to the spectrum of **1**. $C_{50}H_{80}Cl_{12}Ga_{12}N_6O_{17}$ (2299.24): calcd. C 26.15, H 3.48, Ga 36.61; found C 25.10, H 3.02, Ga 37.62.

**X-ray Structure Determinations:** Data collection was performed with a Bruker SMART CCD 1K diffractometer at 295(2) K, with Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 Å; see Table 2 for details). The SAINTPLUS and the SHELXTL-NT program packages were used for data reduction and computations.[32] Empirical absorption correction was applied by using the Bruker SADABS program package. The structures were solved by direct methods. The coordinates of the heavy atoms were taken from the initial solution, and the non-hydrogen atoms were located in subsequent Fourier syntheses. The structures were refined by full-matrix least-squares techniques in an isotropic and then finally in an anisotropic approximation. The details on data collection and bonding parameters are presented in Tables 2, 3, and 4.

CCDC-650370 and -650371 (for **1**and **2**, respectively) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

## Acknowledgments

The authors express their gratitude to A. I. Yanovsky for the valuable discussions of the structure data, to the Swedish Research Council for support of this project and to the Visby Program of the Swedish Institute for the travel grant and allowance to E. V. S. and to the Russian Foundation for Basic Research (Project No. 07-03-00128) for the financial support of this work.

# A Triphenylamine/Bis(terpyridine)Ir$^{III}$ Dyad for the Assembly of Charge-Separation Constructs with Improved Performances

**Lucia Flamigni,*[a] Barbara Ventura,[a] Etienne Baranoff,[b] Jean-Paul Collin,*[b] and Jean-Pierre Sauvage*[b]**

**Keywords:** Charge separation / Electron transfer / Iridium / Photochemistry / Supramolecular chemistry

A new dyad **DII-Ir** consisting of a triphenylamine donor and a bis(terpyridine)Ir$^{III}$ acceptor separated by a bridge composed of two benzamide groups has been synthesized. The electrochemical and photophysical properties of the dyad have been compared to those of a corresponding dyad **D-Ir** characterized by a bridge connecting the donor and the acceptor consisting of a single benzamide unit. We show that, whereas the charge-separation steps are still very efficient in the long dyad (≥99 %), charge recombination is slowed by a factor of three with respect to the short dyad. This encourages the use of this dyad in the assembly of a more elaborate array DII-Ir-A, expected to overcome the disappointingly low charge-separation yield of a previously studied **D-Ir-A** short triad.

## Introduction

The process of producing long-lived charge-separated (CS) states is the basic event in artificial photosynthesis, which aims at efficiently converting light into chemical energy. In spite of the impressive results achieved in the last decade in multi-component arrays,[1] genuine long-lived CS states are still a valuable goal, especially when they involve less common or unexplored chromophores with respect to more conventional tetrapyrrolic or fullerene derivatives.[2] The most convenient and better tested strategy for producing genuine and indisputable CS states is that of using weakly coupled multi-component structures and of moving the electron, through a sequence of electron-transfer events, to molecular components far away from the hole. The first electron-transfer step is driven by light, whereas the following ones are ground-state electron-transfer reactions. A few years ago we started to use (terpyridine-type)Ir$^{III}$ complexes as functional assembling units of multi-component structures having either the role of electron relay[2d,3] or of photosensitizer.[4] The use of this type of complexes proved to be very valuable both for the high energy level (ca. 2.5 eV) of its excited state, a ligand-centered triplet ($^3$LC) occasionally with some charge-transfer triplet ($^3$CT) character, and for the relative ease of reduction, –0.75 V vs. SCE.[5] The high excited-state energy level prevented draining of the electronic energy of the other components due to energy transfer, and the relative ease of reduction of the complex unit provided a high driving force for the primary photoinduced electron transfer starting the sequence. By using arrays with a central bis(terpyridine)Ir$^{III}$ complex and appended porphyrins with suitable metallation to provide a good electron donor [free-base or (porphyrin)zinc complex] or a good electron acceptor [(porphyrin)gold(III) complex], respectively, we succeeded in producing a CS state with a lifetime of 450 ns and 100% yield.[2d,6]

More recently, we studied a **D-Ir-A** triad, where D is a triphenylamine electron donor, A is a naphthalenebis(imide) electron acceptor, and Ir is a bis(terpyridine)Ir$^{III}$ complex (Scheme 1).

The lifetime of the CS state with opposite charges localized at the extremities of the array, produced upon light absorption by either the D or Ir unit is remarkable, of the order of 120 μs at ambient temperature in air-free acetonitrile (100 μs in air-saturated samples), but the yield of charge separation is quite modest, of the order of 10%.[7] The reason for this inefficiency is that the intermediate CS state $D^+$-Ir$^-$-A, formed with a 100% yield by a primary electron-transfer step originating from either an excited D unit ($^1$D) or excited Ir unit ($^3$Ir), can deactivate to the ground state faster ($k = 1.4 \times 10^{10}$ s$^{-1}$) than the rate at which it undergoes a further electron-transfer step ($k = 2.4 \times 10^9$ s$^{-1}$) leading to the final CS state $D^+$-Ir-A$^-$. We reasoned that increasing the D to Ir separation from ca. 1.6 nm in the original system to a distance of ca. 2.3 nm by inserting a further benzamide linker as in **DII-Ir** (Scheme 2), could be a possible strategy to improve the final CS yield in a triad DII-Ir-A.

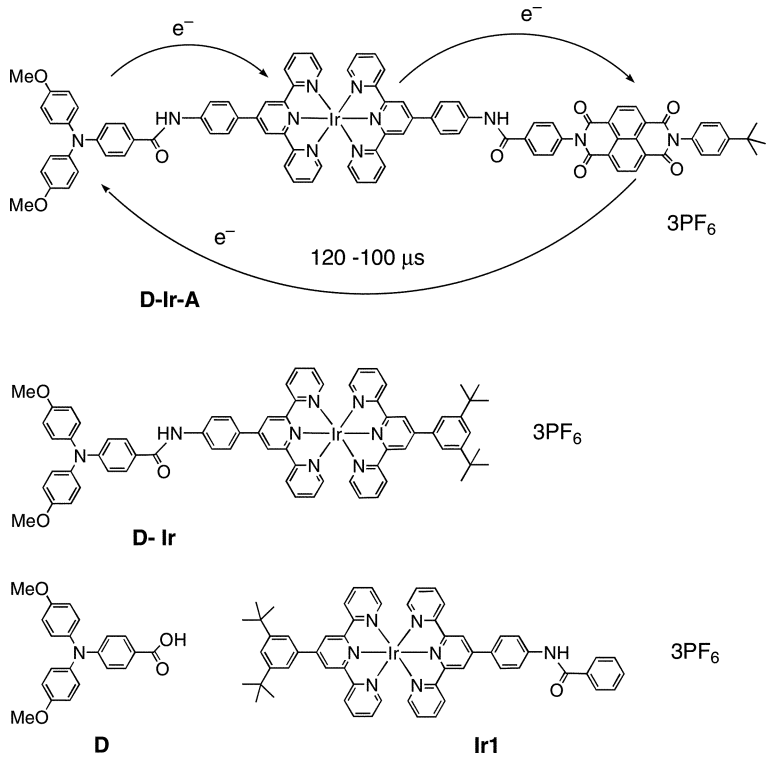
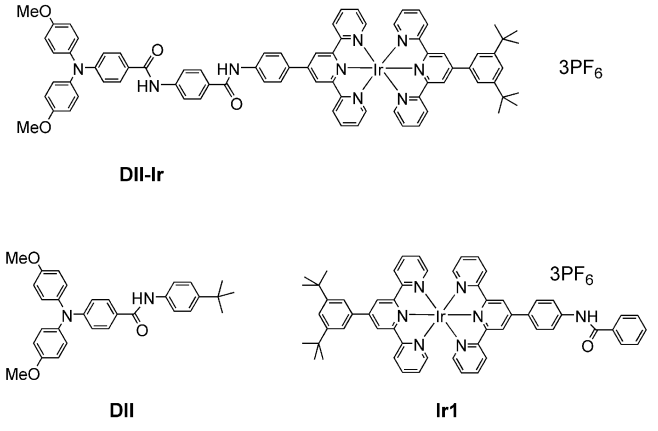


Scheme 1. Structures of the previously reported triad **D-Ir-A** and related models.



Scheme 2. Structures of the dyad **DII-Ir** and models reported in this work.

Decrease of both charge-separation ($^1$DII-Ir or DII-$^3$Ir $\rightarrow$ DII$^+$-Ir$^-$) and charge-recombination (DII$^+$-Ir$^-$ $\rightarrow$ D-Ir) rates are expected after increasing the D–Ir distance but, whereas a slight decrease in the 100% efficiency of the charge separation step can be afforded without being too detrimental to the overall CS process, a decrease in the rate of charge recombination in the dyad **DII-Ir** can have important effects on the overall charge separation over the extreme components in the derived triad DII-Ir-A. Since the synthesis of the latter requires a significant synthetic effort, we decided to verify first if the properties of the component dyad could suggest better performances for the derived triad, before undertaking the demanding synthesis of the more complex array. Therefore, the present report deals with the synthesis and photophysical properties of the dyad **DII-Ir** in order to evaluate its suitability for the construction of a triad DII-Ir-A with improved properties with respect to **D-Ir-A**.

## Results and Discussion

The systems studied in this work are the dyad **DII-Ir** and the pertinent models **DII** and **Ir1**, reported in Scheme 2. Whereas complex **Ir1** had been previously examined and its properties will be only briefly summarized, **DII** and **DII-Ir** will here be examined in detail, and their properties will be compared with those of the short counterparts **D** and **D-Ir** previously reported.[7,8] In the following discussion the terms Ir and DII (not bold) will be used to indicate the Ir metal complex (with model **Ir1**) and the donor units (with model **DII**), respectively, within the dyad.

### Synthesis

The dyad **DII-Ir** has been prepared according to the reactions shown in Scheme 3. The terpyridine **2** was prepared in two steps by homologation of the already known 4′-(4-aminophenyl)-2,2′:6′,2′′-terpyridine[9] with 4-nitrobenzoyl chloride and then by reduction of the nitro group with hydrazine in the presence of a catalytic amount of palladium on charcoal. The terpyridine **3**, bearing a triarylamine donor group linked to the terpy fragment by two amide brid-

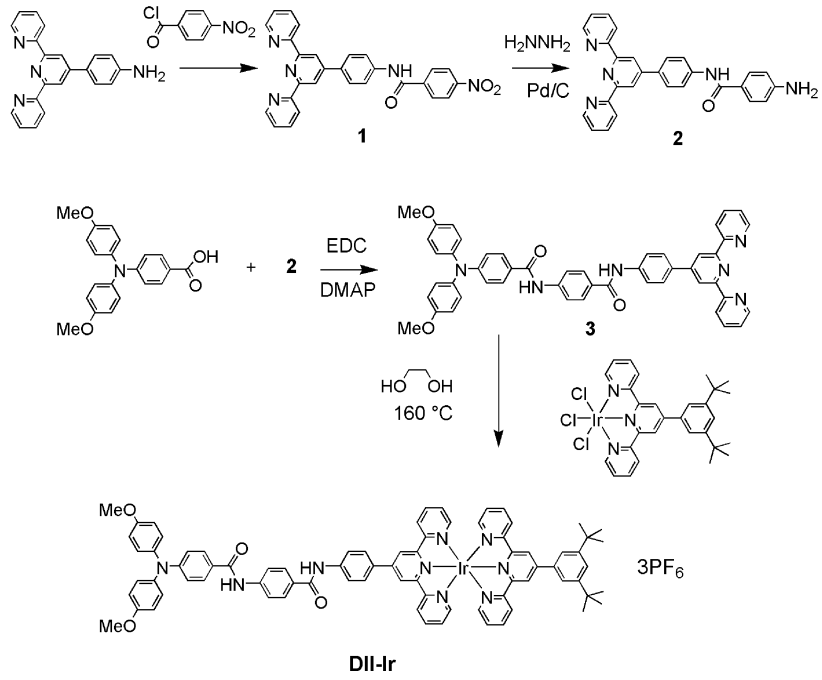

Scheme 3. Synthesis of the dyad **DII-Ir**.

ges, was prepared by condensation of the terpyridine **2** with 4-[bis(4-methoxyphenyl)amino]benzoic acid, in the presence of DMAP and EDC (peptidic coupling).[10] The dyad **DII-Ir** was obtained in 70% yield by reaction of the precursor [4′-(3,5-di-*tert*-butylphenyl)-2,2′:6′,2′′-terpyridine]-$IrCl_3$[5a] with the terpyridine **3** in ethylene glycol at 160 °C during 20 min.

## Electrochemistry

The redox characteristics of the reference compounds **Ir1** and **DII** as well as that of the dyad **DII-Ir** examined by cyclic voltammetry in $CH_3CN$ are reported with the values previously obtained for **D** and **D-Ir** in Table 1. One-electron reversible waves were observed for all the redox processes, in the dyad they were easily assigned to the corresponding individual components. A few mV of difference with respect to the short dyad **D-Ir** are observed in the redox couples of the donor group ($D^+$/D) and of the complex (terpy/terpy$^-$). Clearly, the presence of a second amide bridge in the dyad **DII-Ir** weakens even more the electronic coupling between the two redox entities.

Table 1. Cyclic voltammetry data of the reference compounds **Ir1**, **DII,** and the dyad **DII-Ir** in acetonitrile, 0.1 M $nBu_4NPF_6$, with SCE as a reference. Values for dyad **D-Ir** and model **D** are also reported.[7]

| | $E_{1/2}$ (V vs. SCE) | |
|---|---|---|
| | $D^+$/D | terpy/terpy$^-$ |
| **Ir1** | | –0.76 |
| **D** | 0.80 | |
| **D-Ir** | 0.75 | –0.75 |
| **DII** | 0.76 | |
| **DII-Ir** | 0.76 | –0.78 |

## Absorption Spectroscopy

The absorption spectra in acetonitrile of the components, their superposition, and the experimental spectrum of the array are reported in Figure 1. There is, within experimental errors, a good overlap of the experimental spectrum of **DII-Ir** with the calculated superposition of the model components in the 250–350 nm range, whereas the array spectrum differs slightly from the calculated one above 350 nm. In fact, it displays a slightly higher absorbance and a broadening on the low energy side. Quite remarkably, the broadening toward the low-energy range of the spectrum is less pronounced with respect to the short dyad **D-Ir**, characterized by an absorption extending over 500 nm, see inset of Figure 1. In order to understand this behavior we have to recall that, whereas in $(tpy)_2Ir^{3+}$-type complexes the low-energy absorption band is in general a predominantly LC transition, complexes of the $(tpy)_2Ir^{3+}$-type with benzamide sub-

stituents were recently demonstrated to exhibit photophysical properties at room temperature typical of a CT state, either of metal-to-ligand charge-transfer nature (MLCT) or of intraligand charge-transfer nature (ILCT).[5,11,12] The presence of an amine electron donor as a substituent can strongly enhance the ILCT nature of the transition, with the terpyridine acting as an electron acceptor and the amine as an electron donor, and further shift the absorbance to the red. From this point of view, interposition of a further amide spacer between the terpyridine acceptor and the aromatic amine donor has the effect of increasing the energy of the band, moving it further to the blue, as noticed in the inset of Figure 1 for **DII-Ir** compared to **D-Ir**.

If we ignore the small perturbation of the spectrum of the Ir unit discussed above, there is no evidence from the spectroscopic data of electronic interactions in the array with respect to the models, in agreement with the electrochemical data. This allows us to use a localized description of the individual subunits in the subsequent discussion of the photoinduced energy and electron-transfer reactions.

### Luminescence Spectroscopy

**DII** emits strongly, with a band maximum at 524 nm, slightly blueshifted with respect to the short analog **D** ($\lambda_{max}$ = 540 nm); **Ir1** emits moderately with a maximum at 570 nm (Table 2).

Table 2. Luminescence properties in air-equilibrated nitrile solvents. Acetonitrile at 295 K and butyronitrile at 77 K.

| | State | 295 K | | | 77 K | | |
|---|---|---|---|---|---|---|---|
| | | $\lambda_{max}$ [nm] | $\tau$ [ns] | $\Phi_{em}$ | $\lambda_{max}$ [nm] | $\tau$ [ns] | $E$ [eV] |
| **Ir1**[a,b] | $^3$Ir1 | 570 | 490 | $2.1\times10^{-3}$ | 510 | 80000 | 2.43 |
| **D**[b] | $^1$D | 540 | 0.450 | 0.012 | 422 | 2.6 | 2.93 |
| **D-Ir**[b] | D-$^3$Ir | | – | $\leq6\times10^{-5}$ | 515[d] | – | 2.40 |

| **DII**[c] | $^1$DII | 524 | 1.0 | 0.073 | 414 | 2.0 | 2.99 |
| **DII-Ir** | DII-$^3$Ir[a] | 570 | – | $6\times10^{-5}$ | 516 | | 2.40 |
| | $^1$DII-Ir[c] | | 0.01 | $5\times10^{-4}$ | 400[d] | | 3.10 |

[a] Excitation at 430 nm for steady state, for time-resolved determinations excitation at 373 nm. [b] From ref.[7] [c] Excitation at 330 nm for steady state, for time-resolved determinations excitation at 373 nm, 331 nm, or 355 nm. [d] Weak signal.

The luminescence spectra of the array **DII-Ir** at room temperature upon selective excitation of the Ir unit at 430 nm is compared to those of the model **Ir1** absorbing the same number of photons as the unit in the array (Figure 2, right panel). In the left panel of Figure 2 the luminescence detected in the dyad upon excitation at 330 nm, corresponding to excitation of both DII and Ir complex units (absorbing 50% each), is reported and compared to the luminescence from a solution of **DII** absorbing the same number of photons as the unit in the array. The emission of Ir and DII units in the dyad are nearly completely quenched, to ca. 3% and less than 1%, respectively, indicating the occurrence of an efficient quenching process involving both $^3$Ir and $^1$DII. It should be noticed that the weak residual luminescence in **DII-Ir** could be due to some very minor, unbound component in the dyad and not to a genuine quenched unit in the array; the definitive answer on the effective quenching of the component in the dyad can only be provided by the time-resolved experiments, discussed below.

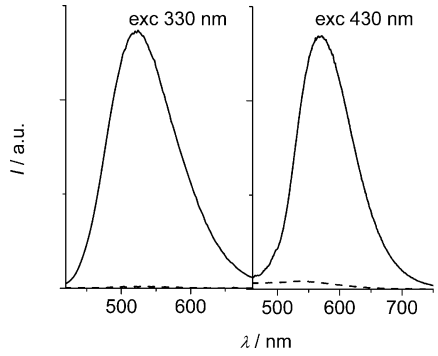

Figure 2. Room-temperature luminescence spectra in acetonitrile. Left panel: excitation at 330 nm, 50% excitation of DII and Ir components, **DII** (solid line) $A$ = 0.056, **DII-Ir** (dashed line) $A$ = 0.12. Right panel: selective excitation at 430 nm of Ir component, **Ir1** (solid line), $A$ = 0.13, **DII-Ir** (dashed line) $A$ = 0.13. The absorbance of the solutions is arranged to provide the absorption of the same number of photons in the model and in the corresponding unit in the array.

Luminescence spectra of the models **Ir1** and **DII** at 77 K in a glassy butyronitrile matrix display emission maxima at 414 and at 510 nm, respectively, with a remarkable hypsochromic shift from fluid (295 K) to rigid (77 K) solvent (see Table 2). This can be explained by a strong CT character for the $^1$DII emitting excited state which is less stabilized in a rigid medium; in the case of **Ir1**, a change in the spectral profile is also detected (compare Figures 2 and 3), indicative of a switching of the excited-state nature from a room-temperature CT to a predominantly ligand-centered state in the glass, as previously discussed.[11]

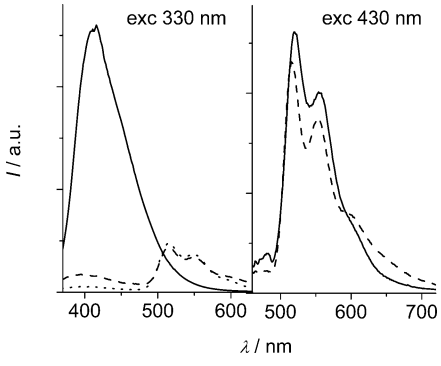

Figure 3. Luminescence spectra in butyronitrile at 77 K. Left panel: excitation at 330 nm, 50% excitation of DII and Ir components, **DII** (solid line) $A$ = 0.1, **Ir1** (dotted line) $A$ = 0.1, **DII-Ir** (dashed line) $A$ = 0.2. Right panel: selective excitation at 430 nm of Ir component, **Ir1** (solid line) $A$ = 0.08, **DII-Ir** (dashed line) $A$ = 0.08. The absorbance of the solutions is arranged to provide the absorption of the same number of photons in the model and in the corresponding unit in the array.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

Luminescence experiments on the models and **DII-Ir** in butyronitrile glass at 77 K show that nearly no quenching of the Ir unit occurs at 77 K, whereas the DII unit is still strongly quenched also at 77 K, as evidenced in Figure 3 which compares the luminescence from **DII** and **Ir1** solutions to that from **DII-Ir** after selective excitation of the Ir complex unit at 430 nm in the right panel, or of the DII and Ir components (absorbing 50% each) at 330 nm in the left panel. With respect to the results previously reported for the short corresponding dyad **D-Ir** both at room temperature and at 77 K, in **DII-Ir** the luminescence quenching is less effective. This is in agreement with a slower electron transfer over the longer bridge connecting the donor to the Ir complex.

The luminescence lifetimes of the model **Ir1** in air-equilibrated acetonitrile solution determined by a single photon nanosecond apparatus, is 490 ns.[7] Any attempt to determine the lifetime of the Ir unit in the dyad was unsuccessful at room temperature, neither a single-photon counting technique with 0.3 ns resolution, nor a streak-camera detection with 10 ps resolution allowed any emission to be registered. Given the very low radiative rate constant of the Ir complex, $k_r \approx 5 \times 10^3$ s$^{-1}$ ($k_r = \phi/\tau$), a technique like the single-shot streak camera is not convenient for detecting such low emissions, therefore we cannot exclude for the $^3$Ir component in **DII-Ir** a lifetime shorter than 0.3 ns. Only the time-resolved absorption data discussed below will clear this point. The strong emission of **DII** was time-resolved by a picosecond streak camera after excitation at 355 nm and displays a lifetime of 1.0 ns. This luminescence is quenched in **DII-Ir** and displays a time profile very similar to the instrumental response (Figure 4) from which a lifetime of ca. 10 ps can be calculated by deconvolution with the instrumental profile. This value is in reasonable agreement with steady-state data, which indicates a reduction in the emission yield of the order of 1% in passing from the **DII** model to the dyad **DII-Ir**. In the case of the short dyad **D-Ir**, no luminescence could be detected from the D component, confirming a more efficient quenching due to electron transfer responsible for charge separation and allowing us to set an upper limit to the lifetime of $\tau << 10$ ps.

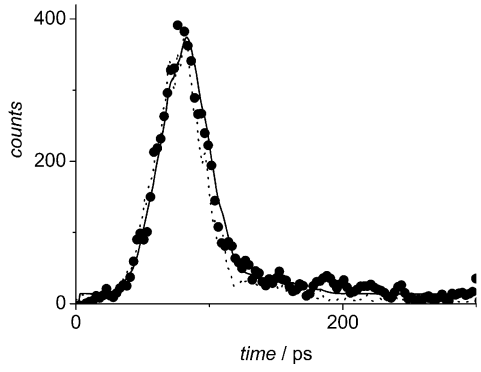

Figure 4. Luminescence registered at 520 nm from **DII-Ir** acetonitrile solution after excitation with a laser pulse (35 ps, 355 nm, 1 mJ) (full circles) with the instrumental pulse profile (dotted line) and the fitting (solid line).

Time-resolved experiments at 77 K in butyronitrile glass allowed the following parameters to be measured. The lifetime of the models **D** and **DII** are 2.6 and 2 ns, respectively, showing a slight temperature dependence. On the contrary, the lifetime of **Ir1** at 77 K is 80 μs, much longer than at room-temperature (Table 2). This has to be assigned to a switch in the nature of the excited state when the medium becomes rigid from $^3$CT, very likely of intra-ligand charge-transfer nature, to a $^3$LC, as already discussed above. In the dyad **DII-Ir**, the lifetime of Ir measured with a time-correlated single photon apparatus is 56 μs compared to the 80 μs of the model, confirming a very modest quenching in agreement with steady-state experiments. The DII unit decay in the dyad **DII-Ir** at 77 K was still extremely fast and of the same order as the exciting profile; an accurate determination of the lifetime was precluded by the strong light scattering in the glass. From the short counterpart **D-Ir** no luminescence could be detected similarly to what occurs at room temperature.

## Transient Absorption Spectroscopy

Valuable information on the products of electron transfer can be gained by transient absorption techniques. The chemically generated cation DII$^+$ (see Exp. Sect. for details) has a peak at 760 nm ($\varepsilon \approx 27400$) and a minor broad band at 590 nm, in agreement with previous reports.[13] It should be noted that at the excitation wavelength, 355 nm, both units of the **DII-Ir** dyad absorb light with the following probability (see Figure 1): 60% for Ir, 40% for D.

The end of pulse transient absorption spectra detected with picosecond resolution of optically matched solutions of the models and **DII-Ir** are reported in Figure 5. **Ir1** displays a strong absorption band with a broad maximum around 780 nm assigned to $^3$Ir1, stable on the 3 ns window of the experiment. **DII** displays a sharp band at 750 nm with a lifetime of ca. 900 ps, in reasonable agreement with the luminescence lifetime of 1.0 ns, indicating that the detected species is the singlet excited state $^1$DII.[14] The time-resolved spectrum of **DII-Ir** has a maximum at 765 nm which, for similarity with the spectrum of D$^+$-Ir$^-$ ($\lambda_{max}$ = 765 nm) and with the chemically generated spectrum of DII$^+$, is assigned to the CS state DII$^+$-Ir$^-$. No trace of the spectral features of DII, which has in fact been shown by luminescence experiments to decay with a lifetime of 10 ps, i.e. during the laser pulse, is detected. Similarly, no absorbance ascribable to $^3$Ir, which would be easily identifiable because of its broad and intense spectrum, appears at the end of the pulse. This set up the unsolved problem of the lifetime of DII-$^3$Ir species, which could not be unambiguously determined by luminescence techniques (see above). By transient absorbance experiments we can set an upper limit of 20 ps for the lifetime of DII-$^3$Ir, a longer lifetime of this species would in fact cause the appearance in the spectrum registered at the end of the pulse of the typical features of the $^3$Ir absorbance (see Figure 5) which are, on the contrary, absent. The time evolution of the spectrum, re-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

ported in Figure 6 with the extracted time profile, allows us to derive a lifetime of the CS state of 210 ps. The absorbance decays to the baseline without leaving any residual absorbance in the longer timescale, as confirmed by nanosecond flash-photolysis experiments on **DII-Ir**. No residual absorbance in the nanosecond time scale can be detected for **DII** either, on the contrary nanosecond flash-photolysis experiments allow us to detect in **Ir1** solutions the full evolution of the $^3$Ir1 species in air-equilibrated samples which has a lifetime of 440 ns, in good agreement with the luminescence lifetime.

The singlet excited state $^1$D derived from the component **D** displayed an identical absorption spectrum but a shorter lifetime of 490 ps and, as far as the CS state is concerned, DII$^+$-Ir$^-$ has a nearly identical spectrum but a much longer lifetime than D$^+$-Ir$^-$ (70 ps).

The transient absorbance data for the models, **D-Ir** and **DII-Ir** are collected in Table 3.

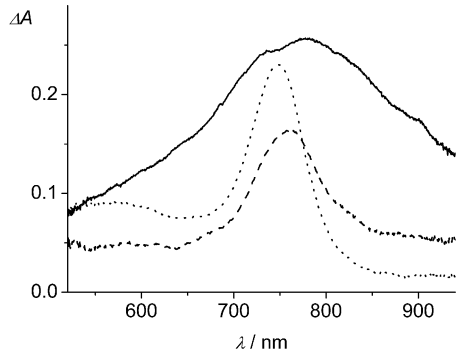

Figure 5. End of pulse absorption spectra of **Ir1** (solid line), **DII** (dotted line), and **DII-Ir** (dashed line) in acetonitrile solutions upon excitation at 355 nm (2.8 mJ/pulse, 35 ps pulse). All solutions had $A$ = 0.51 at the exciting wavelength.

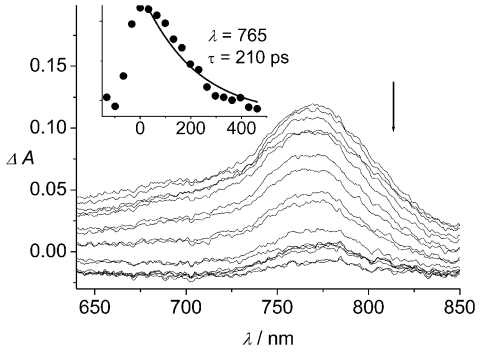

Figure 6. Time evolution of the transient spectrum of **DII-Ir** in acetonitrile (2.5 mJ, $A$ = 0.5); spectra taken with delays of 165 ps. In the inset, the time evolution of the absorbance at 765 nm and exponential fitting are shown.

Table 3. Transient absorption data at room temperature (excitation at 355 nm) in air-equilibrated acetonitrile solutions of **DII-Ir**, **D-Ir**, and models.

| | State | $\lambda_{max}$ [nm] | $\tau$ [ns] |
|---|---|---|---|
| **Ir1**[a] | $^3$Ir1 | 780 | 440 |

## Photoinduced Processes

Scheme 4 shows the energy level diagrams of the present **DII-Ir** dyad and of the corresponding short dyad **D-Ir** [7] and can help to discuss and compare the processes in the two cases.

These diagrams can be drawn from the luminescence data collected in Table 2 and from the electrochemical data reported in Table 1. The excited-state energies are derived from the maxima of the emission at 77 K (Table 2), whereas the charge-separated state energy levels are calculated by simply adding the energy necessary to oxidize the potential donor and the energy necessary to reduce the potential acceptor in acetonitrile (Table 1) without further corrections.

Both dyads are made of an easy to oxidize D or DII component ($E_{1/2}$ = +0.75 V and $E_{1/2}$ = +0.76 V in the pertinent dyads, respectively) and of the iridium complex which can be reduced at low potentials ($E_{1/2}$ = –0.75 V in the short and $E_{1/2}$ = –0.78 V in the long dyad) yielding charge-separated states D$^+$-Ir$^-$ or DII$^+$-Ir$^-$ with an energy of 1.51 and 1.54 eV, respectively (Table 1). These are characterized by an extra electron localized on the metal complex, most probably on the ligand, and a hole on the triphenylamine donor. Charge separation is feasible both from the excited donor, $^1$DII-Ir ($^1$D-Ir) and from the excited acceptor DII-$^3$Ir (D-$^3$Ir) but the excited state quenching mechanism in the two cases will be different. When Ir is excited, a reductive quenching of its excited state will occur, i.e. the electron will move from the HOMO localized on the donor to the HOMO localized on the Ir complex, with $\Delta G^0$ = –0.9 and –0.86 eV for **D-Ir** and **DII-Ir**, respectively. When the donor is excited, an electron will move from the LUMO localized on DII to the LUMO on the Ir complex acceptor, with $\Delta G^0$ = –1.43 eV for **D-Ir** and $\Delta G^0$ = –1.56 eV for **DII-Ir**. Both types of electron transfer take place at room temperature, as testified by the quenching of the luminescent states localized on both units as shown in Figures 2 and 4.

We cannot exclude the possibility of an energy transfer from $^1$DII-Ir to DII-$^3$Ir, which is spin-forbidden but could be made possible by the strong spin-orbit coupling induced by the heavy Ir ion. The overall result would be undistinguishable from a direct electron transfer from the excited state localized on the donor; however, the 77 K experiment seems to indicate that such an energy transfer (expected to be little affected by temperature) does not take place. In the latter case in fact we would expect a sensitization of the Ir luminescence upon excitation of the DII unit at 330 nm,

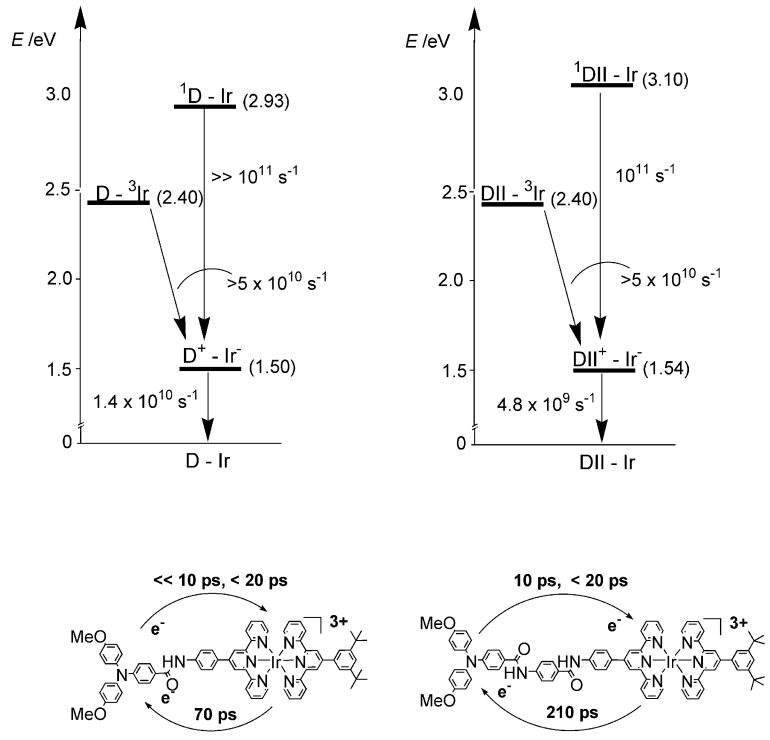

Scheme 4. Energy-level diagrams and schematic representation of the processes for **D-Ir** and **DII-Ir**.

which does not occur (see Figure 3). Therefore, the following discussion will not take the spin-forbidden energy transfer process into account.

Whereas we could measure the reaction rate of $^1$DII-Ir → DII$^+$-Ir$^-$, $k_{cs} = 10^{11}$ s$^{-1}$, corresponding to the lifetime of 10 ps, for the DII-$^3$Ir → DII$^+$-Ir$^-$ reaction we could only set a lower limit, $k_{cs} > 5 \times 10^{10}$ s$^{-1}$, based on the results of the transient absorbance (see above). In the short dyad **D-Ir**, similar results were obtained for the D-$^3$Ir → D$^+$-Ir$^-$ reaction, for which an identical lower limit of the rate constant $k_{cs} > 5 \times 10^{10}$ s$^{-1}$, corresponding to the time resolution of the transient absorbance experiment, was set. For the $^1$D-Ir → D$^+$-Ir$^-$ step, the improved time resolution of the apparatus with respect to previously reported data ($k_{cs} > 5 \times 10^{10}$ s$^{-1}$)[15] allowed us to set a limit of $k_{cs} > 10^{11}$ s$^{-1}$. The driving force of the charge-separation reactions are not very different in going from the short to the long dyad, but the distance between the donor and acceptor changes remarkably, from 1.65 to 2.3 nm. Therefore, a slower charge separation step $^1$DII-Ir → DII$^+$-Ir$^-$ compared to $^1$D-Ir → D$^+$-Ir$^-$ can be measured. On the contrary, for the charge separation starting from the excited state of the Ir metal complex, either DII-$^3$Ir → DII$^+$-Ir$^-$ or D-$^3$Ir → D$^+$-Ir$^-$, it is difficult to make comparisons since the same lower limit for the rate constant has been determined. Overall, a slight decrease in the rate of charge separation can be registered in **DII-Ir** compared to **D-Ir**; however, the yield of charge separation – $\phi_{cs} = k_{cs}/\Sigma k = k_{cs}/(k_{cs} + 1/\tau_0)$, where $\tau_0$ is the lifetime of the excited state in the models – is still of the order of 99% when starting from $^1$DII-Ir ($\tau_0$ = 1 ns) and nearly 100% when starting from DII-$^3$Ir ($\tau_0$ = 490 ns in air). Thus, the insertion of a further benzamide group between the donor and acceptor is not too detrimental to the charge-separation process at room temperature. This is different at 77 K, where the absence of quenching of the Ir component and the persistence of the quenching of the D unit in the dyad at 77 K indicate that electron transfer from DII-$^3$Ir is inefficient and only electron transfer from $^1$DII-Ir continues to be operative with a still remarkable rate of the order of 20 ps (Figure 3 and Table 2). This can be understood if one considers that the rigidity of the medium, preventing solvent molecule reorganization around the CS state, destabilizes the CS level by a value which can be quite high[16] and decreases the driving force for electron-transfer reactions originating from the DII-$^3$Ir and the $^1$DII-Ir states. Under these conditions, the lowest-lying DII-$^3$Ir (ca. 2.4 eV) is unable to transfer an electron, whereas the higher $^1$DII-Ir (ca. 3 eV) has sufficient driving force to transfer the electron also in rigid media at 77 K.

Once the charge-separated state DII$^+$-Ir$^-$ is formed, it decays to the ground state with a lifetime of 210 ps, three-times shorter than D$^+$-Ir$^-$ which has a lifetime of 70 ps. The driving force of the charge-recombination reaction is high, leading us to assume a Marcus-inverted behavior, i.e. the rate slows as the driving force increases.[17] The driving force is slightly higher for **DII-Ir** compared to **D-Ir** ($\Delta G^0$ = –1.54 eV for the long dyad against $\Delta G^0$ = –1.50 eV), but most importantly the insertion of a further benzamide group is effective in electronically decoupling the donor and acceptor units in the long dyad and decreases the charge-recombination rate. The increase from 70 to 210 ps lifetime in passing from **D-Ir** to the long **DII-Ir** dyad, suggests that

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

a newly synthesized long triad DII-Ir-A could be more efficient in producing charge separation over the terminal components. In the **D-Ir-A** triad, as discussed above, the poor efficiency of charge separation was due to the fast step ($k = 1.4 \times 10^{10}\ s^{-1}$) preferably leading $D^+$-$Ir^-$-A to the ground state rather than to the fully CS state $D^+$-Ir-$A^-$ by a further electron transfer step ($k = 2.4 \times 10^9\ s^{-1}$). The decrease of the charge recombination step in $DII^+$-$Ir^-$-A ($k = 4.8 \times 10^9\ s^{-1}$), assuming that the rest of the triad is unchanged with respect to the previously studied **D-Ir-A** triad, would allow us to reach an efficiency of charge separation of the order of 30%. This would be a noticeable improvement with respect to the yield of ca. 10% achieved in the short triad **D-Ir-A** and, if we consider that due to the increased donor–acceptor distance an even longer lifetime of the final CS would be expected in a long triad DII-Ir-A, the demanding synthesis of this structure could be undertaken with some degree of confidence in satisfactory performances.

## Conclusions

We have synthesized a new dyad **DII-Ir** made of a triphenylamine donor and of a bis(terpyridine)$Ir^{III}$ acceptor separated by a bridge composed of two benzamide groups, and we have studied the photoinduced processes. The properties of the dyad have been compared to those of a corresponding dyad **D-Ir** characterized by a bridge connecting the donor and the acceptor consisting of a single benzamide unit. We showed that, whereas the charge-separation steps are still very efficient in the long dyad (≥99%), *charge recombination is slowed by a factor of three with respect to the short dyad*. This is promising and encourages the use of this dyad in the assembly of the more elaborate array DII-Ir-A. This would simply have a further benzamide unit in the spacer connecting DII to Ir, with respect to the already studied **D-Ir-A** triad of Scheme 1 for which an unsatisfactory yield of ca. 10% of charge separation was reported. In the long triad DII-Ir-A, a lifetime of the CS state $DII^+$-$Ir^-$-A of the order of 210 ps would be expected, similar to the dyad studied here. This would decrease the competition of the recombination to the ground state with respect to the further electron-transfer step leading to full charge separation over the extreme components with an efficiency of the order of 30% with respect to the ca. 10% of the previously studied **D-Ir-A** triad. It should also be stressed that, due to the increased D–A distance, an even longer lifetime of the final CS state, with respect to the 120 μs of the short **D-Ir-A** triad, is expected.

## Experimental Section

**General:** $^1H$ NMR spectra were acquired either with a Bruker WP 200 SY, a Bruker AC300, or a Bruker AM 400 spectrometer, using the deuterated solvent as the lock and residual solvent as the internal reference ($CD_3CN$: δ = 1.96 ppm; [$D_6$]DMSO: δ = 2.52 ppm). Electron spray ionization mass spectra (ESI-MS) were recorded with a Bruker MicroTOF instrument. Cyclic voltammetry experiments were performed using an EG&G 273A potentiostat, a Pt working electrode, a Pt counter-electrode, a KCl-saturated calomel electrode (SCE) as a reference, and 0.1 M $nBu_4NPF_6$ in $CH_3CN$ as the supporting electrolyte. The typical sweep rate was 100 mV/s.

**Starting Compounds:** [4′-(3,5-Di-*tert*-butylphenyl)-2,2′:6′,2′′-terpyridine]$IrCl_3$,[5a] tpy-ph-$NH_2$,[9] 4-[bis(4-methoxyphenyl)amino]benzoic acid, **DII** and **Ir1**[7] were prepared according to the published procedures.

**1:** terpy-ph-$NH_2$ (500 mg, 1.54 mmol) was dissolved in dimethylacetamide (8 mL), after which some pyridine (2 mL) was added. Upon addition of *p*-nitrobenzoyl chloride (410 mg, 2.2 mmol, excess), the color of the solution immediately turned from pale yellow to deep yellow. After stirring at room temperature for 28 h, the reaction mixture was added dropwise to cold $Et_2O$ and was placed in the freezer for 30 min to induce precipitation. The dark yellow precipitate of **1** was filtered off and dried under vacuum. Yield: 95% (700 mg). $C_{28}H_{19}N_5O_3$ (473.48): calcd. C 71.03, H 4.04, N 14.79; found C 71.45, H 4.03, N 14.47. $^1H$ NMR ([$D_6$]DMSO, 200 MHz): δ = 10.87 (s, 1 H, NH), 8.86–8.83 (m, 6 H, 6-H, 3-H, 3′-H, 5′-H), 8.44–8.08 (m, 10 H, o1-H, m1-H, o2-H, m2-H, 4-H), 7.72–7.65 (m, 2 H, 5-H) ppm. $^{13}C$ NMR ([$D_6$]DMSO, 75 MHz): δ = 164.1, 153.5, 152.6, 149.6, 149.3, 147.6, 147.5, 140.5, 140.3, 132.0, 129.4, 127.7, 125.6, 123.6, 122.4, 120.9, 118.9 ppm. ES-MS: *m*/*z* (calcd.) = 474.16 (474.15) $[M + H]^+$.

**2:** Compound **1** (230 mg; 0.49 mmol) was suspended in refluxing MeOH/THF (1:1, v/v; 100 mL). Pd/C 5% (108 mg) was added as a solid, and a mixture of hydrazine monohydrate (0.5 mL) in MeOH (5 mL) was added dropwise over a period of 10 min. After the addition, the colorless solution was refluxed for 40 min, cooled to room temperature, filtered through Celite, and concentrated. After one night in the refridgerator, the precipitate was filtered off and washed with water, MeOH, and $Et_2O$. Compound **2** was obtained as a colorless solid. Yield: 97% (210 mg). $C_{28}H_{21}N_5O$ (443.50): calcd. C 75.83, H 4.77, N 15.79; found C 74.14, H 4.63, N 15.20. $^1H$ NMR ([$D_6$]DMSO, 200 MHz): δ = 10.02 (s, 1 H, NH), 8.79 (dd, $^4J$ = 4.7, $^5J$ = 0.8 Hz, 2 H, 6-H), 8.75 (s, 2 H, 3′-H, 5′-H), 8.70 (d, $^3J$ = 7.9 Hz, 2 H, 3-H), 8.06 (m, 2 H, 4-H), 8.00 (m, 2 H, o1-H, m1-H), 7.79 (d, $^3J$ = 8.6 Hz, 2 H, o2-H), 7.55 (ddd, $^3J$ = 7.5, $^4J$ = 4.7, $^5J$ = 1.0 Hz, 2 H, 5-H), 6.64 (d, $^3J$ = 8.6 Hz, 2 H, m2-H) ppm. $^{13}C$ NMR ([$D_6$]DMSO, 75 MHz): δ = 161.5, 152.0, 151.5, 148.8, 145.7, 145.4, 137.7, 133.8, 127.8, 125.9, 123.5, 120.9, 117.3, 117.2, 116.9, 113.7, 108.9 ppm. ES-MS: *m*/*z* (calcd.) = 444.18 (443.17) $[M + H]^+$.

**3:** DMAP (470 mg, 3.64 mmol, 3.3 equiv.) and EDC (420 mg, 2.20 mmol, 1.9 equiv.) were added to a solution of 4-[bis(4-methoxyphenyl)amino]benzoic acid (634 mg, 1.81 mmol, 1.5 equiv.) in freshly distilled $CH_2Cl_2$ (6 mL). After a few minutes of stirring, the solution was deep yellow. **2** (500 mg, 1.13 mmol) and DMF (1 mL) were added, and the reaction mixture was stirred under argon at 40 °C for 10 h. $CH_2Cl_2$ was removed under reduced pressure. Water and saturated $NaHCO_3$ solution (25 mL each) were added resulting in a pale yellow precipitate which was filtered off and washed with $NaHCO_3$ solution, water and then with a mixture of $CH_2Cl_2$/$Et_2O$ (1:1, v/v) to afford **3** as a pale yellow solid in 71% yield (626 mg, 0.81 mmol). $C_{49}H_{38}N_6O_4$ (774.86): calcd. C 75.95, H 4.94, N 10.85; found C 74.97, H 4.76, N 10.46. $^1H$ NMR ([$D_6$]DMSO, 300 MHz): δ = 10.37 (s, 1 H, NH), 10.23 (s, 1 H, NH), 8.78 (d, $^3J$ = 4.1 Hz, 2 H, 6-H), 8.70 (s, 2 H, 3′-H, 5′-H), 8.68 (d, $^3J$ = 7.9 Hz, 2 H, 3-H), 8.08–8.94 (m, 10 H, 4-H, o3-H, m3-H, o4-H, m4-H), 7.82 (d, $^3J$ = 8.9 Hz, 2 H, o5-H), 7.54 (ddd, $^3J$ = 7.5, $^3J$ = 4.9, $^4J$ = 1.1 Hz, 2 H, 5-H), 7.14 (d, $^3J$ = 9.0 Hz, 4 H, a-H), 6.98 (d, $^3J$ = 9.0 Hz, 4 H, b-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

H), 6.74 (d, $^3J$ = 8.9 Hz, 2 H, m5-H), 3.77 (s, 6 H, $CH_3$) ppm. ES-MS: *m*/*z* (calcd.) = 775.31 (775.30) $[M + H]^+$.

**DII-Ir:** A suspension of [4′-(3,5-di-*tert*-butylphenyl)-2,2′:6′,2′′-terpyridine]$IrCl_3$ (48 mg, 0.067 mmol) and **3** (51 mg, 0.066 mmol) in ethylene glycol (15 mL) was homogenized under ultrasound during 25 min, then heated at 160 °C during 20 min under argon. The crude product was precipitated with a saturated solution of $KPF_6$, filtered off, and purified on silica ($CH_3CN/H_2O/KNO_3$, 100:0:0 to 100:7:0.7). After anion exchange, **DII-Ir** was obtained as a yellow solid. Yield: 70% (85 mg). $^1$H NMR ($CD_3CN$, 400 MHz): $\delta$ = 9.15 (s, 1 H, 1-NH), 9.10 (s, 2 H, 3′-D, 5′-D), 9.04 (s, 2 H, 3′-H, 5′-H), 8.82 (s, 1 H, 2-NH), 8.78 (dd, $^3J$ = 8.2, $^4J$ = 0.7 Hz, 2 H, 3-H), 8.73 (dd, $^3J$ = 8.2, $^4J$ = 0.7 Hz, 2 H, 3-D), 8.29–8.22 (m, 6 H, 4-H, 4-D, o3-H), 8.19 (d, $^3J$ = 8.9 Hz, 2 H, m3-H), 8.02 (d, $^3J$ = 8.8 Hz, 2 H, o4-H), 7.99 (d, $^4J$ = 1.7 Hz, 2 H, o-H), 7.90 (d, $^3J$ = 8.8 Hz, 2 H, m4-H), 7.87 (t, $^4J$ = 1.7 Hz, 1 H, p-H), 7.77–7.69 (m, 6 H, o5-H, 6-H, 6-D), 7.52–7.47 (m, 4 H, 5-H, 5-D), 7.17 (d, $^3J$ = 8.9 Hz, 4 H, a-H), 6.96 (d, $^3J$ = 8.9 Hz, 4 H, b-H), 6.7 (d, $^3J$ = 8.9 Hz, 2 H, m5-H), 3.80 (s, 6 H, $CH_3$), 1.52 (s, 18 H, *t*Bu) ppm. HR ES-MS: *m*/*z* (calcd.) = 1678.4467 (1678.4387) $[M - PF_6]^+$.

The **DII$^+$** species was generated by the addition of one drop of $Br_2$ to a solution of **DII** ($2.5 \times 10^{-4}$ M, 2 mm optical path) in acetonitrile, the calculated molar absorption coefficient assuming complete conversion of the starting **DII** was $\varepsilon$ = 27400 $M^{-1}cm^{-1}$ at 760 nm.

For the photophysical experiments, the solvents were spectrophotometric-grade acetonitrile at 295 K and butyronitrile at 77 K. If not otherwise specified, solutions were at ambient temperature and air-equilibrated. Standard 10 mm fluorescence cells were used at 295 K whereas experiments at 77 K made use of capillary tubes in a home-made quartz Dewar filled with liquid nitrogen. Because of geometrical irradiation conditions at 77 K the absolute quantum yield could not be determined, but the relative emission yields could be derived with some confidence. When necessary, solutions were bubbled for 10 min with a stream of argon in home-modified 10 mm fluorescence cells. A Perkin–Elmer Lambda 9 UV/Vis spectrophotometer and a Spex Fluorolog II spectrofluorimeter were used to acquire absorption and emission spectra. Emission quantum yields were determined after correction for the photomultiplier response, with reference to air-equilibrated (3,5-di-*tert*-butylphenyl-2,2′;6′,2′′-terpyridine)$_2$Ir$^{III}$$(PF_6)_3$ with $\phi_{em}$ = 0.022 in air-saturated acetonitrile.[5a] Luminescence lifetimes ($\tau$) were obtained with IBH single-photon counting equipment upon excitation at 373 and 331 nm from a pulsed diode source or with an apparatus based on an Nd:YAG laser (35 ps pulse duration, 355 nm, 0.5 mJ) and a Streak Camera with an overall resolution of 10 ps.[18] Transient absorbance in the picosecond range made use of a pump and probe system based on an Nd-YAG laser (Continuum PY62/10, 35 ps pulse). The third harmonic (355 nm) at a frequency of 10 Hz and an energy of ca. 3 mJ/pulse was used to excite the samples whose absorbance at the excitation wavelength was ca. 0.6. The residual 1064 nm light (ca. 40 mJ) was focused on a stirred 10 cm cell containing a mixture of $D_2O/D_3PO_4$ to produce a white light continuum which was used as analyzing light. A computer-controlled optical delay stage (Ealing) on the path of the excitation beam provided a delay between excitation and analysis. The analyzing light was split into two parts probing irradiated and un-irradiated portions, respectively, of the sample and crossed the sample cell in a nearly collinear geometry with respect to the excitation beam. The transmitted probes were fed through optical fibers into a spectrograph (Spectrapro 275, Acton) and were detected in two separate regions of a CCD detector (Princeton Instruments). The control units for the delay line, for the spectrograph and for the CCD detector were driven by customized software (Eurins) which also allowed us to acquire spectra at increasing time delays between the pump and the probe. Typically, 200–500 laser shots were collected and averaged to obtain a single spectrum at a specific time delay. Kinetic analyses were made by selecting the absorbance values of successive time-resolved spectra at the selected wavelength and by applying standard iterative procedures. More details can be found elsewhere.[19]

Nanosecond laser flash photolysis experiments were performed by a system based on an Nd-YAG laser (JK Lasers, 355 nm, 1.5–8.5 mJ, 18 ns pulse) previously described using a right-angle analysis on the excited sample.[20] Experimental uncertainties are estimated to be within 10% for lifetime determination involving simple exponential, 20% for lifetime determinations involving multiple exponentials or more complex kinetics, 15% for quantum yields, 20% for molar absorption coefficients and 3 nm for emission and absorption peaks. Molecular dimensions were estimated after MM2 energy minimization from CS Chem3D Ultra software.

# Preparation of 3,3-Di-*tert*-butylthiirane *trans*-1,2-Dioxide and Its Reaction with a Platinum(0) Complex To Give a (Disulfenato)platinum(II) Complex: Regioselectivity of the Oxidation of a Related (Sulfenato–thiolato)platinum(II) Complex

**Akihiko Ishii,*[a] Masayuki Ohishi,[a] and Norio Nakata[a]**

*Dedicated to Professor Renji Okazaki on the occasion of his 70th birthday*

**Keywords:** Platinum / Dithiirane / *vic*-Disulfoxide / Oxidative addition / Oxidation

A three-membered *vic*-disulfoxide, 3,3-di-*tert*-butyldithiirane *trans*-1,2-dioxide (**8**), was synthesized by oxidation of the corresponding dithiirane 1-oxide **15** in high yield. Treatment of **8** and **15** with a platinum(0) complex, $[(Ph_3P)_2Pt(\eta^2\text{-}C_2H_4)]$, yielded the (disulfenato)$Pt^{II}$ complex **18** and the (sulfenato–thiolato)$Pt^{II}$ complex **14**, respectively, in high yields. Oxidation of the sulfenato–thiolato complex **14** with an acetone solution of dimethyldioxirane (DMD) took place at the sulfenato sulfur atom to yield the (sulfinato–thiolato)$Pt^{II}$ complex **19**, while the oxidation with $CF_3CO_3H$ occurred at the thiolato-sulfur atom leading to the disulfenato complex **18**. Oxidation of **14** with MCPBA formed both **18** and **19**. The position of oxidation on **14** with DMD was dependent on the acidity of a coexisting acid. Thus, oxidation of **14** with DMD/$CF_3CO_2H$ provided **18** and that with DMD/$PhCO_2H$ gave **19**. Oxidation of **14** with an excess amount of DMD yielded the (disulfonato)$Pt^{II}$ complex **20**.

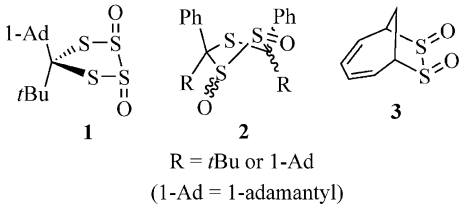
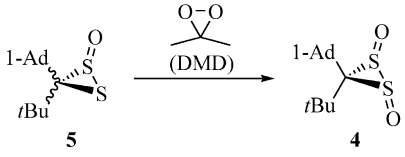
## Introduction

*vic*-Disulfoxides [RS(O)S(O)R] have long been recognized as unstable intermediates in the electrophilic oxidation of disulfides[1–3] until our success in 1999 with the isolation and unambiguous structure determination of tetrathiolane 2,3-dioxide **1**, which has a –S(O)–S(O)– bond.[4,5] Since then we have reported on isolable *vic*-disulfoxides **2**–**4**.[6–10] 3-(1-Adamantyl)-3-*tert*-butyldithiirane *trans*-1,2-dioxide (**4**) is the first three-membered *vic*-disulfoxide synthesized by the oxidation of the corresponding dithiirane 1-oxide **5** with an acetone solution of dimethyldioxirane (DMD) [Equation (1)].[9] An interesting reaction of **4** is its decomposition in refluxing chloroform as shown in Scheme 1 to give sulfine **6** and sulfur monoxide (SO) by the main path. SO was trapped with thioketone **7**, generated from a minor path, to provide dithiirane 1-oxide **5** (Scheme 1). The thermal decomposition was investigated in detail experimentally and theoretically, and, for the theoretical study, 3,3-di-*tert*-butyldithiirane *trans*-1,2-oxide (**8**) was employed as the model compound of **4**.[9]





(1)

In this paper we report on the synthesis and some reactions of *vic*-disulfoxide **8**, focusing, in particular, on the platinum complex of **8** and the related compounds. While the oxidative addition of several types of sulfur–sulfur bonds in cyclic sulfur compounds to platinum(0) complexes is a topic of recent research,[11–24] it has not been clarified whether *vic*-disulfoxides bring about a similar oxidative addition to platinum(0) complexes to provide (disulfenato)$Pt^{II}$ complexes.[20] We have reported the reaction of dithiirane 1-oxides with $[(Ph_3P)_2Pt(\eta^2\text{-}C_2H_4)]$ to provide the corresponding (sulfenato–thiolato)$Pt^{II}$ complexes **9** [Equa-

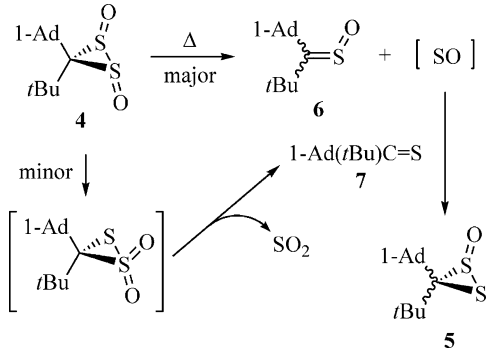

Scheme 1. Thermal decomposition of 3-(1-adamantyl)-3-*tert*-butyldithiirane *trans*-1,2-dioxide (**4**).

tion (2)].[18,19] The oxidation of (dithiolato)$M^{II}$ (M = Ni, Pd, Pt) complexes with molecular oxygen or hydrogen peroxide was studied extensively in relation to their air sensitivity.[25–39] We recently reported the regioselective oxidation of (dithiolato)$Pt^{II}$ complex **10** and its oxides with DMD under neutral conditions [Equation (3)].[24] We observed that the oxidation of the (sulfenato–thiolato)$Pt^{II}$ complex **11** led to the (sulfinato–thiolato)$Pt^{II}$ complex **12** and not the (disulfenato)$Pt^{II}$ complex **13**. This regioselectivity was rationalized in terms of the fact that the sulfenato sulfur is more reactive than the thiolato sulfur because of the back-donation of the platinum atom as Schenk proposed for the reaction of $CpRuL_2[S(O)R]$ (L = phosphane ligands) with DMD [Equation (4)].[40] In order to verify whether this regioselectivity of oxidation is true for the present system and whether the regioselectivity is influenced by the presence or absence of acid, the related (sulfenato–thiolato)$Pt^{II}$ complex **14** was prepared and subjected to an oxidation study.

## Results and Discussion

Di-*tert*-butyldithiirane 1-oxide (**15**) was prepared by the reaction of di-*tert*-butyldiazomethane with $S_8O$ in 12% yield,[41] and was treated with DMD (5.9 molar equiv.) in dichloromethane at –20 °C. The $^1H$ NMR spectrum of the reaction mixture showed the formation of the desired 1,2-dioxide **8**, di-*tert*-butyl thioketone *S*-oxide (sulfine) (**16**), and di-*tert*-butyl ketone in a ratio of 89:10:1 (Scheme 2). The high yield of **8** indicated that the over-oxidation to give the trioxides and higher oxides hardly occurred under these conditions. The dioxide **8** was isolated by recrystallization at –20 °C in 79% yield as pale-yellow plates. The oxidation with *m*-chloroperbenzoic acid (MCPBA) (6 molar equiv.) at –20 °C proceeded slowly to give **8** in 31% yield together with sulfine **16** (6%) and the starting compound **15** (63%) ($^1H$ NMR integral ratio). In the $^1H$ NMR and $^{13}C$ NMR spectra, the two *tert*-butyl groups of 1,2-dioxide **8** are equivalent, and in the $^{13}C$ NMR spectrum, the dithiirane carbon resonated at $\delta$ = 105.9 ppm, shifted to the lower field by 19.6 ppm than that of the 1-oxide **15** ($\delta$ = 86.3 ppm).

The structure of 1,2-dioxide **8** was determined by X-ray crystallography (Figure 1). In the crystal structure of **8** the *C*2 symmetry axis runs through the center of the S–S bond and the dithiirane carbon. The S–S bond length [2.2307(11) Å] is slightly longer than that of **4** [2.242(2) Å], and the dihedral angle O–S–S–O (149.0°) is very similar to that of **4** [149.6(3)°]. The angle between the two *tert*-butyl groups widens to 122.7(2)° as observed in **4** [123.6(5)°].[9]

1,2-Dioxide **8** was stable in the crystalline state at room temperature for a long time, but decomposed gradually in chloroform at room temperature to give sulfine **16** almost quantitatively after 9 d. Heating **8** in refluxing chloroform for 2 h yielded sulfine **16** (78%), dithiirane 1-oxide **15** (14%), and thioketone **17** (4%) [Equation (5)]. The reactions depicted in Scheme 1 can be applied to explain the

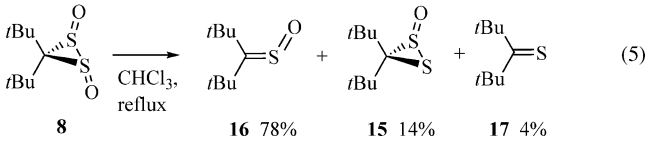
Relevant bond lengths [Å] and angles [°]: S1–O1 1.467(2), S1–C1 1.854(2), S1–S1* 2.2308(11), C1–C2 1.561(2), C1–S1 1.854(2), O1–S1–C1 115.79(10), O1–S1–S1* 113.48(9), C2–C1–C2* 122.7(2), C2–C1–S1* 110.44(10), C2–C1–S1 114.63(10), S1–C1–S1* 73.98(10).

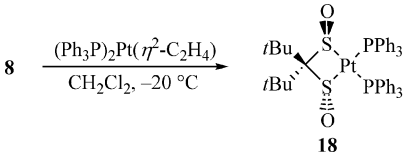
formation mechanism of **15**–**17**. No formation of **15** and **17** on the decomposition in chloroform at room temperature may indicate that the 1,2-oxygen shift of **8** to the dithiirane 1,1-dioxide requires a larger activation energy than the extrusion of SO to give **16**, which is consistent with the theoretical consideration.[9]



(5)

## Platinum Complexes

1,2-Dioxide **8** was treated with [$(Ph_3P)_2Pt(\eta^2\text{-}C_2H_4)$] in dichloromethane at 0 °C. The mixture containing the desired (disulfenato)Pt$^{II}$ complex **18**, sulfine **16**, and **8** was recrystallized from a mixed solvent of hexane and dichloromethane at –20 °C to give **18** as a yellow powder in 56% yield [Equation (6)]. The structure of **18** was supported by the following spectroscopic data. In the $^1$H NMR spectrum, the two *tert*-butyl groups are equivalent ($\delta$ = 1.41 ppm), indicating that the configuration of the two S=O groups in **18** is not *cis* but *trans*. In the $^{31}$P NMR spectrum a singlet accompanying the satellite signals ($^1J_{Pt,P}$ = 2596 Hz) from the $^{195}$Pt isotope is observed at $\delta$ = 15.2 ppm. This $^1J_{Pt,P}$ coupling constant value is comparable to those for phosphorus atoms *trans* to the S=O groups.[12–24] The absorption due to the S=O stretching vibration is observed at 1097 cm$^{-1}$ in the IR spectrum, which is close to those of the reported (sulfenato)Pt$^{II}$ complexes.[12–24] Recrystallization of **18** from benzene provided single crystals (yellow prisms) suitable for X-ray crystal analysis, and the structure was determined unambiguously (Figure 2).



(6)

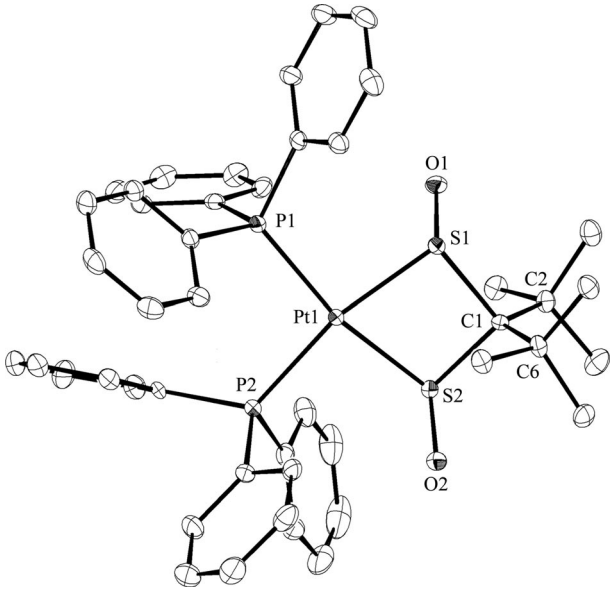


Figure 2. ORTEP drawing of (disulfenato)Pt$^{II}$ complex **18** with 30% probability thermal ellipsoids. Hydrogen atoms and the solvated molecules ($C_6H_6$) were omitted for clarity.

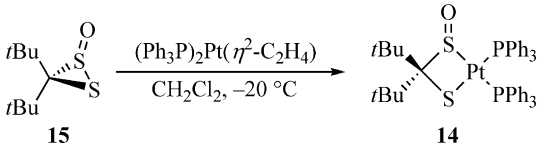
The (sulfenato–thiolato)Pt$^{II}$ complex **14** was prepared by the treatment of dithiirane 1-oxide **15** with [$(Ph_3P)_2Pt(\eta^2\text{-}C_2H_4)$] conducted in dichloromethane at –20 °C [Equation (7)]. The structure was determined by X-ray crystallography as depicted in Figure 3.



(7)

Oxidation of the sulfenato–thiolato complex **14** was investigated [Equation (8)] (Table 1). Oxidation with an equimolar amount of DMD in toluene at 0 °C yielded the (sulfinato–thiolato)Pt$^{II}$ complex **19** as the main product together with the starting complex **14**, sulfine **16**, and [$Pt(PPh_3)_2$-($S_2O_2$)][20,42] (Table 1, Entry 1). The (disulfenato)Pt$^{II}$ complex **18** was not formed at all. The structure of **19** was deter-

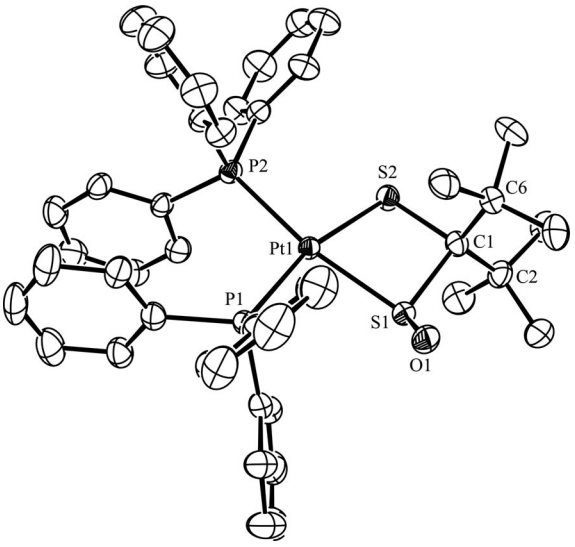

Figure 3. Molecular structure of the (sulfenato–thiolato)$Pt^{II}$ complex **14** with 30% probability thermal ellipsoids. Hydrogen atoms and solvated molecules ($CH_2Cl_2$) are omitted for clarity.

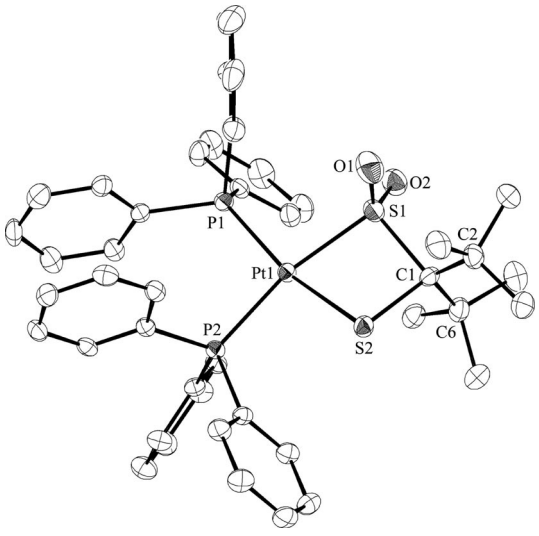

Figure 4. ORTEP drawing of (sulfinato–thiolato)$Pt^{II}$ complex **19** with 30% probability thermal ellipsoids. Hydrogen atoms and solvated molecules ($CH_2Cl_2$) are omitted for clarity.

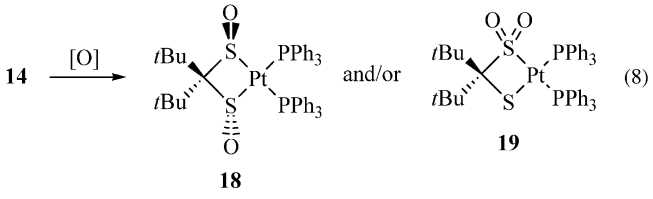
mined from spectroscopic data. In the $^{31}P$ NMR spectrum, two doublets accompanying satellite signals from the $^{195}Pt$ isotope are observed at $\delta$ = 11.6 (d, $^2J_{P,P}$ = 18.6 Hz, $^1J_{Pt,P}$ = 2310 Hz) and 18.7 (d, $^2J_{P,P}$ = 18.6 Hz, $^1J_{Pt,P}$ = 3053 Hz). In the infrared spectrum stretching vibrations from the $SO_2$ group appear at 1067 and 1197 $cm^{-1}$. The structure of **19** was finally determined by X-ray crystallography (Figure 4).



(8)

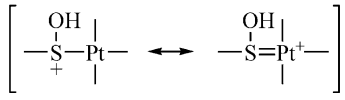
Table 1. Oxidation of (sulfenato–thiolato)$Pt^{II}$ complex **14**.

| Entry | [O] | **18** | **19** | **14**[a] | Others |
|---|---|---|---|---|---|
| 1 | DMD | 0[b] | 62[b] | 32[b] | **16** {6[b], $[Pt(PPh_3)_2(S_2O_2)]$} |
| 2 | $CF_3CO_3H$ | 9[b] | 0[b] | 73[b] | **16** (18[b]) |
| 3 | MCPBA | 6[c] | 9[c] | 29[c] | $Ph_3P{=}O$ (56[c]) |
| 4 | DMD/$CF_3CO_2H$ | 30[b] | 0[b] | 28[b] | **16** (42[b]) |
| 5 | DMD/$PhCO_2H$ | 0 | 84[c] | 0 | $Ph_3P{=}O$ (16[b]) |

[a] Recovery. [b] $^1H$ NMR integral ratio. [c] $^{31}P$ NMR peak height ratio.

Thus, it was verified that the oxidation of the (sulfenato–thiolato)$Pt^{II}$ complex **14** with DMD took place in the same regioselectivity as observed in the oxidation of **11** with DMD to give **12** [Equation (3)].

On the other hand, oxidation of **14** with $CF_3CO_3H$ gave the (disulfenato)$Pt^{II}$ complex **18** without **19** though this reaction was sluggish (a large portion of the starting complex **14** was recovered) and a substantial amount of sulfine **16** was formed as a decomposition product ($^1H$ NMR integral ratio: **18/14/16** ≈ 9:73:18) (Table 1, Entry 2). When MCPBA was employed as the oxidant both **18** and **19** were formed albeit in low yields (**18/19/14**/$Ph_3P{=}O$ ≈ 6:9:29:56) (Entry 3). The oxidation of **14** with DMD in the presence of $CF_3CO_2H$ yielded **18** together with **14** and **16** (**18/14/16** ≈ 30:28:42) (Entry 4), and that in the presence of benzoic acid gave **19** (**19**/$Ph_3P{=}O$ ≈ 81:16) (Entry 5). The change in regioselectivity as described above was explained by protonation on the sulfinyl oxygen atom with the coexisting carboxylic acid leading to a decrease in the electron density on the sulfinyl-sulfur atom [Equation (9)]. The extent of the decrease in the electron density is dependent on the strength of the acid.



(9)

Oxidation of (sulfenato–thiolato)$Pt^{II}$ complex **14** with an excess amount of DMD (5 molar equiv.) provided the (disulfonato)$Pt^{II}$ complex **20** quantitatively [Equation (10)], the structure of which was determined by X-ray crystallography (Figure 5). The $PtO_2S_2C$ six-membered ring has a twist conformation in the crystalline state. While the two *tert*-butyl groups are equivalent in the $^{13}C$ NMR spectrum, they are nonequivalent in the $^1H$ NMR spectrum. In the $^{31}P$ NMR spectrum, a singlet with satellite signals from the $^{195}Pt$ isotope is observed at $\delta$ = 7.10 ppm ($^1J_{Pt-P}$ = 4157 Hz). Formation of a similar sulfonato complex was reported from the oxidation of the (dithiolato)$Ni^{II}$ complex with hydrogen peroxide [Equation (11)].[43] $^{31}P$ NMR spectroscopic data of $Pt^{II}$ complexes **14**, **18**–**20** are summarized in Table 2.

## X-ray Crystallography of Platinum(II) Complexes 14 and 18–20

The selected bond lengths and angles of **14**, **18**, and **19** are summarized in Table 3. The sum of the four angles around the Pt atom in **14** and **18**–**20** is almost 360° and the platinum atoms keep the planarity in these complexes. The puckered angles of the four-membered rings of **18**, **14**, and **19** are 3.6°, 25.2°, and 13.0°, respectively. The S1–Pt1 and S2–Pt1 bond lengths in **18**, **14**, and **19** are not significantly influenced by the oxidation state of the sulfur atoms and lie in the narrow range 2.3065(14)–2.3421(6) Å. The P1–Pt1 and P2–Pt1 bond lengths in **18**, **14**, and **19** also fall into a narrow range [2.2943(14)–2.3347(19) Å], though the P1–Pt1 bonds *trans* to the thiolato ligands in **14** [2.2943(14) Å] and **19** [2.2956(15) Å] are slightly shorter than the others because of the weaker *trans* influence of the thiolato ligands compared with those of the sulfenato and sulfinato ligands. The P1–Pt1 [2.2224(9) Å] and P2–Pt1 [2.2375(9) Å] bond lengths in the disulfonato complex **20**, which are *trans* to the O atoms of the sulfonato ligands, are obviously shorter than the above Pt–P bond lengths.

Table 3. Selected bond lengths [Å] and bond angles [°] of **18**, **14**, and **19**.

[a] Sum of the above four angles around the Pt atom. [b] Puckered angle of the four-membered ring.

The S=O bond lengths of the SO$_2$ group in **19** and **20** [1.434(16)–1.464(5) Å] are shorter than those of the sulfenato ligands in **18** [1.509(3) and 1.511(3) Å] and **14** [1.506(5) Å]. This is in accordance with those for dialkyl

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

sulfones [R–S(O)$_2$–R′, S–O 1.436 Å[44]] and sulfoxides [R–S(O)–R′, S–O 1.497 Å[44]] (R, R′ = alkyl).

The S1–C1 bond [S(O)$_2$–C bond] in **19** is elongated to a length of 1.936(6) Å, which is much longer than those of a similar type in **20** [S1–C1 1.877(3) Å and S2–C1 1.888(3) Å]. This elongation in **19** is explained by a large steric repulsion between the two oxygen atoms and the two *tert*-butyl groups as well as the $PPh_3$ ligand at the *cis* position in the four-membered ring. While ordinary S–C bond lengths in organic sulfides, sulfoxides, and sulfones become shorter in this order (1.819, 1.809, and 1.779 Å, respectively[44]), this is not true for the present, sterically congested system.

## Conclusions

We prepared a three-membered *vic*-disulfoxide, 3,3-di-*tert*-butyldithiirane *trans*-1,2-dioxide (**8**). Complexation of **8** with a platinum(0) complex yielded the (disulfenato)Pt$^{II}$ complex **18** in high yield by oxidative addition. This is the only direct method for the synthesis of (disulfenato)Pt$^{II}$ complexes. We showed that oxidation positions of (sulfenato–thiolato)Pt$^{II}$ complexes, sulfenato sulfur or thiolato sulfur, can be controlled by the acidity of the reaction media.

## Experimental Section

The melting points were determined with a Mel-Temp capillary tube apparatus and are uncorrected. $^1$H, $^{13}$C, and $^{31}$P NMR spectra were determined with Bruker AM400 or DRX400 (400, 100.7, and 162 MHz, respectively) spectrometers using $CDCl_3$ as the solvent at 25 °C, unless otherwise noted. IR spectra were recorded with a Perkin–Elmer System 2000 FT-IR spectrometer. Elemental analyses were performed by the Molecular Analysis and Life Science Center of Saitama University, where those for platinum complexes were performed with $WO_3$ as the combustion improver. An acetone solution of dimethyldioxirane (DMD) was prepared by oxidation of acetone with Oxone® (Sigma–Aldrich).[45]

**3,3-Di-*tert*-butyldithiirane 1-Oxide (15):** A solution of di-*tert*-butyldiazomethane (727.9 mg, 4.719 mmol) in dichloromethane (20 mL) was added to a solution of $S_8O$ (1.548 g, 5.691 mmol) in dichloromethane (250 mL) cooled to 0 °C. The mixture was stirred for 1 h at 0 °C and for 2 h at room temperature. Precipitates were filtered and washed with dichloromethane, and the filtrate and the washings were combined. The solvent was removed under reduced pressure, and the residue was subjected to column chromatography (silica gel: hexane/dichloromethane, 1:2) and then HPLC (hexane/dichloromethane, 3:2) to give dithiirane 1-oxide **15** as a pale-yellow oil (116.8 mg, 12%): $^1$H NMR: $\delta$ = 1.08 (s, 9 H), 1.42 (s, 9 H) ppm. $^{13}$C NMR: $\delta$ = 29.2 ($CH_3$), 31.9 ($CH_3$), 41.2 (C), 41.3 (C), 86.3 (C) ppm. IR (neat): $\tilde{\nu}$ = 1121 cm$^{-1}$. $C_9H_{18}OS_2$ (206.36): calcd. C 52.38, H 8.79; found C 52.63, H 8.82.

**3,3-Di-*tert*-butyldithiirane *trans*-1,2-Dioxide (8):** DMD (0.079 M, 17.0 mL, 1.343 mmol) was added to a solution of 3,3-di-*tert*-butyldithiirane 1-oxide (**15**) (46.8 mg, 0.227 mmol) in dichloromethane (1.5 mL) cooled to –20 °C under argon. The mixture was stirred at –20 °C for 2 h, and the solvent was removed under reduced pressure at 0 °C. The $^1$H NMR spectrum of the residue showed the formation of 1,2-dioxide **8**, di-*tert*-butyl ketone (**17**), and di-*tert*-butyl thioketone *S*-oxide (**16**) in the ratio 89:1:10. The residue was recrystallized from a mixed solvent of hexane and dichloromethane at –20 °C to give 39.9 mg (79%) of 1,2-dioxide **8** as pale-yellow plates. M.p. 85 °C (decomp.). $^1$H NMR: $\delta$ = 1.38 (s, 18 H) ppm. $^{13}$C NMR: $\delta$ = 31.1 ($CH_3$), 41.6 (C), 105.9 (C) ppm. IR (KBr): $\tilde{\nu}$ = 1063 cm$^{-1}$. $C_9H_{18}O_2S_2$ (222.36): calcd. C 48.61, H 8.16; found C 48.87, H 8.22.

**[2,2,4,4-Tetramethylpentane-3,3-dithiolato(2–)-κ*S*,κ*S*′]bis(triphenylphosphane)platinum *trans*-*S*,*S*′-Dioxide [(Disulfenato)Pt$^{II}$ Complex 18]:** A solution of [$(Ph_3P)_2Pt(\eta^2$-$C_2H_4)$] (92.9 mg, 0.124 mmol) in dichloromethane (2 mL) was added to a solution of 1,2-dioxide **8** (27.8 mg, 0.125 mmol) in dichloromethane (5 mL) cooled to 0 °C under argon. The mixture was stirred for 2 h at 0 °C, and the solvent was removed under reduced pressure. The residue was recrystallized twice from a mixed solvent of hexane and dichloromethane at –20 °C to give 66.3 mg (56%) of the (disulfenato)Pt$^{II}$ complex **18**. M.p. 125 °C (decomp.). $^1$H NMR: $\delta$ = 1.41 (s, 18 H), 7.18–7.22 (m, 12 H), 7.29–7.34 (m, 6 H), 7.38–7.43 (m, 12 H) ppm. $^{13}$C NMR: $\delta$ = 31.22 ($CH_3$), 43.97 (C), 128.08 (t, $J_{P,C}$ = 5.3 Hz, CH), 130.20 (dd, $J_{P,C}$ = 57.2, 7.4 Hz, C), 130.27 (CH), 134.21 (t, $J_{P,C}$ = 5.6 Hz, CH) ppm. $^{31}$P NMR: $\delta$ = 15.2 (s, $^1J_{Pt,P}$ = 2596 Hz for the satellite signals) ppm. IR (KBr): $\tilde{\nu}$ = 1097 cm$^{-1}$. $C_{45.5}H_{49}ClO_2P_2PtS_2$ ($C_{45}H_{48}O_2P_2PtS_2$·0.5$CH_2Cl_2$) (984.49): calcd. C 55.51, H 5.02; found C 56.17, H 5.03 (the $^1$H NMR spectrum of the same sample subjected to the elemental analysis showed the presence of 0.50 molecules of $CH_2Cl_2$ and a molecule of **18**). Single crystals suitable for X-ray crystallography were obtained by recrystallization from benzene at room temperature.

**[2,2,4,4-Tetramethylpentane-3,3-dithiolato(2–)-κ*S*,κ*S*′]bis(triphenylphosphane)platinum *S*-Oxide [(Sulfenato–thiolato)Pt$^{II}$ Complex 14]:** A solution of [$(Ph_3P)_2Pt(\eta^2$-$C_2H_4)$] (202.1 mg, 0.218 mmol) in dichloromethane (8 mL) was added to a solution of dithiirane 1-oxide **15** (45.0 mg, 0.218 mmol) in dichloromethane (3 mL) cooled to 0 °C under argon. The mixture was stirred for 2 h at 0 °C, and the solvent was removed under reduced pressure. The residue was recrystallized from a mixed solvent of hexane and dichloromethane at –20 °C to give 152.5 mg (76%) of the (sulfenato–thiolato)Pt$^{II}$ complex **14** as yellow prisms. M.p. 207 °C (decomp.). $^1$H NMR: $\delta$ = 1.12 (s, 9 H), 1.45 (br. s, 6 H), 1.62 (s, 3 H), 7.14–7.20 (m, 12 H), 7.24–7.30 (m, 6 H), 7.38–7.45 (m, 12 H) ppm. $^{13}$C NMR: $\delta$ = 29.30 ($CH_3$), 32.98 (br. s, $CH_3$), 42.60 (C), 46.30 (C), 127. 72 (t, $J_{P,C}$ = 9.9 Hz, CH), 130.01 (CH), 134.3 (m, CH) ppm (signals for aromatic quaternary carbons appear at $\delta$ = 130.425, 130.794, 130.892, and 131.297 ppm, which are not assigned). $^{31}$P NMR: $\delta$ = 16.8 (d, $^2J_{P,P}$ = 24.4 Hz and $^1J_{Pt,P}$ = 3306 Hz for the satellite signals), 17.9 (d, $^2J_{P,P}$ = 24.4 Hz and $^1J_{Pt,P}$ = 2338 Hz for the satellite signals) ppm. $C_{47}H_{52}Cl_4OP_2PtS_2$ ($C_{45}H_{48}OP_2PtS_2$·2$CH_2Cl_2$) (1095.89): calcd. C 51.51, H 4.78; found C 51.24, H 4.66.

**[2,2,4,4-Tetramethylpentane-3,3-dithiolato(2–)-κ*S*,κ*S*′]bis(triphenylphosphane)platinum *S*,*S*-Dioxide [(Sulfinato–thiolato)Pt$^{II}$ Complex 19]:** A solution of DMD (0.085 M, 0.34 mL, 0.029 mmol) was added to a solution of the (sulfenato–thiolato)Pt$^{II}$ complex **14** (27.1 mg, 0.0292 mmol) in toluene (3 mL) cooled to 0 °C under argon. The mixture was stirred for 2 h at 0 °C, and the solvent was removed under reduced pressure at 0 °C. The $^1$H NMR spectrum of the residue (28.7 mg) indicated the presence of **19**, **14**, and sulfine **16** in the ratio 62:32:6, while the $^{31}$P NMR spectrum showed signals from **19** ($\delta$ = 11.6 and 18.7 ppm) and **14** ($\delta$ = 16.8 and 18.9 ppm) together with a small amount of [$Pt(PPh_3)_2(S_2O_2)$] ($\delta$ = 6.3 ppm). The residue was recrystallized from a mixed solvent of hexane and dichloromethane at –20 °C to give 5.1 mg of an ca. 2:1 mixture of **19** and **14**. As we could not obtain **19** in the pure form, even by

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

repeated recrystallization, elemental analysis of **19** was not done. However, a single, yellow crystal suitable for X-ray analysis was obtained. $^1$H NMR: $\delta$ = 1.50 (br. s, 18 H), 7.14–7.21 (m, 12 H), 7.28–7.32 (m, 6 H), 7.38–7.44 (m, 6 H), 7.50–7.55 (m, 6 H) ppm. $^{31}$P NMR: $\delta$ = 11.6 (d, $^2J_{P,P}$ = 18.6, $^1J_{Pt,P}$ = 2310 Hz), 18.7 (d, $^2J_{P,P}$ = 18.6, $^1J_{Pt,P}$ = 3053 Hz) ppm. IR (KBr): $\tilde{\nu}$ = 1067, 1197 ($SO_2$) cm$^{-1}$.

**[2,2,4,4-Tetramethylpentane-3,3-disulfonato(2–)-κ*O*,κ*O*′]bis(triphenylphosphane)platinum [(Disulfonato)Pt$^{II}$ Complex 20]:** DMD (0.083 M, 1.25 mL, 0.10 mmol) was added dropwise to a solution of the (sulfenato–thiolato)Pt$^{II}$ complex **14** (19.3 mg, 0.021 mmol) in toluene (7 mL) at 0 °C under argon. The mixture was stirred for 2 h at 0 °C, and the solvent was removed under reduced pressure at 0 °C to give an almost pure **20** as a yellow-white solid (20.9 mg). The crude material was recrystallized from a mixed solvent of hexane and dichloromethane at –20 °C to give 7.1 mg (34%) of **20** as colorless prisms. M.p. 280 °C (decomp.). $^1$H NMR: $\delta$ = 1.52 (br. s, 9 H), 1.58 (s, 9 H), 7.20–7.26 (m, 12 H), 7.36–7.40 (m, 6 H), 7.53–7.59 (m, 12 H) ppm. $^{13}$C NMR: $\delta$ = 32.91 ($CH_3$), 42.32 (C), 126.10 (d, $J_{P,C}$ = 68.3 Hz, C), 128.47 (t, $J_{P,C}$ = 5.9 Hz, CH), 131.60 (CH), 134.58 (t, $J_{P,C}$ = 5.4 Hz, $CH_3$) ppm. $^{31}$P NMR: $\delta$ = 7.10 (s, $^1J_{Pt,P}$ = 4157 Hz) ppm. IR (KBr): $\tilde{\nu}$ = 1139, 1284 ($SO_2$) cm$^{-1}$. $C_{45}H_{48}O_6P_2PtS_2$ (1006.02): calcd. C 53.73, H 4.81; found C 54.01, H 5.04.

**X-ray Crystallography:** X-ray crystallographic analyses were performed with a Mac Science DIP3000 diffractometer (for **14**) or a Bruker AXS SMART diffractometer (for others) with a graphite-monochromated Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 Å). The structures were solved by direct methods and refined with full-matrix least-squares (SHELXL-97[46]) using all independent reflections.

**Crystal Data for 8:** $C_9H_{18}O_2S_2$, $M_r$ = 222.35 g mol$^{-1}$, yellow prism, crystal size = 0.40 × 0.40 × 0.40 mm, monoclinic, *C*2/*c*, *a* = 14.9253(13), *b* = 7.0524(6), *c* = 11.4484(9) Å, $\beta$ = 105.485(2)°, *V* = 1161.31(17) Å$^3$, $\rho_{calcd.}$ = 1.272 g cm$^{-3}$, *Z* = 4, $\mu$(Mo-$K_\alpha$) = 0.428 cm$^{-1}$. Intensity data of 1069 unique reflections were collected over the range –18 ≤ *h* ≤ 17, –8 ≤ *k* ≤ 8, –13 ≤ *l* ≤ 13 at 223 K. $R_1$ = 0.0412 [$I \geq 2\sigma(I)$, 956 reflections], $wR_2$ = 0.1062 (for all), and Gof = 1.093, 96 parameters; max./min. residual electron density: 0.253/–0.176 e Å$^{-3}$.

**Crystal Data for 18:** $C_{57}H_{60}O_2P_2PtS_2$ ($C_{45}H_{48}O_2P_2PtS_2$·2$C_6H_6$), $M_r$ = 1098.20 g mol$^{-1}$, yellow prism, crystal size = 0.25 × 0.20 × 0.12 mm, triclinic, $P\bar{1}$, *a* = 10.8885(8), *b* = 13.1343(10), *c* = 17.7604(13) Å, $\alpha$ = 81.859(2), $\beta$ = 88.115(2), $\gamma$ = 82.946(2)°, *V* = 2495.0(3) Å$^3$, $\rho_{calcd.}$ = 1.462 g cm$^{-3}$, *Z* = 2, $\mu$(Mo-$K_\alpha$) = 3.001 cm$^{-1}$. Intensity data of 9229 unique reflections were collected over the range –12 ≤ *h* ≤ 13, –15 ≤ *k* ≤ 15, –21 ≤ *l* ≤ 20 at 123 K. $R_1$ = 0.0341 [$I \geq 2\sigma(I)$, 8355 reflections], $wR_2$ = 0.0798 (for all), and Gof = 1.037, 584 parameters; max./min. residual electron density: 1.370/–0.423 e Å$^{-3}$.

**Crystal Data for 14:** $C_{47}H_{52}Cl_4OP_2PtS_2$ ($C_{45}H_{48}OP_2PtS_2$·2$CH_2Cl_2$), $M_r$ = 1095.910 g mol$^{-1}$, yellow prism, crystal size = 0.24 × 0.12 × 0.12 mm, triclinic, $P\bar{1}$, *a* = 11.6740(4), *b* = 14.6560(4), *c* = 15.3800(4) Å, $\alpha$ = 113.041(2), $\beta$ = 94.326(2), $\gamma$ = 91.289(2)°, *V* = 2410.72(12) Å$^3$, $\rho_{calcd.}$ = 1.510 g cm$^{-3}$, *Z* = 2, $\mu$(Mo-$K_\alpha$) = 3.319 cm$^{-1}$. Intensity data of 8622 unique reflections were collected over the range –14 ≤ *h* ≤ 14, –18 ≤ *k* ≤ 18, –19 ≤ *l* ≤ 18 at 298 K. $R_1$ = 0.0422 [$I \geq 2\sigma(I)$, 7676 reflections], $wR_2$ = 0.1179 (for all), and Gof = 1.037, 523 parameters; max./min. residual electron density: 0.958/–1.616 e Å$^{-3}$.

**Crystal Data for 19:** $C_{47}H_{52}Cl_4O_2P_2PtS_2$ ($C_{45}H_{48}O_2P_2PtS_2$·2$CH_2Cl_2$), $M_r$ = 1111.84 g mol$^{-1}$, yellow prism, 0.25 × 0.20 × 0.10 mm, triclinic, $P\bar{1}$, *a* = 11.6339(6), *b* = 14.6630(7), *c* = 15.1190(8) Å, $\alpha$ = 113.4220(10), $\beta$ = 94.0080(10), $\gamma$ = 93.0900(10)°, *V* = 2351.4(2) Å$^3$, $\rho_{calcd.}$ = 1.570 g cm$^{-3}$, *Z* = 2, $\mu$(Mo-$K_\alpha$) = 3.405 cm$^{-1}$. Intensity data of 8731 unique reflections were collected over the range –12 ≤ *h* ≤ 14, –17 ≤ *k* ≤ 16, –13 ≤ *l* ≤ 18 at 153 K. $R_1$ = 0.0438 [$I \geq 2\sigma(I)$, 7944 reflections], $wR_2$ = 0.1144 (for all), and Gof = 1.037, 523 parameters; max./min. residual electron density: 2.599/–1.047 e Å$^{-3}$.

**Crystal Data for 20:** $C_{47}H_{52}Cl_4O_6P_2PtS_2$ ($C_{45}H_{48}O_6P_2PtS_2$·2$CH_2Cl_2$), $M_r$ = 1175.84 g mol$^{-1}$, colorless prism, crystal size = 0.30 × 0.22 × 0.20 mm, monoclinic, $P2_1/c$, *a* = 11.9094(5), *b* = 24.2783(11), *c* = 16.9933(7) Å, $\beta$ = 98.3500(10)°, *V* = 4861.4(4) Å$^3$, $\rho_{calcd.}$ = 1.607 g cm$^{-3}$, *Z* = 4, $\mu$(Mo-$K_\alpha$) = 3.305 cm$^{-1}$. Intensity data of 9053 unique reflections were collected over the range –14 ≤ *h* ≤ 14, –28 ≤ *k* ≤ 29, –20 ≤ *l* ≤ 17 at 123 K. $R_1$ = 0.0294 ($I \geq 2\sigma(I)$, 8018 reflections), $wR_2$ = 0.0716 (for all), and Gof = 1.047, 565 parameters; max./min. residual electron density: 1.444/–0.844 e Å$^{-3}$.

CCDC-655818 (for **8**), -655819 (for **18**), -655820 (for **14**), -655821 (for **19**), and -655822 (for **20**) contain the supplementary crystallographic data. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

**Supporting Information** (see also the footnote on the first page of this article): $^{13}$C NMR spectra of **14**, **18**, and **20**, and $^1$H and $^{31}$P NMR spectra of **19** as a mixture with **14**.

# The Spectroscopic, Electrochemical and Structural Characterization of a Family of Ru Complexes Containing the $C_2$-Symmetric Didentate Chiral 1,3-Oxazoline Ligand and Their Catalytic Activity

**Xavier Sala,[a] Naiara Santana,[a] Isabel Serrano,[a] Elena Plantalech,[a] Isabel Romero,[a] Montserrat Rodríguez,*[a] Antoni Llobet,*[b,c] Susanna Jansat,[d] Montserrat Gómez,[d] and Xavier Fontrodona[e]**

**Keywords:** Ruthenium / N ligands / Epoxidation / Chiral ligands / Atropisomerism

The structural, spectroscopic, and electrochemical characterization and a preliminary catalytic investigation of a family of $Ru^{II}$ complexes with general formula $[Ru(Y)(terpy)(phbox\text{-}R)]^{n+}$ [where terpy is 2,2′:6′,2′′-terpyridine, phbox-R is a $C_2$-symmetric bidentate oxazoline ligand (R = Et or *i*Pr), and Y is a monodentate ligand], are discussed. The X-ray structure of $[RuCl(terpy)(phbox\text{-}i\text{Pr})]^{2+}$ has been solved and confirms, as we described recently, the predicted generation of the less hindered atropisomer, which is determined by the conformation of the stereogenic centers in the bidentate ligand. The catalytic properties of the aquo complexes have been tested in epoxidation reactions, and moderate selectivity for the epoxides is obtained for styrene and *trans*-stilbene when using $PhI(OAc)_2$ as co-oxidant.

## Introduction

$C_2$-Symmetric bis(1,3-oxazolines) have received an increasing amount of attention over the last few years, as can be seen from the increasing number of publications dealing with this type of ligand.[1] Since the first reports of the use of chiral oxazoline ligands in asymmetric catalysis,[2] a great variety of oxazoline-based compounds have been synthesized and successfully tested as catalysts,[3] and their coordination chemistry studied,[4] mainly because of their ease of preparation and versatility.

Atropisomerism, where chirality is generated due to rotational restriction between two isomers containing axially chiral biaryl compounds,[5,6] is a good way of obtaining efficient tools in asymmetric synthesis[6a,7] (for example the rigid molecular frameworks obtained from chiral ligands like BINAP[8]), and has found important applications in diverse areas such as liquid crystals, pharmaceuticals, nanoscale information storage, or biomimetic catalysis.[9]

Transition metal complexes bearing oxazoline ligands have shown good activities and enantioselectivities in a myriad of catalytic organic syntheses involving metals such as Cu or Fe.[10] However, the performance of oxazoline-containing ruthenium complexes as catalysts has been developed only very recently, and the number of contributions in this area is still limited.[11] Their performance as asymmetric epoxidation catalysts with clean oxidants such as $H_2O_2$, where they show good results in terms of both chemo- and enantioselectivity, has been widely studied by Beller and co-workers.[12]

Interest in polypyridylruthenium complexes stems from their multiple applications in scientific fields such as photophysics and photochemistry,[13] catalysis,[14] and bioinorganic chemistry.[15] One of the main goals for this type of complex is the design of structures that allow the fine-tuning of their redox, absorption, and emission properties. Among redox properties, and especially from a catalytic perspective, one of the major aims is the design of Ru=O functional groups and analogues capable of reversibly accepting multiple electrons and protons within a relatively narrow potential range.[16]

With all this in mind, we present here the complete characterization and catalytic activity of a family of ruthenium complexes bearing $C_2$-symmetric oxazoline ligands, including two aquo complexes that are potential pre-catalysts for redox processes involving the above mentioned Ru=O group. The chirality of the complexes prepared is determined by the stereogenic centers in the oxazoline entities

but also by the chiral axes generated upon coordination of the ligand, which leads to atropisomeric forms.

## Results and Discussion

### Synthesis and Solid-State Structure

The complexes described here have the general formula $[Ru(Y)(terpy)(phbox\text{-}R)]^{n+}$, where phbox-R is one of the two oxazoline ligands depicted in Figure 1 and Y is a monodentate ligand [Cl, $H_2O$, MeCN, pyridine (py), or 2-hydroxypyridine (2-OH-py)]. The chlorido complexes ($R_cR_c$,$S_aR_a$)-**2a** and ($S_cS_c$,$R_aS_a$)-**2b** were obtained by reduction of $[RuCl_3(terpy)]$ (**1**) in the presence of the appropriate bidentate oxazoline ligand, and the remaining compounds were derived from these two complexes or their aquo analogs ($R_cR_c$,$S_aR_a$)-**3a** and ($S_cS_c$,$R_aS_a$)-**3b**. The nomenclature of the complexes, as explained in the Experimental Section, involves a variety of chiral configurations arising from (1) the stereogenic centers inherent to each oxazoline ligand (either *R*,*R* or *S*,*S*; see Figure 1), which are represented by the first two letters having a "c" subscript, and (2) the chiral axes generated upon coordination of the ligand to the ruthenium metal center, as symbolized by the two remaining letters of the nomenclature used, with an "a" subscript. The two latter letters correspond to the chiral axis involving the oxazolinyl ring *trans* to the terpy ligand and that involving the ring *trans* to the monodentate ligand Y, respectively. The formation of one or other isomer is determined by the configuration of the oxazoline ligand (see below).

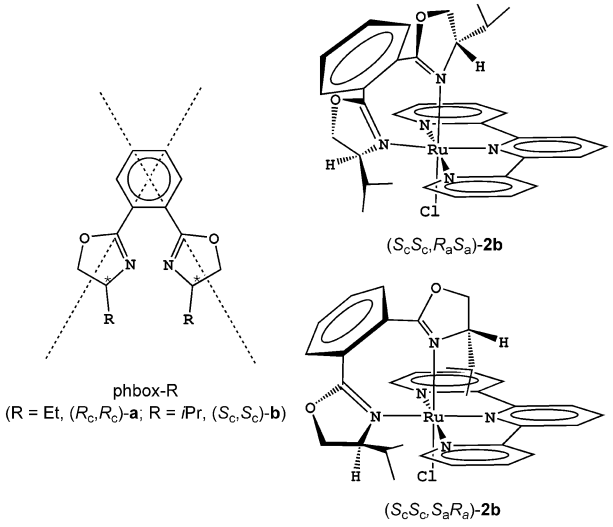

Figure 1. Atropisomers generated upon phbox-R ligand coordination.

The X-ray crystal structure for the cationic moiety of complex ($S_cS_c$,$R_aS_a$)-**2b** is shown in Figure 2; Table 1 lists selected bond lengths and angles. Further crystallographic information for this structure can be found in the Experimental Section. This cation presents a highly distorted octahedral environment around the Ru metal center, with the terpy ligand coordinating in a meridional fashion through its N atoms. Two of the remaining coordination sites are occupied by the didentate oxazoline ligand, whereas the sixth coordinative position is occupied by a chlorido ligand. The high distortion revealed in this cation is partly explained by the structural restrictions imposed by the terpy ligand coordination, which narrows the N1–Ru–N3 bond angle to 157.3°, far from the ideal value of 180° for a regular octahedral geometry.

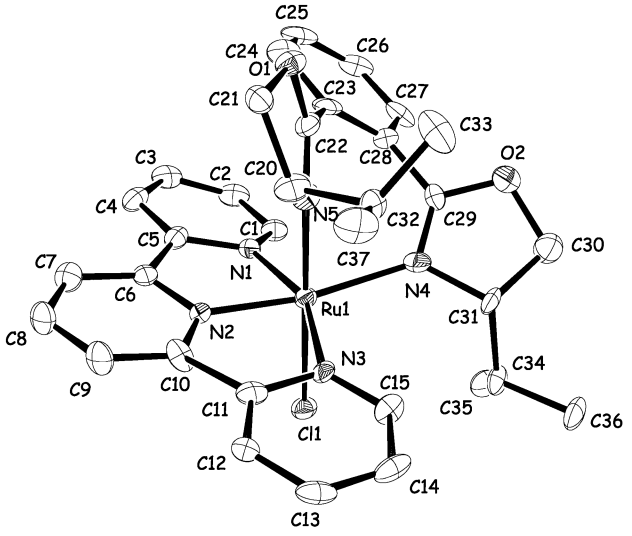

Figure 2. ORTEP plot (ellipsoids at 50% probability) of the cationic moiety of complex ($S_cS_c$,$R_aS_a$)-**2b**, including the atom numbering scheme.

Table 1. Selected bond lengths and angles for complex ($S_cS_c$,$R_aS_a$)-**2b**.

| Bond lengths [Å] | | Bond angles [°] | |
|---|---|---|---|
| Ru1–N1 | 2.042 | N1–Ru1–N2 | 79.26 |
| Ru1–N2 | 1.935 | N1–Ru1–N3 | 157.34 |
| Ru1–N3 | 2.126 | N1–Ru1–N4 | 98.95 |
| Ru1–N4 | 2.162 | N1–Ru1–N5 | 90.97 |
| Ru1–N5 | 2.035 | N2–Ru1–N3 | 78.87 |
| Ru1–Cl1 | 2.416 | N2–Ru1–N4 | 170.06 |
| | | N2–Ru1–N5 | 87.31 |
| | | N3–Ru1–N4 | 103.62 |
| | | N3–Ru1–N5 | 93.86 |
| | | N4–Ru1–N5 | 82.93 |
| | | Cl1–Ru1–N1 | 87.28 |
| | | Cl1–Ru1–N2 | 92.71 |
| | | Cl1–Ru1–N3 | 87.90 |
| | | Cl1–Ru1–N4 | 96.98 |
| | | Cl1–Ru1–N5 | 178.21 |

Coordination of the phbox-*i*Pr ligand, as described previously for analogous complexes,[17] generates a seven-membered ring which is unlikely to keep a planar conformation because of structural restrictions. The ligand is thus forced to bend in order to accommodate itself upon coordination, and this bending leads to two possible atropisomeric configurations depending on the final orientation of the central phenyl ring of the phbox-*i*Pr ligand, in other words over the N1 or N3 pyridyl rings of the terpy ligand (see Figure 1 for schematic drawings of the two possible conformations).

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

The coordination of the ligand also fixes its two oxazolinyl rings in a twisted position with regard to the central phenyl ring plane, thereby generating the two chiral axes depicted in Figure 1. The formation of one or the other atropisomer is governed by the configuration of the stereogenic centers (C20 and C31) of the oxazolinyl rings in such a way that only one atropisomer (the one that keeps the *i*Pr groups farthest away from the terpy plane) is found. The X-ray structural analysis of complex ($S_cS_c,R_aS_a$)-**2b** shows that the atropisomer generated is indeed the $S_cS_c,R_aS_a$ one, as expected for an *S*,*S* configuration of the oxazoline ligand. The N4 and N5 oxazolinyl rings of the phbox-*i*Pr ligand are rotated by 51.47° and 40.26°, respectively, with regard to the central phenyl ring, and the N5–Ru–N4 angle is 82.93°.

The terpy ligand is not perfectly planar and experiments a slight twofold bending, with the two peripheral N1 and N3 pyridyl rings pointing away from the plane of the central N2 ring (the torsion angles are 8.64° and 7.7°, respectively, which gives an overall bending of 15.53° for the ligand). The rotation of the N1 ring of the terpy ligand with regard to the central pyridyl ring in terpy places it in an almost parallel disposition with regard to the central phenyl ring of the phbox-*i*Pr ligand (the angle between these two rings is 19.91°).

Finally, the cationic moieties in the crystal interact with one another through a series of hydrogen bonds that involve the chlorido ligand of one molecule and H7 and H13 of two neighboring molecules, with contact distances of 2.65 and 2.85 Å, respectively. These interactions arrange the complex molecules such that they form pseudo-square channels in the direction of the crystallographic *b* axis, which also allow a certain degree of π-stacking between the terpy ligands of adjacent entities (see the Supporting Information for diagrams of these 3D interactions).

## Spectroscopic Properties

The UV/Vis spectra of complexes **2a**,**b**–**5a**,**b** and **6b** were recorded in dichloromethane and/or phosphate buffer solution. The main absorption wavelengths, together with their assignments, are listed in Table 2. The assignment of the spectral absorptions of $Ru^{II}$ octahedral complexes has already been well documented[18] and, accordingly, the set of highly energetic bands at wavelengths below 350 nm can be assigned to π→π* intraligand transitions. Several charge-transfer dπ(Ru)→π* MLCT absorptions in the visible region of the spectra are also present for this family of compounds. These probably involve the π antibonding orbitals of terpy as the higher aromatic character of this ligand lowers its orbitals' energies with regard to the phbox-R ligand.

No significant differences can be found in Table 2 between analogous complexes containing the phbox-Et or the phbox-*i*Pr oxazoline ligands. However, the electronic nature of the monodentate Y ligand influences the energies of the transitions involving orbitals with $d_{(Ru)}$ character to some extent. Thus, as expected, the π-donor character of the chlorido ligand increases the energy of the $d_{(Ru)}$ filled orbitals, with complexes ($R_cR_c,S_aR_a$)-**2a** and ($S_cS_c,R_aS_a$)-**2b** being the ones that show the most red-shifted MLCT bands. Complexes **5** and **6**, which contain py and 2-OH-py ligands, respectively, show absorption energies similar to those found for the corresponding aquo complexes **3a**,**b**, therefore it can be concluded that the electron-withdrawing π effects of the corresponding aromatic systems in the pyridine-type ligands are minimal. This is consistent with the rapid ligand rotation determined in solution from NMR experiments.[17]

Finally, a comparison of these complexes with structurally similar Ru complexes also containing terpy reveals that, for complexes with bidentate oxazoline ligands,[19] MLCT

Table 2. UV/Vis spectroscopic data for complexes **2a**,**b**–**5a**,**b** and **6b**.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

transitions generally take place at much lower energies than those of analogous complexes having aromatic bidentate ligands,[20] thereby manifesting the increased electron-donor capacity of the oxazoline entities.

Acid-base titration was performed on complex ($S_cS_c$,$R_aS_a$)-**3b** by slow addition of NaOH to an acidic aqueous solution of the complex [Equation (1)].

$$[Ru(terpy)(phbox\text{-}iPr)(OH_2)]^{2+} \rightarrow [Ru(terpy)(phbox\text{-}iPr)(OH)]^{+} + H^{+} \quad (1)$$

The initial and final UV/Vis spectra, together with several intermediate spectra (inset), are displayed in Figure 3. The MLCT bands shift to longer wavelengths (520 and 518 nm) upon deprotonation of the aquo ligand, in agreement with the relative destabilization of the dπ(Ru) levels provoked by the anionic hydroxido ligand in a similar way to that described above for the chlorido ligand.[20d]

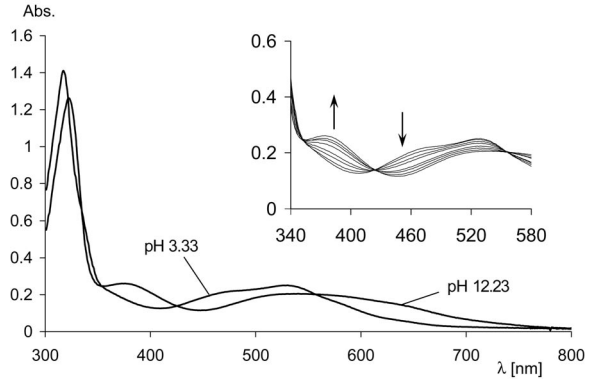

Figure 3. UV/Vis spectra of the aquo and hydroxo forms of complex ($S_cS_c$,$R_aS_a$)-**3b** at pH 3.33 and 12.23, respectively. The inset shows a detail of three of the five isosbestic points found from acid-base titration of the aquo complex with NaOH (pH values are 3.3, 8.81, 9.41, 9.60, 10.21, 10.48, 10.88, and 12.23).

The five isosbestic points at $\lambda$ = 322, 335, 352, 424, and 556 nm suggest that the aquo and hydroxo species interconvert in a net way, without generation of any side product. Addition of *p*-toluenesulfonic acid at the end of the titration regenerates the initial aquo complex. The p$K_a$ of 10.45 calculated for the deprotonation of the aquo ligand from acid-base titration is in good agreement with the value extracted from its Pourbaix diagram (see below). The complex ($R_cR_c$,$S_aR_a$)-**3a** behaves in an analogous manner, and the UV/Vis spectra of its aquo and hydroxido forms are presented as Supporting Information.

### Electrochemical and Catalytic Properties

The redox behavior of the complexes **2a**,**b**–**5a**,**b** and **6b** was studied by cyclic voltammetry. The chlorido complexes ($R_cR_c$,$S_aR_a$)-**2a** and ($S_cS_c$,$R_aS_a$)-**2b** show a simple chemically and electrochemically reversible wave in acetonitrile, which corresponds to the $Ru^{III}/Ru^{II}$ couple, at $E_{1/2}$ values of 0.70 and 0.71 V respectively. The analogous pyridine complexes ($R_cR_c$,$S_aR_a$)-**5a** and ($S_cS_c$,$R_aS_a$)-**5b** undergo an equivalent redox process at higher potential values ($E_{1/2}$ = 1.15 and 1.18 V, respectively), which is consistent with the lower electron-donating capability of the py ligand with regard to the chlorido ligand. Pyridine ligands could, in principle, produce a π-accepting effect involving the empty antibonding orbitals of the aromatic system, although this appears to be negligible for this family of complexes as inferred, as described above, from the NMR and UV/Vis spectra. The π-acceptor nature of the monodentate acetonitrile ligand is significantly manifested in ($S_cS_c$,$R_aS_a$)-**4b**, however, which presents a redox potential of 1.22 V.

The 2-OH-py complex ($S_cS_c$,$R_aS_a$)-**6b** presents a surprisingly low $E_{1/2}$ value of 0.755 V in dichloromethane. Considering the relatively long $Ru–N_{2\text{-}OH\text{-}py}$ bond length inferred from DFT calculations[17] (around 2.23 Å) one would expect a redox potential somewhat higher than those found for pyridine complexes **5a**,**b** due to the decreased σ donation. The OH group in the ring must therefore play a determinant role in the redox behavior of the complex by stabilizing the $Ru^{III}$ oxidation state through extra σ donation, probably involving deprotonation of the ligand (the p$K_a$ value for 2-OH-py is 0.75) and effective coordination of the corresponding anionic, 2-pyridonyl tautomeric form.

The cyclic voltammograms of the aqua complexes ($R_cR_c$,$S_aR_a$)-**3a** and ($S_cS_c$,$R_aS_a$)-**3b** were recorded in both dichloromethane and aqueous phosphate buffer solution. Only one redox process, corresponding to the $Ru^{IV}/Ru^{III}$ redox couple, appears in $CH_2Cl_2$ at $E_{1/2}$ = 0.98 V for both compounds. The intensity decrease or even the disappearance of the $Ru^{III}/Ru^{II}$ wave for this type of complex in dichloromethane is assigned to kinetic factors and has been described previously for similar complexes.[21] Two reversible waves, corresponding to the $Ru^{IV}/Ru^{III}$ and $Ru^{III}/Ru^{II}$ redox couples, can be observed in aqueous solution (pH 6) at $E_{1/2}$ = 0.64 and 0.46 V, respectively, for complex ($R_cR_c$,$S_aR_a$)-**3a** and at $E_{1/2}$ = 0.65 and 0.46 V, respectively, for ($S_cS_c$,$R_aS_a$)-**3b** (the cyclic voltammogram recorded for the latter is provided as Supporting Information).

The difference in the potential values of these two oxidation processes in a specific Ru-aquo complex seems to be directly related to the σ-donor and π-acceptor capacity of the ancillary ligands, as has been described by Meyer and co-workers[22a] on the basis of some empirical parameters previously calculated by Lever.[22b] As shown by the authors, two pseudo-linear relationships correlate the difference between the $E_{1/2}$ value for the two oxidation processes, $\Delta E_{1/2}$ (IV/III – III/II), with an empirical coefficient obtained from the ligands coordinated to the metal center (Figure 4). Two groups of compounds can be clearly distinguished depending on the σ-donor or π-acceptor properties of the ligands, denoted with squares and diamonds, respectively, in Figure 4.

The relatively weak π-acceptor character of the oxazoline ligand (with an empirical Lever contribution of 0.21; see the Supporting Information for a detailed description of the calculations) in complexes ($R_cR_c$,$S_aR_a$)-**3a** and ($S_cS_c$,$R_aS_a$)-**3b** places these complexes in the middle right half of the graph, far away from the central zone for two-electron processes (the aquo complexes described here are represented by a dot in Figure 4).

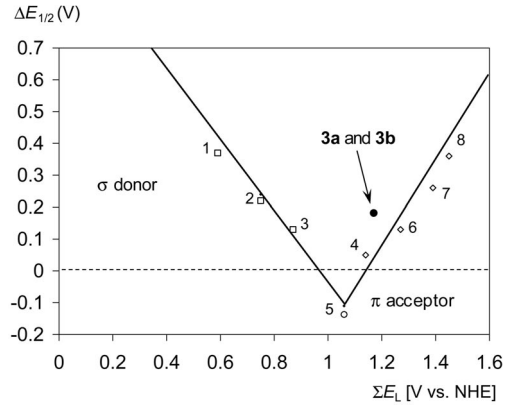

Figure 4. Meyer–Lever plot of $\Delta E_{1/2}$ vs. $\Sigma E_L$. [where $\Delta E_{1/2}$ is the difference between the $E_{1/2}$(IV/III) and $E_{1/2}$(III/II) redox potentials for the family of complexes studied]. (1) $[Ru(terpy)(acac)(OH_2)]^+$; (2) *cis*-$[Ru(terpy)(pic)(OH_2)]^+$ (pic = picolinate); (3) $[Ru(terpy)(tmen)(OH_2)]^{2+}$ (tmen = *N*,*N*,*N*,*N*-tetramethylethylenediamine); (4) $[Ru(CNC)(bpy)(OH_2)]^{2+}$ (see ref.[27]); (5) $[Ru(CNC)(n\text{BuCN})(OH_2)]^{2+}$;[27] (6) $[Ru(terpy)(bpy)(OH_2)]^{2+}$ (bpy = 2,2′-bipyridine); (7) $[Ru(bpy)_2(OH_2)(PPh_3)]^{2+}$; (8) $[Ru(terpy)(dppene)(OH_2)]^{2+}$ [dppene = *cis*-1,2-bis(diphenylphosphanyl)ethylene].

Generation of the higher oxidation state species was followed spectrophotometrically for the aquo complexes **3a**,**b**. Figure 5 shows the spectra obtained upon progressive addition of small amounts of $Ce^{IV}$ to an aqueous solution of complex ($S_cS_c$,$R_aS_a$)-**3b** at pH 1 until addition of one equivalent. The five isosbestic points observed at $\lambda$ = 270, 283, 297, 333, and 420 nm again suggest a net generation of the $Ru^{III}$ species.

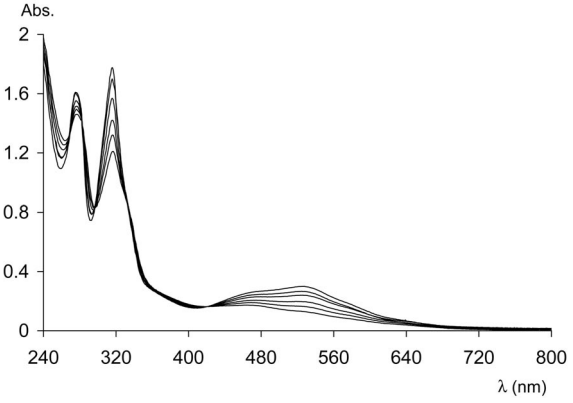

Figure 5. UV/Vis spectra registered after addition of successive amounts of $Ce^{IV}$ (up to 1 equiv.) to a 0.14 mM solution of complex ($S_cS_c$,$R_aS_a$)-**3b** in 0.1 M $HClO_4$.

Addition of a second equivalent of $Ce^{IV}$ produces a further oxidation of the complex that generates the corresponding $Ru^{IV}$-oxo species, which is almost featureless in the visible region, as has been described for analogous complexes.[20d,23] This second redox process also takes place with the presence of isosbestic points, and the manifold of spectra recorded is presented as Supporting Information together with the redox titration of complex ($R_cR_c$,$S_aR_a$)-**3a**, which follows a similar trend.

Ruthenium aquo complexes show a pH-dependence of their redox potentials due to deprotonation of the aqua ligand bonded to the metal center [Equation (2)].

$$Ru^{II}\text{-}OH_2 \underset{+H^+,+e^-}{\overset{-H^+,-e^-}{\rightleftharpoons}} Ru^{III}\text{-}OH \underset{+H^+,+e^-}{\overset{-H^+,-e^-}{\rightleftharpoons}} Ru^{IV}{=}O \quad (2)$$

This dependence is usually reflected in so-called Pourbaix diagrams, and the results obtained for complex ($S_cS_c$,$R_aS_a$)-**3b** are displayed in Figure 6.

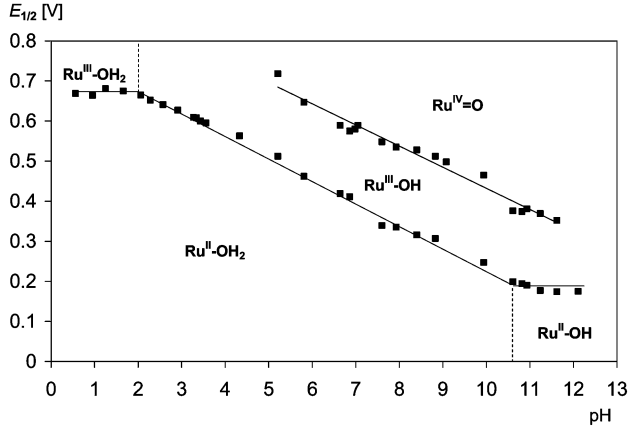

Figure 6. A plot of $E_{1/2}$ vs. pH (Pourbaix diagram) for complex ($S_cS_c$,$R_aS_a$)-**3b**. The pH/potential regions of stability for the various oxidation states and their dominant proton compositions are indicated by using abbreviations such as $Ru^{II}$–$OH_2$, for example, for $[Ru^{II}(terpy)(phbox\text{-}iPr)(H_2O)]^{2+}$. The p$K_a$ values are shown by the vertical dashed lines in the various *E*/pH regions.

The two independent one-electron redox processes that take place with simultaneous proton transfer at pH values between 5 and 10.5 are assignable to $Ru^{II}\rightarrow Ru^{III}$ and $Ru^{III}\rightarrow Ru^{IV}$ oxidations. The corresponding lines present a slope of approximately 59 mV per pH unit, as expected for a one-electron one-proton transfer; see Equation (2). At lower pH, only the $Ru^{III/II}$ couple can be observed. The diminishment or disappearance of the $Ru^{IV/III}$ redox couple in CV experiments is quite common for aquo complexes and is assumed to be caused by slow heterogeneous electron-transfer kinetics from the solution to the electrode surface.[23a,24] The stability regions for species having different proton composition are indicated in the diagram along with the p$K_a$ values for $Ru^{III}$ and $Ru^{II}$ aquo complexes, which are around 1.93 and 10.44. respectively. The latter value is fully consistent with the value determined from acid-base spectrophotometric titration, as described above.

Complex ($R_cR_c$,$S_aR_a$)-**3a** behaves in a similar way to ($S_cS_c$,$R_aS_a$)-**3b** (the corresponding Pourbaix diagram is supplied as Supporting Information). In this case, the $Ru^{IV/III}$ redox couple can be observed even at a pH lower than 4 and the p$K_a$ values for the $Ru^{III}$–$OH_2$ and $Ru^{II}$–$OH_2$ species are 2.1 and 11.1, respectively.

The redox catalytic properties of ($S_cS_c$,$R_aS_a$)-**3b** were tested in the electrochemical oxidation of target substrates such as benzyl alcohol and methyl *p*-tolyl sulfide in aqueous

Table 3. Alkene epoxidation catalyzed by ($S_cS_c$,$R_aS_a$)-**3b**.[a]

| Entry | Substrate | Oxidant | Substr./cat. | % Conversion | % Epoxide yield | % Bz[b] yield | Catalytic cycles |
|---|---|---|---|---|---|---|---|
| 1 | styrene | $PhI(OAc)_2$ | 200:1 | 67.3 | 36.1 | 6.1 | 71.3 |
| 2 | *trans*-stilbene | $PhI(OAc)_2$ | 150:1 | 71 | 37.4 | 4.1 | 57.9 |
| 3 | styrene | PhIO | 200:1 | 48.9 | 22.4 | 10.1 | 44.1 |
| 4 | *trans*-stilbene | PhIO | 200:1 | 74.3 | 44 | 29.6 | 87.6 |

[a] Reactions were performed at room temperature in 1,2-dichloroethane with an oxidant/substrate molar ratio of 2:1. [b] Bz stands for benzaldehyde.

neutral media. The system "0.5 mM **3b**/50 mM substrate/pH 7 phosphate buffer" at an $E_{app}$ of 0.9 V generated the respective oxidation products (benzaldehyde and sulfoxide) with good selectivities but poor yields (50% and 13% respectively), representing up to 50 and 13 catalytic cycles, after seven hours. No *ee* was observed for the sulfoxide obtained from the prochiral sulfide substrate. The electrocatalytic activity for the oxidation of benzyl alcohol is also visible in the cyclic voltammogram, with an increase in the anodic intensity at lower potential in the presence of the catalyst (see Figure S7 in the Supporting Information). The electrocatalytic oxidation of benzyl alcohol was also tested in a basic medium (0.1 M NaOH; applied potential: 0.5 V); conversions and selectivities were similar to those obtained in a neutral medium.

The catalytic activity of ($S_cS_c$,$R_aS_a$)-**3b** was also tested with regard to its ability to epoxidize alkenes. Styrene and *trans*-stilbene were chosen as substrates with PhIO and $PhI(OAc)_2$ as oxidants in 1,2-dichloroethane; the results, which were quantified by GC chromatography, are reported in Table 3. A first glance shows that the main products formed are the corresponding epoxides (styrene oxide and trans-stilbene oxide), along with minor amounts of benzaldehyde, in all cases. However, although good selectivity was achieved for the desired products, the enantioselectivity values for these reactions were low (never higher than 10% *ee*). The selectivity for the epoxide is slightly higher when $Ph(IOAc)_2$ is used as co-oxidant instead of PhIO (compare for instance entries 2 and 4 in Table 3). *trans*-Stilbene also provides better conversion and epoxide yields than styrene, probably due to the tendency of the latter to undergo double-bond cleavage and polymerization under oxidative conditions.

A potential explanation for this low enantioselectivity can be inferred from the complex structure. The approach of a prochiral substrate to the active site of the catalysts takes place in the region of the planar terpy ligand, therefore the stereogenic center in the oxazoline ligand only has a very small effect on the orientation of the substrate (see Figure 2 and the Supporting Information for different structural views of the molecular catalyst). Thus, the catalyst/substrate Interaction can occur through multiple orientations, thereby leading to racemic mixtures of reaction products.

## Conclusion

A new family of ruthenium complexes bearing terpy, oxazoline, and a monodentate ligand has been synthesized and thoroughly characterized. The catalytic activity of the aquo complexes in epoxidation catalysis has been tested. These complexes show moderate activity and chemoselectivity for the epoxide but with only low enantiomeric excesses. We are now working towards the optimization of the reaction conditions by using clean oxidants such as $H_2O_2$, and also towards a redesign of the catalysts' structures in order to achieve higher enantioselectivities.

## Experimental Section

**Materials:** All reagents used in the present work were obtained from Aldrich Chemical Co and were used without further purification. Reagent-grade organic solvents were obtained from SDS and high purity deionized water was obtained by passing distilled water through a nano-pure Mili-Q water purification system. $RuCl_3 \cdot 2H_2O$, was supplied by Johnson–Matthey Ltd. and was used as received.

**Instrumentation and Measurements:** UV/Vis spectra were recorded with a Cary 50 Scan (Varian) UV/Vis spectrophotometer in 1-cm quartz cells. pH measurements were recorded with a Micro-pH-2000 from Crison.

Cyclic voltammetry (CV) experiments were performed in a PAR 263A EG&G potentiostat or an IJ-Cambria IH-660 potentiostat, using a three-electrode cell. Glassy carbon disk electrodes (3 mm diameter) from BAS were used as the working electrode, platinum wire as the auxiliary electrode, and SSCE as the reference electrode. Cyclic voltammograms were recorded at a scan rate of 100 $mV\,s^{-1}$ under either $N_2$ or Ar. The complexes were dissolved in previously degassed solvents containing the necessary amount of supporting electrolyte to yield a 0.1 M ionic strength solution. ($n$Bu$_4$N)($PF_6$) was used as supporting electrolyte when using acetonitrile and dichloromethane as solvents. In aqueous solutions the pH was adjusted from 0 to 2 with HCl. Sodium chloride was added to keep a minimum ionic strength of 0.1 M. From pH 2 to pH 10, 0.1 M phosphate buffers were used, and from pH 10 to pH 12 dilute, $CO_2$-free NaOH was used. All $E_{1/2}$ values reported in this work were estimated from cyclic voltammetry as the average of the oxidative and reductive peak potentials ($E_{p,a} + E_{p,c}$)/2. Unless explicitly mentioned, the concentration of the complexes was approximately 1 mM.

**Catalytic Experiments:** Chemical catalysis was performed using a catalyst:substrate molar ratio of between 1:150 to 1:200, with an oxidant:substrate ration of 2:1, in 1,2-dichloroethane, with a typical catalyst concentration of 1 mM. Electrocatalytic studies at neutral pH were performed in a phosphate buffer solution, at an applied potential of 0.9 V vs. SSCE. At basic pH, a 0.1 M NaOH solution was used as solvent and the potential applied was 0.5 V vs. SSCE. The substrate:catalyst molar ratio was 100:1 in both cases. A carbon-felt electrode from SOFACEL was used as the working electrode. Evolution of the oxidized products was followed with a Shi-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

madzu GC-17A gas chromatography apparatus after chromatography of an aliquot of the reaction mixture over alumina and further re-dissolution in a 20 mM biphenyl solution in diethyl ether, which was used as an internal standard.

**X-ray Structure Determination:** Suitable crystals of ($R_cR_c$,$S_aR_a$)-**2b** were grown by slow diffusion of diethyl ether into a dichloromethane solution of the complex at room temperature. They were obtained as black plates. The crystal was mounted on a nylon loop and intensity data were collected at low temperature [100(2) K] with a Bruker Smart Apex CCD diffractometer using graphite-monochromated Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 Å) in the $\theta$ range 2.12–28.44°. Full-sphere data collection was carried out with $\omega$ and $\phi$ scans. A total of 48274 reflections were collected, of which 7801 ($R_{int}$ = 0.1281) were unique. Programs used: data collection: Smart version 5.625 (Bruker AXS 1997-01); data reduction: Saint+ version 6.36A (Bruker AXS 2001); absorption correction: SADABS version 2.05 (Bruker AXS 2001). The structures were solved by direct methods and refined by full-matrix least-squares methods on $F^2$ with SHELXTL Version 6.12 (Bruker AXS 2001). The non-hydrogen atoms were refined anisotropically. All H-atoms were placed in geometrically optimized positions and forced to ride on the atom to which they are attached.

**Crystallographic Data for 2b:** $C_{33}H_{35}BClF_4N_5O_2Ru$, $M$ = 756.99, orthorhombic, space group $P2_12_12_1$, $a$ = 10.541(2), $b$ = 12.907(3), $c$ = 23.230(5) Å, $\alpha$ = 90.00°, $\beta$ = 90.00°, $\gamma$ = 90.00°, $V$ = 3169.5(11) Å$^3$, $Z$ = 4, $\rho_{calcd.}$ = 1.591 g cm$^{-3}$, $\mu$ = 0.645 mm$^{-1}$. Final $R_1$ = 0.0822, $wR_2$ = 0.1597 [$I > 2\sigma(I)$]. $R_1 = \Sigma||F_o| - |F_c||/\Sigma|F_o|$ and $wR_2 = [\Sigma\{w(F_o^2 - F_c^2)^2\}/\Sigma\{w(F_o^2)^2\}]^{1/2}$, where $w = 1/[\sigma^2(F_o^2) + (0.0551P)^2 + 12.3436P]$ and $P = (F_o^2 + 2F_c^2)/3$.

CCDC-635355 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Center via www.ccdc.cam.ac.uk/data_request/cif.

**Preparations:** The phbox-R [R = Et, ($R_c$)-**a**; *i*Pr, ($S_c$)-**b**; see Figure 1] ligands[25] and [Ru$^{III}$Cl$_3$(terpy)] (**1**)[26] (terpy = 2,2′:6′,2″-terpyridine) were prepared according to literature procedures. The syntheses and specific spectroscopic and electrochemical data for the ruthenium complexes described in this paper {with general formula [Ru(Y)(terpy)(phbox-R)]$^{n+}$, Y = monodentate ligand, see below} have been reported previously[17] but are detailed and discussed here.

The nomenclature used for the absolute configuration of the complexes described is as follows. The first two letters refer to the absolute configuration of the oxazoline ligand and the final two letters refer to the absolute configuration of the chiral rotational axes, as detailed and exemplified in Figure 1 for the chlorido complex **2b**. Thus, the complexes discussed here are ($R_cR_c$,$S_aR_a$)-[RuCl(terpy)(phbox-et)](BF$_4$) [($R_cR_c$,$S_aR_a$)-**2a**], ($S_cS_c$,$R_aS_a$)-[RuCl(terpy)(phbox-*i*Pr)](BF$_4$) [($S_cS_c$,$R_aS_a$)-**2b**], ($R_cR_c$,$S_aR_a$)-[Ru(terpy)(phbox-et)(OH$_2$)](BF$_4$)$_2$ [($R_cR_c$,$S_aR_a$)-**3a**], ($S_cS_c$,$R_aS_a$)-[Ru(terpy)(phbox-*i*Pr)(OH$_2$)](BF$_4$)$_2$ [($S_cS_c$,$R_aS_a$)-**3b**], ($S_cS_c$,$R_aS_a$)-[Ru(terpy)(phbox-*i*Pr)(MeCN)](PF$_6$)$_2$ [($S_cS_c$,$R_aS_a$)-**4b**], ($S_cS_c$,$R_aS_a$)-[Ru(terpy)(phbox-et)(py)](PF$_6$)$_2$ [($R_cR_c$,$S_aR_a$)-**5a**], ($S_cS_c$,$R_aS_a$)-[Ru(terpy)(phbox-*i*Pr)(py)](PF$_6$)$_2$ [($S_cS_c$,$R_aS_a$)-**5b**], and ($S_cS_c$,$R_aS_a$)-[Ru(terpy)(phbox-*i*Pr)(2-OH-py)](PF$_6$)$_2$ [($S_cS_c$,$R_aS_a$)-**6b**].

**Supporting Information** (see also the footnote on the first page of this article): Additional spectroscopic and electrochemical data for the complexes described in this work.

## Acknowledgments

This research was financed by the Spanish Ministerio de Educación y Ciencia (MEC) (projects BQU2003-02884, BQU2002-04112-C02-02, and CTQ2004-01546/BQU). A. L. and M. G. are grateful to the Consell Interdepartamental de Recerca i Innovació Tecnològica (CIRIT), Generalitat de Catalunya, for financial support, and A. L. for the aid SGR2001-UG-291. A. L., M. R., and I. R. also thank Johnson Matthey for a loan of $RuCl_3 \cdot xH_2O$. E. P. and X. S. are grateful for the award of doctoral grants from CIRIT and Universitat de Girona (UdG), respectively.

# Synthesis, Characterization, Structures and Comparative Electrochemical Study of 2,4-Bis(trimethylsilylethynyl)thiophene Coordinated Carbonylcobalt Units

**Avelina Arnanz,[a] Consuelo Moreno,*[a] María-Luisa Marcos,[b] Jaime González-Velasco,[b] and Salomé Delgado[a]**

**Keywords:** Thiophene / Carbonylcobalt complexes / Electrochemistry

The reaction between 2,4-dibromothiophene and trimethylsilylacetylene (TMSA) in the presence of $Pd(PPh_3)_4$, CuI and triethylamine gave rise to the formation of 2,4-bis(trimethylsilylethynyl)thiophene (**2,4T**) and 4-bromo-2-(trimethylsilylethynyl)thiophene (**2,4T′**). Complexes **1**, **2**, **3** or **1′** were obtained by direct reaction between $Co_2(CO)_8$ and **2,4T** or **2,4T′**, respectively. (Diphenylphosphanyl)methane-substituted alkyne carbonyl complexes **4**, **5**, **6** and **2′** were prepared by substitution reaction of carbonyl ligands in the presence of $Me_3NO$ at the $Co_2(CO)_6$ units of **1**, **2**, **3** and **1′**, respectively. Desilylation of the non-metallated and metallated alkynes in **4**, **5** and **6** occurred on treatment with KOH or tetrabutylammonium fluoride to give **7**, **8** and **9**. Crystals of **2′** suitable for single-crystal X-ray diffraction were grown, and the molecular structure of this compound is discussed. A comparative electrochemical study of these complexes in relation to analogous derivatives obtained from the organic ligand 2,5-bis(trimethylsilylethynyl)thiophene (**2,5T**) is reported.

## Introduction

Recently, the search for molecular systems that are able to transmit electronic effects between two or more remote sites efficiently has become an area of increasing endeavour.[1] The interest in this kind of complexes is due, in part, to the stabilising influence of the metal atom on reactive unsaturated carbon chains and polycarbon ligands[1,2] and, on the other hand, to their potential optoelectronic properties as non-linear optical and electroluminescent materials[3] or in the construction of molecular-scale electronic devices.[4,5] Thus, alkynyl or polyynediyl bridging ligands have been shown to be particularly efficient in allowing the passage of electronic effects between redox-active centres[6,7] and therefore the electronic properties can be modified by changing both, metal fragments and/or alkyne ligands.[4b,4d,7b,8] This electronic communication through such potential molecular wires is often evaluated by examining the redox response of electroactive groups.[5i,5j,8a,9]

In recent studies we have shown that complexes, where the redox centres are either $Co_2(CO)_6$, $Co_2(CO)_4$(dppm) or $Co_2(CO)_4$(dppa) linked by 1,3,5-tris(trimethylsilylethynyl)-benzene,[7a] 1,4-bis(trimethylsilyl)butadiyne[7b] and 2,5-bis-(trimethylsilylethynyl)thiophene (**2,5T**)[7d] ligands, present electronic communication between the metal centres. In order to study the effect of the position of the alkynyl substituents on the thiophene ring on the electronic communication between $Co_2(CO)_6$ and $Co_2(CO)_4$(dppm) moieties, we report here the synthesis, characterization and the redox properties of these units linked by the organic ligand 2,4-bis(trimethylsilylethynyl)thiophene (**2,4T**).

## Results and Discussion

### Synthesis and Spectroscopic Characterization

A similar procedure described for 2,5-bis(trimethylsilylethynyl)thiophene (**2,5T**)[10] has been used in our laboratory for the syntheses of the new ligand 2,4-bis(trimethylsilylethynyl)thiophene (**2,4T**). By the coupling reaction of 2,4-dibromothiophene with excess of TMSA [in the presence of $Pd(PPh_3)_4$, CuI and triethylamine] 2,4-bis(trimethylsilylethynyl)thiophene (**2,4T**) (33% yield) and 4-bromo-2-(trimethylsilylethynyl)thiophene (**2,4T′**) (35% yield) were obtained, both as stable yellow oils. Large amounts of a catalyst [5% mol $Pd(PPh_3)_4$ and 10% mol CuI] and higher temperature and reaction time (75 °C for 20 d) were required, causing a side reaction of the terminal acetylene, TMSA, to

afford 1,4-bis(trimethylsilyl)-1,3-butadiyne. Such side reactions were often observed in reactions with less reactive aryl bromides.[11] This synthesis needed a longer reaction time than that to obtain the analogous ligand **2,5T**, because the thiophene positions more suitable to an oxidative addition are 2 and 5. Also, from 2,6-dibromopyridine,[12] under Sonogashira coupling conditions, reasonable yields of both, the partially and fully substituted compounds containing the TMSA group were obtained. Complexes **1**, **2**, **3** or **1′** were obtained by direct reaction between $Co_2(CO)_8$ and **2,4T** or **2,4T′**, respectively.

In order to stabilise the dicobalt units, we have employed the dppm ligand (the small bite angle of dppm was expected to lead to the formation of bridged dicobalt complexes). Thus, dppm-substituted alkyne carbonyl complexes **4**, **5**, **6** and **2′** could only be prepared by substitution reaction of two or four carbonyl ligands in the presence of $Me_3NO$ at the $Co_2(CO)_6$ units of complexes **1**, **2**, **3** and **1′**, respectively (Scheme 1), because of the poor yields obtained by direct reaction between the alkyne and "$Co_2(CO)_6$(phosphane)" under thermal conditions for the analogous complexes from **2,5T**.[7d] The FT-IR spectral changes of these reactions were monitored until the $\nu_{C\equiv O}$ bands of the parent complex had disappeared.

On the basis of the isolated yield for **4** and **5**, it can be observed that the preference of the $Co_2(CO)_4$(dppm) units for coordination at the alkyne in 2-position of the thiophene ring is two times greater than that for the 4-position. This preference is also observed for the analogous complexes **1** and **2** with $Co_2(CO)_6$ units (see Exp. Sect.). Moreover, compound **5**, in $CDCl_3$ solution at room temp. for 48 h, led to **4** (**4** was never observed to yield **5**), and complex **6** decomposed to afford **4** and **5** in a 7:1 ratio [determined by thin-layer chromatography (TLC) using hexane/$CH_2Cl_2$ (5:4) as eluent]. These results can be explained by simple steric or electronic effects.

As both positions have the same substituent on the alkyne ($SiMe_3$), it can be expected that the steric demand at the end-caps are similar. Then, the preference of the $Co_2(CO)_4X$ [X = $(CO)_2$ or dppm] moieties to coordinate the alkyne in position 2 can be explained by electronic factors. In agreement with this, the electron density on the triple bond of the alkyne in position 4 is higher than on the alkyne in position 2, as judged by the $^{13}C$ NMR shifts for the alkyne C atoms; this situation should disfavor the attachment of the Co atoms to the C≡C group in position 4, since back-donation from the Co d-orbitals to the π*-MO of an electron-poor ligand is the stabilizing factor in the bonding.[13]

However, Diederich et al. obtained in the reaction of $Co_2(CO)_8$ with 1,6-bis(triisopropylsilyl)hexa-1,3,5-triyne the exclusive formation of the compound in which the carbonylcobalt fragment is coordinated to the central C≡C triple bond, which was attributed to the presence of the bulky triisopropylsilyl end-caps.[2c]

Removal of the TMS protecting group from **4** and **5** was accomplished by treatment with saturated solutions of KOH in degassed methanol at room temp. to give the terminal diyne compounds **7** and **8**, respectively, isolated as unstable red solids. Complex **9** was synthesized from **6** when stronger desilylation conditions were used (8 equiv. of $Bu_4NF$ in wet THF).

All these compounds have been characterized by spectroscopic data (IR, UV/Vis, $^1H$, $^1H\{^{31}P\}$, $^{13}C\{^1H\}$, $^{31}P\{^1H\}$ NMR, MS) and elemental analysis, details of which are given as Supporting Information, and X-ray crystallography (for **2′**).

The IR spectra of the organic ligands **2,4T** [2165 (w), 2152 (w) $cm^{-1}$] and **2,4T′** [2156 (w) $cm^{-1}$] show weak absorption bands, typically $\nu_{C\equiv C}$ stretches of the alkynyl units, in the characteristic range of diynyl complexes (two $\nu_{C\equiv C}$ stretches at ca. 2060–2200 $cm^{-1}$) and monoynyl complexes (one $\nu_{C\equiv C}$ stretch at ca. 2090–2150 $cm^{-1}$). The $^1H$ NMR spectra of both ligands show two doublet signals due to the thiophene ring protons with coupling constants that are consistent with their chemical formulations. In the $^{13}C$ NMR spectra for **2,4T** and **2,4T′**, the signals belonging to the thiophene ring ($C^3$, $C^4$, $C^5$ and $C^6$) and the alkynyl units ($C^1$, $C^2$, $C^7$ and $C^8$) can be observed, and the assignments were made on the basis of the $\delta$ values and two-dimensional NMR experiments (HMBC and HMQC).

The IR spectra of the (alkyne)cobalt complexes exhibit three strong absorptions in the carbonyl stretching region (2090–2024 $cm^{-1}$) except for compound **3** (four absorptions) due to the asymmetry of the molecule; in dppm-substituted alkyne complexes **4**–**9** and **2′** these absorptions lie at lower frequencies (2027–1950 $cm^{-1}$), and the spectral patterns are similar to those observed for previously reported (alkyne) cobalt and (substituted alkyne)cobalt complexes.[1a,1c,2c,7,14] Complexes **1**, **2**, **4** and **5** contain an uncomplexed C≡C triple bond, which gives a $\nu_{C\equiv C}$ weak absorption at ca. 2157 $cm^{-1}$. For **7** and **8** this absorption could not be observed, but a $\nu_{\equiv C-H}$ one at ca. 3301 $cm^{-1}$ is exhibited. The absence of $\nu_{C\equiv C}$ in the region of 2150 $cm^{-1}$ (for **6** and **9**) and $\nu_{\equiv C-H}$ around 3300 $cm^{-1}$ (for **9**) indicates that the alkynyl bond loses its triple-bond character and both alkyne linkages are coordinated to $Co_2(CO)_4$(dppm) units.

The NMR spectroscopic data, which have been recorded in several solvents, are consistent with the overall geometry established in the solid state for complex **2′** (Figure 1) and with the proposed structures (Scheme 1).

In $^1H$ NMR spectra, the chemical shifts for the $SiMe_3$ and C≡CH protons are found to be very sensitive to cobalt complexation on the adjacent alkyne bond, and they show a significant downfield shift with respect to the free ligands in accordance with the reduction of the C≡C triple-bond character.[15] The signals of all ring protons in the $Co_2(CO)_6$-substituted alkyne complexes are shifted downfield slightly from those of the corresponding alkynylated thiophenes, due to the strong electron-withdrawing effect of the carbonylcobalt moieties. In addition, the values of the $^1H$-$^1H$ coupling constants of $J_{HH} \approx 1.3$ Hz for the thiophene proton signals are in accordance with their non-adjacent positions (Table 1). For dppm complexes **4**–**8** and **2′** the diastereotopic protons of the $-CH_2-$ group are coupled with

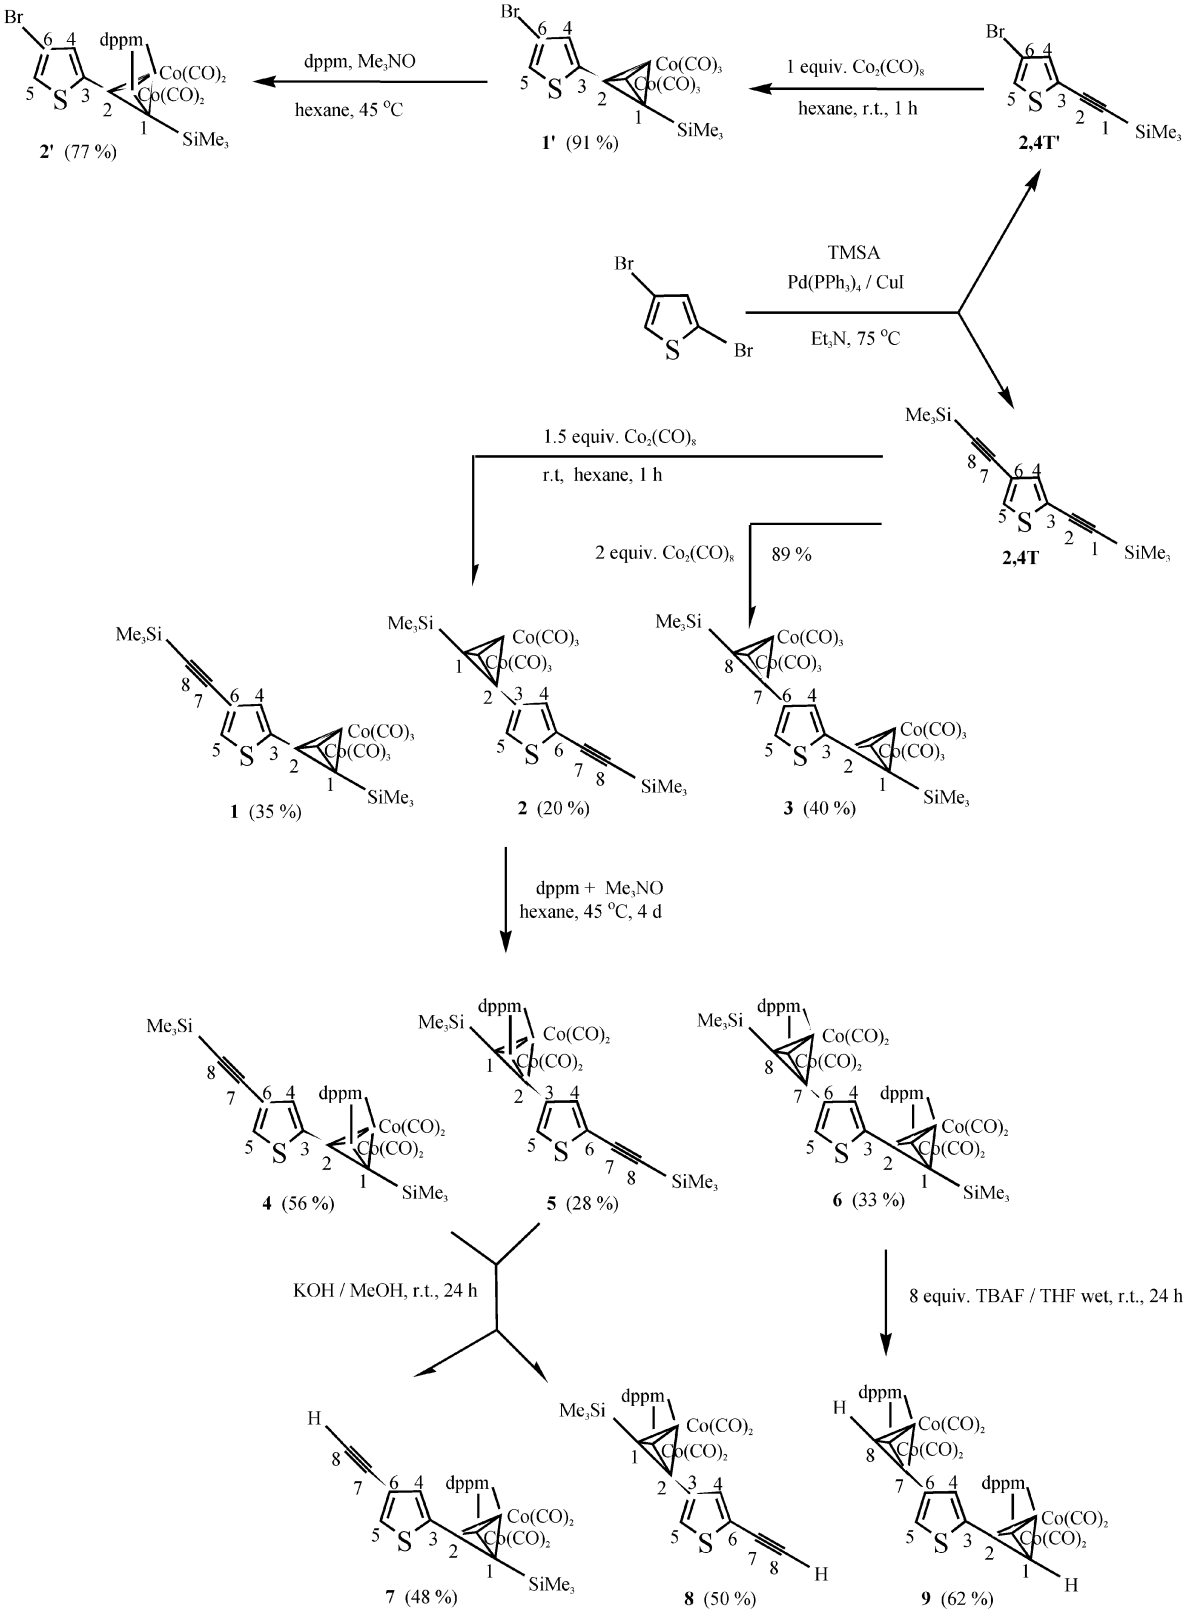

Scheme 1.

the P atoms; thus, they appear as two double triplets with $J_{HH} \approx 13.3$ Hz and $J_{PH} \approx 10.5$ Hz, except in **6**, where the inequivalent $Co_2(CO)_4$(dppm) moieties display four signals in the $^1H$ and $^1H\{^{31}P\}$ NMR spectra in $CD_2Cl_2$. Also, in **9**, the two moieties $Co_2(CO)_4$(dppm) are inequivalent, and this is reflected in the $^1H$ NMR spectrum. This spectrum

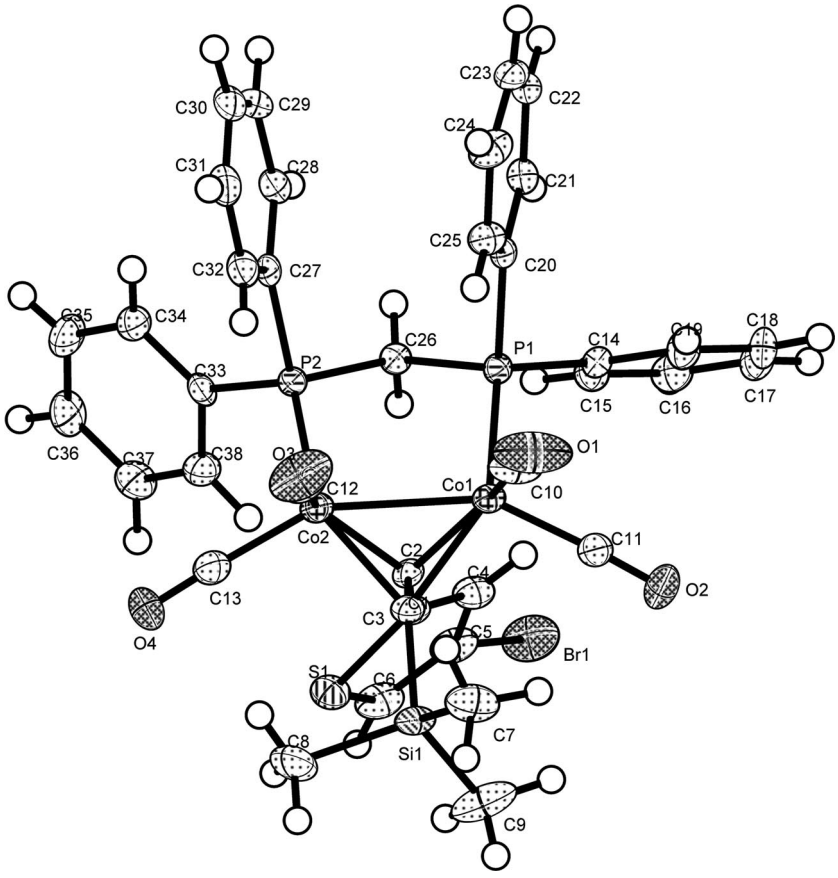

Figure 1. ORTEP diagram of **2′**, with 50% ellipsoids.

shows two resonances for the terminal "alkyne" protons, –(C–C)$_{coord}$–H in the region $\delta$ = 5.72–5.80 ppm, and they are coupled with the P atoms like in similar compounds.[7d,16] As expected,[15,17] because of the reduction in the C≡C triple-bond character, there is a downfield shift in the signal positions of these terminal protons with respect to those of the free ligand ($\delta$ = 3.32 and 2.99 ppm).

The $^{31}$P NMR spectra for **4**, **5**, **7** and **8** present a broad singlet, while for **6** and **9**, which contain two inequivalent $Co_2(CO)_4$(dppm) units, two broad singlets appear. All of them are shifted to higher frequencies (ca. 35 ppm) with respect to that of the free ligand because of the coordination.

The $^{13}$C NMR chemical shifts of the carbonyl groups in all the complexes appear as one (**1**, **2**, **3** and **1′**), two (**4**, **5**, **7**, **8** and **2′**) or four (**6** and **9**) signals at $\delta \approx 200$ and 207 ppm, suggesting that they are rapidly interchanging on the NMR scale. The carbon resonances of the free and coordinated acetylene carbon atoms can be assigned on the basis of the magnitude of the $J_{CP}$ coupling constants, chemical shifts and in comparison with analogous complexes.[1c,2c,7,18] Thus, for **4** and **5**, in $CDCl_3$ and $CD_2Cl_2$, the $C^1$, $C^2$ and $C^3$ atoms display similar triplets with $^{13}$C-$^{31}$P coupling constants of $J_{CP} \approx$ 10.1, 8.9 and 3.0 Hz, respectively. The replacement of the –$SiMe_3$ group by a proton results in a significant deshielding of the $C^1$, $C^2$, $C^7$ and $C^8$ atoms. The thiophene carbon signals appear between $\delta$ = 120 and 150 ppm (Table 2).

Compound **6** exhibits low solubility in $CDCl_3$ and $CD_2Cl_2$, and for that reason the $^{13}$C NMR spectrum was recorded in [$D_8$]THF. The unambiguous assignment of its carbon atoms has been carried out by comparison with published data of analogous compounds[7d] and by using the $^{13}$C NMR spectra of **4** and **5** in the same solvent in addition to HMQC and HMBC spectroscopy (these experiments have also been performed for the rest of the complexes) (Figure 2).

All compounds gave satisfactory mass spectrometric data; thus, the positive FAB mass spectra show the respective molecular ions or [$M^+$ – CO], as well as peaks corresponding to the consecutive loss of the CO ligands. The UV/Vis spectra of all complexes exhibit broad low-intensity absorption bands with $\lambda$ between 520 and 558 nm attributed to the d-d transitions. For **3**, **6**, and **9**, the presence of the second $Co_2(CO)_6$ or $Co_2(CO)_4$(dppm) unit results in a redshift of these absorption bands. These spectra, for complexes **4**–**9** and **2′**, are dominated by the characteristic UV bands below 380 nm associated with π-π* transitions within the phenyl groups of the bis(phosphane) ligand. In addition, strong absorptions are observed around 231, 250 and 276 nm attributed to π-π* transition associated with the thiophene ring.

### Crystal Structure of 2′

The single-crystal X-ray structure determination of 2-{$Co_2(CO)_4$(μ-dppm)[$\mu_2$-$\eta^2$-($SiMe_3C_2$)]}-4-(Br)-$C_4H_2S$ (**2′**) confirms the structure presented in Scheme 1. Compound **2′** consists of a monosubstituted 4-bromo-2-(trimethylsilylethynyl)thiophene ligand with a dimetallic Co unit at the 2-position. The dimetallic Co moiety has two terminal carbonyl ligands on the Co atoms, bridging dppm and trimethylsilylethynyl groups. This geometry has been observed in other carbonylcobalt dimetallic complexes possessing a bridging acetylene ligand.[19] The geometric parameters for **2′** are summarized in Table 5. Table 3 contains selected bond lengths and angles. An ORTEP plot indicating the atom-labelling scheme is given in Figure 1. Complex **2′** crystallizes in the monoclinic space group $P2_1/c$, with one molecule in the asymmetric unit, but contains no crystallographic symmetry.

A highly distorted tetrahedron is formed by the coordination of the dicobalt unit with the ethynyl carbon atoms, with a Co(1)–Co(2) bond length of 2.4850(5) Å, and the average Co–C bond length was determined to be 1.968(2) Å. The Co–Co distance is comparable to those reported for the compounds 2,5-{$Co_2(CO)_4$(μ-dppm)[$\mu_2$-$\eta^2$-($SiMe_3C_2$)]}$_2C_4H_2S$[7d] and [$Co_2(CO)_4$(μ-dppm){$\mu_2$-$\eta^2$-($SiMe_3C_2$)}]$_2$($SiMe_3C{\equiv}C$)(1,3,5-$C_6H_3$)[7a] and may be considered typical for this type of clusters.[14d,20]

The coordination geometry of the Co atom is similar to a pyramid with a pentagonal-shaped base, where the Co atom is in the centre of the pyramid. The distortion of the pyramid is due to the constrained tetrahedron comprised of Co(1)–Co(2)–C(1)–C(2), as well as the bridging of the dppm ligand. The carbonyl moieties coordinate to the Co atoms in the sterically least hindered sites, thus making up the pyramid. The apex of the pyramid is one of the carbonyl groups, and the base is comprised of the carbonyl group, one of the phosphorus atoms of the dppm ligand, the two ethynyl carbon atoms, and the other Co atom. The bond lengths of the apex carbonyl groups to the Co atoms, C(10)–Co(1) and C(12)–Co(2), are 1.797(3) and 1.794(3) Å, respectively. These bond lengths are statistically not different from those of the base carbonyl groups to the Co atoms, which are 1.767(3) and 1.781 Å, for C(11)–Co(1) and C(13)–Co(2), respectively. The dihedral angle Co(1)–C(1)–C(2)–Co(2) was determined to be –84.5(7)°, whereas the dihedral angle C(1)–Co(1)–Co(2)–C(2) was determined to be –52.8(13)°. The bite angle of the dppm ligand was found to be 108.0(12)°, which is consistent with analogous bite angles of dppm in Co–Co complexes.[21]

The C(1)–C(2) bond length of the bridging ethynyl ligand, 1.358(4) Å, is consistent with reported ethynyldicobalt complexes.[22] This reflects the loss of triple-bond character as a result of coordination of the acetylenic moiety to the $Co_2$ unit. The change in hybridisation at C(1)–C(2) is also reflected in the C(1)–C(2)–C(3) angle of 136.0(2)° and the C(2)–C(1)–Si(1) angle of 141.7(19)°.

The bond lengths of the Co atoms to the phosphorus atoms of the dppm ligand are 2.222(7) Å and 2.226(7) Å for Co(1)–P(1) and Co(2)–P(2), respectively. The average P–C distances of the bridging dppm ligand, 1.835(2) Å are normal;[23] the P–C bond lengths are statistically equivalent. All other bond lengths and angles are comparable to those reported for similar structures.[7] The average carbonyl C≡O bond length was determined to be 1.140(3) Å, where all of the bond lengths are sufficiently similar. In addition, the Br–C(5) bond length is 1.894(3) Å and the C(6)–C(5)–Br and C(4)–C(5)–Br angles are 123.7(2)° and 121.5(2)°,

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

respectively. The thiophene ring is essentially planar with a root mean square deviation of 0.0045 Å. There does not appear to be any intramolecular hydrogen bonding within the molecule.

## Electrochemical Studies

The electrochemical behaviour of **1**, **2′** and **3**–**9** in $CH_2Cl_2$ solution was studied by means of cyclic voltammetry (CV) and square wave voltammetry (SWV) techniques. A preliminary study of **1** and **3**–**6** was previously published.[24] Table 4 presents data of $E_{1/2}$ [$E_{1/2} = (E_{pa} + E_{pc})/2$] for the electrochemical reduction and oxidation of **1**, **2′** and **3**–**9**. The organic ligands **2,4T** and **2,4T′** do not show any oxidation or reduction peaks in the potential range between –1.8 V and +1.5 V vs. $Fc^{*+}/Fc^{*}$ (Fc* = decamethylferrocene) in $CH_2Cl_2$.

Table 4. Electrochemical data for **1**, **2′** and **3**–**9**.[a]

### *Electrochemistry of 1 and 3*

CV and SWV of the $Co_2(CO)_6C_2$ derivative **1** at room temp. show chemically irreversible oxidation and reduction waves at moderate sweep rates (EC processes). Thus, when the sweep is reversed after CV reduction, no coupled anodic peak is observed, but a new small one appears at +0.12 V (irreversible). This behaviour indicates that the decomposition of $\mathbf{1}^-$ yields, among other fragments, $Co(CO)_4^-$ (oxidised at 0.12 V).[6d,7,25] The stability of $\mathbf{1}^-$ is greatly enhanced when low temperature decreases the rate of the following chemical reaction, and at –30 °C chemical reversibility is almost completely attained.

Decreasing temperature to –30 °C and increasing the sweep rate to 2 V/s allowed to observe a very small coupled reduction peak on sweep reversal after $\mathbf{1}^+$ formation. The stability of $\mathbf{1}^+$ is lower than that observed for the related cation derived from 2-[$Co_2(CO)_6\{\mu_2$-$\eta^2$-$(SiMe_3C_2)\}$]-5-($Me_3SiC{\equiv}C$)$C_4H_2S$ ($i_{pc}/i_{pa} \approx 0.55$ at –30 °C and 0.1 V/s).[7d] This result is in agreement with the higher overall π-conjugation[26] in complexes containing **2,5T** ($\lambda_{max}$ = 331 nm)[27] as compared to those of **2,4T** ($\lambda_{max}$ = 277 nm). $E_{1/2}$(ox) and $E_{1/2}$(red) for **1** are very similar to those of the corresponding **2,5T** derivative, indicating that the position of the $–C_2SiMe_3$ substituent on the thiophene ring does not have a significant influence on the electrochemical processes.

Compound **3**, with two "almost" equivalent dicobalt redox centers, shows two consecutive monoelectronic reductions and oxidations to achieve $\mathbf{3}^{2-}$ and $\mathbf{3}^{2+}$, respectively. At room temp., reduction of **3** is chemically completely irreversible; however, at –30 °C the chemical stability of the reduced species is greatly enhanced, and two distinct and almost completely reversible reduction waves are observed in CV (Figure 3). The ratio $i_{pa}/i_{pc}$ approaches 1 as the sweep rate increases. As regarding oxidation, two quasi-reversible waves are also observed, $i_{pc}/i_{pa}$ increasing as the temperature decreases.

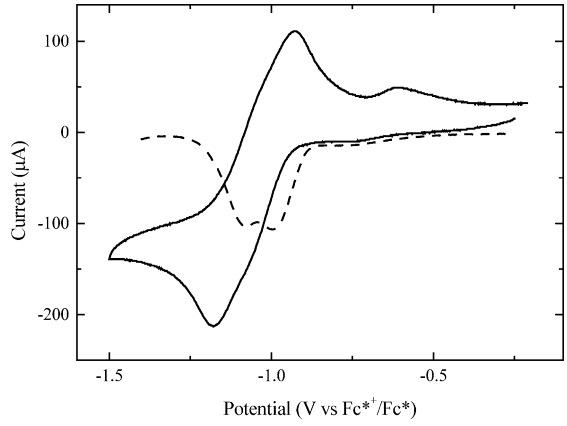

Figure 3. Cyclic (–) and square wave (- - -) voltammograms for the reduction of **3** in $CH_2Cl_2$ containing 0.15 M $TBAPF_6$ at –30 °C on a glassy carbon working electrode. CV: $v$ = 0.5 V $s^{-1}$. SWV: scan increment = 2 mV, SW amplitude = 25 mV, frequency = 15 Hz.

### *Electrochemistry of 2′ and 4–9*

Compounds **2′** and **4**–**9** contain $Co_2(CO)_4(dppm)C_2$ redox centers. The dppm ligand increases the electronic density and makes oxidations easier (less positive $E_{1/2}$) and reductions more difficult (more negative $E_{1/2}$) as observed in Table 4.

The $E_{1/2}$(ox) values are quite similar for all the compounds containing a single $Co_2(dppm)(CO)_4C_2$ redox center, independent of the nature of the other substituent on the thiophene ring (–Br in **2′**, $–C_2SiMe_3$ in **4**–**5** and $–C_2H$ in **7**–**8**) or the location of the $Co_2(dppm)(CO)_4C_2$ unit (position 2 or 4). It should be noted that **7** and **8** could not be isolated, and that an equimolecular mixture of both compounds was used for the electrochemical measurements. A single oxidation and a single reduction peak were obtained for that mixture, indicating that both compounds are oxidised and reduced at almost the same potential value. In the case of $E_{1/2}$(red), differences are not too strong among **2′**, **4**, **5** and **7+8**, but it seems that the presence of a $–C_2SiMe_3$ substituent makes reduction slightly more difficult ($E_{1/2}$ more negative), as a result of the higher electron-donating properties of the $–SiMe_3$ group as compared to –H. The bidentate ligand dppm greatly increases the chemical stability of the cations (oxidations of the compounds with one redox center are chemically completely reversible at 25 °C and 0.1 V/s) and the anions (reductions are quasi-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

reversible at 25 °C and completely reversible a –30 °C) (Figure 4). Potential values and stability trends agree with those of related **2,5T** compounds.[7d]

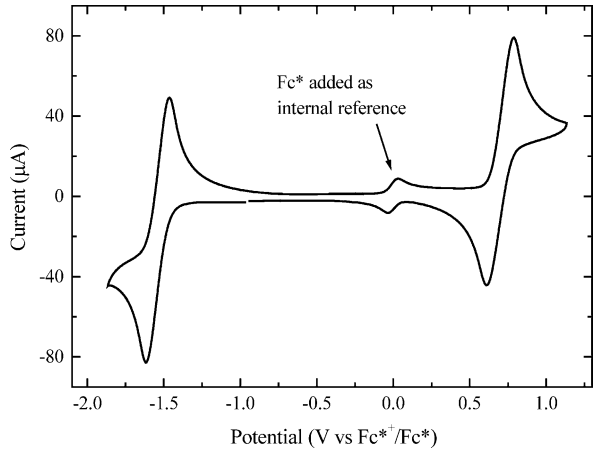

Figure 4. Cyclic voltammogram for the reduction and oxidation of **4** at –30 °C in $CH_2Cl_2$ containing 0.15 M $TBAPF_6$ on a glassy carbon working electrode at $v = 0.05\ V\,s^{-1}$.

**6** and **9** contain two $Co_2(dppm)(CO)_4C_2$ centers and show two consecutive monoelectronic oxidations and reductions. Chemical reversibility is greatly approached at –30 °C (Figure 5), allowing the determination of $E_{1/2}$. Analogous compounds, in which the ligand is **2,5T**, show a greater stability of the corresponding anions and cations, in agreement with the general trends observed in the synthesis of both sets of compounds (**2,4T** and **2,5T** derivatives) and the higher overall π-conjugation of **2,5T**, as the $C^3$–$C^4$ bond in a thiophene ring is known to have less double-bond character than the $C^2$–$C^3$ bond.[28]

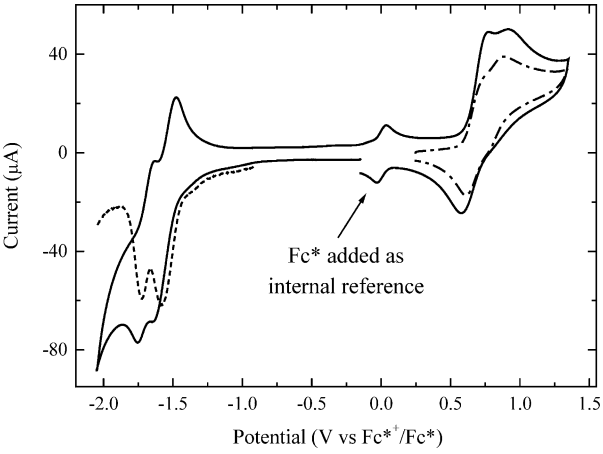

Figure 5. Voltammograms for the reduction and oxidation of **6** in $CH_2Cl_2$ containing 0.15 M $TBAPF_6$. (−) CV at –30 °C on a glassy carbon working electrode, $v = 0.1\ V\,s^{-1}$. (-·-·-) CV at 25 °C on a Pt working electrode, $v = 0.1\ V\,s^{-1}$. (- - -) SWV at –30 °C on a glassy carbon working electrode, scan increment = 2 mV, SW amplitude = 25 mV, frequency = 60 Hz.

The difference between $E_{1/2}$ of consecutive waves in compounds with two equivalent redox centers, $\Delta E_{1/2}$, is usually regarded as an estimation of the amount of electronic interaction between those centers through the bridging ligand.[9a] The two redox centers in **3**, **6** and **9** are not completely equivalent, and the observed $\Delta E_{1/2}$ could be due to intrinsic differences; however, results obtained with **4**–**5** and **7**–**8** (very scarce influence of the position of the redox center on the thiophene ring) allow to assume that most of $\Delta E_{1/2}$ is due to a low-intensity electronic interaction between the centers. The $\Delta E_{1/2}$ values observed for **3**, **6** and **9** can thus be compared to those measured for the related compounds 2,5-$[Co_2(CO)_6\{\mu_2\text{-}\eta^2\text{-}(SiMe_3C_2)\}]_2C_4H_2S$ [$\Delta E_{1/2}$(red) = 0.11 V; $\Delta E_{1/2}$(ox) = 0.24 V], 2,5-$[Co_2(CO)_4(\mu\text{-dppm})\{\mu_2\text{-}\eta^2\text{-}(SiMe_3C_2)\}]_2C_4H_2S$ [$\Delta E_{1/2}$(red) = 0.13 V; $\Delta E_{1/2}$(ox) = 0.29 V] and 2,5-$[Co_2(CO)_4(\mu\text{-dppm})\{\mu_2\text{-}\eta^2\text{-}(HC_2)\}]_2C_4H_2S$ [$\Delta E_{1/2}$(red) = 0.13 V; $\Delta E_{1/2}$(ox) = 0.20 V], respectively.[7d] All $\Delta E_{1/2}$ values (including those of the present work) indicate that a moderate electronic interaction is established through the aromatic ligand backbone, and the complexes belong to group II in the Hush–Robin–Day classification of mixed-valence compounds.[29] Data for the **2,4T** and **2,5T** derivatives show that the $\Delta E_{1/2}$(ox) values are significantly larger for the latter. This seems to indicate that the HOMO (depopulated by oxidation) of the **2,5T** derivatives shows a greater π-delocalization than the HOMO of the **2,4T** derivatives and than the LUMO (populated by reduction) in both groups, in agreement[26] with the higher conjugation observed in **2,5T** derivatives, where the $\lambda_{max}$ value is less blue-shifted relative to that of **2,4T** compounds. The differences in $\Delta E_{1/2}$ indicate a significant contribution of through-bond electronic interactions as compared to through-space ones in these compounds.

## Conclusion

The overall π-conjugation of **2,4T** derivatives is smaller than that of the analogous **2,5T** derivatives, and this results in a lower stability of the ions derived from **2,4T** and a weaker electronic communication through the aromatic ligand backbone. The derivatives of **2,4T** and **2,5T** with two redox centres belong to group II in the Hush–Robin–Day classification of mixed-valence compounds.

## Experimental Section

**Reagents and General Techniques:** All manipulations were carried out by using standard Schlenk vacuum-line and syringe techniques under oxygen-free argon. All solvents for synthetic use were dried and distilled under argon by standard procedures.[30] Column chromatography was performed by using silica gel 100 (Fluka) and preparative TLC glass plates coated with silica gel (SDS 60–17 μm, 0.25 mm thick). 2,4-Dibromothiophene (Lancaster Synthesis Inc.); $Me_3SiC{\equiv}CH$ (TMSA), $Co_2(CO)_8$, KOH (Fluka); 1,2-bis(diphenylphosphanyl)methane (dppm), CuI, a solution 1.0 M of tetrabutylammonium fluoride (TBAF) in THF (Aldrich); $NaHCO_3$, $MgSO_4$ (Panreac) and a solution of HCl (35%) (Prolabo) were used as received. Trimethylamine *N*-oxide (Aldrich) was sublimed prior to use and stored under argon. Compound $Pd(PPh_3)_4$[31] was prepared according to the literature. The $^1H$, $^1H\{^{31}P\}$, $^{13}C\{^1H\}$, $^{31}P\{^1H\}$ NMR spectra and HMQC and HMBC data were recorded with Bruker AMX-300 and -500 instruments. Chemical shifts were

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

measured relative to either an internal reference of tetramethylsilane or residual protons of the solvents. Infrared spectra were measured with a Perkin–Elmer 1650 infrared spectrometer. Elemental analyses were performed with a Perkin–Elmer 240 B microanalyser. Electronic spectra were recorded with a Unicam UV 4 UV/Vis spectrophotometer. Mass spectra were measured with a VG-Autospec mass spectrometer for FAB and EI. Spectroscopy data are available as Supporting Information. Electrochemical measurements were carried out with a computer-driven Par Mo. 273 electrochemistry system in a three-electrode cell under nitrogen in anhydrous deoxygenated $CH_2Cl_2$ containing 0.15 M tetrabutylammonium hexafluorophosphate ($TBAPF_6$) as supporting electrolyte. Cyclic and square wave voltammetry (CV and SWV, respectively) studies were carried out in a three-electrode system. Polycrystalline Pt (0.05 $cm^2$) or glassy carbon were used as working electrodes; the counter electrode was a Pt gauze and the reference electrode was a silver wire quasi-reference electrode. Decamethylferrocene (Fc*) was used as internal standard, and all potentials in this work are referenced to the $Fc^{*+}/Fc^*$ couple. Under the actual experimental conditions, $E_{1/2}$ of the ferrocene couple ($Fc^+/Fc$) was +0.55 V vs. $Fc^{*+}/Fc^*$ in $CH_2Cl_2$ solution. Coulometry of **4** was performed at 1.1 V and 1 mol of electrons per mol of **4** was found to be consumed in the oxidation process. The number of electrons involved in the remaining processes were determined by comparison of peak heights in CV.

**Synthesis of 2,4-Bis(trimethylsilylethynyl)thiophene (2,4T) and 4-Bromo-2-(trimethylsilylethynyl)thiophene (2,4T′):** To a solution of 2,4-dibromothiophene (3.0 g, 12.4 mmol) in $Et_3N$ (100 mL) was added at 0 °C $Pd(PPh_3)_4$ (0.70 g, 0.62 mmol), CuI (0.23 g, 1.24 mmol) and excess of trimethylsilylacetylene (TMSA) (12.1 g, 17.5 mL, 124 mmol). The resulting mixture was stirred first at room temperature for 0.5 h and finally at 75 °C for 20 d. The solvent was removed under reduced pressure and the residue dissolved in $Et_2O$ (100 mL) and wash with (i) a solution of HCl (10%), (ii) a saturated solution of $NaHCO_3$ and dried ($MgSO_4$). The solvent was evaporated and the residue purified by column chromatography with hexane to yield **2,4T** (1.13 g, 33% yield) and **2,4T′** (1.12 g, 35% yield) as stable yellow oils.

**Synthesis of 2-[$Co_2(CO)_6\{\mu_2$-$\eta^2$-$(SiMe_3C_2)\}$]-4-$(Me_3SiC{\equiv}C)C_4H_2S$ (1), 2-$(Me_3SiC{\equiv}C)$-4-[$Co_2(CO)_6\{\mu_2$-$\eta^2$-$(SiMe_3C_2)\}$]$C_4H_2S$ (2) and 2,4-[$Co_2(CO)_6\{\mu_2$-$\eta^2$-$(SiMe_3C_2)\}$]$_2C_4H_2S$ (3):** To a solution of **2,4T** (0.90 g, 3.26 mmol) in hexane (100 mL) was added 1.5 equiv. of $Co_2(CO)_8$. The reaction was monitored by FT-IR and $^1H$ NMR spectroscopy until the signals of the parent compounds **2,4T** and $Co_2(CO)_8$ had disappeared. After the mixture had been stirred at room temp. for 1 h, the solvent was removed under vacuum and the residue purified by thin-layer chromatography (TLC) using hexane as eluent to afford **1** (0.64 g, 35% yield) and **2** (0.36 g, 20% yield) together with **3** (1.24 g, 40% yield) as unstable solids. **3** has also been obtained as the only product in high yield (0.27 g, 89%) from **2,4T** (0.10 g, 0.36 mmol) and 2 equiv. of $Co_2(CO)_8$ and subsequent chromatography with hexane on a silica column.

**Synthesis of 2-[$Co_2(CO)_6\{\mu_2$-$\eta^2$-$(SiMe_3C_2)\}$]-4-(Br)-$C_4H_2S$ (1′):** By a similar procedure as described above, from **2,4T′** (0.75 g, 2.89 mmol) and 1 equiv. of $Co_2(CO)_8$. After the solvent had been removed under vacuum, the product was eluted with hexane on a silica column to afford **1′** (1.43 g, 91% yield) as an unstable red solid.

**Synthesis of 2-[$Co_2(CO)_4$(μ-dppm)$\{\mu_2$-$\eta^2$-$(SiMe_3C_2)\}$]-4-$(Me_3SiC{\equiv}C)C_4H_2S$ (4) and 2-$(Me_3SiC{\equiv}C)$-4-[$Co_2(CO)_4$(μ-dppm)$\{\mu_2$-$\eta^2$-$(SiMe_3C_2)\}$]$C_4H_2S$ (5):** A solution containing **1** and **2** (1.0 g, 1.78 mmol in a 1.75:1 ratio) in hexane (100 mL) was added dppm (0.68 g, 1.78 mmol) and trimethylamine *N*-oxide (0.40 g, 3.56 mmol). The reaction mixture, monitored by FT-IR spectroscopy until the $\nu_{C\equiv O}$ bands of the parent complexes had disappeared, was stirred at 45 °C for 4 d. Finally, the solvent was removed under vacuum and the residue purified by thin-layer chromatography (TLC) using hexane/$CH_2Cl_2$ (6:1) to afford **4** (0.56 g, 56% yield) and **5** (0.16 g, 28% yield) as stable dark red solids.

**Synthesis of 2,4-[$Co_2(CO)_4$(μ-dppm)$\{\mu_2$-$\eta^2$-$(SiMe_3C_2)\}]_2C_4H_2S$ (6):** The same procedure as described above was applied in the preparation of this compound from **3** (0.82 g, 0.97 mmol), dppm (1.94 mmol) and $Me_3NO$ (3.88 mmol). After the solvent had been removed under vacuum, the residue was purified by the same manner. Complex **6** (0.48 g, 33% yield) was obtained as air-stable dark green solid.

**Synthesis of 2-[$Co_2(CO)_4$(μ-dppm)$\{\mu_2$-$\eta^2$-$(SiMe_3C_2)\}$]-4-(Br)-$C_4H_2S$ (2′):** A solution of **1′** (0.27 g, 0.50 mmol) and dppm (0.50 mmol) in hexane (50 mL) was prepared. Trimethylamine *N*-oxide (0.11 g, 1.00 mmol) was added and the reaction mixture, monitored by FT-IR spectroscopy, stirred at 45 °C for 4 d. After the solvent had been removed under vacuum, the residue was purified by thin-layer chromatography (TLC) using hexane/$CH_2Cl_2$ (3:1) to afford **2′** (0.33 g, 77% yield) as stable dark red solid.

**Synthesis of 2-[$Co_2(CO)_4$(μ-dppm)$\{\mu_2$-$\eta^2$-$(SiMe_3C_2)\}$]-4-$(C{\equiv}CH)$-$C_4H_2S$ (7) and 2-$(C{\equiv}CH)$-4-[$Co_2(CO)_4$(μ-dppm)$\{\mu_2$-$\eta^2$-$(SiMe_3C_2)\}$]$C_4H_2S$ (8):** An equimolecular solution of **4** and **5** in MeOH saturated with KOH was stirred for 24 h at 25 °C. Then the solvent was removed under vacuum and the residue extracted with several portions of $Et_2O$ and purified by chromatography on a hexane-packed silica column (200 g) using hexane/$CH_2Cl_2$ (1:1) as eluent to afford **7** (48% yield) together with **8** (50% yield) as unstable solids.

**Synthesis of 2,4-[$Co_2(CO)_4$(μ-dppm)$\{\mu_2$-$\eta^2$-$(HC_2)\}]_2C_4H_2S$ (9):** To a solution of **6** (0.48 g, 0.32 mmol) in wet THF (50 mL) was added TBAF (2.56 mL, 1.0 M in THF, 2.56 mmol) and the mixture stirred at room temp. for 24 h. After the solvent had been removed under vacuum, the product was purified by chromatography on a hexane-packed silica column using hexane/$CH_2Cl_2$ (1:1) as eluent to afford **9** (0.27 g, 62% yield) as unstable dark purplish-red solid.

**X-ray Data Collection, Structure Determination and Refinement of 2′:** Dark red crystals were obtained by recrystallisation of the complex from $CH_2Cl_2$/hexane mixtures. A summary of selected crystallographic data for **2′** is given in Table 5. A red single crystal of approximate dimensions $0.25\times0.12\times0.09$ mm with prismatic shape was mounted on a glass fibre and transferred to a Bruker SMART 6K CCD area-detector three-circle diffractometer with a MAC Science Co., Ltd. rotating anode (Cu-$K_\alpha$ radiation, $\lambda$ = 1.54178 Å) generator equipped with Goebel mirrors at settings of 50 kV and 110 mA.[32] X-ray data were collected at 100 K, with a combination of several runs at different $\phi$ and $2\theta$ angles. The data were collected using 0.3° wide $\omega$ scans, crystal-to-detector distance of 4.0 cm. The raw intensity data frames were integrated with the SAINT program,[33] which also applied corrections for Lorentz and polarization effects. The substantial redundancy in data allowed empirical absorption corrections[34] to be applied using multiple measurements of symmetry-equivalent reflections. A total number of 24250 reflections were collected, and 6989 independent reflections remained after merging $R_{int}$ = 0.0358. The unit-cell parameters were obtained by full-matrix least-squares refinements of the complete data set. The structure was solved and refined using the SHELXTL/PC V 6.10 package.[35] The structure was solved by direct methods, refinement by full-matrix least squares on $F^2$ using

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

all data (negative intensities included). Weighted *R* factors ($R_w$) and all goodness-of-fit (*S*) are based on $F^2$; conventional *R* factors (*R*) are based on *F*. All non-hydrogen atoms were refined with anisotropic displacement parameters. All scattering factors and anomalous dispersions factors are contained in the SHELXTL 6.10 program library. The H-atom parameters were calculated and atoms were constrained as riding atoms with $U_{iso}$ 20% larger than those of the corresponding C atoms for the phenyl H atoms and 50% larger for the methyl H atoms. CCDC-641070 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif. Table 3 contains selected bond lengths and angles. Figure 1 presents a molecular diagram of **2′**.

Table 5. Crystal data and structure refinement for compound **2′**.

| | |
|---|---|
| Empirical formula | $C_{38}H_{33}BrCo_2O_4P_2SSi$ |
| Formula mass | 873.50 |
| Temperature | 100(2) K |
| Wavelength | 1.54178 Å |
| Crystal system | monoclinic |
| Space group | $P2_1/n$ |
| Unit-cell dimensions | $a$ = 16.5425(2) Å |
| | $b$ = 12.19370(10) Å |
| | $c$ = 19.1305(2) Å |
| | $\beta$ = 93.2610(10)° |
| Volume | 3852.65(7) Å$^3$ |
| $Z$ | 4 |
| Density (calcd.) | 1.506 Mg/m$^3$ |
| Absorption coefficient | 9.859 mm$^{-1}$ |
| $F$(000) | 1768 |
| Crystal size | 0.25 × 0.12 × 0.09 mm |
| $\theta$ range for data collection | 3.44–70.52° |
| Index ranges | $-17 \le h \le 19, -14 \le k \le 13, -21 \le l \le 22$ |
| Reflections collected | 24250 |
| Independent reflections | 6989 [$R$(int) = 0.0358] |
| Completeness to $\theta$ = 70.52° | 94.9% |
| Absorption correction | SADABS v. 2.03 |
| Refinement method | full-matrix least squares on $F^2$ |
| Data/restraints/parameters | 6989/0/574 |
| Goodness-of-fit on $F^2$ | 1.032 |
| Final $R$ indices [$I > 2\sigma(I)$] | $R_1$ = 0.0330, $wR2$ = 0.0851 |
| $R$ indices (all data) | $R_1$ = 0.0369, $wR2$ = 0.0874 |
| Largest diff. peak/hole | 1.213/–0.798 e Å$^{-3}$ |

**Supporting Information** (see footnote on the first page of this article): IR, UV/Vis, MS, $^1$H, $^{13}$C, $^{31}$P NMR spectra and elemental analysis of **1**–**9**, **1′**–**2′**, **2,4T** and **2,4T′**.

## Acknowledgments

We express our great appreciation to the Dirección General de Investigación Científica y Tecnológica, Spain (Grants No. BQU2002-02522 and CTQ2006-10940/BQU). X-ray diffraction data were collected at the Monocrystal Diffraction Laboratory SidI. Facultad de Ciencias, Universidad Autónoma de Madrid, Spain.

# Inclusion Complexes for Use in Room-Temperature Gas-Sensor Design

Liwei Mi,[a] Hongwei Hou,*[a] Jiaqiang Xu,[b] Hong Xu,[a] Zhiyong Song,[a] Mingsheng Tang,[a] and Yaoting Fan[a]

**Keywords:** Inclusion compounds / Semiconductors / Sensors / Density functional calculations / Bridging ligands

The inclusion complex $[\{Co(bpy)(H_2O)_4\}\cdot(fcds)]_n$ (**1**), which has been constructed using the guest molecule ferrocene-1,1′-disulfonate (fcds), the bridging ligand 4,4′-bipyridine (bpy) and $d^7$ $Co^{2+}$, contains an infinite zigzag chain formed by the central $Co^{II}$ ion and the bridging bpy ligand. Guest fcds molecules lie between two adjacent zigzag chains. The highly conjugated structure of complex **1** means that it can be used as a metal-organic semiconductor, and it also shows a high response to liquefied petroleum gas (LPG) and ethanol/petroleum ether (EP) at room temperature. The inclusion complexes $[\{Co(bpp)_2(H_2O)_2\}\cdot(fcds)\cdot 4H_2O]_n$ [**2**; bpp = 1,3-bis(4-pyridyl)propane] and $[\{Zn(bpy)(H_2O)_4\}\cdot(fcds)]_n$ (**3**), on the other hand, cannot be employed as room-temperature gas sensors because they are insulators. The electrical resistivity of inclusion complex $[\{Ni(bpy)(H_2O)_4\}\cdot(fcds)]_n$ (**4**) is 621 MΩ, whereas that of $[\{Co(bpy)(H_2O)_4\}SO_4\cdot(4\text{-abaH})_2\cdot 3H_2O]_n$ (**5**) (4-abaH = 4-aminobenzoic acid) is only 137 MΩ. This means that the semi-conducting properties of such inclusion complexes depend on both the conjugated structure and the central metal ions. Furthermore, conjugated inclusion complexes with an odd number of electrons could be useful for the design of highly selective room-temperature gas sensors.

## Introduction

Research into low-cost, selective, sensitive and reliable room-temperature gas-sensitive materials has become increasingly important because gas management has become an issue of vital significance in these environmentally conscious times.[1] For this reason, many inorganic oxide semiconductors, such as $SnO_2$, $TiO_2$ and $WO_2$, have been used as gas sensors.[2] However, their lack of long-term stability and selectivity has prevented the widespread use of this type of sensor. Current research into state-of-the-art gas sensors is focused on metallophthalocyanine (MPC)-based semiconductors due to their high response to many gases at room temperature.[3] Undoped conventional MPCs are insulators and their semi-conducting properties are derived from their most noticeable feature, namely their highly charged conjugated electron system, the readily accessible π and π* orbitals of which allow at least partial oxidization or reduction of the macrocycle with gases such as $NO_2$ or $O_3$.[4]

Our strategy for creating room-temperature gas sensors utilizes metal-organic inclusion complexes[5] because they have already been proved to be promising materials for gas storage and molecular recognition[6] and they can easily be prepared under moderate conditions. Furthermore, metal-organic complexes usually contain highly conjugated metal organic hosts with highly charged conjugated electron systems and ionic guest molecules. We believe that both the highly conjugated systems and the central metals govern the gas-sensitive properties of inclusion complexes, which is in contrast to MPC-based gas sensors, where the π-conjugated system contributes mostly to their semiconducting properties.[7] To verify this assumption, four inclusion complexes[8] containing the guest molecule ferrocene-1,1′-disulfonate (fcds), namely $[\{Co(bpy)(H_2O)_4\}\cdot(fcds)]_n$ (**1**), $[\{Co(bpp)_2(H_2O)_2\}\cdot(fcds)\cdot 4H_2O]_n$ (**2**), $[\{Zn(bpy)(H_2O)_4\}\cdot(fcds)]_n$ (**3**), $[\{Ni(bpy)(H_2O)_4\}\cdot(fcds)]_n$ [**4**; bpy = 4,4′-bipyridine, bpp = 1,3-bis(4-pyridyl)propane], and the inclusion complex[9] $[\{Co(bpy)(H_2O)_4\}SO_4\cdot(4\text{-abaH})_2\cdot 3H_2O]_n$ (**5**; 4-abaH = 4-aminobenzonic acid), which contains the neutral molecule 4-abaH as guest, were synthesized. Complexes **1**, **4**, and **5** show some semi-conducting behavior under an adscititious voltage of 5.0 V. However, only **1** exhibits a high response to gasoline and liquefied petroleum gas at room temperature as both **2** and **3** are insulators under these conditions. Quantum chemical calculations help to reveal some of the mechanisms involved in room-temperature gas-sensor design from inclusion complexes (Scheme 1).

## Results and Discussion

Complex **1** was prepared by combining odd-electron divalent $Co^{2+}$ ions with highly conjugated 4,4′-bpy ligands and disodium ferrocene-1,1′-disulfonate. The molecular structure of **1** consists of two parts. The cationic component $[Co(bpy)(H_2O)_4]^{2+}$ forms an infinite zigzag chain, and fcds makes up the anionic part of **1**. As shown in Figure 1, the central cobalt ions lie at the center of a distorted octahedron formed by four oxygen atoms from water molecules

and two nitrogen atoms from two 4,4′-bpy ligands. The coordinated water molecules form strong hydrogen bonds with the anionic part, with the shortest bond being only 1.854 Å and the longest one 3.013 Å. These bonds make the structure very stable (Tables 1 and 2).

Figure 2 shows that the cationic metal-organic and the anionic organic chains are arrange alternately along the *c* axis. The $[Co(bpy)_2(H_2O)_4]^{2+}$ chains are parallel with a distance of 8.478 Å, which gives rise to a highly conjugated structure, as proved by subsequent quantum calculations. These calculations were conducted at the density functional theory (DFT) level using the LanL2DZ basis set.[10] The results of these calculations show that the frontier molecular orbitals of **1** are primarily based on conjugated fcds [HOMO(α): 49.42%; LUMO(α): 48.75%] and the aryl groups of the bpy pillars [HOMO(α): 50.08%; LUMO(α): 50.81%], as depicted in Figure 3. This means that the whole structure of **1** is highly conjugated and that delocalization of the π-electron cloud might make the electron transfer easier. We can therefore deduce that inclusion complexes can be synthesized with semiconducting properties by a judicious choice of highly conjugated organic layers and guest molecules. The charge-transport properties of conjugated polymers in some organic semiconductors,[11] for example, are very closely associated with their π-electron clouds.[12]

[a] Symmetry transformations used to generate equivalent atoms: **1**: #1 $-x-1, -y, -z$; #2 $x, -y, z-1/2$; **2**: #1 $x+1, y, z+1$; #2 $-x+2, -y+1, -z+2$; #3 $-x+1, -y+1, -z+1$; #4 $x+1, y, z$; **3**: #1 $-x, -y+1, -z$; #2 $x, -y+1, z-1/2$.

It should be noted that various gases can be detected by measuring the change of electrical conductivity induced on a suitable active layer by the absorption of gas molecules on its surface.[1a] This change in the conducting behavior of gas-sensing materials results in their use in gas sensors, although to obtain excellent gas sensors the materials must first of all be semiconductors.

The guest fcds molecules in the solid-state structure are found in the space between two adjacent $[Co(bpy)(H_2O)_4]^{2+}$-containing metal-organic layers (interlayer distance: 8.992 Å). This gives rise to numerous O–H···O hydrogen bonds, the shortest of which are only 1.854 Å. It has been reported that the sorption strength of organic compounds

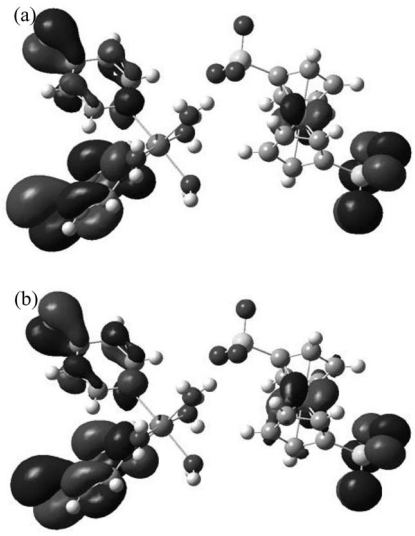

Figure 3. The frontier molecular orbitals of **1**: a) HOMO(α); b) LUMO(α).

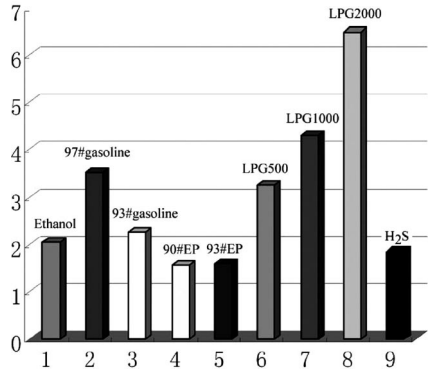

Figure 4. Selectivity of **1** to different gases at room temperature.

depends on similar weak interactions (H-bridge bonds, dispersion forces),[13] therefore the weak interactions in inclusion complexes, especially the H-bonds and π-π interactions between the aryl groups of the pyridine pillars and fcds guests, also contribute to the gas-sensing properties of these complexes. Thus, **1** should have an excellent gas response.

We measured the response of **1** to $H_2S$ (concentration: 50 ppm), ethanol (50 ppm), liquefied petroleum gas (LPG; 50, 1000, and 2000 ppm), 97# gasoline (50 ppm), 93# gasoline (50 ppm), 90# ethanol/petroleum ether (EP; 50 ppm), and 93# ethanol/petroleum ether (EP; 50 ppm) using a commercial gas-sensing measurement system containing HW-30 with no conductive binder added [90# and 97# denote the motor octane number (MON) of the gasoline]. The gas-sensitivity curve was obtained by measuring the change of conductivity at room temperature. As shown in Figure 4, complex **1** displays much higher responses to LPG, EP, gasoline, and alcohol. This behavior is different to that of metal-substituted PCs, which only show a response to highly reactive gases such as $NO_2$, $NH_3$, $Cl_2$, CO, and $N_2$.[14] For comparison, we also measured the selectivity of **1** to gases such as $NO_2$, $N_2$, CO, and $NH_3$; no response was obtained.

The experiment results show that polymeric cobalt inclusion complex **1** could be useful for identifying gases such as LPG, EP, gasoline, alcohol, and $H_2S$ due to its special crystal structure, which contains plenty of hydrogen bonds. However, complex **1** shows no response to $NO_2$, $N_2$, CO, and $NH_3$. The following possibilities must be considered regarding the difference between $NO_2$, $N_2$, CO, $NH_3$, and $H_2S$. The first is that $N_2$, CO, and $NO_2$ cannot easily coordinate to the central cobalt ion in complex **1** because this ion is coordinatively saturated by four coordinated water molecules and two nitrogen atoms from two adjacent 4,4′-bipy bridging ligands. Accordingly, complex **1** cannot be used to identify $N_2$, CO, and $NO_2$. Secondly, both $H_2S$ and $NH_3$ can easily form hydrogen bonds with complex **1**. Previous literature reports have shown that the room-temperature sensing of $H_2S$ gas is possible due to a heterocontact-type sensing mechanism,[15,16] and we believe that a similar mechanism might be functioning in our inclusion complexes. However, the sensing mechanism for $NH_3$ gas is very different to that of $H_2S$, so it is easy to understand why complex **1** can identify $H_2S$ and not $NH_3$.

There are many holes in the crystal structure of **1** which can accommodate numerous small organic gas molecules. The high response of the cobalt inclusion compound to LPG, EP, gasoline, and alcohol at room temperature might be caused by its highly conjugated structure, which possesses a large number of hydrogen bonds, although the regular arrangement of the anionic fcds-containing parts may also enhance the selectivity of this compound. Compound **1** could be reused after heating the gas sensor for a short time, although it should be noted that the selectivity of **1** is slightly lower in the reversible absorption process. This mechanism of action of an inclusion complex contrasts with that of metal-substituted PCs as the latter always contain an unsaturated central metal ion, while the divalent iron ions in our synthesized complex also lie at the center of two negative univalent cyclopentadienyl ions. MPCs could, however, serve as reactive gas sensors. Metal oxide sensor materials also respond to small gas molecules, although most of them only work at high temperature.[17]

A combined TGA-DSC analysis was carried out to study the thermal behavior of inclusion complex **1**. The experiments were performed with samples containing numerous single crystals of each compound under $N_2$/air at a heating rate of 10 °C min$^{-1}$. Crystals of **1** undergo two major weight losses at around 140 and 320 °C (Figure 5). The first weight loss between 140 and 180 °C corresponds to the removal of four coordinated water molecules (calcd. 11.40%; found 11.28%). The remaining compound remained nearly intact until 320 °C, beyond which it decomposed. This thermal behavior study shows that this complex should remain intact after heating to release testing gases such as LPG, EP, gasoline and alcohol.

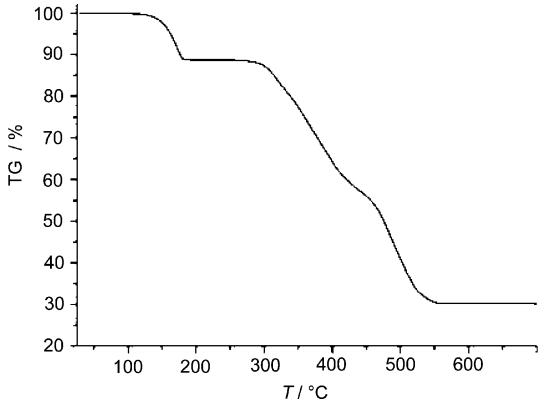

Figure 5. TGA curve of inclusion complex **1**.

Complex **2**, which contains the less conjugated ligand bpp instead of 4,4′-bpy, was synthesized under the same conditions as **1** to check that the gas-sensing properties of inclusion complexes originate from their conjugated π-electron clouds. This complex contains a different motif with double-stranded chains of loops, although it also contains the cationic component $[Co(bpp)_2(H_2O)_2]^{2+}$ and the anionic part contains fcds. As shown in Figure 6, each cobalt center is coordinated by four nitrogen atoms from four bridging bpp ligands and two oxygen atoms from two solvent water molecules. Two nitrogen atoms are nearly coplanar and two oxygen atoms occupy the axial positions. The Co–N bond lengths are 2.205, 2.205, 2.218, and 2.218 Å and all the Co–O bonds are equivalent (2.072 Å). This gives rise to a slightly distorted octahedron. The packing structure of **2** (Figure 7) shows that the double-stranded chain of loops is constructed from central $Co^{II}$ cations and bpp bridging ligands. Due to the long Co···Co distance (11.716 Å) and the distance between the middle carbon atoms of the two diametrically opposing $CH_2CH_2CH_2$ spacers (9.206 Å), the fcds guest molecules do not further bridge $Co^{II}$ cations. It should be noted that these structural factors, especially the introduction of the less conjugated ligand bpp, greatly reduce the conjugation of the whole structure, as was also confirmed by theoretical calculations. The frontier molecular orbitals of **2** (Figure 8) mainly arise from the contribution of the anionic part [HOMO(α): 99.98%; LUMO(α): 99.86%], while the aryl groups of the bpp pillars in **2** contribute very little to these orbitals [HOMO(α): 0.0024%; LUMO(α): 0.14%]. It is therefore clear that only part of **2** is highly conjugated, which means that **2** should show no gas-sensing properties. Indeed, **2** exhibits no response to gases since it shows high electronic resistivity in measurements performed under the same conditions as for **1**.

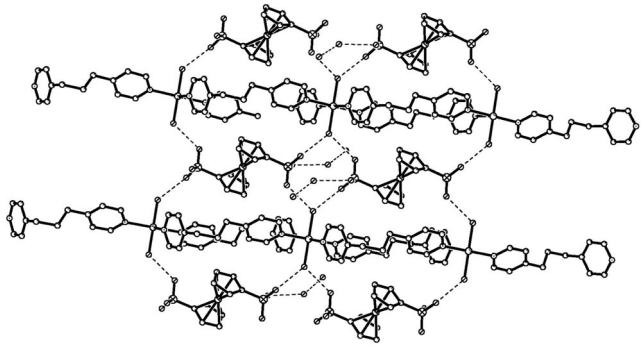

Figure 7. The 3D packing structure of **2**. Hydrogen atoms have been omitted for clarity.

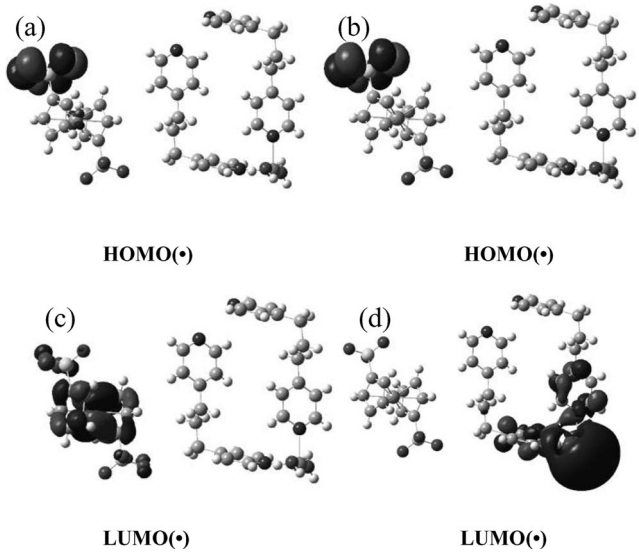

Figure 8. The frontier molecular orbitals of $[\{Co(bpp)_2(H_2O)_2\}\cdot(fcds)\cdot 4H_2O]_n$: a) HOMO(α); b) HOMO(β); c) LUMO(α); d) LUMO(β).

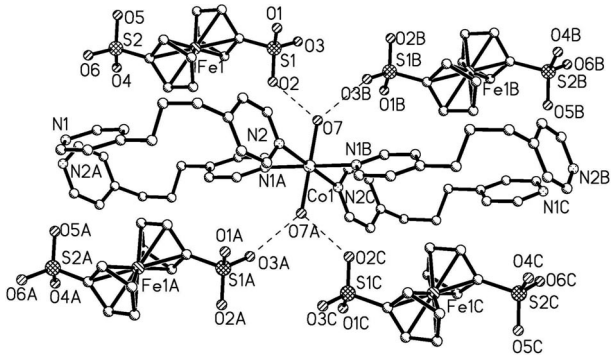

Figure 6. The molecular unit of $[\{Co(bpp)_2(H_2O)_2\}\cdot(fcds)\cdot 4H_2O]_n$ (**2**). Hydrogen atoms have been omitted for clarity.

It has been proven both experimentally and theoretically that highly conjugated molecules can be used as electron conductors.[18] The semiconducting properties of metal-organic inclusion complexes should, however, also depend on the appropriate selection of metal ions. This was further tested by the synthesis of **3**.

The molecular structure of **3** should be highly conjugated as it contains the $d^{10}$ $Zn^{2+}$ cation instead of $Co^{2+}$, highly conjugated 4,4′-bpy and fcds. This complex was synthesized under the same conditions as for **1**. The structure of **3** and its packing are shown in Figures 9 and 10, respectively. Compound **3** has essentially the same molecular structure

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

as **1** but with slightly different bond lengths and angles. The calculations also show that the aryl groups of the 4,4′-bpy pillars and the anionic parts in **3**, respectively, contribute to the frontier molecular orbitals (HOMO: 27.00 and 72.93%; LUMO: 72.66 and 27.16%). Similar to **1**, the whole crystal structure of **3** is highly conjugated. However, in contrast to **1**, **3** displays no gas-sensing properties because the experimental data show that it is an insulator. This means that a highly conjugated structure is not the governing factor in room-temperature metal-organic gas-sensor design. Obviously, the choice of central metal ion also affects the conductivity of metal-organic inclusion complexes. This was confirmed by considering the electronic structures of the central metal ions. The Co 3d orbitals in Co complexes are split due to the odd number of electrons. Cobalt is a typical divalent transition metal and Co complexes have the ability to function as electron-transfer intermediates by permitting a high electron-transfer probability.[19] However, divalent zinc complexes do not permit one-electron reduction due to their spin-coupled electronic structures and the tertiary ionization energy of zinc ions is significantly higher than that of cobalt ions, therefore **3** does not show gas-sensing properties due to its high electrical resistance.

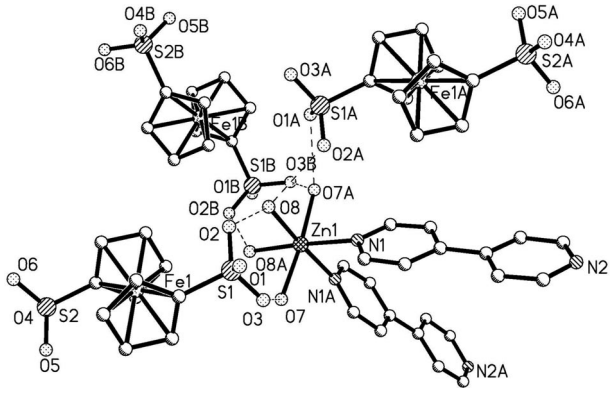

Figure 9. Coordination structure of $[\{Zn(bpy)(H_2O)_4\}\cdot(fcds)]_n$ (**3**). Hydrogen atoms have been omitted for clarity.

Complex **4**, which contains $d^8$ $Ni^{2+}$ instead of $Co^{2+}$ or $Zn^{2+}$, was prepared according to the synthetic method for **1** or **3**. Complexes **1**, **3**, and **4** show extremely similar IR spectra and complexes **1** and **3** have the same molecular structure, which led us to expect that complex **4** would also have the same structure. Elemental analyses and UV/Vis spectra for powdered samples of **1** and **4** were also recorded. The solid UV reflectance spectra of **1** and **4** are shown in Figure 11. It is clear that these compounds have similar solid-state UV spectra, therefore it is likely that **1** and **4** have the same structures expect for the central metal ions.

The gas-sensitivity test showed that the electric resistivity of **4** is 621 MΩ, lower than that of **3** but much higher than that of **1** (1.86 MΩ) as this nickel complex is likely to be low-spin.[20] A comparison of **1** with **3** and **4** showed that besides the highly conjugated systems, the central metal atoms are of significant importance for obtaining a perfect inclusion complex based gas sensor. This was further validated by the gas-sensitivity test of complex $[\{Co(bpy)(H_2O)_4\}SO_4\cdot(4\text{-abaH})_2\cdot 3H_2O]_n$ (**5**). Similar to the structure of **1**, the molecular structure of **5** is also made up of two parts, namely the cation $[Co(bpy)(H_2O)_4]^{2+}$, which forms an infinite chain with neutral 4-abaH, and the $SO_4^{2-}$ anion and lattice water. The electrical resistivity of **5** is 137 MΩ, which is lower than that of **4**, because the central metal atom in **5** is $d^7$ cobalt. Clearly, inclusion complexes with an odd number of electrons are more suitable for use as gas sensors. The electrical resistivity of **5** is higher than that of **1**, and **5** shows only a small response to $H_2S$ and liquefied petroleum gas as its anionic moiety is different to that in **1**.

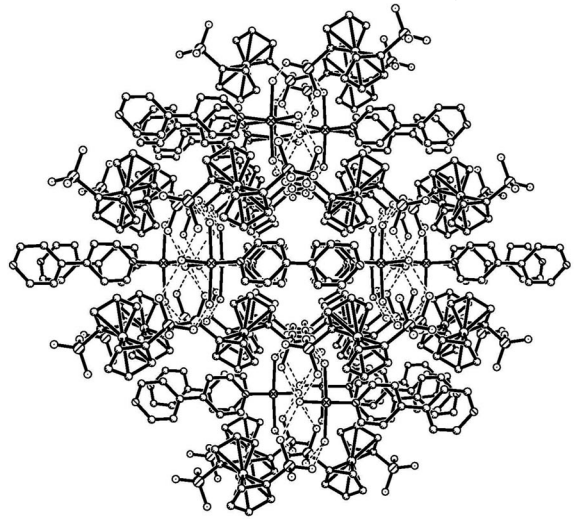

Figure 10. Crystal packing structure of **3**. Hydrogen atoms have been omitted for clarity.

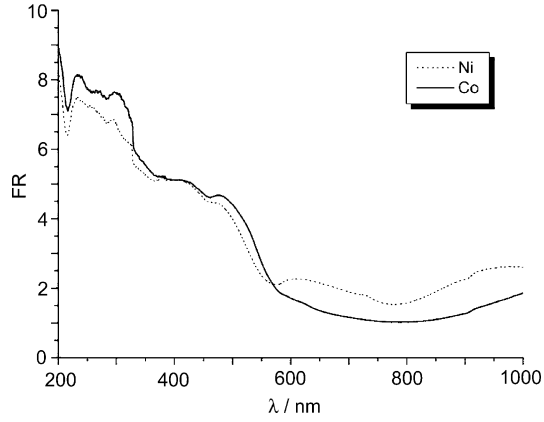

Figure 11.The solid UV reflectance spectra of **1** and **4**.

## Conclusions

The semiconducting cobalt inclusion compound **1** shows a high response to LPG, EG, and gasoline. Inclusion compounds **2** and **3** can not, however, be used as gas sensor because they are insulators. Complexes **4** and **5** have also been synthesized. A comparison of these five complexes has shown that both highly conjugated systems and the appro-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

priate central metal ions are important factors in the design of room-temperature gas sensors containing metal-organic inclusion complexes. This study may be useful in the search for new gas-sensitive materials.

## Experimental Section

**1:** This complex was prepared by treating $CoCl_2 \cdot 6H_2O$ (0.0238 g, 0.1 mmol) with one equivalent of $Na_2fcds$ (0.0390 g, 0.1 mmol) and two equivalents of 4,4′-bipy (0.0312 g, 0.2 mmol) in a mixture of methanol (4 mL) and water (2 mL). The desired complex crystallized at room temperature as a red crystalline solid upon slow evaporation of the solvents. Yield 0.056 g (89%). $C_{20}H_{24}CoFeN_2O_{10}S_2$: calcd. C 38.05, H 3.83, N 4.44, S 10.16; found C 38.21, H 3.88, N 4.38, S 10.13. IR (KBr): $\tilde{\nu}$ = 3300 (s), 1612 (s), 1532 (s), 1418 (m), 1200 (s), 1042 (s), 1013 (m), 823 (m), 731 (m), 637 (s), 481 (s) $cm^{-1}$.

**2:** A methanol solution (3 mL) of $Na_2fcds$ (0.0390 g, 0.1 mmol) was added to a methanol solution (2 mL) of $CoCl_2 \cdot 6H_2O$ (0.0238 g, 0.1 mmol). After stirring for a while, the mixture was added to an ethanol solution of bpp (0.0396 g, 0.2 mmol) then allowed to stand in air at room temperature for a week. This procedure gave red crystals suitable for X-ray diffraction. Yield 0.037 g (41%). $C_{36}H_{48}CoFeN_4O_{12}S_2$ (907.70): calcd. C 47.64, H 5.33, N 6.17, S 7.07; found C 47.61, H 5.38, N 6.28, S 6.93. IR (KBr): $\tilde{\nu}$ = 3439 (s), 3243 (s), 2947 (m), 1615 (s), 1426 (s), 1182 (s), 1041 (s), 839 (m), 642 (s), 493 (s) $cm^{-1}$.

**3:** Complex **3** was prepared in a similar manner to **1** but with $ZnCl_2$ instead of $CoCl_2 \cdot 6H_2O$. Yield 0.052 g (81%). $C_{20}H_{24}FeN_2O_{10}S_2Zn$ (637.76): calcd. C 38.05, H 3.83, N 4.44, S 10.06; found C 37.96, H 3.86, N 4.49, S 10.09. IR (KBr): $\tilde{\nu}$ = 3453 (s), 1612 (s), 1418 (m), 1120 (s), 1067 (s), 810 (m), 659 (s), 499 (s) $cm^{-1}$.

**4:** Complex **4** was also prepared in a similar manner to **1** but with $NiCl_2 \cdot 6H_2O$ instead of $CoCl_2 \cdot 6H_2O$. Yield 0.052 g (83%). $C_{20}H_{24}FeN_2NiO_{10}S_2$ (631.09): calcd. C 38.06, H 3.83, N 4.44, S 10.16; found C 38.18, H 3.91, N 4.51, S 9.98. IR (KBr): $\tilde{\nu}$ = 3339 (s), 1612 (s), 1418 (m), 1199 (s), 1041 (s), 823 (m), 639 (s), 481 (s) $cm^{-1}$.

**Crystallographic Studies:** Diffraction intensity data for the single crystal of **1** were collected at room temperature with a Bruker Smart CCD diffractometer equipped with graphite-monochromated Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 Å). The structures were solved by direct methods and refined by full-matrix least-squares techniques on $F^2$ with anisotropic thermal parameters for all non-hydrogen atoms.[21] Hydrogen atoms were located geometrically and refined isotropically.

**Gas-Sensitivity Test:** Gas sensors were made from as-prepared single crystals of inclusion complexes **1**–**5**. The single crystals were moistured with ethanol and ground in an agate mortar to form a powdery paste. This paste was coated on an alumina tube on which a pair of Au electrodes had previously been printed and dried at room temperature in air. The gas sensitivity was measured in the static state. The tested gases ($C_2H_5OH$, HCHO, $NH_3$, and LPG, 90# gasoline, CO, $O_2$ and $N_2$) were injected into a test bottle and mixed with air. The measuring electrical circuit for the gas sensors is shown in the electronic supporting information. The resistivity of the sensor in air or a test gas can be measured by monitoring $V_{out}$. The gas sensitivity (response magnitude) in this paper was defined as $S = R_a/R_g$, where $R_a$ and $R_g$ are the resistivity of a sensor in air and in the test gas, respectively.

**Supporting Information** (see also the footnote on the first page of this article): Crystallographic data for **1**–**3**. Figure S1 shows the selectivity of **1** to different gases at room temperature, Figure S2 displays the selectivity of **1** to CO and $NH_3$ at room temperature. Figure S3 displays the frontier molecular orbital of $\{[Zn(bpy)(H_2O)_4](fcds)\}_n$, Figure S4 the IR spectra of **1**, **3** and **4**.

# Substitution, Addition, and Recombination Reactions of Precursor Complexes with Ferrocenyl Carboxylate Units

Xia Wang,[a] Linke Li,[a] Hongwei Hou,*[a] Jie Wu,[a] and Yaoting Fan[a]

**Keywords:** Crystal engineering / Bridging ligands / Substituent effects / Precursors

With the use of sodium β-ferrocenylacrylate and sodium *p*-ferrocenylbenzoate as functional ligands, we synthesized mononuclear precursor complexes containing facile leaving groups or coordinatively unsaturated metal ions: $[Cd(\eta^2\text{-}OOCCH{=}CHFc)_2(C_2H_5OH)_2]$ (**1**), $\{[Cd(\eta^2\text{-}OOCC_6H_4Fc)_2(dmf)_2(H_2O)]\}$ (**2**), $\{[Cd(\eta^2\text{-}OOCC_6H_4Fc)_2(phen)(H_2O)](CH_3OH)\}$ (**3**), and $\{[Zn(OOCC_6H_4Fc)_2(phen)](H_2O)\}$ (**4**) (phen = 1,10-phenanthroline). Investigation of the four precursor ferrocenyl carboxylate complexes as building blocks resulted in ten complexes. The complexes $\{[Cd(\eta^2\text{-}OOCCH{=}CHFc)_2(bbbm)](H_2O)\}_n$ (**1a**), $\{[Cd_2(\eta^2\text{-}OOCCH{=}CHFc)_4(pbbm)_2](CH_3OH)_6(H_2O)_4\}$ (**1b**), $\{[Cd(\eta^2\text{-}OOCC_6H_4Fc)_2(py)_3](CH_3OH)_4\}$ (**2a**), $\{[Cd_2(\eta^2\text{-}OOCC_6H_4Fc)_4(btx)_2](thf)_3(CH_3OH)_2\}$ (**2b**), $\{[Cd_2(\eta^2\text{-}OOCC_6H_4Fc)_2(OOCC_6H_4Fc)_2(phen)_2(bbbm)](CH_3OH)_4(thf)_2\}$ (**3a**), and $[Zn(OOCC_6H_4Fc)_2(phen)(H_2O)]$ (**4a**) were obtained by the substitution or addition reactions of the precursor complexes under moderate conditions. As anticipated, the structural integrity of the precursor complexes can be maintained from the precursors to these complexes. We designed the structures of the complexes by controlling the number of leaving groups in the precursor complexes. In addition, a recombination may have taken place in the reactions of the precursor complexes with organic ligands under severe conditions. The "recombinant" complexes $\{[Cd_2(\eta^2\text{-}OOCCH{=}CHFc)_2(\mu_2\text{-}\eta^2\text{-}OOCCH{=}CHFc)_2(L)_2](CH_3OH)_4\}_n$ [L = 1,4-bis(imidazol-1-ylmethyl)benzene (bix), **1c**; L = btx, **1d**], $\{[Cd(\eta^2\text{-}OOCC_6H_4Fc)_2(pbbm)(H_2O)](H_2O)\}_n$ (**3b**) and $\{[Zn(OOCC_6H_4Fc)_2(bbbm)](CH_3OH)_3\}_n$ (**4b**) were also obtained under reflux conditions.

## Introduction

The rational design and synthesis of novel metal–organic frameworks (MOFs) have been of great research interest, not only because of their versatile intriguing architectures and topologies, but also because of their potential applications in smart optoelectronic, magnetic, microporous, and biomimetic materials.[1–13] Considerable progress has been made on the theoretical forecast and practical approaches aimed at controlling the topology structure and geometry of the network. Some structures of MOFs can, to a certain extent, be predicted by exploiting organic ligands as building blocks and elaborately by choosing metal salts to control the coordination geometry.[14–19] However, in many cases it is quite difficult to synthesize a desired MOF in a truly deliberate manner[20–22] owing to the influence of many factors, such as the coordination geometry of the central metal ion and the structural characteristics of the ligand,[23–24] solvent, and temperature.[25–27]

An approach that utilizes precursor complexes as building blocks was presented in recent years.[28–43] Precursor complexes possess specific rigid geometries and potentially extend to a multi-dimensional framework, so this kind of building block is helpful to direct the construction of a given structure.[44–51] Rather than relying on the self-assembly of fundamental building units, an alternative synthetic strategy for the construction of MOFs is to assemble precursor complexes as building blocks into predetermined structures by decoration and expansion of the basic net topologies.[52] We believe that these complexes possess the same framework of precursor complexes. Accordingly, the complexes should be easily constructed with the goal of obtaining predictable structure types from precursor complexes without framework distortion. In addition, sometimes framework distortion will occur from precursor complexes to produced complexes when the reaction conditions are relatively severe.

Nevertheless, the study of the synthesis of complexes by using precursor complexes as building units is still a challenge to chemists. With this background and as an extension of studies on the crystal engineering of coordination polymers, our group recently started a program that aims to explore the production of complexes by using the reactions of precursor complexes containing facile leaving groups or coordinatively unsaturated metal ions. Obviously, if the facile leaving groups could be replaced by appropriate ligands, complexes with the destination topology structures should be obtained by controlling the number of leaving groups in the precursor complexes under moderate reaction conditions. At the same time, complexes could also be syn-

thesized by the addition reaction of coordinatively unsaturated metal ions in the precursor complexes. If there were only one facile leaving group in the precursor complex, a dimer could be obtained by replacing the leaving group with a bidentate bridging ligand. If there were two leaving groups that could easily be removed in the precursor complex, the conformation of a one-dimensional polymer or a dimer could be gained by a substitution reaction with bidentate-bridging ligands. By substituting these leaving groups with monodentate ligands, we could design complexes whose structures were similar to those of the precursor complexes.[53,54] However, under severe reaction conditions, the strengths of coordination bonds become weak, and then "recombinant" complexes may be obtained. This results in the occurrence of framework distortion from precursor complexes to produced complexes. In the present work, we synthesized four mononuclear precursor complexes, from which six complexes without framework distortion were gained under moderate reaction conditions, and four complexes with framework distortion were obtained under severe conditions. Therefore, our findings demonstrate that the number of facile leaving groups in precursor complexes can control the topology structures of the desired complexes under moderate reaction conditions. Additionally, under severe conditions, the reactions of precursor complexes with ligands can lead to the formation of "recombinant" complexes.

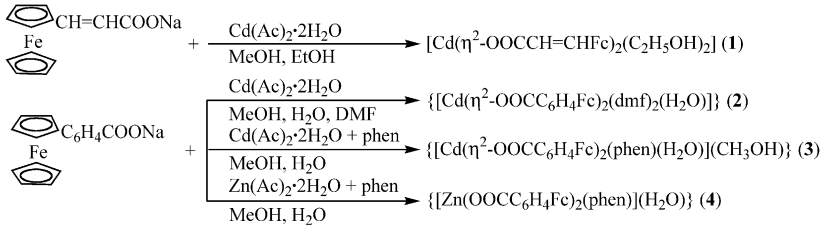
## Results and Discussion

### The Syntheses of Precursor Complexes [Cd(η²-OOCCH=CHFc)$_2$(C$_2$H$_5$OH)$_2$] (1), {[Cd(η²-OOCC$_6$H$_4$Fc)$_2$-(dmf)$_2$(H$_2$O)]} (2), {[Cd(η²-OOCC$_6$H$_4$Fc)$_2$(phen)(H$_2$O)]-(CH$_3$OH)} (3), and {[Zn(OOCC$_6$H$_4$Fc)$_2$(phen)](H$_2$O)} (4)

As is well known, the coordinating capability of ferrocenyl carboxylate groups to metal ions is strong, and the coordination modes are also versatile, such as terminal monodentate, bidentate, and O,O′-bridging coordination modes. It makes the self-assembly of crystal engineering easily available.[55–59] Therefore, we selected sodium β-ferrocenylacrylate and sodium *p*-ferrocenylbenzoate as functional ligands to synthesize the precursor complexes. It is reported that the reaction of the two ferrocenyl carboxylate compounds with some metal salts usually produced coordination polymers.[60] As far as coordination polymers are concerned, they do not dissolve easily in common solvents, and sometimes they contain relatively few facile leaving groups or coordinatively unsaturated metal ions. Hence, coordination polymers are not the best precursor complexes. Mononuclear complexes are dissolved easily, and these complexes may contain facile leaving groups or coordinatively unsaturated metal ions, which allows complexes to be designed by substitution or addition reactions. Moreover, we believe that some coordinated solvent molecules can serve as facile leaving groups in complexes. Some N-donor chelating ligands and solvent molecules were added to the reactions of ferrocenyl carboxylate compounds with metal salts to obtain our desired precursor complexes. Accordingly, mononuclear precursor complexes **1**–**4** were obtained by treatment of FcCH=CHCOONa or FcC$_6$H$_4$COONa with the appropriate metal salts and subsidiary ligands in different solvents (Scheme 1). By using these precursor complexes as building blocks, the corresponding complexes were designed and synthesized.

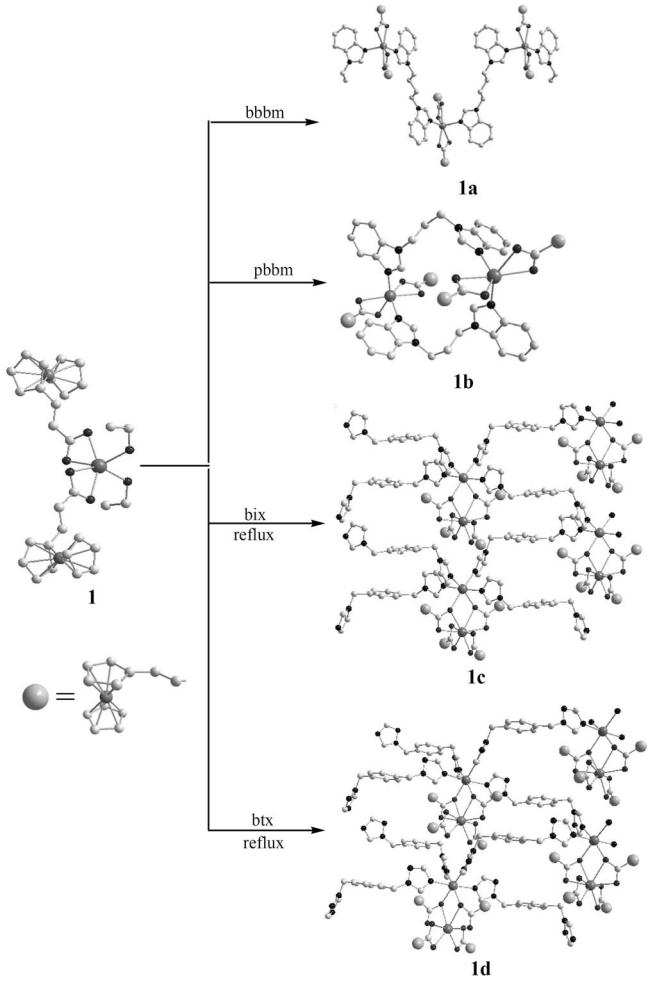
### The Syntheses and Crystal Structures of {[Cd(η²-OOCCH=CHFc)$_2$(bbbm)](H$_2$O)}$_n$ (1a), {[Cd$_2$(η²-OOCCH=CHFc)$_4$(pbbm)$_2$](CH$_3$OH)$_6$(H$_2$O)$_4$} (1b), {[Cd$_2$(μ$_2$-η²-OOCCH=CHFc)$_2$(η²-OOCCH=CHFc)$_2$-(bix)$_2$](CH$_3$OH)$_4$}$_n$ (1c), and {[Cd$_2$(μ$_2$-η²-OOCCH=CHFc)$_2$-(η²-OOCCH=CHFc)$_2$(btx)$_2$] (CH$_3$OH)$_4$}$_n$ (1d)

X-ray diffraction analysis reveals that, in precursor complex **1**, the Cd$^{II}$ ion is six-coordinate with two oxygen atoms from two ethanol molecules and four oxygen atoms from two FcCH=CHCOO$^-$ units. The two ethanol molecules are facile leaving groups. So a one-dimensional polymer or a dimer can be designed by a substitution reaction of **1** with a bidentate bridging ligand under moderate reaction conditions. As anticipated, one-dimensional polymer **1a** was obtained through the reaction of **1** with bbbm [1,1-(1,4-butanediyl)bis-1*H*-benzimidazole] at room temperature. Under the same conditions, dimer **1b** was also obtained by using pbbm [1,1-(1,3-propylene)bis-1*H*-benzimidazole] instead of bbbm (Scheme 2). However, it is reported that two-dimensional ferrocenecarboxylate-containing polymer {[Cd(η²-OOCCH=CHFc)(bbbm)$_{1.5}$Cl]·1.5H$_2$O}$_n$ was obtained from the one-pot reaction of FcCH=CHCOONa, CdCl$_2$·2.5H$_2$O, and bidentate bridging ligand bbbm.[61]



Scheme 1. The syntheses of precursor complexes **1**–**4**.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 



Scheme 2. The synthesis and conversion of precursor complex **1** into complexes **1a**, **1b**, **1c**, and **1d**.

Although the structures of bridging ligands bbbm and pbbm are similar, the structures of **1a** and **1b** have a distinct difference. Two benzimidazole units are connected by $–CH_2–CH_2–CH_2–CH_2–$ and $–CH_2–CH_2–CH_2–$ in ligands bbbm and pbbm, respectively. The torsion angle of C43–C44–C44A–C43A is 180.0° in **1a**, and the angle of C34–C35–C36 is 112.1° in **1b**. So, by using bbbm as a bridging ligand, one-dimensional polymers are easily formed, but dimers are easily obtained by using pbbm as a replacement to bbbm.

Polymer **1a** exhibits one-dimensional zigzag chains (as shown in Figure 1a), each $Cd^{II}$ ion is six-coordinate in a distorted octahedral environment with four oxygen atoms from two terminal chelating $\eta^2$-OOCCH=CHFc$^-$ units and two nitrogen donors from two bridging bbbm ligands. The bbbm ligands connect the $Cd^{II}$ ions by replacing the ethanol molecules, which leads to an infinite one-dimensional chain. In **1b**, two $Cd^{II}$ ions are bridged by two bridging pbbm ligands to form a dimer (Figure 1b). Each $Cd^{II}$ ion is also six-coordinate, and the coordination environment around the $Cd^{II}$ ion is similar to that of **1a**. In addition, the Cd···Cd distance in **1b** (9.603 Å) is distinctly shorter than that of **1a** (14.463 Å).

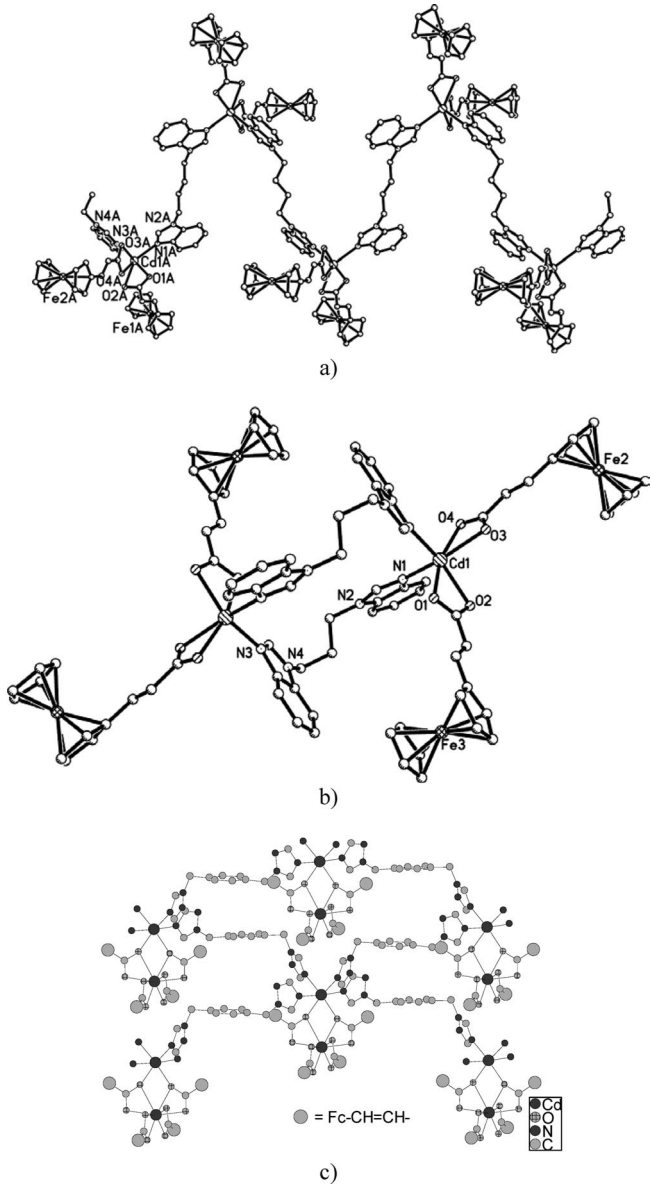


Figure 1. (a) The structure of $\{[Cd_2(\eta^2\text{-OOCCH=CHFc})_4(pbbm)_2](CH_3OH)_6(H_2O)_4\}$ (**1a**) with heteroatom numbering; (b) the structure of $\{[Cd_2(\eta^2\text{-OOCCH=CHFc})_4(pbbm)_2](CH_3OH)_6(H_2O)_4\}$ (**1b**) with heteroatom numbering; (c) two-dimensional network structure of $\{[Cd_2(\mu_2\text{-}\eta^2\text{-OOCCH=CHFc})_2(\eta^2\text{-OOCCH=CHFc})_2(btx)_2](CH_3OH)_4\}_n$ (**1d**) (hydrogen atoms and solvent molecules are omitted for clarity).

Coordination bonds in our precursor complexes are relatively stable except for those formed by the solvent molecules with metal ions under moderate reaction conditions. So the structural integrity of the precursor complexes can be maintained when the precursor complexes react with the ligands, and complexes with destination structures could be designed by using the framework of the precursor complexes, such as the formation of **1a** and **1b**. Nevertheless, the strengths of the coordination bonds become weak under severe reaction conditions (such as reflux). Some coordination bonds were easily broken. Hence, framework distortion will occur from precursor complexes to produced com-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

plexes. As a result, "recombinant" complexes may take place under the influence of the ligands.

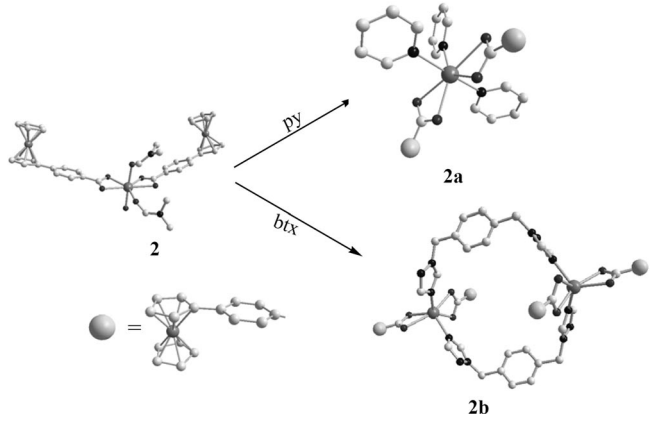
What will happen when precursor complex **1** is treated with bidentate bridging ligands under severe conditions? Herein, two-dimensional network polymers **1c** and **1d** were produced by the reaction of **1** with the organic bix [1,4-bis(imidazol-1-ylmethyl)benzene] or btx [1,4-bis(triazol-1-ylmethyl)benzene] ligands under reflux conditions (Scheme 2). Complexes **1c** and **1d** are produced from framework distortion of precursor complex **1**. From the structures of **1c** and **1d**, it is concluded that the phenomenon of recombination took place in the reaction of **1** with bridging ligands under severe reaction conditions.

Single-crystal X-ray analysis revealed that **1c** and **1d** are isostructural (Figure 1c), and the structures of **1c** and **1d** are distinctly different from those of **1a** and **1b**. It is interesting that the FcCH=CHCOO$^-$ units in **1c** or **1d** display two kinds of coordination modes: one coordinates with one $Cd^{II}$ ion as a chelating bidentate ligand, whereas the other bridges two adjacent $Cd^{II}$ ions as a bridging bidentate ligand. $Cd^{II}$ ions have two kinds of coordination environments in **1c** or **1d**. The coordination sphere of Cd1 is eight-coordinate and binds to four oxygen atoms from two $\eta^2$-OOCCH=CHFc units and four oxygen atoms from two $\mu_2$-$\eta^2$-OOCCH=CHFc units. However, Cd2 is six-coordinate and binds two oxygen atoms from different $\mu_2$-$\eta^2$-OOCCH=CHFc units and four nitrogen atoms from four btx or bix molecules. The neighboring two $Cd^{II}$ ions are connected by $\mu_2$-$\eta^2$-OOCCH=CHFc groups to form a binuclear unit, and all of the binuclear units are joined together by the bix or btx ligands, which leads to an infinite two-dimensional network. The Cd···Cd distances in the binuclear units of **1c** and **1d** are 3.964 and 3.983 Å, respectively, which are longer than those in reported dimeric cadmium–tetracarboxylate complexes (3.278–3.452 Å).[62–64] The Cd–N distances [from 2.290(2) to 2.352(4) Å] associated with the bridging btx and bix ligands are comparable to those found in the literature.[65–68]

### The Syntheses and Crystal Structures of {[Cd($\eta^2$-$OOCC_6H_4Fc)_2(py)_3$]($CH_3OH)_4$} (2a) and {[$Cd_2$($\eta^2$-$OOCC_6H_4Fc)_4(btx)_2$][$thf)_3(CH_3OH)_2$} (2b)

Treatment of $FcC_6H_4COONa$ with $Cd(OAc)_2{\cdot}2H_2O$ in DMF/$H_2O$ yielded precursor complex **2**. The $Cd^{II}$ ion is seven-coordinate with four oxygen atoms from two chelating $FcC_6H_4COO^-$ units, one oxygen atom from one $H_2O$ molecule, and two oxygen atoms from two DMF molecules. The $H_2O$ and DMF molecules are three leaving groups that can easily be displaced. Interestingly, the structure of complex **2** resembles a butterfly and the two coordinated $FcC_6H_4COO^-$ units are the wings. Accordingly, we thought that the syntheses of mononuclear complexes should be completed by substitution reactions of **2** with monodentate ligands. In fact, mononuclear complex **2a** with the framework of **2** was obtained through the addition of pyridine into **2** at room temperature.

It is well known that six or seven-coordinate $Cd^{II}$ is common in ferrocenyl carboxylate complexes. The $Cd^{II}$ is seven-coordinate in precursor complex **2**. So, six- or seven-coordinate $Cd^{II}$ complexes may be obtained by a substitution reaction of **2**. If the coordination number of $Cd^{II}$ in complexes is seven, the structures may form a two-dimensional network by a substitution reaction of **2** with bidentate bridging ligands under moderate reaction conditions. If the $Cd^{II}$ is six-coordinate in the obtained complexes, the structures may be binuclear or form a one-dimensional chain under the same conditions. As a matter of fact, complex **2b** was obtained by a substitution reaction of **2** with the bidentate bridging btx ligand at room temperature (Scheme 3). Because of the spatial configuration and the steric effect of btx, it is difficult to obtain a two-dimensional polymer through the reaction of **2** with btx. Relatively, a dimer or a one-dimensional polymer may be synthesized easily. Just as we thought, **2b** is a dimer, and the coordination number of the $Cd^{II}$ ion is six.



Scheme 3. The synthesis and conversion of precursor complex **2** into complexes **2a** and **2b**.

Mononuclear complex **2a** is depicted in Figure 2a, from which we can see that the $Cd^{II}$ ion is seven-coordinate, and the coordination mode of the central $Cd^{II}$ of **2a** is consistent with that of **2**. The equatorial positions are occupied by O1, O2, O1A, O2A, and N2 (the mean deviation is 0.0811 Å), and the coordination environment around the $Cd^{II}$ ion is a distorted penta bipyramid.

X-ray diffraction analysis revealed that, in **2b**, two $Cd^{II}$ ions are bridged by two bridging btx ligands to form a dimer (Figure 2b). Each $Cd^{II}$ ion coordinates with four oxygen atoms from two chelating $FcC_6H_4COO^-$ units and two nitrogen donors from two btx molecules. The Cd–O bond lengths are in the range of 2.253(5)–2.506(5) Å. In accordance with **2a**, one Cd1–$O_{carboxyl}$ distance in the bidentate mode is longer than those of **2** [from 2.360(5) to 2.454(5) Å], whereas the other distance is shorter than that of **2**. Nevertheless, treatment of $FcC_6H_4COONa$ and $Cd(OAc)_2{\cdot}2H_2O$ with bridging ligand bbp (bbp = 4,4′-trimethylene-dipyridine) generated an infinite one-dimensional ladder-like polymer {[Cd($\mu_2$-$OOCH_4C_6Fc$)($\eta^2$-

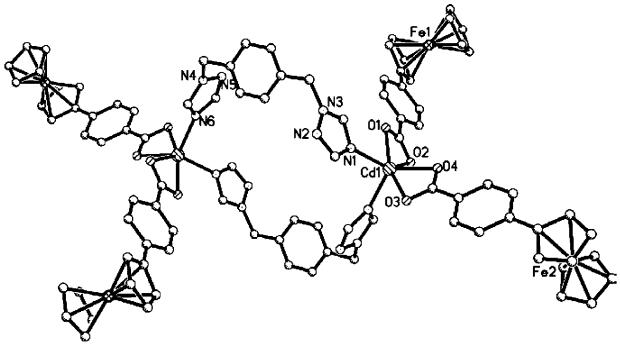
a)



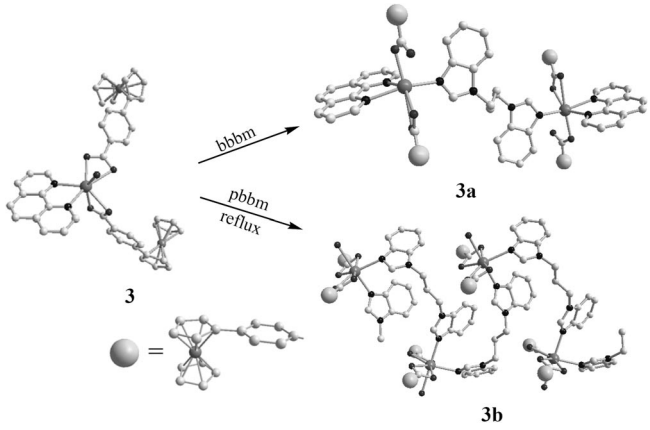
b)

Figure 2. (a) The structure of $\{[Cd(\eta^2\text{-}OOCC_6H_4Fc)_2(py)_3]\text{-}(CH_3OH)_4\}$ (**2a**) with heteroatom numbering; (b) the structure of $\{[Cd_2(\eta^2\text{-}OOCC_6H_4Fc)_4(btx)_2](thf)_3(CH_3OH)_2\}$ (**2b**) with heteroatom numbering (hydrogen atoms and solvent molecules are omitted for clarity).

$OOCH_4C_6Fc)(bbp)](CH_3OH)\}_n$ in which the neighboring $Cd^{II}$ ions are linked by the coaction of the $FcC_6H_4COO^-$ ions and the bbp ligand.[60]

### The Syntheses and Crystal Structures of $\{[Cd_2(\eta^2\text{-}OOCC_6H_4Fc)_2(OOCC_6H_4Fc)_2(phen)_2(bbbm)](CH_3OH)_4\text{-}(thf)_2\}$ (3a) and $\{[Cd(\eta^2\text{-}OOCC_6H_4Fc)_2(pbbm)(H_2O)]\text{-}(H_2O)\}_n$ (3b)

Precursor complex **3** was obtained successfully by using $FcC_6H_4COONa$ as a functional ligand and by introducing the chelate phen ligand and solvent molecule $H_2O$. There is one facile leaving group ($H_2O$ molecule) in **3**. In view of the structural features of **3**, we expected that a dimer could be obtained by using **3** as a building block and by replacing the water molecule with a bidentate bridging ligand under moderate reaction conditions. As anticipated, the reaction of **3** with bbbm resulted in dimer **3a** at room temperature. Because of the framework distortion of **3** that occurs under severe reaction conditions, one-dimensional polymer **3b** was synthesized by a recombination reaction of **3** with pbbm ligands under reflux conditions (Scheme 4).



Scheme 4. The synthesis and conversion of precursor complex **3** into complexes **3a** and **3b**.

The structure of **3a** is shown in Figure 3a, and it features a six-coordinate $Cd^{II}$ ion in a distorted octahedral geometry defined by three oxygen atoms from two coordinated $FcC_6H_4COO^-$ units, two nitrogen donors from one chelating phen, and one nitrogen donor from a bridging bbbm ligand. A bbbm ligand links two $Cd^{II}$ ions to form a dimer.

By comparison with **3**, the $[Cd(\eta^2\text{-}OOCC_6H_4Fc)_2(H_2O)]$ units are bridged by pbbm to form one-dimensional quadrate-wave-like chain polymer **3b** under reflux conditions (Figure 3b). The intrachain Cd···Cd distance (9.841 Å) of **3b** is considerably shorter than that of **3a** (13.640 Å). The $Cd1\text{–}N_{phen}$ distances in dimer **3a** [2.387(7), 2.395(7) Å] are consistent with those in **3** [2.366(7), 2.390(8) Å]. Therefore, the substitution reaction of the bbbm replacing $H_2O$ in **3** has little influence on the phen group. Because of the spatial configuration and the steric effect of the ferrocene group and the pbbm ligand, the length of the $Cd1\text{–}O_{water}$ bond in polymer **3b** [2.512(8) Å] is longer than that in precursor complex **3** [2.347(7) Å].

### The Syntheses and Crystal Structures of $[Zn(OOCC_6H_4Fc)_2\text{-}(phen)(H_2O)]$ (4a) and $\{[Zn(OOCC_6H_4Fc)_2(bbbm)]\text{-}(CH_3OH)_3\}_n$ (4b)

The structure of precursor complex **4** is shown in Scheme 5. Among three $Zn\cdots O_{\eta^2\text{-}OOCC_6H_4Fc}$ distances, two of them [Zn–O1 = 1.992(4) and Zn–O4 = 1.975(4) Å] compare well with the distances found in the reported zinc carboxylate complexes[69] and another [Zn···O2 = 2.448(4) Å] is longer than the common $Zn\text{–}O_{carboxyl}$ bond length; in other words, the O2 atom coordinates to the $Zn^{II}$ ion weakly. We think the Zn···O2 bond is an uncoordinated bond.

The $Zn^{II}$ ion is usually four, five, or six-coordinate in complexes.[70] In precursor complex **4**, the $Zn^{II}$ ion is four-coordinate, thus we can obtain complexes by the addition reaction of **4** with some ligands. As a result, the addition reaction of **4** with $H_2O$ yielded complex **4a** at room temperature. Further, as the emergence of **3b**, one-dimensional

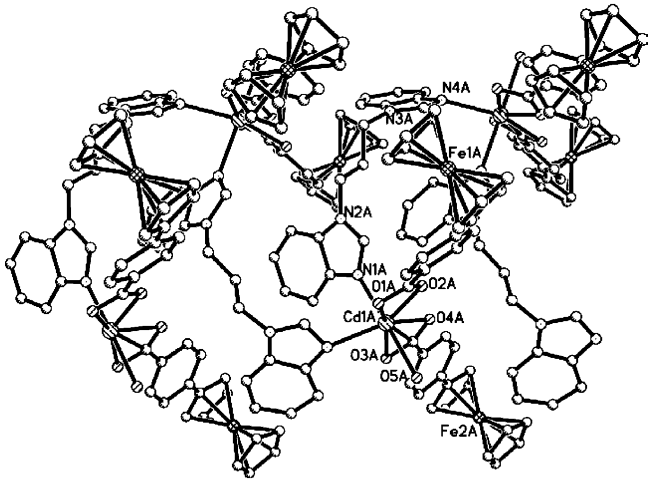
a)



b)

Figure 3. (a) The structure of $\{[Cd_2(\eta^2\text{-}OOCC_6H_4Fc)_2(OOCC_6H_4Fc)_2(phen)_2(bbbm)](CH_3OH)_4(thf)_2\}$ (**3a**); (b) perspective view of the one-dimensional chain structure of $\{[Cd(\eta^2\text{-}OOCC_6H_4Fc)_2(pbbm)(H_2O)](H_2O)\}_n$ (**3b**) (hydrogen atoms and solvent molecules are omitted for clarity).

polymer **4b** was also synthesized by the reaction of **4** with bbbm under reflux conditions (Scheme 5).

The structure of mononuclear complex **4a** is shown in Figure 4a; the $Zn^{II}$ ion is five-coordinate in a distorted square pyramid geometry, and the O1, O5, N1, and N2 atoms are nearly located on the same plane (the mean deviation is 0.0221 Å). Because of the introduction of the $H_2O$ molecule, the distance of $Zn1\text{–}O5_{water}$ (2.088 Å) in **4a** is shorter than Zn···O2 [2.448(4) Å] in **4**. The length of $Zn\text{–}O_{carboxyl}$ in **4a** (1.953 and 2.009 Å) is in conformity with those in **4** (1.975 and 1.992 Å). Therefore, **4a** results from the addition reaction of **4** with $H_2O$. However, the recombi-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

nant reaction of **4** with bbbm yielded one-dimensional chain polymer **4b** (Figure 4b). Each $Zn^{II}$ ion is four-coordinate with two oxygen atoms from two monodentate coordinated $FcC_6H_4COO^-$ units and two nitrogen donors from two bbbm molecules. The torsion angle of C42–C43–C43A–C42A is 180.0°. The $Zn^{II}$ ions are connected by bbbm ligands, and the Zn···Zn distance is 12.310 Å in **4b**.

## Conclusions

The syntheses of precursor complexes **1**–**4** are necessary to obtain the desired complexes. The structural integrity of the precursor complexes can be maintained in substitution or addition reactions of the precursor complexes with ligands under moderate reaction conditions. Noteworthy is the idea that under moderate reaction conditions "the structures of the complexes are dominated by the number of facile leaving groups in the precursor complexes". Because the self-assembly of complexes lies on a delicate thermodynamic balance between enthalpy and entropy effects,[71] and the strengths of the coordination bonds become weak under severe reaction conditions, "recombinant" complexes could be obtained by the reaction of ligands and metal ions. The obtained complexes result from framework distortion of the precursor complexes. In addition, crystals of these complexes that originated from the precursor complexes could not be obtained from one-pot reactions of ferrocenyl carboxylate, metal salts, and organic ligands.

## Experimental Section

β-Ferrocenylacrylic and *p*-ferrocenylbenzoic acid and their corresponding sodium salts were prepared according to literature methods.[72,73] 1,1-(1,4-Butanediyl)bis-1*H*-benzimidazole (bbbm), 1,1-(1,3-propylene)bis-1*H*-benzimidazole (pbbm), 1,4-bis(triazol-1-ylmethyl)benzene (btx), and 1,4-bis(imidazol-1-ylmethyl)benzene (bix) were prepared according to literature methods.[74,63,75] All other staring materials were of reagent-grade quality and were obtained from commercial sources and used without further purification. Elemental analyses (C, H, and N) were carried out with a FLASH EA 1112 elemental analyzer. Infrared spectra data were recorded with a Bruker TENSOR 27 spectrophotometer with KBr pellets in the 400–4000 $cm^{-1}$ region.

**$[Cd(\eta^2\text{-}OOCCH{=}CHFc)_2(C_2H_5OH)_2]$ (1):** FcCH=CHCOONa (55.6 mg, 0.20 mmol) in methanol (8 mL) was added dropwise to a solution of $Cd(OAc)_2{\cdot}2H_2O$ (26.8 mg, 0.1 mmol) in methanol (5 mL) and ethanol (2 mL). The resulting red solution was allowed to stand at room temperature in the dark. Good quality red crystals were obtained several days later. Yield: 48.6 mg (68%). IR (KBr): $\tilde{\nu}$ = 3439 (s), 3126 (s), 2361 (m), 1634 (s), 1519 (s), 1402 (s), 1253 (m), 1102 (m), 1039 (m), 816 (m), 486 (m) $cm^{-1}$. $C_{30}H_{34}CdFe_2O_6$ (714.67): calcd. C 50.42, H 4.80; found C 50.32, H 4.86.

**$\{[Cd(\eta^2\text{-}OOCC_6H_4Fc)_2(dmf)_2(H_2O)]\}$ (2):** $FcC_6H_4COONa$ (65.6 mg, 0.2 mmol) in methanol (6 mL) was added to a solution of $Cd(OAc)_2{\cdot}2H_2O$ (26.8 mg, 0.1 mmol) in methanol (4 mL) and $H_2O$ (3 mL). A red precipitate formed immediately, and DMF (3 mL) was then added to the mixture to dissolve the precipitate. Several days later, good quality red crystals were obtained from the red solution at room temperature in the dark Yield: 53.2 mg (60%). IR (KBr): $\tilde{\nu}$ = 3422 (s), 2367 (m),1633 (s), 1539 (m), 1476 (m), 1400 (s), 1308 (m), 1108 (m), 1053 (m), 813 (m), 710 (m), 519 (m) $cm^{-1}$. $C_{40}H_{42}CdFe_2N_2O_7$ (886.86): calcd. C 54.04, H 4.89, N 3.20; found C 53.77, H 4.82, N 3.15.

**$\{[Cd(\eta^2\text{-}OOCC_6H_4Fc)_2(phen)(H_2O)](CH_3OH)\}$ (3):** A methanol (6 mL) solution of the subsidiary phen ligand (19.8 mg, 0.1 mmol) was added to an aqueous solution (2 mL) of $Cd(OAc)_2{\cdot}2H_2O$ (26.8 mg, 0.1 mmol). A methanol solution (8 mL) of $FcC_6H_4COONa$ (65.6 mg, 0.2 mmol) was then added to the above mixture. The resulting orange solution was allowed to stand at room temperature in the dark. After 1 week, good quality red crystals of **3** were obtained. Yield: 50.5 mg (53%). IR (KBr): $\tilde{\nu}$ = 3420 (m), 1584 (s), 1537 (s), 1395 (s), 1103 (m), 851 (m), 789 (m), 727 (m), 473 (m) $cm^{-1}$. $C_{47}H_{42}CdFe_2N_2O_6$ (952.91): calcd. C 58.01, H 4.05, N 2.68; found C 57.74, H 3.96, N 2.56.

**$\{[Zn(OOCC_6H_4Fc)_2(phen)](H_2O)\}$ (4)** The preparation was similar to that for **3**, except $Zn(OAc)_2{\cdot}2H_2O$ (21.9 mg, 0.1 mmol) was used instead of $Cd(OAc)_2{\cdot}2H_2O$. The resulting orange solution was allowed to stand at room temperature in the dark. After two weeks, good quality red crystals of **4** were obtained. Yield: 43.2 mg (50%). IR (KBr): $\tilde{\nu}$ = 3424 (m), 3080 (m), 1605 (s), 1547 (m), 1387 (s), 1179 (m), 1104 (m), 850 (m), 788 (m), 727 (m), 478 (m) $cm^{-1}$. $C_{46}H_{42}Fe_2N_2O_4Zn$ (863.89): calcd. C 63.94, H 4.92, N 3.20; found C 63.90, H 4.86, N 3.24.

**$\{[Cd(\eta^2\text{-}OOCCH{=}CHFc)_2(bbbm)](H_2O)\}_n$ (1a):** The crystals of complex **1** (17.9 mg, 0.025 mmol) were dissolved in THF (3 mL). A solution of bbbm (7.3 mg, 0.025 mmol) in methanol (6 mL) was added dropwise to the above solution. The resulting red solution was allowed to stand at room temperature in the dark. Good quality red crystals were obtained after several days. Yield: 14.4 mg (62%). IR (KBr): $\tilde{\nu}$ = 3421 (m), 3099 (m), 2932 (m), 1636 (s), 1541 (m), 1508 (m), 1463 (m), 1404 (s), 1291 (m), 1255 (m), 1200 (m), 1105 (m), 1043 (m), 975 (m), 748 (m), 496 (m) $cm^{-1}$. $C_{44}H_{42}CdFe_2N_4O_5$ (930.92): calcd. C 56.72, H 4.51, N 6.02; found C 56.04, H 4.51, N 5.88.

**$\{[Cd_2(\eta^2\text{-}OOCCH{=}CHFc)_4(pbbm)_2](CH_3OH)_6(H_2O)_4\}$ (1b):** The conversion of **1** to **1b** was similar to the procedures mentioned above, except pbbm (6.9 mg, 0.025 mmol) was used instead of bbbm. Three weeks later good quality red crystals were obtained from the red solution at room temperature in the dark. Yield: 17.5 mg (68%). IR (KBr): $\tilde{\nu}$ = 3423 (m), 3103 (m), 1636 (s), 1542 (m), 1510 (m), 1463 (m), 1404 (s), 1290 (m), 1254 (m), 1199 (m), 976 (m), 748 (m), 685 (m), 495 (m) $cm^{-1}$. $C_{92}H_{107}Cd_2Fe_4N_8O_{18}$ (2061.06): calcd. C 53.57, H 5.19, N 5.43; found C 53.02, H 5.08, N 5.50.

**$\{[Cd_2(\mu_2\text{-}\eta^2\text{-}OOCCH{=}CHFc)_2(\eta^2\text{-}OOCCH{=}CHFc)_2(bix)_2](CH_3OH)_4\}_n$ (1c):** A methanol solution (10 mL) of bix (6.8 mg, 0.025 mmol) was added to a THF (4 mL) solution of **1** (17.9 mg, 0.025 mmol) at room temperature. The reaction mixture was heated at refluxed for 10 min. The mixture was then allowed to set at room temperature in the dark for two weeks to afford the product as red crystals. Yield: 14.7 mg (65%). IR (KBr): $\tilde{\nu}$ = 3428 (m), 3120 (m), 1635 (s), 1545 (s), 1402 (s), 1250 (m), 1108 (m), 1027 (m), 936 (m), 824 (m), 657 (m), 496 (m) $cm^{-1}$. $C_{84}H_{88}Cd_2Fe_4N_8O_{12}$ (1809.76): calcd. C 54.49, H 4.76, N 6.05; found C 53.68, H 4.69, N 6.11.

**$\{[Cd_2(\mu_2\text{-}\eta^2\text{-}OOCCH{=}CHFc)_2(\eta^2\text{-}OOCCH{=}CHFc)_2(btx)_2](CH_3OH)_4\}_n$ (1d):** The synthesis was the same as that for **1c**, except with the use of btx (7.8 mg, 0.025 mmol) and **1** (17.9 mg, 0.025 mmol). Yield: 15.3 mg (66%). IR (KBr): $\tilde{\nu}$ = 3423 (m), 3114 (m), 1636 (s), 1547 (s), 1463 (m), 1403 (s), 1280 (m), 1255 (m), 1136

absorption by using empirical scan data. The structure was solved with the *SHELX* program, and refined by full-matrix least-squares methods based on $F^2$,[76] with anisotropic thermal parameters for the non-hydrogen atoms. The hydrogen atoms were located theoretically and not refined.

For **4**, **1a**, **1b**, **1c**, **1d**, **2a**, **3b**, **4a**, and **4b**, single-crystal X-ray diffraction was performed by using a Bruker SMART APEX CCD diffractometer equipped with graphite-monochromated Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 nm) at room temperature. The data were integrated by using the Siemens SAINT program.[77] Absorption corrections were applied. The structures were solved by direct methods and refined on $F^2$ by full-matrix least-squares with SHELXTL.[78] All non-hydrogen atoms were refined with anisotropic thermal parameters. Hydrogen atoms were located at geometrically calculated positions and refined with isotropic thermal parameters.

Selected bond lengths and bond angles are listed in Tables 1 and 2. Crystal data and experimental details for all complexes are contained in Tables 3, 4, and 5. CCDC-627164 to -627177 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

# Olefin Complexes of Low-Valent Rhenium

**Aldjia Choualeb,[a] Olivier Blacque,[a] Helmut W. Schmalle,[a] Thomas Fox,[a] Thomas Hiltebrand,[a] and Heinz Berke*[a]**

**Keywords:** Rhenium / Olefin complexes / Nitrosyl complexes / DFT calculation

Replacement of the MeCN group in the acetonitrile-*cis*-dibromo(nitrosyl)-*trans*-bis(phosphane)rhenium compounds **1a**,**b** (R = *i*Pr **a**, R = Cy **b**) with ethylene afforded the olefin derivatives [Re($\eta^2$-$H_2C{=}CH_2$)(NO)($PR_3$)$_2$Br$_2$] (**2a**,**b**) (R = *i*Pr **a**, R = Cy **b**). Compound **1a** could be converted into the dimethyl species [Re(MeCN)(NO)(P*i*Pr$_3$)$_2$Me$_2$] (**3a**) applying MeLi in toluene; the related methylation of **1b**, however, failed. Abstraction of a $Br^-$ ion from **1a**,**b** with [Na][BAr′$_4$] in acetontrile yields the air-stable salts [Re(MeCN)$_2$(NO)($PR_3$)$_2$Br]$^+$[BAr′$_4$]$^-$ (**4a**,**b**) (R = *i*Pr **a**, R = Cy **b**) and under 1 bar of $H_2$ complexes **1a**,**b** were converted into the known dihydrogen species [Re($\eta^2$-$H_2$)(NO)($PR_3$)$_2$(Br)$_2$] (**5a**,**b**) (R = *i*Pr **a**, R = Cy **b**). Reduction of [Re(MeCN)(NO)($PR_3$)$_2$Br$_2$] (**1a**,**b**) with Na/Hg under 1 bar of $C_2H_4$ afforded the butadiene complex [Re($\eta^4$-$C_4H_6$)($\eta^2$-$H_2C{=}CH_2$)(NO)($PR_3$)$_2$] (**6a**,**b**) (R = *i*Pr **a**, R = Cy **b**) via oxidative coupling of two coordinated ethylene groups followed by double β-H shift and subsequent reductive $H_2$ elimination from the formed dihydride complex. Reduction of the complexes [Re(CO)(NO)($PR_3$)$_2$Cl$_2$] (**7a**,**b**) (R = *i*Pr **a**, R = Cy **b**) with Na/Hg yields the pentacoordinate species [Re(CO)(NO)($PR_3$)$_2$($\eta^2$-$H_2C{=}CH_2$)] (**8a**,**b**) (R = *i*Pr **a**, R = Cy **b**) under the same conditions as for **6a**,**b**. Reaction of **8a** with 1 equiv. of B($C_6F_5$)$_3$ leads to the [Re(CO)$_2${NOB($C_6F_5$)$_3$}(P*i*Pr$_3$)$_2$] compound (**9a**) and to the carbonyl nitrosyl complexes [Re(CO)$_2$(NO)(P*i*Pr$_3$)$_2$] (**10a**) with evolution of ethylene. The same reaction of **8a** and **8b**, but applying 1 bar of CO, leads to exclusive formation of **9a**,**b**. Complexes **4a**, **4b**, **6b**, **8a**, **9a**, and **9b** were characterized by X-ray diffraction studies.

## Introduction

Over a large range of oxidation states rhenium shows generally high bond strengths to carbon donors. However, its affinity to π acceptor ligands can vary with the oxidation state of the metal center, since π back-bonding is expected to depend on the metal-d-electron count. Complexes with rhenium in high oxidation states thus show less propensity for olefin binding, a circumstance, which allows reversible olefin binding in catalytic intermediates, such as those in epoxidations,[1a] olefin metathesis reactions[1b] and in processes, which crucially involve C–H activations.[2] Compounds with rhenium in lower oxidation states are expected to more strongly bind olefins, but such rhenium centers often do not perform well in catalysis, since they frequently show reluctance to form coordinatively unsaturated species. Special ancillary ligand sets may, however, assist dissociations of other ligands. Thus, π acceptors can labilize other π acceptors sharing the metal π electron density and furthermore π donor ligands may exert a kinetic *cis* labilizing effect on *cis* ligands.[3] In this study we therefore wanted to evaluate ethylene binding to rhenium in lower oxidation states[4a] and in various ligand environments. Earlier several pseudo-octahedral or pentacoordinate olefin complexes with rhenium in low oxidation states and a partial π acceptor coordination sphere were studied for their conformational preferences in olefin rotation,[4b] photochemical isomerization processes,[4c] and in stoichiometric C–H activations,[4d] which demonstrated in various ways the basic capability of such rhenium centers to strongly interact with olefins. Our group has recently focused on the development of rhenium bisphosphane nitrosyl systems containing [Re(NO)($PR_3$)$_2$X$_2$][5] (X = halogene) and [Re(NO)$_2$($PR_3$)$_2$][6] fragments. The latter fragments were seen to react with olefins in metathesis catalyses[6] and thus demonstrated affinity to olefins. For the earlier types of fragments a high propensity for olefin uptake was extrapolated based on their capability to bind $H_2$[5] and the close relationship in binding properties of both ligands.[7] Our explorations on ethylene binding were therefore started using [Re(NO)($PR_3$)$_2$X$_2$] fragments possessing a "mixed type" ligand sphere of σ and π donors and π acceptors.

## Results and Discussion

### I. Reactions of [Re($CH_3CN$)(NO)($PR_3$)$_2$Br$_2$]

The reactions of the recently reported [Re(MeCN)(NO)($PR_3$)$_2$Br$_2$] complexes (R = *i*Pr **1a**, R = Cy **1b**)[5] with ethylene produced indeed the ethylene complexes [Re($\eta^2$-

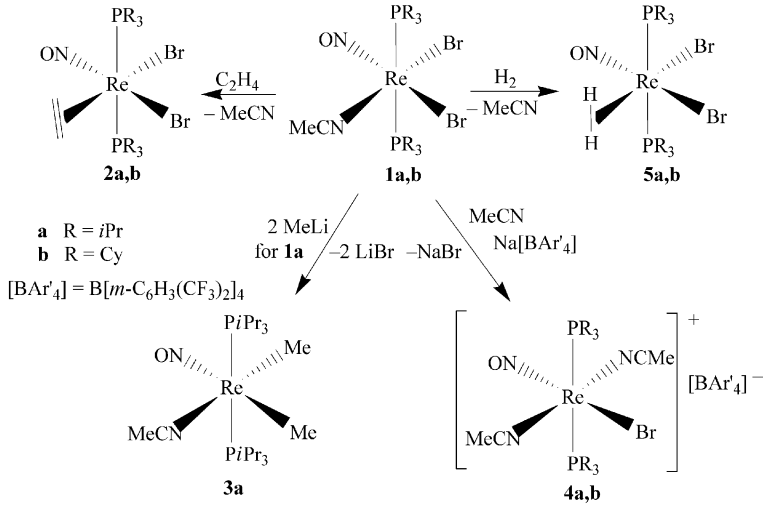

Scheme 1.

$H_2C{=}CH_2)(NO)(PR_3)_2Br_2]$ (R = *i*Pr **2a**, R = Cy **2b**) in good yields (Scheme 1). When ethylene was bubbled through the solutions of **1a**,**b** at 1 bar the color changed from light yellow to purple after 1 h for **2a** and 1.5 h for **2b**, but comparison of the $^{31}P$ NMR spectra indicated only slight changes.[5]

Complexes **2a**,**b** were characterized further by spectroscopic means (IR, $^1H$, and $^{13}C$ NMR) and the pure products showed correct elemental analyses. Studies in solution were some times more difficult for **2b**, since it exhibits low solubilities in many organic solvents. Besides a strong ν(NO) band, the solid state IR spectra of **2a**,**b** displayed ν(CH) bands in the region of 2800 to 3000 $cm^{-1}$ indicating the presence of the Re-coordinated ethylene. ν(C=C) absorptions could not be detected. The $^1H$ NMR spectrum of **2a** revealed two broad resonances at $\delta$ = 2.51 and 2.47 ppm for two chemically different types of protons of the $C_2H_4$ ligand. Apparently there is hindered rotation around the rhenium–ethylene bond with a preferred orientation of the C=C bond parallel to the P–Re–P axis, which leads to distinction of pairs of Z-protons. Even at temperatures as high as 80 °C these signals did not coalesce. In the case of complex **2b** the $^1H$ NMR signals of the olefin overlapped with those of the $PCy_3$ groups so that the hindered rotation of the olefin ligand could not be traced by $^1H$ NMR spectroscopy. However, DFT calculations (vide infra) suggest a substantial barrier of rotation for such types of bis(phosphane) complexes in general. In the $^{13}C$ NMR spectra the two carbon atoms of the $C_2H_4$ moieties are chemically equivalent and appear for **2a** and **2b** as broad triplets at $\delta$ = 39.5 ppm confirming the preferred orientation of the olefin in the P–Re–P axis. In the $^{31}P$ NMR spectra both phosphorus atoms are chemically equivalent and exhibit a singlet at $\delta$ = –13.3 ppm for **2a** and –20.3 ppm for **2b** (40 °C).

Complex **1a** reacts with 2 equiv. of MeLi in toluene to produce the corresponding dimethyl derivative [Re(NO)(MeCN)(P*i*Pr$_3$)$_2$Me$_2$] (**3a**) related to the [Re(NO)(CO)$(PR_3)_2Me_2$] complexes (R = OMe, iOPr, Me, Et) reported earlier.[8] Reaction of **2a** with only 1 equiv. of MeLi does not afford the monomethyl complex [Re(NO)(MeCN)(P*i*Pr$_3$)$_2$MeBr], rather only half an equivalent of **3a**. This could be interpreted in terms of a faster second methylation, faster than the first one. Surprisingly, all attempts to access the dimethyl rhenium species **2b** did not meet with success. A variety of inseparable products were observed indicating a complicated course of the reaction with formation of radicals.

Complex **3a** was characterized by IR, $^1H$, $^{31}P\{^1H\}$, and $^{13}C\{^1H\}$ NMR spectroscopy. Because of the liquid nature of the compound, satisfactory elemental analysis could not be obtained. The IR spectrum recorded in $CH_2Cl_2$ revealed a very strong band at 1588 $cm^{-1}$ for the NO group, as well as a weak band at 2360 $cm^{-1}$ for the coordinated MeCN ligand. Compared to **2a** the ν(NO) absorption of **3a** is shifted to lower wavenumbers by about 100 $cm^{-1}$ indicating a relatively strong π-back-bonding.[9] The $^1H$ NMR spectrum in $C_6D_6$ showed besides the signals of the *i*Pr and MeCN groups, two triplets at $\delta$ = 2.36 ppm ($J$(PH) = 2.2 Hz) and 2.29 ppm ($J$(PH) = 2.0 Hz) for the chemically inequivalent methyl groups. In the $^{13}C\{^1H\}$ NMR spectrum they give rise to broad signals at $\delta$ = 24.6 and 20.6 ppm. Complex **3a** turned out to be very air-sensitive in solution.

Abstraction of a bromide atom from **1a**,**b** using 1 equiv. of [Na][BAr′$_4$] (Ar′ = *m*-$(CF_3)_2C_6H_3$) in acetonitrile occurred within 14 h and proceeded with regiospecific replacement of the bromide *cis* to the NO group affording the [Re(MeCN)$_2$(NO)(PR$_3$)$_2$Br][BAr′$_4$] salts **4a**,**b**. The *trans*-to-NO bromide is apparently bound more strongly experiencing a push-pull stabilization of the π donor with the *trans* π acceptor. Complexes **4a**,**b** were isolated as pure yellow solids and are quite air-stable. The use of an excess of [Na][BAr′$_4$] did not lead to abstraction of the second bromide ion. Because of the cationic nature of the complexes, the solid-state IR spectra of **4a**,**b** showed ν(NO) bands shifted to higher wavenumbers in comparison with the starting materials. Bands for the two coordinated acetonitriles, which should appear in the range of 2350 to 2200 $cm^{-1}$, could not be detected. The NMR spectroscopic data of **4a**,**b** con-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

firmed the presence of $\{Re(MeCN)_2(NO)(PR_3)_2\}$ fragments with two nitrile ligands. The $^1H$ NMR spectra displayed singlets at room temperature at $\delta = 2.89$ ppm for **4a** and at $\delta = 2.93$ ppm for **4b** attributed to the two chemically equivalent *trans* acetonitrile ligands. Singlets also appeared in the $^{31}P\{^1H\}$ NMR spectra at $\delta = 0.4$ for **4a** and –10.2 ppm for **4b**.

The molecular structures of **4a**,**b** were also determined by X-ray diffraction studies and the cations are shown in Figure 1. Complex **4b** crystallized as a $CH_2Cl_2$ solvate. The rhenium coordination was found to be pseudo octahedral with the nitrosyl ligand located *trans* to the Br atom, while the two MeCN and the phosphane groups are disposed *trans*. Selected bond lengths and angles of **4a**,**b** are summarized in Table 1. The nitrosyl groups of both compounds were found disordered with the Br ligands.

As depicted in Scheme 1, $H_2$ rapidly displaces the coordinated MeCN group in **1a**,**b** producing the corresponding dihydrogen derivatives $[Re(\eta^2\text{-}H_2)(NO)(PR_3)_2Br_2]$ (**5a**,**b**) in quantitative spectroscopic yields. Complexes **5a**,**b** were identified by $^1H$ NMR spectroscopy based on the data of their earlier preparations from the reaction of $[NEt_4][Re(NO)Br_5]$ with the corresponding phosphanes in ethanol.[5]

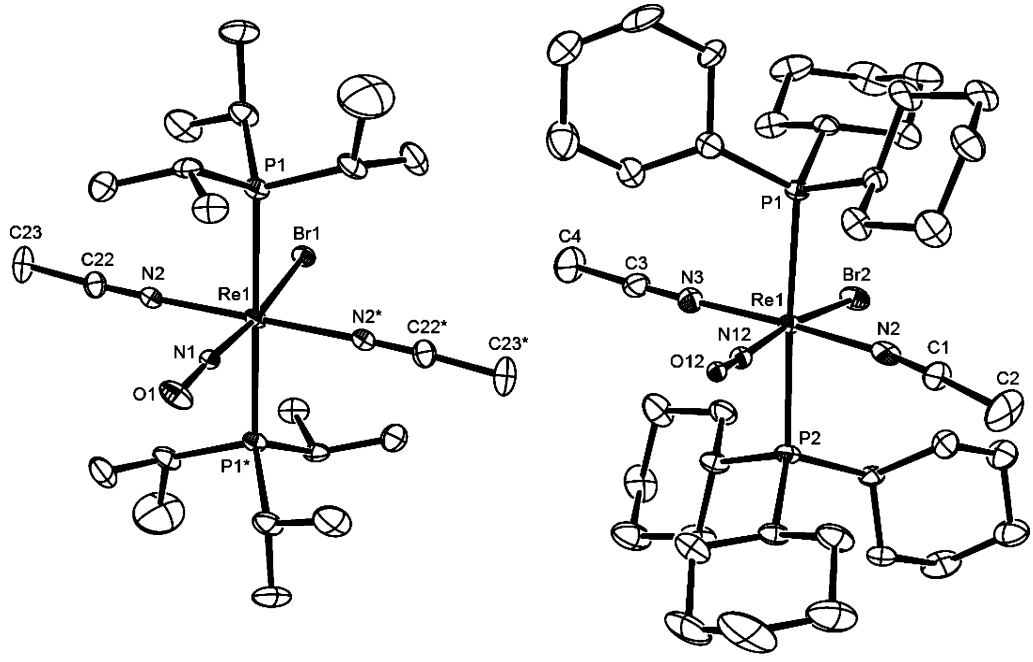

Figure 1. ORTEP drawings of the molecular structures of the cations of **4a** (left) and **4b** (right) (thermal ellipsoids are drawn at the 20 and 30% probability levels, respectively). The rhenium atom of **4a** lies on a center of inversion, only half of the molecule has been refined and the equivalent atoms (*) have been generated by the symmetry transformation $1/2 - x$, $1/2 - y$, $1/2 - z$). The resulting disorder between the NO and Br ligands, the counterions $[BAr'_4]^-$, the $CH_2Cl_2$ solvate molecule of **4b**, as well as all hydrogen atoms have been omitted for clarity.

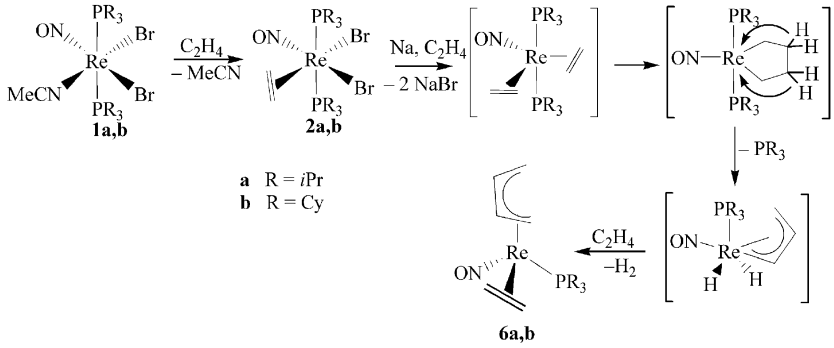

Scheme 2.

We then attempted access to olefin complexes with the rhenium center in a still lower oxidation state than +I. Reduction of **1a**,**b** with sodium amalgam in THF leads at room temperature under 1 bar of ethylene to the butadiene ethylene species $[Re(\eta^4\text{-}C_4H_6)(\eta^2\text{-}H_2C{=}CH_2)(NO)(PR_3)_2]$ (**6a**,**b**) (Scheme 2). These $Re^{-I}$ complexes were isolated as pale yellow powders in yields of 31% for **6a** and of 63% for **6b**.

In Scheme 2 a mechanism for the formation of **6a**,**b** is proposed. First generation of **2a**,**b** and then reduction to a transient $Re(ethylene)_2$ complex is suggested, which eventually converts into a metallacyclopentane structure with oxidative coupling of the two ethylene ligands.[10–12] Double β-hydride elimination and $H_2$ reductive elimination[2,13] is followed by the ethylene replacement of one phosphane ligand.

Single crystals of **6b** were obtained from a mixture of pentane/dichloromethane, 10:1 (Figure 2, Table 2). The X-ray diffraction study established the structure of **6b** in detail. The coordination sphere of **6b** can be viewed as a pseudo tetrahedron counting the butadiene as one ligand or as a pseudo square pyramid with the butadiene moiety occupying two coordination sites. According to the latter view the essentially planar $\eta^4$-butadiene, $\eta^2$-ethylene, and the NO ligand would form the base and the phosphane the apical position of the pyramid. Conformationally, the ethylene group is in parallel orientation with respect to the Re–P axis and the *cis*-butadiene ligand points with its open side toward the $PCy_3$ ligand. The ethylene and the butadiene group are disordered. The disorder could properly be resolved revealing reasonable bonding parameters. The average distance between the internal butadiene carbon atoms of 1.34(2) Å is significantly shorter by 0.09 Å than the average distances of the terminal carbon atoms of 1.43(2) Å speaking for a strong Re-butadiene back bonding with superimposition of the $\pi_3$ orbital of the butadiene moiety. For comparison, the free *cis*-butadiene bond possesses an internal C–C distance of 1.463(3) and terminal olefinic distances of 1.342(2) Å.[14,15] The Re–$C_{int}$ and Re–$C_{term}$ distances are similar and fall into the range of 2.16(3) to 2.27(2) Å emphasizing a genuine $\eta^4$ coordination mode. The Re–$C_{term}$ bond length approximately *trans* to the ethylene group is shorter by 0.09(2) Å than the Re–$C_{term}$ distance *trans* to the NO group. This can be explained via size-able differences in the *trans* influences of ethylene and the NO group with the NO ligand having the stronger effect. The hydrogen atoms of the coordinated olefins could not be located in the Fourier difference maps and they have been calculated after each refinement cycle (riding model).

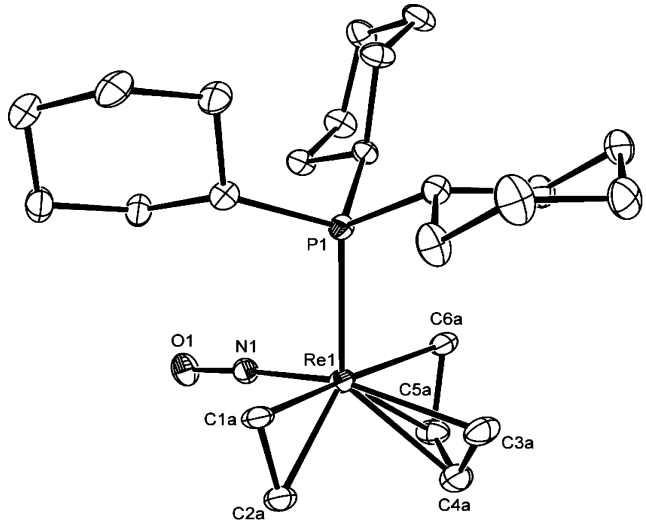

Figure 2. ORTEP drawing of the molecular structure of **6b** (thermal ellipsoids are drawn at the 30% probability level). The disorder observed between the ethylene and butadiene ligands as well as all hydrogen atoms have been omitted for clarity.

Table 2. Selected bond lengths [Å] and bond angles [°] for **6b**.

Principally, butadiene can coordinate to a metal as a *cis*- or *trans*-butadiene. The *trans*-$\eta^4$-diene complexes are normally thermodynamically less stable and they may convert to the corresponding *cis*-$\eta^4$-diene complexes.[16,17] The *cis*-$\eta^4$-diene complexes are known mainly with early transition metal centers, such as in $Cp_2M(diene)$ (M = Ti, Zr, Hf),[16] as well as with Ta.[18]

Two extreme forms of butadiene *cis* coordination were found: the *cis*-$\eta^4$-1,3-diene structure and the metallacyclopent-3-ene structure. NMR spectroscopy is able to distinguish the various coordination modes of the diene ligand on the basis of their coupling constants. In the *cis* coordination the majority of diene complexes reported so far exhibit the $\eta^4$-1,3 diene structure possessing bond lengths of $C_{int}$–$C_{int} \geq C_{term}$–$C_{term}$ and M–$C_{term} \geq$ M–$C_{term}$, the dihedral angles between the planes defined by $C_{term}$, M, $C_{term}$ and $C_{term}$, $C_{int}$, $C_{int}$, $C_{term}$ atoms are generally <90°. When the dihedral angle is greater than 90° and the $C_{int}$–$C_{int}$ bond is significantly shorter than $C_{term}$–$C_{int}$, the bent metallacyclopent-3-ene structure is adopted.[12]

The $^1$H NMR and the $^{13}$C NMR spectroscopic data of **6a**,**b** indeed confirmed their *cis* butadiene structure. Also on the basis of the $^{31}$P NMR spectra, **6a**, however, exists in solution as a mixture of two stereoisomers appearing in a 3:1 ratio. Suggested by the DFT calculations modeled with a $PMe_3$ ligand (vide infra) the isomerism is anticipated to be caused by butadiene rotation. Principally the three rotamers **A**, **B**, and **C** are conceivable (Figure 3). For electronic reasons any of these rotamers are expected to have one leg of the three-legged pianostool in the diene cleft.[19] According to the calculations on a $PMe_3$ model isomer **A** is of lowest energy. **B** and **C** of this derivative lie +3.9 and +8.6 kcal/mol higher in energy. In analogy **6a** is assumed to exist in the equilibrium conformations **A** and **B**. Another point of discussion concerns the kinetics. The barrier for the interconversion of rotamer **A** and **B** apparently is low enough that room temperature thermal energy (<15 kcal/mol) can equilibrate the two isomers of **6a**, however, at a rate which is slow on the NMR time scale. By the same token the energy difference of isomers **A** and **B** of **6b** and their barrier of rotation are expected to be substantially higher than those of **6a**, since the $PCy_3$ ligand possesses a still larger cone angle than $PiPr_3$. For the latter complex the butadiene rotation is therefore considered to be "frozen out" in the energetically preferred rotamer **A**.

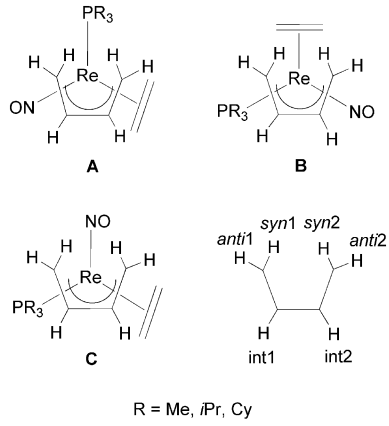

Figure 3. Projections of the rotational isomers of **6a**,**b** and **6-Me** and proton assignment for the butadiene ligand.

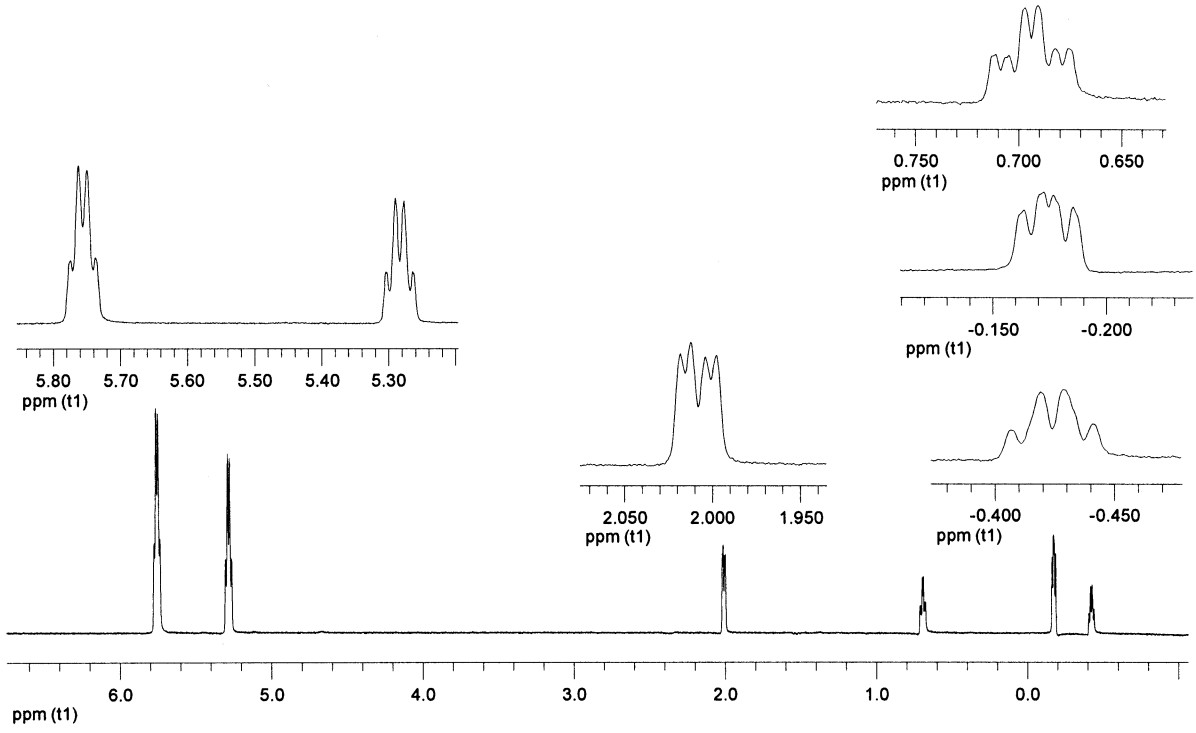

Figure 4. TOCSY for the butadiene ligand of **6b** recorded in $C_6D_6$ (r.t.) with irradiation of one *internal* CH group.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

The $^1$H NMR spectrum of **6b** indeed points to a solution structure according to rotamer **A**, which indeed is the structure in the solid state (Figure 2). Beside the signals of the $PCy_3$ ligand, overlapping with those of the $C_2H_4$ group, the resonances of the butadiene group are attributed to two *anti*, two *syn*, and two *internal* protons. Any of the isomeric structures **A**, **B**, and **C** of **6a**,**b** possesses $C_1$ symmetry and "left/right" asymmetry of the butadiene so that the various types of butadiene protons are doubled and each butadiene proton appears at a distinct chemical shift. For **6b** this could nicely be demonstrated by a TOCSY experiment with irradiation of one *internal* CH group (Figure 4 and Table 3). For **6a**, however, the chemical shift differences between the signals of the butadiene and the ethylene groups of the rotamers **A** and **B** are very small and lead to overlap. The differences in chemical shifts between the *syn* and the *anti* protons of **6a**,**b** were found to be in the range of 0.25–1.42 ppm comparable with the $\Delta\delta$ values of $Fe(CO)_3(\eta^4\text{-}C_4H_6)$[20] and of $RhCp(\eta^4\text{-}C_4H_6)$ (1.3–2.3 ppm) (Table 3). A coupling between the *syn* protons and the phosphorus nuclei was not observed for both complexes.

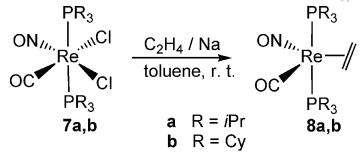
Table 3. $^1$H NMR chemical shift [ppm] for the butadiene ligand of the rotamers **A** and **B** of **6a** and **A** of **6b**.

| | $H_{syn1}$ | $H_{anti1}$ | $H_{int1}$ | $H_{int2}$ | $H_{anti2}$ | $H_{syn2}$ |
|---|---|---|---|---|---|---|
| **6a(A)** | –0.21 | –0.52 | 5.72 | 5.25 | 0.56 | 1.98 |
| **6a(B)** | –0.21 | –0.72 | 5.72 | 5.25 | 0.43 | 2.06 |
| **6b(A)** | –0.17 | –0.42 | 5.76 | 5.29 | 0.70 | 2.01 |

The coupling constants $J(H_{syn1}H_{anti1})$, $J(H_{syn1}H_{int1})$, $J(H_{anti1}H_{int1})$, $J(H_{int1}H_{int2})$, $J(H_{anti2}H_{int2})$, $J(H_{syn2}H_{int2})$ of isomer **A** of **6a**,**b** and isomer **B** of **6a** are 7 and 6 Hz and $J(H_{anti2}H_{syn2})$ 4 and 3 Hz, respectively. On the basis of the couplings of the *anti* protons with the phosphorus nuclei (ca. 7 Hz) it was concluded that the butadiene units in **6a**,**b** have structures close to a *cis*-$\eta^2$-1,3-diene ligand with a minor admixture of a metallacyclo-3-pentene structure. The coordination of the ethylene group in **6a**,**b** was confirmed by $^{13}$C NMR and by NOE measurements. All ethylene protons of **6a** appear in the $^1$H NMR spectrum as chemically distinguished signals indicating hindered rotation.

## II. Reactions of $[Re(NO)(CO)(PR_3)_2Cl_2]$

In order to probe the accessibility of other $Re^{-I}$–olefin complexes, we attempted the reduction of the complexes $[Re(NO)(CO)(PR_3)_2Cl_2]$ (**7a**,**b**) (R = *i*Pr **a**, Cy **b**), related to **1a**,**b** by replacement of the olefin ligand with CO. In the presence of 1.4 bar of ethylene and otherwise under the same conditions as for the reductions of **1a**,**b**, the ethylene derivatives $[Re(NO)(CO)(\eta^2\text{-}H_2C{=}CH_2)(PR_3)_2]$ (**8a**,**b**) were obtained in good yields (Scheme 3) after reaction times of 5 d.



Scheme 3.

The change from yellow to orange became visible after filtration from the amalgam. The formation of **8a**,**b** was accompanied by the formation of a very small amount (about 1%) of the known dihydride complex $[Re(NO)(CO)(H_2)(PR_3)_2]$,[5] which was removed by washing of the solids with pentane. The dihydride complexes were formed in larger amounts (about 34%) when the reaction was carried out under a pressure of 10 bar of ethylene. It was concluded that the formation of the dihydride complex results from the presence of a $H_2$ impurity in the ethylene gas.

The IR spectra of **8a**,**b** reveal ν(CO) and ν(NO) absorptions, which are shifted both by more than 100 $cm^{-1}$ to lower wavenumbers compared to **7a**,**b**[8] indicating increased π-back bonding. ν(C=C) bonds are not observed, but the coordination of the ethylene group is indicated by the presence of characteristic ν(C–H) vibrations. The $^1$H NMR spectrum of **8b** is less informative with respect to a structural assignment, since the $PCy_3$ resonances cover other signals over a large area of chemical shifts. The $^1$H NMR resonances of the ethylene group of **8a** could not be detected in the room temperature spectrum, but were observed at 100 °C as a broad triplet at $\delta$ = 1.86 ppm for all chemically and magnetically inequivalent $C_2H_4$ protons.

The structures of **8a**,**b** were derived from their analytical and spectroscopic data and for **8a** it was confirmed by an exemplary X-ray diffraction study. The structure of **8a** is shown in Figure 5 and selected bond lengths and angles are given in Table 4.

The coordination geometry around the rhenium center corresponds to a distorted trigonal bipyramid with the CO and NO groups and both carbon atoms of the ethylene group located in the trigonal plane of the molecule. The two phosphane ligands occupy apical positions with a P(1)–Re(1)–P(2) angle of 178.16(3)° (Table 4). Contrary to complexes **2a**,**b** the orientation of the C=C bond is perpendicular to the P–Re–P vector, which is indicated by the dihedral angles P(1)–Re(1)–C(2) 90.37(10)°, P(1)–Re(1)–C(3) 90.73(9)°, P(2)–Re(1)–C(2) 90.75(10)°, and P(2)–Re(1)–C(3) 91.04(9)°. It is the electronically preferred orientation in $d^8$ trigonal bipyramidal structures. The C=C bond length of 1.420(8) Å is comparable to those found in other ethylene rhenium complexes.[21] The Re–N bond length of 1.799(3) Å is in accord with the values found in the literature.[22] The N1–O2 bond separation of 1.208(4) Å is in the range of 1.10 to 1.38 Å expected for a linear $NO^+$ type coordination[21–23] [Re–N–O angle of 172.7(3)°]. The positions of the hydrogen atoms of the ethylene ligand were located in a difference electron-density map and their coordinates were fixed, but their isotropic displacement parameters were freely refined.

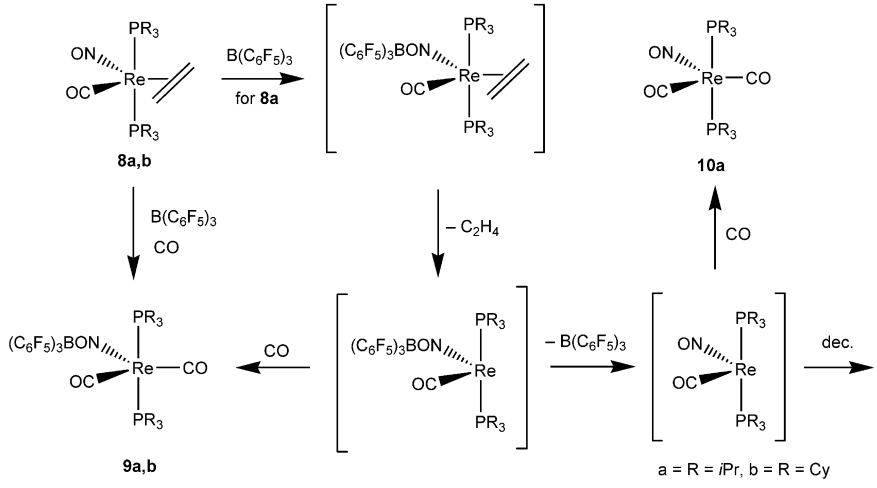
Olefin complexes can be activated by Lewis acids to become alkene polymerization catalysts.[24–30] The olefin gets attacked by the Lewis acid forming a zwitterionic species. The metal cation and the Lewis acid attacked anionic group are covalently linked in some fashion. They have been found to represent a way to modulate ion pairing in these catalysts, thus increasing activity. One important class of these zwitterionic complexes is obtained when the counteranion is located on the alkyl group occupying the reactive wedge of the complex. These types of complexes are called Girdle-type zwitterionic compounds and have been accessed mainly through electrophilic attack of $B(C_6F_5)_3$ on suitable hydrocarbon ligands of neutral group 4 bent metallocenes.[31,32]

With the objective to generate active rhenium-based catalysts, we exemplarily attempted activation of complex **8a** with a Lewis acid. Treatment of **8a** with one equivalent of $B(C_6F_5)_3$ in toluene or benzene at room temperature did, however, not lead to the mentioned zwitterionic species $[Re^{+}(NO)(CO)(PR_3)_2CH_2CH_2B^{-}(C_6F_5)_3]$. The structures of the product showed that the $B(C_6F_5)_3$ electrophile had attacked the more Lewis basic NO site to give eventually the nitrosyl/Lewis acid adduct $\{Re(CO)_2[NOB(C_6F_5)_3](PR_3)_2\}$ (**9a**) and in addition the known complex $[Re(CO)_2(NO)(PR_3)_2]$ (**10a**) with loss of the ethylene ligand in both complexes as depicted in Scheme 4. Complex **10a** was identified



Scheme 4.

by its $^{31}P$ NMR spectrum ($\delta$ = 81.6 ppm) and its IR spectrum reported earlier.[8] $^{1}H$ and $^{31}P\{^{1}H\}$ NMR pursuit of the reaction confirmed generation of free ethylene and formation of **9a** and **10a** in a 1:1 ratio. Formation of the phosphane adduct $iPr_3PB(C_6F_5)_3$ was not observed.[33] Complex **9a** could be separated from **10a** in 38% yield.

Formation of **9a** with replacement of the ethylene group in **8a** by CO requires explanation of how free CO could have formed. It apparently originates from the partial decomposition of the $B(C_6F_5)_3$ adduct of **8a** to yield ethylene and CO. The presence of only low amounts of CO accounts for the low yield of **9a**.

With the objective to access **9a**,**b** in a better yield, we first prepared complex **10a**,**b** by the reaction of **8a**,**b** with CO. The reaction was very sluggish and took more than 5 d. But much to our surprise, no stable adduct formation

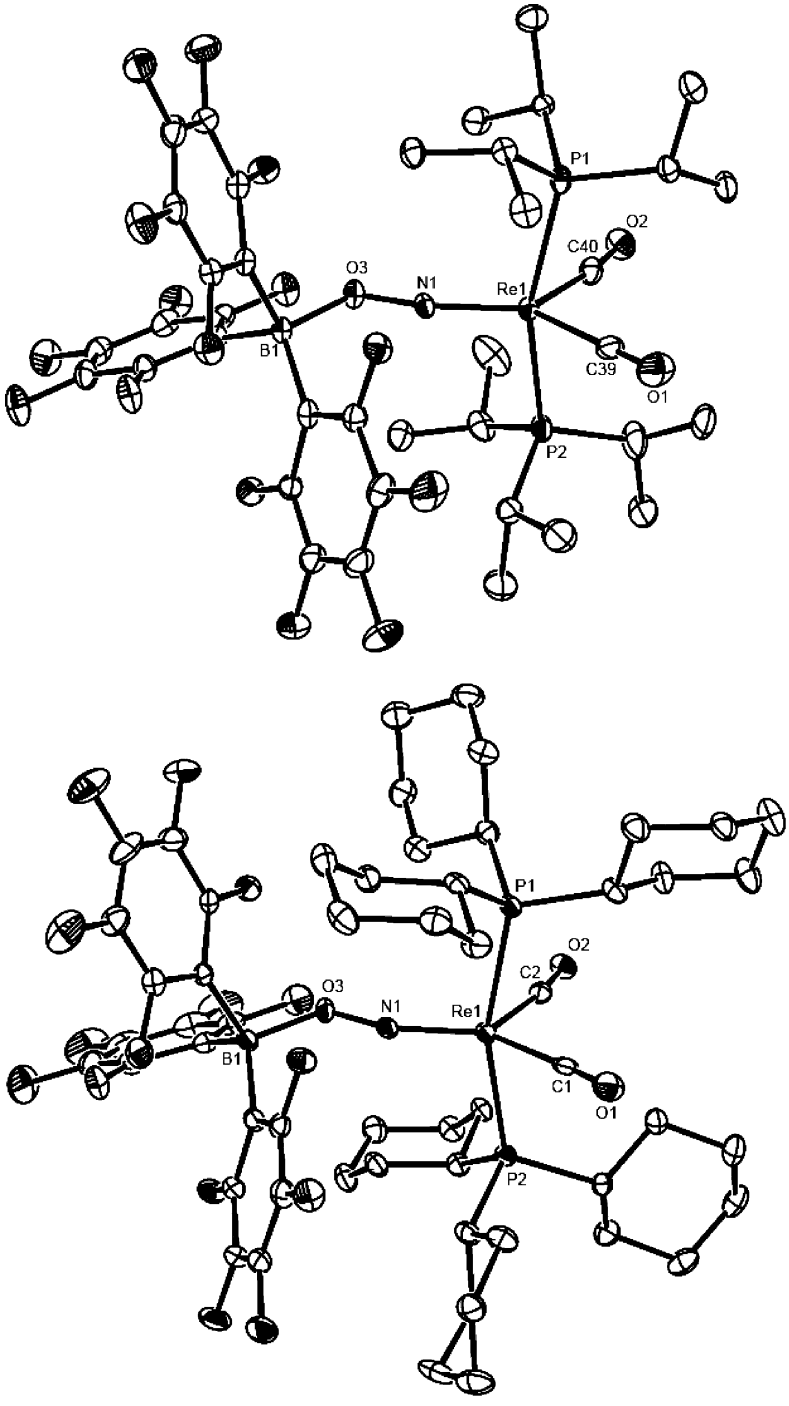

Figure 6. ORTEP drawings of the molecular structures of **9a** and **9b** (thermal ellipsoids are drawn at the 30% probability level). All hydrogen atoms have been omitted for clarity.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

could be observed between **10a**,**b** and $B(C_6F_5)_3$. We have to assume that the additions of $B(C_6F_5)_3$ to **10a**,**b** are kinetically hindered.

When, however, **8a**,**b**, $B(C_6F_5)_3$, and CO were mixed together **9a**,**b** was produced in high yield. This observation stresses the necessity for the involvement of initial $B(C_6F_5)_3$ adducts of **8a**,**b** promoting formation of **9a**,**b** by subsequent ethylene substitution with CO (Scheme 4).

The adducts apparently release ethylene much faster than **8a**,**b** in the presence of CO to trap the unsaturated intermediates. Single crystals of **9a**,**b** were obtained from $CH_2Cl_2$/pentane solutions at –30 °C.

The molecular structures of **9a**,**b** were determined and are shown in Figure 6. The coordination geometries are distorted trigonal bipyramids. The two CO groups and the $NOB(C_6F_5)_3$ fragment are located in the trigonal plane of the molecules and the two phosphanes occupy apical positions. The phosphane ligands are bent towards the two CO groups [(P(1)–Re–P(2) 161.20(5) and 161.92(6)° for **9a** and **9b**, respectively] (Table 5). Such substantial bending of the phosphane molecules may be caused by steric "bumping" of the phosphanes and the $NOB(C_6F_5)_3$ fragment. Significant bending of the phosphanes was also observed in the hydride Lewis acid adducts $[Re(H)(NO)(NOBC_6F_5)_3(P\textit{i}Pr_3)_2]$[33] and $[Re(H)(NO)(NOBF_3)(P\textit{i}Pr_3)_2]$[5] with P(1)–Re(1)–P(2) 134.77(3) and 146.60(6)°, respectively. The electronic and steric factors favor the bending of the axial ligands towards the purely σ-donating hydride ligand and away from the nitrosyl group.[34,35] Similar to the complexes $\{Re(H)(NO)[NOB(C_6F_5)_3](P\textit{i}Pr_3)_2\}$ and $[Re(H)(NO)(NOBF_3)(P\textit{i}Pr_3)_2]$ the Re–N distances of 1.790(4) and 1.785(6) Å are only slightly affected by the coordination of $B(C_6F_5)_3$, but compared to other $\eta^1$ rhenium nitrosyl complexes the N–$OBX_3$ bond is elongated. The nitrosyl ligands are slightly bent upon $B(C_6F_5)_3$ attachment (Re(1)–N(1)–O(3) 166.2(4) and 158.6(6)°); however, it was approximately linear in the cases of $\{Re(H)(NO)[NOB(C_6F_5)_3](P\textit{i}Pr_3)_2\}$ [Re–N–O 175.0(3)°] and $[Re(H)(NO)(NOBF_3)(P\textit{i}Pr_3)_2]$ [Re–N–O 170.0(4)°]. A significant structural effect was recognized upon coordination of $BCl_3$ to a NO group in the compound $[Re(Cp)(SiMe_2Cl)(NOBCl_3)(PPh_3)]$.[36] This compound reveals a marked N–O elongation [1.47(1) Å] accompanied by a shortening of the Re–N bond [1.568(9) Å]. In **9a**,**b** the N–O bond lengths are 1.276(6) and 1.296(8) Å. Nitrosyl/Lewis acid interactions were shown to play a key role in the catalytic oxidation of alcohols,[37] as well as in catalytic hydrogenation and hydrosilylation of olefins and ketones.[33]

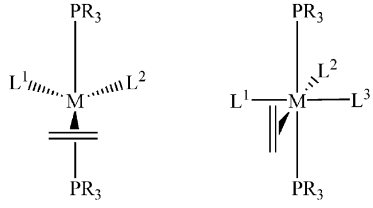
## III. Theoretical Studies on Ethylene Complexes

As a single-faced π acceptor an olefinic ligand quite often shows barriers to free rotation around the metal–olefin bond. Generally, the C=C bond is preferentially oriented in the trigonal plane of three-coordinate complexes, is perpendicular to the plane in four-coordinate square-planar complexes, and is in plane with the trigonal plane of five-coordinate trigonal-bipyramidal complexes (Scheme 5).[38] These prevailing orientations are thought to result mostly from electronic rather than from steric effects. In $d^6$ octahedral complexes olefins do only rarely show rotational barriers, if the *cis* ligands are all the same. Barriers might appear only for cases where the π donor planes at the metal centers are electronically strongly distinguished ($R_3P$–M–$PR_3$ plane electronically more donating than the $L_1$–M–$L_3$ plane of Scheme 5). In $d^8$ trigonal bipyramidal complexes the olefin is preferentially oriented in the trigonal plane regardless of the presence of an axial $R_3P$–M–$PR_3$ arrangement. For instance in the structure of **8a** the olefin orientation is in accord with this general rule.



Scheme 5.

Five-coordinated $d^6$ complexes, as for instance $(\mu^2$-Cl-$[(AlMe_2)_2C\equiv)]W(CH_3)(PMe_3)_2(C_2H_4)$,[39] (bis-mesitylimido)$W(PMe_3)_2(C_2H_4)$,[40] and bis(2,6-diisopropylphenylimido)$Mo(PMe_3)_2(C_2H_4)$ show reorientation of the olefinic group.[41] In pseudo-octahedral complexes with *trans* phosphane ligands *cis* to the olefin, structures are prevailing with a parallel orientation of the olefin with respect to the P–M–P axis.[42–49] Nevertheless, some examples show the olefin lying perpendicular to the P–M–P axis.[50–53] Several of these latter examples might be governed by special effects, since they mostly possess two ethylene ligands in *trans*[50,51] or in *cis* position[52] to each other with one C=C bond parallel to the P–M–P vector and the second one perpendicular to it. To the best of our knowledge, only in the *ortho*-metallated ruthenium complex $RuH(C_2H_4)$(2-phenylpyridine)$(P\textit{i}Pr_3)_2$ has the coordinated ethylene not aligned with the P–Ru–P axis.[53]

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

The most widely accepted model for the bonding of an olefin to transition metals is that proposed by Dewar[54] and by Chatt and Duncanson.[55] This model involves formation of a σ-bond by donation of π-electrons to the metal and formation of a π-bond by back donation from the d orbitals of the metal to the olefin π*-orbital. The precise nature of this bond has been the subject of many theoretical and experimental studies.[56] In order to study the structures of **2a**, **2b**, and **8a** more thoroughly with the olefinic C=C bond lying parallel to the P–Re–P axis in the six-coordinate octahedral complexes **2a** and **2b** and in the trigonal plane of **8a** DFT calculations[57] were carried out on the model complexes $Re(PMe_3)_2X_2(NO)(C_2H_4)$ (X = Br, **2-Me**) and $Re(PMe_3)_2(CO)(NO)(C_2H_4)$ (**8-Me**).

We made use of a well-established bond partitioning scheme,[58] which divides the overall bond energy BE into various contributions from different interactions [Equation (1)], to look at the bond-forming reaction between the metal fragment and ethylene.

$$\Delta E_{int} = -[\Delta E_{elstat} + \Delta E_{Pauli} + \Delta E_{oi}] = -[\Delta E^0 + \Delta E_{oi}] \quad (1)$$

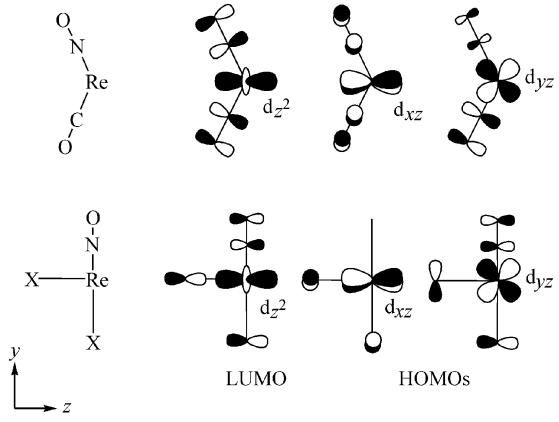
The interaction energy between both fragments $\Delta E_{int}$ is partitioned into three physically meaningful terms, namely the electrostatic interaction $\Delta E_{elstat}$, the Pauli repulsion $\Delta E_{Pauli}$, and the orbital interaction term, $\Delta E_{oi}$. When two suitable, bond-forming fragments are brought together to adapt the geometry of the final molecule, the term $\Delta E_{elstat}$ describes the classical Coulomb interaction between the unmodified and interpenetrating charge distributions of the two fragments. We further have to consider the Pauli repulsion $\Delta E_{Pauli}$, which takes into account destabilizing two-orbital four-electron interactions between occupied orbitals on both fragments. The sum of Pauli repulsion and electrostatic interaction is called the *steric interaction* $\Delta E^0$. The last term in Equation (1), $\Delta E_{oi}$ introduces the attractive orbital interaction between occupied and virtual orbitals on the two fragments, and includes polarization and charge-transfer contributions. Although $\Delta E_{int}$ values are not defined in the same way as bond dissociation enthalpies $\Delta H$, they are reasonable approximations of bond enthalpy terms, which in turn provide a good description for the bond strength.[59] The bonding analysis for **2-Me** and **8-Me** is presented in Table 6.

Table 6. Bond analysis of the [Re]–($\eta^2$-$C_2H_4$) bond for **2-Me** and **8-Me**.

| System | $\Delta E$ | $\Delta E_{Pauli}$ | $\Delta E_{elstat}$ | $\Delta E^0$ | $\Delta E_{oi}$ | $\Delta E_{int}$ |
|---|---|---|---|---|---|---|
| **2-Me** $/\!/$ | 0.0 | +225.23 | –163.13 | +62.10 | –120.86 | –58.76 |
| **2-Me** ⊥ | +23.1 | +127.25 | –90.57 | +36.68 | –59.23 | –22.55 |
| **8-Me** $/\!/$ | +10.2 | +217.96 | –159.16 | +58.79 | –111.64 | –52.84 |
| **8-Me** ⊥ | 0.0 | +194.45 | –143.07 | +51.38 | –113.15 | –61.77 |

For the three studied model complexes, both conformations with the C=C bond of ethylene parallel ($/\!/$) or perpendicular (⊥) to the P–M–P axis have been optimized without any constraints. The relative total energies confirm the structural observations since the parallel orientation is favored for **2-Me** by 23.1 kcal/mol with respect to the corresponding perpendicular conformation and the perpendicular orientation is favored for **8-Me** (by 10.2 kcal/mol with respect to the corresponding parallel conformation). The results from the bond analysis of **2-Me** show that $\Delta E_{oi}$ is the main factor determining the strength of the Re-($\eta^2$-$C_2H_4$) bond. The steric interaction term $\Delta E^0$ is dominated by the Pauli repulsion $\Delta E_{Pauli}$, and thus represents a non-bonding contribution. Despite the fact that the perpendicular orientation of ethylene reduces the steric repulsion between fragments from +62 to +37 kcal/mol (**2-Me**) the attractive orbital interaction $\Delta E_{oi}$ greatly stabilizes the parallel molecular arrangement from about 120 kcal/mol to only 59 kcal/mol for **2-Me** ⊥, respectively. In the case of the trigonal-bipyramidal complex **8-Me**, the three main contributions of **9-Me**$''$ are very similar to those for **2-Me**$''$ (differences are less than 8 kcal/mol). The major change which leads to a favored perpendicular arrangement for **8-Me** comes from the electronic contribution $\Delta E_{oi}$. Calculated $\Delta E_{oi}$ increases from 56 kcal/mol to 113 kcal/mol on going from **2-Me** ⊥ to **8-Me** ⊥, even larger than the value for **8-Me**$''$ (112 kcal/mol). For **8-Me**, both steric (+51 vs. +59 kcal/mol) and electronic terms (–113 vs. –112 kcal/mol) contribute to a better stabilization of the perpendicular arrangement.

According to the Dewar–Chatt–Duncanson model, two molecular orbitals from the metallic fragments $Re(PMe_3)_2$-(NO)(CO) or $Re(PMe_3)_2(NO)Br_2$ can compete for the formation of the π-bond by back donation to ethylene. The metal contribution to these two highest occupied molecular orbitals is mainly $d_{xz}$ and $d_{yz}$ (Scheme 6).



Scheme 6.

Both orbitals can interact with the olefin π*-orbital in a bonding fashion depending on the orientation of ethylene. The LUMO is mainly Re-$d_{z^2}$ and is responsible for the σ-bond by interaction with the filled $\pi_{C2H4}$ orbital. The energy levels of these crucial orbitals of the metal fragments of **2-Me** and **8-Me** in their structures of the optimized molecules are presented in Figure 7 and Table 7. In the pseudo

Table 7. Optimized bond angles [°] and energy levels [eV] of the metallic fragments $Re(PMe_3)_2(NO)Br_2$ of **2-Me** and $Re(PMe_3)_2(NO)(CO)$ of **8-Me**.

| System | Br–Re–Br | Br–Re–$N_{NO}$ | P–Re–Br | P–Re–P | $N_{NO}$–Re–$C_{CO}$ | LUMO | HOMO | HOMO – 1 |
|---|---|---|---|---|---|---|---|---|
| **2-Me**$''$ | 91.8 | 91.4 | 81.1 | 143.1 | | –4.677 ($d_{z^2}$) | –5.685 ($d_{xz}$) | –6.648 ($d_{yz}$) |
| **2-Me** $\perp$ | 88.9 | 89.3 | 85.9 | 168.1 | | –4.679 ($d_{z^2}$) | –5.805 ($d_{xz}$) | –6.590 ($d_{yz}$) |
| **8-Me**$''$ | | | | 159.1 | 136.8 | –3.462 ($d_{z^2}$) | –5.084 ($d_{xz}$) | –5.147 ($d_{yz}$) |
| **8-Me** $\perp$ | | | | 175.0 | 112 | –3.566 ($d_{z^2}$) | –4.488 ($d_{yz}$) | –5.820 ($d_{xz}$) |

octahedral complex **2-Me** the three ligands of the equatorial plane, two halides and one nitrosyl keep more or less their positions during ethylene rotation. The Br–Re–Br and Br–Re–$N_{NO}$ bond angles remain in the range 88.9–91.8° and P–Re–Br increases by only 5° when the ethylene lies in the $ReBr_2(NO)$ plane (Table 7). The orbitals are well separated by about 1 eV and the HOMO is mainly built from Re-$d_{xz}$ which favors the parallel orientation of ethylene with respect to the P–Re–P axis. The second occupied π-type orbital is low in energy through the bonding interaction with the nitrosyl ligand not allowing for efficient further back-bonding with the ethylene.

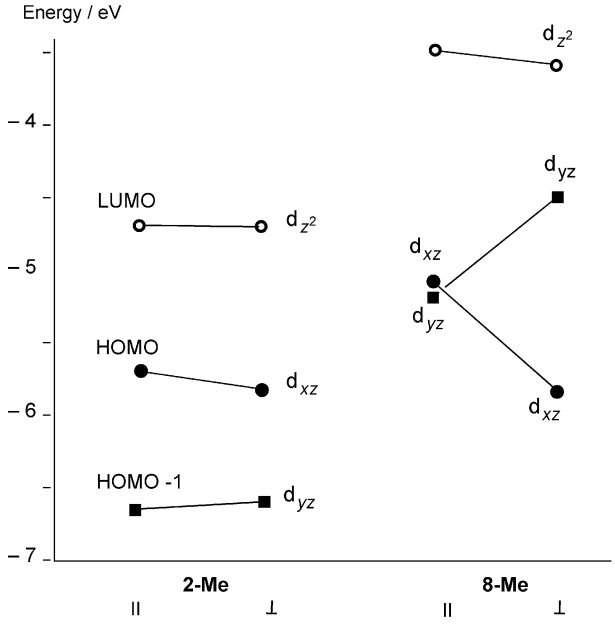

Figure 7. Energy diagram for the $d_{xz}$, $d_{yz}$, $d_{z^2}$ orbitals of the fragments $Re(PMe_3)_2(NO)(CO)$ of **2-Me** and $Re(PMe_3)_2(NO)Br_2$ of **8-Me** in their structures of the optimized molecules.

In the case of the trigonal-bipyramidal complex **8-Me**, the bending distortion of the ligands in both planes and in the opposite direction of the ethylene is easier than for **2-Me** and polarizes the $d_{xz}$ or $d_{yz}$ orbital of the metal for increased back-donation to the ethylene. Nevertheless, the degree of bending of the $PMe_3$ is limited by steric repulsions between $PMe_3$ and CO and NO and between the phosphorus ligands themselves whereas the bending of the carbonyl and nitrosyl group is only limited by electronic and steric interactions between themselves in the equatorial plane. While the P–Re–P angle decreases by 16° from 175.0 (**8-Me** $\perp$) to 159.1° (**8-Me**$''$) the $N_{NO}$–Re–$C_{CO}$ bond angle can become narrower by 25° from the parallel to the perpendicular orientation of ethylene (from 136.8 to 112°). The result is a greater destabilization of the occupied orbital built with Re-$d_{yz}$, since the overlap between Re-$d_{yz}$ and $p_y/p_z$ of the carbonyl and nitrosyl groups is reduced which becomes the HOMO of the metallic fragment. Back bonding to ethylene becomes stronger in the equatorial plane and favors the perpendicular orientation of ethylene with respect to the P–Re–P axis.

It was also challenging to provide understanding for the solution structures of the polyolefin complexes $Re(C_2H_4)(C_4H_6)(PR_3)(NO)$ **6a** and **6b**. In particular the X-ray structure of **6b** provides a good idea about the ground states of **6a** and **6b** which is pseudo tetrahedral with one ethylene group coordinated to the rhenium center in parallel orientation with respect to the Re–P axis, one *cis*-butadiene ligand bound in an $\eta^4$-coordination mode with an essentially planar carbon skeleton, one phosphane and one nitrosyl group. Complex **6a** exists in solution as a mixture of two stereoisomers **A** and **B** with either the phosphane or the olefin in the cleft of the butadiene appearing in a 3:1 ratio on the basis of the $^{31}P$ NMR spectra. Complex **6b** is expected to exclusively exist in the butadiene rotameric form **A** with the phosphane ligand oriented in the cleft of the diolefin. The potential energy surface of the model complex $Re(C_2H_4)(C_4H_6)(PMe_3)(NO)$ **6-Me** could not be fully explored, but the geometries of the global or local minima corresponding to the three possible rotational isomers **A**, **B**, and **C** were fully optimized with the help of the density functional theory (Figure 8).[60] The computed bonding energies of **6-Me** give isomer **A** as the most stable calculated structure, while **B** and **C** lie +3.9 and +8.6 kcal/mol higher in energy and thus confirm the given structural assignments for rotational isomers of **6a** and **6b**. Ethylene rotation was also checked in rotamer **A** of **6-Me**, but no other energetic minimum than the orientation parallel to the Re–P axis was found. The observed isomerism of **6a** could thus not be explained on the basis of ethylene rotational isomerism. The energy differences between structures **A** and **B** or **C** is expected to have a significant steric component and to depend on the size of the phosphane. The larger the phosphane the stronger the preference for structure **A**, since the cleft of the butadiene ligand is the only place in the molecule that provides abundant space. That would explain why **6b** with the bulky $PCy_3$ shows only isomer **A** and **6a** with the smaller $PiPr_3$ leads to rational isomerism.

## Conclusions

This work focused on the chemistry of new olefin rhenium complexes. The ethylene complexes **2a**,**b** were isolated in good yields by replacement of a MeCN group from **1a**,**b**. The ethylene ligand showed an unexpectedly high preference for the orientation parallel to the P–Re–P axis. Reduction of **1a**,**b** with sodium amalgam under 1 bar of ethylene affords the butadiene complexes **6a**,**b**. The salient features in bonding and the coordination geometry of **6a**,**b** have been clarified on the basis of NMR and X-ray analysis coupled with a theoretical treatment. The pentacoordinate $d^8$-olefin complexes demonstrated the olefin to be oriented in the trigonal plane of a trigonal bipyramid. This type of complex revealed a primary attack of the Lewis acid $B(C_6F_5)_3$ at the nitrosyl group rather than on the olefin, which eventually furnished $Re(CO)_2[NOB(C_6F_5)_3](PR_3)_2$ complexes with ethylene replacement in the presence of CO.

## Experimental Section

All operations were carried out under a nitrogen atmosphere using a M. Braun 150 G-B glove box. The solvents were dried with sodium/benzophenone (THF, $Et_2O$, hydrocarbons) or $P_2O_5$ ($CH_2Cl_2$, $CH_3CN$) and distilled under $N_2$ prior to use. The deuterated solvents used in the NMR experiments were dried with sodium/benzophenone ($C_6D_6$, [$D_8$]toluene, [$D_8$]THF) or $P_2O_5$ ($CD_2Cl_2$, $CD_3CN$) and vacuum transferred for storage in Schlenk flasks fitted with Teflon valves. NMR experiments were carried out with Varian Gemini 300, Varian Mercury 200, or Bruker DRX 500 spectrometers using 5-mm diameter NMR tubes equipped with Teflon valves, which allow degassing and further introduction of gases into the probe. Chemical shifts are given in ppm. $^1H$ and $^{13}C\{^1H\}$ NMR spectra were referenced to the residual proton or $^{13}C$ resonances of the deuterated solvent. $^{31}P$ chemical shifts are relative to 85% $H_3PO_4$. Microanalyses were carried out at the Anorganisch-Chemisches Institut of the University of Zürich. IR spectra were recorded with a Bio-Rad FTS-45 spectrometer. The following reagents were purchased from commercial suppliers and used without further purification: MeLi (Fluka), P*i*$Pr_3$ (STREM), ethylene (99.999% purity, MESSER or 99.9995% purity, PanGas), and $H_2$ (99.99995% purity, PanGas). Complexes **1a**,**b** were obtained according to literature procedures.[5]

**Synthesis of $[Re(NO)(P\mathit{i}Pr_3)_2(\eta^2\text{-}C_2H_4)Br_2]$ (2a):** Ethylene was bubbled through a solution of **1a** (0.100 g, 0.135 mmol) in toluene (20 mL) at room temperature for 1 h. After removal of the volatiles under vacuum, the residue was chromatographed on a $SiO_2$ column with toluene as a eluent yielding after drying in vacuo **2a** as a pale yellow powder (0.072 g, 0.1 mmol, 74%). IR (KBr): $\tilde{\nu}$ = 2963, 2920 and 2879 (s, νC–H), 1693 (vs, νNO) $cm^{-1}$. $^1H$ NMR (300.1 MHz, $C_6D_6$): $\delta$ = 3.12–2.95 (m, 6 H, $(CH_3)_2CHP$), 2.51 and 2.47 (2 br. signals, 4 H, $H_2C{=}CH_2$), 1.45–1.32 and 1.35–1.19 (2 m, 36 H, $(CH_3)_2CHP$) ppm. $^{31}P\{^1H\}$ NMR (80.9 MHz, $C_6D_6$): $\delta$ = –13.3 (s) ppm. $^{13}C\{^1H\}$ NMR (75.5 MHz, $C_6D_6$): $\delta$ = 39.5 (br., $H_2C{=}CH_2$), 26.2 (t, *J*(PC) = 11 Hz, $(CH_3)_2CHP$), 19.9 and 19.6 (2 s, $(CH_3)_2CHP$) ppm. $C_{20}H_{46}Br_2NOP_2Re$ (724.55): calcd. C 33.19, H 6.41, N 1.94; found C 33.39, H 6.52, N 1.93.

**Synthesis of $[Re(NO)(PCy_3)_2(\eta^2\text{-}C_2H_4)Br_2]$ (2b):** Complex **1b** (0.086 g, 0.088 mmol) in 100 mL of toluene was heated at 60 °C for one night. After cooling to room temperature, ethylene was bubbled through the solution for 1.5 h. The precipitate was collected and washed with cold THF (3 × 5 mL) and MeCN (3 × 5 mL) to afford **2b** as a pure pale yellow solid (0.066 g, 0.068 mmol, 78%). IR (KBr): $\tilde{\nu}$ = 2926 and 2879 (s, νC–H), 1696 (vs, νNO) $cm^{-1}$. $^1H$ NMR (300.1 MHz, $CD_2Cl_2$, 40 °C): $\delta$ = 3.00–1.32 ($H_2C{=}CH_2$ and $P(C_6H_{11})_3$) ppm. $^{31}P\{^1H\}$ NMR (80.9 MHz, $CD_2Cl_2$, 40 °C): $\delta$ = –20.3 (br. s) ppm. $^{13}C\{^1H\}$ NMR (75.5 MHz, $CD_2Cl_2$, 40 °C): $\delta$ = 39.5 (br., $H_2C{=}CH_2$), 36.5 (t, *J*(PC) = 9 Hz, $P(C_6H_{11})_3$), 29.4, 28.6 and 27.1 (3 s, $P(C_6H_{11})_3$) ppm. $C_{38}H_{70}Br_2NOP_2Re$ (964.93): calcd. C 47.30, H 7.31, N 1.45; found C 47.21, H 7.55, N 1.63.

**Synthesis of $[Re(NO)(P\mathit{i}Pr_3)_2(MeCN)Me_2]$ (3a):** To a solution of **1a** (0.081 g, 0.105 mmol) in 10 mL of toluene, cooled to –30 °C was added rapidly MeLi 1.6 M in $Et_2O$ (132 μL, 0.210 mmol). The color changed immediately from light orange to red. The mixture was stirred at –30 °C for 30 min then allowed to come to room temperature and stirred for additional 30 min. The solution was filtered through celite and the solvent was evaporated under vacuum. The extraction with pentane affords the red beet viscous complex **3a** (0.078 g, 0.128 mmol, 82%). IR ($CH_2Cl_2$): $\tilde{\nu}$ = 2360 (w, ν$MeC{\equiv}N$), 1588 (vs, νNO) $cm^{-1}$. $^1H$ NMR (300.1 MHz, $C_6D_6$): $\delta$ = 2.61–2.43 (m, 6 H, $(CH_3)_2CHP$), 2.36 (t, *J*(PH) = 2.20 Hz, 3 H, ReMe), 2.29 (t, *J*(PH) = 2.03 Hz, 3 H, ReMe), 1.97 (s, 3 H, MeCNRe), 1.32–1.22 (m, 36 H, $(CH_3)_2CHP$) ppm. $^{31}P\{^1H\}$ NMR (80.9 MHz, $C_6D_6$): $\delta$ = –15.9 (s) ppm. $^{13}C\{^1H\}$ NMR (125.8 MHz, $C_6D_6$): $\delta$ = 24.6 (t, *J*(PC) = 11 Hz, $(CH_3)_2CHP$), 20.6 (br. s, ReMe), 20.5 (br. s, ReMe), 20.2 and 20.1 (2s,$(CH_3)_2CHP$) ppm.

**Synthesis of $[Re(NO)(P\mathit{i}Pr_3)_2(MeCN)_2Br][BAr^F_4]$ (4a):** A solid $NaBAr^F_4$ (0.131 g, 0.148 mmol) was added to a solution of **1a** (0.114 g, 0.148 mmol) dissolved in 10 mL of MeCN. The mixture was stirred for 14 h at room temperature. The yellow solution was

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

filtered and the solvent was removed under vacuum. Extraction by $CH_2Cl_2$ and recrystallization from $CH_2Cl_2$/pentane at room temperature affords, after one day, yellow crystals of **4a** (0.188 g, 0.120 mmol, 81%). IR (KBr): $\tilde{\nu}$ = 1712 (vs, νNO) $cm^{-1}$. $^1H$ NMR (300.1 MHz, $CD_2Cl_2$): $\delta$ = 7.73 (m, 8 H, $BAr^F_4$), 7.56 (m, 4 H, $BAr^F_4$), 2.89 (s, 6 H, MeCNRe), 2.83–2.71 (m, 6 H, $(CH_3)_2CHP$), 1.42–1.33 (m, 36 H, $(CH_3)_2CHP$) ppm. $^{31}P\{^1H\}$ NMR (121.47 MHz, $CD_2Cl_2$): $\delta$ = 0.4 (s) ppm. $^{13}C\{^1H\}$ NMR (125.8 MHz, $CD_2Cl_2$): $\delta$ = 162.0 (q, $^1J$(BC) = 50 Hz, *ipso*-$BAr^F$), 137.7 (s, $H_3CCNRe$), 135.1 (s, *o*-$BAr^F$), 129.1 (br., *m*-$BAr^F$), 126.0 (q, $^1J$(CF) = 50 Hz, $CF_3$), 117.8 (br., *p*-$BAr^F_4$), 24.8 (t, *J*(PC) = 11 Hz, $(CH_3)_2CHP$), 19.1 (s, $(CH_3)_2CHP$), 5.2 (s, $H_3CCNRe$) ppm. $^{19}F$ NMR (125.8 MHz, $CD_2Cl_2$): $\delta$ = –64.4 ppm. $C_{54}H_{60}BBrF_{24}N_3OP_2Re$ (1561.91): calcd. C 41.95, H 3.91, N 2.72; found C 42.03, H 4.01, N 2.67.

**Synthesis of [Re(NO)(PCy$_3$)$_2$(MeCN)$_2$Br][BAr$^F_4$] (4b): 4b** (0.078 g, 0.042 mmol, 84%) was obtained by the same procedure described for **4a** by reaction of **1b** (0.050 g, 0.051 mmol) and $NaBAr^F_4$ (0.045 g, 0.051 mmol) in a mixture of THF/MeCN (15:1 mL) at room temperature after 30 h. IR (ATR): $\tilde{\nu}$ = 1703 (vs, νNO) $cm^{-1}$. $^1H$ NMR (300.1 MHz, $CD_2Cl_2$): $\delta$ = 2.94 (s, 6 H, $CH_3CN$-Re), 2.57–1.28 (m, 66 H, $P(C_6H_{11})_3$) ppm. $^{31}P\{^1H\}$ NMR (121.47 MHz, $CD_2Cl_2$): = –10.2 (s) ppm. $^{13}C\{^1H\}$ NMR (75.5 MHz, $CD_2Cl_2$): $\delta$ = 164.0 (m, *ipso*-$BAr^F$), 137.7 (s, $H_3CCNRe$), 135.2 (s, *o*-$BAr^F$), 129.4 (br., *m*-$BAr^F$), 129.0 (m, $CF_3$), 118.0 (br., *p*-$BAr^F_4$), 35.2 (t, *J*(PC) = 10 Hz, $P(C_6H_{11})_3$), 29.6, 28.9 and 26.8 (3 s, $P(C_6H_{11})_3$), 5.7 (s, $CH_3CN$-Re) ppm. $^{19}F$ NMR (125.8 MHz, $CD_2Cl_2$): $\delta$ = –63.9 ppm. $C_{72}H_{84}BBrF_{24}N_3O_2P_2Re$ (1818.28): calcd. C 47.56, H 4.65, N 2.31; found C 47.71, H 4.67, N 2.20.

**Synthesis of [Re(η$^4$-C$_4$H$_6$)(η$^2$-H$_2$C=CH$_2$)(NO)(P*i*Pr$_3$)$_2$] (6a):** In a 50 mL Young tap Schlenk tube the complex [Re(NO)(MeCN)-(P*i*Pr$_3$)$_2$Br$_2$] (**1a**) (0.100 g, 0.135 mmol) was dissolved in 20 mL of THF and 10 g of 0.7% sodium amalgam was added. Without stirring, the solution was frozen and kept under pressure of 1.4 bar of $C_2H_4$ for 5 min. The mixture was warmed to room temperature, and stirred for 3 d. Filtration over celite and removal of the solvent left a yellow residue, which was extracted with toluene and then dried. Final extraction with pentane affords a pure pale yellow powder of **6a** (0.020 g, 0.042 mmol, 31%). IR (ATR): $\tilde{\nu}$ = 2964, 2930 and 2872 (s, νC–H), 1646 (vs, νNO) $cm^{-1}$. $^1H$ NMR (500.25 MHz, $C_6D_6$): $\delta$ = 5.72 (q, *J*(HH) = 6.7 Hz, 1 H, $H_{int}C=CH_{int}$), 5.25 (q, *J*(HH) = 6.7 Hz, 1 H, $H_{int}C=CH_{int}$), 2.20 (m, 1 H, (HHC=CH*H*)Re), 2.06 (m, 0.34 H, $H_{syn2}H_{anti2}$CRe, isomer **B**), 1.98 (dd, $^3J$(HH) = 6.7, $^2J$(HH) = 3.5 Hz, 0.66 H, $H_{syn2}H_{anti2}$CRe, isomer **A**), 1.82 (m, 5 H, $(CH_3)_2CHP$ and (*HH*C=CHH)Re), 1.48 (m, 1 H, (HHC=C*H*H)Re), 1.18–0.98 and 0.95–0.87 (2 m, 18 H, $(CH_3)_2CHP$), 0.56 (td, $^3J$(HH) = $^3J$(PH) = 6.7 Hz, $^2J$(HH) = 3.5 Hz, 0.66 H, $H_{syn2}H_{anti2}$CRe, isomer **A**), 0.43 (td, $^3J$(HH) = $^3J$(PH) = 6.7 Hz, $^2J$(HH) = 3.5 Hz, 0.34 H, $H_{syn2}H_{anti2}$CRe, isomer **B**), –0.21 (m, 1 H, $H_{syn1}H_{anti1}$CRe), –0.52 (q, *J*(HH) = *J*(PH) = 6.7 Hz, 0.66 H, $H_{syn1}H_{anti1}$CRe, isomer **A**), –0.72 (q, *J*(HH) = *J*(PH) = 6.7 Hz, 0.34 H, $H_{syn1}H_{anti1}$CRe, isomer **B**) ppm. $^{31}P\{^1H\}$ NMR (121.5 MHz, $C_6D_6$): $\delta$ = 21.3 (br. s, isomer **A**), 12.9 (br. s, isomer **B**) ppm. $^{13}C\{^1H\}$ NMR (125.8 MHz, $C_6D_6$): $\delta$ = 97.5 (d, *J*(CP) = 2 Hz, $H_{int}C=CH_{int}$, isomer **B**), 96.14 (d, *J*(CP) = 2 Hz, $H_{int}C=CH_{int}$, isomer **A**), 83.0 (br. s, $H_{int}C=CH_{int}$, isomer **A**), 81.97 (br. s, $H_{int}C=CH_{int}$, isomer **B**), 34.0 (d, *J*(CP) = 5 Hz, $H_{syn1}H_{anti1}$CRe, isomer **B**), 32.8 (d, *J*(CP) = 5 Hz, $H_{syn1}H_{anti1}$CRe, isomer **A**), 30.5 (d, *J*(CP) = 6 Hz, $H_{anti2}H_{syn2}$CRe, isomer **A**), 29.7 (d, *J*(CP) = 6 Hz, $H_{anti2}H_{syn2}$CRe, isomer **B**), 29.2 (br. s, $(CH_3)_2CHP$, isomer **A**), 29.0 (br. s, $(CH_3)_2CHP$, isomer **B**), 25.5 (d, *J*(CP) = 8 Hz, (HH*C*=CHH)Re, isomer **A**), 24.9 (d, *J*(CP) = 8 Hz, (HH*C*=CHH)Re, isomer **B**), 24.7 (d, *J*(CP) = 3 Hz, (HH*C*=*C*HH)-Re, isomer **A**), 23.7 (d, *J*(CP) = 3 Hz, (HH*C*=*C*HH)Re, isomer **B**), 19.4 (s, $(CH_3)_2CHP$ isomer **A**), 19.0 (s, $(CH_3)_2CHP$, isomer **B**) ppm. $C_{15}H_{31}NOPRe$ (458.59): calcd. C 39.28, H 6.81, N 3.05; found C 39.46, H 6.93, N 3.18.

**Synthesis of [Re(η$^4$-C$_4$H$_6$)(η$^2$-H$_2$C=CH$_2$)(NO)(PCy$_3$)$_2$] (6b):** Complex **6b** (0.026 g, 0.045 mmol, 63%) was obtained by the same procedure described for **6a** by reduction of **1b** (0.070 g, 0.071 mmol) under a pressure of 1.4 bar of ethylene. IR (ATR): $\tilde{\nu}$ = 2924 and 2846 (vs, νC–H), 1643 (vs, νNO) $cm^{-1}$. $^1H$ NMR (500.25 MHz, $C_6D_6$): $\delta$ = 5.76 (q, *J*(HH) = 6.4 Hz, 1 H, $H_{int}C=CH_{int}$), 5.29 (q, $^3J$(HH) = 6.4 Hz, 1 H, $H_{int}C=CH_{int}$), 2.40–1.05 (m, 37 H, $(H_2C=CH_2)$Re and $P(C_6H_{11})_3$), 2.01 (dd, $^2J(H_{syn2}H_{anti2})$ = 3.3, *J*(HH) = 6.4 Hz, 1 H, $H_{syn2}H_{anti2}$CRe), 0.70 (td, *J*(HH) = 3.3, *J*(HH) = *J*(PH) = 6.4 Hz, 1 H, $H_{syn2}H_{anti2}$CRe), –0.17 (m, 1 H, $H_{syn1}H_{anti1}$CRe), –0.42 (q, *J*(HH) = *J*(PH) = 6.1 Hz, 1 H, $H_{syn1}H_{anti1}$CRe) ppm. $^{31}P\{^1H\}$ NMR (121.5 MHz, $C_6D_6$): $\delta$ = 10.0 (s) ppm. $^{13}C\{^1H\}$ NMR (125.8 MHz, $C_6D_6$): $\delta$ = 95.7 (s, $H_{int}C=CH_{int}$), 83.6 (s, $H_{int}C=CH_{int}$), 33.6 (d, *J*(CP) = 5 Hz, $H_{syn1}H_{anti1}$CRe), 32.2 (d, *J*(CP) = 19 Hz, $P(C_6H_{11})_3$), 31.7 (d, *J*(CP) = 13, $P(C_6H_{11})_3$, 30.5 (d, *J*(CP) = 5, $H_{anti2}H_{syn2}$CRe), 29.8 (br. s, $P(C_6H_{11})_3$, 27.9 (br. s, $P(C_6H_{11})_3$, 28.0 (d, *J*(CP) = 9 Hz, $P(C_6H_{11})_3$), 26.9 (br. s, $P(C_6H_{11})_3$), 25.3 (d, *J*(CP) = 8 Hz, (HH*C*=CHH)Re), 25.1 (d, *J*(CP) = 3 Hz, (HHC=*C*HH)Re) ppm. $C_{24}H_{43}NOPRe$ (578.78): calcd. C 49.80, H 7.48, N 2.42; found C 50.02, H 7.61, N 2.26.

**[Re(NO)(CO)(P*i*Pr$_3$)$_2$(η$^2$-C$_2$H$_4$)] (8a):** In a 60 mL Young tap Schlenk tube **7b** (0.100 g, 0.157 mmol) was dissolved in 30 mL of THF and 10 g of 0.7% sodium amalgam was added. Without stirring, the solution was frozen and kept under pressure of 1.4 bar of $C_2H_4$ for 5 min. The mixture was warmed to room temperature, and stirred for 5 d. The mixture was filtered through celite and the solvent was removed under vacuum. The orange residue was extracted with toluene and washed with cold pentane to afford pure **8a** (0.081 g, 0.136 mmol, 87%). Suitable X-ray crystals were obtained from a solution of **8a** in 3 mL of pentane at –30 °C. IR (ATR): $\tilde{\nu}$ = 2963, 2927 and 2872 (s, νC–H), 1879 (s, νCO), 1576 (s, νNO) $cm^{-1}$. $^1H$ NMR (300.1 MHz, $C_6D_6$, room temp.): $\delta$ = 2.16–1.84 (m, 6 H, $(CH_3)_2CHP$), 1.38–1.19 (m, 36 H, $(CH_3)_2CHP$) ppm. $C_2H_4$ not observed. $^1H$ NMR (300.1 MHz, [D$_8$]toluene, 100 °C): $\delta$ = 2.42–1.31 (m, $(CH_3)_2CHP$ partly overlap with signal of toluene $CH_3$), 1.86 (br. t, 4 H, $H_2C=CH_2$), 1.25–1.09 (m, 36 H, $(CH_3)_2CHP$) ppm. $^{31}P\{^1H\}$ NMR (121.5 MHz, $C_6D_6$, room temp.): $\delta$ = 13.4 (s) ppm. $^{13}C\{^1H\}$ NMR (75.5 MHz, [D$_8$]toluene, 90 °C): $\delta$ = 218.4 (t, *J*(PC) = 12 Hz, C=O), 25.1 (t, *J*(PC) = 23 Hz, $(CH_3)_2CHP$), 23.0 (br. s, $H_2C=CH_2$), 20.6 and 19.3 (2 s, $(CH_3)_2CHP$) ppm. $C_{21}H_{46}NO_2P_2Re$ (592.75): calcd. C 42.55, H 7.82, N 2.36; found C 42.69, H 8.12, N 2.35.

**[Re(NO)(CO)(PCy$_3$)$_2$(η$^2$-C$_2$H$_4$)] (8b):** Complex **8b** (0.086 g, 0.103 mmol, 90%) was obtained by the same procedure as described for **8a** via reduction of $[Re(NO)(CO)(PCy_3)_2Cl_2]$ (0.100 g, 0. 114 mmol) using 10 g of 0.7% sodium amalgam and 1.4 bar $C_2H_4$. IR (ATR): $\tilde{\nu}$ = 2925 and 2848 (s, νCO), 1883 (s, νCO), 1585 (vs, νNO) $cm^{-1}$. $^1H$ NMR (300.1 MHz, $C_6D_6$, room temp.): $\delta$ = 2.17–1.17 ($H_2C=CH_2$ and $P(C_6H_{11})_3$) ppm. $^{31}P\{^1H\}$ NMR (80.9 MHz, $C_6D_6$): $\delta$ = 5.7 (s) ppm. $^{13}C\{^1H\}$ NMR (75.5 MHz, [D$_8$]toluene, –20 °C): $\delta$ = 218.5 (t, *J*(PC) = 12 Hz, C=O), 34.4 (br., $P(C_6H_{11})_3$), 30.7, 30.3, 27.3 (3 s, $P(C_6H_{11})_3$), 23.0 (br. s, $H_2C=CH_2$) ppm. $C_{39}H_{70}NO_2P_2Re$ (833.13): calcd. C 56.22, H 8.47, N 1.68; found C 56.67, H 8.59, N 1.61.

**NMR Tube Reactions. Synthesis of [Re(η$^2$-H$_2$)(NO)(PR$_3$)$_2$Br$_2$] (R = *i*Pr 5a, R = Cy 5b):** A solution of **1a** (0.010 g, 0.013 mmol) in 0.5 mL $C_6D_6$ or **1b** (0.012 g, 0.012 mmol) in 0.5 mL of $CD_2Cl_2$ was

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

sealed under 1 bar of $H_2$. Formation of **5a**,**b** takes place immediately upon shaking of the tubes. All NMR spectroscopic data are in agreement with those previously reported.[5]

**Reaction of [Re(NO)(CO)(P*i*Pr$_3$)$_2$(η$^2$-C$_2$H$_4$)] (8a) with B(C$_6$F$_5$)$_3$ to Yield [Re(CO)$_2${NOB(C$_6$F$_5$)$_3$}(P*i*Pr$_3$)$_2$] (9a) and [Re(NO)(CO)$_2$-(PCy$_3$)$_2$] (10a):** A solution of $B(C_6F_5)_3$ (0.048 g, 0.094 mmol) in 1 mL of toluene was added dropwise with stirring to a solution of **8a** (0.056 g, 0.094 mmol) in the same solvent. The mixture was stirred further at room temperature for 22 h. The solvent was then removed in vacuo and the residue extracted with pentane and recrystallized from the same solvent at –30 °C to afford orange crystals of **9a**; yield 0.039 g, 0.036 mmol, 38%. **9a** and **10a** were identified by their IR spectra: **9a** IR (ATR): $\tilde{\nu}$ = 1968 (s, νCO),

1883 (s, νCO), 1458 (s, νNO) $cm^{-1}$. **10a** IR (hexane): $\tilde{\nu}$ = 1940 (s, νCO), 1852 (s, νCO), 1605 (s, νNO) $cm^{-1}$.

**Synthesis of $[Re(CO)_2\{NOB(C_6F_5)_3\}(PiPr_3)_2]$ (9a):** A solution of $B(C_6F_5)_3$ (0.064 g, 0.124 mmol) in 2 mL of toluene was added to a solution of **8a** (0.074 g, 0.124 mmol) in 15 mL of the same solvent in a Young tap Schlenk tube. Without stirring the mixture was frozen and kept under pressure of 1 bar of CO for 3 min. The mixture was warmed to room temperature and stirred for 15 min. The gas and the solvent were removed in vacuo and the orange residue was extracted with $CH_2Cl_2$ and washed several times using cold pentane to afford pure **9a** (0.126 g, 0.114 mmol, 92%). IR (ATR): $\tilde{\nu}$ = 1968 (s, νCO), 1883 (s, νCO), 1458 (s, νNO) $cm^{-1}$. $^1H$ NMR (300.1 MHz, [D$_8$]toluene): $\delta$ = 0.92–0.80 (m, 6 H, $(CH_3)_2CHP$), 1.82–1.71 (m, 36 H, $(CH_3)_2CHP$) ppm. $^{31}P\{^1H\}$ NMR (121.5 MHz, [D$_8$]toluene): $\delta$ = 32.3 (s) ppm. $^{13}C\{^1H\}$ NMR (125.8 MHz, [D$_8$]toluene): $\delta$ = 215.9 (br., C=O), 24.0 (t, $J$(PC) = 11 Hz, $(CH_3)_2CHP$), 18.6 and 18.4 (2 s, $(CH_3)_2CHP$) ppm. $C_{38}H_{42}BF_{15}NO_3P_2Re$ (1104.68): calcd. C 41.31, H 3.83, N 1.27; found C 41.75, H 3.78, N 1.30.

**Synthesis of $[Re(CO)_2\{NOB(C_6F_5)_3\}(PCy_3)_2]$ (9b):** Complex **9b** (0.088 g, 0.066 mmol, 90%) was obtained using the same procedure as described for **9a** (method B) via the reaction of **8b** (0.062 g, 0.074 mmol), $B(C_6F_5)$ (0.038 g, 0.074 mmol) under 1 bar of CO. IR (ATR): $\tilde{\nu}$ = 1974 (s, νCO), 1875 (s, νCO), 1457 (s, νN–OB) $cm^{-1}$. $^1H$ NMR (200.0 MHz, $C_6D_6$, room temp.): $\delta$ = 2.20–0.81 (m, $P(C_6H_{11})_3$) ppm. $^{31}P\{^1H\}$ NMR (80.9 MHz, $C_6D_6$): $\delta$ = 24.6 (s) ppm. $^{13}C\{^1H\}$ NMR (75.5 MHz, $C_6D_6$): $\delta$ = 211.5 (br., C=O), 37.7 (t, $J$(PC) = 13 Hz, $P(C_6H_{11})_3$, 30.5, 27.4 and 26.0 (3s, $P(C_6H_{11})_3$) ppm. $C_{56}H_{66}BF_{15}NO_3P_2Re$ (1345.07): calcd. C 50.00, H 4.94, N 1.04; found C 50.09, H 5.03, N 1.00.

**X-ray Structure Analyses of Compounds 4a, 4b, 6b, 8a, 9a, and 9b:** All six crystals were protected in hydrocarbon oil and prepared for the X-ray experiment by using a polarizing microscope. Selected crystals of **4a**, **4b**, **6b**, **8a**, **9a**, and **9b** (Table 8) were mounted on the tip of a glass fiber and immediately transferred to the goniometer of an imaging plate detector system (Stoe IPDS diffractometer). The crystals were cooled to 183(2) K and 193(2) K (**8a**) in an Oxford Cryogenic System. The crystal-to-image distances were set to 60, 70, 50, 50, 50, and 50 mm resulting in $\theta_{max}$ values of 28.05, 25.92, 30.43, 30.39, 30.39, and 30.39°. For compounds **8a**, **9a**, and **9b** rotation, and for **4a**, **4b**, and **6b** oscillation scan modes were applied. 8000 (5000 for **9a**) reflections with $I > 6\sigma(I)$ were selected for the cell parameter refinements. A total of 26224 (**4a**), 53039 (**4b**), 51454 (**6b**), 29650 (**8a**), 51447 (**9a**), and 43505 (**9b**) diffraction intensities were collected of which 7594, 15066, 7139, 7583, 13094, and 15287 were unique ($R_{int}$ = 6.52, 8.59, 6.13, 5.01, 14.04, and 8.64%) after data reduction. Numerical absorption corrections based on 12, 17, 8, 10, 15, and 7 crystal faces were applied with FACEitVIDEO and XRED.[60] The structures were solved by the Patterson (for **4a**, **6b**, **8a**, **9a**, **9b**) and by direct methods (for **4b**) using the SHELXS-97 program.[61] Interpretation of the difference electron density maps, preliminary plot generation, and checking for higher symmetry were done with PLATON[62] (1990, 1991–2005) and with the LEPAGE program.[63] All structures were refined with the program SHELXL-97[61] using anisotropic displacement parameters for heavy atoms, some exceptions in disordered structures **4a** and **4b** are given in the CIF files (see CCDC deposition numbers, see below). Positions of H-atoms were calculated after each refinement cycle (riding model). Structural plots were generated using ORTEP III.[64] For the achiral non-centrosymmetric structure of **4b** the correct space group choice ($Pna2_1$, no. 33) was confirmed by Flack's parameter $x$[65] and PLATON.[62] Refinement details are given in the "_exptl_special_details" in the respective cif files.

**Computational Details:** DFT calculations were carried out using the Amsterdam Density Functional program package ADF, release 2004.01.[57] We used the Vosko–Wilk–Nusair[66] local density approximation (LDA) and the generalized gradient approximation (GGA) with corrections for exchange and correlation according to Becke[67] and Lee–Yang–Parr,[68] respectively (BLYP). The ADF approach to DFT-GGA calculations is based on the use of Slater-type orbitals (STO) as basis functions. The valence shells of all atoms were described by double-$\xi$ basis sets augmented by one polarization function (ADF database DZP), except for rhenium for which a triple-$\xi$ basis set was applied (ADF database TZP). The frozen-core approximation was applied for the 1s electrons of carbon, oxygen, and nitrogen, for the 1s-2p electrons of phosphorus and chlorine, for the 1s-3d electrons of bromine and for the 1s-4f electrons of rhenium. Relativistic effects were taken into account in all calculations using the zero order regular approximation (ZORA).[69] The relativistic atomic potentials necessary for the relativistic calculations for each atom were calculated using the auxiliary program DIRAC, which is supplied with the ADF program package. The geometry optimizations were considered converged when the change in the maximum gradient element was smaller than $5.0 \times 10^{-4}$ Hartrees $Å^{-1}$. The other convergence criteria referring to changes in total energy, Cartesian or internal coordinates had to converge to the default values proposed by the program.

CCDC-297768 to -297771 (for **4a**, **4b**, **8a**, **9a**) and -609682 to -609683 (for **6b** and **9b**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from the Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

# Divalent Nickel, Cobalt and Iron Complexes of an Amide-Appended $N_2S_2$ Ligand: Synthesis, Characterization and Reactivity with Hydroxide Anion

**Gajendrasingh K. Ingle,[a] Magdalena M. Makowska-Grzyka,[a] Atta M. Arif,[b] and Lisa M. Berreau*[a]**

**Keywords:** N,S ligands / Amides / Metal effects / Deprotonation

Divalent nickel, cobalt and iron complexes {[(bmppa)-Ni($CH_3CN$)]($ClO_4$)$_2$ (**1**), [(bmppa)Co($CH_3CN$)]($ClO_4$)$_2$ (**2**), [(bmppa)Fe($CH_3CN$)]($ClO_4$)$_2$ (**3**)} of an amide-appended $N_2S_2$-donor ligand {bmppa = *N*,*N*-bis(2-methylthio)ethyl-*N*-[(6-pivaloylamido-2-pyridyl)methyl]amine} have been prepared and characterized using $^1$H NMR, IR, UV/Vis, elemental analysis and magnetic moment measurements. The complexes **2** and **3** were also characterized by X-ray crystallography. When treated with 1 equiv. of $Me_4NOH{\cdot}5H_2O$ in methanol, **1** and **2** form deprotonated amide complexes {[(bmppa$^-$)Ni]$ClO_4$ (**4**), [(bmppa$^-$)Co]$ClO_4{\cdot}H_2O$ (**5**)} which were isolated and characterized by $^1$H NMR, IR, UV/Vis, elemental analysis and magnetic moment measurements. Treatment of the $Fe^{II}$ complex **3** with 1 equiv. of $Me_4NOH{\cdot}5H_2O$ in methanol produced the free bmppa chelate ligand and a precipitate of an unidentified iron species. Heating of **5** at 50 °C in methanol for 5 d resulted in a ca. 50 % yield of amide methanolysis products and a small amount of products resulting from oxidative *N*-dealkylation of the bmppa ligand. It has been previously shown that a zinc analog of **5** undergoes quantitative amide methanolysis under milder conditions. Complex **4** does not undergo amide cleavage upon heating at 50 °C in methanol for 5 d. A rationale for the metal-dependent amide methanolysis reactivity of these complexes is proposed on the basis of structural differences in the "parent" protonated complexes.

## Introduction

Amide cleavage reactions are catalyzed by a variety of metal-containing enzymes. An amide hydrolase that has received considerable recent attention is peptide deformylase (PDF). In the active site of PDF, a nitrogen/sulfur-ligated iron(II) center is involved in the hydrolysis of a formamide moiety during polypeptide biosynthesis.[1–4] Notably, replacement of the $Fe^{II}$ ion with $Ni^{II}$ and $Co^{II}$ produces catalytically active enzyme.[2,3,5–8] However, with $Zn^{II}$ as the active-site metal ion, the enzyme activity is reduced by ca. 100-fold.[7,9]

To investigate the role of the metal center in PDF enzymes, Goldberg and co-workers have investigated the structural and spectroscopic properties of synthetic complexes of relevance to resting state and formato-bound forms of the enzyme.[10–14] These complexes are supported by an $N_2S$(thiolate) ligand {PATH = 2-methyl-1-[methyl(2-pyridin-2-ylethyl)amino]propane-2-thiolate}. A zinc hydroxide complex of the PATH ligand has been shown to promote the hydrolysis of phosphate and carboxy esters;[12,13] however, no reactivity with an amide substrate has been reported.

We recently reported studies of the formyl ester and formamide cleavage reactivity of a $Zn^{II}$–OH complex, [(bmnpaZn)$_2$(μ-OH)$_2$]($ClO_4$)$_2$, supported by an $N_2S_2$ ligand containing an internal hydrogen-bond donor.[15] In acetonitrile, this complex promotes the hydrolysis of methyl formate to produce methanol and a (formato)zinc complex {[(bmnpa)Zn($O_2CH$)]$ClO_4$}. In methanol, the (hydroxido)-zinc complex reacts with the alcohol to produce a (methoxido)zinc complex. Treatment of this Zn–OMe complex with formanilide results in the formation of aniline, methyl formate, and [(bmnpa)Zn($O_2CH$)]$ClO_4$. The formation of both methyl formate and the (formato)zinc complex indicated that both methanolysis and hydrolysis reactions occur in the reaction mixture.

Recently, we investigated in detail the amide methanolysis reactivity of zinc complexes of amide-appended $N_4$, $N_3S$, and $N_2S_2$ donor ligands in the presence of hydroxide anion in methanol.[16–18] The reaction pathway for amide cleavage in these systems was found to involve the initial formation of a (deprotonated amide)zinc complex which subsequently undergoes reaction with methanol to produce a reactive complex for amide methanolysis. The products generated in these amide methanolysis reactions

are a zinc complex of a primary amine-appended chelate ligand, methyl trimethylacetate, and 1 equiv. of $Me_4NClO_4$.[16–18]

The research described herein examines how the amide methanolysis reactivity of divalent metal complexes of an amide-appended $N_2S_2$ ligand is influenced by the nature of the metal center. This work has some relevance to peptide deformylase, as we have examined the structural, spectroscopic, and amide cleavage reactivity properties of $Ni^{II}$, $Co^{II}$, and $Fe^{II}$ analogs of $[(bmppa)Zn](ClO_4)_2$ {bmppa = *N*,*N*-bis(2-methylthio)ethyl-*N*-[(6-pivaloylamido-2-pyridyl)-methyl]amine}.[16,18] To the best of our knowledge, this is the first direct comparison of amide cleavage reactivity in structurally related complexes of these metal ions. Findings of this study include: (1) similar to the chemistry of $[(bmppa)Zn](ClO_4)_2$, the $Ni^{II}$ and $Co^{II}$ analogs form deprotonated amide complexes upon treatment with hydroxide anion, whereas the $Fe^{II}$ analog decomposes to yield free bmppa ligand and unidentified iron species; and (2) of the non-zinc metals only the (deprotonated amide)$Co^{II}$ complex reacts with methanol to yield amide methanolysis products, albeit in lower yield than the zinc analog. A rationale for the metal-dependent amide methanolysis reactivity of these complexes is proposed on the basis of structural differences in the "parent" protonated complexes.

## Results and Discussion

### Synthesis and Characterization of Divalent Metal Complexes

Mononuclear divalent nickel, cobalt, and iron complexes of the bmppa ligand were prepared by treatment of the ligand with $[M(H_2O)_6](ClO_4)_2$ (M = Ni, Co, and Fe) in methanol. Recrystallization of the resulting metal complex from acetonitrile-containing solutions resulted in the isolation of $[(bmppa)M(CH_3CN)](ClO_4)_2$ (**1**: M = $Ni^{II}$; **2**: M = $Co^{II}$; **3**: M = $Fe^{II}$; Scheme 1). Each complex has been characterized by elemental analysis, $^1H$ NMR, FTIR, UV/Vis spectroscopy, mass spectrometry, and a magnetic moment measurement. For **2** and **3**, crystals suitable for single-crystal X-ray diffraction were obtained.

ORTEP drawings of the cationic portions of the X-ray structures of **2** and **3** are shown in Figure 1. Selected bond lengths and angles are given in Table 1. These complexes are nearly isostructural, with both crystallizing in the $P2_1/c$ space group. In each the divalent metal center is ligated by all of the available donor atoms of the chelate ligand and one acetonitrile solvent molecule. The geometry of the metal center in these complexes is distorted octahedral with the acetonitrile molecule positioned in the same plane as the chelate ring containing the amide moiety, thereby bisecting the S(1)–M–S(2) angle. In comparing **2** and **3**, the average M–S (**2**: 2.50 Å; **3**: 2.33 Å) and M–N (**2**: 2.10 Å; **3**: 1.99 Å) bonds are notably longer in the $Co^{II}$ derivative, whereas the M–O(1) distances differ by only ca. 0.06 Å [**2**: Co–O(1) 2.0125(15) Å; **3**: Fe–O(1) 1.956(2) Å].

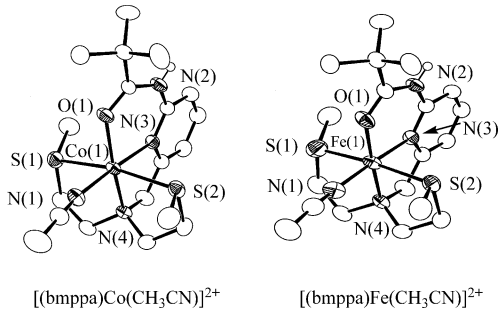

Figure 1. ORTEP drawings of the cationic portions of **2** (left) and **3** (right). Ellipsoids are plotted at the 50% probability level. All hydrogen atoms except the amide proton are not shown for clarity.

The solid-state FTIR spectral features of **1**–**3** in KBr are consistent with amide coordination. Specifically, the amide C–O stretching vibration is shifted to lower energy (ca. 1648–1633 $cm^{-1}$) as compared to the position of this vibration in the free bmppa ligand (1687 $cm^{-1}$). Solution IR spectra of **1**–**3** in acetonitrile (100 mM) have features in the region of 1700–1550 $cm^{-1}$ that are very similar to the solid-state spectra, providing evidence that amide coordination is maintained in solution. In the solid-state FTIR spectra, each complex exhibits a $\nu_{N-H}$ stretching vibration at ca. 3350–3300 $cm^{-1}$. The solution UV/Vis absorption spectral features of **1**–**3** are summarized in Table 2. All complexes show strong ligand-based absorptions at <400 nm. For **2**, a 511 nm ($\varepsilon$ = 44 $M^{-1}cm^{-1}$) transition is consistent with the $Co^{II}$ center having a six-coordinate pseudo-octahedral geometry in solution.[19] Each complex contains a high-spin pseudo-octahedral metal center, as evidenced by solution

[a] Spectra collected in $CH_3CN$.

Complexes **1**–**3** exhibit paramagnetically shifted $^1H$ NMR spectra. These spectra are shown in Figures 2, 3, and 4 to illustrate that each complex exhibits signals that can be identified on the basis of integrated intensity, deuterium substitution, and/or $^1H$-$^1H$ COSY experiments. When dissolved in $CD_3CN$, complex **1** (Figure 2) exhibits a *tert*-butyl methyl signal at $\delta$ = 4.6 ppm and an amide proton resonance at $\delta \approx -6$ ppm, the latter of which was assigned by deuterium substitution (with $D_2O$). In the region of $\delta \approx$ 180–10 ppm are several resonances. A sharp signal at $\delta$ = 14.2 ppm has been tentatively assigned as the γ-H of the pyridyl ring. While the remaining signals have not been conclusively assigned, we believe that the signals at $\delta \approx$ 49 and 73 ppm are for the β-H atoms of the pyridyl ring. For **2** in $CD_3CN$ (Figure 3), the *tert*-butyl methyl signal is found at $\delta \approx$ 28 ppm. The β-H and γ-H signals for this complex have been assigned on the basis of a $^1H$-$^1H$ COSY spectrum. Addition of $D_2O$ to a solution of **2** in $CD_3CN$ failed to reveal the signal of the amide hydrogen atom (by loss of the $^1H$ signal). When dissolved in $CD_3CN$, complex **3** (Figure 4) exhibits resonances in the range of $\delta \approx$ 110–0 ppm. The *tert*-butyl methyl resonance of **3** is found at $\delta$ = 4.2 ppm in dry $CD_3CN$. We tentatively assigned the β-H and γ-H signals for this complex as shown in Figure 4 on the basis of peak width and intensity. The $^1H$ NMR features of this complex exhibit a solvent dependence, with addition of a small amount of $D_2O$ (2 μL) to a water-free $CD_3CN$ solution of **3** producing an upfield shift of the *tert*-butyl resonance to $\delta \approx$ 3.4 ppm. The addition of $D_2O$ also produces changes in the spectrum in the region of $\delta$ = 20–30 ppm. Analysis of the $^1H$ NMR features of **3** as a function of solvent remains under investigation.

### Reactivity of 1–3 with Hydroxide Anion in Methanol – Isolation of Deprotonated Amide Complexes

We have previously reported that treatment of [(bmppa)Zn]$(ClO_4)_2$ with $Me_4NOH{\cdot}5H_2O$ in methanol-containing solutions results in amide methanolysis.[16,18] This reaction proceeds through the initial formation of a depronated amide complex, [(bmppa$^-$)Zn]$ClO_4$, which subsequently undergoes reaction with methanol to produce the reactive species for amide cleavage.[18] Treatment of **1** with $Me_4NOH{\cdot}5H_2O$ in methanol results in the formation of the deprotonated amide complex [(bmppa$^-$)Ni]$ClO_4$ (**4**, Scheme 2) which has been isolated and characterized by elemental analysis, FTIR, UV/Vis, $^1$H NMR spectroscopy, and a solution magnetic moment measurement. The elemental analysis data for **4** is best fit with one perchlorate anion and no coordinated solvent molecules, suggesting an overall coordination number of five for the $Ni^{II}$ center. The FTIR spectrum of **4** differs from that of [(bmppa)Ni$(CH_3CN)](ClO_4)_2$ (**1**) in that intense vibrations found in the region of ca. 1600–1635 $cm^{-1}$ for **1**, which include the $\nu(CO_{amide})$ vibration, are not present in the spectrum of **4**. Instead, a series of intense new vibrations is centered at ca. 1450 $cm^{-1}$, which is consistent with the presence of a deprotonated amide moiety.[17] The UV/Vis absorption spectral features and solution magnetic moment of **4** are given in Table 3. The absorption and $^1$H NMR (Figure 5) spectral features of **4** are different from those of **1**. In the $^1$H NMR spectrum of **4** no signal upfield of zero is present, consistent with amide deprotonation. Two prominent resonances at $\delta \approx 49$ and 73 ppm in the spectrum of **1** appear to have shifted to $\delta \approx 61$ and 64 ppm in **4**. These resonances are assigned to the β-H atoms of the pyridyl ring. It is important to note that resonance structures for the deprotonated amide moiety can be drawn wherein the anionic charge is positioned at the β-carbon atoms of the pyridyl ring, thus providing a rational for why the β-H signals shift upon deprotonation.[17] The *tert*-butyl methyl signal of **4** is shifted slightly downfield ($\delta$ = 5.6 ppm) relative to the position of the same signal of **1** ($\delta$ = 4.6 ppm). The γ-H resonances of **1** and **4** are at nearly identical chemical shifts ($\delta$ = 14.2 ppm).

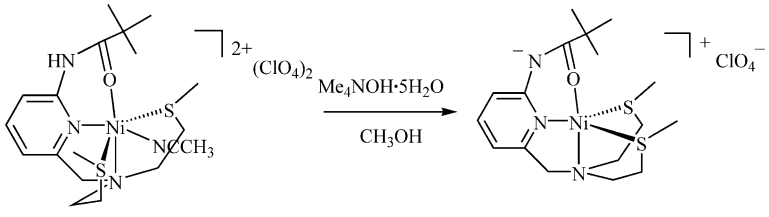
|---|---|---|
| UV/Vis: $\lambda$ [nm] ($\varepsilon$ [$M^{-1}cm^{-1}$])[a] | 530 (20), 835 (20), 1034 (35) | 548 (140) |
| $\mu_{eff}$ [$\mu_B$] | 3.1 | 3.7 |

[a] Spectra collected in $CH_3CN$.

Treatment of [(bmppa)Co$(CH_3CN)](ClO_4)_2$ (**2**) with $Me_4NOH{\cdot}5H_2O$ results in the formation of a brown deprotonated amide complex, [(bmppa$^-$)Co]$ClO_4{\cdot}H_2O$ (**5**). The elemental analysis of **5** is best fit with the inclusion of one water molecule in the bulk, isolated sample of the com-



[(bmppa)Ni$(CH_3CN)](ClO_4)_2$ (**1**) [(bmppa$^-$)Ni]$ClO_4$ (**4**)

pound. Additional evidence for the presence of this water molecule comes from FTIR spectroscopic analysis of a crystalline sample of the complex, which revealed a $\nu_{O-H}$ vibration at 3430 $cm^{-1}$. Also present in the FTIR spectrum of **5** is an intense set of vibrations at ca. 1450 $cm^{-1}$, which is characteristic of the presence of a deprotonated amide moiety.[17] The UV/Vis absorption spectrum of **5** includes a d–d transition at 548 nm ($\varepsilon$ = 140 $M^{-1}cm^{-1}$). The intensity of this absorption band is consistent with the $Co^{II}$ center having a coordination number of five in acetonitrile.[19] On the basis of this spectroscopic data, we propose that the $Co^{II}$ center in **5** is ligated by the five available donors in the deprotonated bmppa$^-$ ligand and that the water molecule is not coordinated to the metal center. The difference in coordination number between **5** and **2** may be the reason why the $^1$H NMR features of **5** (Figure 6) are noticeably different from those of its protonated analog (Figure 3). Specifically, whereas **5** has resonances over a ca. 120 ppm region, the parent complex **2** has signals over a ca. 80 ppm region. Overall, the deprotonated amide complex exhibits generally sharper signals. In terms of specific resonances, complex **5** has a *tert*-butyl methyl resonance at $\delta \approx 22$ ppm whereas for **2** this signal is found at $\delta$ = 29 ppm. Similarly, **5** exhibits a γ-H resonance ($\delta$ = 14.2 ppm) upfield of where this signal appears in the $^1$H NMR spectrum of **2** ($\delta$ = 22.0 ppm). The magnetic moment for **5** ($\mu_{eff}$ = 3.7 $\mu_B$) is slightly below the spin-only value calculated for three unpaired electrons ($\mu_{eff}$ = 3.87 $\mu_B$). Thus far, efforts to generate X-ray quality crystals of **5** have failed, with only microcrystalline solids being isolated.

Treatment of the $Fe^{II}$ complex [(bmppa)Fe(CH$_3$CN)](ClO$_4$)$_2$ (**3**) with $Me_4NOH{\cdot}5H_2O$ in methanol under nitrogen results in the formation of a dark green precipitate in a yellow solution. Physical separation of the precipitate and the soluble components, followed by removal of the solvent from the soluble portion, yielded the free bmppa ligand in 78% yield. The green precipitate was dried under vacuum and analyzed by IR spectroscopy. This solid contains $Me_4NClO_4$ as well as unidentified iron species.

Overall, these studies revealed that, while stable divalent metal ion complexes of the deprotonated amide bmppa$^-$ ligand can be formed for $Ni^{II}$ and $Co^{II}$, an $Fe^{II}$ analog cannot be generated under similar conditions.

### Heating of 4 and 5 in Methanol

Heating of a methanol solution of the (deprotonated amide)$Ni^{II}$ complex **4** at 50 °C for 5 d, followed by removal of the $Ni^{II}$ ion using aqueous $Na_2EDTA$, produced the unaltered bmppa ligand in quantitative yield. Thus, complex **4**, which contains a deprotonated amide moiety akin to that found in [(bmppa$^-$)Zn]$ClO_4$,[17] does not undergo amide methanolysis. A rationale for the difference in reactivity between **4** and [(bmppa$^-$)Zn]$ClO_4$ involves the location of an anion binding site on the metal center. For the (deprotonated amide)$Ni^{II}$ complex, reaction with methanol could produce a pseudo-octahedral complex, wherein the methoxide is in the same plane with the coordinated amide (Figure 7). This orientation would not be productive for intramolecular amide cleavage. For the zinc derivative, we have previously proposed that the reactive species involves a tri-

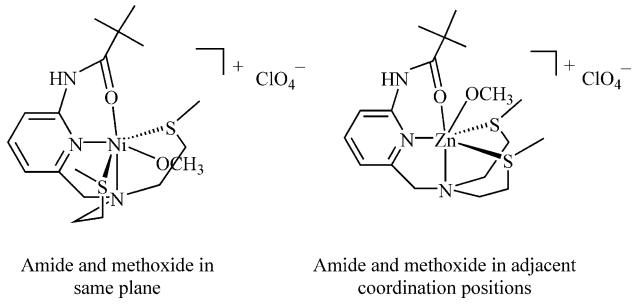

Figure 7. Proposed orientation of amide and methoxide anion in $Ni^{II}$ and $Zn^{II}$ complexes of the bmppa ligand.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

gonal-prismatic structure, wherein the coordinated methoxide nucleophile and amide are in adjacent coordination positions (Figure 7).[17]

Heating of a methanol solution of the deprotonated amide complex **5** at 50 °C for 5 d under nitrogen, followed by removal of the $Co^{II}$ ion using aqueous $Na_2EDTA$ produced the amide methanolysis product bmapa {*N*,*N*-bis(2-methylthio)ethyl-*N*-[(6-amino-2-pyridyl)methyl]amine} in ca. 50% yield, along with unaltered bmppa ligand (ca. 43%), and a third product, *N*-(6-formylpyridin-2-yl)-2,2-dimethylpropanamide (ca. 7%).[21] The other amide methanolysis product (methyl trimethylacetate) is volatile and was not isolated or quantified. We attribute the formation of the aldehyde product to the presence of a trace amount of $O_2$ in the reaction mixture. Cobalt(II) complexes have been previously shown to undergo reaction with $O_2$ to generate reactive $Co^{III}$ peroxide or hydroperoxide complexes that mediate the *N*-dealkylation of supporting chelate ligands.[23] The production of only ca. 50% of the chelate ligand amide methanolysis product after 5 d at 50 °C contrasts with the reactivity of the zinc analog [(bmppa$^-$)Zn]-$ClO_4$, wherein a 96% yield of bmapa is obtained after heating of the complex in methanol at 40(1) °C for 48 h and removal of the $Zn^{II}$ ion. Note that control reactions have demonstrated that the bmppa ligand is unreactive in the absence of a metal ion.[16] On the basis of the structure of **2**, we speculate that a six-coordinate cobalt methoxide species may adopt either of the two structural types shown in Figure 7. If the thermodynamically more stable form is the pseudo-octahedral complex, it may rearrange with increased temperature to produce a pseudo-trigonal-prismatic geometry that is the reactive species for intramolecular amide methanolysis. Of relevance to this chemistry, we note that a trigonal-prismatic type of geometry, as is proposed for the $Zn^{II}$ cation shown in Figure 7, has been previously identified in cadmium and mercury "parent" complexes of the bmppa and beppa {*N*,*N*-bis(2-ethylthio)ethyl-*N*-[(6-pivaloylamido-2-pyridyl)methyl]amine} ligands.[16,24] These complexes undergo methanolysis of the amide when treated with 1 equiv. of base in methanol-containing solutions. In the crystal structures of the $Cd^{II}$ and $Hg^{II}$ complexes a perchlorate anion is coordinated to the metal center (Figure 8). This perchlorate interaction produces an overall distorted trigonal-prismatic geometry at the metal center. We propose that the $-OCD_3$ nucleophile (Figure 7) interacts with the metal center in a similar fashion.

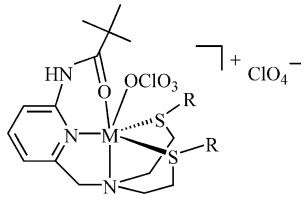

Figure 8. Structural features of cadmium and mercury "parent" complexes of amide-appended $N_2S_2$ ligands.

## Conclusions

Divalent nickel, cobalt and iron complexes of the amide-appended $N_2S_2$ donor ligand bmppa have been isolated and characterized. These "parent" complexes exhibit distorted octahedral structures and amide oxygen coordination. In the presence of base, the $Ni^{II}$ and $Co^{II}$ complexes undergo reaction to yield isolable deprotonated amide complexes that have been characterized by multiple methods. Heating of methanol solutions of these deprotonated amide complexes produces amide cleavage products only in the case of the $Co^{II}$ derivative. Notably, the reaction involving the $Co^{II}$ complex is slower than the corresponding reaction involving a zinc analog. We propose that this difference is due to the reactive zinc complex exclusively adopting a distorted trigonal-prismatic geometry, whereas the $Co^{II}$ analog may also adopt an unreactive distorted octahedral geometry. These results demonstrate the important role of metal coordination geometry preferences in influencing amide cleavage reactivity.

## Experimental Section

**General Remarks:** Reagents and solvents were purchased from commercial sources and were used as received unless otherwise noted. Solvents for glove-box use were dried according to published procedures and were degassed prior to use.[25] FTIR spectra were recorded with a Shimadzu FTIR-8400 spectrometer as KBr pellets or as $CH_3CN$ solutions (100 mM). $^1H$ and/or {$^1H$,$^1H$} COSY NMR spectra of paramagnetic $Ni^{II}$, $Co^{II}$, and $Fe^{II}$ complexes were recorded in dry $CD_3CN$ with a Bruker ARX-400 spectrometer. Chemical shifts (in ppm) are referenced to the residual solvent peak in $CD_3CN$ [$^1H$: $\delta$ = 1.94 (quint) ppm]. The chelate ligand bmppa {*N*,*N*-bis(2-methylthio)ethyl-*N*-[(6-pivaloylamido-2-pyridyl)methyl]amine} was prepared as previously reported.[26] ***Caution!*** Perchlorate salts of metal complexes with organic ligands are potentially explosive. These compounds should be handled in small quantities and with extreme caution, especially in the solid state.[27]

**[(bmppa)Ni($CH_3CN$)]($ClO_4$)$_2$ (1):** $Ni(ClO_4)_2{\cdot}6H_2O$ (0.0395 g, 0.108 mmol) dissolved in methanol (2 mL) was added to a solution of bmppa (0.0384 g, 0.108 mmol) in methanol (2 mL). The resulting purple solution was stirred at room temperature for ca. 30 min. Addition of excess of diethyl ether (ca. 60 mL) to the reaction mixture, followed by cooling at –15 °C for ca. 12 h resulted in the deposition of a purple precipitate, which was isolated and dried under vacuum. Recrystalization of this purple powder by diethyl ether diffusion into $CH_3CN/CH_3OH$ (1:1) at ambient temperature yielded purple needle crystals (0.050 g, 70%). FTIR (KBr): $\tilde{\nu}$ = 3336 ($\nu_{N-H}$), 1649, 1617, 1530, 1457, 1427, 1169, 1103, 1080 ($\nu_{ClO4}$), 796, 623 ($\nu_{ClO4}$) cm$^{-1}$. FTIR ($CH_3CN$, 100 mM, 1700–1550 cm$^{-1}$ region): $\tilde{\nu}$ = 1653, 1620 cm$^{-1}$. $C_{19}H_{32}Cl_2N_4NiO_9S_2$ (652.03): calcd. C 34.97, H 4.95, N 8.59; found C 35.15, H 4.95, N 8.65.

**[(bmppa)Co($CH_3CN$)]($ClO_4$)$_2$ (2):** This complex was prepared in an identical manner to **1**. Deep pink blocks suitable for X-ray diffraction studies were obtained from $CH_3CN/Et_2O$ (0.044 g, 65%). FTIR (KBr): $\tilde{\nu}$ = 3318 ($\nu_{N-H}$), 1635, 1612, 1528, 1452, 1422, 1099 ($\nu_{ClO4}$), 791, 619 ($\nu_{ClO4}$) cm$^{-1}$. FTIR ($CH_3CN$, 100 mM, 1700–1550 cm$^{-1}$ region): $\tilde{\nu}$ = 1653, 1648, 1619 cm$^{-1}$. $C_{19}H_{32}Cl_2CoN_4O_9S_2$ (653.03): calcd. C 34.91, H 4.94, N 8.58; found C 34.89, H 4.83, N 8.36.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

**[(bmppa)Fe($CH_3CN$)]($ClO_4$)$_2$ (3):** Prepared in an identical manner to **1**. Recrystalization of the initially isolated yellow solid from $CH_3CN/Et_2O$ yielded green needle crystals suitable for single-crystal X-ray diffraction (0.043 g, 65%). FTIR (KBr): $\tilde{\nu}$ = 3325 (br., $\nu_{N-H}$), 1633, 1612, 1531, 1455, 1428, 1081 ($\nu_{ClO4}$), 796, 623 ($\nu_{ClO4}$) cm$^{-1}$. FTIR ($CH_3CN$, 100 mM, 1700–1550 cm$^{-1}$ region): $\tilde{\nu}$ = 1636, 1619 cm$^{-1}$. $C_{19}H_{32}Cl_2FeN_4O_9S_2$ (650.03): calcd. C 35.08, H 4.96, N 8.62; found C 34.82, H 4.95, N 8.60.

**[(bmppa$^-$)Ni]$ClO_4$ (4):** $Me_4NOH\cdot5H_2O$ (0.022 g, 0.12 mmol) dissolved in methanol (2 mL) was added to a solution of **1** (0.080 g, 0.12 mmol) in acetonitrile (3 mL). The purple solution turned a light purple/lavender color upon the addition of the base. The resulting reaction mixture was stirred under nitrogen for ca. 4 h. The solvent was then evaporated under reduced pressure. The remaining solid was dissolved in $CH_2Cl_2$ and filtered through a Celite/glass wool plug. The filtrate was concentrated under vacuum to obtain a pale purple oil. This purple oil was dissolved in a minimal amount of methanol, and the product was precipitated using an excess of diethyl ether. Upon cooling to –15 °C for ca. 48–72 h, flaky purple crystals were formed in the solution. The solvent was decanted and the product dried under reduced pressure (0.017 g, 28%). FTIR (KBr): $\tilde{\nu}$ = 3400 ($\nu_{O-H}$), 1618, 1605, 1567, 1489, 1447, 1419, 1107 ($\nu_{ClO4}$), 911, 805, 623 ($\nu_{ClO4}$) cm$^{-1}$. $C_{17}H_{28}ClN_3NiO_5S_2$ (512.69): calcd. C 39.92, H 5.52, N 8.22; found C 39.65, H 5.94, N 8.40.

**[(bmppa$^-$)Co]$ClO_4\cdot H_2O$ (5):** $Me_4NOH\cdot5H_2O$ (0.036 g, 0.20 mmol) dissolved in methanol (2 mL) was added to a solution of **2** (0.13 g, 0.20 mmol) in methanol (3 mL) . The red solution of the cobalt complex turned dark brown upon addition of the base. The resulting reaction mixture was stirred under nitrogen for ca. 6 h. The solvent was then evaporated under reduced pressure. The remaining solid was dissolved in $CH_2Cl_2$ and filtered through a Celite/glass wool plug, The filtrate was concentrated under vacuum to obtain a dark brown oil. This brown oil was dissolved in a minimal amount of acetonitrile and the product precipitated using excess diethyl ether. Upon cooling at –15 °C for 48 h, small dark brown crystals were formed in the solution. The solvent was decanted off and the product dried under reduced pressure to obtain a dark brown powder (0.066 g, 64%). FTIR (KBr): $\tilde{\nu}$ = 3433 (br., $\nu_{O-H}$), 1653, 1617, 1570, 1559, 1457, 1419, 1101 (br., $\nu_{ClO4}$), 806, 624 ($\nu_{ClO4}$) cm$^{-1}$. $C_{17}H_{28}ClCoN_3O_5S_2$ (512.93): calcd. C 39.84, H 5.51, N 8.20; found C 38.21, H 5.28, N 8.19. Trace $H_2O$ (ca. 1.0 equiv.) was present in the elemental analysis sample as indicated by an FTIR spectrum. Inclusion of this water in the calculated values produced a more satisfactory fit to the experimentally determined data. $C_{17}H_{28}N_3O_5S_2ClCo\cdot H_2O$ (530.06): calcd. C 38.49, H 5.70, N 7.93; found C 38.21, H 5.28, N 8.19.

**Reaction of 3 with $Me_4NOH\cdot5H_2O$:** $Fe(ClO_4)_2\cdot6H_2O$ (0.077 g, 0.22 mmol) dissolved in methanol (ca. 2 mL) was added to a solution of bmppa (0.077 g, 0.22 mmol) in methanol (ca. 2 mL). The resulting yellow solution was stirred under nitrogen for ca. 30 min. To this solution was added $Me_4NOH\cdot5H_2O$ (0.039 g, 0.22 mmol) dissolved in methanol (ca. 2 mL). This addition resulted in the immediate deposition of a green precipitate. The reaction mixture was stirred overnight, after which time the solvent was removed under reduced pressure, which yielded a yellow-green solid. Addition of $CH_2Cl_2$ produced a yellow solution, which was carefully transferred to another flask, and the remaining green solid was dried under vacuum. The green solid was washed with diethyl ether (3 × 2 mL), and the wash solutions were combined with the $CH_2Cl_2$ fraction and dried, which left a viscous yellow oil. The $^1$H NMR features of this oil are consistent with those of the bmppa ligand (0.060 g, 78%). The green solid contains $Me_4NClO_4$, as determined by IR spectroscopy, and unidentified iron species.

**Heating of 4 in MeOH:** $Me_4NOH\cdot5H_2O$ (0.03 g, 0.16 mmol) dissolved in methanol (5 mL) was added to a solution of **1** (0.11 g, 0.16 mmol) in methanol (15 mL) and acetonitrile (5 mL). This produced a color change from purple to reddish purple, consistent with the formation of **4**. The reaction mixture was then heated at 50 °C under nitrogen for 5 d. After cooling to room temperature, $Na_2EDTA$ (0.12 g, 0.33 mmol) dissolved in water (15 mL) was added. The pH of the solution was adjusted to 11 with aqueous NaOH, and the solution was stirred at room temperature for ca. 2 h. This aqueous solution was then extracted with $CH_2Cl_2$ (3 × 50 mL). The organic fractions were combined, dried with $Na_2SO_4$, and the solvents evaporated to dryness, which resulted in the isolation of a yellow oily product. $^1$H NMR analysis of this oil indicated the isolation of unaltered bmppa ligand in quantitative yield.

**Heating of 5 in MeOH:** Complex **2** was generated in situ by combining methanol/acetonitrile (ca. 1:1) solutions of $Co(ClO_4)_2\cdot6H_2O$ (0.099 g, 0.25 mmol) and bmppa (0.088 g, 0.25 mmol). The resulting red solution of **2** was stirred under nitrogen for ca. 30 min. To this solution $Me_4NOH\cdot5H_2O$ (0.049 g, 0.25 mmol) dissolved in methanol (5 mL) was added. This produced a color change from red to dark brown, consistent with the formation of **5**. The reaction mixture was stirred at 50 °C under nitrogen for 5 d. The reaction mixture was then cooled to room temperature and $Na_2EDTA$ (0.65 g, 1.74 mmol) dissolved in water (ca. 15 mL) added. The pH of the solution was adjusted to 11 with aqueous NaOH and the resulting mixture stirred at room temperature for ca. 2 h. The solution was extracted with $CH_2Cl_2$. All the organic fractions were collected, dried with $Na_2SO_4$, and the solvents evaporated to dryness to yield a brown oil. The $^1$H NMR spectrum of this brown oil indicated the formation of two major products and one minor product in the reaction mixture. The first major product was *N*,*N*-bis-2-(methylthio)ethyl-*N*-[(6-amino-2-pyridyl)methyl]amine (bmapa) (ca. 50%). The second major product was unaltered bmppa ligand (43%). The third minor product obtained was *N*-(6-formylpyridin-2-yl)-2,2-dimethylpropanamide[22] (ca. 7%). $^1$H NMR ($CD_3CN$, 400 MHz): $\delta$ = 9.87 (s, 1 H), 8.5 (br., NH), 8.41 (d, 1 H), 7.95 (t, 1 H), 7.66 (d, 1 H), 1.28 (s, 9 H) ppm. GC-MS: *m*/*z* (%) = 206 (9) $[M + H]^+$.

**X-ray Crystallography:** Single crystals of **2** and **3** were mounted on glass fibers with traces of viscous oil and then transferred to a NoniusKappaCD diffractometer with Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 Å) for data collection at 200(1) K. Ten frames of data were collected with an oscillation range of 1 °/frame and an exposure time of 20 s/frame. Indexing and unit-cell refinement based on all observed reflections from those ten frames indicated a monoclinic *P* lattice for both complexes. A total of 16639 reflections for **2** and 11278 reflections for **3** were indexed, integrated, and corrected for Lorentz, polarization and absorption effects using DENZO-SMN and SCALEPAC.[28] The structures were solved by a combination of direct and heavy-atom methods using SIR 97.[29] All non-hydrogen atoms were refined with anisotropic displacement coefficients. For **2** all hydrogen atoms except the amide hydrogen atom were assigned isotropic displacement coefficients $U$(H) = 1.2 $U$(*C*) or 1.5 $U(C_{methyl})$ and their coordinates were allowed to ride on their respective carbon atoms using SHELXL97.[30] The amide hydrogen atom of **2** and all the hydrogen atoms of **3** were located and refined independently. Complexes **2** and **3** crystallized in the space group $P2_1/c$. Additional details of the X-ray data collection and refinement are given in Table 4. CCDC-648591 (for **2**), and -648592 (for

# The Influence of Ligand Substitution at the Electron Donor Center in Molecular Cyano-Bridged Mixed-Valent $Co^{III}/Fe^{II}$ and $Co^{III}/Ru^{II}$ Complexes

**Paul V. Bernhardt,*[a] Fernando Bozoglian,[b] Mercè Font-Bardía,[c] Manuel Martínez,*[b] Andrew P. Meacham,[a] Beatriz Sienra,[d] and Xavier Solans[c][†]**

**Keywords:** Mixed-valent compounds / Cyanides / Binuclear complexes

In this paper we report a new variety of dinuclear cyano-bridged $Co^{III}/M^{II}$ (M = Fe or Ru) mixed-valent complexes of the general formula $[L_nCo^{III}(\mu\text{-}NC)M^{II}(CN)_x(bpy)_y]^{z+}$ (where $L_n$ represents a pentaamine macrocycle and M = Fe or Ru with $x = 4$, $y = 1$ and $z = 1$ or $x = 2$, $y = 2$ and $z = 3$)]. The incorporation of the bpy ligand in place of cyano ligands within the coordination sphere raises the $M^{III/II}$ redox potential significantly relative to the hexacyanometalate analogs we have reported previously. However, the metal-to-metal ($M^{II}$ to $Co^{III}$) charge-transfer transitions are shifted to lower energies in accordance with Hush theory as a result of a decreased reorganizational energy component, which result in them overlapping with more intense MLCT ($M^{II}$ to bpy) transitions.

## Introduction

In recent years we have reported on synthetic strategies leading to *molecular*, cyano-bridged, dinuclear[1–4] and trinuclear[5] $d^6$–$d^6$ heterometallic complexes; this work has been reviewed.[6] These $Co^{III}/Fe^{II}$ and $Co^{III}/Ru^{II}$ complexes each display characteristics of a *Class II* Robin and Day asymmetric, low-spin $d^6$–$d^6$ mixed-valent complex,[7] exhibiting metal-to-metal charge-transfer (MMCT, $Fe^{II}$ to $Co^{III}$ or $Ru^{II}$ to $Co^{III}$) transitions in the visible region, in addition to the transitions characteristic of the two isolated metal-complex moieties.

According to Hush theory [Equation (1)],[8] the energy of the MMCT transition ($E_{op}$) is directly related to the free energy difference ($\Delta G°$) between the $Co^{III}$–NC–$M^{II}$ and $Co^{II}$–NC–$M^{III}$ (M = Fe, Ru) forms. The $Co^{II}$–NC–$M^{III}$ form cannot be isolated as it is inherently unstable with respect to the $Co^{III}$–NC–$M^{II}$ complex so this free energy difference cannot be measured directly. However, if the two redox centers do not interact strongly then this free energy difference may be estimated from the difference between the $Co^{III/II}$ and $M^{III/II}$ redox potentials. The reorganizational energy ($\lambda$) associated with the MMCT process is also important and includes both inner sphere (bond length/angle changes) and outer sphere (solvation) terms.

$$E_{op} = \Delta G° + \lambda \quad (1)$$

In previous publications we have demonstrated how the MMCT energy of the $Co^{III}$–NC–$M^{II}$ chromophore is very sensitive to variations at both metal centers. Specifically, the ring size of the pentadentate macrocyclic ligand bound to the $Co^{III}$ ion (e.g. $L_{14}$ or $L_{15}$),[2] its geometric isomeric form (*cis* or *trans*),[3] and the donor set of the macrocycle ($N_5$ or $N_3S_2$)[4] all have an effect on the $Co^{III/II}$ redox potential, which in turn is reflected in variations in the MMCT transition energy in accordance with Hush theory. Alternatively, protonation of the terminal cyanide ligands in the hexacyanoferrate(II) moiety[9] or the substitution of the metal (Ru for Fe)[4] raises the $M^{III/II}$ (M = Fe or Ru) redox potential of the donor and the energy of the MMCT transition accordingly.

In this paper we have explored a new MMCT energy tuning strategy by replacing the hexacyanometalate(II) unit by various combinations of *cis*-$[M(CN)_4(bpy)]^{2-}$ and *cis*-$[M(CN)_2(bpy)_2]$ (M = Fe and Ru, bpy = 2,2′-bipyridyl). This change brings additional complexity to the optical properties of the system, as metal-to-ligand charge transfer (MLCT, $M^{II}$ to bpy) transitions are also possible and inherently more intense than the MMCT transitions.[10] The identification of the MMCT ($M^{II}$ to $Co^{III}$) transitions in these new mixed-valent complexes is consequently not straightforward. Nevertheless, this can be overcome when their intense electronic spectra are compared with that of the mononuclear cyano complexes of $M^{II}$ (Fe or Ru in com-

bination with one or two bpy ligands). This analysis brings additional information regarding the energetics of MMCT in these molecular systems.

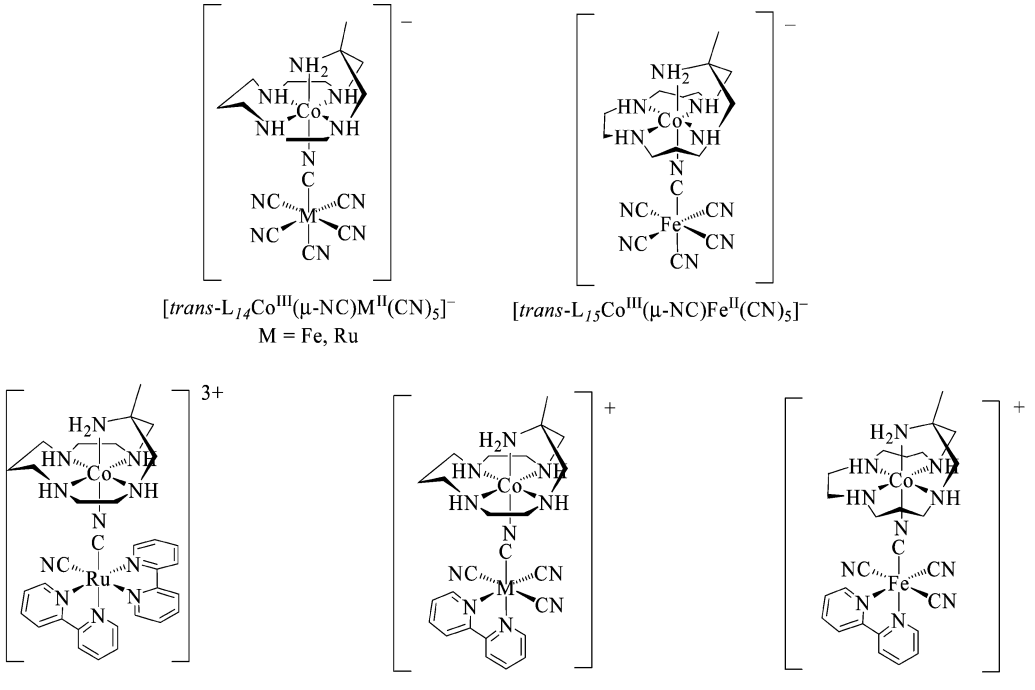
## Results and Discussion

### Synthesis

All complexes were prepared by direct substitution of the aqua ligand on the appropriate *trans*-$[CoL_n(OH_2)]^{3+}$ complex by a single bridging cyano ligand of the $Fe^{II}$ or $Ru^{II}$ precursor. In previous papers[2,11] we have exploited a redox-catalyzed substitution reaction whereby the hexacyanoferrate(II) complex undergoes an outer sphere electron transfer cross reaction with the $Co^{III}$ partner to generate a labile $Co^{II}$ intermediate. However, given the much higher $Fe^{III/II}$ and $Ru^{III/II}$ redox potentials involved, this protocol could not be used. Despite this fact, the careful choice of stoichiometry and reaction conditions allowed the isolation of each desired complex after purification by cation chromatography. In this case the reactions are merely ligand substitutions on the $Co^{III}$ center unassisted by reduction. A detailed mechanistic study of these "uncatalyzed" processes, also applicable in some cases for the preparation of trinuclear complexes of this family, is currently underway.

### Spectroscopic Characterization

The $^1H$ NMR resonances of all the complexes of $L_{14}$ in the high-field region are indicative of retention of the so-called *trans-I* form of the $\{Co^{III}L_{14}\}$ moiety (all NH protons *syn*, see Scheme 1) which has mirror plane symmetry and hence exhibits only five chemically distinct methylene groups.[3] The $^1H$ NMR in the same region for the $\{Co^{III}L_{15}\}$ unit in the corresponding complex is consistent with the *trans-III* form (two NH protons up and two down) which has been identified in other related dinuclear complexes.[1] The low-field region of each spectrum is dominated by the aromatic bpy protons and is useful in assigning the isomeric form involving the bpy ligands for each complex. The $^1H$ NMR spectra of both [*trans*-$L_{14}Co^{III}(\mu\text{-NC})Fe^{II}(CN)_3(bpy)_{eq,ax}]^+$ and [*trans*-$L_{14}Co^{III}(\mu\text{-NC})Ru^{II}(CN)_3(bpy)_{eq,ax}]^+$ (see Figures S1a and S1b in the electronic supporting information) are virtually identical as expected from the structures shown in Figures 1 and 2. Only the two protons in 6- and 6′-positions (equivalent in the free bpy ligand) are clearly separated in the NMR spectrum and appear downfield (>9 ppm) of all other peaks because of the inductive effect of the adjacent coordinated N-atoms. The $^1H$ NMR resonances of the other bpy protons (3/3′, 4/4′ and 5/5′) overlap, despite being chemically inequivalent. The low symmetry is consistent with the *equatorial*,*axial* geometric isomeric form where one bpy N-donor (equatorial) is *trans* to a terminal cyano ligand while the other (axial) is *trans* to the unique bridging cyano ligand. The $^1H$ NMR spectrum of [*trans*-$L_{15}Co^{III}(\mu\text{-NC})Fe^{II}(CN)_3(bpy)_{eq,ax}]^+$ (Figure S1c, supporting information) in this low-field region is found indistinguishable from that of [*trans*-$L_{14}Co^{III}(\mu\text{-NC})Fe^{II}(CN)_3(bpy)_{eq,ax}]^+$ and thus the same *eq*,*ax* isomeric can be assigned. A minor band was



Scheme 1.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

seen in the chromatographic purification of this complex and this is likely to be the more symmetrical *eq,eq* isomer but it was not present in sufficient quantities to characterize fully.

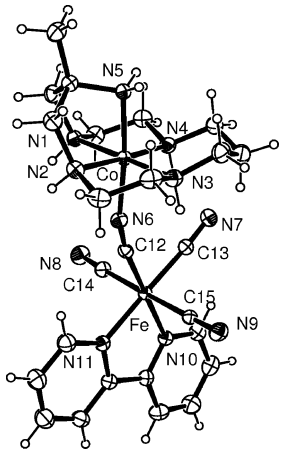


Figure 1. ORTEP drawing of the [*trans*-$L_{14}Co^{III}$(μ-NC)$Fe^{II}(CN)_3$-$(bpy)_{eq,ax}]^+$ cation (30% ellipsoids shown). Relevant bond lengths [Å] and angles [°]: Co–N(5) 1.951(2); Co–N(1) 1.958(3); Co–N(2) 1.952(3); Co–N(3) 1.960(3); Co–N(4) 1.965(3); Co–N(6) 1.897(3); Fe–N(11) 1.986(2); Fe–N(10) 1.994(2); Fe–C(12) 1.870(3); Fe–C(12)–N(6) 170.1(2); Co–N(6)–C(12) 157.5(2).

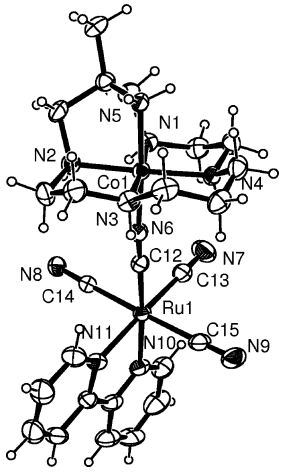

Figure 2. ORTEP drawing of the [*trans*-$L_{14}Co^{III}$(μ-NC)$Ru^{II}(CN)_3$-$(bpy)_{eq-ax}]^+$ cation (30% ellipsoids shown). Relevant bond lengths [Å] and angles [°]: Co–N(5) 1.960(5); Co–N(1) 1.940(5); Co–N(2) 1.953(5); Co–N(3) 1.945(5); Co–N(4) 1.950(6); Co–N(6) 1.906(6); Ru–N(11) 2.108(6); Ru–N(10) 2.116(5); Ru–C(12) 1.958(7); Ru–C(12)–N(6) 177.3(6); Co–N(6)–C(12) 166.7(6).

The $^1$H NMR spectrum of [*trans*-$L_{14}Co^{III}$(μ-NC)$Ru^{II}$-$(CN)(bpy)_{2,cis}]^{3+}$ (Figure S1d, supporting information) is more complex because of the presence of 4 chemically inequivalent pyridyl rings. Interestingly, a pair of high-field protons at the 6-position (from different bpy ligands) is also present, but the other two protons at the 6-position appear well upfield (7.2–7.4 ppm). This effect has also been noted previously for *cis*-$Ru(CN)_2(bpy)_2$ and $[Ru(bpy)_3]^{2+}$, and has been assigned to the shielding effect of the adjacent aromatic ring current.[12]

The IR spectra of all [*trans*-$L_nCo^{III}$(μ-NC)$M^{II}(CN)_3$-$(bpy)_{eq,ax}]^+$ ($n$ = 14 or 15, M = Fe; $n$ = 14, M = Ru) complexes are very similar in the $\tilde{\nu}_{C\equiv N}$ region, exhibiting three bands around 2060, 2080 and 2100 $cm^{-1}$. On the basis of our previous studies,[1,2,4] and those on other related cyano-bridged complexes,[13,14] the highest frequency vibration is invariably due to the bridging cyano ligand. The lowest frequency vibration is twice the intensity of the intermediate frequency band and thus is most likely due to the two equivalent (mutually *trans*) cyano ligands. The intermediate frequency band is consequently assigned to the single cyano ligand *trans* to a bpy N-donor. The IR spectrum of [*trans*-$L_{14}Co^{III}$(μ-NC)$Ru^{II}(CN)(bpy)_{2,cis}]^{3+}$ exhibits only two $\tilde{\nu}_{C\equiv N}$ bands of similar intensity. Again, the higher frequency band is assigned to the bridging cyano ligand by reference to the published IR spectrum of *cis*-$Ru(CN)_2$-$(bpy)_2$ where both ligands are terminal.[14]

## Structural Characterization

The crystal structure of [*trans*-$L_{14}Co^{III}$(μ-NC)$Fe^{II}(CN)_3$-$(bpy)_{eq,ax}]^+$ (Figure 1) shows the typical *trans-I* form of the macrocyclic $L_{14}$ ligand,[2–4] already found in the [*trans*-$L_{14}Co^{III}$(μ-NC)$Fe^{II}(CN)_5]^-$ as well as in the precursor *trans-I*-$[CoClL_{14}]^{2+}$ complexes. The bond angles and distances for the cobalt moiety on the complex do not show any significant deviation with respect to previously characterized structural analogs, and the shortest distance of the cobalt environment is, as usual, that to the cyano ligand. As for the iron $\{Fe^{II}(CN)_4(bpy)\}$ unit in the dinuclear complex, its geometry is close to octahedral with the bpy ligand in an *equatorial*,*axial* disposition, forcing the $\{Co^{III}L_{14}\}$ group to tilt severely producing a Co–N≡C angle of only 157.5°. Only for the oxidized complex [*trans*-$L_{14}Co^{III}$(μ-NC)$Fe^{III}$-$(CN)_5]$ has a tilting of this degree been observed before;[3] as a consequence the $Co^{III}$–$Fe^{II}$ distance becomes effectively shorter than in the rest of $Co^{III}/Fe^{II}$ complexes of this family.[6]

The crystal structure of [{*trans*-$L_{14}Co^{III}$(μ-NC)}$Ru^{II}$-$(CN)_3(bpy)_{eq,ax}](ClO_4)_{1/2}\cdot Cl_{1/2}\cdot 4H_2O$ was also determined. The cation geometry (Figure 2) is very similar to that of the iron analog and the only notable differences are the longer Ru coordinate bonds. There is considerable disorder in the anions both translational and over different orientations. Apart from this feature the salient features of the structure mirror those of the Fe analog.

## Electrochemistry

Electrochemistry of the four dinuclear complexes in aqueous solution identified redox couples from both metal centers. The $Co^{III/II}$ couples for [*trans*-$L_nCo^{III}$(μ-NC)$M^{II}$-$(CN)_3(bpy)_{eq,ax}]^+$ ($n$ = 14 or 15, M = Fe; $n$ = 14, M = Ru) are rather similar (Table 1) and lower than seen in [*trans*-$L_{14}Co^{III}$(μ-NC)$Ru^{II}(CN)(bpy)_{2,cis}]^{3+}$. This fact can be attributed to the electrostatic effects of the dinegatively charged $\{M(CN)_4(bpy)\}^{2-}$ moiety in the [*trans*-$L_nCo^{III}$(μ-

[a] Partially obscured by MLCT band. [b] Totally obscured. [c] Could not be determined. [d] Ref.[2]. [e] Ref.[1]. [f] ref.[4].

NC)$M^{II}(CN)_3(bpy)_{eq,ax}$]$^{+}$ analogs which lowers the $Co^{III/II}$ couple relative to that seen in [*trans*-$L_{14}Co^{III}$(μ-NC)$Ru^{II}$-(CN)$(bpy)_{2,cis}$]$^{3+}$ while the charge neutral {$Ru^{II}(CN)_2$-$(bpy)_2$} moiety exerts no electrostatic influence. The cyclic voltammograms of the Ru complexes are shown in Figure 3. As reported before, the $Co^{III/II}$ redox processes are fully reversible on an Hg working electrode but only quasi-reversible, or even irreversible, on glassy carbon surfaces. That is, the best responses for the $Co^{III/II}$ were obtained on Hg while the high-potential $Fe^{III/II}$ and $Ru^{III/II}$ couples (inaccessible on Hg) had to be measured with a glassy carbon electrode. Also of note are the lower $Co^{III/II}$ couples of the dinuclear hexacyanometalate complexes because of the greater (tetranegative) charge of the anionic cyano {$Fe^{II}(CN)_6$} moiety.

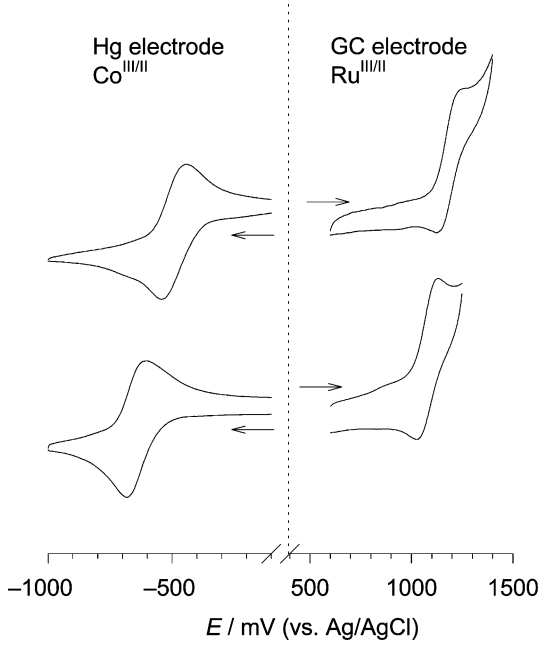

Figure 3. Cyclic voltammograms (500 mV $s^{-1}$) of [*trans*-$L_{14}Co^{III}$(μ-NC)$Ru^{II}$(CN)$(bpy)_{2,cis}$]$^{3+}$(top)and[*trans*-$L_{14}Co^{III}$(μ-NC)$Ru^{II}(CN)_3$-$(bpy)_{eq,ax}$]$^{+}$ (bottom) measured with a glassy carbon (GC) working electrode (right) or a Hg drop electrode (left). The currents have been scaled to compensate for the different electrode areas.

The $Ru^{III/II}$ and $Fe^{III/II}$ couples are both clearly influenced by the tripositively charged {$Co^{III}L_n$}$^{3+}$ moiety. Comparison with the mononuclear redox potentials of $[Fe(CN)_4(bpy)]^{-/2-}$ (380 mV),[15] $[Ru(CN)_4(bpy)]^{-/2-}$ (890 mV)[16] and *cis*-$[Ru(CN)_2(bpy)_2]^{+/0}$ (940 mV)[17] (all vs. Ag/AgCl) illustrates this point. A ca. 200 mV anodic shift is found in each case on going from the mononuclear complex to the cyano-bridged $Co^{III}/M^{II}$ complex, as for the previously studied hexacyano complexes.[1–5] Further comparisons can be made with these redox potentials of the hexacyanometalate analogs that we have already reported (Table 1). Clearly the bpy ligand destabilizes the trivalent Fe and Ru forms relative to a pair of terminal cyano ligands.

Apart from these thermodynamic measurements, there also appears to be a labilizing effect upon oxidation of the $Ru^{II}$ center. As illustrated in Figure 4, the $Ru^{III/II}$ couple of [*trans*-$L_{14}Co^{III}$(μ-NC)$Ru^{II}(CN)_3(bpy)_{eq,ax}$]$^{+}$ is irreversible at a sweep rate of 100 mV $s^{-1}$ (no cathodic peak is observed), while reversibility is restored at sweep rates higher than

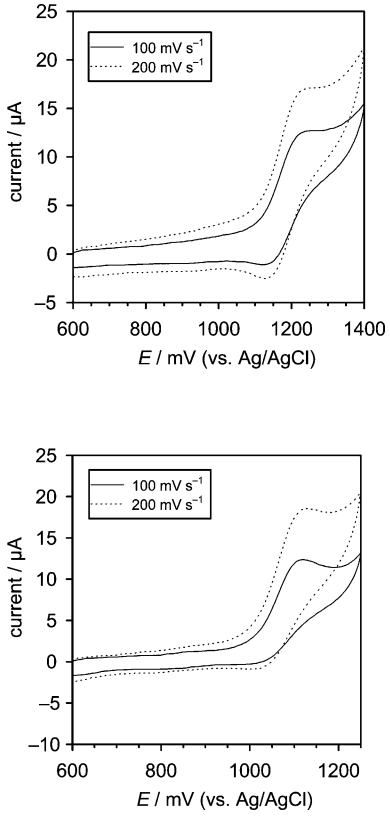

Figure 4. Sweep-rate dependence of the $Ru^{III/II}$ couple potentials for [*trans*-$L_{14}Co^{III}$(μ-NC)$Ru^{II}$(CN)$(bpy)_{2,cis}$]$^{3+}$ (top) and [*trans*-$L_{14}Co^{III}$(μ-NC)$Ru^{II}(CN)_3(bpy)_{eq,ax}$]$^{+}$ (bottom).

500 mV s$^{-1}$. This fact is indicative of a chemical reaction, of uncertain nature, following oxidation. The $Ru^{III/II}$ redox couple in [*trans*-$L_{14}Co^{III}$(μ-NC)$Ru^{II}$(CN)$(bpy)_{2,cis}$]$^{3+}$ appears at even higher potential yet it is reversible at all sweep rates, which rules out catalytic water oxidation as the reason for the loss of the cathodic peak in [*trans*-$L_{14}Co^{III}$(μ-NC)-$Ru^{II}(CN)_3(bpy)_{eq,ax}]^+$ (the higher potential $Ru^{III/II}$ couple should result in a greater rate of water oxidation). It seems that the chemical reaction that follows oxidation has to be related to ligand dissociation at the $Ru^{III}$ center with a first-order rate constant of ca. 15 s$^{-1}$, as determined by examination of the scan-rate dependence of the cathodic/anodic currents.[18] Electrochemical experiments run in dmf (data not shown) revealed a similar result, indicating the chemical irreversibility of the oxidation of the ruthenium center in the complex despite the absence of water. Interestingly the electrochemistry of $[Ru(CN)_4(bpy)]^{2-}$ performed under the same conditions is facile and totally reversible at sweep rates of 100 mV s$^{-1}$, which suggests a destabilizing influence of the attached $Co^{III}$ moiety. Earlier studies[19] on the bromine oxidation of $[Ru(CN)_6]^{4-}$ showed that the product is $[Ru(CN)_5(OH_2)]^{3-}$ which indicates that the intermediate $[Ru(CN)_6]^{3-}$ is unstable with respect to ligand substitution in water. Indeed the $[Ru(CN)_6]^{3-}$ ion has only recently been characterized structurally[20] and, once isolated, it decomposes rapidly upon dissolution.

### *Electronic Spectroscopy*

The energy of the MMCT transition is of interest, given the wide separation of the redox couples of the two metal centers relative to other systems we have investigated (see Table 1). The electronic spectra of [*trans*-$L_{14}Co^{III}$(μ-NC)-$Ru^{II}(CN)_3(bpy)_{eq,ax}]^+$ and [*trans*-$L_{14}Co^{III}$(μ-NC)$Ru^{II}$(CN)-$(bpy)_{2,cis}]^{3+}$ in aqueous solution show an intense MLCT ($Ru^{II}$ to bpy) peak around 400 nm which exhibits a distinct shoulder at its low-energy side (Figure 5); this shoulder is totally absent in the parent $[Ru^{II}(CN)_4(bpy)]^{2-}$ and only the MLCT band is apparent (Figure 5, dashed line). These shoulders then appear to be due to the MMCT ($Ru^{II}$ to $Co^{III}$) transitions both around 500 nm. In other systems we have already studied, such as [*trans*-$L_{14}Co^{III}$(μ-NC)$M^{II}$-$(CN)_5]^-$ (M = Fe and Ru),[2,4] the MMCT transition is dominant, as only much weaker $Co^{III}$ d–d transitions ($\varepsilon \approx 100$ M$^{-1}$ cm$^{-1}$) are seen in the visible region. Equation (1) enables the reorganization energies for each $Ru^{II}/Co^{III}$ complex to be calculated. These values are collected in Table 1.

For both $Fe^{II}$ complexes, the UV/Vis spectra show a rather broad and featureless band at 460–470 nm that may be attributed to the corresponding MLCT ($Fe^{II}$ to bpy) transition (the value being 482 nm, 2400 M$^{-1}$ cm$^{-1}$ for $[Fe^{II}$-$(CN)_4(bpy)]^{2-}$).[21] This band diminishes in intensity on addition of the oxidant $Na_2S_2O_8$ as a result of the oxidation of the iron center and two new bands (506 nm, 110 M$^{-1}$ cm$^{-1}$ and 416 nm, 940 M$^{-1}$ cm$^{-1}$) corresponding to the $[Fe^{III}(CN)_4$-$(bpy)]^-$ chromophore are evident (Figure S2, supporting information). Also, oxidation of the $Fe^{II}$ center must result in loss of the MMCT ($Fe^{II}$ to $Co^{III}$) band, but this was completely obscured by the more intense $Fe^{II}$ to bpy MLCT band so its energy is unknown.

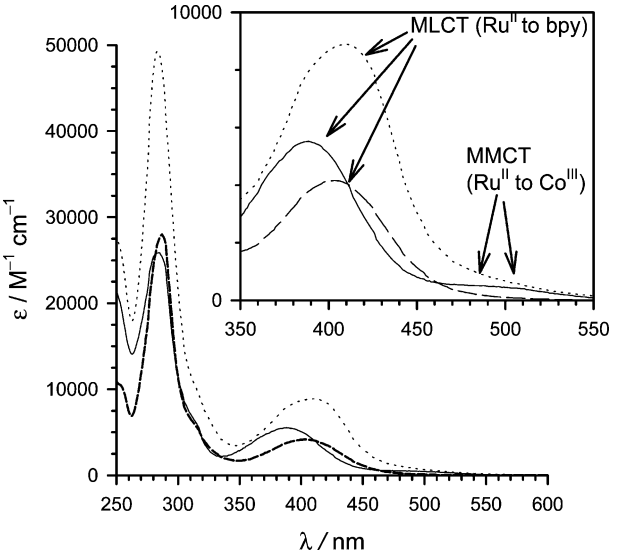

Figure 5. UV/Vis spectra of [*trans*-$L_{14}Co^{III}$(μ-NC)$Ru^{II}$(CN)-$(bpy)_{2,cis}]^{3+}$ (dotted line), [*trans*-$L_{14}Co^{III}$(μ-NC)$Ru^{II}(CN)_3$-$(bpy)_{eq,ax}]^+$ (grey solid line) and $[Ru^{II}(CN)_4(bpy)]^{2-}$ (dashed line). MLCT and MMCT bands are indicated.

Bulk electrolysis oxidation of the $Ru^{II}$–CN–$Co^{III}$ complexes was unsuccessful with decomposition occurring during the experiment. It is likely that loss of one or more cyano ligands from the $Ru^{III}$ center is the origin of this decomposition reaction by analogy with the known instability of $[Ru(CN)_6]^{3-}$.[19,20]

## Conclusions

The present study has illustrated new ways in which the MMCT energy of this extended series of molecular *Class II* mixed-valent $Co^{III}/M^{II}$ complexes can be modified through ligand exchange on the $M^{II}$ electron donor. Although partially obscured by the more intense $Ru^{II}$ to bpy MLCT transitions, the $Ru^{II}$ to $Co^{III}$ MMCT bands have been determined, while in the case of the $Fe^{II}$–CN–$Co^{III}$ systems we were unable to resolve the $Fe^{II}$ to $Co^{III}$ transitions because of their complete overlap with the more intense $Fe^{II}$ to bpy MLCT bands. In each case the substitution of a pair of *cis* cyano ligands with a single bidentate bpy ligand raises the redox potential of the $M^{II}$ donor relative to its hexacyanometalate(II) analog. Interestingly the $Co^{III/II}$ couple is inductively raised by a similar amount, leaving the free energy changes barely affected. The MMCT energy of the $Ru^{II}$–CN–$Co^{III}$ complexes is smaller because of a significant (ca. 60%) decrease in the reorganizational energy of the bpy complexes relative to the hexacyanoruthenate parent, although the variations in charge may also be a factor in addition to specific H-bonding with the number of terminal cyano ligands. We are currently exploring further synthetic

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

routes to novel di- and trinuclear mixed-valent complexes with a view to further being able to tune their optical and electrochemical properties.

## Experimental Section

**Physical Methods:** Proton NMR spectra at 400 MHz were recorded with either a Varian Mercury-400 (Serveis Científico-Tècnics de la Universitat de Barcelona) or Bruker AV400 instrument. All chemical shifts are cited relative to TMS. Cyclic voltammetry employed a BAS100B/W or EG&G 263A potentiostat and using either a glassy carbon disc working electrode, or a PAR Model 303 static Hg drop working electrode. The reference electrode was Ag/AgCl (3 M KCl) and a platinum wire counter electrode was employed. The background electrolyte was either 0.1 M $NaClO_4$ or 0.1 $NaNO_3$ as indicated. All solutions were purged with $N_2$ prior to measurement. UV/Vis spectra were measured with Analytik Jena Specord 210, HP5482A, Cary5, Cary50 and J&M TIDAS spectrophotometers. IR spectra were carried out in an FT-IR Impact 400 Nicolet spectrometer employing KBr disks or a Perkin–Elmer 1600 series spectrophotometer using an ATR assembly.

### Syntheses

**Caution:** All reactions must be carried out in a well-ventilated fume hood as liberation of HCN may occur in some of the preparations if solutions are acidified. Perchlorate salts are potentially explosive and should only be handled in small quantities, never heated in the solid state not scraped from sintered glass frits.

The precursor complexes *trans-I*-$[CoClL_{14}](ClO_4)_2$,[2] *trans-II*-$[CoClL_{15}](ClO_4)_2$,[22] $K_2[Fe(CN)_4(bpy)]\cdot 3H_2O$,[21] $K_4[Ru(CN)_6]$,[23] $K_2[Ru(CN)_4(bpy)]$[24] were prepared using published procedures. The complex *cis*-$Ru(CN)_2(bpy)_2$ was prepared by refluxing *cis*-$Ru(bpy)_2Cl_2$[25] (0.3 g) and excess KCN (0.241 g) in 50% aqueous EtOH (100 $cm^3$) for 5 h; the initial purple color changed to orange during this period. After this time the solvent was removed in vacuo (**caution** – excess cyanide present) and the resultant red/orange powder was dissolved in MeOH and purified on a Sephadex LH-20 size-exclusion column and recrystallized from MeOH/$Et_2O$. All other reagents and solvents were obtained commercially.

**[*trans*-$L_{14}Co^{III}(\mu\text{-}NC)Fe^{II}(CN)_3(bpy)_{eq,ax}](ClO_4)\cdot 4H_2O$:** A solution of *trans-I*- $[CoClL_{14}](ClO_4)_2$ (0.20 g) in water (20 $cm^3$) was adjusted to pH = 10 with NaOH and then stirred for 10 min to give the hydroxo derivative after hydrolysis of the chloro ligand. After addition of a solution of $K_2[Fe(CN)_4(bpy)]\cdot 3H_2O$ (0.22 g) in water (20 $cm^3$), the pH was raised to 6.2 with 1 M NaOH solution; any $KClO_4$ precipitate was filtered off and stirring was continued for 72 h. at 40 °C. The final solution was diluted to 1000 $cm^3$ and loaded to a $30 \times 2$ cm column of Sephadex C-25 cation-exchange resin ($Na^+$ form). Elution with 0.1 M $NaClO_4$ produced two diffuse red bands. The major second band was collected, diluted to 5 L, and reloaded onto another column of the same type. This time elution with 0.05 M $NaClO_4$ produced a narrow major band that was collected and evaporated at reduced pressure to ca. 15 $cm^3$. Standing for a few days at 5 °C produced the desired product in crystalline form (15% yield) suitable for X-ray work. $C_{25}H_{43}ClCoFeN_{11}O_8$ (775.92): calcd. C 38.7, H 5.6, N 19.8; found C 39.1, H 5.7, N 19.2. $^1H$ NMR ($D_2O$): $\delta$ = 1.35 (s, 3 H, $CH_3$), 1.80–3.70 (m, 18 H, $CH_2$), 7.50 (m, 2 H, 5/5′-pyr), 7.98 (t, 2 H, 4/4′-pyr), 8.23 (d, 2 H, 3/3′-pyr), 9.01 (d, 1 H, 6-pyr), 9.28 (d, 1 H, 6′-pyr) ppm. IR: $\tilde{\nu}_{CN}$ = 2061, 2074, 2096 $cm^{-1}$. UV/Vis ($H_2O$): $\lambda$ ($\varepsilon$, L $mol^{-1}$ $cm^{-1}$) = 458 (3380), 332 (3330) nm.

**[*trans*-$L_{15}Co^{III}(\mu\text{-}NC)Fe^{II}(CN)_3(bpy)_{eq,ax}](ClO_4)\cdot 3H_2O$:** The procedure for the preparation of the dinuclear complex is the same one as above except *trans-II*-$[CoClL_{15}](ClO_4)_2$ was used as the precursor. Elution with 0.1 M $NaClO_4$ produced two diffuse red bands. The major second one was collected, diluted to 5 L, and reloaded on another Sephadex C-25 column ($Na^+$ form). Elution with 0.05 M $NaClO_4$ produced an initial major band that was collected and evaporated at reduced pressure to ca. 15 $cm^3$. Standing in a refrigerator for a few days produced the desired product in crystalline form in a 10% yield. $C_{26}H_{43}ClCoFe_{11}O_7$ (1176.32): calcd. C 40.5, H 5.6, N 20.0; found C 40.8, H 5.9, N 21.0. $^1H$ NMR ($D_2O$): $\delta$ = 1.40 (s, 3 H, $CH_3$), 1.90–3.50 (m, 20 H, $CH_2$), 7.52 (m, 2 H, 5/5′-pyr), 8.02 (t, 2 H, 4/4′-pyr), 8.28 (d, 2 H, 3/3′-pyr), 9.10 (d, 1 H, 6-pyr), 9.32 (d, 1 H, 6′-pyr) ppm. IR: $\tilde{\nu}_{CN}$ 2052, 2080, 2106. UV/Vis ($H_2O$): $\lambda$ ($\varepsilon$, L $mol^{-1}$ $cm^{-1}$) = 470 (2500), 338 (2160) nm.

**[*trans*-$L_{14}Co^{III}(\mu\text{-}NC)Ru^{II}(CN)_3(bpy)_{eq,ax}](ClO_4)\cdot 6H_2O$:** *trans-I*-$[CoClL_{14}](ClO_4)_2$ (0.26 g) and $K_2[Ru(bpy)(CN)_4]$ (0.25 g) were refluxed in 50% aqueous MeOH (100 $cm^3$) at pH = 8. The color of the orange solution quickly darkened and developed into a brownish orange. After 6 h the solution was cooled and diluted with water to 5 L and loaded onto a Sephadex C-25 ($Na^+$ form) column and the desired product eluted with 0.1 M $NaClO_4$. Upon concentration of the eluate on a rotary evaporator an orange powder precipitated on standing. This was filtered off and then further purified via size exclusion chromatography (Sephadex LH-20, MeOH) to remove contamination by co-precipitated $NaClO_4$. The orange fraction collected from the Sephadex LH-20 column was left to slowly concentrate and the complex precipitated in a 43% yield. $C_{25}H_{45}ClCoN_{11}O_{10}Ru$ (855.15): calcd. C 35.0, H 5.5, N 18.0; found C 35.1, H 5.7, N 17.9. $^1H$ NMR ([$D_4$]MeOH): $\delta$ = 1.28 (s, 3 H, -$CH_3$), 2–3.55 (m, 16 H, -$CH_2$-), 7.052 (quint, 2 H, 5/5′-pyr), 7.97–8.03, (t, 2 H, 4/4′ pyr), 8.383–8.356 (d, 2 H, 3/3′ pyr), 9.12–9.13 (d, 1 H, 6 pyr), 9.32–9.34 (d, 1 H, 6′ pyr) ppm. IR: $\tilde{\nu}_{CN}$ 2050, 2071, 2105. UV/Vis ($H_2O$): $\lambda$ ($\varepsilon$, L $mol^{-1}$ $cm^{-1}$) = 470 (sh, 550), 389 (5500) 284 (25800) nm. Crystals of the mixed salt [*trans*-$L_{14}Co^{III}(\mu\text{-}NC)Fe^{II}(CN)_3(bpy)_{eq,ax}](ClO_4)_{1/2}\cdot Cl_{1/2}\cdot 6H_2O$ were grown from a solution of the complex in a mixture of $NaClO_4$ and NaCl.

**[*trans*-$L_{14}Co^{III}(\mu\text{-}NC)Ru^{II}(CN)(bpy)_{2,cis}](ClO_4)_3$:** *trans-I*-$[CoClL_{14}](ClO_4)_2$ (0.25 g) and *cis*-$[Ru(CN)_2(bpy)_2]$ (0.3 g) were refluxed in 50% aqueous MeOH (100 $cm^3$) at pH = 8. The color of the orange solution quickly developed in intensity. After 6 h the solution was cooled, diluted with water to 5 $dm^3$ and loaded onto a Sephadex C-25 column ($Na^+$ from). The desired product eluted as the major orange band with 0.3 M $NaClO_4$. Upon concentration of the eluate, an orange powder precipitated and was filtered off. Further purification was achieved with size exclusion chromatography (Sephadex LH-20, MeOH) to remove excess $NaClO_4$. Yield 36%. $C_{33}H_{47}Cl_3CoN_{11}O_{14}Ru$ (1088.16): calcd. C 37.04, H 4.24, N 14.40; found C 36.58, H 4.22, N 14.35. $^1H$ NMR ([$D_3$]MeCN): $\delta$ = 1.20 (s, 3H-$CH_3$), 1.4–3.5 (m, 16H-$CH_2$-), 7.26 (quint d, 2 H), 7.42 (d, 1 H), 7.61 (m, 2 H), 7.72 (td, 1 H), 7.95 (qd, 2 H), 8.11 (t quint, 2 H), 8.33 (dd, 2 H), 8.42 (t, 2 H), 9.30 (d, 1 H), 9.54 (d, 1 H) ppm. IR: $\tilde{\nu}_{CN}$ 2048, 2089. UV/Vis ($H_2O$): $\lambda$ ($\varepsilon$, L $mol^{-1}$ $cm^{-1}$) = 490 (sh, 800), 411 (8900) 283 (49300) nm.

### Crystallography

Cell constants for [{*trans*-$L_{14}Co^{III}(\mu\text{-}NC)$}$Fe^{II}(CN)_3(bpy)_{eq,ax}](ClO_4)\cdot 4H_2O$ and [{*trans*-$L_{14}Co^{III}(\mu\text{-}NC)$}$Ru^{II}(CN)_3(bpy)_{eq,ax}](ClO_4)_{1/2}Cl_{1/2}\cdot 6H_2O$ were determined by a least-squares fit to the setting parameters of 25 independent reflections measured with an Enraf–Nonius CAD4 four-circle diffractometer employing graphite-monochromated Mo-$K_\alpha$ radiation (0.71073 Å).

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

Data reduction was performed with the WINGX[26] suite of programs. Structures were solved by direct methods with SHELXS and refined by full-matrix least-squares analysis with SHELXL-97.[27] All non-H atoms were refined with anisotropic thermal parameters. Aryl, alkyl and amino H-atoms were included at estimated positions using a riding model. Water H-atoms (if any) were not located. Molecular structure diagrams were produced with ORTEP3.[28] Crystal and refinement data are summarized in Table 2, and selected bond lengths and angles appear in the captions of Figures 1 and 2.

# Tetranuclear Nickel(II) Complexes Composed of Pairs of Dinuclear $LNi_2$ Fragments Linked by Acetylenedicarboxylate, Terephthalate, and Isophthalate Dianions: Synthesis, Structures and Magnetic Properties

**Julia Klingele,[a] Marco H. Klingele,[a][‡] Oliver Baars,[b] Vasile Lozan,[b] Axel Buchholz,[c] Guido Leibeling,[d] Winfried Plass,[c] Franc Meyer,[d] and Berthold Kersting*[b]**

**Keywords:** Macrocyclic ligands / Dicarboxylato ligands / Nickel / Polynuclear complexes / Magnetic properties

The tetranuclear nickel(II) complexes $[(LNi^{II}_2)_2$(acetylenedicarboxylate)$][BPh_4]_2$ (**2**$[BPh_4]_2$), $[(LNi^{II}_2)_2$(terephthalate)$][BPh_4]_2$ (**3**$[BPh_4]_2$), and $[(LNi^{II}_2)_2$(isophthalate)$][BPh_4]_2$ (**4**$[BPh_4]_2$), where $L^{2-}$ represents a macrocyclic hexaaza-dithiophenolate ligand, have been synthesized and characterised by UV/Vis spectroscopy, IR spectroscopy, X-ray crystallography, and magnetic susceptibility measurements. Each dicarboxylate dianion acts as a quadridentate bridging ligand linking two bioctahedral $LNi_2$ units via $\mu_{1,3}$-bridging carboxylate functions to generate discrete $[(LNi^{II}_2)_2$(dicarboxylate)$]^{2+}$ dications with a central $LNi_2(O_2C–R–CO_2)Ni_2L$ core. The structures differ mainly in the distance between the center of the Ni···Ni axes of the isostructural $LNi_2$ units (8.841(1) Å in **2**$[BPh_4]_2$, 10.712(1) in **3**$[BPh_4]_2$, and 9.561(1) in **4**$[BPh_4]_2$) and the tilting angle between the two $Ni_2O_2$ planes (86.3° in **2**$[BPh_4]_2$, 58.2° in **3**$[BPh_4]_2$, 20.9° in **4**$[BPh_4]_2$). Magnetic susceptibility measurements on the complexes over the range 2.0–295 K reveal the presence of weak ferromagnetic exchange interactions between the $Ni^{II}$ ions within the dinuclear subunits with values for the magnetic exchange constant $J_1$ of 23.1(5), 18.1(5), and 14.2(5) $cm^{-1}$ for **2**$[BPh_4]_2$, **3**$[BPh_4]_2$, and **4**$[BPh_4]_2$, respectively ($\mathbf{H} = -2J\mathbf{S}_1\mathbf{S}_2$). The magnitude of the exchange interaction $J_2$ across the dicarboxylate bridges is in all cases less than 0.1 $cm^{-1}$, suggesting that no significant interdimer exchange coupling occurs in **2**$[BPh_4]_2$–**4**$[BPh_4]_2$.

## Introduction

The carboxylate group, $RCO_2^-$, can bind to transition metals in a variety of coordination modes giving rise to complexes of great structural diversity.[1] Current activities focus on the coordination chemistry of polycarboxylate ligands, as these offer great potential in the construction of polynuclear aggregates[2] and extended coordination polymers with micro- and mesoporous structures[3–6] or catalytic properties.[7] In addition, polycarboxylate ligands are of importance as spin-coupling bridging ligands[8–15] in the rapidly expanding field of molecular magnetism.[16,17] In this context, an enormous amount of literature has been generated concerning the distance dependence of magnetic exchange interactions between metal atoms linked by extended dicarboxylate ligands. Dinuclear copper complexes bridged by oxalate[18,19] and terephthalate[20–22] dianions form, by far, the largest group of such systems, and it appears that the exchange interactions depend on the M···M distance,[23] the relative orientation of the magnetic orbitals,[24] and the degree of conjugation of the organic spacer unit.[25,26]

Recently, we reported the structures and magnetic properties of an isostructural series of bioctahedral $[LM^{II}_2(OAc)]^+$ complexes, where $L^{2-}$ represents a macrodinucleating $N_6S_2$ supporting ligand (Scheme 1).[27] Intramolecular antiferromagnetic exchange interactions are present in the $Mn^{II}_2$, $Fe^{II}_2$ and $Co^{II}_2$ complexes of this series with $J$ values of –5.1, –10.6, and –2.0 $cm^{-1}$ ($\mathbf{H} = -2J\mathbf{S}_1\mathbf{S}_2$). In contrast, in the corresponding $Ni^{II}_2$ complex a ferromagnetic exchange interaction is present with $J = +6.4$ $cm^{-1}$.

In view of the increasing interest in the targeted assembly of molecular-based magnetic materials using high-spin molecules of higher nuclearity,[28–34] we considered it worthwhile to examine the possibility of linking pairs of dinuclear $[LNi^{II}_2]$ units by dicarboxylate dianions to form tetranuclear species. In the present contribution we report the synthesis and crystallographic characterization of three novel

$[LM^{II}_2(OAc)]^+$ (M = $Mn^{II}$, $Fe^{II}$, $Co^{II}$, $Ni^{II}$)

Scheme 1. Dinuclear acetate-bridged complexes of the hexaazadithiophenolate ligand $L^{2-}$.

tetranuclear nickel(II) complexes of the type $[LNi^{II}_2$dicarboxylate$Ni^{II}_2L]$, where "dicarboxylate" stands for acetylenedicarboxylate, terephthalate, or isophthalate dianions. A schematic representation of these complexes is shown in Scheme 2. These novel complexes differ by the distance between the centre of the Ni···Ni axis of the isostructural $LNi_2$ subunits, their relative orientation, and the nature of the bridging ligands. The ability of the dicarboxylate dianions to mediate magnetic exchange interactions between the dinuclear subunits is examined and discussed in the light of their specific structural features.

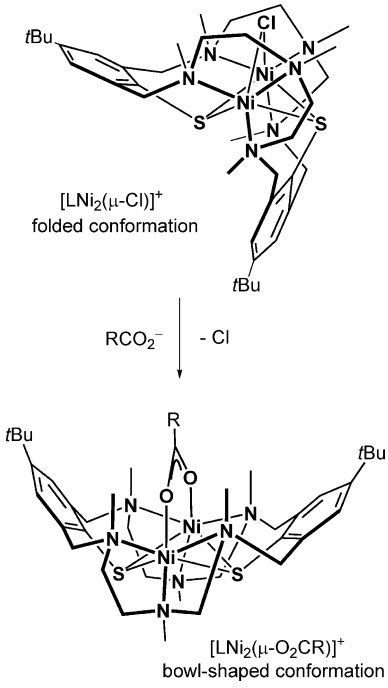
**4**, $[(LNi^{II}_2)_2$(isophthalate)$]^{2+}$

Scheme 2. Complexes prepared and their labels.

## Synthesis and Characterization of the Complexes

The complexes $[(LNi^{II}_2)_2$(acetylenedicarboxylato)$]^{2+}$ (**2**), $[(LNi^{II}_2)_2$(terephthalato)$]^{2+}$ (**3**), and $[(LNi^{II}_2)_2$(isophthalato)$]^{2+}$ (**4**) were readily prepared from the reaction of the dinuclear complex $[LNi^{II}_2(\mu\text{-Cl})]^+$ (**1**) and the corresponding triethylammonium dicarboxylate, prepared in situ from the acid and triethylamine in methanol in a 1:2 molar ratio, and isolated in high yield as the perchlorate or tetraphenylborate salts. The transformations are not simple substitution reactions, because simultaneous conformational changes of the supporting ligand $L^{2-}$ from the folded ($C_s$-symmetric) to the "bowl-shaped" ($C_{2v}$-symmetric) conformation take place (see Scheme 3).[35] Nonetheless, linking of two $[LNi_2]^{2+}$ fragments by the carboxylato ligands is a clean and facile step driven by the low solubility of the products.



Scheme 3. Schematic representation of the two ligand conformations in the chloro- and carboxylato-bridged complexes of $(L)^{2-}$. For these conformational changes metal–ligand dissociations are required.

All compounds gave satisfactory elemental analyses and their IR spectra are marked by the prominent asymmetric and symmetric carboxylate stretching frequencies around 1580 $cm^{-1}$ and 1420 $cm^{-1}$, diagnostic of $\mu_{1,3}$-bridging carboxylate functions.[36] The UV/Vis spectra of **2**–**4** in acetonitrile display two weak bands above 500 nm typical of octahedral $Ni^{2+}$ ($d^8$, $S = 1$) ions. The observed values compare closely with those of the acetato-bridged complex $[LNi^{II}_2(OAc)]^+$,[27] indicative of a pseudo-octahedral $N_3S_2O$ coordination environment about the metal ions. This is confirmed by single-crystal X-ray crystallography.

## Description of the Crystal Structures

Crystals of $\mathbf{2}[BPh_4]_2 \cdot 2MeCN \cdot 0.5H_2O$ were obtained by slow evaporation of an acetonitrile/ethanol (1:1) solution of $\mathbf{2}[BPh_4]_2$. The crystal structure is composed of tetranuclear $[(LNi^{II}_2)_2$(acetylenedicarboxylate)$]^{2+}$ dications, tetraphen-

ylborate anions and acetonitrile and water solvates. Perspective drawings of the structure of **2** are depicted in Figure 1. Selected bond lengths and angles are summarized in Table 1.

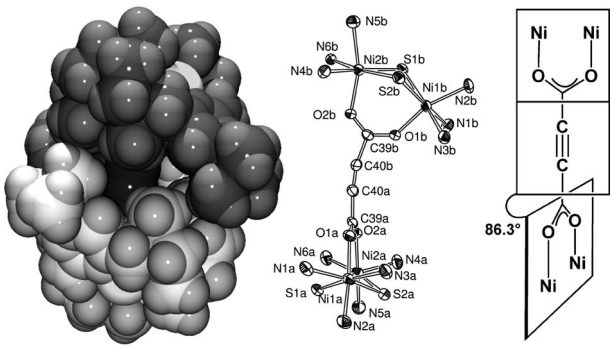

Figure 1. Left: van der Waals plot of the $[(LNi^{II}_2)_2(acetylenedicarboxylato)]^{2+}$ dication in crystals of $\mathbf{2}[BPh_4]_2{\cdot}MeCN{\cdot}0.5H_2O$. Middle: ORTEP representation of the core structure of **2** with the atom labeling Scheme. Ellipsoids are represented at the 50% probability level. Right: Mutual orientation of the $Ni_2$carboxylato planes in **2**.

The acetylenedicarboxylate dianion acts as a tetradentate bridging ligand joining two dinuclear $[LNi^{II}_2]^{2+}$ fragments through its carboxylate functions to give a tetranuclear $Ni_2(O_2CC{\equiv}CCO_2)Ni_2$ array. Each nickel atom is surrounded in a highly distorted octahedral fashion by two sulfur atoms and three nitrogen atoms from the supporting ligand, and one oxygen atom from the acetylenedicarboxylate moiety. The $Ni_2$carboxylato planes are necessarily twisted by 86.3° about the C≡C bond to relieve the unfavourable steric interactions between the bulky *t*Bu groups of the two opposing $[LNi^{II}_2]^{2+}$ subunits. The coligand is also slightly bent (C≡C 1.185(6) Å] such that the intramolecular distances between two nickel atoms of different dinuclear subunits within the tetranuclear complex range from 8.623(1) to 9.769(1) Å. The only system comparable to that of **2** is provided by the complex $[\{Mo_2(DAniF)_3\}_2(O_2CC{\equiv}CCO_2)]$, where DAniF = *N*,*N*′-di-*p*-anisylformamidinate, for which an intramolecular Mo···Mo distance of 9.537 Å has been reported.[37] There are no significant intermolecular interactions between the $Ni^{II}_4$ complexes within the lattice. The shortest intermolecular Ni···Ni distance is at 7.470(1) Å.

Figure 2 shows the structure of the tetranuclear nickel(II) complex **3** in crystals of **3**$[BPh_4]_2$·2EtOH·0.5MeCN·$H_2O$. Again, the terephthalato ligand acts as a bifunctional linker coordinating to two bioctahedral $[LNi^{II}_2]^{2+}$ entities via the carboxylate functions to generate a twisted $Ni_2O_2C–C_6H_4–CO_2Ni_2$ motif.

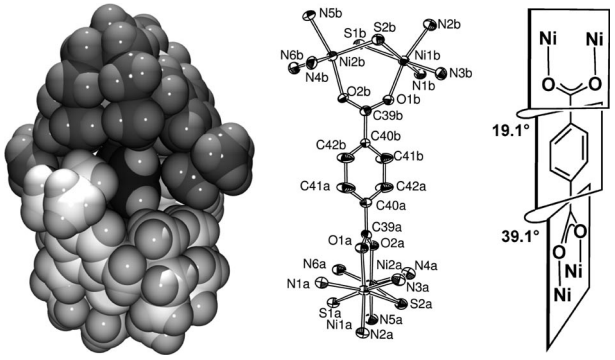

Figure 2. Left: van der Waals representation of the $[(LNi^{II}_2)_2$-(μ-terephthalato)$]^{2+}$ dication in crystals of **3**$[BPh_4]_2$·2EtOH·0.5MeCN·$H_2O$. Middle: ORTEP representation of the core structure of **3** with the atom labeling Scheme. Ellipsoids are represented at the 50% probability level. Right: Relative orientation of the $Ni_2$carboxylato planes in **3**.

The $[LNi_2]^{2+}$ subunits in **2** and **3** are structurally very similar, and the Ni–N, Ni–O, and Ni–S distances lie within very narrow ranges (Table 1). As in **2**, the *t*Bu groups of the two opposing $Ni_2$ clusters are forced to interlock to accommodate the terephthalato ligand. This causes tilting of the carboxylato planes that are rotated by 58.2° with respect to each other and by 19.1° and 39.1° with respect to the aromatic ring of the terephthalato coligand. Again, there are no intermolecular interactions between the tetranuclear complexes other than van der Waals contacts. The intramolecular Ni···Ni distances between the two dinuclear subunits are within the range 10.833(1)–11.155(1) Å (mean 10.990(1) Å]. This is a typical value for terephthalato-bridged nickel(II) complexes.[38,39]

Crystals of **4**$[BPh_4]_2$·4MeCN·EtOH are triclinic, space group $P\bar{1}$. ORTEP views of the structure of the dication **4** and the central core are provided in Figure 3. Selected bond lengths and angles are given in Table 1.

The isophthalate dianion is bonded to two $[LNi^{II}_2]^{2+}$ units through $\mu_{1,3}$-bridging carboxylate functions. The metal–ligand bond lengths within **4** reveal no anomalities and are very similar to those in **2** and **3** (Table 1). Strangely, the twisting of the carboxylato planes is less pronounced than in the previous cases. In fact, the two planes are almost coplanar with the phenyl ring of the bridging isophthalate dianion. The geometrical requirements of the isophthalate moiety with the two carboxylate functions in *meta* orientation leads to a distance of 9.561 Å between the center of the Ni···Ni axes of the dinuclear units. This value should be compared with that of 10.712 Å in **3**, where the two carboxylate functions are in *para* positions. The present coordination mode of the isophthalate dianion forming a discrete $Ni^{II}_4$ cluster is without precedence in the literature.[40–42]

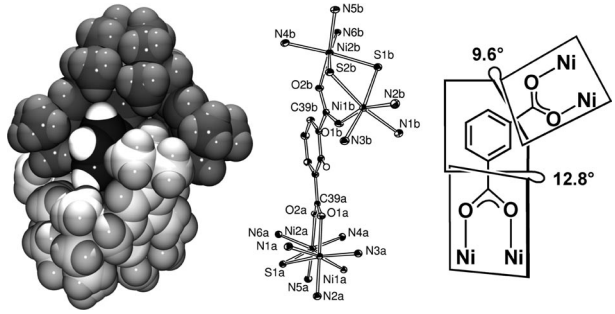

Figure 3. Left: van der Waals representation of the $[(LNi^{II}_2)_2$-(μ-isophthalato)$]^{2+}$ dication in crystals of **4**$[BPh_4]_2$·4MeCN·EtOH. Middle: ORTEP representation of the core structure of **4** with the atom labeling Scheme. Ellipsoids are represented at the 50% probability level. Right: Tilting of the $Ni_2$carboxylato planes in **4**.

In summary, all three new compounds are discrete tetranuclear nickel(II) complexes composed of pairs of bioctahedral $[LNi^{II}_2]^{2+}$ units united by a tetradentate dicarboxylate anion. The calixarene-like conformation adopted by the supporting ligand leads to an almost complete encapsulation of the $Ni_2(O_2C–R–CO_2)Ni_2$ core. As a consequence the $Ni^{II}_4$ clusters are well-separated from each other in the solid state, featuring only intermolecular van der Waals contacts. This aspect of the structures will be relevant in the following discussion of the magnetic properties of the complexes.

## Magnetic Properties

The magnetic properties of the three carboxylato-bridged complexes were examined in view of literature reports that conjugated dicarboxylate ligands are able to mediate long-range magnetic exchange interactions between paramagnetic metal ions.[43] The variable-temperature magnetic susceptibility data for **2**$[BPh_4]_2$, **3**$[BPh_4]_2$, and **4**$[BPh_4]_2$ were measured over the range 2.0–295 K using a SQUID magnetometer and an applied external magnetic field of 0.2 T. Plots of the temperature dependence of the effective magnetic moment $\mu_{eff}$ for the three compounds are shown in Figure 4. The complexes have similar magnetic properties. At room temperature, the respective values of $\mu_{eff}$ are 6.91 $\mu_B$, 6.82 $\mu_B$, and 7.13 $\mu_B$ per tetranuclear complex. With decreasing temperature the $\mu_{eff}$ values increase steadily to maximum values of 7.85 $\mu_B$ (15 K), 7.71 $\mu_B$ (15 K), and 8.03 $\mu_B$ (25 K) for **2**$[BPh_4]_2$, **3**$[BPh_4]_2$, and **4**$[BPh_4]_2$, respectively. On lowering the temperature to 2.0 K, these values decrease slightly down to 7.57 $\mu_B$, 7.02 $\mu_B$, and 5.78 $\mu_B$ at 2 K, presumably due to saturation effects or the zero-field splitting of nickel(II).

In all cases the maximum value of the effective magnetic moment is lower than expected for a spin-only value of 9.84 $\mu_B$ for $S_T = 4$ resulting from ferromagnetic coupling of four $Ni^{II}$ ($S_i = 1$, $g = 2.20$) ions. However, the values are also significantly larger than the value of 6.22 $\mu_B$ calculated for completely uncoupled spins. The overall behaviour indi-

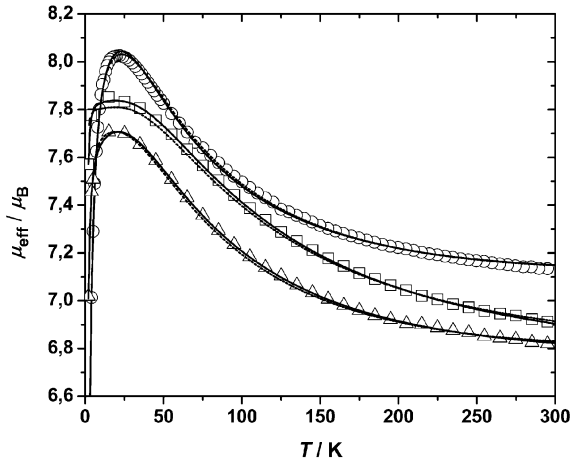

Figure 4. Temperature dependence of $\mu_{eff}$ (per tetranuclear complex) for **2**$[BPh_4]_2$ (open squares), **3**$[BPh_4]_2$ (open triangles), and **4**$[BPh_4]_2$ (open circles). The full lines represent the best theoretical fits to Equation (1). The dashed lines represent the best fits to the dimer model in Equation (3). Experimental and calculated values are provided in the electronic supporting information.

cates the presence of weak ferromagnetic exchange interactions between the $Ni^{2+}$ ions within the dinuclear subunits, but negligible, if any, coupling across the dicarboxylate bridges. The latter behaviour can be attributed to the long distance between the $Ni^{2+}$ ions spanned by the dicarboxylates. In this regard, it is worth noting that very weak exchange interactions have indeed been reported for other terephthalato- or isophthalato-bridged nickel(II) complexes.[26,44,45]

In order to determine the magnitude of the exchange interactions, the magnetic susceptibility data were simulated by using Equation (1), where $\chi_{tetra}$ and $\chi_{mono}$ refer to the molar susceptibilities of a $Ni_4$ complex and a fraction $\rho$ of a mononuclear nickel(II) impurity with Curie constant $C = Ng^2\mu_B{}^2/3kT$.

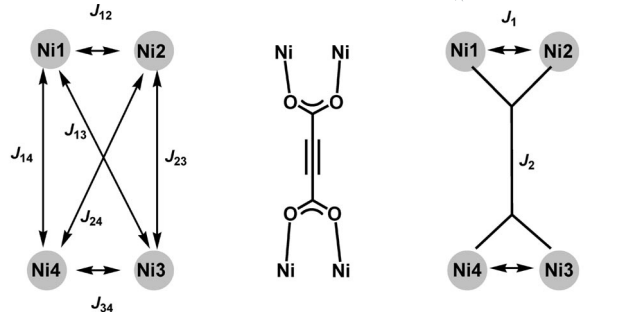
$$\chi = \chi_{tetra}(1-\rho) + 4\chi_{mono}\rho \quad (1)$$

The molar magnetic susceptibility $\chi_{tetra}$ was derived from the appropriate spin-Hamiltonian [Equation (2)] including the isotropic Heisenberg exchange, the single-ion zero-field splitting and the single-ion Zeeman interaction by a full-matrix diagonalization approach.[34]

$$H = -2J_1(\hat{S}_1 \cdot \hat{S}_2 + \hat{S}_3 \cdot \hat{S}_4) - 2J_2(\hat{S}_1 \cdot \hat{S}_3 + \hat{S}_1 \cdot \hat{S}_4 + \hat{S}_2 \cdot \hat{S}_3 + \hat{S}_2 \cdot \hat{S}_4)$$

$$H = H_{ex} + \sum_{i=1}^{4}[D_i(\hat{S}_{iz}^2 - \tfrac{1}{3}S_i(S_i+1)) + g_i\mu_B B_\tau \hat{S}_{i\tau}] \ (\tau = x, y, z) \quad (2)$$

In this model $J_1$ (= $J_{12}$ = $J_{34}$) represents the exchange interaction between the $Ni^{2+}$ ions within the dinuclear subunit, whereas $J_2$ ($J_{13}$ = $J_{14}$ = $J_{23}$ = $J_{24}$) describes the interaction across the dicarboxylate linker. In order to reduce the number of variables, the $D$ and $g$ values were considered to be identical for all of the four $Ni^{2+}$ ions.



The least-squares fitting of the experimental data over the full temperature range led to $J_1$ = +23.1(5) $cm^{-1}$, $J_2$ = –0.0045(10) $cm^{-1}$, $g$ = 2.27(1), $D$ = –1.9(5) $cm^{-1}$, $\rho$ = 0.010(5)% for **2**$[BPh_4]_2$, $J_1$ = +18.1(5) $cm^{-1}$, $J_2$ = –0.0048(9) $cm^{-1}$, $g$ = 2.24(1), $D$ = –1.5(5) $cm^{-1}$, $\rho$ = 0.020(5)% for **3**$[BPh_4]_2$, and $J_1$ = +14.2(5) $cm^{-1}$, $J_2$ = –0.071(9) $cm^{-1}$, $g$ = 2.37(1), $D$ = 9.6(5) $cm^{-1}$, $\rho$ = 0.020(5)% for **4**$[BPh_4]$. The inclusion of the $D$ parameter improves the low-temperature fit significantly, but it represents by no means an accurate value since temperature-dependent magnetic susceptibility measurements are not very appropriate for the determination of $D$.[46,47] The experimentally determined $J_2$ parameters are very small and should be taken as indicative rather than definite, because they are beyond the detection limit of the technique. Nevertheless, it is clear that magnetic exchange interactions via the dicarboxylate linkers are not significant (estimated upper limit for $J_2$: $\pm$0.1 $cm^{-1}$) and that the magnetic properties of the tetranuclear systems are solely based on the exchange couplings in the binuclear $[LNi_2(O_2CR)]^+$ subunits. In this respect, we also tried to simulate the temperature dependence of the magnetic data by using an isotropic dimer model [Equation (3)] for two $Ni^{II}$ ($S$ = 1) ions based on the Hamiltonian in Equation (4).

$$\chi = 2[\chi_{dim}(1-\rho) + 2\chi_{mono}\rho] \quad (3)$$

$$H = -2JS_1S_2 + \sum_{i=1}^{2}[D_i(\hat{S}_{iz}^2 - \tfrac{1}{3}S_i(S_i+1)) + g_i\mu_B B_\tau \hat{S}_{i\tau}] \quad (\tau = x, y, z) \quad (4)$$

The magnetic data could be reproduced equally well by this approach (Figure 4), yielding $J_1$ = +23.4(5) $cm^{-1}$, $g$ = 2.26(1), $D$ = –2.2(5) $cm^{-1}$, $\rho$ = 0.010% for **2**$[BPh_4]_2$, $J_1$ = +19.3(4) $cm^{-1}$, $g$ = 2.23(1), $D$ = –4.8(5) $cm^{-1}$, $\rho$ = 0.035% for **3**$[BPh_4]_2$, and $J_1$ = +15.5(5) $cm^{-1}$, $g$ = 2.35, $D$ = 12.0(5) $cm^{-1}$, $\rho$ = 0.03% for **4**$[BPh_4]$. Again, this analysis establishes a weak ferromagnetic coupling between the two $Ni^{II}$ ions. All of these values are in excellent agreement with those reported for the dinuclear nickel(II) complexes $[LNi^{II}_2(OAc)][BPh_4]$ and $[LNi^{II}_2(OBz)][BPh_4]$,[48] providing further support for the absence of significant interdimer exchange coupling in **2**$[BPh_4]_2$–**4**$[BPh_4]_2$.

There has been much interest in the distance-dependence of superexchange interactions between paramagnetic transition metal ions bridged by extended organic spacer ligands.[22,23] In this regard a large number of dicarboxylato-bridged copper(II) dimers with Cu···Cu separations of 5 to 15 Å have been prepared and their magnetic properties have

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

been determined.[22,23] In general, the magnetic exchange interactions decrease rapidly with increasing M···M separations and the experimentally determined $J$ values approach the values predicted by the Coffman Buettner relation ($|J| \leq 1$ cm$^{-1}$ for $d$(M···M) $\geq 9$ Å).[23,49] Cano et al. have shown that this finding also applies to other paramagnetic metal ions,[26] and the *inter*dimer exchange couplings of the present complexes ($|J| \leq 0.1$ cm$^{-1}$, $d$($Ni_2$···$Ni_2$) 8.623–11.155 Å) are in good agreement with the reported trend. There seems to be no dependence of the *inter*dimer coupling on the mutual orientation of the $Ni_2O_2$ planes, which is in line with our previous observations.[50]

## Conclusions

In summary, we presented the synthesis and characterization of the first members of a new class of tetranuclear nickel(II) complexes in which pairs of dinuclear $Ni_2$-aminethiophenolate complexes are linked by acetylenedicarboxylate, terephthalate and isophthalate groups. The complexes are readily prepared and exist as stable and discrete complexes in solution and in the solid state as ascertained by various spectroscopic methods and X-ray crystallography. The magnetic properties of these compounds reveal the presence of weak ferromagnetic exchange interactions between the $Ni^{II}$ ions of the dinuclear subunits and negligible coupling across the dicarboxylate bridges. A dependence of the *inter*dimer coupling on the mutual orientation of the $Ni_2O_2$ planes was not observed. High-spin molecules of this sort are presumably only accessible with shorter bridging ligands such as oxalate or squarate dianions. These studies are underway.

## Experimental Section

**General Remarks:** Solvents and reagents were of reagent grade quality and used as received unless otherwise specified. [$LNi^{II}_2$(μ-Cl)]$ClO_4$ was prepared according to a literature procedure.[51] Melting points were determined in open glass capillaries and are uncorrected. IR spectra were measured on a Bruker VECTOR 22 FT-IR spectrophotometer as KBr pellets, electronic absorption spectra on a Jasco V-570 UV/Vis/Near IR spectrophotometer. Temperature-dependent magnetic susceptibility measurements on powdered solid samples were carried out on a SQUID magnetometer (MPMS Quantum Design) over the temperature range 2.0–295 K. The measurements were performed at applied magnetic fields of 0.20 and 0.50 T. For all three compounds, the magnetic behaviour does not change with field. The observed susceptibility data were corrected for underlying diamagnetism using Pascal's constants.

**Derivation of the Magnetic Susceptibility Expression for Tetranuclear Ni Complexes:** The complete matrix of $H$ can be calculated by writing out the coupled states and determining the matrix elements by elementary operations with angular momenta operators.[52,53] The resulting Hamiltonian matrix is diagonalized numerically for given values of $J_1$, $J_2$, $g$ and $D$. The slope of $E$ vs. $B$ is calculated at the desired field; this slope is the magnetic moment for the $i^{th}$ energy level. The molar paramagnetic susceptibility, $\chi$, of the system is then calculated as a function of temperature using Equation (1), where $\chi_{tetra}$ and $\chi_{mono}$ refer to the molar susceptibilities of the tetranuclear complex [Equation (5)] and the fraction $\rho$ of a mononuclear nickel(II) impurity with Curie constant $C = Ng^2\mu_B{}^2/3kT$ [Equation (6)]. $\chi_{dim}$ is the molar susceptibility of the binuclear subunit. A least-squares program then compares calculated and observed susceptibility curves and changes the parameters to get the best fit.[34]

$$\chi_{tetra} = \frac{N}{B_0}\frac{\sum_i(-\partial E_i/\partial B)\exp(-E_i/kT)}{\sum_i \exp(-E_i/kT)} \quad (5)$$

$$\chi_{mono} = \frac{Ng^2\mu_B^2}{3kT}\left(\frac{2}{2}\left(\frac{2}{2}+1\right)\right) \quad (6)$$

**Safety note! Caution:** *Perchlorate salts of transition metal complexes are hazardous and may explode. Only small quantities should be prepared and handled with great care.*

**[($LNi^{II}_2$)$_2$(acetylenedicarboxylato)][$ClO_4$]$_2$ (2[$ClO_4$]$_2$):** Triethylamine (50 mg, 0.50 mmol) was added to a solution of acetylenedicarboxylic acid (28.5 mg, 0.250 mmol) in methanol (30 mL). [$LNi^{II}_2$Cl]$ClO_4$ (**1**[$ClO_4$]) (461 mg, 0.500 mmol) was added to this solution with constant stirring. A green precipitate resulted immediately. Additional $LiClO_4 \cdot 3H_2O$ (160 mg, 1.00 mmol) was added to ensure complete precipitation of the product. After stirring for 1 d, the green precipitate was collected by filtration, washed several times with cold methanol and dried in the air. Yield 335 mg (71%), m.p. 302–303 °C (decomp.). IR (KBr): $\tilde{\nu}$ = 3439 (m), 2963 (s), 2869 (s), 2249 (w), 2018 (w), 1596 [s, $\nu_{asym}(RCO_2^-)$], 1463 (s), 1424 (w), 1394 [w, $\nu_{sym}(RCO_2^-)$], 1355 (s), 1264 (m), 1235 (m), 1202 (w), 1170 (w), 1154 (m), 1096 [vs, $\nu_3(ClO_4^-)$], 1039 (s), 1001 (w), 984 (w), 932 (m), 912 (m), 881 (m), 826 (s), 819 (m), 809 (m), 766 (w), 754 (w), 682 (m), 624 [vs, $\nu_4(ClO_4^-)$] (s), 602 (w), 564 (w), 545 (w), 535 (w), 493 (w), 441 (w), 417 cm$^{-1}$ (w).

**[($LNi^{II}_2$)$_2$(acetylenedicarboxylato)][$BPh_4$]$_2$ (2[$BPh_4$]$_2$):** A solution of $NaBPh_4$ (342 mg, 1.00 mmol) in ethanol (50 mL) was added to a solution of **2**[$ClO_4$]$_2$ (188 mg, 0.100 mmol) in acetonitrile (150 mL). The reaction mixture was allowed to stir for 1 h, before the volume of the solution was reduced in vacuo to about 50 mL. The green product was filtered, washed with ethanol and dried in the air to give 190 mg (82%) of **2**[$BPh_4$]$_2$ as a green, air-stable, microcrystalline powder, m.p. 279–280 °C (decomp.). IR (KBr (cm$^{-1}$)): $\tilde{\nu}$ = 3434 (s), 3122 (w), 3054 (s), 3030 (s), 2963 (s), 2867 (s), 2808 (m), 1945 (w), 1880 (w), 1815 (w), 1763 (w), 1597 [s, $\nu_{asym}(CO_2^-)$], 1461 (s), 1425 (m), 1392 [m, $\nu_{sym}(CO_2^-)$], 1355 (s), 1308 (m), 1264 (m), 1235 (m), 1202 (w), 1170 (w), 1154 (m), 1133 (w), 1078 (s), 1058 (s), 1039 (s), 999 (w), 930 (w), 911 (w), 882 (w), 824 (m), 733 [s, $\nu(BPh_4^-)$], 705 [s, $\nu(BPh_4^-)$], 681 (m), 627 (m), 612 (m), 563 (w), 544 (w), 492 (w), 470 (w), 414 (w). UV/Vis ($CH_2Cl_2$): $\lambda_{max}$ ($\varepsilon$) = 656 (32), 1091 nm (82 M$^{-1}$cm$^{-1}$). $C_{128}H_{168}B_2N_{12}Ni_4O_4S_4$ (2323.44): calcd. C 66.17, H 7.29, N 7.23, S 5.52; found C 65.85, H 7.31, N 7.20, S 5.68. Single crystals of **2**[$BPh_4$]$_2$·2MeCN·0.5$H_2O$ suitable for an X-ray structure analysis were grown by slow evaporation of an ethanol/acetonitrile solution of **2**[$BPh_4$]$_2$. These crystals slowly lose solvent molecules of solvent of crystallization at ambient temperature and turn dull.

**[($LNi_2$)$_2$(terephthalato)][$ClO_4$]$_2$ (3[$ClO_4$]$_2$):** Triethylamine (50 mg, 0.50 mmol) was added to a solution of terephthalic acid (41.5 mg, 0.250 mmol) in methanol (30 mL). A solution of [$LNi^{II}_2$Cl]$ClO_4$ (**1**[$ClO_4$]) (461 mg, 0.500 mmol) in methanol (50 mL) was slowly added resulting in the immediate formation of a green precipitate. After the addition was complete, further $LiClO_4 \cdot 3H_2O$ (160 mg,

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

1.00 mmol) dissolved in methanol (2 mL) was added, and stirring was continued for additional 3 h. The pale-green product was collected by filtration, washed several times with cold methanol to remove any soluble impurities, and dried in the air. Yield 358 mg (74%), m.p. 317–318 °C (decomp.). IR (KBr): $\tilde{\nu}$ = 3443 (m), 2962 (s), 2868 (s), 2020 (w), 1719 (w), 1584 [s, $\nu_{asym}(RCO_2^-)$], 1463 (s), 1423 (m), 1392 [s, $\nu_{sym}(RCO_2^-)$], 1364 (m), 1309 (w), 1292 (w), 1265 (w), 1234 (m), 1201 (w), 1170 (w), 1153 (w), 1097 [vs, $\nu_3(ClO_4^-)$], 1060 (s), 1040 (s), 1017 (w), 1001 (w), 982 (w), 931 (m), 913 (m), 881 (m), 825 (s), 807 (m), 752 (m), 694 (w), 669 (w), 623 [s, $\nu_4(ClO_4^-)$], 601 (w), 564 (w), 538 (m), 493 (w), 446 (w), 437 (w), 417 $cm^{-1}$ (w).

**[(LNi$_2$)$_2$(terephthalato)][BPh$_4$]$_2$ (3[BPh$_4$]$_2$):** A solution of $NaBPh_4$ (342 mg, 1.00 mmol) in ethanol (100 mL) was added to a warm solution of **3**[$ClO_4$]$_2$ (194 mg, 0.100 mmol) in acetonitrile (150 mL). The reaction mixture was allowed to stir for 1 h. Upon concentration of the solution a green microcrystalline precipitate formed, which was filtered, washed with ethanol and dried in the air for 2 d yielding 214 mg (90%) of **3**[$BPh_4$]$_2$ as a green powder, m.p. > 365 °C. IR (KBr): $\tilde{\nu}$ = 3436 (s), 3053 (s), 3032 (s), 3121 (w), 2962 (s), 2866 (s), 2807 (m), 1940 (w), 1879 (w), 1812 (w), 1762 (w), 1583 [s, $\nu_{asym}(CO_2^-)$], 1460 (s), 1424 (s), 1390 [s, $\nu_{sym}(CO_2^-)$], 1364 (s), 1308 (m), 1265 (m), 1233 (m), 1201 (w), 1170 (w), 1152 (m), 1112 (w), 1076 (s), 1059 (s), 1041 (s), 1001 (w), 982 (w), 929 (m), 912 (m), 882 (m), 823 (s), 734 [s, $\nu(BPh_4^-)$], 704 [s, $\nu(BPh_4^-)$], 668 (w), 629 (m), 612 (s), 563 (w), 538 (m), 491 (w), 471 (w), 416 $cm^{-1}$ (w). UV/Vis ($CH_2Cl_2$): $\lambda_{max}$ ($\varepsilon$) = 651 (27), 1118 nm (62 $M^{-1}cm^{-1}$). $C_{132}H_{172}B_2N_{12}Ni_4O_4S_4$ (2375.51): calcd. C 66.74, H 7.30, N 7.08, S 5.40; found C 66.50, H 7.16, N 7.09, S 5.66. Single crystals of **3**·[$BPh_4$]$_2$·2EtOH·0.5MeCN·$H_2O$ suitable for an X-ray crystal structure analysis were grown by slow evaporation of a solution of **3**[$BPh_4$]$_2$ dissolved in ethanol/acetonitrile (1:1).

**[(LNi$_2$)$_2$(isophthalate)][ClO$_4$]$_2$ (4[ClO$_4$]$_2$):** Triethylamine (51 mg, 0.50 mmol) and solid [$LNi^{II}_2Cl[ClO_4]$ (**1**[$ClO_4$]) (461 mg, 0.500 mmol) was added to a solution of isophthalic acid (41.5 mg, 0.250 mmol) in MeOH (30 mL) with stirring at ambient temperature. The resulting green suspension was stirred overnight. A methanol solution (5 mL) of $LiClO_4·3H_2O$ (320 mg, 2.00 mmol) was added and stirring was continued for another 3 h. The green precipitate was filtered, washed with cold ethanol, and dried in the air. Yield 368 mg (76%), m.p. 331–332 °C (decomp.). IR (KBr): $\tilde{\nu}$ = 3426 (m), 2962 (s), 2869 (s), 1716 (w), 1607 (s) [$\nu_{as}(RCO_2^-)$], 1573 (s), 1462 (s), 1422 [m, $\nu_s(RCO_2^-)$], 1394 (s), 1364 (m), 1308 (w), 1265 (w), 1233 (w), 1202 (w), 1153 (m), 1096 [vs, $\nu_3(ClO_4^-)$], 1078 (s), 1041 (s), 1000 (w), 982 (w), 931 (w), 913 (w), 881 (w), 825 (m), 818 (m), 808 (w), 739 (w), 713 (w), 624 [m, $\nu_4(ClO_4^-)$], 564 (w), 540 (w), 491 (w), 463 (w), 452 (w), 428 (w), 413 (w), 405 $cm^{-1}$ (w). cessed with the programs SAINT (**2**, **3**)[54] or STOE X-AREA (for **4**)[55] and corrected for absorption.[56] Selected details of the data collection and refinement are given in Table 2. The structures were solved by direct methods[57] and refined by full-matrix least-squares techniques on the basis of all data against $F^2$ using SHELXL-97.[58] PLATON was used to search for higher symmetry.[59] H atoms were placed at calculated positions and refined as riding atoms with isotropic displacement parameters. All non-hydrogen atoms were refined anisotropically, except for those of some disordered solvate molecules.

Some of the solvate molecules in **2**, **3**, and **4** were found to be severely disordered and/or only partially occupied. In the crystal structure of **2**$[BPh_4]_2$·MeCN·$H_2O$ one *t*Bu group and the MeCN and $H_2O$ solvate molecules were found to be disordered over two sites. The respective orientations were refined using a split atom model to give site occupancy factors of 0.51(2)/0.49(2) (for C(32a)–C(34a) and C(32c)–C(34c)), 0.62(2)/0.38(2) (for N(7)C(41a)C(42a) and N(7)C(41b)C(42b), and 0.78(2)/0.22(2) (for O(5a) and O(5b)), respectively. The C, N, and O atoms of the solvate molecules could only be refined isotropically, and geometric constraints using SADI instructions were required to keep the structure of the MeCN molecule reasonable. Water and acetonitrile hydrogen atoms were not included in the refinement. The solvate molecules in **3**$[BPh_4]_2$·2EtOH·0.5MeCN·$H_2O$ were found to be severely disordered. It was not possible to resolve this disorder, and geometric constraints using SADI instructions had to be used to maintain the structure of the solvate molecules reasonable. The occupancy factors of two EtOH and the MeCN were reduced to 0.5. The C, N, and O atoms of all solvate molecules were refined isotropically. Finally, the EtOH molecule in **4** was also found to be disordered over two sites. The disorder was refined by using a split atom model with restrained C–O and C–C distances applying SADI instructions to give site occupancies of 0.59(2) for O(3)C(54A)C(55) and 0.41(2) O(3)C(54B)C(55), respectively. Graphics were produced with Ortep3[60] for Windows.

CCDC-654069 (for **2**), -654070 (for **3**), and -654071 (for **4**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from the Cambridge Crystallographic Data Centre via www.ccdc.cam.ac/data_request/cif.

**Supporting Information** (see also the footnote on the first page of this article): Experimental and calculated magnetic susceptibility data for all compounds.

## Acknowledgments

We sincerely thank the Deutsche Forschungsgemeinschaft (DFG) (priority program 1137 "Molecular Magnetism") for funding of this work.

# Using Chiral Ligand Substituents To Promote the Formation of Dinuclear, Double-Stranded Iron, Manganese, and Zinc Mesocates

**Stuart D. Reid,[a] Claire Wilson,[a] Cristina I. De Matteis,[b] and Jason B. Love*[c]**

**Keywords:** Ligand design / Helical structures / Ligand effects / Supramolecular chemistry / Chirality

The synthesis and structures of dinuclear manganese, iron, and zinc complexes of chiral di-iminodipyrromethane ligands (L) are reported. Schiff base condensation reactions between 5,5′-diformyl-2,2′-dipyrromethane and the chiral amines (–)-(*R*)-CH(Me)*t*Bu and (+)-(*R*)-CH(Me)Ph result in the straightforward synthesis of the new, chiral ligands $H_2L^2$ and $H_2L^3$, respectively. Salt elimination reactions between $K_2L$ and divalent Mn and Fe halides, and protonolysis reactions between $ZnMe_2$ and $H_2L$ result in the formation of the new dinuclear complexes $[M_2(L)_2]$. Investigation of the structures of these compounds in solution and in the solid state reveal that chiral mesocates are formed for L = $L^2$, whereas for L = $L^3$, a racemic mixture of helicates is present.

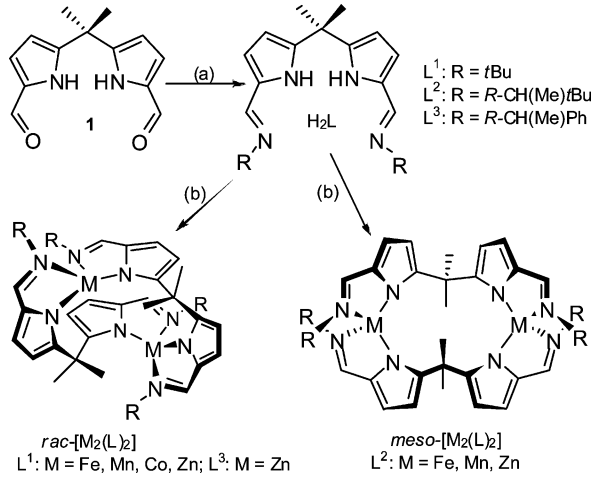
## Introduction

Dinuclear metallohelicates are often viewed as the simplest and most fundamental of chiral supramolecular architectures.[1] The clockwise (*P*) or counter-clockwise (*M*) helical rotation intrinsic to these compounds is inherited from the homochiral mechanical coupling of Δ or Λ chiral metal centres,[2] i.e. ΔΔ or ΛΛ configurations, respectively, while heterochiral coupling (ΔΛ) results in the assembly of the achiral mesocate or box diastereomer. The significance of chirality throughout the natural and physical sciences has prompted increased efforts in supramolecular chemistry to develop simple methodologies that discriminate between the formation of helicate and mesocate diastereomers, and, ultimately, between (*M*) and (*P*) enantiomers of metallohelicates. Racemic mixtures of metallohelicates can be separated by fractional crystallisation or by chromatographic techniques,[3] but a second chiral entity, such as a chiral anion or other templating agents,[4] and/or chiral ligands,[5–7] are necessary to direct the selective synthesis of single enantiomer helicates. The preferential, and diastereoselective, synthesis of mesocates instead of helicates appears controlled by a variety of factors, such as the modification (chiral or not) of the spacer unit between the two donor compartments,[8–10] the variation of the metal,[11–13] and the incorporation of a guest molecule.[14]

We identified previously the donor-extended dipyrromethane $H_2L^1$ (Scheme 1) as a ligand that is suitable for use in the synthesis of neutral, dinuclear metallohelicates due to the rigidity of the iminopyrrole chelates, the preference of iminopyrrole to pyrrole–pyrrole chelation in the potassium salt of the *meso*-$CPh_2$ analogue, $\{K_2[t\text{BuN=CH-}(C_4H_2N)_2CPh]_2\}$,[15] and the presence of the $sp^3$-hybridized hinge group between the two donor compartments. Indeed, divalent Mn, Fe, Co and Zn transition metal complexes of $L^1$ are isolated as the unusually volatile, double-stranded, dinuclear helicates $[M_2(L^1)_2]$ which are isostructural and display distinctive cleft motifs as a result of offset face-to-face π-stacking interactions between iminopyrrole groups



Scheme 1. Synthesis of the dinuclear, double-stranded, helicates and mesocates, $[M_2(L)_2]$. Reagents and conditions: (a) $L^2$: (*R*)-[*t*Bu(Me)HC]$NH_2$, $K_2CO_3$, EtOH; $L^3$: (*R*)-[Ph(Me)HC]$NH_2$, *p*-$C_6H_4MeSO_3H$, MeOH, (b) M = Mn, Fe, Co: (i) KH, THF, (ii) $MX_2$, THF, M = Zn: $ZnMe_2$, toluene, Δ.

of opposing ligand strands; this interaction is observed both in the solid state and in solution at low temperature.[16,17] Herein, we demonstrate that the introduction of chiral imine substituents, derived from chiral primary amines, to these ligands can result in the diastereoselective formation of unusual chiral mesocates,[10] and not the expected enantiopure helicates.

## Results and Discussion

### Synthesis of $[M_2(L)_2]$ Complexes

We have shown previously that the Schiff base condensation reaction between the dialdehyde **1** and *t*BuNH$_2$ in the presence of $K_2CO_3$ results in the formation of the imine-functionalised dipyrromethane ligand $H_2L^1$ in good yield.[16] By using a similar synthetic protocol, the new, chiral ligand $H_2L^2$ [R = (*R*)-CH(Me)*t*Bu] was prepared in good yield (Scheme 1), and was isolated as a volatile, yellow oil that was best purified by vacuum sublimation at 130 °C/$10^{-2}$ mbar. While the synthesis of $H_2L^3$ [R = (*R*)-CH(Me)-Ph] according to this route proved problematic, Schiff base formation was found to be assisted by the addition of a catalytic amount of *p*-toluenesulfonic acid; $H_2L^3$ was isolated as a very viscous orange oil from hot hexanes. The conversion of the dialdehyde **1** into the Schiff base ligands $H_2L$ is supported by the appearance of characteristic imine resonances at $\delta$ = 7.76 and 7.78 ppm in the $^1$H NMR spectra of $H_2L^2$ and $H_2L^3$, respectively, coupled with the loss of the aldehyde proton resonance at $\delta$ = 9.29 ppm in **1**.

The salt elimination reactions between $K_2L^2$, prepared in situ by the reaction between $H_2L^2$ and KH in THF, and $MnCl_2$ and $FeBr_2$ were carried out, and resulted in the respective formation of yellow $[Mn_2(L^2)_2]$ and orange $[Fe_2(L^2)_2]$ as crystalline solids in moderate isolated yields. The 1:1 metal/ligand ratios were supported by elemental analysis, and the formulation of these complexes as dinuclear by electron-impact mass spectrometry (EIMS), in which the molecular ion of $[Mn_2(L^2)_2]$ was observed at *m*/*z* (%) = 898 (14) [M$^+$], and that for $[Fe_2(L^2)_2]$ at *m*/*z* (%) = 900 (21) [M$^+$]. The solution magnetic susceptibilities were determined using Evans' method and found to be $\mu_{eff}$ = 8.06 and 7.28 $\mu_B$ for the Mn and Fe complexes, respectively. These data support the presence of two, spin-isolated tetrahedral Mn ($S$ = 5/2, $\mu_{calcd.}$ = 8.37 $\mu_B$) and Fe ($S$ = 2, $\mu_{calcd.}$ = 6.93 $\mu_B$) paramagnets; these magnetic moments are similar to those observed for the related helicate complexes $[Mn_2(L^1)_2]$ and $[Fe_2(L^1)_2]$, and suggest that neither direct M–M bonding nor magnetic superexchange pathways are present to enable spin coupling.[16] The protonolysis reaction between $ZnMe_2$ and $H_2L^2$ in toluene formed the dinuclear zinc complex $[Zn_2(L^2)_2]$ in good yield. As with the $Mn_2$ and $Fe_2$ complexes above, the 1:1 metal/ligand ratio was supported by elemental analysis, although in this case the complex was found to be solvated by dichloromethane, and EIMS displayed a molecular ion at *m*/*z* (%) = 918 (8) [M$^+$].

### Solid-State Structures of $[M_2(L^2)_2]$

An X-ray crystallographic study on single crystals of the Mn, Fe, and Zn complexes was undertaken in order to determine their structures in the solid state. The $[M_2(L^2)_2]$ complexes were found to have similar structures, with the Mn and Fe compounds isomorphous, and, surprisingly, were not the expected helicates, but were instead dinuclear, double-stranded mesocates that result from opposing ΔΛ configurations at the metal atoms. The solid-state structure of *meso*-$[Zn_2(L^2)_2]$ is shown in Figure 1 as ORTEP and space-filled diagrams, with the space-filled structure of the

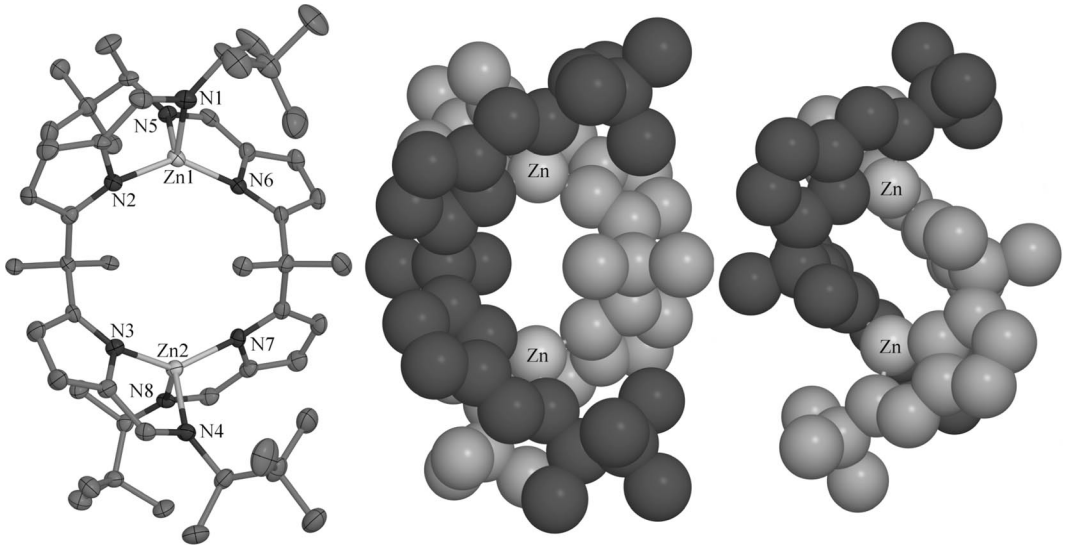

Figure 1. Solid-state structure of the mesocate $[Zn_2(L^2)_2]$ (left). For clarity, only one molecule from the asymmetric unit is shown, all hydrogen atoms are omitted, and thermal displacement ellipsoids are drawn at 50% probability; space-filled diagrams of *meso*-$[Zn_2(L^2)_2]$ (centre) and *rac*-$[Zn_2(L^1)_2]$ (right) are included for comparison.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

helicate analogue, *rac*-$[Zn_2(L^1)_2]$, included for visual comparison; selected bond lengths and angles are described in Table 1 and crystal data in Table 2.

Table 1. Selected bond lengths [Å] and angles [°] of *meso*-$[M_2(L^2)_2]$ complexes, M = Mn, Fe, Zn.

| | M = Mn | M = Fe | M = Zn |
|---|---|---|---|
| M–M | 5.32 | 5.29 | 5.39 |
| M1–N1 | 2.199(4) | 2.096(6) | 2.090(4) |
| M1–N2 | 2.067(4) | 2.024(6) | 1.984(4) |
| M1–N5 | 2.167(4) | 2.134(6) | 2.080(4) |
| M1–N6 | 2.082(4) | 2.005(6) | 1.973(4) |
| N1–M1–N2 | 82.79(15) | 84.8(3) | 85.02(16) |
| N1–M1–N5 | 102.78(16) | 102.1(2) | 103.05(15) |
| N1–M1–N6 | 119.81(14) | 117.9(3) | 120.64(16) |
| N2–M1–N5 | 120.20(16) | 117.8(2) | 119.53(16) |
| N2–M1–N6 | 145.31(14) | 144.6(2) | 140.38(16) |
| N5–M1–N6 | 82.50(15) | 85.4(2) | 85.84(16) |

In each structure, the metal atoms adopt distorted tetrahedral geometries with exceptionally obtuse angles (>140°) towards the intrametallic cavity of the mesocate, as defined by N2–M1–N6. These angles contrast to those observed for other dinuclear mesocates which are generally more acute, for example, the (diphenylmethane-linked iminopyridyl)dicopper complex, $[Cu_2\{CH_2(p\text{-}C_6H_4N{=}CH\text{-}o\text{-}C_5H_4N)_2\}_2]$, displays an N–Cu–N angle of 134.65(16)°,[13] and similarly, the internal N–Zn–N angle in the dizinc mesocate $[Zn_2\{(\text{-}CH_2N{=}CH\text{-}o\text{-}C_6H_4NSO_2C_6H_4Me\text{-}p)_2\}_2]$ measures 110.0(5)°; in this latter complex, however, there does exist a larger angle *exo* to the molecular cleft of 134.2(4)°.[12] The internal angles in the *meso*-$[M_2(L^2)_2]$ complexes are also significantly more obtuse than those of the corresponding helicates, *rac*-$[M_2(L^1)_2]$: 136.59(9)° (M = Mn), 137.35(9)° (Fe), 132.08(11)° (Zn). The M–N(pyrrole) and M–N(imine) bond lengths in the *meso*-$[M_2(L^2)_2]$ complexes are similar to those in *rac*-$[M_2(L^1)_2]$, and are consistent with the transition metals in their divalent oxidation states. The intrametallic M···M separations in *meso*-$[M_2(L^2)_2]$ (5.3–5.4 Å) are significantly longer than those observed for the *rac*-$[M_2(L^1)_2]$ complexes: 4.75 Å (M = Mn), 4.69 Å (Fe), 4.69 Å (Zn), and this lack of metal–metal bonding supports the above magnetochemical analysis.

## Solution Structures

The possible presence of both helicate and mesocate diastereomers in solution was assessed using $^1$H NMR spectroscopy. It was reasoned that the addition of chiral imine substituents located at the termini of the ligand would have no effect on the $D_2$ symmetry of the helicate, whereas that of the mesocate diastereomer would reduce from $C_{2h}$ to $C_2$ (Figure 2).

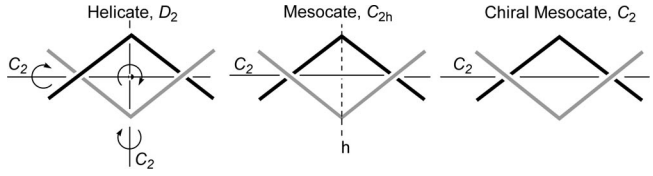

Figure 2. Effect of chiral ligand substituents on the symmetries of *rac*- and *meso*-$[M_2(L)_2]$.

The $^1$H NMR spectrum of $[Fe_2(L^2)_2]$ showed clean, paramagnetically shifted resonances that could be tentatively assigned by integration to the majority of the ligand protons, and was possibly indicative of a reduction in symmetry. However, the $^1$H NMR spectrum of $[Zn_2(L^2)_2]$, recorded in $C_6D_6$ (Figure 3), was more informative, and can be assigned to either a 50:50 mixture of diastereomers of the *rac*-helicate, i.e. (*R**,*R**)-(*M*)-$[Zn_2(L^2)_2]$ and (*R**,*R**)-(*P*)-$[Zn_2(L^2)_2]$, or the chiral mesocate (*R**,*R**)-*meso*-$[Zn_2(L^2)_2]$ as two sets of resonances are observed for each ligand proton environment. To differentiate between these two possibilities, $^1$H NMR NOE spectra were recorded (Figure 3), and show that irradiation of the single *meso*-methyl resonance at $\delta$ =

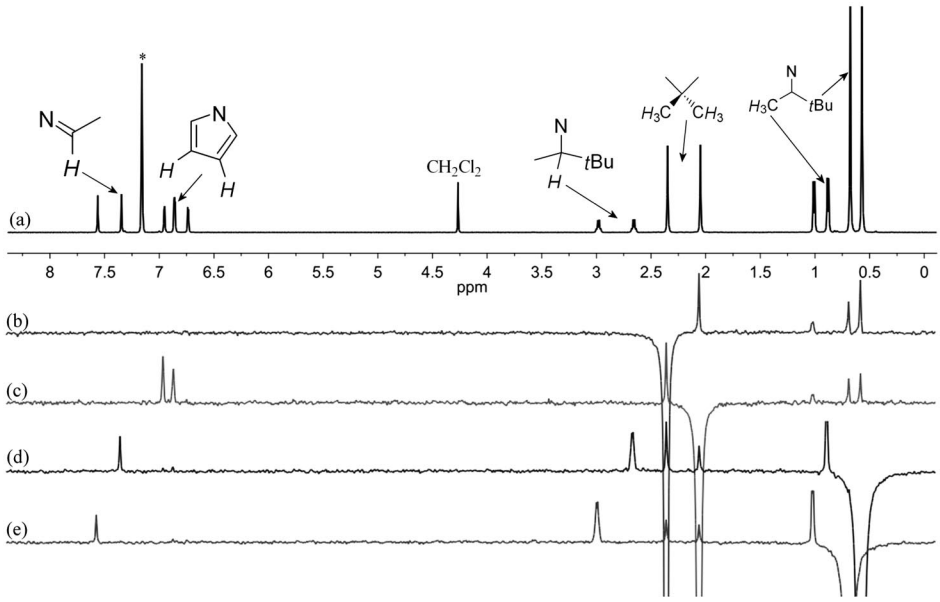

Figure 3. $^1$H NMR NOE experiments for $[Zn_2(L^2)_2]$ in $C_6D_6$ (*) at 298 K: (a) full $^1$H NMR spectrum; (b)/(c) irradiation of *meso*-$CH_3$ groups; (d)/(e) irradiation of terminal *t*Bu groups.

2.34 ppm results in positive NOE with the other *meso*-methyl resonance at $\delta$ = 2.04 ppm, and vice versa. In the helicate, the *meso*-methyl protons are identical by symmetry, and no NOE would be expected between the two (*R**,*R**)-(*M*) and (*R**,*R**)-(*P*) diastereomers as they are magnetically and chemically different; hence, it is clear that the complex $[Zn_2(L^2)_2]$ is a mesocate in solution. This is further corroborated by the observation of positive NOEs for both *meso*-methyl protons on the irradiation of separate *tert*-butyl protons. In the solid state, the *meso*-methyl groups of $[Zn_2(L^2)_2]$ occupy non-equivalent positions inside (*endo*) and outside (*exo*) the intrametallic cleft. It is evident that this structure is also adopted in solution, as positive NOEs between the *meso*-methyl protons at $\delta$ = 2.04 ppm and the pyrrolic protons at $\delta$ = 6.95 and 6.86 ppm are observed, while no NOE between the other *meso*-methyl and the pyrrolic protons is seen, i.e. only the *meso*-methyl protons with resonance at $\delta$ = 2.04 ppm have through-space proximity to the pyrrolic protons and so can be assigned as the *exo*-Me group.

## Helicate Formation

The reaction between $H_2L^3$ and $ZnMe_2$ was carried out to further assess the effect of chiral imine substituents on mesocate and helicate formation, and resulted in the formation of the dinuclear complex $[Zn_2(L^3)_2]$ in good yield; ligand $H_2L^3$ incorporates (*R*)-CH(Me)Ph imine substituents that have the same absolute configuration as those in $H_2L^2$. While we have been unable to determine the solid-state structure of $[Zn_2(L^3)_2]$ by single-crystal X-ray diffraction, the $^1$H NMR spectrum of the crude material in $C_6D_6$ (Figure 4a) was recorded, and was found to be similar to that of *meso*-$[Zn_2(L^2)_2]$ in which two pairs of resonances are observed for each ligand proton environment. However, it was noticed that the crude solid $[Zn_2(L^3)_2]$ was only partially soluble in $Et_2O$, and that after extraction with $Et_2O$, the $^1$H NMR spectrum of the residual solids had changed (Figure 4b) to one in which the two sets of proton resonances were now of unequal intensity (5:1 integral ratio); elemental analysis of these solids supported the 1:1 metal/ligand ratio expected for a dinuclear complex. As such, and in contrast to the complexes of $L^2$, it is clear that a racemic mixture of the two helical diastereomers, (*R**,*R**)-(*M*)-$[Zn_2(L^3)_2]$ and (*R**,*R**)-(*P*)-$[Zn_2(L^3)_2]$, has been formed, and that the two diastereomers can be partially separated by solvent extraction.

It is evident that upon elaboration of the ligand terminus, i.e. changing the imine substituent from *t*Bu to (*R*)-CH(Me)Ph to (*R*)-CH(Me)*t*Bu, there is a change in the gross structures of the dinuclear complexes, from double-stranded metallohelicates to mesocates, and that the effect of ligand variation is extremely subtle. Modifications to ligands that are capable of supporting helical structures have been shown previously to result in changes to the gross molecular structure. For example, variation of the stereo-controlling units between dicatecholate groups can result in the formation of triple-stranded mesocates in preference to helicates.[7,8] In these systems, however, it is likely that host-guest solvate interactions are the primary factor in favouring helicate or mesocate structures.[14] It has also been found that increasing the steric bulk from H to Et at the *ortho* positions of the phenyl spacers in double-stranded dicopper iminopyridine complexes promotes a helical twist at the methylene position, and so results in a change from a mixture of *meso* and *rac* diastereomers to purely *rac*-helicates. In the case of the above $[M_2(L)_2]$ complexes, it is

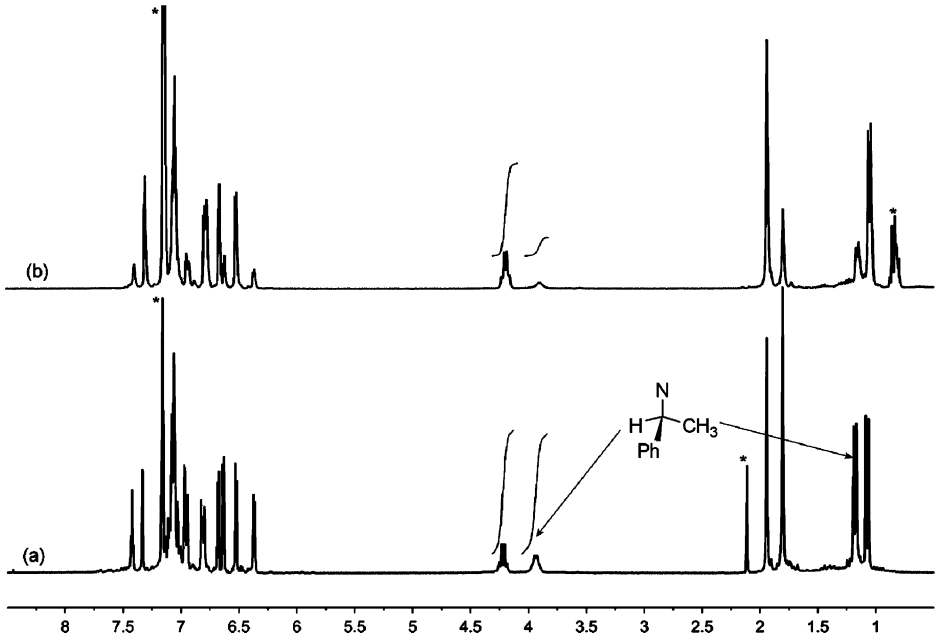

Figure 4. $^1$H NMR spectra of (a) crude $[Zn_2(L^3)_2]$, and (b) $Et_2O$-washed $[Zn_2(L^3)_2]$, in $C_6D_6$ (* $C_6D_6$, toluene and hexanes impurities).

unusual that the use of the chiral ligand substituent CH(Me)*t*Bu at the ligand terminus has resulted in a helicate to mesocate interconversion, as the addition of chiral terminal groups to the ligand usually results in the preferential formation of one helical enantiomer.[5] Furthermore, to the best of our knowledge, there is only a single reported example of a chiral dinuclear mesocate, formed as a result of reaction between an enantiopure tetradentate binaphthoxydiimine ligand and $Cu(OAc)_2$.[10] In this latter case, however, the formation of the chiral mesocate was found to depend on the length of the alkyl chain between the two N-O donor sets, with a shorter alkyl chain length resulting in the preferential formation of an enantiopure trinuclear circular helicate.

It is difficult to account for the favoured formation of the mesocate complexes over the helicates on addition of the bulky chiral imine substituent CH(Me)*t*Bu. However, it is clear that this preference is metal-independent, as Mn, Fe, and Zn helicates are formed using $L^1$, while only mesocates are formed with $L^2$ for the same metals. While it is possible that the salt elimination synthetic methodology could impart diastereoselectivity through host–guest or solvate interactions,[14] this appears unlikely as helicates of $L^1$ are also formed using transamination routes in nonpolar solvents.[16] To try to gain a better understanding of the factors behind the formation of helicates vs. mesocates, molecular-mechanics-based conformational analysis and geometry optimisations were carried out to determine the difference in energy between the helicate and mesocate structures of each of the three Fe complexes $[Fe_2(L)_2]$, where L = $L^1$, $L^2$ and $L^3$. The Fe complexes were chosen because of the availability of crystallographically determined helicate and mesocate Fe complex structures.[16]

## Molecular Mechanics Calculations

Energy differences between the helicate and mesocate structures for each of the Fe complexes were calculated using the Extensible and Systematic Force Field (ESFF) molecular mechanics method, which has been parameterized for all elements up to radon in the Periodic Table.[18] The conformational space of the substituents was explored using dihedral angle driving calculations where rotation around the substituent(C)–imine(N) bond was carried out in 60° increments, followed by energy minimisation of all resulting conformations. The crystallographic structures of the helicate $[Fe_2(L^1)_2]$ and the mesocate $[Fe_2(L^2)_2]$ were used as templates for generating the required pairs of structures. Inspection of the crystal structures of the helicate $[Fe_2(L^1)_2]$ and the mesocate $[Fe_2(L^2)_2]$ indicated that the bond lengths in the pyrrole rings corresponded, as expected, to partial double bonds. The bond lengths of the imine moieties, and the adjoining bond to the pyrrole ring, were more akin to double and single bonds, respectively. These bond types were therefore used in the ESFF calculations, and atom types were assigned accordingly.

The lowest energy structures arising from the dihedral angle driving calculations were identified, and the energy differences between the mesocate and helicate structures determined. While the differences in global minimum energy obtained were small ($<10$ kcal mol$^{-1}$) and insufficient to account for the observed differences in product distributions, it is notable that for $L^1$ ($\Delta E$ = 6.51 kcal mol$^{-1}$) and $L^3$ ($\Delta E$ = 4.75 kcal mol$^{-1}$), the helicate structure is of lower energy, whilst in the case of $L^2$ ($\Delta E$ = –1.26 kcal mol$^{-1}$) the mesocate structure is of lower energy; as such, these calculated energies correlate to the products observed experimentally.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

Although only weak effects, it is therefore likely that the steric demand and relative conformation of the imine substituents are contributory factors towards the preferential formation of the helicate or mesocate structures.

## Conclusions

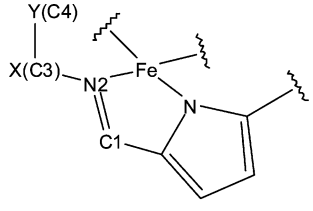
In this work we have shown that the incorporation of the bulky chiral imine substituent (*R*)-CH(Me)*t*Bu at the termini of the tetradentate ligand $H_2L^2$ disrupts the expected formation of the dinuclear, double-stranded helicates $[M_2(L)_2]$ to form preferentially the *meso* diastereomers $[M_2(L^2)_2]$; use of the sterically less demanding (*R*)-CH(Me)-Ph substituent results in racemic mixtures of the diastereotopic helicates, $[Zn_2(L^3)_2]$. The solid-state structures of the mesocates are retained in solution and can be differentiated from the helicates using $^1$H NMR NOE spectroscopy. In the solid state, the M···M separations are considerably longer in the mesocate structures than those of the helicate analogues, and a more obtuse N–M–N angle is subtended towards the intrametallic cleft. This transformation from helicate to mesocate is independent of the metals employed, and provides straightforward methodology to charge-neutral, chiral mesocates. However, the fundamental reasons behind preferential mesocate formation remain unclear, as, while molecular mechanics calculations suggest that the steric influence of the imine-substituent is influential, there remains insufficient thermodynamic distinction between helicate and mesocate structures.

## Experimental Section

**General Remarks:** Unless otherwise stated, all reactions were carried out using standard Schlenk techniques under nitrogen or argon or in a nitrogen-filled Vacuum Atmospheres OmniLab glovebox. Solvents were dried (hexanes, pentane, $Et_2O$ and THF were passed through activated alumina towers;[19] dichloromethane was distilled from $CaH_2$) and stored over molecular sieves (4 Å); all other solvents were used as purchased. Deuteriated benzene was refluxed in the presence of K, vacuum-distilled, and freeze-pump-thaw-degassed three times. The dipyrromethane $Me_2C(C_4H_4N)_2$,[20] and the dialdehyde synthon 5,5′-CHO-$Me_2C(C_4H_4N)_2$ (**1**)[15] were prepared according to literature procedures. $MnCl_2{\cdot}4H_2O$ was dried according to literature methods.[21] The $^1$H NMR and $^{13}$C{H} NMR spectra were recorded with a Bruker DPX-300 spectrometer operating at 300.13 and 75.47 MHz, respectively; residual protiosolvent served as an internal reference for the former. Combustion analyses were carried out by Mr. Stephen Boyer at the London Metropolitan University and EIMS by Dr. Ali Abdul-Sada of the University of Sussex.

**Crystallography. General Methods and Solution and Refinement Details:** Single-crystal diffraction data were collected using graphite-monochromated Mo-$K_\alpha$ X-radiation with either a Bruker SMART1000 {$[Fe_2(L^2)_2]$} or SMART APEX {$[Mn_2(L^2)_2]$, $[Zn_2(L^2)_2]$} CCD area detector diffractometer equipped with an Oxford Cryostream cooling device. All data were collected at 150 K. Details of the individual data collections and refinements are given in Table 2. Structures were solved with SHELXS-97 using heavy-atom methods for $[Mn_2(L^2)_2]$ and direct methods for $[Fe_2(L^2)_2]$ and $[Zn_2(L^2)_2]$. All structures were refined by least-squares full-matrix refinement against $F^2$ using SHELXL-97,[22] and all fully occupied non-H atoms refined with anisotropic atomic displacement parameters (adps). Hydrogen atoms were geometrically placed and refined as part of a riding model. $[Mn_2(L^2)_2]$ showed disorder in the two chiral C(Me)*t*Bu groups C20 and C26 which were modelled over two sites with occupancies 0.60 and 0.40 in both cases. C45 was modelled over two sites with occupancies 0.60 and 0.40. Geometric and rigid-bond restraints were applied in all cases, and partially occupied atom sites were refined with isotropic adps. The chiral C(Me)*t*Bu groups C1 and C45 showed large adps with no disorder model, so were refined with isotropic adps. The poorly defined solvent was accounted for by SQUEEZE and found to be 73 electrons/cell and was assigned as 1.5 molecules of hexane. $[Fe_2(L^2)_2]$ showed disorder in the two chiral C(Me)*t*Bu groups C20 and C45 which were modelled over two sites with occupancies 0.60 and 0.40, and 0.50 and 0.50, respectively. Geometric and rigid-bond restraints were applied in all cases, and partially occupied atom sites were refined with isotropic adps. The poorly defined solvent was accounted for by SQUEEZE and found to be 57 electrons/cell and was assigned as one molecule of hexane. $[Zn_2(L^2)_2]$ contained two molecules per asymmetric unit, and showed disorder in carbon C96 which was modelled over two sites with occupancies 0.45 and 0.55. CCDC-651321 to -651323 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

**Molecular Modeling Calculations:** Molecular mechanics energy calculations were carried out using the Extensible and Systematic Force Field (ESFF), as implemented within the Discover programme.[23] Modification, visualisation and analysis of molecular structures were carried out using the Insight II molecular graphics software.[23] Low-energy structures were obtained by conformational analysis and energy minimisation of the helicate and mesocate geometries of all three Fe complexes $[Fe_2(L)_2]$, where L = $L^1$, $L^2$ and $L^3$. The starting geometries for these complexes were obtained by either using or modifying the crystallographically determined Fe complex structures. For the helicate geometries, the crystal structure of $[Fe_2(L^1)_2]$ was used as a backbone structure, and the substituent altered using the Builder module within Insight II. For the mesocate geometries, the crystal structure of $[Fe_2(L^2)_2]$ was used as a backbone structure, and the CH(Me)*t*Bu substituents altered. In all cases the stereochemistry of the substituents were confirmed as (*R*). Conformational analysis was carried out by rotating around the C(substituent)–N(imine) bond, as defined in Figure 5, and subsequent geometry optimisation of the resulting conformations. The dihedral drive calculation involved rotation of the C1–N2–C3–C4 dihedral angle in each of the four substituents, from –180° to +180° in 60° increments, followed by unrestrained energy



$L^1$: X = $C(CH_3)_2$, Y = $CH_3$
$L^2$: X = $CH(CH_3)$, Y = *t*Bu
$L^3$: X = $CH(CH_3)$, Y = Ph

minimisation of each of the 2401 conformations arising. ESFF partial atomic charges and atom types were assigned; in particular the NH atom type was assigned for the pyrrole nitrogen atom. Minimisations were carried out using steepest descents, followed by conjugate gradient and Newton–Raphson methods, until the convergence criterion (maximum derivative = 0.001) was reached.

**Synthesis of $H_2L^2$:** (–)-(*R*)-3,3-Dimethyl-2-butylamine (4.83 g, 47.7 mmol) and $K_2CO_3$ (5.00 g) were added to a stirred solution of **1** (5.00 g, 21.7 mmol) in EtOH (100 mL). The resulting slurry was stirred for 24 h, after which the mixture was filtered and the precipitate washed once with EtOH (10 mL). The combined filtrate and washings were dried at reduced pressure, the resulting viscous red oil extracted with $CH_2Cl_2$ (10 mL) and transferred to a sublimation tube. The oil was sublimed twice at 130 °C/$10^{-2}$ mbar to yield $H_2L^2$ as a pale yellow oil, 6.46 g, 75%. $^1$H NMR ($C_6D_6$, 298 K): $\delta$ = 9.81 (br. s, 2 H, NH), 7.76 (s, 2 H, CH=N), 6.31 (d, $J$ = 3.6 Hz, 2 H, pyrrole H), 5.95 (d, $J$ = 3.6 Hz, 2 H, pyrrole H), 2.75 (q, $J$ = 6.5 Hz, 2 H, chiral CH), 1.08 (s, 6 H, *meso* $CH_3$), 1.04 (d, $J$ = 7.7 Hz, 6 H, chiral $CH_3$), 0.92 (s, 18 H, chiral $CMe_3$) ppm. $^{13}$C{$^1$H} NMR ($C_6D_6$, 298 K): $\delta$ = 149.7 (s, CH=N), 142.5 (s, $C_q$), 130.6 (s, $C_q$), 114.1 (s, CH), 106.8 (s, CH), 75.7 (s, chiral CH), 36.1 (s, $C_q$), 34.7 (s, $C_q$), 28.8 (s, *meso* $CH_3$), 27.2 (s, chiral $CMe_3$), 18.2 (s, chiral $CH_3$) ppm. ESMS: $m/z$ (%) = 397 (100) [$M^+$].

**Synthesis of $H_2L^3$:** (+)-(*R*)-Phenylethylamine (5.06 mL, 39.6 mmol) and *p*-toluenesulfonic acid (342 mg, 1.80 mmol) were added to a stirred solution of **1** (4.15 g, 18.0 mmol) in MeOH (100 mL). The resulting orange solution was stirred for 1 h and then concentrated to dryness at reduced pressure. The orange residues were extracted with hot hexanes (15 mL), filtered though a plug of Celite and the volatiles removed at low pressure for 24 h to yield $H_2L^3$ as a viscous orange oil, 5.02 g, 64%. $C_{29}H_{32}N_4$ (436.59): calcd. C 79.76, H 7.40, N 12.83; found C 79.68, H 7.87, N 12.57. $^1$H NMR ($C_6D_6$, 298 K): $\delta$ = 8.87 (br. s, 2 H, NH), 7.78 (s, 2 H, CH=N), 7.38 (d, $J$ = 7.1 Hz, 4 H, phenyl H), 7.10 (m, 6 H, phenyl H), 6.27 (s, $J$ = 3.6 Hz, 2 H, pyrrole H), 5.91 (s, $J$ = 3.6 Hz, 2 H, pyrrole H), 4.23 (q, $J$ = 6.6 Hz, 2 H, chiral CH), 1.49 (d, $J$ = 6.6 Hz, 6 H, chiral $CH_3$), 1.07 (s, 6 H, *meso* $CH_3$) ppm. $^{13}$C{$^1$H} NMR ($C_6D_6$, 298 K): $\delta$ = 150.0 (s, CH=N), 145.9 (s, $C_q$), 142.6 (s, $C_q$), 130.2 (s, $C_q$), 128.6 (s, CH), 127.1 (s, CH), 127.0 (s, CH), 114.6 (s, CH), 106.6 (s, CH), 69.5 (s, chiral CH), 35.7 (s, $C_q$), 28.2 (s, *meso* $CH_3$), 24.9 (s, chiral $CH_3$) ppm.

**Synthesis of $[Mn_2(L^2)_2]$:** A solution of $H_2L^2$ (586 mg, 1.48 mmol) in THF (10 mL) was added to a stirred slurry of KH (178 mg, 4.43 mmol) in THF (10 mL). Effervescence occurred immediately and the resulting slurry was stirred for 1 h, after which the ligand salt was added dropwise to a slurry of $MnCl_2$ (186 mg, 1.48 mmol) in THF (10 mL). The resultant yellow slurry was heated at 80 °C for 24 h, after which the mixture was filtered though Celite, and the yellow filtrate concentrated to dryness under reduced pressure. The yellow solid was extracted into hexanes (5 mL) and cooled to deposit 109 mg, 16% of $[Mn_2(L^2)_2]$ as a yellow crystalline solid. Crystals suitable for X-ray diffraction were grown by slow cooling a hexane solution to –30 °C. $C_{50}H_{76}Mn_2N_8$ (899.08): calcd. C 67.31, H 8.54, N 12.46; found C 67.39, H 8.42, N 12.45. EIMS: $m/z$ (%) = 898 (14) [$M^+$], 841 (53) [$M^+$ – *t*Bu], 450 (43) [$MnL^2$], 43 (100) [*t*Bu – Me]. $\mu_{eff}$ ($C_6D_6$) = 8.06 $\mu_B$.

**Synthesis of $[Fe_2(L^2)_2]$:** To a stirred slurry of KH (154 mg, 3.83 mmol) in THF (10 mL) was added a solution of $H_2L^2$ (507 mg, 1.28 mmol) in THF (10 mL). Effervescence occurred immediately and the resulting slurry was stirred for 1 h, after which the ligand salt was added dropwise to a stirred slurry of $FeBr_2$ (291 mg, 1.35 mmol) in THF (10 mL). The resultant red-brown slurry was heated at 80 °C for 24 h, after which the mixture was filtered, and the red filtrate concentrated to dryness under reduced pressure. The resultant orange solid was extracted into $Et_2O$ (5 mL) and cooled to –20 °C to deposit 276 mg, 48% of $[Fe_2(L^2)_2]$ as an orange crystalline solid. Crystals suitable for X-ray diffraction were grown by slow cooling a hexane solution to –30 °C. $C_{50}H_{76}Fe_2N_8$ (900.90): calcd. C 66.65, H 8.52, N 12.44, found C 66.46, H 8.52, N 12.29. $^1$H NMR ($C_6D_6$, 298 K): $\delta$ = 58.7 (s, 2 H) = 48.2 (s, 2 H), 8.6 (s, 2 H), 6.5 (br. s, 6 H), 4.8 (s, 6 H), –0.9 (s, 2 H), –2.4 (s, 18 H), –3.8 (s, 18 H) ppm. EIMS: $m/z$ (%) = 900 (21) [$M^+$], 843 (11) [$M^+$ – *t*Bu], 396 (48) [$L^2$], 339 (100) [$L^2$ – *t*Bu]. $\mu_{eff}$ ($C_6D_6$) = 7.28 $\mu_B$.

**Synthesis of $[Zn_2(L^2)_2]\cdot(CH_2Cl_2)$:** A solution of $ZnMe_2$ (2.0 M) in toluene (1 mL) was added to a stirred solution of $H_2L^2$ (574 mg, 1.45 mmol) in toluene (15 mL). Effervescence occurred immediately and the solution turned pale orange. The reaction mixture was heated at 80 °C under reduced pressure for 24 h, after which the solvents were evaporated under reduced pressure and the residues extracted with $CH_2Cl_2$ (2 mL). Pentane (10 mL) was then added until cloud point, and the solution was cooled, resulting in the deposition of 352 mg, 53% of $[Zn_2(L^2)_2]\cdot(CH_2Cl_2)$ as a pale yellow, crystalline solid. Crystals suitable for X-ray diffraction were grown by diffusion of pentane into a $CH_2Cl_2$ solution. $C_{50}H_{76}N_8Zn_2\cdot CH_2Cl_2$ (1004.9): calcd. C 60.96, H 7.82, N 11.15; found C 61.19, H 8.09, N 11.04. $^1$H NMR ($C_6D_6$, 298 K): $\delta$ = 7.55 (s, 1 H, CH=N), 7.33 (s, 1 H, CH=N), 6.95 (d, $J$ = 3.6 Hz, 1 H, pyrrole H), 6.86 (d, $J$ = 3.8 Hz, 2 H, pyrrole H), 6.73 (d, $J$ = 3.7 Hz, 1 H, pyrrole H), 4.24 (s, 1 H, $CH_2Cl_2$), 2.97 (q, $J$ = 6.8 Hz, 1 H, CH), 2.64 (q, $J$ = 6.6 Hz, 1 H, CH), 2.34 (s, 3 H, *meso* $CH_3$), 2.04 (s, 3 H, *meso* $CH_3$), 1.00 (d, $J$ = 6.8 Hz, 3 H, $CH_3$), 0.87 (d, $J$ = 6.6 Hz, 3 H, $CH_3$), 0.67 (s, 9 H, $CMe_3$), 0.56 (s, 9 H, $CMe_3$) ppm. $^{13}$C{$^1$H} NMR ($C_6D_6$, 298 K): $\delta$ = 159.5 (s, CH) = 158.3 (s, $C_q$), 158.2 (s, $C_q$), 158.0 (s, CH), 134.2 (s, $C_q$), 120.4 (s, CH), 120.1 (s, CH), 113.1 (s, CH), 112.5 (s, CH), 72.8 (s, CH), 68.3 (s, CH), 53.1 (s, $CH_2Cl_2$), 39.1 (s, $C_q$), 34.8 (s, $C_q$) ppm. 34.7 (s, $C_q$), 31.9 (s, *meso* $CH_3$), 26.8 (s, $CMe_3$), 26.7 (s, $CMe_3$), 23.3 (s, *meso* $CH_3$), 16.6 (s, $CH_3$), 15.8 (s, $CH_3$). EIMS: $m/z$ (%) = 918 (8) [$M^+$], 863 (26) [$M^+$ – *t*Bu], 49 (100) [*t*Bu – 8 H].

**Synthesis of $[Zn_2(L^3)_2]$:** A solution of $ZnMe_2$ (2.0 M) in toluene (0.5 mL) was added dropwise to a stirred solution of $H_2L^3$ (393 mg, 0.9 mmol) in toluene (10 mL). Gas evolved immediately and the resulting yellow-brown solution was heated at 80 °C for 24 h, after which the orange-yellow solution was dried at reduced pressure and the pale yellow solids inspected by $^1$H NMR spectroscopy. $^1$H NMR ($C_6D_6$, 298 K): $\delta$ = 7.60 (s, 2 H, CH=N), 7.34 (s, 2 H, CH=N), 7.3–6.7 (m, 20 H, phenyl H), 6.68 (d, $J$ = 3.5 Hz, 2 H, pyrrole H), 6.63 (d, $J$ = 3.5 Hz, 2 H, pyrrole H), 6.51 (d, $J$ = 3.5 Hz, 2 H, pyrrole H), 6.36 (d, $J$ = 3.5 Hz, 2 H, pyrrole H), 4.22 (q, $J$ = 7.1 Hz, 2 H, chiral CH), 3.92 (q, $J$ = 6.2 Hz, 2 H, chiral CH), 1.93 (s, 6 H, *meso* $CH_3$), 1.80 (s, 6 H, *meso* $CH_3$), 1.19 (d, $J$ = 7.0 Hz, 6 H, chiral $CH_3$), 1.08 (d, $J$ = 7.0 Hz, 6 H, chiral $CH_3$) ppm. The yellow solids were then extracted into $Et_2O$ (5 mL) and cooled. The resulting slurry was filtered and the liquors concentrated to dryness to yield 112 mg, 25%, of $[Zn_2(L^3)_2]$ as yellow solids. $C_{58}H_{60}N_8Zn_2$ (999.93): calcd. C 69.67, H 6.05, N 11.21; found C 69.54, H 6.15, N 11.15.

# Decomposition Cascades of Dicoordinate Copper(I) Chalcogenides

Heiko Jacobsen*[a][‡] and Mark J. Fink[b]

**Keywords:** Bond energy / Copper / Chalcogens / Density functional calculations / Dispersive interactions

Cu–E, Si–E, and Cu–P bond energies of $R_3PCuESiR_3$ and $CuESiR_3$ complexes (E = O, S, Se) have been investigated using PBE density-functional calculations, and including empirical corrections for dispersive interactions (DFT-D). The bond energies have been used to investigate likely pathways of molecular decomposition. The energy profile for thermal decomposition is to a large degree independent of the nature of the phosphane ligands and silyl groups. Oxides, sulfides, and selenides have qualitatively the same thermal decomposition profile. Thermal decomposition is not likely to produce copper chalcogenide units CuE, but elemental copper Cu instead. Consideration of intermolecular van der Waals attraction suggests that the linear geometry of system $t$Bu$_3$PCuOSiPh$_3$ as found in the crystal is most likely due to crystal packing and intermolecular forces.

## 1. Introduction

Copper(I) oxide and chalcogenide complexes find extensive usage in a broad variety of applications ranging from catalysis[1] over photovoltaic devices[2,3] to metallaprotein models.[4] In addition, this class of compounds displays a rich chemistry with a great diversity of stoichiometries and geometries, which is governed by the ability of the group 16 element to adopt either terminal or bridging coordination modes. Variations in the ligand framework around the copper center lead to polymeric or oligomeric cluster compounds,[5] structures with a cyclic $Cu_2E_2$ core,[6] and monomeric complexes.[7]

Copper also plays a major role in meeting the challenges of ever increasing requirements for electrical performance of on-chip wiring, because it is a key element of the interconnection network on a chip of high-performance semiconductor components.[8] One key technique in the design of such devices is chemical vapor deposition (CVD), and with the synthesis of new copper complexes that can be used in CVD applications, coordination chemistry is stretching the limits of micro-electronics technology.[9]

Recently, we reported the synthesis and characterization of the first triad of monomeric dicoordinate copper(I) chalcogenide complexes $t$Bu$_3$PCuESiPh$_3$ (**1**, E = O; **2**, E = S; **3**, E = Se).[10] The X-ray analyses of the copper silylchalcogenolates reveal significant structural structure differences originating from the nature of the chalcogen atom E. The oxygen atom in complex **1** has a linear coordination geometry in contrast to the highly bent sulfur and selenium analogs, **2** and **3**.

In a first theoretical analysis of dicoordinate copper(I) chalcogenides we have performed a detailed analysis of the structure and bonding of representative $H_3PCuESiH_3$ and $CuESiH_3$ model complexes.[11] In the present work, we focus on the thermochemistry of Cu–P, Cu–E, and Si–E bonds in this class of compounds. It is hoped that elucidation of possible decomposition cascades will provide valuable insight into the CVD applicability of copper chalcogenides. In addition, we provide an analysis and rationale of the unexpected molecular geometry of $t$Bu$_3$PCuOSiPh$_3$ **1** as found in the solid state.

## 2. Results and Discussion

The Cu–P, Cu–E, and Si–E bond energies for a variety of dicoordinate copper(I) chalcogenides have been investigated. The compound numbering of our model complexes is illustrated in Scheme 1.

Bond energies for Cu–P, Cu–E, and E–Si bonds have been estimated from dissociation enthalpies in the gas phase. For calculations of the bond-dissociation enthalpies at 0 K, $\Delta H^0$, reactants and products have been considered to adopt the geometry and electronic structure of their ground states. The decomposition pathways considered in this work are outlined on Scheme 2.

**2.1 The Copper–Phosphane Bond:** We begin our discussion with a detailed analysis of the Cu–P bond. The bond properties of the phosphane ligand have received considerable attention in the literature, and various concepts

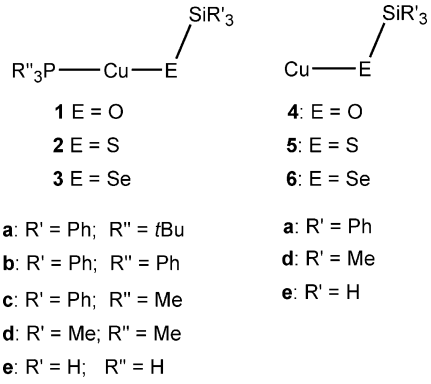


Scheme 1.

like the Tolman angle,[12] basicity parameters[13] or the lone-pair energy of the phosphane donor[14] find extensive use to predict and reason the bonding behavior of phosphanes toward transition-metal fragments. Here, we shall look at bond-dissociation enthalpies $\Delta H^0$, and we will make use of a partitioning of the so called bond-snapping energy $BE_{snap}$[15] into orbital contributions $\Delta E_{int}$ and steric terms $\Delta E^0$. The bond-snapping energy describes the interaction of two suitably prepared fragments, having the right geometry of the final molecule and an electron configuration that allows for bond formation. We model the Cu–P as donor–acceptor bond, and Cu–E and Si–E bonds as covalent bonds formed in the coupling of two radical fragments. In this work, $BE_{snap}$ contains an additional contribution due to dispersive interactions $E_{disp}$ between the phosphane ligands and the silyl groups, and the breakdown that is used here is given in Equation (1).

$$BE_{snap} = -[\Delta E^0 + \Delta E_{int} + E_{disp}] \quad (1)$$

We have drawn on this analysis extensively in our previous work on copper chalcogenide complexes,[11] and in addition we refer the reader to the literature[16] for a detailed account of the energy decomposition scheme employed in this work.

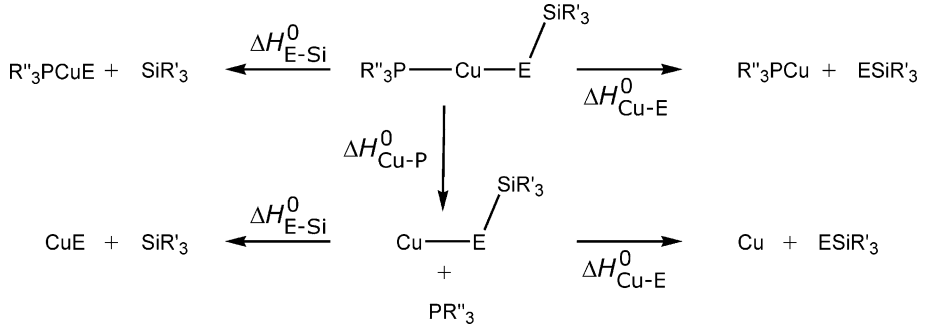
Bond-dissociation enthalpies $\Delta H^0$ and bond-snapping energies $BE_{snap}$ are collected in Table 1. Also included are the individual contributions to $BE_{snap}$ due to steric interaction $\Delta E^0$, orbital interaction $\Delta E_{int}$, and dispersive interaction $E_{disp}$.

Table 1. Energy terms (in kJ/mol) for the Cu–P bond of various copper(I) chalcogenides.

| | $\Delta E^0$ | $\Delta E_{int}$ | $E_{disp}$ | $BE_{snap}$ | $\Delta H^0$ |
|---|---|---|---|---|---|
| **1a** | –59 | –203 | –8 | 270 | 268 |
| **1b** | –17 | –221 | –13 | 251 | 250 |
| **1c** | –59 | –182 | –3 | 244 | 245 |
| **1d** | –48 | –178 | –1 | 227 | 213 |
| **1e** | –17 | –171 | 0 | 188 | 173 |
| **2a** | –38 | –194 | –10 | 242 | 235 |
| **2b** | –4 | –207 | –14 | 225 | 220 |
| **2c** | –40 | –172 | –4 | 216 | 212 |
| **2d** | –29 | –165 | –1 | 195 | 183 |
| **2e** | 1 | –155 | 0 | 154 | 140 |
| **3a** | –30 | –195 | –11 | 236 | 233 |
| **3b** | 0 | –199 | –11 | 210 | 209 |
| **3c** | –32 | –176 | –6 | 214 | 212 |
| **3d** | –23 | –165 | –1 | 189 | 177 |
| **3e** | 5 | –153 | 0 | 148 | 136 |

The bond-dissociation enthalpies follow the expected trend O > S ≈ Se; the $\Delta H^0$ values for the oxygen compounds are about 30 kJ/mol larger than those for the heavier chalcogenides. Within a series of chalcogenide compounds, the bond-dissociation enthalpies span a range of about 130 kJ/mol, where the P*t*Bu$_3$ compounds define the higher end, and the PH$_3$ complexes the lower end of the scale. Overall, the values are in good agreement with bond-dissociation enthalpies at 0 K. Discrepancies arise due to the fact that the geometric preparation energy[15] has not been accounted for, but the overall agreement justifies the derivation of trends based on a more detailed analysis of the bond-snapping energy $BE_{snap}$.

When we consider the individual components of the bond-snapping energy, we notice that the steric interaction $\Delta E^0$ constitutes a bonding rather than repulsive interaction. This indicates that attractive electrostatic interaction outweighs the contribution of the Pauli repulsion. The magnitude of the stabilizing steric interaction terms of the phosphane ligands PR$_3$″ can be ordered in terms of the R″ group as *t*Bu > Me > Ph > H. This trend correlates well with the accepted basicity of the phosphane ligands.[13] When the silyl group carries methyl rather than phenyl substituents, both the PR$_3$′′ ligand and the SiR$_3$ group compete for electrostatic interaction with the chalcogenide–metal core CuE. As a consequence, $\Delta E^0$ for the PMe$_3$ ligand is reduced



Scheme 2.

(compare entries **1c** and **1d**, **2c** and **2d**, **3c** and **3d** in Table 1).

The major contribution to $BE_{snap}$ arises from the orbital interaction energy $\Delta E_{int}$. If we extend the basicity arguments and restrict the interaction between a phosphane ligand and a copper–chalcogenide core to electron donation only, the phosphane lone-pair energies provide a measure of the ligand donor strength, and thus a measure of $\Delta E_{int}$. We then would expect the same qualitative ranking found for the steric interaction to be reciprocated in the orbital interaction: *t*Bu > Me > Ph > H. Inspection of the data in Table 1, however, indicates that the triphenylphosphane ligand unexpectedly shows the strongest orbital interaction.

By now, it is well recognized that the bond between the phosphane ligands and transition-metal fragments contains a sizeable contribution due to π-backdonation,[17] and an early DFT investigation of $(CO)_5Cr(PH_3)$ reports a metal–phosphane bond strength of 144 kJ/mol, with a contribution of about 25% attributed to π-backdonation.[18] Employing orbital-based arguments, the amount of backdonation between [P] and [CuE] fragments is qualitatively represented by the $HOMO_{[CuE]}$–$LUMO_{[P]}$ gap. An orbital analysis of model system has revealed the fact that Cu–E $\pi_{dp}$-antibonding orbitals are among the set of highest occupied molecular orbitals of the copper-chalcogenide core, and that backdonation from Cu-based d orbitals to σ* orbitals of the phosphane ligand strengthens the Cu–P bond.[11]

An inspection of the frontier-orbital energies of the phosphane ligands and copper–chalcogenide cores corroborates the trends in Cu–P bonding indicated thus far, and also provides an explanation for the unusually high $\Delta E_{int}$ contribution of the $PPh_3$ ligand. HOMO and LUMO energies for the CuE cores **4a**, **5a**, and **6a** and for the phosphanes $PR_3''$, R'' = *t*Bu, Ph, Me, H, are depicted in Figure 1.

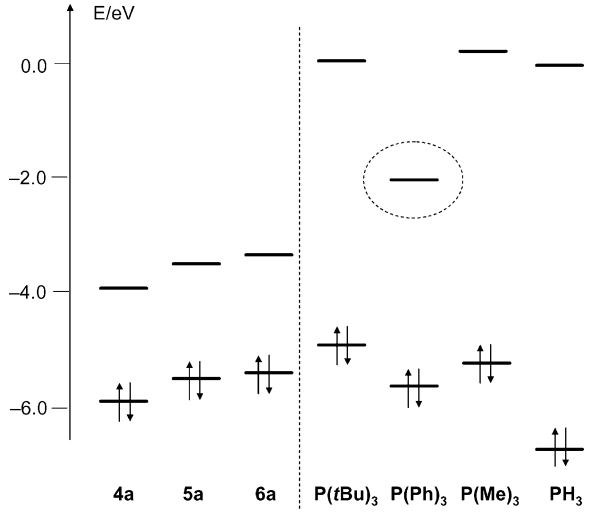

Figure 1. Frontier-orbital energies for copper–chalcogenide fragments (left) and phosphane ligands (right). The LUMO of $PPh_3$ is at an unexpectedly low energy level (dotted circle).

Trends in basicities correlate well with relative $HOMO_{[P]}$ energies. The LUMO of triphenylphosphane is at exceptionally low energy, which causes a reduced $HOMO_{[CuE]}$–$LUMO_{[P]}$ gap, and consequently enhances the backdonation. This observation accounts for the unexpectedly strong orbital interaction of triphenylphosphane.

When assessing the Cu–P bond strength, it is instructive to compare the Cu–P bond strength for the Cu atom to that for CuE cores. The Cu–P bond strength in $H_3P$–Cu is calculated to amount to 104 kJ/mol.[19] In contrast, the Cu–P bond-snapping energies $BE_{snap}$ in **1a**, **2a**, and **3a** are stronger by 69, 36, and 32 kJ/mol, respectively. The presence of the chalcogen atom significantly strengthens the Cu–P bond. This is due to backdonation out of filled Cu–E $\pi_{dp}$-antibonding orbital into empty σ* orbitals of the phosphane ligand.

Dispersive interactions $E_{disp}$ provide additional bond stabilization of up to 14 kJ/mol for systems with sterically demanding phosphane ligands and large silyl groups. We will return to the importance of dispersive interactions at a later point in our discussion.

**2.2 Bonds Involving Chalcogen Atoms:** The bond-dissociation enthalpies $\Delta H^0$ of Cu–E and E–Si bonds are displayed in Figure 2. The Cu–E, and E–Si bond strengths follow the expected trend O > S > Se. The silicon–oxygen bond is a strong bond with a dissociation energy of 536 kJ/mol,[20]

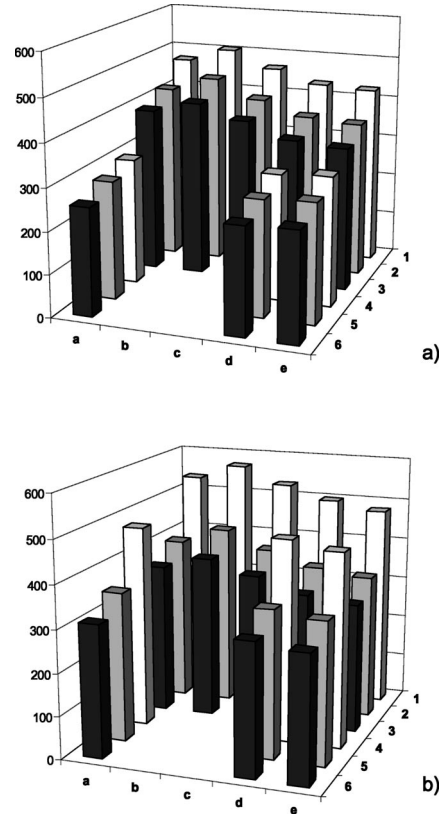

Figure 2. Bond-dissociation enthalpies $\Delta H^0$ (in kJ/mol) of copper–chalcogen bonds (Cu–E; Figure 2, a) and silicon–chalcogen bonds (Si–E; Figure 2, b).

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

and the O–Si bond-dissociation enthalpies for the copper chalcogenides fall all around this value. When we compare Cu–E bond energies of systems with phosphane ligands (**1**, **2**, **3**) with bond energies of systems without phosphane ligands (**4**, **5**, **6**), we find that coordination of a $PR_3$ significantly enhances the Cu–E bond strength. For example, if we consider the "real" systems **1a**, **2a**, **3a**, the copper–chalcogenide Cu–E bonds are stronger by 174 kJ/mol (E = O), 141 kJ/mol (E = S) and 138 kJ/mol (E = Se), in comparison to the "phosphane-free" systems **4a**, **5a**, and **6a**.

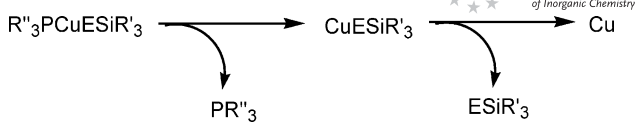
Not only does the presence of a chalcogen atom strengthen the Cu–P bond, as discussed above, but the presence of a phosphane ligand also induces a stabilization of the Cu–E bond. This synergistic effect is caused by enhanced π-backbonding from the copper center to the phosphane ligand. As mentioned before, Cu–E $\pi_{dp}$-antibonding orbitals are among the set of highest occupied molecular orbitals of the Cu–E core. Backdonation from Cu-based d orbitals to σ* orbitals of the phosphane ligand not only strengthens the Cu–P bond, but at the same reduces the antibonding Cu–E interaction and thus strengthens the Cu–E bond.

The Si–E bonding interaction too is enhanced due to the presence of an additional phosphane ligand. This secondary intrinsic effect amounts to 22 kJ/mol (E = O), 10 kJ/mol (E = S) and 9 kJ/mol (E = Se) for model compounds with $PH_3$ ligands and $SiH_3$ groups. For real systems with P*t*$Bu_3$ ligands and $SiPh_3$ groups, this effect is more pronounced and yields a secondary intrinsic stabilization energies of 59 kJ/mol (E = O), 43 kJ/mol (E = S) and 41 kJ/mol (E = Se), respectively.

If we compare relative Si–E and Cu–E bond strengths, we find that for systems without $PR_3$ ligands, the Si–E bonds are always stronger than the Cu–E bonds. The average energy differences are about 165 kJ/mol for oxygen complexes, but only about 65 kJ/mol and 50 kJ/mol for sulfur and selenium compounds, respectively. When we turn to phosphane complexes, we find modifications in this general trend due to the fact that the presence of phosphorus ligand significantly enhances the Cu–E bond strength. For the O complexes the energy difference between Si–O and Cu–O bonds decreases to about 60 kJ/mol, still in favor of the silicon–oxygen bond. For the heavier chalcogen atoms, the relative bond strengths between Si–E and Cu–E bonds is now inverted; and the S and Se complexes all have Cu–E bonds that are stronger than Si–E bonds by about 25 and 35 kJ/mol, respectively.

When we investigate the influence of the R′ and R′′ ligands on the strength of the Cu–E and Si–E bonds, we find that for phosphane systems these bond energies vary within a range of about 80 kJ/mol. For complexes without an additional phosphane ligand, we find that independent of the nature of the R′ group, for a given chalcogen element the values for Cu–E and Si–E bond-dissociation enthalpies are approximately the same.

**2.3 Decomposition Cascades:** We are now at a point that we can discuss possible decomposition pathways of dicoordinate copper(I) chalcogenides, Scheme 3.



Scheme 3.

For all complexes investigated in the present work, the Cu–P bond always constitutes the weakest link. Thus, thermal decomposition of a dicoordinate copper(I) chalcogenide (DCC) is most likely initiated by dissociation of the phosphane ligand; a process that results in formation of a monocoordinate copper(I) chalcogenide (MCC). For this type of compounds, contrary to DCCs, the Cu–E bond is always weaker than the Si–E bond. Therefore, the second step in thermal decomposition most likely involves cleavage of the Cu–E bond. Thermal decomposition is not likely to produce copper chalcogenide units CuE, but elemental copper Cu instead. Furthermore, the energy profile for thermal decomposition is to a large degree independent of the nature of the phosphane ligands and silyl groups. Oxides, sulfides, and selenides all have qualitatively the same thermal decomposition profile. In addition, sulfides and selenides display approximately the same quantitative thermodynamics.

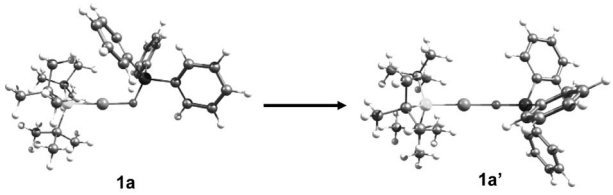
**2.4 The Structure of *t*$Bu_3$PCuOSi$Ph_3$ in the Gas Phase and in the Solid State:** X-ray crystallography has shown that the Cu atoms in the copper silylchalcogenolates *t*$Bu_3$PCuE-$SiPh_3$ (**1**, E = O; **2**, E = S; **3**, E = Se) have either a linear or a near-linear coordination geometry in all three complexes. Interestingly, the O atom in complex **1** is also linear, which is in contrast to the highly bent S and Se analogs, compounds **2** and **3**, respectively.[10] Our initial calculations on $H_3$PCuE$SiH_3$ model compounds have indicated that the unusual geometry of the oxygen compound **1** is not caused by intermolecular orbital interactions such as extended π-delocalization, but are the result of a fine balance of electrostatic interaction and Pauli repulsion.[11] In the last section of this work, we will address the unusual solid-state structure of *t*$Bu_3$PCuE$SiPh_3$ (**1a**) in more detail.

Our geometry optimization of **1a**, the gas-phase analog of the solid-state structure **1**, resulted in a bent geometry with an angle ∠(Cu–O–Si) of 117°. In addition, we optimized a linear structure **1a**′ by fixing the angle ∠(Cu–O–Si) at 180°. In the gas phase, the linear structure is 23 kJ/mol higher in energy compared to the bent ground state geometry, and an energy partitioning for the linearization process is outlined in Figure 3.

When complex **1a** takes on a linear, rather than a bent geometry, the distance between the P and Si centers of the sterically demanding peripheral ligands increases from 493 pm to 556 pm, and Pauli repulsion is reduced. As a consequence, the linear geometry is favored in terms of the steric interaction $\Delta E^0$. However, the orbital interactions $\Delta E_{int}$ as well as dispersive interaction are stronger in a bent arrangement, and as a consequence, the linear structure **1a**′ is higher in energy.

Our calculations indicate that the dispersive interactions $E_{disp}$ lead to an increase in bond energy in **1a** and therefore

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 



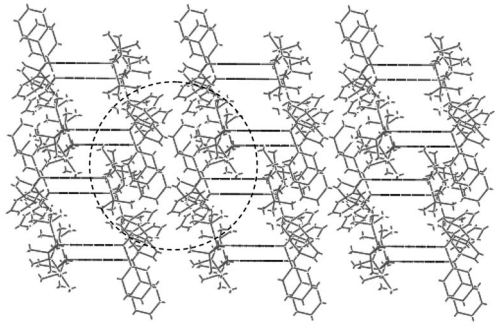
$\Delta E^0$ = –40 kJ/mol; $\Delta E_{int}$ = 56 kJ/mol; $\Delta E_{disp}$ = 7 kJ/mol; $\Delta E$ = 23 kJ/mol

Figure 3. Bond linearization of $t$Bu$_3$PCuOSiPh$_3$ in the gas phase.

to a larger barrier to planarity. We attribute this increase to an enhanced long-range $1/r^6$-induced dipole-induced dipole attraction. van der Waals forces not only incorporate short-range exponential repulsion arising from Pauli orthogonalization, but long-range dispersive attraction as well. Due to the large separation of the sterically demanding ligands, the long-range attraction outweighs the short-range repulsion, and nonbonded interactions strengthen, but not weaken, the Cu–P, Cu–E, and Si–E bonds.

Although the barrier to planarity is increased due to *intramolecular* dispersive attraction, in the crystal there exists the possibility of *intermolecular*, long-range dispersive interaction, which might lower the barrier to planarity or even favor a linear coordination geometry over a bent arrangement.

Compound **1** crystallizes in the highly symmetric space group $P\bar{3}$, in which the linear P–Cu–O–Si skeleton lies exactly on a crystallographic threefold rotation axis. The crystal packing for **1** is displayed in Figure 4; also indicated are neighboring phosphane ligands and silyl groups that give rise to dispersive stabilization.



**1a**(bent, solid state) → **1a'**(linear, solid state) $\Delta E_{disp}$ = –28 kJ/mol

Figure 4. Crystal packing of $t$Bu$_3$PCuOSiPh$_3$. Neighboring phosphane ligands and silyl groups from different molecular units undergo dispersive interaction (dotted circle).

We have calculated intermolecular dispersion energies for the linear geometry **1a**′ based on the crystal structure of **1**. The dispersion forces in the solid state for a bent geometry **1a** were modeled after the crystal structure of the sulfur analog, and if we compare the dispersive lattice energies we find that the linear arrangement is favored over a packing of a bent molecular unit by 28 kJ/mol per molecule. The energetic stabilization of a linear arrangement due to packing forces slightly outweighs the preparation energy required to distort the bent structure and we conclude that the unusual molecular structure of $t$Bu$_3$PCuOSiPh$_3$ as observed in the solid state results from crystal packing, and is not an indication of unusual intermolecular bonding.

Molecular structures as obtained from crystal structure analysis are not always good representations for the geometry of the isolated and unperturbed molecule. If the potential energy surface of internal molecular coordinates is shallow and does not display a pronounced minimum, intermolecular dispersive forces as well as intermolecular electrostatic interaction[21] might significantly influence the geometry of the molecular unit in the solid state.

## 3. Conclusion

As stated in the introduction, one of the main goals of the present work was to elucidate the CVD applicability of copper chalcogenides, and in conclusion of this work, we shall summarize our findings with respect to this question. We found that the energy profile for thermal decomposition is to a large degree independent of the nature of the phosphane ligands and silyl groups. We also found that oxides, sulfides, and selenides have qualitatively the same thermal decomposition profile.

A minor aspect of the current work was the analysis and rationalization of the unexpected molecular geometry of $t$Bu$_3$PCuESiPh$_3$ as found in the solid state. Consideration of intermolecular van der Waals attraction suggests that the linear geometry of system $t$Bu$_3$PCuOSiPh$_3$ as found in the crystal is most likely due to crystal packing and intermolecular forces.

## 4. Computational Details

Density-functional calculations have been carried out using the Amsterdam Density Functional ADF suite of programs, version ADF2006.01.[22] The calculation were based on the local-density approximation with Slater exchange[23] and VWN-V correlation.[24] Gradient corrections as proposed by Perdew, Burke and Enzerhof[25] have been added self-consistently.

Molecular orbitals were expanded in an uncontracted set of Slater-type orbitals (STOs). For H and C the basis used was of double-ζ quality, whereas for O, Si, P, S, and Se a triple-ζ basis has been employed, and both basis sets were augmented with one set of polarization functions (ADF basis sets III and IV, respectively). The transition metal was described by a triple-ζ basis augmented with two sets of polarization functions (ADF basis set V). The core shells (C, O: 1s; Si, P, S, Cu: 1s2s2p; Se: 1s2s2p3s3p3d) were treated by the frozen-core approximation, and an auxiliary set of s, p, d, f and g STOs was used to fit the molecular density and to represent the Coulomb and exchange potentials accurately in each SCF cycle.[26]

Geometries have been optimized according to the method developed by Versluis and Ziegler.[27] Frequencies for molecules with R′ = R′′ = H have been calculated analytically,[28] and served as basis for zero-point-energy corrections. Empirical corrections for intramolecular dispersive forces between $SiR_3'$ groups and $PR_3''$ ligands have been included for geometry optimization and energy calculations (DFT-D).[29]

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

Intermolecular dispersive interactions in the crystal have been calculated with the Generalized Lattice Utility Program GULP.[30] These calculations employ an undamped dispersion potential of the form suggested by Tang and Toennies.[31]

The consistency of the density functional calculations has been checked by single point calculations using other pure and hybrid density functionals, as well as different basis sets. These calculations are documented in the Supporting Information.

**Supporting Information** (see also the footnote on the first page of this article): Cartesian coordinates and final energies for optimized complexes. Results of consistency calculations.

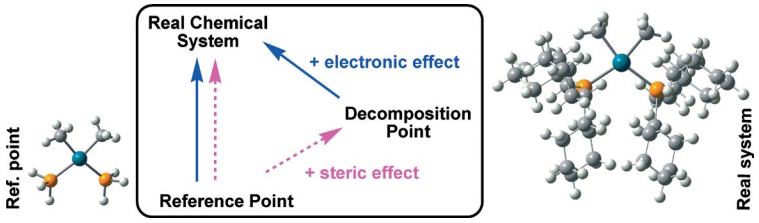
Critical Effect of Phosphane Ligands on the Mechanism of Carbon–Carbon Bond Formation Involving Palladium(II) Complexes: A Theoretical Investigation of Reductive Elimination from Square-Planar and T-Shaped Species

**Keywords:** C–C coupling / Palladium / Catalysis / Steric effect / Electronic effect / Phosphane ligands



Relative reactivity in carbon–carbon bond formation involving a four-coordinated pathway follows the order: L = $PPh_3$ > $PH_3$ > $PCy_3$ > $PMe_3$. However, for reductive elimination involving T-shaped complexes by the ligand predissociation pathway, relative reactivity changes in the order: L = $PCy_3$ > $PPh_3$ > $PH_3$ > $PMe_3$.

# Transition-Metal-Free Boron–Carbon Bond Activation: Insertion of an NNP Fragment into a Boron–Carbon Bond

**Markus Kowalewski,[a] Burkhard Krumm,[a] Peter Mayer,[a] Axel Schulz,*[b,c] and Alexander Villinger[b]**

*Dedicated to the memory of Nils Wiberg*

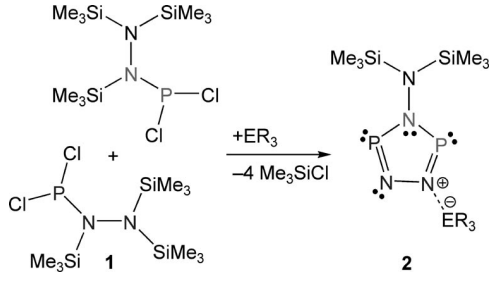
**Keywords:** Azaphosphole / Diazadiphosphetidine / Insertion / Lewis acids / Boranes / X-ray elucidation

The influence and reactivity of fluorine-containing Lewis acids such as neat $BF_3$, $BF_3{\cdot}OEt_2$, and $B(C_6F_5)_3$ on $Me_3SiCl$ elimination in $(Me_3Si)_2N–N(SiMe_3)–PCl_2$ was investigated. The reaction with $B(C_6F_5)_3$ resulted in the formation of a novel diazadiphosphetidine with a phosphorus(III) atom attached to a pentafluorophenyl group, which can be regarded as a formal NNP fragment insertion into a B–C bond.

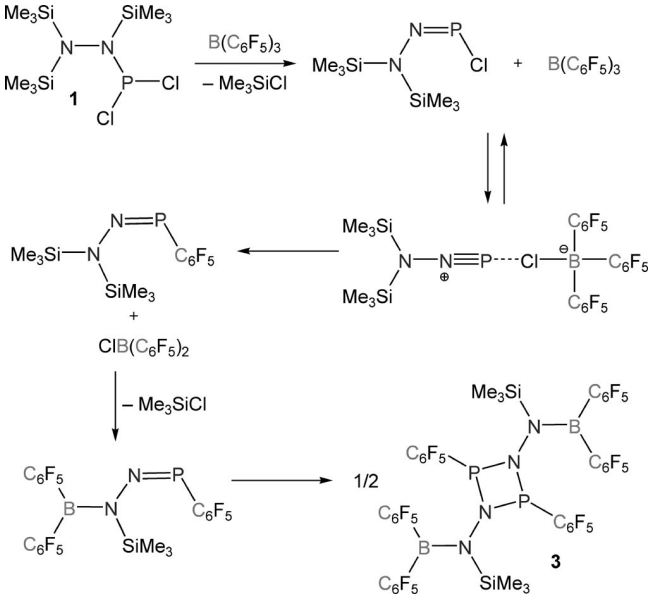
(© Wiley-VCH Verlag GmbH & Co. KGaA, 69451 Weinheim, Germany, 2007)

## Introduction

The $GaCl_3$-assisted elimination in silylated dichloro(hydrazino)phosphane,[1–3] $(Me_3Si)_2N–N(SiMe_3)–PCl_2$, followed by a formal [3+2] cycloaddition[4] represents an elegant approach to the formation of triazadiphospholes and tetrazaphospholes, which was introduced only recently (Scheme 1). As this reaction sequence only occurs when $GaCl_3$ is added into a solution of $(Me_3Si)_2N–N(SiMe_3)–PCl_2$ (**1**) in common organic solvents (e.g. $CH_2Cl_2$, benzene, etc.), this new reaction type was named a $GaCl_3$-assisted [3+2] cycloaddition. The ambivalent $(Me_3Si)_2N–N(SiMe_3)–PCl_2$ displays both dipolarophile and/or 1,3-dipole characteristics. $GaCl_3$ is required to release the hidden dipolarophile and/or 1,3-dipole by decreasing the activation barrier to $Me_3SiCl$ elimination. In this context, we studied the influence of fluorine-containing Lewis acids such as neat $BF_3$, $BF_3{\cdot}OEt_2$, and $B(C_6F_5)_3$ on the $Me_3SiCl$ elimination in



Scheme 1. Lewis acid assisted [3+2] cycloaddition with ambivalent dichloro(hydrazino)phosphane (**1**) to yield a triazadiphosphole [$ER_3$ = $GaCl_3$, $B(C_6F_5)_3$].



Scheme 2. Proposed mechanism of the $B(C_6F_5)_3$-assisted 1,2-elimination of $Me_3SiCl$ in **1** followed by an unusual insertion of a NNP fragment into a B–C bond, which finally results in the formation of **3**.

$(Me_3Si)_2N–N(SiMe_3)–PCl_2$. Herein, we detail the reactivity of these fluorine-containing Lewis acids towards $(Me_3Si)_2$-N–$N(SiMe_3)$–$PCl_2$, which proceeds in the case of $B(C_6F_5)_3$, by the first reported example of an unusual NNP fragment insertion into a boron–carbon bond (Scheme 2).

## Results and Discussion

Absolutely no reaction was observed when a large excess of neat $BF_3$ (b.p. –100 °C, ca. 15 mL) was added to **1** at –110 °C. Also, after further stirring of this reaction mixture for 5 h at –100 °C no $Me_3SiCl$ elimination could be observed; only the starting material was isolated after removal of $BF_3$. Obviously, thermal activation is needed to trigger $Me_3SiCl$ elimination. Hence, **1** was treated with $BF_3$ in diethyl ether at ambient temperature. This reaction led to complete decomposition. Compounds $[N_2H_5]^+[BF_4]^-$,[5] $Me_3SiF$, and $PFCl_2$ could be identified amongst the decomposition products.

These failures prompted us to utilize the sterically demanding fluorine-containing Lewis acid $B(C_6F_5)_3$. Again, no reaction was observed when **1** was added to a solution of $B(C_6F_5)_3$ in $CH_2Cl_2$ at ambient temperature. Only upon heating of this solution in a sealed tube up to 70 °C did slow $Me_3SiCl$ elimination occur, which was completed after 3 d of stirring as shown by $^{31}P$ NMR spectroscopic studies (**1**: $^{31}P$ NMR: $\delta$ = 166.6 ppm disappeared).

Contrary to the reaction of **1** with $GaCl_3$, the reaction with $B(C_6F_5)_3$ yielded two products: (1) a highly soluble $B(C_6F_5)_3$ adduct of the expected trizadiphosphole (**2**) (NMR yield 24%, Scheme 1, multiplets in the $^{31}P$ NMR spectrum at $\delta$ = 317.4 and 286.4 ppm; cf. $GaCl_3$ adduct: 317.2 and 292.1 ppm)[1] and (2) a new species (NMR yield 42%, $^{31}P$ NMR: $\delta$ = 253 ppm). Surprisingly, upon cooling of the above reaction mixture down to 5 °C, a large amount of beautiful orange crystals of the new species was obtained (isolated yield 29%). Single-crystal X-ray studies revealed a surprising 2,4-bis(pentafluorophenyl)-1,3-bis[*N*-trimethylsilyl-*N*-bis(pentafluorophenyl)boranyl]amino[1,3,2,4]diazadiphosphetidine (**3**) as the product (Scheme 2, Figure 1).

Pure dry **3** is stable at temperature up to 400 °C (m.p. 225 °C), is neither heat nor shock sensitive, and decomposes even only slowly in water and on air indicating a good kinetic protection by the bulky $C_6F_5$ groups. It should be mentioned that **3** is almost insoluble in any common solvent at ambient temperature.

X-ray elucidation of the orange crystals revealed a four-membered P–N heterocatenated ring (**3**) with two P–$C_6F_5$ and two N–R [R = $N(SiMe_3)(B(C_6F_5)_2)$] centers, and its formation can be described as a dimerization of monomeric R–N–N=P–$C_6F_5$, which is formed by $Me_3SiCl$ elimination (Figure 1 and Scheme 2) followed by an intriguing transfer of one pentafluorophenyl group (see below). Compound **3** crystallizes in cubes in the triclinic space group $P\bar{1}$ with one unit per cell. The asymmetric unit of **3** consists of only half of the molecule. The entire molecule can be generated by an inversion center sited on the centroid of the $P_2N_2$ four-membered ring. Moreover, this molecule is found to be disordered. Two different positions, which displays the existence of two conformers, are found for both P–$C_6F_5$ moieties with an occupation of 61.5 (**A**) and 38.5% (**B**). Both positions correspond to a rotation about the N–N axis with an angle of 109.2° between both rings. In both conformers the $P_2N_2$ ring is ideally planar [∠ P2–N2–P2′–N2′ = 0.0° (**A**), ∠ P1–N2–P1′–N2′ = 0.0° (**B**)].

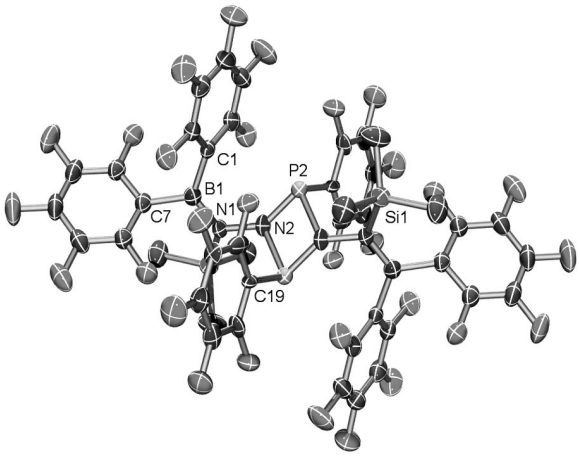

Figure 1. ORTEP drawing of the molecular structure of **3** (conformer **A**) in the crystal. Thermal ellipsoids with 50% probability at 200 K (hydrogen atoms omitted for clarity). Selected bond lengths [Å] and angles [°]: P2–N2 1.664(2), P2–N2′ 1.793(2), P2–C13 1.913(3), P2–P2′ 2.649(2), Si1–N1 1.818(2), N1–B1 1.400(3), N1–N2 1.442(3); N2–P2–N2′ 80.0(1), N2–P2–C13 105.2(2), N2–P2–P2′ 41.78(7), B1–N1–N2 117.4(2), B1–N1–Si1 125.4(2), N2–N1–Si1 115.4(1), N1–N2–P2 131.8(2), P2–N2–P2′ 100.0(1), N1–B1–C7 122.2(2), C1–B1–C7 114.3(2).

$^{31}P$ MAS NMR studies proved the existence of two conformers in the solid state (Figure S1),[6] which is indicated by two resonances at $\delta$ = 264.0 (isomer **A**, Figures 1 and 2) and 240.7 ppm (isomer **B**, Figure 2). Interestingly, we were able to assign these two resonances on the basis of the excellent agreement between theoretically and experimentally obtained values of the $^{31}P$ NMR chemical shift tensor (see Supporting Information).[6a]

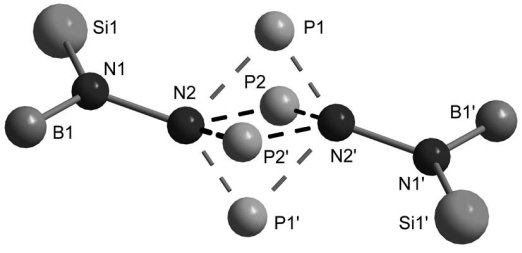

Figure 2. Illustration of the disorder problem in **3**. Conformer **A** corresponds to the N2–P2–N2′–P2′ plane, **B** to the N2–P1–N2′–P1′. All H, C, and F atoms are omitted for clarity.

Conformer **A** is shown in Figure 1, and it displays a *trans* arrangement of the two $C_6F_5$ groups attached to the P atoms, which is also found in conformer **B**. As expected for tricoordinated phosphorus(III) species, two rather long and two short P–N distances are found [*d*(P2–N2) = 1.664(2) Å,

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

*d*(P2–N2′) = 1.793(2) Å (**A**); *d*(P1–N2) = 1.631(2) Å, *d*(P1–N2′) = 1.838(3) Å (**B**)]. Comparison with the sum of the covalent radii [$d_{cov}$(N–P) = 1.8 Å, $d_{cov}$(N=P) = 1.6 Å] indicates partial π bonding for the shorter P–N distance in both conformers [1.664(2) and 1.631(2) Å]. A large and a small angle are found for the $P_2N_2$ ring [∠ N2–P2–N2′ = 80.0(1)°, ∠ P2–N2–P2′ = 100.0(1)° (**A**); ∠ N2–P1–N2′ = 79.5(1)°, ∠ P1–N2–P1′ = 100.5(1)° (**B**)]. Selected structural data of both conformers are summarized in Tables S2 and S3.[6b]

The complete mechanism for the formation of a triazadiphosphole (**2**) according to Scheme 1 is still unknown although 1,2-elimination of $Me_3SiCl$ was experimentally proven as the initial step.[3] When $B(C_6F_5)_3$ is used as the Lewis acid two things are worthy to be discussed: (1) a large thermal activation (3 d at 70 °C) is needed to trigger $Me_3SiCl$ elimination (cf. $GaCl_3$ reaction: 1 h at 20 °C) and (2) the formation of a different species, a diazadiphosphetidine (**3**), as the main product beside **2** is observed (Schemes 1 and 2).

Presumably, after the initial elimination of $Me_3SiCl$, free borane can attack the second chlorine atom attached to the phosphorus atom of the iminophosphane chloride, which leads to chlorine/$C_6F_5$ exchange (Scheme 2). The intermediate $ClB(C_6F_5)_2$ reacts under $Me_3SiCl$ elimination to give monomeric **3**. Reactions of $ClB(C_6F_5)_2$ with $Me_3Si$-substituted amines are known,[7] for example, $ClB(C_6F_5)_2$ treated with $HN(SiMe_3)_2$ yields $HN(SiMe_3)[B(C_6F_5)_2]$ or $HN[B(C_6F_5)_2]_2$ depending on the stoichiometry. Moreover, the $ClB(C_6F_5)_3^-$ anion is well known.[8] Finally, dimerization results in the formation of diazadiphosphetidine **3**. For kinetic reasons, the formation of **3** is favored when $B(C_6F_5)_3$ is used, whereas only **2** is observed when $GaCl_3$ is used as the Lewis acid. The overall reaction of **1** with $B(C_6F_5)_3$ can be regarded as the insertion of $Me_3Si$–NNP (covalent azide analogue containing one phosphorus atom) into one B–C bond, followed by a final dimerization process or a formal [3+2] addition of the borane to $Me_3SiNNP$, which is generated in situ after elimination of two molecules $Me_3SiCl$. It should be emphasized that both reactions according to Schemes 1 and 2 can be reproduced.

Transfer reactions involving the $C_6F_5$ group are well known in transition-metal chemistry,[9] and they are often responsible for catalyst poisoning.[10] Such transition-metal-induced $C_6F_5$ transfer reactions often follow after the formation of intermediates, and they are stabilized by F···M agostic interactions with a cationic transition-metal center (M).[11] The latter interaction often leads to C–F activation, which may even result in M–F bond formation by C–F bond cleavage. Metal-free C–F bond activation is also known, for example, when secondary phosphanes such as $(Me_3C_6H_2)_2PH$ are treated with $B(C_6F_5)_3$ to yield $(Me_3C_6H_2)_2PH(C_6F_4)BF(C_6F_5)_2$.[12] Shifts of the $C_6F_5$ group are known to possess large activation barriers, for example, a large activation barrier for a 1,2-shift of a $C_6F_5$ group has already been observed by Metzler and Denk in a silylene–borane adduct, which slowly rearranges to a stable silylborane with a half-life of about one month.[13]

To estimate the thermodynamics of the formation of **2** and **3** and to obtain insight into the bond-formation process, computations were carried out at the B3LYP/6-31G(d,p) level of theory.[6d,6e,14] The calculated energy for the formation of triazadiphosphole (**2**) is an exothermic and an exergonic process for all of the Lewis acids studied [Scheme 1; $\Delta_{298}G^0$ = –317.3, –331.2, –348.6, and –304.2 kJ mol$^{-1}$ for $BF_3$, $BCl_3$, $BBr_3$, and $B(C_6F_5)_3$, respectively]. The latter value can be compared with the formation of **3** for which a smaller energy release was calculated ($\Delta_{298}G^0$ = –258.0 kJ mol$^{-1}$). The formation of the monomeric species [according to **1** + $B(C_6F_5)_3$ → ½**3** + 2$Me_3SiCl$] is associated with an energy gain of –135.8 kJ mol$^{-1}$, whereas dimerization is slightly endergonic with 13.6 kJ mol$^{-1}$. It is interesting to note that monomeric **3** is observed with a large intensity in the mass spectrum besides the dimer.

As expected, according to NBO analysis (natural bond orbital)[6d,6e,15] the NP bonds within the $P_2N_2$ ring of **3** are purely σ in character and are strongly polarized (N: 77%, P: 23%) with a partial charge of +1.28*e* at the phosphorus atom and –0.95*e* at the nitrogen atom. We calculate a charge of –0.86*e* at the exocyclic nitrogen atom and a positive charge of +0.87*e* and +1.93*e* at the boron and silicon atoms, respectively.

## Conclusion

The formation of **3** represents the first example of the insertion of a NNP fragment into a B–C bond. In this context, our results offer a new perspective on the insertion and activation of boron–carbon bonds. Moreover, **3** is the first example of a structurally characterized diazadiphosphetidine with phosphorus(III) attached to a perfluoro group.

## Experimental Section

**3:** To a stirred solution of dichloro[*N*,*N*′,*N*′-tris(trimethylsilyl)hydrazino]phosphane (1.75 g, 5 mmol) in dichloromethane (10 mL) was slowly added a solution of tris(pentafluorophenyl)borane (2.82 g, 5.5 mmol) in dichloromethane (10 mL) by syringe at ambient temperature. The yellowish solution was heated in a sealed tube under reflux for 3 d at 70 °C, which resulted in an orange suspension. After cooling to room temperature, the solution was concentrated to a total volume of 10 mL and stored at 0 °C overnight to afford an orange, microcrystalline powder. Dichloromethane (10 mL) was added, and the orange residue was filtered (F4) and washed several times by repeated back distillations of the solvent. The product was dried in vacuo to yield 0.94 g (29%) of **3** as an orange solid. M.p. 225 °C. FTIR (KBr): $\tilde{\nu}$ = 2992 (vw), 2964 (vw), 2908 (vw), 1648 (m), 1519 (s), 1480 (s), 1397 (m), 1366 (m), 1312 (m), 1285 (m), 1259 (m), 1150 (m), 1089 (m), 1043 (w), 1017 (w), 976 (s), 928 (w), 854 (s), 778 (m), 722 (w), 669 (w), 629 (w), 503 (w) cm$^{-1}$. Crystals suitable for single-crystal X-ray studies were obtained by cooling the reaction solution slowly to 5 °C. An X-ray quality crystal of **3** was selected in silicon oil at ambient temperature and was cooled to 200(2) K during measurement. The data for compound **3** was collected with a Nonius Kappa CCD diffractometer by using graphite-monochromated Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073). The structure was solved by direct methods and refined by full-matrix least-squares procedures (SHELXL-97).[16] All non-hydrogen atoms were refined anisotropically; hydrogen atoms were included in the refinement at calculated positions by using a riding model. The P($C_6F_5$) unit was split over two positions and the occupancy of each part (**A** and **B**) refined. For the carbon atoms of the split $C_6F_5$ rings, rigid group refinement was performed. A second X-ray study from a different experiment gave the same result (see Supporting Information). CCDC-653980 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge from the Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

**Supporting Information** (see footnote on the first page of this article): Full experimental details and characterization data, X-ray crystallographic refinement data, selected bond lengths and angles, and computational details of **3**.

# pH-Induced Luminescence Changes of Chromophore-Quencher Tricarbonylpolypyridylrhenium(I) Complexes with 4-Pyridinealdazine

**Mauricio Cattaneo,[a] Florencia Fagalde,[a] Néstor E. Katz,*[a] Claudio D. Borsarelli,[b] and Teodor Parella[c]**

**Keywords:** Donor-acceptor systems / Rhenium / Photochemistry / Molecular devices / Mixed-valent compounds

The new chromophore-quencher tricarbonylrhenium(I) complexes $[Re(4,4'\text{-}X_2\text{-bpy})(CO)_3(PCA)]^+$, $[(4,4'\text{-}X_2\text{-bpy})(CO)_3Re(\mu\text{-PCA})Re(CO)_3(4,4'\text{-}X_2\text{-bpy})]^{2+}$, and $[(4,4'\text{-}X_2\text{-bpy})(CO)_3Re^{I}(\mu\text{-PCA})Ru^{II}(NH_3)_5]^{3+}$ (X = Ph or $CO_2Me$ and PCA = 4-pyridinealdazine) have been synthesized as their $PF_6^-$ salts and characterized by spectroscopic, electrochemical, and photophysical techniques. In contrast to previously reported species with X = Me or H, these complexes emit at room temperature in $CH_3CN$. The recovery of luminescence can thus be ascribed to the change of energy levels induced by adding electron-withdrawing substituents to the 2,2′-bipyridine ring, since the emissive $Re^{II}(X_2bpy^-)$ excited state becomes much lower in energy than the $Re^{II}(PCA^-)$ non-emissive excited state. For the mononuclear and symmetric dinuclear rhenium(I) complexes with X = $CO_2Me$, consecutive protonation of both the pyridinyl and imine N atoms of PCA in aqueous solution leads to unusual bell-shaped curves for both the absorption and the emission intensities vs. pH because of opposite effects on the electronic delocalization of PCA. This latter property can be employed to devise novel luminescent pH sensors of the on-off-on type. The corresponding unsymmetrical dinuclear complexes $[(4,4'\text{-}X_2\text{-bpy})(CO)_3Re^{I}(\mu\text{-PCA})Ru^{III}(NH_3)_5]^{4+}$ have been obtained in situ by oxidizing the $[Re^{I},Ru^{II}]$ precursors in $CH_3CN$ solution. Spectral and electrochemical measurements with these complexes lead to the values of the metal-to-metal electronic coupling elements.

## Introduction

Tricarbonylpolypyridylrhenium(I) complexes of the type *fac*-$[Re(\alpha\text{-diimine})(CO)_3L]^+$ (L = auxiliary monodentate ligand) have very interesting properties, such as relatively high thermal and photochemical stabilities, high redox potentials, and luminescence in the visible region that have led to their applications as light switches,[1] ion sensors,[2] intercalating agents for nucleic acids,[3] probes for biological molecules,[4] and models in fundamental studies of energy- and electron-transfer reactions relevant to solar energy conversion.[5] Tuning the physicochemical properties of these complexes by changing the nature of the diimine and/or L offers a high degree of versatility for the design of new supramolecular systems that may perform useful specific functions.[5r]

We have recently described the novel chromophore-quencher tricarbonylrhenium(I) complexes $[Re(4,4'\text{-}X_2\text{-bpy})(CO)_3(PCA)]^+$ and $[(4,4'\text{-}X_2\text{-bpy})(CO)_3Re(\mu\text{-PCA})Re(CO)_3(4,4'\text{-}X_2\text{-bpy})]^{2+}$ (bpy = 2,2′-bipyridine, X = $CH_3$ or H, and PCA = 4-pyridinealdazine).[6,7] Emission from the lowest-energy metal-to-ligand charge-transfer excited state $^3MLCT$ $[d_\pi(Re)\rightarrow\pi^*(X_2bpy)]$ is completely quenched in these complexes by the presence of PCA in the mononuclear species at room temperature in $CH_3CN$. Quenching of luminescence has been observed before in tricarbonylpolypyridylrhenium(I) complexes with electron-acceptor ligands (L) such as *N*-methyl-4,4′-bipyridinium ($MQ^+$), *N*-benzyl-4,4′-bipyridinium ($BzQ^+$), or *N*-(4-pyridyl)-β-(*N*-methylpyridinium-3-yl)acrylamide ($pyAm\text{-}Mepy^+$).[8] In the case of L = PCA, the emission was also found to be quenched in aqueous solution at high pH values, and when the pH was lowered until one of the imine N atoms of PCA became protonated, alteration of the ligand conjugation brought about a recovery of luminescence. We thus concluded that these complexes can be employed as luminescent pH sensors.[7]

In this work, we have prepared and studied the new complexes $[Re(4,4'\text{-}X_2\text{-bpy})(CO)_3(PCA)]^+$, $[(4,4'\text{-}X_2\text{-bpy})(CO)_3Re(\mu\text{-PCA})Re(CO)_3(4,4'\text{-}X_2\text{-bpy})]^{2+}$, and $[(4,4'\text{-}X_2\text{-bpy})(CO)_3Re^{I}(\mu\text{-PCA})Ru^{II/III}(NH_3)_5]^{3+/4+}$ (X = Ph and $CO_2Me$), thereby completing the previously studied series. We expected that introducing substituted bipyridines with strongly electron-withdrawing groups would have different

effects on the emission properties. Indeed, we found that the emission is recovered at high pH values, and protonation changes in the PCA ligand can now be employed to devise novel luminescent switches of the on-off-on type. The effect of pH on the emission properties of the previously reported complex $[Re(bpy)(CO)_3(4,4'\text{-bpy})]^+$ (4,4′-bpy = 4,4′-bipyridine)[9] was also studied in order to compare the behavior of complexes containing an auxiliary ligand with one protonation site (4,4′-bpy) with that of those containing an auxiliary ligand with two protonation sites (PCA). Finally, dinuclear unsymmetrical complexes with $[Ru(NH_3)_5]^{n+}$ as electron donor ($n$ = 2) or acceptor ($n$ = 3) groups have been prepared and characterized in relation to intramolecular electron transfer in the Marcus inverted region.[10]

The structures of the ligands, along with the atom numbering for NMR assignments, are shown in Scheme 1; the structures of the complexes are shown in Scheme 2.

## Results and Discussion

### Syntheses, Solubilities, and IR and NMR Spectral Characterizations

The synthetic methods used to obtain the new mono- and dinuclear tricarbonylpolypyridylrhenium complexes described in this work are slightly different from those previously developed in our laboratory.[6,7,11,12] All the complexes are soluble in acetonitrile, dichloromethane, and acetone and their purity was confirmed by chemical analysis, CV, and IR, NMR, and UV/Vis spectroscopy. The ester complexes are soluble in water and are stable for several days in neutral solutions at low concentrations ($\leq 10^{-4}$ M), whereas the phenyl complexes are not soluble in water, even with $Cl^-$ as the counterion. The solubility of rhenium(I) complexes in water has a direct impact on their applications in radiopharmaceuticals.[7] The values of the carbonyl stretching frequencies ($\nu_{CO}$) in the IR spectra of complexes **1** and **2** (2032 and 1918 $cm^{-1}$, respectively) are almost the same as those reported for related complexes of the type *fac*-$[Re(4,4'\text{-}X_2\text{-bpy})(CO)_3(L)]PF_6$,[6,7,11,12] whereas the values of the carbonyl stretching frequencies in the IR spectra of complexes **5** and **6** (2037 and 1927 $cm^{-1}$, respectively) are slightly higher than those of **1** and **2**, thereby indicating a stronger π-backbonding effect from Re to the bipyridine rings substituted with moderately strong electron-withdrawing groups, as reported previously for complexes such as *fac*-$[Re(4,4'\text{-}X_2\text{-bpy})(CO)_3(L)]PF_6$ {X = $C(O)NEt_2$, $CO_2Et_2$ and L = py-PTZ [10-(4-picolyl)phenothiazine]}.[13] All these values of $\nu_{CO}$ are consistent with a facial configuration of the carbonyl groups of local $C_{3v}$ symmetry. Both the mono- and dinuclear species were completely characterized by NMR spectroscopy (see Experimental Section).

Six signals are observed for the protons of coordinated PCA in the mononuclear complexes due to coordination of only one of the pyridinyl N atoms to one rhenium center. For the dinuclear complexes, only three signals are observed for the protons of PCA due to the symmetry imposed by coordination of both pyridinyl nitrogen atoms of PCA to two rhenium centers. As a general trend, metal coordination induces slight displacements of the chemical shifts of the PCA moiety in all complexes to higher fields with respect to the values in the free ligands. Diffusion coefficients ($D$) were also determined to gain more insight into their overall molecular size.[14] The $D$ values (in $CD_3CN$ at 25 °C) of the mononuclear species **1** and **5** are $10.00 \times 10^{-10}$ and $10.23 \times 10^{-10}$ $m^2 s^{-1}$, respectively, and for the dinuclear species **2** and **6** $7.94 \times 10^{-10}$ and $8.31 \times 10^{-10}$ $m^2 s^{-1}$, respectively. These changes of 25% in the $D$ value between the mono- and dinuclear species strongly agree with the corresponding increase in molecular weights (about 75%) and hydrodynamic radius (7.2 and 7.0 Å for the mononuclear species **1** and **5** and 9.0 and 8.7 Å for the dinuclear complexes **2** and **6**, respectively). Furthermore, the characteristic $^{15}N$ chemical shifts of the nitrogen atoms from the different ligands provide direct experimental evidence for the existence of an Re–N bond. Thus, the $^{15}N$ chemical shifts of the two pyridinyl nitrogen atoms of PCA in the mononuclear species appear at $\delta \approx +323$ (free N) and +238 ppm (N bonded to Re), whereas a single resonance appears at $\delta \approx +238$ ppm in the dinuclear complexes. Figure 1 shows the $^1H$ NMR spectrum of complex **2** as a representative example.

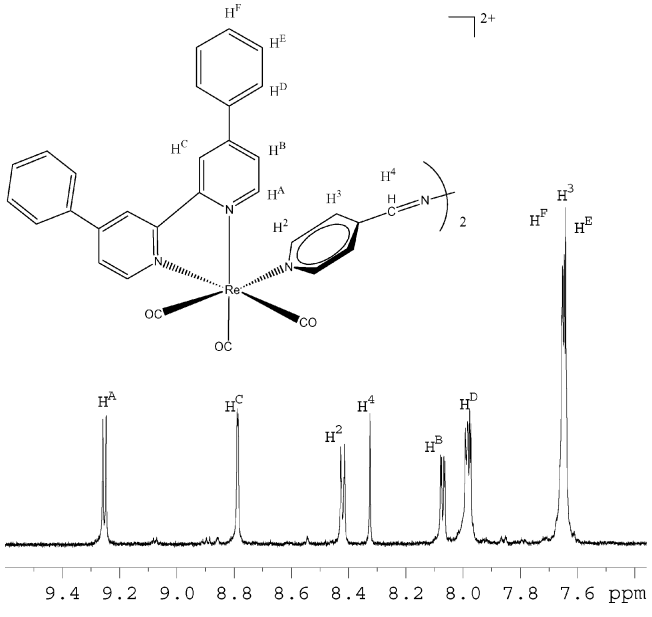

Figure 1. $^1H$ NMR spectrum of complex **2** in $CD_3CN$ at 500.13 MHz.

## UV/Vis Spectra

Table 1 shows the spectroscopic data for complexes **1**–**8** in $CH_3CN$. Characteristic spin-allowed intraligand $\pi \rightarrow \pi^*$ transitions of the polypyridyl ligands give rise to intense UV absorptions between 200 and 330 nm.[6,7,9] The mononuclear complexes **1** and **5** present minimum-energy absorptions at $\lambda_{max}$ = 346 and 352 nm, respectively, which can be assigned, as observed previously in the analogous complexes $[Re(X_2bpy)(CO)_3(L)]^+$ ($\lambda_{max}$ = 330–380 nm),[6,7] to overlapping metal-to-ligand charge transfers (MLCT) of the type $d_\pi(Re) \rightarrow \pi^*(X_2bpy)$ and $d_\pi(Re) \rightarrow \pi^*(PCA)$. These same bands are redshifted to $\lambda_{max}$ = 350 and 355 nm, respectively, in the homodinuclear $Re^I$–$Re^I$ complexes **2** and **6**, as reported previously for symmetric dinuclear complexes of the type $[(X_2bpy)(CO)_3Re(L)Re(CO)_3(X_2bpy)]^{2+}$.[6,7,9] Figure 2 shows the UV/Vis spectrum of complex **6** as a representative example. It is noteworthy that both the $\pi \rightarrow \pi^*$ transitions of $X_2bpy$ as well as the MLCT $d_\pi(Re) \rightarrow \pi^*(X_2bpy)$ transitions are shifted to longer wavelengths when increasing the electron-accepting strength of the substituent X, as already reported for similar species.[9,13,15] On the other hand, when comparing the effect of ligands L in complexes of the type $[Re(bpy)(CO)_3L]^+$, a

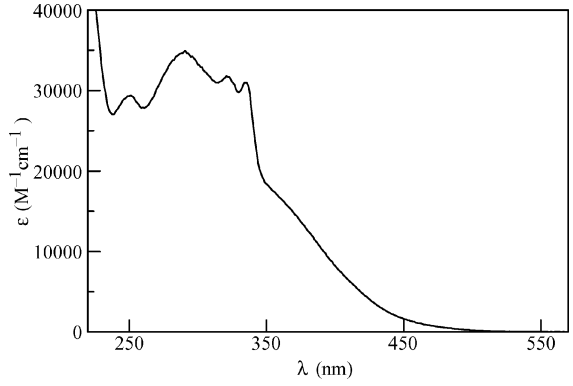

Figure 2. UV/Vis spectrum of $[\{4,4'\text{-}(MeO_2C)_2\text{-}bpy\}(CO)_3Re(\mu\text{-}PCA)Re(CO)_3\{4,4'\text{-}(MeO_2C)_2\text{-}bpy\}]^{2+}$ (**6**) in $CH_3CN$.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

blueshift of the (Re→bpy) MLCT band can be observed with increasing electron-withdrawing power of L; in effect, the values of $\lambda_{max}$ in $CH_3CN$ decrease in the order 4-Etpy ($\lambda_{max}$ = 352 nm)[16] > 4,4′-bpy ($\lambda_{max}$ = 340 nm)[9] > PCA ($\lambda_{max}$ = 332 nm),[7] thus pointing to an increasing stabilization of the $d_\pi$(Re) energy levels.

With respect to the UV/Vis spectra of the unsymmetrical dinuclear complexes **3**, **4**, **7**, and **8**, we can assign the bands in the $Re^{I}$–$Ru^{II}$ complexes **3** and **7** at $\lambda_{max}$ = 350 and 560 nm to $d_\pi(Re)\rightarrow\pi^*(X_2bpy, PCA)$ and $d_\pi(Ru)\rightarrow\pi^*(PCA)$ MLCT transitions, respectively. For the $Re^{I}$–$Ru^{III}$ complexes **4** and **8**, which were prepared in situ by oxidation of **3** and **7**, respectively, with bromine, the bands at $\lambda_{max}$ = 560 nm disappear completely, and the new bands that appear at $\lambda_{max}$ = 497 and 501 nm, respectively, whose values were obtained by Gaussian deconvolution, as shown in Figure 3 for complex **4**, can be assigned to $Re^{I}\rightarrow Ru^{III}$ MMCT transitions, with some contribution from $PCA\rightarrow Ru^{III}$ LMCT bands, as discussed previouly for the analogous species with $Me_2$bpy and bpy.[6,7]

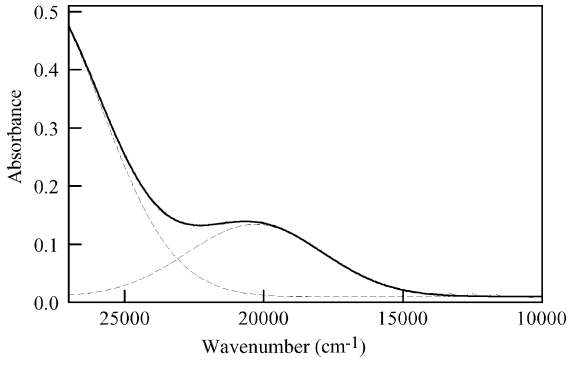

Figure 3. Gaussian deconvolution of the visible bands of the mixed-valent complex $[(Ph_2bpy)(CO)_3Re^{I}(\mu\text{-}PCA)Ru^{III}(NH_3)_5]^{4+}$ (**4**; approx. $3\times10^{-5}$ M) obtained by $Br_2$ oxidation (in $CH_3CN$) of the dinuclear complex **3**.

Figure 4 shows the results of a controlled-potential electrolysis of complex **3** in $CH_3CN$ at 800 mV. The results obtained are consistent with those obtained upon bromine oxidation. In effect, the $d_\pi(Ru)\rightarrow\pi^*(PCA)$ MLCT band at $\lambda_{max}$ = 560 nm disappears completely, and a new MMCT band (combined with an LMCT band) appears near 500 nm. When reverting the oxidation process in the spectroelectrochemical experiment, the intensity of the $d_\pi(Ru)\rightarrow\pi^*(PCA)$ MLCT band at $\lambda_{max}$ = 560 nm is not recovered completely, which is consistent with the results obtained upon $Sn^{2+}$ reduction. We consider that, besides mere electron transfer, the formation of a *cis* isomer is possibly favored on oxidation.

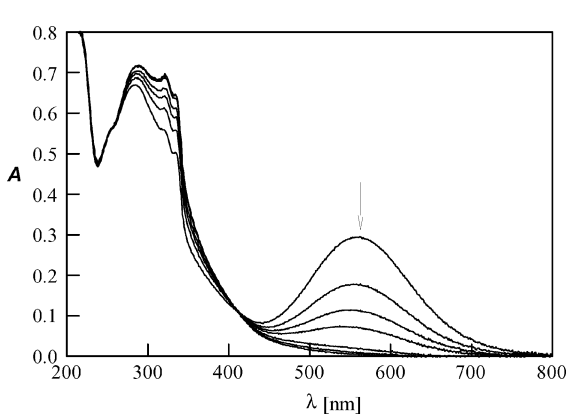

Figure 4. Controlled potential electrolysis of a $CH_3CN$ solution of $[(Ph_2bpy)(CO)_3Re^{I}(\mu\text{-}PCA)Ru^{II}(NH_3)_5]^{3+}$ (**3**; approx. $2\times10^{-5}$ M) at 800 mV in an OTTLE cell. The arrow indicates increasing times: $t$ = 0, 1, 2, 3, 4, 8, and 10 min.

## Photophysical Properties

In contrast to the previously reported complexes with $Me_2$bpy and bpy,[6,7] the complexes studied in this work emit in $CH_3CN$ solution at room temperature. The shape and position of the emission maxima are typical of $Re^{II}$-(diimine$^-$) MLCT excited states.[13] Table 2 shows the data obtained at 22 °C for the emission maxima, lifetimes, and emission quantum yields for complexes **1**, **2**, **5**, and **6**. The same lifetimes were obtained both by laser flash photolysis and by pulsed luminescence decay in argon-saturated solutions, thereby indicating that the luminescence properties are not due to impurities. Furthermore, the reported chemical analyses and the spectral and electrochemical data point to a high degree of purity of the complexes under study. The observed quantum yields, which were calculated and corrected by taking into account the refractive indices of the solvents and absorbance differences, as described in the literature,[17] are much lower (by a factor of about $10^2$) than those reported for related complexes with the same chromophore,[13] which can be attributed to intramolecular luminescence quenching induced by the presence of the PCA ligand.[6,7] This quenching was attributed in the $Me_2$bpy derivative to crossing to a neighboring $[(X_2bpy)(CO)_3Re^{II}$-$(PCA^-)]^+$ excited state, as confirmed by laser flash photolysis and low-temperature emission measurements.[6] The radiative rate constants $k_r$ (approx. $10^3$–$10^4$ $s^{-1}$), on the other hand, are lower than those expected (approx. $10^5$ $s^{-1}$) for $Re^{I}$ complexes of the type $[Re(bpy)(CO)_3X]$ (X = substituted pyridine).[13] Energy transfer from $^3$MLCT (Re→bpy) to PCA to give an excited intraligand triplet state ($^3$PCA*) that decays non-radiatively to the ground state may be the cause of these low values of $k_r$. In support of this argument, it should be noted that changes in photophysical properties brought about by MLCT or intraligand excited states placed very close to the luminescent excited state have al-

Table 2. Photophysical data (in $CH_3CN$) of complexes of the type $[Re(4,4'\text{-}X_2\text{-}bpy)(CO)_3(PCA)]^+$ and $[(4,4'\text{-}X_2\text{-}bpy)(CO)_3Re$-$(\mu\text{-}PCA)Re(CO)_3(4,4'\text{-}X_2\text{-}bpy)]^{2+}$ at 22 °C.

| X | Complex | $\lambda_{em}$ [nm] | $\Phi_{em}$[a] | $\tau$ [ns] |
|---|---|---|---|---|
| Ph | **1** | 552 | 0.0010 | 690 |
| | **2** | 552 | 0.0045 | 865 |
| $CO_2Me$ | **5** | 570 | 0.0004 | 132 |
| | **6** | 565 | 0.0017 | 187 |

ready been observed in related complexes.[18] Moreover, a recent review by Schmehl et al. gives a detailed discussion of similar systems in which reversible energy transfer between a long-lived $^3$IL state and a $^3$MLCT state leads to longer lived $^3$MLCT emission.[19] In complex **2**, laser flash photolysis showed the emergence of a transient with $\lambda_{max}$ = 380 nm, which is typical of the absorption of the radical anion of bpy ligands, as shown in Figure 5, together with emission bleaching at $\lambda_{max}$ = 550 nm. The lifetime ($\tau$) is 865 ns, which is about two orders of magnitude higher than the lifetime of the excited state of $[Re(Me_2bpy)(CO)_3(PCA)]^+$. These findings are consistent with formation of an $Re^{II}(Ph_2bpy^-)$ excited state. The mononuclear complex $[Re(Ph_2bpy)(CO)_3(PCA)]^+$ has a lower lifetime ($\tau$ = 690 ns) but with a similar transient spectrum. We conclude that, since $Ph_2bpy$ is a much better π-acceptor than $Me_2bpy$ and bpy, the energy of the emissive $Re^{II}(Ph_2bpy^-)$ excited state becomes much lower than that of the non-emissive $Re^{II}(PCA^-)$ excited state, with consequent recovery of luminescence at room temperature. As shown in Table 2, the quantum yields and lifetimes for the complexes containing $(CO_2Me)_2bpy$ are lower than those of the $Ph_2bpy$ complexes. Luminescence in the series of complexes $[Re(4,4'\text{-}X_2\text{-}bpy)(CO)_3(PCA)]^+$ and $[(4,4'\text{-}X_2\text{-}bpy)(CO)_3Re(\mu\text{-}PCA)Re(CO)_3(4,4'\text{-}X_2\text{-}bpy)]^{2+}$ can thus be finely tuned by changing the nature of X: when X = Me or H, the emission is almost completely quenched,[6,7] whereas when X = Ph or $CO_2Me$, emission is partially recovered because of the less effective intramolecular quenching by PCA.

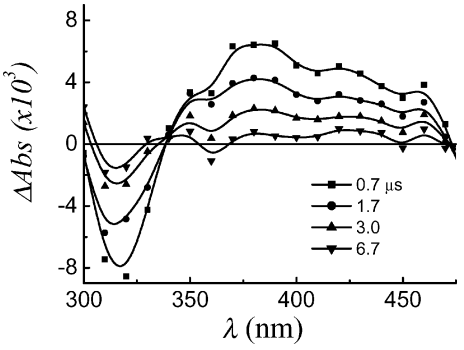

Figure 5. Transient spectra of $[(Ph_2bpy)(CO)_3Re(\mu\text{-}PCA)Re(CO)_3(Ph_2bpy)]^{2+}$ (**2**) in deaerated $CH_3CN$ solution at 22 °C.

## Protonation Equilibria

These studies were carried out with complexes **1**, **2**, **5**, and **6** since the heterodinuclear complexes **3**, **4**, **7**, and **8** have very low stability in aqueous solutions, as already reported for analogous complexes.[7] Table 3 shows the acidity constants obtained from the spectrophotometric and spectrofluorometric titrations of all the measured complexes. Complexes **1** and **2** were measured in a 1:4 mixture of $CH_3CN/H_2O$ because of their poor solubility in water. The effect of the organic solvent could be to lower all p$K_a$ values with respect to those in aqueous solution. In water, complexes **5** and **6** emit very weakly between $\lambda_{max}$ = 565 nm at pH 8.5 and $\lambda_{max}$ = 575 nm at pH 1.5 ($\lambda_{ex}$ = 380 nm). When performing the experiment at constant ionic strength, a decrease in pH brings about not only an increased emission from the Re→$X_2$bpy MLCT excited state but also a noticeable isomerization/hydrolysis process of the PCA and $(CO_2Me)_2bpy$ ligands, which becomes enhanced at extreme pH values. Evidence for ligand isomerization has been presented before,[6,7] and evidence of ester hydrolysis emerges when comparing the final spectra, obtained after several hours, with the spectra of the corresponding complexes of carboxylic acid substituted bipyridines. On the other hand, more accurate values of the protonation constants could be obtained when the protonation studies were done with larger volumes of solution since the decomposition processes were negligible during the time taken for the measurements. This latter method has therefore been used for reporting the values in Table 3, except for the reference complex $[Re(bpy)(CO)_3(4,4'\text{-}bpy)]^+$, which proved to be very stable in aqueous solutions.

Consistent and reproducible values of p$K_a$ for both ground and excited states could only be obtained for the mononuclear complex **5** starting from basic aqueous solutions. Both the absorbance and luminescence data can be fitted with a three-species diagram involving protonation equilibria of the ground and excited states of PCA complexes, as shown in Scheme 3. Two ground-state p$K_a$ values were detected by fitting the UV/Vis absorptivity changes with pH at $\lambda$ = 330 nm, as shown in Figure 6(a). The first of these (p$K_{a1}$ = 2.15) corresponds to one of the imine N atoms of coordinated PCA and the second one (p$K_{a2}$ = 5.59) corresponds to the free pyridine N atom of coordinated PCA. This latter value is 0.4 units larger than the

Table 3. Values of p$K_a$ for the ground and excited states of complexes **1**, **2**, **5**, and **6** at 22 °C in aerated aqueous solution.

| Complex | p$K_a$ | p$K_a$* |
|---|---|---|
| $[Re(Ph_2bpy)(CO)_3(PCA)]^+$ (**1**)[a] | p$K_{a1}$ < 1<br>p$K_{a2}$ = 5.08 ± 0.23 | p$K_{a1}$* < 1 |
| $[(Ph_2bpy)(CO)_3Re(\mu\text{-}PCA)Re(CO)_3(Ph_2bpy)]^{2+}$ (**2**)[a] | p$K_{a1}$ < 1 | p$K_{a1}$* < 1 |
| $[Re\{4,4'\text{-}(MeO_2C)_2\text{-}bpy\}(CO)_3(PCA)]^+$ (**5**)[b] | p$K_{a1}$ = 2.15 ± 0.03<br>p$K_{a2}$ = 5.59 ± 0.06 | p$K_{a1}$* = 2.34 ± 0.17<br>p$K_{a2}$* = 3.33 ± 0.05 |
| $[\{4,4'\text{-}(MeO_2C)_2\text{-}bpy\}(CO)_3Re(\mu\text{-}PCA)Re(CO)_3\{4,4'\text{-}(MeO_2C)_2\text{-}bpy\}]^{2+}$ (**6**)[c] | p$K_a$ < 1 | not detected |
| $[Re(bpy)(CO)_3(4,4'\text{-}bpy)]^{+}$[c] | p$K_a$ = 3.70 ± 0.07 | p$K_{a1}$* = 4.03 ± 0.05 |

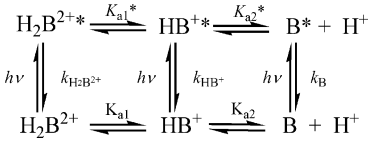
value for the free ligand, probably because of the $Re^{I}\rightarrow$PCA π-backbonding effect. Both p$K_a$ values are very similar to those corresponding to the previously studied complex $[Re(bpy)(CO)_3(PCA)]^+$ (p$K_{a1}$ = 1.98 and p$K_{a2}$ = 5.41),[7] thereby indicating little influence of the nature of the substituent X on the basicity of coordinated PCA.



Scheme 3. Three-species diagram for the protonated equilibria of the ground and excited states of PCA complexes. B is the non-protonated species.

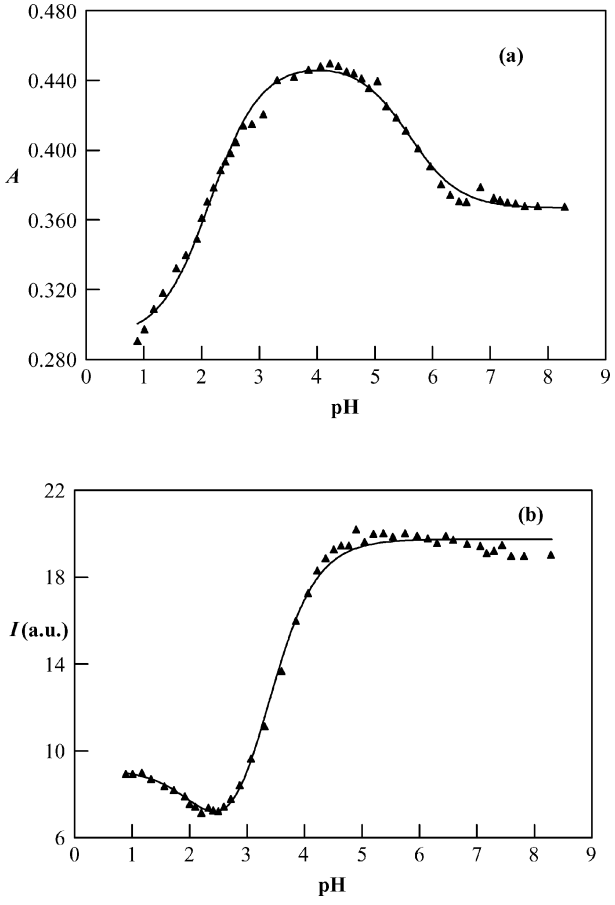


Figure 6. Variation of (a) absorbance $A$ (at $\lambda$ = 330 nm) and (b) emission intensity (at $\lambda_{ex}$ = 380 nm and $\lambda_{em}$ = 570 nm) for $[Re\{4,4'\text{-}(MeO_2C)_2\text{-}bpy\}(CO)_3(PCA)]^+$ (**5**) in aqueous buffer, with pH. The lines indicate the best fits using a three-species model in each case.

As found before in related unsubstituted bpy complexes,[7] protonation of the pyridine N atom of PCA leads to an absorbance increase at $\lambda$ = 330 nm due to an increased $d_\pi$(Re)-π*(PCA) coupling. The MLCT band corresponding to this transition is expected to fall in this region.[6] Protonation of the imine N atom of PCA leads instead to an absorbance decrease at $\lambda$ = 330 nm because the energy of the lowest-lying π* orbital of PCA is increased and $d_\pi$(Re)-π*(PCA) coupling is consequently diminished. The result is a bell-shaped curve which can be reproduced in an inverted way when fitting the emission intensities at different pH values. This is in contrast to similar carbonylrhenium complexes, where only sigmoid curves have been observed.[2,7] As shown in Figure 6(b), complex **5** presents two adjustable excited-state p$K_a$* values: the first one, p$K_{a1}$* = 2.34, corresponds to the imine N atom of coordinated PCA and the second one, p$K_{a2}$* = 3.33, corresponds to the free pyridine N atom of coordinated PCA. No better fitting could be obtained between pH = 5 and 9, and in any case the observed deviations from the fits are within the experimental uncertainties of the intensity measurements. The first basicity constant of the excited state is higher than that of the ground state (by around 0.2 p$K$ units), as expected for tricarbonylrhenium(I) complexes,[2] but lower than that of the complex $[Re(bpy)(CO)_3(PCA)]^+$ (by around 0.4 units),[7] thereby evidencing the effect of decreasing the electron density on PCA as a result of including a more electron-accepting bipyridine ligand. Strikingly, the value of p$K_{a2}$* is 2.26 units lower than that of the ground state, which points to the fact that since more electron density has been delocalized in the excited state, $[(CO_2Me)_2bpy^{-}(CO)_3\text{-}Re^{II}(PCA)]^+$, to the substituted bpy ligand, less electron density is available at the remote N atom of the coordinated PCA ligand, and possibly evidencing some contribution of the p$K_a$ of the carboxylate-substituted bpy that results from hydrolysis of the ester-substituted bpy.

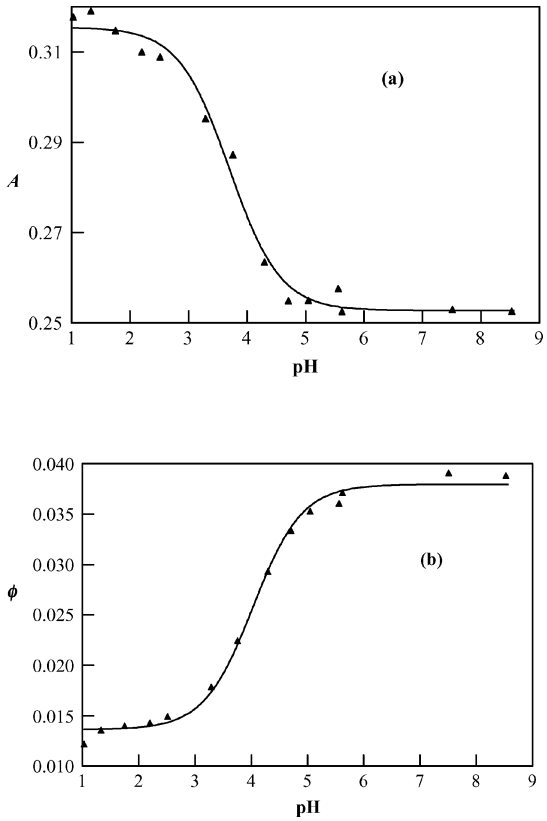

Figure 7. Variation of (a) absorbance $A$ (at $\lambda$ = 350 nm) and (b) emission quantum yield $\Phi_{em}$ (at $\lambda_{ex}$ = 350 nm and $\lambda_{em}$ = 552 nm) for $[Re(bpy)(CO)_3(4,4'\text{-bpy})]^+$ in aqueous buffer, with pH. The lines indicate the best fits using a two-species model in each case.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

There is only one protonation site possible in the model complex $[Re(bpy)(CO)_3(4,4'\text{-bpy})]^+$, namely the free pyridyl N atom. As shown in Figure 7, a value of the ground-state $pK_a$ of 3.70, which agrees with those reported for polypyridylruthenium complexes, is obtained by fitting absorbance changes with pH.[20] However, we obtain a $pK_a^*$ value of 4.03 for the excited state when fitting the emission quantum yields with pH. This value is higher than that of the ground state by 0.33 units and points to much less electron density being delocalized onto the unsubstituted bpy ligand in the excited state.

We conclude that when the free pyridine N atom of coordinated PCA is protonated, the π* excited state of PCA decreases in energy, and the emission is partially quenched, as observed before for $MQ^+$,[8] but when the imine N atom of coordinated PCA is protonated, the π* excited state of PCA increases in energy, due to alteration of the ligand conjugation, and emission is recovered again. In effect, when decreasing the pH from 4 to 1, the band assigned to the π-π* transition of PCA at $\lambda_{max}$ = 290 nm is shifted to lower wavelengths, thereby indicating a proton-induced energy increase of the π* levels of PCA. The mononuclear species **5** can therefore be used as a novel luminescent pH sensor of the on-off-on type.

## Electrochemistry

Table 4 shows the electrochemical data for the studied complexes. The redox potentials for the $Re^{II}/Re^{I}$ couple of the mononuclear $Re^{I}$ species **1**, the $Re^{I}$–$Re^{I}$ dinuclear species **2**, and the $Re^{I}$–$Ru^{II}$ dinuclear species **3** are very similar, with $E_{1/2}$ values between 1.8 and 1.9 V, with some degree of irreversibility, as expected for carbonyl(diimine)rhenium(I) complexes.[6,7,11,12] The redox potentials for the $Re^{II}/Re^{I}$ couple in complexes **5**, **6**, and **7** are higher than 2.0 V and could not be detected. The PCA ligand is reduced irreversibly at $E_{peak} \approx -0.8/-1.0$ V in all complexes except **7**. The first reduction of $X_2$bpy appears at $E_{peak} \approx -1.2$ V, while a second irreversible reduction at $E_{peak} \approx -1.4$ V can be attributed to an $Re^{I/0}$ couple, as reported previously for the related $Me_2$bpy complex.[6]

The voltammetric wave that appears in the asymmetric $Re^{I}$–$Ru^{II}$ dinuclear complexes **3** and **7** at $E_{1/2}$ = 0.46 and 0.48 V, respectively, which is absent in the mononuclear rhenium complexes, can be readily assigned to the $Ru^{III}/Ru^{II}$ couple by comparison with similar complexes.[6,7] The high $\Delta E_p$ values (92–134 mV) suggest redox-induced ligand isomerization processes, and experimental evidence of redox-induced ligand isomerization has been described previously.[6] Varying the sweep rate gave no better $\Delta E$ values at higher sweep rates. The differences between the redox potentials of both metallic couples in **3** and **7** are: $\Delta E_{1/2} = E_{1/2}(Re^{II}/Re^{I}) - E_{1/2}(Ru^{III}/Ru^{II})$ = 1.52 and 1.54 V, respectively.

## Intramolecular Electron Transfer

The reorganization energy, $\lambda$, for the intramolecular electron transfer through the PCA bridge can be calculated from the Marcus–Hush equations and the experimental

Table 4. Electrochemical data (in $CH_3CN$) at 22 °C.[a]

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

data of the MMCT transition in the heterodinuclear complexes **4** and **8**[21] to be approximately 0.9 eV, a value similar to that obtained previously for the analogous complexes with $Me_2$bpy and bpy.[6,7] The values determined for the metal–metal electronic coupling elements ($H_{AB} = 8.8 \times 10^2$ and $6.2 \times 10^2$ $cm^{-1}$ for the Ph and $CO_2Me$ derivatives, respectively) are consistent with those obtained previously for mixed-valent symmetric and unsymmetrical dinuclear complexes of PCA.[6,7] These complexes might be considered as prototypes for simulating primary charge separations in the inverted region.

## Conclusions

Continuing our previous studies on proton-induced luminescence of chromophore-quencher tricarbonylpolypyridylrhenium(I) complexes, we have shown in this work that quenching of luminescence in these complexes can not only be turned on and off by changing the substituents on the 2,2′-bipyridine acceptor group but also by changing the acidity of their aqueous solutions. In particular, the mononuclear complex $[Re\{4,4'\text{-}(MeO_2C)_2\text{-}bpy\}(CO)_3(PCA)]^+$ can be employed as a novel luminescent pH sensor of the on-off-on type rather than the recently reported luminescent off-on-off switches based on polypyridylruthenium complexes.[22]

## Experimental Section

**Materials and Techniques:** All chemicals used were p.a. grade. $CH_3CN$ was distilled from $P_4O_{10}$. Tetrakis(*n*-butyl)ammonium hexafluorophosphate (TBAH) was recrystallized from ethanol three times and dried at 150 °C for 72 h. IR spectra were recorded (as KBr pellets) with an FTIR Perkin–Elmer Spectrum RX-I spectrophotometer. UV/Vis spectra were recorded with a Varian Cary 50 spectrophotometer for solutions in 1-cm cells. Redox titrations were performed stoichiometrically by adding aliquots of a stock solution of $Br_2$ in $CH_3CN$ which had previously been standardized by known procedures.[20] Reductions were carried out by adding solid $SnCl_2$ to $CH_3CN$ solutions of the oxidized complexes. Electrochemical measurements were performed in $CH_3CN$ (0.1 M TBAH) with a BAS Epsilon electrochemical equipment. A standard three-electrode compartment cell was used, with Ag/AgCl (3 M KCl) as a reference electrode, vitreous C as a working electrode, and Pt wire as an auxiliary electrode. All redox potentials ($E_{1/2}$) are referenced to Ag/AgCl. Spectroelectrochemical measurements were performed in an OTTLE (optically transparent thin layer electrolysis) type cell from BAS. Emission studies were performed with a Shimadzu RF-5301 PC spectrofluorometer in 1-cm fluorescence cells. Laser-flash photolysis (LFP) experiments were carried out with a Q-switched Nd:YAG laser (Continuum Minilite II) generating 355-nm pulses (fwhm: 10 ns; 5 mJ per pulse). The signals were recorded with a Luzchem m-LFP 112 system and fed into a transient Tektronik TDS 3032B recorder. Time-resolved luminescence detection was carried out with a home-made system composed of an *f*/4 monochromator (PTI-101, 1200 blazes) coupled with a red-extended PMT (Hamamatsu R928) placed at right angles to the excitation laser pulse. The output of the detector was fed to the Tektronix TDS3032B digital oscilloscope linked to an on-line PC for data transfer and analysis. Typically, about 100–200 laser cycles with the excitation laser operating at 15 Hz were averaged in order to obtain the decay times with a suitable signal-to-noise ratio. NMR spectra were recorded in $CD_3CN$ with an Avance Bruker 500.13 MHz spectrometer. Full $^1H$, $^{13}C$, and $^{15}N$ chemical shift assignments were performed by collecting 2D COSY, 2D $^1H$-$^{13}C$ HSQC, 2D $^1H$-$^{13}C$ HMBC, 2D $^1H$-$^{15}N$ HMBC, and 2D NOESY (mixing time: 500 ms) experiments. Diffusion NMR coefficients were measured at 25 °C using the LEDBP pulse sequence (diffusion time: 150 ms) with sample spinning at 20 Hz to minimize convection effects.[14] Argon was bubbled through the solutions for 15 min prior to electrochemical and photophysical measurements. Chemical analyses for C, H, and N were done at INQUIMAE, University of Buenos Aires, Argentina, with an estimated error of ±0.5%.

**Preparation of PCA and 4,4′-$(MeO_2C)_2$-bpy:** The ligands 4-pyridinealdazine and 4,4′-bis(methoxycarbonyl)-2,2′-bipyridine were prepared as described previously.[23,24]

**Preparation of $[Re(Ph_2bpy)(CO)_3(PCA)]PF_6 \cdot H_2O$ (1) and $[(Ph_2bpy)(CO)_3Re(\mu\text{-}PCA)Re(CO)_3(Ph_2bpy)](PF_6)_2$ (2):** These salts were prepared by a procedure similar to that reported in the literature.[6,7] In a typical experiment, $[Re(CO)_5Cl]$ (181 mg, 0.50 mmol) and 4,4′-diphenyl-2,2′-bipyridine (154 mg, 0.50 mmol) were heated at reflux in toluene (20 mL) for 1 h. It was cooled and then precipitated with hexane (40 mL). The solid obtained after additional cooling was collected, washed with hexane and diethyl ether, and dried in vacuo. The resulting complex $[Re(Ph_2bpy)(CO)_3Cl]$ (272 mg, 0.443 mmol) and $Ag(CF_3SO_3)$ (114 mg, 0.443 mmol) were heated at reflux in thf (40 mL) for 30 min. PCA (139 mg, 0.664 mmol) was then added to the reaction mixture and heating at reflux was continued for 2 h. After removal of AgCl by filtration, the solvent was removed in a rotary evaporator to give a yellow oil. This oil was dissolved in 80 mL of 3:1 (v:v) $MeOH/H_2O$, 2 g of $NH_4PF_6$ dissolved in 20 mL of water was added, and the mixture was put in the freezer. The yellow precipitate that formed was filtered and washed with copious amounts of $H_2O$ and three times with portions of diethyl ether. This solid was dissolved in a minimum amount of 1:4 (v/v) acetonitrile/dichloromethane, adsorbed onto a silica gel (Kieselgel 60) column and eluted with the same solvent. The yellow fractions (the first is complex **2** and the second is complex **1**) were concentrated to dryness, redissolved in acetone, and precipitated with hexane. **1:** Yield: 66 mg (14%). $C_{37}H_{28}F_6N_6O_4PRe$ (951.84): calcd. C 46.7, H 2.97, N 8.83; found C 46.5, H 2.74, N 8.10. **Preparation of [($Ph_2$bpy)(CO)$_3$Re$^I$(μ-PCA)Ru$^{II}$($NH_3$)$_5$]($PF_6$)$_3$·6$CH_2Cl_2$ (3):** Complex **1** (30 mg, 0.032 mmol) was stirred in acetone (10 mL) under argon for 30 min and [Ru($NH_3$)$_5$($H_2O$)]($PF_6$)$_2$ (16 mg, 0.032 mmol), prepared as described in the literature,[25] was then added. The mixture was stirred under argon in the dark for 2 h. Diethyl ether (100 mL) was added to precipitate the complex, which was re-dissolved in a minimum amount of acetone. Dichloromethane (40 mL) and diethyl ether (40 mL) were added to re-precipitate the complex, which was filtered and washed with dichloromethane, diethyl ether, and water. It was finally dissolved in acetonitrile and purified by chromatography on Sephadex LH-20, using acetonitrile as the eluting solvent. The first, blue fraction was collected, concentrated to dryness, re-dissolved in acetone, precipitated with dichloromethane, filtered, washed with dichloromethane and diethyl ether, and dried in vacuo over $P_4O_{10}$. Yield: 30 mg (66%). $C_{43}H_{53}Cl_{12}F_{18}N_{11}O_3P_3ReRu$ (1919.6): calcd. C 26.9, H 2.8, N 8.0; found C 26.6, H 2.8, N 8.5.

**Preparation of [($Ph_2$bpy)(CO)$_3$Re$^I$(μ-PCA)Ru$^{III}$($NH_3$)$_5$]$^{4+}$ (4):** This heterodinuclear ion was generated in situ by adding bromine to an acetonitrile solution of **3** or by electrochemical oxidation. The oxidation progress was monitored by measuring the absorbance changes in the 200–1100 nm range.

**Preparation of [Re{4,4′-($MeO_2C$)$_2$-bpy}(CO)$_3$(PCA)]$PF_6$·$H_2O$ (5) and [(4,4′-($MeO_2C$)$_2$-bpy)(CO)$_3$Re(μ-PCA)Re(CO)$_3${4,4′-($MeO_2C$)$_2$-bpy}]($PF_6$)$_2$ (6):** [Re(CO)$_5$Cl] (181 mg, 0.50 mmol) and 4,4′-bis-(methoxycarbonyl)-2,2′-bipyridine (136 mg, 0.50 mmol) were heated at reflux in toluene (20 mL) for 1 h. Precipitation was achieved by adding hexane (20 mL) to the cooled solution. The red solid obtained after additional cooling was collected, washed with hexane and diethyl ether, and dried in vacuo. The resulting complex [Re{4,4′-($MeO_2C$)$_2$-bpy}(CO)$_3$Cl] (280 mg, 0.485 mmol) and Ag($CF_3SO_3$) (114 mg, 0.443 mmol) were heated at reflux in thf (40 mL) for 30 min. PCA (153 mg, 0.728 mmol) was then added to the reaction mixture and heating at reflux was continued for 2 h. After removal of AgCl by filtration, the solvent was removed in a rotary evaporator to give an orange oil. This oil was dissolved in 40 mL of 3:1 (v/v) MeOH/$H_2O$, 2 g of $NH_4PF_6$ dissolved in 10 mL of water was added, and the mixture was put in the freezer. The yellow precipitate that formed was filtered and washed with copious amounts of $H_2O$ and three times with portions of diethyl ether. It was then dissolved in a minimum amount of 1:4 (v/v) acetonitrile/dichloromethane, adsorbed onto a silica gel (Kieselgel 60) column and eluted with the same solvent. The yellow fractions (the first is complex **6** and the second is complex **5**) were concentrated to dryness, redissolved in acetone, and precipitated with hexane. **5:** Yield: 107 mg (24%). $C_{29}H_{24}F_6N_6O_8PRe$ (915.72): calcd. C 38.0, H 2.6, N 9.2; found C 37.9, H 2.1, N 9.0. IR (KBr): $\tilde{\nu}$ = 2037 (s), 1927 (s), 1735 (s), 1616 (m), 1560 (w), 1440 (m), 1408 (m), 1327 (m), 1308 (m), 1266 (m), 1232 (m), 1134 (w), 981 (w), 843 (s), 785 (w), 766 (m), 722 (w), 644 (w), 558 (m) cm$^{-1}$. $^1$H NMR (500.13 MHz, $CD_3CN$, 25 °C): $\delta$ = 9.40 (dd, $J$ = 5.7, 0.7 Hz, 2 H, $H^A$), 8.91 (dd, $J$ = 1.6, 0.7 Hz, 2 H, $H^C$), 8.70 (dd, $J$ = 1.7, 4.5 Hz, 2 H, $H^2$), 8.45 (s, 1 H, $H^4$), 8.42 (s, 1 H, $H^{4'}$), 8.30 (dd, $J$ = 5.2, 1.6 Hz, 2 H, $H^{2'}$), 8.22 (dd, $J$ = 1.6, 5.6 Hz, 2 H, $H^B$), 7.69 (dd, $J$ = 1.7, 4.5 Hz, 2 H, $H^3$), 7.64 (dd, $J$ = 1.6, 5.2 Hz, 2 H, $H^{3'}$), 4.02 (s, 6 H, Me) ppm. $^{13}$C NMR (125.6 MHz $CD_3CN$, 25 °C): $\delta$ = 54.3 (C of Me), 123.0 ($C^3$), 125.3 (C), 125.7 ($C^{3'}$), 129.0 ($C^B$), 141.4 (C), 142.7 (C), 145.0 (C), 151.6 (C), 153.8 (C), 153.8 ($C^{2'}$), 156.1 ($C^2$), 157.6 ($C^{4'}$), 158.3 (C), 161.4 ($C^4$), 164.4 (C) ppm. $^{15}$N NMR (50.69 MHz $CD_3CN$, 25 °C; chemical shifts extracted from the $^1$H-$^{15}$N HMBC spectrum): $\delta$ = 248.0 ($N^{A'}$), 237.2 ($N^{1'}$),322.9 ($N^1$), 373.0 ($N^{5'}$), 375.5 ($N^5$) ppm. **6:** Yield: 48 mg (12%). $C_{46}H_{34}F_{12}N_8O_{14}P_2Re_2$ (1585.2): calcd. C 34.9, H 2.2, N 7.1; found C 34.7, H 2.1, N 6.8. IR (KBr): $\tilde{\nu}$ = 2037 (s), 1927 (s), 1735 (s), 1618 (m), 1560 (w), 1440 (m), 1408 (m), 1327 (m), 1307 (m), 1266 (m), 1232 (m), 1134 (w), 981 (w), 843 (s), 785 (w), 766 (m), 722 (w), 644 (w), 558 (m) cm$^{-1}$. $^1$H NMR (500.13 MHz, $CD_3CN$, 25 °C): $\delta$ = 9.37 (dd, $J$ = 5.6, 0.6 Hz, 4 H, $H^A$), 8.88 (dd, $J$ = 1.7, 0.6 Hz, 4 H, $H^C$), 8.27 (dd, $J$ = 1.7, 5.2 Hz, 4 H, $H^2$), 8.27 (s, 2 H, $H^4$), 8.20 (dd, $J$ = 5.6, 1.6 Hz, 4 H, $H^B$), 7.57 (dd, $J$ = 1.7, 5.2 Hz, 4 H, $H^3$), 4.00 (s, 12 H, Me) ppm. $^{13}$C NMR (125.6 MHz $CD_3CN$, 25 °C): $\delta$ = 54.2 ($C^{Me}$), 125.3 ($C^C$), 125.7 (C), 129.0 (C), (C), 142.7 (C), 144.6 ($C^3$), 153.9 ($C^2$), 156.0 ($C^A$), 157.5 ($C^4$), 158.5 (C), 164.4 (C), 191.6 ($C^{CO}$*trans*), 196.3 ($C^{CO}$*cis*) ppm. $^{15}$N NMR (50.69 MHz $CD_3CN$, 25 °C; chemical shifts extracted from the $^1$H-$^{15}$N HMBC spectrum): $\delta$ = 250.5 ($N^{A'}$), 238.1 ($N^1$), 377.6 ($N^5$) ppm.

**Preparation of [{4,4′-($MeO_2C$)$_2$-bpy}(CO)$_3$Re$^I$(μ-PCA)Ru$^{II}$($NH_3$)$_5$]-($PF_6$)$_3$·$CH_2Cl_2$ (7):** Complex **5** (50 mg, 0.056 mmol) was stirred in acetone (10 mL) under argon for 30 min, and [Ru($NH_3$)$_5$-($H_2O$)]($PF_6$)$_2$ (28 mg, 0.056 mmol), prepared as described in the literature,[25] was added. The mixture was stirred continuously under argon in the dark for 2 h. Diethyl ether (100 mL) was then added to precipitate the complex, which was redissolved in a minimum amount of acetone. Dichloromethane (60 mL) and diethyl ether (60 mL) were added to re-precipitate the complex, which was filtered and washed with dichloromethane, diethyl ether, and water. It was finally dissolved in acetonitrile and purified by chromatography on Sephadex LH-20 using acetonitrile as the eluting solvent. The first, blue fraction was collected, concentrated to dryness, redissolved in acetone, precipitated with dichloromethane, filtered, washed with dichloromethane and diethyl ether, and dried in vacuo over $P_4O_{10}$. Yield: 55 mg (71%). $C_{31}H_{39}Cl_2F_{18}N_{11}O_7P_3ReRu$ (1470.8): calcd. C 25.3, H 2.7, N 10.5; found C 25.1, H 2.7, N 10.8.

**Preparation of [{4,4′-($MeO_2C$)$_2$-bpy}(CO)$_3$Re$^I$(μ-PCA)Ru$^{III}$-($NH_3$)$_5$]$^{4+}$ (8):** This heterodinuclear ion was generated in situ by adding bromine to an acetonitrile solution of **7** or by electrochemical oxidation. The oxidation progress was monitored by measuring the absorbance changes in the 200–1100 nm range.

**Preparation of [Re(bpy)(CO)$_3$(4,4′-bpy)]$PF_6$ (9):** This complex was available from previous studies.[11]

**Protonation Studies:** For p$K_a$ determinations, pH titrations by spectrophotometric and spectrofluorometric techniques were performed with two kinds of experiments. In the first one, Britton and Robinson's buffer, which consists of a mixture of 0.04 M acetic acid, 0.04 M phosphoric acid, and 0.04 M boric acid with variable amounts of a solution of 0.2 M NaOH, was used, and the ionic strength was fixed at 0.1 M with a solution of NaCl. The complexes were dissolved in aqueous solutions of 0.1 M NaCl and stirred for about 5 h until the filtered solution showed a final average absorbance of about 0.4. Each sample was prepared just before measurement with 2 mL of buffer and 2 mL of a stock solution of the complex. The pH value of each fraction was then determined with a Metrohm pH-meter. Reversal of the pH values of the extreme fractions was done by adding 3 M HCl or 3 M NaOH. In each titration, 12–15 points were recorded. In the second experiment, the ionic strength was not regulated. Only one solution (approx. 30 mL) was used, with Britton and Robinson's buffer, which con-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

sists of 0.02 M acetic acid, 0.02 M phosphoric acid and 0.02 M boric acid with a small amount of 3 M NaOH solution up to pH = 10. The complex was dissolved by adding a drop of acetonitrile and rapidly mixing with the buffer solution. 3 M HCl (40–60 μL) was added to lower the pH to 1.5. In each titration, 40–50 points were recorded. Both methods gave consistent results. Luminescence and absorption measurements were performed with air-saturated solutions. We used a previously reported technique to fit the obtained data for all complexes.[7] The experimental data were fitted with the PSI Plot software. The fits were all satisfactory, giving consistent and reasonable values of p$K_a$ and p$K_a$*.

## Acknowledgments

We thank the Universidad Nacional de Tucumán (UNT), the Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), and the Agencia Nacional de Promoción Científica y Tecnológica (ANPCyT), all from Argentina, for financial support. The Deutscher Akademischer Austauschdienst (DAAD) is gratefully acknowledged for the donation of the Bioanalytical Systems equipment. F. F., N. E. K., and C. D. B are members of the Research Career from CONICET, Argentina. M. C. thanks CONICET for a graduate fellowship and specially his father for being an exemplary person.

**Keywords:** Mixed-valence compounds / Molybdenum / Cyclic voltammetry / Electronic structure / Density functional calculations

The homobimetallic complex $(Bu_4N)_2$[MoO(mnt)Mo{*o*-aminobenzothiolato(3–)-*N*,*S*}$_2$(mnt)] (**2**; mnt = 1,2-dicyanoethylenedithiolate) has been synthesized as a dark green solid by treating $(Bu_4N)_2[Mo_2O_4(mnt)_2]$ (**1**) with *o*-aminothiophenol in $CH_3CN$. An X-ray crystal structure analysis of **2** reveals that it possesses an asymmetric structure where one Mo has a distorted octahedral geometry and the other a square-pyramidal geometry. The basal plane of the two Mo centers makes an angle of 26.41°, which is nearly one quarter of 90°. The shape of the ν(Mo=O) band in the IR spectrum of **2** suggests that these Mo atoms may have different oxidation states. The different reactivity of **1** with *o*-aminothiophenol and 2-aminoethanethiol was followed by EPR spectroscopy, and analysis of the different end-products from these reactions supports the proposal that **2** is a mixed-valence compound containing $Mo^{VI}$ and $Mo^{IV}$ centers. The electronic structures of **1** and **2** have been calculated at the DFT level of theory to analyse the effect of a deviation of the basal plane on the metal–metal bond in **2**. The cyclic voltammetric responses of **1** and **2** have been measured to correlate the data with the computational results. TDDFT calculations have been performed on **1** and **2** in the gas phase and also in a solvent medium to assign the transitions corresponding to the peaks found in the respective experimental electronic absorption spectra of these complexes.

## Introduction

Terminal oxido- or sulfido-coordinated higher-valent Mo complexes with dithiolene as co-ligand are good models for molybdenum-based enzymes.[1,2] Hexacoordinate $Mo^{VI}$ complexes[3] generally adopt a distorted octahedral geometry with *cis* dioxido or oxido-sulfido groups, whereas related $Mo^{IV}$ complexes generally adopt a square-pyramidal geometry[4] with a terminal Mo=O group or trigonal biprismatic geometry with a terminal Mo–SR (thiolato) moiety.[5] Molybdenum(V) complexes[6] are generally stabilized by di-$\mu_2$-oxido or mono-$\mu_2$-oxido bridging groups and have the general formula $\{M_2X_2Y_2\}^{2+}$, where X (terminal group) and Y (bridging group) are a combination of O and S atoms. The stability of di-$\mu_2$-oxido-bridged dimeric $Mo^V$ complexes arises from a strong Mo($d_{xy}$)–Mo($d_{xy}$) σ bond[7,8] supplemented by pπ bonding between the bridging ligand atoms and the two Mo atoms, which remain almost in the same plane. Imidomolybdenum complexes, which are isoelectronic to oxido complexes, are also known,[9,10] and two Lewis structures have been proposed for the Mo–N binding mode of the imido group to Mo (Scheme 1).[11] In the first, the nitrogen atom acts as a four-π-electron donor and Mo–N–R angle is close to 180°, whereas in the second the nitrogen atom acts as a two-electron donor and the Mo–N–R linkage is bent. The majority of monomeric Mo-imido complexes have a linear imido linkage and most imido-bridged Mo complexes have a bent imido linkage.

Scheme 1. Two possible binding modes of the imido group at an Mo center.

Dialkyldithiocarbamato (dtc)-coordinated dimeric $Mo^V$ complexes with terminal and/or bridging imido linkages have been synthesized from the corresponding oxido and/or sulfido complexes[9] by substitution reactions. Most $Mo^{VI}$-imido complexes[10] have a linear Mo–N–R linkage. The re-

action of a dtc-coordinated oxido-$Mo^{VI}$ complex with 2-aminothiophenol has been reported to produce the intermediate imido complex $[Mo^{VI}(dtc)_2(NC_6H_4S)(OCH_3)]$,[11] which reacts further to give $[Mo^{V}O(dtc)(\mu_2\text{-}NC_6H_4S)_2\text{-}Mo^{V}(dtc)]$ on heating in the solid state under vacuum. The chemistry of oxidomolybdenum complexes varies with the co-ligand, which ranges from dtc to dithiolene-type ligands such as 1,2-dicyanoethenedithiolate (mnt).[12] Although both these co-ligands are sulfur donor bidentate ligands they differ in the bite angle on coordination to the Mo center. In this article we report the reaction of 2-aminothiophenol with a symmetrical di-$\mu_2$-oxido $Mo^{V}$ dithiolene complex to form an asymmetric dimeric dimolybdenum mnt-coordinated complex. The di-$\mu_2$-oxido groups are replaced by imido coordination arising from coordination of the deprotonated 2-aminothiophenol to asymmetric oxidomolybdenum and desoxomolybdenum centers. The reaction is followed by EPR spectroscopy to understand its course, and DFT and TDDFT calculations of the synthesized complex have been carried out to correlate its spectral properties with electronic structure.

## Results and Discussion

### Synthesis and IR Studies

The dithiolene-coordinated dimeric $Mo^{V}$ complex $[Bu_4N]_2[Mo_2O_4(mnt)_2]$ (**1**) has been reported recently.[6a] One of the di-$\mu_2$-oxido groups in **1** is readily protonated in the presence of a weak acid and the conjugate base of the acid then coordinates to the metal center to give linear mono $\mu_2$-oxido-bridged dimeric $Mo^{V}$ complexes with the general formula $[Mo_2O_3(mnt)_2(X)_2]^-$ [X = SPh (**1a**), Cl (**1b**), and Br (**1c**)].[6a] It has been shown that **1a**–**c**, which possess an $\{Mo_2O_3\}^{2+}$ core, hydrolyze back to **1** in the presence of traces of moisture via an EPR-active monomeric $[MoO(mnt)(X)(OH)]^-$ species. This EPR-active intermediate is readily dimerized to a stable di-$\mu_2$-oxido-bridged form due to the presence of two monodentate ligands in adjacent equatorial positions. Our goal was to synthesize a monomeric $Mo^{V}$ species with three S donor atoms (two from a dithiolene ligand and one from an SR group) to mimic the half-reduced state of sulfite oxidase.[13] The vacant fourth site in the equatorial plane of the expected square-based pyramidal Mo complex could be filled by an N-donor therefore we decided to use 2-aminothiophenol and 2-aminoethanethiol, both of which provide one S and one N atom. Both these ligands are in a zwitterionic form in solution, like an amino acid, although 2-aminoethanethiol, unlike 2-aminothiophenol, lacks $\pi$ delocalization. Treatment of **1**, **1a**, **1b**, or **1c** with 2-aminothiophenol in dichloromethane causes the color of the solution to change to light green, which suggests the formation of a new species, although addition of petroleum ether allowed only **1** to be isolated. The light-green species is EPR-active and the isolation of only **1** from such a reaction mixture clearly suggests that the 2-aminothiophenolato-coordinated $Mo^{V}$ monomer (EPR active) is in equilibrium with **1** in solution and that addition of the second solvent shifts the equilibrium towards **1**. The use of a more polar solvent such as acetonitrile led to a similar reactivity, whereas employing more drastic reaction conditions changed the course of the reaction. Thus, refluxing **1** with 2-aminothiophenol in acetonitrile yielded **2**. Unlike dtc-coordinated Mo complexes, however, **1** does not react with aniline or substituted anilines.

Addition of a solution of 2-aminoethanethiol in methanol to an acetonitrile solution of **1** caused a color change of the reaction mixture from yellow to dark-orange and finally to green, followed by immediate precipitation of yellow $[Mo^{VI}O_2(SCH_2CH_2NH_2)]$[14] in 48% yield. Further workup yielded 46% of $[(Bu_4N)_2][Mo^{IV}O(mnt)_2]$ from the mother liquor (Scheme 2). Reaction of $[Mo^{VI}O_2(mnt)_2]^{2-}$ with 2-aminothiphenol or 2-aminoethanethiol yielded $[Mo^{IV}O(mnt)_2]^{2-}$ quantitatively, with no formation of any imido-coordinated complex.[15] Similar reactions of these aminothiols with dtc-coordinated $Mo^{VI}$ complexes have shown a different chemistry.[10]

On the basis of the total charge and the diamagnetic nature of **2**, the possible formal oxidation states of the two Mo(1)/Mo(2) centers are either +5/+5 or +6/+4. This question can be resolved by considering the Mo=O stretching vibration of this unsymmetrical complex as the $\nu$(Mo=O) vibration in molybdenum complexes is sensitive to the formal oxidation state of Mo. Thus, this vibration in pentacoordinate bis-dithiolene $Mo^{IV}$ complexes[16] generally appears below 940 $cm^{-1}$, whereas in related $Mo^{V}$ species it

Table 1. Values of ν(Mo=O) [$cm^{-1}$] for selected Mo complexes.

| Complexes | ν(Mo=$O_t$)[a] | Ref. |
|---|---|---|
| $[Mo_2O(mnt)_2\{o\text{-aminobenzothiolato}(3-)\text{-}N,S\}_2]^{2-}$ | 937 | this work |
| $[Mo^{IV}O(mnt)_2]^{2-}$ | 932 | [3c] |
| $[Mo^{IV}O(mnt)(Bu_2bpy)]$ | 939 | [4d] |
| $[Mo^{V}{}_2O_4(mnt)_2]^{2-}$ | 977 | this work |
| $[Mo^{V}{}_2O_2(mnt)_2(\mu\text{-SPh})_2(\mu\text{-OR})]^{-1}$ (R = Me, Et, *i*Pr) | 951, 958, 961 | [6a] |
| $[Mo^{V}{}_2O_2(mnt)_2(\mu\text{-O})(\mu\text{-SPh})(\mu\text{-Br})]^{-2}$ | 960 | [6a] |
| $[Mo^{V}{}_2O_2(mnt)_2(\mu\text{-O})(\mu\text{-SPh})(\mu\text{-CH}_3SO_3)]^{-2}$ | 957 | [6a] |
| $[Mo^{V}{}_2O_2(mnt)_2(\mu\text{-O})(\mu\text{-SEt})(\mu\text{-CH}_3SO_3)]^{-2}$ | 952 | [6a] |

[a] t = terminal.

appears above 950 $cm^{-1}$ (Table 1). The appearance of ν(Mo=O) at 937 $cm^{-1}$ in **2** therefore indicates that the Mo(2) center is formally in the $Mo^{IV}$ state, which fixes the oxidation state of Mo(1) as +6.

## EPR Studies

The reaction leading to **2** involves the initial formation of an EPR-active $Mo^{V}$ species. This intermediate could not be identified in the case of 2-aminoethanthiol as rapid precipitation of yellow $[Mo^{VI}O_2(SCH_2CH_2NH_2)]$[14] from the reaction mixture took place with the formation of an equivalent amount of $[(Bu_4N)_2][Mo^{IV}O(mnt)_2]$.[14] Such a behavior can be explained by a disproportionation reaction where removal of the oxidized part of the product as a solid drives the reaction quickly to completion. In contrast, a similar reaction with 2-aminothiophenol led to the formation of an EPR-active $Mo^{V}$ signal (Figure 1) which was stable for hours, thereby indicating the inability of the complex formed to undergo a disproportionation reaction.

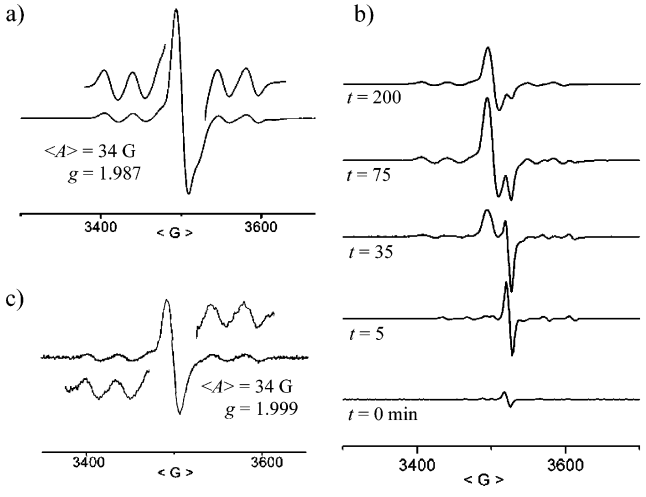

Figure 1. EPR spectra of the reaction of $(Bu_4N)_2[Mo^{V}{}_2O_4(mnt)_2]$ (**1**) with 2-aminothiophenol in acetonitrile at room temperature: a) at the initial stage (5 min), $<A>$ = 34 G, $g$ = 1.987; b) EPR signal at different time intervals showing the appearance of another EPR active species ($<A>$ = 34 G, $g$ = 1.999); c) after 24 h.

Attempts to isolate this species were unsuccessful and only the starting complex **1** was obtained. We were able to identify the formation of an intermediate $Mo^{V}$ species ($<g>$ = 1.987; Figure 1, a) in the initial stages of the reaction which was stable for a long time and only disappeared on heating the solution. This EPR signal is associated with another EPR $Mo^{V}$ signal ($<g>$ = 1.999; Figure 1), although this second signal remains even after the disappearance of the main EPR signal (Figure 1, c). The broad nature of the EPR signal (13 G) prevented us from identifying any superhyperfine interaction arising from nearby protons. Changing the reaction medium to a less polar solvent like dichloromethane did not help to reduce the line width. In the frozen state (liquid nitrogen), the EPR spectrum shows a tetragonally distorted line shape with ($A_{\parallel}$ = 45 G, $g_{\perp}$ = 1.990, $g_{\parallel}$ = 1.955, $g_{average}$ = 1.979; see electronic supporting information). For a square-planar-based Mo complex where the metal is coordinated to the sulfur atoms of mnt and the nitrogen of *o*-aminothiophenol, the fourth corner is presumably occupied by a hydroxido ligand, as shown in Scheme 3. The proton associated with this hydroxido group is positioned in such a way that it interacts with the unpaired electron of $Mo^{V}$ in the $d_{xy}$ orbital. Such super hyperfine splittings generally appear in the 2–7 G range for a $Mo^{V}$–OH interaction.[17a,17b] In the present case the broad nature of the EPR signal [component line width (peak separation) = 30 G] prevents us from identifying any H-related superhyperfine splitting. The retention of a weak $Mo^{V}$ signal at $<g>$ = 1.999 could be associated with the formation of a side product. This EPR signal also loses its intensity on prolonged standing and finally disappears.

A green tarry product, which is soluble in dichloromethane but not in benzene or toluene, was obtained from the mother liquor after removal of the solvent. This solubility difference suggests that the by-product does not contain a neutral complex with an $\{Mo(NS)_3\}$ core.[17] If this product were to contain a $Mo^{V}$ monomeric tris-chelated by-product like $[Mo^{V}(abt)_3]^{-}$ type complex[17] then the appearance of a more delocalized $<g>$ value near to 2 would be likely and the core of the complex would probably be $\{MoS_6\}$ or $\{Mo(NS)_3\}$, or a combination of these two.[17] Further characterization of this species is currently underway. It is important to note that **2** could only be isolated in good yield after refluxing the reaction mixture for 20 h; shorter reaction times led to the isolation of large amounts of unreacted **1**. These observations can be interpreted as follows. Complex **1** reacts initially with 2-aminothiophenol by opening the oxido-bridged dimeric structure, which results in the

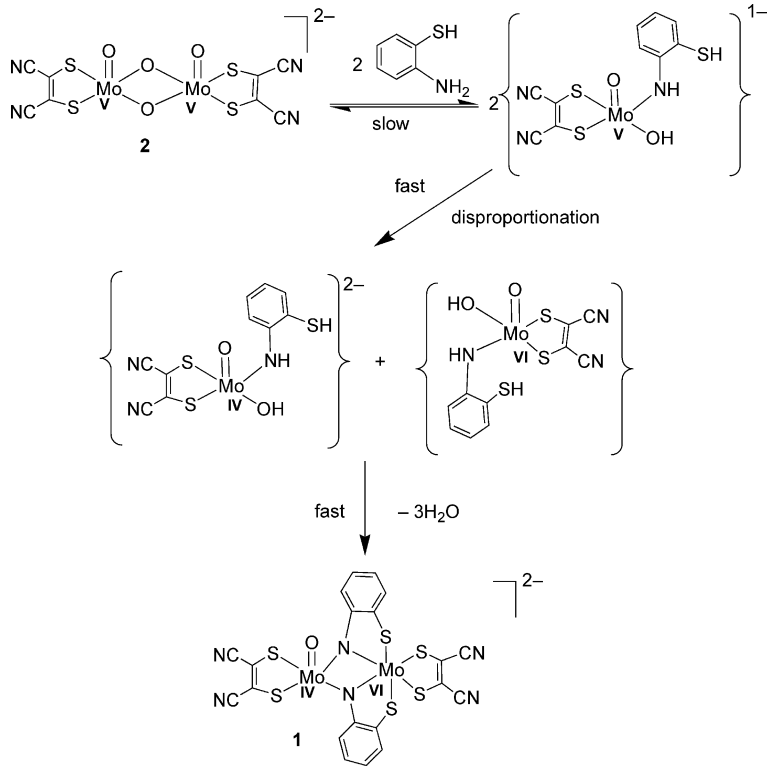

Scheme 3. Proposed mechanism for the formation of $(Bu_4N)_2[Mo^{IV}O(mnt)Mo^{VI}(mnt)\{o\text{-aminobenzothiolato}(3-)\text{-}N,S\}_2]$ (**2**) from the reaction of $(Bu_4N)_2[Mo^{V}_2O_4(mnt)_2]$ (**1**) with 2-aminothiophenol via an EPR-active intermediate species.

appearance of a $Mo^V$ signal and a complex with an $\{Mo^V(O)(S)_2(RNH)(OH)\}$ core, which disproportionates to $\{Mo^{IV}(O)(S)_2\}$ and $\{Mo^{VI}(O)(S)_2\}$ moieties upon heating (Scheme 3). These intermediates interact with the dangling SH groups that result from weak oxido coordination to $Mo^{VI}$. This leads to complete deprotonation of the $RNH^-$ groups (finally releasing three equivalents of $H_2O$), which becomes a bridging $RN^{2-}$ ($sp^2$-hybridized, isoelectronic to $O^{2-}$) ligand (Scheme 3).

The reaction of **1** with $HSCH_2CH_2NH_2$ in $CH_3CN$ initially gives a green solution, which turns orange upon precipitation of a yellow complex. This complex was identified as $[Mo^{VI}O_2(SCH_2CH_2NH_2)]$ by subsequent comparison with literature data[14] and its formation is accompanied by that of $[Bu_4N]_2[Mo^{IV}O(mnt)_2]$.[3c] Both complexes were isolated in a 1:1 ratio, thus confirming the disproportionation of EPR-active $Mo^V$ into $Mo^{IV}$ and $Mo^{VI}$ species. In this case the absence of a phenyl ring means that there is no π interaction, which may speed up the disproportionation reaction. The discrete monomeric intermediates further rearrange in a ligand-exchange reaction to yield $Mo^{IV}$ monoxido and $Mo^{VI}$ dioxido complexes.[3c]

## Structural Descriptions

The structure of **1** has been reported previously.[6a] An ORTEP view of the anion of **2** is shown in Figure 2 and selected bond lengths and angles are listed in Table 2. Compound **1** is a symmetrical dimeric $Mo^V$ complex in which each molybdenum center of the anion of **1** possesses a pentacoordinate square-pyramidal geometry where the basal plane contains two S donor atoms from one mnt ligand and two bridging oxido groups. One terminal oxido group in the axial position completes the square-pyramidal geometry. The Mo atoms lie around 0.73 Å above their respective basal planes (S1–S2–O3–O4 and S3–S4–O3–O4, Figure 2). The two Mo atoms are bonded by a metal–metal σ bond with a relatively short bond length of 2.582 Å. The average Mo–$O_t$ bond lengths are 1.68 Å and the two mnt ligands are nearly symmetrically bonded to two Mo atoms, with a mean Mo–S distance of 2.433 Å.

Complex **2** is asymmetric (Figure 2). The asymmetric unit of **2** contains two tetrabutylammonium cations and one anionic dimeric Mo complex. Interestingly, the two Mo centers in **2** have different coordination environments: the first one is a desoxo [Mo(1)] moiety whereas the other [Mo(2)] is an oxidomolybdenum moiety. Mo(1) has a distorted octahedral geometry and is coordinated to three bidentate ligands, whereas Mo(2) has a square-pyramidal geometry with one terminal oxido group at its axial position. The basal plane ($N^1$–$N^2$–$S^3$–$S^4$) of this square pyramid contains two imido N atoms from an aminothiophenolato ligand and two S atoms from a dithiolene ligand. The Mo(2)–O distance is 1.681 Å. Two metal centers are bridged (denoted by br) by two $RN^{2-}$ (bent imido linkage, Scheme 1) units where each N is in a trigonal planar geometry ($sp^2$ hybridization) and the average $N_{br}$–$C_{C_6H_4SN}$ distance is 1.393 Å, which indicates a strong π delocalization of the Mo d electron throughout the benzene ring of the bridging ligand via the bridging N atom. The Mo(2)–$N_{br}$ distances (2.008 and 2.022 Å) are longer than the Mo(1)–$N_{br}$ distances (1.940 and 1.925 Å), which imposes an asymmetry in the bonding at the two metal centers. The choice of the XY coordinate plane for a distorted octahedral geometry or a basal plane for comparison with the basal plane of the Mo(2) center (square-pyramidal geometry) is very difficult for such an asymmetric molecule. However, we can consider that the $N_1$, $N_2$, $S_1$, and $S_6$ donor atoms contribute to the XY coordinate plane or basal plane in this octahedral geometry due to the metal–metal bond formation. The basal plane of Mo(1) ($N_1$–$N_2$–$S_1$–$S_6$) makes an angle 26.41° (Figure 3) with the basal plane (XY coordinate plane) of the Mo(2) center (mean plane of the N1, N2, S1, and S6 donor atoms), which is nearly a quarter of 90°. The Mo–Mo bond is somewhat longer (2.685 Å) than that for **1**. The metal–metal bond length in most bridged bimetallic system depends on the size of the bridging atoms and for N atoms it should be shorter than O atoms (Mo–Mo distance is 2.58 Å for **1**), although the reverse is observed here. This is probably due to the overlap of the corresponding σ- and π-bonding orbitals. The Mo–Mo bond lengths in a series of dithiolene-coordinated dimeric Mo complexes are listed in Table 3.

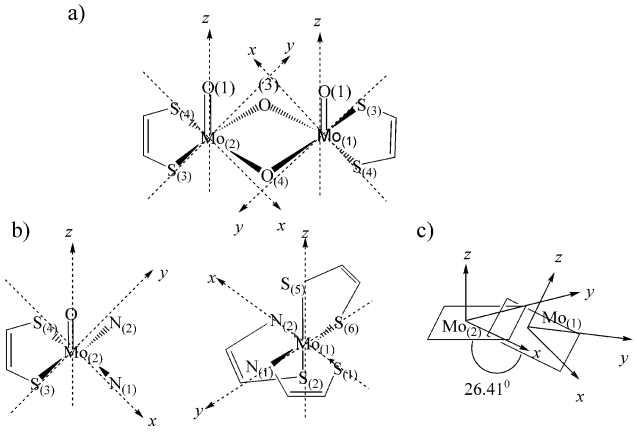

Figure 3. View of the basal plane containing the Mo center in $(Bu_4N)_2[Mo^V_2O_4(mnt)_2]$ (**1**) (a) and $(Bu_4N)_2[Mo^{IV}O(mnt)$-$Mo^{VI}(mnt)\{o\text{-aminobenzothiolato}(3\text{–})\text{-}N,S\}_2]$ (**2**; b and c).

Most dtc-coordinated diimido-bridged dimeric $Mo^V$ complexes with an $\{Mo^V_2O_2(\mu\text{-}NR)_2\}^{2+}$ core are structurally symmetrical[9] like **1**, whereas diimido-bridged dimeric $Mo^V$ complexes like $[Mo^VO(dtc)(\mu_2\text{-}NC_6H_4S)_2Mo^V(dtc)]$[10] are asymmetric. The desoxomolybdenum center in this compex is very close to trigonal prismatic whereas in **2** the

same center adopts a distorted octahedral geometry. This difference is due to the small bite angle of the dtc ligand compared to mnt. The trigonal-prismatic distortion may have a different bonding scheme that does not affect the Mo–Mo bond length as much as in the corresponding symmetric systems. The average Mo–S bond lengths of all these complexes are very similar although the Mo–Mo bond length in **2** is slightly longer (Table 3) than in dtc-coordinated diimido-bridged dimeric $Mo^{V}$ complexes.

### Electronic Structure Calculations

The results of the IR and EPR studies and the difference in reactivity of **1** with 1,2-aminothiophenol and 1,2-aminoethanethiol strongly support that compound **2** may possess a mixed-valent $\{M_2\}$ unit. In view of the different nature of the two Mo centers in **2**, we decided to calculate the ground-state electronic structures of **1** and **2** at the DFT (B3LYP) level of theory to determine the energies and compositions of their molecular orbitals (MOs). In both cases the initial geometry was taken from the crystal structure and the geometry was optimized in the gas phase. Additional single-point calculations taking into account a solvent effect were also performed. Selected frontier molecular orbitals, together with their percentage contributions estimated from a Mulliken population analysis calculated in acetonitrile medium, are shown in Figure 4. The assignment of the type of each MO was made on the basis of its composition and by visual inspection of its localized orbital. The coordinate frames for both compounds were assigned by a visual inspection of the $d_{z^2}$ and $d_{xy}$ orbitals and this assignment was found to agree with previous assignments.[7,8] Because of the presence of two different coordinate frames in one molecule that differ from planarity, two additional single-point calculations were carried out using two different coordinate frames (as described in Figure 3) to calculate the percentage contribution of the atomic orbital to the MOs. A table comparing selected bond lengths obtained from the crystal structure and the gas-phase-optimized geometry is given as supporting information. The percentage contributions of the atomic orbitals to selected MOs for **1** and **2** are listed in Table 4.

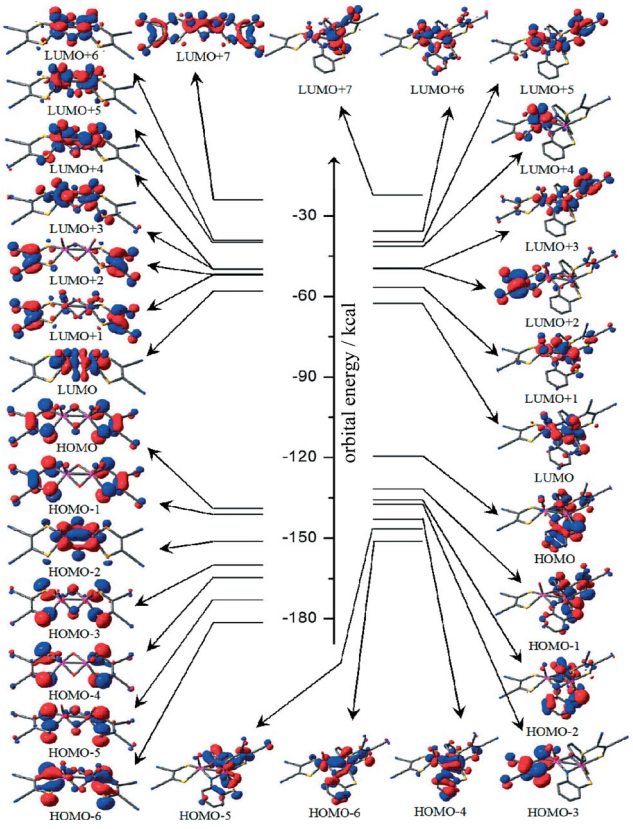

Figure 4. Pictorial representation of the molecular orbitals with levels energy (kcal mol$^{-1}$; seven highest-occupied and eight lowest-unoccupied) of $(Bu_4N)_2[Mo^{V}_2O_4(mnt)_2]$ (**1**) (left) and $(Bu_4N)_2$-$[Mo^{IV}O(mnt)Mo^{VI}(mnt)\{o\text{-aminobenzothiolato}(3-)\text{-}N,S\}_2]$ (**2**) (right) calculated in acetonitrile.

Figure 4 shows the frontier orbitals of **1** and **2** that control the electronic transitions and electrochemical behaviors of these complexes. The two highest molecular orbitals (HOMO and HOMO–1) for **1** have a large contribution

Table 4. Percentage contributions of atomic orbitals to selected molecular orbitals of $(Bu_4N)_2[Mo^{V}_2O_4(mnt)_2]$ (**1**) and $(Bu_4N)_2[Mo^{IV}O$-$(mnt)Mo^{VI}(mnt)\{o\text{-aminobenzothiolato}(3-)\text{-}N,S\}_2]$ (**2**), calculated in acetonitrile.

| MO | 1 | 2 |

from the π* antibonding orbital of the dithiolene ligands (mnt). The next lowest lying and deeply buried occupied orbital (HOMO–2) is formed from a σ-bonding interaction between the $d_{xy}$ orbitals of two Mo centers (each with 32%) and the O π orbital of the bridging oxygen atoms. HOMO–3 to HOMO–6 have only a π orbital contribution from the S atoms of two dithiolene ligands. The LUMO is formed from an antibonding interaction between the $d_{xy}$ orbitals of two Mo centers (38% each) and the O π orbitals of the bridging oxygen atoms. The next two highest energy virtual orbitals (LUMO+1 and LUMO+2) have contributions from the C–CN π antibonding orbital of mnt. The rest of the metal d orbitals involved in lateral π overlap are empty and in a high energy state. The Mo–Mo σ bond of most symmetric dimeric di-$\mu_2$-oxido $Mo^V$ ($d^1$ system) complexes is formed by the head-on overlap of the $d_{xy}$ orbitals of each Mo center. This is also the case for complex **1**, where the HOMO–2 and LUMO correspond to the σ bonding and antibonding molecular orbitals, respectively, and are formed by the usual overlap of two $d_{xy}$ orbitals from each metal center.

The situation for **2** is somewhat more complicated because of its unsymmetrical nature and the fact that the two metal centers have different geometries. These metals are bridged by an $RN^{2-}$ anion and hence should have different bonding. The HOMO, HOMO–1, and HOMO–2 are ligand (mnt and 2-aminothiophenolate) S π based orbitals, and a deeply buried HOMO–4 shows the bonding interaction between the two Mo centers, which originated from the overlap of the $d_{xy}$ orbital of Mo(2) (18%) and a mixture of three d orbitals ($d_{xy}$, $d_{xz}$, and $d_{yz}$) of Mo(1) (8%, 6%, and 5% respectively; Table 4). The total contribution of the metal d orbitals is 37%. The higher energy LUMO, LUMO+1, and LUMO+3 (Figure 4, Table 4) show antibonding interactions with Mo(2) ($d_{xy}$) and Mo(1) ($d_{xy}$, $d_{yz}$, and $d_{xz}$), whereas LUMO+2 has a maximum contribution from the N≡C–C=C–C≡N π* antibonding orbital. Based on the total metal contribution to HOMO–4 the extent of bonding for the σ bond is 37%, and based on the full contribution of the Mo(2) ($d_{xy}$) orbital (considering only a σ-bonding interaction between the two metal centers), the extent of σ-bonding overlap of the $d_{xy}$, $d_{yz}$, and $d_{xz}$ orbitals of Mo(1) is approximately 50, 25, and 25% respectively.

Cotton and co-workers[18] have established the formation of a maximum of four M–M bonds (σ, 2π, δ) for any $\{M_2\}$ unit where both the metal centers contribute atomic orbitals of the same symmetry to give maximum overlap and form a particular metal–metal bond, although the possible formation of five M–M bonds has also been reported recently.[19] The formation of an M→M′ dative bond with different orbitals ($Md_{z^2}$, $M'd_{x^2-y^2}$) in heterobimetallic systems involves the *xy*-coordination frame of the respective metal center as orthogonal to each other.[20] The complex $[Mo_2(O\textit{i}Pr)_4(dmpe)_2]$ is an interesting example with dissimilar coordination of two metal centers.[21] The strength of the multiple Mo–Mo bonds in this complex is maximum for a perfectly eclipsed configuration of the basal planes and tends to zero for a fully staggered configuration. This has been related to the extent of π and δ overlap, which is itself dependent on the twist angle.[22] However, the situation may differ for a σ bond when the angle between the basal planes of the two metal centers is about one quarter of 90°, as we observed for **2**. None of the five d orbitals of a metal center in the $\{M_2\}$ moiety can be transformed to another center by rotating the coordinate frame by an angle of one quarter of 90°. This deviation from planarity of the coordination framework of two metal centers will minimize the extent of overlap of their respective d orbitals. This deviation is 26.41° for complex **2**, which forbids a perfect σ overlap between the Mo(2) $d_{xy}$ and Mo(1) $d_{xy}$ orbitals. However, a partial symmetry is allowed for the overlap of Mo(2) ($d_{xy}$) and Mo(1) ($d_{xy}$, $d_{yz}$, $d_{xz}$) orbitals for a direct Mo–Mo interaction where the two bonding electrons come from $Mo(2)^{IV}$ (MO energy level diagram shown in Figure 3). The extent of bonding is only about 35% accounted for by σ donation from a metal d orbital, therefore the Mo–Mo distance is longer then expected (according to the size of the bridging atom). This bond also involves some degree of π interaction, as reflected by the Mo(1)–$N_{br}$ bond length being shorter than Mo(2)–$N_{br}$ and high delocalization of the metal centers with the ligand π orbitals throughout the molecule. Thus, the interaction of two asymmetric metal center fragments can be viewed as a donor–acceptor interaction where partial σ overlap between one donor and three acceptor orbitals (or a hybrid of three metal d orbitals) as well as a π (ligand) donor/acceptor interaction supplement the resulting bond; this explains the diamagnetism of **2**. Under such circumstances, it is difficult to assign the exact oxidation states of the two Mo centers in **2**, although assigning the formal oxidation state of Mo(1) center as +6 and the Mo(2) center as +4 is a good approximation that solves the problem of electron bookkeeping and supports the experimental results.

A population analysis (Mulliken and NBO) of the partial atomic charges for complexes **1** and **2** was carried out using the same method and basis set. The partial atomic charge distributions of selected atoms are listed in Table 5. The overall charge distribution is symmetric in **1** and asymmetric in **2**. The atomic charge distribution of the S atoms is nearly zero for both **1** and **2**, and the N and O atoms both

carry negative charges. The two Mo centers in **1** have the same positive atomic partial charges whereas the charge distribution at the two metal centers in **2** is unequal and is lower than **1** [Mulliken for **2** Mo(1): 0.13, Mo(2): 0.59; NBO Mo(1): 0.35, Mo(2): 0.96]. Although the formal oxidation state of Mo(2) is +4, which is less than that (+6) of Mo(1), the Mo(2) center has a greater positive charge. This may be due to the presence of a highly electron-withdrawing Mo=O moiety at Mo(2). Similarly, the presence of all-thiol ligation in Mo(1) clearly reflects the high delocalization of the ligand π orbitals, which reduces its positive atomic partial charge.

### Cyclic Voltammetry

The cyclic voltammograms (CVs) of **1** (Figure 5) and **2** (Figure 6) were recorded in a $10^{-3}$ M solution in acetonitrile at 298 K at a scan rate of 100 mV $s^{-1}$. The potential was measured using a glassy carbon electrode with Ag/AgCl as reference electrode with 0.1 M tetrabutylammonium perchlorate as supporting electrolyte. The CV of **1** shows one irreversible oxidation at 1.22 V and one quasi-reversible reduction at –1.56 V. The CV of **2** shows two irreversible ligand oxidations at 0.85 and 1.08 V and a fully reversible reduction at –1.16 V.

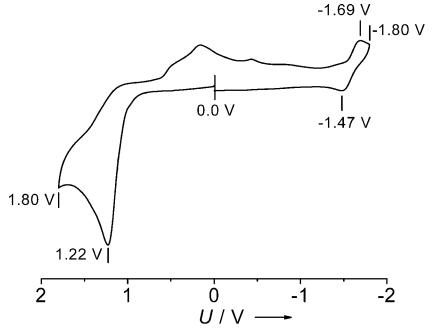

Figure 5. Cyclic voltammogram of $(Bu_4N)_2[Mo^V_2O_4(mnt)_2]$ (**1**) in acetonitrile. Scan rate: 100 mV $s^{-1}$, *U* stands for voltage.

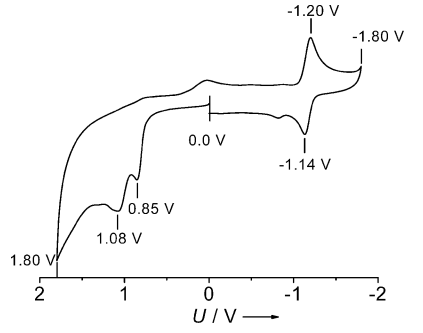

Figure 6. Cyclic voltammogram of $(Bu_4N)_2[Mo^{IV}O(mnt)$-$Mo^{VI}(mnt)\{o$-aminobenzothiolato(3–)-*N*,*S*$\}_2]$ (**2**) in acetonitrile. Scan rate: 100 mV $s^{-1}$, *U* stands for voltage.

The CV responses can easily be explained by the nature of the HOMOs and LUMOs. Thus, the irreversible oxidation of **1** is due to oxidation of the mnt ligand because the HOMO of **1** is a ligand S π* orbital of mnt. The two irreversible oxidations observed for **2** are associated with two types of ligand oxidation because the HOMO, as the potential electron donor, is predominately populated by the S π* orbitals of mnt and the 2-aminothiophenolato ligand. The quasi-reversible reduction of one of the $Mo^V$ centers is viewed as the population of an electron on the LUMO, which is formed by the antibonding interaction of two metal $d_{xy}$ orbitals. In the LUMO of **2** the Mo(2) $d_{xz}$ orbital is predominantly populated and a fully reversible reduction of $Mo^{VI}$ center is possible. This reversibility clearly indicates that the one-electron reduction of **2** does not significantly affect the Mo–Mo bond because of the high delocalization by σ donation and π acceptance through the bridging ligands between the two Mo centers of the respective fragments and also through the benzene rings of the bridging ligands. The one-electron reduction of **1** makes this system unstable because the addition of this electron to the σ* antibonding orbital reduces the bond order and directly affects the Mo–Mo bond. The less negative potential for reduction of the Mo center of **2** compared to **1** correlates nicely with the smaller HOMO–LUMO gap found for **2** by the DFT calculations.

### Optical Absorption Spectra

The electronic spectra of complexes **1** and **2** were recorded in acetonitrile. Complex **1** shows only one peak at 353 nm, whereas complex **2** shows two peaks at 338 and 439 nm in the UV region. Two other low energy bands observed for **2** in the visible region at around 580 and 648 nm, with almost equal intensity, are absent in **1**. The absorption spectra of **1** and **2** are shown in Figure 7. The metal-mnt complexes and the free $Na_2$mnt ligand show an absorption band at around 364 nm due to an intraligand charge-transfer transition. The electronic spectra of complexes **1** and **2** were also measured in other solvents with different polarities (dichloromethane and dmf; see electronic supporting information). No remarkable changes in the position of the maximum absorption wavelength ($\lambda_{max}$), the optical absorption coefficient, or the overall nature of the absorption spectra of **1** and **2** were observed on changing the solvent polarity.

TD-DFT calculations on **1**, **2**, and the free ligand $[\{S_2C_2(CN)_2\}^{2-}]$ were carried out at the G03/B3LYP level in the gas phase and with a solvent effect (COSMO) on the gas phase optimized geometry to assign the experimentally observed low-lying electronic transitions in the visible region. The time-dependent DFT approach (TD-DFT) is a rigorous method for calculating vertical electronic excitation spectra. The solvent dielectric constant and radius were considered as being those of acetonitrile. The free mnt ion is not soluble in acetonitrile and its experimental spectrum was therefore recorded in methanol, thus the solvent effect was calculated for the solvents acetonitrile and methanol. Singlet excited states were calculated based on the singlet ground-state geometry. The lowest 40 singlet excited states with oscillator strengths greater than 0.01 ($f > 0{:}01$)

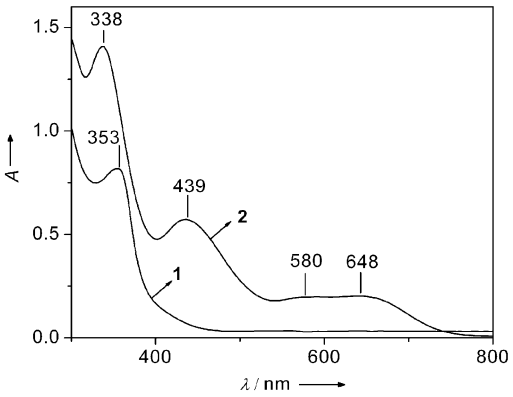

Figure 7. Electronic absorption spectrum of a $5 \times 10^{-5}$ M solution of $(Bu_4N)_2[Mo^V_2O_4(mnt)_2]$ (**1**) and $(Bu_4N)_2[Mo^{IV}O(mnt)Mo^{VI}(mnt)\{o\text{-aminobenzothiolato}(3-)\text{-}N,S\}_2]$ (**2**) in acetonitrile.

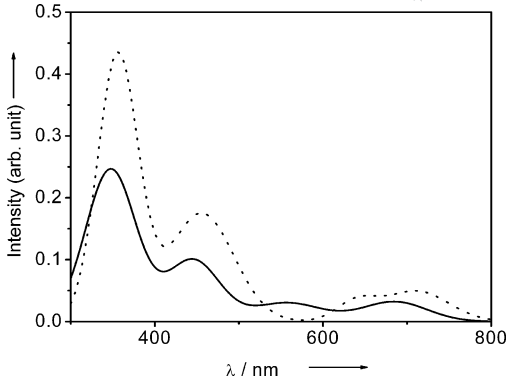

Figure 9. Computed absorption spectrum of $(Bu_4N)_2[Mo^{IV}O(mnt)\text{-}Mo^{VI}(mnt)\{o\text{-aminobenzothiolato}(3-)\text{-}N,S\}_2]$ (**2**) in the gas phase (solid line) and in acetonitrile (dotted line).

were considered for TD-DFT calculations, and the singlet excited states were fitted to Gaussian line shapes. The simulated CT spectra were prepared by fitting each excited state energy to a Gaussian curve with a full-width-at-half-maximum of 45 nm for complex **1** and 63 nm for complex **2**. A table containing the low-energy excitation wavelengths and oscillator strengths (OS) for compounds **1**, **2**, and the free ligand in the gas phase and in acetonitrile is provided as supporting information. The computed electronic spectra of **1** and **2** in the gas phase and in acetonitrile are shown in Figures 8 and 9 respectively. According to the TD-DFT calculations the free ligand mnt has only one absorption band in the visible region at around 427 nm in the gas phase and around 415 nm in both solvents. The calculated band in these three different media shows a blue shift with respect to the experimental value (approx. 364 nm) and this band is due to the intraligand charge transfer from S–C=C–S π* (HOMO) to NC–C=C–CN (LUMO) π*.

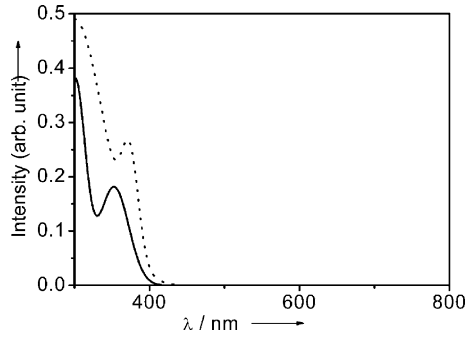

Figure 8. Computed absorption spectrum of $(Bu_4N)_2[Mo^V_2O_4(mnt)_2]$ (**1**) in the gas phase (solid line) and in acetonitrile (dotted line).

One intense charge-transfer band was found at 368 nm in the gas phase and at 370 nm in the solvent phase for complex **1**. The experimentally observed peak at 364 nm can be assigned as either a ligand S–C=C–S π* (HOMO) to ligand NC–C=C–CN (LUMO+3) internal charge-transfer transition or an intraligand charge-transfer transition. Another high energy charge-transfer band was computed in the lower UV region. This is responsible for the higher energy transition ($\lambda < 300$, experimentally observed) which is due to an MLCT transition from HOMO–2 to LUMO+6. Unfortunately, the solvent absorption prevented us from recording the experimental absorption spectrum in the region below 300 nm.

The single electron in the $d_{xy}$ ($Mo^V$) orbital, which is engaged in metal–metal bond formation, is deeply buried and does not take part in any electronic transition in the visible region, although it does appear in the very high energy region ($\lambda < 300$). The other empty d orbitals are highly destabilized by π interactions and this may be the reason why **1** does not show any MLCT or LMCT transition in the 300–1000-nm region.

The most intense absorption bands at 335 nm in the gas phase and 342 nm in the solvent phase for **2** match well with the experimentally observed absorption band at 338 nm. This can be assigned as the sum of major overlapping HOMO–2 to LUMO+5 and LUMO+6, HOMO–5 to LUMO+3, and HOMO–5 to LUMO+3 electronic transitions with ligand S π to metal d orbital charge transfer character (LMCT). The second LMCT band is at 429 nm in the gas phase and at 451 nm in the solvent phase in the visible region, which is compatible with the experimentally found absorption at 439 nm. There are also some slightly lower intensity transitions found within ±30 nm of the 439 nm band. The experimentally observed band at 439 nm can therefore be assigned as a multiple LMCT band originating from different types of ligand S π* antibonding orbital to metal antibonding d orbital transitions. Because of the multiple nature of the charge-transfer transitions appearing in a very close region, this absorption is broad in nature and its half width is larger than that of the peak at 338 nm. The two experimentally observed low energy and less intense peaks around 648 and 580 nm are broad in nature. The calculated absorption peaks found in this region at three different wavelengths (683, 617, and 549 nm) in the gas phase are shifted to 705, 636, and 554 nm, respectively, in the solvent phase and have almost the same intensity. These three peaks give rise to two absorptions at 683 and

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

at 558 nm in the gas phase and at 705 and at 563 nm in the solvent phase, respectively. Thus, the experimentally found peak at 580 nm is due to a charge-transfer transition from two different types of ligand S π* antibonding orbitals to metal antibonding d orbitals (HOMO to LUMO+1 and HOMO–1 to LUMO). The peak at 648 nm (experimental) can be assigned as a ligand S π orbital to metal antibonding d orbital (HOMO to LUMO) transition. The simulated spectra of **1** and **2** show a shift of the wavelength of some charge-transfer bands between the solvent model and the gas phase, although the experimental absorption spectra recorded in solvents with different polarities show no such shifts.

## Conclusions

Most known higher valent (+4, +5, and +6) dimeric Mo complexes are symmetrical with respect to the two molybdenum centers, therefore complex **2** is unique in that it features one oxido and one desoxo Mo moiety bridged by a common ligand that imparts a different coordination framework around each Mo center. Such structural asymmetry, the presence of an Mo–Mo bond between the two Mo centers, extended π delocalization throughout the molecule, the position of the $\nu_{(Mo=O)}$ absorption, and a detailed EPR study support the presence of a mixed-valent $\{Mo_2(RN)_2\}$ unit in **2**. The individual Mo centers [Mo(1) and Mo(2)] in **2** may have nearly +6 and +6 oxidation states. The redox chemistry observed in the CVs for both **1** and **2** has been correlated with the theoretical results, and the observed electronic absorption spectra have been analyzed by TD-DFT calculations. Analysis of the bonding by DFT calculations has shown a new bonding feature in the asymmetric dimeric complex **2**. The plausibility of a σ-type overlap involving one d orbital from one metal center and a hybrid orbital of three d orbitals from the other metal center in a dimeric molecule has been investigated in a situation where the deviation of the angle between the respective basal planes is around 26°. While checking such a possibility the overlap of one donor metal d orbital and three acceptor metal d orbitals to form a molybdenum–molybdenum bond is invoked. The possibility of influencing such bonding by changing the donor or the acceptor is currently being explored.

## Experimental Section

**Starting Materials and Physical Methods:** All reactions were carried out in air and under ambient conditions. $Bu_4NBr$, 2-aminothiophenol, and 2-aminoethanethiol were obtained from Aldrich and NaCN and ammonium heptamolybdate from S. D. Fine chemicals Ltd. India. $Na_2[S_2C_2(CN)_2]$ ($Na_2$mnt) was prepared according to a literature method.[12] Solvents and reagents were distilled and dried by standard procedures. IR spectra were recorded as CsI pellets with a Bruker Vertex 70 FT-IR spectrophotometer. Elemental analyses for carbon, hydrogen, nitrogen, and sulfur were obtained with a Perkin–Elmer 2400 microanalyser. Electronic spectra were recorded with a Cintra 10 UV/Vis spectrophotometer. Low-temperature (frozen state, 77 K) EPR spectra were recorded with a Varian E-109 (X-band) spectrometer in dual cavity mode and the EPR parameters were calculated from the measured spectra using DPPH ($g$ = 2.0023) as calibrant. Room-temperature solution spectra were recorded with a Bruker EMX X-band EPR spectrometer using DPPH ($g$ = 2.0023) as calibrant and the EPR parameters were calculated using the Bruker WINEPR system. Samples for room-temperature solution EPR spectra were prepared under argon and then transferred into a flat quartz cell fitted with a gas-tight septum. Cyclic voltammetric measurements were performed with a BASi Epsilon-EC Bioanalytical systems, Inc. instrument. Cyclic voltammograms of $10^{-3}$ M acetonitrile solutions of the compounds were recorded with a glassy carbon working electrode and 0.1 M $Bu_4NClO_4$ as supporting electrolyte; all experiments employed an Ag/AgCl reference electrode and platinum auxiliary electrode. All electrochemical experiments were performed under argon at 298 K.

**Synthesis of $(Bu_4N)_2[Mo^{IV}O(mnt)Mo^{VI}(mnt)\{o$-aminobenzothiolato-(3–)-*N*,*S*$\}_2]$ (2):** $(Bu_4N)_2[Mo_2O_4(mnt)_2]$ (1020 mg, 1 mmol) was dissolved in 15 mL of dry acetonitrile and 2-aminothiophenol (2 mL, 2 mmol) was added dropwise with constant stirring, whereupon the color of the solution changed from yellow to bright green. The mixture was refluxed for 6–8 h, after which time the color of the solution had changed to dark green. The reaction mixture was cooled to room temperature. A microcrystalline product was isolated directly from this solution upon addition of 2-propanol and diethyl ether (840.0 mg 69%). The compound was recrystallized from acetonitrile, 2-propanol and diethyl ether. $C_{52}H_{80}Mo_2N_8OS_6$ (1217.54): calcd. C 51.53, H, 6.58, N 9.21, S, 15.78; found C 51.48, H 6.82, N 9.35, S 15.75. FT-IR (CsI): $\tilde{\nu}$ = 939 $cm^{-1}$ (vs, Mo=O). UV/Vis: $\lambda_{CH_2Cl_2}$ ($\varepsilon$) = 338 nm (22659 $M^{-1}cm^{-1}$), 439 (10819), 586 (3713), 645 (3796).

**Reaction of $(Bu_4N)_2[Mo_2O_4(mnt)_2]$ with $HSCH_2CH_2NH_2$:** $(Bu_4N)_2[Mo_2O_4(mnt)_2]$ (1020 mg, 1 mmol) was dissolved in 15 mL of dry acetonitrile then a solution of 2-aminoethanethiol (0.16 g, 2 mmol) in 5 mL of methanol was added with constant starring, whereupon the color of the solution changed from yellow to dark orange and finally to brownish green with precipitation of an orange solid. The reaction mixture was allowed to stand for a few hours to complete the precipitation and was then filtered. The filtrate was washed with 2-propanol and finally with diethyl ether and dried under vacuum (A; 408 mg, 46%). Addition of 2-propanol and diethyl ether to the filtrate resulted in the precipitation a dark-green crystalline product, which was washed with 2-propanol and diethyl ether and dried under vacuum (B; 134 mg, 48%).

**Analysis for A:** The analytical and spectrochemical data were identical to those for $[Bu_4N]_2[Mo^{IV}O(mnt)_2]$.[3c]

**Analysis for B:** The analytical and spectrochemical data were identical to those for $[Mo^{VI}O_2(SCH_2CH_2NH_2)]$.[14]

**X-ray Structure Determination:** Suitable crystals of $(Bu_4N)_2[Mo^{IV}O(mnt)Mo^{VI}(mnt)\{o$-aminobenzothiolato(3–)-*N*,*S*$\}_2]$ (**2**) were obtained from the crystallization procedures described in the synthesis. A single crystal of **2** was glued to a glass fiber and mounted on a Bruker Smart Apex diffractometer equipped with a CCD area detector and data were collected using graphite-monochromated Mo-$K_\alpha$ radiation ($\lambda$ = 0.71069 Å) at low temperature (100 K). An empirical absorption correction was applied using the SADABS program. Cell constants were obtained from the least-squares refinement of three-dimensional centroids by recording narrow $\omega$ rotation frames until completion of almost all reciprocal space in the stated $\theta$ range. The data were collected with SMART 5.628 (Bruker, 2003), and were integrated with the Bruker SAINT

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

program. A total of 20591 reflections were collected ($\theta$ = 1.91 to 28.41°), of which 14704 reflections were unique {$R_{int}$ = 0.0320 [$I > 2\sigma(I)$]}. The space group of this compound was determined based on the lack of systematic absences and intensity statistics. The structure was solved using SIR97[23] and refined using SHELXL-97[24] in the space group $P\bar{1}$. Full-matrix least-squares/difference Fourier cycles were performed to locate the remaining non-hydrogen atoms. All non-hydrogen atoms were refined with anisotropic displacement parameters. The final $R$ factor was 6.81% ($wR2$ = 13.30%). Some of carbon atoms of the butyl group of one of the tetrabutylammonium cation were found to be disordered over two positions and were refined with the free part instruction using SHELXL-97. The crystal structure was produced with ORTEP.[25] Selected crystallographic data parameters for **2** are listed in Table 6.

Table 6. Crystallographic data parameters of $(Bu_4N)_2[Mo^{IV}O(mnt)Mo^{VI}(mnt)\{o\text{-aminobenzothiolato}(3-)\text{-}N,S\}_2]$ (**2**).

CCDC-274974 (for **2**) contains the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Center via www.ccdc.cam.ac.uk/data_request/cif.

**Computational Details:** All calculations were performed with the Gaussian 03 package (revision B.04).[26] Molecular orbitals were visualized using Gauss View. Geometry optimizations, single point calculations, and population analysis of the molecular orbitals were carried out at the density functional theory (DFT) level with Becke's three-parameter hybrid exchange functional,[27] the non-local correlation provided by the Lee, Yang, and Parr expression, and the Vosko, Wilk, and Nuair 1980 correlation functional (III) local (B3LYP) 6-31g*+ basis set[28] were used for H, C, N, O, and S atoms. The LANL2DZ[29] basis set and LANL2 pseudo-potentials of Hay and Wadt[30] were used for the Mo atom. The initial geometry of the anions of **1** and **2** were taken from the crystal structure[6a] and each geometry was optimized without any symmetry constraints. The initial geometry of the $[S_2C_2(CN)_2]^{2-}$ ($mnt^{2-}$) was modeled using the same geometrical parameters as in the Mo complex. The optimized minima were characterized by harmonic vibration frequency calculations where minima have no imaginary frequency. For the medium effect, additional single-point energy calculations and time-dependent DFT (TD-DFT) calculations were carried out on the gas phase optimized geometries with the same method, same basis set, and the conductor like screening model[31] (COSMO). The solvent chosen was acetonitrile. The lowest 40 singlet excited states were considered for TD-DFT calculations.

**Supporting Information** (see also the footnote on the first page of this article): Table showing a comparison of selected bond lengths obtained from the crystal structure and gas-phase optimized geometry; experimental and computed UV/Vis absorption spectra; the HOMO and LUMO of $[S_2C_2(CN)_2]^{2-}$; a table containing low-energy excitation wavelengths and oscillator strengths (OS) for **1**, **2** and $[S_2C_2(CN)_2]^{2-}$; and EPR spectra.

# Benzylideneruthenium Complexes Bearing Pyridine-Based Ligands and Their Influence on the Formation of Mono- or Bis(pyridine) Complexes

**Wen-Zhen Zhang,[a] Ren He,*[a] and Rong Zhang[a]**

**Keywords:** Metathesis / Ruthenium / N ligands / Ligand effects / Homogeneous catalysis

Benzylideneruthenium complexes bearing the N-heterocyclic carbene (NHC) ligand 1,3-bis(2,6-dimethylphenyl)-4,5-dihydroimidazol-2-ylidene ($H_2$IMe) and one or two pyridine-based ligands have been prepared by treating [$RuCl_2$(=CHPh)($H_2$IMe)($PPh_3$)] with the corresponding pyridine derivative. X-ray crystallographic and mass spectrometric evidence is used to investigate the interconversion between mono- and bis(pyridine) complexes and the influence of the pyridine ligand on the formation of these complexes. The catalytic activity of these complexes has been tested in the ring-closing metathesis (RCM) reaction of diallylmalononitrile and the cross metathesis (CM) reaction of acrylonitrile with terminal olefins.

## Introduction

Alkylideneruthenium complexes, which exhibit remarkable air and water stability and significant functional-group tolerance, have been applied extensively as efficient metathesis catalysts in organic synthesis and polymer chemistry.[1] In particular, the second-generation Grubbs catalyst,[2] which contains a saturated NHC ligand instead of one of the $PCy_3$ ligands of the first-generation Grubbs catalyst,[3] exhibits a dramatically enhanced catalytic activity.[4] Further substitution of the $PCy_3$ ligand in the second-generation Grubbs catalyst with pyridine or 3-bromopyridine has resulted in the successful development of fast-initiating catalysts **I**[5] and **II**[6] (Figure 1). The alkylidene complex **IV**, analogous to complex **II**, is also a fast initiator of olefin metathesis.[7]

With regard to catalysts **I**–**IV**, bis(pyridine) complexes are considered to be formed preferentially to mono(pyridine) complexes. The solid-state structures of bis(pyridine) complexes **I** and **IV** have been confirmed by X-ray crystallography, although Grubbs has also observed that the mono(pyridine) complex [$RuCl_2$(=CHPh)($H_2$IMes)($C_5H_5N$)] can be formed by recrystallizing complex **I** and then drying it under vacuum. This implies that the six-coordinate bis(pyridine) complex **I** can easily lose pyridine under vacuum to give the five-coordinate mono(pyridine) complex.[5]

Five-coordinate benzylidenemono(pyridine)ruthenium complexes can be obtained exclusively under certain circumstances. Thus, the reaction of complex **I** with NaI affords the benzylidenediiodidoruthenium complex **V** with a single pyridine ligand rather than the corresponding bis(pyridine) complex, probably due to the relatively large size of the iodido ligands and the lower electrophilicity at the metal center.[5] Fogg has reported that modification of the anionic ligands of [$RuCl_2$(=CHPh)(IMes)($Py)_2$] with aryloxido ligands also results in a series of five-coordinate benzylidenemono(pyridine)ruthenium catalysts (**VII**–**XI**).[8] X-ray crystallographic analysis of complex **VII** clearly showed mono(pyridine) coordination, presumably because of steric hindrance.[8a] Similarly, Buchmeiser et al. have reported that treatment of [$RuCl_2$(=CHPh)($Mes_2$-THP)($PCy_3$)] ($Mes_2$-THP = 1,3-dimesityltetrahydropyrimidin-2-ylidene) with an excess of pyridine gives the mono(pyridine) complex **VI**, which they tentatively attributed to the increased donor capability and steric hindrance of the $Mes_2$-THP ligand compared to $H_2$IMes.[9] Accordingly, the steric and electronic properties of the NHC and anionic ligands around the metal center have a pronounced effect on the formation of mono- or bis(pyridine) complexes. The influence of the pyridine ligand on the formation of mono- or bis(pyridine) complexes has rarely been investigated, however.

Herein we describe the synthesis, X-ray crystallographic structures and mass spectrometric behavior of benzylideneruthenium complexes containing various pyridine ligands and the interconversion between mono- and bis(pyridine) complexes. These studies provide some insight into how the pyridine ligands influence the formation of mono- or bis(pyridine) complexes. Additionally, the catalytic ac-

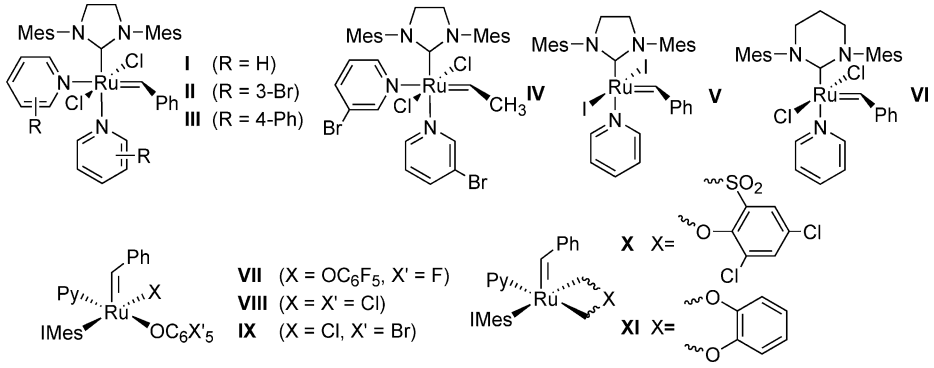

Figure 1. Benzylidenebis- and -mono(pyridine)ruthenium complexes used as metathesis catalysts (IMes = 1,3-dimesitylimidazol-2-ylidene; Mes = 2,4,6-trimethylphenyl).

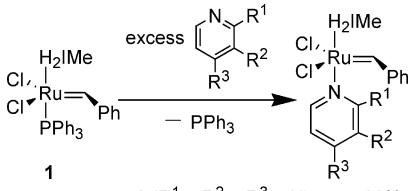
tivity of these complexes is tested in the ring-closing metathesis (RCM) reaction of diallylmalononitrile and the cross metathesis (CM) reaction of acrylonitrile with terminal olefins.

## Results and Discussion

### Synthesis and X-ray Crystallography

Benzylideneruthenium complexes **2**–**5** were prepared in good yield by treating $[RuCl_2(=CHPh)(H_2IMe)(PPh_3)]$ (**1**) [10] with the corresponding pyridine derivative according to the procedure described by Grubbs (Scheme 1).[5,6] Complex **1**, which bears a $PPh_3$ ligand instead of the $PCy_3$ ligand of the second-generation Grubbs catalyst, was used in this reaction because dissociation of the $PPh_3$ ligand in complex **1** proved to be easier than that of $PCy_3$ in the Grubbs catalyst.[11] Complex **2**, which contains a more labile ligand, was found to be unsuitable as a precursor for the synthesis of other complexes containing pyridine-based ligands because of the difficulty in separating the two complexes.



Scheme 1. Synthesis of mono(pyridine) complexes.

Complexes **2** and **3** are easily accessible, although the synthesis of complexes **4** and **5**, which contain an *ortho*-substituted pyridine ligand to weaken the coordination of the pyridine ligand to the ruthenium atom and accelerate initiation through steric hindrance, proved time-consuming and relatively difficult to perform. The reaction of complex **1** with 2,6-dimethylpyridine, quinoline, or 2-bromopyridine failed to yield the corresponding complexes, probably due to an excessive weakening of the coordinating ability of these pyridine-based ligands.

The $^1H$ NMR spectroscopic and mass spectrometric data of complexes **2**–**5** suggested that they are mono(pyridine) complexes. Complexes **2**, **4**, and **5** were investigated by X-ray crystallography to confirm their five-coordinate mono(pyridine) structure. Crystals suitable for X-ray analysis were obtained by slow diffusion of pentane into saturated chloroform/hexane (for complexes **2** and **5**) or dichloromethane/hexane (for complex **4**) solutions of the complexes. Crystals of complex **3** suitable for X-ray analysis could not be obtained. The crystal structures of complexes **2**, **4**, and **5** are shown in Figures 2, 3, and 4, respectively. Selected bond lengths and angles are summarized in Table 1, and crystal data and other details of the structure analysis are given in the Experimental Section.

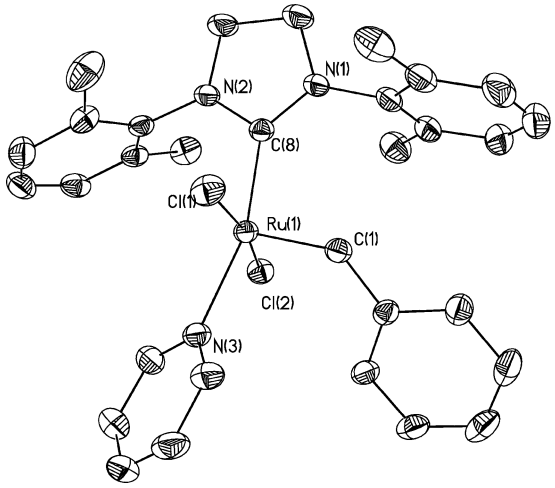


Figure 2. Molecular structure of **2** with thermal ellipsoids drawn at the 30% probability level. Hydrogen atoms have been omitted for clarity.

X-ray analysis confirmed that complexes **2**, **4**, and **5** are five-coordinate mono(pyridine) complexes. The coordination geometries of these complexes are distorted square pyramids with the two chlorido ligands and the pyridine and NHC ligands in a mutually *trans* arrangement and the apical positions occupied by the benzylidene ligands. The

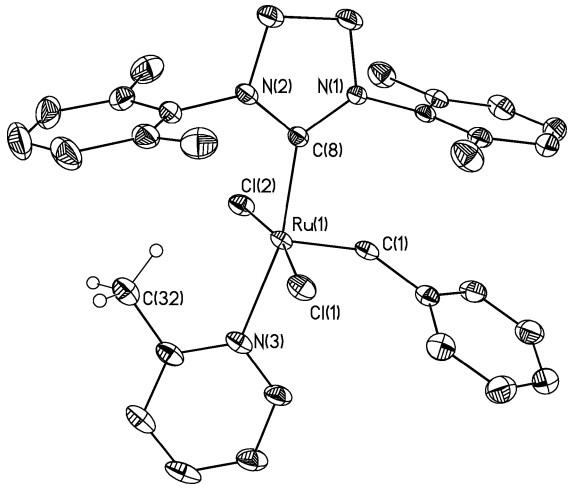

Figure 3. Molecular structure of **4** with thermal ellipsoids drawn at the 30% probability level. Most hydrogen atoms have been omitted for clarity.

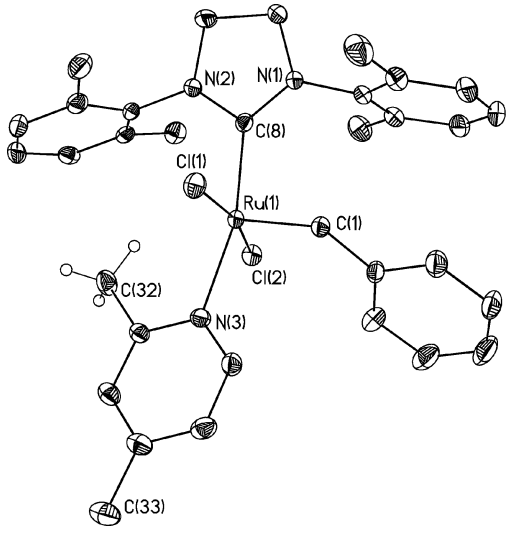

Figure 4. Molecular structure of **5** with thermal ellipsoids drawn at the 30% probability level. Most hydrogen atoms have been omitted for clarity.

Ru–N(3) bonds of **4** [2.165(3) Å] and **5** [2.160(3) Å] are longer than that of **2** [2.156(2) Å], which suggests a weaker interaction between the ruthenium atom and the pyridine ligands in complexes **4** and **5** due to the steric hindrance of the *ortho*-methyl group. The fact that the Ru–C(8) (N-heterocyclic carbene) bonds of **4** [2.042(3) Å] and **5** [2.043(3) Å] are longer than that of **2** [2.025(3) Å] is likely due to the relatively moderate *trans* effects of *ortho*-substituted pyridines, which also reflects the trend of the Ru–N(3) bond lengths. Complex **5** has slightly shorter Ru–N(3) and longer Ru–C(8) bond than complex **4**, which can be attributed to the electron-donating effect of the *para*-methyl group in the 2,4-dimethylpyridine ligand. The dihedral angles between the NHC ring and the pyridine ring of **4** (11.7°) and **5** (23.0°) are narrower than that of **2** (42.1°), and the C(8)–Ru–N(3) angles of **4** [165.45(14)°] and **5** [165.62(14)°] are slightly wider than that of **2** [163.82(10)°], both of which might be due to the steric demands of the *ortho*-methyl group in the pyridine ligand of complexes **4** and **5**. Accordingly, it can be concluded that the steric demand of the *ortho*-methyl group in the pyridine ligand plays a crucial role in the formation of five-coordinate mono(pyridine) complexes **4** and **5**.

Additionally, the ruthenium centers in complexes **4** and **5** do not appear to have the agostic interactions that are known to stabilize four-coordinate 14-electron ruthenium(II) complexes as the closest Ru···C [other than C(1) and C(8); 3.04 Å for **4** and 3.03 Å for **5**] and Ru···H distances (other than $H_{carbene}$; 2.37 Å for **4** and **5**) are all too long for an agostic interaction.[12]

## Interconversion between Mono- and Bis(pyridine) Complexes

As described by Grubbs, the bis(pyridine) complex **6** can also change into the mono(pyridine) complex **2** upon loss of one pyridine ligand under vacuum, and complex **2** can easily reconvert into complex **6** in the presence of an excess of pyridine (Scheme 2). For instance, a crystal of complex

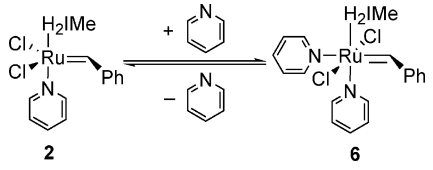
**6** suitable for X-ray analysis can be obtained by slow diffusion of pentane into a chloroform/hexane solution of complex **2** (10 mg) and pyridine (0.1 mL, approx. 75 equiv.). Figure 5 illustrates the molecular structure of complex **6**, and Table 1 summarizes selected bond lengths and angles. Crystal data and other details of the structure analysis are presented in the Experimental Section.



Scheme 2. Interconversion between mono(pyridine) complex **2** and bis(pyridine) complex **6**.

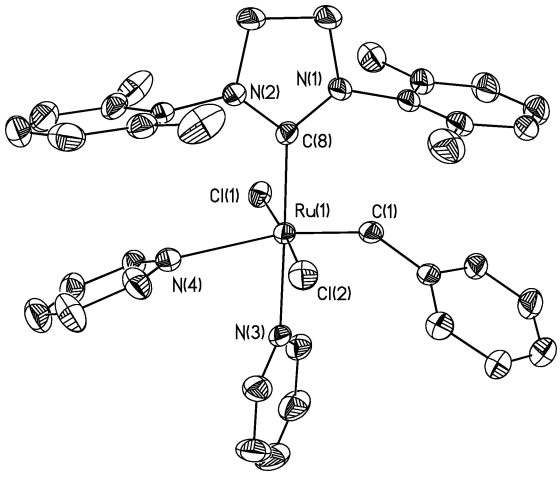


Figure 5. Molecular structure of **6** with thermal ellipsoids drawn at the 30% probability level. Hydrogen atoms have been omitted for clarity.

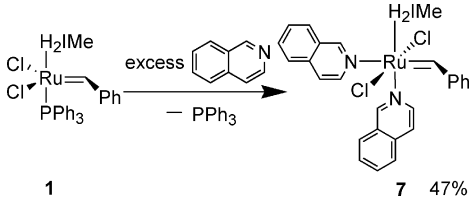
Complex **6** has a pseudo-octahedral geometry with the two chlorido ligands in a *trans* arrangement and two pyridine ligands in a mutually *cis* arrangement and *trans* to the NHC and the benzylidene ligand, respectively. The Ru–C, Ru–N, and Ru–Cl bonds in complex **6** are all longer than in complex **2**, presumably due to the increased steric demand and relatively lower electrophilicity at the metal center when another pyridine ligand is introduced *trans* to the benzylidene ligand. Similarly, the C(8)–Ru–N(3) and Cl(1)–Ru–Cl(2) angles are widened to 178.95(19)° and 175.74(6)°. The Ru–N(4) [2.367(5) Å] bond in complex **6** is 0.16 Å longer than Ru–N(3) [2.205(5) Å], which implies that the pyridine ligand *trans* to the benzylidene ligand is more likely to dissociate than the pyridine ligand *trans* to the NHC ligand. Removal of the pyridine ligand *trans* to the benzylidene ligand in bis(pyridine) complex **6** can therefore be easily carried out to form mono(pyridine) complex **2** under certain circumstances, for example under vacuum or in solution. The pyridine ligand in complex **2** is relatively difficult to remove because the Ru–N(3) interaction is strengthened, whereas the steric environment and relatively higher electrophilicity at the metal center allow for the association of one pyridine ligand at the coordination site *trans* to the benzylidene ligand.

Interestingly, treatment of complex **1** with an excess of isoquinoline gives the six-coordinate bis(isoquinoline) complex **7** even after drying the product under vacuum for 24 h (Scheme 3). Crystals of complex **7** suitable for X-ray analysis were obtained by slow diffusion of pentane into a saturated chloroform/hexane solution of the complex. As shown in Figure 6 and Table 1, the molecular structure of complex **7** is similar to that of complex **6**. The Ru–N(4) [2.359(4) Å] bond is 0.15 Å longer than Ru–N(3) [2.207(4) Å], which means that the isoquinoline ligand *trans* to the benzylidene ligand is more likely to dissociate than the isoquinoline ligand *trans* to the NHC ligand. The Ru–N(4) bond of **7** [2.359(4) Å] is shorter than that of **6** [2.367(5) Å], which suggests that the interaction between the ruthenium atom and the isoquinoline ligand *trans* to the benzylidene ligand in complex **7** is stronger than the interaction between the ruthenium atom and the pyridine ligand *trans* to the benzylidene ligand in complex **6**. Additionally, the saturated vapor tension of isoquinoline is lower than that of pyridine, which means that bis(isoquinoline) complex **7** cannot be converted into the corresponding five-coordinate mono(isoquinoline) complex under vacuum. However, this conversion can easily be carried out under other conditions, for example in solution.



Scheme 3. Synthesis of bis(isoquinoline) complex **7**.

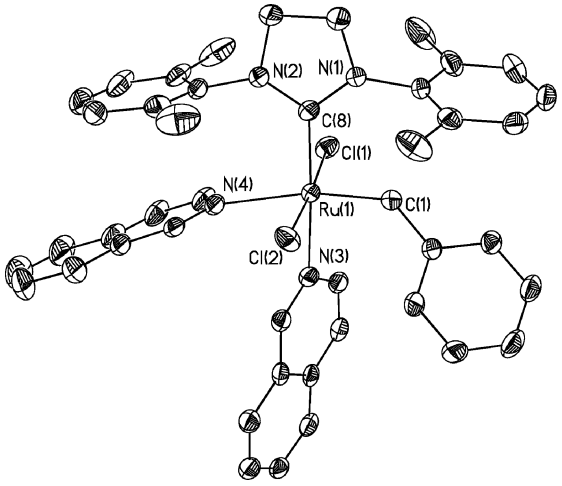


Figure 6. Molecular structure of **7** with thermal ellipsoids drawn at the 30% probability level. Hydrogen atoms have been omitted for clarity.

## Mass Spectrometric Study

Tandem mass spectrometry[13] can be performed when the complexes are delivered to the ionization source in

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

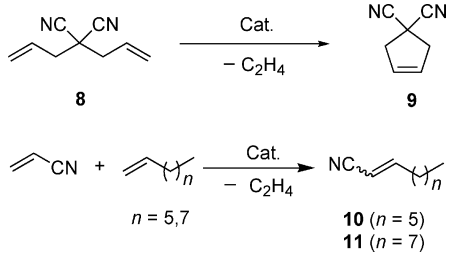
$CH_2Cl_2/CH_3CN$ solution and the collision cone voltages are changed sequentially. All mass spectra are available as Supporting Information. At collision cone voltages of 3 V the $[M - Cl + CH_3CN]^+$ cations are found as base peaks for complexes **2** and **3**, which indicates that the pyridine ligands are still bound to the metal center. However, the base peak for complex **4** is the $[M - Cl - py + 2\ CH_3CN]^+$ cation under the same conditions, which means that 2-methylpyridine has dissociated from the metal center and $CH_3CN$ has occupied the vacant coordination site. The different behaviors of these complexes show the different labilities of their ligands. Thus, the 2-methylpyridine ligand in complex **4** dissociates more easily than the pyridine ligands in complexes **2** and **3**. The dissociation of all pyridine ligands in complexes **2**–**4** was found to be easier than that of $PPh_3$ in complex **1**, which is consistent with the different initiation rates determined by NMR spectroscopy or UV/Vis kinetic studies.[6]

The mono(isoquinoline) species $[M - Cl - quinoline + CH_3CN]^+$ was found as the base peak for the bis(isoquinoline) complex **7** (collision cone voltage: 3 V), which suggests that one of the isoquinoline ligands in complex **7** is prone to dissociate under these conditions.

When complex **1** is delivered to the ionization source in $CH_2Cl_2$/pyridine solution, the bis(pyridine) species $[M - Cl - PPh_3 + 2\ pyridine]^+$ is detected, whereas, when complex **4** is delivered to the ionization source in $CH_2Cl_2$/2-methylpyridine/$CH_3CN$ solution, no bis(pyridine) species is found and the $[M - Cl + CH_3CN]^+$ cation is the base peak. This suggests that a bis(pyridine) complex can be formed in the presence of excess pyridine, whereas a bis(2-methylpyridine) complex cannot be formed even in the presence of an excess of 2-methylpyridine, probably due to steric hindrance from the *ortho*-methyl group.

### Metathesis Activity

The catalytic activities of complexes **2**–**5** and **7** were tested in the RCM reaction of diallylmalononitrile and the CM reaction of acrylonitrile with terminal olefins (Scheme 4).[14]



Scheme 4. RCM of diallylmalononitrile and CM of acrylonitrile with terminal olefins.

Studies by Grubbs have suggested that the catalyst efficiency during metathesis of cyano-containing olefin is related to dissociation rate of the ligands.[6] As shown in Tables 2 and 3, complex **4** has a higher catalytic activity than the other complexes as either dissociation of the sterically hindered 2-methylpyridine ligand is rapid and/or rebinding of it is slow.

Table 2. RCM reaction of diallylmalononitrile.[a]

| Catalyst | Cat. [mol-%] | Time [h] | Conversion [%][b] |
|---|---|---|---|
| **1** | 5 | 12 | 44 |
| **2** | 1 | 1 | 70 |
| **3** | 0.5 | 1 | 95 |
| **4** | 0.5 | <0.5 | 99 |
| **4** | 0.2 | 1 | 96 |
| **5** | 0.5 | 1 | 93 |
| **5** | 0.2 | 1 | 90 |
| **7** | 0.5 | 1 | 79 |

Table 3. CM reaction between acrylonitrile and α-olefins.[a]

| Catalyst | *n* | Yield [%][b] | *E*/*Z*[c] |
|---|---|---|---|
| **2** | 5 | 56 | 1:3.2 |
| **3** | 5 | 75 | 1:2.1 |
| **4** | 5 | 81 | 1:2.8 |
| **5** | 5 | 70 | 1:3.0 |
| **7** | 5 | 57 | 1:2.9 |
| **2** | 7 | 67 | 1:3.0 |
| **3** | 7 | 83 | 1:1.9 |
| **4** | 7 | 95 | 1:2.9 |
| **5** | 7 | 76 | 1:3.0 |
| **7** | 7 | 49 | 1:3.1 |

[a] 0.1 M acrylonitrile (1.0 equiv.) in $CH_2Cl_2$, α-olefin (2.0 equiv.), catalyst (2 mol-%), 40 °C, 12 h. [b] Yield of isolated product. [c] Ratios determined by $^1H$ NMR spectroscopy.

Addition of 10 equiv. of pyridine (relative to complex **2**) to the mixture of the RCM reaction of **8** catalyzed by complex **2** (Table 2) did not alter the conversion, which suggests that the catalytic activity of bis(pyridine) complex **6** is the same as that of mono(pyridine) complex **2**. The 16-electron mono(pyridine) complex **2** loses a pyridine ligand to form the 14-electron catalytically active intermediate, therefore the process whereby the 18-electron bis(pyridine) complex **6** converts into the 16-electron mono(pyridine) complex **2** must occur so fast that it can be neglected.

## Conclusions

Benzylideneruthenium complexes containing pyridine-based ligands have been prepared by treating complex **1** with various pyridine ligands. The steric demands of these pyridine ligands play a crucial role in the formation of mono- or bis(pyridine) complexes: *ortho*-substituted pyridine ligands form five-coordinate mono(pyridine) complexes whereas pyridine ligands without *ortho* substituents form both six-coordinate bis(pyridine) complexes and five-coordinate mono(pyridine) complexes. The bis- and mono(pyridine) complexes can interconvert under certain circumstances by loss or association of the pyridine ligand *trans* to the benzylidene ligand. This interconversion has very little effect on the catalytic activities of these complexes. The *ortho* substituents of the pyridine ligands can weaken the

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

interaction between the ruthenium center and the ligands due to steric hindrance and therefore accelerate the dissociation of these ligands, which enhances the initiation of the catalysts. Complex **4**, which bears a 2-methylpyridine ligand, exhibits the highest catalytic activity for the RCM reaction of diallylmalononitrile and the CM reaction of acrylonitrile with terminal olefins, of complexes **2**–**5** and **7**.

## Experimental Section

**General Procedures:** Oxygen- and/or moisture-sensitive materials were manipulated using standard Schlenk techniques under dry nitrogen. NMR spectra were recorded with a Varian Inova instrument (400 MHz for $^1$H, 160 MHz for $^{31}$P, 100 MHz for $^{13}$C). High-resolution mass spectra were recorded with a Q-TOF mass spectrometer (Micromass, England) equipped with a Z-spray ionization source. GC analyses were performed with a Hewlett–Packard HP 6890 equipped with an FID and an HP-5 column. Pyridine, 3-bromopyridine, 2-methylpyridine, 2,4-dimethylpyridine, and acrylonitrile were freshly distilled before use. Ruthenium complex **1**[9] and diallylmalononitrile[15] were prepared according to literature procedures. Dichloromethane was dried with $CaH_2$, distilled, and stored under nitrogen, whereas thf, toluene, and hexane were dried and distilled from Na/benzophenone. All other reagents were of analytical grade, were purchased commercially, and used as received, unless noted otherwise.

**[$RuCl_2$(=CHPh)($H_2$IMe)($C_5H_5N$)] (2):** Pyridine (10.0 mL, 0.124 mol) was added to complex **1** (1.10 g, 1.37 mmol) in a 150-mL Schlenk flask; no additional solvent was required. The reaction mixture was stirred at room temperature for 10 min, during which time a color change from red-brown to green was observed. Hexane (120 mL) was then added at room temperature and a green solid precipitated. This precipitate was filtered, washed four times with 10 mL of hexane, and dried in vacuo for 6 h to afford **2** as a green powder (0.79 g, 93% yield). $^1$H NMR (400 MHz, $CDCl_3$): $\delta$ = 19.12 (s, 1 H, Ru=C*H*Ph), 8.64 (br. s, 2 H, pyridine), 7.79–6.93 (multiple peaks, 14 H, pyridine, *ortho* C*H*, *para* C*H*, *meta* C*H*, 2,6-dimethylphenyl aromatic C*H*), 4.13 (s, 4 H, NC$H_2$C$H_2$N), 2.67 (br. s, 6 H, *ortho* C$H_3$), 2.32 (br. s, 6 H, *ortho* C$H_3$) ppm. $^{13}$C NMR ($CDCl_3$, 100 MHz): $\delta$ = 307.32 (m, Ru=*C*HPh), 220.41 [s, Ru–*C*(N)$_2$], 152.23, 150.44, 136.70, 136.08, 130.64, 130.29, 129.65, 129.04, 128.41, 128.13, 124.04, 123.80, 48.32, 22.85, 18.69 ppm.

**[$RuCl_2$(=CHPh)($H_2$IMe)(3-Br-$C_5H_4N$)] (3):** 3-Bromopyridine (6.0 mL, 62.1 mmol) was added to complex **1** (1.90 g, 2.37 mmol) in a 150-mL Schlenk flask; no additional solvent was required. The reaction mixture was stirred at room temperature for 20 min, during which time a color change from red-brown to green was observed. Hexane (120 mL) was then added at room temperature and a green solid precipitated. The flask was sealed under nitrogen and allowed to stand at 0 °C overnight. The green precipitate was then filtered, washed four times with 10 mL of hexane, and dried in vacuo for 6 h to afford **3** as a green powder (1.53 g, 92% yield). $^1$H NMR (400 MHz, $CDCl_3$): $\delta$ = 19.05 (s, 1 H, Ru=C*H*Ph), 8.74 (br. s, 1 H, pyridine), 8.59 (br. s, 1 H, pyridine), 7.90–7.04 (multiple peaks, 13 H, pyridine, *ortho* C*H*, *para* C*H*, *meta* C*H*, 2,6-dimethylphenyl aromatic C*H*), 4.13 (s, 4 H, NC$H_2$C$H_2$N), 2.63 (br. s, 6 H, *ortho* C$H_3$), 2.36 (br. s, 6 H, *ortho* C$H_3$) ppm. $^{13}$C NMR ($CDCl_3$, 100 MHz): $\delta$ = 316.34 (m, Ru=*C*HPh), 216.63 [s, Ru–*C*(N)$_2$], 152.73, 151.48, 148.13, 138.80, 134.57, 132.23, 132.13, 130.33, 130.26, 128.85, 128.09, 127.04, 124.57, 120.78, 51.46, 20.58, 18.93 ppm. $C_{31}H_{32}BrCl_2N_3Ru$ (698.5): calcd. C 53.31, H 4.62, N 6.02; found C 53.12, H 4.59, N 6.07.

**[$RuCl_2$(=CHPh)($H_2$IMe)(2-Me-$C_5H_4N$)] (4):** 2-Methylpyridine (6.0 mL, 60.8 mmol) was added to complex **1** (0.50 g, 0.62 mmol) in a 150-mL Schlenk flask; no additional solvent was required. The reaction mixture was stirred at room temperature for 12 h, during which time a color change from red-brown to green was observed. Hexane (100 mL) was then added at room temperature and a green solid precipitated. The flask was sealed under nitrogen and allowed to stand at 0 °C overnight. The green precipitate was then filtered, washed four times with 10 mL of hexane, and dried in vacuo for 6 h to afford **4** as a green powder (0.33 g, 84% yield). $^1$H NMR (400 MHz, $CDCl_3$): $\delta$ = 19.64 (s, 1 H, Ru=C*H*Ph), 8.49 (br. s, 1 H, pyridine), 8.01 (br. s, 1 H, pyridine), 7.57–7.02 (multiple peaks, 7 H, pyridine, *ortho* C*H*, *para* C*H*, *meta* C*H*), 6.82 (br. s, 4 H, 2,6-dimethylphenyl aromatic C*H*), 6.55 (br. s, 2 H, 2,6-dimethylphenyl aromatic C*H*), 4.16 (s, 2 H, NC$H_2$C$H_2$N), 3.95 (s, 2 H, NC$H_2$C$H_2$N), 2.76 (br. s, 9 H, pyridine C$H_3$, *ortho* C$H_3$), 2.25 (s, 6 H, *ortho* C$H_3$) ppm. $^{13}$C NMR ($CDCl_3$, 100 MHz): $\delta$ = 312.64 (m, Ru=*C*HPh), 218.09 [s, Ru–*C*(N)$_2$], 159.53, 151.74, 151.34, 140.53, 139.08, 137.94, 137.75, 137.28, 136.59, 130.91, 130.33, 129.35, 128.99, 128.76, 128.67, 128.33, 128.04, 127.80, 127.62, 126.49, 125.17, 121.32, 120.93, 51.76, 50.85, 31.58, 20.34, 18.41 ppm.

**[$RuCl_2$(=CHPh)($H_2$IMe)(2,4-$Me_2$-$C_5H_3N$)] (5):** 2,4-Dimethylpyridine (2.0 mL, 17.2 mmol) was added to complex **1** (0.14 g, 0.17 mmol) in a 150-mL Schlenk flask; no additional solvent was required. The reaction mixture was stirred at room temperature for 2 h, during which time a color change from red-brown to green was observed. Hexane (100 mL) was then added at room temperature and a green solid precipitated. The green precipitate was filtered, washed four times with 10 mL of hexane, and dried in vacuo for 6 h to afford **5** as a green powder (0.10 g, 89% yield). $^1$H NMR (400 MHz, $CDCl_3$): $\delta$ = 19.61 (s, 1 H, Ru=C*H*Ph), 7.99 (br. s, 1 H, pyridine), 7.57–6.38 (multiple peaks, 13 H, pyridine, *ortho* C*H*, *para* C*H*, *meta* C*H*, 2,6-dimethylphenyl aromatic C*H*), 4.16 (s, 2 H, NC$H_2$C$H_2$N), 3.95 (s, 2 H, NC$H_2$C$H_2$N), 2.75 (br. s, 9 H, pyridine C$H_3$, *ortho* C$H_3$), 2.24 (s, 6 H, *ortho* C$H_3$), 2.12 (s, 3 H, pyridine C$H_3$) ppm. $^{13}$C NMR ($CDCl_3$, 100 MHz): $\delta$ = 312.49 (m, Ru=*C*HPh), 218.38 [s, Ru–*C*(N)$_2$], 158.75, 151.24, 148.08, 140.46, 139.07, 137.86, 130.80, 130.15, 129.23, 128.89, 128.69, 128.53, 128.20, 126.01, 122.41, 51.63, 50.71, 31.51, 21.48, 20.45, 18.34 ppm.

**[$RuCl_2$(=CHPh)($H_2$IMe)($C_9H_7N$)$_2$] (7):** Isoquinoline (1.0 mL, 8.4 mmol) was added to complex **1** (0.30 g, 0.37 mmol) in a 150-mL Schlenk flask, then 5 mL of toluene was added as solvent. The reaction mixture was stirred at room temperature for 1 h, during which time a color change from red-brown to green was observed. Hexane (100 mL) was then added at room temperature and a green solid precipitated. The green precipitate was filtered, washed four times with 10 mL of hexane and dried in vacuo for 6 h to afford **7** as a green powder (0.14 g, 47% yield). $^1$H NMR (400 MHz, $CDCl_3$): $\delta$ = 19.18 (s, 1 H, Ru=C*H*Ph), 9.32 (s, 1 H, isoquinoline), 8.92 (s, 1 H, isoquinoline), 8.59 (s, 1 H, isoquinoline), 8.50 (s, 1 H, isoquinoline), 8.16–6.99 (multiple peaks, 21 H, isoquinoline, *ortho* C*H*, *para* C*H*, *meta* C*H*, 2,6-dimethylphenyl aromatic C*H*), 4.14 (s, 4 H, NC$H_2$C$H_2$N), 2.63 (br. s, 6 H, *ortho* C$H_3$), 2.35 (s, 6 H, *ortho* C$H_3$) ppm. $^{13}$C NMR ($CDCl_3$, 100 MHz): $\delta$ = 314.44 (m, Ru=*C*HPh), 218.31 [s, Ru–*C*(N)$_2$], 155.17, 152.80, 151.31, 150.52, 148.40, 144.56, 143.12, 138.17, 136.16, 135.73, 135.40, 131.45, 130.31, 130.13, 129.56, 128.94, 128.04, 127.90, 127.41, 127.22, 126.64, 126.46, 126.17, 121.18, 120.91, 120.40, 51.80, 20.45, 18.82 ppm.

**X-ray Crystallographic Studies:** Crystals suitable for X-ray diffraction were mounted on glass fibers. Data collection was performed

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

with a Bruker Smart APEX CCD diffractometer using graphite-monochromated Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 Å) at 273 K (for complex **2**) or 180 K. The diffraction frames were integrated using the SAINT package. The structures were solved by direct methods using the program SHELXS-97. Structure refinements by full-matrix least squares on $F^2$ were carried out with the program SHELXL-97. All non-hydrogen atoms of the complexes were assigned anisotropic displacement parameters. The hydrogen atoms were constrained to idealized geometries and assigned isotropic displacement parameters equal to 1.2-times the $U_{iso}$ values of their respective parent atoms. Crystal data and other details of the structure analyses are presented in Table 4. CCDC-635304 (**2**), -645279 (**6**), -642416 (**4**), -642417 (**5**), and -642415 (**7**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Center via www.ccdc.cam.ac.uk/data_request/cif.

**Tandem Mass Spectrometry:** The samples were delivered to the ionization source in $CH_2Cl_2$/$CH_3CN$ solution. The complexes were dissociated by collision-induced dissociation (CID) in the collision cell of a Micromass Q-Tof with a capillary voltage of 2300 V, an extraction cone voltage of 2 V, and a sample cone voltage of 10 V. The desolvation temperature was set to 190 °C and the source temperature to 100 °C. Nitrogen was used as both drying and nebulizing gas with flow rates of 450 and 50 L h$^{-1}$, respectively. The CID spectra were obtained by selecting the precursor ion of interest with the quadrupole and then collision with argon gas in the CID cell and finally mass analysis by Tof. The collision-cell pressure was maintained at 6 psi. Fragment ions were obtained upon adjusting the collision cone voltage of the mass spectrometer to higher values (for example 19 V).

**General Procedure for Ring-Closing Metathesis:** In a typical experiment, catalyst **4** (2.5 mg, 3.9 μmol) and diallylmalononitrile (117 mg, 0.8 mmol) were weighed into a dried, two-necked flask equipped with a reflux condenser, and 8 mL of solvent was then added. The resulting mixture was then stirred under the conditions given in Table 2. After completion of the reaction, the mixture was filtered through a short pad of silica gel and the solvent removed in vacuo. Conversion was measured by GC-FID and confirmed by NMR spectroscopy. Compound **8**: $^1$H NMR (400 MHz, $CDCl_3$): $\delta$ = 5.90 (ddt, $J$ = 7.2, 10.4, 16.8 Hz, 2 H, $CH_2$=C*H*$CH_2$), 5.45 [dd, $J$ = 0.8, 10.4 Hz, 2 H, (*Z*) C$H_2$=CH$CH_2$], 5.41 [dd, $J$ = 0.8, 16.8 Hz, 2 H, (*E*) C$H_2$=CH$CH_2$], 2.69 (d, $J$ = 7.2 Hz, 4 H, $CH_2$=CHC$H_2$) ppm. HRMS (EI): calcd. for $C_9H_{10}N_2$ [M]$^+$ 146.0844; found 146.0851. Compound **9**: $^1$H NMR (400 MHz, $CDCl_3$): $\delta$ = 5.81 (s, 2 H, $CH_2$C*H*=C*H*$CH_2$), 3.22 (s, 4 H, C$H_2$CH=CHC$H_2$) ppm. HRMS (EI): calcd. for $C_7H_6N_2$ [M]$^+$ 118.0531; found 118.0532.

**General Procedure for the Cross Metathesis Reaction of Acrylonitrile with α-Olefins:** In a typical experiment, catalyst **4** (16.4 mg, 25.9 μmol) was weighed into a dried, two-necked flask equipped with a reflux condenser, then 1-octene (290 mg, 2.6 mmol) and acrylonitrile (67 mg, 1.3 mmol) in $CH_2Cl_2$ (13 mL) were added. The resulting mixture was then stirred under the conditions listed in Table 3. After completion of the reaction, the mixture was filtered through a short pad of silica gel and the solvent removed in vacuo. The crude mixture was purified by chromatography on silica gel to yield the product (140 mg, 81%); the (*E*)/(*Z*) ratio was determined by $^1$H NMR spectroscopy to be 1:2.8. Compound **10**: $^1$H NMR (400 MHz, $CDCl_3$): $\delta$ = 6.69 [dt, $J$ = 6.8, 16.4 Hz, 1 H, (*E*) $CH_2$C*H*=CHCN], 6.47 [dt, $J$ = 7.6, 10.8 Hz, 1 H, (*Z*) $CH_2$C*H*=CHCN], 5.30 [d, $J$ = 16.4 Hz, 1 H, (*E*) $CH_2$CH=C*H*CN], 5.28 [d, $J$ = 10.8 Hz, 1 H, (*Z*) $CH_2$CH=C*H*CN], 2.39 [q, $J$ = 7.6 Hz, 2 H, (*Z*) C$H_2$CH=CHCN], 2.19 [q, $J$ = 6.8 Hz, 2 H, (*E*) C$H_2$CH=CHCN], 1.26–1.31 (m, 8 H), 0.86 (t, $J$ = 6.8 Hz, 3 H) ppm. Compound **11**: $^1$H NMR (400 MHz, $CDCl_3$): $\delta$ = 6.71 [dt, $J$ = 6.8, 16.4 Hz, 1 H, (*E*) $CH_2$C*H*=CHCN], 6.49 [dt, $J$ = 7.6,

# Synthesis, Crystal Structures and Thermal Properties of New $ZnBr_2$(pyrimidine) Coordination Compounds

**Christian Näther,*[a] Gaurav Bhosekar,[a] and Inke Jeß[a]**

**Keywords:** Coordination compounds / Synthesis / Crystal structure / Thermal reactivity

Four new bromidozinc(II) coordination compounds with pyrimidine as a ligand were prepared, either in solution or by thermal decomposition reactions, and the thermal reactivity and thermodynamic stability of these compounds were investigated. These results are compared with those for the corresponding $ZnI_2$(pyrimidine) compounds. The ligand-rich 1:2 compound dibromidobis(pyrimidine-*N*)zinc(II) (**I**) crystallizes in the monoclinic space group $P2_1/n$. In this structure the zinc atoms are coordinated by two bromido ligands and two pyrimidine ligands within distorted tetrahedra. On heating, compound **I** is transformed into the ligand-deficient 2:3 intermediate bis(dibromido)bis(pyrimidine-*N*)($\mu_2$-pyrimidine-*N*,*N*′)dizinc(II) (**II**), which crystallizes in the monoclinic space group *C*2/*c*. The crystal structure consists of two $ZnBr_2$(pyrimidine) subunits, which are connected by an additional pyrimidine ligand through μ-*N*,*N*′ coordination. Thermal decomposition of compound **II** leads to the formation of the ligand-deficient 1:1 compound dibromido($\mu_2$-pyrimidine-*N*,*N*′)zinc(II) (**III**), which crystallizes in the orthorhombic space group *Pmma*. In compound **III**, the zinc atoms are coordinated by four bromine atoms and two pyrimidine ligands within distorted octahedra. The $ZnBr_2$ units are connected through common edges into chains, which are linked by the pyrimidine ligands into layers. On heating, compound **III** is transformed into the ligand-deficient 2:1 compound $(ZnBr_2)_2$(pyrimidine) (**IV**), which decomposes to give $ZnBr_2$. Solvent-mediated conversion experiments in solution show that not all of the compounds can be prepared by treating $ZnBr_2$ and pyrimidine in the molar ratio given by the formula of the final product.

## Introduction

Investigations on coordination polymers, inorganic–organic hybrid compounds and metal–organic frameworks are attracting increasing interest[1] because of the potential applications of these systems as electric, magnetic, optical or porous materials.[2] Most of these compounds are normally prepared in solution, where different stable and metastable species exist in equilibrium. In view of this, mixtures of compounds are often obtained during the synthesis, and some specific target compounds cannot be prepared at all. Recently we have demonstrated that thermal decomposition of ligand-rich precursor materials is a suitable alternative method for the convenient synthesis of new coordination compounds.[3] In this method, ligand-rich precursors are heated, leading to ligand-deficient coordination compounds by stepwise liberation of the ligands. One advantage of this method is that the equilibrium is shifted irreversibly in the direction of the ligand-deficient coordination compounds, and thus new compounds which are metastable or unstable in solution can be discovered and prepared as phase-pure solids.

Recently we have reported on new iodidozinc(II) coordination compounds with pyrimidine as a ligand.[4] Altogether, seven different compounds were obtained, including three polymorphic modifications (Figure 1). The ligand-rich 1:2 compound **1** decomposes in several steps, in which ligand-deficient compounds **2**, **3** and **4** [2:3 (**2**), 1:1 (**3**) and 2:1 (**4**)] are formed as intermediates. Detailed analysis of the crystal structures of these compounds clearly indicates a strong correlation between the crystal structures of the reactants and the products for the first two thermal reactions. Slight changes in the reaction conditions lead to the formation of a further 1:1 compound of composition $[ZnI_2(pyrimidine)]_4(acetonitrile)_{0.25}$ (**5**). On heating, compound **5** loses acetonitrile and decomposes to give a new 1:1 polymorphic modification **6**. Compound **6** undergoes a polymorphic phase transition to yield the new compound **7**, which is finally transformed into the 1:1 compound **3**. Solvent-mediated conversion experiments clearly show that compound **3** represents the thermodynamically most stable form at room temperature, whereas **5**, **6** and **7** are metastable. Our results clearly show that different stable and metastable species are in equilibrium and that product formation in such thermal decomposition reactions depends on the actual structure of the ligand-rich precursor compound.

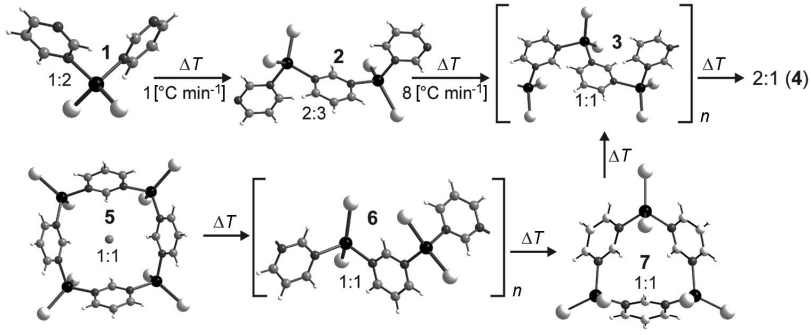

Figure 1. Schematic presentation of the thermal reactions of $ZnI_2$(pyrimidine) coordination compounds.[4]

In order to gain more insight into such reactions, we have investigated the corresponding compounds with $ZnBr_2$ and pyrimidine. Here we report on the results of these investigations.

## Results and Discussion

### Crystal Structures

The ligand-rich 1:2 compound **I** crystallizes in the monoclinic space group $P2_1/n$ with four formula units in the unit cell and all atoms in general positions. The crystal structure of **I** is isomorphous to $ZnI_2$(pyrimidine)$_2$.[4] In the crystal structure, there are discrete complexes, in which the zinc atoms are coordinated by two bromine atoms and two nitrogen atoms of the pyrimidine ligands within distorted tetrahedra (Figure 2: top and Table 1). The pyrimidine ligands of adjacent complexes are stacked in the direction of the crystallographic *a* axis, which indicates π–π interactions (Figure 2: bottom).

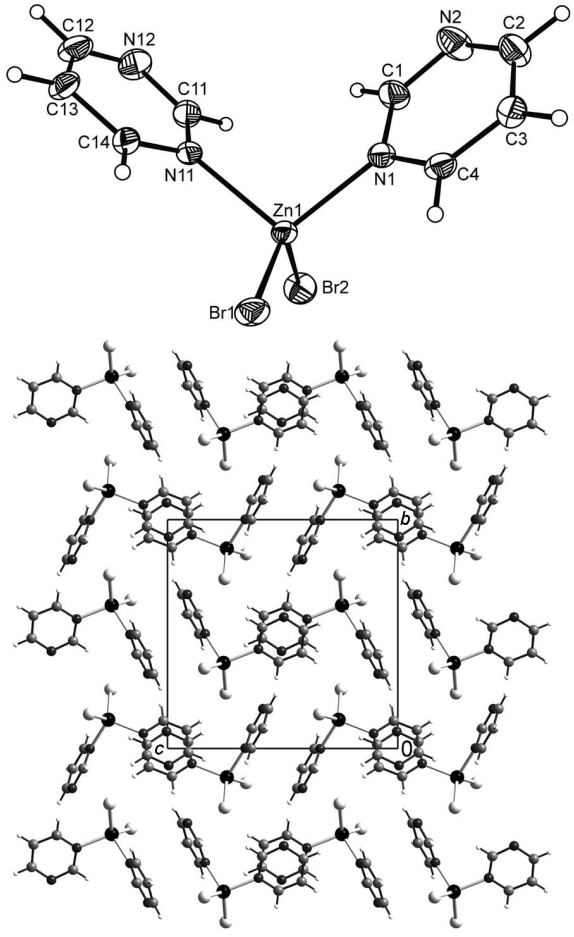

Figure 2. Crystal structure of compound **I** with a view of the coordination sphere of the zinc cations with labelling and displacement ellipsoids drawn at the 50% probability level (top) and a view of the crystal structure in the direction of the crystallographic *a* axis (bottom).

The ligand-deficient 2:3 intermediate **II** crystallizes in the monoclinic space group $C2/c$ with eight formula units in the unit cell. This compound is isomorphous to $(ZnI_2)_2$(pyrimidine)$_3$.[4] In the crystal structure discrete $[(ZnBr_2)_2$(pyrimidine)$_3]$ units are found, which are located in special positions (Figure 3: top). Each zinc atom is coordinated by two bromine atoms and two nitrogen atoms, one on a terminal and one on a bridging pyrimidine ligand (Figure 3: top and Table 1). The zinc atoms are bridged by a pyrimidine ligand with μ-*N*,*N*′ coordination. The terminal pyrimidine rings are stacked in the direction of the crystallographic *b* axis, indicating π–π interactions (Figure 3: bottom).

The ligand-deficient 1:1 compound **III** crystallizes in the orthorhombic space group *Pmma* with two formula units in the unit cell. The zinc and the bromine atoms as well as the pyrimidine ligands are located on crystallographic mirror planes. This compound is not isomorphous to the corresponding iodido analogue $ZnI_2$(pyrimidine).[4] In this structure the zinc atoms are coordinated by four bromine atoms and two nitrogen atoms of pyrimidine ligands within slightly distorted octahedra (Figure 4: top and Table 1). The zinc atoms are connected by the pyrimidine ligands into zigzag chains, which elongate in the direction of the crystallographic *a* axis (Figure 4: middle). The zinc octahedra are additionally connected through common Br edges into corrugated layers, which are located in the *ab* plane (Figure 4: bottom).

## Thermoanalytical Investigations

Five mass steps are observed for compound **1** on heating, of which the first four steps are accompanied by endothermic events in the DTA curve (Figure 5). From the MS trend scan curve it is evident that only pyrimidine ligands ($m/z$ = 80) are liberated in the first four steps and the DTG curve shows that not all of the steps are well resolved. The experimental mass loss in each of the first four TG steps is in good agreement with that calculated for the removal of half of the pyrimidine ligands in each step ($\Delta m_{theo}$ –1/2 pyrimidine = –10.4%) (Figure 5). Thus, it can be inferred that in these steps a ligand-deficient 2:3, 1:1 and 2:1 compound is formed, which finally decomposes to give $ZnBr_2$, which vaporizes on further heating.

In order to determine the nature of the thermal decomposition products, additional thermogravimetric measurements were performed in which the heating was stopped after each step. The residues thus obtained were investigated by X-ray powder diffraction (Figure 6) and elemental analysis; the results are presented in the Experimental Section.

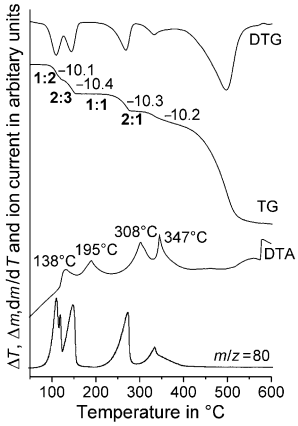

Figure 5. DTA, TG, DTG and MS trend scan curves for compound **I** [heating rate: 4 °C min$^{-1}$; $m/z$ = 80 (pyrimidine)]; given are the mass changes [%] and the peak temperatures $T_p$ [°C].

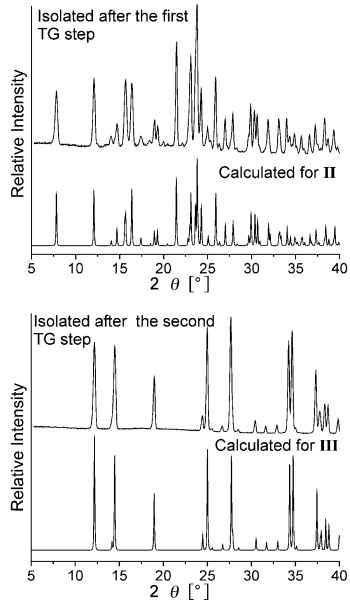

Figure 6. Experimental X-ray powder diffraction pattern of the residue obtained after the first (top) and second (bottom) TG step in the thermal decomposition of the ligand-rich 1:2 compound **I**, accompanied by the calculated X-ray powder diffraction patterns for compounds **II** and **III**.

The experimental X-ray powder diffraction patterns of the residues formed in the first and second TG steps are in excellent agreement with those calculated for compounds **II** and **III**, clearly indicating that in the first TG step the ligand-deficient 2:3 intermediate **II** is formed, and then it is transformed into the ligand-deficient 1:1 compound **III** on further heating (Figure 5 and Figure 6). In addition, the results of an elemental analysis of the residues agrees with the expected results for a 2:3 and 1:1 compound (Experimental Section). These results show that both compounds are obtained as phase-pure solids even though the first TG step is not well resolved. It is interesting to note that the powder pattern of the residue formed in the third step matches well with that of the pattern of a solid obtained by stirring a crystalline suspension of $ZnBr_2$ and pyrimidine in *n*-hexane for several days. This result indicates that the ligand-deficient compound **IV** can also be prepared in solution.

The elemental analysis of the residue formed in the third TG step corresponds to a new compound of 2:1 stoichiometry of composition $(ZnBr_2)_2$(pyrimidine) (**IV**). As expected, the experimental X-ray powder diffraction pattern of this compound is completely different from that calculated for compounds **II** and **III** and for $ZnBr_2$ (Figure 7).

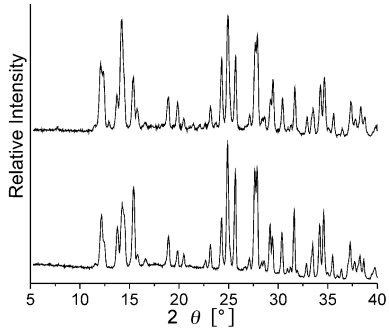

Figure 7. Experimental X-ray powder diffraction pattern of the residue obtained after the third TG step during the thermal decomposition of the ligand-rich 1:2 compound **I** (top) and the experimental X-ray powder diffraction pattern for compound **IV** obtained from solution (bottom).

## Investigations on the Stability of the Compounds in Solution and in the Solid State

The stability of compounds **I**, **II** and **III** as solids was investigated by time-dependent X-ray powder diffraction. These investigations show that compounds **II** and **III** are stable over several days, whereas the ligand-rich 1:2 compound **I** decomposes even at room temperature within a few days to give compound **III**.

The stability of these compounds was further investigated in solution by solvent-mediated conversion experiments. In these experiments the metal salt and ligand are mixed in different stoichiometric ratios by using acetonitrile as a solvent. These crystalline suspensions were stirred for a week in order to obtain the thermodynamically most stable form. Afterwards the products were investigated by X-ray powder diffraction (Table 2). These experiments clearly showed that all compounds are stable and can also be prepared in solution. However, it is to be noted that not all of these compounds can be prepared simply by mixing the reactants stoichiometrically as given by the formula. Thus, the reaction of $ZnBr_2$ and pyrimidine in 2:3 mol ratio results in the formation of the 1:1 compound **III**, whereas

Table 2. Result of the crystallization experiments in different solvents as a function of the molar ratio between metal and ligand (pyrimidine).

| $ZnBr_2$/Ligand | 1:4 | 1:3 | 1:2 | 2:3 | 1:1 | 2:1 |
|---|---|---|---|---|---|---|
| Compound | **I** (1:2) | | **II** (2:3) | **III** (1:1) | | **IV**(2:1) |

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

the reaction in a 1:2 mol ratio leads to the formation of the 2:3 compound **II** (Table 2). This indicates that for the preparation of the ligand-rich compounds, an excess of the ligand must always be used. The ligand-deficient compound **IV** is difficult to prepare, because in many cases it is contaminated with compound **III** or $ZnBr_2$ (Table 2).

### Comparison of $ZnX_2$(pyrimidine) Coordination Compounds (X = Cl, I)

As mentioned earlier, for the corresponding coordination compounds with $ZnI_2$ a variety of compounds and polymorphic modifications were found.[4] The different polymorphic modifications were detected when the pseudopolymorphic 1:1 compound $[ZnI_2(pyrimidine)]_4(acetonitrile)_{0.25}$ was decomposed, which was prepared by fast precipitation under kinetic control from a solution of $ZnI_2$ and pyrimidine in acetonitrile by adding an antisolvent in which the compound is insoluble. In view of this observation, several attempts were made to prepare the corresponding acetonitrile solvate of the bromide compound. However, this always resulted in the formation of the ligand-deficient 1:1 compound **III**. From $ZnI_2$ and pyrimidine, two metastable polymorphic modifications of the 1:1 compound could also be prepared by performing the crystallization under kinetic control.[4] Similar attempts to prepare such forms of the bromide compound by nucleation-controlled crystallization[5] did not result in any polymorphic modifications. It must also be noted that the reaction of $ZnCl_2$ with pyrimidine leads only to one compound of composition $ZnCl_2$(pyrimidine),[6] which shows that the number of possible compounds in the $ZnX_2$(pyrimidine) [X = I, Br, Cl] system decreases from iodine to chlorine.

Differences between the $ZnI_2$ and $ZnBr_2$ coordination compounds are also found in the thermal reactivity of the ligand-rich 1:2 compounds, which are isotypic. On slow heating $ZnI_2(pyrimidine)_2$ (**1**) is transformed directly into the ligand-deficient 1:1 compound $ZnI_2$(pyrimidine) (**3**), without the formation of the ligand-deficient 2:3 intermediate **2**. Compound **2** can only be obtained by thermal decomposition if fast heating rates are used, which shows that kinetics plays an important role in product formation. In contrast, thermal decomposition of $ZnBr_2(pyrimidine)_2$ (**I**) leads directly to the formation of the 2:3 compound $(ZnBr_2)_2(pyrimidine)_3$, regardless of the actual heating rate.

In this context, it must be mentioned that for the decomposition reaction of the discrete units in $ZnI_2(pyrimidine)_2$ (**1**), via the oligomeric units in $(ZnI_2)_2(pyrimidine)_3$ (**2**), to the chains in $ZnI_2$(pyrimidine) (**3**), a smooth reaction pathway can be found (Figure 8: left).[4] In contrast, only for the reaction of $ZnBr_2(pyrimidine)_2$ (**I**) to give $(ZnBr_2)_2(pyrimidine)_3$ (**II**) a smooth reaction pathway is found, whereas for the transformation of the 2:3 intermediate **II** into the ligand-deficient 1:1 compound **III**, large translational and rotational changes are needed and thus no smooth reaction pathway can be expected (Figure 8: right).

## Conclusions

In this contribution we have presented four new coordination compounds based on $ZnBr_2$ and pyrimidine, which can be prepared by thermal decomposition from the ligand-rich compound $ZnBr_2$(pyrimidine). These compounds can also be prepared in solution; however, the ligand-rich compounds are only accessible if an excess of ligand is used. The reaction of $ZnBr_2$ and pyrimidine in a ratio given by the formula of the final compound does not lead to compounds **I** and **II**. This phenomenon is frequently observed in the preparation of such compounds, and therefore new compounds can be easily overlooked if the synthesis is performed only in solution. In contrast, by thermal decomposition of the ligand-rich compounds, all ligand-deficient compounds can be detected in a single measurement. A comparison of the thermal properties of these bromido complexes with those of the corresponding iodidozinc(II) and chloridozinc(II) coordination compounds reveals several differences, which include the influence of the actual heating rate on product formation, the mechanism of such reactions and the possibility of the preparation of thermodynamically metastable compounds and different polymorphic modifications.

## Experimental Section

**Synthesis of Compound I:** $ZnBr_2$ (112.59 mg, 0.5 mmol) and pyrimidine (240.24 mg, 3.0 mmol) were mixed in acetonitrile (0.5 mL).

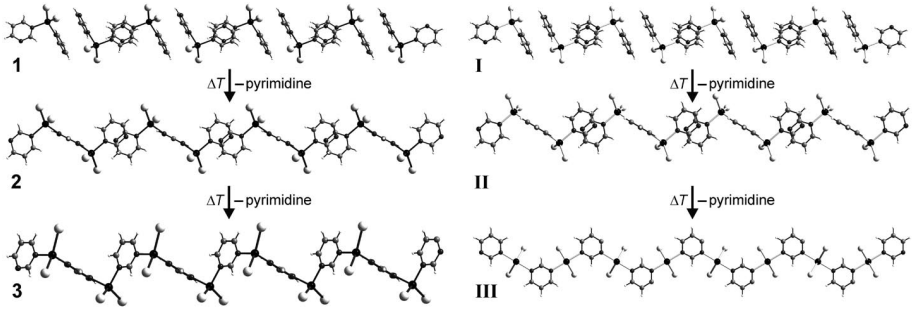

Figure 8. Structural relationships between the crystal structures of the $ZnI_2$(pyrimidine) (left) and $ZnBr_2$(pyrimidine) coordination polymers.

Afterwards, diethyl ether (1.0 mL) was added to the clear solution for precipitation. Yield: 133.6 mg (69.36%) based on $ZnBr_2$. $C_8H_8Br_2N_4Zn$ (385.37): calcd. C 24.93, H 2.09, N 14.54; found C 25.02, H 2.18, N 14.63. IR (KBr): $\tilde{\nu}$ = 1591 (s), 1561 (m), 1471 (m), 1406 (s), 1369 (w), 1237 (w), 1174 (m), 1082 (m), 1016 (m), 817 (w), 705 (m), 688 (m), 643 (m) $cm^{-1}$. Single crystals were prepared by the reaction of $ZnBr_2$ (56.29 mg, 0.25 mmol) and pyrimidine (120.12 mg, 1.5 mmol) in acetonitrile (0.5 mL). Slow evaporation of the solvent from the clear solution yields colourless crystals in about a week.

**Synthesis of Compound II:** $ZnBr_2$ (112.59 mg, 0.5 mmol) and pyrimidine (80.08 mg, 1.0 mmol) were mixed in acetonitrile (0.5 mL). Afterwards, diethyl ether (1.0 mL) was added to the clear solution for precipitation. Yield: 161.9 mg (93.77%) based on $ZnBr_2$. $C_{12}H_{12}Br_4N_6Zn_2$ (690.66): calcd. C 20.87, H 1.75, N 12.17; found C 21.00, H 1.72, N 12.14. IR (KBr): $\tilde{\nu}$ = 3121 (w), 3095 (w), 3064 (m), 1594 (s), 1560 (s), 1472 (s), 1409 (s), 1228 (w), 1173 (m), 1081 (s), 1017 (m), 814 (m), 705 (s), 644 (m) $cm^{-1}$. Single crystals were prepared by the reaction of $ZnBr_2$ (112.59 mg, 0.5 mmol) and pyrimidine (80.08 mg, 1.0 mmol) in a mixture of acetonitrile (2.0 mL) and water (0.3 mL). Slow evaporation of the solvent yielded colourless crystals in about 4 d.

**Synthesis of Compound III:** $ZnBr_2$ (112.59 mg, 0.5 mmol) and pyrimidine (40.04 mg, 0.5 mmol) were mixed in acetonitrile (0.5 mL). Afterwards diethyl ether (1.0 mL) was added for precipitation. Yield: 129.3 mg (84.71%). $C_4H_4Br_2N_2Zn$ (305.28): calcd. C 15.74, H 1.32, N 9.18; found C 15.87, H 1.29, N 9.09. IR (KBr): $\tilde{\nu}$ = 3121 (w), 3075 (w), 1595 (s), 1569 (m), 1465 (s), 1402 (s), 1356 (w), 1220 (m), 1180 (m), 1145 (w), 1081 (s), 1028(m), 933 (w), 801 (m), 688 (s), 661(s) $cm^{-1}$. Single crystals were prepared by the reaction of $ZnBr_2$ (22.51 mg, 0.1 mmol) and pyrimidine (8.08 mg, 0.1 mmol) in water (0.3 mL). Slow evaporation of the solvent yielded colourless crystals in about one week.

**Synthesis of Compound IV:** This compound was difficult to obtain in solution, because in most cases it was contaminated with compound **III**. From several reactions with different stoichiometric ratios of $ZnBr_2$ and pyrimidine, we obtained only one batch which was phase-pure. Its X-ray powder diffraction pattern is shown in Figure 7. However, the pure compound can be prepared in quantitative yield by thermal decomposition of compound **I**, **II** or **III**. $C_4H_4Br_4N_2Zn_2$ (530.46): calcd. C 9.06, H 0.76, N 5.28; found C 9.13, H 0.81, N 5.35. IR (KBr): $\tilde{\nu}$ = 3106 (w), 3082 (w), 1684 (w), 1596 (s), 1569 (m), 1465 (s), 1403 (s), 1220 (m), 1180 (s), 1082 (s), 1028 (s), 801 (m), 689 (s), 660 (s) $cm^{-1}$.

**Elemental Analysis of the Residues Obtained in the Thermal Decomposition of Compound I**

(A) Isolated after the first heating step (compound **II**) $C_{12}H_{12}Br_4N_6Zn_2$ (690.66): calcd. C 20.87, H 1.75, N 12.17; found C 20.94, H 1.69, N 12.20. (B) Isolated after the second heating step (compound **III**) $C_4H_4N_2Br_2Zn$ (305.28): calcd. C 15.74, H 1.32, N 9.18; found C 15.86, H 1.28, N 9.08. (C) Isolated after the third heating step (compound **IV**) $C_4H_4Br_4N_2Zn_2$ (530.46): calcd. C 9.06, H 0.76, N 5.28; found C 8.48, H 1.47, N 4.98.

**Single Crystal Structure Analysis:** All investigations were performed with an Imaging Plate Diffraction System (IPDS-1) from STOE & CIE. Structure solutions were performed with direct methods by using SHELXS-97,[7] and structure refinements were performed against $F^2$ with SHELXL-97.[7] For all structures a numerical absorption correction was applied by using X-Red[8] and X-Shape.[8] All non-hydrogen atoms were refined with anisotropic displacement parameters. All hydrogen atoms were positioned with idealized geometry and were refined with fixed isotropic displacement parameters [$U_{eq}$(H) = 1.2·$U_{eq}$(C)] by using a riding model with $d_{C–H}$ = 0.95 Å. Details of the structural determination are given in Table 3 and in the Supporting Information.

CCDC-651854 (**I**), -651855 (**II**) and -651856 (**III**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

**X-ray Powder Diffraction:** X-ray powder diffraction experiments were performed by using a STOE STADI P transmission powder diffractometer with Cu-$K_\alpha$-radiation ($\lambda$ = 154.0598 pm), which is equipped with a position-sensitive detector (scan range: 5°–45°) from STOE & CIE.

**Differential Thermal Analysis, Thermogravimetry and Mass Spectrometry:** The heating-rate-dependent DTA-TG measurements were performed under a nitrogen atmosphere (purity: 5.0) with

$Al_2O_3$ crucibles in a STA-409CD instrument from Netzsch. The DTA-TG-MS measurements were performed with the same instrument, which is connected to a quadrupole mass spectrometer from Balzers by a Skimmer coupling from Netzsch. The MS measurements were performed in analog and trend scan mode in $Al_2O_3$ crucibles in a dynamic nitrogen atmosphere (purity: 5.0) by using heating rates of 4 °C min$^{-1}$. All measurements were performed with a flow rate of 75 mL min$^{-1}$ and were corrected for buoyancy and current effects. The instrument was calibrated by using standard reference materials.

**Elemental Analysis:** CHN analysis has been performed with a EURO EA Elemental Analyzer, fabricated by EURO VECTOR Instruments and Software.

**Supporting Information** (see footnote on the first page of this article): Tables with bond lengths and angles and details of the structure determinations. Experimental and calculated X-ray powder diffraction patterns for compounds **I**–**III**. IR and Raman spectra of compounds **I**–**III**.

# New Mixed-Metal Aggregates Derived From Dinickel Complexes on a 2-Formylphenolate Template: Counteranion Dependent Formation of 1D Chain and Discrete $NaNi_2$ Complexes

**Alok Ranjan Paital,[a] Masahiro Mikuriya,[b] and Debashis Ray*[a]**

**Keywords:** Mixed-metal complexes / Imidazolidine / Dinuclear $Ni^{II}$ complexes / Crystal structure / Magnetic properties

The combination of 2-formylphenol (Hfp) and the dinucleating ligand $H_3L$ {2-(2′-hydroxyphenyl)-1,3-bis[4-(2-hydroxyphenyl)-3-azabut-3-enyl]-1,3-imidazolidine} with $Ni(NO_3)_2 \cdot 6H_2O$ leads to the self-assembly of a $Ni_2$ complex capable of showing anion dependent $Na^+$ coordination. The terminal aqua coordinated $[Ni_2(fp)L(H_2O)] \cdot 3H_2O$ (**1**·$3H_2O$) neutral fragment, formed in the absence of any $Na^+$ source, produces a 1D chain complex $[\{Ni_2(fp)L(N_3)(Na)(H_2O)\} \cdot 5H_2O]_n$ (**2**·$5H_2O)_n$ and a discrete $NaNi_2$ complex $[Ni_2(fp)L(Na)(H_2O)_2] \cdot ClO_4 \cdot H_2O$ (**3**·$ClO_4$·$H_2O$) through its weak oxophilic interaction with a $Na^+$ cation of the coordinated trisphenolate unit of $L^{3-}$ as observed in metallacrowns. In complexes **2** and **3**, the $Ni^{II}$ ions are coupled ferromagnetically to yield $S = 2$ ground states. The magnetic data can be modeled by using the Van Vleck equation incorporating intermolecular interactions.

## Introduction

Mixed-metal aggregates, involving intimate association of $Na^+$ ions with transition-metal clusters,[1] have recently drawn attention because of their interesting structural and magnetic properties and also because of their contribution towards the understanding of molecular recognition in biological systems.[2] Structural characterization of $Na^+$- and $Ca^{2+}$-bound $Mn_4$ clusters has shown promise in recent times for their relevance in understanding the oxygen-evolving center of photosystem II (PS II).[3] Salicylaldimines[4] and its substituted analogues[5] are known to exhibit simultaneous coordination of transition and alkali metal ions. In recent years, we and others were interested in the multinucleating properties of the ligand $H_3L$ {2-(2′-hydroxyphenyl)-1,3-bis[4-(2-hydroxyphenyl)-3-azabut-3-enyl]-1,3-imidazolidine, Scheme 1} for various reasons, which include their importance in bioinorganic chemistry, molecular magnetism, and catalysis.[6–11]

During the course of these investigations, we observed that under certain conditions, complexation reactions with $Mn^{III}$, $Fe^{III}$, $Co^{III}$, or $Cu^{II}$ leads to the hydrolysis of the imidazolidine ring[12–14] and even the destruction of the imine bond.[15] The instability of some of the dinuclear $Ni^{II}$ complexes of a related ligand was also reported.[16] While investigating the use of 2-formylphenol (Hfp) as a hydrolysis-inhibiting template ligand in nickel phenolate chemistry of $H_3L$, we recently observed that hydrolysis can be prevented by use of the appropriate *o*-formylphenols as coligands, namely 2-formylphenol (Hfp, Scheme 1, right) and 2,6-diformyl-4-methylphenol (Hdfp).[17] The terminal single-water–coordinated, neutral complex $[Ni_2L(fp)(H_2O)] \cdot 3H_2O$ (**1**·$3H_2O$) was synthesized on the formylphenolate template as reported recently.[17] The substitution reaction of the coordinated water molecule was tested in a reaction with $NaN_3$ and provides a 1D chain complex $\{[Ni_2L(fp)(N_3)(Na)(H_2O)] \cdot 5H_2O\}_n$ (**2**·$5H_2O)_n$ that links $Ni_2$ neutral fragments by $(H_2O)NaN_3$ units. The role of the anion, which has the potential to remove the terminal water molecule coordinated to one of the nickel ions, for the metallacrown-ether-like coordination of the $Na^+$ cation through the coordinated trisphenolate unit of $L^{3-}$ is further verified by a second reaction of **1** with $NaClO_4 \cdot H_2O$ that forms $[Ni_2L(fp)(Na)(H_2O)_2] \cdot ClO_4 \cdot H_2O$ (**3**·$ClO_4$·$H_2O$). In complex **3**, as the coordinated water molecule cannot be substituted by bulky perchlorate anion because of steric effects, it remains uncoordinated. These reactions constitute rare examples in which simultaneous incorporation of both

cation and anion in a charge neutral complex is observed. The oxophilic nature of $Na^+$ allows its coordination to the trisphenolate unit first, after which anions are either incorporated or remain uncoordinated in order to provide 1D chain or discrete $NaNi_2$ complexes, respectively. The typical arrangement of $L^{3-}$ around the $Ni^{II}$ ions in **1** leads to the formation of a [–O–Ni–O–Ni–O–] moiety disposed so as to provide three *facial* oxygen donors that form distorted square-pyramidal and trigonal coordination environments around $Na^+$ cation, which is different from the most common octahedral coordination.[8,18]

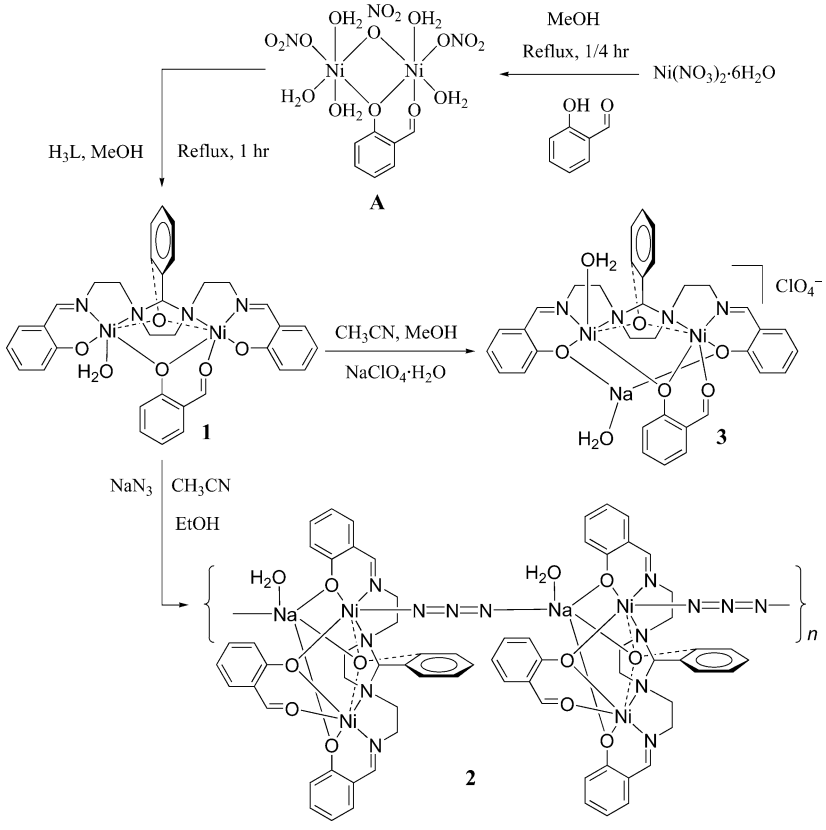
Herein, we report the synthesis, crystallographic characterization, and magnetic properties of two different $Na^+$-bound $Ni_2$ complexes assembled on formylphenolate templates and with a coordinated capping dinucleating $L^{3-}$ ligand. The anion-dependent binding of $Na^+$ ions leads to a novel 1D $Ni_2(O_3)$–Na–$N_3$–$Ni_2(O_3)$ chain and a discrete $NaNi_2$ complex.

## Results and Discussion

### Syntheses, Reactivity, and Spectroscopic Characterizations

The ligand $H_3L$ {2-(2′-hydroxyphenyl)-1,3-bis[4-(2-hydroxyphenyl)-3-azabut-3-enyl]-1,3-imidazolidine} was prepared according to a literature procedure.[19] The aqua $Ni_2$ complex **1** was prepared on a 2-formylphenolate ($fp^-$) template by using $Ni(NO_3)_2{\cdot}6H_2O$ and $H_3L$ in MeOH solvent under refluxing conditions following a standardized procedure reported by us.[17] In that report we noticed that in solution, $H_3L$ is unstable during reactions with nickel(II) salts and crystals of the hydrogen-bonded dimer of the mononuclear complex cations $[Ni(HL')]_2^{2+}$ were produced in low yield ($H_2L'$ is the hexadentate proligand formed from the imidazolidine ring hydrolysis of $H_3L$).[17] Since the 2-formylphenolate ($fp^-$) moiety is generated from the hydrolysis of $L^{3-}$, the ligand decomposition could be inhibited in the presence of the former as a template. The process of ligand hydrolysis, however, is inhibited completely if Hfp is mixed beforehand with a solution of $Ni(NO_3)_2{\cdot}4H_2O$, which presumably leads to the formation of intermediate **A** (Scheme 2). This results in the formation of complex **1** after addition of $H_3L$, where the deprotonated 2-formylphenolate ($fp^-$) behaves as a tridentate bridging ligand that stabilizes the $Ni^{II}_2$ complex. In the present work, we have studied the anion-dependent metalloligand behavior of **1** towards the binding of the sodium ion. A general procedure was followed for the synthesis of complexes **2** and **3** by using two sources of $Na^+$ such as $NaN_3$ and $NaClO_4{\cdot}H_2O$ in MeCN at room temperature in air. The reaction of complex **1** with $NaN_3$ in a 1:1 or 1:2 molar ratio in $CH_3CN$/MeOH (1:1) solvent mixture with stirring in air gives a green microcrystalline complex **2** in 78% yield (Scheme 2).

Addition of excess $NaN_3$ could not displace the formylphenolate template from **1** to produce any azido-bridged dinickel complex. The reaction of complex **1** with $NaClO_4{\cdot}H_2O$ in $CH_3CN$/EtOH (1:1) whilst stirring in air at room temperature yields **3** as a green microcrystalline com-



Scheme 2.

plex in 75% yield. Both of these reactions show that oxophilic $Na^+$ ions could be attached at the trisphenolate metaloligand site of the $Ni_2L$ fragment and that charge neutrality is maintained by anions. All the compounds are insoluble in water and separate directly from the reaction mixture, and were thoroughly washed with water before characterization. The formulation of all the complexes is consistent with elemental and metal analysis and solution electrical conductivity data in $CH_3CN$. The molar conductivity values ($\Lambda_M$) are 16 and 130 $\Omega^{-1}cm^2\,mol^{-1}$ (28 °C) and are consistent with the charge neutral and 1:1 electrolyte behavior of **2** and **3**, respectively. FTIR and UV/Vis spectral analyses also confirm the formation of **2** and **3**.

### Infrared Spectroscopy

The FTIR spectra of **2** and **3** show strong absorption bands at 1639 and 1642 $cm^{-1}$, respectively, which are characteristic of the coordinated C=N functionality of the ligand $L^{3-}$, and these values are slightly lowered in energy relative to that of the free ligand $H_3L$. Broad medium bands spanning the 3600 to 3200 $cm^{-1}$ range with maxima at 3411 and 3421 $cm^{-1}$ are observed, which can be assigned to ν(OH) stretching vibrations from both the metal-ion-coordinated and lattice water molecules in complexes **2** and **3**, respectively. Both the asymmetric and symmetric stretching vibrations are in this range. Strong bands at 1598 and 1600 $cm^{-1}$ are observed, which correspond to ν(C=O) of the coordinated functionality of $fp^-$ in complexes **2** and **3**, respectively. In addition, complex **2** shows a very strong sharp band at 2074 $cm^{-1}$ for the $\nu_{as}(N_3^-)$ stretching band.[20] The FTIR spectrum of complex **3** contains the characteristic vibration at 1121 $cm^{-1}$ for the uncoordinated tetrahedral perchlorate anion.[21]

### Electronic Spectroscopy

Hexacoordination of the metal centers in **2** and **3** is also retained in solution as evidenced by the UV/Vis absorption spectra. The light green solution of complex **2** shows three broad electronic absorption bands at 932 ($\nu_1$, $\varepsilon$ = 90 $M^{-1}cm^{-1}$), 783 ($\nu_2$, $\varepsilon$ = 35 $M^{-1}cm^{-1}$) and 603 nm ($\nu_3$, $\varepsilon$ = 60 $M^{-1}cm^{-1}$). These can be assigned to the $^3A_{2g}(F)\rightarrow{}^3T_{2g}(F)$, $^3A_{2g}(F)\rightarrow{}^1E_{1g}(D)$, and $^3A_{2g}(F)\rightarrow{}^3T_{1g}(F)$ ligand-field transitions in accord with $d^8$ ions in near octahedral coordination environments.[22] Apart from these, two other bands at 375 ($\varepsilon$ = 12605 $M^{-1}cm^{-1}$) and 271 nm ($\varepsilon$ = 17235 $M^{-1}cm^{-1}$) are observed, which arise from charge-transfer transitions. Similarly, for complex **3**, bands at 922 ($\varepsilon$ = 85 $M^{-1}cm^{-1}$), 783 ($\varepsilon$ = 30 $M^{-1}cm^{-1}$), and 510 nm ($\varepsilon$ = 55 $M^{-1}cm^{-1}$) are observed as a result of d–d transitions assigned to $^3A_{2g}(F)\rightarrow{}^3T_{2g}(F)$, $^3A_{2g}(F)\rightarrow{}^1E_{1g}(D)$, and $^3A_{2g}(F)\rightarrow{}^3T_{1g}(F)$ transitions, respectively. Apart from these, two other bands at 375 ($\varepsilon$ = 12870 $M^{-1}cm^{-1}$) and 295 nm ($\varepsilon$ = 14485 $M^{-1}cm^{-1}$) are observed for the charge-transfer transitions. The band arising from the $^3A_{2g}(F)\rightarrow{}^3T_{1g}(P)$ transition is probably hidden under the intense absorption bands in the near ultraviolet region of the spectrum at 375 nm.

### Description of Structures

Green blocklike single crystals suitable for X-ray structure determination were obtained by slow evaporation of $CH_3CN$ and $CH_3CN$/EtOH (1:1) solutions of **2** and **3**, respectively, after a week. Atom labeling scheme and molecular views (ORTEP) of the complexes are shown in Figures 1–9. Selected interatomic distances and angles are collected in Table 1 and Table 2.

### *$\{[Ni_2(fp)L(N_3)(Na)(H_2O)]\cdot5H_2O\}_n$ $(2\cdot5H_2O)_n$*

The molecular structure of **2** in Figure 1 reveals a dinuclear asymmetric unit that is similar to that in complex **1** with the coordination of azide to the $Ni^{II}$ ion instead of water. One $Na^+$ cation sits on the *facial* trisphenolate unit of the $Ni_2L$ fragment, and $N_3^-$ anion maintains the charge neutrality within the molecule. In all other respects, the asymmetric unit of **2** has a similar structural description as that of **1** and also exhibits similar metric parameters. The asymmetric units in **2** are interconnected through end-to-end[23] azide bridges between Ni2 and Na1, and the 1D chain[24] in complex $\{[Ni_2L(fp)(Na)(N_3)(H_2O)]\cdot5H_2O\}_n$ $(2\cdot5H_2O)_n$ is propagated (Figure 2).

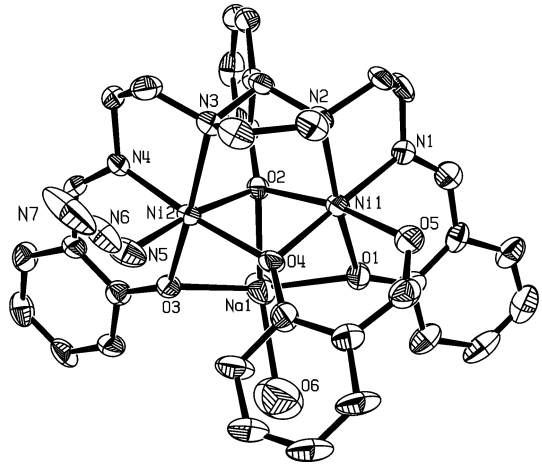

Figure 1. ORTEP representation of an asymmetric unit of $[Ni_2L(fp)(Na)(N_3)(H_2O)]$ (**2**) at the 50% probability level. Hydrogen atoms are omitted for clarity. Only independent non-carbon atoms are labeled.

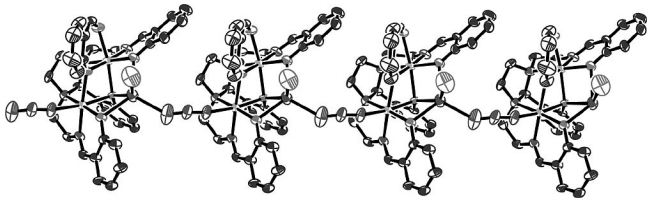

Figure 2. ORTEP representation of $\{[Ni_2L(fp)(Na)(N_3)(H_2O)]\cdot 5H_2O\}_n$ (**2**·$5H_2O$)$_n$ at the 50% probability level. Hydrogen atoms are omitted for clarity.

Complex **2** (Figure 1) is an aggregate of two $Ni^{II}$ ions linked together by the $N_4O_3$ heptadentate ligand $L^{3-}$ (Scheme 1). The bridging function is accomplished by the central imidazolidine group (NCN group) and phenoxide moiety (one μ-O atom) of $L^{3-}$, while the imine N atom and the phenoxide O donor at each side of the ligand occupy two additional coordination sites of each $Ni^{II}$ center. An exogenous bidentate 2-formylphenolate ($fp^-$) ligand contributes to the bridging within the complex through the phenolate O donor and introduces asymmetry by binding to only one Ni atom through its carbonyl moiety. Hexacoordination around the other Ni ion is then achieved through the binding of an azide ion. The two Ni atoms are thus coordinated in distorted octahedral $N_2O_4$ and $N_3O_3$ environments; the two octahedra share the edge defined by the bridging phenolate oxygen atoms (Scheme S1). The planes intersecting at this edge form an angle of 153.37° as a result of the folding imposed by the imidazolidine ring [N2···N3 distance of 2.272(5) Å]. The geometric restrictions resulting from $L^{3-}$ also lead to different Ni–O–Ni angles, 97.6(3)° and 99.2(3)° for the endogenous and exogenous phenolate oxygen atoms, respectively. The intramolecular Ni···Ni distance is 3.139(4) Å relative to 3.056 Å in complex **1**, which clearly indicates that this distance is increased as a result of 1D chain formation. The imidazolidine nitrogen atoms [Ni–$N_{imd}$ (imd = imidazolidine) distances of 2.176(9) and 2.196(9) Å] are further away from $Ni^{II}$ than the imine nitrogen atoms [Ni–$N_{im}$ (im = imine) distances of 1.997(8) and 2.025(10) Å]. The O–Ni–O angles [78.7(3) and 77.1(3)°] within the metallacyclic $Ni_2(\mu\text{-}O)_2$ diamond core indicate distortions of the metal ion octahedra. The degree of distortion from an ideal octahedral (90°) geometry is reflected in the *cisoid* [105.2(3)–77.1(3)°] and the *transoid* [175.6(4)–166.5(3)°] angles. The bridging Ni–O(phenolate) distances (av. 2.073 Å) are longer than the terminal distances (av. 2.005 Å). The terminal Ni–O(carbonyl) and Ni–N(azide) distances are 2.099(8)° and 2.083(12) Å, respectively. The particular arrangement of $L^{3-}$ around the $Ni^{2+}$ ions leads to the formation of a [–O–Ni–O–Ni–O–] moiety (Figure 3 left) disposed so as to provide three facial donors that form an isosceles triangular face in order to favorably interact with the sodium ion through one oxygen atom of each of the phenolate groups [$d$(Na–$O_{Ph}$) = 2.264(9)–2.377(8) Å] (Scheme 3 left). These distances fall within the ranges observed for other metallacrowns or metallacryptates.[25] The sodium ion is found in an overall five-coordinate geometry ($NO_4$ donors); the three phenolate O atoms, a water O atom [$d$(Na–O6) = 2.513(16) Å], and a bridging azido N atom [$d$(Na–N7) = 2.364(19) Å]. Its coordination geometry can be viewed as a distorted square-pyramid in which the azido ligand is located in the apical position (Figure 3 right).

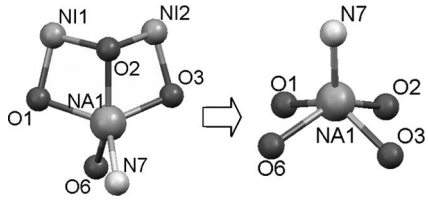

Figure 3. Left: the $NaNO_4Ni_2$ core in **2**; right: the square-pyramidal coordination environment around the $Na^+$ ion.

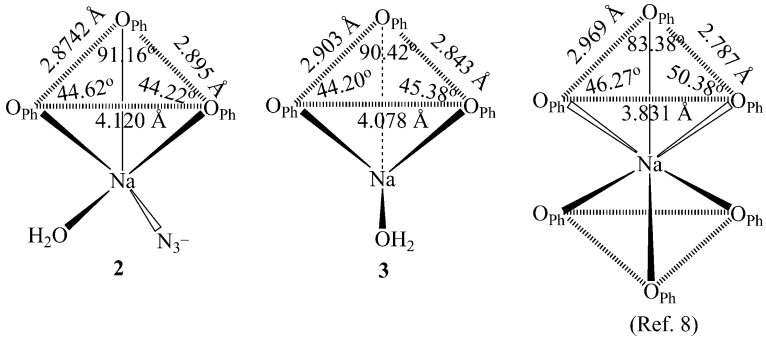
 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 



Scheme 3. Different coordination environments around $Na^I$. Left: the coordination of a trisphenolate isosceles triangular face within a $NaNO_4$ core in **2**; middle: the same $O_3$ triangular face within a $NaO_4$ core in **3**; right: the relative orientation of two such faces in a $NaO_6$ core in a reported $Cu_4$ complex (ref.[8]).

The staggered face-to-face orientation of two such triangular faces of the O donors of each ligand in $Cu_2L(N_3)$ is responsible for trapping the $Na^+$ cation in a distorted octahedral geometry, as reported earlier[8] (Scheme 3 right). Thus, the 1,3-bridging mode of the azido group between Ni and Na prevents any formation of a $Ni_4$-type cluster and leads to a 1D network with a Ni2···Na1 distance of 6.108 Å. The torsion angle around Ni2–N5–N7–Na1 is –89.09°, which indicates a *cis* bridging of $N_3^-$ in a *gauche* conformation (Figure 4). The crystal-packing diagram along the crystallographic *a* axis is depicted in Figure S1.

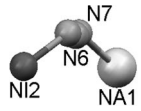


Figure 4. The *gauche* conformation of the $N_3$ bridge between Na and Ni.

The coordinated and lattice water molecules in **2** form an intermolecular hydrogen-bonded 2D network (Figure 5). Three of the five water molecules of crystallization [containing the O7, O8, O11 atoms] are involved in a zigzag intermolecular hydrogen-bonding network – the O6 atoms coordinated to the $Na^+$ ions connect two adjacent rows of azide-bridged 1D molecular chains made up of Ni2···Na1 units through a hydrogen-bonding network along the crystallographic *b* axis (Figure 6). The interatomic distances within this network are 2.78(3), 3.07(3), 2.70(3), and 2.82(3) Å, respectively, for the O6···O11, O11···O7, O7···O8, and O8···O6 interactions. The O7 atom is further hydrogen bonded with the template carbonyl oxygen atom O5 [O5···O7, 2.867(17) Å], which generates another network along the *a* axis (Figure 7). The remaining two water molecules of crystallization show strong hydrogen bonding [O9···O10, 2.43(4) Å], and O9 is further hydrogen bonded with the azide N7 nitrogen atom with a distance of 2.985(5) Å.

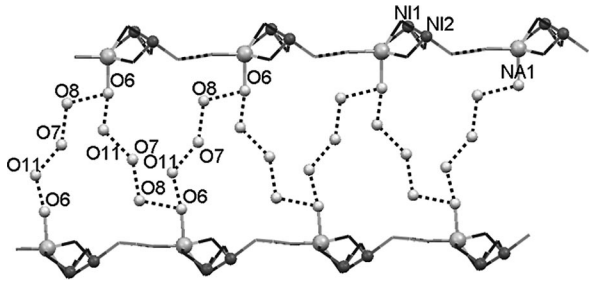

Figure 6. The hydrogen-bonded 1D water chain running along the crystallographic *b* axis between the two azido-bridged 1D molecular chains in **2**.

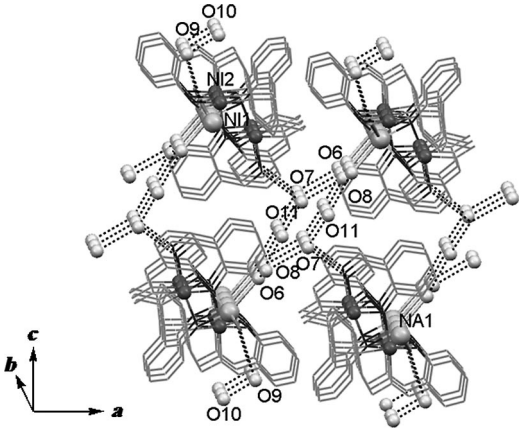

Figure 5. The intermolecular hydrogen-bonded 2D network viewed along an arbitary axis in **2**.

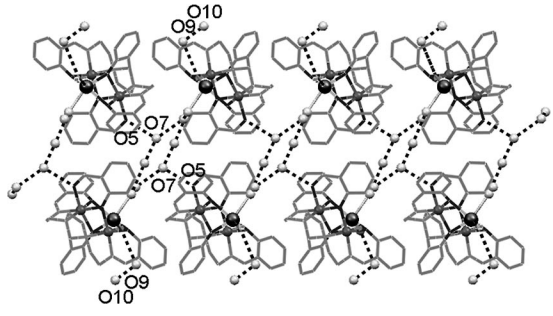

Figure 7. The hydrogen-bonded 1D chain connecting the $NaNi_2$ units along the crystallographic *a* axis in **2**. Ni: dark gray; O: light gray; Na: black.

### *[$Ni_2$(fp)LNa($H_2O$)$_2$]·$ClO_4$·$H_2O$ (3·$ClO_4$·$H_2O$)*

The molecular structure of **3** reveals a $[Ni_2L(fp)Na(H_2O)_2]^+$ complex cation and a $ClO_4^-$ anion with one water molecule of crystallization. Complex **3** (Figure 8) is a dinuclear aggregate of $Ni^{II}$ ions bridged and chelated by the ligand $L^{3-}$ in the same manner as in complex **2**, with the exception that one $Na^+$ cation is coordinated to two terminal phenolate oxygen atoms and one water molecule of crystallization.

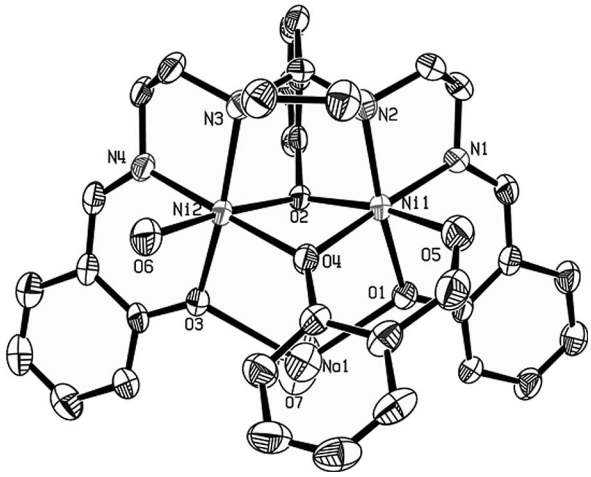

Figure 8. ORTEP representation of $[Ni_2L(fp)(Na)(H_2O)_2]^+$ (**3**) at the 40% probability level. Hydrogen atoms are omitted for clarity. Only independent non-carbon atoms are labeled.

An exogenous 2-formylphenolate ($fp^-$) ligand contributes to the bridging in the complex through the phenolate O donor and introduces asymmetry into the complex by binding to only one Ni atom through its carbonyl moiety. The Ni–O(carbonyl) distance of 2.069(7) Å is typical for this type of linkage, as in Ni–O(urea).[26] Hexacoordination around the other Ni ion is achieved through the binding of a molecule of water. Each Ni atom is thus coordinated in a distorted octahedral $N_2O_4$ environment; the two octahedra share the edge defined by the bridging phenolate oxygen atoms (Scheme S1). The planes intersecting at this edge form an angle of 152.46°, as a result of the folding imposed by imidazolidine ring [N2···N3 distance of 2.296(5) Å]. The O–Ni–O angles [80.5(2) and 78.6(2)°] within the metallacyclic $Ni_2(\mu\text{-}O)_2$ diamond core indicate distortions of the metal ion octahedra. The degree of distortion from an ideal octahedral (90°) geometry is reflected in the *cisoid* [104.2(3)–78.6(2)°] and the *transoid* [177.8(3)–169.2(2)°] angles. The Ni–$O_{Ph}$ bond lengths are in the range 2.006(5)–2.154(6) Å. The bridging Ni–O(phenolate) distances (av. 2.037 Å) are comparable with the terminal distances (av. 2.036 Å). The terminal Ni–O(carbonyl) and Ni–O(water) distances are 2.069(7) Å and 2.154(6) Å, respectively. The geometric restrictions resulting from $L^{3-}$ also lead to different Ni–O–Ni angles [96.3(2)° and 96.9(2)° for endogenous and exogenous phenolate oxygen atoms, respectively]. The intramolecular Ni···Ni distance is 3.042 Å and is comparable to 3.056 Å in complex **1**. The imidazolidine N atoms [Ni–$N_{imd}$ distances of 2.118(7) and 2.189(7) Å] are further away from $Ni^{II}$ than the imine N atoms [Ni–$N_{im}$ distances of 2.006(7) and 2.018(7) Å]. The $O_4$ coordination environment around the $Na^+$ cation is a distorted tetrahedral with O–Na–O bond angles within the range 107.1(3)–110.4(6)°. The particular arrangement of $L^{3-}$ around the metal ions provides three facial donors that form an isosceles triangular face such that they can favorably interact with the $Na^+$ ion (Scheme 3, middle), which is loosely held by the terminal phenolate O atoms of the $Ni_2L$ fragment as evidenced from the Na–$O_{Ph}$ bond lengths of 2.498(8) and 2.570(7) Å, which are comparable to the Na–$O_{water}$ distance of 2.496(18) Å in **2**.

The central endogenous phenolate oxygen atom is 3.310 Å away from the $Na^+$ cation, which is longer than 2.388(9) Å in **2**. The oxygen atom (O6) of the coordinated water molecule to $Ni^{II}$ is engaged in hydrogen bonding with the oxygen atom (O8) of the lattice water molecule and one of the oxygen atoms (O11) of the perchlorate anion with distances of 2.698 [O6···O8] and 3.028 Å [O6···O11], respectively (Figure 9). A crystal-packing diagram along the *b* axis is depicted in Figure S2.

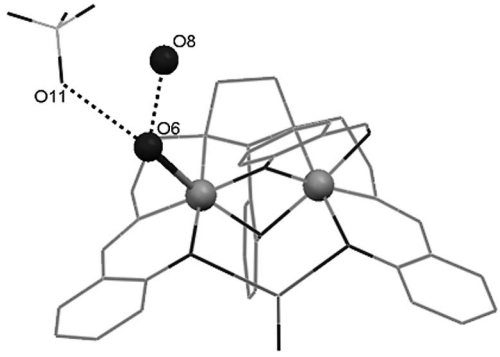

Figure 9. Intramolecular hydrogen bonding between the coordinated water molecule and the anion and the lattice water molecule viewed along an arbitary axis.

## Magnetic Properties

### *{[$Ni_2$(fp)L($N_3$)(Na)($H_2O$)]·5$H_2O$}$_n$ (2·5$H_2O$)$_n$*

The magnetic exchange within the 1D polymeric motif of complex **2** was investigated by means of bulk magnetization methods. Measurements were collected under a constant magnetic field of 0.5 T in the temperature range 4.5–300 K. The effective magnetic moment at 300 K of the 1D chain is 4.66 $\mu_B$ per molecule of the above complex; this value is 4.72 $\mu_B$ at 4.5 K. The plots of $\chi_M$ and $\mu_{eff}$ as a function of *T* for this complex are represented in Figure 10 ($\chi_M$ is the molar paramagnetic susceptibility and $\mu_{eff}$ is effective magnetic moment). At room temperature, $\chi_M$ is slightly higher than that expected for a pair of independent $Ni^{II}$ ions with a *g* value of 2.29, and it increases upon cooling, with a more pronounced slope as the temperature approaches zero. This behavior clearly shows that the intramolecular coupling is ferromagnetic. The magnetic data were fitted by consider-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

ing the intermolecular interactions. The model involves the use of a $\chi_M = f(T)$ expression [Equation (1)] derived from the Van Vleck equation.

$$\chi_M = \frac{2Ng^2\beta^2}{k(T-\theta)}\left[\frac{5+\exp(-4J/kT)}{5+3\exp(-4J/kT)+\exp(-6J/kT)}\right] \quad (1)$$

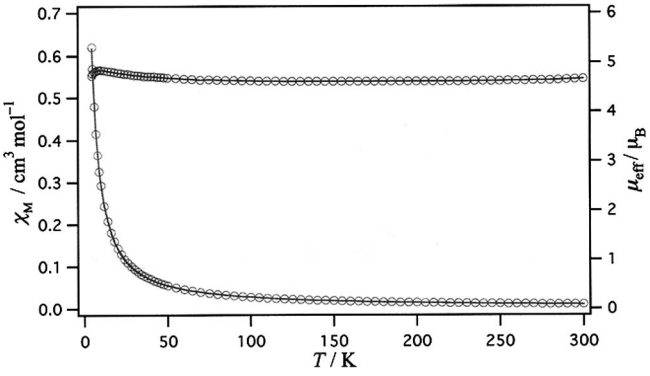

Figure 10. Plot of the temperature dependence of $\chi_M$ and $\mu_{eff}$ for **2**.

The parameters for this fit are $J = 2.02\ cm^{-1}$, $g = 2.29$, and $\theta = -1.7$ K. The small and ferromagnetic intramolecular coupling may be ascribed to the Ni–O–Ni angles formed by the phenolate bridges [between 97.6(3) and 99.0(3)°], which are within the range predicted for ferromagnetic interactions between the two nickel(II) ions, or to the imidazolidine –NCN– bridge, which also has been shown to facilitate ferromagnetic Ni···Ni exchange interaction.[17] The weak interdimer antiferromagnetic coupling is mediated by the Ni–$\mu_{1,3}$-$N_3$–Na···Ni bridges.

### *[$Ni_2$(fp)L(Na)($H_2O$)$_2$]·$ClO_4$·$H_2O$ (3·$ClO_4$·$H_2O$)*

The magnetic exchange within the binuclear motif of complex **3** was investigated by means of bulk magnetization methods. Measurements were made under a constant magnetic field of 0.5 T in the temperature range 4.5–300 K. The effective magnetic moment at 300 K of the binuclear complex **3** is 4.54 $\mu_B$ per molecule of the above complex; this value is 4.99 $\mu_B$ at 4.5 K. The temperature dependence of the magnetic moment was analyzed by the same $\chi_M = f(T)$ expression [Equation (1)] as that for complex **2**. The plots of $\chi_M$ and $\mu_{eff}$ as a function of $T$ for this complex are represented in Figure 11. The parameters for this fit are $J = 3.04\ cm^{-1}$, $g = 2.24$, and $\theta = -0.87$ K. This behavior clearly shows that the intramolecular coupling is ferromagnetic in nature.

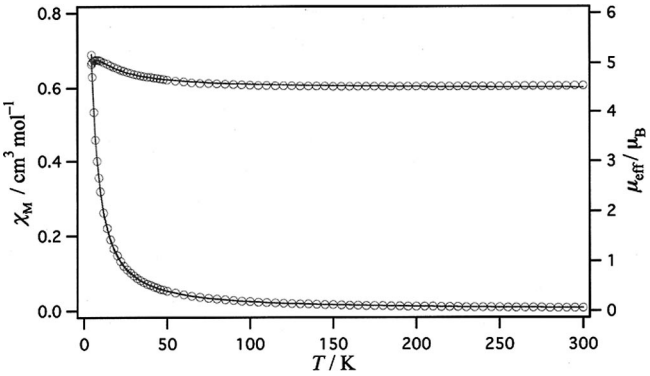

Figure 11. Plot of the temperature dependence of $\chi_M$ and $\mu_{eff}$ for **3**.

## Concluding Remarks

As part of the interesting metal–ligand chemistry of $L^{3-}$, we have previously shown that reaction of $H_3L$ with $Ni^{II}$ on 2-formylphenolate as a template leads to the high yield formation of the terminal aqua coordinated neutral metalloligand [$Ni_2$(fp)L($H_2O$)]·3$H_2O$ (**1**·3$H_2O$) in the absence of any $Na^+$ source. Now we have shown that reaction of complex **1** with two different sodium salts produces counteranion–controlled, new, mixed-metal 1D chains {[$Ni_2$(fp)L($N_3$)(Na)($H_2O$)]·5$H_2O$}$_n$ (**2**·5$H_2O$)$_n$ and discrete $NaNi_2$ complexes [$Ni_2$(fp)L(Na)($H_2O$)$_2$]·$ClO_4$·$H_2O$ (**3**·$ClO_4$·$H_2O$) through the metallacrown-like coordination of $Na^+$ ions to the trisphenolate face of the $Ni_2L$ fragments. Magnetic measurements indicate that complexes **2** and **3** exhibit ferromagnetic superexchange between the $Ni^{II}$ centers to yield $S = 2$ ground states. We are currently working to exploit the asymmetry induced by the external template bridges in this reaction system to obtain heterometallic complexes.

## Experimental Section

**Materials and Physical Measurements:** The chemicals used were obtained from the following sources: triethylenetetramine, sodium azide, and nickel nitrate hexahydrate from S.D. Fine Chem. (India) and 2-hydroxy benzaldehyde from SRL (India). All other chemicals and solvents were reagent grade materials and were used as received, without further purification. The elemental analyses (C, H, N) were performed with a Perkin–Elmer model 240C elemental analyzer. FTIR spectra were recorded with a Perkin–Elmer RX1 spectrophotometer. The solution electrical conductivity and electronic spectra were obtained by using a Unitech type U131C digital conductivity meter with a solute concentration of about $10^{-3}$ M and a Shimadzu UV 3100 UV/Vis/NIR spectrophotometer, respectively. The room temperature magnetic susceptibilities in the solid state were measured with a home-built Gouy balance fitted with a Polytronic d.c. power supply. The experimental magnetic susceptibilities were corrected for the diamagnetic response by using Pascal's constants. Magnetic measurements were carried out on polycrystalline samples (ca. 70 mg)with a Quantum Design MPMS-5S SQUID magnetometer operating at a constant magnetic field of 5000 G between 4.5–300 K. The experimental magnetic moment was corrected for the diamagnetic contribution from the sample holder and the diamagnetic response from the sample, which was evaluated from Pascal's constants.

**General:** All experimental procedures were carried out in air at room temperature. The ligand $H_3L$ {2-(2′-hydroxyphenyl)-1,3-bis[4-(2-hydroxyphenyl)-3-azabut-3-enyl]-1,3-imidazolidine} was prepared according to a literature procedure.[19] Complex **1** was synthesized by a literature procedure.[17]

**$\{[Ni_2L(fp)(N_3)(Na)(H_2O)]\cdot 5H_2O\}_n$ $(\mathbf{2}\cdot 5H_2O)_n$:** A methanolic solution of $NaN_3$ (0.033 g, 0.52 mmol) was added dropwise to a $CH_3CN$ solution (50 mL) of complex **1** (0.4 g, 0.52 mmol) over 15 min, and the mixture was stirred for 1 h. The resulting solution was filtered and left undisturbed so that the solvents could slowly evaporate. After 4 d, a green crystalline product was obtained (≈78% yield). The solid was isolated, washed with cold methanol, and dried under vacuum over $P_4O_{10}$. $C_{34}H_{44}N_7NaNi_2O_{11}$ (867.17): calcd. C 47.09, H 5.11, N 11.30; found C 46.89, H 5.24, N 11.18%. Molar conductance (MeCN solution): $\Lambda_M = 16\ \Omega^{-1}cm^2mol^{-1}$. UV/Vis spectrum ($CH_3CN$): $\lambda_{max}$ ($\varepsilon_{max}$, $M^{-1}cm^{-1}$) = 932 (90), 783 (35), 603 (60), 375 (12605), 271 (17235) nm. Selected IR bands (KBr): $\tilde{\nu}$ = 3411 (br.), 2074 (s), 1639 (s), 1598 (s), 1535 (m), 1486 (m), 1447 (s), 1400 (m), 1341 (m), 1291 (m), 1150 (w), 760 (m) cm$^{-1}$.

**$[Ni_2L(fp)(Na)(H_2O)_2]\cdot ClO_4\cdot H_2O$ $(\mathbf{3}\cdot ClO_4\cdot H_2O)$:** A methanolic solution of $NaClO_4\cdot H_2O$ (0.073 g, 0.52 mmol) was added dropwise to a $CH_3CN$ solution (50 mL) of **1** (0.4 g, 0.52 mmol) over 15 min, and the mixture was stirred for 1 h. The resulting solution was filtered and left undisturbed so that the solvents could slowly evaporate. After 7 d, a green crystalline product was obtained (≈75% yield). The solid was isolated, washed with cold methanol, and dried under vacuum over $P_4O_{10}$. $C_{34}H_{38}ClN_4NaNi_2O_{12}$ (870.51): calcd. C 46.91, H 4.39, N 6.43; found C 46.86, H 4.22, N 6.34. Molar conductance (MeCN solution): $\Lambda_M = 130\ \Omega^{-1}cm^2mol^{-1}$. UV/Vis spectrum ($CH_3CN$): $\lambda_{max}$ ($\varepsilon_{max}$, $M^{-1}cm^{-1}$) = 922 (85), 783 (30), 510 (55), 375 (12870), 295(14485) nm. Selected IR bands (KBr): ν = 3421 (br.), 1642 (s), 1628 (s), 1600 (s), 1540 (m), 1484 (m), 1461 (m), 1445 (s), 1290 (m), 1121 (s), 758 (m) cm$^{-1}$.

**X-ray Crystallographic Procedures for 2 and 3:** Information concerning X-ray data collection and structure refinement of the compound is summarized in Table 3. The intensity data of the complexes **2** and **3** were collected on Nonius CAD4 X-ray diffractometer that uses graphite monochromated Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 Å) by ω-scan method. Data were collected at 293 K. For complex **2**, total of 6680 reflections were recorded with Miller indices, $h_{min}$ = 0, $h_{max}$ = 22, $k_{min}$ = 0, $k_{max}$ = 10, $l_{min}$ = –26, $l_{max}$ = 25. For complex **3**, a total of 6724 reflections were recorded with Miller indices, $h_{min}$ = 0, $h_{max}$ = 14, $k_{min}$ = 0, $k_{max}$ = 20, $l_{min}$ = –20, $l_{max}$ = 20. In the final cycles of full-matrix least-squares on $F^2$ all non-hydrogen atoms were assigned anisotropic thermal parameters. The positions of the H atoms bonded to C atoms were calculated (C–H distance 0.97 Å). The structure was solved using the programme SHELX-97[27] and refined by full-matrix least-squares methods with use of the programme SHELX-97.[28] CCDC-628157 and -628158 for complexes **2** and **3** contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

**Supporting Information** (see footnote on the first page of this article): The distorted octahedral $N_2O_4$ and $N_3O_3$ environments around the Ni centres in complexes **2** and **3** and the packing diagrams of complexes **2** and **3** are presented.

The reaction between the $Ni_2$ assembly on a formylphenolate template with a coordinated terminal water molecule and a capping imidazolidine ligand and $N_3^-$ or $ClO_4^-$ anions leads to two different types of products. The metallacrown-type coordination of the $Na^+$ cations results in new $NaNi_2$ complexes engaged in ferromagnetic interactions.

# Synthesis and X-ray Characterization of Mono- and Polynuclear Thiolatocopper(I) Complexes: The Effect of Steric Bulk on Coordination Number and Nuclearity

**Shiri Zeevi[a] and Edit Y. Tshuva*[a]**

**Keywords:** Copper / S ligands / Cluster compounds / Coordination modes / Metallochaperones

We have synthesized a number of $Cu^{I}$ complexes of thiophenolato ligands with different alkyl substituents in the *ortho* positions in a single-step procedure starting from a readily available copper(I) precursor to evaluate the coordination preferences of the metal atom. In most cases similar reaction conditions led to the formation of two complexes: a mononuclear complex and a polynuclear cluster, as evident from X-ray crystallography. One dinuclear complex formed has the unique geometry of an $L_2Cu_2(\mu\text{-}L)_2$ core that has not previously been observed for related systems. The steric bulk around the metal atom has a clear effect on the coordination sphere of the complex obtained. Ligands with no *ortho* substituents and those with one substituent with a size varying from methyl to *tert*-butyl all lead to the formation of three-coordinate complexes for the mononuclear species, and clusters of different sizes where larger substituents lead to larger cages and all copper centers are three-coordinate as well. The introduction of two methyl substituents (one in each *ortho* position) leads to either a mononuclear two-coordinate copper complex or a polynuclear cluster where two copper centers are three-coordinate and three are two-coordinate.

## Introduction

The recent discovery of a number of proteins from the family of copper metallochaperones, and their structural identification by X-ray crystallography, has refocused attention on copper(I) chemistry.[1–14] These proteins have a conserved motif of MTCXXC (single-letter abbreviation of amino acids, where X represents any amino acid), and binding to the copper(I) center is achieved through the two cysteine residues, with a potential third ligand in some cases. This coordination sphere, namely a low coordination number and soft thiolato ligands, favors the valence state of copper(I) over copper(II) and thus lowers the oxidation potential, which means that the possibly harmful redox behavior of copper is avoided as is any interference with other beneficial redox processes.

Numerous studies have been reported on copper(II) chemistry, including those directed towards modeling various copper protein active sites.[15–18] Herein we focus on understanding the structure and coordination preferences of thiolatocopper(I) complexes of monodentate ligands and evaluating the conditions required to obtain two-coordinate copper centers.[19–32] Hence, thiophenolato ligands with varying steric demands were employed, leading to complexes with different coordination spheres around the copper center (Scheme 1).

## Results and Discussion

Our reaction conditions were aimed at obtaining two-coordinate copper(I) complexes as structural models for the active site of copper metallochaperones.[4,33] Thus, our straightforward and single-step synthetic procedure generally involved mixing of the commercially available copper(I) precursor CuCl with approximately 1 equiv. of $Et_4NX$ (X = Cl, Br) in thf or dmf and stirring overnight at room temp., followed by addition of 1.5–2 equiv. of the thiolato ligand which had previously been stirred with an excess of NaH overnight, and stirring the resulting mixture for 24 h. Crystallization from a suitable solvent gave single crystals suitable for X-ray crystallography. In most cases the mononuclear complex obtained was accompanied by a polynuclear cluster, which was crystallized under similar reaction conditions, occasionally in the same flask. The complexes formed do not necessarily feature the stoichiometry employed between the copper(I) salt, ligand (**1a**–**4a**), and counterion, and the net reaction stoichiometry of the different complexes formed is presented in Scheme 1. We will begin our discussion with the series of mononuclear complexes obtained (**1b**–**4b**), followed by a description of the clusters (**2c**–**4c**).

### Mononuclear Complexes

Treatment of the sodium salt of **1a** with the copper(I) precursor in thf (Scheme 1) gave a colorless solution. Crystallization from thf at –30 °C gave colorless crystals that were analyzed by crystallography despite their significant disorder. The structure of one anion of the product $[Et_4N]_2[Cu\{S(p\text{-}tBuC_6H_4)\}_3]$ (**1b**), out of several found in the asymmetric unit, is presented in Figure 1, and selected bond lengths and angles for this molecule are summarized in Table 1. All molecules in the asymmetric unit are very similar to one another in terms of general structure and bond characteristics.

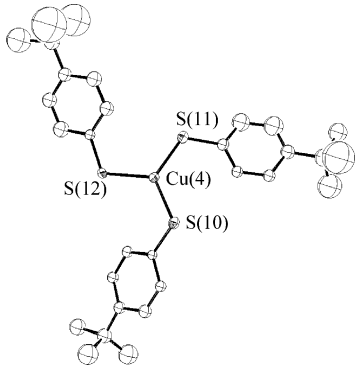

Figure 1. ORTEP drawing of one dianion in $[Et_4N]_2[Cu\{S(p\text{-}tBuC_6H_4)\}_3]$ (**1b**) showing 50% probability ellipsoids. H atoms, solvent molecules, counterions, and disorder have been omitted for clarity.

The structure features a three-coordinate copper(I) center with a highly planar-trigonal geometry, as shown by the sum of the angles around the metal atom (360.0°). Three thiolato ligands bind to the metal atom with two $Et_4N^+$ counterions stabilizing the copper(I) state. All Cu–S bond lengths (2.24–2.26 Å) are similar, thereby indicating one average bond type of mostly covalent nature. A somewhat broader range is observed for the S–Cu–S angles (117–124°), with a mean value of 120° in agreement with the trigonal geometry. These values are also in agreement with those obtained for other related three-coordinate $Cu^I$ complexes of thiophenolato ligands without *ortho* substituents.[21–23] These latter complexes were obtained under different reaction conditions, the main difference being the significantly lower ligand to metal stoichiometry employed in our case. This suggests that the coordination number of three is favored for the copper(I) center in this system.

Table 1. Selected bond lengths [Å] and angles [°] for a representative dianion of **1b**–**3b**.

| | | | |
|---|---|---|---|
| $[Cu\{S(p\text{-}tBuC_6H_4)\}_3]^{2-}$ in **1b** | | | |
| Cu(4)–S(10) | 2.257(3) | S(10)–Cu(4)–S(11) | 124.17(11) |
| Cu(4)–S(11) | 2.234(3) | S(11)–Cu(4)–S(12) | 117.49(12) |
| Cu(4)–S(12) | 2.244(3) | S(12)–Cu(4)–S(10) | 118.33(12) |
| $[Cu\{S(o\text{-}iPrC_6H_4)\}_3]^{2-}$ in **2b** | | | |
| Cu(1)–S(1) | 2.251(1) | S(1)–Cu(1)–S(2) | 118.78(4) |
| Cu(1)–S(2) | 2.271(1) | S(2)–Cu(1)–S(3) | 115.37(4) |
| Cu(1)–S(3) | 2.239(1) | S(3)–Cu(1)–S(1) | 125.68(4) |
| $[Cu\{S(o\text{-}tBuC_6H_4)\}_3]^{2-}$ in **3b** | | | |
| Cu(1)–S(1) | 2.232(2) | S(1)–Cu(1)–S(2) | 122.89(6) |
| Cu(1)–S(2) | 2.244(2) | S(2)–Cu(1)–S(3) | 115.06(7) |
| Cu(1)–S(3) | 2.291(2) | S(3)–Cu(1)–S(1) | 121.67(7) |

We were now interested in exploring the influence of steric effects on the coordination number of the complex formed, and found that increasing the bulk by adding an *ortho*-isopropyl group, or even a larger -*tert*-butyl group, does not have a significant influence on the outcome as regards the coordination parameters of the copper(I) complex obtained. Thus, treating the sodium salt of **2a** or **3a** with the copper(I) precursor in dmf under similar reaction conditions (Scheme 1) gave colorless solutions from which $[Et_4N]_2[Cu\{S(o\text{-}iPrC_6H_4)\}_3]$ (**2b**) and $[Et_4N]_2[Cu\{S(o\text{-}tBuC_6H_4)\}_3]$ (**3b**) were crystallized, respectively, by slow diffusion of thf/hexane at room temperature. The X-ray structures of **2b** and **3b** are presented in Figures 2 and 3, respectively, and selected bond lengths and angles are summarized in Table 1.

Both **2b** and **3b** feature a similar anionic three-coordinate copper(I) complex with a $D_{3h}$-symmetric core, which is reduced to the $C_3$ symmetry of the entire anion by the ligand structure. Two anions surrounded by two $Et_4N^+$ cations each are present in the asymmetric unit of each structure. The bond lengths and angles are in a similar range to those of **1b** (Table 1) and most of the previously reported three-coordinate (thiophenolato)copper(I) structures.[21–23,34] The high planarity of the core is only very slightly reduced by the substituents' bulk, with the sum of the S–Cu–S angles being 359.8° for **2b** and 359.6° for **3b**, which indicates little influence of the steric groups.

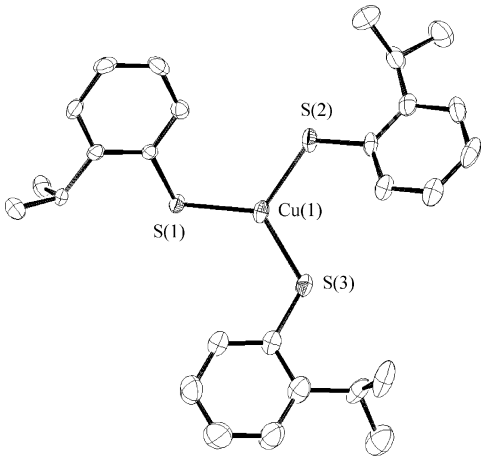

Figure 2. ORTEP drawing of one dianion of $[Et_4N]_2[Cu\{S(o\text{-}iPrC_6H_4)\}_3]$ (**2b**) showing 50% probability ellipsoids. H atoms, solvent molecules, and counterions have been omitted for clarity.

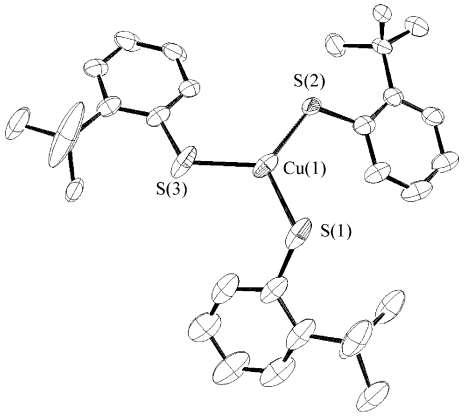

Figure 3. ORTEP drawing of one dianion of $[Et_4N]_2[Cu\{S(o\text{-}t BuC_6H_4)\}_3]$ (**3b**) showing 50% probability ellipsoids. H atoms, solvent molecules, and counterions have been omitted for clarity.

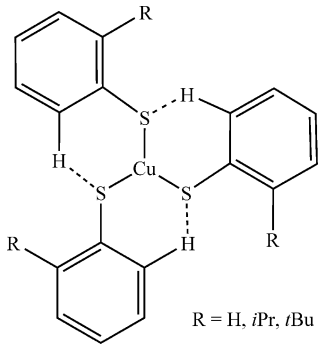
The H···S distance between the hydrogen atom in the second *ortho* position and the nearest sulfur atom in the structures of **2b** and **3b** (Scheme 2) is between 2.7 and 3.0 Å, which suggests that an additional bulky substituent at this position should interfere with the trigonal structure and may lead to a different coordination sphere.[19] Indeed, treatment of the copper(I) precursor with the sodium salt of ligand **4a** (Scheme 1) according to the same procedure as for **1a**–**3a** gave a colorless solution from which single crystals formed upon diffusion of a thf/hexane solution at room temperature. The X-ray structure of the anion of product $[Et_4N][Cu\{S(o,o'\text{-}Me_2C_6H_3)\}_2]$ (**4b**) is presented in Figure 4, and selected bond lengths and angles are summarized in Table 2.



Scheme 2.

Table 2. Selected bond lengths [Å] and angles [°] for the anion of **4b**.

| $[Cu\{S(o,o\text{-}Me_2C_6H_3)\}_2]^-$ | | | |
|---|---|---|---|
| Cu(1)–S(1) | 2.127(1) | S(1)–Cu(1)–S(2) | 165.22(7) |
| Cu(1)–S(2) | 2.111(3) | C(1)–S(1)–Cu(1)–S(2) | 166.1 |
| | | C(1)–S(1)–S(2)–C(9) | 42.1 |

The structure features a two-coordinate copper(I) anionic center with one $Et_4N^+$ counterion. The position of S(2) at 70% probability gives an S–Cu–S angle of 165.2°, which deviates quite substantially from linearity. The short Cu–S bond lengths of 2.11–2.13 Å[19,20] are in accordance with strong covalent-type bonds. Interestingly, a comparison of the X-ray structure of **4b** with the two previously reported two-coordinate thiolatocopper(I) complexes[19,20] showed two distinctive features for **4b**, namely the above-mentioned substantial deviation of the S–Cu–S angle from

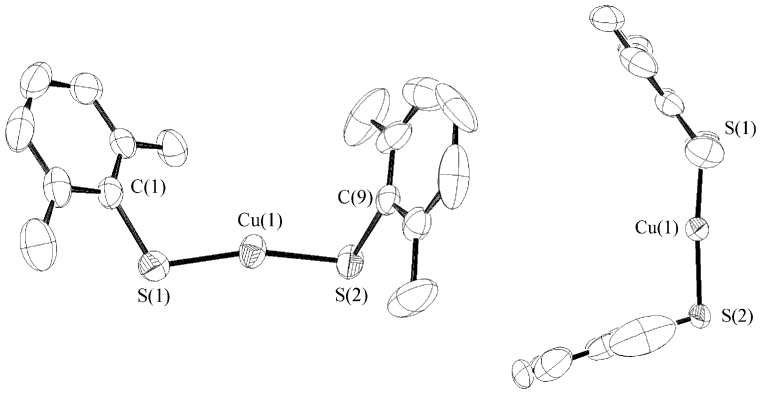


Figure 4. ORTEP drawing of the $[Cu\{S(o,o'\text{-}Me_2C_6H_3)\}_2]^-$ anion in **4b** showing 50% probability ellipsoids. H atoms, the counterion, and disorder have been omitted for clarity.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

linearity and the fact that the aromatic rings of the ligands both face in the same direction as the Cu–S bonds in this solid-state structure.

Complex **4b** may thus be considered as a basic structural model of copper metallochaperone proteins, which feature a two-coordinate copper(I) center bound to two thiolato ligands.[4,33] It has been suggested that additional coordination of a third ligand to the copper atom may take place in the natural systems,[4,9,10,35,36] and further support for this notion comes from the S–Hg–S angle observed in the X-ray structure of Atx1 (167°).[4] This actually means that **3b** bears a high coordination resemblance to the active site of Atx1, resulting from its simple steric demands and crystal packing, without the protein folding surroundings.

### Polynuclear Clusters

Complex **1b** was the only product that we were able to identify in several reactions with ligand **1a**, both according to X-ray crystallography and NMR spectroscopy (see above). In contrast, all other bulkier ligands (**2a**–**4a**; Scheme 1) allowed the identification of trace amounts of a polynuclear complex under conditions similar to those applied for formation of the mononuclear complexes **2b**–**4b**, although with a small difference in the applied stoichiometric ratio of ligand/metal in some cases. Thus, another type of colorless single crystals was obtained from the same reaction flask where **2b** had been crystallized following the reaction of the sodium salt of **2a** with the copper(I) precursor in a ligand/metal ratio of about 1.5:1. The X-ray structure of these crystals indicated the formation of the dinuclear complex $[Et_4N]_2[Cu_2\{\mu\text{-}S(o\text{-}i\text{Pr}C_6H_4)\}_2\{S(o\text{-}i\text{Pr}C_6H_4)\}_2]$ (**2c**; Figure 5); selected bond lengths and angles are summarized in Table 3.

Complex **2c** features a $C_2$-symmetric $Cu_2SC^{Ar}_4$ core where the two copper(I) centers are each three-coordinate with very high planarity, as shown by the value of 360.0° for the sum of the S–Cu–S angles around each metal center. Two thiolato ligands are terminal and two bridge the two metal atoms, thereby preserving the 2:1 ligand/metal ratio, with a total of two $Et_4N^+$ counterions. Two of the aromatic rings of the thiolato ligands face in the same direction, giving rise to a nonpropeller-type geometry. The Cu–S bond lengths of the bridging ligand (2.30–2.34 Å) are longer than those of the terminal ones (2.18–2.19 Å), as expected, and similar values are observed between each bridging ligand and the copper centers, thus indicating a similar average bond for the symmetrical core. Naturally, one S–Cu–S angle for each metal atom (90.4–91.0°) is more acute than the other two (123.9–145.0°) to accommodate the four-membered ring of the Cu–S–Cu–S core. Additionally, the steric demands of the ring also contribute to rather acute Cu–S–Cu angles (mean value of 67.5°). The Cu···Cu distance is 2.584 Å, with no evidence of a metal–metal interaction. To the best of our knowledge, this is the first example of a dinuclear thiolatocopper(I) complex where both copper atoms are three-coordinate.

Table 3. Selected bond lengths [Å] and angles [°] for the dianion of **2c**.

| $[Cu_2\{\mu\text{-}S(o\text{-}i\text{Pr}C_6H_4)\}_2\{S(o\text{-}i\text{Pr}C_6H_4)\}_2]^{2-}$ | | | |
|---|---|---|---|
| Cu(1)–S(1) | 2.340(1) | S(1)–Cu(1)–S(2) | 91.00(4) |
| Cu(1)–S(2) | 2.300(1) | S(2)–Cu(1)–S(3) | 145.05(4) |
| Cu(1)–S(3) | 2.180(1) | S(3)–Cu(1)–S(1) | 123.94(4) |
| Cu(2)–S(1) | 2.338(1) | S(1)–Cu(2)–S(2) | 90.44(4) |
| Cu(2)–S(2) | 2.325(1) | S(2)–Cu(2)–S(4) | 127.56(4) |
| Cu(2)–S(4) | 2.188(1) | S(4)–Cu(2)–S(1) | 142.00(4) |

Under similar conditions to those that led to **3b** as discussed above (Scheme 1), both in terms of reaction procedure and crystallization conditions, formation of another type of light yellow crystals was observed. X-ray analysis revealed their structure to be $[Et_4N]_2[Cu_4\{\mu\text{-}S(o\text{-}t\text{Bu}C_6H_4)\}_6]$ (**3c**), as shown in Figure 6; selected bond lengths and angles are summarized in Table 4.

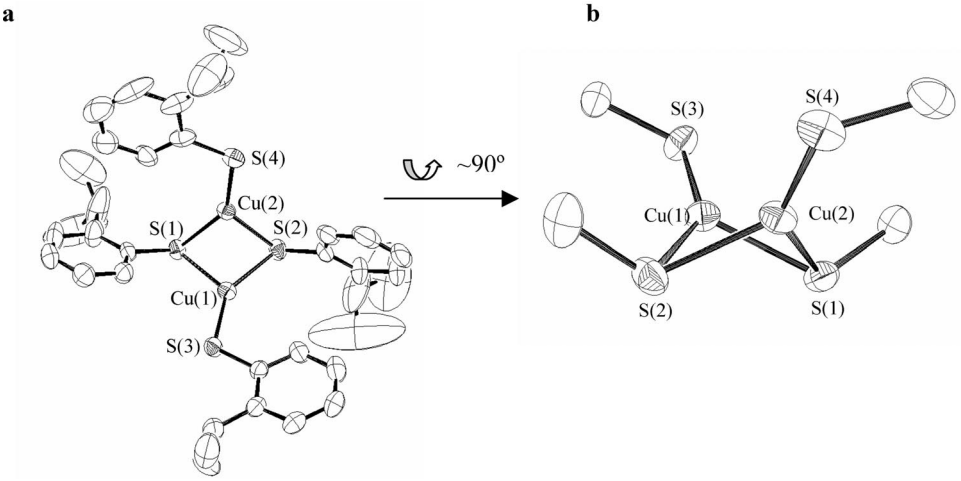

Figure 5. ORTEP drawings of the $[Cu_2\{\mu\text{-}S(o\text{-}i\text{Pr}C_6H_4)\}_2\{S(o\text{-}i\text{Pr}C_6H_4)\}_2]^{2-}$ dianion of **2c** (50% probability ellipsoids) showing the full structure (a) and a structure where the aromatic rings of the ligands have been omitted for clarity (b). H atoms, counterions, and solvent molecules have also been omitted for clarity in both structures.

The structure features an adamantane-like tetrahedron of metal atoms enveloped by a disordered octahedron of six $\mu_2$-thiolato ligands.[22–24,27–30,37–39] Each of the six ligand units in the tetranuclear copper(I) cluster bridges the edges of the tetrahedral array of copper atoms, and each copper center is three-coordinate with high planarity of the trigonal geometry (sum of the angles around the copper center of 359.6–359.9°), with a total of two $Et_4N^+$ counterions. The high $T_d$ symmetry of the core is reduced by the substituted aromatic ligands and their position, where the aromatic rings on two of the bound thiolato ligands for three of the four copper atoms [Cu(1), Cu(2), and Cu(3); Figure 6] face in opposite directions rather than giving the propeller-type geometry observed for Cu(4).[24] The ranges of Cu–S bond lengths (2.24–2.33 Å) and S–Cu–S angles (99–138°, with a mean value of 119.0°)[24] are somewhat broader than the equivalent values obtained for **1b**–**3b**, and the Cu···Cu distances (2.71–2.78 Å) provide no significant structural evidence for a copper–copper interaction. The Cu–S–Cu angles lie in a somewhat narrower range (72.0–74.6°). The Cu–S bond lengths, Cu···Cu distances, S–Cu–S angles, and Cu–S–Cu angles are also all similar to those obtained for other $Cu_4S_6$ clusters of ligands having no significant steric bulk, including both aliphatic thiolato ligands[22,27,30] and thiophenolato ligands having no *ortho* substituents,[23,24,29] which are commonly obtained from $Cu^{II}$ precursors with higher ligand/metal stoichiometric ratios. In addition, these values deviate only slightly from the ideal values of 2.64 Å for a Cu···Cu distance and 2.29 Å for a Cu–S distance in such cores,[22,23] which suggests that the *ortho* substituents do not have much effect on the metal–sulfur core.

The disubstituted ligand **4a** (Scheme 1) also leads to a polynuclear structure upon treatment of its sodium salt with the copper(I) precursor under the reaction conditions used for the synthesis of **4b**. The pentanuclear complex $[Et_4N][Cu_5\{\mu\text{-}S(o,o'\text{-}Me_2C_6H_3)\}_6]$ (**4c**) crystallized from dichloromethane at –30 °C as pale-yellow single crystals suitable for X-ray crystallography. The structure of this complex is presented in Figure 7 and selected bond lengths and angles are summarized in Table 5.

The structure features a trigonal bipyramid of copper atoms within a trigonal antiprism of $\mu_2$-thiolato ligands, with a $D_3$-symmetrical core.[25,31,32] A single $Et_4N^+$ cation counters the cluster charge. Three of the five copper atoms in the cluster of **4c** are two-coordinate and two are three-coordinate. The three-coordinate centers have a trigonal geometry with a somewhat reduced planarity (sum of the angles around the metal atom 358.7°). All six thiolato ligands are bridging, with Cu–S distances of 2.24–2.29 Å that are rather similar to the ones obtained for previous three-coordinate structures. The shorter distances to the two-coordinate metal atoms (2.17–2.19 Å) are only slightly shorter than those obtained for **4b**. The S–Cu–S angles range from 112 to 130° for the three-coordinate copper atoms, which is only a slightly broader range than that obtained for **1b**–**3b**. The S–Cu–S angles for the two-coordinate copper atoms are 164–166°, similar to the value obtained for **4b**, and again deviate significantly from linearity. The mean value of the Cu–S–Cu angles (75.5°) is somewhat higher than that

observed for the smaller cluster in **3c**. The Cu···Cu distances range between 2.67 and 3.88 Å, with no significant structural evidence for a metal–metal interaction. The $Cu_5S_6$-type cluster observed for **4c** is less common but is nonetheless similar in its general geometry to other previously reported $Cu_5S_6$ core structures that have been obtained mainly from $Cu^{II}$ precursors with aliphatic thiolato ligands exhibiting no significant steric bulk, with higher ligand/metal stoichiometric ratios.[20,25,31,32]

## Conclusions

We have obtained a series of mononuclear thiolatocopper(I) complexes accompanied by a series of polynuclear clusters obtained from the same ligands under similar reaction conditions. Clearly, increasing the steric bulk around the metal atom by adding a second substituent in the position *ortho* to the thiol group reduces the coordination number. Generally, the preferred coordination number of the metal atom obtained with ligands inducing small steric effects is three, regardless of the stoichiometric ratio employed. This coordination number was obtained with a ligand having no *ortho* substituents as well as with a range of ligands singly *ortho*-substituted, namely, with H to *t*Bu *ortho* groups, both in the mononuclear complexes and in all of the copper atoms in the polynuclear structures obtained from these ligands. Two-coordinate copper(I) centers have only been observed with the dimethylthiophenolato ligand, which has two *ortho* substituents, both in the mononuclear complex and for three of the copper centers in the pentanuclear cluster. Additionally, if we consider the steric effects produced by the ligands to follow the order 2 *ortho*-Me groups > 1 *ortho*-*t*Bu group > 1 *ortho*-*i*Pr group > 0 *ortho* substituents (H atoms), when exploring the clusters obtained taking this order into consideration we find that the larger the steric bulk the larger the cage that is formed under the conditions employed, with the smallest dinuclear structure exhibiting a unique geometry that has not been observed previously with related ligands. Tuning steric effects can therefore have a major influence on the coordination sphere of the copper(I) complexes obtained.

## Experimental Section

4-*tert*-Butylthiophenol (**1a**; 97%), 2-isopropylthiophenol (**2a**; tech. 90%), 2,6-dimethylthiophenol (**4a**; 95%), and tetraethylammonium bromide (98%) were purchased from Aldrich Chemical Company Inc. and used without further purification. 2-*tert*-Buthylthiophenol (**3a**; tech. 80%) was purchased from Alfa Aesar Inc. and used without further purification. Tetraethylammonium chloride (98%) was purchased from Sigma Inc. and used without further purification. Copper chloride (CuCl) was purchased from Fluka Inc. and used without further purification. All syntheses that required a conditions were performed in an M. Braun dry box or under nitrogen using Schlenk line techniques. Anhydrous dmf was purchased from Aldrich Chemical Company Inc. and used without further purification. All other solvents were distilled from K or K/benzophenone under nitrogen and stored in the dry box. X-ray diffraction data were obtained with a Bruker Smart Apex diffractometer. CCDC-647993 to -647999 contain the supplementary crystallographic data

for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Center via www.ccdc.cam.ac.uk/data_request/cif. NMR spectroscopic data were recorded with an AMX-300 or AMX-400 Bruker spectrometer. Elemental analysis was performed in the microanalytical laboratory of our institute. Reliable elemental analysis for complexes of coordination number higher than two could not be performed due to their enhanced susceptibility to oxidation.

**$[Et_4N]_2[Cu\{S(p\text{-}tBuC_6H_4)\}_3]$ (1b):** A suspension of sodium hydride (0.58 mmol) in 2 mL of thf was added to a solution of **1a** (0.25 mmol) in thf (2 mL) at room temp. under nitrogen. Copper(I) chloride (0.13 mmol) in thf (2 mL) was added to a solution of tetraethylammonium bromide (0.13 mmol) in thf (2 mL) at room temp. under nitrogen and the two solutions were stirred separately in sealed flasks for 24 h. The solution containing the ligand was then added to the solution containing the copper salt and the reaction mixture was stirred overnight. The thf was removed under reduced pressure, and colorless crystals of **1b** (33 mg, 49%) were obtained from thf at –30 °C. $^1$H NMR (300 MHz, $CDCl_3$, $Me_4Si$, 25 °C): $\delta$ = 7.2 (d, $J$ = 8.3 Hz, 6 H, Ar), 6.9 (d, $J$ = 8.3 Hz, 6 H, Ar), 3.2 (q, $J$ = 7.2 Hz, 16 H, $NCH_2CH_3$), 1.2 (s, 27 H, $t$Bu), 1.2 (tt, $J$ = 7.2, 1.8 Hz, 24 H, $NCH_2CH_3$) ppm. **Crystal Data:** Complex **1b** was crystallized from thf at –30 °C. The asymmetric unit contains five anions and ten cations and is disordered. $C_{46}H_{79}CuN_2S_3$, $M$ = 819.83, triclinic, $a$ = 20.317(3), $b$ = 25.894(3), $c$ = 27.231(3) Å, $\alpha$ = 109.280(2), $\beta$ = 101.349(2), $\gamma$ = 96.776(2)°, $V$ = 12997(3) Å$^3$, $T$ = 173(2) K, space group $P\bar{1}$, $Z$ = 10, $\mu$(Mo-$K_\alpha$) = 0.569 mm$^{-1}$, 146212 reflections measured, 56251 unique ($R_{int}$ = 0.1079). $R(F_o^2)$ for [$I > 2\sigma(I)$] = 0.2100, $Rw$ for [$I > 2\sigma(I)$] = 0.4616.

**$[Et_4N]_2[Cu\{S(o\text{-}iPrC_6H_4)\}_3]$ (2b):** Complex **2b** was synthesized in analogy to **1b** by treating a solution of **2a** (0.28 mmol) previously stirred with sodium hydride (0.46 mmol) in dmf with a solution of copper chloride (0.19 mmol) previously stirred with tetraethylammonium chloride (0.21 mmol) in dmf. Colorless crystals of **2b** (17 mg, 23%) were obtained from hexane and thf by slow diffusion at room temp. $^1$H NMR (300 MHz, $CDCl_3$, $Me_4Si$, 25 °C): $\delta$ = 7.7 (dd, $J$ = 7.5, 1.5 Hz, 3 H, Ar), 7.0 (dd, $J$ = 7.4, 1.8 Hz, 3 H, Ar), 6.8 (dt, $J$ = 7.3, 1.7 Hz, 3 H, Ar), 6.7 (dt, $J$ = 7.2, 1.8 Hz, 3 H, Ar), 4.0 [sept, $J$ = 6.9 Hz, 3 H, $CH(CH_3)_2$], 3.1 (q, $J$ = 7.3 Hz, 16 H, $NCH_2CH_3$), 1.2 [d, $J$ = 6.9 Hz, 18 H, $CH(CH_3)_2$], 1.2 (tt, $J$ = 7.28, 1.5 Hz, 24 H, $NCH_2CH_3$) ppm. **Crystal Data:** Complex **2b** was crystallized from hexane and thf by slow diffusion at room temp. The asymmetric unit contains two anions and four cations. $C_{43}H_{73}CuN_2S_3$, $M$ = 777.75, orthorhombic, $a$ = 24.386(2), $b$ = 24.543(2), $c$ = 15.3518(14) Å, $V$ = 9188.4(14) Å$^3$, $T$ = 100(2) K, space group $P2(1)2(1)2$, $Z$ = 8, $\mu$(Mo-$K_\alpha$) = 0.640 mm$^{-1}$, 98306 reflections measured, 18045 unique ($R_{int}$ = 0.0521). $R(F_o^2)$ for [$I > 2\sigma(I)$] = 0.0488, $Rw$ for [$I > 2\sigma(I)$] = 0.1290.

**$[Et_4N]_2[Cu\{S(o\text{-}tBuC_6H_4)\}_3]$ (3b): 3b** was synthesized in analogy to **1b** by treating a solution of **3a** (0.49 mmol) previously stirred with sodium hydride (0.62 mmol) in dmf with a solution of copper chloride (0.23 mmol) previously stirred with tetraethylammonium chloride (0.26 mmol) in dmf. Colorless crystals of **3b** (70 mg, 52%) were obtained from hexane and thf by slow diffusion at room temp. $^1$H NMR (300 MHz, $CDCl_3$, $Me_4Si$, 25 °C): $\delta$ = 7.6 (br. s, 3 H, Ar), 7.1 (br. s, 3 H, Ar), 6.7 (s, 6 H, Ar), 3.2 (q, $J$ = 7.2 Hz, 16 H, $NCH_2CH_3$), 1.5 (s, 27 H, $t$Bu), 1.16 (tt, $J$ = 7.2, 1.8 Hz, 24 H, $NCH_2CH_3$) ppm. **Crystal Data:** Complex **3b** was crystallized from hexane and thf by slow diffusion at room temp. The asymmetric unit contains two anions, four cations, and solvent. $C_{46}H_{79}CuN_2S_3$·0.5thf, $M$ = 855.88, monoclinic, $a$ = 16.607(4), $b$ = 25.473(6), $c$ = 23.608(5) Å, $\beta$ = 102.922(4)°, $V$ = 9734(4) Å$^3$, $T$ = 100(1) K, space group $Ia$, $Z$ = 8, $\mu$(Mo-$K_\alpha$) = 0.611 mm$^{-1}$, 53563 reflections measured, 21026 unique ($R_{int}$ = 0.0406). $R(F_o^2)$ for [$I > 2\sigma(I)$] = 0.0749, $Rw$ for [$I > 2\sigma(I)$] = 0.1903.

**$[Et_4N][Cu\{S(o,o'\text{-}Me_2C_6H_3)\}_2]$ (4b):** Complex **4b** was synthesized in analogy to **1b** by treating a solution of **4a** (0.51 mmol) previously stirred with sodium hydride (0.70 mmol) in thf with a solution of copper chloride (0.30 mmol) previously stirred with tetraethylammonium chloride (0.32 mmol) in thf. Colorless crystals of **4b** (57 mg, 48%) were obtained from hexane and thf by slow diffusion at room temp. $C_{24}H_{38}CuNS_2$ (468.25): calcd. C 61.56, H 8.18, N 2.99; found C 62.01, H 8.44, N 3.10. $^1$H NMR (400 MHz, $CDCl_3$, $Me_4Si$, 25 °C): $\delta$ = 6.9 (d, $J$ = 7.4 Hz, 4 H, Ar), 6.7 (t, $J$ = 7.4 Hz, 2 H, Ar), 2.7 (q, $J$ = 7.3 Hz, 8 H, $NCH_2CH_3$), 2.5 (s, 12 H, $CH_3$), 1.0 (tt, $J$ = 7.3, 1.7 Hz, 12 H, $NCH_2CH_3$) ppm. **Crystal Data:** Complex **4b** was crystallized from hexane and thf by slow diffusion at room temp. The asymmetric unit contains one anion, one cation and one disordered S atom. $C_{24}H_{38}CuNS_2$, $M$ = 468.21, monoclinic, $a$ = 11.0173(8), $b$ = 14.5458(11), $c$ = 15.5467(12) Å, $\beta$ = 101.0680(10)°, $V$ = 2445.1(3) Å$^3$, $T$ = 173(2) K, space group $P2_1/c$, $Z$ = 4, $\mu$(Mo-$K_\alpha$) = 1.074 mm$^{-1}$, 27240 reflections measured, 5808 unique ($R_{int}$ = 0.0554). $R(F_o^2)$ for [$I > 2\sigma(I)$] = 0.0564, $Rw$ for [$I > 2\sigma(I)$] = 0.1269.

**$[Et_4N]_2[Cu_2\{\mu\text{-}S(o\text{-}iPrC_6H_4)\}_2\{S(o\text{-}iPrC_6H_4)\}_2]$ (2c):** Complex **2c** was synthesized similarly to **2b** by treating a solution of **2a** (0.28 mmol) previously stirred with sodium hydride (0.46 mmol) in dmf with a solution of copper chloride (0.19 mmol) previously stirred with tetraethylammonium chloride (0.21 mmol) in dmf. Colorless crystals of **2c** (approx. 10 mg, 10%) were obtained from hexane and thf by slow diffusion at room temp. **Crystal Data:** Complex **2c** was crystallized from hexane and thf by slow diffusion at room temp. The asymmetric unit contains one anion and two cations. $C_{52}H_{84}Cu_2N_2S_4$, $M$ = 992.53, monoclinic, $a$ = 15.1590(9), $b$ = 17.7437(10), $c$ = 20.2433(12) Å, $\beta$ = 90.9740(10)°, $V$ = 5442.0(6) Å$^3$, $T$ = 173(2) K, space group $P2_1/c$, $Z$ = 4, $\mu$(Mo-$K_\alpha$) = 0.969 mm$^{-1}$, 59897 reflections measured, 11892 unique ($R_{int}$ = 0.0291). $R(F_o^2)$ for [$I > 2\sigma(I)$] = 0.0702, $Rw$ for [$I > 2\sigma(I)$] = 0.1970.

**$[Et_4N]_2[Cu_4\{\mu\text{-}S(o\text{-}tBuC_6H_4)\}_6]$ (3c):** Complex **3c** was synthesized similarly to **3b** by treating **3a** (0.34 mmol) previously stirred with sodium hydride (0.66 mmol) in dmf with copper chloride (0.39 mmol) previously stirred with ammonium chloride (0.39 mmol) in dmf solution. Pale-yellow crystals of **3c** (approx. 8 mg, 10%) were obtained from hexane and thf by slow diffusion at room temp. **Crystal Data:** Complex **3c** was crystallized from hexane and thf by slow diffusion at room temp. The asymmetric unit contains one anion and two cations. $C_{76}H_{118}Cu_4N_2S_6$, $M$ = 1506.24, monoclinic, $a$ = 18.4258(14), $b$ = 29.451(2), $c$ = 21.0690(16) Å, $\beta$ = 101.9630(10)°, $V$ = 11185.0(15) Å$^3$, $T$ = 100(2) K, space group $Ia$, $Z$ = 4, $\mu$(Mo-$K_\alpha$) = 0.890 mm$^{-1}$, 59102 reflections measured, 24286 unique ($R_{int}$ = 0.0730). $R(F_o^2)$ for [$I > 2\sigma(I)$] = 0.0879, $Rw$ for [$I > 2\sigma(I)$] = 0.2423.

**Keywords:** Chiral complexes / Cobalt / Chiral amino alcohols / Supramolecular chemistry / Ligand-controlled nuclearity

Chiral amino alcohol based tridentate Schiff bases, derived from 5-OMe-, 5-H-, and 5-$NO_2$-substituted salicylaldehydes and (*S*)-(+)-2-phenylglycinol and (*S*)-(–)-2-amino-3-phenyl-1-propanol, were found to act as versatile ligands in their coordination behavior towards cobalt and gave a range of complexes like mononuclear low-spin $Co^{III}$ complexes, mixed-valence trinuclear $Co^{III}$–$Co^{II}$–$Co^{III}$ complexes, and a mixed-valence tetranuclear $(Co^{III})_3Co^{II}$ complex on 1:1 molar ratio reaction with $Co(CH_3COO)_2{\cdot}4H_2O$ in methanol at room temperature. The steric and electronic properties of these ligands are found to control the overall geometry and nuclearity of the resulting complexes. 5-OMe-Substituted ligands ($\mathbf{H_2L^1}$ and $\mathbf{H_2L^2}$) gave mononuclear low-spin $Co^{III}$ complexes $[CoL^1(HL^1)]{\cdot}0.25DMF$ (**1**) and $[CoL^2(HL^2)]{\cdot}0.25DMF$ (**2**). Single-crystal X-ray structure analysis of complex **2** revealed that the relevant complex crystallizes with four mononuclear units in the asymmetric unit ($Z' = 4$), and these units self-assemble through O–H···O hydrogen-bonding interactions resulting in the formation of homochiral supramolecular helices in the crystal lattice. The 5-H- and 5-$NO_2$-substituted ligands ($\mathbf{H_2L^3}$, $\mathbf{H_2L^4}$, $\mathbf{H_2L^5}$) afforded mixed-valence trinuclear $Co^{III}$–$Co^{II}$–$Co^{III}$ complexes $[Co(CoL^3{}_2)_2{\cdot}H_2O]{\cdot}2DMF{\cdot}2H_2O$ (**3**), $[Co(CoL^4{}_2)_2{\cdot}H_2O]{\cdot}2DMF{\cdot}H_2O$ (**4**), and $[Co(CoL^5{}_2)_2{\cdot}DMF]{\cdot}2DMF{\cdot}H_2O$ (**5**), respectively. Crystal structure analyses of complexes **3** and **5** revealed rare trinuclear geometries of these complexes, in which two terminal octahedral low-spin $Co^{III}$ complexes act as chelating ligands for a central high-spin $Co^{II}$ center through alkoxide bridging. For steric reasons, the central cobalt adopts a highly distorted geometry in these complexes viz. distorted trigonal bipyramidal in complex **3** and distorted square planar in complex **5**. The ligand $\mathbf{H_2L^6}$ gave an interesting tetranuclear mixed-valence complex, $H[Co(CoL^6{}_2)_3]{\cdot}H_2O$ (**6**), in which three octahedral low-spin $Co^{III}$ complexes act as ligands for a central high-spin $Co^{II}$ center in distorted trigonal prismatic geometry. Interestingly, the three types (mononuclear: **1**, **2**; trinuclear: **3**, **4**, **5**; tetranuclear: **6**) of complexes showed large variations in their nuclearity and overall geometry despite the fact that the experimental conditions for all these complexes were identical. This fact highlights the influence of different substitutions on ligands in determining the final geometry of the resulting complexes in these reactions. Complexes **1**–**6** were characterized by elemental and routine spectral analyses. Compounds **2**, **3**, **5**, and **6** have been unequivocally characterized by single-crystal X-ray structure determinations as well. Chiral properties of these complexes were confirmed by circular dichroism (CD) spectral studies.

## Introduction

Synthesis of enantiopure metal complexes having predetermined properties is an important task in modern chemistry; one successful approach towards this goal being the use of well designed chiral ligands.[1] The quest for the development of improved chiral ligand systems necessitates the identification of novel and versatile chiral sources, in addition to the traditional chiral pools such as natural amino acids.[2] Presently, chiral amino alcohols have emerged as a promising chiral source for the preparation of asymmetric catalysts, chiral auxiliaries, and biologically relevant compounds.[3] Schiff bases of chiral amino alcohols are widely employed in catalysis and complexes of these ligands with various metal ions have been successfully employed as catalysts for a number of asymmetric transformations.[4] A thorough understanding of the coordination properties of such ligands will, therefore, be of great importance in designing more efficient systems. Structural studies including single-crystal X-ray crystallography can reveal the collective as well as complex roles of various structure-directing elements (such as steric and electronic effects) of the ligand systems in determining the overall geometry, and hence properties, of the resulting complexes. However, the number of structurally characterized amino alcohol based chiral complexes is surprisingly limited in the literature.[5]

At the same time, identification of new cobalt-containing proteins in recent years (e.g., nitrile hydratase, methionine aminopeptidase etc.) points to the need to acquire a much wider knowledge of the coordination properties of cobalt in various ligand environments, especially chiral environments.[6] Chiral amino alcohol based Schiff bases, with their phenolic and alcoholic donor groups and potential for steric and electronic fine-tuning, are suitable candidates for bioinorganic modeling studies as well. In our efforts to understand the structure-directing effects of chiral amino alcohol based ligands on the coordination properties of biologically and catalytically relevant metal ions,[7] we report here the syntheses, crystal structures, and properties of some fascinating enantiopure cobalt complexes **1**–**6**, derived from chiral amino alcohol based Schiff bases $\mathbf{H_2L^1}$–$\mathbf{H_2L^6}$ (Scheme 1).

Scheme 1.

We have described herein how the steric and electronic properties of substituents 'X' and 'Y' on the ligand backbone (see Scheme 1) affect the overall geometry and nuclearity of this series of compounds **1**–**6** in identical experimental conditions. It was found that, the 5-OMe-substituted ligands ($\mathbf{H_2L^1}$ and $\mathbf{H_2L^2}$) furnished mononuclear low-spin $Co^{III}$ complexes $[CoL^1(HL^1)]\cdot 0.25DMF$ (**1**) and $[CoL^2(HL^2)]\cdot 0.25DMF$ (**2**). The 5-H- and 5-$NO_2$-substituted ligands ($\mathbf{H_2L^3}$, $\mathbf{H_2L^4}$, $\mathbf{H_2L^5}$) are responsible for the isolation of mixed-valence trinuclear $Co^{III}$–$Co^{II}$–$Co^{III}$ complexes $[Co(CoL^3{}_2)_2\cdot H_2O]\cdot 2DMF\cdot 2H_2O$ (**3**), $[Co(CoL^4{}_2)_2\cdot H_2O]\cdot 2DMF\cdot H_2O$ (**4**), and $[Co(CoL^5{}_2)_2\cdot DMF]\cdot 2DMF\cdot H_2O$ (**5**) respectively. Interestingly, the combination of X = Ph and Y = $NO_2$ ($\mathbf{H_2L^6}$) afforded a tetranuclear mixed-valence compound $H[Co(CoL^6{}_2)_3]\cdot H_2O$ (**6**) in which three mononuclear low-spin $Co^{III}$ complexes act as ligands for a central high-spin $Co^{II}$ center that is in distorted trigonal prismatic geometry. The following sections describe and analyze the above-mentioned observations in detail.

## Results and Discussion

### Synthesis and Characterization of Chiral Ligands $H_2L^1$–$H_2L^6$

The chiral ligands (Scheme 1) were synthesized in good yields by the Schiff base condensation of 1 equiv. of salicylaldehyde/substituted salicylaldehyde with 1 equiv. of the respective chiral amino alcohol in methanol solutions at room temperature. The IR spectra of all the ligands show broad peaks in the range of 3210–3500 $cm^{-1}$ because of the phenolic and alcoholic OH groups. Peaks observed around 1600, 1490, and 1450 $cm^{-1}$ are most probably due to aromatic C=C stretching vibrations. These Schiff bases exhibit a $\nu$(C=N) band in the range of 1626–1649 $cm^{-1}$ and the peaks in the range 1028–1070 $cm^{-1}$ are assigned to alcoholic C–O stretching. $\nu_{asym}$ and $\nu_{sym}$ stretches of the –$NO_2$ group present in ligands $\mathbf{H_2L^5}$ and $\mathbf{H_2L^6}$ appear at 1545, 1350 and 1543, 1346 $cm^{-1}$ respectively.[8]

The electronic absorption spectra of the chiral Schiff base ligands $\mathbf{H_2L^1}$–$\mathbf{H_2L^6}$ in acetonitrile solvent exhibit characteristic absorption bands at about 320 and 255 nm, which are assigned to transitions of the intramolecularly hydrogen-bonded salicylidenimino chromophore. These ligands also show circular dichroism (CD) spectra that have multiple Cotton effects corresponding to the electronic absorption maxima (see Figure S2 in the electronic supporting information for a representative CD and an electronic spectral curve for the ligand $\mathbf{H_2L^1}$). The negative sign of these observed Cotton effect bands can be correlated with the absolute configuration of the respective amino alcohol moiety.[9]

### Synthesis of Complexes 1–6

Complexes **1**–**6** were synthesized by reacting one molar equivalent of the corresponding Schiff base ligand with one molar equivalent of cobalt acetate tetrahydrate in methanol solutions at room temperature. The red-brown solutions thus obtained were evaporated completely and subsequently extracted with dichloromethane (DCM). The DCM solutions on evaporation gave dark red-brown solids that were recrystallized from dimethylformamide (DMF) solutions. Coordination of the imine nitrogen to the metal center is seen in the $\nu$(C=N) IR band of the complexes in the range 1651–1641 $cm^{-1}$. In some complexes, this value is found to be slightly higher than that of the uncoordinated Schiff base. Although this is uncommon, it has been reported in the literature.[10] The strong band at ca. 1540 $cm^{-1}$ is characteristic of the phenolic C–O stretching mode acquiring partial double bond character through conjugation with the imine system in chelate rings. The C=C stretch appears at ca. 1600 $cm^{-1}$ as a shoulder band. Elemental analytical data of the complexes did not conform to a general molecular formula. Based on elemental and other characterization data, described in the following sections, it was found that complexes **1**–**6** showed variations in their nuclearity and overall geometry despite the fact that the experimental con-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

ditions were identical. It was also found that all the complexes contain at least one $Co^{III}$ center in their molecular structure, probably formed by the oxidation of $Co^{II}$ acetate used in the syntheses. Atmospheric oxygen is the possible oxidizing agent here, and this oxidation is facilitated by the alkoxide and phenoxide groups present on the ligands. $\mathbf{H_2L^1}$ and $\mathbf{H_2L^2}$ gave mononuclear low-spin $Co^{III}$ complexes, while ligands $\mathbf{H_2L^3}$, $\mathbf{H_2L^4}$, and $\mathbf{H_2L^5}$ gave mixed-valence trinuclear $Co^{III}$–$Co^{II}$–$Co^{III}$ complexes. The ligand $\mathbf{H_2L^6}$ gave an interesting tetranuclear cobalt complex with rather uncommon trigonal prismatic geometry around the central cobalt. Tetradentate Schiff base–oxovanadium complexes having electron-donating or -withdrawing groups at the 5-position of the salicylaldehyde moieties are reported to show similar structural diversity, where the 5-MeO-substituted complex is monomeric and the 5-H- and 5-$NO_2$-substituted complexes are found to be polymeric.[11]

In order to rule out the possibility that the observed changes in nuclearity of complexes **1**–**6** might have been caused by slight changes in the experimental conditions rather than the influence of ligand substitutions, the synthetic reactions of complexes **1**–**6** were carefully reproduced many times and in each case the reported products were obtained in good yields as the main product, confirming that the substitution on the ligand backbone is mainly responsible for the observed changes in nuclearity.

## Electronic and Circular Dichroism Spectra of Complexes 1–6

The electronic and circular dichroism spectra of complexes **1**–**6** were recorded in acetonitrile solutions. The electronic spectra show two weak bands in the 650–700 nm and 520–535 nm ranges. These bands are tentatively assigned to $^1A_{1g} \rightarrow {}^1T_{1g}$ and $^1A_{1g} \rightarrow {}^1T_{2g}$ ligand field transitions respectively, characteristic of an octahedral $Co^{III}$ center.[12] It appears that the relatively high intensities of these d-d

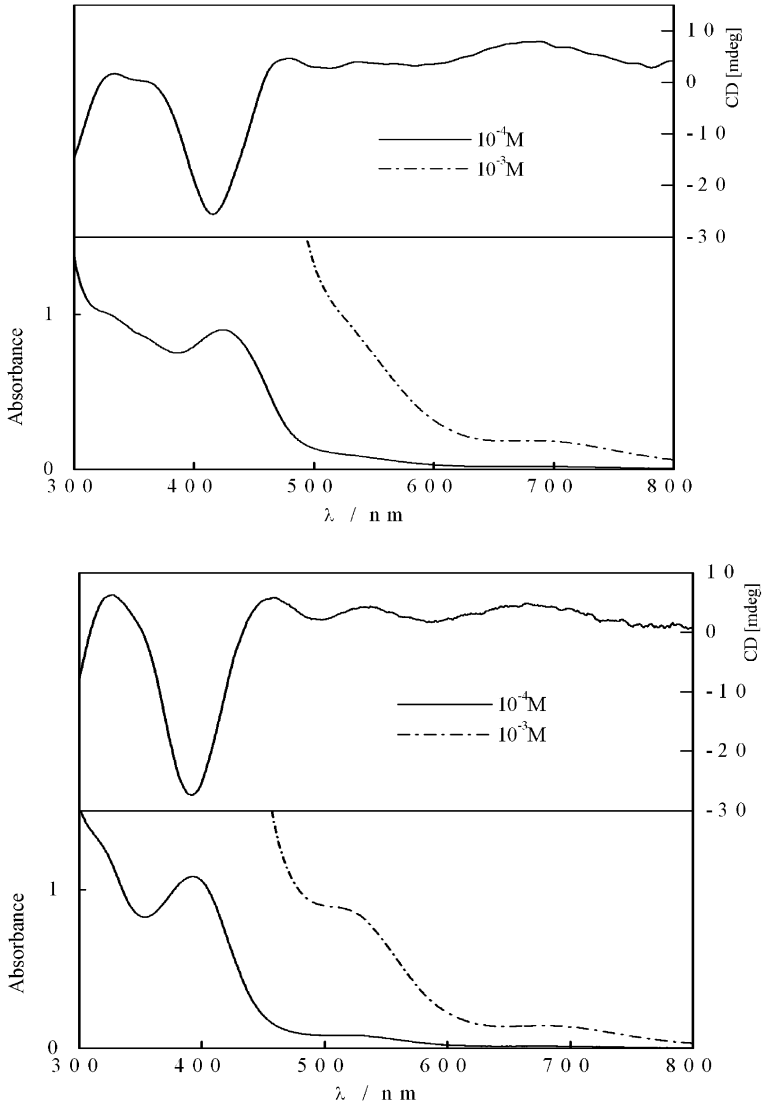

Figure 1. The electronic and circular dichroism spectra of complexes **1** (top) and **3** (bottom).

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

bands are due to strong tail-from-charge transfer transitions. The intense band observed around 400 nm is assigned to phenolate $(O^{-})p_{\pi} \rightarrow Co^{III}$ charge-transfer transition (LMCT). The other intense transitions in the spectra are assigned to intraligand charge-transfer transitions (ILCT). The transitions due to $Co^{II}$ centers are not observed in mixed-valence complexes **3**–**6**, probably because these transitions might have been obscured by the intense absorptions due to $Co^{III}$ centers of these complexes.[13] Two representative electronic absorption spectra are shown in Figure 1.

A general blueshift in band positions is observed for these complexes with electron-withdrawing substituents on ligands. This blueshift originating from the electron-withdrawing nature of the substituents has been observed previously in some similar complexes.[14]

The circular dichroism spectra of these complexes show bands corresponding to their respective electronic absorptions. The visible bands due to the d-d transitions are positive, while the charge transfer transitions appear as negative Cotton effects. The electronic and CD spectra of complexes **1**–**6** are similar despite their structural changes. The appearance of $Co^{III}$ d-d bands for all six complexes confirms the presence of at least one $Co^{III}$ center in each of the complexes. The representative CD curves are presented in Figure 1.

### Magnetic Properties

The magnetic susceptibility measurements of complexes **1**–**6** were performed on powdered samples at room temperature. Complexes **1** and **2** were found to be diamagnetic, as expected for a low-spin $Co^{III}$ state. Magnetic moments in the range of 3.4–5.1 BM were observed for complexes **3**–**6**, which indicate the presence of a high-spin $Co^{II}$ center ($S$ = 3/2) with three unpaired electrons in these complexes. The magnetic properties of polynuclear complexes are extremely sensitive to structural modifications. The $Co^{II}$ center present in these complexes (**3**–**6**) is found to exist in a variety of structural environments ranging from distorted trigonal bipyramidal in **3** to distorted trigonal prismatic in complex **6**. Therefore, the large spread of the observed $\mu_{eff}$ values for these complexes is attributed to their geometric distortions that influence the magnitude of the ligand field splitting. The observed low effective magnetic moment for complex **3** (3.4 B.M.) implies that the orbital contribution to the spin-only value (3.87 B.M.) is fairly small in this complex.

### Crystal Structure of Complex 2

Single crystals of complex **2** suitable for X-ray crystallography were grown from DMF solutions by slow evaporation method. The complex crystallizes in the chiral space group orthorhombic $P2_12_12_1$. The asymmetric unit consists of four mononuclear cobalt complexes and one solvent DMF molecule. The cobalt complexes are almost octahedral in shape and their tridentate ONO donor Schiff base ligand binds the metal in a meridional manner. The molecular geometry and the atom-labeling scheme for a representative mononuclear unit are given in Figure 2 (see Table S4 in the electronic supporting information for selected bond lengths and bond angles for this complex). Although the respective hydrogen atoms are not located in the difference Fourier maps, it is assumed that in each mononuclear unit one of the ligands is doubly deprotonated while the second

(a) (b)

Figure 3. O–H···O hydrogen-bonding interaction pattern in the asymmetric unit of complex **2** resulting in hydrogen-bonded dimers.

one is singly deprotonated. It is observed that in each mononuclear unit one of the Co–$O_{alk}$ bond lengths is considerably longer than the other [for example Co1–O2 1.906(5) Å while Co1–O5 1.944(4) Å], probably for the above-mentioned reason. This conclusion is also consistent with the overall charge balance of the system. The average Co–$O_{phe}$ [1.882(5) Å], Co–$O_{alk}$ [1.932(5) Å], and Co–$N_{imi}$ [1.902(6) Å] bond lengths are within the range reported for low-spin $Co^{III}$ complexes.[15] The room-temperature magnetic-moment measurements showed that the complex is diamagnetic, also indicating a low-spin $Co^{III}$ complex.

The four mononuclear cobalt complexes present in the asymmetric unit self-assemble through intermolecular O–H···O interactions resulting in the formation of homochiral supramolecular helices in the crystal lattice (Figures 3 and 4).

Each mononuclear complex contains two alcoholic oxygen atoms, one of which is protonated and the other deprotonated. The protonated alcoholic oxygen atom acts as the hydrogen-bond donor while the deprotonated alcoholic oxygen atom acts as the acceptor. The four mononuclear complexes can be labeled as Co1, Co2, Co3, and Co4 (Figure S4, supporting information). The complexes Co1 and Co2 are interconnected by a strong hydrogen bond between alcoholic oxygen atoms O2 and O8 [O2···O8 2.442(6) Å] and exist as a hydrogen-bonded dimer as shown in Figure 3 (a). Similarly, the mononuclear units Co3 and Co4 also exist as a dimer (Figure 3, b), formed by the hydrogen-bonding interactions between alcoholic oxygen atoms O14 and O23 [O14···O23 2.386(7) Å]. These independent dimers are further linked to each other through two O–H···O interactions [O5···O17 2.464(6) Å and O11···O20 2.425(6) Å] resulting in supramolecular hydrogen-bonded homochiral helices in the relevant crystal lattice, as presented in Figure 4. The resulting O–H···O interactions are strong, as evident from the rather short O···O distances.

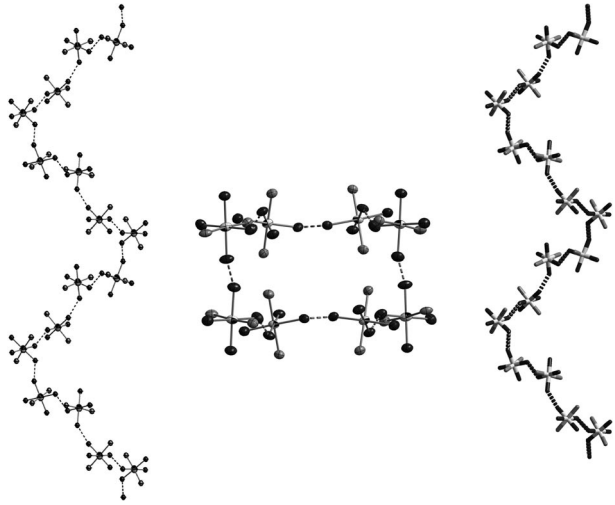

Figure 4. View illustrating intermolecular O–H···O hydrogen-bonding interactions among adjacent molecules that lead to the formation of supramolecular homochiral helices in the crystal lattice of complex **2**. Left: ball-and-stick representation. Right: wire frame representation of the helix. Middle: view down the crystallographic *b* axis showing the helical groove.

One full turn of the helix contains eight mononuclear complexes (Figure 4, left and right), that is, each hydrogen-bonded dimer (Figure 3) in the asymmetric unit repeats twice in one helical turn. The pitch distance is found to be 25.508 Å. The path of the helix can be traced by following the hydrogen bonds counter-clockwise around the twofold screw axis of the helix. The complex is chiral and the crystal contains only one enantiomer of the complex. This local

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

chirality translates into the formation of only left-handed helices on the supramolecular level. Figure 4 clearly depicts the hydrogen-bonding pattern in the asymmetric unit and the mode of propagation of helices in the crystal lattice.

### Crystal Structure of Complex 3

The single crystals of complex **3** suitable for X-ray analysis were grown from DMF solutions by a slow evaporation method. The complex crystallizes in noncentrosymmetric triclinic space group $P\bar{1}$. X-ray analysis shows that the asymmetric unit of complex **3** contains one trinuclear cobalt complex, two solvent DMF molecules, and two water molecules. The molecular structure, with atom-labeling scheme of the complex, is shown in Figure 5. The relevant crystallographic parameters are given in Table 1 (see Table S5 in the supporting information for selected bond lengths and angles observed in complex **3**).

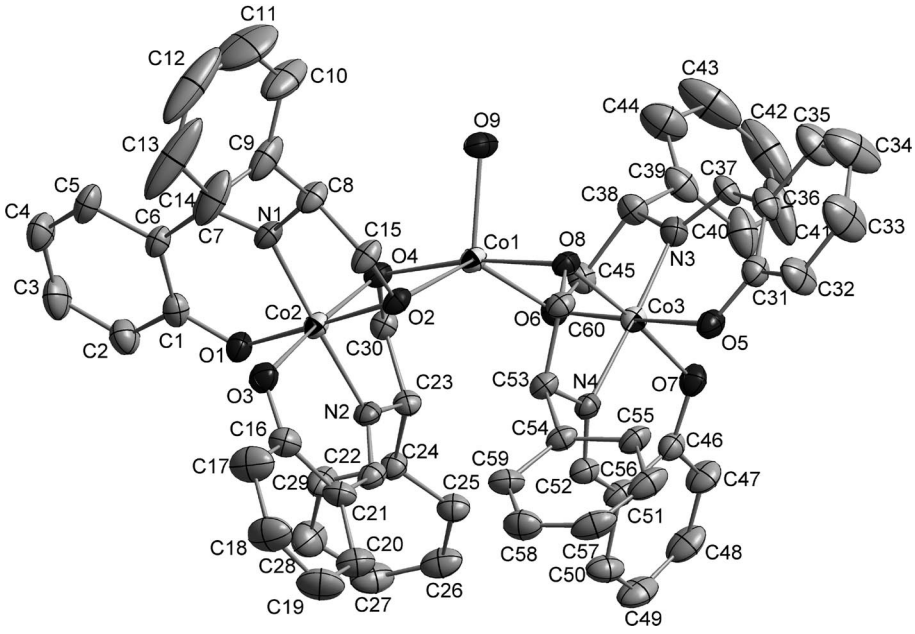

Figure 5. Molecular structure of complex **3** showing atom-labeling scheme. Hydrogen atoms and solvent molecules are omitted for clarity. Thermal ellipsoids are represented by their 30% probability level.

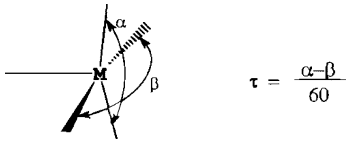
In the trinuclear geometry of complex **3**, the two terminal cobalt centers are distorted octahedral with $N_2O_4$ coordination sphere. The doubly deprotonated Schiff base ligands act as tridentate donors and bind the cobalt ions in a meridional fashion. The square base of the octahedron is made up of two phenoxo oxygen atoms and two alkoxide oxygen atoms, about which the two imine nitrogen atoms are situated at *trans* positions. The average Co–$N_{imi}$ [1.909(5) Å for Co2 and 1.904(6) Å for Co3], Co–$O_{phe}$ [1.880(5) Å for Co2 and 1.900(5) Å for Co3], and Co–$O_{alk}$ [1.914(5) Å for Co2 and 1.904(4) Å for Co3] distances observed are consistent with the corresponding values observed in related octahedral $Co^{III}$ complexes.[15] The observed distortions from ideal octahedral geometry are caused by the small bite angle of the Schiff base group [N2–Co2–O4 83.6(2)° for Co2 and N4–Co3–O8 83.9(2)° for Co3].

These two terminal octahedral cobalt complexes act as chelating ligands to the central cobalt Co1 through alkoxide oxygen bridging. The central cobalt is five-coordinated with an $\{O_5\}$ coordination sphere. The five coordination sites are satisfied by four bridging alkoxide oxygen atoms and a water molecule. The geometry around Co1 can be considered as distorted trigonal bipyramidal in which the axial Co–O bond lengths Co1–O4 and Co1–O8 [av. 2.113(5) Å] are significantly longer than the other three Co–O bonds, which are considered as equatorial bonds [av. 1.994(5) Å]. The distortion along the axial direction is also obvious from the O4–Co1–O8 angle of 170.38(17)°. The $\tau$ value for the central cobalt, as explained by Addison et al.,[16] is calculated to be 0.66, as shown in Scheme 2, confirming a distorted trigonal bipyramidal (tbp) geometry around it ($\tau$ = 1 for ideal trigonal bipyramidal geometry, $\tau$ = 0 for ideal square-pyramidal geometry). This distortion from ideal tbp geometry can be rationalized by the formation of two constrained four-membered rings around Co1 (Figure 5) as a result of the alkoxide oxygen bridging. Steric factors caused by the bulky terminal cobalt centers may also contribute to the observed distortions. The two four-membered rings attached to the central cobalt are inclined to each other at an angle of 54°.



$$\tau = \frac{\alpha - \beta}{60}$$

Scheme 2.

The Co–O bond lengths [av. 2.042(5) Å] around the central cobalt Co1 are significantly longer than those around the terminal cobalt ions, indicating that the central cobalt is divalent while the terminal ones are trivalent. The variations in $Co^{III}$–O and $Co^{II}$–O bond lengths can be expected because the Shannon radius of $Co^{II}$ (0.885 Å) is larger than that of $Co^{III}$ (0.75 Å).[17] The trimer is therefore formulated as a $Co^{III}$–$Co^{II}$–$Co^{III}$ mixed-valence complex, as shown in Figure 5. This assignment is also supported by the fact that there should be two $Co^{3+}$ ions and one $Co^{2+}$ ion in complex **3** to balance the net charge of $8^-$ created by four doubly deprotonated ligands in the molecule.

The average Co···Co separation is found to be 3.011(11) Å in complex **3**, which is considerably smaller than the Co···Co separations [3.821[18a], 3.872,[18b] and 3.066[18c] Å] found in similar mixed-valence trinuclear cobalt complexes. The Co2–Co1–Co3 angle is found to be 136.33(3)°.

There are hydrogen-bonding interactions among the coordinated water molecule and the solvent DMF molecules in the molecular structure of complex **3**. The two DMF molecules are connected to the coordinated water molecule through O–H···O hydrogen-bonding interactions. The relevant O···O distances are O9···O10#1 2.591(9) Å and O9···O11#2 2.610(10) Å where #1 = $x$, 1 + $y$, –1 + $z$ and #2 = $x$, 1 + $y$, $z$ (see Figure S5, electronic supporting information, for hydrogen-bonding in compound **3**).

## Crystal Structure of Complex 5

X-ray analysis on a single crystal of compound **5** indicates that the asymmetric unit of complex **5** contains one trinuclear cobalt complex, two solvent DMF molecules, and one solvent water molecule. The complex crystallizes in the monoclinic space group $P2_1$. Crystallographic details are presented in Table 1.

Quite similar to the structure of complex **3**, the molecular structure of complex **5** also consists of a trinuclear cobalt geometry, as shown in Figure 6. The two terminal cobalt complexes in this molecule are in distorted octahedral $N_2O_4$ coordination sphere and have doubly deprotonated amino alcohol Schiff base ligand $\mathbf{H_2L^5}$ satisfying the coordination sites around the cobalt in a meridional manner. The deviations of bond angles from ideal octahedral values are within ±7° (see supporting information, Table S6). The average Co–$N_{imi}$ [1.887(10) Å for Co2 and 1.912(9) Å for Co3], Co–$O_{phe}$ [1.884(8) Å for Co2 and 1.895(8) Å for Co3], and Co–$O_{alk}$ [1.898(8) Å for Co2 and 1.901(7) Å for Co3] distances observed for the terminal cobalt centers are consistent with corresponding values observed in related octahedral $Co^{III}$ systems.[15]

The two terminal octahedral Co complexes act as chelating units for the central cobalt Co1 through alkoxide oxygen bridging. As expected, the central cobalt is five-coordinated, the fifth coordination site being occupied by a solvent DMF molecule. Two four-membered rings are formed around Co1 as a result of the chelation through alkoxide oxygen atoms by the two terminal cobalt octahedral complexes. Because of this, Co1 assumes a highly distorted geometry, which is almost intermediate between trigonal bipyramidal (tbp) and square-pyramidal (sp), as evidenced by the $\tau$ value of 0.40 (see Scheme 2).[16] It can be concluded from this value that the distortion is more towards square-pyramidal in this case. The two four-membered rings attached to the central cobalt are inclined to each other at an angle of 44°.

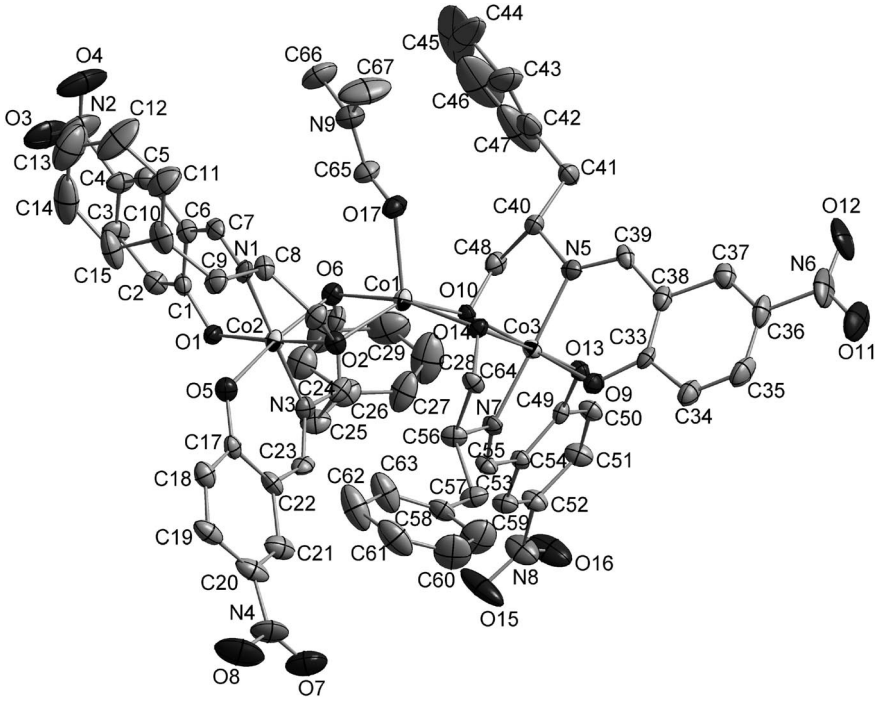

Figure 6. Molecular structure of complex **5** showing atom-labeling scheme. Hydrogen atoms and solvent molecules are omitted for clarity. Thermal ellipsoids are represented by their 30% probability level.

As in the case of complex **3**, the bond lengths around the central cobalt Co1 are significantly longer than those around the terminal cobalt centers in complex **5** as well, indicating that the central cobalt is divalent while the terminal ones are trivalent. The average Co–O distance for Co1 is 2.039(9) Å. Based on the bond length analysis, charge balance, and magnetic moment measurement studies, the trimer in complex **5** can be regarded as a $Co^{III}$–$Co^{II}$–$Co^{III}$ mixed-valence complex.

Similar to complex **3**, the Co···Co separations of 2.992(3) Å [Co2···Co1] and 2.969(3) Å [Co3···Co1] are found to be smaller than the Co···Co separations reported for similar mixed-valence systems.[18] The Co2–Co1–Co3 angle is 140.01(8)°.

### Crystal Structure of Complex 6

The single crystals of complex **6** suitable for X-ray analysis were grown by slow evaporation of DMF solutions. The complex crystallizes in the chiral tetragonal space group $P4_12_12$. The molecular structure and atom-labeling scheme of the complex are presented in Figure 7.

The asymmetric unit contains half of the complex molecule and a solvent water molecule. The crystal structure reveals an interesting tetranuclear geometry for complex **6**, in which three mononuclear cobalt complexes act as chelating ligands for a central cobalt ion. The terminal cobalt complexes are almost octahedral in shape, having two ONO donor Schiff base ligands satisfying the coordination sites of each cobalt in a meridional style.

The central cobalt Co1 is six-coordinated. The coordination polyhedron exhibits, surprisingly, a distorted trigonal

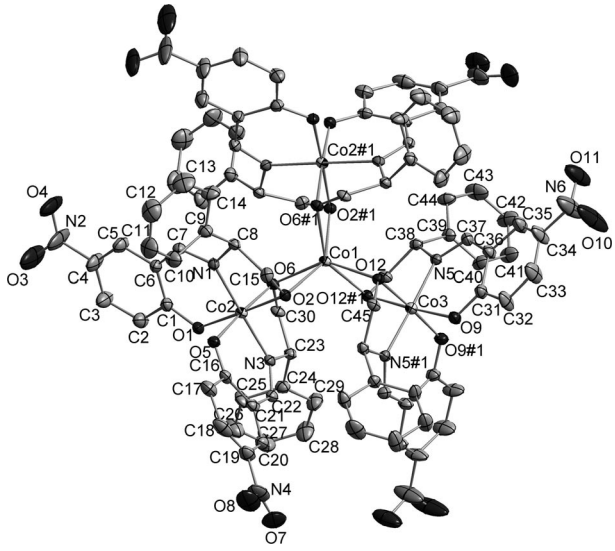

Figure 7. Molecular structure of complex **6** showing atom-labeling scheme. Symmetry-generated atoms are mostly unlabeled. Hydrogen atoms and solvent water molecule are omitted for clarity. Thermal ellipsoids are represented by their 20% probability level.

prismatic (tp) geometry, which is rather scarce for polynuclear cobalt complexes. Four chelating alkoxide oxygen atoms [O2, O6, O12, and O12#1] from cobalt centers Co2 and Co3 form the square base for the trigonal prism. The oxygen atoms O2#1 and O6#1 from the third cobalt center Co2#1, occupy the remaining two vertices to complete the trigonal prismatic coordination sphere around the central Co1 as shown in Figure 8.

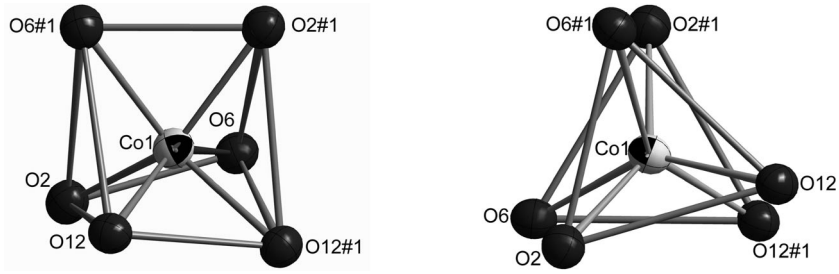

Figure 8. Left: coordination sphere depicting the distorted trigonal prismatic geometry around the central cobalt in complex **6**. Right: view down the trigonal faces of the coordination sphere showing distortion from ideal trigonal prismatic geometry.

The two trigonal faces of the trigonal prism (made up of oxygen atoms O2, O6#1, O12 and O2#1, O12#1, O6) are not equilateral and the square base also shows distortion from ideal geometry. The torsion angle involving opposing corners and the centroids of the trigonal faces are 17.39°, 17.39°, and 16.50° (see Figure 8, right). The distortion from the ideal trigonal prismatic geometry is possibly due to the severe steric overcrowding caused by the three bulky cobalt complexes that act as ligands for the central cobalt ion.

The average Co–$N_{imi}$ [1.897(5) Å for Co2, Co2#1 and 1.875(4) Å for Co3], Co–$O_{phe}$ [1.899(4) Å for Co2, Co2#1 and 1.899(4) Å for Co3], and Co–$O_{alk}$ [1.885(4) Å for Co2, Co2#1 and 1.883(4) Å for Co3] distances observed for terminal cobalt complexes are comparable to the corresponding values observed in related octahedral $Co^{III}$ systems[15] (see supporting information for selected bond lengths and bond angles (Table S7) for complex **6**). The average Co–O bond length of 2.148(3) Å around Co1 is found to be considerably longer than those around the terminal cobalt atoms. By the same argument given in the case of complexes **3** and **5**, it can be assumed that the central cobalt is in 2+ oxidation state. The steric crowding might have caused an additional increase in length of these bonds compared to those in complexes **3** and **5**.

Oxidation state assignment in complex **6** is also supported by the magnetic moment measurements and electronic spectroscopic studies. The electronic spectrum of the complex is similar to the mononuclear $Co^{III}$ complexes **1** and **2**, which indicates the presence of $Co^{III}$ units in the complex. Also the complex shows a net magnetic moment of 5.1 B.M. at room temperature, corresponding to the presence of a high-spin $Co^{II}$ center. If all the tridentate ligands are doubly deprotonated in the molecule, there will be an excess of one negative charge in the complex. It is assumed that this extra negative charge might have been compensated for by one proton (probably because of single deprotonation of one of the ligands) at an unknown position in the complex. A similar situation is reported in the literature for a mononuclear $Co^{III}$ complex with a similar ligand system.[19]

Calculations using the CALC VOID option in PLATON[20] showed a potential solvent access area of 8601.5 $Å^3$ (54.3%) per unit cell of the complex. This fact is also supported by the relatively low $\rho_{calcd}$ value of 0.822 $g\,cm^{-3}$ observed by the X-ray analysis. This void is created as a result of intermolecular C–H···O hydrogen-bonding interactions of the complex with its surrounding molecules, generating a three-dimensional hydrogen-bonded network in the crystal lattice (Figure 9). In these interactions, the oxygen atoms O3, O7, and O10 of the $–NO_2$ group act as the hydrogen-bond acceptor while the aromatic carbon atoms C28, C3, and C11 act as the donors. The relevant hydrogen-bonding

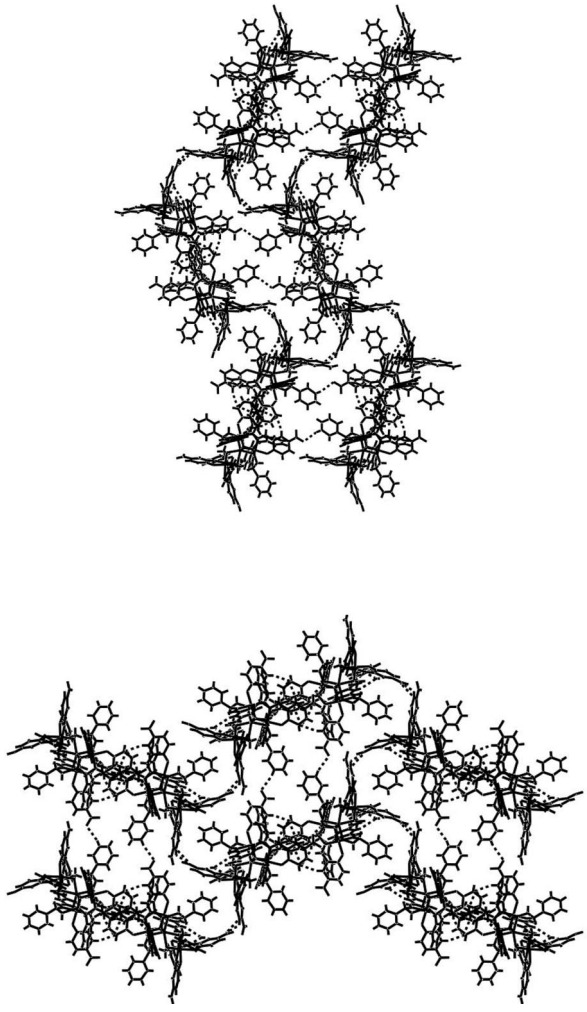

Figure 9. Packing diagrams of complex **6** showing the intermolecular C–H···O hydrogen-bonding interactions that lead to the formation of voids in the crystal lattice. View along the *a* axis (top) and view along the *b* axis (bottom).

parameters are given in the supporting information (Table S8). The extension of hydrogen-bonding interactions in a three-dimensional manner thus leads to porosity in the crystal lattice with an overall solvent access area of above 50% in the unit cell. This area is partly occupied by solvent water molecules. The solvent water oxygen O13 is involved in C–H···O hydrogen-bonding interactions with the complex molecule carbons C20 and C22.

## Conclusions

Many interesting observations are made in this study using simple chiral Schiff base ligands and cobalt acetate. The basic coordination sites and geometries of the ligands $H_2L^1$ to $H_2L^6$ are kept the same, changing the substitution on the salicylaldehyde part and the length of the amino alcohol side chain. It is found that these changes control the overall coordination geometries of the resulting cobalt complexes even though the experimental conditions were identical. Complexes of ligands with unsubstituted and 5-nitro-substituted salicylaldehydes prefer multinuclear arrangement while the methoxy-substituted derivatives prefer mononuclear arrangement. In complexes **1**–**6**, the ligands contain both phenolic and alcoholic OH groups. Although both phenol and alkoxy groups can act as bridging functionalities, in these complexes the phenolic oxygen atoms do not act as a bridging group. In complexes **3**–**6** only alkoxide oxygen atoms were found to act as a bridging group. We can assume that the bridging ability of alkoxide oxygen atoms predominates in these complexes probably because of factors like steric and overall crystal packing effects.

In the multinuclear complexes studied here, the high-spin cobalt(II) adopts geometries ranging from distorted trigonal bipyramidal (tbp) and distorted square-pyramidal (sp) to distorted trigonal prismatic (tp). One of the reasons for such distortions may be steric effects caused by the bulky octahedral cobalt(III) complexes acting as ligands. These new edge-sharing octahedral-tbp/sp/tp-octahedral complexes **3**–**6** are complementary to the previous reports of edge-sharing octahedral-tetrahedral-octahedral and face-sharing all-octahedral trinuclear complexes.[21] From the present study, it is also clear that alkoxide oxygen atoms are capable of stabilizing high-spin cobalt(II) ions in a variety of rare geometrical arrangements.

High-spin $Co^{II}$ has a definite preference for octahedral over trigonal prismatic geometry. The previously reported trigonal prismatic complexes of $Co^{II}$ are mostly made up of rigid multidentate ligands.[22] The structure of complex **6** demonstrates that even bulky coordination complexes can stabilize such a geometry around high-spin $Co^{II}$, despite its preference for octahedral geometry. The extensive hydrogen-bonding interactions and the crystal-packing forces might have played some role in dictating such a geometry around the central cobalt in complex **6**.

The nitro-substituted ligands $H_2L^5$ and $H_2L^6$ gave both tri- and tetranuclear complexes. Here the steric effect of the lengthy side arm might have played a crucial role in dictating the said geometries. The lengthy $CH_2Ph$ group creates more steric crowding around the central cobalt in complex **5**, unlike the Ph-substituted derivative in complex **6**, thus preventing another octahedral complex from approaching and coordinating to it.

The crystal structures of complexes **3** and **5** belong to the limited number of structurally characterized trinuclear cobalt complexes with mixed oxidation states. There are two main reported classes of trinuclear cobalt complexes of mixed-spin states. One includes mixed-valence trinuclear complexes of the form $Co^{III}$($S$ = 0)–$Co^{II}$($S$ = 3/2)–$Co^{III}$ ($S$ = 0),[13,18f] and another, mixed-spin trinuclear complexes of the form $Co^{II}$ ($S$ = 1/2)–$Co^{II}$ ($S$ = 3/2)–$Co^{II}$ ($S$ = 1/2).[23] The trinuclear complexes **3**–**5** discussed here belong to the former category.

Finally, it has been shown that the tridentate chiral Schiff base ligands $H_2L^1$–$H_2L^6$ are very versatile in their coordination behavior towards cobalt and can readily form stable mono-, tri-, and tetranuclear chiral complexes with interesting structural features. Besides the isolation, characterization, and analysis of properties of chiral mono-, tri-, and tetranuclear cobalt complexes, we have demonstrated that the introduction of a different substitution on the ligand backbone can result in unexpected structural modifications of resulting complexes.

## Experimental Section

**General Information:** Microanalytical (C,H,N) data were obtained with a FLASH EA 1112 Series CHNS Analyzer. A Shimadzu 3101-PC UV/Vis/NIR spectrophotometer was used to record the electronic spectra. Infrared spectra were recorded by using KBr pellets with a Jasco-5300 FTIR spectrophotometer. $^1$H NMR spectra in $CDCl_3$ solutions were recorded with a Bruker DRX-400 spectrometer, using $Si(CH_3)_4$ as an internal standard. Room temperature solid-state magnetic susceptibilities were measured by using a Sherwood Scientific magnetic susceptibility balance. The CD spectra were measured in solution phase with a JASCO J-810 spectropolarimeter. Salicylaldehyde, 5-nitrosalicylaldehyde, 5-methoxysalicylaldehyde, (*S*)-(+)-2-phenylglycinol, and (*S*)-(–)-2-amino-3-phenyl-1-propanol were purchased from Lancaster (India) and used as received. Solvents used for UV/Vis and CD analyses were of HPLC grade and procured from E. Merck (India). All other chemicals were of analytical grade and were used without further purification.

**Synthesis of Chiral Schiff Bases $H_2L^1$–$H_2L^6$:** The synthesis and characterization of chiral Schiff bases $H_2L^3$, $H_2L^4$, $H_2L^5$, and $H_2L^6$ have been reported elsewhere.[7]

**$H_2L^1$:** (*S*)-(+)-2-Phenylglycinol (0.137 g, 1 mmol) and 5-methoxysalicylaldehyde [2-hydroxy-5-methoxybenzaldehyde] (0.152 g, 1 mmol) were stirred together in methanol (15 mL) for 3 h at room temperature. The resulting yellow solution was filtered and the filtrate was kept open at room temperature for slow evaporation. A yellow solid, thus obtained, was washed with hexane and dried at room temperature. Yield 0.25 g, 92%. $C_{16}H_{17}NO_3$ (271.31): calcd. C 70.83, H 6.32, N 5.16; found C 70.77, H 6.25, N 5.11. IR (KBr): $\tilde{\nu}$ = 3485, 2860, 1635, 1589, 1491, 1272, 1157, 1068, 1028, 902, 831, 790, 761, 700, 534, 457 cm$^{-1}$. $^1$H NMR (400 MHz, $CDCl_3$): $\delta$ = 3.77 (s, 3 H, $OCH_3$), 3.92–3.94 (d, $J$ = 6.5 Hz, 2 H, $CH_2$), 4.46–4.49 (t, $J$ = 6.44 Hz, 1 H, CH), 6.78–6.94 (m, 3 H, Ar), 7.26–7.39

(m, 5 H, Ar), 8.45 (s, 1 H, HC=N) ppm. UV/Vis ($CH_3CN$): $\lambda_{max}$ ($\varepsilon$, $M^{-1}cm^{-1}$) = 343 (5039), 258 (10309) nm. CD ($CH_3CN$, $10^{-4}$ M): $\lambda_{max}$ (mdeg) = 343 (–12.70), 258 (–19.80) nm.

**$H_2L^2$:** (*S*)-(–)-2-Amino-3-phenyl-1-propanol (0.151 g, 1 mmol) and 5-methoxysalicylaldehyde (0.152 g, 1 mmol) were stirred together in methanol (15 mL) for 3 h at room temperature. The resulting yellow solution was filtered and the filtrate was kept open for slow evaporation. A yellow semi-solid was obtained and washed with hexane and dried at room temperature. Yield: 0.26 g, 90%. $C_{17}H_{19}NO_3$ (285.34): calcd. C 71.56, H 6.71, N 4.91; found C 71.3, H 6.56, N 5.01. IR (KBr): $\tilde{\nu}$ = 3422, 1635, 1591, 1493, 1379, 1334, 1271, 1224, 1159, 1037, 908, 821, 761, 702 $cm^{-1}$. $^1H$ NMR (400 MHz, $CDCl_3$): $\delta$ = 2.8–3.0 (m, 2 H, $CH_2$), 3.51 (m, 1 H, CH), 3.73 (s, 3 H, $OCH_3$), 3.77–3.82 (m, 2 H, $CH_2$-OH), 6.57–6.95 (m, 3 H, Ar), 7.13–7.27 (m, 5 H, Ar), 8.03 (s, 1 H, HC=N) ppm. UV/Vis ($CH_3CN$): $\lambda_{max}$ ($\varepsilon$, $M^{-1}cm^{-1}$) = 343 (5025), 258 (7916), 230 (20892) nm. CD ($CH_3CN$, $10^{-4}$ M): $\lambda_{max}$ (mdeg) = 343 (–11.6), 258 (–19.2) nm.

**$H_2L^5$:** (*S*)-(–)-2-Amino-3-phenyl-1-propanol (0.151 g, 1 mmol) and 5-nitrosalicylaldehyde (0.167 g, 1 mmol) were stirred together in methanol (15 mL) for 3 h at room temperature. The resulting yellow solution was filtered and the filtrate was kept for 2 d in an open beaker for slow evaporation. The yellow precipitate of **$H_2L^5$** thus obtained was washed with hexane and dried at room temperature. Yield 0.27 g, 90%. $C_{16}H_{16}N_2O_4$ (300.31): calcd. C 63.99, H 5.37, N 9.33; found C 64.05, H 5.29, N 9.18. IR (KBr): $\tilde{\nu}$ = 3470, 1649, 1618, 1543, 1487, 1446, 1404, 1346, 1226, 1134, 1064, 941, 904, 835, 756, 729, 700, 630 $cm^{-1}$. $^1H$ NMR (400 MHz, $CDCl_3$): $\delta$ = 2.97 (m, 2 H, $CH_2$-Ph), 3.65 (m, $^1H$, CH), 3.86 (m, 2 H, $CH_2$-OH), 6.92 (d, 1 H, Ar, *ortho* to OH), 7.2 (m, 5 H, Ar), 8.04 (s, 1 H, HC=N), 8.06 (d, 1 H, Ar, *ortho* to $NO_2$), 8.15 (m, 1 H, Ar, *ortho* to $NO_2$) ppm. UV/Vis ($CH_3CN$): $\lambda_{max}$ ($\varepsilon$, $M^{-1}cm^{-1}$) = 401 (6950), 325 (9931), 260 (17447), 240 (17111) nm. CD ($CH_3CN$, $10^{-4}$ M): $\lambda_{max}$ (mdeg) = 401 (–2.66), 320 (–4.66), 260 (–5.85), 240 (–3.85) nm.

**Synthesis of Cobalt Complexes 1–6:** All six cobalt complexes **1**–**6**, reported here, were prepared according to the following general procedure.

$(CH_3COO)_2Co{\cdot}4H_2O$ (0.249 g, 1 mmol) was added to a methanolic solution (25 mL) of the respective chiral ligand (1 mmol). The mixture was stirred at room temperature in air overnight. The resultant dark red-brown solution was evaporated to dryness using a rotavapor and a vacuum pump. The solid thus obtained was extracted with dichloromethane and evaporated to give a red-brown microcrystalline solid, which was recrystallized from a solution of DMF.

**$[CoL^1(HL^1)]{\cdot}0.25DMF$ (1):** Yield 0.23 g, 74%. $C_{32}H_{31}CoN_2O_6{\cdot}0.25C_3H_7NO$ (616.81): calcd. C 63.77, H 5.35, N 5.11; found C 64.06, H 5.29, N 5.23. IR (KBr): $\tilde{\nu}$ = 2928, 1635, 1539, 1469, 1423, 1298, 1259, 1219, 1157, 1033, 947, 819, 769, 702, 528, 418 $cm^{-1}$. **X-ray Crystallography:** A summary of the crystallographic data for compounds **2**, **3**, **5**, and **6** is given in Table 1. Data for complexes **2**, **3**, and **6** were collected at room temperature with a Bruker SMART APEX CCD area detector system [$\lambda$(Mo-$K_\alpha$) = 0.71073 Å], graphite monochromator, 2400 frames were recorded with an $\omega$-scan width of 0.3°, crystal-detector distance 60 mm, collimator 0.5 mm. The data were reduced using SAINTPLUS[24] and a multiscan absorption correction using SADABS[24] was performed. The structures were solved by direct methods and refined on $F^2$ by full-matrix least-squares procedures using SHELX-97 programs.[25] Hydrogen atoms were introduced on calculated positions and included in the refinement riding on their respective parent atoms. The absolute configurations for the complex molecules were successfully determined by refining the respective Flack parameters.[26] In the case of complex **2**, all the non-hydrogen atoms are refined anisotropically. The hydrogen atoms associated with some of the alcoholic oxygen atoms were not located in the difference Fourier maps. For complex **3**, all the non-hydrogen atoms except that of the uncoordinated solvent molecules are refined anisotropically. Some of the benzene rings show disorder and some restraints were applied. Hydrogen atoms were not located in association with coordinated and solvent water molecules. For complex **6**, the $R_{int}$ value was considerably higher (0.1235). Such a high $R_{int}$ value is attributed to the long *c* axis [46.257(3) Å] and the subsequent difficulty in neatly resolving adjacent reflections and to the low diffraction power of the relevant crystal characterized by a large fraction of weak intensities. Also this particular complex contains a large amount of void space. All the non-hydrogen atoms except the water oxygen are refined anisotropically. The hydrogen atoms associated with the sol-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

vent water molecule are not located in the difference Fourier maps. Single crystals of complex **5** were grown by slow evaporation of a dimethylformamide solution. Unit cell determination and the data collection were performed on an Enraf–Nonius Mach3 single-crystal diffractometer using graphite-monochromated Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 Å). An empirical absorption correction was applied to the data based on the $\psi$-scans of three reflections.[27] Programs of WinGX[28] were used for data reduction and absorption correction. The structure was solved by direct methods and refined on $F^2$ by full-matrix least-squares procedures using the SHELX-97 program.[25] All the non-hydrogen atoms except the uncoordinated solvent molecules were refined anisotropically. Some benzene rings show disorder and some restraints were applied. Hydrogen atoms were not located in association with water molecule oxygen atom. A high $R_{int}$ value (0.1510) observed in this case is probably due to the low diffraction power of the crystal characterized by a large fraction of weak intensities.

CCDC-651783 (for **2**), -651784 (for **3**), -651785 (for **5**), and -651786 (for **6**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Center via www.ccdc.cam.ac.uk/data_request/cif.

**Supporting Information** (see also the footnote on the first page of this article): Detailed synthesis and characterization of the Schiff bases (ligands) $\mathbf{H_2L^1}$–$\mathbf{H_2L^6}$; representative $^1$H NMR spectrum of $\mathbf{H_2L^6}$; representative UV and CD spectra of $\mathbf{H_2L^1}$; crystal structure description of the ligand $\mathbf{H_2L^5}$; additional figures for crystal structures of the complexes; tables (selected bond lengths and angles) for compounds **2**, **3**, **5**, and **6**; a table for hydrogen-bonding parameters for compound **6**; a table for summary of electronic spectra and room temperature magnetic moments for compounds **1**–**6**.

# Critical Effect of Phosphane Ligands on the Mechanism of Carbon–Carbon Bond Formation Involving Palladium(II) Complexes: A Theoretical Investigation of Reductive Elimination from Square-Planar and T-Shaped Species

**Valentine P. Ananikov,*[a,b] Djamaladdin G. Musaev,[b] and Keiji Morokuma[b]**

**Keywords:** C–C coupling / Palladium / Catalysis / Steric effect / Electronic effect / Phosphane ligands

A theoretical ONIOM study has been carried out to understand the influence of phosphane ligands on the structure of Pd complexes and their reactivity in C–C bond formation. The calculations were performed for Me–Me reductive elimination with the ligands L = $PPh_3$, $PCy_3$, $PMe_3$, $PH_3$, and vinyl–vinyl, Ph–Ph, ethynyl–ethynyl, vinyl–Me, vinyl–Ph and vinyl–ethynyl couplings with L = $PPh_3$ for $[PdR_2L_n]$ complexes ($n$ = 1, 2). The calculations revealed critical changes in the reactivity of palladium complexes depending on the mechanism and ligand type. In the case of the standard four-coordinate pathway ($n$ = 2) the relative reactivity in carbon–carbon bond formation follows the order: L = $PPh_3$ > $PH_3$ > $PCy_3$ > $PMe_3$. However, for reductive elimination involving T-shaped complexes by the ligand predissociation pathway ($n$ = 1), the relative reactivity changes in the order: L = $PCy_3$ > $PPh_3$ > $PH_3$ > $PMe_3$. The theoretical study suggested that the steric effect of phosphane ligands has the largest impact on the structure of the initial palladium complexes, while the electronic effect is most influential on the transition states of C–C coupling in these complexes.

## 1. Introduction

Palladium-catalyzed reactions have had a major impact on developing new synthetic methods for C–C and C–X bond formation.[1–4] On several reactions it was established that the choice of an appropriate phosphane ligand for the palladium complex plays a crucial role in creating and optimizing new catalytic methodologies.[1,2] Utilization of organic chlorides (aryl chlorides, etc.)[5] in cross-coupling reactions is an outstanding recent example of tuning catalytic activity by steric and electronic effects of ligands. The key finding was to carry out the cross-coupling reaction with very electron-rich ligands.[6,7] Undoubtedly, further development of the field strongly depends on our understanding of reaction mechanisms and rationalization of the influence of phosphane ligands, especially on the reactivity of the intermediate metal complexes involved in these catalytic transformations.[8,9]

Different approaches, including IR frequencies, NMR chemical shifts and coupling constants, electronic density distribution, etc.,[10,11] have been developed to characterize steric and electronic effects of phosphane ligands on the ground-state geometry of transition-metal complexes. An attempt has been made to correlate structural and energetic properties of Pt and Pd complexes with steric and electronic properties of phosphane ligands.[12] In contrast to ground-state properties, predicting the reactivity of transition-metal complexes is a much more challenging problem. A recent study has suggested the MESP (Molecular Electrostatic Potential) approach to characterize the electron-donating ability of phosphane ligands.[13] A later work criticized this approach and concluded that MESP is unsubstantiated for characterizing the donating ability of phosphanes.[14] However, a further analysis again provided some evidence that MESP could be a good measure of the electron-donating ability of phosphanes.[15,16] Finally, a recent review on the subject made uncertain conclusions concerning the usage of modern theoretical methods to deal with the problem.[16] This example clearly emphasizes the complexity of the question and indicates the necessity of a clarifying study in this fascinating field.

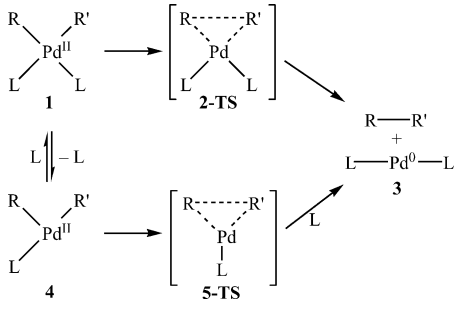
 WILEY InterScience DISCOVER SOMETHING GREAT © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

A very important question concerns the nature of transition-metal complexes involved in the reductive elimination reaction. In a number of experimental reports it has been proposed that phosphane ligand dissociation accelerates C–C and C–X bond formation on Pd and Pt complexes (via T-shaped intermediates).[17,18] A computational study performed for the C–H reductive elimination reaction from Pt complexes with model $PH_3$ and $PMe_3$ ligands has suggested, however, that direct reductive elimination without ligand dissociation is preferred for four-coordinate complexes.[19] The study raises a question concerning the relative reactivity of four-coordinate vs. three-coordinate complexes in C–C bond formation.

The above discussion reveals a rather complex picture of C–C bond formation on transition-metal complexes with strong dependence on the complex type, substituents and ligand environment, which may not find a concise explanation based on available mechanistic knowledge. So far, only simple $PH_3$ and $PMe_3$ ligands were mostly utilized in theoretical studies of C–C bond-formation reactions.[20–25] However, detailed investigation of the systems with real-size ligands is required to link available experimental data with computations.

In the present study we have evaluated the effect of phosphane ligands on C–C bond formation from $Pd^{II}$ complexes (Scheme 1) through the reductive elimination mechanism (**1** → **2-TS** → **3**) involving four-coordinate initial complexes as well as the dissociative pathway (**4** → **5-TS** → **3**) involving three-coordinate species. We have calculated the most frequently used triphenylphosphane ligand ($PPh_3$) and trialkylphosphanes ($PMe_3$ and $PCy_3$) with different bulkiness of the organic groups. For comparative purpose, we have also calculated the $PH_3$ model ligand widely used in earlier theoretical studies.



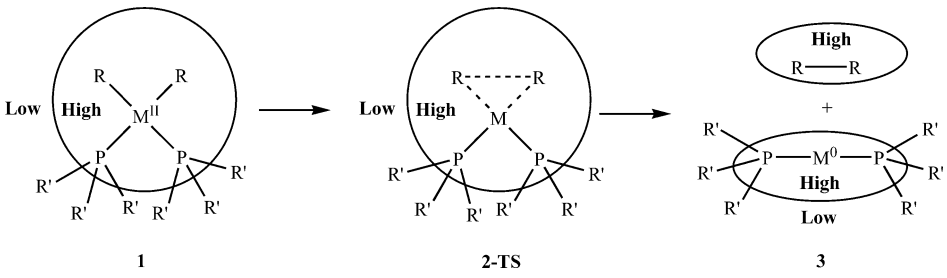
Scheme 1. Carbon–carbon coupling through four-coordinate and three-coordinate mechanisms; R, R′ = $CH_3$, $CH{=}CH_2$, $C_6H_5$, C≡CH; L = $PH_3$, $PMe_3$, $PPh_3$, $PCy_3$.

## 2. Computational Procedure

All calculations were performed by utilizing the two-layer ONIOM approach.[26,27] In the ONIOM partitioning the studied $[MR_2(PR'_3)_2]$ complexes (L = $PR'_3$) were divided into two layers: the first layer includes the ligands R, metal center and phosphorus atoms, and the second layer includes the substituents at the phosphane ligands (R′). A graphical representation of the partitioning scheme is given in Scheme 2.

The first layer was treated at the high B3LYP/BSI level. The basis set BSI consists of the SDD basis set[28] for the metal atom and the 6-311G(d) basis set[29] for the other atoms. The second layer was treated at the relatively low HF/Lanl2mb level. Therefore, this two-layer ONIOM approach used in the present study was denoted as ONIOM-(B3LYP/BSI:HF/Lanl2mb) and it was utilized for geometry optimization and frequency calculations throughout the paper, unless otherwise mentioned. Single-point energy calculations were carried out at the ONIOM(B3LYP/BSI:B3-LYP/Lanl2dz) level by using ONIOM(B3LYP/BSI:HF/Lanl2mb)-optimized geometry: this approach was denoted as ONIOM(B3LYP/BSI:B3LYP/Lanl2dz)//ONIOM(B3LYP/BSI:HF/Lanl2mb).

In the ONIOM studies the normal-coordinate analysis has been performed for all stationary points to characterize the nature of TSs and equilibrium structures and to calculate Gibbs free energies (298.15 K, 1 atm, rigid rotor harmonic oscillator approximation). All calculations were performed without symmetry constraints with the Gaussian 03 program.[30] The reliability of the chosen theory level in geometry optimization and energy calculations has been confirmed by a special study (see Supporting Information).



Scheme 2. Model (the first layer, in circle) and real systems used in the ONIOM calculations, which are treated at high and low levels, respectively.

## 3. Results

First, we analyze the effect of the phosphane ligand on the geometry of the $[Pd(CH_3)_2L_2]$ complexes, followed by a discussion of the potential-energy surfaces of Me–Me coupling for both (four- and three-coordinate) pathways of the reductive elimination reaction. Finally, C–C bond formation between the unsaturated organic groups (vinyl, phenyl and ethynyl) and unsymmetrical couplings will be considered with the triphenylphosphane ligand.

### A. Effect of Phosphane Ligands on the Geometry of the $[Pd(CH_3)_2L_2]$ Complexes (1_A to 1_D)

In this section we analyze how sensitive the geometry parameters of the initial metal complexes are to the nature of the phosphane ligands. Both Pd–C and Pd–P bonds will be involved in the comparison. The shortest Pd–C distance was calculated for the L = $PH_3$ case, and substituted phosphane ligands increased the Pd–C distance by 0.018–0.032 Å (Table 2). The following trend in Pd–C bond length was obtained for the ligands studied (in Å):[31] **1_B** (2.132; L = $PMe_3$) > **1_D** (2.127; L = $PCy_3$) > **1_C** (2.118; L = $PPh_3$) > **1_A** (2.100; L = $PH_3$).

Alkyl-substituted phosphanes gave longer Pd–C bonds relative to L = $PPh_3$ and $PH_3$. The longest Pd–C bond was calculated for L = $PMe_3$ having the smaller substituent size

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

as compared to L = $PCy_3$. However, rather small changes in the bond length do not provide the necessary basis for further analysis. The calculations agree with available experimental data; according to the X-ray studies, M–$C_{methyl}$ distances span a range of 2.08–2.16 Å and are not much sensitive to the identity of the phosphane ligand.[32] Indeed, the influence of the crystal-packing effect may diminish the small differences in M–C bond lengths caused by the ligand effect.

The following trend in Pd–P bond length was calculated for the studied ligands (in Å):[31] **1_D** (2.432; L = $PCy_3$) > **1_C** (2.373; L = $PPh_3$) > **1_A** (2.367; L = $PH_3$) > **1_B** (2.322; L = $PMe_3$)

Longer Pd–P bonds for L = $PCy_3$ can be explained by the bulkiness of this ligand. The presence of large steric repulsions in the case of $PCy_3$ is also evident from increased P–Pd–P angles and decreased C–Pd–C angles, as compared to the other ligands (Table 2). Despite the obvious geometry changes caused by the $PCy_3$ ligand, the overall trend cannot be easily rationalized. Similar conclusions can be drawn upon analysis of experimental geometries determined in X-ray studies.[32]

### B. Effect of the Organic Group on the Geometry of the $[PdR_2(PPh_3)_2]$ Complexes (1_E to 1_J)

The structures **1_E** to **1_G** with unsaturated organic ligands and L = $PPh_3$ (Table 2) can be compared with similar compounds for L = $PH_3$ studied earlier.[23] Introducing Ph substituents into the phosphane ligand increased on average the length of the Pd–C bonds by 0.01–0.03 Å, while the trends in the Pd–P distances and P–Pd–P angles were less pronounced; the average changes were <0.02 Å and <1°, respectively.

It is important to point out that the conformational flexibility of $PPh_3$ caused some deviations towards an asymmetric ligand environment. In fact, Pd–C1 and Pd–C2 bonds, as well as Pd–P1 and Pd–P2 bonds, within the same complex (**1_E** to **1_G**, as well as **1_C**) differ by 0.01–0.02 Å (Table 2). The expected relationship of the shorter Pd–C bond *trans* to the longer Pd–P bond in these complexes originates from the *trans* effect (Table 2). It should be pointed out that experimental X-ray studies have also reported unsymmetrical ligand environments with similar differences in the bond lengths.[32] Finally, in agreement with the discussion in section A, no clear trends between the geometry parameters of the initial complexes and the nature of phosphane ligands can be outlined.

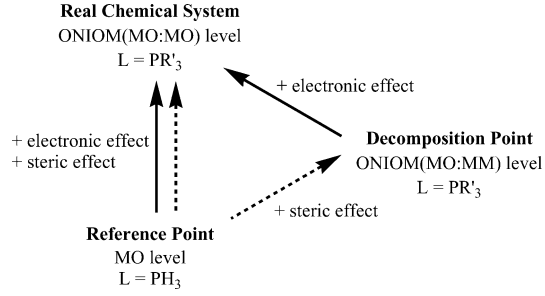
### C. Effect of Phosphane Ligands on the Energetics of Reductive Elimination from the Four-Coordinate $[Pd(CH_3)_2L_2]$ Complexes (1_A to 1_D)

The investigated reductive elimination reactions occur by a concerted mechanism (Figure 1). In such a case, movement along the reaction coordinate involves elongation of Pd–C bonds and an increase in P–Pd–P angles, as well as shortening of C–C bonds and a decrease in C–Pd–C angles. Optimized geometry parameters for the initial complexes and transition states reflect these structural changes (Table 2).

According to the calculated barriers ($\Delta H^{\neq}$), the reactivity of the studied complexes in the reductive elimination reaction decreases in the order (Table 1): **1_C** (L = $PPh_3$) > **1_A** (L = $PH_3$) > **1_D** (L = $PCy_3$) > **1_B** (L = $PMe_3$).

Therefore, the lowest reactivity in C–C bond formation was predicted for the complex with the $PMe_3$ ligand, while the complex with the $PPh_3$ ligand should be the most reactive. All reactions are exothermic; energy gain upon product formation follows the trend: **1_C**, **1_D** > **1_A**, **1_B** (Table 1).[33] The calculated $\Delta E$ and $\Delta H$ values are nearly identical, with a difference of <1.5 kcal/mol. In terms of $\Delta G$ the reactions are highly exoergic (due to the entropy contribution as well), and the activation barriers are slightly decreased (Table 1).[34]

The calculated reactivity order can not be easily understood on the basis of the known properties of the ligands. In order to estimate the electronic and steric effects of the ligand on reaction energetics, we have applied decomposition analysis based on ONIOM calculations at different levels (Scheme 3). The system with the simplest ligand (L = $PH_3$) computed at the MO level was used as a reference point. From the reference point we cannot directly estimate the desired steric and electronic effects in the real chemical system (L = $PR'_3$) calculated at the ONIOM(MO:MO) level. However, the analysis can be simplified by carrying out ONIOM(MO:MM) calculations on the real systems, for the decomposition point, which includes only the steric effect of substituents R′. The difference between the reference and decomposition points provides information about the steric effect in the studied system, while the electronic effect can be revealed by comparing the real system and the decomposition point (Scheme 3).



Scheme 3. ONIOM decomposition analysis to evaluate steric and electronic effects of phosphane ligands in the studied complexes.

For the decomposition point, we have carried out single-point ONIOM(B3LYP/BSI:UFF) calculations with the UFF molecular mechanics force field as the low level (Table 3). Comparison of ONIOM(B3LYP/BSI:UFF) energies for L = $PMe_3$, $PPh_3$, $PCy_3$ with the B3LYP/BSI energy for L = $PH_3$, reveals a small and noncharacteristic change for the $PMe_3$ ligand, while the activation barriers for the $PPh_3$ and $PCy_3$ ligands are decreased by 4–7 kcal/mol (see Tables 1 and 3). This trend is in good qualitative agreement

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

with the steric bulkiness of the ligands: $PCy_3$, $PPh_3 > PMe_3 \approx PH_3$.[35]

Table 3. Calculated $\Delta E$ relative energies of the stationary points **1**, **2-TS** and **3** at the ONIOM(B3LYP/BSI:UFF)//ONIOM(B3LYP/BSI:HF/Lanl2mb) level [kcal/mol].

| System | M | L | $R^1$, $R^2$ | **1** | **2-TS** | **3** |
|---|---|---|---|---|---|---|
| B | Pd | $PMe_3$ | Me | 0.0 | 26.8 | –32.9 |
| C | Pd | $PPh_3$ | Me | 0.0 | 17.8 | –46.7 |
| D | Pd | $PCy_3$ | Me | 0.0 | 20.7 | –43.8 |

In the present metal complexes, the steric effect includes repulsion between the phosphane ligands and between the phosphane and $CH_3$ ligands. These steric repulsions destabilize both the initial complex **1** and the transition state **2-TS**. The decrease in the activation barrier ($\Delta E^{\neq}$) at the ONIOM(B3LYP/BSI:UFF) level suggests that the initial complex **1** is more destabilized by the steric repulsions relative to the transition state **2-TS**.[36] This energy trend is in excellent agreement with geometry parameters, because in the transition state both P–Pd–P and P–Pd–$C_{cis}$ angles become larger. The energy gain ($\Delta E$) calculated at the ONIOM(B3LYP/BSI:UFF) level is almost the same for the $PMe_3$ ligand and significantly higher for the $PPh_3$ and $PCy_3$ ligands relative to the ONIOM(B3LYP/BSI:B3LYP/Lanl2dz) level (see Tables 1 and 3, respectively), which is also evident from minimizing steric repulsions in **3**.

Now we can consider the influence of the electronic effect. In the present system the interaction between the phosphane ligand and the metal center affects both the initial complex and the transition state. The nature of the electronic effect can be revealed by comparative analysis of the ONIOM(B3LYP/BSI:UFF) energy surface, which includes only the steric effect, and the ONIOM(B3LYP/BSI:B3LYP/Lanl2dz) energy surface, which includes both electronic and steric effects. Comparison of the ONIOM(B3LYP/BSI:-UFF) and ONIOM(B3LYP/BSI:B3LYP/Lanl2dz) energies [both evaluated by using the same ONIOM(B3LYP/BSI:HF/Lanl2mb) optimized geometries] has shown that for L = $PMe_3$, $PPh_3$, $PCy_3$, inclusion of the electronic effects increased the activation barriers by 3–8 kcal/mol (see Tables 1 and 3, respectively). This suggests that electronic effects may have more influence on the transition state than on the initial complex.[37] It appears that the weak metal–carbon bond in the transition state is more sensitive to the electronic effect than the relatively strong bond of the initial complex.

### D. Reductive Elimination from the Three-Coordinate $[Pd(CH_3)_2L]$ Complexes (4_A to 4_D) by the Phosphane Ligand Predissociation Mechanism

Another pathway of C–C bond formation may involve phosphane ligand dissociation **1** → **4** followed by **4** → **5-TS** reductive elimination (Scheme 1). Reassociation of the phosphane ligand after releasing the organic product results in the same product, **3**.[38] An example of the optimized structures of **4_C** and **5-TS_C** is shown in Figure 2. Complex **4_C** affords T-shaped geometry with nonequivalent Pd–C bonds, which is shifted towards Y-shaped geometry upon moving to **5-TS_C**. However, the transition-state structure did not become symmetric as was evident from different Pd–C1 and Pd–C2 bond lengths (Table 2) and P–Pd–C angles.[39] Similar geometry changes were also observed for the other three-coordinate structures considered in the present study. Comparing corresponding **2-TS** and **5-TS** geometries, one may clearly notice an earlier character for **5-TS** (shorter Pd–C bonds and longer C–C bonds for **5-TS**, see Table 2).

In agreement with geometry trends, phosphane ligand predissociation significantly lowers activation energies of the reductive elimination process. The calculated **4** → **5-TS** activation barriers on the $\Delta E$, $\Delta H$ and $\Delta G$ surfaces have similar values in the range 11–13 kcal/mol for all of the studied complexes (**4_A** to **4_D**), which are much smaller than **1** → **2-TS** activation barriers of $\Delta H^{\neq}$ = 22–29 kcal/mol (**1_A** to **1_D**). Therefore, if monoligated $[PdR_2L]$ species **4** would be involved as the initial complexes (in such a case ligand predissociation is not required) in the C–C reductive elimination, the reaction would be faster and less sensitive to the ligand effects. In the case of four-coordinate initial complexes the activation barriers **1** → **5-TS** should be considered to estimate the relative reactivity order (because **4** is higher in energy than **1** on the $\Delta H$ surface), which follows the trend (see Table 1): L = $PCy_3$ > $PPh_3$ > $PH_3$ > $PMe_3$.

As evident from Table 1, the potential surface is dramatically influenced by the value of the Pd–P bond energy (energy difference between **4** and **1**). The calculated Pd–P bond energy (in $\Delta H$) for the first phosphane ligand dissociation from the $[Pd(CH_3)_2L_2]$ complexes **1_A** to **1_D** decreases in the order: $PMe_3$ (18.8 kcal/mol) > $PH_3$ (15.0 kcal/mol) > $PPh_3$ (12.1 kcal/mol) > $PCy_3$ (10.6 kcal/mol).

Comparison of the $PH_3$ and $PMe_3$ ligands (both having relatively small steric effects) indicates that electron donation from the ligand to the metal center increases the Pd–P bond energy in the present complexes. However, for the more bulky $PCy_3$ ligand, the steric repulsions in **1** decrease the Pd–P bond energy and facilitate phosphane ligand dissociation. As a result, carbon–carbon bond formation through the **1** → **4** → **5-TS** → **3** pathway for L = $PCy_3$ is energetically even less demanding than that through the **1** → **2-TS** → **3** pathway for L = $PPh_3$ ($\Delta H^{\neq}$ = 21.9 and 22.2 kcal/mol, respectively). The entropy contribution should provide additional energetic favor to the dissociation pathway on the $\Delta G$ surface.[34]

### E. Reductive Elimination of Unsaturated Vinyl, Phenyl and Ethynyl Groups from the Four-Coordinate $[PdR_2(PPh_3)_2]$ Complexes (1_E to 1_G) and the Three-Coordinate $[PdR_2PPh_3]$ Complexes (4_E to 4_G)

Vinyl–vinyl, phenyl–phenyl and ethynyl–ethynyl couplings on $Pd^{II}$ centers with the $PPh_3$ ligand also proceeded through the concerted transition states (Figure S1, Supporting Information). However, these reductive elimination re-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

actions require the overcoming of smaller activation barriers (Table 1). According to the calculated $\Delta H^{\neq}$ values, the reactivity in C–C bond formation among the present complexes follows the trend: **1_E** (vinyl–vinyl) > **1_F** (Ph–Ph) > **1_G** (ethynyl–ethynyl) > **1_C** (Me–Me). The formation of buta-1,3-diene (**3_E**) and biphenyl (**3_F**) is exothermic by $\Delta H \approx$ –43 kcal/mol; the formation of buta-1,3-diyne (**1_G**) is less exothermic with $\Delta H$ = –24.4 kcal/mol.[40]

The Pd–P bond energy increases in the order ($\Delta H$ [kcal/mol]): **1_F** (9.4) < **1_E** (10.5) << **1_G** (20.7) for the vinyl, phenyl and ethynyl complexes, respectively (Table 1). The higher bond energy in the case **1_G** is consistent with the shorter Pd–P bond in this compound (Table 2). Therefore, according to the calculated energetics (Table 1), vinyl–vinyl and Ph–Ph couplings are likely to involve the three-coordinate reaction pathway (**1** → **4** → **5-TS** → **3**), while ethynyl–ethynyl coupling should follow the standard pathway with four-coordinate species (**1_G** → **2-TS_G** → **3_G**). The calculated energetic trend is in excellent agreement with available experimental studies showing that $[Pd(CH_3)_2L_2]$ complexes are rather stable in solution, whereas analogous diphenylpalladium complexes are unstable.[17d,41] It has also been shown that replacement of Me groups by Ph groups in the $PMe_xPh_{3-x}$ ligands increases the rate of C–C bond formation within the catalytic cross-coupling cycle.[1d]

### F. Unsymmetrical Coupling of Methyl–Vinyl, Phenyl–Vinyl and Ethynyl–Vinyl Groups from the Four-Coordinate $[PdR^1R^2(PPh_3)_2]$ Complexes (1_H to 1_J) and the Three-Coordinate $[PdR^1R^2PPh_3]$ Complexes (4_H to 4_J)

Reductive elimination of Me and vinyl groups by the four-coordinate pathway (**1_H** → **2-TS_H** → **3_H**) requires overcoming the activation barrier of $\Delta H^{\neq}$ = 11.1 kcal/mol and is exothermic by $\Delta H$ = –39.8 kcal/mol (Table 1). These values are intermediate between the vinyl–vinyl ($\Delta H^{\neq}$ = 3.0 kcal/mol, $\Delta H$ = –43.7 kcal/mol) and Me–Me ($\Delta H^{\neq}$ = 22.2 kcal/mol, $\Delta H$ = –38.5 kcal/mol) couplings. Thus, the following relative reactivity should be expected: vinyl–vinyl > vinyl–Me > Me–Me. The same relationship was calculated for the other studied unsymmetrical couplings: the vinyl–Ph coupling is intermediate between the vinyl–vinyl and Ph–Ph couplings, and the vinyl–ethynyl coupling is intermediate between the vinyl–vinyl and ethynyl–ethynyl couplings (Table 1).

Remarkably, this tendency remains valid for the three-coordinate pathway,[42] although the difference in activation barriers was rather small (**4** → **5-TS**; $\Delta H$ [kcal/mol]): vinyl–vinyl (2.5) > vinyl–Me (6.6) > Me–Me (12.1); vinyl–vinyl (2.5) > vinyl–Ph (2.9) > Ph–Ph (3.3); vinyl–vinyl (2.5) > vinyl–ethynyl (6.2) > ethynyl–ethynyl (6.4).

Geometry parameters are in line with the energy data and follow the trends discussed above; optimized geometry parameters are listed in Table S1 (see Supporting Information).

## 4. Discussion

It was shown that geometry parameters of initial $[PdR_2L_2]$ complexes are not very sensitive to the nature of the phosphane ligands. Therefore, electronic and steric properties derived from the initial metal complexes or from the free ligands should be used with care for predicting the reactivity of transition-metal complexes. Moreover, the calculations have shown that the influence of the conformational changes on geometry may be of the same order of magnitude as the ligand effects.

Applying ONIOM decomposition analysis, we have found that the steric effect of phosphane ligands mostly influences the initial $Pd^{II}$ complex, while the electronic effect has the greatest impact on the transition state. The larger steric effect of R′ decreases the activation barriers of C–C reductive elimination. The electronic effect changes the reactivity in the opposite manner: inclusion of the electronic effect increases the activation barriers.

In sections 2C and 2D we have analyzed the four-coordinate and three-coordinate pathways separately; here we provide a joint analysis of both pathways to predict the overall reactivity in the studied system. The reductive elimination reaction from $Pd^{II}$ complexes by the four-coordinative pathway follows the trend: L = $PPh_3$ > $PH_3$ > $PCy_3$ > $PMe_3$. However, in the case of the three-coordinate pathway the complex with the tricyclohexylphosphane ligand becomes more reactive: L = $PCy_3$ > $PPh_3$ > $PH_3$ > $PMe_3$.[43] The relative reactivity through these two pathways is determined by the strength of the metal–phosphorus bond. The calculated Pd–P bond dissociation enthalpy for $[Pd(CH_3)_2L_2]$ decreases in the order: L = $PMe_3$ > $PH_3$ > $PPh_3$ > $PCy_3$. Easy dissociation of the $PCy_3$ ligand favors C–C coupling by the three-coordinate pathway. Considering both potential energy surfaces, for L = $PCy_3$ the reaction is most likely to undergo the three-coordinate predissociation pathway involving T-shaped complexes, for L = $PH_3$ and L = $PMe_3$ the classical four-coordinate pathway, and for L = $PPh_3$ both pathways should be accessible.

The results of theoretical studies of C–H reductive elimination from platinum complexes with $PH_3$ and $PMe_3$ ligands[19] are in excellent agreement with our study of C–C bond formation on Pd; for these ligands the four-coordinate pathway should be preferred. At the same time, this indicates that for studies of the ligand effect, $PH_3$ and $PMe_3$ are unreliable models of $PPh_3$ and $PCy_3$. Explicit consideration of substituents is required to obtain agreement with experiment.

Coupling of different organic groups from $[PdR_2(PPh_3)_2]$ complexes was predicted to be in the following reactivity order: vinyl–vinyl > Ph–Ph > ethynyl–ethynyl > Me–Me for the four-coordinate pathway and vinyl–vinyl, Ph–Ph > Me–Me > ethynyl–ethynyl for the three-coordinate pathway. The Pd–P bond dissociation enthalpy depends on the nature of the organic group being eliminated that is attached to the palladium atom as was calculated for the series of $[PdR_2(PPh_3)_2]$ complexes: R = Me, ethynyl > Ph, vinyl. Therefore, vinyl–vinyl and Ph–Ph couplings are

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

likely to proceed by the three-coordinate predissociation pathway; however, ethynyl–ethynyl coupling can start directly from the four-coordinate complex.

Special note should be made concerning the solvent effect. Using PCM calculations it was reported that the solvent effect does not change in a substantial manner the potential energy surfaces of four-coordinate reductive elimination pathways involving neutral metal complexes.[22] In case of the predissociation pathway, the solvent could coordinate to a vacancy in the metal center. However, taking into account that most organic solvents (toluene, benzene, dichloromethane, chloroform, hexanes, etc.) are weakly coordinated to a metal center, this process is unlikely to introduce principal changes to the mechanism.[44]

## 5. Conclusions

The study has clearly shown that the ligand effect on C–C bond formation should be considered in view of the reaction mechanism, otherwise it may be a source of inconsistencies or even erroneous conclusions. The influence of steric and electronic factors depends on the nature of reacting species and the ligand environment as well as the type of organic groups being eliminated.

The calculations revealed that different ligands may involve different mechanisms of the C–C reductive elimination reaction. Among the ligands studied, $PCy_3$ should be used to facilitate the T-shaped pathway by the predissociation mechanism and increase the reactivity. The $PMe_3$ ligand should be utilized for stabilizing the four-coordinate complexes and decrease the reactivity in reductive elimination reactions. The $PPh_3$ ligand represents a more universal choice, since it showed good reactivity for both mechanisms.

According to the calculated activation barriers, the relative reactivity orders were found for a series of C–C coupling reactions involving various organic groups. Particularly, for the four-coordinate pathway: vinyl–vinyl > vinyl–Ph > vinyl–ethynyl > Ph–Ph > vinyl–Me > ethynyl–ethynyl > Me–Me; and for the three-coordinate pathway: vinyl–vinyl > vinyl–Ph > vinyl–ethynyl, Ph–Ph > vinyl–Me, ethynyl–ethynyl > Me–Me. The relative reactivity orders for both pathways coincide, except that rather small activation barriers in the latter case did not allow us to draw a clear distinction for some reactions.

Finally, we would like to point out that ONIOM calculations provide reliable results not only for the evaluation of geometries and energy data, but also for analyzing electronic and steric effects. ONIOM partitioning to high and low levels gives a flexible tool to define a region of interest, whose steric and electronic properties are analyzed.

**Supporting Information** (see footnote on the first page of this article): Testing the reliability of geometry optimization (Section 1). Testing the reliability of energy calculations (Section 2). Optimized structures of the initial complexes, transition states and products for vinyl–vinyl, Ph–Ph and ethynyl–ethynyl coupling from $[PdR_2(PPh_3)_2]$ (Figure S1); their important geometry parameters are given in Table 2 and the energetic data is listed in Table 1. The calculated selected bond lengths [Å] and angles [°] for the systems **H**–**J** at the ONIOM(B3LYP/BSI:HF/Lanl2MB) level (Table S1).

[33] In the present study we do not consider the intermediate σ or π complexes, which may lie on the potential energy surface

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

between **2-TS** and **3**. Stationary point **3** is of most practical importance, since it corresponds to the product-releasing stage of the catalytic reactions. Numerous studies on the structure and stability of σ or π complexes are already available in the literature (see, for example refs.[20–23]).

[34] It should be noted that gas-phase calculations may overestimate the entropy contribution. For that reason we mainly involve the Δ*H* surface in the discussion. Although, it is clearly established that the dissociation process in solution is more favorable on the Δ*G* surface.

[35] An exact quantitative estimation is unlikely to be obtained in this simple comparison scheme.

[36] An opposite case (if TS is more destabilized than the initial complex) would lead to an increase in the activation energy.

[37] An important issue, which should also be considered for the precise evaluation of the electronic and steric effects by this method, is the quality of the force field (for instance, in terms of the correct reproduction of nonbonded repulsions, etc.). The ONIOM(B3LYP:UFF) level covers a broad range of systems and was utilized in the present study; however, further clarification may be required to investigate the scope of this approach in more detail.

[38] In this case intermediate σ or π complexes may undergo a ligand-substitution reaction (see also ref.[33]).

[39] Values of the P–Pd–C1 and P–Pd–C2 angles [°]: 160.0, 138.0 (**5-TS_A**); 163.1, 138.5 (**5-TS_B**); 160.9, 141.3 (**5-TS_C**); 159.4, 143.1 (**5-TS_D**). Steric bulkiness of the ligands decreases the difference between these angles: 26.0 (**5-TS_A**); 24.6 (**5-TS_B**); 19.6 (**5-TS_C**); 16.3 (**5-TS_D**).

[40] Similar reaction and activation energy changes were predicted for the complexes with $PH_3$ ligands analyzed in detail earlier (see ref.[23]). Therefore, we do not concentrate on the differences between the organic groups, the phosphane ligand effect will be considered instead.

[41] A. Moravskiy, J. K. Stille, *J. Am. Chem. Soc.* **1981**, *103*, 4182.

[42] In the calculations of the three-coordinate pathway we assume dissociation of the phosphane ligand *trans* to the vinyl group, because the Pd–P bond was calculated to be relatively weaker for that case.

[43] Under experimental conditions these pathways may be switched by addition of an excess of phosphane ligand (to retard ligand dissociation from the Pd complex and favor the four-coordinate pathway) or by using low-ligated palladium species (to facilitate the three-coordinate pathway).

[44] Due to the high *trans* effect of the σ-bonded carbon ligand the solvent molecule most likely will dissociate prior to C–C reductive elimination, which in such a case will undergo the same **4** → **5-TS** → **3** pathway. If the solvent molecule remains coordinated, this will correspond to an intermediate case between the strongly bound phosphane ligand (**1** → **2-TS** → **3** pathway) and the three-coordinate pathway (**4** → **5-TS** → **3**).

# Efficient Increase of DNA Cleavage Activity of a Diiron(III) Complex by a Conjugating Acridine Group

Xiao-Qiang Chen,[a] Xiao-Jun Peng,*[a] Jing-Yun Wang,[b] Yan Wang,[b] Song Wu,[b] Li-Zhu Zhang,[a] Tong Wu,[a] and Yun-Kou Wu[a]

**Keywords:** DNA cleavage / Iron complex / Diiron(III) complex / Intercalator / Acridine

A new diferric complex, $Fe_2L_b$, in which a DNA intercalator (acridine) is linked to a precursor diferric complex ($Fe_2L_a$), has been designed and synthesised as a hydrolytic cleaving agent of DNA. Compared with $Fe_2L_a$ (without the DNA intercalator) ($L_a$: 2,6-bis{[(2-hydroxybenzyl)(pyridin-2-yl)methylamino]methyl}-4-methylphenol), $Fe_2L_b$ [$L_b$: 5-(acridin-9-yl)-*N*-(3,5-bis{[(2-hydroxybenzyl)(pyridin-2-yl)methylamino]-methyl}-4-hydroxybenzyl)pentanamide] leads to a 14-fold increase in the cleavage efficiency of plasmid DNA due to the binding interaction between DNA and the acridine moiety. The interaction has been demonstrated by UV/Vis absorption, CD spectroscopy, viscidity experiments and thermal denaturation studies. The hydrolytic mechanism is supported by evidence from T4 DNA ligase assay, reactive oxygen species (ROS) quenching and BNPP [bis(4-nitrophenyl) phosphate, a DNA model] cleavage experiments. The pH dependence of the BNPP cleavage by $Fe_2L_a$ in aqueous buffer media shows a bell-shaped pH–$k_{obs}$ profile with an optimum point around a pH of 7.0 which is in good agreement with the maximum point of the pH-dependent relative concentration curve of active species from the pH titration experiments. The determination of the initial rates at a pH of 7.36 as a function of substrate concentration reveals saturation kinetics with Michaelis–Menten-like behaviour and $Fe_2L_a$ shows a rate acceleration increase of $4.7 \times 10^6$ times in the hydrolysis of BNPP.

## Introduction

Mimicking the activities of nucleases is currently an attractive research area in molecular biology and therapy owing to its essential role in artificial restriction enzyme and conformational probes of nucleic acids.[1–4] A number of oxidative cleavage reagents have been used with great success in DNA footprinting[5] for locating base mismatches and loop regions,[6] for locating conformational variations in DNA[7] and as chemotherapeutic agents.[8] However, these oxidative cleavage agents require the addition of an external agent (e.g., light or hydrogen peroxide) to initiate cleavage. Furthermore, oxidative cleavage is mediated by reactive oxygen species (ROS) which can cause other severe cytotoxic effects. These drawbacks of the oxidative reagents hinder their potential applications in vivo. For eliminating the possibility of significant cytotoxic side effect of ROS, pathways that result in DNA cleavage by hydrolysis mechanisms have been considered to be preferable. However, the phosphodiester bonds of DNA are exceptionally resistant to hydrolysis under physiological conditions and it is a great challenge to find new catalysts to enhance the hydrolysis.[9–11] In the past decade, a variety of metal complexes which can promote the hydrolysis of DNA and phosphodiesters have been reported, including complexes based on $Cu^{II}$, $Zn^{II}$, $Co^{III}$ and lanthanide ions.[12–21] Furthermore, many elegant dinuclear complexes have been developed as structural or functional models of the enzymes.[22] Compared with mononuclear complexes, dinuclear complexes have the higher activity as a result of the cooperative interaction of metal ions in stabilising the transition state of phosphodiester cleavage.

Among the physiologically relevant metal ions, iron has been much less studied in the hydrolytic reaction[23–25] due to the fact that Fe-dependent DNA cleavage is often involved in oxygen free radical processes such as the Fenton reaction. In fact, purple acid phosphatases (PAP), comprising diiron active centers can catalyse the hydrolysis of certain phosphate esters, including nucleoside di- and triphosphates and aryl phosphates under weakly acidic conditions.[26] On the other hand, many efforts have so far been made to enhance the reactivity of metal complexes cleaving DNA. One of these strategies is the conjunction of metal complexes and intercalating groups to increase the DNA affinity of cleavage agents.[27–29] Tecilla et al. synthesised a series of $Zn^{II}$ complex-intercalator conjugates, the struc-

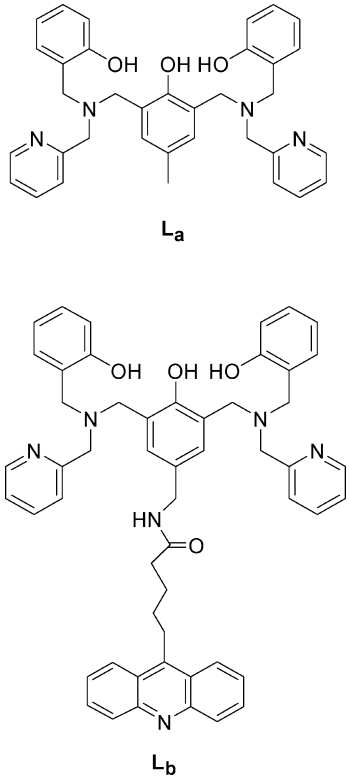
tures of which feature a *cis*,*cis*-triaminocyclohexane chelating subunit linked to an anthraquinone moiety through alkyl spacers with different lengths and reactivity studies showed that the length of the spacer which tethers the intercalating unit to the catalytic group is a key element in the cleavage activity.[28] An earlier complex was reported by Lawrence and co-workers, who appended acridine to a pentadentate N5 ligand and used it as a cofactor for $Fe^{II}$-promoted DNA oxidative cleavage.[29] However, examples of dinuclear complexes appended to the intercalating groups as hydrolytic agents are surprisingly rare.

In our work, the new diferric complex $Fe_2L_b$ is derived from $L_b$ (Scheme 1), the structure of which features a binuclear $Fe^{III}$ complex subunit linked an acridine moiety through a long spacer. The intercalating role of acridine has been confirmed by UV/Vis absorption, CD spectroscopy, viscidity experiments and thermal denaturation studies. The hydrolytic role of the diiron(III) subunit has also been confirmed from the efficient cleavage of the BNPP [bis(4-nitrophenyl) phosphate]. Furthermore, the conjugate can effectively promote the hydrolysis of plasmid DNA.



Scheme 1. Molecular structures of ligands used.

## Results and Discussion

### Synthesis and Characterisation

$L_a$ was prepared according to a procedure previously described by Neves et al.[30] $L_b$ was synthesised according to the reaction sequences depicted in Scheme S1. The previous report by Tecilla and co-workers has shown that the flexible spacer is very important in enhancing the activity of the conjugate toward DNA cleavage. Consequently, 5-(acridin-9-yl)pentanoic acid was chosen to link with the dinuclear metal moiety through an imide bond.[28] The acid was synthesised according to the method provided by Nadukkudy et al.[31] The compound 2-[3,5-bis(chloromethyl)-4-hydroxybenzyl]isoindole-1,3-dione, reported in our earlier publications,[32] was incubated with 2-{[(pyridin-2-ylmethyl)-amino]methyl}phenol in the presence of triethylamine to yield the intermediate **2**. After deprotection of **2** with hydrazine hydrate in ethanol at room temperature, the amine obtained was then linked to the acridinium subunit by an amide bond to afford the ligand $L_b$ in a yield of 50%. The diiron(III) complex $[Fe^{III}_2(BBPMP)(\mu\text{-}OAc)_2]$ with acetate bridging groups using $L_a$ as a ligand has been previously reported by Neves and co-works.[30] In accordance with this report, we initially obtained two complexes with acetate bridging groups using $L_a$ and $L_b$. Unfortunately, the solubilities in water were too low to carry out DNA experiments. Based on the modified synthesis, the complexes $Fe_2L_a$ and $Fe_2L_b$ were obtained and both have high solubility in water. Attempts to obtain the structures of $Fe_2L_a$ and $Fe_2L_b$ by X-ray diffraction were not successful although $Fe_2L_a$ and $Fe_2L_b$ were characterised by elemental analysis and spectroscopic methods (see Figures S1–S11 in the electronic supporting information). The binuclear structures of the complexes were supported by the calculated isotopic distributions which are in agreement with those measured using high-resolution ESI-MS (Figures S2 and S6–S9, supporting information). For $Fe_2L_a$, the observed species at $m/z$ ($z$ = 1) = 731.1150 corresponds to the singly-charged diiron species $[Fe^{III}_2(L_{a-3H})(OCH_3)_2]^+$. The six positive charges due to the two $Fe^{3+}$ ions and the five negative charges due to three phenolates ($L_a$–3 H) and the two methoxy ligands (from the exchange of ligand during ESI-MS using $CH_3OH$ as flowing phase) result in a single positively charged species. A similar analysis can also be applied to $Fe_2L_b$.

### pBR322 DNA Cleavage by Binuclear $Fe^{III}$ Complexes

In the absence of any added reductant or oxidant, when plasmid DNA pBR322 (0.02 $\mu g\,\mu L^{-1}$, 32 μM bp) is incubated at 37 °C for 1 h in 20 mM HEPES at pH 7.0 with $Fe_2L_a$ or $Fe_2L_b$, activity can already be observed with less than 50 μM of the catalysts and DNA becomes converted from supercoiled (form I) to nicked (form II) to an extent which depends on the concentration of the dinuclear complexes (Figure 1). A comparison between the activity of $Fe_2L_a$ and $Fe_2L_b$ provided clear evidence for the important role of the acridine subunit in promoting the efficiency of cleavage, while just 5 μM $Fe_2L_b$ is required to cleave 81% of supercoiled DNA after 1 h at 37 °C, the concentration of $Fe_2L_a$ necessary to provide the same effect is more than 20 μM. From Figures 2 and 3 it may also be seen that the relative amount of supercoiled plasmid DNA decreases upon increasing the incubation time. Through exponential decay fitting, the rate constant of the supercoiled DNA

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

cleavage for 20 μM $Fe_2L_b$ was determined to be $1.0 \times 10^{-2}$ $s^{-1}$ (Figure S12) which corresponds to a half-life of a minute. The rate constant represents a 14-fold increase in the cleavage efficiency when compared with the $Fe_2L_a$ species ($7.1 \times 10^{-4}$ $s^{-1}$, Figure S13). A similar rate acceleration (15-fold) was also reported by Tecilla et al. with a Zn-triaminocyclohexane complex tethered to an anthraquinone intercalator.[28] In order to verify the impact of the intercalation, we carried out the cleavage experiments in the presence of the mixture of acridine (5 μM) and $Fe_2L_a$ (5 μM). As shown in Figure S14, the extent of DNA cleavage by the mixture of acridine and $Fe_2L_a$ is similar to $Fe_2L_a$ and the activity is much less than for $Fe_2L_b$ (covalently linked with acridine). Furthermore, the kinetic experiment using the mixture show cleavage rate for form I is $6.9 \times 10^{-4}$ $s^{-1}$ (Figure S15–S16) which is also similar to $Fe_2L_a$ ($7.1 \times 10^{-4}$ $s^{-1}$). In contrast, the rate constant of $Fe_2L_b$ is much larger ($1.0 \times 10^{-2}$ $s^{-1}$). All of this evidence indicates that conjugation between the acridinium group and the diiron(III) subunit is necessary to get a fast cleavage rate.

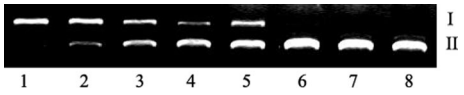


Figure 1. Agarose gel electrophoresis of pBR322 plasmid DNA treated with $Fe_2L_a$ (lane 2–4) and $Fe_2L_b$ (lane 5–8) for 1 h in an HEPES buffer (20 mM, pH 7.0) at 37 °C. Lane 1: control DNA, lane 2: $Fe_2L_a$ 10 μM, lane 3: $Fe_2L_a$ 20 μM, lane 4: $Fe_2L_a$ 50 μM, lane 5: $Fe_2L_b$ 5 μM, lane 6: $Fe_2L_b$ 10 μM, lane 7: $Fe_2L_b$ 20 μM, lane 8: $Fe_2L_b$ 50 μM.

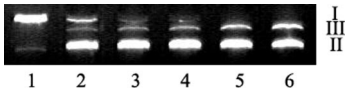

Figure 2. Time-dependence of pBR322 plasmid DNA cleavage by 20 μM $Fe_2L_a$ in an HEPES buffer (20 mM, pH 7.0) at 37 °C. Lane 1: control, lane 2: $Fe_2L_a$ 30 min, lane 3: 1 h, lane 4: 2 h, lane 5: 4 h, lane 6: 16 h.

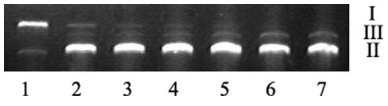

Figure 3. Time-dependence of pBR322 plasmid DNA cleavage by 20 μM $Fe_2L_b$ in an HEPES buffer (20 mM, pH 7.0) at 37 °C. Lane 1: control, lane 2: $Fe_2L_b$ 5 min, lane 3: 10 min, lane 4: 15 min, lane 5: 20 min, lane 6: 30 min, lane 7: 50 min.

The DNA cleaving systems based on mono-ferric complexes mostly involve the $Fe^{II}$ ion and DNA cleavage by these systems, such as Fe-bleomycin and the Fenton agent, occur by an oxidative mechanism. The $Fe^{III}$-based agents so far reported are relatively few although $Fe^{III}$ is present in the active site of some phosphatases. Two $Fe^{III}$ complexes with high hydrolytic activity in DNA cleavage have been reported and both of them are binuclear. The first complex $Fe_2$(HPTB), described by Schnaith, Que and co-workers in 1994[25] showed a surprising reactivity: in the presence of the complex at a concentration of 10 μM at 25 °C and a pH of 8.0, the supercoiled form was completely degraded immediately after mixing. However, the cleavage system was very complicated because high activity depended on "oxidative" conditions, i.e. the presence of $H_2O_2$ or $O_2$ and a reductant (dithiothreitol or ascorbate). No rate constant was reported which might result from the fact that the cleavage occurred with the initial burst of activity and the extent of cleavage did not increase after lengthening the reaction time. The second diiron(III) complex $Fe_2$(DTPB) was investigated by Liu and co-workers.[23] In the presence of such a complex at 37 °C, a pH of 7.0 and a concentration of 100 μM, the supercoiled DNA was degraded with a rate constant of $2.0 \times 10^{-3}$ $s^{-1}$ and the cleavage did not depend on the presence of $O_2$. Compared with $Fe_2$(DTPB), the activity of $Fe_2L_a$ seems somewhat lower ($7.1 \times 10^{-4}$ $s^{-1}$) at 20 μM. However, for $Fe_2L_b$ with a rate constant of $1.0 \times 10^{-2}$ $s^{-1}$ at a concentration as low as 20 μM, the cleavage efficiency is evidently better than for $Fe_2$(DTPB).

## Complex–DNA Interaction

The DNA binding ability of $Fe_2L_b$ was studied using UV spectroscopy by following the absorbance intensity changes of the acridine group at 253 nm. Upon addition of increasing amounts of DNA to the complex, 48% hypochromism was observed (Figure 4) which indicates the interaction between acridine group and DNA. From the plot of [DNA]/($\varepsilon_a - \varepsilon_f$) vs. [DNA], the intrinsic binding constant of the complex with DNA was calculated to be $(5.0 \pm 0.1) \times 10^5$ $M^{-1}$. The moderate binding for this complex is comparable to those observed for many other acridine derivatives.[33]

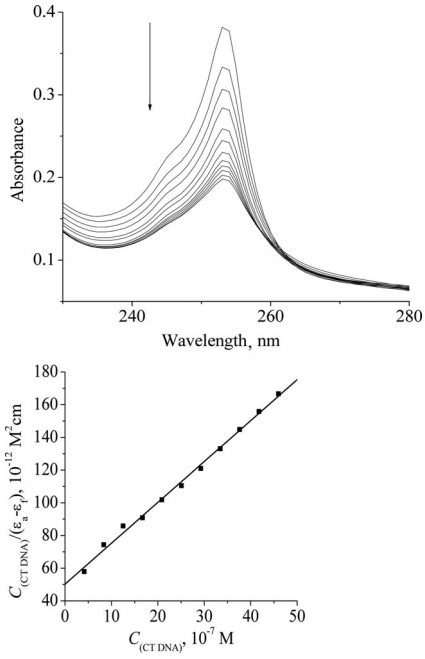

Figure 4. Top: absorption spectra of $Fe_2L_b$ ($0.67 \times 10^{-5}$ M) in the presence of increasing amounts of CT DNA ($6.27 \times 10^{-4}$ M) at 25 °C. Bottom: plot of [DNA]/($\varepsilon_a - \varepsilon_f$) vs. [DNA].

As a means for further clarifying the binding of the binuclear complex, viscosity measurements were carried out on calf thymus DNA by varying the concentration of the complex. Acridine, a classical intercalator, causes a moderated increase in the viscosity of the DNA solution due to the separation of base pairs at intercalation sites and hence an increase in overall DNA length (Figure 5). In contrast, $Fe_2L_a$ causes a decrease in DNA solution viscosity under the same conditions which can be attributed to the binding between $Fe_2L_a$ and DNA through charge affinity leading to a distortion of the DNA structure. Compared with $Fe_2L_a$, $Fe_2L_b$ further decreases the viscosity of DNA and the result suggests that the cooperation between the diiron complex and the acridine subunit makes distortion of the DNA more intense. The thermal denaturation studies show that the addition of $Fe_2L_b$ to the calf thymus DNA could raise $T_m$ from (78.3 ± 0.2) °C to (80.0 ± 0.5) °C but no change was observed in the case of $Fe_2L_a$ (Figure S17). The CD spectra also show the difference in the interaction between $Fe_2L_a$ and $Fe_2L_b$ with CT DNA (Figure S18): Incubation of DNA and $Fe_2L_a$ caused the intensities of both the positive and negative ellipticity bands to decrease, while incubation of DNA and $Fe_2L_b$ caused the intensities of the negative ellipticity band to increase and the positive ellipticity band blue-shift. This suggests the acridine moiety has a significant effect on the conformational changes of DNA.

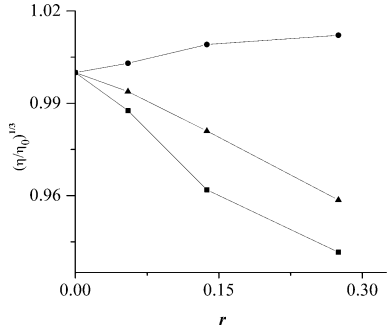

Figure 5. Effect of increasing the amounts of the compounds on the relative specific viscosity of calf thymus DNA. Viscosity is presented as $[\eta/\eta_0]^{1/3}$ in accord with the theory of Cohen and Eisenberg (1969). ● acridine + CT DNA, ▲ $Fe_2L_a$ + CT DNA, ■ $Fe_2L_b$ + CT DNA. $r = C_{compound}/C_{DNA}$.

## Cleavage Mechanism Analysis

The earlier two diiron(III) complexes $Fe_2$(DTPB) and $Fe_2$(HPTB), described respectively by Liu[23] and by Que,[25] have shown the yielding linearised DNA can be quantitatively relegated by confirming the occurrence of a hydrolytic mechanism. In our cases, the linearised DNA has also been relegated by T4 ligase (Figure 6), although the relegation is not complete. In some cases, the hydrolytic products either did not end at the required 5′-phosphate and 3′-OH (ribose) termini or the complex sometimes bound to the termini of cleaved DNA. These reasons would result in the relegation being incomplete or even failing completely.[34,35] To explore the effects of molecular oxygen on the degradation of DNA by the complexes, reactions were also performed under anaerobic conditions (Figure S19) and the results showed that $Fe_2L_a$ and $Fe_2L_b$ still effectively cleaved pBR322 DNA with little inhibition. In contrast, the oxidative cleaving system $Fe(EDTA)^{2-}$/DTT showed very strong oxygen dependence. Another general way to discriminate the hydrolytic mechanism from the oxidative mechanism is the examination of the DNA cleavage in the presence of reactive oxygen species (ROS) scavengers. Figure 7 indicates little effect on the cleavage efficiency of DNA with $Fe_2L_b$ when DMSO or $NaN_3$ are added and superoxide dismutase (SOD) can even promote the cleavage efficiency. The experimental results suggest that hydroxyl radical, singlet oxygen and superoxide are not involved in the diiron DNA cleavage system. Additionally, the possibility of hydroxyl radical formation in the presence of $Fe_2L_a$ can also be evaluated by monitoring the changes in absorbance at 552 nm for the dye rhodamine B. Degradation of the dye can provide a direct measure of the concentration of the hydroxyl radical formed.[36] In the presence of $Fe_2L_a$, no obvious decrease in absorbance of the dye was detected over the time of the experiment (Figure S20) even after $H_2O_2$ was added, indicating that the hydroxyl radical is not formed under these conditions. An oxidative pathway can therefore be ruled out in the cleavage of DNA by diiron(III) complexes and, evidently, the cleavage occurs through a hydrolytic mechanism.

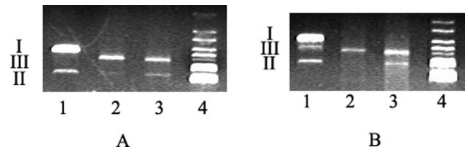

Figure 6. Ligation of pBR322 DNA cleaved by $Fe_2L_a$ and $Fe_2L_b$. A, lane 1: supercoiled (upper) and nicked (lower) pBR322 DNA, lane 2: linearised pBR322 DNA cleaved by $Fe_2L_a$, lane 3: ligation of linearised pBR322 DNA by T4 DNA ligase, lane 4: λ DNA-EcoT14 I digest markers. ## Hydrolysis of BNPP Catalysed by $Fe_2L_a$

Cleavage experiments of phosphodiesters were also carried out to further verify the hydrolytic activity of diiron complexes. In these kinds of experiments, BNPP is often used as a DNA model compound in the assessment of phosphodiesterase activity. For ensuring the solubility of the binary of the catalyst-substrate compound, the mixed solu-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

tion including DMSO (10 vol.-%) was used. The reaction was monitored by following the increase in the absorbance at 400 nm which indicates the release of NP from BNPP. The determination of the initial rates at a pH of 7.36 as a function of substrate concentration revealed saturation kinetics with Michaelis–Menten-like behaviour (Figure 8). A linearisation after Lineweaver–Burke gave the following kinetics values: $K_M = (3.1 \pm 0.1) \times 10^{-3}$ M, $V_{max} = (3.1 \pm 0.6) \times 10^{-9}$ mol L$^{-1}$ s$^{-1}$, and the catalytic constant $k_{cat} = V_{max}/[Fe_2L_a]_0 = (5.2 \pm 0.2) \times 10^{-5}$ s$^{-1}$. The second-order rate constant, $k_{BNPP}$ (= $k_{cat}/K_M$) for BNPP is $(1.7 \pm 0.1) \times 10^{-2}$ M$^{-1}$ s$^{-1}$ and the substrate binding constant $K_b = 1/K_M = (3.2 \pm 0.1) \times 10^2$ M$^{-1}$. From the kinetic data obtained under these conditions, a rate acceleration toward BNPP of ca. $(4.7 \pm 0.2) \times 10^6$ times was found. The rate is comparable to that observed for other binuclear transition metal-based complexes.[17]

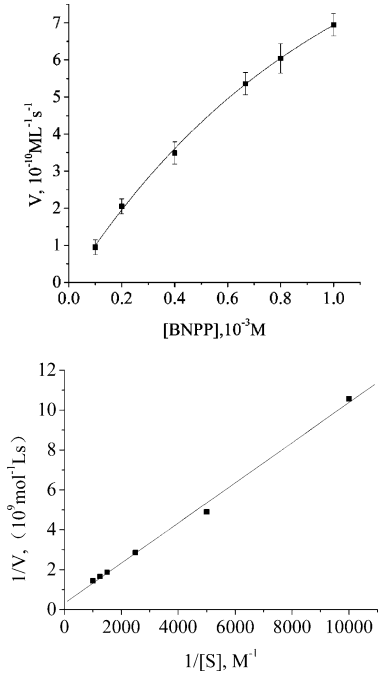

Figure 8. Top: saturation kinetic experiments for the cleavage of BNPP by $Fe_2L_a$ at a pH of 7.36 and 50 °C. $I$ = 0.10 M ($NaNO_3$), $[Fe_2L_a]_0$ = 0.06 mM, [HEPES buffer] = 50 mM, 10 vol.-% DMSO solution. Bottom: Lineweaver–Burke plot.

It was noted that the pH dependence of the catalytic activity between pH values of 5.9 and 8.5 shows a bell-shaped profile (Figure 9) with an optimum point at about pH 7.0. On the other hand, potentiometric titration of $Fe_2L_a$ shows two successive titratable protons in a 1:9 DMSO/$H_2O$ solvent mixture (Figure 10). Sigmoidal fitting gives the p$K_a$ values of 5.3 and 8.5, respectively. From the titration curve, we propose a processes according to the equilibria represented by Equations (1) and (2).

$$\underset{\mathbf{a}}{[Fe_2L_a(H_2O)(H_2O)]} \rightleftharpoons \underset{\mathbf{b}}{[Fe_2L_a(H_2O)(OH)]} + H^+ \quad (1)$$

$$\underset{\mathbf{b}}{[Fe_2L_a(H_2O)(OH)]} \rightleftharpoons \underset{\mathbf{c}}{[Fe_2L_a(OH)(OH)]} + H^+ \quad (2)$$

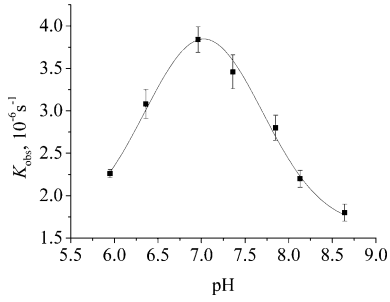

Figure 9. Dependence of the reaction rate on the pH under the following conditions: 10 vol.-% DMSO solution, 50 °C, $[Fe_2L_a] = 6.0 \times 10^{-5}$ mol L$^{-1}$, [BNPP] = $2 \times 10^{-4}$ mol L$^{-1}$, [buffer] = $5.0 \times 10^{-2}$ mol L$^{-1}$ (buffer: MES or HEPES), $I$ = 0.1 mol L$^{-1}$ ($NaNO_3$).

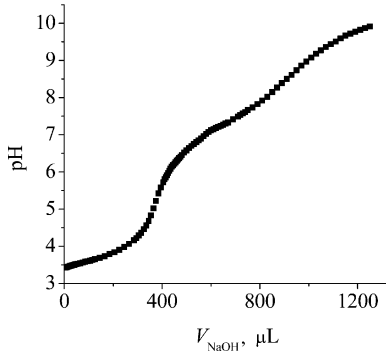

Figure 10. Potentiometric titration of $Fe_2L_a$ ($2.0 \times 10^{-4}$ M) with an increasing amount of 0.01 M NaOH in DMSO/$H_2O$ (1:9).

The distribution curves (Figure 11) of the deprotonated products of $Fe_2L_a$ in a 1:9 DMSO/$H_2O$ mixture display maximum monohydroxo species concentrations at a pH of 6.9 which is in good agreement with the optimum point for the catalytic activity at a pH of 7.0. These results indicate that the b species is the active species for the cleavage of phosphodiesters. As proposed previously [equilibria (1) and (2)], monohydroxo species can provide a labile Fe–$OH_2$ bond for phosphodiester binding and another $Fe^{III}$ bound hydroxide group for nucleophilic attack on the phosphorus atom. The decrease in the reactivity at pH > 7.0 most probably arises from the presence of the fully deprotonated form c, in which the tendency of the $OH^-$ ion from the Fe–OH group to leave becomes reduced even though a more concentrated $OH^-$ solution can increase the nucleophilic reactivity.

## Conclusions

In summary, we have designed and synthesised a new diiron complex $Fe_2L_b$ with an acridine group as an intercalator of DNA. The cleavage experiments indicate that the intercalative function can lead to a 14-fold increase in the cleavage efficiency. Furthermore, the hydrolytic mechanism studies demonstrate the potential of binuclear ferric complexes as catalyst models for artificial nucleases. In future work, we plan to link diiron(III) complexes with recognisable functional groups in the hope of realising the sequence-selective cleavage of DNA.

## Experimental Section

**General:** When necessary, reactions and manipulations were carried out under an atmosphere of nitrogen. All reagents and solvents were analytical reagent grade and were used without further purification unless otherwise noted. UV/Vis spectra were recorded with a Lambda 35 UV/Vis spectrometer. ESI–MS spectra and high-resolution mass spectra were recorded on an HP 1100 MSD and an HPLC-Q-Tof MS (Micro) instrument, respectively. NMR spectra were recorded with a 400-MHz Varian INOVA system. IR spectra were obtained by using an FTIR-430 spectrometer. Elemental analyses were performed on a Vario EL III instrument. The potentiometric titration was performed on a PHS-3C pH meter. Viscosity measurements were recorded with a NXE-1B viscometer. Circular dichroism spectra of DNA were obtained with a JASCO J-20 automatic recording spectropolarimeter. The ImageMaster VDS system (Pharmacia Biotech) was used for electrophoresis experiments.

### Syntheses

Bis(4-nitrophenyl) phosphates (BNPP) were prepared and purified following a modified literature method.[37]

**2-(4-Hydroxy-3,5-bis{[(2-hydroxybenzyl)pyridin-2-ylmethylamino]-methyl}benzyl)isoindole-1,3-dione (2) (Scheme S1):** A solution of 2-[3,5-bis(chloromethyl)-4-hydroxybenzyl]isoindole-1,3-dione (0.61 g, 3.0 mmol), 2-{[(pyridin-2-yl)methylamino]methyl}phenol (1.40 g, 6.5 mmol) and $Et_3N$ in $CH_2Cl_2$ was stirred at ambient temperature for 2 d. The reaction mixture was then diluted with $CH_2Cl_2$ and washed with brine. The organic phase was dried with $Na_2SO_4$ and the solvent was removed by evaporation. Purification on silica gel using EtOAc as eluent gave the desired product (71%). $^1$H NMR ($CDCl_3$): $\delta$ = 8.60 (d, $J$ = 4.4 Hz, 2 H, Py-H), 7.84 (m, 2 H, Py-H), 7.65–7.70 (m, 4 H, $PhCH_2Ph$-H), 7.26 (d, $J$ = 6 Hz, 4 H, Py-H), 7.23 (t, $J$ = 4.4 Hz, 2 H, Py-H), 7.10 (t, $J$ = 7.2 Hz, 2 H,H-Ph), 7.02 (d, $J$ = 7.2 Hz, 2 H, Ph-H), 6.72–6.76 (t, $J$ = 7.2 Hz, 4 H, Ph-H), 4.71 (s, 2 H, Ph−$CH_2$−Pht), 3.83 (s, 4 H, N−$CH_2$−Py), 3.80 (s, 4 H, N−$CH_2$−Ph), 3.77 (s, 4 H, N−$CH_2$−Ph) ppm. ESI-MS: $m/z$ 706.3 $[M + H]^+$, HRMS calcd. for $C_{43}H_{39}N_5O_5$ 706.3029, found 706.3022.

**4-Aminomethyl-2,6-bis{[(2-hydroxybenzyl)pyridin-2-ylmethylamino]-methyl}phenol (3):** Compound **2** (0.52 g, 7.4 mmol) was suspended in EtOH (10 mL) and hydrazine hydrate (0.22 g, 4.5 mmol) was added. The solution was heated to reflux for 2 h and stirred at ambient temperature overnight and the solvent was then evaporated under reduced pressure. The resultant solid was treated with 2 M HCl then extracted with $CH_2Cl_2$ and dried with $Na_2SO_4$. Evaporation of the solvent yielded 0.36 g (85%) of the product. $^1$H NMR ($CD_3COCD_3$,): $\delta$ = 8.61–8.64 (m, 2 H, Py−H), 7.79 (dt, $J$ = 7.7, 1.8 Hz, 2 H, Py−H), 7.32–7.38 (m, 4 H, Py−H), 7.07–7.14 (m, 6 H, Ph−H), 6.71–6.76 (m, 4 H, Ph−H), 4.30 (s, 2 H, Ph−$CH_2$−N), 3.87 (s, 4 H, N−$CH_2$−Py), 3.80 (s, 4 H, N−$CH_2$−Ph), 3.77 (s, 4 H, N−$CH_2$−Ph) ppm. ESI-MS: $m/z$ 576.3 $[M + H]^+$. HR-MS calcd. for $C_{35}H_{37}N_5O_3$ 576.2975, found 576.2980.

**5-(Acridin-9-yl)pentanoic Acid (4):**[31] Diphenylamine (1.69 g, 0.01 mol), hexanedioic acid (4.38 g, 0.03 mol) and anhydrous $ZnCl_2$ (6.8 g, 0.05 mol) were mixed well and heated at 230 °C for 20 h. $H_2SO_4$ (20 mL, 20 vol.-%) was then added to the reaction mixture which was subsequently heated to reflux for 4 h. The mixture was cooled and neutralised using aqueous $NH_3$ (25 vol.-%) solution. A solid product precipitated. After purification by silica gel column chromatography [eluted by a mixture (1:1) of EtOAc and petroleum ether], the pure compound was obtained. $^1$H NMR ($CD_3COCD_3$,): $\delta$ = 8.40 (d, $J$ = 8.8 Hz, 2 H, Acr-H), 8.15 (d, $J$ = 8.8 Hz, 2 H, Acr−H), 7.84 (t, $J$ = 7.6 Hz, 2 H, Acr−H), 7.64 (t, $J$ = 7.4 Hz, 2 H, Acr−H), 3.68 (t, $J$ = 7.2 Hz, 2 H, $CH_2$Acr), 2.3 (t, $J$ = 6.4 Hz, 2 H, $CH_2$COOH), 1.75 [m, 4 H, −$(CH_2)_2$−] ppm. ESI-MS $m/z$: 278.0 $[M - H]^-$.

**5-(Acridin-9-yl)-*N*-(3,5-bis{[(2-hydroxybenzyl)(pyridin-2-yl)methylamino]methyl}-4-hydroxybenzyl)pentanamide ($L_b$):** 5-(Acridin-9-yl)-pentanoic acid (0.126 g, 0.45 mmol) was heated to reflux in $SOCl_2$ (1 mL) for 2 h and the excess $SOCl_2$ was removed under reduced pressure. The dry solid was redissolved in dry acetonitrile (2 mL) and cooled in an ice bath. Compound **3** (0.22 g, 0.38 mmol) and triethylamine (0.5 mL) were added to the acetonitrile solution which was stirred under argon overnight as the temperature gradually returned to room temperature. Removing the solvent and purification on a column of silica gel using MeCN/$H_2O$ (95:5) as the eluent gave 0.16 g (50%) of the desired product. $^1$H NMR ($CD_3Cl$): $\delta$ = 8.56 (d, $J$ = 4.8 Hz, 2 H, Py−H), 8.35 (d, $J$ = 8.8 Hz, 2 H, Acr−H), 8.2 (d, $J$ = 8.8 Hz, 2 H, Acr−H), 7.77 (t, $J$ = 7.6 Hz, 2 H, Acr−H), 7.60 (t, $J$ = 7.8 Hz, 2 H, Py−H), 7.53 (t, $J$ = 7.6 Hz, 2 H, Acr−H), 7.15–7.21 (m, 4 H, Py−H), 7.10 (t, $J$ = 7.6 Hz, 2 H, Ph−H), 6.96 (s, 2 H, Ph−H), 6.92 (d, $J$ = 8 Hz, 2 H, Ph−H), 6.79 (d, $J$ = 6.4 Hz, 2 H, Ph−H), 6.93 (t, $J$ = 7.6 Hz, 2 H, Ph−H), 6.36 (br., 1 H, −NHCO−), 4.27 (d, $J$ = 5.2 Hz, 2 H, NH−$CH_2$−Ph), 3.77 (s, 4 H, N−$CH_2$−Py), 3.71 (s, 4 H, N−$CH_2$−Ph), 3.65 (s, 4 H, N−$CH_2$−Ph), 3.61 (t, $J$ = 7.2 Hz, 2 H, $CH_2$−Acr), 2.34 (t, $J$ = 7.2 Hz, 2 H, $CH_2$−CONH), 1.95–1.99 (m, 2 H, −$CH_2CH_2$−), 1.82–1.84 (m, 2 H, −$CH_2CH_2$−) ppm. ESI-MS $m/z$ 837.5 $[M + H]^+$, HRMS calcd. for $C_{53}H_{52}N_6O_4$ 837.4128, found 837.4135.

**Synthesis of the Binuclear Complexes $Fe_2L_aCl_3{\cdot}3H_2O$ ($Fe_2L_a$) and $Fe_2L_bCl_3{\cdot}4H_2O$ ($Fe_2L_b$):** $L_a$ (0.05 g, 0.09 mmol) and 2 equiv.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

$FeCl_3 \cdot 6H_2O$ (0.049 g, 0.18 mmol) were dissolved in $H_2O$ and heated at 50 °C for 1 h to obtain a dark blue solution and the solution was then concentrated under reduced pressure. The target product $Fe_2L_a$ was the obtained as a solid residue. $C_{35}H_{39}Cl_3Fe_2N_4O_6$ ($Fe_2L_aCl_3 \cdot 3H_2O$): calcd. C 50.66, H 4.74, N 6.75; found C 50.64, H 4.49, N 6.81. High-Resolution ESI-MS ($CH_3OH$ as flowing phase) (Figure S1–S2) *m/z*: $[Fe^{III}Fe^{III}(L_{a-3H})(OCH_3)(OCH_3)]^+$ 731.1150; $[Fe^{III}Fe^{III}$ ($L_a$–3 H) $(OCH_3)]^{2+}$, 350.1511. IR (KBr) (Figure S3): $\tilde{\nu}$ = 3427–3066 (br., s), O–H of water and C–H of aromatic ring; 2922 (m) and 2855 (m), C–H of methane; 1609 (s) and 1475 (s), C=C of aromatic ring; 1264 (s), C–O of phenol; 759 $cm^{-1}$ (s), C–H of aromatic ring. UV/Vis ($H_2O$): $\lambda_{max}$ ($\varepsilon_m$, L $mol^{-1}$ $cm^{-1}$) (Figure S4): 260 (shoulder, 20000) attributed to the π–π* transition of the ligand; 531 nm(4400) attributed to the iron(III)−ligand charge transfer. Similarly, spectroscopic data of $Fe_2L_b$ were obtained. $C_{53}H_{57}Cl_3Fe_2N_6O_8$ ($Fe_2L_bCl_3 \cdot 4H_2O$): calcd. C 56.63, H 5.11, N 7.48; found C 56.92, H 4.45, N 7.62. High-Resolution ESI-MS ($CH_3OH$ as flowing phase) (Figure S5–S9) *m/z*: $[Fe^{III}Fe^{III}$ ($L_b$–3 H) $(OCH_3)H]^{3+}$ 325.6591; $[Fe^{III}Fe^{III}$ ($L_b$–3 H) $(OH)]^{2+}$ 480.9854; $[Fe^{III}Fe^{III}$ ($L_b$–3 H) (OH)(HCl)$]^{2+}$ 498.9745; $[Fe^{III}Fe^{III}$ ($L_b$–3 H) $(OCH_3)$(HCl)$]^{2+}$ 505.9684; $[Fe^{III}Fe^{III}$ ($L_b$–3 H) (OAc)(HCl)$]^{2+}$ 520.9583. IR (KBr) (Figure S10): $\tilde{\nu}$ = 3417–3000 (br., s), O–H of water and C–H of aromatic ring; 2925 (m) and 2857 (m), C–H of methane; 1635 (s) and 1478 (s), C=C of aromatic ring; 1265 (strong), C–O of phenol; 759 $cm^{-1}$ (strong), C–H of aromatic ring. UV/Vis ($H_2O$): $\lambda_{max}$ ($\varepsilon_m$, L $mol^{-1}$ $cm^{-1}$) (Figure S11): 253 (56300) and 354 (13300) attributed to the π–π* transition of ligand; 531 nm (2980) attributed to the iron(III)−ligand charge transfer.

**pBR322 DNA Cleavage Experiments by the Binuclear Metal Complexes:** DNA cleavage experiments were performed using pBR 322 (Takara) in a 20 mM HEPES buffer, pH 7.0, with incubating DNA (0.4 μg) at 37 °C in the presence and absence of the metal complex for the specified time. The cleavage reactions were stopped by addition of 3 μL of a loading buffer (0.25% bromphenol blue, 25% glycerol, 1 mM EDTA, 2% SDS). The electrophoresis of DNA cleavage products was performed on 1% agarose gel. The gels were run at 130 V for 45 min in a 0.01 M pH 7.0 TAE buffer. The resolved bands were visualised by ethidium bromide staining and were then quantified. A correction factor of 1.22 was utilised to account for the decreased ability of ethidium bromide to intercalate into form I DNA compared with forms II and III.[38]

**Cleavage of pBR322 in the Presence of ROS Scavengers:** Scavengers of reactive oxygen intermediates (DMSO, $NaN_3$ and SOD) were added alternatively to the reaction mixtures. Cleavage was initiated by the addition of $Fe_2L_b$ and stopped by 3 μL of a loading buffer (0.25% bromphenol blue, 25% glycerol, 1 mM EDTA, 2% SDS). Further analysis was conducted using the standard procedures described above.

**Absorption Titration of $Fe_2L_b$ Binding to DNA:** The solutions of CT DNA gave a UV absorbance ratio at 260 and 280 nm, $A_{260}/A_{280} > 1.8$, indicating that the DNA was sufficiently free of protein.[39] The concentrated stock solution of CT DNA (stored at 4 °C and not used for more than 6 d) was prepared and the concentration of DNA in the nucleotide phosphate was determined by UV absorbance at 260 nm after a 1:10 dilution. The molar absorption coefficient of CT DNA was taken as 6600 $M^{-1}$ $cm^{-1}$.[39] A solution (3 mL) of $0.67 \times 10^{-5}$ M $Fe_2L_b$ in water was incubated for 30 min at 25 °C. With addition of increasing amounts of 2 μL aliquots of DNA ($6.27 \times 10^{-4}$ M), the influence of volume was found to be negligible. The binding constant was determined using the following equation: $C_{DNA}/(\varepsilon_a - \varepsilon_f) = C_{DNA}/(\varepsilon_b - \varepsilon_f) + 1/K_b(\varepsilon_b - \varepsilon_f)$, where $\varepsilon_a$, $\varepsilon_f$, and $\varepsilon_b$ correspond to $A_{obsd}$/[complex], the extinction coefficient for the free iron complex and the extinction coefficient for the iron complex in the fully bound form, respectively. The intrinsic binding constant $K_b$ was given by the ratio of the slope to intercept through the plot of $C_{DNA}/(\varepsilon_a - \varepsilon_f)$ vs. $C_{DNA}$.

**Viscosity Measurements:** Viscosity experiments were carried out on a NXE-1B viscometer at 25 °C. The concentration of DNA was 280 μM in the nucleotide phosphate and the flow times were determined with a manually operated timer. Data were presented as $[\eta/\eta_0]^{1/3}$ vs. [complex]/[DNA] ($\eta$ is the viscosity of DNA solution in the presence of the compound and $\eta_0$ is the viscosity of DNA alone).

**Ligation Experiment on the DNA Fragments:** Enzymatic assays were performed using T4 DNA ligase to determine whether the cleaved products were consistent with hydrolysis of the phosphodiester linkages in DNA. First, the linearised DNA was isolated from the pBR 322 DNA cleavage products by $Fe_2L_a$ or $Fe_2L_b$. Then, the following reaction was carried out for relegation: 1.5 μL of 10× ligation buffer, 10 μL of linearised pBR 322 DNA, 1 μL of T4 ligase (2 units), and 2.5 μL of $H_2O$ were mixed and incubated at 16 °C for 24 h. The ligation products were monitored by the electrophoresis and visualised by staining in an ethidium bromide solution.

**Anaerobic Reactions:** Deoxygenated water was prepared by four freeze-pump-thaw cycles. Before each cycles the water was equilibrated with nitrogen to assist the deoxygenating process. The deoxygenated water was stored under a nitrogen atmosphere prior to use. All anaerobic stock solutions were prepared in Schlenk tubes under nitrogen using the deoxygenated water. Reaction mixtures were prepared by the addition of the appropriate volumes of the stock solutions to the tubes and were incubated in a nitrogen-filled glovebag.

**Thermal Denaturation of DNA:** In 0.01 M $Na_2HPO_4$ buffer (pH 7.0), the absorption values of DNA as well the mixture of DNA and dinuclear $Fe^{III}$ complexes at 260 nm were recorded by increasing the temperature in 5 °C increments from 55 °C to 95 °C in a thermostatic bath where the controls were the buffer and the buffers in the absence and presence of the diiron complex, the concentration of which was the same as that in the sample.

**CD Spectra Measurements:** Circular dichroism spectra of DNA were obtained on a JASCO J-20 automatic recording spectropolarimeter operating at 25 °C. The region between 200 and 300 nm was scanned for each sample.

**Kinetic Measurements:** The kinetic measurements were performed at 50 °C in buffered solutions of a 1:9 mixture of DMSO/water. 2-(Morpholino)ethanesulfonic acid (MES) and 2-[4-(2-hydroxyethyl)-piperazin-1-yl]ethanesulfonic acid (HEPES) were used as buffers. The ionic strength was fixed to 0.1 M with sodium nitrate. In a typical experiment, aqueous buffer solution (1.5 mL) was mixed with complex $Fe_2L_a$ stock solution (in water) (0.9 mL) and DMSO (0.3 mL) in a temperature-controlled spectrometric cell. After the mixture was equilibrated for 15 min, BNPP stock solution (in water) was added (0.3 mL) and data collection was started immediately. The cleavage of BNPP was measured by following the increase in the absorption of 4-nitrophenolate (NP) at 400 nm. NP concentrations were determined using the molar extinction coefficients for NP of 2500, 4500, 9000, 12800, 16800, 17900, 19900 $M^{-1}$ $cm^{-1}$ at pH values of 5.95, 6.36, 6.96, 7.36, 7.85, 8.13 and 8.64, respectively. The activities of the complexes were determined by the method of initial rates. At least three independent measurements were made.

**Potentiometric Titration of $Fe_2L_a$:** To an aqueous solution of $Fe_2La$ ($2.0 \times 10^{-4}$ M) containing 10 vol.-% DMSO was added a solution of

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

0.01 M NaOH dropwise. Each data point was obtained by adding 2–20 μL of NaOH solution at 25 °C.

**Supporting Information** (see also the footnote on the first page of this article): Synthesis of $L_b$ (Scheme S1). High-Resolution ESI-MS spectrum of $Fe_2L_a$ (Figure S1, S2). IR spectra of $Fe_2L_a$ (Figure S3). Absorption spectra of 60 μM $Fe_2L_a$ (Figure S4). High-Resolution ESI-MS spectrum of $Fe_2L_b$ (Figure S5–S9). IR spectra of $Fe_2L_b$ (Figure S10). Absorption spectra of 60 μM $Fe_2L_b$ (Figure S11). Time course of DNA cleavage by 20 μM $Fe_2L_b$ (Figure S12). Time course of DNA cleavage by 20 μM $Fe_2L_a$ (Figure S13). Agarose gel electrophoresis of pBR322 DNA treated with $Fe_2L_a$, the mixture of acridine and $Fe_2L_a$, $Fe_2L_b$ (Figure S14). Time-dependence of DNA cleavage by the mixture of 20 μM $Fe_2L_a$ and 20 μM acridine (Figure S15). Time course of DNA cleavage by the mixture of 20 μM $Fe_2L_a$ and 20 μM acridine (Figure S16). Thermal Denaturation studies of DNA (Figure S17). The CD spectra of CT DNA with complexes (Figure S18). Anaerobic and aerobic cleavage of pBR322 DNA by diiron(III) complexes and $Fe(EDTA)^{2-}$/DTT (Figure S19). Quantification of hydroxyl radicals by following the degradation of rhodamine B (Figure S20).

# Tetranuclear Complexes of $Pd^{II}$ with Tridentate [*C*,*N*,*O*] and [*O*,*N*,*O*] Ligands: Synthesis, Reactivity and Structural Isomerism

**Jesús J. Fernández,*[a] Alberto Fernández,[a] Digna Vázquez-García,[a] Margarita López-Torres,[a] Antonio Suárez,[a] Nina Gómez-Blanco,[a] and José M. Vila*[b]**

**Keywords:** Palladium / Cyclometallation / Metallacycles / Tridentate [*C*,*N*,*O*] ligands / C–H activation

Treatment of the Schiff base ligand 2,3,4-$(MeO)_3C_6H_2C(H)=N[2\text{-}(OH)\text{-}5\text{-}t\text{Bu}C_6H_3]$ (**a**) with palladium(II) acetate in toluene gave the cyclometallated complex $[Pd\{2,3,4\text{-}(MeO)_3C_6HC(H)=N(2\text{-}O\text{-}5\text{-}t\text{Bu}C_6H_3)\}]_4$ (**1a**) with the tridentate ligand [*C*,*N*,*O*]. The complex showed a tetranuclear arrangement of the cyclometallated monomers with a $P_4O_4$ core. Reaction of $2,6\text{-}(Me)_2C_6H_3C(H)=N[2\text{-}(OH)C_6H_4]$ (**b**) and $2,5\text{-}(Me)_2C_6H_3C(H)=N[2\text{-}(OH)C_6H_4]$ (**c**) with palladium(II) acetate under similar conditions yielded the tetranuclear complexes $[Pd\{6\text{-}Me\text{-}2\text{-}CH_2C_6H_3C(H)=N(2\text{-}OC_6H_4)\}]_4$ (**1b**) and $[Pd\{5\text{-}Me\text{-}2\text{-}CH_2C_6H_3C(H)=N(2\text{-}OC_6H_4)\}]_4$ (**1c**), respectively, in which the tridentate [*C*,*N*,*O*] ligand is bound through the aliphatic methyl carbon. Treatment of $2,4\text{-}(Me)_2C_6H_3C(H)=N[2\text{-}(OH)C_6H_4]$ (**d**) with palladium(II) acetate yielded a mixture of isomers, $[Pd\{4\text{-}Me\text{-}2\text{-}CH_2C_6H_3C(H)=N\text{-}(2\text{-}OC_6H_4)\}]_n[Pd\{2,4\text{-}(Me)_2C_6H_2C(H)=N(2\text{-}OC_6H_4)\}]_{4-n}$ ($n$ = 0–4), also bearing a tetranuclear structure. However, the tetramer was assembled by two types of mononuclear Pd(ligand) building blocks: the ligand is coordinated through the aliphatic methyl carbon in one and through the aromatic *ortho* carbon in the other. The crystal structure of one such isomer confirmed the spectroscopic data. Treatment of $2\text{-}(OH)\text{-}4,6\text{-}(MeO)_2C_6H_2C(H)=N[2\text{-}(OH)C_6H_4]$ (**e**) and $2\text{-}(OH)C_6H_4\text{-}C(H)=N[2\text{-}(OH)C_6H_4]$ (**f**) with palladium(II) acetate yielded the tetranuclear complexes $[Pd\{2\text{-}O\text{-}4,6\text{-}(MeO)_2C_6H_2C(H)=N(2\text{-}OC_6H_4)\}]_4$ (**1e**) and $[Pd\{2\text{-}OC_6H_4C(H)=N(2\text{-}OC_6H_4)\}]_4$ (**1f**), respectively, after double deprotonation of the ligand, which coordinates to the metal through the two phenoxy oxygen atoms and the imine nitrogen atom in these complexes. Reaction of compounds **1a**–**1f** with tertiary phosphanes in acetone gave mono- and dinuclear complexes, after cleavage of the tetranuclear structure. In these complexes, the tertiary phosphane is bonded *trans* to the nitrogen atom. The crystal structures for **1a**, **1c**, **1e**, **1d/1d′** are reported; they show the characteristic $Pd_4O_4$ core.

## Introduction

Cyclometallated compounds have been extensively surveyed,[1–5] and they exhibit a good number of applications related to organic as well as to organometallic compounds, metallomesogens and catalytic materials;[6–13] they also promote unusual coordination environments.[14] The more common cyclometallated complexes encountered in the literature are the palladium(II) five-membered ring species after activation of aromatic $C(sp^2)$ atoms. Analogous compounds containing alkyl $C(sp^3)$–Pd bonds are also known although these are more scarce.[15–19]

On the other hand, the building of supramolecular assemblies has also attracted much attention in the past years,[20–24] and among these, examples containing square-planar palladium(II) units have been of great interest in view of their potential applications.[25] Nevertheless, few examples of supramolecular species with cyclometallated building blocks have been reported,[26–31] many of which correspond to tetrameric assemblies derived from palladium(II) cyclometallated complexes with [*C*,*N*,*X*] (*X* = *O*, *S*) tridentate ligands. Thus, for the [*C*,*N*,*S*] species, thiosemicarbazones give tetranuclear structures with an eight-membered $Pd_4S_4$ core,[32–34] and tetranuclear cluster complexes derived from benzothiazolines[35,36] are also known. As for the [*C*,*N*,*O*] derivatives,[37–40] they also exhibit an analogous tetranuclear structure with a $Pd_4O_4$ core. In order to attain neutrality the ligand is usually deprotonated in the complex, at the hydrazine nitrogen atom, at the benzothiazoline nitrogen atom or at the phenol oxygen atom. Even when there is no metal–carbon bond formation, the tetranuclear structure is reached only after deprotonation, as has been reported for a coordination compound derived from a [*N*,*N*,*S*] ligand.[41]

The purpose of this paper is twofold: first, to study the activation of aromatic carbon atoms against aliphatic carbon atoms by checking the bonding possibilities of *N*-phenol Schiff base ligands, and secondly, to determine the

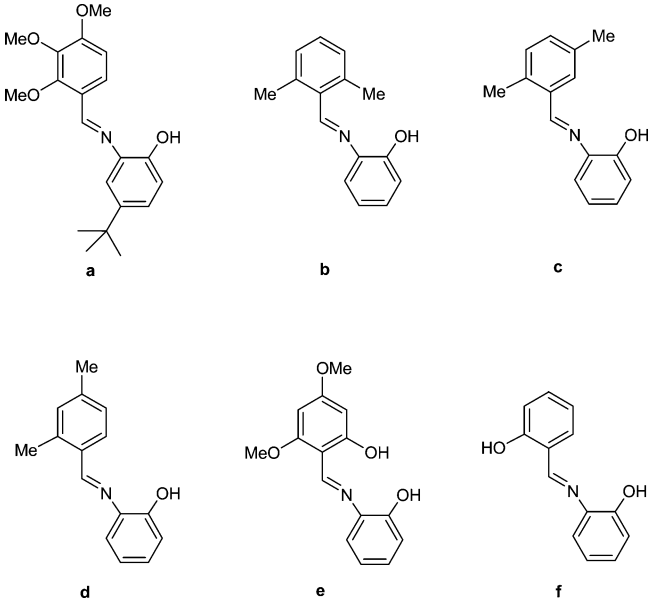
structural particularity of the resulting complexes in terms of their polynuclear nature.

## Results and Discussion

The ligands employed provide several coordination approaches as a function of the substitution pattern of the phenyl ring. Thus, only **a**, **c**, **d** and **f** have available aromatic $sp^2$ carbon atoms suitable for metallation, as well as MeO, Me and OH substituents liable to carbon–metal and oxygen–metal bond formation. On the other hand, **b** and **e** may bind to the metal only through the MeO or OH groups; accordingly, different alternatives of palladation were found. Hence, in **a** the metal atom was found to be bonded exclusively through the C-6 atom, with no sign of metallation of the C-2 methoxy group, resulting in the formation of a five-membered palladated ring. For **b** and **c**, either the C-2 Me group or the C-6 Me group was metallated to render a six-membered palladated ring in each case. Metallation of the C-6 carbon atom in ligand **c** was not observed, quite possibly because of the steric hindrance imposed by the neighbouring C-5 Me group. The reaction of ligand **d** with palladium acetate provided a mixture of products, one rendering metallation at the aromatic C-6 atom, and another one at the aliphatic C-2 Me group, yielding $–CH_2–$Pd bond formation. Most outstanding for the tetranuclear structure of the **d** species was that, as opposed to the [*C*,*N*,*S*] or [*C*,*N*,*O*] tetramers previously reported where the four cyclometallated moieties were identical, the present case poses an unprecedented example of a tetranuclear structure with two distinct palladated groups having five and six-membered metallated rings. As for **e** and **f**, *C*-metallation was not accomplished in any instance; the deprotonation of both phenoxy groups favoured the coordination of the ligands as [*O*,*N*,*O*]. In all the cases depicted above the resulting products after palladation of the ligands were tetranuclear compounds, irrespective of the metallated atom, including the [*O*,*N*,*O*] bonded ligands.



For the convenience of the reader the compounds and reactions are shown in Schemes 1, 2, 3 and 4. The compounds described in this paper were characterized by elemental analysis (C, H, N), by IR and $^1H$, $^{31}P\{^1H\}$ NMR spectroscopy, and, in part, by FAB mass spectrometry and single-crystal X-ray diffraction (Experimental Section).

The reaction of **a** with palladium(II) acetate in toluene at 60 °C gave [Pd{2,3,4-$(MeO)_3C_6HC(H)$=N(2-O-5-$t$Bu$C_6H_3$)}]$_4$ (**1a**) as an air-stable solid, which was fully characterized. The IR spectrum showed the shift of the ν(C=N) stretch toward lower wavenumbers from the free ligand value, because of nitrogen coordination of the imine,[42,43] and the absence of the ν(O–H) stretch, as compared to the ligand (3427 cm$^{-1}$), in accordance with loss of the –OH proton. In the $^1$H NMR spectrum the *H*C=N and 5-H resonances were high-field shifted, as compared to the uncoordinated ligand, by 1.43 and 0.9 ppm, respectively; the low $\delta$ values in these cases were due to the structure of the complexes, which puts the *H*C=N and 5-H protons in the proximity of the shielding zone of the phenyl rings of a neighbouring metallated ligand.[32,33,37,39] Likewise, absence of the O*H* resonance in the $^1$H NMR spectrum confirmed deprotonation.

The FAB mass spectra showed the cluster of peaks characteristic of the [MH]$^+$ fragment centred at 1792 uma; the isotopic pattern was in good agreement with the tetrameric formulation.

### Crystal Structure of 1a

Suitable crystals were grown by slowly evaporating chloroform from a solution. Crystal data are given in Table 1. The ORTEP illustration of complex **1a**·$H_2O$ is shown in Figure 1. The core of the tetrameric molecule consists of an eight-membered ring of alternating palladium and oxygen atoms. Each palladium atom is bonded to the ligand through an aryl carbon, a C=N nitrogen, and a phenoxy oxygen atom, and also to a bridging oxygen atom of a neighbouring cyclometallated ligand monomer, in a slightly distorted square-planar arrangement. The mean deviations from the least-squares plane are: Pd1, C1, N1, O1, O9, 0.0215 Å; Pd2, C21, N2, O5, O13, 0.0208 Å; Pd3, C41, N3, O5, O9, 0.0166 Å; Pd4, C69, N4, O1, O13, 0.0300 Å. The bond lengths at palladium are within the expected values.[37–40] The resulting cluster has approximate $C_2$ symmetry; the $C_2$ axis is perpendicular to and bisects Pd1···Pd2 and Pd3···Pd4. The Pd1···Pd2 and Pd3···Pd4 distances of 3.378(1) and 3.412(1) Å, respectively, preclude any Pd–Pd interactions. Two of the quasi-planar Pd ligand units are parallel and almost orthogonal to the other two parallel monomer moieties.

Treatment of **1a** with triphenylphosphane or diphosphanes (dppm, dppe) gave the mononuclear [Pd{2,3,4-$(MeO)_3$-$C_6HC(H)$=N(2-O-5-$t$Bu$C_6H_3$)}($PPh_3$)] (**2a**) or dinuclear [{Pd(2,3,4-{MeO}$_3C_6HC${H}=N{2-O-5-$t$Bu$C_6H_3$})}$_2$(μ-$PPh_2CH_2PPh_2$)] (**3a**) and [{Pd(2,3,4-{MeO}$_3C_6HC${H}=N{2-O-5-$t$Bu$C_6H_3$})}$_2${μ-$PPh_2(CH_2)_2PPh_2$}] (**4a**) species, as air-stable solids, which were fully characterized (Experimental Section), with opening of the polynuclear structure after P–$O_{bridging}$ bond cleavage; the Pd–$O_{chelating}$ bond remained intact in all cases. The $^1$H NMR spectrum of **2a** showed the resonances of the 5-H and *H*C=N protons as doublets, coupled to the $^{31}$P nucleus of the phosphane ligand ($J_{H,P}$ = 3.4 and 10.7 Hz, respectively), and the $^{31}$P{$^1$H} NMR spectrum showed the phosphorus resonance as a singlet at $\delta$ = 34.2 ppm; these findings were in agreement with an arrangement in which the phosphorus atom is *trans* to the nitrogen atom.[44–47] The *H*C=N proton resonance, at $\delta$ = 8.14 ppm, showed a smaller high-field shift than that in compound **1a**, as compared to the free ligand, in agreement with the opening of the polynuclear structure.[39] Only one singlet was observed in the $^{31}$P{$^1$H} NMR spectra of **3a** and **4a** for the two equivalent phosphorus nuclei.

The reaction of **b** and **c** with palladium(II) acetate in toluene at 60 °C gave the tetranuclear complexes [Pd{6-Me-2-$CH_2C_6H_3C(H)$=N(2-$OC_6H_4$)}]$_4$ (**1b**) and [Pd{5-Me-2-

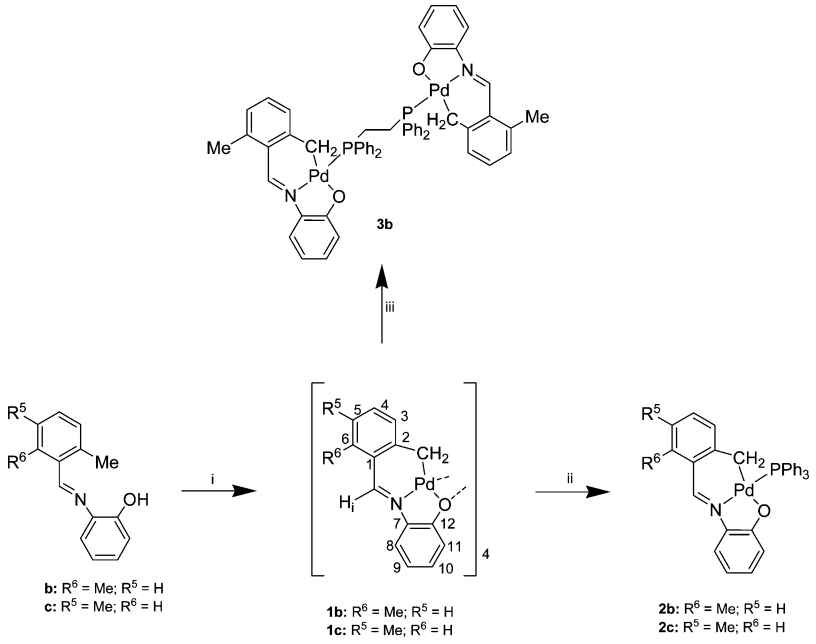

Scheme 2. (i) $Pd(AcO)_2$, (toluene); (ii) $PPh_3$ (acetone, 1:4 molar ratio); (iii) diphosphane (acetone, 1:2 molar ratio).

$CH_2C_6H_3C(H)=N(2\text{-}OC_6H_4)\}]_4$ (**1c**), respectively, as air-stable solids which were fully characterized (Experimental Section). Bonding of the metal was attained through a methyl group in both cases; the integration for the multiplet signals in the $^1H$ NMR spectrum of **1c** showed that the C-6 atom was not metallated. The spectroscopic data was in agreement with nitrogen coordination of the C=N group and deprotonation of the phenoxy group, vide supra (Scheme 2, see the Experimental Section). The resonances at $\delta \approx 3.5$ ppm and $\delta \approx 2.5$ ppm were assigned to the AB system of the two nonequivalent methylene protons ($J_{H,H}$ = 13.6 and 14.1 Hz for **1b** and **1c**, respectively). Their diastereotopic nature follows from the tetrameric structure of the complex, which renders both methylene protons, on either side of the metallated moiety, magnetically nonequivalent (see the crystal structure of **1c**). The singlet resonance at $\delta$ = 2.28 ppm (**1b**) and $\delta$ = 2.44 ppm (**1c**) were assigned to the nonmetallated methyl groups. An interesting feature in the $^1H$ NMR spectrum of **1c** is the presence of weak signals, four low-intensity doublets ascribed to the 11-H and $CH_2$ protons were identified, which could be indicative of the presence of other species in solution. However, we were unable to isolate the minor components of the mixture by column chromatography or by any other methods. The $^1H$ NMR spectrum of **1c** recorded at 323 K displayed the same weak signals with no appreciable difference in either the chemical shift or in the relative intensities. When **1c** was treated with triphenylphosphane to give the mononuclear complex **2c**, vide infra, only the signals corresponding to this complex appeared in its spectrum; this seems to suggest that the weak resonances mentioned above could be due to a different grouping of the cyclometallated monomer fragments in the polynuclear structure, which when cleaved only yields **2c** in solution. The presence of weak and poorly resolved signals has been observed earlier in a similar complex.[37]

The synthesis of **1c** is one of the rare examples where activation of an aliphatic carbon, rather than an aromatic carbon, is preferred for metallation.[15–19] This is particularly interesting because activation of the aliphatic carbon implies the formation of a six-membered chelate ring as opposed to the more stable five-membered one.

## Crystal Structure of 1c

Suitable crystals were grown by slowly evaporating chloroform from a solution. Crystal data are given in Table 2. The ORTEP illustration of complex **1c** is shown in Figure 2. Compound **1c** shows as tetranuclear structure with a $Pd_4O_4$ core similar to that described for **1a**; the most noticeable difference being the metallated carbon, which in this case was an $sp^3$ $CH_2$ carbon as opposed to the aromatic $sp^2$ carbon atom in **1a**. The coordination geometry about the palladium atoms is slightly distorted square-planar. The mean deviations from the least-squares plane are: Pd1, C14, N1, O1, O2, 0.0271 Å; Pd2, C34, N2, O2, O1#1, 0.0342 Å. The bond lengths and angles are in the range of those previously reported.[16,18,37–40] Another central feature of this complex is the planar disposition of the six-membered cyclometallated ring.

Several structures of cyclometallated complexes derived from Schiff bases in which the ligand is coordinated through a $CH_2$ carbon have been described previously; however, with the exception of a recent example reported by us,[48] in the remaining cases the six-membered cyclo-

Symmetry transformations used to generate equivalent atoms: # 1 – *x* – 1/2, –*y* + 1/2, *z*

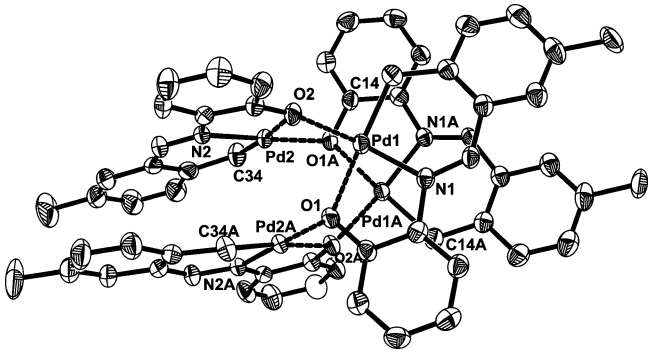

Figure 2. Molecular structure of [Pd{5-Me-2-$CH_2C_6H_3C(H)$=N(2-$OC_6H_4$)}]$_4$ (**1c**). Ellipsoids drawn at the 40% level.

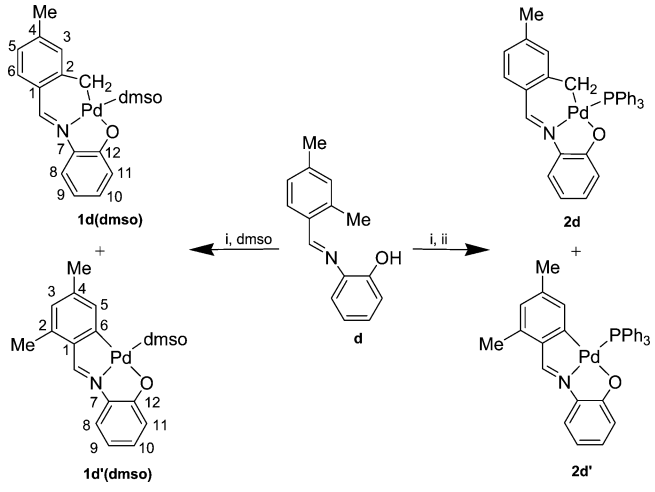
metallated ring showed a nonplanar geometry with a boat-like structure.[16,18,49–53] We believe that in **1c** the tetranuclear structure brings close two of the cyclometallated ligands, thus imposing planarity of the ring in order to avoid mutual steric repulsion.

Treatment of **1b** and **1c** with triphenylphosphane yielded the mononuclear complexes **2b** and **2c**, respectively, upon cleavage of the P–$O_{bridging}$ bond. The $^1$H NMR spectra showed a doublet resonance assigned to the two equivalent $CH_2$ protons, consequent on splitting of the tetranuclear structure, coupled to the $^{31}$P nucleus, $\delta$ = 2.96 ppm ($^3J_{P,H}$ = 5.8 Hz) and $\delta$ = 2.93 ppm ($^3J_{P,H}$ = 5.8 Hz) for **2b** and **2c**, respectively.

The reaction of **1b** with the tertiary diphosphane $Ph_2P(CH_2)_2PPh_2$ (dppe) gave the dinuclear cyclometallated complex, [{Pd(6-Me-2-$CH_2C_6H_3C${H}=N{2-$OC_6H_4$})}$_2${μ-$PPh_2(CH_2)_2PPh_2$}] (**3b**), which was fully characterized. The $^1$H NMR spectrum showed only one set of signals for the two cyclometallated moieties, and a singlet at $\delta$ = 33.2 ppm in the $^{31}$P{$^1$H} NMR spectrum was assigned to the two equivalent phosphorus nuclei.

Treatment of **d** with palladium(II) acetate, under the same conditions as those used for the synthesis of **1a**–**1c**, yielded a mixture of isomers, [Pd{4-Me-2-$CH_2C_6H_3C$-(H)=N(2-$OC_6H_4$)}]$_n$ and [Pd{2,4-$(Me)_2C_6H_2C$(H)=N(2-$OC_6H_4$)}]$_{4-n}$ ($n$ = 0–4), featuring dissimilar cyclometallated units arising from the different metallation site chosen by the metal: aromatic sp$^2$ phenyl carbon atoms or aliphatic sp$^3$ methyl carbon atoms. The $^1$H NMR spectrum in $CDCl_3$ showed extended overlapping of the signals as expected for a complex mixture, as an outcome of which only five partially overlapped doublets, of the ten required, were assigned to the $CH_2$ protons at $\delta \approx$ 3.5–4.0 ppm. The signals corresponded to the isomers bearing a metallated methyl group, [Pd{4-Me-2-$CH_2C_6H_3C$(H)=N(2-$OC_6H_4$)}]$_n$[Pd{2,4-$(Me)_2C_6H_2C$(H)=N(2-$OC_6H_4$)}]$_{4-n}$ ($n$ = 1, 3, 4) and two isomers with $n$ = 2, depending on whether the two cyclometallated monomers [Pd{4-Me-2-$CH_2C_6H_3C$(H)=N(2-$OC_6H_4$)}] were opposite or adjacent in the tetranuclear arrangement (a sixth isomer is possible when metallation is through the C-6 carbon atom: [Pd{2,4-$(Me)_2C_6H_2C$-(H)=N(2-$OC_6H_4$)}($PPh_3$)]$_4$). Surprisingly, the $^1$H NMR spectrum recorded in a donor solvent such as [$D_6$]dmso showed two singlet signals at $\delta$ = 8.82 ppm and $\delta$ = 8.41 ppm assigned to two chemically different *H*C=N protons, putting forward the existence of only two species in the solution in the aftermath of the tetranuclear structure break-up caused by coordination of the solvent, which yielded the mononuclear fragments [Pd{4-Me-2-$CH_2C_6$-$H_3C$(H)=N(2-$OC_6H_4$)}([$D_6$]dmso)], **1d**(dmso), and [Pd{2,4-$(Me)_2C_6H_2C$(H)=N(2-$OC_6H_4$)}([$D_6$]dmso)], **1d′**(dmso), with C(sp$^3$)–Pd and C(sp$^2$)–Pd bonds, respectively (see Scheme 3). Hence, only one singlet was observed for the $CH_2$ protons at 3.26 ppm, as opposed to the AB system in the tetranuclear structure, vide supra. The relative molar ratio of the complexes in solution was 1:0.5 [**1d**(dmso)/**1d′**(dmso)]. Regardless of the reaction time and temperature used in the synthesis, the final relative molar ratio remained unchanged.



Scheme 3. (i) $Pd(AcO)_2$, (toluene); (ii) $PPh_3$ (acetone, 1:4 molar ratio).

We suggest that in nondonor solvents such as chloroform the [Pd{4-Me-2-$CH_2C_6H_3C$(H)=N(2-$OC_6H_4$)}] and [Pd{2,4-$(Me)_2C_6H_2C$(H)=N(2-$OC_6H_4$)}] building blocks were randomly arranged into tetranuclear moieties. Therefore, four isomers were present in the solution (vide supra), in addition to the two "pure" complexes [Pd{4-Me-2-$CH_2C_6H_3C$(H)=N(2-$OC_6H_4$)}]$_4$ and [Pd{2,4-$(Me)_2C_6H_2C$-(H)=N(2-$OC_6H_4$)}]$_4$. However, when the mixture was dissolved in a donor solvent the tetranuclear structure was cleaved, and the two distinct mononuclear moieties could

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

be isolated. Another approach to the separation of the mononuclear isomers was treatment of the complex mixture with triphenylphosphane in acetone, which yielded complexes [Pd{4-Me-2-$CH_2C_6H_3C(H)=N(2\text{-}OC_6H_4)$}$(PPh_3)$] (**2d**) and [Pd{2,4-$(Me)_2C_6H_2C(H)=N(2\text{-}OC_6H_4)$}$(PPh_3)$] (**2d′**), which were fully characterized (Experimental Section). The above-mentioned assumption was confirmed by the crystal structure of one of the isomers.

### Crystal Structure of the Mixture of [Pd{4-Me-2-$CH_2C_6H_3C(H)=N(2\text{-}OC_6H_4)$}]$_3$[Pd{2,4-$(Me)_2$-$C_6H_2C(H)=N(2\text{-}OC_6H_4)$}]

Crystal data are given in Table 3, and the ORTEP illustration is shown in Figure 3. A single crystal was isolated from a chloroform solution of the mixture of isomers and its resolved crystal and molecular structure showed the characteristic tetranuclear arrangement described for **1a** and **1c** bearing a central $Pd_4O_4$ core. Each palladium atom was coordinated to the ligand **d** through the C=N nitrogen, and to two phenoxy oxygen atoms, one of the latter two pertaining to a neighbouring metallated unit. However, the fourth coordination position was occupied by the C46 aromatic carbon for the Pd3 atom and by the C67 methylene carbon atom for Pd4. The ligand coordinated to Pd1 was found to be disordered, the major component (70%) corresponded to a ligand coordinated through the C7A methylene carbon and the minor component through the C6B aromatic carbon. The ligand coordinated to Pd2 was also disordered (50% for each component) and coordinated through the C26B aromatic or the C27A aliphatic carbon atoms, respectively, for each component.

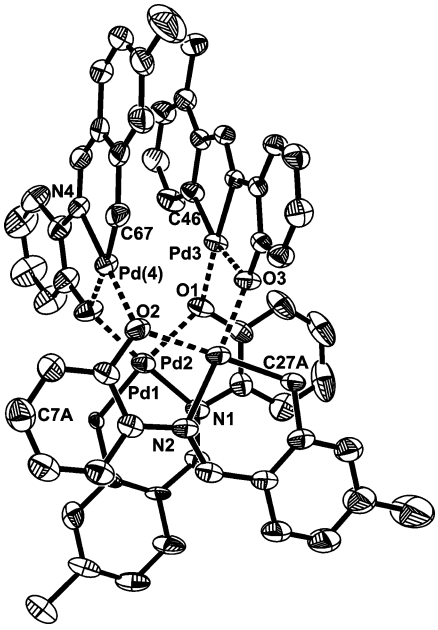

Figure 3. Molecular structure of the mixture of [Pd{4-Me-2-$CH_2C_6H_3C(H)=N(2\text{-}OC_6H_4)$}]$_n$ and [Pd{2,4-$(Me)_2C_6H_2C(H)=N(2\text{-}OC_6H_4)$}]$_{4-n}$ ($n$ = 3). Minor components of the disordered structure have been omitted for clarity. Ellipsoids drawn at the 40% level.

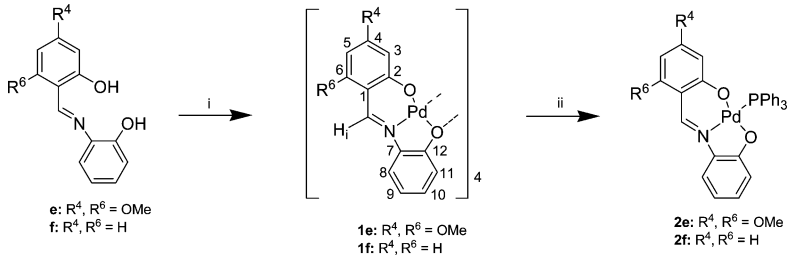
The reaction of **e** and **f** with palladium(II) acetate in toluene gave the non-cyclometallated complexes [Pd{2-O-4,6-$(MeO)_2C_6H_2C(H)=N(2\text{-}OC_6H_4)$}]$_4$ (**1e**) and [Pd{2-$OC_6H_4C(H)=N(2\text{-}OC_6H_4)$}]$_4$ (**1f**) as yellow and red air-stable solids, respectively. The IR spectroscopic data was in good agreement with nitrogen coordination of the imine,[42,43] and absence of the ν(O–H) bands, indicated double deprotonation of the ligands; the latter was confirmed by the absence of the O*H* resonances in the $^1$H NMR spectra. While the $^1$H NMR spectrum for **1e** showed a high-field shift of the *H*C=N resonance ($\delta$ = 1.19 ppm), similar to that observed for **1a**–**1c**, the *H*C=N resonance for



Scheme 4. (i) $Pd(AcO)_2$, (toluene); (ii) $PPh_3$ (acetone, 1:4 molar ratio).

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

**1f** appeared at $\delta$ = 8.94 ppm (shifted by 0.24 ppm), putting forward that the *H*C=N proton was not in the shielding area of the phenyl ring of an adjacent metallated ligand, probably because of cleavage of the tetranuclear structure caused by the coordination of [$D_6$]dmso used as the NMR solvent (vide supra). The IR, NMR and mass spectra of these complexes did not definitely establish their tetranuclear nature; nevertheless, resolution of the molecular structure of **1e** evidenced the tetrameric arrangement of the palladated fragments (Scheme 4).

Whereas for ligand **e** coordination is only possible through the phenoxy oxygen atoms, ligand **f** holds two coordination sites, the C-6 carbon and the phenoxy oxygen atoms; however, regardless of the reaction conditions used, the cyclometallated complex was not obtained in any case.

### Crystal Structure of 1e·2$CH_2Cl_2$

Suitable crystals were grown by slowly evaporating dichloromethane from a solution. Crystal data are given in Table 4, and the ORTEP illustration of complex **1e** is shown in Figure 4. The molecular structure of **1e**·2$CH_2Cl_2$ showed a [Pd(ligand)]$_4$ tetrameric structure, in which each palladium atom was coordinated in a slightly distorted square-planar geometry through the two deprotonated phenoxy oxygen atoms, the C=N nitrogen and an oxygen atom from another Pd(ligand) unit. The mean deviations from the least-squares plane are: Pd1, O1, O2, O14, N1, 0.0091 Å; Pd2, O5, O6, O10, N2, 0.0015 Å; Pd3, O2, O9, O10, N3, 0.0285 Å; Pd4, O6, O13, O14, N4, 0.0074 Å. The core was formed by an eight-membered $Pd_4O_4$ ring of similar geometry to those described above. Each palladium atom belongs to two fused five- and six-membered rings, which are planar, and coplanar with the two phenol rings. The four units are arranged as parallel pairs in two sets at nearly right angles. Bond lengths and angles are within the expected values.[16,18,37–40]

Table 4. Selected bond lengths [Å] and angles [°] for complex **1e**.

| | | | |

| O6–Pd2–O10 | 92.62(14) | O14–Pd4–O6 | 94.51(14) |
| Pd1–O2–Pd3 | 121.28(17) | Pd3–O10–Pd2 | 120.78(18) |
| Pd2–O6–Pd4 | 116.87(17) | Pd4–O14–Pd1 | 118.98(17) |

The reaction of **1e** and **1f** with triphenylphosphane yielded the mononuclear complexes [Pd{2-O-4,6-(MeO)$_2$-$C_6H_2C$(H)=N(2-$OC_6H_4$)}($PPh_3$)] (**2e**) and [Pd{2-$OC_6H_4$C-(H)=N(2-$OC_6H_4$)}($PPh_3$)] (**2f**) after cleavage of the tetranuclear structure, as air-stable solids, which were fully characterized. The $^{31}$P NMR spectroscopic data were in accordance with an arrangement in which the phosphorus atom is *trans* to the nitrogen atom. Contrary to the case of five-membered ring palladacycles, the 3-H protons and (in **2e**) the C-4 MeO group were not affected by shielding from the phosphane phenyl rings; expansion of the metallated ring to six members places these nuclei away form the appropriate shielding zone.

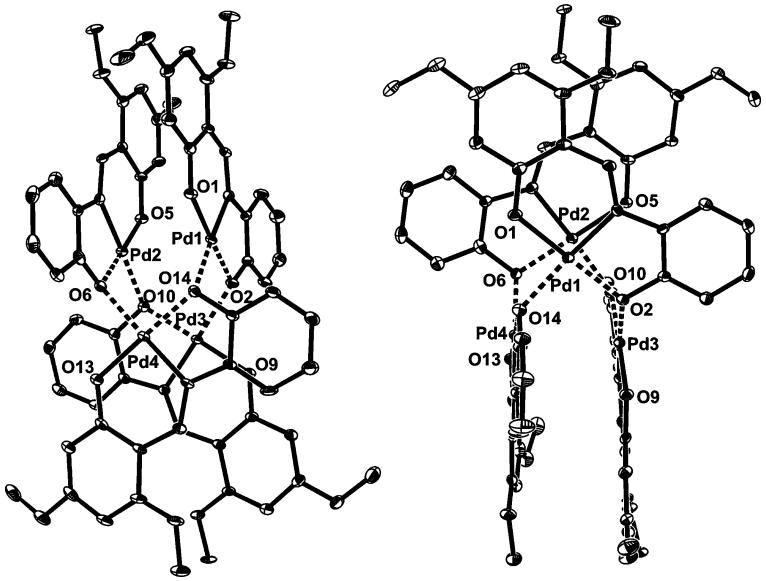

Figure 4. Molecular structure of [Pd{2-O-4,6-(MeO)$_2C_6H_2C$(H)=N(2-$OC_6H_4$)}]$_4$, (**1e**). Ellipsoids drawn at the 40% level.

## Conclusions

We have shown that Schiff base ligands derived from 2-aminophenol offer different bonding modes to palladium(II) because of the various donor atoms they possess, behaving as tridentate [*C*,*N*,*O*] or [*O*,*N*,*O*] ligands. In all cases, tetranuclear compounds were formed upon reaction of the ligand with the metal salt through metallation of a substituted phenyl ring. As with the tridentate [*C*,*N*,*S*] thiosemicarbazones, formation of the central eight-membered $Pd_4O_4$ core seems to favour tetranuclear clusters, as opposed to the dinuclear moieties obtained from didentate [*C*,*N*] Schiff bases. Where choice was possible, five-membered ring metallacycles were preferred over six-membered ones; nevertheless, the latter may be obtained when substituents hinder attack of the metal atom on the phenyl ring. In the case of ligand **d**, where metallation may proceed through a phenyl or a methyl carbon atom, mixed five- and six-membered palladated moieties build up the tetrameric structure, thus constituting an unprecedented example of a tetranuclear cyclopalladated compound.

## Experimental Section

**General Procedures:** Solvents were purified by standard methods.[54] Chemicals were reagent grade. The phosphanes $PPh_3$, $Ph_2PCH_2PPh_2$ (dppm) and $Ph_2P(CH_2)_2PPh_2$ (dppe) were purchased from Aldrich Chemie. Microanalyses were carried out with a Carlo Erba Elemental Analyzer, Model 1108. IR spectra were recorded by using Nujol mulls or KBr discs with a Perkin–Elmer 1330 and a Mattson spectrophotometer. NMR spectra were obtained in $CDCl_3$ solutions and referenced to $SiMe_4$ [$^1H$, or 85% $H_3PO_4$ $^{31}P\{^1H\}$]; they were recorded with a Bruker AC-2005 spectrometer. All chemical shifts were reported downfield from the standards. The FAB mass spectra were recorded by using a Quatro mass spectrometer with a Cs ion gun; 3-nitrobenzyl alcohol (3-NBA) was used as the matrix.

**Syntheses**

**2,3,4-$(MeO)_3C_6H_2C(H)=N[2-(OH)-5-tBuC_6H_3]$ (a):** 2,3,4-$(MeO)_3C_6H_2COH$ (1.000 g, 6.06 mmol) was added to a solution of 2-amino-4-*tert*-butylphenol (1.188 g, 6.06 mmol) in dry chloroform (50 $cm^3$). The solution was heated under reflux in a Dean–Stark apparatus for 4 h. After cooling to room temperature the chloroform was removed, and a brown solid was obtained. Yield: 1850 mg, 89%. $C_{20}H_{25}NO_4$ (343.18): calcd. C 69.9, H 7.3, N 4.1; found C 68.5, H 7.0, N 3.8. IR: $\tilde{\nu}$ = 3427 (m, $\nu_{O-H}$), 1589 (s, $\nu_{C=N}$) $cm^{-1}$. $^1H$ NMR (200 MHz, $CDCl_3$): $\delta$ = 1.13 (s, 9 H, *t*Bu), 3.92, 3.95, 4.02 (s, 9 H, MeO), 6.80 (d, $^3J_{H5,H6}$ = 8.3 Hz, 1 H, 5-H), 7.92 (d, $^3J_{H5,H6}$ = 8.3 Hz, 1 H, 6-H), 6.95 (d, $^2J_{H,H}$ = 8.3 Hz, 11 H), 7.4 (m, 2 H, 8-H, 10-H), 8.76 (s, 1 H, OH) (resonance taken from a spectrum recorded in [$D_6$]dmso), 8.97 (s, 1 H, $H_i$) ppm. FAB-MS: *m*/*z* = 344 $[MH]^+$.

Schiff base ligands **b**–**d** were prepared similarly as brown solids.

**2,6-$(Me)_2C_6H_3C(H)=N[2-(OH)C_6H_4]$ (b):** Yield: 1214 mg, 89%. $C_{15}H_{15}NO$ (225.12): calcd. C 79.9, H 6.7, N 6.2; found C 68.5, H 7.0, N 3.8. IR: $\tilde{\nu}$ = 3396 (m, $\nu_{O-H}$), 1621 (s, $\nu_{C=N}$) $cm^{-1}$. $^1H$ NMR (200 MHz, $CDCl_3$) $\delta$ = 2.64 (s, 6 H, Me), 7.2 (m, 7 H), 9.1 (s, 1 H, $H_i$), 10.8 (br, 1 H, OH) ppm.

**2,5-$(Me)_2C_6H_3C(H)=N[2-(OH)C_6H_4]$ (c):** Yield: 1188 mg, 88%. $C_{15}H_{15}NO$ (225.12): calcd. C 79.9, H 6.7, N 6.2; found C 79.8, H 6.7, N 6.1. IR: $\tilde{\nu}$ = 3375 (s, $\nu_{O-H}$), 1608 (sh, $\nu_{C=N}$) $cm^{-1}$. $^1H$ NMR (200 MHz, $CDCl_3$): $\delta$ = 2.41, 2.59 (s, 6 H, Me), 6.95 (dt, $^3J_{H,H}$ = 7.5 Hz, $^4J_{H,H}$ = 1.2 Hz, 1 H), 7.06 (dd, $^3J_{H,H}$ = 8.0 Hz, $^4J_{H,H}$ = 1.2 Hz, 1 H), 7.3 (m, 5 H), 7.91 (s, 6-H), 8.9 (s, 1 H, $H_i$), 9.8 (br, 1 H, OH) ppm.

**2,4-$(Me)_2C_6H_3C(H)=N[2-(OH)C_6H_4]$ (d):** Yield: 1589 mg, 97%. $C_{15}H_{15}NO$ (225.12): calcd. C 79.9, H 6.7, N 6.2; found C 79.4, H 6.4, N 6.1. IR: $\tilde{\nu}$ = 3043 (m, $\nu_{O-H}$), 1619 (s, $\nu_{C=N}$) $cm^{-1}$. $^1H$ NMR (200 MHz, $CDCl_3$): $\delta$ = 2.40, 2.61 (s, 6 H, Me), 6.5 (br, 1 H, OH), 6.94 (t, $^3J_{H,H}$ = 7.6 Hz, 1 H), 7.3 (m, 5 H), 7.91 (d, $^3J_{H6,H5}$ = 7.8 Hz, 1 H, 6-H), 8.97 (s, 1 H, $H_i$) ppm.

Schiff base **e** was prepared similarly as a yellow solid.

**2-(OH)-4,6-$(MeO)_2C_6H_2C(H)=N[2-(OH)C_6H_4]$ (e):** Yield: 1523 mg, 93%. $C_{15}H_{15}NO_4$ (273.10): calcd. C 65.9, H 5.5, N 5.1; found C 65.8, H 5.5, N 5.1. IR: $\tilde{\nu}$ = 3430 (m, $\nu_{O-H}$), 3385 (sh), 1625 (sh, m, $\nu_{C=N}$) $cm^{-1}$. $^1H$ NMR (200 MHz, $CDCl_3$): $\delta$ = 3.85, 3.84 (s, 6 H, MeO), 5.6 (br, 1 H, OH), 5.9, 6.1 (s, 2 H, 3-H, 5-H), 7.0 (m, 4 H), 8.9 (s, 1 H, $H_i$), 10.8 (br, 1 H, OH) ppm.

Schiff base **f** was prepared similarly as a red solid.

**2-$(OH)C_6H_4C(H)=N[2-(OH)C_6H_4]$ (f):** Yield: 1176 mg, 92%. $C_{13}H_{11}NO_2$ (213.08): calcd. C 73.2, H 5.2, N 6.6; found C 73.1, H 5.0, N 6.3. IR: $\tilde{\nu}$ = 3500 (m, $\nu_{O-H}$), 1630 (m, $\nu_{C=N}$) $cm^{-1}$. $^1H$ NMR (200 MHz, $CDCl_3$): $\delta$ = 5.7 (br, 1 H, OH), 7.2 (m, 8 H), 8.7 (s, 1 H, $H_i$), 12.2 (br, 1 H, OH) ppm.

**$[Pd\{2,3,4-(MeO)_3C_6HC(H)=N(2-O-5-tBuC_6H_3)\}]_4$ (1a):** A pressure tube containing 2,3,4-$(MeO)_3C_6H_2C(H)=N[2-(OH)-5-tBuC_6H_3]$ (0.456 mg, 1.33 mmol), palladium acetate (0.300 g, 1.33 mmol) and dry toluene (20 $cm^3$) was sealed under argon. The resulting mixture was heated at 60 °C for 24 h. After cooling to room temperature the solution was filtered through Celite to remove the small amount of black palladium formed. The solvent was removed under vacuum to give a red oil, which was recrystallized from dichloromethane/hexane to give the desired product as a red solid. Yield: 1191 mg, 50%. $C_{80}H_{92}N_4O_{16}Pd_4$ (1791.28): calcd. C 53.6, H 5.2, N 3.1; found C 53.0, H 5.1, N 3.1. IR: $\tilde{\nu}$ = 1571 (sh, m, $\nu_{C=N}$) $cm^{-1}$. $^1H$ NMR (200 MHz, $CDCl_3$): $\delta$ = 1.24 (s, 9 H, *t*Bu), 3.38, 3.81, 4.03 (s, 9 H, MeO), 5.81 (s, 1 H, 5-H), 6.75 (d, $^4J_{H8,H10}$ = 2.2 Hz, 1 H, 8-H), 6.99 (dd, $^3J_{H10,H11}$ = 8.8 Hz, $^4J_{H8,H10}$ = 2.2 Hz, 1 H, 10-H), 7.35 (d, 1 H, 11-H), 7.54 (s, 1 H, $H_i$) ppm. FAB-MS: *m*/*z* = 1792 $[MH]^+$, 896 $[M/2]^+$.

Compound **1b** was prepared similarly as a brown solid.

**$[Pd\{6-Me-2-CH_2C_6H_3C(H)=N(2-OC_6H_4)\}]_4$ (1b):** Yield: 98 mg, 30%. $C_{60}H_{52}N_4O_4Pd_4$ (1318.75): calcd. C 54.4, H 4.3, N 4.2; found C 53.9, H 4.1, N 4.1. IR: $\tilde{\nu}$ = 1583 (s, $\nu_{C=N}$) $cm^{-1}$. $^1H$ NMR (200 MHz, $CDCl_3$): $\delta$ = 2.28 (s, 3 H, Me), 2.60, 3.49 (d, $J_{gem(H,H)}$ = 13.6 Hz, 2 H, -$CH_2$-), 6.51 (dt, $^3J_{H9,H8}$ = 8.3 Hz, $^3J_{H10,H9}$ = 7.2 Hz, $^4J_{H11,H9}$ = 1.3 Hz, 1 H, 9-H), 6.80 (d, $^3J_{H5,H4}$ = 7.6 Hz, 1 H, 5-H), 6.86 (m, 2 H, 8-H, 4-H), 7.04 (d, $^3J_{H4,H3}$ = 7.4 Hz, 1 H, 3-H), 7.5 (dt, $^3J_{H10,H9}$ = 7.2 Hz, $^3J_{H11,H10}$ = 8.3 Hz, $^4J_{H10,H8}$ = 1.3 Hz, 1 H, 10-H), 7.84 (dd, $^3J_{H11,H10}$ = 8.3 Hz, $^4J_{H11,H9}$ = 1.3 Hz, 1 H, 11-H), 8.13 (s, 1H, $H_i$) ppm. FAB-MS: *m*/*z* = 331 $[(M/4)H]^+$.

Compound **1c** was prepared similarly as a red solid.

**$[Pd\{5-Me-2-CH_2C_6H_3C(H)=N(2-OC_6H_4)\}]_4$ (1c):** Yield: 40 mg, 45%. $C_{60}H_{52}N_4O_4Pd_4$ (1318.75): calcd. C 54.4, H 4.3, N 4.2; found C 54.2, H 4.3, N 4.1. IR: $\tilde{\nu}$ = 1582 (s, $\nu_{C=N}$) $cm^{-1}$. $^1H$ NMR (200 MHz, $CDCl_3$): $\delta$ = 2.44 (s, 3 H, Me), 2.45 (d, $J_{gem(H,H)}$ = 14.1 Hz, 1 H, -$CH_2$-), 3.59 (d, $J_{gem(H,H)}$ = 14.1 Hz, 1 H, -$CH_2$-), 6.50 (dt, $^3J_{H9,H8}$ = 7.8 Hz, $^4J_{H11,H9}$ = 0.9 Hz, 1 H, 9-H), 6.8 (m, 3 H), 7.2 (m, 3 H), 7.13 (s, 1 H, $H_i$), 7.74 (dd, $^3J_{H11,H10}$ = 8.3 Hz, $^4J_{H11,H9}$ = 0.9 Hz, 1 H, 11-H) ppm.

Compound **1e** was prepared similarly as a yellow solid.

**[Pd{2-O-4,6-$(MeO)_2C_6H_2C(H)=N(2-OC_6H_4)$}]$_4$ (1e):** Yield: 117 mg, 75%. $C_{60}H_{52}N_4O_{16}Pd_4$ (1510.75): calcd. C 47.7, H 3.5, N 3.7; found C 47.5, H 3.4, N 3.5. IR: $\tilde{\nu}$ = 1612 (s, $\nu_{C=N}$) cm$^{-1}$. $^1$H NMR (200 MHz, $CDCl_3$): $\delta$ = 3.70, 3.82 (s, 6 H, MeO), 5.57, 5.73 (d, H5, $^4J_{H5,H3}$ = 1.9 Hz, 2 H, 3-H), 6.59 (t, $^3J_{H9,H8}$ = 7.5 Hz, 1 H, 9-H), 7.09 (m, 2 H, 8-H, 10-H), 7.71 (s, 1 H, H$_i$), 8.33 (d, $^3J_{H11,H10}$ = 8.3 Hz, 1 H, 11-H) ppm.

Compound **1f** was prepared similarly as a red solid. Different reaction times (5 h, 24 h and 5 d) were used with similar yields.

**[Pd{2-$OC_6H_4C(H)=N(2-OC_6H_4)$}]$_4$ (1f):** Yield: 118 mg, 86%. $C_{52}H_{36}N_4O_8Pd_4$ (1270.75): calcd. C 49.2, H 2.8, N 4.4; found C 48.9, H 2.8, N 4.3. IR: $\tilde{\nu}$ = 1609 (s, $\nu_{C=N}$) cm$^{-1}$. $^1$H NMR (200 MHz, [D$_6$]dmso): $\delta$ = 7.17 (m, $^3J_{H10,H11}$ = 8.3 Hz, $^3J_{H10,H9}$ = 7.0 Hz, $^4J_{H10,H8}$ = 1.3 Hz, 1 H, 10-H), 7.30 (m, $^3J_{H,H}$ = 8.0 Hz, $^3J_{H,H}$ = 6.8 Hz, $^4J_{H,H}$ = 1.3 Hz, 1 H), 7.34 (dd, H8, $^3J_{H9,H8}$ = 8.3 Hz, 1 H), 7.57 (dd, $^3J_{H,H}$ = 8.7 Hz, $^4J_{H,H}$ = 1.3 Hz, 1 H), 7.60 (m, $^4J_{H,H}$ = 1.3 Hz, 1 H, 9-H), 7.93 (m, $^3J_{H,H}$ = 8.6 Hz, $^3J_{H,H}$ = 6.8 Hz, $^4J_{H,H}$ = 1.8 Hz, 1 H), 8.18 (dd, $^3J_{H,H}$ = 8.0 Hz, $^4J_{H,H}$ = 1.8 Hz, 1 H), 8.33 (dd, 1 H, 11-H), 8.94 (1 H, H$_i$) ppm. FAB-MS: $m/z$ = 637 [M/2]$^+$.

**[Pd{2,3,4-$(MeO)_3C_6HC(H)=N(2-O-5-tBuC_6H_3)$}($PPh_3$)] (2a):** $PPh_3$ (6.99 mg, 0.026 mmol) was added to a suspension of **1a** (12 mg, 0.006 mmol) in acetone (15 cm$^3$). The mixture was stirred for 12 h, and the solvent was removed to give a violet solid, which was recrystallized from acetone/hexane. Yield: 15 mg, 80%. $C_{38}H_{38}NO_4PPd$ (710.11): calcd. C 64.3, H 5.4, N 1.9; found C 64.3, H 5.3, N 1.8. IR: $\tilde{\nu}$ = 1544 (s, $\nu_{C=N}$) cm$^{-1}$. $^1$H NMR (200 MHz, $CDCl_3$): $\delta$ = 1.27 (s, 9 H, *t*Bu), 2.92, 3.73, 3.98 (s, 9 H, MeO), 5.49 (d, $^4J_{H5,P}$ = 3.4 Hz, 1 H, 5-H), 6.45 (d, $^3J_{H10,H11}$ = 8.7 Hz, 1 H, 11-H), 6.96 (dd, $^3J_{H10,H11}$ = 8.7 Hz, $^4J_{H8,H10}$ = 1.9 Hz, 1 H, 10-H), 7.05 (d, $^4J_{H8,H10}$ = 1.9 Hz, 1 H, 8-H), 8.14 (d, $^4J_{H_i,P}$ = 10.7 Hz, 1 H, H$_i$) ppm. $^{31}$P{$^1$H} NMR (80.96 MHz, $CDCl_3$): $\delta$ = 34.2 (s) ppm.

Compounds **2b**–**2f** were prepared similarly as red or brown (**2b**) solids.

**[Pd{6-Me-2-$CH_2C_6H_3C(H)=N(2-OC_6H_4)$}($PPh_3$)] (2b):** Yield: 10 mg, 60%. $C_{33}H_{29}NOPPd$ (592.98): calcd. C 66.8, H 4.9, N 2.4; found C 66.5, H 4.7, N 2.3. IR: $\tilde{\nu}$ = 1581 (s, $\nu_{C=N}$) cm$^{-1}$. $^1$H NMR (200 MHz, $CDCl_3$): $\delta$ = 2.55 (s, 3 H, Me), 2.96 (d, $^3J_{CH_2,P}$ = 5.8 Hz, 2 H, -$CH_2$-), 6.43 (t, $^3J_{H10,H9}$ = 7.3 Hz, 1 H, 10-H), 6.52 (t, $^4J_{H5,CH_2}$ = 4.4 Hz, 1 H, 2-H), 6.92 (m, 3 H), 7.09 (t, $^3J_{H,H}$ = 7.8 Hz, 1 H), 8.69 (d, $^4J_{H_i,P}$ = 12.7 Hz, 1 H, H$_i$) ppm. $^{31}$P{$^1$H} NMR (80.96 MHz, $CDCl_3$): $\delta$ = 33.4 (s) ppm.

**[Pd{5-Me-2-$CH_2C_6H_3C(H)=N(2-OC_6H_4)$}($PPh_3$)] (2c):** Yield: 29 mg, 60%. $C_{33}H_{29}NOPPd$ (592.98): calcd. C 66.8, H 4.9, N 2.4; found C 66.4, H 4.8, N 2.3. IR: $\tilde{\nu}$ = 1581 (s, $\nu_{C=N}$) cm$^{-1}$. $^1$H NMR (200 MHz, $CDCl_3$): $\delta$ = 2.28 (s, 3 H, Me), 2.93 (d, $^3J_{CH_2,P}$ = 5.8 Hz, 2 H, -$CH_2$-), 6.43 (t, $^3J_{H10,H9}$ = 7.5 Hz, 1 H, 10-H), 6.66 (d, $^3J_{H3,H4}$ = 7.8 Hz, 1 H, 3-H), 6.89 (m, 2 H, 4-H, 11-H), 7.09 (t, $^3J_{H9,H8}$ = 7.5 Hz, $^4J_{H11,H9}$ = 1.5 Hz, 1 H, 9-H), 7.25 (d, $^3J_{H9,H8}$ = 7.5 Hz, 1 H, 8-H), 7.27 (s, 1 H, 6-H), 8.32 (d, $^4J_{H_i,P}$ = 12.7 Hz, 1 H, H$_i$) ppm. $^{31}$P{$^1$H} NMR (80.96 MHz, $CDCl_3$): $\delta$ = 33.8 (s) ppm. FAB-MS: $m/z$ = 592 [M]$^+$.

Compounds **2d** and **2d′** were prepared by a similar procedure to the one described for **2a** using as starting material the mixture of isomers **1d/1d′**. The compounds were obtained as a mixture [in a 1:0.5 (**2d/2d′**) molar ratio] from which the pure compounds could not be isolated by column chromatography or by other methods.

**[Pd{4-Me-2-$CH_2C_6H_3C(H)=N(2-OC_6H_4)$}($PPh_3$)] (2d) and [Pd{2,4-$(Me)_2C_6H_2C(H)=N(2-OC_6H_4)$}($PPh_3$)] (2d′):** Yield: 23 mg, 50%. $C_{33}H_{29}NOPPd$ (592.98): calcd. C 66.8, H 4.9, N 2.4; found C 66.3, H 4.7, N 2.3. IR: $\tilde{\nu}$ = 1581 (s, $\nu_{C=N}$) cm$^{-1}$. $^1$H NMR (200 MHz, $CDCl_3$): $\delta$ = 2.67 (s, 6 H, Me′), 2.25 (s, 3 H, Me), 2.93 (d, $^3J_{CH_2,P}$ = 5.8 Hz, 2 H, -$CH_2$-), 5.67 (d, $^4J_{H5,P}$ = 3.4 Hz, 1 H, 5′-H), 8.20 (d, $^4J_{H_i,P}$ = 10.3 Hz, 1 H, H$_i$′), 8.32 (d, $^4J_{H_i,P}$ = 12.7 Hz, 1 H, H$_i$) ppm. $^{31}$P{$^1$H} NMR (80.96 MHz, $CDCl_3$): $\delta$ = 34.6 (**2d′**), 33.8 (s) (**2d**) ppm.

**[Pd{2-O-4,6-$(MeO)_2C_6H_2C(H)=N(2-OC_6H_4)$}($PPh_3$)] (2e):** Yield: 29 mg, 60%. $C_{33}H_{28}NO_4PPd$ (639.97): calcd. C 61.9, H 4.4, N 2.2; found C 61.5, H 4.1, N 2.0. IR: $\tilde{\nu}$ = 1611 (s, $\nu_{C=N}$) cm$^{-1}$. $^1$H NMR (200 MHz, $CDCl_3$): $\delta$ = 3.67, 3.88 (s, 6 H, MeO), 5.63, 5.78 (d, $^4J_{H5,H3}$ = 2.2 Hz, 2 H, 3-H, 5-H), 6.64 (t, $^3J_{H10,H9}$ = 7.5 Hz, 1 H, 10-H), 6.90 (d, $^3J_{H11,H10}$ = 7.5 Hz, 1 H, 11-H), 7.03 (t, 1 H, 9-H), 7.72 (d, $^3J_{H9,H8}$ = 8.3 Hz, 1 H, 8-H), 9.12 (d, $^4J_{H_i,P}$ = 18.1 Hz, 1 H, H$_i$) ppm. $^{31}$P{$^1$H} NMR (80.96 MHz, $CDCl_3$): $\delta$ = 23.4 (s) ppm. FAB-MS: $m/z$ = 639 [M]$^+$.

**[Pd{2-$OC_6H_4C(H)=N(2-OC_6H_4)$}($PPh_3$)] (2f):** Yield: 25 mg, 66%. $C_{31}H_{24}NO_2PPd$ (579.92): calcd. C 64.2, H 2.4, N 4.2; found C 64.3, H 2.3, N 4.0. IR: $\tilde{\nu}$ = 1603 (s, $\nu_{C=N}$) cm$^{-1}$. $^1$H NMR (200 MHz, $CDCl_3$): $\delta$ = 6.61 (d, $^3J_{H5,H4}$ = 8.5 Hz, 1 H, 5-H), 6.7 (m, 2 H, 3-H, 10-H), 6.92 (dd, $^3J_{H11,H10}$ = 8.3 Hz, $^3J_{H11,H9}$ = 1.2 Hz, 1 H, 11-H), 7.08 (dt, $^3J_{H10,H9}$ = 6.9 Hz, $^3J_{H9,H8}$ = 8.3 Hz, 1 H, 9-H), 7.22 (dt, $^3J_{H5,H4}$ = 8.6 Hz, $^3J_{H4,H3}$ = 6.8 Hz, $^3J_{H4,H2}$ = 1.8 Hz, 1 H, 4-H), 7.74 (dd, $^3J_{H9,H8}$ = 8.3 Hz, $^4J_{H10,H8}$ = 1.4 Hz, 1 H, 8-H), 8.61 (dd, $^4J_{H_i,P}$ = 17.1 Hz, 1 H, H$_i$) ppm. $^{31}$P{$^1$H} NMR (80.96 MHz, $CDCl_3$): $\delta$ = 23.3 (s) ppm. FAB-MS: $m/z$ = 579 [M]$^+$.

Compounds **3a** and **4a** were obtained as violet solids by a similar procedure, but with a 1:2 complex **1a**/ diphosphane molar ratio.

**[{Pd(2,3,4-{MeO}$_3$C$_6$HC{H}=N{2-O-5-*t*BuC$_6$H$_3$})}$_2$(μ-$PPh_2CH_2PPh_2$)] (3a):** Yield: 19 mg, 60%. $C_{65}H_{68}N_2O_8P_2Pd_2$ (1280.03): calcd. C 60.9, H 5.3, N 2.2; found C 60.2, H 5.2, N 2.1. IR: $\tilde{\nu}$ = 1544 (s, $\nu_{C=N}$) cm$^{-1}$. $^1$H NMR (200 MHz, $CDCl_3$): $\delta$ = 1.32 (s, 9 H, *t*Bu), 2.89, 3.70, 3.95 (s, 9 H, MeO), 5.39 (d, $^4J_{H5,P}$ = 4.3 Hz, 1 H, 5-H), 6.46 (d, $^3J_{H10,H11}$ = 9.2 Hz, 1 H, 11-H), 7.1 (m, 2 H, 10-H, 8-H), 7.99 (d, $^4J_{H_i,P}$ = 10.7 Hz, 1 H, H$_i$) ppm. $^{31}$P{$^1$H} NMR (80.96 MHz, $CDCl_3$): $\delta$ = 25.6 (s) ppm.

**[{Pd(2,3,4-{MeO}$_3$C$_6$HC{H}=N{2-O-5-*t*BuC$_6$H$_3$})}$_2${μ-$PPh_2(CH_2)_2PPh_2$}] (4a):** Yield: 21 mg, 65%. $C_{66}H_{70}N_2O_8P_2Pd_2$ (1294.06): calcd. C 61.3, H 5.4, N 2.1; found C 61.1, H 5.3, N 2.0. IR: $\tilde{\nu}$ = 1544 (s, $\nu_{C=N}$) cm$^{-1}$. $^1$H NMR (200 MHz, $CDCl_3$): $\delta$ = 1.30 (s, 9 H, *t*Bu), 2.85, 3.72, 3.97 (s, 9 H, MeO), 5.38 (s, 1 H, 5-H), 6.51 (d, $^3J_{H10,H11}$ = 8.7 Hz, 1 H, 11-H), 7.01 (dd, $^3J_{H10,H11}$ = 8.7 Hz, $^4J_{H8,H10}$ = 1.9 Hz, 1 H, 10-H), 7.09 (d, $^4J_{H8,H10}$ = 1.9 Hz, 1 H, 11-H) ppm. $^{31}$P{$^1$H} NMR (80.96 MHz, $CDCl_3$): $\delta$ = 35.0 (s) ppm.

Compound **3b** was obtained following a similar procedure as a brown solid.

**[{Pd(6-Me-2-$CH_2C_6H_3C\{H\}$=N{2-$OC_6H_4$})}$_2${μ-$PPh_2(CH_2)_2PPh_2$}] (3b):** Yield: 23 mg, 70%. $C_{56}H_{50}N_2O_2P_2Pd_2$ (1057.80): calcd. C 63.6, H 4.8, N 2.6; found C 63.6, H 4.7, N 2.6. IR: $\tilde{\nu}$ = 1581 (s, $\nu_{C=N}$) cm$^{-1}$. $^1$H NMR (200 MHz, $CDCl_3$): $\delta$ = 2.55 (s, 3 H, Me), 2.90 (d, $^3J_{CH_2,P}$ = 9.1 Hz, 2 H, -$CH_2$-), 6.43 (t, $^3J_{H10,H9}$ = 6.8 Hz, 1 H, 10-H), 6.74 (t, $^4J_{H_3,CH_2}$ = 2.3 Hz, 1 H, 3-H), 6.84 (dd, $^3J_{H,H}$ = 8.3 Hz, $^4J_{H,H}$ = 0.9 Hz, 1 H), 6.94 (d, $^3J_{H,H}$ = 4.9 Hz, 1 H), 7.10 (dt, $^3J_{H,H}$ = 8.3 Hz, $^4J_{H,H}$ = 1.4 Hz, 1 H), 8.71 (m, 1 H, $H_i$) ppm. $^{31}P\{^1H\}$ NMR (80.96 MHz, $CDCl_3$): $\delta$ = 33.2 (s) ppm.

**X-ray Crystallographic Study:** Three-dimensional, room temperature X-ray data were collected with a Siemens Smart CCD diffractometer by the $\omega$ scan method with graphite-monochromated Mo-$K_\alpha$ radiation (Table 5). All the measured reflections were corrected for Lorentz and polarisation effects and for absorption by semiempirical methods based on symmetry-equivalent and repeated reflections. The structures were solved by direct methods and refined by full-matrix least-squares on $F^2$. Hydrogen atoms were included in calculated positions and refined in riding mode. The C60 atom of **1a** was disordered over two positions with occupancies of approximately 50%. The C1–C9 and C21–C28 carbon atoms, corresponding to the benzal phenyls of two of the cyclometallated ligands in complex **1d/d′** were found to be disordered over two positions (with occupancies of approximately 70% [C1–C9] and 50% [C21–C28] for the major components). The refinement was carried out by taking into account the minor components. Refinement converged at a final $R$ = 0.0598, 0.0311, 0.0432 and 0.0401 (for complexes **1a**, **1c**, **1d/d′** and **1e**, respectively, observed data, $F$) and $wR_2$ = 0.1891, 0.0808, 0.1332 and 0.0909 (for complexes **1a**, **1c**, **1d/d′** and **1e**, respectively, unique data, $F^2$), with allowance for thermal anisotropy of all non-hydrogen atoms. The structure solution and refinement were carried out by using the program package SHELX-97.[55]

CCDC-608700 (for **1a**), -608701 (for **1c**), -608702 (for **1d/d′**) and -608703 (for **1e**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

# Synthesis, Crystal Structures, and Photophysical Properties of Lanthanide Complexes Containing Pyrrole-Derivatized Carboxylate Ligands

Ga-Lai Law,[a] Ka-Leung Wong,[b] Kok-Kin Lau,[a] Hoi-Lam Tam,[c] Kok-Wai Cheah,[c] and Wing-Tak Wong*[a]

**Keywords:** Lanthanide / Luminescence / Terbium / Europium / Pyrrole

Two pyrrole-deriviatized carboxylic acids [$\mathbf{L^1}$ = 1-methylpyrrole-2-carboxylate] and [$\mathbf{L^2}$ = *N*-methyl-3-indoleglyoxylate] were used as ligands to prepare six lanthanide coordination compounds $[(\mathbf{L^1})_3Ln]_n$ (Ln = Eu, **1**; Gd, **2**; Tb, **3**) and $[(\mathbf{L^2})_n$-$Ln(NO_3)(MeOH)_2]_n$ (Ln = Eu, **4**; Gd, **5**; Tb, **6**). These complexes have been synthesized and structurally characterized by single-crystal X-ray diffraction. The phosphorescence behavior of the ligands in the $Gd^{3+}$ complexes show that modification of the ligands can tune the triplet energy levels of the ligands so that they match the $^5D_0$ energy level of $Eu^{3+}$ and the $^5D_4$ energy level of $Tb^{3+}$; thus, the energy transfer efficiency from antenna to $Eu^{3+}$ and $Tb^{3+}$ is improved, and the $Eu^{3+}$ and $Tb^{3+}$ emission intensity is enhanced. This concept can be applied towards improving the luminescent properties of $Ln^{3+}$ complexes by the modification of coordinating ligands.

## Introduction

One topic of current interest in materials research is the synthesis of lanthanide complexes because of their promising photoluminescent properties. The major advantages of lanthanide complexes as luminescent materials are the long emission lifetimes and narrow bandwidths.[1–3] Because lanthanide f–f transitions are Laporte forbidden, the direct excitation of electrons in lanthanide-metal ions is very inefficient; thus, the resulting emissions from lanthanide-metal ions are very weak.[4–6] One way to improve the weak luminescence properties of lanthanide ions is to use sensitizing chromophores or antennae as ligands in lanthanide-metal complexes.[7–8] Through complexation with a chromophore, the luminescence of the lanthanide ions can be enhanced greatly (by more than $10^4$ fold).[9] This enhancement is mainly because direct excitation of the lanthanide ions can be avoided. In other words, luminescence in lanthanide–ligand complexes results from the electronic excitation of the coordinated chromophore followed by ligand-to-lanthanide energy transfer.

The choice of ligand for complexation plays a key role in constructing efficient luminescent lanthanide complexes. Two common requirements for selecting a ligand for coordination with lanthanide ions are the metal binding strength and ultraviolet (UV) absorption properties of the ligand. Among several categories of organic ligands, aromatic carboxylate ligands are one of the most common groups that fulfil the above two basic requirements. Aromatic carboxylate ligands are frequently used as sensitizing agents for enhancing the luminescence in the lanthanide species because they can chelate the lanthanide-metal ions tightly through their anionic carboxylate groups and strongly absorb UV radiation; the energy absorbed is subsequently transferred to the lanthanide-metal centre.[10–11]

Herein we report six lanthanide–organic complexes that incorporate two types of carboxylic acid ligands 1-methylpyrrole-2-carboxylate ($\mathbf{L^1}$) and *N*-methyl-3-indoleglyoxylate ($\mathbf{L^2}$) (Figure 1). These ligands are complexed with lanthanide(III) nitrate salts to form [Ln(1-methylpyrrole-2-carboxylate)$_3$(MeOH)$_2$($H_2O$)] (Ln = Eu, Gd, and Tb for **1**, **2**, and **3**, respectively) and $[Ln_2$(*N*-methyl-3-indoleglyoxylate$)_6$-$(MeOH)_4]_n$ (Ln = Eu, Gd, and Tb for **4**, **5** and **6**, respectively). Both of $\mathbf{L^1}$ and $\mathbf{L^2}$ show strong antenna effects with high quantum efficiency, and two molecular structures (**1** and **4**) of the newly synthesized complexes have been elucidated in this work.

## Results and Discussion

### Crystal Structures of 1 and 4

The X-ray diffraction analysis reveals that **1** and **4** adopt a highly symmetrical, polymeric structure in which the europium metal ions form the skeleton. All europium ions in the two europium complexes adopt a nine-coordinate geometry. In **1**, each europium ion is bidentately coordinated by three bidentate carboxylate ligands and monodentately coordinated by another three tridentate, bridging carboxylate ligands. Two of the three tridentate, bridging carboxylate ligands are bidentately chelated to an adjacent europium ion, and the remaining tridentate, bridging carboxylate ligand is bidentately coordinated to another adjacent europium ion (Figure 2). Each europium ion can be described as a nine-coordinate, twisted tricapped trigonal prism, in which the top plane is formed by O(1), O(4), and O(6) atoms, whereas the bottom plane is defined by the other equivalent, but offset in position, O(1), O(4), and O(6) atoms. The O(2), O(3), and O(5) atoms cap three quadrilateral faces of the trigonal prism. The packing diagram of **1** is shown in Figure 3.

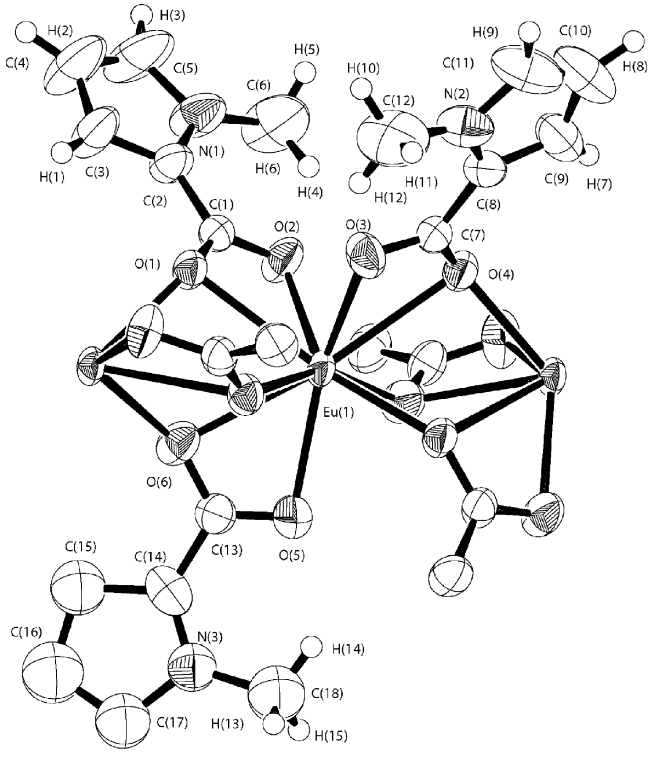

Figure 2. ORTEP drawing of **1**.

The Eu–Eu bond length and Eu–Eu–Eu bond angle in **1** are 3.793 Å and 178.38°, respectively. The bond length is much shorter and the bond angle is much larger than those in $[Eu_2(Benzoate)_6(MeOH)_4]_n$ (4.915 Å and 165.7°). The Eu–O bond lengths in **1** range from 2.400(3) to 2.727(3) Å, which are longer than those of $[Eu_2(Benzoate)_6(MeOH)_4]_n$ [2.309(6) to 2.535(6) Å].[11] The average Eu–O bond length (2.410 Å) for the carboxylate O atoms chelated by only one

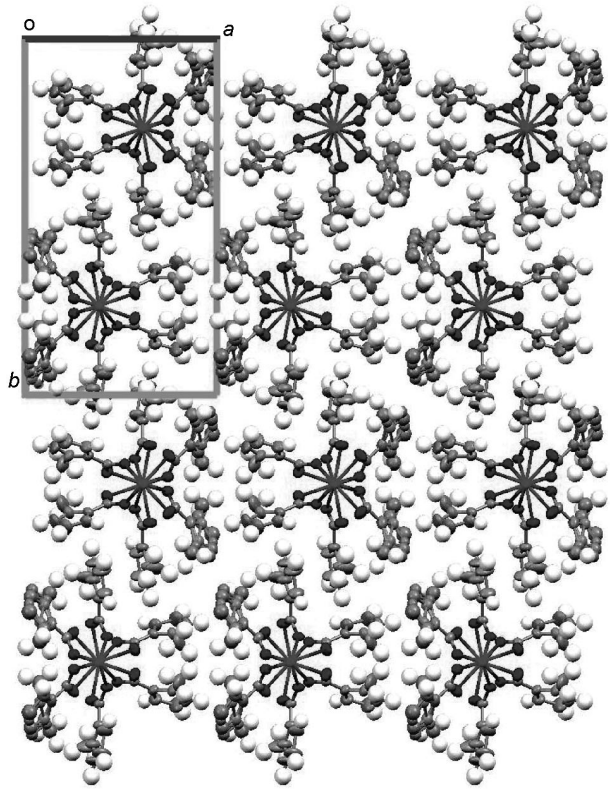

Figure 3. Packing diagram for **1** projected down the *c* axis.

europium ion is shorter than the average Eu–O bond length (2.672 Å) for the carboxylate O atoms chelated by two europium ions, which is obviously because of steric hindrance. The average C–O(CO) distance and O(CO)–C–O(CO) angle are 1.268 Å and 119.6,° respectively. The average C–O–Eu bond angle (88.1°) for the carboxylate O atoms chelated by two europium ions is much smaller than the average C–O–Eu bond angle (101.3°) for the carboxylate O atoms chelated by only one europium ion. The average O(CO)–Eu–O(CO) bond angle is 50.77°.

Recrystallization of the europium complex that contained the glyoxylate ligand gave light yellow, plate-like crystals of **4**, which were studied by X-ray diffraction crystallography. The perspective view of **4** is shown in Figure 4. The packing diagram of **4** projecting down the *a* axis is shown in Figure 5. Summaries of the crystallographic data and experimental parameters for **1** and **4** are supplied in the Supporting Information along with selected bond lengths and angles.

Complex **4** is a polymeric chain, in which europium ions constitute the skeleton. As shown in Figure 4, each europium ion in **4** is nine-coordinate, with five oxygen atoms from three glyoxylate ligands, two oxygen atoms from one nitrate molecule and two oxygen atoms from two methanol solvent molecules. The presence of an additional carbonyl group in glyoxylate ligands relative to that in carboxylate ligands results in an unusual coordination between the glyoxylate ligands and the lanthanide ions. In the structure

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

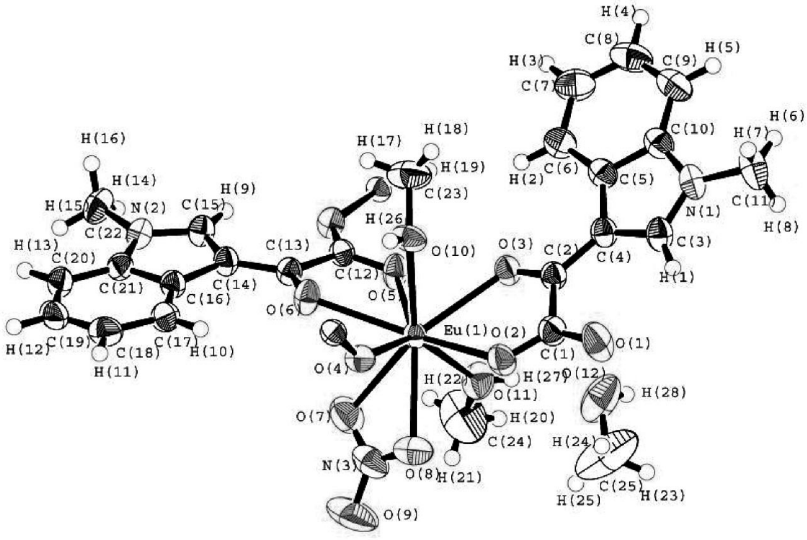

Figure 4. ORTEP drawing of **4**.

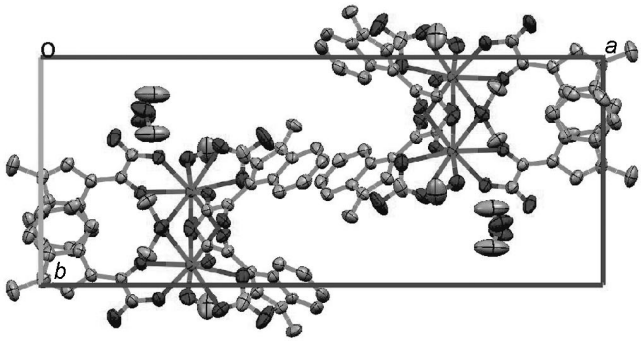

Figure 5. Packing diagram of **4** projected down the *a* axis.

of **4**, each europium ion is coordinated to two carbonyl oxygen atoms of two glyoxylate ligands and three carboxylic oxygen atoms of three glyoxylate ligands. In other words, two carboxylate groups of two or three glyoxylate ligands coordinate as bidentate bridges between two europium ions, whereas the carboxylate group of the remaining glyoxylate ligand coordinates as bidentate bridges between one europium ion and one hydrogen atom of a MeOH molecule. The Eu–Eu bond length and Eu–Eu–Eu bond angle in **4** (6.322 Å and 116.21°, respectively) are much longer and smaller than those in $[Eu_2(Benzoate)_6(MeOH)_4]_n$ (4.915 Å and 165.7°, respectively).[11] The longer Eu–Eu bond in **4** probably results from the greater steric hindrance associated with the *N*-methyl-3-indoleglyoxylate group than the benzoate group. The average Eu–O(carboxyl), Eu–O(carbonyl), Eu–O(MeOH), and Eu–O(nitrate) bond lengths in **4** are 2.405, 2.479, 2.474, and 2.496 Å, respectively. The average C–O (carboxyl and Eu-coordinated) bond length and O(carbonyl)–Eu–O(carboxyl) bond angle are 1.252 Å and 64.3°, respectively. There are four different hydrogen bonds in **4**. Two hydrogen bonds form between the hydrogen atom of one of the coordinated MeOH molecules and the two carboxylic oxygen atoms of one of the coordinated glyoxylate ligands [O(10)–H(26)···O(4) 2.62(5) Å and O(10)–H(26)···O(5)$^{i}$ 1.99(5) Å; i: $x$, 3/2 – $y$, 1/2 + $z$]. The third hydrogen bond is formed between the hydrogen atom of the free MeOH molecule and the non-coordinated carboxylic oxygen atom of one of the glyoxylate ligands [O(12)–H(28)···O(1)$^{ii}$ 1.95(7) Å; ii: $x$, 1/2 – $y$, 1/2 + $z$]. The fourth hydrogen bond is formed between the non-coordinated MeOH molecule and one of the coordinated MeOH molecules [O(11)–H(27)···O(12) 2.01(6) Å].

The different number of carbonyl groups in $\mathbf{L^1}$ and $\mathbf{L^2}$ (Figure 1) should result in structural differences in the corresponding lanthanide complexes. Ligand $\mathbf{L^1}$ has only one carbonyl group so is expected to form $Ln^{3+}$ complexes with four-membered rings, whereas $\mathbf{L^2}$ has two carbonyl groups so is expected to form $Ln^{3+}$ complexes with five-membered rings (Figure 4 and Figure 5).

## Photophysical Properties of 1–6

The UV/Vis absorption behavior of ligands $\mathbf{L^1}$ and $\mathbf{L^2}$ and their lanthanide complexes are shown in Figure 6 and Figure 7. The three absorption bands observed for **1**–**3** (see the arrows in Figure 6: ca. 32258 $cm^{-1}$, ca. 28986 $cm^{-1}$, and ca. 23256 $cm^{-1}$) and one band observed for **4**–**6** (Figure 7, ca. 30480 $cm^{-1}$) are similar to the peaks observed in the UV/Vis spectra of the ligands. By comparison of the UV/Vis spectra for **1**–**6** with that of the ligands, the bands can be attributed to benzyl π–π* transitions, which undergo red shifts of approximately 1000 $cm^{-1}$ upon complexation.[12] Moreover, a very close resemblance is observed between the UV/Vis absorption spectra of **1**–**6** and analogous lanthanide complexes that are coordinated by equivalent ligands.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

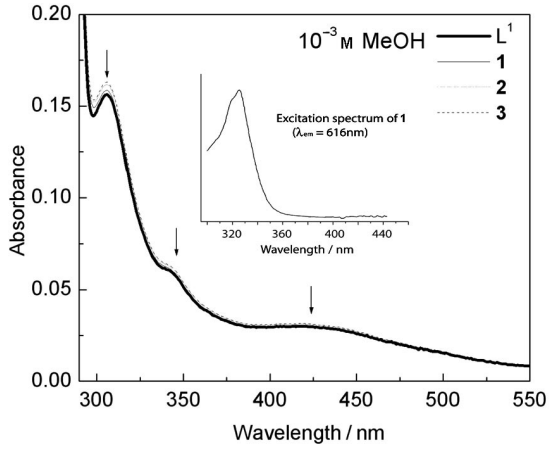

Figure 6. UV/Vis absorption spectra of $\mathbf{L^1}$ and of their complexes **1**–**3**, and the excitation spectra of complex **1** (inset).

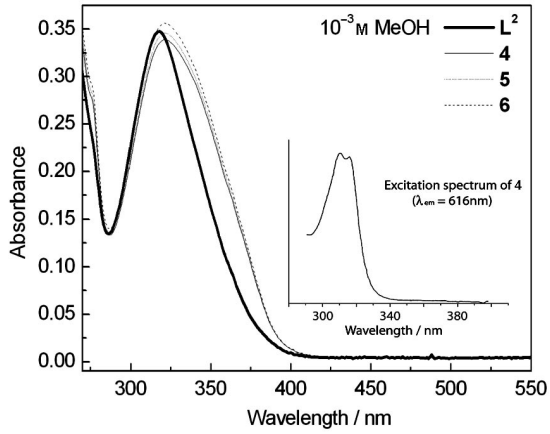

Figure 7. UV/Vis absorption spectra of $\mathbf{L^2}$ and of their complexes **4**–**6**, and the excitation spectra of complex **4** (inset).

The high degree of similarity in the UV/Vis absorption bands of **1**–**6** and those of analogous lanthanide complexes that incorporate equivalent ligands implies that they are likely to have similar or the same ligand–metal coordination modes, and hence similar or the same coordination structure. The slight band broadening observed in the absorption spectra of the complexes **4**–**6** upon complexation is induced by the steric effect of the ligands, which are not equivalent in **4**–**6** (Figure 7).

The luminescence properties of the ligands and of their lanthanide complexes were measured in the solid state at room temperature (Figures 8 and S1). The intense, linear broad emission band ($\lambda_{ex}$ = 325 nm) characteristic of ligands $\mathbf{L^1}$ and $\mathbf{L^2}$ are shown in the Supporting Information (Figure S1). The emission bands observed for $\mathbf{L^1}$ and $\mathbf{L^2}$ at ca. 400 and 410 nm, respectively, are attributed to the benzyl π–π* relaxation ($S_1 \rightarrow S_0$). The four structured, narrow emission bands at 480, 545, 580, and 620 nm for Tb complexes **3** and **6** and bands at 594, 620, 650 and 700 nm for Eu complexes **1** and **4** are assigned to an electronic energy transition between the $^5D_4 \rightarrow {}^7F_J$ ($J$ = 6, 5, 4, 3) states. The transitions $^5D_0 \rightarrow {}^7F_J$ ($J$ = 1, 2, 3, 4) are shown in the linear process for two types for Tb and Eu complexes.[13] There are great variations between the emission intensity in the Tb and Eu complexes. The matching of the triplet states in these lanthanide systems is an important criteria for the energy transfer from the ligand to the lanthanide (Figure 9 and Figure 10).

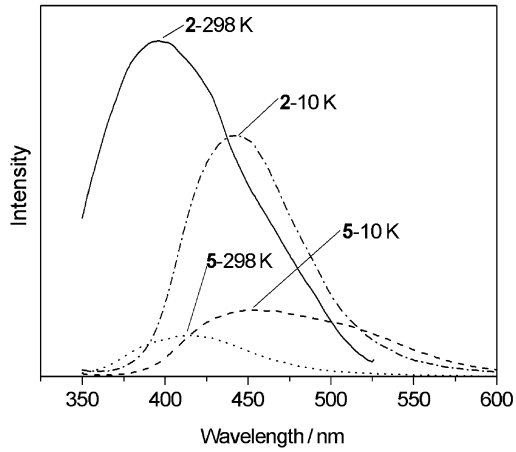

Figure 8. Solid-state emission spectra for Gd complexes **2** and **5** (298 K and 10 K), $\lambda_{ex}$ = 325 nm.

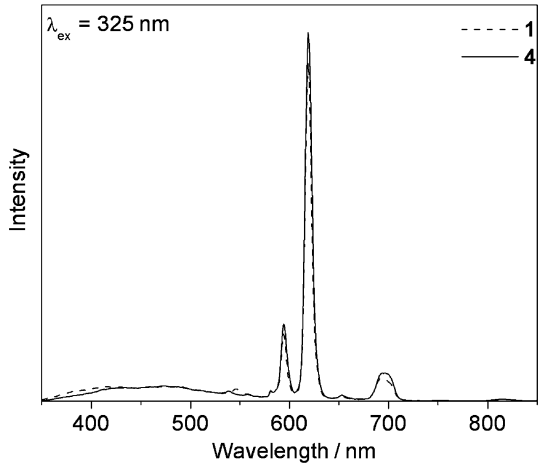

Figure 9. Solid-state normalized emission spectra for Eu complexes **1** and **4** (10 K), $\lambda_{ex}$ = 325 nm.

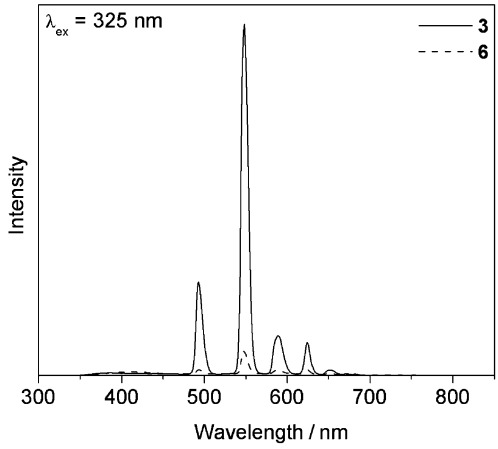

Figure 10. Solid-state normalized emission spectra for Tb complexes **3** and **6** (10 K), $\lambda_{ex}$ = 325 nm.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

Table 1. The solid-state luminescence lifetime ($\tau$) and quantum yield ($\Phi$) of the ligands and lanthanide complexes at 10 K. ($\lambda_{ex}$ = 337 nm, **L¹** $\lambda_{em}$ = 405 nm, **L²** $\lambda_{em}$ = 410 nm, **1** and **4** $\lambda_{em}$ = 616 nm, **2** and **5** $\lambda_{em}$ = ca. 450 nm, **3** and **6** $\lambda_{em}$ = 545 nm).

| | **L¹** | **L²** | **1** | **2**[a] | **3** | **4** | **5**[a] | **6** |
|---|---|---|---|---|---|---|---|---|
| $\tau$ [ms] | $9.1\times10^{-6}$ | $17.6\times10^{-6}$ | 1.29 | $7.67\times10^{-3}$ | 1.14 | 0.86 | $5.53\times10^{-3}$ | 1.33 |
| $\Phi$[b] | – | – | 0.23 | – | 0.18 | 0.21 | – | 0.06 |

[a] The phosphorescence lifetimes of in **2** and **5** ($\mathbf{T_1}\rightarrow \mathbf{S_0}$) are measured at 10 K.[15] [b] Quantum yield obtained by comparison with sodium salicylate (as standard).[16–17]

The lowest energy level of $Gd^{3+}$ ($^6P_{7/2}$) is much higher than energy levels of the ligands; therefore, it is assumed that there are no energy transitions between the ligand and metal.[14] The phosphorescence of these Gd complexes was measured under cold conditions (10 K) in the solid state (see Figure 8).

The luminescence lifetimes were recorded to verify the fluorescence and phosphorescence at 10 K. The emission lifetimes on a nanosecond scale ($S_1 \rightarrow S_0$) were measured at ca. 400 and 415 nm for **L¹** and **L²**, respectively, and on a microsecond scale ($T_1 \rightarrow S_0$) at ca. 440 and 470 nm for **L¹** and **L²**, respectively. The details of the luminescence lifetimes are shown in Table 1.

In line with the foregoing experimental results, the schematic energy level diagram, which includes the triplet state energy levels of the Gd complexes, and the energy transfer process are shown in Figure 11. Given that the energy level $^5D_4$ for Tb is ca. 20500 $cm^{-1}$, the energy gap between the ligand triplet state and the metal centre is greater than 2000 $cm^{-1}$ in Tb complexes of ligand **L¹** , which is too high to allow an effective back transfer. In contrast, the triplet state energy levels in the Gd complexes of **L²** are too close to $^5D_4$, so is too low to prevent thermally competitive back energy transfer from the $^5D_4$ to the ligand triplet state; Hence, only a weak green f–f emission band was observed.[18]

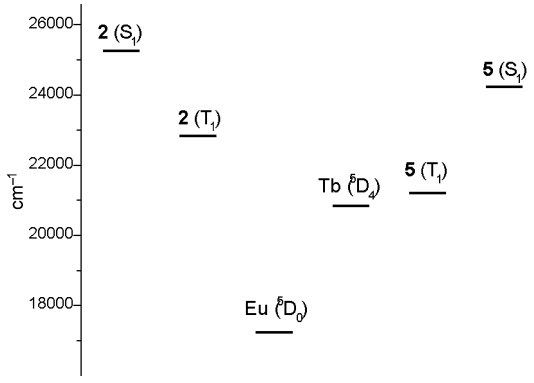

Figure 11. The lowest triplet-state energy levels of the ligands in the Gd complexes (**2** and **5**) and the resonance energy level of $Eu^{3+}$ and $Tb^{3+}$ ions.[19]

The energy gap between the ligand triplet states and the europium is greater than 2000 $cm^{-1}$, which is similar to the Tb complexes described above; however, the energy level of the $^5D_0$ state for Eu is ca. 17500 $cm^{-1}$, which is 3000 $cm^{-1}$ lower than the Tb ($^5D_4$) energy level. According to the Lativa empirical rules,[19] an optimal ligand-to-metal transfer process for $Eu^{3+}$ requires more than 2500 $cm^{-1}$. Comparison of the energy for the triplet states of **2** (22837 $cm^{-1}$) and **5** (21173 $cm^{-1}$) with that for the $^5D_0$ state for Eu (17240 $cm^{-1}$) suggests that the europium complexes exhibit better luminescence properties than the terbium complexes because the energy transfer from the ligands is better converted.[21]

## Conclusions

Two series of lanthanide complexes coordinated with aromatic chromophore-containing pyrrole-derivatized carboxylate ligands were successfully synthesized and characterized by MS and FT-IR spectroscopic analyses. The solid-state molecular structures of some of these complexes were also precisely determined by X-ray crystallography. The X-ray diffraction studies reveal that the lanthanide complexes that incorporate bidentate carboxylate ligands (1-methylpyrrole-2-carboxylic acid and *N*-methyl-3-indoleglyoxylic acid) could attain highly symmetrical polymeric structures without any coordination with luminescence-quenching solvent or water molecules. Several europium and terbium complexes were found to be capable of exhibiting solid-state luminescence of high intensity, long lifetimes and high efficiency.

## Experimental Section

**General Remarks**: All solvents were purified and dried by standard methods prior to use.[20] All chemicals, unless otherwise stated, were purchased commercially and used as received. Ligands 1-methylpyrrole-2-carboxylic acid (**L¹**) and *N*-methyl-3-indoleglyoxylic acid (**L²**) were acquired from commercial sources. Sodium hydroxide (1.0 equiv.) was added to a solution of **L¹** and **L²** (1.0 equiv.) in MeOH (20 mL). After stirring the solution for about 1 h at room temperature, lanthanide(III) nitrate hexahydrate (Ln = Eu, Gd and Tb) (1.0 equiv.) was added to the reaction mixture. The resulting reaction mixture was then stirred at room temperature for another 24 h. The precipitate that was formed was isolated by suction filtration and purified by washing with $CH_2Cl_2$ and MeOH. The purified product was finally isolated as a powder.

**[(1-Methylpyrrole-2-carboxylate)$_3$Eu]$_n$ (1):** 1-Methylpyrrole-2-carboxylic acid (150 mg) was used as the chelating ligand, and the purified product was isolated as a dark brown powder. Yield: 349 mg (56%). MS (ESI, MeOH): *m*/*z* = 526 [$M^+$ + 2], 525 [$M^+$ + 1], 524 [$M^+$], 523 [$M^+$ – 1]. IR (KBr): $\tilde{\nu}$ = 1560 and 1545 [asymmetric $\nu(COO^-)$], 1458 [symmetric $\nu(COO^-)$] $cm^{-1}$. $C_{18}H_{18}EuN_3O_6$ (534.2): calcd. C 41.23, H 3.46, N 8.01; found C 41.22, H 3.45, N 8.05.

**[(1-Methylpyrrole-2-carboxylate)$_3$Gd]$_n$ (2):** 1-Methylpyrrole-2-carboxylic acid (150 mg) was used as the chelating ligand, and the purified product was isolated as a dark brown powder. Yield: 360 mg (57%). MS (ESI, MeOH): *m*/*z* = 534 [$M^+$ + 4], 533 [$M^+$ + 3], 532 [$M^+$ + 2], 531 [$M^+$ + 1], 530 [$M^+$], 529 [$M^+$ – 1], 528 [$M^+$ – 2]. IR (KBr): $\tilde{\nu}$ = 1560 and 1545 [asymmetric $\nu(COO^-)$], 1458 and 1425 [symmetric $\nu(COO^-)$] cm$^{-1}$. $C_{18}H_{18}GdN_3O_6$ (529.6): calcd. C 40.82, H 3.43, N 7.93; found C 40.83, H 3.46, N 7.91

**[(1-Methylpyrrole-2-carboxylate)$_3$Tb]$_n$ (3):** 1-Methylpyrrole-2-carboxylic acid (150 mg) was used as the chelating ligand, and the purified product was isolated as a dark brown powder. Yield: 318 mg (50%). MS (ESI, MeOH): *m*/*z* = 531 [$M^+$], 530 [$M^+$ – 1], 529 [$M^+$ – 2]. IR (KBr): $\tilde{\nu}$ = 1541 [asymmetric $\nu(COO^-)$], 1466 and 1429 [symmetric $\nu(COO^-)$] cm$^{-1}$. $C_{18}H_{18}N_3O_6Tb$ (521.2): calcd. C 40.69, H 3.41, N 7.91; found C 40.66, H 3.46, N 7.90.

**[(*N*-Methyl-3-indoleglyoxylate)$_2$Eu(NO$_3$)(MeOH)$_2$]$_n$ (4):** *N*-Methyl-3-indoleglyoxylic acid (200 mg) was used as the chelating ligand, and the purified product was isolated as a bright greenish-yellow powder. Yield: 346 mg (52%). MS (ESI, MeOH): *m*/*z* = 683 [$M^+$ + 1], 682 [$M^+$], 681 [$M^+$ – 1], 680 [$M^+$ – 2]. IR (KBr): $\tilde{\nu}$ = 3700–2700 [$\nu$(O–H)(coordinated MeOH)], 1636 [$\nu$(C=O)], 1576 [asymmetric $\nu(COO^-)$], 1466 [$\nu$(N–O)(coordinated)], 1437 and 1405 [symmetric $\nu(COO^-)$], 1254 [$\nu$(N–O)(coordinated)], 1091 [$\nu$(N–O)(coordinated)] cm$^{-1}$. $C_{25}H_{28}EuN_3O_{12}$ (714.4): calcd. C 42.03, H 3.95, N 5.88; found C 42.01, H 3.96, N 5.87.

**[(*N*-Methyl-3-indoleglyoxylate)$_2$Gd(NO$_3$)(MeOH)$_2$]$_n$ (5):** *N*-Methyl-3-indoleglyoxylic acid (200 mg) was used as the chelating ligand, and the purified product was isolated as a bright greenish-yellow powder. Yield: 342 mg (51%). MS (ESI, MeOH): *m*/*z* = 691 [$M^+$ + 3], 690 [$M^+$ + 2], 689 [$M^+$ + 1], 688 [$M^+$], 687 [$M^+$ – 1], 686 [$M^+$ – 2], 685 [$M^+$ – 3]. IR (KBr): $\tilde{\nu}$ = 3700–2700 [$\nu$(O–H)(coordinated MeOH)], 1637 [$\nu$(C=O)], 1576 [asymmetric $\nu(COO^-)$], 1466 [$\nu$(N–O)(coordinated)], 1431 and 1405 [symmetric $\nu(COO^-)$], 1252 [$\nu$(N–O)(coordinated)], 1091 [$\nu$(N–O)(coordinated)] cm$^{-1}$. $C_{25}H_{28}GdN_3O_{12}$ (719.7): calcd. C 41.72, H 3.92, N 5.84; found C 41.73, H 3.96, N 5.81.

**[(*N*-Methyl-3-indoleglyoxylate)$_2$Tb(NO$_3$)(MeOH)$_2$]$_n$ (6):** *N*-Methyl-3-indoleglyoxylic acid (200 mg) was used as the chelating ligand, and the purified product was isolated as a bright greenish-yellow powder. Yield: 323 mg (48%). MS (ESI, MeOH): *m*/*z* = 689 [$M^+$], 688 [$M^+$ – 1], 687 [$M^+$ – 2]. IR (KBr): $\tilde{\nu}$ = 3700–2700 [$\nu$(O–H)(coordinated MeOH)], 1637 [$\nu$(C=O)], 1574 [asymmetric $\nu(COO^-)$], 1466 [$\nu$(N–O)(coordinated)], 1431 and 1405 [symmetric $\nu(COO^-)$], 1253 [$\nu$(N–O)(coordinated)], 1090 [$\nu$(N–O)(coordinated)] cm$^{-1}$. $C_{25}H_{28}N_3O_{12}Tb$ (721.4): calcd. C 41.62, H 3.91, N 5.82; found C 41.63, H 3.96, N 5.81.

**Crystallography Data:** Single crystals that were suitable for X-ray crystallographic analyses of complexes **1** and **4** were mounted in glass capillaries. Diffraction data were collected at room temperature with a Bruker AXS SMART CCD diffractometer equipped with graphite-monochromated Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 Å). Crystallographic collection data and structure refinements are summarized in Table 2. Intensity data were also corrected for Lorentz and polarisation effects, and an approximation of absorption correction by inter-image scaling was applied. The space groups of both crystals were determined from a combination of Laue symmetry checks, and their systematic absences were confirmed by successful refinement of the structures. The structures were solved by direct methods, SIR 92[22] or SHELXS 97,[23] along with Fourier-difference techniques. Structural refinements were made on *F* by full-matrix least-squares analysis. The hydrogen atoms of the organic moieties were generated in their idealized position. All calculations were performed on a personal computer by using the program package CrystalStructure.[24] CCDC-600404 and -641121 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cam-

**Photophysical Measurements:** The UV/Vis absorption spectra were recorded by using a HP UV-8453 spectrophotometer to measure the range between 200 and 1100 nm in MeOH ($10^{-3}$ M). The solution-state excitation spectra were recorded by using a Perkin–Elmer LS 50B Luminescence spectrophotometer that was equipped with a R928 photomultiplier tube, and the spectra were corrected for detector response and stray background light. The solid samples were housed in an Oxford (CC1104) instruments closed-cycle cryostat pulsed by cryodrive (Edwards 1.5) for luminescence spectra collected at 10 K. The temperature was adjusted from 10 K to 300 K by using a programmable intelligent temperature controller (Oxford IT502). A He–Cd laser (Kimmon IK5352R-D) at 325 nm with a maximum power of 5 mW was used. The excitation light was modulated at 20 Hz by using a mechanical chopper (Stardford SR540). The emitted light from the sample was then collected and detected by using a 25-mm focal length double monochromator with a thermoelectrically cooled photomultiplier tube (PMT) (Hamamatsu R363–10) as the detector. For lifetime measurements, the 337-nm pulsed line from a nitrogen laser was used as the excitation light. The sample was pulsed by this light source with a 4-ns pulse width. The decay-time spectra were examined by a HP5452A 500 MHz oscilloscope.[15]

**Supporting Information** (see footnote on the first page of this article): Selected bond lengths and angles for **1** and **4**; solid-state emission spectra of the ligands $\mathbf{L^1}$ and $\mathbf{L^2}$.

# Transition-Metal Porous Coordination Polymers with a Podand Ligand: Structure of Discrete Water Clusters and Variable-Temperature Magnetism

**Subhadip Neogi,[a] E. Carolina Sañudo,[b] and Parimal K. Bharadwaj*[a]**

**Keywords:** Water clusters / Coordination polymers / Metal–organic frameworks / Podand ligands / Magnetism

The podand ligand tris(4-carboxy-2-phenoxyethyl)amine ($ptaH_3$) readily reacts with $Co^{II}$, $Mn^{II}$ and $Ni^{II}$ salts at room temperature to afford porous coordination polymers, $\{Co(ptaH)\cdot 5H_2O\}_n$ (**1**), $\{[Mn(ptaH)(H_2O)]\cdot 4H_2O\}_n$ (**2**), and $\{[Ni(ptaH)(4H_2O)]\cdot 6H_2O\}_n$, (**3**). Crystallographic studies performed on these systems reveal that their structures are based on infinite chains of interlinked metallacycles. The bridging carboxylate groups extend the open framework structures, with oval-shaped voids. Supramolecularly assembled water clusters of different sizes, whose structures are proportionate with the size and shape of the MOFs, fill these voids. While discrete $(H_2O)_{10}$ clusters are present in **1** and **2**, both $(H_2O)_2$ and $(H_2O)_{16}$ clusters occupy the voids in **3**. Magnetic susceptibility measurements, in the temperature range 2–300 K, on **1** and **2** reveal that the metal centers are antiferromagnetically coupled in each case.

## Introduction

Supramolecular association of water molecules in diverse environments has been a subject of considerable current interest.[1–5] This is because the key to test and calibrate theoretical studies in order to understand the properties of bulk water is the precise structural data of hydrogen-bonded small water clusters in diverse environments. The advantage of clusters is the possibility to simply vary the size and to investigate the development of properties of the condensed phase in a step by step manner. Bulk water exhibits a fascinating array of properties, some of which are considered anomalous, and this is due to tremendous fluctuations in H-bonding interactions and rearrangement dynamics among the water molecules in a group. However, this diversity of H-bonding interactions is very crucial in the biological world as it can enforce a delicate balance[6] between several possible conformations of enzymes essential for expressing their functional behavior. In the abiological world, the degree of structuring of the water clusters can influence the structure of metal–organic open frameworks (MOF), where both water–MOF and water–water interactions can be the driving force that affects the overall structure. It follows, therefore, that an understanding of the formation of water clusters is important from the perspective of stabilization and functioning of biomolecules, as well as the structure of MOFs. In addition, they are of relevance in the study[7] of cloud and ice formation, solution chemistry, among others.

MOF structures of paramagnetic metal ions are particularly interesting as these may give rise to a series of novel framework structures with potential applications in the fields of molecular magnetism[8] and materials chemistry.[9] A commonly used strategy in building such extended network structures is to employ bridging ligands that are capable of transmitting magnetic interactions in addition to propagating the network.

We have initiated a research program to synthesize porous coordination polymers with the ultimate goal(s) of having new materials for magnetism, supramolecular storage of guest molecules, and catalysis among other applications. We describe here the formation of three MOFs with $Mn^{II}$, $Co^{II}$, and $Ni^{II}$ metal ions and a tripodal ligand,[10] with an aromatic carboxylate group at each terminal. The position of the carboxylate groups in the ligand excludes the formation of a homoleptic metal complex and favors the binding of more than one metal ion, which leads to a carboxylate-bridged MOF structure. This ligand, therefore, allows us to study the magnetic behavior of the MOF formed, as well as the structure of the water clusters present in the voids.

## Results and Discussion

The MOFs once isolated are found to be stable in air and insoluble in water or any common organic solvent. All the compounds show strong IR absorption bands between 1350 and 1550 $cm^{-1}$ characteristic[10] of coordinated carboxylate groups.

The structure of **1** consists of $Co^{II}$ ions, a partially deprotonated $ptaH^{2-}$ ligand, and water molecules. Hexacoordination of the metal is fulfilled by four carboxylate groups from four different ligand units (Scheme 1). Here, two carboxylate groups donate both their O atoms, one carboxylate group donates one O atom (the other O atom is donated to a different $Co^{II}$ ion), while the fourth carboxylate is protonated and donates a single O atom. This leads to a 2D coordination polymer built from metallacycles that extend along the crystallographic *a* axis (Figure 1). The bridging carboxylate group extends the structure in the third dimension. The position of the H atom attached to the carboxylate group could not be located in the difference maps. In this structure, Co–O(carboxylate) bond lengths span the range 2.018(2)–2.179(2) Å and compare well with the distances found in other octahedral $Co^{II}$–carboxylate structures.[11] Bond angles around the metal do not deviate significantly from the ideal octahedral coordination geometry. The overall structure of **1** is quite similar to the Cd complex reported by us previously.[10c] However, subtle differences remain between the two structures.

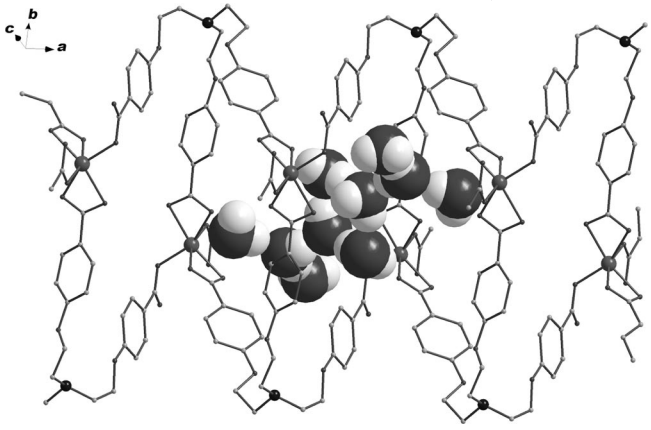

Figure 1. Perspective view of the decameric water cluster in the metallacyclic cavity in **1**.

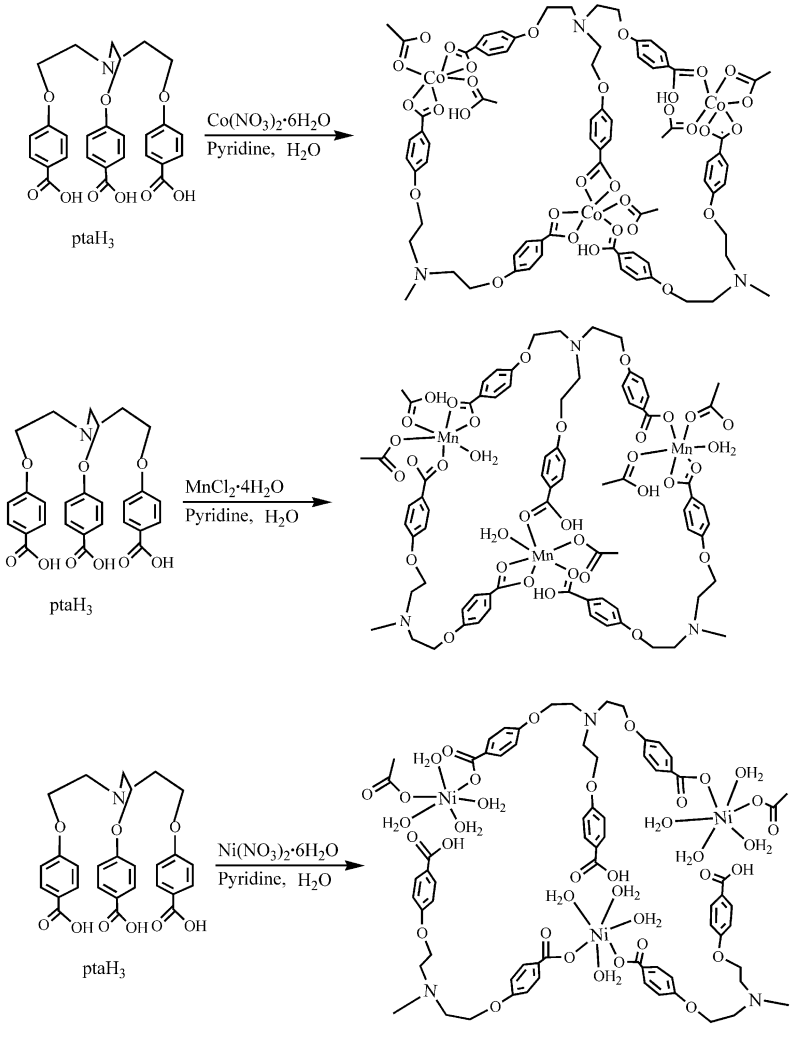
The coordination mode of $Mn^{II}$ in **2** is slightly different from that of **1**. Each $Mn^{II}$ ion is bonded to four carboxylate groups from four different $ptaH^{2-}$ units and to one water



Scheme 1. Bonding scheme for the compounds **1**, **2** and **3**.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

molecule. While one carboxylate group donates both its O atoms, the remaining three donate one O atom each, and the sixth coordination position is occupied by an $H_2O$ molecule (Scheme 1). As in **1**, the metallacycles propagate along the crystallographic *a* axis (Figure 2).

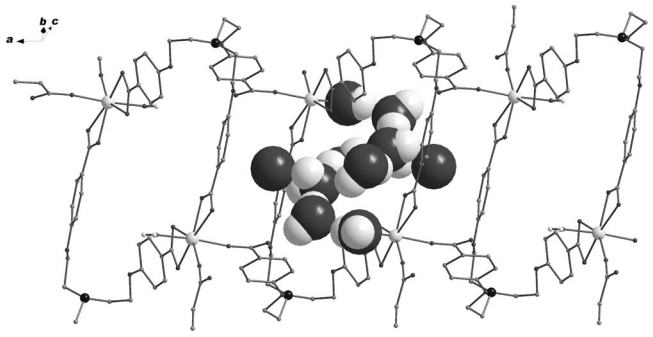


Figure 2. The oval-shaped cavity in **2** with embedded discrete $(H_2O)_{10}$ cluster.

In **3**, only two arms of $ptaH^{2-}$ are bonded to the $Ni^{II}$ ions, while the third arm is free. Each metal ion is hexacoordinate, with ligation from two carboxylate O atoms from two different ligands and four water molecules to form a coordination polymeric chain extending along the crystallographic *a* axis. Two metal-bound water molecules from one polymeric chain is H-bonded to the uncoordinated carboxylate group of another chain to form an overall 2D structure (Figure 3) with cavities that are much larger than those present in **1** and **2**. As in the previous cases, the H atom attached to one of the carboxylate groups of the ligand could not be located in the difference maps.

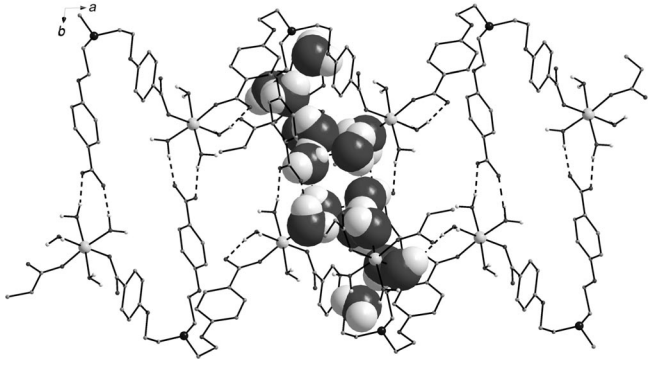

Figure 3. A view of the hexadecameric water cluster inside the H-bonded interlinked metallacycles in **3**. Only the H atoms attached to the water molecules are shown for clarity.

In **1**, the metallacycles have two different dimensions. In the first, two $Co^{II}$ ions exhibit a distance of 9.37 Å, while the distance between two bridgehead nitrogen atoms is 18.92 Å. For the adjacent matallacycle, these dimensions are 10.71 and 18.38 Å, respectively. Similarly, in **2**, in one metallacycle, the $Mn^{II}\cdots Mn^{II}$ distance is 9.98 Å, while the N···N distance is 18.67 Å. For the adjacent metallacycle, these distances are 11.15 and 17.81 Å, respectively. It follows, therefore, that the cavity in **1** is narrower than that of **2**. This difference is reflected in the structures of the $(H_2O)_{10}$ clusters present in the cavities of the two MOFs.

The $(H_2O)_{10}$ cluster in **1** can be viewed as that derived from a cyclic tetramer connected by acyclic trimers at the two opposite ends (Figure 4a). The tetrameric unit is quasiplanar, similar to that predicted theoretically[12] and found in several crystal hydrates.[13] The Ow···Ow distances (2.84–2.76 Å) and O···H–O angles (158.5–169.1°) suggest strong H-bonding interactions between the water molecules. The atoms Ow1, Ow2, Ow1′ and Ow2′ act as H-bond donors to the available carboxylate O atoms with Ow···O (carboxylate) distances in the range 2.76–2.82 Å (Table 1), which maintain strong water–MOF interactions as well. The distance between Ow5 and Ow5′ is within H-bonding distance (2.79 Å). However, these atoms are related by a center of symmetry, and their corresponding H atoms are oriented either towards or away from each other and are not considered to be H-bonded. The H···H separation of 1.07 Å is, however, shorter than the shortest intermolecular H···H separation (1.949 Å) found in the polymorph A of 1,2,3,5-

tetra-*O*-acetyl-β-D-ribofuranose[14a] or in a $Zn^{II}$ complex[14b] that crystallizes in presence of nitrobenzene as the guest. The repulsive interaction associated with this short distance is compensated by strong nonbonding water–MOF interactions.

The water decamer in **2** has a different structure. The cyclic tetramer is connected to two dimers at opposite ends, where two single water molecules are also H-bonded (Figure 4b). This cluster of water molecules requires more space than those present in **1** and therefore **2** has a larger void space. The water molecules are quite strongly H-bonded to each other as evident from the O···O distances (2.54–2.87 Å) and O···H–O angles (136.9- 171.0°). It is to be noted here that the H atoms attached to Ow5 could not be located in the difference maps. As in the case of **1**, Ow5 and Ow5′ are within H-bonding distance (2.43 Å). Since they are related by a center of symmetry, they are not considered to be H-bonded following the same argument as that made for **1**. This cluster is H-bonded to available carboxylate O atoms with Ow···O distances in the range 2.73–2.75 Å. Buck et al. had suggested[15] that the minimum energy conformation for the decamer is an octameric cube with two water molecules fused at one of the edges, while a more recent calculation showed that two fused parallel pentamers to be the energetically most stable from.[16] Whereas few water decamers[17] with different structures have been identified in metal–ligand hybrids or purely organic crystals, decamers in the form of two fused parallel cyclic pentamers with staggered conformation have been characterized[18] in organic hosts. The structures of the $(H_2O)_{10}$ clusters in **1** and **2** are different from any of these and result from strong water–MOF and water–water interactions.

The large H-bonded cavity in **3** can accommodate higher nuclearity clusters. Eight water molecules from each asymmetric unit are supramolecularly connected to centrosymmetrically related eight more molecules to form a $(H_2O)_{16}$ cluster that occupies the void between two polymeric chains (Figure 3). The structure can be described as a tetrameric core to which two hexameric units are attached at opposite ends. A $(H_2O)_{16}$ cluster in a $Cu^{II}$-containing MOF was identified earlier[19] to resemble the shape and size of the void for optimum MOF–water interactions. Theoretical calculations on the $(H_2O)_{16}$ cluster[20] show a number of local minima, including fused cubes derived from the $D_{2d}$ and $S_4$ forms of the $(H_2O)_8$ unit as well as five-membered rings, two of which also contain one six-membered ring. A closer view of the $(H_2O)_{16}$ cluster in **3** (Figure 4c) shows a wide variation in the O···O nonbonding distances (2.96–2.71 Å) relative to 2.759 Å in ice $I_h$ or 2.85 Å in liquid water.[21] The O···O···O angles also vary widely (133.5–87.2°) with an average value of 110.3°. The shape of the cavity in **3** closely follows the shape of the water cluster to maximize the strength as well as the number of interactions with the MOF.

Thermal gravimetric analysis of compound **1** in air shows that weight loss begins at 60 °C, and the loss of 13.6%, which corresponds to the loss of all water molecules (calculated 13.72%), takes place above 200 °C, and soon after, the compound decomposes. The thermogravimetric curve of **2** shows a plateau, and weight loss begins at 60 °C, and the loss of 13.7%, which corresponds to the loss of all water molecules (calculated 13.80%), takes place beyond 200 °C. Complete breakdown of the structure takes place at about 270 °C. Thermal gravimetric analysis of **3** in air shows that the removal of water occurs in stages, beginning at 50 °C, and the loss of 24%, which corresponds to the loss of all water molecules (calculated 24.1%), takes place above 150 °C. Complete decomposition is achieved above approximately 240 °C.

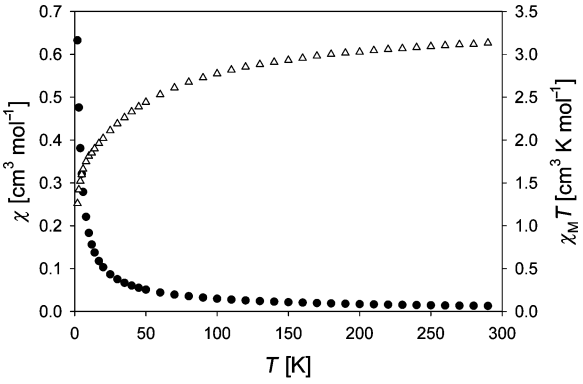
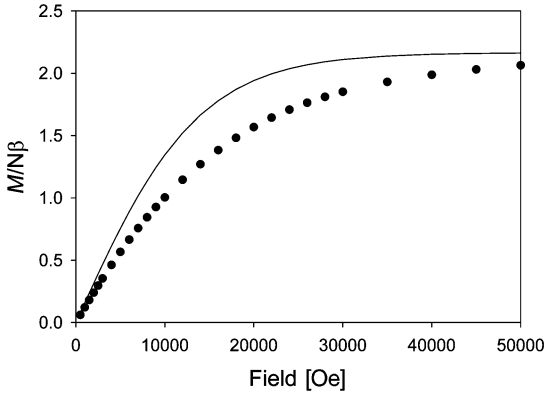
## Magnetic Studies

Since paramagnetic transition metal ions are present with carboxylate bridges in both **1** and **2**, magnetic susceptibility studies were performed on **1** and **2**. Variable-temperature magnetic susceptibility data were collected for **1** in the temperature range 2–300 K with an applied magnetic field of 0.5 T. The susceptibility increases smoothly with decreasing temperature (Figure 5a), and the change in susceptibility as a function of temperature follows the Curie–Weiss law at temperatures above 200 K. The value of the Curie constant (3.38 $cm^3 K mol^{-1}$) is consistent with hexacoordinate high-spin $Co^{II}$ ions (2.8–3.4 $cm^3 K mol^{-1}$) [22]; the Curie–Weiss constant has a negative value of –23.71 K, which indicates antiferromagnetic interactions between the metal centers. When analyzing the $\chi T$ versus $T$ plot, the decrease observed is due to the depopulation of the $J$ = 5/2 state and the preferential population of the $J$ = 1/2 state, in addition to any possible interaction between the $Co^{II}$ ions. The $\chi T$ value of 3.14 $cm^3 K mol^{-1}$ per $Co^{II}$ ion at 300 K is in agreement with the expected value for a distorted octahedral $Co^{II}$ ion with strong spin-orbit coupling. As the temperature decreases, so does the value for $\chi T$, until at 2 K, it reaches the value of 1.26 $cm^3 K mol^{-1}$ per $Co^{II}$ ion. This value is significantly smaller than that expected for isolated $Co^{II}$ centers (1.875 $cm^3 K mol^{-1}$). The magnetization versus field plot (Figure 5b) saturates at a value of 2.06 at 5.0 T, as expected, which is significantly lower than that predicted by the Brillouin law ($Co^{II}$ ion with spin-orbit coupling $S_{eff}$ = 1/2 and $g$ = 4.33[21]); this further supports a weak antiferromagnetic coupling between the $Co^{II}$ ions in **1**. In the 3D network, the $Co^{II}$ ions are grouped in pairs, bridged by two *syn*-, *anti*-carboxylate arms of the $ptaH^{2-}$ ligands. This type of bonding leads to weak antiferromagnetic interactions,[23] as observed in **1**.



(a)



(b)

Figure 5. (a) Temperature dependence of the magnetic susceptibility of **1**. $\chi$ is shown as circles, $\chi T$ is shown as triangles. (b) Magnetization plot for compound **1**. The solid line is the Brillouin function for a $Co^{II}$ ion with spin-orbit coupling.

Figure 6 shows the temperature dependence of the magnetic susceptibility of compound **2** at an applied DC field of 0.3 T in the temperature range 2–300 K and at 200 G below 25 K. In the solid-state structure of **2**, the $Mn^{II}$ ions are arranged in dimers, which, in turn, are organized into a 3D network by the ligands. The dimers are held at an average distance of 10 Å by the $ptaH^{2-}$ ligand, and thus, from a magnetic point of view, the sample has been treated as isolated $[Mn^{II}]_2$ units. The $\chi T$ product at 300 K has a value of 9.2 $cm^3 K mol^{-1}$, slightly above that expected for two noninteracting $Mn^{II}$ ions (4.375 $cm^3 K mol^{-1}$ per $Mn^{II}$, $S$ = 5/2). As the temperature decreases, the $\chi T$ product decreases very slowly to a value of 8.0 $cm^3 K mol^{-1}$ at 50 K and then sharply decreases to 1.1 $cm^3 K mol^{-1}$ at 2 K, which indicates weak antiferromagnetic coupling between the manganese centers, leading to $S$ = 0. The magnetization at 2 K rises continuously with the field to a value of 2.8 at 5 T, without reaching saturation, and confirms the $S$ = 0 value predicted from the susceptibility versus $T$ data. A simple Van Vleck equation[24] for a dimeric $S$ = 5/2 system was used to fit the experimental data. A good agreement between the experimental and calculated data was obtained for $J$ = –0.70 $cm^{-1}$ and $g$ = 2.07, with a TIP of $120 \times 10^{-6}$ $cm^3 mol^{-1}$ over the entire temperature range. The fit is shown in Figure 5 as a solid line. The weakness of the coupling is easily explained, given the very long Mn–Mn separation: the only possible exchange pathways are two *syn*-, *anti*-carboxylate groups from the ligand unit that hold the $Mn^{II}$ ions 3.86 Å apart. Only very weak coupling can be expected under these conditions, as confirmed by the experimental data. We have recorded FTIR spectra of all three compounds (see Supporting Information) to characterize the vibrational stretching frequency of the O–H bond of the water clusters. In each case, a broad peak appears that centers around 3420 $cm^{-1}$, which can be attributed to the water cluster. The IR spectrum of ice[13] shows the O–H stretching band at 3220 $cm^{-1}$, while this stretching vibration in liquid water[13] appears at 3490 and 3280 $cm^{-1}$. This suggests that the water clusters in **1**–**3** show O–H stretching vibrations similar to that of liquid water. This broad band significantly reduces on heating the compounds under vacuum (0.1 mm), which suggests that the water molecules escape from the lattice. Deliberate exposure to water vapor does not lead to reabsorption of water into the

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

lattice as monitored by FTIR spectroscopy. Powder X-ray diffraction patterns of the compounds before and after desolvation show major changes in the peak positions as well as in their intensities. Therefore, loss of water from the lattice leads to the breakdown of the framework structure, which supports the thermal analysis results.

## Conclusions

In conclusion, we have characterized three different MOF structures of transition-metal ions with the tripodal ligand. The large voids present in the MOFs contain supramolecularly bound water molecules of different nuclearity. The size and shape of these water clusters closely follow the available volume of the void spaces. These water clusters act as a "glue" to reinforce the coordination polymeric chains and to extend the open framework structures. Variable-temperature magnetic susceptibility measurements on **1** and **2** reveal that the metal centers are *anti*-ferromagnetically coupled.

## Experimental Section

**Materials:** The metal salts were obtained from Aldrich and used as received. All other chemicals were procured from S. D. Fine Chemicals, India. All solvents were purified prior to use.

**Physical Measurements:** Spectroscopic data were collected as follows: IR (KBr disk, 400–4000 $cm^{-1}$) Perkin–Elmer Model 1320; X-ray powder pattern (Cu-$K_\alpha$ radiation at a scan rate of 3°/min, 293 K) Siefert ISODEBYEFLEX-2002 X-ray generator; thermogravimetric analysis (heating rate of 5 °C/min) Perkin–Elmer Pyris 6. Microanalyses for the compounds were obtained from the Central Drug Research Institute, Lucknow, India. Magnetic data were collected at the Unitat de Mesures Magnètiques at the Universitat de Barcelona by using crushed crystals of the sample on a Quantum Design MPMS-XL SQUID magnetometer equipped with a 5 T magnet. Diamagnetic corrections were calculated using Pascal's constants, and an experimental correction for the sample holder was applied.

**Synthesis**

The ligand tris(4-carboxy-2-phenoxyethyl)amine ($ptaH_3$) was prepared following the method described previously.[10c]

**{[Co(ptaH)]·5H$_2$O}$_n$ (1):** The tripodal ligand $ptaH_3$ (0.13 g, 0.25 mmol) was dissolved in a thf solution (10 mL) containing tetraethyl ammonium hydroxide (1.2 mL). To this, an aqueous solution of $Co(NO_3)_2{\cdot}6H_2O$ (0.15 g, 0.51 mmol) was added dropwise, and the reaction mixture stirred for 2 h at room temperature. Rectangular pink crystals suitable for X ray diffraction were obtained after 7 d on slow evaporation of the filtrate. Yield approximately 60%. $C_{27}H_{35}CoNO_{14}$: calcd. C 49.39, H 5.37, N 2.13; found C 49.97, H 5.16, N 2.34.

**{[Mn(ptaH)(H$_2$O)]·4H$_2$O}$_n$ (2):** The tripodal ligand $ptaH_3$ (0.13 g, 0.25 mmol) was dissolved in thf (10 mL) containing tetraethyl ammonium hydroxide solution (1.2 mL) whilst continuously stirring at room temperature. To this, an aqueous solution of $MnCl_2{\cdot}4H_2O$ (0.10 g, 0.50 mmol) was added, and the reaction mixture stirred for 2 h at room temperature. The resulting clear solution was allowed to evaporate at room temperature. Colorless, parallelepiped crystals of **2** were recovered after 10 d. Yield approximately 55%. $C_{27}H_{35}MnNO_{14}$: calcd. C 49.70, H 5.40, N 2.14; found C 50.18, H 5.17, N 2.65.

**{[Ni(ptaH)(4H$_2$O)]·6H$_2$O}$_n$ (3):** Compound **3** was isolated as dark green rectangular crystals following a similar method to that described for **1**, by using $Ni(NO_3)_2{\cdot}6H_2O$ in place of $Co(NO_3)_3{\cdot}6H_2O$ at room temperature. Yield approximately 60%. $C_{27}H_{45}NNiO_{19}$ (746.36): calcd. C 43.45, H 6.08, N 1.87; found C 43.68, H 6.21, N 2.04.

**X-ray Structural Studies:** Single-crystal X-ray data on **1**–**3** were collected at 100 K with a Bruker SMART APEX CCD diffractometer by using graphite-monochromated Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 Å), and the structures were solved and refined as described earlier.[8a] The H-bonding distances and angles for the water clusters in **1**–**3** are summarized in Table 1, and the crystal and refinement data are collected in Table 2. CCDC-646841 to -646843 for **1**–**3** contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

**Supporting Information** (see footnote on the first page of this article): IR, TGA, X-ray powder diffraction patterns are presented. Additional figures showing structures of compounds **1**–**3** are also included.

# Synthesis, Characterization and X-ray Structures of [α-Diphenylethanedione bis(4-ethylthiosemicarbazonato)]palladium(II) and 1,2,4-Triazine-3-thione–Zinc(II) Complexes Obtained by Metal-Induced Cyclization

**Ana I. Matesanz,[a] Cesar Pastor,[b] and Pilar Souza*[a]**

**Keywords:** Thiosemicarbazones / Cocrystals / Palladium(II) / Zinc(II) / X-ray diffraction

The new cyclic 5-ethoxy-4-ethyl-5,6-diphenyl-4,5-dihydro-2*H*-[1,2,4]-triazine-3-thione ligand (HTa3T-Et) has been obtained by an intramolecular cyclization reaction of α-diphenylethanedione bis(4-ethylthiosemicarbazone) ($H_2$BbTSC-Et). The cyclization may be promoted either by hydroxylic solvents or by $Zn^{II}$ ions. Thus, the reaction of $H_2$BbTSC-Et with $ZnCl_2$ led to the formation of $[Zn(HTa3T\text{-}Et)_2Cl_2]$ containing not the ligand $H_2$BbTSC-Et but the cyclic HTa3T-Et ligand that forms during the reaction. On the other hand, crystallization of $H_2$BbTSC-Et from DMSO/EtOH produces a cocrystal containing the open-chain $H_2$BbTSC-Et ligand together with the cyclic HTa3T-Et molecules, which are linked to a DMSO molecule by hydrogen bonds. However, reaction of the cocrystal with $Pd^{II}$ ions yields a planar tetracoordinate complex in which only the $H_2$BbTSC-Et ligand, in the deprotonated form, is present. The preparation and molecular structures of these compounds are discussed.

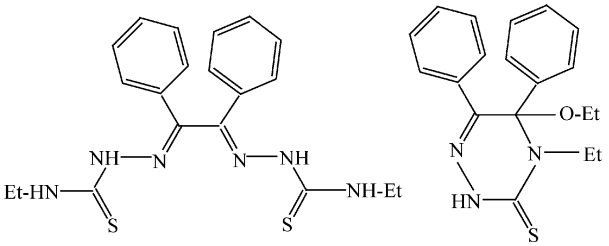
## Introduction

Thiosemicarbazones (TSCs) are a versatile type of ligand because of the number of donor atoms they possess, among which sulfur is of paramount importance in the metal–ligand linkage; moreover, their configurational flexibility creates the possibility of a variety of coordination modes.[1–3] Thiosemicarbazone derivatives have raised considerable interest in chemistry and biology because of the antibacterial, antiviral and antitumor activity that many of them have shown.[4,5] In some cases, the highest activity is associated with a metal complex rather than the free thiosemicarbazone.[6]

It is well known that thiosemicarbazones derived from 1,2-dicarbonyl compounds easily cyclize during the synthesis process, especially when hydroxylic solvents are used or when solutions in such solvents are allowed to crystallize over several days.[7] In all cases, this cyclization leads to 1,2,4-triazine-3-thione ligands (Scheme 1); these ligands are very versatile and are able to form mono-, di- and polynuclear metal complexes as a result of two different coordination modes: as a monodentate, neutral ligand with coordination through the sulfur atom or as an anionic bidentate ligand with coordination through the sulfur and nitrogen atoms.[8]



$H_2$BbTSC-Et HTa3T-Et

Scheme 1. Structures for the open-chain $H_2$BbTSC-ET and the cyclic HTa3T-Et ligands.

Compounds containing the 1,2,4-triazine moiety have been found in natural products and some of these have important applications in various fields. For example, 1,2,4-triazine-3,5-diones represent aza analogues of pyrimidine nucleic acid bases, some neutral antibiotics are derivatives of pyrimido[5,4-*e*]-1,2,4-triazine, and 4-amino-6-*tert*-butyl-3-methylthio-1,2,4-triazine-5-one and 4-amino-3-methyl-6-phenyl-1,2,4-triazine-5-one are used as agricultural chemicals.[9]

As part of our systematic investigation on the coordination chemistry of thiosemicarbazone derivatives,[10,11] we recently reported a paper that focuses on the structure–antitumor activity relationships of a series of palladium and platinum α-diphenylethanedione bis(thiosemicarbazone) derivatives. In all compounds studied there, the ligands unambiguously show the bis(thiosemicarbazone) form.[12] To extend

our studies, particularly with respect to the coordination properties of $H_2$BbTSC-Et and the stereochemistry and molecular structure of the complexes, we planned to synthesize new metal derivatives. It was possible, after numerous attempts at crystallization of the $H_2$BbTSC-Et ligand, to obtain good quality crystals suitable for X-ray analysis from DMSO/EtOH solution. These proved to be cocrystals containing, together with $H_2$BbTSC-Et, the cyclic derivative formed by an intramolecular cyclization reaction. To the best of our knowledge, this is the first report of the isolation of a bis(thiosemicarbazone) molecule and the cyclized form as single crystals. Interestingly, the reaction of the new cocrystal isolated with palladium(II) ions gave the mononuclear $N_2S_2$-tetracoordinate bis(thiosemicarbazone) complex instead the binuclear $CNS_2$-tetracoordinate complex recently reported by us.[12]

Some of the different routes published that undergo the cyclization of thiosemicarbazones use a metallic salt ($Zn^{2+}$, $Cu^{2+}$ and $Fe^{3+}$). On this basis and in order to search for novel cyclized compounds, we also report here the reaction of $H_2$BbTSC-Et with $ZnCl_2$. The reaction yields a new zinc(II) compound containing, in neutral form, the cyclic ligand 5-ethoxy-4-ethyl-5,6-diphenyl-4,5-dihydro-2*H*-[1,2,4]-triazine-3-thione (HTa3T-Et, see Scheme 1).

## Results and Discussion

### Synthesis of the Ligands

The preparation of crude $H_2$BbTSC-Et was carried out according to ref.[12] Analytical and spectroscopic properties are consistent with those reported.

Attempted slow recrystallization of $H_2$BbTSC-Et from DMSO/EtOH resulted in the isolation of a cocrystal $H_2$BbTSC-Et/HTa3T-Et in a 1:1 ratio that also contains DMSO molecules. The structural data suggests that some $H_2$BbTSC-Et molecules may be transformed into the final 1,2,4-triazine-3-thione ligand by an intramolecular cyclization reaction, similar to that described by Alsop et al.[13] The cyclization with concomitant insertion of ethanol and elimination of 4-ethylthiosemicarbazide seems to be favoured when hydroxylic solvents are used or when solutions in such solvents are allowed to crystallize over several days.

### Structures of the Ligands

The structure of the cocrystal $H_2$BbTSC-Et/HTa3T-Et consists of one $H_2$BbTSC-Et molecule and one cyclic triazine molecule HTa3T-Et together with one dimethylsulfoxide molecule of crystallization (Figure 1). Selected bond lengths and angles are given in Table 1.

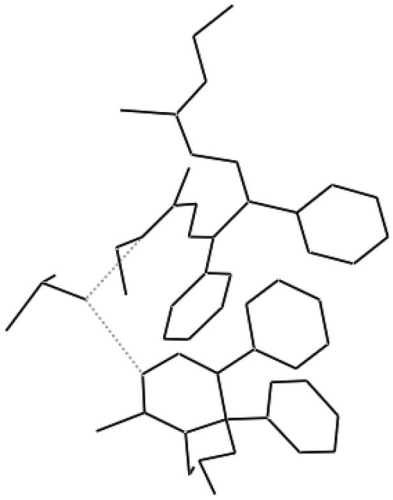

Figure 1. Structure of the cocrystal $H_2$BbTSC-Et/HTa3T-Et.

| | | N9–C24 | 1.281(4) |

The crystal and molecular structures with the numbering schemes of the $H_2$BbTSC-Et and HTa3T-Et molecules are shown in Figure 2.

The $H_2$BbTSC-Et molecule consists of two distinct essentially planar sections, which are pivoted about the C5–C4 "backbone" of the ligand, with a C15–C5–C4–C9 torsion angle of 79.4(3)°. Within each planar section, the C–N and N–N bond lengths, intermediate between the ideal values of corresponding single and double bonds, are indicative of a delocalized system. The existence of the thiosemicarbazone groups in the thione form, in the solid state, is evidenced by the C–S bond lengths of 1.681(3) and 1.689(3) Å, which are close to a formal C=S bond length.[13]

The HTa3T-Et molecule is a triazine–thione formed from an intramolecular reaction during the recrystallization process. This six-membered heterocyclic $C_3N_3$ ring is close to planar [torsional angles: C25–N7–C23–N8 10.0(4)°, N9–N8–C23–N7 1.5(4)°, N8–N9–C24–C25 –0.4(4)°]. Although

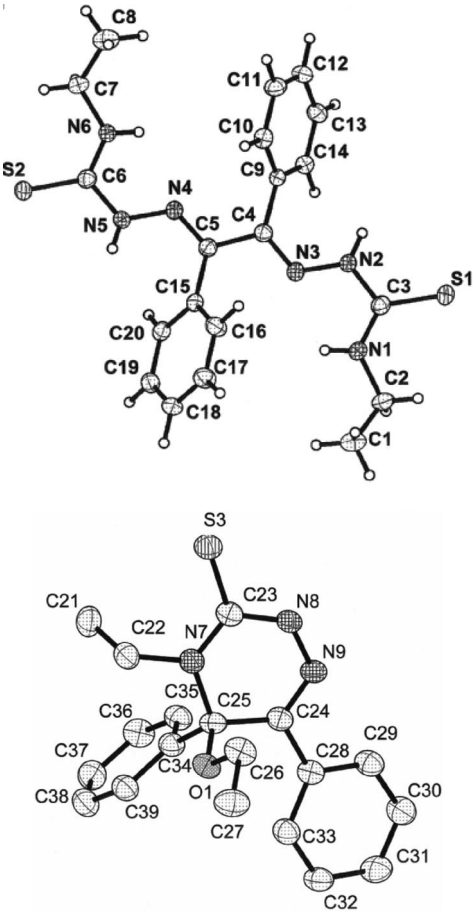

Figure 2. Molecular structure of the $H_2$BbTSC-Et (top) and HTa3T-Et (below) molecules, which shows the atom numbering scheme.

the C–S bond length of 1.679(3) Å is in the range of a C=S bond, some electronic delocalization occurs in the ring formed. Thus, while the bond length for N9–C24 of 1.281(4) Å is consistent with a C=N bond, both N8–C23 and N7–C23 bonds [1.354(4) and 1.344(4) Å, respectively] are considerably shorter than the predicted length of 1.47 Å for a C–N bond. Further, the N8–N9 bond with a length of 1.359(4) Å is significantly shorter than the predicted N–N bond length of 1.45 Å. On the other hand, the N7–C25 bond [1.490(4) Å] is slightly longer than the predicted C–N bond, and the C24–C25 bond [1.523(4) Å] is slightly shorter than the predicted length 1.54 Å for a C–C bond.[14]

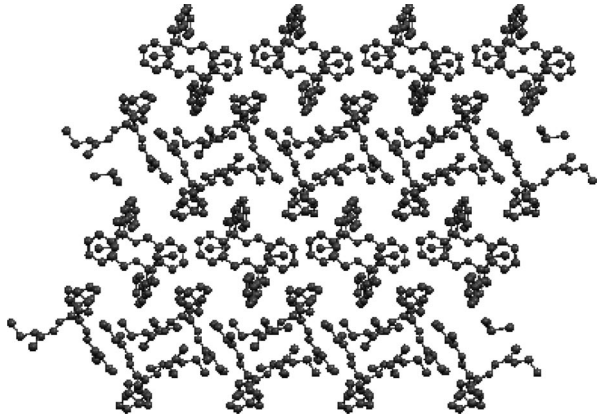

Figure 3. View of cocrystal $H_2$BbTSC-Et/HTa3T-Et along the *b* axis.

Within the crystal, the two independent molecules are linked to a DMSO molecule by N–H···O bonds. The crystal packing along the *b* axis (Figure 3) shows parallel alternating lines of $H_2$BbTSC-Et and HTa3T-Et molecules.

## Synthesis and Structure of the Complex [Pd(BbTSC)]

We have recently verified that the reaction of crude $H_2$BbTSC-Et with $Li_2PdCl_4$ in methanol undergoes *ortho*-metallation to give a dinuclear bis(thiosemicarbazone) complex.[12] Thus, we decided to investigate the coordinating properties of the cocrystal $H_2$BbTSC-Et/HTa3T-Et to palladium(II). The analytical and spectroscopic data of the isolated compound are in agreement with the formula [Pd(BbTSC)], in which the $H_2$BbTSC ligand is in the doubly deprotonated form. Green single crystals were obtained on recrystallization from DMSO, and the X-ray diffraction study confirmed the proposed formulae.

An ORTEP representation of [Pd(BbTSC)] together with the atom labelling scheme is shown in Figure 4, and selected bond lengths and angles are given in Table 2. This neutral $Pd^{II}$ complex crystallizes in the monoclinic *C*2/*c* space group with $Z = 4$ as discrete $C_{20}H_{22}N_6S_2Pd$·DMSO molecules.

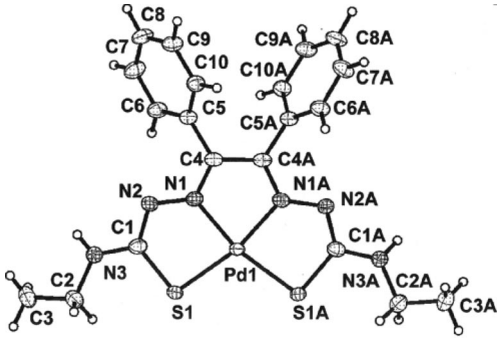

Figure 4. Molecular structure of [Pd(BbTSC)].

On the basis of other α-diketone bis(thiosemicarbazones),[15] the mode of coordination for this complex is as expected; two iminic nitrogen atoms and two thiolato sulfur atoms bond to palladium on the loss of the hydrogen atoms of N2 and N2A from both thiosemicarbazone moieties to give an approximately planar, four-coordinate complex. Thus, the coordination of the bis(thiosemicarbazone) results in the formation of three five-membered chelate rings (PdSCNN, PdNCCN and PdNNCS).

A careful examination of the bond length data shows that the Pd–$N_{iminic}$ and Pd–S distances are comparable with those reported for other thiosemicarbazone palladium(II) complexes with strong Pd–N coordination.[10] Since the Pd–S bonds are significantly longer than the Pd–N bonds, the coordination geometry around the metal ion is more trape-

| S1A–Zn1–S1 | 103.79(3) | S1A–Pd1–S1 | 108.69(4) |

zoid than square. The overall impression from the values of the bond lengths and angles in the vicinity of the palladium atom is that the ligand cavity is too small to accommodate the $Pd^{2+}$ ion ideally. Thus, the N–Pd–N bond angles are less than 90°, and the sulfur ends of the ligand arms are pushed outwards beyond the natural position that would be adopted by the planar ligand, with S–Pd–S bond angles of ca. 109°.

The loss of the protons originally bonded to N2 and N2A atoms produces a negative charge delocalized in the ligand system, which is consistent with the C–N distances (intermediate between formal single and double bonds) and C–S distances (see Table 2). This substantiates the displacement of the tautomeric equilibrium to the thiol form in the ligand.

The terminal uncoordinated nitrogen atoms are involved in intermolecular hydrogen bonds with the oxygen atoms of the solvent molecules; the contact distances and angles are N3···O1 2.897(4) Å and N–H–O 162(4)°.

### Synthesis and Structure of the Complex [Zn(HTa3T-Et)$_2$Cl$_2$]

The reaction of crude $H_2$BbTSC-Et ligand with $ZnCl_2$ in ethanol led to the formation of the crystalline yellow [Zn(HTa3T-Et)$_2$Cl$_2$] complex. The analytical, spectroscopic, and X-ray diffraction data (see Experimental Section) revealed that $H_2$BbTSC-Et is transformed into cyclic 5-ethoxy-4-ethyl-5,6-diphenyl-4,5-dihydro-2*H*-[1,2,4]-triazine-3-thione (HTa3T-Et) during the complexation reaction. An analogous cyclization of 2-pyridinformamide 4-ethylthiosemicarbazone that is promoted by the presence of silver(I) ions was reported recently by Castiñeiras et al.[16]

The mother liquor was allowed to stand at 4 °C. After several days, crystalline pale yellow needles were isolated, which were identified as the free ligand $H_2$BbTSC-Et by X-ray diffraction analysis. Its molecular structure essentially shows the same structural characteristics as that of the open-chain molecule in the cocrystal $H_2$BbTSC-Et/HTa3T-Et. Selected bond lengths and angles are given in Table 1.

The crystal packing (Figure 5) shows parallel pseudochains of molecules, and the absence of any solvent of crystallization indicates possible existence of noncovalent interactions between the individual bis(thiosemicarbazone) molecules. A closer look reveals π–π stacking interactions between successive thiosemicarbazone moieties (3.62 Å). These extended intermolecular interactions are responsible for holding the crystal together.

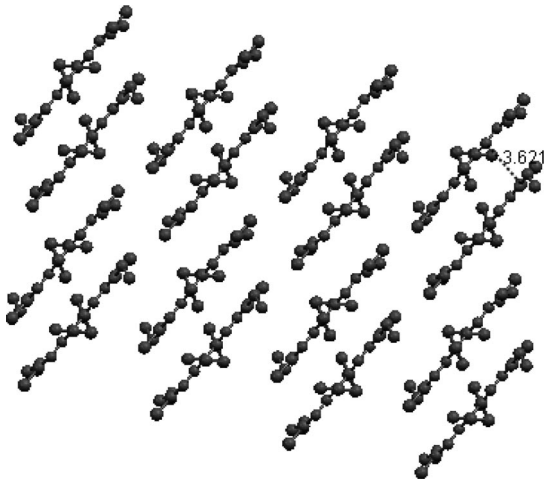

Figure 5. Side view of $H_2$BbTSC-Et, which shows the parallel disposition of the molecules as a result of π–π stacking.

An ORTEP representation of [Zn(HTa3T-Et)$_2$Cl$_2$] together with the atom labelling scheme is shown in Figure 6, and selected bond lengths and angles are given in Table 2.

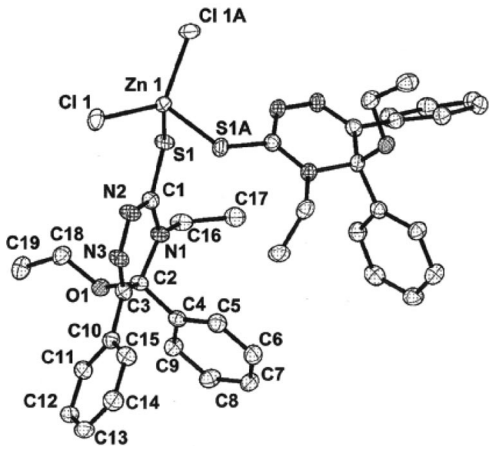

Figure 6. Molecular structure of [Zn(HTa3T-Et)$_2$Cl$_2$] (H atoms were omitted for clarity).

This neutral complex crystallizes in the orthorhombic *Fdd*2 space group with $Z = 8$. The zinc atom is tetracoordinated by two chlorido ligands and two sulfur atoms from the neutral monodentate ligands HTa3T-Et. The largest angular distortion from ideal tetrahedral geometry is shown by Cl1A–Zn–Cl1 [124.74(3)°]. Although the chlorido ligands participate in the hydrogen bonding, the distances Zn–Cl [2.238 Å] fall in the range of the shortest lengths for

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

terminal Zn–Cl bonds.[17] The Zn–S and C–S distances [2.369 and 1.711 Å, respectively] are similar to those found in other complexes with thiocarbonyl sulfur atoms.[18] The 4-ethyl substituent on the N1 atom reduces the possibilities for hydrogen bonding. Thus, only two intramolecular N2–H···Cl bonds are present in the complex.

An analysis of the relative disposition of the complex molecules in the crystal structure highlights the importance of aromatic–aromatic edge-to-face interactions in the packing that takes place when the crystal is formed.[19,20] The perpendicular (ca. 96°) distance between C–H and the plane of π system is ca. 2.88 Å.

## Conclusions

The investigations show that the synthesis of bis(thiosemicarbazone) derivatives from α-diketones with alkyl substituents can be complicated by the formation of cyclized products. Typically, the α-bis(thiosemicarbazones) are made by heating a thiosemicarbazide under reflux with an α-diketone in an alcoholic solvent with an acid catalyst. Although it is well known that such solvents favour cyclization, we have not found the cyclic 1,2,4-triazine-3-thione form in our previous studies. However, slow recrystallization of the $H_2$BbTSC-Et from DMSO/EtOH affords a cocrystal composed of a 1:1 ratio of open-chain $H_2$BbTSC-Et and cyclic 1,2,4-triazine-3-thione. The formation of the cocrystal could be favoured by the presence of DMSO molecules since they each form two hydrogen bonds with the terminal nitrogen atom of one thiosemicarbazone moiety (hindering the cyclization) and with the hydrazinic nitrogen atom of the other thiosemicarbazone moiety (favouring the cyclization).

The intramolecular cyclization reaction may also be promoted by the presence of the salt $ZnCl_2$. Thus, we have achieved the isolation of a $Zn^{II}$–1,2,4-triazine-3-thione complex in which the zinc atom is tetracoordinated by two chlorido ligands and two sulfur atoms from the neutral monodentate cyclic ligands. Although the different steps involved in this process are not completely understood, it has been assumed that the metal ion plays an important role in this process, probably because of both inductive and stereochemical effects, as do the solvent and the counterion of the metal.

However, reaction of the cocrystal with $Li_2PdCl_4$ yields a planar tetracoordinate complex in which the bis(4-ethylthiosemicarbazone) ligand in the deprotonated form is present. In this case, the clear preference for a planar environment of the $Pd^{II}$ ion assists the stabilization of the bis(thiosemicarbazone) form.

In summary, the conversion of $H_2$BbTSC-Et to the cyclic 1,2,4-triazine-3-thione form is relatively rapid in hydroxylic solvents, and when a metallic salt is present, the formation of the metal complex stabilizes one of the forms according to its structural preferences. Thus, the cyclization of the $H_2$BbTSC-Et ligand can be controlled by selection of the appropriate metal salt and reaction conditions. Moreover, in this case, the presence of either the phenyl rings, which allow extensive delocalization, or the $^4$N substitution appears to facilitate the cyclization of the $H_2$BbTSC-Et ligand.

## Experimental Section

**Materials:** Solvents were purified and dried according to standard procedures. 4-Ethylthiosemicarbazide, 1,2-diphenylethanedione, lithium chloride, palladium(II) chloride and zinc chloride were commercially available from Aldrich.

**Preparation of the Ligands:** $H_2$BbTSC-Et was synthesized according to ref.[11]. Yield: 0.35 g (77%). Analytical and spectroscopic properties are consistent with those reported. Attempted slow recrystallization of $H_2$BbTSC-Et from DMSO/EtOH resulted in the isolation of a cocrystal, which is composed of a 1:1 ratio of $H_2$BbTSC-Et and cyclic HTa3T-Et according to its crystal and molecular structure.

**[Zn(HTa3T-Et)$_2$Cl$_2$]:** The reaction of $ZnCl_2$ (0.3 mmol) in ethanol (40 mL) with $H_2$BbTSC-Et (0.3 mmol), over 5 h whilst stirring and refluxing, led to the formation of a yellow solution, which was filtered and allowed to evaporate at room temperature overnight to give a yellow crystalline solid. The product was identified as the [Zn(HTa3T-Et)$_2$Cl$_2$] complex, which does not contain the $H_2$BbTSC-Et ligand but the cyclic HTa3T-Et molecule. Single prismatic crystals suitable for X-ray diffraction were selected directly from the reaction vessel. Yield: 0.17 g (71%). MS (FAB$^+$ with mNBA matrix): *m/z* (%) = 816.1 [M + H]$^+$, 340.1 (100) [HTa3T – Et + H]$^+$. IR (KBr): $\tilde{\nu}$ = 3252 (s, NH), 1574 (s, CN), 854 (w, CS-thioamide IV band). $^1$H NMR ([D$_6$]DMSO): $\delta$ = 9.72 (s, 1 H, $^2$NH), 7.72–7.20 (m, 6 H, Ph), 3.64–3.59 (m, 3 H, $CH_2CH_3$), 3.35–3.33 (m, 3 H, $OCH_2CH_3$), 1.30–1.25 (t, $J$ = 3.0 Hz, 2 H, $CH_2CH_3$), 1.20–1.15 (t, $J$ = 2.0 Hz, 2 H, $OCH_2CH_3$) ppm. After filtering the $Zn^{II}$ complex, the mother liquor was allowed to stand at 4 °C, and after several days, pale yellow needles of the free ligand $H_2$BbTSC-Et suitable for X-ray analysis were obtained. Analytical and spectroscopic properties are consistent with those previously reported.[11]

**[Pd(BbTSC-Et)]:** The reaction of cocrystal $H_2$BbTSC-Et/HTa3T-Et (1 mmol) with a methanol solution of lithium tetrachloropalladate prepared in situ from palladium(II) chloride (1.2 mmol) and lithium chloride (4.4 mmol), over 5 h at room temperature while stirring, led to a dark green solution, which was filtered. From the solution, a dark green solid was isolated by slow evaporation of the solvent, which could then be recrystallized from DMSO to give green crystals suitable for X-ray analysis. On the basis of the molecular structure of [Pd(BbTSC-Et)], the coordinated doubly deprotonated ligand was unambiguously identified as $H_2$BbTSC-Et. Yield: 0.15 g (30%). $C_{20}H_{22}N_6S_2Pd$·DMSO (595.08): calcd. C 44.40, H 4.70, N 14.10, S 16.15; found C 44.00, H 5.00, N 13.50, S 15.40%. IR (KBr): $\tilde{\nu}$ = 3237, 3187 (s, NH), 1547 (s, CN), 842 (w, CS-thioamide IV band) cm$^{-1}$. $^1$H NMR ([D$_6$]DMSO): $\delta$ = 8.10 (t, $J$ = 4.0 Hz, 1 H, $^4$NH), 7.17–7.11 (m, 6 H, Ph), 3.26 (m, 2 H, $CH_2CH_3$), 1.23 (m, 3 H, $CH_2CH_3$).

**Physical Measurements:** Elemental analyses were performed on a LECO CHNS-932 microanalyzer. Fast atom bombardment (FAB) mass spectra were performed with a VG AutoSpec spectrometer (nitrobenzyl alcohol matrix). $^1$H NMR spectra ([D$_6$]DMSO) were recorded with BRUKER AMX-300 spectrometer. All cited physical measurements were obtained from the Servicio Interdepartamental de Investigación (SIDI) of the Universidad Autónoma de Madrid.

Infrared spectra (KBr discs) were recorded with a Bomen–Michelson spectrophotometer (4000–400 cm$^{-1}$).

**X-ray Crystallographic Studies:** A summary of the crystal data, experimental details and refinement results is listed in Table 3. The X-ray measurement was performed on a Bruker SMART 6 K CCD area-detector three-circle diffractometer with a rotating anode generator (Cu-$K_\alpha$ radiation, $\lambda$ = 1.54178 Å) equipped with Goebel mirrors at settings of 50 kV and 110 mA. X-ray data were collected at 100 K. The software package SHELXTL version 6.10 was used for space group determination, structure solution and refinement. The structures were solved by direct methods, completed with difference Fourier syntheses, and refined with full-matrix least-squares techniques against $F^2$ by using SHELXL-97.

CCDC-649679 (ligand $H_2$BbTSC-Et), -649677 (cocrystal $H_2$BbTSC-Et/HTa3T-Et), -649678 {compound [Zn(HTa3T-Et)$_2$Cl$_2$]} and -634275 {compound [Pd(BbTSC-Et)]} contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

# Syntheses, Crystal Structures, Thermal Stabilities, and Magnetic and Luminescent Properties of 3D Heterometal Phosphonates: $NaM[O_3PCH(OH)CO_2]$ (M = Mn, Fe, Co, Zn)

**Zhuzhi Lai,[a] Ruibiao Fu,[a] Shengmin Hu,[a] and Xintao Wu*[a]**

**Keywords:** Crystal structure / Phosphorus / Luminescence / Magnetism / Thermal stability

Four heterometal 2-hydroxyl(phosphono)carboxylates, $NaM[O_3PCH(OH)CO_2]$ [M = Mn (**1**), Fe (**2**), Co (**3**), Zn (**4**)], were synthesized hydrothermally. Single-crystal X-ray diffraction data reveal that they are isostructural and crystallize in the orthorhombic space group *Pbca* (No. 61) with $a$ = 10.1365(16)–10.4557(5) Å, $b$ = 9.6890(9)–9.8265(4) Å, $c$ = 10.7942(19)–10.9353(1) Å, $V$ = 1060.2(3)–1123.22(7) Å$^3$, and $Z$ = 8. Each $[MO_6]$ (M = Mn, Fe, Co, Zn) octahedron contacts three neighboring $[NaO_5]$ pyramids through two edges and one corner to form a Na/MO layer. The layers are further connected by $O_3PCH(OH)CO_2^{3-}$ groups into an interesting 3D heterometallic framework. Thermogravimetric and powder X-ray diffraction analysis indicate that solids **1**–**4** are thermally stable up to 350, 250, 340, and 350 °C, respectively. Magnetic measurements show the presence of antiferromagnetic interaction for $M^{II}$ ions (M = Mn, Fe, Co) in compounds **1**–**3**. These solids exhibit bright cyan (for **1**, **2**, and **4**) or purple (for **3**) luminescence after induced by fluorescent whitener, and the luminescence can be irreversibly transformed into bright yellow (for **1** and **4**) or red (for **3**) simply by annealing treatment at 300 °C.

## Introduction

The design and construction of new inorganic–organic hybrid materials based on metal phosphonates is of current interest owing to their potential applications as catalysts, ion-exchangers, small molecular sensors, and nonlinear optics.[1] During the past two years, phosphonic acids containing a second functional group such as hydroxy, amine, carboxyl, and pyridyl, were successfully introduced as bridging ligands for the isolation of new metal phosphonates with intriguing structures and properties.[2–5] This is mainly due to the additional functional groups that can improve the solubility and crystallinity of metal phosphonates, which results in the growth of suitable single crystals for X-ray structural analysis. Then, an instinctive strategy of attaching two additional functional groups to the phosphonic acid was performed to obtain several novel solids, such as $M_x[Fe(O_2CCH_2)_2NCH_2PO_3]_6{\cdot}nH_2O$ (M = Na, K, Rb), with a maple leaf lattice and lanthanide phosphonates possessing homochiral porous frameworks as well as blue, red, or near IR luminescence.[6] In this regard, we focused on utilizing 2-hydroxy(phosphono)acetic acid (Hpaa) containing three functional groups (–OH,–COOH, and–$PO_3H_2$) to construct four-layered hybrid materials that are antiferromagnetic and one 3D polar open-framework with nonlinear optical activity and high thermal stability.[7] On one hand, there are few reports on heterometal phosphonates with multifunctional phosphonic acids as bridging groups.[6a,8] On the other hand, Hpaa would adopt numerous coordination modes through 6 active oxygen donors to bond a maximum of 15 metal atoms. Therefore, a series of experiments was carried out to search for new heterometallic polymers with Hpaa as bridging ligands. In this paper, we report the syntheses, structures, and properties (including thermal stability, magnetism, and luminescence) of four new heterometal phosphonates with a 3D framework, namely, $NaM[O_3PCH(OH)CO_2]$ (M = Mn: **1**; Fe: **2**; Co: **3**; Zn, **4**).

## Results and Discussion

### Syntheses and Characterization

**$Na_2L$** is a commercial fluorescent whitener; if it exists in the initial reaction mixture, the products are denoted as **1a**–**4a** and if not as **1b**–**4b**. Initially, the usage of **$Na_2L$** is to grow suitably sized single crystals of the metal phosphonates, because $M^{2+}$(M = Mn, Fe, Co, Zn) ions can be easily precipitated by **$Na_2L$**, which prevents the formation of large amounts of $NaM[O_3PCH(OH)CO_2]$ (M = Mn, Fe, Co, Zn). $NH_4Cl$ may serve as a structure-directing agent to grow suitable single crystals. When NaF is treated with acetic acid, HF is produced, which can increase the solubility of

these compounds and result in the growth of single crystals for X-ray structural analysis. Single crystals of these compounds can also be obtained without the salts or acetic acid. However, their size and quality are not suitable for single-crystal XRD.

Experimental powder XRD patterns of **1a**–**4a** are all consistent with those simulated from single-crystal X-ray data of compounds **1**–**4**, which indicates that final products **1a**–**4a** are homogeneous phases, and elemental analyses of **1a** and **3a** are in accord with the calculated values. Furthermore, the IR spectra of **1a** and **3a** are consistent with those of **2b** and **4b** and do not include absorption bands around 1198 and 1182 $cm^{-1}$, which are assigned to the asymmetric stretching vibrations of the sulfonate group (Supporting Information, Figure S1).[9] These results indicate that crystals of **1a** and **3a** that have been repeatedly rinsed with distilled water under ultrasonic treatment contain few residual $Na_2L$.

As shown in Figure S1 (Supporting Information), the IR spectra of **1a**, **2b**, **3a**, and **4b** have a medium band in the range of 3003–3049 $cm^{-1}$, which originates from the O–H stretching vibration of the hydroxy group. Additionally, a very strong band around 1590 $cm^{-1}$ and a medium band near 1373 $cm^{-1}$ are attributed to the carboxylate group. It is interesting that the P=O stretching vibration appears around 1176 $cm^{-1}$, which exhibits a redshift of about 24 $cm^{-1}$ relative to those in [M{$HO_3PCH(OH)CO_2$}] (M = Mn, Fe, Co, Zn) and $(NH_4)Zn[O_3PCH(OH)CO_2]$.[7] Both diffuse reflectance spectra of compounds **3** and **3**–**300** have a broad and strong absorption band around 539 nm, which corresponds to the d–d transition of the $Co^{II}$ ion (Supporting Information, Figure S2); the π–π* transitions of the C=O moiety for compounds **3** and **3**–**300** appear at 232 and 217 nm, respectively.

### Structural Descriptions

Single-crystal XRD patterns revealed that compounds **1**–**4** are isostructural and feature a 3D heterometallic framework. In addition, all experimental powder XRD patterns of compounds **1**–**4** are in agreement with those simulated from single-crystal X-ray data of solid **1** (Figure 1). Therefore, only the structure of **1** will be discussed in detail as a representative. The asymmetric unit of **1** consists of one $Mn^{II}$ ion, one $Na^{I}$ ion, and one $O_3PCH(OH)CO_2^{3-}$ group (Figure 2). The $O_3PCH(OH)CO_2^{3-}$ group is chelated to the $Mn^{II}$ ion through one phosphonate oxygen atom (O2a) and one carboxylate oxygen atom (O5) to form a Mn–O–C–C–P–O six-membered chelating ring; the $Mn^{II}$ ion is also chelated by another equivalent $O_3PCH(OH)CO_2^{3-}$ group through the hydroxy group (O4c) and another carboxylate oxygen donor (O6) into a Mn–O–C–C–O five-membered chelating ring, which results in an obvious small bond angle [O4c–Mn1–O6 = 67.20(11)°]. This is similar to those in [M{$HO_3PCH(OH)CO_2$}] (M = Mn, Fe, Co, Zn).[7a] As a

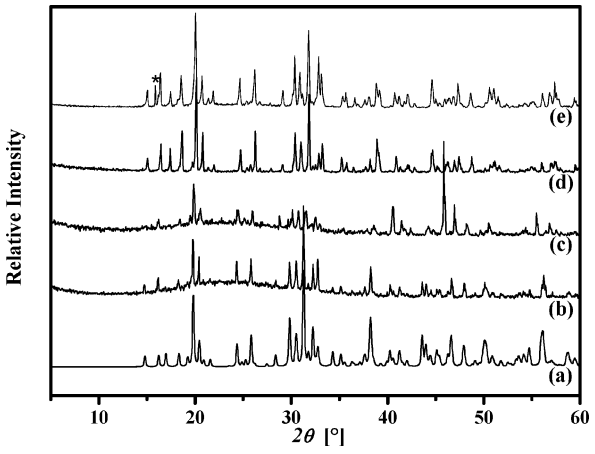

Figure 1. (a) The simulated XRD pattern of compound **1**; (b)–(e) experimental powder XRD patterns for compounds **1**–**4**, respectively. (*) The additional peak at about 15° may result from the background.

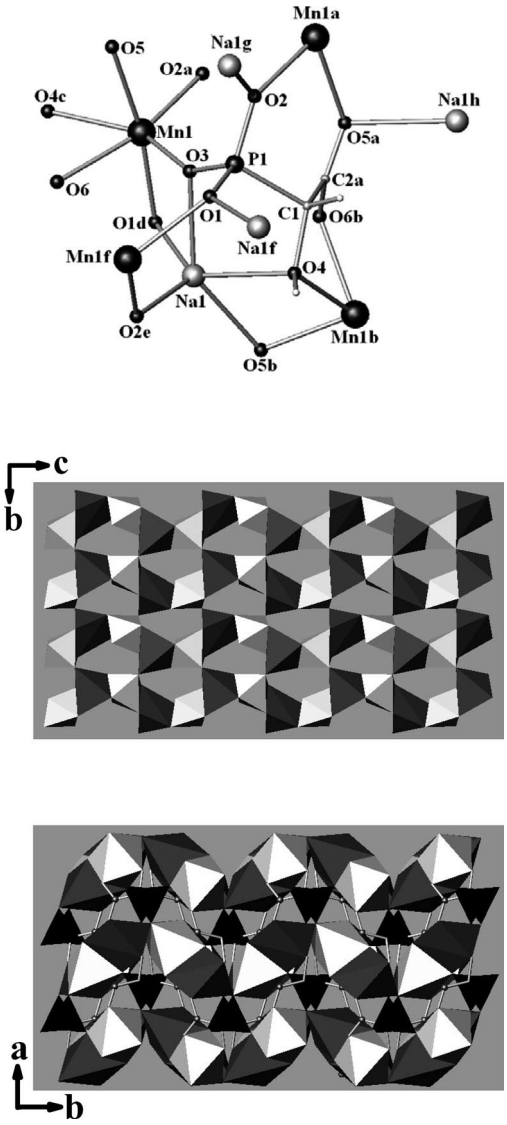

Figure 2. (Top) Ball–stick view of the coordination geometries of sodium, manganese, and phosphorus in compound **1**; (middle) polyhedral representation of the Na/MnO layer; and (bottom) 3D framework in compound **1**.  © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

result, the $Mn^{II}$ ion is located in a distorted [$MnO_6$] octahedral coordination geometry, which is completed by another two phosphonate oxygen atoms from two different equivalent $O_3PCH(OH)CO_2^{3-}$ groups (O1d and O3). The values of the Mn–O bond lengths are in the range of 2.198(3)–2.343(3) Å, whereas the $Na^I$ geometry is a [$NaO_5$] pyramid, defined by three phosphonates oxygen atoms, one carboxylate oxygen donor, and one hydroxy group from four equivalent $O_3PCH(OH)CO_2^{3-}$ groups. The Na–O distances range from 2.349(3) to 2.485(3) Å. Except for O6b, which is only coordinated to one $Mn^{II}$ ion, another oxygen atom of $O_3PCH(OH)CO_2^{3-}$ bonds one $Mn^{II}$ ion and one $Na^I$ ion. So, the $O_3PCH(OH)CO_2^{3-}$ group exhibits a new octadentate mode to combine four $Mn^{II}$ ions and four $Na^I$ ions. This is obviously different from the tetradentate mode in $(NH_4)Zn[O_3PCH(OH)CO_2]$ and the tridentate mode in $M[HO_3PCH(OH)CO_2]$ (M = Mn, Fe, Co, Zn).[7]

Each [$MnO_6$] octahedron shares two edges and one corner with neighboring three [$NaO_5$] pyramids, respectively, to form a Na/MnO layer consisting of six-membered rings (6MRs), and the Na/MnO layers are further bridged by $O_3PCH(OH)CO_2^{3-}$ groups and strong hydrogen bonds between –OH and –COO [O4–H2···O6$_{(x, -y-1/2, z+1/2)}$ = 2.632(4) Å] into an interesting 3D organic–inorganic hybrid framework.

## Thermal Stabilities

Thermogravimetric analyses (TGA) of compounds **1**–**4** illustrate that under an atmosphere of nitrogen gas there is little weight loss for these compounds up to 410, 380, 390, and 370 °C, respectively (Figure 3). Thereupon, sharp weight-loss stages appear due to the decomposition of their frameworks. Furthermore, after solids **1**–**4** are annealed at 350, 250, 340 and 350 °C, respectively, their powder XRD patterns are all essentially in agreement with those simulated by single-crystal XRD data, which unambiguously indicate little change in their frameworks (Supporting Information, Figures S3–S6).

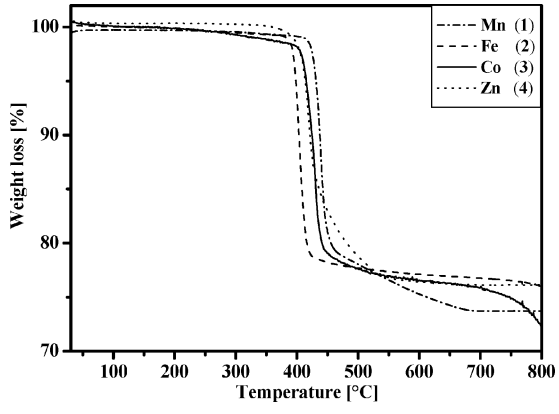

Figure 3. TGA curves of compounds **1**–**4**.

## Magnetic Properties

The temperature dependence of the $\chi_m T$ product, magnetic susceptibility ($\chi_m$) and inverse magnetic susceptibility ($1/\chi_m$) for compounds **1**–**3** at 5 kOe from 2 K to room temperature are shown in Figure S7 (Supporting Information).

The molar magnetic susceptibility of compound **1** increases with decreasing temperature and reaches a maximum at 5 K. At 305 K, the effective magnetic moment per manganese atom (5.70 $\mu_B$) is consistent with the expected spin-only value of 5.92 $\mu_B$ ($g$ = 2, $S$ = 5/2), and also according to the reported magnetic moments of $Mn^{II}$ ranging from 5.2 to 5.9 $\mu_B$.[7] Upon cooling, $\chi_m T$ product decreases slowly from 305 to 50 K. Thereupon, $\chi_m T$ decreases more quickly to 1.41 emu K mol$^{-1}$ at 2 K. In the temperature range of 2–305 K, the magnetic susceptibility follows the Curie–Weiss law [$\chi_m^{-1}$ = 1.82(5) + 0.2401(3)$T$] ($r$ = 0.9999), with $C$ = 4.16 emu K mol$^{-1}$ and $\theta$ = –7.6 K. The above results demonstrate antiferromagnetic interaction of the $Mn^{II}$ ions.[7a,10]

The effective magnetic moment per $Fe^{II}$ ion (5.25 $\mu_B$) for compound **2** at 307 K is slightly higher than the expected spin-only value of 4.90 $\mu_B$ ($g$ = 2, $S$ = 2).[10] With decreasing temperature, the effective magnetic moment decreases slowly down to 100 K (5.17 $\mu_B$) and then rapidly to 2.75 $\mu_B$ at 2 K. Between 2 and 305 K, the magnetic susceptibility also fits well with the Curie–Weiss law [$\chi_m^{-1}$ = 1.28(2) + 0.2859(1)$T$] ($r$ = 0.99999), with $C$ = 3.50 emu K mol$^{-1}$ and $\theta$ = –4.49 K. The decrease in the value of $\chi_m T$ with decreasing temperature and negative $\theta$ value indicate antiferromagnetic interaction of the $Fe^{II}$ ions.[7a,10]

Unlike those of compounds **1** and **2**, the $\chi_m T$ product of **3** decreases gradually from 2.86 emu K mol$^{-1}$ at 303 K down to 0.63 emu K mol$^{-1}$ at 2 K. From the above-mentioned equation, at 303 K the effective magnetic moment per cobalt atom ($\mu_{eff}$ = 4.78 $\mu_B$) is obviously higher than the reported spin-only value of 3.87 $\mu_B$. However, the value lies in the range of 4.4–5.2 $\mu_B$ owing to orbital contribution at room temperature.[10] In the range of 10–303 K, the magnetic susceptibility is consistent with the Curie–Weiss law [$\chi_m^{-1}$ = 4.87(9) + 0.3362(6)$T$] ($r$ = 0.9999), with $C$ = 2.97 emu K mol$^{-1}$ and $\theta$ = –14.5 K. The decrease in the value of $\chi_m T$ with decreasing temperature and negative $\theta$ value suggests antiferromagnetic interaction of the $Co^{II}$ ion.[7a,10] In addition, the magnetic susceptibility and thermal dependence of the $\chi_m T$ product are almost in agreement with those of pristine solid after polycrystalline **3** was previously heated at 300 or 340 °C for 2 h in an air atmosphere (Supporting Information, Figure S8). This result indicates little change in the valence of cobalt during the annealing treatment.

## Luminescent Properties

The solid-state luminescent properties of solids **1**–**4** were investigated under ambient temperature. Compounds **1b**–**4b** show no luminescence under our experimental conditions. In contrast, compounds **1a**–**4a** display bright blue-green (for **1a**, **2a** and **4a**) or purple (for **3a**) emission (Figure 4). The maximum band of **3a** is 434 nm, which exhibits a 11, 22, and 20-nm blueshift relative to those of compounds **1a**,

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

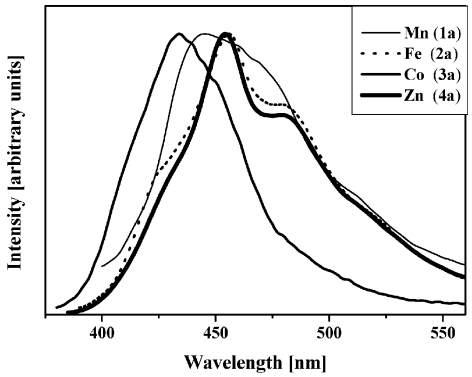

Figure 4. Normalized fluorescent emission spectra of **1a**–**4a** at room temperature in the solid state.

**2a** and **4a**, respectively. The blueshift is due to self-absorption through d–d transition of the $Co^{II}$ ion in the range of 428–654 nm. These emissions cannot be attributed to MLCT (metal-to-ligand charge transfer) and LMCT (ligand-to-metal charge transfer) in nature, and may probably be assigned to the intraligand n–π* transition for two reasons: (1) a bright blue-green emission with $\lambda_{max}$ = 460 nm can also be observed from a solution of $(H_2O_3P)$-$CH(OH)(CO_2H)$ and (2) all maximum bands of corresponding excitation spectra for solids **1a**–**4a** and $(H_2O_3P)$-$CH(OH)(CO_2H)$ solution fall in the range of 360–377 nm (Supporting Information, Figure S9, S10).[5] The lifetimes for $\lambda_{ex,em}$ = 380,450 nm of **1a** and $\lambda_{ex,em}$ = 368,460 nm of **2a** are 1.67(2) and 2.08(4) ns, respectively, which matches

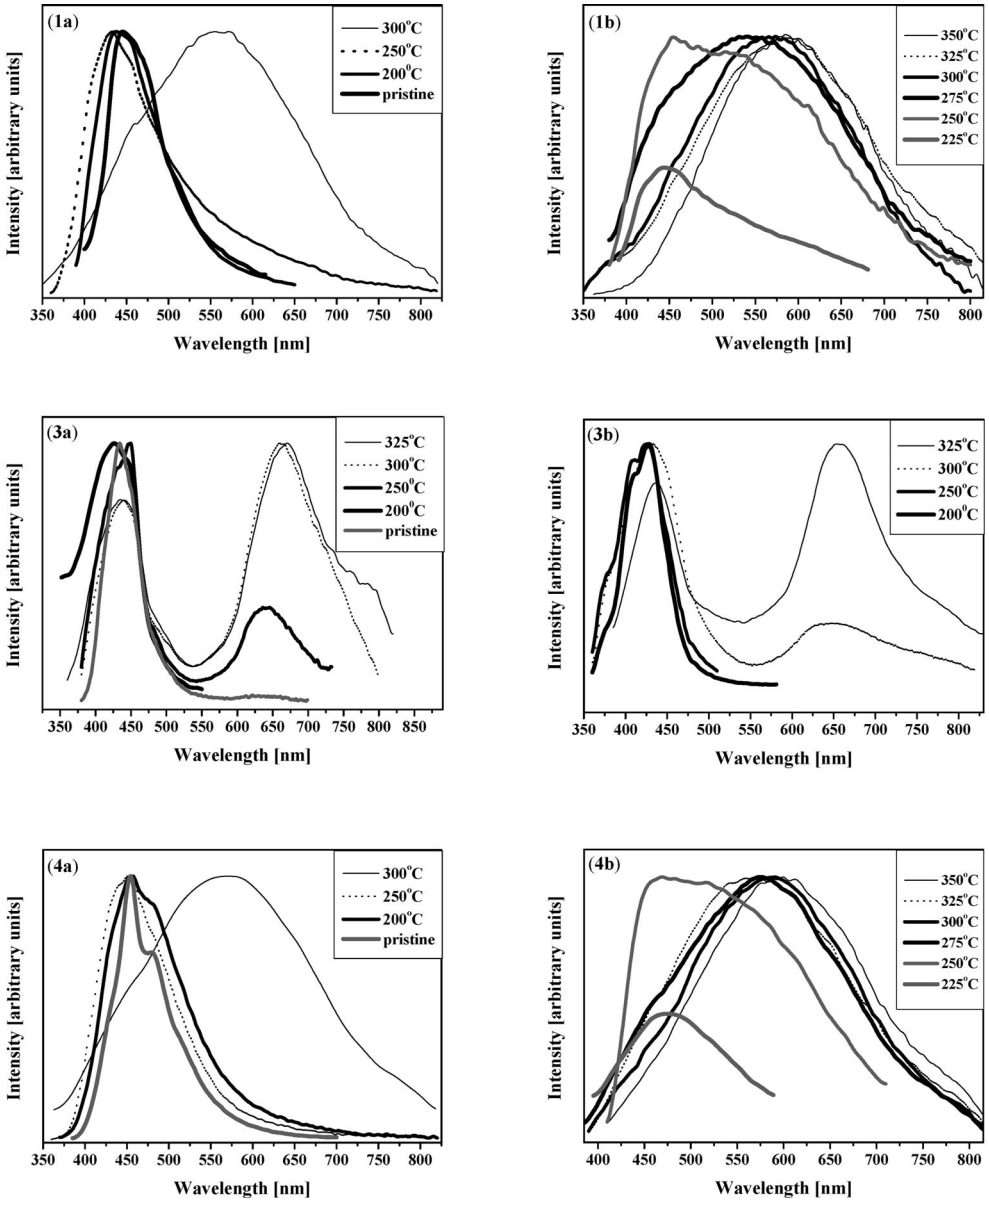

Figure 5. Room-temperature solid-state normalized fluorescent emission spectra of pristine **1a**, **1b**, **3a**, **3b**, **4a**, and **4b** − compounds were previously annealed at different temperatures.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

that of Hpaa [2.69(5) ns for $\lambda_{ex,em}$ = 370,462 nm], whereas solid **3a** has a very short lifetime [0.35(2) ns, for $\lambda_{ex,em}$ = 352,430 nm]. Preliminary experimental results revealed that the luminescent intensities of **1a** and **3a** are about 16 and 27% of that of $\mathbf{Na_2L}$, respectively. Furthermore, it is surprising that if **3b** is previously immersed in dilute $\mathbf{Na_2L}$ solution for 6 d and then rinsed with distilled water under ultrasonic treatment repeatedly, it can also give off bright-purple luminescence similar to that of **3a** (Supporting Information, Figure S10). This phenomenon is also observed for **1b**. The above results indicate that $\mathbf{Na_2L}$ would induce intrinsic luminescence of **1**–**4**. However, the mechanism of how $\mathbf{Na_2L}$ induces the luminescence is still unknown. Furthermore, solid **3a** can also emit bright-purple luminescence if $\mathbf{Na_2L}$ is reduced to 0.01 mmol in the synthetic mixture, which indicates that the luminescent properties may not depend on the amount of $\mathbf{Na_2L}$ in the synthetic mixture. In addition, annealing treatment at 225 °C (for **1b** and **4b**) or 200–250 °C (for **3b**) can also induce weak blue-green (for **1b** and **4b**) and bright-purple (for **3b**) luminescence.

Another attractive feature of compounds **1**, **3**, and **4** is their irreversible transformation of luminescent color through annealing treatment (Figure 5). Both **1a** and **4a** will give off bright-yellow luminescence ($\lambda_{max}$ = 571 nm) with a broad profile if they are previously annealed at 300 °C. The full width at half maximum heights (FWHM) of **1a** and **4a** are 239 and 258 nm, respectively. Because d–d transition for the $Co^{II}$ ion would absorb blue and green light with a maximum at 539 nm, **3a** can emit both purple and red emissions after annealing treatment, which is different to those of **1a** and **4a**. The intensities of purple and red emissions for **3a** will be tuned with different annealing temperature. For example, if **3a** is previously annealed at 250 °C, it displays bright purplish red luminescence, and the intensity ratio between the two peak bands at 449 and 636 nm is –2.6. After **3a** is annealed at 300 °C, red luminescence is intensified to reduce the ratio between the two maximum bands at 440 and 659 nm to –0.78, resulting in bright-red emission. Noteworthy is that the luminescent spectra of **3a** that was previously annealed at 250 and 300 °C are similar to the absorption spectra of chlorophyll a and b, respectively, which indicates that **3a** is an attractive candidate to be used in light conversion agriculture materials [light conversion agriculture material has the function of converting a light spectrum (like UV, green light) into blue and red light so as to promote the growth of vegetables].

Similar transformations of luminescent color with annealing treatment can also be observed on solids **1b**, **3b**, and **4b**. Because the $Mn^{II}$ ion is an important luminescent activator that gives off red emission, it seems that the transformation of luminescent colors for solids **1**, **3**, and **4** are not related to the transition-metal centers.[11] So, the IR spectra of solids **3** and **4** with different annealing temperatures were recorded to investigate the changes in the $O_3PCH(OH)CO_2^{3-}$ anion (Supporting Information, Figures S12, S13). However, all IR spectra are in agreement with those of the pristine solids. A suitable single crystal of **3** was carefully selected and annealed at 300 °C, and X-ray single-crystal diffraction revealed that the bond lengths of C=O and P–O in compound **3**–**300** are slightly shorter than those in pristine **3**, which results in the slight contraction of the unit-cell volume. This is in accord with the π–π* transition of C=O of compound **3**–**300**, which shows about a 15-nm blueshift relative to that of pristine **3** for strengthening the C=O band after the annealing treatment. Such slightly irreversible changes in the $O_3PCH(OH)CO_2^{3-}$ anion may cause the transformations of luminescent colors from blue-green to yellow (for **1**, **4**) or from purple to red (for **3**). In addition, the corresponding excitation spectra exhibit broad profiles in the range of 250–400 nm, which may be assigned to intraligand π–π* as well as n–π* transitions (Supporting Information, Figures S14–S19).

Furthermore, lifetimes for blue emission of solids **1** and **4** range from 1.6(1) to 3.21(7) ns, which are shorter than those of yellow emission [3.3(2)–6.3(4) ns] (Figures 6 and 7). For compound **3**, the lifetimes for purple and red luminescence are in the range of 0.35(4)–0.90(2) and 1.8(1)–2.7(2) ns, respectively (Figures 8 and 9).

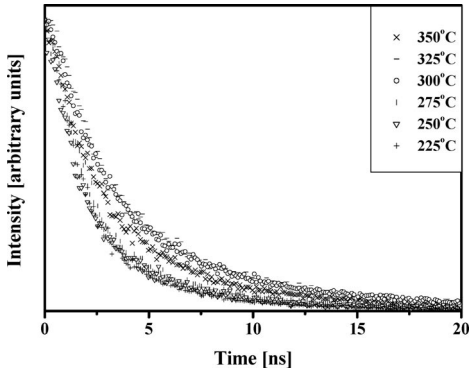

Figure 6. Room-temperature solid-state fluorescent intensity as a function of time for **1b** previously annealed at 225 ($\lambda_{ex,em}$ = 365, 445 nm), 250 ($\lambda_{ex,em}$ = 365, 420 nm), 275 ($\lambda_{ex,em}$ = 365, 458 nm), 300 ($\lambda_{ex,em}$ = 365, 575 nm), 325 ($\lambda_{ex,em}$ = 367, 580 nm), and 350 °C ($\lambda_{ex,em}$ = 370, 580 nm), respectively.

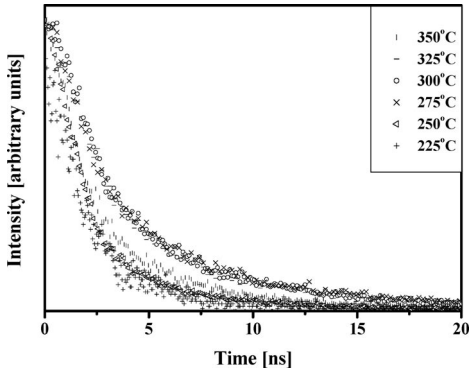

Figure 7. Room-temperature solid-state fluorescent intensity as a function of time for **4b** previously annealed at 225 ($\lambda_{ex,em}$ = 370, 478 nm), 250 ($\lambda_{ex,em}$ = 365, 460 nm), 275 ($\lambda_{ex,em}$ = 368, 573 nm), 300 ($\lambda_{ex,em}$ = 330, 588 nm), 325 ($\lambda_{ex,em}$ = 362, 562 nm), and 350 °C ($\lambda_{ex,em}$ = 365, 584 nm), respectively.

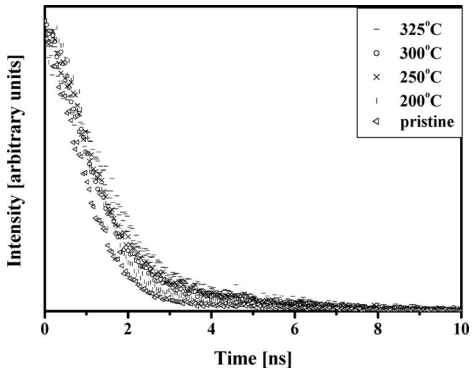

Figure 8. Room-temperature solid-state fluorescent intensity as a function of time for **3a** ($\lambda_{ex,em}$ = 352, 430 nm) as well as **3a** previously annealed at 200 ($\lambda_{ex,em}$ = 350, 428 nm), 250 ($\lambda_{ex,em}$ = 330, 445 nm), 300 ($\lambda_{ex,em}$ = 340, 440 nm), and 325 °C ($\lambda_{ex,em}$ = 362, 436 nm), respectively.

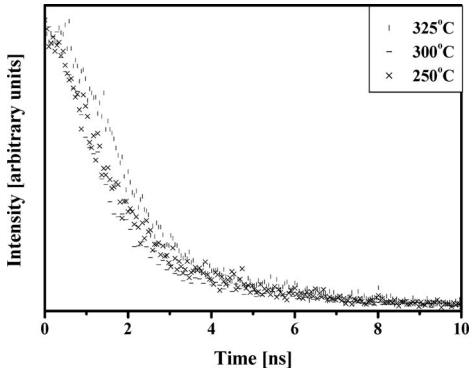

Figure 9. Room-temperature solid-state fluorescent intensity as a function of time for **3a** previously annealed at 250 ($\lambda_{ex,em}$ = 360, 640 nm), 300 ($\lambda_{ex,em}$ = 340, 660 nm), and 325 °C ($\lambda_{ex,em}$ = 365, 668 nm), respectively.

## Conclusions

In summary, the hydrothermal syntheses, crystal structures, and properties (including thermal stability, magnetism, and luminescence) of four new heterometal 2-hydroxyl-(phosphono)carboxylates were described. Solids **1**, **3**, and **4** are the first phosphonate-based compounds that possess intrinsic blue-green or purple luminescence properties induced by fluorescent whitener (**$Na_2L$**) or heat treatment. The luminescent colors can be irreversibly transformed into yellow or red emission by simple annealing treatment. These properties make them of interest for potential application as emitters in displaying technology, as well as advanced anticounterfeiting technical products.

## Experimental Section

**Materials and Instrumentation:** Hydroxy(phosphono)acetic acid solution was obtained from Changzhou City Jianghai Chemical Factory as water treatment agent (48.0 wt.-%). All other chemicals were obtained from commercial sources and used without further purification. Compounds **1**–**4** were synthesized in 25-mL Teflon-lined stainless steel vessels under autogenous pressure. The reactants were stirred homogeneously before heating. Elemental analyses were carried out with a Vario EL III element analyzer. Infrared spectra were obtained with a Nicolet Magna 750 FTIR spectrometer. The diffuse reflectance spectra of compounds **3** and **3**–**300** (polycrystalline **3** was previously annealed at 300 °C for 2 h in an air atmosphere) were recorded with a Perkin–Elmer Lambda 35 UV/Vis spectrometer. Fluorescent properties of solids **1**–**4** were investigated with FLS920 and LifeSpec-ps at ambient temperature. Thermogravimetric analysis was performed with a NETZSCH STA449C under nitrogen gas flow at a heating rate of 10 °C min$^{-1}$ (for **1** and **4**) or 15 °C min$^{-1}$ (for **2** and **3**) from room temperature to 800 °C. Powder X-ray diffraction (XRD) patterns were acquired with a DMAX-2500 diffractometer by using Cu-$K_\alpha$ radiation in an ambient environment. Magnetic properties of compounds **1**–**3** were measured with a Quantum Design PPMS at a magnetic field of 5000 Oe from 2 K to room temperature.

**$NaMn[O_3PCH(OH)CO_2]$ (1):** A mixture of $Mn(CH_3COO)_2{\cdot}4H_2O$ (0.2536 g, 1.035 mmol), disodium 4,4′-bis(2-sulfonatostiryl)biphenyl (**$Na_2L$**; 0.5821 g, 1.035 mmol), $NH_4Cl$ (2.2102 g, 41.32 mmol), NaF (0.0904 g, 2.153 mmol), $(H_2O_3P)CH(OH)(CO_2H)$ solution (0.5 mL, 2 mmol), and $H_2O$ (10.0 mL) was heated at 140 °C for 96 h. The final mixture was repeatedly rinsed with distilled water under ultrasonic treatment to obtain pure colorless crystals of **1**. Experimental powder XRD pattern of the product was in agreement with that simulated from single-crystal X-ray data, which indicated a homogeneous phase. The yield was 67% (0.1594 g) based on $Mn(CH_3COOH)_2{\cdot}4H_2O$. Final pH value of this reaction mixture was 3.72. $C_2H_2MnNaO_6P$ (230.94): calcd. C 10.40, H 0.87; found C 10.63, H 1.24. IR (KBr pellet): $\tilde{\nu}$ = 999 (w), 999 (vs, $\upsilon as_{CO}$), 999 (s), 3049 (m, $\upsilon_{O-H}$), 2929 (w, $\upsilon_{C-H}$), 2786 (w), 2733 (w), 2625 (w), 2520 (w), 1589 (vs, $\upsilon as_{CO}$), 1423 (s, $\delta_{C-H}$), 1373 (m, $\upsilon s_{CO}$), 1273 (m, $\delta_{C-H}$), 1176 (s, $\upsilon_{P=O}$), 1144 (s, $\upsilon_{P-O}$), 1095 (vs, $\upsilon_{P-O}$), 1056 (w, $\upsilon_{P-O}$), 995 (m, $\upsilon_{P-O}$), 983 (w), 847 (w), 796 (m), 767 (w, $\upsilon_{C-P}$), 748 (w, $\upsilon_{C-P}$), 665 (w), 588 (m), 542 (m), 494 (s) cm$^{-1}$. Crystals of **1** can also be obtained in the absence of **$Na_2L$** and $NH_4Cl$ as follows: A mixture of $Mn(CH_3COO)_2{\cdot}4H_2O$ (0.1225 g, 0.4998 mmol), NaF (0.3500 g, 8.335 mmol), $(H_2O_3P)CH(OH)(CO_2H)$ solution (1.0 mL, 4 mmol), acetic acid (2.0 mL), and $H_2O$ (8.0 mL) was heated at 120 °C for 144 h. The final mixture was also rinsed with distilled water under ultrasonic treatment many times to obtain pure colorless crystals of **1**. Experimental powder XRD pattern of the product was in accord with that simulated from single-crystal X-ray data, which indicated a homogeneous phase.

**$NaFe[O_3PCH(OH)CO_2]$ (2):** A mixture of $FeCl_2{\cdot}4H_2O$ (0.1014 g, 0.5100 mmol), $NH_4Cl$ (2.5 g, 47 mmol), NaF (0.4 g, 9.5 mmol), $(H_2O_3P)CH(OH)(CO_2H)$ solution (0.7 mL, 3 mmol), and $H_2O$ (10.0 mL) was heated at 140 °C for 96 h. The final mixture was repeatedly rinsed with distilled water under ultrasonic treatment to obtain pure colorless crystals of **2**. Experimental powder XRD pattern of the product was in agreement with that simulated from single-crystal X-ray data, which indicated a homogeneous phase. The yield was 33% (0.0383 g) based on $FeCl_2{\cdot}4H_2O$. Final pH value of this reaction mixture was 3.79. $C_2H_2FeNaO_6P$ (231.85): calcd. C 10.36, H 0.87; found C 10.32, H 1.16. IR (KBr pellet): $\tilde{\nu}$ = 3026 (m, $\upsilon_{O-H}$), 2931 (w, $\upsilon_{C-H}$), 2786 (w), 2733 (w), 2625 (w), 2524 (w), 1591 (vs, $\upsilon as_{CO}$), 1426 (s, $\delta_{C-H}$), 1374 (s, $\upsilon s_{CO}$), 1275 (s, $\delta_{C-H}$), 1177 (s, $\upsilon_{P=O}$), 1148 (s, $\upsilon_{P-O}$), 1088 (vs, $\upsilon_{P-O}$), 1056 (w, $\upsilon_{P-O}$), 993 (s, $\upsilon_{P-O}$), 985 (s), 845 (m), 806 (m), 773 (w, $\upsilon_{C-P}$), 753 (w, $\upsilon_{C-P}$), 665 (m), 594 (m), 549 (m), 490 (s) cm$^{-1}$. Crystals of **2** can also be obtained with **$Na_2L$** in an initial mixture as follows: A mixture of $FeCl_2{\cdot}4H_2O$ (0.1001 g, 0.5035 mmol), **$Na_2L$** (0.2801 g, 0.4980 mmol), NaF (0.4001 g, 9.528 mmol), $(H_2O_3P)CH(OH)(CO_2H)$ solution (1 mL, 4 mmol), acetic acid (2.0 mL), and

$H_2O$ (8.0 mL) was heated at 120 °C for 144 h The final mixture was also rinsed with distilled water under ultrasonic treatment many times to obtain pure crystals of **2** Experimental powder XRD pattern of the product was also in agreement with that simulated from single-crystal X-ray data, which indicated a homogeneous phase.

**$NaCo[O_3PCH(OH)CO_2]$ (3):** A mixture of $Co(CH_3COO)_2{\cdot}4H_2O$ (0.249 g, 1.00 mmol), **$Na_2L$** (0.5843 g, 1.039 mmol), NaF (0.1657 g, 3.946 mmol), $(H_2O_3P)CH(OH)(CO_2H)$ solution (0.7 mL, 3 mmol), acetic acid (2.0 mL), and $H_2O$ (8.0 mL) was heated at 140 °C for 96 h. The final mixture was repeatedly rinsed with distilled water under ultrasonic treatment to obtain pure red crystals of **3**. Experimental powder XRD pattern of the product was in agreement with that simulated from single-crystal X-ray data, which indicated a homogeneous phase. The yield was 93% (0.2172 g) based on $Co(CH_3COOH)_2{\cdot}4H_2O$. Final pH value of this reaction mixture was 3.80. $C_2H_2CoNaO_6P$ (234.93): calcd. C 10.23, H 0.86; found C 10.26, H 1.22. IR (KBr pellet): $\tilde{\nu}$ = 3003 (m, $\upsilon_{O-H}$), 2936 (m, $\upsilon_{C-H}$), 2787 (w), 2729 (w), 2619 (w), 2521 (w), 1595 (vs, $\upsilon as_{CO}$), 1428 (s, $\delta_{C-H}$), 1373 (m, $\upsilon s_{CO}$), 1273 (m, $\delta_{C-H}$), 1177 (s, $\upsilon_{P=O}$), 1151 (s, $\upsilon_{P-O}$), 1090 (vs, $\upsilon_{P-O}$), 1054 (w, $\upsilon_{P-O}$), 987 (vs, $\upsilon_{P-O}$), 846 (m), 813 (m), 777 (w, $\upsilon_{C-P}$), 756 (w, $\upsilon_{C-P}$), 671 (m), 660 (m), 593 (m), 557 (m), 492 (s) $cm^{-1}$. Crystals of **3** can also be obtained in the absence of **$Na_2L$** as follows: A mixture of $Co(CH_3COO)_2{\cdot}4H_2O$ (0.249 g, 1.00 mmol), NaF (0.2001 g, 4.765 mmol), $(H_2O_3P)$-$CH(OH)(CO_2H)$ solution (0.5 mL, 2 mmol), acetic acid (0.5 mL), and $H_2O$ (8.0 mL) was heated at 120 °C for 144 h. The final mixture was also rinsed with distilled water under ultrasonic treatment many times to obtain pure red crystals of **3**. Experimental powder XRD pattern of the product was also in agreement with that simulated from single-crystal X-ray data, which indicated a homogeneous phase.

**$NaZn[O_3PCH(OH)CO_2]$ (4):** A mixture of $Zn(CH_3COO)_2{\cdot}2H_2O$ (0.11 g, 0.501 mmol), NaF (0.35 g, 8.3 mmol), $(H_2O_3P)CH$-$(OH)(CO_2H)$ solution (1.0 mL, 4 mmol), acetic acid (2.0 mL), and $H_2O$ (8.0 mL) was heated at 140 °C for 96 h. The final mixture was repeatedly rinsed with distilled water under ultrasonic treatment to obtain pure crystals of **4**. Experimental powder XRD pattern of the product was in agreement with that simulated from single-crystal X-ray data, which indicated a homogeneous phase. The yield was 46% (0.0490 g) based on $Zn(CH_3COO)_2{\cdot}2H_2O$. Final pH value of this reaction mixture was 2.84. $C_2H_2NaO_6PZn$ (241.37): calcd. C 9.95, H 0.84; found C 9.95, H 1.24. IR (KBr pellet): $\tilde{\nu}$ = 3023 (m, $\upsilon_{O-H}$), 2935 (w, $\upsilon_{C-H}$), 2792 (w), 2737 (w), 2625 (w), 2524 (w), 1591 (vs, $\upsilon as_{CO}$), 1433 (s, $\delta_{C-H}$), 1376 (s, $\upsilon s_{CO}$), 1277 (m, $\delta_{C-H}$), 1179 (s, $\upsilon_{P=O}$), 1154 (s, $\upsilon_{P-O}$), 1083 (vs, $\upsilon_{P-O}$), 1062 (w, $\upsilon_{P-O}$), 994 (s, $\upsilon_{P-O}$), 985 (w), 848 (m), 808 (m), 776 (w, $\upsilon_{C-P}$), 755 (w, $\upsilon_{C-P}$), 673 (m), 663 (m), 594 (m), 558 (m), 500 (s), 490 (s) $cm^{-1}$. Crystals of **4** can also be obtained with **$Na_2L$** in an initial mixture as follows: A mixture of $Zn(CH_3COO)_2{\cdot}2H_2O$ (0.2195 g, 1.000 mmol), NaF (0.2001 g, 4.765 mmol), **$Na_2L$** (0.5602 g, 0.9960 mmol), $(H_2O_3P)$-$CH(OH)(CO_2H)$ solution (0.5 mL, 2 mmol), acetic acid (0.5 mL), and $H_2O$ (8.0 mL) was heated at 140 °C for 96 h. The final mixture was rinsed with distilled water under ultrasonic treatment many times to obtain pure crystals of **4**. Experimental powder XRD pattern of the product was also in agreement with that simulated from single-crystal X-ray data, which indicated a homogeneous phase.

**Single-Crystal X-ray Diffraction:** X-ray data were collected at 293(2) K with a Siemens SMART-CCD diffractometer (for **1**), a Rigaku Mercury CCD/AFC diffractometer (for **2**–**4**), and a Saturn 70 CCD diffractometer (for **3**–**300**) by using graphite-monochromated Mo-$K_\alpha$ radiation [$\lambda$(Mo-$K_\alpha$) = 0.71073 Å]. Data of compound **1** were reduced and absorption corrected with SMART and SADABS software, respectively, whereas data of compounds **2**–**4** and **3**–**300** were reduced with CrystalClear v1.3. These structures were solved by direct methods and refined by full-matrix least-squares techniques on $F^2$ by using SHELXTL-97.[12] All non-hydrogen atoms were treated anisotropically. The positions of hydrogen atoms were located from difference Fourier map and assigned with fixed isotropic thermal parameter. Crystal data are summarized in Table 1. CCDC-629750 to -629753 for compounds **1**–**4**, respectively, contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

**Relative Luminescent Intensity:** Coin-like tablets of solids **1a**, **3a**, and **$Na_2L$** with about 1.3-cm diameter and 0.1-cm thickness were prepared at room temperature. First, a tablet of **$Na_2L$** was excited at 372 nm to obtain the emission spectrum, and then all the experimental conditions (including optical set up, focalization point, illuminated cross-section, sample holder, and emission and excitation slits width) were held constant and a tablet of solid **1a** was excited at 376 nm to obtain the emission spectrum. Second, a tablet of **$Na_2L$** was excited at 410 nm to obtain the emission spectrum, and then all the experimental conditions (including optical set up, focalization point, illuminated cross-section, sample holder, and emis-

# Luminescent Organically Templated Lanthanide Oxalate–Selenate Hybrids

Mei-Ling Feng[a,b] and Jiang-Gao Mao*[a]

**Keywords:** Hydrothermal syntheses / Lanthanides / Selenium / Crystal structures / Luminescent properties

Hydrothermal reactions of lanthanide nitrates with selenic acid, sodium oxalate, and organic amines led to two series of new organically templated lanthanide oxalate–selenate hybrids with 2D-layer or 3D-network structures, namely, $Ln_2(SeO_4)_2(C_2O_4)(H_2O)_4$·pip (Ln = Eu **1**; Tb **2**; Dy **3**; Er **4**; Yb **5**) (pip = piperazine) and $[H_2pip]_2[Ln_2(SeO_4)_2(C_2O_4)_3]$·$H_2O$ (Ln = Er **6**; Yb **7**; Lu **8**; Y **9**). Their structures were established by X-ray single-crystal diffraction. Isostructural compounds **1**–**5** feature a 2D inorganic–organic hybrid neutral layer of $Ln_2(SeO_4)_2(C_2O_4)(H_2O)_4$. The neutral piperazine molecules are located at the interlayer spaces and interconnect with the inorganic skeleton through hydrogen bonds. Compounds **6**–**9** are isostructural and possess 3D pillared layered architectures composed of lanthanide oxalate layers bridged by selenate anions (the pillar). The template cations are located at the tunnels of the structure. Compounds **1**, **2**, and **3** display emission bands in the red-, green-, and pink-light regions, respectively, and these compounds have lifetimes of 0.178, 0.962, and 0.276 ms, respectively. Compounds **6** and **7** both exhibit emission bands in the near-IR region.

## Introduction

Recent studies on the preparations of new compounds possessing inorganic open frameworks with guest organic entities have revealed the diversity of such materials in terms of structure topology and composition, particularly in the presence of organic amines as structure-directing agents, which usually occupy the structural voids and are well isolated from the inorganic skeleton.[1–3] The main interest in this class of compounds stems from their potential applications in the areas of catalysis, sorption, and separation processes.[3–5] So far, a remarkable variety of such materials has been reported and most of the reports are based on metal phosphates.[6] Recently, this research field has been extended to the oxido anions of group 16 elements such as metal sulfates.[7] Selenium exists in many different oxidation states and various forms such as $H_2SeO_3$, $HSeO_3^-$, $SeO_3^{2-}$, $Se_2O_5^{2-}$, and $SeO_4^{2-}$.[8] As for the oxido anions of $Se^{IV}$, a few organically templated transition-metal selenites with various structural types have been reported.[9–11] 3D open-framework $[NH_2(CH_2)_4NH_2]_{0.5}[M(HSeO_3)(Se_2O_5)]$ (M = Zn, Co, Ni) with a diamondoid network containing both hydrogenselenite and diselenite anions were reported by Rao et al.[12] A series of organically templated or organically bonded copper(II), indium(III), and gallium(III) selenites were prepared in our laboratory recently.[13] Both organically templated and linked vanadium and $Mo^{VI}$ selenites were isolated.[14–16] However, reports on organically templated metal selenates are still relatively rare hitherto, in particular lanthanide ones. The oxido anions of Se differ from those of S in their most stable oxidation states and their redox behaviors.[17] The most stable oxidation state of S is +6 as in $SO_4^{2-}$, whereas that of Se is +4 as in $SeO_3^{2-}$ or $Se_2O_5^{2-}$. The reduction potential of the $XO_4^{2-}/XO_3^{2-}$ couple is 0.03 V in alkaline medium for Se and 0.119 V for S, which has strong effects on the thermal stabilities of their metal compounds. It is, therefore, difficult to stabilize a metal selenate framework under the hydrothermal conditions especially in the presence of reducing amine templates.[18a] So far the organically templated 1D cadmium(II) selenate $[H_2en][Cd(HSeO_4)_2(H_2O)_2]$, layered lanthanide(III) selenates $[H_2en]_{0.5}[Ln(SeO_4)_2(H_2O)_2]$ (Ln = La, Nd, or Pr) and $[H_2pip]_{0.5}[La(SeO_4)_2]$·$0.5H_2O$, and 3D lanthanum(III) selenate $[H_2en][La_2(SeO_4)_4(H_2O)_3]$·$H_2O$ were isolated by Rao et al.[18] The organically templated lithium[19] and zinc selenates[20] were been reported. Several organically templated uranyl selenates were obtained by the Krivovichev group.[21] Very recently, the organically templated indium selenates $[H_2en]_{0.5}[In(SeO_4)(C_2O_4)(H_2O)_2]$ and $[H_2en][InF_3(SeO_4)]$ were prepared in our laboratory.[13b]

Lanthanide compounds are of special interest due to their unique luminescent properties.[22,23] It is assumed that organically templated lanthanide selenates with a rigid second ligand such as oxalate would have novel structural architecture and good luminescent properties.[24] The combination of two types of ligands (selenate and oxalate) may

enhance the energy transfer efficiency from ligands to lanthanide ions and improve the luminescent properties of the lanthanide compounds due to the so-called "antenna effect".[24a–24c,25] Furthermore, the coordination of both types of ligands with the lanthanide ion may reduce or eliminate aqua ligands that usually quench the luminescence of the $Ln^{III}$ ions.[24a,24b] Our current research efforts in this aspect resulted in two series of new luminescent organically templated lanthanide(III) oxalate–selenate hybrids with 2D-layer and 3D-network structures, namely, $Ln_2(SeO_4)_2(C_2O_4)(H_2O)_4$·pip (pip = piperazine; Ln = Eu **1**; Tb **2**; Dy **3**; Er **4**; Yb **5**) and $[H_2pip]_2[Ln_2(SeO_4)_2(C_2O_4)_3]$·$H_2O$ (Ln = Er **6**; Yb **7**; Lu **8**; Y **9**). Herein we report their syntheses, crystal structures, and luminescent properties.

## Results and Discussion

Compounds **1**–**9** represent first members of organically templated lanthanide(III) oxalate–selenate hybrids. $Ln_2(SeO_4)_2(C_2O_4)(H_2O)_4$·pip (Ln = Eu **1**; Tb **2**; Dy **3**; Er **4**; Yb **5**) have a layered structure, whereas $[H_2pip]_2[Ln_2(SeO_4)_2(C_2O_4)_3]$·$H_2O$ (Ln = Er **6**; Yb **7**; Lu **8**; Y **9**) feature a pillared layered structure. It should be noted that the synthetic conditions for the two series of compounds are almost the same except for the amount of $Na_2C_2O_4$ used. $Ln_2(SeO_4)_2(C_2O_4)(H_2O)_4$·pip (Ln = Eu **1**; Tb **2**; Dy **3**; Er **4**; Yb **5**) were obtained when the $Ln/C_2O_4$ molar ratio was about 3:1. When the amount of $Na_2C_2O_4$ was doubled, $[H_2pip]_2[Ln_2(SeO_4)_2(C_2O_4)_3]$·$H_2O$ (Ln = Er **6**; Yb **7**; Lu **8**; Y **9**) were isolated, and the open frameworks of the compounds were dominated by lanthanide oxalates. Therefore, the amount of second metal linker plays an important role in the chemical compositions and crystal structures of the inorganic–organic hybrids formed.

Compounds **1**–**5** are isostructural; hence, only the structure of **5** will be discussed in detail as a representative example. As shown in Figure 1a, the asymmetric unit of **5** consists of 14 independent non-hydrogen atoms, 11 of which belong to the neutral framework (one Yb atom, one Se atom, one C atom, six O atoms, and two aqua ligands) and the remaining three for the organic amine (one N atom and two C atoms). The ytterbium(III) ion is eight-coordinate and is chelated by two $SeO_4^{2-}$ anions in a monodentate fashion, one oxalate anion in a bidentate chelating fashion and one in a unidentate fashion, and three aqua ligands. One of the aqua ligands (O1W) bridges two $Yb^{III}$ ions. The Yb–O1W distance [2.204(3) and 2.259(3) Å] is significantly shorter than the Yb–O2W (terminal) bonds [2.425(3) Å] (Table 1). The other Yb–O ($C_2O_4^{2-}$ and $SeO_4^{2-}$) bond lengths vary from 2.275(3) to 2.514(3) Å (Table 1), which are comparable to those reported in other ytterbium(III) selenates and oxalates.[26a,26b] The oxalate anion is hexadentate: it chelates two $Yb^{III}$ ions (O5, O6) by forming two Yb–O–C–C–O five-membered rings and also it bridges two other $Yb^{III}$ ions. The O6 atom is bidentate, whereas the O5 atom is unidentate. The selenate anion is bidentate bridging.

The interconnection of the $Yb^{III}$ ions by chelating and bridging oxalate anions and as well as bridging O1W led to a 2D layer of ytterbium(III) oxalate parallel to the *bc* plane (Figure 1b), which is different from the lanthanide oxalates with 1D-chain and 3D-porous network structures previously reported.[24b,24c] Four-membered rings (Yb–O1W–Yb–O6) and 12-membered rings composed of four $Yb^{III}$ ions, two carboxylate groups, and two aqua ligands are present within the 2D layer. The selenate groups hang above and below the central lanthanide oxalate layer and form a 2D neutral layer of $Yb_2(SeO_4)_2(C_2O_4)(H_2O)_4$. The interlayer distance is 9.3 Å. The piperazine molecules are located at the interlayer spaces and form hydrogen bonds with the noncoordinating selenate oxygen atoms [N1···O1 2.736(5) and N1···O3 (symmetry code: $x$, $-y + 1/2$, $z - 1/2$) 2.757(5)] (Figure 1c and Table 1).

The use of more oxalate anions in the preparation afforded $[H_2pip]_2[Ln_2(SeO_4)_2(C_2O_4)_3]$·$H_2O$ (Ln = Er **6**, Yb **7**, Lu **8**, and Y **9**) with a 3D pillared layered structure. Their 3D pillared layered architectures are built from 2D lanthanide oxalate layers bridged by selenate anions (the pillar) (Figure 2c). The structure of the $Er^{III}$ compound will be described in detail as an example. The asymmetric unit of **6** consists of 22 independent non-hydrogen atoms, 15 of which belong to the anionic framework (1 Er atom, 1 Se atom, 3 C atoms, and 10 O atoms), 6 for the template cation (2 N atoms and 4 C atoms), and 1 for a lattice water molecule (Figure 2a). The erbium(III) ion is eight-coordinate and is chelated by two $SeO_4^{2-}$ anions in a monodentate

Table 1. Selected bond lengths [Å] for compounds **1**, **3**, **5**, **6**, and **9**.[a]

| Ln–O | **1** (Eu) | **3** (Dy) | **5** (Yb) | Ln–O | **6** (Er) | **9** (Y) |
|---|---|---|---|---|---|---|

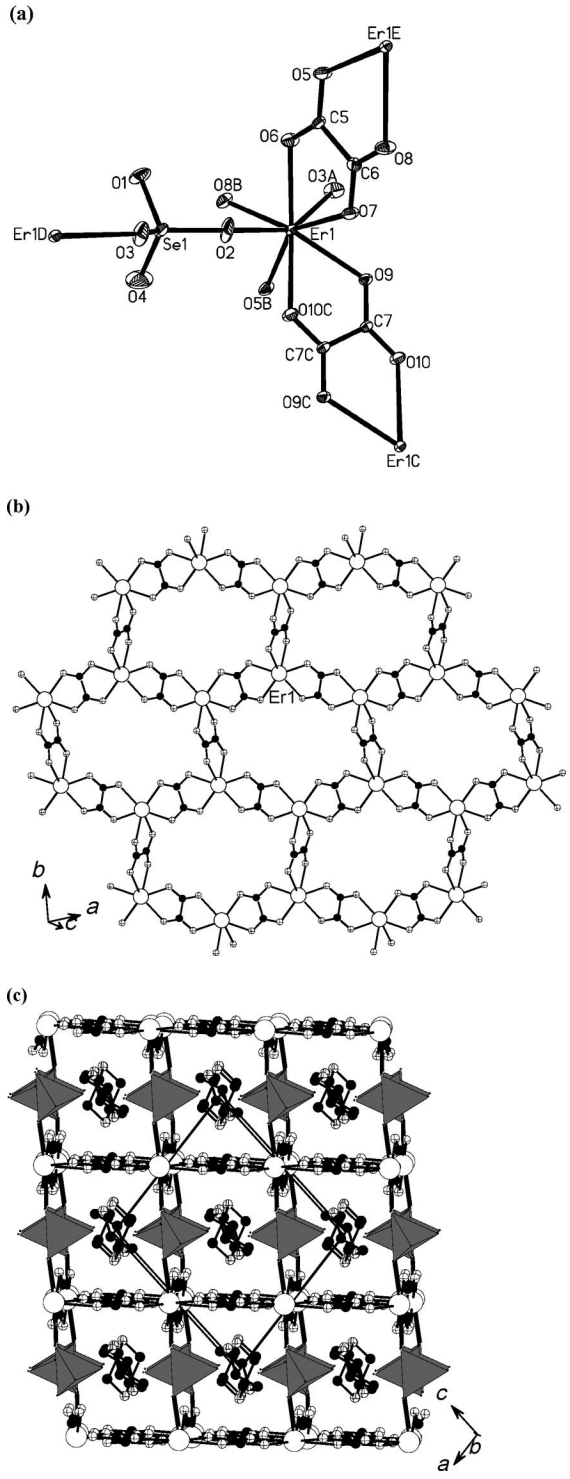

Figure 2. (a) ORTEP drawing of the selected unit in compound **6**. Thermal ellipsoids are drawn at the 50% probability level. Symmetry codes for generated atoms: a) $x + 1/2, -y + 1/2, z - 1/2$; b) $x - 1/2, -y + 1/2, z - 1/2$; c) $-x, -y, -z + 1$; d) $x - 1/2, -y + 1/2, z + 1/2$; e) $x + 1/2, -y + 1/2, z + 1/2$. The template cation and the lattice water molecule are omitted for clarity; (b) A (–202) erbium(III) oxalate layer in compound **6**. The Er, O, and C atoms are drawn as white, crossed, and black circles, respectively; (c) view of the structure of **6** down the *b* axis. The Er, O, C, and N atoms are drawn as white, crossed, black, and octanded circles, respectively. The selenate tetrahedra are shaded in medium grey.

fashion and three oxalate anions all in a bidentate chelating fashion. The Er–O distances fall in the range of 2.297(3)–2.429(3) Å (Table 1), which are comparable to those reported for other erbium(III) selenates and oxalates.[26b,26c] The selenate anion is bidentate and bridges two $Er^{III}$ ions. Different from that in compounds **1**–**5**, each oxalate anion in compound **6** is tetradentate and forms two Er–O–C–C–O five-membered chelating rings.

The interconnection of the $Er^{III}$ ions through the chelating and bridging oxalate anions results in the formation of a (–202) erbium(III) oxalate layer. Different from the lanthanide oxalate layers in compounds **1**–**5**, the erbium(III) oxalate layer in **6** is based on 24-membered rings composed of 6 $Er^{III}$ ions and 6 carboxylate groups (Figure 2b). The lattice water molecule is located at the center of the above ring. The above layers of lanthanide oxalates are further cross-linked by selenate anions into a 3D pillared layered architecture with large tunnels running along the *b* axis (Figure 2c). The tunnel is formed by 16-membered rings composed of 4 $Er^{III}$ ions, 2 selenate anions, and 2 carboxylate groups. The solvent accessible volume in compound **6** is 38.1% according to calculations performed by using the PLATON program.[27] The doubly protonated piperazine cations are located at the above tunnels. No hydrogen bonds are found between the template cations and oxygen atoms from the framework (Figure 2c).

The IR spectra of compounds **1**–**9** clearly exhibit the characteristic vibration bands for the selenate (893–696 and 586–416 $cm^{-1}$) and oxalate groups (1654–1627 and 1384–1315 $cm^{-1}$). The broad bands in the range of 3609–2461 $cm^{-1}$ correspond to the stretching vibrations of water molecules and organic amines in all compounds.

The TGA curves of compounds **1**–**3** and **5**–**9** are shown in Figure S1 (see the Supporting Information). The TGA curves of compounds **1**–**3** and **5** are similar and display three main steps of weight loss (Figure S1a). Compound **1** was used as an example. The first step in the 160–306 °C range corresponds to the release of the four aqua ligands and neutral piperazine molecule, the observed weight loss of 17.7% is close to the calculated value of 18.9%. The second step covering from 306–560 °C can be assigned to the partial decomposition of the selenate and oxalate anions. The third step in the range of 560–1000 °C represents further combustion of the compound. The total weight loss at 1000 °C is 54.1%, and on the basis of the slope of the TGA curves, the decomposition is not complete. The thermal decomposition mechanism of the metal selenate is very complicated; the selenate anion was reported to decompose into $SeO_2$ and $O_2$, and the final residues are probably a mixture of metal oxide and metal selenide.[18a] The TGA diagrams of compounds **6**–**9** are similar and display three main weight losses (Figure S1b). Compound **6** is used as an example. The first step began at 60 °C and was completed at 140 °C, which corresponds to the release of the lattice water molecule. The observed weight loss of 1.72% is very close to the calculated value (1.67%). The second step covered from 140 °C to 434 °C, which corresponds to the release of the piperazine cations and the par-

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

tial decomposition of the selenate and oxalate anions. The third step is the further combustion of the compound. The total weight loss at 1000 °C is 61.8%, and on the basis of the slope of the TGA curves, the decomposition is not complete. Similar to those in **3**, the final residues are expected to be mainly a mixture of metal oxide and metal selenide.[18a]

## Luminescent Properties

The solid-state luminescent properties of compounds **1**–**7** and the ligands ($Na_2C_2O_4$ and $H_2SeO_4$) were investigated at room temperature. Compounds **4** and **5** and the ligands do not show observable emission bands under our experimental conditions. The emission spectra of compounds **1**, **2**, **3**, **6**, and **7** are given in Figure 3. Compound **1** shows the characteristic emission bands for the $Eu^{III}$ ion in the visible region under excitation at 363 nm (Figure 3a). They are due to $^5D_0 \rightarrow {}^7F_J$ ($J$ = 0, 1, 2, 3, and 4) transitions: 577 nm ($^5D_0 \rightarrow {}^7F_0$); 585, 589, and 600 nm ($^5D_0 \rightarrow {}^7F_1$); 608, 611, 618, 620, and 625 nm ($^5D_0 \rightarrow {}^7F_2$); 654 nm (weak, $^5D_0 \rightarrow {}^7F_3$), and 688, 694, 698, 701, and 703 nm ($^5D_0 \rightarrow {}^7F_4$).[28] The splitting of the $^5D_0 \rightarrow {}^7F_1$, $^5D_0 \rightarrow {}^7F_2$, and $^5D_0 \rightarrow {}^7F_4$ transition bands is due to the "crystal field effect" of the $Eu^{III}$ ion in a $C_1$ symmetry, which led to the complete degeneracy of the $^7F_J$ ($J$ = 1 and 2) and the partial degeneracy of the $^7F_4$ states. The most intense transition is $^5D_0 \rightarrow {}^7F_2$ in the red light region. The Eu ($^5D_0$) lifetime ($\lambda_{ex,em}$ = 363, 618 nm) of **1** was measured to be 0.178 ms. Compound **2** displays the characteristic emission bands for the $Tb^{III}$ ion under excitation at 354 nm (Figure 3b). The emission bands can be assigned to $^5D_4 \rightarrow {}^7F_J$ ($J$ = 6, 5, 4, and 3) transitions of the $Tb^{III}$ ion: 484 nm ($^5D_4 \rightarrow {}^7F_6$), 541 and 546 nm ($^5D_4 \rightarrow {}^7F_5$), 589 nm ($^5D_4 \rightarrow {}^7F_4$), and 626 nm ($^5D_4 \rightarrow {}^7F_3$).[29] The Tb ($^5D_4$) lifetime for compound **2** under

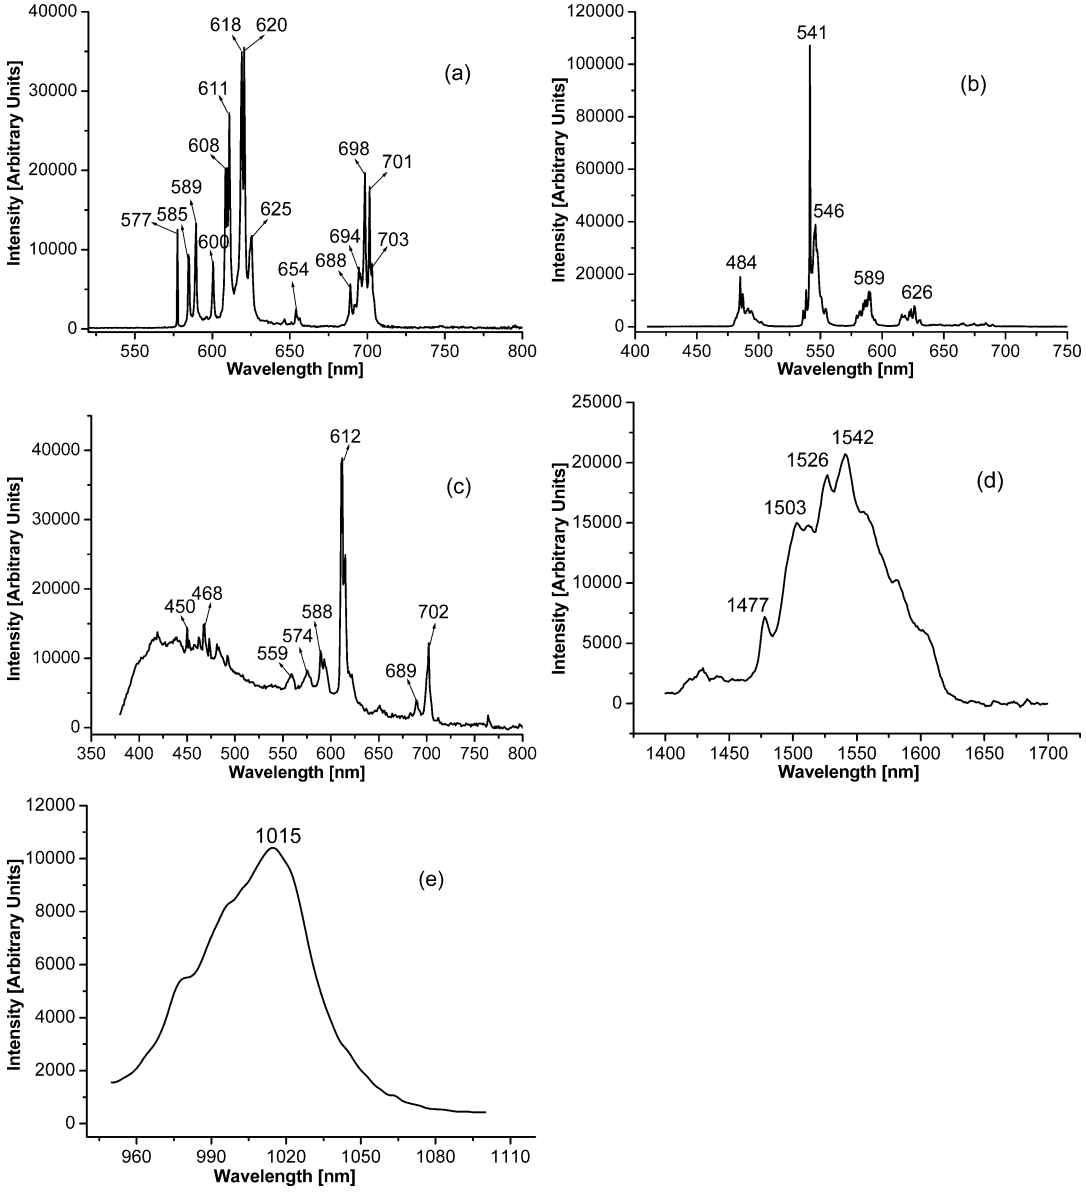

Figure 3. Solid-state emission spectra for (a) **1**; (b) **2**; (c) **3**; (d) **6**; and (e) **7** at room temperature.

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

$\lambda_{ex,em}$ = 354, 548 nm is 0.962 ms. Compound **3** displays both broad and sharp emission bands that are characteristic for $Dy^{III}$ ions when excited at 285 nm (Figure 3c). The broad emission bands at about 450 and 468 nm can be assigned to the $^4F_{9/2}\rightarrow{}^6H_{15/2}$ transition, the weak emission bands at 559, 574, and 588 nm are due to the $^4F_{9/2}\rightarrow{}^6H_{13/2}$ transition, and the emission bands at 612 and 702 nm can be assigned to the $^4F_{9/2}\rightarrow{}^6H_{11/2}$ and $^4F_{9/2}\rightarrow{}^6H_{9/2}$ transitions of the $Dy^{III}$ ion.[29,30] The $^4F_{9/2}\rightarrow{}^6H_{15/2}$ and $^4F_{9/2}\rightarrow{}^6H_{13/2}$ transitions were split into several sub-bands, which may result from the Stark sublevel splitting of the $^6H_{15/2}$ and $^6H_{13/2}$ energy levels by the ligand field.[29] The Dy ($^4F_{9/2}$) lifetime for $\lambda_{ex,em}$ = 285, 612 nm is about 0.276 ms. The emission spectrum of **6** exhibits emission bands in the near-IR region ($\lambda_{ex}$ = 520 nm, Figure 3d). The emission bands at 1477, 1503, 1526, and 1542 nm can all be attributed to the $^4I_{13/2}\rightarrow{}^4I_{15/2}$ transition of the $Er^{III}$ ion.[24b,31,32] The splitting of the $^4I_{13/2}\rightarrow{}^4I_{15/2}$ transition bands is probably due to the ligand field effect of erbium(III) located at a site with a $C_1$ symmetry. Compound **7** shows only a broad fluorescence emission band centered at 1015 nm in the near-IR region ($\lambda_{ex}$ = 937 nm, Figure 3e), which is assigned to the $^2F_{5/2}\rightarrow{}^2F_{7/2}$ transition for the $Yb^{III}$ ion.[33] No emission bands in the near-IR region were observed for compounds **4** and **5**, which is probably due to the quenching effect of the luminescence state by high-frequency vibrating aqua ligands.[24a,24b] Therefore, the luminescence of the inorganic–organic hybrids formed can be significantly enhanced if more rigid oxalate anions are incorporated into the frameworks of the lanthanide selenates.

## Conclusions

In summery, through the introduction of the rigid linker oxalate as the second metal linker, novel organically templated lanthanide oxalate–selenates with 2D and 3D structures were hydrothermally synthesized. Furthermore, the introduction of the rigid linker oxalates into the lanthanide(III) selenates can afford new inorganic–organic hybrids with novel structures and enhanced luminescent properties. Compounds **1**, **2**, and **3** are respectively capable of producing red-, green-, and pink light in electroluminescent devices, whereas **6** and **7** are luminescent materials in the near IR region. We believe that a wide range of other new lanthanide open frameworks and microporous materials can be developed by self-assembly or structurally directed synthesis by using a similar technique.

## Experimental Section

**Materials and Methods:** All chemicals were purchased from commercial sources and used without further purification. Elemental analyses were performed with a Vario EL III elemental analyzer. IR spectra were recorded with a Magna 750 FTIR spectrometer photometer as KBr pellets in the range of 4000–400 $cm^{-1}$. Thermogravimetric analyses were carried out with a NETZSCH STA 449C unit at a heating rate of 10 °C $min^{-1}$ under a nitrogen atmosphere. X-ray powder diffraction (XRD) patterns (Cu-$K_\alpha$) were collected in a sealed glass capillary with a XPERT-MPD $\theta$–$2\theta$ diffractometer. Photoluminescence analyses were performed with an Edinburgh FLS920 fluorescence spectrometer.

**General Method for the Preparation of $Ln_2(SeO_4)_2(C_2O_4)(H_2O)_4\cdot$pip (Ln = Eu 1; Tb 2; Dy 3; Er 4; Yb 5):** A mixture of $H_2SeO_4$ solution (40%, 0.24 mL, 0.93 mmol), piperazine·$6H_2O$ (0.105 g, 0.54 mmol), $Na_2C_2O_4$ (0.018 g, 0.13 mmol), and $Ln(NO_3)_3\cdot6H_2O$ (0.32 mmol) in distilled water (2 mL) was sealed in an autoclave equipped with a Teflon liner (23 mL) and then heated at 100 °C for 5 d. The initial and final pH values of the solution did not show appreciable change and were close to 5.0

**1:** Prepared by the general method. Brick-shaped crystals. Yield: 0.052 g (48% based on $C_2O_4^{2-}$). IR (KBr): $\tilde{\nu}$ = 3583 (s), 3359 (s), 2963 (w), 2835 (w), 2731 (w), 2461 (w), 1627 (s), 1453 (m), 1315 (m), 1090 (m), 1008 (m), 974 (w), 886 (s), 863 (w), 848 (s), 806 (w), 711 (s), 585 (m), 538 (m), 444 (w), 423 (s) $cm^{-1}$. $C_6H_{18}Eu_2N_2O_{16}Se_2$ (836.06): calcd. C 8.62, H 2.17, N 3.35; found C 8.51, H 2.25, N 3.20.

**2:** Prepared by the general method. Brick-shaped crystals. Yield: 0.049 g (45% based on $C_2O_4^{2-}$). IR (KBr): $\tilde{\nu}$ = 3591 (s), 3357 (s), 2961 (w), 2834 (w), 2730 (w), 2478 (w), 1654 (w), 1629 (s), 1453 (m), 1317 (s), 1212 (w), 1091 (m), 1008 (w), 974 (w), 889 (s), 866 (w), 851 (m), 812 (w), 727 (s), 696 (w), 586 (m), 535 (m), 448 (w), 425 (s) $cm^{-1}$. $C_6H_{18}N_2O_{16}Se_2Tb_2$ (849.98): calcd. C 8.48, H 2.13, N 3.30; found C 8.16, H 2.55, N 3.14.

**3:** Prepared by the general method. Brick-shaped crystals. Yield: 0.048 g (43% based on $C_2O_4^{2-}$). IR (KBr): $\tilde{\nu}$ = 3596 (s), 3358 (s), 2961 (w), 2835 (w), 2731 (w), 2479 (w), 1633 (s), 1454 (m), 1318 (s), 1212 (w), 1092 (m), 1008 (m), 974 (w), 889 (s), 866 (w), 851 (s), 814 (w), 734 (s), 697 (w), 586 (m), 536 (m), 449 (s), 426 (s) $cm^{-1}$. $C_6H_{18}Dy_2N_2O_{16}Se_2$ (857.14): calcd. C 8.41, H 2.12, N 3.27; found C 8.30, H 2.16, N 3.22.

**4:** Prepared by the general method. Brick-shaped crystals. Yield: 0.013 g (12% based on $C_2O_4^{2-}$). IR (KBr): $\tilde{\nu}$ = 3607 (s), 3394 (s), 2961 (w), 2787 (w), 2479 (w), 1633 (s), 1454 (w), 1320 (m), 1212 (w), 1092 (w), 1008 (w), 974 (w), 891 (s), 867 (w), 853 (m), 816 (w), 740 (m), 697 (w), 587 (m), 533 (m), 452 (w), 429 (s) $cm^{-1}$. $C_6H_{18}Er_2N_2O_{16}Se_2$ (866.65): calcd. C 8.32, H 2.09, N 3.23; found C 8.24, H 2.76, N 3.15.

**5:** Prepared by the general method. Brick-shaped crystals. Yield: 0.023 g (20% based on $C_2O_4^{2-}$). IR (KBr): $\tilde{\nu}$ = 3609 (s), 3379 (s), 2963 (w), 2834 (w), 2788 (w), 2473 (w), 1632 (s), 1454 (m), 1320 (s), 1211 (w), 1093 (m), 1008 (m), 974 (w), 893 (s), 868 (m), 855 (m), 826 (w), 753 (s), 695 (w), 587 (m), 535 (m), 454 (w), 426 (s) $cm^{-1}$. $C_6H_{18}N_2O_{16}Se_2Yb_2$ (878.21): calcd. C 8.21, H 2.07, N 3.19; found C 8.23, H 2.10, N 3.17.

**General Method for the Preparation of $[H_2pip]_2[Ln_2(SeO_4)_2(C_2O_4)_3]\cdot H_2O$ (Ln = Er 6; Yb 7; Lu 8; Y 9):** The synthetic procedure for the preparation of compounds **6**–**9** was similar to that of compounds **1**–**5** except that the amount of $Na_2C_2O_4$ used was doubled. The initial and final pH values of the solution were close to 5.5.

**6:** Prepared by the general method. Prism-shaped crystals. Yield: 0.043 g (46% based on $C_2O_4^{2-}$). IR (KBr): $\tilde{\nu}$ = 3435 (s), 3040 (w), 1630 (s), 1421 (w), 1384 (w), 1315 (m), 1080 (w), 1005 (w), 882 (s), 856 (s), 798 (m), 789 (m), 583 (m), 499 (m), 460 (m), 420 (w) $cm^{-1}$. $C_{14}H_{26}Er_2N_4O_{21}Se_2$ (1078.83): calcd. C 15.59, H 2.43, N 5.20; found C 15.64, H 2.49, N 5.21.

**7:** Prepared by the general method. Prism-shaped crystals. Yield: 0.029 g (31% based on $C_2O_4^{2-}$). IR (KBr): $\tilde{\nu}$ = 3435 (m), 3218 (w), 2973 (w), 1632 (s), 1422 (w), 1315 (m), 1081 (w), 883 (s), 856 (s),

798 (m), 788 (m), 583 (s), 499 (s), 461 (m) $cm^{-1}$. $C_{14}H_{26}N_4O_{21}Se_2Yb_2$ (1090.39): calcd. C 15.36, H 2.40, N 5.12; found C 14.93, H 2.93, N 4.93.

**8:** Prepared by the general method. Prism-shaped crystals. Yield: 0.030 g (32% based on $C_2O_4^{2-}$). IR (KBr): $\tilde{\nu}$ = 3435 (s), 3219 (w), 3042 (w), 1632 (s), 1423 (w), 1316 (s), 1081 (w), 883 (s), 868 (s), 856 (s), 798 (m), 788 (m), 583 (m), 498 (m), 460 (m), 417 (w) $cm^{-1}$. $C_{14}H_{26}Lu_2N_4O_{21}Se_2$ (1094.25): calcd. C 15.33, H 2.39, N 5.11; found C 14.85, H 2.86, N 4.92.

**9:** Prepared by the general method. Prism-shaped crystals. Yield: 0.027 g (34% based on $C_2O_4^{2-}$). IR (KBr): $\tilde{\nu}$ = 3449 (m), 3219 (w), 3038 (w), 1631 (s), 1453 (w), 1423 (w), 1315 (s), 1080 (m), 882 (s), 857 (s), 798 (s), 789 (s), 584 (m), 499 (m), 459 (m), 416 (w) $cm^{-1}$. $C_{14}H_{26}N_4O_{21}Se_2Y_2$ (922.13): calcd. C 18.19, H 2.84, N 6.06; found C 18.14, H 2.88, N 6.04.

On the basis of X-ray powder diffraction studies, compounds **1**–**9** were obtained as pure phases. The measured patterns are in good agreement with those simulated from single-crystal structures (see Figure S2, Supporting Information).

**X-ray Crystallography:** Data collection for compounds **1**, **2**, **4**, **7**, and **8** were performed with Siemens Smart CCD and compounds **3**, **5**, **6**, and **9** with a Rigaku Mercury CCD diffractometer both equipped with graphite-monochromated Mo-$K_\alpha$ radiation ($\lambda$ = 0.71073 Å). Lattice parameter measurements indicate that compounds **1**–**5** are isostructural as are compounds **6**–**9**; hence, full data collections for only compounds **1**, **3**, **5**, **6**, and **9** were performed. Intensity data were collected by the narrow frame method at 293 K and corrected for Lorentz and polarization effects as well as for absorption by the SADABS program.[34] All structures were solved by direct methods and refined by full-matrix least-squares cycles in SHELX-97.[34] All non-hydrogen atoms were refined with anisotropic thermal parameters. Hydrogen atoms attached to C and N atoms and for aqua ligands in compounds **1**, **3**, and **5** were located at geometrically calculated positions and refined with isotropic thermal parameters. Hydrogen atoms for water molecules in compounds **6** and **9** were not included in the refinements. Crystallographic data and structural refinement parameters for compounds **1**–**4** are summarized in Table 2 and for compounds **5**–**9** in Table 3. Important bond lengths for compounds **1**, **3**, **5**, **6**, and **9** are listed in Table 1.

CCDC-644791 (for **1**), -644792 (for **3**), -644793 (for **5**), -644794 (for **6**), and -644795 (for **9**) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

**Supporting Information** (see footnote on the first page of this article): TGA curves for compounds **1**–**3** and **5**–**9** and X-ray powder diffraction patterns for compounds **1**–**9**.

**The EUChemSoc Societies have taken the significant step into the future by merging their traditional journals, to form two leading chemistry journals, the *European Journal of Inorganic Chemistry* and the *European Journal of Organic Chemistry*. Three further EUChemSoc Societies (Austria, Czech Republic and Sweden) are Associates of the two journals.**

## COVER PICTURE

**The cover picture shows** two spotlights illuminating the structure of the first sandwich complex featuring an all-heavy group 14 element-consisting $Si_4$-cyclic ligand, namely, a derivative of ($\eta^5$-cyclopentadienyl)($\eta^4$-tetrasilacyclobutadiene)cobalt [($\eta^4$-$R_4Si_4$)-CoCp] (R = SiMe*t*Bu$_2$). The Me and *t*Bu groups on the Si substituents, as well as the H atoms on the Cp ring, are removed for simplicity. The title compound was smoothly prepared by a ligand exchange reaction between the tetrasilacyclobutadiene dianion salt $K^+_2$·[$R_4Si_4$]$_2$ and [$CpCoI_2$-($PPh_3$)]. Systematic comparison of the complex [($\eta^4$-$R_4Si_4$)CoCp] and its carbon analogue [$\eta^4$-($Me_3Si$)$_4C_4$]CoCp revealed important structural distinctions between the two complexes that result from the different ring sizes of the cyclobutadiene ligands $\eta^4$-$R_4E_4$ (R = SiMe*t*Bu$_2$, E = Si vs. R = $SiMe_3$, E = C). Details of the synthesis of the novel Co complex, as well as of its structural and electronic peculiarities, are discussed in the Short Communication by A. Sekiguchi et al. on p. 5471ff.

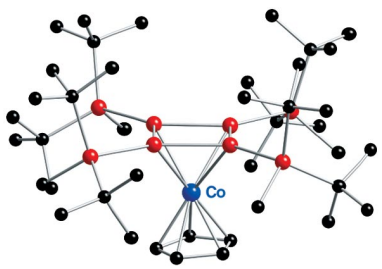
($\eta^5$-Cyclopentteadienyl)($\eta^4$-tetrasila- and $\eta^4$-trisilagermacyclobutadiene)cobalt: Sandwich Complexes Featuring Heavy Cyclobutadiene Ligands

**Keywords:** Cobalt / Cyclobutadiene ligand / Cyclopentadienyl ligand / Germanium / Silicon



($\eta^5$-Cyclopentadienyl)($\eta^4$-tetrasila-cyclobutadiene)cobalt complex **2**

($\eta^5$-Cyclopentadienyl)($\eta^4$-tetrasila- and $\eta^4$-trisilagermacyclobutadiene)cobalt sandwich complexes [($\eta^4$-$R_4Si_4$)CoCp] (**2**) and [($\eta^4$-$R_4Si_3Ge$)CoCp] (**4**) (R = SiMe*t*$Bu_2$) were synthesized by reaction of the dipotassium salts of tetrasilacyclobutadiene dianion $K^+_2$·$[R_4Si_4]^{2-}$ (**1**) and trisilagermacyclobutadiene dianion $K^+_2$·$[R_4Si_3Ge]^{2-}$ (**3**) with $[CpCoI_2(PPh_3)]$. The structures of the new Co complexes were confirmed by X-ray analysis.

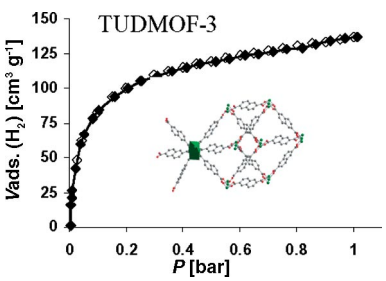
## FULL PAPERS

### Metal–Organic Frameworks

**I. Senkovska, J. Fritsch, S. Kaskel* ..... 5475–5479**

New Polymorphs of Magnesium-Based Metal–Organic Frameworks $Mg_3(ndc)_3$ (ndc = 2,6-Naphthalenedicarboxylate)

**Keywords:** Metal–organic frameworks / Magnesium / 2,6-Naphthalenedicarboxylic acid / Solvent effects / Gas adsorption



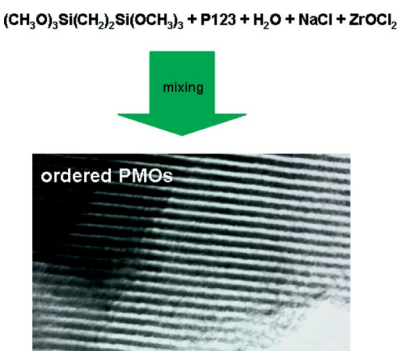
Two new magnesium 2,6-naphthalenedicarboxylate (ndc) metal–organic frameworks, $[Mg_3(ndc)_3(dif)_4]$ (**1**) (dif = *N*,*N*-diisopropylformamide) and $[Mg_3(ndc)_3(dmf)_2(CH_3OH)(H_2O)](dmf)$ (**2** = TUDMOF-3) (dmf = *N*,*N*-dimethylformamide), have been synthesised. TUDMOF-3 has a permanent porosity with a Langmuir surface area of 632 $m^2\ g^{-1}$, a specific pore volume of 0.21 $cm^3\ g^{-1}$ and a hydrogen storage capacity of 1.23 wt.-% (77 K, 1 bar). Compound **1** is not porous.

### Hybrid Mesostructures

**S.-R. Zhai, S. S. Park, M. Park, M. H. Ullah, C.-S. Ha* ..... 5480–5488**

Direct Synthesis of Zr-Containing Hybrid Periodic Mesoporous Organosilicas with Tunable Zirconium Content

**Keywords:** Silicates / Template synthesis / Orangic–inorganic hybrid composites / Mesoporous materials



Highly ordered Zr-containing periodic mesoporous organosilicas (ZrPMO) were successfully synthesized, for the first time, by employing a $ZrOCl_2$/NaCl combination as the promoting agent; the addition of extra amounts of acid was not needed throughout the synthetic process.

## Contrast Agents

The propylene bridge in the skeleton of the $H_5EPTPACH_2OH$ ligand optimizes the water-exchange rate of the $[Gd(EPTPA\text{-}CH_2OH)(H_2O)]^{2-}$ complex, for efficiency as a MRI contrast agent, as a result of the steric compression imposed around its water binding site, as shown by solution relaxometric characterization. The hydroxymethyl substituent group is useful for conjugation of the reporter group. However, these changes, relative to those incurred by the DTPA chelate, significantly decrease its thermodynamic and kinetic stability.

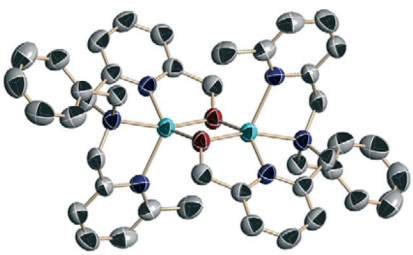
$H_5EPTPACH_2OH$: Synthesis, Relaxometric Characterization and $^1H$ NMR Spectroscopic Studies on the Solution Dynamics of Its $Ln^{III}$ Complexes

**Keywords:** Lanthanides / Contrast agents / MRI / Microscopic protonation scheme / Stability constants

## Isomerism of Copper Complexes

The preference for axial or equatorial positioning of the bridging atoms and of the amine or pyridine N centers of tridentate ligands L in $LCu^{II}(\mu\text{-}X)_2Cu^{II}L$ complexes was probed experimentally and by DFT calculations. Their preference for either a *syn* or *anti* configuration in an equatorial/equatorial situation was also evaluated.



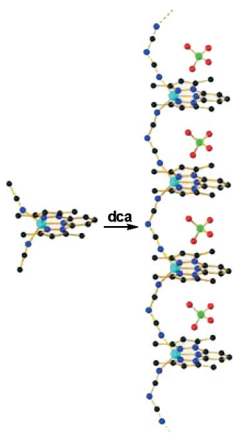
**J. Manzur,* A. Vega,* A. M. García, C. Acuña, M. Sieger, B. Sarkar, M. Niemeyer, F. Lissner, T. Schleid, W. Kaim* ..... 5500–5510**

Coordination Alternatives in Dinuclear Bis(pyridin-2-ylalkyl)benzylaminecopper(II) Complexes with $OH^-$, $RO^-$, $F^-$, or $Cl^-$ Bridges: Experimental Structures and DFT Preferences

**Keywords:** Copper / EPR spectroscopy / Isomerism / N ligands / Structure

## Coordination Oligomers/Polymers

Reactions of three preformed $Cu^{II}$/bdmpp complexes [bdmpp = 2,6-bis(3,5-dimethyl-1*H*-pyrazol-1-yl)pyridine] with 4,4′-bipy, dicyanamide (dca), azide, and $MCl_2$ (M = Cu, Co, Ni) lead to a series of homo- and heterometallic coordination oligomers and polymers. Their structures and redox properties were investigated.



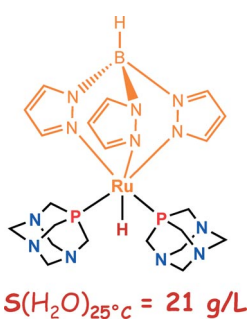
**G.-F. Liu, Z.-G. Ren, H.-X. Li, Y. Chen, Q.-H. Li, Y. Zhang, J.-P. Lang* ..... 5511–5522**

Homo- and Heterometallic Coordination Oligomers and Polymers Derived from the Preformed Complexes $[Cu(bdmpp)(MeCN)_2](ClO_4)_2$, $[Cu(bdmpp)(N_3)_2]$, and $[Cu(bdmpp)(N_3)(\mu\text{-}N_3)]_2$ [bdmpp = 2,6-bis(3,5-dimethyl-1*H*-pyrazol-1-yl)pyridine]: Syntheses, Structures, and Redox Properties

**Keywords:** Copper / Structures / Oligomers / Polymers / Redox properties

## Water-Soluble Ruthenium Complexes

A series of [tris(pyrazolyl)borato]ruthenium complexes bearing the water-soluble cage phosphane 1,3,5-triaza-7-phosphaadamantane (PTA) and its boranyl adduct $PTA(BH_3)$, including the water-soluble hydride $[TpRuH(PTA)_2]$, have been synthesised and characterised. Cyclic voltammetric studies in MeCN and dmso generally show reversible $Ru^{II/III}$ oxidation waves and the values of $E_{1/2}^{ox}$ reflect the electron-donating character of the ligands, whose Lever electrochemical parameter ($E_L$) is estimated for the first time.



**S. Bolaño, J. Bravo,* J. Castro, M. Mar Rodríguez-Rocha, M. F. C. Guedes da Silva, A. J. L. Pombeiro,* L. Gonsalvi, M. Peruzzini* ..... 5523–5532**

Synthesis, Reactivity, X-ray Crystal Structures and Electrochemical Behaviour of Water-Soluble [Tris(pyrazolyl)borato]-ruthenium(II) Complexes of 1,3,5-Triaza-7-phosphaadamantane (PTA)

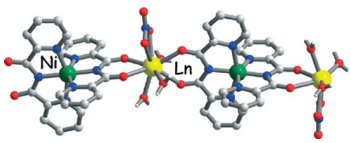
## 3d–4f Coordination Polymers

**A. M. Madalan, K. Bernot, F. Pointillart, M. Andruh,* A. Caneschi* ..... 5533–5540**

First $Ni^{II}$–$Ln^{III}$ Coordination Polymers Constructed by Using $[Ni(bpca)_2]$ as a Building Block [Hbpca = bis(2-pyridylcarbonyl)amine]: Synthesis, Crystal Structures and Magnetic Properties



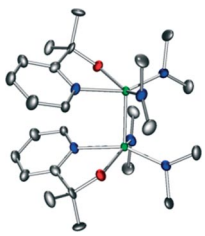
Three new heterobimetallic 1D coordination polymers have been obtained by assembling the $[Ni(bpca)_2]$ complex, as a building block, with lanthanide cations: $[\{Ln(O_2NO)(H_2O)_3\}\{Ni(bpca)_2\}](NO_3)_2 \cdot 3H_2O$ (Ln Gd **1**; Tb **2**; Dy **3**). Their static and dynamic magnetic properties were investigated and discussed.

**Keywords:** Nickel / Lanthanides / Heterobimetallic coordination polymers / Magnetic properties

## Ditungsten(III) Complexes

**O. Coutelier, R. M. Gauvin,* G. Nowogrocki, J. Trébosc, L. Delevoye, A. Mortreux* ..... 5541–5547**

A New Donor-Stabilized Ditungsten Amido Alkoxido Species: Synthesis, Crystal Structure, Fluxionality, and Grafting onto Silica



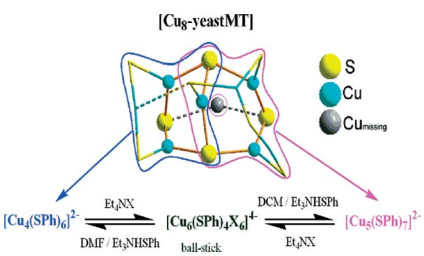
A new dimeric tungsten(III) complex containing amido and chelating pyridine–alkoxido ligands was synthesized through protonolysis of $[W_2(NMe_2)_6]$ by 2-(2-pyridyl)propan-2-ol and fully characterized. Grafting of this compound onto silica has been investigated by elemental analysis, DRIFTS, and solid-state NMR spectroscopy.

**Keywords:** Tungsten / Metal-metal multiple bonds / Ligand design / Grafting / Silica / Alkyne metathesis

## Copper–Thiolate Clusters

**B. K. Maiti, K. Pal, S. Sarkar* ..... 5548–5555**

Flexible $Cu^{I}$–Thiolate Clusters with Relevance to Metallothioneins



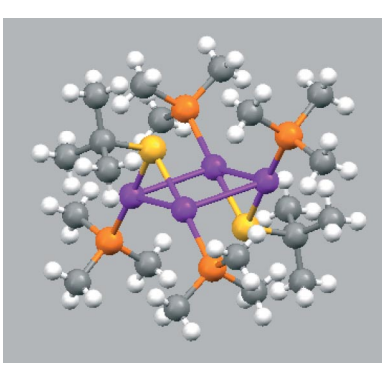
The structural diversity in some Cu–thiol small clusters with relevance to the chemistry of Cu-containing metallothioneins was investigated. Solvent polarity and the copper/thiol ratio may change the local cluster geometry, which causes flexibility of the copper–sulfur bond. These small clusters have superposition motifs in bigger clusters such as $Cu_8$-yeastMT.

**Keywords:** Metallothioneins / Flexibility / Coordination modes / Copper / Sulfur / Photoluminescence

## Au–Au Interactions

**F. Balzano, A. Cuzzola, P. Diversi,* F. Ghiotto, G. Uccello-Barretta ..... 5556–5562**

Cationic Gold(I) Phosphanyl Thiolates: Aurophilic Interactions in the Solid State and in Solution



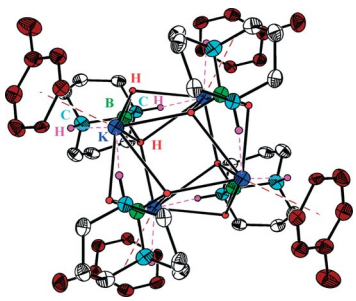
Cationic gold(I) phosphane alkanethiolates of the formula $[Au_2(StBu)(phosphane)_2][BF_4]$ were investigated in solution by MS and NMR spectroscopy. These compounds are dimeric in the solid state and are bound through aurophilic interactions; some of these compounds maintain the integrity of the Au–Au bonds in solution depending on the nature of the phosphane.

**Keywords:** Gold / Sulfur / Thiolates / Aurophilicity / Aggregation / ESI MS / NMR spectroscopy

 © 2007 Wiley-VCH Verlag GmbH & Co. KGaA, Weinheim 

## Organohydroborate

Based upon single-crystal X-ray diffraction analysis, the potassium salt of the 9-BBN hydroborate anion has a tetrameric structure when associated with toluene, methyl THF, or a mixture of toluene/THF, and THF/diethyl ether. While with the chelating solvent DME, it has a dimeric structure.

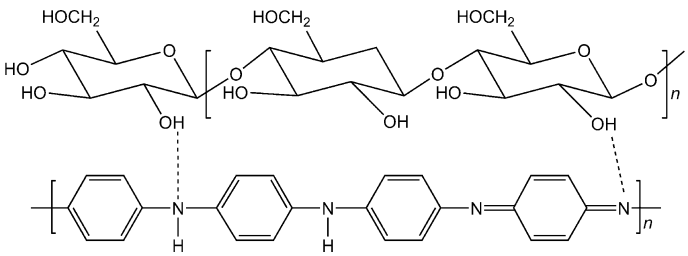


**X. Chen, S. Liu, B. Du, E. A. Meyers, S. G. Shore* ..... 5563–5570**

The Structure of Potassium and Tetramethylammonium Salts of the Cyclic Organohydroborate Anion $[H_2BC_8H_{14}]^-$ with Different Solvent Ligands

**Keywords:** Agostic interactions / X-ray diffraction / Organohydroborate / Potassium salts

## Hybrid Materials



Conducting polymer/cellulose fibre composites, using polypyrrole and polyaniline, have been successfully prepared. By utilising the redox active nature of the conducting polymer coatings, silver nanoparticles have been deposited on the surface of the composite fibres. This additionally gives rise to fibres with antimicrobial properties.

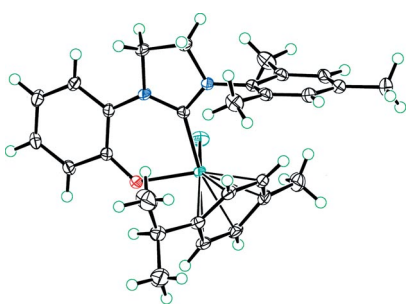
**F. M. Kelly,* J. H. Johnston, T. Borrmann, M. J. Richardson ..... 5571–5577**

Functionalised Hybrid Materials of Conducting Polymers with Individual Fibres of Cellulose

**Keywords:** Polypyrrole / Polyaniline / Cellulose / Fibres / Conductivity / Antimicrobial activity

## Olefin Metathesis Catalysts

The use of Ru-based NHC-arene complexes as alternatives to the Grubbs-type catalysts used in olefin metathesis is described.



**N. Ledoux,* B. Allaert, F. Verpoort ..... 5578–5583**

Ruthenium-Based NHC-Arene Systems as Ring-Opening Metathesis Polymerisation Catalysts

**Keywords:** Carbene ligands / Homogeneous catalysis / Olefin polymerisation / Ruthenium

## Catalytic Ethylene Oligomerization

A series of iron, cobalt and nickel complexes bearing 2-arylimino-9-phenyl-1,10-phenanthrolines has been synthesized, characterized and evaluated for ethylene oligomerization. Most of the complexes show good catalytic activity for ethylene oligomerization, with the cobalt catalysts being more active than their iron analogues.
